(Received 26th Jan 2018; accepted 10th May 2018)

Abstract. Based on the observed atmospheric CO_2 concentration data from the GAW (Global Atmosphere Watch) stations, we constitute a dynamical heterogeneous dataset of atmospheric CO_2 concentration that varies monthly within the regional climate model domain around China referring to the heterogeneity of CO_2 concentration in different economic regions and land use types. By running RegCM4-CLM3.5 climate model with this dataset, the climate warming rate was simulated and was compared with the control run with uniform CO_2 concentration. The simulation study shows that CO_2 greenhouse effect might have been aggrandized about 10% in the prevailing climate simulation due to improper assumption of uniform atmospheric CO_2 concentration. The effect of CO_2 itself (changing atmospheric transmissivity) is not the main reason for the reduction of temperature. The change of atmospheric CO_2 concentration affects the CO_2 partial pressure between air and interior of plant cells, and then the land plants adjust to this change by altering their stomatal conductance, which affects the water evapotranspiration from plant leaf to atmosphere consequently. On the one hand, this effect affects environmental temperature through the evaporation cooling, and on the other hand, the evaporated moisture alters the air humidity and influence the amount of low cloud by diffusion effect. This phenomenon is especially obvious in summer when the plants grow vigorously. The change of low cloud amount changes the short-wave radiation to the ground, which leads to the change of temperature.
Keywords: *dynamic heterogeneous distribution of CO_2, greenhouse effect, climate simulation, radiation budget and cloud feedback, physiological forcing effect*

Introduction

Climate model is the most popular tool in routine climate prediction and climate change study because of its capability of handling the greenhouse effect quantitatively with various greenhouses gasses such as CO_2, CH_4 etc, which are closely related to human activities (Kiehl and Ramanathan, 1983; Szu-cheng and Liou, 1983; Smith et al., 2017). Unfortunately, the spatio-temporal heterogeneity of CO_2 concentration in the atmosphere is not taken into consideration by the prevailing climate models, either global climate model (GCM) or regional one (RCM). For instance, in the prevailing GCM of CAM3.0, the volumetric mixing ratio of CO_2 was assumed to 355 ppmv (Collins et al., 2004). While in the popular mesoscale model MM5, the mixing ratio of CO_2 was 330 ppmv (Dudhia et al., 1998). The latest regional climate model RegCM3.1 and RegCM4.0 issued by ICTP

DOI: http://dx.doi.org/10.15666/aeer/1604_37113728

(Abdus Salam International Centre for Theoretical Physics) has considered the CO_2 concentration variation from 1750 to 2100 (Elguindi et al., 2010), but seasonal, monthly and even daily CO_2 concentration variations were not taken into consideration. Besides, within the model domain, the CO_2 concentration was still assumed to be uniform. The greenhouse effect plays the most important role in climate warming; the untrue atmospheric CO_2 concentration in climate model should twist simulation (or prediction) accuracy.

China is a large country and covers several different climate zones. The vegetation types are diverse, and the source (or sink) of CO_2 varies seasonally. The intense human activities and the uneven population density cause heterogeneous CO_2 concentration distribution around China (Zhou et al., 2008; Zhao and Sun, 2014). Besides, the economic development level from east to middle and west of China is different, and the phenology from south to north of China is different as well, which causes CO_2 concentration heterogeneities around China (Liu et al., 2011). The same is true for other big countries, particularly for the big developing countries.

The baseline atmospheric CO_2 concentration and $\delta^{13}C$ observation have proved that the annual and daily periodic variation of photosynthesis and respiration of the terrestrial ecosystems affects the CO_2 concentration significantly (Liu et al., 2011). The large-scale ecological engineering construction around China, such as the Nature Forest Protection, Three-North Protection Forest Belt Construction, and Replacing Farm Land with Forest (or Grass) Engineering etc., changes CO_2 source (or sink) structure and then CO_2 concentration heterogeneities (Lin and Li, 1998).

Changing atmospheric CO_2 concentration was the primary driver of global climate change even in the early Eocene (Anagnostou et al., 2016). So, the global network for CO_2 concentration observation is set around the world gradually. The preliminary observation data shows that CO_2 concentration is not uniform, but it shows significant temporal and spatial heterogeneity. The constant CO_2 concentration used in the prevailing climate model is not proper, and there is a lack of work on climate simulation under heterogeneous atmospheric CO_2 concentration at the moment. Therefore, we think it is necessary to study the possible climate changes that may arise from the heterogeneous distribution of CO_2 concentration relative to the uniform distribution and to reveal the mechanism of these changes, which may provide a theoretical basis for improving the climate simulation. Based on this considerations, we collected CO_2 concentration observation data around China, considering possible CO_2 sources (or sinks) formation by social economic development factors, human activity and vegetation types etc., and configured a monthly varied dataset of heterogeneous CO_2 concentration within the model domain, which was used to run the regional climate model RegCM4-CLM3.5 for 108 months from March 2000 to February 2009. The model outputs were compared with the control run in the same period and with constant CO_2 concentration. On this basis, we discussed the regional climate effect caused by the heterogeneous CO_2 concentration. Furthermore, according to the order of annual mean radiant flux, cloud feedback effect and CO_2 physiological forcing effect, the possible mechanism of heterogeneous CO_2 concentration affecting the temperature change is gradually explored from outside to inside.

Materials and methods

The dataset formation

According to the CO_2 emission inventory issued by IPCC and the actual situation in China (Lin and Li, 1998; IPCC AR4, 2007), the factors that cause CO_2 concentration

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37113728

heterogeneity include energy production, industrial emission, land use and land cover variation, and population density. The above factors are simplified to two categories: 1) factors related to industrial emission and economy development, 2) LULC variation related to agriculture and forestry. The details of dataset formation are illustrated in the *Appendix* after the article.

Combining with the temporal and spatial variation, monthly heterogeneous atmospheric CO_2 concentration dataset in the model domain can be obtained (*Fig. 1*). The distributional pattern is reasonable as thinking about the plant phenological period, economic development level, and as well the population density etc. The CO_2 concentration is high in the big city area and the East Coast of China. The annual variation with a high value in winter and lower value in summer is clear. The more details in winter, which is rather higher CO_2 concentration occurrs in the forested area caused by respiration of the woody plants since the photosynthesis is weaker in this season. From May to July, however, CO_2 concentration is lower in the land than that over the sea because most plants are in their vigorous growing season and assimilate more CO_2. Statistics carried on within the model domain shows that the amplitude of yearly variation curve of the CO_2 concentration varied for different LULC types (*Fig. A3* in the *Appendix*). The correlation coefficient between the fitted curve and the observation data is 0.78. The area-weighting averaged value of CO_2 concentration in the model domain was 382.5×10^{-6}, a rather popular value of the present atmospheric CO_2 concentration cited frequently by climate change researchers.

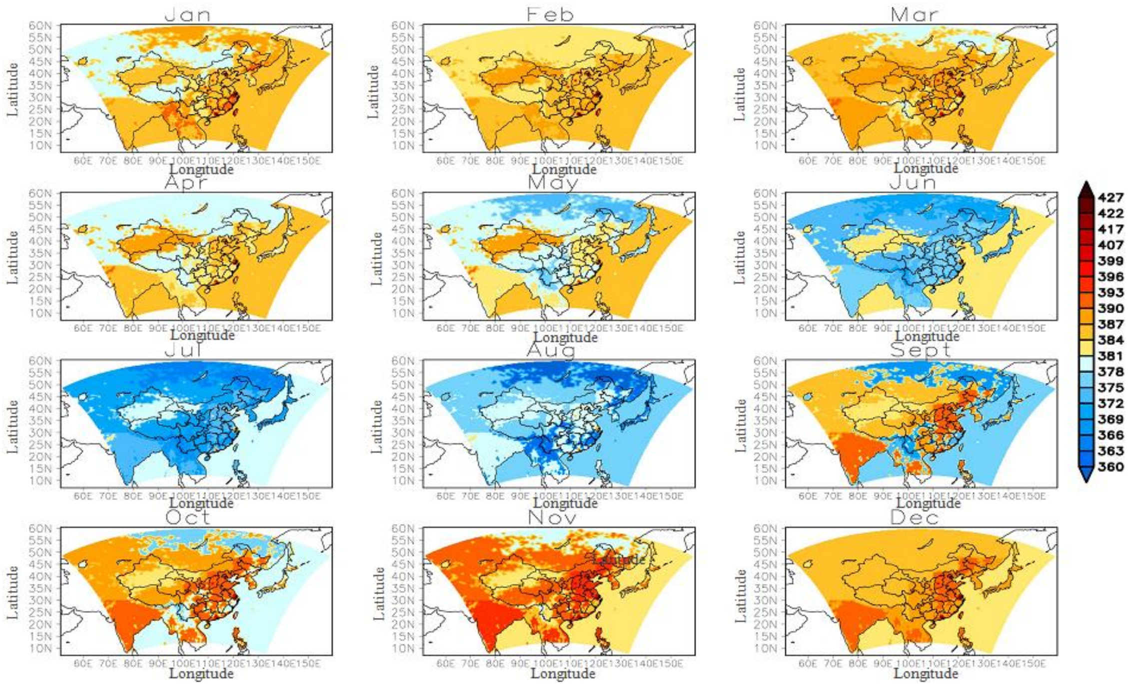

Figure 1. *Monthly dynamical heterogeneous atmospheric CO_2 concentration dataset within a regional domain around China (units: ppmv). The dataset is based on the baseline concentration data of atmospheric CO_2 observed from the GAW stations, considering the heterogeneous distributional characteristics of CO_2 concentration among different economic regions and land use types. The details of dataset formation are illustrated in the Appendix after the article*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37113728

We emphasize that the dynamic and heterogeneous CO_2 concentration distributional pattern presented here is not perfect, nor is it the unique one. With the increasing atmospheric baseline stations, the temporal and spatial heterogeneity of CO_2 concentration will be understood more clearly. It is just to remind on the dynamics and heterogeneity of the atmospheric CO_2 concentration only.

Model description and numerical simulations

The regional climate model (RCM) used here is the version of RegCM4-CLM3.5 issued by ICTP in June 2010 (Elguindi et al., 2010). Compared with the previous version, RegCM4 incorporates a new land surface model of CLM3.5, which is from NCAR's Global Climate System Model CCM4 (Oleson et al., 2008). CLM3.5 is welcomed warmly by modelers because it can describe the land surface in more details, particularly in the carbon cycling process of land surface to reflect the feedback mechanism between the biosphere and climate system (Cox et al., 2000; Friedlingstein et al., 2006). Besides, RegCM4 also incorporates a sea surface temperature prediction module, which is essential to improve momentum flux in the sea-atmosphere interaction layer and is important to the present simulation study since one-third of the model domain is the ocean.

The horizontal grid is the same with the CO_2 concentration dataset shown by *Figure A.2* in the *Appendix*, vertically, the atmosphere is divided into 18 layers; the model top is set at 5 hPa level. Physical parameterization scheme is as usual (Elguindi et al., 2010). A 12-grid exponential relaxing boundary is used in the lateral boundaries of the model domain. The land surface process is modeled by CLM3.5. The time integration step for land surface and upper atmosphere is 600 and 150 s respectively. Radiation module is updated every 30 min; the lateral boundary condition is updated every 6 h using NCEP reanalysis data.

Besides the NECP reanalysis data, the OISST sea surface temperature (SST) data is also used in the model run. The model was run 110 months from January 1, 2000 to March 1, 2009. The first two-month data was removed since spin-up period and the left data of 108 months were used to analyze the effects of dynamic heterogeneous CO_2 concentration on the climate change.

The model system was run for three CO_2 concentration scenarios (*Table 1*).

Table 1. *Three scenarios of atmospheric CO_2 concentration*

Name of scenarios	Atmosphere CO_2 concentration × 10^{-6}	Distributional pattern of CO_2	Comments
Sce1	280	Uniform and constant	Pre-industry
Sce2	382.5	Uniform and constant	CO_2 concentration at present published by IPCC
Sce3	382.5	Dynamic and heterogeneous	CO_2 concentration at present published by IPCC

Sce1 represents the pre-industry stage when the atmospheric CO_2 concentration is 280 ppmv, and Sce2 is the averaged status of Sce3, with which a constant CO_2 concentration of 382.5 ppmv was used, Sce3 refers to a particular model run using a dynamic and heterogeneous atmospheric CO_2 concentration dataset as mentioned above. The comparison study was carried out first between Sce1 and Sce2 (Sce2 minus Sce1,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37113728

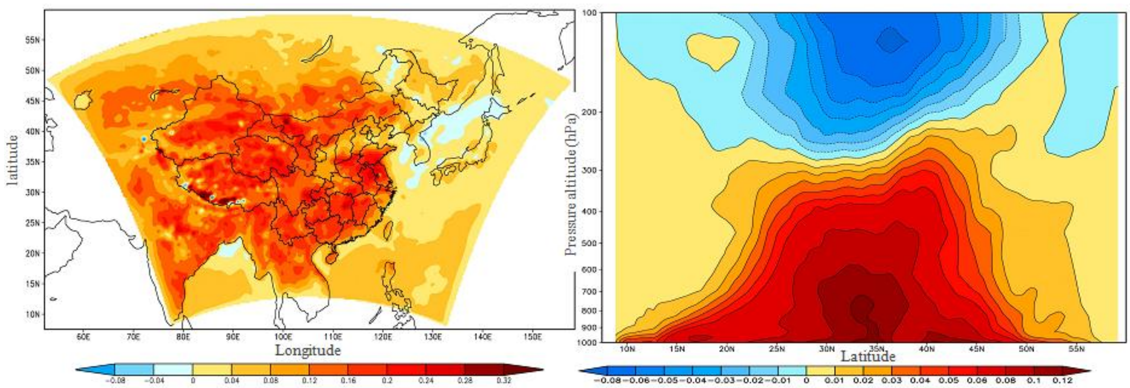
hereafter referred as EXP1) to test the model capability. Later on, we compared the difference of model outputs between Sce2 and Sce3 (Sce3 minus Sce2, hereafter referred as EXP2) to understand what the climate change will be if we use actual dynamic and heterogeneous CO_2 concentration.

Results

Comparison between Sce1 and Sce2 (EXP1)

Figure 2 gives out averaged temperature difference at 2-m high of EXP1. As the atmospheric CO_2 concentration increased from 280 ppmv to 382.5 ppmv, the temperature increased (*Fig. 2a*) clearly, particularly in the continent, where the increment is more than 0.12 °C. Over the sea, it is less than 0.08 °C, and the mean value in the domain is 0.11 °C. Considering the integrate time is about 10 years; this value is in good agreement with IPCC AR4's reports (2007). There are small areas in the Sea of Japan, northeast of China, and Bay of Bengal where temperature decrease, but the amount is small; in general, the CO_2 increase does cause surface layer warming.

Figure 2b is a latitude-high section showing vertical structure of temperature difference. The warming occurs in the lower part of the atmosphere below a level of 300h Pa. Above this level, the temperature difference shows negative. It had been reported that the greenhouse effect warms the troposphere and cool the stratosphere as compensation (Govindasamy and Caldeira, 2000). The model is acceptable in simulating greenhouse effect as atmospheric CO_2 concentration increased.



(a) (b)

Figure 2. *Averaged value of temperature difference in the EXP1 (units: centigrade), (a) 2-m high temperature variation; (b) latitude-high section of the temperature difference*

Comparison between Sce2 and Sce3 (EXP2)

Figure 3 shows the temperature difference of EXP2. As compared with the status of uniform CO_2 concentration, the temperature was decreased in most areas of the model domain, which means we had aggrandized the greenhouse effect by assuming uniform and stable CO_2 concentration in the climate model. The most significant temperature reduction happened in the middle, west and northeast of China's continent and the north of India. The decrement is -0.03~-0.15 °C. There are also some areas where the temperature increased including middle part of Inner Mongolia, The triangle of Beijing-Tianjin-Tangshan and the Delta Economic Zone of Yangtze River, the southeast coast

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37113728

of China and the southeast of India etc. These areas are recognized as developed areas where the population density is high and human activities are intense. The average temperature of the whole domain is reduced by -0.01 °C. The White Paper of China's Policy and Action on Climate Chang reported that in average, the temperature was increased by 1.1 °C during the past 100 years (from 1908 to 2007) in China or 0.11 °C in every decade, the temperature reduction of 0.01 °C accounts for about 10% of this value. In other words, because of the uniform and stable CO_2 concentration assumption in the climate model, the greenhouse effect of CO_2 was aggrandized about 10% in the prevailing climate modeling.

The latitude-high section of the temperature difference in EXP2 was shown in *Fig. 3b*. An opposite shape occurred as compared with EXP1 (*Fig. 2b*). In the lower level below 250 hPa, the temperature decreased, while above this level, the temperature increased. The most significant temperature difference occurred in the middle latitude between 30-40°N, and the values are rather small in the lower or higher latitude. Again, a negative feedback mechanism of the stratosphere to compensate the troposphere is clear.

The statistics were carried out for each LULC types (*Table 2*) in every economic zone in EXP2. The woodland and grassland show temperature reduction with larger values in the 2-class economic zone, and the urban and barren area show temperature increase except in the 3rd economic zone, where the value is -0.46. Water body causes temperature reduction as well since it sequestrates CO_2 from the atmosphere.

Discussion

Radiation budget

Table 3 shows the comparison of various radiation elements, cloud amount and the temperature difference in EXP2. The statistics were carried out on clearly and cloudy day separately. Whenever the total cloud fraction is larger than 0.01, it is classified as a cloudy day. Otherwise, it is a clear day.

Table 3. *Bias of atmospheric radiative flux and cloud amount in the Exp2*

Items	Clear day	Cloudy day
Income shortwave (SW) radiation flux at the top layer of the model ($\times 10^{-2}$ W·m^{-2})	0.4	-2.0
SW radiation forcing by cloud	-2.4	
Out longwave radiation (OLR) in clear day	-1.2	-0.4
Longwave radiation forcing by cloud	-0.8	
Energy budget	-1.6	
Surface longwave radiation flux ($\times 10^{-2}$ W·m^{-2})	-0.1	-3.2
Out longwave radiation at the surface	-2.0	-3.8
Atmospheric radiation flux ($\times 10^{-2}$ W·m^{-2})	0.5	1.2
Cloud amount ($\times 10^{-2}$ percentage)	Total cloud amount 0.09	
	High cloud amount -0.04	
	Middle and low cloud amount 0.13	
Temperature difference at 2-m high (×10-2 °C)	0. 1	-1.3

In clear days, compared with Sce2, Sce3 gives a temperature increment of 0.1×10^{-2} °C, which is mainly caused by the increment SW radiation in the top layer (0.4×10^{-2} W/m^2), reduction of OLR (1.2×10^{-2} W/m^2) and the increase of atmospheric absorption of LR (0.5×10^{-2} W/m^2), though the income surface SW radiation is reduced (0.1×10^{-2} W/m^2). The atmospheric radiation penetration is not the main reason to cause the temperature reduction in Sce3.

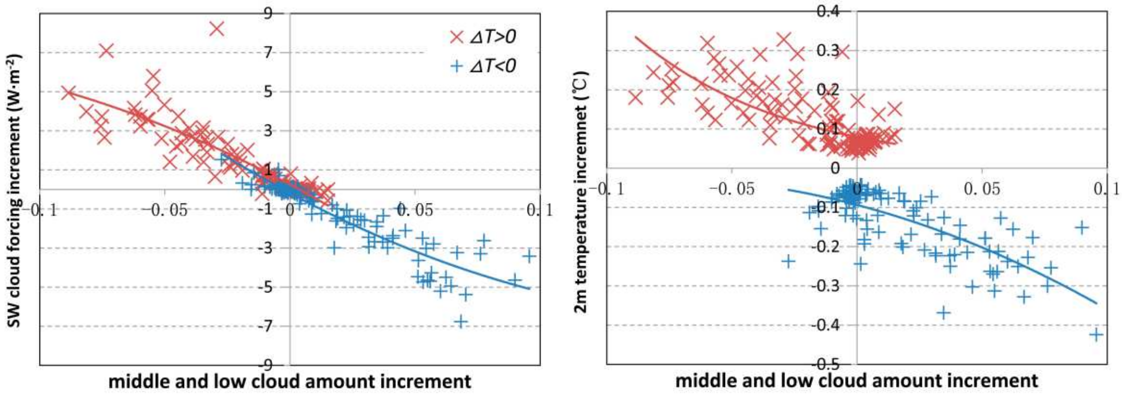
In cloudy days, however, Sce3 gives a temperature reduction of -1.3×10^{-2} °C, which is mainly caused by the reduction of income SW radiation (-2.0×10^{-2} W/m^2), the negative energy budget (-1.6×10^{-2} W/m^2), reduction of income SW radiation at the surface (-3.2×10^{-2} W/m^2) and reduction of radiation forcing by cloud (-2.4×10^{-2} W/m^2) though atmospheric absorption is increased ($1.2\ \times10^{-2}$ W/m^2). The statistics for all cloudy day shows that high cloud amount reduced -0.04% in Sce3, but the total cloud amount increased 0.09% on average and the middle and low cloud increased 0.13%. The increased cloud can capture more LW radiation in the atmosphere, but it resists more shortwave radiation getting into the atmosphere, the integrated effect is to cause cooling (Andrews et al., 2012; Forster et al., 2015). So the cloud is the main reason to reduce greenhouse effect in dynamic and heterogeneous CO_2 concentration scenario.

Cloud amount variations

The latest studies showed that temperature reduction is mainly due to cloud sensitivity to the CO_2 concentration variation (Gregory and Webb, 2008; Andrews and Forster, 2008; Williams et al., 2008), and the cloud feedback mechanism is the main

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37113728

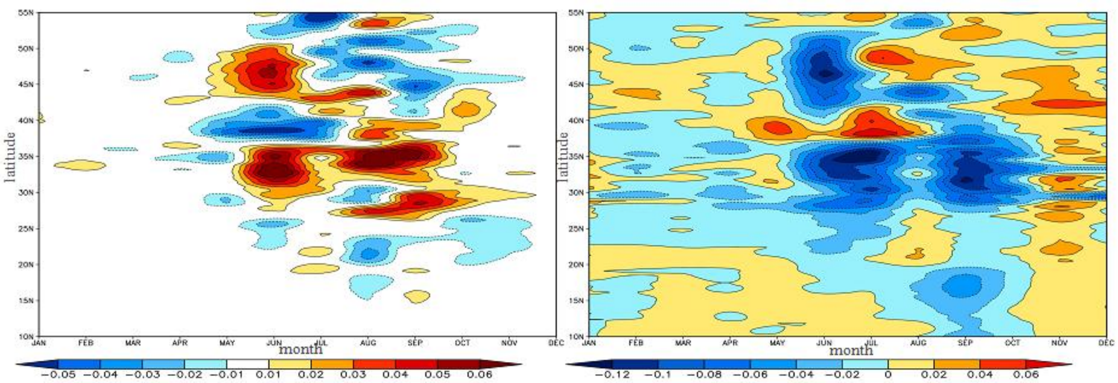
reason that causes difference among climate models (Bony et al., 2006; Caldwell et al., 2013). The cloud amount variation in EXP2 (Sce3 minus Sce2) is further analyzed by plotting all simulated examples to show the relationship among cloud amount, SW radiation and temperature reduction since high cloud is of less importance, and only the middle and low cloud data were used (*Fig. 4*). All the numerical grids either of temperature increase (red cross) or decrease (blue cross) are accounted though the former is of less number than the later. *Figure 4a* shows that with increased cloud amount, both SW radiation and temperature reduction increased, the correlation coefficient reaches to -0.87 in temperature increased grid and -0.91 in temperature decreased grid. This means middle and low cloud increase is the main reason to reduce temperature in Sce3.



a **b**

Figure 4. *Scatter diagram showing the relationship between middle and low cloud amount increment and (a) shortwave radiative forcing increment and (b) 2 m high temperature reduction*

The close relationship between cloud amount and temperature reduction can be illustrated by latitude-time section. *Figure 5* also shows the temporal and spatial variability of cloud amount and the temperature difference between Sec2 and Sce3.



(a) (b)

Figure 5. *latitudinal mean-month section of (a) low cloud amount variation and (b) temperature difference (units: centigrade) in EXP2*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37113728

The most significant difference occurred in a middle latitude zone between 30-50°N during the summer from May to October. Wherever and whenever the middle and low cloud amount is increased (decreased), the temperature decreased (increase), and a negative correlation is clear.

Physiological mechanism

With the causality of CO_2 concentration increasing and plant physiological adaptation being noticed widely, the consequence to the cloud formation, the radiation forcing and temperature reduction are also reported frequently (Lambert and Chiang, 2007; Lambert et al., 2011). Our simulation study shows that in summer, the CO_2 concentration is rather lower, and the plant stomata conductance increases physiologically to adapt insufficient CO_2 supply (Sellers, 1996; Sellers et al., 1997; Betts et al., 1997), which causes rather stronger plant transpiration and adds more water vapor into the atmosphere (Boucher et al., 2009; Joshi and Gregory, 2008; Abe et al., 2015). Moreover, this phenomena is more significant in the growing seasons of summer in the East Asian monsoon climate zone and in the middle latitude where the vegetation is dense. The plant transpiration cools the plant canopy and then the lower part of the atmosphere, which stimulates the formation of convective cloud (Joshi et al., 2008; Doutriaux-Boucher et al., 2009). In winter, however, most plants are in hibernation period, and the biological vigor is weaker, so plants show less sensitive to the outside CO_2 concentration variation.

The present climate model and the relevant land surface model output affected by various plant physiological factors shows such ratiocination. *Figure 6* illustrates regularity of some physiological parameters. Since most plants are vigorous in summer in the East Asian monsoon climate zone, the statistics were carried on the data in summer (June–November) only. The geographical difference can be classified into three regions based on *Figure 6*. To the south of 25°N, the averaged stomata resistance (a) shows an increase, so the canopy transpiration (b), canopy evaporation (c) and 2-m high air humidity (d) show a decrease, which consequences the increase of absorbed radiation (e) and the 2-m high temperature (f). Between 25 to 40°N, all the curve's phases were reversed, because of the increased stomata conductance, the canopy transpiration, canopy evaporation and 2-m high air humidity increased, which causes increased cloud amount and decreased absorbed radiation and 2-m high temperature. To the north of 40°N, the curve tends to less amplified; it consists of the rather flat stomatal conductance.

In general, the lower CO_2 concentration always occurs in the growing season and the densely vegetative area, and the plant responses with larger stomatal conductance, which leads to more canopy evaportranspiration, higher air humidity, and increment of the middle-low cloud. It is the main reason causing the temperature reduction in the growing season and vegetative areas. Since the vegetative area covers a rather larger portion of the model domain, the weighting averaged value of temperature reduced. This physiological mechanism can be extended to the diurnal variation of CO_2 concentration as well, the periodic diurnal variation of CO_2 concentration just like the yearly one. In the daytime, when the plant is in its vigorous period and the CO_2 concentration is lower, which causes less greenhouse effect and mitigate warming, in the night. The CO_2 concentration is high because of the plant respiration, but the greenhouse effect is weaker. Unfortunately, this paper has not incorporated diurnal

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37113728

heterogeneity of CO_2 concentration into the modeling, but it is expected the temperature reduction could be even larger if it is considered.

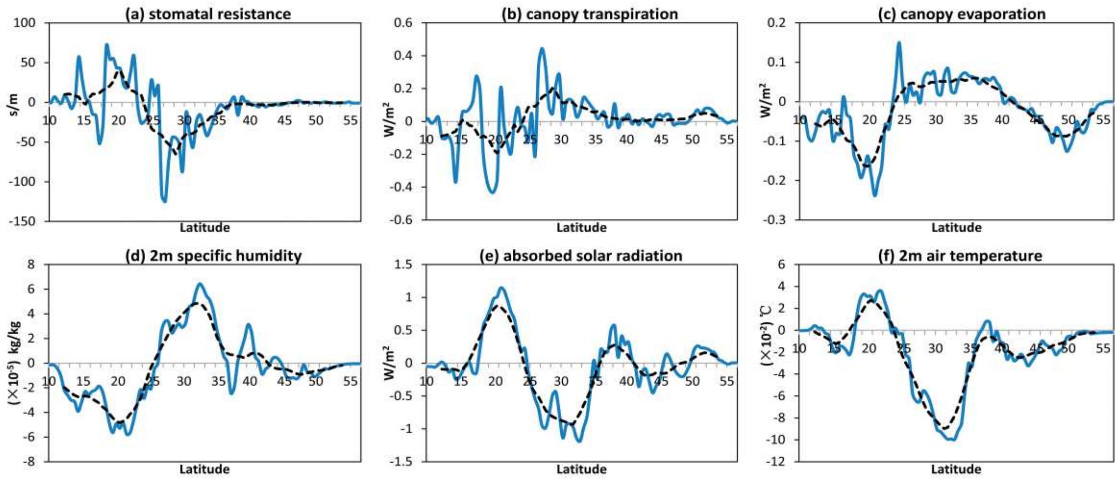


Figure 6. *Zonal mean increment change of (a) stomatal resistance, (b) canopy transpiration, (c) canopy evaporation, (d) 2 m specific humidity, (e) absorbed solar radiation, (f) 2 m high air temperature in the EXP2, the dashed line means the five-latitude moving average*

For proving the physiological mechanism that dynamic and heterogeneous CO_2 concentration causes less climate warming, a supplement model run was conducted, in which the land surface model CLM3.5 was replaced with BATS in EXP2 to remove any physiological effect in Sce3 since BATS uses constant plant parameters (Elguindi et al., 2010). The simulated temperature reduction is shown in *Figure 7*. Compared with *Figure 3b,* there is no significant temperature reduction in the troposphere in middle latitude, rather, there is a slight temperature increase, and the absolute values are much smaller as compared with *Figure 3b*.

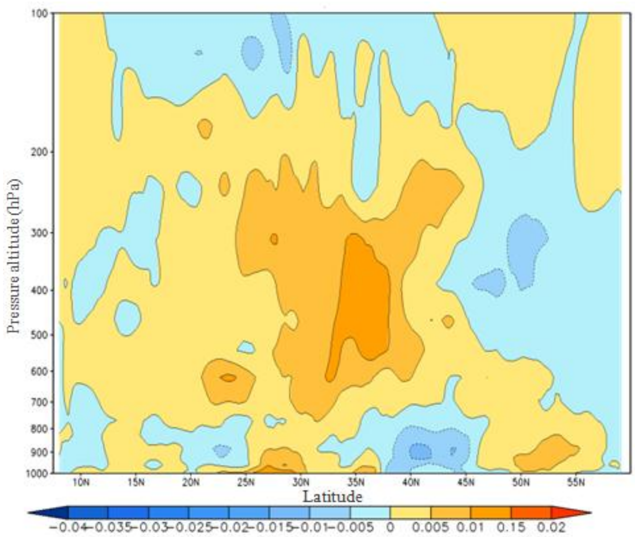

Figure 7. *Latitude-high section of the temperature difference (units: centigrade) from the supplement run, same with EXP2 but replace the land surface model CLM3.5 with BATS in Sce3*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37113728

Conclusions

1) The uniform atmospheric CO_2 concentration data used in the prevailing climate modeling is improper, the greenhouse effect of CO_2 might be aggrandized about 10% because of the data flaw.

2) The simulation study reveals the main mechanism that dynamic and heterogeneous CO_2 concentration reduces temperature increment. The variety of atmospheric CO_2 concentration influences on the CO_2 partial pressure between atomosphere and internal plant cell first. The land plants adapt to this change by altering their stomatal conductance, which affects the water evepotranspiration from plant canopy to the atmosphere, and the evaporated moisture increases air humidity then the formation and amount of low cloud. And the relevent evaporation cooling accelerates cloud formation as well. This mechanism is significant in summer when the most plants are in vigorous growing period and in the middle latitude where vegetation coverage is high.

3) With the increasing atmospheric baseline stations with CO_2 concentration observation, the temporal and spatial heterogeneity of CO_2 concentration will be clearer in the future, which should be used in the climate modeling to improve the accuracy of climate change prediction.

Because the dataset and model regions in this work are targeted at China, so the conclusion of the fourth part of the article (Analysis on the simulation results) is specific to the region of China. But the mechanism of the impact of the CO_2 physiological effects on the climate change revealed in the fifth part of the article (Mechanism analyses) is universal. So we believe that in any region of the world, the climate effects that take into account the heterogeneity of CO_2 concentration are similar, but the sensitivity of temperature change may be different. Therefore, it is very meaningful to carry out relevant research by using global climate model and CO_2 concentration data of satellite detection.

In addition, it is expected that if the diurnal variation of atmospheric CO_2 concentration is taken into consideration, the atmospheric CO_2 concentration will be lower when the physiological activity of the plant is strong during the day, which may lead to the stronger physiological forcing effect and the greater amplitude of cooling, which is another issue worth studying.

APPENDIX

Details of the dataset formation

The two-dimensional horizontal heterogeneity was assigned according to the different categories, and each category has its own monthly variation curve. The grid dataset of heterogeneous CO_2 concentration suitable for numerical simulation is shown in *Fig. A1*. The domain center was set at 35°N, 105°E, and the grid resolution was 60 km. In addition, the longitudinal and latitudinal grid were 120 and 90 respectively. Lambert map project scheme was used in the model.

Appendix 1

Economy development consideration

The model domain was divided roughly into three different economic zones (*Fig. A.1*): 1) to the east of 110°E China, heavy industrial northeast of China, north of Indian plain (altitude is lower than 1000 m), Burma, Vietnam and Philippine etc., the first category was classified as the most economically developed area where the population density is high, and CO_2 emission is the highest; 2) The China's territory

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37113728

within 100～110°E, and 20～38°N, Japan, Korea peninsula, Taiwan and Hainan Island of China etc. This category was classified by the following considerations: the middle of China is less developed as compared with the east of China with rather backward science and technology. The CO_2 emission of unit GDP is higher, but the population density is rather lower than that in the east of China. So the total CO_2 concentration was classified as the second category, and Japan, Korea and Taiwan are with high population density. But compared with the first class area, the manufacture configuration is more reasonable, energy efficiency is high and the advanced high-tech utilization is more popular, so the CO_2 emission from unit land is lower than those in the first class area; 3) The left area was classified as the third class, where the CO_2 emission and CO_2 concentration was assumed to be least, because the population is sparse and the economy is backward compared with above two classes. The water body itself is CO_2 sink to absorb CO_2 from the atmosphere. The CO_2 emission over the water body by human activity was assumed to be zero, so it is classified separately as the fourth class. Based on the above assumption, the model domain area was classified with different CO_2 concentration as shown in *Figure A1*.

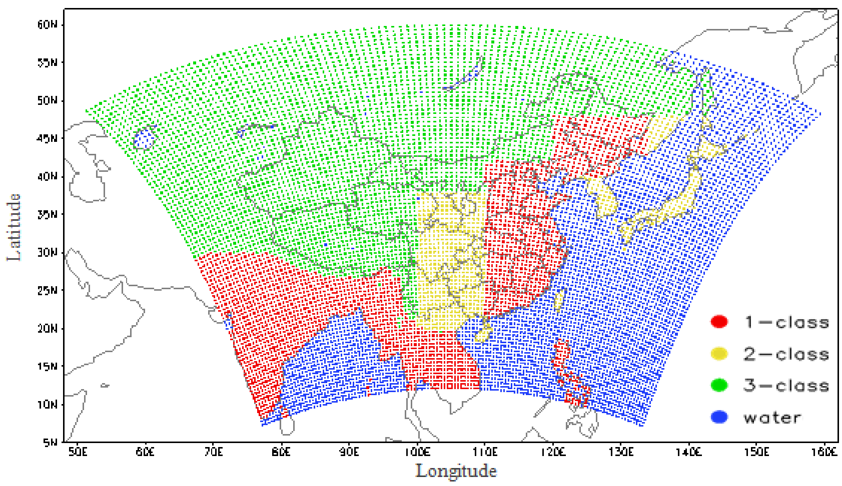

Figure A1. *Distributional pattern of CO_2 concentration classified according to economic development and population density*

Appendix 2

LULC variation consideration

The LULC was classified into 5 categories to reflect their differences in CO_2 sequestration capability according to the IPCC's relevant document (Busche, 2006). Those are forest, grass (or crop), urban, water, and barren land (include rock and Gobi, vegetation-free land, ice and snow). The original data was from the 1 km resolution LULC data derived from EOS/MODIS satellite information (hereafter called IGBP data). The 1-km resolution data of the land surface model BATS (Biosphere-Atmosphere Transfer Scheme; http://edcdaac.usgs.gov/glcc/glcc.html) was also used to compensate missing data in the mainland territory of China, which was from the NOAA's AVHRR dataset and commonly called GLCCD data. The 1-km resolution was then projected on the model domain to form a new dataset with a specific LULC type of the highest portion in each grid square only (*Table A1*), which is a benefit to differ the

DOI: http://dx.doi.org/10.15666/aeer/1604_37113728

CO_2 sequestration capability of different LULC types. Since the big city has a special function in CO_2 emission, the grids are defined as city whenever the city portion in a grid square exceed 20%. The LULC difference in the model domain is shown in *Figure A2.*

Table A1. *Merging scheme of multi-types and high-resolution land use data based on the IGBP and GLCCD*

ID	LULC type classification	IGBP (2004)	GLCC (1992~1993)

DOI: http://dx.doi.org/10.15666/aeer/1604_37113728

Appendix 3

Dynamics of the atmospheric CO_2 concentration

Intra-year variation of CO_2 concentration for each LULC type was formed by referring to the baseline observation data, including the global atmospheric baseline stations, regional background stations, field and/or city temporal data logging (Wu et al., 2005; Cheng et al., 2003; Zhou et al., 2007; Wang et al., 2003). The data from the barren area (Waliguan Station) and ocean showed the smaller amplitude of CO_2 concentration variation (*Table A2*), and these data were used to present the large-scale background data. While those from forest, grass and urban areas showed larger amplitude, and the CO_2 concentration were affected by biological activities and local emission, which presents the local heterogeneity of CO_2 concentration. In general, the CO_2 concentration is higher in the east of China than in the west of China because of the intense human activity and higher population density.

Table A2. *Information of referenced stations for atmospheric CO_2 concentration*

LULC type	Name of the station	Latitude (N)	Longitude (E)	Altitude /m	Vegetation type	CO_2 concentration /10^{-6}	Data collection year
Woodland	Longfen Mountain	44°44’	127°36’	310	Subsidiary forest	365±20	2003
	Changbai Mountain	44°08’	128°06’	740	Broad leaf-Korea Pine forest	370±20	2003
	Suyukou in Ningxia Autonomous Region	38°44’	105°55’	1950	Northwest arid area	297±16	2006
Grassland /Crop	Linan	30°18’	119°45’	130	Agricultural mixing	380±15	2003
	Xinglong	40°24’	117°30’	940	shrubs	375±15	2000
	Haibei	37°37’	101°17’	3400	Short grass and wetland shrubs	315±20	2004
	Wulanchabu	41°47’	111°53’	1450	Typical grassland	330±18	2006
	Dashuiqugou of Ningxia Autonomous Region	38°39’	105°57’	1330	Hungriness grassland	335±20	2006
Urban	Beijing	38°58’	116°22’	30	Urban	400±40	2002
	Shang Dianzi	40°39’	117°07’	290	Sub-urban area	375±25	2003
	Huaian	30°16’	118°59’	40	Middle-side city	400±30	2006
	Hefei	31°52’	117°17’	30	Reservoir close to city	390±30	2008

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37113728

	Wuxi	31°25’	44°44’	10	Lake-side rural area	405±20	2003
Other	Waliguan	36°18’	100°54’	3820	Hungriness grass	375± 5	2004
Water	Ocean				Oceanic boundary layer	375± 5	2004

Supposing the CO_2 concentration of each LULC type varies regularly in a same economic zone, the average value of five LULC categories in four different economic zones are listed in *Table A3*. These values are used to feed the model at the initial state but vary as time of model integration (see next section).

Table A3. *Model initial data of CO_2 concentration for different economic regions and land use types*

	Woodland	**Grassland/Crop**	**Urban**	**Barren land (desert, permanent ice and snow)**	**Water**
1-class	380	386	410	388	
2-class	378	384	405	386	
3-class	376	382	400	384	
Water					383

The dynamic characteristics of CO_2 concentration were divided into two parts, the inter-annual variation and monthly variation in a specific year. The former followed the IPCC and reported values (ftp://crgd.atmos.uiuc.edu/pub/post-sres/A2-conc.txt) from 2000 to 2009. The later was assigned by thinking of growing period for different plants and the phenology in different climate zones. The monthly differential values of CO_2 concentration from the average for five LULC types were listed and graphed in *Figure A3*.

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sept	Oct	Nov	Dec
water	1.7	2.4	3.1	4	3.1	1	-2.2	-5.5	-5.8	-2.7	-0.2	1
forest	11.8	8.0	4.3	2.8	-1.0	-5.5	-11.5	-16.8	-7.0	0.5	5.0	9.5
grass	-1.3	1.3	4.3	-1.3	-3.1	-8.0	-12.0	-5.2	4.8	6.7	9.0	4.7
urban	20.1	24.9	5.3	-4.1	-13.2	-17.0	-18.4	-19.4	-8.9	0.6	12.5	17.7
other	1	2	3	4	3	-1.5	-5.5	-6.2	-3.8	-2	-1.5	-0.5

Month

Figure A3. *Monthly atmospheric CO_2 concentration increment for different land use types*

APPLIED ECOLOGY AND ENVIRONMENTAL RESEARCH 16(4):3711-3728.
http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37113728

The seasonal CO_2 concentration variation is clear, and particularly in the urban area, forest and grass. The average value of the amplitude of CO_2 concentration variation curve in the forest is about 10 ppmv, and those in urban area is 20 ppmv. The later reflects the intense human activity in the big cities such as house heating in winter, car running and other vehicles, over the water body and in the barren area, however, the amplitude is much smaller.

(Received 22nd Feb 2018; accepted 10th May 2018)

Abstract. Sustainability indicators were applied in river basins of a state in Northeastern Brazil, aiming to outline and support effectively sustainable actions of water resources management. Twelve indices and three indicators of Sustainability focused on socioeconomic, hydrological and institutional issues were calculated for six hydrographic regions, quantitatively and qualitatively. Partial scales for all indices related the calculated values to levels of performance (Very High, High, Medium, Low, and Very Low). Posteriorly the indices were grouped in global scales, constructed with levels of water sustainability for all indicators. The results have shown an overall intermediate performance in the assessed river basins, indicating the need to adopt priority measures in the hydrological dimension, especially in relation to groundwater; attention to primary sanitation, with regard to public supply; reduction in water demand and waste; implementation of management tools; consolidation and support to river basin committees. The spatialization of water sustainability indicators enabled a clearer perception and an unmistakable assessment of each river basin surveyed.
Keywords: *water resources, decision-making, indicators, sustainability, river basin*

Introduction

The imbalance between water availability and demand causes its scarcity, which has become one of the most pressing problems in the world (Peterson and Schoengold, 2008). This situation may worsen due to population growth, global climate change and deterioration of water quality (Qu et al., 2013). Demand for water is expected to increase by more than 40% by 2050. By 2025, about 1.8 billion people will live in countries or regions where water is scarce, and two-thirds of the earth may live in a condition where the supply of clean water does not meet its demand (UN, 2015; Ross, 2017).

In Brazil, water demand has grown significantly in the last decades due to the economic development process, the increase of population clusters and the quantification, increasingly grounded, of environmental needs (Carvalho and Curi, 2013). Although Brazil has an abundance of water, it is poorly distributed in relation to the demographic density of the country, with 80% of the water being in the Amazon region and a severe scarcity existing in the Northeastern region (ONU, 2007). However, in addition to misdistribution, Brazil faces more severe issues, such as permanent contamination and waste of the remaining clean water (Bragatto et al., 2012).

DOI: http://dx.doi.org/10.15666/aeer/1604_37293754

According to Oelkers et al. (2011), one of the key solutions to this global water crisis is better management of this valuable natural resource. The literature reports that, as the complexity of issues related to water resources has increased, there have been extensive studies to combine the concept of sustainability with water management matters (Loucks e Gladwell, 1999; Loucks et al., 2000; Starkl and Brunner, 2004; Mays, 2006; Policy Research Initiative, 2007). An integrated view of water is essential because it can add social, economic, environmental and institutional aspects to all management processes (Juwana et al., 2010), contributing to understand the evolution of the water system and its influences, that is, the achievement of a sustainable management of water resources (Sun et al., 2016).

According to the OECD (2003, p. 19), "water is the perfect example of a sustainable development challenge – encompassing environmental, economic and social dimensions." The sustainable management of water resources, therefore, implies not only the indefinite continuation of physically and biologically stable systems, but also concern for the other dimensions of sustainable development, such as the economic efficiency of water use, the equitable distribution of the costs and benefits of water resource developments and participatory approaches to policy-making and decision-taking (Ioris et al., 2008).

Sustainability indicators have become relevant tools for the integrated planning and management of water resources (Hooper, 2010). Very useful in decision-making, they enable the simplification of information on complex phenomena and the identification of primary demands (Barros and Silva, 2012). The adoption of indicators to assess and monitor progress towards sustainable development is highly recommended by scientists (Moldan et al., 2012; Cornescu and Adam, 2014; Bolcárová and Kološta, 2015), policy developers (UN, 2007), financial institutions (OECD, 2014; WWAP, 2003), governments (OSE, 2008), business sector (WBCSD, 2000) and nongovernmental organizations (WWF, 2010), as they are means to assess the level of satisfaction of several criteria, helping to translate abstract concepts into measurable parameters (Lee and Huang, 2007).

In Brazil, several authors have used indicators to analyze and propose suggestions aimed at enabling water management in an integrated and sustainable method in river basins (He et al., 2000; Pompermayer et al., 2007; Chaves and Alipaz, 2007; Ioris et al., 2008, Vieira and Studart, 2009; Magalhães Júnior, 2010; Carvalho et al., 2011; Maynard et al., 2017), fact also occurs in river basins in several countries, according to studies carried out by UNESCO (2008), Ioris et al. (2008), Catano et al. (2009), Cortés et al. (2012), Pellicer-Martínez and Martínez-Paz (2016).

Currently, society is seeking a broader debate on sustainable development in terms of rational use and valuation of natural resources. Therefore, discussing aspects related to water management in river basins by using indices and indicators in order to enable a more integrated and sustainable water management brings relevant contributions to the current scenario.

This article it is proposed to a holistic assessment of river basins through indicators that measure how water management is progressing in the perspective of sustainability in a strategic region of Brazil, located between the semiarid Northeastern region and the Amazon region.

As a background, specifically regarding water resources in Maranhão, the area used to perform this study, Dias (2018) points out that there is a notable gap in literature on water resource management, which presents an unfavorable framework regarding the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37293754

implementation of management instruments. There are no studies that address the issue of water sustainability in the State of Maranhão.

