Abstract. The Balkhash Lake is a unique natural water body with a gradient of the total content of dissolved salts along its longitudinal axis and the increased level of toxic pollutions. To assess the spatial distribution of environmental factors along the Balkhash Lake surface, methods of bioindication and statistical mapping were used. An assessment of the overall level of toxic pollution was carried out using the Water Ecosystem State Index (WESI). Phytoplankton has been used to assess the ecological state of the Balkhash Lake in the summer of 2004. A total of 92 species were found in the algal communities, with prevalence of Chlorophyta in the western, fresher water part, and Bacillariophyta in the eastern, brackish part. Mapping showed a positive relationship between the species richness in algal Divisions and macrophytes. Changes in the proportion of indicator species within the composition of phytoplankton reflected the spatial gradient of depth, TDS, pH-values, organic pollution. According to bioindication data, the waters of the Balkhash Lake are moderately polluted, water quality class III. The WESI index calculation revealed the effect of the total toxic pollution on the phytoplankton of the Western Balkhash. The spatial distribution of the WESI index showed that in the zone the influence of river flow has stimulating effect of biogenic elements on phytoplankton but was partially leveled by the increased level of toxic pollution.
Keywords: *bioindication, heavy metals, organic pollution, total dissolved solids, WESI index, phytoplankton, Balkhash Lake, Kazakhstan*

Introduction

The Balkhash Lake is located in arid zone of the southeastern Kazakhstan, on sedimentary carbonate soils with granites, porphyries, tuff and slates in its northern and western parts (Sidorenko, 1972; Leonov, 2013). The water area is the third largest following the Caspian Sea and Aral Sea. One distinct feature about the lake is its spatial heterogeneity of the content of Total Dissolved Solids (TDS) in water (Tarasov, 1961). The arid climate also conditions interannual changes of TDS associated with fluctuations of level of the Balkhash Lake.

Due to the rich reserves of polymetallic ores (Mazurov, 2005), there are mining and processing industry facilities in the region (Kudekov, 2002). The territory south of Balkhash Lake is used for agriculture and pasture cattle. The combination of natural

and anthropogenic factors determines the increased level of pollution and substantial heterogeneity of ecological conditions on various parts of the water area of the Balkhash Lake.

Recently, methods of the biological analysis have been used more and more for assessment of quality of water. Phytoplankton serves as a good instrument for that purpose (Barinova et al., 2006; Barinova and Chekryzheva, 2014; Klymiuk and Barinova, 2016; Krupa et al., 2016; Krupa and Barinova, 2016; Barinova and Krupa, 2017), and its application has not exhausted its potential (Barinova et al., 2015a). Water quality assessment is carried out both on the basis of structural indicators of biological communities (abundance, biomass, ratio of divisions in quantitative indicators, average cell volume, diversity indices), and with indicator species distribution.

The basis for using indicator algae for bioindication is their relation to environmental factors - the amount of organic matter, oxygen conditions, salinity of water, etc. The system for assessing the level of organic pollution of water bodies on the basis of the ratio of indicator species of various systematic groups was developed by V. Sládeček (1973). S. S. Barinova (Barinova et al., 2006; Barinova, 2011; Barinova and Fahima, 2017; Barinova, 2017a) compiled the electronic database on algal indicators with species-specific ecological preferences in the world. This database on the ratio of algal species, in addition to the level of organic contamination, allows assessing a wider range of environmental factors such as temperature, oxygen conditions, salinity, prevailing depths, and water pH.

When assessing the ecological status of any waterbody, it is most difficult to detect the effect of toxic pollution, in particular the effect of heavy metals, on biological communities. This is due to the fact that the toxicity of heavy metals depends on the multidirectional action of a complex of environmental factors. So, high temperature intensifies, and increased salinity and pH reduce the toxic properties of heavy metals for living organisms (Li et al., 2013). These same environmental factors affect the absorption of heavy metals by submerged plants (Fritioff et al., 2005) and thereby to self-purification processes in aquatic ecosystems.

One of the new methods, allowing in an integrated form to assess the effect of the general level of toxic pollution on phytoplankton communities, is the Water Ecosystem State Index (WESI) (Barinova et al., 2006; Barinova, 2011, 2017a, b). The indicator significance of this index was demonstrated by us earlier when assessing the ecological state of water bodies in Kazakhstan and other regions (Barinova et al., 2011, 2015a, b; Barinova and Chekryzheva, 2014; Barinova and Krupa, 2017).

The research on phytoplankton of Balkhash Lake has begun in 1929. In the years 1929-1930 the microalgae were represented by 308 species and forms (Abrosov, 1973). The main contribution to the diversity of algal flora was made by benthic species of algae, which did not play a significant role in plankton. Data on quantitative parameters of algal flora during this period are absent. The Kapshagay reservoir began to fill from the Ili River in 1970 and the Ili River is the main filling source of the Balkhash Lake. Reduction of the volume of river flow led to a decrease in the water level and intensification of toxic pollution of the lake. The biomass of phytoplankton in the summer of 1976-1978 after the completion of the Kapshagay reservoir filling, reached 0.51-1.64 g m^{-3} (Vorobyeva et al., 1982; Fokina, 1982). During the period from 1998 to 2012, the variety of planktonic algae ranged from 82 to 146 species (Ponomareva et al., 2005; Krupa et al., 2014a). The mean annual biomass averaged 0.94 g m^{-3}, fluctuating from 0.17 to 1.86 g m^{-3} across different years. The diatom algae dominated the biomass

most often, followed by blue-greens. Studies of long-term dynamics (1972-2012) revealed the influence of the invader, the bivalve *Monodacna colorata* on phytoplankton biomass (Krupa et al., 2013), and the relationship between the long-term variability of phytoplankton biomass and regional and global climatic factors (Krupa et al., 2014b). The spatial distribution of total species richness (Barinova et al., 2017) and structural variables of phytoplankton (Krupa et al., 2017a, 2018) was studied along the Balkhash Lake in a gradient of abiotic factors based on the materials of 2004.

There is no information in the recent publications on the indicator species of planktonic algae and their using for assessment of organic and toxic pollution level of the Balkhash Lake.

The aim of the present work is to assess the organic contamination, hydrochemical and oxygen conditions, and water pH by the mapping of spatial distribution of indicator species of planktonic algae in the Balkhash Lake as well as assess the overall level of toxic pollution of the reservoir on the basis of spatial distribution of the Water Ecosystem State Index (WESI). For Lake Balkhash this will be done for the first time.

Materials and methods

Sampling and chemical analysis

The research of phytoplankton, the content of biogenic elements and heavy metals in the water was carried out by means of a grid of 58 stations (*Figs. 1* and *2*) in June and July of 2004. The measures of the temperature and pH values of the surface water layers were taken in the field environment. Water transparency was measured with Secchi disk. Coordinate referencing of the stations was done by Garmin eTrex GPS-navigator. The samples for heavy metals were fixed in the site by adding nitric acid; samples for biogenes were fixed with chloroform. All collected samples were transported to the lab in an icebox. One-liter samples of phytoplankton were sampled from surface layer of the lake water.

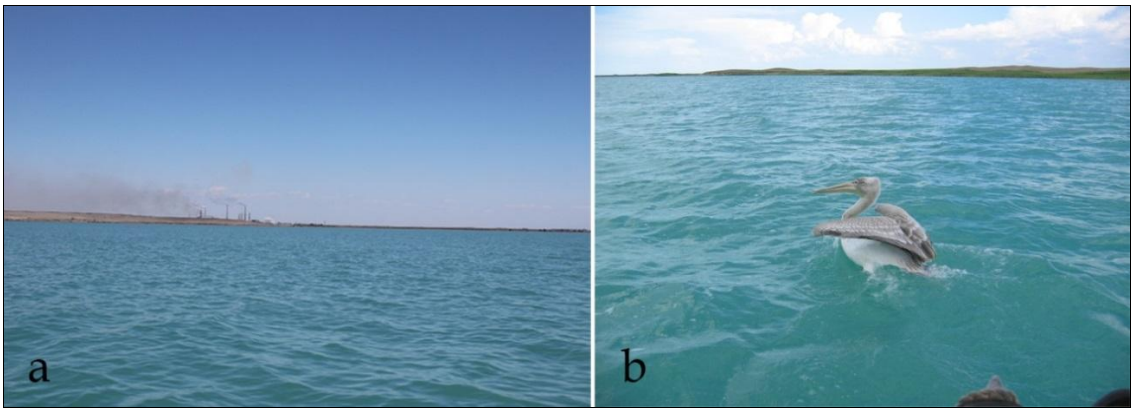

Figure 2. *Western (a) and eastern parts (b) of the Balkhash Lake, 2004*

Conventional methods of chemical analysis of water were used (Semenova, 1977; Fomin, 1995). Water samples were analyzed in three – four replications. The error of estimate for major ions in the water was 0.5–5.0%, depending on the analysis. Concentrations of heavy metals were determined by the atomic absorption method using an AAS-1N spectrophotometer (Germany). The device allows for the detection of the various chemical elements in complex matrices, including those in the sea and grey water and in the biological objects in micro-trace quantities Test-sensitivity of AAS-1N spectrophotometer – 0.001–0.0025% Mass.

The settling method was used (Kiselev, 1956) to process phytoplankton samples. Species identification of planktonic algae was performed using determinant handbooks for relevant divisions (Gollerbach et al., 1953; Zabelina et al., 1951; Popova, 1955; Moshkova et al., 1986; Palamar-Mordvintseva, 1982; Matvienko, 1954).

Bioindication

The ecological characteristics of algal species were obtained from the database compiled for freshwater algae of the world from multiple analyses of algal biodiversity by Barinova et al. (2006), according to substrate preference, temperature, oxygenation, pH, salinity, organic enrichments, as well as N-uptake metabolism and trophic states according Van Dam et al. (1994). The ecological groups were separately assessed according to their significance for bioindications. Species that respond predictably to environmental conditions were used as bioindicators for particular variables of aquatic ecosystems, the dynamics of which are related to environmental changes.

The correspondence between the classificational indicators of ecosystem according to the biogenic elements and those of saprobity indices was conducted through calculating the index of the ecosystem state (WESI, Water Ecosystem State Index) as the quotient from the classification rank on biota divided by the classification rank on the nitrates. The WESI index ranges from 0 to 9. If it is less than one, then the ecosystem is exposed to the toxic effects; if equal to or greater than 1 – the self-purification is not suppressed (Barinova et al., 2006, Barinova, 2011).

Statistical methods

The statistical methods used were those recommended by Heywood (2004) for the development of taxonomic studies. The innovative approach with spatial mapping in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

wafer plots construction was applied using the Statistica 12.0 program for analysis of biological and environmental variables distribution over the lake surface. For this type of calculation we used GIS coordinates of each sampling station. Data of biological variables for the Balkhash lake sampling stations were inserted to the Statistica 12.0 program and maps were created for each variable. Statistically generated maps are better if we have numerous sampling points. The maps have some prognostic properties and let to assume the level of each mapped variable between sampling points.

Description of the study site

The Uzun-Aral Channel divides the Balkhash Lake into two parts: western, which is shallow and wide (Western Balkhash), and eastern, which is narrow and deep (Eastern Balkhash). The lake is elongated from southwest to northeast (*Fig. 1*). Its length makes up to 614 km, and the area is approximately 16400 km^2 if the water level is 342 m above sea level. Width of the lake reaches 9-19 km in the eastern part and up to 74 km in western part (Kudekov, 2002). The lake is fed by rivers Ili, Karatal, Lepsy and Aksu. There is constant flow of water from the west to the east (flow of run-off) (Tarasov, 1961). The movement of water masses begins from the mouth of Ili River and flows into the Western Balkhash. Encroaching on the opposite shore, the current is directed to the northeast and reaches the Uzun-Aral Channel. Further flow is caused by a difference of levels between the western and eastern parts as the Karatal, Lepsy and Aksu rivers do not fully compensate the evaporation from a surface of the Eastern Balkhash.

Results

Hydrophysical characteristics

The Western and Eastern Balkhash significantly differ in environmental variables (*Table 1*). The shallow western part of the lake is characterized by lesser transparency and pH-values of water, poorer distribution of stiff macrophytes (reed, cane, cattail), but it is more overgrown with soft macrophytes (pondweed plants, *Myriophyllum*). Macrophytes developed mainly in the southern and southeast parts of the lake where rivers discharge their waters such as the Ili River in the Western Balkhash, and the Karatal, Aksu and Lepsy rivers in the Eastern Balkhash.

Table 1. *Hydrophysical and morphometric characteristics of Balkhash Lake, summer 2004*

Variable	Whole Balkhash	Western Balkhash	Eastern Balkhash
Temperature, °C	24.14±0.14	23.49±0.16	24.77±0.14
Depth, m	5.58±0.49	4.34±0.28	6.86±0.81
Transparency, m	1.13±0.15	0.53±0.02	1.74±0.25
Macrophytes Hard, %	20.05±3.03	18.03±3.00	22.14±5.36
Macrophytes Soft, %	25.18±2.68	28.28±3.29	22.00±4.24
pH	8.63±0.04	8.52±0.02	8.74±0.09

Hydrochemical and toxicological characteristics

Total Dissolved Solids (TDS) content in the East Balkhash is statistically significantly higher, than in the western part (*Table 2*). In Western Balkhash, the

© 2018, ALÖKI Kft., Budapest, Hungary

concentration of nitrates, nitrites, total phosphorus, iron, zinc and copper is higher than in the eastern part. Phosphates, easily oxidized organic matter, cadmium, lead, nickel and cobalt were present in the waters of the East Balkhash in large concentration. The content of ions of ammonium and silicon did not differ in the two parts of the lake.

Note: Temperature preferences (T): temp – temperate temperature, eterm – eurythermic, Substrate preferences (Hab): P – planktonic, P-B – plankto-benthic, B – benthic. Oxygenation and water moving (Reo): st – standing water, str – streaming water, st-str – low streaming water, aer – aerophiles. Acidity (pH) degree according to Hustedt (1957): alf – alkaliphiles, ind – indifferents; acf – acidophiles; alb – alkalibiontes. Halobity degree according to Hustedt (1938-1939) (Hal): i – oligohalobes-indifferent, hl – halophiles, mh – mesohalobes. Organic pollution indicators according to Watanabe et al. (1986) (D): sx – saproxenes, es – eurysaprobes, sp – saprophyles. Trophic state (Tro) (Van Dam et al., 1994): o – oligotraphentic; o-m – oligo-mesotraphentic; m – mesotraphentic; me – meso-eutraphentic; e – eutraphentic; o-e – oligo-eutraphentic. Nitrogen uptake metabolism (Aut-Het) (Van Dam et al., 1994): ats – nitrogen-autotrophic taxa, tolerating very small concentrations of organically bound nitrogen; ate – nitrogen-autotrophic taxa, tolerating elevated concentrations of organically bound nitrogen; hne – facultatively nitrogen-heterotrophic taxa, needing periodically elevated concentrations of organically bound nitrogen; hce – nitrogen-heterotrophic taxa, needing elevated concentrations of organically bound nitrogen. Species-specific Index of Saprobity (s). Self-purification zone preferences (Sap): x – xenosaprob; o – oligosaprob; o-b – oligo-beta-msosaprob; o-a – oligo-alpha-mesosaprob; b – beta-mesosaprob; b-o – beta-oligo-mesosaprob; b-a – beta-alpha-mesosaprob; a-o – alpha-oligo-mesosaprob; a – alpha-mesosaprob

In the Western Balkhash, where Chlorophyta prevailed (*Fig. 3*), the number of species of planktonic algae (74) was higher than in the Eastern Balkhash (69). Bacillariophyta primarily formed the species richness in communities in brackish eastern part. Despite the specified distinctions, trends of distribution of the abundance of species per taxonomic Division almost coincided in eastern and western parts of the water area, which testified to the similarity of species structure in the lake as a whole. In the Western Balkhash, dinophyte *Peridinium* sp., diatom *Cyclotella meneghiniana*, euglenophyte *Trachelomonas* sp. were found rather often. In the Eastern Balkhash, besides the two latter species, diatom *Navicula* sp., green *Francei*a sp., cyanobacteria *Snowella lacustris*, *Gomphosphaeria aponina,* and *Gloeocapsa* sp. were widespread.

In relation to the habitat preferences, planktonic-benthic and planktonic species were prevalent within phytoplankton. Revealed species-indicators prefer alkaline waters (alkaliphiles) or are indifferent to pH, and serve as indicators of moderately oxygenated waters, temperate temperatures, and are indifferent to salinity (*Fig. 3*). In comparison with the western part, the Eastern Balkhash had more planktonic algae species that are associated with temperate temperature waters, not cold, more indicators of oxygenated waters, and halophiles with presence of mesohalobes. Despite these differences, *Figure 3* illustrates that the lines of polynomial trends nearly coincided for all the indicator distributions in the Eastern and Western Balkhash, except pH-indicators. Here, there is an essential difference: the water of the eastern part of the lake, according to bioindication, is more alkaline than in the western part, and tops of trend lines are shifted into opposite directions of pH-spectrum.

Distribution of algae species-indicators of organic pollution of water show that the water quality of the lake generally corresponded to Class III (*Fig. 4*) according to Sládeček (1973), or Watanabe et al. (1986). In comparison with the west, the eastern part of the lake was characterized by slightly higher level of trophy, and that has been

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_20892111
© 2018, ALÖKI Kft., Budapest, Hungary

reflected by the presence of saprophiles (according to Watanabe et al., 1986) within phytoplankton species. Among algae-indicators of the nutrition type, there were mostly species that use photosynthesis and are stable against moderate concentration of organic nitrogen (ate). The number of species of this ecological group of algae was higher in the Eastern Balkhash. It should be noted that in the context of difference in species-indicators structure (*Fig. 3*), the distributions trends of the nutrition type indicators in the Eastern and Western Balkhash almost coincided (*Fig. 4*).

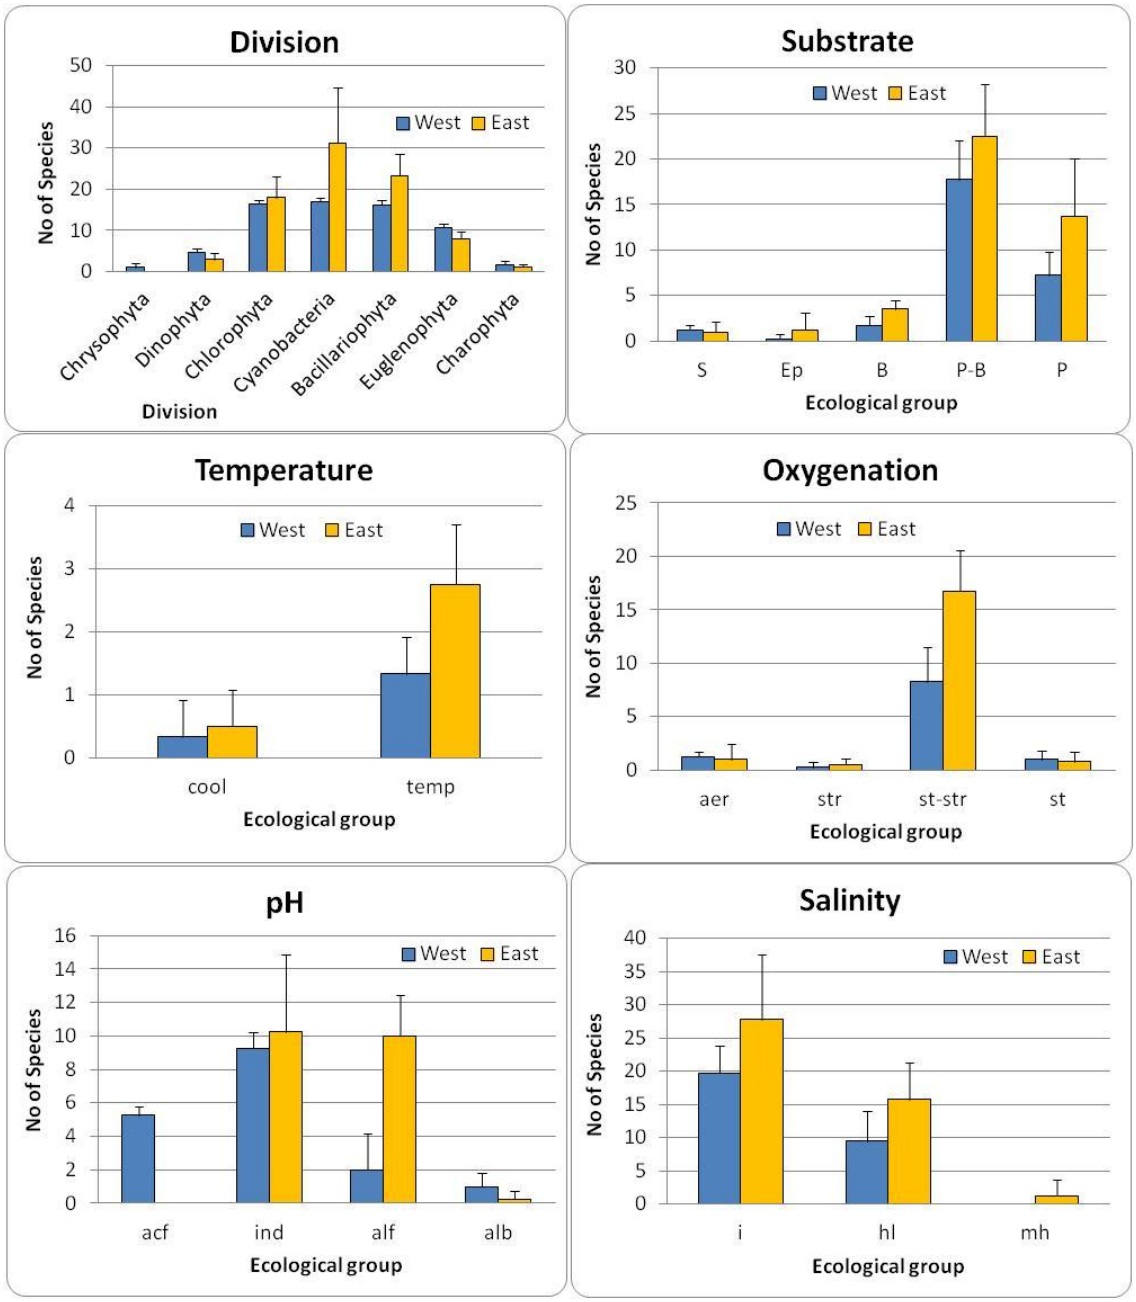

Figure 3. *Distribution of the number of species-indicators over taxonomic divisions and ecological groups in the Western and Eastern Balkhash according to phytoplankton species' preferences to habitat type, water temperature, pH, water mobility and saturation by oxygen, water pH, and salinity in summer 2004*

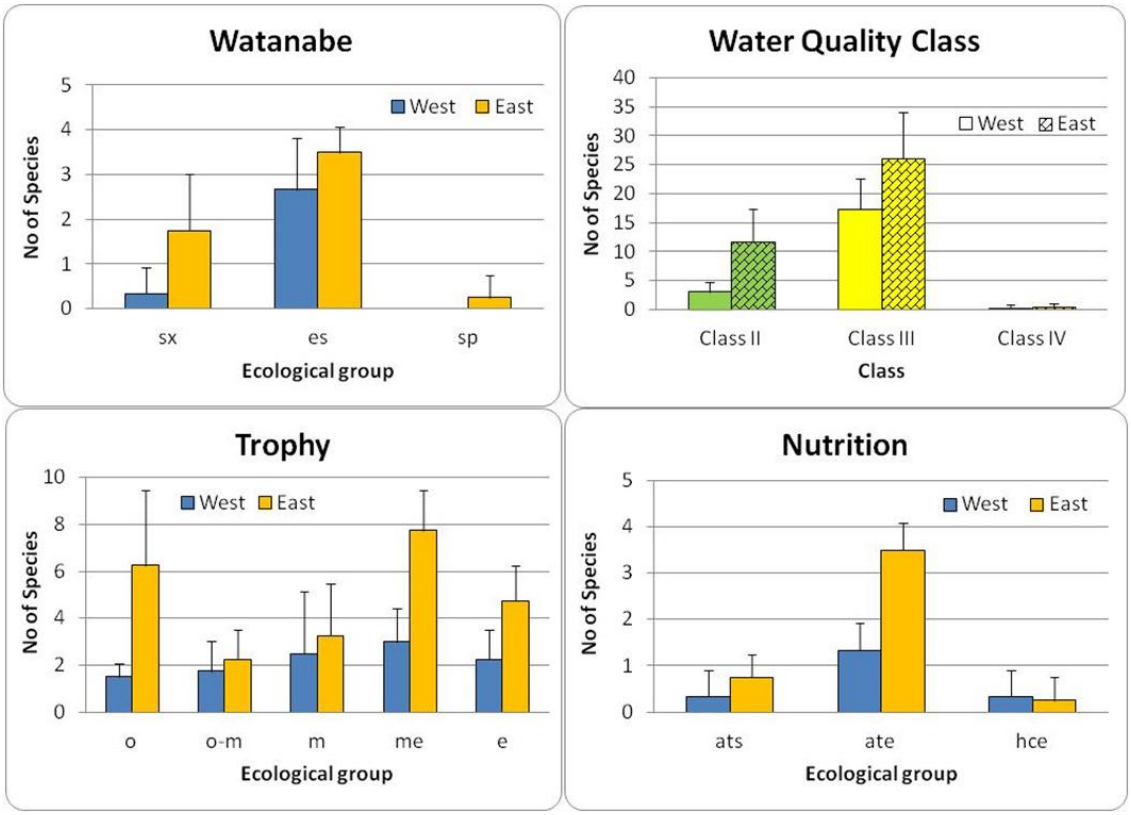

Figure 4. *Assessment of the ecological state of the Balkhash Lake according to phytoplankton species-indicators in relation to organic pollution according to Watanabe (1986) and Sládeček (1973), trophic status and nutrition type, summer 2004. Coloring of the histogram in the figure of water quality classes corresponds to the codes of the EU scale: Class II – green; Class III – yellow; Class IV – orange. Abbreviations for indicator groups of algae as in Table 3*

Wide groups of algae ranging from oligotrophs to eutrophs (*Fig. 4*) represented indicators of trophy. In Eastern Balkhash, mesotrophs had larger number of species, and the presence of eutrophs shifted the trend line of distribution of the indicators for this part of the water area towards a eutrophy.

Spatial distribution

The set of ecological maps have been constructed to assess the spatial distribution of indicator species across the water area of the Balkhash Lake. The majority of planktonic algae species has been spread unevenly, with outbursts of species richness on limited areas. Bacillariophyta was prevail in species number in areas of the Ili River discharge (the Western Balkhash), as well as the Karatal, Lepsy and Aksu rivers (the Eastern Balkhash) (*Fig. 5a*).

Chrysophyta was found in the Western Balkhash only, and together with Charophyta, it was most represented in area of the Ili River discharge (*Fig. 5b)*. The Cyanobacteria was discovered with high species richness in the eastern part of the water area (*Fig. 5c*). The spatial distribution of Dinophyta (*Fig. 5d*), Euglenophyta (*Fig. 5e*) and Chlorophyta species richness (*Fig. 5f*) did not follow certain patterns, but there were more of them in the western part.

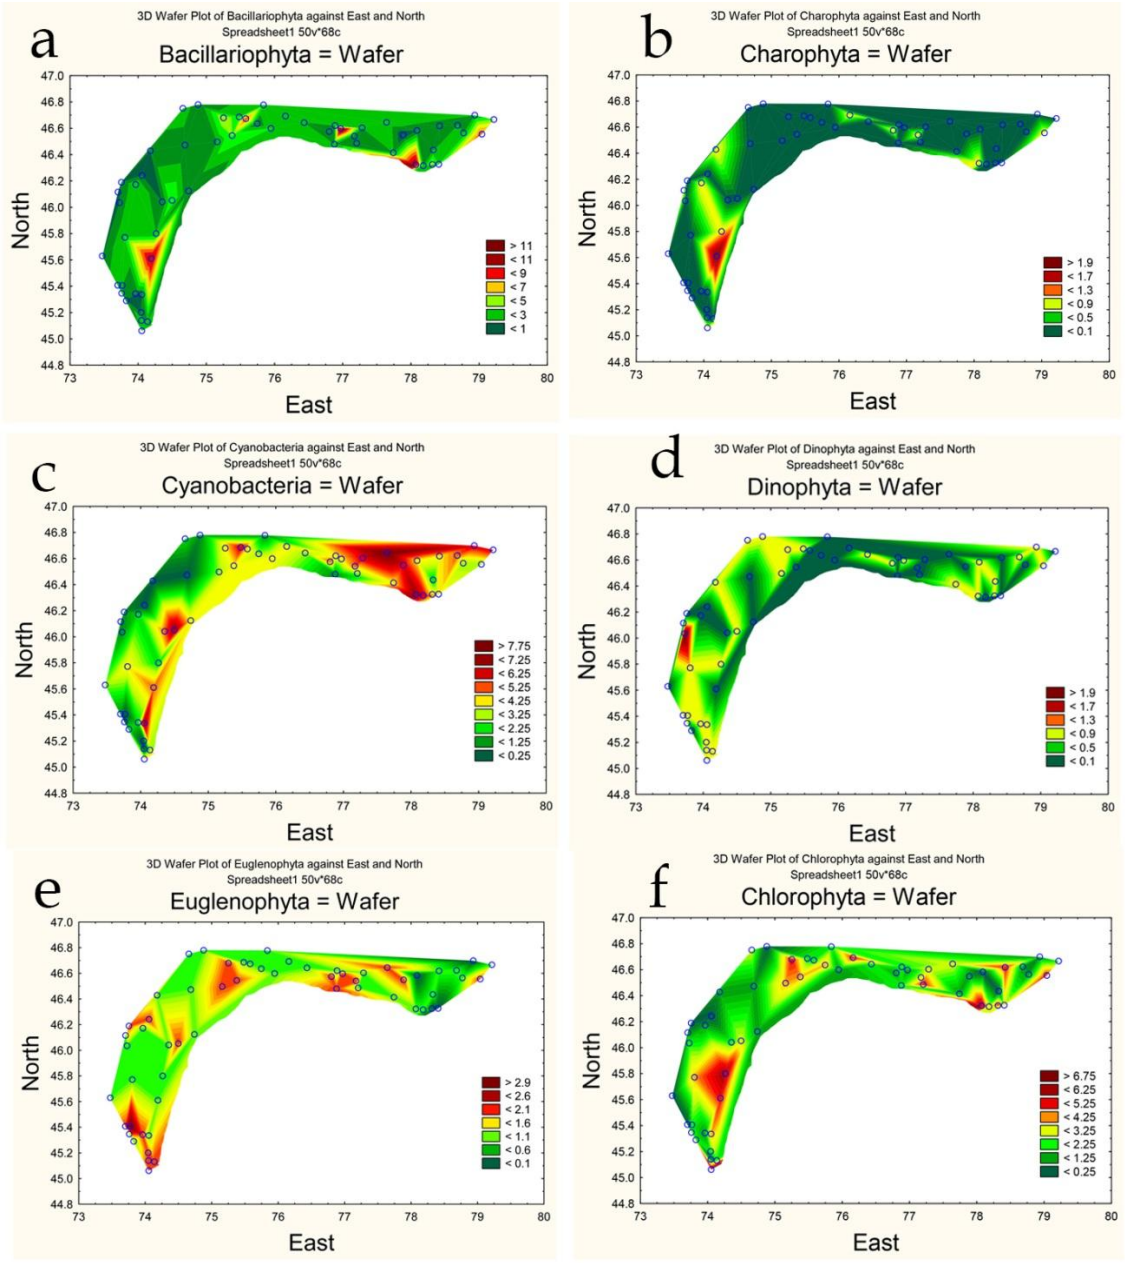

Figure 5. *The distribution of total phytoplankton species richness in the algal Divisions over the water surface of the Balkhash Lake, summer 2004*

We analyzed distribution of species indicators of substrate preferences. Planktonic algae prevailed in communities of the eastern deep-water part of the lake (*Fig. 6a*). Planktonic-benthic algae were widespread across the entire water area, with the highest species richness being recorded near the southeastern coast of the Western Balkhash and with the homogenous distribution of the number of species in the eastern part of the water area (*Fig. 6b*). Benthic species of algae preferred the areas of river discharge (*Fig. 6c*). Sparse species that have vital connection with a substrate such as epiphytes and soil related species were found across the whole lake water area with higher concentration near the coastal zones (*Fig. 6d*).

Algae – inhabitants of the poorly oxygenated standing waters were represented by the greatest number of species in the western relatively shallow part of the lake (*Fig. 7c*), whereas the distribution of algae that prefer moving and oxygenated waters did not adhere to clear patterns (*Fig. 7d, e, f*).

Distribution maps of water pH indicators show that acidophiles (*Fig. 8a*) and alkalibionts (*Fig. 8c*) preferred the Western Balkhash, whereas alkaliphiles – the Eastern Balkhash (*Fig. 8d*). Species-indifferents were found across the whole water area, and they were drawn towards the southeastern coast of the Western Balkhash, towards northern and partially the southern and eastern coast of the Eastern Balkhash (*Fig. 8b*). There is notable absence of extreme groups of pH-indicators (acidophiles and alkalibionts) in the eastern part of the lake. That is, the western part of the water area is more varied regarding of water pH. Apparently, it is connected with the inflow of fresh water from the Ili River, and also with the general heterogeneity of conditions in the Western Balkhash.

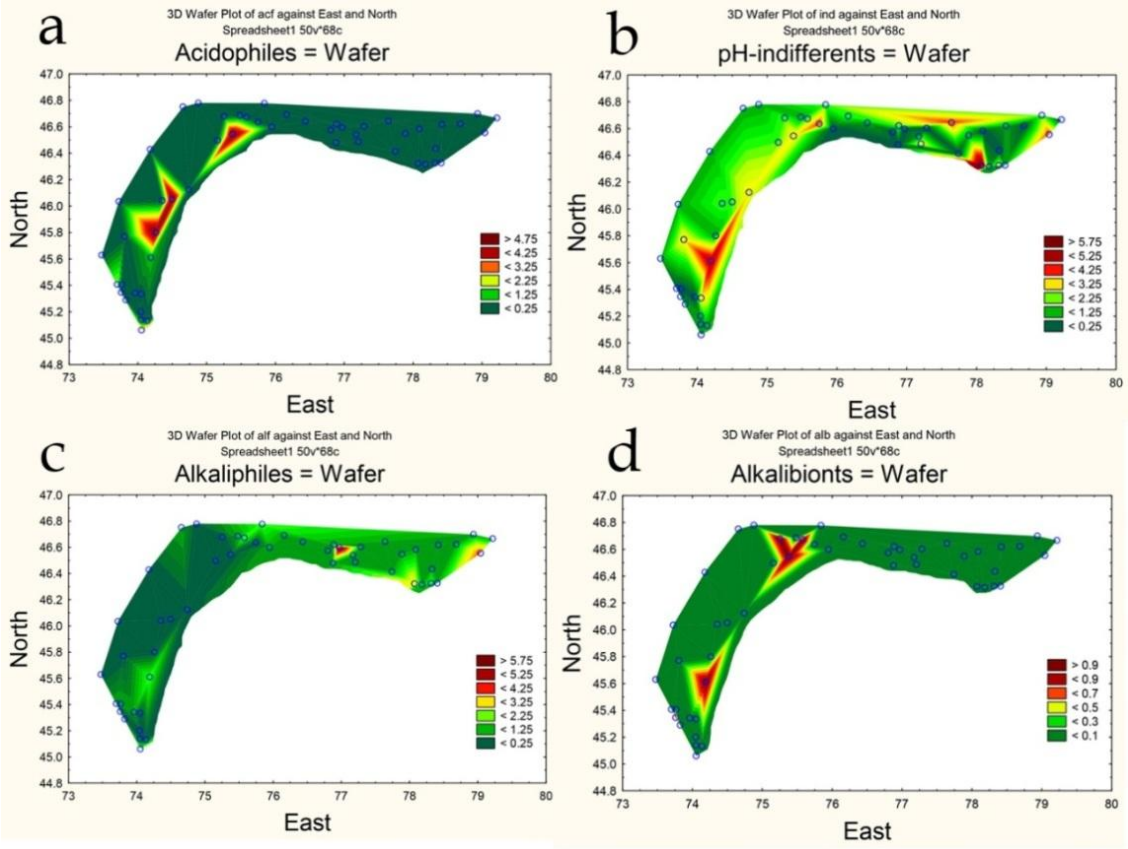

Figure 8. *The distribution of algal species-indicators of water pH over the water surface of the Balkhash Lake, summer 2004*

Maps of salinity indicators distribution demonstrated that mesohalobes were revealed only in the east brackish part of the water area (*Fig. 9a*). Species salinity-indifferents were widespread across the whole water area (*Fig. 9c*), and halophiles preferred the Eastern Balkhash and adjacent part of the water area of the Western Balkhash (*Fig. 9b*).

Algae – indicators of trophic state ranged from oligotraphentic to eutraphentic. Oligotraphentic species were most various in the Eastern Balkhash (*Fig. 10a*), oligo-

© 2018, ALÖKI Kft., Budapest, Hungary

mesotraphentic – in the Western Balkhash (*Fig. 10b*). Mesotraphentic, meso-eutraphentic and eutraphentic algae were recorded across the whole water area (*Fig. 10c, d, e*).

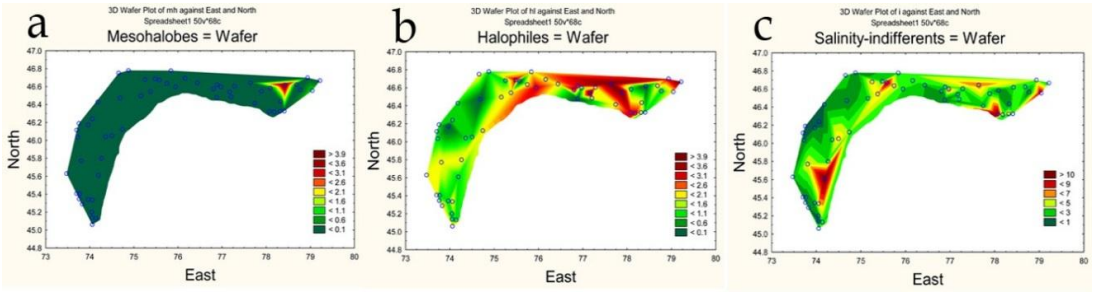

Figure 9. *The distribution of algae species-indicators of salinity over the water surface of the Balkhash Lake, summer 2004*

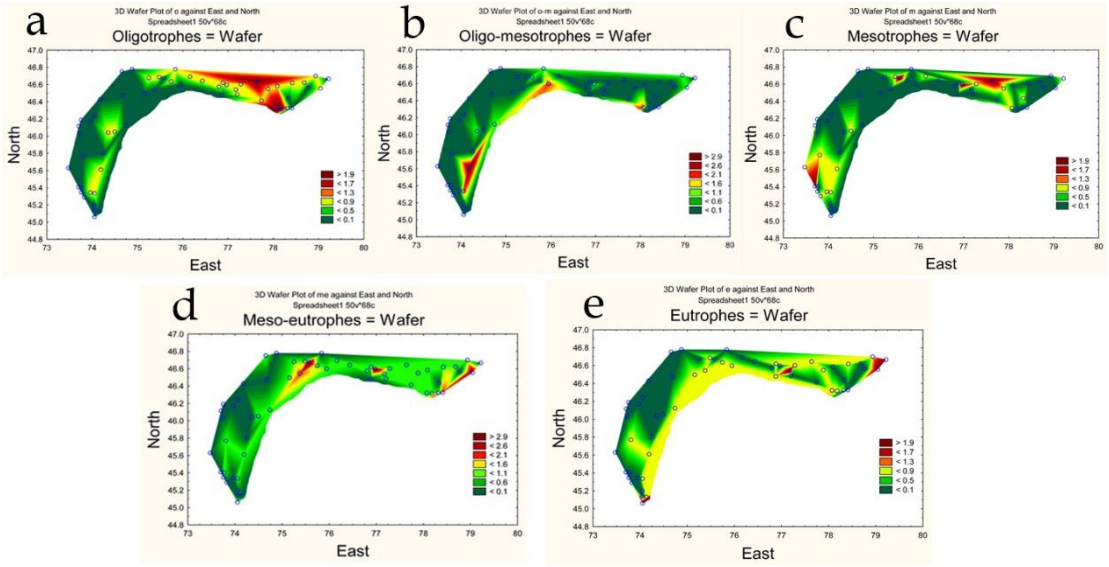

Figure 10. *The distribution of algae species – trophic indicators over the water surface of the Balkhash Lake, summer 2004*

The maps of distribution of species-indicators of nitrogen uptake metabolism show that nitrogen-autotrophic taxa, tolerating very small concentrations of organically bound nitrogen (*Fig. 11a*) and nitrogen-autotrophic taxa, tolerating elevated concentrations of organically bound nitrogen (*Fig. 11b*) preferred areas of river drain discharge and shallow areas of the Eastern Balkhash. Trace amounts of facultative heterotrophs were found across the whole water area of the lake (*Fig. 11c*). Indicators of organic pollution (according to Watanabe, 1986) demonstrated similar distribution patterns for inhabitants of pure waters – saproxenes (*Fig. 11d*) and those of waters moderately saturated with organic matter – eurysaprobes (*Fig. 11e*).

The majority of algal indicators of organic pollution according to Sládeček (1973) pointed to the moderate level that corresponds to water quality class III (*Fig. 12*). Average values of saprobity index S (*Table 2*) confirmed this conclusion, even though they were slightly higher in the western part of the lake.

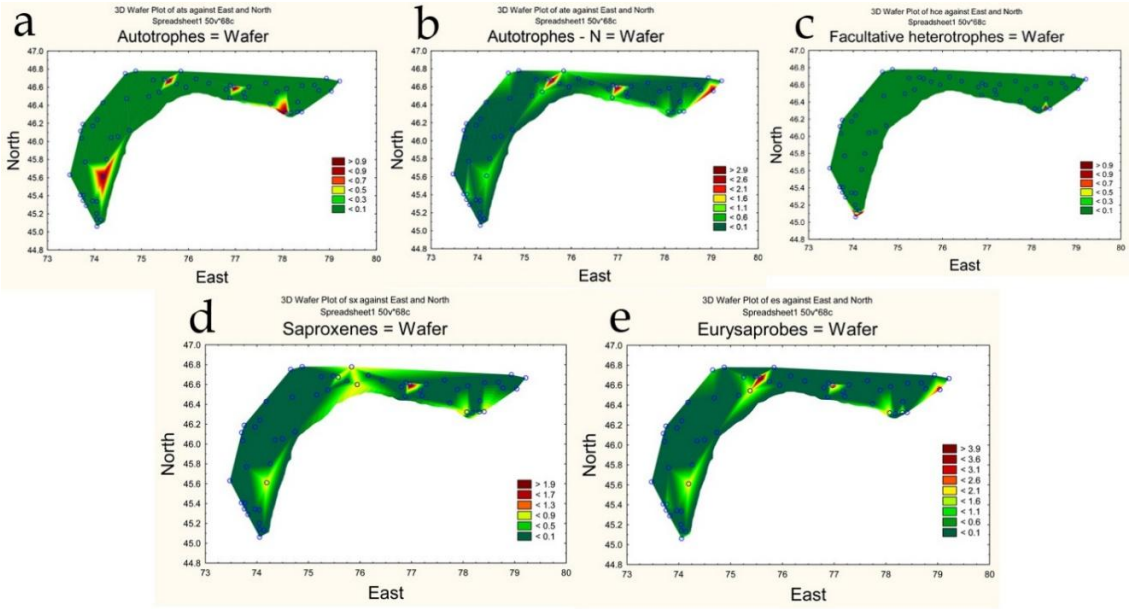

Figure 11. *The distribution of algal species – nutrition type indicators over the water surface of the Balkhash Lake, summer 2004*

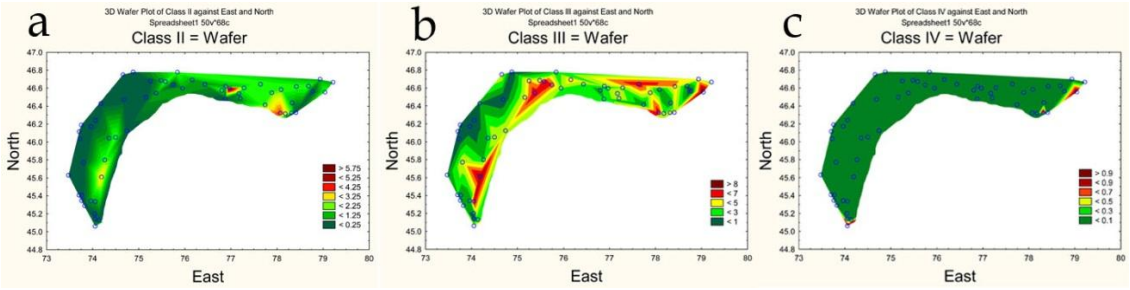

Figure 12. *The distribution of algal species-indicators of the water quality class over the water surface of the Balkhash Lake, summer 2004*

No significant correlation was revealed in the distribution of indicator species of phytoplankton and the content of heavy metals in water of the Balkhash Lake. The influence of the total concentration of toxicants on phytoplankton was evident using WESI index. The considerable part of the water area of the Western Balkhash was characterized by the WESI index being less than one, and that demonstrated an oppression of photosynthetic activity of algae (*Fig. 13*). According to index values, the toxic pollution did not affect the phytoplankton communities in the Eastern Balkhash.

Discussion

The Balkhash Lake is a unique natural water body with gradient of salt saturation of water along a longitudinal axis of the lake. Besides hydrochemical conditions, the western and eastern parts of Balkhash differ in other environmental variables. As can be seen on summer 2004 investigation results, water of the Western Balkhash contained increased concentrations of nitrates, nitrites, total phosphorus, iron, zinc and copper,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_20892111
© 2018, ALÖKI Kft., Budapest, Hungary

and in the Eastern Balkhash, phosphates, easily oxidized organic matter, cadmium, lead, nickel and cobalt were prevalent.

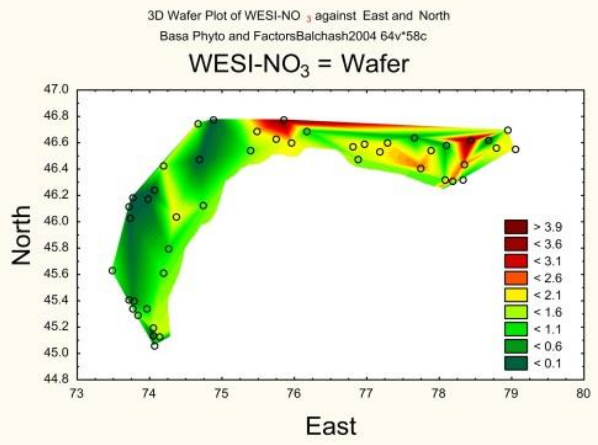

Figure 13. *The distribution of the WESI index values over the water surface of the Balkhash Lake, summer 2004*

Phytoplankton in the Balkhash Lake was represented by 92 species of algae in summer 2004. Bacillariophyta prevailed in species richness in brackish eastern part, whereas Chlorophyta in the Western Balkhash. Differences between total number of algal species in western freshwater part (74) and eastern brackish part of Balkhash (69) were insignificant. In the same time, a negative correlation was found between the number of species in phytoplankton community and water salinity in water body of another regions such as Eastern Mediterranean (Barinova et al., 2009), Northern (Klymiuk et al., 2014; Barinova et al., 2015b) and Eastern Black Sea region (Bilous et al., 2016), and Northern Kazakhstan (Barinova et al., 2011). Mapping illustrated that local outbreaks of the species richness Bacillariophyta, partly Charophyta, Cyanobacteria, Chlorophyta are associated with the shallow, macrophytic areas of the water surface that are under the influence of river discharge. We have previously demonstrated a positive relationship between the spatial distribution of the total number of species of plankton algae along the Balkhash Lake and macrophytes coverage (Barinova et al., 2017). Detailing the results obtained earlier in the present study showed that the species of the Bacillariophyta, Charophyta, Cyanobacteria, and Chlorophyta divisions contribute roughly to the increase in species richness in the areas where macrophytes are developed.

The analysis of published data showed that the relationship between the species richness of hydrocenosis and macrophytes could be both positive and negative (Peretyatko et al., 2009; Muylaert et al., 2010; Pieczyńska et al., 1999; Kuczyńska-Kippen and Joniak, 2015). Previously noted positive relationship between macrophytes and the number of species of phytoplankton in the water bodies in the arid zone of Kazakhstan (Barinova and Krupa, 2017) may have been because the presence of macrophytes enhances the role of small species in zooplankton, mainly rotifers (Krupa, 2012), that has no significant effect on algae.

The data visualization showed that the planktonic species are more widely represented in the Eastern Balkhash, which is consistent with the increase in depth in this part of the water area. The active reaction of water clearly divided the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_20892111
© 2018, ALÖKI Kft., Budapest, Hungary

phytoplankton communities into two parts: of the Western Balkhash with predominance of pH-indifferent species and of the Eastern Balkhash with predominance of alkaliphiles, which is coherent with our pH measurements. The predominance of mesohalobes and halophiles in the phytoplankton of the Eastern Balkhash reflected a higher concentration of dissolved salts in this part of the lake water. The response of phytoplankton to the temperature and water oxygen saturation was approximately the same for the Eastern and Western Balkhash, while the zones of influence of river discharge and shallow waters substantially affected the distribution of indicator species.

Bioindication data has identified the Balkhash Lake as moderately polluted, with water quality class III. The distribution of algal species – indicators of the trophic state (the presence of nutrients) and the ratio of species to the total level of organic pollution of water (according to Sládeček) made for different estimates of the eastern and western parts of the lake. In comparison with the west, the eastern part of Balkhash has been characterized by a higher level of trophy, as evidenced by the appearance of saprophiles in the phytoplankton composition, the presence of more eutrophic species and species resistant to moderate concentrations of organic nitrogen.

This evaluation was supported by the spatial dynamics of phosphates (*Table 2*) which are present in low concentrations in the reservoirs of Kazakhstan (Nikolaenko, 1989) and therefore have a stronger limiting effect on phytoplankton compared to nitrogen compounds. Maps of the spatial distribution of algal species – trophic indicators showed a higher content of nutrients in the mouths of rivers and in shallow waters. The water quality assessment by Sládeček (1973) also characterized a level of organic pollution of the Balkhash Lake as moderate and mesosaprobic, however, with slightly higher values of the saprobity index in the western part. This assessment showed that pollutants primarily come with the waters of the Ili River which flows into the Western Balkhash. This confirms the conclusion we made earlier when analyzing the spatial distribution of biogenic elements and total phosphorus in the waters of the Balkhash Lake (Krupa et al., 2017b). The supply of nutrient elements with river waters stimulated an increase in the quantitative variables of phytoplankton communities in this zone, which we showed earlier (Krupa et al., 2018).

The effect of total toxic pollution on phytoplankton of the Balkhash Lake has not been tracked when analyzing the distribution of indicator species, but it was evident when using the WESI index. The small values of the index – 0.46 on average, have been recorded in the zone of the Ili River discharge (*Fig. 1*) and on the opposite coast of the lake – 0.97 on average, where the discharge current flows directly from the estuarine zone. The main contribution to the inhibition of algal communities in this part of the western Balkhash water area was by zinc and copper that come with river waters at concentrations of 0.080-0.264 mg dm^{-3} and 0.02-0.06 mg dm^{-3}. Thus, the pollutants entering the lake along with the river runoff have a mutually opposite effect on the communities of Lake Balkhash. Biogenic elements have a stimulating effect on phytoplankton, whereas an increased level of toxic pollution partially suppresses its development. This was only possible to reveal using the WESI index.

The average content of zinc and copper was also higher in the western part of the water area compared to the eastern. In the Eastern Balkhash, there was cadmium, lead, nickel and cobalt; however, the total amount of toxic substances did not adversely affect the phytoplankton of this part of the lake, as evidenced by the WESI index values. That means high self-purification capacity of the Balkhash Lake ecosystem. This may be due to the increased content of dissolved salts in the Eastern Balkhash, which together with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_20892111
© 2018, ALÖKI Kft., Budapest, Hungary

high pH-values (*Table 1*) weaken the toxic properties of heavy metals by making the latter insoluble (Nikanorov and Zhulidov, 1991). The stress that we have identified for algal communities in the Western Balkhash is not only related to anthropogenic influence, but is also caused by natural increased potentially toxic elements background due to the lake being located in the metallogenic province (Mazurov, 2005). Earlier, we have detected an increased content of some heavy metals and their negative impact on algal communities of small lakes in Kazakhstan, both in protected areas (Krupa et al., 2016; Krupa and Barinova, 2016) and in conditions of moderate anthropogenic pollution (Barinova et al., 2011). That said the alkaline reaction of the lake water partially neutralizes the toxic effect of heavy metals on phytoplankton as evidenced in the eastern part of the Balkhash Lake.

Conclusion

In summer 2004, phytoplankton of the Balkhash Lake was represented by 92 species. In the western, freshwater part of the lake, green algae prevailed, in the eastern, brackish part it was diatoms. The larger total number of algal species in the Western Balkhash (74), compared to the Eastern one (69). Mapping showed a positive relationship between the species richness of algal Divisions and macrophytes. Changes of the proportion of indicator species within the phytoplankton composition reflected the spatial gradient of environmental variables – an increase in depth, TDS and pH-values in the direction from west to east. According to bioindication analysis, the water of the Balkhash Lake is moderately polluted, water quality class III with high self-purification of its ecosystem. The WESI index calculation revealed the effect of the total toxic pollution on the phytoplankton of the Western Balkhash. The spatial distribution of the WESI index showed that the pollutants entering the lake with river flow had a mutually opposite effect on the phytoplankton communities: the stimulating effect of biogenic elements from one hand, and the partial suppression by an increased level of toxic pollution from the other.

In general, the method of statistical mapping of indicators in combination with bioindication based on the algae can be recommended for use of future monitoring of changes in water quality and identify sources of pollution of the unique natural water body – the Balkhash Lake.

Abstract. Semiarid ecosystems are more sensitive to environmental changes than other terrestrial ecosystems, which makes their monitoring very important. Determining soil quality is critical to precise monitoring of semiarid area, and its evaluation involves the assessment of soil properties. In this study, the soil chemical properties and enzyme activities were measured and compared in order to determine soil quality. Four plots were chosen in the cold and warm sites in the Khabr national park and Ruchun wildlife refuge with grazed and not grazed areas. Samples of surface soil (0–10 cm) were collected in spring and autumn. The results showed that chemical properties of the soils were significantly affected by site (soil organic carbon, total nitrogen, available phosphorus and soil moisture) and season (pH, total nitrogen, available phosphorus and soil moisture) but not by grazing. All assayed enzyme activities were significantly influenced by site and season. Alkaline phosphatase activity was affected by grazing, too. Soil chemical properties (soil organic carbon, total nitrogen, and available phosphorus content and soil moisture) and enzyme activities (acid phosphatase, alkaline phosphatase, invertase, β-glucosidase, urease and arylsulfatase) showed higher value at cold sites. The positive correlation between all assayed enzymes and soil organic carbon (r= 0.189-0.639) indicated the important role of soil organic carbon availability in soil enzyme activities. Seasonal variation was observed in soil chemical properties except for electrical conductivity. In addition, temporal variation was observed in enzyme activities with more activity in spring samples except for arylsulfatase activity. According to more value in nutrient content and enzyme activities, it can be concluded that soil at cold sites have higher quality than warm sites. In conclusion, the warm sites with poor soil quality need more concern to be protected.
Keywords: *grazing, monitoring, seasonal, semiarid, soil quality*

Introduction

Semiarid ecosystems approximately cover 40% of the Earth's land and are increasing in proportion due to global warming and consequent desertification. The soils, in these ecosystems, characteristically contain less organic matter and plant biomass (Reyes-Reyes, 2007). The fragility of soil in semiarid environments, caused by low organic matter content, lack of vegetation exposes soil to wind and soil erosion, and salty crusts impede root growth, makes soil quality monitoring and management imperative.

Various physical, chemical, biological and biochemical indicators have been used to estimate soil quality. It is important to take into account sensitivity to soil management in a wide range, sampling error, cost of measurement and required time. The measurement of soil enzyme activities provides an early indication of changes in soil quality, as they are involved in the mineralization of nutrients such as N, P and C (Trasar-Cepeda et al., 2008). Soil enzymes participate in almost every transformation process of decomposition and play a central role in maintaining soil fertility by releasing mineral nutrients from complex organic resources (Baldrian and Stursová, 2010). Since soil enzyme activities are linked with several ecosystem processes and exhibit rapid response to both natural and anthropogenic disturbances, they have been adopted as a suitable indicators for soil quality (Das and Varma, 2010).

Iran, with an area of 164 million hectares, is located in the mid-latitude belt of arid and semiarid regions of the Earth. The arid and semiarid regions cover more than 60% of the country, which is vulnerable to land degradation and, in consequence, desertification due to the increasing population pressure on the land due to grazing and the consumption of water resources (Amiraslani and Dragovich, 2011). The Khabr National Park and the Ruchun Wildlife Refuge is located in the southeast of Iran with various ecological systems and different habitats for plants and animals (Najmizadeh and Yavari, 2006). While the quality of a soil is related to its physical, chemical and biological properties, only several studies has been conducted on physical processes, chemical properties and the biology of soil flora and fauna in the semiarid areas of Iran (Bagheri et al., 2009; Rajabi et al., 2011; Shirvani, 2012; Sharafatmandrad et al., 2014; Mirzaei et al., 2017). There is very little information on soil biological indicators in the Iranian semiarid areas (Raiesi and Riahi, 2014; Kabiri et al., 2016). Indeed, there has not been any study on soil enzyme activities in the Khabr National Park and the Ruchun Wildlife Refuge. Therefore, this study addresses the information gap that exists on the effects of site, season and grazing on soil enzyme activities as important soil quality indicators in this park, which is needed to aide in the overall quality assessment of the ecosystems contained within this park. It was hypothesized that soil chemical properties and enzyme activities are different at cold and warm sites and is also affected by season and grazing. For this purpose, the variation in soil chemical properties and enzyme activities was studied of selected cold and warm sites, which were either grazed or not grazed in spring and autumn seasons.

Materials and methods

Field site, experiment design and soil sampling

The study area is located in the southeast of Iran within the semiarid steppe region of Khabr National Park and Ruchun Wildlife Refuge, Kerman province, Iran. This park extends from 28°28' to 28°58' N and from 56°02' to 56°38' E. The mean annual temperature and precipitation varies between 17.5-21.0°C and 200-350 mm, respectively. Mean monthly temperature and precipitation has been given in *Figure 1*. Two plots at the cold sites and two plots at the warm sites were selected as sampling plots for this study. The altitude of the warm site is 1,707 m above sea level (a.s.l) and the vegetation is dominated by *Artemisia siberi*. The cold sites have an altitude of 2,365 m (a.s.l), and the vegetation is dominated by *Stipa hassknechti* and *A. siberi*. At both the cold (C) and warm (W) sites, grazed (G) and not grazed (NG) areas were selected (*Fig. 2*). Thus, in the analysis, four treatments were considered as follows: (1) cold-grazed

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_21132127
© 2018, ALÖKI Kft., Budapest, Hungary

(CG), (2) cold-not grazed (CNG), (3) warm-grazed (WG) and (4) warm-not grazed (WNG).

Eight soil samples were collected from the top 10 cm of soil from a plot area 100× 100 m in mentioned treatments in spring (S, June) and autumn (A, November). In the laboratory, collected samples were thoroughly mixed and homogenized by sieving through a 2 mm sieve. Room-temperature, dried soil was used in chemical analysis. Enzyme activities assays were done on soil samples stored at -20 °C.

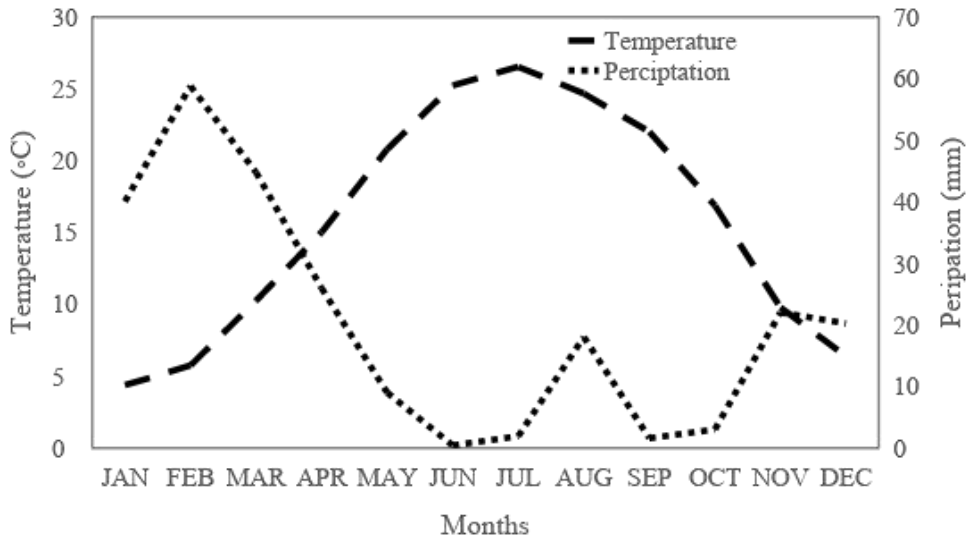

Figure 1. *Mean monthly temperature and precipitation during 2007-2017 at the Khabr National Park and Ruchun Wildlife Refuge*

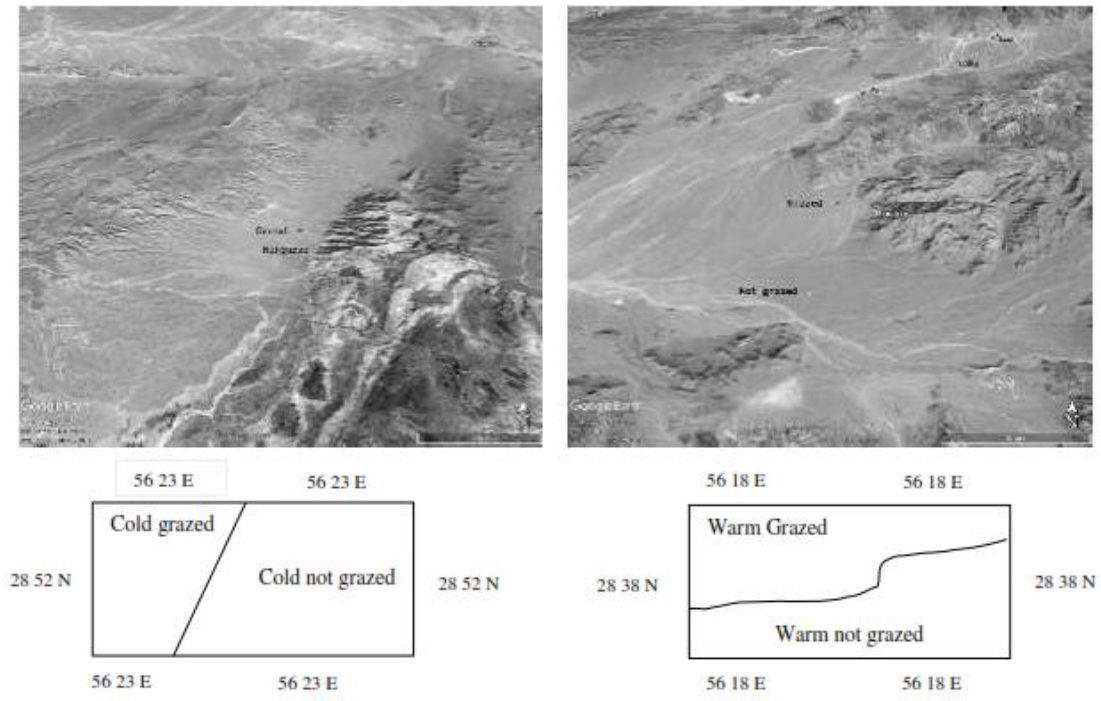

Figure 2. *Precise location of grazed and not grazed areas at the cold (left) and the warm (right) sites (Google Earth)*

Soil chemical properties

Soils chemical properties values were measured based on standard methods. The soil pH and electrical conductivity were measured in soil suspensions (Mclean, 1982). Soil water content was measured by drying soil samples at 105 °C (Schlichting and Blume, 1966). The soil texture was determined by the hydrometric method (Toogood, 1958). A wet digestion method (Walkley and Black, 1934) was used to measure soil organic carbon. The soil available phosphorus (AP) was determined using the molybdenum blue method (Olsen and Summers, 1982) following extraction by sodium bicarbonate. A micro Kjeldahl method (Bremner and Mulvaney, 1982) was used to measure total nitrogen (TN) in soil samples.

Soil enzyme activities

The activity of seven hydrolytic enzymes was determined using their specific substrates. Acid phosphatase, alkaline phosphatase, arylsulfatase and β-glucosidase activity were measured in soil samples based on assays described by Schinner et al. (1996). Invertase and urease activity were determined as described by Schinner and von Mersi (1990) and Kandeler and Gerber (1988), respectively. The enzyme activities were assayed in duplicates at their optimal pH. The controls were soil samples to which substrate were added after the incubation step. An outline of studied enzymes, their substrate and assay pH has been given in *Table 1*.

Table 1. *Soil enzymes assayed in this study with their substrates and assay conditions*

Enzyme	Substrate	Assay condition (pH)
Alkaline Phosphatase	p-nitrophenyl phosphate hexahydrate	11
Acid Phosphatase	p-nitrophenyl phosphate hexahydrate	6.5
β-glucosidase	p-Nitrophenyl-β-D-glucopyranoside	6
Invertase	Sucrose	5.5
Urease	Urea	7
Aryl Sulfatases	p-Nitrophenyl sulfate	5.8

Statistical analysis

The data of variables were checked for their normality with Shapiro-Wilk test. If necessary, the variables were transformed by Jonson transformation using Minitab software to improve normality. Three -way analysis of variance (ANOVA) was used to assessment significant effects of site, season and grazing on soil chemical and enzyme activities. Non-normal data were analyzed using Mann-Whitney U test to evaluate the main effects of studied factors. Mean comparisons were evaluated by the Least Significant Difference (LSD) test at the 5% level of significance. In order to explore links between soil chemicals and enzyme activities, Pearson's correlations were calculated. Reporting of data as histograms was conducted using Microsoft Excel 2010.

Results

Soil chemical properties

The soil types are Haplic Calcisoils according to according to the soil classification of the World Reference Base (WRB) for Soil Resources. All soils were characterized as sandy loam texture with an average of 10% clay, 30% silt and 60% sand. None of soil chemical properties was affected by grazing (*Table 2*). Only the effect of season was significant ($p< 0.01$) on soil pH (*Table 3*). The pH value was higher in the soil samples, collected in autumn (November) than soil samples collected in spring (June) samples (*Table 4*). The effect of site and season was significant ($p< 0.01$) on total nitrogen (TN) and available P (AP) but not grazing (*Table 2*). Whereas the spring samples had higher available P than autumn samples, the value of TN was more in autumn samples than spring samples (*Table 4*). In addition, site and season interaction was significant ($p< 0.01$) on AP (*Table 2*) with the highest available AP in samples taken from cold sites in spring (*Fig. 3*).

Table 2. *Mean squares of studied factors and their interactions for normalized parameters*

Treatments	Independent variables			
	EC	**TN**	**AP**	**SM^T**
Site	0.001^{ns}	37.20^{**}	324.00^{**}	13.88^{**}
Season	0.08^{ns}	6.45^{**}	196.00^{**}	26.62^{**}
Season × site	0.049^{ns}	0.20^{ns}	676.00^{**}	0.03^{ns}
Replication × (season× site)	1.57	0.49	12.28	0.14
Grazing	0.03^{ns}	0.04^{ns}	36.00^{ns}	0.03^{ns}
Season × grazing	0.41^{ns}	0.09^{ns}	36.00^{ns}	0.23^{ns}
Site × grazing	0.02^{ns}	0.01^{ns}	36.00^{ns}	0.12^{ns}

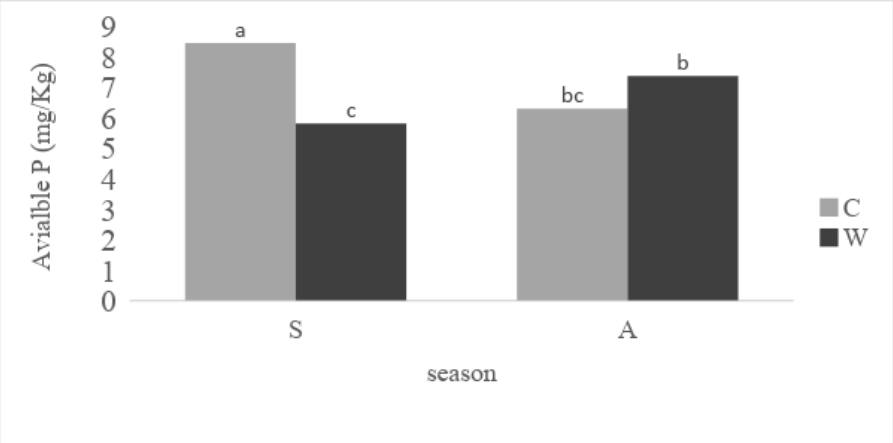

Figure 3. *Phosphorus availability in soil developed under interaction of site (C= cold and W= warm) and season (S= spring and A= autumn) conditions. Different letters indicate significant difference at the p< 0.05 level*

As given in *Table 3,* only site had significant (p< 0.01) effect on soil organic carbon (SOC) with more value in cold sites (*Table 4*). Measured soil water content showed significantly higher values in cold sites and autumn samples in comparison to warm sites and spring samples, respectively (*Tables 2* and *4*).

Table 4. *Mean comparison (n= 8) between sites and season in soil chemical properties*

Soil chemical	Site		Season	
	Cold	Warm	Spring	Autumn
pH	7.75[a]	7.85[a]	7.9[b]	8.3[a]
Total nitrogen (%)	0.08[a]	0.05[b]	0.06[b]	0.07[a]
Available phosphorus	35.00[a]	30.5[b]	34.50[a]	31.00[b]
Soil organic carbon (%)	0.65[a]	0.29[b]	0.39[a]	0.45[a]
Soil moisture (%)	4.44[a]	1.32[b]	0.93[b]	4.83[a]

Different letters show significant difference at p< 0.05 level.

Soil enzyme activities

As shown in *Table 5,* the effect of site (p< 0.01), season (p< 0.01) and grazing (p< 0.05) was significant on alkaline phosphatase activity (*Table 5*). Activity of soil alkaline phosphatase decreased by 28, 22 and 15% in warm sites, autumn samples and not grazed areas in comparison to cold sites, spring samples and grazed areas, respectively (*Table 6*). The effect of site and season was significant on acid phosphatase but not grazing (*Table 3*). Acid phosphatase activity decreased by 32 and 66% in warm site and autumn samples in comparison with cold sites and spring samples (*Table 6*), respectively.

The results indicated significant effect (p< 0.01) of site and season on β-glucosidase and invertase activity (*Table 5*). The β-glucosidase activity decreased by 33 and 52% in warm site and autumn samples (*Table 6*). Grazing did not affect significantly β-glucosidase activity. However, the interaction of site and grazing was significant (p< 0.05) on its activity (*Table 5* and *Fig. 4*).

There was similar trend in invertase activity, as its activity decreased by 76 and 28% in warm site and autumn samples (*Tables 5* and *6*).

Measurement of urease activity showed that only the season caused significant difference on its activity (*Table 5*). The urease activity decreased by 29% in autumn samples in compared with spring samples (*Table 6*).

The effect of site and season was significant ($p < 0.01$) on arylsulfatase activity (*Table 5*). As shown in *Table 6,* there was a decrease in value of arylsulfatase activity in warm site (17.5%) and spring samples (17%).

The correlation between soil properties and enzyme activities

According to Pearson correlation coefficient values, soil electrical conductivity did not show any correlation with other soil chemical properties (*Table 7*). Soil pH correlated negatively with soil available phosphorus and soil moisture (*Table 7*). Whereas the correlation between soil organic carbon and total nitrogen was positive ($r = 0.774$, $p < 0.001$), they correlated negatively with soil moisture (*Table 7*).

The Pearson correlation indicated no significant correlation between soil EC and enzyme activities (*Table 7*). Whereas there was no correlation between soil pH and alkaline phosphatase activity, other assayed enzyme activities correlated negatively with soil pH except for arylsulfatase (*Table 7*). The correlation between soil available phosphorous and enzyme activities was positive except for urease and arylsulfatase activity. Total nitrogen showed positive correlation with alkaline phosphatase and arylsulfatase activity (*Table 7*) with higher correlation with arylsulfatase activity ($r = 0.609$, $p < 0.001$). The activity of all assayed enzymes correlated positively with SOC contents (*Table 7*). The highest correlation was observed with arylsulfatase activity ($r = 0.630$, $p < 0.001$). Based on Pearson values, soil moisture positively correlated with acid phosphatase, β-glucosidase, invertase and urease activity (*Table 7*) except for arylsulfatase activity ($r = -0.689$. $p < 0.001$).

Discussion

In this study, 11 soil variables including soil chemical properties and enzyme activities were measured to determine soil quality in a semiarid area.

Soil pH and EC are known as the principal indicator of the chemical characteristic of a particular soil, playing significant role in soil biogeochemical processes, solubility of soil nutrients, plant growth, microbial growth and enzyme activities (Aciego Pietri and Brookes, 2008; Sinsabaugh et al., 2008). Our results indicated that some of soil chemical properties did not easily change, which supported by other studies (Zarekia et al., 2012; Mureithi et al., 2014; Vargas-Gastelum et al., 2015). The less value of pH in spring samples can be explained by production of CO_2 by plant roots and bacteria that temporarily lower the pH value in natural ecosystem (Subba Rao, 2009).

Available phosphorus (AP), total nitrogen (TN) and soil organic carbon (SOC) are used as important indicators of soil fertility and long-term ecosystem sustainability (da Silva et al., 2008; Wienhold et al., 2009). There are some evidences that plant cover slows losing nutrients from soil (Porder and Chadwick, 2009; Deekor et al., 2012), supporting more TN, AP and SOC content in cold sites with dense plant cover in comparison with warm sites. The less concentrations of SOC at warm sites is attributed to faster turnover of organic C in warm sites and negative correlation between temperature and soil organic carbon (Friedlingstein et al., 2006). Whereas there was no

© 2018, ALÖKI Kft., Budapest, Hungary

seasonal variation in SOC content, TN and AP changed seasonally. The temporal alteration of available P was contradictory to total nitrogen seasonality. Plants uptake more P with increasing temperature (Yan et al., 2012), depleting the available phosphorus in soil from spring to autumn which is in accordance with our results. The more TN in autumn can be related to more activity of nitrogen fixing bacteria, which possibly increase the TN content (Zeng et al., 2009). In general, seasonal differences in AP and other nutrients are due to change in soil pH, moisture and temperature (Turner et al., 2013).

*, ** and *** indicate significant correlation at $p< 0.05$, $p< 0.01$ and $p< 0.001$, respectively. EC: electrical conductivity, AP: available phosphorus, TN: total nitrogen, SOC: soil organic carbon, SM: soil moisture, ACP: acid phosphatase, AlP: alkaline phosphatase, β-Glu: β-glucosidase, INV: invertase, UR: urease and AS: arysulfatase.

The soil enzyme activities is the metrics predominantly used to provide information on soil quality. We studied the activity of six extracellular enzymes, involved in P, C, N and S cycling. Soil phosphatases play a major role in the mineralization processes of organic phosphorus substrates. The activity of alkaline phosphatase was more than acid phosphatase, possibly related to soil pH (> 7), which makes condition more favourable for alkaline phosphatase activity than acid phosphatase activity. Whereas phosphatases show pH-dependent activity profile, with specific optimum pH for their maximum activity and stability, only acid phosphatases showed strong negative correlation ($r= -0.835$, $p< 0.001$) with soil pH. The soil pH values in studied areas were in the range of near optimum pH for the alkaline phosphatase activity, explaining why this enzyme did not correlate with soil pH (Olander and Vitousek, 2000; Renella et al., 2007).

The positive correlation between alkaline and acid phosphatase activity with SOC and available P is attributed to more activity of these enzymes in cold sites. Generally, a positive correlation is expected between enzyme activities and soil organic carbon, increasing soil enzyme activities as organic carbon increase in soil. The major reason for increased enzyme activities with increasing soil organic carbon could be attributed to the greater availability of soluble organic C, nutrients which stimulate microbial growth and activity as main source of soil enzymes (Debnath et al., 2015). Although

© 2018, ALÖKI Kft., Budapest, Hungary

our results showed a positive correlation between available P content and both phosphatase activities, this relationship is usually complicated and not constant, since a positive, a negative or no relationship between them has been reported (Kang et al., 2009; Lemanowicz et al., 2011; Piotrowska-Długosz and Wilczewski, 2014). A significant and positive relationship between phosphatase activity and available phosphorus is observed usually in natural soils and those with a low content of nutrients, where phosphorus deficiency occurs (Šarapatka, 2003). Furthemore, the uptake of available phosphorus by plants may complicate this correlation. The observed positive correlation between total nitrogen and alkaline phosphatase is supported by Piotrowska-Dlugosz and Wilczewski (2014) and Shi et al. (2008) findings. The significant and positive correlation between the acid phosphatase activity and the soil moisture is in agreement with Zheng et al. (2015) and but in contrast with Brockett et al. (2012) findings. The soil moisture content, by altering conditions for soil microbiota, causes changes in soil microbial growth and enzyme activities (Kim et al., 2008; Borowik and Wyszkowska, 2016).

Invertase and β-glucosidase play critical role in C cycle and release low molecular weight sugars that are important as energy sources for microorganisms. The positive correlation between β-glucosidase and invertase activity with soil pH was in consistent with other studies (Piotrowska and Koper, 2010; Shao et al., 2015; Zhang et al., 2015). Although a negative or no correlation between soil pH and invertase and β-glucosidase activity has been reported (Shi et al., 2008; Tan et al., 2014). The positive correlation between β-glucosidase and invertase activity with soil phosphorus is in agreement with Zheng et al. (2015) and Cheng et al. (2013). β-glucosidase and invertase activity were positively correlated with the soil organic carbon content. Similarity, Shi et al. (2008), and Böhme and Böhme (2006) observed significant and positive correlation between β-glucosidase and invertase activities with organic carbon content in soil samples, indicating the important role of organic matter in maintaining their activities. In addition, the observed positive correlation between soil organic matter and available phosphorus with invertase and β-glucosidase can explain more activity of these enzymes in cold sites, which is in agreement with various studies (Böhme and Böhme, 2006; Shi et al., 2008; Piotrowska and Koper, 2010). Our results did not confirm any significant correlation between soil total nitrogen and β-glucosidase and invertase, which is in agreement with Shi et al. (2008) and Zheng et al. (2015) but in contrast with Cheng et al. (2013) and Zhang et al. (2015) findings.

Urease is associated with the transformation, biological turnover and bioavailability of nitrogen in soil (Piotrowska-Długosz and Wilczewski, 2014). According to our results, there was a correlation between soil urease activity with soil pH ($r= -0.312$, $p< 0.05$), soil organic carbon ($r= 0.023$, $p< 0.05$), total nitrogen ($r= 0.178$, $p<0.05$) and soil moisture ($r = 0.307$, $p < 0.05$). Similar results have been reported by Tan et al. (2014), Zhang et al. (2013), and Piotrowska-Dlugosz and Wilczewski (2014). Soil urease activity did not show any correlation with soil EC and available phosphorus, which is in agreement with Melero et al. (2006) and Tan et al. (2014) findings.

Arylsulfatase activity, involved in S cycle, had a significant correlation with soil pH ($r= 0.290$, $p< 0.05$), soil organic carbon ($r= 0.630$, $p< 0.001$), total nitrogen ($r= 0.609$, $p< 0.001$) and soil moisture ($r= -0.689$, $p < 0.001$) which are supported by Mankolo et al. (2012) and Green et al. (2007). The strong positive correlation between SOC and arylsulfatase highlights the important role of soil organic carbon in arylsulfatase activity (Mankolo et al., 2012).

There is no constant pattern in seasonal variation in soil enzyme activities, depending on assayed enzymes, soil properties and ecosystem types. The enzyme seasonal variation is governed by parameters that regulate enzyme activities such as soil temperature, moisture and substrate availability (Wittmann et al., 2004; Niemi et al., 2005; Baldrian et al., 2008). Although seasonal variations in enzyme activities was not supported by Boerner et al. (2005) and Wallenstein et al. (2008), there was seasonal variation in all studied enzymes. The observed seasonal variation in acid and alkaline phosphatase, β-glucosidase, invertase and urease can be explained by more plant root exudates and seasonal variation in the microbial biomass which is in agreement with Devi and Yadava (2006), Yang et al. (2010) and Wallenstein and Weintraub (2008) findings. The all enzymes had more activity in spring except for arylsulfatase activity. Our finding on more intense activity of arylsulfatase in autumn is opposite with Margesin et al. (2014) report, but can be supported by Whalen and Warman (1996) findings. The more arylsulfatase activity in autumn samples can be related to presence of non-competitive inhibitors, possibly removed by plants during growth season and increasing arylsulfatase activity in autumn samples (Whalen and Warman, 1996).

Although the soil enzyme activities values were more in grazed area but the difference was not significant between grazed and not grazed areas except for alkaline phosphatase activity, showing its more sensitivity to environmental changes. It has been approved that the effect of grazing on soil properties depends on grazing intensity and period (Steffens et al., 2008; Fang et al., 2013).

Conclusion

It has been accepted that soil chemical properties and enzyme activities are important indicators in soil quality assessment. This study was conducted to illustrate the effect of site, season and grazing on soil chemical properties and enzyme activities. The results revealed the significant influence of site and season on some of soil chemicals and extracellular enzymes activities in semiarid areas but not grazing. The higher activity of all assayed enzyme activity in soils at cold sites can be attributed to the more soil organic carbon as there was a positive correlation between SOC and all assayed enzymes except for urease. There were also significant seasonal dynamics among different enzyme activities. Among the enzymes studied alkaline phosphatase was affected by grazing, which shows its higher sensitivity to soil management. In conclusion, it seems the soil quality is poor in warm sites according to both soil chemical and enzyme activities. Then soil in warm sites are more vulnerable to degradation and need more concern to be protected.

Abstract. Studies were conducted on the eleven largest and oldest ponds in the mesoregion Western Polesie in Eastern Poland. The aim of the study was to analyze the influence of environmental variables on species richness and vegetation cover of ponds. The analyzed variables included hydraulic parameters of ponds, water quality and buffer zone management. Detrended correspondence analysis (DCA), principal component analysis (PCA) and redundancy analysis (RDA) were applied to reveal principal variation patterns within the data. There were a different number of species comprising the phytolittoral zone in the investigated ponds. This study also showed that ponds are valuable for plant biodiversity. In total 75 species of plants occurred in the studied complex. The total number of species ranged from 10 to 49 in pond. The water of the ponds is characterized by very low value for most tested water quality indicators. The ponds are characterized by statistically significant differences of the buffer zone management. They have similar environmental conditions (temporariness of flooding period, low depth, water quality) and they potentially can share similar species. Our results also showed that the relationships between macrophyte species and cover depends on buffer zone management and some physicochemical variables of water.
Keywords: *water body, plant community, water quality, buffer zone management, ordination methods*

Introduction

Owing to their important contribution to aquatic biodiversity, ponds should be considered as an important target system in strategic plans that aim at conserving or developing aquatic biodiversity at the landscape scale. Such plans can only be effective if based on a solid knowledge of the factors that affect pond community structure and diversity. In issue, several studies document clear associations between the aquatic community characteristics and a variety of ecologically relevant, such as hydroperiod (Della Bella et al., 2008), surface area (Céréghino et al., 2008a), salinity and pond connectivity (Oertli et al., 2007; Boix et al., 2008; Gascón et al., 2008). In the first European Pond Workshop devoted to the Conservation and Monitoring of Pond Biodiversity launched a European network of people and institutions to collaboratively work on solving fundamental scientific issues and developing practical applications to protect ponds (Heino et al., 2015).

Ponds, particularly temporary ones, are aquatic habitats with multiple constraints due to their great abiotic spatial variability. However, this abiotic variability can provide certain, well adapted species, advanced opportunities to succeed (Lemmens et al., 2013). Drought is the principal constraint limiting macrophytes development and establishment in ponds. This constraint is even greater because of its unpredictability and alternation of dry and wet phase varies (Della Bella et al., 2008). The development of life cycles with different length, the dominance of one form of reproduction, the major or minor investment in seed production and the germination patterns, might concur in structuring the macrophyte assemblages in wetlands with different hydroperiod length (Ierotheos et al., 2010).

Research, driven both by the need to improve pond conservation strategies and by increasing interest in fundamental aspects of pond ecology (Heino et al., 2015), has started to shed new light on pond ecosystem structure and function. As a result, there is growing evidence that ponds are functionally different from larger lakes (Bornette et al., 2011) and that despite their small size they are collectively biologically diverse (Ierotheos et al., 2010). Ponds also show greater biotic and environmental temporal amplitudes than rivers and lakes (Céréghino et al., 2008b; Søndergaard et al., 2010).

In the mesoregion Western Polesie several pond complexes exist among which are the Sosnowica and Libiszów pond complexes. These pond complexes have been altered for harbouring and breeding carp. From an economic point of view, eutrophication is beneficial as it stimulates the growth of organisms that serve as the base of the food chain for fish. Hypertrophy is an adverse phenomenon resulting from over-fertilizing of ponds. In addition the data generated, so that this information may be used as the decision maker for conservation and effective utilization of water bodies particularly the reservoirs (Grzywna, 2013).

Studies were conducted on the eleven largest and oldest ponds in this region. They have been for one fish farming since World War I (Grzywna and Nieścioruk, 2016). The aim of the study was to evaluate the richness and distribution of aquatic macrophytes in fishing farm and to examine the relationships between habitat characteristics, environmental conditions, and aquatic macrophyte compositions. The ponds were all located within the border parts of protected natural areas of the Natura 2000 zone – the Forest of Parczew PLB060006. Data concerning physical and chemical properties of water, as well morphology, landscape and macrophytes were collected.

The aim of the study was to analyze the influence of environmental variables on species richness and vegetation cover of ponds. The analyzed variables included hydraulic parameters of ponds, water quality and buffer zone management. Hydraulic parameters of ponds were characterized by 2 values. Water quality was determined based on 10 physical and chemical properties of water. Five ways of using the buffer zone were identified.

Materials and methods

The paper presents the results of water quality tests, buffer zone management and richness of macrophyte species. Studies were carried out in July 2016 in two pond complexes in Western Polesie (Eastern Poland). The first complex, Sosnowica, consists of 6 fish ponds located in the Piwonia river basin (51°30'N, 23°05'E). The second complex, Libiszów, consists of 5 fish ponds located in the Konotopa river basin (51°40'N, 22°50'E). Both ponds in spring time are filled with water from the Wieprz

© 2018, ALÖKI Kft., Budapest, Hungary

and Krzna Canal (*Fig. 1*). They were all shallow with a different water area – WA, and depth – D (*Table 1*). The three largest ponds in each of the investigated complexes were flowing ponds connected by a system of ditches with the river Piwonia and river Konotopa. The rest of the studied ponds were standing ponds. All the studied ponds were temporary, having shorter wet-phase duration < 200 days. The ordination analysis covered 75 species, 11 study sites and 17 environmental variables.

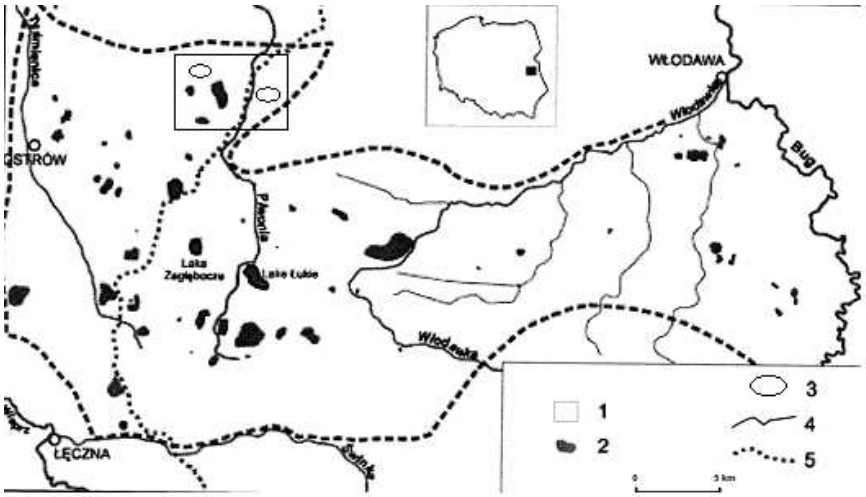

Figure 1. *Location of the study area in the Western Polesie. 1 – study area, 2 – lakes, 3 – ponds, 4 – river, 5 – Wieprz-Krzna Canal*

Minimum and maximum water depth was measured in situ using a meter stick. Pond area, water surface and buffer zone management (BZM) were estimated using ortho-image interpretation. Detailed analysis of land use types were carried out in ponds buffer zones, assuming the same radius length for ponds, 100 m, measured from the centroid of ponds and set automatically by the ArcGIS 10.0 software. Five ways of using the buffer zone were identified – Infrastructure (I), Water surface (W), Grasslands (G), Forests (F), Bushes (B).

Conductivity (Con), dissolved oxygen (DO) and pH were measured in situ with a multi-parameter probe. Three subsamples were taken and preserved at 4 ^{o}C to be analyzed in the laboratory later. Two of the subsamples were glass filtered to determine chlorides (Cl), sulphates (SO_4), nitrate nitrogen ($N\text{-}NO_3$) and ammonia nitrogen ($N\text{-}NH_4$). The third subsample, which was unfiltered, was used to determine total phosphorus (TP) and total nitrogen (TN). Water transparency was measured by visual evaluation Secchi disc (SD) (Grzywna et al., 2015).

Total surface covered with all studied groups of plants was calculated on the basis of macrophyte analysis in horizontal transects, extending from the edge of the embankment of the pond to the maximum colonization depth in pond. Aquatic transects radiated inward towards the centre of the pond for the length of macrophyte occurrence and were uniformly distributed along the entire shoreline every 100 m. The spatial structure of macrophytes was analysed in detail from 9 (the smallest pond) to 25 (the biggest pond) transects within the each pond. In each transect we collected emergent macrophytes using frames with sampling area of 0.5 m^2. Each measurement was repeated five times. Submerged and floating leaves macrophytes were sampled using a floristic Bernatowicz type of sampler (area 0.16 m^2) (Sender, 2016). On this basis, we determined species composition and the range of occurrence of particular groups of macrophytes in ponds. We recorded all species among 4 groups of macrophytes (emergent – EM, submerged – SM, floating – FM and flood meadow taxa – MT).

To calculate the present proportion of the different plant groups in ponds ArcGIS 10.0 software was used. Total coverage and range of particular groups of plants occurrence was done by a retrospective photointerpretative analysis (Chmielewski et al., 1996) using orthophotomap (2013), bathymetry maps of ponds, as well as field investigations. Maximum depth and GPS location were determined using the sonar Elite no. 5 of LOWRENCE. Aquatic plants were grouped in five class of coverage (1 = 1–5%, 2 = 5–25%, 3 = 26–50%, 4 = 51–75% and 5 = 76–100%), following the phytosociologic approach (Braun-Blanquet, 1976). Phytosociological units were distinguished using a systematic and nomenclature system by Matuszkiewicz (2008).

The data set was first subjected to detrended correspondence analysis (DCA) which showed a first-axis gradient length of 0.68 in standard deviation units. Therefore we decided to apply linear methods of ordination as principal component analysis (PCA) and redundancy analysis (RDA). PCA with standardized environmental variables was used to visualize patterns of environmental variation across ponds. Prior to the analysis, redundant environmental variables (with linear correlation coefficient $r > 0.7$) were omitted to avoid collinear rite (Blanchet et al., 2008). Further analysis took the following environmental variables into account: W, G, F (buffer zone management); TN, TP and Con (water quality). Significant PCA axes were selected with both Kaiser-Gutman criterion and the broken-stick model (Borcard et al., 2011). In the next stage, redundancy analyses with forward selection were performed. We carried out an RDA with all environmental explanatory variables, as well as for two subsets of variables (BZM and plant cover). We decided to apply Hellinger transformation to the species data (Legendre and Gallagher, 2001). Environmental data was cube root transformed and standarized to fulfill the assumption of normality. The RDA results were used to produce an ordination triplot. Statistical analyses were performed using vegan package in R (R Core Team, 2015; Oksanen et al., 2016).

Results

The water of the ponds is characterized by very low value for most studied water quality indicators. It applies mainly concentrations of such indicators as: Cl, SO_4, N-NO_3, N-NH_4, conductivity (con.), water reaction (pH), as well as TN. The concentration of DO and TP were different and rather high in studied ponds. The DO concentration reached average value 2.3 $mgO_2 \cdot dm^{-3}$ (range from 1.9 to 2.8 $mgO_2 \cdot dm^{-3}$), while, TP concentration ranged from 0.62 to 4.35 $mgP \cdot dm^{-3}$ (*Table 2*).

Statistically insignificant differences in physical and chemical parameters of water are characteristic of the analyzed ponds.

The ponds are characterized by statistically significant differences of the buffer zone management. The zone is predominantly overgrown with forests and bushes (accounting for > 50% of the total area). In the case of ponds situated in the central part of the complexes the water of the neighbouring ponds constitutes more than 40% of the ecotone area (*Table 3*).

Distribution of plants in the ponds was heterogeneous (mosaic). Phytolittoral zones often developed from one bank to another. Four different growth groups of macrophytes were found: submerged, emergent, floating and flood-meadow taxa. In total, 75 species of plants occurred in the studied complex. The number of species ranged from 10 in Morski pond to 49 in Anielski pond. There was a different number of species comprising the phytolittoral zone in the investigated ponds. The most abundant aquatic plant species found in the ponds were flood-meadow species (*Table 4*). They were represented by 49 (up to 67%) of aquatic species in some ponds. The species richness of

the pond was up 6 to 34 species. The most common species were: *Bidens trpartita, Lycopus europaeus, Scirpus sylvaticus.* They overgrow the embankment area, beyond the permanent water surface. Emergent macrophytes (EM) were represented by 10 species, occurring in all ponds. The dominant species among emergent macrophytes were *Phragmites australis* and *Typha angustifolia*. Submerged macrophytes (SM) comprised the poorest group, representing only 7 species. Species of this group occur in only 6 ponds. The most common species of SM was *Ceratophyllum demersum*. Floating macrophytes (FM) were represented by 9 species occurring in 9 ponds. The species richness of the pond was up to 5 species. The most common FM species were: *Lemna minor* i *Polygonum amphbium*. Among the species present in the investigated ponds were protected ones including: *Nuphar lutea*, and *Nymphea alba*. The total pond area covered with vegetation ranged from 5.0 to 39.6%.

Table 4. *Characteristic of the macrophytes occurrence*

Pond	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	**11**
Macrophyte cover [%]											
Floating	2.7	8.9	3.7	0	1.0	1.9	0.4	0	0.4	0	0.5
Submerged	2.2	3.2	3.9	0	0	2.8	4.9	4.4	0	0	0
Emergent	5.4	13.2	12.1	5.0	2.2	4.3	5.2	7.4	3.2	2.1	1.1
Flood-meadows	9.2	4.7	19.9	6.9	2.6	4	3.2	2.3	2.3	3.1	3.4
Total cover	19.5	30	39.6	11.9	5.8	13	13.4	14.1	5.9	5.2	5.0
Species number											
Floating	2	6	7	0	3	3	1	0	2	0	2
Submerged	0	2	3	0	0	3	3	3	0	0	0
Emergent	7	7	6	3	3	5	2	3	2	4	4
Flood-meadows	25	34	22	10	12	20	17	15	9	6	12
Total number	35	49	38	13	18	31	23	22	13	10	18

PCA axes 1 and 2 explained 72.06 % of a total variance (*Fig. 2*). Axis 1 explained 48.55 % of the total variance with forest and grassland coverage and conductivity showing high positive loading ($\lambda = 1.04, \lambda = 0.81, \lambda = 0.77$, respectively) and total phosphorus and total nitrogen showing a negative loadings ($\lambda = 0.75, \lambda = 0.71$, respectively). Axis 2 explained 23.52 % of the total variance and showed high negative loading for water coverage ($\lambda = -0.87$) and a positive loading of total nitrogen ($\lambda = 0.73$). Forest coverage and conductivity are highly positively correlated. Water and grassland coverage are negatively correlated. Total nitrogen and water coverage have nearly orthogonal arrows, indicating a correlation close to 0.

Redundancy analysis results are visualized in an ordination diagram (*Fig. 3*). All environmental variables explained 76.28% of the total variation (Legendre and Birks, 2012). The first two RDA axes explained 35.58% of the total variation in the species data (RDA1 = 18.8%, RDA2 = 16.78%). We performed a statistical significance test using the *anova* function in the vegan package for all variables and received a significant result (p = 0.039). The results of the forward selection and permutation tests indicated that only total phosphorus are significantly related to the species data (p = 0.02; R^2 = 0.67). When the subset of variables related to plant cover was considered, a total inertia of 26.85% was explained (p = 0.03; R^2 = 0.29). After the

© 2018, ALÖKI Kft., Budapest, Hungary

forward selection procedure the variable total phosphorus was selected as significant. However, when the subset BZM of environmental variables were taken into account, the explained total inertia was slight (34.87%) and not significant ($p = 0.105$; $R^2 = 0.35$). Among the strongest species-environment associations, we found that the species *Iris pseudoacorus* was positively associated with total phosphorus. *Typha angustifolia* and *Eupatorium cannabinum* were negatively associated to total phosphorus. Variable total phosphorus seemed to be associated to the negative part of Axis 1.

Discussion

Biodiversity in ponds is frequently studied because ponds are rich in microhabitats (Céréghino et al., 2008a) and provide appropriate conditions for aquatic vegetation development and establishment. Specifically, occasional breaks in the surrounding canopy on pond banks create changes in sediment properties that foster the development of plants (Gallego et al., 2014; Gallego et al., 2015).

Ordination analysis included 11 study fish ponds and 17 environmental variables. This study also showed that ponds are valuable for plant biodiversity. In total 75 species of plants occurred in the studied complex. The total number of species ranged from 10 in Morski pond to 49 in Anielski pond. In the studied ponds, a high number of aquatic plants were found according to the most recent works in Europe. In the studied ponds in the Mediterranean there were 51 species (on average 24 species per pond). In a study of lowland ponds in Great Britain an average number of 6 species in standing ponds and 11 species in flowing ponds was recorded and in ponds located in central Italy the average was 9 species (Della Bella et al., 2008; Gallego et al., 2014).

Maintaining the greatest diversity of macrophytes, as well as stable quality water, provides high economic effects in the studied ponds (Lemmens et al., 2013). Landscape characteristics mainly played an important role in species composition-environmental conditions relationships, ale chemical characteristics were significant (Hrivnák et al., 2013). The chemical parameters of the water to a large degree determine the occurrence of macrophytes; however, this is not the only type of pressure. Also, the development of the catchment area and of the littoral zone of the aquatic ecosystems has a significant effect on water and rush plant communities. Studies on the effect of the method of development of the littoral zone of lakes in the state of Wisconsin show that housing development definitely has a negative effect on submerged and floating-leaf plants. Such an effect was not observed for emergent vegetation. On the other hand, a lower share of forests in the catchment basin reduced the development of all macrophyte groups (Ahrenstarff et al., 2009; Akasaka et al., 2010).

The results of the forward selection tests indicated that only floating leaves are significantly related to the cover. They cover the water's surface and in this way provide fish the benefits of shade, protection and breeding areas. Ponds as a rule are shallow and during the summer their temperature rises very fast. This could cause a rapid increase in algal (Lin-lin et al., 2012). The proper buffer zone management (forest mixed meadow) could limit the penetration of sunlight (Sender, 2016). In these places, where the buffer zone is without shading vegetation, they cool the water for the fish and give fish a place to hide. But they could decrease the occurrence of submerged macrophytes. Submerged macrophytes, in the investigated ponds, were not numerous. So, in our opinion a compensation phenomenon appeared in these ponds, like in the shallow lakes from the Polesie region (Sender et al., 2015). Floating leaves may grow well in water with low transparency, well sunlit (Feldmann and Nöges, 2007), so it seems that ponds create the best habitat for them. The litoral and especially the zone of floating leaved plants decrease with increasing lake area due to wind stress related to the height and strength of waves (Feldmann, 2012; Kolada, 2014).

Ponds are ecosystems created by man and like each type of such ecosystem they require man's constant interference (regulation of water level, feeding fish). They are usually formed in unattractive agricultural places, while their presence significantly increases the natural values of the area. Antrophogenic waters provide suitable environmental conditions for the potential establishment and growth of macrophytes,

© 2018, ALÖKI Kft., Budapest, Hungary

floating-leaved and flood-meadow taxa. The analysed ponds could be an excellent example of sustainable development.

Conclusions

In conclusion, this study highlighted that temporary ponds in Western Polesie have different macrophyte species composition, with aquatic species exclusively found in each pond. Temporary ponds, while capable of hosting some hydrophytes, are tightly linked to humid meadows. They have similar environmental conditions (temporariness of flooding period, low depth, water quality) and they potentially can share similar species. Our results also showed that the relationships between macrophyte species and cover depends on buffer zone management and some physico-chemical variables of water. The PCA analysis showed a positive effect of the presence of grassland and forests in the buffer zone on the diversification of plant vegetation. We observe a negative effect on the diversity of vegetation in the case of high concentration of nitrogen and total phosphorus and increasing surface of the ponds. The RDA analysis showed a statistically significant negative effect of the total phosphorus concentration on macrophyte differentiation.

For conservation purposes, the studied temporary ponds hosted some species of conservation interest at regional scale: *Nuphar lutea*, *Nymphea alba* and *Epipactis palustris* (Lower Risk Category) are exclusively found more than in only one of pond. Therefore, the ponds should be preserved or created because both could give an irreplaceable contribution to the conservation of aquatic plant diversity of small water bodies.

Studies on physical and chemical parameters and occurrence of aquatic vegetation should be carried out in subsequent years at different times of the year. These factors are subject to seasonal and long-term changes. In the future, these studies will allow to determine the directions of changes and their causes.

ASSESSMENT OF THE CONTENT OF SELECTED TRACE ELEMENTS IN COCKSFOOT AND MAIZE MANURED WITH SEWAGE SLUDGE MIXED WITH HARD COAL ASH

GODLEWSKA, A.

Faculty of Natural Science, Siedlce University of Natural Sciences and Humanities
B. Prusa St. 12, 08-110 Siedlce, Poland
e-mail: agnieszka.godlewska@uph.edu.pl

(Received 18th Dec 2017; accepted 19th Mar 2018)

Abstract. The objective of the study was to determine changes in the content of selected trace elements in the biomass of test plants as affected by manuring with fresh and composted sewage sludge, hard coal ash, sewage sludge mixed with coal ash and liming at the background of mineral fertilisation. The experimental design was a completely randomised arrangement with three replicates. The following factors were examined: fertilisation with organic and mineral materials (fresh sewage sludge; composted sewage sludge; hard coal ash; calcium carbonate) and mineral fertilisation (no fertilisation; NPK fertilisation). An application of sewage sludge, hard coal ash, and sludge-ash mixtures significantly enhanced lithium content in the biomass of the 1st cut of cocksfoot, and molybdenum content in the 2nd cut grass. Hard coal ash mixed with sewage sludge contributed to an increase in lithium contents in the cocksfoot biomass of the 1st cut, titanium content in the 2nd cut of grass. Soil liming significantly increased lithium content in the plant biomass of 1st and 2nd cuts, as well as molybdenum contents in maize biomass. NPK nutrition significantly increased lithium, and titanium concentrations in the biomass of test plants.
Keywords: *organic fertilisation, mineral fertilization, liming, heavy metal*

Introduction

In recent years, a decline in the amount of organic manures applied to crops has been observed, which can frequently result in a negative soil balance of micro-elements. The phenomenon may disturb the appropriate content of micro-elements in crop plants which, in turn, is a very important qualitative characteristic taken into account while evaluating consumption- (Wojciechowska-Solis and Soroka, 2017) and feedstuff-related characteristics of the crops. Molybdenum and titanium are the elements which are indispensable for plant growth and development because they take part in metabolic processes. Additionally, molybdenum is a component of enzymes participating in transformations of nitrogen, phosphorus and sulphur compounds (Williams and Frausto, 2002; Bambara and Ndakidemi, 2010). The elements are also necessary for an appropriate development of animals and man (Kabata-Pendias and Mukherjee, 2007; Han et al., 2016).

Natural products for crop nourishment (Ciepiela and Godlewska, 2014; Ciepiela et al., 2016), industrial and municipal waste may be a valuable source of micro-elements and organic matter (Kalembasa and Godlewska, 2009a; Gondek, 2010; Kardos et al., 2011; Niewiadomska et al., 2015). Sewage sludge is of particular interest as it can be used for manuring purposes. However, sewage sludge may contain not only valuable nutrients but also harmful and toxic compounds (Usman et al., 2012) which, in turn, can be harmful for the environment, particularly if soil is acidic (Delibacak et al., 2009). The influence of these undesirable compounds may be reduced by an addition of substances such as hard coal ash or calcium carbonate, which contributes to an increase

in sewage sludge pH thus reducing the solubility and phytoavailability of the majority of metals (Maksimovic et al., 2008; Kalembasa et al., 2008). It would make it possible to achieve two important economic goals, that is remediation of ash landfills and sewage sludge management.

The objective of the study was to determine changes in the content of selected trace elements in the biomass of test plants as affected by manuring with fresh and composted sewage sludge, hard coal ash, sewage sludge mixed with coal ash and liming at the background of mineral fertilisation.

Materials and methods

A pot experiment was established in a glasshouse located at the experimental unit of Siedlce University of Natural Sciences and Humanities in Poland (52.169° N, 22.280° E). The experimental design was a completely randomised arrangement with three repetitions. The following factors were examined:

I – nutrition with organic and mineral materials (sewage sludge – raw and composted during three months) obtained from the sewage treatment plant in Siedlce – municipal and industrial sewage; hard coal ash from Energy Works in Siedlce; calcium carbonate). Sewage sludge was applied once, adding 5% relative to soil weight. Sewage sludge and coal ash were mixed at the ratio of 2:1 (DM).

II – mineral nutrition (with or without NPK fertilization) Mineral fertilisers: urea, triple superphosphate and potassium sulphate, were applied pre-plant.

The soil used in the experiment was very loamy sand obtained from the 0-20 cm layer of grey brown podzolic soil. Before the experiment was set up, soil contents of nitrogen, carbon, available phosphorus and potassium were determined (respectively: 1.10, 8.20, 0.052 and 0.071 g kg^{-1}). Pots were filled with the soil at the amounts of 10 kg and humidity was maintained at the level of 60% of the full water capacity during the vegetation period.

Cocksfoot (*Dactylis glomerata*) was the test plant in the first study year; it was sown at the amount of 1.0 g pot^{-1}, and three cuts per growing season were harvested. In the second study year, maize (*Zea mays*) was grown at the density of 3 plants per pot, and harvested at the flowering stage to determine the relationship between mineralization rate of the organic materials tested in the study and plant uptake of nutrients. In the dried and powdered plant biomass, the total quantities of Mo, Ti, and Li were determined by means of the ICP–AES technique (Boss and Fredeen, 2004) after 'dry' mineralisation. Plant material (1 g) was digested in a muffle furnace at 450 °C with gradually increased temperature; then digested samples were dissolved in water solution of hydrochloric acid ($HCl:H_2O$, 1:1) and evaporated until dry to decompose carbonates and separate silicates. The ash obtained was transferred to measure flasks containing 10% HCl solution through a hard filter paper. Total molybdenum, titanium and lithium contents in sewage sludge and hard coal ash were also determined by the ICP-AES method following 'dry' mineralisation.

The program STATISTICA (data analysis software system), version 12 (www.statsoft.com) was used to statistically analyse the results. Significance of differences between means for the experimental factors was checked using Tukey's test at the significance level of $\alpha \leq 0.05$.

Results and discussion

Hard coal ash and sewage sludge are composite materials whose chemical content and properties depend on many factors (Kalembasa et al., 2008). Sewage sludge applied in the experiment (*Table 1*) contained several times smaller amount of Li and Ti as hard coal ash. Molybdenum content in the sewage sludge and hard coal ash was similar and amounted to 5.67 and 3.76 mg kg^{-1}, respectively.

Table 1. *The content of Mo, Ti and Li in D.M. in sewage sludges and ash hard coal*

Element	Sewage sludge (mg kg^{-1})	Ash hard coal (mg kg^{-1})
Mo	3.76	5.67
Li	43.6	53.0
Ti	92.6	617

The cocksfoot grown in the experiment contained 2.74 mg molybdenum kg^{-1} DM, on average, the amount varying in particular cuts and depending on the experimental factors (*Table 2*). In the first study year, molybdenum content increased in subsequent grass cuts in plots with no NPK nutrition, but the opposite tendency was observed in NPK-fertilised units. It may indicate that the process of organic compound mineralisation accelerated due to additional mineral nutrition. An application of fresh sewage sludge significantly increased molybdenum quantity in the biomass of the 2nd cocksfoot cuts, whereas composted sludge and hard coal ash contributed to a decline in molybdenum content in the 1st-cut plants compared with the control. Also McBride (2005) reported increased Mo contents after sludge application.

By contrast, according to Wichard (Wichard et al., 2009) molybdenum in soils can bind to organic matter, which can cause limiting its availability to plants.

Table 2. *The content of Mo (in mg kg^{-1} DM) in cocksfoot*

Ash mixed with composted sludge significantly increased molybdenum content in cocksfoot but its mixture with fresh sewage sludge contributed to a decline in molybdenum concentration in test plants. Liming of the soil to which sludge-ash mixtures were incorporated, significantly enhanced the molybdenum uptake by cocksfoot. Mineral nutrition of the 1st cut plants significantly increased molybdenum content in cocksfoot whereas in the 2nd and 3rd cuts a decline was observed.

Average molybdenum concentration in the biomass of maize grown in the second study year was 0.786 mg kg^{-1} DM (*Table 3*), on average, and significantly depended on the waste materials applied. An application of sewage sludge, ash, and a sludge-ash mixture – both fresh and composted – significantly increased molybdenum content in maize compared with control plants. Soil liming increased the amount of the element in maize biomass as compared to control plants. Also, liming significantly enhanced molybdenum uptake by maize in plots where fresh and composted sludge-ash mixtures had been applied. Kalembasa and Godlewska (2009b) found that soil liming increased Mo content in plants, which was also confirmed in the present study.

For explanations see *Table 2.*

Titanium content in cocksfoot biomass (*Table 4*) was 2.88 mg kg^{-1} DM, on average, and increased in subsequent cuts. The waste materials applied significantly reduced the titanium concentration in the 1st cut grass as compared to control plants. An addition of ash to fresh and composted sewage sludge resulted in a significant decline in titanium content in the biomass of the 1st cut cocksfoot. However, ash added to sludge increased titanium quantity in the 2nd cut of test grass. NPK nutrition had a significant effect only for the 1st cut grass whose titanium content was significantly higher.

The average titanium content in maize (*Table 5*) was 2.40 mg kg^{-1} DM. Liming significantly increased titanium content in plants fertilised with fresh sewage sludge mixed with hard coal ash. Titanium concentration in maize grown in plots treated with composted sludge, ash, and fresh sludge mixed with ash was lower as compared to control plants. Also Kalembasa and Wysokiński (2009) reported higher titanium amounts in control maize compared with sewage sludge-treated plants. NPK nutrition significantly increased titanium concentration in the test plants.

The average lithium content in cocksfoot biomass (*Table 6*) amounted to 23.4 mg kg^{-1} DM, and it was affected by the experimental factors. Waste materials contributed to significant differences between the cuts, but lithium content did not exceed 50 mg kg^{-1} DM, which is assumed as the limit for root crops. The content was lower in all the cuts of control cocksfoot biomass compared with the remaining units. Hard coal ash mixed with fresh and composted sewage sludge contributed to increased lithium contents in the cocksfoot biomass of each cut the differences being significant for the 1st cut only. Soil liming in plots where sludge-ash mixtures were used, enhanced the quantity of the element in all the cuts of the test plants. Moreover, there were recorded significantly higher lithium concentrations in 1st and 2nd cut plants harvested from limed plots, and a significantly higher mean concentration calculated across the three cuts for limed units

compared with the control grass, which was not consistent with other authors' reports. According Aral and Vecchio-Sadus (2008) plant uptake of lithium is greater in acidic soils than in alkali soils. By contrast, Wysokiński and Kalembasa (2009) found a higher lithium content in sunflower grown in plots manured with fresh and composted sewage sludge mixed with brown coal and CaO, compared with plants manured with sewage sludge only. Mineral nutrition increased the lithium content in the 1st and 2nd cuts but it insignificantly affected the lithium uptake by cocksfoot in the 3rd cut.

Lithium level in maize biomass (*Table 7*) was 14.5 mg kg^{-1} DM, on average. Although no significant differences were found, lithium content tended to increase in maize plants due to an application of waste materials and their mixtures compared with the control. Hard coal ash mixed with fresh and composted sewage sludge had no effect on the uptake of lithium by plants. Mineral nutrition was the only factor which contributed to a significant increase in the maize content of lithium.

Conclusions

An application of sewage sludge, hard coal ash, and sludge-ash mixtures significantly enhanced lithium content in the biomass of the 1st cut of cocksfoot, molybdenum content in the 2nd cut grass. Hard coal ash mixed with sewage sludge contributed to an increase in lithium contents in the cocksfoot biomass of the 1st cut, titanium content in the 2nd cut of grass. Soil liming significantly increased lithium content in the plant biomass of 1st and 2nd cuts, as well as molybdenum contents in maize biomass. NPK nutrition significantly increased lithium, titanium and barium concentrations in the biomass of test plants.

In summary, it should be noted that the degree of organic matter decomposition and origin has a considerable effect on the characteristics discussed in the work. Further studies are needed to develop more comprehensive results and evaluate the impact of different rates of organic and mineral materials.

(Received 2nd Nov 2017; accepted 3rd Apr 2018)

Abstract. The knowledge of evapotranspiration variation is necessary not only for climatology reasons but also for agriculture and hydrology purposes to understand the amount of water resources and its distribution in territory. Here, we present an exhaustive study of spatial distribution of crop evapotranspiration (ET_c) in Europe, both for seasonal and annual time-shifts related to the present (2011–2040) and the future (2041–2070). The method is based on the crop coefficients (K_c) and the climate modes. The seasonal ET_c varies in Europe from 0 mm to 772 mm in the present period and from 0 mm to 848 mm in the future period. The annual ET_c ranges from 0 mm to 1385 mm year^{-1} for the present while the future calculations indicate values which range from 0 mm to 1496 mm year^{-1}. Elevated values of annual ET_c were depicted in the Iberian Peninsula, Balkan Peninsula, Italian Peninsula, and Pannonian basin. These findings are the base for the water resources quantity in Europe for the 21st century, with major help in the hydrological and climatological studies, but also for the agriculture and planning strategies, policymakers' decisions, and considerable scientific contribution.
Keywords: *climate change, spatial climate data, evapotranspiration mapping, land cover, crop coefficients, GIS*

Abbreviations: GIS: geographical information systems, K_c: crop coefficients, ET_c: crop evapotranspiration, ET_0: potential evapotranspiration, $K_{c\ ini}$: initial season coefficient, $K_{c\ mid}$: mid-season coefficient, $K_{c\ end}$: end season coefficient, $K_{c\ cold}$: cold season coefficient

Introduction

The changes in the planet's geospheres are continuously also in relations with the climate. A lot of natural systems and artificial conceptions depend on an optimum standard to maintain its functionality. The Earth's climate is warming (Haeberli et al., 1999; Oerlemans, 2005), a fact for which the equilibrium of different entities is triggered in many places, regions, and continents. Increase of the mean air temperature in the last 140 years was observed on the climate trend (IPCC, 2001). Moreover, for the 21st century, an increase in the mean air temperature up to 3 °C and a decrease of precipitation in different places across the globe were predicted (IPCC, 1996, 2001; Stavig et al., 2005; The Canadian Climate Models, 2014). The obvious findings about global warming have been carried out by studying the glaciers, which are the most sensitive indicators of climate change (Haeberli et al., 1999; Kargel et al., 2005; Dong et al., 2013; Nistor and Petcu, 2015). An increase in the mean sea level was calculated, taking into account the Arctic regions and negative trends of the ice field areas, and ice caps were depicted. However, the impact of climate change on the Earth is not related only to the glaciers melting; it also implies numerous negative outcomes on agriculture, land use, and hydrology. Parmesan and Yohe (2003), Campos et al. (2013) and Prăvălie et al. (2014) indicated the climate change negative impact on ecosystems and on water

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

resources. The components of ecosystems and the ecolines could be easily affected by climate change. Due to this reason, many ecosystems and several natural reservations are exposed to major changes in their composition and biodiversity (Nistor, 2013; Nistor and Petcu, 2014).

Regarding the water resources, the negative impact of climate change on surface water has been claimed by scientists to be indicated by the decrease in river discharge and the reduction in runoff (Piao et al., 2010). These facts have a direct impact on water availability (Čenčur Curk et al., 2014). On the other hand, the northern sides of Europe and the Alpine region are faced with the increase of the stream flow discharge in the spring period due to the melting of glaciers and snow, which leads to floods and erosion in many places due to extreme events (IPCC, 2007). Numerous surveys on groundwater and climate change were completed in the last two decades as a consequence of global warming by numerous scientists (Loàiciga et al., 2000; Bachu and Adams, 2003; Brouyère et al., 2004; Nistor et al., 2014; Prăvălie et al., 2014). The majority of them have found that the negative effects of climate change on groundwater recharge were mainly related to the reduction in spring flow discharge and seawater intrusion into coastal areas due to sea level rise. The negative impact of climate change on groundwater quality is related to the increase in groundwater temperature (Taylor and Stefan, 2009; Kløve et al., 2014) and "dissolved oxygen concentrations" (Figura et al., 2011; Kløve et al., 2012, 2014; Haldorsen et al., 2012). Jiménez Cisneros et al. (2014) summarize a series of quantity and quality problems related to climate change in the "IPCC 2014 report". The most important issue of the surface waters and groundwater quantity is directly related to the evapotranspiration amount. Mojid et al. (2015) report the contribution of the impacts of climate change on crop water demand.

In the Southeast Europe region, climate change also negatively affects the evapotranspiration (Nistor et al., 2017a). Several hydrological and climatological studies used the potential evapotranspiration (ET_0) and actual evapotranspiration for the water balance calculations and water surplus determination (Li et al., 2007; Rosenberry et al., 2007; Gowda et al., 2008). These calculations are more accurate and realistic if the climate data are well combined with the vegetative pattern. This task contributes to find the appropriate values of the ET_c. Allen et al. (1998) and Allen (2000) proposed a method for ET_c calculation using K_c values, extracted from the evapotranspiration ratio of the ET_c and ET_0. They calculated the K_c values for different large varieties of crops, including also the tropics and temperate zones. In the same period, Grimmond and Oke (1999) have conducted a significant research on the K_c values related to the urban areas of different cities from the United States. Later, considering Allen et al.'s (1998) method and Grimmond and Oke's (1999) additional work, Nistor and Porumb-Ghiurco (2015) have calculated and completed the spatial distribution of the ET_c in the Emilia-Romagna region from Italy. They used the climatological data grids to calculate the ET_0 and the land cover layer to create the evapotranspiration rate in four seasons. Due to its high applicability, their method has been widely used in ET_c mapping for many regions of Europe. Thus, Nistor et al. (2017b) found the ET_c in the Pannonian basin using the climate models of 30 years for the present (1991–2020) and future (2021–2050) and the K_c values. They observed an increase of ET_c for the future period due to increase in the mean air temperature. In the mountain area of the Carpathian region, the ET_c have been calculated by Nistor et al. (2016) and the research findings indicate the increase of ET_c values for recent decades. These results were connected to the negative climate warming effects on the evapotranspiration and possible decrease in water availability

© 2018, ALÖKI Kft., Budapest, Hungary

for the next half century. Using the groundwater modelling under climate change, the water table levels in Geer Basin from Belgium will be expected to decrease in future (Brouyère et al., 2004). A comprehensive study about the evapotranspiration parameters, based on accurate methods in Western Macedonia from Greece, was done by Ambas and Baltas (2012). The REMO and ALADIN regional climate model simulations have been used by Ladányi et al. (2015) in the Kiskunság National Park from Hungary to investigate the future drought hazard. Anda et al. (2015) and Blanka et al. (2017) have completed the investigations related to evapotranspiration and water management in Central Europe. Kurnik et al. (2014) applied a model of Soil Water Balance European Water Accounting to assess the evapotranspiration of main agricultural regions from Europe. Recently, using the regional fuzzy chain model, Güçlü et al. (2017) calculated the evapotranspiration in the Kingdom of Saudi Arabia. Based on Geographical Information System (GIS) and remote sensing technology, Zhan et al. (2015) have calculated the reference evapotranspiration at a regional scale in China. Ramírez-Cuesta et al. (2017) did the appropriate work in the South of Spain. In the Hungarian-Serbian cross-border area, Fiala et al. (2014) analyzed the severity of drought and its influence on agricultural production.

Considering the threats posed by climate change to agriculture and hydrological resources in one of the most important and diversified continents of the world, our work aimed to calculate ET_c in two time periods (2011–2040 and 2041–2070) based on the high-resolution climate models and land cover data.

Materials and methods

Study area

The European continent extends from 34°35’ to 80°42’ latitude N and from 0°0’ to 8°59’ longitude W and from 0°0’ to 66°42’ longitude E (*Fig. 1a*). Here, we were able to complete the ET_c only for the main realm of Europe and few islands. The Eastern extremity of Europe and some islands such as Iceland have not been included in this investigation due to a lack of climate data.

Europe is a very varied continent from the relief, climate, and land cover points of view. The northern, western and southern coastal line is unregulated, with many peninsulas and islands. The altitudes of the continent range from slightly below 0 m in the Netherlands and some lowlands such as the Danube Delta to 4810 m in Mont Blanc Peak from the Alps Range.

The most extended landforms in Europe are the plains, followed by hilly areas and mountains. Thus, in the eastern part of Europe is the East Europe Plain while in the central and northern sides is located the North European Plain. Other plains are present in different regions of the continent, e.g. the Po Plain extends in the North of Italy, Île-de-France in the North of France, the Romanian Plain in the South of Romania, and the Pannonian basin in the South-central part of Europe.

More important for the land cover biodiversity and for the air mass movement are the mountain ranges too. In the South there are the Alps Mountains which extend on approximately 1000 km in length; in the central and eastern sides there is the Carpathian Mountains; the elevated southern sides of Europe are represented by the Dinaric Mountain and in the North are located the Scandinavian Mountains. In the West of Europe, between France and Spain, there are the Pyrenees Mountains, in the South of Europe are the Apennines Mountains, while in the North of the British Islands there are

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

the Scottish Mountains. In Spain, the high plateau can be found as "Meseta Central", but also other hilly areas extend in Europe, generally interposed between the mountains and plains (e.g. Prealps between the Alps Range and Po Plain, Sub-Carpathians between the Carpathian Range and the Romanian Plain).

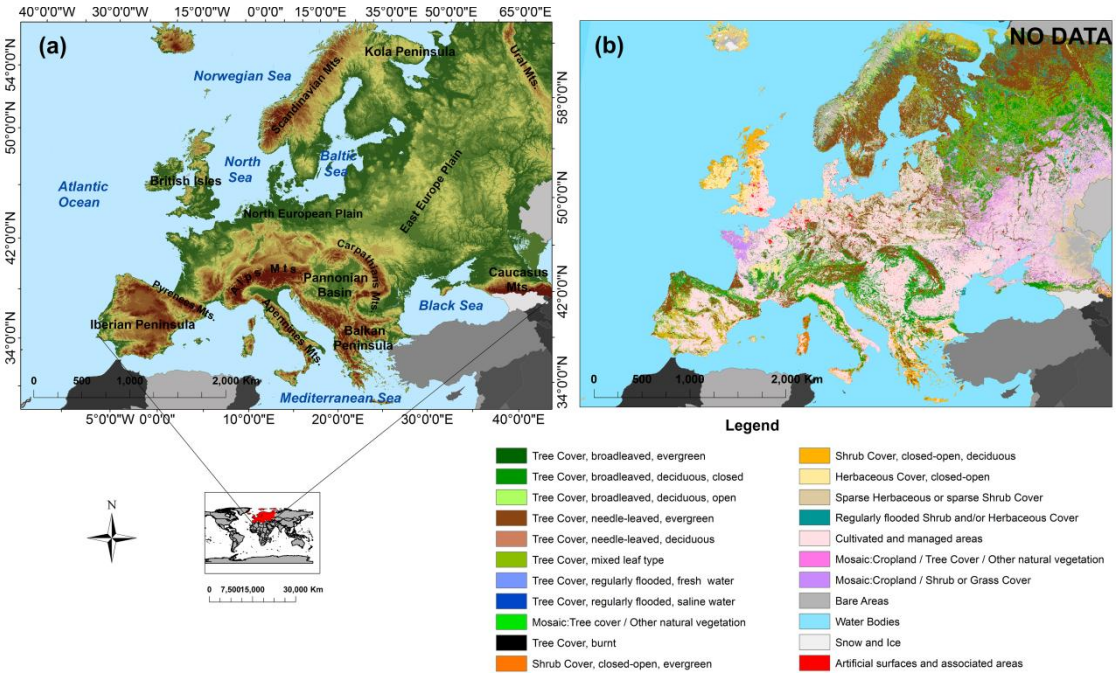

Figure 1. *(a) The physical map of European continent and its location on global map. (b) Land cover of Europe*

The high extension in latitude and also the presence of the Atlantic and Arctic Oceans in Europe's surroundings are going to influence the different types of climate. In the North of Europe, the climate is Baltic; in the West of Europe there is the ocean influence. In the South of the continent, the Saharan and Mediterranean influences are felt. The continental influences that occur in the East of Europe and the transitional climate between oceanic and continental is more present in the Romanian landscape. The local climates may be depicted in the mountain and near the coastal areas (e.g. in the Alps, in the Carpathians, near the Black Sea, around the Mediterranean Sea). Cfa climate was verified in the central, North-central, Southern and some territories of the southeastern parts of Europe (Kottek et al., 2006). This type of climate is characterized by the warm temperate climate with hot summer and a fully humid period during one year. The Dfa and Dfb climates, which represent the cool climate with hot and warm summers, could be found in the eastern and southeastern sides of Europe. In the Scandinavian Peninsula and northeastern sides, the Dfc cool climate with the cool summers has been identified (Kottek et al., 2006). The South of Europe, mainly the southern sides of the Italian and Balkan Peninsulas, has the Cfc climate. The Csb climate, characterized by dry and warm summers extends to the North of the Iberian Peninsula while the Csa climate, characterized by hot summers and limited precipitation, extends to the South of the Iberian Peninsula. Due to the very low

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

temperatures during the winter season, in the Scandinavian Peninsula and in the elevated areas of the Alps Range, the polar tundra climate is easy to find.

In the direct relationship with the climate and relief conditions, the vegetation pattern shows an intense biodiversity in Europe. First, the favourable plain lands and coastal areas are highly recognized for their agriculture lands and urban developed areas. Generally, in the mountains, the coniferous and evergreen forests are growing. In the hilly areas and low mountains, the land cover is mainly composed of mixed and deciduous forests and includes such species as oak (Quercus), beech (Fagus), hornbeam (Carpinus), and elms (Ulmus) (European Environment Agency, 2007). Pasture, transnational woodland, and shrubs predominantly cover the alpine areas. The agricultural crops, hay, and herbaceous vegetation are typically for the lowlands and plain areas. The northern sides of Europe are covered by tundra vegetation. In the North of the Mediterranean Sea, the Mediterranean vegetation of stone pine (Pinus pinea) and maquis vegetation are presented. In the beach areas and drylands such as the South of Europe, the sclerophyllous vegetation is characteristic. The harbour areas, deltas, lagoons, marshes, beaches and dunes are also located in the coastal areas. *Figure 1b* shows the main land cover of Europe.

Climate data models

Climate models of the monthly air temperature and annual precipitation at high spatial resolutions have been used for the understanding of Europe's climatic parameters and for the seasonal and annual ET_c calculations. The models related to the present (2011–2040) and future periods (2041–2070) are the two main datasets for which the ET_c was computed. Climate projections were obtained from a publicly available database of high resolution climate grids for Europe (*http://tinyurl.com/ClimateEU*, Hamann et al., 2013). The database builds on the Parameter Regression of Independent Slopes Model (PRISM) to generate monthly precipitation grids for the 1961–1990 climate normal period, generated by Daly (2006). The ANUSplin interpolation method was used to generate monthly temperature grids for the 1961–1990 normal period. Future projections for temperature and precipitation are based on 15 AOGCMs of the CMIP5 multi-model dataset overlayed on the 1961–1990 baseline grids using the delta method. Further details on the climate database are described by Hamann et al. (2013). Both datasets are bias corrected and calibrated by using an anomaly method. The eastern extremity of Europe does not have available climate data, thus our study does not include this part of the continent.

Land cover data

A significant dataset in the ET_c calculation is the land cover layer, which expresses in the best way the vegetation spatial distribution in a certain field. To identify the main crops of Europe and the existing categories of the land cover type, here we used the CORINE Land Cover 2000 database. Even if it dates from 2000s years, CORINE database detailed up to the 3rd level is a raster data 250 m in spatial resolution elaborated and revised by the European Environment Agency (2016). The main advantages of the CORINE are the details and spatial resolution and the fact that this database covers the whole of Europe better than other versions of the CORINE 2006 and 2012 in that half the territory of Europe is not represented. Moreover, the raster grid of land cover is easy to integrate into the GIS environment. Both land cover and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_21492168
© 2018, ALÖKI Kft., Budapest, Hungary

climatological data were set at 1 X 1 km spatial resolution. This resolution was adopted also by Nistor et al. (2016) in their mapping ET_c study.

Potential evapotranspiration (ET_0)

To calculate the seasonal ET_c, the monthly ET_0 was performed both for present and future periods. Due to the worldwide use and efficient performance, the Thornthwaite (1948) method was applied for this study. The monthly raster grid data of mean air temperature for present and future periods have been used to carry out the monthly ET_0. Seasonal and annual ET_0 were computed from the monthly raster data of ET_0.

The Thornthwaite (1948) formula (*Eq. 1*) is widely considered in the climate, hydrology and agricultural studies (Čenčur Curk et al., 2014; Nistor et al., 2015) but also provides good results at a regional scale (Nistor et al., 2016).

$$ET_0 = 16\left(\frac{10T_i}{I}\right)^{\alpha} \quad \text{(Eq.1)}$$

where:
ET_0 monthly potential evapotranspiration [mm]
T_i average monthly temperature [°C], $ET_0 = 0$ if $\bar{Tm} < 0$
I heat index (*Eq. 2*)
α complex function of heat index (*Eq. 3*)

$$I = \sum_{i=1}^{12} \left(\frac{T_i}{5}\right)^{1.514} \quad \text{(Eq.2)}$$

where:
T_i monthly air temperature

$$\alpha = 6.75 \times 10^{-7} I^3 - 7.71 \times 10^{-5} I^2 + 1.7912 \times 10^{-2} I + 0.49239 \quad \text{(Eq.3)}$$

where:
I annual heat index

Crop coefficients (K_c)

The key to the land cover evapotranspiration research and ET_c calculation at spatial scale in this approach are the values of K_c. For each type of land cover was assigned a specific K_c, accordingly with the specific literature (Allen et al., 1998) and previous scientific works (Nistor and Porumb-Ghiurco, 2015; Nistor, 2016a; Nistor et al., 2016, 2017a, b).

Understanding it as being the ratio between ET_c and ET_0, the K_c could have a slight variation for the same crops, depending on the annual period, local micro-climate conditions, dry or wet state of the Earth surface, latitude, and crop growth (Allen et al., 1998; Grimmond and Oke, 1999; Nistor et al., 2017b). For this reason in the present paper we adopt the standard methodology of the single crop (Allen et al., 1998) and also the values proposed by Nistor (2016a). Allen et al. (1998) published testing values of the K_c for different zones of the world in the Food and Agriculture Organization Paper 56 report. Regarding the evapotranspiration in the bare soil and urban areas, Grimmond

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_21492168
© 2018, ALÖKI Kft., Budapest, Hungary

and Oke (1999) carried out the K_c values by measurements in different locations across the United States. Appropriate values of K_c have been chosen for Europe, considering the latitude as the main factor of relevance.

An important aspect of the spatial representation of the K_c is coming from the calendar crops growth. For the temperate zone, the plant growth stage has been set in four seasons during one year: (i) initial season from March to May, (ii) the mid-season from June to August, (iii) the end season during September and October, and (iv) the cold season during January, February, November, and December. Nistor (2016b) also inserts one season between initial season and mid-season, the so-called developed season, but in his work the daily ET_c for a not-so-extensive area was done. Due to the overlapping of the crop calendar (Nistor et al., 2016), at the regional and continental scales the seasonal ET_c may be divided into four seasons. Thus, in function of the crops and land cover components, the specific values for the initial season coefficient ($K_{c\ ini}$), mid-season coefficient ($K_{c\ mid}$), end season coefficient ($K_{c\ end}$), and cold season coefficient ($K_{c\ cold}$) were set for the whole land cover pattern of Europe. *Figure 2* indicates the spatial distribution of K_c on the European continent. *Table 1* reports the values of K_c in the four chosen stages.

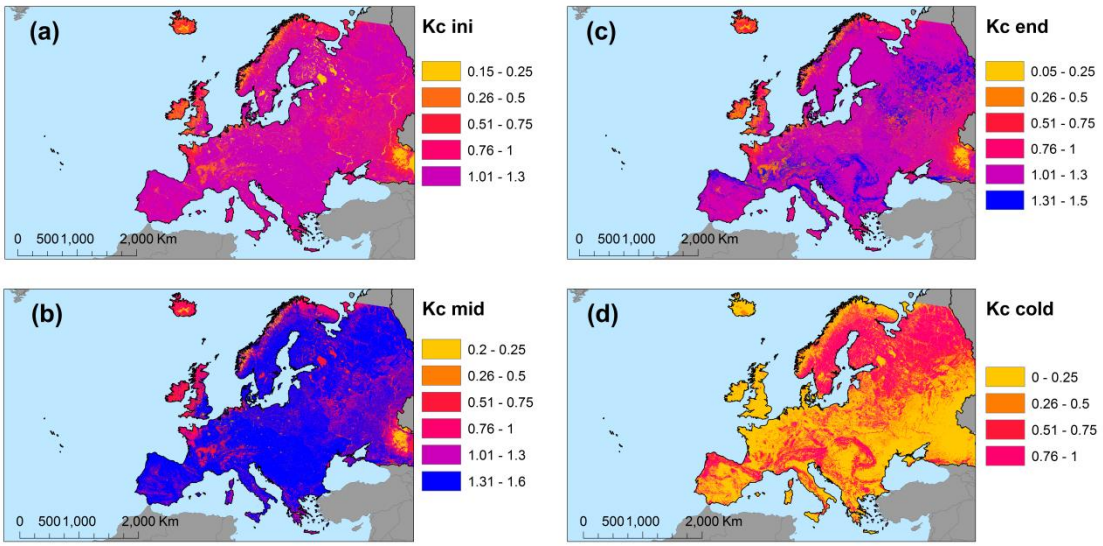

Figure 2. *Spatial distribution of K_c in Europe related to the land cover. (a) $K_{c\ ini}$ for the initial stage. (b) $K_{c\ mid}$ for the mid-season stage. (c) $K_{c\ end}$ for the end stage. (d) $K_{c\ cold}$ for the cold stage*

Crop evapotranspiration (ET_c)

The original procedure to calculate the ET_c is to multiply the K_c with ET_0 (*Eq. 4*). The mathematical calculations were completed using the 'Raster Calculator' function, from the ArcGIS 10.3 environment. The powerful spatial data analysis, climatological phenomena mapping and environmental surveys are the main advantages of the Spatial Analyst Tools from the ESRI software (Baltas, 2007; Dezsi et al., 2015; Nistor and Petcu, 2015).

Both seasonal and annual ET_c for Europe are related to the 2011–2040 and 2041–2070 periods, with the purpose of observing the effects of climate change on the amount of evapotranspiration during the 21st century. The four seasons of ET_c have been calculated, multiplying the K_c of the respective season with the seasonal ET_0 from the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_21492168
© 2018, ALÖKI Kft., Budapest, Hungary

same period stage. Thus, the initial ET_c ($ET_{c\ ini}$) (*Eq. 4*), the mid-season ET_c ($ET_{c\ mid}$) (*Eq. 5*), the end season ET_c ($ET_{c\ end}$) (*Eq. 6*), and the cold ET_c ($ET_{c\ cold}$) (*Eq. 7*) were computed for Europe. Successively, the sum of the seasonal ET_c was done to calculate the annual ET_c for the present and the future (*Eq. 8*).

$$ET_{c\,ini} = ET_{0\,ini} \times K_{c\,ini} \quad \text{(Eq.4)}$$

$$ET_{c\,mid} = ET_{0\,mid} \times K_{c\,mid} \quad \text{(Eq.5)}$$

$$ET_{c\,end} = ET_{0\,end} \times K_{c\,end} \quad \text{(Eq.6)}$$

$$ET_{c\,cold} = ET_{0\,cold} \times K_{c\,cold} \quad \text{(Eq.7)}$$

$$\text{Annual } ET_c = ET_{c\,ini} + ET_{c\,mid} + ET_{c\,late} + ET_{c\,cold} \quad \text{(Eq.8)}$$

Results

Climate models indicate a rise in mean air temperature trend for the current century from 21.4 °C (*Fig. 3a*) to 22.8 °C (*Fig. 3b*) in Europe. For both the present and future periods, the maximum values of the mean annual temperature could be found mainly in the South of Europe, on the Mediterranean coast, in the West sides of the continent, especially in the Iberian Peninsula, and in some places from the southeastern sides of Europe, near the Black Sea and Marmara Sea. The Scandinavian Peninsula, North of Great Britain Island, and the mountain ranges (the Alps, Carpathians, Dinaric, Pyrenees, and North of Caucasus) are the territories with low values of temperature in Europe (below 6 °C). Annual precipitation pattern varies from 160 mm to 3539 mm and from 140 mm to 3487 mm in the present respective future periods (*Fig. 4a, b*). The main changes of the spatial distribution of annual precipitation were depicted in the central and eastern sides of the continent. The high values (over 2500 mm) of the annual precipitation are frequently in the West of the Scandinavian Peninsula, Alps Range, Dinaric Range and North of the British Island. The lands with low precipitation are located in the South of the Iberian Peninsula, East and South-East of Europe near the Black Sea, and in the South of the Balkan Peninsula. As a consequence of the temperate regime, the annual ET_0 reaches values over 1200 mm year^{-1} in the present and over 1400 mm year^{-1} in the future period. The highest values of annual ET_0 were depicted in the southern and western sides of Europe while the lowest values of ET_0 were depicted in the northern and northeastern sides of the continent, but also in the mountain areas. *Figure 5* shows the annual spatial distribution of ET_0 in Europe for the current and future set time periods.

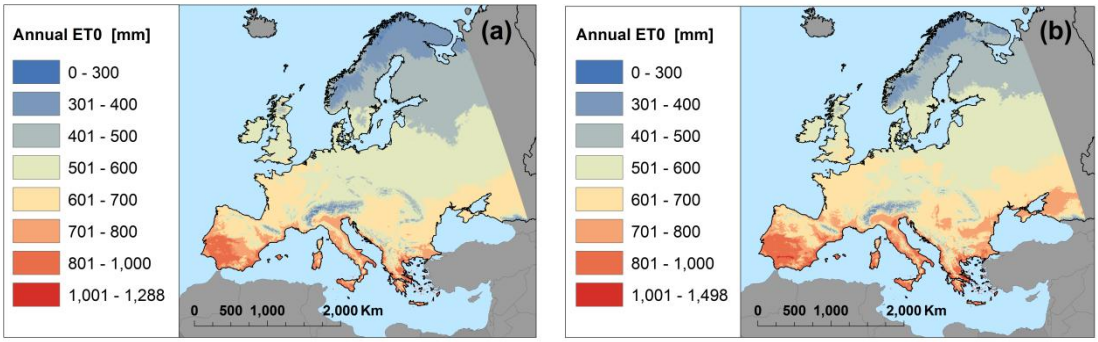

Figure 5. *(a) The average annual ET_0 between 2011 and 2040. (b) The average annual ET_0 between 2041 and 2070*

Based on climate models and land cover data, the seasonal ET_c mapping has been completed and analysed for the periods 2011–2040 and 2041–2070. In both times shifts, the seasonal ET_c calculations illustrate the maximum values during the mid-season, as a consequence of high temperatures and ET_0 values in the summer months but also because of the $K_{c\ mid}$ values, which exceed 1.3 in major parts of the continent.

In the present period (2011–2040) the $ET_{c\ ini}$ values range from 0 to 240 mm, whereas in the future period (2041–2070) the $ET_{c\ ini}$ ranges from 0 to 248 mm (*Fig. 6a, b*). The few changes between the present and the future may be explained by the contribution of climate change to the increase of ET_0 in the spring months (March–May). The high values of $ET_{c\ ini}$ were found in the West of the Iberian Peninsula and in the south-central part of the continent. The lowest values of the $ET_{c\ ini}$ are overlapping to the North and northwestern sides of the Scandinavian Peninsula, Alps Range, Pyrenees and Caucasus Mountains. Low $ET_{c\ ini}$ values were depicted also in the West of the British Islands and in the northwestern sides of Europe.

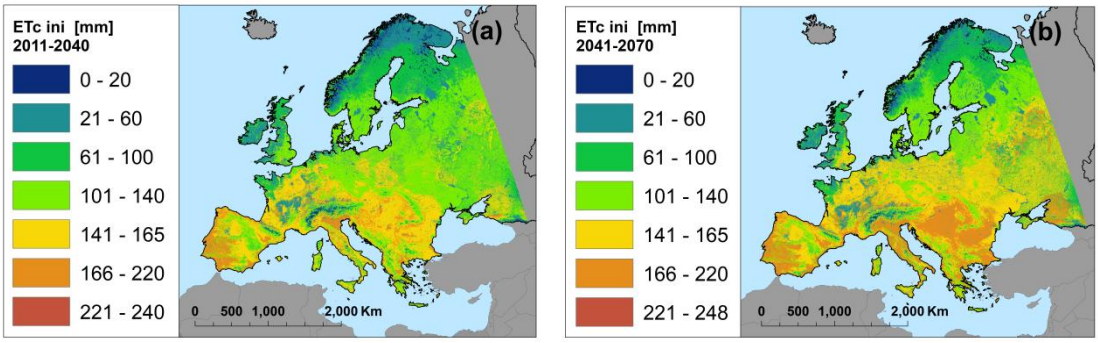

Figure 6. *Spatial distribution of $ET_{c\ ini}$ in Europe. (a) $ET_{c\ ini}$ for the initial stage (2011–2040). (b) $ET_{c\ ini}$ for the initial stage (2041–2070)*

The $ET_{c\ mid}$ ranges in the present period from 0 to 772 mm, whereas in the future period the $ET_{c\ mid}$ values range from 0 to 848 mm. The highest values of the $ET_{c\ mid}$ (over 600 mm) were depicted in the South of the Iberian Peninsula and in the South of the Balkan Peninsula. The more significant aspect of the $ET_{c\ mid}$ spatial distribution in Europe is that in the future period the areas of high values extend in a large territory, especially in the South and central sides of the Iberian Peninsula and also on the northern coast of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_21492168
© 2018, ALÖKI Kft., Budapest, Hungary

Aegean Sea. The sides with lower $ET_{c\ mid}$ are found in the elevated mountains of Europe such as the Alps and the Caucasus ranges, in the North and West of the Scandinavian Peninsula, in the central and northern parts of France, and in some sides of northeastern Europe. *Figures 7a* and *7b* illustrate the spatial distribution of $ET_{c\ mid}$ in Europe.

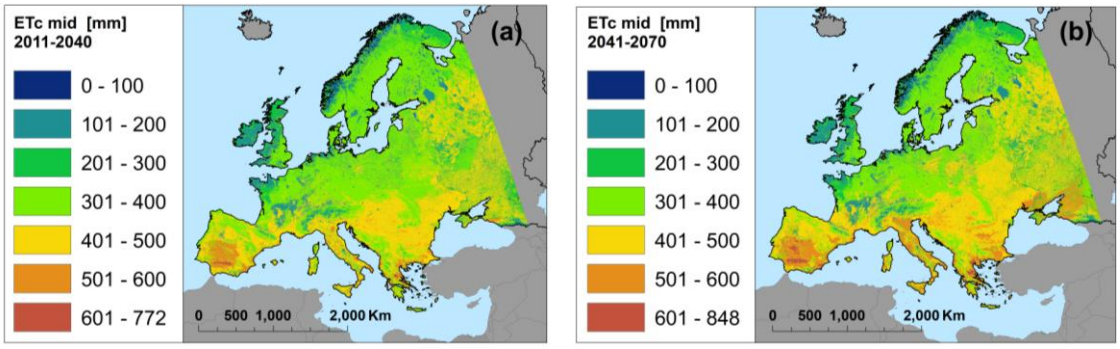

Figure 7. *Spatial distribution of $ET_{c\ mid}$ in Europe. (a) $ET_{c\ mid}$ for the mid-season stage (2011–2040). (b) $ET_{c\ mid}$ for the mid-season stage (2041–2070)*

For the present period the $ET_{c\ end}$ varies from 0 to 334 mm and for the future period the $ET_{c\ end}$ varies from 0 to 359 mm. The high values of $ET_{c\ end}$ are located in the West and South of Europe, mainly in the Iberian and Italian Peninsulas, but several places with high $ET_{c\ end}$ values were depicted in the Balkan Peninsula and Mediterranean Islands such as Sardinia, Sicily, and the Aegean Islands. The lower values of $ET_{c\ end}$ are sparsely located in the centre of the continent, the Northern and Eastern parts of Europe, and on the western sides of the British Islands. No significant differences in the spatial distribution pattern between the present and the future are observed. Spatial distribution of $ET_{c\ end}$ in Europe is shown in *Figure 8a, b*.

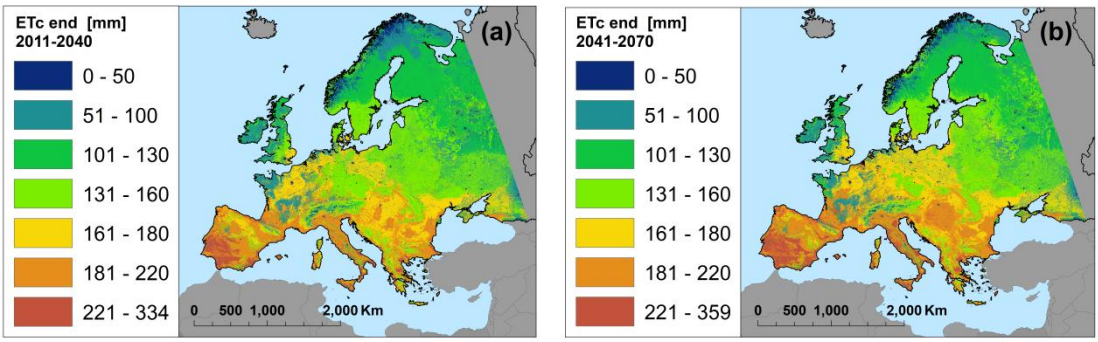

Figure 8. *Spatial distribution of $ET_{c\ end}$ in Europe. (a) $ET_{c\ end}$ for the end stage (2011–2040). (b) $ET_{c\ end}$ for the end stage (2041–2070)*

As we expected, the low values of seasonal ET_c were depicted during the cold season. In the present period the $ET_{c\ cold}$ ranges from 0 to 178 mm, whereas in the future period the $ET_{c\ cold}$ ranges from 0 to 181 mm. The high values of $ET_{c\ cold}$ were found in the center, South, South-East and West of Europe. In contrast to other seasons, the spatial distribution of ET_c overlaps mainly to the elevated areas covered by forest and vegetation that have a significant $K_{c\ cold}$. Interestingly, the maximum values of the ET_c

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_21492168
© 2018, ALÖKI Kft., Budapest, Hungary

$_{cold}$ could be easily identified in the North, North-West, and North-East of the Iberian Peninsula. Significant values of $ET_{c\ cold}$ are also in the South of the Scandinavian Peninsula, North of the Caucasus Mountains, Carpathian Mountains, and sparsely in the Balkan Peninsula (*Fig 9a, b*).

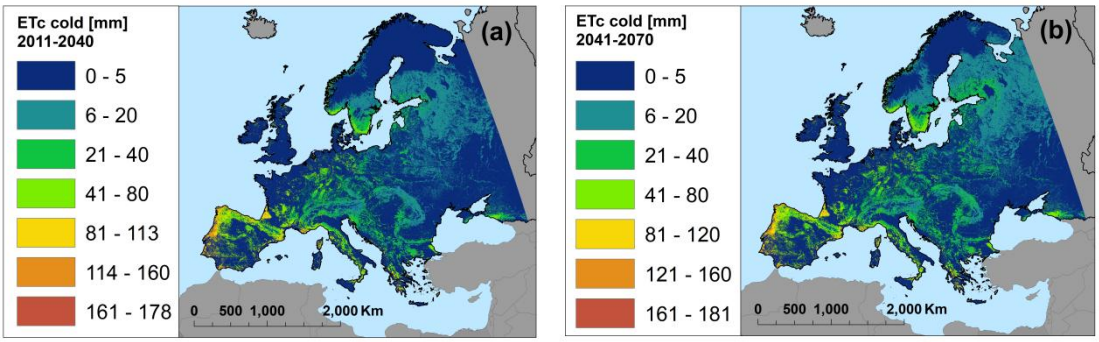

Figure 9. *Spatial distribution of $ET_{c\ cold}$ in Europe. (a) $ET_{c\ cold}$ for the cold stage (2011–2040). (b) $ET_{c\ cold}$ for the cold stage (2041–2070)*

The annual ET_c ranges in the present period from 0 to 1385 mm year^{-1} and in the future period from 0 to 1496 mm year^{-1}. The high values (over 1000 mm) of the annual ET_c may be found in the South, West, and South-East of Europe, mainly on the Mediterranean coast. In the central and eastern sides of the continent, the medium values (400 mm year^{-1} to 800 mm year^{-1}) of the annual ET_c extend, while the low values (below 400 mm year^{-1}) of the annual ET_c could be found in the North of Europe, the Alps and the Caucasus Ranges, the central land of France, and the West of the British Islands. The elevated values of the annual ET_c in the future period occupy more territory than in the present, especially in the Iberian Peninsula, Balkan Peninsula, Pannonian basin, and on northern sides of the Black Sea. *Figures 10a* and *10b* show the spatial distribution of the annual ET_c in Europe.

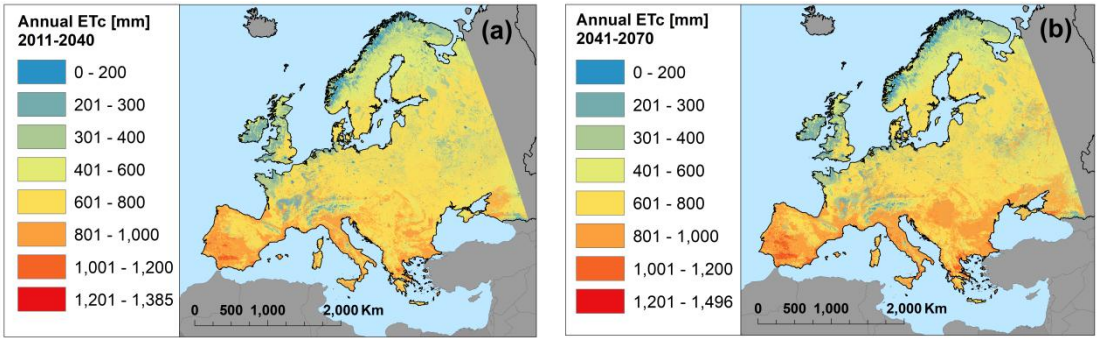

Figure 10. *Spatial distribution of annual ET_c in Europe. (a) Annual ET_c for the period 2011 and 2040. (b) Annual ET_c for the period 2041 and 2070*

Discussion

The main goal of the work was to determinate and complete the spatial distribution of the seasonal and annual ET_c in Europe during the 21st century. Numerous calculations and few presences in the specialty literature of this type of research are

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

available. The applied method, based on the land cover and climate models, allow us to bring forward one of the most important climatic parameters at European scale, the seasonal and annual ET_c. Considering the recent climate change (Haeberli, 1999; IPCC, 2001, 2007; Oerlemans, 2005; Nistor, 2014, 2017; Nistor and Petcu, 2015), the first observations about the general climate of Europe have come to affirm the continental warming about 1.4 °C for the future period (2041–2070). Additionally, the precipitation amount is expected to be slightly lower with a minimum of 50 mm $year^{-1}$ and an increase in the annual ET_0 by 200 mm $year^{-1}$ is shown for the 2041–2070 period. These findings are acceptable while we use the climate models based on the RCP4.5 and not RCP8.5, which may provide the worst scenarios.

The climate variables used in the present study are in line with the findings of existing regional models. Čenčur Curk et al. (2014) and Cheval et al. (2017) carried out the mean air temperature, mean annual precipitation, and annual ET_0 for South East Europe. In this part of Europe, Cheval et al. (2017) carried out a maximum difference of 1.4 °C in the mean air temperature between 1991–2020 and 2021–2050 periods, while Čenčur Curk et al. (2014), in their studies about climate change and mitigation of the water resources in South East Europe, illustrate the reduction of the annual precipitation pattern by 60 mm and increases of the ET_0 between the future and present periods. Thus, in the present period Čenčur Curk et al. (2014) indicated values of annual ET_0 up to 957 mm $year^{-1}$, while in the future they have found 1040 mm $year^{-1}$ of annual ET_0. In the present work, the values of annual ET_0 are more appropriate than the annual values of ET_0 carried out by Čenčur Curk et al. (2014).

Best for our contribution to the European researches, up to the present, no studies regarding ET_c were done on a Europe scale due to the complex procedure of monthly ET_0 calculations and K_c integration. Few regional works of ET_c bring forward the effects of climate change on evapotranspiration. Annual values of ET_c obtained in the present paper are comparable to the values obtained by Nistor et al. (2017b) in South East Europe. They determined the annual ET_c in two time shifts (1991–2020 and 2021–2050) in which the maximum values of the annual ET_c registered 1297 mm, respective 1410 mm. More than this, even if Nistor et al. (2017b) have used regionally coupled models (RCMs) for the climate data, the spatial distribution of high values of ET_c were found in the South of the Balkan Peninsula, like in the present paper. Appropriate results of the annual ET_c at European scale are in line with annual ET_c carried out at the regional scale of the Pannonian basin and Carpathian region by Nistor et al. (2017a), respective Nistor et al. (2016). In the first case, the maximum annual values of 1083 mm for the present period (1991–2020) and 1148 mm for the future period (2021–2050) have been calculated for the ET_c in the Pannonian basin, while in the Carpathian region the annual ET_c reached 1019 mm in the period of 1991–2010. At the European scale, in these territories the annual ET_c values indicate 600–1000 mm for the present and 800–1200 mm for the future. Based on the historical data of the 1991–2005 period, Nistor and Porumb-Ghiurco (2015) have found maximum values of annual ET_c around 1118 mm $year^{-1}$ in the Emilia-Romagna region from Italy, while in our study, the annual ET_c for the same region indicates 1000–1200 mm $year^{-1}$.

Between present and future periods, the seasonal ET_c indicates higher difference in the mid-season and end season. Thus, an increase from 772 mm to 842 mm it was calculated during the mid-season for 2011–2040 respective 2041–2070. Regarding the end season, the values of $ET_{c\ end}$ are expected to increase between present and future from 334 mm to 359 mm. These results may have drastic influences on the hydrology of Europe but also

on the biodiversity of the territory mainly in the summer and early autumn. The negative impact of the current and future climate in Europe on the evapotranspiration is quite alarming, especially for the western and southern sides of Europe. The above-mentioned comparison with the previous surveys in various regions of Europe is a good outcome in agreement with the European map of ET_c. However, our work has some limitations, which are closer to the direct evapotranspiration measurements that can improve the results, but only in the local sites. To generalize the field measurements of each crop type to the whole of Europe is not a suitable method for the fact that we have chosen to integrate the standard values proposed by Allen et al. (1998), Nistor and Porumb-Ghiurco (2015), Nistor (2016), Nistor et al. (2017a). Moreover, these shortcomings do not affect the research because the study was done on a continental scale and the land cover and climate data are represented using high resolutions.

The results of the advanced calculations of the seasonal ET_c related to the four stages show not only an increase in the ET_c amount for all stages but also the widening of the territories with high values. In the initial season, the higher values of $ET_{c\ ini}$ are often found in warm areas with the land covered by broad-leaved forests, cultivated lands, and managed agricultural areas. The herbaceous areas and croplands backed with the high mean air temperature indicate the highest values for the $ET_{c\ mid}$ season such as in the South of the Iberian Peninsula and east-central sides of Greece. During the $ET_{c\ end}$ season, tree cover, needle-leaved forest, deciduous forests and agricultural areas from West, South and South-East sides of Europe represent the main vegetation with high evapotranspiration capacity. The $ET_{c\ cold}$ pattern looks very interesting, both for the present and future periods. The elevated values of the $ET_{c\ cold}$ are located especially in the areas covered by the mixed leaf associated trees, needle-leaved and deciduous forests, and evergreen forests which have the $K_{c\ cold}$ higher than 0.6 and the hilly and mountainous areas. In this season, the agriculture and urban lands indicate very low values (below 20 mm) of the $ET_{c\ cold}$ due to the low temperatures, but in major cases the $ET_{c\ cold}$ is 0 mm due to no value for the $K_{c\ cold}$. In the cold months, due to the negative values of air temperature, the monthly index I of the Thornthwaite formula cannot return the positive values for the respective territories. Corrections of the index I raster data including the "0" values in that parcels was done with the aim to complete the ensemble of 12 months which served as the annual heat index I. These operations were needed because the seasonal and annual ET_0 indicated "no data" in certain areas with low-temperature values, but in reality the ET_0 is null there. Integrating the monthly heat index I and alpha parameter into the ET_0 equation, the seasonal and annual ET_0 and ET_c were found. In broad terms, both annual ET_0 and ET_c have a correlated spatial distribution with the latitude and altitudes; moreover, good correlation exists between West and East, respectively the oceanity and continentality influences. Thus, on the southern and western sides of Europe, at low latitudes and closer to the Atlantic Ocean, the ET_0 and ET_c have high values, whereas on the northern and eastern sides, at high latitudes and close to the Asia continent, the ET_0 and ET_c have lower values. In the central parts of Europe, likely as a strike from West to East, the ET_0 and ET_c register medium values, slightly decreasing over the East. Comparing both maps, the details of the annual ET_c indicates a more realistic situation of the European evapotranspiration because it incorporates the vegetation factor. As we expected for the British Islands, the annual ET_c reaches values between 300 and 500 mm, with decreasing spatial distribution from West to East due to the ocean air mass direction, but also the higher mean air temperature in the eastern areas.

A significant observation should be made on the annual ET_c in the urban areas and land with water bodies. Due to the low K_c and no values of this coefficient during the cold season for the urban and water body lands, the annual map of ET_c shows evapotranspiration amount below 200 mm year^{-1}.

Conclusions

Overall, the seasonal and annual ET_c in Europe were mapped for the 2011–2070 period, using long-term climate models and detailed CORINE Land Cover data. Variations of seasonal ET_c values between the present and future are found for all four set stages, with significant increase in the mid-season and end season. The most striking seasonal findings refer to the $ET_{c\ mid}$ when the maximum values increase from 772 mm to 848 mm and the distribution of high values extends considerably in the area. Significant changes of the annual ET_c could also be shown between the present and future periods. The annual ET_c values increase from 1385 mm to 1496 mm due to the impact of climate change in the second half of the 21st century.

Using the K_c and climate models, the present study shows a reliable approach to assessing the ET_c at the spatial level even if the crop calendar may have some overlapping times due to the cultivations and complexity of vegetation development in the European continent. Nistor and Porumb-Ghiurco (2015) and Nistor et al. (2017a) illustrated in their studies how the methodology at a regional scale works.

Based on the findings, the impact of climate change indicates a negative aspect in terms of drought and water availability in several areas of Europe. The southern, western, southeastern, and central sides of Europe are faced with the high annual ET_c (over 1000 mm year^{-1}), a fact which may produce problems on the surface and groundwater resources, also a slight desertification may also occur in those areas. Even if few, the important areas with low annual ET_c were found in the Alps Range, Pyrenees Range, Caucasus Range, Scandinavian Peninsula, western and northern sides of the British Islands, centre of France and sparse parts of East Europe. These areas are not drastically affected by global warming and can be a considerable source of water supply. In this sense, our work highlights the spatial variation of evapotranspiration under climate change. The findings could be important keys for the scientists in climatology, hydrology, and agriculture. Moreover, the maps made in this survey represent a tool for urban and environmental planning, water resources and land irrigation strategies, reports and further scenarios of derivate indices regarding the land use policy and climate change mitigation. We strongly recommend to complete more investigations of water availability in the areas where the annual ET_c exceed 1000 mm year^{-1}, especially in the southern, western, southeastern, and central sides of Europe. The investigation of these areas should include groundwater monitoring and vulnerability assessment to climate change. Surface waters quality evaluation through in-situ methods (water sampling from rivers, irrigation channels) in the South of Europe will allow providing sustainable water resources and durable ecosystems. The aquifers located near the coastal areas are supposed to be in danger due to sea level rise and seawater intrusions. For a proper management and sustainable groundwater resources in the coastal areas, we suggest to each region to complete temporal water sample analysis (once two years) regarding the salinity variation and to organize workshops to provide solutions for fresh water sustainability in the regions where the salinity in groundwater increases.

(Received 3rd Nov 2017; accepted 7th Mar 2018)

Abstract. In this contribution, a simple way of quantification of ecological changes in a territory is proposed. Six degrees of ecological stability (from 0 for an anthropic element to 5 for natural and nature-close environments) and a coefficient of ecological stability (CES) related to land cover have been used to measure local ecological stability. The cadastral territory Báb (near Nitra, Slovakia) was segmented into 1 ha sized squares (1,870) to estimate ecological situation by fuzzy clustering. For each of the three time horizons, well documented time snapshots (distant past, present and possible future) of the model territory, three clusters with negative, neutral and positive ecological characteristics (CES based) were identified. Positive as well as negative changes have been detected and localized in space. Negative (from the past to the present state) and positive (landscape consolidation project based state) landscape development has been observed in the study area. Introduced procedures can help to assess effects of proposed ecological measures in land consolidation projects.
Keywords: *coefficient of ecological stability, land time horizons, multicriterial analysis, clustering, Slovakia*

Introduction

Monitoring of particular land elements, their spatial representation, spatial configuration, and dynamics (Lipský and Kvapil, 2000; Angelovičová et al., 2015) is used when observing landscape changes in time. Investigation of land development from the distant past to the present times is important for ecological analyses leading to proposals of sustainable land utilization. Many factors as climate change (Lovejoy and Hannah, 2005), urbanization (Izakovičová et al., 2017), deforestation (Padonou et al., 2017), water quality deterioration (Dumbrovský et al., 2016; Petrovič et al., 2017), natural disasters (Yu et al., 2010), soil degradation (Van Oost et al., 2000), loss of biodiversity (Verburg et al., 2009) do play a role.

Spatial heterogeneity expressed by the landscape structure is linked to functional properties of land and is determined by natural, semi-natural, and anthropogenic factors, see e.g. Hoang and Denmukhametov (2015). Landscape structure can be described by land use classes in a certain time (e.g. Munteanu et al., 2014). Detection of changes is possible by comparing several time horizons. Every landscape is characterized by two processes: the process of the destruction of the original structure and the consequent development of a new one (e.g. Špulerová et al., 2016).

Slovakia's landscape significantly changed particularly since the 50's of the 20th century when the large-scale farming was introduced (Tarasovičová et al., 2013; Žabenský et al., 2016). For about 50 years, any obstacle (balks, unpaved roads, drainage) was removed that hampered the large-scale land management. A landscape with an average land unit of approximately 250 ha causes increased water and wind erosion (Húska et al., 2017), deterioration of the water source quality (Pekárová and

© 2018, ALÖKI Kft., Budapest, Hungary

Pekár, 1996), low ecological stability and consequent decline in biodiversity (e.g. Bezák et al., 2016), whirlwinds, floods (Urban et al., 2013), and droughts (Tárník, 2017).

Since 1991, land consolidations (LCs) address the landscape issues in Slovakia, Muchová et al. (2017). LCs are considered in many countries (Hartvigsen, 2014, 2016) as unique tools, able to harmonize ownership (Noszczyk and Hernik, 2016; Jin et al., 2016), functionality and ecological measures (Moravcová et al., 2017). Land ownership defragmentation (Kwinta and Gniadek, 2017; Janus and Markuszewska, 2017; Muchová and Jusková, 2017; Muchová, 2017) is a prerequisite for wider regional development of rural areas, which includes improvements to public facilities in compliance with the protection of natural resources (Pasakarnis and Maliene, 2010; Sallaku et al., 2010).

In this contribution, the level of anthropogenic impacts on the landscape is quantified by detection, measuring, spatial localization, evaluation, and visualization of land use / land cover changes. Presented procedures are intended for objective assessment of A) the quality of ecological measures in a territory (proposals and implementations, current and historical situation) and B) for directing decision-making activities in compliance with the environmental protection.

Material and methods

Quantification of anthropogenic impacts on a landscape was processed as follows:

1. Selection of study area: A territory with finished land consolidation project was chosen to allow for assessment of possible future changes in the landscape.
2. Land cover classification: Refined land use classes from Slovak cadaster of real estates have been used as a basis for estimation of ecological stability of particular landscape elements.
3. Use of time horizons: Three well documented time snapshots (distant past, present and possible future) of the study area provided means for determining landscape changes.
4. Determination of local ecological stability: Six degrees of ecological stability and a coefficient of ecological stability have been introduced to measure and visualize the state of the landscape in a given time.
5. Segmentation and clustering: A grid with 1 ha sized squares was used to segment the study area. Similarity of the ecological stability in particular squares was estimated using a fuzzy analysis.

Study area

Cadastral territory Báb, 2,009.09 ha, (*Fig. 1*) is located in Nitra region, Nitra district. Agricultural land covers 83.4% of Báb total area (arable land 76.4%), forests 6.9%, water bodies 2.2%, build-up areas 5.1% and other areas 2.5%.

From the geographical point of view, the territory belongs to a hilly area with the relief formed by medium to mildly steep slopes with significant manifestations of water erosion and floods (*Fig. 2A*). The territory belongs to a dry and warm climatic area with frequent droughts. It is a typical land of intensive agricultural use with top-quality soils. The Báb creek flows through the territory with a small irrigation reservoir (*Fig. 2B*) of 18 ha and a capacity of 600,000 m^3. Flora and fauna are dominated by xerophytic and thermophilic species, especially of the Pannonian origin.

Land cover classification

The Slovak cadaster of real estates recognizes 10 land use (LU) classes (arable land, hop garden, vineyard, garden, orchard, permanent grassland, forest, water area, build-up area, and other area). All official maps use this nomenclature. LU classes are not suitable for quantification of ecological stability on a small scale, therefore refined LU elements have been used (Muchová et al., 2009).

Time horizons

Three time horizons, well-documented snapshots of the land use in Báb cadaster in distant past, present and possible future describe the landscape evolution. The first time horizon (TH1, distant past) represents historic land use (*Fig. 3*) in the year 1839 (second military mapping, also called Francis mapping, in the Austro-Hungarian Empire).

Figure 3. *Distant past land use, TH1: A) military mapping II (geoportal.gov.sk), B) vectored map of land use classes, C) land use classes in ha*

DOI: http://dx.doi.org/10.15666/aeer/1603_21692182
© 2018, ALÖKI Kft., Budapest, Hungary

The second time horizon (TH2, present) represents current land use (*Fig. 4*). Detailed mapping of the entire cadastral area was carried out in 2006 by Geotop Nitra and Geodézia Bratislava (with accuracy of 0.14 m). The update from 2006 to 2016 was performed by additional measurements by the authors of this article. Only minor changes (on 1% of the territory) have been recorded.

Figure 4. *Present land use, TH2: A) orthophotomap (Eurosense), B) special purpose topographic mapping with land use classes, C) land use classes in ha*

The third time horizon (TH3, possible future) represents proposed land use (*Fig. 5*). New functional arrangement of the territory after the land consolidation (LC) project with new roads, erosion control, water management, and ecological measures is binding and expected to be implemented in near future.

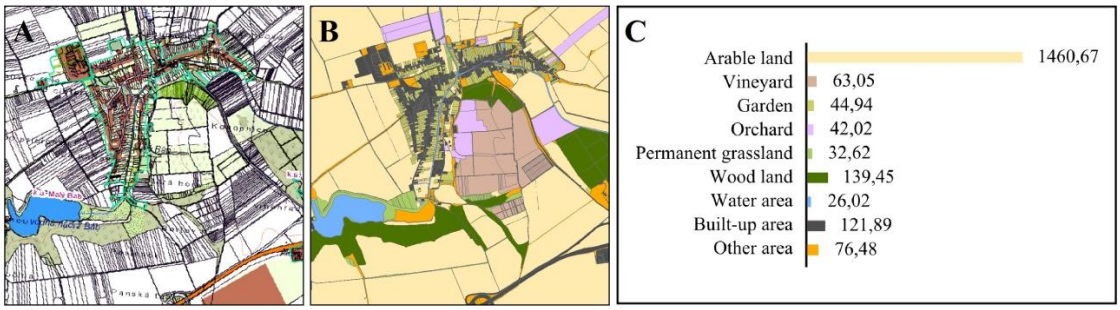

Figure 5. *Possible future land use, TH3: A) cadastral map (https://zbgis.skgeodesy.sk), B) revised cadastral map with land use classes, C) land use classes in ha*

Determination of local ecological stability

The ecosystems are best to be studied through elements of land use, as stated in several sources (e.g. Asner et al., 2004). In general, individual elements (refined land use classes) have a different character and different environmental quality (environmental stability). Each element is assigned a degree of ecological stability from 0 to 5 according to the origin of vegetation (Löw, 1995); 0 for an anthropic element, without vegetation and artificially designed (e.g. built-up areas, paved roads), 1 (e.g. intensively utilized, large-scale blocks of arable land), 2 (e.g. intensively used orchards, vineyards, reclaimed meadows), 3 (e.g. lawn orchards), 4 (e.g. forests, meadows with the predominance of naturally occurring species, natural water areas with semi-natural vegetation) and 5 for natural and nature-close environments (e.g. natural forests, natural

© 2018, ALÖKI Kft., Budapest, Hungary

herbaceous communities, wetlands, peat bogs, watercourses with natural bottom, banks and with characteristic water and coastal flora). Degrees of local ecological stability for past, present and future are depicted in *Figure 6*.

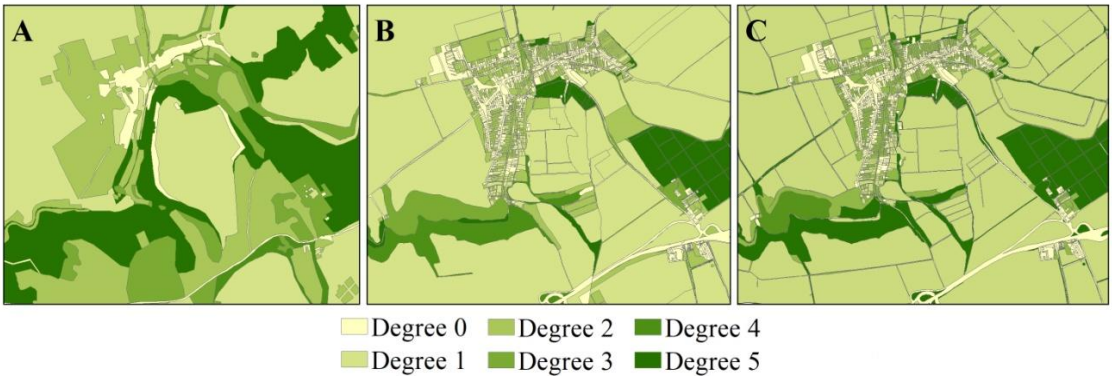

Figure 6. *Degree of ecological stability for A) distant past land use, TH1, B) present land use, TH2, C) possible future land use, TH3*

A coefficient of ecological stability (CES) can be defined (Muchová et al., 2009; Muchová et al., 2016; Kupková, 2001; Streďanský and Šimonides, 1995) as (*Eq. 1*):

$$CES = \frac{P_5 + P_4 + P_3}{P_2 + P_1 + P_0} \quad \text{(Eq.1)}$$

P_i variables (i from 0 to 5) denote the areas of refined land use classes of a given degree of ecological stability. *CES* is < 0.4 for a landscape / area with very low ecological stability, 0.41 – 0.80 low ecological stability, 0.81 – 1.20 stable, > 1.21 high ecological stability.