Thus, this study also intends to help fill a specific gap in the Northeastern part of Brazil, where there is little literature related to integrated management of water resources aiming at the sustainability of river basins.

Taking into consideration these arguments and the relevance of this issue in the context of water management and sustainability, this article aims to diagnose, through indicators, the water sustainability of river basins in the State of Maranhão, in Northeastern Brazil, and to substantiate the decision-making process for the integrated management of water resources.

Materials and methods

Characterization of the study area

The study was conducted in the State of Maranhão, which is located in the Northeastern part of Brazil, between the coordinates of 02° to 10° south latitude and 44° to 48° west longitude. Covering an area of 331,935,507 km², Maranhão has approximately 7 million inhabitants, being the fourth most populous state in Northeastern Brazil (IBGE, 2017).

It is located in a transition area between the Amazon (wet) and Northeastern (semiarid) regions, favoring great annual rainfall contrasts. The portion of Legal Amazon in Maranhão covers an area equivalent to 80% of the territorial area of the State, about 264,000 km². The region of transition between the Amazon and Cerrado biomes is characterized by a high diversity of ecosystems and biodiversity. (Silva et al., 2016).

The State of Maranhão is divided into twelve hydrographic regions, of which six were selected for this research: Parnaíba, Tocantins, Gurupi, Munim, Mearim and Itapecuru (*Fig. 1*).

Basin	Area (km²)	Population	% over the State area	Population density in the basin (inhabitant/km²)	No. of cities in the basin
Tocantins River	30,665.15	498,105	9.24%	16.24	23
Parnaíba River	66,449.09	717,723	20.02%	10.80	39
Gurupi River	15,953.91	178,302	4.81%	11.18	12
Mearim River	99,058.69	1,681,307	29.84%	16.97	83
Munim River	15,918.04	320,001	4.79%	20.10	27
Itapecuru River	53,216.84	1,019,398	16.03%	19.16	57

Selecting indicators and setting indices

The selection process was initially based on an extensive bibliographical research on indices and indicators applied to water resources, aiming at meeting the need to evaluate water sustainability conditions in the basins of Maranhão.

Based on the information required to compose each indice and indicator and the information available in the river basins studied, we have decided to use the methodology elaborated by Vieira (1999) and modified by Campos et al. (2014). Thus, based on these authors, we have chosen to apply the following indicators:

(a) Indicator of Potentiality, Availability and Demand (IPAD), to assess information regarding potentiality and availability of the water from the river basin, as well as the capacity to meet demands; (b) Indicator on Water Resources Management (IWRM), to reflect how entities are implementing it and instruments of the water resources policy; and (c) Water Use Efficiency Indicator (WUEI), to inform the conditions of environmental sanitation in the river basin and the level of efficiency of public utilities in the distribution of the captured water. These sustainability indicators were applied at the river basin level, which is the water resources management unit. Chaves and Alipaz (2007) highlight that this consideration is important, since the assessment of water resource sustainability cannot be limited by jurisdictional boundaries.

The process of choosing indicators also considered whether they meet the four criteria of sustainability: social, economic, environmental and institutional, as described by Pires et al. (2017). In this evaluation, the three indicators IPAD, IWRM and WUEI meet most sustainability criteria. Thus, the chosen indicators can be applied to reliably diagnose the sustainable use and water management in selected river basins. In addition, they are interesting tools that allow us to see some of the multiple aspects of water management and use from specific angles.

The following criteria were taken into consideration to define the indices constituting each indicator: (a) relevance (ability to translate the phenomenon); (b) local adherence (ability to capture the phenomenon produced or that can be transformed at the local level); (c) availability (coverage and timeliness of data); and (d) ability to allow time comparisons (Campos et al., 2014).

Frame 2 shows the indices selected for each indicator.

Frame 2. *Indicators and their respective indices selected for this research. (Based on Campos et al., 2014)*

Indicator	Indice	Description
IPAD Indicator of Potentiality, Availability and Demand	Activation of Potentialities **(IAP)**	Relation between availability and potentiality
	Use of Potentialities **(IUP)**	Relation between demand and potentiality
	Use of Availabilities **(IUA)**	Relation between demand and availability
IWRM Indicator on Water Resources Management	River Basins Committees **(IRBC)**	Existence and scope of operations
	Grant **(GI)**	Level of implementation of the grant
	Collection **(CI)**	Level of implementation of the collection
WUEI Water Use Efficiency Indicator	Households Supplied by Wells **(IHSW)**	Percentage of households supplied by wells in relation to the total number of households
	Households Supplied by a Water Supply System **(IHSWSS)**	Percentage of households supplied by a water supply system in relation to the total number of households
	Sewer Connections **(ISW)**	Percentage of households with a sewage network or a septic tank in relation to the total number of households
	Sewage Treatment **(IST)**	Percentage of households with sewage treatment in relation to the total number of households
	Solid Waste Treatment **(ISWT)**	Percentage of households with waste collection in relation to the total number of households
	Water Loss in the Network **(IWLN)**	Average percentage of physical losses (leaks) and billed losses (illegal connections)

Data collection and calculation of indices

The information used in this study was obtained by bibliographic research. To determine the IPAD, the values of availabilities, potentialities and surface water demands were obtained from the most recent report prepared by the Geoenvironmental Nucleus of the State University of Maranhão (NUGEO, 2010), entitled "Estimation of demand and water availability of river basins in Maranhão". The determination of demands by river basin has taken into consideration human supply (urban and rural), industry, irrigation and livestock (*Frame 3*).

Frame 3. *Potentialities, availabilities, and surface water demands, by river basin, in the State of Maranhão. (Source: NUGEO, 2010)*

Basin	Potentialities (h^3/year)	Availabilities (h^3/year)	Demands (h^3/year)
Parnaíba River	3828.41	1475.17	288.38
Munim River	4098.95	269.8	66.44
Itapecuru River	6599.97	1112.55	306.64
Tocantins River	11692.44	2412.15	432.4
Mearim River	13971.85	665.21	290.47
Gurupi River	5970.17	1263.94	27.62

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37293754

Information on availability, potentialities and underground water demands were based on data from Brasil (2009) and Santos (2010). In the calculation of the water demands, we have considered human supply (urban and rural), industry, irrigation, livestock, agricultural production and environmental demands (*Frame 4*).

Frame 4. *Potentialities, availabilities, and underground water demands, by river basin, in the State of Maranhão. (Source: Brasil, 2009; Santos, 2010)*

Basin	**Potentialities (h^3/year)**	**Availabilities (h^3/year)**	**Demands (h^3/year)**
Parnaíba River	9030	1107.92	2076.08
Munim River	3120	183.85	220.87
Itapecuru River	1550	219.54	267.68
Tocantins River	500	81.11	150.08
Mearim River	3490	639.16	656.18
Gurupi River	2510	90.85	299.72

The data necessary for the calculations of the indices composing the WUEI were obtained on the platforms of the Brazilian Institute of Geography and Statistics (IBGE, 2010) and the National Information System on Sanitation (Sistema Nacional de Informações Sobre Saneamento - SNIS) for the reference year of 2010.

Data on total households, households supplied by wells, households supplied by a water supply system, households supplied by a sewage network or septic tank, households with sewage treatment, households with waste collection and information on water losses in the supply network were gathered by municipality (see *Appendix*). The final indice, by river basin, was calculated from the average among municipalities that compose the basin.

Currently SNIS has the most comprehensive data on the sanitation sector in Brazil, constituting the largest and most important information tool on water services, collection and treatment of sewage since 1995, as well as solid waste management since 2002 (SNIS, 2015). Thus, the information in this study is very relevant regarding the reliability of its data.

Information on Grant, Collection and Committees required to compose the IWRM was obtained from the Superintendency of Water Resources of the State Department of Environment and Natural Resources of Maranhão (SEMA), the agency responsible for water resources management in Maranhão.

Partial scales

According to *Frame 2,* the indices constituting IPAD are the following: IAP, IUP and IUA. These indices show that regions with IUA > 1 are under situations of exhaustion of availability (Fernandes, 2002).

Vieira (1999) states that due to natural physical limitations, the maximum IUP value would be equal to 0.8. Thus, IUP values > 0.7 would indicate a critical situation of use of water resources in a river basin.

The IAP indice, on the other hand, would represent the level of efficiency of the water resources of a basin, being larger as they are closer to 1 (Fernandes, 2002).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37293754

Thus, the partial scale for all indices relates the calculated values to levels of performance (Very High, High, Medium, Low, and Very Low). For example, a IUA value greater than 1, a IUP value greater than 0.7 and a IAP value closer to 0 were related to “Very Low” performance levels; a IUA and a IUP equal to zero and a IAP closer to 1 are related to “Very High” performance levels.

These indices were calculated by river basin considering superficial and underground waters, which allows us to observe the relations of the demands with availabilities and potentialities. Vieira and Gondim Filho (2006) strongly recommend that these indicators are spatially implemented in terms of surface and ground potentiality.

The indices that make up the IWRM (IRBC, GI, CI) are subjective and determined from the analysis of their application to the hydrographic basin being studied. The partial scales for these indices are qualitative (*Frame 5*).

For the indices that make up the WUEI (IHSW, IHSWSS, ISW, IST, ISWT, IWLN), the partial scales (also from Very High to Very Low) are related to percentages ranging from 0 to 100%. For example, an indice with a value equal to 60% is classified as “Medium”, while another with a value equal to 25% is considered “Low”. These indices were calculated for all the cities that compose the river basins.

Frame 5. *Partial scales for IWRM indices. (Source: Campos et al., 2014)*

LEVEL	DESCRIPTION
Indice of River Basins Committees (IRBC)	
Very High	The committee is well articulated and has a high rate of problem solving in the basin
High	The committee has been operating for a few years and has a mean rate of problem solving in the basin
Medium	The committee has been recently set up and has a low rate of problem solving in the basin
Low	The committee has been proposed by law and is being set up
Very Low	There is no action for creating a committee in the basin
Grant Indice (GI)	
Very High	The grant has been implemented, it is very well supervised and there is a high reduction in water consumption
High	The grant has been implemented and the level of inspection and reduction in water consumption is medium
Medium	The grant has been implemented and the level of inspection and reduction in water consumption is low
Low	The grant has been proposed by law and is being implemented
Very Low	There is no action for deploying a grant in the basin
Collection Indice (CI)	
Very High	The collection has been implemented, a high amount is being collected and there is a high level of development in the basin
High	The collection has been implemented, a significant amount is being collected and there is a good level of development in the basin
Medium	The collection has been recently implemented and involves a deficit
Low	The collection has been proposed by law and is being implemented
Very Low	There is no action for deploying a collection in the basin

Global scales

When the indices are grouped, global scales are constructed with levels of water sustainability for all indicators in order to allow a better understanding of the value obtained for each indicator. The levels of the scales are qualitative, varying according to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37293754

the values obtained when grouping the indices. This grouping can occur by considering the average of the indices (IPAD) and (WUEI), or by joining the management instruments (IWRM) (*Frame 6*).

After obtaining the indicators and respective level of water sustainability for each basin surveyed, the indicators IPAD, IWRM and WUEI were spatially distributed. For the development of maps, we used ArcGIS 10.3 software (ESRI, 2011), a GIS (Geographic Information System) tool that allows the manipulation of geospatial, matrix and vector databases.

Frame 6. *Global scale for the indicators used in this research. (Adapted from Campos et al., 2014)*

LEVEL	**IPAD and WUEI** **Average (%)**	**IWRM** **Joint Indices (J)**
Very High	80 ≤ M	Committee, grant and collection in full operation in the basin, generating a high reduction in demand
High	60 ≤ M < 80	Committee, grant and collection operating for a few years, generating little reduction in demand
Medium	40 ≤ M < 60	Committee, grant and collection (one or more) recently implemented, but with operational problems
Low	20 ≤ M < 40	Committee, grant and collection (one or more) proposed by law, in the process of installation
Very Low	M < 20	There is no action to apply a committee, a grant and a collection in the basin (one or more)

Results

Indicator on water resources management - IWRM

The assessment of the performance indicator for the water resources management system can be observed in *Table 1*.

Table 1. *Classification of the indices composing IWRM*

Basin	Indice of River Basins Committees (IRBC)	Grant indice (GI)	Collection indice (CI)
Parnaíba River	Very Low	Medium	Very Low
Munim River	Medium	Medium	Very Low
Itapecuru River	Very Low	Medium	Very Low
Tocantins River	Very Low	Medium	Very Low
Mearim River	Medium	Medium	Very Low
Gurupi River	Very Low	Medium	Very Low

Water use efficiency indicator – WUEI

Table 2 shows classification of the indices composing WUEI.

Water sustainability

The assessment of the sustainability indicators used in this research is described in *Table 4*.

Table 4. *Classification of water sustainability indicators*

BASIN	IWRM	WUEI	IPAD	
			sur	**und**
Mearim River	M	L	H	L
Itapecuru River	M	L	VH	M
Parnaíba River	M	L	VH	M
Tocantins River	M	VL	VH	L
Munim River	M	L	VH	M
Gurupi River	M	L	VH	VL

Indicators: IWRM - Indicator on Water Resources Management; WUEI - Water Use Efficiency Indicator; IPAD - Indicator of Potentiality, Availability and Demand; sur - surface; und - underground. Classification: (VH), Very High; (H), High; (M), Medium; (L), Low; (VL), Very Low

All basins of the state showed a "Medium" level of sustainability for IWRM (*Fig. 2*).

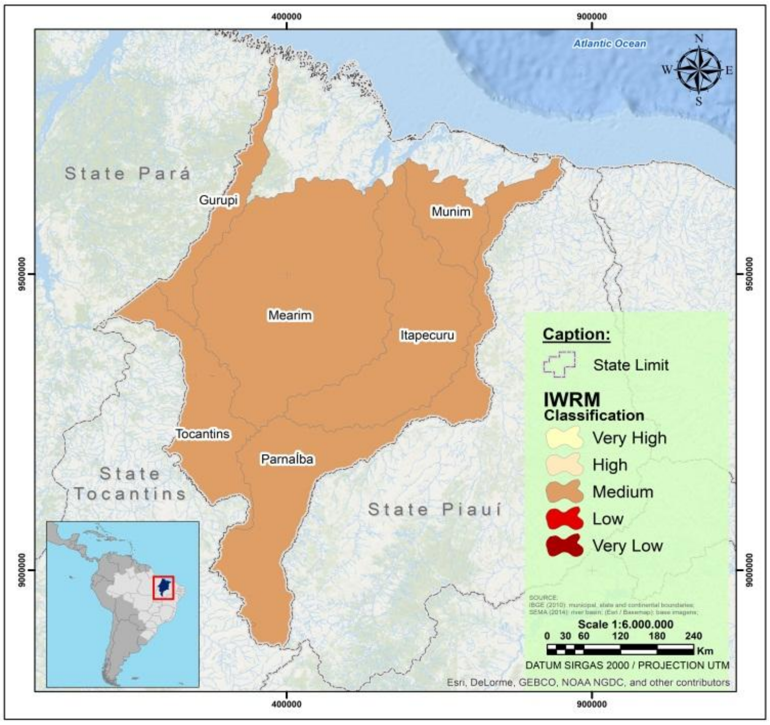

Figure 2. *Spatial distribution of IWRM*

The WUEI showed a sustainability level ranging from "very low" to "low" in the state river basins (*Fig. 3*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37293754

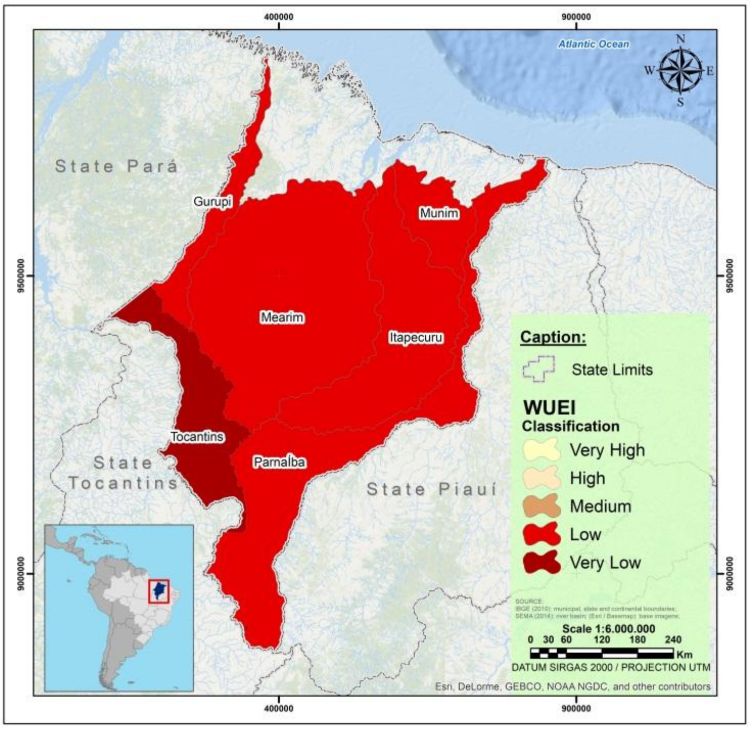

Figure 3. *Spatial distribution of WUEI*

On the global scale, for surface water the IPAD showed a sustainability level ranging from "Very High" to "High" (*Fig. 4*), depicting surplus availabilities in relation to demands and indicating that water resources are not fully available in the basins studied.

Figure 4. *Spatial distribution of IPAD, for surface water*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37293754

The global scale of IPAD for groundwater showed sustainability levels varying from "very low" to "low" and "medium" (*Fig. 5*), due to demands higher than the available water resources, which means that the potential of the basins is not fully activated. Despite these results, the indissociability of surface and underground waters should be noted, as well as the importance of groundwater in maintaining the flow of the Maranhão rivers that have perennial characteristics.

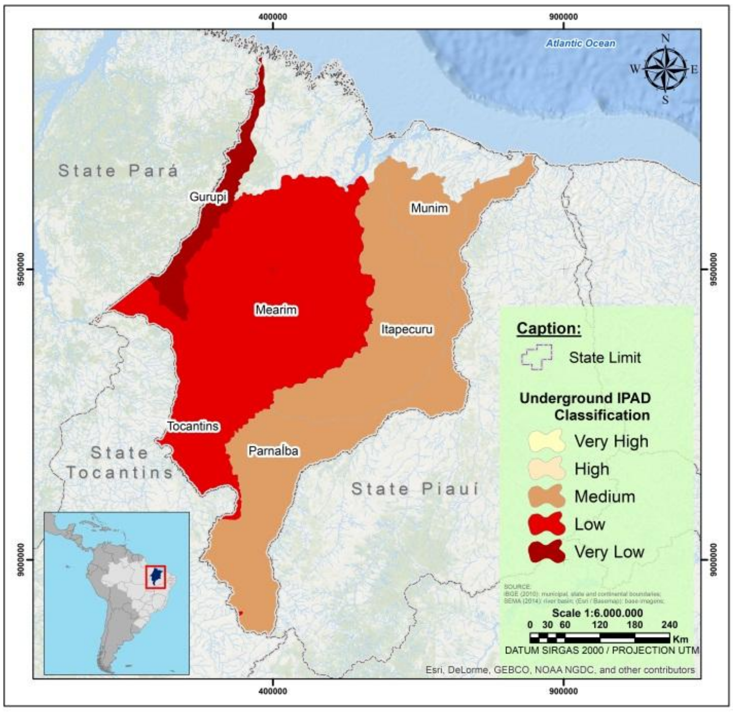

Figure 5. *Spatial distribution of IPAD, for groundwater*

Discussion

About IWRM, the grant indice had a "medium" level in all basins in Maranhão because this instrument is implemented, but it has a low level of inspection and reduction in water consumption. The collection indice has shown a "very low" level in all basins because the collection for the use of water is only established in the state policy of water resources (Brazilian Law no. 8.149/2004). The effective implementation of this instrument would require legal regulation, but there is still no state action in this regard in any of the basins studied in this research. The indice of river basins committees has shown a "very low" level for the Parnaíba, Tocantins, Itapecuru and Gurupi river basins, since none of these has a committee; and a "medium" level for the Mearim and Munim river basins, because they are the only ones that have a recently installed committee, but both have a low rate of problem solving.

Despite the average level of sustainability obtained in the IWRM, the shallow institutionalization of management instruments (grant with problems in implementation undergoing a bureaucratic process, poor inspection, collection for the use of nonexistent water) is clear.

Only two committees have been created so far in the state, which have little or no economic and political sustainability, indicating the existence of issues and fragilities in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37293754

their effective performance and resulting in the low performance of these organizations. The river basin committees which are members of the National System of Water Resources Management play a relevant role in water management. The effective performance of these entities implies in the democratization of water resources management and in sharing the power to decide. This requires effort from the public authorities to share power, and effort from users and civil society to share responsibilities.

The IHSW and IHSWSS indices, which make up the water use efficiency indicator, were “very low”, indicating little coverage of water supply (including by wells).

According to a diagnosis carried out by the National Information System on Sanitation - SNIS, approximately 83% of the Brazilian population is served by a water supply system (Brazil, 2016). Although it appears to be a positive percentage, 17% do not have access to this basic utility, which represents more than 35 million people, mainly concentrated in the Northern and Northeastern regions of the country (Araújo et al., 2016).

Almost all basins studied have shown “very low” ISW and IST levels, except for the Tocantins and Gurupi river basins, whose ISW was “low”. These data show a poor service of collection and sewage treatment. In the calculation of IST, for example, we have observed that in some cities there were no data available on sewage treatment or, when this type of treatment did not occur in the region being studied, the percentage was equal to zero. It should be noted that the National Plan for Basic Sanitation (Plano Nacional de Saneamento Básico - PLANSAB) considers as an appropriate sanitary sewage service not only the presence of a sewage collection and treatment network, but also the use of a septic tank. This fact may have contributed to increasing the level of the ISC indicator, since it also considers the households served by septic tank, the main type of treatment adopted in the cities of Maranhão.

It is important to note that the percentage of cities in Maranhão that has appropriate systems of sewage treatment, with effective removal of organic load, is minimal. Most cities only implement sewage removal in urban regions, with in natura discharge in surface waters, or preliminary treatment, facts that may have contributed to the low level obtained in the IST indicator. According to ANA (2017), the lowest levels of organic load removal from sewage are found especially in the Northern and Northeastern regions of the country. Of the 5,570 cities, 70% remove at most 30% of the organic load generated.

The ISWT indicator also reached a “very low” level in all the basins surveyed, indicating a deficiency in solid waste collection services. The collection of waste in general is not a guarantee that this waste will receive proper treatment, because despite the goal of closing all dumps in Brazil by 2014 as established by the National Policy on Solid Waste, Brazilian Law no. 12.305/2010, Maranhão is now the second State of Brazil with the largest number of dumps, totaling 250 in operation that are responsible for receiving daily almost three thousand tons of waste (ABRELPE, 2017).

The inappropriate disposal of solid waste has become a worldwide issue and can cause damages to the environment, particularly water pollution. This type of pollution can change the characteristics of the aquatic environment through leachate percolation associated to rainwater and springs in the waste disposal sites (Pires et al., 2016).

As for the IWLN indice, which measures the percentage of physical and billed losses, the level shown in the Mearim, Itapecuru and Parnaíba river basins was “medium”. In the Tocantins and Gurupi river basins it was “low” and in the Munim

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37293754

river basin it was “high”, above 60%. Elevated levels of loss in water distribution systems have been reported in Northeastern Brazil, including in Maranhão, reaching 60% and 70% (Maranhão, 2014; Araújo et al., 2016).

Except for the basins with low indices, the others are above the national average, which is 37.57% (Brazil, 2016). In addition, all the basins assessed are above the level of water loss considered acceptable by Cambrainha and Fontana (2015), which is 10%.

A survey released by IBNET (International Benchmarking Network for Water and Sanitation Utilities) showed that, in terms of water loss, Brazil ranks 20th in a ranking of 43 countries (Instituto Trata Brasil, 2015). According to the institute, around 6.5 billion cubic meters of treated water were lost in Brazil in 2013, which amounts to a financial loss of 8.015 billion Reais.

The elevated level of loss of water resources observed in this research indicates the fragility and precariousness of the sanitation system and of the companies that operate water supply services in the regions studied. This also results in many problems, not only economic and social, but mainly environmental, since this loss increases the need for exploration of surface and underground sources of water (Morais et al., 2010).

The the low degree of sustainability of WUEI revealed alarming sanitation conditions, such as low coverage of supply by public utilities, poor or non-existent sewage collection and treatment, incipient waste collection and significant losses of water in the distribution network, which reflects the current reality of Maranhão although the data and information refer to 2010.

As for the IPAD, the Indice of Use of Availabilities - IUA for surface waters ranges from 0.02 to 0.028 and 0.44, resulting in “Very High”, “High” and “Medium” levels, respectively. A “Medium” level of sustainability was observed in the Mearim river basin, being the greatest demand considered for irrigation. The “High” level was observed in the Itapecuru river basin, in which the higher demand is mainly used for urban supply. The “Very High” level was seen for the Gurupi river basin, which presents demands for multiple uses, such as urban and rural supply, industry, irrigation and livestock. The assessment of this indicator revealed surplus availabilities in relation to demands, meaning there is no unmet demand.

The indice of use of underground availability evidences demands higher than availability, which results in a “Very Low” level of sustainability in all basins analyzed. Therefore, there is a situation of exhaustion of availability, with repressed demands in all basins, which would imply the need to increase supply by drilling more wells or adopting other measures such as demand rationalization. Currently, the situation is even more critical as demand has been growing mainly for urban supply, industrial use and irrigation.

Specifically, with respect to groundwater, Costa (1994) already observed that its availability was, in general, lower than the total demand in most regions of Northeastern Brazil. Vieira and Gondim Filho (2006), using potentiality, availability and demand indicators in river basins in Northeastern Brazil, classified the groundwater of the Itapecuru, Mearim and Tocantins basins as little sustainable due to the high demands in these regions. Recent articles show that groundwater resources are under increasing pressure in developing regions and in other regions that are more crucial to economic development (Mukherjee et al., 2015; Watto and Mugera, 2015).

The “Very High” IUP levels for surface waters and the “Very High” and “High” IUP levels for underground waters indicates a comfortable situation regarding the use of potentiality of water resources in all basins.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37293754

The IAP indice, on the other hand, showed that water resources are not efficiently available in all basins, especially in relation to groundwater, for which the level obtained in all the basins was “Very Low”. As for surface water, the IAP levels ranged from “Very Low” to “Low”, meaning that the basins potential is not fully activated.

Relevant information was observed in this research by assessing the IPAD for 2010. On the other hand, it is necessary to calculate such indice with updated data to allow comparisons and to obtain a more current picture on the balance of demand, availability and potentialities of the river basins in the State of Maranhão.

Currently, in the case of surface water, it is already possible to identify conflicts over the use of water in some regions of Maranhão, especially in times of water scarcity. In the Parnaíba river basin, for example, conflicts in the southern region of the State are related to the use of water for irrigation. In the Mearim river basin, in addition to demands for irrigation, there is a growing use of water for intensive and semi-intensive fish farming, associated with illegal abstractions and effluent releases without the authorization from the water resources management authority. In this basin there are also problems with floods, especially in the Pindaré and Grajaú rivers, two important tributaries of the Mearim river. In the Itapecuru river basin, the demand for urban supply stands out because the Italuís system, which supplies a large part of the metropolitan region of São Luís, the state capital, will have its uptake flow doubled by the end of 2018. In addition, deforestation, silting and irregular sand extraction are some of the main environmental problems found in the course of the main river. In recent years, the Tocantins river basin has undergone droughts and significant reductions in the level of the main river and its tributaries, compromising the basin’s sustainability, multiple uses of water and also the production of energy, as the basin houses the hydroelectric power plant of Estreito, which has an installed rated capacity of 1,087 MW.

Concerning groundwater, particularly in the metropolitan region of São Luís, there are reports of wells with high levels of salinization. In 2013, there were a total of 462 records of deep wells, distributed by several municipalities of the State (Cunha et al., 2013). Currently, there are more than 11,000 wells drilled (CPRM, 2018), which may indicate a scenario of overexploitation of the aquifers in Maranhão.

Conclusion

This study presents the application of a methodology that uses river basin sustainability indicators, bringing a contribution to the related literature, in particular to water resources management in terms of diagnosis of sustainability and support to planning and decision making. Sustainability indicators were used in the context of river basins, analyzing surface and underground waters when possible, since water resources are part of an integrated whole that has great relevance in the constitution of life and in a balanced ecosystem.

The application of the methodology to the basins of the state of Maranhão, located in Northeastern Brazil, determined sustainability with an overall intermediate performance in the river basins assessed in this research. These basins require priority measures in the hydrological dimension, especially for underground waters; attention to basic sanitation, including with regard to public supply; reduction of demands and waste; in addition to proper sewage collection and treatment. The results also highlighted the need to improve the state water management system, with actions oriented to the implementation and consolidation of the water resources policy instruments and promotion and support to river basin committees.

The spatialization of the indicators enables a clearer view of the water sustainability of the basins in Maranhão, so that all concepts regarding the performance of the water management structure, efficient use of available water as well as potentialities, availability and water demands could be unequivocally considered.

The application of this methodology may be a model for the assessment of other river basins, especially with conditions similar to the ones evaluated in this study. This tool, provided it is regularly applied, can provide an appropriate description of the evolution of basin conditions in terms of sustainability, assisting different stakeholders and water managers in the planning, decision-making and implementation of local strategies for sustainable development. Authors such as Corrêa and Teixeira (2006) recommend that sustainability indicators are annually applied to observe their evolution and to evaluate the effectiveness of the actions proposed from the surveys of the previous period.

Carvalho et al. (2011) have shown that the adoption of an average value as a measure to build the sustainability indice may be an area of weakness, which may represent a fragility in this study. Another difficulty found when conducting this research was the scarce availability of data in most of the state river basins, a fact that prevented the inclusion of other basins in this analysis and limited the assessment of more indicators.

However, we may conclude that these results were satisfactory and are applicable in regions with scarce data. Consideration was given to variables that fulfill the main components of sustainability, with social, economic, hydro-environmental and institutional characteristics, despite their incommensurability and the complexity of grouping information from indicators of such diverse nature, in particular in places where data availability is scarce. In addition, the aspects of the indicators used here allowed the joint and separate analysis of each dimension. This allows a unique look at the most critical issues of each basin, so as to act correctively and/or preventively to solve the main negative items.

The bottlenecks and limitations identified in this study represent a window of opportunity to improve the current situation in the basins, but it requires a more efficient coordination between the different institutions involved in water resources management.

In this specific application in river basins in the Northeastern part of Brazil, the results are particularly relevant, since there is a considerable gap in the literature on the integrated management of water resources for this region, and especially in the state of Maranhão, which can support more sustainable management actions.

As for future studies, it is recommended that researches shall be carried out on the potentialities, availabilities as well as superficial and underground water demands, by river basin, portraying the current reality of water resources in the State. It is also recommended that other studies shall be carried out to address the issue of water sustainability indicators at the site, including a greater number of indicators that consider other water sustainability criteria.

Abstract. The field experiment was conducted in Poland between 2013 and 2015. The research was carried out in the split plot design with three replications. The following grass species were used in the experiment (factor B): *Lolium perenne*, *Festuca rubra* and *Poa pratensis*. Another experimental factor tested in the research was soil conditioners (factor A) as Substral (S), Humus Active Papka (HAP), Eko-Użyźniacz (EU), UGmax (UG). In each year of the experiment, among other things, grass growth, i.e. its slow rate of growth, was assessed. It was based on measurements of the height of plants before harvest. A 9-point scale was used. This assessment was conducted in three seasons (spring, summer, autumn). In all seasons red fescue had the most desirable intensity of growth (the slowest) and permanent ryegrass the fastest, both determined as an average effect of all soil conditioners. Of the applied soil conditioners, lawns treated with Humus Active Papka, grew the most slowly, taken as an average for all grass species and for all seasons. Of all grass species tested in the experiment red fescue had the smallest variation of growth intensity during the research.
Keywords: *lawns, regrowth, soil condition, grasses, Lolium perenne, Festuca rubra, Poa pratensis*

Introduction

In recent years a popular conviction has developed that presence of lawns in the vicinity of residential houses and in areas adjacent to various companies and establishments builds a positive image, demonstrating a high standard of living of their owners, or high performance in business (Czeluściński et al., 2017; Jankowski et al., 2017). In a situation when people are increasingly preoccupied with their professional life, a limited time they have to spend on treatment and maintaining lawns in a suitable condition has become a problem (Jankowski et al., 2012a,b,d,e). According to Rutkowska and Dębska-Kalinowska (2000) widely relevant species of grass planted on lawns used extensively include: red fescue (*Festuca rubra*), smooth-stalked meadow-grass (*Poa pratensis*), and perennial ryegrass (*Lolium perenne*).

According to many authors (Domański and Andrzejewska, 2011; Domański, 1998; Harkot and Czarnecki, 1998; Jankowski et al., 1999a,b; Prończuk and Prończuk, 2006), with a limited time devoted to lawn maintenance, a required feature of grass is its slow pace of growth. Therefore, it is important that species of grass selected for lawns should grow slowly. The slower growth of a species of grass, the more it is used as a component of a lawn mixture (Knot et al., 2017; Pooya et al., 2013; Salehi and Khosh-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37553765

Khui, 2004). Slow growth of lawn grass considerably reduces mowing frequency, which directly translates into smaller costs of maintaining a lawn (Prończuk and Prończuk, 2008).

To make lawn maintenance simple, new solutions aiming at limiting amount of work, or at making it simpler, need to be worked out. It can be done by a proper selection of grass species, but also by use of special nutrients and growth regulators (Jankowski et al., 2012b,c,d). One of such solutions is application of organic products called soil conditioners, for a longer time positively affecting release of soil minerals and making it possible for plants to survive stressful conditions (Chen et al., 2004; Gąbka and Wolski, 2008). Use of such soil conditioners can be beneficial from a financial point of view, limiting the amount of money spent on grass lawn maintenance (Prończuk and Prończuk, 2008). Such products reduce mowing frequency, saving time and petrol, and with them applied, grass does not need as much fertiliser.

In the literature on the use of lawns there has been little information on possible use of soil additives to improve lawn maintenance. That is why, the aim of this paper is to investigate the impact of such products on grass quality, assessed by determining the rate of growth.

Material and methods

Characteristics of study species

Set up in 2012 the field experiment was conducted in the experimental facility of the Siedlce University of Natural Sciences and Humanities in Poland (52°12 ' N, 22°28 ' E) between 2013 and 2015. The research was carried out as a mini-plot experiment, in the split plot design with three replications and the plot area of 1 m^2. The following grass species were used in the experiment (factor B): *Lolium perenne* - variety Info, *Festuca rubra* - variety Nil, and *Poa pratensis* - variety Alicja. They were sown on their own, each of them at the rate of 28 g/m^2.

Characteristics of fertilizers

Another experimental factor tested in the research was soil conditioners (factor A). Soil conditioners used in the experiment improve soil properties, according to the Institute of Soil Science and Plant Cultivation (IUNG) in Puławy. The composition of the soil conditioners used in the research is presented in *Table 1.*

The UGmax soil conditioner is an extract from compost, containing macronutrients (N, P, K, Mg, Na) and micronutrients (Mn). It also contains lactic acid bacteria, photosynthetic bacteria, *Azotobacter*, *Pseudomonas*, yeast, and *Actinomycetes*. The micro-organisms in the conditioner have a capacity of processing organic and natural fertilizers into compost and humus. These processes are conducive not only to the production of humus but also to improving soil structure, which in turn has a positive effect on water balance in the soil. In addition, the UGmax soil conditioner increases disease resistance, keeping plants healthy, but it also stimulates the development of the root system and supports the biological reduction of molecular nitrogen.

Humus Active Papka contains macronutrients (N, P, K, Ca, Mg), trace elements (Mn, Fe, Zn, Cu), and active humus with useful microorganisms. According to the manufacturer Humus Active, among other beneficial effects, positively affects plant health as well as soil structure, and releases nutrients not readily available to plants.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37553765

Table 1. *Composition of soil conditioners applied in the experiment*

Soil conditioner	Macronutrients ($g \cdot kg^{-1}$)						Micronutrients ($mg \cdot kg^{-1}$)					Microorganism and others
	N	P	K	Ca	Mg	Na	Mn	Fe	Zn	Cu	Mo	
Substral (S)	220	21.8	83		12.06		12	50	12.5	12.5	1	-
Humus Active Papka (HAP)	0.2	1.3	4.6	3.0	0.5	-	15	500	3	1	-	Active humus with useful microorganisms
Eko-Użyźniacz (EU)	0.6	0.3	0.7	-	-	-	-	-	-	-	-	Endo micorhizza, fungi, bacteria, enzymes of earthworms
UGmax (UG)	1.2	0.2	2.9	-	0.1	0.2	0.3	-	-	-	-	lactic acid bacteria, photosynthetic bacteria, Azotobacter, Pseudomonas, yeast, Actinomycetes

Eko-Użyźniacz is extracted from bovine vermicompost and contains the main macronutrients (N, P, K), micro-organisms, and enzymes related to metabolism of earthworms. This soil conditioner stimulates biological life in soil degraded chemically, mechanically, or biologically, and increases plant resistance to different stress factors.

Soil conditioners were applied annually in spring (mid-May) in the following doses: UGmax – 25 ml $\cdot$ m^{-2} (0.6 l in 250 l of water), Eko-Użyźniacz - 100 ml $\cdot$ m^{-2} (10 l in 100 l of water), and Humus Active Papka - 250 ml $\cdot$ m^{-2} (0.2 l for 10 l of water). In turn, Substral, a slow release fertilizer used on lawns, was used in the quantity of 20 g $\cdot$ m^{-2}.

Experimental design

In each year of the experiment, among other things, grass growth, i.e. its slow rate of growth, was assessed. It was based on measurements of the height of plants before harvest. That assessment was made according to the methodology developed by Domański (1998). A 9-point scale was used, in which 9 meant the highest value, with the following description: 1-very high; 3-large; 5-average; 7-small; 9-very small. This assessment was conducted in three seasons (spring, summer, autumn). In each year of the research spring assessment was made around 20 May, summer assessment around 20 August, and autumn assessment around 10 October.

The experiment was set up on the soil developed from loamy sand, belonging to anthropogenic soils of the culture-earth order, and of the type of hortisole (Systematics of Polish Soils). Chemical analysis showed that the soil was alkaline, with high content of magnesium and phosphorus, and low potassium content.

Characteristics of weather conditions

Meteorological data between 2013 and 2015 were obtained from the Hydrological and Meteorological Station in Siedlce. The average air temperature during the experiment was very similar to the long-term average temperature *(Table 2*). In each year of the research the highest temperature was in July (19.3 on average) and August (19.0), while the lowest temperature, taking into account only the growing season, was in April (an average of 8.5) and October (an average of 8.2).

Table 2. *Average air temperature (°C) and precipitation (mm) in individual months of the growing seasons*

Year	Month							
	Apr.	**May**	**June**	**July**	**Aug.**	**Sept.**	**Oct.**	**Means**
Temperature (°C)								
2013	7.5	15.3	17.7	18.8	18.3	11.4	9.6	14.1
2014	9.7	13.7	15.1	20.5	17.8	13.7	8.4	14.1
2015	8.2	12.3	16.5	18.7	21.0	14.5	6.5	14.0
Means	8.5	13.8	16.4	19.3	19.0	13.2	8.2	14.1
Long-term means	8.5	14.0	17.4	19.8	18.9	13.2	7.9	14.2
Rainfall (mm)								
2013	57.6	145.8	111.9	49.1	44.1	86.6	18.0	73.3
2014	39.5	79.5	74.2	37.5	105.7	26.3	3.0	52.2
2015	30.0	100.2	43.3	62.6	11.9	77.1	39.0	52.0
Means	42.4	108.5	76.5	49.7	53.9	63.3	20.0	59.2
Long-term means	33.0	52.0	52.0	65.0	56.0	48.0	28.0	47.7

A meteorological element with major temporal fluctuations is rainfall (Skowera and Puła, 2004). By analyzing its amount in different months of the experiment it was found that the lowest average monthly precipitation was in 2015 (52.0 mm), but still it was higher by 2.3 mm than the long-term average. In the growing season of 2013 the average monthly precipitation of 73.3 mm was the highest. May 2013 was a month in which rainfall was the highest of all months during the experiment (145.8 mm). The lowest rainfall was recorded in October 2014 (3.0 mm) and August 2015 (11.9 mm).

Optimal temperature and moisture conditions were only in April 2014 and in September 2015. In the remaining months of all the growing seasons the weather conditions were not as favourable, varying from extremely dry in August 2015 to extremely wet in May 2013. Throughout the experiment the best conditions occurred at the beginning of each growing season. It can be concluded that the most difficult period for plants was in 2015, when, apart from May and the end of the growing season, the weather conditions ranged from quite dry to extremely dry.

Statistical analysis

The test results were evaluated statistically with the analysis of variance. Tukey's test ($P \leq 0.5$) was used to find significantly different means of the effects of experimental factors and their interaction. Based on grass growth ratings, standard deviation and coefficient of variation were calculated for separate seasons, years, and soil conditioners.

Results and discussion

Spring grass regrowth

There was diversity of grass growth rate, depending on the species of grass, soil conditioner applied, and season of the year (*Tables 3-5*). In springtime this rate was varied in relation to all experimental factors (*Table 3*). Throughout the experiment during spring seasons, the slowest growth rate, as an average for all grass species, was in result of Humus Active Papka application (5.29) and the most intensive after using UGmax (4.71^{o}) or Substral (4.74^{o}). According to Prończuk and Prończuk (2006), in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37553765

Denmark and in the Netherlands no mineral fertilisers are used on municipal lawns, which slows down the growth of grass and reduces the need for frequent mowing. In the USA, in an extensive system, most lawns (80%) are maintained without the use of mineral fertilisers as well (Cook, 2005).

Table 3. *Grass growth rates on a 9-point scale in spring seasons between 2013 and 2015*

Year (C)	Species (B)	Fertiliser (A) (S)	(EU)	(HAP)	(UG)	$\bar{x}$
2013	Smooth-stalked meadow-grass	6.8	5.2	5.0	7.2	6.05

		Mean effect of year				
2013		7.43	6.9	6.53	7.33	7.05
2014		1.57	3.97	3.97	2.17	2.92
2015		5.23	4.47	5.37	4.63	4.92

$LSD_{0.05}$
A=NS, B=2.12, C=2.12
A/B=NS, B/A=NS, A/C=NS
C/A=NS, B/C=2.69, C/B=2.69

In spring seasons, the fastest growth was observed on lawns with perennial ryegrass (3.95°) and the slowest for red fescue (6.33°), with the differences being statistically significant. Considering the effect of soil conditioners on different grass species, it was noted that perennial ryegrass treated with Substral and smooth-stalked meadow-grass treated with UGmax grew the fastest (3.6° and 3.7°, respectively). In turn, the slowest growth was on lawns with red fescue, with its responses to different soil conditioners ranging from 6.2° to 6. 43°.

In assessing grass growth in spring throughout the research, it was found that the most intensive growth was in 2014 (the average of 2.92°) and the least in 2013 (7.05°), with those differences between the effects of spring seasons being statistically significant. In springtime the type of applied soil conditioner had a greater impact on grass growth level than weather conditions. As regards the values of precipitation and air temperature (*Table 2*), the worst weather conditions occurred in the spring of 2015, when the intensity of grass growth was moderate (the average rate of 4.92°). In the spring of 2013 weather conditions were very conducive to grass growth (the average air temperature of 7.5°C in April, 15.3°C in May, and 17.7°C in June, and the precipitation of 57.6, 145.8, 111.9 mm, respectively), while the intensity of grass growth was the weakest (7.05°), comparing with the other spring seasons of the research. According to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37553765

Martiniello and D'Andrea (2006) in warm and humid habitats, growth of green mass is faster and lusher. However, the excessive increase in air temperature, together with strong evaporation, can undermine the balance between energy spent on respiration and on accumulation of photosynthetic products necessary for growth.

Summer grass regrowth

In summer seasons, intensity of grass growth was also varied (*Table 4*), and, like in spring, perennial ryegrass grew the fastest (4.28) and red fescue the most slowly (6.54). Studying the effects of soil conditioners on different species it was found that, like in spring, the most intensive growth was on plots with perennial ryegrass treated with Substral (2.67^{o}) and on plots with smooth-stalked meadow-grass treated with UGmax (2.6^{o}). In turn, smooth-stalked meadow-grass and red fescue had the slowest growth when treated with Humus Active Papka (7.6^{o} and 7.43^{o}).

Table 4. *Grass growth rates on a 9-point scale in summer seasons between 2013 and 2015*

Year (C)	Species (B)	Fertiliser (A) (S)	(EU)	(HAP)	(UG)	$\bar{x}$
2013	Smooth-stalked meadow-grass	2.1	8.9	8.6	2.9	5.63
	Perennial ryegrass	2.9	7.8	8.4	4.1	5.8
	Red fescue	4.8	7.7	8.2	5.3	6.5
2014	Smooth-stalked meadow-grass	3.2	9.0	8.9	2.9	6.0

2015		5.33	3.73	5.43	3.87	4.59

$LSD_{0.05}$
A=2.55, B=NS, C=NS
A/B=2.05, B/A=1.84, A/C=2.05
C/A=1.84, B/C=1.59, C/B=1.59

The slowest growth in summer, taken as an average for all grass species, was caused by Humus Active Papka (6.97^{o}) and the fastest by UGmax (3.86^{o}). These results confirmed the justification of the use of those soil conditioners on lawns. According to Hamza and Suggars (2001) bio products are based on natural substances like plant extracts, phyto hormones, or humic substances. Therefore, they have positive impact on plant metabolism, stimulating life processes to overcome adverse environmental conditions.

Throughout the experiment grass growth varied in summer seasons. The worst weather conditions for the development of grass occurred in 2015 (the air temperature

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37553765

of 18.7 in July and 21.0 in August and precipitation of 62.6 and 11.9 mm, respectively), which was not reflected in slow growth. In 2015 the average value of this parameter for all species was 4.59, which was the fastest growth of all three summer seasons, suggesting that like in the spring, it was more dependent on the type of applied soil conditioners than on weather conditions. Of all summer seasons throughout the entire research grass had the slowest growth (best) in 2013, when treated with Humus Active Papka (8.4^{o}) or Eko-Użyźniacz (8.13^{o}). According to Calvo et al. (2014) this type of bio products facilitates assimilation of nutrients, which in turn affects metabolism of plants and at the same time quality of a lawn, like grass density or growth rate. In the present experiment grass treated with Substral had the worst, from the point of view of the user, growth rate in 2013 (3.27^{o}). Differences in the intensity of growth between applied soil conditioners in various years of research were statistically significant.

In other studies (Jankowski et al., 2011; Salehi and Khosh-Khui, 2004) it was found that the regrowth of lawn grass in monoculture was mainly dependent on the species of grass selected to be planted, as well as on the year of the studies, which was associated with weather conditions.