Segmentation and clustering

A grid with 1 ha sized squares was used to segment (see e.g. Muchová et al., 2015; Stejskalová et al., 2013) the Báb cadaster (*Fig 1D*). Local ecological stability (degrees of ecological stability of land use classes / elements and coefficient of ecological stability) was determined for each segment as described above.

Fuzzy clustering (R Core Team, 2017; Maechler et al., 2017) was applied to determine similarity of individual squares.

Ecological risk was estimated for each cluster using the CES value. Spatial analyses and map sets were processed by the GIS tool ArcMap 10.2 (ESRI, 2017).

Results and discussion

1,870 defined squares were assigned into three clusters (i.e. three for each time horizon) based on the similarity in local ecological stability (*Fig. 7*).

The clusters can be described as follows:

- Cluster characterized as negative contains 945 squares mostly in the degree 1 of ecological stability for the historical land use (TH1), i.e. 50% of the territory. 1,161 squares belong to it in present land use (TH2), also primarily in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_21692182
© 2018, ALÖKI Kft., Budapest, Hungary

the degree 1 of ecological stability, covering 62% of the territory. 778 squares are members of it in the possible future land use (TH3), mostly degree 1 of stability (41% of the total area).

- Cluster with neutral characteristic contains 592 mostly ecological stability degree 2 squares (31%) for the historical land use (TH1). 361 predominantly stability degree 2 and 3 squares (19%) are assigned to it in present land use (TH2). 599 (32%) mostly ecological stability degree 2 squares are members of it in the possible future land use (TH3).
- Cluster with positive characteristic contains 333 mostly ecological stability degree 5 segments (17%) for the historical land use (TH1), 348 squares (18%) of predominantly stability degree 3 and 5 in present land use (TH2) and 493 mostly ecological stability degree 5 squares (26%) in the possible future land use (TH3).

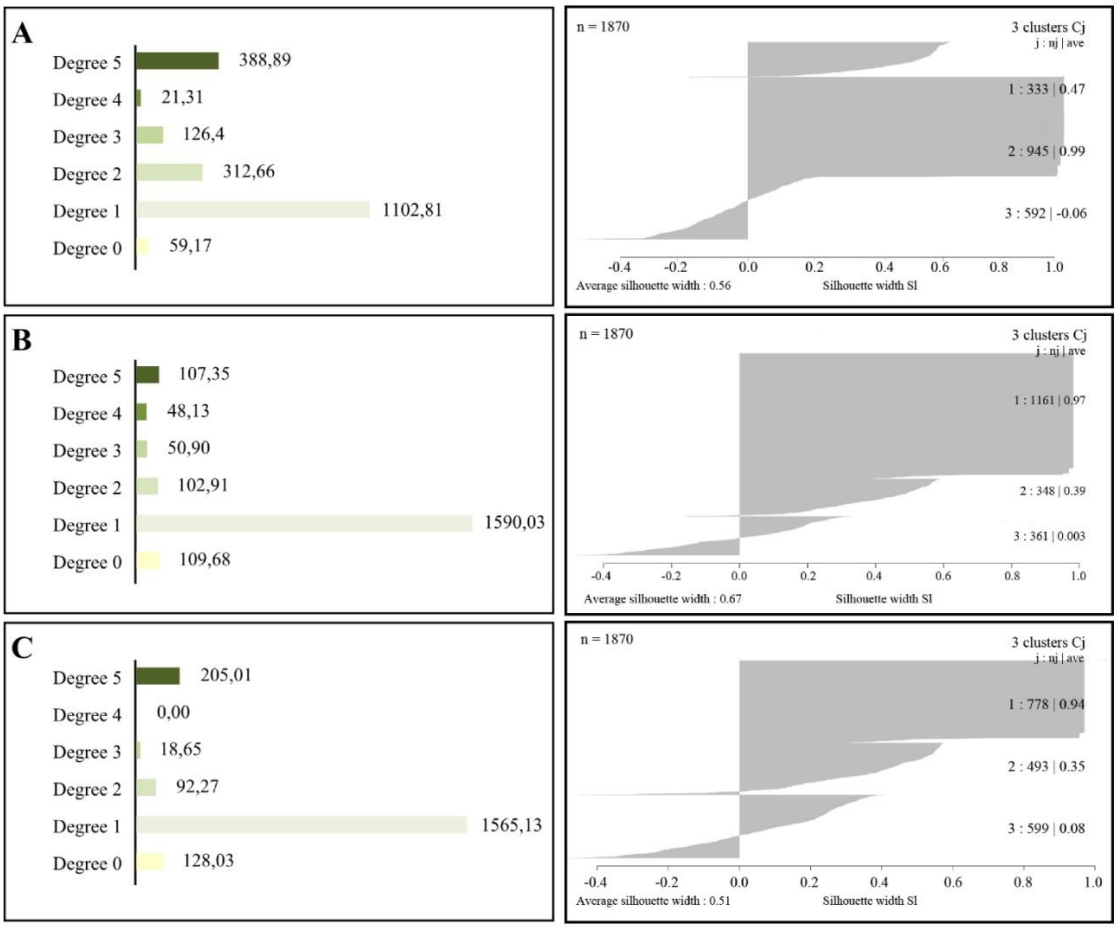

Figure 7. *Local ecological stability for time horizons (in ha) and results of the cluster analysis A) TH1 (past), B) TH2 (present), C) TH3 (future)*

The results of clustering have been visualized by marking individual segments according to cluster membership (*Fig. 8*).

Based on the spatial distribution of ecologically similar areas, the time evolution of the landscape can be observed (*Fig. 9*). 805 squares of land changed between past (TH1) and present (TH2) and 686 between TH2 and possible future (TH3).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

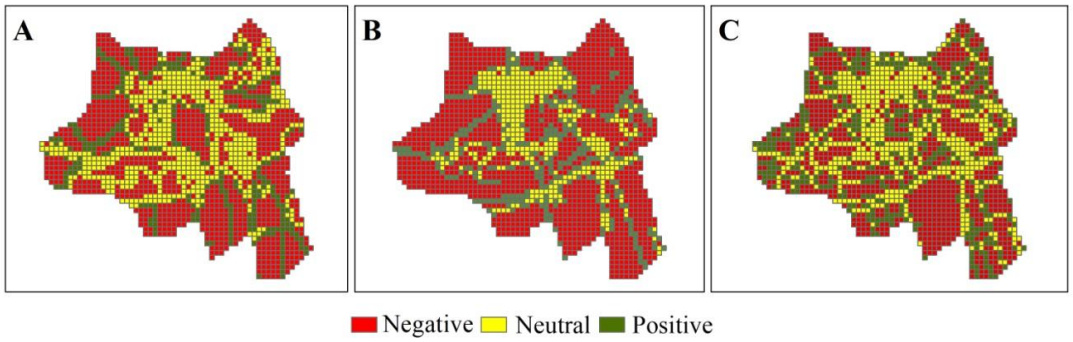

Figure 8. *Cluster membership of individual segments A) historical land use (TH1), B) present land use (TH2), C) possible future land use (TH3)*

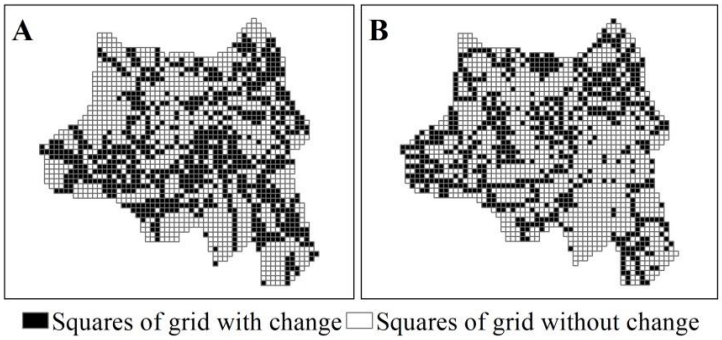

Figure 9. *Local land cover changes: A) between past (TH1) and present (TH2), B) between TH2 and possible future (TH3)*

A desirable (positive) local change can be identified when a segment moves from a lower to a higher category of cluster in time (*Fig. 10A, B*), negative change (*Fig. 10C, D*) means moving in the opposite direction in time.

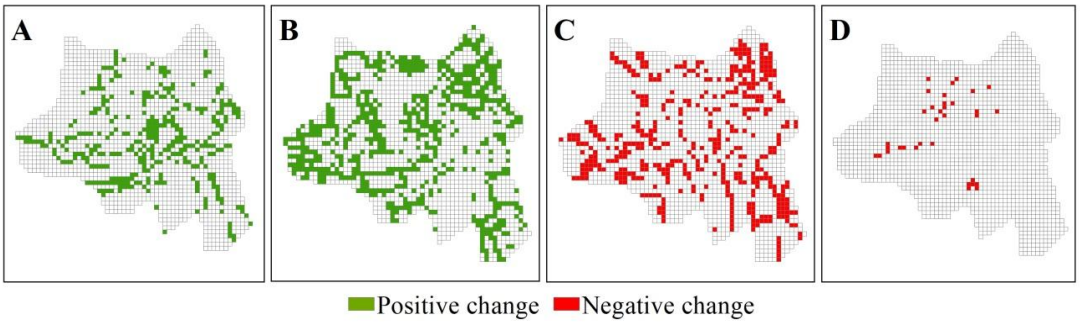

Figure 10. *Positive changes A) from TH1 to TH2, B) from TH2 to TH3. Negative changes C) from TH1 to TH2, D) from TH2 to TH3*

Ecologically negative changes clearly dominate in the landscape evolution from the past (TH1) to the present (TH2) state (463 squares, *Fig. 10C*). Positive changes are rarer (341 segments, *Fig. 10A*) and are connected to construction of road bodies with natural elements increasing the ecological stability such as tree lines, windbreaks or other

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

habitat corridors (*Fig. 11*). The negative transformations are related to: ploughing the balks, groves, and small-scale elements of non-forest woody vegetation; construction of new buildings; turning marshlands and water areas into large-scale arable land or removing forest covers (*Fig. 12*).

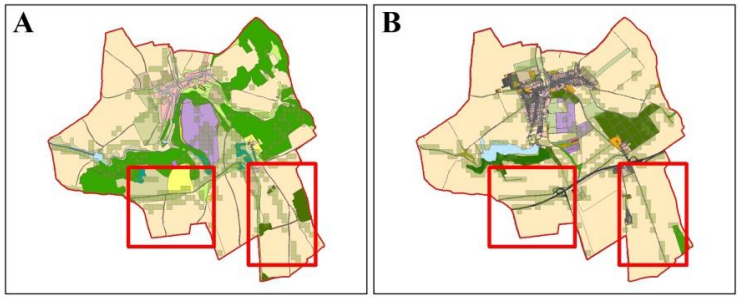

Figure 11. *Unpaved roads with accompanying vegetation as an example of a positive change between the past (A, TH1) and the present (B, TH2) landscape*

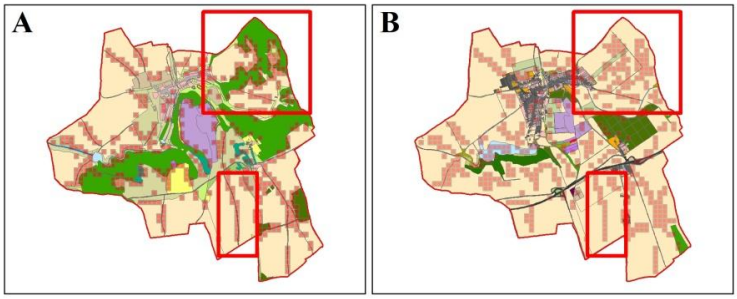

Figure 12. *Examples of negative transformations (e.g. removing forest covers, ploughing balks) between the past (A, TH1) and the present (B, TH2) landscape*

Land consolidation project (possible future land use, TH3) in the Báb area did not neglect ecological aspects as witnessed by the number of segments with positive changes between the present (TH2) state and the proposed (TH3) one (652, *Fig. 10B*). Through the LC project in the model territory, positive ecological changes were proposed on 35% of the total land area. Positive transformations (*Fig. 13*) include e.g. reinforced unpaved roads enriched by accompanying green such as windbreaks, habitat corridors, disruption of slopes by ditches; grassing the valley lines.

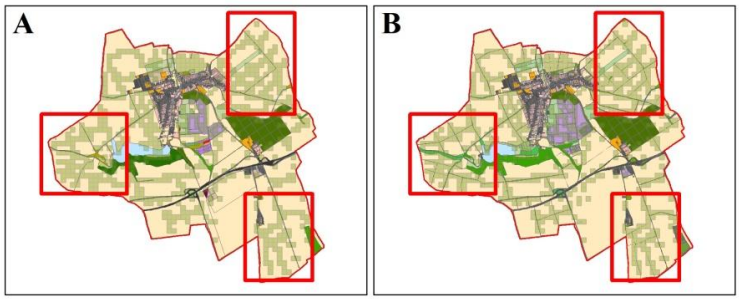

Figure 13. *Localization of some positive changes (protective vegetation mostly) between the present (A, TH2) state and the proposed (B, TH3) one after the LC project*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_21692182

Negative changes (between the present state and the proposed one) have been detected on 34 squares only (*Figs. 10D* and *14*).

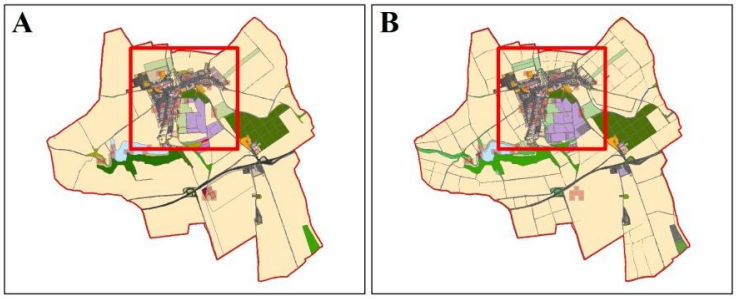

Figure 14. *Localization of main negative changes (construction related) between the present (A, TH2) state and the proposed (B, TH3) one after the LC project*

The changes observed when moving from the historical land structure (TH1) to the present day one (TH2), see *Table 1*, can be characterized by a significant increase in arable land (+45.24%) and built-up areas (+324.95%) accompanied by a decrease in permanent grassland (-97.74%) and forests (-67.18%).

Land use changes from TH1 to TH2 definitely represent a negative development trend (particularly in relation to the ecological stability of the landscape). Many authors also do consider land interventions of the 50's of the 20th century negative due to the application of radical land reforms (Schmitt, 1993; Mathijs, 1997). According to Kabát and Hagedorn (1997), the primary goal of collectivization was to provide large-scale agricultural production and production increase at the expense of the land. Homogenization of the land and removal of its microstructure are typical features of the socialistic agriculture, see e.g. Bezák and Mitchley (2014). The original mosaic of

© 2018, ALÖKI Kft., Budapest, Hungary

arable land, meadows and pastures, marshlands, balks and groves, and unpaved roads turned into homogeneous areas of arable lands or meadows. Availability of the land both for biota and for humans decreased due to it (Young et al., 2007). According to McDonald (2013), a problem of the land future is also the farmer – their relationship with the land was destroyed during the socialist period by the forced collectivization with the consequent much more inconsiderate behavior of land users towards the environment.

Changes between present land structure TH2 and the possible future one (as proposed in the LC project) TH3 (*Table 2*) include a slight decrease of the arable land areas (-5.00%). Splitting of large-scale land units by green areas can help to limit consequences of natural disasters. Permanent growth of built-up areas (+18.00%) is caused mainly by establishing industrial zones and housing construction, which is typical for those cadastral territories located in close vicinity of district towns (Báb lies near Nitra on a highway). There is an expected increase of green spaces (+444.42%), mostly in the form of protective vegetation – functional vegetation, original and unoriginal non-woody vegetation.

Since 1991, 427 LC projects and 23 implementations have been started in Slovakia. Correctly conceived LC projects are tackling the landscape issues as a whole. The realization of expected benefits requires interdisciplinary coordination (e.g. Pasakarnis and Maliene, 2010) and compliance with a methodology since the projects are related to areas as regional development, environment, agriculture, infrastructure… The ratio of positive to negative changes in properly designed land consolidation projects, as is the case for the Báb area, objectively shows that a project can bring positive (ecological) landscape interventions and reduce impacts of anthropogenic land interventions. Extensive land consolidations in the Czech Republic (Jusková and Muchová, 2014) with numerous realizations of proposed ecological measures (Moravcová et al., 2017) also provide experiences that point to a positive impact (Kaulich, 2013) of comprehensive transformations of rural landscape. The success in resolving landscape

© 2018, ALÖKI Kft., Budapest, Hungary

issues (including the ecological ones) is so predominant (Sklenička et al., 2009) that comprehensive landscape consolidation projects have priority and are expanding there. Correct quantification (detection, measurement, evaluation, localization, visualization) of impact of proposed measures on ecological stability is evidently possible (as documented above) and can help to ensure the materialization of expected benefits of regulated landscape interventions.

Conclusion

In order to be able to assess the ecological stability of a territory in the course of (anthropogenic) land interventions a correct quantification of the changes is needed. The aim of this paper was to propose a way to do it. Measurement of the ecological stability was based on six degrees of ecological stability and a coefficient of ecological stability (CES) related to land cover / origin of vegetation (from 0 for an anthropic element to 5 for natural and nature-close environments). The study area (cadastral territory Báb near Nitra, Slovakia) was segmented into 1 ha sized squares (1,870) for the evaluation purposes. Similarity of ecological situation was estimated using fuzzy clustering. Three clusters with negative, neutral and positive ecological characteristics (CES based) were identified for each of the three time horizons, well-documented time snapshots (distant past, present and possible future) of the model territory. Positive (segment moves from a lower to a higher category of cluster in time) and negative changes (segment moves from a higher to a lower category of cluster in time) have been detected and localized in space. The cadastral territory of Báb served as an example of both a negative landscape development (from past to the present) as well as positive interventions (proposed future state from the finished landscape consolidation project). The second case documented that properly designed land consolidation projects can bring about significant improvement of ecological stability (on 35% of the total area). Procedures introduced in this contribution can help to quantify effects of proposed ecological measures in land consolidation projects and thus aid in correct decision making.

(Received 28th Nov 2017; accepted 20th Feb 2018)

Abstract. The aim of this study was to evaluate the effects of trace element supplementation on semi-continuous anaerobic digestion processes of sugar beet pressed pulp. We also investigated the phytotoxicity of anaerobic sludge via an ecotoxicological test for white mustard (*Sinapis alba*) and spring barley (*Hordeum vulgare* L.). To determine the accumulation of microelements, the spring barley test was followed by microelement analysis of sludge, soil and barley biomass samples. The results show that average values of specific methane yields were 11.0 and 11.7% higher in the supplemented and supplemented plus iron trials compared to the non-supplemented trial, respectively.
In the root elongation test of white mustard, the highest stimulation rate (-59.41%) was observed for the 10-fold dilution in the treatment with trace element and iron supplementation. We observed major stimulation of spring barley biomass production in all trials, with the strongest effect (stimulation of -62.80%) in the trace element supplementation plus iron trial. In sludge samples, cobalt levels increased by 14 and 16 times, nickel by 10 and 14 times, boron by 1.8 and 1.9 times, iron by 1.6 and 2.1 times, respectively, in the supplemented and supplemented + Fe trials. The bioaccumulation factors of different elements varied widely (0.07-110.8).
Keywords: *anaerobic sludge, microelement, phytotoxicity, Sinapis alba, Hordeum vulgare*

Introduction

The use of sugar beet pressed pulp (SBPP) in anaerobic digestion is one way to abrogate sugar production waste (Tukacs-Hájos et al., 2014). The obtained renewable energy can be applied for heat or electricity production, but there is a secondary derivative, such as fermented sludge, which has a great potential in the application on agricultural and forestry fields for fertilisation (Govasmark et al., 2011; Demirel et al., 2013; Dong et al., 2013). By this complex use we can nearly reach a waste-free technology.

The digester effluents could provide the essential nutrients for plant growth when used as organic fertilisers (Achiba et al., 2010). Since sludges are complex mixtures of

different substances, speciation of toxic materials would be expected to increase or reduce toxicity (Gómez et al., 2001; García-Delgado et al., 2007; Tu et al., 2012; Li et al., 2010). Effluents used for irrigation water may cause a risk of decreasing crop production due to high salinity (Ullman and Mukhtar, 2007).

Optimal anaerobic digestion can be reached by addition of different trace elements based on to microbial requirements (Zhang and Jang, 2012; Qiang et al., 2013). The most commonly studied elements are iron, cobalt and nickel (Choong et al., 2016). Apart from the positive impact on methane production, the accumulated heavy metals in the sludge could have adverse effects on the soil ecosystem (Walter et al., 2006; Salazar et al., 2012). This negative effect can be prevalent for soil flora and fauna (Carbonell et al., 2009). The most critical point of view is the availability of microelements by plants from the soil, which could be affected by anaerobic digestion and lower mobility of metals from digested slurry (Marcato et al., 2009; Pagnanelli et al., 2009). Zhu et al. (2014) state that Cu, Zn, Mn, Ni and Cd may be grouped as toxic and active components in sludge. The different trace elements can appear in food chain systems through cultivated plants from contaminated soil (Wahsha et al., 2014; Le et al., 2015).

Information on the phytoavailability changes with trace element supplementation of anaerobic sludge are scarce. There are two main methods to assess bioavailability: chemical measurements in the soil matrix and biological measurements using organisms exposed to soil (Walsh et al., 1991; Harmsen, 2007). To investigate the injurious effects, different acute and chronic ecotoxicological tests are applied in practise (Rosa et al., 2007; Roig et al., 2012; Young et al., 2012). *Lactuca sativa* seed germination and root elongation inhibition tests are used for assessing the toxicity reduction from anaerobic digestion based on measuring main chemical operational parameters (Young et al., 2012). Hybská et al. (2017) examined the ecotoxicological properties of granulated slag from the pilot production of gray iron with red mud addition and concrete composites with the application of this slag by testing highly-cultivated plant *Sinapis alba*. Their results confirmed that the application of the hazardous waste in the production of gray iron produced waste slag with no toxic properties.

The main aims of this study were to investigate the improved methane yield by supplementation of trace elements and to evaluate the ecotoxicological effects on fermented sludge in the application of nutrient replacement for soils.

The biological approach consisted of microelement uptake assessment in growth chamber experiments with spring barley.

Materials and methods

Anaerobic digestion

Biogas reactors

The anaerobic digesters were 1-L working volume bottles (2.5 L capacity threaded brown bottles, Merck, Germany). The digesters were incubated in a water bath (Memmert WNB 14 Basic, Memmert GmbH. & Co.) at a constant temperature of 38°C. The anaerobic digester inoculum was active, adapted to sugar beet pressed pulp substrate (HRT 20 days) obtained from a biogas plant (Sugar factory, Kaposvár, Hungary). The reactors were manually mixed three times per day and the produced biogas was collected by Tedlar® gas sampling bags; volume was measured with a

DOI: http://dx.doi.org/10.15666/aeer/1603_21832195
© 2018, ALÖKI Kft., Budapest, Hungary

Hamilton gas-tight syringe (Sigma Aldrich Co). Biogas and methane yields were recalculated to the standard conditions for pressure and temperature.

Experimental design

Sugar beet pressed pulp as substrate was applied in our semi-continuous lab-scale experiments. The organic loading rate was raised to 5.2 $gVSL^{-1}d^{-1}$ by day 19; subsequently, because of the high tVFA concentration in all trials (up to 10 000 mg L^{-1}), feeding was stopped for two days. After this, a moderate loading rate was performed from day 22 to day 44, with a maximum of 3.8 $gVSL^{-1}d^{-1}$; subsequently, the organic loading rate (OLR) remained stable until day 81.

Three parallel reactors were run in all cases of non-supplemented (without trace element supplementation), supplemented (2 $\mu L\ L^{-1}d^{-1}$ of trace element solution) and supplemented + Fe (2 $\mu L\ L^{-1}d^{-1}$ of trace element solution + 82 $\mu LL^{-1}d^{-1}$ of Fe(III)-chloride 40% aqueous solution – technical grade). The application of high doses of iron is explained by its detoxification effect on sulphide inhibition, as described by (Gonzalez-Silva et al., 2009).

The trace element supplement solution contained 1 625 mg of zinc, 13 640 mg of manganese, 93 mg of boron, 20 000 mg of nickel, 600 mg of copper, 50 000 mg of cobalt, 228 mg of molybdenum and 113 mg of selenium in a special organic complex form per kg of solution (42.2% TS). Dosing of microelements was based on our former experiment (Tukacs-Hájos et al., 2014).

Analytical methods

Sludge samples (10 mL) were taken for chemical analysis before feeding. Samples were centrifuged for 10 min at 3 420 RCF (EBA 21, A. Hettich Co, Germany). From the resulting supernatant, 5 mL were used for determination of titrated VFA (tVFA) levels (every 5th day), using a potentiometric pH meter (EuTech PC 510, Thermo Fisher Scientific), and calculated in acetic acid equivalents (Rétfalvi et al., 2011).

The components of biogas were analysed using an Ecoprobe 5-IR (RS Dynamics Ltd, Czech Republic).

Determination of COD was carried out according to the Hungarian standard protocol (MSZ ISO 6060). Determination of ammonium and total phosphorus was carried out according to the Hungarian standard protocols MSZ ISO 7150-1 and MSZ 488/18-77, respectively (Rétfalvi et al., 2015).

Ecotoxicological tests

Preparation of aqueous extracts

The quantities of original sludges were weighted, corresponding to 100 ± 0.1 g of dry matter, and 1 L of demineralised water was added. Subsequently, the samples were shaken for 6 h. The extracts were then left for 18 h to sediment and after sedimentation, solid phases were separated by filtration through a paper filter with a pore size of 3 ± 2 µm.

Root elongation test with white mustard

The acute toxicity test was applied according to the Slovakian standard of STN 83 8303:1999. The tested organism was white mustard (*Sinapis alba*), a member of the *Brassicaceae* family. The sorted white mustard seeds were ochre-yellow, with a size of

1.5 to 2.5 mm, and germination power was higher than 99%. Thirty seeds were placed uniformly into Petri dishes (diameter of 120 to 140 mm) and 10 mL of the prepared aqueous extracts were added (*Table 1*).

Three parallel tests were applied in all dilution rates (dilution of 10, 50, 100 and 200 x) of non-supplemented, supplemented and supplemented + Fe sludges, respectively.

As diluent, water stock solutions of salts were prepared and also used for the control. The pH of the diluent water varied around 7.6-8.0.

Exposition period	72 hours
Monitored response	Root growth inhibition compared to control, IC

The basis of inhibition/stimulation effect on root growth was the average length of root determined in the individual concentrations of sludge in comparison with the average root length in the control.

The inhibition–stimulation effect (IC%) on root growth was calculated using the following equation:

$$IC\% = \frac{L_k - L_v}{L_k}.100,$$

where
L_v is the average length of root in the tested concentration of aqueous sludges in cm,
L_k is the average length of root in the control in cm.

Spring barley

The effect of microelement accumulation on terrestrial flora was tested using the Slovakian standard STN EN 14735:2006-03 (83 8300). The static acute toxicity test was designed for investigation of spring barley (*Hordeum vulgare* L.) biomass in a growth chamber experiment; the germination power of seeds was higher than 97% (*Table 2*).

Table 2. *Conditions of spring barley static acute toxicity test*

Testing organism	*Hordeum vulgare* L., germination > 97%, six seeds in pots, artificial soil mixture
Temperature	22 ± 1°C
Humidity	28-30%, HH2 Moisture Meter (Delta-T Devices of Cambridge, England)
Control	Distilled water
Exposition period	21 days
Monitored response	Grown biomass, trace element accumulation

The experiment was carried out in pots filled with 500 g of artificial soil mixture of 10% peat, 20% kaolin clay and 70% industrial quartz sand. The soil was irrigated with aqueous extracts and control samples were watered with distilled water; subsequently, six spring barley seeds were planted into each pot.

The controlled conditions were: constant temperature of 22 °C and constant humidity of 28-30%, which was ensured by daily measurement with a HH2 Moisture Meter (Delta-T Devices of Cambridge, England) hygrometer.

After an incubation time of 21 days, the grown biomass was weighted for the inhibition-stimulation test and dried for trace element analysis.

Trace element analysis

Air-dried soil and sludge samples were ground, sieved through a 2-mm sieve, dried at 105 °C and ground in a mortar. The plant samples were also dried at 105 °C and ground in a mortar. About 1 g of each sample was measured in a Teflon bomb and we added 5 mL cc HNO_3 and 2 mL H_2O_2 (30% m/m). During the digestion period of 3 h, the bombs were kept in an oven at 110 °C. After filtration, the supernatants were acidified with cc HNO3 and filtrated again. Subsequently, 50 ml of supernatant were evaporated, followed by adding 1 ml cc HNO_3 and washing into a 25-ml volumetric flask. Elemental analysis was carried out by ICP-OES (iCAP 6300 Duo ICP-OES, Thermo Fisher Scientific Inc, Waltham, MA USA).

Statistical analysis

The software package STATISTICA 10 (Version 10, StatSoft, Tulsa, OK, USA) was used for performing (analysis of variance) and single factor dispersion analysis to evaluate the results of the ecotoxicological tests. Graphical presentation of ANOVA and Duncan's test results was performed using 95% confidence intervals for average immobilisation and inhibition values for individual samples (Hybská et al., 2017).

Results and discussion

Methane production

The effect of microelement supplementation was examined via methane production (*Fig. 1*) The average values of specific methane yield (SMY) (403.8 ± 4.51^{a} mL CH_4 gVS^{-1} in case of non-supplemented, 448.3 ± 9.91^{b} mL CH_4 gVS^{-1} in case of supplemented and 451.1 ± 9.16^{b} mL CH_4 gVS^{-1} in case of supplemented + Fe trial, different letters indicate significant difference at $P \leq 0.05$) represent the 11.0% and 11.7% benefit effect of supplementations. This observation is in agreement with the findings of Wall et al. (2014). They reported an increase in SMY in the mono-digestion of grass-silage by 12% to 404 L CH_4 kg^{-1} VS by the effects of Co, Fe and Ni addition. The specific methane yields were balanced during the uploading stage, with average values being 285.2, 317.6 and 328.9 mL CH_4 g VS^{-1} for the non-supplemented, supplemented and supplemented + Fe trial, respectively (*Fig. 1*). Values of the average SMY values of supplemented and supplemented + Fe compared to non-supplemented increased by 12.6 and 23.0% during the drastic overloading period (day 12-19). The most significant effect of microelement supplementation on SMY was recognised during the reloading stage. In the first seven days of this period, SMY values increased by 22.2 and 32.3% and then decreased by 6.5 and 29.3% in the supplemented

© 2018, ALÖKI Kft., Budapest, Hungary

fermenters. During the stable run at moderate OLR levels, the effects of microelement supplementation on SMY rates were lower (5.8 and 1.8%, respectively).

The methane content of biogas was not significantly influenced by microelement supplementation. Average methane values and ranges of daily biogas production were 53.95 (51.68-56.74%), 54.19 (51.66-58.32%) and 53.49% (50.36-58.69%) for the non-supplemented, supplemented and supplemented + Fe trial, respectively.

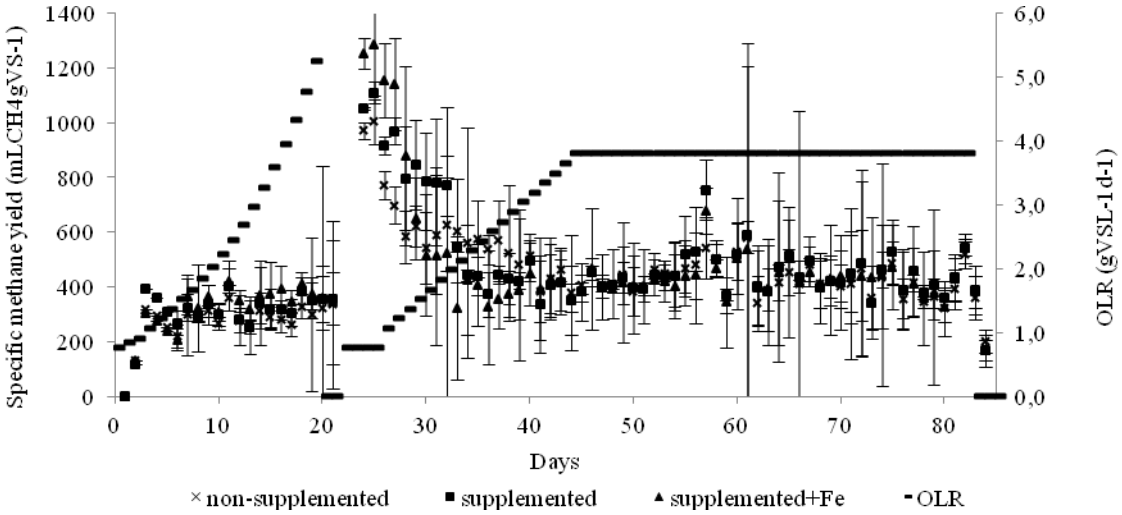

Figure 1. *Alteration of specific methane yields of non-supplemented, supplemented and supplemented + Fe trials during the experiment*

The initial tVFA level of the sludge was 2 440 mg L^{-1}. By increasing the OLR rate, the tVFA levels raised, but remained under 4 500 mg L^{-1} during the first 1 days of the experiment in all cases. On day 20 at 5.2 g VSL^{-1} d^{-1}, OLR average and standard deviation of tVFA levels increased to 12 496 ± 1 452 mg L^{-1}, 11 421 ± 917 mg L^{-1}, 9 943 ± 1 211 mg L^{-1} in the non-supplemented, supplemented and supplemented + Fe trial, respectively. Based on the effect of interrupted OLR, acid levels decreased by 12.9, 21.2 and 17.6%, respectively, thus moderate uploading (constant 0.76 $gVSL^{-1}$ d^{-1} for four days, then increasing up to 3.80 g $VSL^{-1}d^{-1}$ in the 19-day period) was started at day 22. Before reaching a stable run period, tVFA levels decreased rapidly by 58.1, 69.4 and 70.3%, respectively, by day 30 of the experiment. Until the end of the experiment, tVFA concentrations remained at low levels of 2 500-3 000 mg L^{-1} in all cases. Similar effects of microelement supplementation were described in the study of Qiang et al. (2013), who found that at 6.3 kg m^{-3} d^{-1} OLR level of high-solid food waste, the addition of 10 mg L^{-1} Fe^{2+}, 1 mg L^{-1} Co^{2+} and 1 mg L^{-1} Ni^{2+}, approximately every 45 days, resulted in efficient methane fermentation. A comparison of our microelement supplementation level with the above-mentioned date is not relevant due to the different bioavailability of the chelate-form and inorganic ions.

The most relevant chemical parameters (COD, soluble NH_4^+ and total P) of the sludges were determined every two weeks during the experiments; no significant difference was found between the groups. Average values of sludge COD, NH_4^+ and total P used for ecotoxicological experiments were 4 920 ± 173 mg L^{-1}, 1 457 ± 106 mg L^{-1} and 40 ± 4 mg L^{-1}; 5 104 ± 147 mg L^{-1}, 1 422 ± 93 mg L^{-1} and 36 ± 4 mg L^{-1}; 5 157

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

± 214 mg L^{-1}, 1 349 ± 71 mg L^{-1} and 35 ± 2 mg L^{-1} in the non-supplemented, supplemented and supplemented + Fe trials, respectively.

Zhang and Jahng (2012) reported the essential role of iron in the long-term anaerobic digestion of food waste. They found that the operational parameters (CH_4 yield, pH value, tVFA concentration) of anaerobic digestion of food waste remained stable in a year-long experiment in the case of microelement (Co, Mo, Ni, Fe) supplementation. Contrary to our results, they did not find increasing SMY levels with microelement supplementation.

Ecotoxicological tests

Root elongation test with white mustard

A decreased inhibitory effect could be determined in the non-supplemented treatment with increasing dilution rates (*Fig. 2*). The highest stimulating rate (-59.41%) was found for a 10-fold dilution in the supplemented + Fe trial. Iron completion had no significant effect on IC% values.

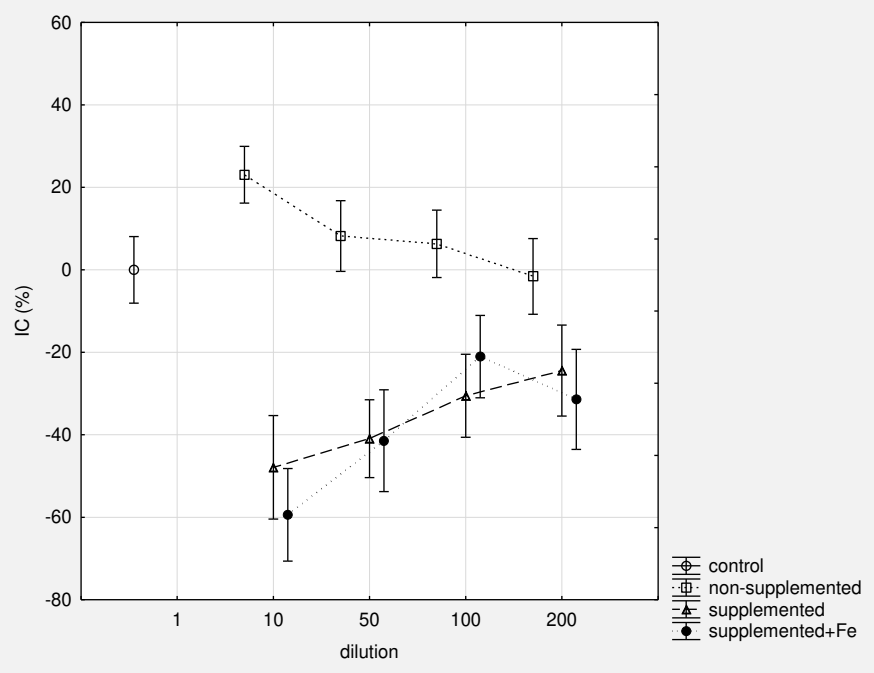

Figure 2. *Effects of dilution rates of anaerobic sludge on root growth of white mustard (0-100 IC%: inhibition, 0-100 IC%: stimulation)*

The preliminary test was negative as root growth inhibition was less than 30% and stimulation was lower than 75% compared to the control; therefore, further tests were not necessary (STN 83 8303:1999).

To correct the two-sample t-test, which, if used in more couples, would produce incorrect results, Duncan´s probability of equality test was used. Based on the results in *Table 3,* the difference between control and non-supplemented (50 x dilutions) was 28.7%, while the difference between control and non-supplemented (100 x dilution) was 38.2% and that between control and non-supplemented (100 x dilution) was 82.6%. All other dilution combinations and samples were significantly different from the control.

Spring barley

The effect of trace element supplementation of anaerobic sludge was studied using the static acute toxicity test for spring barley. There was no inhibition on grown biomass, and a major stimulation on biomass production was observed in all trials. The stimulation ratio increased with supplementation; the strongest effect (stimulation of -62.80%) was determined in the case of supplementation with iron, as shown in *Table 4*. Iron is a part of the active groups of enzymes and involved in many physiological processes. The most important process is the formation of chlorophyll, which is a photosynthetically active dye. In our study, supplementation affected net assimilation rate and thus the amount of biomass produced. Regarding to the results of biomass production based on Duncan´s probability test, equality of samples different significantly from the control and between the pairs of samples, respectively.

Table 4. *Stimulation effects of anaerobic sludge on biomass production of spring barley (0-100 IC%: inhibition, 0-100 IC%: stimulation)*

Sample	Stimulation (%)			
	Average	Standard deviation	-95.00%	95.00%

Our results partly contradict by the findings of Roig et al. (2012), who did not observe a correlation between heavy metal contamination and ecotoxicology of different sewage sludges due to the low metal content. They suggested that organic pollutants, such as phenols, have a higher significance than inorganic compounds.

Trace element analysis

The effect of microelement-enriched anaerobic sludge on element accumulation during the spring barley test was followed by microelement analysis of sludge, soil and barley biomass samples (*Table 5*). Application of microelement supplementation during anaerobic digestion enhanced element levels in the sludge (*Table 5*). Cobalt levels increased by 14 and 16 times, nickel by 10 and 14 times, boron by 1.8 and 1.9 times, iron by 1.6 and 2.1 times higher in the supplemented and supplemented + Fe trial, respectively. Despite zinc supplementation with iron addition, the concentration of zinc decreased by 33%. Interpretation of this phenomenon has not revealed yet. The metal contents of the sludges were significantly lower than those in the study by Roig et al. (2012), considering 10-100 times higher metal concentrations in sewage sludge.

Similar observations can be found while studying the effect of irrigation with anaerobic sludges on the microelement composition of soil samples (*Table 5*). Due to the initial high iron content of the soil, sludge amendment did not elevate iron levels. Barium levels were increased through sludges originating from SBPP digestion.

The results obtained in alteration of metals in soil by the effect of sludge amendment are similar to previous study (Carbonell et al., 2009). The amendment of sludges originating from municipal wastewater treatment resulted in significantly higher concentrations of Zn and Cu in soils due to the high Zn and Cu content of the sludge. No significant difference was observed for Cd, Cr and Ni concentrations.

Bioaccumulation factors (BF) of different elements varied widely (0.07-110.8). Extremely high values were found for cadmium (more than 100 times higher) in the supplemented + Fe treatment, which were 10 times higher than those in the supplemented or non-supplemented samples. This can be explained by the synergic effect of iron on cadmium accumulation. Similar impacts were found for cobalt and chromium deposition. Microelement supplementation of sludge had a negative effect on boron BF; the accumulation of microelements in spring barley samples is shown in *Table 5*. Cobalt concentrations increased by 4.2, 21.0 times and 40.0 times in the non-supplemented, supplemented and supplemented + Fe trial, respectively. A similar tendency (1.7, 2.4 and 5.8 times higher) was found for nickel. The significant accumulation of cadmium, chrome and lithium in barley samples, observed in the supplementation + Fe trial, cannot be explained by the relevant values of the sludges.

Conclusion

This study has highlighted the importance of trace element supplementation for anaerobic digestion of SBPP. In addition, we investigated the ecotoxicological effects of sludges on root elongation (white mustard) and accumulation on terrestrial flora (spring barley).

Based on the average values of SMY, supplementation (supplemented and supplemented + iron) increased the values by 11.0 and 11.7% compared to the non-supplemented control trial. The methane content of the produced biogas was not significantly influenced by microelement supplementation. This means that anaerobic digestion with trace element supplementation is more stable and flexible, while during an imbalance caused by overload stress, tVFA values remained 9-11% lower in the supplemented trials compared to the control, indicating that the systems could regenerate faster.

Ecotoxicological assessment of anaerobic sludges is extremely important to determine application possibilities that could adversely affect forestry and agriculture.

The applied tests were appropriate indicators to determine the differences of inhibition-stimulation effects. In the white mustard root elongation test, the highest stimulation rate (-59.41%) was found for the 10-fold dilution in the supplemented + iron trial. The results of static acute toxicity test of spring barley showed that the stimulation ratio increased with supplementation; the strongest effect (stimulation of -62.80%) was determined supplementation with iron. This stimulation effect of sludge originating from SBPP metal-supplemented anaerobic digestion highlights the fact that plant-derived sludges have a lower ecotoxicology compared to sludges with high metal contents (Roig et al., 2012).

Bioaccumulation factors (BF) of microelements in spring barley/soil samples varied widely between 0.07 and 110.8. According to the results of the sludge trace element analysis, irrigation of barley with sludge impacts soil metal concentrations. Therefore, additional physico-chemical and microbiological data should also be considered in order to better understand the long-term implications of plant-derived anaerobic sludge addition to forest and agricultural soils.

(Received 5th Dec 2017; accepted 7th Mar 2018)

Abstract. Four experiments were conducted at the University of Limpopo Experimental farm, Limpopo province, South Africa to determine the effect of legume inclusion on the performance of Pedi bucks on a basal diet of forage sorghum hay. *Vigna ungiculata* (cowpea), *Lablab purpureus* (lablab) and *Mucuna pruriens* (mucuna) hays were used in this trial at different inclusion levels. Fifteen yearling Pedi bucks with average weights of 15 ± 4 kg (Experiment 1), 18 ± 2 kg (Experiment 2) and 17 ± 3 kg (Experiment 3) were used in the first three experiments in a completely randomised design. Nine goats with an average weight of 20 ± 4 kg were used in Experiment 4. Mucuna hay had the highest ($P < 0.05$) hydrolysable tannin contents. Lablab hay had higher ($P < 0.05$) total polyphenolics than mucuna, cowpea and sorghum hays. Dry matter intake and digestibility increased with increasing levels of the respective forage inclusion levels. Cowpea and mucuna hay improved ($P < 0.05$) final live weights and feed conversion ratio, while goats on lablab hay lost weight. Diet intake, digestibility and final live weights of the goats were optimized at different forage inclusion levels. This may indicate that legume inclusion levels for optimal productivity will depend on the particular parameter of interest.
Keywords: *legume inclusion, optimal intake, polyphenolic, digestibility, goats*

Introduction

Goats are economically, nutritionally and culturally important livestock species among the agrarian rural communities of South Africa. Additionally, the indigenous Pedi goats in Limpopo Province of South Africa constitute a valuable source of genetic material because of their relative adaptation to harsh climatic conditions and their ability to better utilise the limited and poor quality feed resources (Brown and Ngambi, 2017). However, their productivity is limited by acute shortages of good quality feed, especially during the dry and winter seasons (Brown et al., 2017). Available fodder during this period is fibrous and low in nitrogen resulting in low voluntary intake and digestibility (Tolera et al., 2000). Poor nutrition results in loss of body weight and reproductive performance (Matlebyane et al., 2010). Supplementation with forage legumes may be appropriate alternative for increasing intake and digestibility of these poor quality roughages (Mupangwa, 2002).

Forage legumes such as *Vigna ungiculata* (cowpeas), *Lablab purpureus* (lablab) and *Mucuna pruriens* (mucuna) are commonly grown by farmers in Limpopo province of South Africa. These legumes have high nitrogen contents and hence there is potential to increase the productivity of indigenous goats feeding on low quality roughages. Legumes can supply the limiting nitrogen in the form of amino acids and peptides. Abule et al. (1995) reported increased total dry matter (DM) intake in calves fed straw supplemented with either cowpea or lablab hay. Umunna

et al. (1995) reported increased average daily gain in sheep fed oat hay supplemented with lablab leaf meal. Similar results were reported in sheep fed scrubland herbage supplemented with lablab leaf meal (Ndlovu and Sibanda, 1996). Mupangwa et al. (2002) concluded that inclusion of *Mucuna pruriens*, (mucuna) in low quality grass hay diets increased protein availability in sheep by increasing the supply of both rumen degradable and undegradable proteins. However, some of these legumes may contain polyphenolic compounds which may reduce diet intake and digestibility (Reed, 1995). The effects of such compounds in tropical legumes on diet intake and digestibility have not been extensively studied in indigenous goat breeds. Thus, extensive evaluation of these forage legumes in terms of their polyphenolic effects on diet intake, digestibility and productivity is appropriate. Therefore, the objective of this study was to determine the effect of mixture level of forage sorghum with cowpea, lablab or mucuna legumes on diet intake, digestibility growth and blood metabolites of indigenous Pedi goats of South Africa.

Materials and methods

Study site

This study was conducted at the University of Limpopo Experimental Farm, South Africa (latitude 27°55 S and longitude 24°77 E). The ambient temperature at the study site ranges between 20 and 36°C in summer (November - January) and between 5 and 25 °C in winter (May – July). Mean annual rainfall ranges between 446.8 and 468.44 mm. The vegetation is a mixture of shrubs (mainly *Vachellia* species), trees and grass.

Forages

Forage sorghum, cowpea (*Vigna ungiculata*), lablab (*Lablab purpureus*) and mucuna (*Mucuna pruriens*) hays were grown in large plots under irrigation in January, 2012. At harvesting, the legumes were at the flowering stage while forage sorghum was at early grain filling stage. The forages were harvested using a mower, and dried under the shade to prevent nutrient loss. After drying, the forages were chopped (12.7 mm length) to reduce selection by animals when feeding (Mentu et al., 2001). The dried and chopped forages were then thoroughly mixed according to the different ratios and packed into sacks as hay for winter-feeding.

Experimental procedures, treatments and designs

This study was divided into a series of experiments due to lack of equipment to conduct the whole study in one session. The experimental design was a completely randomized design, with individual animals placed in metabolic cages as experimental units. A total of four experiments were conducted. Experiments 1 to 3 involved cowpea, lablab and mucuna hays, respectively, while Experiment 4 determined the inclusion level for optimal intake from each of the first three experiments, as indicated below. The dietary treatments for optimal intake were determined from the quadratic equations described under statistical analysis. The experimental treatments were as listed below:

$S_{68}L_{32}$	A mixture of 68% forage sorghum and 32% lablab
$S_{77}M_{23}$	A mixture of 77% forage sorghum and 23% mucuna

Animals

All procedures involving animals were approved by the Animal Research Ethics Committee of the University of Limpopo, South Africa. Fifteen growing yearling Pedi bucks (a local breed in Limpopo province of South Africa) with mean live weights of 15 ± 4 kg (Experiment 1), 18 ± 2 kg (Experiment 2), and 17 ± 3 kg (Experiment 3) were used. Nine goats with a mean live weight of 20 ± 4 kg were used in Experiment 4. In each experiment, different goats were used but of similar ages. Thus, a total of 54 goats were used in the study. Each treatment had three replicates with one goat per replicate as described by Brown and Ng'ambi (2017). The animals were housed in individual metabolic cages that allowed the separation of faeces and urine (5.5' x 2.0') and were given the experimental diets during the study period. The goats were drenched with an anthelmintic (Valbazen® broad-spectrum dewormer, Pfizer Inc, NY, USA) before the start of the experiment.

An adjustment period of 2 weeks allowed goats to become acclimatized to the metabolic cage before the start of the study. Each goat was initially fed 700 g of feed per day in individual troughs. This amount was adjusted accordingly so that a 10% feed refusal was maintained to avoid selection. Goats were fed once a day at 08.00 hours and feeds offered and refused were determined. Each experiment lasted for 21 days, the last 7 days being collection period. Animals had access to feed and water *ad libitum*. The goats were weighed weekly. Average daily gain was determined. The weighing of the goats was carried out before morning feeding to avoid feed effect (Sarwatt et al., 2003). Feeds were collected from each diet and stored for laboratory analysis. During collection, daily faecal outputs for each animal

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_21972212
© 2018, ALÖKI Kft., Budapest, Hungary

were collected, mixed and recorded. Ten percent of the faeces were sub-sampled and kept for analysis. All the sub-sampled faeces were pooled on animal basis, dried and kept until required for chemical analysis. From the food eaten and faecal matter secreted, apparent digestibility of the nutrients was calculated (McDonald et al., 2010). Blood samples were taken from each goat via the jugular vein just before the morning feeding on the first and last day of the experiment (Olafadehan, 2011). The blood samples were collected from each animal, before feeding at the beginning and end of the study, into anticoagulant free bottles, allowed to coagulate at room temperature and centrifuged at 1500ˈx *g* for 10 min. The supernatant sera were then harvested and stored at -20°C for subsequent analysis.

Laboratory analyses

Samples of the forages (cowpea, lablab, mucuna and sorghum) were ground to pass a 1 mm screen for nutrient analysis. Samples for tannin analysis were further ground to pass through a 0.2 mm screen. Dry matter of feeds, refusals and faeces were determined by the method described by AOAC (2005). Ash was determined by the method described by AOAC (2005). Acid detergent fibre and neutral detergent fibre were determined by the method described by Van Soest et al. (1991). Nitrogen content was determined for feeds and faeces using the Kjedahl procedure (AOAC, 2005). Sodium oxalate fluoride was used for glucose preservation, while the blood glucose was determined by enzymatic colorimetric test (Quimica Clinical Applicada, SA). Serum urea was obtained by the method of Valley et al. (1980). Extraction of polyphenolics from plant material was done using the method described by Makkar et al. (1995). Condensed tannins, hydrolysable tannins and total polyphenols were determined using the methods described by Porter et al. (1986).

Statistical analysis

All data on diet intake, digestibility, weight change, feed conversion ratio, nitrogen balance, and blood metabolites were analysed using the General Linear Model procedures of SAS (SAS, 2010). Covariance analysis was done using initial bodyweight of the goats as covariate. Treatment means were compared using Tukey's HSD and significant differences were declared at $P < 0.05$. The responses in optimal intake, digestibility, weight change, feed conversion ratio, nitrogen balance, and blood metabolites were modelled using the following quadratic equation:

$$Y = a + b_1x + b_2x^2$$

where Y = Intake, digestibility, weight change, feed conversion ratio, nitrogen balance or blood metabolites; a = intercept; b = coefficients of the quadratic equation; x = level of inclusion and $-b_1/2b_2$ = level of inclusion value for optimal production response (Brown and Ng'ambi, 2017).

Results

Nutrient composition of feeds

Results of the chemical composition of the experimental feeds are presented in *Table 1*. Cowpea, lablab and mucuna hay had higher ($P < 0.05$) protein contents than sorghum hay. There were traces of tannins and polyphenolic compounds in all the forages. However,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_21972212
© 2018, ALÖKI Kft., Budapest, Hungary

mucuna hay had higher ($P < 0.05$) condensed and hydrolysable tannin contents when compared to sorghum, lablab and cowpea. Lablab hay had higher ($P < 0.05$) total polyphenolics (1.24 mg/g) when compared to mucuna (0.35 mg/g), cowpea (0.05 mg/g) and sorghum (0.17 mg/g) hays. Cowpea hay had lower ($P < 0.05$) total polyphenolics, condensed and hydrolysable tannin contents.

Table 1. *The chemical composition of the experimental feeds*[#]

[a,b,c]Means in the same row with different superscripts are significantly different
NS: Not significant
*$P < 0.05$

Cowpea inclusion

The results of the effect of cowpea hay inclusion level on diet intake, digestibility, live weight change, nitrogen balance and blood serum chemistry of indigenous Pedi bucks fed a basal diet of forage sorghum hay are presented in *Table 2*. Daily dry matter intakes of cowpea were similar ($P > 0.05$) across dietary treatments, ranging from 370 to 511 g per goat per day. Similarly, goats consumed similar ($P > 0.05$) amounts of organic matter (OM) and neutral detergent fibre (NDF) contents. However, Pedi bucks on diets 20, 30, 40 or 50% cowpea hay inclusion levels had higher ($P < 0.05$) crude protein (CP) and acid detergent fibre (ADF) intakes than those on diets with 10% cowpea hay. Pedi goats on a diet with 50% cowpea hay inclusion level had higher ($P < 0.05$) DM, OM and CP intakes per metabolic weight as compared to those on other dietary treatments. Goats on diets having a 30% cowpea hay inclusion level had lower ($P < 0.05$) NDF and ADF intakes per metabolic weight than those on other dietary treatments. Dry matter, OM, NDF and ADF digestibility values were similar ($P > 0.05$) across the dietary treatments. However, goats on diets having 20, 40 or 50% cowpea hay inclusion levels had higher ($P < 0.05$) dietary CP digestibility values than those on diets having 10 or 30% cowpea hay inclusion levels. Pedi goats fed diets having 20, 30, 40 or 50% cowpea hay inclusion levels had higher ($P < 0.05$) nitrogen intakes than those on a diet with 10% cowpea hay inclusion level. Similarly, goats on diets having 20, 40 or 50% cowpea hay inclusion levels retained higher ($P < 0.05$) amounts of nitrogen than those on 10 or 30% cowpea diets. Cowpea inclusion level did not ($P > 0.05$) have effects on blood glucose concentration of the bucks. However, goats fed diets having 20, 40 or 50% cowpea hay inclusion levels had higher ($P < 0.05$) blood

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

urea than those on diets with 10 or 30% cowpea hay inclusion levels. Cowpea hay inclusion level did not ($P > 0.05$) have effect on weight gain of goats. However, dietary treatment had effect ($P < 0.05$) on the final live weight of goats. Goats fed diets having a 10% cowpea hay inclusion level had the lowest final weight as compared to those on 30% inclusion level. Feed conversion ratio was improved ($P < 0.05$) in goats fed diets having a 50% cowpea hay inclusion level. Cowpea hay inclusion levels of 39, 39, 54 and 33% optimized DM, OM, CP and ADF intakes while nitrogen retention and blood glucose were optimized at 56 and 33% levels, respectively (*Table 3*).

*P < 0.05

Daily DM, OM, CP, NDF and ADF intakes were similar (P > 0.05) across dietary treatments. Pedi goats fed a diet having a 40% lablab hay inclusion level had higher (P < 0.05) dry matter intakes per metabolic weight than those on 10 or 20% inclusion levels. Goats fed diets having 30, 40 or 50% lablab hay inclusion levels had higher (P < 0.05) CP intakes per metabolic weight than those on other dietary treatments. Pedi goats had similar (P > 0.05) DM, OM, NDF and ADF digestibility values across the dietary treatments. Goats on diets having 30, 40 or 50% lablab hay inclusion levels had higher (P < 0.05) crude protein digestibility values than those on diets having 10 or 20% lablab hay inclusion levels. Daily nitrogen intakes were similar (P > 0.05) across dietary treatments. However, goats fed diets having 40 or 50% lablab hay inclusion levels had higher (P < 0.05) nitrogen retention values than those on 10 or 20% lablab hay inclusion levels. Lablab hay inclusion level did not have effect (P > 0.05) on blood glucose and serum urea of goats. Similarly, lablab hay inclusion level did not have effect (P > 0.05) on the live weights of Pedi goats. However, weight losses were observed across all dietary treatments. Dry matter, OM, CP and ADF intakes were optimized at 32.29, 34.04, 41.14 and 32.48% lablab hay inclusion levels, respectively, while nitrogen retention was optimized at 39.17% lablab hay inclusion level (*Table 5*).

Discussion

The legume species have higher protein contents (18% and above) than sorghum hay (13%). The protein values of cowpea, lablab and mucuna hays were similar to the protein values reported by Nielsen et al. (1997) and Adjorlolo et al. (2001), respectively. Thus, these legumes can be used as protein supplements where low quality roughage is used as a basal diet for goats. Forage sorghum hay contained higher amounts of acid detergent fibre than the legumes. Higher acid detergent fibre contents may indicate lower digestibility values (Buxton et al., 1996). Lablab hay had the highest concentrations of total polyphenols. Mokoboki (2007) reported similar high values of total polyphenols and extracted condensed tannins in lablab hay. Mucuna hay had the highest concentrations of both condensed tannins and hydrolysable tannins. Chikanga-Malunga et al. (2009) reported similarly high concentrations of total tannins in whole mucuna plants at 123 days after planting.

Cowpea hay inclusion increased crude protein intake and digestibility by goats. This result is similar to the findings of Ravhuhali (2010) who reported higher intake responses in goats fed a basal diet of buffalo grass supplemented with cowpea hay. Anelea et al. (2010) also reported increased dry matter and crude protein intakes by goats fed cowpea haulms. The authors attributed this to the high protein content in cowpea hay. In the present study, the level of inclusion for optimal intake was 38.66% of the diet. The optimal intake at this level was calculated to be 500 g per goat per day. This high diet intake may be attributed to the high protein content in cowpea hay. It may, also, be attributed to increases in DM and OM digestibility with increasing levels of cowpea hay inclusion as observed in the present study. In the present study, cowpea inclusion improved nitrogen retention and feed conversion ratio. Nitrogen retention was optimized at 56.25% level of cowpea inclusion, while feed conversion ratio improved linearly with increasing level of cowpea. Live weight of goats also increased linearly with increasing level of cowpea hay inclusion. This linear increase in live weight may be explained in terms of increases in diet intake and digestibility of the legume. This observation has been reported elsewhere in the literature (Savadogo et al., 2000; Ravhuhali, 2010). Cowpea hay inclusion significantly increased blood serum urea. This is similar to the results of Turner et al. (2005) who found increase of urea in the blood serum of goats given *Lespedeza cuneata* or alfalfa (*Medicago sativa*) hays.

Lablab hay inclusion increased diet DM intake and digestibility by goats. The level of inclusion for optimal intake was 32.29% of the diet. The optimal intake at this level was calculated to be 576 g per goat per day. According to Goodchild and McMeniman (1994), animals on supplements with higher protein contents exhibit better intake, digestibility and live weight gain responses. However, lablab inclusion had a negative effect on live weight gain. Weight lost was observed at all inclusion levels. Nsahlai and Umunna (1996) reported no effect on live weight gain of sheep fed a basal diet of oat hay supplemented with lablab. This adverse effect may be explained in terms of the high concentrations of polyphenols in lablab hay. High concentrations of polyphenols in a diet tend to reduce nutrient availability to the animals, thus adversely affecting its live weight gains (Tanner et al., 1990). It was possible that the protein in lablab hay was not available to the animals due to the high tannin content which tend to bind with proteins and hence reducing their digestion (D'Mello, 1992). Similarly, other dietary nutrients such as carbohydrates and vitamins may have been adversely affected by the total polyphenols in the digestive tract, thus negatively affecting nutrient availability and growth at tissue level (Makkar, 2003). Other studies have

© 2018, ALÖKI Kft., Budapest, Hungary

shown that lablab supplement to low quality hay increased average daily gain of ruminants (Ndlovu and Sibanda, 1996; Festus et al., 2008). In the present study, lablab hay inclusion improved nitrogen retention. A low inclusion level of 39.17% optimized nitrogen retention. This observation may be ascribed to high concentrations of total polyphenols in lablab hay. Tannin-protein complexes in an animal's gut are believed to be responsible for low protein digestibility and increased faecal nitrogen concentrations (McNabb et al., 1993).

Mucuna hay inclusion improved diet CP intake and OM digestibility. The results are in agreement with that of Mupangwa et al. (2002). Other studies have shown that mucuna hay is a good crude protein supplement for ruminants fed low quality forages such as maize stover and tropical grass hays (Mupangwa et al., 2002; Nyambati and Sollenberger, 2003). Additionally, mucuna hay inclusion improved feed conversion ratio of the goats. Level of inclusion for optimal live weight change and feed conversion was 42%. Such a level is recommended when performing dose-response trials. Mucuna hay inclusion improved live weight of the animals despite the presence of high levels of tannins in the diet. The improvement in live weight may be explained in terms of increases in diet intake and digestibility by goats. This result is similar to the findings of Brown et al. (2017) who reported higher live weight gains in indigenous Pedi bucks fed tanninferous *Acacia karroo* leaf meal. Solaiman et al. (2010) also reported improved weight gains in goats fed forages high in condensed tannins. Usually, tannins tend to reduce dietary intake and digestibility (Reed, 1995). However, there is evidence that low to moderate tannin content in diet may increase the efficiency of protein utilisation by ruminants (McNabb et al., 1993). Tannins bind with proteins at the rumen pH of 5.5 to 7.0 and protect protein from microbial degradation. These complexes are unstable at low pH in the abomasum, thus the proteins become available for digestion in the small intestines upon appropriate change in pH (McArthur et al., 1992). Mucuna hay significantly increased blood serum urea level. This observation may be ascribed to an increase in diet digestibility. Increased serum urea would, thus, suggest increased absorption of amino acids (Silanikove et al., 1996).

When levels of forage inclusion for optimal intake were used (Experiment 4)**,** goats on cowpea or lablab hays had similar NDF intakes which were higher than those on mucuna hay. Dry matter, OM and NDF intakes per metabolic weight of cowpea hay were higher than those of lablab and mucuna hays. Goats fed lablab hay had the highest final live weight (25.4 kg). Goats fed mucuna hay had better feed conversion ratio than those on cowpea and lablab hay inclusions. However, these values could not be compared due to lack of sufficient information in literature.

Conclusion

All the legumes used in this study had higher protein contents than sorghum hay and thus, have the potential to be utilised as protein supplements, where low quality hay is used as a basal diet for goats. Feed intake, digestibility and final live weights of the goats were optimized at different levels for all the legumes. This may indicate that levels for optimal productivity will depend on the particular parameter of interest. Lablab hay had negative effects on live weight gain of goats. The high concentration of polyphenol in the diet may have exerted adverse effects on the performance of animals. Further studies are required to ascertain this observation.

INTRASPECIFIC VARIATIONS IN THE IVORY FEATHERLEG *PLATYCNEMIS DEALBATA* (INSECTA: ODONATA) FROM TURKEY

MİROĞLU, A.

Fatsa Faculty of Marine Sciences, Ordu University, Fatsa-Ordu, Turkey
(e-mail: alimiroglu@gmail.com; phone: +90-452-423-5053; fax: +90-452-423-9953)

(Received 20th Dec 2017; accepted 3rd Apr 2018)

Abstract. Intraspecific variations can be observed in many types of animal species in Turkey due to the geographical and ecological characteristics of the region. The aim of this research is to study the *Platycnemis dealbata* populations in Turkey and to survey how the Anatolian Diagonal affects them. The *Platycnemis dealbata* specimens were collected from Kahramanmaraş and Iğdır Provinces of Turkey in 2010, 2012, 2015, and 2017. Variations were found between these two populations. The variations seen in the *Platycnemis dealbata* populations were examined and demonstrated with illustrations.
Keywords: *Odonata, damselfly, Turkey, taxonomy, biodiversity*

Introduction

The genus *Platycnemis* is represented by three species (*P. pennipes*, *P. kervillei,* and *P. dealbata*) in Turkey (Kalkman et al., 2003; Kalkman, 2006). *P. dealbata* males have enlarged white legs and an ivory body. *P. dealbata* males and females differ from other species (*P. pennipes* and *P. kervillei*) in this region by the unmarked tibia of the mid and hind legs (Kalkman, 2006; Boudot et al., 2009). *P. dealbata* can be found from Northwest India through Kashmir and Afghanistan and west to the Caucasus, southeastern Turkey, Iran, Iraq, Lebanon, Israel, Syria and Jordan (Askew, 1988; Steinmann, 1997; Boudot et al., 2009). It is most abundant in Syria, Lebanon, and Israel (Dumont, 1977). The species occurs in southeastern Turkey and in the coastal area in the southeast (but does not occur beyond the Taurus range in the northwest of Turkey) (Kalkman, 2006; Boudot et al., 2009).

Anatolia is located in the Alpine-Himalayan mountain belt between Europe, Asia, Africa, and Arabia. Its landform is primarily due to its geological history of collision of the Arabian and African plates with the European plate, resulting in the closure of the Tethys Sea (Rögl, 1998; Mutun, 2010; Kapli et al., 2013). Because of that, Anatolia experienced the upheaval and folding of the Caucasus and the Taurus Mountains, and the uplift of the Central Anatolian Highlands (Mutun, 2010). Anatolia is considered to be either a bridge or a barrier for species dispersal between Asia, Europe, and the Ethiopian region because of its position and geological history (Kapli et al., 2013).

There is a highland dividing Anatolia, known as the Anatolian Diagonal, and it has been suggested that the Anatolian Diagonal is an important geographic barrier contributing to the current composition of various species across Anatolia and dividing species distribution in the east and west (Davis, 1971; Çıplak et al., 1993; Mutun, 2010). This barrier has isolated many species in East and West Anatolia (Çıplak et al., 1993). Anatolia has a mountainous land and various climate types, so various subpopulations were generated there for all insect groups (Çıplak et al., 1993).

According to Martens (1996), *P. dealbata* and *P. kervillei* can be observed to the east of the Anatolian Diagonal, while *P. pennipes* shows distribution to the west (*Fig. 1*). *P.*

dealbata and *P. kervillei* show distribution together in Turkey, Syria, Iraq and Iran (the east of Anatolian Diagonal) (Boudot et al., 2009; Kiany et al., 2016; Schneider and Ikemeyer, 2016, 2017).

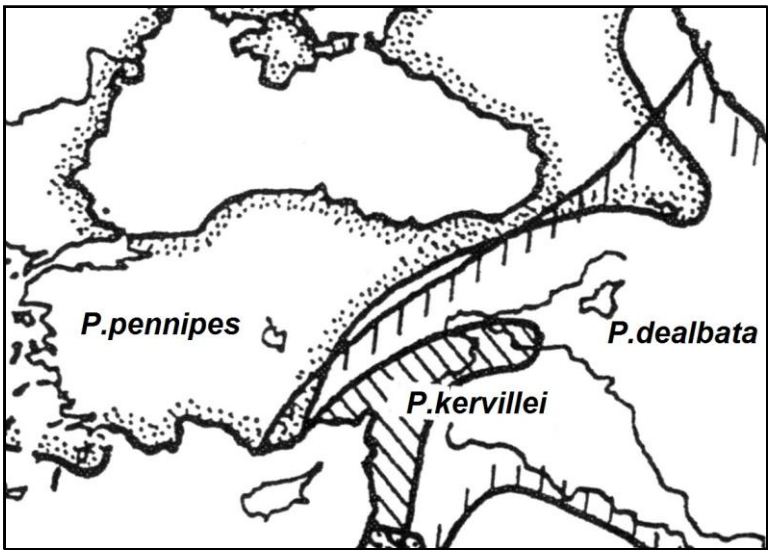

Figure 1. *Distribution of genus Platycnemis in Turkey and neighbouring countries (Martens, 1996)*

This study is mainly focusing on the populations of the ivory featherleg *P. dealbata* in Turkey and the observed effect of the Anatolian Diagonal on these populations. For this reason, samples were collected from Kahramanmaraş and Iğdır Provinces. As a result of the study, it was determined that there are variations between these two populations and these variations are revealed. It was mentioned that this could be caused by the Anatolian Diagonal.

Material and methods

The *P. dealbata* specimens were collected and identified from Kahramanmaraş and Iğdır Provinces (Turkey) in 2010, 2012, 2015, and 2017 (*Fig. 2*). The examined specimens were collected with aerial nets. The habitat consists of running water and is associated with weeds. Relevant literature (Martens, 1996; Dijkstra and Lewington, 2006; Kalkman, 2006) was used for taxonomic examination and identification of the specimens.

The material examined: 52 male and 26 female specimens, collected from Kahramanmaraş (20 male and 12 female specimens) and Iğdır (32 male and 14 female specimens) Provinces, Turkey in 2010, 2012, 2015, and 2017; leg. and det. Miroğlu, A. All materials are deposited in the Museum of Fatsa Faculty of Marine Sciences, Ordu University, Ordu, Turkey.

Results

The variations of the *P. dealbata* male include spots on the head (especially on the frons), on the abdominal segments (S7-9), and on the pronotum. Its variations have been presented by illustrations (*Figs. 3, 4* and *5*). In some specimens, these areas are all

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_22132218
© 2018, ALÖKI Kft., Budapest, Hungary

white, while others have black spots. The spreading of the black spots varies from narrow to wide.

When the head is viewed from the dorsal aspect, a weak and continuous or discontinuous black stripe can be seen on the frons (especially between the antennae). In some specimens (especially from Iğdır Province), the black stripe is stretching between the antennae. At the same time, the spreading of the black transverse band on the occiput and on the vertex varies from narrow to wide (*Fig. 3a, b*).

Figure 2. *Topographic position of P. dealbata collection localities, with dashed line showing the "Anatolian Diagonal"*

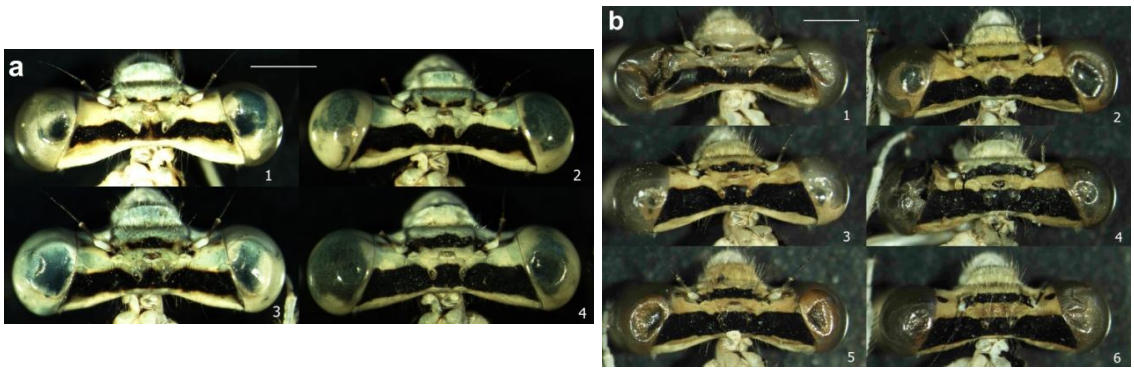

Figure 3. *Head dorsal view (a) Kahramanmaraş Province (b) Iğdır Province; scale bars 1.0 mm*

Also, black spots are exhibited on the pronotum similar to those on the frons and on the occiput-vertex. However, especially in the Kahramanmaraş Province specimens, those spots are seen to be different (*Fig. 4a, b*).

In *P. dealbata*, the spots and the color on the abdomen are very important. While the specimens from Iğdır Province have pale blue abdomen, their abdomen is ivory colored in Kahramanmaraş Province. In both localities (Iğdır and Kahramanmaraş Provinces), the specimens have black spots on the S7-9, but, those spots are observed much less on the Kahramanmaraş Province specimens (*Fig. 5a, b*).

Discussion

In the genus *Platycnemis*, although many characteristics for identification are taken into account, the most important characteristics are the spots and the color on the abdomen. According to Dijkstra and Lewington (2006), males of these species are identified by their ivory bodies and enlarged white legs. In this case, the abdomen is almost all white, with the S7-9 being seldom marked with black, never with blue and pruinose. Although the S7-9 is marked with black in the examined specimens, it is seldom so. This situation has been determined in many samples. Furthermore, a pale blue abdomen has been observed in the Iğdır Province specimens.

Although differences in color and spots have been observed within the species, there are also differences between the two populations (Kahramanmaraş and Iğdır). Specimens in the Iğdır population have more intense spots than specimens in the Kahramanmaraş population. Besides, Iğdır specimens have pale blue coloration, particularly on the abdomen.

As described previously, the Anatolian Diagonal may lead to diversity in species, and it may also contribute to intraspecific variations. At this point, Kahramanmaraş is located in an important region. While Kahramanmaraş is located on the Anatolian Diagonal, Iğdır is found on the eastern part of the Diagonal. According to Çıplak (2008), this region is known as the Maraş triangle, and it is rich in species. At this time, the region has a high intraspecific diversity (Mutun, 2010). It may be considered that the differences (both ecological and geographical) between the two populations (Kahramanmaraş and Iğdır) are probably due to the Anatolian Diagonal.

Conclusion

Samples should be collected from more regions where *P. dealbata* is distributed to find out whether there are variations in these populations. Phylogenetic studies are also needed to reveal whether there is a genetic diversity between the Kahramanmaraş and Iğdır populations.

Abstract. Slope revegetation is claimed to be accelerated with the right choice of plants and effective planting techniques for the root establishment. In addition, microorganisms also promote plant growth via nutrient intensification and soil-root enhancement, hence may alleviate soil surface erosion. Thus, this study is aimed to identify the effects of microbial application on plant growth, soil properties and soil erosion rate at different vegetation densities. Six experimental plots were set up at the Guthrie Corridor Expressway, Selangor, Malaysia, with different amount of microbial application and vegetation density. Dense vegetation cover with microbial application (DM) plot exhibited the highest soil microbes abundance and fungal/bacteria (F/B) ratio after 24 months of observation. Meanwhile, photosynthetic rate and root length density of *Lantana camara* in the DM plot revealed the highest rate, followed by *Melastoma malabathricum* and *Bauhinia purpurea*. Moreover, the soil of DM plot had also increased in CEC, total N, and respiration rate, reflecting the soil quality. Consequently, erosion rate of DM plot exhibited the 52.6% of total decrement from the initial experiment. Thus, microbes are proven to be relatively good promoters for the improvement of plant growth performance, the soil quality and alleviate the soil erosion of the slope.
Keywords: *microbes, vegetation cover, plant growth, soil properties, erosion rate, slope stability*

Introduction

Soil is claimed to be degraded via two domains on slopes; weathering processes and intervention of human activities (Guerra et al., 2017). The torrential rains in tropical regions may elevate the frequency and magnitude of surface erosion processes and subsequently, slope failures (Crozier, 2010). Soil erosion alters the slope environment in various ways, from degrading the soil structure and nutrient content, to contributing to serious landslide tragedies. Although the technical or engineering approaches can be used to provide a significant contribution to mitigate slope instability, replacement of sustainable control of soil erosion such as plant communities is highly desirable. The establishment of vegetative elements has become an alternative approach for slope stabilizing against erosion as well as minimizing the occurrence of landslides (Normaniza and Barakbah, 2011; Liu et al., 2016). Moreover, soil structure itself is not static, but is affected by the activity of plant materials, microbes and plant-microbial interaction (Hawkes et al., 2005).

The key ecosystem processes of soil habitats are driven by microbial communities, where local assemblages of microorganisms interact with each other and their environment (Konopka, 2009). Generally, similar land-use types usually have similar soil properties and microbial communities (Tian et al., 2017). Hence, we predict that the heterogeneity of cut slope soils may contributes to varying the microbial community and their composition will be highly localized. Soil microorganisms are sensitive to the changes of some environmental factors and play critical part in regulating many ecological processes such as litter decomposition, soil nutrient turnover as well as the plant growth performance (Liu et al., 2010; Wardle et al., 2004). Apart from that, soil microbes have also been reported to have dependency upon soil water availability (Chen et al., 2005; Liu et al., 2009). The soil water availability indirectly influences soil microorganisms via increasing decomposition of litter and soil organic matter (SOM) and subsequently alters the carbon substrates (Risch et al., 2007; Garcia-Pausas et al., 2008). On the other hand, previous studies have found that the bacterial diversity and abundance are influenced by ecological and geological factors such as vegetation type, soil temperature and pH level that establish the complex interaction among them (Bryant et al., 2008; Young and Crawfor, 2004). Given the revegetation process is an ecologically challenging task of restoring the ecosystem on the "problematic area" (cut slope), together with additional use of commercial biofertilizers, we predict that it will positively affect soil microbial activities and influence on revegetation success as well as the slope stability.

Topography is one of the most important factors controlling revegetation success on slope. Nevertheless, how the vegetation adjusts to terrain effects and the implications of the vegetation-hydrology processes and stability are the most substantial. Vegetation is known to have a major role in slope stability through hydrological and mechanical processes. Mechanical and hydrological processes are strongly interacted to each other and these two processes need to be considered together when assessing the stabilization of slopes by vegetation (Ghestem et al., 2011). Plants establishment on slopes typically intercepts rainfall through dense vegetation cover (Liu et al., 2016; Park and Cameron, 2008), their roots improve the soil structure by modifying aggregate stability (Fattet et al., 2011); and these functions will improve the stability of the slope and enhancing the biodiversity of landscapes (Zou et al., 2012). Additionally, since the topsoil and vegetation were destroyed during the slope cuttings, the slope soil properties are also changed (Chen et al., 2016). Rutigliano et al. (2004) has reported that the vegetation covers significantly affect the soil properties through the input of organic matter to the soil via the carbon and energy supplied from root exudates and plant remains. Whilst other studies have also discovered that as the age of vegetation increased, the soil physical and chemical properties are also enhanced (Zhu et al., 2010; Wang et al., 2015). Therefore, the ability to adapt on the harsh conditions and balance the soil water consumption need to be considered when implementing the vegetation screening for the slope.

From a practical perspective, it is imperative to select the optimal vegetation type that not only effective to control soil erosion, but can also maintain sustainable vegetation restoration (McVicar et al., 2010; Duan et al., 2016). Despite of considering the in situ environmental conditions (e.g. soil and temperature etc.), the easily measurable plant traits with a sound geotechnical basis are also need to be considered (Mickovski et al., 2006). Typically, trees have been used for erosion control, however, they are not recommended for planting on steep slopes because of the risk of uprooting that can cause mass movement (Pawlik, 2013). While the grasses that usually applied

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

via hydroseeding are also not guaranteed as the extreme microclimates (e.g. heat stress and shade) can inhibit the establishment of sustainable grass covers and subsequently impair their capabilities for erosion mitigation (Bunnell et al., 2005). In this study, we had chosen shrubs as alternative pioneers that are capable of forming relatively dense evergreen cover on the cut slopes in tropical climate of Malaysia. *Lantana camara* is a perennial shrub, which is useful in covering the ground with a fine leaf mulch and was found to improve the fertility of soil (Ghisalberti, 2000) as well as exhibited a significantly higher photosynthetic capacity at higher temperatures (Zhang et al., 2014). Whilst *Melastoma malabathricum* was chosen due to its outstanding capacity to survive in extreme soil conditions and known as an aluminum accumulating plant (Saifuddin et al., 2016; Watanabe et al., 2008). This species exhibited the best physiological performance on slope, which is attributed to high growth rate and the higher planting density contributed in alleviating the erosion rate of slope soils (Aimee and Normaniza, 2015). Another shrub, *Bauhinia purpurea* was also been selected as it can grow on a dry on hill slopes and has deep root system and high root: shoot ratio, which is suitable for slope stabilization (Orwa et al., 2009). Therefore, these species exhibited the best potential as the slope species. All of the species studied have the root type M and VH, contributing to surface erosion control and soil reinforcement for slope stabilisation (Saifuddin and Normaniza, 2016)

To date, there is a lack of integral concept related to the interactions between microbes and the soil hydrological properties, soil nutrients content, and plants physiological performance. Thus, this study attempts to relate the microbes (bio-fertilizer) application on slope towards the growth performance (above-ground and below-ground properties) of the plants chosen and with respect to different plant density. It is anticipated that these findings would enhance the ability of the life growing plant on slopes, modify and improve the soil properties on the slope and reduce soil erosion, resulting in a more stable slope.

Materials and methods

Study area

The study area (*Fig. 1*) is located at the Guthrie Corridor Expressway, Selangor, Malaysia, at the geographical coordinates of N 03°13’24.1” and E 101°30’50.2” and annual average precipitation is 2663.34 mm. It has minor rill and minor to moderate gully erosions on the cut slope area with a slope gradient ranging between 26° to 35° (temperature 25–32 °C, maximum Photosynthetically Active Radiation (PAR) 2100 mE m^{-2} s^{-1}, and relative humidity of 60–75%). Most of the soil texture was dominated by sandy clay loam (moderately to slightly acidic; pH 3.78–5.37). Moreover, this area consisted of Kenny Hill formation, an agglomeration of mixed silts, sands, clays, and even some phyllites which vary from stiff to soft in consistency.

Experimental setup

In order to avoid the influences of slope aspect, the experimental plots were established on the similar slope properties and aspects (*Table 1*). Six experimental plots were assigned to three different vegetation coverages; bare (control), less dense (50% of plant coverage), and dense (80% of plant coverage) with the size of 8 m × 8 m of each in a complete randomized design (CRD). The buffer zone between the plots was 3 m.

The second main factor was the bio-fertilizer application with microbe-M and non-microbe-NM were applied on each plant coverage; bare (BM and BNM), less dense (LDM and LDNM), and dense (DM and DNM).

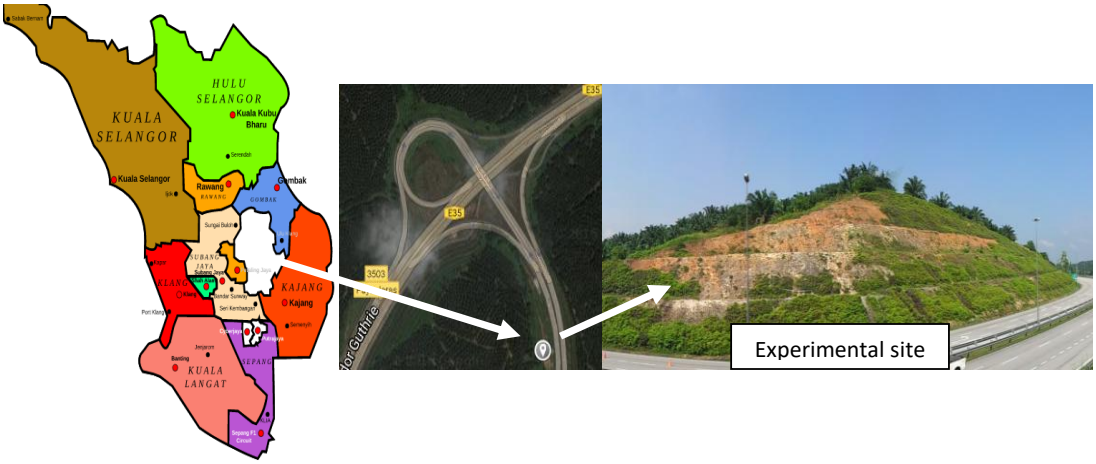

Figure 1. *Location of the study area at the Guthrie Corridor Expressway, Selangor, Malaysia*

Table 1. *Basic information of the selected plots*

Plot	Slope (%)	Elevation (m)	Vegetative coverage (%)	Number of plants
Bare	53	63.5	0	0
Less dense	55	64.1	50	32
Dense	57	64.5	80	52

Transplanting technique and microbes (bio-fertilizer) amendment

Three potential slope plants (as described in the introduction); *Lantana camara, Melastoma malabathricum,* and *Bauhinia purpurea* were transplanted onto slopes using a Microclimate Plant Propagation Technique with modified soil depth (Normaniza and Barakbah, 2011). Each seedling was transplanted into holes by using soil coring machine (Eijelkamp Agrisearch Equipment, Model Cobra, The Netherlands) at 0.6 m of soil depth. Plant supplements: NPK fertilizer, sphagnum moss and rock-phosphate (15 g each/hole) were applied only in the beginning of treatment in order to initiate the establishment of the roots and other physiological processes to take place in a "micro-environment", which could be more conducive for plant establishment and adaptation.

After a week of transplanting, 50 g bio-fertilizer (containing a consortium of bacteria and fungi) was applied at 10 cm of soil depth near the transplanted plants, representing the microbe treated plots. Applications were carried out in a single dose and the transplanted plants grew without any management practices.

Measurements

Isolation and enumeration of soil microbes

The soil samples (n = 3) for each plot were collected four times throughout the two-year observation. A Soil sample was taken at 10 cm radius from the stem of the studied plant (n = 3) using sterile spatula and containers. Bacteria and fungi were isolated on

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_22192232
© 2018, ALÖKI Kft., Budapest, Hungary

soil extract agar and potato dextrose agar media, respectively. Soil sample (1 g) was ten-fold serially diluted with quarter strength Ringer's solution and 100 µl of the soil suspension were spread on to agar plates in triplicates. All the agar plates were incubated for 3 to 7 days at 28 °C. Growth of bacteria and fungi were enumerated as colony forming unit per gram of soil (cfu/g).

Plant growth

Physiological parameters such as photosynthetic rate of the species studied were measured within six months interval and the root length density was measured at the end of the experiment. Photosynthetic rate was measured using a portable photosynthesis system (Li6400XT, LICOR, U.S.A.) in an open system mode, between 1030 and 1230 h with a Photosynthetically Active Radiation (PAR) ranged between 400 and 2100 µE m^{-2} s^{-1}.

After twenty-four months, the soils were sampled in triplicates at 0.45 m of soil depth and 0.1 m from the plant stem using a soil coring machine (Eijelkamp Agrisearch Equipment, Model Cobra, The Netherlands) to determine the root length density.

Soil physico-chemical properties, respiration rate and erosion rate

The soil samples of each plot were taken at every six months interval. The samples were air-dried and milled to pass through a 2 mm sieve and stored in plastic bags prior to laboratory analysis.

Cation Exchange Capacity (CEC) was measured by summing the calcium, magnesium and potassium measured in the soil testing procedure with an estimate of exchangeable hydrogen obtained from the buffer pH (Warncke et al., 1980; Raman and Sathiyanarayanan, 2009). Furthermore, nitrogen content in soil was quantified as the important soil nutrients that affects the plant growth (Sardans et al., 2008) and the microbes are the one that providing a basic mechanism for producing plant-available N (Huang et al., 2015). Total N was determined using the modified Kjeldahl method (Bremner and Mulvaney, 1982). Soil respiration was measured at the study site between 1030 and 1230 h using the closed respiration chamber system (EGM-4CO_2, PP Systems, U.S.A.). Each plot was enclosed with 25 cm height of wooden wall and the eroded soils was channelled to the sediment tank. The eroded soil deposited at the bottom of the tank was calculated in g/m^3.

Statistical analysis

All the data obtained were analysed by a two-way analysis of variance (ANOVA) test ($P < 0.05$) using SPSS 20.0 software. Where significant, the first post hoc, least significant difference (LSD) test was calculated to compare the mean values. All results presented in the text are expressed as mean values ($n = 3$). Meanwhile the relationships between variables were determined by using regression analyses.

Results

Microbial abundance in soil

The fungal and bacterial abundances were ranged from 4.3×10^2 to 1.8×10^4 and 3.3×10^2 to 3.7×10^6 cfu/g, respectively. The F/B ratio varied between 0.02 and 1.52, being

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_22192232
© 2018, ALÖKI Kft., Budapest, Hungary

the highest in DM at the end of the experiment (*Fig. 2*). Fungal and bacterial abundances and the F/B ratio were shown to be affected by microbial application and vegetation density. The F/B ratio decreased in all treatments after two years of experiment except for DM and BM treatments.

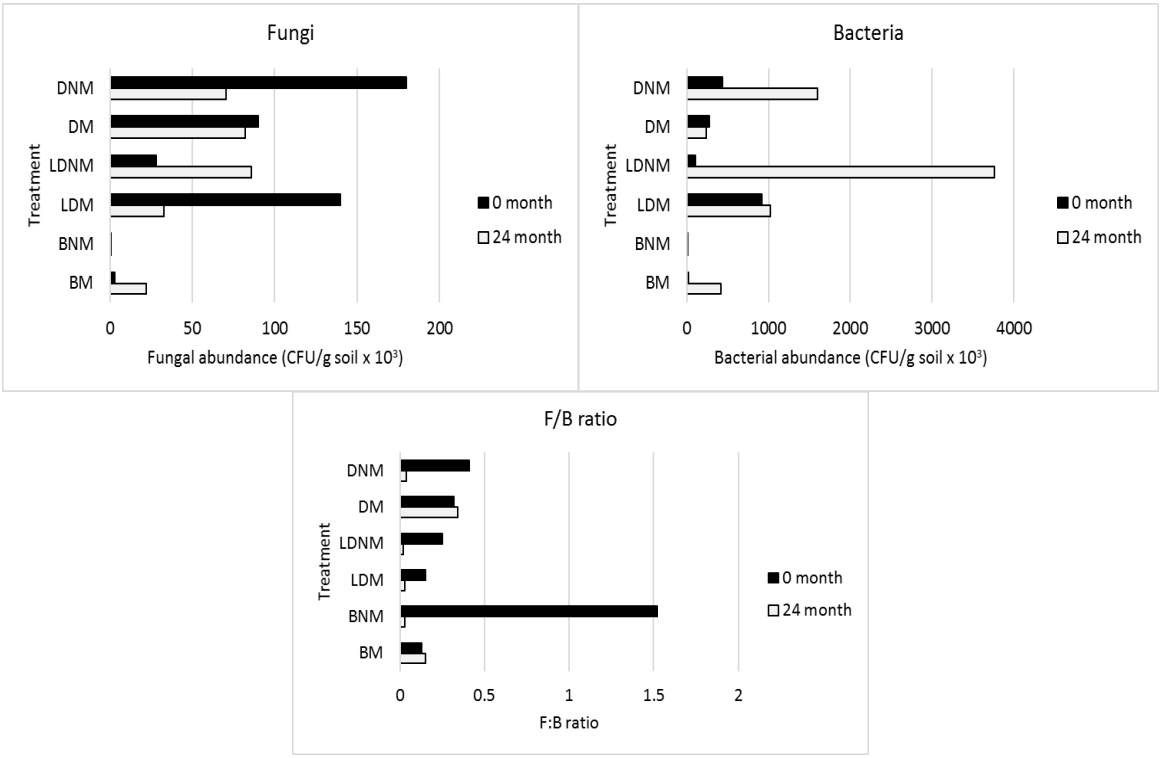

Figure 2. *Fungal and bacterial abundances and F/B ratio for microbes and vegetation density treatments on slope*

Plant growth performance

Figure 3 shows the photosynthetic rate and root length density performances of the species studied after a two-year bio-fertilizer application on the vegetation density treatment plots. *L. camara* in DM plot exhibited the highest photosynthetic rate followed by *M. malabathricum* and *B. purpurea*. In comparison between plots, photosynthetic rate of *L. camara* in DM plot was higher by 22%, 26% and 29% than that of in LDM, DNM and LDNM plots, respectively. Similarly, roots of *L. camara* grew rapidly in DM plot, attaining root length density of 284 cm m^{-3}, in which 66% of a total increment from the early of experiment. Moreover, all the species studied showed the higher total values of root length density in DM plot, followed by the plants in DNM, LDM, and LDNM plots.

Soil properties

Table 2 shows soil physico-chemical properties and respiration rate at the planting site after 24 months of bio-fertilizer application, grown with dense and less dense of vegetation densities. The microbial application had shown the prominent effects in reducing the porosity especially in the plots with vegetation density treatments (DM and LDM plots). Furthermore, vegetation coverage treatment with the bio-fertilizer

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_22192232
© 2018, ALÖKI Kft., Budapest, Hungary

amendment positively influenced the cation exchange capacity, indicating a greater capacity to hold cations. Whilst the soil N contents exhibited slightly increment at the end of the experiment except for control plot (BNM). A further analysis of soil performance in comparing between the initial and a 2-year treatment data had gave a better perspective on the changes in respiration rate. A significantly higher respiration rate was observed in microbe-treated soil, with dense plants density (DM plot).

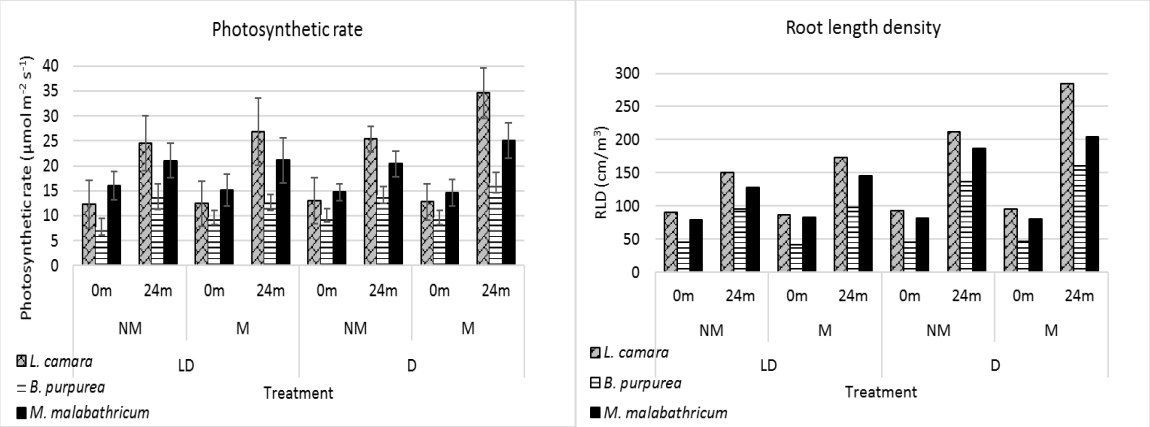

Figure 3. *Photosynthetic rate (left) and root length density (right)of the species studied at 0 and 24 month*

Table 2. *Descriptive data (mean ± standard deviation) for soil water content, physico-chemical properties and respiration rate of the experimental plots*

	CEC ($cmol^{(+)}/kg$)		**Total N (%)**		**Respiration rate ($mg\ CO_2\ m^2\ h^1$)**	
	0 m	**24 m**	**0 m**	**24 m**	**0 m**	**24 m**
DNM	7.68±0.3	10.61±0.4	0.11±0.03	0.15±0.04	421.5±198.6	837.8±480.3
DM	8.81±0.4	15.83±0.6	0.1±0.01	0.19±0.03	418.3±201.1	1103.5±577.3
LDNM	7.13±0.4	9.55±0.5	0.09±0.03	0.11±0.05	367.8±115.6	577.7±268.3
LDM	7.58±0.2	10.33±0.4	0.14±0.02	0.17±0.02	401.2±187.6	595.6±331.1
BNM	8.16±0.6	8.04±0.5	0.12±0.09	0.11±0.03	368.9±200.5	377.4±189.6
BM	6.97±0.4	7.52±0.4	0.09±0.02	0.11±0.04	388.1±211.7	402.5±225.7

Erosion rate

In general, the erosion rates were reduced through time in all treatments except for fluctuated trend observed in bare plot (*Fig. 4*). It was clear that erosion rate was strongly affected by vegetation type and total plant coverage. DM plot showed the lowest erosion rate, exhibiting the 52.6% of a total decrement from the initial experiment. Meanwhile, BM and BNM plots were presented inconsistent in erosion rate as no vegetation in these plots, hence, expose to the direct impact of rainfall to the soil surface.

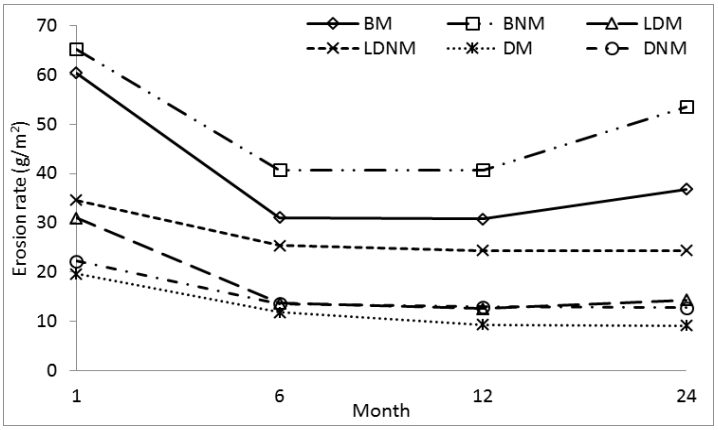

Figure 4. *The erosion rates of the experimental plots*

Relationship analysis

Some correlations were also observed in this study. The results showed that there is a relationship between microbes abundance and erosion rate (R = 0.7; *Fig. 5*). Likewise, microbes abundance seemed to have a weak correlation with plant physiology (photosynthetic rate) (R = 0.3; *Fig. 5*).

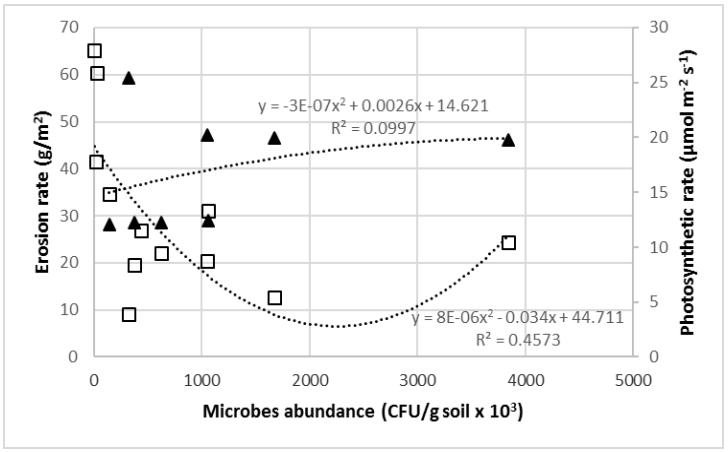

Figure 5. *Relationship between microbes, erosion rate and photosynthetic rate of the experimental plots*

Discussion

Our study showed an application of bio-fertilizer (microbes) in higher vegetation density on the slope with the species chosen as the pioneers, marked a positive response in microbe abundance after 24 months of observation (*Fig. 2*). Generally, in most cases, bacteria dominate under conventional tillage due to a direct contact between bacteria and substrate hence, encouraging the bacterial growth, whereas the fungi dominate under no tillage (Beare et al., 1997). In contrast, based on the abundance of the microbes observed throughout the experiment (*Fig. 2*), the bacterial abundance that we found were somewhat far higher than the fungal abundance since our study area is considered under no tillage. Finding by Malik et al. (2016) revealed that a lower fungal

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_22192232
© 2018, ALÖKI Kft., Budapest, Hungary

biomass has been linked to lower capacity of such soils to sequester C, material basis of soil fertility. Thus, our finding suggested that the vegetated-plot and the microbe amendment would establish a good condition for plant growth, which resulted in a good plant-soil interaction. Furthermore, a higher vegetation density contributed to the increase of decomposition processes in litter, in which the main decomposition pathways in soil are either bacterial-based or fungal-based (de Vries et al., 2006). Therefore, the biomass of fungi compared to bacteria can be considered as an indicator for the activity of two pathways of the soil food web, represented by fungal: bacterial (F/B) ratio (Malik et al., 2016).

The F/B ratio has been extensively used in soil ecology particularly in the context of land management (Strickland and Rousk, 2010). While it was not entirely clear the cause in the difference of F/B ratio on the studied plots, it appears to be due to subtle differences in the total of aboveground plants coverage. It indicates that microbial application and higher vegetation density in DM enhance the F/B ratio of the microbial community through ecological complementarity effects such as higher supply of resources for microorganisms (Lange et al., 2014). It was also observed that F/B ratio was extremely decreased in the control plot (BNM), implying that the bare surface of soil and direct raindrops impact suppressed the microbial community. Hence, we verify that microbial application and dense vegetation density can probably serve a good condition for microbial communities in soil hence, improve the fertility of soil and provide surface erosion protection.

Apart from that, the microbial application and dense vegetation cover had also shown a significant enhancement in photosynthetic rate and the root length density in plants chosen (*Fig. 3*). We do not anticipate the results as the high vegetation densities were expected to thrive in the highly competitive plant community. However, our finding verifies the prominent contribution of the species chosen as the outstanding pioneers on the slopes. On the other hand, microbial communities influence the plants by modifying soil structure (e.g. aggregate stability) via litterfall supply (Wallenstein et al., 2007), and by releasing photosynthetic products into the soil, which feeds heterotrophic soil microorganisms (Staddon et al., 2003). In return, soil microbial communities help in obtaining the nutrients for the plant use (Dobermann and Fairhust, 2000) as well as enhancing the soil fertility on slope.

Meanwhile, root reinforcement has been considered as the main mechanical contribution of vegetation to the stability (Yildiz et al., 2015). Throughout the 24 months of experiment, the total root length density (RLD) of DM plot was higher compared to the root densities in other plots (*Fig. 3*). The results were mainly attributed to high in microbial community and dense vegetation cover, which most likely resulted in increased of water absorption by root and soil water loss through transpiration. Consequently, these plant growth patterns; photosynthetic rate and root length density, had positive effects indirectly and directly, respectively, in increasing the safety aspect of the slope and enhancing the soil stability of the slope.

Based on the two-year observation of physiological performances of the species chosen, *L. camara* has shown the greater plant growth performance as compared to other species (*Fig. 3*). This finding was in line with Sharma et al. (2005), in which has described that this invasive species showed an outstanding performance in growth rate on the harsh environment. Thus, this result implies that the sun tolerant feature of *L. camara* as well as having higher number of branching and leaves, resulting in the increased of stomata and subsequently lead to the significant light utilization efficiency

of the plants in photosynthesis. The second prominent species in this study was shown by *M. malabathricum.* Study by Aimee and Normaniza (2015) revealed that this species plays an important role as erosion control plant especially on highly eroded areas where it is low in nutrients content. This species also has dense root system that implies the ability of the species to absorb water from the soil. In addition, as the current global warming trend has remarkable changes in temperature and precipitation as well as rising the concentrations of CO_2 that may inhibit the plant growth (Parmesan, 2006), thus, we suggest that these two species can serve as good pioneers at the initial phase of succession on the slope.

The microbial application and vegetation density treatments were relatively effective in enhancing soil properties in the studied slope (*Table 2*). Cation exchange capacity (CEC) is an important measure of the soil's ability to retain and to supply nutrients (Raman and Sathiyanarayanan, 2009). The CEC values of the soils in the study area were affected by microbial amended and vegetation density. Adding microbes to the soil with dense vegetation cover caused a significant increase in the CEC of the soil, suggesting an improvement in soil fertility and nutrient retention (Jien and Wang, 2013). Additionally, further analysis of soil nutrient level comparing the initial and the final properties would give a better perspective on changes in fertility level. Soil with microbial amended and dense vegetation cover showed important improvement in total N, indicating that the presence of heavy litter and humus contents in the surface layers of the studied plot. Hence, the high amount of organic matter may also enhance the richness of N in the vegetated area as compared to bare surface.

Soil respiration from the soil surface is one of the most important components of the C cycle in terrestrial ecosystems (Adachi et al., 2006). Soil respiration rates observed in 24-months were greater than those observed at the initial study. Several studies had found that the soil respiration is composed of respiration from both roots and microbes, and there was a relationship between soil respiration and the underground environment (e.g. root and soil microbial biomass) (Søe and Buchmann, 2005; Neergaard et al., 2002). Thus, the high soil respiration rate observed in the microbes applied and dense vegetation cover treatment plots may have been due to high microbial activities.

Concomitant to the positive microbial-vegetation density feedback, soil erosion rates were steadily decreased in all treatments except in the bare plots (*Fig. 4*). The soil erosion rate decreased significantly in dense vegetation cover, indicating that the microbial incorporation reduced the potential of soil to be eroded. Therefore, based on our results, we deduced that the major reason for reduction of soil loss after the addition of microbes was the extensive integration between microbial community with the plants properties (root system), contributing to the aggregate stability and macroaggregate formation (Cantón et al., 2009), maintaining soil porosity and subsequently decrease the soil erosion.

A strong relationship between microbes abundance and erosion rate (R = 0.7; *Fig. 5*) implies that microbes-plant interaction improve the soil porosity and dense root length density (*Fig. 3*) could help to reinforce the soil by increasing its shear strength and alleviate the erosion. On the other hand, a weak correlation of microbes abundance with plant physiology (photosynthetic rate) (R = 0.3; *Fig. 5*) indicates that the dense vegetation cover is attributed to the higher in decomposition process, hence, enhance the nutrients available for the plant growth.

Conclusion

A two-year observation revealed a positive influence of the microbial application and dense vegetation cover on the slope stability. The performance of the treated plots was accelerated when the promising pioneers, *Lantana camara, Melastoma malabathricum,* and *Bauhinia purpurea* were grown together in the plots. In particular, the increased microbes abundance lead to increase in CEC, increase in total N and respiration rate, indicating the outstanding microbes-plant interaction. The increase of photosynthetic rate and root length density of the species studied was considerably indirect influenced by the microbial activities in soil. In aftermath, positive effect on slope stability was proven in the negative relationship between microbe abundance and erosion rate. It is concluded that microbial amendment in soil with dense vegetation cover could positively influence the plant growth performance and soil quality, which subsequently may alleviate the soil erosion problem of the slope.

Abstract. In East Africa, climate change is understood as a period of drought or floods. In real sense, it is the universal changes in the behavior of weather patterns based on statistical predictions for a long period of time. The region has experienced severe climatic changes of droughts, floods that negatively affect agricultural production causing food insecurity. This has caused both internal and regional migrations across East African borders especially by pastoral groups. These impelled migrations often cause insecurity. Literature searches have been used to gather information about what has been done and what should be done to safeguard communities from food insecurity caused by climate shocks. Results show that over 31% of the people are affected by undernourishment, an indicator of food insecurity and this has been to a great extent brought about by destruction of ecosystems which has enhanced climate change. Proposed mitigation and adaptation strategies include traditional and non-traditional measures. Policy issues have also been emphasized. In conclusion, destruction of fragile ecosystems contributes to climate change. Failure to adopt new technologies and neglect of some traditional technologies are greatly responsible for food insecurity in East Africa.
Keywords: *adaptation, anthropogenic, ecosystem, migrations, mitigation*

Introduction

In many parts of East Africa, most of the people perceive climate change as real due to variability in terms of temperature rise, rainfall reductions, erratic rains and prolonged droughts (Gichangi et al., 2015; Bryan et al., 2013; Souverijns et al., 2016; Leal et al., 2017). This is also a result of catastrophic rains characterized by storms, floods and landslides in some areas. Although perceived in such terms, it is understood inadequately. It is the universal changes in the behavior of weather patterns based on statistical predictions for a long period of time. It is any long term change in the statistics of weather over periods of time that range from decades to millions of years (IPCC, 2001). These changes are attributed directly or indirectly to the anthropogenic activities which affect sustainability of the biosphere in natural state, thus causing disruptive effects. In East Africa and Sub-Saharan Africa as a whole, there is an

DOI: http://dx.doi.org/10.15666/aeer/1603_22332254
© 2018, ALÖKI Kft., Budapest, Hungary

increase in awareness about climate change even when the initiative to take adaptation and mitigation measures are still low. Surprisingly, as most of the people in the developing world increasingly understand this phenomenon, there is a decline about climate concerns alongside an increase in skepticism regarding its seriousness and anthropogenic causes in the developed countries (Spence, 2011).

The National Aeronautics and Space Administration (NASA) observed that the Earth's 2016 surface temperatures were the warmest since modern record keeping began in 1880, and it may continue over years if no measures are put in place to counteract the effects (Potter, 2016). Due to these climatic variations, people have faced food insecurity as result of crop failure and livestock death. Warming and prolonged droughts in North Eastern Uganda, Kenya, Ethiopia, and Tanzania have caused movements of people across borders searching for water and pastures. This is because of insufficient rainfall which drives them to migrate to new areas (Salerno, 2016). This has created conflicts and insecurity, cattle raids, land degradation, killing of park animals, bush burning in traditionally cattle raiding areas and food insecurity (Ojore, 2017; Okoroafor, 2017; Johnston, 2017; IAWG, 2017) and has put pressure on the natural resource base.

The main objective of this paper therefore, is to suggest possible traditional and non-traditional adaptation and mitigation measures to address food insecurity as a result of climate changes.

Climate change in East Africa and its effects

East Africa has been hit by climate change leaving millions at the verge of starvation as thousands of livestock die and crops fail due to drought. There is continuous decline in precipitation amounts (Souverijns et al., 2016) as temperatures continuously rise. In many areas of the region, rain-fed agriculture has practically failed. It is estimated that about 11 million people are dangerously food insecure and in need of humanitarian assistance (OXFAM, 2017). Although most areas have been affected by drought, some areas have been affected by floods i.e. Eastern Uganda where over 400 people died due to floods (The International Federation's Disaster Relief Emergency Fund, 2010). Climate change will influence human mobility, resulting in humanitarian crises (Baldwin, 2017). This will create climate migrants or climate refugees and may result into disease outbreak and competition for resources in the recipient areas. Mobility of people with large herds of animals will not only cause conflict but also poor management of animal manure. This will increase greenhouse gases (GHGs). In Ethiopia which has the largest livestock population in Africa (Yohannes, 2016; Amdu, 2010), the large numbers of livestock contribute greatly to emission of GHG. According to a report published by Ethiopian government, 50% of GHG emissions in the country are attributed to agriculture. Livestock was estimated to have contributed 65 Mt CO2 equivalent in 2010 (FDRE, 2011).

Agricultural production in the region contributes greatly to the Gross Domestic Product (GDP) and is dominated by smallholder farmers. The adverse climatic effects will affect food production and will substantially reduce the economic base of all the countries in the region. This will affect job creation for the population, majority being the youth, affecting their livelihood. The population growth in the region is among the highest in the world (African Union, 2017) and employment is a big problem and any effect on agricultural production will exacerbate the situation. Furthermore, malnutrition and high mortality in children is likely to increase due to failed agricultural system

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

which does not produce sustainably for such a large population. The prices for staple food crops like cereals will rise at the detriment of poor consumers (Karugia et al., 2011).

Climate change will increase human suffering by affecting infrastructure especially in city suburbs as well as agricultural production. This will negatively impact the health of many people (Labbé et al., 2015) and food security respectively.

Materials and methodology

Profile of the study area

East Africa is a region that begins in Tanzania in the south and extends north through the great grasslands of Kenya and Uganda and Ethiopia, including the Great Rift Valley (*Fig. 1*).

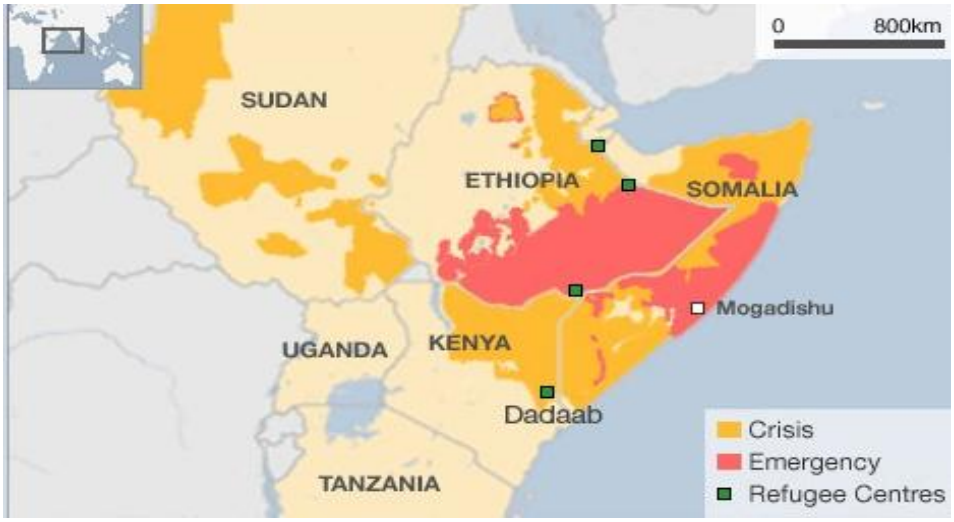

Figure 1. *Areas affected by food insecurity and climate change in East Africa. (Source: UNHCR/USAID, 2011)*

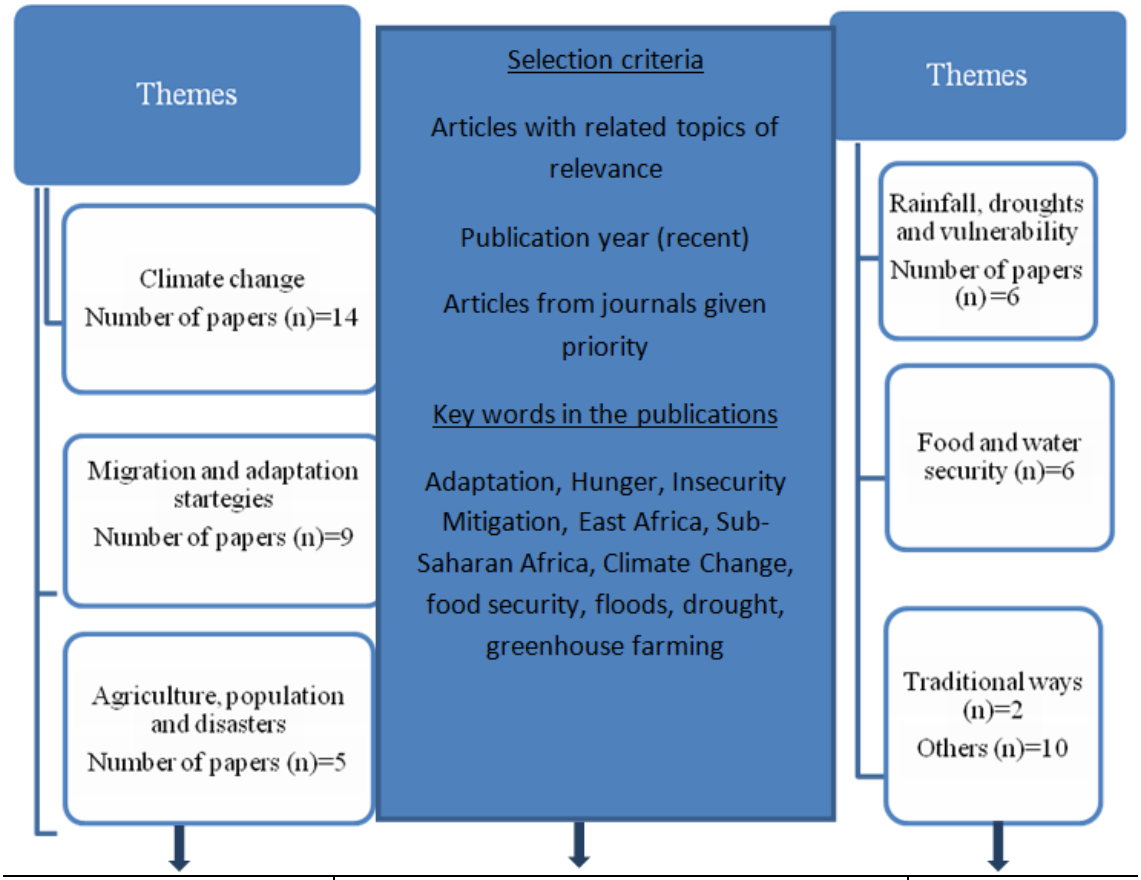

The region also comprises the countries of South Sudan, Somalia, Djibouti, Eritrea, Rwanda and Burundi.

The world's second-largest lake by surface area is Lake Victoria, which borders Uganda, Tanzania, and Kenya.

In this article, we obtained data from different sources, mostly indexed journals such as Climate change, Environmental Management and other popular sources. UN Organizations such as FAO were also searched to get reports. In our search, we focused on papers that were published in English and are recent 2010-2017. However, some papers were published in 1996, 1999, 2001 and 2005. These were included to highlight on what was previously done and recent work. The terms commonly used in the search strategy were climate change, adaptation, mitigation and food security in East Africa. To manage and screen data well, the articles were grouped into themes and sub-themes. In total, 128 papers were retrieved for possible inclusion from where 52 papers were selected as seen in *Table 1*.

Table 1. *Summary of the key main articles selected. (Source: Authors)*

Sub-themes	Key findings	Authors
Silos/post harvest handling	Currently, most food produce is sold from the garden directly. There is nothing to keep in silos and no silos anymore	Afedraru, 2013
Climate change responses	Climate change has affected and changed the Masai traditional culture	Leal et al., 2017
Population	The population growth rate in East Africa is one of the fastest on the continent	African Union, 2017
Farmers perception	Farmers in Ethiopia recognize temperatures, frequency of drought and flood. Rainfall pattern has become unpredictable, a sign of climate change	Amdu, 2010
Climate change and migrations	Migrations due to climate change have resulted into climatic refugees	Baldwin, 2017
International trends in public perception about climate change	The seriousness of climate change is exaggerated, with an almost doubling of this perception over the 5-year period	Capstick et al., 2015
Adaptation to climate change by smallholder farming communities	The key adaptation measures include: practices that improve soil fertility and moisture, increase soil carbon storage, reduce soil degradation and increase crop diversification	Chandra et al., 2016
Hydrological cycle	Human activities affect hydrological cycle which influence global climate changes and agricultural production	Evans, 1996
Food insecurity and vulnerability	Food and water security of countries still need to improve despite slight progresses	FAO, 2001

Climate change, water and food security	Policy response to climate variability and change should be flexible and sensible	FAO, 2011
Climate-smart agriculture	Most of the impacts of climate change in agriculture and rural livelihoods are expected to result from changes in the water cycle hence rainfall variability	FAO, 2013
Communities and climate change adaptation	Policies should undergo periodic evaluation to incorporate traditional knowledge and science among different communities to adapt to climate change	Ingty, 2017
Agriculture and water management in Uganda, Burkina Faso and Morocco	Water harvesting holds a great potential in increasing yields and improving food security in rain-fed farming areas	FAO, 2016
Edible insects	Insect rearing for food remains a sector in its infancy	FAO Forestry Paper, 2013
The state of food insecurity in the world	Prevalence of food insecurity and malnutrition is significantly higher in protracted crisis contexts resulting from conflict and natural disasters	FAO, IFAD and WFP, 2015
Ethiopia's climate-resilient green economy:	Livestock emissions are estimated to be 65 Mt CO2e in 2010 – more than 40% of total emissions today. Crop cultivation contributes to concentration of GHGs by requiring the use of fertilizers	Federal Democratic Republic of Ethiopia (FDRE) (2011)
Hidden hunger	A new focus must be undertaken to address longer-term determinants of nutrition insecurity and hidden hunger	Francesco et al., 2011
Temperature and climate	Due to increasing climate change, there is a likelihood of air temperatures exceeding the optimum range for many species of crops. Cool season crops will have a constrained growing season due to high temperatures	Hatfield and Prueger, 2015
Drought crisis	More than 15 million people in Ethiopia, Kenya and Somalia are facing food and water shortages	IAWG, 2017
Adaptation and vulnerability	Developing countries, particularly the least developed countries, have lesser capacity to adapt than do developed countries	IPCC, 2001
Encroachment of wetlands	Multi-faceted approach, coordination of the various stakeholders and engagement of wetland-dependent communities as part of the solution, might require zoning out the wetland and restricting certain activities to specific zones	Isunju, 2016
Tackling climate change	Without global efforts to reduce emissions and to help the world's poorest people cope with the effects of climate change, this crisis will continue to repeat itself	Johnston, 2017
Food prices	The prices for staple food crops like cereals will rise at the detriment of poor consumers	Karugia, 2011
Adaptation to climate risks in East Africa	Adoption of adapted varieties of crops might be successful to enhancing resilience of farming systems in the short-term	Kelvin, 2017
Beekeeping as integrated watershed conservation and climatic change adaptation	Beekeeping is an environmentally sound, and economically feasible income generating activity for poverty alleviation and food security	Kumsa and Gorfu, 2014

Vulnerability to the health effects of climate variability, Uganda	Vulnerability to the health impacts of climate change will be shaped by existing burdens of ill-health, climate-sensitive infrastructures, limited technological capacity and political inequality and is expected to be highest in socioeconomically marginalized populations	Labbé et al., 2015
Achieving mitigation and adaptation to climate change	Agroforestry systems readily bundle both mitigation and adaptation strategies and provide several pathways to securing food security for poor farmers, while contributing to climate change mitigation	Mbow et al., 2013
Vulnerability to climate change	Higher standards of living in Tibet have enabled herders to deploy the coping strategies of sheltering livestock and feeding them supplements	Yeh et al., 2014
water availability in a changing climate	Changing rainfall patterns affect seasonal availability and manageability of water	Milly, 2005
Migration as an adaptation measure	A model to predict future climate change-migration relationships developed	MCLeman and Smit, 2006
Food relief in North East Uganda	Elderly and children affected by drought. 80 people died because of lack of food in 2 counties	Ojore, 2017
Drought in East Africa	Thousands of animals including cows, goats, and sheep have already been lost	Okoroafor, 2017
climate change and drought in East Africa	Nearly eleven million people in Kenya, Ethiopia and Somalia are dangerously hungry and in need of humanitarian aid	OXFAM, 2017
Temperature rise	Earth's 2016 surface temperatures were the warmest since modern record keeping began in 1880	Potter, 2016
Neglected and underutilized crop	Key to future food and nutrition security may very well lie in the untapped potential of neglected and underutilized crops	Pauline, 2015
Rainfall distribution patterns	Reduced interannual variability occurred, the percentage of dry years did not increase but the percentage of wet and very wet years decreased	Ramos, 2001
Indigenous knowledge related to climate variability	The rich indigenous knowledge can be combined with science to monitor climate change	Speranza et al., 2017
Food security and seasonal climate	Extreme climate events, such as droughts and floods, and lower agricultural productivity contribute to food insecurity	Rarieya and Fortun, 2010
Managing vulnerability to drought and enhancing livelihood resilience: Technological, institutional and policy option	Drought represents one of the most important natural factors contributing to malnutrition and famine that affects the most vulnerable communities, especially women, children and the elderly	Shiferaw et al., 2014
East African precipitation	Precipitation amounts over East Africa have been declining over the last decades	Souverijns, 2016
Perceptions of climate change	There is a decline about climate concerns alongside an increase in skepticism regarding its seriousness and anthropogenic causes in the developed countries	Spence, 2011
Africa's hidden hunger	Many families in East Africa, eat one meal in a day	Stefan, 2012
Attribution of extreme weather and climate	Climate models show an increased occurrence of extreme temperature and rainfall events worldwide which are attributed to anthropogenic activities	Stott et al., 2016

Floods and landslides	An estimated 400 people were killed by floods and landslides in Eastern Uganda	DREF, 2010
Lake Victoria ecological changes	Decline in fish species is the highest documented loss of biodiversity caused by humans in an ecosystem	Witte, 1999
Climate change and agriculture	Climate change has relationship with agriculture in one or another way	Yohannes, 2016
Climate variability-farmers perception, Kenya	Farmers are aware of climate changes because of decrease in rainfall amount, rainfall variability, erratic rains and prolonged drought periods	Gichangi et al., 2015
Adapting agriculture to climate change-Kenya	Households face considerable challenges in adapting to climate change, need for greater investments to support households to make strategic, long-term decisions	Bryan et al., 2013
Migrations and decision making	Insufficient rainfall drives agro pastoralists to migrate to new areas	Salerno, 2016
Climate change and environmental threats	Increased evaporation rates, will increase levels of salinity in the lake, harm fish stocks worsening food security situation	Human Rights Watch, 2015
Drought tolerant maize for farmer adaptation	Major barriers to crop adoption is unavailability of seeds	Fisher, 2015
African indigenous cattle: Unique genetic resources	African livestock genetic resources are in danger due to uncontrolled crossbreeding	Mwai, 2015

Results

From *Table 1,* six themes have been developed to summarize information published and give suggestions on mitigation and adaptation strategies.

Anthropogenic activities contributing to climate change in East Africa

Anthropogenic activities have caused challenges to mankind (Stott et al., 2016) by greatly contributing to climate change. There is a growing trend in awareness about this in some parts of the world including East Africa although in other areas, there is a decline in knowledge by the public about climate change being caused by human actions (Capstick et al., 2015).

Activities such as forest clearing for charcoal, bush burning as a way of facilitating growth of fresh grass for animals and swamp destruction for agriculture contribute greatly to climate change. They negatively influence biogeochemical cycles of evapotranspiration, hydrological cycles, rainfall distribution and amount, increase flood and drought frequencies (Evans, 1996; Ramos, 2001).

Industrial and agricultural development

Climate change with reduced precipitation levels has characterized most of the areas in East Africa. Over the past several years, Ethiopia has embarked on a massive plan for dams, water-intensive irrigated cotton, sugar plantations, irrigation canals and other infrastructural developments in the Omo River Basin. Predictions indicate that these developments could have a devastating impact on water bodies particularly Lake Turkana, dropping water levels and potentially causing the lake to recede into two small pools. If these predictions are accurate, areas of Lake Turkana with high levels of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_22332254
© 2018, ALÖKI Kft., Budapest, Hungary

biological productivity that are critical for fish breeding will dry up causing significant effects on fisheries. In addition, dramatic reductions in freshwater from the Omo River into Lake Turkana, will increase salinity and temperature in the lake. This will harm fish stocks worsening the already dire food security situation in the region and affecting the lives of many people (Human Rights Watch, 2015).

In *Figure 2a,* eucalyptus trees were planted by a tea factory in what used to be a wetland, to be used for firewood as a form energy in tea processing and it has drained the water leaving the land dry while in *Figure 2e,* the water level and quantity has dropped substantially due to drainage and destruction of the vegetation. Most ecosystems in Uganda and East Africa as a whole have been destroyed and this hinders carbon sequestration processes, increasing greenhouse gases (GHGs).

Figure 2. *A destroyed ecosystem in Hoima District, Uganda. (Source: Authors)*

Food and water security in East Africa due to climate change

Food and water are inseparable and are useful for sustenance of life. They influence the quality of life people have. Despite having significant land and water resources, East Africa is one of the world's most food-insecure regions. There is water stress despite the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_22332254
© 2018, ALÖKI Kft., Budapest, Hungary

presence of rivers and lakes. River Nile, Lake Victoria, Lake Tanganyika and Lake Turkana are some of the important water bodies in the region. Current management of these water resources needs improvement as a result of exploitation of fishery resources and pollution of water ecosystems by industrial and agricultural activities. The Nile basin which covers the biggest area in the region is an example of a drainage system that would shock absorb the adverse effects of climate change if managed sustainably by all countries in the Nile Basin Initiative. The technology to draw water for various agricultural operations is still undeveloped. Agro-pastoral groups move across borders instead of tapping such water that is near them. Changing rainfall patterns affect seasonal availability and manageability of water, and by 2070, there will be less water in East Africa and other parts of the world (Milly et al., 2005; FAO, 2011).

More so, the water level in Lake Victoria has dropped and warmed. The surface water has warmed by almost 1.2°C in 82 years, and the temperature has risen by 1.6°C in water greater than 50 m deep over the same time period (FAO, 2016). Whereas global climatic changes may have primarily contributed to these changes, anthropogenic activities like forest and swamp destruction cannot be underestimated. High temperatures will impact fisheries productivity by lowering the quantity and size of fish but may affect water ecology as well. The warm temperatures lead to faster depletion of the limited oxygen supply, negatively impacting fish development. The impact of climate change on commercial fishing in East Africa's water bodies is uncertain, and reductions in water levels and the impacts of extreme climate events resulting from climate change are likely to have significant negative effects on the water bodies. Decline in fish species in Lake Victoria is the highest documented loss of biodiversity caused by humans in an ecosystem (Witte, 1999). This is a big concern as fish is an important source of protein and income to many people.

According to the Food and Agriculture Organization of the United Nations (2001) "Food security is a situation that exists when all people, at all times, have physical, social and economic access to sufficient, safe and nutritious food that meets their dietary needs and food preferences for an active and healthy life". This means that food should be available, accessible, utilizable and stable. The current food situation in East Africa cannot make it possible for most households to have enough, nutritious and even have preference of certain foods to others. The food insecurity problem is compounded by climatic changes of drought and floods which affect agricultural production in many ways (Rarieya and Fortun, 2010).

Besides, there is another problem of "hidden hunger" that affects many communities. This is caused by low intake of vitamins from vegetables. This is a serious public health concern affecting many families in East African countries (Stefan, 2012). Surprisingly, it is not understood well and for that reason, most people are not aware about it (Francesco et al., 2011). Climate change is a complex global problem involving food constraints, water scarcity even in abundance, movements of people, climate health related illnesses and above all occurrence of unpredictable disasters (*Table 2*).

Low developed countries are the most affected, particularly Sub-Saharan Africa and South-Eastern Asia. People line up early in the morning hours to collect water in some areas in Uganda (*Fig. 3a*) while in *Figure 3b,* women and children trek long distance to get water from a river whose depth has also been reducing due to a long dry spell.

The situation is worse in conflict stricken areas like Somalia where there are internally displaced people (*Figure 3c*). The dwindling water levels in surface water and other water sources is related to anthropogenic activities.

DOI: http://dx.doi.org/10.15666/aeer/1603_22332254
© 2018, ALÖKI Kft., Budapest, Hungary

Food security and water access in the region remain one of the serious development bottlenecks that impact other key sectors and have led to dismal realization of sustainable development goals.

Misuse of natural resources

In many ways, water, wetlands have either been diverted, drained in expansion of cities or polluted and degraded with permanent horticultural facilities such as greenhouse facilities which discharge effluent (Entebbe in Uganda) and Kisumu in Kenya all located on the shore of Lake Victoria. These activities affect water quantity and quality. When water is displaced from its natural watershed where it sustains healthy ecosystem, due to diversion or expansion of towns, natural hydrological cycle is affected. Agrochemical pollutants from the greenhouse flower farms end up in surface water causing eutrophication. This affects fisheries development. It also creates a need to search for ground water using boreholes which reduce the water cycle. Urbanization, deforestation and wetland destruction greatly destroy water-retentive landscapes and lead to the loss of precipitation over the affected area. If there are no trees to receive the rain, it will evaporate, creating desert-like conditions. An example is Kampala, Uganda's capital city, where Nakivubo wetland covered by natural vegetation has reduced by approximately 14% in 5 years while cultivated area in the lower Nakivubo wetland had increased by more than 350% in the same period. (Isunju, 2016).

In *Figure 4a,* a bulldozer clears the area for a flower farm in Lutembe, Entebbe-Uganda. The area, deemed to be of international importance under an international convention on wetlands was destroyed to set up a flower farm on a bay off the shores of Lake Victoria. In *Figure 4b,* buildings have been constructed there and the wetland is no more while in *Figure 4c,* the residents of Ndemi, Michore, Kieni and Rukuma, destroy pipes that are used to draw water from river Malewa by Mahee Flower farm in Kenya. The residents accuse Mahee Flowers farms of polluting the water with chemical effluents and blocking water movement.

Discussion

As seen in *Table 1,* a number of researches have been done about climate change and people in the region are aware of the problem. Climate change theme is a dominant topic that is discussed and covered in most researches. It is however evident in most papers and reports that the issue of traditional measures and technologies to address food insecurity have not been emphasized in mitigating effect. Most publications have tackled on causes and implications of the problem. It is important that research on non-traditional technologies and modern technologies be emphasized (*Fig. 5*) and if possible be improved for the sake of resource constrained people who are the majority in the region. This can promote sustainable and inclusive development. Policies that encourage farmers and emphasize the re-establishment of such structures should be implemented.

Furthermore, the problem of food insecurity is exacerbated by some farmers who sell food from the garden directly, *Table 1*. This could be due to economic hardships faced by the people, and a weak government policy that does not enforce keeping food in silos to prepare for disasters like droughts. The issue of food security and climate change seem to be intertwined that it is almost impossible to talk about one while leaving the other.

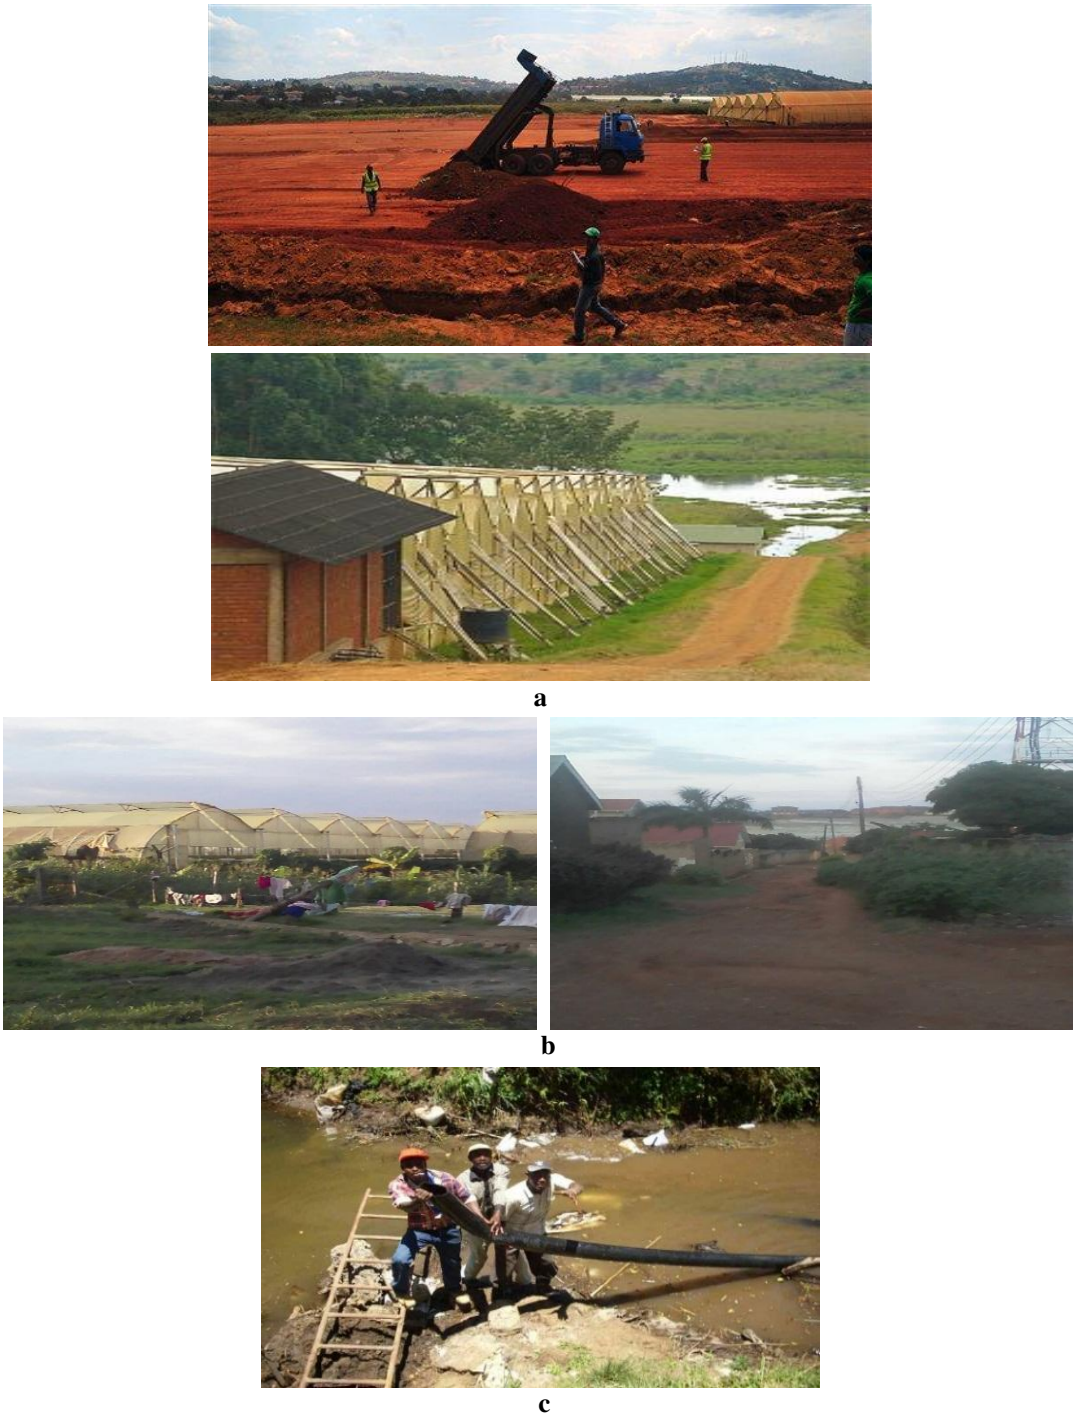

Figure 4. *Destruction of wetland and river ecosystems in Uganda and Kenya. (Source: Authors)*

The destruction of ecosystem for agricultural activities, urban development is one of the reasons that partly explain why climatic disasters continue to affect East Africa. Many fragile ecosystems have been damaged in most areas (*Figs. 2* and *4*). Most agricultural activities take place in areas that act as buffers for carbon sequestration i.e. wetlands and forests. When these are destroyed, there is a disturbance in carbon dioxide flux management, hydrological cycles and species extinction that are interlinked in a complex manner. This situation is intensified by grazing huge numbers of livestock that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_22332254
© 2018, ALÖKI Kft., Budapest, Hungary

move within countries and across the region as is it the case with almost all pastoral groups in East Africa (Karamajong of Uganda, Turkana of Kenya, Masai of Tanzania and the Ethiopians). This causes soil erosion due to vegetation loss and emission of GHGs, thus global warming. The phenomenon is more complex with other problems of wars in South Sudan, Somalia and general political instabilities in the region which contribute to food insecurity.

It is evident that the number one climatic disaster affecting East Africa is drought (*Table 3*). It causes more misery than all the other disasters combined and is more recurrent. This increasing trend and frequency in drought is a sign of degenerating environmental problem that is brought about by climate change induced by anthropogenic activities. The frequency of droughts is higher than that of any other climatic disaster. This explains the movements of pastoral groups across borders where they end up fighting with the local people hence increasing insecurity.

Table 3. *People affected by climatic disasters in Uganda, East Africa, since 1979. (Source: Adjusted from Climate Policy Paper, 2012)*

Year	Population	Disaster
1979	500000	Drought
1987	600000	Drought
1997	153500	Floods
1997	100000	Epidemic
1998	126000	Drought
1999	700000	Drought
2001	655000	Drought
2005	600000	Drought
2007	718045	Floods
2008	11000000	Drought
2010	338	Landslides
2013	500000	Drought

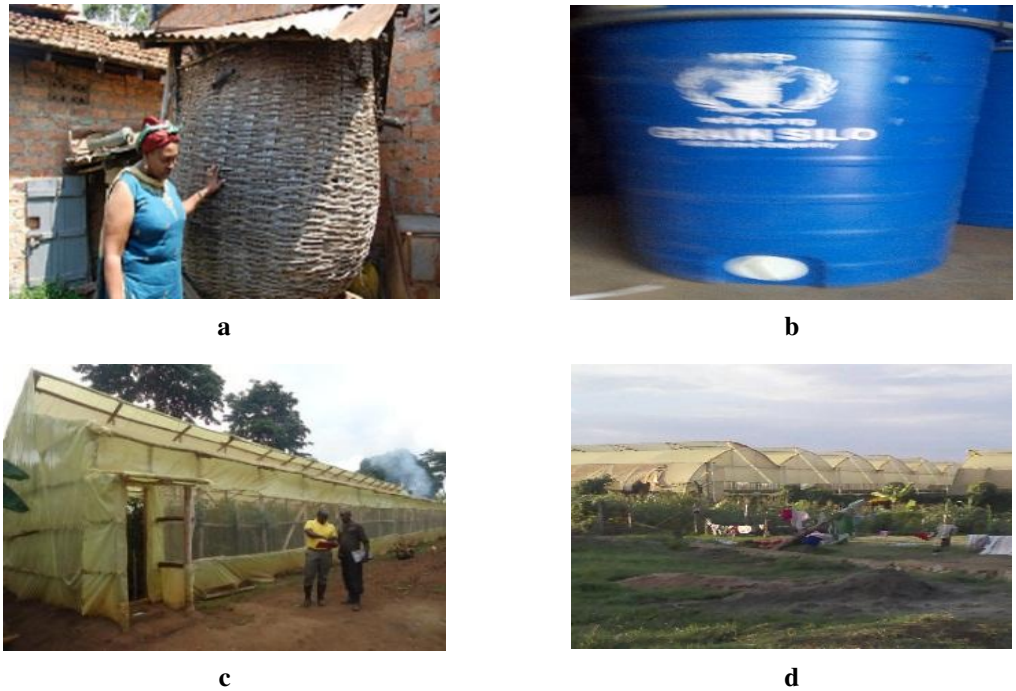
Hunger and "hidden hunger"

Pregnant women, children and elderly need vegetables regularly. Unfortunately, most of indigenous vegetables are at the verge of extinction in most communities, especially in war torn areas of South Sudan and Somalia. This is because of inadequate conservation measures and insecurity. Those vegetables used to be grown in back yard gardens but in recent times, people live in urban areas and cannot access them. East Africa remains the sub-region with the biggest hunger problem, with over 31% undernourished people (FAO, IFAD, WFP, 2015). This phenomenon is further complicated by inadequate clean water supply in most of the rural areas and some areas in urban centers of East Africa (*Fig. 3*).

Suggested mitigation and adaptation measures to guard against food insecurity

1. Traditional strategies

Traditional ways of guarding against food insecurity in East African communities were very important in preparing people for any future disaster that could occur. These



http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_22332254
© 2018, ALÖKI Kft., Budapest, Hungary

technologies were cheap and did not need any expertise to harness. In most communities however, these simple technologies phased out. Therefore, communities and policy makers should do the following:

Revive use of silos

Most areas in East Africa used to have silos controlled by government at sub-county level where farmers would collectively store food but also, individual families owned silos for grains (Afedraru, 2013). They played a crucial role in periods of bumper harvests to store what the markets could not absorb at reasonable prices. This practice worked well to safeguard families from future risks of climatic disasters. On the contrary, most of the farmers in most communities nowadays, have no silos and sometimes sell their food crops even when it is still in the garden risking the lives of their members in case of food shortage. The few government silos that are still in existence are empty and in a very bad state. This has been noticed in recent times when most communities in the region, particularly Uganda, have been affected by various disasters, especially drought.

Traditional silos (*Fig. 5a*) are very few and even where they exist, they have no grains to store. Modern silos (hermetic) (*Fig. 5b*) are being promoted by WFP in some parts of East Africa. Improvised greenhouses (*Fig. 5c*) can be useful to resource constrained farmers while commercial farmers can use semi-automated greenhouses (*Fig. 5d*) to address food insecurity and erratic weather. In mitigating impact of climate change on food security, silos are not an option but a requirement (Afedraru, 2013).

© 2018, ALÖKI Kft., Budapest, Hungary

Growing indigenous vegetables

This can address the problem of "hidden hunger". Most of the homesteads in East Africa used to have these vegetables in backyard gardens. They are unique and well adopted to the local conditions. They can reduce GHG emissions which come from heavy use of fertilizers and pesticides used in growing introduced varieties. They respond well to organic soil amendment, can grow reasonably well in water scarce conditions (Pauline et al., 2015) and are resilient to climate change (*Fig. 6*).

Most of these vegetables are rich in vitamins. However, most farmers have opted to grow the hybrid varieties because of economic gains leaving indigenous species at the verge of extinction.

Figure 6. *Indigenous vegetables at the verge of extinction in East Africa (a) Lycoperscum esculentum (b) African night shade (c) Solanum anguivi. (Source: Authors)*

Apiary projects

Combined with agroforestry, it is possible to run these profitable enterprises. In a situation where food is scarce, honey can be a good source of carbohydrates, medicine and source of income. Beekeeping is an environmentally sound, technically suitable and economically feasible income generating activity for poverty alleviation and food security (Kumsa and Gorfu, 2014). Beekeeping could be one of the major sources of income, food for people in local communities that are struggling with climate change.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_22332254
© 2018, ALÖKI Kft., Budapest, Hungary

2. *Non-traditional strategies*

Non-traditional measures are modern ways, services and technologies that can enhance resilience of communities to effects of climate change in enhancing food security. They are more expensive compared to non-traditional measures and require expertise.

Insurance

With climate change continuing to ravage the region, farmers need viable and affordable ways to manage these weather-related risks which threaten food security and economic stability. Most farmers in East Africa lack access to insurance services.

Greenhouse farming

Farmers need to adopt the use of this technology to grow crops. It has many advantages i.e. growing of crops throughout the year, easy management of pests and diseases and efficient water use. Although there are challenges with this type of farming like the cost of the technology, especially to smallholder, financially constrained farmers, there are many benefits if well maintained. Governments needs to draft policies on how to help farmers access these important agricultural technologies cheaply and where possible, establish agricultural financing mechanisms to enable resource constrained but knowledge equipped farmers to have them.

3. *Other strategies*

Acceptance of new foods

In some areas of East Africa, certain foods like insects and worms are not eaten due to negative perceptions yet they are a good source of protein just like fish, chicken and meat. If promoted as food, insects emit fewer GHGs (FAO Forestry Paper, 2013) than livestock. There are diverse types of insects that can play nutritional roles and they are easy to farm compared to traditional sources of animal protein. Incorporation of insect farming in other farming enterprises is a good way of diversifying livelihoods and enhancing resilience to climate change (Chandra et al., 2016).

Good Agricultural Practices (GAPS)

Agroforestry programs

These should be integrated in all aspects of land and natural resources management. Activities such as cutting trees should be prohibited with strictness. As a land use system, agroforestry provides immense benefits such as CO2 sequestration and enhances soil fertility. Most of these functions have direct benefits for local adaptation while contributing to global efforts to control atmospheric GHG concentrations (Mbow et al., 2013). Agroforestry approaches are sustainable and cheaper. Some of the known agroforestry trees that are of use include: mango (Mangifera indica), Paw paw (Carica papaya), mulberry (Morus alba). Agroforestry provides many of the principles for developing climate-smart agricultural systems (FAO, 2013).

New crop varieties and resistant animal breeds

These can be tolerant to drought conditions and survive heat stress respectively. Climate change greatly affects crop yield by limiting crop growth and development

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_22332254
© 2018, ALÖKI Kft., Budapest, Hungary

(Hatfield and Prueger, 2015) and therefore food crops i.e. maize, beans need to be drought resistant and high yielding. Cash crops like coffee can also be of resistant varieties. An example is the Drought Tolerant (DT) maize varieties that have been developed and tested by the Drought Resistant Maize for Africa (DRMA) project in Eastern and Southern Africa, with superior characteristics. The challenge is adoption due to unavailability of improved seeds, high prices and inadequate information (Fisher et al., 2015). As for animal breeds, some local pastoral groups have kept their indigenous breeds that withstand local conditions although others have made steps to cross breed for resistance, milk and beef production. Generally, breeding improvement programs of African indigenous livestock are still few even when the demand of livestock products is continually increasing (Mwai et al., 2015).

Water storage

This is one of the biggest challenges that most smallholder farmers still face. This is because most of the technologies required to harvest and store water for a considerable long time require money. Construction of ponds and other surface water storage methods to facilitate micro irrigation should be enhanced. Water harvesting is an integral part in agricultural production to eradicate hunger. In situations where farmers are unable to harvest and store water using dams, reservoirs and tanks, they should conserve soil moisture by mulching, zero tillage and terraces.

Settled farming

Although migrations are taken as an adaptation strategy to reduce vulnerability to harsh environmental conditions (Ingty, 2017; McLeman and Smit, 2006; Speranza et al., 2009; Yeh et al., 2014), different communities in East Africa have problems relating to land i.e. there is no more land to allow unplanned migrations. This is due to population growth influencing people to protect their land. Governments need to plan and set laws that restrict movement of animals in large numbers to new areas. Farmers should be encouraged to plan agricultural activities which can make individuals develop a sense of responsibility and ownership. Land in East Africa has caused conflicts especially in Uganda.

Maintain and restore degraded ecosystems

Destruction of ecosystems is one of the serious causes of GHGs, which contribute to warming of the Earth. In some communities, forests and swamps have been degraded (*Fig. 2*). Restoration of damaged ecosystems is key in sequestration of carbon.

Policies

Climate change policies and laws need to be harmonized to tackle similar challenges facing the region. Policies on agriculture, water management and movements of people need to be updated to reflect current regional problems (*Fig. 7*).

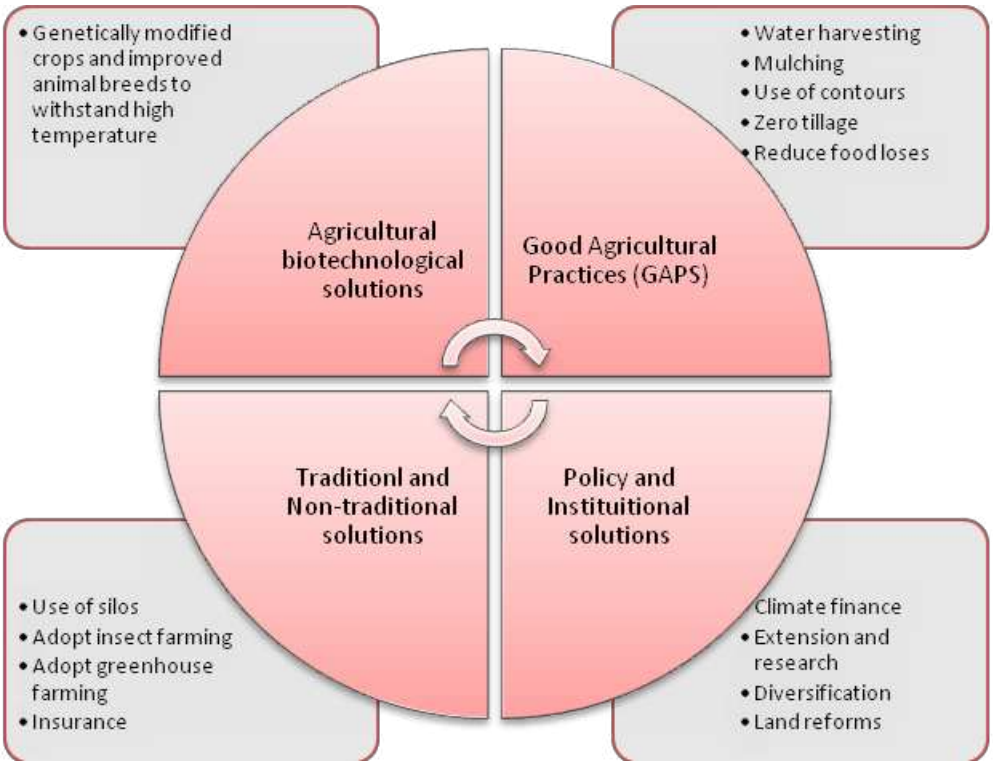

Figure 7. *Mitigation and adaptation strategies. (Source: Authors)*

Countries should try all possible options to streamline the policies to stabilize food security and increase resilience in agricultural systems (Kelvin et al., 2017). Policies that strengthen institutions and agricultural technologies can improve adaptation and resilience of communities (Shiferaw et al., 2014). Policies need to revive traditional and non-traditional options to fully optimize available options of dealing with climate change and food insecurity.

Policies have to be designed in a way that is integrative across sectors and interlinked but avoid duplication. They should be clear and easy to implement, supported by regional governments to improve resilience of communities to climate change shocks.

Conclusions and recommendations

Generally, the results of this paper reveal the following:

The destruction of fragile ecosystems by man's ill-judged activities is greatly responsible for climate change in East Africa that in turn causes food insecurity and other disasters.

Simple but useful technologies like use of silos commonly termed as granaries which used to exist and help in preservation of food have slowly been neglected and have contributed to food insecurity.

Farmers sell from their gardens before crops reach maturity stage for harvesting and this exacerbated food insecurity.

We recommend and emphasize integration of traditional and non-traditional measures to guard against food insecurity and climate change. Governments should focus on working out a "solid" policy that protects natural resources like wetlands,

© 2018, ALÖKI Kft., Budapest, Hungary

promotes both traditional and non-traditional technologies and support farmers to adopt new agricultural technologies. This needs synergy across all the East African countries through investment in research, technologies and collaborations to improve on peoples' livelihoods.

There is need to find out why silos and back yard gardens that characterized rural East African communities have reduced yet they would provide cheap sources of food to fight "hidden hunger".

Acknowledgements. This research is funded by Chongqing Research Program for Basic Research and Frontier Technology, No. cstc2016jcyjA0460. We thank the government of Uganda and the Peoples' Republic of China for supporting Natamba's studies. Abstract. In our experiment, the effect of water extract of *Silybum marianum* (L.) Gaertn. on germination and early growth of *Zea mays* L. was examined in laboratory circumstances. The examined concentrations (m/v%), originated from dried *S. marianum* water extract were the following: 1%, 5%, 7.5% and 10%. The fresh and dry weight of maize, the length of coleoptile and radicle and the nutrient element contents were measured. The results demonstrate that the 1% milk thistle water extract treatment has a significant positive effect on all of the measured parameters of maize. In the case of higher concentrations, the fresh and dry weight of coleoptile significantly decreased compared to the control. The same tendency can be observed for the radicle. N, K, Ca, Mg and Zn concentration of radicle and K, Ca and Zn concentration of coleoptile increased when maize was treated with milk thistle extract, at all kind of concentration levels. The Cu and Fe content of maize seedlings decreased at all applied concentrations. Our results demonstrate the importance of *S. marianum's* appearance in field because it has very strong allelopathic effects. Further examination is needed to determine if the remaining plant residues have an effect on germination and growth of crops.
Keywords: *biomass production, corn, milk thistle, growth inhibition*

Introduction

Allelopathy refers to the beneficial or harmful effects of one plant on another plant, both crop and weed species, from the release of biochemicals, known as allelochemicals, to plant parts by leaching, root exudation, volatilization, residue decomposition and other processes in both natural and agricultural systems. Allelochemicals are a subset of secondary metabolites not required for metabolism (growth and development) of the allelopathic effects and are important part of plant defence against herbivory (Fraenkel, 1959; Stamp, 2003).

Commonly cited effects of allelopathy include reduced seed germination and seedling growth (Lehoczky et al., 2011a, b, 2014). Inhibition due to allelopathy is complex and can involve the interaction of different chemical classes, like phenolic compounds, flavonoids, terpenoids, alkaloids, steroids, carbohydrates and amino acids

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

with different compound mixtures sometimes having higher allelopathic effect than individual compounds alone (Győri et al., 2014; Lehoczky et al., 2016; Nwaichi and Ayalogu, 2010).

The basic approach used in allelopathic research for agricultural crops has been to screen both crop plants and natural vegetation for their capacity to suppress weeds (Lehoczky and Gólya, 2013). To demonstrate the phenomenon and mechanism of allelopathy, plant origin, production, and identification of allelochemicals have to be established as well as persistence in the environment over time in concentrations sufficient to affect different plant species. Interactions among allelopathic plants, host crops, and other non-target organisms must also be considered (Ferguson and Rathinasabapathi, 2012).

Many researchers have documented the allelopathic effect of milk thistle on mustard, cucumber, wheat and sorghum (Isam and Hussain, 1988), but there is little knowledge on the effect on maize. Qasem and Foy (2008) established, that milk thistle have the potential to be used in solving problems of other weed species and represents an excellent source of natural chemicals that may be involved in developing natural herbicides.

S. marianum is by far the most widely known species. Milk thistle, also known as the Marian, St. Mary's or Our Lady's thistle, is native to the Mediterranean region of Europe and is grown commercially as a medical plant in Egypt, Tunisia, China and Argentina (Anonymous, 1995; Penksza and Szerdahelyi, 2009) but it has been reported as a noxious weed in many other countries. Otherwise, milk thistle is a serious weed in many areas of North and South America, Africa, Australia and the Middle East (Holm et al., 1997).

Weeds are an important variable in crop production (Bilalis et al., 2010; Efthimiadou et al., 2009; Karkanis et al., 2010; Lehoczky et al., 2013, 2015). Weed science will be advantageously positioned in the future if research focuses on research – decision process, weed biology and ecology, weed control and management practices, herbicide resistance, issues related to transgenic plants, environmental issues, and potential benefits of weeds (Hall et al., 2000).

Weeds have serious effect on crop production. Nowadays, the milk thistle is one of the most prevalent weeds found in the fields in North Africa. This research will be positioned for the future, focusing on interaction, weed biology and ecology, weed control and management practices, herbicide resistance.

The basic aim of the experiment was to make bioassay examination which assesses the allelopathic effects of *Silybum marianum* (L.) Gaertn. on maize seedlings in laboratory circumstances. The test plant's (maize) element composition, germination and growth inhibition were also investigated at the end of the experiment.

Materials and methods

The *Silybum marianum* (L.) Gaertn. leaves were dried on 45 °C. After drying, the sample was chopped than milled. The plant material of *S. marianum* was collected from agricultural area. The element content of milk thistle is shown in *Table 1*.

The first 150 ml of the 10% concentration water extract was made by soaking 15 g powdered plant sample in 150 ml tap water. The mixture was kept at room temperature for 24 h and was mixed occasionally. After 24 h, the extract was filtered through MN 619 G ¼ filter paper. The 10% concentration water extract was diluted to obtain the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_22552265
© 2018, ALÖKI Kft., Budapest, Hungary

concentrations of 1%, 5% and 7.5%. Tap water was used as a control (Ø). Twenty maize seeds (*Zea mays* L.) were placed separately into 18 cm diameter Petri dishes on MN 640 m filter paper. 15 ml of each concentration of water extracts were added to the Petri dishes in four replications. All of them were placed in a Binder APT Line KBW plant growing chamber at 21 ± 1 °C for 7 days.

Table 1. *Element content of Silybum marianum L. Gaertn. leaves (mg kg^{-1}, N (%)) N = 2 ± SD*

N	P	K	Ca	Mg
2.42 ± 0.09	1764 ± 42	34165 ± 54	35432 ± 2917	5156 ± 59
Fe	**Mn**	**Cu**	**Zn**	**Mo**
321 ± 86	30.4 ± 2.4	14.8 ± 0.7	43.5 ± 0.5	1.07 ± 0.15

The used experimental design and method have already been published by Lehoczky et al., (2011a, b, 2017).

Seven days after the start of the experiment, the shoots and roots of every seedling were measured with millimetre paper. The fresh weight of the shoots and roots was determined at the same time. After drying, the dry weight was also measured.

Determination of the seedling nutrient concentrations for P, K, Ca, Mg, Fe, Mn, Cu, Zn and Mo was carried out with ICP-OES method after microwave Teflon bomb digestion with cc. HNO_3 + H_2O_2. The nitrogen concentration of samples was determined using the Kjeldahl method.

The substances with allelopathic effects of the *Silybum marianum* L. Gaertn. sample have been investigated by HPLC. According to the methanol extract, 1 g plant sample contained 63 µg rutin and 194 µg salicylic acid. Both rutin and salicylic acid have inhibitory effects on germination (Basile et al., 2000; Szepesi, 2009; Szabó, 1997).

ANOVA (Analysis of Variance) was used to evaluate the significant differences. On the figures the error bars indicate the standard deviation and the a–e indicate significant differences within treatments at the 5% level of probability according to Duncan's test. For the statistical analysis Sigma Plot 12.0 was used. Examinations were carried out in three replications and in different cases with four replications. The experiments were conducted in controlled environmental conditions, so there was no difference between the results of three biological replications. The data of three repetitions were summarized and used for statistical analysis – results were calculated from twelve data.

Results

Usually, the effects of allelopathy include reduced seed germination and seedling growth. All maize seeds started to germinate by the end of the seventh day, hence the germination percentage was 100% in all treatments. However, the number of seeds with a length of a few mm shoot have increased in parallel with increasing extract concentration (*Fig. 1a, b*).

Decrease of shoot and radicle length was observed at the 5, 7.5 and 10% extract treatments. The length of shoot increased by 18% in the 1% extract treatment. The increase is significant compared to the control. The length of radicle increased by 18%

in the 1% milk thistle extract treatment. The decrease is parallel with the increasing concentration of milk thistle extracts.

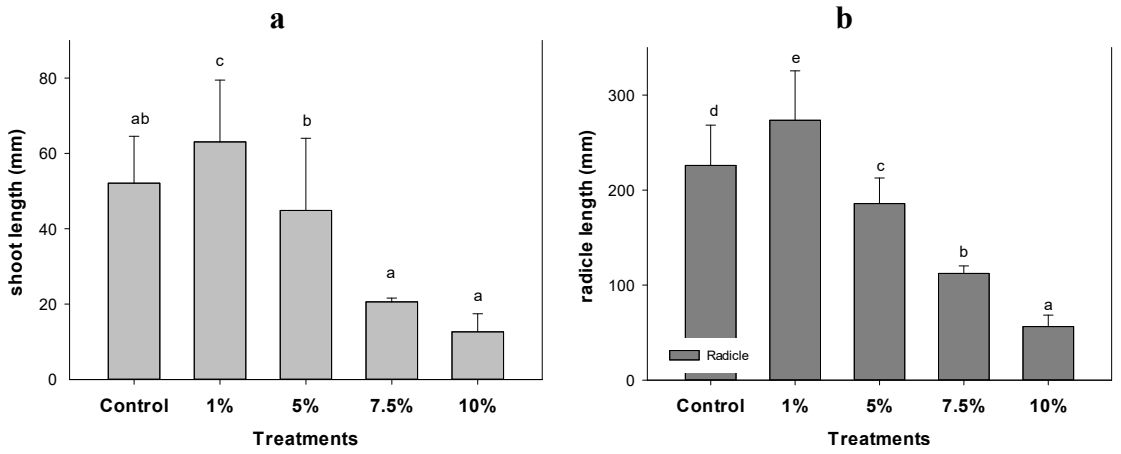

Figure 1. *The effect of Silybum marianum L. Gaertn. water extracts (a) on the length of shoot of maize ($LSD_{5\%}$ 12.36) N = 240 ± SD and (b) on the length of radicle of maize ($LSD_{5\%}$ 49.80) N = 240 ± SD*

Additionally, the effect of *S. marianum* was observed on the fresh weight of shoot (coleoptile) and root (radicle) of maize (*Fig. 2a, b*).

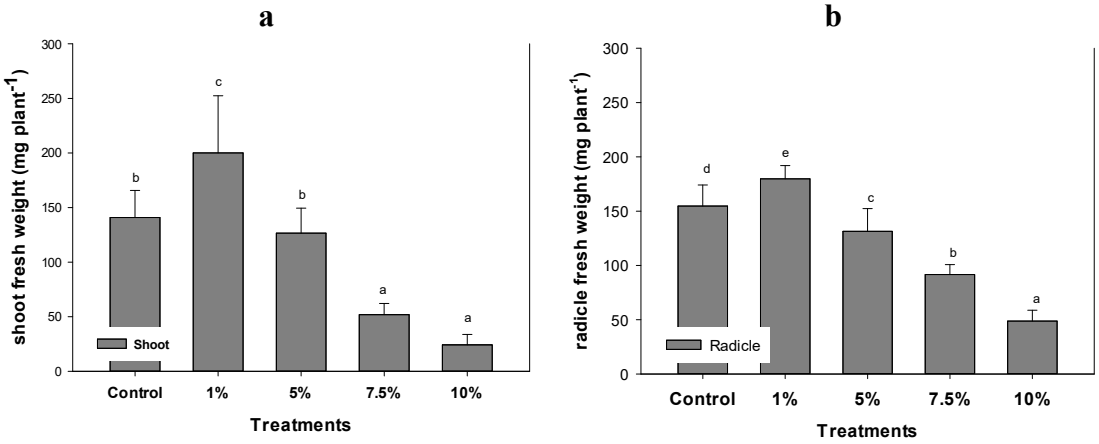

Figure 2. *The effect of Silybum marianum L. Gaertn. water extracts (a) on the fresh shoot weight of maize ($LSD_{5\%}$ 35.11) N = 12 ± SD and (b) on the fresh radicle weight of maize ($LSD_{5\%}$ 18.86) N = 12 ± SD*

The positive effect was observed when 1% extract was applied. The fresh weight of coleoptile was significantly increased by 30% in the 1% treatment. At the higher concentrations, the effect was negative on fresh weight. The fresh weight of shoot decreased by 11%, 64% and 83% in the 5%, 7.5% and 10% treatment, respectively. In the case of the highest concentration the decrease was significant compared to the control. The same tendency can be observed in the case of the fresh weight of radicle (*Fig. 2b*). The fresh weight of radicle increased by 14% in the 1% extract treatments.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_22552265

Decrease was observed at the higher concentration. The highest decrease was in the case of the 10% extract treatment. The dry weight of shoots and radicles also were measured (*Fig. 3a, b*).

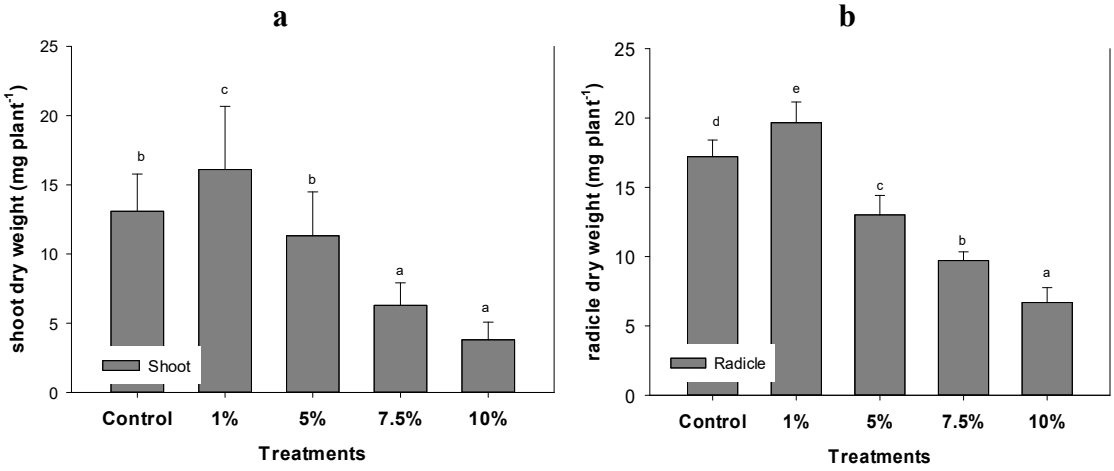

Figure 3. *The effect of Silybum marianum L. Gaertn. water extracts (a) on the dry weight of shoot of maize ($LSD_{5\%}$ 4.06) N = 12 ± SD and (b) on the dry weight of radicle of maize ($LSD_{5\%}$ 1.72) N = 12 ± SD*

The 1% extract treatment had less positive effect on dry weight than on fresh weight of shoot. The dry weight of shoot increased with 19%. The decrease at the higher extract concentrations also had less negative effect on the dry weight of shoots as well as on the fresh weight of shoot. The decrease was mathematically proven in both cases.

Figure 4 shows the different extract treatments on the shoot/root dry weight rate of maize. The shoot/root dry weight ratio of seedlings was higher in the case of 1 and 5% concentrations compared to the control (0.76), which is a trend that is not statistically significant.

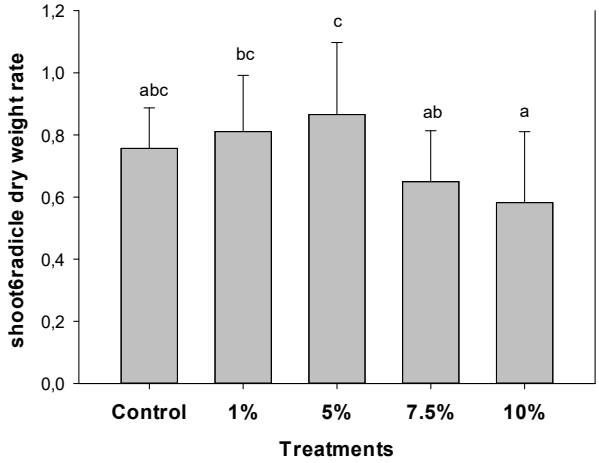

Figure 4. *The effect of Silybum marianum L. Gaertn. water extracts on the shoot/root dry weight rate of maize ($LSD_{5\%}$ 0.33) N = 12 ± SD*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

In the case of the 1% extract treatment, the mass of the root and shoot both increased, but the increase of shoot weight was greater than of root weight. Similar results were observed at 5% concentration level regarding the ratio, however the root and shoot growth was also inhibited (*Fig. 3a, b*). The inhibitory effect was more strongly manifested in the case of roots, which explains the growth of shoot/root dry weight ratio shown in *Figure 4*. In the case of the 7.5 and 10% extract treatments the shoot/root ratio was significantly lower compared to the treatment with 5% concentration. The background in both cases is the strong growth inhibiting effect of the extracts, in which the shoot growth inhibition was stronger than the root growth inhibition, thus the significant reduction of the ratio can be explained.

Tables 2 and *3* show the element concentrations of shoot and radicle of maize. The concentration of N is significantly decreased in shoot in 1%, and increased in 5, 7.5 and 10% treatment in radicle. The concentration of P significantly decreased by 22% in the 10% extract treatment in shoot compared to the control, but there was no significant difference detected in radicle between *S. marianum* treatments and control. The concentration of K is significantly increased in both shoot and radicle in 5%, 7.5% and 10% water extracted milk thistle treatments. The increment is 36%, 32% and 36% in shoot, and 53%, 54% and 56% in radicle, respectively. The concentration of K was not changed significantly parallel with the increasing water extract concentration. The content of calcium significantly increased in all extract treatments; the highest increase could be observed at 7.5% water extract concentration in shoot and at 5% in radicle treatment compared to the control. In order to protect roots against the adverse effects of high concentrations of various other cations in the soil solution, the Ca^{2+} concentrations required for optimal growth have to be substantially higher in soil solution than in balanced flowing nutrient solutions (Asher and Edwards, 1983). Also increment was determined in the Mg content in the radicle of maize when maize was treated with milk thistle extract. Mg is also required for optimal plant growth. At permanently insufficient root supply, remobilization of Mg from mature leaves reduces their longevity (Lange et al., 1987). The content of Cu decreased parallel with the increasing extract concentration. The Fe content decreased in the all treatments. The concentration of molybdenum in shoot was changed significantly in the 10% treatments, while no significantly changes were observed in radicle compared to the control.

Discussion

Allelopathic effect of milk thistle on different crops has been documented sporadically, but there is no literature on its effect on maize.

Therefore, a laboratory based allelopathic extracts bioassay was conducted. During our experimental period the allelopathic effects of donor species on germination and seedling growth of maize was observed. Results has been shown, *Silybum marianum* L. extract did not have any effect on the germination of maize. The maize seedlings growth was inhibited by 5, 7.5 and 10% extract of *Silybum marianum* L. but growth stimulation effect was observed by 1% concentration extract.

Sultana and Asaduzzaman (2012) also observed inhibition effect on the above-mentioned parameters in case of canola and ryegrass. They established that the extracts from fresh water at 100% was more toxic to receiver species followed by 50% concentration of fresh and 100% from hot water extracts. This concentration reduced the root, shoot growth of ryegrass and canola by 84.97%, 84.27% and 89.90%,

DOI: http://dx.doi.org/10.15666/aeer/1603_22552265
© 2018, ALÖKI Kft., Budapest, Hungary

respectively. The result also revealed that the allelopathic pattern of hot water extracts was the same; however, it was less toxic to both receiver species.

The allelopathic potential of *S. marianum* was investigated by Khan et al. (2011) on kidney bean (*Phaseolus vulgaris* L.), mung bean (*Vigna radiate* L.), chickpea (*Cicer arietinum* L.) and soybean (*Glycine max* L.). The results show that by increasing the leaves extract concentration of *S. marianum*, a significant decrease was noted in the germination percentage, mean germination time, germination index and seed vigor index of test species. The tolerance order of the mung bean and soybean against the extract concentration of *S. marianum* was higher than the other two species, while the chickpea was more susceptible to the toxicity of milk thistle.

Milk thistle is a major weed in sugar beet, wheat and canola causing large yield reductions (Shimi et al., 2006). However, research has documented the allelopathic effect of milk thistle on mustard, cucumber, wheat and sorghum (Inam and Hussain, 1988; Lehoczky et al., 2017).

In our experiment, the uptaken elements, e.g. K, Ca and Zn, were increased both in the shoot and root when maize was treated with *S. marianum*, but the Cu and Fe content decreased as a result of the milk thistle extract treatment.

In summary, the microelement concentrations decreased by the application of milk thistle water extracts. The micronutrients have prominent effect on dry matter, grain and straw yield (Aller et al., 1990). Fe plays role e.g. in nitrogen fixation (Römheld and Marschner, 1991) and it is very essential for normal plant growth (Fageria, 2007). Mn is utilized in enzyme activation (Burnell, 1988), Zn is important to membrane integrity and protein synthesis (Zhao et al., 2012). So, the adequate uptake of micronutrients has an effect on plant growth and development. Otherwise, plant will suffer from growth inhibition.

Seed germination is affected by the nutritional status of the mother plant and therefore by nutrient concentration in the seeds (*Table 1*). P and K concentrations of below 0.3% in seeds negatively affect their total germination (Hrdlicková et al., 2011). Seed germination and the time required for the 50% of the seeds to germinate are significantly affected by nitrogen (Hejcman et al., 2012). There was no detected inhibited germination in our experiment.

In our experiment the inhibition effect of milk thistle on the measured parameters of maize was also observed. Significant decrease was observed at increasing milk thistle extract concentration in the fresh and dry weight of shoot and radicles of maize, length of shoot and radicle. Compared to the stimulating 1% treatment, the 5, 7.5 and 10% extract resulted in significant reduction of the fresh weight of coleoptile, which was 11, 6 and 83%, respectively. The length of shoot deceased by 12% in the 5% extract treatment, 60% in the 7.5 and 76% in the 10% milk thistle extract treatments. But a remarkable stimulating effect was observed in 1% extract treatment on the fresh weight (30%) and length (14%) of coleoptile.

Lehoczky et al. (2017) investigated the allelopathic effect of milk thistle on winter wheat. According to their results, the winter wheat is more sensitive for applied concentrations of *S. marianum* than the maize. The concentrations of 1%, 2%, 3%, 4% and 5% of water extract were used. They found that the allelopathic potential of milk thistle increased with increasing concentration. The fresh and the dry weight and the length of the shoot and radicle of wheat significantly decreased at 5% concentration.

Recent assessment of allelopathic effect of weed on weed has the goal of using naturally produced allelochemicals to reduce reliance on herbicides (Putman and Duke, 1978). Milk thistle is a worldwide known weed. It has a special allelopathic effect, therefore, there is a significant difference when we grow milk thistle as medicinal plant

or it acts as a weed. In the latter case, *S. marianum* may decrease the yield due to its allelopathic effect. So, special attention should be given to the plant residues of milk thistle to be worked in the soil after the vegetation period.

(Received 17th Nov 2017; accepted 13th Mar 2018)

Abstract. A two-year field study was conducted during 2016 and 2017 to determine the influence of harvesting times on biomass yield, quality and bio-methane yield of sorghum. Harvesting times considerably influenced the growth attributes, biomass quality and bio-methane yield. The maximum plant height, and dry matter (DM) yield were recorded 105 DAS, whilst lowest values of these parameters were recorded 60 DAS. Similarly, the maximum protein and sugar concentration were found 60 days after sowing (DAS), after that a substantial reduction in protein and sugar concentration were found with advancing maturity. Moreover, the highest acid and neutral detergent fiber, lignin, cellulose and hemi-cellulose were found 120 DAS whereas; minimum acid detergent fiber, neutral detergent fiber, lignin, cellulose and hemi-cellulose were observed 60 DAS. Likewise, maximum specific methane yield was recorded 60 DAS, while minimum specific methane yield were recorded 120 DAS, conversely, maximum methane yield ha^{-1} were recorded after 105 DAS owing to higher dry matter yield ha^{-1}. Interestingly, we also found strong positive correlation between dry matter yield and methane yield and negative relationship between lignin concentrations and specific methane yield. In conclusion, sorghum crop can be harvested after, 105 DAS owing to high dry matter yield ha^{-1} for maximizing its potential for bio-methane yield.
Keywords: *harvesting time, biomass yield, sorghum, biomass quality, methane yield*

Introduction

Energy is essential for substantial growth and development of nations; in addition, energy security and resource scarcity are key issues globally. The depletion of fossil fuels and increase in the green house gases due to combustion of fossil fuels has promoted the interest of environmentalists and policy makers for alternate energy sources (Monti et al., 2012). Amongst the alternate energy sources plant biomass is considered to be a sustainable and cheap source. Moreover, the plant biomass could cater the above-mentioned problems. Energy crops are imperative biomass sources which can be used for the production of bio-energy. Among energy crops, sorghum is an indispensible crop cultivated globally for the production of bio-methane. Variety of attributes including, low water requirement, salinity and drought tolerance (Vasilakoglou et al., 2011; Hassan et al., 2018a), short growth period and well adoptability in arid and semi-arid regions (Reddy and Sanjana, 2003) makes it a promising bio-energy crop. Moreover, sorghum crop can efficiently transfer the available water into dry matter production than the other C_4 crops (Dercas and Liakatas, 2007).

Together with productivity, the quality of the biomass is important to bio-fuel conversion production systems. The quality of the produced can be optimized by just selecting the optimum harvesting time. Stage of harvesting is an imperative factor which substantially influences the biomass yield, chemical composition as well as biomass digestibility (Ball et al., 2001). The variations in biomass composition and yield have been reported owing to cultivar, environment and harvesting stage (Pordesimo et al., 2005; Hassan et al., 2018b). Prolonged maturity enhances the structural fiber and lignin concentrations and decreases biomass digestibility (Pordesimo et al., 2005) and consequently the bio-methane yield. The most common changes linked with harvesting time are biomass yield (Ayub et al., 2003), biomass quality i.e. protein concentrations, structural fiber and lignin concentrations and biomass digestibility and its conversion to bio-energy (Schittenhelm, 2008). So far, in Pakistan most of the research on sorghum has been focused on its fodder production aspects. There is no report available regarding the effect of harvesting time on chemical composition and biomass yield in the context of methane production. Therefore, this study was planned to determine the influence of harvesting times on biomass yield, chemical composition and bio-methane yield.

Materials and methods

Study site

A field study was conducted during 2016 and 2017 at Post Graduate Agriculture Research (PARS), University of Agriculture, Faisalabad, Pakistan. The study site comes under a sub-tropical climate, with a mean temperature of 27-39 °C during summer season and 6-21 °C during winter season (Chattha et al., 2017a). Furthermore, the prevailed climatic conditions during both the years are given in *Table 1*. The soil samples were collected before sowing crop in each season, and were analyzed by standard procedures of Homer and Pratt (1961). The soil was sandy loam and averagely the soil had a pH of 7.95, Ec (1.2), organic matter (0.89%), nitrogen (0.03%) phosphorus (6.43 ppm) and potassium (186 ppm) respectively.

Table 1. *Prevailing climatic conditions for the experimental site during year 2016 and 2017*

Months	Monthly mean maximum temperature (°C)		Monthly mean minimum temperature (°C)		Monthly average temperature (°C)		Rainfall (mm)		Relative humidity (%)	
	2016	2017	2016	2017	2016	2017	2016	2017	2016	2017
May	39.8	41.1	25.6	26	32.7	33.5	25	10.1	28.8	29.8
June	40.2	39.8	28.5	27.3	34.4	33.5	39.9	41.6	38.9	44.5
July	36.6	38.5	27.4	28.9	32	33.7	193.5	161.4	59.6	70
August	35.7	38.1	26.5	28.6	31.1	33.4	48.1	66	62.2	68.9

Experimental design and crop cultivation

The experiment was composed of five harvesting times i.e. 60, 75, 90, 105 and 120 days of sowing and a randomized complete block design with three replications were used for study. The final seed bed was prepared by ploughing three times followed by planking. The net plot size was 5 m × 3 m. In both years, nitrogen (N) as urea (46% N) 60 kg ha^{-1} was applied, while phosphorus as single super phosphate (21% P)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_22672276
© 2018, ALÖKI Kft., Budapest, Hungary

40 kg ha^{-1} was applied. The sorghum variety YS-2016 was collected from Fodder Research Institute Faisalabad. The sorghum variety YS-2016 is late maturing. All the P and half of N were applied at the sowing, while rest of the N was applied with first irrigation. The crop was sown on 2nd May and 6th May during the year 2016 and 2017 respectively. In total three irrigations were applied during both the years. First irrigation was applied as soaking irrigation, second irrigation was applied 35 days after sowing and third irrigation was applied 68 days after sowing. All other management practices were kept normal and uniform during both years for good stand establishment.

Sampling and measurements

Ten plants were selected at each harvesting time in order to determine the plant height, leaves per plant, stem diameter, fresh and dry weights per plant. Moreover, the whole plots were harvested and dried to determine the biomass yield and later on mathematically converted to tones per hectare basis.

Biomass analysis

The samples for chemical analysis were oven dried, ground and sieved through 1 mm mesh screen. The concentrations of protein and ash were determined according to the AOAC (1990). Sugar, acid detergent fiber (ADF), neutral detergent fiber (NDF) and lignin concentrations (% DM) were determined according to Dubois et al. (1956), Georing and Van-Soest (1970) and Van-Soest et al. (1991). Methane measurement was taken using Bioprocess Control's AMPTS equipment. Liquid manure was used a source of bacteria in order to anaerobically digest the sorghum sample. The 16 g of substrate was used in each digester after that the total volume of digesters were made up to 400 ml. Afterwards, digesters were perched with nitrogen gas in order to create the anaerobic conditions. The temperature of digesters was kept at 37 °C by standing them in water bath. The samples were allowed to digest for 28 days, in laboratory. The methane produced by each sample on every day was recorded from computer operated systems. At the end by using the amount of volatile solids the quantity of specific methane produced by each sorghum sample was calculated. Later on the specific methane produced by each sample was converted into hectare basis mathematically.

Statistical analysis

The collected data were analyzed by computer software Statistix 8.1 and least significant difference test was used to compare the treatments means at 5% probability level (Steel et al., 1997). The graphs were generated by using Sigma plot software 9.

Results

The results revealed that harvesting times had substantiated influence on the growth attributes of sorghum i.e. plant height, stem diameter and leaves per plant (*Table 2*). The plant height ranged between 164-212 cm in 2016 and 161-210 cm in 2017. Plant height increased progressively and reached the maximum extent at 105 days after sowing (DAS), after that there was no increase observed in plant height. Similarly, the maximum stem diameter was observed when crop was harvested 105 DAS, whereas the minimum stem diameter was observed 60 DAS. Likewise, maximum leaves per plant

© 2018, ALÖKI Kft., Budapest, Hungary

was recorded after 60 DAS afterwards, a substantial reduction in leaves per plant were recorded with minimum leaves at 120 DAS (*Table 2*).

There were significant differences among the harvesting times for fresh weight per plant, dry weight per plant and dry matter yield (DM; *Table 2*). The maximum fresh weight and dry weight per plant were recorded 105 DAS, after that both fresh and dry weight per plant started declining, whereas the minimum fresh weight per plant and dry weight were recorded at 60 DAS. Similarly, the crop harvested 105 DAS produced maximum DM yield (16.26 t ha^{-1}, 16 t ha^{-1}), followed by crop harvested after 120 DAS, while the minimum DM yield (10.46 t ha^{-1}, 10.06 t ha^{-1}) were obtained at 60 DAS.

There were considerable differences among the harvesting times for qualitative attributes (*Table 3*). The highest protein and sugar concentrations (% DM) were obtained from the earliest harvesting (60 DAS), while lowest protein and sugar was obtained from latest harvesting (120 DAS). Moreover, the harvesting times also had considerable influence on the acid detergent fiber (ADF), neutral detergent fiber (NDF), lignin, cellulose and hemi-cellulose concentrations (% DM) (*Fig. 1*). A linear increase in ADF, NDF, lignin, cellulose and hemi-cellulose were found with advancing maturity. The maximum ADF and NDF concentrations were recorded 120 DAS that was comparable with 105 DAS, whilst lowest ADF and NDF concentrations in plant biomass were recorded at 60 DAS (*Fig. 1a, b*). The highest lignin, cellulose and hemi-cellulose concentrations in plant biomass were recorded at 120 DAS that was comparable with 105 DAS, whilst, lowest lignin, cellulose and hemi-celluloses, were recorded 60 DAS among the harvesting times (*Fig. 1c, d*). Similarly, ash concentrations significantly decreased with maturity, with maximum ash concentration (10.53, 10.76%) were observed 60 DAS, while lowest ash concentration (7.63, 7.80%) were recorded 120 DAS that was comparable with 105 DAS (*Table 3*).

Values sharing different letters differed at $p < 0.05$, DAS: days after sowing

The results revealed that harvesting times substantially influenced the specific methane yield and methane ha^{-1} basis (*Fig. 2*). The specific methane yield (SMY) considerably decreased with advancing maturity, with maximum SMY were observed at 60 DAS, followed by 75 DAS, whilst lowest SMY were recorded at 120 DAS (*Fig. 2a*). Conversely, methane yield ha^{-1} increased with advancing the maturity up to 105 DAS with maximum methane yield ha^{-1} were recorded after 105 DAS, followed by 120 DAS, while lowest methane yield ha^{-1} were recorded 60 DAS (*Fig. 2b*). We also observed the significant positive correlation between DM yield and methane yield during both the years (*Fig. 3*); an increase in DM yield appreciably increased the methane yield. Interestingly, a negative correlation was observed SMY and lignin concentrations (*Fig. 4*); it was found that increase in lignin concentrations substantially reduced the specific methane yield.

Discussion

Results revealed that harvesting times significantly influenced the dry matter yield, biomass quality and bio-methane yield. The plant height increased with delaying the harvesting up to 105 days after sowing (DAS), afterwards, delay in harvesting had no significant effect on the plant owing to termination of stem elongation. These results are in consistence with earlier finding of Tariq et al. (2011), who also found the appreciable influence of harvesting times on plant height. Similarly, the maximum stem diameter was found 105 DAS that was due to continuous accumulation of fibrous compounds in central stem. Current findings are supported by Naeem et al. (2007) and Amodu et al. (2007) who also proved a significant effect of harvesting time on stem diameter. The DM yield positively increased with delaying maturity up to 105 DAS, afterwards a little bit reduction in DM yield was found. The lower DM yield at early stage can be ascribed to lower plant height and stem diameter, moreover, the maximum DM yield at 105 DAS was possibly due to maximum plant height and stem diameter. These results are in accordance with findings of Chattha et al. (2017b), Ram et al. (2007) and Hussain et al. (2002) who also reported the substantial increase in DM yield with advancing maturity. Nonetheless the reduction in DM yield after 105 DAS might be due to reduction in the availably of water soluble carbohydrates, more falling of leaves and initiation of plant senescence. The protein concentrations decreased positively with the passage of time with minimum protein concentration were found 120 DAS. Moreover, leaves are rich source of protein and stems are considered to be low in protein concentrations. Therefore, the reduction in protein concentrations with advancing maturity can also be due loss of leaves and increase in stem proportion. Other researchers also reported the considerable reduction in protein concentrations with advancing the maturity (Ayub et al., 2002; Butler and Muir, 2003). Similarly, the maximum sugar concentration was found at earlier harvesting and lowest sugar concentrations were found at later harvesting stage. We suppose that younger plants have more physiological activities, thus have more sugar production. These findings are corroborated with earlier results of Umer et al. (2017b) who also reported the considerable influence of harvesting times on the sugar concentrations. Similarly, structural fibers including ADF, NDF, cellulose, hemi-cellulose and lignin concentrations tended to increase, whereas the ash concentrations tended to decrease with advancing the maturity stage. The structural fibers including cellulose, hemi-cellulose and lignin are parts of secondary cell wall, and they appear during the formation and thickening of cell walls, therefore, cell wall thickening increases with maturity which in turn influences the structural fiber and lignin concentrations. Earlier researchers also reported structural fiber and lignin contents considerably increased with the advancing maturity (Filya, 2004; Carmi et al., 2005; Miron et al., 2006). The ash concentrations decreased with delayed harvesting owing to loss of plant leaves and translocation of inorganic nutrients form vegetative plant parts to reproductive parts. The considerable differences in ash concentrations with varying harvesting stages have also been documented by Kitaba and Tamir (2007).

We also reported the considerable influence of harvesting times on the specific methane yield and methane yield per hectare basis. The negative correlation between SMY and lignin concentration might be due to the reason that the higher lignin concentration decrease the digestibility of biomass and consequently decrease SYM and vice versa. The maximum SMY were reported 60 DAS, whereas, the minimum SMY were reported 120 DAS, conversely, maximum methane yield ha^{-1} were found 105 DAS, whereas the minimum were reported at 60 DAS (*Table 2*). The maximum SMY at

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_22672276
© 2018, ALÖKI Kft., Budapest, Hungary

60 DAS can be ascribed to lower lignin concentrations, because lower lignin concentrations resulted in earlier and better digestibly of dry matter which leads to higher specific methane yield. In addition, higher lignin concentrations substantially reduced the DM digestibility (Yosef et al., 2009) and ultimately the specific methane yield. Similarly, despite of the lower SMY at 105 DAS, the methane yield ha^{-1} increased due to higher dry matter production ha^{-1} basis.

Conclusion

Harvesting times had considerable influence on the biomass yield, biomass quality and bio-methane yield. Early harvesting produced the crop significantly lower in DM yield and also lower in structural fiber and lignin concentrations. Moreover, later harvesting produced the crop higher both in DM yield and structural fiber and lignin concentrations. Similarly, maximum SMY were recorded 60 DAS, however, it was over compensated by 105 DAS owing to higher dry yield ha^{-1}. Conclusively, harvesting 105 DAS have advantage over the other harvesting times due to higher DM yield in order to get maximum methane yield ha^{-1}. However, further studies are needed to include more cultivars to explore the effect of different harvesting times and other agronomic factors i.e. sowing times, planting geometry and locations on chemical composition and bio-methane yield of sorghum under climatic conditions of Pakistan.

Abstract. Simulation of yield response to water and fertilizer plays a key role in improving the efficiency of agricultural water. In this regard, the purpose of this study is the calibrating and validating of the CropSyst model to evaluate the effect of nitrogen fertilization and irrigation on the growth of rice in the crop field at the Rasht Rice Research Institute between 2013 and 2014. Three irrigation treatments (continuous, around five and eight days) were considered as the main factors and the amount of nitrogen in four concentration (0, 90, 120, and 150 kg N ha^{-1}) as a sub-factor. Based on the evaluation results it can be concluded that the CropSyst model, with the normalized root mean squared error ($RMSE_n$) 7 and 15% with explanation factor, R^2 of 0.73–0.84 for simulating the rice grain yield, and also $RMSE_n$ 9 and 10%, R^2 of 0.77–0.82 for simulating the biological yield, had the appropriate accuracy of the simulations. According to $RMSE_n$ 1 and 0.8%, R^2 of 0.58–0.73 for simulating the leaf area index, suggested a moderate simulation. These results showed that a reasonable estimate of the model as the efficiency of a model for the grain yield, biological yield, and LAI were 0.87, 0.98, and 0.80, respectively. The results of the simulation based on the amount of transpiration water productivity for both years showed that treatment I_3N_2 and I_3N_3had the highest amount. The amount of evaporation in irrigation water management two-year period only 39% of evapotranspiration is evaporated, While the amount of intermittent irrigation management 5 and 8 days, respectively, 35% and 32% respectively. These subjects simulations suggest that, given the good models and maximum data consistency, if management is aimed at maximizing the efficiency of water use can solve these models as a means to support the planning application.
Keywords: *intermittent irrigation, nitrogen, modeling, simulation*

Introduction

Water consumption improvement in agriculture is very important, compared with other sectors, because of the existing complexity in production, and the exploitation process and optimized application of irrigation water and nitrogen, especially in dry and semi-dry areas facing water constraints, is an important goal in this field (Raza et al., 2014). Climate changes, degrading of water resources and continuous drought has influenced agriculture in general and farmers' incomes specifically (Rezaei et al., 2013). As rice receives more irrigation water than other grain crops, developing water-saving

irrigation approaches for rice re seen as a key component to deal with water shortages (Li and Barker, 2004). In recent years, many efforts have been applied in Iranian rice farms to decrease water consumption, and numerous reports have been published about the effect of low irrigation in decreasing water consumption and increasing rice efficiency (Pirmoradian et al., 2004; Razavipour and Kavosi, 2007). According to these reports, by changing the irrigation method from flood to intermittent irrigation without decreasing yield, or with an acceptable percent in decline, we can economize the use of water and increase the efficiency (Asadi et al., 2003). One of the most important zones of rice production in Iran is Guilan Province. Currently, climate change, reduction of fresh water, inappropriate use of water resources, construction of several dams across the White River basin, and the drought in the agricultural sector have threatened rice production and the income of farmers in the region (Zare et al., 2014)

These reports showed that permanent flood irrigation is not only a necessity but, also in dry and semi-dry areas in which the higher efficiency is important, we need to accept the expense of management to decrease the time and amount of irrigation (Razavipour and Kavosi, 2007). Additionally, in some cases, the average water pressure was recommended for better yield (Asadi et al., 2003). In some physiological periods of rice, intermittent pressure, as compared with permanent flood irrigation, caused an increase in the yield, although increasing the pressure will result in a decreased yield (Asadi et al., 2003).

Due to different intervals of time and place, it is difficult to determine various levels of yield through farm experiments. As such, computer simulation models can be used as appropriate tools for cultivation system studies and prepare optimized consumption patterns for the two inputs. Using simulation models is a way to predict and check water balance, growth process simulation, and the study of different management scenarios (Amiri and Rezaei, 2013a). One of the effective methods to reach these goals is the use of some models for plant growth, such as CropSyst (Crop Simulation System), which is a simulation model for rice growth that enables us to obtain the correct results through calculations of data statistics regarding the situation of water, weather, Earth, management system, and plant genetics *(*Amiri and Rezaei, 2013b). By using this model and its results, we can prevent excess consumption of water and nitrogen fertilizers.

Improvement of the CropSyst model was started by Stokel and colleagues in 1994. CropSyst had been developed during the last 15 years to a multi-crop, multi-year simulation model and can be connected to GIS software, which consist of programs like the CropSyst cultivation simulator system, reconstruction of meteorological data (ClimGen), GIS connection program (ArcCs), watershed models, and several other useful programs (Singh, 2008). This model has been used in various cases and in different areas (Saadati et al., 2012). In Southeast Australia, the CropSyst model could simulate the phenology, dry material, and the yield of wheat, green pea, and mustard (Diaz-Ambrona et al., 2001). Quite well. Since the 1980s, crop modellers have been pointing their attention on rice productions. Part of the APSIM crop models (Confalonieri et al., 2009), and the models of the CERES family basically implement a RUE based approach. Part of the models include crop growth equations based on the transpiration use efficiency (Keating et al., 2003). WARM (Confalonieri et al., 2006) is a novel model for paddy rice simulations developed by an interdisciplinary network of scientists working in different fields of rice research and modelling. The simplified model (CropSyst) may cost less in parameterization terms than the more complex models to achieve a similar level of confidence in the results, but WARM proved more

© 2018, ALÖKI Kft., Budapest, Hungary

accurate than the simplified model. The complexity of WOFOST is required to test hypotheses about processes at a lower level (Confalonieri et al., 2006). Therefore, models that are relatively simple to use with minimal input data that is readily available or easy to obtain may be a more useful analytical tool for technical staff, water managers, policy makers and other end-users in less developed countries (Khov et al., 2017).

Regarding the importance of rice cultivation in Guilan Province, and the necessity to optimize economic use of agriculture inputs, and the need to use simulation models of plant growth in irrigation management, this experiment has been conducted with the aim of gaining the best management for irrigation, nitrogen, and evaluate the application of the CropSyst model for rice yield under various water and nitrogen management scenarios.

Materials and methods

Field experiments

A two-year field experiment was conducted at the experimental farm of the Iranian Rice Research Institute in Rasht (37' 12° N; 49' 38° S; 7 m below sea level) from 2013–2014. The experimental design was a split plot with a complete randomized block and three replicates. The plot size for the subplots was 15 m^2 (3 m × 5 m). In this experiment, the main plots were three irrigation regimes: pond during growth period as a control treatment (I1), 5-day intervals (I2), and 8-day intervals (I3), and subplot treatments of four levels of N (no N application (N1), 90 kg (N2), 120 kg (N3), and 150 kg (N4)); urea was the source of N. A mixed commercial fertilizer was applied at the rate of 25 kg ha^{-1} of phosphorus (P) (in the form of phosphorus pentoxide (P_2O_5)) and 75 kg ha^{-1} of potassium (K) (in the form of dipotassium oxide (K_2O)). The rice variety 'spring' resulted in the highest yield in Guilan Province. Field experiments (*Table 1*) were carried out on a clay soil tissue (9% sand, 44% silt, and 47% clay). For determining the soil characteristics site of this experiment, several random samples of soil were obtained from a depth of 0–30 cm before transplanting and adding fertilizers and, after mixing soil samples, soil was sent to the laboratory for analyzing the soil in terms of physical and chemical properties (the results are shown in *Table 1*). Nitrogen fertilizer was applied three times during bolting, 50% at the time of transplanting to the field, 25% at maximum tillering, and 25% of the land. Irrigation was applied 20 days after transplanting management and to measure how many water counters in each plot were used.

Daily weather data on maximum and minimum temperatures, rainfall, and sunshine hours were collected for the entire growing season from a meteorological station beside the Iranian Rice Research Institute (*Fig. 1*).

Table 1. *Characteristics of the used soil*

pH of dough	Total N (%)	OC (%)	P (ppm)	K (ppm)	CEC (meq/100 g)	Tissue	Depth soil (cm)

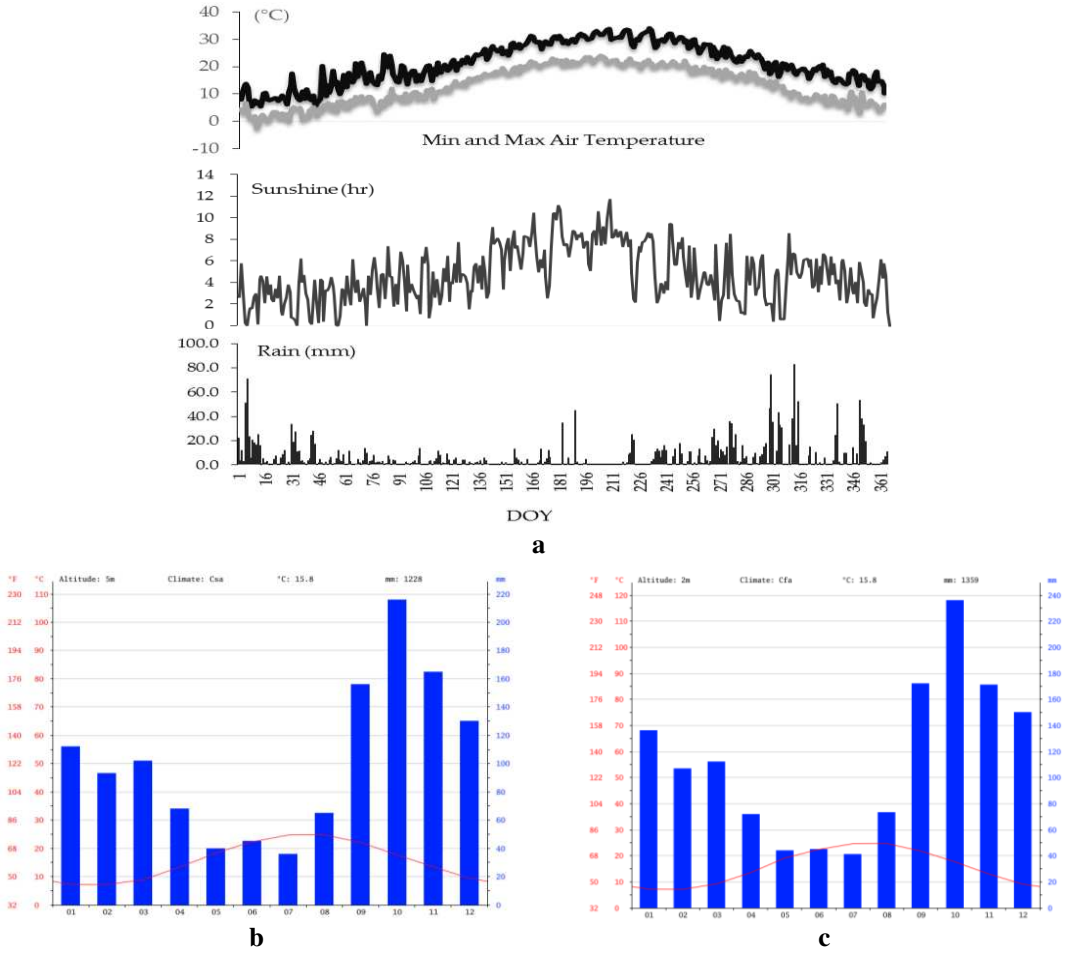

Figure 1. *a: Measured daily meteorological variables at the study site for the two years of the experiment (from 1 January 2013–22 September 2014). DOY is day of year. b, c: Measured daily Temperature and rainfall at the study site for the two years of the experiment (2013, 2014)*

The continuous irrigation amount during the growing season was about 5 cm. Samples of each plot have been studied with respect to the growth using a destructive analysis method. Plant harvesting was on 11–15 August in all years of the experiment. All plots were bonded and separated by 0.5-m-wide strips of bare soil to avoid lateral movement of water and nutrients among treatments. The plots were hydrologically separated by plastic sheets installed 40 cm below the soil surface to restrict water and N flow between adjacent plots. Measurements of samples were collected at the beginning of transplanting in all treatments, Crop samples were taken at regular intervals of 10–15 days to determine leaf area index (LAI) and total and panicle biomass over two years. The LAI of plants was measured by a Model GA-5 manufactured by OSK Japan meter. In other to evaluation of biological yield, 1 m^2 of each plot were harvested (Includes all vegetative and reproductive organs of plants top of the soil) and then placing it in the oven until (Drying machine plant material) dried.

CropSyst model descriptions

Version 3 of the CropSyst model was used in this study. Crop development was simulated on the basis of the accumulated thermal time required to reach each

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_22772293
© 2018, ALÖKI Kft., Budapest, Hungary

phenological stage. In order to evaluate the simulation effects of nitrogen fertilizer and irrigation on the growth yield of rice, some models were used which simulate the plant growth on a day-by-day and phase-by-phase basis to obtain the results. To run the models four sets of data were required as input. File locations, soil, and plant management definition, application, and all required parameters of the model range were stated in the manual model (Stöckle, 2003). Model inputs for the simulation consisted of daily weather information (including maximum and minimum temperature, precipitation, and solar radiation), soil (including physical and chemical properties of each layer), the cultivar characteristics (such as growth factors, growth, yield, and biomass) and crop management practices (including the use of irrigation and fertilizer), and the culture system (Amiri and Rezaei, 2013b).

Simulation model

Yield simulation of the CropSyst model depended on the total biomass, which accumulated at physiological maturity (B_{PM}), and the harvest index (HI = harvestable yield/aboveground biomass; *Eq. 1*):

$$Y = B_{PM}\,HI \qquad \text{(Eq.1)}$$

Where Y is yield (kg m^{-2}) and B_{PM} is also in kg m^{-2}.

To introduce the processes of the CropSyst simulation, some equations are more important in this study, so they are presented here. Crop transpiration is dependent on biomass production (B_{Pt}) and LAI were effective in the output of CropSyst based on calibration results. The third equation is the yield, which was one of the main evaluated outputs. Therefore, these three equations are presented in this paper; also, more information can be found in another study (Stöckle et al., 2003). There is a relationship between crop transpiration and biomass production, which is based on carbon and vapor exchange in leaves. Thus, the potential daily biomass production can be calculated as (*Eq. 2;* Kumar et al., 2006):

$$AGB_{PT} = \frac{k_{BT} T_P}{VPD} \qquad \text{(Eq.2)}$$

Where AGB_{PT} is the crop transpiration-dependent biomass production (kg m^{-2} day^{-1}), T_P is the crop potential transpiration (kg m^{-2} day^{-1}), VPD is Average daily steam pressure loss (kPa), and K_{BT} is a biomass-transpiration ratio (kPa).

Water productivity estimation

In this study, the amount of water productivity was calculated (*Eq. 3*) based on the sum of water and rainfall, with respect to the amount of water productivity WP_{I+R} (kg/m^2), where Y is the yield (kg/h), I is the amount of irrigation (mm), and R is the precipitation (mm). The amount of rainfall, evaporation, average maximum daily temperature, and irrigation in the years studied is shown in *Table 2*.

$$WP = \frac{Y}{I + R} \qquad \text{(Eq.3)}$$

	496		461	N_3	
	466		429	N_4	

Calibration of the models

Initially, soil, weather, and irrigation files were prepared similarly for all models. Then measured and estimated crop parameters were inserted in the models. After calibration of the model and determination of the optimal coefficients, a validation model was performed by using the second year of treatment (*Table 3*). In these models, plant development was measured with respect to temperature time (°C–days). From the start to the increase in the planting stage, temperature time must be specified for each phenological stage. Based on the type of plant phenology, the important and fundamental steps included the emergence, flowering, time of maximum leaf area index, end of flowering, start of grain filling, and physiological maturity.

Table 3. *Some relevant crop parameters used in the CropSyst model for the rice simulation*

Parameters	Amount	Unit
Optimum temperature (T_{opt})	27	°C
Maximum water uptake	10	mm day^{-1}
Maximum rooting depth	1.5	m
Maximum expected leaf area index (LAI)	5.9	$m^2 m^{-2}$
Specific leaf area (SLA)	30	$m^2 kg^{-1}$
Leaf duration	750	°C-days
Extinction coefficient for solar radiation (k)	0.5	-
Emergence Stage	135	°C-days

Model evaluation

Several statistical methods were used to compare the simulated and observed results. In this article, we used a combination of graphical analyses and statistical measures to compare the simulated and measured final biomass and yield and LAI graphically. In this article, we evaluated model performance by using the absolute root mean square error (RMSE), normalized root mean square error ($RMSE_n$), coefficient of residual mass (CRM), coefficient of determination (R^2), and effective modeling (EF). RMSE, $RMSE_n$, CRM, and R^2, index of agreement (IOA), and EF characteristics are common tools to test the goodness of fit of simulation models (*Eqs. 4–9;* Pala et al., 1996; Fila et al., 2003):

$$RMSE = \left[\frac{\sum_{i-1}^{n} \left(P_i - O_i \right)^2}{n} \right]^{1/2} \quad \text{(Eq.4)}$$

$$RMSEn = \frac{RMSE}{\overline{O}} \quad \text{(Eq.5)}$$

$$R2 = \frac{\sum_{i-1}^{n} \left(P_i - O_i \right)^2}{\sum_{i-1}^{n} \left(O_i - \overline{O} \right)^2} \quad \text{(Eq.6)}$$

$$EF = \frac{\sum_{i-1}^{n} \left(O_i - \overline{O} \right)^2 - \sum_{i-1}^{n} \left(O_i - \overline{O} \right)^2}{\sum_{i-1}^{n} \left(O_i - \overline{O} \right)^2} \quad \text{(Eq.7)}$$

$$CRM = \frac{\sum_{i-1}^{n} O_i - \sum_{i-1}^{n} P_i}{\sum_{i-1}^{n} O_i} \quad \text{(Eq.8)}$$

$$IOA = \frac{\sum_{i-1}^{n} \left(P_i - O_i \right)^2}{\left| \left(P_i - \overline{P} \right) \right| + \left| \left(O_i - \overline{O} \right) \right|} \quad \text{(Eq.9)}$$

Where Pi is the simulated value, Oi is the measured value, and n is the number of measurements. The simulation was considered excellent if the normalized RMSE was less than 10%, was considered good if the normalized RMSE was greater than 10% and less than 20%, was considered fair if the normalized RMSE was greater than 20% and less than 30%, and was considered poor if the normalized RMSE was greater than 30%. The amounts of RMSE and $RMSE_n$ were at an optimum status if the simulated and observed were the same, and was equal to zero. If the *p*-value (*p*(t)) from the paired *t*-test was greater than 0.05, it was concluded that there were no significant differences existing between the measured and simulated values (Eitzinger et al., 2004). The IOA is also used to evaluate the model; it is a descriptive parameter value between zero and one, indicating how weak the model is in predicting results (Eitzinger et al., 2004).

Results and discussion

Calibration of the models

Initially, soil, weather, and irrigation files were prepared similarly for all models. Then, measured and estimated crop parameters were inserted in the models. The crop parameters used in this study are presented in *Tables 4–6* for the models. A revalidation of the model depends upon its successful calibration based on field experimental data, and the accurate estimation of the specific model's coefficients in a given environment (Eitzinger et al., 2004).

Validation and evaluation of the models

The model validations were based on the comparison between simulated and observed data for all treatments other than those used in the model calibration. Results showed that the average grain yield of RMSE under calibration and validation conditions was 461 and 847 kg per hectare, respectively. The average $RMSE_n$ of grain yield under calibration and validation conditions were 7% and 15%, respectively. The amounts of the measured grain yield showed a desirable simulation of this parameter in the agriculture season by the model which we could then use in irrigation planning and nitrogen rice fertilizer management (*Tables 4* and *6*). Araya et al. (2010) who report a deviation range of validation data of −13 to 15.1% for grain yield.

Table 4. *Observed and simulated grain yields and relative error for rice in 2013*

Treatment		Relative error (%)	Simulation grain yield (kg/ha)	Observed grain yield (kg/ha)

Table 6. *Validation results of crop parameters in the CropSyst model for rice simulation in 2014*

Plant parameters	EF	C_{RM}	IOA	T test	$RMSE_n$ (%)	RMSE	R^2	Number of samples
Biological Yield	0.80	–0.04	0.96	0.27	10	1219	0.82	12
Grain Yield	0.98	–0.14	0.98	0.03	15	847	0.84	12
LAI	0.38	–0. 7	1	0.02	68	82	0.82	12

Notes: $RMSE_n$ (%) is the normalized root mean square error; R^2 is the adjusted linear correlation coefficient between simulated and measured values; EF is the efficiency of model; IOA is the index of agreement; T test: tested the amounts with respect to the mean; CRM is the coefficient of residual mass

The results of treatment evaluations showed that the average RMSE was equal to 847 kg per hectare, relative RMSE was 15%, and CRM was –0.14, which, compared with 386 kg per hectare, 8%, and 0.12, was greater than the calibration phase, and indicates the closeness of the simulation amounts and validation values. For both calibration and validation phases, the amount of CRM that excluded the maximum LAI and dry material in the first year was negative, which showed that the amount in the simulation in most treatments was more than the observation amounts. In other words, in most treatments, the estimated amount of the model was more than the real amounts. Ouda et al. (2015), who reported The RMSE was 8% of the mean observed yield.

The EF under the calibration and evaluation conditions was also 0.89 and 0.87, respectively. Based on the studies, simulation of this model under different levels of nitrogen was performed on corn plants, and the EF of the calibration and evaluation phases were 0.52 and 0.90, respectively (Mohseni, 2008). Additionally, in other studies of the simulation of wheat plant yield by the CropSyst model, the value of the RMSE was equal to 0.21 Mg/ha and the value of the correlation factor was 0.72 (Sadras, 2002). Modeling efficiency (EF) were 0.82 and 0.75 for biomass and soil water content, respectively (Bellocchi et al., 2002; *Tables 5* and *6*)

According to the research on the simulation of rice plant yield in North Italy, using the CropSyst model, the $RMSE_n$ amplitude of dry material simulated measured for the calibration and validation year was 11%–29% and 10%–52%, respectively, and the CRM amplitude of dry material simulated measured for calibration and validation years was –0.03% to 0.17% and –0.02% to 0.17%, respectively (Confalonieri and Bocchi, 2005). Moreover, based on studies of the evaluation of the CropSyst model on the simulation of both the effects of water and nitrogen on wheat plants, the value of the RMSE for the simulation yield in the CropSyst model was 0.36 Mg/ha. The value of the RMSE for the simulation of dry material in CropSyst was 1.27 Mg/ha (Saadati et al., 2012). The comparison of these results with the values gained in this research for rice plants showed that the CropSyst model could also simulate the rice yield well.

Results showed that the average RMSE yield biology under calibration and validation conditions were 1264 and 1219 kg per hectare respectively. The amounts of average $RMSE_n$ yield biology under calibration and validation conditions were also 9% and 10%, respectively. The EF that was obtained under calibration and evaluation conditions is also equal to 0.99 and 0.80, respectively. For performance recognition of the CropSyst model in the simulation of dry material production and the yield of the reaction to the water and nitrogen, researchers studied the separate products in a season under experimental conditions with extensive preparations from dry to full irrigations

© 2018, ALÖKI Kft., Budapest, Hungary

and from low nitrogen existing in the soil to high level conditions. In these evaluations, the reported value of RMSE was 0.443 t/ha (Pala et al., 1996). Simulation results showed satisfactory application by suitable value of RMSE of biomass growth (0.58-3.52 t ha^{-1}) and water content in the soil profile (20.9-50.6 mm) (Raza et al., 2014).

Results showed that the average RMSE under calibration and validation conditions were 1 and 0.80 m^2 of leaf surface in each square meter at ground level. The values of $RMSE_n$ for the maximum LAI under calibration and validation conditions were 29 and 23, respectively. The results showed an acceptable accuracy of this model for simulation of the maximum LAI. The amounts of the measured parameters indicated that the medium simulation of this parameter, as well as the agriculture season by which this model can be used for planning of rice irrigation and nitrogen fertilizer management. The EF under calibration and evaluation conditions obtained were 0.12 and 0.32, respectively.

Our observations showed that relative error of simulation yield in the calibration phase was –15% to 15% and, in the evaluation phase, it was between 2% and 52%. Additionally, the amount of biomass simulation relative error in the calibration phase was –22% to 2% and in the evaluation phase, it was between –10% and 27%. Other research indicated that the amplitude amount of error for the growth simulation of the wheat plants between the simulation and observation yield in this plant was 2.7–37.2% and, for dry material, it was between 2.2–30% (Mohseni et al., 2008). Results showed that R^2 for the calibration model data was 0.84, which means that the model is suitable for grain yield simulation. Additionally, a relatively high R^2 value means low dispersion of the data (Amiri and Rezaei, 2013a).

The amount of IOA (Willmott agreement index) was one of the most important indicators of the plants' assessment modeling. The IOA under calibration (first year) conditions for maximum LAI, grain yield, and dry material was 1, 0.99, and 0.97, respectively. Additionally, the IOA under evaluation conditions for maximum LAI, grain yield, and dry material was 1, 0.98, and 0.96, respectively. Results of the research by Zhang et al. (2011) show that IoA was in the excellent range (Zhang et al., 2011).

Tables 7–11 show the comparisons between the amounts of simulated and measured grain yield.

Results showed a change from flood to intermittent irrigation, the real grain yield decreased, and the increase of nitrogen consumption led to the grain yield increasing. The model also showed a decrease and an increase in simulated grain yield pretty well. The minimum amount of grain yield was under the condition of the non-use of nitrogen fertilizer, and the maximum yield was under the nitrogen treatment condition of 120 kg N per hectare, with intermittent irrigation was every 5–8 days.

It is worth noting that low irrigation is also effective in this matter. In 5-day irrigation management, the model could not simulate the yield well because of incompetent ability to estimate grain yield. The existence of some weather parameters, such as wind speed and carbon dioxide changes in the farm, which were not present in the model (the model anticipates grain yield according to other climate parameters) might also be another reason for the decrease in foresight accuracy by the model (Honar et al., 2010).

In testate fertilizer amounts, the error percent of the model was higher, but it will be decreased by increasing the fertilizer amounts so that after forth fertilizer application the error will be erased completely. Changes in the amount of simulated grain yield by the CropSyst model for the first and second year are shown in *Figure 2*. The minimum amount of grain yield was under the condition of the non-use of nitrogen fertilizer, and maximum yield was under nitrogen treatment condition of 120 kg nitrogen per hectare and intermittent irrigation was every eight days. The results showed that the gain yield would increase by increasing the nitrogen consumption. The model also showed fluctuations in simulated grain yield rather well. The amount of grain yield will increase by adding more nitrogen via irrigation management, but in higher levels of nitrogen (150 and 120 kg ha^{-1}) a slight increase will be shown. According to other indices to

© 2018, ALÖKI Kft., Budapest, Hungary

assess irrigation regimes and fertilizer levels, the most suitable treatments regarding environmental aspect were 5-day irrigation regime and 45 kg N ha^{-1} (Zare et al., 2014).

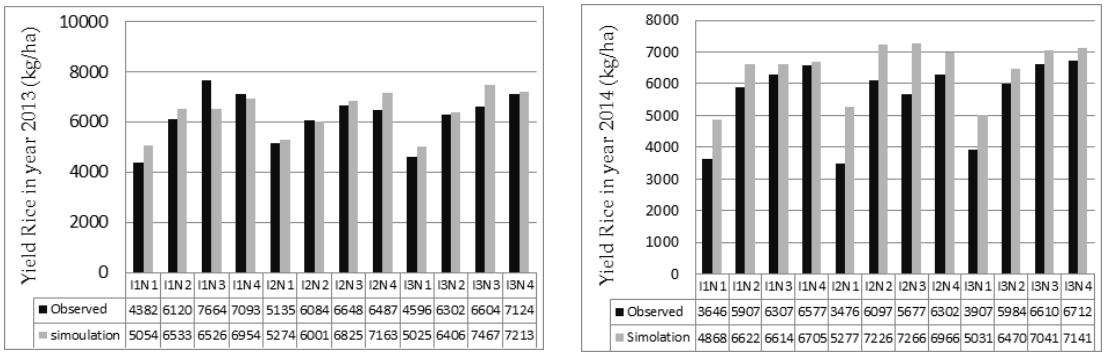

Figure 2. *Observed and simulated grain yields for rice in 2013 and 2014. Irrigation. (I1 = continuously flooded, I2 = 5 per day, I3 = 8 per day) and N fertilizer (N1 = 0, N2 = 90, N3 = 120, N4 = 150 (kg/ha))*

On the other hand, the grain yield will decline under flood irrigation conditions. Additionally, by changing the irrigation model from flood to intermittent treatments of every 5–8 days, simulated grain yield will show a slight increase; this indicates that the amount of nitrogen consumption is more than the nutritional needs of the spring type of rice in this research. Changing of the irrigation from flood to intermittent will reduce hydrostatic pressure at the ground level, which causes a reduction of water loss through leakage and deep percolation (Bouman et al., 2007).

Results of the research showed that the change in flood irrigation management reduced deep losses. Therefore, investigation of results about the amount of leakage and deep percolation in the period of the research showed the minimum and maximum water loss through deep percolation as 117 and 221 mm, respectively, under flood and non-flood management (Amiri and Rezaei, 2013a). Results also indicated that changing from flood to non-flood irrigation reduced irrigation water, which was consistent in other studies (Pirmoradian et al., 2004; Amiri and Rezaei, 2013a).

Other studies showed that changing the irrigation method from flood to non-flood will result in saving irrigation water. Due to the increasing competition for water, water-saving technologies, such as alternate wetting, drying, and aerobic rice are being developed to reduce water consumption while maintaining a high yield. The components of the water balance of these systems need to be disentangled to extrapolate water savings from the field scale to the irrigation system scale (Bouman et al., 2007). As shown in this study, irrigation and N fertilizer management improved the efficiency of water consumption and, thus, reduced the impact of water shortages. The results of this study provided a basic information base for making irrigation and N management decisions in the study area.

Water productivity estimation

The amount of water productivity was calculated based on the sum of water and rainfall, as shown in *Table 12*. The results show that the change in flood irrigation management increased water productivity. The model also showed the simulated

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

decrease and increase rather well. Additionally, results from the treatments of I_3N_3 and I_3N_4 in both models showed the greatest amount of water productivity was in the first and second years. This result suggests that the mechanism of the plant's production performance, despite the reduction in available water to the surface, has been successful. Furthermore, the value of the evaporation results in the CropSyst model showed that, in irrigation flood management, up to 39% of evapotranspiration occurs. While the value of intermittent irrigation management of five and eight days, respectively, was 35% and 32%. The amount of water productivity was calculated based on the sum of water and rainfall, with greater reliance on management practices, especially irrigation methods. The results Jalotal et al. (2006) suggest that water productivity in rice can be enhanced mainly by adjusting the transplanting date. The enhanced water productivity in delayed transplanted paddy was due to reduction in ET while the yield remained unaffected (Jalotal et al., 2006). Results of the research by Umair et al. (2017) E was 30% of total ETa and results closely matched the observed data collected during the MLM and isotopes approach (Umair et al., 2017).

Results of the research by Amiri and Rezaei (2013a) show that the change in flood irrigation management reduces deep losses (Amiri and Rezaei, 2013a). So that investigation of results about the amount of leakage and deep percolation in a period of the research show the minimum and maximum of water dissipation through deep percolation as 117 and 221 mm, respectively, in flood and non-flood conditions. Results of that study also indicates that changing from flood to non-flood irrigation reduces irrigation water consumption, which is consistent with the research of Pirmoradian et al. (2004). They showed that changing irrigation methods from flood to non-flood will result in saving irrigation water (Pirmoradian et al., 2004).

Irrigation and N fertilizer management, as shown in this study, improves the efficiency of water use and, thus, reduces the impact of limited water. The results of the study provided an information base for making irrigation and N management decisions in the study area. These results suggest that due to the good simulation models and maximum data consistency that the CropSyst model can be used to support the management and optimization of water and nitrogen fertilizer to cultivate rice.

Conclusions

The CropSyst model was sufficiently accurate in the simulation of yield underwater-saving and crop density conditions for our study site. The results of this study clearly indicate that the CropSyst model can be used with a high degree of accuracy for yield simulation and were similar to those of other researchers (Asadi et al., 2003; Bouman et al., 2007; Amiri and Rezaei, 2013a; Umair et al., 2017). The CropSyst model could also simulate the rice yield rather well. An agreement index (IOA) was also used to evaluate the model. Given the negligible difference between observed and simulated value performance, it can be concluded that this model might be useful as a simulated model of the effect of water and nitrogen management which can be used in yield estimates. The results of this study showed that the model generally predicted grain yield and final biomass fairly satisfactorily across a range of datasets covering levels of irrigation and N conditions within two years in Northern Iran.

Thus, the most optimal conditions to offer to farmers was under nitrogen treatment condition of 120 kg nitrogen per hectare and intermittent irrigation was every eight days.

In the current study, the CropSyst crop simulation model was calibrated, validated, and used as a tool to provide estimates of water productivity of rice under a range of N fertilizer and water regimes in a humid region of Iran. The simplicity of the model in its required minimum input data, which are readily available or can be easily collected, makes it user friendly. The authors suggest that for better validation of models using other models and other concentration Nitrogen and Irrigation Management in Other areas suitable for rice cultivation.

Aknowledgments. The authors are grateful to the Rasht Rice Research Institute, for providing resources and for providing facilities.

Author contributions. Farzad Paknejad, Ebrahim Amiri, Bahram Mirshekari, Mojtaba Mirakhori designed and performed the research. Ebrahim Amiri analyzed the data, discussed the results and wrote the paper. Bernd Honermeier, commented and edited the manuscript.

Conflicts of interest. The author claimed no conflict of interest.

(Received 4th Dec 2017; Accepted 7th Mar 2018)

Abstract. The present study primarily aims to investigate the histopathological effects which a glyphosate based herbicide could cause on the gills of two economically important Cyprinid fish (common carp and bighead carp), and to determine which species is more sensitive in terms of glyphosate contamination. The pesticide concentrations tested in laboratory conditions were decreasing (72 mg/l, 40 mg/l and 20 mg/l) and prepared by dilution of the stock solution of the commercial product used in plant protection. The experiment was short-term of 96 h. In general, the herbicide caused different pathological alterations in the fish gills, such as lamellar lifting, edema, proliferation of the glandular cells and epithelium, covering the gill filament, fusion, vasodilatation of the secondary lamellae and aneurysms. In addition, we observed a tendency towards the enhancement of the gill histological changes which degree of expression was proportional to the increasing pesticide concentrations. However, bighead carp was more sensitive compared to common carp when it comes to the tested chemical and the alterations in the gill histological structure were more pronounced.
Keywords: *histopathology, fish, biomarkers, pesticide, contamination*

Introduction

Pollution of water is mainly due to contamination with hazardous chemicals from agricultural runoff and waste water from household and different industries. One of the major chemicals from agricultural runoff are pesticides which play an important role in the agricultural productivity and have been widely applied to protect agricultural crops. On the other hand, they can cause severe damage to non-target organisms, both in the terrestrial and aquatic environment (Magar and Shaik, 2013; Grung et al., 2015).

The glyphosate herbicides, post-emergent herbicides with a broad-spectrum and low selectivity, have been intensively applied on numerous field cultures, urban and industrial areas to control unwanted plants, including the macrophytes in aquatic systems (Nedelkoska and Low, 2004; Kolpin et al., 2006; Cąvas and Konen, 2007). In addition, most of the commercial formulations of herbicide-based glyphosate consist of glyphosate isopropylamine salt (IPA) and a surfactant in order to increase the herbicide's efficacy (Tsui and Chu, 2003).

Fish are among the group of non-target aquatic organisms which represent the largest and most diverse group of vertebrates and a number of characteristics make them excellent experimental models for toxicological research (Raisuddin and Lee, 2008). In this sense, fish are often used as indicators of pesticide water contamination due to the fact that they respond to it with physiological and behavioral alterations (Banaee et al., 2011, 2013; Murthy et al., 2013).

Cyprinidae is a family of freshwater fish which consists of 1600 species. This makes it the most diverse family. The most popular species, common carp (*Cyprinus carpio* Linnaeus, 1758) is a wide-spread and econocmically important fish which has immense significance for aquaculture. Carp is also very popular in sports fishing due to its fast growth rate, hardiness and prolific breeding in confined water. Furthermore, it has been proposed as a test organism in toxicological research because it is relatively insensitive and as a consequence, survives and accumulates contaminants even at heavily polluted sites (Snyder et al., 2004; Brumbaugh et al., 2005; Reynaud and Deschaux, 2005; Oruc and Usta, 2007; Reynders et al., 2008; De Boeck et al., 2010; Georgieva et al., 2014; Stoyanova et al., 2015). Bighead carp (*Aristichthys nobilis* Richardson, 1845) is another Cyprinid species which has become popular in aquaculture in recent years. It is usually bred with common carp and silver carp (*Hypophthalmichthys molitrix* Valenciennes, 1844) for better results. Similarly to common carp, it grows quite rapidly and its meat has started increasingly to be preferred for consumption in more countries (Čihař, 1975; Karapetkova and Jivkov, 2010). However, it has not been that widely studied in terms of the effects of different pollutants compared to common carp (Li et al., 2005; Hu et al., 2010; Li et al., 2014). Thus, in the present study we propose this Cyprinid species together with common carp as model species for ecotoxicological research.

Viana et al. (2013) suggest that the biomonitoring and risk assessment processes should include analyses at different levels of biological organization, from sub-cellular and cellular analysis of tissues and organs, to those of population and community levels. Therefore, Van der Oost et al. (2003) also suggest the use of biomarkers as biological indicators from an exposure to a stressor responding in various ways which can be successfully applied. In this sense, according to Van Dyk and Pieterse (2008) histology is an important diagnostic and sensitive tool to detect the direct effects of chemical compounds on target organs and can therefore, be used to assess the health of fish populations in contaminated aquatic systems. The advantage of histology as a biomarker lies in its intermediate location with regard to the level of biological organization. Furthermore, the histological changes appear as a medium-term response to sub-lethal stressors, and histology provides a rapid method to detect the effects of irritants, especially chronic ones, in various tissues and organs (Devi and Mishra, 2013; Binukumari and Vasanthi, 2014). Thus, the histopathological changes due to various pesticides have been extensively studied in different fish species (Ullah and Zorriehzahra, 2015).

The gills are efficient tools for monitoring of aquatic ecosystems because of their large area which is in contact with the water and their high permeability (Oliveira Ribeiro et al., 2005; Evans et al., 2005; Vigliano et al., 2006). They are the main respiratory organ and have a large surface area, a thin water-blood diffusion distance and play an important role in osmoregulation and acid base equilibrium. In fish, the gills are also the main target organs of xenobiotic molecules. The changes in gill tissue affect respiration and ion uptake in freshwater fish (Fernandes and Mazon, 2003; Fanta et al., 2003; Bhuvaneshwari et al., 2015). Moreover, Nowak (1992) states that the gill histological changes, such as hyperplasia and hypertrophy, epithelial lifting, and aneurysms have been more pronounced in this particular organ after pesticide exposure.

The impact of glyphosate on fish has been studied mainly in commercial products which included other active ingredients and not just glyphosate itself (Neškovic et al., 1996; Ramirez-Duarte et al., 2008; Ayoola, 2008). We did not find any data regarding the effects of glyphosate on bighead carp which is economically important species in aquaculture and it is artificially bred together with common carp for better results. Thus, the present study primarily aims to investigate the histological effects which a glyphosate based herbicide could possibly cause on the gills of two economically important Cyprinid freshwater fish (common carp and bighead carp) and to determine which species is more sensitive in terms of pesticide contamination. The second objective aims to establish the degree of expression of each histological alteration which could be observed.

Material and Methods

Chemicals and experimental setup

The test pesticide in the present study was a glyphosate (IUPAC name N-(phosphonomethyl)-glycine) based herbicide which is used to control grasses, herbaceous plants, including deep-rooted perennial weeds, some broadleaf trees, shrubs, and conifers (Standing Committee on Plant Health, 2001). We used decreasing glyphosate concentrations of 72 mg/l, 40 mg/l and 20 mg/l under laboratory conditions for a total acute period of 96 h. All three concentrations were prepared in advance by dilution of the commercial product stock solution used in plant protection, given by the company which produces the chemical. The concentrations we used are lower than those actually applied in agriculture as a particular amount of the chemicals enter the water ecosystems through rainfall and wind drift.

Forty healthy common and bighead carps were obtained from the Institute of Fisheries and Aquaculture, Bulgaria where the fish are reared under strict controlled conditions. The fish were of the same size-group (mean length 17.6 cm ± 2.9 and mean body mass 46.3 g ± 8.4 for common carp and mean length 18.65 cm ± 1.33 and mean body mass 53.02 g ±5.3 for bighead carp) with no observed external pathological abnormalities. After transportation, the fish were moved in 100 l glass aquaria with chlorine-free tap water (by evaporation) to acclimatize for a week. They were randomly divided into four groups, including control (n=10) and not fed during the experiment.

The water physico-chemical characteristics, such as pH, temperature, dissolved oxygen, oxygen saturation and conductivity were measured once per day according to a standard procedure (APHA, 2005). All experiments were conducted in accordance with Directive 2010/63/EU.

Histopathological analysis

The fish dissection was performed according to the procedures given in the EMERGE Protocol (Rosseland et al., 2003). The samples were placed in vials with 10% neutral buffered formaldehyde solution (pH 7.0). Then they were rinsed in tap water, dehydrated in a graded series of ethanol concentrations, cleared in xylene, embedded in paraffin wax with melting point of 54–56 ºC, sectioned to a thickness of 5–7 μm using a rotary microtome (Leica RM 2125) and mounted on sterilized glass slides. The sections were then deparaffinised, stained with hematoxylin and eosin (H&E) for histological examinations and prepared for light microscopy analysis (Romeis, 1989).

Semi–quantitative scoring

Ten paraffin sections were produced from the gills of each specimen. Each section was taken from a different location from the paraffin block, instead of in series. The histological alterations in the gill structure of each paraffin section were analyzed by observing the whole gill surface. The degree of expression was studied, including the corresponding changes in the gill surface in relation to the normal histological structure. The histological alterations in the gill epithelium were determined semi–quantitatively by using the grading system of Pierce et al. (1978) and Zimmerli et al. (2007) which we combined and modified. Each grade represented specific histological characteristics and was categorized as follows:

(0) – no histological alterations which represented normal histological structure;
(1) – mild histological alterations;
(2) – moderate histological alterations;
(3) – severe histological alterations;
(4) – very severe histological alterations in the gill surface architecture.

Statistical analysis

The statistical program which was used was Graph Pad Prism 7 for Windows. In order to study the differences between the degree of expression of each histological alteration between the control and treated with different glyphosate concentrations groups, *t*-test was applied. *P* value was set at 0.05. This was possible as for each degree of expression a numerical value from 0 to 4 was given. Ten fish from each test group and species were analyzed. The results are presented as average.

Results and Discussion

No histopathological changes were observed in the control fish gills. Gill structural details of the control carps are shown in *Figure 1A* and *2A*. With regard to the grading system, proposed as the control carp histological characteristics, these were evaluated as relatively normal (0). Comparing both Cyprinids exposed to glyphosate, we found in the gill structure proliferative changes (lamellar lifting, edema, proliferation of epithelial covering the filament and glandular cells, proliferation of cartilage, fusion), degenerative changes and changes in the circulatory system (vasodilatation of the primary sinus and blood vessels in the secondary lamellae) which all varied in their degree of expression (*Figure 1, 2*).

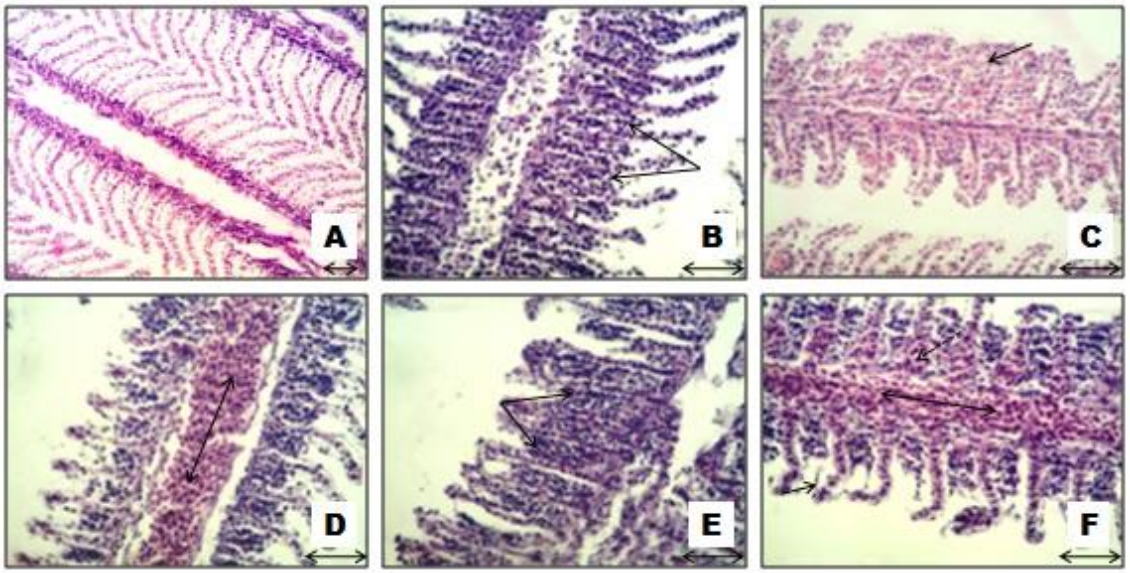

Figure 1. *Histopathological alterations in common carp gills, (H&E): A – control group fish gills, x200; B – proliferation of the gill epithelium, x400; C – fusion of the secondary lamellae, x400; D – vasodilatation of the central venous sinus, x400; E – epithelium proliferation, x400; F – lamellar lifting, vasodilatation of the central venous sinus and the secondary lamellae (dashed arrow), x400*

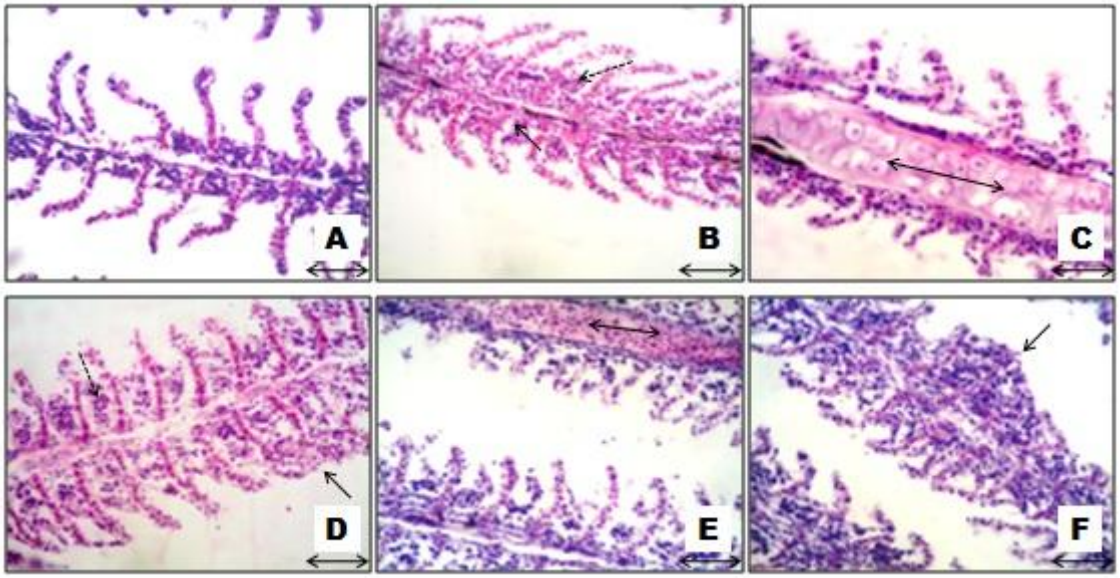

Figure 2. *Histopathological alterations in bighead carp gills, (H&E), x400: A – control group fish gills; B – proliferation of the gill epithelium (dashed arrow) and edema; C – proliferation of the cartilage tissue; D – proliferation of the gill epithelium (dashed arrow) and fusion; E – vasodilatation of the central venous sinus; F – fusion of the secondary lamellae*

For the degree of expression of each alteration the statistical analysis showed that there was a significant difference ($P < 0.05$) between the control for both Cyprinids and all test groups exposed to glyphosate (72 mg/l, 40 mg/l and 20 mg/l).

Table 1 shows that lamellar lifting and edema were more pronounced – in severe and very severe degree of expression in both tested species, when increasing the concentrations of glyphosate. We consider that lamellar lifting and edema actually represent a compensatory-adaptive mechanism which increased the distance between the epithelium and blood vessels in the secondary lamellae. Hence, the changes found in the fish gills could slow down the oxygen access into the blood circulatory system which in turn would result in a gas exchange limit. As reported by Schwaiger et al. (2004) and Camargo and Martinez (2007) lamellar lifting and edema could lead to oxygen deficiency and subsequent oxidative stress for the fish. In addition, we found proliferation of the filamentous epithelium as probably another type of compensatory-adaptive mechanism in the fish gills exposed at all herbicide concentrations. It increased the thickness and the layers of the different epithelial cells which could likely delay the toxicant access through the gills. Proliferation of the filamentous epithelium was expressed mainly in a severe degree in the gills of common carp, while in the bighead carp gills it was found in a very severe degree of expression. Furthermore, proliferation of the connective cartilage tissue, leading to increased volume of gill filaments, was presented only in the gills of bighead carp which showed specificity in regards to glyphosate contamination. Ramah (2011) also reported cartilage hyperplasia in *Ctenopharyngodan idella* gills under herbicide exposure but in general this histopathological alteration is not often found in fish gills under the influence of different pesticides. Fusion as a more severe form of proliferation of the filamentous stratified epithelium was presented in a similar degree of expression in both tested species. In terms of the proliferative changes, we consider that bighead carp showed higher sensitivity under the influence of glyphosate compared to common carp because we also observed very severe proliferation of the filamentous epithelium and cartilage hyperplasia.

We found changes in the gills circulatory system such as vasodilation in the secondary lamellae and the main venous sinus. Vasodilatation was presented in a moderate degree of expression in the bighead carp gills at all glyphosate concentrations, while this change was in such a degree in the common carp gills only at the highest glyphosate concentration (*Table 1, Figure 1, 2*). Therefore, we consider that bighead carp had higher sensitivity in relation to the pesticide effects which could be found even at the lower concentrations of the toxicant. It also enhanced the blood cell flow and increased the internal pressure of the blood vessels. However, aneurysms in the secondary lamellae were observed only in the common carp gills. Cengiz (2006) also reported aneurysms in the secondary lamellae in common carp gills under the effect of deltamethrin.

We did not found aneurysms in the bighead carp gills in our previous studies (unpublished data) related to pesticides effects, either. Thus, we suggest that the bighead carp blood vessels could have higher resistance to pesticide contamination. Despite of the internal pressure and vasodilatation in blood vessels, aneurysms in the secondary lamellae of the bighead carp gills did not occur (*Table 1*).

Degenerative changes in the gills were also presented in both fish species which were found in a moderate and severe degree in the bighead carp gills at all glyphosate concentrations, while they were presented in a severe degree in the common carp gills only at 72 mg/l glyphosate (*Table 1*).

The high degree of degenerative changes could lead to thinning of the epithelial filaments and secondary lamellae, which on the other hand could lead to more rapid toxicant penetration. Similarly to us, Santhakumar et al. (2001) reported histopathological effects such as degenerative and necrotic changes in fish gills under the influence of sublethal concentrations of monocrotophos. Ghanbahadur et al. (2015) found degenerative alterations and necrosis in *Rasbora daninonius* gills after acute and chronic endosulfan exposure. Such results were also reported in common carp gills under lindan exposure by Binukumari and Vasanthi (2014) and under deltamethrin exposure by Cengiz (2006), respectively. The observed proliferative and degenerative histopathological alterations in this study suggest the development of a two-way process in the fish gills under the glyphosate influence. On one hand, the toxicant induced a compensatory-adaptive process which was related to transport delay of the toxicant by lamellar lifting and edema, as well as induced process of mitosis in the gill epithelium and cartilage in the bighead carp gill. On the other hand, glyphosate induced degenerative changes which were related with necrotic processes. Regarding the two Cyprinids separately the t-test proved significant differences ($P < 0.05$) for the degree of expression of proliferation of glandular cells between the fish exposed to 20 mg/l and 72 mg/l. Similar differences were also proved for fusion and vasodilatation of secondary lamellae between 20 mg/l and 72 mg/l (*Table 1*). Regarding the degree of expression of the histological alterations in bighead carp, the statistical analysis proved significant differences for lamellar lifting and fusion between the groups treated again with the lowest and highest glyphosate concentrations.

Comparing the two fish species together, statistically significant differences were found in the degree of proliferation of stratified epithelium in common carp and bighead carp between 20 mg/l and 72 mg/l. These were also found for proliferation of cartilage tissue and aneurysms between 20 mg/l and 72 mg/l, and for degeneration of gill epithelium but between 20 mg/l and 40 mg/l ($P < 0.05$).

In sum, we observed proliferative and degenerative changes in the bighead carp gills at all glyphosate concentrations. However, pronounced proliferative histopathological alterations in the common carp gills were found at the highest pesticide concentration. These results showed bighead carp as a more sensitive species in comparison to common carp. Therefore, we believe that bighead carp is an appropriate species for ecotoxicological tests, as well as a good bioindicator for pesticide pollution of water bodies. We consider that the results from such *ex situ* experiments could be applied for better plant protection practices, in the field of water legislation for reducing maximum allowable concentrations of organic pollutants, and the protection of freshwater fauna by using bioindicators and applying histological biomarkers. Last but not least, we suggest that further research in this particular area need to be carried out in order to better study the glyphosate toxicity in different commercial mixtures used in plant protection, and its interactions (antagonistic and synergistic) with other pollutants.

Abstract. Medicinal plants have a proven long history for their effective use to prevent and treat diseases. During the recent decades, the modern drug discovery approaches have refocused on traditional medicinal plants because of their higher contribution for providing new drugs, drug candidates, novelty and mechanism insights. *Juglans regia* L. is very famous for providing precious and medicinal dry fruits which are extensively being used in many parts of the world. In this study four parts of *J. regia* i.e. fruits, leaves, stem bark and green husk were investigated for metal contamination by using atomic absorption spectroscopy and found that Cd contamination in its fruits, Cu and Mg concentration in all parts of *J. regia* (fruits, leaves, stem bark and green husk) were critically above the standard permissible limits. Methanolic extracts of various parts for *J. regia* were screened for antimicrobial activities against twelve different human pathogens which indicated that fruits, leaves, stem bark and green husk were proved to be potential source of antimicrobial activities in comparison to the standard clinical drugs i.e. ciprofloxacin and nystatin which was used as positive control. Whereas, *J. regia* fruit had potent antioxidant properties with IC_{50} value of 6.938693 mg mL^{-1}. Total phenolic contents were ranged from 12.6987 to 31.9685 mg of GA g^{-1} whereas, highest flavonoid contents were found in the fruit's extract which was 25.8231 mg g^{-1} and lowest in leaves extract of *J. regia* i.e. 7.2861 mg g^{-1}. Breast cancer is the top most prevalent cancer in women worldwide and is responsible for nearly 58% of all cancer deaths. The *Juglans regia* fruits, green husk, stem bark and leaves showed promising antiproliferative activities against MCF-7 breast cell lines. Fruit of *J. regia* was proved to be more potent as compared to other parts screened with highest antiproliferative activity i.e. GI_{50} 1.581722 at conc.1 mg/mL.
Keywords: *Juglans regia, toxic metals, antimicrobial, antioxidants, anticancer, total phenolic, flavonoids*

Introduction

Therapeutic plants are the manufacturing plants of medicinal phytochemicals which carry the nature designed unmatched structural novelties and properties that bind to bio macromolecules for the critical modulations to regulate disorders. These therapeutic plants are as yet being utilized extensively by rural people as natural remedies to treat diseases without legitimate standardization or regulations and that which poses genuine danger to human health especially, because of unwanted metals defilements and lack of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

dosage standardization that results into various unwanted interactions with bio macromolecules and toxins. Emergence of drug resistance (primarily due to wicked adaptive native nature of microorganisms and unregulated excessive use of anti-infectious drugs), emergence of new diseases, insufficiencies of the existing drugs and poor outcomes of drug discovery programs have created a highly critical emergency for the discovery and development of new antimicrobial drugs, templates and leads (Gutmann et al., 1998; Cohen, 1992). Natural biological processes essentially require energy which comes through oxidation responses but imbalanced and excessive oxidation due to reactive oxygen species (ROS). ROS are highly reactive species which unwantedly and harmfully modulate the structures and hence the functions of bio macromolecules including nucleic acids, proteins and lipids. Subsequently, this give birth to various biological disorders including deadly tumors, neurodegenerative, cardiovascular disorders, cataracts, diabetes, aggravations and atherosclerosis (Aruoma, 1998). Nature has unmatched metabolic designing and manufacturing enzymatic machinery which provide new drugs, leads, knowledge and inspiration for the design and discoveries of the medicinal and organic chemists for their efforts of new drug development as well as synthetic methodologies to fight diseases including caused by the deadly infections and reactive free radicals. Medicinal plants have been used for a long time in the treatment of various diseases. In today's World over 70% of the clinical molecular drugs are either natural products based or derived (Recio et al., 1989; Silver et al., 1993). Pakistan is naturally blessed with diverse climatic ranges that start from northern Himalayas to southern costal condition which lies after middle hot range. This diverse climatic range in turns provides diverse and rich fauna and flora contain numerous medicinal species. These medicinal species are being used by the local are traditional herbal medicines since long time. Pakistan has rich history, society and learning of utilizing these therapeutic species to treat and prevent different diseases. Thus, Pakistani is a major producer, user and supplier of medicinal species (Saeed et al., 2012). Biological screening of these therapeutic plants is the key beginning stage for the discovery of biologically relevant natural products from these medicinal plants. Unwanted and excessive generation of free radicals based diseases poses the urgent needs for the discovery of new antioxidant molecules and plants made, phenols, flavonoids, tannins and anthocyanidins are the most promising skeletons for the new drug discovery and development against these diseases (Saeed et al., 2012; Peschel et al., 2006).

Walnut (*J. regia*) possesses high medicinal properties because of its diverse natural chemical constituents and its mineral contents. Its different parts (leaves, barks and natural products) have been and are being utilized as a part of traditional herbal medicinal products. Leaves of *J. regia* are being used for treating venous inadequacy, hemorrhoids, hypoglycemia, and looseness of the bowels, microbial infections, dental caries contamination and strums bruises. Its leaves also treat skin diseases, purify the blood and helminthic, and are calming, astringent and depurative. They are being used as major herbal component for the treatment of clogging, endless hacks, asthma, looseness of the bowels, dyspepsia astringency, keratosis, diarrhea, hypoglycemia, sinusitis, cool and stomach throb (Mouhajir et al., 2008; Vaidyaratnam, 2005). Green husk of *J. regia* has cancer preventing properties and is antifungal, astringent, wart vendor impacts and treats skin diseases (Noumi et al., 2010; Amaral et al., 2003). Stem bark of *J. regia* is used to treat gastric, liver and lung tumor (Liu et al., 2004; Baytop, 1999). People utilized the fruits of *J. regia* as pharmaceutical to recuperate intestinal

© 2018, ALÖKI Kft., Budapest, Hungary

sickness, enhance memory shortages in transgenic mouse model of Alzheimer's ailment. It is being used as insect lithic, diuretic, anthelmintic and stimulant as well as for the treatment of low back torment, incessant pee, shortcoming of legs, unending hack, asthma and clogging (Tagarelli et al., 2010).

Keeping in view the importance of *J. regia* as dietary and folk remedial source, this study was aimed to assess the toxic metal contaminations, antimicrobial properties, antioxidant potential, phenolic contents and flavonoids contents of locally grown plants.

Material and methods

Plant material collection and preparation

Juglans regia L. is locally known as Akhrot and was collected from Rayala, Dhirkot, Azad Kashmir, Pakistan. Fruits, leaves, green husk and stem bark of *Juglans regia* L. were used to investigate the toxic metal contaminations, antimicrobial, antioxidant, total phenolic and flavonoids contents. The samples were carefully collected, separated and packed into bags and then transported to the laboratory for investigation.

Preparation of extract

Each part of the plant was shade dried for 10 days at room temperature then, were ground into fine powder with the help of electrical grinder and were stored at 4 ºC for further studies. The 100 g dried powder of each part of *J. regia* was separately macerated in 500 mL of methanol and kept at room temperature (25 ± 2 °C) for 10 days. After maceration period, the solvent extracted material was filtered. These extracts of plants portions were dried on rotary evaporator at low temperature (60 °C) and reduced pressure.

Acid digestion, sample preparation for the estimation of metal contaminations

One gram of dry powder of each part of *J. regia* was subjected to acid digestion for the estimation of their metal contaminations. 1 g of powder of each part of *J. regia* was taken in a glass beaker and 6 mL of concentrated nitric acid (HNO_3) and hydrogen peroxide (H_2O_2) were added (in 2:1 V V^{-1}). Mixture was stirred slowly at room temperature. The glass beaker was covered with a petri dish and heated at 70 °C for 3 h. Small volumes of HNO_3 and H_2O_2 were added to this mixture along with continuous heating at 70 °C till a clear solution was obtained. The excess of acid was evaporated and a semi dry mass was obtained. This semi dry mass was solubilized in 10 mL HNO_3 (0.1 M) and was transferred to a 50 mL volumetric flask. Total volume of solution was made 50 mL with the addition of distilled water.

Specification of AAS

Operating parameters of Atomic Absorption Spectrophotometer (AAS) AAnalyst^{700} was used in the analysis of trace metals using respective Wavelength in the range of 190-900 nm, Diffraction grating: 1800 lines mm^{-1} blazed at 236 nm and 597 nm, Grating area: 64 × 72 mm, reciprocal linear dispersion: 1.6 nm mm^{-1} (nominal), Focal length: 267 mm, Spectral bandwidths: 0.2, 0.7 and 2.0 nm, dual height, motorized slit drive for automatic slit selection with wide-range segmented solid-state detector.

© 2018, ALÖKI Kft., Budapest, Hungary

AAnalyst[700] used winlab 32 program to automatically calculate the mean of three reading of each samples of *J. regia* for each metal.

Determination of antimicrobial activity

Preparation of sample solutions for anti-microbial activity

10 mg of dried methanolic extract of each part of *J. regia* was dissolved in 1 mL of respective solvent in 5 separate air tight eppendorf tubes to prevent contamination and were kept for four days to ensure solubility.

Test microorganisms

Twelve common human pathogens viz., three gram positive bacteria (Staphylococcus aureus, Proteus vulgaris and Bacillus subtilis), four gram negative bacteria (Pseudomonas aeruginosa, Klebsiella pneumoniae, Escherichia coli and Bordetella bronchiseptica), three fungi (Aspergillus flavus, Fusarium solani, Rhizopus stolonifer) and two yeasts (Saccharomyces cerevisiae, Candida albicans) were used to assess the antimicrobial properties of the selected plant's parts.

Antimicrobial bioassay

In vitro screening of the methanolic extracts of four parts of *J. regia* was performed by disc diffusion method as described by (Scorzoni et al., 2007). Two series of experiments were conducted for testing the antibacterial, antifungal and anti-yeast activities of these extracts. These extracts were tested for their antimicrobial activities with reference to standard reference antibiotics (ciprofloxacin and nystatin). All the steps, inoculums, petri dishes, preparation of dilution were performed under aseptic conditions. The plates containing bacterial culture were incubated for 24 h at 37 °C whereas, fungi and yeast dilution were incubated at 25 °C for 72 h. After incubation period, all plates were examined for the presence of zone of inhibition (mm) to assess their antimicrobial activity. Each experiment was performed in triplicates.

Determination of antioxidant activity

Sample preparation for antioxidant activity

10 mg of dried methanolic extract of each part of *J. regia* was dissolved in 2 mL of methanol in 5 separate test tubes. DPPH radical cation decolorization assay was used to evaluate the antioxidant properties of the methanolic extracts of *J. regia*.

DPPH decolorization assay for antioxidant activities

DPPH (1,1-diphenyl-2-picrylhydrazyl) scavenging activities were analyzed to evaluate the antioxidant properties of the extracts of four parts of *J. regia* according to the method (Amarowicz et al., 2004). DPPH stock solution was prepared by reacting potassium per sulphate and DPPH (33.75 mg potassium persulphate + 64.8 mg of DPPH in 100 mL of distilled water) and allowed to stand in dark for 16 h to generate DPPH radical acation. Absorbance of the standard solutions was recorded at 734 nm ($Ao_{Control}$) after diluting with water up to respective volume. For percent scavenging activity (% RSC) of each extract, 1 mL of DPPH and 200 µL of each extract concentration (1 mg, 2 mg and 5 mg crude extracts each dissolved in per mL MeOH) were mixed and then

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_23072321
© 2018, ALÖKI Kft., Budapest, Hungary

followed by the addition of 1.8 mL water to make the volume of reaction mixture up to 3 mL. The absorbance (Ai) of each reaction was recorded for each sample at 734 nm and the blank used for each sample contained 2.8 mL of distilled water and 200 µL of extract solutions. All measurements were taken in triplicates. The percentage radical scavenging activities (% RSC) were calculated using the formula:

$$\% \text{ RSC} = \frac{\left[\text{Ao}_{\text{Control}} - \text{Ai}_{\text{Sample}}\right]}{\text{Ao}_{\text{Control}}} \times 100$$

Total phenolic and flavonoid contents

Total phenolic contents in four parts of *J. regia* were determined by Folin–Ciocalteu method (Jimoh et al., 2007). Phenolic contents were expressed as gallic acid (GA) equivalents (mg of GA g^{-1} of extract). Total flavonoid contents in four parts of *J. regia* were measured as described previously by Piccolella et al. (2008). The total flavonoid contents were calculated as rutin equivalents (mg of Rutin g^{-1} of extract).

Anticancer activity

Cell lines and cell viability assay

Human breast disease (MCF-7) cells were obtained from ATCC (Rockville, MD). All cells were cultured in a humidified 5% CO_2 environment at 37 °C in an incubator and refined in RPMI-1640 medium supplemented with 10% warm inactivated infant calf serum, 100 IU/mL penicillin and 100 µg/mL streptomycin. Restraint of cell multiplication by the walnut extracts was measured by the MTT test. Rapidly, PC3 cells were plated in 96-well culture plates (1 × 105 cells/well) independently. After 24 h incubation, cells were treated with *Juglans regia* crude extracts (0.5 mg/mL and 1 mg/mL; eight wells for every focus) for 24 h; MTT concentration (5 mg/mL) was then poured to each well. After 4 h incubation, the formazan particles were kept in dimethyl sulfoxide (100 µL) and afterward the absorbance was measured in an ELISA at 570 nm. Cell reasonability proportion was computed by following formula:

$$\text{Cell viability } (\%) = \frac{\left[\text{Ac} - \text{At}\right]}{\text{Ac}} \times 100$$

where Ac is the absorbance of control cell and At absorbance of treated cells, respectively.

Cytotoxicity was expressed as the concentration of the extracts in growth inhibition of cell by 50% (GI_{50} value).

Statistical analysis

All values were expressed as mean ± standard error of means. By using one-way analysis of variance (ANOVA) technique (Steel et al., 1980). The mean was compared by using LSD at 5% (0.05) probability level by using statistic 8.1 software.

Results and discussion

Metal contaminations of J. regia

During current study the contaminations of six metals (Cd, Cr, Cu, Mn, Mg and Zn) in four parts of *J. regia* extracts using Atomic Absorption Spectrophotometry (AAS) were investigated. The wave length were taken to measure the concentrations of each metal in each extract and the mean concentration of each metal in each extract (in mg L^{-1}) are given in *Table 1*.

Table 1. *Metal concentration in J. regia for the estimation of metal contamination (mg/L)*

#	Part used (Analyte absorbance)	Cd (228.8 nm)	Cr (357.9 nm)	Cu (324.8 nm)	Mn (279.5 nm)	Mg (285.2 nm)	Zn (213.9 nm)
1	Fruits	4.872	0.156	19.84	0.469	105.5	1.139
2	Leaves	0.323	0.047	4.555	0.313	124.9	0.417
3	Stem bark	0.037	0.815	3.612	0.260	113.0	0
4	Green husk	0.037	0.079	4.175	0.110	94.0	0

The present study reports the estimation of metal contaminations of six metals, namely; Cd, Cr, Cu, Mn, Mg and Zn in selected parts of *J. regia* and were compared with the standard permissible limits (SPLs) by the FAO/WHO to evaluate their potential impact on the health. These studies indicated that Cd concentration in fruits and leaves, Cr concentration in fruits, stem bark and green husk, Cu and Mg concentration in all parts of *J. regia* (fruits, leaves, stem bark and green husk) were above the standard permissible limits, Mn concentration in fruits and leaves and Zn concentration in all plant's parts of *J. regia* were below the standard permissible limits, Zn was not found in stem bark and green husk of *J. regia*. The concentration of each metal in all four tested parts were also represented in *Fig. 1*.

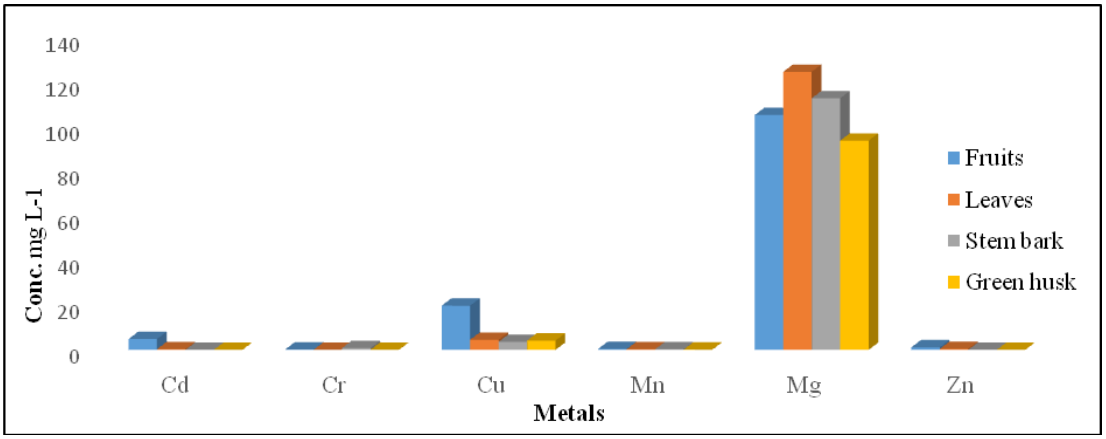

Figure 1. *Metal contaminations in four parts of J. regia*

Higher Cd concentration in fruits and leaves of *J. regia* was the major contributing reason to the potential health risk in Nanning, China (Cui et al., 2004) and in Boolaroo, Australian (Kachenko and Singh, 2006). The main contaminations of Cd were reported in grape, spinach and celery. Therefore, these results should be used as important

guidelines for the producers, traders, consumers and regulatory authorities. Unfortunately, in these areas there are no regulatory practices for the assessment of these walnut fruits which are extensively used by the local inhabitants and sold in the market throughout the country. The amount of Cu was critically above the standard permitted limit which indicate the high composition of the Cu in these selected area that ultimately accumulate in the flora, fruits and vegetables. It also worth noticing, that Zn was also omitted in the samples of *J. regia.* The standard acceptable limits (SPLs) of metal contamination (in dietary and medicinal species) are: Cd = 0.06 mg L^{-1}, Cr = 0.05 mg L^{-1}, Cu = 0.1 mg L^{-1}, Mn = 0.26 mg L^{-1}, Mg = 50 mg L^{-1} and Zn = 5.0 mg L^{-1} (Singh et al., 2010).

Antimicrobial activities of J. regia

Antibacterial activities of the methanolic extracts were assessed by the disc diffusion method against twelve common human pathogens. Zone of inhibition (mm) of all these extracts were mentioned in *Table 2*.

Table 2. *Anti-microbial activity of methanolic extracts of four parts J. regia against tested human pathogens*

Mean diameter of zones of inhibition (mm) ± standard error of means (S.E.M)							
#	**Pathogens**	**Fruits**	**Stem bark**	**Green husk**	**Leaves**	**Ciprofloxacin**	**Nystatin**

Note: the means followed by same letters are non-significant

Results of the sensitivity tests were expressed as (0) for no sensitivity, (7-10 mm) for low sensitivity, (11-18 mm) for moderate sensitivity and (> 19 mm) for high sensitivity. Fruit's extract of *J. regia* exhibited significant zone of inhibitory activities (11-18 mm); 14.33 ± 0.33, 13.67 ± 0.3, 13.33 ± 0.67 and 11.67 ± 0.33 against *S. aureus, P. aeruginosa, E. coli* and *R. stolonifer*, while it showed marginal activity against *K. pneumonia, P. vulgaris, B. subtilis and B. bronchiseptica* i.e. 8.67 ± 0.33, 8.67 ± 0.33, 7.67 ± 0.33 and 9.67 ± 0.00, respectively. The low sensitivity conferred by gram negative bacteria was due to composition of their cell wall as previous study of Parekh and Chanda (2007) depicted that gram negative bacteria were more resistant than gram positive bacteria against all the drugs tested. Fruit extract showed no activity against other tested microorganisms whereas, the extract of stem bark exhibited significant activity; 13.33 ± 0.67, 12.67 ± 0.33, 15.16 ± 0.28, 11.33 ± 0.33, 16.33 ± 0.57 and 13.67 ± 0.33 against *S. aureus, P. aeruginosa, P. vulgaris, E. coli, B. subtilis* and *B.*

bronchiseptica, respectively, while other strains of tested microorganism were found to be resistant to stem bark extract of *J. regia*. The finding of Salar and Suchitra (2009) suggested that polar extract showed higher antimicrobial properties against tested microorganisms which are in line with the current study. Methanolic extract of the green husk of *J. regia* showed considerable activity against *S. aureus* (11.67 ± 0.33), *P. aeruginosa* (18.16 ± 0.28), *K. pneumonia* (13.33 ± 0.67), *P. vulgaris* (12.67 ± 0.33), *E. coli* (12.33 ± 0.67) and *A. flavus* (13.67 ± 0.33) whereas, *B. subtilis, B. bronchiseptica, F. solani, R. stolonifer, S. cerevisiae* and *C. albicans* were found to be resistant to green husk extract of *J. regia. A. flavus* was also inhibited by the extract used however all other fungal and yeast strains were found resistant as shown in *Figures 2 and 3*.

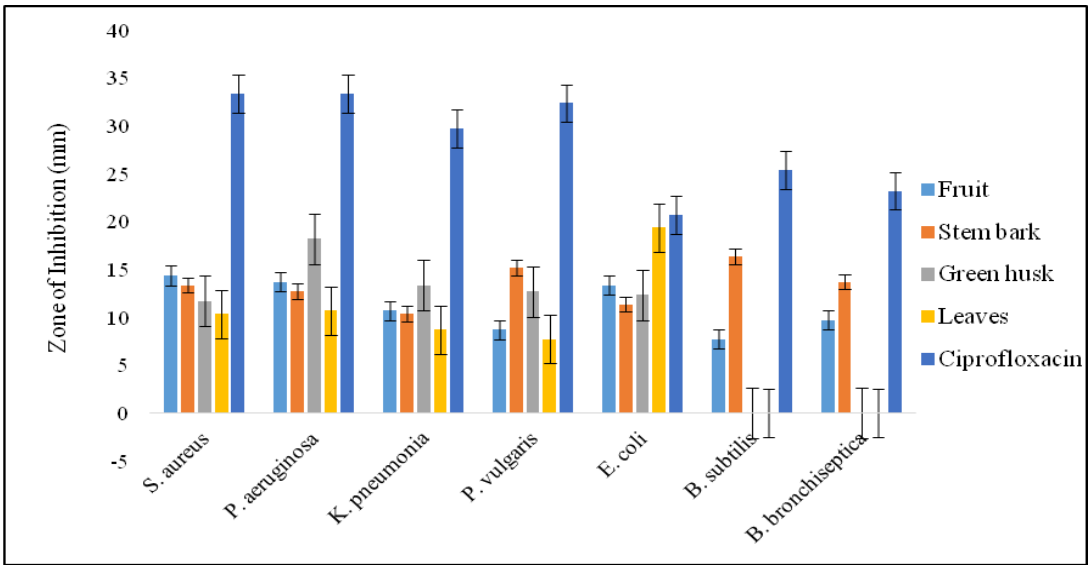

Figure 2. *Antibacterial activities of the methanolic extract of J. regia*

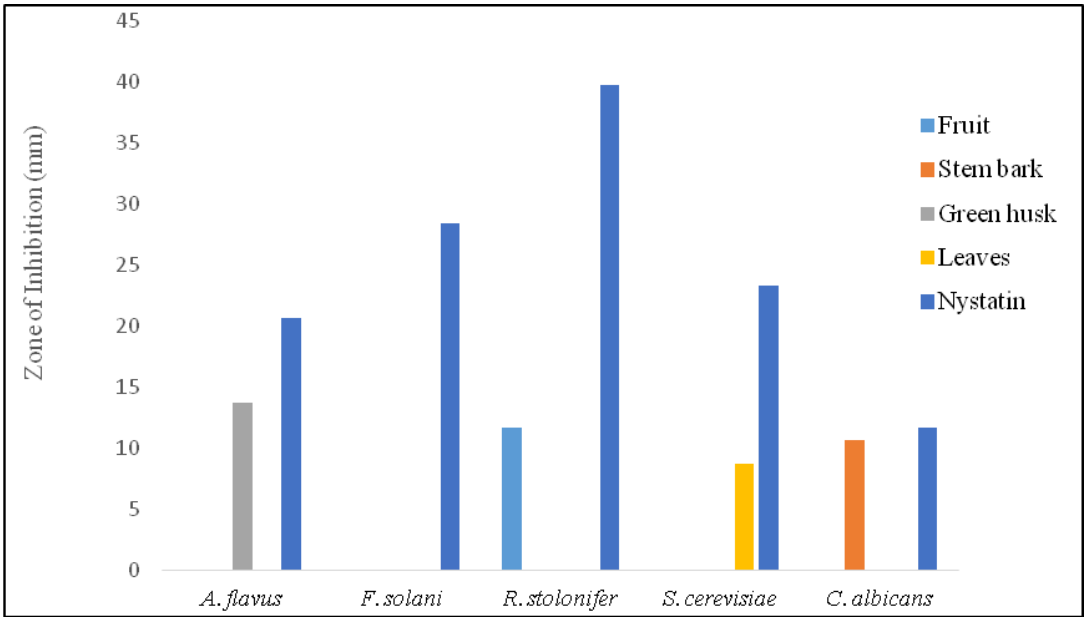

Figure 3. *Antifungal activities of the methanolic extract of J. regia*

These results were in accordance with the previous studies which also deduced that plant extracts were more effective against bacteria than fungi (Mehmood et al., 2013). Methanolic extract of leaves of *J. regia* conferred high activity i.e. 19.33±0.57 mm against *E. coli* while, it showed low activity (10.33 ± 0.33, 10.67 ± 0.33, 8.67 ± 0.33, 7.67 ± 0.33 and 8.67 ± 0.33) against *S. aureus, P. aeruginosa, K. pneumonia*, *P. vulgaris* and *S. cerevisiae,* respectively. Extract of its leaves was found inactive against other bacterial and fungal strains. These results were in harmony with the previous investigations of Naika et al. (2012). Moreover, the current study revealed that plant parts extracts were more active against gram positive bacteria as compared to gram negative bacteria tested due the fact that the outer membrane of the cell wall of gram negative bacteria acts as a barrier to many synthetic and natural antibiotics (Tortora and Funke, 2001).

Antioxidant activities of J. regia

Antioxidant properties of the methanolic extracts of four parts of *J. regia* under discussion were measured by DPPH radical decolorization assay. Three concordant readings were taken for each extract at 734 nm and mean (Ai) was calculated. Value of control (Ao) at 734 nm was 0.1. The percentage radical scavenging activity (% RSC) was calculated using the formula: % RSC = $[(Ao_{Control} - Ai_{Sample})] / Ao_{Control} \times 100\%$. All results for these methanolic extracts are summarized in *Table 3*. It was observed that the methanolic extract of *J. regia* fruit showed stronger free radical scavenging ability with 6.938693 mg mL^{-1} IC_{50} value. Similarly, methanolic extracts of leaves, stem bark and green husk showed 9.224862 mg mL^{-1}, 8.901780 mg mL^{-1} and 13.862772 mg mL^{-1} IC_{50}, respectively. Methanol extracts are generally found to possess higher antioxidant activity because the polar solvents in extraction of all the phenolic compounds and that might be carrying the most of the bioactive compounds from plants (Fatima et al., 2007). Our results are graphically shown in *Figure 4* including the IC_{50} values of all of methanolic extracts.

Table 3. *Antioxidant activity of the methanolic extracts of four parts of J. regia*

#	Part used	1 mg mL^{-1}	3 mg mL^{-1}	5 mg mL^{-1}	IC_{50}
1	Fruits	35.26	39.29	42.13	6.938693
2	Leaves	21.13	27.07	30.02	9.224862
3	Stem bark	18.26	22.61	27.16	8.901780
4	Green husk	10.16	17.24	24.02	13.862772

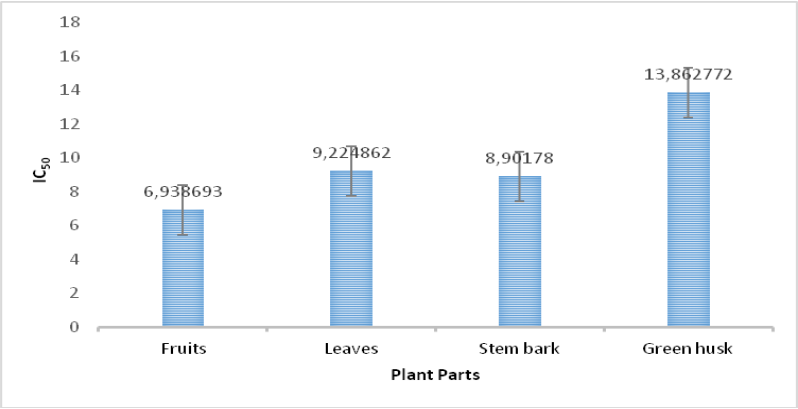

Figure 4. *IC_{50} values of the methanolic extracts of four parts of J. regia*

Phenolic contents of four parts of J. regia

Total phenolic contents of methanolic extract of four parts of *J. regia* were assessed by using Folin-Ciocalteu phenol reagent and results are tabulated in *Table 4*. The values ranged from 12.6987 to 31.9685 mg of GA g^{-1} of extract. The highest value was recorded in the stem bark extract which was 31.9685 mg GA g^{-1} and lowest value in green husk which was 12.6987 mg GA g^{-1} (*Fig. 5*). The phenolic contents estimated in this studies were probably, responsible for the free radical-scavenging activity of *J. regia*. The phenolic compounds were attributed to the overall antioxidant activities, it is important to point out that during present study studies it was recorded that the relationship between antioxidant activities and amount of phenolic contents in all extracts which are also in agreement with the previous investigations (Anwar et al., 2013).

Table 4. *Total phenolic contents of J. regia (in methanolic extracts of fruits, leaves, stem bark and green husk)*

#	Part used	Conc. Used	Absorbance	mg of GA g^{-1} of extract
1	Fruits	2.5 µL	70.90	$30.2689_a \pm 3.46a$
2	Leaves	2.5 µL	80.75	$19.8762_b \pm 2.32b$
3	Stem bark	2.5 µL	79.25	$31.9685_a \pm 4.33a$
4	Green husk	2.5 µL	22.32	$12.6987_b \pm 1.74_b$

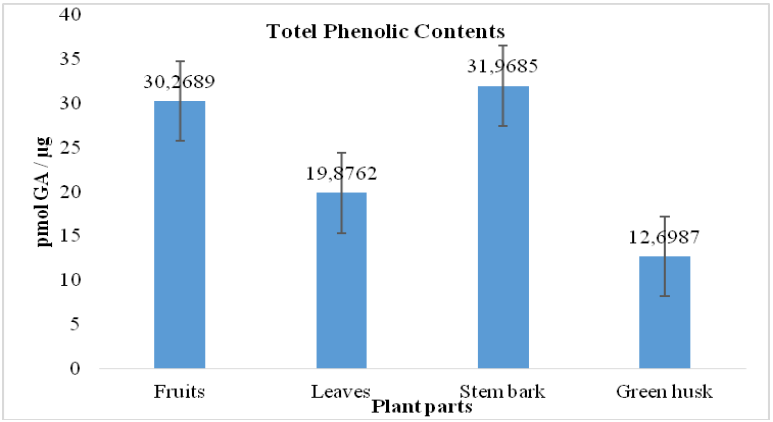

Figure 5. *Total phenolic contents of fruits, leaves, stem bark and green husk of J. regia*

Flavonoid contents in the methanolic extracts of four parts of Juglans regia

The total flavonoid contents in the methanolic extracts of the all selected parts of *J. regia* are tabulated in *Table 5*.

Table 5. *Total flavonoid contents of J. regia (methanolic extracts of fruits, leaves, stem bark and green husk)*

#	Part used	Conc. Used	Absorbance	(mg of Rutin g^{-1} of extract)
1	Fruits	10 µL	0.49	$25.8231_a \pm 2.32$
2	Leaves	10 µL	0.170	$7.2861_c \pm 1.15$
3	Stem bark	10 µL	0.315	$17.2896_b \pm 2.88$
4	Green husk	10 µL	0.298	$15.9864_b \pm 2.33$

The highest contents were found in the fruit's extract 25.8231 mg g^{-1} and lowest value in leave's extract of *J. regia* i.e. 7.2861 mg g^{-1} (*Fig. 6*). The plant extract usually containing flavonoids and phenols has already been reported to possess promising biological activities (Maria et al., 2014).

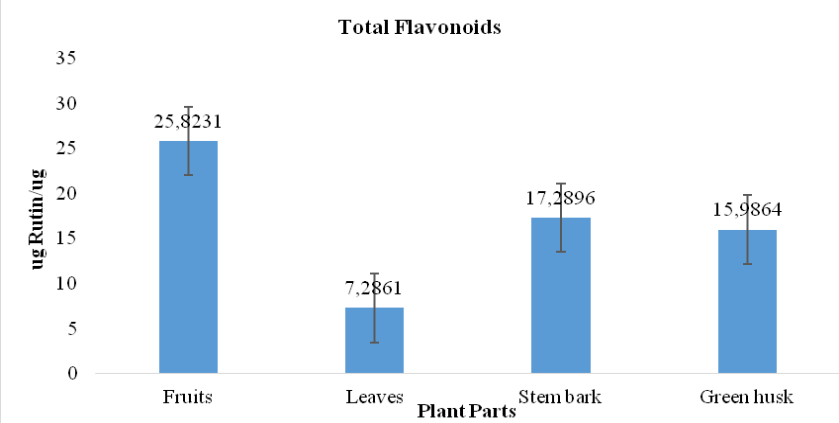

Figure 6. *Total flavonoid contents of fruits, leaves, stem bark and green husk of J. regia*

Anticancer activity of four parts of J. regia

Juglans regia fruits, leaves, stem bark and green husk extracts were evaluated for anti-cancer activity in MCF-7 cell line using the MTT assay against the human breast cancer. The (Growth inhibition) GI_{50} value of all four extracts of *Juglans* were calculated in 0.5 mg mL^{-1} and 1 mg mL^{-1} concentrations. GI_{50} value gave an indication of the potency of each plant extracts as shown in *Table 6* and *Figure 7*.

Juglans green husk extract at concentrations of 0.5 mg/mL and 1 mg/mL exhibited a strong anticancer effect which depicted that only 7% and 14% of the cells were alive and 93% and 86% cells were damaged, respectively.

J. regia green husk proved valuable potential that could enhance cytotoxicity against MCF-7 breast cancer and could be used as therapy against breast cancer. Tested crude extract had medicinal advantages not only for MCF-7 cell line but found to be potent against other type of cancer also. Similar studies have been carried out by Hasan et al. (2011) and Alshatwi et al. (2012) which suggested that green husks and root bark extracts of walnut brought apoptosis in MDA-ME231 human breast cancer and prostate cancer cell lines PC-3 by up-regulating bax gene, caspase 8 and caspase 3 expression and down-controlling Bcl-2 gene expression. Methanolic extract of Stem bark of *J. regia* conferred sensitivity as 10% and 25% against tested cell lines at concentration of 0.5 mg mL^{-1} and 1 mg mL^{-1} whereas 90% and 75% alive cells were recorded. Study of Sanchez-Gonzalez et al. (2014) also suggested that consumption of walnuts could help to reduce the risk of developing cancer. The extract of walnut fruits exhibited significant activity at concentration in 0.5 mg mL^{-1} that were 33% cancer cell were alive and 67% cell damaged, at 1 mg mL^{-1} concentration only 2% cancer cell were observed alive and 98% were damaged.

The walnut fruit extract was assessed against MCF-7 cells line. The extract demonstrated a dosage dependent inhibition effect. 1 mg/mL concentration conferred best anti-proliferative property as compared to 0.5 mg/mL concentration of the extract used. Oguzhan and Zeynep (2016) also reported anticancer activity of walnut fruit

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_23072321
© 2018, ALÖKI Kft., Budapest, Hungary

against MCF-7 cells. Anticancer potential of leaves extract of *Juglans regia* at concentration 0.5 mg/mL recorded as 24% cells were alive and 76% cells were damaged, at 1 mg/mL concentration only 12% cancer cell were observed alive and 88% were damaged.

The leaves crude extract of *J. regia* was found to be more powerful against tested cancer cells that may reduce malignancy cells by means of suppression of the p65 phosphorylation, which is supposed to be safe component to reduce malignant disease in cells. Early finding of Taghizadeh et al. (2011) also suggested that plants extract showed higher cytotoxicity potential against MCF-7 cells which was in harmony with current study.

Table 6. *Anticancer activity of J. regia (methanolic extracts of fruits, leaves, stem bark and green husk)*

#	Part used	GI_{50} at 0.5 mg/mL	GI_{50} at 1 mg/mL
1	Fruits	32.51318	1.581722
2	Leaves	23.6417	11.89427
3	Stem bark	90.15817	74.69244
4	Green husk	6.821963	13.47754

Conclusion

Present investigations concluded that dietary and medicinal plants should be analyzed for metal contamination before use. The results of toxic metal contamination in *J. regia* indicated that the contaminations of Cd were above SPLs in fruit of *J. regia* whereas Zn was below the SPLs. Therefore, these results should be used as important guidelines for the producers, traders, consumers and regulatory authorities to assure the recommended amount of metals in this important dietary fruit by focusing on soil conditions of walnut growing area. Moreover this medicinal plant was proved as potential source of anti-cancer, anti-microbial, anti-oxidant activity. The compounds like phenolic and flavonoids found in different parts of walnut may be used as food supplement and in pharmaceutical industry to cure fatal ailments after detail study both in vivo and in vitro.

Abstract. As water scarcity increases globally due to rapid population growth, unsustainable use, water degradation and climate change, water security is increasingly becoming a serious and growing concern. Sustainable water resources management and development are central to addressing this pressing concern. One of the ways forward is through the development of multi-purpose dams. However, dam development is often mired with controversies over its environmental and social impacts. It is anticipated that multi-purpose dam development is going to gain attention in Malaysia; the question at issue is not only about the multi-purpose dam development per se, but the sustainable water resources management. This article attempts to discuss water security issues in the Malaysian context, the needs for sustainable water resources management and environmentally sustainable multi-purpose dam development.
Keywords: *water security, sustainable water resources management, multi-purpose dam, environment, social, economy, climate change*

Introduction

By 2025, it is projected that about 1.8 billion people will experience absolute water scarcity. Severe water stress affecting 1/3 of the world's population is expected to double to 2/3, and water withdrawals are predicted to increase by 50% in developing countries and 18% in developed countries. (BERNAMA, 2012).

Water scarcity may be defined as when the issue of water insecurity persists for a significant period of time, that is, when a large number of people in a region do not have access to safe and affordable water to satisfy their daily needs or livelihoods. Water security is defined as the capacity of a population to safeguard sustainable access to adequate quantities of acceptable quality water for sustaining livelihoods, human well-being, and socio-economic development. Many factors contribute to water security, ranging from biophysical and infrastructural, institutional, political, social, financial – many of which lie outside the water realm. Addressing this goal therefore require interdisciplinary collaboration across sectors, communities and political borders.

The American Society of Civil Engineers gives a holistic definition of sustainable water resources systems. Water resources systems should be designed and managed to fully contribute to the objectives of society, now and in the future, while maintaining their ecological, environmental, and hydrological integrity (Petersson and Ostrowski, 2003). Providing water for drinking and irrigation, producing hydropower and flood protection are by all means functions that contribute to the objectives of society. Water shortage will not be possible to solve without dams, although solving it only by means of dams will clearly not be preferable solution. Many collateral impacts of dams are running contradictory to society's objectives, or either the ecological or the economic integrity of the water resources system. To ensure the identification and implementation of widely accepted and sustainable solutions for water and energy development, it will be of major importance to implement well-structured and transparent planning processes for multi-purpose dam from the very beginning (Petersson and Ostrowski, 2003). This article attempts to discuss the current water security issues in the Malaysian context, the needs for sustainable water resources management and environmentally sustainable multi-purpose dam development.

Water security issues: The Malaysian context

Malaysia is a tropical country, having an average annual rainfall of 2400 mm and relatively rich in water resources. In the early decades of independence, Malaysia never experienced any serious water crisis. However, Malaysia is facing water shortage and having frequent water rationing nowadays, especially in Kuala Lumpur, Selangor and Putrajaya. The situation is exacerbated by the *El Nino* phenomenon which is anticipated to further worsen the water crisis in Malaysia (Raja Zainal Abidin, 2004). Such a paradox of plenty is due to the complexity of water security issues and must be sustainably addressed (Chan et al., 2003).

Over the past decades, Malaysia was lacking of a central agency entrusted with the overall responsibility of holistic planning and management of the overall aspects of water resources. There are too many agencies having jurisdiction over different aspects of water resources management either direct or indirectly. *Table 1* shows the responsibilities of the Malaysian water related agencies.

Table 1. *Malaysia's water related agencies*

Agency	Area of responsibility	Description
National Water Resources Council (NWRC)	Water resources matters – cross boundaries/interstate/issues of national interest	Ensure coordination between various State Governments in the management of river basins
Ministry of Natural Resources and Environment	Policy matters	Formulates policies/guidelines/regulations for the national water resources
Ministry of Energy, Green Technology and Water (KeTTHA)	Policy matters	Formulates the policies and strategies for national water supply and sanitation
Ministry of Finance – Water Asset Management Inc, PAAB	Asset management	Acquire and manage all state owned water related assets
National Water Services Commission (SPAN)	Regulatory matters	Regulate water service industry (water and sewerage services)
State and Territory Governments (13 states and three territories)	Raw water matters	Regulates raw water abstraction and catchment management

Conflicts in water resources management such as allocation of water rights, flood management, pollution control, environmental protection, etc are resolved through inter-agency coordination and consultation. Such a mechanism has led to sectoral management of water, conflicting/competing objectives and disputes between agencies.

Malaysia also suffers from a plethora of sector-based water laws, both at federal and state levels, and from the lack of a comprehensive water law. *Table 2* shows legislations that relevant to Malaysian water resources management. All these legislations are contained within the laws that are enforced by the various water-related government agencies, and many of these laws are outdated, redundant or ambiguous and need to be reviewed in today's context. These diversified water legislations are also not comprehensive enough and do not deal directly with water issues, thus the government agencies are having difficulty to enforce effectively.

Table 2. *Legislation that relevant to Malaysian water management*

Purpose	**Laws and regulations**
Parliamentary acts	• National Policies of Government of Malaysia - Third National Agricultural Policy (1998–2010) • Federal Constitutions • Ministerial Functions Act 1969 (Perintah Menteri-Menteri Persekutuan 2004): DID Role In On River Management in Flood Mitigation and River Conservancy • Water Act 1920 (Revised 1989)

Malaysia is still practising the traditional water management system which employs and depends heavily on the water supply management approaches – cater to demand. *Table 3* shows the water production and consumption in Malaysia where production increases to cater the increasing water consumption. With the increasing demand and consumption, more water has to be produced and supplied. Thus, more structures like dams, water treatment plants and water distribution pipes need to be built. This approach is unsustainable in the long run as water demand may eventually surpass water supply. There are plans by the government to privatize water supply in almost every state. However, several water privatization schemes have not produced desirable results. The water privatization process is still lacking transparency and accountability. Unsuccessful privatization leads to unsustainable water management.

Table 3. *Water production and consumption in Malaysia 2009–2012 (MLD)*

	2009	**2010**	**2011**	**2012**
Production	13,495	14,065	14,564	15,145
Consumption	8,551	8,972	9,164	9,532
Buffer	4,944	5,093	5,400	5,613

The average water tariff of Malaysia is 0.39 USD/m^3. Comparing to that of Indonesia (0.77 USD/m^3) and Singapore (1.88 USD/m^3), water tariffs in Malaysia can be deemed as one of the lowest in the world. Such a situation does not encourage water conservation but instead leads to water wastage and overuse of water, both of which undermine the sustainability of water. *Table 4* shows the average urban water use (litre/capita/day) in Asian countries. Malaysian average urban water use (litre/capita/day) is 344, which is much higher than that recommended by UN (165) and other Asian countries, i.e. Japan, China, Singapore and Indonesia. Agriculture accounts for 68% of total water consumption in Malaysia. However, the irrigation efficiency is 50% at best in the larger irrigation schemes and less than 40% in the smaller ones. There is also no recycling of irrigated water being practised and these factors have contributed to high rate of water wastage.

Table 4. *Average urban water use (litre/capita/day) in Asian countries*

Country	**Average urban water use (litre/capita/day)**
Malaysia	344
Japan	314
China	204
Singapore	153
Indonesia	130

The national average of non-revenue water (NRW) is 36% (36 l loss out of every 100 l) which is way too high. *Table 5* shows the NRW in all states in Malaysia 2013. The high level of NRW in Malaysia is caused by aged pipe network, poor maintenance of pipe network, illegal connections and absence of coherent implementation for active leakage control. It is estimated that 40% or 50,900 km of the pipe network was laid 40 to 60 years ago or longer. However, the lacking of funding for asset replacement and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_23232347
© 2018, ALÖKI Kft., Budapest, Hungary

poor construction resulted in increasing leakage in the pipe network. Such a situation is further exacerbated by illegal connections which significantly contribute to commercial losses and revenue loss to the utilities. Thus, all these have now become the focus of regulatory oversight under the new licensing regime and areas to be improved (SPAN, 2012).

Table 5. *Non-revenue water (NRW) in all states in Malaysia 2013 (SPAN, 2012)*

State	System input volume	Billed authorized consumption	NRW	NRW (%)
Johor	1,580	1,163	417	26.4
Kedah	1,326	651	675	50.9
Kelantan	430	202	228	53.1
Labuan	63	46	16	25.9
Melaka	482	375	107	22.1
Negeri Sembilan	734	468	267	36.3
Pulau Pinang	988	809	180	18.2
Pahang	1,065	504	561	52.7
Perak	1,200	835	365	30.4
Perlis	211	80	132	62.4
Sabah	1,132	530	602	53.2
Sarawak	1,150	790	359	31.3
Selangor	4,564	2,989	1,575	34.5
Terengganu	623	413	210	33.8
MALAYSIA	15,549	9,855	5,694	36.6

Climate change and water pollution issues also threaten the water security. The changing weather pattern is not adequately taken into account of the water resources planning. The weather and climate change, locally and globally, affect water resources in Malaysia. For example, *El Nino* phenomenon that occurred in 1997/98 has brought severe drought resulting in water crises in many parts of Malaysia. Many water catchments in Malaysia have yet to be gazetted and legally protected. Water catchments are exposed to incompatible development resulting in adverse environmental effects, which ultimately make water resources degraded and unsustainable. Water pollution reduces total water availability considerably as the increasing cost involved in treating polluted will not be economically viable and in some instances, polluted water are not treatable for consumption. Almost half of the rivers in Malaysia are getting polluted nowadays. There are 1,064 monitoring stations in Malaysia, out of this number, 619 (58%) were found to be clean, 359 (34%) were slightly polluted and 86 (8%) were polluted (WEPA, 2006).

Sustainable water resources management

Without the conscious efforts in addressing water resources management issues, it would not able to safeguard quantity and quality of water for sustaining livelihoods, human well-being, and socio-economic development (Cosgrove and Rijsberman, 2000).

Robust water policy

Efforts to develop, conserve, utilize and manage water resources have to be guided by a robust national water policy to ensure water resources in the country are managed sustainably and holistically. The re-structuring of water services industry which was initiated by the federal government has established a holistic water policy which covers not only water supply but also sewerage services to improve the efficiency of the water services sector for the benefit of the people as well as to maintain the sustainability of water resources. The national water policy is outlined in the National Policy Objectives for the Water Supply and Sewerage Services Industry. The policy aims to establish a transparent and integrated structure for water supply and sewerage services that delivers effective and efficient services to consumers. The policy provides a regulatory environment which facilitates financial self-sustainability amongst the operators in water services industry in the long term and an effective system accountability and governance between operators in water services industry. It also aims to regulate tariffs and ensure the provision of affordable water services on an equitable basis; the safety and security of water services systems and the long-term benefits of the consumers. The policy ensures long-term availability and sustainability of water supply including the conservation of water and contributes to the sustainability of watercourses and water catchments. The policy also facilitates the development of competition to promote economy and efficiency in water services industry and improve the quality of life and environment through the effective and efficient management of water services (PAAB, 2013). Also, the water policy should always keep up to the pace with climate change in view of climate change is also a challenging issue in managing water resources whereby the dynamic climatic condition could affect the availability and sustainability of water resources.

Effective governance and institutional matters

The government is primarily responsible for the planning, development and management of water resources projects in the country. As discussed in the previous section, there is no central agency entrusted with the overall responsibility of holistic planning and management of water to manage the overall aspects of water resources. To establish an effective governance structure for water resources in the country, it is necessary to recognize and understand the close relationship between land use and water resources management issues. The National Water Resources Council (NWRC) which was established in 1997 is a step forward towards integrated approach in managing water resources. Besides coordinating function and ensuring uniformity in policies, standards and priorities, being the forum where the federal and state governments link water and land strategy can be formulated resulting in optimal utilization and conservation of the nation's water resources, the NWRC should be provided with legal mandate to plan, coordinate and execute Integrated Water Resources Management (IWRM) in which it balances the conditions for sustainable development (national interest) and desirable socio-economic development (public interest) with ecological conditions (environmental integrity) (Azhar, 2000).

Water economic efficiency

Due to the increasing water shortage issues, water has become an economic good that has its own economic value. In Malaysia, government subsidies are common and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_23232347
© 2018, ALÖKI Kft., Budapest, Hungary

tariff is practically very low because water is still regarded as a social good where the concept of full cost recovery is not observed because of sociopolitical considerations. In addition, the absence of established economic regulation complicates the problem. Increasing tariff to cost recovery levels often faced with resistance resulting water utilities are not able to comply with its service obligations. In view of the highly capital-intensive nature of the water service industry, more private investment is required to lighten the fiscal burden of the government. There is also a need to revise the tariffs which balance full cost recovery and consumer's ability to pay and it can be achieved if the capital investment cost can be kept as low as possible and the tariff set at an economic value. The tariff for domestic and non-domestic water supplies are expected to move towards those of developed nations whereby gradually tariff revision is needed to reflect closely the actual costs of developing water resources facilities. Also, to ensure the efficiency of the water services, specific actions need to be taken particularly in reducing leakages and non-revenue water. With the effective addressing non-revenue water issues and raising public awareness on water saving, hence the water resources can be conserved (Salleh, 2011).

Sustainable water resources development

In line with the increasing water demand, water resources development have to meet the rapid growth in population, industries, tourism and other economic activities. We also recognize the challenges in water shortage, rising water pollution and other environmental pressures. Hence, it is necessary to ensure sustainable water resources development. Integrated and holistic approaches which require engagement and close partnership between stakeholders, including federal and states governments, regulatory authorities, environmental agencies, health agencies, water service providers, contractors, land users, consumers, etc are needed especially in conducting a detailed environmental impact assessment prior to the initiation of new water resource development projects. In addition, the identified sites for dam development should be conserved and gazetted as water catchment areas to ensure project can be implemented as planned because there may not be any other suitable alternative sites available for dam construction (Salleh, 2011).

Effective construction, operation and maintenance of water structures

Apart from proper planning of water structures, safety is particularly concern in ensuring effective water structure construction, operation and maintenance. An Inter-Departmental Committee on dam safety was established in May 1986 which consists of Drainage and Irrigation Department Malaysia, National Electricity Board, Penang Water Authority, Malacca Water Board, Muda Agricultural Development Authority, Sabah Electricity Board and Sarawak Electricity Supply Corporation under the stewardship of Public Works Department Malaysia. The committee has launched the Guidelines for Operation, Maintenance and Surveillance of Dams in October 1989 to provide specific procedures and practice to suit site and management conditions of individual dams. The guidelines are applicable to all dams (except tailings dams). The guideline not only prepares an operation and maintenance manual for the dam, it also stipulates the responsibilities for operation and maintenance activities, routine inspections as well as adequate instructions and arrangements for emergency actions. Continuous examination of the condition of a dam and its appurtenant structures and the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_23232347
© 2018, ALÖKI Kft., Budapest, Hungary

review of operation, maintenance and monitoring procedures and results are needed in order to determine whether a hazardous trend is developing or appears likely to develop. These surveillance activities should be conducted throughout its active life by trained and competent personnel and the published guidelines should be diligently followed and reviewed periodically by the dam owners to ensure the sustainability of multi-purpose dam (Othman, 2006).

Potentials of multi-purpose dam development in Malaysia

International Commission on Large Dams defined large dam – more than 15 m in height, while including smaller dams up to 10 m height as well, if they are otherwise significant with respect to storage volume, density of population, etc. Dam is an artificial barrier together with appurtenant works constructed for the purpose of holding water or any other fluid or silt across a natural water course or on the periphery of reservoir to control the flow or the level of the water (DID, 2009). By proper altering the spatial and temporal distribution of runoff, dam could serve several functions (Zhou and Guo, 2013).

With the rapid economic development, the role of dam has become more and more important to meet society's water requirements as the dam is the cornerstone in the development and management of water resources of a river basin. The International Commission on Large Dams (ICOLD) has been promoting the theme of a water-food-energy nexus and integrated solution whereby one problem cannot be solved without thinking of the other sides of the problem. This has highlighted the importance of multi-purpose dams in resolving the issues of water, food and energy. However, most of the existing dams in the world are single-purpose dams (49.2%). Among the single-purpose dams, 48% are for irrigation, 20% for hydropower (production of electricity), 13% for water supply, 9% for flood control, 5% for recreation and 5% for navigation, fish farming and others. ICOLD recorded only 16.8% of the worldwide dams can be categorized as multi-purpose dams where they are mostly built for irrigation purposes (24%), followed by flood control (19%), water supply (17%), hydropower (16%), recreation and navigation/fish farming (19%) and others (5%) (ICOLD, 2014). A multi-purpose dam is gaining importance as it fits well into regional development programs, such as improving food production, electricity supply, and the general physical and social infrastructure in rural areas. In addition, multi-purpose dams can complement strategies for climate change adaptation. For example, hydropower generation can be combined with increased water storage or flood regulation.

To date, there are 65 major dams that have been developed in Malaysia. *Table 6* shows the major dam development in Malaysia from 1950s to 2000s. Most of them were constructed for water supply. There were also dams built for hydropower, irrigation, flood mitigation, environmental and recreation purposes. Since 1980s, massive development has been devoted for water supply dams considering the increasing water demand due to population growth and country transformation from an agriculture-based economy into an emerging industrial manufacturing entity. It is noted that only 9 out of 65 dams in Malaysia serve more than one purpose in their function. Thus, it can be affirmed that the multi-purpose dam concept is still not very popular in the water resources planning and development of Malaysia.

The growing of water demand requires either better water supply management or additional supplies. Dam management plays a vital role in ensuring equitable water supplies. The management of dams in Malaysia is divided into four groups, i.e. flood mitigation, hydroelectric, water supply and agriculture as shown in *Table 7*. Generally, the water supply dams in Malaysia are managed and operated by private and water board of respective states. Drainage & Irrigation Department (DID) is presently managing 15 dams within Malaysia and providing adequate irrigation water, flood mitigation and silt retention. More dams are scheduled for implementation in the future to meet the ever increasing demands and social expectations of the public. Tenaga Nasional Berhad, the main Malaysian energy provider, is operating 3 hydroelectric schemes in the peninsular Malaysia with an installed generating capacity of 1,911 MW. They are the Sungai Perak, Terengganu and Cameron Highlands hydroelectric schemes with 21 dams in operation. Despite having most of the dams for water supply purpose, Malaysia is still facing water shortage crisis. Water supply is relatively unstable in some parts of the country, particularly in Klang Valley. The development and population growth is occurring at a robust pace, and even now the residents are starting to experience water shortage and water rationing, which can be more acute in the next decade. Syarikat Bekalan Air Selangor Sdn Bhd (SYABAS) had issued a warning that the Klang Valley will face a water crisis unless the authorities implement three water resource projects by 2014. The projects are the Sungai Langat 2 water treatment plant, the Pahang-Selangor raw water tunnel and the Salak Tinggi dam projects, which have not taken off so far because of the differences between the federal and state government, particularly over land acquisition and water price (Bedi and Avineshwaran, 2013). According to SYABAS, these three water resource projects must be expedited to meet the rising demand for water supply in Selangor, Kuala Lumpur and Putrajaya, which is growing by 3.5% yearly. Such a situation has triggered the need to investigate the feasibility of multi-purpose dam development in Malaysia. With the increasing water demand in Malaysia, multi-purpose dam is likely to become relevant in ensuring equitable water demand management. The multi-purpose dam is not only accelerating socio-economic growth but also mitigating the miseries of the population from suffering of the vagaries of floods and droughts.

Table 7. *Dams management in Malaysia (as of 2006)*

4	Agriculture	Others

Aspects to be considered in developing multi-purpose dam

There are generally five interconnected aspects, namely legal, technical, economic, social and environment in developing a dam. These aspects need to be considered in the planning, funding, constructing, operating and maintaining of a multi-purpose dam to ensure the sustainability of water resources.

Legal aspects

Existing legal framework and institutional matters

Legal and regulatory issue is one of the areas concerned in managing water resources. However, there is no specific act available for dam development and management, particularly multi-purpose dam in Malaysia. The only dam development relevant legal requirements are shown in *Table 8* which are covered under Environmental Quality (Prescribed Activities) (Environmental Impact Assessment) Order 1987 for the construction of dams of drainage and irrigation, power generation and transmission as well as water supply (CIDB, 2008).

Table 8. *Environmental Quality (Prescribed Activities) (Environmental Impact Assessment) Order 1987 for dam construction*

Schedule	Activities	
3 (a)	Drainage and irrigation	Construction of dams and man-made lakes and artificial enlargement of lakes with surface areas of 200 ha or more
13 (b)	Power generation and transmission	Dams and hydro-electric power schemes with either or both of the following: (i) Dams over 15 m high and ancillary structures covering a total area in excess of 40 ha (ii) Reservoirs with a surface area in excess of 400 ha
19 (a)	Water supply	Construction of dams or impounding reservoirs with a surface area of 200 ha or more

Taking other countries as benchmark, Japan enacted "Specified Multipurpose Dam Law" in 1957 to centralize the construction and administration of dams under the control of river administrators (Musiake and Koike, 2009) and South Korea enacted "Specific Multi-Purpose Dam Law" in 1966 to address various issues including financing of the construction of dams, support for flood victims, rational use and development of water resources to promote economic development and enhance the quality of life (Ministry of Strategy and Finance, Republic of Korea (2013). An adequate legal planning in the construction of multi-purpose dam is necessary. In 1966–1975, the South Korea's government has established master plans to construct multi-purpose dams for water supply and control. After 1990's, the scope of multi-purpose dams was expanded to cover water supply, water control, and environmental preservation (Moon and Kwon, 2003). Under Water Resources Bureau of Ministry of Construction and Transportation, the entities namely Water Resources Policy Team and Water Resources Development Team are responsible to dam related policy making, research and development, dam related public relation, dam related National Assembly matters and budget, operation of dam related acts and system improvement, handling of property rights of dams and water facilities, planning and coordination, budget and setting and supervision of multi-purpose dam construction. However, in the Malaysia's context, as mentioned earlier, the government is still practicing the traditional water resources management system which employs and depends heavily on the water supply management approaches – cater to demand. Besides, Malaysia is also lacking a regulatory framework to govern the development and management of dam, particularly multi-purpose dam, as compared to other advanced countries.

Prior to 2005, water supply was under the purview of respective state government. The state governments mostly own the water infrastructures and operate the water services. There are also some states, such as Selangor and Johor, where the water services are privatized and responsible for the treating and supplying of water to consumers. Therefore, institutional issues such as the water industry were not centrally regulated, causing inconsistency in service delivery. The varying degree of quality of water supply and services, different rules, procedures, key performance indexes (KPIs) and level of services, non-uniform in legislation and tariff setting principles have become challenges for the development of water industry. In the states where water services are privatized, operations are fragmented with several private operators involved in providing water supply to the states which is highly inefficient (PAAB, 2013). The federal government takes the initiative to reform the industry for the benefits of all stakeholders including federal government, state governments and consumers in the early of 2003. It was an extensive process which included amendments to the constitution and passing of new legislations to enable the government to mobilize the reformation. An amendment to federal constitution pertaining to jurisdiction on water supply was gazetted on 10 February 2005 whereby water services and supplies are listed under concurrent list between state governments and federal government. The amendment to the ninth schedule involves the transfer of water supplies and services from the state list to the concurrent list whereby the water supplies and services are shared responsibility between the state and the federal governments. It was a pertinent move which gave the federal government authority over the water services in the states. The tenth schedule was also amended. The revenue from water supplies and services (previously assigned to the states) is now under the federal government. *Figure 1* shows the water governance before and after the federal constitution amendment in 2005.

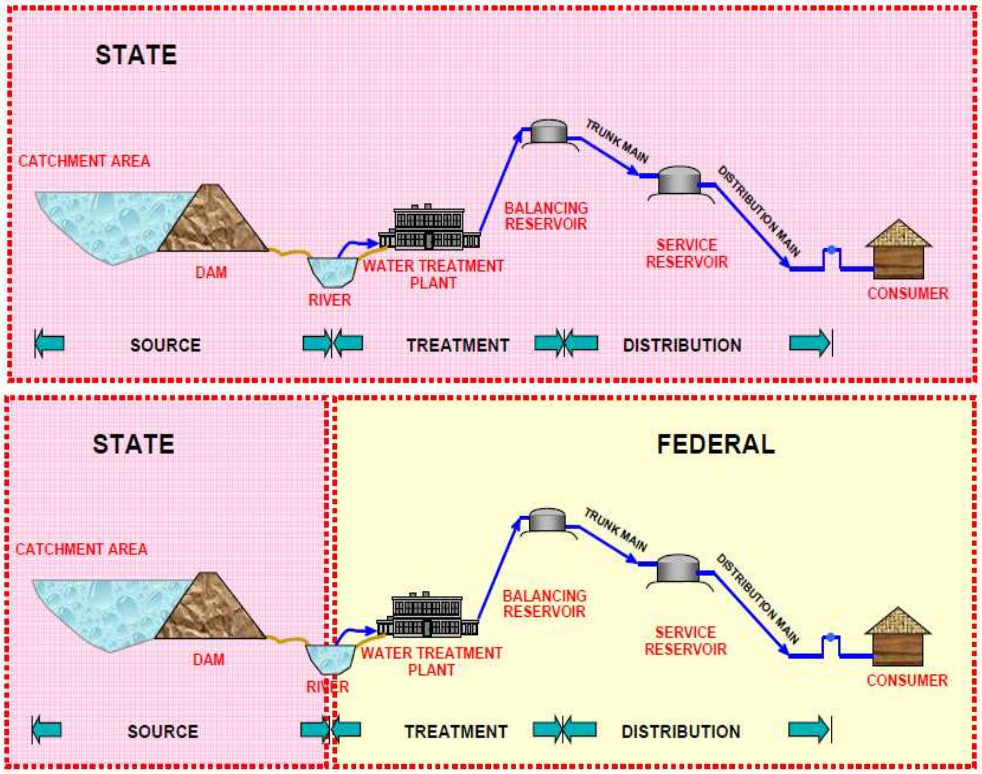

Figure 1. *Water governance after federal constitution amendment in 2005 (Wahab, 2011)*

With effect from 21 March 2005, the federal government holds the right in regulating water treatment, distribution until the delivery to consumer whereas the ownership and control of rivers, canals, dam and water catchment remains under the state governments. The state governments retain the power to declare and regulate water catchment areas, water sources and river basins (Wahab, 2011). *Figure 2* shows the roadmap of acts amendments. Further amendments were carried out in July 2006 whereby parliament passed two new legislations namely the National Water Services Commission Act 2006 and Water Service Industry Act 2006 (WSIA). *Table 9* shows the policy and institutional framework on water services reform. National Water Services Commission Act provides for the establishment of National Water Services Commission (SPAN) as the technical and economic regulator and set out the function and power of SPAN. Water Service Industry Act provides the legal framework required for the regulation of the water and sewerage service industry. The Acts were enforced on 1st February 2007 and 1st January 2008, respectively.

Figure 2. *Roadmap of water services acts amendments (PAAB, 2013)*

Table 9. *Policy and institutional framework on water services reform (Wahab, 2011)*

Body	Area of responsibility	Description
Federal Government	Policy matters	Development of a holistic water policy for the country by setting policy directions
State Government	Raw water matters	Regulate raw water abstraction and catchment management
National Water Resource Council (NWRC) – chaired by Prime Minister	Water resources matters – cross boundaries/inter state/issue of national interest	Ensures coordination with the various State Governments in the management of the water basins
National Water Services Commission (SPAN)	Regulatory matters	Regulate the Water Services industry (Water and Sewerage services)

Impact assessments and monitoring

Under Environmental Quality (Prescribed Activities) (Environmental Impact Assessment) Order 1987, the construction of dams requires obtaining the following approvals from the Director-General of Department of Environment prior to project commencement:

i. Environmental impact assessment for prescribed activities
ii. Site suitability evaluation
iii. Written notification or permission to construct
iv. Written approval for installation of equipment
v. License to occupy and operate prescribed premises and prescribed conveyances

However, the schedules only cover drainage and irrigation; power generation and transmission and water supply. There is no specific schedule for multi-purpose dam construction. Considering constructing a multi-purpose dam is a complex process as it needs to take into account of the challenges of social, environment and its sustainability and it would be a challenge for the proposal to construct a multi-purpose dam.

Constructing a dam represents a potential water resource which is tantamount to potential hazard to downstream life, property and natural resources. Failure of any type of dam structure can result in loss of life, property and natural resources. Thus, a dam structure needs to be planned, constructed, and kept under proper surveillance, maintained to keep them in safe serviceable condition. A manual on Dam Safety, Inspection and Monitoring has been developed by Department of Irrigation and Drainage (DID) of Malaysia specifies the dam safety, inspections and monitoring throughout the lifecycle of the dam. *Figure 3* shows the lifecycle of a dam where it starts from planning, design, construction, commissioning, reservoir filling, operation, maintenance and surveillance to abandonment or rehabilitation. Each stages, the roles of government and consultants in monitoring the lifecycle of the dam is shown in *Table 10* (DID, 2009).

Lawsuits and dispute settlement

Lawsuits and dispute settlement is another legal and regulatory aspect to be taken into account in constructing a multi-purpose dam, particularly over environmental impact assessments (EIA) and community relocation. According to Sovacool and Bulan (2011), critiques related to reliance EIA on inadequate data, poor or incomplete hydrological analysis, and predictions of sediment delivery incorrect by more than one order of magnitude, as well as flawed projections about the effect on biodiversity and displaced communities have led to lawsuits filed against the dam construction projects in Malaysia. Non-governmental organization (NGOs) banded together to oppose dam construction projects, where they argued that consultation with the displaced communities was prone to multiple errors related to surveys of land, compensation, choice of contractors and consultants for the site, and the logistics of the relocation itself. The ineffective executions of the environmental and social impact assessment for the dam construction planning have resulted dispute and questioned on the legitimacy of parts of EIAs.

In South Korea, the "Act on Dam Construction and Assistance, Etc. To Neighbourhood Area" has been enforced in 10th Dec 2009 to give a guideline for construction, management of dams and support for residents of dam construction area.

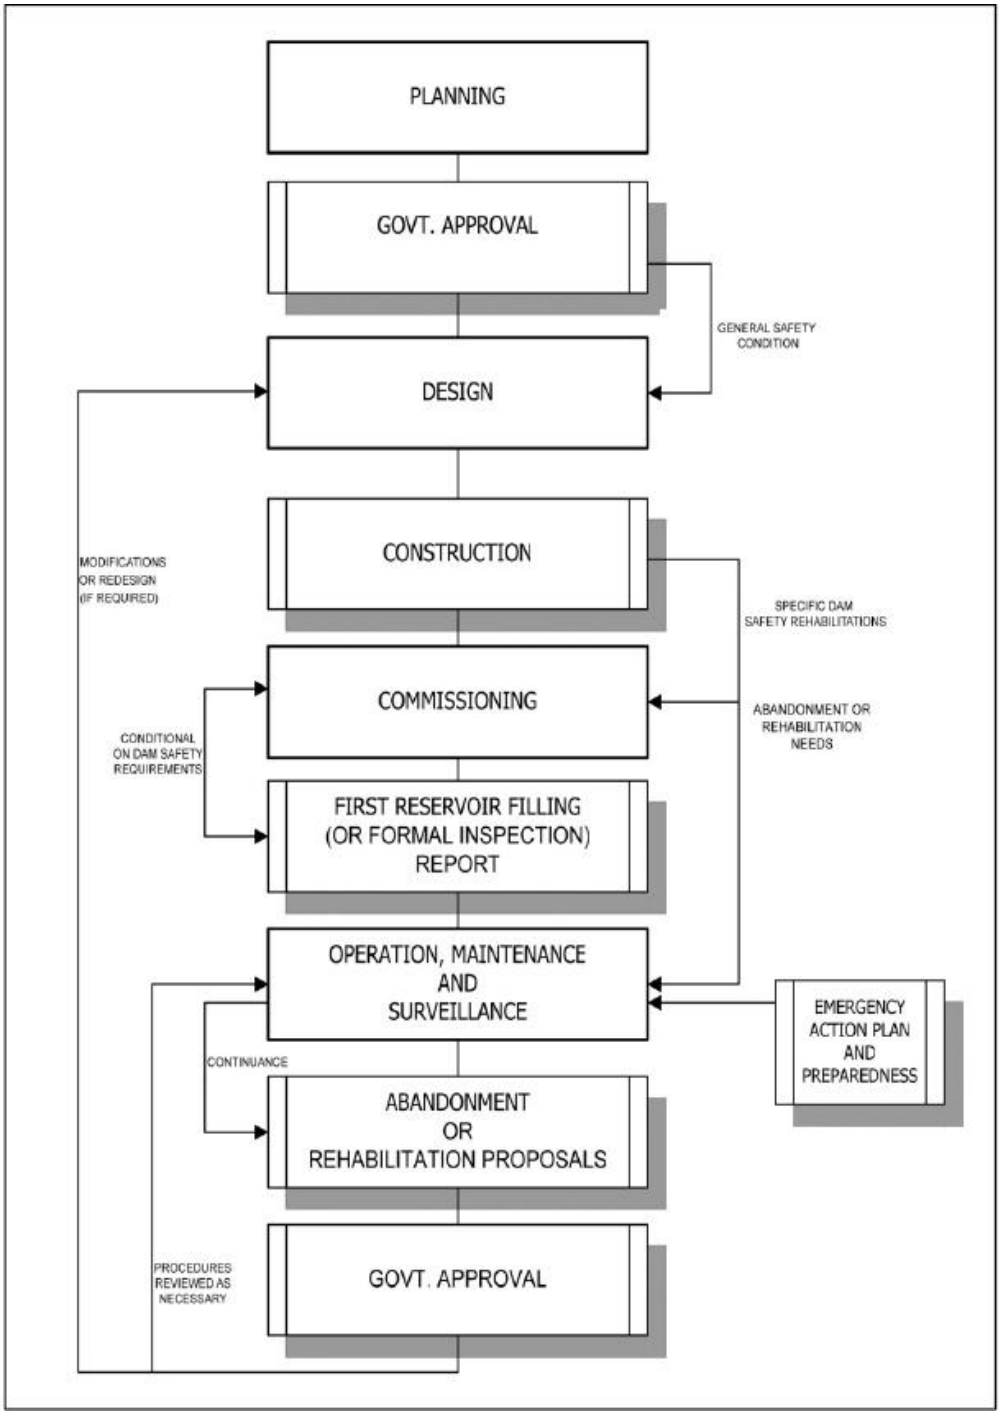

Figure 3. *Lifecycle of a dam (DID, 2009)*

The purpose of the Act is to contribute to the development of the national economy through the rational development and utilization of water resources by providing for the construction and management of dams, the reuse of construction costs, environment countermeasures according to the construction of dams and assistance to the residents of areas adjacent to dams (Ministry of Land, Transport and Maritime Affairs Korea 2009). Malaysia is still lacking an Act to be enacted specifically for dam development and management which is able to provide a guideline for developing environmentally and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

sustainable sound dams. In the Act, a holistic dam planning, development and management mechanism should be expounded where a pre-survey, social and environmental impact assessment shall be carried out effectively together with the local residents' councils and civil organization to avoid dispute and ensure construction of dams in harmony with local environment and communities.

Table 10. *Roles of government and consultants in dam's life cycle (DID, 2009)*

Stage	Activity	Role of government/DID	Consultants
Planning	• Concept	- Ascertain need - Reconnaissance	
	• Prefeasibility study	- Prepare TOR/Invite proposals - Appoint consultants/Finance	- Carry out investigations and prepare report
	• Feasibility study	- Review report of consultants - Prepare TOR/Invite proposals - Appoint consultants/Finance - Review report of consultants	- Carry out investigations and prepare report, including EIA, EMP and socio-economic study of the people affected by the project
Design	• Detailed design	- Prepare TOR/Invite proposals - Appoint consultants/Finance - Review report of consultants - Review consultants production	- Carry out investigations and prepare report including design and O&M manual prepare tender documents including drawings specifications, etc
Construction	• Tendering	- Prequalify/Call for tenders	- Prepare criteria/NIT - Assist government/DID in evaluation
	• Construction	- Evaluate tenders/Award - Supervise construction, executed by constructors - Make payment to the contractors as per contracts	- Assist DID in supervision of construction of works, including evaluation of the work executed, preparation of payment to the contractor and evaluation of contractual claims, if any
First reservoir filling	• Vigilance	- Exercise vigilance till reservoir is full, and after	- Assist government/DID in exercising vigilance
		- To keep liaison with relevant authorities for emergency preparedness	- Prepare First Reservoir Filling Report, including inspection and monitoring and assessment of dam's performance
Operation and maintenance	• Surveillance • Monitoring • Inspection • Operation • Maintenance	- Execute - Execute - Execute - Execute	
Aging	• Rehabilitation	- Seek assistance of consultants preferably designers	- Design and supervise construction executed by contractors
Abandoning	• Decommissioning	- Execute, get structures dismantled as and if required	- Advise/Design dismantling, if required

Technical aspects

Hydrology, rainfall and sedimentation

The complexity in planning, constructing, operating and maintaining of multi-purpose dams is a major challenge in its realization. These activities involve sophisticated technical requirements. In the planning and constructing of a multi-purpose dam, hydrology of the water catchment is one of the main challenges to be overcome. The dam should be designed to cater the rainfall volume. Learning from the experience of Bakun (Sovacool and Bulan, 2011) whereby Bakun area was prone to lots of rainfall, more than 4500 mm per year in some years. Building a dam in that type of weather proved difficult. The underestimation of the rainfall has caused unsuitable design and led to the redesign of Bakun dam. Such a flawed dam design has caused a big lost to the investment. In addition, sedimentation is also a challenge, in which logging, land clearing and unsustainable agricultural practices have caused the severe deforestation. High rainfall will cause the runoff of large amounts of sediment, silt, clay and gravel into the water body. Such a high sedimentation rate may impede the dam construction, operation and maintenance whereby extra technical considerations need to be taken into account to avoid damage to the dam.

Geographical isolation and provision of infrastructure

Due to the geographical and hydrological needs, the location of the dam construction is usually planned in an isolated area whereby no access roads and other infrastructure around the construction site. Transporting the construction materials, turbine and transformer components to the dam site is a challenge as the items are way too heavy to be transported. Therefore, a massive infrastructure development from scratch is required to take place to bring in construction materials and generators. Despite the said necessity for the dam construction, there are also needs to supply accommodation, medical service, food, clean water, electricity to the construction staffs before construction could commence. In other words, building a dam is not solely concerning about the reservoir only, but it needs a holistic planning for the adjacent development to ensure the sustainability of a dam (Sovacool and Bulan, 2011).

Dam excavation, construction, coordination and human resources

In addition to the provision of infrastructure, the dam excavation and construction are of the main technical challenges whereby each dam needs river diversion, tunnelling, channelling and access to the dam to transport machines and turbines (Sovacool and Bulan, 2012). The complexity of the project hence required coordination and human resources for the excavation and construction. Over thousands of skilled workers, engineers and contractors are needed in the construction of dam in building spillways, powerhouses, transformers, turbines, and the dam face. In developing country like Malaysia, there is lack of technical capacity to build dam, hence thousands of foreign workers need to be imported to participate in the dam construction. Besides that, building a dam also needs joint venture with many sub-contractors in which the selection of the competent sub-contractors is particularly important. The coordination of these workers and sub-contractors is formidable because any flaw in coordination will cause a major disaster to the project.

Infrastructure operation and maintenance

The challenge of operating a multi-purpose dam is the balancing of competing demands. For example, the water level often needs to be as high as possible in view of the stored water in the dam serves as the stored energy for hydroelectric power generation purpose. However, for flood control purpose, the water level needs to be as low as possible to provide the storage space for rainwater runoff. Operators need to release enough water for downstream navigation, but store enough water to have a safety margin for electricity generation. River flow in a tropical rainfall country can rise as much as 10 m per day, 20 m when raining or flooding (Sovacool and Bulan, 2011). Such a contrast makes the operation of multi-purpose dam critical and challenging in the management of water level, mismanagement and misoperation might cause catastrophic damage in the downstream area with a clean sweep of the life and property that comes in its way. For instance, a tragedy happened in Cameron Highlands in 2013, whereby at least three people are dead and dozens of houses and cars were damaged after flood water was released from the dam. The operator claimed that the water was released "as a measure to avoid flooding the entire Bertam Valley", following heavy rains and flash flooding that "caused an overflow into Lake Ringlet that surpassed maximum levels". Local sources reported that one of the dam's four gates was opened to help lower the water level, and that if it had not been opened, all four dam gates might have opened automatically which potential to cause even more damage (Hydroworld.com, 2013). The dam maintenance is another challenge for the dam due to the huge sheer size and volume, underwater maintenance of tunnels, intake structures and the reservoir, completely shut down for 80–90 days is required for the turbines maintenance service to take place every 10–15 years (Sovacool and Bulan, 2011). With the high rainfall around the reservoir makes the service maintenance work difficult to be carried out.

Economical aspects

Future water demand

The population of Malaysia is continuing to grow where the population of Peninsular Malaysia will double its size from 18.1 million in 2000 to 38 million in 2050. The future water demand is depending on the population growth and socio-economic development. Urbanization and migration from rural to urban area is also evident where a relative number of the population concentrated in urban areas where high economic activities exist. The increasing population associated with the increasing economic development gives improvements in the standard of living results in the increased demand for water supply. Thus, it has given a pressure on the water resources. The challenge is not only to provide adequate water for the increasing demand but also stimulate the development in rural areas to relieve migration and reduce the pressure in the urban areas. The domestic and industrial water demand for Peninsular Malaysia is projected to increase 3-fold from 9543 MLD (3483 million m^3/yr) in 2000 to 31,628 MLD (11,543 million m^3/yr) in 2050. On a Peninsular Malaysia-wide basis, during periods of severe drought, the average natural or unregulated flows can barely meet the projected demand in 2050 of 31,628 MLD. Therefore, new dams or water reservoirs are needed as new sources to augment water supply over the next 50 years (Mohamad Salleh, 2011).

© 2018, ALÖKI Kft., Budapest, Hungary

Capital intensity, financing and returns on investment

Constructing a dam is a huge investment in the water infrastructure and its affiliated infrastructure. Financing remains a big challenge relating to where the money will come to meet the project plan. Building a dam is normally financed by public borrowing. Any cost overruns in building a dam can increase the stock of debt. The recurring financing cost can further escalate if interest rates go up. For example, the actual cost of Pakistan's Tarbela dam, the majority of which was borrowed from external sources, amounted to 23% of the increase in Pakistan's external public debt stock between 1968 and 1984 (Flyvbjerg et al., 2014). In addition, the cost analysis of the dam construction often omits the effects of inflation and the risks of unanticipated inflation which resulting financed with additional debt. For example, the hyperinflation in Argentina, Brazil, Turkey and Yugoslavia caused staggering nominal cost overruns, e.g. 7-times initial budget for Brazil's Estreito dam (1965–1974), or 110-times initial budget for Yugoslavia's Visegrad dam (1985–1990). Also, the effects of unanticipated inflation exacerbate when the dam takes longer than planned time to complete a project. For example, during the planning stage of Pakistan's Tarbela dam, it was assumed that inflation would not have a significant impact on the project's costs. A general contingency of 7.5% has been added in accordance with normal practice for the project of this size and duration. However, the project which was launched in 1968, was meant to commence in 1976, but the opening was delayed until 1984. Such a delay has caused the actual cost of the dam in nominal terms nearly four times the initial budget due to the actual cumulative inflation in Pakistan during 1968–1984 was 380%. It is about 8 out of 10 large dams delay of 2.3 years in completion whereby the expected annual inflation rate to be 2.5% but it turned out to be 18.9%. Large dams particularly have a high tendency to face unanticipated inflation. Thus, the outsides view suggests that in most cases dam will be too challenging in absolute terms and take too long time to build and deliver a positive return on investment (Flyvbjerg et al., 2014).

Social aspects

Community relocation, resettlement and compensation

The construction of dams often, if not always, involves relocation of communities and livelihoods. When relocation and resettlement take place, compensation is recognized as providing support to displaced people and to the maintenance of the legitimacy of socio-political structures and the modernization project (Wang et al., 2013). Affected community have to make the difficult decision of abandoning their homes and livelihoods, causing emotional distress. Therefore, adequate compensation is needed to compensate their loss of natural resources, social heritage and land which cause misery to their distressed livelihood. Without adequate compensation, resettlement of people into a new area will not improve the lives of the community and this has failed to accomplish the purpose of resettlement (Sovacool and Bulan, 2011). Thus, the relocation, resettlement and compensation of the community are of the most challenging social barrier to be taken into account prior to the construction of dam.

Community livelihood and welfare

Social impacts on community livelihood and welfare caused by the relocation and resettlement are diverse. For example, the relocation of residents due to Manwan Dam

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_23232347
© 2018, ALÖKI Kft., Budapest, Hungary

China has caused the diversified income sources, widened income gaps and gave an overall adverse impact on standard of living (Fu and He, 2003). Also, the displacement of the entire indigenous population (around 10,000 people) in Bakun dam region has caused a drastic process of socio-economic disintegration and cultural extinction of the indigenous communities. Such a displacement has also caused the abandonment of traditional livelihood and economic activities which were adapted to local ecosystem and the complete loss of knowledge of these practices within the local population (Choy, 2005). It is also argued that the construction of Three Gorges Dam has impacted the cultural heritage whereby it has eradicated some historical heritage sites and unique sources of knowledge due to dam inundation (Jackson and Sleigh, 2000).

Environmental aspects

Climate change

The future climate change is going to impact the hydrological regime and water resources in Malaysia (Wong et al., 2009). *Table 11* shows the projected rainfall for 2025–2050 for Malaysia. This hydroclimate projection study shows a projection increase in average annual precipitation (mm) in Perak, Kedah, Terengganu, Kelantan and Pahang. However, a decrease in average annual precipitation (mm) is projected in developed urban areas like Klang, Selangor and Johor (Kavvas et al., 2007). Higher maximum and lower minimum rainfall observed could result in more extreme hydrological conditions. These changes in rainfall have led to changes in the river flows. The flood flow changes range from +6% to +47%, while the low flow changes range from -35% to -93%, in which more frequent floods and droughts are projected in future (Zakaria and Shaaban, 2007). Climate change is a challenging factor in the planning and constructing of a multi-purpose dam in a tropical country like Malaysia as the dynamic condition of the local region could change the climatic condition as well as the level of hydrological regime.

Table 11. *Average annual rainfall (Kavvas et al., 2007)*

Regions	**Sub regions**	**Average annual precipitation (mm)**		
		1984–1993 (1)	**2041–2050 (2)**	**(2)–(1)**
North West Region	West Coast	2151.0	2099.3	-51.7
	Perak	2314.8	2398.0	83.1

Land clearing, deforestation, degradation, impoundment and greenhouse gas emission

The most significant environmental challenge is the land clearing, deforestation, land degradation, impoundment of reservoir and greenhouse gas emission (Sovacool and Bulan, 2011). A huge area of bare land is needed for water impoundment. Therefore, extensive logging is the only way to acquire land within the catchment area. It is noted by Choy (2005) that the deforestation and submerging of the catchment area will destroy biomass home to rare and endangered species, protected bird species, protected mammals, protected plants including herons, eagles, woodpeckers, silvered leaf monkeys, Bornean gibbons, langurs, and flying squirrels. To accelerate the logging process, access roads is built to the dam and further worsen the deforestation and lead to the degradation of the exposed bare land. It is also noted that impoundment process during the dam construction will become a significant source of greenhouse gas emissions, especially carbon dioxide and methane arising from microbial decomposition of the submerged forest, vegetation, wildlife and soil. *Figure 4* shows microbial and methanogenesis and denitrification of impoundment process. The inundated forest biomass will be transformed into carbon dioxide (CO_2) and methane (CH_4) and nitrous oxide (N_3O) through decomposition, microbial methanogenesis and denitrification. The anoxic condition in the deep reservoir will trigger the conversion of organic carbon into CH_4 instead of CO_2. CH_4 in shallow waters may form bubbles and release to the atmosphere. The emission of these greenhouse gases may be built up in the atmosphere as a heat trapping layer. Carbon emission is primarily contributed by the flooded biomass. Other sources of carbon emission include (i) carbon from the soil and peat of the reservoir; (ii) dissolved organic carbon/particulate organic carbon; (iii) organic debris from the catchment and; (iv) decomposition of animals and algae in the reservoir following their death.

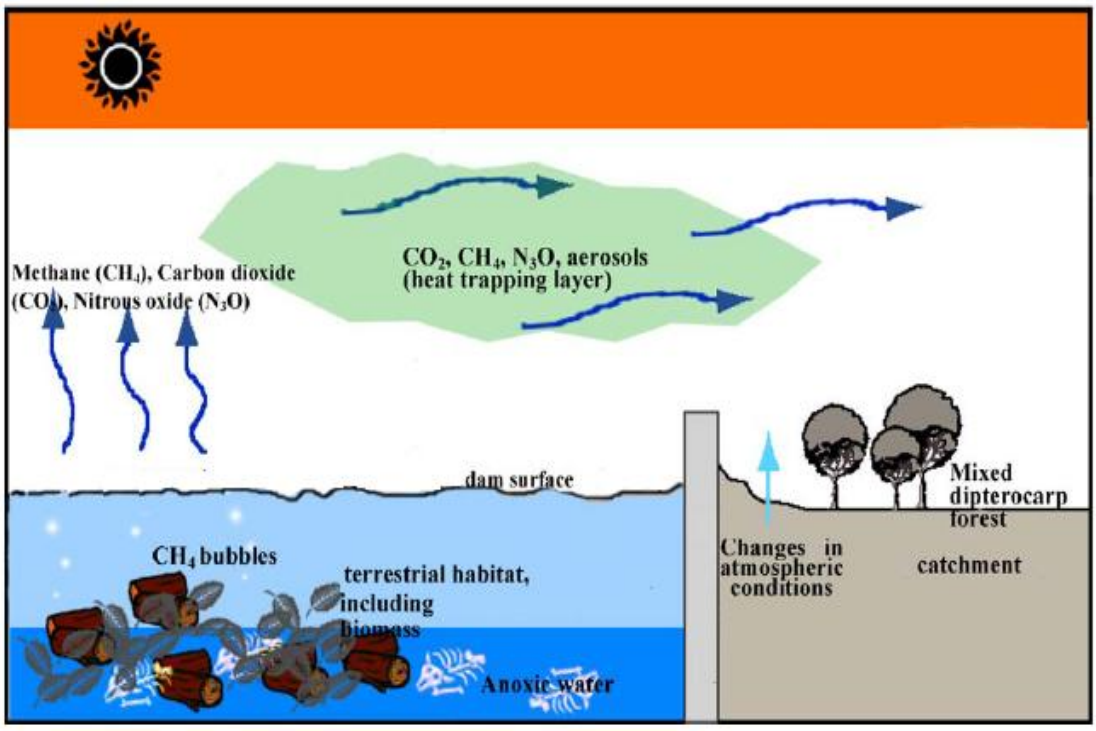

Figure 4. *Microbial methanogenesis and denitrification of the impoundment process (Choy, 2005)*

The warming effect is also associated with greenhouse gas emission when the extra energy attempts to leave the earth surface in the form of infrared radiation, but much of it will be absorbed in the atmosphere by the principal heat-trapping gases such as water vapour, CO_2 and CH_4. This turn of event will not only contribute to global warming, but also affects the sink capacity for atmospheric pollution and hydrological conditions in the surrounding area of dam. This sequence of climatic change will pose a severe ecological threat on forest ecosystem in the catchment area. As illustrated by Choy (2005) in *Figure 5*, the microclimate change in the surrounding area of dam is mainly attributed to the complete exposure of the dam surface to direct solar irradiance. Some of the heat is reflected to the space immediately from the top of the clouds (17%) while adsorbing about 4% of it. The rest is absorbed by the atmosphere (23%) or the surface (46%). Respectively, the aerosols and terrestrial surface reflect about 8% and 6% of the incoming radiation in the form of infrared radiation but much of it is trapped in the atmosphere by the heat trapping gases (CO_2, CH_4, N_2O, and water vapour). This serves to worsen the warming effect.

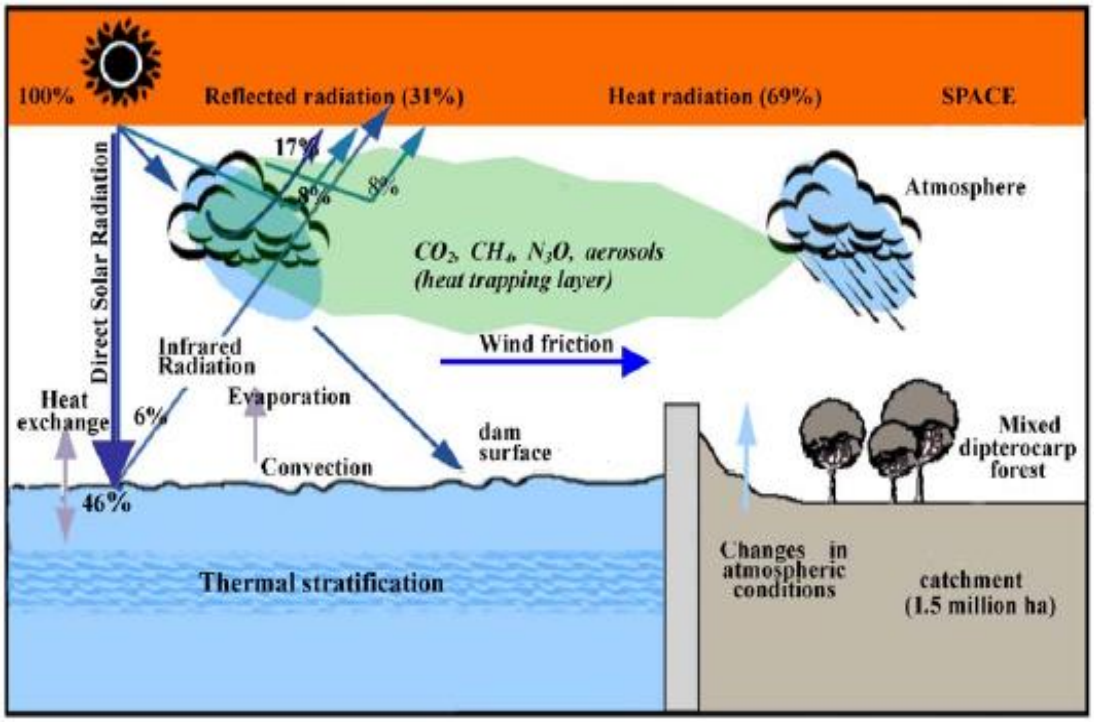

Figure 5. *Warming effect and seasonal microclimate change at the surrounding area of dam (Choy, 2005)*

Changes to water quality and river flow

Another environmental challenge is noted by Sovacool and Bulan (2011) where the construction, impoundment and operation of dam will also affect the water quality, hydrology as well as river flow. The development project will negatively influence the water quality of the catchment area through changes in the concentration of dissolved oxygen, nutrient loads, suspended sediments, and that tidal encroachment could aggravate bank erosion. During the land clearing and construction stage, due to the extensive logging and construction activities, the water body of catchment is affected by

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

the increased turbidity, loss of pool nursery habitat, reduced organic input and impaired the migration of fish. The environment would be further impacted during impoundment where river flow and organic input will be reduced and resulting in loss of habitat due to reduced water depth. The impoundment also results in increased phytoplankton production. Fish migration will be impaired due to the replacement of natural riverine habitat with artificial deep lake habitat. During the operation of the dam, the rapid water fluctuations resulting from the operation of the spillway would also increase downstream riverbank erosion, wash away trees, and prevent the spawning of fish. It would negatively influence the population of freshwater fish which become easily disoriented in slow moving waters, and fish living near the dam would be susceptible to pulverization from passing through the turbines or super-saturation and excess nitrogen from the water around the concrete face. It would also alter upstream species composition and replace native riverine species with lake-adapted species in reservoir.

Concluding remarks

Water security has become a serious issue due to rapid population growth, unsustainable use, water degradation and climate change. Sustainable water resources management and development is needed to overcome the water security issue. Therefore, multi-purpose dam has been proposed to provide affordable water and energy for agriculture, industrial and domestic sectors and ensure essential irrigation water supplies for food security. No doubt that water resources are necessary for sustainable economic development of a country. However, building a dam should not primarily be considered as an economic decision, which ascertains that the total benefit obtained from the dam operation exceeds the total cost incurred by building and maintaining the dam. Dam has to be understood as an anthropogenic interference at a central position of a complex natural system, having multiple impacts, mainly on the downstream drainage basin. Having only proper development of multi-purpose dam for management of river waters can improve economic viability, preserve ecosystem and enhance social justice of the country in the coming years.

(Received 31st Dec 2017; accepted 16th Apr 2018)

Abstract. The issue of food security is considered an inseparable part of international development policies, so creating a nationally effective system to ensure food security, in addition to supporting the nutrition and health of the community, improves food industry status and increases production and income levels. To this end, the present study was carried out to identify the essential requirements for establishing innovative rural institutions to improve the food security of rice growers in Mazandaran, Iran. Economic, socio-cultural, infrastructure, policy-making, educational, and technical requirements were investigated, with each considered an observed variable with some items for each and to survey the impact of them on dimensions of food security and finally food security itself. The dependent variable was food security, measured by the five dimensions of availability, access, use, sustainability and safety. From a total of 113,141 rice growers in Mazandaran Province, Iran 216 were selected as the sample according to the Cochran method. Structural equation modelling and Amos 22 software were used in this study. The results showed that all six requirements mentioned above have an effect on food security, with technical requirements exhibiting the greatest effect, with a coefficient of 0.914. Suggestions are proposed for implementing these requirements.
Keywords: *innovative organizations, rural institutions, food security, rice growers, small-scale farmers, requirements*

Introduction

Food security is a great challenge, and due to food prices and global economic crises, the number of malnourished people has meteorically increased (Herbel et al., 2012). The Food and Agriculture Organization (FAO, 2010) has expressed that "Food security exists when all people at all times have physical and economic access to healthy, adequate and nutritious food to meet dietary requirements and food preferences for an active and healthy life." Food security is important because the goal of ensuring food security addresses all aspects of development. Food security is a complex concept with three basic pillars: 1) the availability of food, which means a sufficient amount of food based on a stable diet; 2) access to food, which means the ability to obtain adequate and nutritious food; and 3) the use of food, which means meeting food needs and cultural preferences (Asian Development Bank, 2013).

Finally, according to various researchers, food security can be divided into five elements: sustainability, availability, accessibility, utility, and safety. To conduct a comprehensive analysis and discussion, identifying the relationship among all five elements is necessary (Pereira et al., 2014).

To reduce future food insecurity, the International Food Policy Research Institute (IFPRI) recommends a revision of the global food system focusing more on quality (nutrition) and safety and diversity than on expertise; a reduction in food and waste losses; and gender issues. Increasing sustainable products should focus on nutrition. To achieve this goal, approaches have been suggested that include investing in agricultural research and development to produce more nutritious food, leveraging more small-scale agricultural production for the value chain with a greater sensitivity to food quality (being nutritious), empowering women to link farming with nutrition, supporting policies and institutions for better nutrition and ensuring security in food systems (European Commission, 2015).

The latest estimates of the FAO show that a reduction in global hunger is continuing; from 2012 to 2014, approximately 805 million people in the world suffered from chronic malnutrition, a decrease of 100 million over the last decade of approximately 209 million people compared to 1990–1992. Since 1990, the prevalence of malnutrition in the world has fallen from 18.7% to 11.3%, and in the developing world, it has dropped from 23.4% to 13.5%. The FAO developed the Food Insecurity Experience Scale (FIES) to fill the global gap of food security monitoring, especially for assessing access levels at the individual and household levels. The FIES measures the severity of food insecurity, which is described as the number of people experiencing problems in obtaining food. The measurement of food insecurity through experience-centric scales is not an entirely new approach. These types of scales have been widely used to assess food insecurity in the United States since 1995. Similar tools such as the Household Food Insecurity Access Scale, Food and Nutrition Technical Assistance (FANTA) and the FAO Food Security Scale in the Caribbean and Latin America are currently being accepted at national, regional and project levels (FAO, IFAD and WFP, 2014).

In Iran, as in many countries, food security has been addressed through agricultural and rural development approaches, and there have been ongoing efforts to increase food availability in rural and urban communities (Hamidifar, 2012). According to Bakhshi et al. (2008), Iran's ranking in Southwest Asia based on indices of vulnerability and food security showed that Iran has high nutritional energy consumption, ranked sixth. In terms of the combined index of nutrition and food security, Iran is the twelfth-ranked country in Southwest Asia. In the economic access index, Iran is ranked fourteenth; in the agricultural macroeconomic index, fifth; in food availability index, fifteenth; in the cultural-health index, tenth; and in the total index of vulnerability, ninth. Moreover, Iran ranked first among the least vulnerable countries among the twenty countries in the region. Food security studies have identified food insecurity as a major problem in most societies with respect to the amount of food intake and nutritional, economic, social and cultural status (Rostami et al., 2014).

Rice is one of the cheapest and most effective foods available to eliminate acute malnutrition. Many studies show great potential for increasing rice production, especially in Asia. Food security in Asia has traditionally been defined as maintaining basic prices for rice in the main rural markets in the country, which provide the main food supply to more than 50% of the population. Thus, reaching self-sufficiency in terms of rice production is an effective method to promote food security at the national level. Sustainable production of rice in South Asia is the main source of food security in this region. Rice paddies have full potential for self-sufficiency in rice production, as is currently occurring in India and Pakistan. Since poverty is one of the factors directly affecting food insecurity, through employment in agricultural activities and projects

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_23492368
© 2018, ALÖKI Kft., Budapest, Hungary

currently underway in many countries in this area, people can escape extreme poverty. A survey conducted in South Asia shows that the easiest way to promote national food security is obtaining self-sufficiency in rice production (Bishwajit et al., 2013).

A study by John and Fielding (2014) in South Asia indicates that the most important limitation in rice production in this region is the socio-economic constraint of production, which was examined according to seven factors:

1. Difficult access to water for irrigation
2. Lack of quality grain
3. High cost of irrigation
4. Expensive nitrogen fertilizer of limited supply
5. Insufficient farmer knowledge
6. Lack of access to agricultural information
7. High prices of input

Given the above-mentioned issues, one can categorize the major issues and problems that have arisen due to the lack of attention to rural innovative institutions in achieving food security as follows:

1. Failure to achieve food security due to problems in the five aspects of availability, accessibility, utility, sustainability and safety (Herbel et al., 2012)
2. Failure to achieve food security due to the lack of access of small farmers to natural resources, productive assets, markets, and knowledge and information (Herbel et al., 2012)
3. Failure to achieve food security due to inappropriate management models in rural areas (Moradi and Popzan, 2014)

Among the most important benefits and achievements of this research is help in creating effective production organizations to improve food security. Overall, productive and sustainable production organizations and institutional arrangements with market agents and policymakers are also dependent on the three types of relationships developed by small-scale producers (Herbel et al., 2012):

1. Connection or linkage or intergroup relationships among small-scale producers within organizations
2. Establishing communication or inter-group relationships between small producer organizations to create reference organizations
3. Establishing communication or inter-group relationships between small producer organizations and market agents and policymakers

The main goal of this study is to finding the set of requirements that important for establishing rural innovative institutions to improve food security from rice grower's perspective in Mazandaran Province, Iran. In this regard, the following objectives were extracted:

- Recognizing the economic requirements to establishing rural innovative institutions for improving food security of rice growers in Mazandaran Province
- Recognizing the socio-cultural requirements to establishing rural innovative institutions for improving food security of rice growers in Mazandaran Province

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

- Recognizing the infrastructural requirements to establishing rural innovative institutions for improving food security of rice growers in Mazandaran Province
- Recognizing the policy-making requirements to establishing rural innovative institutions for improving food security of rice growers in Mazandaran Province
- Recognizing the educational requirements to establishing rural innovative institutions for improving food security of rice growers in Mazandaran Province
- Recognizing the technical requirements to establishing rural innovative institutions for improving food security of rice growers in Mazandaran Province

Theoretical framework

Governments and international organizations are seeking effective institutional frameworks for managing and helping rural and agricultural development to address the challenges of increasing farmers' integration in local and regional markets and value chains, increasing public-private investment in agriculture, increasing concern regarding food security in the world, rural poverty, regional disparities, flexibility, and climate adaptability in land use. The overall challenge is to strengthen rural development processes in government to ensure positive effects and new opportunities for micro-farmers, rural communities, local economies and communities and nations as a whole. The expected outcomes are to reduce vulnerability and increase social capacity, flexibility and sustainability in agricultural systems on a larger scale than exists today. New institutional arrangements and partnerships create a link between the private and public sectors needed to strengthen the governance of natural resources and land; improve information, consultation, and technical development; and support the families of farmers, communities, and rural areas to achieve sustainability (Natural Resources Institute, 2016).