Autumn grass regrowth

In the autumn the intensity of grass growth was also varied (*Table 5*). Among the species of grass, perennial ryegrass had the most intensive growth (3.62^{o}), similar to previous seasons (spring, summer), while red fescue had the slowest growth (5.85^{o}). Differences in the intensity of growth between these species were statistically significant. Looking for best species and varieties of grass to be used on extensive lawns, Prończuk and Prończuk (2006) found that red fescue tolerated lack of nutrients in the soil better than other species. It is obvious that mineral fertilizers, mainly nitrogen, stimulate the growth and growth rate of grass.

Grass regrowth in regard to soil conditioners, species and study year

Throughout the three-year period red fescue treated with UGmax had the slowest (the best) growth (6.1^{o}) and perennial ryegrass with UGmax the most intensive (the worst) (2.97^{o}). Of the applied soil conditioners Humus Active Papka had the biggest effect on slowing grass growth (5.08^{o}). Throughout the research there were statistically significant differences in the intensity of growth in autumn, in which season lawn grass grew the most quickly in 2014 (3.83^{o}), while in 2013 the growth was the slowest (5.53^{o}). In various years of research the differences in the intensity of grass growth with different soil conditioners applied were statistically significant. In other studies Jankowski et al. (2012b,e) found that due to different weather conditions in various years of research there were also important significant differences in grass growth. Trinexapak ethyl used in the experiment conducted by the above authors showed favourable interaction between grass and mineral soil conditioners in terms of growth rate.

In assessing the intensity of grass growth (*Table 6*) as an average of all experimental years it was found that red fescue had the slowest growth (the average of 6.24^{o}), and perennial ryegrass the fastest (the average of 3.95^{o}). These differences were statistically significant. Of all species, red fescue treated with Humus Active Papka had the slowest growth of 6.44^{o}, as the three-year average. Comparing the effects of soil conditioners it was found that Humus Papka had the best ability to slow the intensity of grass growth, with the growth rate of 5.78^{o}, determined as an average for all species.

***Table 5.** Grass growth rates on a 9-point scale in autumn seasons between 2013 and 2015*

Year (C)	Species (B)	Fertiliser (A)				$\bar{x}$

These results were confirmed by studies of other authors (Pooya et al., 2013; Jankowski et al., 2012a), who found that growth of lawn grass is an unstable feature, depending on the species, habitat conditions, content of macro-and micronutrients in the soil, and on the way the lawn is used.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37553765

Similarly, throughout the years of research there was a varied intensity of grass growth. The slowest growth was achieved in 2013 as a result of treatment with Humus Active Papka (6.92^o). Similarly, in the following years of research on the same experimental units the growth was slow. According to many authors (Jankowski et al., 2011; Prończuk and Prończuk, 2008; Knot et al., 2017) lawn grass species, in addition to ensuring good appearance of a lawn, should be characterized by slow growth after mowing.

Determined as an average of all separate seasons (spring, summer, autumn) growth rate was the slowest in summer seasons (5.31^o). According to Martiniello and D'Andrea (2006) a decrease in growth and a smaller weight gain of grass during summer months is a natural phenomenon and to a large extent depends on temperature. Air temperature above 30^{o}C can completely stop weight gain of grass by stepping up the process of breathing. Among the applied soil conditioners in the summer, lawn treated with Humus Active had the slowest growth rate (6.79^o). In the autumn grass in the same experimental unit had the least intensive growth, too.

Grass regrowth variation

The calculated coefficient of variation of grass growth (*Table 7*) indicated that during the experiment the smallest variation of this parameter was for red fescue (39.1), with the slowest average growth (6.24), a feature most awaited by the user of the lawn.

Table 7. *Standard deviation and coefficient of variation of grass growth rate*

Species	Min.	Max.	Mean	Standard deviation	variation coefficient
Smooth-stalked meadow-grass	1	9	4.98	2.17	43.57
Perennial ryegrass	1.4	8.4	3.95	2.18	55.19
Red fescue	1.8	9	6.24	2.44	39.10

variation coefficient: 0 – 20% small variation, 20 – 40 % average variation,
40 – 60% large variation, > 60% very large variation

Conclusions

1. Growth rate was varied in relation to both the species of grasses (smooth-stalked meadow grass, perennial ryegrass, red fescue), the applied soil conditioner, and seasons and years of research.
2. In all seasons red fescue had the most desirable intensity of growth (the slowest) and permanent ryegrass the fastest, both determined as an average effect of all soil conditioners.
3. Of the applied soil conditioners, lawns treated with Humus Active Papka, containing in their composition not only a large amount of minerals but also permanent active humus with useful microorganisms, grew the most slowly, taken as an average for all grass species and for all seasons (spring, summer, autumn).
4. Among the species of grass, it was found that in the spring red fescue treated with Eko-Użyźniacz had the slowest growth of grass. In summer both smooth-stalked meadow-grass and red fescue treated with Humus Active Papka and in autumn red fescue treated with UGmax grew the most slowly. This proves the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37553765

equivocal effect of soil conditioners on the level of growth rate of various grass species at different times of the year.

5. Of all seasons (spring, summer, autumn) it was found that, as an average for all species, grass grew the most slowly in summer and most intensely in springtime. This could be related to physiological development of grass as well as to the effects of the weather. During summer seasons grass treated with Humus Active Papka had the slowest growth, but it was the fastest as a result of the use of UGmax or Substral.
6. Of all grass species tested in the experiment red fescue had the smallest variation of growth intensity during the research, which, from a practical point of view, is a feature most appreciated by the user, as such grass does not require frequent mowing. In addition, Humus Active Papka deserves further attention as regards its potential for reducing grass growth.

Abstract. *Euphorbia guyoniana* is a medicinal plant endemic to Algeria. It is used by local populations for its medicinal properties. This study was to determine the antibacterial effect of the aqueous extract from *Euphorbia guyoniana* on pathogenic bacteria of telluric origin. The aqueous extract was obtained by confrontation with organic solvents method with a yield of 1.7%. The total content of the flavonoïd extract was evaluated by the method of Aluminum Trichloride and was found to be 0.31 mg EQ/gE. The extract obtained was characterized by Infrared Spectroscopy and revealed a richness of phenol, aldehyde and ester then analyzed by High-Performance Liquid Chromatography, which allowed us to identify 27 flavonoid compounds. The extract was tested by the diffusion method on agar, on 12 bacterial strains isolated from a henhouse and identified by VITEK. These strains seem to be sensitive to the flavonoids of *Euphorbia guyoniana* with MICs varying from 1.47 to 61.78 mg/ml. The order of sensitivity of the bacterial strains to the extract is represented in the following order: *Staphylococcus aureus* > *Streptococcus faecalis* > *Escherichia coli*. Thus, the flavonoids of *Euphorbia guyoniana* may be an alternative to chemical control of certain pathogenic microorganisms.
Keywords: *Euphorbia guyoniana, flavonoids, antibacterial activity, HPLC, VITEK*

Introduction

Within microbial communities in the soil, there may be some microorganisms that are pathogens for plants, animals and humans (Raaijmakers, 2009). Soil is a natural habitat that can contain some primary and opportunistic pathogenic bacteria. The rhizosphere may contain certain opportunistic bacteria such as *Burkholderia spp., Ochrobactrum spp.* and *Stenotrophomonas spp.* (Berg et al., 2005). *Pseudomonas aeruginosa* is a highly encountered bacterium in the soil (Colinon et al., 2013). Some primary pathogenic bacteria are natural soil inhabitants, such as *Bacillus cereus* and *Bacillus anthracis*, which can cause serious diseases in humans (food poisoning and pneumonia) (Ticknor et al., 2001; Reis et al., 2014). Other bacteria are highly pathogenic to humans such as *Clostridium botulinum* and *Clostridium tetani* (Smith, 1978, 1979). There are certain categories of bacteria with a saprophyte life in soil such as *Listeria monocytogenes* (Freitag et al., 2009). The importance of these pathogens from land-based sources is growing with the increasing practice of monoculture, mainly in the Mediterranean regions (Tramier, 1986).

Control of pathogens from land-based sources has always been difficult, however the use of biocidal soil disinfection products such as chloropicrin and methyl bromide has been found to be very dangerous for humans and useful organisms' cultures. Fortunately, these products have been definitely banned, which does not solve the problem of the control of diseases of land-based origin. Vector control during epidemics

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37673781

is achieved through chemical insecticides, but their use continues to give rise to a high level of contamination and ecological imbalance due to the appearance of resistance. This is why the World Health Organization (WHO) insists on the search for new methods of control that are basically biological.

Euphorbiaceae contains several families of chemical compounds such as alkaloids (De Nazare et al., 2005), flavonoids, Cyanogenetic compounds (Hunsa et al., 1995), ellagic acid (Mavar et al., 2004) Saponins (Tripathi and Tiwari, 1980) and terpenes (Mazoir et al., 2008). Among the species endemic to Algeria, *Euphorbia guyoniana* had a particular importance in the pharmacopoeia. According to Bellakhdar (1997), it is used by many Saharan populations against poisonous bites and stings and various infections. The latex of the plant is used to attack warts and to extirpate thorns.

This study attempts to establish for the first time the effect of the aqueous extract of a medicinal plant (*Euphorbia guyoniana*) on the human bacterial pathogen in the telluric environment for the purpose of biological control.

Materials and methods

Plant material

Experiments were carried out on the aerial and underground parts of *Euphorbia guyoniana*, collected from the Ghardaïa region (South Algeria) in February 2016. The botanical identification of the species was carried out at the botanical laboratory of the Higher National School of Agronomy (ENSA) in El-Harrach (Algeria). The whole plant (stems, flowers, leaves and roots) was used for the preparation of the extract. The plant material was ground after drying at ambient temperature in dark place in order to preserve the integrity of the molecules. The obtained ground product was stored in a hermetically sealed flask (*Photo 1*).

Photo 1. *Aerial part of Euphorbia guyoniana*

Extraction procedure

The extraction of flavonoids was carried out according to the Bruneton protocol (1999). The principle of this technique is based on the treatment of the plant material

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37673781

with various solvents. It is based on the degree of solubility of flavonoids in organic solvents. The recovered aqueous extract was stored in the dark in hermetically sealed vials and subjected to chemical and biological analysis.

Colorimetric determination of the flavonoïc extract

The content of *Euphorbia guyoniana* in flavonoids was determined by the method of Aluminum Trichloride ($AlCl_3$) cited by Bahorun et al. (1996); Djeridane et al. (2006) and Ayoola et al. (2008). This method is based on the formation of an aluminum flavonoid-ion complex having a maximum absorbance at 430 nm. The concentration of flavonoids was calculated from the calibration curve established with Quercetin and expressed in equivalent milligrams of Quercetin per gram of extract weight (mg EQ/gE).

Infrared spectroscopy analysis of the extract

The infrared spectrum of the aqueous extract, for a frequency range between 400 and 4000 cm^{-1}, was obtained by a NICOLET 560 type spectrometer.

High performance liquid chromatography (HPLC)

Qualitative analysis of the aqueous extract was realized using HPLC. The apparatus consisted of a Young Line YL9100 liquid phase chromatograph, equipped with a YL 9101 quaternary pump with integrated degasifier YL 9101, a UV/Visible detector YL 9120 and a YL 9131 oven. The column used was Agilent eclips XDB C 18 (5 µm) with a length of 25 cm and an internal diameter of 4.6 mm. The mobile phase was a mixture of ultrapure water / acetonitrile / acetic acid (50:47:2.5) in an isocratic system with a flow rate of 1 ml/min. The volume of extract and standards injected was 20 µl. The detection of the compounds was done with a UV detector at a wavelength of 280-320 nm.

Isolation and identification of pathogenic bacteria

The bacteria were isolated from the soil of a henhouse in the Bouira region (Algeria). Soil sampling was carried out by the suspension-dilution method described by Vidhyasekaran et al. (1997). The identification of bacteria was made by fresh macroscopic observation based on morphological criteria of the colony, microscopic observation including methylene blue staining and Gram staining, biochemical galleries and confirmed by VITEK.

Several bacterial strains have been identified in this soil, such as *E. coli* which is a commensal bacterium of the human digestive tract as well as of many animals. At a rate of 10^7 to 10^9 Colony Forming Unit (CFU) per gram of faeces, it accounts for 80-90% of the most dominant species of the aerobic bacterial flora of the human intestine (Tenaillon et al., 2010). These strains are both responsible for intestinal and extra-intestinal infections (urinary infections, bacteremias, meningitis ...) (Locatelli., 2013). It is mainly via the natural excretion of fecal matter by animals that these pathogenic bacteria have been introduced into aquifers, rivers and soil (Solo-Gabriele et al., 2000; An et al., 2002; Byappanahalli et al., 2006).

Enterococcus faecalis is also a commensal bacterium of the intestines of humans and warm-blooded animals. It is a species found in human excreta at concentrations ranging

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37673781

from 10^5 to 10^7 per gram of faeces (Noble, 1978; Leclerc et al., 1996). It is also found in faeces of animals such as cattle, poultry, pigs and sheep, but to a lesser extent (Leclerc et al., 1996; Franz et al., 1999; Wheeler et al., 2001). This species is an opportunistic pathogen, affecting only individuals with weakened immune systems, particularly in hospitals (Morrison et al., 1997). It may cause endocarditis, bacteremia, meningitis, urinary tract infections, intraabdominal infections and surgical wound infections (Chenoweth and Schaberg., 1990; Jett et al., 1994). Because of its natural presence in the intestines and fecal matter of humans and animals, this bacterium is frequently found in soil and on plants (Mundt., 1961; Fujioka et al., 1998; Byappanahalli et al., 2012; Valenzuela et al., 2012; Ran et al., 2013).

Staphylococcus aureus is a ubiquitous bacterium that is found specifically on mucous membranes, the nasopharyngeal sphere and skin of warm-blooded animals and humans (Ostyn et al., 2012). Staphylococci producing coagulases are essentially represented by the species *Staphylococcus aureus*. In addition to food poisoning and nosocomial infections in humans, this species may cause clinical and subclinical mastitis in ruminants, particularly cows, which is a common reason for milk contamination (Ostyn et al., 2012).

Evaluation of the resistance of isolated bacteria to antibiotics

The resistance of the isolated bacteria was tested by synthetic antibiotics, using the Muller Hinton agar diffusion method. The antibiotics used are Erythromycin (E_{15}) (15 mcg) Ciproflaxacin (Cip_5) (5 mcg) Clindamycin (Cl_{25}) (25 mcg) Nalidixic Acid (Na_{30})(30 mcg) and Carbenicillin (Cb_{100}) (100 mcg). Areas of inhibition were determined according to the recommendations of the National Committee for Clinical Laboratory Standards (NCCLS, 2006) and bacteria were classified as resistant or susceptible to antibiotics.

Evaluation of the antibacterial activity

The evaluation of the antibacterial activity of the aqueous extract of *Euphorbia guyoniana* was carried out by the diffusion method in agar medium recommended by several authors (Belaiche, 1979; Garbonnelle et al., 1987; Joffin and Leyral, 2014; Koba et al., 2004). Petri dishes containing the Muller Hinton agar were inoculated with a quantity of bacterial suspension (0.5 McFarland), according to the recommendations of the NCCLS. Sterilized paper discs of 6 mm of diameter, impregnated with 10 μL of extract were placed on the surface of agar. The plates were kept for 2 h at 4 °C and then incubated overnight at 37 ° C. The sensitivity of the strain to the extract is manifested by the size of the diameter of the bacterial-free zone surrounding the disc. The antimicrobial activity was determined by measuring the Minimum Inhibitory Concentrations (MICs). Three replicates are performed for each bacterium.

Statistical analysis

The results were expressed as mean ± Standard Error of Mean (M ± ESM). The statistical analysis was performed using the Statistica software® (version 6, Genistat Conseils Inc., Montreal). After the analysis of the variance, the comparison of the averages is performed by the student's test for matched samples. The test is considered statistically significant when the value of $p \leq 0.05$, for a confidence interval of 95%.

Results

Extraction yield on flavonoids

Aqueous extract containing flavonoids was obtained with a yield of flavonoids of 1.7%. The reason of using the aqueous extract for the study of the antibacterial activity in spite of its low rate is its richness in very polar flavonoids.

Colorimetric determination of flavonoids

The content in flavonoïds is reported in equivalent mg of quercetin/g of the plant. The concentration of the flavonoid in the aqueous extract is 0.31 mg EQ/gE.

Infrared spectroscopy analysis of flavonoic extracts

The results of the infrared characterization of the aqueous extract are shown in the *Table 1*.

Table 1. *Infrared analysis of the flavonoïc extract*

Wave lengh (cm^{-1})	Bonds	Nature of the bond	Function
3406.58	-OH free	Broad band	Phenol
1609.47	C=O	Mean band	Aldehyde
1079.29	C-O	Weak band	Ester

In the aqueous extract of *Euphorbia guyoniana,* and referring to the work of Mabry et al. (1970), the broad band around 3406.58 cm^{-1} is associated with the elongation vibration of the OH bond (phenol function). The mean band at 1609.47 cm^{-1} corresponds to the elongation vibration of the C=O bond (aldehyde function). Finally, a weak band of 1079.29 cm^{-1} is associated with the elongation vibration of the C-O bond (ester function).

HPLC

The HPLC analysis revealed the presence of 41 compounds, of which 27 could be identified in the flavonoid extract of *Euphorbia guyoniana* (*Fig. 1, Table 2*).

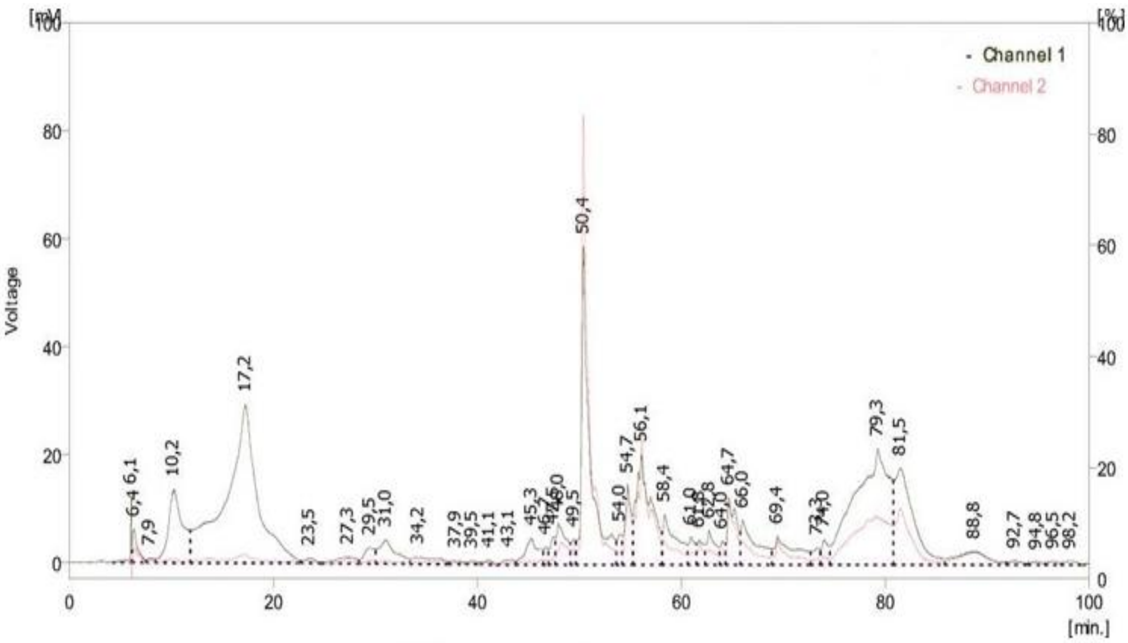

Figure 1. *Chromatogram of HPLC applied to flavonoids*

The analysis showed that the aqueous extract of *Euphorbia guyoniana* is rich in molecules with antibacterial activity. The major compounds are ellagic acid (19.1%), gallic acid (9.5%), Myricetine and Quercetin-3-O-α-rhamnoside (6.6%), Apigenin-7-Orutinoside (4.7%), Hydroxytyrosol (4.4%) and Kaempferol (4.0%), The other identified molecules are present at rates of less than 3%.

Identification of isolated bacteria

The results of the identification of isolated bacteria are shown in *Tables 3* and *4*.

In total, twelve bacterial strains are isolated and identified from a henhouse soil belonging to three species: *Escherichia coli* (Gram negative), *Staphylococcus aureus* (Gram positive) and *Enterococcus faecalis* (Gram positive).

Antibacterial activity

Isolated strains used to evaluate antimicrobial activity showed an important resistance to the extract, *Tables 5* and *6* show the results.

The results showed that the antibacterial activity of the aqueous extract of the plant differs from one strain to another. An important antibacterial activity of the extract is observed for *Staphylococcus aureus* with zones of inhibition ranging from 21 (± 1) to 31.33 (± 1.5) mm, and positive controls for Erythromycin, Ciproflaxacin And clindamycin which showed respectively clear inhibition zones of 6 (± 0) to 34 (± 1) mm, 6 (± 0.5) to 36 (± 0.5) mm and 6 (± 0) to 20 (± 0.5) mm according to the strain (*Fig. 2*). A high sensitivity of *enterococcus faecalis* to the extract was noted with zones of inhibition ranging from 22 (± 2) to 28.33 (± 1.2) mm, and also positive controls for Erythromycin, Ciproflaxacin, clindamycin, And nalidixic acid with inhibition zones of 6 (± 0.5) to 20 (± 2.6) mm, 6 (± 0) to 34 (± 0) mm, 6 18 (± 0) mm and 6 (± 0.5) to 15 (± 0) mm respectively (*Fig. 3*). Finally, a lower sensitivity was observed in *Escherichia coli* for the extract with an inhibition zone between 18.33 (± 1.5) and 28.66 (± 1.5) mm,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37673781

and positive controls for Ciproflaxacin, Clindamycin and carbenicillin with inhibition zones of 40 (± 0) to 42 (± 1) mm, 12 (± 1) to 25 (± 0) mm, and 8 (± 0) to 32 (± 1) mm respectively (*Fig. 4*).

Table 5. *Antibiotic and extract susceptibility tests*

Strain		**Areas of Antibiotic Inhibition**					**Areas of extract inhibition**
		E_{15}	**Cl_{25}**	**Cip_5**	**Cb_{100}**	**NA_{30}**

S: sensitive; R: resistant; /: unaccomplished

Table 6. *Values of minimum inhibitory concentrations*

Strain		**MIC_S (mg/ml)**
Escherichia coli	01	61.78
	02	55.12
	03	55.12
	04	50.23
Staphylococcus aureus	01	1.47
	02	8.88
	03	3.25
	04	4.75
Enterococcus faecalis	01	23.23
	02	25.87
	03	19.87
	04	17.05

From the results obtained above, it is clear that the aqueous extract of *Euphorbia guyoniana* is much more active against the different microbial strains than the synthetic antibiotics by exhibiting larger zones of inhibition. These results are confirmed by significant tests with $p < 0.05$. Except for Ciproflaxacin, which exhibits slightly larger inhibition zones on the Escherichia coli strains compared to the extract. This important antibacterial activity is due to the richness of the extract in flavonoïds, known to be effective antibacterial substances.

Discussion

The value of the flavonoid yield of the *Euphorbia guyoniana* plant found in our study (1.7%) was higher than that obtained by Kemassi (2014) for the aqueous extract of the same plant harvested from the Ghardaïa region which was obtained by Maceration with acetone, ie 0.082%. In addition, higher yields were noted by Herouini et al. (2015) for the flavonoid extract of the roots (6.3%) and the aerial part (4.3%) of *Euphorbia guyoniana* harvested in Oued sebseb (Algerian Sahara) obtained by reflux. According to Haba et al. (2008), *Euphorbia guyoniana* is a plant rich in secondary metabolites including diterpenes, triterpenes, steroids and aromatic compounds. The yield of flavonoids appears to depend on the nature of the biotope and the extraction method, knowing that the number of washes carried out in the extraction protocol could lead to substantial losses of the aglycones, hence the disadvantages of the method of extraction by solvent confrontation. Similar works have reported the existing of variability in the yield values extraction of secondary metabolite depending on the procedure of extraction (Moreira et al., 2005; Sagdic and Ozcan, 2003; Celiktas et al., 2007; Turkmen et al., 2007).

Concerning the concentration of aqueous extract in flavonoids; Andrianarisoa and Tsirinirindravo (2009) found a concentration of approximately 63.39 µg/µl for the aqueous extract of the leaves of *Dalechampia clematidifolia* (*Euphorbiaceae)* harvested in Madagascar, which represents a significantly lower value to that found for the species *Euphorbia guyoniana*.

HPLC analysis by Smara et al. (2014) on the aerial parts of the same plant (*Euphorbia guyoniana*) harvested from the Oued Souf region (Algerian Sahara) revealed the presence of a hydrolyzable tannin, a single coumarin and two flavonoids (flavonol) namely Quercetin-3O-β-D-glucuronide and kaempferol-3O-β-D-glucuronide. In our study, Quercetin is detected as a molecule, and associated with galactoside, glucoside or rhamnoside. As for kaempferol, this compound is also identified in the free form.

Very little study concerning the antibacterial activity of the aqueous extract of *Euphorbia guyoniana* was carried out. Herouni et al. (2015) used separately the flavonoid aqueous extracts of the aerial and subterranean parts of *Euphorbia guyoniana* on *Staphylococcus aureus* and *Escherichia coli* isolated from several infections, and noted a less marked activity than that observed in our study. These authors obtained zones of inhibition comprised between 7 and 8 mm.

This difference in the inhibitory effect of the bacterial growth observed may be related to the richness of the extract tested in flavonoid compounds known for their antibacterial activity. In the case of this study, the important antibacterial effect observed can be attributed either to the richness of the extract of flavonoid compounds (ellagic acid, gallic acid, Myricetine, Quercetin-3-O-α-rhamnoside, Apigenin-Orutinoside, Hydroxytyrosol and Kaempferol) or to the virulence of the bacterial strain.

Moreover, the efficiency of an extract of a plant also depends on the extraction method (Moreira et al., 2005; Sagdic and Ozcan, 2003; Celiktas et al., 2007; Turkmen et al., 2007), the part of the plant used (Yeo Sounta, 2014; Natarajan et al., 2005) and the harvest season.

Conclusion

The evaluation of the antibacterial activity of the aqueous flavonoid extract of the medicinal plant *Euphorbia guyoniana* showed a remarkable inhibitory effect on pathogenic bacteria of telluric origin. In perspective other studies are necessary for the development of formulations for pharmaceutical use based on this extract in order to fight against these pathogens.

(Received 9th Feb 2018; accepted 31st May 2018)

Abstract. A two-year study was carried out with split-plot factorial arrangement based on randomized complete block design in three replications in Khorramabad, Iran, during 2012-2014. The studied factors in the main-plots included end season drought stress at three levels (normal irrigation, mild stress and severe stress with irrigation based on 40%, 60% and 80% moisture depletion of soil water available to plants) and mycorrhizal biofertilizer factors and methanol spraying at four levels (without mycorrhiza inoculation + distilled water spraying, control; mycorrhiza inoculation + distilled water spraying; without mycorrhiza inoculation + methanol spraying; and mycorrhiza inoculation + methanol spraying). Moreover, the three irrigated wheat cultivars Aflak, Dena and Alvand with factorial arrangement were in sub-plots. Results demonstrated that drought stress decreased stomatal conductance, leaf transpiration, photosynthesis rate and grain yield. Crop plants under mild stress conditions experienced lower carbon dioxide in sub-stomatal chamber, whereas, its accumulation in those plants that were under severe stress conditions increased significantly. The studied cultivars responded to drought stress differently. Yield reduction in Alvand was more severe than in Aflak and Dena under mild and severe drought stress conditions. The results suggested that mycorrhizal inoculation and methanol spraying play an important role in enhancing drought tolerance in susceptible wheat cultivars to drought stress. Moreover, they can be used in irrigated wheat farming to reduce damages caused by end season drought stress.
Keywords: *irrigation, photosynthesis, severe stress, transpiration, methanol spraying, wheat*

Introduction

As the most important cereal in many parts of the world, wheat is the main food for most people (Rauf et al., 2007; Shewry, 2009). Wheat is one of the most important cereal crop and considered as a staple food of the vast majority of the human population including urban and rural societies and it is also a major source of straw for animal feeding (Sharma et al., 2012).

Drought is one of the critical environmental adversities affecting the growth, development and final yield of crop species (Geng et al., 2016; Daryanto et al., 2017), and the frequency and severity of drought stress events are expecting to increase due to global climate change (Cook et al., 2014; Zhao and Dai, 2015; Joshi et al., 2016). Drought stress perturbs a broad range of plant physiological and biochemical processes, including decreased plant water status, inhibited photosynthetic processes, induced oxidative stress damage and so on, which ultimately lead to growth retardation and the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37833803

reduction of crop yield (Perdomo et al., 2015; Saeidi and Abdoli, 2015; Daryanto et al., 2017). Drought stress is one of the major problems in successful crop production throughout the world (Auge, 2001) as well as in Iran. Drought stress is a key environmental phenomenon affecting cereal yields, often occurs over the wheat grain filling period, and eventually reduces crop yield in most cultivated areas in the world (Altenbach et al., 2003). In Iran, a significant portion of the 2.4 million hectares of irrigated wheat is damaged due to drought stress during flowering and grain filling phases (Jalal Kamali et al., 2012).

Crop growth is reduced under drought stress conditions due to limited photosynthetic rate. The damage caused by drought is primarily attributed to the inhibition and disruption of photosynthesis, which is the main mechanism of plant growth and maintenance of natural environments, and it threats the growth and yields of plants (Shao et al., 2016). Water deficit is often complemented by high temperatures that increase evapotranspiration and affect photosynthesis and ultimately decrease yield (Mir et al., 2012). Water deficit affects photosynthesis negatively by changing inner structure of the chloroplast, mitochondria and chlorophyll content and minerals (Huseynova et al., 2016). Allahverdiyev and Huseynova (2017) reported that stomatal conductance, net photosynthesic rate and transpiration rate decreased significantly in flag leaves of wheat genotypes in response to drought stress at anthesis. The intercellular CO_2 concentration in flag leaf of most genotypes increased under drought condition. Mild drought stress reduces photosynthesis through reversible stomatal factors. Under more severe or prolonged stress conditions, non-stomatal factors aggravate unfavorable conditions and the effects of stress generally become irreversible (Ahmadi and Baker, 2000). Blum et al. (1981) suggested that those genotypes are suitable for dry regions that are capable of retaining more water without closing their stomata.

Since crops production and, therefore, food security depend on the management of limiting factors, it is necessary to develop efficient strategies that allow the improvement of crop yield under water deficit stress (FAO, 2012). Water is undisputedly the major factor for the declining food production in many parts of the world, particularly in the arid and semiarid regions. Consequently, the world is now being challenged to produce “more crop per drop” of water. Therefore, in recent years there are increasing numbers of studies to understand the mechanism by which plants alleviate drought stress, and arbuscular mycorrhizal (AM) fungi seems to be an excellent alternative to serve the purpose. However, the mechanism by which AM fungi promotes drought tolerance is still to be understood well (Dar et al., 2018). Recently, it has been observed that the symbiotic interaction of plants with AMF, in addition to being important from the agricultural and ecological point of view (Yang et al., 2008), could be a sustainable mitigation practice for water deficit stress (Aroca, 2012). AM fungi allow host plants to grow more efficiently under biotic and abiotic stress conditions (Gholamhoseini et al., 2013). A recent finding indicates that AM fungus have a key role in modifications of root hairs consequently helping the plants to overcome the drought (Li et al., 2014). In association with symbiotic AM fungi, plants could explore larger volumes of soil to absorb water and nutrients thereby impart stress tolerance to the plants (Smith et al., 2009). Arbuscular mycorrhizal (AM) symbiosis often modifies gas exchange of the host plant (Koide, 1993; Smith and Read, 2008; Ruiz-Lozano and Aroca, 2010; Auge et al., 2014). Mycorrhizal association has been shown to increase the carbon fixation abilities of the plants. In a number of systems, higher photosynthetic rates have been reported when the plants are in association with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37833803

AM fungi. For instance, in black locust, Yang et al. (2014) observed high stomatal conductance, high transpiration rates and high photosynthetic rates with reduced internal CO_2 concentration in fungal colonized plants than the non-colonized plants. Such higher photosynthetic rate as a consequence of fungal association has also been reported by Zhu et al. (2012). They observed high photosynthetic and transpiration rates in AM fungi colonized plants of maize than in non-colonized plants both under control and drought stress conditions. Arbuscular mycorrhiza stimulation of carbon exchange rate, stomatal conductance, and transpiration rate has been significantly associated with mycorrhizal stimulation of shoot dry weight, leaf phosphorus, leaf nitrogen:phosphorus ratio, and percent root colonization. (Auge et al., 2016). This relationship between the stomatal opening and the relative increase in the photosynthetic activity have been described in corn (Estrada et al., 2013),

Studies over recent years revealed that growth and yield of C_3 plants improved by methanol spraying, and methanol can be considered a carbon source for such plants. In general, the main contribution of these substances is to reduce the effects that stresses induced on crops have in performing photorespiration (Downie et al., 2004). Since nearly 90% of plant dry matter results from carbon dioxide assimilation through photosynthesis, an increase in photosynthesis rate can boost the crop production capacity (Makhdum et al., 2002). Methanol is a carbon source therefore increases CO_2 concentrations in plants and enhances growth and yield because the most important factor that affects dry weight of plants is CO_2 assimilation through photosynthesis (Mirakhori et al., 2009). Higher photosynthetic capacity can be achieved by using compounds including methanol, ethanol, propanol, and butanol as well as amino acids including glycine, glutamate and aspartate (Ramberg et al., 2002). In plants facing drought stress, methanol spraying prevents reduction of biomass (Rajala et al., 1998).

This study attempted to determine the effect of end season drought stress on yield and on photosynthesis and leaf gas exchange in three wheat cultivars so as to identify cultivars that are susceptible or tolerant to end season drought stress. Moreover, this study intended to analyze and clarify the effect of mycorrhiza inoculation and methanol spraying on wheat yield and leaf gas exchanges in an effort to mitigate and moderate the adverse effects of drought stress.

Materials and methods

Experimental site and treatments

A two-year experiment was carried out with split-plot factorial arrangement based on randomized complete block design in three replications in Khorramabad (33°20′N 48°21′E, altitude = 1171 m), Iran, during 2012-2014. The main factor included end season drought stress at three levels (normal irrigation, mild stress and severe stress with irrigation based on 40%, 60% and 80% moisture depletion of soil water available to plants) and factorial combination of mycorrhizal inoculation and methanol spraying (non-inoculation + non-praying as control; mycorrhizal inoculation; methanol spraying; mycorrhizal inoculation + methanol spraying) with wheat cultivars of Aflak, Dena and Alvand considered as sub factors. The climatic parameters (annual and long-term) of the experimental site are presented in *Table 1* during cropping years 2012-2013 and 2013-2014.

Two bread wheat (*Triticum aestivum* L.) cultivars of Aflak and Alvand are spring and intermediate types, respectively, and Dena, as durum wheat (*T. durum* L.) cultivar, has a spring growth habit (Saeidi et al., 2005). The studied cultivars have been introduced by the Agricultural Research, Education and Extension Organization (AREEO) in the past few years, and are cultivated in temperate, tropical and subtropical regions of Iran. The mycorrhiza bio-fertilizer was a combination of two mycorrhiza fungi species called *Funnelifomis mosseae* and *Rhizophagus intaradices* and contained 15 spores g^{-1} and 930 hyphae of mycorrhiza cm^{-3}. Before sowing, Mycorrhiza (40 kg ha^{-1}) was poured uniformly into the sowing lines at the depth of 6-7 cm. Sowing density was 450 seeds m^{-2}. Each sub-plot consisted of 6 sowing lines with a spacing of 20 cm. The area of each plot was 7.2 m^2.

Prior to sowing, the soil was sampled to determine its physical and chemical characteristics (*Table 2*). Based on the soil analysis results, the chemical fertilizers of urea, triple super phosphate and potassium chloride were applied at 200, 100 and 50 kg ha^{-1}, respectively. Given the conventional practices in the region and the amount of regional rainfall, irrigation operations were carried out if necessary in all the experimental plots uniformly prior to beginning stage of stress treatments. At the wheat spike emergence phase, the normal irrigation and stress treatments were applied. Irrigation in normal irrigation and stress treatments were based on moisture depletion of soil in the range of field capacity to permanent wilting point. Soil moisture depletion percentage was measured by a Time Domain Reflectometer (TDR), which determines the volumetric percentage of soil moisture at the desired depth. Irrigation water volume for normal irrigation, mild stress and severe stress was 185, 132.5 and 80 mm, respectively in cropping year 2012-2013, and this amount was 147.5, 90 and 42.5 mm, respectively in cropping year 2013-2014. Industrial methanol (98%) at the concentration of 20% v/v was sprayed at spike emergence three times at 10-days intervals. Moreover, to each liter of the methanol solution, 1 g of the amino acid glycine and 1 mg of tetrahydrofolate were added.

Table 2. *Soil physical and chemical characteristics at the experimental site*

Leaf gas exchange measurement

The photosynthesis and leaf gas exchange measurements on the field were made by using a portable gas analyzer (ADC, Hoddeston UK, model LCA4) to measure the photosynthesis rate per leaf area unit (μmol CO_2 m^{-2} s^{-1}), stomatal conductance (mmol m^{-2} s^{-1}), transpiration rate (mmol H_2O m^{-2} s^{-1}) and internal CO_2 concentration (mmol). Measurements were conducted at 11 AM, at 26-27 °C and at the light intensity of 1100-1200 micromole photon m^{-2} s^{-1}. From each plot, five plants were randomly selected. Then, the flag leaves of the selected plants were placed inside a glass container of LCA-4 for 40 s and the related value was read and recorded (*Fig. 1*). Grain yield was measured at full maturity in the harvesting area of 3 m^2 from the middle four rows of each plot. Then, the seeds were weighed for grain yield calculation.

Data analysis

Combined analysis of the data obtained from two experimental years was performed using the expected value of mean square treatment. Moreover, the variance tests were also performed based on expected value of variance for the sources of variations. ANOVA operations and statistical calculations, comparison of the means, and calculation of simple correlation coefficients of traits were carried out using SAS, SPSS and MSTATC. The diagrams were drawn using Excel, and comparison of the means of the traits was performed employing Duncan's multiple range test (DMRT) at the 5% probability level.

Results

Leaf gas exchange

Effect of year on stomatal conductance, leaf transpiration, internal CO_2 concentration and photosynthetic rate was significant (*Table 3*). Stomatal conductance and photosynthetic rate in the second year improved and leaf transpiration and internal CO_2 concentration were higher in the first year than in the second year (*Table 4*) which could be due to variations in climatic conditions among experimental years.

ns, *, and ** are non-significant, significant at 5% and 1% probability levels, respectively.

Effect of water deficit stress on leaf gas exchange was significant (*Table 3*). Mild and severe water deficit stress decreased leaf stomatal conductance by 55.5% and 69.2%, leaf transpiration by 18.6% and 45.1% and photosynthetic rate by 15.6% and 69.2%, respectively, compared to the normal irrigation. Mild stress resulted in 26.6% decrease in internal CO_2 concentration while severe stress resulted in 26.9% increase in internal CO_2 concentration, compared to the normal irrigation (*Table 4*).

Increasing depletion of plant available water under normal irrigation to 60% and 80% of moisture depletion and increasing stress intensity, stomatal conductance and leaf transpiration decreased in all treatments and the highest decreasing observed at

80% depletion of soil available water. The highest decreasing trend was devoted to the control and the lowest was for combined treatment. Under normal irrigation, mild and severe stresses, stomatal conductance and leaf transpiration in mycorrhizal inoculation, methanol spraying and combined treatment were more than control (*Figs. 2a* and *3a*).

By increasing the depletion of soil available water content internal CO_2 concentration decreased in all treatments, so that it was at the lowest level under mild stress condition (60% soil moisture depletion). But this decrease value in mycorrhizal inoculation, methanol application and combined treatment was less than control (*Fig. 4a*). By increasing the stress intensity and increasing the percentage of soil moisture depletion to values higher than 60%, the amount of carbon dioxide covered by the intestinal space gradually increased in all treatments and increased to extreme stress (80% soil moisture depletion). However, the internal CO_2 concentration in the case of mycorrhizal inoculation and methanol spraying was less than control (*Fig. 4a*). Under normal irrigation conditions, stomatal conductance of leaves in Dena cultivar was more than Aflak and Alvand cultivars (*Fig. 2b*). Leaf transpiration rate in Aflak cultivar was more than Alvand cultivar, while transpiration rate in Dena and Alvand cultivars and Aflak and Dena cultivars showed no significant difference (*Fig. 3b*). Internal CO_2 concentration under normal irrigation showed no significant difference. Under mild and

DOI: http://dx.doi.org/10.15666/aeer/1604_37833803

severe stress conditions, stomatal conductance in Aflak and Dena cultivars was more than in Alvand cultivar (*Fig. 2b*). Under severe stress conditions, internal CO_2 concentration increased for all cultivars compared to normal irrigation, but CO_2 concentration in Aflak and Dena cultivars was less than in Alvand cultivar (*Fig. 4b*).

Under mild stress conditions, transpiration in Aflak and Dena cultivars was more than in Alvand. Under severe stress, there was no significant difference among three cultivars and Dena and Alvand cultivars had the highest and the lowest transpiration rate, respectively (*Fig. 3b*). Mild stress decreased internal CO_2 concentration for three studied cultivars compared to normal irrigation. However, decreasing value in Aflak and Dena cultivars was less than in Alvand which could be attributed to higher drought resistance of cultivars. Severe stress resulted in increasing CO_2 (*Fig. 4b*).

Photosynthetic rate

Increasing depletion of plant available water under normal irrigation up to 60% and 80% and increasing stress level resulted in the decrease of photosynthestic rate in all treatments which the highest decrease observed in 80% moisture depletion. The highest deceasing trend devoted to control and the lowest was for methanol+mycorrhiza application. At all irrigation levels, photosynthetic rate in mycorrhizal inoculation, methanol spraying and combined application treatment was more than in the control (*Fig. 5a*).

According to our results, effect of water deficit stress on stomatal conductance was significant (*Table 3*). Mild and severe water deficit stresses resulted in the decrease of stomatal conductance compared to normal irrigation (*Table 4*); therefore, one of the effective factors on declining photosynthetic rate in the current study could be stated as decrease in stomatal conductance at both mild and severe stress conditions. The positive and significant correlation between photosynthesis and stomatal conductance (*Table 5*) confirms that decrease in stomatal conductance causes decrease in photosynthetic rate.

Increasing depletion of plant available water under normal irrigation up to 60% and 80% and increasing stress level resulted in the decrease of photosynthetic rate and the

highest decrease was at 80% moisture depletion (severe stress), however decrease in Aflak and Dena cultivars was less than in Alvand. The highest decreasing trend was observed in Alvand and the lowest in Dena (*Fig. 5b*).

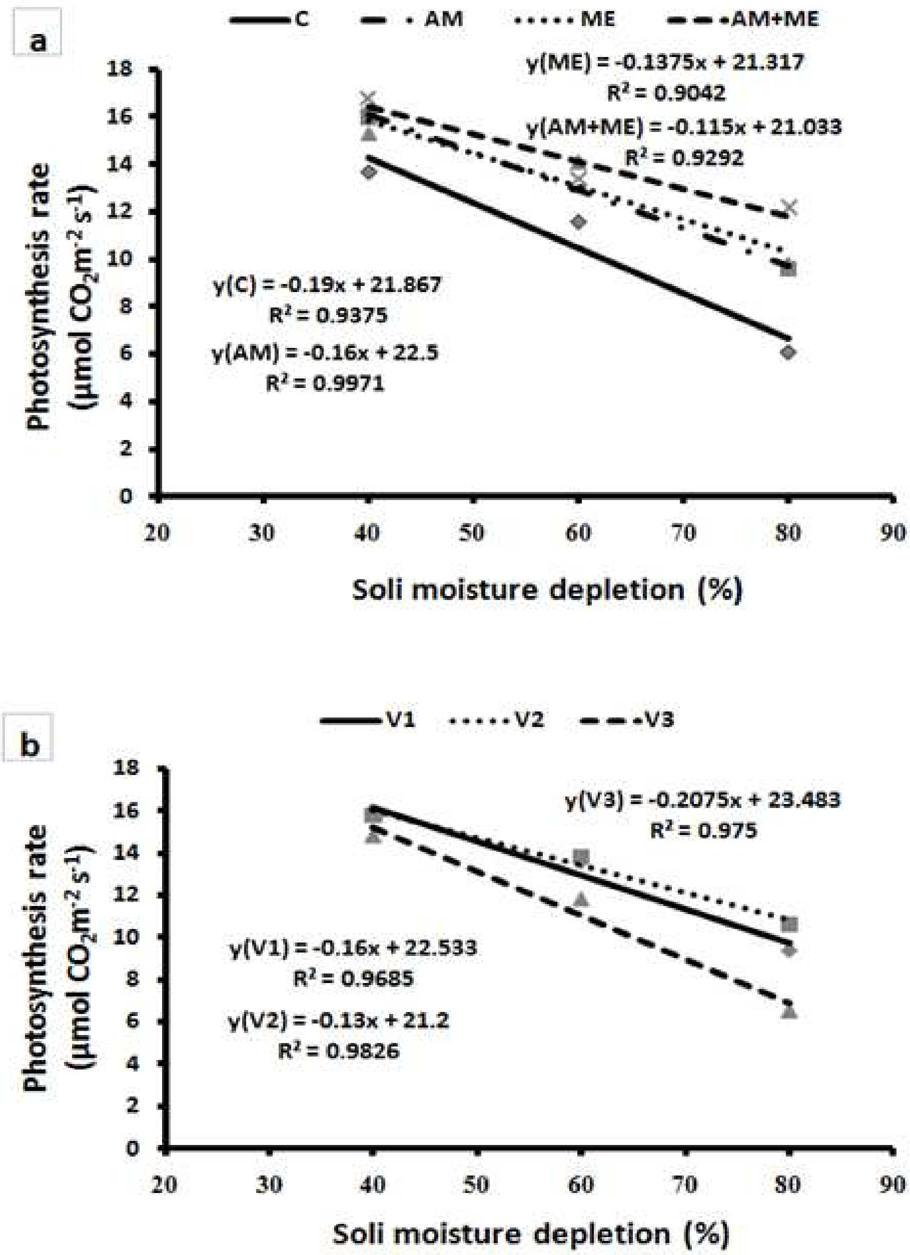

Figure 5. *Regression curve for interaction of irrigation levels × mycorrhiza- methanol (a), irrigation levels × cultivar (b) on leaf photosynthetic rate. (C: control, AM: mycorrhiza inoculation, ME: methanol spraying, V1: Aflak, V2: Dena, V3: Alvand)*

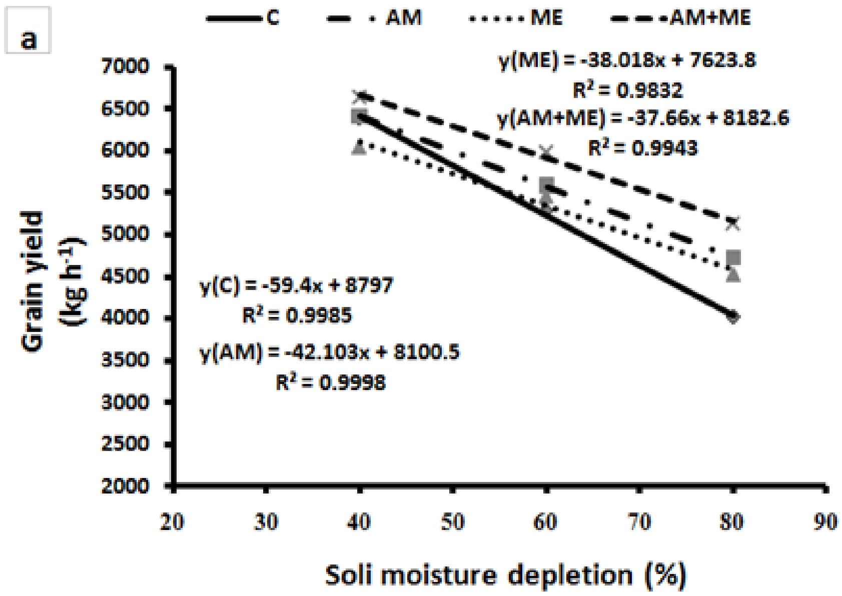
Grain yield

Interaction of water deficit stress×mycorrhiza-methanol and water deficit stress×cultivar on grain yield were significant (*Table 3*). Grain yield under mild and severe stress conditions decreased by 12.6% and 30% compared to normal irrigation,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37833803

respectively (*Table 4*). Increasing depletion of plant available water under normal irrigation up to 60% and 80% and increasing stress level resulted in yield reduction for all studied treatments and highest decrease was at 80% moisture depletion. The greatest decreasing trend observed in control and the lowest in combined treatment application. At all irrigation levels grain yield in mycorrhizal inoculation, methanol spraying and combined treatment was more than in the control (*Fig. 6a*).



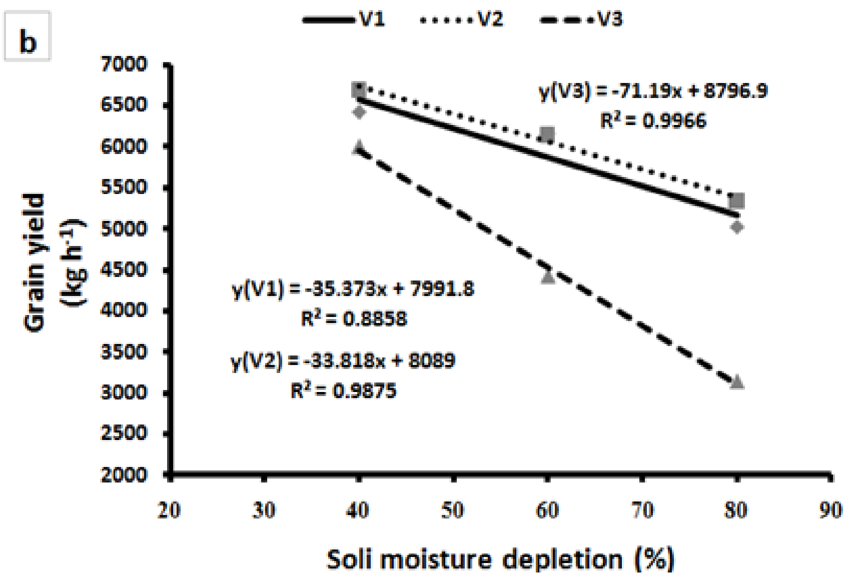


Figure 6. *Regression curve for interaction of irrigation levels × mycorrhiza- methanol (a), irrigation levels × cultivar (b) on leaf photosynthetic rate. (C: control, AM: mycorrhiza inoculation, ME: methanol spraying, V1: Aflak, V2: Dena, V3: Alvand)*

Increasing depletion of plant available water under normal irrigation up to 60% and 80% and increasing stress intensity resulted in the decrease of grain yield and the

highest decrease was at 80% moisture depletion; however, decrease in Aflak and Dena cultivars were less than in Alvand. The highest decreasing trend was in Alvand cultivar and the lowest in Dena cultivar (*Fig. 6b*).

Mean comparisons showed that in control treatment, all studied cultivars had significant difference in terms of grain yield and the highest and the lowest yield associated to Dena and Alvand, respectively. Aflak and Dena cultivars reacted well to mycorrhizal inoculation, so that their yield increased by 12.8% and 7% compared to control, while there was no significant difference in yield of Alvand between control and mycorrhizal inoculation treatments. Studied cultivars had different response to methanol application. Aflak and Dena had no significant difference in terms of grain yield in methanol spraying, but Aflak showed 7.1% increase compared to the control (*Fig. 7*).

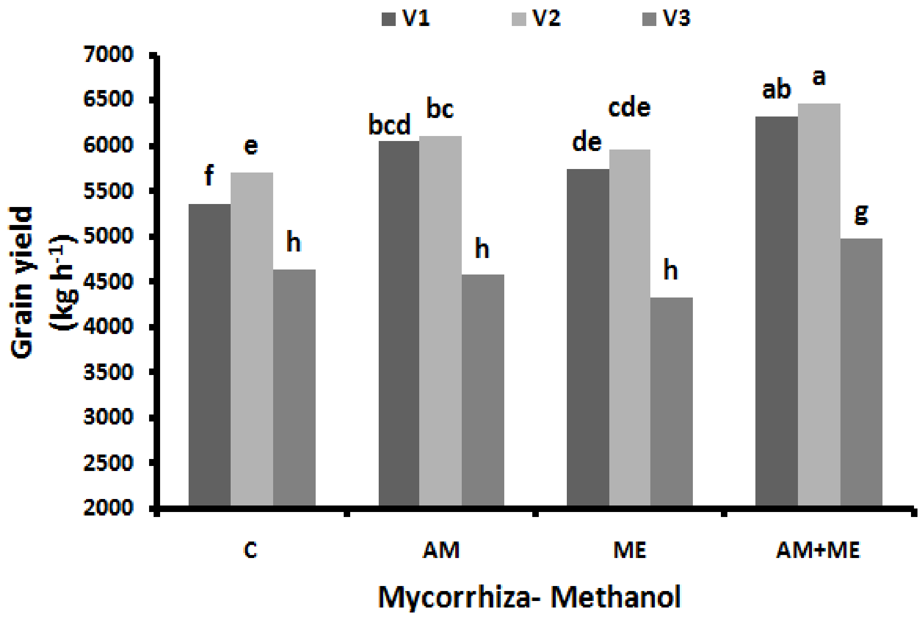

Figure 7. *Mean comparisons for interaction of mycorrhiza- methanol × cultivar on grain yield (e). Discussion

Leaf gas exchange

Siddique et al. (1999) found that wheat plants under drought stress conditions had considerable decrease in photosynthetic rate and stomatal conductance. Allahverdiyev and Huseynova (2017) report stomatal conductance, net photosynthetic rate and transpiration rate decreased significantly in flag leaves of wheat genotypes in response to drought stress at anthesis. Possibly increase in stomatal conductance in methanol spraying under water deficit conditions could be attributed to methanol contribution in enhancing stomata cells turgor and decrease in stomata closure. Nonomura and Benson (1992) concluded that methanol spraying in plant aerial parts increased plant turgor and prevented leaves subjected to direct sunlight from wilting, especially in hot regions. Zheng et al. (2008) reported that methanol spraying caused an increase in stomatal

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37833803

conductance and wheat plant photosynthesis. In a study conducted on cotton plants in Pakistan dry areas, methanol spraying resulted in the increase of stomatal conductance in treated plants (Makhdum et al., 2002). Zheng et al. (2008) found that methanol spraying increased wheat plant transpiration. Mycorrhizal symbiosis caused to delay in declining water content in leaves during drought stress and therefore stomata could be open for a longer period (Simpson and Duff, 1990). In another study on bean plants conducted by Zlatov and Yordanov (2004) resulted that intracellular CO_2 concentration decreases under drought stress conditions, which closes the leaf stomata and prevents the entry of CO_2 into the leaves. Arbuscular mycorrhiza stimulation of carbon exchange rate, stomatal conductance, and transpiration rate has been significant (Auge et al., 2016). Arbuscular mycorrhizal (AM) symbiosis often modifies gas exchange of the host plant (Koide, 1993; Smith and Read, 2008; Ruiz-Lozano and Aroca, 2010; Auge et al., 2014).

It was found that higher drought stress resistance in wheat cultivars is associated to higher stomatal conductance and partially to mesophilic conductance (Siosehmardeh et al., 2004). Difference in transpiration rate could be due to difference in sensitivity and tolerance rate of these cultivars to drought stress and stomatal reactions to water deficiency. Aflak and Dena cultivars kept their stomata less closed due to drought stress tolerance and had higher stomatal conductance and consequently had greater transpiration. Resistant wheat genotypes to drought having higher transpiration rate under drought stress conditions are able to uptake more water from soil and have higher leaf water content. Consequently, these genotypes have higher stomatal conductance and transpiration rate in comparison with drought sensitive cultivars. Roohi and Siosemardeh (2008) reported that leaf stomatal conductance and transpiration in resistant wheat genotypes was higher than in sensitive genotypes under water deficit conditions by 27% and 24%, respectively. The intercellular CO_2 concentration in flag leaf of most genotypes increased under drought condition (Allahverdiyev and Huseynova, 2017). It appears that Aflak and Dena had stomata openness ability due to drought stress resistance and therefore decrease in internal CO_2 concentration under mild stress condition was lower than in Alvand which had lower drought stress resistance. Also, these cultivars had lower destructive impact of severe stress conditions on biochemical processes and owing to higher mesophilic conductance, internal CO_2 concentration was lower than in Alvand. Mild drought stress reduces photosynthesis through reversible stomatal factors. Under more severe or prolonged stress conditions, non-stomatal factors aggravate unfavorable conditions and the effects of stress generally become irreversible (Ahmadi and Baker, 2000). Decrease in photosynthesis under higher drought levels is due to destructive biochemical processes (Johnston and Fowler, 2002). Photosynthesis limiting factors divided into stomatal factors which cause decrease in CO_2 diffusion into intercellular space due to decrease in stomatal conductance and non-stomatal factors which limit photosynthetic rate through direct impact of water deficit on carbon processing biochemical processes (Ahmadi and Baker, 2000).

Photosynthetic rate

The damage caused by drought to plants is primarily attributed to the inhibition and disruption of photosynthesis, which is the main mechanism of plant growth and maintenance of natural environments, and it threats to the growth and yields of plants (Shao et al., 2016). Siddique et al. (1999) concluded that wheat plants under drought stress had considerable decrease in stomatal conductance and photosynthetic rate. It appears that methanol foliar application resulted in the increase of CO_2 concentration in leaf cells and largely compensated CO_2 deficit and prevented further decrease in photosynthesis under drought stress conditions. Methanol, in comparison with CO_2, is a smaller molecule which could be easily utilized by C_3 plants for increasing photosynthetic rate (Li et al., 1995; Kotzabasis et al., 1999). Increase in photosynthetic rate through methanol foliar application has been reported by many authors (Setua et al., 2009; David et al., 2003). Zheng et al. (2008) studied the effect of methanol foliar application at various concentrations on winter wheat and reported that methanol increased stomata conductance, transpiration rate, internal CO_2 concentration and photosynthesis rate. It appears that methanol impact on C_3 plants is due to decrease in their photorespiration, because under filed conditions when air temperature, light intensity and consequently photorespiration were high, methanol foliar application increased plant growth (Nonomura and Benson, 1992; Fall and Benson, 1996). Photosynthesis rate in mycorrhizal plants was more than non-mycorrhizal plants which could be resulted from the effect of mycorrhiza on stomata opening. It is known that plants subjected to water deficit stress decrease photosynthesis because of an accumulation of ROS that damages the photosynthetic apparatus (Abbaspour et al., 2012), which can limit the NADPH and ATP supply of the Calvin cycle. As a consequence of AMF symbiosis, plants improve the water status, which increases photosynthesis by increasing stomatal conductance and, therefore, CO_2 fixation (Boldt et al., 2011). Relationship between the stomatal opening and the relative increase in the photosynthetic activity have been described in corn (Estrada et al., 2013). Mycorrhizal association has been shown to increase the carbon fixation abilities of the plants. In a number of systems, higher photosynthetic rates have been reported when the plants are in association with AM fungi. For instance, in black locust, Yang et al. (2014) observed high stomatal conductance, high transpiration rates and high photosynthetic rates with reduced internal CO2 concentration in fungal colonized plants than the non-colonized plants.

Grain yield

Drought is one of the critical environmental adversities affecting the growth, development and final yield of crop species (Geng et al., 2016; Daryanto et al., 2017), and the frequency and severity of drought stress events are expecting to increase due to global climate change (Cook et al., 2014; Zhao and Dai, 2015; Joshi et al., 2016). Drought stress perturbs a broad range of plant physiological and biochemical processes, including decreased plant water status, inhibited photosynthetic processes, induced oxidative stress damage and so on, which ultimately lead to growth retardation and the reduction of crop yield (Perdomo et al., 2015; Saeidi and Abdoli, 2015; Daryanto et al., 2017). It can be inferred that mycorrhizal inoculation and methanol application under mild and severe drought stress conditions inhibited from decrease in grain yield and lead to decreased and mediated damages due to water deficit stress in wheat crop. Under water stress conditions, mycorrhizal inoculated wheat plants produced better yield than control. It can be concluded that under moisture stress, mycorrhiza had effective contribution and increased water and nutrient uptake from soil through developing hypha and fungi mycelium and prevented from decrease in growth and grain yield under drought stress conditions. Mycorrhiza treatment improved all of wheat growth traits and drought resistance (Abo-ghalia and Khalafallah., 2008). Mycorrhiza fungi establish

DOI: http://dx.doi.org/10.15666/aeer/1604_37833803

symbiotic association with roots of many plants cause increase in nutrient and water uptake, alleviating negative impacts of environmental stresses and improvement in plant growth and yield in sustainable agriculture systems (Sharma, 2002). Al-Karaki et al. (2004) concluded that under normal irrigation and drought stress conditions, mycorrhiza improved wheat grain yield and biomass and had great contribution in alleviating impacts of drought stress in field conditions. Some authors reported that methanol foliar application had no significant difference on most of studied traits in wheat (Milton et al., 1995; Ekiz et al., 1996). Contrarily, some authors reported that methanol spraying improved wheat growth and yield (Nonomura and Benson, 1992; Zheng et al., 2008). Other studies have shown that methanol application in crop plants under water deficit increased their biomass, while treating water-supplied plants with methanol, decreased their biomass (Nonomura and Benson, 1992; Ramirez et al., 2006).

Results of the present study revealed positive and significant correlation among grain yield with photosynthetic rate (r = 0.84), stomatal conductance (r = 0.86) and transpiration rate (r = 85) (*Table 5*). Grain yield under moisture stress decreased photosynthetic rate and stomatal conductance increased, while in mycorrhizal inoculation, methanol spraying and combined treatments, grain yield decreased less compared to control due to higher photosynthetic rate and stomatal conductance (*Figs. 6a, 1a* and *5a*).

Table 5. *Correlation of grain yield with photosynthetic rate and leaf gas exchanges under mild and severe water deficit stress conditions*

ns, *, and ** are non-significant, significant at 5% and 1% probability levels, respectively.

Under mild and severe stress conditions, yield for all studied cultivars decreased compared to normal irrigation, but decreasing value in Alvand (26.1% and 42.5%, respectively) was more than in Aflak (4.2% and 22% respectively) and in Dena (8.1% and 20.2%, respectively) cultivars (*Table 4*), which could be due to the fact that Alvand is a late maturing cultivar and the observed decrease represents more sensitivity of Alvand to late season water deficit stress. Karimzadeh Shurshjani et al. (2012) reported that Durum wheat cultivars, being early mature had less yield decrease compared to bread wheat cultivars under late season drought and yield decrease was higher in drought sensitive cultivars. Other authors have reported significant reductions in wheat yield due to late season drought stress (Dastfal et al., 2009; Gonzalez et al., 2010). The reason for decreasing grain yield for Alvand cultivar compared two other ones is that stomatal conductance, leaf tranpiration and photosynthetic rate decreased more under mild and severe drought stress conditions (*Figs. 1b, 2b* and *5b*). These results show that Alvand cultivar is more vulnerable to late season drought stress than other cultivars. Siosemardeh et al. (2005) found that decrease in stomatal conductance and mesophyll conductance and consequently decrease in photosynthetic rate are the main factors

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_37833803

affecting yield of various wheat cultivars under drought stress conditions and resistant cultivars have higher stomatal conductance and mesophyll conductance as well as photosynthetic rate than sensitive cultivars.

Ekiz et al. (1996) understood that yield of irrigated wheat cultivars had no significant difference in methanol spraying treatments. In combined treatments, there was no significant difference between Aflak and Dena, while Alvand had lower yield than other two cultivars. Yield of cultivars studied increased compared to control in combined treatment. Results of other studies represent various responses of wheat cultivars to mycorrhizal inoculation (Vierheilig and Ocampo, 1991).

Conclusion

According to the results obtained, it can be concluded that late season drought stress caused decrease in stomatal conductance, leaf transpiration, photosynthetic rate and increase in internal CO_2 concentration and consequently decreased grain yield of wheat, while mycorrhizal inoculation and methanol spraying alleviated negative impacts of water stress and improved photosynthetic rate and leaf gas exchanges compared to control under drought stress conditions and consequently increased grain yield. Also, the differential response of cultivars to imposed water stress condition indicates the drought tolerance ability of wheat cultivars. Results showed that cultivar and vulnerability rate and their tolerance are effective in wheat response to late season drought stress. Decrease in photosynthetic rate, gas exchanges and yield in Alvand cultivar under mild and severe drought stress was more than in Aflak and Dena cultivars; that represent sensitivity of Alvand cultivar to late season drought stress conditions. In total, it can be concluded that use of drought-tolerant wheat cultivars cause decrease in destructive impacts of terminal season drought stress. Also, mycorrhizal application and methanol spraying improve photosynthesis, leaf gas exchanges and grain yield and could be considered as cropping management strategies for decreasing damages of late season drought stress in irrigated wheat crop systems. In the future studies, it is recommended for evaluation of effect of milder levels of water deficit stress on the growth and yield of wheat, because severe stress have a lot of negative impact on leaf gas exchange and growth, and the sharp decline in wheat yield.

Abstract. This paper deals with cobalt and arsenic accumulation in above-ground parts of herbs growing in intermittent field ponds with no outlets in Poland. Those ponds were located in different surroundings. In the experiment described here the following herbs were analysed: *Potentilla anserina* L., *Mentha arvensis*, *Achillea millefolium* L., *Comarum palustre* L., *Lysimachia vulgaris* L. and *Lycopus europaeus* L. Both plant and soil samples were collected from three moisture sections: wet, periodically wet and dry. Cobalt and arsenic content in plants and soil was determined with inductively coupled plasma-atomic emission spectrometry, or the ICP–AES method, after dry mineralization of the material. Cobalt and arsenic content was significantly dependent on the herb species. The highest content of cobalt was found in *Mentha arvensis*, and arsenic in *Lysimachia vulgaris* L. and *Comarum palustre* L., with *Achillea millefolium* having the lowest content of arsenic. The highest content of those metals was in the bottom sediment and in the soil from the depression with arable land around. Arsenic had a higher accumulation coefficient in herbs than cobalt. Cobalt content in herb biomass did not exceed the limits, but in the case of arsenic it was too high in all herbs apart from *Achillea millefolium* L.
Keywords: *selected heavy metals, plants, soil, in-field ponds*

Introduction

Arsenic and cobalt belong to elements very common in the environment, and in higher levels they are poisonous to humans and animals (Bowell, 1994; Hamilton, 1994; Kabata-Pendias and Pendias, 1999). Arsenic compounds are used as herbicides and defoliants in agriculture and forestry mainly. The amount of arsenic in soil depends on its content in parent rock, the type of soil formation and on anthropogenic factors. Anthropogenic pollution is mainly of industrial origin but there are other sources like using communal and industrial waste or plant protecting products in agriculture (Krysiak and Karczewska, 2007). In soil, arsenic is adsorbed by iron oxides, mainly by iron hydroxides of different degrees of crystallisation (Bowell, 1994; Voigt et al., 1996; Wenzel et al., 2001). Because of that this metal is not very mobile and not easily available to plants. A change of soil pH or soil aeration can cause a partial destruction of iron oxides, and adsorbed arsenic is released (Masscheleyn et al., 1991; Marin et al., 1993).

Gál et al. (2008) indicate that there are different kinds of cobalt ions in soil depending on soil pH, which, together with reduction potential, determines bioavailability of the metal. Suttle et al. (2003) and Bakkaus et al. (2008) provide

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38053814

different degrees of cobalt bioavailability, from 3 to 13% and from 1.5 to 37%, respectively. In agricultural areas free from industrial pollution, cobalt can get into the soil together with phosphorus fertilisers.

Of course, its presence, like presence of other heavy metals in the soil-plant environment, can be harmful to people and animals. Plants growing in natural habitats, even if not directly exposed to pollution, can contain amounts of heavy metals which are too high (Ražic et al., 2008; Malinowska and Jankowski, 2016, 2017; Bolan et al., 2017).

The aim of the experiment was to determine cobalt and arsenic content in herbs used in the pharmaceutical, cosmetic and food industries. They were sampled from different moisture sections of three in-field ponds.

Materials and methods

The plant material was sampled in 2014, from mid June till the end of July. Six herb species growing in the areas of three field ponds on the Siedlce Plateau were sampled: *Potentilla anserina* L., *Mentha arvensis*, *Achillea millefolium* L., *Comarum palustre* L., *Lysimachia vulgaris* L., *Lycopus europaeus* L. Three experimental areas with three ponds were marked with capital letters: A, B and C (*Fig. 1).*

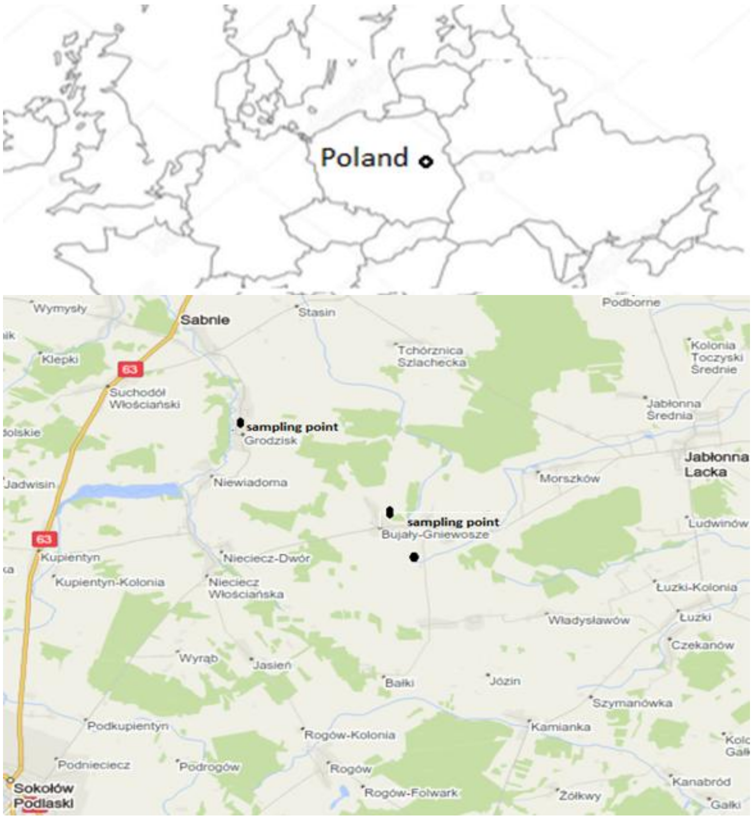

***Figure 1.** A map of the sampling site in an urban area, Poland*

Pond A was surrounded by arable land, B by permanent grassland and pond C was overgrown with bushes, with cultivated fields 100 m away from it. What decided about the choice of the ponds was the fact that they were surrounded by fields, but also the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38053814

diversity of vegetation and the pond sizes, ranging from 15000 m^2 to 850 m^2. According to the administrative division they were located in the Sokołów Podlaski County, the eastern part of the Mazovian Voivodeship, with luvisols and rusty soil mostly. Each experimental area was divided into three transects, with the length varying from 18 to 80 m, stretching from the edge of the pond to the edge of the field. Around each pond in every transect three concentric moisture sections were marked: I – wet, with water stagnating in early spring after snow has melted or after heavy rainfall; II – periodically wet, with water stagnating only in early spring after snow has melted; III – dry, without any water stagnating there (Franczak and Franczak, 2015). The number of plant and soil samples taken from the transects varied from 85 to 100 in each experimental area. Additionally, bottom sediment samples were taken from each pond. 5-7 plants of each species were collected from each transect.

Plant material (from above-ground parts, without roots) was ground to particles of 0.25 mm in diameter, and 1 g of it was weighed and put into a porcelain crucible. Then the crucible was placed in a muffle furnace for 15 h to oxidise organic matter at the temperature of 450 °C. Next 10 ml of hydrochloric acid solution (1:1) was added and the mixture was put into a sand bath to evaporate, to decompose carbonates and to remove silica. After adding 5 ml of 10% hydrochloric acid solution, the contents of the crucible were filtered through a hard filter into a 100 ml volumetric flask and water was added up to the mark. Cobalt and arsenic concentration was determined using Inductively Coupled Plasma Atomic Emission Spectrometry (ICP-AES). An internal quality control procedure was used to verify the accuracy of the methods. It was assumed that the average recovery for each spike concentration should be between 85 and 115% of true value. Two measurements were taken for each series of samples with the recovery being within the 85÷115% range. The limit of detection for arsenic and cobalt was 0.01 $mg \cdot kg^{-1}$. Soil pH, the value of which ranged from 5.45 to 6.50, was measured with the potentiometric method.

All of the data were statistically analysed and differences between means were assessed using analysis of variance (The Statistica programme, Version 10.0 StatSoft, was applied). Tukey's test was used to determine $LSD_{0.05}$ for means that were significantly different (StatSoft, Inc. 2011). The intensity of cobalt and arsenic accumulation by the herbs was determined with the accumulation coefficient (AC).

$$AC = c_p / c_s$$

where c_p is the metal content in the plant and c_s is the metal content in the soil (Wesołowski and Radecka, 2003). The results were interpreted as follows:
AC < 0.01 - no accumulation;
AC < 0.1 - slight accumulation;
AC - 1 - medium accumulation;
AC > 1 - high accumulation.

Additionally, the correlation coefficient between the content of each metal in the soil and the same content in the plants was calculated.

Results and discussion

Cobalt concentration in the biomass of herbs used in the experiment significantly varied, depending on the plant species and on the moisture section, and ranged from

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38053814

0.011 to 0.931 mg·kg^{-1} DM (*Table 1*). There was no significant variation in this concentration between moisture sections in the area with arable land. Out of all experimental areas and all moisture sections the highest average concentration of this metal was in *Mentha arvensis* (0.600 mg·kg^{-1}), and the lowest, over 16 times lower, in *Achillea millefolium* L. (0.037 mg·kg^{-1}). The average cobalt concentration in herbs sampled from different moisture sections was the highest in the periodically wet sections (0.261 mg·kg^{-1}), while the lowest was in the dry sections (0.189 mg·kg^{-1}).

A - area with the cultivated field; B - area with permanent grasslands; C - area with bushes; I - wet section; II - periodically wet section; III - dry section; n.s. - not significant difference

Among different experimental areas, the highest average concentration of cobalt was in herbs growing around the pond with permanent grasslands (0.271 mg·kg^{-1}), while the lowest was in herbs from the area with bushes (0.172 mg·kg^{-1}). Bakkaus et al. (2005) say that dicotyledonous plants can contain much more cobalt than monocotyledonous plants. Like iron, cobalt in vascular plants is transported to tissues in an active and passive way (Palit et al., 1994). Because of the similarity of the uptake process there might be an antagonistic relationship between cobalt and other metals, in particular iron and manganese. According to Kabata-Pendias and Pendias (1999) cobalt concentration in plants should range from 0.08 to 0.1 mg·kg^{-1}, while the toxic concentration of this metal varies between 30 and 40 mg·kg^{-1} DM. In the present experiment the average cobalt concentration in the plants was 0.219 mg·kg^{-1}, which is lower than the limit. Symanowicz et al. (2014) found a similar cobalt concentration in *Galega orientalis* Lam., with mineral fertilisers applied.

Arsenic concentration in the analysed herbs varied considerably depending on the plant species and the moisture section (*Table 2*). Concentration of this metal ranged from 0.301 to 1.36 mg·kg^{-1} DM. The highest concentration of arsenic was found in *Lysimachia vulgaris* L. (0.848 mg·kg^{-1}) and in *Comarum palustre* L. (0.757 mg·kg^{-1}), with the lowest in *Achillea millefolium* L. (0.448 mg·kg^{-1}). The average concentration of this metal in all the herbs was 0.645 mg·kg^{-1}. The natural barrier for the uptake of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38053814

arsenic by the above-ground parts of plants is the root system. Das et al. (2004) say that the concentration of arsenic in plant roots is ten times higher than in the above-ground parts. According to the Ministry of Health Regulation (2003) arsenic concentration in medicinal herbs and dry culinary herbs should not be higher than 0.5 mg·kg^{-1} DM. In the experiment described here, out of six analysed herbs, only *Achillea millefolium* L. had arsenic concentration below the limit. In all the other herbs the concentration was much higher that the limit set by the Regulation of 2003. Thus, in *Lysimachia vulgaris* L. the concentration was 70% higher, and in *Comarum palustre* L. it was 50% higher.

A - area with the cultivated field; B - area with permanent grasslands; C - area with bushes; I - wet section; II - periodically wet section; III - dry section

When it comes to moisture sections the highest average concentration of arsenic was in herbs from periodically wet sections (0.734 mg·kg^{-1}), it was lower in wet sections and the lowest in dry sections (0.554 mg·kg^{-1}). This diversity might have been caused by leaching of plant protection products into groundwater. The average arsenic concentration was also different in different experimental areas. The most arsenic was in plants growing around the pond with permanent grasslands and the lowest in the area with bushes, on average 0.779 mg·kg^{-1} and 0.520 mg·kg^{-1}, respectively.

Cobalt and arsenic concentration in bottom sediment of the three different ponds varied (*Table 3*). The highest concentration of cobalt (3.12 mg·kg^{-1}) and arsenic (4.38 mg·kg^{-1}) was found in the bottom sediment sampled from the pond surrounded by arable land. In the sediment from the pond with bushes the concentration was much lower, with 2.03 mg Co·kg^{-1} and 2.87 mg As·kg^{-1}. Many publications (Dhar et al., 1997; Kondo et al., 1999; Karim, 2000; Anawar et al., 2003), report that arsenic can get into groundwater and accumulate in bottom sediment. Reduction processes, taking place in permanently flooded areas, can be the main source of contamination of groundwater by arsenic in south eastern Asia, in countries like Bangladesh, India and Vietnam (Burton et al., 2008).

As	4.38	3.54	2.87	3.60

A - area with the cultivated field; B - area with permanent grasslands; C - area with bushes

The amount of cobalt and arsenic in the soil was also related to the moisture section and to the experimental area (*Table 4*). On average the highest concentration of both metals was in the soil of the depression with arable land. Out of all three moisture sections the highest concentration of cobalt and arsenic was in the wet section (1.74 mg·kg^{-1} and 2.06 mg·kg^{-1}, respectively). The amount of those metals in the soil was much lower than their amount in non-contaminated soil reported by Kabata-Pendias and Pendias (1999). The release of arsenic into the soil is a complicated process, chemical and physicochemical, but first of all it involves a biochemical reduction of the components, both solid and liquid parts (Anawar et al., 2003; Solaiman et al., 2009; Postma et al., 2010). One of the main factors affecting this process is humus content in the soil.

There was a wide range of accumulation coefficient values of the soil-plant system (*Figs. 2* and *3)*. The accumulation coefficient for arsenic was higher than for cobalt but for both heavy metals it was lower than one, on average 0.111 for cobalt and 0.353 for arsenic. When the value of accumulation coefficient is higher than one, then the accumulation of the metal in plants is high (Kloke et al., 1984). According to the above publication both cobalt and arsenic have the lowest accumulation coefficient of all heavy metals, ranging from 0.01 to 0.1. The values obtained in this experiment are within the same range. The accumulation coefficient was closely related to the herb species, with the highest value for cobalt in *Mentha arvensis*, and arsenic in *Lysimachia vulgaris* L.. *Achillea millefolium* L. had the lowest value of the accumulation coefficient both for cobalt and arsenic.

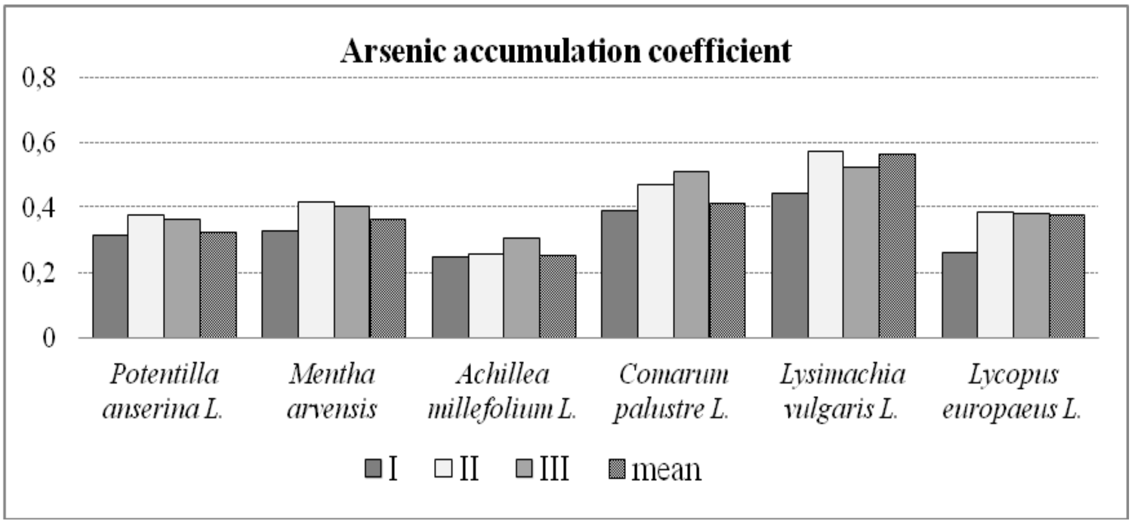

Figure 3. *Arsenic accumulation coefficient in plants growing in different experimental areas and different moisture sections. (A - area with the cultivated field; B - area with permanent grasslands; C - area with bushes; I - wet section; II - periodically wet section; III - dry section; S - species; M - moisture section)*

In plants growing in periodically wet and dry sections accumulation coefficient was much higher than in plants growing in wet sections where the concentration of both metals was the highest. There was also a relationship between cobalt and arsenic accumulation and the experimental area. The accumulation coefficient was much higher in plants from the area with permanent grassland than in the area with arable land. Accumulation of soil heavy metals by plants depends on many factors, first of all on pH but also on soil moisture and organic matter content. According to Kabata-Pendias and Pendias (1999) plants can alter chemical mobility and, at the same time, availability of metals in the rhizosphere. Additionally, the correlation coefficient between cobalt and arsenic content in the soil and in the plants was calculated but there was no significant relationship between those values (*Table 5*).

Table 5. *Correlation coefficient between cobalt and arsenic concentration in the soil and in the biomass of herbs*

Species	Co	As
Potentilla anserina L.	0.149	0.533

Conclusions

There were significant differences between cobalt and arsenic content in the biomass of different species. Out of all moisture sections and experimental areas the highest

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38053814

concentration of cobalt was in *Mentha arvensis*, for arsenic it was the highest in *Lysimachia vulgaris* L. and Comarum *palustre* L., and the lowest in *Achillea millefolium* L.

The highest content of cobalt and arsenic was found in bottom sediment and in the soil of the area with arable land, which might have been a result of plant protection products application and intensive fertilization of cereals.

In the soil-plant system the accumulation coefficient was higher for arsenic than for cobalt. For both of the metals the coefficient was lower than one, which means that the accumulation was low.

Abstract. The use of microbial consortia composed of bacteria and fungi presents higher rates of polycyclic aromatic hydrocarbon (PAH) degradation and is, therefore, essential for the remediation of contaminated soils. A microbial consortium compound comprising *Ochrobactrum intermedium* and white rot fungus *Pleurotus ostreatus* was found to be capable of degrading PAHs of crude oil in soil. This research studied the degradation capacity of a consortium composed of *O. intermedium* and *P. ostreatus* and the degradation capacity of both the bacteria and the fungus individually. The soil was artificially contaminated using two crude oil concentrations corresponding to 86,000 and 172,000 mg kg^{-1}. The concentrations of PAHs extracted from the two concentrations of crude oil were 138.16 and 268.03 mg kg^{-1}, respectively, with respective extraction resins of 78.3 and 73.5%. In total, the biodegradation of 10 PAHs were studied. Fluoranthene, indene[1,2,3-cd]pyrene and benzo[g,h,i]perylene were completely removed by the consortium after 50, 80 and 50 d of incubation, respectively. The rate at which anthracene, pyrene, chrysene and benzo[a]anthracene biodegraded in the presence of the microbial consortium were 96%, 86%, 98% and 98%, respectively, after 110 d of incubation. In this study, higher rates of degradation were obtained with the consortium than when the components were used individually, showing that consortia composed of fungi and bacteria are an efficient technology for degrading xenobiotics, as is the case with PAHs.
Keywords: *PAHs, soil microcosm, microbial consortium, biodegradation, white-rot fungi*

Introduction

The most resistant components of petroleum, polycyclic aromatic hydrocarbons (PAHs) are environmentally problematic due to their toxic, mutagenic and carcinogenic properties (Sahoo et al., 2012; Sinha et al., 2012). Low molecular weight (LMW) PAHs exhibit highly toxic characteristics and affect reproduction rates and mortality in aquatic biota, while high molecular weight (HMW) PAHs have higher mutagenic and carcinogenic effects in living beings (Boonchan et al., 2000). There are different transformation pathways for PAHs in nature, such as volatilization, adsorption, photooxidation, chemical oxidation, bioaccumulation and microbial degradation (Yuan et al., 2002). Soil is one of the abiotic resources most affected by PAH pollution. Physical-chemical technologies are generally used to reduce PAH soil contamination, although they have drawbacks, among which are their high cost, difficulty of operation and generation of secondary contaminants (Mamma et al., 2004). Bioremediation is an

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38153829

economical and efficient method for both eliminating PAHs from the soil and reducing the toxicity of the medium (Frenzel et al., 2010).

The bioremediation technology is based on the use of the catabolic ability of microorganisms using xenobiotics as energy sources. Successful bioremediation requires microorganisms with the capacity to degrade the contaminant (Venosa and Zhu, 2003). The application of isolated pure microorganisms or microbial consortia that have the ability to degrade PAHs and which have been taken from contaminated sites represents a possible alternative for the bioremediation of contaminated sites with similar environmental characteristics if the soil lacks the microbial flora capable of degrading the contaminant (Liu et al., 2011). Numerous studies have focused on degrading PAHs to deal with environmental pollution, reporting the use of a large number of species, with the most studied genera being *pseudomonas*, *mycobacterium*, *alcanivorax*, *sphingomonas*, *microbulbifer*, *shingomonas*, *micrococcus*, *cellulomonas*, *gordonia*, and *penicillium*, among others (Brito et al., 2006; Vila et al., 2010). Fungi genera such as *Chrysosporium*, *Bjerkandera*, *Irpex*, *Agrocybe*, *Lentinus*, *Pleurotus* and *Trametes* are among those that are reported to have been used (Valentín et al., 2006; Chupungars et al., 2009).

Although various studies have been able to degrade PAHs using pure microorganisms, these results can be improved through the use of microbial consortia (Bacosa et al., 2010; Colombo et al., 2011) and bacteria-fungus consortia (Boonchan et al., 2000; Li et al., 2008). One of the advantages of using microbial consortia is their multiple metabolic capacities, which increase the efficiency of the degradation process (Ghazali et al., 2004), the degradation of PAHs with consortia formed by using bacteria-fungus is a very promising technique because of the beneficial characteristics of both kingdoms. Thus, the aim of this study was to evaluate the capacity of the consortium formed by *Ochrobactrum intermedium* and *Pleurotus ostreatus* to degrade PAHs in a microcosm of soil contaminated with oil, with the objective of achieving superior remediation results than those achieved with individual microorganisms.

Materials and methods

Chemicals

The crude oil used in this study was obtained from the Lázaro Cardenas refinery in Minatitlán, Veracruz, Mexico. The chemicals used in the extraction and cleaning of the PAHs were of analytical grade, while the chemicals used in the quantification of the PAHs were of an HPLC grade, with both procured from Sigma-Aldrich (USA).

Microorganisms and culture medium

The bacterium was isolated from sediments in a hydrocarbon contaminated creek in Poza Rica, Veracruz, Mexico, at a depth of 40 cm from a site constantly polluted by oil, located at coordinates 20°32’28.77”N and 97°28’02.60”O. Bushnell Haas medium (BHM) was used as the culture medium in this study, with the following composition: (g l^{-1}): 2 NH_4NO_3; 2 KH_2PO_4; 2 K_2HPO_4; 1 NaCl; and, 0.2 $MgSO_4.7H_2O$. The micronutrients used were (mg l^{-1}): 1 $CaCl_2.2H_2O$; 1 $MnSO_4.H_2O$; 1 $FeCl_3$; 0.5 $ZnSO_4.7H_2O$; and, 2 $CuSO_4$. The pH was adjusted to 7.0 using 10.5 M NaOH. The BHM was sterilized by autoclaving at 121 °C for 15 min. *P. ostreatus* (ATCC38540) was grown in darkness on a potato dextrose agar (PDA) plate at 27 °C for 3 d.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38153829

Enrichment and isolation of the PAH-degrading bacterium

The pre-enrichment medium used to isolate the PAH-degrading bacterium was BHM with dextrose (1 g) as a carbon source. The inoculated flasks were incubated in darkness for seven days at 30 °C at 150 rpm, after which 10 ml of said culture was transferred to a flask containing 90 ml of BHM supplemented with 1 g of dextrose and 1 g of oil as carbon sources. The flasks were then incubated under the same conditions described above, with the procedure then undertaken five further times using 1 g of petroleum as a unique carbon source. The PAH-degrading bacterium was isolated via enrichment, using Maya crude oil, while the isolation of the strain was carried out on nutrient agar plates by means of conventional spread-plate techniques, with the plates incubated at 30 °C for 48 h. The isolated strain was stored at -20 °C in liquid culture containing 20% glycerol (v/v). The PAH-degradation capacity of the isolated strain was determined by means of a qualitative evaluation. Petri dishes with BHM agar and oil as a carbon source were inoculated with 1 ml of isolated strain culture and incubated in darkness at 30 °C for 72 h. A Petri dish without inoculate served as a control to determine the loss of hydrocarbons due to abiotic factors (Bacosa et al., 2013). The emulsification capacity was evaluated by adding 10 ml of the bacterial culture after 48 h of incubation to an Erlenmeyer flask containing 90 ml of BHM supplemented with 2 ml of oil and 1 ml of Tween 80. An uninoculated control flask was also used. All flasks were incubated in darkness at 30 °C in an orbital shaker set to 150 rpm. Each assay was performed in triplicate.

The 16S rRNA sequence analysis of isolated strain

The cells of the strain were grown in 50 ml Luria Bertani medium at 30 °C in darkness for one night. DNA was extracted according to Sambrook and Roussell (2001). To amplify the 16S rDNA gene, a polymerase chain reaction (PCR) was performed using two universal primers, the forward primer Eu 530F (5'-TGA CTG ACT GAG TGC CAG GAC CCG CGG-3') and the reverse primer Eu 1449R (5'-TGA CTG ACT GAG GCT ACC TTG TTA CGA CTT-3'), described by Borneman et al. (1996). Each 50 µl reaction contained the following: 3 µl of DNA template; 0.25 µl of Eu 530F; 0.25 µl of Eu 1449R (final concentration 20 pmol); 25 µl of master mix (Vivantis); 0.5 µl of $MgCl_2$ (final concentration 2.0 mM/L); and, 21 µl of water. The PCR mixtures were preheated in Eppendorf Mastercycler EP Gradient thermal cycler at 95 °C for 5 min prior to running the following cycles: 95 °C - 1 min; 55 °C - 1 min; and, 72 °C – 1 min. The reactions were conducted for 30 cycles in a DNA thermal cycle. After the last cycle had been completed, a chain-elongation step was carried out at 72 °C for 5 min. The amplified DNA was sequenced by the Macrogen Company (Korea). The sequence was subjected to a BLAST similarity search on the NCBI-USA website (http://www.ncbi.nlm.nih.gov) and deposited into GenBank. Many relevant 16S rDNA gene sequences with authenticated and published names were selected as references from Gen-Bank, while the phylogenetic tree was constructed using the MEGA 6.0 software.

Experimental design

The degradation of PAH in a soil microcosm by the microbial consortium consisting of *P. ostreatus* and isolated bacteria was evaluated via the application of a 3 × 3 × 2 factorial design, using controls comprising contaminated soil and soil contaminated with substrate, both without inoculum, while each treatment was performed in triplicate. The bacterial degradation was determined using 50 g of sieved soil (2 mm) placed into

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38153829

glass bottles (150 ml), while the fungal and consortium degradation were assessed in 40 g of sieved soil and 10 g of substrate (corn stubble and coffee pulp 1: 1, w: w) to obtain a final weight of 50 g. The moisture content was adjusted to 70%, while the molar ratio C: N: P was 100: 10: 1. All soil samples were autoclaved for 60 minutes at 121 °C. 4.3 with 8.6 g of crude oil added dropwise to each bottle to achieve uniform distribution and final concentrations of 86,000 and 172,000 mg of total petroleum hydrocarbons kg^{-1} soil. 30 ml of acetone was then added, after which a homogeneous mixture of the soil was obtained. 30 ml of acetone was added to homogenize the soil with the oil of the soil, after which the acetone was completely evaporated from the glass bottles. Then, 3 ml of bacterial inoculum (3.2×10^8 CFU/ml) was added to a set of bottles containing 50 g of soil, while another set of bottles contained 40 g of soil and 10 g of substrate invaded with the consortium, and the third set of bottles contained only 40 g of soil and 10 g of substrate invaded with mycelium of *P. ostreatus*. All bottles were incubated at 30 °C in the dark, under three different incubation times (50, 80 and 110 d).