Allameh (2012) described the following factors affecting food security:

- Political, social and economic stability
- Type of resources available to community producers
- Conservation and sustainable use of sustainable resources
- Different consumption cultures
- Level of income and financial ability of households
- Demographic indicators
- Price policies
- Rural and agricultural development

Allameh showed the aspects and components of food and nutrition security as presented in *Figure 1*.

Keshavarz and Karami (2014) investigated the causes and factors affecting food insecurity and provided recommendations for policymaking in the field of extension to improve the food security of rural households. The authors used the Sen (1981) perspective and the study by him as shown in *Figure 2* to explain the framework for their research.

Materials and methods

The above-described principles and techniques were used in this study with the aim of solving executive problems and applying practical knowledge in Mazandaran province of Iran. The research process was both qualitative and quantitative and cross-sectional in terms of the timeline. The research approach was quasi-experimental, and the researcher had some control over the variables. The study involved a survey considering data collection. The population consisted of 113,141 rice growers in Mazandaran and used a stratified random sampling method with proportional allocation. The original sample volume was determined using the Cochran formula (*Eq. 1*) for 216 people (Cronbach, 1951).

$$n = \frac{Nt^2 s^2}{Nd^2 + t^2 s^2} \qquad \text{(Eq.1)}$$

The tool used in this study for data collection was a questionnaire. The questionnaire consisted of eight sections:

- Section 1: Economic requirements (11 items)
- Section 2: Social-cultural requirements (10 items)
- Section 3: Infrastructure requirements (6 items)
- Section 4: Policymaking requirements (9 items)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_23492368
© 2018, ALÖKI Kft., Budapest, Hungary

- Section 5: Educational requirements (7 items)
- Section 6: Technical requirements (6 items)
- Section 7: Personal treatments (15 items)
- Section 8: Food security dimensions (Availability (7 items), Accessibility (7 items), Utility (5 items), Sustainability (5 items), Safety (4 items))

To evaluate the content validity of the questionnaire, portions were provided to professors of agricultural promotion and development as well as to experts and specialists in the field of rice and members of the rice community. Cronbach's alpha method was used to calculate reliability. A pre-test was used, and 30 questionnaires were distributed among the rice growers to calculate Cronbach's alpha. Structural equation modelling using a classical approach was used, and SPSS 16 and Amos 22 software were used for analysis.

Results

Describing the data

For a better understanding of the nature of the population studied in the research and to become more familiar with the research variables, it is necessary to describe these data before the analysis of statistical data (*Table 2*).

Table 2. *Demographic characteristics of the subjects (n = 216)*

Items	Mean	Median	Mode	Min	Max	SE
Age (year)	51.68	50	40–50	25	90	0.85
Gender	-	-	Male			
Level of education	-	-	Diploma			
Family members	4 persons		-			
Land size (m^2)	7752	7000	8000	2000	50000	4.72
Amount of yearly rice production (ton/year)	3.35	3	2.4	0.50	25	0.23
Experience in agriculture	27.27 years	25 years	30 years	2	70	1.19
Ownership	-	-	Personal			
Familiar with Rice Institution	-	-	No			
Membership in Mazandaran's Rice Institution	-	-	No			

Table 2 shows that the average age of respondents was over 51 and that most of them were males with a high school diploma. Moreover, the average number of people in households was 4, their average agricultural land area was less than 1 hectare, and they produced more than 3 tons of rice per year. A significant percentage of respondents were not only not members of their province's rice association but were not familiar with the association.

Inferential statistics

To determine the estimation method for unknowns in the equation of structural equations, the contribution of each unknown to the parameter volume is first calculated. Given the sample size (n = 216) and the number of unknown parameters of the model (NPar = 119), the contribution of each unknown parameter was calculated to be 1.81 (*Eq. 2*).

$$\frac{n}{NPar} = 1.81 \qquad \text{(Eq.2)}$$

However, given that all research questions had a 5-point Likert scale, the normal assumption of multiple-variable observations was not confirmed. There are two approaches for solving this problem: 1) using the Bayesian approach or 2) using the latent variable assignment approach to each question that has a Likert scale. In this research, we chose the second approach for the following reasons.

The measures to check goodness of fit using the Bayesian approach are mostly graphical, while in the classical approach, all criteria are quantitative and easy to compute and compare.

To use the Bayesian approach, it is better to have the statistical information of an expert population available to provide a useful analysis. If this is not the case, there are no significant differences between the Bayesian and classical approaches (Lee, 2007).

After assigning a latent variable with a normal distribution to items with Likert scales, using the AMOS22-embedded equation approach with ten times the original sample size, we generated 2160 random numbers from the normal multivariate distribution. The generated data with multivariate normal distribution were the basis of our calculation. As the share of each unknown parameter of 2160 generated randomized samples was 10.8 and there was a multivariate normal assumption, using the maximum likelihood method in the classical approach, the unknown parameters were estimated.

After charting using AMOS22 software, the software outputs are presented in tables as well as a graph of the structural equation model as shown in *Figure 4*.

We present some of the goodness-of-fit criteria of the model in *Table 3*.

Table 3. *Some of the goodness-of-fit criteria of the model*

Model	X^2 Value	df	p-value	X^2/df	RMSEA	Pr (RMSEA≤0.05)
Fitted model	2974.055	2914	0.214	1.020	0/019	0.999
Saturated model	0.000	0			Uncountable	Uncountable
Dependence model	4592.630	2926	0.000	1.569	0.103	0.000

Given the goodness-of-fit criteria presented in *Table 3,* the p-value in the fitted model is 0.214, which is greater than 0.05. Thus, it is at an acceptable level. The RMSEA value is 0.019, which is less than 0.05, and the chi square over the degree of freedom ($1 < x^2 / df < 3$) is calculated as 1.020, both of which are acceptable. Therefore, the fitted model is a suitable and dependable model in terms of all criteria for goodness of fit.

According to *Table 4,* the technical requirements had the greatest impact on food security, with a coefficient of 0.919, followed by educational requirements with a path coefficient of 0.914, socio-cultural requirements with a path coefficient 0.862, infrastructure requirements with a coefficient of 0.844, policymaking requirements with a path coefficient of 0.771 and, finally, economic requirements with a path coefficient of 0.775. Moreover, by examining the effect of each of the requirements on the five aspects of food security, one can see that the technical, educational, socio-cultural, infrastructure, policymaking and economic requirements with path coefficients of 2.344, 1.196, 1.465, 1.789, 1.999 and 2.113, respectively, had the greatest impact on access to food security.

Table 5 summarizes the impact of each of the five dimensions of availability, access, use, sustainability and safety on food security.

Table 5. *Total effect (standardized) of each dimension of food security on the dependent variable (food security)*

Independent variables (observed variables)	Dependent variable (food security)
Availability	0.672
Accessibility	0.642
Sustainability	0.632
Utility	0.629
Safety	0.521

Table 5 shows the impact of each of the five aspects of food security on the dependent variable (food security), which, according to the results presented, shows that the dimension of availability is the most effective, with a coefficient of 0.672, followed by access, sustainability, use and safety. The effect of each of the observed (independent) variables on food security (dependent variable) is presented in *Table 6*.

Table 6. *The total effect of standardized variables on the dependent variable (food security)*

Independent variables (observed variables)	Dependent variable (food security)
Educational Requirements	
• Launching publications and journals on rice crop operations	0.808
• Conducting workshops on rice crop operations	0.811
• Increasing human capital through training an expert force	0.810
• Using the FFS method and holding a rice farm day	0.809
• Organizing various local classes, such as development classes, etc.	0.810
• Strengthening the proper use of indigenous and local knowledge	0.808
• Strengthening access to knowledge and information	0.814
Technical Requirements	
• Using new technologies in agriculture, such as nanotechnology, nuclear technology, etc.	0.812
• Using proper technology in planting, preservation and harvesting	0.807
• Using new methods in irrigation	0.806

• Making multifunctional use of rice cultivation such as rice cultivation with breeding of ducks, fish, etc.	0.805
• Using hybrid seeds and modified varieties	0.807
• Using machines in transplantation	0.804
Infrastructure Requirements	
• Creating industries and conversion and complementary enterprises in villages	0.807
• Improving access to information and communication technology (ICT)	0.807
• Improving the access of farmers to the proper equipment for the preparation and renovation of arable land	0.809
• Improving access of skilled rice growers to a proper transportation system	0.809
• Improving access of farmers to suitable arable lands for cultivation	0.804
• Strengthening the access of rice growers to water resources and optimal management	0.812
Policy-making Requirements	
• Ensuring that the voices of small-scale producers are heard by the authorities to participate in the policymaking and decision-making process	812/0
• Promoting local governance and decentralization in rural management programs	0.801
• Integrating land under rice growth	0.804
• Adopting appropriate rules to reduce conflicts on land	0.801
• Creating a targeted, coordinated and coherent planning system in villages	0.808
• Improving product pricing policies	0.808
• Improving lending policies for subsidizing loans to rice growers	0.808
• Improving supportive policies for saving and securing energy	0.806
• Improving the import and export policies of rice crops	0.807
Sustainability (Food security)	
• Managing and conserving resources, especially water resources, for sustainable livelihoods	0.654
• Managing risk in rice production (use of inputs, weather conditions, etc.)	0.633
• Confronting the structural causes of food insecurity	0.658
• Monitoring food security and finding effective factors in the vulnerability of rice growers	0.641
• Creating diversity in agriculture and employment	0.577
Utility (Food Security)	
• Improving food security policies to improve food patterns and cultural patterns	0.646
• Teaching the correct use of natural resources and adapting to climate change	0.643
• Teaching the proper use of water resources and new methods of irrigation	0.638
• Improving the diagnosis of quality product	0.644
• Increasing the knowledge and information of skilled workers in using the product	0.577
Safety (Food Security)	
• Improving the quality of rice grains through training new cultivation practices	0.526
• Using mechanisms to ensure the health of the food	0.546
• Improving the quality of food	0.438

• Accessing healthy and nutritious food	0.577
Accessibility (Food Security)	
• Improving access to credit and savings systems	0.651
• Improving access to input and outlet markets	0.653
• Strengthening access to knowledge and information	0.656
• Empowering women and improving their access to resources	0.652
• Improving access to natural resources (land, water)	0.651
• Increasing revenue for microprocessors	0.655
• Improving the supply of food for the vulnerable majority	0.577
Availability (Food Security)	
• Improving and restoring resources, especially land	0.655
• Investing in new and consistent technologies	0.656
• Investing in rural markets	0.654
• Investing in infrastructure in villages	0.657
• Improving consumption patterns through a variety of training programs	0.651
• Improving research and innovation in agriculture	0.648
• Possibly improving food production in the countryside, especially through small-scale farmers	0.577
Social-Cultural Requirements	
• Ensuring the effectiveness of institutions in improving local innovation capacity through the creation of craft exhibitions, food industry, holding rice festivals, etc.	0.812
• Empowering small-scale producers to participate in the policymaking and decision-making process	0.804
• Reducing poverty reduction through self-sufficiency in rice production	0.805
• Improving gender equality through empowerment of rural women	0.803
• Promoting institutional networking and interaction between institutions (collaboration among cooperatives, etc.) in sharing information	0.805
• Strengthening social capital (trust, honesty, goodwill, self-healing, hedonism, friendship, solidarity, sacrifice, etc.)	0.803
• Building capacity and empowerment of local people	0.795
• Improving nutritional patterns and food preferences through culture	0.799
• Increasing flexibility in vulnerable populations through increased awareness	0.804
• Improving nutritional quality and food security	0.800
Economic Requirements	
• Improving access (physical and financial) to imported markets (seeds, fertilizers, poisons, etc.)	0.812
• Improving access (physical and financial) to outbound markets (product)	0.812
• Determining guaranteed purchase price	0.797
• Strengthening access for financial assistance to financial services (insurance, etc.)	0.805
• Improving collective investment by fundraisers and community members	0.799
• Creating sustainable livelihoods through the development of tourism and home care	0.804
• Reducing the cost of merchant transactions (such as shipping costs, marketing, etc.)	0.801

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_23492368
© 2018, ALÖKI Kft., Budapest, Hungary

• Increasing reliance on non-agricultural economies (agriculture)	0.800
• Ensuring the effectiveness of rural institutions in improving government finance and credit, such as loans, subsidies, etc.	0.804
• Creating job opportunities for farmers	0.803
• Increasing income of rice growers	0.800

According to the results presented in *Table 6,* we conclude the following:

Among the observed variables, the greatest impact is related to the following variables in order of importance:

- "Strengthening access to knowledge and information" is related to educational requirements with a path coefficient of 0.814.
- "Using new technologies in agriculture, such as nanotechnology, nuclear technology, etc." is related to technical requirements with a path coefficient of 0.812.
- "Strengthening the access of rice growers to water resources and optimizing their management" is related to infrastructure requirements with a coefficient of 0.812.
- "Ensuring that small farmers' voices are heard by the authorities to participate in the policy and decision-making process" is related to policy requirements with a path coefficient of 0.812.
- "Ensuring effectiveness of institutions in improving local innovation capacity through the creation of handicraft exhibitions, food industry, holding rice festivals, etc." is related to socio-cultural needs with a path coefficient of 0.812.
- Improving access (physical and financial) to imported markets (seeds, fertilizers, pesticides, etc.) and "improving access (physical and financial) to outsourced markets (product)" related to economic requirements with a path coefficient of 0.812.

Moreover, all of these variables were the most important variables according to the research background and experts' opinions.

Discussion

Ciheam (2013) asserted that by providing a consistent set of services, rural innovative manufacturing organizations can increase farmers' incomes and improve food security. These services include improving access to and management of natural resources, information and technology and facilitating participation in policymaking processes.

- In the present research, economic requirements have a positive impact on improving food security, which include the following:
  - Improving the financial and physical access of farmers to input markets (seed, fertilizer, poison, etc.) and improving the financial and physical access of outsiders to outsourced markets (the product), which are consistent with the findings of the studies by CIHEAM (2013), Mumuni and Oladele (2016),

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_23492368
© 2018, ALÖKI Kft., Budapest, Hungary

IFAD (2008), Silvestri et al. (2015), Olayemi and McIntyre (2014) and Herbel et al. (2012).
- Strengthening access of rice growers to financial services (insurance, etc.), which is in line with the findings of CIHEAM (2013), FAO (2016) and NRI (2016).
- Reducing transaction costs for traders (such as product cost, marketing, etc.), which is consistent with the findings of Biénabe and Sautier (2005).
- Improving collective investment of rice growers and members of the association and institution, which is in line with the findings of Mumuni and Oladele (2016) and Herbel et al. (2015).
- Increasing income and creating job opportunities for rice growers, which is in line with the findings of Keshavarz and Karami (2014), IFAD (2003) and Wabwoba and Wakhungu (2013).
- Improving government finance and credit, such as loans, input subsidies, etc., which is in line with the findings of CIHEAM (2013) and Keshavarz and Karami (2014).
- Creating sustainable livelihoods through the development of tourism and home care, which is consistent with the findings of Uphoff and Buck (2006).
- Determining the guaranteed purchase price, a variable that has been extracted from the results of interviews with experts in the Delphi qualitative section.

- The results showed that socio-cultural requirements have a positive effect on improving food security, which include the following:
  - Empowering small-scale producers to participate in policymaking and decision-making processes, which is in line with the findings of Herbel et al. (2012), FAO (2016) and IFAD (2003).
  - Reducing poverty through self-sufficiency in rice crops, which is consistent with the findings of Bishwajit et al. (2013).
  - Strengthening social capital (trust, honesty, good luck, self-esteem, hedonism, friendship, solidarity, sacrifice, etc.), which is consistent with the findings of Nejatian et al. (2014).
  - Building capacity and localization of locals, which is in line with the findings of Waters-bayer et al. (2015) and IFAD (2003).
  - Promoting institutional networking and inter-institutional interaction (collaboration between institutions) in sharing information, which is consistent with the findings of Agrawal and Perrin (2009) and NRI (2016).
  - Improving nutritional patterns and food preferences through culture, which is consistent with the findings of Saadi et al. (2014) and Guyomard et al. (2012).
  - Improving the quality of nutrition and food security, which is consistent with the findings of Mcinerney (2014), European Commission (2015), Waters-bayer et al. (2015) and Balie (2009).
  - Ensuring the effectiveness of institutions in enhancing local innovation capacity through the creation of handicraft exhibitions, food industry, rice festivals, etc., which is consistent with the findings of Waters-bayer et al. (2015).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_23492368
© 2018, ALÖKI Kft., Budapest, Hungary

- Increasing flexibility in vulnerable populations by raising awareness, which is consistent with the findings of CIHEAM (2013), Mumuni and Olade (2016), NRI (2016), European Commission (2015) and Waters-bayer et al. (2015).
- Improving gender equality through empowerment of rural women, which is consistent with the findings of Movahedi and Samian (2014) and Mcinerney (2014).

- In this study, infrastructure requirements had a positive effect on improving food security, which include the following:
  - Strengthening access to water resources and optimal management, which is consistent with the findings of John and Fielding (2014), Mcinerney (2014), CIHEAM (2013), Herbel et al. (2012) and FAO (2016).
  - Improving the access of rice growers to cultivated land suitable for cultivation, which is consistent with the findings of Keshavarz and Karami (2014) and Wabwoba and Wakhungu (2013).
  - Improving the access of rice growers to appropriate equipment for the preparation and modernization of agricultural land, improving the access of rice growers to the appropriate transportation system, improving access of rice growers to ICT, and creating conversion and supplementary factories in villages, all of which were extracted through interviews with experts and using the Delphi qualitative method.

- Moreover, according to the results, policy requirements for improving food security have a positive effect on food security. These requirements are as follows:
  - Ensuring that the voice of small-scale producers heard by the authorities to participate in the policymaking and decision-making processes, which is consistent with the findings of Herbel et al. (2012), FAO (2016) and IFAD (2003).
  - Promoting local governance and decentralization in rural management programs, which is consistent with the findings of Moradi and Papzan (2014), NRI (2016), Agrawal and Perrin (2009) and Briner and Wittmer (2000).
  - Establishing appropriate rules to reduce conflicts over land, which is consistent with the results of NRI (2016).
  - Establishing a targeted, coordinated and coherent planning system in villages, which is in line with the findings of Wabwoba and Wakhungu (2013) and the European Commission (2015).
  - Improving product pricing policies, which is consistent with the results of Keshavarz and Karami (2014) and Balié (2009).
  - Improving the policy of subsidizing loans to farmers, improving support policies for energy saving and energy, improving the policies for the import and export of rice products, and integrating land slabs, all of which are extracted from the results of interviews with experts using the qualitative Delphi method.

- The results of the research show that educational requirements have a positive effect on the improvement of food security, which include the following:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_23492368

- Strengthening access to knowledge and information, which is in line with the findings of Mumuni and Oladele (2016), John and Fielding (2014), Silvestri et al. (2015) and Herbel et al. (2012).
- Holding a variety of local classes, such as developmental classes, etc., which is in line with the findings of McInerney (2014), CIHEAM (2013), Herbel et al. (2012) and Saadi et al. (2014).
- Increasing human capital through specialist training, which is in line with the findings of Keshavarz and Karami (2014).
- Using the FFS method and organizing a rice farm day, holding workshops on rice crop operations, organizing publications and journals on rice crops, and enhancing the proper use of indigenous and local knowledge, which are derived from expert interviews using the Delphi qualitative approach.
- Finally, based on the results of the research, technical requirements affect the improvement of food security, including the following:
- Using modern technologies in agriculture such as nanotechnology; using appropriate technology in planting, preserving and harvesting; using modern methods in irrigation; using hybrid seeds and modified varieties; using machines for transplanting; and multipurpose use of rice cultivation such as rice cultivation with duck breeding, fish, etc., all of which are in line with the findings of Herbel et al. (2015), John and Fielding (2014), Mbaga (2013), Keshavarz and Karami (2014) and Uphoff and Buck (2006).

Conclusion

Poverty and food insecurity are closely interrelated; poor food and nutrition have a major effect on human health, reduce human development and, in the long-run, reduce labor productivity. Food security is an integral part of international development policies. Creating a nationally effective system for ensuring food security, in addition to helping to improve nutrition and community health, will improve food industry and increase production and income levels. Thus, improving the infrastructure and existing policies is important in creating a nationally effective food control system (Pereira et al., 2014).

Innovative institutions, as living structures and organizational dynamics, have a positive effect on creativity and innovation as these structures are less formalized and focused. With their greater flexibility, these institutions can adapt to the needs of the environment to facilitate creativity and innovation. The environment is constantly evolving; therefore, organizations, including cooperatives, must adapt to new conditions to survive and even to maintain the status quo. Such adaptations require factors such as innovation and creativity in the organization. In fact, innovation is a response by organizations to the transformation of the market to compete with other companies to ensure their survival and growth and to improve management considering the innovations of the day. Certain principles and frameworks applied by companies in a competitive environment are applicable for transforming organizations in terms of structure, workflow, the identification of the main and secondary processes, organizational culture, etc. Improving the adaptability of organizations has attracted the attention of many experts, and adaptability can make organizations more effective and efficient in the turbulent and uncertain world of today (Moosavi et al., 2014). One of the main functions of innovative rural organizations is to improve food security. The

DOI: http://dx.doi.org/10.15666/aeer/1603_23492368
© 2018, ALÖKI Kft., Budapest, Hungary

definition of household food security is the physical, social and economic access of members of the family to healthy, complete and sufficient diets all the time that satisfy dietary requirements and their willingness to eat to have a healthy life. Access to healthy and nutritious foods, receiving adequate food and being free from hunger are essential. In addition to having food available to the household, there must be the financial ability to buy food to have "food security."

Findings of this research show that the Technical Requirements have the most impact on Food Security so the rural innovative institutions can train and educate the new technologies to the small- scale farmers such as Nano technologies and Nuclear technologies. For example, Silver Nano particles that could raise the efficiency of rice fields and production of rice varieties that resistant to the drought and salinity through nuclear technology.

Also, one of the important and innovative matters in these results that should considered is the impact of all the requirements on accessibility in food security, because of geographic condition and lack of water resources the rural innovative institutions could work on some practical ways for these problems, include the improving access to the small dams and reduce the water consumption with the new methods such as System of Rice Intensification (SRI) and Rice Dry-Soil.

At the end, the following suggestions are made to improve food security through the creation of rural innovative institutions:

- Acquiring indispensable materials at the local level: For the development of agriculture in developing countries, access to five essential resources is essential: capital (land, machinery, and renewable resources such as water), markets (for example, infrastructure adequacy, communication networks that provide farmers with access to the latest prices and the ability to meet the supply standards in supermarkets), credit (preventing early product sales by small farmers or improving access to basic facilities such as fertilizers), knowledge (in cases where there is an urgent need to invest in agricultural subsidiary services to help research be transformed to the work environment) and risk management tools.
- Improving access to social support: Support networks in the country can be created by rural cooperatives in different rural areas, making food products locally much cheaper to the people of the same area. Agricultural policies, which generally take into account macroeconomic interests, should pay attention to the food security of people in deprived areas at a micro level, as the development of these areas will play a major role in the development of the country in the future. The most important point is preventing the compound burden of malnutrition, hunger and poverty, and all the social disadvantages of poverty, which will extend into other areas of the country. Providing food security in remote rural areas is only possible through social and agricultural support.
- Improving access to land and other assets by implementing programs based on social risk management and the empowerment of poor rural households. The strengthening of social capital and the use of collective action and sharing scarce resources can help improve the livelihoods of small-scale farmers and poor households.
- Promoting the culture of nutrition in rural areas by conducting educational courses and developing radio and television programs.

© 2018, ALÖKI Kft., Budapest, Hungary

- Holding vocational relearning courses to increase the level of education of the head of household to increase human capital.
- Policy-makers and development practitioners need to improve their understanding of institutional change.
- Innovative partnerships between small producers, governments and the private sector must be considered and built.

Recommendation for future studies:

- In this research, innovative organization was studied for rice growers we recommend that other researcher study on wheat grower.
- The requirements of establishing rural innovative institution in this research were surveyed in six variables as independent (observe) variables and the dependent variable is food security. So, we recommend that other researchers work on other factors such as environmental requirements.

Abstract. To manage watersheds, simulations of hydrological phenomena are very important. This paper investigates hydrological modelling of Taleqan basin in Iran, and studies the effects of land use scenarios on the model runoff using Soil and Water Assessment Tool (SWAT). For this purpose, hydro-meteorological data, soil map, land use maps, and digital elevation model of the area were prepared and used for model parameters' sensitivity analysis, model calibration, and validation. Sensitivity analysis was performed using SUFI-2 algorithm. Model performance was evaluated by using time series visual comparison plots and statistical indicators of Nash-Sutcliffe (NS) and the coefficient of determination (R^2). It was shown that the model has high potential to predict monthly runoff. Then, the effects of land use changes on surface runoff in the basin were studied. For this purpose, practicable land use options in the watershed such as agroforestry, afforestation, expansion of agricultural land, and agriculture on terrace were considered. Hence, various management scenarios resulted from combinations of land use activities. They were applied to the calibrated model, and their effects on surface runoff were studied. The results show that management scenarios may have significant effects on runoff control.
Keywords: *hydrological simulation, land use change, management scenario, model calibration, sensitivity analysis, SWAT*

Introduction

Surface runoff in a watershed is a major issue in hydrological watershed studies, because most hydrological processes are associated with it directly or indirectly and are somehow affected by it. Understanding hydrological processes and their simulations in a watershed scale and predicting changes of these processes in the future have been perpetual challenges for hydrologists.

Thus, hydrological models are widely used by managers and hydrologists as a tool for understanding natural and human activities affecting watershed hydrology and its planning and management in recent years (Ouyang et al., 2014). These models can provide a precise scientific framework for analysing the water movement in the watershed, and can create a reliable database on the system behaviour. Developments of hydrological models largely depend on geographic information system that made it possible to simulate large areas (Afzal et al., 2015; Jung and Kim, 2017).

Soil and Water Assessment Tool (SWAT) is commonly used for watershed modelling. The good performance of this model to assess the effects of land management practices on water, sediment, and agricultural products in large and complex watersheds with varying soils, land use, various management conditions during different periods of time and topography has been proved (Kim, 2015).

However, along with successful applications of the mentioned models due to some shortcomings, some numerical processing such as parameters calibration and sensitivity analysis are also essential (Romagnoli et al., 2017). Through sensitivity analysis of model parameters, identifying sensitive parameters based on their effects on the output of the model is possible. Identifying sensitive parameters lead to uncertainty reduction and better simulation (Shahoei et al., 2017).

Ghoraba (2015) conducted a study with the aim of watershed modelling in Simly dam, Pakistan. He used SWAT to estimate monthly volume of water entering the reservoir and determined the water balance to help administrators to plan and manage these important water reservoirs.

Vilaysane et al. (2015) studied the feasibility and performance of the SWAT model to predict river flow in the Xedone river basin, in the southern part of Laos.

Gosain et al. (2006) successfully used the SWAT model to predict the impacts of climate changes on river basin hydrology in 12 areas in India.

Setegn et al. (2008) conducted hydrologic modelling of Lake Tana basin and Pereira et al. (2014) studied the effects of deforestation on water balance components in the watershed located in the eastern coast of Brazil using SWAT model. Li et al. (2014) introduced some approaches for evaluating the effects of land use changes and biophysical conditions on the discharge. Santos et al. (2014) conducted a study on the effects of climate change, human interventions, and modelling uncertainties on the estimation of river basin and its components' characteristics.

In this paper, SWAT was used for modelling the basin that is located in the Northwest of Karaj, Alborz Province, Iran. This watershed is one of the most important sources of water supply for the province of Tehran. The main objectives of this study are to simulate surface runoff and identify sensitive hydrological parameters associated with it, and study the effects of different management scenarios on watershed stream flow. Sensitive parameters were determined by applying sensitivity analysis tool using SWAT-CUP software. More sensitivity analysis of the three most sensitive parameters and their effects on the normalized surface runoff changes is performed. The SWAT model was calibrated according to the changes in the values of the sensitive parameters within authorized ranges. Model calibration and validation were done by using SWAT-CUP software and SUFI2 algorithm. Then, simulation results with measured values of runoff in watershed outlets were compared. Then, the effects of applying different management scenarios on surface runoff were investigated. For this purpose, possible land use options in the watershed such as agroforestry, afforestation, expansion of agricultural land, and agriculture on terrace and their combinations were considered. Therefore, sixteen management scenarios were created. They were applied to the calibrated model, and the results were studied. Considering all possible combinations of management options to obtain all practical solutions could be very interesting not only for experts and decision makers but also for the general public who are following these issues seriously. Modelling these scenarios helps local and national managers to make the best decisions considering efficiency, condition, time, and cost. This may prevent environmental and social impacts, and waste of time and money.

Study area

The Taleqan watershed is located on the southern slopes of the Alborz Mountains, at 120 km northwest of Tehran, Iran. Most of the area is mountainous with steep slopes with annual average precipitation of 632 mm. Annual average temperature is 10.5 °C and due to Meteorological Organization reports the area prevailing climate type is cold semi-wet. The study area average elevation above sea level is 2735 m. The most precipitation in the region is in the form of snow. Prevailing watershed hydrology system is based on high volume of runoff in the spring due to melting snow and considerable spring rains. *Figure 1* shows the location of studied area located in the upstream of Taleqan dam basin, which is located at 36° 04' to 36° 21' of northern latitude and 50° 38' to 51° 12' eastern longitude. Most land use in this area is pasture. Part of the land is used by irrigated and rain-fed agriculture. Soil of the basin is mainly loamy and silt loamy.

The main gauging station is Gelinak Station. Two other gauging stations, Joestan (middle of the basin) and Gatehdeh (beginning of the basin) stations, were selected to compare the results with the results of the Gelinak findings.

Materials and methods

SWAT model and performance evaluation

In this study, the SWAT model was used to simulate Taleqan watershed hydrological response. SWAT is a semi-distributed and continuous mathematical model that needs various information to run. This model first used in Agricultural Research Service of United States of America, in order to simulate the hydrological processes and predict the impact of management practices on water, sediment and agricultural chemical balance in the large and complex basins. (Azzellino et al., 2015; Bonansea et al., 2015).

In the SWAT model, watershed is divided into subbasins according to DEM input map, which are linked with each other through a network of streams. Then, on the basis of soil and land use in the subbasin, they are divided into smaller units known as HRUs. For each hydrological unit, water and sediment and nutrient and losses cycles are determined and weighted average is calculated for each subbasin. Then, after the accumulation of these quantities of the river network to the basin outlet, the final amount is determined for the basin (Neitsch et al., 2011).

This model allows the modelling of the basin without monitoring data, as well as providing predictive scenarios based on input changes such as land cover, land use operations, climate on nutrient cycling, water quality and quantity for users.

To assess the qualitative and quantitative performance of the model, visual comparison of the time series plots, and statistical indicators such as Nash–Sutcliffe index (NS) and coefficient of determination (R^2) are addressed (Rahman et al., 2013).

The coefficient of determination R^2 is defined as the squared value of the coefficient of correlation. It is calculated as (*Eq. 1*):

$$R^2 = \left(\frac{\sum_{i=1}^{n} (O_i - \overline{O})(P_i - \overline{P})}{\sqrt{\sum_{i=1}^{n} (O_i - \overline{O})^2} \sqrt{\sum_{i=1}^{n} (P_i - \overline{P})^2}} \right)^2 \quad \text{(Eq.1)}$$

with O and P indicate observed and predicted values, respectively. R^2 can also be expressed as the squared ratio between the covariance and the multiplied standard deviations of the observed and predicted values. (Krause et al., 2005)

The efficiency index NS proposed by Nash and Sutcliffe (1970) is defined as one minus the sum of the absolute squared differences between the predicted and observed values normalized by the variance of the observed values during the period under investigation. It is calculated as (*Eq. 2*):

$$NS = 1 - \frac{\sum_{i=1}^{n} (O_i - P_i)^2}{\sum_{i=1}^{n} (O_i - \overline{O})^2} \quad \text{(Eq.2)}$$

According to performance rating (Cho and Olivera, 2009), Nash–Sutcliffe Efficiency values greater than 0.75 are very good and greater than 0.65 are good. Moreover, the coefficient of determination (R^2) should be greater than 0.60 (Santhi et al., 2001).

Model input data

The input required for the SWAT model includes digital elevation maps, soil data, precipitation data, temperature, meteorology, soil map, and land use map (Arnold et al., 1998; Neitsch et al., 2011).

-*Meteorological data:* In this study, monthly and daily meteorological data for the 15-year period from 2000 to 2014 were received from the Meteorological Organization and Iran Water Resources Management Company. Daily data include maximum and minimum daily temperature and precipitation. The climatologic stations are listed in *Table 1*. Moreover, monthly data such as average solar radiation, dew point temperature, and average wind speed of the study area were introduced to the model.

Table 1. *Rainfall and temperature stations*

Station name	X (UTM)	Y (UTM)	Elevation (m)
Hasanjun	477266	4009639	1990
Joestan	490956	4004551	2220
Nesa	4900835	3998736	2310
Dehdar	505796	4004490	2400

-*Digital Elevation Map (DEM):* To prepare basin DEM map, digital topographic map of 2013 with a scale of 1:25000, provided by the National Cartographic Centre, was used.

-*Soil map:* In order to provide digital soil map and soil information of the basin, soil maps and reports of the Institute of Soil and Water Research (2001) was used.

-*Land use map:* To prepare the land use map (*Fig. 2*), interpretation of aerial photographs, updated digital maps of land use by satellite images ETM, and written reports related to Taleqan Basin, provided by Soil and Water Conservation Research Centre, were used.

Figure 2. *Watershed land use map*

Results and discussion

Model implementation

Hence, to run the model, the data layers described in previous sections are presented as input to the model and the basin is divided into 35 subbasins and each subbasin is divided into hydrological response units (HRU). *Figure 3* shows the study area subbasins, stream flow, weather stations, and hydrometric stations.

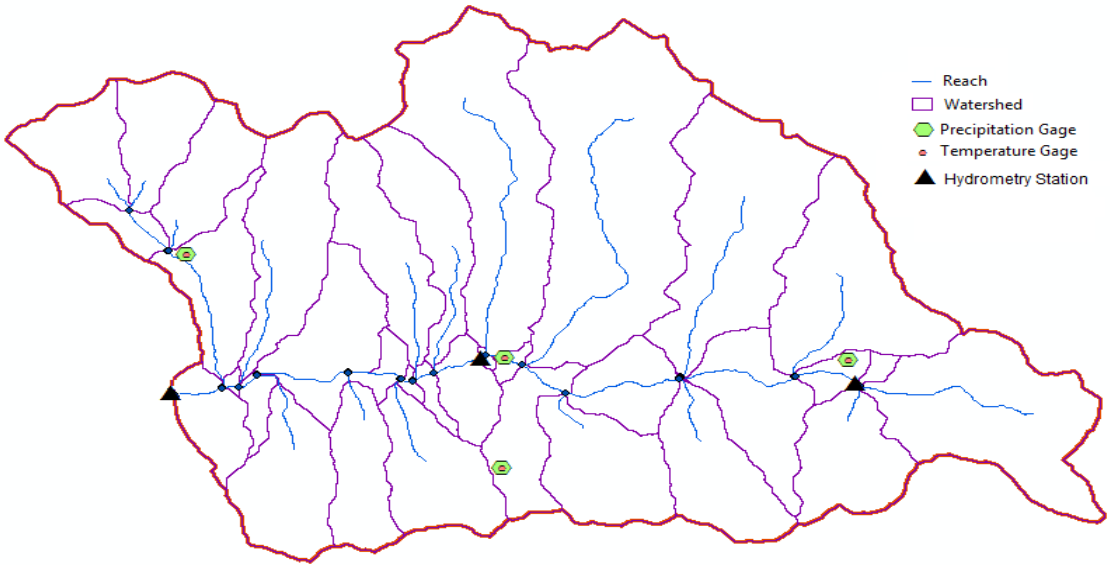

Figure 3. *Taleqan watershed, stream flow, weather stations and hydrometric stations*

Sensitivity analysis

The relative importance of input parameters with respect to its output is evaluated typically by using a sensitivity analysis. Parameters represent processes, and sensitivity analysis provides information on the most important processes in the study region. Many parameters are involved in the SWAT model to simulate rainfall-runoff. Thus, reducing the number of parameters by neglecting less effective parameters seems necessary (Zhang et al., 2009; Malago et al., 2017). The sensitivity analysis is performed by means of SWATCUP software, SUFI-2 algorithm. In this algorithm, parameters are changed, and a large number of runs are performed in order to see the impact of each parameter on the objective function. The advantage is that this produces more reliable results. This method uses a multiple regression approach to quantify sensitivity of each parameter (*Eq. 3*):

$$g = \alpha + \sum_{i=1}^{n} \beta_i b_i \qquad \text{(Eq.3)}$$

Where g is the objective function value, α is the regression constant, β is the coefficient of parameters, and b is the relative significance of each parameter (Abbaspour et al., 2018).

After sensitivity analysis, 18 parameters were determined as parameters to which the model is more sensitive. Sensitivity analysis showed that the parameters of the curve

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_23692389
© 2018, ALÖKI Kft., Budapest, Hungary

number (CN) is the most important factor, and soil evaporation compensation factor (ESCO) and soil available water capacity (SOL_AWC) are among the most important factors controlling the flow in the basin, respectively. The parameters' sensitivity ranking is given in *Table 2*.

Table 2. *Sensitive parameters description and ranking*

Sensitivity order	Parameter	Description	Domain	Fitted value
1	CN2	Curve number	.mgt	-0.291
2	ESCO	Soil evaporation compensation factor	.hru	0.965
3	SOL_AWC	Available soil water capacity	.sol	0.379
4	GW_DELAY	Time required for water leaving the bottom of the root zone to reach the shallow aquifer	.gw	56.213
5	SNO50COV		.bsn	0.578
6	ALPHA_BF	Baseflow alpha factor, lower number means a slower response	.gw	0.142
7	SNOCOVMX	Minimum snow water content that corresponds to 100% snow cover	.bsn	446.116
8	SMTMP	Snow melt base temperature	.bsn	-6.297
9	SNO_SUB	Initial snow water content	.sub	96.040
10	SFTMP	Snowfall temperature	.bsn	2.902
11	ALPHA_BNK	Baseflow alpha factor for bank storage	.rte	0.078
12	GWQMN	Threshold depth of water in the shallow aquifer required for return flow to occur	.gw	0.451
13	EPCO	Plant uptake compensation factor	.hru	0.387
14	SOL_CBN	Organic carbon content (% soil weight)	.sol	13.160
15	SURLAG	Surface lag coefficient; controls fraction of water entering reach in one day	.bsn	16.062
16	SOL_BD	Soil bulk density	.sol	0.879
17	GW_REVAP	Rate of transfer from shallow aquifer to root zone	.gw	0.317
18	SOL_K	Saturated hydraulic conductivity	.sol	0.376

More sensitivity analysis of the three most sensitive parameters and their effects on the normalized surface runoff changes is done. The results are shown in *Figure 4*. The runoff shows the greatest sensitivity to CN parameter. CN is a dimensionless parameter, which is linked to land use and soil type. Hence, by 10% positive and negative changes, runoff changes become very significant.

The second parameter in terms of sensitivity is ESCO. ESCO value reduction causes more water transfer to the upper layers of the soil, leading to an increase in the surface runoff. The third sensitive parameter is SOL_AWC. By reducing the amount of this parameter, surface runoff increases. As the empty spaces to hold water decrease, the amount of surface runoff increases.

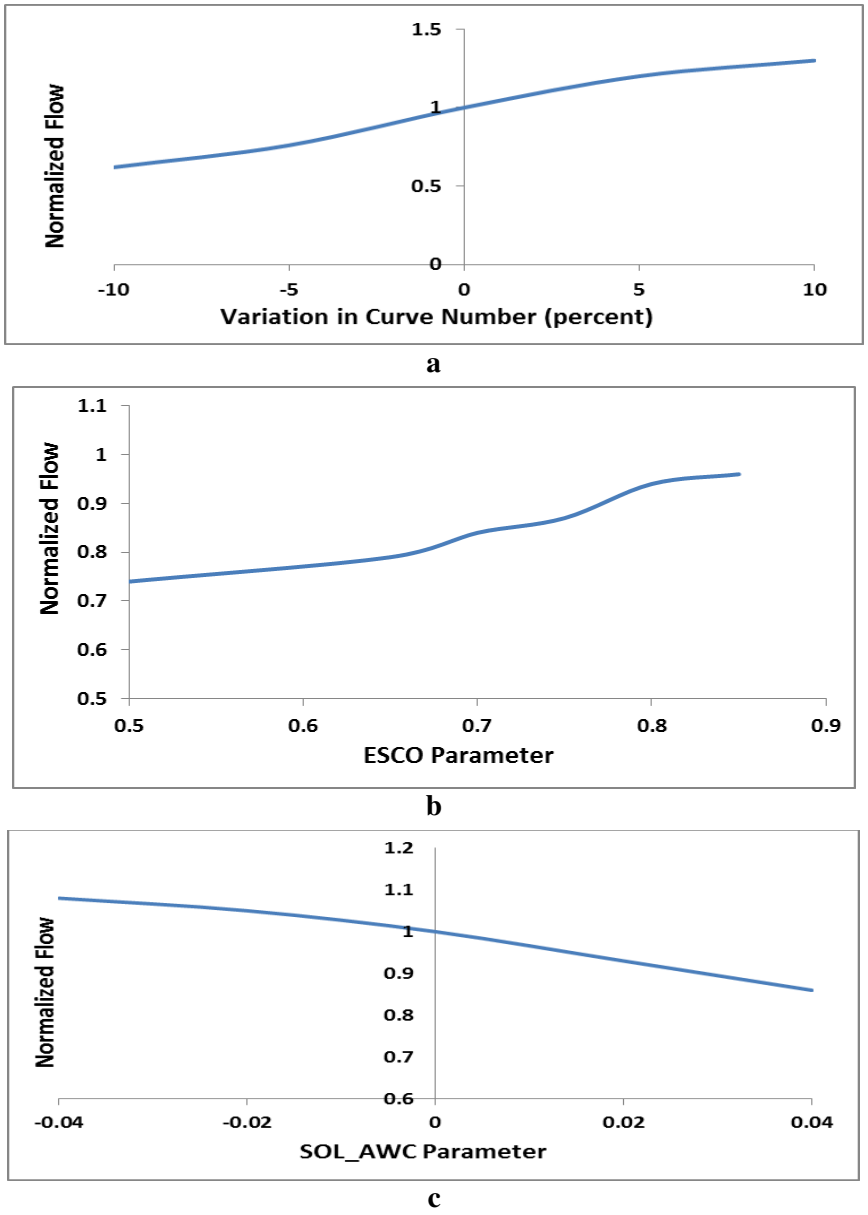

Figure 4. *Normalized flow changes due to (a) curve number changes; (b) ESCO parameter changes; (c) SOL_AWC parameter changes*

Calibration and validation

After determining the most sensitive model parameters, the model was calibrated using SUFI-2 algorithm (Abbaspour, 2008) for the years 2000 to 2010, using observed flow data by three hydrometric stations in which characteristics are shown in *Table 3*. Daily runoff data from these three stations in Iran is collected by the Water Research Institute of Iran. The optimal values of the parameters after calibration are presented in *Table 2*.

Runoff calibration results in these three stations are shown in the *Figure 5*. As can be seen, simulated runoff follows observed runoff curve in terms of both the values and the peak values occurrence time. Nash–Sutcliffe coefficient values of statistical indicators (NS) and R^2 before and after calibration are shown in *Table 4*. The values of these

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

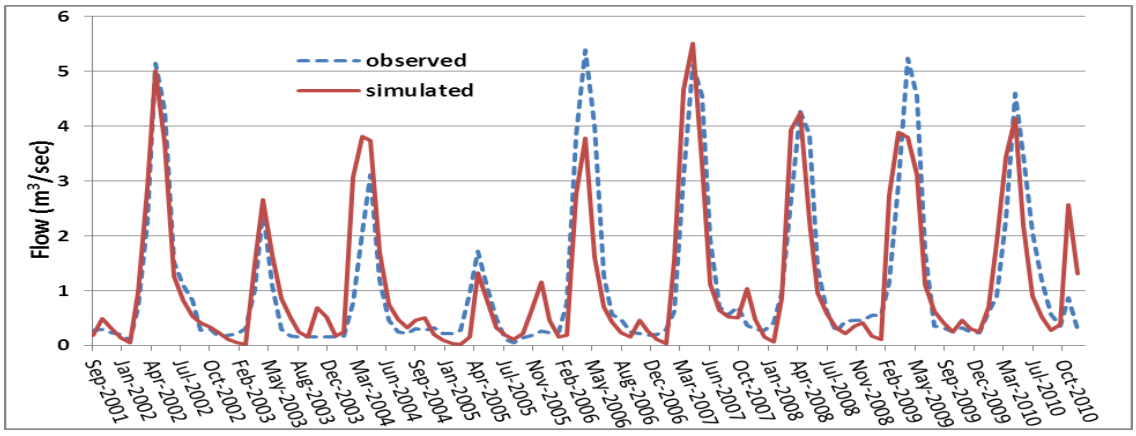
© 2018, ALÖKI Kft., Budapest, Hungary



coefficients after calibration compared to the pre-calibration values are very different. NS coefficients in Gatehdeh, Joestan, and Gelinak are respectively, 0.8, 0.78 and 0.84 and R^2 values for these three stations had been estimated 0.86, 0.81 and 0.87, respectively. The values of these coefficients indicate that the simulation of basin is of good quality. In *Figure 6,* scatter chart of observed runoff due to simulated runoff values for Gelinak station is shown. It shows high correlation between the observed and simulation values.

Table 3. *Watershed hydrometric stations*

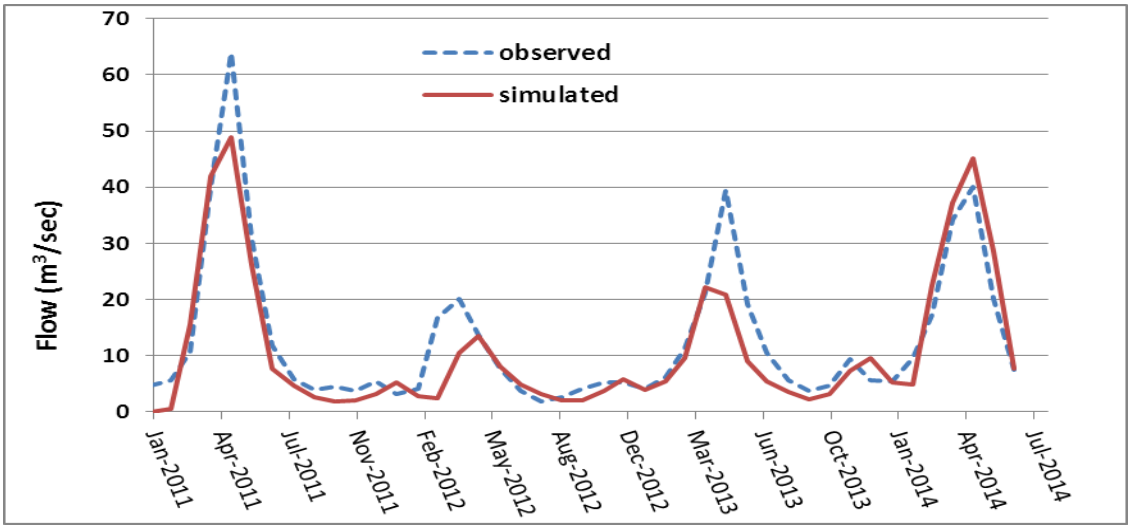

Figure 7. *Monthly observed and simulated surface runoff in validation period in Gelinak station*

For example, for Gelinak station which is the main basin outlet, the coefficients are 0.79 and 0.84 respectively, which shows the quality of modelling and suitable parameters setting in calibration period.

In *Figure 8,* a scatter chart of simulated and observed runoff values for the Gelinak station is shown during validation, which indicates acceptable correlation between observed and simulated values

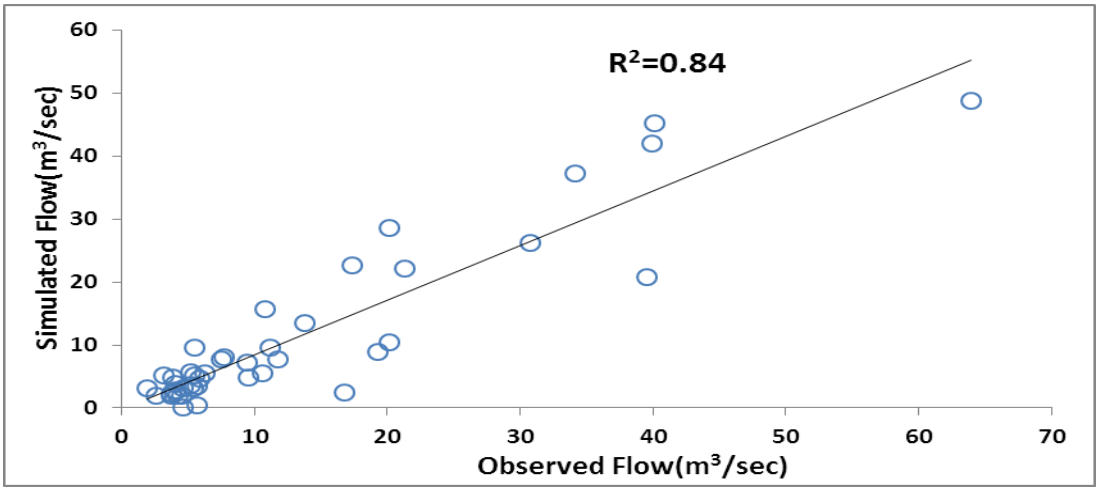

Figure 8. *Scatter chart of observed runoff due to simulated runoff values in validation period in Gelinak station*

Effects of land use scenarios on surface runoff

After watershed modelling, the effects of land use changes on surface runoff are investigated. For this purpose, practicable management activities in the watershed are listed in *Table 6* by considering existing restrictions. These management options and the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

required conditions are based on the studies performed in Agriculture Office of Alborz Province. The areas in which each management activity can be applied, considering *Table 6* conditions, are specified in *Figure 9*.

Table 6. *Management activities and specifications*

Management activity	Executable areas specifications
Afforestation	Lands with semi-deep or deep soil, low density land cover, max. slope 45% and max. elevation 2600 m
Agroforestry	Agricultural lands with slope of 15% to 30% with semi-deep or deep soil
Expansion of agricultural land	Agricultural lands with max. slope of 12% with deep soil and max. elevation 2400 m
Agriculture on terrace	Agricultural lands with slope of 12% to 15% with deep soil

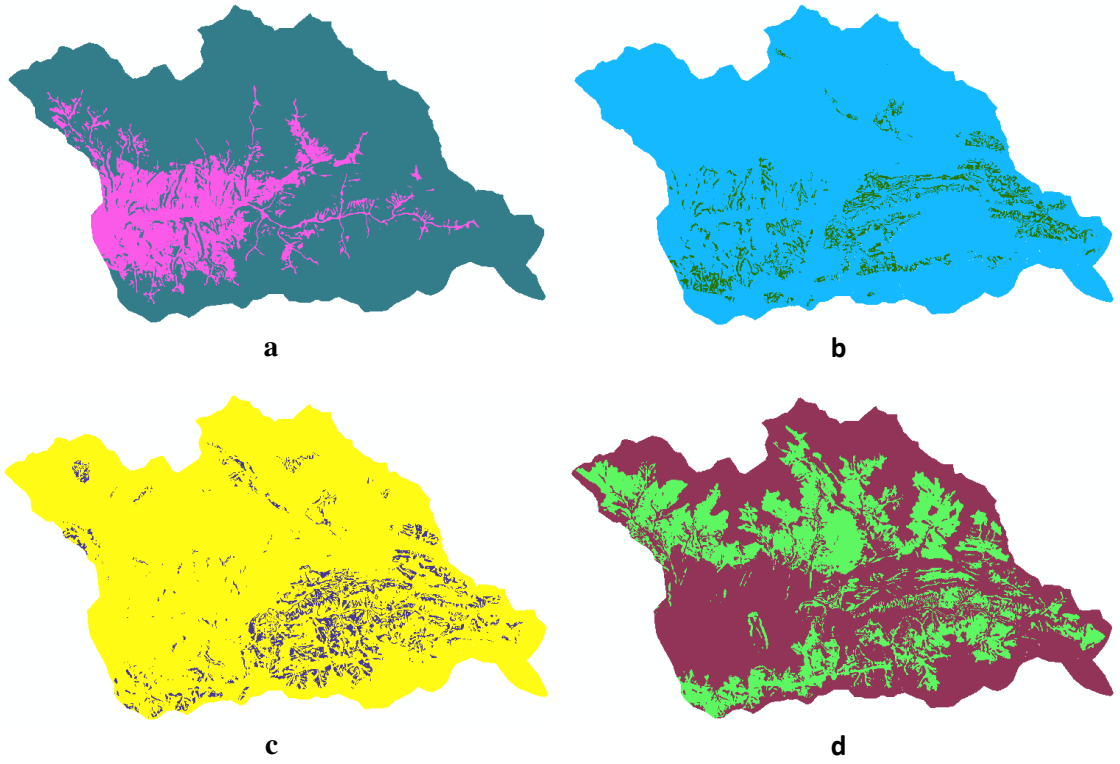

Figure 9. *Regions in which each management activity can be applied (a) agricultural land; (b) agriculture on terrace lands; (c) agroforestry lands; (d) forest lands*

So, combinations of 2^n possible management activities are obtained. Where n is the number of distinct management activities. These management scenarios are shown in *Table 7,* where scenario sn1 represents the current land use. *Table 8* expresses each scenario land use details in percent. *Figure 10* shows each scenario information, including different types of land uses and corresponding areas.

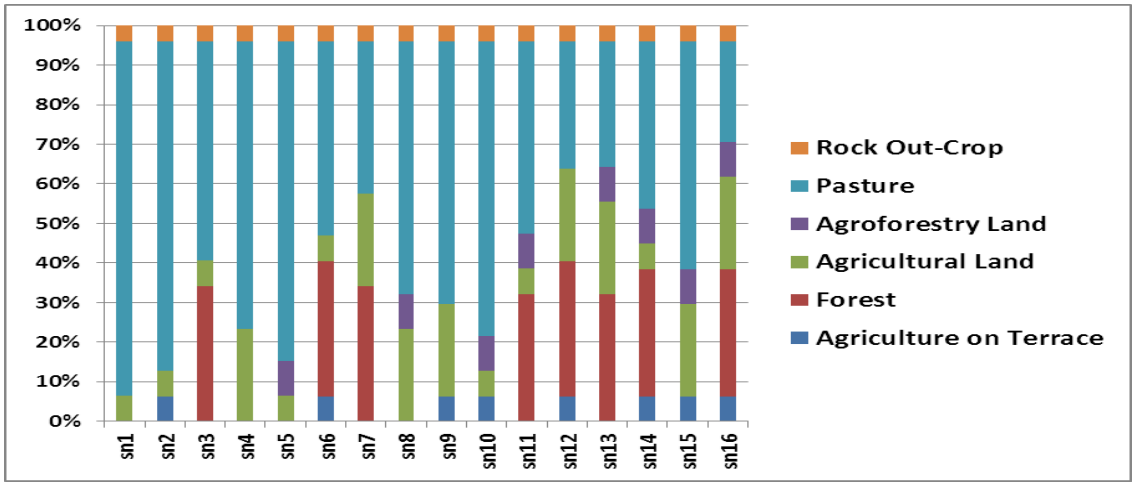

Figure 10. *Types of land uses and corresponding areas for each scenario (in percent)*

To estimate surface runoff from changes in land use scenarios, the SWAT model was run in the range of calibrated parameters. *Table 9* shows changes in average seasonal and annual surface runoff (in percent) for each management scenario. According to the results, applying management scenarios to the watershed leads to changes in runoff compared to current condition. It can be seen that applying scenario sn2 (agriculture on

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_23692389
© 2018, ALÖKI Kft., Budapest, Hungary

terrace) reduces average annual surface runoff less than 2%. However, sn3 (afforestation) decreases average annual runoff about 5%. Expansion of agricultural lands and agroforestry activities change runoff by 3.15% and 3.62%, respectively. Among individual scenarios, sn3 is the most effective management activity for runoff control due to good potential of this watershed for afforestation.

Each of scenarios sn6 to sn11 is obtained by combining two management activities. Application of sn6 (combination of agriculture on terrace and afforestation) reduces average runoff by 8%. Scenario sn7 (combination of expansion of agricultural land and afforestation) affects average annual runoff about 10%. Scenarios sn8 (combination of expansion of agricultural land and agroforestry), sn9 (combination of expansion of agricultural land and agriculture on terrace) and sn10(combination of agroforestry and agriculture on terrace) reduce surface runoff less than 7%. However, by applying sn11 (combination of agroforestry and afforestation activities), the average runoff is decreased more than 12% compared to current land use condition. Considering combinations of two management options (scenario sn6 to scenario sn11), it can be observed that the most effective scenario for runoff management is sn11.

Considering combinations of three management options (scenario sn12 to scenario sn15), sn13 (combination of afforestation, expansion of agricultural land and agroforestry activities) have the greatest impact on reducing runoff. By applying scenario sn13, average annual surface runoff is reduced by 19%. The second effective scenario in this category is sn14, which reduces runoff more than 16%. This scenario is the combination of afforestation, agriculture on terrace and agroforestry activities. Sn12 (combination of afforestation, agriculture on terrace and expansion of agricultural land activities) and sn15 (combination of expansion of agricultural land, agriculture on terrace and agroforestry activities) affects watershed average runoff by 14.43% and 13.48%, respectively.

Table 9. *Average seasonal and annual runoff changes (in percent) for each management scenario*

Seasonal/ annual interval	Management scenarios															
	sn1	**sn2**	**sn3**	**sn4**	**sn5**	**sn6**	**sn7**	**sn8**	**sn9**	**sn10**	**sn11**	**sn12**	**sn13**	**sn14**	**sn15**	**sn16**
Spring	0	-1.64	-4.71	-3.14	-3.32	-7.44	-8.66	-6.53	-5.81	-6.61	-12.02	-14.06	-18.29	-16.18	-13.12	-21.88
Summer	0	-1.86	-5.10	-3.40	-4.17	-9.83	-11.34	-7.84	-6.72	-7.11	-13.33	-15.22	-19.85	-17.47	-14.24	-23.52
Autumn	0	-1.78	-4.92	-3.28	-3.87	-8.12	-10.08	-7.21	-6.36	-6.89	-12.55	-14.71	-18.94	-16.88	-13.75	-22.69
Winter	0	-1.70	-4.17	-2.78	-3.12	-6.93	-9.58	-6.21	-5.44	-6.73	-11.68	-13.73	-18.68	-15.55	-12.82	-21.16
Annual	0	-1.75	-4.68	-3.15	-3.62	-8.08	-9.92	-6.95	-6.08	-6.84	-12.40	-14.43	-18.94	-16.52	-13.48	-22.31

The last management scenario is the combination of all land use options. Scenario sn16 land use map is shown in *Figure 11*. It can be observed that by applying this scenario, surface runoff decreases more than 22% compared to the current condition. This scenario makes the most significant effect on the average runoff compared to the other management scenarios. Moreover, by considering average seasonal runoff changes, it can be seen that the most decrease in surface runoff occurs in summer in each scenario. On the other hand, the least changes occur in winter.

Figure 12 shows average annual surface runoff resulted from each scenario application. Terrace agriculture (sn2) does not affect surface runoff considerably. However, from scenario sn6 (combination of management options) onwards, decrease

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_23692389
© 2018, ALÖKI Kft., Budapest, Hungary

in surface runoff is noticeable. It can be seen that average annual runoff is 126 m^3/s considering current land use. However, it is reduced to 108 m^3/s by applying sn11 (combination of agroforestry and afforestation activities) and to 100 m^3/s by applying sn13 (combination of afforestation, expansion of agricultural land and agroforestry activities). The main change occurs when sn16 land use scenario is applied to the model and the average annual runoff is reduced to about 95 m^3/s.

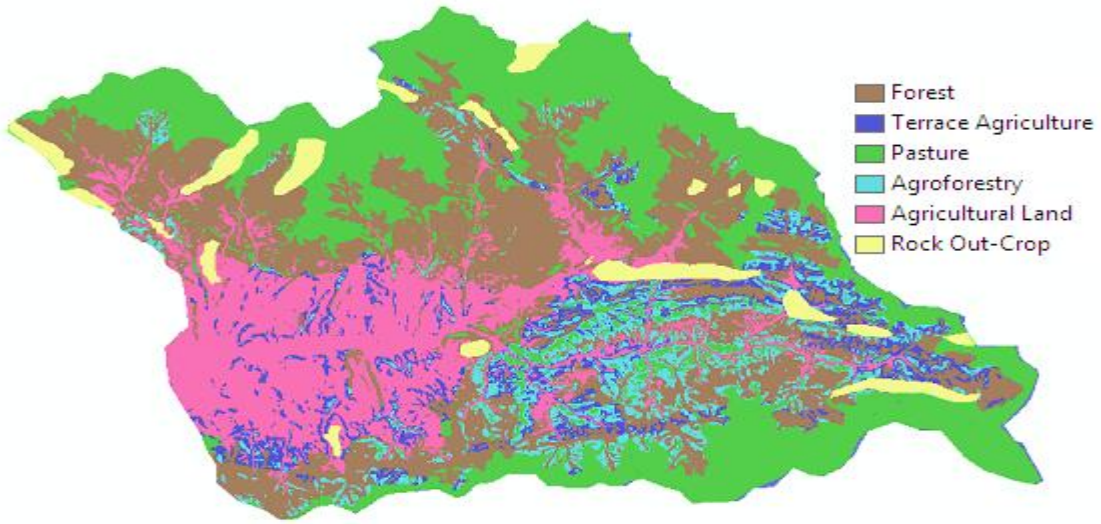

Figure 11. *Scenario sn16 land use map*

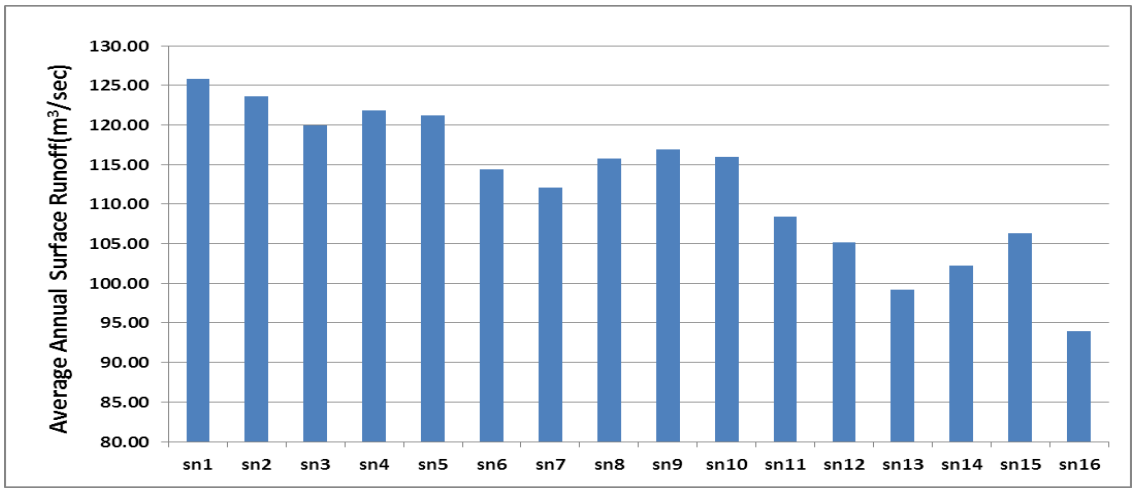

Figure 12. *Average annual surface runoff resulted from each scenario application*

In recent years, some researches were performed to study the impacts of land use changes on the study area flow. In a study by Kazemi and Bayat (2017), by using topographical maps and aerial photographs, land use maps of 1971, 1988 and 2003 were prepared. Then land use change was calculated. Then relationship between low flow indices and land use in the period of study were investigated. The results showed that the low flow indices have experienced an upward trend. Increasing rangeland coverage during these years was in accordance with the increasing of indices in the period

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_23692389
© 2018, ALÖKI Kft., Budapest, Hungary

studied. It was concluded that land use changes due to human intervention has a direct impact on the trend of low flow indices.

Hosseini et al. (2012) studied the effects of land use changes on water balance of the Taleqan catchment before and after the dam construction by using SWAT. The results indicated progressive increase in surface runoff and decline in interflow and groundwater flow. Therefore, one of the main challenges facing development planners is the control of the accelerated degradation of the natural resources.

In these researches, the impacts of land use changes on the watershed in the past time periods were studied. However, in the current work all possible land use scenarios were introduced to the model to study the corresponding future land use scenarios effects on the watershed. Since, decision makers can make the best decisions due to environmental consequences by assessing the results of each land use scenario simulation before implementation.

Conclusions

In this study, Taleqan watershed modelling was done using the Soil and Water Assessment Tool (SWAT). In order to do this, different kinds of information such as digital elevation model (DEM), soil data, temperature and precipitation data, and soil and land use maps in standard formats were provided as inputs for the model.

The relative importance of input parameters with respect to its output was evaluated using sensitivity analysis. Sensitivity analysis showed that the curve number (CN) parameter is the most important factor and Soil Evaporation Compensation Factor (ESCO) and soil available water capacity (SOL_AWC) are among the most important factors affecting the flow in the basin, respectively.

Calibration was performed by SUFI-2 algorithm, using river flow observation of three hydrometric stations within the basin.

It was observed that simulated values follow observed values of both the amplitude and the time of couriers. Nash-Sutcliffe coefficients in Gatehdeh, Joestan, and Gelinak stations are respectively 0.8, 0.78, and 0.84 and the R^2 values for these three stations were 0.86, 0.81, and 0.87, respectively. It was shown that the values of these statistical indicators after calibration compared to the pre-calibration values are very different. The statistical indicators values indicate that the basin modelling and simulations were performed with good quality.

After model calibration, it is necessary to ensure the quality of the modelling by means of validation process. Validation results in hydrometric stations show watershed modelling quality and suitable parameter settings in calibration period. NS and R^2 coefficients values were convenient. For example, in Gelinak station, which is the main outlet of the watershed, these indexes are 0.79 and 0.84. Moreover, scatter charts of observed and simulated surface runoff showed good correlation between these values in both calibration and validation intervals.

The effects of land use changes on the basin surface runoff were studied. It was seen that by applying scenario sn16, the most reduction in surface runoff was obtained compared to the other scenarios. Application of this scenario leads to 22.31% reduction in runoff compared to current condition. Moreover, in all scenarios, effects of management activities in the summer are the most. This can be due to the evolution of land cover and canopy, which in addition to significant evapotranspiration, makes runoff to decrease. According to results, management options combinations reduce

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

surface runoff considerably compared to individual activities. Afforestation is the most effective activity among single options. Considering combinations of two management options, the most effective scenario is sn11 (a combination of afforestation and agroforestry activities), which changes surface runoff about 12.4% compared to current land use condition. On the other hand, sn9 has the least impact on runoff (about 6% reduction). However, in this condition, runoff decreases more than scenario sn5 (the most effective singular activity).

Considering combinations of three management options, sn13 (a combination of afforestation, expansion of agricultural land, and agroforestry activities) have the greatest impact on reducing runoff. By applying scenario sn13, surface runoff is reduced by 18.94% compared to the current condition, which is considered a significant change. Moreover, scenario sn14 reduces surface runoff by 16.52%. This scenario applies a combination of afforestation, agriculture on terrace, and agroforestry activities.

Abstract. Due to the widespread use of silver nanoparticles (nAg) in different products, the possibility of their leakage into the environment has been increasing. It is, therefore, crucial to study the possible effects of nAg on plants as the key components of ecosystems. In the present study, the effects of different concentrations of colloidal nAg on sweet maize were investigated at the anatomic level. Using dynamic light scattering and electron microscopy, the size of the nAg was estimated less than 80 nm. After one week of treatment, thin cross sections of roots and shoots were prepared and studied by light and fluorescence microscopes. Results showed that cortex and vascular cylinder area of roots and shoots of treated plants significantly ($P<0.05$) decreased versus control. Significant ($P<0.05$) reduction in diameter of metaxylem vessels was also identified. In addition, deform cells and Ag accumulations in root tissues of treated seedlings were observed. The results of this study indicate that nAg can enter into plant root and make considerable adverse effects on the plant root anatomy suggesting that nAg can become a future emerging pollutant.
Keywords: *auto fluorescent, bioaccumulation, metaxylem, micrograph, uptake*

Introduction

Due to their small size (1-100 nm) and the increase in their surface-to-volume ratio, nanoparticles have special properties making them suitable for various practical applications. Nowadays, variety of engineered nanoparticles are being used to make a wide range of products including personal care products, next-generatin batteries and solar cells, and environmental remediation of water, sediments, and soil (Buzea et al., 2017). Therefore, the particle's exposure to the environment and plants has been drastically increasing. Researchers are trying to carefully assess the risks and potential effects of nanoparticles on plants and humans and animls health and to propose methods to prevent or reduce the contamination of the environment with nanoparticles as emerging pollutants (Ghorbanpour et al., 2017).

Among various engineered nanoparticles, silver nanoparticles (nAg) due to their special properties (antimicrobial, electrical, optical and catalytic), have found applications in industries (Sintubin et al., 2012). Nowadays, engineered silver nanoparticles are used to make products such as food packages, textiles, electronic devices, home appliances, cosmetics, medical devices, water disinfectants, sprays (Varner et al., 2010), and also to produce pesticides (Thul et al., 2013). Increasing the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_23912401
© 2018, ALÖKI Kft., Budapest, Hungary

production and use of products containing nAg will eventually lead to an increase in the probable release of these particles to the environment from production to disposal/reuse precedures; so there is an urgent need to study the effects of engineered nanoparticles on plants which are the important members of ecosystems and food chain.

The effects of nanoparticles can be investigated at different levels in plants. These effects can vary according to size, shape, and concentration of nanoparticles, and age, and species of plants (Rico et al., 2011). In recent years, numerous research studies have been carried out on the effects of nanoparticles on plants and toxic effects of nAg have been reported. For example, cytotoxicity and genotoxicity in onion (*Allium cepa* L.) and broad bean (*Vicia faba* L.) roots treated with nAg have been observed by decreasing in mitotic index and chromosomal aberrations (Kumari et al., 2009; Patlolla et al., 2012). Mustante and White (2012) reported a decrease in biomass of pumpkin (*Cucurbita pepo* L.) plants treated with nAg. Wang et al. (2013) reported toxic effects of nAg accumulated in poplar (*Populus deltoides* × *nigra*) and arabidopsis (*Arabidopsis thaliana* (L.) Heynh.) on evapotranspiration. Also, uptake of nAg by roots and transport to the shoots was observed in arabidopsis (Geisler-Lee et al., 2014). However, the mechanisms of the nAg impacts and their targets in plants are not adequately studied in the literature hence more research needs to be done at different levels such as anatomical, cytological, cytogenetical and molecular.

At anatomical level there are only few research studies on the impacts of nanoparticles. For instance, Thuesombat et al. (2014) reported low impact on the leaf anatomy of rice (*Oryza sativa* L.) plants treated with nAg (20 nm; 10 ppm), while a significant change was observed at 100 ppm concentrations in the anatomical traits. This study demonstrated that the effects of nanoparticle were concentration dependent. Pokhrel and Dubey (2013) also studied the number of metaxylem vessels (a type of transport tissue in vascular plants) in the primary root of maize exposed to 75 ppm of citrate coated nAg. They reported an increase in the number of metaxylem vessels in treated plants. In the study of Mousavi Kouhi et al. (2015), significant changes were observed in the anatomy of leaf and root of canola (*Brassica napus* L.) treated with zinc oxide nanoparticles.

Due to the paucity of the research on anatomical responses of plants exposed to nanoparticles, in this paper, the effects of nAg on maize seedlings at anatomical level were investigated. In addition to being an important crop, maize is considered to be a model plant in the environmental and genetic studies (Strable and Scanlon, 2009). It is worth noting that silver is an unnecessary element with unknown physiologically functions in plants. However increasing the concentration of the element to a certain extent can be fatal for plants.

Materials and Methods

Preparing suspensions and solutions

Coloidal nAg with a concentration of 4000 ppm (NanoSilver-W4000) GEBER was purchased fromBaran Chemistry Pasargad Company. The size of the nanoparticles was measured with the dynamic light scattering (DLS) method (*Figure 1A*) and with a particle size analyser device (Particle Metrix GmbH, Germany) less than 80 nm. Also, the shape and size of the nanoparticles were examined by a high resolution field emission scanning electron microscope (FE-SEM) (MIRA3 TE SCAN, Czech

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_23912401
© 2018, ALÖKI Kft., Budapest, Hungary

Republic) (*Figure 1B*). Using distilled water, concentrations of 300, 200, and 100 ppm were prepared from a homogenous suspension of 4000 ppm. The homogeneity of the suspensions was also maintained after dilution.

Since studies have shown that part of the nAg effects is due to the release of silver ions from them (Mcshan et al., 2014), in this study, silver nitrate was used as silver ion and positive control for comparison. The silver nitrate solution, as a positive control, was made from white powder of silver nitrate (Sigma-Aldrich) and distilled water at concentrations of 300, 200, and 100 ppm. For the sake of brevity, in the rest of the paper, nAg1, nAg2, nAg3, AgN1, AgN2, and AgN3 have been used correspond to the treatments with nAg of 100, 200, and 300 ppm and with silver nitrate of the same concentrations, respectively.

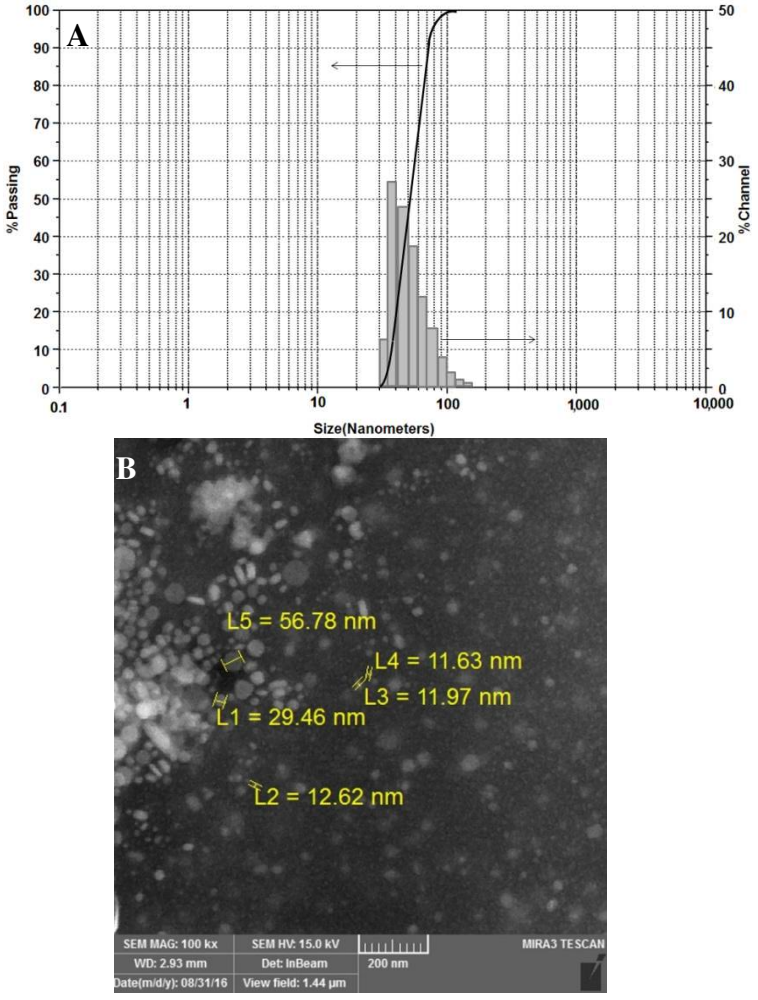

Figure 1. *A) The dynamic light scattering graph and B) the field emission scanning electron (FE-SEM) micrograph of the colloidal nAg (NanoSilver-W4000) GEBER show that the size of these spherical particles is less than 80 nm.*

Seeds

The sweet maize (*Zea mays* L. var. *Saccharata* 'Ksc 403') seeds were obtained from the Seed and Plant Improvement Research Institute, Karaj, Iran. In order to reduce the probability of contamination, the seeds were first put in ethanol 70% for 30 seconds and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_23912401
© 2018, ALÖKI Kft., Budapest, Hungary

then rinsed three times with sterile distilled water. Thereafter they were immersed in sodium hypochlorite 5% solution for 10 minutes. Next, they were rinsed three times with sterile distilled water (Rao et al., 2006). Decontaminated seeds were laid in Petri dishes on sterile filter papers. Petri dishes containing seeds and 15 mL distilled water were incubated in dark at 25 °C for one week.

Seedling's treatments

Triplicates of seven-day-old seedlings with equal size were selected for a completely random design experiment. nAg suspension and silver nitrate solution were poured into the 15 mL tubes. Distilled water was used as the negative control. The entrance of the tubes was covered by a selefon with a small hole in its center so that only the seedling's root could be passed through it. In this condition, the seed and shoot were not directly in contact with the contents of the tube. In order to prevent the effect of light exposure, the tubes were covered by aluminum foil. The seedlings were exposed to daily photoperiod of 16 hours of light and eight hours of darkness at 25 °C for one week.

Anatomical analyses

For anatomical studies, the root and shoot were isolated separately and fix in the ethanol 70%:glycerol. Using regular flat shaving razor blades, thin cross sections of roots and shoots were obtained from the root cellular maturation zone and 2 cm above the crown of shoot, respectively. For staining, the sections were immersed in toluidine blue 0.5% (in phosphate buffer) for 20 seconds and then rinsed with tap water. The specimens were studied with an optical microscope (Olympus). Due to the fact that some of the cell wall componds (e.g. phenolic compounds), are auto-fluorescent (Mylle et al., 2013), some specimens were studied without staining to evaluate the possible changes in their fluorescence properties using a fluorescent microscope (E800-Nikon, Japan). Digital images were made from the slides and the cortex area, vascular cylinder area, the ratio of cortex area to the vascular cylinder area, and the diameter of openings of metaxylems were calculated using Image Tool software V. 3.0 calibrated by a micrometer slide.

Data analysis

Analysis of variance (ANOVA)($P<0.05$) was performed using SPSS ver.18 software and the Duncan test was used to diagnose the different means. Charts were plotted using MATLAB software.

Results

Figure 2 shows non-stained transverse sections of the primary roots for controls and treatments.The cross-section of negative control seedling's root demonstrates that, from outside to inside, there are root hairs, epidermis, cortex parenchyma, endodermis, a layer of pericycle cells, bundles of phloem, protoxylems, metaxylems, and the pith. As is seen in this figure, the pith cells are spherical and the walls of endodermal cells are thicker on the three sides (U thickening). Also, the number of metaxylam cells in the majority of the sections was counted 6 and 7, the xylems and phloems are in alternative order, the type of stele is medullated protostele, and the arrangement of xylems is

exarch. In the cross-sections of the roots treated with nAg100, black areas in the root hairs and epidermis are observed. The black region in the corresponding positive control sections (AgN100) are visible from the epidermis to endodermis. In the cross sections of roots treated with nAg200, black areas are visible in the cortical parenchyma and from the sites of emergence of lateral root primordia to the pricycle cells. In its corresponding positive control (AgN200) sections, in addition to the cortex, the black areas are visible around the metaxylems. In the transverse sections of primary roots at the highest concentration of the study (nAg300), black accumulations are visible in the vascular cylinder cells and the protoxylem cells and the bundles of phloem vessels are deformed and distorted. Also, the pith cells are darkened and deformed. The primary root sections of its corresponding positive control (AgN300), exhibit greater amounts of silver penetration. The black areas and accumulations from the epidermis to the pith cells are visible. Here, the shape of the cells is normal in bundles of phloem vessels.

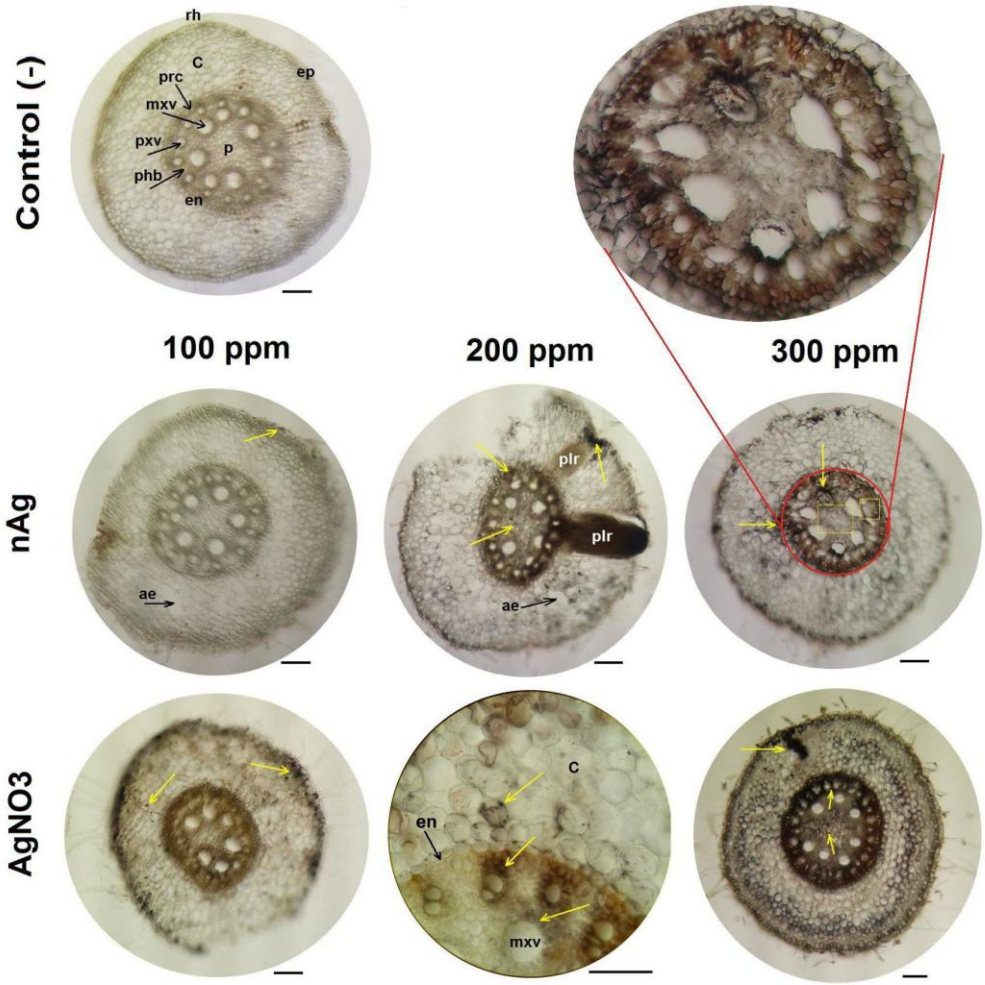

Figure 2. *Light micrographs represent impacts of silver treatments on maize primary root in non stained transverse sections. The fluorescent micrographs of *Figure 3* demonstrate the auto-fluorescent properties of the cell walls of the control and treated roots. In these images the walls of endodermal cells with U-shaped thickening are more reflective and distinguishable from the pericycle and cortical cells. As seen, in nAg300, the accumulation of silver prevents the reflection of light from the thick walls of endodermal cells. Furthermore these micrographs show that by increasing the concentration there is more penetration of Ag into root tissues resulting in less light reflection.

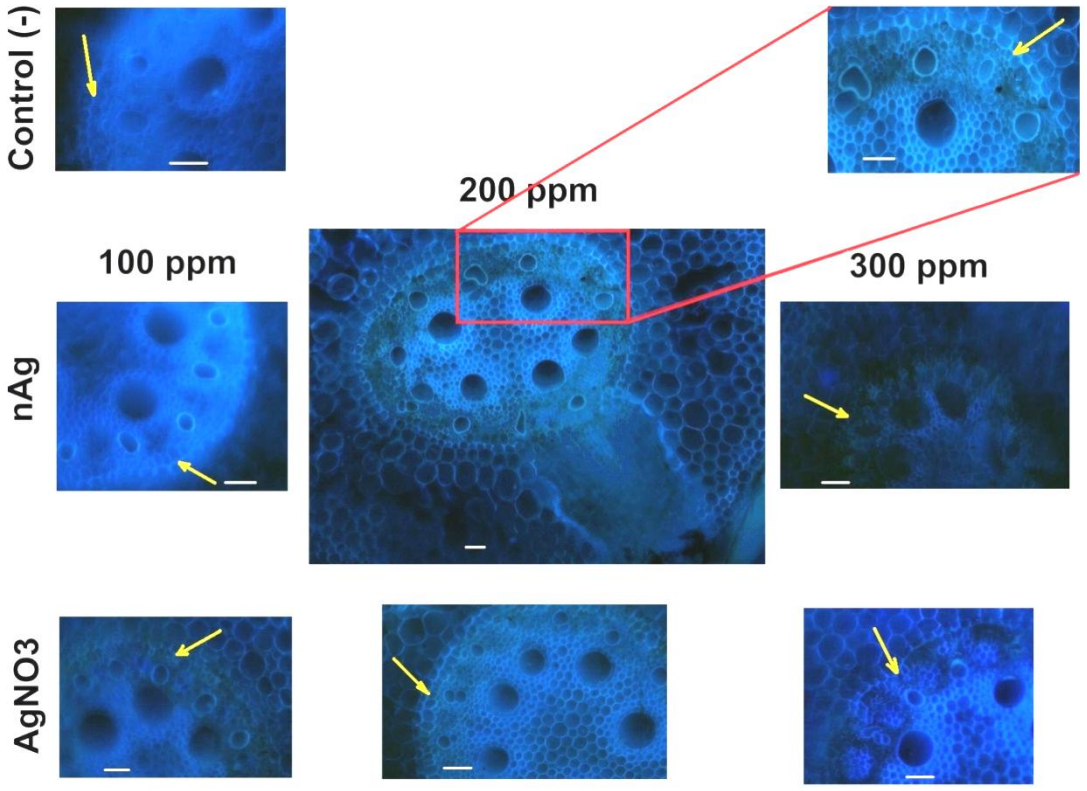

Figure 3. *The Fluorescent micrographs of non stained transverse sections of maize primary roots exposed to silver treatments. Arrows indicate U thickening of endodermis cell walls. In nAg 300 ppm treatment, silver accumulation reduced light reflection; Bars= 50 µm*

As seen in *Figure 4* in the cross section prepared from mesocotyls of shoots, from outside to inside, there are epidermis, cortical parenchyma, endodermis, and vascular cylinder. The vascular cylinder here, in contrast to the transverse section of roots, is not completely circular. Also, adventitious roots are observed in some sections (*Figure 4A*). There is no significant morphological difference in the mesocotyl sections of nAg100 treated seedlings compared to negative and positive controls (*Figure 4B, C*). Also, in the nAg200 and nAg300 treatments, and in their corresponding positive control, there was no significant morphological difference in the shoot transverse sections to negative control.

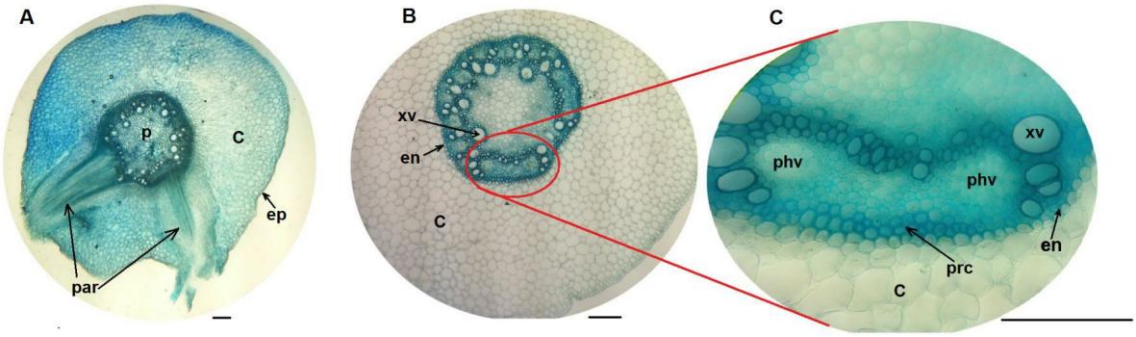

Figure 4. *The light micrographs represent transverse sections of two weeks old maize shoots(mesocotyl). Sections were prepared from two centimeters above the crown. A) Negative control, B) nAg 100 ppm treatment, C) magnification of one part of the vascular cylinder.c: cortex, en: endoderm, ep: epiderm, p: pith, par: primordium of adventitious root, phv: phloem vessel, prc: pericycle, xv: xylem vessel. Bars = 100µm*

As *Figure 5A* shows, there is not significant difference (P <0.05) between the means of cortex area of negative control and nAg100 treatment, however there is 88% significant increase versus its corresponding positive control. Also, there is no significant difference between the means of vascular cylinder and the ratio of cortex to the vascular cylinder area with negative control (P <0.05) (*Figure 5B, C*). The number of metaxylem in this treatment and in the corresponding positive control were counted 6. In the case of shoots, the means of the cortex and the the vascular cylinder area relative to the negative control is reduced 19 and 47%, respectively (*Figure5A, B*). However, the ratio of cortex to vascular cylinders area is 53% higher than negative control (*Figure 5C*).

According to *Figure 5A, B,* the means of the cortex and the vascular cylinder area of the root treated with nAg200 versus negative control is respectively 35 and 29% higher. In the later treatment there is no significant difference between the means of ratio of cortex to vascular cylinder area. Compared to the corresponding positive control, the means of the cortex and vascular cylinder area is respectively 53 and 41%, higher in nAg200 treatment (*Figure A, B5*). The number of metaxylem vessels in this treatment are 5, 6 and 7, and in the corresponding positive control, 6. The shoot cortex area and the vascular cylinder area were 64% and 27%, higher than negative control respectively, and 66% and 86% less than the corresponding control, respectively (*Figure 5A, B*). The ratio of areas versus negative and positive controls is reduced 30% and 10%, respectively (*Figure 5C*).

Figure 5A, B shows that the average of the root cortex and vascular cylinder area in nAg300 treatment is 46% and 39% lower than the negative control, respectively. In this treatment, the mean area of the vascular cylinder is 32% less than the corresponding positive control (AgN300). There is no significant difference between means of the ratio of cortex area to vascular cylinder area (*Figure 5C*). The number of metaxylem vessels in this treatment was 6 and in the corresponding positive control, 7 and 8. The mean of shoot cortex area and vascular cylinder area in this treatment is 29 and 26% less than negative control respectively (*Figure A, B5*). The ratio of areas is 23% less than the corresponding positive control, and there is no significant difference with the negative control (*Figure C5*).

The means of metaxylem opening diameter are provided in *Table 1*. As presented in the nAg100 treatment xylem diameter is less than the negative control and more than the corresponding positive control. The mean of metaxylem's diameter in the nAg200 treatment is less than negative control and does not have a significant difference with the corresponding positive control. The diameter of the metaxylem vessels is significantly less than the negative control and is more than the corresponding positive control in nAg300 treatment.

Discussion

The results of this study indicated that Ag^0 / Ag^+ was uptaken by the maize primary roots. Observation of black aggregates in micrographs of transverse sections of seedling's roots treated with nAg and silver nitrate showed that silver could enter into the roots. According to the observations, nAg entered more through the apoplastic pathway and intercellular free spaces and less through symplastic pathway (across cytoplasm) to the root tissues and were accumulated there or entered the emptied cellular elements of vessels via water uptake . It should be noted that as described by Zhao et al. (2012) nanoparticles may enter through natural nano or micro-size pores of plant cell walls. However, the size of the particles used in this study was greater than the size of the cell wall pores of maize primary root which are about 6.6 nm as estimated by Asli and Neumann (2009). The study of transverse sections with fluorescence microscopy showed that the accumulation of silver or the combination of silver with other molecules in endodermal cells at the highest concentration of the present study reduced light reflection.

Qualitative traits, for example, the shape of cells at the highest concentration used in this study (nAg300), have undergone dramatic changes in the vascular cylinder of the root so that the cells of the phloem vessels became distorted (*Figure 2*). Also, the opening of the xylems in the transverse sections are not circular anymore. Silver aggregates appear to have a mechanical pressure on the vascular cylinder cells. These changes can also be due to the interaction of nAg with cell wall components. Rico et al. and Dietz and Herth (2011) also noted that nanoparticles due to their small size and high surface activity can interact with cell structures and components. Not observing these changes in silver nitrate treatments with a corresponding concentration reflects the different effects of nAg.

Micrometrics measurements showed significant reduction in root and shoot cortex area and the vascular cylinder area versus negative control in all treatments except for nAg200. However, the ratio of areas in the root has no significant difference with negative control. The observed differences in the measured traits in the nAg200

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_23912401
© 2018, ALÖKI Kft., Budapest, Hungary

treatment as well as the study of non-stained cross sections suggests that it is due to the absorption of different amounts of silver. In other words, silver absorption was not linear as many factors could influence it. For example, nanoparticles are more likely to penetrate from the sites of lateral root emergence as in these sites the integrity of root tissues is lost.

The number of metaxylems in the root transverse sections of all treatments was similar to the negative control and was 6 or 7. Only in nAg300 treatments 8 metaxylems were observed. Furthermore, a significant reduction of xylem's opening diameter was observed in all treated roots versus control. These results suggest that silver could affect the anatomical traits of root tissues specially the transport tissues. The small proportion of the root vascular cylinder to the cortex area indicates that the Ag^0/ Ag^+ uptaken by the roots cause interference in water and nutrients transportation and as shown in *Figures 2* and *3*, lead to death of many root cells. However, there were no significant difference in the anatomical traits of the shoots of treated seedlings. According to the results the behavior of nAg is relatively similar to that of silver nitrate suggesting that part of the nAg impacts is by releasing of silver ions from them.

Conclusion

The results of this study show that nAg can be absorbed by maize root and subsequently affect the growth of the shoots. Accumulation, mechanical stress, and interaction with cell wall components are the possible mechanisms for the effect of nanoparticles used in this study. Moreover, the findings of this research demonstrate the usefulness of anatomical traits (alongside the study of effects at other levels) for evaluating the effects of nanomaterials in plants. The results of this reseach could raise concerns over possible nAg leakage into the environment and human health risks. The authors plan to explore other stages of maize life in treatment with different size and concentrations of nAg.

(Received 4th Jan 2018; accepted 16th Apr 2018)

Abstract. The aim of the experiment was to evaluate the effects of a growth regulator on alfalfa (*Medicago x varia* T. Martyn). The authors of the experiments had had the regulator patented in Poland. There were following experimental variants with different application times: Control – application of distilled water both during the six-true-leaf stage and during the early-bud stage, AF_1 – application of the regulator during the six-true-leaf stage and distilled water during the early-bud stage, AF_2 – application of distilled water during the six-true-leaf stage and the regulator during the early-bud stage, $AF_{1,2}$ – application of the regulator both during the six-true-leaf stage and during the early-bud stage. The results were processed statistically with the analysis of variance, while differences between means were verified with Tukey's test ($p \leq 0.05$). It was found that the growth regulator increased stomatal width and the length of the stomatal pore in the stomata of the upper epidermis of the leaf blade. The application positively affected the length and mass of shoots, the number of shoots, but also the mass of inflorescence and roots. In the aboveground biomass there was a rise in the content of protein, phosphorus, calcium, potassium, magnesium, and titanium.
Keywords: *auxin, cytokinin, alfalfa, titanium chelate, stomata, biometrics, phytochemistry*

Introduction

Flow of hormones, organic substances secreted by plants, regulates physiological processes, stimulating, among other things, cell division and plant growth (Kocira et al., 2016; Sosnowski et al., 2016a, b, 2017a, b). Some exogenous plant hormones, like auxin and cytokinin, affect the function and growth of stomata (Dodd, 2003; Saibo et al., 2003). In an experiment with pea plants Gupta et al. (1999) and Pospišilovă (2003) found that synthetic hormones regulate the opening and closing of stomata and, at the same time, the intensity of photosynthesis and transpiration. According to Schroeder et al. (2001) red and blue parts of the light spectrum cause stomatal opening, probably with auxin and cytokinin playing an active role in activating proton pump H+-ATPase. There have not been many publications about the effects of synthetic hormones on the changes in the number of stomata and changes in their sizes or about the relationship between those features.

The relationship between the number of stomata per unit area and gas exchange has been proven in experiments with such plants as soya, strawberry (Klamkowski et al., 2008). It was also hypothesised that stomatal reaction to exogenous hormones might be dependent on hormone concentration (Pospišilovă, 2003). A concentration which is too high causes blocking of stomatal pore opening and hinders gas exchange (Ruclová and Pospišilovă, 2001; Dodd, 2003). One of the features of plant hormones is their ability to interact with other hormones, for example, when synthetic auxin and cytokinin, in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24032414
© 2018, ALÖKI Kft., Budapest, Hungary

higher amounts**,** both stimulate ethylene biosynthesis in plant tissue (Lorteau et al., 2001; Khan et al., 2002). However, many supposed reactions of the plants to those hormones may be simply reactions to a high level of ethylene. Another example of interaction is again that between cytokinin and auxin, with them both stimulating cell division in the cambium and vascular system formation. It results in a more effective transport of photosynthetic products throughout the plant and increases plant resistance to stress (Aldesuquy, 2000).

During the last few years an interest in the effects of chemical compounds having hormone-like properties on plants has been growing. Some of the most important exogenous synthetic auxins are: Indole-3-acetic acid (IAA), Indole-3-butyric acid (IBA), Beta-naphtoxy acetic acid (NOA), 1-Naphthaleneacetic acid (NAA) and 2,4-dichlorophenoxyacetic acid (2,4-D). The best known exogenous synthetic cytokinins are: 6-benzylaminopurine (BAP) and kinetin also called N6-furfuryladenines (Scacchi et al., 2009). The prospect of using other bio stimulants, one of which is titanium in the form of mineral compounds diluted in water, is also of growing importance. Titanium application can regulate biochemical processes, increasing and speeding up biomass growth. Moreover, it stimulates pollination, fertilization, fruit and seed formation, and increases resistance to bacterial and fungal diseases (Carvajal and Alcaraz, 1998). Titanium speeds up growth and development of leaves and is a catalyst making it easier for a plant to take up and process nutrients from soil and from foliar sprays more efficiently (Carvajal and Alcaraz, 1998).

The aim of the experiment was to evaluate the effects of a growth regulator on *Medicago* x *varia* T. Martyn cv. Kometa. An assumption was that its application would affect vegetative and generative development of selected morphological features, influencing the concentration of biomass minerals, such as P, K, Ca, Mg, Mn, Zn, Mo, Cu, Ti and organic compounds, like protein, crude fibre, Neutral Detergent Fibre (NDF), Acid Detergent Fibre (ADF), Acid Detergent Lignin (ADL), cellulose, and hemicellulose. Furthermore, the ratios of macro elements Ca:P and K:(Ca+Mg) were calculated.

Material and methods

Design of the experiment

The experiment was carried out in the plant breeding room of the University of Natural Sciences and Humanities in Siedlce (Poland) in 2014, in controlled conditions with the temperature of 24±2/16±2 °C, humidity of 40%, high pressure sodium lamps used to insure photoperiod of 16/8 and light intensity at 200 µmol m^{-2} s^{-1}. *Medicago* x *varia* T. Martyn cv. Kometa, the plant to be tested, was grown in pots. The experiment was set out in a randomised design, with a control unit, and was replicated four times. The pots were filled with 5 kg of soil, which was loamy medium sand taken from the plough layer of the 3d class according to the Polish classification system. The main characteristics of the soil were as follows: phosphorus - 0.48 g kg^{-1} DM, magnesium - 0.10 g kg^{-1} DM; potassium - 0.13 g kg^{-1} DM, copper - 8.7 mg kg^{-1} DM, and zinc - 22.3 mg kg^{-1} DM; boron - 2.3 mg kg^{-1} DM), manganese - 191 mg kg^{-1} DM and iron - 1570 mg^{-1} DM. Additionally, soil pH measured in KCl was 6.3, N-NO_3 concentration was 1.4 mg kg^{-1} DM, N-NH_4 concentration was 60.9 mg kg^{-1} DM, and C_{org} (organic carbon) concentration was 17.1 g kg^{-1}.

The alfalfa seeds were sown in mid-March at a depth of 2-3 cm in pots (h = 300 mm, ∅ = 200 mm). When the seeds germinated, three representative seedlings in each pot were left to grow and to be used in the experiment later. The growth regulator applied and exclusively used for the experiment was given a patent by the Patent Office of the Republic of Poland (P/407/790). The regulator contained synthetic auxin (concentration of 35 mg dm^{-3}), cytokinin (concentration of 35 mg dm^{-3}) and titanium chelate (concentration of 1 mg dm^{-3}). The plants were sprayed until they were thoroughly wet, using 0.20 dm^3 of fluid per pot (0.067 dm^3 per plant). The plants were treated twice with different experimental combinations, at the six-true-leaf stage, i.e. during the vegetative stage of *Medicago* x *varia* T. Martyn and at the early-bud stage, i.e. during the generative stage of *Medicago* x *varia* T. Martyn.

Experimental treatment

- Control – distilled water application during the sixth-leaf stage and during the early-bud stage,
- AF_1 – regulator application during the sixth-leaf stage, distilled water application during the early-bud stage,
- AF_2 –distilled water application during the sixth-leaf stage, regulator application during the early-bud stage,
- $AF_{1,2}$ - regulator application during the sixth-leaf stage and during the early-bud stage.

All experimental variants were replicated four times.

Analysis of selected morphological features

The following measurements were recorded**:** the number of stomata per 1 mm^2 of the upper epidermis of the leaf blade, stomatal length and breadth (μm), the length of the stomatal pore (μm), stem length (cm), the number of shoots per plant, the number of leaves per shoot, root collar diameter (mm), the total mass of the plant (g DM), the total mass of shoots (g DM), the mass of leaves (g DM) the mass of inflorescence (g DM), the mass of roots (g DM), the mass of the aboveground part together with the mass of roots per plant (g DM).

The biometric measurements were taken after the plants were harvested at the end of flowering. Earlier than that, from the beginning till the end of flowering, each newly bloomed flower was counted. Stomatal parameters were determined with the microscope camera (HDCE Delta Optical). The material to be viewed under the microscope was taken from the central part of upper leaf blade surface, with five leaves of each experimental variant used. The dark-field microscope with a magnification of 400 times was applied. Microscope camera images were sent to the computer and all measurements were taken with microscopic imaging software ScopeImage 9.0.

The methods of chemicals estimation

The plants were harvested, dried and ground to determine the concentration of the following chemical elements: potassium, calcium, magnesium, phosphorus, manganese, zinc, copper, molybdenum, and titanium. Shoots, leaves, and roots were used to determine titanium concentration, but in the case of potassium, calcium, magnesium, potassium, manganese, zinc, copper, and molybdenum a mixture of shoots and leaves

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24032414
© 2018, ALÖKI Kft., Budapest, Hungary

was used to analyse concentration of those metals. The mineral analyses were reduplicated three times for each experimental variant. Total concentration of potassium, calcium, magnesium, phosphorus, manganese, zinc, copper, and molybdenum was determined with ICP – AES, after dry mineralization in a muffle furnace at 450 °C. Then, 5 ml of a 50% solution of HCl was added to the crucible and evaporated in a sand bath to dissolve carbonates and separate silica. Next, 10 ml of a 10% solution of HCl was added and the contents were poured into a 100 ml volumetric flask.

Furthermore, the ratios of macro elements Ca:P and K:(Ca+Mg) were calculated. Then, the concentration of protein, simple sugars, Neutral Detergent Fibre (NDF), Acid Detergent Fibre (ADF), Acid Detergent Lignin (ADL), cellulose, and hemicellulose was measured (g kg^{-1} DM). The air-dry matter was shredded and ground, and the obtained material was subjected to chemical analysis to determine protein, simple sugars, and dry matter concentration, the latter by determining moisture content. The method of determination was near infrared spectroscopy (NIRS), using the NIRFlex N-500 spectrometer and ready to use INGOT calibration applications.

The results physiological and biometric parameters, the concentration of chemical elements and chemical compounds in the biomass, were statistically processed, using analysis of variance. Tukey's test was used to determine $HSD_{0.05}$ for means that were significantly different, and standard error was calculated to find out how the values spread. The Statistica 6 programme was used for all data analysis.

Results and discussion

The results of the experiment showed that regulator application to alfalfa plants did not affect the number and the length of stomata in the epidermis of the leaf blade (*Table 1*). However, the regulator increased the breadth of stomata, with the widest ones being in variants sprayed one time at the six-true-leaf stage (13.7 μm) and in plants treated twice during the six-real-leaf stage and during the early-bud stage (13.9 μm). There was a similar effect in the case of stomatal pore length, where the highest increase, compared to the control, was also in plants treated twice (8.5%). Additionally, treating plants during their early-bud stage, or, broadly speaking, during their generative stage, did not affect their stomata in any way.

The data in *Tables 2* and *3* show that as a result of regulator application there were considerable differences between alfalfa plants it terms of the development of their parts and the growing of their mass. In plants treated twice the shoots, in a statistically significant way, were 27.2% longer than in control plants.

There were similar results when it comes to the number of shoots. In pots where plants were treated twice there were 21.7% more shoots than in control plants treated with distilled water. As a result, the mass of shoots was 25% higher than the mass in the control. Generally, compared to the control, there was a statistically significant increase in the mass of shoots, inflorescence, and roots, both in plants growing in pots where the regulator was applied during the growing stage (AF_1) and in plants treated twice ($AF_{1,2}$). However, statistical analysis did not show any increase in the number of leaves per shoot, root collar diameter, or leaf mass per plant.

Application of synthetic growth regulators affects nutrient absorption and, at the same time, regulates accumulation and distribution of nutrients. Additionally, there is dependence between application of such regulators and the content of macro and microelements in the aboveground vegetative parts. In the experiment described here (*Tables 4* and *5*), in the plants treated with the regulator there was an increase only in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

the content of phosphorus, manganese, and potassium, with the latter having the highest increase. In the pots with plants treated once, during the vegetative stage (variant AF_1), potassium content, compared to the control, grew by 32%, while for plants treated twice the accumulation of this metal was 28.6% higher.

The application of the regulator once, during the vegetative stage, and twice, during both vegetative and generative stages, increased phosphorus and manganese content by over 20%. Additionally, there was a considerable change in titanium concentration in many parts of plants (*Table 6*). The highest concentration of titanium was in leaves (from 3.24 to 4.01 mg kg^{-1} DM), with a relatively high concentration in shoots (from 2.01 to 2.89 mg kg^{-1} DM), and the lowest amounts in roots (from 0.99 to 1.67 mg kg^{-1} DM). Treating plants with the regulator increased the total amount of titanium in biomass, with the highest increase in plants treated twice (variant $AF_{1,2}$). Compared to the control, the content of titanium in shoots increased by 43.8%, in leaves by 23.8%, and in roots by as much as 68.7%. Regulator application during the vegetative stage in the strongest way affected the content of titanium in the biomass of roots, by 54.5%. In turn, treating plants in the generative stage resulted in a slight change in the amount of the above metals in plants only by several percent, and the change was statistically

insignificant. A higher amount of those chemical elements affected ion ratios between some macro elements (*Table 7*).

Table 7. *The effects of growth regulator applied at different times on the ratio of some macroelements to others in the above ground part*

Variants	Ratio			
	Ca:P Mean ± SE	+, - [%]	K:(Ca + Mg) Mean ± SE	+, - [%]
Control	5.04 ±1.21	-	0.88 ±0.71	-
AF_1	4.05 ±0.93	-19.6	1.14 ±0.84	+29.5
AF_2	4.99 ±1.12	-1.0	1.01 ±0.62	+14.8
$AF_{1,2}$	3.36 ±1.02	-33.3	1.09 ±0.48	+23.9
$HSD_{P=0.05}$	0.61	-	0.11	-

Mean value ± standard error (SE), +, -,% − increase, decrease to the control, A – regulator, F_1 – sixth-leaf stage, F_2 – early-bud stage

The lowest Ca: P ratio was in plants treated twice (3.36), but when the regulator was applied during the six-real-leaf stage the ratio was 4.05, while in the control it was wider, with the value of 5.04. Application during the generative stage did not affect the ratio of Ca: P. The ratio of K: (Ca + Mg) was in a statistically significant way higher for plants treated with the regulator in all variants of the experiments and ranged from 1.01 to 1.14.

In the biomass, regulator application affected the amount of organic compounds, like protein, fibre, and structural carbohydrates making up the skeleton of the plant cell wall. The effect of regulator application was dependent on the plant development stage at the time of application (*Table 8*). When the plants were treated during the six-true-leaf stage, a part of the vegetative stage, the content of protein in the biomass increased by 14.5%, while crude fibre decreased by 7.0%. There was a similar effect in plants treated with the regulator twice (variant $AF_{1,2}$). However, compared to the control, regulator application during the early-bud stage, or generative stage, did not affect in a statistically significant way the content of protein and crude fibre. The regulator influence was particularly noticeable in the changing content of cell wall fractions:

Neutral Detergent Fibre (NDF), Acid Detergent Fibre (ADF), Acid Detergent Lignin (ADL), cellulose, and hemicellulose (*Table 9*).

Table 8. *The effects of growth regulator applied at different times on total protein and crude fibre concentration in the above-ground parts [g kg^{-1} DM]*

Variants	Total protein		Crude fibre	
	Mean ± SE	+, - [%]	Mean ± SE	+, - [%]
Control	193 ±12	-	301 ±17	-
AF_1	221 ±13	+14.5	280 ±16	-7.0
AF_2	191 ±11	-1.03	297 ±19	-1.3
$AF_{1,2}$	227 ±17	+17.6	278 ±18	-7.6
$HSD_{P=0.05}$	21.5	-	16.4	-

Mean value ± standard error (SE), +, - [%] - increase, decrease to the control, A – regulator, F_1 – sixth-leaf stage, F_2 – early-bud stage

Additionally, the changes in the content of the above fractions, like in the case of protein and fibre, showed that there was a relationship between the amount of those compounds and the time when the regulator was applied. Acid Detergent Fibre was an exception, with its concentration ranging from 324 to 341 g kg^{-1} DM, without any statistically significant differences between plants of different experimental variants. As regards NDF, ADL, cellulose, and hemicellulose, regulator application resulted in lower content of those compounds in the dry matter of plants treated during the vegetative stage (variants AF_1 and $AF_{1,2}$).

One of the characteristics of hormones is their interaction with other hormones, an example of which is exogenous cytokinin and auxin, in particular in high doses, stimulating ethylene biosynthesis in plant tissue (Lorteau et al., 2001; Khan et al., 2002). Due to the effect of cytokinin and auxin application, different responses of plants treated may be an effect of a greater ethylene concentration, not a reaction to those hormones themselves. Some of such responses may be earlier flowering and fruiting in some plants (Pandey et al., 2003). Another example is an interaction of cytokinin with auxin in stimulating cambium growth and in the forming of vascular tissue, which results in a better transport of photosynthesis products and, in consequence, in a higher yield (Aldesuquy, 2000). In the past synthetic hormones were used for flower thinning to regulate the fruit number. By dropping off some buds and flowers, the plant regulates the number of fruit (Bangerth, 1989).

However, it happens that too many buds or flowers fall off and then the number of fruits is smaller and so is the yield. Some plants, including soya, bloom profusely but young flowers and pods, contrary to fully grown and ripe fruits, drop off in a considerable number (Cho et al., 2002). As a result, the production potential of such plants is smaller (Rylott and Smith, 1990). Generally, there are differences between plants when it comes to the process of flowering, and those differences are also caused by different hormone activity (Galoch et al., 1996). There is relationship between the amount of endogenous cytokinin and the number of fallen flowers and pods from soybean plants (Noden et al., 1990). According to another study, treating plants with synthetic cytokinin prevents this process, balancing hormone level and activity (Nagel et al., 2001). Some researchers have found that auxin is especially important, in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

particular in legumes, with their yield potential not fully achieved despite the fact that those plants can produce large quantities of organic matter (Reinecke et al., 1999). In the Polish climate soybean is one of plants in which the level of auxin in young flowers is too low, which again may be the cause of flowers and pods falling off, resulting in lower yield. Auxin application may change this process if only because there are some enzymes in plants decomposing natural auxin relatively quickly (Rylott and Smith, 1990).

The seed yield depends on pod formation and, to a large extend, on the amount of photosynthetic products and other nutrients transported to pods. Plant hormones, like auxin and cytokinin, take part in distribution of photosynthetic products, stimulating their transport and storage (Rodrigo et al., 1997). Hormones also take part in regulating transport and distribution of nutrients by affecting growth of recipient sink sells and the activity of enzymes dealing with phloem loading and unloading, but they also function as signal substances indicating that sink cells need to be filled with photo assimilates. Plant hormones affect flower stalk thickening by regulating vascular tissue development, at the same time making transport of photo assimilates from vegetative to generative parts more efficient, which, in turn, increases seed yield (Nagel et al., 2001; Aldesuquy, 2000).

Hormones, apart from regulating transport of nutrients, also affect their uptake by plants and their remobilisation during seed formation, at the same time influencing the yield (Czapla et al., 2005). The growth of aboveground mass and of mineral content in plants as a result of regulator application is in fact an effect of a bigger growth of the root system, in particular the lengthening of the root hair zone (Bertell and Eliasson, 1992; Metwally et al., 1997). In consequence, the absorption of water and dissolved mineral nutrients is more intensive. Auxin is the most important factor in this process because it sends out a signal about the demand of sink sells for nutrients and about their state (Haiser and Jönsson, 2006).

Rylott and Smith (1990) found that in plants treated with synthetic auxin, there may be a growing dominance of generative parts over vegetative parts. It was also confirmed by the research of Pandey et al. (2003), who treated cotton plants with IAA and found increased flower sizes. In turn Nagel et al. (2001) discovered that synthetic cytokinin stimulates vascular tissue development and improves transport of bio assimilates from

© 2018, ALÖKI Kft., Budapest, Hungary

vegetative to generative parts, increasing their content in conducting tissue of plants. Finally, Barcley and McDavid (1998) found that pigeon pea plants developed much bigger pods with bigger mass if they were treated with 6-benzylaminopurine (BAP).

Recently there has been a growing interest in foliar treatment with mineral growth regulators in the form of titanium chelate. It has turned out that this chemical compound increases chlorophyll content in leaves, improves immunity to fungal and bacterial diseases, fosters development and growth of leaves, increasing plant yield (Pais, 1993; Prusiński and Kaszkowiak, 2005). Titanium chelate is predominantly used in growing vegetables. Cucumber plants treated three times with a 0.02% solution of this chelate had up to 100% more seeds. Dressing pea seeds with titanium chelate increased the number of pods and resulted in a 60% growth in their yield. In an experiment with bean plants the weight of seeds was also higher but the yield increased by several percent only (Nalborczyk, 1993).

In an experiment carried out by Prusiński and Kaszkowiak (2005) on the effect of titanium in a form of Tytanit, a foliar fertilizer, on yellow lupine, there was a significant increase of the yield, by 7.4-18%. In fact titanium did not significantly increase the seed yield from the main stem, but its application resulted in a significant rise in the number of pods and seeds from branches. However, protein content and its structure in seeds were more affected by the hydro-thermal conditions than by the application of titanium. Similarly, titanium did not affect seed thickness, which was closely related to growth conditions rather than titanium application. Even if titanium affects the activity of photosynthesis (Pais, 1993), decreasing symbiosis efficiency after plant blossom fall (Ruszkowska, 1991), its effect on the supply of assimilates to seeds is still too low to diversify seed plumpness. However, a better formation of seeds in the pods on the main stem and a significantly higher yield of seeds from branches show a substantial role of titanium in the processes of photosynthesis and accumulation. A double application of a 0.02-0.04% solution of titanium straight after plant blossom fall and 7-10 days later resulted in the highest lupine yield (Prusiński and Kaszkowiak, 2005). Titanium applied to legume plants increases intensity of photosynthesis and the mass of the aboveground parts. As a result of an experiment on the effect of titanium application on tomato plants grown on rockwool it was found that the application of titanium at an annual dose of 960 g $Ti \cdot ha^{-1}$ significantly increased total and marketable yields (Kleiber and Markiewicz, 2013). Plant nutrition with titanium resulted in a significant increase in the yield of fruit with the greatest diameters in comparison with other tested combinations. Titanium application positively affected the content of the following nutrients: nitrogen, phosphorus, calcium, magnesium, and potassium.

Conclusion

1. Treating *Medicago* x *varia* T. Martyn plants with a mixture of synthetic growth hormones and titanium chelate increased the breadth of stomata and the length of the stomatal pore. The same treatment affected the length of plant shoots, the number of shoots, but also the mass of shoots, flowers, and roots. In consequence, the total mass of plants was higher.
2. There was a change in plant phytochemistry, with an increase in the content of protein, phosphorus, potassium, manganese, and titanium in aboveground parts. What is more, plants treated with this substance had a lower

concentration of crude fibre, NDF and ADL fractions, cellulose, and hemicellulose.

3. Furthermore, it should be noted that the best results were achieved after the plants were treated in the vegetative period, during the six-true-leaf stage (variant AF_1) and when the plants were treated twice (variant $AF_{1,2}$).

(Received 9th Jan 2018; accepted 3rd Apr 2018)

Abstract. A study was conducted to investigate the effects of feeding hydroponics maize fodder on performance and nutrient digestibility of weaned pigs. A total of 36 pigs were allocated in a completely randomized design to 3 treatments. Treatment 1 contained 100% concentrate (Con_{100}); Treatment 2 contained 50% concentrate and 50% hydroponics maize fodder ($Con_{50}HM_{50}$) while Treatment 3 had 100% hydroponics maize fodder diet (HM_{100}). Each treatment had 12 weaned pigs with three replicates of four pigs per replicate. The experiment lasted for six weeks. Dietary treatments had significant effects ($P < 0.05$) on final weight, weight gain and feed conversion ratio of the pigs. Pigs fed Con_{100} had the highest ($P < 0.05$) final weight while the lowest weight was recorded in pigs on diet HM_{100}. Feed intake and weight gain were highest ($P < 0.05$) in pigs fed concentrate diet (Con_{100}) while the lowest intake was in animals fed HM_{100}. Feed conversion ratio (FCR) was improved ($P < 0.05$) in pigs fed Con_{100} and $Con_{50}HM_{50}$ respectively. Crude protein, crude fibre and ether extract digestibilities were improved ($P < 0.05$) in animals fed Con_{100}. Pigs fed dietary mixtures of concentrate and hydroponics maize fodder ($Con_{50}HM_{50}$) had better ($P < 0.05$) CP and CF digestibility as compared to those on HM_{100}. Inclusion of hydroponics maize fodder in pig nutrition improved performance and nutrient digestibility of weaned pigs.

Introduction

Pig production is one of the fastest growing livestock sector in developing countries like Nigeria (Imonikebe and Kperegbeyi, 2014). Compared to ruminants, pigs are prolific, have high feed conversion efficiency, early maturing, require small space and easy to manage (Ouma et al., 2014). According to Tewe and Egbunike (1998), pig production represents the cheapest means of correcting animal protein shortage among the impoverished people in Nigeria. However, their production is facing tremendous set back and on the verge of collapse due to unavailability of feed, which accounts for 70-80% of the total cost of production (Olomu and Oboh, 1995). The major factors responsible for the shortage of green fodder are scarcity of land due to small land holding size, water shortage and labour (Naik et al., 2015).

A possible way of solving this problem of feed scarcity in pig industry is through the use of hydroponic farming systems. Fodder produced by growing plants in water or nutrient rich solution but without using any soil is known as hydroponics fodder, sprouted grains or sprouted fodder (Dung et al., 2010a). Production of hydroponics fodder involves

© 2018, ALÖKI Kft., Budapest, Hungary

growing of plants without soil but in water or nutrient rich solution in a greenhouse (hi-tech or low cost devices) for a short duration - approx. 7 days - (Naik et al., 2015).

Hydroponics technology has been recognized as a viable method of producing vegetables (tomatoes, lettuce, cucumbers and peppers) as well as ornamental crops such as herbs, roses, freesia and foliage plants. Different types of fodder crops such as barley (Reddy et al., 1988), oats, wheat (Snow et al., 2008); sorghum, alfalfa, cowpea (AI-Karaki and AI-Hashimi, 2012) and maize (Naik et al., 2012) can be produced by hydroponics technology. Hydroponics fodder is more palatable, digestible and nutritious while imparting other health benefits to the animals (Suraj et al., 2016). Naik et al. (2015) reported yields of 5-6 folds of fresh hydroponics maize fodder in 7 days. Supplementation of sprouted fodder in the ration of pigs is a viable possible alternative technology to conventional green fodder (Naik et al., 2015). However, there is paucity of information on the use of hydroponically sprouted maize fodder in weaned pigs. Therefore, the objective of this study was to determine the effect of feeding hydroponics maize fodder on the growth performance and nutrient digestibility of weaned pigs.

Materials and methods

Study site and experimental design

This study was carried out at the Piggery Unit, Teaching and Research Farm, University of Ibadan, Ibadan, Nigeria. The farm is situated in Southern Nigeria at $7^{0}20^{1}$N, $3^{0}50^{1}$E at an altitude of 200-300 m above sea level. A total of 36 weaned pigs were purchased from a reputable farm in Ibadan, Oyo state, Nigeria. The pigs were fed *ad libitum* and cool clean water was provided. The pigs were allotted into three groups consisting of 12 animals per group, replicated three times with four pigs per replicate in a completely randomized design. The groups were allocated into 3 treatments as follows- Pigs fed 100% concentrate diet (Con_{100}), pigs fed 50% concentrate diet and 50% hydroponics maize fodder ($Con_{50}HM_{50}$) and pigs fed 100% hydroponics maize fodder (HM_{100}). The concentrate composition is presented in *Table 1*. The experiment lasted for six weeks. Pigs were housed in properly disinfected pens and all routine management practices were strictly observed.

Table 1. *Gross composition of concentrate fed to weaned pigs*

Ingredient	Percentage (%)
Maize	43.00
Soyabean meal	15.00
Wheat offal	15.00

The hydroponic system

The production of hydroponic maize fodder, that is, sprouted maize grown in a nutrient solution was conducted under natural illumination in growth chamber as described below. The maize used was grown for 7 days.

Planting material

Maize grains were obtained from a local market. The seeds were cleaned from debris and other foreign materials and were subjected to a germination test to check for viability. Clean seeds were washed, sterilized in Hydrogen Peroxide (H_2O_2) solution and soaked in tap water for 24 h before distribution in the trays.

Seed planting and irrigation

Seeds of maize were sown in the planting trays. The seedling rate used was 500 g of maize grain per tray. Trays were irrigated manually with organic hydroponics nutrient solution twice a day (07:30 and 17:30 hr) at a fixed rate of 250 ml/tray/day using a spray gun for 20 s. Drained water were collected in plastic containers which were placed under each planting tray and measured. The seeds were scattered uniformly within the tray. The tray was kept in cool and well illuminated environment.

Green fodder harvesting

The sprouted seeds were grown in the greenhouse for a period of 7 days. The fully grown fodder (*Fig. 1*) was then given to the pigs as whole feed.

Figure 1. *Hydroponic maize fodder (Source: Adebiyi et al., 2018)*

Fodder yield

Samples of the green fodder were taken weekly to determine the dry matter and nutrient contents. The quantity of hydroponics fodder and biomass production was recorded daily by weighing the seeds before planting and weighing the fodder produced.

Growth performance

Growth parameters of the pigs were observed and recorded throughout the experiment. Feed intake was obtained by subtracting the leftover feed from the total quantity of feed served. Weight gain was determined by subtracting the initial live

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24152422
© 2018, ALÖKI Kft., Budapest, Hungary

weight from the final live weight. Feed conversion ratio was defined as the quantity of feed (kg) consumed to gain a unit of live weight (kg):

$$FCR = \frac{\text{Feed Intake}}{\text{Weight Gain}}$$

Nutrient digestibility

At day 37, three animals were randomly selected from each treatment. The selected pigs were kept in metabolic cages for 5 days. Feed intake and total faecal collection from individual animals were recorded. The experimental feed and faecal samples were dried. The feed and faecal samples were further analyzed for crude protein (CP), crude fibre (CF), ether extract (EE) and ash contents using the procedure of AOAC (2000). The nitrogen free extract (NFE) contents of the samples were obtained using the equation:

$$NFE = 100 - (CF + CP + EE + Ash)$$

Statistical analysis

Data on performance and nutrient digestibility were analysed using the General Linear Model (GLM) procedures of the statistical analysis of variance (SAS, 2010). Duncan Multiple Range Test was applied for mean separation where there were significant differences ($P < 0.05$).

Results and discussion

The results of the proximate composition of the hydroponics maize fodder are presented in *Table 2*. There are changes in the nutrient content of the maize grains and hydroponics fodder. The average dry matter (DM) content of the maize seed was 95.08% whereas the hydroponic maize fodder was 25.00%. The decrease observed in the DM may be due to the decrease in the starch content of the hydroponics fodder. During sprouting, starch is catabolized to soluble sugars for supporting the metabolism of energy requirement of the growing plants for respiration and cell wall synthesis, so any decrease in the amount of starch causes a corresponding decrease in DM (Naik et al., 2015). This result is similar to the findings of Thadchanamoorthy et al. (2012), who reported a DM content of 26.07% for sprouted maize fodder. The crude protein content in the present study showed that hydroponic maize fodder contained 13.75% CP as compared to 8.7% in maize seed. This observation has been reported by other authors (Dung et al., 2010a; Naik et al., 2015). According to Dung et al. (2010a), the use of nutrient solution enhances the CP content of the hydroponics fodder which is higher than the tap water, thus leading to the uptake of nitrogenous compounds. Additionally, sprouting has been reported to alter the amino acid profile of maize seeds and increases the crude protein content of hydroponic fodder (Morsy et al., 2013). In the present study, ether extract of the hydroponics maize fodder was 3.55%. The value reported in the current study was slightly higher than the range of 3.27-3.49% obtained by Singh (2011) and Naik et al. (2015). The increase in the EE content of the hydroponics fodder

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24152422
© 2018, ALÖKI Kft., Budapest, Hungary

may be due to the increase in the structural lipids and production of chlorophyll associated with the plant growth (Naik et al., 2015).

The CF content of 14.77% was within the range of 7.35-21.20% reported by Naik et al. (2015). Increase in CF contents of hydroponics maize fodder may be attributed to the build-up of cellulose, hemicelluloses and lignin (Cuddeford, 1989). The value of total ash (3.33%) observed in the hydroponic maize fodder in the current study is within the range of 1.75-3.80% reported by Naik et al. (2014). During the sprouting process, the total ash content increases due to the absorption of minerals by the root (Dung et al., 2010b). The NFE content observed (60.72%) was higher than that of hydroponically sprouted grains reported by earlier workers - 1.56-3.64% (Naik et al., 2015).

Table 2. *Proximate composition of hydroponics maize fodder*

Parameter	Percentage (%)
Dry matter	25.00
Crude protein	13.75
Ether extract	3.55
Crude fibre	14.77
Ash	3.33
Nitrogen free extract	60.72

The results of hydroponics maize fodder on the performance of pigs are shown in *Table 3*. Dietary treatments had significant effects ($P < 0.05$) on final weight, weight gain and feed conversion ratio of the pigs. The final weight ranges from 9.04-17.08 kg. Pigs fed Con_{100} had the highest ($P < 0.05$) final weight while the lowest weight was recorded in pigs fed HM_{100}. Feed intake and weight gain were highest ($P < 0.05$) in pigs fed concentrate diet (Con_{100}) while the lowest intake was in animals fed HM_{100}. Feed conversion ratio (FCR) was improved ($P < 0.05$) in pigs fed Con_{100} and $Con_{50}HM_{50}$ respectively. In the present trial, pigs fed dietary mixture of concentrate and hydroponics maize fodder ($Con_{50}HM_{50}$) performed better than those fed solely on sprouted fodder (HM_{100}). Helal (2015) reported higher dry matter intake, final body weight and improved FCR in goats fed dietary mixture of sprouted barley grains and barley straw. Similar results were reported by Fayed (2011) and Helal (2012). Hydroponic sprouts are rich sources of bioactive enzymes and contain grass juice ingredients that improve the performance of livestock (Naik et al., 2013). The increase in weight gain of pigs may be attributed to enhancement of microbial activity in the gut. According to Kruglyakov (1989), hydroponics fodder has simpler forms of vitamin, starch, protein and lipids which have positive effect on the performance of the animals. Nutritional value of sprouted fodder improves due to the modification of heterogeneous compounds into essential form (Chavan et al., 1989). Sprouting of grains has resulted into increase in quantity and quality of protein, sugars, minerals and vitamin (Naik et al., 2015). Weight loss was recorded in pigs fed solely on hydroponics fodder (HM_{100}). This observation may be due to the low DM intake of the pigs. Additionally, pigs being monogastric cannot thrive solely on fodder-based diet.

Feeding hydroponics maize fodder to pigs led to a decrease in the total daily feeding costs of experimental rations, $Con_{50}HM_{50}$ (#61.96) and HM_{100} (#53.97) as compared to Con_{100} (#70.00) which was mainly a concentrate diet (*Table 3*). Feed costs (#/kg)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24152422
© 2018, ALÖKI Kft., Budapest, Hungary

significantly reduce as the inclusion of the maize fodder increases. This result is similar to the findings of Fayed (2011) and Helal (2012) who found the lowest feed cost and highest profit in lambs fed dietary mixture of sprouted barley grains and *Tamarix mannifera*. In terms of economic efficiency, it is more profitable (feed cost per weight gain) to feed pigs on $Con_{50}HM_{50}$ (#228.01) as compared to Con_{100} (#316.4) and HM_{100} (#-446.91).

Table 3. *Performance and cost benefit of feeding hydroponics maize fodder to pigs*

Parameters	Con_{100}	$Con_{50}HM_{50}$	HM_{100}	SEM	P-value
Initial BW (Kg)	9.90	10.00	9.97	0.009	0.6094
Final BW (Kg)	17.08^{a}	13.35^{b}	9.04^{c}	0.775	0.0026
Feed intake (DM Kg)	30.89^{a}	12.72^{b}	8.00^{c}	1.334	0.0001
Weight gain	7.18^{a}	3.46^{b}	-0.93^{c}	0.783	0.0021
FCR	4.52^{a}	3.68^{a}	-8.69^{b}	1.425	<0.0001
*Feed cost/kg (#)	70.00	61.96	53.73		
Feed cost/weight gain (#/kg)	316.4^{a}	228.01^{b}	-466.91^{c}

^{a,b,c}Means within the same row with different letters are significantly different ($P < 0.05$)
BW: body weight, DM: dry matter, FCR: feed conversion ratio
*Calculated by multiplying the cost/kg of each ingredient used to formulate the diet by the quantity of the ingredient

Nutrient digestibility of pigs fed hydroponic maize fodder is presented in *Table 4*. Crude protein, crude fibre and ether extract digestibilities were improved ($P < 0.05$) in animals fed Con_{100}. However, animals fed dietary mixtures of concentrate and hydroponics maize fodder had better ($P < 0.05$) CP and CF digestibility as compared to those on HM_{100}. Helal (2015) recorded highest digestibility coefficients of CP, CF, EE, NDF and hemicellulose in goats fed sprouted barley. Similar results were reported by Fayed (2011) and Naik et al. (2015). Feeding of hydroponics fodder increased the digestibility of the nutrients which could be attributed to the tenderness of the fodder (Naik et al., 2014). The digestibility of the nutrients of the hydroponics fodder was comparable with the highly digestible legumes like berseem and clovers (Pandey and Pathak, 1991). According to Chung et al. (1989), highly soluble protein and amino acids in response to the early plant growth and enzymatic transformations of sprouted grains are responsible for improved digestibility in animals. The low CF digestibility reported in HM_{100} may be attributed to the minimal crude fibre utilization in monogastrics.

Table 4. *Nutrient digestibility of pigs fed hydroponics maize fodder*

Parameter	Con_{100}	$Con_{50}HM_{50}$	HM_{100}	SEM	P-value
CP	70.51^{a}	66.27^{b}	55.41^{c}	1.50	<0.0001
EE	72.98^{a}	67.37^{c}	68.43^{b}	0.57	<0.0001
CF	50.91^{a}	48.77^{b}	34.82^{c}	1.68	<0.0001
Ash	39.45^{b}	43.52^{a}	42.63^{a}	0.41	0.0001

Conclusion

Inclusion of hydroponic maize fodder in pig nutrition improved performance and nutrient digestibility of weaned pigs. Thus, there is great potential for developing hydroponic technology for fodder production in pig farming. Sole feeding of hydroponic maize fodder exerted negative effects on the performance of the animals. Further research is needed to establish the potential health benefits of hydroponic fodder in monogastrics.

Abstract. The management of municipal solid waste (MSW) is one of biggest challenges that developing countries are currently facing. Despite several environmental friendly alternatives being available, in Chile 90 % of MSW is disposed of in landfills, which produces large amounts of greenhouse gases (GHG) by the uncontrolled anaerobic digestion of its organic fraction. In addition, the way in which MSW is collected and transported increases the negative impact to the environment, especially when wastes classification is not properly performed at the generation point. On the other hand, the use of resulting biogas, in a decentralized off-grid form, at the generation point, could directly reward to waste producers with economic saving. This strategy will reinforce population motivation and an important reduction of the GHG emissions can be expected. Thus, this paper explores the biogas potential of food wastes by using reactors with no heating and stirring devices, with the aim of assessing the minimum expectable energy and $CO_{2,eq}$ savings. Based on laboratory tests at batch and semi-continuous mode and Chilean historical data, it is concluded that more than 1,704 Gg of $CO_{2,eq}$ can be avoided per year and an average of 425 GWh primary energy may be saved by Chilean householders.
Keywords: *CO_2 emission, psychrophilic, food waste, household scale, waste management*

Introduction

Municipal solid waste (MSW) is currently a great concern for modern societies. A sustainable coping strategy is required in order to protect not only environment but human health as well. The increase in the urban population growth rate has led to increased issues related to MSW management, especially in developing countries where traditional landfill disposal is the most common method of MSW management (Guerrero et al., 2013). It is obvious, in accordance with the residues management hierarchy that the most favorable option to deal with MSW is prevention. However, the reduction of the current levels of MSW must be accompanied by better management of the waste since and it may be highlighted that some parts are inedible and will unavoidably become a waste stream.

There are countless alternatives to manage the organic fraction of MSW which is mainly composed by food waste (FW) and garden waste. However, anaerobic digestion (AD) has been highlighted as the most reliable and efficient technology for minimizing the environmental impact of FW waste disposal in terms of greenhouse gas (GHG) emissions, which are generated during landfilling. In addition, AD of FW offers an

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24232439
© 2018, ALÖKI Kft., Budapest, Hungary

opportunity to produce a large energy yield of biogas and it has been demonstrated rapid public health improvements with important reductions in pathogens (Remais et al., 2009).

The AD process is well known, and related technology has already been successfully tested although MSW collection and separation still remain as key unknown factors for determining the feasibility of AD plants (Olsson and Fallde, 2015). Different systems for FW separation and collection at the generation point are successfully implemented in developed countries, in decentralized or centralized form. However, all these alternatives were supported by several subsystems, which are not yet extended in Chile, such as: the existence of a formal recycling industry, optimal distribution of curbside services and the development of policies for raising awareness, in terms of wastes classification, etc. Several countries have lately developed micro-scale applications to reduce transport requirements by means of creating a "biorefinery" that would dispose of local waste and produce energy (Walker et al., 2017). These micro-scale applications were developed by specific consortium of companies but general public was not included as an active stakeholder. In other words, the main goal was the enhancement of some industrial process rather than the minimization of urban waste management issue. These examples incorporated several complex devices such as; mixers, filters, feeding pumps, water heat exchangers, etc. that increase the installation and operation costs which have been highlighted as the most critical barrier for the popularization of biogas technology (Walekhwa et al., 2009).

On the contrary, small fixed dome digesters that work without stirring or heating have been successfully operated on the long term, mainly in developing countries with installation costs that range from 80 to 150 USD/m^3 (Buysman and Mol, 2013). These AD reactors show very low energy performance since the more complex the reactor configuration is, the more biogas will be produced and fewer impurities will be contained. Moreover, these simple AD plants are designed without cleaning and upgrading biogas stages and consequently power generation or methane grid injection are rarely considered. In spite of such limitations, household scale biogas reactors contribute to reduce $CO_{2,eq}$ emissions, soil and water pollution as well as improve sanitation by reducing pathogenic content of substrate materials. For instance, it has been showed that AD at 20°C reduced indigenous populations of total coliforms by 97.9 to 100 %, indigenous populations of E. coli by 99.6 to 100 %, and provided undetectable levels of indigenous strains of Salmonella, Cryptosporidium, and Giardia (Massé et al., 2010). Besides, the use of biogas represents an opportunity for lowering family expenditures cooking and/or heating fuels which ensure the participation, ownership and responsibility of the final users (Bond and Templeton, 2011), otherwise the lack of proper awareness among user (i.e. householders) inhibits the adaptation of technology.

The proposal

MSW management is nowadays especially worldwide discussed but specially into the Chilean context due to the reviewed national strategies regarding the environmental sustainability politics.

The first step for designing a properly strategy must be always the collection of characteristic data. However, the first national report was published in 2010 and till nowadays no further official update has been provided. Furthermore, Chilean statistics,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24232439
© 2018, ALÖKI Kft., Budapest, Hungary

regarding MSW management, show important differences, depending on whether data are provided by public services (CONAMA, 2009; OECD, 2005) or by previous research (Perez, 2010). Besides, some data regarding the organic fraction amount of MSW are missed (see *Fig. 1*). Nevertheless, by accepting data provided by this first national report, Chile is ranked as the major MSW producer in Latin America, with an annual average of 382.4 kg per capita and the organic fraction of Chilean MSW accounts for up to 60 % (90 % FW and 10 % garden wastes) (CONAMA, 2010a).

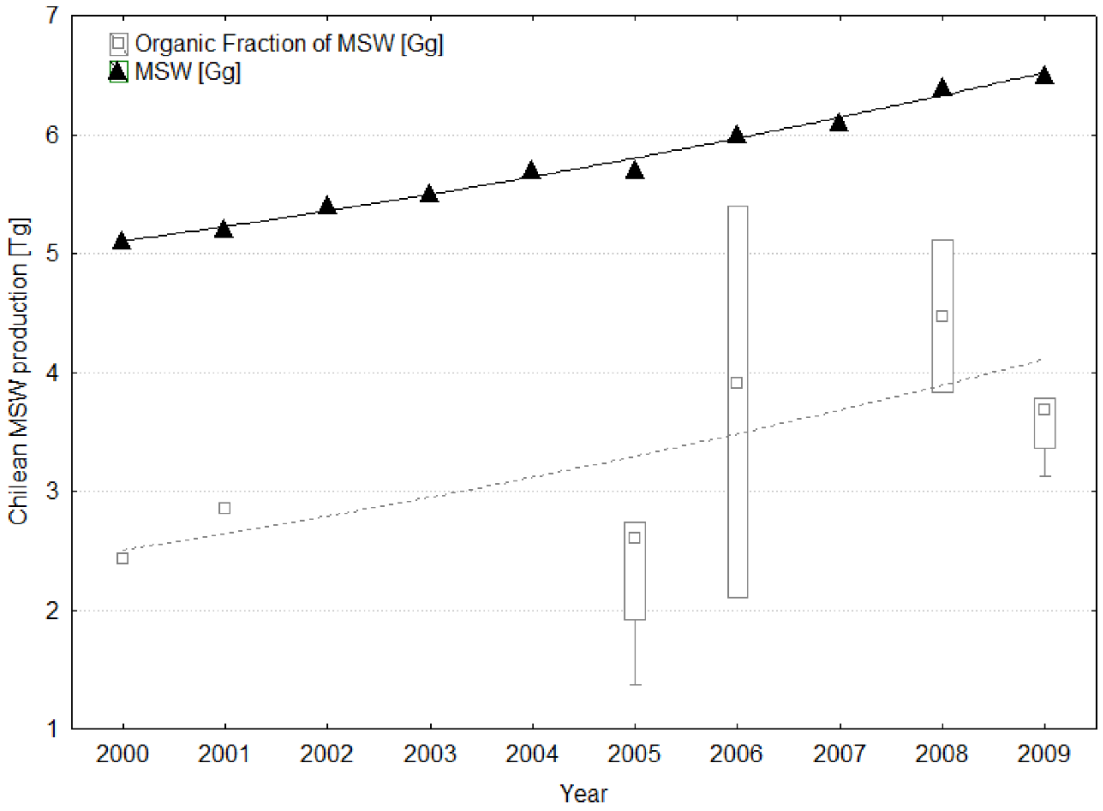

Figure 1. *Statistics of the Chilean MSW production and the amount of organic matter contained by the MSW*

Regarding the available MSW treatment facilities, Chile owns approximately 120 recycling facilities focused on plastics, cartons, oils and metals. These installations are able to recycle approximately 61 % of metals (including aluminium), 55 % of oils, 41 % of papers and cartons, 29 % of glass and 4 % of plastics. However, only 10 % of the organic fraction is currently treated. This organic matter is composed of 90 % food waste (FW) and 10 % gardening waste. Hence, there are 13 installations designed for composting and four that are based on co-incineration. The remaining organic waste is disposed of in 25 sanitary landfills and 139 uncontrolled waste dumping sites which receive MSW from approx. 239 cities. Distances between cities and these places range between 5 and 30 km (CONAMA, 2010b). Despite annual FW generation exhibiting increasing trends, there are no planned future investments, in the short-term, in terms of revalorization or recycling facilities.

MSW is not only an economic and social concern but also an environmental issue, since it is one of the major carbon emission sources from city operations (Galina, 2008).

According to the Chilean Ministry of Environment (2011), landfills gas emissions account for approximately 2,300 Gg of $CO_{2,eq}$ and these emissions are mainly produced by the uncontrolled AD of the organic matter. From this point of view, it is clear that a reduction of organic matter content leads to a decrease in GHG emissions. Since there is no gas collection and flaring systems in most of Chilean landfills, at present, landfills are the highest contributors to GHG emissions. In addition, MSW introduces another source of environmental impact, the so-called horizontal $CO_{2,eq}$ flows. These refer to the cumulative gases emission produced by the collection (i.e. from single households or other waste generation units) and transportation of collected MSW to landfills. In Chile, collection and transportation is performed by collection trucks that are fuelled by fossil fuels (i.e. diesel).

On the other hand, fossil fuels consumption highly impacts on the national economy since Chile does not own fossil fuels. In spite of Chile lacks of fossil fuel resources, more than 60 % of the energy, in terms of primary energy, is provided by imported fossil fuel. As result, the highest percentage of Chilean household expenses corresponds to energy supplies and this cost is increased year by year (e.g. from 2008 to 2012 natural and liquefied gas consumption was increased by 720 %) according to the Ministry of Economy, Promotion and Tourism (SERNAC, 2015).

As it has been previously stated, AD may address all these aspects by reducing the amount $CO_{2,eq}$ emissions and the household expenses related to the energy consumption. However, the key factor for a successful strategy, regarding MSW, is always related to the waste generation point (i.e. householders). Hence, it has been demonstrated that any strategy for MSW management should be well supported by citizen participation and therefore participation and motivation of population is always required to ensure the success of any waste management policy (Wen et al., 2016). At this point, any proposal must consider the waste producer (i.e. the householder) as the most important player.

It is well understood, that a decentralized strategy highly reduces the transportation of waste materials, which represents the main source of pollution regarding the MSW management chain (Alfonso et al., 2009). Besides, AD of FW contributes to reduce energy demand, and the aforementioned MSW impacts. However, one of the main difficulties of sustaining decentralized facilities is the organic waste availability for feeding the anaerobic digester (Righi et al., 2013) (i.e. the cooperation of waste producers). Therefore, in accordance with similar experiences in other countries (Reddy, 2004), this paper assesses the use of FW, generated by households, for biogas production by using household scale fixed dome reactors which will be daily loaded with this FW. However, the proposal cannot be based on expensive units but on simple small reactors working at psychrophilic range by means of simple fixed dome reactors.

The proposal considers that each building would incorporate a single stage reactor and biogas would be directly used on site by means of boilers or cooking stoves. With the aim of lowering the costs the proposal does not considered the use of biogas for electrical power generation or its injection to the natural gas grid. Consequently, complex cleaning biogas systems are not required and the corresponding installation costs are highly reduced. The FW generated would be disposed of in this AD unit and the effluent would be direct discharged as wastewater in sewers (see *Fig. 2*).

Despite previous authors have estimated a decade ago that biogas might contribute up to 45 % to reduce natural gas consumption in Chile (Seiffert et al., 2009; Bidart et al., 2013), currently AD provides approx. 0.03 % out of total primary energy

© 2018, ALÖKI Kft., Budapest, Hungary

consumption. This unexpected result is explained by two main reasons. On the one hand, authors assumed the expansion of the existing gas pipeline, but no relevant changes have been performed during last decade and this highly impacts economic feasibility. On the other hand, calculations were mainly based on residues provided by forestry industry, wood processing and energy crops which are already being used by other markets (Ignaciuk et al., 2006). In addition, it must be mentioned that co-digestion of FW with other household waste streams has not been considered. In spite of literature has demonstrated that specific biogas yield (SBY) is certainly improved by co-digestion (Iqbal et al., 2014) the potential inhibition of AD (e.g. detergents or papers towels) would make the proposal less reliable (Chen et al., 2008).

The proposal was assessed by determining the technical feasibility of the AD at psychrophilic temperature and by estimating the impact in terms of $CO_{2,eq}$. AD tests were performed in two phases: firstly batch and then semi-continuous operation mode, both at laboratory scale. This, since the batch test is of necessity performed with different substrate mass fractions than the semi-continuous test, and the substrate/inoculum ratio affects the kinetics. Finally, the obtained results were used for calculating the amount of $CO_{2,eq}$ that might be avoided.

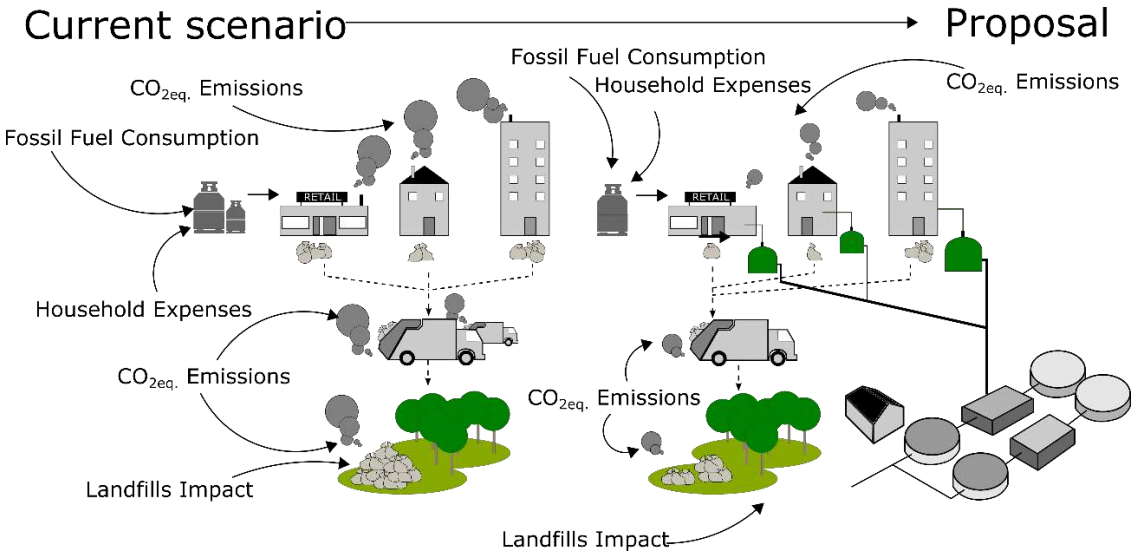

Figure 2. *Diagram of the decentralized AD approach proposed for reducing CO_{2eq} emissions by saving fossil fuels and fugitive emissions*

Materials and methods

AD tests

The AD test was divided into three stages. In the first step, FW and inoculum were characterized. Then, these values were used for setting the biochemical methane potential (BMP) tests. Finally, a semi-continuous experiment with lab-scale digester was carried out, along 90 days, maintaining a fixed organic load rate. These last two stages were performed in accordance with VDI 4630:2016-11.

The canteen, at the Autonomous University of Chile, provided FW on a weekly basis. This included animal and fish bones, fruits and vegetable peelings, seeds and any other organic matter. FW was blended with an industrial blender in order to permit comparison between the results of different fermentation tests (particle sizes of less than

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24232439
© 2018, ALÖKI Kft., Budapest, Hungary

10 mm) (Omniblend TM767, Chile) and homogenized. Then, 250 g of FW (approx. 250 g) was used for determining FW characteristics and 250 g of FW was frozen (-20 °C) till being used for loading reactors. An industrial partner, who operates a nearby AD plant, provided the inoculum. This AD plant works on mono-digestion, based on pig manure, at psychrophilic range. Inoculum was sieved throughout a 5 mm mesh for removing the death matter.

Regarding the FW and inoculum characteristics, total solids, (TS) and volatile solids (VS) were determined using an electric furnace set at 105 °C and 600 °C, respectively. Total soluble solids (TSS) and Total Dissolved Solids (TDS) were determined according to 2450-D and 2450-C methodology of the Standard Methods (APHA, AWWA, and WEF, 2005). Soluble nitrogen was measured using HANNA nitrogen determination (chromotropic acid method; range: 10 to 150 mg/L N at 420 nm; accuracy: ± 3 mg/L or ± 4 % of reading at 25 °C). The pH and Oxide Reduction Potential (ORP) were determined using a WTW pH 3110-2. Chemical Oxygen Demand (COD) was analyzed by COD Cell Test (Spectroquant®, Merck KGaA, 64271 Darmstadt, Germany) and the applied method corresponds to DIN ISO 15705, which is analogous to EPA 410.4, APHA 5220 D and ASTM D1252-06B. C:N ratio was determined following the standard methodology proposed by The U.S. Department of Agriculture and the U.S. Composting Council (TMECC, 2002). Total carbohydrates were quantified by following the visible range method using phenol-sulfuric. Total oils and fats were determined in accordance with the method extraction Soxhlet (APHA, AWWA, and WEF, 2005) and protein quantification was determined by means of the Pierce BCA Protein Assay Kit (Thermo scientific).

BMP was determined in triplicate (Ra, Rb, Rc) at laboratory scale (5 L batch reactors) (see *Fig. 3*). In spite of containers used for the fermentation test use to be 0.5 L, 1 L or 2 L flasks, in case of inhomogeneous substrate standards recommend to have larger fermentation volumes as this makes it easier to obtain representative samples. These reactors were equally filled with 150 g. of FW (i.e. 7.5 g VS/L), 1000 mL of inoculum and 3000 mL of fresh water. Hence, headspace volume was set at approx. 1000 mL. It must be highlighted that the organic total matter added from inoculum is quite lower than the recommended by standards and therefore the ratio substrate to inoculum rate (SIR) is higher. The main reason for using a high SIR is explained by two considerations. On the one hand, the results, provided by the semi-continuous test, in the long-term are not influenced by the inoculum used in the batch tests. On the other hand, further assays will be focused on the analysis of SIR in order to assess FW buffering capacity, which are not included within the present paper.

Reactors were kept at room temperature without stirring in order to simulate the conditions of the proposed household scale reactors by following VDI 4630:2016-11. The substrate temperature has been continuously measured and recorded by using a stainless steel temperature probe and data logger (Testo, Germany).

In spite of the initial pH adjustment is considered in different way, depending on the followed standards, previous authors have demonstrated that below an initial pH of 6.0, AD of FW is inhibited (Zhai et al., 2015). Thus, the pH was adjusted to 7.0, by means of NaOH, in all batches. Reactors were sealed and remaining air was removed by nitrogen gas flow.

According to VDI 4630:2016-11 guidelines when the new biogas production was found below 0.5 % after three days, the AD batch was ended and the semi-continuous phase took place.

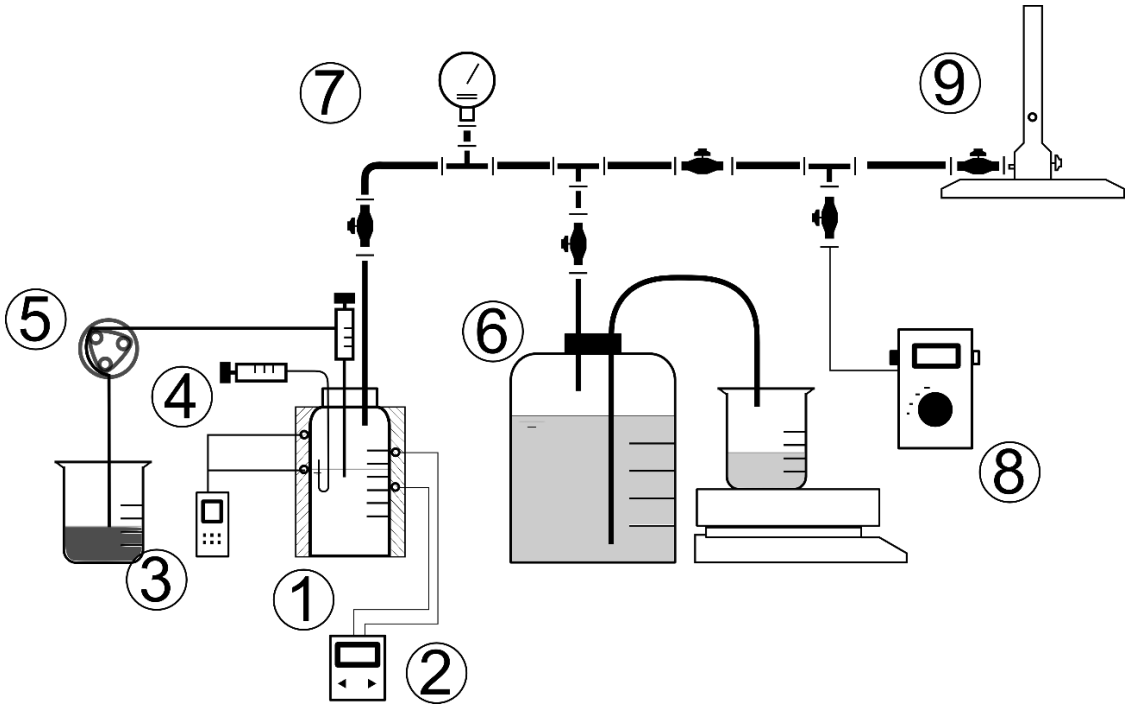

Figure 3. *The schematic representation of experimental laboratory scale biogas test showing (1) 5 L reactors; (2) Temperature probes and data logger; (3) pH and ORP probes; (4) overflow collection; (5) peristaltic pump for loading FW; (6) gas meter; (7) manometer; (8) gas analyzer; (9) burner*

Same reactors were used at semi-continuous stage and running without stirring and without temperature control. AD of FW is prone to instability at high organic load rate and because of that OLR was set at 1 g-VS/L day (i.e. 1-day-portions of 20 g FW) with a volumetric FW to water dilution of 1:2. During the loading operation, reactors were not de-areated. Feeding and digestate removal ware carried out automatically once every day by means of a peristaltic pump, during 90 days and removed digestate included solids and liquid.

The overflowed digestate was analyzed with the aim of determining whether this effluent meet with the requirements set by the national policies and guidelines on wastewater disposal systems. Therefore, parameters such as salinity, electrolytic conductivity (EC), ORP and TDS were measured by using a HI9828 probe made by Hanna.

The measured wet biogas and methane volumes were measured by water displacement and adjusted to the volumes at standard temperature (0 ºC) and pressure (1 atm). The effect of the vapor pressure of water was corrected by using the Antoine equation and the average methane content during the semi-continuous phase was showed (Angelidaki et al., 2009).

Calculations

Energy calculations have been calculated based on the primary energy carried by methane. Since statistics are developed at a regional scale, energy production is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24232439
© 2018, ALÖKI Kft., Budapest, Hungary

calculated as the sum of every regional contribution, in accordance with similar previous studies (Moreda, 2016; *Eq. 1*):

$$E = VS \cdot Q_{CH_4} \cdot H_{CH_4} \cdot \sum_{i}^{n} q_i \cdot f_i \quad \text{(Eq.1)}$$

where VS is the average volatile solids content of MSW (g VS/Mg); Q_{CH4} is specific biomethane yield (m^3/g_VS); H_{CH4} is volumetric heating value (kWh/m^3) of biomethane at standard conditions; q is regional MSW and fi is the percentage of FW within MSW (%).

Regarding the $CO_{2,eq}$, calculations have taken into account two main aspects: On the one hand, the $CO_{2,eq}$ emissions avoided by both the reduction of organic waste disposed of at landfills and the corresponding horizontal flows, (i.e. those produced by collection and transportation). On the other hand, the impact of the substitution of fossil fuels (i.e. natural and liquefied gas) by biogas has been quantified.

Despite AD mainly produces CO_2 and CH_4, only CH_4 emissions have been accounted. This because of CO_2 release is only a partial "return" to the atmosphere of the same gas used by photosynthetic organisms to build their biomass (Calabrò, 2009). In addition, for the purpose of estimation, it is assumed that there is no methane oxidation in landfills cover soil and 100 % is released into the atmosphere. Hence, it is possible to estimate the avoided equivalent carbon emissions, based on the conversion factor of methane, in accordance with previous authors (Uusitalo et al., 2014; Friedrich and Toris, 2016; Liamsanguan and Gheewala, 2008). The system boundaries also include collection and transportation of FW from its source to landfills, the so-called horizontal $CO_{2,eq}$ flows. These refer to the cumulative effort of loading waste from single households or other waste generation units from the first stop to the last stop on the collection route and include driving the full truck to the point of unloading. In the estimation, only the energy used for operating the collection trucks is considered. GHG emissions created in the production of collection bags, bins and containers or the manufacture and maintenance of collection vehicles themselves are not considered (Eisted et al., 2009). Due to the on-site AD operation, the overall MSW weight requiring transportation is reduced which highly impacts on $CO_{2,eq}$ emissions produced by collection system (Lee et al., 2007; Lundie and Peters, 2005). In Chile, MSW transportation is performed by diesel-motor trucks. Hence, its contribution may be calculated by the following expression (*Eq. 2;* Zhou et al., 2014):

$$Q = M \cdot P \cdot \mathrm{C} \cdot \mathrm{D} \cdot \rho \quad \text{(Eq.2)}$$

where M is the mass of FW per annum (Mg/y); P: is the average diesel consumption for transportation of FW (0.022 L/(Mg km)); C is the carbon content of the diesel (86.86 %); D is the average transportation distance of the MSW from city to landfill (approx. 15 km) and ρ is the density of the diesel (0.85 kg/L).

It can be noted that these estimations account only for the collection and transportation of the FW fraction since the proposal does not avoid the use of trucks for collecting the rest of waste produced by households. Therefore, values provided by other authors (Larsen et al., 2009) that include diesel consumption for driving empty truck from garage to collection area and from point of unloading to collection area or garage have been not considered. Furthermore, produced biogas is substituted for fossil fuels and consequently another reduction of GHG emissions must be considered. The

© 2018, ALÖKI Kft., Budapest, Hungary

avoided impacts due to the use of AD effluent as fertilizer have been excluded since compost may not comply with specific legislative requirements. Despite the remaining digestate may substitute nitrogen, phosphorous and potassium fertilizers with an efficiency of 34.5 %, 46 % and 60 %, respectively (Salemdeeb et al., 2017), effluent should be dewatered and refined, which leads to a more complex design. On the contrary, if the effluent is directly used as fertilizer, without further treatments, some problems such as pathogens, antibiotics and/or heavy metals, among others, might be expected in the long term.

Results and discussion

AD tests

It must be highlighted that it is particularly difficult to obtain representative FW samples and, therefore, an approach appropriate based in statistical methods is required. Despite the randomly strategy for collecting samples and the long term at it was performed, the results might show some scattering when they are comparing, mainly, due to the different eating habits. However, results (summarized in *Table 1*) were found within the range showed by previous authors (Lie et al., 2009; Yirong et al., 2015; Li et al., 2013). Only, carbohydrate and proteins contents were highlighted lower than average values 55.2 %, 15 % and 23.9 %, respectively in dry basis (Zhang et al., 2014).

[1]Wet basis; [2]dry basis; (-) values between parenthesis show standard deviation

These differences in FW composition highly influence biogas production since substrates poor in easily degradable carbohydrates yield the lowest methane potential. For instance, the aforementioned average values (Zhang et al., 2014) might produce a theoretical SBY of approx. 864 mL/g-VS while the theoretical biogas in case of used FW is approx. 573 mL/g-VS (Drosg et al., 2013). However, there are some other parameters that highly influence the biogas production, such as temperature and waste to inoculum ratio, among others (Liu et al., 2009; Deepanraj et al., 2015).

Batch test clearly shows three different steps (see *Fig. 4a*) and the shape of the obtained curve corresponds to the so-called retarded degradation. The first phase is provided by the substrate itself and the inoculum as the carrier of the methanogenic bacteria consortium. Then, there is an intermediate lag phase, in which hydrolysis is developed and pH drops from 7.00 to 6.00 because of the formed acids. This stage is followed by an exponential growth in biogas production that ends when most of the organic matter is transformed (Córdoba et al., 2016). At this point, the average biogas production was 150±13 mL/g-VS and at the end of the test pH value is set above 6.8 which indicates that the fatty acid concentration does not exceed 200 mg/L and therefore the measurement is accepted. Nevertheless, SBY is lower than values provided by previous BMP tests which are commonly performed at higher temperatures. Temperature plays an important role in terms of SBY regarding the anaerobic biodegradation of the complex organic matter. Thus, several authors have showed a reduction on biogas yield that varies from 31 to 60 % when AD temperature decreases from 30 °C to 15 °C and 55 °C to 20 °C, respectively (Kumar et al., 2016; Bouallagui et al., 2004).

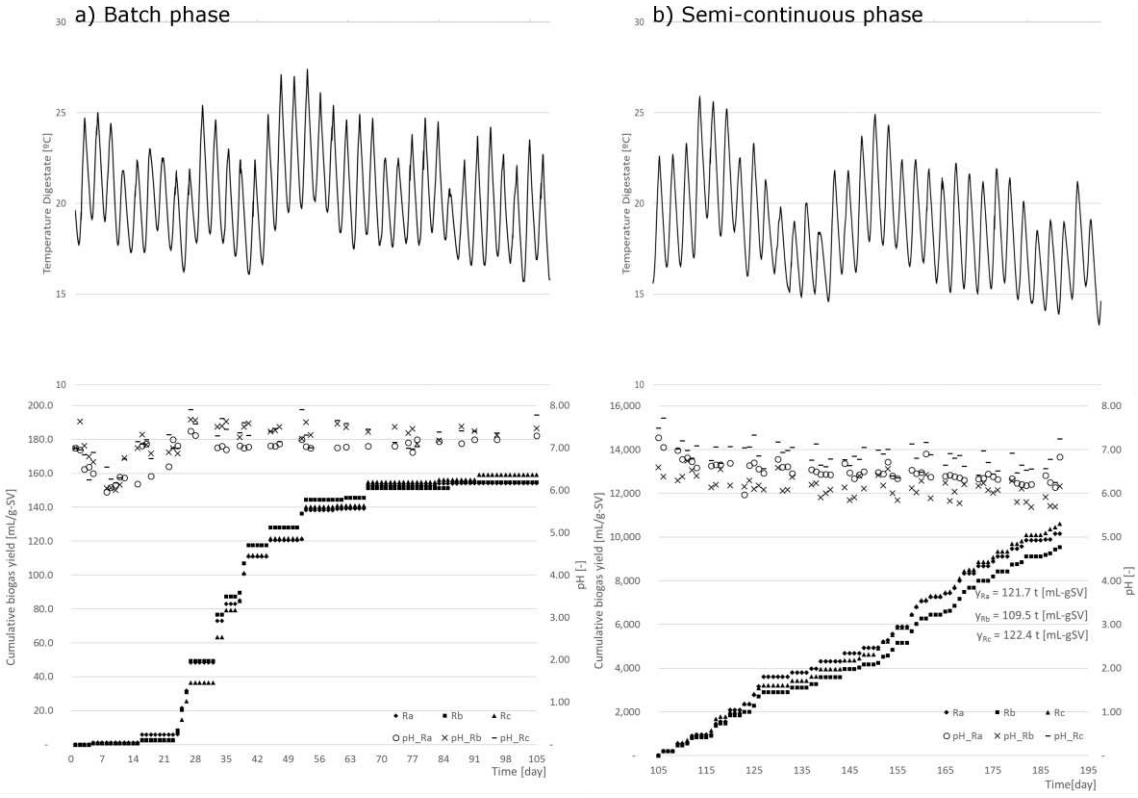

Figure 4. *SBY, temperature and pH during a) batch assays and b) semi-continuous assays*

Although latest reviews have demonstrated the lack of enough researches, regarding AD of FW at psychrophilic temperature, for comparing results (Komilis et al., 2017; Leung and Wang, 2016) the obtained values are still lower than the ones reported by some authors (Bernstad et al., 2013). Comparing SBY can prove difficult as different methods and protocols can all differ from one test to another (Angelidaki, 2009). For instance, the lower SBY, obtained in this research, may be explained due to the SIR. This ratio highly

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24232439
© 2018, ALÖKI Kft., Budapest, Hungary

affects AD kinetics and SBY. Thus, SBY may be reduced up to 55 % when SIR is increased from 1.6 to 5.0 (Liu et al., 2009). Other authors, showed even higher variations (approx. 80 %) when SIR is increased from 1.3 to 4.0 (Kumar et al., 2016).

Regarding the semi-continuous phase (see *Fig. 4b*), the temperature lowered, compared to the batch assays from an average of 20.26 ± 2.33 °C to 18.66 ± 2.53 °C. In addition, pH slightly decreased. Hence, batch assays finished with a pH of 7.51 while the semi-continuous operation mode showed a pH of 6.75 after 90 days. During three months, the SBY was approx. constant with an average slope of 118 ± 7 mL/g-VS day. Related to the semi-continuous operation mode there are rare reports about successfully operating single-stage anaerobic digestion of FW at psychrophilic temperature. Besides, to the best of our knowledge, AD of FW without stirring has not been addressed. Stirrer devices are commonly used, at any scale, for avoiding foaming and floating layers. An appropriate agitation technology is essential since stirring has a crucial influence on the microbial community structure and the SBY. Thus, it has been highlighted by previous authors a SBY reduction between 30 % to 40 % when the digestate is unmixed (Rusin et al., 2017; Rojas et al., 2010).

From this point of view, it may be argued whether the effectiveness of a more complex reactor since it has been demonstrated the more complex the reactor, the higher the SBY (Rajagopal et al., 2017). However, complex reactors lead to increase the installation costs and the economic issue surely reduce the number of installed reactors and consequently the available amount of FW treated might be highly reduced. Nevertheless, when similar reactors were operated at similar operation conditions, (i.e. HRT, OLR) other authors found similar biogas production and methane content (Khalil et al., 2016; Lou et al., 2013).

Biogas contained an average of 57.7 % (3 %) of CH_4. H_2S was not detected and a minimum amount of CO (approx. 4 ppm) was measured. Based on SBY and its composition it can be concluded that the expectable amount of methane, in the semi-continuous running mode is approx. 14 L of methane per kg of FW. The biogas composition has been kept quite similar which is a good indicator of the AD stability. Despite volatile organic acids and total inorganic carbonate have not been measured, the pH has not set below 6.8 and the methane content has not decreased. These two latest indicators suggest there was not an ongoing rise in acid concentration.

It is clear that the biogas production is actually low but also clear that the system is very cheap to install and operate. Regarding the organic load rate (OLR) that should be considered for the proposed reactor design, it must be noted that mono-digestion of FW might lead to acidification of the fermentation process via an increasing of OLR (Kastner et al., 2012).

For this reason, it is important to consider the size of the proposed small household reactors according to the estimated daily FW produced by a typical Chilean household (approx. 1.5 kg of FW per day). Thus, cases reported by literature (Khalil et al., 2016; Lou et al., 2013) showed a continuous operation for basic small reactors when OLR varied between 0.6 and 1.0 kg VS/(m^3 day). This suggests a reactor volume from 500 m^3 up to 2000 m^3, depending on the building size as long as the HRT which should be set at approx. 60 days.

COD removal is also a key factor for promoting this decentralized off-grid system, since effluents must abide by Chilean laws (NCh 1333) prior to being discarded to the drainage lines. After the laboratory tests, the substrate showed a final COD value of 269 mg O_2/L. It can be observed that COD was reduced by 97 %, which is in concordance

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24232439
© 2018, ALÖKI Kft., Budapest, Hungary

with the ranges shown in the literature of 80 to 95 % (De Mes et al., 2003). The final obtained COD is even lower than the concentrations of most typical sanitary effluents from human manure, which range between 260 and 480 mg O_2/L (Suarez and Puertas, 2005). In addition, other values related to this effluent quality (see *Table 2*) also meet regulatory standards for being discharged into the municipal sewer system. Hence, it is concluded that the effluent can be directly emptied into the general drainage line without further treatment.

Table 2. *Effluent characteristics*

Energy savings and avoided $CO_{2,eq}$

Chile produces yearly more than 3.5 Gg of FW suitable for AD. Assuming that the difference between the FW production from single- and multi-family households is not statistically significant (Schott et al., 2013), the total average amount of FW per household generated in Chile per year can be estimated at 510 kg per household, while in the European Union or India only 190 kg and 319 kg of FW are produced per annum and household, respectively (Bernstad et al., 2012; Rocky et al., 2014).

Results, categorized by region, are summarized in *Table 3*. Despite the metropolitan region (RM) is the largest contributor with more than 1.5 Gg, regions of Arica-Parinacota (XV), Araucania (IX) and Aysen (XI) showed the highest potential methane production due the amount of FW produced per household. In addition, Arica and Parinacota (XV) is one of the smallest regions, in terms of households, which means that could be considered for testing the proposal. On the contrary, the regions of B. O'Higgins (VI), Atacama (III) and Antofogasta (II) show the lowest potential savings, as less FW is produced and more energy is demanded per household each year. It must be noted that the energy consumed by each household, used for estimating potential savings, is based on the substitution of biogas for natural and/or liquefied gas.

Despite the theoretical and economic potential, differences of up to 30 % may be observed due to the reliable amount of FW that can actually be used, in case of decentralized off-grid system, both values may be assumed to be similar (Rios et al., 2016).

Hence, the overall Chilean potential primary energy generation from semi-continuous operation accounts for nearly 425 GWh per year, which represents approximately 0.2 % of the total primary energy consumption (approx. 419.8 TWh). Comparing these results with other values from similar research studies, similar outcomes were found in terms of the percentage of domestic energy consumption: Sweden (0.2 %) (Schott et al., 2013), Mexico (0.8 %) (Rios et al., 2016), Brazil (0.26 %) (Salomon and Lora, 2009) and Uruguay (0.2 %) (Moreda, 2016). From this point of view, AD of FW at a decentralized scale does not seem to be the best option for adding renewable energy to the Chilean energy supply.

Table 3. *Summary of FW produced, energy consumption and potential energy generation by AD of FW categorized by household and region*

Region	Total FW produced [t]	FW produced per household [kg]	Potential energy from AD of FW per household [kWh]
I	105,266.4	1,141.5	195.9
II	108,861.9	685.7	117.7
III	57,363.9	684.1	117.4
IV	122,489.0	541.3	92.9
V	325,883.0	585.5	100.5
VI	133,011.4	484.0	83.1
VII	199,579.5	633.2	108.7
VIII	358,202.3	581.8	99.8
IX	235,839.8	795.5	136.5
X	205,160.4	802.4	137.7
XI	24,911.5	751.4	128.9
XII	35,785.0	721.1	123.7
XIV	81,838.4	697.9	119.8
XV	63,495.6	1,200.2	206.0
RM	1,556,899.0	738.6	126.8

However, households may achieve an average saving of 1.5 % in terms of primary energy consumption, which reinforces the separation of FW at the generation point and the corresponding reduction of organic matter disposal. In spite of relatively low potential energy savings, there is an important impact in terms of avoided GHG emissions. These can be divided into two main categories: horizontal flows, produced by the MSW transport systems and the direct GHG emissions from landfills and fossil fuels replacement. Then, approximately 713 Gg $CO_{2,eq}$ can be avoided yearly from landfills emissions and 878.6 Gg $CO_{2,eq}$ from the reduction of fuel consumption in MSW transportation services. In addition, taking into account that biogas has a neutral carbon cycle and considering EPA emissions factors, which report an average of 2.15 kg $CO_{2,eq}$ per cubic meter of natural gas (measured at normal conditions), it can be estimated that around 112.8 Gg $CO_{2,eq}$ might be avoided when this fuel is replaced by methane.

Conclusions

The results suggest that AD of FW in Chile might incorporate approx. 425 GWh per annum (in terms of primary energy) by using household scale reactors in a decentralized off-grid system. Hence, firewood and natural or liquefied gas households can be partially replaced which impacts on the reduction of household expenses.

Despite the energy provided is quite lower than other alternatives based on high rate anaerobic reactors at psychrophilic temperature, depending on the corresponding installation costs of, it may be desirable to operate economical and simpler versions while these have shown a positive impact in terms of environmental protection.