PAH extraction and analytical methods and data analysis

The extraction of PAHs was undertaken in accordance with Li et al. (2008), with the soil dried and passed through a 60-mesh sieve, and approximately 2 g of dry soil placed in a 50 mL test tube, to which 15 mL of acetone:dichloromethane (1:5) mixture was added. The PAHs were extracted via sonication for 40 min in an ultrasonic bath (Brand Branson, MH Series, MOD 1800), after which two extractions were taken from each sample and the supernatants then mixed. The extracts were concentrated in a rotary evaporator and resuspended in 2 ml of cyclohexane. For the cleaning, 2 ml of the sample resuspended in cyclohexane was eluted with 15 ml of a dichloromethane:hexane mixture (2:3) through a C-18 cartridge. The eluate was concentrated and resuspended in 2 ml of acetonitrile (Tian et al., 2008), while the characterization of residual PAH in the soil after the completed incubation times was performed using an Agilent 1260 HPLC System with a diode array and fluorescence detectors. The separation of the 16 PAHs was carried out on a ZORBAX Eclipse PAH (4.6 mm x 50 mm, 1.8 µm) column. The mobile phase comprised an acetonitrile:water mixture (60:40), a flow rate of 0.8 mL/min, a sample volume of 20 µl, and a run time of 16 min. The data was recorded as means ± standard deviation. One-way analysis of variance (ANOVA) was conducted to determine the significant differences in the degradation of the PAHs by microorganisms at different time periods. The differences between treatments were analyzed via a Tukey (HSD) test using the SAS 9.0 software. Differences between means at a level of 5% ($P < 0.05$) were considered significant.

Results and discussion

Degradation of PAHs by O. intermedium

Figure 1 shows the biodegradation of PAHs by *O. intermedium, P. ostreatus* and the consortium of both microorganisms. When the PAH concentration was 138 mg kg^{-1}, during the 80 d of incubation, a linear degradation was observed, while an increase in the rate of degradation was observed after 80 d of incubation. During the incubation of Control A, soil contaminated with oil without inoculum, a slight decrease of non-significant PAHs was observed. A trend of increasing degradation was observed at

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38153829

268 mg kg^{-1} PAH. As with Control A, Control B did not present a significant decrease of PAHs. This study found that *O. intermedium* has a higher rate of degradation when exposed to a concentration of 268 mg kg^{-1} of PAHs, and offers higher degradation potential the longer the incubation time, with the degradation trend presenting a constant drop along with falling PAH concentrations (Tirado-Torres et al., 2017). Cerqueira et al. (2011) observed that the most challenging method of PAH elimination is that which uses microorganisms.

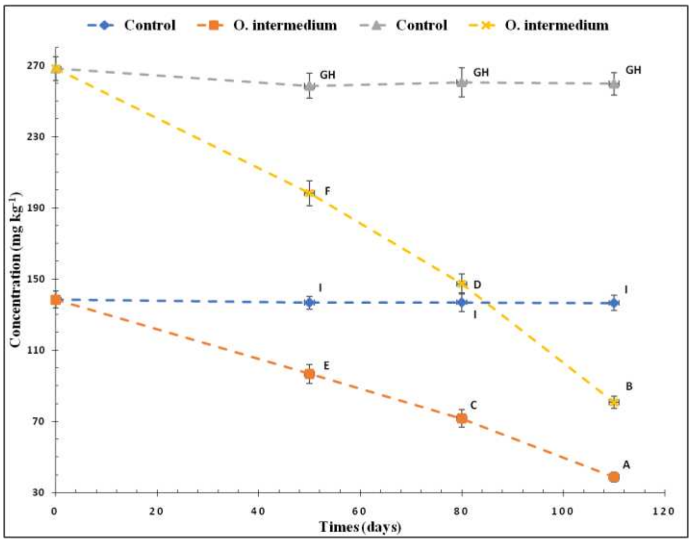

***Figure 1.** Changes in the concentrations of PAHs during biodegradation in crude oil PAH-contaminated soils. Control: Sterile soil without inocula. Letters represent significant differences among treatments (Tukey, P < 0.05)*

Limited by the low bioavailability of high molecular weight compounds, native microbial flora has a low capacity to remove PAHs from contaminated soils. Therefore, soil remediation processes are extremely complex in the case of hydrocarbon contamination (Janbandhu and Fukelar, 2011). The isolation of certain microorganisms with the ability to degrade PAHs has enabled significant progress in the development of bioaugmentation techniques and soil remediation (Mao et al., 2012). While few studies of *O. intermedium* have been conducted and especially research seeking to verify its potential to degrade PAHs, it is well known that microorganisms producing biosurfactants present a better option for the bioremediation of contaminants with hydrophobic characteristics, such as hydrocarbons, given that they increase their bioavailability (Wang et al., 2008).

In this study, *O. intermedium* was isolated and adapted to degrade oil PAHs in contaminated soils. Previous studies were reported to use *O. intermedium* isolated from the rhizosphere in soils contaminated by heavy metals and that it has the ability to reduce metal contaminants and subsist in contaminated soils (Sultan and Hasnain, 2007; Waranusantigul et al., 2011). Recently, a study carried out in a liquid medium proved that the species produces biosurfactants with a high level of thermal stability and tolerance to extreme levels of salinity and, thus, able to degrade up to 40% of PAHs in sludge contaminated with oil, while, in soil, the microcosms are able to degrade 70% of the most hydrophobic compounds in only three weeks (Bezza et al., 2015).

DOI: http://dx.doi.org/10.15666/aeer/1604_38153829

Degradation of PAHs by P. ostreatus

Figure 2 shows the action of *P. ostreatus* on PAHs in soils contaminated with oil during incubation at 50, 80 and 110 d in this study. Compared to control assays, *P. ostreatus* presented significant degradation rates at concentrations of 138 mg kg^{-1}, at which a constant degradation between 80 and 110 d of incubation was observed. *P. ostreatus* was observed to significantly degrade PAHs at concentrations of 268 mg kg^{-1}. An adaptation stage was observed to occur during the first 50 d, while, at 80 and 110 d, a linear decreasing trend was observed, signifying a higher rate of degradation.

Initially, the study of the degradation potential of microorganisms was given on a laboratory scale and mainly comprised degradation tests on liquid culture. Earlier studies found that the *P. ostreatus* strain ATCC38540 is highly efficient in degrading PAHs in liquid culture (Tirado-Torres et al., 2016). Therefore, this study inoculated *P. ostreatus* in soil contaminated with petroleum to study its capacity to degrade the PAHs present in the crude oil.

P. ostreatus was able to degrade up to 115.2 mg kg^{-1} of a PAH concentration of 138.3 mg kg^{-1} and 186.2 of 268.2 mg kg^{-1} after 110 d of incubation compared to the respective control. During the first 50 d of remediation, the PAH elimination efficiency was attributed to the sorption of the contaminant in the co-substrate added to the treatment, plus the soil particles (Johnsen et al., 2005). At 80 and 110 d, the elimination of PAHs was attributed to the release of ligninolytic enzymes produced by *P. ostreatus* to break the cellulose of the co-substrate, since at those it was observe traces of co-substrate and an increase of the biomass of *P. ostreatus*. This suggests that the addition of the co-substrate enabled the fungus to execute an efficient cometabolic process (Bouchez et al., 1999).

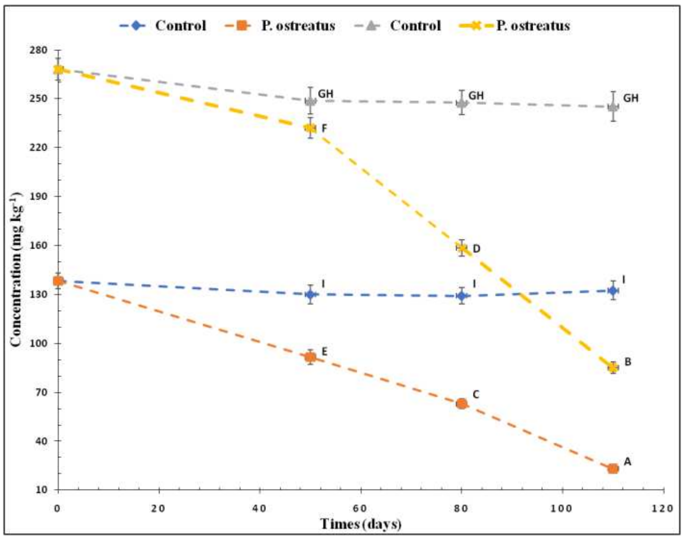

Figure 2. *Concentrations of PAHs during biodegradation in crude oil PAH-contaminated soils for fungus. Control: Sterile soil without inocula. Letters represent significant differences among treatments (Tukey, P < 0.05)*

Basidiomycetes act by means of extracellular enzymes in the co-metabolism process, during which these extracellular compounds act on the contaminant (Namhyun et al., 2000). White-rot fungi are basidiomycetes with the capacity to generate extracellular

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38153829

enzymes such as laccase, lignin peroxidase and manganese peroxidase, which are found to obtain good results in the degradation of xenobiotic agents (Hatakka, 1994). Acevedo et al. (2011), studied the efficacy of eliminating PAHs with a Chilean white-rot fungus (*Anthracophyllum discolor*) in contaminated soil, finding that *A. discolor* showed a high PAH removal capacity associated with the production of the extracellular enzyme MnP, results which are comparable with the ability of *P. ostreatus* to degrade PAHs as they are both white-rot fungi. In previous studies conducted in liquid culture, the presence of PAHs has been shown to stimulate MnP production in *P. ostreatus* (Bezalel et al., 1996). The production of ligninolytic enzymes by white-rot fungi, as well as other biochemical molecules, is known to facilitate the removal of xenobiotic agents such as PAHs (Baldrian et al., 2008).

Degradation of PAHs by O. intermedium-P. ostreatus consortium

This section presents the residual concentrations of PAHs in contaminated soils during the biodegradation induced by the consortium formed by *O. intermedium* and *P. ostreatus* (*Fig. 3*). As observed, after the inoculation of the consortium, the PAHs were efficiently degraded by 110 d, attaining a degradation efficiency of 86.7 and 75.5% for the PAH concentrations of 138 and 268 mg kg^{-1}, respectively.

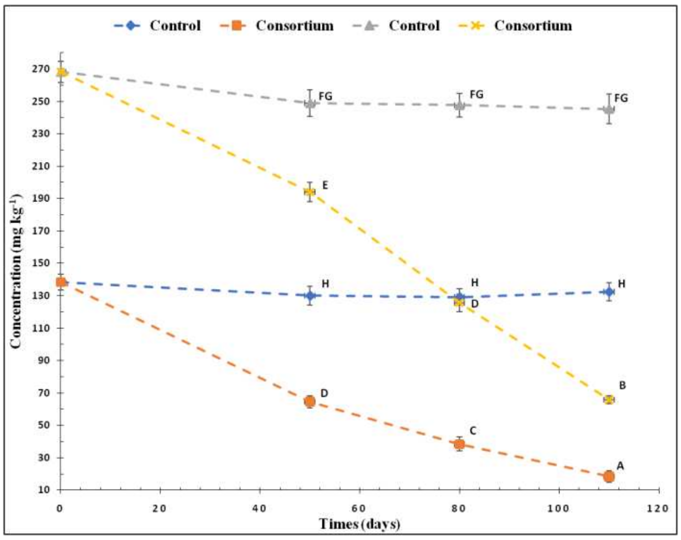

Figure 3. *Concentrations of PAHs during biodegradation in crude oil PAH-contaminated soils for consortium. Control: Sterile soil without inocula. Letters represent significant differences among treatments (Tukey, P < 0.05)*

While the consortium was observed to present a high rate of degradation at 138 mg kg^{-1} of PAHs after 50 d of incubation, a decrease in degradation efficiency occurs between 80 and 110 d. However, the consortium requires less time to adapt to the contaminated environment than the organisms used separately. At PAH concentrations of 268 mg kg^{-1}, the consortium presented similar behavior to that obtained at 50 d of incubation with 138 mg kg^{-1} of PAHs. An increase in the degradation response is observed between 50 and 80 d of incubation, while a decrease in the rate of degradation is observed between 80 and 110 d due to the decreasing concentration of PAHs. These results demonstrate that the consortium presents a greater degradation capacity in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38153829

first 80 d of remediation than the microorganisms in their isolated form. This part of the study reveals that *O. intermedium* and *P. ostreatus* act in synergy to efficiently metabolize PAHs from contaminated soil.

In this study, the consortium proved to have a greater capacity to degrade soil PAHs due to the synergism between the two microorganisms, which facilitates the degradation of PAHs. The consortium removed 119.9 and 202.4 mg kg^{-1} of PAHs at respective concentrations of 138.3 and 268.2 mg kg^{-1} in soil at 110 d of incubation. This is attributed to the enzymatic activity of the fungus, which formed a habitat that was less toxic to the bacteria (Chagas-Spinelli et al., 2012). Basidiomycetes normally synthesize enzymes that, to an extent, degrade complex PAHs (Sack et al., 1997; Aranda et al., 2010). Bacteria that generate enzymes such as laccase can contribute to an improved degradation of PAHs (Zeng et al., 2010). At 110 d of incubation at the two concentrations handled in this study, it was observed that the consortium achieved the highest level of PAH removal, while the other two treatments achieved levels close to the degradation rate of the consortium. This can be attributed to the limitation of nutrients necessary for the consortium (Hollender et al., 2003), while limiting the source of energy can also affect the efficiency of microorganisms (Kim et al., 2009). The consortium's efficiency in degrading PAHs is due to the qualities of the co-metabolism generated by *P. ostreatus*, as initiated by the addition of co-substrate, which, when decomposed by the extracellular enzymes expelled by the fungus, releases nutrients outside the cell that are available both for their products and for the bacteria (Šnajdr et al., 2011).

In addition, bacteria are able to form biofilms around fungal hyphae in order to bridge pores and penetrate soil aggregates (Kohlmeier et al., 2005). Fungi can also actively take and transfer PAHs through their hyphae via the cytoplasmic stream (Furuno et al., 2012). The primary degradation strategy carried out by fungi and bacteria comprises the release of biosurfactants in order to obtain greater contaminant bioavailability (Johnnsen and Karlson, 2004; Bento et al., 2005). The strong competitive capacity of a particular fungal species is considered a premise of successful soil colonization (Baldrian, 2008). Although, in this study, *P. ostreatus* has been shown to coexist with *O. intermedium*, other studies have reported decreasing *P. aeruginosa* biomass when forming a consortium with *P. ostreatus* (Tornberg et al., 2003). In contrast, Federici et al. (2007) observed an increase in bacterial counts of *mycobacterium, nocardia* and *rhodococcus* when used in consortium with *P. ostreatus* (DeBruyn et al., 2007). It should be noted that interactions between fungi and bacteria can positively affect biodegradation applied metabolically in conjunction with a fungal co-metabolism (Mueller et al., 1989), as well as negatively affecting the degradation of PAHs in soil (Borras et al., 2010). In some cases, the use of consortia has not obtained results showing the potential to degrade xenobiotics (Tornberg et al., 2003), while, in other cases, the positive cohabitation of consortium has been obtained with high rates of PAH degradation (Federici et al., 2007).

In this study, the consortium degraded 75.5 to 86.7% of PAHs, while Gallego et al. (2007) observed that a microbial consortium degraded from 31 to 55% of PAHs. It should be reiterated that, as Toledo et al. (2006) state, the comparison of results varies greatly due to the concentrations of hydrocarbons and the incubation times obtained. In another successful study of consortia, Díaz-Ramirez et al. (2008) formed a microbial consortium of six strains which, after 18 d of incubation, degraded 31% of PAHs. Ruberto et al. (2006) found that a combination of bioaugmentation and biostimulation in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38153829

a microbial consortium caused a 46.6% elimination of 1,744 mg kg^{-1} of phenanthrene in soil after 56 days of incubation in Antarctic soil. The results obtained in this study show that fungal and bacterial consortia can be an efficient technology for degrading xenobiotics, as is the case for PAHs.

Bioremediation treatments: individual PAH removal

Previous studies have reported that microbial consortia obtain higher degradation efficiencies in liquid culture with the addition of surfactants in order to increase the bioavailability of xenobiotics (Bautista et al., 2009; Molina et al., 2009; González et al., 2011). The present study was carried out in soil without the addition of surfactants in order to observe the capacity of the consortium without needing to apply biostimulation. Sixteen PAHs were used in this study, of which six were not detected in the initial treatment period: acenaphthene (ACE); Acenaphthylene (ACY); benzo [b] fluoranthene (BBF); benzo [k] fluoranthene (BKF); Benzo [a] pyrene (BaP); and, dibenzo [a, h] anthracene (DahA). *Table 1* shows the 10 compounds detected in the chromatographic analysis and the degradation efficiencies obtained by the treatments at 110 days of incubation under a constant temperature of 30 °C. It can be seen that the compounds which were completely removed by both the consortium and *P. ostreatus* are FLT, IND and BgP. The compounds that showed significant degradation are ANT and CHY, with removal efficiencies ranging from 96 to 98%.

These results can be used for future studies of those compounds which have been totally eliminated. *Figure 4* shows the degradation kinetics generated by the three treatments for each PAH. FLT was completely degraded after 80 d of treatment with both *P. ostreatus* and the consortium. IND was completely degraded after 50 d of treatment with the consortium, whereas treatment with *P. ostreatus* achieved complete degradation after 80 d. BgP, the aromatic compound used in this study with the greatest number of rings, was the PAH that was completely eliminated in less than 50 d of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38153829

treatment with the consortium, whereas it was totally degraded after the 50 d of *P. ostreatus* treatment. The time required to obtain total degradation was shortest for BgP, followed by IND and, finally, FLT. Several studies have concluded that petroleum components have different susceptibilities to degradation by microorganisms (Greenwood et al., 2008; Bacosa et al., 2010).

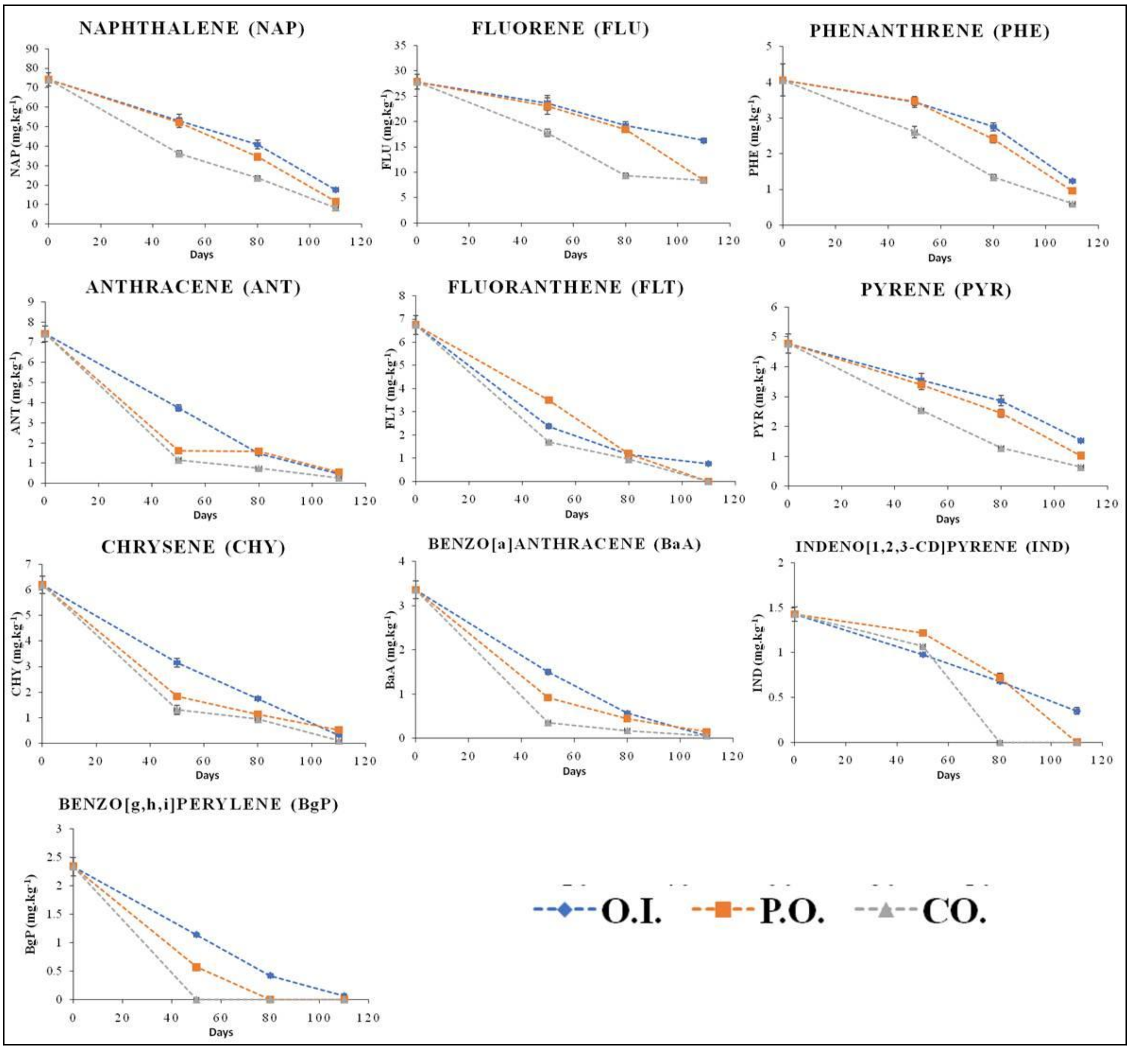

***Figure 4.** Concentration of individual PAH compounds during the 110-day experimental period for O.I. (O. intermedium), P.O. (P. ostreatus) and CO. (consortium) treatments*

Degradation efficiencies of 69.7 to 85.2% PHE were obtained, proving that this compound can be degraded by actions associated with the microorganisms used in this study. Other studies using microorganisms have reported the biodegradation of PHE by such microorganisms as *Sphingobacterium* sp., *Achromobacter* sp., and *Bacillus* sp. (Janbandhu and Fulekar, 2011), while, in consortia, they have been able to degrade PHE at rapid rates without any additional carbon source (Arulazhagan and Vasudevan, 2009). Chagas-Spinelli et al. (2012), studied the degradation of PAHs via three treatments, including BSBA consortium, obtaining, after 126 d of incubation, degradation efficiencies similar to those found in this study. PAHs comprising two aromatic rings,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38153829

such as NAP and FLU, achieved high degradation efficiencies, of 100 and 98.3%, at concentrations of 2.1 and 12.3 mg kg^{-1}, respectively. Although the concentrations used in the present study were much higher, the high degradation can be attributed to the fact that LMW-PAHs degrade more easily due to their lower hydrophobicity than those of HMW-PAHs (Lors et al., 2012).

The total degradation of FLT and IND was found to be possible in this research, results which are superior to those reported by Chagas-Spinelli et al. (2012), who obtained 86.6 and 93.9% degradation in their most effective treatment, with the FLT concentration 2.4 times lower and the IND concentration 4.4 higher than the concentrations used in this study. The efficiency of *O. intermedium* was found to be similar to that obtained by the research undertaken with the BSBA microbial consortium, whereas the consortium used in this study managed to eliminate both FLT and IND completely, meaning that the use of consortia formed by fungi and bacteria is more efficient than the microbial consortia. This is attributed to the ability of *P. ostreatus* to both generate extracellular enzymes and obtain greater xenobiotic bioavailability for microorganisms (Namhyun et al., 2000). As PYR is classified as an HMW, its degradation process is more difficult than that of LMWs. This compound has been previously studied in liquid culture using a microbial consortium, in which it was degraded by up to 80%, although the increased PAH concentration decreased the degradation capacity of the consortium (Arulazhagan and Vasudevan, 2009). It is known that HMW PAHs, due to their high hydrophobicity, require longer degradation time and sometimes different microorganisms to degrade them (Luo et al., 2009; Boonchan et al., 2000). In this study, the concentrations of PYR were low so that its high degradation efficiencies had to be obtained by all three treatments. These results show that consortia composed of a bacteria-fungus mixture can more efficiently degrade existing LMW and HMW PAHs in soil (Li et al., 2008).

Conclusions

The consortium formed by certified *P. ostreatus* strain and *O. intermedium* strain isolated from soil contaminated with hydrocarbons were able to degrade PAHs in soil. The highest rate of degradation occurred using the consortium during the first 80 days of incubation, suggesting synergistic effects. In particular, the total degradation of HWM indene [1,2,3-cd] pyrene and benzo [g, h, i] perylene Haps was achieved using the consortium. The results of this study show that the consortium is a promising technology for the elimination of PAHs from soils contaminated with hydrocarbons; however, further research on the consortium must be undertaken through a field study as well as toxicity testing of the treated soils.

Abstract. In this study, the heavy metals magnesium (Mg), zinc (Zn), copper (Cu), manganese (Mn), lithium (Li), tin (Sn), cobalt (Co) and selenium (Se) levels were determined in the feathers of Armenian Gull (*Larus armenicus*), which is a species classified as near threatened (NT) according to IUCN categories. The Gull lives on the islands of Turkey's largest lake, Lake Van. Different levels were detected due to the urban and rural location of the study areas. The highest levels of Mg, Zn, Mn, chromium (Cr), and Li were determined in the Sıhke pond near the city's dumpsite. The lowest levels were determined on Adır island, with the least human factors. While the levels of Co, Se, and Sn were high in the samples taken from Akdamar Island, the lowest levels were determined on Çarpanak Island and in Sıhke pond.
Keywords: *toxicology, bird, Akdamar Island, Çarpanak Island, Adır Island, Sıhke Pond*

Introduction

The increase in human population, and developing industry and technology have resulted in more waste disposal into nature. Human-derived wastes affect other species that are an indispensable part of the ecosystem in the wild. Although heavy metals are found at certain concentrations in nature and in living organisms, they have a durable and bio-accumulative nature, and therefore pose great risk to the food chain and wildlife with the effect of anthropogenic factors (Zolfaghari et al., 2007; Costa et al., 2013; Nriagu and Pacyna, 1988; Metcheva et al., 2010). Birds, in the higher trophic level of the food chain, which are most rapidly affected by degrading environmental conditions and respond to this change, are referred to as bioindicators (Burger, 1993). Hence, a suitable method for detecting metal accumulation in nature is to determine the amount of it in bird feathers. Heavy metals in the feathers can be due to external (direct contact) and internal (via blood) factors (Movalli, 2000). Heavy metals enter a birds' body via feeding and accumulate in the calamus area, which is connected to blood vessels (Dauwe et al., 2000, 2003). For heavy metal analysis, the use of feathers removed from the body without harming the organism is more convenient than using other organs (Burger, 1996; Movalli, 2000; Battaglia et al., 2005). Samples taken from living things are particularly good for species that are in danger or whose numbers are decreasing (Movalli, 2000). The Armenian Gull lives in limited areas located in Turkey, Israel, Egypt, and Iran (Anonymous, 2017). Unique to Turkey's eastern Anatolia and spread throughout the region, these birds feed on the endemic Lake Van fish of Van Lake in the summer while living on garbage in the city center in winter (Adızel et al., 2010; Nergiz and Durmuş, 2017). The number of these species, listed as near threatened (NT), by the International Union for Conservation of Nature (IUCN), is declining day-by-day

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38313837

in Turkey because of habitat degradation and the lack of healthy diet (Anonymous, 2017).

The aim of this study was to (a) determine the concentrations of heavy metals in the feathers of Armenian gulls, which live in different locations of the Van Lake Basin and are found on the higher trophic level of the food chain, (b) explain the differences in the concentrations between the areas ecologically, and (c) compare the results with similar studies.

Materials and methods

Feather samples of the Armenian gull were collected from dead gulls in Akdamar (328345 X; 4245530 Y), Çarpanak (333264 X; 4275058 Y), and Adır Islands (357054 X; 3203307 Y) in Van Lake and in Sıhke Pond (362132 X; 4266574 Y) near the city's dumpsite between May and June 2017 when reproduction largely takes place (*Fig. 1*).

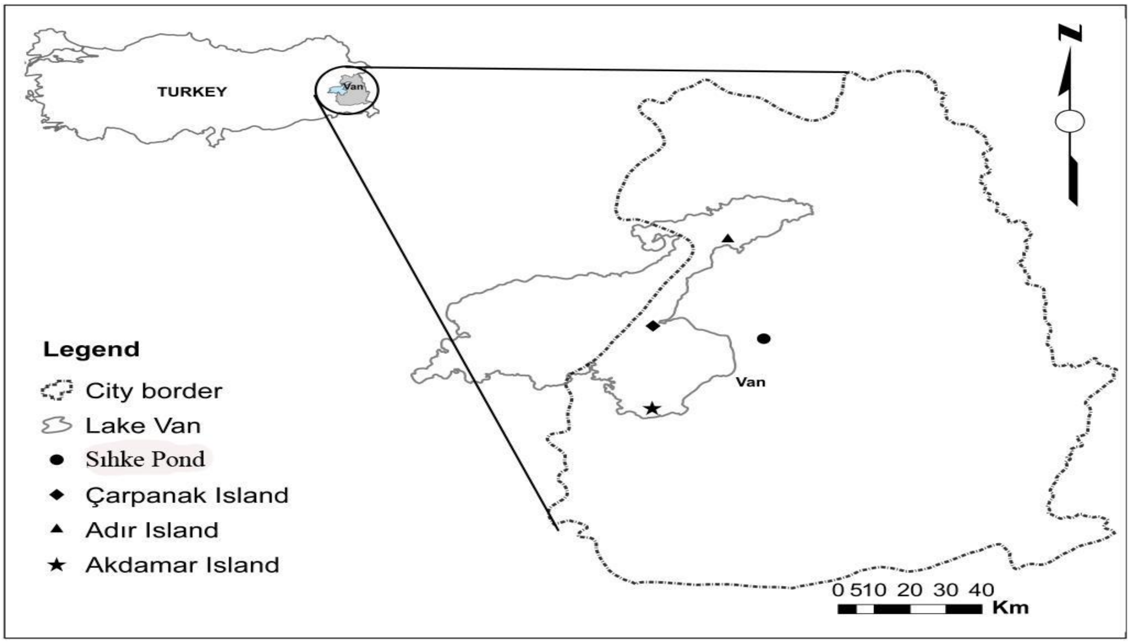

Figure 1. *Islands from which feather samples were taken in the Van Lake Basin*

Water samples were also taken from different regions of the lake for comparison. The 3 islands in Van Lake are the areas where these birds reproduce, mostly in the spring. During the breeding season, there is intensive activity to feed the offspring and deaths occur in adults and young as a result of this rush. In each area, the wing feathers were taken from 10 dead adult gulls. The feathers were put into plastic bags and taken to the Van Yuzuncu Yil University Scientific Research Centre for analysis.

Analysis of the samples

The feather samples brought to the laboratory were washed 3 times with distilled water and acetone in order to remove environmental pollutants such as soil and feces (Goede and Bruin, 1984). Next, the samples were placed in glass containers and dried in the drying oven at 70 °C for 24 h. The dried feathers were cut with steel scissors and at

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38313837

least 2 g (dry weight) from each sample was weighed on a precision scale and placed in glass containers. The prepared feather samples were burned using the tissue sample program in a microwave heating unit (Ethos Easy Advanced Microwave Digestion System, Milestone, 230/50 Hz, Italy) by adding 8 mL of 65% HNO_3 and 2 mL of H_2O_2 (Blust et al., 1988; Janssens et al., 2001). A 2 mL solution from the incinerated samples was diluted with distilled water to 10 mL and analyzed on the ICP-AAS (Thermo Scientific ICAP 600 series) instrument.

Calibration of the instrument was done with a certified solution (Multi element ICP QC standard solution-QCS-01-23E, Belgium). All of the metals were compared to the National Institute of Standards and Technology (NIST) and Standard Reference Material (SRM) standards. Accepted recoveries ranged from 95% to 105%.

Statistical analysis

The statistical analysis was done using SPSS software v23. Means and standard deviations (SD) are given in *Table 1*. The Kruskal-Wallis and Tukey post-hoc comparison tests were used to evaluate the effects of the heavy metal concentrations according to the localities.

Table 1. *Heavy metal concentrations (mg/kg dry weight) in the feathers of Larus armenicus*

Metal	n	Akdamar Island Mean ± SD (min–max)	Adır Island Mean ± SD (min–max)	Çarpanak Island Mean ± SD (min–max)	Sıhke Pond Mean ± SD (min–max)	Water samples Mean ± SD (min–max)	Fr	*p*

The Kruskal-Wallis test followed by Tukey's comparison test between islands and water concentrations of metals. Statically significance was accepted at $P < 0.005$

Results and discussion

Different metal concentrations were determined in all of the feather and water samples taken from the study areas ($P < 0.005$). The mean metal concentrations in the water and feather samples from the 3 islands and a pond are shown in *Table 1*. In all of the areas, it was determined that the highest concentrations were magnesium (Mg) and zinc (Zn). The levels of cobalt (Co), chromium (Cr), lithium (Li), Mg, manganese (Mn), selenium (Se), tin (Sn), and Zn in all of the areas were different and statistically significant. The samples taken from Akdamar Island turned out to have concentration

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38313837

densities of Mg> Zn> Mn> Cr> Co> Se> Sn> Li (P < 0.005). The rank of concentrations from Adir Island was Mg> Zn> Cr> Mn> Se> Sn> Li> Co, on Çarpanak island it was Mg> Zn> Cr> Mn> Se> Li> Sn> Co, whereas in Sıhke Pond it was Mg> Zn> Mn> Cr> Co> Li> Se> Sn (P < 0.005).

In all of the studied areas, it was determined that the highest Mg (48.27 mg/kg), Zn (2.83 mg/kg), Mn (0.877 mg/kg), Cr (0.41 mg/kg), and Li (0.038 mg/kg) levels were in Sıhke Pond, which is in the vicinity of the city's dumpsite. The lowest levels of these same metals were found on Adır Island, where human activities are the least. The Co (0.089 mg/kg), Se (0.043 mg/kg), and Sn (0.032 mg/kg) levels were the highest in samples taken from Akdamar Island. While the lowest Co (0.002 mg/kg) and Sn (0.012 mg/kg) levels were determined on Çarpanak Island, and the lowest Se (0.027 mg/kg) concentration was detected in Sıhke Pond (*Table 1*).

Many studies have been carried out to determine the levels of heavy metals in bird feathers. Burger (1995, 1996), in his study of Herring gull feathers showed that metals accumulating in the feathers change depending on sex, age, and nutrition. It was also indicated that the level of Se in the samples taken from the dead gulls was higher than that in the living ones. In their study, it was shown that the level of Se was lower in adults than in juveniles. In our study, it was observed that the level of Se in adult gulls was lower than those of other metals and differed based on the feeding areas. From the data obtained in this study, it can be said that the concentrations were not at levels lethal enough to kill gulls but were sufficient to restrict locomotor activity and facilitate death to same extent (Burger, 1995).

Se levels in gull and tern feathers ranged from 1.200 to 18.700 ppb, with a median of 3.900 ppb (Burger, 1994). In this study, the Se concentration in the feathers as dry weight (mg/kg) (0.027 mg/kg–0.043 mg/L) exceeded the average value in the literature.

The accumulation of metals in the birds varies depending on the concentration and variety of food available (Zolfaghari et al., 2007). The highest heavy metal levels were found in the studies of predatory avian feathers at the top of the food chain (Braune and Gaskin, 1987). The Armenian gull is located in the higher trophic levels of the food chain in terms of being carnivorous, although it is not literally a predator. The concentration levels varied depending on the region and density of the fish that they feed on. In this study, it was observed that the levels in the gulls at Sıhke Pond near the city garbage dump were higher than the levels in other areas.

Se, Cr, and Mn levels have been determined in studies concerning the metal levels of ocean birds (Burger and Gochfeld, 2001). The levels determined in this study were higher than those reported in other studies. In the literature, an average of 11.8 ppm Mn was determined for marine birds (Burger, 1993). This level is much higher than thhat found in the present study, which is thought to be due to the density of the food.

Zn, Mn, Mg, Co, and Cr were analyzed in the feathers of cattle egret that are feeding with fish such as gull, during their reproduction period (Malik and Zeb, 2009). According to the results obtained, the Zn, Mn, and Mg levels were parallel but the Co and Cr levels were lower than those we determined.

When the Mn level obtained from this study was compared with studies conducted on fish-fed aquatic birds, the level (0.232 ± 0.051) found on Akdamar Island overlaped with that (0.021 mg/kg) which Abdullah et al. (2015) found in the feathers of *Bubulcus ibis*, while it was found that the concentrations in *Ardea cinerea* (0.099 ± 0.036) and *Egretta garzetta* (0.094 ± 0.027) found by Kim and Koo (2008) were similar to those on the islands of Adır (0.079 ± 0.011) and Çarpanak (0.088 ± 0.009).

Pearl mullet (*Alburnus tarichi* Güldenstädt, 1814), an endemic species of fish, is the Armenian gulls' basic food during their breeding season. Pearl mullet, an anadromous fish, goes into fresh water to lay eggs in spring and is much hunted by the seagulls during this period. Species feeding on larger fish have been shown to accumulate higher levels of metals than those feeding on smaller fish (Burger, 2002). However, the size of the fish caught by the gulls is average and does not vary by much.

The levels of metals in the species of birds feeding on plant seeds, leaves, and fruit were found to be lower than those feeding on meat (Zolfaghari et al., 2007; Behrooz et al., 2009). However, the species we were studying is a carnivorous species and does not feed on plants. The levels of Mn and Cr detected in the studies of the phytophagous great tit (*Parus major*) were lower than those in our study, but the Se levels were higher than our findings.

As for in the vicinity of the industrial and residential areas, the concentrations of metals appear to increase and pose risks (Dauwe et al., 2000; Frantz et al., 2012). In India, the heavy metal concentrations in the feathers of 11 species of birds living in both urban and rural areas were examined. It was stated that among the reasons for the high levels of heavy metals are the vehicle traffic in urban areas, metal manufacturing industries, and human-derived factors (Manjula et al., 2015), which seems parallel with our results. The Mg, Zn, Mn, Cr, and Li levels were significantly higher in the populations of gulls around Sıhke Pond, where the pollution was most intense. Statistical differences between the areas were significant ($P < 0.005$).

Conclusion

Wetlands in Turkey are increasingly affected by contamination as a consequence of agricultural, industrial, and anthropogenic sources. Therefore, it is inevitable that these effects on wildlife, especially birds, be investigated. However, previous studies on contamination in Turkey were limited to a few studies of contaminants in water birds (Ayas and Kolankaya, 1996; Ayas et al., 1997; Ayaş, 2007).

The aim of this study was to determine the concentrations of heavy metals (Mg, Zn, Cu, Mn, Li, Sn, Co) and Selenium in gull feathers, indigenous to the eastern Anatolian region of Turkey and breeding on the islands in Lake Van. During the feathering period, the levels of some metals in internal tissues drop as they are stored in their feathers. The metal levels in the first emerging feathers show a combination of the stored state of the organic mercury that accumulates at the end of the feather, as well as the current diet intake (Burger, 1995; Zolfaghari et al., 2007). Feather samples from the dead gulls were taken from 3 islands in the lake and from the coasts of a pond (Sıhke) close to the city dumpsite. In all the feather samples taken, heavy metals were detected at different concentrations. Levels of Mg and Zn were determined as high in all of the areas. It was determined that the levels of Mg, Zn, Mn, Cr, and Li were higher in Sıhke Pond than in the other fields when the samples were analyzed. The absence of contaminating factors and contamination in the other 3 sites was the main reason for this disparity. In parallel with the increase of pollutant factors in natural ecosystems, the biological accumulation in living things is also increasing (Burger, 1993). Therefore, as it is in this study, the use of natural and contaminated areas is very useful for comparing metal concentrations in living organisms.

Although there are many studies on heavy metals in various species of seagulls in the literature (Burger, 1995; 1996), none has been done on the Armenian gull. Moreover,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38313837

this is the first study that considers correlations between the element levels of *Larus armenicus* feathers. Our results are meaningful due to an adequate sample size from the relative areas and the number of detected elements.

Depending on environmental pollution, increased accumulation amounts, and harmful effects should be observed in all of the study localities. Additional studies are required to determine whether the levels measured in the individual feathers were toxic.

(Received 22nd Feb 2018; accepted 24th May 2018)

Abstract. With the rapid development of science tourism, geoparks are brought into focus of many geologists and tourists because there are of high scientific values for experts and we can disseminate science to the public. In recent years, there have been many problems in the construction of geoparks in China. The quick demand growth of geoparks conflicts with the ecological health of the area prominently. It is of great significance for ameliorating the planning and improving the development potential of a geopark and evaluate the ecological health of a geopark by combining qualitative and quantitative indicators. Illustrated by the example of Xiaonanhai National Geopark in Qianjiang, Chongqing and based on the theory of ecological health, this paper constructs the eco-health evaluation system for geological parks through DPSIR conceptual model. We use entropy and multi-level fuzzy synthesis evaluation method to determine the factor's proportion and calculate Geopark Ecological Health Index. The result shows that the highest score of Qianjiang Xiaonanhai Geopark is 0.6643, and the lowest score is 0.6120. Though the score reveals a general trend of increase, the gap between scores of indicators is large. Based on the conclusion, some countermeasures and suggestions to improve the eco-construction and management planning of Qiannan XiaonanHai National Geopark are put forward.
Keywords: *Qiannan Xiaonanhai National Geopark, health degree, index evaluation system, DPSIR conceptual model, fuzzy comprehensive evaluation*

Introduction

Geopark is a new name created by UNESCO in the study on the feasibility of the Geoparks Project. According to the definition of geoparks by the Ministry of Land and Resources of the People's Republic of China No. 77 (2000), geoparks should be relic resources with special scientific value, popular science education value, and aesthetic value at the national and even international levels. It is necessary to provide geological records that can present important geological evidence for a certain geological event or stage in a certain area, and have special geological features, fossils, or geological relics with typical geomorphological meaning.

In other countries, some research studies have already been conducted on geoparks in the past. In 1999, UNESCO officially launched the World Geopark Program. Italian studies expounded the scientific and educational importance about geological remains of soil profiles, tourism and recreational value, and demonstrated that the protection of geological sites could be better achieved through the implementation of geographic databases (Edoardo and Costantini, 1986). Researchers studied two cities and towns in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38393859

the United States that carried out geological tourism and elaborated on its unique practices including the key points of geological tourism cooperation, social promotion, education innovation, and field discipline (Wandersee and Clary, 2005). The concept of geoscience tourism is likened to the three dimensions of a box, metaphorically referring to shapes, processes and tourism.

However, the research on geoparks in China started late, but in recent years, more research has been done on the geoparks. Characteristics of geological tourism were analyzed in the United States National Park, focusing on the study of the protection of geological landscapes, eco-system, resource and environment in the United States National Park while conducting tourism activities and thinking that it is of siginificant reference for China (Xie and Liu, 2003). The protection status of Wudalianchi Global Geopark was analyzed and the sustainable development model was studied. The proposed elements of the model were the followings: leading community residents to participate in tourism development, strengthening the legislative system, reforming the geopark management system, establishing an information base, creating a network of geological relics and training specialized management personnel (Qian and Zhao, 2006). Scholars at home and abroad mainly focused on the development, construction, and problems of geoparks, discussed and studied the types and protection of geological relics, geoparks, and tourism economy. In response to the initiative of UNESCO to establish the "Global Geopark Network System", the Ministry of Land and Natural Resources, which are in charge of the declaration, approval and construction of geoparks as well as the formulation of the relevant laws, regulations and policies of geoparks, officially launched the plan of China's national geopark construction in 2000. After more than 10 years of development, China has become a geopark power in quantity.

Geoparks not only provide a public place for scientific sightseeing, leisure, health care, public education, cultural and entertainment, but also bring great social and economic benefits because of its irreproducibility as geological landscape, cultural landscapes and ecological focus protected areas, which has great scientific research value.

Tourism industry used to be considered as a "smoke-free industry" and would not cause environmental problems (Li, 2012). However, with the continuous development of society and economy, the contradiction between tourism development and ecological protection has become increasingly prominent. The contradiction between the social and economic benefits and ecological and environmental benefits has become the major problem that geoparks face on the way of sustainable development. At present, the protection of the ecology and environment has become a hot topic in the field of academic research. The earliest health degree which was used to measure the health of the human body from multiple dimensions such as body, spirit, and society, gradually extended to other disciplines, which means a quantitative measurement of the health level of an industry or an experimental site. The research methods were mostly based on the characteristics of a certain industry and the index systems of evaluation were constructed based on the actual situation of the industry. Then the industry's health degree was evaluated, as an important indicator to measure socio-economic and ecological environmental benefits of the scenic area (Wang, 2016). Health degree is becoming more and more important in the field of ecological health.

Taijin was took as an example to establish an index system of urban ecosystem health assessment considering the aspects of vitality, organizational structure, resilience,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38393859

ecosystem service function, and population health of the urban ecosystem (Zhao et al., 2013). The basic principles and methods of regional ecosystem health assessment were explored in the aspects of regional types, target units, model methods, selection of indicators, thresholds, and weight settings (Peng et al., 2007). The "pressure-state-response" (PSR) framework model was applied to establish an indicator system and constructed evaluation model for the ecosystem health assessment of river basins (Yan et al., 2008).

Nowadays, although some academic achievements have involved the evaluation of ecosystem health and various indicators of the tourism industry, the overall quantity is small and the comprehensiveness is inadequate. Moreover, index systems in the aspect of evaluation for the health of geoparks are rarely used. Constructing a health evaluation index system suitable for geological parks means a conceptual model for measuring and evaluating environmental and sustainable health development. It analyzes the interaction between human and environmental systems from a systemic perspective, and comprehensively analyzes and describes environmental problems and their common models for social development. It is divided into driving forces (D) indicators, pressure (P) indicators, status (S) indicators, impact (I) indicators and response (R) indicators (Qin and Lu, 2014). Evaluating the overall health of the geoparks is a new area that needs to be researched and developed urgently in the tourism industry and those research are of high innovativeness and practical value.

Based on the field investigation of the socio-economic development and eco-environmental protection of Qianjiang Xiaonanhai Geopark, this paper starts with the concept of health degree of tourism industry, and selects the factors that have an important influence on the eco-health of the geopark as evaluation indices. We construct the evaluation index system of eco-health of geoparks through DPSIR conceptual model, and use fuzzy comprehensive evaluation method to calculate each factor and overall health index of Qianjiang Xiaonanhai Geopark, in order to analyze the connotation of ecological health of Xiaonanhai Geopark and its significance provides a theoretical basis and references for its declaration of the world-class geopark, to promote its scientific planning, rational construction and sustainable development. At the same time, this paper tries to build a business-ecosystem assessment system suitable for geoparks, promote the development of standardized, rationalized, scientific and sustainable geoparks, and propose measures and advice for integrating internal and external resources and optimizing current development models in order to increase their efficiency, so as to make due contributions to local economic development.