© 2018, ALÖKI Kft., Budapest, Hungary

Hence, due to the reduction of the amount of MSW that requires collection, transportation and disposal and the partial substitution of natural gas, it is estimated that 1,704 Gg $CO_{2,eq}$ emissions can be avoided annually.

This positive effect on environment may be used by Chilean authorities in order to support the required financial policies which have been highlighted as an encouraging key factor in other countries (mostly in China, India and EU). Results must be considered as a basic framework that may orient the decision-making process for the implementation of short-term environmental policies. At this point, XV region is suggested for testing this proposal at pilot scale due to the high estimated savings. Further investigations should be developed regarding the operational aspects with the aim of improving the technical design of reactors or the maintenance operations, among others.

Abstract. Biocrust, as photosynthetic organisms, has been considered to show an inversely proportional relationship with vascular plant cover. However, some studies report association and facilitation relationships between them. This research explores whether i) biocrust is associated with shrub species, ii) biocrust cover is higher in undershrub microenvironments than in open areas between plants and, iii) soil moisture and solar radiation affect biocrust distribution. Biocrust cover was analyzed by morphotype in microenvironments under the canopy of two dominant shrub species (*Larrea tridentata* and *Parthenium incanum*) and in open areas. Soil moisture and solar radiation were recorded at each microenvironment. Thirty-three interception lines (975 points) were used to analyze the association between vascular plants and biocrust and 20 sampling plots to estimate morphotype cover. Results reveal a positive association between biocrust and plant species compared to open areas. Lichens and cyanobacteria showed a higher cover under *L. tridentata* than under *P. incanum* and in open areas, suggesting a species-specific facilitative association with *L. tridentata*, maybe due to a higher soil water content in this microenvironment. Mosses had lower cover in the open area where the highest solar radiation was recorded. Lichens and cyanobacteria distribution appeared to be related to soil moisture.
Keywords: *creosote bush, cyanobacteria, lichens, mosses, northeastern Mexico*

Introduction

Biological soil crusts are made up of extremely long-lived organisms, they provide continuous ecosystem services (Castillo-Monroy and Maestre, 2011) and have been considered as long term environmental indicators (Belnap et al., 2001) that provide structure to the soil (Richer et al., 2012), contribute to water balance, erosion control and nutrient cycling (Castillo-Monroy and Maestre, 2011). Furthermore, the presence of lichen crusts improves soil resistance to erosion and increases its water holding capacity (Abed et al., 2013).

Vegetation dynamics and the microenvironments that plants create affect biological crust distribution (Zhao et al., 2010) particularly in arid environments where plant species are arranged in patches on a bare soil matrix (Puigdefábregas and Sánchez, 1996) creating islands of resources (Reynolds, 1999). However, the way vascular plant cover affects the biological soil crust (BSC) distribution remains controversial; some authors have found a positive relation between shrub cover and total BSC cover, but a negative relation with lichen cover (Ochoa-Hueso et al., 2011; Root and McCune, 2012). Others report that BSC cover and species richness was higher in microsites

without vegetation, either grazed or cultivated than in vegetated sites (Eldridge et al., 2000). The relationship between cover of biological crusts and vascular plants has been found to be inversely proportional (Belnap et al., 2001).

Vascular plants are successful competitors for resources such as light, nutrients, and water (Löbel et al., 2006) and this may result in a disadvantage for BSC growing under them. However, microenvironments under shrubs are likely to have more nutrients and higher water holding capacity, thus favoring the BSC development (Bowker et al., 2005); creating facilitation relationships between vascular plants and BSC as has been shown for *Stipa tenacissima* and *Cladonia convoluta* in Spain (Maestre, 2003).

Biological soil crusts dominated by mosses are usually more abundant in moist microenvironments of arid and semiarid environments (Maestre et al., 2001). In these environments, the presence of vascular vegetation may favor the occurrence of some components of BSC (mainly bryophytes), since it may provide moister microsites protected from direct solar radiation (Concostrina-Zubiri et al., 2014; Núñez and Toledo, 2013; Haughian and Burton, 2015). Contrarily, crusts constituted mainly by lichens are related to the areas most exposed to solar radiation and heat, with low moisture and nutrient availability (Haughian and Burton op cit.), even though the water availability has been considered critical for the establishment and development of lichens (Gignac, 2001). Open areas with the dominance of BSC have been found to have the higher cover of cyanobacteria and lichens and less of mosses compared with microsites under the canopy of plants (Mendoza-Aguilar et al., 2014).

However, Gutiérrez et al. (2017) found a higher cover of lichens, cyanobacteria, and mosses underneath vascular plants than in open areas and considered that this might be due to a lower competition for space between the BSC components than in other areas that have higher densities of these components. Because BSC components do not have roots to uptake water and nutrients, these resources are likely to be captured from the atmosphere or through direct contact with the soil (St. Clair et al., 2002). Thus, competition for space becomes very important for BSC components, because it secures access to more resources (Bowker et al., 2010).

These contrasting results highlight the relevance of continuous evaluation of the BSC component distribution and their relation to vascular plant species, exploring association, facilitation and competition relationships between them. This, in turn, may have an impact on nutrient and water flux dynamics and in the overall functioning of the ecosystem. Hence, this research is aimed at determining whether there is a positive or negative association between BSC and vascular plants or they are randomly distributed and whether this distribution pattern is equal for all the components of the BSC in the area.

The Mexican Plateau floristic Province (Rzedowski, 2006) is dominated by arid and very arid climates which favored the development of xerophilous shrublands (63%) and pastures (28%) (Espinosa et al., 2008). In the low and flat areas, the most abundant shrub species is creosote bush (*Larrea tridentata* (Moç. & Seseé ex DC.) Coville) which grows alone or mixed with other drought tolerant species. In addition to the vascular vegetation cover, the area also includes communities of biological soil crusts (BSC). These communities consist of soil particles in association with cyanobacteria, green algae, lichens, fungus, and bryophytes. These biocrusts have physiological qualities such as resistance to desiccation and temporary suspension of breathing, which allow them to develop in environments with scarce water availability (Belnap et al., 2001).

Several authors have stated that the composition of biological crusts differs depending on whether they are under vascular plants or in open areas (Maestre et al., 2001; Maestre, 2003; Mendoza-Aguilar et al., 2014) and that they might also differ depending on the plant species that they grow under, due to differences in microenvironments. Hence, in this study, the biological crust cover was analyzed in microenvironments under the canopy of the two dominant shrub species (*Larrea tridentata* (Moç. & Seseé ex DC.) Coville and *Parthenium incanum* Kunth) and in open areas. Soil moisture and solar light intensity were recorded for each microenvironment. We hypothesized that i) BSC is positively associated with shrub species, ii) Cover of BSC components is higher in the undershrub microenvironments than in the open area between shrubs, iii) Cover of BSC components differs between the vascular species under which they grow, and iv) solar radiation is more closely related to BSC distribution than soil moisture.

Materials and methods

Study area

This research was carried out in an area of xerophilous scrub in the Mexican Plateau floristic Province (Rzedowski, 2006) in the southern region of the Chihuahuan Desert (24˚47'11" N; 100˚41'54"W) in northeastern Mexico at 1900 m above sea level. The climate of the area is BS_0k (x'): arid, temperate (García, 1981); its mean annual temperature is 15 °C; with an average maximum monthly temperature of 36.6 °C in April and a minimum of -4.9 °C in January (CONABIO, 2016; CNA, 2016). Mean annual rainfall is 429 mm, with a maximum in January (318 mm) (CNA, 2016). Soils are haplic and calcic xerosols with petrocalcic physical phase. These soils support microphyllous desert scrub in the alluvial areas (CONABIO, 2016). This vegetation type, which covers about 49% of the soil surface, is mainly distributed in flat or very gentle slope areas and it is formed by species that support high concentrations of salts with *Larrea tridentata* ((Moç. & Seseé ex DC.) Coville) as the most common species mixed with *Fouquieria splendens* Engelm, *Flourensia cernua* DC., *Zinnia acerosa* DC., *Parthenium incanum* Kunth, *Jatropha dioica* Cerv., *Koeberlinia spinosa* Zucc. and some spiny shrubs (Granados-Sánchez et al., 2011). There is no agriculture in the area, but there is evidence of light cattle and equine grazing.

Methods

Association analysis

Plant species abundance and frequency were previously evaluated in the area. We selected the two most abundant species to analyze their association to biological soil crusts. These species were *Larrea tridentata* (density by m^2 = 0.806; relative frequency = 13.52%) and *Parthenium incanum* (density by m^2 = 0.521; relative frequency = 8.74%). Thirty-three interception lines (Canfield, 1941) of 30 m long were used to record the presence of BSC underneath the two most abundant plant species and in the spaces between them. Lines were established 0.5 km apart with sampling points every 0.5 m. We analyzed the association between plant species and BSC with a total of 975 points: 537 open area points (105 with BSC; 432 without BSC), 266 under *Larrea tridentata* (234 with BSC; 32 without BSC), and 172 under *Parthenium incanum* (161

DOI: http://dx.doi.org/10.15666/aeer/1603_24412451
© 2018, ALÖKI Kft., Budapest, Hungary

with BSC; 11 without BSC). The remaining points fell either on other plant species or on litter.

We tested four microenvironments: i) underneath *Larrea tridentata* (ULt), ii) underneath *Parthenium incanum* (UPi), iii) open area (OA) and (iv) underneath vascular plant (Uvp), defined by adding the data of microenvironments i) and ii). Biological soil crusts communities were classified according to the morphology of their components (Eldridge and Rosentreter, 1999) and the following categories were established: lichens, mosses, cyanobacteria, and hepatics, named herein as morphotypes. *Endocarpon pusillum* (Hedw.) and *Collema coccophorum* (Tuck.) are the most common species of the lichen morphotype, with frequencies of 70 and 46% out of the total of lichens. Cyanobacteria morphotype is mainly composed of species of Scytonema and Microcoleus genera. Liverworts are characterized by species of Riccia and Oximitra genera. Mosses were not identified.

Relationships between BSC morphotype cover and plant species at each microenvironment

Twenty sampling plots (20 m x 20 m) were randomly selected in the area. At each plot, one individual of *Larrea tridentata* and one of *Parthenium incanum* with BSC under them were selected and crusts sampled. Also, biological crusts of corresponding open areas were sampled. Open area sites were sampled at a distance shorter than one meter from the limit of the plant canopy projection to reduce soil variability (Bowker et al., 2006). Six samples were collected from under each plant and six in their corresponding open area; having 20 replicates of each microenvironment with 120 samples each.

Before sampling, the soil surface was sprayed with distilled water to avoid breaking off the crusts, and a sample of the topsoil layer was collected using a Petri dish (9 cm in diameter by 1 cm in depth) taking care that the soil surface remained unaltered. Biological soil crust collected samples were taken to the laboratory to estimate cover by morphotype using a template with 8 radial divisions, stereoscope, microscope, and identification guides (Brodo et al., 2001; Barreno and Pérez-Ortega, 2003; Rosentreter et al., 2007). Percentage cover was visually estimated within each radial division; percentages were then added for each Petri dish and extrapolated to square meter. The soil moisture and solar radiation were recorded at each microenvironment (ULt, UPi and OA). Soil moisture was determined by the gravimetric method and solar radiation was recorded using a luxometer (Extech Instruments, model 401025). Sampling was done from May to December 2014 at different times of the day due to the time required to reach all sampling quadrats; hence, extreme caution was taken to record at virtually the same time all the microenvironments within the same sampling quadrat and data were analyzed as paired t tests (Dytham, 2011).

Chi-square tests (χ^2) were used to determine association (Dytham, 2011) between BSC and vascular plants. To measure the degree of association, contingency tables 2 x 2 were used and the strength of association was determined using *Equation 1* (Badii et al., 2008):

$$V = \left(\frac{ad - bc}{\sqrt{mnrs}} \right) \quad \text{(Eq.1)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24412451
© 2018, ALÖKI Kft., Budapest, Hungary

where V = Association coefficient; a = points where both, the plant and the BSC, are present; b = points where only the BSC is present; c = points where only the plant is present; d = points where plants and BSC are absent; m = a + b; n = c + d; r = a + c and s = b + d.

The data were further analyzed using not only BSC presence-absence data but the percentage cover of each BSC morphotype in each microenvironment. These analyses were carried out for three conditions: i) under *Larrea tridentata* (ULt), ii) under *Parthenium incanum* (UPi) and iii) in open areas (OA). The data of the BSC morphotypes cover, solar radiation, and soil moisture were analyzed for normality (Shapiro-Wilk test) and homoscedasticity (Levene test). When data did not meet the former assumptions, a non-parametric analysis was carried out. The comparison of BSC morphotypes cover among the microenvironments was done through the non-parametric Kruskal-Wallis analysis. When significant differences were detected, Mann-Whitney U tests were performed. Solar radiation and soil moisture were analyzed by the Wilcoxon´s test as a non-parametric alternative to the Student's t-test for related samples (Dytham, 2011). All statistical analysis was performed using the SPSS® Statistics software version 19.

Results

Chi-square results showed an association between BSC and microenvironment under vascular plants (Uvp) (χ^2 = 483.012, df = 2, p = 0.001); with a positive association intensity of 0.715. Both plant species showed an association with BSC (χ^2 = 338.535, df = 1, p = 0.001; χ^2 = 313.676, df = 1, p = 0.001) for *Larrea tridentata* and *Parthenium incanum* respectively. Association intensity was positive and similar for both plant species (0.652 for *Larrea tridentata* and 0.655 *Parthenium incanum*).

Cover of lichens (χ^2 = 31.76, df = 2, p = 0.001) cyanobacteria (χ^2 = 7.14, df = 2, p = 0.028) and mosses (χ^2 = 27.28, df = 2, p = 0.001) differed among conditions or microenvironments. Liverwort cover was not included in the analysis due to their very low surface cover (< 0.3%) across samples.

Larrea tridentata microenvironment (ULt) showed a higher cover of lichens and cyanobacteria than *Parthenium incanum* (UPi) (p = 0.001; 0.031) and open areas (OA) (p = 0.001; 0.015) microenvironments. The moss morphotype had similar cover in ULt and in UPi and this was higher than in OA (p = 0.001) (*Fig. 1*).

Water content in the soil was low across sampling dates (< 9.8%) for all microenvironments and samples. Soil moisture content differed between microenvironments; the highest content was recorded in the ULt microenvironment (6.36%). Soil water content for UPi and OA microenvironments were similar (p = 0.911) (*Table 1*).

Solar radiation values ranged from 2,400 to 95,300 lux. The three microenvironments had statistically different solar radiation values (ULt vs. OA p = 0.001; UPi vs. OA p = 0.001; ULt vs. UPi p = 0.002). Solar radiation was higher for the OA microenvironment, followed by ULt and then UPi (*Table 1*).

Cover of mosses was lower in the OA microenvironment which showed the highest solar radiation. Lichens and cyanobacteria cover were not related to solar radiation since their highest cover was in the ULt microenvironment that has an intermediate solar radiation.

Table 1. *Solar radiation and soil moisture (mean ± standard error) for each microenvironment. Different letters in columns are for statistical differences ($p < 0.05$)*

Microenvironments	Solar radiation (lux)	Soil moisture (%)
Underneath *Parthenium incanum* (UPi)	16253 ± 24.36 a	5.49 ± 0.31 a
Underneath *Larrea tridentata* (ULt)	29143 ± 38.61 b	6.36 ± 0.39 b
Open area (OA)	41018 ± 40.45 c	5.48 ± 0.32 a

Discussion

The results of this study showed an association between BSC and microenvironment under vascular plants (Uvp). These findings are consistent with observations of Maestre and Cortina (2002), who found a positive association between spatial patterns of BSC, composed of cyanobacteria and lichens, and cover patterns of *Stipa tenacissima*; a dominant plant species in the semi-arid southeast of Spain. Other studies have also shown a facilitative relationship between BSC and plant species, specifically *Stipa tenacissim* and *Cladonia convoluta* (Maestre, 2003). Here, both plant species (*Larrea tridentata* and *Parthenium incanum*) showed a positive and similar association intensity with BSC.

There seems to be a consensus that vascular plant-biocrust interactions are highly species specific, dependent on the BSC dominating organism's traits and plant characteristics (Rivera-Aguilar et al., 2005; Serpe et al., 2006; Deines et al., 2007). BSC dominated by *Diploschistes* sp. reduced plant emergence (Escudero et al., 2007; Serpe et al., 2008) maybe due to the sealing of the soil pores by the biocrust which might reduce water availability and thus inhibit germination (Eldridge et al., 2010). St. Clair et al. (1984) found higher germination for three grass species on algal crusts compared with mixed crusts of lichens, mosses and algae.

Interactions between biocrust and vascular plants could have multiple effects, either facilitative (more soil moisture for the biocrust, more nutrient availability for the vascular plant and biocrust) or inhibitory (less water availability for the vascular plant, lack of sunlight for the photosynthesis of the BSC's photobiont). For instance, biocrust had a negative effect on water availability in an area covered with microbiotic crust in southern China, as rainfall infiltration was about half of that recorded in the area without crust (Uchida et al., 2000). However, in an independent study in the same area, Tateno et al. (2003) found a dependence of *Pinus massoniana* Lamb. on N fixed by the microbiotic crust, which improved tree productivity, despite the fact that biocrust decreased the amount of available rainfall.

In contrast, Eldridge et al. (2000) found a significantly higher BSC cover in unvegetated microsites in grazed and ungrazed grasslands in Southeastern Australia than in those with vascular plants. Núñez and Toledo (2013) found that although areas under the shade of vascular plants favor the growth of microorganisms present in the BSC when BSC were analyzed by morphotype, the highest cover of lichens and cyanobacteria was recorded in open areas with higher exposure to solar radiation. Similarly, Mendoza-Aguilar et al. (2014) found a higher cover of cyanobacteria and lichens in the open areas than under plants, which differs to our findings.

We found a higher cover of lichen and cyanobacteria under *L. tridentata* than in open areas. Even though several authors have found that when the BSC were composed mainly of lichens there is an inversely proportional relationship between them and vascular plants (Belnap et al., 2001; Ochoa-Hueso et al., 2011; Núñez and Toledo, 2013) and that lichens are likely to occupy open areas due to a lower competitive ability with respect to vascular plants in obtaining resources (Löbel et al., 2006), in contrast to our results. Such differences in lichens and cyanobacteria distribution may be due to lower competition for space in our study area, where total cover of lichens, cyanobacteria and mosses under *L. tridentata* was 18.8% compared to 54.9% found by Mendoza-Aguilar et al. (2014) for a semiarid area in Alicante, Spain or 85.34% in Valle de Quibor, in Venezuela (Núñez and Toledo, 2013). At high densities, competition for space is frequent between components of the BSC (Castillo-Monroy and Maestre, 2011).

Very little has been studied about the effect of competition among the components of BSC. Lichens and bryophytes have chemical compounds that play an important role in nutrient intake (Hauck et al., 2009), so that species with different chemical compounds could benefit greatly if they are associated (Castillo-Monroy and Maestre, 2011), but there can also be competition between them. After studying BSC lichen communities in a gypsum outcrops area in central Spain, Maestre et al. (2008) found that there were fewer species combinations and less co-occurrence of those lichens than expected by chance. These results were in agreement with their hypothesis that BSC lichen communities are mainly structured by competitive interactions.

Competitive interactions between BSC components have been documented, both at the pair and species level, and have concluded that the intensity of competition at the community level increases as aridity increases (Bowker et al., 2010). It is most likely that, in more arid conditions, competition would increase and the lichens that are now distributed under the shrubs, would occupy the open areas. Probably, aridity in regions where lichens are mainly distributed in the inter-shrub spaces is more severe than in our study area.

Vascular plant canopy tends to favor certain biological soil crust morphotypes over others and may enhance biocrust formation; however, it can also create unfavorable conditions such as depriving crusts of adequate light for photosynthesis or bury the biocrusts with heavy litterfall (Zhang et al., 2016). These, among other factors, may cause vascular species to facilitate or inhibit BSC components.

In this study, we found that cover of lichen and cyanobacteria was higher under *L. tridentata* that under *P. incanum* indicating an association that could be the result of facilitation. This could be due to the higher soil water content recorded for ULt microenvironment and the fact that *P. incanum* has a denser canopy which prevents lichens and cyanobacteria from receiving enough sunlight for photosynthetic processes. *P. incanum* also accumulates more litterfall which may difficult the establishment of lichens and cyanobacteria. A facilitative association was established by Bu et al. (2016) who found that BSC cover exhibited a clear positive correlation with a cover of *Artemisia desertorum* (Spreng), and a negative correlation with *Caragana korshinskii* (Kom) and *Stipa bungeana* (Trin) cover in a temperate, semi-arid Province of Shaanxi in China. Similar results, although studying bryophytes have been reported by Ingerpuu et al. (2005) who found a species-specific facilitative effect between two out of three tested vascular species (a legume: *Trifolium pratense* L., a grass: *Festuca pratensis* Huds. and a forb: *Prunella vulgaris* L.) and two bryophyte species (*Brachythecium rutabulum* (Hedw.) B.S.G. and *Rhytidiadelphus squarrosus* (Hedw.) Warnst.). Only the first two vascular plants had a significant effect on bryophytes.

In our study, the moss morphotype had a higher cover in the two microenvironments, with lower solar radiation (ULt and UPi) than in the open inter-shrub spaces (OA). Mosses covered, as an average, four times more surface in the ULt and UPi microenvironments than in the open area. Mosses seem to be related to conditions of lower solar radiation and to tolerate competition from vascular plants better than lichens (Löbel et al., 2006). These results are consistent with those of other authors (Maestre et al., 2001; Ingerpuu et al., 2005; Castillo-Monroy et al., 2010; Mendoza-Aguilar et al., 2014; Haughian and Burton, 2015) who found higher cover of mosses under vascular plants than in open areas.

Conclusions

The results presented here reveal a positive association between BSC and the plant species *Larrea tridentata* and *Parthenium incanum*, compared to open areas; thus confirming our first hypothesis.

The lichen and cyanobacteria morphotypes showed a higher cover under *Larrea tridentata* (ULt) than under *Parthenium incanum* (UPi) and in open areas (OA) suggesting a species-specific facilitative association with *L. tridentata*. The moss morphotype had a higher cover in ULt and UPi microenvironments which is perhaps a result of lower solar radiation than in OA.

Distribution of BSC components can be potentially relevant for ecosystem functioning (e.g. hydrophobicity and water re-distribution, C sequestration and N fixation). Hence, studies aimed at determining how microclimate could modify BSC distribution would improve our understanding of the functioning of ecosystems. The results reported here make an important contribution to the knowledge of the interactions between vascular plants and biocrust components.

(Received 10th Jan 2018; accepted 19th Apr 2018)

Abstract. The survey was conducted to determine chemical weathering indices in modern river sediments in Poland. Weathering Index of Parker (WIP), Chemical Index of Alteration (CIA), Vogt's Residual Index (V), Harnois's Chemical Index of Weathering (CIW), and Plagioclase Index of Alteration (PIA) was calculated for 178 sediment samples taken from the Vistula River and its tributaries as well as for 114 samples from the Odra River and its tributaries. The indices values were in the ranges: WIP 0.5–20; CIA 4–80; V 0.1–2.8; CIW 4–82; and PIA 3–81.7. The observed variation of values resulted from a varied sample lithology and varied climatic conditions in the Poland area. Sediments from the upper parts of the Odra and the Vistula drainage basins (southwestern part of the country), where pre-Quaternary rocks are exposed, are more resistant to chemical weathering and characteristic for lower susceptibility to leaching of elements. The highest elements losses due to leaching are characteristic for samples taken from the lower parts of the Odra and the Vistula drainage basins, dominated by Quaternary deposits. Additionally, it was found that larger indices values, reflecting effects of stronger weathering, are observed in the southwestern part of the country (with the warmer and more humid climate) comparing to the northeastern part (with prevailed colder and drier climatic conditions).
Keywords: *river sediments, indices of chemical weathering, drainage basins, Poland, moderate climate, lithology*

Introduction

The chemical composition of modern river sediments is affected by many factors, primarily the lithology of river basins and climatic conditions. However, there are also other important factors, including topography of the terrain, vegetation type, and land use of the drainage area (Bahlburg and Dobrzinski, 2011).

Sediments that accumulate on the river bottom are derived from material originating from erosion and the weathering of rocks occurring within the drainage area (e.g. quartz grains, feldspars, carbonates, clay minerals and heavy metals) and from in-situ material (debris of dead plants and animals, and minerals precipitated from water, e.g. goethite, fluoroapatite and makinavite). In industrialised, urbanised and agricultural areas, the sediment is also enriched in organic and inorganic contaminants contained in wastewater discharged into the surface water, as well as those transported by surface runoff (Bojakowska et al., 2006; Ciszewski, 1997, 2002, 2005; Cempiel et al., 2014).

Under surface conditions, clay minerals (notably illite and kaolinite) and iron hydroxides, e.g. goethite, form within weathering covers due to chemical weathering of unstable minerals, especially feldspars. The weathering covers are also depleted in Ca^{2+}, K^{+}, Na^{+} and Mg^{2+} ions as a consequence of their leaching (Fedo et al., 1995; Bland and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

Rolls, 1998; Bahlburg and Dobrzinski, 2011). As a result of erosion, material from the weathering covers and soils is transferred to river channels and partly deposited there.

To reflect the intensity of chemical weathering processes and to determine the degree of depletion of soils and river sediments in mobile components relative to immobile ones due to the weathering process, the chemical weathering indices are used (Price and Velbel, 2003). They are widely employed in research of both modern and fossil weathering profiles and marine and lacustrine sediments (Harnois, 1988; Nesbitt and Young, 1982; Bäumler and Zech, 2000). The weathering indices are also useful for monitoring the variability of components in longitudinal river profiles, and for evaluating soil fertility and development (Chetelat et al., 2013; Li and Yang, 2010; Bilinski, 2008; Shao et al., 2012; Price and Velbel, 2003 after Delvaux et al., 1989). These indices reflect the effects of climate on the weathering of parent rocks, characterise neotectonic-related transformation, quantify the properties of the regolith, and allow for a better explanation of elemental mobility during weathering processes (Neall, 1977; Fedo et al., 1996; Sharma and Rajamani, 2000). The ideal index should allow for a comparison of studies carried out at different locations, on various materials, and in weathering profiles of different ages. The index should also be easy to apply and based on elements commonly found in surface environments (Harnois, 1998).

The purpose of the study was to determine the factors affecting significantly the weathering of sediments based on variations in the values of weathering indices in the Vistula and Odra river basins. The results of geochemical studies carried out within the framework of the National Environmental Monitoring (PMS) were used.

Weathering indices

The most frequently used weathering indices are: Weathering Index of Parker (WIP), Chemical Index of Alteration (CIA), Chemical Index of Weathering (CIW), Vogt's Residual Index (V), and Plagioclase Index of Alteration (PIA) (*Table 1*). They are sensitive even to minor geochemical changes such as hydrothermal alterations along fault lines, and groundwater level fluctuations.

Table 1. *Chemical weathering indices*

Index	Formula	Reference
Weathering Index of Parker (WIP)	$WIP = \left(\frac{2Na_2O}{0.35} + \frac{MgO}{0.9} + \frac{2K_2O}{0.25} + \frac{CaO}{0.7} \right) \times 100$	Parker (1970)
Vogt's Residual Index (V)	$V = \frac{Al_2O_3 + K_2O}{MgO + CaO + Na_2O}$	Vogt (1927)
Chemical Index of Alteration (CIA)	$CIA = \frac{Al_2O_3}{Al_2O_3 + CaO + Na_2O + K_2O} \times 100$	Nesbitt and Young (1982)
Chemical Index of Weathering (CIW)	$CIW = \frac{Al_2O_3}{Al_2O_3 + CaO + Na_2O} \times 100$	Harnois (1988)
Plagioclase Index of Alteration (PIA)	$PIA = \frac{Al_2O_3 - K_2O}{Al_2O3 + CaO + Na_2O - K_2O} \times 100$	Fedo et al. (1995)

Weathering Index of Parker **(WIP)** involves the mobility of sodium, potassium, magnesium and calcium during weathering processes. These are the most mobile major elements and therefore the index is not recommended for the analysis of strongly weathered material (Eswaran et al., 1973; Price and Velbel, 2003). The index of Parker is most useful for reflecting changes in the amount of Na^+, K^+, Ca^{2+} and Mg^{2+} cations, if the alteration of feldspars into clay minerals is the major chemical (hydrolytic) weathering process, and there are similar mobilities between the major cations (Parker, 1970). The WIP is the appropriate index for the assessment of weathering of rocks where hydrolysis is the main weathering process (Gupta and Rao, 2001). The WIP value is in the range from 0 to 100, and its maxima correspond to the least weathered rocks.

The source of inaccuracy in calculating the index is the assumed simplification that the total amount of calcium in the rock is contained in silicate minerals. This simplification is particularly disadvantageous if the rock contains large amounts of detritus or carbonate cement. Doubts also arise as to not involving relatively immobile phases, such as Al_2O_3, in the formula, which makes it impossible to observe changes in the composition of essential minerals (Bahlburg and Dobrzinski, 2011). The disadvantages of the WIP are eliminable using the Chemical Index of Alteration (CIA) that involves all geochemical data of the rock (Nesbitt and Young, 1982).

Vogt's Residual Index **(V)** is defined by the ratio of the amount of oxides of immobile cations (mainly Al) to mobile cations (magnesium, calcium and sodium) with the assumption that the potassium content remains constant during the weathering process (Haskins, 2006). This index is an attempt to determine the maturity of residual sediments, and its greater value indicates higher intensity of weathering processes (Price and Velbel, 2003; Haskins, 2006). Vogt's index was used to compare the chemistry of glacial tills and marine clay deposits, showing that glacial tills are much more heavily weathered than marine clays. This suggests that the weathering process ended before deposition of marine sediments (Roaldset, 1972).

Chemical Index of Alteration **(CIA)** is the most commonly used proxy in research of fluvial deposits. Its value clearly reflects an increase in weathering intensity of silicates from the river's lower to upper reach. Evaluation of CIA values combined with a comprehensive facies analysis allows for a precise approximation of chemical and physical weathering conditions in the past (Shao et al., 2012).

The CIA illustrates the ratio of Al_2O_3, mostly immobile during weathering, to the mobile cations Na^+, K^+ and Ca^{2+} (Bahlburg and Dobrzinski, 2011). High CIA values indicate washing out of the mobile Ca^{2+}, Na^+ and K^+ cations during weathering in relation to immobile components (Al^{3+}, Ti^{4+}) (Nesbitt and Young, 1982). Its low values suggest lack of chemical alterations and cool and/or arid climate conditions (Fedo et al., 1995). The greatest CIA value (up to 100) is typical of kaolinite weathering. For illite the figures vary between 75 and 90, for muscovite it is 75, and for feldspars 50. Fresh basalts show CIA values in the range of 30–45, and fresh granites and granodiorites 45–50 (Nesbitt and Young, 1982; Fedo et al., 1995).

Harnois's Chemical Index of Weathering **(CIW)** is calculated similarly to the CIA, eliminating only the K_2O contribution. In the calculations, aluminium, which is associated with potassium feldspars, is not separated, thus the CIW can reach very high values in the case of rocks rich in these minerals, no matter whether the rocks are chemically weathered or not (Fedo et al., 1995).

Plagioclase Index of Alteration **(PIA)** has been proposed as a substitute for the CIW. It is particularly applicable for the separate monitoring of weathering of plagioclases.

© 2018, ALÖKI Kft., Budapest, Hungary

The PIA attains values of 50 in non-weathered rocks and close to 100 in clay minerals such as kaolinite, illite and gibbsite, in accordance with the values derived from the CIA formula.

Study area and research methods

Characteristics of the study area

The Vistula River basin covers an area of 183,176 km^2, which is ca. 59% of the total land area of Poland. According to the physic-geographical regionalization, the Vistula River basin is located within the following subprovinces: Central Western Carpathians, Outer Western Carpathians, Eastern Beskids, Eastern Subcarpathia, Northern Subcarpathia, Silesian–Cracow Upland, Małopolska Upland, Lublin–Lviv Upland, Polesie, Central Polish Lowlands, Podlasie–Belarus Uplands, South Baltic Lakelands, East Baltic Lakelands, Southern Baltic Coast, and Eastern Baltic Coast (Kondracki, 2009).

In the Upper Vistula River basin, which is a very diverse area in terms of geology, there are pre-Quaternary deposits. The most elevated part of the basin, the Tatra Mountains, is composed partly of crystalline rocks (gneisses, schists and granites) and sedimentary rocks (conglomerates, quartzites, clays, limestones, and marls). The Pieniny Klippen Belt is composed of Jurassic–Cretaceous and Paleogene carbonates. In Podhale, there are Paleogene sandstones and shales, while the Outer Carpathians are built of sandstones and shales, the so called flysch. Outcrops of pre-Quaternary rocks are also found in the Lublin Upland (Cretaceous limestones and marls), Małopolska Upland (limestone and marls in the Nida Trough), Holy Cross Mountains (limestones, dolomites, sandstones and quartzites) and Silesian–Cracow Upland (conglomerates, limestones, dolomites, clays and sandstones) (Marks et al., 2006).

Most of the Lower Vistula River basin area is covered by Quaternary deposits. These are Pleistocene glacial tills, ice-dammed lake clays, glaciofluvial and fluvial sands, fluvial gravels and sands, and peats and muds. Some areas of the Małopolska Upland and Lublin Upland are covered by loess and loess-like deposits. The river valleys are filled with Holocene alluvial and fluvial muds, sands and gravels (Marks et al., 2006).

The Odra River basin covers an area of 118,861 km² (of which 106,056 km² in Poland), including the Warta River basin of 54,529 km². In the physic-geographical regionalization of Poland, the Odra River basin is located within the area of the following subprovinces: the Sudetes and Sudetes Foothills, Central Polish Lowlands, Silesian–Lusatian Lowlands, South Baltic Lakelands, and Southern Baltic Coast (Kondracki, 2009). Almost the entire area of the Odra River basin is covered by Quaternary glacial and fluvial deposits (tills, sands, muds, peats) (Kondracki, 2009). In some places, for example in the Opawa River basin, Quaternary loess is found. In the Sudetes area, situated in the southwestern part of the drainage basin (upper reaches of the Odra River's left tributaries: the Kwisa, Bóbr and Orlica), pre-Quaternary magmatic, metamorphic and sedimentary rocks are exposed on the surface. The oldest rocks include gneisses, granitogneisses and migmatites of the Sudetes Mountains. In the Kaczawskie Mountains, Kłodzko region, and north of Strzegom, in the Sudetes Foreland, there are rocks metamorphosed in the much shallower, so called greenschist zone. These are various types of phyllites (which are metamorphosed mudstones and clay shales), metasandstones, metavolcanites, and crystalline limestones.

Sedimentary rocks of the Sudetes are represented by conglomerates, sandstones, greywackes, mudstones and clay shales. In the Paleozoic, two basic groups of igneous rocks were formed: (1) gabbro, peridotites and serpentinites (Nowa Ruda–Słupca, Ząbkowice Śląskie (Szklary) region in the Sudetes Foreland, Ślęża and its vicinity and (2) granites (Karkonosze Ridge, the massifs between Złoty Stok and Kłodzko, Kudowa region). Younger sedimentary formations are represented in the Sudetes and their foreland by the Upper Permian limestones, marls and gypsum, Triassic red sandstones and mudstones, as well as limestones and marls, and Upper Cretaceous sandstones and marls (Table Mountains, and the vicinity of Lwówek Śląski, Wleń, Bystrzyca Kłodzka and Międzylesie). This area was covered by Quaternary ice sheets, resulting in the accumulation of glacial, fluvial, eolian and slope deposits: various types of clays, sands, gravels, loesses and alluvial muds (Cwojdziński and Kozdrój, 2007).

Fluvial sediments in the area of Poland are dominated by quartz; carbonates and feldspars are present in smaller quantities. These components are represented by grain fractions >0.06 mm, which usually account for more than 90% of the sediment. This material originates mainly from the erosion of rocks occurring in the drainage basin. Fine-grained fractions (<0.06 mm) contain mostly minerals of the mica/illite group, and quartz, kaolinite and chlorite. Carbonates, feldspars, pyroxenes and amphiboles are less frequent. Significant amounts of organic matter and hydrated iron and manganese oxides are also present (Bojakowska and Sokołowska, 1998).

The area of Poland lies within the transitional climate zone. Change of isotherms system depending on season from latitudinal to longitudinal is a characteristic feature of Poland's climate. Summer temperature drop from south to north is connected with the increase of latitude. Winter temperature drop from west to east is in contrast conditioned by atmospheric circulation. In spatial distribution of temperatures Baltic coast is the warmest in the coldest months, whilst mountain peaks are the coldest. In July predominant part of Poland has the average temperature about 17.0–18.0 °C (Richling and Ostaszewska, 2005). The lowest average annual air temperatures are characteristic for the highest areas. Generally, besides mountain areas average annual air temperatures lower than 7 °C are distinctive for eastern part of Masurian Lake District and Region of Podlasie (Woś, 2010).

In Poland, similarly like in western and northern Europe, south-westerly, westerly and north-westerly winds are dominant. Wind field is deformed by Baltic Sea, lakes and land relief (mountains) (Richling and Ostaszewska, 2005).

"Zoning" is the most significant feature of spatial distribution of total annual precipitation on the area of Poland. Lowland zone receives below 600 mm of precipitation per year, so less than the average annual rainfall. Especially small rainfalls occur in the central Poland (about 500 mm). In the north of the country rainfall is larger, but precipitation level does not achieve there 700 mm. Precipitation increases together with elevation above sea level towards south from lowlands zone in central Poland. And so, Małopolska and Lubelska Upland receive on average over 550 mm of precipitation, and Holy Cross Mountains zone over 650 mm. Precipitation amounts quickly increase southwards and in the highest parts of the Tatra Mountains elevate even 1600–1700 mm. In the Sudetes precipitation levels are sometimes higher than at the same heights in the Carpathians (1200–1300 mm). Sudeten Foreland receives in turn less rainfalls than the Carpathian Foothills, what is associated with different land relief (Richling and Ostaszewska, 2005).

Research methods

The research is based on results of analyses of 178 sediment samples collected from the Vistula River and its tributaries (Bug, Dunajec, San, Pilica, Bzura and Narew rivers) and 114 sediment samples from the Odra and Warta rivers and their tributaries (Nysa Łużycka, Bóbr, Kwisa, Kaczawa, Bystrzyca, Barycz, Nysa Kłodzka and Mała Panew rivers). The sediments were analysed within the framework of the National Environmental Monitoring (PMŚ) in 2015. Sampling sites are shown in the sketch map (*Fig. 1*). Sediment samples were collected at sites located along the rivers, downstream of the mouths of tributary rivers and other watercourses longer than 50 km, and downstream of major cities or towns where industrial plants are located.

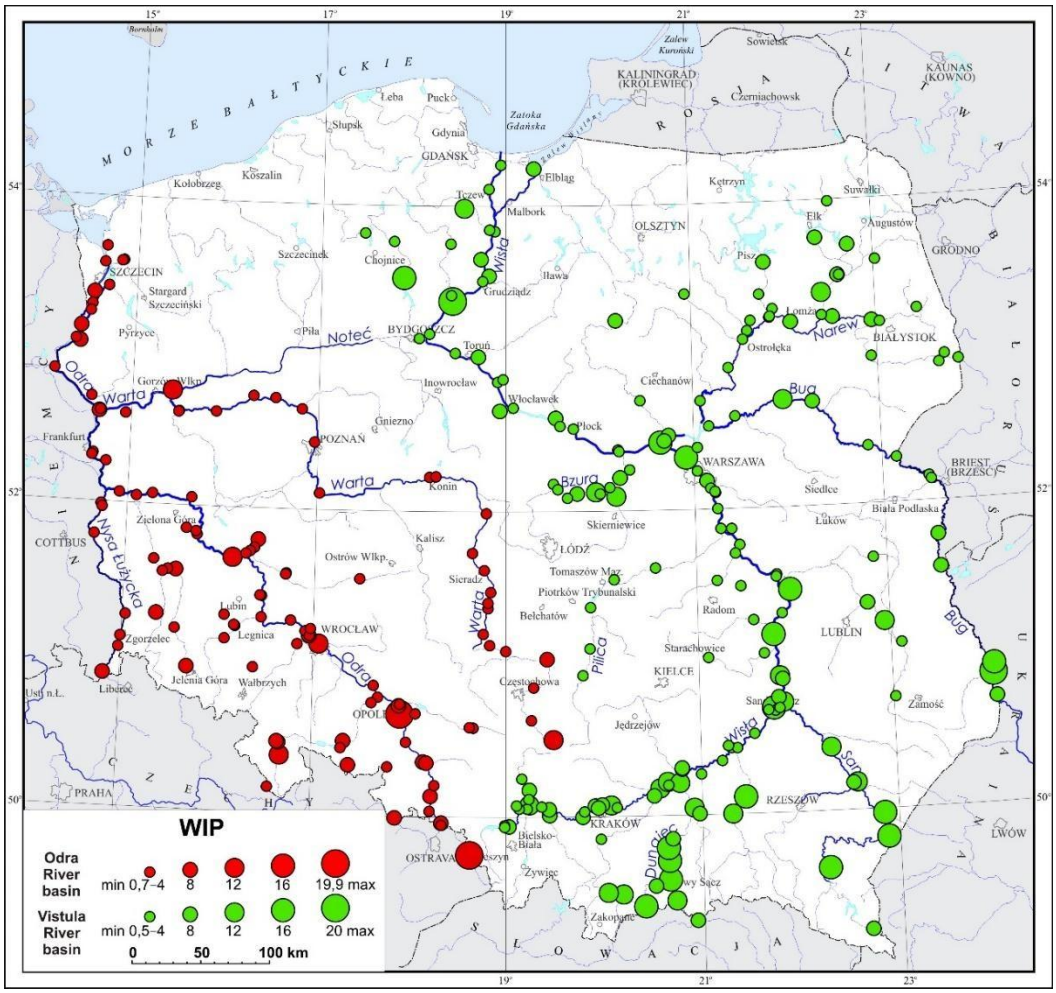

Figure 1. *Sampling sites and Weathering Index of Parker values*

Sediment samples were taken with an aluminium scoop from river banks, where the accumulating sediment is characterised by the highest content of the mud and clay fraction (*Fig. 2*). Each sample was an averaged sample of four or five samplings from a 5-cm thick surface sediment layer over a stretch of about 50 m. The sediment samples were dried at room temperature and then sieved through nylon sieves with a mesh size of 0.2 mm. The Al, Ca, Mg, K and Na concentrations were determined using atomic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24532473
© 2018, ALÖKI Kft., Budapest, Hungary

plasma emission spectrometry (ICP–OES) after digestion of the samples in aqua regia (*Fig. 3*). The detection limits were 0.01% for Al, Ca, Mg and K, and 0.001% for Na.

Results of the Al, Ca, Mg, K and Na determinations were used to calculate WIP, V, CIA, CIW and PIA values according to the formulas shown in *Table 1* (molecular proportions of oxides).

Statistical parameters (the minimum, maximum, median, mean and geometric mean) for the contents of elements and the calculated weathering indices were determined using the Statistica program. Maps of the variability of weathering indices in sediments were compiled using ArcGIS software.

Figure 3. *iCAP 6500 duo Thermo Scientific ICP–OES instrument used for determination of analysed chemical elements. (Photo: I. Jaroń)*

Research results

The Al content in sediments of the Vistula River basin ranges from 0.08 to 1.95%, and its mean, geometric mean and median values are 0.39%, 0.31% and 0.28%, respectively (*Table 2*). The calcium contents vary in the range of 0.04–4.22%, and the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

mean, geometric mean and median values are 0.93%, 0.61% and 0.64%, respectively. The magnesium content varies from 0.01 to 0.92%, and its mean, geometric mean and median values are 0.19%, 0.12% and 0.12%, respectively. The sodium content in sediments of the Vistula River basin ranges from 0.003 to 0.103%; the mean value is 0.014%, the geometric mean 0.012%, and the median 0.011%. The potassium contents range between 0.02 and 0.40%, and its mean, geometric mean and median values are 0.07%, 0.06% and 0.06%, respectively. Standard deviation values for all elements of the Vistula River basin were in a range between 0.01 and 0.84, whereas coefficient of variation (CV) values were between 71 and 100 (*Table 2*). Because of the clear variability in the contents of individual elements in the Vistula River basin, the drainage basins of the Dunajec, San, Pilica, Bzura, Bug and Narew rivers have also been discriminated, for which the content ranges of the elements and the mean, geometric mean and median values are determined (*Table 2*).

The Al content in sediments of the Odra River basin is in the range of 0.12–1.52%, and its mean, geometric mean and median values are similar to those determined in the Vistula River basin (*Table 2*). The calcium content varies between 0.04 and 4.54%, which is close to the values recorded for sediments from the Vistula River basin, but the mean and median values were below 0.5%. The magnesium content varies in the range of 0.01–0.69% (the median 0.06%), the sodium content is 0.006–0.172% (the median 0.018%), and the potassium content is 0.03–0.28% (the median 0.06%). The mean, geometric mean and median values for magnesium are much higher in the Vistula basin sediments, for sodium in the Odra basin, whereas for potassium the values are very similar (*Table 2*). Standard deviation values for the elements in the Odra basin varied between 0.02 and 0.61 and coefficient of variation values between 63 and 142. Like with the case of the Vistula and Odra river basins, separate statistical parameters have also been determined for the Warta River basin (*Table 2*).

The WIP values in sediments of the Vistula River basin varied between 0.5 and 20, and the mean, geometric mean and median values were 5.1, 3.7 and 3.8, respectively, whereas standard deviation and coefficient of variation values were 4.05 and 79 respectively (*Table 3, Fig. 1*). The highest value of this index was recorded in sediments of the Fryba River in Chełmno, where the bedrock is represented by limestone, opoka

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

(polish name of siliceous-carbonate rock), mudstone and claystone. Values ranging from 17.1 to 13.5 are reported from sediments of the Bug River near the border with Ukraine (limestones and dolomites), and of the Vistula River in Potrawin (limestones, opokas and marls) and Sandomierz (sands, gravels, alluvial muds, Pleistocene peats and muds, with the bedrock composed of loess, limestone, marl and opoka). The lowest WIP value was measured in sediments of the Kamienna River in Starachowice (the bedrock is composed of conglomerates, sandstones and mudstones). Low WIP values are typical of sediments of the Radomka River in Ryczywół, and of the Pilica River in Mniszew (alluvial sands, gravels and muds).

The V index values in the Vistula drainage basin were in the range between 0.1 (Brda River in Tuchola) and 2.8 (Pszczynka River in Jedlina), with the mean of 0.4, geometric mean 0.3, median 0.3, standard deviation 0.32 and coefficient of variation 80. In the Vistula basin, the highest levels of the chemical weathering index V were found in the tributaries of the Upper Vistula River (Pszczynka, Soła and Iłownica rivers) and in the middle course of the Pilica River (in Spała) (*Table 3, Fig. 4*). In turn, the lowest values were reported from sediments of the Brda River, middle course of the Wieprz River, Bug River, and the Narew River and its tributaries.

The CIA values in sediments of the Vistula River basin are in the range of 4–80; the mean is 27.6, geometric mean 24.3, and median 24.2. Standard deviation value is 14.07 and coefficient of variation is 51 (*Table 3, Fig. 5*).

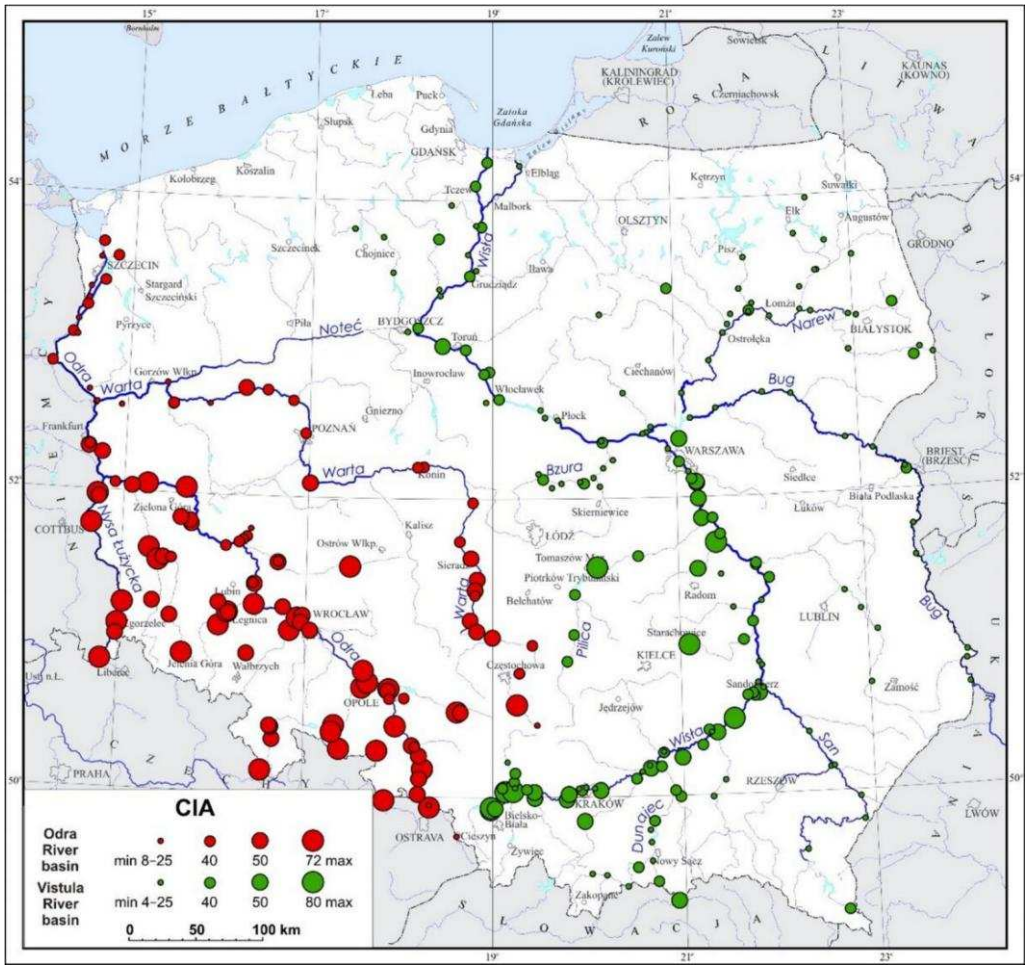

Figure 5. *Chemical Index of Alteration values*

The highest values are found in sediments of the Pszczynka River in Jedlina and the Soła River (sands, gravels, alluvial muds and peats), while the lowest ones are observed in sediments of the Brda River in Tuchola (upon the bedrock composed of limestones, opokas, marls, phosphorites and cherts) and of the Wieprz River in Jaszczów (Cretaceous limestones, opokas and marls).

In sediments of the Vistula River basin, the CIW values varied from 4 (Brda River in Tuchola) to 82 (Pszczynka River in Jedlina), and the mean, geometric mean and median values were 28.9, 25.3 and 25, respectively. Standard deviation amounted 15.20 and coefficient of variation 53 (*Table 3, Fig. 6*).

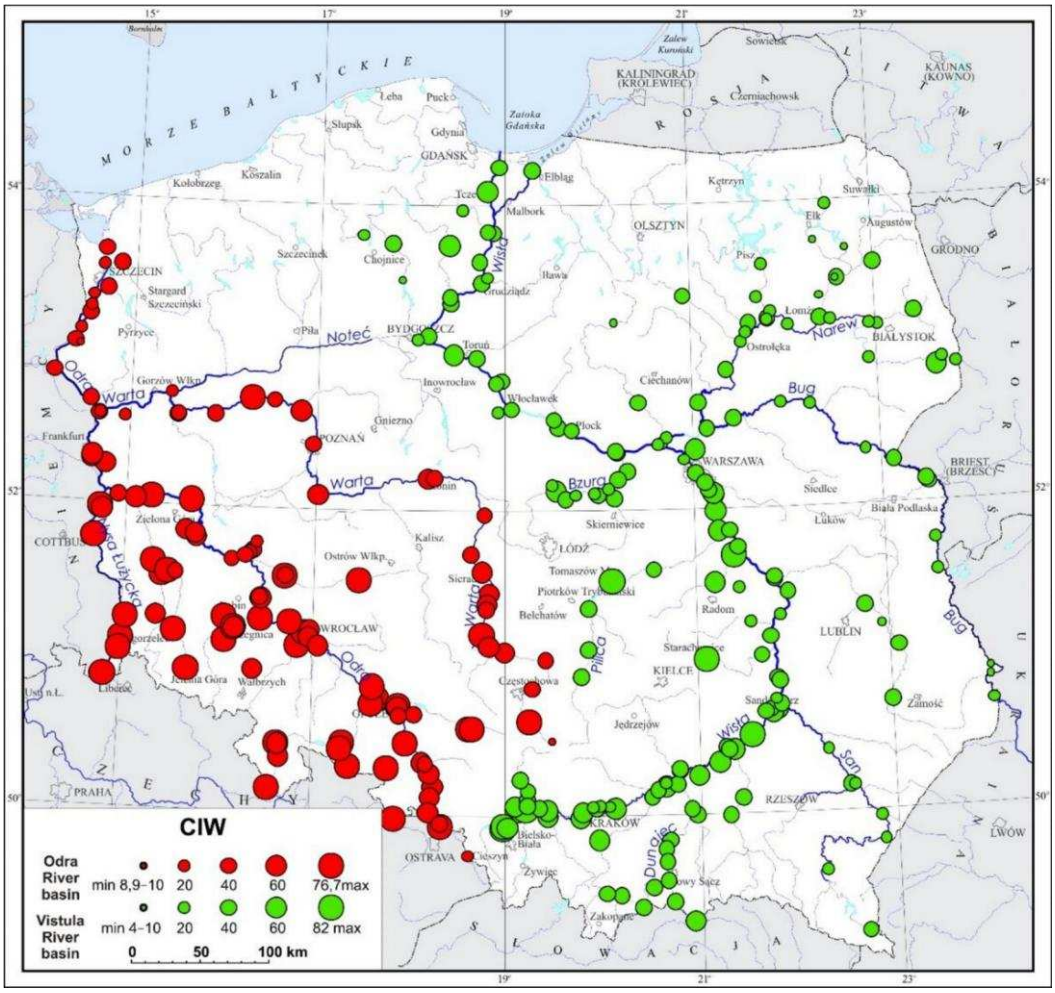

Figure 6. *Chemical Index of Weathering values*

The PIA values ranged from 3 (Brda River in Tuchola) to 81.7 (Pszczynka River in Jedlina); the mean was 26.2, geometric mean 22.5, and median 22.2, standard deviation 14.79 and coefficient of variation 56 (*Table 3, Fig. 7*).

In sediments of the Odra River basin, the Parker index values ranged from 0.7 to 19.9, and the mean, geometric mean and median values were 3.2, 2.5 and 2.3, respectively. Standard deviation and coefficient of variation values were 2.95 and 92 (*Table 3, Fig. 1*). The highest WIP value was found in sediments of the Olza River in Ropice (draining the Cretaceous carbonates), and the lowest one is reported from the

Czerna Wielka River with the bedrock composed of sands, gravels and muds. The values of 17.1–10.1 were found in sediments of the Olszanka and Warta rivers in Kromołów and Santok.

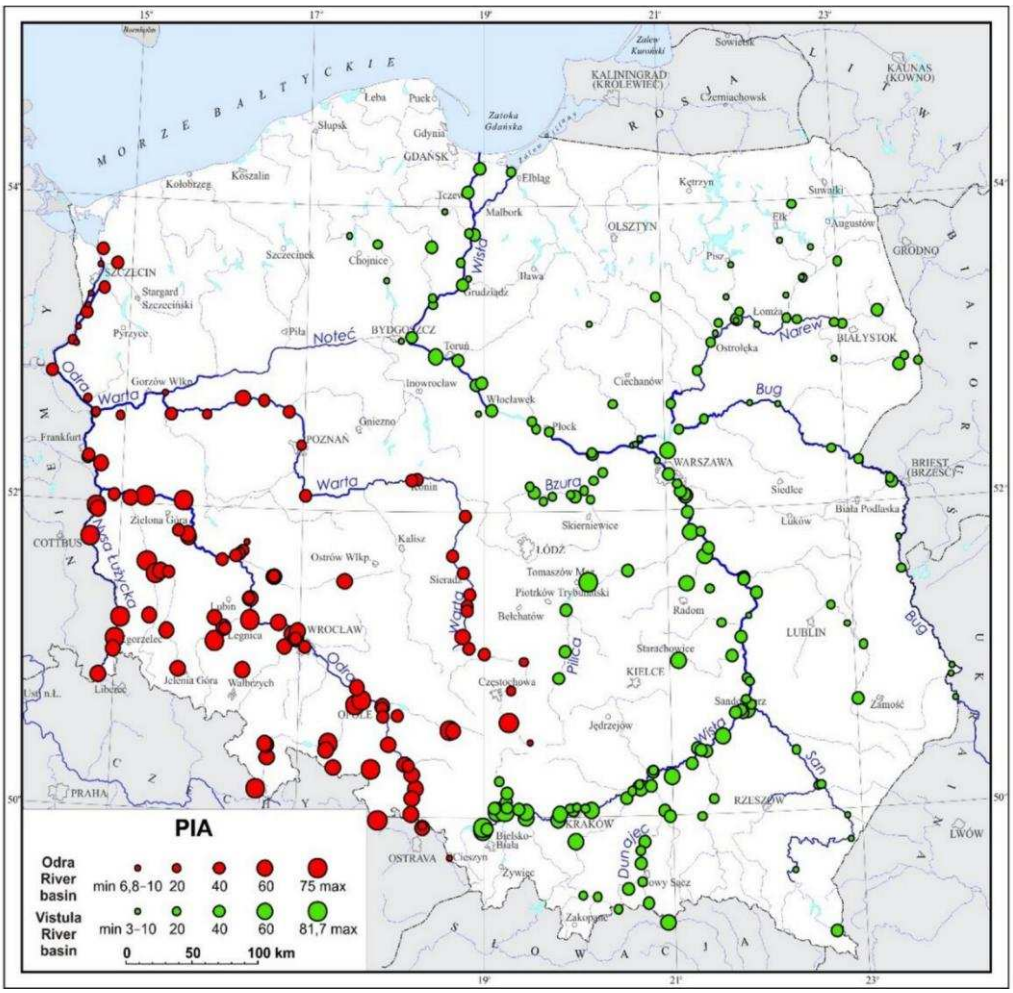

Figure 7. *Plagioclase Index of Alteration values*

The V index values in sediments of the Odra River basin are in the range from 0.1 (Warta River in Kromołów) to 2 (Zimny Potok stream in Ciemnice); the mean was 0.8, geometric mean 0.7, and median 0.8, standard deviation 0.46 and coefficient of variation 58 (*Table 3, Fig. 4*). The Vogt's index values are very high in the upper course of the Nysa Łużycka River, at its confluence with the Odra River, and at the confluence of the Kwisa and Bóbr rivers. The lowest values were recorded in the lower reach of the Odra River, at its mouth to the Baltic Sea, and near the confluence with the Warta River in the middle course of the Odra.

The CIA values varied between 8 and 72, and the mean, geometric mean and median values were 45, 40.8 and 48.9, respectively. Standard deviation and coefficient of variation values were 16.73 and 37, respectively (*Table 3, Fig. 5*). The highest levels were observed in sediments of the Nysa Łużycka River in Zasieki (sands, gravels, alluvial muds and peats), and the lowest values were recorded in sediments of the Rurzyca River near its confluence with the Odra (glacial tills in the bedrock). Very high

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24532473
© 2018, ALÖKI Kft., Budapest, Hungary

values were also found in the Zimny Potok stream in Ciemnice (fluvial clays, muds and sands) and in the Nysa Łużycka River in Zgorzelec. Low values are reported from the Warta River in Kromołów – a district of Zawiercie (Jurassic limestones) – and from the Olza River (Cretaceous limestones and shales).

The CIW values ranged from 8.9 (Rurzyca River in Nawodna) to 76.7 (Nysa Łużycka River in Zasieki), and the mean, geometric mean and median values were 48.4, 43.7 and 52.9, respectively. Standard deviation amounted 18.57 and coefficient of variation was 38 (*Table 3, Fig. 6*).

The PIA values varied between 6.8 (Rurzyca River in Nawodna) and 75 (Nysa Łużycka in Zasieki), and the mean, geometric mean and median values were 44.9, 39.9 and 48.5, respectively. Standard deviation value was 18.47 and coefficient of variation value was 41 (*Table 3, Fig. 7*).

Graphical representation of the distribution of chemical weathering indices shows that they distinctly differ between the Odra basin and the Vistula basins, and that the WIP index reveals the lowest variability (*Fig. 8*).

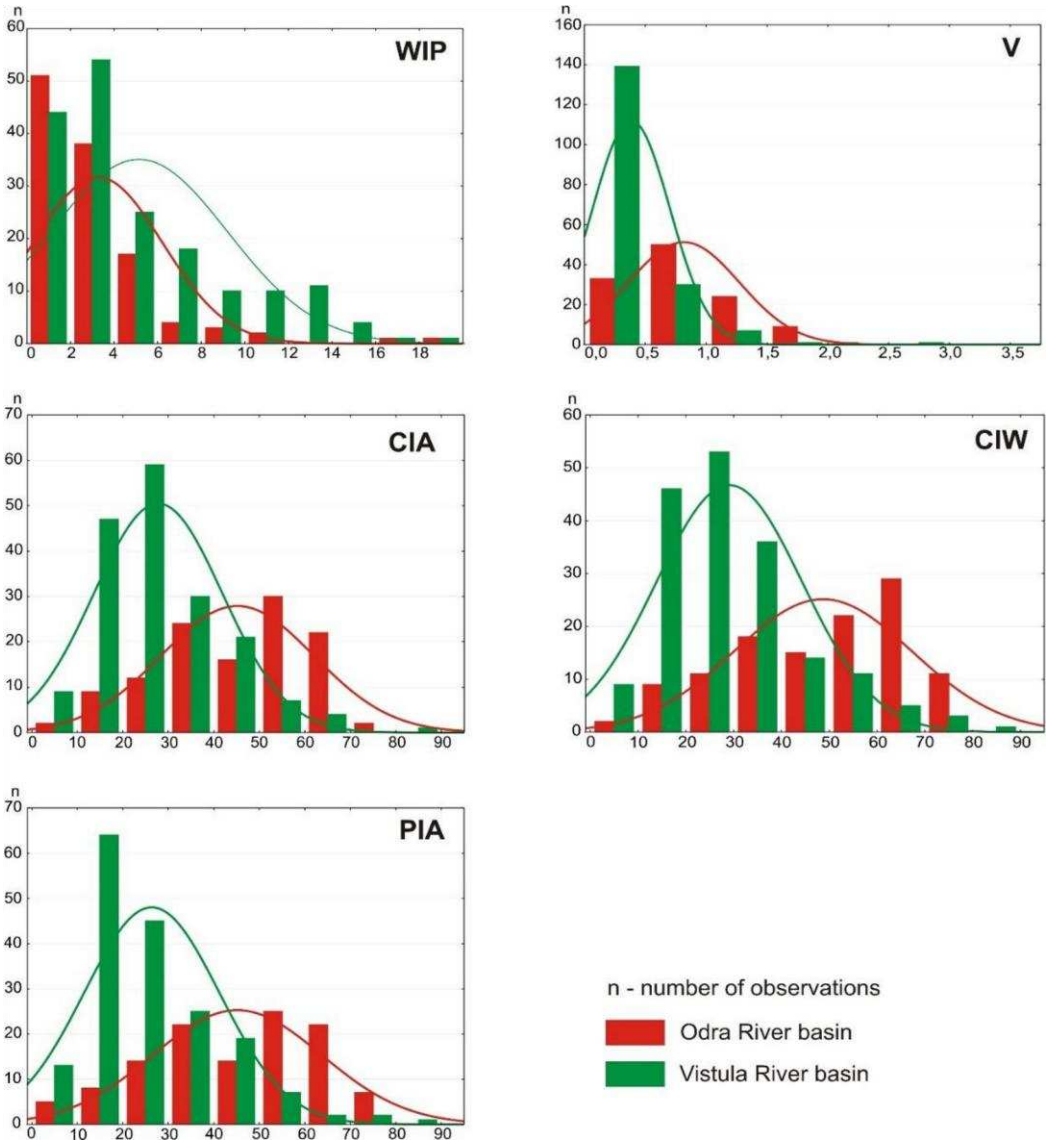

Figure 8. *Histograms of chemical weathering indices*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24532473
© 2018, ALÖKI Kft., Budapest, Hungary

The dominant WIP values in sediments of both basins are from 0 to 4. In the case of the Odra basin sediments, the WIP values are usually in the range of 0–2, and less frequently of 2–4. In the Vistula basin, the most common values vary from 2 to 4, and less frequently from 0 to 2. The CIA values in the Odra basin are generally in the range of 30–70, while in the Vistula basin they vary between 10 and 40 (*Fig. 8*). The distribution of the values of the plagioclase index of alteration is similar. The most common PIA values in the Odra basin sediments are in the range of 30–70, while in the Vistula basin they are between 10 and 50 (*Fig. 8*). In the Vistula basin, the dominant Vogt's index values are up to 0.5, while in the Odra basin between 0.5 and 1.0. The CIW values also differ between both basins. In the Vistula basin, the dominant values are in the range of 10–40, while in the Odra basin they vary from 30 to 70. In general, fluvial sediments in the Odra River basin are characterised by a greater number of samples with low values of the weathering indices than those in the Vistula basin, except for the WIP.

The most common values of the analysed indices (the percentile range is 25–75) in sediments of the drainage basins are well illustrated in the box plots (*Fig. 9*).

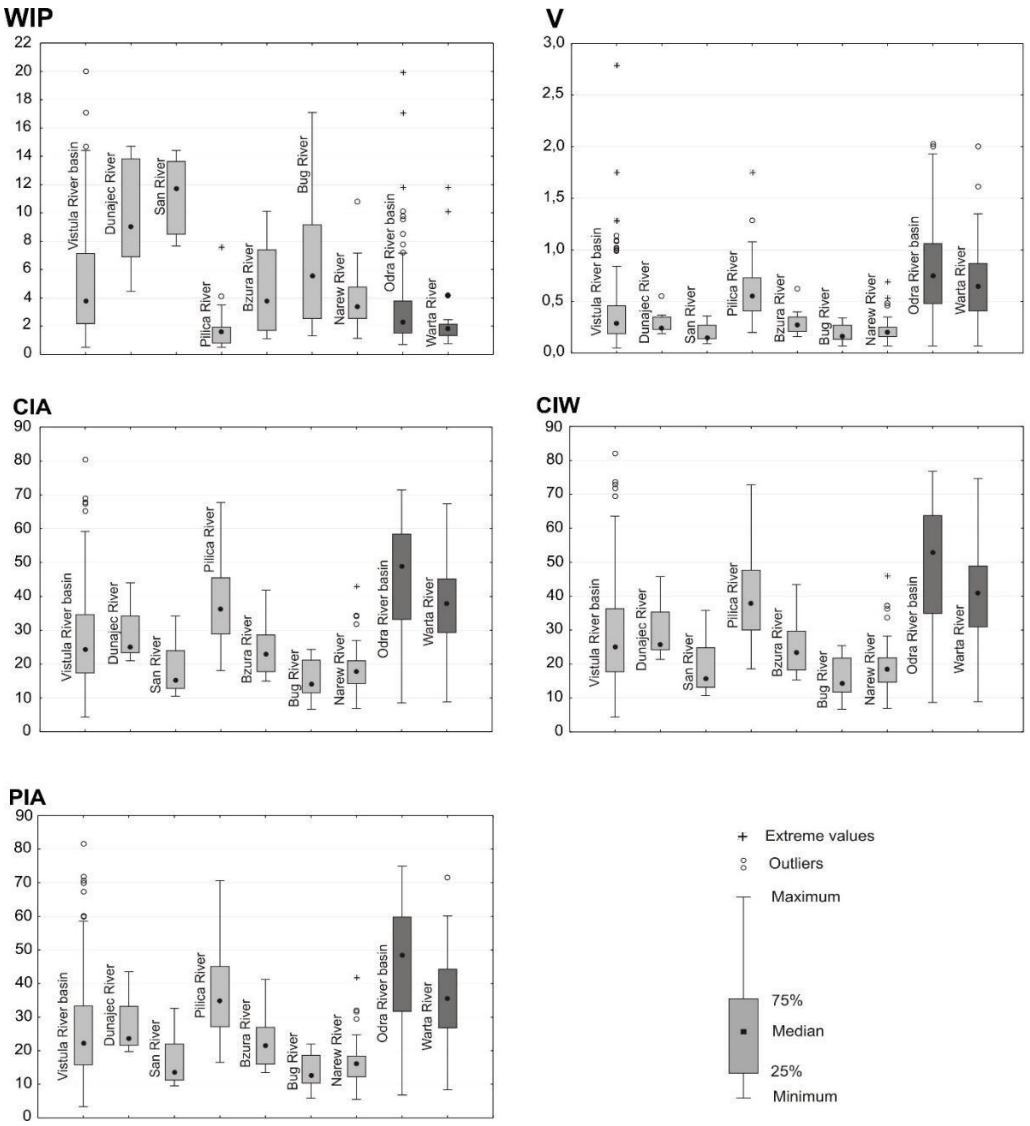

Figure 9. *Boxplots of chemical weathering indices in sediments of selected rivers*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24532473
© 2018, ALÖKI Kft., Budapest, Hungary

The range of the most common WIP values for sediments of the Odra basin (1.5–3.8) is much narrower than for those of the Vistula River system (2.2–7.1). For the Bug, Dunajec and Bzura rivers, the range is very wide, for the San River it is narrower, and the narrowest is for lowland rivers: the Narew, Pilica and Warta. The highest WIP values are observed in sediments of the drainage basins of the Dunajec and San rivers that drain the Carpathians and Subcarpathia. The lowest values are recorded in sediments of the Warta and Pilica basins (*Fig. 9*).

Discussion

The calculated indices are complementary and show similar trends. Sediments supplied into the Lower Odra River basin were subjected to stronger chemical weathering during transport (because they carry away more mobile elements) and mixing with the sediments of the Warta River.

High values of standard deviation and coefficient of variation indicate on a very extensive dispersion of data in relation to average values. Variability of data in the case of majority of elements for both Vistula and Odra River basins and their tributaries is below 100, what gives information about moderate differentiation of elements content. Much higher values than 100 in the case of Ca and Mg were present for Pilica, Odra and Warta River basins and they inform about huge results variability. It is worth highlighting that Warta and Pilica have their sources on Małopolska Upland area, which is built of carbonate rocks. Coefficient of variation values for V, CIA, CIW and PIA indices point to moderate diversification of results. WIP is an exception among them and its values vary from 604 (San) to 2906 (Pilica). These values show extremely huge variability of obtained results. CV values below 200 suggest that these elements distribution in sediments is moderately homogenous and mainly involved with their natural (lithogenic) origin. CV values above 200 indicate on uneven distribution of data set and suggest that the part of elements was artificially provided to the environment. It is clearly visible in *Table 3*.

The WIP values in sediments of the Odra and Vistula basins are much lower as compared with those from other regions of the world. The WIP value for samples of suspended fine particles in Chinese rivers varies from 24.7 to 58.3, and the average is 38.8. In samples from floodplain areas the values range from 26.4 to 59.4, and the mean value is 44.4 (Shao et al., 2012). This index value in fluvial sands of Taiwan is in the range of 18–65 (Garzanti and Resentini, 2016), and it varies between 40.8 and 47.6 in stream sediments of the Alaknanda River basin (India) (Panwar and Chakrapani, 2016).

The range of the most frequent CIA values in the Odra basin (33.2–58.4) is wider than in the Vistula basin (17.4–34.6). The greatest variability of CIA values is observed in the case of sediments of the Pilica and Warta rivers. For the Bzura, Dunajec, San and Bug rivers, the variability is moderate, and for the Narew River it is the lowest.

The average CIA values calculated for the rivers of Poland are much lower than the average values for the rivers in the world, Asia and North America, although high levels have been sporadically recorded in some samples. The CIA value in sediments of various rivers across the world varies between 48.2 and 89.9, and the average is 72, with the highest levels in the African rivers (83.4 on average) as compared with the other continents. The lowest value observed in the North American rivers is 66.0. In the Asian rivers, the average value of this index is 71.7, which is close to the world's average. The highest CIA values are found in sediments of the Congo River (89.9), and the lowest

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24532473
© 2018, ALÖKI Kft., Budapest, Hungary

ones are recorded in watercourses of the Kola Peninsula in the Arctic area (48.2) (Li and Yang, 2010). The CIA values in suspended matter of the Chinese rivers were between 58.8 and 91.3, with the average of 71.4, which is close to the world's average. In floodplain areas, the values varied from 44.5 to 84.3, with the average of 61.3. For comparison, sands of the Taiwan rivers show the CIA values in the range of 46–77. The values in the Chinese rivers are 72–88, and in the Alaknanda River basin (India) the average value is 56 (Garzanti and Resentini, 2016; Shao et al., 2012; Selvaraj and Chen, 2006; Panwar and Chakrapani, 2016). The highest levels of this index (88.9–94.5) were recorded in stream sediments of southwestern Nigeria (Madukwe et al., 2016).

The compilation of curves for V, CIA, CIW and PIA values for the individual river subbasins shows that they are comparable and the highest levels are observed in sediments of the Warta and Pilica river basins. In the remaining subbasins they are lower (*Fig. 7*). The similarity is undoubtedly due to the similar lithologies of the underlying rocks. The neighbouring drainage basins drain the area of the Mid-Polish Lowlands, and the rivers' headwaters are located within the Małopolska Upland, where limestones and marls are the important lithologic components.

The lowest V, CIA, CIW and PIA values are found in sediments of the drainage basins of the Narew, Bug and San rivers of eastern Poland, which drain areas of diverse geological structures. In the San drainage basin area, there are mainly flysch deposits. In the Bug River basin, carbonate-rich rocks (limestones, marls and loess) account for a considerable proportion, whereas in the Narew basin area there are only glacial deposits.

The V and CIW values in sediments of the Vistula and Odra river basins are definitely lower than in other regions of the world. The V index levels in weathering profiles of the Coweeta Basin, North Carolina, USA, are 1.9–16.2 (Price and Velbel, 2003). In sands of the Taiwan rivers, the CIW values are in the range of 47–95 (Garzanti and Resentini, 2016), and in stream sediments of Nigeria they vary between 89 and 98, locally reaching 95.3–98.2 (Gajere et al., 2015; Madukwe et al., 2016).

Similarly, the PIA values in the rivers of Poland are lower than the values observed in rivers of other climatic zones. In the fluvial sands of Taiwan, the PIA values vary from 46 to 94, and in sediments of the Kaoping River the average is 66 (Garzanti and Resentini, 2016; Selvaraj and Chen, 2006). The highest values of this index (94–98) were recorded in stream sediments of SW Nigeria (Madukwe et al., 2016).

In Poland, the length of sediment transport by rivers is likely to have little effect on the value of chemical weathering indices. Their decreasing values from the south towards the north of Poland in the analysed sediments of the whole study area indicate the dominant role of the chemical composition of bedrocks in the drainage basins.

This observation clearly confirms the different range and values of WIP, which are significantly smaller in the Odra River sediments than in the Vistula River sediments. The greatest variability of the WIP in the upper parts of the river basins (*Fig. 1*) is related to the drainage of igneous, metamorphic and sedimentary rocks of the Sudetes in the upper Odra River basin, and of the Carpathian flysch in the upper Vistula River basin. In the lower reaches of the rivers, the WIP, CIA, V and PIA values are less varied, indicating that their values are influenced mainly by the geological structure of those parts of the drainage basins where Quaternary deposits are exposed: glacial tills, clays, sands, gravels, peats and alluvial muds.

The greatest effect on the values of weathering indices in particular river subbasins can also be attributed to the lithologies.

In the Bug River basin, the high WIP value and the low values of other indices are due to high calcium contents in sediments (derived from the drainage of loess, limestones and marls). In contrast, the Warta and Pilica river basins, which drain Quaternary deposits over almost the entire drainage basins, the WIP values are the lowest, as opposed to the values of the other indices (*Fig. 7*).

CIA values are used to assess the effect of climate on the rate and mode of weathering more often than the other indices are. At lower geographical latitudes, the average annual temperatures are higher and the intensity of chemical weathering decreases. In the present research, the CIA values show a dependence on the average annual temperature and precipitation. A moderate level of chemical weathering dominates in central Poland (Wielkopolska Lake District, Wielkopolska Lowland and Mazovian Lowland), in the area of the lowest annual precipitation. Fluvial sediments in northern Poland (Lower Odra and Lower Vistula drainage basins), with elevated annual precipitations (600–700 mm), are characterised by the highest degree of weathering. High weathering levels are also typical of sediments in the Sudetes and the Carpathians, where the annual precipitation is 800–1200 mm. The high intensity of chemical weathering in the Carpathians is best illustrated by the CIA values, while in the Sudetes by the WIP values.

Conclusions

1. The values of weathering indices in river sediments of Poland vary in a wide range, but they are lower than the values found in other warmer and humid climates of the world.
2. The values of weathering indices in river sediments are affected mainly by the chemical composition of bedrocks of the drainage basins. In those parts of the drainage basins, which are underlain by pre-Quaternary rocks, the sediments show greater resistance to chemical weathering and lower susceptibility to leaching of elements. The highest losses of elements due to leaching are characteristic of the lower parts of the Odra and Vistula drainage basins composed of Quaternary deposits.
3. The degree of chemical weathering of sediments of the analysed rivers of Poland varies according to climatic conditions that differ between the north and the south of the country. The highest degree of weathering is observed in the lower drainage basins of the Odra and Vistula rivers and in mountainous areas (the Sudetes and the Carpathians). In central Poland, the moderate degree of chemical weathering is dominant.
4. Comparison of chemical weathering indices variability in river sediments in southern Poland will be very worthwhile, especially in the Carpathians e.g. Dunajec and Wisłoka rivers and in the Sudetes (Nysa Łużycka and Bóbr).

(Received 23rd Nov 2017; accepted 7th Mar 2018)

Abstract. Natural recovery of abandoned agricultural fields take decades due to biotic and abiotic constraints. A key question is how does soil physico-chemical properties prevent the transition from degraded to restored state. This study examined changes in soil physico-chemical properties between old field sites that were abandoned 35 year ago and adjacent natural sites in Lapalala Wilderness, located in the Limpopo Province of South Africa. Top soils were collected from three paired sites (old field and natural sites) in five different locations, over three months and were quantified for soil moisture, total soil macro elements (N, C and P), pH, exchangeable cations (K, Ca, Mg, Na), resistivity, penetration resistance, cumulative infiltration and hydraulic conductivity. Results show that soils in old field sites had lower pH, total N and C, K, Mg, gravimetric soil moisture and were compact compared to soils in adjacent natural sites. Soil resistivity, total P, Na, Ca, cumulative infiltration and hydraulic conductivity showed no significant ($p > 0.05$) differences between the two sites. It appears that the soils in old field sites have poor properties, and indication that soil manipulation techniques e.g. fertilizer addition, top soil removal and soil transfer must be considered for vegetation recovery to take place.
Keywords: *land abandonment, soil reconstruction, soil fertility, soil nutrient, litter*

Introduction

Land abandonment commonly referred to as the termination of crop cultivation or livestock grazing is a widespread phenomenon in South Africa (Andrew et al., 2003). Social (rural depopulation, poor land use practices), economic (globalization of agricultural markets, shortage of capital) and ecological (declining soil fertility) reasons have been highlighted as causes for land abandonment (Andrew et al., 2003; Kakembo and Rowntree, 2003). The abandonment of land has a wide range of ecological consequences e.g. soil erosion, competitive exclusion, increased wildfires and invasion by invasive plants. All these consequences are linked to habitat loss and decline in ecosystem service provision (Plieninger et al., 2014). To restore abandoned agricultural lands (also referred to as old fields), models of ecological restoration (successional and alternative state) have been tried and they have produced mixed results (Hobbs and Suding, 2008). The broader objective of these models is to restore natural ecosystem processes, functions, and structure (Hobbs and Suding, 2008). For example, soil manipulation in old fields has aimed to improve soil properties with the view that improved soils will facilitate native vegetation recovery (Blumenthal et al., 2003; Ruwanza et al., 2012). Recent studies have shown that soil transfer from intact natural

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24752486
© 2018, ALÖKI Kft., Budapest, Hungary

areas to old fields has the potential to recover both soils and plants in old fields (Wubs et al., 2016; Bulot et al., 2017).

The effect of land abandonment on soils has been varied. Some studies have shown that soils in old fields have high chemical properties compared to natural areas, this a result of past cultivation (Hooker and Compton, 2003; Gabarrón-Galeote et al., 2015). Additionally, some studies have shown that vegetation recolonization in old fields can influence soil changes (Bonet and Pausas, 2004), although the duration change is unclear. Since vegetation is known to be a driver of soil changes, variations in soil properties tend to be highly dependent on plant colonization (Gabarrón-Galeote et al., 2015). For example, secondary succession in Mediterranean environments usually starts with grasses and herbs, with a gradual increase in woody species over time (Rey Benayas, 2005; Cuesta et al., 2012). The above-mentioned changes in vegetation type contributes to changes in soil properties due to litter deposition and decomposition. Other studies have shown that the persistence of grassland cover combined with the slow recovery of woody species in semi-arid old fields result in the slow recovery of soil properties (Rey Benayas, 2005; Ruiz-Sinoga and Martínez-Murillo, 2009).

An understanding of changes in soil properties within old fields has the potential to improve our knowledge of ecological restoration in these areas. For instance, understanding the changes in soil properties in old fields has contributed to the development of new soil manipulation techniques (e.g. top soil removal and soil transfers) that are yielding successful plant and soil recovery (Wubs et al., 2016; Bulot et al., 2017). Besides that, insights into soil properties in old fields has helped our general understanding of bacterial and fungal activities, nutrient uptake and plant-soil interactions (McKinley et al., 2005). Therefore, the objective of this study was to assess the differences in soil physico-chemical properties between old field sites and adjacent natural sites in Lapalala Wilderness, South Africa. The research question was whether soil properties, namely soil physico-chemical properties, resistivity, penetration resistance, infiltration and hydraulic conductivity are different between old field sites and adjacent natural sites. Results of this study are envisaged to guide future restoration initiatives in Lapalala Wilderness old fields.

Materials and methods

Study sites and soil collection

Soils were collected at three different sites that were located at Lapalala Wilderness in the Limpopo province of South Africa (*Table 1* and *Fig. 1A*). The three sites were approximately 200 m apart to provide a measure of independence (Galatowitsch and Richardson, 2005), and each old field site was paired with a natural site, approximately 10 m from each other (road demarcation). The mean annual rainfall in this area is approximately 500 mm, which falls in the summer months between October and February. Temperatures in the area are cold in winter and hot in summer with mean daily maximum and minimum temperatures of 30 °C in January and 14 °C in June. Vegetation in the area is classified as Waterberg Mountain Bushveld, which is found in the savanna biome (Mucina and Rutherford, 2006). Soils in the area are nutrient poor sandy soils derived from the Kransberg subgroup of the Waterberg groups (Mucina and Rutherford, 2006). However, the central sections of Lapalala Wilderness are dominated by nutrient rich clay soils derived from norite/epidiorite intrusions. The dominant plant species in the natural areas include *Dichrostachys cinerea*, *Sclerocarya birrea*,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24752486
© 2018, ALÖKI Kft., Budapest, Hungary

Vachellia tortilis, *Ziziphus mucronata*, *Grewia* spp, *Arisitida congesta*, *Panicum maximum*, *Eragrostis rigidior* and *Aristida adscensionis.* The old field sites were previously used for tobacco and cattle farming approximately 35 years ago. Currently, they are used for animal grazing and are dominated by few scattered woody pioneer species (*V. karroo*) and low grass cover.

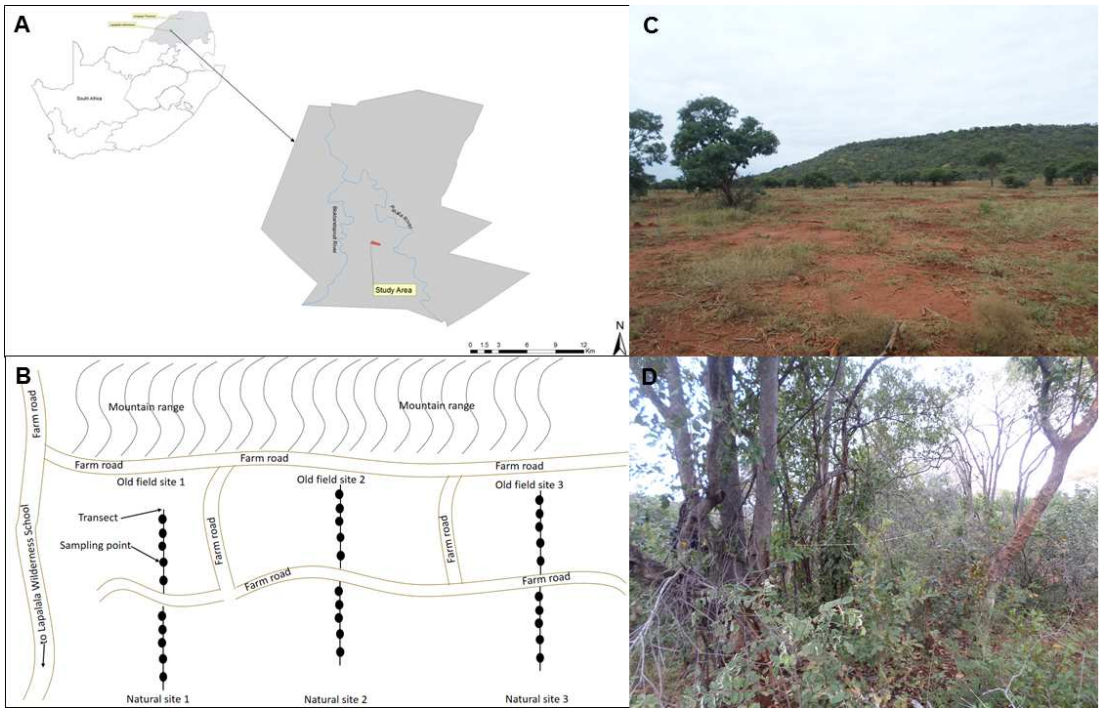

Figure 1. *Map showing (A) the location of the Lapalala Wilderness study area in the Limpopo Province, South Africa and (B) the experimental setup in the old fields, (C) photo of old field, and (D) photo of natural site. Location details of the sites are presented in Table 1. Photos taken by Sheunesu Ruwanza*

At each site, a 40 m transect (from west to east) running into the site, with the first point being 2 m from the road demarcating paired sites, was established. The above-mentioned transect comprised five soil collecting points that were 10 m apart (*Fig 1B*). Therefore, a total of 30 soil collecting points were marked, thus five soil samples points per site from six sites (three old field sites and three natural sites). In April 2017, two soil cores (30 cm apart) were collected at each collecting point for soil physico-chemical and moisture analysis. The soil physico-chemical analysis was done once due to limited finance. Besides, the expectation that repeated monthly measurements on soil physico-chemical properties would yield variations within three months was less. During the months of May and June, 30 soil cores per month were collected for soil moisture measurements only. Therefore, a total of 60 soil sample were collected in April (30 for physico-chemical analysis and 30 soil moisture measurements) and 30 soil cores per month for the months of May and June for soil moisture measurements. The soils were collected using a soil core measuring 8 cm in diameter and 8 cm depth after the hand removal of overlying debris. After soil collection, both soil physico-chemical properties and soil moisture measurements were assessed under laboratory conditions at the University of Venda in Thohoyandou, South Africa. Measurements on soil

penetration resistance level and infiltration rate were conducted under field conditions at each of the soil collecting points for all the three months.

Soil chemical properties and pH

Soil pH was measured in 1:5 soil:KCl extract (Rhoades, 1982). Soil total P was analyzed using Bray-II extract method (Bray and Krutz, 1945). Soil total N was analyzed using the complete combustion method using an elemental analyzer (Euro EA; Eurovector, Milan, Italy). Soil total C was analyzed using the modified Walkley-Black method (Chan et al., 2001). Exchangeable cations were extracted in a 1:10 ammonium acetate solution using the centrifuge procedure (Thomas, 1982), filtered and analyzed by atomic absorption spectrometry (SP428; LECO Corporation, St. Joseph, Michigan, USA).

Soil physical properties

Soil resistivity, gravimetric soil moisture, and soil penetration resistance levels

Soil resistivity was measured using a resistivity meter. Gravimetric soil moisture, which calculates soil moisture using the difference between the fresh and dry weight, was calculated by first weighing wet soils, drying them in an oven at 105 °C for 72 h, then reweighing to obtain the water content (Black, 1965). Gravimetric soil measurements were expressed as a percentage. Soil penetration resistance levels were measured using a pocket penetrometer (SOILTEST, Inc., Evanston, Illinois, USA). When the penetrometer is pushed into the soil, it pushes a metal ring to scale, marking the penetration resistance value in kg cm^{-2} (Leung and Meyer, 2003).

Soil infiltration and hydraulic conductivity

Soil infiltration rate and hydraulic conductivity were measured using a mini disk infiltrometer (Decagon Devices, Pullman, WA, USA). The infiltrometer, an acrylic tube with a semipermeable plastic disk and a rubber stopper, consists of two chambers which were all filled with water. The upper chamber controls suction, whilst the lower chamber allows infiltration and a small tube inside the disk regulates the suction rate, which was set at 2.0 cm in this experiment (Latorre et al., 2013). Measurements were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24752486
© 2018, ALÖKI Kft., Budapest, Hungary

taken on the soil surface after hand removal of litter. The water infiltration rate was measured at every 30 s intervals for 5 min from the drop-in water level of the lower chamber in mL. The infiltration rate was determined from the measured cumulative infiltration rate over time using the method of Zhang (1997). The level of soil hydraulic conductivity was calculated from the infiltration data using the van Genuchten-Zhang method (Zhang, 1997, 1998). For more information regards the method of calculating hydraulic conductivity and the equation used see mini disk infiltrometer manual at Decagon Devices (2014).

Statistical analysis

Data were analyzed using STATISTICA version 13 (StatSoft, 2015). Proof of normality and homogeneity of variance were assessed on all measurements using Kolmogorov-Smirnov tests and Levene's test respectively and data were normally distributed. Comparisons on soil Ph, resistivity, total nutrient concentrations (P, N and C) and exchangeable cations (K, Na, Ca and Mg) between old field sites and natural sites were analyzed using a *t*-test since data were collected once in April. Gravimetric soil moisture content, soil penetration resistance levels, and soil hydraulic conductivity were analyzed using a repeated measures ANOVA since data were collected over 3 months on the same transect. Where ANOVAs were significant, the Tukey's honestly significant difference Unequal *n* test was used to determine the differences between site conditions and months at $p < 0.05$, $p < 0.01$ and $p < 0.001$.

Results

Soil chemical properties and pH

Soils in both old field sites and natural sites were clay (57%) and loam (43%). The soils in old field sites were very acidic with an average pH of 4.73 ± 0.15 and those in natural soils were strongly acidic with an average pH of 5.13 ± 0.20, with no significant ($p > 0.05$) difference between the two sites (*Table 2*). Similarly, soil P showed no significant ($p > 0.05$) difference between old field sites and natural sites (*Table 2*). Both soil total N and C were significantly ($p < 0.001$) higher in natural sites than in old field sites. The exchangeable cations of K and Mg were significantly ($p < 0.01$) higher in natural sites than in old field sites (*Table 2*). In contrast, the exchangeable cations of Na and Ca showed no significant ($p > 0.05$) difference between old field sites and natural sites (*Table 2*).

Soil physical properties

Soil resistivity, gravimetric soil moisture, and soil penetration resistance levels

Soil resistivity showed no significant ($p > 0.05$) difference between old field sites and natural sites (*Table 2*). The gravimetric soil moisture content varied significantly between the two sites ($p < 0.001$) and the three months ($p < 0.001$). Gravimetric soil moisture content was significantly ($p < 0.001$) higher in natural sites (8.13 ± 0.63) compared to old field sites (5.94 ± 0.31). The observed above-mentioned significant ($p < 0.001$) differences were recorded in April and June, but not in May (*Fig. 2A*). There was significant interaction ($p < 0.01$) between the site conditions and the months for gravimetric soil moisture content (*Fig. 2A*). Soil penetration resistance levels also

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24752486
© 2018, ALÖKI Kft., Budapest, Hungary

varied significantly between the two sites ($p < 0.001$) and the three months ($p < 0.001$). Significantly ($p < 0.001$) higher soil penetration resistance levels were recorded in old field sites (3.87 ± 0.07) than in natural sites (1.43 ± 0.08). These above-mentioned significant ($p < 0.001$) differences were observed in all the three months (*Fig. 2B*). Interactions between site conditions and months in relation to soil penetration resistance levels showed significant ($p < 0.001$) difference (*Fig. 2B*).

Table 2. *Soil physico-chemical properties of soil samples taken from old field sites and adjacent natural sites. Data are means ± se and t-test results are shown ($^{*}p < 0.05$, $^{**}p < 0.01$, $^{***}p < 0.001$). NS = not significant and $p > 0.05$*

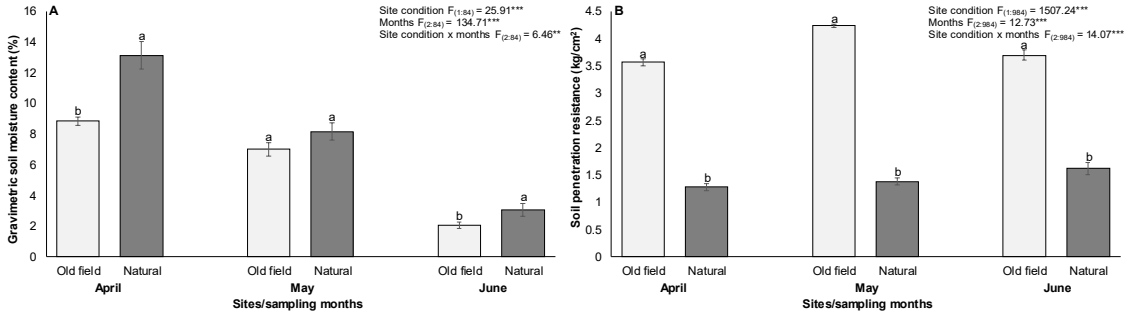

Figure 2. *Results show (A) gravimetric soil moisture content (%) and (B) soil penetration resistance levels (kg/cm^2) in soil samples taken from old field sites and adjacent natural sites. Bars represent mean ± se and results of repeated measures ANOVAs are shown ($^{*}p < 0.05$, $^{**}p < 0.01$, $^{***}p < 0.001$). Bars with different superscripts are significantly different at $p < 0.05$. NS = not significant and $p > 0.05$*

Soil infiltration and hydraulic conductivity

Cumulative infiltration rates showed no significant ($p > 0.05$) difference between old field sites and natural sites (*Fig. 3A, B, C*). The average cumulative infiltration rates for all the three months in the old field sites was 23.78 ± 1.5 cm, compared to 17.31 ± 1.1 cm in the natural sites after 5 min, and these showed no significant ($p > 0.05$) difference between the three months (*Fig. 3A, B, C*). Contrary, interactions between site conditions and months in relation to cumulative infiltration rates showed significant ($p < 0.01$)

difference (*Fig. 3A, B, C*). Soil hydraulic conductivity levels varied significantly between the two sites ($p < 0.05$), but not between the three months ($p > 0.05$). The observed above-mentioned significant ($p < 0.05$) differences between sites showed higher soil hydraulic conductivity levels in natural sites (12.99 ± 2.67) than in old field sites (8.75 ± 2.04) (*Fig. 4*). Monthly differences in soil hydraulic conductivity levels were only observed in June. Interactions between site conditions and the three months in relation to soil hydraulic conductivity levels showed no significant ($p > 0.05$) difference (*Fig. 4*).

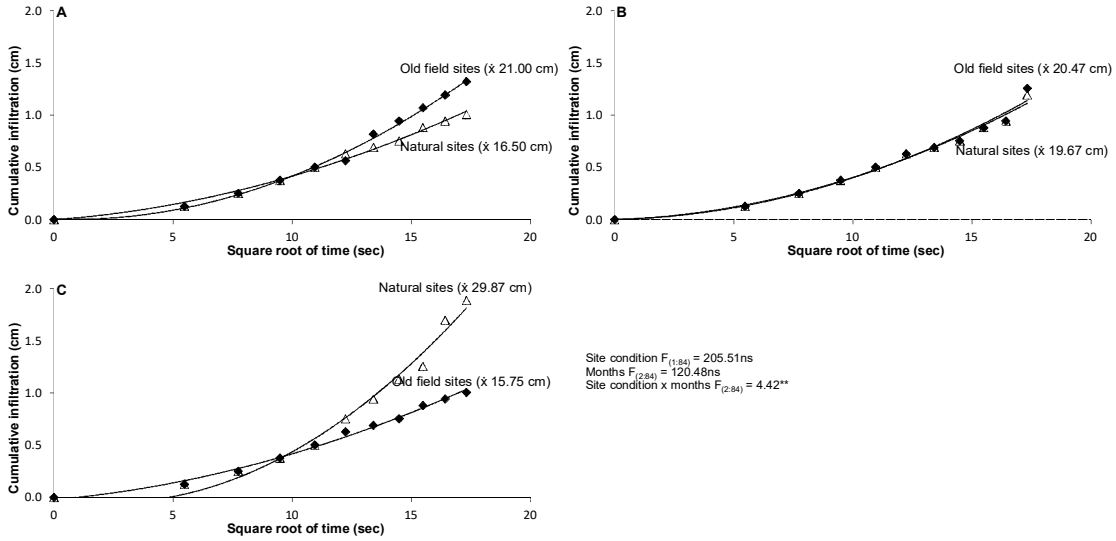

Figure 3. *Cumulative infiltration levels in soil samples taken from old field sites and adjacent natural sites for the months (A) April, (B) May, and (C) June. Results of repeated measures ANOVAs (based on average infiltration rate after five minutes) are shown ($^{*}p < 0.05$, $^{**}p < 0.01$, $^{***}p < 0.001$). NS = not significant and $p > 0.05$*

Discussion

Results of this study showed that soil properties differ between old field sites and adjacent natural sites. Soils under natural sites had higher pH, total N, total C, K, Mg, gravimetric soil moisture and were less compact compared to soils in old field sites. Contrary, soil resistivity levels, total P, Na, Ca, cumulative infiltration and soil hydraulic conductivity (except in June) showed no significant differences between the two sites. These results (for some soil chemical properties) concur with previous studies that have shown reduced soil properties in old fields with such reductions linked to years since abandonment (Odum et al., 1984; Feng et al., 2007; Cuesta et al., 2012). Odum et al. (1984) showed that soil P and Ca declined in top soils 10 years after land abandonment. Feng et al. (2007) showed mixed results, a decrease in available P and an increase in total and available N, K and total P with increase in field abandonment age. Cuesta et al. (2012) reported higher soil C, NH_4N, and available N in reforested areas than in old fields, however, they also showed no changes in soil pH, total N, P, K, NO_3N and P between the two sites. These above-mentioned studies point to current environmental conditions (e.g. type of plant species present in both old fields and natural sites) as the driver to changes in soil properties (Odum et al., 1984; Feng et al., 2007; Cuesta et al., 2012). For example, different plant communities differ in their capacity to modify soil properties, given that plant functional traits such as growth form, biomass allocation, and tissue chemistry can affect organic matter decomposition and nutrient dynamics (Carrera et al., 2009).

Changes in soil properties in our old fields could be a result of several factors that include past fertilization, vegetation recovery stage and the type of plant species present in the old fields (Feng et al., 2007; Cramer et al., 2008; Cuesta et al., 2012). Theories on soil recovery following land abandonment posit that soil nutrients especially N, C and P will be high soon after land abandonment because of previous agricultural practices (McLauchlan, 2006: Cramer et al., 2008). As the recovery process progresses and plant communities begin to occupy old fields, some soil nutrients tend to decrease due to utilization by plants (Feng et al., 2007). However, as vegetation cover and organic matter content increase, soil nutrients are likely to increase with time, although this is dependent on the type of colonizing plants. Contrary, soil nutrient losses during early vegetation recovery stages are exacerbated by soil erosion and nutrient leaching which are known to be high in less vegetated old fields (Shen and Hong, 2003).

Based on above-mentioned vegetation recovery theories in old field, we anticipated that soil properties in our 35-year old fields should be similar to those in natural sites. Contrary, we found the opposite for some soil properties. We suggest that the lack of vegetation, which is linked to increased soil erosion, could explain the observed reduced soil nutrient in old field sites. Only a few scattered pioneer trees (e.g. *Vachellia karoo* and *Senegalia nigrescens*) and grass (e.g. *Cynodon dactylon* and *Panicum maximum*) species were observed in old fields (Sheunesu Ruwanza, personal observation; see photo on Fig. 1C). Previous studies have shown that the absence of vegetation in old fields is associated with low soil nutrient levels (McLauchlan, 2006: Cramer et al., 2008), this linked to reduced litter content, organic matter, and decomposition rate. Plant litter accumulation is known to improve soil nutrients especially soil N, C, and P, this because of decomposing residual (McLauchlan, 2006; Austin and Ballaré, 2010; Bansal et al., 2014). There is considerable evidence that litter plays an important role in soil carbon storage and nutrient cycle which in turn affect soil nutrients (Aerts and de Caluwe, 1997; Marínez-Yrzar et al., 2007), this likely to be the case in reported high

soil nutrient content in natural sites which are vegetated. It is well reported that soil pH influences solubility of soil nutrients, making them available in insufficient quantities in acidic soils (Kidd and Proctor, 2001), as are the soils in Lapalala Wilderness old field sites. Besides soil pH being a factor affecting soil nutrient availability, the reported soil compaction and low soil moisture levels in old field sites can explain soil nutrient reductions. Moist and less compact soils are known to promote decomposition and release of soil nutrients as compared to dry and compact soils (Wolf et al., 2013; Van Horn et al., 2014), as are the soils at Lapalala Wilderness old field sites.

Low vegetation cover in old field sites, which created barren soil surfaces, has been reported to promote soil erosion and nutrient leaching (Lesschen et al., 2008). Loss of soils due to erosion is directly linked to a decrease in soil nutrients (Xue et al., 2011). Also, lack of vegetation which is linked to low above-ground biomass and litter can reduce C input into soils, which then influences soil micro-aggregate formation leading to accelerated soil erosion (Wan and Luo, 2003). This likely to take place in less vegetated old field sites than in vegetated natural sites. The reported compact soils in the old field sites could also facilitate erosion and nutrient leaching due to low infiltration capacity which promotes runoff. Indeed, previous studies have reported that soil compaction reduces soil porosity (Silva et al., 2008) thus causing low soil water infiltration (Nawaz et al., 2013) which subsequently increase soil erosion.

Conclusions

This study provides evidence of the poor state of soils in Lapalala Wilderness old fields, several years after land abandonment. The persistence of these soils in a poor state may hamper both soil and vegetation recovery. Therefore, active soil manipulations techniques should be considered if soils in Lapalala Wilderness old fields are to be improved. Different techniques to improve soil properties in old fields can be used e.g. soil nutrient manipulation (fertilizers or organic matter addition), top soil removal and soil transfer (Blumenthal et al., 2003; Ruwanza et al., 2012). The above-mentioned approaches have been shown to improve soil properties in old fields (Holmes, 2008; Blumenthal et al., 2003; Wubs et al., 2016; Bulot et al., 2017). Not only do they improve soil properties, they also steer plant community recovery (Wubs et al., 2016). However, the feasibility of these above-mentioned techniques in Lapalala Wilderness old fields needs to be tested.

Acknowledgements. This research study was funded by the University of Venda under the research and development directorate. We are grateful to the owners, the managing director (Mr. Anton Walker), the conservation manager (Mr. Hermann Muller) and the research coordinator (Dr. Annemieke van der Goot) at Lapalala Wilderness for permission to conduct my research work and for logistical help during our field work.

Abstract. Paddy soils are a main soil resource for food production and they cover a large area of the world's surface. A geochemistry study was performed on a catenary sequence of Paddy and Non-Paddy soils in the lowland and upland areas of Ghaemshahr City in Mazandaran Province, Iran. 10 soil profiles were investigated and then, a comparison was made between the Paddy and Non-Paddy soils based on their geochemical compositions and developments. Soil clay mineralogical analysis showed that the Non-Paddy soils had a large amount of vermiculite, whereas smectite was the dominant clay mineral of the Paddy soils. The cation exchange capacity, clay content, and bulk density are higher in the Paddy soils. Rice cultivation increases the amount of amorphous Fe and decreases the amount of free Fe-oxide. The results of free Fe-oxide and amorphous Fe assessments, revealed that the Non-Paddy and upland soils were more developed than the Paddy and lowland soils. The mean concentrations of the major elements did not show any significant differences between the two types of soils. The mean values of all the heavy metals, except for Mn and As, in the Paddy soils were lower than those of the Non-Paddy soils. The reason for the reduction of heavy metals in the P compared to NP soils was their probable relationships with Fe/Mn oxide minerals and subsequent leaching. Based on principal component analysis, the differences between the Paddy and Non-Paddy soils were related to Mn and Fe group elements. The results indicated that the concentrations of the elements and other properties of the Paddy soils were dependent on the soil parent materials, especially on the textures of the sedimentary layers.
Keywords: *geochemistry, heavy metal, principal component analysis, soil development, smectite*

Introduction

The chemical composition of soil in primary stage of pedogenesis, will be reflect the chemical composition of the parent material, whereas the chemical composition of adult soils highly controls by the factors of weathering environment (Thanachit et al., 2006). Rice is the main source of food for more than half of the world's population and is cultivated on almost 155 million hectares in 114 countries (Kögel-Knabner et al., 2010). Paddy soils are anthropogenic soils widely distributed in eastern Asia and some other parts of the world (Huang et al., 2015). The formation of P soil, which is hydromorphic, is severely influenced by anthropogenic factors (Gong, 1983). It is not a natural soil and can be strongly affected by such management techniques as leveling, tillage, puddling,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

submerging (Wissing et al., 2013), and the use of fertilizers. Its formation is also enforced by a special management, which can lead to its characteristic redoximorphic features (Kölbl et al., 2014). Frequent flooding leads to anoxic situation in the soil and decrease rates of organic matter decomposition (Sahrawat, 2005), while it exacerbates mineral weathering (Nanzyo et al., 1999) and leaching process.

In paddy rice management, soils are held submerged for several months of the year and as a result, their geochemical, micromorphological, and mineralogical features undergo some changes triggered by periodic submergence and drainage. Moreover, P soils grow from various parent materials and may be extremely altered by their chemical compositions, mineralogies, and other properties, such as texture (Kyuma, 2004; Chandrajid, 2005; Prakongkep et al., 2008). Hasannezhad et al. (2008) and Sano et al. (2006) reported that clay mineralogy is further influenced by its parent material rather than by redoximorphic conditions. In contrast, Hasannezhad et al. (2008) found an enhanced formation of smectite that was caused by the hydromorphic conditions of the P soils developed on alluvial materials. Elements concentrations in P soils have been studied by Chandrajith et al. (2005), Prakongkep et al. (2008), and Halim et al. (2015). Prakongkep et al. (2008) discovered that the concentrations of the elements and other properties of Thai P soils frequently depended on their parent materials, especially on the textures of the alluvial layers.

Many P soils become contaminated with heavy metals (Wong et al., 2002; Kyuma, 2004), while some useful trace elements become deficient due to geochemical variations or crop harvest (Kon et al., 2001). The affluence of trace elements in tropical Asian P soils is significantly diverse. Trace elements in agronomical soils mainly depend on the geochemical compositions of their parent materials during the primary stage of tillage (De Temmerman et al., 2003). Mitchell (1974) reported that the total amounts of trace elements in soils basically depend on the types of their parent materials and on which pedogenic processes occur.

Halim et al. (2015) studied the heavy metals of P soils in Bangladesh and reported that the average amounts of Zn, As, Mn, Ni, Cu, Pb, and Cr found in the P soils and sub-soils were less than those causing the mean and moderate pollutions of the selected soils of the world. Domingo and Kyuma (1983), Wang et al. (2003), and Wong et al. (2002) investigated the concentrations of elements in the P soils of many tropical Asian countries and found significantly different abundances of trace elements in them. Each region was rich in some particular elements. Although the concentrations of trace elements in different soils and plants have been measured in numerous studies in several parts of the world (Kabata-pendias, 2011), little research has been conducted in this field in Iran.

Therefore, this paper aimed to firstly evaluate the concentrations of the major and trace elements in the studied P soils and secondly compare the P and NP soils under study based on geochemistry and soil development.

Material and methods

Study area and sampling

The study area was located in Ghaemshahr, Mazandaran Province in northern Iran (*Fig. 1*). Its average annual temperature and precipitation are 16.1°C and 734 mm, respectively. The soils were developed under xeric and thermic soil moisture and temperature regimes, respectively (Banaei, 1998). The parent materials in the studied

area were derived from alluviums altered from primary rocks content calcite, dolomite and loess moved to this flatland. 10 representative profiles were selected along a catena based on their topography for this research: 5 pedons for P and 5 others for NP soils. Soil colors were determined by Munsell color system (Munsell, 2014). The soils were defined and classified based on Soil Taxonomy (Soil Survey Staff, 2014; *Table 1*).

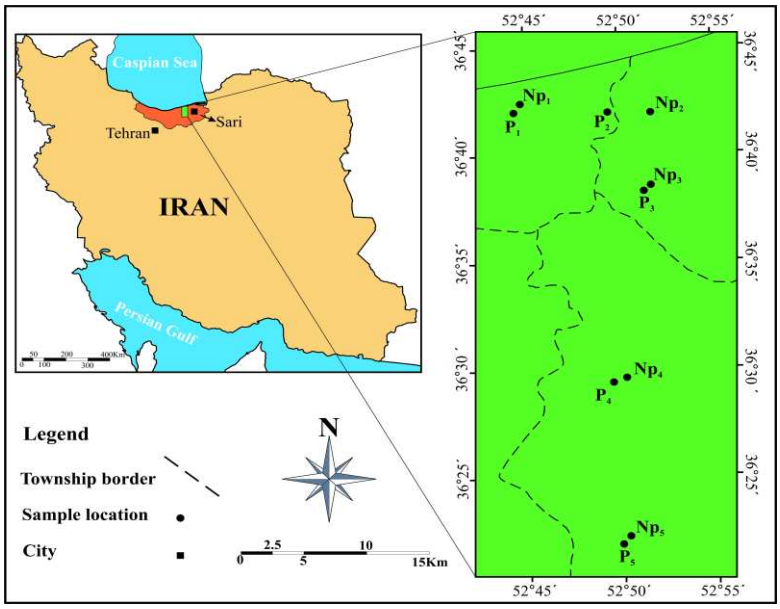

Figure 1. *Location of the study area and sampling sites along the 10 Pedons are indicated*

Physico-chemical analysis

Particle-size distribution was defined by the method of Bouyoucos hydrometer (Bouyoucos, 1962). The organic carbon contents of the soils were obtained through wet oxidation by using chromic acid and via return titration by using ferrous ammonium sulphate based on the method described by Nelson (1982). The pH of the soil samples was measured with a pH electrode in a suspension of 1:1 (soil: H_2O). Sodium acetate (NaOAc) was applied at pH 8.2 to evaluate CEC (Chapman, 1965). A titration method was employed to assess carbonate content (US Salinity Laboratory Staff, 1954). In addition, the method of Mehra and Jackson (1960) was used to evaluate dithionite-extractable Fe (Fe_d) for the bulk soil samples of < 2 mm. The taken samples were dried at 105°C for 24 h in an oven and weighted to determine Bulk Density (BD) through the method of paraffin sections (Blake and Hartge, 1986). Amorphous Fe (Fe_o) was extracted by using 0.3 M of ammonium oxalate solution (pH 3) in a dark place (McKeague and Day, 1966).

Mineralogical analysis

The method of Mehra and Jackson (1960) was utilized to eliminate the attaching chemical factors and dissociate the clay fractions (Kittrick and Hope, 1963). For clay discretion (< 2 μm), centrifugation of the iron-lacking soil samples at 750 rpm was done for 5.4 min (Kittrick and Hope, 1963). A D8 ADVANCE X-ray (Bruker) diffractometer was used to perform an X-ray analysis on the fine and coarse clay fractions (Jackson, 1975). To make a credible comparison between the Relative Peak Intensities (RPIs) of

© 2018, ALÖKI Kft., Budapest, Hungary

the different samples, we made use of equal concentrations of the clay suspensions. 001 reflections were considered after Mg and K saturations and Ethylene Glycol (EG) salvation. Perusing of the K-saturated samples was followed after performing the drying and heating processes at 330 °C and 550 °C for 4 h. An overnight treatment of the samples with 1 N HCl solution at 80 °C was carried out for kaolinite identification in the presence of trioctahedral chlorite. A semi-quantitative assessment of the clay minerals was conducted based on the respective peak areas obtained from X-Ray Diffraction (XRD) in the glycol-treated samples (Johns and Grim, 1954).

Geochemical analysis

The geochemical analyses of the soil samples were done via X-Ray Fluorescence (XRF) spectroscopy of the compacted powder/pellets (Nisbet et al., 1979) and aqua regia digestion with a blend of $HClO_4$, HNO_3, HCl, and HF at 200 °C followed by ICP/OES and ICP/MS for the major and trace elements, respectively. Also, many trace elements were analyzed through Instrumental Neutron Activation Analysis (INAA) (Hoffman, 1992). The geochemical analyses were performed at the Actlabs laboratory (Ontario, Canada).

Statistical analysis

The concentration of elements and physicochemical properties including texture and CEC of P and NP soils were statistically analyzed using Principle Component Analysis (PCA) with the SPSS (version 21). Also Independent Samples T-test was applied to compare the concentration of elements in P and NP soils and if there were significant differences between two land uses based on the concentration of elements by the SPSS (version 21).

Results and discussion

Physico-chemical properties

The major physicochemical and morphological properties of the studied soils are presented in *Table 1*. As depicted in this table, the soils have Munsell colors ranging from 2.5Y to 10YR. The P soils were poorly drained since displaying a 2.5Y hue resulted from the annual redoximorphic conditions over many years. The evidence showed that endosaturation was responsible for the redoximorphic properties of the soils. A considerable diversity was observed between the textures of the P and NP soils, from clay to silty clay loam. A higher amount of clay was found in the lowland area (*Table 1*). This could be explained by the depositions of the clay-size particles originated from the upland area (Khormali et al., 2009). Wilding et al. (1982) reported that soil texture in a lowland area is finer than in any other locations. According to *Table 1,* Profile NP_5 has a coarser texture compared with the other profiles (SiCL). The other soils have a relatively heavy texture (silty clay to clay). $CaCO_3$ percentage ranges from 2% in the C horizon of NP_4 to 27% in the A horizon of P_4. BD showed considerable differences in the 2 selected land uses. BD was higher in the P than in the NP soils. P_2 and NP_2 had the highest and lowest contents of BD, respectively. Soil compaction caused by tillage processes had increased BD in the P soils. According to Dang et al. (2002), tillage practices decrease soil Organic Matter (OM) and result in a higher BD and lower total porosity.

Bar graphs of mean values of Fe_d and Fe_o for surface horizon of soil profiles are shown in *Figure 2*. In most soils, based on morphological properties, pedogenic Fe and clay content, soil age is estimated (Costantini and Damiani, 2004). Dethier et al. (2012), reported that, the Dominant forms of Fe in soils, are Fe_t, Fe_d, Fe_o. Therefore, (Fe_d-Fe_o) indicates crystalline form of Fe, Fe_o/Fe_d represents the degree of crystallinity of Fe oxides, and finally (Fe_d-Fe_o)/Fe_t indicates the ratio of crystalline to total Fe (Schaetzl, 2005). Rezapoor et al. (2009) studied different forms of Fe oxides and their distribution in calcareous soils in Northwest of Iran, and reported that, with increasing weathering, Fe_d increases and Fe_o/Fe_d decreases. In hydromorphic condition and deficiency of oxygen, Fe is converted to Fe (II), and in this condition, the possibility of forming a crystalline Fe oxides is lower, resulting in a higher Fe_o/Fe_d ratio. In this study, paddy soils have a higher amount of Fe_o compared to non-paddy soils, whereas, non-paddy have a higher content of Fe_d. B_k horizon of NP_5 has a higher content of Fe_d and lower content of Fe_o, whereas, C_g horizon of P_1 has a lower content of Fe_d and a higher content of Fe_o. The studied paddy soil samples have higher contents of Fe_o results in higher ratios of Feo/Fed compared to non-paddy soils. Along the catena, from lowland to upland, this ratio always decreases, which is probably an indication of higher weathering in upland soils compared to the lowland soils.

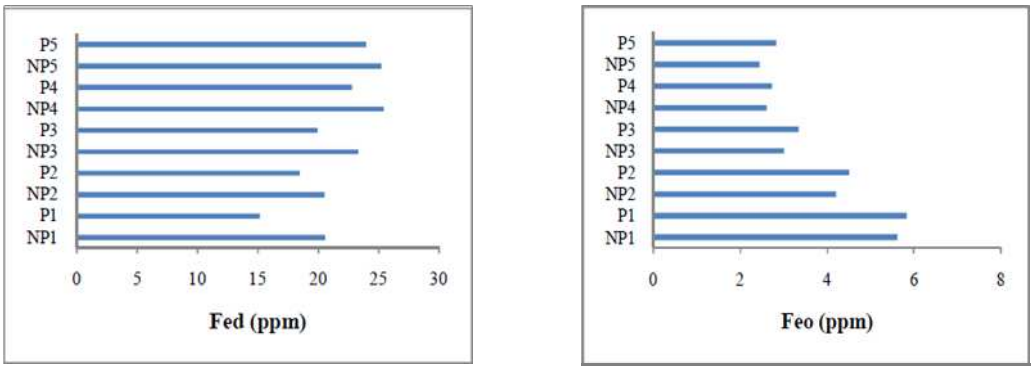

Figure 2. *Bar graphs of mean values of Fe_d and Fe_o for surface horizon of soil profiles*

Mineralogical characteristics

Figure 3 demonstrates the results of X-ray diffractograms recorded in the selected P and NP soils. Two cases of peaks were shown for almost identical results. As can be observed, illite, chlorite, kaolinite, smectite, and vermiculite exist in the clay fraction.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24872501
© 2018, ALÖKI Kft., Budapest, Hungary

The main mineral found in the P soils was smectite whereas in NP soils was illite. Illite and chlorite as clay minerals are mostly seen in areas with a limited process of soil formation (Wilson, 1999). Their existence in parent materials mostly determines their abundance in soils. The P soils in this study displayed a higher amount of smectite due to their several months of poor drainage and saturation each year (*Fig. 3b*). In these conditions, smectite neo-formation had occurred due to the reduction of some iron in the presence of some soluble ions like Al, Mg, and Si coming from the adjacent uplands (Borchardt, 1989). Small amounts of kaolinite were also found in all the studied soil profiles. In the NP soils, vermiculite was present in large amounts (*Fig. 3a*). Vermiculite occurrence in these soils was mainly caused by high leaching conditions and K removal from mica (Douglas, 1989).

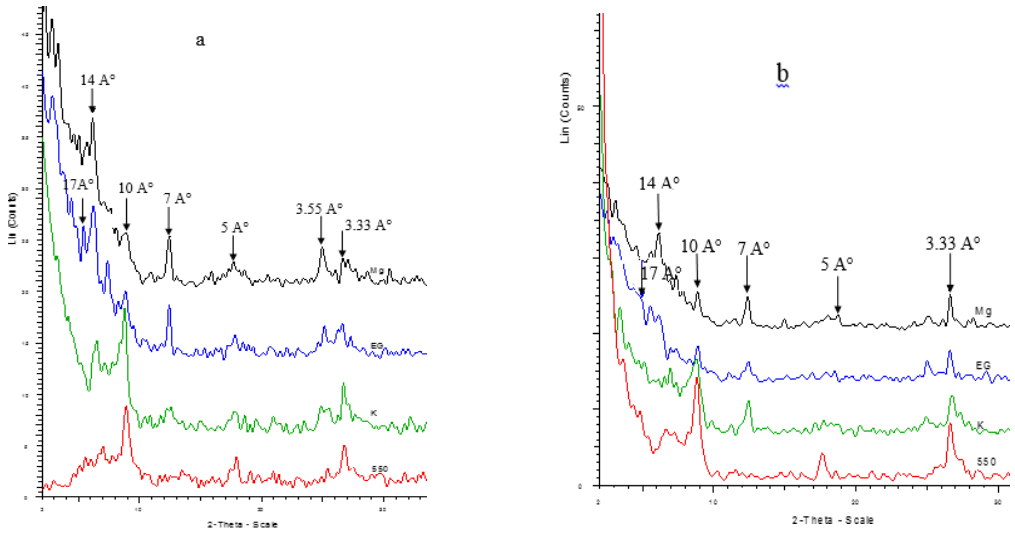

Figure 3. *X-Ray diffraction patterns of clay fraction for the representative soil profiles. (a) Bkg_1 horizon of NP_2 and (b) Bwg horizon of P_2*

Geochemical analysis

The full geochemical analyses of the soils are not demonstrated because of the large data set obtained, but the mean concentrations of the P and NP soils are exhibited in *Table 2*. Si, Al, Ca, Fe, Mg, and K were the most elements found in both P and NP soils. None of the major element concentrations showed any significant differences between the P and NP soils. The contents of Ba, Cs, S, and Zr in the P soils were higher, but Br and Rb amounts were lower than those of the NP soils. The mean values of all the heavy metals in the P soils, except for Mn and As, were lower than those of the NP soils.

Strong associations were found between Fe/Mn oxides and other heavy metals in the P soils. In paddy rice management, soils are commonly submerged and thus, excessive soil water may elevate leaching and migration of soluble heavy metals. Talyor and Mckenzie (1966) discovered that Co content was dependent on Mn oxide minerals. Therefore, the lower heavy metal contents in the P compared to the NP soils could be ascribed to Fe/Mn oxide minerals.

The mean concentrations of Si, Mn, Mg, As, Co, Cr, Cs, Cu, Ni, and Rb in the studied soils were higher than the amounts reported for normal surface soils worldwide

(Essington, 2004; Kabata-Pendias, 2011), whereas the mean values of Mn, Ti, As, Co, Cr, Cu, Ni and Zn were higher than the amounts reported for the other contaminated P soils (Wong et al., 2002; Wang et al., 2003; Chandrajith et al., 2005). Only Pb concentration was lower than those of the global and other unpolluted P soils. The amounts of other elements in the studied P soils were comparable to the values obtained for the normal surface soils and P soils in the world. Pb concentration is lower than both worldwide and other unpolluted paddy soils. In comparison to the critical soil concentration values established, only Cr values were higher (Alloway, 1995).

Table 2. *The mean values of some oxides and elements in studied P and NP soil samples, mean values for uncontaminated P soils, mean values of normal surface soils worldwide and critical soil concentration for contaminated soils*

Independent Samples T-test

An Independent Samples T-test was applied to compare the concentration of elements in P and NP soils and if there were significant differences between two land uses based on the concentration of elements. Levene's test was conducted to evaluate homogeneity of variance. Results are presented in *Table 3*. As seen in *Table 3,* Result of Levene and T-test of all elements were not statistically significant ($p > 0.05$). The results indicated that there was no significant difference between the mean (M) and standard deviation (SD) of concentration of elements in P and NP soils.

Parent material uniformity

The relationship between the total amounts of Ti and Zr was applied as an index of uniformity for soil parent materials (Alonso et al., 1991). As shown in *Figure 4,* P_1 and NP_1 have the Ti/Zr ratios of about 56-58 and 59-60 through their profiles in the lowland

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_24872501
© 2018, ALÖKI Kft., Budapest, Hungary

area, respectively. In P_3 and NP_3, Ti/Zr ratios are relatively constant around 52-53 and 56-59, respectively. Finally, in the upland region, Ti/Zr ratios in P_5 and NP_5 are nearly 47-54 and 48-51, respectively. Few differences were observed in Ti/Zr ratios in the C compared to the other horizons, which demonstrated uniformity of the parent materials. Nable et al. (1999) and Marques et al. (2004) reported that the slight variations of 5 and 16 units respectively in Ti/Zr ratios in the profiles indicate the uniformity of parent materials. Therefore, the studied soil parent materials were uniform.

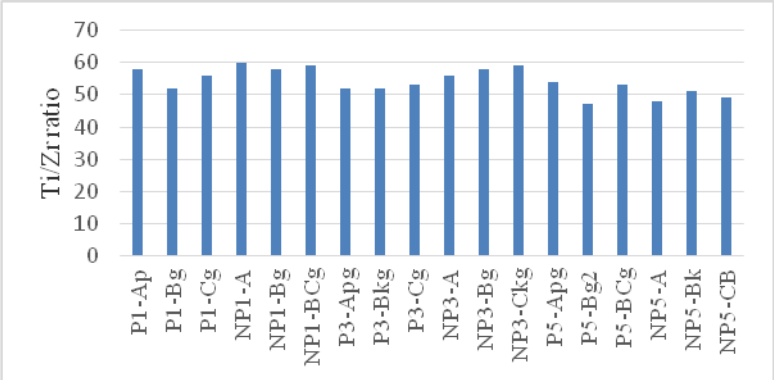

Figure 4. *Bar gragh of Ti/Zr ratio of studied paddy and non-paddy soils*

Principal component analysis

Principal component analysis (PCA) was applied to assess the elements under similar geochemical treatments and group the soil samples according to their geochemical associations (Weber and Davis, 1990; Bellehumeur et al., 1994). PCA of the concentrations of the introduced elements and physicochemical properties, including texture and CEC, were applied for all the P and NP soils. The PCA results of the concentrations of the elements and physicochemical properties of the NP soils are displayed in *Figure 5b*. 2 factors illustrated only 72% of variation in the data. Finally, 4 affinity groups were identified. The first group was composed of Si, Zr, and Na relevant to the textures of the soils. Quartz (SiO_2) was the basic mineral in the sand fraction. Zr was a residual element in the soils, the main (Stiles et al., 2003; Kabata-Pendias, 2011) and abundant (Lukashev and Pietukhova, 1974) mineral of which is zircon ($ZrSiO_4$) in sandy soils. The second group contained Ca, Co, and Fe. The reasons for the presence of Ca in this group were unknown. The third group included CEC, Zn, Cs, and Br and the last group was comprised of clay, Al, K, Ni, Mg, Cr, Sr, and Ba. This group was associated with clay content since the mentioned elements were parts of oxides and clay minerals (Kabata-Pendias, 2011; Sterckeman et al., 2006).

The PCA results of the concentrations of the elements and physicochemical properties of the P soils are exhibited in *Figure 5b*. 68% of variation in the data for these soils was illustrated by 2 factors. 3 groups of properties were distinguished. The first group contained sand, Na, Zr, and Si, which were linked to the textures of the soils. The second group consisted of CEC, clay, Al, Fe, K, Ni, As, Cs, Co, Pb, Zn, Rb, Ba, Mn, and Mg. Al, K, Rb, and Cs were related to feldspar and clay contents (Sterckeman et al., 2006; Kabata-Pendias, 2011). Being parts of the group of subordinate oxides, Mn, Pb, Zn, Ni, Zn, Ni, Co, As, and Cu were linked with Fe since they can be exchanged with Fe in the oxide structure (Kabata-Pendias, 2011). Manganese is responsible for the

great degree of assembly of Mn concretion with some trace elements, especially with Pb, Cr, and As. Moreover, the oxidation of these metals by Mn oxides probably controls their redox behaviors in soils (Bartlett, 1986). The third group included Ca, Sr, Br, and S. Strontium belongs to the alkaline earth metals and has the same behavior as Ca. Its physical properties, particularly the size of its ionic radius, are partly similar to those of Ca, indicating their possibility of being replaced with each other (Kabata-Pendias, 2011).

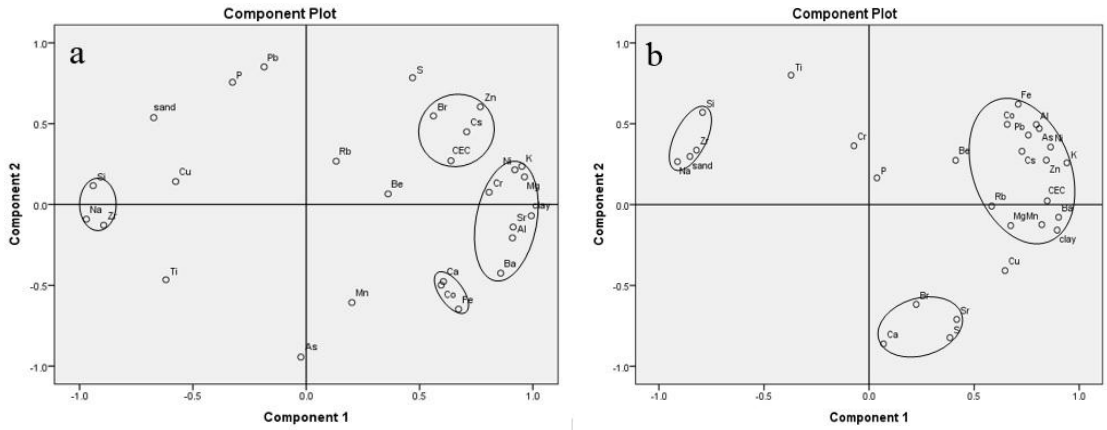

Figure 5. *PCA results for the chemical composition and physicochemical properties of studied soils: (a) distribution of elements and soil properties of non-paddy soils (b) distribution of elements and soil properties of paddy soils*

Based on PCA, the difference between the P and NP soils was related to the group elements of Mn and Fe. In the P soils, most of the heavy metals were gathered in one group and linked with Fe and Mn, while they were diffused in the NP soils. Mn and Fe are the most frequent metals in the lithosphere and thus, their oxides and hydroxides cause the solubility or alluviation of heavy metals in soils (Jounes and Jacobson, 2009). These oxides and hydroxides also play a main role in As, Pb, Cu, Zn, Cr, and Ni preservations in soils (Aydinalp and Marinova, 2003).

Conclusions

This research revealed that the concentrations of the elements and other properties of P soils depend on soil parent materials, especially the textures of sedimentary layers. Ti/Zr ratio confirmed uniformity of the parent materials along the catena and within the profiles. Profiles P_5 and NP_5 with a deep water table were the most weathered soils based on Fe_d and Fe_o values. The studied profiles had higher Si amounts and lower Ca, Mg, and K contents compared with the other pedons of the catena; however, Al and Fe amounts were uniform. Profiles P_1 and NP_1 were less weathered because they had the lowest positions in the landscape with shallower water tables. In the collation between the P and NP soils, the Ca, S, Sr, Ba, and Zr contents of the former soils were found to be higher than those of the latter soils. Contrarily, the amounts of Cr, V, and some heavy metals, including Pb, Ni, Cu, and Zn were higher in the latter soils compared to those of the former soils. The reason for the reduction of heavy metals in the P compared to NP soils was their probable relationships with Fe/Mn oxide minerals and

subsequent leaching. Clay mineralogy revealed that Smectite amount was higher in the P soils because of its poor annual drainage and saturation for a long period of time. Vermiculite was the dominant clay mineral under well-drained conditions. There were two reasons for finding no significant differences between the P and NP soils under study based on geochemical properties: 1) short period of rice cultivation; and 2) lack of any significant differences between them in terms of drainage.

We suggested that complementary studies, including microprobe analysis, be performed on thin sections of the studied soils in order to determine if the smectite in clay fraction of soils is formed from other minerals deformation or in situ formation.

Abstract. Earthworm is the crucial actor in vermicompost production. Separating the worms with the least harm will decrease the costs of the vermicompost production. One of the key factors in using heat for separation of the worms is the determination of the thermal diffusivity of vermicompost. The thermal diffusivity of vermicompost has been determined by using a one-dimensional (1D) Fourier equation applied to a cylinder. The measurements have been carried out at 40, 50, 60, 70 ºC temperature levels and moisture contents of 10, 20, 30, 40, 50 % (wet base). The experiments have been conducted by heating vermicompost in an insulated box. The thermal diffusivity is estimated by keeping time–temperature records. The values of the thermal diffusivity of vermicompost ranged from 1.3973×10^{-7} to 2.861×10^{-7} m^2 s^{-1}. By increasing the moisture content of vermicompost from 10% to 50%, the thermal diffusivity of vermicompost is decreased. The thermal diffusivity of vermicompost increases with increases in the temperature from 40 ºC to 70 ºC. The relationship between thermal diffusivity (α), moisture content (MC), and temperature (T) is described using a polynomial model, with the coefficient of determination being 0.99.
Keywords: *Fourier's equation, moisture content, polynomial model, temperature, cooling time*

Introduction

One of the most important methods for processing municipal wastes is recycling them to vermicompost. Because of this process, in addition to reducing health and environmental problems, significant quantities of organic fertilizers, known as vermicompost, are produced. Vermicompost is a biological and organic fertilizer, which is produced by means of constant and calm passing of decaying organic matter from the digestive tract of earthworms and the excretion of these substances from the worm body (Ismail et al., 2003). These materials will be smeared with mucus, vitamins, and enzymes while passing through the body of the worm and will be ultimately enriched as an organic fertilizer. This type of fertilizer can be produced and used for building and improving soil nutrients. Therefore, vermicompost is a worm extract with a percentage of organic matter and food and carbohydrate substrates (Sathe, 2005). Farmers use this type of compost, which is a mixture of processed organic matter, due to its unique and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

specific modification effects on the physical, chemical, and biological properties of soil and consequently growth and increase of the product (Manna et al., 2003). Effective separation of earthworms from the organic media after completing a vermicomposting batch process could increase the rate of waste bioprocessing by earthworms and minimize the monetary investment in earthworms for such operations.

There are various methods for separating worms from vermicompost. Among them are mechanical separation, reducing the moisture of the vermicompost, using infra-red rays and using electric shock (Chaoui and Keener, 2008). The mechanical separation is of little efficiency and kills a large number of worms. Moisture Reduction is time-consuming and needs large space(Fieldson, 1988). Using infra-red rays and electric shock kills too many worms.(Chaoui and Keener, 2008)

In the controlled-heat and layered method of separation the worms are made to move to layers with lower temperature and with their arrival on the surface they can be separated from the vermicompost. The thermal properties of vermicompost are needed to predict heat transfer and increasing temperature in vermicompost for separating earthworms by heating from the organic media after completing vermicomposting.

The physical significance of thermal diffusivity is associated with the propagation of heat into the medium during temperature changes with time. The higher the thermal diffusivity, the faster the propagation of heat into the medium (Jain and Pathare, 2007). In any constant temperature of the thermal source, the more the value of the thermal diffusivity coefficient, the faster the object gets into thermal stability. Thus, there will be fewer temperature differences in the object (Bairi et al., 2007).

The measurement of thermal diffusivity can be divided into two groups: direct measurement and measurement by the values of thermal conductivity, namely specific heat and density, in an experimental manner (indirect prediction). The best method is the direct measurement of thermal diffusivity (Dickerson, 1965). There are four common methods to determine the thermal diffusivity experimentally: least squares estimation, use of heat penetration data, use of time–temperature charts, and use of analytical solutions (Singh, 1982). The thermal diffusivity of cheddar cheese was determined by using the analytical solution for an infinite cylinder with experimentally obtained time–temperature data (Marschoun et al., 2001). The thermal diffusivity of pet food was measured by center temperature data (Kee et al., 2002). The thermal diffusivity of Marquis wheat seed was studied in bulk at 9.2% (dry base) of the moisture content, and the value of thermal diffusivity was determined by indirect method (Babbit, 1945). The thermal diffusivity of rough rice was obtained in the moisture range of 12% to 20% (d.b) (Wratten et al., 1969). The thermal diffusivity of dairy cattle manure was measured in different moisture and temperature range (Amin-nayyeri et al., 2009). The thermal diffusivity of the sawdust was determined by using heat conduction and specific heat capacity in an indirect way (Ahn et al., 2009).

The objectives of this study were to determine the thermal diffusivity of vermicompost and to develop a mathematical model of the thermal diffusivity of vermicompost within the experimented temperature and moisture content limits. The research results have potential applications in separating earthworms by heating from the organic media after completion of vermicomposting.

Material and Methods

Sample preparation

The vermicompost used in this study produced at the Vermicompost production unit located at the Vermicompost Production Industrial Center in Tehran, Iran.

The particle size of the tested vermicompost was 38.9% with a size of 0.3, 44.85% with a size of 0.6 and 16.25% with a size of 1.18 mm and was determined as powder particles.

To determine the initial moisture content of the vermicompost, 100 g of vermicompost according to ASAE S358.2 standard was placed in the oven at 103 ± 3 ° C for 48 hours. (ASAE Standards S269.4, 1998).

Experimental setup

The vermicompost sample was put in an aluminum cylinder with a length of 150 mm and diameter of 7.5 mm. The very thin wall of the cylinder had very low thermal resistance to conduction. A K-type thermocouple was fixed on the central axis and at the middle length of the sample-holder cylinder to sense the central temperature of the sample.

The cylinder was put into water with a certain temperature until the sample temperature was changed by the equilibration on the water. Next, the sample-holder cylinder was cooled by a water bath at temperatures of 30, 40, 50, 60 ºC for the initial temperature of the sample (T_0) 50, 60, 70, 80 ºC, respectively. The temperature of the sample center was measured and recorded in a data logger (CHY 502 A, Taiwan) at an interval time of 2 min. *Figure 1* shows the schematic of the apparatus used for measuring the thermal diffusivity of the vermicompost sample.

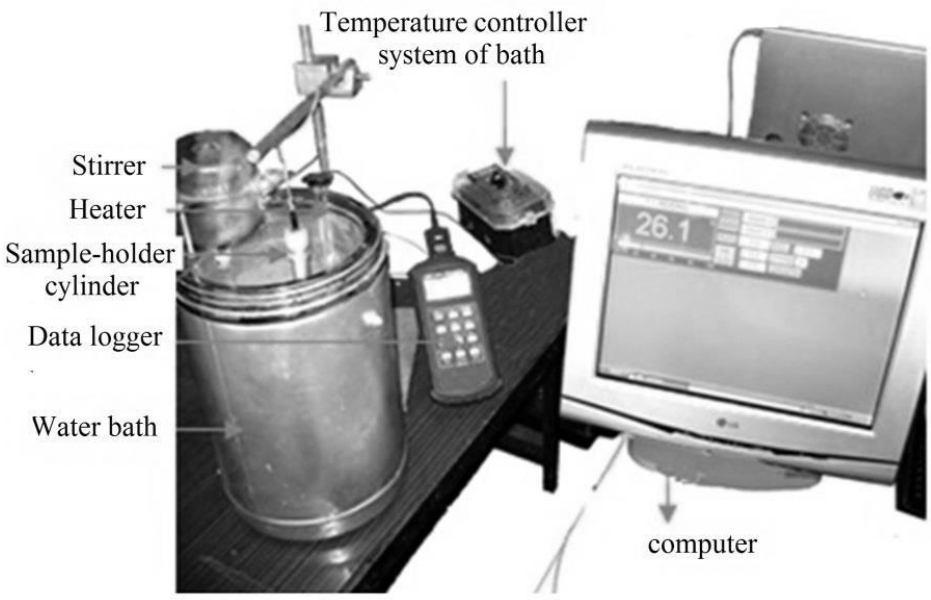

Figure 1. *Schematic of the apparatus used for measuring the thermal diffusivity of vermicompost*

Theoretical principle

Thermal diffusivity includes the effects of properties like mass density (ρ), thermal conductivity (k), and specific heat capacity (C_p) this is described by Equation 1 (Mohsenin, 1980).

$$\alpha = \frac{k}{\rho C_p} \quad \text{(Eq.1)}$$

When heat is transferred by conduction through solid material it generates a temperature field can be described by Fourier equation in cylindrical coordinates:

$$\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial T}{\partial r}\right) + \frac{\partial^2 T}{\partial x^2} = \frac{1}{\propto}\frac{\partial T}{\partial t} \quad \text{(Eq. 2)}$$

Where: T is temperature in ^{o}C; r is radius in m; x is axial coordinate in m; a thermal diffusivity in $m^2\ s^{-1}$; and t is time in s.

Considering the very small internal temperature gradient, the derivative $\frac{\partial^2 T}{\partial x^2}$ is ignored. As the cylinder is long enough to consider that the heat exchanges are made quasi-exclusively through the lateral surface, the problem is simplified and becomes one-dimensional (1D). Thus, the Equation 2 can be rewritten as Equation 3:

$$\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial T}{\partial r}\right) = \frac{1}{\propto}\frac{\partial T}{\partial t} \quad \text{(Eq. 3)}$$

Equation 3 can be solved as Equation 4 (Bairi and Laraqi, 2003):

$$\theta = \frac{T_m - T_e}{T_0 - T_e} = 2\sum_{n=1}^{\infty} exp(-\varphi_n^2 Fo_c)\frac{1}{\varphi_n}\frac{J_1(\varphi_n)}{J_0^2(\varphi_n) + J_1^2(\varphi_n)}J_0(\varphi_n r^*) \quad \text{(Eq. 4)}$$

Equation 4 can become linear after a long time and then only the first term of the series solution can be acceptable to solve it. Thus, Equation 4 can be rewritten as Equation 5:

$$\theta = \frac{T_m - T_e}{T_0 - T_e} = \beta\ \exp\left(-\varphi_1^2 F_0\right) \quad \text{(Eq. 5)}$$

Where the constant β is given by Equation 6:

$$\beta = 2\frac{1}{\varphi_n}\frac{J_1(\varphi_1)}{J_0^2(\varphi_1) + J_1^2(\varphi_1)}J_0(\varphi_n r) \quad \text{(Eq. 6)}$$

The Fourier number is given by Equation 7:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_25032512
© 2018, ALÖKI Kft., Budapest, Hungary

$$Fo_c = \frac{\alpha t}{r^2} \quad \text{(Eq. 7)}$$

Therefore, Equation 5 can be rewritten as Equation 8:

$$\theta = \frac{T_m - T_e}{T_0 - T_e} = \beta \exp\left(-\varphi_1^2 \frac{\alpha t}{r^2}\right) \quad \text{(Eq. 8)}$$

The parameters are defined below:

θ: dimensionless temperature ratio, T_0: initial temperature of the vermicompost in ºC, T_m: temperature of the center of vermicompost in ºC, T_e: temperature of the environment in ºC, Fo_c: Fourier number in dimensionless, r: radial cylindrical coordinate, φ_n, φ_1: positive roots of the Bessel's equation, J_0 and J_1: the Bessel function of first kind of order 0 and 1, r^*: the reduced radius ($r^* = r/R$), and t: time in s.

The value for the first root φ_1 is 2.405. Thus, thermal diffusivity can be calculated by measuring the slope of Equation 9 (Bairi et al., 2007):

$$\alpha = \frac{1}{\tau}\left(\frac{R}{2.405}\right)^2 \quad \text{(Eq. 9)}$$

Where τ is the time constant.

Results and Discussion

The logarithmic dimensionless temperature ($Ln\theta$) was plotted against the cooling time for the vermicompost sample with four variable temperatures with the moisture content of 40% (*Fig. 2*). *Figure 2* represents the linear relationship with a negative slope between the logarithmic dimensionless temperature and the cooling time for four temperature levels. Moreover, the values of slope ($/A/$) increased with decreases in the temperature.

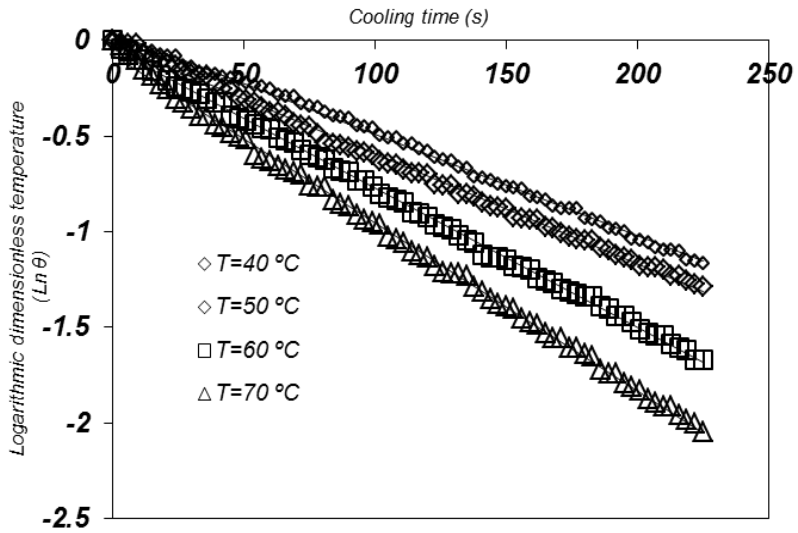

Figure 2. *Evaluation of dimensionless temperature (Lnθ) during the cooling time for vermicompost at 40% and different temperatures*

A regression analysis was performed to show the linear relationship between the cooling time and the logarithmic dimensionless temperature. *Table 1* illustrates the parameters of the linear relationship and correlation coefficients between logarithmic dimensionless temperature and cooling time. The coefficient of determination, R^2, ranged from 0.9924 to 0.9996, and the standard error was found to vary from 0.01821 to 0.09386. The higher R^2 and lower standard error represent the higher accuracy of the computation of thermal diffusivity. According to *Table 1*, the value of slope (*|A|*) increases with increases in temperature, while it decreases with increases in the moisture content from 10% to 50% on wet base (w.b).

The thermal diffusivity was calculated by using Equation 9. The value of thermal diffusivities, α, in $m^2\ s^{-1}$ ranged from 1.3973×10^{-7} to 2.861×10^{-7} $m^2\ s^{-1}$. These values are within the general range of the thermal diffusivity of agricultural materials. The thermal diffusivity of Marquis wheat seed was studied in bulk at 9.2% (d.b) of the moisture content, and the value of thermal diffusivity was equal to 1.15×10^{-7} $m^2\ s^{-1}$ (Babbit, 1945). The thermal diffusivity of rough rice was obtained from 0.856×10^{-7} to 1.05×10^{-7} $m^2\ s^{-1}$ in the moisture range of 12% to 20% (d.b) (Wratten et al., 1969). The value of thermal diffusivity of manure was reported to be 1.65×10^{-7} $m^2\ s^{-1}$ (Houkom et al., 1974). The thermal diffusivity of dairy cattle manure was measured from 0.904×10^{-7} to 2.11×10^{-7} $m^2\ s^{-1}$ (Amin-nayyeri et al., 2009). *Table 2* presents the variance analysis results of the thermal diffusivity of the vermicopost sample that include the effects of temperature and moisture parameters as well as of their interactions. As presented in *Table 2*, the temperature and moisture parameters have become significant ($P < 0.001$), but their interaction happens to be non-significant.

Figure 3 presents the effect of moisture content on the thermal diffusivity of vermicompost. By increasing the moisture content of vermicompost from 10% to 50% (w.b), thermal diffusivity decreases from 2.861×10^{-7} to 1.3973×10^{-7} m^2 s^{-1}. The results for thermal diffusivity of vermicompost are in general agreement with the findings of some previous researchers. The thermal diffusivity of guna seed decreased from 9.311×10^{-8} m^2 s^{-1} to 8.5×10^{-8} m^2 s^{-1} as the moisture content increased (Avira et al., 2008). The investigation showed that the thermal diffusivity of millet grains decreased from 2.03×10^{-7} to 1.52×10^{-7} m^2 s^{-1}. (Subramanian and Viswanathan, 2003).

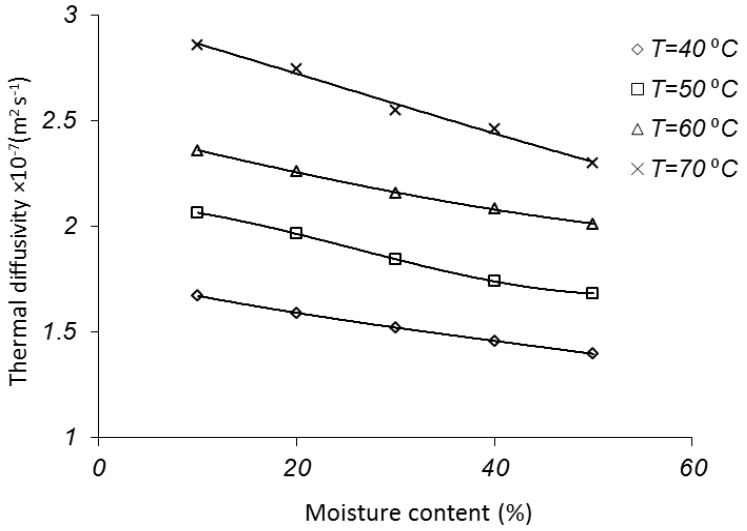

Figure 3. *Thermal diffusivity of vermicompost versus moisture content at different temperatures*

Figure 4 shows the effect of temperature on the thermal diffusivity of vermicompost. The thermal diffusivity of vermicompost increased with rising temperatures (*Fig. 4*). Moreover, the line of 10% moisture content is higher than other moisture content levels. The thermal diffusivity of solid food increased almost linearly with increases in the temperature (Fito et al., 1984). The investigation showed that the thermal diffusivity of cumin seed increased from 0.653×10^{-7} to 16.64×10^{-7} m^2 s^{-1} (Singh and Goswami, 2000).

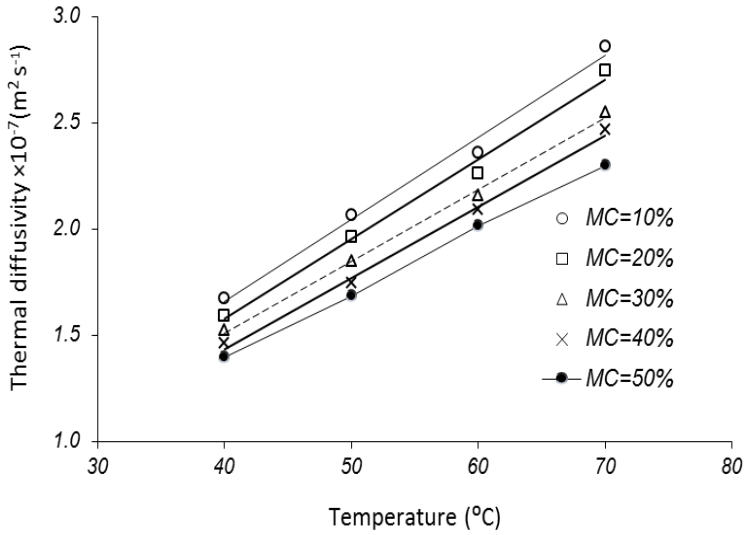

Figure 4. *Thermal diffusivity of vermicompost versus temperature at different moisture contents*

A polynomial relationship among the thermal diffusivity (α), temperature (T), and moisture content (MC) was obtained by multiple regression analysis with a value of 0.99 for the coefficient of determination as Equation 10:

$$\alpha = 1.01\times10^{-7} + 1.35\times10^{-9}T + 1.93\times10^{-11}T^2 - 1.3\times10^{-9}MC + 4.57\times10^{-}12\ MC^2 \quad \text{(Eq. 10)}$$

Table 3 shows that the effect of temperature (high F-value) on the thermal diffusivity is more than that of moisture content. The significance of respective regression coefficients in Equation 10 also confirms the results.

Table 3. *Analysis of variance (ANOVA) for effect of parameters in Equation 10 on thermal diffusivity of vermicompost*

Source of variation	Sum of squares	Degree of freedom	Mean sum of squares	Fcal-value	Probability
Regression	3.47E-14	4	8.67E-15	38403.03***	0.0000
T	2.55E-16	1	2.55E-16	1130.22***	0.0000
T^2	7.48E-17	1	7.48E-17	331.05***	0.0000
MC	3.02E-17	1	3.02E-17	134.02***	0.0000
MC^2	3.43E-17	1	3.43E-17	151.97***	0.0000
Residual	3.38E-18	15	2.25E-19		
Total	3.47E-14	19			

*** Highly significant

Any comparison between the measured and estimated values of the thermal diffusivity (*Fig. 5*) showed that the maximum differences were within $\pm0.01\times10^{-7}$ m^2s^{-1}, showing reasonable accuracy for estimating the thermal diffusivity.

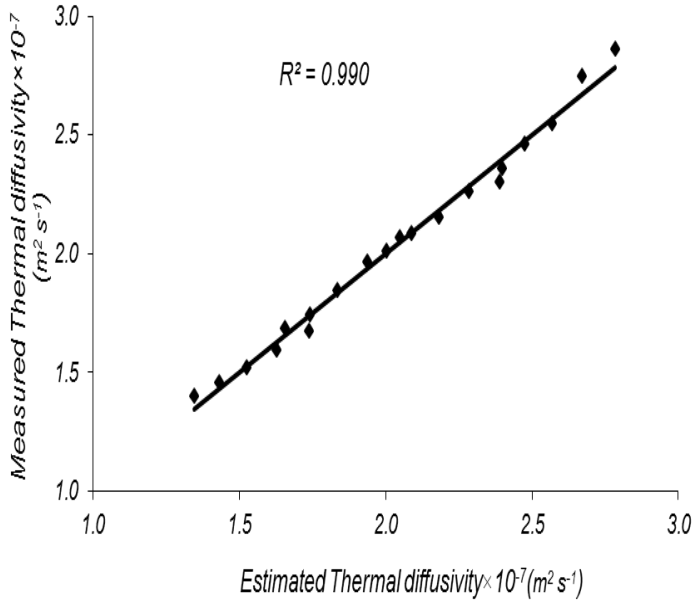

Figure 5. *Estimated versus measured values of the thermal diffusivity of vermicompost*

Conclusions

The thermal diffusivity of vermicompost was determined using a *1D* solution of the Fourier equation of heat. The thermal diffusivity of vermicompost is dependent on the latter's moisture content and temperature. The effect of temperature on the thermal diffusivity was more than that of moisture content. By increasing the moisture content of the vermicompost sample from 10% to 50%, its thermal diffusivity decreased from 2.861×10^{-7} to 1.3973×10^{-7} m^2 s^{-1}. The thermal diffusivity of vermicompost increases with rising temperature. The developed model can also be used acceptably within the range of variables studied in this research where the thermal diffusivity of the vermicompost ranged from 1.3973×10^{-7} to 2.861×10^{-7} m^2 s^{-1}. The resulting thermal diffusivity of vermicompost can be used to develop heat transport models for the design of more optimal temperature control in composting systems.

Abstract. One of the most fundamental problems of societies is environmental problems that have emerged as the result of human behaviors which can be summarized as "dominating nature" and "using nature carelessly". The main causes of climate change and greenhouse gas emissions, which are considered to be most important environmental problem nowadays, are used of fossil fuel resources intensively in order to overcome the energy requirement. Carbon dioxide (CO_2) is the largest share of greenhouse gas emissions. To reduce CO_2 emissions, significant studies have been done in the world. In this study, we tried to classify member countries of OECD according to CO_2 emissions indicators from fossil fuel consumption. For the clustering, both the classical cluster analysis and the fuzzy cluster analysis were implemented. The clusters obtained from both methods are simply interpreted.
Keywords: *fuzzy clustering, Paris climate agreement, Kyoto Protocol, climate change, greenhouse gas emission*

Introduction

Climate change can be described in a very general way in the form of "regardless of their cause, long-term and slow-growing changes in climate conditions" (Türkeş, 2003).

However; with the industrial revolution, in addition to natural climate variability, it has entered a new era of human activities that affect the climate. Since the industrial revolution, the accumulation of greenhouse gases in the atmosphere has been rapidly increasing, especially; as a result of human activities such as burning of fossil fuels, land use changes, deforestation and industrial processes. With the understanding that these increases in the concentration of greenhouse gases are beginning to pose serious threats, and that this problem can be resolved with global efforts, global scale co-operation and organizations have been started to form. In this process, The "Framework Convention on Climate Change" signed at the United Nations Conference on Environment and Development held in Rio de Janeiro in June 1992 under the auspices of the United Nations and The "Kyoto Protocol" formed as a result of the "Third Party Conference" held in Japan in December 1997 are special important development (Dam, 2014).

One of the main reasons why the Kyoto Protocol is so important is that it obligates the parties with greenhouse gas reductions on certain dates and at certain rates. In addition, the Kyoto Protocol has introduced three new mechanisms that provide flexibility for greenhouse gas reduction (Gençer, 2008). These mechanisms called the Kyoto Protocol Flexibility Mechanisms, allow countries for greenhouse gas reduction to undertake joint activities outside their own borders. Turkey, in 2004, has became a party to the United Nations Framework Convention on Climate Change, signed the protocol

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

in 2009 and has been the 178th of countries that ratified the Kyoto Protocol. Between 2008 and 2012, Turkey had no obligation to any greenhouse gas emission reduction. On the other hand; according to the protocol, Turkey aims to reduce at least 20% reduction in carbon emissions until 2020.

The Kyoto Protocol is the first step in the climate protocol. However, this protocol is not a result. Because, only developed countries took on the greenhouse gas reduction obligation in the Kyoto Protocol. The world was trying to establish a new agreement on the global scale since Kyoto Protocol. In Paris on December 12, 2015, countries adopted an international agreement to address climate change that requires deeper emissions reduction commitments from all countries—developed and developing. The Paris Climate Agreement, in which 196 countries have reached consensus and 187 countries have proposed a reduction plan (INDC), includes countries that account for more than 96% of total global emissions. The objective of the agreement is to maintain the increase in global temperatures well below 2 degrees Celsius above pre-industrial levels, whilst making efforts to limit the increase to 1.5 degrees (Savaşan, 2017).

The agreement aims to ensure global greenhouse gas emissions peak as soon as possible, and to balance emissions and removals of greenhouse gases in the second half of this century. Furthermore, the agreement addresses adaptation to climate change, financial and other support for developing countries, technology transfer and capacity building, as well as loss and damage (Savaşan, 2017).

This new agreement has set countries' minimum obligations, implemented mechanisms to spur additional action in developing countries, supported the most vulnerable countries in addressing climate change, and established systems to hold countries to their commitments. The Paris Agreement will be strengthened over time using its solid framework.

Turkey, in the context of the struggle against climate change, presented the Intended Nationally Determined Contribution (INDC) plan as a volunteer to the UN Secretariat before the Climate Summit in Paris. Turkey stated that aims to increase greenhouse gas emissions less than 21% from the reference scenario until 2030 in this declaration. Turkey which refers to special conditions in INDC Plan, set targets for renewable energy use and the transition to nuclear energy. Also, Turkey declared that greenhouse gas emissions will be reduced by low-carbon investments that will provide energy efficiency in urbanization, transport and industry sector (Karakaya, 2015).

The atmosphere, which is of vital importance to the living creatures in the world, contains many gases in it. Nitrogen (78.08%) and oxygen (20.95%) in the atmosphere form 99% of the volume of clean and dry air. The remaining dry air section consists of argon (0.93%), an inert gas, and some trace gases, which are very small in quantity. Although its deposition in the atmosphere is very small, the CO_2, which is an important greenhouse gas, is in fourth place with 0.03% (Türkeş, 2008). Carbon dioxide (CO_2) is the most important greenhouse gas that is effective on global warming. Although it is at a very low volumetric rate in the atmosphere, its share in total greenhouse gases exceeds 80% (Koçak, 2006). As a result of from decay of plants, volcanic activity, human and animal breath and also combustion of fossil fuels such as coal, oil and natural gas, CO_2 accumulates in the atmosphere. Because of burning fossil fuels, forest fires, etc., the CO_2 concentration has been increasing rapidly since the beginning of this century. While CO_2 concentration is 290 ppm in the early 20th century, it is estimated that CO_2 concentration will increase to 500 ppm at the end of the 21st century. CO_2 absorbs some of the infrared heat energy released from the earth. Therefore, an increase in CO_2

concentration will cause an increase in the average surface temperature of the world scale (Koçak, 2006).

Turkey's carbon dioxide emissions data table and chart are given in *Table 1* and *Figure 1* between 1990 and 2015.

According to the *Table 1,* the total greenhouse emissions of 2015 as CO_2 equivalents increased 122% compared to 1990. Total greenhouse gas emissions in 2015 were calculated as 475.1 million tonnes (Mt) CO_2 equivalent. The largest share of the CO_2 equivalent in 2015 emissions was energy-related emissions with 71.6% followed by industrial operations and product use by 12.8%, agricultural activities by 12.1% and waste by 3.5%. There are many studies on climate change and greenhouse gas emissions. In this study, we tried to classify in terms of CO_2 emissions the Organisation for Economic Co-operation and Development (OECD) countries which also Turkey is a member. For this purpose, we used fuzzy c-means algorithm which is most commonly

known in fuzzy partition. Then, in order to make a comparison, analyzes were made by classical k-medoid algorithm. For analysis of greenhouse gas emissions, which is one of the important ecological issues, it is aimed to be shown that besides classical techniques, fuzzy techniques which are more flexible can be used.

Methods and materials

Clustering

Clustering analysis or simply clustering is one of the multivariate statistical methods helps to divide data labels of which are not exactly known to subgroups according to similarities and explore different correlation and structures in large data sets. The desired goal in this analysis is to divide the data set so that the elements assigned to the same cluster are as similar as possible but that the two objects in different clusters should not be as similar as possible. Hence, clustering analysis tries to model the ability in clustering similar objects into homogeneous classes or categories. In clustering, initially the number of clusters and number of object that assigned to clusters is not certain. By collecting similar objects into clusters, clustering analysis tries to recreate unknown clusters, hoping that each cluster found represents an actual object category or category. Classifying datasets, clustering analysis only uses some mathematical criteria on the composition of clusters. For this reason, clustering algorithms are equipped with distance measures to measure the similarity of the presented samples.

Clustering techniques are distinguished according to how assignments are made, in other words, according to their assignment patterns (Hartigan, 1975). In classical cluster analysis, each datum must be exactly assigned to a cluster. These classical methods convert non-empty partitions of the data into non-empty and double disjoint subclasses. Such hard data aggregation way can be insufficient when data is equal distance to two or more clusters. Such special data points may represent similar hybrid or mixed objects at a rate equal to two or more species. Classical (hard) partition forces these data points to be fully assigned to one of the clusters; but they should belong to all at equal rates. Hard partition is defined as below;

Let $X = \{x_1, x_2, \ldots x_n\}$ be a set of n vectors in R^d, representing the data. For an integer $c > 2$, a hard clustering of X into c clusters consists of c disjoint subsets of X', $S_1, \ldots, S_c$

whose union is X. An equivalent way of defining clusters is achieved by using functions. For each $i = 1, \dots, c$ define $u_i: X \to \{0,1\}$ by $u_i(x) = 1$ if $x \in S_i$ and $u_i(x) = 0$ if $x \notin S_i$ (Bezdek, 1973).

These functions are called membership functions. Because it determines each data point belongs a specific cluster. In hard clustering, membership value is equal to 1 if the data belongs to the cluster, and 0 otherwise. As can be seen, in classical clustering theory, boundaries of clusters and adjectives of clusters are definite. In real life, however, the boundaries of each cluster and the attributes of each element belonging to these clusters are not so certain. Thus, it can be seen that the concept of classical clustering is inadequate in some situations encountered in real life.

Classical clustering analysis is organized under hierarchical and non-hierarchical headings. Hierarchical methods generate arrays of clusters usually starting from clusters that contain a single unit, by performing concatenation until all units are aggregated in a cluster or they generate clusters by starting from cluster that contain all units and separating units sequentially. Non-hierarchical techniques are methods which aim to divide units into clusters that are homogeneous in themselves and heterogeneous among themselves and estimate the parameters of sub-populations (group or cluster mean vectors and covariance matrices) through prototype sets. The most common non-hierarchical methods are k-means clustering, k-medoid clustering and fuzzy clustering. In this study we will study k-medoid and fuzzy methods.

K-medoids algorithms

It attempts to reduce the distance between a point labeled on the cluster and center of cluster. The method selects medoid, which means point the closest to center of cluster, instead of the average of data as a cluster center. Medoids for each cluster are calculated by using the following formula (*Eq. 1*) by finding the object i within the cluster that minimizes

$$\sum_{j \in C_i} d(i, j) \qquad \text{(Eq.1)}$$

where c_i is the cluster containing object i and $d(i,j)$ is the distance between objects i and j.

There are two advantages of using existing rules as the centers of the clusters. First, a medoid rule serves to usefully describe the cluster. Second, there is no need for repeated calculation of distances at each iteration, since the k-medoids algorithm can simply look up distances from a distance matrix. The most common realization of *k*-medoid clustering is the partitioning around medoids algorithm and is as follows (Kaufman and Rousseeuw, 1990):

- Initialize: randomly select *k* of the *n* data points as the medoids.
- Assignment step: associate each data point to the closest medoid.
- Update step: for each medoid *m* and each data point *o* associated to *m* swap *m* and *o* and compute the total cost of the configuration (that is, the average dissimilarity of *o* to all the data points associated to *m*). Select the medoid *o* with the lowest cost of the configuration. Repeat alternating steps 2 and 3 until there is no change in the assignments.

Kaufman and Rousseeuw suggested the use of silhouettes both to determine which objects lie well within their clusters and which do not and also to judge the quality of the clustering obtained. For each object i, let $a(i)$ be the average distance of i from all other objects in cluster c_i . For every other cluster $c \neq c_i$, let $d(i,c)$ be the average distance of i from the objects in c. After computing $d(i,c)$ for all clusters $c \neq c_i$, let $b(i)$ be the smallest. The cluster for which this minimum is attained is called the neighbour of i. The number s(i) is given by using *Equation 2:*

$$s(i) = \frac{b(i) - a(i)}{\max(a(i), b(i))} \quad \text{(Eq.2)}$$

If $s(i)$ is close to 1, object i can be said to be 'well classified'. If $s(i)$ is close to 0, it is unclear whether i should belong to cluster $c_i$or to its neighbor. A negative value suggests that i has been misclassified. The following summary values are also defined:

- The mean of $s(i)$ for all objects i in a cluster is called the average silhouette width of that cluster.
- The mean of $s(i)$ for all the objects is called the average silhouette width for the entire data set and is denoted by $\bar{s}(c)$, where c is the number of clusters.

Kaufman and Rousseeuw suggest that $\bar{s}(c)$, can be used for the selection of a best value of c, by choosing that k for which $\bar{s}(c)$, is maximal (Richards and Rayward-Smith, 2001).

Fuzzy clustering

Fuzzy clustering is the generalization of this point of view. In fuzzy set theory, an element belongs to a cluster with membership values between 0 and 1, including 0 and 1. In other words, in a fuzzy set, a fuzzy set element belongs partially to a cluster.

A fuzzy clustering of X into c clusters consist of functions $u_1, \ldots, u_c$ where $u_i: X \to [0,1]$ and $X_i u_i(x) = 1$, for all $x \in X$. Formally, given a set of objects, $\{x_1, x_2, \ldots x_n\}$a fuzzy clustering of k fuzzy clusters, $c_1, \ldots, c_k$, can be represented using a partition matrix, $U = [u_{ij}].(1 \leq i \leq n, 1 \leq j \leq k)$, where u_{ij} is the membership degree of x_i in fuzzy cluster c_j. The partition matrix should satisfy the following three requirements:

- For each object, x_i, and cluster, c_j, $0 \leq u_{ij} \leq 1$. This requirement enforces that a fuzzy cluster is a fuzzy set.
- For each object, x_i, $\sum_{j=1}^{k} u_{ij} = 1$. This requirement ensures that every object participates in the clustering equivalently.
- For each cluster, c_j, $0 < \sum_{i=1}^{n} u_{ij} < n$. This requirement ensures that for every cluster, there is at least one object for which the membership value is nonzero.

Fuzzy cluster analysis therefore allows gradual memberships of data points to clusters in [0, 1]. This gives the flexibility to express that data points belong to more than one cluster at the same time. Furthermore, these membership degrees offer a much finer degree of detail of the data model. Aside from assigning a data point to clusters in (equal) shares, membership degrees can also express how ambiguously or definitely a data point should belong to a cluster.

The first use of this method based on fuzzy set theory in clustering analysis was carried out by Bellman et al. (1966). Many fuzzy clustering algorithms are based on the optimization of the objective function. The most widely used algorithm is the fuzzy c-means algorithm (Ruspini, 1970).

Fuzzy c-means algorithms

The fuzzy c-means algorithm is presented in its initial form by Dunn (1974) as an alternative to the classical k-means clusters and is completed by Bezdek (1974). The fuzzy c-means algorithm is based on the objective function. A large family of fuzzy clustering algorithms have been created to attempt to minimize the objective function of these basic c-means algorithms. In short, the most basic algorithm for fuzzy clustering analysis is the fuzzy c-means algorithm. The mentioned objective function is defined as *Equation 3* (Bezdek, 1981):

$$J(X;U,V)=\sum_{j=1}^{c}\sum_{i=1}^{n}\left(u_{ji}\right)^{m}\left\|x_i-v_j\right\|^2 \qquad \text{(Eq.3)}$$

where n is the total number of patterns in a given data set and c is the number of clusters;$X=\{x_1,\ldots x_n\}\subset R$ and $V=\{v_1,\ldots,v_c\}\subset R$ are the feature data and cluster centroids; $U=[u_{ji}]$ and $c\times n$ is a fuzzy partition matrix composed of the membership grade of pattern xi to each cluster j. value is the total of pattern measurement of all weighted least square errors. The weighting exponent m is called the being effective on the clustering performance of FCM (Şahinli, 1999).

Unfortunately, the object function $J(X;U,V)$ can not be directly minimized. Therefore, an iterative algorithm is used, which alternately optimizes the membership degrees and the cluster parameters. That is, first, the membership degrees are optimized by using *Equaition 4* for fixed cluster parameters, then the cluster parameters are optimized by using *Equation 5* for fixed membership degrees:

$$U_t=J_U\left(V_{t-1}\right) \qquad \text{(Eq.4)}$$

and

$$V_t=J_V\left(U_t\right) \qquad \text{(Eq.5)}$$

The main advantage of this scheme is that the optimum can be computed directly in each of two steps. By iterating the two steps, the joint optimum is approached (although it cannot be guaranteed that the global optimum will be reached—the algorithm may get stuck in a local minimum of the objective function *J*).

The update formulae J_U and J_V are derived by simply setting the derivative of the objective function J w.r.t. the parameters to optimize equal to zero (Höppner et al., 1999). Independent of the chosen distance measure the following update formula (*Eq. 6*) for the membership degree and following update formula (*Eq. 7*) for prototype is obtained from J(X;U,V):

© 2018, ALÖKI Kft., Budapest, Hungary

$$u_{ji} = \left[\frac{1}{\sum_{k=1}^{c} \left[\frac{\left\| x_i - v_j \right\|}{\left\| x_i - v_k \right\|} \right]^{2/(m-1)}} \right], 1 \le j \le c, 1 \le i \le n \qquad \text{(Eq.6)}$$

$$v_j = \frac{\sum_{i=1}^{n} \left(u_{ji} \right)^m x_i}{\sum_{i=1}^{n} \left(u_{ji} \right)^m}, \quad 1 \le j \le c \qquad \text{(Eq.7)}$$

In *Table 2* a brief description of the fuzzy *c*-means algorithm is given. Algorithm can be terminated when the relative change in the cluster centers gets very small or the objective function *J* cannot be minimized anymore (Bezdek, 1974).

Table 2. *FCM algorithm steps*

- Select the fuzzifier exponent *m* (*m* > 1) and initialize the fuzzy partition matrix $U = (u_{ji})$ randomly
- **while** termination conditions not met **do**
1. Compute the cluster centers v_j
2. Update the fuzzy partition matrix $U = (u_{ji})$
end while

The fuzzy c-means algorithm detects clusters in the form of dots. It is not effective in finding other cluster shapes. Also, the fuzzy c-means algorithm has some advantages and disadvantages. Sensitivity to noise points, adherence to initial values, long-running computation time are the disadvantages of the algorithm. On the other hand, unsupervised and constant convergence are the main advantages of the algorithm.

As seen in the first step of the fuzzy c-means algorithms, determining of the number of initial clusters is an important task. The fact that the number of the initial cluster is not known in advance makes it necessary to test the validity of the clusters. The validity indices are used to determine which set of clusters is appropriate clustering from the clusters in the fuzzy clusters. There are many validity indices in the literature. The most commonly used index in fuzzy clustering analysis is the Xie-Beni index. The Xie-Beni index is defined as follows in *Equation 8* (Xie and Beni, 1991):

$$XB(c) = \frac{\sum_{j=1}^{c} \sum_{i=1}^{n} \left(u_{ji} \right)^m \left\| x_i - v_j \right\|^2}{N \min_{ji} \left\| x_i - v_j \right\|^2} \qquad \text{(Eq.8)}$$

Xie-Beni index is also known as the density and separation index. It is based on two basic features; compactness and separation. In *Equation 8,* the numerator shows the closeness of the fuzzy partition, i.e. the closeness of the elements in the cluster, and the denominator shows the strong separation between the clusters, i.e. the distance between

© 2018, ALÖKI Kft., Budapest, Hungary

the clusters (Xie and Beni, 1991). It is seen in empirical studies that this index should take small values.

Results and discussion

In this study, it is aimed to determine the classification of the OECD countries by fuzzy clustering and classical clustering analysis in terms of the indicators from fossil fuel consumption and detect the cluster Turkey belongs, and other countries in this cluster, and evaluate whether it shows similar functions between Turkey and these countries or not. For the analysis, we used CO_2 emissions data from fuel combustion by sector from open access platform -International Energy Agency (IEA). 32 countries and five variables are used. The variables used are shown in *Table 3*.

Table 3. *Used variables*

Variables ID	Variables
X_1	Electricity and heat production
X_2	Other energy industry own use
X_3	Manuf. industries and construction
X_4	Transport
X_5	Other sectors

For the application, R studio 3.4.0 which is an environment for statistical computing program and "fclust" package was used. In order to apply the algorithm, the initial parameters (excluding the number of cluster) were selected randomly. The Xie-Beni results were calculated to determine the number of clusters.

As seen in *Table 4* and *Figure 2,* the experimental results revealed that for fuzzy c - mean algorithms, the elbow was located at c = 4. On the other hand, the smallest value of Xie-Beni index is the number of cluster is 4.

As a result of the analysis, with the help of fuzzy c-means clustering, the number of cluster has been determined as 4. As can be seen in *Table 6,* the first cluster was determined as New Zealand, Chile, Austria, Belgium, Czech Republic, Denmark, Israel, Finland, Greece, Hungary, Ireland, Netherlands, Norway, Poland, Portugal, Slovakia, Sweden, Switzerland. While United States took place in the second cluster, the third cluster were identified as Canada, Mexico, Australia, South Korea, France, Italy, Poland, Spain, Turkey and Great Britain. The countries in the last group were designated as Japan and Germany.

In order to compare the results of fuzzy clustering, the k-medoid clustering method of classical clustering methods is also used. NCSS program was used for analysis. After data entry in NCSS for k-medoid application, "Medoid Partitioning" was selected from the "Clustering" section in the analysis section and the number of clusters was entered as minimum 2 and maximum 10 in order to determine the optimal number of clusters. The results are shown in *Table 7*.

Conclusions

Societies are increasingly fragile against atmosphere-related natural disasters. As a result of increasing greenhouse gas emissions due to human activities, the link between industry-climate change is getting stronger. Although the kyoto protocol is the basic protocol, the results have not been effective. For this reason, the Paris Climate Agreement, which is one of the important protocols on fighting climate change, was organized in 2015. The main objective of the protocol is to reduce the emissions of all greenhouse gases, primarily carbon dioxide. For each country, the measures are clearly stated in the protocol.

The changes in the atmosphere of the earth largely took place in the years following the industrial revolution and especially in the 20th century. In the 21st century, it is estimated that greenhouse gas emissions will further increase the global average temperature. Carbon dioxide (CO_2), the most important of the six greenhouse gases, its emission have increased especially during the past century. In this study, CO_2 emissions resulting from the fuel combustion of 32 countries were classified by using fuzzy c-means algorithm - based on fuzzy logic-, and classical k-medoid algorithm. As a result of the analysis, in the fuzzy clustering analysis, the cluster number is 4; whereas in classical clustering analysis, the number of clusters was found to 2.

It can be said that the k-medoid clustering analysis is created an artificial cluster because the first cluster is only formed by the USA. It can also be said that the classification based on the fuzzy c-means algorithm reflects the natural classification resulting from the combination of the variables in the data matrix. Since the data used in the study show a global structure, the fuzzy c-means method of conventional fuzzy clustering methods was used and produced useful results.

Japan and Germany, being in fourth cluster in the clustering result, are ranked 2nd and 3rd, respectively, according to CO_2 emission values for 2015. According to the year 2015 statistics, the total CO_2 emission was 32.294 million metric tons in the world, while the emission value of the US was 4997 million metric tons. As for the analyzed CO_2 emission variables of the USA, clustering of the US in a single cluster is an important and verifiable result in this matter.

According to the 2015 greenhouse emission inventory report, published by the Turkish Statistical Institute, in Turkey, total greenhouse gas emissions in 2015 were 475.1 million tons (mt), equivalent to CO_2. In this inventory, the largest share of CO_2 emissions for 2015 created energy-driven emissions.

CO_2 emissions in the world has being estimated to increase by an average of 2% each year since 1971 and by 45% until 2030. With this study, it is aimed to shed light on researchers working on environment and climate change. However, classification for carbon dioxide emission can be enriched by adding other countries besides OECD countries or different greenhouse gas statistics can be clustered for countries. Thus, greenhouse gas emissions of countries can be scrutinized from a wider perspective.

(Received 31st Jan 2018; Accepted 26th Apr 2018)

Abstract. Climate change has reached the highest rates of the last 1.400 years. This has begun to attract the attention of researchers, and the number of studies on estimation of the environmental impacts of climate change on species has also begun to increase. *Ips mannsfeldi* (Wachtl, 1879) is a bark beetle (Curculionidae: Scolytinae) species spreading on black pine (*Pinus nigra*) fields in Turkey. This study aims to model the current and future (2070) distribution of the species according to two different global climate change scenarios. Locations of *I. mannsfeldi* specimens that were collected in different stands were recorded with GPS. Current and future potential distribution areas of the species have been determined using maximum entropy modeling. RCP4.5 and RCP8.5 emission scenarios reported in IPCC5 were used to estimate the future potential distribution of the species. As a result of the study, it is determined that the species distributes on the Black pine (*Pinus nigra*) forests throughout the Mediterranean part of Turkey at the present time. According to projections to 2070 the distribution area will expand towards the Aegean region. Depending on the changing climatic conditions, it can be seen that this species expands its distribution area and may be a potential pest that causes economic damage to black pine fields in the coming period.
Keywords: *Ips mannsfeldi, MaxEnt, Pinus nigra, climate change, future prediction, modeling*

Introduction

The last three decades have been successively warmer periods of the last 1.400 years in the Northern Hemisphere. Evidence regarding impacts of observed climate change is the strongest and most comprehensive for natural systems. In addition to these impacts, many terrestrial, freshwater and marine species have to shift their geographic ranges, seasonal activities, migration patterns, abundances and species interactions in response to ongoing climate change (IPCC, 2014). Especially, insect communities may severely be impacted by increasing temperature which will affect almost all life history parameters, such as emergence, growth rate, and voltinism (Bale et al., 2002; Cornelissen, 2011). One of the important insect assemblages suffering from climate change is inhabitants of the forest ecosystems because plants and their associated phytophagous insects comprise a major proportion of terrestrial biodiversity (Strong et al., 1984; Wilson, 1988; Chapman, 2009). So, understanding the potential impacts of climate change on insects, especially forest dependent species, is essential for

© 2018, ALÖKI Kft., Budapest, Hungary

management strategies (Met Office, 2011). In this context, bark beetles are among the most serious forest pests world-wide (Epanchin-Niell et al., 2014). One of these beetles is *Ips mannsfeldi* (Wachtl, 1879) which distributes only in black pine and scots pine forests of Austria, Corsica, Romania, Croatia, Bosnia Herzegovina, Macedonia and Turkey (Pfeffer, 1995; Stauffer et al., 1997; Selmi, 1998). The distribution of *I. mannsfeldi* is congruent with the natural range of its host trees (Pfeffer, 1995).

Species distribution models estimate the distribution of species by examining the relationships between the occurrence records of species and the environmental characteristics of the occurrence sites (Elith, 2011). MaxEnt is a software for species distribution modeling which estimates the distribution of species using presence-only records and maximum entropy algorithm (Phillips, 2017).

The aims of the study were to model the current and future (2070) distributions of *Ips mannsfeldi* in Turkey according to RCP4.5 and RCP8.5 (Representational Concentration Pathways) climate change scenarios reported in The Fifth Assessment Report of the Intergovernmental Panel on Climate Change (IPCC5).

Materials and Methods

Occurrence Data

Specimens were collected from trees weakened by other insects or drought, trunks in forest stands and trap woods that were placed by Forestry Administration. Specimens were collected coincidentally during field works (*Figure 1*).

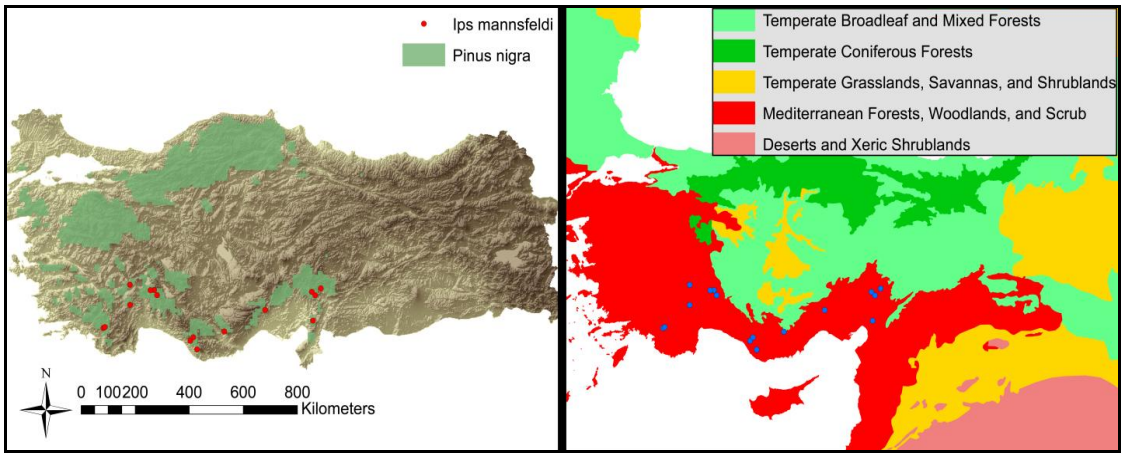

Figure 1. *Distribution of the host tree Pinus nigra in Turkey and the occurrence localities (left). Biome map of Turkey (right)*

The study extent was limited to the part of the Mediterranean biome in Turkey (Olson, 2001) where the host tree *Pinus nigra* is distributed and 10.000 background points also called the "pseudo-absences" (Merow et al., 2013) were selected from this area (*Figure 1*). This approach is ideal as limiting the study extent to areas that are accessible to the species being studied improves the model performance and prevents over-inflation of evaluation metrics (Barve et al., 2011; Soberon and Peterson, 2005; Jimenez-Valverde et al., 2008).

Environmental Data

SRTM30 digital elevation model (Farr and Kobrick, 2000) and 19 Bioclim variables of the WorldClim database (Hijmans et al., 2005) were used as the environmental variables. Variables showing strong correlation were identified using Spearman's rank correlation coefficient (rs > 0.7). Among the correlated variables the ones that are expected to contribute to the distribution of the species were selected. Five environmental variables were used in the final model (*Table 1*). Bioclim variables for 2070 (CCSM4) and two greenhouse gas emission scenarios RCP4.5 and RCP8.5 were used to project the model. All variable rasters were at 30 arc-seconds resolution.

Table 1. *Environmental variables used in the study*

Variable	Description
Elevation*	-
WC1	Annual Mean Temperature
WC2	Mean Diurnal Range (Mean of monthly (max temp - min temp))
WC3*	Isothermality (WC2/WC7) (* 100)
WC4	Temperature Seasonality (standard deviation *100)
WC5	Max Temperature of Warmest Month
WC6	Min Temperature of Coldest Month
WC7*	Temperature Annual Range (WC5-WC6)
WC8	Mean Temperature of Wettest Quarter
WC9	Mean Temperature of Driest Quarter
WC10	Mean Temperature of Warmest Quarter
WC11	Mean Temperature of Coldest Quarter
WC12	Annual Precipitation
WC13*	Precipitation of Wettest Month
WC14*	Precipitation of Driest Month
WC15	Precipitation Seasonality (Coefficient of Variation)
WC16	Precipitation of Wettest Quarter
WC17	Precipitation of Driest Quarter
WC18	Precipitation of Warmest Quarter
WC19	Precipitation of Coldest Quarter

* indicates the variables used in the final model

Distribution Modeling

MaxEnt version 3.4.1 (Phillips et al., 2006; Phillips et al., 2017) was used through the R package "dismo" (Hijmans et al., 2017) to model the distribution of the species. The model was fine-tuned using the R package "ENMeval" (Muscarella et al., 2014) with trying all combinations of feature types and regularization multiplier values 0.5, 1-10. Since the sample size is low (n=11) k-1 jackknife method described in Pearson et al. (2007) was used to validate the model. Akaike Information Criterion corrected for small samples sizes (AICc) was used as the model selection criterion (Warren et al., 2011). Final binary distribution maps were generated using the threshold value which maximized sensitivity (true positive rate) plus specificity (true negative rate) since this value also maximizes the True Skill Statistic and is not affected by pseudo-absences and prevalence (Liu et al., 2005; Allouche, 2006). Multivariate environmental surface similarity (MESS) plots (Elith et al., 2010) were created using the R package "Ecospat" (Broennimann et al., 2016). Finally, the limiting factor surface map (Elith et al., 2010) was calculated using the R package "rmaxent" (Baumgartner et al., 2017).

Results

The final model was selected based on the fine tuning using the AICc value and the best model only used Linear and Quadrat features with a regularization multiplier value of 0.5 (*Figure 2*). The ROC curve of the final model shows a high predictive power with an AUC score of 0.88 (*Figure 3*).

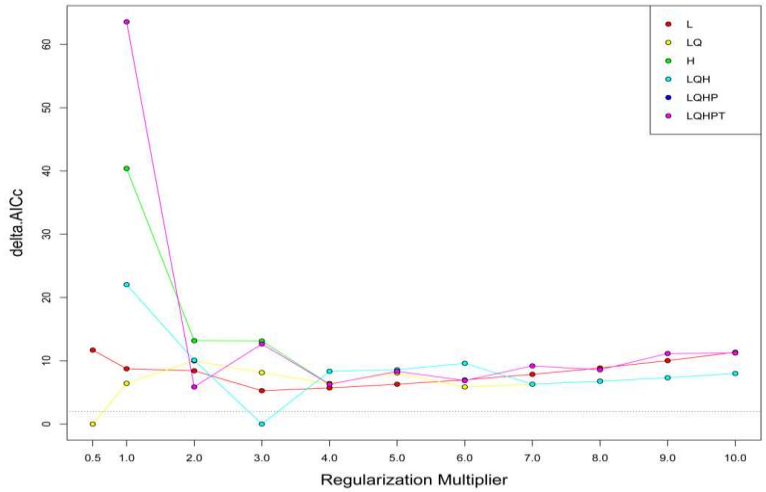

Figure 2. *Results of the fine tuning. X axis corresponds to the beta regularization value of that model. Y axis corresponds to the difference between the smallest AICc value and the AICc value of that model. Legend shows six different combinations of the feature types*

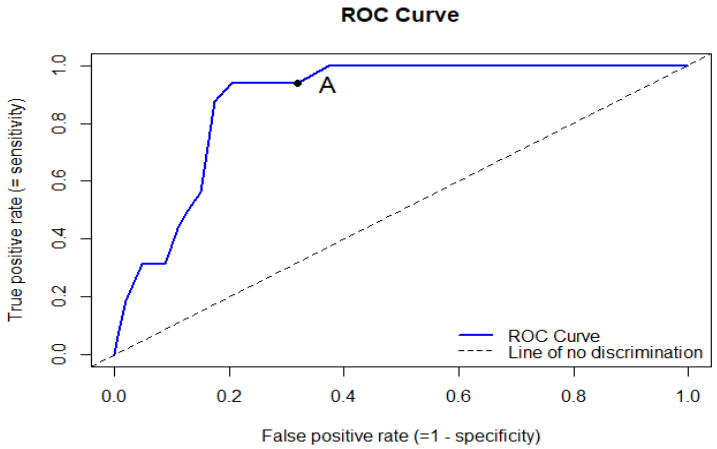

Figure 3. *The Receiver Operating Characteristic curve of the final model. The AUC score is the area under this curve and the AUC score of this model is 0.88. The AUC score of the line of no discrimination is 0.5 which means no predictive power. The point A corresponds to the threshold value of 0.58 used in producing the binary maps*

The most important variable for the model was elevation (*Figure 4*). It appears to have the most useful information as well as more unique information then other variables.

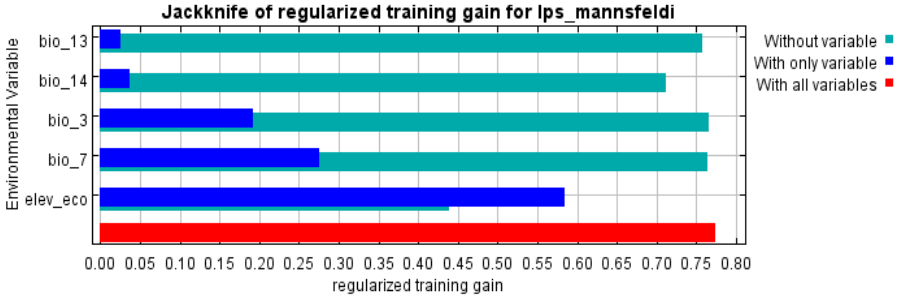

Figure 4. *Results of jackknife test of variable importance (Light blue: without variable, Blue: with only variable, Red: with all variables)*

The threshold value that maximized the sum of true positive rate and true negative rate was 0.58 (*Figure 3*). This value was used to generate the binary maps of current and future distributions (*Figure 5*). Projections predict an expansion of the distribution area towards north-western part of Turkey in both climate change scenarios.

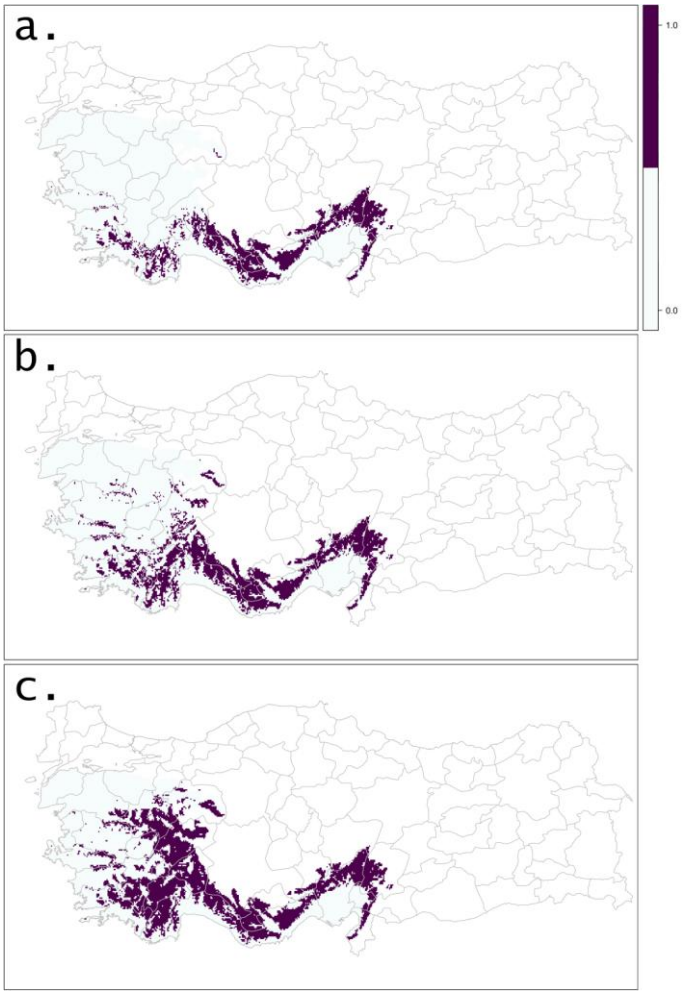

Figure 5. *Distribution maps of Ips mannsfeldi according to the model (a: current distribution, b: Distribution in 2070 according to RCP4.5 climate change scenario, c: Distribution in 2070 according to RCP8.5 scenario)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_25272535

MESS plots show how much the model has to extrapolate in a given region (*Figure 6*). While the areas with negative values are extrapolated into, the areas with positive values require no extrapolation.

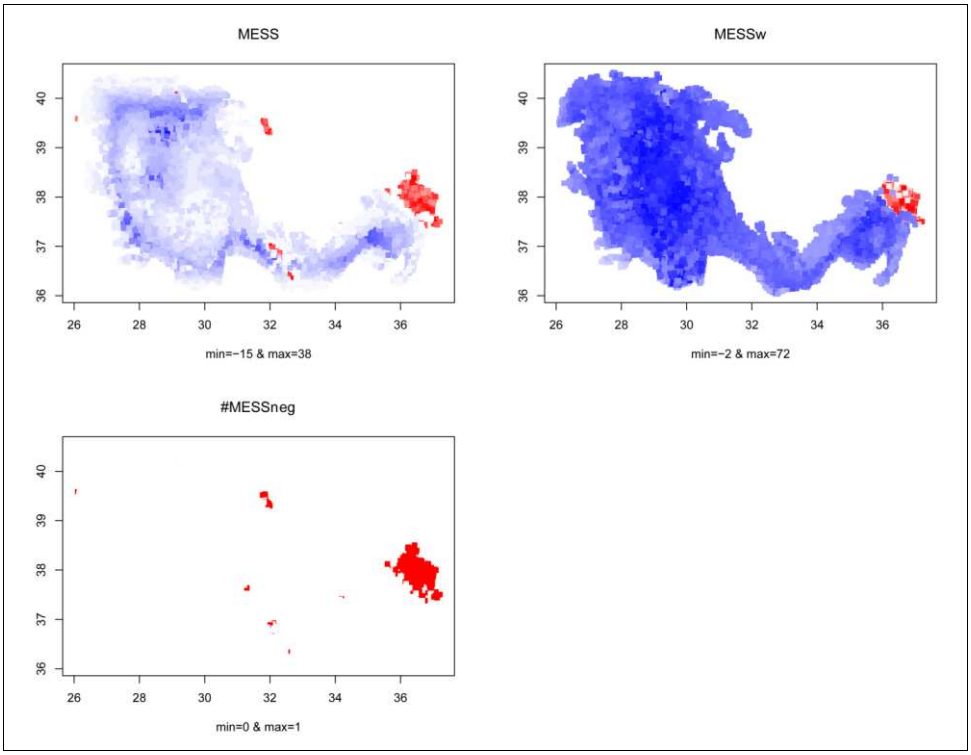

Figure 6. *MESS plots of the model projection to 2070 according to RCP8.5. Pixels in red indicate sites of extrapolation. MESSw plot is the MESS plot weighted by the number of extrapolating predictors. MESSneg plot shows how many predictors are extrapolating in each site*

Predictions into negative MESS areas should be approached carefully. Limiting factors map is shown in *Figure 7*.

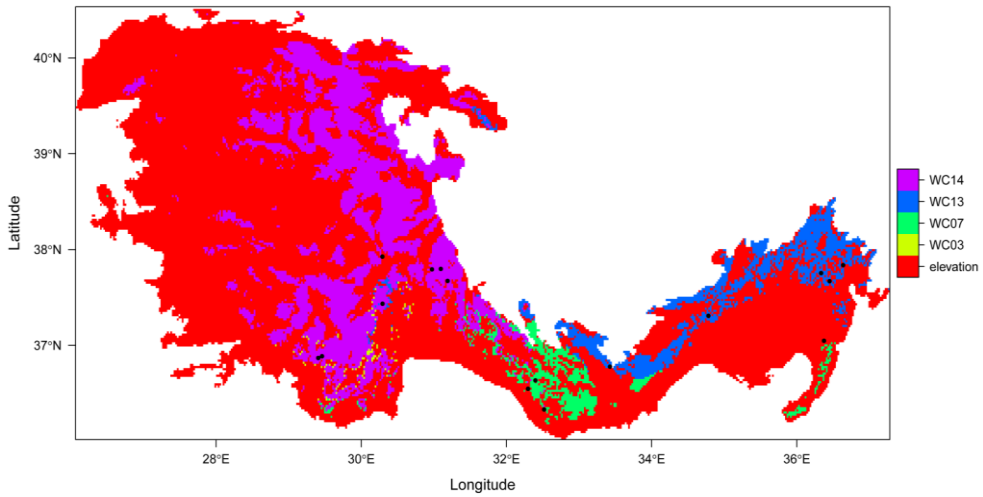

Figure 7. *Limiting factors map. This map indicates the most limiting factor in each grid cell*

Discussion

Our results show that *Ips mannsfeldi* will expand its range towards north-western part of Turkey (*Figure 5*). The most important factor for the distribution of the species is elevation. However, it's important to note that elevation showed strong correlation with most of the bioclim variables regarding temperature in our case. We chose to keep elevation as a predictor because of its relevance to the distribution of the host tree *Pinus nigra* which occurs between 1000-1800m along the Taurus Mountains in the Mediterranean region and in the inner Anatolian region (Atalay and Efe, 2012). Elevation is also the most limiting factor for the distribution of the species (*Figure 7*). Another curious result is that the second most limiting factor which also prevents the distribution towards north-west part of Turkey is the precipitation of the driest month (WC14). A map of ΔWC14 shows that according to RCP8.5 climate change scenario precipitation of the driest month will drop in those regions (*Figure 8*). Precipitation is known to be important in the distribution of other Scolytinae species. For example, in their work Mendoza et al. (2011) found that *Dendroctonus rhizophagus* had a narrow ecological niche in terms of precipitation. Furthermore, in their ecological niche factor analysis with 19 bioclim variables the species was "essentially linked to the precipitation of the driest month". According to our model the decrease in this variable will make the Aegean region (north-western area of Turkey) available to the species by 2070.

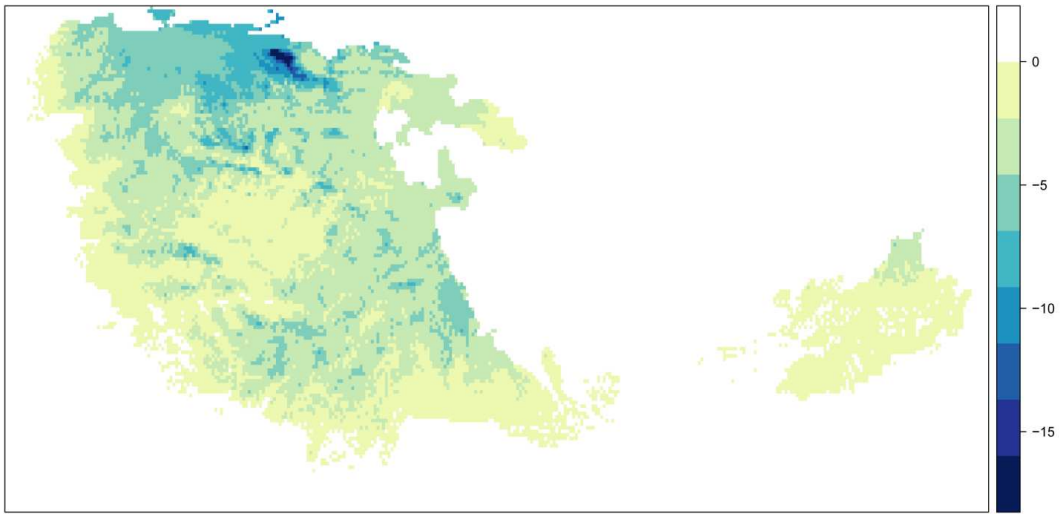

Figure 8. *The map showing the difference between the precipitation of the driest month value (WC14) of current and 2070 RCP8.5 data of each grid cell*

Conclusion

In light of this data, the species has the potential to be an important pest species in the future. The data on the biology and the distribution of *Ips mannsfeldi* is very limited at the moment. Further studies are needed to explore the specific geographical distribution of *Ips mannsfeldi* which depends on forest characteristics across its potential distribution area.

Abstract. *Mentha spicata* plants were subjected to various abiotic stresses in order to evaluate the triggering of signals and the phenolic compound levels of leaves. Total phenolic compound levels exhibited specific responses to a particular abiotic stress factor that responded rapidly to drought exposure, light intensity, and with a slight change in response to salt stress and heat stress. A parallel change was found in an elevation in hydrogen peroxide (H_2O_2) contents. Change in anthocyanin and carotenoid contents in response to drought, different light intensities, salinity and temperature stress was encountered with a change in H_2O_2. A change in the malondialdehyde level was also exhibited, depending on the levels of oxidant and antioxidant availability during particular abiotic stress factors. This risk was accomplished by the regulation of phenylalanine ammonia lyase activity. Prolonged exposure showed a reduction in chlorophyll content. Higher anthocyanin, carotenoid, H_2O_2 and total phenolic compound levels were expressed in the plasticity of plant acclimation at different levels. The tolerance of abiotic stress factors is apparently closely associated with the non-enzymatic antioxidant system via metabolome readjustment. We suggest that biosynthesis of these compounds is tightly regulated, reflecting plant plasticity when acclimating to different types of abiotic stress.

Keywords: *acclimation, climate changes, phenylalanine ammonia lyase, signaling molecules, stresses*

Introduction

Spearmint (*Mentha spicata* L.) belongs to the Lamiaceae family. It is an aromatic plant cultivated as a crop for their secondary metabolites products. Hence, is widely used in the food products, cosmetics and pharmaceuticals industries (Elmastas et al., 2005; Snoussi et al., 2015). In addition, spearmint leaf and oil are used for folk medicine (Nozhat et al., 2014; Snoussi et al., 2015).

Spearmint leaf contains high contents of phenolic compounds and hence could possess strong antioxidant activities among other different antioxidant compounds such as anthocyanin, carotenoids, and ascorbic acids (Kaur and Kapoor, 2002; Qader et al., 2011; Chon et al., 2012; Cao et al., 2015). Moreover, the high phenolic contents consider a promising source of bioactive secondary metabolites in the food industry and in human health (Kaur and Kapoor, 2002; Mimica-Dukic and Bozin, 2008; Soni et al., 2015).

Environmental factors including abiotic and biotic are key to spearmint growth due to the perennial nature of the crop. These variables have a direct impact on biochemical pathways, accordingly affecting the metabolism of secondary metabolites products (Muniram et al., 1992; Edwards et al., 2000; Fletcher et al., 2010). Furthermore, plant tolerance and minimizing the damage caused by stress are based upon stress perception,

© 2018, ALÖKI Kft., Budapest, Hungary

activation of complex signaling pathways in order to respond in a rapid and efficient manner for coping effectively with abiotic and biotic stimuli (Jones and Dangl, 2006; Rejeb et al., 2014). Signaling pathways induced by stress involve the accumulation of metabolites and positively affects a plant's response to stress. These metabolites include reactive oxygen species (ROS), phytohormones, phenolic compounds, ion flux (like $Ca^{2+)}$, activation of mitogen-activated protein kinases (MAPKs), protein phosphorylation and others (Dixon and Paiva, 1995; Lattanzio et al., 2006; Arbona et al., 2013; Baxter et al., 2014; Rejeb et al., 2014).

Review of literature

Abiotic environmental stresses activate a multiple response resulting in changes in primary and secondary metabolites production. Accumulation levels of secondary metabolites including phenolic compounds are controlled in response to environmental cues (Dixon and Paiva, 1995; Payyavula et al., 2012). These compounds are synthesized through derivatives of the pentose phosphate, shikimate, and phenylpropanoid pathways in plants and are stress induced (Randhir et al., 2004). Phenylalanine ammonia lyase (PAL) is the key enzyme in the biosynthesis of phenylpropanoid compounds (Solecka, 1997). These include wide ranges of secondary metabolites (Dixon and Paiva, 1995; LaCamera et al., 2004). Phenylpropanoids have important functions in several different pathways in: plant defense against pathogens and predators; protection from UV irradiation; signal transduction and communication with other organisms; and as regulatory molecules (Dixon and Paiva, 1995; Ferrer et al., 2008; Vogt, 2010). Phenylalanine ammonia lyase regulates entry into the phenylpropanoid pathway and is influenced by environmental stimuli, including pathogens, UV radiation, light intensity, temperature and drought, among others (Dixon and Paiva, 1995; Yoshioka et al., 1996; Rivero et al., 2001; MacDonald and D'Cunha, 2007).

Abiotic environmental stresses particularly drought and salinity have the most effect on spearmint growth and production. Moreover, it had shown is sensitive to water stress (Delfine et al., 2005; Telci et al., 2010; Okwany et al., 2012). Furthermore, this sensitivity was experienced through photosynthetic performance changes included stomatal conductance, chlorophyll fluorescence, and chlorophyll content. In addition, all of which affects photosynthetic capacity and eventually productivity in general (Delfine et al., 2005). Hence, the biosynthesis of secondary plant metabolites significantly increases within a plant species under abiotic stressful conditions (Selmar and Kleinwachter, 2013; Stavroula and Rahul, 2017). For that, spearmint has significant antioxidant activity (Elmastas et al., 2005).

M. spicata has been reported to have high phenolic contents among other studied vegetables (Kaur and Kapoor, 2002). The aim of the present work was the examine the biochemical changes of spearmint leaf tissue due to environmental effects. To achieve this aim, the assessment of the alterations in anthocyanins, carotenoids, H_2O_2, MDA, total phenolic compounds, chlorophyll contents and PAL activity of *M. spicata* leaves due to the insults of abiotic environmental factors (drought, salinity, heat shock and light quantity) in time dependent manner to visualize the attempt of these biochemical changes to protect leaves tissues against these insults.

Materials and methods

Plant materials and growth conditions

Spearmint (*M. spicata* L.) was grown under controlled conditions (14 h light with~ 54 µE, and 21 °C/10 h dark and 20 °C, 55-60% relative humidity) in 2:1:1 peat moss, perlite and vermiculite. Trays filled with cultured pots were transferred to a growth chamber with controlled conditions and after 6 weeks of the process of germination, the plants were exposed to one of the following types of abiotic stress, i.e., light, salinity, temperature, and drought, with different lengths of exposure, relative to the abiotic stress type, or kept in growth chamber conditions without any changes. After the specified time periods of exposure to specific abiotic stress conditions the samples were analyzed in order to investigate the physiological changes in response to the type, duration and intensity of abiotic stress.

Abiotic stress treatments

For drought treatment, plants were irrigated with tap water three times a week for a period of six weeks of growth under controlled conditions. Then the plants were introduced to a water deficit continuing on for three time periods (3 days, 6 days or 9 days), withholding water. At the end of each specific drought exposure plant sample leaves were collected directly in liquid nitrogen in plant growth chamber and stored at -80 °C until further analysis (Egert et al., 2013). Controlled samples were irrigated continually three times a week for a further period (3, 6 or 9 days) and again after the plant reached a period of six weeks' growth under controlled conditions. Salinity treatment was of 6-week-old plants were irrigated with NaCl solution (100 mM) three times per week for up to 14 days. Samples collected in interleaves started at 2 days, 6 days, 10 days and 14 days in a growth chamber (Nishizawa et al., 2008). Controlled samples continued to be irrigated three times a week for a further 2 days, 6 days, 10 days and 14 days with tap water under controlled growth conditions. Heat shock was imposed by transferring 6-week-old plants to grow at 4 °C (cold), 25 °C, 30 °C and 35 °C. Samples collected in interleaves started after 2 h, 4 h and 6 h of incubation at the desired temperature (Egert et al., 2013). Finally, 6-week-old plants were grown at light quantity ≈54 µmol photon/m^2s (control), then light quantity treatment plants were then transferred to grow under 10 µmol photon/m^2s, 100 µmol photon/m^2s, or 1000 µmol photon/m^2s. Samples collected in interleaves started after 2 h, 6 h, 12 h and 24 h of growth under the desired light quantity described by Oelze et al. (2011).

Quantification of chlorophylls, anthocyanins and carotenoids

Chlorophylls quantification was performed according to Porra (2002). In briefly, 20 mg of the tissue samples were ground in 1 ml cold 80% acetone followed by 1 h darkness incubation then centrifugation at 13,000 rpm, 4 °C for 10 min. The supernatant was read on 646.6 and 663.6 nm.

Cold methanol/HCl/water (90:1:1, vol:vol:vol) was used as extraction solution of anthocyanins and carotenoids. Sims and Gamon (2002) was used for quantification of anthocyanins and carotenoids contents.

Measurement of H_2O_2

The leaf hydrogen peroxide content was analyzed as described by Christou et al. (2013) with minor modification. 0.1 g frozen leaf material was thoroughly mixed on ice with 0.1%

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

(w/v) trichloroacetic acid. The homogenate was then spinning at 15,000 *g* for 15 min at 4 °C. In a new tube, 500 µl of the supernatant was collected to 500 µl of 10 mM potassium phosphate buffer (pH 7.0) and 1 ml of 1 M KI and mixed gently. The absorbance of the assay mixture was read at 390 nm and the content of H_2O_2 was calculated based on a standard curve of known concentrations of H_2O_2.

Lipid peroxidation

The level of lipid peroxidation was analyzed to determine malondialdehyde (Hodges et al., 1999). Briefly, 50 mg of aerial tissue was homogenized in 1 mL of 80% (v/v) ethanol on ice. The homogenate was centrifuged at 16,000 g for 20 min at 4 °C and 0.5 mL of supernatant was mixed together with 0.5 mL of 20% (w/v) trichloroacetic acid containing 0.65% (w/v) thiobarbituric acid. The mixture was incubated at 95 °C for 30 min and then immediately cooled in an ice bath. After centrifugation at 10,000 g for 10 min, the absorbance of the supernatant was measured at 532 nm, subtracting the value for nonspecific absorption at 600 nm. The MDA concentration was calculated from the extinction coefficient 155 mM^{-1} cm^{-1}.

Protein quantification

Protein extracts were determined based on the Bradford method (1976). Briefly, 50 mg of aerial tissue was homogenized in 1 mL of 100 mM HEPS buffer (pH 7.6) on ice. The homogenate was centrifuged at 13,000 rpm for 10 min at 4 °C. 0.2 mL aliquot of supernatant was mixed with 1 ml Bradford reagent, then the absorbance of the supernatant being measured at 595 nm. The content of protein was calculated based on a standard curve of known concentrations of BSA.

Determination of total phenolic content

Total phenolics were determined using the Folin-Ciocalteu (Singleton and Rossi, 1965) reagent and as described by Kaur and Kapoor (2002). 2 g Tissue samples were homogenized in 80% aqueous ethanol at room temperature and centrifuged in cold at 10,000 g for 15 min after which the supernatant was saved. The residue was re-extracted twice with 80% ethanol and the supernatants were pooled, put into evaporating dishes, and evaporated to dryness at room temperature. The residue was dissolved in 5 mL of distilled water. One-hundred micro liters of this extract were diluted to 3 mL with water and 0.5 mL of Folin-Ciocalteu reagent was added.

After 3 min, 2 mL of 20% of sodium carbonate was added and the contents were mixed thoroughly. The absorbance measured at 650 nm with UV/VIS split beam spectrophotometer (SPUV-16, SCO, Germany) for 60 min using catechol as a standard. The results were expressed as mg catechol/100 g of fresh weight material.

Assay of PAL activity

PAL activity in the leaf extract was determined according to Campos et al. (2004). Briefly, 0.2 ml of the protein extract was incubated at 40 °C for 30 min with 2 ml of 50 mM borate buffer (pH 8.5) and 110 µl of 100 mM l-phenylalanine (pre-dissolved in 50 mM borate buffer pH 8.5). Before doing the absorbance readings, the proteins were precipitated by adding TCA at 4% (w/v). The samples with TCA were incubated for 5 min at room temperature and then centrifuged at 10,000 g for 5 min. The absorbance

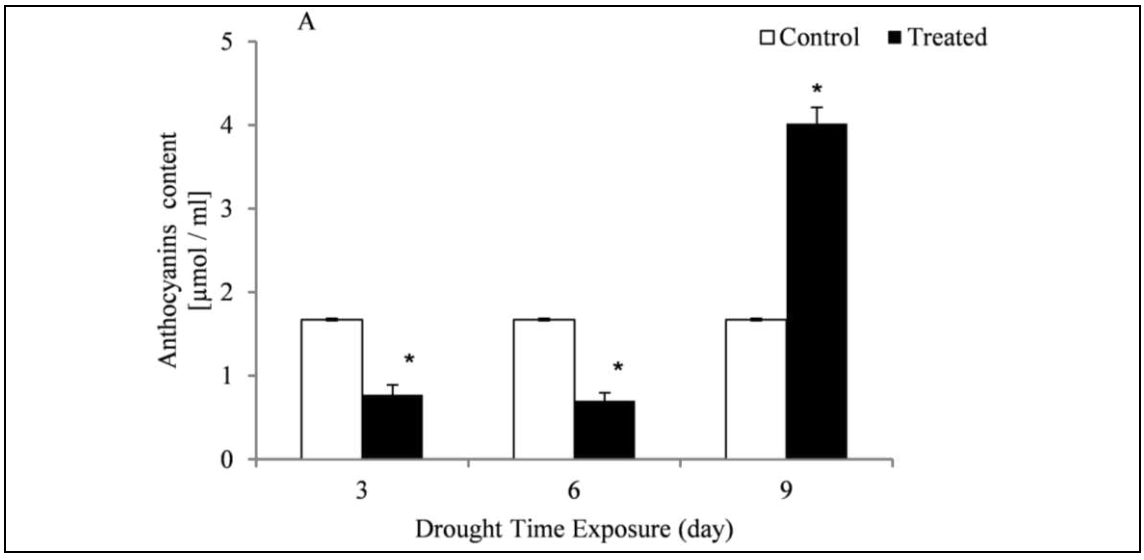
DOI: http://dx.doi.org/10.15666/aeer/1603_25372564
© 2018, ALÖKI Kft., Budapest, Hungary

of the supernatant was read at 290 nm at the beginning and after the incubation time. PAL activity was calculated as µmol of cinnamic acid per min and mg protein under the specified conditions.



Statistical analysis

For all experiment, samples were analyzed and all the assays were carried out in triplicate. Results are expressed as mean± SD. The comparison between two samples was performed by student's *t*-test and the *P* value of ≤ 0.05 was considered as significant.

Results

Effects on anthocyanin and carotenoid contents

Anthocyanin contents increased significantly 2.3 fold over the control in plants harvested only after nine days of drought treatment. The contents increased significantly in plants exposed to different light regimes (10 µE, 100 µE and 1000 µE) compared with the control (54 µE). However, the rising in content depends on the light quantity and duration of exposure. A significant 4 folds increase in contents was detected in plants exposed to 1000 µE among all time points. 100 µE light exposure showed two points of increments; first after 2 h and the second rising which was mostly constant after the next time points of detections. The behavior of anthocyanins content after 10 µE light exposure showed high elevation after 2 h reaching 7 folds of increment then the rest time points showed around 3 folds of increment. The highest contribution to salinity treatment showed significantly increment reached 1.7 and 1.5 fold after ten and fourteen days of exposure, respectively when compared with the control. Anthocyanin contents were significantly increased after 4 °C treatment at $t = 4$ and after 35 °C at $t = 2$ when compared with the control (25 °C; *Fig. 1*).

Continuous for long duration of drought (9 d) and salinity (14 d) showed the highest H_2O_2 levels reaching 21 and 9 folds when compared with the control, respectively. The basal steady state level of H_2O_2 was 0.4 µmol/g FW instantly raised after short-term (2 h) of different light intensities as well as temperature fluctuations exposure. After 24 h of sustained light intensity exposure, the content was constant despite the light dose (10 µE, 100 µE and 1000 µE compared to growth condition) which reached the maximal level of 4.6 folds compared with the control. The maximal level of H_2O_2 at 4 °C, 30 °C and 35 °C was 10, 9 and 4 folds after 6 h, 4 h and 2 h of exposure, respectively.

Lipid peroxidation changes with abiotic stressors

MDA was analyzed as measuring the end products of lipid peroxidation caused by ROS triggered by various abiotic stresses. The results showed that the lipid peroxidation level significantly increased and reached 1.7 fold after six days of drought treatment, around 2 folds after 6 h of 10 µE exposure and remain constant, 1.7 folds after 6 h of 1000 µE exposure and 2.2 folds after 4 h of 4 °C exposure when compared with the control conditions, as shown in *Figure 4*.

Total phenolic contents

In this study, the amount of phenolic compounds (TPC) as example of nonenzymatic antioxidants (*Fig. 5*). A significant increase in TPC levels was detected in plants of moderate duration drought exposure reached 1.9 fold, strongly related to any change in light intensity regardless to the period of exposure (> 7 folds); the shifting from normal light to low light, moderate light and high light intensities and finally for moderately high temperatures intensity regardless to the period of exposure; 30 °C reached more than 1.7 fold versus the control conditions.

Effects on PAL-specific activity

Activation of PAL enzyme is also a key component of the antioxidative system of abiotic-challenged spearmint leaves. The results showed that activity of PAL was induced significantly to prolonged exposure to drought, light intensity, salinity and high temperature stresses (*Fig. 6*). PAL-specific activity in leaves of *M. spicata* significantly increased more than 1.4 fold after 6 d of drought treatment, moderate and high light caused more than 1.5 fold activity increments after 24 h of treatment, salinity was caused 1.5 fold increments and 35 °C elevated the activity around 1.4 fold after 6 h of exposure when compared with the control conditions. The overall pattern in the PAL enzyme activity showed similarity to the anthocyanin, H_2O_2 and TPC pattern in plants under prolonged abiotic stress conditional shift.

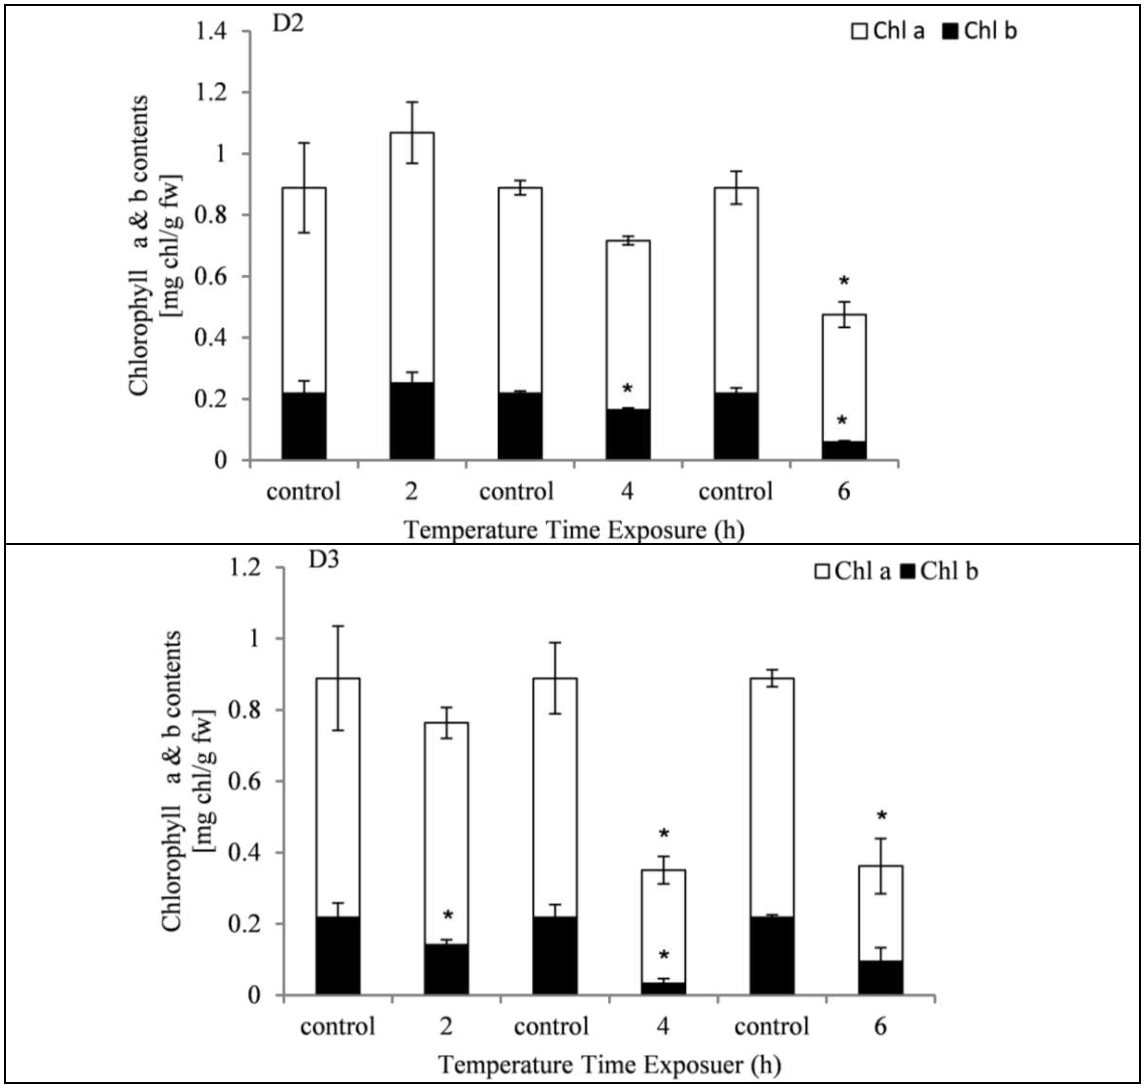

Figure 7. *Chlorophyll a and b contents in leaves M. spicata subjected to various abiotic stresses. A- Drought. B- Light intensity (B1- 10 µE, B2- 100 µE and B3- 1000 µE). C- Salinity. D- Heat (D1- 4 °C, D2- 30 °C and D3- 35 °C). The effect with different time points in comparison with control. Data represent mean values ± SD of n = 3. The significance of difference was calculated using the Student's t test with P ≤ 0.05*

Chlorophyll *a* contents decreased significantly after different light intensities and moderate and high temperatures exposure. While chlorophyll *b* contents decreased significantly after moderate and high light intensities and moderate and high temperatures exposure. These reductions caused strongly reduction in total chlorophyll content.

Discussion

The accumulation of secondary metabolites occurs in plants naturally and under adverse kinds of environmental stress (Akula and Ravishankar, 2011). However, such metabolites play a major role in the adaptation of plants to the environment and in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_25372564
© 2018, ALÖKI Kft., Budapest, Hungary

acclimatizing to stress conditions. Such accumulation is dependent upon the type, severity and the period of exposure to abiotic stress factors.

Anthocyanin in foliage is stimulated by different abiotic and biotic factors (Chalker-Scott, 1999; Winkel-Shirley, 2001). Accumulation there is influenced by the type of abiotic stress and greatly increased in light (Chalker-Scott, 1999) in order to ensure that the leaf tissue has acclimated to the experimental conditions.

Anthocyanin accumulation, known as signalling, is marked by or linked to the browsing of plant stress (Close and Beadle, 2003; Eryılmaz, 2006) and supposedly has a role in the screening of underlying photosynthetic tissues, increasing light saturation, and light compensation points (Albert et al., 2009) protecting against photoinhibition, and serving as an osmotically active solute and an antioxidant of free-radicals, in addition to functioning as a UV screen (Close and Beadle, 2003; Neill and Gould, 2003; Hughes et al., 2005). However, it must be said that stress tolerance may be a consequence of an improved resistance to oxidative stress (Eryılmaz, 2006). The evidence for these changes in anthocyanin accumulation occurred in line with H_2O_2 accumulation during exposure to different light intensities, to drought for long periods, and to low temperature for short periods of exposure. Consequentially, PAL-specific activity increased with drought and long term light and salinity exposure. In addition, its protection and tolerance roles were apparent when the chlorophyll content was affected by prolonged exposure to abiotic stress factors, such as different light intensities, and different temperatures exposure.

Carotenoids act as light-harvesting pigments and protect photosynthetic systems like nonenzymatic antioxidant compounds against reactive oxygen species generated during stress (Loggini et al., 1999; Chu et al., 2010). Thus, maintaining a higher or constant level of total carotenoids during a stressful condition allows the plant to tolerate this and to cope with oxidative stress (Munné-Bosch and Alegre, 2000). Among the key biological functions of carotenoids are the sensing and signalling of oxidative stress conditions through nonenzymatic oxidation by ROS (Ramel et al., 2012).

Our results are in agreement with previous studies related to plant acclimation to stress (Loggini et al., 1999; Ruban and Horton, 1999; Chu et al., 2010). An elevation of endogenous carotenoid content was strongly apparent with different light intensities, under prolonged drought and salinity exposure. Carotenoids are considered to be the first line of defense for plants against Singlet oxygen ($^1O_2$) toxicity (Knox and Dodge, 1985). Light stress generates the oxidation of the carotenoid β-carotene, leading to the accumulation of different volatile derivatives. They were found to cause changes in the expression of a large set of genes identified as $^1O_2$ responsive genes. Therefore, next to their antioxidant and light-harvesting functions, carotenoids, through their oxidation by ROS, play a role in the sensing and signaling of oxidative stress conditions as well (Ramel et al., 2012). In addition, carotenoid content induction under salt stress is an attempt to protect the cell against harm and to detoxify plants from the effects of ROS (Verma and Mishra, 2005; Kachout et al., 2013). This is a consequence of H_2O_2 accumulation in spearmint leaves under the same treatment. Results of the present study showed that H_2O_2 accumulation in spearmint leaves was slight in the short term but great under long term drought stress exposure, that sensitivity to the quantity of light was dependent upon the time period of exposure and that salinity was greater after long periods of exposure. Damage from temperature stress was greater from a shock of cold and increased markedly with time. Being subjected to a moderately high temperature caused greater damage than being subjected to a high temperature. Under abiotic stress,

the production of ROS clearly increased as one of the earliest responses of plant cells to stress (Jajic et al., 2015). H_2O_2 accumulation was found to precede the activation of signaling and to be a consequence of signaling, whereas, H_2O_2 acted as a central player in stress signal transduction pathways, for its features were freely diffusible and relatively long-lived (Hossain et al., 2015). However, H_2O_2 accumulation depends on the balance between the rates of its production and its enzymatic and non-enzymatic utilization.

ROS levels can rise significantly in plants subjected to various types of abiotic stress. Drought induction of H_2O_2 accumulation was in line with the manner of the severity of drought stress since several organelles are the seats, as well as the first target, of reactive oxygen species produced under drought stress (Sharma and Dubey, 2005; Farooq et al., 2009). The accumulation of H_2O_2 is considered to be one of the main features of a plant leaf's response to light stress (Mullineaux et al., 2006; Gondim et al., 2013). In addition, salinity stress has an impact on the H_2O_2 content in leaves, which is in agreement with previous reporting (Gondim et al., 2013). All of these abiotic stress factors rising of H_2O_2 accumulation; result from its role as a signalling molecule for initiating intracellular and systemic signalling or promoting oxidative stress, triggering the signalling process associated with cell death (Mullineaux et al., 2006; Upadhyaya et al., 2007; Oelze et al., 2011). In addition, induction might be associated with the ability of H_2O_2 to generate antioxidant enzymatic defenses in order to reduce abiotic stress deleterious effects, since H_2O_2 is a probable signalling molecule that mediates crosstalk between signalling pathways and contributes to the protection against other types of stress (Neill et al., 2002). However, among the ROS, a variety of plant responses has been found to be triggered by H_2O_2, such as the acclimation to stress and developmental stages (Ślesak et al., 2007; Jajic et al., 2015). Those transcriptome responses include photosynthetic light reaction genes, genes in the phenylpropanoid pathway, ROS scavenging, photorespiration, the reductive pentose phosphate pathway, and hormone biosynthesis and response (Cheeseman, 2007). This was in line with PAL-specific activity changing in response to the same abiotic stress factors (*Fig. 6*).

Non-enzymatically formed RES resulting from ROS accumulation measured by MDA levels tends to correlate with oxidative stress (Pintó-Marijuan and Munné-Bosch, 2014). However, MDA levels do not correlate with the intensity of the stress applied, and supposedly are a latent RES signal synthesized in the plant cells involved in fast-response gene activation (Farmer and Mueller, 2013). Despite its relationship to oxidative conditions, MDA accumulated under abiotic stress and has an activity biased towards abiotic stress gene expression (Weber et al., 2004). For that reason, induced lipid peroxidation is involved in diverse signalling processes in order to protect plants from oxidative stress by scavenging ROS (Mène-Saffrané et al., 2009). This thorough production of lipid fragmentation, including carotenoid fragmentation as well as radical amplification, generates a process by which defense genes protect against oxidative stress (Ramel et al., 2012; Zoeller et al., 2012).

Drought increases the generation of the MDA level particularly after moderate time exposure and exposure to light quantities, enhancing the raising of the MDA level after exposure for a moderate period of time, and at all times, after exposure to low light intensity. Salt stress causes a slight increase in the MDA level after a particular period of exposure. Heat stress raises the MDA level in response to a shock of cold. These changes in the MDA levels in response to different abiotic stress factors are in line with H_2O_2 content changes under the same abiotic stress factors. ROS causes oxidative stress

in plants (Farooq et al., 2009). ROS can directly attack membrane lipids and increase lipid peroxidation (Mittler et al., 2004). Overproduction of ROS increases the content of MDA and is considered to be an indicator of oxidative damage (Moller et al., 2007).

The production of phenolic compounds in plant tissues rises under abiotic stress conditions (Król et al., 2014). Phenolic compounds include several classes that enhance and prod plant metabolic plasticity, enabling plants to survive under different types of environmental stress. Indeed, plant exposure to environmental constraints results in the harmful impact on plant growth and yield. The impact of severe drought stress on the accumulation of phenolic compounds showed a considerable increase in their protective action against the oxidative stress and dehydration of the leaves (Gregorová et al., 2015). Phenolic accumulation is generated by different light intensities and the UV-B activation of the phenolic biosynthetic pathway. Scavenging role of ROS results in hampering UV-B penetration, thus protecting the photosynthetically active tissues (Mazza et al., 2000; Airaki et al., 2012). Low temperatures alter membrane structure and also affect the activity of membrane-bound enzymes, as the deleterious effects of production of ROS can be associated with chilling. Moreover, low temperatures impair the whole antioxidant plant response. Hence, plants activate ROS scavenging systems (Oh et al., 2009; Airaki et al., 2012).

Secondary metabolites provide resistance that is both passive (continuously available) and active (in response to specific stressors). Phenolic compounds have been shown to be more effective antioxidants *in vitro* and *in vivo* than Vitamin A and Vitamin C, even when synergistically amplifying their biological effects (Blokhina et al., 2003; Kasote et al., 2015). Their antioxidant effectiveness is due to their high reactivity as hydrogen or electron donors, and they stabilize and delocalize unpaired electrons, chelate transition with metal ions, and alter peroxidation kinetics (action of flavonoids) and hydrogen peroxide scavenging (Rice-Evans et al., 1997; Blokhina et al., 2003).

The deleterious effect of high H_2O_2 accumulation was encountered with the rise in anthocyanin and carotenoid content for the same period of drought exposure. At the same time, total phenolic compound accumulation at moderate drought exposure was in line with increased lipid peroxidation levels and with PAL-specific activity changing in response to drought stress at all times of exposure.

The highest total phenolic compound accumulation for abiotic stress factors was in response to the exposure to different light intensities after being transferred from normal light growth intensity. This was done to protect against the highest H_2O_2 accumulation, lipid peroxidation levels and what might be the action of anthocyanin and carotenoid accumulation, including at the highest level and the increase in PAL-specific activity in response to different light intensities, particularly when increasing the time exposure. The change in total phenolic compounds did not reflect being subjected to a high level of salinity, which might be due to the moderate salt concentration (100 mM NaCl). However, prolonged exposure raised both the H_2O_2 accumulation and the MDA levels. This internal imbalance was modulated with a strong accumulation in anthocyanin and carotenoid content by greatly increasing the PAL activity by the same factor. Exposing plants to a sudden temperature shift showed the accumulation of phenolic compounds due to low and moderate temperatures. This results in an elevation in H_2O_2 content, an increase in PAL activity, and affects chlorophyll content. Low temperature impairs the whole antioxidant plant response. Hence, plants activate ROS scavenging systems when

heat stress has been reported in order to reduce Chl content (Oh et al., 2009; Aien et al., 2011; Airaki et al., 2012).

Phenylalanine ammonia lyase activity was shown to be regulated when exposed to stress (MacDonald and D'Cunha, 2007). Thus, PAL has been recognized as a marker of environmental stress. Long-term drought stress increases PAL activity with consistent effects on lignin content since drought stress causes disruption of lignin deposits in leaves (Terzi et al., 2013). Different light intensities revealed that PAL activity was induced in leaves (Ali et al., 2006). PAL activity increased linearly and positively correlated with increased NaCl concentrations (Gao et al., 2008). High temperatures can mediate changes in secondary cell wall metabolism and possibly regulate the lignin biosynthetic pathway through a differential expression of proteins involved in cell wall biosynthesis (Han et al., 2009). In addition, low temperature had an effect on PAL activity, as well as on the rate of accumulation of different phenolic compounds in leaves (Solecka et al., 1999; Solecka and Kacperska, 2003). Moreover, our results showed that PAL activity increased in response to a prolonged exposure to different abiotic stress factors (*Fig. 6*).

Increased PAL activity could be a response to the cellular damage provoked by either the severity of abiotic stress or the duration of the stress. It seems that in spearmint leaves the enhancement of PAL activity could be related to the involvement of this enzyme as the plant response to abiotic stress factors. Phenylpropanoid compounds act as protectants against adverse environmental stress. The overall pattern of PAL activity was consistent with the change in anthocyanin, carotenoid, H_2O_2, MDA and total phenolic compound levels in response to drought stress (Gholizadeh, 2009).

PAL activity was higher in plants exposed to bright light (1000 μE) than when compared to those in normal light. The enzyme involved in lignin biosynthesis that increased lignification, may be caused by the light intensity level due to the enhancement of phenylpropanoid enzymes as an acclimation response (Ali et al., 2006). Increased PAL activity was linearly and positively correlated with the duration of increased salt stress. This elevation could be a response to the cellular damage caused by the duration of salt stress exposure. Moreover, anthocyanin and carotenoid contents were elevated in line with the change in H_2O_2 content and the increase in PAL activity (Gao et al., 2008)

Concentrations of chlorophyll components are normally used to quantify leaf senescence in stressed plants. Leaf maturation and senescence exhibit chlorophyll degradation and can be induced by stress. However, both are processes involving the regulation of plant hormones (Zhang et al., 2016). Drought can lead to a decrease in chlorophyll content, depending on the duration and severity of drought (Terzi and Kadioglu, 2006). Exposure to a higher light intensity induced a loss of chlorophyll (Jagtap et al., 1998). Salinity adversely affects Chl content (Meloni et al., 2003). Chlorophyll pigments decreased under high temperature treatments (Aien et al., 2011). Our results of Chl content showing a decrease in the early period of drought stress, and with an increase in later periods are in agreement with the findings of Terzi and Kadioglu (2006). Different light intensities exhibited that prolonged exposure to low, moderate and bright light can cause greater degradation, and consequently, a reduction in the levels of total chlorophyll as a result of the limitation of the concentration of carotenoids, which can prevent chlorophyll photo-destruction (Gonçalves et al., 2005; Zervoudakis et al., 2012). Salinity stress (100 mM NaCl) showed slight effects on Chl content, though starting in later periods, it might not be a high concentration.

Nevertheless, the observed decrease in Chl content may be attributed to both an inhibited synthesis of that pigment and a damaged PS antenna system. Low temperature stress showed a slight gradual decrease in Chl content with the increased time duration of exposure. Low temperature can influence plant photosynthesis and lower the utilization of light Chl biosynthesis (Wu et al., 1997; Tewari and Tripathy, 1998). Moderate and high temperatures also reduced Chl content, which might be an effect of Chl biosynthesis (Tewari and Tripathy, 1998). Temperature stress may have caused a reduction or increase in the synthesis of enzymes or the corresponding mRNA responsible for Chl biosynthesis.

Conclusion

In conclusion, among the several markers used to evaluate the oxidative status of plant tissues in response to abiotic stress are the photosynthetic pigments chlorophyll and carotenoid, Reactive oxygen species, Reactive carbonyl species, Antioxidant systems and Transcriptomics and Proteomics (Pintó-Marijuan and Munné-Bosch, 2014).

The present results lead us to conclude that under different levels of abiotic stress anthocyanin, carotenoid and total phenolic compound content are enhanced in an attempt to protect leaf tissues against any damage. Signals such as ROS, and particularly in H_2O_2, might, due to its features, be the major trigger. The PAL activity and the chlorophyll content changes were used to explore the crosstalk and complexity of the responses.

The present study introduces new data about the *M. spicata* leaves responses to different abiotic stress factors that were focused on some biochemical changing. For that, study data recommend further investigation need to cover other partner and major players in plant responses such as flavonoids, glutathione, ascorbate contents and antioxidant enzymes activities, in particular, total ascorbate peroxidase, glutathione reductase, and polyphenol oxidase.

Abstract. Global food security is continuously being haunted by the rapid increase in population and drastic climate changes. Drought stress (DS) negatively affects the soil fertility and plant growth. Drought often induces cell dehydration and ultimately inhibits cell expansion and division, leaf size, stem elongation, root proliferation, disturbed stomatal oscillations, plant water and nutrient uptake. Biochar (BC), being a carbon-rich material, ameliorates the adverse effects of drought on plants. BC is a carbon-rich (65–90%) solid product of biomass pyrolysis that contains numerous pores and oxygen functional groups and aromatic surfaces. BC application modifies microbial habitats by improving the soil's physical properties. Additionally, BC porosity can decrease soil bulk density and improve soil aeration conditions. BC can increase the available water contents that influence nutrient accessibility to microbial cells. BC application increases the plant growth, biomass and yield of crops under water deficit conditions. It also enhances nutrient uptake, photosynthesis and modifies gas exchange characteristics in plants growing under water paucity. Additionally, it improves the physical, biological properties and water holding capacity of the soil. Keeping in view the tremendous importance of BC, this review highlights its potential in mitigating the DS in plants and sums up by revealing future prospects regarding its role in improvement of soils. Overall, this review can contribute towards the better understanding of the BC-mediated tolerance mechanisms in plants under low water availability.
Keywords: *drought, soil, reclamation, remediation, pyrolysis*

Introduction

The current world population is approximately 7.3 billion and is predicted to reach 8.5 billion by 2030 (Warner and Jones, 2017). As we know that global food security is continuously being haunted by the rapid increase in population, shrinking resources and drastic climatic changes therefore, to feed the large population, improved cropping systems and strategies are dire need of time (Khalil et al., 2016; Lesk et al., 2016; Rauf et al., 2016). In many regions of the world, biotic and abiotic stresses such as drought, high salinity and extreme temperatures results in the most injurious limitations for the plant's growth and productivity (Khan et al., 2017; Noman et al., 2017; Thalmann and Santelia, 2017; Islam et al., 2018a,b). Among the abiotic stresses, DS is reckoned as the most injurious environmental factor causing significant losses of growth as well as yield of the plants (Ali et al., 2016; Calvo-Polanco et al., 2016; Dubois et al., 2017). The drought has severely affected terrestrial agriculture in the past and recent times. DS along with other abiotic stresses like heavy metal contamination not only limits plant production but also pose more risks to human health (Arshad et al., 2016; Noman and Aqeel, 2017). For example, Liu et al. (2017d) revealed that DS differentially influenced the translocation and redistribution of Cadmium in peanut plants during various developmental stages. It often induces cell dehydration and ultimately result in inhibition of cell expansion and division, leaf size, stem elongation, root proliferation, disturbed stomatal oscillations, plant water and nutrient uptake as well as enhance proline accumulation (Kaushal and Wani, 2016; Khalil et al., 2016; Noman et al., 2015). Moreover, it also curtails photosynthesis (Khalil et al., 2016; Khan et al., 2017). Additionally, it causes oxidative stress through the production of reactive oxygen species (ROS) (Apel and Hirt, 2004; Cruz de Carvalho, 2008). It lowers soil water potential and water use efficiency (WUE) (Kaushal and Wani, 2016). Consequently, combating DS is a challenging task for achieving food security under the drastic climatic changes worldwide.

Historically, several techniques were utilized to improve the soil structural and biochemical properties. For example, thousands year ago, Romans and Greeks incorporated the animal manure and human feces in the soil as an organic amendment to increase the soil quality and fertility. At that time they knew that previously legumes grown field can be beneficial for wheat crop cultivation. Earlier different materials (e.g., plant residues, farm manure sea-shells, and other waste) were adopted as an organic amendment to improve the crop growth. Currently, BC, compost and animal manure as a soil amendment is well-known while crop straw, sewage sludge, peat, wood shavings, and sawdust are also used for soil amendment to improve quality and fertility. BC amendments have large-scale agricultural, economic and environmental benefits (Kumar et al., 2017). BC is a highly porous, fine-grained charcoal that can hold carbon combusted under low oxygen at relatively high temperatures (Fazal and Bano, 2016). Like bioethnol, it can be produced from different organic materials such as plant residues (Llorach-Massana et al., 2017; Tayyab et al., 2018), pecan shells, sawdust (Komnitsas et al., 2016), peanut hulls (Chu et al., 2017), Hardwood (Laird et al., 2017), paper mill sludge (Cho et al., 2017), Palm kernel shell and Palm oil sludge (Lee et al., 2017), pine and jarrah woods (Jiang et al., 2017), rice straw (Liu et al., 2017a), cotton stem, wheat straw, rice husk, corn stem, peach branch, walnut shell, yak manure, eucalyptus wood sawdust (Wang and Liu, 2017), hemlock char and switchblade grass char (Yu et al., 2017) poultry manure (Barati et al., 2018) and pig manure (Liu et al., 2017a). Different types of biomass and the thermochemical conditions are used to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

pyrolyze it significantly to influence the quality of BC and its potential uses (Chen et al., 2011; Yu et al., 2017a). The production of BC is quite similar to charcoal, the production of which is one of the oldest developed technologies (Lehmann and Joseph, 2009). However, it is entirely different from charcoal as it is not primarily used as a fuel, but for atmospheric carbon (C) capture and storage, or bio-sequestration. The porous structure of char particles enhances the water-retaining capacity and nutrient retention of soil, as well microbial accumulation. Due to its perceived benefits of increasing nutrient and water retention, it is used as a soil conditioner that is very promising and useful for soil amendments (Skjemstad et al., 2002; Yu et al., 2017a Sarfraz et al., 2017). Additionally, BC modifies microbial habitats by improving the soil's physical properties. Its porosity can decrease soil bulk density and improve soil aeration conditions. It can also increase the available water contents that influence nutrient accessibility to microbial cells. In addition, it can increase water contents at the permanent wilting point, which indicates the capability of BC, via its high porosity, to store water that is unavailable to plants. Keeping water in this manner is beneficial, especially in sandy and degraded soils (Abel et al., 2013; Skjemstad et al., 2002). Moreover, the improved water retention capacity means that there is a more excellent capability of the soil to hold water against dry-wet cycles in the natural environment, which can favor the maintenance of a stable microbial activity (Liang et al., 2014). A significant body of knowledge reported that BC amendment enhances plant growth, seed production, biomass and nutrient absorption under the drought conditions (Bamminger et al., 2016; Gonzaga et al., 2017; Paneque et al., 2016). However, according to our literature survey, a comprehensive review of the beneficial and effective role of BC upon plants under water deficit conditions is not documented yet. Hence, we reviewed the BC application in agricultural production under DS to give attention to the development of soil health and fertility to feed the increasing population.

Adverse effect of drought stress on soil properties

Drought is one of the most severe abiotic stresses. It strongly affects soil microbial activity, fungal properties, soil respiration and litter decomposition (Geng et al., 2015; Hoogmoed et al., 2016; Mariotte et al., 2015; Schmidt et al., 2017). The significance of the microbial community in soil ecosystem functioning is well known which plays a pivotal role in soil fertility and improvement in soil structure (Wall and Bardgett, 2012; Arafat et al., 2017). For example, microbial communities produce enzymes and are responsible for 90% of soil organic matter (SOM) decomposition (C mineralization), which determines nutrient turnover (Bastida et al., 2013; Swift et al., 1979). Nevertheless, drought can affect soil microbial communities by restricting diffusion of substrate, inhibitory compounds (e.g., plant and antimicrobial secondary metabolites), enzymes and inducing microbial physiological stress (Davidson and Janssens, 2006). As compared to fungal communities, bacterial communities are sensitive to disturbances caused by drought and their response directly affects soil fertility and soil structure (Bardgett and Wardle, 2010).

Adverse effect of drought stress on plant yield and biomass

Drought negatively influences the plant growth and crop production. It affects the plant development causing severe reductions in crop productivity. Additionally, it can initiate a series of physiological and biochemical changes in plants. It also decreases dry matter production, leaf area index, number of seeds per plant, seed size and finally the grain yield. Moreover, reduction in intercellular carbon dioxide concentration, stomatal conductance and transpiration is also associated with it. Chlorophyll fluorescence is negatively correlated with DS as it has severe effects on leaf gaseous exchange rate and chlorophyll fluorescence depending on various developmental stages of the plant and the duration of DS. Under drought, some processes such as plant hydraulic status, phytohormones, osmotic adjustment, and ROS signaling control the reduction of plant growth.

Production and physicochemical characteristics of biochar amendments

BC is a recalcitrant source of soil organic carbon combusted under low oxygen at relatively high temperatures (Fazal and Bano, 2016). Theoretically, almost any form of organic material can be utilized for its production (Kuppusamy et al., 2016). However, its properties can vary widely depending on feedstock and processing conditions (Brewer et al., 2017). For attaining several benefits of sustainable agriculture, the amendment of BC is being increasingly discussed as a drought mitigation tool. In the last decade, tremendous increase in the number of publications using a variety of BCs addressed as drought mitigation approach shows the high interest of researcher regarding the enhancing scope of BC. Tripathi et al. (2016a) presented the concept of sustainable BC production. Standard techniques used for BC production are rotating kilns, vertical silo-type reactors, hydrothermal carbonization, gasification, and slow and fast pyrolysis. BCs are categorized with a high concentration of total organic carbon (30-70%) depending upon the pyrolysis conditions (aeration, temperature and time), mineral contents (Na, Mg, K, Fe, etc.) EC, pH, volatile matter and ash concentration (Jindo et al., 2014; Qayyum et al., 2015; Yu et al., 2017). However, the BC properties are significantly affected by the feedstock nature (Brewer et al., 2017). It is produced from the thermal conservation of biomass feedstock's (*Fig. 1*). Among various techniques (e.g., pyrolysis, gasification, and hydrothermal carbonization), pyrolysis which heats the biomass at relatively low temperatures (300-900°C) in the absence of oxygen, is the most cost-effective and efficient method for BC production (Cha et al., 2016; Qian et al., 2015). Additionally, pyrolysis can be subdivided into slow and fast pyrolysis, according to the different heating rates. Even though, there exist some disadvantages such as energy inefficiency and demand for long production duration, slow pyrolysis is still widely used for BC production presently due to the comparatively higher BC yield (Liu et al., 2015; Tripathi et al., 2016a). The characterization of sophisticated methods contains the quantification and identification of surface functional groups, polycyclinc aromatic hydrocarbon, aromatic compounds, active surface area and scanning electron microscopy (Hale et al., 2012; Harris et al., 2013). BC has demonstrated its multifunctional roles in carbon sequestration (Crombie et al., 2013). The linkage of BC properties and its application are shown in *Figure 2*. Consequently, before their implementation, BC must be carefully analyzed (Aller et al., 2017; Kuppusamy et al., 2016). BC amendments may have large-scale environmental, economic as well as agricultural benefits. Deep investigation of the BC-mediated plant

resistance mechanisms against abiotic and biotic stresses will enhance our further understanding of the better agronomic management of economically important crops (Kumar et al., 2017).

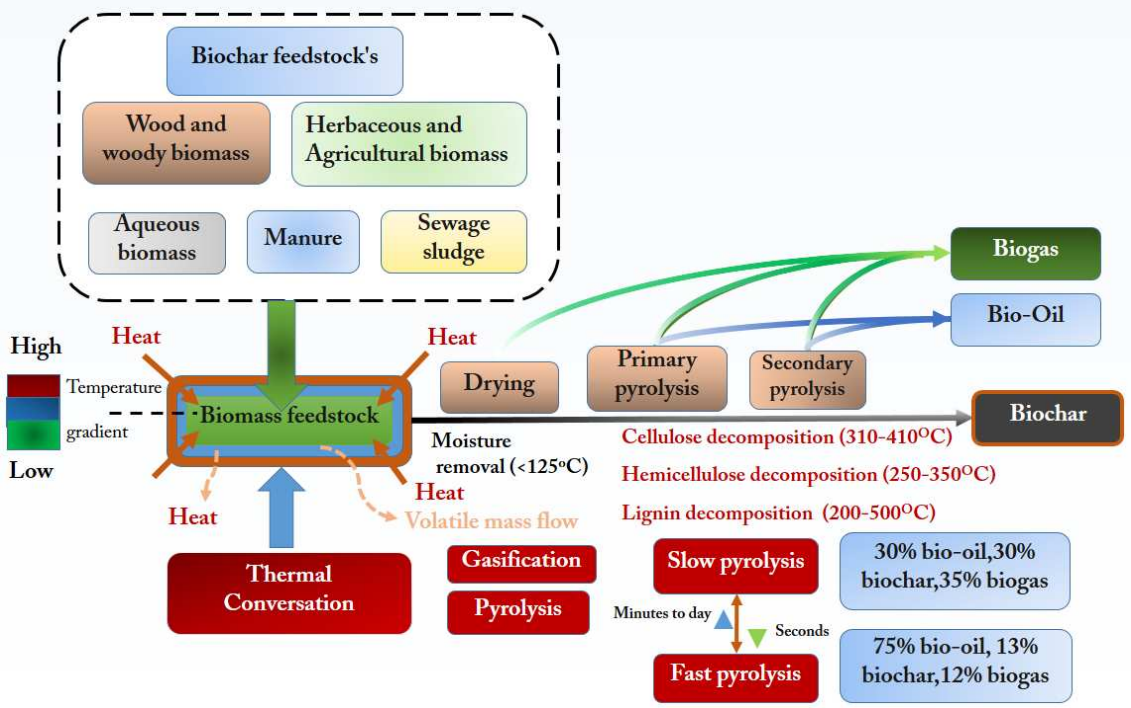

Figure 1. *The brief introduction of biochar feedstock and its production processes (slightly modified from Xiao et al., 2016)*

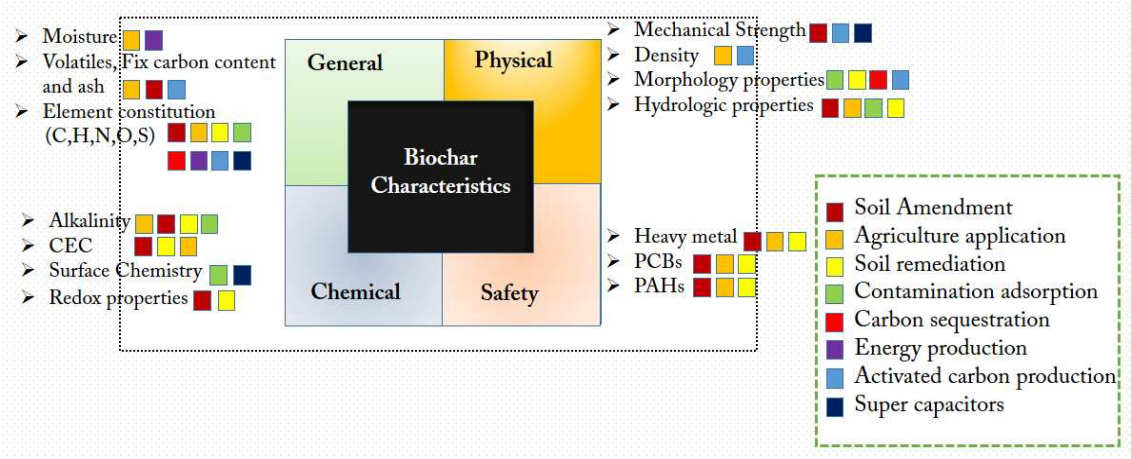

Figure 2. *A brief introduction of the linkage between biochar properties and its application (modified from Xiao et al., 2016). Here, the more number of square boxes designate the improvement in various soil properties via utilization of biochar through various applications which are represented by different color. Moreover, the abbreviations included are C (carbon), H (hydrogen), N (Nitrogen), O (Oxygen), S (Sulpher), CEC (Cation exchange capacity), PCB (Polychlorinated biphenyl) and PAH (Polycyclic aromatic hydrocarbons)*

Biochar improves plant development and biomass under drought stress

The beneficial effects of BC application under limited water conditions have been widely reported (Akhtar et al., 2015; Paneque et al., 2016; Ramzani et al., 2017; Rogovska et al., 2014). The BC amendment improved growth and biomass of plants under drought-stress (*Table 1; Fig. 3*). Similarly, use of BC exhibited the highest vegetative growth and seed production of field-grown sunflower under non-irrigation conditions (Paneque et al., 2016). Its application enhanced tomato fruit quality, growth and yield under deficit irrigation (Agbna et al., 2017). Similarly, its use supports the growth of winter rapeseed under drought conditions (Bamminger et al., 2016). Likewise, Basso et al. (2013) found a significant increase in soil WHC in a soil column study with hardwood BC and predicted that the increased WHC might enhance available water capacity (AWC = available water between field capacity and permanent wilting point) for crops. Tomato seedlings were protected from wilting due to improved soil moisture content with higher (30% v/v) rates of BC amendments in sandy soils (Mulcahy et al., 2013).

Improving plant WUE has the potential to decrease plant susceptibility to limited water conditions. Amending BC with soil has been proposed as a way to ameliorate the WUE as it has been revealed to improve the WHC of soils (Licht and Smith, 2017). It enhanced hydrology characteristics, soil physical properties, increased soil water content and grain yields and WUE under natural conditions (Xiao et al., 2016). Different BCs have different impacts on soil water relations. For example, amendment of fresh BC with sandy loam soil enhanced the plant available water (PAW) but not aged BC. Addition of fresh and aged BC amendment with silt loam soil did not affect PAW and WUE. It indicates that BC type and BC age have variable impacts on PAW and WUE, meaning that BC amendments can increase plant growth and soil water relations under water-limited conditions for some but not all soils (Aller et al., 2017). Similarly, in another study, Licht and Smith (2017) demonstrated amendment of lignocellulosic BC to forest soils reduced DS in pine-oak systems. Akhtar et al. (2014)

described that under limited freshwater resources, application of partial rootzone drying irrigation (PRD) in combination with BC might be a promising approach for saving water and enhancing productivity and quality of tomato. Similarly, Agbna et al. (2017) revealed that integration of BC amendment (BA) with deficit irrigation (DI) represents a viable technique that can save water without reducing tomato yields as well as improving the quality of the fruits. This method can mainly be used in areas that regularly struggle with water shortage. More precise optimal levels would likely need to be determined for commercial purposes in future studies as they are likely to be case specific, depending on soil texture, BC type and climate among other factors (Karer et al., 2013). Vaccari et al. (2015) suggests that BC amendment may ensure the same yield while using less external input such as irrigation water. A 10% yield increase of barley (*Hordeum vulgare*) with BC amendment in a chernozem region under prolonged DS was attributed to increased water availability. Githinji (2014) reported that the leaf quality rate of tomato increased with BC application in sandy loam soil as compared to the unamended control. Barley is grown in the coarse sandy subsoil underwater, use of 1% straw gasification BC increased the root and growth shoot. However, gasification BC was not active on barley growth under water stress in sandy loam soils (Hansen et al., 2016). Studies have described that the application of BC improved the photosynthesis of plants under DS (Haider et al., 2015; Lyu et al., 2016; Xiao et al., 2016).

BC significantly improved the relative water contents (RWC), stomatal conductance (Gs), chlorophyll contents, WUE, photosynthetic rate (Pn) and stomatal density of drought-stressed tomato leaves (Akhtar et al., 2014). Its application increased the leaf relative water contents (RWC), transpiration rate and osmotic potential of drought-stressed maize as compared to the control (Haider et al., 2015). Kammann and Graber (2015) study the influence of BC on drought tolerance of Chenopodium quinoa displayed increased drought tolerance, growth and water-use efficiency of quinoa. BC amendment in soil improves the soil water content, photosynthesis, leaf water potential and transpiration under scarce water conditions. However, application of BC resulted in increased soil water content in Danish coarse sandy soil under drought. Leaf water potential, photosynthesis, and transpiration of Maize plants were maintained by 2 and 3% BC addition to the subsoil (Ahmed et al., 2016). Similarly, Haider et al. (2015) reported that BC use in poor sandy soils could improve plant growth by enhancing soil-plant-water relations and photosynthesis under both deficit and excess water. Lyu et al. (2016) revealed the addition of BC could strengthen the defense of plant leaves against DS by influencing electron transfer and regulating the activity of protective enzymes, thereby reducing the effects of drought damage to the photosynthetic apparatus. This showed that BC response under DS might vary with soil, BC type and plant species.

Biochar inoculate with microorganisms mitigate drought stress

Studies have shown that BC may minimize water stress in plants when applied with microorganisms (Liu et al., 2017b; Nadeem et al., 2017). Egamberdieva et al. (2017) reported inoculation of BC with Bradyrhizobium sp. Enhance the growth, biomass, phosphorus (P) uptake and nitrogen (N), and nodulation in lupin (*Lupinus angustifolius L.*) seedlings under DS as compared to the only microbial inoculation. Nadeem et al. (2017) reported inoculation of BC with Pseudomonas fluorescens, reduced the harmful impact of DS on cucumber (*Cucumis sativus L.*) growth, increased the shoot length,

DOI: http://dx.doi.org/10.15666/aeer/1603_25652583
© 2018, ALÖKI Kft., Budapest, Hungary

shoot biomass, root length and root biomass as compared to inoculated control. Besides, significant improvements in chlorophyll and relative water contents, as well as a reduction in leaf electrolyte leakage, demonstrated the effectiveness of this approach. In another study, Liu et al. (2017b) reported that inoculation of BC (birch wood, 500 °C) with Rhizophagus irregularis decreased the WUE, N, leaf area, P in potato and did not adversely impacted the root biomass and soil pH under limited root zone water as compared to control. However, under limited irrigation soil amendment with wood-derived BC (30 $mg.ha^{-1}$) had no significant effect on soil biota groups such as protozoa, bacteria, fungi, nematodes and arthropods (Pressler et al., 2017).

The application of BC with Arbuscular mycorrhizal fungi can enhance drought tolerance of the host plant by physiological mechanisms in nutrient adsorption and biochemical mechanisms, e.g. hormones, osmotic adjustment and antioxidant systems. However, application of BC to the agricultural soil with Arbuscular mycorrhizal fungi stimulated the growth of extra-radical hyphae in soil and increased mycorrhizal colonization of roots. As the water potential of the soil was the same with and without BC amendment, it is unlikely that the observed effects on plant growth were related to possible benefits from the water holding capacity of the BC (Mickan et al., 2016).

Previous studies have revealed that the utilization of BC by microbial inoculation can be helpful in alleviating DS in plants, depending on the type of BC or other factors. Additionally, BC is increasingly discussed as a climate change (drought) mitigation tool, but there is limited knowledge about its interactive effects with future soil DS, possibly influencing its stability as well as its beneficial effects on soil microorganisms and plants.

Biochar improves soil biological and physiochemical properties

Several studies have shown that BC improves the physical properties of soil under DS conditions (Bamminger et al., 2016; Hansen et al., 2016; Zhang et al., 2017). Ye et al. (2015) has shown BC had features that could improve soil properties such as density, acidity, moisture retention, and the stability of heavy metal ions in the soil. Zhang et al. (2017) has shown that soil physicochemical properties improved by the BC and increased abundance and diversity of bacteria have contributed to the ability of BC to protect plants against tobacco bacterial wilt. Total porosity (TP) increased and soil bulk density (BD) decreased, air properties improved (FAC and FAP) and there was an increase in the retention of water available for plants (Pranagal et al., 2017). Liang et al. (2014) also reported that BC application in calcareous soils decreased the significantly bulk density of soil while soil WHC increased. Abel et al. (2013) showed that BC application in sandy soil increased the total pore space, decreased the soil Bulk density (BD) and water retention at permanent wilting point. The equilibration of corn residue BC in a sandy loam soil for 30 days decreased the BD and increased water holding capacity WHC of the soil (Igalavithana et al., 2017). The BC amendment decreases the BD as well as an increase in the soil water contents, have observed in a variety of soils with different soil texture (Herath et al., 2013; Igalavithana et al., 2017). Burrell et al. (2016) showed that straw BC was the most effective at improving plant available water and soil aggregate stability in a coarse-textured soil. Similarly, Baiamonte et al. (2015) reported that application of BC had increased the aggregate stability in sandy-clay soil. However, under crop cultivation, more detailed studies are required to appraise the impact of BC on soil aggregate stability. In general, BC amendment improves the soil

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_25652583
© 2018, ALÖKI Kft., Budapest, Hungary

physical properties under reduced water supply and beneficial for plant growth under semiarid conditions. Though, under drought, additional investigations are required about the BC amendment. In addition, BC aging affected the soil properties, and more studies are needed to evaluate the BC aging effect on soil properties under DS (Arthur et al., 2015). In addition, soil water retention may vary with BC sources and pyrolysis condition. For example, Similarly, Narzari et al. (2017) demonstrated that the BC produced at higher temperature had higher pH and WHC. However, it is suitable for soil having water retention capacity as an amendment. Further investigations, by using different BCs at different rate of application and various pyrolysis conditions might be useful to improve the effectiveness of BC on the soil WHC under DS (Lee et al., 2015). The addition of BC increases the WHC of the soil, which is a critical factor in enhancing plant growth and yield under drought (Akhtar et al., 2015; Basso et al., 2013; Foster et al., 2016; Lehmann et al., 2011). An increase in the WHC of soil under DS might be because of higher CEC and porous structure of BC (Laghari et al., 2016). Studies testified that application of BC improved the soil CEC as compared (Lychuk et al., 2015). Artiola et al. (2012) reported that the application of pine forest waste BC in the soil retained water in the soil, however under laboratory conditions; significant portion of BC pores remained empty. However, there might be the difference in the WHC of BC under field conditions, which need to be investigated in the near future. The application of BC at vineyard improved the soil water content measured on different time (Baronti et al., 2014). BC amendment to sandy soils increased WHC and to retain vast amounts of PAW for crops for more extended periods of times (Basso et al., 2013). Liu et al. (2017c) revealed BC with a high intraporosity and irregular shapes will most efficiently increase water storage in coarse soils. Feedstock, pyrolysis temperature and charring residence time are various factors involved might be useful to produce BC with varying porosity.

Ajayi and Horn (2016) compared the potential of clay and BC in improving mechanical resilience and water retention of sandy soil. Soil water retention capacity increased with Na-bentonite at more negative matric potentials, whereas BC was efficient to increasing soil water retention capacity at saturation which might be caused by the increase in soil porosity. The BC application in the sandy loam soil improved the WHC of the soil used for rice cultivation (De Melo Carvalho et al., 2014). The field application of BC in vertisol increased the wheat growth and developed the ability of soil to retain water under semiarid Mediterranean conditions (Olmo et al., 2014). Githinji (2014) reported that application of BC in the field increased the macroporosity of loamy sand soil.

These studies revealed that BC might be efficient to increase the WHC of soils. Most of the studies were conducted in sandy soils. However, more studies are needed to explore the functions of BC in increasing the WHC of soil with different texture and environmental conditions. Limited research investigated characteristics of BC produced from various feedstocks to determine which are the most effective for improved soil water holding capacity WHC of soil.

How biochar can be applied to improve crop yield

When applying BC to soil for improving its fertility, the BC should be located near the soil's surface in the root zone, where the bulk of nutrient cycling and uptake by plants takes place. Certain systems may benefit from the application of BC in layers

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

below the root zone, for example during landscaping for carbon (C) sequestration or moisture management. Similarly, if BC is to be applied to soil solely for C sequestration purposes, placement should be done deeper in the soil. When deciding how to apply BC to soil, the specific cropping system must be taken into consideration. The likelihood of wind and water erosion losses of BC is reduced when it is thoroughly incorporated into soil, however, plowing and soil mixing are not possible or desirable in all cropping systems, at all times. In conventional field cropping systems, BC should ideally be managed using traditional farm machinery and incorporated into routine field operations. This will ensure that the costs of using BC are kept as low as possible. For example, BC can be applied and incorporated together with lime, since lime is often applied as a fine solid which must be well incorporated into soil. The majority of BC field trials reported to date used this method for incorporating BC into soil (Haque et al., 2014; Julie Major et al., 2010; Yamato et al., 2006). Broadcasting can be done by hand on small scales or on larger scales by using lime/solid manure spreaders or broadcast seeders. Moistened BC materials may be better suited to application with manure spreaders than lime spreaders. Incorporation can be achieved using any plowing method at any scale, including hand hoes, animal draft plows, disc harrows, chisels, rotary hoes, etc. As mentioned above, wind losses from applying and incorporating fine BC materials can be significant and precautions must be taken to minimize this. Banding of seeds and fertilizers is a routine operation in mechanized agriculture and involves applying an amendment in a narrow band, usually using equipment that cuts the soil open, without disturbing the entire soil surface. Banding allows BC to be placed inside the soil while minimizing soil disturbance, making it possible to apply BC after crop establishment. However, the amounts of BC that can be applied in this way are lower than those which can be achieved by broadcast applications. Wheat yields in Western Australia were improved by banding BC (Blackwell et al., 2007). When working by hand, BC can be applied in furrows opened using a hoe and closed after applying BC. Mixing it with other soil amendments such as manure, compost or lime before soil application can improve efficiency by reducing the number of field operations required. Since BC has been shown to sorb nutrients and protects them against leaching (Major et al., 2009), mixing with BC may improve the efficiency of manure or other amendment application. BC can also be mixed with liquid manures and applied as a slurry. Fine BCs will likely be best suited to this type of application using existing application equipment, and dust problems associated with these would be addressed. It could also be mixed with manure in holding ponds and could potentially reduce gaseous nitrogen losses as it does when applied to soil (Spokas et al., 2009; Yanai et al., 2007). Where high-resolution data on soil characteristics and farm machinery equipped with geographical positioning systems are available, it would possible to apply BC preferentially to areas of fields where fertility is low. Further studies are needed to address how long BC intraporosity, particle size, and particle shape will last after field application.

Conclusion and future perspectives

DS severely decreases crop yield and growth. Studies reported above showed that BC application increased the plant growth and biomass under DS. BC application in soil increases the nutrient uptake, photosynthesis and modified gas exchange features in plants. More studies are required to evaluate the role of BC under DS conditions. The

© 2018, ALÖKI Kft., Budapest, Hungary

studies mentioned above showed that BC application with microbes might improve the plant tolerance against DS. However, time-course and detailed studies are needed to explore the long-term effectiveness of BC + microbes on the growth of plants and to separate the effects of BC on different stages of microbial life cycles under prevailing conditions of limited water. Amendment of BC with the inoculation of Arbuscular mycorrhizal fungi can enhance drought tolerance mycorrhizal plants through physiological mechanisms in nutrient uptake and biochemical mechanisms regarding adjustment, osmotic, hormones and antioxidant systems. Extensive studies are needed for the development of models for the better recommendation of BC rate based on soil, plant, and environmental conditions.

Abstract. Bahabad plain in central Iran contains vital groundwater resources, mainly used in agriculture. A well-field at the centre is discharging water for a further located mining and industrial site, results in a closed depression in water-table which divides the aquifer system into southern (S) and northern (N) zones. In this research, the sustainability of groundwater resources was evaluated by groundwater balance studies and safe yield analyses. The annual safe yields are estimated to be 22.3 and 3.7 million cubic meter (MCM) for the zones S and N, respectively. Based on balance studies, total annual abstractions (33.9 and 8.6 MCM, respectively) are greater than the total inputs, exceeding the safe yield, as well. So, the aquifer is over-exploited and groundwater is withdrawn from storage, declining water-table with an average rate of 50 cm annually. In contrast to the public perception of the major impact from well-field abstractions, this research clarifies the role of both industrial and agricultural abstractions in depletion of Bahabad aquifer. Therefore, safe yield must be considered in order to avoid further aquifer mining. It can be attained by decreasing industrial and agricultural abstractions and managing recharge to augment the aquifer storage, assuring the sustainability of the groundwater resources.
Keywords: *aquifer mining, groundwater balance, over-exploitation, safe yield, Yazd*

Introduction

The components of the water cycle are in a balancing state, naturally. However, human interventions, for example over-exploitation of the groundwater resources, disturb the balance leading to unfavorable impacts on the environment. Groundwater resources as a part of the water cycle are important in terms of water supply for different uses in many regions of the world, especially in arid and semi-arid areas where surface-water resources are not generally available. Over-exploitation (abstractions over than the recharge) of these vital resources results in ''groundwater mining'' which is followed by negative effects including depletion of aquifer storage, saline water intrusion, groundwater level decline, land subsidence and other environmental, economic and social problems (Brown et al., 1999). To avoid the problems, a proper management plan is required, assuring the sustainability of the groundwater resources. In this regard, concepts such as safe yield or sustainable yield were applied in groundwater managing strategies, generally restricting the withdrawals at values without negative impacts on the groundwater reservoirs. (Naik and Awasthi, 2003; Alley, 2004; Kalf and Woolley, 2005; Zhou, 2009). Safe yield of the groundwater system is defined as the amount of groundwater that can be exploited continuously without detrimental effects on the groundwater reservoirs (Central Groundwater Board, 1984). It includes all exploitable groundwater originating within the catchment (Naik and Awasthi, 2003).

To ensure sustainability, it is essential that the yield constraints is established based on the hydrological mass balance (Sophocleous, 2000). "The water balance is the

© 2018, ALÖKI Kft., Budapest, Hungary

perfect tool for a better understanding of the valuable groundwater resource which is nothing more than a material balance that accounts for all inputs, outputs and changes in storage within a system defined by prescribed boundaries" (Sophocleous, 2000).

Safe yield, as a feasible managing concept introduced by Naik and Awashti (2003) was implemented by many researchers (Voudouris, 2006; Taheri Tizro et al., 2007; Türker et al., 2013), considering water balance equation to establish the yield restrictions. Voudouris (2006) studied water balance and safe yield in coastal aquifer of Korinthia, an agrotourism center in Greece, where total abstractions are greater than the recharge and the safe yield, resulting in signs of aquifer depletion, seawater intrusion and groundwater quality contamination. The integrated water management through measures that augment the groundwater budget in the coastal aquifer was recommended. Estimating groundwater balance of the alluvial aquifer of Kangavar in west Iran confirmed current abstractions which exceed both recharge and safe yield of the aquifer system are not sustainable and the aquifer system has overexploited. Artificial recharge of the aquifer through river beds, as well as water-saving techniques such as spray and drip irrigation were proposed in order to support sustainable management of groundwater resources in this area (Taheri Tizro et al., 2007). The results of safe yield analysis for the Yeşilköy aquifer in Cyprus (Türker et al., 2013) showed that annual safe yield exceeds the natural aquifer recharge and sustainability of the aquifer is not foreseen. Decreasing groundwater abstraction by lowering the water volume for irrigation use or providing another source like seawater desalination for domestic use were recommended to attain the safe yield.

Bahabad plain is an important agricultural area in Yazd province at central Iran. Excessive groundwater withdrawals for both agricultural and industrial usages impose more stress on the aquifer, results in continuous decline of water table with an average rate of 50 cm annually. Depleting aquifer storage, reduction of groundwater availabilities and increase in pumping costs are the main negative possible impacts which have decreased agricultural activities in the region, enhancing migration to the neighboring cities (personal communication with local governor). Reduction of quantity of the water resources increases the concerns that the safe yield of the aquifer has been exceeded, challenging sustainable development of this arid region. Hence, the aim of this study was to assess the sustainability of groundwater resources, considering estimation of safe yield and water balance. In this regard, the roles of agricultural and industrial abstractions in depleting the aquifer storage were also examined and strategies to achieve the safe yield were discussed.

Study area description

Bahabad plain, 220 km far from Yazd city at central Iran (*Fig. 1*), locates between two parallel NE-SE highlands. The alluvial sediments of the plain are situated principally in a graben structure, where the thickness increases more than 580 m at the center (Yazd Regional Water Authority, 1996). The quaternary alluvial deposits include old terraces, younger terraces, fluvial sediments and salty mud flats. There is a general trend of decreasing grain size of the sediments from south to the north, following the topographic surface slope (*Fig. 2*).

Bahabad unconfined aquifer with an area of about 366 km^2 lies between latitudes of 31° 43' and 32° 12' N and longitudes of 55° 42' and 56° 17' E. Groundwater levels are being monthly monitored in a network of 14 piezometers (*Fig. 2*) since 2002.

Bahabad aquifer is discharged by 78 pumping wells including 51 agricultural, 22 industrial and 5 municipal wells (*Fig. 1*), extracting the aquifer with an average annual rate of 25.5, 6.2 and 4.8 million cubic meter (MCM), respectively (Shirafkan, 2013). Three qanats in southern part are also discharging the aquifer with an average rate of about 1 MCM yr^{-1}. A qanat is an underground gallery dug out inside the alluvium, in order to transfer groundwater to the ground surface by gravitation force.

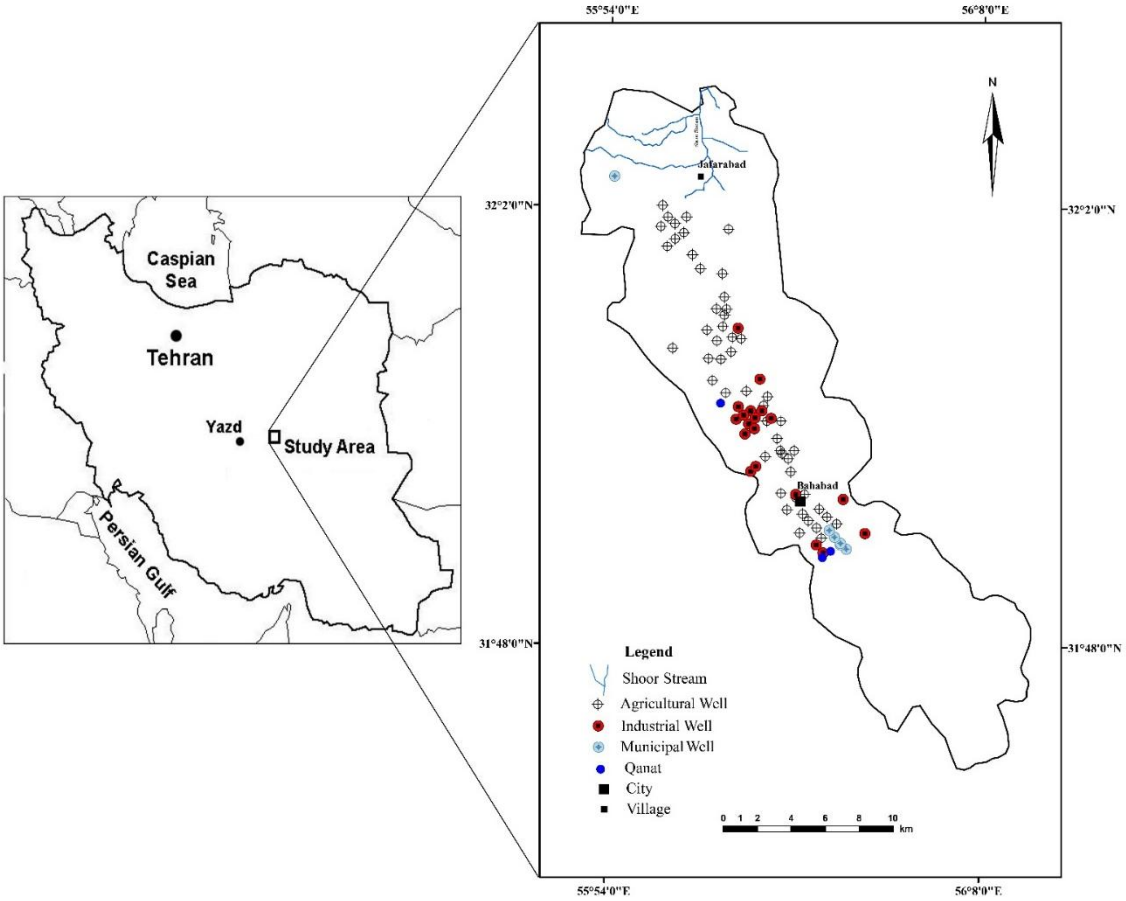

Figure 1. *Map showing location of the study area and spatial distribution of the wells and qanats in the Bahabad aquifer*

Based on iso-potential (contour) map of the aquifer, the groundwater flow is generally directed from south to the north (*Fig. 2a*). A closed depression in water table occurred at the center of the aquifer, where it is locally pumped by a well-field including 10 wells which extract groundwater for industrial uses. It must be mentioned that most of the water pumped by industrial wells is used in the Chadormalu Mining and Industrial Company which is located out of the aquifer basin, 75 km far from the Bahabad city. Due to the well-field abstraction, the flow lines are concentrated toward the center of the well-field and the groundwater divides at the vicinity of the piezometers P7 and P8 (*Fig. 2a*). It results in bisecting the aquifer system into two separated hydrological zones.

Depth to groundwater is highly decreased at the north of the plain, where the aquifer is permanently drained by the Shoor stream (*Fig. 1*).

Materials and methods

Groundwater Balance

Groundwater balance is based on the comparison of the total inputs and outputs to/from the aquifer during a specified period (balance period), written as:

$$\sum \text{Inputs} - \sum \text{Outputs} = \text{Change in aquifer storage}$$

Considering inputs and outputs to/from the Bahabad aquifer, the following balance equation was applied:

$$\left(G_{in} + R_r + I_{rf} + W_{rf}\right) - \left(G_{out} + G_d + G_w\right) = \pm\Delta V \qquad \text{(Eq.1)}$$

where G_{in} is groundwater inflow through aquifer boundary, R_r rainfall recharge, I_{rf} return flows from irrigation, W_{rf} recharge by municipal wastewater, G_{out} groundwater outflow from boundary of the aquifer, G_d groundwater drainage into Shoor stream, G_w groundwater withdrawal and ΔV change in aquifer storage volume. All terms are expressed as volume of water during the balance period (MCM yr^{-1}).

In addition to water balance formulation (*Eq. 1*), change in aquifer storage volume (ΔV) is also calculated by *Equation 2* to validate the groundwater balance calculations.

© 2018, ALÖKI Kft., Budapest, Hungary

$$\Delta V = A \times Sy \times \Delta H \quad \text{(Eq.2)}$$

where A, Sy and ΔH denote aquifer area (m^2), mean specific yield of the aquifer (dimensionless) and spatially averaged rise or decline in groundwater level during balance period (m), respectively. As the water levels are not uniform in the aquifer, the spatially monthly averaged groundwater level (H) is calculated using *Equation 3*.

$$H = \sum_{i=1}^{n} \frac{(h)_i \times a_i}{A} \quad \text{(Eq.3)}$$

where $(h)_i$ is the height of groundwater table above datum (sea level) in piezometer i (m), a_i the area of the Thiessen's polygon surrounding piezometer i (m^2), A the total aquifer area (m^2) and n the number of piezometers installed in the aquifer.

Specific yield (Sy) is defined as the ratio of the volume of water gravitationally drained, after saturation, to the total volume of the drained soil (Todd and Mayes, 2005). In the present study, Sy was determined using standard values in literatures (Johnson, 1967; Lerner et al., 1990) considering soil texture in aquifer's drilling logs. The method is generally acceptable (Fetter, 2000), employed by many researchers in areas like the study area devoid pumping test data (e.g. Obuobie et al., 2012; Lerner et al., 1990).

Safe yield

In this research the safe yield was estimated by *Equation 4* adapted from Naik and Awasthi (2003). It includes all exploitable/utilizable groundwater originating within the aquifer basin, consisting exploitable dynamic groundwater reserve (Q_{ed}), value of groundwater pumped for irrigation and other uses in wet season (Q_{wet}) and return flows from irrigation and sewage (Q_{rw}). All terms are expressed as volume per time (MCM yr^{-1}).

$$\text{Safe yield} = Q_{ed} + Q_{wet} + Q_{rw} \quad \text{(Eq.4)}$$

The exploitable dynamic groundwater (Q_{ed}) represents the long-term average annual recharge under conditions of maximum groundwater abstraction (dry season). Generally, maximum groundwater extraction occurs in Bahabad region when irrigation starts from beginning of the June until December. Thus, Q_{ed} is estimated using *Equation 5:*

$$Qed = \sum_{i=1}^{n} a_i \times (Sy)_i \times (D_{ld})_i \quad \text{(Eq.5)}$$

where $(Sy)_i$, and $(D_{ld})_i$ denote the specific yield (dimensionless) and the value of water level decline during the dry season (June to December) in piezometer i (m), respectively. Parameters a_i and n were defined before in *Equation 3*.

Value of groundwater pumped in wet season (Q_{wet}) refers to the discharge mainly by agricultural and industrial wells during January to May. In this period the total recharge by the rainfall is occurred and aquifer discharge rates by agricultural wells are mostly

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_25852602
© 2018, ALÖKI Kft., Budapest, Hungary

diminished in response to reduction in evapotranspiration and irrigation demands. This value plus return flows from irrigation and sewage are also considered as utilizable groundwater sources in the region to calculate the safe yield.

Results and discussion

Assessing groundwater balance of the Bahabad aquifer

Regarding the impact of the industrial well-field on the groundwater flow pattern (*Fig. 2a*) the aquifer was divided into two hydrological zones namely as N and S and the groundwater balance in each zone was calculated for water-year 2010-2011 (starting at September 23). Based on *Equation 1* the inputs and outputs to/from Bahabad aquifer were determined as the following:

Inputs

Rainfall recharge, groundwater flow through aquifer boundary and return flows from irrigation and domestic uses are the main inputs into the Bahabad aquifer.

a) Rainfall recharge (R_r)

Rainfall data from Bahabad climatological station at the plain center was used to determine the mean representative rainfall on the aquifer. Regarding the surface area (366 km^2) and relatively flat topography of the aquifer, the rainfall measurements in this station are representative to the whole aquifer, as the rain-gauge density in the plains is proposed be one station per 520 km^2 (Raghunath, 2009). Based on the data measured in this station for a period of 22-year (1988-2010) the depth of annual precipitation varies from 28.5 to 120.5 mm and the average annual rainfall of the plain is 81.5 mm. It mainly occurs during winter (January-March) and spring (April-May) seasons.

The relationship between groundwater recharge and precipitation is governed by different factors such as type of precipitation, climatic conditions, soil moisture prior to storm, storm characteristics (duration, intensity, peak intensity), topography of ground surface, perviousness of ground surface and vegetation cover (Bear, 1979). The rainfall recharge coefficient in adjacent areas having the same climate and lithological formations to the study area was directly measured using the experimental lysimeters (Parab Fars, 2008), which varied from 5 to 10% for the fine and coarse soils, respectively (Parab Fars, 2008). Therefore, the rainfall recharge coefficient was decided to be 10% for the zone N, which is mainly covered by sand and medium gravel sediments and 5% for the zones S with silt/clay rich alluviums (*Fig. 2b*). The annual rainfall during balance period (water-year 2010-2011 starting at September 23) was 30 mm, then annual recharge rate to the aquifer zones of S and N was estimated as the following:

$$R_r = \text{Rainfall depth} * \text{Rainfall recharge coefficient} * \text{Aquifer area}$$

$$R_r = \left(30*10^{-3}\right) * \left(10\%\right) * \left(235*10^{6}\right) = 0.7*10^{6} m^3 yr^{-1} = 0.7 \text{ MCM yr}^{-1} \text{ Zone S}$$

$$Rr = \left(30*10^{-3}\right) * \left(5\%\right) * \left(131*10^{6}\right) = 0.2*10^{6} m^3 yr^{-1} = 0.2 \text{ MCM yr}^{-1} \text{ Zone N}$$

b) Groundwater inflow through aquifer boundary (G_{in})

The entire inflow boundary of the aquifer was divided into segments named as Ij or I'j where index j denotes the number of the segment. The groundwater inflow through the segment (G_{Ij}) (MCM yr^{-1}) was calculated by Darcy's law (*Eq. 6*) considering average aquifer transmissivity along the segment (T_j) (m^2/day), length of the segment (Wj) (m) and component of the hydraulic gradient normal to it (i_j) (m/m). Flows into the segments were summed to calculate total groundwater inflow through aquifer boundary (G_{in}) (MCM yr^{-1}).

$$G_{in} = \sum_{j=1}^{m} (G_{I_j}) = \sum_{j=1}^{m} (W_j \times T_j \times i_j) \quad \text{(Eq.6)}$$

in which, the index m stands for the maximum number of the segments.

Three inflow segments were identified on the contour map of the groundwater surface in each of the zones S and N of the aquifer (*Fig. 2a*). The average transmissivity of the aquifer along the segments (T_j) has only been measured by pumping test in one exploration well at the south (segment I_1) which is about 3664.5 m^2/day. In other segments the transmissivity values were estimated by multiplying hydraulic conductivity, inferred from soil texture in aquifer drilling logs, and aquifer thickness (Shirafkan, 2013). It varies from 300 to 792.9 m^2/day at the center, decreases to about 5.5 m^2/day at the northern parts of the aquifer (*Table 1*). The decreasing trend in transmissivity values is in consistent with changes in aquifer soil texture from gravelly sand and medium gravel in south and center to silt/clay rich alluvium at the north (*Fig. 2b*).

Table 1. *Values of groundwater inflow and outflow through boundaries of the aquifer balance areas S and N during water-year 2010-2011*

Aquifer zones	Inflow (I) or outflow (O) segment	Segment width (m)	Hydraulic gradient (m/m)	Transmissivity (m^2/day)	Annual inflow or outflow (MCM yr^{-1})

In each segment, hydraulic gradient (i_j) was calculated from iso-potential map of the aquifer (*Fig. 2a*) considering head difference (dh_j) in a selected distance of dl_j ($i_j = dh_j/dl_j$). It varies from 0.001 to 0.003 m/m at inflow boundaries (*Table 1*). The highest value are observed at inflow segment I'_3 in the north of the aquifer where the slit/clay rich alluviums are dominant. Applying *Equation 6,* the total annual volume of groundwater entering the zones S and N of Bahabad aquifer were calculated as 14.4 and 5.9 MCM, respectively (*Table 1*). As a result, the main groundwater flow into the Bahabad aquifer (9.86 MCM yr^{-1}) is taking place through segment I_1 at the south of the plain.

c) Recharge due to water returns (I_{rf} and W_{rf})

Return flow consists of a portion of the water applied for irrigation, industry and domestic uses in the region, which is not used up as "consumptive use" but infiltrates, and eventually reaches the water table. It is estimated that 63.7 and 98.5% of the total extracted groundwaters in the S and N zones of Bahabad aquifer are used for agricultural activities, respectively (Shirakan, 2013). Irrigation return flow coefficients (percent ratio of return flow to the applied irrigation water) in other areas with the same soil texture, climate and irrigation management practices were determined using lysimeters. They varied from 0.4 to 38.7% depending on the total applied water, field length, irrigation management and soil texture (Jafari et al., 2012). In the present study, irrigation return flow coefficients of 15 and 10% were decided for the zones S and N, respectively. The lower value in the zone S is related to the finer texture of the surface soils. The adopted values are nationally acceptable, as they are in the range applied in many groundwater budget studies around the country (Iran Water Resources Management Company, 1991).

Annual volumes of groundwater discharged by agricultural wells and qanats at the zones S and N of Bahabad aquifer are 20 and 6.5 MCM, respectively. Therefore, the annual amounts of recharge from agricultural activities were estimated at 3 and 0.6 MCM, respectively.

$$I_{rf} = \text{Agricultural discharge rate} * \text{Irrigation return flow coefficient}$$

$$I_{rf} = 20 * 15\% = 3 \text{ MCM yr}^{-1} \quad \text{Zone S}$$

$$I_{rf} = 6.5 * 10\% = 0.6 \text{ MCM yr}^{-1} \quad \text{Zone N}$$

Disposal wells in the Bahabad urban and rural areas have the potential to recharge the aquifer, too. Per the norm prescribed by Iran Water Resources Management Company (1991), 50-70% of the water used in urban areas, percolates down in shallow disposal wells and reaches the underlying aquifer. Total annual discharges by municipal wells in the zones S and N of the Bahabad aquifer are 4.7 and 0.1 MCM, respectively. Thus, annual recharge due to the return seepage from water applied for municipal uses was estimated 2.8 and 0.05 MCM, considering return coefficients of 60 and 50% in the zones S and N, respectively. The difference in the coefficients is mostly related to variations in soil texture as it was discussed before.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_25852602
© 2018, ALÖKI Kft., Budapest, Hungary

$$W_{rf} = \text{Municipal discharge rate} * \text{Municipal return flow coefficient}$$

$$W_{rf} = 4.7 * 60\% = 2.8 \text{ MCM yr}^{-1} \quad \text{Zone S}$$

$$W_{rf} = 0.1 * 50\% = 0.05 \text{ MCM yr}^{-1} \quad \text{Zone N}$$

It must be mentioned that total groundwater discharged by industrial wells in the zone S is transferred and consumed out of the study's aquifer area; therefore, no recharge return flow to the aquifer from industrial uses is expected.

Outputs

a) Groundwater outflow from aquifer boundary (G_{out})

Groundwater flows out of the aquifer balance area through segments symbolized as O and O' in *Figure 2*. Same as the groundwater inflows, the values of groundwater outflows were estimated using Darcy's law (*Eq. 6*). The values of aquifer transmissivity in outflow segments vary from 5.5 to 300 m^2/day and hydraulic gradients change from 0.002 to 0.016 (*Table 1*). Applying *Equation 6,* the total annual volumes of groundwater leaving zones S and N were estimated to be 3 and 0.9 MCM, respectively (*Table 1*).

b) Drainage into the Shoor stream (G_d)

Shoor stream with an average discharge rate of about 40 lit/s (Shirafkan, 2013) is a gaining (effluent) river which drains the Bahabad aquifer only at the northern part (zone N). All the baseflow in the stream is derived from groundwater, as water table elevations in the vicinity of the stream are higher than the stream bed (Shirafkan, 2013). The baseflow was separated from direct runoff using straight-line method (Chow, 1988), considering lowest discharge during the year. It was estimated to be about 0.035 m^3/sec (*Fig. 3*). So, the annual volume of groundwater drained by the Shoor stream was estimated to be about 1.1 MCM.

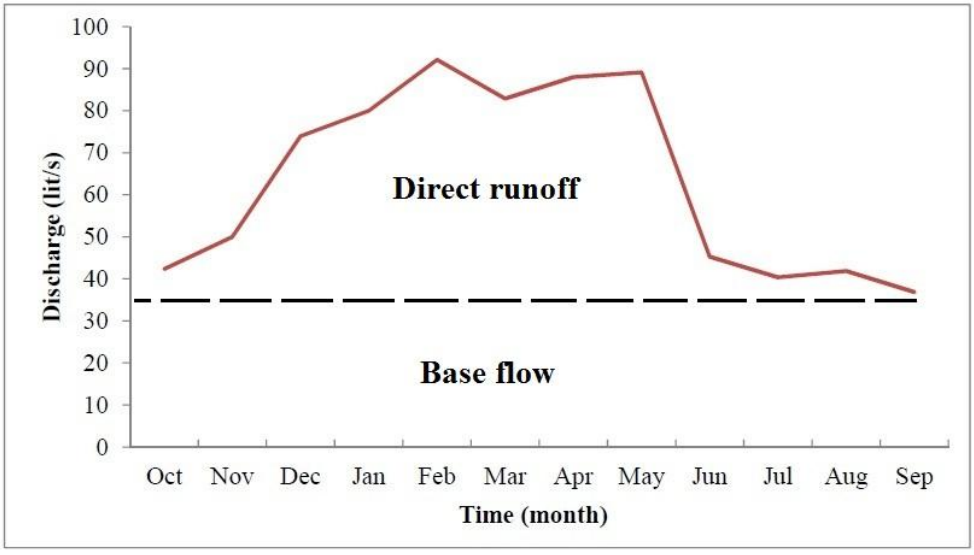

Figure 3. *Mean monthly hydrograph of Shoor stream during 1992 to 2011.*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_25852602
© 2018, ALÖKI Kft., Budapest, Hungary

$$G_d = 0 \qquad \text{Zone S}$$

$$G_d = 0.035\ m^3/sec = 1.1\ MCM\ yr^{-1} \quad \text{Zone N}$$

c) Groundwater withdrawal (G_w)

Water is withdrawn from Bahabad aquifer by deep and semi-deep wells and qanats. Based on measured data from Yazd regional water authority (Shirafkan, 2013), annual volume of groundwater extracted by agricultural, municipal and industrial wells, as well as, qanats in the zone S were 19, 4.7, 6.2 and 1 MCM, respectively. Discharge by agricultural wells in the zone N was 6.5 and by industrial wells was 0.1 0 MCM yr^{-1}. No qanats and municipal wells are presented in this zone (*Fig. 1*). Total values of groundwater withdrawn from zones S and N of the Bahabad aquifer were calculated as below:

G_w = Discharge by agricultural wells + Discharge by municipal wells + discharge by industrial wells + Discharge by qanats

$$G_w = 19 + 4.7 + 6.2 + 1 = 30.9\ MCM\ yr^{-1} \quad \text{Zone S}$$

$$G_w = 6.5 + 0.1 + 0 + 0 = 6.6\ MCM\ yr^{-1} \quad \text{Zone N}$$

Groundwater balance

The components of groundwater balance in the S and N zones of Bahabad aquifer are presented in *Table 2*. The groundwater balance of the aquifer in the zones S and N was calculated by *Equation 1* as the following:

$$(Gin + Rr + Irf + Wrf) - (Gout + Gd + Gw) = \pm\Delta V$$

$$(14.4 + 0.7 + 3.0 + 2.8) - (3.0 + 0 + 30.9) = 20.9 - 33.9 = -13\ MCM\ yr^{-1} \quad \text{Zone S}$$

$$(5.9 + 0.2 + 0.6 + 0.05) - (0.9 + 1.1 + 6.6) = 6.8 - 8.6 = -1.8\ MCM\ yr^{-1} \quad \text{Zone N}$$

Total annual outputs from S and N zones are calculated 33.9 and 8.6 MCM, exceeding the total inputs of 20.9 and 6.8 MCM, respectively. A negative groundwater balance of about 13 and 1.8 MCM yr^{-1} was estimated for these zones during water-year 2010-2011.

In order to validate the aquifer balance calculations (*Table 2*), change in aquifer storage (ΔV) was also estimated using *Equation 2,* considering measured water levels in piezometers and aquifer specific yield. The values of groundwater height in each month were spatially averaged using *Equation 3* and groundwater hydrographs for the zones S and N were depicted in *Figure 4* for a period of about 9-year from October 2002 to 2011. The basic data used in drawing the hydrographs are presented in the Appendix. The figure shows monthly variations of groundwater level and precipitation in the two zones of Bahabad aquifer, started at October as the first month of the water-year.

Groundwater level has been declined about 6 m in the zone N and 4.5 m in the zone S during 2002-2011. So, the mean annual declines (ΔH) in the zones S and N are about 65 and 51 cm, respectively.

Typical values of Sy in each piezometer were determined based on the referred standard values in literature for dominant lithology of the drilling logs (*Table 3*). One-third of this laboratory measurements were considered as the field values of the Sy, because of the air entrapped near the water table, aquifer stratification and slow drainage of materials above the water table (Mcworther and Sunada, 1977). The spatially averaged values of Sy in the zones S (piezometers P1 to P8) and N (piezometers P9 to P14) were estimated to be 0.07 and 0.03, respectively. The values are in the range accepted for most aquifers in Iran.

Table 3. *Estimated values of specific yield at different locations in the Bahabad aquifer*

Piezometer	Dominant soil texture	Laboratory measured specific yield (dimensionless)	Estimated field specific yield (dimensionless)
P1	Gravelly sand	0.25[1]	**0.083**
P2	Gravelly sand	0.25[1]	**0.083**

[1]Johnson (1967)
[2]Lerner et al. (1990)
*Mean

Change in groundwater storage volume was calculated as the following:

$$\Delta V = A \times Sy \times \Delta H$$

$$\Delta V = \left(235*10^{6}\right) * \left(0.07\right) * \left(-0.65\right) = -11.2*10^{6} m^{3} yr^{-1} = -11.2 \text{ MCM } yr^{-1} \text{Zone S}$$

$$\Delta V = \left(131*10^{6}\right) * \left(0.03\right) * \left(-0.51\right) = -2.02*10^{6} m^{3} yr^{-1} = -2.02 \text{ MCM } yr^{-1} \text{Zone N}$$

These values are consistent with the negative balances calculated by *Equation 1* (-13 MCM yr^{-1} for the zone S and -1.8 MCM yr^{-1} for the zone N), validating aquifer groundwater balance calculations.

© 2018, ALÖKI Kft., Budapest, Hungary

On the basis of groundwater balance study of the Bahabad aquifer in water-year 2010-2011 (*Table 2*), total outputs are exceeding the total inputs and the balance is negative. It confirms the aquifer system is over-drafted and the groundwater storage has diminished, notifying the current withdrawals mainly by abstraction wells are not sustainable.

Safe yield

The negative balance of the Bahabad aquifer necessitates calculation of safe yield to restrict the withdrawals at rates without detrimental effects. So, the safe yield which includes all exploitable groundwater reserves was calculated using *Equation 4*. In order to calculate dynamic groundwater storage (Q_{ed}), the value of water table decline in each piezometer during dry period (June to December) was determined and presented in *Table 4*. It varies from 22 to 76 cm in the zone S and 10 to 44 cm in the zone N. The values of Sy and area of Theissen's polygon (*Fig. 2b*) surrounding the piezometer (effective area) were also defined and Q_{ed} was calculated using *Equation 5*. It was 6.6 MCM yr^{-1} for the zones S and 1 MCM yr^{-1} for the zone N (*Table 4*).

Table 4. *Dynamic groundwater storage (Qed) at the zones S and N of the Bahabad aquifer*

Aquifer zone	Piezometer	Specific yield (dimensionless)	Effective area (m^2)	Average decline of water table in dry season (m)	Dynamic groundwater storage (MCM yr^{-1})

Volume of groundwater pumped during wet season (Q_{wet}) was calculated based on data from Yazd regional water authority, multiplying discharge rate and operation time of the wells. It was about 9.9 and 2.0 MCM yr^{-1} for the zones S and N, respectively, generally comprises about 31-32% of the total discharge by wells and qanats in these zones.

Total volume of return flows from irrigation and sewage (Q_{rw}) was deduced from aquifer balance calculations (*Table 2*). Based on the following, it was estimated to be 5.8 and 0.65 MCM yr^{-1} for the zones S and N, respectively.

$$Q_{rw} = Irf + Wrf$$

$$Q_{rw} = 3.0 + 2.8 = 5.8 \text{ MCM yr-1} \quad \text{Zone S}$$

$$Q_{rw} = 0.6 + 0.05 = 0.65 \text{ MCM } yr^{-1} \quad \text{Zone N}$$

Finally, the groundwater safe yields for the S and N zones of the Bahabad aquifer were estimated by *Equation 4* as follows:

$$\text{Safe yield} = Q_{ed} + Q_{wet} + Q_{rw}$$

$$\text{Safe yield} = 6.6 + 9.9 + 5.8 = 22.3 \text{ MCM } yr^{-1} \quad \text{Zone S}$$

$$\text{Safe yield} = 1.0 + 2.0 + 0.65 = 3.7 \text{ MCM } yr^{-1} \quad \text{Zone N}$$

From aforementioned estimates (*Table 2*), it is obvious that the total abstractions from Bahabad aquifer in the zones S (30.9 MCM yr^{-1}) and N (6.6 MCM yr^{-1}) are greater than the safe yield. Therefore, the aquifer system has been over-drafted and the groundwater mining has occurred. It proves that the sustainability of the aquifer system is not foreseen under current circumstances. Depletion of groundwater resources and deterioration of the groundwater quality and subsequent soil salinization of the agricultural lands (Zalidis et al., 2002) are the main environmental problems predicted, as a result of continued groundwater over-exploitation. In this regard, the effect of intensive groundwater abstraction by deep and semi-deep agricultural and industrial wells on storage depletion of the Bahabad aquifer is investigated in more details as follows:

Industrial abstractions: As it was previously mentioned, the pumped water by industrial wells is totally transferred out of the groundwater basin area. Therefore, no recharge by return flows from industrial uses is expected. Assuming this water is consumed on the zone S of Bahabad aquifer, having return flow coefficient of about 60% (Iran Water Resources Management Company, 1991), the negative groundwater balance or aquifer budget deficit will be decreased to 9.2 MCM yr^{-1}. However, change in groundwater flow pattern due to the concentrated pumping would still be occurred.

Agricultural abstractions: The specific role of agricultural discharge on depletion of the aquifer storage was investigated by assuming zero discharge for industrial wells in water balance equation. The results show the budget deficit of about 6 MCM yr^{-1} in the aquifer zone S, drawing attention to the more significant role of agricultural abstractions

© 2018, ALÖKI Kft., Budapest, Hungary

in Bahabad aquifer depletion. This is in contrast to the public perception of considering industrial abstractions as the major cause of depletion.

Conclusions and recommendations

The sustainability of groundwater resources of the Bahabad aquifer in central Iran was evaluated by groundwater balance studies and the safe yield analyses. The aquifer is highly discharged by 78 deep and semi-deep wells for agricultural and industrial uses. A closed depression in water table which formed due to concentrated groundwater pumping by the industrial wells has changed groundwater flow patterns, dividing the aquifer system into southern (S) and northern (N) zones. The main inputs (rainfall recharge, inflow through aquifer boundaries, recharge due to return flow from irrigation and sewage) and outputs (outflow through aquifer boundaries, drainage into stream and groundwater withdraw) to/from the aquifer zones were estimated in water-year 2010-2011 (starting at September 23). The rainfall recharge as well as irrigation and municipal return flow coefficients were decided as 5-10, 10-15 and 50-60%, respectively. The lower values are related to the zone N which mainly covered by silt/clay rich alluvium, as it compared with dominant lithology of gravel and sand in the zone S. As the pumping test results are so occasional (only one in the aquifer south), the values of transmissivity and specific yield of the Bahabad aquifer were determined as 5.5-3664.5 m^2/day and 3-8%, respectively, considering aquifer drilling logs and the values prescribed in literature. The Bahabad aquifer is permanently drained by Shoor stream at the north. Baseflow separation of the stream hydrograph yields drainage volume of about 1.1 MCM yr^{-1}.

On the basis of the water balance study, total inputs to the zone S and N are about 20.9 and 6.8 MCM yr^{-1}, lower than the total outputs of about 33.9 and 8.6 MCM yr^{-1}, respectively. Excess of outputs over inputs which is followed by a water table decline of 65 and 51 cm yr^{-1}, respectively, confirms the aquifer system has overexploited. The safe yield which consists all exploitable groundwater resources was calculated about 22.3 MCM yr^{-1} for the zone S and 3.7 MCM yr^{-1} for the zone N. Obviously, total abstractions from Bahabad aquifer in the zones S (30.8 MCM yr^{-1}) and N (6.5 MCM yr^{-1}) are greater than the safe yield. Therefore, the aquifer system is over-drafted and the groundwater mining has occurred. It proves that the sustainability of the aquifer system is not foreseen under current circumstances. The effects of intensive groundwater abstraction by deep and semi-deep agricultural and industrial wells on storage depletion of the Bahabad aquifer was investigated which highlights, in contrast to the public opinions, the important role of agricultural withdrawals.

This research clarifies the role of both industrial and agricultural abstractions in depletion of Bahabad aquifer. It is evident that the present exploitations are not sustainable and the management of this aquifer is not safe. Therefore, safe yield as a managing tool must be considered avoiding groundwater overexploitation and aquifer mining with negative consequences for the development of the region. For the aquifer system of the study area, the safe yield can be attained by a decrease in groundwater abstractions, increase in recharge or a combination of both. In order to achieve the safe yield, the following recommendations are proposed:

1. Total abstractions for use in both agricultural and industrial sectors must be reduced. In this regard improvement or change of traditional irrigation systems can be effective to reduce groundwater consumption. Industrial abstractions must be

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_25852602
© 2018, ALÖKI Kft., Budapest, Hungary

immediately decreased at least 50%, because their values are currently about two times more than the permissible limits planned by local water authorities. In a similar international problem, management strategies including application of water-saving methods such as spray and drip irrigation were proposed to solve water balance disequilibrium of a coastal aquifer system in Greece (Voudouris, 2006).

2. Aquifer recharge must be managed by reliable methods to increase the aquifer storage. In this regard, artificial recharge projects should be developed in the region to balance the quantity of water exported for industrial uses, having no return flows to the aquifer system. Renovation of the performed projects by removing fine sediments accumulated on the surface of the recharge basins to enhance the infiltration rate is also recommended. Field tests in other places (Hionidi et al., 2002; Voudouris, 2006) confirmed the positive impacts of artificial recharge on augmentation of aquifer storage and improvement of the groundwater quality.

3. Industrial wells should be distributed throughout the aquifer system, avoiding local changes in the flow dynamics. Changes in flow direction due to the closed depression formed by industrial well-field will enhance the intrusion of the more saline groundwater of the northern part and deteriorate quality of the aquifer. An increasing trend of electrical conductivity (EC) from 3000 μmhos/cm to 3800 μmhos/cm is observed in a well located at the north of the well-field during a period of 10-year from 2001 to 2011 (Shirafkan, 2013). Other impacts such as ground settlement (Chen et al., 2003) would also be prevented.

A new research conducted in the study area after completion of the present work (Khatibinia, 2016) revealed continuity in groundwater level decreasing with a measured rate of about 0.5 m yr^{-1}. It forces immediate actions in implication of the appropriate managing strategies like mentioned above, in order to prevent groundwater mining and further depletion of the Bahabad aquifer.

Abstract. Surface irrigation, including border, basin and furrow irrigation is used more than pressurized irrigation due to the low cost and energy requirement. However, more precise selection of design parameters for efficient design of surface irrigation is required for higher irrigation efficiency, and the accurate prediction of the infiltration rate is of prime importance. Field data sets for irrigation events during sugar beet growing season were collected for characterizing infiltration properties in alternate, fixed and conventional furrow irrigation (AFI, FFI and CFI, respectively), carried out on a clay loam soil in Karaj, Iran. The treatment was applied in two consecutive years (2013 and 2014) as randomized complete block design with three replications. Therefore, this research was conducted to determine the parameters of Lewis–Kostiakov infiltration model based on the data obtained in advancing stage and two-pointed method. Less runoff losses and large infiltration rate observed in AFI as compared to CFI due to increased lateral water movement to non-irrigation furrow. Having different infiltration characteristics in AFI, design will be different from CFI in the same field. Results indicated that the final soil infiltration was $1.6*10^{-4}$ $m^3/m/min$ at the beginning of the growing season and decreased in CFI, FFI and AFI management system by 44, 38 and 30% respectively, at the end of growing season. The amount of 'a' coefficient variations in Kostiakov–Lewis model, showed a decreasing trend during the growing season, but the 'k' coefficient had an incremental trend in CFI, FFI and AFI irrigation management system. AFI had greater infiltration rate than FFI, the steady infiltration rate in AFI and FFI was higher than CFI. Consequently, alternate furrow irrigation management with reduced drainage achieved maximum water use efficiency (WUE).

Keywords: *furrow irrigation, final infiltration, drainage, surface irrigation, irrigation management*

Introduction

Water sources suitable for utilization are on the decline in many parts of the world. Therefore, appropriate irrigation management plays a great role in the quality and quantity of these sources, and can help in realizing production potential and in obtaining high yields through reducing runoff losses and by delivering the required water to the root zone (Sepaskhah and Afshar-Chamanabad, 2002). Surface irrigation is used more than pressurized irrigation due to low cost and energy requirements. Innovative surface irrigation techniques are used for higher irrigation efficiency, among which alternate

furrow irrigation decreases deep percolation, thereby increasing water use efficiency (Sepaskhah and Kamgar-Haghighi, 1997).

The major problem in surface irrigation is its low efficiency resulting from poor irrigation management (Khatri and Smith, 2006). The design, evaluation and simulation of surface irrigation systems dependent on a knowledge of infiltration properties of the soil and the movement of water over the field. Infiltration affects the advance, recession, runoff, and volume of infiltration during irrigation (Fonteh and Podmore, 1993). Spatial variation of infiltration rates makes the management of surface irrigation systems a very complex process (Rasoulzadeh and Sepaskhah, 2003). Infiltration is one of the most important parameters for designing surface irrigation systems, mainly for furrow irrigation (Walker and Skogerboe, 1987). It has a significant effect on water flow and solute transport in the soil surface and subsurface (Ebrahimian, 2014). Quantification of water infiltration into a soil is of great significance in the management of watersheds (Mukheibir, 2008). The performance of the mathematical models to simulate overland flow in fields within surface irrigation systems is dependent on the accuracy of estimation of infiltration parameters. Initial reduction in infiltration is related to the physical process of slaking to the development of an apedal, harvesting surface soil layer (Emdad et al., 2004). There are numerous methods for estimation of infiltration parameters in surface irrigation based on input data requirements, infiltration equations and solution methods (Bautista and Walker, 2010).

Gillies et al. (2007) reported that high irrigation efficiencies in surface irrigation were not out of reach if correct irrigation management was exercised and temporal and spatial changes in soil characteristics were considered. However, precise design for surface irrigation is required for higher irrigation efficiency and accurate prediction of the infiltration rate is of prime importance (Zerhun et al., 1996). There are two types of alternate furrow irrigation: 1) Alternate Furrow Irrigation (AFI) in which irrigated furrow (or non-irrigated furrow) is alternatively changed for every irrigation, and 2) Fixed Furrow Irrigation (FFI) in which irrigated furrow (or non-irrigated furrow) is fixed for every irrigation. This irrigation method has been known to improve water productivity in agricultural lands especially in arid and semi-arid regions (Ebrahimian et al., 2012). Application of alternate furrow irrigation would be expected to alleviate water shortages due to rapid population and decreasing per-capita water. Infiltration rate in alternate (every-other) furrows would be different from conventional furrows in the same field (Gillies and Smith, 2005).

Application of AFI can lead to increased lateral infiltration and decreased deep percolation, which will ultimately result in improved irrigation efficiency (Dialameh et al., 2017).

Slatni et al. (2011) also showed that the CFI treatment had the highest infiltration per unit area as compared to AFI and FFI. Alternate furrow irrigation succeeded in reducing infiltration in the experimental conditions, thus potentially reducing deep percolation losses. Field investigation and modeling on the infiltration process in alternate furrow irrigation would be helpful to reach the precise design of this kind of furrow irrigation system.

Many researchers used the Lewis–Kostiakov equation for infiltration in furrow irrigation and proposed methods for determination of its parameters (Scaloppi et al., 1995). Consequently, several equations have been proposed to describe furrow infiltration as a function of effectual factors on it. The commonly used equations are those proposed by Kostiakov and Kostiakov–Lewis (Nasseri and Neyshabori, 2006).

Neshat and Parehkar (2007) showed in their research that the Lewis–Kostiakov model was the most suitable model for estimating cumulative infiltration and infiltration rate. Yongyong et al. (2012), determine the effectual infiltration variables, to evalute the performance of four classical infiltration models. The performance of four infiltration models (Philip model, Kostiakov–Lewis model, Kostiakov model, and Horton model) was investigated on the basis of evaluation indices. The Kostiakov–Lewis infiltration model with three parameters provided the best description of the relationship between cumulative infiltration and time.

The objective of this research was to determine the parameters of Lewis–Kostiakov infiltration equation in two types of alternate furrow irrigation (AFI and FFI) and conventional furrow irrigation in several irrigation events during sugar beet growing season. For this purpose, two-pointed method (Elliott and Walker, 1982) used to estimate the infiltration parameters of the Lewis–Kostiakov equation.

Material and methods

Field experiments of furrow irrigated sugar beet were conducted at the research field of the Kamalabad station of the Sugar Beet Research Institute in Karaj, Iran, at 50°55'E longitude, 35°55'N latitude and 1313 m altitude during 2013 and 2014 growing season of sugar beet. Climate in this region is semi-arid with total annual precipitation of 265 mm. The soil in this area no salinity and drainage problems such as water table. Some physical properties of the experimental field soil are presented in *Table 1,* and some chemical irrigated water quality properties are shown in *Table 2.*

Table 1. *Some physical properties of experimental field soil*

Depth cm	Clay %	Silt %	Sand %	Texture	Bulk density gr/cm^3	Field capacity %	Permanent wilting point %
0-30	31.4	42	26.6	Clay loam	1.47	27.4	14
30-60	34.6	27.4	38	Clay loam	1.42	26.6	14.9

[1]Electrical conductivity
[2]Specific absorption rate

The soil at the trial site up to 60 cm deep (effective depth for sugar beet root development), a uniform Clay loam soil texture with EC=0.58 dS.m^{-1}, that does not limited growing plants. The soil has a high maintenance capacity that suitable for sugar beet cultivation.

Also water irrigation quality in term of salinity was suitable (0.5 dS.m^{-1}) and not limited for sugar beet cultivation.

The experiments were conducted in the same field for the 2-year period. The experimental design was a randomized block with three replications. Each plot consists

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26032614
© 2018, ALÖKI Kft., Budapest, Hungary

of 12 row of sugar beet that was 90 m long and 0.5 m wide, the slope of furrow was about 0.00019 $m.m^{-1}$. Sowing density was 3-6 plants per meter.

The design consisted of three irrigation methods. The irrigation methods were alternate furrow irrigation (AFI), fixed furrow irrigation (FFI) and conventional furrow irrigation (CFI).

Outflow rate from the furrows was measured employing a Washington State College (WSC) flume (type II) that was put at the end of the furrow. The inflow rate was measured for each furrow using the volumetric method. The inflow-outflow hydrograph method was employed to calculate the final infiltration rate, which was obtained from the following equation (*Eq. 1*) when a constant outflow rate was reached (Fattah and Upadhyaya, 1996):

$$f_0 = \frac{Q_{in} - Q_{out}}{L} \quad \text{(Eq.1)}$$

Where, Q_{in} is the inflow rate in m^3/min, Q_{out} the outflow rate in m^3/min, L the length of the furrow in m, and f_0 base infiltration rate in m^3/m/min. The volume of infiltrated water was calculated using the inflow and outflow volumes, and the Lewis–Kostiakov equation was employed to obtain the infiltration relation, which was as follows (*Eq. 2*):

$$Z = kt^a + f_0 t \quad \text{(Eq.2)}$$

where, Z is the volume of infiltrated water per unit length of the furrow in m^3/m, f_0 final infiltration rate into the soil in m^3/m/min, t time in minutes, and 'a', 'k' the empirical coefficients of the equation. The two-point method introduced by Elliott and Walker (1982) was employed to calculate the empirical parameters in the Lewis–Kostiakov equation of infiltration. For this purpose, furrows were marked with stakes at 10 m intervals, and the time water reached each station was recorded using a chronometer.

Walker (1989) used the empirical equation describing the advance curve in furrow irrigation to determine the infiltration parameters (k; a) as follows (*Eq. 3*):

$$x = pt^r \quad \text{(Eq.3)}$$

where, x is the distance from the beginning of the furrow in m, t time in minutes, and r, p coefficients of the equation can be evaluated from the two advance points and a simple logarithmic transformation of the power curve equation. The coefficients a, k, in the Lewis–Kostiakov equation can be calculated by using the water balance method in the furrow considering its two middle and end points. The coefficient "a" can be calculated from the following equation (*Eq. 4*):

$$a = \frac{\ln \frac{V_L}{V_{0.5L}}}{\ln \frac{t_L}{t_{0.5L}}} \quad \text{(Eq.4)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26032614
© 2018, ALÖKI Kft., Budapest, Hungary

Where t_L and $t_{0.5L}$ are the time water reaches the end and middle of the furrow, respectively, and V_L and $V_{0.5L}$ are determined using the following equations (*Eqs. 5* and *6*):

$$V_L = \frac{Q_0 t_L}{L} - \delta_y A_0 - \frac{f_0 t_L}{1+r} \quad \text{(Eq.5)}$$

$$V_{0.5L} = \frac{2Q_0 t_{0.5L}}{L} - \delta_y A_0 - \frac{f_0 t_{0.5L}}{1+r} \quad \text{(Eq.6)}$$

where the inflow rate into the furrow is in m^3/min, A_0 is the cross section of the inflow (which, in this study, was measured in the field), and δ_y the flow shape factor was considered to be 0.8. The coefficient "k" was determined using *Equation 7:*

$$k = \frac{V_L}{\delta_z t_L^a} \quad \text{(Eq.7)}$$

Where δ_z is the shape factor for infiltration into the furrow that is determined from the following equation (*Eq. 8*):

$$\delta_z = \frac{a + r(1-a) + 1}{(1+a)(1+r)} \quad \text{(Eq.8)}$$

After the parameters in the equation of water infiltration into the furrows were determined, the volume of infiltrated water at various distances from the beginning of the furrow was calculated in irrigations. Infiltration opportunity at any time T_n in minutes was determined using *Equation 9:*

$$T_n = T_r - T_a \quad \text{(Eq.9)}$$

Where, T_a and T_r are the water advancing and retreating time in the furrow, respectively, which were measured in the field in this research. The volumes of water infiltrated at specific points in the furrow were determined by putting the infiltration opportunities in the equation of infiltration into the furrow.

The amount of irrigation water, in the basis of soil moisture in depths of 0-30 and 30-60 cm was measured, and amount of water demand in each layer in the region of plant root relation was obtained by *Equation 10*.

$$dn = \Sigma \left(\theta fci - \theta i\right)\Delta z \quad \text{(Eq.10)}$$

where dn is the net irrigation depth (m), θfci and θi are the volumetric soil water contents in layer i at field capacity and before irrigation, respectively (m^3/m), Δz is the soil layer thickness (m) and n is the number of soil layers. In the first year 13 irrigations were done and second year 11 irrigations were applied.

The objective of this research was to determine the parameters of Lewis–Kostiakov infiltration equation in AFI, FFI and CFI with irrigation events. Various models were

fitted to the measured values and were studied the various management in order to determine the trend of changes in final infiltration with irrigation events.

Results

ANOVA of final infiltration rate is shown in *Table 3*. ANOVA was significant for irrigation events.

Table 3. *ANOVA of final infiltration rate*

Year	Treatment	df	Sum of squares	MS	F-value	Sig.

Mean values with the same superscript letters (a, b, c, d or e) were similar and no statistically significant differences were observed for these samples

Figure 1 shows trends of variation in final infiltration rate into the soil in the various irrigation management during the season with irrigation events in two years.

As shown in *Table 4,* the final infiltration rate decreased at end of the season in all management with logarithmic model. In first year, the final infiltration rate the start of the period $1.6*10^{-4}$ and decreased by 44, 31 and 25% in CFI, FFI and AFI management and in second year, the final infiltration rate the start of the period $1.7*10^{-4}$ and decreased by 45, 37 and 36% in CFI, FFI and AFI management. Finally, *Table 4* shows that final infiltration rate was decreased by 44, 34 and 30% in CFI, FFI and AFI management. Emdad et al. (2004) show that final infiltration rate was decreased 40% at the end of the season in clay loam soil texture.

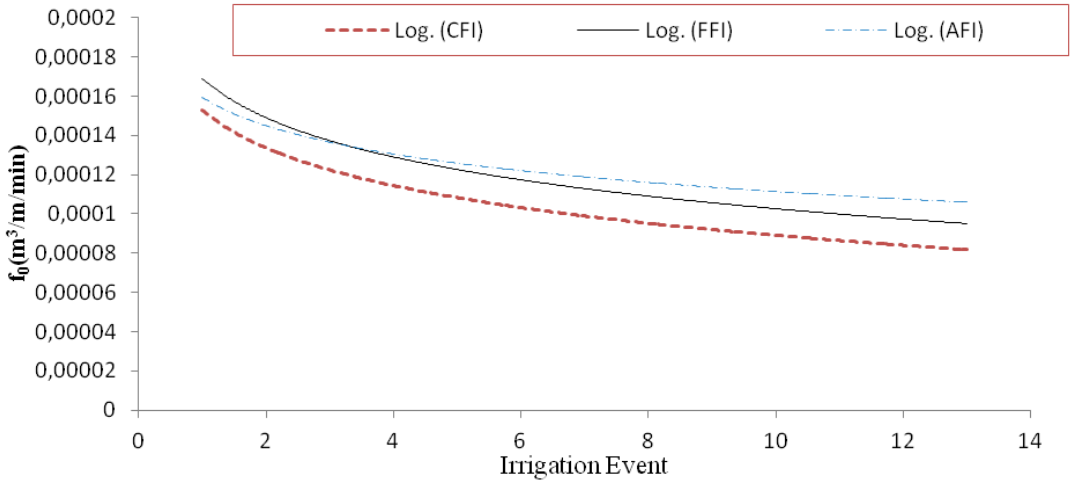

Figure 1. *Final infiltration rate as a function of irrigation event (average of two years)*

Various models were evaluated to determine the best regression fit between values of final infiltration rate and irrigation events. Models were evaluated by SAS software and their significant was investigated. The logarithmic model, presented below, was the best regression model with the highest correlation coefficient (*Eqs. 11-13*):

$$f_{0CFI} = -0.000028ln(\mathrm{IE}) + 0.000153 \qquad R^2 = 0.85 \qquad \text{(Eq.11)}$$

$$f_{0FFI} = -0.000029ln(\mathrm{IE}) + 0.000169 \qquad R^2 = 0.79 \qquad \text{(Eq.12)}$$

$$f_{0AFI} = -0.000021ln(\mathrm{IE}) + 0.000159 \qquad R^2 = 0.91 \qquad \text{(Eq.13)}$$

Where f_{0AFI} is final infiltration rate in AFI management (m^3/m/min), f_{0FFI} is final infiltration rate in FFI management (m^3/m/min), f_{0CFI} is final infiltration rate in CFI management (m^3/m/min) and IE is irrigation event.

Regression analysis showed that there was a logarithmic relationship between final infiltration rate and irrigation event, which is a good function and significant (*Fig. 1*).

ANOVA of 'a' parameter in the Lewis–Kostiakov equation is shown in *Table 5*. ANOVA was significant for irrigation events. The effect of irrigation events on 'a' parameter in the Lewis–Kostiakov equation significant, and the result of Duncan's multiple range tests showed significant differences ($t < 0.001$) on three managements.

ANOVA of 'k' parameter in the Lewis–Kostiakov equation is shown in *Table 6*. ANOVA was significant for irrigation events. The effect of irrigation events on 'k' parameter in the Lewis–Kostiakov equation significant, and the result of Duncan's multiple range test showed significant differences ($t < 0.001$) on three managements.

Table 5. *ANOVA of 'a' parameter in the Lewis–Kostiakov equation*

Changes in infiltration parameters in the Lewis–Kostiakov equation were slight so that when the values of 'a', 'k' were studied in one growing season, it was observed that they declined very little. The related results are presented in *Figures 2* and *3,* and the obtained equations are as follows:

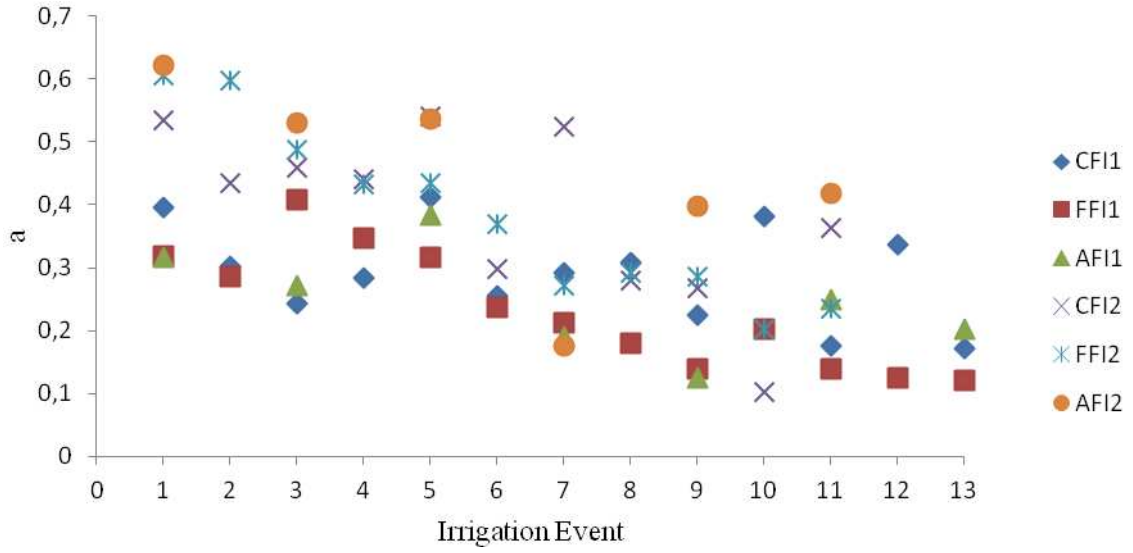

Figure 2. *Lewis–Kostiakov parameters 'a' as a function of irrigation event*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26032614
© 2018, ALÖKI Kft., Budapest, Hungary

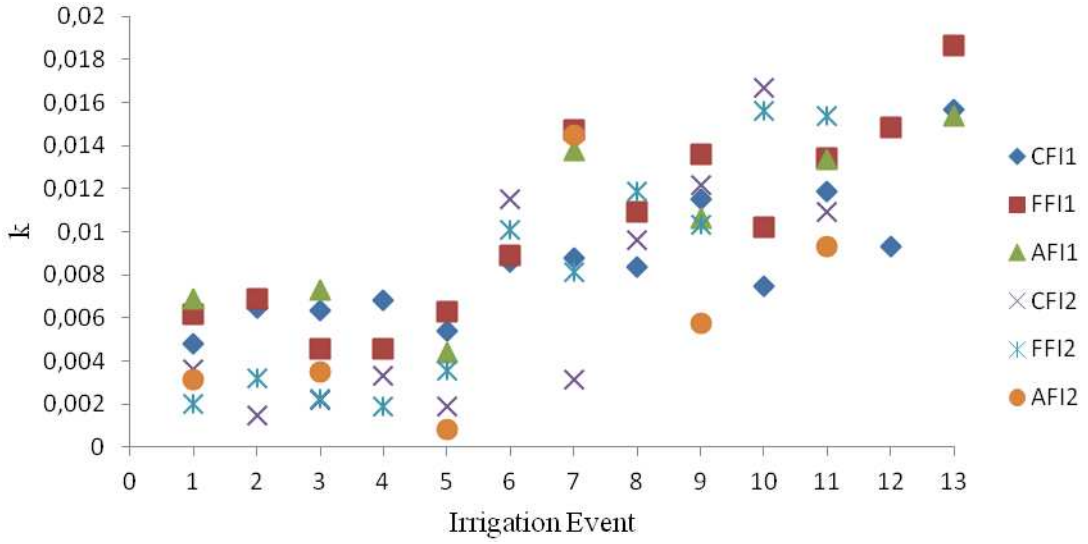

Figure 3. *Lewis–Kostiakov parameters 'k' as a function of irrigation event*

Amount of 'a' coefficient variations in Kostiakov–Lewis model, showed a decreasing trend during the growing season, but the 'k' coefficient had an incremental trend in CFI, FFI and AFI irrigation management system. The average value for 'k' tended to decrease with time during the season for all treatments. Indicated that 'k' and "a" were each significantly different between the early and late season period.

Discussion

The results of this study showed that at the beginning of the cultivating period, the final soil infiltration, due to increasing soil porosity by plowing increases too. Some soil physical properties, such as porosity, decrease due to the surface irrigation and low soil aggregate stability, which directly affects the hydraulic conductivity of saturated soil, in other words, it affects the final soil infiltration, therefore as a result, the final infiltration rate decreases (Slatni et al., 2011). Results show changes in final infiltration rate into the soil followed a descending trend. Soil compaction (subsidence) and destruction of the surface layer (disintegration of aggregates and surface crust formation) were the reasons for the decline in final infiltration rate during the period. Compaction and destruction of soil surface layer, together with decreased aggregate stability and crust formation, reduced final infiltration into the soil.

After the first irrigation, soil aggregate stability decreases due to the surface irrigation by formation of a crack on the surface of the soil. The simultaneous effect of these two factors causes a significant reduction in the final soil infiltration, therefore final soil infiltration according to *Figure 1* is close to a constant limit. final soil infiltration was 1.6×10^{-4} $m^3/m/min$ at the beginning of the growing season in the first year and decreased in CFI, FFI and AFI management system by 44, 37 and 29% respectively, at the end of growing season. Similarly, in the second year, the final soil infiltration at the beginning of the season was 7.4×10^{-4} $m^3/m/min$, which was decreased, by 44, 39 and 32%, at the end of growing season, respectively. Parlange et al. (1982) showed that in furrow irrigation cropping system, the water infiltration rate during the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26032614
© 2018, ALÖKI Kft., Budapest, Hungary

first irrigation immediately following cultivation can often be markedly higher than later irrigation.

The AFI management showed the lowest infiltration losses, as compared to FFI and CFI. The infiltration rates in final irrigation were generally smaller in CFI than FFI and AFI. These results are in agreement with those by Sepaskhah and Afshar-Chamanabad (2002), who reported that the infiltration rate in the irrigated furrow of the FFI treatment was higher than in CFI furrows. As a consequence, the advance time would be higher in alternate furrows than in conventional furrows. Slatni et al. (2011), reported that the CFI treatment showed highest infiltration per unit area, compared to AFI and FFI. In this study, the infiltration per unit area was also higher for CFI than for both AFI and FFI management. However, infiltration per irrigated furrow was higher for AFI and FFI than for CFI, due to increased lateral water movement towards non-irrigated furrows.

In this research, indicated that 'k' and 'a' were significantly different between the early and late season period. Results of research conducted by Raine and Mcclymont (1997) and Zapata and Playan (2000) conform to those found in our research.

There was not a particular trend in the amount of coefficient changes during the crop growth period. In other words, the amount of 'a' was not predictable by the model, because of the existence of small seams in heavy soil texture which is an important factor in disturbing of time variation of 'a' coefficient during plant growth periods. According to the results of Hunsaker et al. (1993), Changes in 'a' coefficient have not shown conformity with logarithmic or linear model.

Although the 'k' coefficient is an experimental coefficient which is affected by the initial moisture (before irrigation) (Philip, 1957). Therefore, if in the various irrigation, the initial moisture content is approximately the same, the 'k' coefficient is expected to remain almost constant. The results showed that 'k' coefficient correlates with the failure of specific trend or with the irrigation that has been carried out at different initial moisture levels.

Therefore 'k' and 'a' coefficients of Lewis–Kostiakov equation fixed in estimation equation and amount is 0.1-0.5 for 'a' and 0.001-0.01 for 'k'.

Finally, cumulative infiltration decreased during plant growth season. Therefore to achieve proper management with considerable seasonal decrease of infiltration, time of irrigation must be increased.

AFI was successful in reducing infiltration in the experimental conditions, thus potentially reducing deep percolation losses. Also application efficiency increased in AFI management. Alternate furrow irrigation management in sugar beet may be feasible for water saving and reducing drainage. It can be concluded that using alternate furrow irrigation is a good water management technique to protect the environment by reducing runoff and increase water application efficiency (AE).

Conclusions

The results of this research showed that there were not specific trend changes in the values of the 'k' and 'a' coefficients in Lewis–Kostiakov penetration equation in different irrigation intervals during the growth periods. The initial penetration rate had a decreasing trend, which was predictable from logarithmic models.

Final infiltration rate decreased in CFI, FFI and AFI management system by 44, 38 and 30% respectively, at the end of growing season. High infiltration and steady infiltration rate in alternate furrows were found in this study. More horizontal water

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

movement to non-irrigated furrows could establish this large difference between alternate and conventional furrow irrigation managements. Having different infiltration characteristics in alternate furrows, design variables of alternate furrow irrigation will be different from conventional furrow irrigation in the same field. This difference is even existed between AFI and FFI systems because of different infiltration characteristics. Therefore, the design and management of such irrigation methods should differ from conventional furrow irrigation. Field experiments indicated the AFI management could reduce large runoff losses in every irrigation events during sugar beet growing season.

Alternate furrow irrigation management in sugar beet may be feasible for water saving and reducing drainage. It can be concluded that using alternate furrow irrigation is a good water management technique to protect the environment by reducing runoff and increase water application efficiency (AE).

The current study has been done in clay loam texture soil and it might be different in other soil mixtures. Therefore, it is recommended that further experiments can be implemented in various soil textures and furrow lengths to evaluate infiltration parameters on irrigation managements.

Acknowledgments. The research was supported by the Sugar Beet Seed Institute.

(Received 18th Oct 2017; accepted 12th Feb 2018)

Abstract. Aerosols play a major role in atmospheric solar radiation budget, air quality degradation and climate change. In order to accurately evaluate aerosols effects, we require an in-depth knowledge of spatio-temporal distributions of their parameters. The focus of this paper is to analyze spatio-temporal distributions and trends of aerosol parameters over Pakistan. In present study, Terra-MODIS data have been used during April 2000-March 2014 to analyze AOD (550 nm), Angstrom exponent (470-660) ($AE_{470-660}$), small mode fraction (SMF) and mass concentration (MC). Values of coefficient of determination (R^2) between Terra-AOD and AERONET-AOD are found to be 0.718 and 0.745 for Lahore and Karachi respectively. Terra-AOD has also been compared with other satellite-based observations obtained from Aqua, MISR and SeaWiFS. A notable spatial variability in mean annual Terra-AOD values (0.15-0.87) has been observed with high values (~0.8) over northeastern and southern Pakistan. $AE_{470-660}$ ranges from 0.56 to 1.44 showing high values (greater than 0.8) over northern Pakistan and relatively low values (less than 0.8) over southern Pakistan. MC is found to be in the range from 7.6 μg/cm^2 to 56.2 μg/cm^2 with spatial distribution quite similar to AOD. Overall mean values of AOD, $AE_{470-660}$, SMF and MC are found to be 0.43 ± 0.16, 0.68 ± 0.06, 0.11 ± 0.05 and 28.2 ± 9.71 μg/cm^2 respectively.
Keywords: *AOD, Angstrom exponent, SeaWiFS, small mode fraction*

Introduction

Aerosols contribute to atmospheric climate forcing, air quality degradation, hydrological cycle and precipitation processes (Charlson et al., 1992; Ramanathan et al., 2001; Lohmann and Feichter, 2005; Kosmopoulos et al., 2008). They are also recognized as a major factor that affects the global climate change (IPCC, 2007). It is well established fact that aerosol particles affect the climate directly by scattering and absorption of incoming solar radiation and indirectly by serving as cloud condensation nuclei (Forster et al., 2007; Carslaw et al., 2010; Arneth, A. et al., 2010; Mahowald, 2011). All types of aerosols except black carbon cause cooling at top of the atmosphere and reduce the warming caused by greenhouse gases (Forster et al., 2007). In order to achieve better air quality, reduction in anthropogenic emissions may weaken this useful effect (Arneth, et al., 2009; Mickley et al., 2012; Makkonen et al., 2012).

Aerosols also have harmful effects on human health and ecosystem services (Smart et al., 2011). Long term and detailed studies have shown a significant relationship between aerosol concentrations and human health. The studies have been conducted over various regions of the world and the results have established considerable effects on human health due to aerosols. Due to human health and environmental implications, knowledge of properties and spatio-temporal distribution of aerosols is essential.

Insufficient observations of aerosols have caused dominant uncertainties in the climate modeling (Koukouli et al., 2010; Bennouna et al., 2013). In order to accurately

© 2018, ALÖKI Kft., Budapest, Hungary

evaluate the climate forcing, an in-depth knowledge of optical and physical properties of aerosols at different spatial and temporal scales is required (He et al., 2012; Luo et al., 2014). Different types of aerosols affect the sign and magnitude of climate forcing distinctively (Kaskaoutis et al., 2007). For instance, black carbon aerosols emitted from biomass burning cause positive climate forcing (Jacobson, 2001; Penner et al., 2003), while mineral dust particles show negative forcing at shortwave by scattering the solar radiations (Sokolik and Toon, 1996).

Although ground based observations provide more detailed and authentic information about the atmospheric aerosols, they do not have large-scale spatial coverage (Tariq and Ali, 2015; Tariq, 2017). Aerosol concentrations are extremely variable in both time and space. Satellite remote sensing has the ability to monitor aerosols burden and their properties at large scales (Tariq and Ali, 2015). A number of studies have discussed spatio-temporal variability and trends of aerosols concentrations over the study region and its adjoining areas of Indian subcontinent (Prasad et al., 2006; Alam et al., 2011; Dani et al., 2012; Gupta et al., 2013; Sreekanth, 2013). Prasad et al. (2006) and Dani et al. (2012) found a sharp increase in aerosol optical depth (AOD) over Indian region, due to enhanced urbanization and industrialization. Alam et al. (2011) discussed seasonal variability of MODerate resolution Imaging Spectro-radiometer (MODIS, Chu et al., 2003; Wang and Christopher, 2003) derived AOD for different areas of Pakistan during 2002-2008. They found the highest AOD values during summer season linked to high dust/sand aerosols. Sreekanth (2013) reported an increasing trend in MODIS-AOD during 2002-2011 over Bangalore (India) due to sustained increase in the seasonal averaged AOD during summer. Gupta et al. (2013) analyzed the spatial and temporal patterns of aerosols over two megacities of Pakistan namely Karachi and Lahore by using MODIS data for the period 2001-2010. The major aim of their study was to evaluate the standard of MODIS data for air quality and climate applications. Tariq et al. (2015, 2016) have analyzed the optical properties of aerosols over Lahore using multi-sensor data during intense biomass burning events.

To the best of our knowledge, no detailed study has been conducted so far to analyze the spatio-temporal distributions of aerosol parameters such as mass concentration (MC), small mode fraction (SMF) and Angstrom exponent (AE) over Pakistan. The main objective of this paper is to investigate the spatio-temporal distributions and trends in aerosol parameters over Pakistan using long-term (15 years) data. In the present study, Terra-MODIS data is used for the period April 2000-March 2014 to analyze the AOD (550 nm), Angstrom exponent (470-660) ($AE_{470-660}$), SMF and MC. AOD from different satellite sensors have also been compared with ground-based AOD. Furthermore, Terra-AOD has also been compared with other satellite-based observations obtained from Aqua, MISR and SeaWiFS.

Material and methods

Study area

Pakistan is a South Asian country with estimated population exceeding 191 million and an area of about 796100 km^2. It is bordered by India to the east, China to the northeast, Afghanistan to the west and Iran to the southwest (*Fig. 1a*). It also has a coastline of about 1046 km along the Arabian Sea and Gulf of Oman. Ranging from the coastal areas of the south to the glaciated mountainous areas of the north, Pakistan's land-cover varies from plains to deserts (i.e. Cholistan and Thar), forests, hills and

DOI: http://dx.doi.org/10.15666/aeer/1603_26152637
© 2018, ALÖKI Kft., Budapest, Hungary

plateaus. These different landscapes together with extremely variable climatic conditions make Pakistan a distinctive country for studying spatio-temporal patterns of aerosols (Alam et al., 2011). Major sources of anthropogenic aerosols in Pakistan are petroleum refineries, power plants, fertilizer plants, industries, crop residue burning and fossil fuels combustion in vehicles (Ghauri et al., 1994; Biswas et al., 2008; Tariq and Ali, 2015). High amounts of aerosols are released from industrial areas and biomass burning in northeastern Pakistan and regions across the border in India such as Amritsar, Chandigarh and Bathinda (Raja et al., 2010). *Figure 1b* shows fire aggregates retrieved by MODIS-Terra and MODIS-Aqua during April 2000-March 2014. The figure clearly exhibits high frequency of fire events in Indo-Gangetic plain (IGP). Transboundary aerosols also contribute to the aerosol burden over Pakistan (Tariq et al., 2015, 2016). Winds transport aerosols released from coal based power plants in India to northeastern Pakistan. Dust/sand aerosols are the major source of natural aerosols in Pakistan. High amounts of desert dust dominate the central and southern parts of Pakistan due to comparatively low humidity and high temperature (Tariq and Ali, 2015) (*Fig. 2*). Dust storms in the region are largely associated with the easterly movements of low-pressure systems (Tariq and Ali, 2015).

In order to show prevailing meteorological conditions, specific humidity at 850 mb, wind speeds at 850 mb and surface temperature have been mapped during April 2000-March 2014 using NCEP–Reanalysis-2 data from NOAA/OAR/ESRL PSD, Boulder, Colorado, USA (*Fig. 2*). It can be noted from *Figure 2a* that central and southeastern parts of Pakistan have high temperatures (above 20 °C). *Figure 2b* shows that northeastern parts of Pakistan are characterized by relatively high values of average specific humidity (> 6 g/kg), whereas central and southeastern areas have relatively dry air (specific humidity < 6 g/kg). In *Figure 2c* strong winds (~3 ms^{-1}) can be observed over southern parts of Pakistan.

Methodology and datasets

In the present study we have used Terra-MODIS data for the period April 2000-March 2014 to analyze AOD (550 nm), Angstrom exponent ($AE_{470-660}$), small mode fraction (SMF) and mass concentration (MC) of aerosols over Pakistan. AOD from different satellite sensors have also been compared with ground-based AOD. Spatail maps of AOD, $AE_{470-660}$, SMF and MC have been produced uding MATLAB software. The trends in seasonal-mean latitudinal and longitudinal averaged values of Terra-AOD are simulated with the help of linear equations. Linear trend parameters, correlation coefficients and relative changes (%) per year for AOD, AE, SMF and MC on seasonal and annual basis are also calculated.

MODIS

MODIS sensor was launched by NASA onboard Terra satellite in 1999 and Aqua satellite in 2002. MODIS is primarily designed to monitor aerosol fields, cloud cover and radiation budget (King et al., 1992). Terra satellite crosses the equator from north to south in the morning (10:30 local time) while Aqua satellite crosses it from south to north in the afternoon (13:30 local time). The orbits of Terra and Aqua are so designed that they image the whole globe in one to two days. MODIS instrument has a swath width of ~2330 km and acquires data in thirty-six spectral bands. It provides a high radiometric resolution (12 bits) data in all the thirty-six spectral bands from 0.4 μm to 14.4 μm, with spatial resolution of 1 km, 0.5 km and 0.25 km depending on the wavelength band. In the present work Terra-MODIS derived AOD (550 nm), $AE_{470-660}$, SMF and MC have been analyzed for a period from 2000 to 2014. We have used monthly gridded MOD08_M3.051 data product with spatial resolution of 1° × 1° obtained from NASA Goddard Earth Sciences Data and Information Center. These datasets are available via Giovanni website: http://giovanni.gsfc.nasa.gov. Missing values are not considered while calculating annual/monthly means and standard deviations. Due to difference in the surface characteristics, aerosol retrieval algorithms of MODIS are different for oceans (Tanré et al., 1997) and land (Kaufman et al., 1997). The aerosol retrieval algorithms have recently been greatly improved to correct the systematic biases (Remer et al., 2005; Levy et al., 2007). Detailed description of MODIS sensor, data products, retrieval algorithms, retrieval accuracy and validation can be found elsewhere (e.g., Remer et al., 2005 and references therein).

AERONET

The AErosol RObotic NETwork (AERONET) is a network of ground based remote sensing instruments administered by NASA (Holben et al., 1998). It provides detailed data of optical and physical properties of aerosols. AERONET data are processed at three different quality levels: level 1 (unscreened), level 1.5 (cloud screened) and level 2 (quality assured). AERONET instrument measures the direct sun and sky radiances within spectral ranges of 340 nm – 1020 nm and 440 nm – 1020 nm respectively (Holben et al., 1998). AOD and AE are calculated from direct sun radiances while single scattering albedo, asymmetry parameter and refractive index are computed from sky radiances (Dubovik and King, 2000). Currently, there are only two operational AERONET sites in Pakistan: Lahore (a central location in Pakistan) and Karachi (a coastal city of Pakistan). Lahore has a semi arid climate with hot and long summers and cool winters (Ali et al., 2014). From May to September temperatures are high with dust

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26152637
© 2018, ALÖKI Kft., Budapest, Hungary

storms followed by rainfall. Karachi is the most densely populated city of Pakistan and located in southern region adjacent to Arabian Sea. Being a coastal city, Karachi has relatively mild climate. It has one of the busiest ports of the region and is a hub of industrial and economic activity in Pakistan. In this study Terra-AOD observations have been compared with level-2 AERONET-AOD values over Lahore and Karachi.