Materials and Methods

The overview of the research area

Qianjiang Xiaonanhai National Geological Park is located in the Qianjiang District, Chongqing, the junction of Chongqing and Hubei province (east longitude 108°38'20"--108°49'48", north latitude 29°31'14"--29°43'27"). It is 32 kilometres north of the county seat, covers an area of about 30 square kilometres. On the June 10, 1856, a 6.25-magnitude earthquake with an intensity of 8° on the ground cut off rivers and blocked the lake, creating the magnificent landscape for the complete ancient earthquake ruins. Dakuayan and Xiaokuayan in the north, two precipices, and other relics remain clearly visible. The place is rich in multi-type geological resources. As a national geopark, Xiaonanhai is a non-renewable and non-replicable landscape with a high value of both

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38393859

science popularization for public and scientific research for experts and scholars. It can provide sightseeing, leisure and other tourist activities with scientific education. *Figure 1* shows the research site.

Figure 1. *The experimental site of Qianjiang Xiaonanhai National Geopark*

Qianjiang Xiao Nanhai scenic area health evaluation index content

Driving force indicators

According to the explanation of the driving force in DPSIR model, the "driving force" in the evaluation of the health of geoparks is the potential cause of environmental change. It can be divided into two categories: natural driving force and socio-economic driving force. The natural driving force mainly includes climate change and natural disasters. Their impact on the geoparks often take a long time to emerge. The landscape of Qianjiang Xiaonanhai Geopark is relatively stable, and the aim of evaluation is the current situation, so the driving force indicator here mainly refers to the socio-economic driving force. Socio-economic driving force includes population growth, tourism demand (number) growth, GDP growth and other factors. Population growth can easily lead to encroachment on landscape land. Economic growth has a direct impact on scenic spots development.

Pressure indicators

The pressure on geoparks is mainly caused by the contradiction between the ever-increasing demand for tourism and the irreproducibility and expansibility of geological landscape resources. Compared with other industries, tourism industry tend to be more vulnerable and often face the threat of being constantly weakened. The population density, regional development index, utilization of tourist space and environmental

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38393859

carrying capacity are chosen to reflect the pressure on natural environment of geoparks caused by human activities.

State indicators

Geopark health status is the result of the driving force and pressure. The status and dynamic changes of the geoparks eco-environment are the basis of the health degree analyses of geoparks. The eco-system can be mainly refelected by the vegetation, biology, air quality, surface water quality and landscape state. When selecting natural state indicators, forest coverage, biodiversity, negative oxygen ion content, landscape fragmentation, surface water quality, comprehensive air pollution index can be selected to describe the eco-system status of Qianjiang Xiaonanhai Geopark comprehensively. In terms of social and economic status, the level of tourists' consumption is chosen as the representative to reflect attractiveness.

Impact indicators

Impact indicators are related to human health and life closely. The changing health level in tourist area will in turn have an impact on many aspects of human life quality, health, socio-economic structure and so on. The impact indicators of the DPSIR model of Qianjiang Xiaonanhai Geopark is used to describe the final social and economic effect when the health degree of the geopark change. Its impact on society and economy is mainly reflected in the change of visibility of tourist areas abroad, the satisfaction of tourists, total tourism revenue, economic growth and people's living standards. Common indicators reflecting these changes include area visibility, tourist satisfaction, tourist period, GDP per capita and so on.

Response indicators

The pressure is caused by socio-economic and natural factors which shaped current status of geoparks. The current status, in turn, affects the scenic area development potential and direction in the future and affects the scenic economic belt. Therefore, a corresponding social response must be made. People tend to promote the sustainable development of geoparks by adopting active countermeasures and policies such as improving resource utilization efficiency, reducing pollution and increasing investment in environmental protection. Therefore, choosing the ratio of environmental protection input to GDP, infrastructure construction in tourist areas, improvement of laws and regulations reflects the human's guiding role in the process of sustainable development of the park.

Evaluation methods

The Qianjiang Xiaonanhai tourist spot is a complex ecosystem. There are many indicators involved in ecosystem health assessment and the ambiguities are difficult to determine. Therefore, the entropy method is adopted to get the weight of each evaluation indicators, and the multi-level fuzzy comprehensive evaluation method is adopted to calculate the geology park health index.

Evaluation system construction

The ecological health system of Qianjiang Xiaonanhai National Geological Park is typical and complex. It is a growing giant system with multilevel. For the giant

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38393859

multivariable system, we use the description of state variables to reflect its inherent laws. According to the principle of representativeness, the selection of indicators was based on a large number of the results of previous literature and studies (Qin et al., 2013). Based on the "Driving Force-Pressure-State-Influence-Response" (DPSIR) model, an assessment index system of ecosystem health in Qianjiang Xiaonanhai Geopark was constructed. According to the actual situation of Qianjiang Xiaonanhai Geopark, 22 evaluation indices were selected, including 3 driving force indicators, 4 stress indicators, 7 state indicators, 5 impact indicators and 3 response indicators (*Table 1*).

The source of evaluation indicators

The research data are mainly from "Qianjiang 2012-2016 National Economic and Social Development Bulletin", "Chongqing Province Statistical Yearbook", "Qianjiang Yearbook", public data of Qianjiang District Protection Bureau of Chongqing Municipality, field investigation of Qianjiang Xiaonanhai Geopark, and from the principal office of the park.

Determine the indicators weight

The weight of eco-health evaluation index in tourist area is to empower the evaluation index relative to the importance of eco-health in scenic area to distinguish its contribution size. Determining the weight of an evaluation indicator is a very important element that directly affects the outcome of the evaluation.

The method of determining the index weight can be divided into two major categories: subjective weighting and objective weighting. Among them, the subjective empowerment method mainly based on expert advice and experience, such as expert scoring method, analytic hierarchy process, etc., objective empowerment is calculated by certain mathematical methods, such as principal component analysis, mean square error, the coefficient of variation method (Zhu et al., 2012). In this paper, according to the actual situation of ecological indicators in Xiaonanhai Geopark, in order to minimize the limitation of weight calculation, entropy weight method was used to empower each evaluation index of Xiaonanhai Geopark. In a specific operation, entropy weight method was based on the degree of variation of each index, then the entropy of each index was calculated, and the weight of each index was corrected through the entropy so as to obtain more objective and scientific index weight. Based on the data of health degree of Qianjiang Xiaonanhai Geopark from 2012 to 2016, the objective weight is determined according to the basic idea of entropy weight method, the size of index variability. In the comprehensive evaluation, the smaller information entropy of an index indicates the greater difference between the index values, the more relevant information provided, the more important role an index plays in the comprehensive analysis and evaluation, and thus the greater weight it should have; and vice versa (Shi and Chen, 2015).

Before evaluating, the data needs to be dimensioned before the metrics are empowered. In order to get a more objective weight, in this study, the objective weight of the indicator is calculated by the entropy method, and the calculation principle of the entropy method are as follows (Zhu, 2014):

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38393859

1) Each indicator's dimensions and units are different and cannot be directly compared and calculated. Therefore, before each indicator's weight is calculated, it needs to be standardized:
   When the indicator is a positive indicator, the standardization formula is:

$$x_{ij}^{'} = \frac{x_{ij} - x_j^{\min}}{x_j^{\max} - x_j^{\min}} \tag{Eq.1}$$

   When the indicator is a negative indicator, the standardization formula is:

$$x_{ij}^{'} = \frac{x_j^{\max} - x_{ij}}{x_j^{\max} - x_j^{\min}} \tag{Eq.2}$$

2) In order to eliminate the negative value of the translation process, after some standard values are normalized, there may be small or negative values. For normalization and convenience of calculation, the normalized values are shifted to eliminate the above situation.

$$x_{ij}^{'} = H + x_{ij}^{'} \tag{Eq.3}$$

   where H is the magnitude of the index shift, generally takeing 1.
3) The dimensionless process of the original data:

$$y_{ij} = \frac{x_{ij}^{'}}{\sum_{i=1}^{n} x_{ij}^{'}} \tag{Eq.4}$$

4) The entropy of each index is calculated as follows:

$$e_j = -\frac{1}{\ln n} \sum_{i=1}^{n} y_{ij} \ln y_{ij} \tag{Eq.5}$$

5) The difference coefficient of the first index is calculated as follows:

$$g_j = 1 - e_j \tag{Eq.6}$$

   (Among them, j = 1 ，2 ，the index number is p).
6) The weight of the first indicator is calculated as follows:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38393859

$$\omega_j = \frac{g_j}{\sum_{j=1}^{p} g_j} \qquad \text{(Eq.7)}$$

(Among them, j = 1 , 2 , the index number is p).

Table 1. shows the the weights of indicators.

Table 1. *Qianjiang Xiaonanhai Geopark ecosystem health*

Object Layer	Criterion Layer	Indicator Layer	Weights	Tendency
Qianjiang Xiaonanhai Geopark ecological health index system	Driving force (D)	Natural population growth rate（D1）	0.0391	-
		Tourist growth rate（D2）	0.0457	+
		GDP growth rate（D3）	0.0417	+
	Pressure (P)	Population density（P1）	0.0402	-
		Regional Development Index（P2）	0.0366	-
		Visitor space utilization concentration (P3)	0.0311	-
		Natural disaster days（P4）	0.0324	-
	Status (S)	Forest Coverage（S1）	0.0375	+
		Biodiversity（S2）	0.0387	+
		Tourism per capita consumption level（S3）	0.0487	+
		Negative oxygen ion content（S4）	0.0356	+
		Landscape fragmentation（S5）	0.0521	-
		Surface water quality（S6）	0.0684	+
		Air Pollution Index（S7）	0.0393	-
	influences (I)	Tourist area visibility（I1）	0.0414	+
		Tourist satisfaction（I2）	0.0818	+
		Suitable period（I3）	0.0345	+
		Total tourism revenue and GDP ratio（I4）	0.0485	+
		Per capita GDP（I5）	0.0358	+
	response (R)	The proportion of environmental protection in GDP（R1）	0.0466	+
		Tourism infrastructure intact rate（R2）	0.0424	+
		Improvement of laws and regulations（R3）	0.0818	+

"+" stands for positive indicators, "-" stands for negative indicators

According to the relationship between indicators and ecological health, we divided Qianjiang Xiao Nanhai scenic ecological health assessment indicators into two categories:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38393859

1) Positive indicator. The index is positively correlated with the degree of ecological health (positive index).The higher the index is, the higher the degree of ecological health will be. These indicators are e.g.: GDP growth rate, biodiversity and forest coverage indicators.
2) Negative indicator. The index is negatively correlated with the degree of ecological health (negative index), the higher the index is, the lower the degree of ecological health will be. These indicators are e.g.: the natural population growth rate, air pollution index.

Evaluation criteria

After confirming indicators and evaluation methods of Xiaonanhai Scenic Spot, the determination of each indicator was essential, which was the key to health degree assessment. The standard value (or reference value) of eco-system health evaluation of geoparks is constantly changing. The evaluation criteria of this study are mainly referring to the international, national, industrial and local standards, and the relevant standards in previous literature. According to the background and target value of the local tourism area, the ecological system of Xiaonanhai Geopark is divided into five subtypes: morbid (0.0-0.2), generally morbid (0.2-0.4), sub-healthy (0.4-0.6), healthy (0.6- 0.8), very healthy (0.8 ~ 1.0). *Table 2* shows the health rating and content of geopark.

Table 2. *Geological park ecological health rating and content*

Rating level	Very healthy	Healthy	Sub - healthy	General morbid	Morbid
Normalized Value	0.8～1.0	0.6～0.8	0.4～0.6	0.2～0.4	0～0.2

The Evaluation of established model

Fuzzy comprehensive evaluation method combines qualitative and quantitative analysis, unifies accuracy and inaccuracy, and integrates multiple factors (Zhu et al., 2012). The mechanisms and factors that affect the eco-health of tourism areas are very complicated. There are many things and factors that have ambiguous properties (Li, 2012).The interaction between them and the influence of each factor on system function are hard to accurately measure in terms of quantity. Therefore, in this paper, fuzzy comprehensive evaluation method is used to calculate the health index of Qianjiang Xiaonanhai Geopark, so as to scientifically evaluate the health status of its ecosystem.

Establish evaluation set

It is assumed that the fuzzy evaluation result of the evaluation index of the geologic park health degree is V. The evaluation grades are divided into morbid, generally morbid, sub-healthy, healthy and very healthy. The five rating criteria are set to s1, s2, s3, s4, s5. The standard value of each indicator and standard source have been described above. Constructed fuzzy evaluation sets V is:

V = {v1, v2, v3, v4, v5} = {disease, general morbid, sub-healthy, healthy, very healthy}.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38393859

Determine membership function

Membership function has various forms. The determination of the membership function was based on the nature of the evaluation index. General evaluation indices can be divided into two categories: positive (or inverse) and moderate indicators. For the positive (or inverse) index, the greater the value (or smaller), the better; for the moderate index, it is a better value when it is in the satisfactory range. The farther away from this interval, the worse its evaluation status will be (Yue and Liu, 2008):

1) The membership function of positive index
   According to the analysis of geology park health evaluation of the reality and evaluation purposes, ascending trapezoidal distribution function and linear triangular function can be used for the positive index membership function. The results are as follows:

$$y_{D1}(x)=\begin{cases} 0 & x \geq s_2 \\ \dfrac{s_2-x}{s_2-s_1} & s_1 < x < s_2 \\ 1 & x \leq s_1 \end{cases} \quad \text{(Eq.8)}$$

$$y_{D2}(x)=\begin{cases} 0 & x \leq s_1 or x \geq s_3 \\ \dfrac{x-s_1}{s_2-s_1} & s_1 < x \leq s_2 \\ \dfrac{s_3-x}{s_3-s_2} & s_2 < x < s_3 \end{cases} \quad \text{(Eq.9)}$$

$$y_{D3}(x)=\begin{cases} 0 & x \leq s_2 or x \geq s_4 \\ \dfrac{x-s_2}{s_3-s_2} & s_2 < x < s_3 \\ \dfrac{s_4-x}{s_4-s_3} & s_3 \leq x < s_4 \end{cases} \quad \text{(Eq.10)}$$

$$y_{D4}(x)=\begin{cases} 0 & x \leq s_3 or x \geq s_5 \\ \dfrac{x-s_3}{s_4-s_3} & s_3 < x < s_4 \\ \dfrac{s_5-x}{s_5-s_4} & s_4 \leq x < s_5 \end{cases} \quad \text{(Eq.11)}$$

$$y_{D5}(x)=\begin{cases} 0 & x \leq s_4 \\ \dfrac{x-s_4}{s_5-s_4} & s_4 < x < s_5 \\ 1 & x \geq s_5 \end{cases} \quad \text{(Eq.12)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38393859

2) The membership function of a reverse index
According to the analysis of geologic park's health status, the membership function of inverse indicators can adopt the half-trapezoidal distribution function and the linear triangular function as follows:

$$y_{D1}(x)=\begin{cases} 0 & x\le s_2 \\ \dfrac{x-s_2}{s_1-s_2} & s_2<x<s_1 \\ 1 & x\ge s_1 \end{cases} \tag{Eq.13}$$

$$y_{D2}(x)=\begin{cases} 0 & x\ge s_1 or x\le s_3 \\ \dfrac{s_1-x}{s_1-s_2} & s_2<x\le s_1 \\ \dfrac{x-s_3}{s_2-s_3} & s_3<x<s_2 \end{cases} \tag{Eq.14}$$

$$y_{D3}(x)=\begin{cases} 0 & x\le s_4 or x\ge s_2 \\ \dfrac{s_2-x}{s_2-s_3} & s_3<x\le s_2 \\ \dfrac{x-s_4}{s_3-s_4} & s_4<x<s_3 \end{cases} \tag{Eq.15}$$

$$y_{D4}(x)=\begin{cases} 0 & x\le s_5 or x\ge s_3 \\ \dfrac{s_3-x}{s_3-s_4} & s_4<x\le s_3 \\ \dfrac{x-s_5}{s_4-s_5} & s_5<x<s_4 \end{cases} \tag{Eq.16}$$

$$y_{D5}(x)=\begin{cases} 0 & x\ge s_4 \\ \dfrac{s_4-x}{s_4-s_5} & s_5<x<s_4 \\ 1 & x\le s_5 \end{cases} \tag{Eq.17}$$

where, x is the measured value of the evaluation index; s1 is the first level of the evaluation index (morbid) standard value; s2 is the second level of the evaluation index (general morbid) standard value; s3 is the third level of the evaluation index (Sub-healthy); s4 is the fourth level (healthy) of the evaluation index; s5 is the fifth level (very healthy) of the evaluation index.

The results of ecological health evaluation and empirical analysis

Membership matrix

Combined with the standard values of Table 2 and the intragroup weights of each indicator obtained through the normalization method, the data of 2012-2016 are

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38393859

calculated by MATLAB 2010b software, and the membership matrix of the driving force indicator is obtained as follows:

$$R_D^{2012} = \begin{bmatrix} 0 & 0.15 & 0.85 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad \text{(Eq.18)}$$

$$R_D^{2013} = \begin{bmatrix} 0 & 0 & 0.85 & 0.15 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad \text{(Eq.19)}$$

$$R_D^{2014} = \begin{bmatrix} 0 & 0 & 0.95 & 0.05 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad \text{(Eq.20)}$$

$$R_D^{2015} = \begin{bmatrix} 0 & 0.05 & 0.95 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad \text{(Eq.21)}$$

$$R_D^{2016} = \begin{bmatrix} 0 & 0 & 0.6 & 0.4 & 0 \\ 0 & 0.5867 & 0.4133 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad \text{(Eq.22)}$$

Fuzzy comprehensive evaluation

WD = (0.3089,0.3613,0.3298)

Thus, we can get the fuzzy evaluation result of driving force health degree from 2012 to 2016:

$$\begin{aligned} H_D^{2012} &= W_D \bullet R_D^{2012} \\ &= (0.3089, 0.3613, 0.3298) \bullet \begin{bmatrix} 0 & 0.15 & 0.85 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \\ &= (0, 0.0463, 0.2626, 0, 0.6911) \end{aligned} \quad \text{(Eq.23)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38393859

$$H_D^{2013} = W_D \bullet R_D^{2013}$$
$$= (0.3089, 0.3613, 0.3298) \bullet \begin{bmatrix} 0 & 0 & 0.85 & 0.15 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad \text{(Eq.24)}$$
$$= (0, 0, 0.2626, 0.0463, 0.6911)$$

$$H_D^{2014} = W_D \bullet R_D^{2014}$$
$$= (0.3089, 0.3613, 0.3298) \bullet \begin{bmatrix} 0 & 0 & 0.95 & 0.05 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad \text{(Eq.25)}$$
$$= (0, 0, 0.2935, 0.0154, 0.6911)$$

$$H_D^{2015} = W_D \bullet R_D^{2015}$$
$$= (0.3089, 0.3613, 0.3298) \bullet \begin{bmatrix} 0 & 0.05 & 0.95 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad \text{(Eq.26)}$$
$$= (0.3613, 0.0154, 0.2935, 0, 0.3298)$$

Health index

In this paper, we can get the result of comprehensive evaluation of driving force factor by using fuzzy centroid method, that is, the driving force factor health index is as follows (where cj takes the median of health score threshold, ie c1 = 0.1, c2 = 0.3, c3 = c5 = 0.9):

$$C_D^{2012} = \sum_{j=1}^{5} (h_j c_j) = 0.7672 \quad \text{(Eq.27)}$$

$$C_D^{2013} = \sum_{j=1}^{5} (h_j c_j) = 0.7857 \quad \text{(Eq.28)}$$

$$C_D^{2014} = \sum_{j=1}^{5} (h_j c_j) = 0.7795 \quad \text{(Eq.29)}$$

$$C_D^{2015} = \sum_{j=1}^{5} (h_j c_j) = 0.4843 \quad \text{(Eq.30)}$$

$$C_D^{2016} = \sum_{j=1}^{5} (h_j c_j) = 0.6143 \quad \text{(Eq.31)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38393859

By the same token, we can calculate the stress, status, influence, response factors and the health index integrated in 2012-2016.

The stress factor health index is calculated as follows:

$$C_P^{2012} = \sum_{j=1}^{5}(h_j c_j) = 0.4326 \quad \text{(Eq.32)}$$

$$C_P^{2013} = \sum_{j=1}^{5}(h_j c_j) = 0.4956 \quad \text{(Eq.33)}$$

$$C_P^{2014} = \sum_{j=1}^{5}(h_j c_j) = 0.5296 \quad \text{(Eq.34)}$$

$$C_P^{2015} = \sum_{j=1}^{5}(h_j c_j) = 0.5169 \quad \text{(Eq.35)}$$

$$C_P^{2016} = \sum_{j=1}^{5}(h_j c_j) = 0.5672 \quad \text{(Eq.36)}$$

The state factor health index is calculated as follows:

$$C_S^{2012} = \sum_{j=1}^{5}(h_j c_j) = 0.6270 \quad \text{(Eq.37)}$$

$$C_S^{2013} = \sum_{j=1}^{5}(h_j c_j) = 0.5930 \quad \text{(Eq.38)}$$

$$C_S^{2014} = \sum_{j=1}^{5}(h_j c_j) = 0.5324 \quad \text{(Eq.39)}$$

$$C_S^{2015} = \sum_{j=1}^{5}(h_j c_j) = 0.5152 \quad \text{(Eq.40)}$$

$$C_S^{2016} = \sum_{j=1}^{5}(h_j c_j) = 0.5967 \quad \text{(Eq.41)}$$

The impact factor health index is calculated as follows:

$$C_I^{2012} = \sum_{j=1}^{5}(h_j c_j) = 0.7293 \quad \text{(Eq.42)}$$

$$C_I^{2013} = \sum_{j=1}^{5}(h_j c_j) = 0.7635 \quad \text{(Eq.43)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38393859

$$C_I^{2014} = \sum_{j=1}^{5}(h_j c_j) = 0.7189 \quad \text{(Eq.44)}$$

$$C_I^{2015} = \sum_{j=1}^{5}(h_j c_j) = 0.7214 \quad \text{(Eq.45)}$$

$$C_I^{2016} = \sum_{j=1}^{5}(h_j c_j) = 0.7214 \quad \text{(Eq.46)}$$

The response factor health index is calculated as follows:

$$C_R^{2012} = \sum_{j=1}^{5}(h_j c_j) = 0.5546 \quad \text{(Eq.47)}$$

$$C_R^{2013} = \sum_{j=1}^{5}(h_j c_j) = 0.5958 \quad \text{(Eq.48)}$$

$$C_R^{2014} = \sum_{j=1}^{5}(h_j c_j) = 0.6097 \quad \text{(Eq.49)}$$

$$C_R^{2015} = \sum_{j=1}^{5}(h_j c_j) = 0.8109 \quad \text{(Eq.50)}$$

$$C_R^{2016} = \sum_{j=1}^{5}(h_j c_j) = 0.8273 \quad \text{(Eq.51)}$$

The general health index is calculated as follows:

$$C^{2012} = \sum_{j=1}^{5}(h_j c_j) = 0.6298 \quad \text{(Eq.52)}$$

$$C^{2013} = \sum_{j=1}^{5}(h_j c_j) = 0.6455 \quad \text{(Eq.53)}$$

$$C^{2014} = \sum_{j=1}^{5}(h_j c_j) = 0.6216 \quad \text{(Eq.54)}$$

$$C^{2015} = \sum_{j=1}^{5}(h_j c_j) = 0.6120 \quad \text{(Eq.55)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38393859

$$C^{2016} = \sum_{j=1}^{5}(h_j c_j) = 0.6643 \qquad \text{(Eq.56)}$$

Results

According to the results of the fuzzy comprehensive evaluation, the overall ecological health status of Xiaonanhai Geopark in 2012-2016 is "healthy", which is consistent with the reality of Xiao Nanhai scenic spot. The factors and indicators status analysis are as follows:

First, the "driving force" factors are all "healthy" except the "sub-healthy" state of 2015, but the score in 2015 and 2016 has dropped significantly. The economic benefits of Qianjiang Xiaonanhai Geopark generally show a downward trend. The natural growth rate of the local population is relatively high, which has a great burden on the environment. The growth rate of tourist numbers fluctuates from year to year shows even negative growth in 2015. This is also the main reason why the driving force declines in the score. The economic benefits brought by the geoparks are relatively limited. The driving force for economic growth and tourism development needs further improvement.

Second, the "stress" factor has been in a "sub-healthy" state (health degree: 0.4326-0.5672). However, due to the slowdown of the social and economic development in the "driving force" factor, the "stress" factor has a good development trend. The key indicators that have a negative effect on the "stress" factors are the "regional development index", "concentration of tourist space utilization" and "days of natural disasters". The method to balance the contradiction between the socio-economic benefits of the park and the pressure of the natural environment still needs to be further explored.

Third, the "state" factor is basically in a "sub-healthy" state except in "healthy" state in 2012. Due to the "stress" factor, the "state" factor tends to be "healthy" in 2016. However, the change of "pressure" factor is larger than that of "state" factor, which shows that the influence of "pressure" factor on the ecosystem health of Xiaonanhai scenic spot has some lag. According to the score, the overall state of the Xiaonanhai Geopark in Qianjiang is relatively stable, and the status of vegetation, biology and air quality are in a healthy state and above. However, the pollution status of surface water needs to be improved.

Fourth, affected by the "state" factor, the "impact" factor is basically in a "healthy" state (health: 0.7635-0.7214). Overall tourist satisfaction has brought positive publicity to the scenic spots. However, because of the limitations of such factors as the landscape quality, the geographical location of the park and the incompleteness of the surrounding recreational facilities, the popularity and the exposure of the media is relatively low. To a certain extent, all these limited the further development of the park.

Fifthly, due to the good development of "influence" factor, "health" has been maintained. In the face of "sub-health" state of "stress" factor and "state factor" (Health: 0.5546) The status gradually improved to become "very healthy" (Health: 0.8273). The state of infrastructure in the park is intact. With increasing investment in infrastructure and environmental protection in the park, the government has also formulated more complete laws and regulations for the tourist attractions and improved the internal governance framework of the park.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38393859

Sixthly, although the "stress" factor and the "status" factor have the threat of being "sub-health", the overall health status of the park has shown a "healthy" state in recent years, and the overall development trend is good. However, due to the obvious difference between the indicators, the key factors affecting the health of Qianjiang Xiaonanhai Geopark are also the focus of sustainable development in the future. The main focus is on the growth of tourist population, regional development index, tourist space utilization, and tourist popularity of these indicators. In short, the protection should be taken into account to ensure the healthy development of regional ecosystems without exploiting.

Compared with previous studies, this paper adopts fuzzy comprehensive evaluation method instead of the commonly used AHP method, which can more comprehensively evaluate the health level of geoparks; Moreover, because the health assessment methods are relatively new, no one has yet addressed special evaluation of the health of geoparks. Therefore, this paper has a strong innovation in the establishment of the evaluation index system for geoparks and the calculation methods.

Figure 2 shows the 2012-2016 overall condition of factors and comprehensive score trends of the Qianjiang Xiaonanhai Geopark.

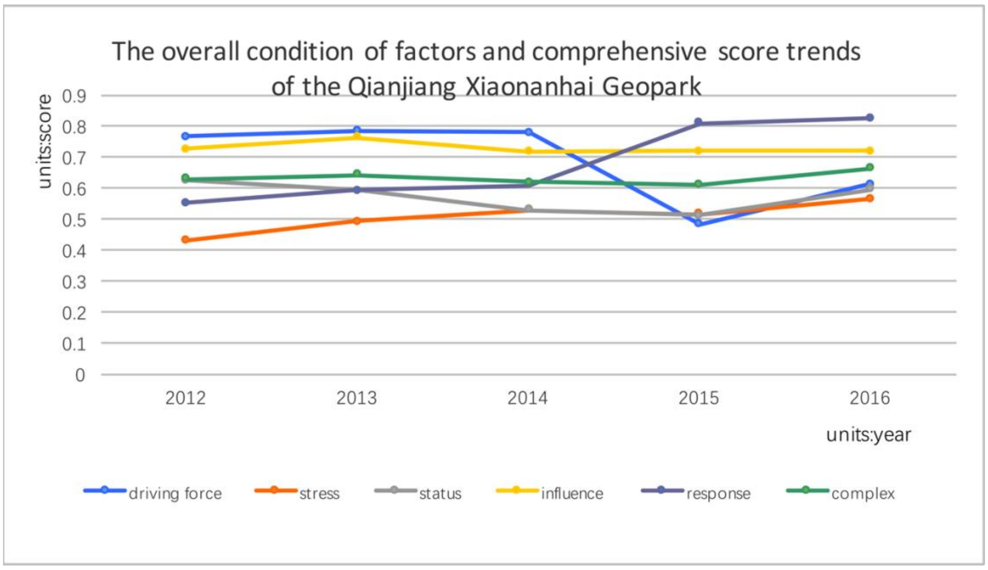

Figure 2. *The overall condition of factors and comprehensive score trends of the Qianjiang Xiaonanhai Geopark*

The protection and countermeasures of development

The Qianjiang Xiaonanhai Geopark has developed steadily in recent years, and the overall ecological health level is "healthy", but some indicators are too low, reflecting the obvious shortcomings in the construction and development of the geopark. Based on the results of empirical analysis and field investigation, we propose the following countermeasures and suggestions for Xiaonanhai Geopark:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38393859

Improve the mechanism of talent introducing and the overall quality and management level of employees

The development of the Xiaonanhai Geopark needs leaders with long-term development strategic vision and a group of managers with the rich professional knowledge to undertake the important task of protecting geological relics. The duties of all staff positions should be cleared. The assessment system should be formulated, and all aspects should be introduced to professionals. They can provide professional guidance for the construction of geoparks based on the needs of the park.

Establish Qianjiang Xiaonanhai Geopark Museum, improve public facilities within the park, and further carry out popular science education, geological teaching and geological heritage tourism

At present, the science popularization facilities in Xiaonanhai Geopark are still in a backward state. We should further speed up the construction of popular science museums in the park, improve the design and the layout of geological knowledge explaining cards, equip the park with the corresponding geo-knowledge voice explaining equipment, give full play to the characteristics of science popularization in geological parks, set up a tourism network that takes science tourism as the leading role and build boutique tourism route.

Organize the implementation of funds, speed up the construction of key scenic spots and improve the surrounding facilities

Due to funding constraints, the process of Xiaonanhai Geopark internal construction is extremely slow. At present, the level of the key scenic spots construction in the Xiaonanhai Geopark is very low, and tourists have a very poor view. There are almost no matching facilities around the scenic spots and the tour process is extremely inconvenient. On the one hand, sources of funds can seek the support of national policies; on the other hand, the park can set up the Qianjiang Xiaonanhai Geopark Sustainable Development Fund, accepting donations and financing from all walks of life to provide the material guarantee for the internal construction of scenic spots.

Cooperate with scientific research organizations of universities, formulate scientific and feasible scientific research plans so that the sites can be scientifically protected and developed

The site of Xiaonanhai Geopark has great scientific value and potential for scientific research, and its future research should attract the attention of scientific research organizations in relevant disciplines. Xiaonanghai Geopark can cooperate with the organizations of universities and colleges in the relevant disciplines, regularly repair and reinforce the sites and formulate a series of scientific and feasible scientific research plans so as to protect better and scientifically utilize the precious relic resources.

Organize high-quality science popularization activities in geosciences, improve foreign media window and the public and media exposure and enhance the scenic spot popularity

The small amount of tourists in the Xiaonanhai geological park, to a large extent, is caused by the low popularity of the scenic spot. Geoparks can regularly organize activities of science popularization to increase the public interaction rate. At the same

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38393859

time, the park can establish and improve self-media platforms such as Weibo, official account of wechat and websites of scenic spots so as to improve the amout of information output and radiate influence and enhance the visibility of scenic spots.

Plan scenic spot development, improve space utilization efficiency and further improve the management system

At present, the interior planning of the Xiaonanhai Geopark is rather chaotic. There are 7 major programs in Xiaonanhai such as scenic spot planning, holiday area planning and nature reserve planning. The plans do not converge with each other. Therefore, the park planning and implementation are difficult. There should be a unified planning and layout designing of the Xiaoganhai Geopark, and a further improvement of the park's internal management system should be implemented, such as implementing the smooth management to avoid the restriction of various departments so as to enhance the efficiency of planning and implementation.

Based on the predecessors' ecological health theory, we compared most of the existing research index system evaluations to a large industry, such as tourism, and there is no specific evaluation index system for specific environments. There is very little research on a new concept, and we have constructed an ecological health assessment index system based on the DPSIR conceptual model specifically for geoparks, which makes up for the gap in this area to a certain degree, aiming at future generations to address the health of geoparks. The degree study provides reference. It has a high degree of innovation and uses Minjiang Xiaonanhai Park as a specific case. It proposes an evaluation method for the ecological health index of geopark tourist areas based on fuzzy mathematics and shows how to evaluate the ecology of the target area. The complete process of health puts forward scientific countermeasures and suggestions according to local conditions, which has high practical value and responds to the call of green tourism and is conducive to sustainable development.

Discussion

Based on the theory of ecological health, this paper takes Chongqing Xiaojianghai Xiaonanhai Geopark as an example. Based on the DPSIR conceptual model, an ecological health index evaluation system suitable for geoparks is constructed. The weights are confirmed by entropy weight method and multilevel fuzzy synthesis is used. The evaluation method calculates the ecological health degree of the geopark and concludes that the comprehensive health index of the park in the past five years is in a generally healthy state. The results show that the highest score of Qianjiang Xiaonanhai Geopark is 0.6643, and the lowest score is 0.6120. Based on local conditions, reasonable suggestions are proposed for the sustainable development of the Qianjiang Xiaonanhai Geopark.

Based on the predecessors' ecological health theory, compared with most of the existing research index system evaluations to a large industry, such as tourism, we found that there is no specific evaluation index system for specific environments. There is very little research on a health degree, and we have constructed an ecological health assessment index system based on the dpsir conceptual model specifically for geoparks, which makes up for the gap in this area to a certain degree, aiming at future generations to address the health of geoparks. The degree study provides future reference and has a high degree of innovation. It proposes an evaluation method for the ecological health

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38393859

index of geopark tourist areas based on fuzzy mathematics, and shows the complete process of how to evaluate the ecology of the health degree of a target area. Moreover, it can put forward scientific countermeasures and suggestions according to local conditions, which have high practical value. This research responds to the call of green tourism, which is conducive to sustainable development.

Conclusion

Ecological health and its evaluation are a very new and constantly updating field and ecological health of tourism areas is a new research direction. The development and protection of geopark tourism areas is a hot topic in current tourism industry. This article introduces the concept of a comprehensive assessment of health, and it is a groundbreaking and exploratory work in the geopark tourist area. However, due to time and energy and data acquisition reasons, there are still some fields worth deep study:

First, the size of sample on the study should be increased and a more detailed investigation and analysis should be done. More common conclusions could be drawn and further improvement of the construction of index evaluation system could be implemented.

Second, further follow-up research should be carried out, through longer-term data tracking and analysis, to understand the relevant factors and mechanisms of ecosystem health, and to select the same type of tourist areas at different stages of development for comparative research. Different tourism development stages should be compared and continuously study on the impact of ecological health.

Third, the concept of ecological health assessment could be applied to other areas and the research could be further expanded. The cross-contrast between different industries should be enhanced and the conceptual connotation of the research field should be enriched.

(Received 12th Feb 2018; accepted 17th May 2018)

Abstract. Vegetation coverage seasons are affected by climatic elements and changes in climatic elements influence the vegetation growth period. The purpose of this research is to identify the vegetation coverage seasons of Iran, with the help of the Enhanced Vegetation Index (EVI). In this research, 16-day data of Iran's Enhanced Vegetation Index (EVI) was downloaded from MODIS Aqua website from July 14, 2002 to March 14, 2015. Then, on the basis of nearly 10 billion cells, the long-term mean of the 16-day EVI was calculated, and a time-location array was obtained at a dimension of 23*7541502. The results of cluster analysis on the Euclidean distances of this array were investigated by Ward method. This study shows that according to the local pattern of EVI in Iran, there are three different seasons, including a massive/dense season (from the April 14th to the June 1st) that the highest density is in the north and west of Iran, a transition season (from the June 17th to the October 7th) that the highest compression on the Caspian Sea coast, and less severity along the Alborz heights, and the season of thinning (from the October 23rd to the March 29th), the highest density of which is along the coast of the Caspian Sea, on the Khuzestan plain, and also in the southern half of the country.
Keywords: *vegetation, cluster analysis, EVI, MODIS, Iran*

Introduction

The MODIS sensor provides comprehensive information on the surface of the Earth, the Oceans, and the Atmosphere in a variety of different spectrums (Babu et al., 2016). By using the data of the MODIS, better maps of the vegetation coverage of the Earth can be provided. With these maps, estimates of the distribution of different types of vegetation coverage at ground level would be obtained (Mumtaz et al., 2017). Changes of vegetation coverage that occur during a year through different seasons, can be used as a factor for the interpretation of vegetation coverage maps (Di Vittorio and Georgakakos, 2018). In fact, the growing seasons show the growth conditions of different types of vegetation coverages throughout the year (Yang et al., 2017). The growing seasons are the most affected by the climate (Tsalyuk et al., 2017; Moriondo and Bindi, 2007) which determine the start and termination of the climate systems of the beginning and end of the growing seasons (Testa et al., 2018). In a study the relationship of vegetation coverage changes between the border of the desert of Africa and the West of Africa, which is known to have a minor effect on the monsoon cycle, was investigated (Zheng and Eltahir, 1998; Zhang et al., 2015); therefore, the coastal deforestation may be the cause of the disappearance of the monsoon, and have a great effect on the precipitation of the area (Ardo et al., 2018). According to research Ratana et al. (2005), the vegetation coverage index in Korado shows a high seasonal contradiction in the dry season between June and August, and the wet season between November and March; and also Muhammad et al. (2016) and Shi et al. (2017) have classified important products and vegetation coverage based on the Enhanced Vegetation Index (EVI) and images from the MODIS sensor.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38613872

Erasmi et al. (2009) investigated the reduction of forage productivity, a 10-day combination index of the normalized vegetation coverage, that was used for imaging (and measuring) the 250-meter resolution of the MODIS sensor. In a study, using MODIS sensor data to rebuild the vegetation coverage dynamics, in response to climate patterns for the period 2001-2005 was used for North America. In a study by Cabello et al. (2012), the regional and spatial responses of the enhanced vegetation coverage profile are attributed to environmental factors, but in the dry regions of the Southeast of Spain on an annual scale is reviewed, and the effect of climate on this index has been revealed (Villani et al., 2011; Knezevic et al., 2017). The research results of Lorenz et al. (2013) show that vegetation coverage phenology has a limited effect on the mean of European summer climate (Hilker et al., 2015). The results of Jamali et al. (2011) showed that NDVI and EVI are highly correlated with soil moisture at all sites up to a 1 m depth implying strong relationships between vegetation growth and soil moisture at these depths, where most of the root biomass is located. Furthermore, EVI shows slightly higher correlations with soil moisture than NDVI at all sites during the growing season. In addition, EVI responds to soil moisture changes earlier than NDVI by about 0-4 days at the sub-Saharan sites where rainfall is a controlling factor. These slightly stronger relationships with EVI might occur because of improved corrections for variations in atmosphere, soil, and canopy background which make it sufficient for monitoring open canopy areas such as grasslands and savannas (Huete et al., 1997). Based on Peng et al. (2017) the effects of rainfall on vegetation coverage vary according to the rainfall time and the type of growing form, so that in urban areas, there is no significant relationship between the amount of precipitation and the vegetation coverage, in any time scale. In pasture lands, the strongest correlation is observed between the spring rainfall and the vegetation coverage changes, while the forest area shows the strongest correlation with annual precipitation (Pisek et al., 2015), and the strongest correlation with rainfall in spring and March is seen in the arable land (Allen et al., 2010), In the meadow areas, there is also a stronger correlation between rainfall and bushes (Son et al., 2014). Regarding the identification and classification of changes in the plant growth index (EVI) by MODIS sensor in Jiangxi province of China (Zhang et al., 2014; and Raghavendra and Aslam, 2017), in Karnatkay of India, in the southern part of Vietnam, and in Uttar Pradesh of India some research studies were done (Bansal et al., 2017). Since the vegetation coverage seasons show the condition of the vegetation coverage compression of an area throughout the year, and also its effect on the life of plant and animal ecosystems, the purpose of this study is to identify the seasons of Iran's vegetation coverage, based on the enhanced vegetation index (EVI) by using the MODIS Aqua sensor.

Data and Methods

In this research, the data of MODIS Aqua sensor were used for dividing the vegetation coverage into seasons in Iran. The MODIS Aqua sensor was launched on the June 4th, 2002 by NASA (Vermote et al., 2002). The time the satellite passed over the equator was 13:30 local time (Wang and Xie., 2009). To find the seasonal vegetation coverage of Iran, at first, the 16-day data of the Enhanced (Growth of) Vegetation Index (EVI) of the MODIS-Aqua with a local resolution of 500 meters in the time interval from July 14, 2002 to March 14, 2015were extracted from the MODIS website, which covered the territory of Iran in 6 tiles. The dimensions of each tile was 3600*2400 cells,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38613872

and each square cell was 463.31 meters. Six tiles were said to be one mosaic, which means that there are 23 mosaics of 16 days throughout the year. Due to the fact that the used data also included the extraterritorial land of Iran, with the help of the in-polygon function of the MATLAB software, only the data that were covering the geographical intra-boundary of Iran were extracted. The long-term mean of vegetation coverage of Iran was calculated for every 16-days, that for each, an array of 7200*4800 cells was obtained. These estimates are representative of the local behavior of vegetation coverage in every 16-days of the year, with the arrangement of a time-local array of dimensions of 23*75841502. This array was the basis of our judgments for dividing the vegetation coverage into seasons in Iran.

EVI was developed to optimize the vegetation signal with improved sensitivity in high biomass regions and improved vegetation monitoring through a de-coupling of the canopy background signal and a reduction in atmosphere influences (Aulia et al., 2016; Ogilive et al., 2015).

$$\text{EVI} = G\,\frac{N - R}{N + C_1 R - C_2 B + L} \tag{Eq. 1}$$

where N, R, and B are atmospherically corrected or partially atmosphere-corrected (Rayleigh and ozone absorption) surface reflectances in near-infrared, red and blue bands respectively; G is a gain factor; C1, C2 are the coefficients of the aerosol resistance term, which uses the blue band to correct for aerosol influences in the red band, and L functions as the soil-adjustment factor, attributed to the interaction and feedbacks between the soil-adjustment factor and the aerosol resistance term (Liu and Huete, 1995; Jiang et al., 2008). The coefficients adopted in the MODIS EVI algorithm are, L = 1, C_1 = 6, C_2 = 7.5, and G = 2.5. EVI has been used recently in a wide variety of studies, including those on land cover/land cover change (Wardlow et al., 2007), estimation of vegetation biophysical parameters (Chen et al., 2004; Houborg et al., 2007), phenology (Ahl et al., 2006; Zhang et al., 2003; Bolton and Friedl, 2013), evapotranspiration (Nagler et al., 2005; Nouri et al., 2016), biodiversity (Waring et al., 2006; Sloan et al., 2014), and the estimation of gross primary production (GPP) (Rahman et al., 2005; Zhang et al., 2014).

Accordingly, at first by calculating the Euclidean distance of the vegetation coverage of the entire local points of the array k before all the mosaics, we measure the dissimulated degree of the sites (*Eq. 2*).

$$d_{rs}^2 = (k_r - k_s)(k_r + k_s)' \tag{Eq. 2}$$

d_{rs}^2 is the Euclidean distance of the point *r* with the coordinates of $(\varphi_r . \lambda_r)$ and the point *s* with the coordinates of $(\varphi_r . \lambda_r)$ or the Euclidean distance of the *r* group and the *s* groups;

k_r is the vegetation coverage of the *r* spot or group;

k_s is the vegetation coverage of the *s* spot or group;

After measuring the Euclidean intervals, a cluster analysis was performed by Ward method into an array of distances (M), and the 75841502 point of the *k* array was arranged together in accordance with the simulated degree (*Fig. 2*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38613872

In the method, the R and S groups are merged if the increase in the variance resulting from their integration is minimized relative to the integration of each of them with other groups (*Eq. 3*):

$$d(x.y) = \frac{n_r + n_s + n_{rs}^2}{(n_r + n_s)} \quad \text{(Eq. 3)}$$

Here n_{rs}^2 is the distance between the group *r* and the group *s*, that are obtained by the central transplant method. n_r is the number of members of the group *r*, and n_s is the number of members of the group *s*. Based on this analysis, Iran has three seasonal vegetation coverages (*Fig. 2*). For a better understanding of the phenomena, the Iranian Digital Elevation Model (DEM) is depicted in 500-m location with a sine-image system (*Fig. 3*). By distinguishing the vegetation coverage of each of the *k* array local spot, the map of seasonal vegetation coverage of Iran was drawn (*Figures 4, 5, 6*).

Results and Discussion

Figure 1 shows the Enhanced Vegetation Index (EVI). According to the definition of EVI the values between 1-0.8 represent a very dense vegetation cover, 0.8-0.6 represent dense cover, 0.6-0.4 stands for average cover, 0.4-0.2 correspond to sparse, 0.2-0 represent a poor and the background soil (Chakraborty et al., 2016). of course, a range of 0.1 indicates the background soil, and 0.2-0.1 can also indicate grasslands and bushes (Zhou et al., 2016), which are known as the soil in this research. The values of less than zero are also known as water resources, which may be lakes, wetlands, dams, snow, and even mountain ice (in the cold season). In general, in this study, the EVI values are considered to be more than 0.2 as vegetation covering.