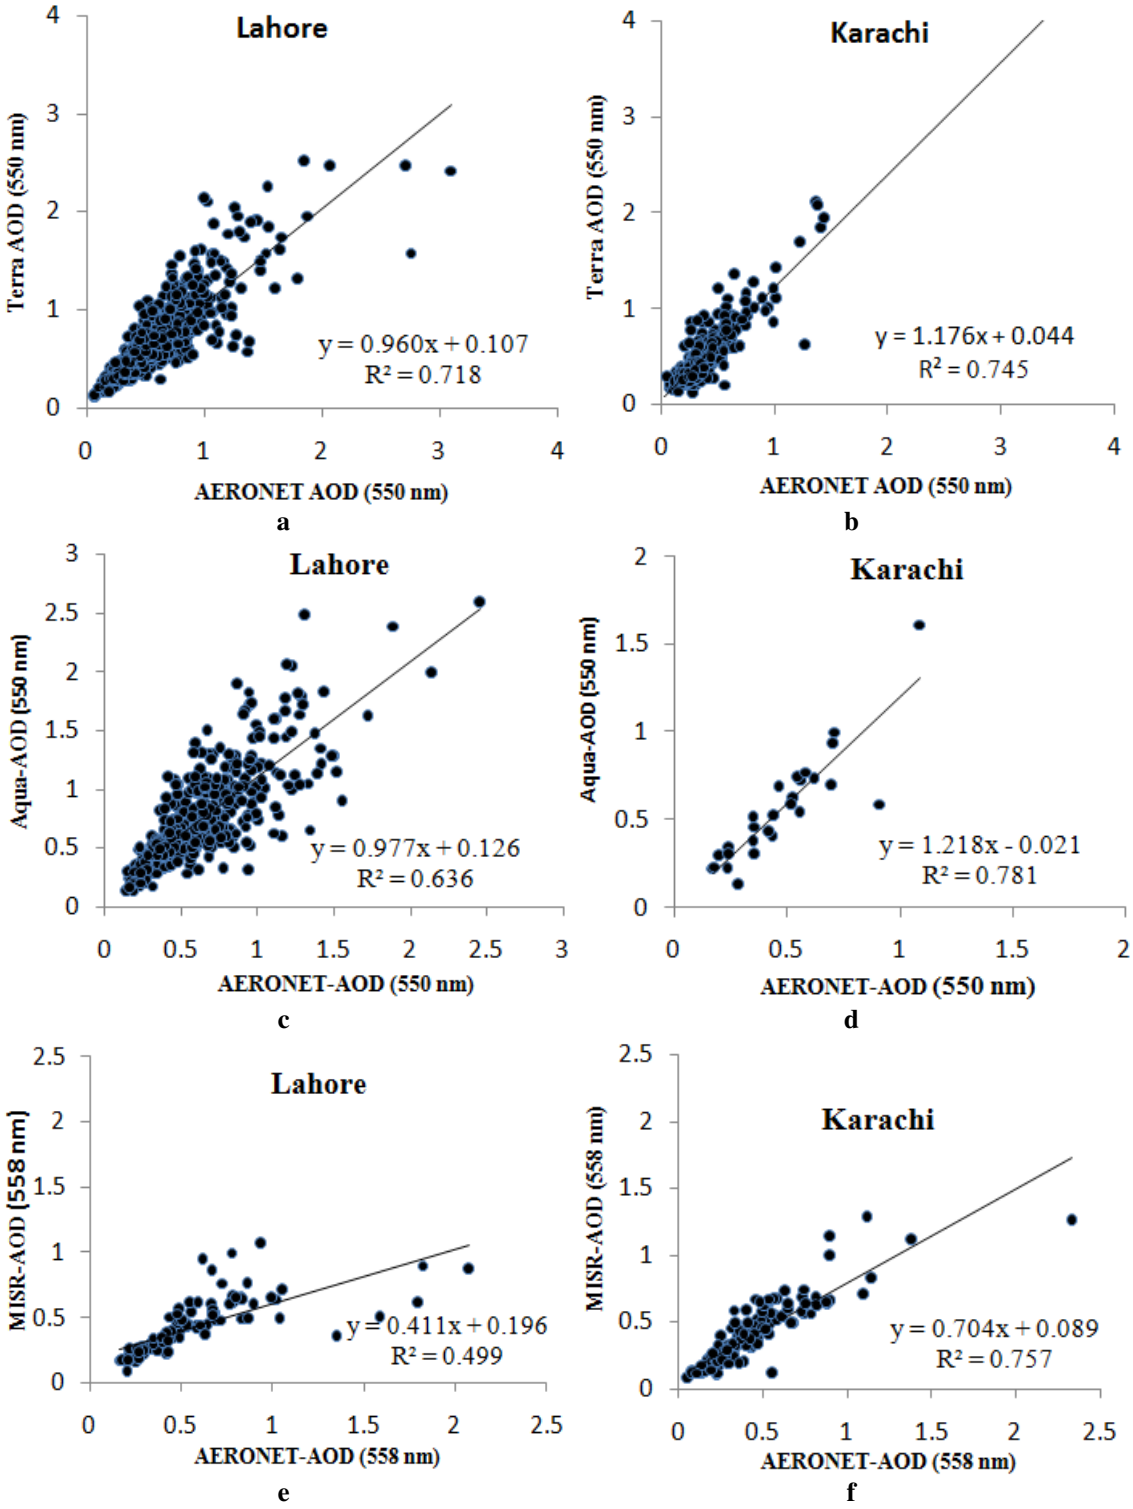
MISR

The MISR (Multi-angle Imaging Spectroradiometer) onboard Terra satellite was launched by NASA in 1999 at an altitude of 705 km. It has variable spatial resolutions of 1 km, 275 m and 250 m and temporal resolution of 16 days. It can view the Earth at nine different angles and hence it has the capability to measure the amount of sunlight scattered in different directions (Diner et al., 2001). It is primarily designed to monitor trends and types of aerosol particles produced from natural and anthropogenic activities. In this study we have used MISR AOD at 555 nm and prepared at level 3 version 004 available from NASA Goddard Earth Sciences Data and Information Center. Detailed information of MISR instrumentation, retrieval algorithms and methodology can be found in Diner et al. (2001) and Kahn et al. (2005, 2010).

SeaWiFS

The SeaWiFS instrument onboard SeaStar satellite was launched in 1997. It has a swath width of 1502 km and provides global coverage in approximately 2 days. It was primarily designed to measure ocean color parameters and has a very accurate and stable calibration to measure small contribution of the ocean to the reflected solar radiance at top-of-atmosphere (TOA) (Eplee Jr. et al., 2011). The high quality of calibration and long-term data of SeaWiFS make its AOD more reliable. Its deep blue aerosol retrieval algorithm over land was developed by Hsu et al. (2004, 2006). SeaWiFS SWDB_L3M10_HDF4.004 AOD product at 550 nm is used which can be downloaded from NASA Goddard Earth Sciences Data and Information Center.

Results and discussion



Comparison of satellite sensed AOD with ground based AOD

Ground-based observations are used to validate satellite aerosol products. Daily Terra-AOD, Aqua-AOD, MISR-AOD and SeaWiFs-AOD have been compared with ground based interpolated AERONET-AOD for Lahore and Karachi during 2006-2013 (*Fig. 3*). For the validation of AOD derived from Terra, Aqua, MISR and SeaWiFs, AERONET observations taken at 15-min intervals under cloud free conditions are used (Holben et al., 1998). For the purpose of comparison, only those data pixels have been considered that fall within a radius of about 27.5 km from the selected AERONET site (Petrenko et al., 2012). In order to have observations closest in time, only those observations are taken that fall within ±30 min (30 min before and after) of satellite overpass time (Petrenko et al., 2012).

It can be seen in *Figure 3a-h* that the values of coefficient of determination (R^2) for Lahore are found to be slightly lower than Karachi which is in partial agreement with Bibi et al. (2015). Slope and intercept of linear regression calculated from the comparison of collocated datasets are of great importance (Levy et al., 2010). The slope of linear regression equation demonstrates the closeness of the assumed aerosol type to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26152637
© 2018, ALÖKI Kft., Budapest, Hungary

the local aerosol type over a particular region, and the intercept reveals error due to surface reflectance (Tripathi et al., 2005; Hyer et al., 2011). The slope = 1 and intercept = 0 indicate a perfect correlation between satellite observations and ground-based AOD (Tripathi et al., 2005). Slope > 1 indicates over estimation while slope < 1 refers to under estimation. Non-zero intercepts are linked with the errors in calibration or in surface reflectance (Chu et al., 2002; Tripathi et al., 2005).

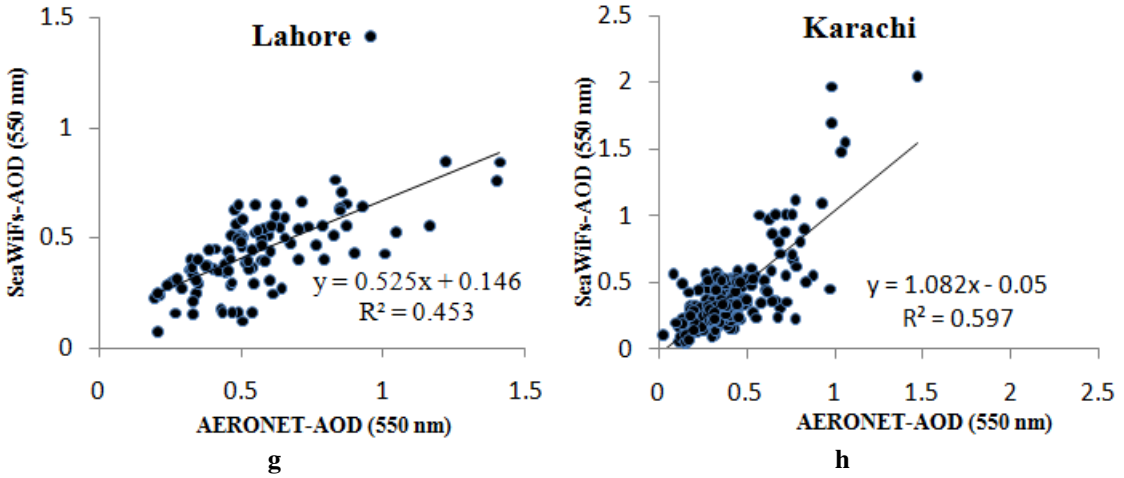

Figure 3. *Validation of daily (a, b) Terra-AOD, (c, d) Aqua-AOD, (e, f) MISR-AOD and (g, h) SeaWiFs-AOD with ground based interpolated AERONET-AOD over Lahore and Karachi for the period 2006-2013. The coefficient of determination (R^2) and equation of linear fit are also given*

All the satellite sensors exhibited under estimation over Lahore while for Karachi all the satellite sensors except MISR showed over estimation. In the present study, values of intercepts for Lahore are found to be 0.107, 0.126, 0.196 and 0.146 for Terra, Aqua, MISR and SeaWiFs respectively. For Karachi, values of intercepts are found to be 0.044, -0.021, 0.089 and -0.05 for Terra, Aqua, MISR and SeaWiFs respectively.

Comparison of Terra-AOD with Aqua, MISR and SeaWiFS observations

To achieve accuracy in measurements and realize the remote sensing capabilities, numerous studies have compared MODIS observations with MISR data (Prasad and Singh, 2007; Xiao et al., 2009; Kumar et al., 2015). Comparison of monthly Terra-AOD with available observations of Aqua-AOD (550 nm), MISR-AOD (555 nm), and SeaWiFS-AOD (550 nm) during the study period has been shown in *Figure 4*. The highest correlation (R^2 = 0.968) observed between Terra-AOD and Aqua-AOD is due to the fact that both Terra and Aqua have the same type of sensor and algorithms for aerosol retrieval (Remer et al., 2005). Also slope of 1.044 and y-intercept of -0.011 indicate very slight difference in the observed AOD from these platforms. This small inconsistency is associated with different overpass times of Terra (10:30 local time) and Aqua (13:30 local time). The coefficient of determination (R^2) between Terra-AOD and MISR-AOD is found to be 0.919. Slope (0.680) and y-intercept (0.018) of linear fit between Terra-AOD and MISR-AOD show that the MISR under-estimates the values of AOD as compared to Terra. These differences are attributed to different algorithms and wavelengths used for the retrieval of aerosols (Martonchik et al., 1998; Diner et al., 1998; Remer et al., 2005). The lowest coefficient of determination (R^2 = 0.750) is found between Terra-AOD and SeaWiFS-AOD. Values of slope (0.359) and y-intercept (0.117) of linear fit for SeaWiFS-AOD also exhibit under estimation. Despite of having same wavelength of operation, the different aerosol model assumptions and instrument calibrations of Terra-MODIS and SeaWiFS cause this under estimation (Hsu et al., 2004, 2006; Remer et al., 2005).

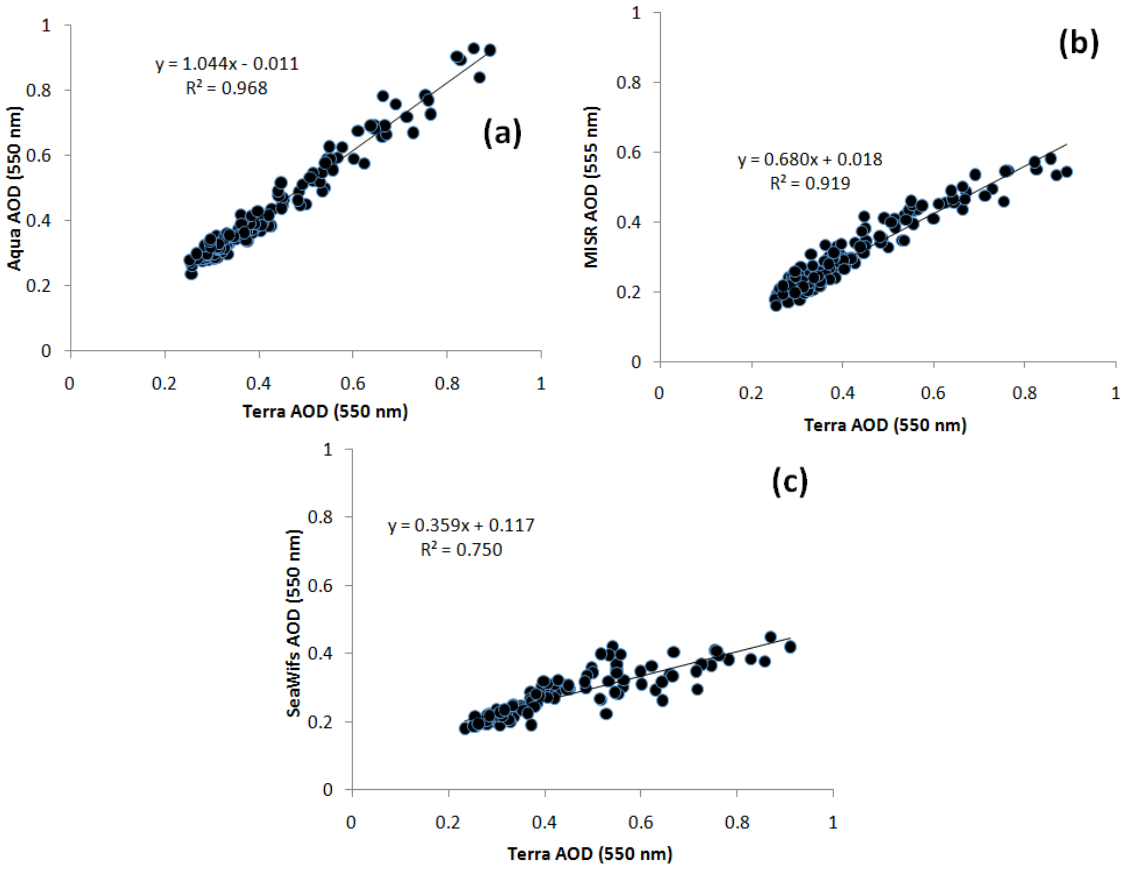

Figure 4. *Comparison between (a) Terra-AOD (550 nm) and Aqua-AOD (550 nm), (b) Terra-AOD (550 nm) and MISR-AOD (555 nm) and (c) Terra-AOD (550 nm) and SeaWiFS-AOD (550 nm) over Pakistan during the study period. The equation of linear fit and coefficient of determination (R^2) are also given*

Spatial distributions of aerosol parameters

Spatial distributions of Terra-AOD, $AE_{470\text{-}660}$, SMF and MC for the period 2000-2014 have been shown in *Figure 5*. White spaces in the figure represent no data/fill values. A significant spatial variability in Terra-AOD values (0.15-0.87) has been observed as shown in *Figure 5a*. It can also be noted from *Figure 5a* that high values (~0.8) of mean annual Terra-AOD exist over northeastern and southern Pakistan. Several studies have reported heavy air pollution due to intense crop residue burning in Pakistan and adjoining regions (Ul-Haq et al., 2015a, b, 2016, 2017). Tariq and Ali (2015) highlighted high aerosol burden over northeastern Pakistan due to open field crop residue burning. Also elevated concentrations of aerosols are associated with the activities at industrial areas in northeastern Pakistan and regions across the border in India such as Amritsar, Chandigarh and Bathinda (Raja et al., 2010). Wind patterns favor transport of aerosols released from anthropogenic activities such as biomass burning and fossil fuel combustion in power plants in India to northeastern Pakistan. On the other hand, high AOD values over the southern Pakistan are mainly contributed by desert/dust aerosols largely transported from local areas including Thar and Cholistan deserts (Tariq and Ali, 2015). Influx of desert/dust aerosols from desert regions of Arabia and Africa (Middleton, 1986; Prospero et al., 2002; Singh et al., 2004; Prasad

and Singh, 2007; Kumar et al., 2012; Alam et al., 2014; ul-Haq et al., 2016) also contributes to the aerosol burden over this region.

Furthermore, the spatial distribution of Terra-AOD follows the Sulaiman–Kirthar range pattern that acts as a barrier for the desert/dust aerosols coming from the Thar and Cholistan deserts (Tariq and Ali, 2015). Alam et al. (2011) also found high AOD values over southern Pakistan due to high population, increased urbanization, heavy industrialization, and nearness of Thar and Cholistan deserts (Qureshi, 2010). We observe low values of Terra-AOD over northern and northwestern parts of Pakistan due to the fact that most of the areas in northern and northwestern Pakistan are agricultural and less populated in agreement with Alam et al. (2011).

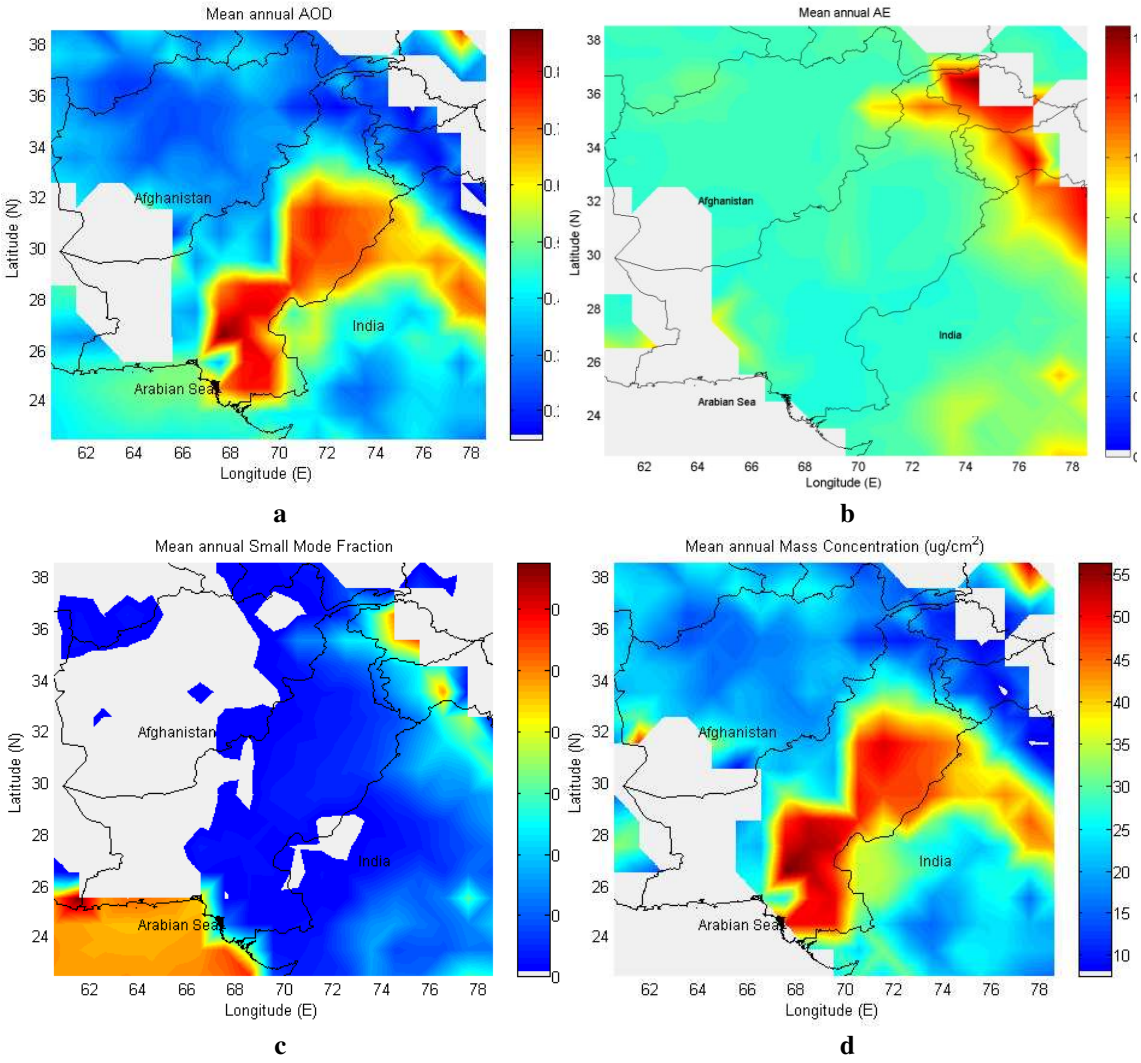

Figure 5. *Mean annual spatial distributions of (a) Terra-AOD, (b) $AE_{470\text{-}660}$, (c) SMF and (d) MC of aerosols over Pakistan from April 2000 to March 2014*

Since AOD only describes the overall aerosol burden without any information of aerosol composition, we have also analyzed other parameters such as Angstrom exponent and small mode fraction to differentiate the fine mode and coarse mode aerosol particles. The Angstrom exponent (AE) is an important qualitative parameter to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26152637
© 2018, ALÖKI Kft., Budapest, Hungary

assess the size of aerosol particles (Angstrom, 1929). It is inversely related to the size of aerosol particles; values of AE less than or equal to 1 indicate the dominance of coarse mode aerosol particles (radii ≥ 0.5 μm) such as dust and sea-salt, while AE ≥ 1 indicates the dominance of fine mode aerosol particles (radii ≤ 0.5 μm) such as urban pollution and biomass burning (Westphal and Toon, 1991; Eck et al., 1999). The AE has been used in various studies to assess the size distribution and classify different types of aerosols (Eck et al., 1999, 2001; O'Neill et al., 2001; Schuster et al., 2006; Kalapureddy and Devara, 2008; Kedia and Ramachandran, 2009). *Figure 5b* shows spatial distribution of mean annual $AE_{470\text{-}660}$ over Pakistan during the study period. Wide range of $AE_{470\text{-}660}$ (0.56 to 1.44) indicates considerable variability in the size of aerosol particles. The northern Pakistan is characterized by high values (greater than 0.8) of $AE_{470\text{-}660}$ due to dominance of fine mode aerosols (i.e., anthropogenic aerosols), whereas relatively low values (less than 0.8) over southern Pakistan indicate the dominance of coarse mode aerosols (i.e., sand/dust). Various epidemiological studies have reported a significant correlation between exposure to fine particles in the atmosphere and adverse health effects. Therefore, people residing in the northern parts of Pakistan may experience more harmful health effects due to fine mode aerosol particles.

SMF is the ratio of small mode AOD to the total AOD (Kaufman et al., 2005a, b). High values of SMF are associated with small aerosol particles such as those released from anthropogenic sources (i.e. biomass burning) while low values of SMF indicate naturally occurring large aerosol particles such as sea-salt and dust (Bellouin et al., 2005). The spatial distribution of mean annual SMF (*Fig. 5c*) is found to be almost similar to that of $AE_{470\text{-}660}$ i.e., high values over northern Pakistan and low values over southern Pakistan. It can further be noted from *Figure 5c* that fine mode aerosols are dominating over Arabian Sea. The high values of SMF over Arabian Sea are possibly associated with the presence of sea-salt aerosols. *Figure 5d* shows the spatial distribution of mean annual MC of aerosols over Pakistan. It can be noted that the spatial distribution of MC is quite similar to that of AOD. The MC showed a significant spatial variability (i.e., 7.6 to 56.2 $\mu g/cm^2$). The high values of MC over south and northeastern Pakistan indicate heavy aerosol loading.

Latitudinal and longitudinal gradients in seasonal AOD

Figure 6 shows latitudinal and longitudinal gradients in seasonal Terra-AOD during 2000-2014 over the study region. The latitudinal AODs are averaged over a longitude range of 60.5°E-78.5°E, and longitudinal AODs have been averaged over a latitude range of 22.5°N-38.5°N. *Figure 6a* shows that Terra-AOD remained relatively high on all the latitudes during summer and low during the winter. Unstable atmosphere in summers uplifts the aerosols causing enhanced values of AOD. On the contrary, stable atmosphere during winters entraps the aerosols to lower heights resulting in small values of AOD in agreement with Prasad et al. (2007), Alam et al. (2010) and Ali et al. (2014). Prasad et al. (2007) analyzed the aerosol variations over IGP and they found higher AOD in summer and lower AOD in winter. Alam et al. (2010) found higher values of AOD in summer and lower values in winter over ten different cities of Pakistan. Similarly, Ali et al. (2014) reported high value of AERONET derived AOD over Lahore, a northeastern megacity of Pakistan, due to increased temperatures and frequent dust storms. As a general rule the Terra-AOD in all the four seasons has increased northward from 22.5°N with a maximum value at 28.5°N and then it

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26152637
© 2018, ALÖKI Kft., Budapest, Hungary

decreases towards 35.5°N followed by a little increase between 35.5°N-38.5°N. The maximum decrease (0.63) in latitudinal Terra-AOD is observed during summer season. It showed averaged peak values of 0.52, 0.92, 0.57 and 0.47 during spring, summer, autumn and winter seasons, respectively, at a latitude of 28.5°N. The peak values at 28.5° N is linked to biomass burning in IGP covering northeastern Pakistan and regions across the border in India (*Fig. 1b*; Tariq et al., 2016; ul-Haq et al., 2016). The lowest AODs are observed to be 0.29, 0.30, 0.20 and 0.19 during spring, summer, autumn and winter seasons, respectively, at a latitude of 36°N.

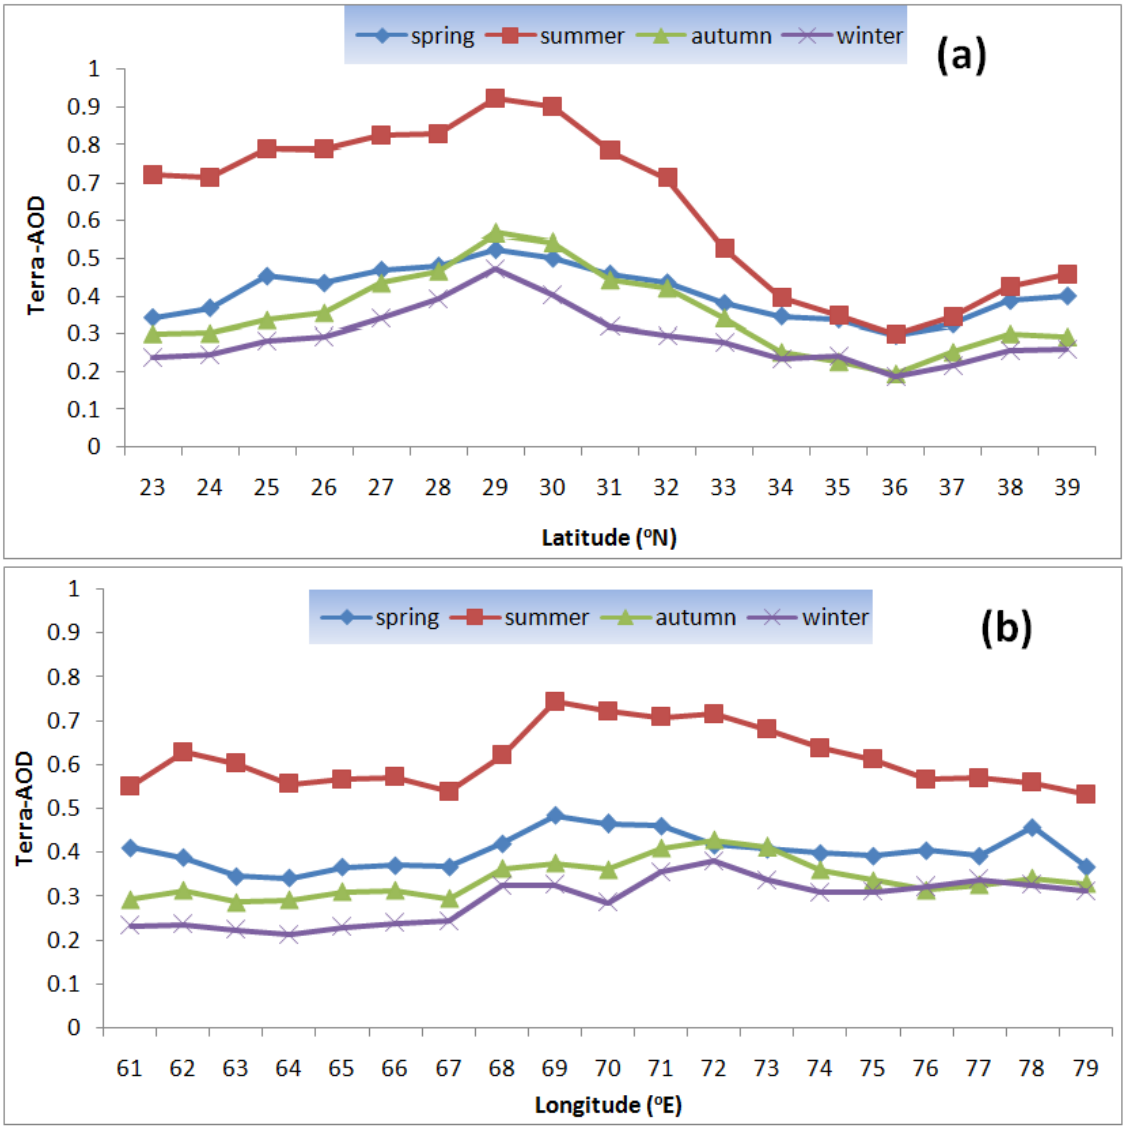

Figure 6. *Seasonal variation in Terra-AOD over different latitudes (a) and longitudes (b) in Pakistan during April 2000-March 2014*

Figure 6b shows seasonal variations in Terra-AOD over different longitudes in the study region. It is observed from the *Figure 6b* that longitudinal Terra-AOD remains higher in summer than all the other seasons. During summer and spring, peak values of longitudinal Terra-AOD have been observed over 69°E, while for winter and autumn

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26152637
© 2018, ALÖKI Kft., Budapest, Hungary

peak values of Terra-AOD are observed over 72°E. The peak values of longitudinal Terra-AOD are found to be 0.48, 0.74, 0.43 and 0.38 during spring, summer, autumn and winter respectively. The peak values at 69°E and 72°E are associated with biomass burning and dust activity in part of IGP in Pakistan (see *Figs. 1b* and *5a*) (Tariq et al., 2016; ul-Haq et al., 2016). It is noticed that the trends in seasonal-mean latitudinal and longitudinal averaged values of Terra-AOD are better simulated with the help of following linear equations (*Eqs. 1* and *2*):

$$\mathrm{AOD} = a \times \mathrm{Lat} + b \quad \text{(Eq.1)}$$

$$\mathrm{AOD} = a \times \mathrm{Long} + b \quad \text{(Eq.2)}$$

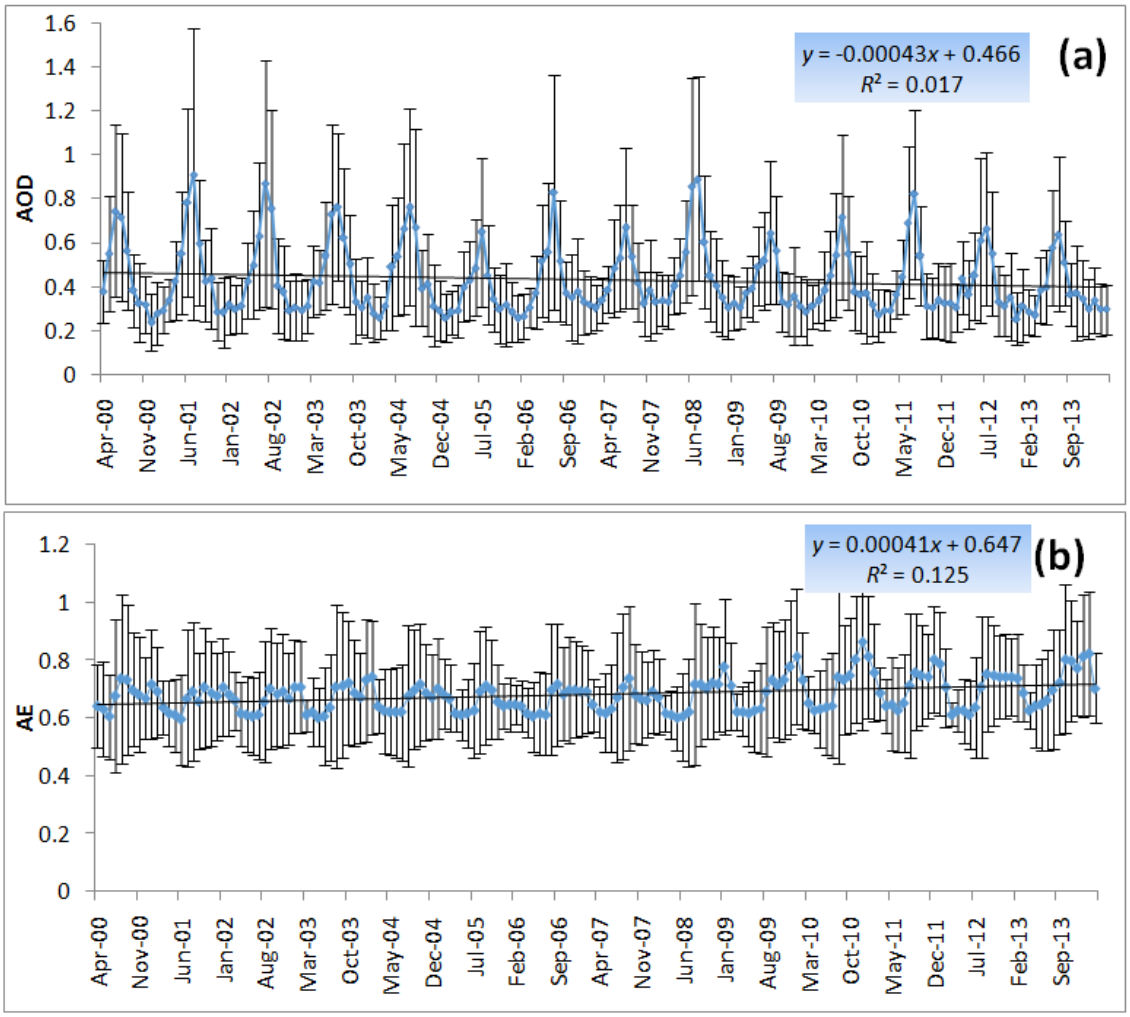
Table 1 shows the values of constants *a* and *b*, and coefficient of determination (R^2) for different seasons over Pakistan during April 2000-March 2014. Some important conclusions drawn from the *Table 1* are as follows:

(i) For latitudinal AOD, the slope *a* is negative during all the seasons showing a decrease in Terra-AOD values towards northern Pakistan. Relatively large values of slope and R^2 in summer indicate less scatter in the linear fit with the largest south to north gradient for latitudinal AOD.

(ii) For longitudinal AOD, positive values of slopes during all the seasons indicate an increasing trend towards eastern Pakistan. Comparatively greater values of slopes and R^2 in winter season indicate less scatter in the linear fit with greatest west to east gradient for longitudinal Terra-AOD.

Table 1. *Values of the a and b coefficients in the equation AOD = a × Lat + b for latitudinal Terra-AOD and AOD = a × Long + b for longitudinal Terra-AOD averaged over the longitudinal region 60.5°E-78.5°E and latitudinal region 22.5°N-38.5°N, respectively, applied to the seasonal-mean values over Pakistan during the study period. The coefficient of determination R^2 represents the scatter of the data values from the fitting linear form*

Season	*a*	*b*	R^2
For latitudinal AOD			
spring	-0.0052	0.4545	0.1564
summer	-0.033	0.9325	0.5977
autumn	-0.0085	0.4321	0.1548
winter	-0.0049	0.3358	0.1141
For longitudinal AOD			
spring	0.0021	0.382	0.085
summer	0.0003	0.6111	0.0007
autumn	0.0032	0.3082	0.174
winter	0.007	0.222	0.5844



Monthly climatological variations in aerosol parameters

Figure 7a shows a time series of monthly mean Terra-AOD spatially averaged over Pakistan along with standard deviations from April 2000 to March 2014. The Terra-AOD ranges from 0.24 to 0.91 with an overall mean value of 0.43 ± 0.16. The highest value (0.91) of Terra-AOD is observed in July 2001 while the lowest value (0.24) is found in December 2000. The broad range variations in time series of Terra-AOD

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26152637
© 2018, ALÖKI Kft., Budapest, Hungary

values are attributed mainly to the high values observed over northeastern and southern Pakistan during summer season. The major contributors of high AOD values are dust aerosols originated from the local deserts (i.e., Thar and Cholistan) and anthropogenic activities. Desert/dust aerosols from desert regions of Arabia and Africa (Middleton, 1986; Prospero et al., 2002; Singh et al., 2004; Prasad and Singh, 2007; Kumar et al., 2012; Alam et al., 2014; ul-Haq et al., 2016) also contribute to the aerosol burden over the region. An overall negative change (-15.4%) in the Terra-AOD values is observed indicating that the total aerosol burden is decreasing over Pakistan. However, a positive change (10.6%) has been noticed in $AE_{470\text{-}660}$ values (*Fig. 7b*) indicating that the contribution of fine mode aerosol particles towards total aerosol burden is increasing. The increasing trend in AE with time is linked to anthropogenic activates such as industrial production, residential combustion and biomass burning.

Gupta et al. (2013), while analyzing AOD observations from MODIS during 2001-2010, also showed a decreasing trend in AOD with slope of -0.07 over Lahore (Pakistan). Analysis shows that $AE_{470\text{-}660}$ ranges from 0.60 to 0.86 with a mean of 0.68 ± 0.06. The highest value (0.86) of $AE_{470\text{-}660}$ has been detected in December 2010 and the lowest value (0.60) in June 2001. Similarly, a positive change in SMF is also found (*Fig. 7c*) with an overall mean of 0.11 ± 0.05.

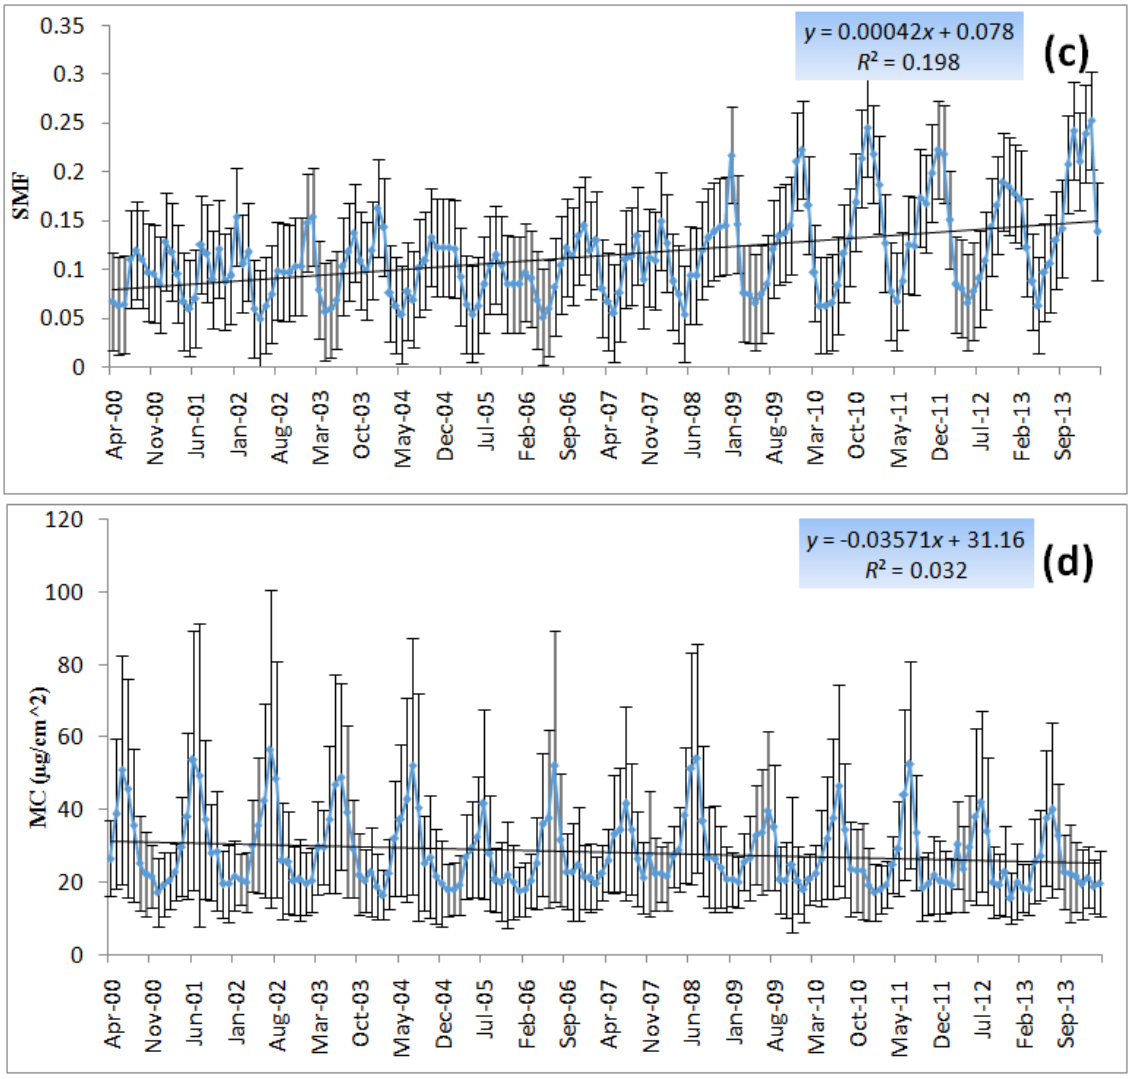

Figure 7. *Time series of (a) AOD, (b) $AE_{470\text{-}660}$, (c) SMF and (d) MC derived from Terra-MODIS over Pakistan during April 2000-March 2014. The error bars show standard deviations from the corresponding mean values*

Extremely low mean value of $AE_{470\text{-}660}$ signifies the dominance of coarse mode aerosols in the atmosphere of Pakistan during the study period. *Figure 7d* shows time series of MC spatially averaged over Pakistan from April 2000 to March 2014. The MC values have been found to be ranging from 15.8 µg/cm^2 to 56.6 µg/cm^2 with an overall mean value of 28.2 ± 9.71 µg/cm^2. Like AOD, MC also shows a negative change (-19.2%) with time. We find the highest value (56.63 µg/cm^2) of MC in July 2002 and the lowest value (15.76 µg/cm^2) in December 2012.

Figure 8a-d shows the variations in monthly average values of AOD, $AE_{470\text{-}660}$, SMF and MC derived from Terra-MODIS over Pakistan during April 2000-March 2014. Error bars represent the standard deviations from the mean values. It can be observed from *Figure 8a* and *d* that AOD and MC derived from Terra satellite have similar behaviors. Both AOD and MC have increased from January to their maximum values in July followed by a decrease to minimum values in December. The peak values of both Terra-AOD (0.71 ± 0.37) and MC (43.36 ± 26.8 µg/cm^2) have been found in July with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26152637
© 2018, ALÖKI Kft., Budapest, Hungary

corresponding values of $AE_{470-660}$ and SMF to be 0.64 ± 0.16 and 0.09 ± 0.02 respectively. Elevated values of standard deviation for AOD and MC indicate that aerosols are highly variable in space. The lowest values of standard deviation for Terra-AOD (0.09) and MC (6.7) are found in February indicating almost uniform distribution of aerosols over Pakistan. Our study is in agreement with the results from Alam et al. (2010) who showed that AOD increases from April, reaching its peak value in July and decreases afterwards to attain a minimum value in December. The increase of AOD in summer (June, July and August) is caused by dust transported from the Thar Desert (India) and Dasht Desert (Iran), sea-salt aerosols carried by strong south-westerly winds and increase in humidity within this region (Alam et al., 2010, 2011). Ranjan et al. (2007) analyzed the spectral variation of total column AOD over Rajkot (India) and they showed that water vapor content and AOD are proportional to each other, therefore, enhanced concentration of water vapor in summer results in higher AOD. *Figure 8b* and *c* show the variations of monthly averaged $AE_{470-660}$ and SMF during the study period. It can be noted that both $AE_{470-660}$ and SMF show a quite similar seasonal pattern. Both the parameters are found to be decreasing from January to attain their minimum values during May-June. Peak values of $AE_{470-660}$ (0.73 ± 0.18) and SMF (0.16 ± 0.05) are found in January. Relatively high values of standard deviation are linked to the higher fine mode aerosol concentration over northeastern Pakistan and lower over southern Pakistan. Low values of $AE_{470-660}$ and SMF and their corresponding standard deviations during May-June are associated with dominance of desert dust aerosols over the entire Pakistan.

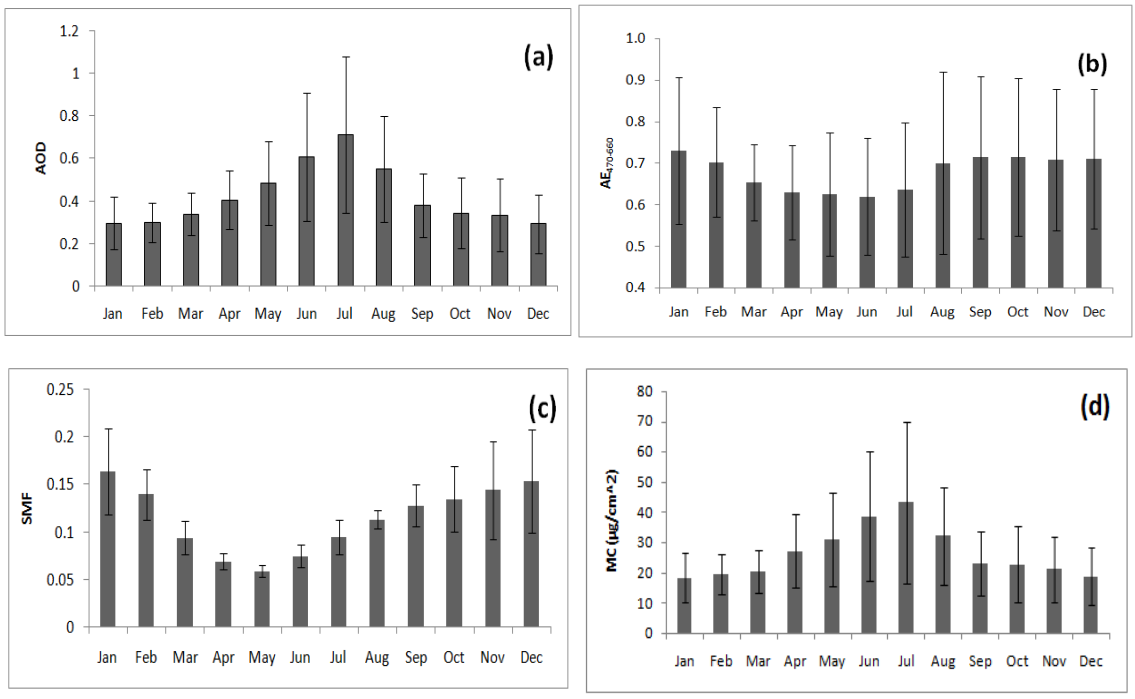

Figure 8. *Temporal variations in monthly average values of (a) AOD, (b) $AE_{470-660}$, (c) SMF and (d) MC derived from Terra-MODIS over Pakistan during April 2000-March 2014. The error bars show standard deviations from the corresponding mean values*

Table 2 shows the linear trend parameters, correlation coefficients and relative changes (%) per year of AOD, AE, SMF and MC on seasonal and annual basis over Pakistan. It can be observed from the table that slopes are negative for Terra-AOD

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26152637
© 2018, ALÖKI Kft., Budapest, Hungary

during all the seasons except winter. AOD in summer showed the greatest declining trend of -1.170% per year. The highest values of relative change per year of AOD (0.325%) and AE (1.115%) are found during winter while the highest value of percentage change per year of SMF (7.427%) is found during autumn. MC shows decreasing trend both on seasonal and annual basis. Significant (at 0.01 level) positive correlation is found for AE (r = 0.775) and SMF (r = 0.920) on mean annual data. Values of relative change per year are found to be negative for AOD (-0.615%) and MC (-0.986%), and positive for AE (0.570%) and SMF (4.344%).

Table 2. *Linear trend parameters of equation of the form ax + b, where a is slope and b is y-intercept, of AOD, AE, SMF and MC over Pakistan. Correlation coefficient (r) and relative change (%) per year are also given. ** and * represent correlation significance at the 0.01 and 0.05 levels (2-tailed) respectively*

Conclusions

In the present study we have used Terra-MODIS data for the period April 2000-March 2014 to analyze AOD (550 nm), Angstrom exponent ($AE_{470-660}$), small mode fraction (SMF) and mass concentration (MC) of aerosols over Pakistan. AOD from different satellite sensors have also been compared with ground-based AOD. Values of coefficient of determination (R^2) between Terra-AOD and AERONET-AOD are found to be 0.718 and 0.745 for Lahore and Karachi respectively. Terra-AOD has also been compared with other satellite-based observations obtained from Aqua, MISR and SeaWiFS. We find significant correlations of Terra-AOD with Aqua-AOD (R^2 = 0.968) and MISR-AOD (R^2 = 0.919). A significant spatial variability in mean annual AOD values (0.15-0.87) has been found with high values (~0.8) observed over northeastern and southern Pakistan. The $AE_{470-660}$ amounts from 0.56 to 1.44 with high values (greater than 0.8) over northern Pakistan and relatively low values (less than 0.8) over

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26152637
© 2018, ALÖKI Kft., Budapest, Hungary

southern Pakistan. Strong similarity in the spatial distributions of mean annual SMF and $AE_{470\text{-}660}$ has been found. The MC, ranging from 7.6-56.2 μg/cm^2, has spatial distribution quite similar to that of AOD. The latitudinal AOD shows peak values of 0.52, 0.92, 0.57 and 0.47 during spring, summer, autumn and winter seasons, respectively, over latitude of 28.5°N. A negative change (-15.4%) in the AOD values is observed indicating a decrease in the total aerosol burden over Pakistan. However, a positive change (10.6%) is observed in $AE_{470\text{-}660}$ which indicates mounting contribution of fine mode aerosol particles towards total aerosol burden. The peak mean monthly values of both AOD (0.71) and MC (43.36 μg/cm^2) are observed in July with corresponding $AE_{470\text{-}660}$ and SMF values of 0.64 and 0.09, respectively. The overall mean values of the AOD, $AE_{470\text{-}660}$, SMF and MC are found to be 0.43 ± 0.16, 0.68 ± 0.06, 0.11 ± 0.05 and 28.2 ± 9.71 μg/cm^2 respectively. Trends and spatial distributions of different aerosol parameters discussed in this study are important in policy making for human health protection and environmental remediation. Furthermore, the assessment of aerosol concentrations presented in this study can be correlated with harmful effects on human health and drought indices, which can be a possible further research topic.

Acknowledgements. We are grateful to the MODIS, MISR, SeaWiFS and AERONET science teams and associated NASA personnel for data processing provided via GES-DISC. We are thankful to NOAA/OAR/ESRL PSD, Boulder, Colorado, USA, for providing NCEP–Reanalysis 2 data. We are also thankful to anonymous reviewer and editor for their useful comments to improve the original manuscript. This research project was funded by the University of the Punjab, Lahore, Pakistan.

(Received 23rd Jan 2018; accepted 25th Apr 2018)

Abstract. This study extends research into power in the supply chain (SC) on the basis of three "patterns". The first one is the "pattern of sustainability". From the aspect of sustainability, the "golden thread" connecting all actors and influencing relationships between actors in the SC is the sustainability orientation. The second one is the "pattern of sustainability-oriented (SO) actors". Transformation towards sustainability in the SC requires the SO behavior of numerous actors. The third one is the "pattern of SO collaboration". Sustainability results from the complementary effect of numerous actors' behaviors, so this study suggests the SO collaboration paradigm as a way to sustainability. These three patterns of embedding sustainability in the SC can also be observed as the three stages of the transformation of the SC into the sustainability-oriented supply chain (SO-SC). In the first stage of embedding sustainability in the SC, actors voluntarily and/or under pressures accept some sustainability initiatives. In the second stage, the number of SO actors behaving sustainably increases. The SO-SC and the achievement of the goals of the sustainable development (SD) require the sustainable behavior of all (or at least) the majority of actors and SO collaboration.
Keywords: *sustainable development, Agenda for sustainable development, environmental awareness, co-creation of value, consumer*

Introduction

Individuals, companies and countries are faced with an SD challenge. According to "The 2030 Agenda for Sustainable Development" (UN, 2015), all countries and all stakeholders are actors taking part in a collaborative partnership, in which Governments, civil society, the private sector, the United Nations' system and other actors are brought together and all available resources are mobilized. Lozano et al. (2015) proposed the 'Sustainability-Oriented Theory of the Firm', which is based on the holistic perspective of corporate sustainability. SO actors enable transformations in the SC. In compliance with the Agenda for SD (UN, 2015), all actors and all stakeholders are actors taking part in a collaborative partnership in the SC, where consumers, the focal firm, employees, suppliers, regulators and governments, the general public, environmental and social pressure groups, NGOs, neighborhood communities, the media and schools are brought together. Starting from the literature review, the purpose of the study is to present and analyze the collaborative partnership paradigm in the SO-SC as a way to sustainability. "Sustainability-oriented" (SO) means a holistic approach to sustainability by covering all the three dimensions (economic, environmental and social) in the dynamic process (Rakic and Rakic, 2017b). According to the collaborative partnership paradigm in the SO-SC, all actors are engaged in co-creating SO values. Consumers are the most important co-creators of values. Opportunities for firms are the

© 2018, ALÖKI Kft., Budapest, Hungary

speed (of business and change), digitalization and the SO-SC. These are also the sources of companies' competitive advantages.

The structure of the study is as follows. In the next section, the related literature is reviewed. Then, the conceptual framework – the collaborative partnership paradigm is presented and described, as a way to sustainability in the SC. The conclusions and the agenda for further research are presented at the end of the paper.

The engagement of co-creators in sustainable supply-chain management

In firms, there are stakeholders with different priorities because of the protuberance of their values and issues, for which reason the same are often compelled to make trade-offs. For example, owners' and managers' focus is on profitability, whereas concerns of a community's members are probably related to the overall livability of the community and production's environmental impacts. How to balance environmental issues and sound business practices in such a dynamic, complex and uncertain setting is challenging. One research, however, suggests that it is impossible for all stakeholders to be satisfied at all points in time. Ambitiously environmentally targeted strategic decisions can generate real economic costs (Pagell et al., 2010). Firms have increasingly been facing pressure from external stakeholders (e.g. NGOs, customers, regulators) in order for them to maintain sustainable supply chains (Grimm et al., 2014). Searcy (2014) differentiates three groups of stakeholders for the sustainability of an enterprise:

- focal firm stakeholders – employees, unions, managers, owners/investors
- supply chain stakeholders – suppliers, distributors, consumers (individuals, groups or other firms), reclaimers (collectors, re-users, recyclers, remanufacturers or disposers)
- stakeholders beyond the supply chain – government, communities, competitors, NGOs, media.

The engagement of co-creators in the sustainability-oriented internal value chain

Focal firms are those usually (1) ruling or governing the supply chain, (2) providing the customer with a direct contact, and (3) designing the product or service offered (Seuring and Muller, 2008). The focal firm is capable of arranging for the maximum benefit for all the participants of the supply chain through their coordination, the inhibition of an opportunistic behavior, and the maintenance of the sustainability of the supply chain (Li et al., 2014).

The influences of external stakeholders

It is possible to group external drivers at three levels, and by rule they include:

- Regulators and governments at the regulatory level
- Customers, suppliers and competitors at the market level
- Non-governmental organizations (NGOs) and the general public at the societal level (Harms et al., 2013).

From the historical point of view, firms used to accumulate all the resources they were in need of in-house. Today, firms have shifted away from this vertical–integration model and have started programs intended for accessing specialized, global suppliers (Prahalad and Krishnan, 2008). Production processes are frequently dispersed throughout the globe. Supply-chain focal firms might be held responsible for their

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26392650
© 2018, ALÖKI Kft., Budapest, Hungary

suppliers' environmental and social performance (Seuring and Muller, 2008). Focal firms, buyers, are required to take their suppliers' responsibility, sustainably arranging for their supply chains' actions. It is frequently the case that external stakeholders do not differentiate the focal firm's behavior from the one of its suppliers, simultaneously holding the focal firm responsible for all activities performed within the manufacture of a product (Grimm et al., 2014; Rao, 2002; Koplin et al., 2007). Any party in the supply chain that does not comply with the focal firm's corporate sustainability standards can potentially incur damage to corporate reputation and/or harm customer confidence (Grimm et al., 2014) (Seuring and Muller, 2008). This is particularly the case with brand-owning firms, since they show a tendency of being exposed to pressure from stakeholders, e.g. non-governmental organizations (NGOs). Mattel (Barbie), Nike (Football) and Nestlé (KitKat) are outstanding examples to have demonstrated the way in which firms' brands can suffer from non-compliant sub-suppliers (Barnett and King, 2008; Choi and Linton, 2011; Grimm et al., 2014; Wagner et al., 2009). On the other hand, when the focal firm is exposed to pressure, it usually passes such pressure on to suppliers (Seuring and Muller, 2008). The idea is that the focal firm in the supply chain will compel its upstream suppliers to adopt and adapt the technology and practices resulting in more efficient and environmentally friendly material sources, engage in labor practices deemed to be ethical and result in the lower emissions of the greenhouse gas and a low impact on the environment. As it has been suggested that "a firm is only as sustainable as it suppliers".

Gualandris and Kalchschmidt (2014) recommend that the growing awareness on the stakeholders' part should be acknowledged by managers and that they should be prepared to address strict environmental and social requirements made by the customer. Customer pressure is found to be the essential driver motivating firms to initiate and sustain the process of the SSCM development. Customer pressure refers to end-consumers' and business customers' requests and their requirements, i.e. those made by important primary-stakeholder groups, so that the firm could make its environmental and social performance upgraded (Gualandris and Kalchschmidt, 2014). One of the key criteria for decision making that has so far been missing from green, SSC models is the consumer's role. Many businesses selling environmentally friendly, green or sustainable, low-carbon-emission products show a tendency of costing more. The consumer is usually passed on this cost in the form of higher prices. For the purpose of making green or sustainable products more marketable and sellable, many businesses will not only have to quantify the benefits, but also to justify the value proposition to the customer (Hassini et al., 2012). The factors related to marketing and public relations refer to firms' efforts intended for the creation of a value proposition for the customer, in particular when an "environmentally friendly" product costs more. Also, firms must create the awareness of the practices leading to a more environmentally friendly or sustainable product. Just like focal firms in the supply chain compel their upstream suppliers to be greener and more sustainable, they also try to educate and convince their customers to purchase their green products. As an external pressure, NGO's can turn to boycotts or detrimental publicity campaigns designed to shame the firm into offering more sustainable products (Hassini et al., 2012).

Customer expectations have become the most important external pressure (Doonan et al., 2005). The increasing of his/her environmental, ecological and ethical awareness by the end-customer and demands to save energy, reduce pollution and waste, as well as ensure consumer safety, expose supply management to pressure (Lintukangas et al., 2015).

The factors related to the policy and regulations originate from governments either through legislation or via a regulator requesting from firms to obey certain environmental standards (Hassini et al., 2012). "If conservationists, environmentalists and animal advocates join forces, perhaps there will be some reason for optimism" (Erdos et al., 2017, p. 188).

From dyadic, via triadic to multiple relationships in supply chain

From a traditional point of view, power relationships are surveyed at the dyadic level (Touboulic et al., 2014), namely most frequently between the local firm (the buyer) and its suppliers (Brammer et al., 2011; Kumar and Rahman, 2015). One side of the relationship dyad has been the subject matter of such studies (Nyaga et al., 2013). Mainly, one actor's responsibilities, namely those on the part of the focal firm (the buying firm) are singled out. Relationships existing between the focal firm other actors, e.g. retailers, are researched into to a lesser extent (Chaurasia, 2014). The end consumer is rarely the focal subject matter of research. When buyers are mentioned and an analysis of them performed, authors actually analyze relationships between the focal firm and suppliers (in which case, the focal firm is considered as the buyer, i.e. the firm as the buyer). This study emphasizes the role of the end consumer.

Apart from dyadic relationships, authors have also done research into triadic relationships (Touboulic et al., 2014), as well as into network relationships (Lacoste and Johnsen, 2015; Tachizawa and Wong, 2015). Touboulic et al. (2014) observe multiple triadic relationships drawing in a large buyer and its small suppliers, in order to check thoroughly into the manner in which relative power may affect the implementation of sustainable supply-management practices. They are analyzed at the triad level of analysis: the buyer–the supplier–the supplier. According to the results of the research, it is possible for a powerful organization to drive sustainability in its SC. When a situation such as the described one occurs, dependent suppliers are not left too much choice – they can but adhere to requirements made by the buyer and it is their obligation to specifically perform a thorough check into the relationship in order to become more sustainable. The findings are conforming to the work previously conducted, in which a suggestion was made that the buyer power stands for a resource to be used for the purpose of compelling the supplier to be compliant with sustainability requirements (Touboulic et al., 2014).

Tachizawa and Wong (2015) propose that a supply network perspective should be used to carry out an analysis of the effectiveness of the mechanisms of governance of green supply chain management (GSCM), not to apply a linear view. There are increasing societal pressures that encircle firms' accountability for the environment, which is accompanied, too, by an ever-larger number of environmental scandals concerning supply networks. It may prove to be insufficient to only apply the traditional frameworks of the governance of the GSCM for the purpose of dealing with this new reality, because the supply network structure/complexity is not taken into consideration, nor is the manner in which these factors interact with different mechanisms of governance is considered, either (Tachizawa and Wong, 2015). It is possible to understand that the supply network is a set of firms taking part, directly or indirectly, in supplying industrial inputs to the focal firm, with or without that company being aware or knowledgeable of it (Choi and Krause, 2006; Choi et al., 2001). Supply networks are viewed by Tachizawa and Wong (2015) as emergent, allowing for different parties

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26392650
© 2018, ALÖKI Kft., Budapest, Hungary

capable of shaping the supply network and the implementation of the GSCM. For a long time, the importance of power and dependence in relationships has been the subject matter of consideration by IMP. In the IMP literature, power distribution is considered as being dependent on the pattern of the 'interaction' (Hakansson and Waluszewski, 2013; Lacoste and Johnsen, 2015). The IMP paradigm of the interaction approach takes place within the context of relationships between companies embedded in networks (Campbell, 1984; Hakansson, 1986; Lacoste and Johnsen, 2015; Smith and Easton, 1986). Zhao et al. (2008) pointed out the impact of relationship commitment on the integration between actors in the SC. Relationship commitment is one party's willingness to make an investment of its own financial, physical or relationship-based resources in a relationship (Morgan and Hunt, 1994). Quite a large amount of time and resources are invested by firms in the development, maintenance and improvement of the relationships between them in the supply chain since demonstrable benefits in terms of operational and financial performance are offered by such relationships (Nyaga et al., 2013). Firms cooperate with their respective partners in the supply chain so that they could have access to critical resources, mitigate transactional complexity and improve their performance (Fawcett et al., 2011; Nyaga et al., 2013; Zacharia, 2009). It is possible to foster sustainability by making a connection between the concept of co-creation and the concept of relationship management. Co-creation implies an inclusion of well-selected stakeholders, e.g. customers or suppliers, in the innovation process on a targeted basis (Arnold, 2017).

Traditionally in the SC literature, the concept of power in buyer–supplier exchange has been a significant subject matter of researches conducted. When a shift from supply chain management (SCM) to sustainable supply chain management (SSCM) is considered, it is possible for relationship-management strategies to undergo significant changes so as to be able to accommodate sustainability goals with e.g. dominant buyers who do not exploit their power over dependent suppliers but instead treat them as if they were strategic partners (Pagell et al., 2010; Touboulic et al., 2014). In prior researches, a strong accent has been put on cooperation between SC partners for the purpose of facilitating sustainability initiatives (e.g., Gold et al., 2010; Grekova et al., 2016; Lacoste and Johnsen, 2015; Sancha et al., 2016; Seuring and Muller, 2008; Touboulic et al., 2014). While, on the one hand, cooperation has been publically supported as the best manner to manage SC relationships regarding sustainability, that the fact that the major part of the SSCM literature tends to focus on actions performed by large corporations, on the other, is an interesting one to perceive. Cooperation with suppliers has been regarded as a critical component of creating sustainable SCs (Touboulic et al., 2014). Little research has been done that may challenge the collaborative paradigm in SSCM, and power relationships stay underexplored (Hoejmose and Adrien-Kirby, 2012; Walker et al., 2012). A larger number of the case studies appearing in the SSCM literature are a demonstration of some sort of power imbalance, which will not only determine the agenda driver, but also have an impact on the implementation and outcomes of sustainability initiatives (Touboulic et al., 2014).

Conceptual framework – the collaborative partnership paradigm in the sustainability-oriented supply chain as the way to sustainability

This study is focused on the SO collaboration paradigm (*Fig. 1*). According to the SO collaboration paradigm, all actors and all stakeholders act in a collaborative

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

partnership, bringing together consumers, focal firm, employees, suppliers, regulators and governments, the general public, environmental and social pressure groups, NGOs, neighborhood communities, media, schools and universities. The full line shows the relations between actors from the aspect of the focal firm. The interrupted (dotted) line shows the relations of other actors which the focal company does not directly participate in.

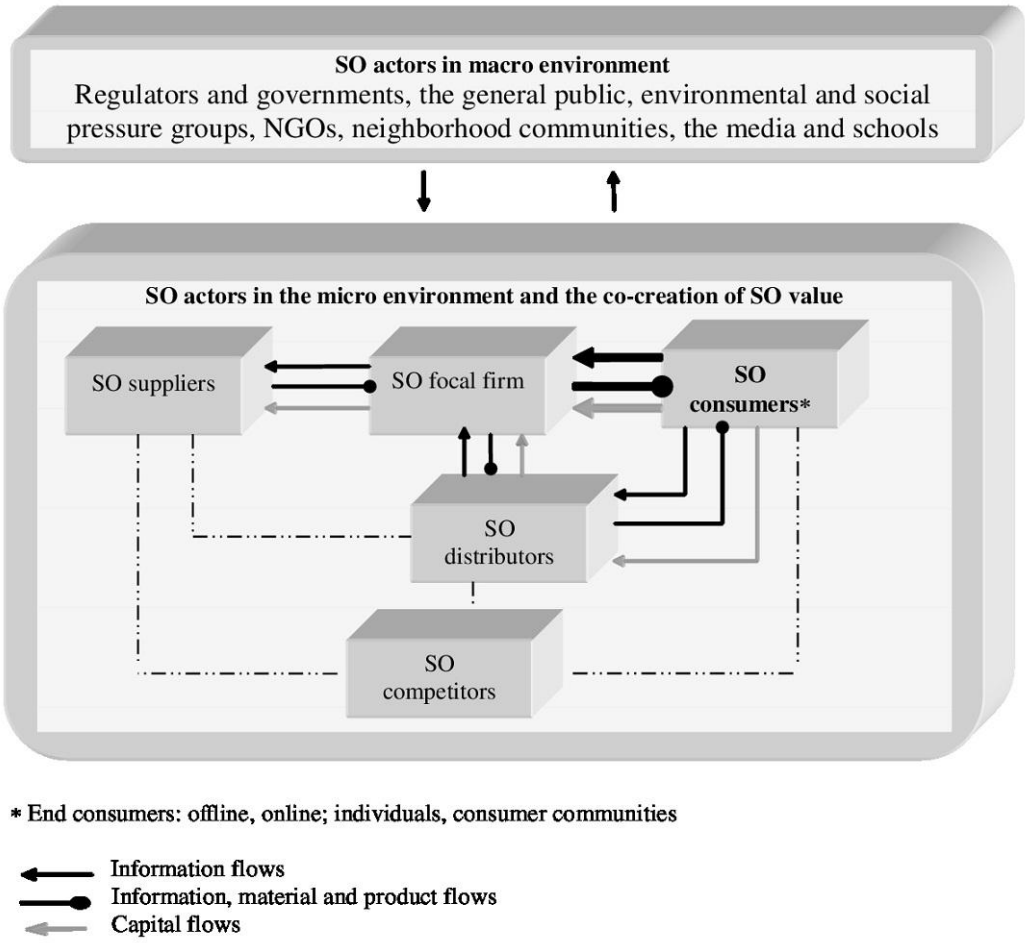

Figure 1. *Conceptual Framework – the Collaborative Partnership Paradigm in the Sustainability-Oriented Supply Chain as the Way to Sustainability (Source: Authors)*

Each of the foregoing actors has its own "patterns of sustainable behavior" and has an influence on other actors and the SC as a whole. SO actors co-create SO value (Rakic and Rakic, 2015a,b, 2017a,b). The focal firm (the brand name) appears in the market in public and is frequently considered to be the main responsible actor. The SO-SC, however, depends on numerous actors' sustainable behavior. The key actors are consumers, focal firms, suppliers, competitors and distributors.

The thickness of the line in Figure 1 between consumers and the focal firm places an accent on the fact that consumers are in focus and that end consumers' needs and wants are (or at least should be) the starting point. Consumer behavior (of end consumers) has an influence on the buying behavior of organizations (B2B). The SO lifestyle of end consumers is "the foundation of sustainability". In the traditional and digital worlds,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26392650
© 2018, ALÖKI Kft., Budapest, Hungary

consumers appear as individuals and within consumer communities. The power that consumers have in the digital world is even greater. Consumers in the digital era are in a position to be the most important co-creators of value; yet, they are not aware of their power. The speed of content distribution on the Internet (via social media – especially through social networks and blogs, portals, etc.), the consumers' awareness of a healthy lifestyle and the tendency to preserve the environment will affect the sustainable behavior of an increasing number of consumers. This will further affect the sustainable behavior of all other stakeholders in the supply chain. Consumers can create, comment and share content through social media. Consumers can influence the business and image of firms. On the other hand, the firms based on word-of-mouth marketing can influence the word-of-mouth communication of consumers. Content, like a virus, can be transmitted over the Internet. Responsible actors can use the power of viral marketing to create content about the importance of sustainable behavior for all actors. Companies can encourage influential people (bloggers and various activists in the field of sustainable development) to create, comment and share the content about sustainable behavior.

If end consumers behave sustainably, then firms as buyers also have to behave sustainably. SO consumers have an influence on the "sustainability mindset" and behavior on the B2B market. Then, the focal firm (as the buyer) has to conduct sustainable production, purchase sustainable inputs from SO suppliers and submit sustainable inputs to SO consumers directly and/or through SO distributors. The SO-SC is an opportunity, not a threat, for firms. The speed (of business and change), digitalization and the SO-SC are opportunities for firms.

SO actors in the macro-environment (regulators and governments, the general public, environmental and social pressure groups, NGOs, neighborhood communities, the media and schools) have the roles of setting "the patterns of sustainable behavior", promotions, pressures and controls of actors' sustainable behavior.

This conceptual framework presents:

- SO actors in a macro-environment;
- SO actors in a micro-environment;
- the mutual relations of the macro-environment and the micro-environment;
- the mutual relations of actors in the micro-environment;
- the collaborative partnership of actors in the process of the co-creating of SO value;
- actors in the SC as the co-creators of SO value;
- information, the material, the product and capital flows in the micro-environment;
- end consumers as offline and online consumers; individuals and consumer communities;
- the dominant role of SO consumers in the process of the co-creation of SO value in the SC;
- the power of SO consumers as the co-creators of SO value –the impact of consumer behavior and the consumers' SO lifestyle on the SO behavior of all actors in SC-SO consumers as the initiators of the co-creating of SO value;
- the SO-SC as a result of the complementary action of numerous actors' sustainable behavior; and
- the SO behavior of all actors in the SC for the purpose of achieving SD goals.

The New Agenda for Sustainable Development emphasizes the need for "transforming our world". Embedding sustainability into the SC is part of the holistic perspective of sustainability. Actors have become involved in embedding the principles of sustainable development in the SC. Adaptations in the SC are based on three patterns. The first one is "the sustainability pattern", i.e. the acceptance and adherence to sustainability initiatives. The second one is the "pattern of SO actors". In order to achieve sustainability in the SC, it is needed that numerous SO actors should be engaged, including consumers, the focal firm, employees, suppliers, regulators and governments, the general public, environmental and social pressure groups, NGOs, neighborhood communities, the media, schools and universities. Many actors' "SO mindsets" have an influence on the achievement of the SD goals. For that reason, SO collaboration and the application of the "pattern of SO collaboration" are needed. These are simultaneously the three stages in embedding sustainability in the SC and the three stages on the pathway from SO actors in the SC to the SSC. In phase one, the introduction of sustainability in the SC is understood and accepted. In the second phase of embedding sustainability in the SC, for a more significant acceptance of sustainability in the SC as many SO actors as possible need to be engaged towards achieving sustainable behavior, amongst them – end consumers in particular. Ultimately, in the third phase, in order to achieve SD goals, the majority of actors need to be SO and behave in a sustainable manner, so that the "pattern of SO collaboration" is in focus.

Conclusion

According to the SO collaboration paradigm, all actors and all stakeholders act in a collaborative partnership for the purpose of achieving SD goals. The SO-SC is a result of a complementary action of numerous actors' sustainable behavior. Embedding sustainability in the lifestyle of end consumers is the basis of end-consumer sustainability. Embedding sustainability in the SC of firms as buyers (B2B) is one part of the holistic perspective of corporate sustainability. Embedding sustainability in actors' behavior is one part of the holistic perspective of the SD. SO actors in the SC influence the sustainability of individuals, companies and countries. Actors' sustainable behavior and collaborative partnership lead "to achieving SD in its three dimensions – economic, social and environmental – in a balanced and integrated manner" (UN, 215, p. 3).

The contributions of this paper are as follows:

- placing an emphasis on the co-creating of SO value in the SC,
- the presentation of the co-creators of SO value in the SC,
- the presentation of the SO behavior of all actors in the SC for the purpose of achieving SD goals,
- the SO-SC as a result of the complementary action of the sustainable behavior of numerous actors,
- placing an emphasis on the power of SO consumers as the co-creators of SO value - the impact of consumer behavior and the consumers' SO lifestyle on the SO behavior of all actors in the SC,
- the presentation of the three patterns of embedding sustainability in the SC,

- the presentation of the three stages of the transformation of the SC into the SO-SC,
- the presentation and analysis of the conceptual framework: the collaborative partnership paradigm in the SO-SC as a way to sustainability.

Our proposed framework (*Fig. 1*) require empirical validation. Those could be the bases for future research. The research questions could be:

- Are stakeholders in the supply chain aware of the fact that they are the co-authors of values?
- Can stakeholders from the macro-environment influence the SO behaviour of consumers and other actors in the micro-environment?
- Can the focal firm influence the behaviour of other actors in the supply chain?
- Are consumer behaviour and the consumer lifestyle the basis of sustainability?
- Does SO consumer behaviour influence the SO behaviour of other actors in the supply chain?
- Are consumers aware of their having the power and of the fact that, by purchasing products/services, they can affect the survival of companies? Are consumers aware of the fact that their responsible behaviour can affect the responsible behaviour of companies and of all other stakeholders?
- Can sustainability marketing influence the behaviour of actors?
- Is viral marketing an opportunity or threat for actors in the supply chain in today's digital world?
- What and how can the co-creators of value in the supply chain do for sustainable development and sustainability?

The conclusion is that consumers are the most important co-creators of values. The trends in the field, such as digitalization and the orientation towards sustainable development, will affect consumers in such a manner as to make them understand the power they have as the initiators of the co-creation of SO value. Other stakeholders, especially firms, should realize that the sources of a competitive advantage today are: the speed, digitalization and the co-creation of SO value. The conceptual framework – the collaborative partnership paradigm in the SO-SC could be a way to sustainability.

(Received 14th Oct 2017; accepted 3rd Apr 2018)

Abstract. Silicon carbide (SiC) nanoparticles are widely used in industrial applications; however, some reports indicate they are safe while others claim the opposite. We aimed to characterize the physicochemical properties of SiC nanoparticles and investigate their impact on the multicellular animal model, *Caenorhabditis elegans* and the plant parasitic nematode *Meloidogyne incognita*. The X-ray diffractogram patterns and chemical analyses confirmed that the content is SiC. Furthermore, N_2 sorption isotherm analyses revealed that Brunauer–Emmett–Teller (BET) surface area was 37.6 m^2/g and single point adsorption total pores volume of pores less than 126.1853 nm in diameter at p/p° = 0.984417366 was 0.124975 cm^3/g. Furthermore, adsorption average pore width was 13.26382 nm. Scanning electron microscopy showed that the SiC nanoparticles have a semi-crystalline shape with uncompleted faces. Some edges are angular whereas others are curved and smooth with an average particle size of 50 nm ± 21.5. The bioassays indicated that SiC nanoparticles did not affect hatching of larvae of both nematodes, whereas they affected dramatically the survival of the first stage larvae (L1) of *C. elegans,* but not the second stage juveniles J_2s of *M. incognita*. There was no effect of SiC on length and width of the dead L1; however, internal organs, particularly the intestine, exhibited black color indicating uptake of the SiC nanoparticles.
Keywords: *physicochemical properties, toxicity, electron microscopy, X-ray*

Introduction

Silicon carbide (SiC), also known as carborundum, is a hard, covalently bonded material produced by the carbothermal reduction of silica using the Acheson process (Acheson, 1895). Approximately 200 SiC poly-types exist due to its periodic stacking in alternate layer arrangements (Sudarshan, 2004). SiC nanoparticles appear in the form of a grayish white powder and cubic morphology with a melting point of 2730 °C with numerous industrial applications. Thus, SiC nanoparticles research is an area of intense scientific interest (Mahawish et al., 2017; Attalla et al., 2018).

SiC nanoparticles hardness, good wear, corrosion resistance, low density and price make them suitable for multiple industries. Initially utilized for grinding and cutting purposes (Cowles and Cowles, 1885; Acheson, 1895). SiC later appeared in ceramic plates, bullet proof vests, glass casting and high performance "ceramic" automobile brake

© 2018, ALÖKI Kft., Budapest, Hungary

discs (Kaufmann et al., 2003; Langhof et al., 2016). Further industrial applications include rubber tire manufacturing, resistance heating element manufacture, and UV protective mirror coatings. SiC nanoparticles are also now used in the copper matrix nanocomposite (Zhang et al., 2004; Ataee-Esfahani et al., 2009; Mula et al., 2011; Zhu et al., 2011).

SiC nanoparticles widespread use including biomedical industry, necessitates an in-depth investigation of their eco-toxicity. To our knowledge, few studies investigated the toxicity of SiC nanoparticles in the environment; however, several studies focused on the potential health impacts. Several studies report that SiC nanoparticles are an inert and do not harm lung tissues (Bruch et al., 1993a, b); however, research also suggests that SiC may have significant cytotoxic and genotoxic effects (Vaughan et al., 1993; Cullen et al., 1997; Akiyama et al., 2007). Vaughan et al. (1993) showed that SiC was toxic for rats and showed chronic inflammation in necropsies during the study. Another study also found that SiC accumulates in rat's lungs over the course of a year (Cullen et al., 1997). These findings necessitate further research to determine the toxicity of SiC to human health, and the potential implications on the environment.

Toxicity depends on the physicochemical characteristics such as particles' size, curvature, shape and surface characteristics charge, functional groups, and free energy (Pourchez et al., 2012). Based on this characterization, some particles generate adverse biological outcomes by causing proteins to unfold, thus resulting in a loss of enzymatic activity. Another pattern is the release of toxic ions in a suspending medium or biological environment (Xia et al., 2008). Thus, several reports have recommended the reevaluation of SiC nanoparticles use (Barillet et al., 2010a, b; Pourchez et al., 2012).

Nematodes as soil organisms were used to evaluate nanoparticles' toxicity (Ma et al., 2009; Cromwell et al., 2014). Nematodes are prevalent and highly distributed in almost every ecological habitat (Hodda, 2011). Some are restricted to a specific geographical environmental condition while others are ubiquitous (Hodda, 2011). The bacterial feeding nematode *Caenorhabditis elegans* is a well-known multicellular model organism and is used extensively in toxicity assessment studies (Ma et al., 2009; Hunt, 2017). *Meloidogyne incognita*, a plant parasitic nematode belonging to the root knot nematodes family (RKN), was also challenged with several nanoparticles, such as silver, titanium, and silicon nanoparticles (Ardakani, 2013; Cromwell et al., 2014). The response of *M. incognita* to the three nanoparticles was recorded in laboratory and pot experiments to assess toxicity (Ardakani, 2013). Results showed that RKN J_2s were highly sensitive to silver nanoparticles while they were less sensitive to titanium and silicon nanoparticles in laboratory. It was also shown that 0.02% (W/W) of silver and titanium nanoparticles totally controlled RKN in pots.

So far, data are missing regarding the effect of SiC on soil nematodes and physicochemical characteristics which are factors determining the nanoparticle´s toxicity. Therefore, the aim of this study is to characterize the physicochemical properties of SiC nanoparticles and investigate their impact on hatching, mortality and morphology of the nematodes *Caenorhabditis elegans* and *Meloidogyne incognita*.

Materials and methods

Characterization of SiC nanoparticles

Synthetic SiC nanoparticles were obtained from Hefei Ev Nano Technology Company (China). Stock concentration of SiC nanoparticles suspensions were prepared (250 mg/l) in sterile, de-ionized water. In order to obtain stable nanoparticles suspension, an

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26512662
© 2018, ALÖKI Kft., Budapest, Hungary

ultrasonic processor (UP 200S, Germany) was used to disperse the nanoparticles. In addition, carboxyl methyl cellulose (CMC, BDH chemicals Ltd Poole England) was added (1% CMC by weight) for dispersion and stabilization of suspension. The acidity (pH) and salinity (measured as electrical conductivity (EC)) were measured for the two concentrations. A half strength concentration was prepared from the stock solution to obtain a suspension of 125 mg SiC nanoparticles/l with 0.5% CMC. The two concentrations (250 and 125 mg/l) were then used in bioassays.

Chemical and physical properties of SiC nanoparticles were characterized. X-ray powder diffraction (XRD) patterns were recorded using Cu Kα radiation source by Shimadzu X-ray diffractometer (XRD–6000). The chemical composition of the nanoparticles powder was determined by X-ray fluorescence (XRF) analysis measurements using a sequential X-ray spectrometer (Shimadzu XRF-1800). Nanoparticle surface area and pore size distribution were calculated based on nitrogen adsorption method using Micromeritics' Gemini® VII 2390 Series of surface area and porosity analyzers. SiC nanoparticle morphology was investigated using a Scanning Electron Microscope (SEM) from FEI company- Inspect F50/FEG (Schottky Field Gun) high Vacuum (6e-4 Pa Everhart-Thornley SE detector Solid-State BSED, Netherlands).

Nematode cultures

Caenorhabditis elegans

The wild type of *C. elegans*, used in this work, was obtained from the *Caenorhabditis* Genetics Centre (University of Minnesota). The nematodes were cultured on nematode growth medium (NGM) which consists of 20 g/l agar, 2.5 g/l peptone, 5 mg/l cholesterol, 25 mM KPO_4 (KH_2PO_4 and K_2HPO_4) buffer, 51 mM NaCl and 1 mM $MgSO_4$. A loopful of the bacteria *E. coli* strain OP50, obtained from the *Caenorhabditis* Genetics Centre, was added to the medium as a source of food for the nematode. The bacterial isolate was maintained on Luria-Bertani (LB) medium (5 g /l of yeast extract, 10 g /l of tryptone, and 10 g /l NaCl). The *C. elegans* culture was maintained periodically and incubated at 24 °C.

To obtain the synchronized eggs or first stage larvae (L1) for bioassays, the nematodes, including the females and the eggs, were washed off the NGM plates with sterile water and placed in a beaker. The nematode suspension was poured on 2 ml eppendorf tubes with a total volume of 1 ml. Each 1 ml of nematode suspension was lysed by adding 120 µl of 5 N sodium hydroxide (NaOH) and 120 µl of 6.5% sodium hypochlorite (NaOCl). This procedure hydrolyzes the adult and juvenile nematodes, but not the eggs. The tubes were vortexed every 30 s for 5 min. After that the tubes were centrifuged at 6000 rpm for 1 min, supernatant was decanted and the pellets containing the eggs were suspended in 1 ml sterile water. Tubes were vortexed and centrifuged again to clean the eggs from remaining NaOH and NaOCl mixture. The eggs suspension in water was collected and used immediately in the hatching bioassays or eggs were incubated at 24 °C for 8 h until L1 hatched and then were used in the toxicity bioassays.

Meloidogyne incognita

The egg masses and second stage juveniles (J_2s) of the plant parasitic nematode *M. incognita* were used in this assay. The egg masses of *M. incognita* in the hatching assay were handpicked from the roots of infected tomato plants grown in the glass house at the University of Jordan, Amman, Jordan. Egg masses were either directly exposed to the SiC nanoparticles in the hatching bioassay or were incubated in water at 24 °C until the J_2s

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26512662
© 2018, ALÖKI Kft., Budapest, Hungary

were hatched. The newly hatched J_2s were subjected to the SiC nanoparticles to assess the nematode survival rate.

Nanoparticles suspension

Eggs or larvae of *C. elegans* were exposed to 1 ml of SiC nanoparticle suspensions (688 µl of either SiC nanoparticles concentrations suspended in CMC, 62 µl 0.5 M KCl, 100 µl 0.5 M NaCl, and 150 µl of sterile water contained eggs or larvae). Egg masses and J_2s of *M. incognita* were exposed to 5 ml of either concentrations (3440 µl of either concentration of the nanoparticles suspended in CMC, 310 µl 0.5 M KCl, 500 µl 0.5 M NaCl, and 750 µl of sterile water contained egg masses or J_2s). All bioassays had two final concentrations of SiC nanoparticles, 86 and 172 mg/l. The nanoparticles were vortexed and sonicated for 15 min before the application to prevent the agglomeration of the particles.

Effect of SiC nanoparticles on L1 hatching of C. elegans

Approximately 400 eggs were exposed to the nanoparticles suspensions in a 24-well tissue culture plate. The 0.5% CMC, 1% CMC and water served as controls. Every treatment was replicated three times. Plates were incubated for 24 h at 24 °C. The treated eggs were checked for L1 hatching after 24 h using a dissecting light microscope (Nikon, SMZ645) and the percentages of hatching were calculated and tabulated.

Effect of SiC nanoparticles on L1 survival of C. elegans

In this bioassay, two concentrations of SiC nanoparticles were used: 86 and 172 mg/l. A total of 50 L1 were exposed to 1 ml volume of the nanoparticles in a 24-well tissue culture plate. Treatments contained 0.5% CMC, 1% CMC and water only served as controls. Every treatment was replicated three times. Plates were incubated for 6 h at 24 °C. Numbers of dead and live L1 were counted 24 and 36 h after treatment using inverted binocular compound microscope (MEIJI TECHNO ML VT-T-PC) and the percentages of mortality were calculated and tabulated. The LC50 value was determined by using the polynomial regression curve.

Observations on dead L1 were documented with photos. Lengths and widths of five L1 from each treatment were measured and tabulated.

Effect of SiC nanoparticles on J_2s hatching of M. incognita

In this bioassay, egg masses were exposed to the two concentrations: 86 and 172 mg/l of SiC nanoparticles. Similar size egg masses were used in all replicates of all treatments. Every treatment consisted of three egg masses and was replicated three times. 0.5, 1% CMC and water served as controls. Plates (with a total of 5 ml of SiC nanoparticles) were incubated for seven days at 24 °C. The treated egg masses were checked for J_2s hatching after 2, 4 and 7 days of treatment using a dissecting light microscope (Nikon, SMZ645) and the number of hatched J_2s after 2, 4, and 7 days were calculated and tabulated.

Effect of SiC nanoparticles on J_2s survival of the M. incognita

Approximately 50 J_2s of *M. incognita* were treated with concentrations of 86 and 172 mg/l of SiC nanoparticles. The 0.5% CMC, 1% CMC and water served as controls. Every treatment was replicated three times. Plates (with 5 ml each) were incubated for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26512662
© 2018, ALÖKI Kft., Budapest, Hungary

four days at 24 °C. The numbers of dead and live nematodes were counted using a dissecting light microscope (Nikon, SMZ645) for four consecutive days and the mortality rates were tabulated.

Data analyses

Data obtained from all bioassays were subjected to analysis of variance and the means were separated using least significant differences (LSD) (Little and Hills., 1974).

Results

Characterization of SiC nanoparticles

The X-ray diffractogram patterns revealed that the mineral content is Silicon Carbide (SiC) (*Fig. 1*). The major peak was at 2 Θ = 35.68°, 41.42°, 60.01°, and 71.77°. The chemical analyses confirmed that 99.2 wt % of the nano-powder was SiC (*Fig. 2*). The pH and the electrical conductivity (EC) of the stock solution (250 mg/l) was 7.8 and 50 µS/cm respectively. N_2 sorption isotherm analyses showed that BET surface area was 37.6 m²/g and single point adsorption total pore volume of pores less than 126.1853 nm diameter at p/p° = 0.984417366 was 0.124975 cm³/g. Furthermore, adsorption average pore width was 13.26382 nm.

SiC nanoparticle morphology was investigated using scanning electron microscopy (SEM). *Figure 2* shows that the morphology of the SiC nanoparticles has a semi-crystalline shape with incomplete faces. Some edges are angular whereas the others are curved and smooth. The average particle size is 50 nm ± 21.5.

Effect of SCi nanoparticles on the nematode C. elegans L1 hatching and survival

To investigate the effect of SiC on *C. elegans* viability and survival, we exposed the nematode eggs and L1 to 86 and 172 mg/l of the nanoparticles. Results showed that percentage of hatched L1 was significantly higher when eggs were exposed to SiC nanoparticles compared with controls (*Table 1*).

Treatment	Hatching* %	Mortality** %	
		Exposure time	
		24 h	36 h
SiC nanoparticles 172 mg/l	97.5 a ± 0.47	19.3 a ± 1.6	69.6 a ± 5.3
SiC nanoparticles 86 mg /l	98.0 a ± 0.32	17.2 a ± 2.8	66.4 a ± 8.7
CMC 1% and salts	94.0 b ± 1.31	3.5 b ±1.2	17.7 b ± 1.5
CMC 0.5% and salts	94.0 b ± 1.93	2.1 b ± 1.0	15.2 b ± 4.8
Water only	95.0 b ± 1.17	2.6 b ± 2.4	9.6 b ± 3.9

*The data points represent the means of the three replicates followed by ± standard deviation, approximately 400 eggs per replicate. Means with the same letter are not significantly different at 0.05 *P* level

**The data points represent the means of the three replicates, approximately 50 L1 per replicate. Means with the same letter are not significantly different at 0.05 *P* level

Exposure of L1 individuals to SiC nanoparticles for 24 h resulted in a significant ($P < 0.05$) increase in mortality compared to control treatments. Around 17 and 19% of L1 died in SiC nanoparticle treatments compared to up to 3.5% L1 mortality in controls (*Table 1*). After 36 h of exposure to both concentrations of SiC nanoparticle, the survival of L1 was dramatically decreased and reached 30% (70% mortality) and 34% (66% mortality) when treated respectively with 172 mg/l and 86 mg/l; however, the percentage of survived L1 in control treatments were 82, 85 and 90 in 1% CMC, 0.5%

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26512662
© 2018, ALÖKI Kft., Budapest, Hungary

CMC and water controls, respectively. In general, there was no significant difference of survived L1 exposed to 172 mg/l compared with those exposed to 86 mg/l SiC nanoparticles after 24 and 36 h of exposure (*Table 1*). Using the regression equation ($y = -4E\text{-}05x^2 + 0.0103x - 2E\text{-}15$, $R^2 = 1$), the value of LC50 was 65 mg/l after 36 h of exposure.

The SiC nanoparticles at both concentrations slightly increased the length and width of L1 compared to salt and water only treatments, but the difference was not significant (*Fig.* 3).

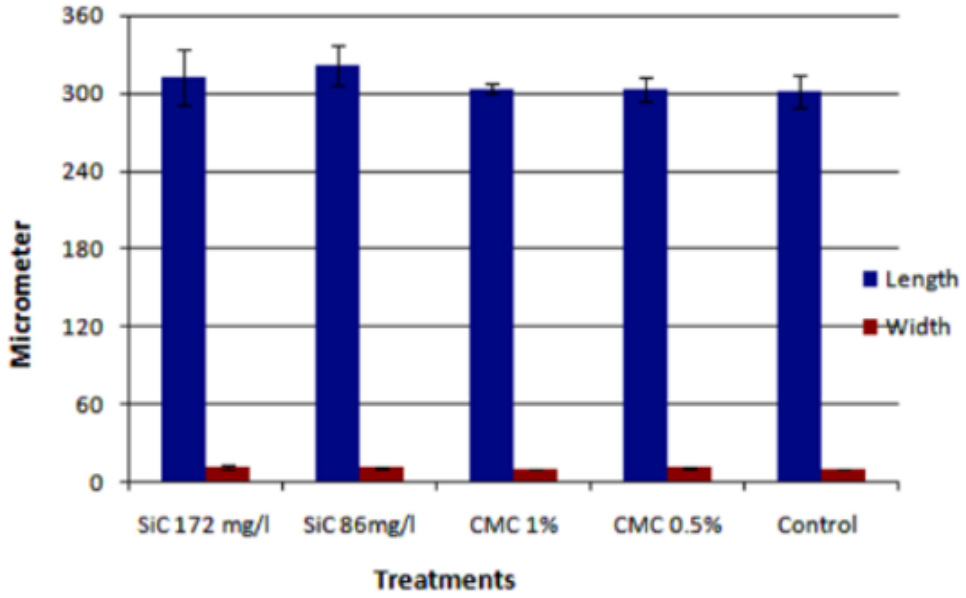

Figure 3. *Effect of SiC on length and width of the soil nematode Caenorhabditis elegans. Length and width of the first stage larvae (L1) of the soil nematode Caenorhabditis elegans after 24 h of exposure to the two concentrations (172 and 86 mg/ l) of silicon carbide nanoparticles and salts (1% and 0.5% CMC) and water controls with E. coli added as a food. The data points and error bars represented the means and standard deviation respectively, of the three replicates, approximately 50 L1 per replicate*

The black color was observed in the internal organs including intestine of the dead L1s that were exposed to the nanoparticles while internal organs were transparent in controls (*Fig. 4*).

Effect of SiC nanoparticles on M. incognita J_2s hatching and survival

To investigate the effect of SiC on J_2s hatching egg masses of *M. incognita* were treated with 86 and 172 mg/l of the nanoparticles. In all treatments hatching of J_2s increased with time. However, treatments with both concentrations of SiC nanoparticles and the two concentrations of CMC salts resulted in higher number of hatched J_2s than those placed in water only at the three monitored times. The use of 86 mg/l SiC nanoparticles caused the highest hatching followed by concentration (172 mg/l) but without significant differences (*Table 2*).

	Exposure for		
	2 days	4 days	7 days
SiC nanoparticles 172 mg/l	41 ± 23.8	76 ±24	205 ± 82.6
SiC nanoparticles 86 mg /l	41 ± 17.2	90 ±35	254 ± 33.1
CMC 1% and salts	48 ± 30.4	71 ± 35.1	192 ± 93.1
CMC 0.5% and salts	62 ± 35.9	106 ± 83.8	185 ± 133.4
Water only	23 ± 3.51	41 ± 1.5	104 ± 10.5

*The data points represented the means of the three replicates followed by ± standard deviation, approximately 3 egg masses per replicate. No significant differences at 0.05 *P* level

Similar to the *C. elegans* L1, the two concentrations of SiC nanoparticles did not decrease the *M. incognita* J_2s survival. The concentration (172 mg/l) of SiC nanoparticles caused a slight reduction in survival of J_2s where it decreased to 93% (7% mortality) after one day of exposure and continued to decrease to reach 92% (8% mortality) after two days and did not change up to four days of exposure. On the other hand, the low concentration (86 mg/l) of SiC nanoparticles did not cause mortality after two days of exposure and caused only 2% mortality on the third day and stayed steady after the fourth day of exposure (*Table 3*). Few J_2s that were placed in water only died after one day of exposure and no change in the number of live nematodes up to the fourth day of treatment. Similar results were noticed on J_2s placed in 0.5% CMC, while a slight decrease was noted in the number of live J_2s treated with 1% CMC (*Table 3*).

Discussion

In this study, we showed the hatchability and the survival of two soil nematodes under the exposure to the SiC nanoparticles. The nematode *C. elegans* was used to test the toxicity of SiC nanoparticles since basic physiological processes and stress responses are conserved between this nematode and humans (Lee et al., 2007; Hunt, 2017). We used the L1 of *C. elegans* since several reports showed that L1 is more sensitive than both L4 and young adult of *C. elegans* to nanoparticles such as Al nanoparticles and others (Wu et al., 2011).

Hatching of juveniles from eggs of both tested nematodes was not affected and in fact number of hatched juveniles was more in eggs exposed to the SiC nanoparticles suspension than the controls. Similarly, a complete oocyte development was observed and this development ends with the hatching of the L1 within the parent's body of *C. elegans* after the exposure to silica nanoparticles (Pluskota et al., 2009). This suggests that SiC and other nanoparticles did not penetrate the eggshell of the eggs and thus hatching was not affected.

The bioassay showed that SiC nanoparticles were lethal to L1 of *C. elegans* and dead nematodes exhibited black internal organs, indicating that SiC black nanoparticles were taken up during feeding. This supports results from other studies, which showed that nanoparticles taken by the nematode L1 *C. elegans* during feeding were translocated to primary and secondary organs, including epithelia cells, intestines and reproductive organs (Pluskota et al., 2009; Wu et al., 2011). On the contrary, few J_2s of the plant parasitic nematode *M. incognita* died when they were exposed to SiC nanoparticles and lacked the obvious black color in the intestine. This could be attributed to wider mouth of the L1 of *C. elegans,* which allowed for a larger amount of the SiC nanoparticles to be taken up during feeding. Additionally, the root knot nematodes, *Meloidogyne* spp. are obligate sedentary endoparasites and the J_2s do not feed when they are found in the soil or in a solution, thus, the uptake of nanoparticles mechanism by these plant parasites should be investigated. We believe that the lethality of the nanoparticles is not due to pH since nematodes have a wide pH tolerance that ranged from 3 to 12 (Khanna et al., 1997).

This study showed that the SiC nanoparticles of the size of 50 nm with LC50 of 65 mg/l did not affect hatching of either nematode but did affect the survival of *C. elegans*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26512662
© 2018, ALÖKI Kft., Budapest, Hungary

Several reports showed that smaller sizes of nanoparticles are more toxic than larger ones (Khare et al., 2011; Park et al., 2011). It was also shown that silver nanoparticles of a size of 20 nm were more toxic than the larger nanoparticles (80 and 113 nm) (Park et al., 2011). Similarly, TiO_2 and ZnO nanoparticles less than 25 nm were toxic to the nematode *C. elegans* with LC50 of 77 mg/l and 0.32 mg/l, respectively (Khare et al., 2011). Whereas TiO_2 nanoparticles with a size larger than 25 nm were non-toxic and LC50 of 2 mg/l was recorded for < 100 nm ZnO nanoparticles. This might explain the contradictory reports that on SiC nanoparticles' toxicity. However, other characteristics of nanoparticles may affect toxicity and therefore more investigations are needed regarding the comparison of sizes as well as other characteristics.

Conclusion

The physicochemical characterized SiC nanoparticles showed a toxic effect on L1 of the multicellular animal, the soil nematode *C. elegans,* and reduced its survival. The dead L1s that were exposed to either 86 or 172 mg/l of SiC nanoparticles exhibited black internals. In contrast, the two studied concentrations of SiC nanoparticles did not have such an effect on the second stage juveniles J_2s of the plant parasitic nematode *M. incognita*. However, these SiC nanoparticles did not have an effect on the eggs of either nematodes, and instead accelerated hatching. Future work should focus on the physical and chemical characteristics of SiC nanoparticles' toxicity. Additionally, more histological and biochemical studies are needed to assess the mechanism of toxicity.

Acknowledgements. Authors are thankful to *Caenorhabditis* Genetics Centre (University of Minnesota) for affording the *C. elegans* wild type which was used in this study. Authors are also thankful to Hamdi Mango Center for Scientific Research / The University of Jordan for funding this work and thankful to Mrs Sarah Barnhart for critically reading and editing the manuscript.

(Received 14th Jan 2018; accepted 16th Apr 2018)

Abstract. Climate change causes major shifts in both the spatial distribution of wine-growing areas and their specific types of wine production. With the increase of heliothermal resources, the viticultural potential of temperate wine regions grows, becoming more suitable for quality wine production and for the diversification of the wine types production. The shifts in the viticultural potential of the Averești wine-growing region from Romania during the last decades are evidence of these evolutions. Between 1961-2013, the average annual temperature in the area increased by 0.47 °C, the temperature of July by 1.26 °C, the sunshine duration by 78.6 h and the global radiation by 1.69 kcal/cm^2. Against this background, the area passed from viticultural potential mainly for white table wines to viticultural potential for quality white wines and red table wines. The new viticultural potential is exploited in the Averesti wine-growing region after 2000 by expanding into culture the international winegrape varieties for quality white wines and by introducing the *Cabernet Sauvignon, Merlot* and *Pinot noir* winegrape varieties for red wines into cultivation. The study demonstrates the need to evaluate the new viticultural potential generated by climate change and the need to delineate the viticultural homogeneous zones in the wine-growing regions beneficiary of climate change, in order to correctly zone newly introduced winegrape varieties in such areas.
Keywords: *grapevine, viticulture, Averești, wine, suitability*

Introduction

The specific varieties of wine-growing regions have been established throughout the time by maintaining in their area the winegrape varieties best suited to local relief, climate and soil conditions. These environmental factors have a decisive influence on grapevine growing and fruiting (van Leeuwen and Seguin, 2006; Winkler et al., 1974). In relation to the influence of the climate, winegrape varieties whose grapes reach full ripening each year and which best express their quality potential have been maintained (Seguin, 1986). As a result, today each wine-growing region has its own specific winegrape varieties best adapted to the local environment and which provide the most qualitative wines that can be obtained in the area (Wolkovich et al., 2018).

Due to this close dependence of winegrape varieties on the climate, one of the consequences of climate change (IPCC, 2013) might be their modification and implicitly, the one of the types of wine production specific to affected wine-growing regions. The first predictions in this regard have been made since the 1990s by Kenny and Harrison (1992), and confirmations of this evolution appear more and more

frequent in recent years (Stock et al., 2005; Bucur and Dejeu, 2016; Irimia et al., 2017b). The modification of wine-growing regions' specific winegrape varieties is, in fact, an adaptation of wine-growing regions to the new climatic context, with particularities from one geographic area to another. For example, in case of the Mediterranean wine-growing regions, where high temperatures already affect the well-established sensory profile of wines (Nemani et al., 2001), it might be necessary to replace local varieties with some more adapted to the warm climate ones (Wolkovich et al., 2018). On the contrary, in cool vineyards where the climate becomes more suitable to viticulture (Gaal et al., 2012; Kryza et al., 2015; Nesbitt et al., 2016; Kovacs et al., 2017; Irimia et al., 2017a) varieties for white table wines, could be replaced by varieties for quality white wines and even by varieties for red wines.

In the context of climate change (Busuioc et al., 2010; Piticar and Ristoiu, 2012; Dumitrescu et al., 2014; Bandoc et al., 2018) recent studies indicate that Romania's viticulture undergoes structural and spatial changes of climatic suitability for viticulture (Bucur and Dejeu, 2016; Irimia et al., 2017a). Climatic suitability for red wines is advancing from S to N, overlapping traditional white wine production areas; climate suitability for white wines is advancing northwards and at higher altitudes, beyond the limits of traditional wine-growing areas. Significant shifts are also recorded in vineyards on a fine scale (Irimia et al., 2017b).

As a result of this evolution of climatic suitability for viticulture, the traditional varieties of vineyards in the northern part of Romania, which is colder, have begun to undergo important changes: In the vineyards of Transylvania, a wine-growing region specialised in white wine production, *Pinot noir, Merlot* and the native *Feteasc*ă *neagr*ă red varieties have recently been introduced (Urcan et al., 2016), while in the vineyards of Moldavia, also producing white wines, *Cabernet Sauvignon, Merlot, Pinot noir* and *Feteasca neagr*ă have been introduced.

The purpose of this study is to reveal the changes in viticultural potential as a result of climate change in the Averești wine-growing region, as well as the changes in its specific winegrape varieties in this context. Previous studies have already revealed the suitability of this area for white wine production (Irimia and Patriche, 2009, 2010). On the background of climatic change, after 2000 winegrape varieties such as *Cabernet Sauvignon, Merlot, Pinot noir* and *Feteasca neagr*ă were introduced in the area. For the accumulation of anthocyanins and the production of quality wines, winegrape varieties for red wine require high heliothermal resources (Dokoozlian and Kliewer, 1996). The location of the new red winegrape varieties in the Averești area was not based on a zoning study, which is why this study aims to evaluate the accuracy of their zoning. Inadequate location of a winegrape variety in a vineyard limits the expression of its qualitative potential and produces ordinary wines (Asselin et al., 2001; Riou et al., 1994).

Assessment of the viticultural potential is based on the analysis of the spatial distribution and suitability for the winegrape varieties of the climate, relief and soil factors (Jones and Duff, 2007; Tomasi et al., 2013; Irimia et al., 2014; Nowlin and Bunch, 2016). Studies based on bioclimatic indices (Blanco-Ward et al., 2017; Quenol et al., 2017), soil and lithological parameters (Morlat and Bodin, 2006) and their combined influence (Jacquet and Morlat, 1997) are also used. This study uses the GIS-based methodology for assessing the viticultural potential in temperate climate conditions of Romania (Irimia et al., 2014), which takes into account the fine-scale

© 2018, ALÖKI Kft., Budapest, Hungary

spatial distribution and the suitability for winegrape growing of 15 parameters representative for vineyards' relief, soil and climate.

The study is designed in four parts, namely: the structure and suitability of the relief, soils and climate in the area; the viticultural potential and the specific winegrape varieties during 1961-1979; the viticultural potential of the 1981-2013 period and the current winegrape varieties; the analysis of the current location of winegrape varieties in the area.

Materials and methods

Study area

The study area is the Avereşti wine-growing region, located in the eastern part of Romania, at 46°46'50" N latitude and 28°0'37" E longitudes (*Fig. 1*).

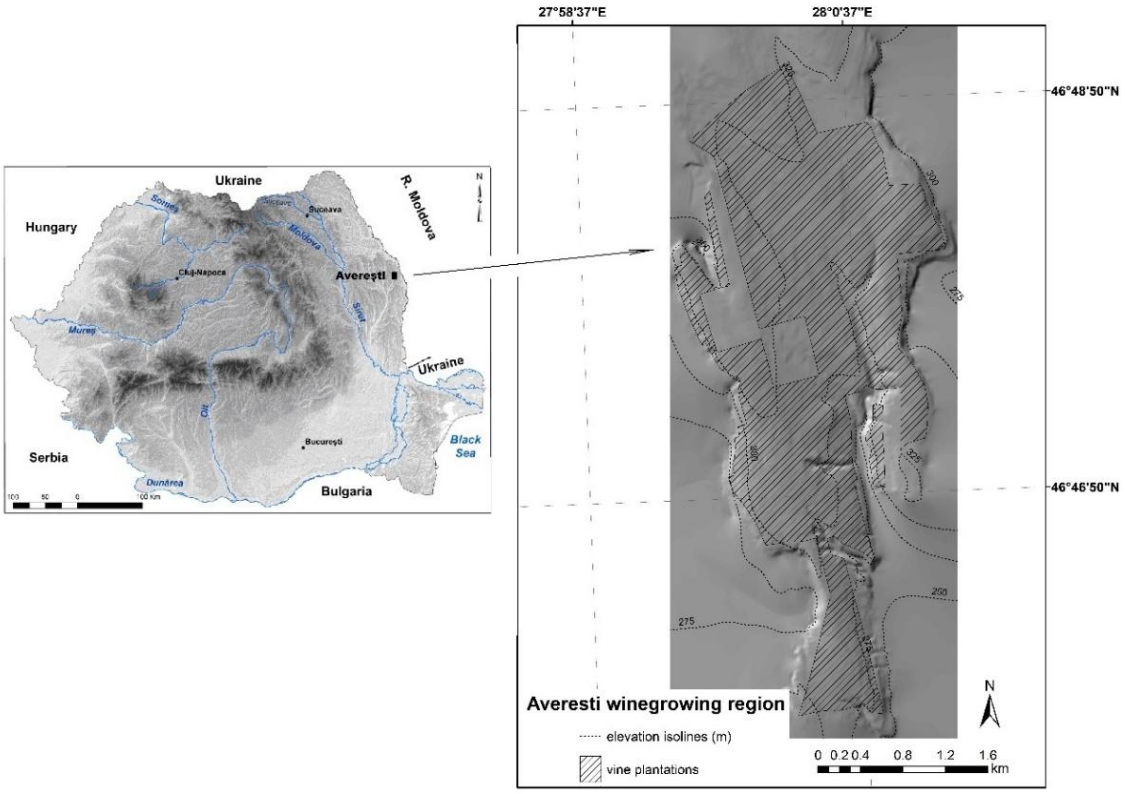

Figure 1. *The map of the Avereşti wine-growing region and its geographical location*

The area has a surface of about 670 ha and it is a compact massive vineyard, situated on a long interfluvial plateau, bordered by river valleys in the east and west and having a slope which causes a difference of about 80 m between the northern (338 m asl elevation) and the southern limit (257 m asl). The area has a temperate continental climate, Dfb in the Koppen-Geiger climate classification (Kottek et al., 2006), with warm and sometimes dry summers, and harsh and sometimes frosty winters. Soils are predominantly represented by Luvisols, with a higher content of clay and humus in the plateau area and thinner, poorly fertile and well drained on east and west slopes.

Methods

The climate data used for this study were extracted from ROCADA database (Dumitrescu and Bîrsan, 2015) for one point situated in the middle of the vineyard (46°47'94" N latitude, 28°0' 21.6" E longitude, 303.59 m asl). For this location, we extracted daily values of climate parameters, including the mean, maximum and minimum temperatures, precipitations, sunshine duration and relative humidity. The values were exported in Excel for quality check and processing. The spatialization of these punctual data was achieved in GIS environment, starting from a 5 × 5 m digital elevation model (DEM) and vertical temperature and precipitation gradients (Patriche et al., 2011). The DEM was computed with high accuracy, on the basis of the elevation information extracted from 1:5000 topographic maps. The mean annual and monthly vertical gradients for temperature and precipitations were derived from WorldClim database (Hijmans et al., 2005) and SRTM elevation model for the entire Romanian territory.

The potential solar radiation and sunshine duration maps were computed in SAGA-GIS 2.0.8, using the Incoming Solar Radiation module and DEM as input raster. A correction was then applied to the potential global radiation (Entekhabi, 1997), based on the sunshine fraction, in order to achieve the actual global radiation. The actual sunshine duration was derived by multiplying the potential sunshine duration and the sunshine fraction.

The bioclimatic indices were achieved in GIS environment by applying the specific formulas (Irimia et al., 2014).

The terrain slope and aspect were derived based on DEM, and the respective rasters were classified according to the methodology.

For soil cover characterization, we used the data from 11 soil profiles taken from a fine scale agrochemical study of Averești vineyard. The clay content was interpolated by ordinary kriging, while in the case of humus content a spline interpolation was performed. Then, the spatial distributions and clay and humus contents were classified according to the methodology. The analysed soils from Averești vineyard had no skeleton content in the first 50 cm.

The viticultural potential of the area was assessed using Irimia et al. (2014) methodology for viticultural potential assessment in Romanian wine-growing regions conditions. According to this method, the averages of 15 climatic, pedological and topographical parameters for the Averești area for two time periods (1961-1979 and 1980-2013) were mapped and then classified into three suitability classes, ranked from 5 to 10 points (*Table 1*). What is more, the values within the range defined by each suitability class determine and characterize under the temperate continental climate of Romania, a certain type of wine production (Irimia et al., 2014). The choice of the two periods is based on a previous study (Irimia et al., 2017b), which points out that the warming process began consistently in the 1980's for the neighbouring wine-growing region of Cotnari (Romania). Also, the charts made up at Global and European level (EEA, 2017) show that the beginning of abrupt temperature change occurred during the same time period.

The spatial information layers for each ecological category and for each time period were further combined into a GIS database, and the average ranking points (arp) at the pixel level (5 × 5 m) were calculated in order to obtain topographical, pedological and climate suitabilities. The three maps of suitability for each time period were further combined into a GIS database, and the average of ranking points at the pixel level (5 × 5

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26632680
© 2018, ALÖKI Kft., Budapest, Hungary

m) was calculated in order to obtain the viticultural potential. According to this methodology, the averages of ranking points have the following meanings (*Table 2*): 5 arp = viticultural potential for white table wines, sparkling wines and wines for distillates (WTW, SW, WD); 6 arp = viticultural potential for white table wines, sparkling wines, wines for distillates as well as for white quality wines in warmer growing seasons (WTW, SW, WD + QWW); 7 arp = viticultural potential for quality white wines (QWW); 8 arp = viticultural potential primarily for quality white wines and secondarily for red table wines (QWW + RTW); 9 arp = viticultural potential primarily for quality red wines and secondarily for quality white wines (QRW + QWW); 10 arp = viticultural potential for quality red wines (QRW). The 10 arp and 9 arp were grouped into class I – QRW; 8 arp and 7 arp into class II – QWW; 6 arp and 5 arp into class III - WTW, SW, WD; and the pixels where restrictive values appeared were classified as class IV, as unsuitable for wine production (*Table 2*).

Table 1. *Ecological factors and bioclimatic indices ranked according to their suitability for different types of wine production in temperate continental climatic conditions of Romanian wine-growing regions (according to Irimia et al., 2014)*

Ecological category	Parameters (abbreviation*, units)	Suitability interval within Romanian winegrowing regions	Unsuitable	Suitability classes/ranking points		
			IV/0	III/5	II/8	I/10
			Restrictive for grapevine growing	Type of wine production**

Table 2. *Characterizing viticultural potential according to the average of ranking points (arp) (Irimia et al., 2014)*

Class	Average of ranking points (arp)	Viticultural potential of the area
I	10	Viticultural potential for quality red wines (QRW)
	9	Viticultural potential primarily for quality red wines and secondarily for quality white wines (QRW + QWW)
II	8	Viticultural potential primarily for quality white wines and secondarily for red table wines (QWW + RTW)
	7	Viticultural potential for quality white wines (QWW)
III	6	Viticultural potential for white table wines, sparkling wines, and wines for distillates, as well as for quality white wines in very suitable years, in terms of climate (WTW, SW, WD + QWW)
	5	Viticultural potential for white table wines, sparkling wines, and wines for distillates (WTW, SW, WD)
IV	0	Unsuitable for grape growing (UNS)

The accuracy of the current winegrape varieties zoning was carried out by comparative analysis of the red varieties plots location with the viticultural potential of the area in which they are situated. In the case of red winegrape varieties, we assed the framing of their plots into areas with viticultural potential for RTW; and in the case of white wine varieties, we assed their framing into areas suitable for QWW and RTW.

Results

Structure and suitability of topography, soils and climate of the studied area

The Avereşti winegrowing region is situated in a hilly area with an important variation of the slope and of terrain aspect (*Fig. 2*). The slope varies between 0 and 45%, with a predominance of < 8% on about 80% of the area (*Fig. 2a*), while the terrain aspect is represented by all types, from those unsuitable for grapevine growing such as the northern ones to the very suitable ones like south (*Fig. 2b*). However, the eastern terrain aspect is predominant in the area by 38.6%, followed by northeastern by 11.2% and by southern and southeastern by about 9%.

Spatial variation of the slope and of the terrain aspect make the Avereşti area present all topographical suitability classes for wine production, were classes III and II are predominant (*Fig. 3* and *Table 3*): class III, suitable for WTW, SW and WD, characterizes 50% of the area, while class II, suitable for QWW, characterizes 35.6% of the area. 14% of the surface is characterized by class I of topographic suitability (QRW), and by slopes of 8-15% inclination with southern and predominantly southern terrain aspects.

Regarding the pedological suitability, the whole area is characterized by class II, suitable for QWW, of which 66% has an average of 7 arp (QWW), and 34% has an average of 8 arp (QWW + RTW) (*Fig. 3* and *Table 3*). Pedological suitability is given by the low humus content, ranging from 0.14 to 1.99% (class I) for 100% of the area; lack of limestone fragments from soils (class III) on 100% of the surface; and a clay content of 14-29% (class II) for 100% of the area. The low humus content of the soil is a factor that favours grape quality and is not restrictive when it falls below 1.5% because it is corrected by fertilization.

While relief and soils are stable ecological factors that do not cause temporal variations in the quality of wine production, climate is the factor that determines both spatial and temporal variation (Le Roux et al., 2017). In the case of Avereşti wine-growing region, the changes caused by the climate change in climate suitability for wine production between 1961 and 2013 are obvious in the data from *Table 4* and in the maps in *Figure 4*.

Table 4. *Structure of climate suitability for wine production in the Avereşti wine-growing region, for the 1961-1979 and 1980-2013 time periods*

Between 1961 and 1979, 100% of the Avereşti wine-growing region was characterized by climate suitability for WTW, SW, WD and for QWW in the warm growing season (*Table 4*). This reduced climatic suitability is due to low values of heliothermic factors (*Table 5*)*:* AAT of 8.47 °C, below the lower limit for the economical cultivation of wine varieties; Σt_u of 1110 °C, value at the lower limit of suitability for wine production; ASD of 1447 h, sufficient only for the production of white wines; LGS of 172 days, sufficient only for early winegrape varieties; IAOe of 4178 units, sufficient only for the production of white wines.

Climate suitability during the 1980-2013 period is much higher than the one for the 1961-1979 time period (*Table 4*): class III of climate suitability has practically disappeared, currently characterizing only 0.2% of the area; class II has appeared and currently characterizes 99.8% of the surface, of which 64.4% is suitable for QWW and

© 2018, ALÖKI Kft., Budapest, Hungary

35.3% suitable for QWW and RTW, which is an absolutely new type of suitability for this area. This change in suitability is due to the increase in averages of the heliothermic factors, amid a slight decrease in precipitation (*Table 5*): AAT is of 8.94 °C in the recent period, higher by 0.47 °C than the one between 1961-1979; WMT increased by 1.26 °C reaching the value of 20.72 °C today; GR is higher by 1.69 kcal/cm^2; ASD is also higher by 78.6 h; PP are smaller by 14.1 mm; and IAOe is higher by 133 units, the current value of 4311.4 units placing IAOe in the class of suitability for QWW and RTW.

The viticultural potential and the structure of winegrape varieties during 1961-1979

The results of the research reveal the existence of three viticultural homogeneous zones in the area, characterized by 6, 7 and 8 arp, but whose surface and share in the area radically changed between the 1961 and 2013 as a result of climate change (*Table 6*).

Between 1961-1979, Avereşti wine-growing region provided mainly WTW, SW, WD and QWW, its viticultural potential having the following structure (*Table 6*)*:* 0.03% of the area was characterized by a mean of 5 arp, the viticultural potential for WTW, SW, WD; 72.3% of the area was characterized by an average of 6 arp, the viticultural potential for WTW, SW, WD and QWW in warm years; 26.3% of the area was characterized by an average of 7 arp, the viticultural potential for QWW; 1.4% of the area was characterized by an average of 8 arp, the viticutural potential for QWW and RTW. The viticultural potential for QWW and RTW characterized the slopes with western aspects, while the viticultural potential for WTW, SW, WD characterized the plateau area (*Fig. 5a*).

The winegrape varieties for the 1961 to 1979 were the ones selected in time by the cultivation of the best adapted varieties. 100% was represented by varieties for white wines: *Fetească albă* (FA), *Fetească regală* (FR), *Zghihară de Huşi* (Z), *Aligoté* (AL). Due to the viticultural potential for mainly white wines, the winegrape varieties were well located, with ones for quality white wine such as *Feteasca albă* and *Feteasca regală* which were grown on slope areas with QWW potential, and productive ones, such as *Zghihară de Huşi* and *Aligoté* which were grown in areas with viticultural potential for WTW, SW, WD (*Fig. 5b*).

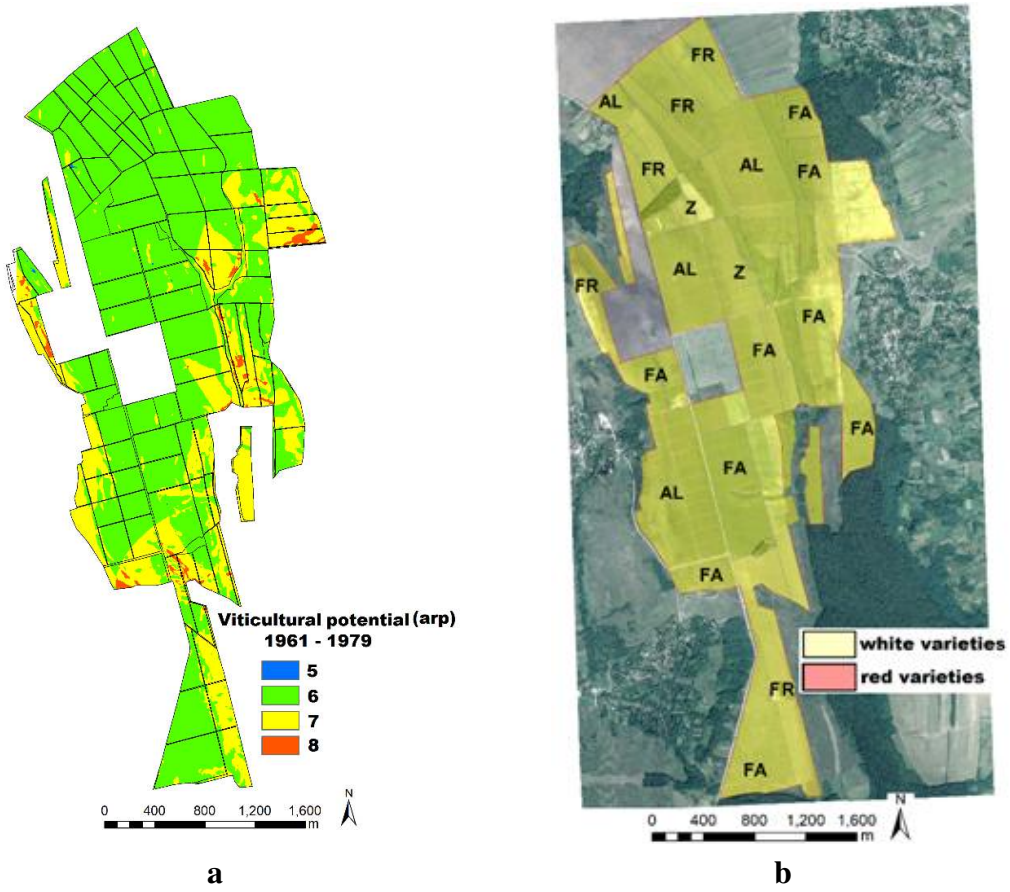

Figure 5. *Viticultural potential (a) and winegrape varieties (b) of the Avereşti wine-growing region between 1961 and 1979*

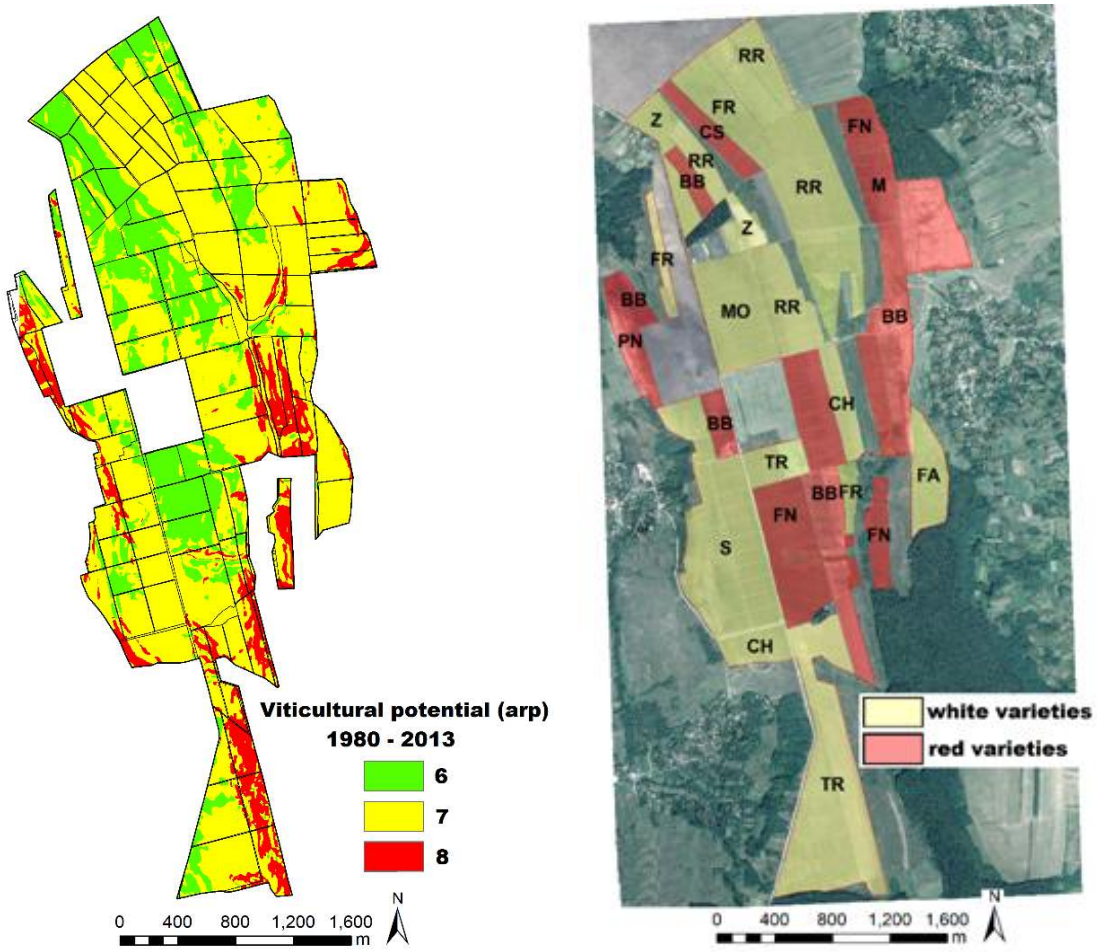

The viticultural potential between the 1980-2013 and the current structure of the winegrape varieties grown within the area

According to the data presented in *Table 6,* the current structure of the viticultural potential of the area is radically different from that of the 1961-1979: the viticultural potential characterized by 5 arp disappeared; the viticultural potential characterized by WTW, SW, WD and QWW in warm years, declined from 72.3% to 24.1%; the viticultural potential with an average of 7 arp increased from 26.3% to 65.5%; and the viticultural potential with an average of 8 arp extended from 1.4% to 10.5%. Basically, after 1980, the wine-growing region became suitable for the QWW and RTW production, unlike the previous period when it was particularly suitable for the WTW, SW and WD production. This new type of viticultural potential, the potential for RTW, characterizes the slopes with western and eastern terrain aspects, where the potential for QWW prevailed in the previous time period, while today's plateau areas, formerly characterized by the WTW, SW and WD potential, have viticultural potential for QWW (*Fig. 6a*).

The current winegrape varieties of the area, grown after the year 2000, are represented mainly by the international varieties for quality white wines such as *Sauvignon* (S), *Chardonnay* (CH), *Muscat Ottonel* (MO), to which Romanian varieties like *Tămâioasa românească* (TR), *Feteasca albă* (FA) and *Fetească regală* (FR) are

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

added (*Fig. 6b*). For red wines, *Cabernet Sauvignon* (CS), *Merlot* (M), *Pinot noir* (PN) and Romanian variety *Feteasc*ă *neagr*ă (FN) were introduced in the area for the first time (*Fig. 6b*). In order to capitalize on the new viticultural potential, the *Busuioaca de Bohotin* (BB) variety, of Mediterranean origin (from the *Muscat* group), which requires high heliothermal resources and produces aromatic red wines, was also introduced into area. Still, as an anticipated adaptation to climate change, the *Rhine Riesling*, a late variety that preserve better acidity was introduced in area in the detriment of earlier local variety *Feteasca albă*, whose acidity can be affected by increasing temperatures in the context of climate change. For the area with WTW and SW potential, the *Zghihara de Huşi* (Z) variety, with a high production potential has been maintained in cultivation.

a **b**

Figure 6. *Viticultural potential between for the 1980 to 2013 (a) and spatial distribution of current winegrape varieties (b) in the Averești wine-growing region*

Analysis of winegrape varieties location in the area

The location of winegrape varieties introduced in the area after 2000 was based on empirical observations. As a result, white wine varieties were located mainly on flat terrains, while varieties for red wine on slopes and on some flat terrains, appreciated as suitable.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26632680
© 2018, ALÖKI Kft., Budapest, Hungary

However, the analysis of the varieties location reveals 15.6% accuracy for the red wine varieties and 73% for the white wine varieties (*Table 7*). About 66% of the area planted with red wine varieties is located on surfaces with viticultural potential for QWW and 18%, even on surfaces with viticultural potential for WTW, SW and WD. The total area suitable for red wines is of 70.4 ha while the present area growing varieties for red wines is of 220.5 ha, the maximum potential utilization for RTW being of about 32% compared to 15.6% realized. The variability analysis reveals the 100% location of the *Cabernet Sauvignon* variety in the zone with QWW potential (*Fig. 6b*); 88.9% of the *Merlot* surface is located in the area suitable for QWW and only 3.2% in the area suitable for RTW; 59.2% of the *Pinot noir* surface is located in the area suitable for RTW and only 40.6% in the area suitable for QWW (*Table 7*).

Table 7. *Framing of the winegrape varieties for red wines newly planted in the area, within the zones with different types of viticultural potential (arp)*

Viticultural potential (arp)	Framing red and white winegrape varieties within suitability classes (%)		Framing within suitability classes from area (%) of the red winegrape varieties*				
	Red varieties	White varieties	BB	CS	FN	M	PN
6	18.0	27.7	14.1	0.0	36.5	7.9	0.2
7	66.4	64.2	68.8	100.0	53.4	88.9	40.6
8	15.6	8.1	17.1	0.0	10.1	3.2	59.2
Total	**100**	**100**	**100**	**100**	**100**	**100**	**100**

*BB = *Busuioaca de Bohotin*; CS = *Cabernet Sauvignon*; FN = *Feteasca neagră*; M = *Merlot*; PN = *Pinot noir*

Growing winegrape varieties for red wine in unsuitable areas limits the expression of their quality potential and the possibility to produce quality wines. In the Avereşti area, the lack of suitability for red wines of the zones suitable for WTW, WD, SW and QWW is given by the small values of IAOe (< 4300 units), ASD (< 1450 h), TWM (< 20 °C), Cly content (< 15%), Gra (< 10%) and northern aspects. Obtaining quality red wines is conditioned by the high exposure of the vine canopy to direct solar radiation, higher temperatures and sunshine duration. In wine-growing areas close to the northern limit of vine growing area, these conditions are more difficult to meet, generally occurring on slopes with predominantly southern terrain aspects, well-drained and less fertile soils, and using training systems that ensure the highest percentage of grapevine leaves exposure to direct solar radiation.

Discussion

The GIS-based multicriteria analysis of the viticultural potential of the Averesti wine-growing region, situated close to the northern limit of grape growing (50° N lat.), reveals its increase during the 1961-2013 time period as a consequence of climate change. With the increase of the viticultural potential, changes in specific winegrape varieties have occurred, new winegrape varieties for quality white wines and even varieties for red wine being planted.

The originality of this study is that the area's viticultural potential has been assessed by taking into account the values of 15 ecological parameters representative of the vineyards' relief, soils and climate, and determinants of the quality and characteristics of wines. This approach ensures the accurate assessment of the viticultural potential, which must include the influence of relief and soils (Irimia et al., 2014). The accuracy of the study is given by: the use of a digital elevation model with a resolution of 5 × 5 m; the use of daily temperatures, precipitation and sunshine duration for the period 1961-2013 from the ROCADA database (Dumitrescu and Bîrsan, 2015); the use of pedological data representing the whole viticultural area.

Previous research on the ecological characteristics of the Avereşti wine-growing region revealed the significant spatial variation of the terrain aspect, slope, annual average temperature and sunshine duration (Irimia and Patriche 2009, 2010). The complete evaluation of the viticultural potential has revealed the existence of three homogeneous viticultural zones in the area, whose share changed between 1961 and 2013 as a result of climate change. The cause of the change of the viticultural potential is the climate change that in the region manifests by: AAT increase by 0.47 °C between 1961 and 2013; TWM increase by 1.26 °C; LGS extension by 2 days between 1961-2013; PP increase by 14.12 mm; and IAOe increase by 132.8 units. The results are consistent with the outcomes of the research on the evolution of temperatures, insolation and precipitation on Romania territory between 1961 to 2010 (Busuioc et al., 2010; Piticar and Ristoiu, 2012; Dumitrescu et al., 2014) and those communicated for this part of Europe by Karl (1998) and Klein Tank and Köhnnen (2003).

The study reveals that climate change not only modifies the vineyards' specific types of wine production. The Avereşti wine-growing region, characterized in the past by a cool, less suitable climate, passed between 1961 and 2013 from mainly WTW, SW and WD viticultural potential to mainly QWW and even RTW viticultural potential. The results are in line with those recorded for the Cotnari wine-growing region, located 200 km to north, in the same region (Irimia et al., 2017b). So are they in line with the regional developments, the whole of Romania's viticulture being affected by major shifts in climate suitability for the wine production (Bucur and Dejeu, 2016; Irimia et al., 2017a). The results of this study are in accordance with the expected developments for the viticulture of Central and Eastern Europe predicted by Stock et al. (2005), which assessed the evolution of current climate as favoring the expansion of red wine varieties in these areas. In the Avereşti wine-growing region, the *Cabernet Sauvigon, Merlot, Pinot noir, Fetească neagră* and *Busuioacă de Bohotin* red winegrape varieties, not previously existing in the area, were introduced due to the viticultural potential increase determined by climate change.

However, the study demonstrates the need to evaluate the current viticultural potential and to delimit the homogeneous viticultural zones of the wine-growing regions close to the northern limit of vine growing area, that are the beneficiaries of climate change, with a view to the correct zoning of the newly introduced winegrape varieties. In the absence of such an assessment, in the Avereşti wine-growing region only 15.6% of the area planted with red wine varieties is located in zones suitable for RTW; about 66% of the area is located on surfaces suitable for QWW and 18% on area suitable for WTW, SW, WD. It is expected that in the context of climate change, the area's potential for RTW will increase, but currently it is not at the level where high quality red wines can be obtained.

The results of the study are especially useful for the Avereşti wine-growing region where the management of vine plantations can be optimized and strategies for capitalizing on the wine production can be elaborated. The study also provides information to researchers and to the entire wine sector on the impact of climate change on the vineyards viticultural potential and their specific wine types.

Conclusions

The study has shown that the viticultural potential of the Averesti wine-growing region has radically changed in the context of climate change. Evolutions are similar to those found in previous researches on vineyards climate in this geographical region. They are also consistent with the outcomes of other researches on the evolution of viticulture in this part of Europe, namely the increase of the viticultural potential due to the increase of the heliothermal resources. The Averesti wine-growing region evolved between 1961-2013 from the prevalent white table wine production between 1961-1979, to the prevailing potential for quality white wines and red table wines between 1980 and 2013. The new viticultural potential is being exploited in the Averesti wine-growing area by expanding the international varieties for quality white wines and by introducing red wine varieties in culture, an absolutely new wine type production for the area. These developments are specific to wine-growing regions close to the northern limit of vine culture, but this study demonstrates the need to assess the viticultural potential determined by climate change and to delimit the homogeneous viticultural zones in such areas. Although heliothermic resources have increased, they have not yet reached the level at which to obtain high quality red wines. To this the significant spatial variation of the ecological factors is added, which determines the existence in the vineyard area of the homogeneous viticultural zones with different viticultural potential in relation to winegrape varieties requirements. However, due to the frosty winters in the area that still maintain their harshness, further studies on the matching and behaviour of newly introduced wine-grape varieties into Averești wine-growing region are still needed.

Abstract. This paper aims to provide technical insights on revitalizing urban river water quality through structural approach in Alur Ilmu urban river, National University of Malaysia @ *Universiti Kebangsaan Malaysia (UKM)* Bangi Campus. The structural approach consists of three main parts: site profiling, water quality assessment to determine spatial distribution of pollutions and on-site water treatment system. The selected water quality parameters were Dissolved Oxygen, Ammoniacal Nitrogen, pH, Total Suspended Solid, Chemical Oxygen Demand and Biological Oxygen Demand. The obtained values were indexed in accordance with Water Quality Index (WQI) of National Water Quality Standard (NWQS) for Malaysia and interpolated to produce thematic maps indicating the point sources of pollution using Kriging model. A series of on-site water treatment system, namely constructed wetland, gross pollutant trap, permeable pavement wall and floating treatment wetland were then strategically constructed using both information obtained from site profiling and spatial distribution. The structural approach has been deployed since 12 June 2015 and has shown significant improvement on average WQI for all thirteen stations from 68.85 to 79.87 in less than 10 months. The most influential point for source of pollution was detected at AL5 (FST Café), it has improved the most, from 51.36 to 73.18. The structural approach has successfully improved Alur Ilmu water quality and should be complemented with non-structural approach to ensure the sustainability of water resource.
Keywords: *site profiling, water quality assessment, spatial distribution, Kriging model, onsite treatment system*

Introduction

Under circumstances of technology advancement, social change and economic development have given impetus to rapid urbanization and land expansion, pristine water quality and natural appealing urban river are apparent if we incorporate environmental consideration into our current practice and future planning. Good governance of urban river through integrated water resource management has tapped valuable potentials for many developed countries towards economic, social and environmental benefits. Cleaner urban river water contributes to alternative water

resource, i.e. groundwater recharging and stormwater harvesting (Lim and Lu, 2016), fulfilling public demand for better environmental health (Environmental Protection Agency (EPA), 2016), enhancing their quality of life, and providing nature aesthetic appreciation and gentrification for safe, efficient and greener neighbourhood (Reese, 1991; Lim et al., 2013). Besides, it establishes a niche on revitalizing urban rivers through various methodologies and water treatment systems. However, the options available in adopting management and water treatment system have created ambiguity to decision makers and engineers to suit their local context. A flaw adoption of water treatment and management will exacerbate more than only urban river water problems. For example, poor understanding of the urban river water pollution dynamics from introduction of point and non-point sources of pollution (Curriero, 2007), resulting to unnecessary site's geomorphological change and selection of ineffective water treatment system. This creates more loss as more pollutants created from land change, financial strain from high maintenance of unsuitable water treatment system and discontentment from the public.

In revitalizing urban river, structural approach is one of the best management practices (BMP) to remove the pollutants from the water body (Lim and Lu, 2016; Thomas and Reese, 2003). The goal of BMP is to provide sufficient pollution reduction of mass inflow i.e. from point and non-point sources of pollution to meet the targeted mass outflow provided by local standards and guidelines (Thomas and Reese, 2003). Challenges of the structural approach in BMP are the complex urban rainfall-runoff contributing to various types of pollution, myriad of biological, chemical and pollution reactions in the water body. Moreover, despite with careful planning of constructed water treatment systems, the reduction of pollutions was inconsistent (Thomas and Reese, 2003; Brown and Clarke, 2007; Lim and Lu, 2016), therefore it is hard to achieve replicable results from previous case studies. Hence, structural approach is designed in a set of action plan using scientific analyses that optimise both aspects of the site features and the selected water treatment systems by mitigating the pollutions close to its source according to standards stipulated by local authorities or government. Similar to most of the developed countries, Malaysia government has outlined national water quality standard for inland water quality namely Water Quality Index (WQI) to identify and classify the level of acceptance of water quantity and quality for human use and environmental health (Natural Resources and Environment Malaysia (NRE), 2006). The WQI comprises of six water quality parameters, namely dissolve oxygen (DO), Ammoniacal Nitrogen (NH_3-N), total suspended solid (TSS), chemical oxygen demand (COD) and biological oxygen demand (BOD), are calculated into a cumulative value of the 6 parameters in sub-indices with weightage that can be classified into five classes and usages. *Table 1a* is National Water Quality Standard (NWQS) for Malaysia with limits for classes of pollutant concentration acceptance level of the subindices Malaysia's WQI (NRE, 2006). *Table 1b* is DOE WQI Classification for Malaysia with limits for inland water quality (NRE, 2006). *Table 1c* is the description list of the classes and its utilities that have been mentioned in *Tables 1a* and *1b.* Water with Class I in WQI indicates clean and is the most suitable for human consumption and usage. Increasing in WQI indicates the more polluted of urban river water quality is, which is harmful for human use and to the environment.

This paper aims to provide insights on the technical aspects of revitalizing urban river water quality through structural approach using site profiling, spatial distribution analysis of WQI and on-site treatment system. Therefore, the current research enables

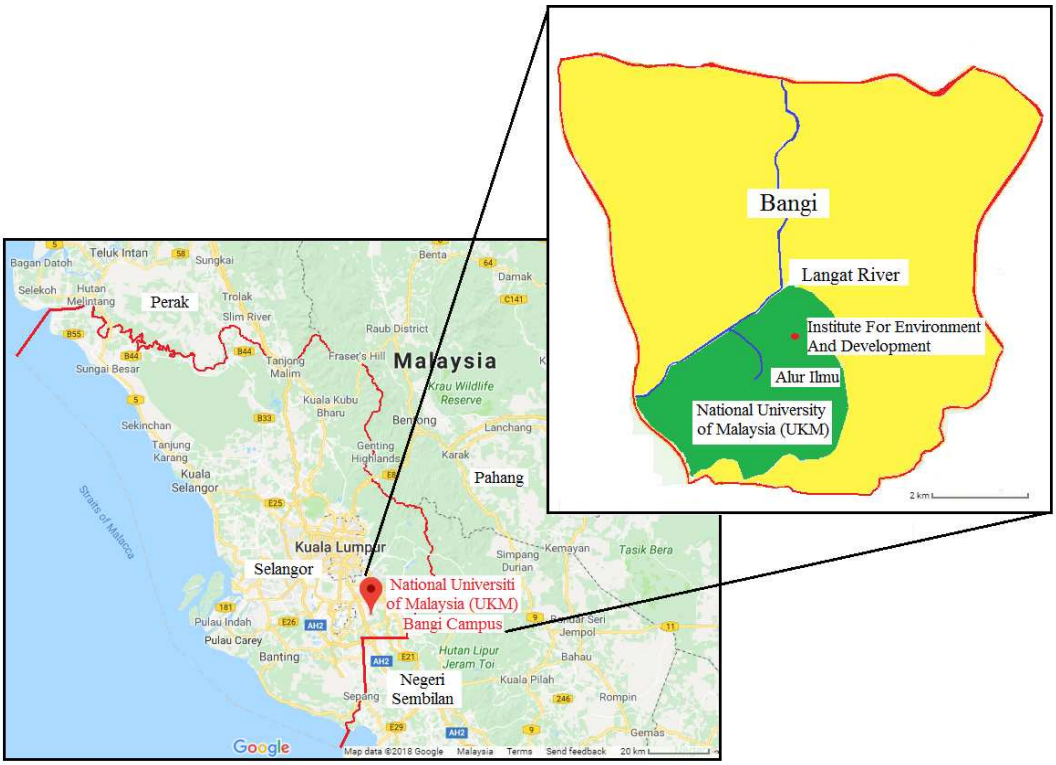
decision makers and engineers to target and apply treatment to remove pollutants in the water body as close as possible to the source of pollution based on the case study in Alur Ilmu, National University of Malaysia @ *Universiti Kebangsaan Malaysia* (UKM) Bangi Campus, Selangor, Malaysia.

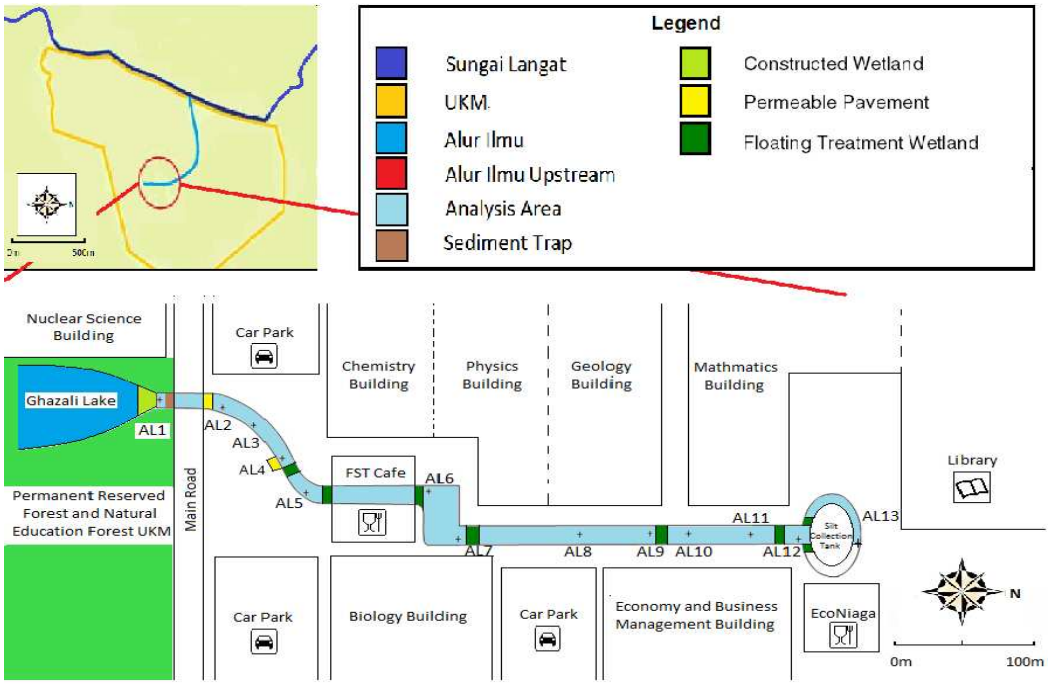
Methods

Study area



Alur Ilmu is a 1.79 km urban river long stretching across the main campus of the National University of Malaysia (UKM), Bangi, Selangor, Malaysia before flowing into the Langat River. *Figure 1a* is the location of National University of Malaysia (UKM), Bangi Campus, Selangor, Malaysia. *Figure 1b* shows the location of the revitalization of water quality study through structural approach at first 500 m of Alur Ilmu urban river upstream, UKM Bangi, Selangor, Malaysia with sampling sites and the placement of the on-site water treatment system. The first 100 m of Alur Ilmu is located at the lowest elevation point of hilly terrain and flows with normal elevated terrain, closely surrounded by impervious area from building and impervious pavement. It receives water source from the Permanent Reserved Forest and Natural Education Forest (*Hutan Simpan Kekal and Hutan Pendidikan Alam*) UKM, rain water and stormwater runoff. Alur Ilmu has been reinforced from a natural river into a concreted urban river in 1970s concurrent with the construction of the first batch of UKM's faculty buildings without changing its original flow (*Universiti Kebangsaan Malaysia* (UKM), 1978). Alur Ilmu serves as an irrigation system to remove excess water from impervious area nearby the urban river and avoid flooding. Alur Ilmu is a model of an urban river as it receives clean forest water from the upstream and surrounded by the growth of technology, social and economic activities along the urban river which convergences into Langat River at the downstream. In this study, revitalization of Alur Ilmu water quality was conducted within the upstream (500 m length and 5 m width starting from Ghazali Lake to Silt Collection Tank). Average water depth is about 1.8 m with land coverage of 95% impervious area (*Universiti Kebangsaan Malaysia* (UKM), 1978). The average water velocity of the urban river is 0.1 ms^{-1} during dry season and increases to an average of 6 ms^{-1} during rain. In *Figure 1b,* the light blue colour indicates the area selected for spatial distribution analysis. The area was selected to identify point and non-point sources of pollutions in Alur Ilmu and eliminate complication of spatially interpolating within non-convex or irregularly shaped regions (Ghafouri and Swain, 2005). The WQI was reported depreciating from Class II (Chong, 1999) to Class III in 2003 (Mokhtar et al., 2005) to Class IV in 2012 (Din et al., 2012) and Class V in 2017 (Hafiyyan et al., 2017a).

Structural approach



Structural approach is a systematic action plan to understand a complex set of anthropogenic and natural physical, chemical and biological factors which act as pollution to the receiving water and provide effective hardware solution to remove pollutants in the receiving water. The main goal of the structural approach is to obtain optimum pollution reduction perpetuated throughout the years in compliance to management goals and local water quality standards. The approach consists of three components: 1) site profiling, 2) water quality assessment and 3) on-site water treatment

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

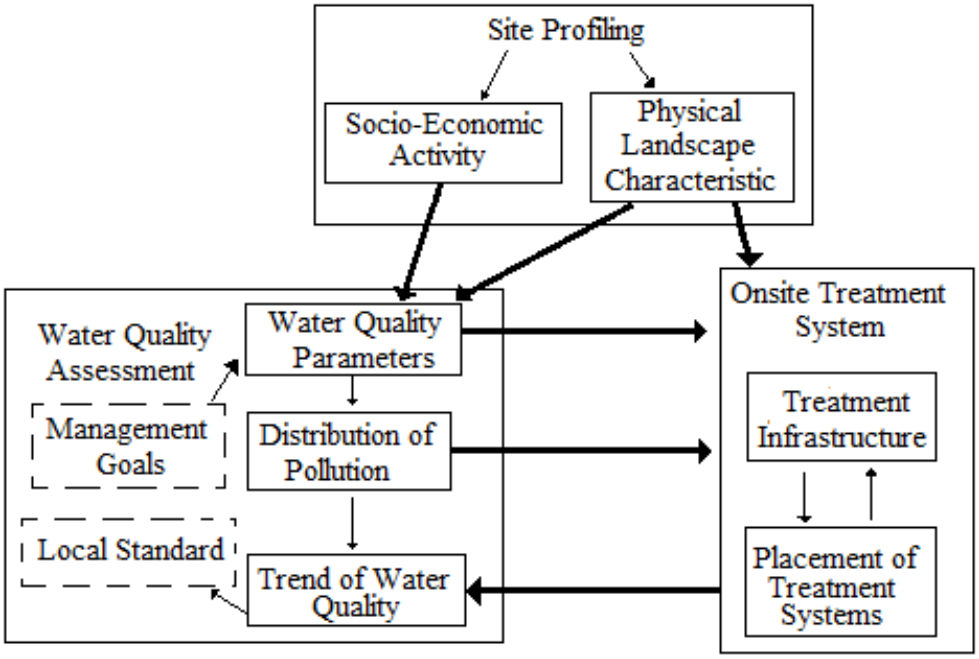

Figure 2. *Research strategy for the structural approach and its components in urban river water revitalization*

The first part of the approach is to develop a site profile of the study location comprises of its socio-economic activities and physical landscape characteristic along Alur Ilmu. Socio-economic activities refer to any human activities that occur nearby the urban river that can influence its water quality through point and non-point sources of pollutions. The physical landscape characteristic encompasses an outline of the urban river and its surrounding location including its geomorphological of the terrain, physical characteristic of the urban river and flow pattern of the urban river. The geomorphology of the terrain encompasses the slopes and nearby land use. Physical characteristic of the urban river is the distinctive feature or quality that describes the urban river and flow pattern is the water depth and water velocity of the urban river. Information of socio-economic activities and physical landscape characteristic are instrumental for identification of the type and cause of pollution.

The second part of the structural approach is water quality assessment of Alur Ilmu. The assessment is conducted by underpinning three aspects which are water quality parameters, distribution of pollution and trend of its water quality. The water quality parameters refer to the physical, chemical and biological characteristic of the water (Water Environment Partnership in Asia (WEPA, 2017) that to be complied with management goals and local standards to protect the end user including human, animals, and ecosystem health or industrial and agriculture activities (Environmental Protection Agency (EPA), Ireland 2001). The water quality assessment for Alur Ilmu was conducted through in-situ monitoring and ex-situ analysis in accordance with National Water Quality Standards for Malaysia, namely Malaysia's WQI (Department of Environment Malaysia (DOE), 2007). Malaysia's WQI is a mathematical value from comprehensive calculation of selected water quality parameters namely dissolved oxygen (DO), pH, Ammoniacal Nitrogen (NH_3-N), total suspended solid (TSS), biological oxygen demand (BOD) and chemical oxygen demand (COD). The purpose of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

the index is to benchmark the water quality of surface water in Malaysia to the public about its uses (American Public Health Association (APHA), 2005). The obtained WQI is used to determine the distribution of pollution through spatial distribution analysis to produce a thematic map determining the distribution of point and non-point sources of pollution entering Alur Ilmu water body.

The selection of on-site water treatment system is based on two aspects, 1) the treatment infrastructure which includes its water treatment application, design criteria, specification, operation and maintenance and 2) the placement of the treatment system. The data obtained from site profiling and water quality assessment are rudimentary for the selection of the on-site treatment system.

Sampling and analytical method

Thirteen stations were selected based on inlets identified along first 500 m of Alur Ilmu and their GPS coordinates were recorded using Garmin Etrex 20 for spatial distribution analysis. Six water parameters were selected for in-situ monitoring and ex-situ analysis for the water quality assessment, based on the National Water Quality Standards for Malaysia (Department of Environment Malaysia (DOE), 2007). The parameter were dissolved oxygen (DO), pH, and Ammoniacal Nitrogen (NH_3-N) for in-situ monitoring and total suspended solid (TSS), biological oxygen demand (BOD) and chemical oxygen demand (COD) for ex-situ analysis. The in-situ monitoring for DO (% saturation), pH (value) and NH_3-N (mg/L) were measured using YSI Multiparameter Sonde during mid-day (11 am – 1 pm) and water samples were collected for analysis. For ex-situ analysis, TSS (mg/L) was sampled using polyvinyl bottle and measured using gravimeter method Method 208D (American Public Health Association (APHA) (2005). BOD (value) was analysed by BOD_5 Method by incubating the water samples for 5 days under temperature of 20 °C in an incubator and analysed using YSI EcoSense Self-stirring BOD Probe. Differences between DO_{first} and DO_{final} were recorded for BOD net value (American Public Health Association (APHA), 2005). COD parameter was carried out using 5220B chemical oxygen demand, closed reflux, titrimetric method and was analysed using HACH Spectrophotometer DR3900 Laboratory VIS Spectrophotometer with RFID* Technology (American Public Health Association (APHA), 2005). The six water quality parameters for each station in Alur Ilmu were used to calculate WQI value using WQI formula and calculation in *Equation 1*. The obtained WQI of each station was compared with DOE WQI Classification in Malaysia and uses (NRE, 2006) in *Tables 1a* and *1b* for water pollution classification and limits. The six parameters: DO, pH, NH_3-N, TSS, BOD and COD are the water quality parameters approved by the Malaysia's DOE for evaluation (*Eq. 1*) of overall status of surface water including urban river water. From *Equation 1*, DO carries the maximum weightage of 22% and pH carries the minimum of 12% in the WQI equation. The WQI equation constitutes of sub-indices of the six water quality parameters calculated according to the best-fit relations given in *Equations 2* to *7*. Variation of the sub-indices with concentrations of the respective pollutants are depicted in *Figure 3*. Better quality of the water represented by high value of the index (Mamun and Zainudin, 2013).

WQI	< 92.7	76.5 – 92.7	51.9 – 76.5	31.0 – 51.9	> 31.0
Pollution level	Clean 100 - 81		Slightly polluted 80 - 60	Polluted 0 - 59	

Table 1c. *Malaysia's WQI classification (NRE, 2006)*

CLASS	USES
Class I	Conservation of natural environment Water Supply I - Practically no treatment necessary Fishery I - Very sensitive aquatic species
Class IIA	Water Supply II - Conventional treatment Fishery II - Sensitive aquatic species
Class IIB	Recreational use body contact
Class III	Water Supply III - Extensive treatment required Fishery III - Common, of economic value and tolerant species, livestock drinking.
Class IV	Irrigation
Class V	None of the above

Data acquisition and statistical analysis

WQI before treatment was obtained in June 2015 and WQI after treatment was taken in October 2016 to March 2017. The WQI for the thirteen stations were interpolated to produce thematic maps of spatial distribution of pollution using Kriging model via Surfer® 11 for water quality modelling. Kriging model was chosen in this study because it is the most accurate model to present interpolation of water quality data for liquid flowing in a conduit that does not completely enclose the liquid, i.e. concreted stream and river (Ghafouri and Swain, 2005). Kriging is a geostatistical gridding method which expresses trend within the source of data. For example, alternatively of forming isolated peaks at the similar location on the map, it allows the peaks to connect and form as a ridge (Golden Software, 2017). Below is the general linear regression model for Kriging map interpolation (*Eq. 8*), showing how WQI value treated via interpolation (predicted) for notation purposes. From the equation, *s* is denoted as a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26812699
© 2018, ALÖKI Kft., Budapest, Hungary

generic spatial location that continuously contrasts over some domain of interest. Y(*s*) is the result of interest from the interpolation value of non-sample WQI data at *s*.

$$\hat{Y}(s) = \beta_0 + \beta_1 X_1 + \varepsilon(s) \quad \text{(Eq.8)}$$

$X_1(s)$ expresses a potential covariate indexed by location *s* which may have more than one covariates. β_1 is the covariate's associated regression effect while β_0 is the constant term and ε(s) is error term. The uncertainty within the universal regression approach is modelled with the random error term ε(s), assumed to have zero means, constant variance and a multivariate correlation structure to accommodate spatial dependence (Murphy et al., 2010). The current study focuses on WQM-generated concentration of the WQI obtained. Using Kriging gridding method, WQI can be generated for all locations within the area, representing as the covariate [$X_1(s)$]. The expected value of a parameter (i.e. $\beta_0 + \beta_1$[Modelled WQI(*s*)]) is different by location and is a function of the WQM-generated concentration. Residual error term is accounted for expected value which deviates in value and varies spatially. Thus, the Kriging gridding method reduces the concern regarding station in a flowing water body by accounting for a spatial varying expected value.

On-site water treatment system

The selection of on-site water treatment system undergoes screening of two general aspects which are treatment infrastructure and placement of treatment system. Both of the aspects should be complemented with the information gathered from site profiling and water quality assessment. Four components were considered in the treatment infrastructure, namely removal efficiency, design criteria, water treatment specification as well as operational and maintenance. Removal efficiency is the ability of water treatment to address targeted water quality parameters in the water body. Design criteria are the installation and development of the water treatment for on-site operation including the size and mechanism involved. Water treatment specification is the requirement for optimal efficiency and better performance and water treatment management suitability (Lim and Lu, 2016; Thomas and Reese, 2003; Din et al., 2012; Murphy et al., 2010). For the placement of the treatment system, two components are deliberated namely space limitation and strategic target close to the source of pollution.

From the aforementioned criteria, the selected on-site water treatment systems were constructed wetland, permeable pavement wall and floating treatment wetland. *Figure 4* depicts the selected on-site water treatment systems used to revitalize Alur Ilmu water quality. All of the water treatment systems were fully deployed to Alur Ilmu on January 2016. The three water treatment systems were opted to complement Alur Ilmu's site profile through which Alur Ilmu is located close to human development and economic activities, i.e. faculty infrastructures, cafe and tarred road, hence the water quality is susceptible to water pollution. Surrounded by impervious hilly terrain, the concreted urban river received large surface runoff during rain. The constructed wetland was placed at the upstream of Alur Ilmu as it is effective to sink suspended solids using Bent Flag Alligator (*Thalia geniculate)*. Permeable pavement wall and floating treatment wetland were selected because of flexible design criteria which can be retrofitted into the minimum available space of Alur Ilmu and effective on domestic water pollution and surface runoff. Four free-floating plants were studied to remove NH_3-N, TSS, and BOD concentration in the water sample.

In order to determine the most effective free-floating plants to remove pollutions from the urban river water, four free-floating plants were selected for feasibility of phytoremediation in pollution removal of Alur Ilmu water sample. The selected free-floating plants are water hyacinth, *Eichhornia crassipes* (Mart.) Solms, water lettuce, *Pistia stratiotes.* L.*,* rose water lettuce, *Pistia sp.* L. and pennywort*, Centella asiatica,* (L.) Urb. Base on the study, Water Hyacinth was chosen to be planted on top of the floating treatment wetland (coverage area ~ 40 m^2) because its effectiveness in removing urban storm water pollution and resilient to urban water dynamic (Hafiyyan et al., 2017b; Wang et al., 2013).

Results

Table 2 shows the inventory of the site profile of Alur Ilmu by which the urban river is bounded with infrastructures and has limited space for large on-site treatment system, namely swale, infiltration basin and wetland.

Table 2. *Site profiling of Alur Ilmu urban river's socio economics activities and physical landscape characteristic*

Site Profile		
Socio-economic activities	● University setting (public) (UKM, 1978; UKM, 2013) ● Two Cafeterias (Economic activities) (UKM, 2013)	
Physical landscape characteristic	Geomorphological of the terrain	● Hilly terrain (UKM, 2013) ● 95% paved area (UKM, 2013)
	Physical characteristic of the urban river	● 500 m study area (from from Ghazali Lake to Silt Collection Tank) ● Concreted urban river (from a natural river into a concreted urban river) (UKM, 1978) ● No change of its original flow ● Bounded with paved area (Building and infrastructures) (UKM, 1978; UKM, 2013) ● First 100 m of Alur Ilmu is located at the lowest elevation point of hilly terrain and flows with normal elevated terrain
	Flow pattern of the urban river	● Receives water source from the Permanent Reserved Forest and Natural Education Forest, rain water and stormwater runoff (Hafiyyan et al., 2017a) ● Average water depth is about 1.8 m ● average water velocity is 0.1 ms^{-1} during dry season ● average water velocity of 6 ms^{-1} during rainy season

The options available are to exercise major remodelling of Alur Ilmu which may harm the integrity of infrastructures in the vicinity or use Low Impact Development (LID) (Thomas and Reese, 2003) by retrofitting on-site water treatment system to the urban river. Based on *Figure 4*, the first part of Alur Ilmu being AL1 is suitable to use constructed wetland as it is the only large area available for effective filtration and detention of soil, sediment and large solids, i.e. plastics, dead branches and debris. The area was planted with Bent Flag Alligator (*Thalia geniculate*) and has the predominant removal mechanism for detention system. It enables to hold water for a period of time,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26812699
© 2018, ALÖKI Kft., Budapest, Hungary

allowing for settling of solid pollutants, filtration through vegetation, biological and chemical transformation, i.e. bioabsorptions (Thomas and Reese, 2003).As AL2 to AL13 have limited space for large on-site treatment system, the main culvert was built with permeable pavement wall. In addition, it is a retrofitted stormwater filtration system engineered to physically reduce the concentration of suspended solids, soil and silt by filtering the water vertically past through the porous medium (Thomas and Reese, 2003). Alur Ilmu water body is susceptible to myriad of pollutions from discharged points and surface runoff. Floating treatment wetland (FTW) plots were chosen and deployed into Alur Ilmu. During and after the installation of FTW, no change in any physical landscape characteristic was made because the plots were retrofitted into the urban river hence it is ideal to limited space urban setting. Previous study in 2017 has revealed the feasibility of phytoremediation in pollution removal of Alur Ilmu water sample (Hafiyyan et al., 2017b). Four free-floating plants were studied to remove NH_3-N, TSS, and BOD concentration in the water sample. The free-floating plants were water hyacinth, *Eichhornia crassipes* (Mart.) Solms, water lettuce, *Pistia stratiotes.* L.*,* rose water lettuce, *Pistia sp.* L. and pennywort*, Centella asiatica,* (L.) Urb. The result showed rose water lettuce has the highest concentration reduction followed by water lettuce, water hyacinth and pennywort. However, among all four plants, water hyacinth was the most adaptable plants thus make it a better option for on-site phytoremediation of Alur Ilmu water. Water hyacinth (*Eichhornia crassipes*) was used for floating treatment wetland as regional stowmwater control (Hafiyyan et al., 2017b) The regional stormwater control is defined as facilities designed to manage stormwater runoff from multiple inlets for on-site control (Thomas and Reese, 2003; Martin et al., 2007). The floating treatment wetland designed for the regional stormwater control can maximize the utilization of developable land, to reduce operation and maintenance cost, retrofit potential and highly visible for enhancing natural aesthetical value. Hence, Water hyacinth was selected because of its effectiveness in large application of urban water body (Wang et al., 2013; Hafiyyan et al., 2017b). The thematic map in *Figure 5* depicts the strategic design of the on-site treatment system layout at Alur Ilmu urban river and in thematic map of WQI improvement.

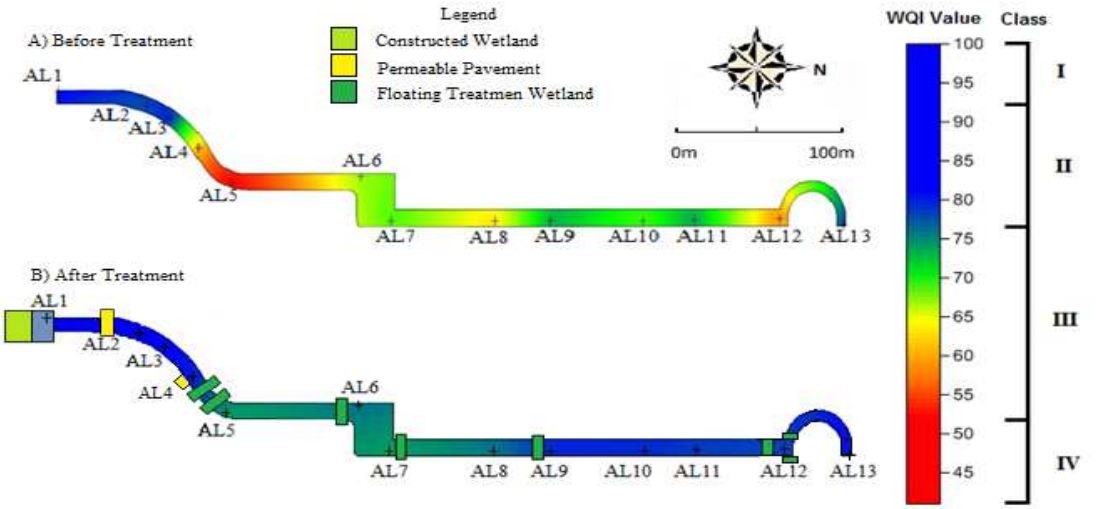

Figure 5. *Comparison of spatial distribution of WQI in Alur Ilmu before and after the structural approach*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_26812699
© 2018, ALÖKI Kft., Budapest, Hungary

As shown in *Table 3,* the average WQI was 68.85 (Class III) in June 2015 (before treatment) and it has been improved to 79.87 (Class II) in October 2016 (after treatment) within 10 months with 16.00% of improvement in WQI. The highest average WQI after implemented structural approach was reported in Feb 2017 being 81.98 (Class II) with 19.07% of improvement in WQI. After implementing treatment, average WQI stabled at Class II ranging from 78.60 to 81.98 in WQI. The thematic maps show a general and clear pattern difference of WQI distribution before and after implementing the structural approach in Alur Ilmu. All the thirteen stations along 500 m of Alur Ilmu have generally improved spatially in WQI. The highest improvement of WQI was recorded at AL5 with 46.47% of improvement from 51.36 (Class IV, June 2015) to 75.23 (Class III, Feb 2017).

Discussion

Figure 5 shows that structural approach has a positive effect in revitalizing the urban river water quality. *Figure 6* is a visual comparison of Alur Ilmu urban river before (top) and after (bottom) implementation of the structural approach. Based on *Figure 5* and *Figure 6*, the structural approach has successfully improved both aesthetic and water quality of Alur Ilmu. The overall design of the structural approach is depending on the understanding of the complex pollution dynamic from natural phenomenon and anthropogenic factors of physical, chemical and biological forces emanating into the urban river (Thomas and Reese, 2003). Based on the aforementioned methodology, the water quality assessment and spatial distribution analysis are the tools used to understand pollution accumulation and urban hotspot (Thomas and Reese, 2003) of the land use prior to improve water quality of the urban river. Alur Ilmu is located at the lowest elevation level of hilly terrain, surrounded by imperious surface area and economic activities. Therefore, it is vulnerable to point and non-point sources of pollution.

The methodology of the current study followed the urban stromwater management manual for Malaysia (*Manual Saliran Mesra Alam, MSMA)* (Department of Irrigation and Drainage – DID, 2012), a guideline for non-point source of pollution control. The on-site treatment system used in the current study complied the key aspect of the manual which is to control pollution source using methods that produce the least impact towards the environment.

The thematic map before treatment is the superlative example to represent the pollution dynamic in the water body caused by point and non-point sources of pollution. The map indicates that pollutions accumulate at station AL5, AL8 and AL12. In relation to urban hotspot, AL5 and AL12 are both nearby to Cafeteria and AL8 is nearby to car park and faculty buildings. The introduction of pollution into the water body may come from the leakage of pipes and poor maintenance of pipes to channel waste produced into designated water treatment system and discarded properly through schedule waste disposal (Chong, 1999).

Wang et al. (2013) has shown positive results on revitalizing Lake Caohai (10.5 km^2), China water quality which is bounded by urban infrastructure using onsite treatment system by deploying a large scale confined growth of Water hyacinth (coverage area ~ 4.3 km^2) on N removal (761 t) (64% removal) within 6 months. The current study and Wang et al. (2013) were differ in water parameter tested because of different type of water pollutants were introduced into the water body respectively. Both of the studies used similar methodology to revitalize the water quality by profiling the study site and defining water quality parameters.

However, using spatial distribution analysis of water quality, the current study is able to determine optimal area for strategic placement of on-site treatment system needed that close to pollution source and using only approximate 1.6% of the study area to improve 16% of average WQI compared to Wang et al. (2013) that used 40.95% of the study area for 64% average N removal.

Figure 7 depicts WQI temporal trend of Alur Ilmu. The WQI trend projected that Alur Ilmu WQI will be more polluted if conventional management and practices are still continued. The intervention of structural approach has been proven able to bring back the water quality to Class II (Mokhtar et al 2005) after 10 months. Further improvement of the urban river WQI can be obtained if both structural and non-structural approaches are used through integrated management.

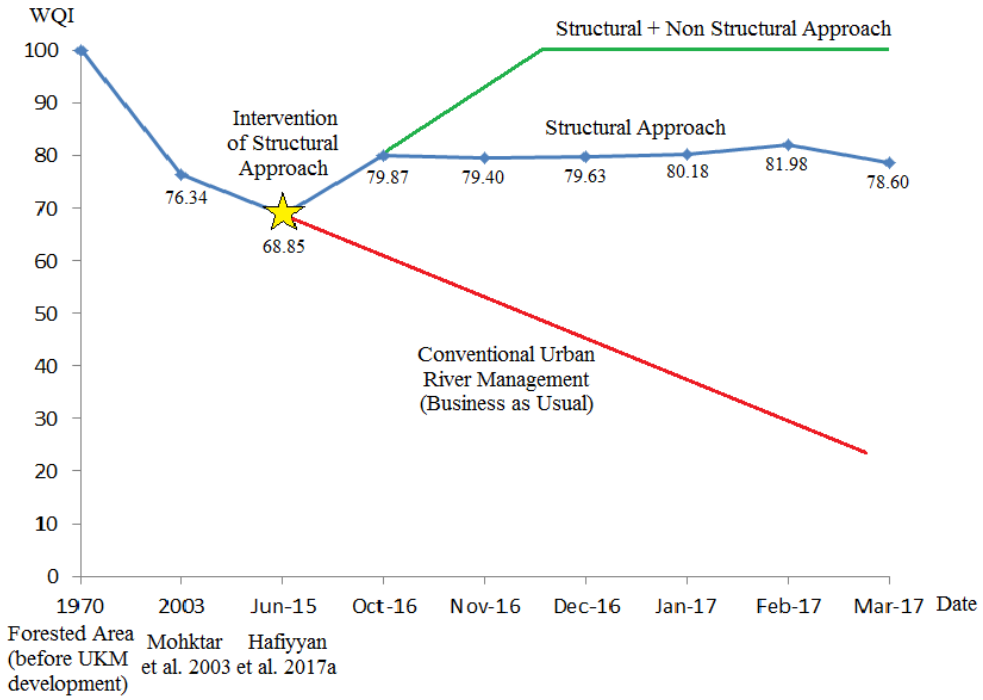

Figure 7. *WQI temporal trend of Alur Ilmu*

Conclusion

The result shows that the structural approach using constructed wetland, gross pollutant trap, permeable pavement wall and floating treatment wetland in revitalizing urban river's water quality have a positive effect to revitalize the water quality. The average WQI was 68.85 (Class III) in June 2015 (before treatment) and it has been improved to 79.87 (Class II) in October 2016 (after treatment) within 10 months with 16.00% of improvement in WQI. However, the structural approach should be complemented with a non-structural approach to control pollution before and after entering the urban river's water body as conventional infrastructure developments and economic activities with less consideration of environmental protection will cause various pollutions that can impair the capacity of the on-site treatment system. Realizing sustainable water resource management through revitalization urban river water quality, it is recommended to incorporate the urban river uses and functions into the urban masterplan that include environmental protection and gentrification as well as values for money.

APPLICATION OF ECOTOURISM OPPORTUNITIES SPECTRUM METHOD IN ECOTOURISM RESOURCES: A CASE STUDY OF SAMANDAĞ COASTAL AREAS IN SOUTHERN TURKEY

SALICI, A.

Department of Landscape Architecture, Faculty of Architecture, Mustafa Kemal University
31040 Antakya, Hatay, Turkey
(e-mail: salici_aylin@hotmail.com; phone: +90-326-221-4112; fax: +90-326-221-1489)

(Received 17th Jan 2018; accepted 10th May 2018)

Abstract. The aim of the study is to identify the areas that might serve as ecotourism focuses in the Samandağ coastal zone and its surroundings, located on the southern border of Turkey, and to develop an optimum ecotourism route. The methodology used is Ecotourism Opportunity Spectrum (ECOS). The methodology is comprised of three stages. In the first stage areas that can serve as ecotourism focuses have been identified. In the second stage ECOS method has been applied to the identified focuses. In this regard, 10 criteria and 40 sub-criteria that determine the level of suitability for identifying an ecotourism route have been identified. Both these criteria and the sub-criteria have been scaled and ecotourism opportunity spectrum value has been determined for each criterion. According to these calculations, the highest ecotourism opportunity spectrum value is 400. In the study, the focus that is closest to this value is considered as the most suitable for identifying an ecotourism route according to the planning criteria. As a result of the study, Samandağ coastal zone and its surroundings has very high importance with respect to preserving, planning and development of the resources with a sustainable approach. In this area, 20 focuses have been identified for being used for ecotourism. The highest spectrum value calculated by applying this method is 271.86 and it belong to Vakıflı focus, while the lowest spectrum value is 136.92 for the Milleyha focus.
Keywords: *ecotourism focuses, ecotourism route, natural resources, ecotourism activities, criteria and values*

Introduction

It is known that the idea of ecotourism, its use as a technical term and its applications had existed before it was termed conceptually. The concept of ecotourism had begun in the 1980s, with alternative tourism debates, as a search for a different kind of tourism that serves as a new alternative to mass tourism and does not cause negative social and ecological effects like mass tourism (Long et al., 2013). In the following years the concept of ecotourism developed with an increasing awareness towards environmental protection and the general acceptance of sustainability principles. Some researchers such as Fennell (2001), Blamey (2001), Goodwin (1996), who study ecotourism, define it basically as a sustainable kind of tourism that is based on learning and experiencing the nature, has lower ethical impacts, focuses on the local rather than consumption.

In this regard, ecotourism has strong ties with sustainable tourism due to its characteristics like preserving the natural habitats or taking the requirements of local people into consideration.

Suitable management for ecotourism development is essential in order to conserve and maintain the biological richness of the area. In addition, ecotourism can be defined as an opportunity to promote the values in the protected areas. In this respect, ecotourism evaluation should be regarded as an important tool for sustainable development of tourism in a protected area. This can be judged with the help of criteria and indicators approach, which is basically a concept of sustainable ecotourism

planning developed in a set of principles, criteria and indicators (Bunruamkaew and Murayam, 2011).

The selected area of study is the Samandağ coastal zone and its surroundings located in the Hatay province of Turkey and it has numerous characteristics such being the habitat of Mediterranean seals, nesting area of sea turtles, buxus gene preservation forest, wild life development area, and involving endemic plants, monumental trees, and archaeological protected areas. The region has a high potential for ecotourism with its resources. Therefore, the purpose of the study has been to identify the areas that could serve as ecotourism focuses within the region of Samandağ coastal zone in the Hatay province and its surroundings, and identify an optimum ecotourism route. In this regard, Ecotourism Opportunity Spectrum Method has been used.

Materials and methods

Study area

The study area is the Samandağ coastal zone and its surroundings, located in the Hatay Province in the Eastern Mediterranean region of Turkey (*Fig. 1*). The area is approximately 14 km long. It is surrounded by Musa Mountain in the northwest, Keldağ in the southeast, and the Mediterranean in the south. The Orontes River that flows through the area is born in Syria and meets the Mediterranean in Samandağ. The delta formed by the river is the breeding ground for "Green Sea Turtles" (*Chelonia mydas*), which is an endangered species according to the International Union for Conservation of Nature (IUCN) criteria (IUCN, 2006). The study area is therefore highly rich in terms of biodiversity.

Since the study area contains protected areas such as breeding sites for sea turtles and features venues that shall support religious tourism, it has been declared as "Hatay Samandağ Tourism Zone" in the official journal no. 21731 dated 17.10.1993 based on the decree of the Cabinet of Ministers no. 93/4833 within the framework of the Tourism Strategy Action Plan of Turkey.

Methodology

The methodology of the study, which was formed to identify an ecotourism route involving quality ecotourism resources, is as follows:

1. Identifying the areas that can serve as ecotourism focuses,
2. Applying the ECOS method in order to determine the source values of the identified spots,
3. Identifying the optimum ecotourism route in line with the data obtained through applying ECOS.

Identifying the focuses

The areas that are mentioned as ecotourism areas and fall within the study area according to the Hatay Province 2016 Environmental Status Report, UCTEA Samandağ Study Group Report, Hatay Province Tourism Strategy and 2018-2023 Action Plan Report and maps obtained from the local administrations related with the study area, have been accepted as ecotourism focuses.

Applying the ECOS method on the identified spots

When the studies on the planning of ecotourism areas are analyzed, it is seen that methods like Limits of Acceptable Change-LAC, Environmentally Based Tourism Planning Model-EBT, Recreation Opportunities Spectrum (ROS), and Tourism Opportunities Spectrum (TOS) have been used. Drawn up on the basis of all these methods, the Ecotourism opportunity spectrum (ECOS) attracts attention as both an opportunity and a new method put forward depending on the available approaches for the development of ecotourism in rural areas.

Even though the ECOS method was developed to provide a conceptual management approach to ecotourism, it depends on the already available models in the literature. The method particularly combines the methods of ROS and TOS and this is called the Ecotourism Opportunity Spectrum (ECOS) with several fundamental alterations and pluses. The method comprises eight sub-components in total; (1) accessibility, (2) relationship between ecotourism and other resource uses, (3) attractions in a region, (4) presence of existing tourism infrastructure, (5) level of user skill and knowledge required, (6) level of social interaction, (7) degree of acceptance of impacts and control over level of use, (8) type of management needed to ensure the viability of areas on a long-term basis. Such 8 criteria are the determinative amongst decision-makers and users in long-term use of the area as an ecotourism area (Body and Butler, 1996).

The Ecotourism Opportunity Spectrum (ECOS) method has been applied in order to evaluate the availability of the focuses identified in the study. Since the study area involves critical regions, the criteria used in the ECOS method have been enhanced and applied accordingly.

In this regard, 10 criteria have been determined relying on the studies of Hvenegaard (1994), Boyd and Butler (1996), Fennell and Weaver (2005), Tsaur et al. (2006), Bender (2008), Barzekar et al. (2011), Yılmaz et al. (2013), Ashok et al. (2017), Dhami et al. (2017), Nino et al. (2017). These 10 criteria have been presented in *Table 1*. These criteria have been divided into sub-criteria in order to offer relative values that define the level of availability for determining an ecotourism route (*Table 1*).

It has been observed that researchers who study ecotourism assign relative values that vary between 1-3, 1-5, -3-+3, 1-10, 1-100 to the sub-criteria. Gold (1980) and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

Giles-Corti et al. (2005) emphasize that the range of weight values may be small if the elements under evaluation are similar in terms of concept. Additionally, the literature used as references of the study and the opinions of experts and scholars of the subject have been taken into consideration. As a result, each sub-criteria has been given relative values between 1-4 in accordance with their suitability for determining an ecotourism route. High values between 1-4 represent the availability for being an ecotourism focus and high sustainability of naturalness. In low values this situation is the contrary.(4. Extremely Important, 3. Important, 2. Unimportant, 1. Extremely Unimportant).

Table 1. *The criteria, sub-criteria and relative values for ECOS method*

Criteria	Sub-criteria	Relative values
1. Accessibility	Presence of road easily accessible during all seasons of the year	4
	Presence of road accessible during certain seasons of the year	3
	Presence of road where transportation is frequently interrupted	2
	No means of transportation	1

	Inadequate recreational superstructure, but suitable for improvement	3
	Inadequate recreational superstructure	2
	No recreational superstructure	1
8. Social interaction level	Intense interaction level between both the local populace and the eco-tourists	4
	Intense interaction level between eco-tourists and the local populace	3
	Intense interaction level only between eco-tourists	2
	Insignificant interaction level between all groups	1
9. Knowledge level of the eco-tourists on both the area and the source, and their attitude and behavior concerning the core of the ecotourism activities	High	4
	Medium	3
	Low	2
	Very inadequate knowledge and behaviors	1
10. Effects of visitor use on the ecotourism source	High level of positive impact due to use	4
	Positive impact due to use	3
	Negative impact due to use	2
	High level of negative impact due to use	1

While finalizing the planning decisions the comparative weighted scores of criteria should be determined. This stems from the fact that the level of importance of each criterion in terms of identifying an ecotourism route is not the same. Thus, the criteria have been weighted in the second stage. In this regard, a total of 30 experts with at least 5 years of professional experience from Mustafa Kemal University Faculty of Architecture Department of Landscaping Architecture (4 individuals), Hatay Metropolitan Municipality (10 individuals), Hatay Provincial Directorate of Culture and Tourism (5 individuals), Hatay Directorate of Environment and Urbanization (6 individuals), Branch Offices of Forestry and Rural Affairs (5 individuals) were given a questionnaire. During the execution of the study, 34 experts working in these institutions were identified and 30 of them could be given the questionnaire. A score ranging from 1-10 was assigned for each criterion at the questionnaire. All the points obtained for each criterion have been added and their weighted arithmetic mean scores were calculated. The weighted arithmetic mean scores have determined the weighted score of each criterion that ranges from 1 to 10. The ecotourism opportunity spectrum value of each criterion was calculated by multiplying the weighted scores and the score each focus has according to *Table 1*. According to these calculations, the highest total value is 400. In the study, the focus that is closest to this value is considered as the most suitable for identifying an ecotourism route according to the planning criteria.

Identifying the optimum ecotourism route

In order to take correct and rational planning decisions, the obtained ecotourism opportunity spectrum values have been categorized, taking the level of availability to be used as ecotourism areas into consideration and the areas that would form the optimum ecotourism routes have been determined.

Results

The results of the study have been gathered under three titles as 1. Findings about ecotourism focuses, 2. Findings obtained by applying ecotourism opportunity spectrum, 3- optimum ecotourism route.

Findings about ecotourism focuses

In accordance with the reports and maps obtained from the local administrations 20 focuses suitable for ecotourism purposes were identified in the study area (*Fig. 2*). Six of these focuses are located in Samandağ coastal zone and the remaining 14 are located in the surroundings of Samandağ coastal zone.

The identified focuses incorporate many features in terms of both nature and culture. The availability of such focuses for ecotourism activities has been evaluated relying on the basic approach of the institutions and organizations conducting research on ecotourism, such as "World Tourism Organization-UNWTO" (UNWTO, 2002), "The International Ecotourism Society-TIES" (TIES, 2005), and the works of researchers such as Butler and Waldbrook (2003), Turoğlu and Özdemir (2005), Stepanova (2008), Şenkaya et al. (2012), Shieh et al. (2014). The types of activities applicable on the focuses within this context are given in *Table 2*.

Findings Obtained From "Ecotourism Opportunity Spectrum"

First, the condition of the focuses in accordance with the specified criteria was propounded in order to implement the ecotourism opportunity spectrum method. The results obtained are presented in *Table 3*.

According to the accessibility criteria presented in *Table 1,* the focuses that are accessible throughout the year are Hıdırbey, Çubukçu, Tomb of St. Hızır and surroundings, Çevlik port and surroundings, Eriklikuyu, Yoğunoluk and Sutaşı. Therefore, the ECOS method relative value of these focuses is set as 4 (*Table 3*).

Keldağ, İskenderun-Arsuz wildlife improvement site, Amanos mountains Musa mountain zone, Titus tunnel and its surrounding areas are very close to the beach at Samandağ coastal zone on the Mediterranean. Accessibility of these focuses is frequently interrupted due to flood tides during winter. Therefore, the ECOS method relative value is set as 2 in terms of accessibility (*Table 3*).

İskenderun-Arsuz wildlife improvement site is one of the 79 wildlife improvement sites in Turkey. Covering an area of 27.063 ha, this site was taken under protection in 2006 according to Law on Land Hunting of the Ministry of Forestry and Water Affairs of Turkey in order to protect Chevrotain (*Capra aegagrus*) and Roe-deer (*Capreolus capreolus*) species which have limited habitats in Turkey. 7000 ha of the improvement

In Batıayaz there is the buxus (*Buxus sempervirens*) gene forest. This forest has been announced as a Gene Preservation Forest in order to be used as a gene source for improvement studies today and in the future. The ECOS relative value is set as 4 for Batıayaz due to this situation and its incorporating many habitats in accordance with the protected ecosystem elements criterion listed in *Table 1*.

All the other focuses have been evaluated in accordance with the criteria listed in *Table 1* and the results obtained are given in *Table 3*.

The criteria were weighted in the second phase of the ECOS method. For this purpose, a questionnaire was conducted among a group of 30 experts directly involved in the subject matter and work at Mustafa Kemal University Faculty of Architecture Department of Landscaping Architecture (4 individuals), Hatay Metropolitan Municipality (10 individuals), Hatay Provincial Directorate of Culture and Tourism (5

In the last phase of the ECOS method, the ecotourism opportunity spectrum values have been determined. The values are calculated by multiplying the relative values and weighted scores are of each focus. The determined ecotourism opportunity spectrum values have been given in *Table 5*.

As seen in *Table 5,* a multitude of ecotourism opportunity spectrum values that range from 1.37 to 39.73 are available for the study area. Achieving practicable results for assessments in such a broad range is only possible by categorizing the ecotourism opportunity spectrum values. In this case, calculating the weighted mean value of the ecotourism opportunity spectrum values can prove to be indicative in determination of the availability of the focuses.

The resulting weighted mean value of the figures given in *Table 5* is calculated to be around 20.20. This value means that the focuses with a spectrum value of 20.20 on average, or higher values, can be considered to have low improvement priority in terms of being used as an ecotourism site. It might be deduced that when the spectrum value wanes from the mean value, the possibility of that site being used as an ecotourism site

shall decrease and the improvement priority shall increase. In this context, ecotourism opportunity spectrum values are categorized in 8 classes as indicated in *Table 6*.

Table 5. *Ecotourism opportunity spectrum value of the focuses*

Ecotourism focuses	Criteria***

Table 6. *Ecotourism opportunity spectrum value classes*

Class number	Value Classes	
1	0-5	High improvement priority
2	5.1-10	
3	10.1-15	
4	15.1-20	
5	20.1-25	Low improvement priority
6	25.1-30	
7	30.1-35	
8	35.1-40	

The following findings could be obtained when the data in *Tables 5* and *6* are analyzed:

- In terms of accessibility, Keldağ, İskenderun-Arsuz wildlife improvement site, Amanos mountains Musa mountain zone, Titus tunnel and surroundings, and Çamlıyayla are the 5 focuses with high improvement priority. The other 15 focuses

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_27012715
© 2018, ALÖKI Kft., Budapest, Hungary

have low improvement priority. The improvement priority of 5 focuses is high since their availability for being used as ecotourism sites is insufficient. The other 15 focuses are available as ecotourism sites.

- In terms of hosting different ecotourism activities, 4 focuses including İskenderun-Arsuz wildlife improvement site, Çubukçu, Titus tunnel and surroundings, and Milleyha wetland have high improvement priority. The other 16 focuses have low improvement priority. These 4 focuses mentioned are categorized among areas with low availability for hosting different ecotourism activities and high improvement priority due to their incorporating protected areas.

- When the focuses are analyzed in terms of resource variety, 7 focuses including Tomb of St. Hızır and surroundings, Çevlik port and surroundings, Milleyha wetland, Çamlıyayla, Aknehir, Eriklikuyu, and Yoğunoluk have high improvement priority. This stems from partial damage done to the flora and fauna of the focuses.

- The focus with the highest value (36.14) in terms of protected ecosystem elements is Amanos mountains Musa mountain zone. This is because the focus has a variety of habitat. The focuses with low values in terms of protected ecosystem elements are Çubukçu, Tomb of St. Hızır and surroundings, Vakıflı village, Çamlıyayla, Aknehir, Eriklikuyu, Yoğunoluk, and Sutaşı.

- The focuses with the highest value in terms of visual attractiveness are Amanos mountains Musa mountain zone (39.20), Keldağ (39.04), İskenderun-Arsuz wildlife improvement site (38.52), Titus tunnel and surroundings (38.24), Vakıflı village (36.8), and Batıayaz (36.4), respectively. These sites have visually rich landscape. The focus with the lowest score in terms of visual attractiveness is Yaylıca'dır (6.47).

- All focuses are inadequate with respect to available tourism infrastructure. Therefore, they should be improved with priority.

- All focuses have high improvement priority in terms of available tourism superstructure.

- In terms of social interaction level criterion, the focuses with the highest values are Hıdırbey village (38.27), Batıayaz (37.87), Vakıflı village (37.06), Mağaracık (34.8), Meydan village (32.13), respectively. At these focuses the interaction level is quite high both among local people and eco-tourists.

- The focuses with the highest value in terms of the knowledge level of eco-tourists about both the site and the resource, and their attitudes and behaviours in relation to the core of ecotourism activities, are Vakıflı village (39.4), Tomb of St. Hızır and surrounding (38.0), Çubukçu (36.0), Hıdırbey village (35.6), Eriklikuyu (33.08), Titus tunnel and surrounding (30.8), respectively.

- In terms of usage effect of visitors on the ecotourism resource, Çevlik port and surrounding (21.1), Titus tunnel and surrounding (23.1), İskenderun-Arsuz wildlife improvement site (21.1) have been affected positively from the visitors. Among the other 17 focuses, the most negatively affected one was Yaylıca (4.0).

- The highest ECOS value of Meydan village is visual attractiveness of the focus (34.96), and the lowest is effects of visitor use on the ecotourism source (9.67). The focus needs prior development in terms of available tourism infrastructure (9.8), available tourism superstructure (17.5), knowledge level of the eco-tourists on both the area and the source, and their attitude and behavior concerning the core of the ecotourism activities (18.39), effects of visitor use on the ecotourism source (9.67).

- Keldağ focus needs prior development in terms of accessibility (16.07), available tourism infrastructure (4.73), available tourism superstructure (1.4), social interaction

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_27012715
© 2018, ALÖKI Kft., Budapest, Hungary

level (15.4), knowledge level of the eco-tourists on both the area and the source, and their attitude and behavior concerning the core of the ecotourism activities (10.86), and effects of visitor use on the ecotourism source (11.73).

- İskenderun-Arsuz wildlife improvement site has high scores as an ecotourism focus in source diversity of the focus (35.6), protected ecosystem elements (38.0), visual attractiveness of the focus (38.52), effects of visitor use on the ecotourism source (21.1). But this focus should be developed priorly in other criteria. The lowest value of the focus is available tourism superstructure (1.5).

- Yaylıca got the highest ECOS value in protected ecosystem elements (32.13) and the lowest in effects of visitor use on the ecotourism source (4.0).

- Amanos mountains Musa mountain zone has the highest ECOS value in visual attractiveness of the focus (39.2) and the lowest ECOS value in available tourism superstructure (1.4). Its use as en ecotourism focus is low in terms of accessibility, available tourism infrastructure, available tourism superstructure, knowledge level of the eco-tourists on both the area and the source, and their attitude and behavior concerning the core of the ecotourism activities, effects of visitor use on the ecotourism.

- Batıayaz has the lowest ECOS value in terms of available tourism infrastructure (4.2), available tourism superstructure (6.53), effects of visitor use on the ecotourism source (8.2) criteria. The social interaction level (37.87) value of the focus is the highest among other criteria.

- Mağaracık has the lowest values in terms of available tourism infrastructure (17.2), available tourism superstructure (11.2), effects of visitor use on the ecotourism source (5.24). On the other hand, it has the highest value in protected ecosystem elements with 35.86.

- Kapısuyu village is inadequate as an ecotourism focus in terms of available tourism infrastructure (11.2), available tourism superstructure (5.2), social interaction level (13.2), knowledge level of the eco-tourists on both the area and the source (19.41), and their attitude and behavior concerning the core of the ecotourism activities, and effects of visitor use on the ecotourism source (15.73).

- Hıdırbey village is inadequate as an ecotourism focus in terms of available tourism infrastructure (5.93), available tourism superstructure (3.38), and effects of visitor use on the ecotourism source (14.27). This focus got the highest value in level of responding to distinct ecotourism activities (38.54).

- Çubukçu has the highest values in accessibility (36.8), source diversity of the focus (27.6), and visual attractiveness of the focus (27.51). In terms of other 7 criteria, the focus is inadequate as an ecotourism focus.

- While Titus tunnel and surroundings is available for ecotourism in terms of source diversity of the focus (28.4), protected ecosystem elements (28.6), visual attractiveness of the focus (38.24), knowledge level of the eco-tourists on both the area and the source, and their attitude and behavior concerning the core of the ecotourism activities (30.8), and effects of visitor use on the ecotourism source (23.1), it should be developed in other 5 criteria.

- Tomb of St. Hızır and surroundings is available for ecotourism in terms of accessibility (39.3), level of responding to distinct ecotourism activities (26.7), social interaction level (26.5), knowledge level of the eco-tourists on both the area and the source, and their attitude and behavior concerning the core of the ecotourism activities (38.0).

- Vakıflı village is inadequate as an ecotourism focus in terms of protected ecosystem elements (17.4), available tourism infrastructure (11), available tourism superstructure (18.9), and effects of visitor use on the ecotourism source (15.6). However, this focus got the highest ECOS value calculated for optimum ecotourism route.

- Çevlik port and surroundings got the highest value compared to other focuses in accessibility (39.73). In addition, it is available as an ecotourism focus in terms of level of responding to distinct ecotourism activities (26.4), protected ecosystem elements (27.1), visual attractiveness of the focus (26.19), and effects of visitor use on the ecotourism source (21.1).

- Milleyha wetland is among low priority focuses only in accessibility (28.0) and protected ecosystem elements (35.06). The other 8 criteria should be developed in priority.

- Çamlıyayla is among the low priority group only in terms of level of responding to distinct ecotourism activities (24.1) and visual attractiveness of the focus (29.44). The other 8 criteria should be developed in priority.

- Aknehir is among the focuses with low priority in terms of accessibility (25.6), level of responding to distinct ecotourism activities (26.7), and visual attractiveness of the focus (21.51).

- Eriklikuyu needs development in terms of source diversity of the focus (17.14), protected ecosystem elements (17.8), available tourism infrastructure (4.5), available tourism superstructure (1.5), social interaction level (15.2), and effects of visitor use on the ecotourism source (15.4).

- Yoğunoluk has the lowest value compared to other focuses in terms of available tourism superstructure (1.37). The focus has low priority in accessibility (32.67), level of responding to distinct ecotourism activities (35.6), and visual attractiveness of the focus (29.2).

- Sutaşı has low priority in accessibility (37.6), level of responding to distinct ecotourism activities (26.5), and available tourism infrastructure (33.2).

Optimum ecotourism route

The total ecotourism opportunity spectrum values of the focuses have been calculated in order to determine the ecotourism route of the study area (*Table 5*). The highest spectrum value for the ecotourism route is 400. When total spectrum values of the focuses in *Table 5* are analyzed, the highest value among the focuses that comprise the ecotourism route belongs to Vakıflı village (271.86), and the lowest value belongs to Milleyha wetland (136.92).

The other focuses have been categorized in terms of spectrum values that make up the ecotourism route and in this respect

- the focuses with the highest values for identifying the ecotourism route are Vakıflı village (271.86) and Hıdırbey (256.49), respectively;

- the focuses with the medium values for identifying the ecotourism route are Meydan village (241.08), Mağaracık (230.9), Batıayaz village (227.9), Titus tunnel and surroundings (211.94), Kapısuyu village (211.46), Çevlik port and surroundings (211.45), Çubukçu (203.47) and Tomb of St. Hızır and surroundings (200.09), respectively;

- the focuses with the lowest values for identifying the ecotourism route are Eriklikuyu (198.9), İskenderun-Arsuz wildlife improvement site (195.77), Yoğunoluk

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_27012715
© 2018, ALÖKI Kft., Budapest, Hungary

(192.51), Yaylıca (189.79), Amanos mountains Musa mountain zone (185.3), Sutaşı (181.61), Keldağ (181.06), Aknehir (159.8), and Çamlıyayla (152.25), respectively.

Conclusion

In the light of the obtained findings, the results that can contribute to identifying the optimum ecotourism route among the studied focuses are as follows:

- The Samandağ coastal zone and its surroundings, selected as the study area, involves many ecotourism areas rich in natural, cultural, religious, and historical heritage. Considering these areas/focuses, which are evaluated individually, collectively in such a way as to form an ecotourism route demonstrates the significance of the study.
- The Samandağ coastal zone and the surrounding ecotourism sites close by have been accepted as ecotourism focuses within the scope of this study and 20 focuses have been identified. The "ecotourism opportunity spectrum" method has been applied in order to analyze these focuses in such a way to determine an optimum ecotourism route.
- By determining the optimum ecotourism route, the purpose was to evaluate the availability of the options that would comprise the route. The highest spectrum value calculated by applying the method was 400. The aim was forming an ecotourism route with focuses at this value.
- However, when the spectrum values of the focuses were analyzed, it was seen that they could not reach the 400 target. While the highest spectrum value belonged to Vakıflı village with 271.86, the lowest spectrum value was 136.92 for Milleyha wetland.
- The spectrum values between 271.86 and 136.92 have been divided into three categories according to their weighted scores. In this categorization the focuses with the highest value were considered to be the most suitable ones for the route. The other two categories involve medium and low value focuses.
- The suitable medium and low value focuses have been analyzed at the results section in terms of criteria determined with the Ecotourism opportunity spectrum method. The analysis is both important for determining the availability of focuses for the ecotourism route according to criteria and the improvement priority of focuses for being used as ecotourism sites. The spectrum value of focuses improved in terms of their lower criteria will rise and thus they will reach the optimum level for ecotourism route.
- The ECOS method used in the study is advantageous in evaluating the availability of the focuses compared to other methods. The results obtained through this method can serve as a basis for studies like ecotourism management plan or site use plan.

Abstract. To reach the emission standard of PCDD/Fs, different influencing factors of removal efficiency of traditional activated carbon injection (ACI) process were considered in this research. Besides, a modified activated carbon injection (ACI) process was developed to improve the removal efficiency of PCDD/Fs. Results showed that removal efficiency of PCDD/Fs using activated carbon A (fitted the dioxin molecular size) was higher than using B (commercially available powder activated carbon) with the same dosage of 1000 mg/m^3. And contact time extended to 8 s was a better choice. Vapor pressures of PCDD/Fs congeners influenced the gas/particle partitioning of PCDD/Fs removal efficiencies. The modified ACI - pulse ACI process demonstrated higher dioxins removal efficiency (~99.6%) than the traditional method due to the increased thickness of carbon layer and total residence time of carbon.
Keywords: *pulse activated carbon injection, dioxins, carbon species, dosage, contact time, vapor pressure*

Introduction

The incineration of medical waste discharges large quantity of polychlorinated dibenzo-p-dioxins and polychlorinated dibenzofurans (PCDD/Fs), widely known as dioxins. Dioxins are potentially toxic chemicals with serious health hazard even at extremely low doses. The majority of dioxins tend to travel long distances before falling to earth with rainfall or settling as particle (Singh and Prakash, 2007). Additionally, dioxins are extremely persistent with an estimated half-life of 7-11 years in humans (Schecter et al., 2006). Currently, activated carbon injection (ACI) in combination with bag filter has been found to be an effective alternative to the conventional process for the removal of vapor-phase dioxins at low concentrations in the flue gas from waste incinerator (Abad et al., 2003; Gunes et al., 2015; Chi et al., 2008). However, the low attainment rate of the PCDD/Fs discharge from medical waste incineration flue gas in the whole country indicates that the traditional ACI is far less efficient to meet the national requirement 0.5 TEQ ng/m^3 (MEP, 2001). Especially in Shanghai, the new emission standard of 0.1 TEQ ng/m^3 is much stricter. Thus, there is an urgent need for a more efficient PCDD/Fs removal method for old projects transformation and new projects construction. Besides, the use of the adsorbents is less efficient and may lead to an increase in the total amount of emissions from the incineration plant (flue gas + cyclone ash + reacted ash) (Chang and Lin, 2001). Another issue is the reliability of results on dioxins formation based on laboratory studies, which depends on the use of model compounds (Debecker et al., 2011). Several factors influence the removal efficiency of ACI and bag filter system, including gas/particle partitioning of PCDD/Fs

(Chang et al., 2002), species and dosage of activated carbon (AC) (Abad et al., 2003; Kim et al., 2007; Tejima et al., 1996), injection rate (Gunes et al., 2015), contact time of activated carbon and PCDD/Fs (Karademir et al., 2004), gas/particle partitioning (Karademir et al., 2004), and injection method among others. Tejima et al. (1996) reported that the removal efficiency of PCDD/Fs could reach over 99% with activated carbon dosage of 50-100 mg/m^3. Similar results were reported by Abad et al. (2003) and Everaert et al. (2003). Gunes et al. (2015) reported that the optimum ACI rate for PCDD/Fs was 66 mg/m^3 with removal efficiency was 97% and no significant difference in efficiency was observed at ACI rate of 197 mg/m^3. Some studies have reported the use of a double-bag activated carbon adsorption process on the basis of the traditional ACI process with a single bag for the removal of PCDD/Fs in a medical waste incinerator system (Kim et al., 2007; Mckay, 2002; Chen et al., 2014; Lin et al., 2008). Though higher removal efficiency was achieved using less amount of activated carbon, the capital and operating costs increased significantly. Li et al. (2008) added a bio-solution (NOE-7F) to the raw materials, which inhibited PCDD/F formation and combining both ACI and NOE-7F had a high potential for practical application. By the addition of NOE-7F in the stack flue gas, the fraction of total PCDD/F was reduced by 92.4%, which was not high enough to meet the EU emission standard. Ooi et al. (2008) reported the removal of vapor phase PCDD/Fs by adsorbing into plastics instead of activated carbon and the removal efficiency was over 99%. The experiments, however, were conducted in an electric arc furnace steel plant. There have been no reports so far about modification of ACI method as applied to medical waste incinerators.

Therefore, this paper introduces the very first modified injection method for PCDD/Fs removal examined in a commercial-scale medical waste incineration facility in Shanghai and evaluates its efficiency. Influences of traditional injection method on PCDD/Fs removal are also examined for comparison, including species and dosage of activated carbon, contact time, and gas/particle partitioning.

Materials and methods

Full-scale medical waste incinerator

The medical waste incinerator researched is located in Shanghai, China. The dealing capacity of the incinerator plant is 2400~2500 metric ton/day and operates 300 days per year. The incinerator has a two-stage combustion system consisting of a rotary kiln of 4.3 m diameter. The temperatures of the rotary kiln head and kiln are 870~890 °C and 1020~1050 °C separately. The original air pollution control system included quench tower, dry-type reactor, traditional ACI, bag filter, and wet scrubbing tower, and the efficiency was 97.5%, which met the Chinese emission standard of dioxins (0.5 TEQ ng/m^3). However, to reach the Shanghai limit (0.1 TEQ ng/m^3), the ACI process needs to be retrofitted. Besides, SO_2 and HCl are captured by powdered $Ca(OH)_2$ injection.

Activated carbon A used in the test fitted the dioxin molecular size (the average relative molecular size of dioxins and furans is 10 angstroms (1 nm)). Activated carbon B is commercially available powder activated carbon. Their characteristics are presented in *Table 1*.

The International Theoretical and Applied Chemistry Federation has defined the pore size as follows: small pores: < 2 nm in diameter, middle pores: 2-5 nm in diameter, large pores: > 50 nm in diameter. Iodine value is an index reflecting the level of iodine adsorption in water, which shows the micro pore volume of activated carbon. Molasses

Description of the Pulse ACI Unit

Activated carbon injection is an important approach to control dioxins in flue gas. Traditional ACI process injects activated carbon continuously for cleaning the flue gas (Abad et al., 2003; Gunes et al., 2015). Since the activated carbon adsorption process is carried out at high temperature and humidity, and at a wide concentration range of dioxins in the flue gas, the equilibrium adsorption capacity and contact time is limited by the thermodynamics. Therefore, to achieve a dioxins removal efficiency of over 99%, a modified ACI technology is needed in addition to using the increased amount of activated carbon and contact time.

The AC injection method was modified in this study and is known as pulse activated carbon injection method. During the bag cleaning cycle, first dose of large amount of activated carbon was injected in a short time and then a small amount of AC was added steadily. The whole process was carried out periodically. Since the diagram of the activated carbon dosage and time represents like a pulse signal, the method is termed as pulse ACI. The improved method does not increase the amount of activated carbon dosage needed. The bag cleaning cycle is one hour. During the bag cleaning cycle, there were two dosage stages. In the first stage, it took 30 s to dose 50% of the total activated carbon dosage. In the next stage, it took the one hour to dose the remaining 50% of the total activated carbon continuously and uniformly. The pulse method is shown in *Figure 1*. The dotted line represents the traditional method while the solid line represents the pulse method. Keeping the total activated carbon dosage same in both methods, the areas of the shadow in the *Figure 1* are equal in one bag cleaning cycle.

Sampling and analyses

Flue gas samples were taken from four sampling points and the locations of flue gas sampling points are shown in *Figure 2*. The emission of PCDD/Fs in flue gas was measured simultaneously at four sampling points.

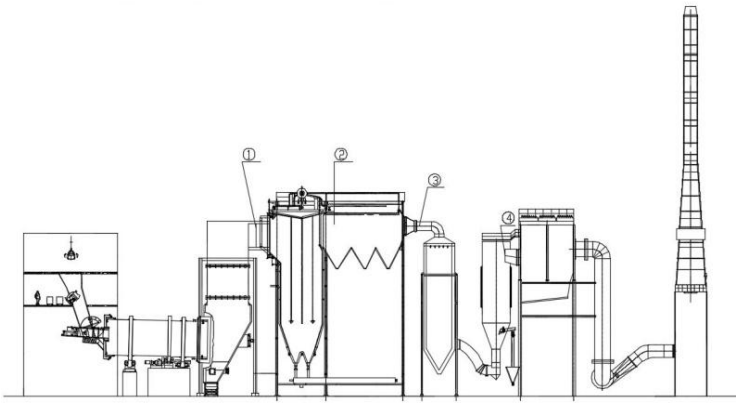

Figure 2. *Sampling points: (1) the post-combustion chamber outlet; (2) the high temperature point in the waste heat boiler (entrance point); (3) the waste heat boiler outlet; (4) the bag filter inlet*

Sampling procedures are as follows. First, the sampling device was installed according to European Standard Protocols EN1948-1 and the air tightness of the sampling system was checked. Then the sampling tube was inserted into the flue sampling point, and the sampling hole was closed. And then the sampling nozzle was aligned with the gas flow direction, and the sampling pump was started to adjust the sampling rate. During the sampling period, when the pressure and temperature changed greatly, it was necessary to adjust the flow rate in time. If the resistance of the filter cylinder increased too large to keep a constant sampling speed, the filter cartridge should be replaced and then continue to sample. In the process of sampling, special attention was paid to keeping the gas phase adsorption column out of light and below 30 °C. After sampling, the sampling pump was stopped and the sampling tube was drawn out at the same time. Besides, time, cumulative flow and other parameters were recorded. At last, the sampling device was removed without light and the cartridge was also removed and wrapped with aluminum foil. The sampling tubes and connecting pipes were washed with toluene. Washing liquid and condensed water were saved in brown reagent bottle.

Main apparatus and equipment used in field sampling (shown in *Fig. 3*) include four sets of quartz cooling, buffer bottle, adsorption bottle, and so on (self-designed); four ice baths with circulating pump sampling box; three sampling device lifting frames; one aneroid barometer; digital temperature and humidity meter (Finland HM34); digital pressure gauges (German MUR DM9100); S-type Pibtot's tubes and hot bulb anemometers.

Analysis was conducted by the Belgian SGS company. The analytical method was US EPA Method 23 (US EPA1995). Identification and quantification of PCDD/Fs were performed by HRGC/HRMS using a 7890 Series gas chromatograph (Agilent, USA) and AutoSpec Premier (Waters).

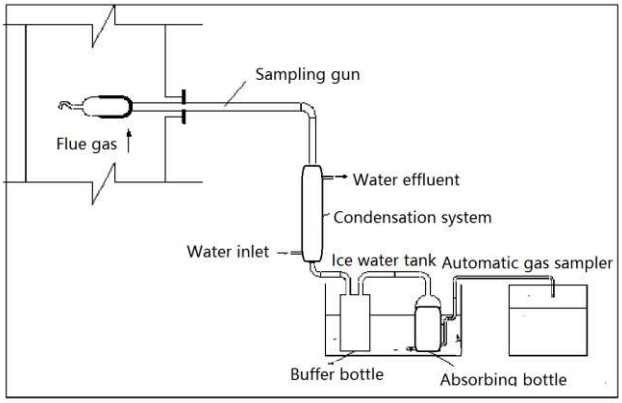

Figure 3. *Flow chart of sampling system*

The results of each selected influencing factors of PCDD/Fs removal efficiency were statistically analyzed. If the factor had significant influence on PCDD/Fs removal efficiency, the probability in the result of variance analysis must be less than 0.05 or at least equal to 0.05 ($P \leq 0.05$).

Results and discussion

PCDD/Fs removal efficiencies of conventional ACI process

Effect of activated carbon types and dosage on PCDD/Fs removal efficiencies

ACI method involves injecting a certain amount of solid adsorbent into the flowing gas before bag filter and then separating the adsorbent before discharging the gas (Karademir et al., 2004). ACI technique transfers dioxins from gas phase to solid phase and further treatment (such as bag filter) is usually required. As discussed above, activated carbon type and dosage are two important factors that affect the removal efficiency of dioxins. These two factors were examined in this study. Both activated carbon A and activated carbon B were added at the entrance of the bag to study the effect of activated carbon types on dioxins removal. The dosages of activated carbon A and B were 100 mg/m^3 and 1000 mg/m^3. The results are summarized in *Table 2*.

It can be seen from *Table 2* that ACI technology showed high removal efficiency for PCDD/Fs. ACI system and bag filter are used to remove the gas phase and particle phase PCDD/Fs, respectively (Gunes et al., 2015). Since PCDD/Fs compounds in gas phase comprised of the majority of the pollutants tested, adsorption of gas phase compounds on the AC and then removal of AC and compounds in particle phase on filter was proved to be an effective way of removal of total PCDD/Fs in flue gas instead of using bag filter alone.

The addition of same dosage (i.e., 100 mg/m^3) of activated carbon, the average removal efficiency of activated carbon A was much higher (92%) than that of activated carbon B (82%). Abad et al. (2003) reported 92-96% PCDD/Fs removal efficiency at activated carbon dosage of 100 mg/m^3. Everaert et al. (2003) also found the removal efficiency of 93-94% at activated carbon dosage of 50-100 mg/m^3 in ACI. However, the results showed that the PCDD/Fs removal efficiency at this dosage is still very low to meet the strict emission requirements of 0.1 TEQ ng/m^3.

Table 2. *Removal efficiencies of PCDD/F congeners by different AC species and dosage*

Congener	Removal efficiency (%)			
	A 100 mg/m^3	**A 1000 mg/m^3**	**B 100 mg/m^3**	**B 1000 mg/m^3**
2378-TCDF	93.7	97.5	88.8	96.6
12378-PeCDF	95.2	96.3	84.8	94.9
23478-PeCDF	92.5	96.0	86.4	92.5
123478-HxCDF	95.5	96.0	87.1	94.2
123678-HxCDF	95.9	96.5	87.7	91.6
234678-HxCDF	93.2	95.8	82.4	92.7
123789-HxCDF	93.4	93.8	87.5	89.1
1234678-HpCDF	91.6	96.3	88.1	90.7
1234789-HpCDF	90.6	95.8	81.7	90.1
OCDF	85.5	96.1	82.6	87.1
2378-TCDD	85.1	94.2	81.2	79.2
12378-PeCDD	93.0	94.6	89.0	91.8
123478-HxCDD	94.1	95.7	86.3	90.8
123678-HxCDD	94.1	96.3	89.4	90.5
123789-HxCDD	92.6	95.3	87.1	89.1
1234678-HpCDD	90.1	97.1	87.8	89.7
OCDD	84.2	97.9	85.6	88.2
PCDD/Fs	89.5	96.0	86.6	92.1

Single factor analysis of the data of these two types of AC had P-value of 1.22×10^{-5} (< 0.05), indicating that AC types has a significant effect on the PCDD/Fs removal efficiency. Since activated carbon A has higher specific surface area and pore size, which is ideal for the removal of dioxins, it has higher adsorption capacity and removal efficiency.

Higher dosage of activated carbon was needed to achieve higher removal efficiency. The dosages of the activated carbon A and B were both increased from 100 to 1000 mg/m^3. The single factor analysis of the data for activated carbons A and B had P-values of 2.15×10^{-5} and 0.000347, respectively, which are far below 0.05, indicating that the dosage also has a significant effect on the removal efficiency. For both types of activated carbon, removal efficiency improved with increasing the dosage. However, the increase in efficiency was not obvious. For activated carbon A, removal efficiency of low and high chlorine content congeners increased more compared to medium chlorine content congeners. For activated carbon B, the efficiency showed variability with the increase of the chlorine atom number. For the congeners with same number of chlorine atoms, the efficiency differed with the position of chlorine atom substituted and differed from dioxins to furans, especially 2,3,7,8-TCDD and 2,3,7,8-TCDF, which showed significant difference. Although activated carbon A at 1000 mg/m^3 had the highest removal efficiency for all congeners, the advantage was not significant; likely due to saturation of its adsorption capacity. Since the injection point of activated carbon at the batch experiment was at the inlet of the bag filter, the contact time of the flue gas and activated carbon was limited, which could have resulted overall low removal efficiency (~96%).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_27172728
© 2018, ALÖKI Kft., Budapest, Hungary

Since the flue gas generation rate from medical waste incinerator is significantly less than that from large domestic waste incinerator, the dosage of the activated carbon A was increased to 1000 mg/m^3 which resulted in increase in the removal efficiency of PCDD/Fs from 90 to 96%. However, the increase of PCDD/Fs removal efficiency was not always consistent with the increased dosage of activated carbon. Everaert et al. (2003) reported no significant change in removal efficiency at injection rates over 200 mg/m^3. Chang et al. (2001) expressed that the higher AC injection would not significantly increase the dioxin removal efficiency when the injected AC concentration was over 50 mg/Nm^3 and a large amount of activated carbon would lead to an increase in total dioxin emissions (flue gas + cyclone ash + reacted ash). Gunes et al. (2015) also reported no significant difference in removal efficiency at 197 mg/m^3 and 66 mg/m^3 AC injection rate, and the efficiency decreased at 332 mg/m^3 of AC injection rate. Although the efficiency greatly improved at 1000 mg/m^3 of AC dosage, it still failed to consistently meet the EU 2000 guidelines for dioxin emission standards. Considering the dosage of 1000 mg/m^3 was extremely high, no further test was conducted at higher dosage of activated carbon from the thermodynamics stand point. Similarly, increasing the dosage of activated carbon B by 10-folds could only reduce the dioxin emissions by about 50% (from 0.15 to 0.08 TEQ ng/m^3). No further significant improvement was achieved at higher dosage of activated carbon injection. Thus, there is a need to explore advanced technology to improve the removal efficiency of the flue gas contaminants.

Effect of contact time on PCDD/Fs removal efficiencies

Contact time or residence time, is very important factor affecting adsorption of organic compounds on activated carbon (Karademir et al., 2004). However, only very limited studies has explored the effect of contact time on adsorption of organic compounds on activated carbon at full-scale medical waste incinerator. Since the concentration of dioxins in flue gas is at TEQ ng/m^3 level, the driving force for the mass transfer from flue gas to activated carbon is relatively small compared to emissions of other pollutants at significantly high concentrations. In order to improve the mass transfer rate, a reasonable increase in contact time of activated carbon and flue gas becomes an important factor to increase the adsorption rate and efficiency. The previous injection point was at the entrance of the bag filtration and the average contact time was less than 2 s. After modification of the injection point to the dry fluidized bed, the average contact time was more than 8 s. The removal efficiency was compared under the same injection and burning conditions as shown in *Figure 4*. The injected activated carbon types and dosage were specialized ones with 1000 mg/m^3.

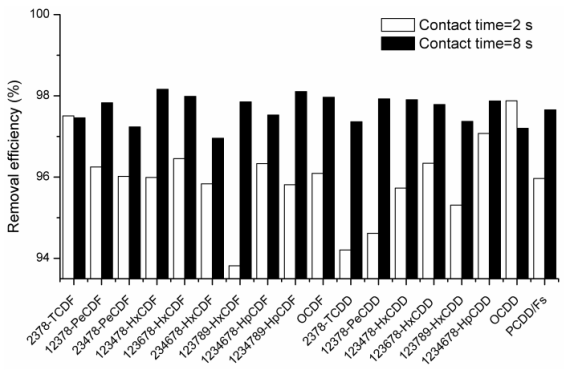

Figure 4. *Removal efficiencies of PCDD/F congeners through different contact time*

DOI: http://dx.doi.org/10.15666/aeer/1603_27172728
© 2018, ALÖKI Kft., Budapest, Hungary

Figure 4 shows that removal efficiency of PCDD/Fs improved from 96 to 98%. The removal efficiency of 17 congeners except 2,3,7,8-TCDF and OCDD increased. The highest increase in removal efficiency was from 93.8 to 97.9% for 1,2,3,7,8,9-HxCDF and the lowest increase was from 97.1 to 97.9% for 1,2,3,4,6,7,8-HpCDD. Although the increase in contact time improved the removal efficiency, the removal efficiency was still below the emission standard. Thus, modified ACI process was examined to improve the efficiency as discussed in the following section.

Effect of activated carbon on the removal of dioxins in the gas and solid phases

The distribution of dioxins in gas and solid phases is a very important factor for dioxins removal. The effect of activated carbon on the removal of dioxins in gas phase and solid phase was studied in order to further study the improvement of the active carbon injection method. The injection condition was activated carbon A dosage of 1000 mg/m^3 at the dry fluidized bed and the burning condition was discussed in section 2.1. The results are presented in *Figure 5*.

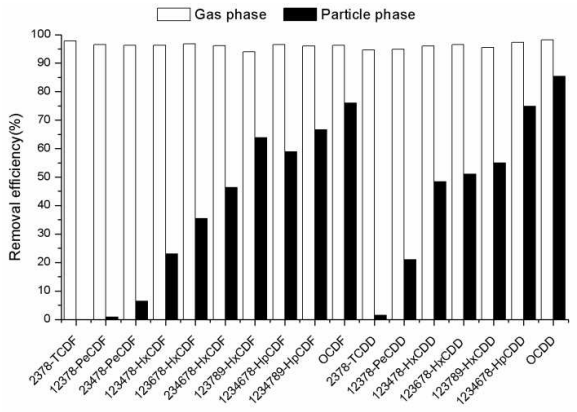

Figure 5. *Removal efficiencies of PCDD/F congeners for gas and particle phase*

Activated carbon has high removal efficiency of dioxins in the flue gas. The removal efficiency of PCDD/Fs in flue gas was 97.1%. But the removal efficiency was much lower for the particle state (~75.5%), indicating that ACI was more effective to treat dioxins in gas phase. The removal efficiencies of particulate dioxins and PCDD/Fs with higher molecular weight were higher than that with lower molecular weight. The increase in removal efficiency showed a linear trend with increase in molecular weight, which indicates that part of PCDD/Fs with low molecular weight was in the nanometer aerosol state leading to low efficiency of traditional ACI process. However, considering that the proportion of dioxins in the gas phase was more than 98%, gaseous dioxins were the main target of the dioxin emission control.

From other aspect, the removal efficiencies of both low chlorinated and high chlorinated congeners in gas phase were high in PCDD and PCDF, while the efficiencies of congeners in particle phase increased with the increase of chlorine content of both PCDD and PCDF. This is mainly attributed to different vapor pressures of congeners and adsorption capacity of activated carbon for dioxins in gas and solid phases (Chang et al., 2002). Less chlorinated congeners have higher vapor pressure and tend to exit in gas phase, which are more likely to be adsorbed by activated carbon

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_27172728
© 2018, ALÖKI Kft., Budapest, Hungary

(Gunes et al., 2015). On the other hand, higher chlorinated congeners tend to exist in solid phase due to their lower vapor pressures. Hence, the removal efficiency of less chlorinated congeners in gas phase is higher than that in the solid phase, while the removal efficiencies of higher chlorinated congeners show the opposite trend. With the increase in chlorine content, the removal efficiencies of congeners in particle phase increased because more congeners tend to exist in particle phase. *Figure 6* shows the average efficiencies of the three tests for PCDD/F homologues and their relationship with the vapor pressure (log P) at 25 °C (Li et al., 2008).

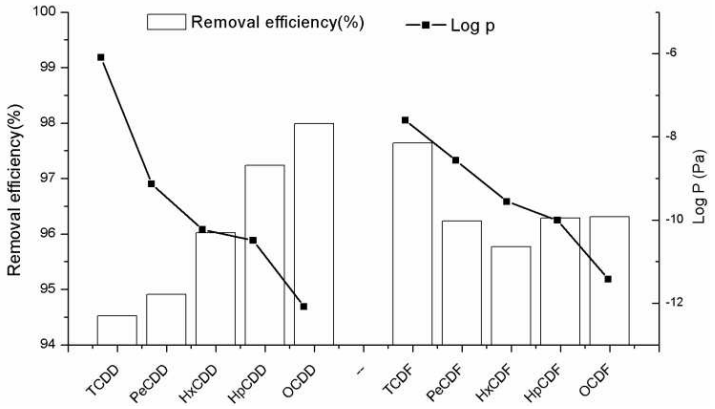

Figure 6. *Average removal efficiencies of PCDD/F homologues*

Figure 6 shows that as chlorination level of PCDD homologue increased, removal efficiencies increased while vapor pressure declined. For PCDF, both removal efficiencies and vapor pressure declined with increasing chlorination. The results of PCDF removal were in consistent with other studies (Chang et al., 2002; Karademir et al., 2004). The PCDD removals, however, showed the opposite trend with that of the above literature. Further studies are needed to identify the discrepancy.

The traditional ACI tests showed that the highest removal efficiency was 97.7% with 1000 mg/m^3 of activated carbon A injected in the dry fluidized bed (contact time is 2 s). In practical projects, activated carbon dosage is far less than 1000 mg/m^3 because of the reasons mentioned above, so the highest removal efficiency was 96%. When the TEQ concentration of PCDD/Fs in the flue gas was higher than 5 TEQ ng/m^3 (the lowest emission concentration), the emission standard of 0.1 TEQ ng/m^3 could not be achieved through the traditional ACI process. Therefore, to achieve higher removal efficiency, activated carbon injection method needs to be modified besides increasing the amount of activated carbon, selecting an appropriate activated carbon, and increasing contact time.

PCDD/Fs removal efficiencies of pulse ACI process

The two methods, namely pulse ACI and continuous ACI, were tested under the same conditions with the same activated carbon dosage to evaluate their efficacies in PCDD/Fs removal. The results are shown in *Figure 7*.

The removal efficiency of total dioxins increased from 96.9 to 99.7%, and the emissions were reduced by more than 90% (from 49.62 TEQ ng/m^3 to 1.56 TEQ ng/m^3).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_27172728
© 2018, ALÖKI Kft., Budapest, Hungary

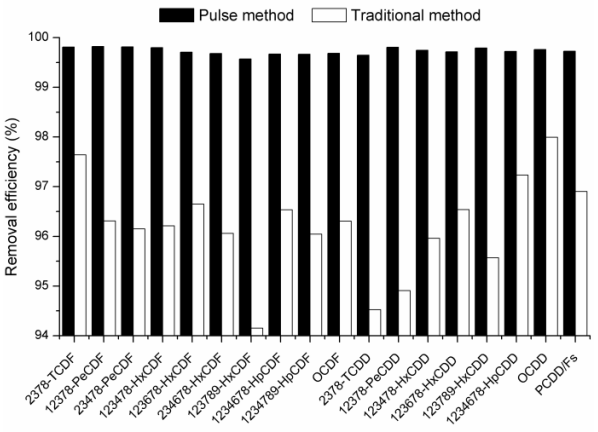

Figure 7. *Removal efficiencies of PCDD/F congeners by traditional and pulse method*

From *Figure 7* it can be seen that for the 17 PCDD/F congeners, PCDD/Fs removal efficiency of pulse ACI method was obviously higher than that of continuous ACI method. The results clearly show that the removal efficiency of dioxins by pulse method was higher than that by continuous method, especially for middle chlorine (4-6) compounds.

The average removal efficiencies of PCDF and PCDD with continuous stable method were nearly same (e.g., 96.2% and 96.1%, respectively). The removal efficiencies of both PCDF and PCDD with pulse method were much higher at 99.7%, indicating that modified method was effective for both PCDD and PCDF removal. Removal efficiencies of 17 congeners with pulse method were very consistent while the efficiencies of continuous stable method varied greatly from PCDF to PCDD and with the chlorine content. Since congener profiles and formation mechanism of PCDD/Fs in flue gas are influenced significantly by chlorine content (Wang et al., 2003) and temperature (Mckay, 2002), and high emission of MWIs (medical waste incinerators) may result from non-continuous operations, irregular waste feeding (Choi et al., 2008), and poor operating conditions (WHO, 2011), it is often difficult to maintain stable emission. Hence, the pulse method, which provides relatively stable removal efficiency, has broad application prospects.

As discussed earlier, activated carbon mainly adsorbs dioxins in the gas phase. Taking into account that dioxins and activated carbon are basically maintained at the same flow rate for contact during the continuing activated carbon adsorption process and since the movement between gas and the solid is relatively small and the gas film on the surface of activated carbon is thick, the mass transfer process mainly relies on molecular diffusion. Under such circumstance, the adsorption rate in gas phase is low and thus the utilization of activated carbon. Another drawback is that the activated carbon contained pollutants is enriched on the surface of the bag, increasing the possibility of partial overheating and further release of the pollutants to the flue gas.

Large amount of activated carbon are injected in pulse ACI process in a short time in order to form activated carbon layers on the surface of the bag quickly and then reduce the injection rate, while in continuous ACI process, activated carbon injection rate is constant. The surface of the bag type dust collector also acts as a fixed bed when in contact with flue gas. These two types of activated carbon processes were combined in one system thereby saving the space. Due to different gas and solid velocities, turbulent

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_27172728
© 2018, ALÖKI Kft., Budapest, Hungary

flow occurs in the gas phase thereby reducing the thickness of gas film around the surface of the activated carbon. This results in an improvement in mass transfer efficiency. Moreover, the length of activated carbon layers exceeds the length of the mass transfer zone that prevents penetration at the beginning and the reduction in efficiency. Thus, the inner layer of the activated carbon layer remains relatively cleaned for further purification of the gas through the bag to avoid gaseous phase PCDD/Fs release from the contaminated filters of the aged bag filters because of memory effect (Li et al., 2011).

Studies are being currently conducted focusing on reducing the time of second period which is continuing the PAC adsorption process, in order to reduce the total amount of injected carbon.

Conclusions

In this study, different influencing factors of traditional ACI method removal efficiency and a developed ACI technology in a medical waste incineration plant were investigated.

Vapor pressures of PCDD/Fs congeners influenced the gas/particle partitioning of PCDD/Fs and dioxin removal efficiencies. The vapor pressure of PCDD/Fs congeners decreases with increasing chlorination and ACI was more effective to remove dioxins in gas phase than in the solid phase.

The removal efficiency could be improved by selecting appropriate adsorption activated carbon species, increasing the dosage of activated carbon, and increasing the gas solid contact time. Activated carbon A was better than B with dosage of 1000 mg/m^3 at a contact time exceeding 8 s.

At the current optimal conditions using the traditional continuously stable activated carbon injection method, average removal efficiency was not high enough to meet the flue gas dioxin emission standards of 0.5 TEQ ng/m^3. Thus, the EU dioxin emission limits in waste incineration of 0.1 TEQ ng/m^3 is very unlikely to be achieved. The pulse activated carbon injection (Pulse ACI) method developed in this study has shown that higher dioxin removal efficiency of 99.7% than the current traditional method could be obtained, making it possible to achieve the dioxin emission limit of 0.1 TEQ ng/m^3.

(Received 25th Jan 2018; accepted 25th Apr 2018)

Abstract. The aim of this study was to determine the influence of biological preparations and mineral fertilizers on total protein and crude fiber in *Dactylis glomerata* and *Lolium perenne*. The study was carried out in years 2011-2014 in three repetitions, on 3 m^2 experimental plots. There were mineral, biological or both mineral and biological fertilization applied on the grass. Mineral fertilization included nitrogen, phosphorus, potassium. There were used three biological preparations named UGmax, Humus Active Papka and Eko-Użyźniacz in the studies. For both grass species Eko-Użyźniacz applied together with mineral fertilizers increased protein content in fodder. Application of Humus Active Papka with mineral fertilizers lowered crude fiber concentration in fodder. The highest concentration of total protein was in *Dactylis glomerata* and *Lolium perenne* from the plots where soil conditioners together with mineral fertilizers were applied. The most advantageous concentration of crude fiber was in *Dactylis glomerata* growing on the plot with Humus Active Papka together with mineral fertilizers applied, while in *Lolium perenne* on the plot with Eko-Użyźniacz applied, without mineral fertilizers.
Keywords: *Dactylis glomerata, Lolium perenne, biopreparate, soil amendment, soil fertilizer, grass*

Introduction

The vegetation of pastures and meadows consists mainly of grass, so important in ruminant nutrition, with *Dactylis glomerata* being one of the most nutritional species there (Stewart and Ellison, 2011; Billman et al., 2017; Jones et al., 2017). It contains a high amount of total protein, but a lot of substances, like crude fiber, lower its digestibility (Ellis et al., 2011; Tilvikiene et al., 2014; Cullen, 2017). Another popular grass species in permanent grasslands is *Lolium perenne* but, contrary to *Dactylis glomerata*, its total protein content is lower even if it is more digestible because of low fiber content (Turner, 2006a; Xiong et al., 2006; Robins and Lovatt, 2016,). According to many publications total protein content in fodder from permanent grasslands in Poland is diversified (Heinsoo et al., 2010; Jankowska-Huflejt and Wróbel, 2010; French, 2017). This content varies dependent on the species, its variety, the amount of nutrients in the soil (mainly nitrogen), the growing stage of the plant, the weather, and the grass cutting (Walter et al., 2012; Grant et al., 2014; Zielińska et al., 2014; Loaiza, 2017). Minimum content of total protein should range from 150 to 170 g kg^{-1}. This amount of protein is indispensable for proper absorption of nutrients in the digestive system of dairy cows (Peeters, 2008; Grygierzec, 2012). Crude fiber has a big impact on nutritional value of the feed and animal health, and its concentration is dependent on the species, the variety of a plant, its age, the cutting, the fertilizers used, and precipitation

(Mertens, 2002; Pozdisek et al., 2003; Arzani et al., 2004; Jankowska-Huflejt and Wróbel, 2010). For a balanced level of nutrient digestibility and energy value of feeds, the concentration of fiber should not exceed 28 - 30% DM (Bumane, 2010).

Now there is a growing interest in organic farming and biological products such as fertilizers, soil conditioners, and similar substances approved by the Institute of Soil Science and Plant Cultivation (IUNG) in Puławy. This growing interest in biological products enhancing quality and quantity of crops is reflected in many publications (Sosnowski, 2012; Sosnowski et al., 2014; Sosnowski and Jankowski, 2015; Truba et al., 2017). However, not many studies are concerned with the effects of those products on the content of total protein and crude fiber in forage grass.

Considering the above, the aim of this paper is to study the effects of some soil conditioners on the content of total protein and crude fiber in *Dactylis glomerata* and *Lolium perenne*.

Materials and methods

Characteristic of field site

A randomised experiment in blocks replicated three times was set up in the experimental station of the Department of Grassland and Green Areas Creation of the University of Natural Sciences and Humanities in Siedlce in Poland (52.169°N, 22.280°E). According to the Polish soil classification system (Systematics of Polish Soils, 2011), the soil used in the experiment was the culture soils with the hortisole type, developed from loamy sand (*Table 1*).

Table 1. *Soil granulometric composition*

Percentage share of soil fractions (diameter in mm)			
2.0-0.05	0.05-0.002	>0.002	Granulometric group
85	13	2	ps

Based on the analysis performed at the Regional Chemical Station in Wesoła, it was found that the soil was of neutral pH (pH in 1n KCL = 6.8), with a high content of humus (3.78%), available phosphorus ($H_2PO_4^-$ - 170 mg kg^{-1}), magnesium (Mg^{2+} - 84 mg kg^{-1}), and moderate content of total nitrogen (N - 1.3 g kg^{-1}) and available potassium (K^+ - 114 mg kg^{-1}).

Characteristic of preparations used in experiment

The aim of the experiment was to compare soil conditioners of the following trade names: UGmax, Eko-Użyźniacz, and Humus Active Papka, used separately and supplemented with NPK fertilizers. In the experiment, there were the following experimental units:

1. control (with no fertilizers),
2. UG (UGmax soil conditioner),
3. EU (Eko-Użyźniacz soil conditioner),
4. HA (Humus Active Papka soil conditioner),
5. NPK,
6. UG + NPK,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_27292739
© 2018, ALÖKI Kft., Budapest, Hungary

7. EU + NPK,
8. HA + NPK.

The UGmax soil conditioner is an extract from compost, containing macronutrients (N, P, K, Mg, Na) and micronutrients (Mn). It also contains lactic acid bacteria, photosynthetic bacteria, *Azotobacter*, *Pseudomonas*, yeast, and *Actinomycetes* (*Table 2*). The microorganisms in the conditioner have a capacity of processing organic and natural fertilizers into compost and humus. These processes are conducive not only to the production of humus but also to improving soil structure, which in turn has a positive effect on water balance in the soil. In addition, the UGmax soil conditioner increases disease resistance, keeping plants healthy, but it also stimulates the development of the root system and supports the biological reduction of molecular nitrogen.

Humus Active Papka contains macronutrients (N, P, K, Ca, Mg), trace elements (Mn, Fe, Zn, Cu), and active humus with useful microorganisms (*Table 2*). According to the manufacturer Humus Active Papka, among other beneficial effects, positively affects plant health as well as soil structure, and releases nutrients not readily available to plants.

Eko-Użyźniacz is extracted from bovine vermicompost and contains the main macronutrients (N, P, K), microorganisms, and enzymes related to metabolism of earthworms (*Table 2*). This soil conditioner stimulates biological life in soil degraded chemically, mechanically, or biologically, and increases plant resistance to different stress factors.

Table 2. *Ingredients of the soil conditioners*

Soil conditioner	Macronutrients (g kg^{-1})						Micronutrients (mg kg^{-1})					Microorganism and others
	N	P	K	Ca	Mg	Na	Mn	Fe	Zn	Cu	Mo	
Humus Astive Papka (HA)	0.2	1.3	4.6	3.0	0.5	-	15	500	3	1	-	Active humus with useful microorganisms
Eko-Użyźniacz (EU)	0.6	0.3	0.7	-	-	-	-	-	-	-	-	Endo micorhizza, fungi, bacteria, enzymes of earthworms
UGmax (UG)	1.2	0.2	2.9	-	0.1	0.2	0.3	-	-	-	-	Lactic acid bacteria, photosynthetic bacteria, *Azotobacter, Pseudomonas*, yeast, *Actinomycetes*

The above biological soil conditioning products were applied in the experiment every year in spring at the following doses: UGmax - 0.6 L ha^{-1}, Eko-Użyźniacz - 15 L ha^{-1}, and Humus Active Papka - 50 L ha^{-1}.

Mineral fertilizers with nitrogen, phosphorus, and potassium (NPK) were applied at the following doses: N – 150, P (P_2O_5) – 80, and K (K_2O) – 120 kg ha^{-1}. Mineral nitrogen was supplied in the form of ammonium nitrate (NH_4NO_3), phosphorus in the form of granulated triple superphosphate ($Ca(H_2PO_4)_2$), and potassium as high

© 2018, ALÖKI Kft., Budapest, Hungary

percentage potassium salt (KCl). Phosphorus was applied once a year in spring, while potassium and nitrogen were used in three doses, before the growing season and before the second and third cuttings.

Plant material and analysis

The above products were tested on two grass species: *Dactylis glomerata* of the Bora variety and *Lolium perenne* of the Info variety, sown in the autumn of 2011 according to the standards of 18 and 23 kg ha^{-1}, respectively. The area of the experimental plot was 3 m^2.

During the three-year experiment in each growing season the grass was harvested three times with dry matter yield determined and chemical analyses carried out. Chemical tests for all the cuttings of the last three years of the experiment were done at the Institute of Technology and Life Sciences in Falenty using near infrared spectroscopy (NIRS) with the Infra Analyzer 450. First of all, the content of total protein and crude fiber was determined.

Weather conditions

Meteorological data for the years of research were obtained from the Hydrological and Meteorological Station in Siedlce. Sielianinov's hydrometric coefficient (K) was worked out to determine variability of weather conditions and their impact on plant vegetation (Skowera and Puła, 2004).

In the first year (2012) optimal weather conditions, with regard to temperature and rainfall, were only in June and October (*Table 3, Fig. 1*). In the rest of the growing season, there was not enough rain, with periods of drought and severe drought. In the next years, dry periods were followed by wet periods, with optimal conditions only in April of 2013 and 2014 but also in July of 2014. In each year of the experiment, the best weather conditions were in the first part of the growing season.

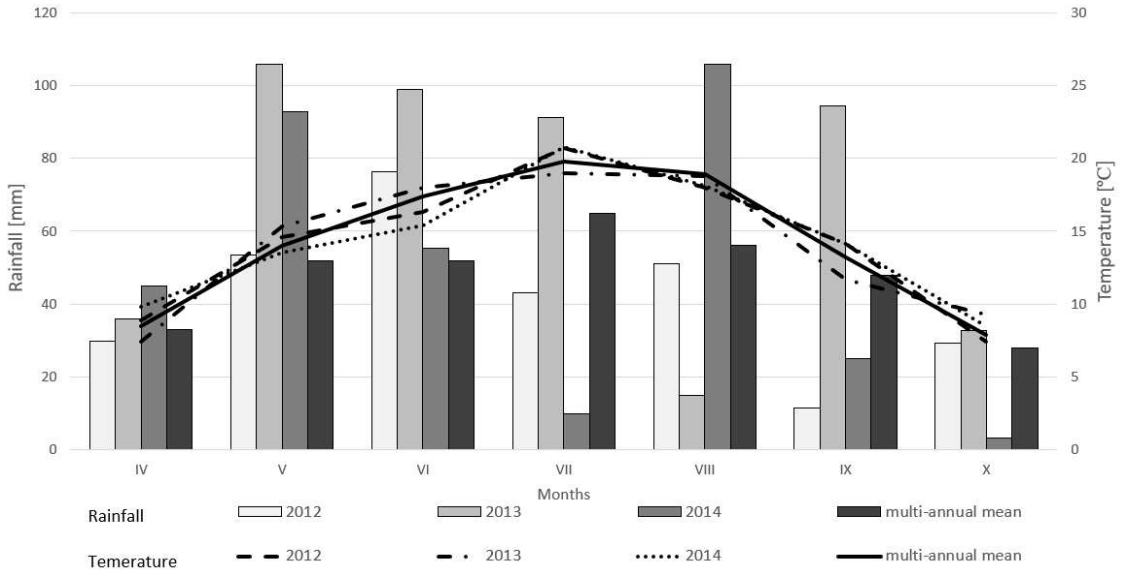

Figure 1. *Average of air temperature and sum of atmospheric precipitation in the months of the growing seasons during the research*

2013	1.60 (o)	2.20 (w)	1.80 (mw)	1.50 (o)	0.25 (ed)	2.70 (sw)	1.22 (md)
2014	1.53 (o)	2.29 (w)	1.20 (md)	0.16 (ed)	1.95 (mw)	0.59 (sd)	0.13 (ed)

$K \leq 0.4$ extreme drought (ed); $0.4 < K \leq 0.7$ severe drought (sd); $0.7 < K \leq 1.0$ drought (d); $1.0 < K \leq 1.3$ moderate drought (md); $1.3 < K \leq 1.6$ optimal (o); $1.6 < K \leq 2.0$ moderately wet (mw); $2.0 < K \leq 2.5$ wet (w); $2.5 < K \leq 3.0$ severely wet (sw); $K > 3.0$ extremely wet (ew)

Statistics analysis

The collected data were analysed statistically using the Statistica 12.0. The mean arithmetic were calculated. Effects of tested factors (grass species, preparations used in experiment, year or cutting) on the content of crude fiber and total protein in plant were estimated using three-way analysis of variance. Detailed comparisons of the mean values were based on Tuckey's test at $p \leq 0.05$.

Results and discussion

Total protein content

Total protein content in the grass species tested in the experiment (*Tables 4* and *5*) varied depending on the fertilizers used, the year of the experiment and the cutting. Generally, no matter what grass species it was, the highest total protein content (*Table 4*) was in experimental variants where bio products together with mineral fertilizers were applied. The highest content of total protein (158.6 g kg^{-1}) was found in the dry matter with Eko-Użyźniacz together with NPK applied. The lowest content of total protein was in grass where the bio product UGmax (127.6 g kg^{-1}) was applied. Low content of total protein could be caused by a lack of nitrogen fertilization or by a late harvest. A lot of publications (Valk et al., 2000; Johnson et al., 2001; Tas et al., 2006; Grant et al., 2014) hold that total protein concentration does not always rise with fertilizer doses. Walter (2012) points out that it may be caused by dilution of total protein concentration in the high amount of yield.

Comparing all years of the experiment (*Table 4*) it was found that no matter what the combination of fertilizers and conditioners was, the highest amount of total protein in dry matter (151.0 g kg^{-1}) was found in the second year (2013) of the experiment, with the lowest (141.9 g kg^{-1}) in the first year (2012) of the experiment, but these differences were not statistically significant. Differences in total protein concentration were caused through the various weather conditions. In the first year of the research objects contained less total protein, in second year compound content increased when time of the regrowth was moderated by the weather. In the last year in growing season occurred a lot of dry periods, therefore protein content decreased.

In the study, there were no significant differences in total protein content between *Dactylis glomerata* and *Lolium perenne* (*Table 5*). According to Turner et al. (2006b) nitrophilous grass species like *Dactylis glomerata*, which contains 212 g of total protein in 1 kg DM, accumulate the highest amounts of this nutrient. A little less protein is produced by *Lolium perenne,* with 129 g in 1 kg DM.

© 2018, ALÖKI Kft., Budapest, Hungary

protein (160.7 g kg^{-1}), while the lowest was in the grass of the first cutting (134.5 g kg^{-1}). The difference between following cutting was approximately 7 to 11%. Despite of dry period before third cutting, content of total protein in grass was high. It could be caused through the concentration of total protein in mass of grass. Pontes et al. (2007) come up with different results when protein concentration in the biomass of *Dactylis glomerata* and *Lolium perenne* was the highest in the second and third cutting and was the lowest in the first cutting (*Table 5*).

Crude fiber content

The concentration of crude fiber was not significantly varied depending on the dose of fertilizers (*Table 6*). However, in data was observed decrease of crude fiber content in the Humus Active Papka plot and Humus Active with mineral fertilization plot approximately 4 to 6% relative to the control object. On the others experimental objects crude fiber content was similar to the control plot.

Comparing experimental years (*Table 6*) it was found that no matter what fertilizers were used and which species of grass was tested, the highest concentration of crude fiber (230.9 g kg^{-1}) was in the grass of the last year (2014) and the lowest (212.1 g kg^{-1}) in the second year (2013) of the experiment. There was a statistically significant difference between crude fiber concentrations in each year. Variable content of crude fiber in the years 2012-2014 was caused through the difference in weather conditions, where in the last one year dry period could caused significant increase of this factor.

Table 6. *The effect of the fertilizer and the experimental year on crude fiber concentration (g kg^{-1}) of grass species*

Species	Year	Fertilizer								Mean
		0	NPK	UG	EU	HA	UG+NPK	EU+NPK	HA+NPK

The study showed significant interaction between such variants as fertilizers, grass species and experimental years. Taking into account both different fertilizers and experimental years (*Table 6*) it was found that the highest concentration of crude fiber was in *Dactylis glomerata* (265.4 g kg^{-1}) in the first year (2012) with the UGmax soil

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

conditioner applied, and in *Lolium perenne* the highest concentration (269.5 g kg^{-1}) was also in the plot with the UGmax but in the last year (2014) of the experiment.

Comparing both grass species (*Table 7*) it was found that no matter what fertilizers were applied *Dactylis glomerata* had a higher concentration of fiber than *Lolium perenne* (239.1 g kg^{-1} and 201.3 g kg^{-1}, respectively). The difference between crude fiber concentrations was statistically significant. Tendency to accumulate of crude fiber in *Dactylis glomerata* species is widely documented in the literature (Ates and Tekeli, 2005; Skládanka et al., 2008; Tilvikiene et al., 2014).

$HSD_{0.05}$ for: species = insignificant; cutting = insignificant; fertilizer/species = insignificant; fertilizer /cutting = insignificant; species/cutting = insignificant; species/cutting/fertilizer = 53.4

Content of crude fiber in the both species of grass and the all combinations of fertilizer were not statistically significant. The lowest content of crude fiber in *Dactylis glometara* was on the plot with the Humus Active Papka with mineral fertilization 226.4 g kg^{-1} DM (the value 8% lower than on the control object), while in *Lolium perenne* biomass from the plot with Eko-Użyźniacz fertilizers 177.5 g kg^{-1} DM (11% lower than on the control object).

Differences between crude fiber content in the cutting was not statistically significant. However, there was seen decreasing trend of crude fiber content from first cutting (239.9 g kg^{-1} DM) to third cutting (201.3 g kg^{-1} DM). Similarly, Jankowska-Huflejt and Wróbel (2010) found the lowest concentration of crude fiber in the grass of the third cutting (261.8 g kg^{-1} DM), and the highest in the grass from the second cutting (313.7 g kg^{-1} DM). Contrary to that Skládanka et al. (2008) found that crude fiber concentration in the biomass of *Dactylis glomerata* was the highest in the third cutting and successively increased in the following cuttings. Large variety of crude fiber content in the cuttings between literature and this publication was probably caused by differences in hydro-thermal conditions of the weather.

Conclusions

1. For both grass species Eko-Użyźniacz applied together with mineral fertilizers increased protein content in fodder.
2. Application of Humus Active Papka with mineral fertilizers lowered crude fiber concentration in fodder.
3. The highest concentration of total protein was in Dactylis glomerata and Lolium perenne from the plots where soil conditioners together with mineral fertilizers were applied.
4. The highest concentration of crude fiber was in Dactylis glomerata growing on the plot with Humus Active Papka together with mineral fertilizers applied, while in Lolium perenne on the plot with Eko-Użyźniacz applied, without mineral fertilizers.
5. Taking into account the studied grass species and fertilizer combinations, Lolium perenne had better quality parameters than Dactylis glomerata, especially fertilized with EU+NPK or HA+NPK. Therefore, the species of this grass fertilized with these fertilizers should be recommended in agricultural practice.

Abstract. According to large daily temperature difference, strong solar radiation and significant change of air humidity in the alpine area of Tibet, a field experiment was conducted to analyze the oat's diurnal variation of the leaf water potential (ψ_L), transpiration rate (Tr) and net photosynthetic rate (Pn). Meanwhile, the relationship between oat's physiological indicators and typical meteorological factors (atmospheric temperature (T), solar radiation (R_s), relative air humidity (RH)) were investigated with regression models. Results showed that the oat's daily change curve of ψ_L showed 'V-type' in the seeding and heading stages and 'W-type' in the jointing and tillering stages. As shown in the results, oat's Pn presented a decreasing tendency in a day and the peak appearing between 9:00 and 10:00 at one day in each growing stage. The Tr presented double-peak curves and midday depression in the seeding and heading stages. The variation tendency about oat's Tr in the tillering stage and jointing stage was "Multi-peak" type without distinct midday depression and parabolic tendency. By multiple regression analysis between the data of oat's physiological indexes and comprehensive factors, the ψ_L, Tr and Pn of oat in alpine region can be predicted under condition of adequate water supply.
Keywords: *oat, leaf water potential, transpiration rate, net photosynthetic rate, meteorological factor, high-altitude area*

Introduction

In recent years, with the development of pasture land water conservancy, the study of artificial grass water requirement and irrigation program is a public concern. Then the moisture physiological characteristics of pasture are of special note. For example, Liu et al. (2009) studied the effect of soil water stress on osmoregulation substance content of oat leaf. However, the relationship between leaf water potential (Ψ_L), transpiration rate (Tr), photosynthetic rate (Pn), which are the important parameters in the water cycle processes and meteorological factors are rarely investigated.

The leaf water potential is a basic indicator to reveal the status of crop water. The change of leaf water potential depends on many requirements of soil-plant-atmosphere continuum and complex interaction among the regions of plant. The daily variation rule of leaf water potential about winter wheat in the filling stage under the condition of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

sprinkling irrigation and surface irrigation were investigated by Yao et al. (2009). It found that the leaf water potential of winter wheat irrigated by sprinkling irrigation was higher than that by surface irrigation. Due to the individual and environmental variations, the leaf water potential of different plants will be different. The value of leaf water potential is associated closely with its yield, which is also varied with environmental factors. Kang et al. (1994) found that the Ψ_L of winter wheat will decrease with crop growing. Fu et al (2012) showed that the soil moisture content and temperature were the main factors for the leaf water potential change of *Phragmites* in arid areas. However, the relationship between leaf water potential of oat and meteorological indexes is remains unclear.

Transpiration regulates the water balance in plants and is influenced indirectly by environmental factors through effects on stomatal opening (Tamang and Sadok, 2018). Liu et al. (2003) studied the transpiration diurnal characteristics of spring wheat and found that the solar radiation and temperature will affect transpiration obviously. Peng et al. (2005) considered that the reduction of soil water content would put off the diurnal maximum of transpiration of late rice. His study also showed that there were different effects degree of vapor pressure deficit and stomatal conductance on transpiration of late rice in the different growth stages. Evapotranspiration and stomatal conductance are known to decrease as leaves age increasing in many species (Sobrado et al., 1994). Meanwhile, stomatal conductance for transfer of water vapor from the interior of the leaf to the atmosphere is affected by irradiance, leaf age, temperature, leaf water status, and the difference in absolute humidity between ambient air and the interior of the leaf (Wardlaw et al., 1967; Johnsonet al., 1983; Ku et al., 1977; Li and Zhou, 2004; Zhao et al., 2011). Some studies found that there was significantly correlational relationship between stomatal conductance and temperature, humidity and leaf water potential. At present, the model about relationship between stomatal conductance and environmental factors is composed of two classes. One is empirical model, such as Jarvis, Ball and so on (Ball et al., 1987; Jarvis et al., 1976; Leuning, 1995). Others are the optimization theory of stomatal regulation proposed by Cowan and Farquhar (1977) and optimization model of stomatal conductance established by Medlyn et al. (2011).

The diurnal variation of plant photosynthesis is not only the basic unit of material accumulation and physiological metabolism in the plant's production process but also an important method to analyze the impact of environment on plant growth and metabolism. Under normal circumstances, the daily change curve of plant photosynthesis is a bimodal type or unimodal type. Yu et al. (2015) reported that the diurnal variation of net photosynthesis of *maize* presenting the bimodal curve with apparent photosynthetic "noon break" phenomenon. The diurnal variation of plant photosynthesis is different from the separate plant species and the surrounding environment change (Farquhar and Sharkey, 1982). Many environmental factors will affect the plant photosynthesis, such as Photon flux density, temperature, relative humidity and so on. Under natural conditions, the influence of environmental factors on plant photosynthesis is the result of combination. However, there is hardly any research on the impact of meteorological indexes on oat photosynthesis is rarely.

The objectives of this research are:

(1)To investigate the daily variation of oat's Ψ_L, *Pn* and *Tr* in different growth stages on the condition of full irrigation in plateau area.

(2)To determine the relationships between oat's physiological indexes and meteorological factors in plateau area.

Materials and methods

Experimental site

Tibet, which is mainly located in Qinghai-Xizang Plateau, is in the average elevation of 4000 m. There are 820 million ha natural grasslands in the alpine area of Tibet and the meteorological characteristics are large daily temperature difference, strong solar radiation and significant change of air humidity in this area. The problems of uneven distribution of water-heat resource in space-time and soil depletion are severe in the northern of Tibet plateau region especially. The special physiographic factors and production custom make the grass irrigation technology lagged far behind.

Field experiments were conducted in the central Tibet with longitude 90°45'-91°31' and north latitude 29°31'-31°04' in the Damxung County in Lasa (*Fig. 1*). The region with an average altitude of 4200 m is plateau-continental climate and the rainy season and dry season are clear. The annual mean precipitation is 480 mm and the rain mainly fall between June and September. In the region, with multi-year average evaporation being 1966 mm, the frost-free period is only 60 days and percentage of sunshine is above 60% in a year. The study area has adequate solar resource but is lack of hot resource. *Table 1* presents information on the physical properties of the soil in the field area. Surface soil above 40 cm mainly consists of loam, while the lower layer mainly consists of silver sand and rubble.

Table 1. *Physical properties of the soil in the field area*

Soil horizon (cm)	Field capacity (%)	Soil bulk density (g/cm³)	Percent clay (%)	Percent loam (%)	Percent sand (%)	Soil texture
0-10	17.96	1.48	7.8	44.07	48.13	Loam
10-20	16.14	1.59	7.66	43.48	48.85	Loam
20-30	18.03	1.55	7.51	42.8	49.69	Loam
30-40	18.28	1.56	8.08	47.11	44.81	Loam

Agronomy

The experimental design was a randomized complete block with 3 replications. Each experimental plot was 12 m long by 5 m wide (60 m^2) with 30 cm height ridge. A buffer zone spacing of 2.00 m was provided between the plots. The oat (Danmai 444) was used for the experiment and planted on June 15th in 2013. The sowing rate was 187.5 kg/ha and the planting method was strip seeding with line spacing of 25 cm. Before planting, 4.5 t/ha organic fertilizer and 224.9 kg/ha N (as ammonium nitrate) were fertilized. One and half months after planting, a further 74.96 kg/ha of N (as ammonium nitrate) was applied. Crops were manually harvested when ripe rate reached about 95% (early September). Soil moisture was measured once every 7 days using TDR and validated by soil samples using soil drilling. The experiment was carried out without water stress. When the soil moisture was lower than the lower irrigation limit (W_{cg}), the irrigation would be carried out with ground irrigation. The detailed growing period information of oat and lower irrigation limit are shown in *Table 2*.

Table 2. *Growing period of oat and lower irrigation limit*

Growth period	Seeding stage		Tillering stage	Jointing stage	Heading stage
	Pre-emergence	After emergence			
P_g	Early June-late June	Late June-early July	Early July-middle of July	Late July- middle of August	Late August-harvest
W_{cg}	70(%) FC	70(%) FC	70(%) FC	75(%) FC	70(%) FC

Notes: (a) Each stage water condition refers to the percentage of maximum field capacity (FC); W_{cg}: Lower irrigation limit in different growth period with full irrigation (b) P_g: The beginning and ending of growth period

Meteorological factors

Due to the large daily temperature difference, strong solar radiation and significant change of air humidity, in the research district, we selected the *T*, R_s and *RH* as the typical meteorological factors. The data of *RH* and *T* were measured by the meteorological station in farmland of Damxung and R_s was calculated from the *Equations 1* and *2* (Allen et al., 1998).

$$R_a = \frac{12\times60\times G_{sc}\times dr[(\omega2-\omega1)\sin(\Phi)\sin(\delta)+\cos(\Phi)\cos(\delta)\sin((\omega2)-\sin(\omega1))]}{\pi} \quad \text{(Eq.1)}$$

$$R_s = \left(0.25 + 0.5\times\frac{n}{N}\right)\times R_a \quad \text{(Eq.2)}$$

where R_a is extraterrestrial radiation, MJm^{-2} h^{-1}; R_s is solar radiation, MJm^{-2} h^{-1}; G_{sc} is solar constant, 0.082; *dr* is the reciprocal of relative distance between the sun and earth; δ is the solar declination; *Φ* is the geographical latitude; *ω1*(*ω2*) is the solar hour angle in the early (late) period and n/N is the relative sunshine duration.

Measurements

Oat blade with well growth, normal color and size (second leave from the top of plant in seedling stage and third leave from the top of plant in tillering stage, jointing

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

stage and heading stage) were selected to monitor the leaf water potential (ψ_L, MPa) with 3 plants replication using the water dew point meter (Psypro, Wescor Inc in USA) every one hour. Oat blades with well growth and normal color and size were selected to monitor the transpiration rate (*Tr*, millimol•m^{-2} s^{-1}) and net photosynthetic rate (*Pn*, μmol•m^{-2} s^{-1}) using automatic portable photosynthesis system (LCPro-SD, ADC in British) every 1 h with 3 plants replication. The meteorological characteristics of measurement's days are better sunshine, gentle breeze and no rainfall. The ψ_L was measured for one day in seeding, tillering and heading stage, and measured for 6 days at jointing stage. The *Tr* and net *Pn* were measured for one day in seeding, tillering, jointing and heading stage, respectively.

Data analysis

The data were subjected to the analysis of regression for meteorological factors and crop physiological indexes using SPSS software. The significance of regression model was determined with an F test. The F-protected least significance difference (LSD) was calculated at the 0.05 and 0.01 probability level, respectively.

Results and discussion

Daily variation of oat's leaf water potential, net photosynthetic rate and transpiration rate at different growth stages

Daily variation of oat's leaf water potential in different growth stages

Under conditions of full irrigation, ample sunshine and suitable temperature, diurnal variation of ψ_L in different growth stages were selected to contrast (*Fig. 2*). According to the data, the diurnal ψ_L in growth periods ranged largely with maximum of 6 MPa under the special environment of high altitude, strong radiation and large diurnal temperature range in Tibet. However, the ψ_L of winter wheat's variation value was only 3 Mpa and the ψ_L of Mongolian blue-beard grew in the alpine region is only 1.24 Mpa (Han et al., 2008; Tong et al., 2005).

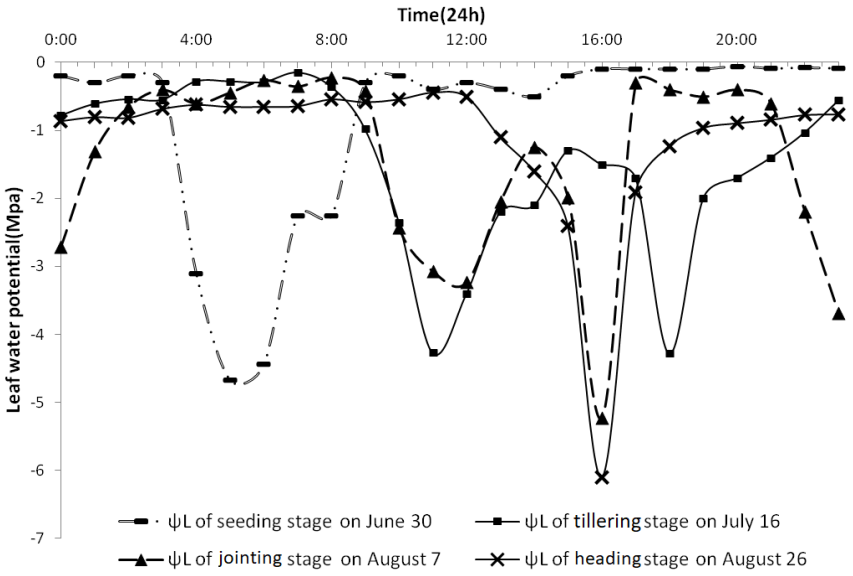

Figure 2. *Daily variation of ψ_L under different growing periods*

In the seedling stage, the ψ_L usually changed at night and the minimum of -4.67 MPa appeared at day break, and the change trend showed "V-type". The trough of ψ_L happened five hours before sunrise, when T and R_s were lower with the RH being larger. The ψ_L would reach the larger value in the day time. This is due to cells of seedling leaf avoiding to be damaged by radiation or avoiding the effect of water stress on crops by excessive transpiration. The frequent fluctuations of ψ_L at dawn reflected the frequent water exchange with external and stronger life activity in the seedling stage of oat. This indicates that the oat could adapt to the low temperature at night in the seedling stage. In contrast, high temperature and radiation will inhibit the growth of oat in the seedling stage, which is related to the undeveloped oat root and immature mechanism of stomata cell for opening and closing.

(2) In the tillering stage, the oat grew quickly and exchange moisture with external environment frequently. The ψ_L fluctuated significantly at daytime and the trend showed "W-type". The lowest trough of ψ_L appeared at the 10:00 to 11:00 with a minimum value of -4.27 MPa and 18:00 with a minimum value of -4.28 MPa (*Fig. 1*). With the rise of R_s and T, the oat reduced their own tissue water potential to absorb more moisture for the life activity. The ψ_L decreased after sunrise. The temperature reached the maximum at noon. Through regulating the stomata opening and closing, the oat reduced water loss. Then as the sun set, the T fell, ψ_L reduced again to absorb more moisture. The ψ_L returned to a higher value of -1.7 MPa at 21:00. The results support the conclusions of Guo, et al. (2006) and Tong et al. (2005) that the trend of ψ_L showed "W-type" on the condition of full-irrigation. The oat had already certain adaptability to the change on meteorological factors in the tillering stage. The life activity at daytime was going to be vigorous than it at night.

(3) The jointing stage is the critical period for the organic synthesis and accumulation of plant (Tian et al., 2012). The diurnal variation of ψ_L tended to be stable and the trends were similar to that in the tillering stage with two troughs. The time when the first trough appeared at 11:00 was consistent with the moment of tillering stage's first trough; however, the second trough was about two hours upfront than that in tillering stage with a minimum value of -5.22 Mpa. This phenomenon can be attributed to the special meteorological conditions. The general trend of ψ_L was higher in the morning and evening and the ψ_L was significantly reduced with great fluctuations. At 14:00, the ψ_L was at a high value of -1.24 MPa, when the oat's stomatal conductance decreased rapidly, guard cell shrinkage and partial stomata closure in response to intense light and drying air. Therefore through short "nap", the oat could adapte the change of weather factor and control water balance of the body (Kang et al., 1991).

(4) In heading stage, the reproductive growth replaced the vegetative growth gradually. The ψ_L maintaining a relatively high value tended to "V-model" with a minimum of -6.1 MPa at 16:00 (*Fig. 1*). The occurrence time of trough agree with the moment of the second trough appeared in tillering and jointing stages. The results are keeping with the conclusions of Guo et al. (2006) that the trend of ψ_L showed "V-type". This proved that water currently had strong driving force to promote water from soil to root at 16:00-18:00 under non-water stress condition. To some extent, it indicates that the heading stage is the critical period to translate the energy to organics and so the lack of water will affect the quality of artificial grassland. However, further study is needed to confirm why the ψ_L with a minimum of -6.1 Mpa at high altitudes lower than other areas obviously.

Daily variation of net photosynthetic rate of oat in different growth stages

In low elevation regions, previous studies suggested that the curves of diurnal variation on *Pn* of gramineous plants presented double-peak, and an obvious midday depression at 12:00 o'clock (Li et al., 2013; Liu et al., 2006). This study showed that *Pn* has its unique change rule at high altitudes. The daily variation patterns of *Pn* of oat are presented in *Figure 2*. As the trend lines implied in *Figure 3,* it presented a decreasing tendency in a day. The variation tendency of oat's *Pn* were basic consistent without fixed peaks and troughs model in different growth stages. The *Pn* on the morning was higher than that on the afternoon and the peak appeared between 9:00 and 10:00 at one day. After the peak value appeared, there would be a reduction and the downturn would last a long time in the tillering stage and heading stage. The maximum of *Pn* in the seeding stage, tillering stage, jointing stage and heading stage were 10.56 μmol m^{-2} s^{-1}, 9.91 μmol m^{-2} s^{-1}, 10.01 μmol m^{-2} s^{-1} and 9.01 μmol m^{-2} s^{-1}, respectively.

At 12:00 am and 4:00 pm, an obvious valley appeared in the seeding stage; likewise the valley appeared on the morning and afternoon in the jointing stage, while the minimum values of P_n were 5.1 μmol m^{-2} s^{-1} and 5.4 μmol m^{-2} s^{-1}, respectively. The *Pn* in tillering stage witnessed significant downturn at 12:00-14:00, which was similar to the *Pn* in heading stage at 11:00-14:00, troughs appeared with the minimum value of 5.2 μmol m^{-2} s^{-1} and 4.4 μmol m^{-2} s^{-1}, respectively.

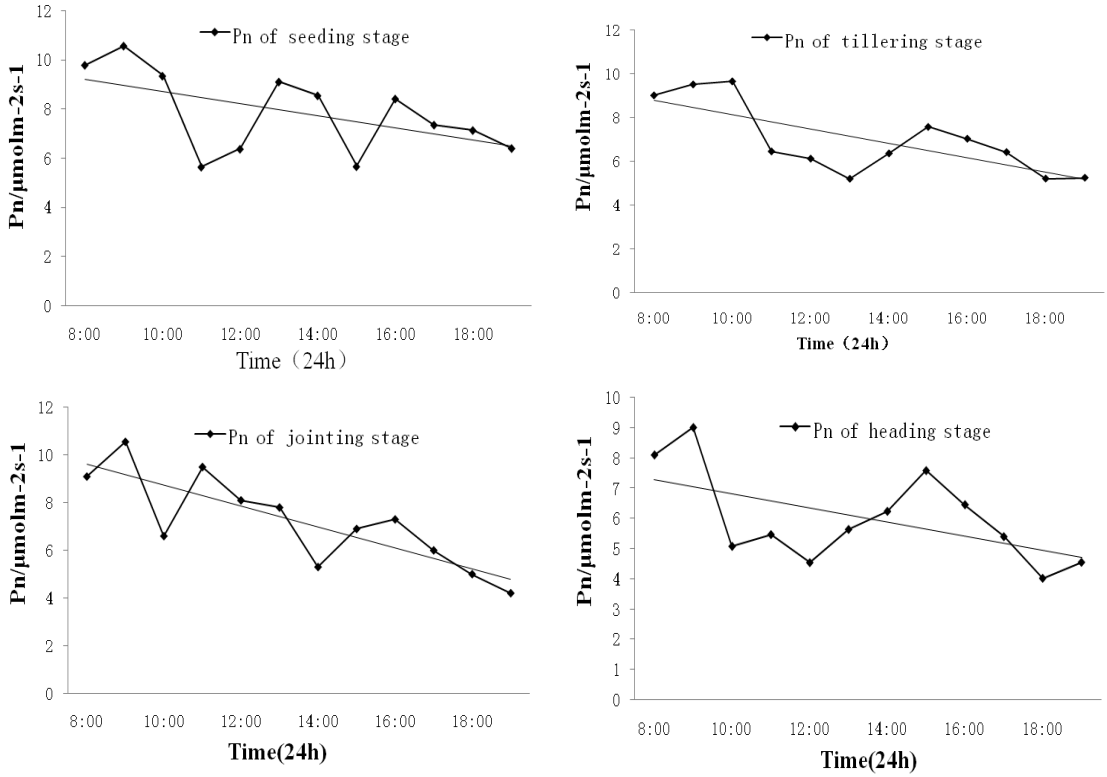

Figure 3. *Daily variation of Pn under different growing periods*

Daily variation of oat's transpiration rate at different growth stages

The *Tr* of oat in the seeding stage is obviously less than that in the tillering stage, jointing stage and heading stage (*Fig. 4*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_27412754
© 2018, ALÖKI Kft., Budapest, Hungary

(1) The *Tr* presents double-peak curves and midday depression in the seeding and heading stage

The obvious tendency of bimodal patterns about *Tr* are appeared in the seeding stage and heading stage of oat. This changing trend is similar to the result reported by Luo et al. (2011), the curves of diurnal variation in *Tr* of Medicago sativa had two peaks and an obvious midday depression with or without water stress at lower altitude. At 12:00, the *Tr* in the seeding stage peaks at the maximum of 45.3 millimol•m^{-2} s^{-1}, while the midday depression appearing from 13:00 to 16:00. The *Tr* value is the minimum of one day with being 15.2 millimol•m^{-2} s^{-1} at 8:00 in the morning. In heading stage, the maximum value (64.5 millimol•m^{-2} s^{-1}) of *Tr* appeared at 11:00 and the minimum value (13.7 millimol•m^{-2} s^{-1}) of Tr appeared at 20:00. The curves of diurnal variation in *Tr* had an obvious midday depression between 12:00 and 14:00.

(2) The *Tr* presents "Multi-peak" type in the tillering stage and jointing stage

Different from the current research about grass, the variation tendency on *Tr* of oat in the tillering stage and jointing stage was "Multi-peak" type without distinct midday depression and parabolic tendency. In tillering stage, the *Tr* would rise rapidly after sunrise and reach to the first summit (66.1 millimol•m^{-2} s^{-1}) at 11:00, and there were more peak values which appeared at 14:00 and 17:00 respectively in one day. In jointing stage, the *Tr* reached to the first peak (73.8 millimol•m^{-2} s^{-1}) at 11:00 similarly, and there were more peak values which appeared at 13:00, 15:00 and 17:00 respectively in one day. In this research, the variation tendency of in the tillering stage and jointing stage was different from most graminaceous plants with a single peak (Philip et al., 1966; Yuan et al., 2009).

This study investigated its emergence reason and regulation. On one hand, the result is due to the strong nutritional growth of oat in the tillering stage and jointing stage. There are frequent matter and energy exchange with the environment in these two phases. On the other hand, it is related to the specific weather conditions (such as amounts of moisture in atmosphere vary greatly as a direct result of stronger solar radiation and frequent rainfall in a day) in Tibet alpine pasture.

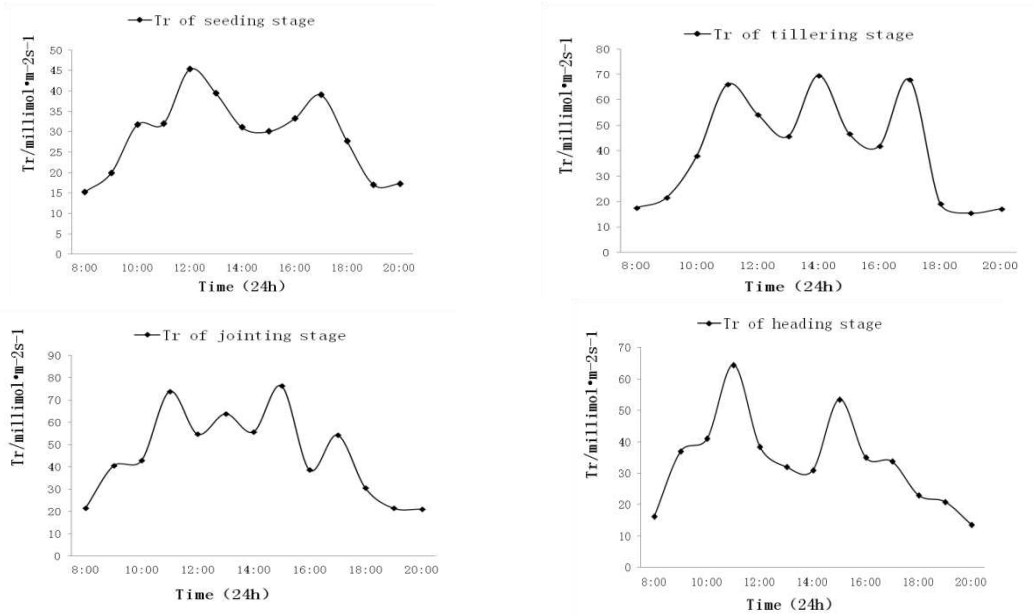

Figure 4. *Daily variation of Tr under different growing periods*

Relationships between physiological indexes of oat and single meteorological factor

The daily variation relationships between ψ_L, *Tr*, *Pn* and *T*, R_s, *RH* were analyzed with SPSS and presented in *Table 3*. Results showed that the change trend of ψ_L could be predicted simply by typical meteorological factors, as many studied reported that there were obvious relationships between the *T*, R_s, *RH* and ψ_L (Zhang et al., 2008). The correlation order of *T*, R_s, *RH* with ψ_L was: $T > RH > R_s$with correlation coefficients of 0.728, 0.676 and 0.353, respectively. From the models, the ψ_L decreased by 1.96 Mpa with the temperature increasing by 10°C. Due to the R_s was always positive number, the relationship between ψ_L and R_s was inversely proportional quadratic parabola trend. Different from the other two meteorological factors, the logarithmic relationship appeared between ψ_L and *RH*.

Table 3. *Regression model of single meteorological factors and crop physiological indexes*

Crop physiology index	Meteorological factor	Regression model	Determinate coefficient R^2	F test value
ψ_L (Mpa)	*RH*	ψ_L=-30.46+6.65*ln(RH)	0.676**	45.413
	R_s	ψ_L=-2.066-0.647R_s-0.077R_s^2	0.353*	4.523

Tr (millimol•m^{-2} s^{-1})	*RH*	*Tr*=-43.544+2.481RH-0.021RH^2	0.504*	5.584
	R_s	*Tr*=12.121*exp(0.2880*R_s)	0.360*	6.180
	T	*Tr*=-19.369+13.897*ln(T)	0.328*	5.867
*P*n (μmol•m^{-2} s^{-1})	*RH*	*P*n=-43.465+2.198*RH-0.0002*RH^3	0.529*	6.173
	R_s	*P*n=28.165+8.008R_s	0.354*	3.041
	T	*P*n=12.947*$T^{0.392}$	0.538*	8.166

*Correlation is significant at the 0.05 level
**Correlation is significant at the 0.01 level
Number of samples for ψ_L was 216 (24 × 9 = 216), number of samples for *Tr* was 48 (12 × 4 = 48) and number of samples for *P*n was 48 (12 × 4 = 48)

The R_s guarantees the energy for crop transpiration. The crop transpiration rate (*Tr*) increases with the increase in water potential gradient, caused by stronger R_s, higher temperature and reduced atmospheric water. The correlation order between *Tr* and *T*, R_s, *RH* was: $RH > R_s > T$ with correlation coefficient of 0.504, 0.36 and 0.328, respectively. The relationship trend between *Tr* and *RH* was the quadratic downward. The relationship between *Tr* and *RH* was different from ψ_L with the trend of inversely proportional quadratic parabola. The maximum *Tr* appeared when the *RH* equaled to 59.07% and the *Tr* would decreased with *RH* increasing when the *RH* was greater than 59.07%. Differently from others, the relationship trend between *Tr* and R_s was exponential. The minimum *Tr* was 12.121 millimol•m^{-2} s^{-1} while R_s was 0. Logarithmic relationship was shown between *Tr* and *T* and there was not transpiration when the temperature was less than 4.03 °C. Then the transpiration rate will increase with the increase in temperature.

The impact factors on *Pn* of oat are not only the temperature but also the crop stomatal opening, transpiration changes and intercellular carbon dioxide concentration.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_27412754
© 2018, ALÖKI Kft., Budapest, Hungary

Nevertheless, the *Pn* will affect the crop development. The correlation order between *Pn* and *T, R_s, RH* was: $T > RH > R_s$ with correlation coefficient of 0.538, 0.529 and 0.354, respectively. Different from the *Tr*, the relationship trend between *Pn* and *RH* was the cubic polynomial. The linear relationship was presented between *Pn* and R_s. An 80.08 μmol•m^{-2} s^{-1} *Pn* increment appeared when the R_s increased by 10 MJ m^{-2} h^{-1}. The relationship trend between *Pn* and *T* was different from others. Power function was showed between *Pn* and temperature with the power exponent of 0.392.

Then the relationship between ψ_L and physical signs will be introduced in great detail. If irrigation is sufficient, the change trend of ψ_L is affected not only the different growth stages but also the meteorological factors. The change of ψ_L can reflect the crop ability adapting to the environment.

With the uncertain meteorological condition, the data of ψ_L and meteorological factors collected from August 7th to August 12th when the weather conditions and humidity were suitable for analysis, in order to eliminate the particular of observation data as much as possible in one day. The metrological and ψ_L data observed over six days were averaged, which is an effective measure to reduce the error caused by the particular data.

(1) The diurnal variation relationship between ψ_L and R_s

From the change curve (*Fig. 5*), the change trend about the ψ_L and R_s are negative correlation ($R^2 = 0.353$). The R_s started to change from negative value to positive value at 5:00. It reached maximum (3.45 MJ m^{-2} h^{-1}) at 12:00. However, the ψ_L decreased rapidly from -0.32 MPa at 7:00, reached the first minimum at 13:00 and started to increase after two slight rebounds between 13:00-15:00. The fluctuation of ψ_L may be impacted by other meteorological factors (Yang et al., 2012). From the above analysis, the changes of ψ_L lagged behind the changes of R_s.

(2) The diurnal variation relationship between ψ_L and *RH*

The change trend of ψ_L and *RH* are a positive correlation ($R^2 = 0.676$; *Fig. 5*). After the sunrise, *RH* tended to drop off over time with the maximum 87% at 8:00. The minimum appeared at 18:00 with 42.67%. Both ψ_L and *RH* started to rise after the sunset and the ψ_L reached to -1.8 Mpa in the end.

(3) The diurnal variation relationship between ψ_L and *T*

The change trend of ψ_L and *T* are a negative correlation obviously ($R^2 = 0.728$) (*Fig. 5*). At daylight, the ψ_L decreased while *T* was rising, and *T* reached to minimum of 3.15 °C at 7:00, however ψ_L was at a higher value with -0.32 Mpa. *T* tended to drop off after it reached the maximum value of 27.5 °C at 15:00. In addition, the continuous high temperature would lead to ψ_L picks up again with "nap".

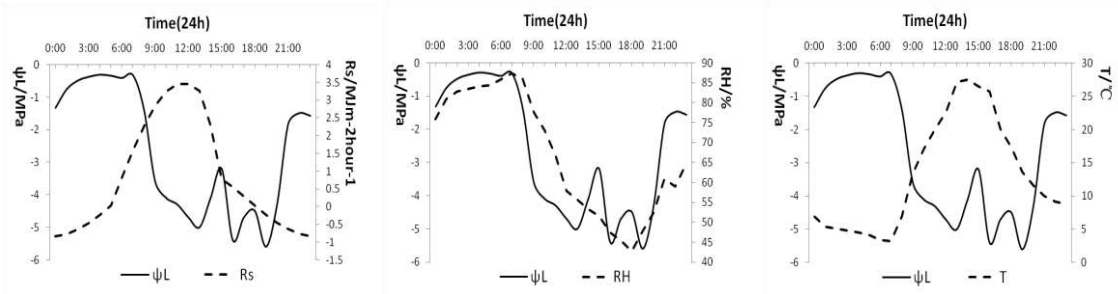

Figure 5. *The relationship between daily variation of leaf water potential and meteorological factors*

Relationships between physiological indexes of oat and comprehensive factors

The crop physiological indicators are usually influenced by multiple meteorological factors comprehensively, such as temperature, humidity and so on. For example, the daily variation of ψ_L is little on cloudy days with large humidity and wind speed, while the daily variation of ψ_L is larger on sunny day with small wind speed and moderate humidity. By multiple regression analysis between the data of oat's physiological indexes and comprehensive factors, the ψ_L, *Tr* and P_n of oat in alpine region can be predicted under condition of adequate water supply. The regression models between ψ_L, *Tr, Pn* and meteorological factors are presented in *Table 4*. The correlation coefficients are 0.86, 0.78 and 0.66, respectively.

Table 4. *Regression model of multi-meteorological factors and crop physiological indexes*

Crop physiology index	Regression model	Determinate coefficient R^2	F test value
ψ_L (Mpa)	ψ_L=-11.271-0.882R_s+0.076T+0.123RH	0.86**	40.95
Tr (millimol•m^{-2} s^{-1})	*Tr*=-39.375+1.606T+0.453RH+0.056R_s	0.78*	11.90
*P*n (μmol m^{-2} s^{-1})	*P*n=-7.603+0.919T+0.319RH+5.848R_s	0.66*	10.40

*Correlation is significant at the 0.05 level
**Correlation is significant at the 0.01 level
Number of samples for ψ_L was 216 (24 × 9 = 216), number of samples for *Tr* was 48 (12 × 4 = 48) and number of samples for *P*n was 48 (12 × 4 = 48)

Conclusions

With the water resources becoming scarcer, the water-saving agriculture in Tibet plateau has drawn much attention. At the same time, the oat physiological indexes research is indispensable for water-saving agriculture. The results show that the daily oat's ψ_L changed obviously during the different growth stages. The daily change curve of oat's ψ_L showed 'V-type' in the seeding and heading stages, and the lowest value appeared at 5:00 and 16:00 respectively. However, oat's ψ_L showed 'W-type' in the jointing and tillering stages in which the lowest value both appeared in the morning and afternoon. The maximum change range of ψ_L can reach to 6 MPa in a day.

The variation tendency of oat's *Pn* was basically consistent without fixed peaks and troughs model in different growth stages. As the facts mentioned above, *Pn* presented a decreasing tendency in a day. The *Pn* on the morning was higher than that on the afternoon and the peak appeared between 9:00 and 10:00 at one day. The maximum of *Pn* in the seeding stage, tillering stage, jointing stage and heading stage were 10.56, 9.91, 10.01 and 9.01 μmol m^{-2} s^{-1}, respectively.

The *Tr* of oat at the seeding stage was obviously less than that in the tillering stage, jointing stage and heading stage. The *Tr* presented double-peak curves and midday depression in the seeding and heading stage. Different from the current research about grass, the variation tendency about *Tr* of oat in the tillering stage and jointing stage was "Multi-peak" type without distinct midday depression and parabolic tendency.

Based on the regression analysis, the correlation coefficients between meteorological factors and oat's four physiological indicators were: $T > RH > R_s$; $RH > R_s > T$; $T > RH > R_s$, respectively for ψ_L, *Tr* and *Pn.* By multiple regression analysis between the data of oat's physiological indexes and comprehensive factors, the ψ_L, *Tr* and *Pn* of

oat in alpine region can be predicted under condition of adequate water supply. These results are useful to understand the hydrologic cycle of the irrigated grass and determine the scientific irrigation schedule to improve water use efficiency of grass in the alpine area.

The studies about ψ_L, *Tr* and *Pn* in this paper are under the condition of full irrigation. Therefore, in order to determine the scientific irrigation schedule, the influence of water stress on ψ_L, *Tr* and *Pn* will be the focus of the further study.

(Received 4th Feb 2018; accepted 2nd May 2018)

Abstract. Rural households have over decades depended on forests and forest products for sustenance and livelihood values. This dependence is usually driven by the individual household's dynamics, forests availability and accessibility. However, with overexploitation and agricultural expansion, these forests are rapidly declining putting in peril household livelihoods. This study aims at examining and analyzing household dynamics and how these dynamics combine with other factors to influence household dependence on forest resources in the Rumpi hills of Cameroon. Data were collected from 484 households, across 20 villages and at four selected sites through household surveys and 20 focus group discussions. Household characteristics such as uneducated heads (p-value 0.000381) significantly influenced the use of forest resources than male heads (P-value 0.000642) and years of residence (11–15) (p-value 0.00624) in the village at the 95% level of significance. Forest dependence was mostly conditioned by the household's ability to farm, forest abundance, and unemployment. Additionally, income from agriculture and forest resources respectively constituted 36.7% and 34.1% of the average total rural household income. Investment in climate-smart agriculture, non-wood domestic cooking energy, agroforestry systems and reliable rural transport systems is necessary in order to curb forest dependence and improve on livelihoods and sustainable forest management initiatives.
Keywords: *rural livelihoods, household income, forest dependency, sustainable forest management*

Introduction

With a national forest cover estimated at 42%, Cameroon harbours enormous forests and marine resources embedded in a mosaic of landscape structures along basins, plains and mountains. These forests are mostly situated in the south where they make-up the

western margins of the large tract of the Congo Basin Forests (Robiglio et al., 2010; Ekoungoulou et al., 2018a). However, rural communities live in and around these forests where they depend on several forest resources and products for sustenance and livelihood. Besides serving as sources of wood, farmlands, medicinal plants and hunting grounds, these forests also serve sociocultural and recreational purposes (Etongo and Glover, 2012; Tieguhong et al., 2012; Mukete et al., 2016a).

This dependence which is likely to increase in the coming decades challenges the very existential purposes of these forests often resulting in associated forest degradation, deforestation and constituent biodiversity loss. This stems from the observable depletion of forests due to the combined effects of agricultural expansion, wood harvesting for cooking, heating and wood works (Kimengsi and Lambi, 2015; Mukete et al., 2018b).

Various studies have examined household dependence and the contributions of forest resources to household income and rural livelihoods. For instance, Makoudjou et al. (2017) found forests to contribute on average 38% of total annual household income. Here, 19, 13 and 6% of such contributions according to their study came from illegal logging, hunting and harvesting of plant-related non-timber forest products (NTFPs). NTFPs include goods of biological origin other than wood and timber, derived from forests and other land uses such as fallows, woodlots, agroforestry systems, and plantations (Dembner and Perlis, 1999). In the Rumpi hills forest, NTFPs primarily gathered from forests and other land uses include land snails (*Archachatina marginata*), bush mango (*Irvingia gabonensis*), bitter cola (*Garcinia cola*), njansang (*Ricinodendron heudelotii*), country onion (*Afrostyrax lepidophyllus*), bush pepper (*Piper guineense*), and several edible species of mushrooms (Ofundem et al., 2017; Mukete et al., 2018b).

In another study, rural households with better access to forested land such as national parks and forest reserves in Malawi were found to have higher total income, forest income, and relative forest income (Kamanga et al., 2009). Meanwhile, the amount of forest income that households earned was found to vary significantly across study sites in Zambia. This variation was influenced by market and household level factors as well as the occurrence and abundance of forest resources and products (Bwalya, 2013). Accordingly, Belcher et al. (2015) affirmed that, households whose members were relatively more educated are likely to obtain more income from forest related activities than less educated households. Similarly, households made-up mostly of younger members were more dependent on collecting forest products. This is attributed to their starting families and possessing lower agricultural household assets than older and better-established households (McElwee, 2008). On the other hand, households with relatively larger family sizes were found to be more forest resource dependent than those with smaller family sizes (Mamo et al., 2007). Other factors such as geographical location and topographical conditions have also been observed to influence forest resource dependence and use (Zenteno et al., 2013).

Many other studies have linked household forest resource dependence vis-a-vis sustainable forest management initiatives. For instance, Lambi et al. (2012) observed that management and development initiatives that influence households' use of forest resources and forest dependence will invariably affect household employment status and skills through capacity building. Beside household's characteristics, limited opportunities for non-forests livelihood diversification options still prevails, thereby creating a situation of more reliance on forest resources. Such overdependence on forest resource use does not only induce more deforestation and forest degradation, but also

© 2018, ALÖKI Kft., Budapest, Hungary

questions the effectiveness and sustainability of protected area (PAs) initiatives (Ewane et al., 2015).

Sustainable forest management initiatives especially PAs initiatives, can provide significant socioeconomic benefits especially to forest dependent rural communities. Jindal et al. (2012) are of the opinion that, forest management and development initiatives are likely to be compromised should they not tally with household's dynamics and their livelihood activities. Accordingly, Arnold and Perez (2001), Ambrose-Oji (2003), Lambi et al. (2012) and Hajost and Zerbock (2013) observed that, the unabated active participation and interest of local forest dependent rural communities in forest management and development initiatives is closely related to their individual household's characteristics and requirements. Lambi et al. (2012) and Ofoegbu et al. (2017) also found direct links between household characteristics and their decision to carry-out forest related activities. In related studies, factors linked to household conditions were found to influence their motivation and willingness of host communities to participate in forest carbon conservation activities in Mozambique (Jindal et al., 2012), Cameroon (Chia et al., 2013) and Bolivia (Zenteno et al., 2013).

Some studies on sustainable forest management activities have also found that, the long-term sustainability of such initiatives are likely to be efficient if and only if the socioeconomic needs and characteristics of local communities are taken into cognizance. For example, Ambrose-Oji (2003) in her study on the contributions of NTFPs to local livelihoods observed that, forest value could be increased by valorizing the use and importance of NTFPs to local forest dependent rural communities in the Southwest Region of Cameroon. Accordingly, this valorization could then translate into incentives and encourage local villagers to embrace sustainable forest management strategies for the production of livelihood benefits (Ambrose-Oji, 2003). Similarly, Levang et al. (2015) studied the importance of forests concessions to the lives of local forest dependent communities of the east and south regions of Cameroon. Their study found agricultural expansion, unregulated hunting and logging inside the concessions to be setbacks to forest resources utilization for the local communities. They concluded that curtailing these setbacks would necessitate the inclusion of these local communities into stakeholder decision making discussions. Also, Ewane et al. (2015) reported on the importance of a general national reform policy in forest governance and management such as to ensure future sustainable forest management in Cameroon. The study proposed a participatory approach involving both local forest-dependent communities and government institutions which will foster collaboration and adaptive management in forest management. However, tackling the multiple challenges related to forest-dependent rural communities and the implications for strategic and practical forest planning has not been carefully done in Cameroon (Lang, 2015; Mukete et al., 2018a). Therefore, additional studies that identify drivers of household forest dependence and the determinants of livelihood patterns for forest-dependent communities are necessary. These would aid in reducing negative impacts on forest resources while ensuring forests are sustainably utilized.

Within the past three decades, the absence of reliable overall quantitative data on household forest resources dependence has preoccupied researchers in Cameroon. In this regard, several studies started addressing different aspects of household forest resources dependence, contributions to household income and rural livelihoods such as: economic contribution to livelihoods (Levang et al., 2015; Makoudjou et al., 2017), poverty alleviation (Ambrose-Oji, 2003; Tieguhong et al., 2012), role of NTFPs (Timko

© 2018, ALÖKI Kft., Budapest, Hungary

et al., 2010; Ofundem et al., 2017), drivers of dependence (Etongo and Glover, 2012; Ewane et al., 2015) and Reducing Emissions from Deforestation and Forest Degradation (REDD+) initiatives (Chia et al., 2013; Awono et al., 2014). These REDD+ initiatives are mechanisms via which developing countries are financially rewarded for achieving carbon emissions reductions and associated with a decrease in the conversion of forests to alternate land uses (Parker et al., 2009; Chia et al., 2013; Awono et al., 2014). Aside financial rewards, reduced deforestation and forest degradation, it facilitates the conservation and enhancement of forest carbon stocks as well as promotes sustainable forest management (Peskett et al., 2008).

Studies that directly address the topic of household characteristics and forest resource dependence in Cameroon are lacking and this is the very first study that addresses the topic in the Rumpi hills of the South West Region of Cameroon. This study bridges that knowledge-gap as it examines household characteristics and forest resource dependence. It also makes an analysis of how household characteristics may influence a household's dependence on forest resource use. This baseline information may help improve macro-level poverty estimates and serve as an input into conservation policy. It may also serve as a knowledge platform for effective collaboration between forest dependent communities, forestry stakeholders and policy makers to design effective community-based forest management and rural development programs aimed at reducing deforestation and forest degradation.

Materials and methods

Study area

The Rumpi hills forests (4°49' N 9°10' E) and their characteristic horse-shoe shaped Rumpi Hills Forest Reserve, (RHFR) (Latitude: 4°51′26″ Longitude: 9°07′15″) are located in Ndian division (Latitude: 4° 50' 00Longitude: 8° 50' 00"). Ndian division is an administrative unit in the South West Region of Cameroon covering an estimated area of 6626 km^2. Its mountainous areas are characterized by undulating Rumpi hills ranging from 400-1800 m with the highest peak at Mount Rata located in the eastern borders of the study area (*Fig. 1;* SWPA, 2016; Mukete et al., 2018b).

The RHFR is one of the oldest protected areas in Cameroon. Previously known as the Rumpi Hills Native Administration Forest Reserve, it was created in 1941 and occupies an area equivalent to 455 km^2 spread across four local council areas in Ndian division. The eastern borders are in Dikome Balue, southern borders in Ekondo Titi, western borders in Mundemba and northern borders in Toko local councils, respectively (Mukete et al., 2018b).

Mangroves and creeks dominated estuary forms a very low and indented point of contact with the sea in the Rio del Rey Estuary along the Gulf of Guinea making-up over 40% of Ndian. About 25% of the remaining land area is flat while the other 35% is mountainous and dominated by the Rumpi hills – our study area. Based on 2001 population survey in addition to future projections, the population of Ndian division is estimated at 362201 of which 17% are semi-urban and 83% rural. The average population density is 54.7 inhabitants per km^2. This density drops to an estimated 20 inhabitants per km^2 in the Rumpi hills and maritime areas. Meanwhile, around the semi-urban centers in Ekondo Titi and Mundemba, the population density increases to about 220 inhabitants per km^2 (BUCREP, 2015; Mukete et al., 2018b).

Covering over 2300 km^2, the Rumpi hills forests constitute a combination of montane, coastal evergreen, drier northern semi-evergreen forests, and other vegetation types (Mukete et al., 2017). These forests are very rich in terrestrial and marine ecological diversity with plant and animal species that range from simple to complex organisms. About 198 bird species including the endangered white-throated mountain-babbler (*Kupeornis gilberti*) and white-necked pigeon (*Columba albinucha*) have been identified. Also, many tropical montane mammal, reptile and amphibian species such as the endangered drill (*Mandrillus leucophaeus*) and forest shrew (*Myosorex rumpii*) have also been identified (Linder, 2013; Birdlife International, 2014).

The soils are composed of Precambrian clays and sandstones which may have emanated from various volcanic eruptions (Yerima and van Ranst, 2005). The area exhibits two seasons, a dry season from December to February and a rainy season from May to October with annual rainfall ranging from 4027 to 6368 mm. Temperature varies little throughout the year with mean monthly maximum temperatures in the dry season being 31.8 °C and in the rainy season 18.2 °C. The relative humidity is high during most of the year with minimum monthly values ranging between 78% and 90% (Etongo and Glover, 2012; Mukete et al., 2017).

Approximately 90% of the local population directly or indirectly relies on forests for their livelihood where food and cash crops including yams, spices, vegetables, cocoyams, plantains, cocoa, and oil palm are widely cultivated. The local population especially in the rural areas also depends on the harvesting of NTFPs primarily as an offseason job when pressure on crop cultivation is reduced. In the high altitude forest areas of Dikome Balue and Toko local councils, hunting and NTFPs gathering are important activities for the local communities. The rural population also benefits from employment as labourers provided by the agroindustrial giant Pamol Plantations Plc, smallholder plantations and in small private businesses. The national road N16 from Kumba in Meme division passes through the major semi-urban areas of Ekondo Titi and Mundemba in the southern and western zones (*Fig. 1*). Moreso, the different maritime ports of the Rio del Rey estuary also provide excellent access points by water to neighbouring Nigeria, Equatorial Guinea and Gabon which facilitates the evacuation of forest resources (Malleson, 2000; Mukete et al., 2018b).

Sampling of rural communities

Data on the drivers of household characteristics and forest resources dependence were obtained through different methods. They include household surveys – semi-structured, close and open-ended recall questions, and 20 focus group discussions (FGDs) with household heads and forestry stakeholders (Mukete et al., 2017). Majority of the studied villages are adjacent to the RHFR and are among those that had existed and had been using the forest even before the horse shoe-shaped RHFR was created. These villages thus represent an important source for historical data. The number of households in each village was obtained from the local village chiefs because official census data are lacking. In villages with less than 25 households, only semi-structured and open ended questionnaires through a door to door survey were used. Meanwhile, villages with more than 25 households were divided into groups for easy implementation of FGDs. The number of participants in a FGD was limited to 10 and included volunteers and or randomly selected farmers of at least 18 years old (as required by Cameroon Law). Their National Identity Cards were verified and in cases where this was unavailable, recommendation was sought from the local village chief or

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

his representative. In instances where potential participants were unable to effectively communicate in English language, "Pidgin English" or Oroko dialect was used by the first author to ensure proper understanding. The interview captured at least 70% of the households per village giving a total of 484 interviews of households across the 20 adjacent villages.

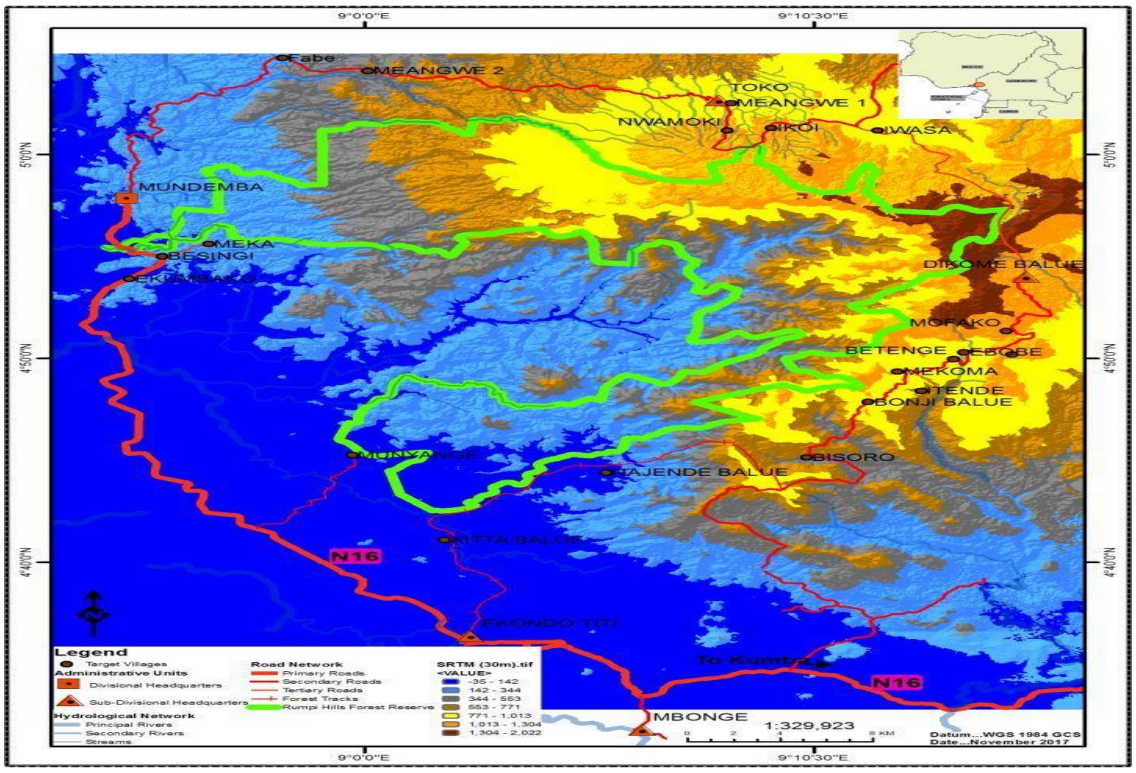

Figure 1. *Location map of the study area*

The household which was the basic unit for this research was defined *as a group of people living together in the same house who regularly cook and eat from the same pot*. Here, questions were centered on the gender, age, annual income, income sources, educational level, marital status, ethnicity; farming practices and off-farm activities of the household head. Information was also collected from local forestry stakeholders on the drivers of deforestation at the micro level, their engagement of rural households in mitigating the effects of deforestation in addition to the implementation of forest management policies. The questionnaires were designed so as to gain an understanding of household characteristics, the driving causes of their dependence on forests and its implications for forest sustainability. A two-point type scale (Yes = important, No = not important) was used to examine the importance of forests to household income, sustenance, livelihood and access into protected areas (Ofoegbu et al., 2017).

Statistical analyses

Data collected through the questionnaire-based survey were analyzed using Stata 13.0 for Mac. A regression analysis was also conducted to determine the relationship between the dependent and independent variables. Hence, the dependent variables were regressed on independent variables in order to determine if there was a statistically

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_27552779
© 2018, ALÖKI Kft., Budapest, Hungary

significant relationship and how much variation of the dependent variables was explained by the independent variables. The p-value ≤ 0.05 represented statistical significance at the 95% confidence interval and the data analysis procedure used in this paper was adopted from Kleinbaum et al. (1998) and Mbatu (2006).

The econometric model is expressed as follows (*Eq.1*):

$$Y = \beta_o + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + ? + \beta_n X_n + E \quad \text{(Eq.1)}$$

where Y is the dependent variable and represents household forest dependence. The eight variables examined in this study and used as dependent variables are included in *Table 1*.

Meanwhile, X_n are the independent variables which represent the potential causes or human forces that influence the variability of dependent variables. These are the household characteristics that affect forest dependence or 20 explanatory variables that have been classified in *Table 1*.

β_o is a constant or intercept and it represents the change in the dependent variable when there is no change in the independent variables.

β_n are the regression coefficients and represent the percentage change in the dependent variable when the independent variables increase by 1%.

E is the error term or error component. It represents the variations of the dependent variable that are not explained by the independent variables included in the model.

Table 1. *Variables used in the econometric model*

Dependent variables (Y)	Independent variables (X_n)
Little or no financial cost to use forests	Gender of household heads: male and female
Forest resource abundance	Age of household heads: 0-21 years, 22-60 years, over 60 years old
Easy access to forest	Residence period in village: 0-5 years, 6-10 years, 11-15 years, 16-20 years, and over 20 years
Absence of alternative energy	Educational level of household heads: university, secondary, primary, and uneducated
Unemployment	Residential status of household heads: indigenous and migrant
Shock avoidance	Marital status of household heads: married, single, divorced, and widowed
Farming ability	
Animal rearing ability	

Results

Age and gender characteristics of the household

Out of the 484 households (164 in Dikome Balue, 96 in Ekondo Titi, 119 in Mundemba and 105 in Toko, respectively), 57% were male-headed while 43% were female-headed, most of whom were either widows or divorced and were in the 21-40 age group. Besides Ekondo Titi — a hotspot for immigrants from other parts of the country, the respondents especially in the villages have lived there for more than 20 years. Therefore, the period of residence in the villages was greater than one year and majority of the respondents were indigenous and also married. For household age

composition, 18.8% belonged to the 0-21 years age group, 39.6% in the 21-40 years (very active age group), 25.6% in the 41-60 years (active group) and 16% in the 61+ years age (retirement or inactive) age group. Additionally, a minuscule 2.3% respondents had acquired university education, 20.4% had secondary education while 37.3% had completed primary education. Therefore, an average of 40% respondents across the case study villages had no formal education and could neither read nor write. This lack of formal education does not qualify them for formal jobs either with the government or private sector but were actively involved in agriculture and other extractive activities (*Table 2*).

Table 2. *Demographic and socioeconomic characteristics of the household heads across the four study sites. Here, 57% were male-headed while 43% were female-headed, and where 39.6% were in the 21-40 years (very active age group)*

Occupation, income sources and levels

Households are mainly involved in cash and food crop cultivation with the latter mainly practiced through shifting cultivation and agroforestry systems. Farm sizes were instrumental in the choice of practice engaged by farm households because those having 0.2 to 2.5 hectares (ha) of land mostly cultivated both food and limited amount of cash crops in the so-called agroforestry systems. Meanwhile, cash crop cultivation primarily occurred on farmlands ranging between 2.5 and 10 ha. In agroforestry systems, cash crops (cocoa, oil palm), fruits trees (mango, African plum and oranges) and food crops (cassava, maize, and yams) are intercropped or farmed together.

Aside farming, domestic animals have been part of the culture, tradition and lifestyle of the local populations for as long as they have existed. Many of the households (64%) domesticate animals like fowls, goats, pigs and dogs. This culture, tradition and lifestyle is also embedded in household environmental resources consumption and marketing of forest products including wood, rattan and bamboo products, fruits and nuts; hunting and fishing products such as rodents, birds, snails, tilapia, mudfish and shrimps.

Off-farm income mainly from petty businesses was reported by 31.1% of the surveyed households. In addition, fewer numbers of households corresponding to 3% also earned income from rendering services such as transportation. Other additional income sources particularly during the farming season include shared labour in the form of hire, meeting groups and two-party. *Two party is a practice whereby at harvest time, the crops are shared with the land owner on the basis of usually a verbal agreement* (Mukete et al., 2017). Similarly, households derived 65.9% of their average total household income from farming and animal rearing. Meanwhile, forest products including fuelwood collection and wood harvesting were also important livelihood and household income sources contributing over 34.1% of household income.

From *Table 3,* fruits and nuts include banana, mango, oil palm, plantain, cashew, plum; spices are mostly bush pepper, grains of paradise, ginger; vegetables are pepper, okra, tomato, egusi, garden eggs; root crops refer to tubers such as yams, cocoyams, cassava, and potatoes; cereals comprise simply of corn while others include cocoa, tea, coffee, rubber and sugar cane.

Table 3. *Percentage contribution of farming, animal rearing and forest resources harvesting to household income*

Aside domestic animals, others include hunted animals such as rodents, birds, monkeys, antelopes, and deer. Meanwhile, forest products include wood harvested for construction, chewing stick, woodwork and charcoal production; bamboo products include mats, bags, thatches, and fishing tools; rattan products include baskets, chairs. Others include ropes, gum, fish, njangsang, bush onion, bush mango.

Drivers of household forest resources dependence

Results indicated that agricultural skill is the most important driver of household forest dependence as reported by 91% of the surveyed households (*Table 4*). Other drivers that influenced forest dependence as mentioned by respondents included easy access to forests in a village, little or no financial cost to use forests, forest abundance, absence of alternative energy sources and unemployment. Statistical analysis also found these drivers to be statistically significant (P-value = 0.000) at the 95% confidence interval although differently across the study area.

Table 4. *Reasons for household forest resources dependence in the study area. Here, agricultural skills or ability to farm was the most important factor responsible for household forest dependence*

Results of the statistical analysis are presented in *Table 5* while causal relationships between drivers of household forest resources dependence and household characteristics are presented in *Table 6*. Each model represents the relationship between a dependent variable and the two independent variables with most significant affects. For instance, easy access to forest resources correlated significantly ($P < 0.01$) with male household heads and also with uneducated household heads (*Table 6*). Furthermore, forest abundance was statistically significant ($P < 0.05$) and correlated significantly with household heads that were over 60 years of age and have acquired just primary education. Similarly, the desire to avoid shocks as a result of poor harvest and job loss

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_27552779
© 2018, ALÖKI Kft., Budapest, Hungary

was significant ($P < 0.01$) and related positively with household heads whose status was single and divorced (*Table 6*).

The people that have lived in study areas for 6 to 10 years and who were also married were the two variables that significantly affected the dependent variable, little or no financial cost to use forests (*Eq. 2*). Here, a 1% increase for households that have lived for 6 to 10 years in the communities, the lower their cost of using forest resources by 3.02%. Therefore, forest dependence is expected to increase especially if majority of the surveyed households have lived in the area for 6 to 10 years. Meanwhile, a 1% increase for household heads that were married would decrease forest dependence by 0.92% although the impact is not statistically significant.

$$Cost = 102 + 3 * R_610 - 0.9 * Married \quad \text{(Eq.2)}$$

Similarly, the two variables – household heads that were over 60 years old and with just primary education have significant impacts on forest resources abundance as expressed in *Equation 3*. Hence, a 1% increase in this age group and education level decreases household dependence on forests by 2.11% and 1% respectively. Therefore, as the number of elders and children increases, forest dependence decreases.

$$Abundance = 139.4 - 2.1 * Age_60 - 1 * Primary \quad \text{(Eq.3)}$$

Easy access to forests is significantly affected by the number of male household heads and people with no education. Contrary to conventional thinking that male-headed households are likely to have more access to forest resources, results indicated that a 1% increase in male headed households also decreases their easy access to forests by 1.93% and by implication their dependence (*Eq. 4a* and *Table 6*). On the other hand, a 1% increase among uneducated household heads resulted to a 1.36% increase in their easy access to forest resources. It shows therefore that, local communities are likely to become more forest-dependent as illiteracy rate increases given that all other factors are held constant (*Eq. 4b* and *Table 6*).

$$Access = 135.3 - 1.9 * M_heads + 1.3 * Uneducated \quad \text{(Eq.4a)}$$

$$Access = -57.5 + 1.9 * F_heads + 1.3 * Uneducated \quad \text{(Eq.4b)}$$

Furthermore, a 1% increase for household heads that were over 60 years of age resulted to a 6.27% decrease on the lack of alternative sources of energy. For household heads that have lived in their respective communities for 11 to 16 years, an increase of 1% also increases their lack of alternative energy sources by 0.58%. This implies that, as the number of household's increases especially for those that have resided in the area for 11 to 16 years and those who also lack alternative energy sources beside the use of wood energy, their dependence on forests will also increase (*Eq. 5*).

$$Alternative\ energy = 160.6 - 6.2 * Age_60 + 0.5 * R_115 \quad \text{(Eq.5)}$$

Based on *Equation 6* and *Table 6*, a 1% increase for households who have resided in the respective communities for a period of 6 to 10 years increases forest dependence

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_27552779
© 2018, ALÖKI Kft., Budapest, Hungary

especially for those that were unemployed by 199.3%. It is observed here that, a 1% increase among uneducated household heads also decreases unemployment by 47.26%.

$$Unemployment = -226.2 + 199.2 * R_610 - 47.2 * Uneducated \quad \text{(Eq.6)}$$

Accordingly, *Equation 7* represents the relationship between the number of people that depended on forests in order to avoid shocks based on two marital status — single and divorced. Results showed that a 1% increase for those that were single decreases their shock avoidance by 4.3% or people who are single are less forest-dependent. Additionally, a 1% increase for divorced households would cause shock avoidance to increase by 12.52%, hence forest dependence is likely to increase as the number of divorced households increases.

$$Shock\ avoidance = 34.7 - 4.3 * Single + 12.5 * Divorced \quad \text{(Eq.7)}$$

In *Equation 8,* the number of people with farming ability was regressed at two levels: households who lived in the study area for 16 to 20 years and who were also married. It was observed that an increase by 1% for households, who have lived in the villages for 16 to 20 years, also increased their farming activities by 1.58%. Therefore, as the number of households who have lived in these communities for 16 to 20 years increases, forest dependence will also increase as a result of farming activities. This is because households search for new farmlands in the forests when the productivity of their current fields shows signs of decrease. On the other hand, a 1% increase for household heads that were married also decreases farming activities by 1.54%.

$$Farming\ ability = 162.1 + 1.5 * R_1620 - 1.5 * Married \quad \text{(Eq.8)}$$

The number of people with animal rearing ability was modeled against the number of people aged 21 years at most and who were also married. Regression results showed that a 1% increase in household heads that are married would cause animal rearing to increase by 4.46%. Therefore, a 1% increase for household heads that were at most 21 years of age increases animal rearing by 0.5%. Thus, forest dependence also increases as the number of young people increases and as more people get married (*Eq. 9*).

$$Animal\ rearing = -218.2 + 0.5 * Age_021 + 4.46 * Married \quad \text{(Eq.9)}$$

Discussion

Household characteristics and forest resource dependence

Households' forest dependence was found to be significantly influenced by characteristics such as gender and the level of education of household heads, age, marital status, and years of residence in the village. As the number of uneducated household heads increases, forest dependence due to easy access to forest resources also increases. This implies that, rural households become more forest-dependent as the illiteracy rate increases. Farm households primarily lack the basic education that could enable them gain any type of formal employment. As such, these households largely depend on agriculture (food and case crop cultivation) and other extractive activities such as the harvesting of NTFPs from the forest and other land uses. Even when farmers are aware of other options for livelihood diversification, translating such knowledge into practice is confronted with socio-cultural, economic, institutional and even environmental constraints. Therefore, with constraints on rural households that depend primarily on land and forests, their dependence on forests resources is a more feasible option to augment household income and improve on livelihoods (Etongo et al., 2015; Mukete et al., 2018b).

Additionally, households' forest dependence due to minimal or no financial costs associated to the use of forest resources was mostly determined by the number of household heads who had lived in the villages for 6 to 10 years and also among those that were married. Therefore, as the number of households who have lived in these villages for 6 to 10 years increased, forest dependence also increased. This is due to the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_27552779
© 2018, ALÖKI Kft., Budapest, Hungary

absence of other options for livelihood such as in the industrial sector unavailable in most towns of Cameroon. Similarly, household forest dependence as a result of forest resources abundance was determined by the quota of household heads that were over 60 years old with primary education as their highest qualification. Hence, an increase in the number of elderly people and children decreased forest dependence. This may be related to the fact that both groups of people do not have the physical capabilities required for exploiting forest resources especially across a roughed terrain such as the Rumpi hills.

Also, household forest dependence as a result of no alternative source of household domestic energy beside wood energy was observed to be driven by the number of respondents above 60 years and those who had lived in these villages for 11 to 16 years. Just as in the little or no financial cost in the use of forest resources, forest dependence decreased as the people get older. Given the youthful population in the study area, dependence on forest resources is a common process because harvesting of forest products requires not only lots of energy but in most case longer distances have to be cover in the forests — conditions that are likely to be fulfilled by the younger and energetic youthful male population. Therefore, as the male population grow older; their ability to harvest forest resources decreases often due to lack of physical strength and in some cases poor health conditions.

In addition, forest dependence in order to avoid shocks correlated with the number of people who were single and also those that were divorced. This infers that singles are less likely to use forest resources because they have less responsibility in the form of the number of mouths to be fed. On the other hand, forest dependence increased as the number of divorced cases increased. In this case, divorced people may still have mouths to feed and were more likely to avoid shocks (poor crop harvests and job loss) through the use of forest resources for household subsistence.

From another perspective, forest dependence due to subsistent activities such as animal rearing increased as more people got married. Most of the household heads that were married with relatively younger families had low capital and labour inputs. For majority of such households, forest dependence is greatest as nearby bushes and forests are cleared for cropping and harvesting of fodder for livestock. The relatively younger families also bear the brunt of early child-bearing years and face the greatest pressures to increase forest dependence in order to augment their limited labour force which likely insufficient to allow the household to self-sufficient on food crop cultivation (Murphy et al., 1999; Mukete et al., 2018b).

According to Malleson (2000), households that are involved in animal rearing and who have also lived long in the villages are likely to be more forest depended. This is due to the relatively low cost associated with supporting their livelihood strategies. Therefore, forest resources, their availability, access and abundance around rural communities generally favour animal rearing as a livelihood strategy. Related studies Bwalya (2013), Tieguhong et al. (2012) and Angelsen et al. (2014) observed that income and the rate of consumption of forest products by a household were more likely to increase its demand for forest-related livelihood activities.

Economic drivers and household forest resources dependence

Generally, there is a high dependency on forest and farm related income sources which are a reflection of low household annual income, an overview of the differences in income levels and a lack of access to credit schemes as well as government subsidies

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

(Mukete et al., 2018a). Estimates on poverty based on the United Nations global poverty index correspond to people living on less than 1.25 USD (United State Dollars) or 625 FCFA (Central African Franc) a day and where majority are located in developing countries particularly in rural areas (Phimmachanh et al., 2015). From these various estimates, 49.2% of the households were found to be poor and belong to the lowest income group of less than 460 USD per annum. This explains the high dependency on forest and agriculture related activities in order for these households to meet their daily livelihood requirements. Also, rural households have not fully engaged off-farm sources of income and a minuscule or in most cases, a complete absence of the industrial sector additionally explain their high dependency on forest and agriculture related activities (Mukete et al., 2016b). Meanwhile, household daily income was estimated in the local currency, the Franc CFA at 1 USD = 500 FCFA (Etongo and Glover, 2012).

From another perspective, the high dependency on the harvesting of forest resources, food and cash crop cultivation, and hunting portrays a higher price advantage with respect to the other income sources at both village and distant markets. These have provided strong incentives for agricultural and forest resource extraction. Additionally, majority of households lack access to credit schemes and government subsidies. As such, they primarily depend on family circles, friends and farmers' groups for loans. This lack of access to finance has also been a driving force for agricultural and forest resource dependence in the Rumpi hills (Malleson, 2000; Mukete et al., 2017). This is also because poverty limits the household's ability to invest in agriculture at a larger scale, thus local household agricultural investments continue to remain at the subsistence level.

Similar studies by Babulo et al. (2009) and Angelsen et al. (2014) found a relationship between household income and resource dependency. These studies observed that low income households were more dependent on natural resources leading to ecological degradation. Meanwhile Kamanga (2009) and Nguyen et al. (2015) observed a high variability in the relationship between poverty and ecological degradation. Narain et al. (2008) and Bwalya (2013) on the other hand found middle income households to be less dependent on forest resource as compared to the poorest and relatively richer households. Also Zenteno et al. (2013) used social ecological systems theory (SES) to analyze change in forest communities in the northern Bolivian Amazon. Their study observed that despite the various changes in both internal and external policies, population growth, competition among households and more profitable economic opportunities still threaten forest resources dependence. Garekae et al. (2017) studied the level of household forest dependency using a range of socio-economic factors around the Chobe Forest Reserve of Botswana. Their study found age and education to significantly influence household forest resource dependence. Their study also showed forest dependence to decrease with increasing respondent age and educational level. Therefore, the youth were likely to be more forest dependent when compared to the elderly age group with higher levels of educational attainment who are likely to be less forest dependent.

Conclusion

It is necessary to integrate household dynamics and surrounding forest conditions in forest related studies especially in remote forest depended communities. This is because

household reliance on forest resources is conditioned by various household characteristics and forest outcomes — structure, composition and abundance. As such forest dependence by households can be comprehensively evaluated through the lens of household and farm characteristics, access to forests and forest incomes.

Household characteristics such as gender and education of household heads, age, marital status, and years of residence in the village influence household's dependence on forest resources. Aside from household characteristics, other factors particularly related to surrounding forest conditions such as easy access to forests in a village, minimal or no financial costs on the use of forests and forest abundance are likely to influence a household's dependence on forest resources. These household characteristics when considered in isolation did not usually influence forest resources dependence except when considered in combination with surrounding forest conditions. For instance, as the number of uneducated household heads increases, forest dependence due to easy access to forest resources increases. This implies that, rural households become more forest-dependent as the illiteracy rate increases ceteris paribus. Formal education and the level of attainment especially higher education are important not just for formal employment but can position farm households to effectively engage in agriculture in a sustainable way with little reliance on NTFPs collection. But this is not the case in the rural areas in Cameroon and the Rumpi hills in particular as majority of the farm households are uneducated. The capacity building that is to be provided by the agricultural extension workers also run short of staff and contacts with farmers are minimal and not available in most cases.

Meanwhile, household characteristics such as the number of people above 60 years and those who have lived for 11 to 16 years in their villages influenced household forest dependence as a result of the lack of alternative source of energy beside fuelwood. Therefore, forest dependence decreased as the people get older and given the youthful population in the study area, dependence on forest resources is forecasted to increase in the coming decade except a transition from wood to more renewable energy sources becomes evident. Meanwhile, a household's forest dependence is also influenced by its desire to avoid shocks and this is conditioned by household characteristics such as the number of single and divorced households in the village. This implies that singles are less likely to use forest resources because they have less responsibility in the form of the number of mouths to feed.

This study also observed that a household's dependence on forest resources portrays a higher price advantage with respect to the other income sources at both village and distant markets. These have provided strong incentives for agricultural and forest resource extraction because majority of households lack access to credit schemes and government subsidies, but depend primarily on family circles, friends and farmers groups for loans. This lack of access to finance which in turn limits a households' ability for livelihood diversification has also been a driving force for agricultural and forest resource dependence in the Rumpi hills.

The study also corroborates existing scientific literatures that forest resources dependence at the household level is usually conditioned by household characteristics, surrounding forest conditions and prevailing household economic dynamics. It has also brought forward an understanding of the major factors that influence household forest resources dependence especially in remote communities. Some of these factors include household characteristics (gender, educational level, marital status, and age of household heads); surrounding forest conditions (forest resource abundance and easy

access to forest) and economic dynamics (absence of alternative energy, shock avoidance, unemployment, income sources and levels as well as the ability to farm and rear animals). Using these factors, effective policies can be developed that take into cognizance socioeconomic needs and characteristics of forest dependent communities. These policies will also include a broad-based assessment of local community socioeconomic conditions before the development, implementation and monitoring of forest management and exploitation initiatives.

APPENDIX

Drivers of household forest resources dependence

The econometric model is expressed as follows:

$$Y = \beta_o + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + ? + \beta_n X_n + E \quad \text{(Eq.1)}$$

where Y is the dependent variable and represents household forest dependence. The eight variables examined in this study and used as dependent variables are included in *Table 1*.
Xn are the independent variables and represent the potential causes or human forces that influence the variability of dependent variables. These are the household characteristics that affect forest dependence or 20 explanatory variables.
βo is a constant or intercept and it represents the change in the dependent variable when there is no change in the independent variables.
βn are the regression coefficients and represent the percentage change in the dependent variable when the independent variables increase by 1 percent.
E is the error term or error component and represents the variations of the dependent variable that are not explained by the independent variables included in the model.

Abstract. Selenium (Se) is an essential micronutrient for humans, animals and plant growth. The consumption of plant products containing a high Se concentration, is the most efficient and safe way of Se supplementation. Selenium concentrations in plants vary depending on exogenous selenium levels, plant species and variety. In the recent pot experiment, the effects of exogenous selenium (0, 0.5, 1.0, 2.5 and 5 $mg \cdot kg^{-1}$) on the selenium uptake and transport of three *Brassica* vegetables (*Brassica rapa ssp. chinensis* L., *Brassica rapa ssp. pekinensis* L. and *Brassica oleracea* var. *capitata* L.) were studied. The expression levels of selenium metabolism related genes families, such as APS, APR, SAT, SMT, CysD and MMT, were also detected using qRT-PCR assays. The results showed that selenium concentration in leaves, stems and roots of the three *Brassica* vegetables increased with the increase of soil selenium level. The selenium concentration in the leaves of the three *Brassica* vegetables was the highest at selenium level of 5 $mg \cdot kg^{-1}$. Leaf selenium concentration of *Brassica rapa ssp. chinensis* L. was significantly 1.39-3.02 times higher than that of the other two vegetables. Under the same selenium treatment, selenium concentration, selenium accumulation coefficient and transport coefficient of edible parts of *Brassica* vegetables were the highest in *Brassica rapa ssp. chinensis* L. and the lowest in *Brassica oleracea* var. *capitata* L. At soil selenium level of 5 $mg \cdot kg^{-1}$, the expression levels of SAT, SMT and MMT in leaves of *Brassica rapa ssp. chinensis* L. and the expression levels of SAT, APS, SMT, APR and MMT in leaves of *Brassica pekinensis* L. significantly increased. *Brassica rapa ssp. chinensis* L. had the best selenium enrichment effect among the three *Brassica* vegetables.
Keywords: *selenium, Brassica, bioconcentration factor, qRT-PCR, selenium metabolism related genes*

Abbreviations: Se – selenium, APS – ATP sulfurylase, APR – APS reductase, SAT – Serine acetyltransferase, CysD – Cysteine desulfurase, MMT – S-adenosyl-L-Met:L-Met S-methyltransferase, SMT – selenocysteine methyltransferase, MeSeCys – methylselenocysteine, SeMet – Selenomethionine, OAS – O-acetylserine, BCF – bioconcentration factor, TF – translocation factor, SeMM – methyl-Semethionine, SMM – thiomethyl methionine

Introduction

Selenium (Se), a vital trace element for humans, is important for preventing disease, improving health, and preventing aging and has been considered a life-protecting agent (Gupta et al., 2016). Most soils of the world has a selenium content of 0.01-2.0 $mg \cdot kg^{-1}$, with an average content of 0.4 $mg \cdot kg^{-1}$. In selenium-deficient soil, Se content is less than 0.15 $mg \cdot kg^{-1}$. The world's selenium-deficient population reaches 1.5 billion (Zhu et al., 2009). About 72% of China's land area has varying degrees of selenium deficiency (Zhou et al., 2016). Selenium content of less than 0.05 $mg \cdot kg^{-1}$ in human

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

© 2018, ALÖKI Kft., Budapest, Hungary

foods results in selenium deficiency, but greater than 5 $mg \cdot kg^{-1}$ can be toxic (Wen, 2006). Inorganic selenium supplementation not only has the problem of low uptake and conversion rate, but also will adversely affect human health because of the narrow safe dose range of selenium (Keskinen et al., 2010; Zhao et al., 2017). Bio-selenium is the safest and most effective way to supplement human selenium (Ellis and Salt, 2003; Song et al., 2017). By absorbing and enriching exogenous selenium and converting it to safe and effective bioorganic selenium, crops improve human or animal selenium nutrition in low and selenium-deficient areas (Zhang et al., 2014; Li et al., 2015; Liu et al., 2017).

Selenium levels in plants vary depending on exogenous selenium levels, plant species and variety (Longchamp et al., 2015; Bañuelos et al., 2016). Under the same soil selenium level, the selenium concentrations in fruits of different tomato varieties were ranked as Luobeiqi > KT30 > Defumm-8 (Zhao et al., 2017). The selenium concentration in shoot, stem and root of *Brassica rapa* Linn L. was higher than that of *Brassica tumida* Tsenet Lee L. at the same soil selenium level (Xie, 2016). However, there are also reports to the contrary. Yawata et al. (2010) conducted a study on three cruciferous crops [Indian mustard (*Brassica juncea*), nozawana (*Brassica rapa* var. *hakabura*) and komatsuna (*Brassica rapa* var. *peruviridis*)] and found that there was no significant difference in selenium concentration among the three crops. However, due to its rapid growth and larger biomass, komatsuna has higher selenium accumulation.

ATP sulfurylase (APS) exerts a rate limiting effect on selenate reduction and selenium assimilation (Matich, et al., 2012; Zhang, 2014). Overexpression of APS in transgenic plants promoted APSe separation into AMP and selenite and increased selenium accumulation (Xie, 2016; Zhao et al., 2017). APR (APS reductase) is the APS reductase gene. Methylation is the major metabolic pathway for selenium in plants. After selenomethionine (SeMet) production, selenium is converted to methylselenocysteine (MeSeCys) by the methylation pathway under the action of selenocysteine methyltransferase (SMT) (Song et al., 2017). SMT activity is closely linked to the high accumulation of selenium in eight species of Astragalus with different selenium enrichment ability (Fang et al., 2017; Schiavon and Pilon-Smits, 2017). McKenzie et al. (2009) reported that 200 μM selenium application resulted in an over-expression of SMT transgene in crops, which increased selenium accumulation in crops by 2-4 times, made MeSeCys content reach 20% of the total selenium, with MeSeCys directly converted to methyl second-generation selenium. In addition, CysD (Cysteine desulfurase), MMT (S-adenosyl-L-Met:L-Met S-methyltransferase) and SAT (Serine acetyltransferase) were also found to be the main genes for plant metabolism and selenium accumulation. Co-expression of SAT and SMT promoted the increase of OAS (O-acetylserine), which in turn promoted the expression of sulfur transporter as well as plant uptake and accumulation of selenium (Çakır et al., 2012; Song et al., 2017).

Brassica has the strongest selenium enrichment ability (Wiesner-Reinhold et al., 2017). At present, there are many reports on selenium-enriched crops at home and abroad (Matich, et al., 2012; Zhao et al., 2017). However, there are few reports of Se enrichment difference and Se related gene expression in *Brassica* vegetables (Xie, 2016). In this experiment, *Brassica rapa ssp. chinensis* L. (pakchoi), *Brassica rapa ssp. pekinensis* L. (Chinese cabbage) and *Brassica oleracea* var. *capitata* L. (cabbage) were used as materials to compare the differences in selenium uptake, selenium transformation and transport among the three *Brassica* vegetables. Also, selenium metabolism related gene expression of the three *Brassica* vegetable s was tested.

Materials and methods

Plant material, soil and Se treatments

The seeds of *Brassica rapa ssp. chinensis* L., *Brassica rapa ssp. pekinensis* L. and *Brassica oleracea* var. *capitata* L. were purchased from Xiema farmer's market in Beibei district, Chongqing, China. The experimental soil was taken from Jiulongpo District of Chongqing, China. The soil pH was 6.70, soil organic matter was 9.08 $g \cdot kg^{-1}$, soil total nitrogen was 0.64 $g \cdot kg^{-1}$, soil available nitrogen was 72.77 $mg \cdot kg^{-1}$, soil available phosphorus was 54.81 $mg \cdot kg^{-1}$, soil available potassium was 216.7 $mg \cdot kg^{-1}$, soil cation exchange capacity was 30.3 $cmol \cdot kg^{-1}$, soil total selenium was 0.42 $mg \cdot kg^{-1}$ and soil available selenium was 0.029 $mg \cdot kg^{-1}$.

Pot experiment was conducted at No. 1 glass greenhouse of College of Resources and Environment of Southwest University, Beibei District, Chongqing, China (106.4N, 29.8E), from November 4, 2014 to February 25, 2015. Five selenium levels (0, 0.5, 1.0, 2.5 and 5 $mg \cdot kg^{-1}$) prepared from Na_2SeO_3 were set up. Considering the larger biomass of *Brassica oleracea* var. *capitata* L. than *Brassica rapa ssp. chinensis* L. and *Brassica rapa ssp. pekinensis* L., two $plant \cdot pot^{-1}$ of *Brassica oleracea* var. *capitata* L., three $plant \cdot pot^{-1}$ of *Brassica rapa ssp. chinensis* L. and *Brassica rapa ssp. pekinensis* L. respectively were planted in black plastic basin (25 cm in diameter and 17 cm in height), each basin was loaded with 5 kg of air-dried soil screened with 5 mm sieve. The total dosage of nitrogen fertilizer, phosphate fertilizer and potassium fertilizer was 180 $mg \cdot kg^{-1}$, 100 $mg \cdot kg^{-1}$ and 150 $mg \cdot kg^{-1}$, respectively. Ammonium nitrate, monopotassium phosphate and potassium sulphate were used as nitrogen, phosphate and potassium fertilizers, respectively. Each treatment was repeated 3 times and arranged randomly. During the cultivation period, pure water was used to maintain soil water content at 60% -80% of the maximum water holding capacity of the field. Considering the longer growth period of *Brassica oleracea* var. *capitata* L., *Brassica oleracea* var. *capitata* L. was harvested after 85 days, and *Brassica rapa ssp. chinensis* L. and *Brassica rapa ssp. pekinensis* L. were harvested after 65 days. Edible parts of vegetables were taken, quick-frozen by liquid nitrogen and placed in -80℃ refrigerator for later RNA extraction.

Analysis of soil physicochemical properties

The soil pH was ascertained in 1:5 (soil: water), and available phosphorus, available potassium and total nitrogen in soil was determined in term of a previously report (Rayment and Higginson, 1992). The soil cation exchange capacity and soil organic matter content was determined on the basis of a previously published method (McCleod, 1975).

Analysis of Se concentrations in soil and plants

Soil and plant samples were ground and digested at 170°C using 10 mL of acid mixture (8 mL of ultrapure nitric acid and 2 mL of perchloric acid) (Kyodan et al., 1988). The acid mixture was heated until white smoke appeared; further, 10 mL of 6 $mol \cdot L^{-1}$ hydrochloric acid was added, and the mixture was heated until the white smoke reappeared (Kyodan et al., 1988). The residual sample was then diluted in 25 mL of ultrapure water (Kyodan et al., 1988). The concentration of Se in the solution was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1603_27812793
© 2018, ALÖKI Kft., Budapest, Hungary

analyzed using hydride generation atomic fluorescence spectrometry (PF6.3, Beijing Purkinje General Instrument Co. Ltd., China).

Detection of gene expression

RNA was extracted from edible part of the sample stored in the refrigerator at -80 ℃. The specific procedure followed the operation manual of the RNA extraction kit purchased from Tiangen Biotechnology Company (Beijing, China). Purification of total RNA, RNA detection, synthesis of reverse transcription cDNA, primer design and synthesis, PCR amplification of cDNA and real-time quantitative PCR were done according to Zhao et al. (2017) method.

The statistical analysis

Data were analyzed by one-way analysis of univariate ANOVA and followed by Duncan's multiple comparison tests using SPSS version 21.0 (IBM Corp., Armonk, NY, USA). The variables analyzed separately were Se concentration, bioconcentration factor (BCF) and translocation factor (TF) of Se in three *Brassica* vegetables. The BCF refers to the ratio of the Se concentration in tissues to the exogenous Se. TF is the ratio of Se concentration in shoots to that in roots (Renkema et al., 2011). The level of significance was 0.05.

Results

Selenium concentration

As can be seen from *Figure 1,* the selenium concentration in leaves, stems and roots of the three *Brassica* vegetables increased with the increase of soil selenium level. The selenium concentration in leaves, stems and roots of the three *Brassica* vegetables was the highest at the maximum level of soil selenium (5 $mg \cdot kg^{-1}$). At this time, leaf selenium concentration of *Brassica rapa ssp. chinensis* L. was significantly higher than that of the other *Brassica* vegetables by 1.39-3.02 times. Under the same selenium level, selenium concentration in stem and root of *Brassica oleracea* var. *capitata* L. was the lowest among the three *Brassica* vegetables.

Selenium transport ability

In order to better compare the differences in selenium uptake, transport and accumulation among the main *Brassica* vegetables, bioconcentration factor (BCF) and transport factor (TF) were introduced in this study to characterize the enrichment and transport of selenium in different *Brassica* vegetables. A higher BCF value indicates stronger selenium enrichment ability. A higher TF value suggests stronger ability of plants to transport selenium absorbed by the roots to shoot.

As can be seen from *Table 1,* $BCF_{leaves/soil}$ of *Brassica rapa ssp. chinensis* L. reached the maximum at 0.5 $mg \cdot kg^{-1}$ selenium, and decreased with the increase of soil selenium level. Selenium treatment had no significant effect on the $BCF_{leaves/soil}$ of *Brassica rapa ssp. pekinensis* L. and *Brassica oleracea* var. *capitata* L. With the increase of soil selenium levels, $BCF_{stem/soil}$ of three *Brassica* vegetables firstly decreased and then increased, reaching the highest at 0.5 $mg \cdot kg^{-1}$ selenium.

With the increase of soil selenium level, $BCF_{root/soil}$ of the three vegetables decreased first, reaching the lowest value at 1 $mg \cdot kg^{-1}$ soil selenium level, and then increased again, but still lower than that of non-selenium treatment. $BCF_{root/soil}$ of *Brassica oleracea* var. *capitata* L. was significantly reduced at high levels of selenium (5 $mg \cdot kg^{-1}$), which was 39.01% lower than in the case of 0.5 $mg \cdot kg^{-1}$ selenium level. Selenium transport coefficient of *Brassica rapa ssp. chinensis* L. and *Brassica rapa ssp. pekinensis* L. increased with the increase in exogenous selenium, indicating that greater soil selenium levels enhanced the ability of the two *Brassica* vegetables to transport selenium from the root to the shoot. On the contrary, *Brassica oleracea* var. *capitata* L. showed the opposite trend. For selenium transport coefficient (TF), that of *Brassica rapa ssp. chinensis* L. > *Brassica rapa ssp. pekinensis* L.≈*Brassica oleracea* var. *capitata* L., indicating that among the three tested *Brassica* vegetables, *Brassica rapa ssp. chinensis* L. has the strongest ability to transport selenium to shoot. In comparison of selenium enrichment factor of edible parts among the three *Brassica* vegetables, *Brassica rapa ssp. chinensis* L. ranked the top, while *Brassica oleracea* var. *capitata* L. was at the bottom.

Expression of selenium metabolism related gene

As can be seen from *Figure 2,* at soil selenium level ≤ 0.5 $mg \cdot kg^{-1}$, the SAT expression level was not significant in the leaves of *Brassica rapa ssp. chinensis* L. When the soil selenium level increased to 1 $mg \cdot kg^{-1}$, SAT expression level decreased drastically, reaching the lowest at 2.5 $mg \cdot kg^{-1}$ selenium, but significantly increased at 5 $mg \cdot kg^{-1}$ soil selenium level.

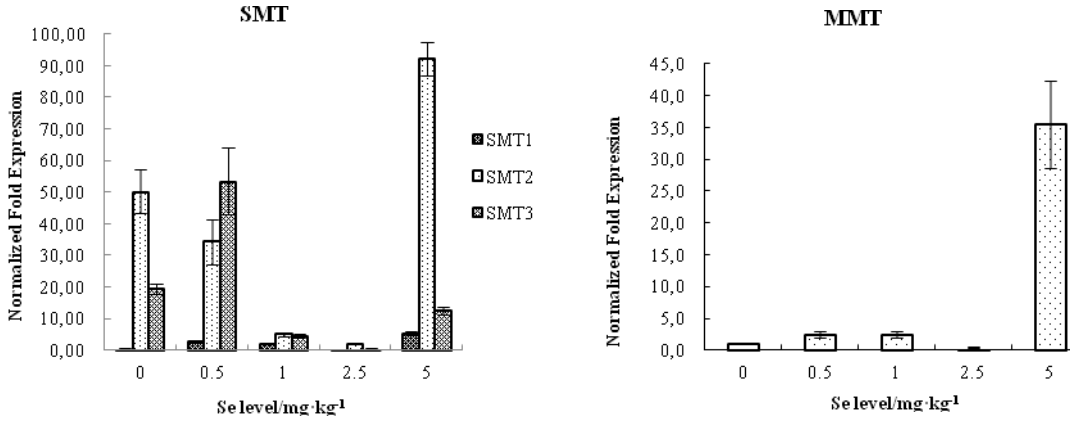

Figure 2. *Real-time PCR analysis of Se metabolism associated genes in leaf of Brassica rapa ssp. chinensis L.*

The expression level of SAT4 gene was the highest in SAT genes family of *Brassica rapa ssp. chinensis* L. at the same selenium level. Exogenous selenium inhibited the expression of APS4. At 0.5 mg·kg^{-1} soil selenium level, the expression levels of APS1, APS2 and APS3 increased by 1.10-12.20 times compared with those of non-selenium treatment. At soil selenium level ≥ 1 mg·kg^{-1}, expression level of APS was in order of APS2 > APS1 > APS3 > APS4 under the same selenium treatment. CysD gene expression level decreased first with the increase of soil selenium level, reaching the lowest level at 2.5 mg·kg^{-1} selenium, and then increased. However, CysD expression level in all selenium treatments was lower than that of non-selenium treatment. With the increase of soil selenium level, APR gene expression level first increased, reaching the highest level at 0.5 mg·kg^{-1} selenium, and then decreased. Under the same selenium treatment, APR expression level was ranked as APR3 > APR2 > APR1. With the change of soil selenium level, SMT2 expression level was the lowest at 2.5 mg·kg^{-1}, reaching the peak at 5 mg·kg^{-1}. SMT2 expression level was 1.84 times that of non-selenium treatment. Variation trend of SMT1 and SMT3 gene expression was consistent with that of APR. At soil selenium level ≤ 2.5 mg·kg^{-1}, there was no significant difference in MMT gene expression level. When selenium level increased to 5 mg·kg^{-1}, MMT expression level significantly increased, which was 33.42 times that of non-selenium treatment. Except MMT, selenium metabolism-related gene expression in leaves of *Brassica rapa ssp. chinensis* L. was inhibited at 1 mg·kg^{-1} and 2.5 mg·kg^{-1} selenium.

As can be seen from *Figure 3,* at soil selenium level ≤ 2.5 mg·kg^{-1}, expression levels of SAT, APS, SMT and APR in leaves of *Brassica rapa ssp. pekinensis* L. were low, but increased significantly at 5 mg·kg^{-1} selenium level. The expression level of SAT2, SAT4, APS2, SMT2 and APR2 was found the highest in the SAT, APS, SMT and APR genes family respectively. Exogenous selenium inhibited CysD expression level in leaves of *Brassica rapa ssp. pekinensis* L. MMT expression level first decreased with the increase of soil selenium level, reaching the lowest at 1 mg·kg^{-1} selenium level, and then increased, reaching the highest level at 5 mg·kg^{-1} soil selenium level.

As can be seen from *Figure 4,* except that APR1 expression in leaves of *Brassica oleracea* var. *capitata* L. was inhibited by exogenous selenium, the expression of other genes in leaves of *Brassica oleracea* var. *capitata* L. increased and then decreased with

the increase of soil selenium levels, reaching the highest at 0.5 mg·kg^{-1} selenium level. The APS expression in wild cabbage leaves was the highest among all the six genes, and APS4 expression level in leaves of *Brassica oleracea* var. *capitata* L. was up to 994.62 at 0.5 mg·kg^{-1} selenium.

The qRT-PCR assays of all Se metabolism related genes showed that the expression levels of detected genes in *Brassica oleracea* var. *capitata* L. were more severely regulated than that in other two vegetables at the same soil Se level. Moreover, the expression levels of all detected genes in *Brassica oleracea* var. *capitata* L. was much higher than that in other two vegetables even at soil selenium level ≤ 2.5 mg·kg^{-1} (*Figs. 2, 3* and *4*). It indicated that *Brassica oleracea* var. *capitata* L. might be more tolerant to exogenous Se and may has more complicate Se metabolism processes than *Brassica rapa* ssp. *chinensis* L. and *Brassica rapa* ssp. *pekinensis* L.

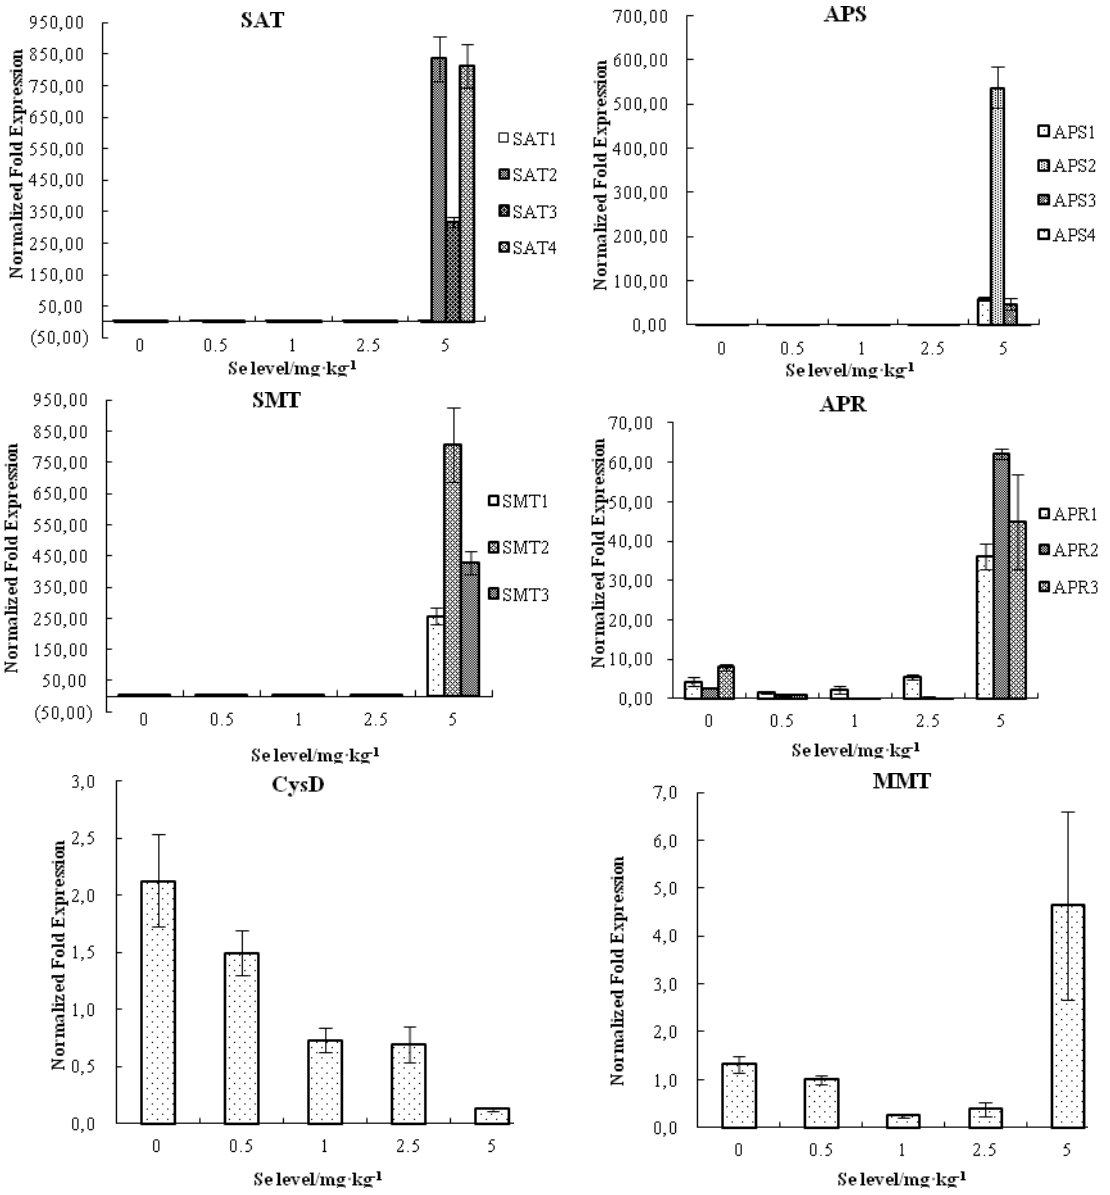

Figure 3. *Real-time PCR analysis of Se metabolism associated genes in leaf of Brassica rapa ssp. pekinensis L.*