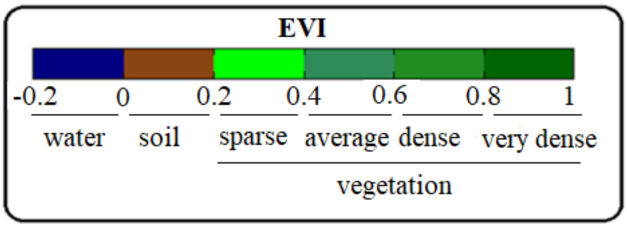

***Figure 1.** The Defined Values of EVI in this Research*

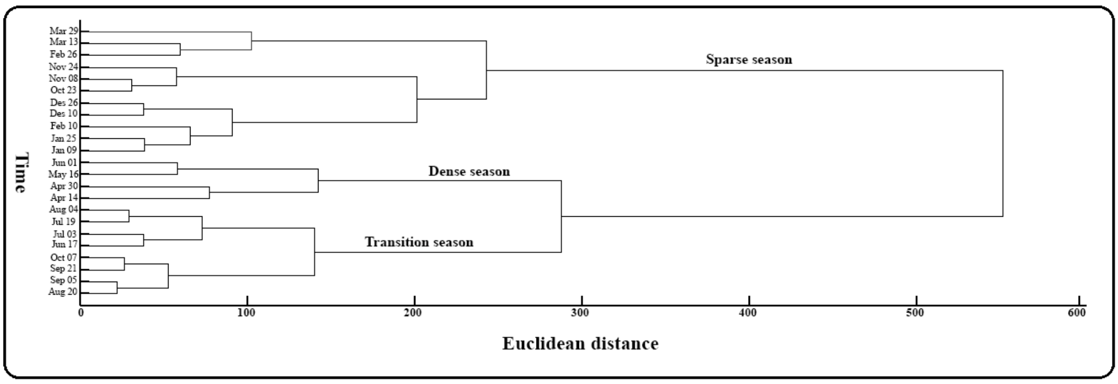

***Figure 2.** The Clustering of EVI by Ward method*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38613872

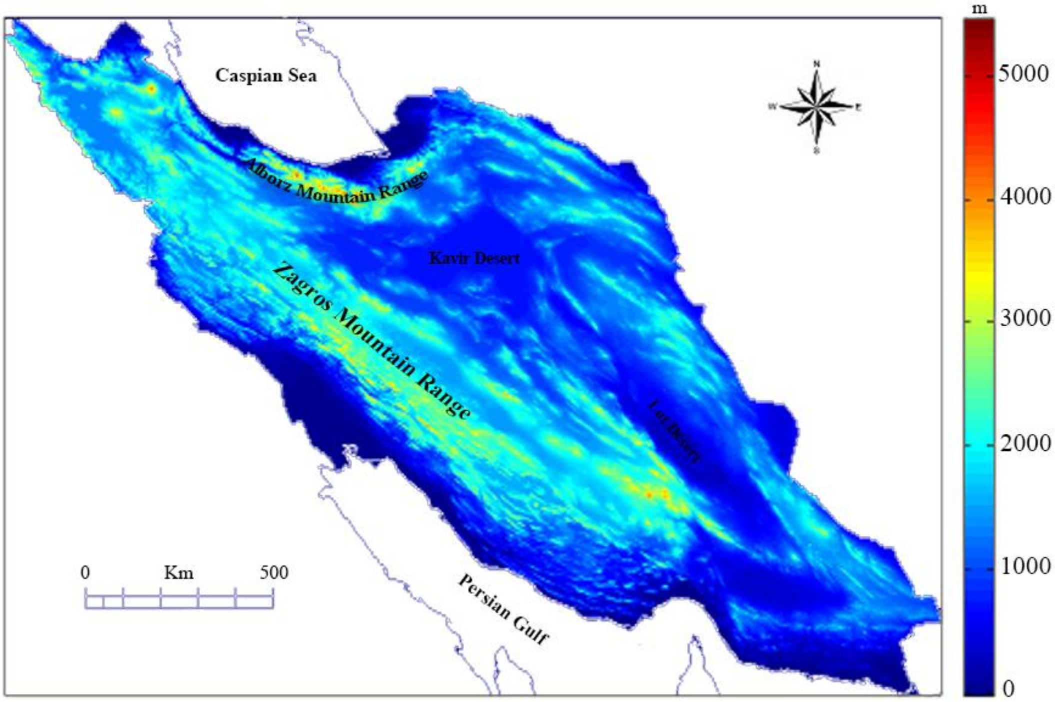

Figure 3. *Digital Elevation Model of Iran in 500 m spatial resolution with a sine image system*

By analyzing the clustering method, the country of Iran was divided into three dense, transition, and sparse seasons, regarding the vegetation coating, as shown in *Figure 2*.

The Sparse Season

Figure 4 shows the long-term mean of the vegetation coverage of the sparse season in the period from the October 23rd to the March 29th. During this time period, the vegetation coverage is insignificant, so that only 2.5 percent of the country's coverage is covered, and this amount is also sparse. The highest density of vegetation coverage in the Northern half of the country was only seen along the coasts of the Caspian Sea, and in the Southern half of the country in the plain of Khuzestan, Bushehr, West of Kohgiluyeh and Boyerahmad, South of Fars and Kerman, North and Northeast of Hormozgan. The main cause of the most densely populated vegetation cover in the mentioned areas is temperate temperature and winter rainfall, while in other parts of the country, there is no plant in this time period due to the low temperature, snow and ice cover. In addition to the mentioned areas, in the central regions of Southern Tehran, Qom and the East of Isfahan, in the Western regions of Western Kermanshah, East of Ilam and West of Lorestan, in the East of the country in the West and South of Xorasan Razavi and North of the South Xorasan, and finally in the North of the country, in the North of Ardabil Province, in the plain of Moghan very weak and dotted areas of the sparse vegetation coverage were observed. Mean, dense, and very dense vegetation is not seen in any part of the country. Because of the low temperature, snow and rain, the area of snow, ice cover and water is maximum amounts, that cover about 1.3 percent of the country's coverage. Through the broad surface, in the Northern parts of China (Mao et al., 2014), the coasts of Africa (Fetzel et al., 2015), the North of America (Potter et

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38613872

al., 2008), and the coastline of the country Mali (Spiekermann et al., 2015) seasonal variations of temperature changes the plant's vegetation coverage. The blue color in the map shows from one side, the snow cover on the Alborz and Zagros heights and the peaks of Sabalan and Sahand, and on the other side, the waters of Urmia Lake and the lakes of Fars Province. About 96 percent of the country's land is covered by poor vegetation/soil cover.

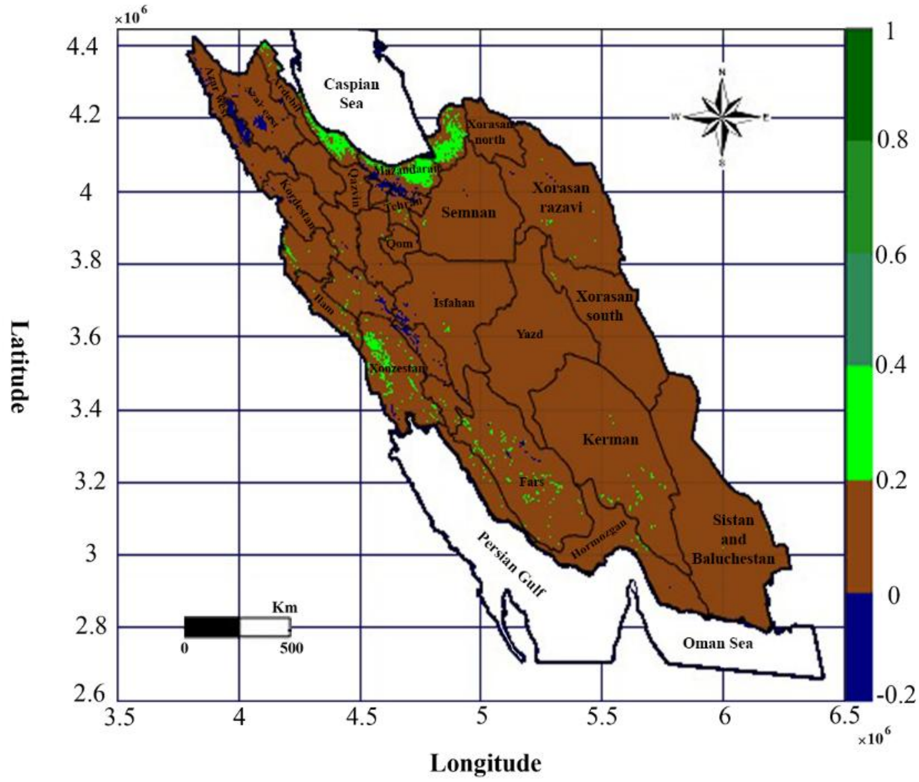

Figure 4. *The Long-term mean Sparse season from October 23rd to March 29th*

The Dense Season

Figure 5 shows the long-term mean of vegetation coverage of the dense season in the period from the April 14th to the June 1st when the vegetation coverage growth is at its peak. In this period, the sparse vegetation coverage is still very wide and covers about 12.5 percent of the country, its highest density was observed in the Western half of the country, along the Zagros mountains and throughout the Northern half of the country, and even the Northeast of the country. The mean vegetation coverage in this interval is at its maximum amount, and covers about 1.5 percent of the country. The highest density of the mean vegetation coverage was observed along the coasts of the Caspian Sea; in addition to this area, it was observed in the Northwest of the country in the provinces of West Azerbaijan, and also the Sahand slopes in Azar East and the Sabalan slopes in Ardabil and in the Western provinces of the country, the provinces of Kermanshah, Hamedan and Lorestan, also in the provinces of Chaharmahal and Bakhtiari and Kohgiluyeh and Boyer Ahmad in the Southern half of the country. Also, in the mountains of Southern Alborz slope and central regions of the provinces of Fars and Kerman, there is the mean vegetation coverage, spottedly. In this period of time,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38613872

since it is at its peak of growing, there is also a dense vegetation covering about 1480 square kilometers of the country that only was observed by the Caspian Sea, especially by its Southern coast. The soil surface has declined due to the significant increase in vegetation coverage over this time period, and covers about 85.4 percent of the country. The coverage of snow, ice, and water involves about 0.4 percent of the country. The color blue on the map, in this period, shows the other water resources and rivers of the country, such as the lakes of Fars Province, Shadegan wetland in Khuzestan, Hirmand River in Sistan and Baluchestan, Zayandehrud in Isfahan, as well as rivers along the Alborz and Zagros heights. At this time, the extent of the snow and ice cover is very small, and can only be spotted in the Alborz and Zagros heights. In general, during the dense season 14.14 percent of the country is covered by vegetation including sparse, transition, and dense. Even in this season, where vegetation is maximized, there is no massive vegetation, and it shows the poor vegetation of Iran.

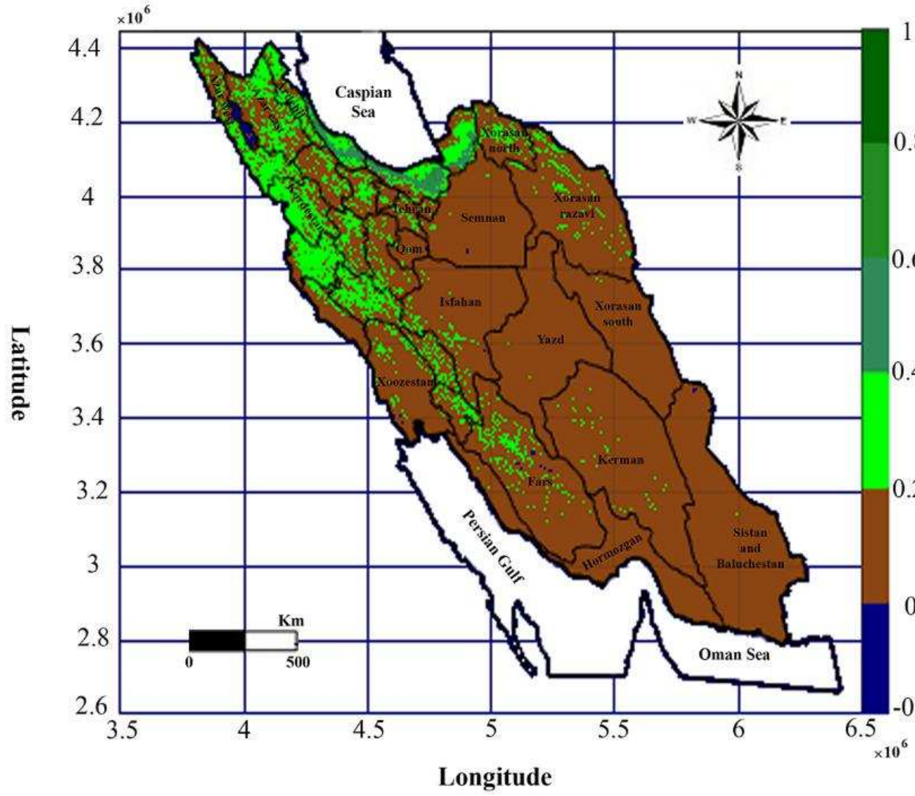

Figure 5. *The Long-term mean Dense season from April 14th to June 1st*

The Transition Season

Figure 6 indicates the long-term mean vegetation coverage of the transition season in the period from the June 17th to October 7th, which is exactly in the warm period of the year. During this period, the sparse vegetation coverage, which is sporadic in most parts of the country except the central and Eastern deserts of the Southeast, it covers about 3.8 percent of the country's territory. By looking at the map, it can be seen clearly that the sparse vegetation coverage, except the Caspian shores, in other parts of the country almost everywhere is consistent with the high altitudes of the country, so that in the Northern half of the country, this vegetation coating along the Alborz highlands, in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38613872

Western half of the corresponding of the Zagros heights and in the North-East of the country, which is in line with the altitudes of Xorasan. In addition to the mentioned areas, in the southern regions of the country, the sparse vegetation coverage in this interval is almost in line with the high altitudes, so that the existense of the vegetation coverage of Zagros, in the range of Kohgiluyeh and Boyer Ahmad provinces, Chaharmahal and Bakhtiari and Fars, as well as in the desert provinces of Kerman and Yazd, on the highlands of Laleh Zar and Shirkooh, are well known. The reason for the presence of denser vegetation coverage on the heights compared to the plain areas in this time interval on the one hand can be attributed to the presence of adequate amount of water, on the other hand to the proper temperature, which helps the growing of vegetation cover. In addition to the above altitudes, there is also the presence of sparse vegetation coverage along Zayandehrud and Khuzestan plain. The mean vegetation coverage covers about 1.2 percent of the country and its highest density is along the coasts of the Caspian Sea due to its favorable rainfall and temperate temperature in this area during this time period for vegetation cover. After the coasts of the Caspian Sea in the North and West of the country, the mean vegetation coverage is significant in the province of the East Azarbayjan, in the Sahand slopes along the Aras river in the North of this province, and in the Azar West Province, in the West of the Urmia Lake. In addition to the mentioned areas, the average vegetation cover is also found in limited areas in the southern Alborz and the central and northern heights of the Zagros Mountains. The dense and very dense vegetation coatings at this time, are not visible at any point in the country. The water content is also 0.34 percent. At this time of year, the amount of soil is significant and covers about 94.5 percent of the country's total area.

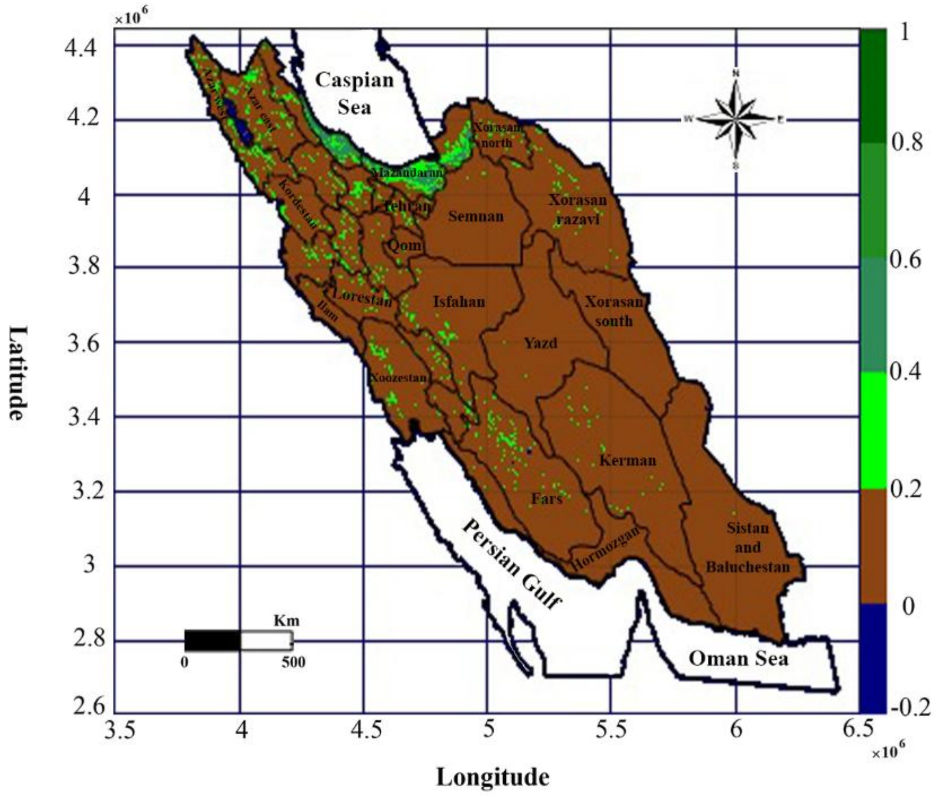

Figure 6. *The Long-term mean Transition season from June 17^{th} to October7^{th}*

DOI: http://dx.doi.org/10.15666/aeer/1604_38613872

Conclusion

The vegetation coverage changes that occur during a year through different seasons, can be used as a factor in the interpretation of vegetation coverage maps. The purpose of vegetation coverage indices is to predict and evaluate some of the characteristics of the vegetation coating, such as the crown covering, biomass, leaf spread, or the percentage of vegetation coating. In this study, initially, from the total of 23 maps of the 13-years long-term mean period was taken, and in the next step a cluster analysis was carried out resulting in the creation of clusters of maps that are similar to each other. Then, it was classified into Iran's growing seasons by the Ward method; Iran has three vegetation (and growing) seasons over the year; the first season has a dense vegetation coating, and its period is from the April 14th to the June 1st. In this season, about 14 percent of Iran's area, due to the temperature and precipitation adjustments, is covered by plants. Its highest density is seen in the Zagros, Alborz, Northeastern highlands and along the coasts of the Caspian Sea. In the second season, the vegetation coverage is in the transitional stage, and covers the period from the June 17th to October 7th, and its highest density is observed along the coasts of the Caspian Sea and the highlands of Alborz and Zagros. The third season has a sparse vegetation covering, and its period is from the October 23rd to March 29th, and due to the coldness of the air in most parts of the country, only 2.5 percent of Iran's territory is covered. Its highest density is along the coasts of the Caspian Sea, Khuzestan plain, and Southern half of the country. For future studies, it is recommended to compare vegetation indices such as EVI and NDVI in the study area.

(Received 22nd Feb 2018; accepted 24th May 2018)

Abstract. This research was carried out in order to determine the effects of worm fertilizer and nitrogen-phosphorus fertilizer dosage differences on flowering of hyacinth as a bulbous ornamental plant from 2016 to 2017 in Siirt University, Turkey. Solid worm fertilizer was applied at dosages of 25 g/bulb (V1), 50 g/bulb (V2), 75 g/bulb (V3) and 2 kg/decare (NP1), 4 kg/decare (NP2), 8 kg/decare (NP3) Nitrogen-Phosphorus (NP) were applied during the growth of hyacinth (*Hyacinthus orientalis* L. cv. "Purple Star"). According to the results, the lowest (the earliest time) mean values of the first flowering time, full flowering time, and harvest time were obtained as 135.25 days, 136.54 days, and 137.70 days in V1 treatment, respectively. The highest mean value on leaf number (5.71), leaf length (128.21 mm), stalk thickness (13.50 mm), and floret diameter (28.14 mm) were determined in V1. The highest mean values belong to flower diameter (66.96 mm) and length (116.33 mm) were evaluated in V2 and V3, respectively. Among NP fertilizers, in NP1 the highest mean value on floret number (37.69) while in NP2 the highest mean value on floret length (26.76 mm) were obtained. The highest mean values on leaf diameter and plant height were found as 28.86 mm and 179.54 mm in NP3 treatment. As a result, it has been determined that the hyacinth can be grown with worm fertilization without chemical fertilizer use under ecological conditions of Siirt province. Considering the adverse effects of chemical fertilizers on the environment, it is proved that there are no statistically significant differences between them and the worm fertilizer, which is a bio-fertilizer.
Keywords: *chemical fertilizer, flowering, hyacinth, ornamental plant, plant growth, worm fertilizer*

Introduction

Hyacinthus orientalis L. is a herbaceous flower belonging to the hyacinth branch of the Liliaceae family species (Hu et al., 2015). This species was originally cultivated in the Mediterranean region and in South Africa (van Sheepen, 1991). In 1768, more than 2000 varieties of this species were recorded (Darlington et al., 1951). According to Shen et al. (2004), nowadays the common hyacinth cultivars used for gardening are Holland and Rome species (Hu et al., 2015). The genus of hyacinths consists of 30 species among which only *H. orientalis* have horticultural importance due to their longevity as cut flowers. As well as grown hyacinths are generally between 10 and 30 cm tall and come in a wide range of colors. The swollen portion consists mostly of fleshy, food storing scales attached to a short flat stem. The plants start flowering in the first part of February (Smigielska et al., 2014). The plant prefers moist but light sandy to loamy soils. These soils could be acidic, neutral or alkaline. The hyacinth is widely cultivated in pots and is used as a cut flower worldwide (Hu et al., 2015). Its fragrance and graceful style have provided this flower with considerable ornamental value. Also, many distinctive ornamental plant groups live in Turkey due to its location that is the cross- section point of Mediterranean, Europe-Siberia and Iranian-Turanian phytogeographical regions and because different climatic conditions prevalent in its

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38733884

region, which cause natural floristic richness, biological difference and several habitat characteristics which are unique. Flower cultivation, which has a large natural potential in Turkey, is gradually growing importance and become a productive agricultural and commercial branch. Cut flower cultivation is a development of ornamental plant production having the largest part either in production or economic value. Cut flower production includes the processes, where fresh or dried flowers or their parts are used in clamps and arrangements in their original or colored forms.

This study was formulated to investigate the potential role of bio-fertilizer application for enhancing growth, and flowering of *Hyacinthus orientalis* in a sustainable agricultural production system in order to reduce the amount of excessive chemical material released to the environment. The experiment was conducted with varying dosage of nitrogen-phosphorus (NP) and worm fertilizer (V) on *Hyacinthus orientalis to* find out the effects on criteria of growth and flowering of plants.

Literature Review

Activities such as growing, choosing, procession, classification, storing and marketing of flowers are included in the cut flower production process. Nearly 50 countries produce cut flowers. Turkey is among the most important countries having the largest potential for cut flower growing with its climatic and topographical characteristics (Sönmez et al., 2013). Generally, farmers use chemical fertilizers to improve soil fertility and hence increase the yield of their crops. However, the use of chemical fertilizers causes a great impact on the soil quality and the surrounding environment. Vermicomposting is a non-thermopiles and simple biotechnological process of composting, in which certain species of earthworms and microorganisms are used for biological degradation of organic waste (Arancon and Edwards, 2005; Khan and Ishaq, 2011). Sangwan et al. (2010) who inferred that soil amended with 30% vermicompost produced more number of flowers in marigold (*Tagetes erecta* L.). The plants were grown in pot culture experiments and the largest flower diameter was produced in soil amended with 40% vermicompost. Further, the beneficial effect of vermicompost might be due to increased soil organic matter and improved physical properties of soil like bulk density and better aggregation. Edwards (1998) reported that vermicompost could promote early and vigorous growth of seedlings (Gopinathan and Prakash, 2014). Vermicompost has found to effectively enhance the root formation, elongation of stem and production of biomass, vegetables, ornamental plants etc. Also Chamani et al. (2008) studied the impact of vermicompost on the growth and flowering of *Petunia hybrida* 'Dream Neon Rose' in greenhouse conditions using 0, 20, 40 and 60% ratio of vermicompost and reported that vermicompost had positive, significant influence on the number of flower, leaf growth, and branch fresh and dry weights as compared to plants grown in vermicompost-lacking soil. Edwards and Burrows (1988) reported that vermicompost increased ornamental seedling emergence compared with those in control commercial plant growth media, using a wide range of test plants such as pea, lettuce, wheat, cabbage, tomato and radish however fertilizers are soil improvements applied to increase plant growth, the main nutrients added in fertilizer are nitrogen, phosphorus, potassium, other nutrients are added in small amounts. Fertilizers are required to bring out the best features of ornamental potted plants. For natural plants to grow and increase they need a number of chemical elements. Ashoorzadeh et al. (2016) found that vermicompost and NPK significantly improved the growth, yield and quality of rose flowers compared to control and that the improvement was greater when vermicompost and NPK fertilizers were mixed. Gangadharan and Gopinath (2000) reported that application of 10 t of vermicompost ha^{-1} + 80 percent recommended NPK dose per ha for obtaining higher yield and net return per ha in *Gladiolus* spp. was successful. Also Amarjeet et al. (1996) recorded an increase of flower stalk height and leaf length in tuberose with an application of a higher dose of NPK and increased flowering period and the largest panicle length was produced with 200:200:400 kg/ha NPK. In addition, they are eco-friendly, easily available and cost effective.

Materials and Methods

Experimental Site

The present experiment was carried out in the research and practice field of Siirt University Faculty of Agriculture, during the 2016-2017 vegetation periods (*Figure 1*). The research site is situated at the 37°58'12'' North latitude and 41°50'54'' East longitudes and at an altitude of 650 meters above sea level.

Figure 1. *Location of sampling site (Google maps, 2018)*

Siirt province has a semi-arid and subtropical climate with hot and dry summers, where maximum temperatures exceed 45°C, the winters are cold and the minimum temperatures can reach as low as 5°C in December and January months. Some climatic properties were presented in *Table 1.*

The soil is categorized as sandy loam with low aggregation. The chemical composition of the soil collected from 0-30 cm depth before planting of *Hyacinthus* bulbs. Some soil properties were determined as clay for texture type, neutral for pH, non-saline, medium lime, low for organic matter and phosphorus (P_2O_5) and sufficient for potassium (K_2O).

Experimental Details

This study was carried out with *Hyacinthus orientalis* L. cv. “Purple Star” as plant material. The experiment was laid out in a randomized block design with 7 treatments and three replicates including 12 bulbs per replicates. The plants were planted in November 2016, with solid worm fertilizer and 20:20:0 N:P:K fertilizer. The used solid worm fertilizer is obtained from *Eisenia foetida* culture worms known as red California worm produced by EkosolFarm producer company. Worm fertilizer dosages were used as 25 (V1), 50 (V2) and 75 (V3) g/plant on each bulb hole. 2 (NP1), 4 (NP2), and 8 (NP3) kg da^{-1} dosages calculated from N and P_2O_5 containing inorganic fertilizer were applied. The fertilizers were given at the time of planting.

Morphological Observations and Phenological Properties

Some of the observations and measurements performed are shown in *Figure 2*.

Figure 2. *Hyacinths in experimental site*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38733884

First flowering time (day): The period taken for the opening of the floret was recorded from the date of spike initiation for the first florets opening.
Full flowering time (day): A number of days required for the full flowering time or the floret opening from the plantation moment to 50 percent sprouting of florets.
Harvest time (day): When the last 1-2 florets closed have been seen.
Leaf number/plant: A number of leaves per plant were counted at harvest time.
Leaf length (mm): Leaf length was measured with digital compass.
Leaf diameter (mm): Leaf diameter was measured with digital compass.
Plant height (mm): Plant height was measured from the soil surface to the top of the plant.
Flower height (mm): The height of the flower was measured from the bottom floret to the top floret.
Flower diameter (mm): The width of the flower was measured for each flower.
Floret length (mm): The height of the floret was measured at full flowering time.
Floret diameter (mm): The diameter of floret was measured at full flowering time.
Floret number/flower: The number of florets per one flower was counted at full flowering time.
Stalk thickness (mm): The stalk thickness was measured at full flowering time.

Statistical Calculations

Data were analyzed by the analysis of variance method for two-factor randomized block design, by SAS 9.1 Statistical Package Program. The LSD multiple comparison test was used to compare the averages. Tests were conducted at α= 0.05 significance level (Düzgüneş et al., 1987). Descriptive statistics, like mean and standard errors, were presented for the investigated features.

Results and Discussions

The results of the present investigation related to the impact of NP fertilizers and worm fertilizer treatments, mainly on growth and floral parameters are explained in this section. The effects of all fertilizer types on parameters were not found statistically significant. The data of the final observations of the various parameters during growth and flowering period were subjected to statistical analysis and the results have been presented through tables and suitable diagrams.

Phenological Observations

First flowering time (day)

The data regarding days to first flowering time are presented in *Table 2*. No significant difference was observed in the case of first floret opening of hyacinth. The first floret opening was the earliest (135.25 days) in V1 which was closely followed by V3 and NP2 (*Figure 3a*). The control plants took the maximum days (136.35) which was followed by other treatment for the first floret open. Sönmez et al. (2013) showed that the lowest number of days to primary candle formation were 116 days, the lowest number of days to mature flower formation were 117 days, the lowest number of days to harvest were 121 days, the lowest number of days to primary candle formation were 123 days, in the case of gladioli plant. Sharma et al. (2003) observed that on onion growth. In the study, flowering and bulb production attributes of tuberose were recorded that among the different nitrogen dosages minimum time for sprouting were 14.74 days, which was recorded with the application of 300 kg N/ha whereas maximum time for the sprouting of bulbs (21.57 days) was recorded in control. Early sprouting in tuberose with higher doses of nitrogen, phosphorus, and their interaction might be due to the stimulation of bulbs by comparatively high nutrient availability (N and P) and their respective absorption through bulbs surface and primary roots. Keisam et al. (2014) observed that first flowering time of gladioli was greatly influenced by different combinations of organic and inorganic fertilizers.

Full Flowering Time (day)

The data concerning the days taken to full flowering time, as influenced by different treatments were presented in *Table 2*. Statistically no significant difference was observed in the case of full flowering time (days) of hyacinth by different levels of NP and worm fertilizers. However, it can be revealed that days to the full flowering time was the earliest (136.54 days) in V1 which was closely followed NP2 and other treatments *(Figure 3b)*. Full flowering took the longest (138.38 days) for the control plant. However, Rajadurai and Beaulah (2000) also found that increasing levels of NPK fertilizers resulted in the full flowering of African marigold, which also brought about full flowering, contains essential plant nutrients like N, P, K, Ca, Fe, S, Mg, Zn, Mo, Cu, Mn, Co and B in a balanced amount in addition to organic fertilizers, which gave rise to full flowering.

Harvest time (day)

The data belonging to days taken to harvest time, as influenced by different treatments were presented in *Table 2* and *Figure 3c*. No significant difference was observed in the case of harvest time (day) of hyacinth by different levels of NP fertilizers and worm fertilizer. However, it can be revealed that days to the harvest time was the earliest (137.70 days) in V1 which was closely followed NP2 and other treatments. Harvest time took the longest time (140.92 days), for the control plants (*Figure 3c)*.

Similar results were also found by Chakkaborty et al. (2009). On the other hand, manure brought about the late flowering of marigold in 78.3 days i.e. 94.8 days later than in the case of worm fertilizer. The flowering period was also maximsed (up to 24.51 days) due to application of worm fertilizer. This could have arisen from differences in their

DOI: http://dx.doi.org/10.15666/aeer/1604_38733884

source and nutrients composition as well as timing of nutrients availability to the flowering plants.

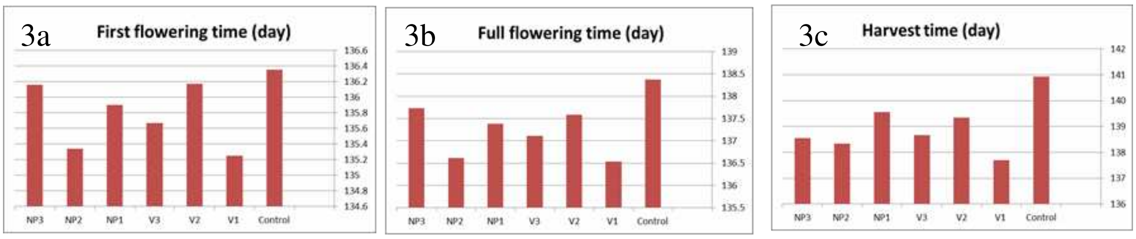

Figure 3. *Phenological properties a-First flowering, b-Full flowering, c-Harvest times (day)*

Morphological Properties

Leaf number

Leaf number was counted and no significant difference was found due to different levels of NP and worm fertilizer presented in *Table 2*. Leaf number varied from 5.41 to 5.71 per plant. The maximum number of leaf (5.71) was recorded with the V1 treatment. Results reveal *Figure 4a* that the increasing level of NP increasing the leaf number of hyacinth. And that is the increasing level of worm fertilizer decreased the leaves number of hyacinth. It was not a significant result because a maximum number of leaves was recorded in V1 and followed by other treatment. This result is in agreement with the findings of El-Desuki et al. (2006). They observed that nitrogen application had no significant effect on leaf number of onion. Also Sultana et al. (2015a) observed that number of leaf/plant of summer onion was found insignificant when the influence of integrated N from urea, cow dung, and worm fertilizer was compared. The highest number of leaves/plant (6.00) was observed after the treatment with 120 kg N/ha supplied from urea followed by other treatments. Alternatively, the minimum number of leaves (4.98) per plant was found in control plots, where no fertilizer was applied. Also Keisam et al. (2014) observed that leaf number of gladioli was greatly influenced by different combinations of organic and inorganic fertilizers. The highest number of leaves (5.60) was obtained from the mixture consisting of vermicompost (2.5 t ha^{-1}) + humic acid (0.2%) + Vesicular Arbuscular Mycorrhiza.

Leaf length (mm)

Leaf length of hyacinth varied from 118.88 mm to 128.28 mm over the treatments (*Table 2*). The leaf length (128.28) was recorded with V1 which was closely followed by NP1 and NP2 and V3. The minimum leaf length (118.88 mm) was produced from the control treatment. Results reveal (*Figure 4b*) that the increasing level of NP decreased the leaf height of hyacinth. However, the best performance was recorded in the leaf height with V1. On the other hand, Sönmez et al. (2013) observed that the highest leaf length (47.9 cm), the highest plant length (70.6 cm), and the highest leaf length 30.78 mm) was obtained in waste mushroom compost application, in the case of gladioli plant. Sultana et al. (2015b) observed that the results showed that the rate of effects within NPK fertilizers and worm fertilizer treatments were not found significant on leaf length of (*Zinnia elegans*) flowers. However, Keisam et al. (2014) observed that leaf length of gladioli was greatly influenced by different combinations of organic and inorganic fertilizers. The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38733884

highest leaf length (50.03 cm) was obtained from the mixture consisting of vermicompost (2.5 t ha-1) + humic acid (0.2%) + Vesicular Arbuscular Mycorrhiza.

Leaf diameter (mm)

Leaf diameter of hyacinth varied from 26.30 mm to 28.86 mm over the treatments (*Table 2*). The widest leaf (28.86 mm) was recorded with NP3 which was followed by and statistically similar with NP1 and V1 and V2 *(Figure 4c)*. The narrowest leaf (26,30 mm) was produced from the control closely followed by other treatments. There was no significant difference. Sönmez et al. (2013) observed that the highest leaf length (47.9 cm), the highest plant length (70.6 cm). While the highest leaf diameter (30.78 mm) was obtained in waste mushroom compost application on gladioli plant. Keisam et al. (2014) observed that leaf width of gladioli was greatly influenced by different combinations of organic and inorganic fertilizers. The highest leaf width (8.62 cm) was determined on the mixture consisting of vermicompost (2.5 t ha-1) + humic acid (0.2%) + Vesicular Arbuscular Mycorrhiza.

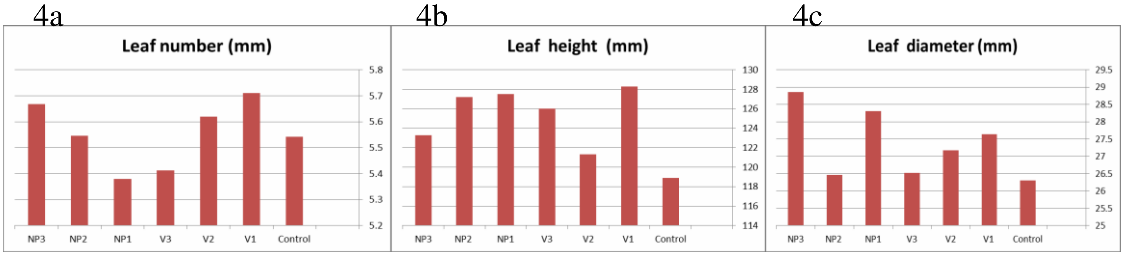

Figure 4. *Under treatments a-Leaf number, b-Leaf length, c-Leaf diameter (mm)*

Plant height (mm)

Plant height of hyacinth was measured on flowering. It was observed that plant height was not significantly influenced by different levels of NP and worm fertilizer application (*Table 2*). The tallest plant (179.54 mm) was recorded in NP3, which was followed by and statistically similar to other treatment. The shortest plant (165.28 mm) was found in control. No significant difference was found proving that the increasing level of NP are increasing the plant height of *H. orientalis* and that the increasing level of worm fertilizer increases the plant height of hyacinth (*Figure 5a*). El-Desuki et al. (2006) stated that plant height of onion increased with increasing rates of N up to 125 kg/ha and decreased thereafter. Also, Sultana et al. (2015b) observed that the impact of NPK fertilizers on the shoot heights of *Zinnia* plant was found similar with that of control. Shoot heights of plant increased with the rates of vermicompost application but the values obtained in the 10% and 20% were not significantly different.

Flower height (mm)

A noticeable variation in the flower height was recorded due to application of different levels of NP and worm fertilizer presented in *Table 2*. The longest flower (116.33 mm) was measured with V3, which was statistically similar with that of NP1, V1, and V2 and other treatment. The shortest flower (103.16 mm) was produced with control. Results revealed (*Figure 5b)* that the increasing level of NP decreased the flower height of hyacinth and that the increasing level of worm fertilizer increased the flower height of hyacinth. A similar result was found that soil application of fertilizer increased

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38733884

flowering branch length as compared to its foliar application and no-fertilization on gladioli plant (Mohammadi et al., 2014). Turkoglu et al. (2008) observed that flower height of narcissi plants as 18.38 mm.

Flower diameter (mm)

Flower diameter was not significantly influenced by different levels of NP and worm fertilizer supplement (*Table 2*). The highest flower diameter of 66.96 mm was found in plants grown under V2 which was closely followed by NP2, V1, NP1 and other treatments. The lowest flower diameter (60.72 mm) was recorded with the V3 closely flowed by control (*Figure 5c).* On the other hand, Mohammadi et al. (2014) found that soil application of fertilizer increased flower diameter compared to its foliar application and no-fertilization on gladioli plant.

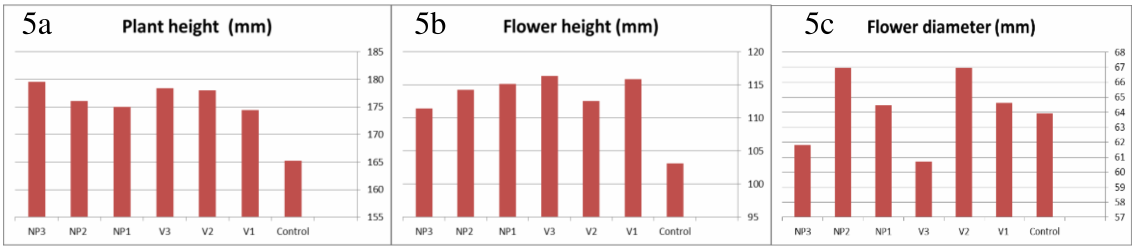

Figure 5. *Under treatments a-Plant height, b- Flower height, c- Flower diameter (mm)*

Floret length (mm)

Floret length of hyacinth was measured after full flowering time. It was observed that floret length was not significantly influenced by different levels of NP and worm fertilizer application (*Table 2*.). The highest floret length (26.76 mm) was recorded in NP2 which was followed by and statistically similar with other treatment without control, and the lowest floret length (24.08 mm) was found in control. Results revealed (*Figure 6a*) that the increasing level of NP2, increased the floret height but increasing level of NP3, decreased the floret length of *H. orientalis* and that the increasing level of V2, decreased the floret height but increasing level of V3, not significantly increased the floret height of hyacinth.

Floret diameter (mm)

Floret diameter was not significantly influenced by different levels of NP and worm fertilizer is presented in *Table 2*. The highest floret diameter (28.14 mm) was found in plants grown under V1, which was closely followed by other treatment except for V3. The lowest floret diameter (25.69 mm) was recorded with the V3. Results revealed (*Figure 6b)* that the increasing level of NP2, increased the floret diameter but increasing level of NP3, decreased floret diameter of hyacinth flower. And the increasing level of worm fertilizer do not increase the floret diameter of hyacinth.

Floret number/flower

Floret number was counted and no significant variation was found due to different levels of NP and worm fertilizer is presented in *Table 2*. Floret number varied from 32.14 to 37.69 per plant. The maximum number of floret (37.69) was recorded with the NP1. The lowest

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38733884

number of floret per plant was noted with the V1, (32.14) closely followed by NP3, V3 *(Figure 6c)*. Similar results were recorded by Sultana et al. (2015b). The rate of the effect of NP fertilizers was not found significant in the production of flowers of *Zinnia* plant. Also, Mohammadi et al. (2014) found that soil application of fertilizer increased flower number compared to its foliar application and no-fertilization in the case of gladioli. A similar result Senthilkumar et al. (2004) concluded that the appropriate ratio application of worm fertilizer resulted in higher bud number, flower number, shoot weight, root weight and plant height, which is in agreement with our study.

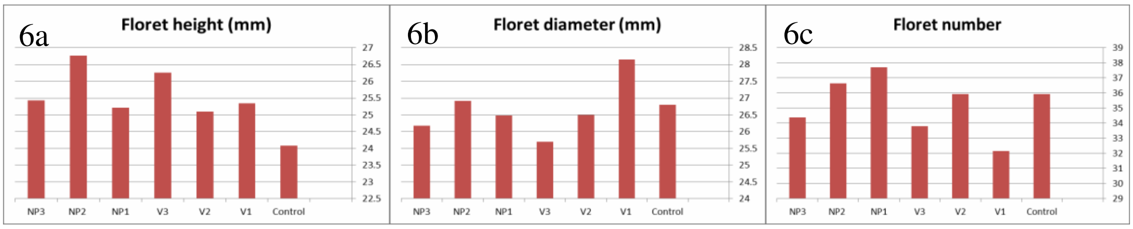

Figure 6. *Under treatments a-Floret height, b- Flower diameter (mm), c- Flower number*

Stalk thickness (mm)

Stalk thickness for hyacinth was not significantly influenced by different levels of NP and worm fertilizer supplement (*Table 2*). The highest stalk thickness of 13.50 mm was found in plants grown under V1. The lowest stalk thickness of 12.34 mm was recorded with the control and closely followed by other treatment except for V1, NP1. It is presented that the increasing level of NP decreased the stalk thickness of plants (*Figure 7*). Also, Turkoglu et al. (2008) observed 5.56 mm of stalk thickness in the case of narcissi plant. Padem and Alan (1995) observed that combined NPK applications may elevate the nitrogen, potassium and phosphorus contents and the increase in stalk length might be due to elevated levels of macronutrients which have a positive effect on floral characteristics of tomatoes.

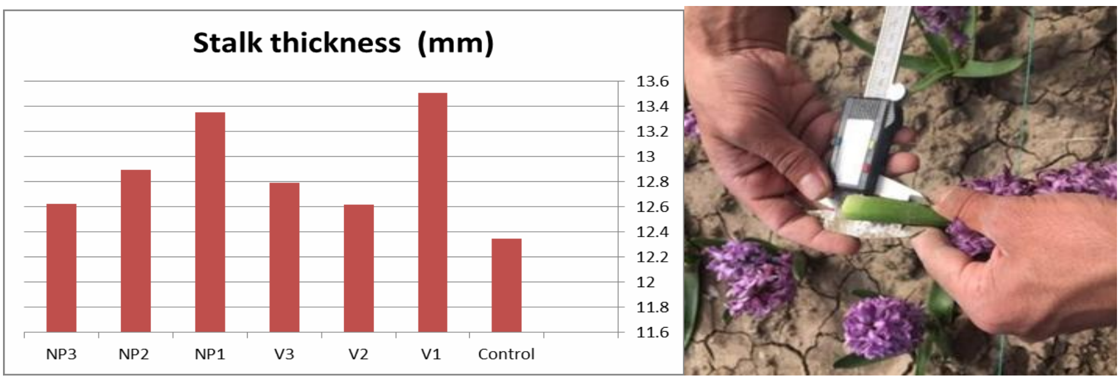

Figure 7. *Under treatments stalk thickness (mm)*

Conclusions

In this present study concerning the effects of dosages of worm fertilizer and nitrogen-phosphorus fertilizer on plant growth of hyacinth (*Hyacinthus orientalis* L. cv. “Purple Star”) in ecological conditions of Siirt was investigated. It is known that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38733884

chemical fertilization has negative effects when it is used unconsciously and in excess, by mixing with soil and water. Since aesthetics are important in ornamental plants, it is considered that the best performance of the flower criteria is possible with fertilization and excessive chemical fertilization is carried out if necessary. However, the same effect can be made without harming the environment. In Siirt province there is no commercial production in terms of cut flowers, bulbous ornamental plants, indoor or outdoor ornamental plants. However, due to its climate structure, Siirt province is suitable for growing many ornamental plants. According to this study, worm fertilizer, which is new for Turkey not known or used in Siirt province yet, has positive effects on the flowering bulbous ornamental plants to encourage especially hyacinth growing. As a result, for some plant growing and flower criteria, worm fertilizer can be used instead of chemical fertilizer.

Acknowledgements. This study is a part of Ms. thesis and is supported with the project no 2016-SİÜFEB-29 by Siirt University Coordinator of Scientific Research and Projects.

(Received 6th Mar 2018; accepted 21st May 2018)

Abstract. The aim of this work was to evaluate the effects of *Bacillus subtilis* inoculation on the growth and the photosynthetic activity of maize plants under conditions of water stress in two regimes of light intensity. Plants were inoculated with two strains of *B. subtilis* directly onto the soil and maintained for 40 days in a growth chamber under controlled conditions. Two experiments were carried out under two conditions of light intensity (300 and 900 µmol m^{-2} s^{-1} photons). During the conduction of the plants, two water supply regimes based on evapotranspiration replacement were established. At 35 days of plant growth, the following physiological parameters were evaluated: photosynthetic rate, intercellular CO_2 concentration, stomatal conductance, transpiration and water use efficiency. Plants were collected (40 days) to evaluate the production of dry biomass. *B. subtilis* increased the water use efficiency in maize plants submitted to water stress under two light intensities. The maize gas exchange response to water stress and presence of rhizobacteria were differentiated for the two light conditions. The low light intensity condition provided lower stomatal conductance and CO_2 assimilation and greater efficiency in water use in plants inoculated with *Bacillus subtilis* (AP-3) under conditions of water deficit. The high intensity condition provided significant differences in the reduction of stomatal conductance in plants with stress compared to plants without stress when inoculated with *B. subtilis* PRBS-1.
Keywords: *rhizobacteria, gas exchange, Zea mays, abiotic stress, seed inoculation*

Introduction

The unpredictability of climate variability is one of the main sources of risk for agricultural activities (Hardaker et al., 1997). Most of the problems found in tropical crops are due to climatic causes: droughts, heavy rains and frost. For example, losses from drought reach up to 50% in some important tropical crops, such as bean, maize and soybean (Vivan et al., 2015).

Nowadays, plant growth-promoting rhizobacteria (PGPR) has been used as alternative for promoting plant resistance to environmental stresses, such as drought conditions. (Liu et al., 2013). Among the known PGPR, *Bacillus subtilis* [Ehrenberg. (1835) Cohn 1872] has received special attention because of its catabolic versatility and ability to colonize roots, as well as to induce the production of a large number of enzymes and metabolites that favor the growth of plants, under conditions of stresses (Mayaket al., 2004). Recently, Li et al. (2016) reported that *Bacillus subtilis* promoted an increase in the efficiency of water use under drought conditions by *Vicia faba*, and this effect was explained through the regulation of stomata during the stress period. Regarding this, Messina et al. (2015) reported that the impact of water deficit on maize yield can be mitigated by the management practices adopted and physiological characteristics of the hybrid used, reporting that the limitation of transpiration may also contribute to improving corn tolerance to drought.

Also, it is known that *B. subtilis* produces phytohormones, such as auxins and gibberellins (Katz and Demain, 1977; Araujo et al., 2005) and these hormones could ameliorate the effect of stress in plants (Liu et al., 2013).

The metabolic alterations affecting plants under drought occur due to oxidative damage at the cellular level, which happens due to the unbalance between the formation of reactive oxygen species and their detoxification (Sandhya et al., 2010). There is a significant interaction between drought stress and the activity of antioxidant enzymes in plants. In this case, inoculation of rhizobacteria in plants could reduce the harmful effects by the activation of the antioxidant enzyme system (Han and Lee, 2005). Sandhya et al. (2010) found a decreased activity of the antioxidant enzymes in maize, under drought condition, inoculated with PGPR. In addition, C4 plants present high photosynthetic rate in response to optimal growth conditions. Although the factors limiting the photosynthesis have not yet been well known, Usuda et al. (1985) found that light intensity drives the increase on the production of enzymes related to photosynthesis.

When roots are sensitized by drought, they transmit chemical signals that regulate the stomatal mechanism and shoot growth (Davies and Zhang, 1991). These chemical signals are mainly composed of plant hormones, such as cytokinins, abscisic acid (ABA) and ethylene (Dodd, 2003). The production of indole-acetic acid and cytokinins induced by rhizobacteria would be an additional mechanism to attenuate the deleterious effects of water deficit in plants (Arkhipova et al., 2007). Specifically, inoculation of a cytokinin-producing strain of *B. subtilis* increased the growth of lettuce plants in water deficit soils (Arkhipova et al., 2007).

The hypothesis of this study is that *B. subtilis* could ameliorate the effect of drought on growth and photosynthesis in maize. Thus, this study evaluated the effects of *B. subtilis* inoculation on the growth and photosynthetic activity of maize under drought conditions and two regimes of light intensity.

Material and methods

Bacillus subtilis

Two strains of *Bacillus subtilis* (AP-3 and PRBS-2) were used in the experiments. They were isolated from soil under soybean cultivation and are characterized by Araujo et al. (2005). The strains were maintained in nutrient agar culture medium under refrigerated conditions.

Study site, treatments and experimental set-up

The study was conducted in laboratory of Unoeste, Presidente Prudente, São Paulo, Brazil. The experiments were carried out in a completely randomized arrangement, in a 3 × 2 factorial scheme (control and treatments with inoculation of two *B. subtilis* isolates in two irrigation regimes) and five replications, which totaled 30 plots. In the first experiment, plants were conducted under a light intensity regime of 900 µmol m^{-2} s^{-1} and in the second experiment plants were conducted at the intensity of 300 µmol m^{-2} s^{-1}. Both experiments were conducted for 40 days in a growth chamber and were maintained in the same photoperiod, temperature and humidity conditions.

The soil used in the experiments was collected from the 0-20 cm horizon and characterized as an acrisol (FAO, 1998), whose chemical characteristics showed the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38853895

following values: pH ($CaCl_2$ 0.01 mol L^{-1}) 5.7; 3.9 mg dm^{-3} of P (Mehlich^{-1}); 2.2 mmolc dm^{-3} of K; 20.3 mmol dm^{-3} of Ca; 4.3 mmol dm^{-3} of Mg; 14.3 mmol dm^{-3} of H + Al; 151 mmole dm^{-3} of CEC and 65% of base saturation. Soil base saturation was increased to 80% (Raij et al., 1997) with application of dolomitic limestone. The soil was conditioned in plastic pots (2.5 kg), irrigated until field capacity and incubated for 60 days.

Corn seeds (*Zea mays* L. Hybrid SYN 7205) were inoculated with *B. subtilis* isolates at the time of sowing. The aqueous suspension containing each isolate at the concentration of 10^9 cells per mL was applied directly onto the seeds in the planting pit in the amount of 0.1 mL. After sowing and inoculation of the rhizobacteria, the pots were allocated into a plant growth chamber model FITOTRON® SGC 120 (Weiss Technik, UK) under temperature conditions of 28/18 °C day / night and cycle of 16/8 h day/night. Relative humidity was programmed to 60%. Initially, soil moisture was maintained at 100% field capacity. After 15 days of plant emergence, the water stress was induced in the pots by the replacement of only 30% of the evapotranspirated water, and the control plants received 100% replacement. The daily control of evapotranspiration was carried out using the gravimetric method (Catuchi, 2011). Soil moisture contents were monitored by humidity and temperature sensors (Prochek®, Decagon Devices).

CO_2 and H_2O gas-exchange

At 35 days of plant growth the physiological parameters related to photosynthesis were evaluated through an infrared gas analyzer (IRGA, model Li- 6400XTR, Li-Cor). Spot measurements were performed on 5 plants per treatment under photons saturating irradiance of 1,200 µmol m^{-2} s^{-1}. The following parameters were evaluated: liquid assimilation of CO_2 (A, mmol m^{-2} s^{-1}), stomatal conductance (gs, mmol m^{-2} s^{-1} H_2O), intercellular CO_2 concentration (Ci, ppm) and transpiration (E, mmol m^{-2} s^{-1} of H_2O). From these variables, the water use efficiency was calculated as A/E (WUE, mmol mol^{-1}).

Plant growth analysis

The plants were harvested 40 days after sowing, separating the root system and above-ground biomass to determine dry biomass. The shoot was separated from the root 2 cm above the soil level and washed in water containing mild detergent to remove soil. The quantification of biomass dry weight was performed in the laboratory after drying the material on forced ventilation oven (60-70 °C) to constant weight. The evaluation of the growth promotion was carried out by comparing the dry root and shoot masses of the inoculated plants and control, within each water replacement condition.

Data analysis

The data obtained as mean value of five replicates and significance was considered at the 95% confidence level. Normality test and ANOVA using SISVAR software (Ferreira, 2014) was performed to evaluate the effect of rhizobacteria at water stressed and non-stressed conditions and the Tukey test was used to compare the means.

Results

ANOVA showed highly significant ($P \leq 0.05$) effects of treatments with *B. subtilis* in in most variables analyzed. It is also possible to emphasize the interactions found between aerial part and concentration of intercellular CO_2 in the two light intensity (*Table 1*).

Plant growth analysis

The highest luminous intensity (900 µmol m^{-2} s^{-1}) promoted a reduction on shoot growth under drought condition, but did not alter root growth. Although rhizobacteria could ameliorate the drought stress, the inoculation of both strains of *B. subtilis* was not able to interfere significantly with the damages caused by drought in plant growth (*Table 2*). For root growth, *B. subtilis* (PRBS-1) reduced the root biomass in the non-stressed-plants, when compared to the non-inoculated control.

Table 2. *Shoot and root growth as a function of inoculation with B. subtilis in maize plants submitted to water stress under high light intensity*

Mean ± standard error. Values followed by distinct letters, lowercase in the columns and upper case in the lines, differ by Tukey test at 5%

In the second experiment under a lower luminous intensity (300 µmol m^{-2} s^{-1}), maize plants showed different responses regarding the presence of rhizobacteria than those found under the greater luminous intensity. It was found that plant inoculation with the *B. subtilis* (PRBS-1) resulted in increased shoot and root biomass production under drought condition (*Table 3*).

CO_2 and H_2O gas-exchange

Under high light intensity, maize did not show significant changes in photosynthetic parameters in non-inoculated plants under drought condition, but there was an increase in water use efficiency. Inoculation of maize with *B. subtilis* (PRBS-1) promoted a reduction in the rate of CO_2 assimilation and stomatal conductance when the plants

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38853895

underwent drought condition as compared to the non-stressed plants (*Table 4*). Under drought condition, plants inoculated with *B. subtilis* (AP-3) showed a significant reduction in intercellular CO_2 concentration. On the other hand, under normal condition, *B. subtilis* (AP-3) provided the highest rates of intercellular CO_2 than non-inoculated plants.

Maize plants inoculated with *B. subtilis* (AP-3) showed higher water use efficiency compared to non-inoculated plants, both under normal and drought condition (*Table 5*). However, the plant-water saving observed in the inoculated plants was not reflected in the improvement or maintenance of the physiological variables related to photosynthesis. It suggests that, under high luminous intensity, the economy of water may have been resulting of other effects promoted by the presence of PGPR.

With lower luminous intensity (300 µmol m^{-2} s^{-1}) the assimilation and intercellular concentration of CO_2 were reduced in the non-inoculated plants under drought condition. In the absence of drought, plants inoculated with *B. subtilis* (PRBS-1) showed a lower photosynthetic rate as compared to the non-inoculated plants; this condition could be explained by the decrease in stomatal conductance (*Table 6*). However, under drought condition, inoculation of plants with both *B. subtilis* (AP-3 and PRBS-1) did not result in photosynthesis alteration; although plants inoculated with the *B. subtilis* (PRBS-1) have shown higher intercellular CO_2 concentration and lesser stomatal conductance.

Inoculation with *B. subtilis* promoted a lesser transpiration in plants under drought condition. It means that inoculated plants presented lower water losses, as a direct consequence of the stomatal conductance reduction. However, this reduction of stomatal conductance in inoculated plants was not sufficient to decrease the photosynthetic activity. This fact may have contributed to the improvement of the inoculated plants' performance in terms of water use efficiency (*Table 7*), both under normal and drought conditions.

Comparing the behavior of the plants inoculated with *B. subtilis* (AP3) in relation to the non-inoculated plants, it was observed that in the condition of low light intensity there were larger changes in the photosynthetic parameters of the inoculated plants (*Fig. 1*).

Discussion

Net CO_2 assimilation rate (A) increased with the increase of light intensity but did not correlate with increased conversion of CO_2 to carbohydrates (Sun et al., 2012). In our study it was verified that the plants under high luminous intensity assimilated more than twice CO_2 and presented greater stomatal conductance compared to the plants under low light intensity. However, the concentration of intercellular CO_2 (Ci) was similar in both conditions. One of the primary effects of drought condition in plants is related to the partial or total closure of the stomata (Lopes and Lima, 2015). However, other studies have shown that photosynthesis is not only regulated by the CO_2 diffusion through stomata, and that other non-stomatal factors can affect photosynthetic activity in response to stressful environments (Becker and Fock, 1986; Yuet et al., 2009). Becker and Fock (1986) reported the reduction of CO_2 assimilation, but did not observe changes in intercellular CO_2 (Ci), in plants under drought condition. However, these authors found a marked reduction in the activity of important enzymes in the photosynthetic process.

Confirming hypothesis, the results found in our study suggest that *B. subtilis* can ameliorate the deleterious effects of drought stress, by interfering with the gas flow related to photosynthesis, and water status of the plants. However, this activity was affected by light intensity, because in the low light intensity there were significant changes in few parameters evaluated, including plant growth. Based on the interactions found by ANOVA (*Table 1*), it was observed that the high light intensity condition provided stress interactions with the treatments in the stomatal conductance and water use efficiency parameters, which was absent in the low light intensity condition.

Li et al. (2016) concluded that leaf application of *B. subtilis* in beans (*Phaseolus vulgaris*) improved the efficiency of water use, mainly by the closure of the stomata. These same authors also reported that the restriction of photosynthesis can be attributed to the reduction of the atmospheric CO_2 input caused by the stomatal limitation induced by the presence of the rhizobacteria. *B. subtilis* (PRBS-1) inoculation in maize resulted

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38853895

in lower stomatal conductance when plants were subjected to water stress conditions. The partial reduction of stomatal conductance proportionally limits transpiration more than CO_2 entry into leaves (Chaves and Oliveira, 2004). Our results corroborate this findings, since in the condition of lower luminous intensity, the effects of rhizobacteria inoculation occurred by the reduction of transpiration under drought condition. However, the reduction of transpiration was not followed by a reduction in photosynthesis, which resulted in higher water use efficiency (WUE). The observed increase in intercellular CO_2 concentration as an effect of the PRBS-1 isolate under water stress conditions explain the absence of reduction in the photosynthetic activity of the inoculated plants. Previous studies also indicated that the accumulation of intercellular CO_2 acts as a defense mechanism against water deficit, since carbon and water retention in foliar tissue are observed with the increase of the WUE (Blum, 2005; Tardieu, 2012).

Liu et al. (2013) concluded that the increase in the growth of *Platycladus orientalis* plants when inoculated with *B. subtilis* under drought conditions, results from the effect of increased cytokinin concentration in the leaves. It is also noteworthy that the *B. subtilis* isolates used in this study have already been characterized as phytohormone producers (Araujo et al., 2005). However, it is well known that when plants are stimulated to close the stomata in stressful situations, there may be an improvement in their efficiency in the use of water (Davies et al., 2002). Our results showed higher values of water use efficiency in *B. subtilis* inoculated plants, besides increased plant growth when plants were submitted to water stress in lower light intensity conditions, when compared to non-inoculated plants. However, the interaction with water stress only occurred with the condition of high luminous intensity.

In the analysis of the parameters related to the gas exchange, for both water regimes it was verified that in the condition of lower light intensity, the plants were more responsive to the rhizobacteria inoculation, mainly in the condition of water stress. In *Figure 1* it can be verified that the isolate AP-3 of *B. subtilis* provided better photosynthetic performances in the plant when it was cultivated in the condition of lower luminosity. Under a lower luminous intensity, there was a reduction in stomatal conductance and consequently lower water loss due to transpiration as the effects of *B. subtilis* plant inoculation. The reduction of transpiration in plants inoculated by rhizobacteria has been reported by Bresson et al. (2013) as a mechanism supporting plant tolerance to drought. Messina et al. (2015) concluded that maize hybrids with limited transpiration characteristics would be more suitable for cultivation in regions with a higher prevalence of dry periods. In this respect, it was observed that *B. subtilis* (PRBS-1) reduced the transpiration of maize plants even in the absence of water deficit, and on the other hand, promoted a significant increase of plant dry mass (*Table 6*). However, when the plants were conducted under higher luminous intensity, the transpiration was not influenced by water stress or rhizobacteria inoculation.

Few studies compare the photosynthetic activity of corn in different conditions of light flux, under water stress. It is known that C4 plants have great potential for acclimatization to environmental changes and that too much light absorption can cause serious problems, which is why special mechanisms protect the photosynthetic system from excessive light (xanthophyll cycle). The multiple levels of photosynthesis control enable plants to successfully grow in a changing environment with different habitats (Taiz and Zeiger, 2004). In a study with maize growth in two light conditions under direct sunlight (2000 $\mu mol\ m^{-2}\ s^{-1}$) and in the growth chamber (400 $\mu mol\ m^{-2}\ s^{-1}$), plants

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38853895

grew 2.3 times more at the lowest luminous density (Usuda et al., 1985). In our study, the plants in conditions of low light density had lower photosynthetic rates and also had decreased shoot growth. Mojses and Kalapos (2008) in a study with luminous intensity variation in invasive and non-invasive C4 plants verified differences and the adaptation potential of these plants to semiarid conditions, represented by the lower luminous intensity, where there was a greater reduction of gas exchange by stomata and an increase in water use efficiency. The condition of lower light intensity in corn and inoculation of *B. subtilis* (AP-3) also resulted in greater closure of the stomata and increase in water use efficiency, comparing the non-inoculated plants (*Fig. 1*). In this sense, maize cultivation in tropical regions, at times of the year with less light radiation, such as winter, can provide better responses to inoculation of rhizobacteria in order to mitigate the effects of drought.

Several studies have already presented the potential of the *B. subtilis* rhizobacterium as a plant growth promoter, highlighting the production of antibiotics in the control of pathogens (Araujo et al., 2005); production of growth regulators (Molla et al., 2001) and nutrient solubilization (Kim et al., 1998), among others. In addition to these benefits previously presented in other studies, we can indicate that this species demonstrates potential to reduce the damages caused by water stress in agricultural crops, confirming what has already been reported by Li et al. (2016), who concluded that *B. subtilis* acts as a regulator of photosynthesis and promotes improvements in the efficiency of water use. However, light intensity can influence this regulation by factors not evaluated in this study. In this sense, our findings on the effects of the inoculation of *B. subtilis* on maize growth, in water deficit conditions, may foster new studies about this mechanism of action with a focus on field experiments.

Conclusion

In conclusion, the inoculation of *B. subtilis* increased the water use efficiency in maize plants subjected to water stress, under two light intensities. The maize gas exchange response to water stress and presence of rhizobacteria were differentiated for the two light conditions. The low light intensity condition provided lower stomatal conductance and greater efficiency in water use, in plants inoculated with *Bacillus subtilis* AP-3 under conditions of water deficit. The high intensity condition provided significant differences in the reduction of stomatal conductance in plants with stress compared to plants without stress when inoculated with *B. subtilis* PRBS-1.

THE USAGE OF ARTIFICIAL NEURAL NETWORKS IN MICROBIAL WATER QUALITY MODELING: A CASE STUDY FROM THE LAKE İZNİK

KATIP, A.

Department of Environmental Engineering, Faculty of Engineering, Uludag University Görükle Campus, 16059 Bursa, Turkey
(e-mail: aballi@uludag.edu.tr; phone:+90-224-294-0918)

(Received 12th Mar 2018; accepted 12th Jun 2018)

Abstract. The aim of this study was to develop faecal pollution model structures with artificial neural networks (ANNs) for cost-effective lake water quality management studies. In this study 5 artificial neural networks model structures were applied to predict the Faecal coliform concentrations for 4 different coast areas "Göllüce, İnciraltı, Darka, Orhangazi" and all data of the coasts in Lake İznik-Turkey. The Levenberg–Marquardt and backpropagation algorithm was proposed for feed-forward neural networks training. According to performance functions root mean squared error (RMSE), neural network model structures provided acceptable results. Correlation values (R) were found between 0.590 and 0.999. Increasing the number of hidden layer in the model structures was not raised the model efficiency in each trial. Type and number of input parameters were more effective for some model efficiency. Increasing the number of hidden layer and inputs in the model structures did not raise the model efficiency in each trial. Because depending on the numbers and chemical compositions of the substrates in the lake water microorganism's metabolism and their growth rates could be influenced differently and the larger error values of the modeling results determined in Göllüce and Orhangazi Coasts which influenced by pollution sources. Water quality modeling studies and increasing of monitoring would provide more productive results for protection and management of coastal.
Keywords: *faecal pollution, mathematical modeling, deep lake, water management, Turkey*

Introduction

One of the main elements that compose the rich biodiversity in the world and Turkey is wetlands. While wetlands of different qualifications increase the ecosystem diversity on one hand, the species using these wetlands raise the species' and genetic diversity on the other hand (Karadeniz et al., 2009). However, wetlands, especially lakes, are considered to be potential agriculture-residential-industrial areas in the development plans for years because of their high values. Wetlands are polluted by domestic, industrial and agricultural pollutants, and thus their biological diversities are destroyed (Oktem et al., 2012).

Contaminations of the environment with pathogen, hazardous and toxic chemicals are the major problems facing the industrialized nations and urbanized regions today. Microbial pollution in coastal and wetland areas is quite important for human and other species (Cordier et al., 2014). Particularly, pathogens, which include bacteria, viruses and protozoans, can come from a variety of point and nonpoint sources. For over a century, bacterial indicator organisms have been used in the USA to assess the presence of faecal contamination, and consequently pathogens, in drinking and bathing waters (NRC, 2004). Commonly used indicators are total coliform, faecal coliform, faecal streptococci, Escherichia coli and Enterococcus (Mas and Ahlfeld, 2009).

Artificial Neural Networks studies starting in 1940s are performed in hydrology, meteorology, ecology and water quality fields (Morid et al., 2007; Ranković et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38973917

2010; Kim and Valdes, 2003; Partal and Kişi, 2007; Reimer and Sodoudi, 2004; Mishra and Desai, 2006; Belayneh and Adamowski, 2012). Several lake water quality studies were related to especially phytoplankton production, algal blooms, dissolved oxygen and other spatial and temporal variability of limnological properties and eutrophication (Soyupak et al., 2003; Karul et al., 2000). Microbial contaminants are non-conservative, irregularly distributed and may even increase in concentration due to growth in the environment. The interrelationship and interactions between microbial communities in water creates additional modeling challenges that have been overcome by applications of ANNs to multi-parameter databases. Important and meaningful results were obtained with modeling of pathogens with ANN (Neelakantan et al., 2002; Brion and Lingireddy, 2003; Mas and Ahlfeld et al., 2007; Ogwueleka and Ogwueleka, 2010; WHO, 2010; Wu et al., 2014).

The purposes of this study were to design and develop ANN model structures for prediction of fecal coliform in order to evaluate microbial contamination and to predict the pollution impact on bathing, agricultural, aquaculture, recreation and tourism areas of Lake İznik as this has national and international importance, and also to observe the differences among the modeling results in the lake coasts occurring due to sewage inputs or nonpoint sources according to relevant environmental conditions. This study would be supportive of data management and could be the basis for basin and coastal management and the early warning system studies for public health. Also, this study was important with regards to international environmental scientific developments because the feed forward neural network (FNN) models could supply cost-effective environmental management tools for the investigation of any monitoring stations and pathogenic pollution.

Materials and methods

Study area and data

Lake İznik, the largest lake in the Marmara region and the fifth largest in Turkey, is located between the districts of İznik and Orhangazi in the Province of Bursa. It is located between 40°23′ and 40°30′N latitudes and 29°20′ and 29°42′E longitudes. The lake, which is located 85 m above sea level, has a length of 32 km and a maximum width of 12 km. It is about 15-16 km from the Bay of Gemlik. It has a surface area of 310 km^2 and a water volume of 12.2 billion m^3. The maximum depth of the lake (80 m) has been measured near Karacakaya (Ozturk et al., 2005; Yağcı and Ustaoğlu, 2012). It has 1 outlet, Karsak stream, and 5 inlets, Orhangazi, Kuru, Karasu, Ekinlik and Söloz streams. Karsak stream connects the lake to the Sea of Marmara but it has a number of natural and artificial barriers that marine fishes are unable to cross (Özuluğ, et., al., 2005).

Lake İznik, one of the 76 wetlands of international importance in Turkey, is a natural protected (NP) wetland according to the criteria of The Convention on Wetlands of International Importance (The Ramsar Convention) (RAMSAR, 2007). The ecosystem of Lake İznik was declared to be a natural protected area in 1990 and conforms to the international criteria with its characteristics (BGPEFD, 2008) and The Lake İznik and İznik basin had been an area of settlement throughout the history. The archeological findings in the tumulus in İznik depression suggest that human settlement started 7150 years ago. İznik town later became an important cultural center during the Roman, Byzantine and Ottoman empires (Ülgen et al., 2012).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38973917

Moreover, Lake İznik is a significant bird watching area in Turkey; there are eight host and five stationary bird species, 13 in total, in this area (Akpınar et al., 2010). Lake İznik is a significant water resource not only with its water capacity but also in terms of agriculture, industry, water productions and recreational activities for the region (Başar et al., 2004). Therefore pollution monitoring and preservation of the Lake are important nationally and internationally.

Point and nonpoint (diffuse) pollution sources existed in the watershed, which discharge pollutants into the lake. The pollution loading sources of Lake İznik are agricultural, animal, sewage, forest, aerial (Akkoyunlu et al., 2011) and industrial (Oktem et al., 2012). Partially treated and untreated sewage and nonpoint pollution of fertilizers and pesticides from surrounding agricultural areas reached the lake (Akçaalan et al., 2014; Albay and Aykulu, 2002). Lake water is also used for irrigation and the lake is a popular place for recreation during summer months. Around the lake, especially in Orhangazi region in the west banks of the lake, the planless misuse of 1st class farming lands (open to settlement), which are appropriate for irrigation farming, puts the future of the Lake İznik in danger (Meşeli, 2010).

It is a well-known fact that the pollution in Lake İznik increases proportionately to the population growth. The common use of the septic tanks in Orhangazi and İznik around the lake causes the pollution of the lake to increase. Also there are 45 villages were around the lake and pollution loads of their domestic waste water affects the lake. But a certain amount of the used water (70-90% in general) is thought to return to the sewages (Oktem et al., 2012). Moreover, Lake İznik is polluted by the waste water of the Orhangazi Industrial Area, the tankages of İznik and Osmangazi, Marmara Birlik Olive Processing Plants in İznik, and by Ispak industrial plants in Orhangazi. Moreover, the lake was under threat because of the small olive oil plants around it and chemistry, automotive, metal and food industry sectors were present in the lake basin (WWF, 2011). Industries using the water of the lake in processing goods discharge their waste water to the lake without sufficient purification. Phosphorus in the industrial pollution was determined to be 3 times higher than that in the domestic waste water; and nitrogen in the industrial pollution was determined to be 1.5 times higher than that in the domestic waste water. In addition Istanbul-Bursa highway passes through Orhangazi on the west coasts of the Lake İznik and this heavy traffic caused air pollution (Oktem et al., 2012).

Several studies investigated the extent of anthropogenic pollution, such as nutrients, lead, and polycyclic aromatic hydrocarbons (PAH) in the sediment of the recent past and identified differences in the spatial distribution and sedimentation history (Franz et al., 2006; Ünlü et al., 2010; Viehberg et al., 2012). The spatial distribution of Pb indicating anthropogenic pollution sources coincides with elevated concentration in the delta area of the Sölöz stream which feeding of the Lake İznik. Interestingly, Ünlü et al. (2010) identified high concentrations of polycyclic aromatic hydrocarbons in the same area, thus supporting human-induced contamination (Viehberg et al., 2012).

Samples were taken from 4 different stations from 2010 to 2015. Sampling stations and regions were given in *Table 1* and features of the sampling stations were as follows:

Göllüce Village is located in the district limits of İznik sub-province. It is on the main road interconnecting with Gemlik and İznik sub-provinces. There are aggregated reeds at the entrance to the lakeside public beach. İnciraltı public beach is nearby the İznik sub-province. The Darka area is a public beach in front the Darka Holiday Village. Orhangazi Area is near the outlet of the Lake and Orhangazi sub-province. All

Health. Total coliform, fecal coliform and fecal streptococci parameters were evaluated and modeled. The samples collected for measurements were taken from 30 cm below of the surface and put into the polyethylene (PE) single use bottles of 500 mL volume, kept in the thermo isolated boxes, having cooling bars at +4 °C, and brought to the lab in 24 h at the most. Bacterial count were performed by membrane filtration (MF) method and determined as CFU/100 mL (APHA, 1992; YSKY, 2006).

ANN model and training algorithm

Artificial neural networks are formed of a set of simple elements, the alleged artificial neurons. These elements are inspired by biological nervous systems. Models of neural networks are separated into two categories: feed forward neural networks and recurrent neural networks. Feed forward neural networks propagate data linearly from input to output and they are the most popular and most widely used models in many practical applications. (Hornik, 1991) Showed the feed forward neural network (FNN) with as few as a single hidden layer and arbitrary bounded and smooth activation functions can approximate a continuous nonlinear function (Şen, 2004). The multilayer FNN represented in *Figure 2* (Rankovic et al., 2010; Efe and Kaynak, 2002; Okkan and Mollamahmutoğlu, 2010).

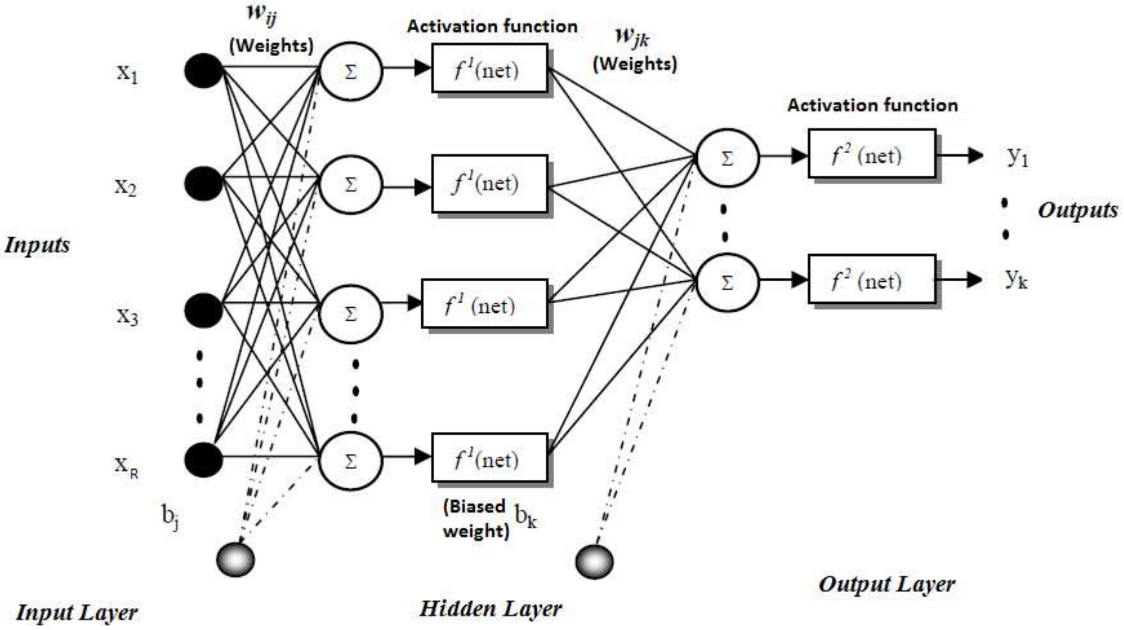

Figure 2. *Multi layer feed forward neural network*

As shown in *Figure 2,* the elements constituting ANN are input layer, hidden layers (number of hidden layers are one or might be more), output layer linkages between the layers and linkage weights.

The data of the problem is in the input and output layers. Productivity and importance of information in the input layer are provided with the weights. Net (basis) function expresses that productivity of input data to neuron. For an analytical study, the connection networks are mathematically represented by a basis function u (w, x). The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38973917

net value is a linear combination of the inputs and the output of a neuron can be expressed as *Equation 1:*

$$out = f(n) \tag{Eq.1}$$

where (*Eq. 2*)

$$n = \sum_{j=1}^{R} w_j x_j + b \tag{Eq.2}$$

$x_1, x_2, \ldots, x_R$ are the input signals; $w_1, w_2, \ldots, w_R$ are the weights of neuron; b is bias value; and $f(\cdot)$ is the activation function.

Activation function is a function determining the neuron output with processing the net inputs obtained from net function. The linear and sigmoid are common used activation functions in the construction of artificial neural networks.

An example of the sigmoid is the logistic function, defined by *Equation 1:*

$$f(n) = \frac{1}{1+e^{-n}} \tag{Eq.3}$$

Also, as sigmoid function can be used hyperbolic tangent function and it gives the outputs range between [0-1] (*Eq. 2;* Haykin, 1999):

$$f(n) = \frac{1-e^{-n}}{1+e^{-n}} \tag{Eq.4}$$

The inputs $x_1, x_2, \ldots, x_R$ are multiplied by weights $w_{i,j(1)}$ and summed at each hidden neuron i. Then the summed signal (*Eq. 5*):

$$n_{i(1)} = \sum_{j=1}^{R} w_{i,j(1)} x_J + b_{i(1)} \tag{Eq.5}$$

The node activates a nonlinear function $f_{(n)}$. The output y at a linear output node can be calculated as *Equation 6:*

$$y = \sum_{i=1}^{z} w_{1,i(2)} \frac{1-e^{-\left(\sum_{i=1}^{R} x_j w_{i,j(1)} + b_{i(1)}\right)}}{1-e^{-\left(\sum_{i=1}^{R} x_j w_{i,j(1)} + b_{i(1)}\right)}} + b_{1(2)} \tag{Eq.6}$$

where R is the number of inputs, z is the number of hidden neurons, wi.j(1) is the first layer weight between the input j and the i^{th} hidden neuron, w1,i(2) is the second layer weight between the i^{th} hidden neuron and output neuron, bi(1) is a biased weight for the ith hidden neuron and b1(2) is a biased weight for the output neuron (Rankovic et al., 2010).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38973917

The learning algorithms using in ANN are heuristics, partial Newton methods, matched gradient methods and Levenberg Marquardt methods. In this study feed forward neural network structure was used and Levenberg Marquardt training algorithm supervised training algorithms was preferred for training. Pupose Levenberg Marquardt algorithm is the least squares calculation method based on maximum neighborly idea (Hagan and Menhaj, 1994). The sum of squared errors of any one of the element in the training set (N number of elements) could be calculated as follows (*Eqs. 7* and *8*)*:*

$$E(w) = \frac{1}{2}\sum_{i=1}^{N}(y_{mi} - y_i)^2 = \frac{1}{2}(y_m - y)^T(y_m - y) \tag{Eq.7}$$

$$w = [w_{1,1(1)}, w_{1,2(1)}, \dots, w_{z,R(1)}, b_{1(1)}, b_{2(1)}, \dots, b_{z(1)}, w_{1,1(2)}, w_{1,2(2)}, \dots, w_{1,z(2)}, b_{1(2)}]^T \tag{Eq.8}$$

Two number of different hidden layer neuron for each input neurons was tested in this study. This was because; in the recent study were two different approaches used in determining the number of hidden layer neurons. The first approach for a network model which in the N number of neuron in the input layer: (N + 1) / 2 and the second approach: (2 * N + 1) were introduced (Hagan and Menhaj, 1994; Oğuztürk, 2010).

Performance and sensitivity analysis of ANN

The performance of the forecasts from the data-driven models was evaluated. The Pearson correlation coefficient is one of the most commonly used performance in selecting proper inputs for the ANN (Rankovic et al., 2010). Correlation coefficient is described as the degree of correlation between the empirical and modeled values (*Eq. 9*):

$$r = \frac{\sum_{i=1}^{N_0}(y_i - \bar{y})(y_{mi} - \bar{y}_m)}{\sqrt{\sum_{i=1}^{N_0}(y_i - \bar{y})^2 \sum_{i=1}^{N_0}(y_{mi} - \bar{y}_m)^2}} \tag{Eq.9}$$

where y_i and y_{mi} enounce the network output and measured value from the i^{th} element; $\bar{y}$ and $\bar{y}_m$ conceive their average respectively, and N_o describes the number of measurements.

Another performance measure is mean absolute error (MAE). The MAE is used to measure how close forecasted values are to the observed values. It is the average of the absolute errors. The smaller values of MAE and MSE (mean square error) provide the better performance (Belayneh and Adamowski, 2012). MAE and MSE are estimated as follows (*Eqs. 10* and *11*):

$$MAE = \frac{1}{N_0}\sum_{i=1}^{N_0}|y_{mi} - y_i|^2 \tag{Eq.10}$$

$$MSE = \frac{1}{N_0}\sum_{i=1}^{N_0}(y_{mi} - y_i)^2 \tag{Eq.11}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

ANN application

In this study, the total coliform, fecal coliform and fecal streptococci parameters, which were measured between the years of 2010 and 2015, were modeled. The total number of measurements used in modeling for each parameter was 108 and 27 number of data was evaluated for each of lake coasts and parameters.

The amount of data needed to train a neural network is very much problem-dependent. The quality of training data (i.e., how well the available training data represents the problem space) is as important as the quantity (i.e., the number of records, or examples of input-output pairs). The key is to use training data that generally span the problem data space. For relatively small datasets (fewer than 20 input variables, 100 to several thousand records) a minimum of 10 to 40 records (examples) per input variable is recommended for training (NNMP, 2016). The total data number used in ANN modeling studies, related to water quality, ranged from 60 and 442 (Brion and Lingireddy, 2003; Mas and Ahlfeld, 2007; Radojevic et al., 2013). For these reasons the total number of data used in this study is suitable for water quality studies.

In this study, all the ANN model structures were created with the MATLAB ANN toolbox (Matlab, R2015). The tangent sigmoid transfer function was the activation function for the hidden layer, while the activation function for the output layer was a linear function. All the ANN models in this study were trained using the Levenberg Marquardt (LM) back propagation algorithm. The LM back propagation algorithm was chosen because of its efficiency.

All the ANN models the cross validation technique was used to partition the data sets; 80% of the data was used to train the models, while the remaining 20% of the data was used to test and validate the models, with 10% used for testing and 10% used for validation (Principe et al., 1999; Keskin et al., 2011; Keskin et al., 2009; Belayneh and Adamowski, 2012). In microbiological modeling studies, between 60 and 80% of the total data were used in training process, between 10 and 20% were used in test and validation stage (Brion and Lingireddy, 2003; Mas and Ahlfeld, 2007; Radojevic et al., 2013).

The training set was used to compute the error gradient and to update the network weights and biases. The error from the validation set was used to monitor the training process. If the network overfits the data the error in the validation set will begin to rise. The testing data set is an independent data set and is used to verify the performance of the model.

The data based on monthly average values was used in this study and 4 model structure (a, b, c, d) were tested for each 5 model (Model 1-Total data of the Lake, Model 2-Göllüce area, Model 3-İnciraltı area, Model 4-Darka area and Model 5-Orhangazi area). The results in the model structures related to ANN modeling experiments with a different number of hidden layers were defined in a comparative way.

In the (a) and (b) model structures total coliform and fecal streptococci and in the (c) and (d) model structures total coliform were chosen as input parameters. In all of the model structures, fecal coliform was selected as output parameter.

Total coliform parameter does not always indicate fecal contamination or the presence of the pathogens in water. Some bacteria, which are non-fecal source, answer to the definition of coliform bacteria. Most of the fecal streptococci bacteria are fecal source and in practice, they are the most important indicator of contamination with human feces. However, certain types and their subtypes are also present in plant

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38973917

material. Fecal streptococci rarely grow in contaminated water and are more resistant than coliform bacteria. Fecal coliforms are a subgroup of the total coliform bacteria and are of fecal origin. While total coliforms may be given some permission since they are phytogenetic and soil born, fecal coliforms are allowed to a very limited number of permission (Casadevall and Pirofski, 2014; Alberts et al., 2002). For this reason, Fecal coliform was chosen as an output parameter and modeled with the aim of estimating the sewages containing human and animal waste and providing support to the prevention works afterwards.

Results and discussion

Water quality and basic statistic of the data set

According to the "Blue Flag Criteria" (TÜRÇEV, 2013), microbial contaminant levels for the last 4 years are required in order to determine the level of pollution of beaches. Therefore, the measurements performed at the Lake coasts during the swimming season, in other words in summer months, between the years of 2010 and 2015, were evaluated within the context of this study. The results of the measurements were evaluated according to "Table of Criteria for Water Quality Required for Swimming and Recreation in Swimming Water Quality Act" (*Table 2*).

Table 2. *Table of criteria for water quality required for swimming and recreation (YSKY, 2006)*

Parameters	Reference values	Mandatory values
Total coliform /100 ml	1000 (2006-2014 years) 500 (2015 year)	10000
Faecal coliform /100 ml	200 (2006-2014 years) 100 (2015 year)	2000
Faecal streptococci /100 ml	100	1000

According to this table; if the measured values are under the reference values, the water is in good quality, between the reference values and mandatory value is in medium quality and above the mandatory value, is in poor quality.

When the variation of microbial pollution in the coastal areas was examined the parameters were changed with good and medium quality. However, according to the values of 2015, faecal coliform and faecal streptococci parameters were found to be in good class and the pollution decreased in the all coasts. It was determined that total coliform and faecal streptococci concentrations were no statistical difference among the months but slight increase in these parameter's concentrations were observed in the each month until late spring to early fall. These parameters could be soil and plant origin. Therefore intensive agricultural activity and rain in these months may increase the concentrations (Akkoyunlu et al., 2011; WWF, 2011). According to the statistical calculations (ANOVA tables) for all of the Lake there was no difference among the months and monitoring stations of the coasts. But the differences among the years for faecal coliform and faecal streptococci parameters were found significant ($p \leq 0.05$) statistical. According to the ANOVA analysis results for the each station the monthly

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38973917

alterations of faecal streptococci in Darka and Orhangazi public beaches were found as significant ($p \leq 0.05$) statistically (Demirci and Can, 2015). Basic statistic of the data set for this water quality and modeling studies was given in *Table 3*.

Table 3. *Basic statistic of the data set*

Coasts	Parameters (CFU / 100 ml)	Mean	Std	Max	Min
Göllüce Public Beach	Total coliform	511.148	636.474	3210	5
	Faecal coliform	135.093	132.533	521.5	2
	Faecal streptococci	73.537	63.613	220	2
İnciraltı Public Beach	Total coliform	310.296	315.901	1500	28
	Faecal coliform	110.222	113.191	440	7.5
	Faecal streptococci	65.370	89.917	420	2
Darka Holiday Village	Total coliform	310.611	301.155	1200	15
	Faecal coliform	66.889	75.676	400	2.5
	Faecal streptococci	51.889	62.364	250	3
Orhangazi Public Beach	Total coliform	518.185	690.173	3300	5
	Faecal coliform	110.259	110.555	425	2
	Faecal streptococci	78.130	92.063	400	2
Lake	Total coliform	412.560	520.574	3300	5
	Faecal coliform	105.616	111.137	521.5	2
	Faecal streptococcus	67.231	77.799	420	2

Moreover, the correlation of the three parameters with each other was considered statistically significant ($p < 0.05$). In previous scientific studies, when the correlation between indicator bacteria has been examined, it has been determined that the numbers of indicator bacteria decreased or increased in parallel with each other (Demirci and Can, 2015; Gürün and Kımıran-Erdem, 2013).

The effect of neural network structure on performance function (RMSE) and model estimation power (R)

The effect of neural network structure by changing of inputs and number of hidden neurons (layer) on model performance was investigated. Root Mean Square Error (RMSE) has been adopted as a measure of performance (as performance function) for comparing the effectiveness of tested structures (Belayneh and Adamowski, 2012; Soyupak et al., 2006). The performance function (RMSE) values and correlation coefficients (R) obtained for training, validation, testing and whole data sets. The model structures and their performance functions (RMSE) values and correlation coefficients (R) of the data sets were presented in *Table 4*. In all model structures, Faecal coliform was chosen as output parameter.

In "Model 1" all data of Lake İznik a and b structures, total coliform and faecal streptococci parameters were chosen as inputs. These models were run quite efficiently. But RMSE values of model 1-b were smaller than model 1-a, R correlation numbers of model 1-b were bigger than model 1-a except verification values. Enhancing of hidden

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38973917

neuron numbers in Model 1-b was raised to whole data set of R correlation number. In model 1 –c and d total coliform parameter was selected as input. These models were run efficiently. In model 1-d, hidden neuron numbers were raised. For this reason RMSE values of training and testing stages decreased and these R values and R number of whole data increased. İznik sub-province had advanced biological treatment plant with membrane technology and its sewerage system had completed. But the first stage of the treatment plant was put into use just (BUSKİ, 2016). Even so the treatment plant was not run at full capacity the pollution in the lake decreased (Demirci and Can, 2015). Also the monthly variations of the parameter's concentration was not been considered as statistically significant (Demirci and Can, 2015). This situation could be attributed that the pollution load was not belong to a specific period and point pollution sources disturb the ecological balance of the environment because of their uninterrupted waste inputs and therefore change the competitive environment among microorganisms continuously (Gürün and Kımıran Erdem, 2013). As a consequence, it was estimated that there was some inaccuracy in the model results and R values were not too high. Bursa Metropolitan Municipality planned to start up the second stage of the biological treatment plants in İznik sub-province. So it was estimated that microbiological and chemical pollution in the Lake would decrease (BBB, 2016).

In Göllüce Coasts "model 2" a and b structures, total coliform and faecal streptococci parameters were inputs as model 1. These models were run efficiently. RMSE values of model 2-a and b training and testing stages were bigger than model 1-a and b but verification RMSE values were smaller than model 1. Also verification R values were bigger than model 1, others not. It was found that the performance of model 2 (Göllüce area) less than model 1 (All Data of the Lake). Livelihood of the village of Göllüce was fruit and vegetable farming, especially olive cultivation. Therefore pesticides and fertilizers polluted this coast as diffuse sources. Moreover entering of domestic wastewater was in this coast because of incomplete sewerage system (LGP, 2016).

Microbial growth on and utilization of environmental contaminants as substrates have been studied by many researchers. Most times, substrate utilization results in removal of chemical contaminant, increase in microbial biomass and subsequent biodegradation of the contaminant (Okpokwasili and Nkweke, 2005). Wastewaters from industrial, municipal and agricultural sources are characterized by presence of mixtures of chemicals. Pollutant mixtures may contain only organic chemicals or may also include inorganic substances such as heavy metals. Co-contamination of natural environments with mixtures of pollutants is an important problem. The removal of one component may be inhibited by other components in the mixture and different conditions may be required to degrade different compounds within the mixture. Strong interactions among components of a pollutant mixture have been reported (Egli, 1995; Klečka and Maier, 1988; Meyer et al., 1984; Saéz and Rittmann, 1993). The utilization pattern can change with different mixture compositions, depending on the chemical nature and concentration of the substrate, oxygen concentration and microbial growth rates. In addition to biodegradation stimulation due to increased growth at low substrate concentrations, stimulation of one compound by another in a mixture can be by induction of catabolic enzymes required for degradation of the second pollutant (Arvin et al., 1989). This mechanism produces simultaneous degradation of pollutants in mixtures and has been reported for pentachlorophenol and chlorinated aromatics, toluene and *p*-xylene (Okpokwasili and Nkweke, 2005).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_38973917

Model 1 (All of the Lake data) had more data than model 2. Therefore performance of model 2 might be fallen. Also, it was found that pollution concentrations of Göllüce coast higher than Lake Average. Because it was considered that pollution loads and varieties concentrated in Göllüce coast. For this reason metabolisms and growth rate of microorganisms were affected and model performance dropped.

In model 2-c and d total coliform parameter was selected as input. These models were run efficiently. In model 2-d, hidden neuron numbers were raised. For this reason RMSE values of validation and testing stages decreased and R values of validation and whole data were increased. The structure of b in model 2 like model 1 was the most efficient structure among the others. Increasing of the numbers of input parameters and neurons in hidden layer raised the model 2 performance.

In İnciraltı coasts "Model 3" a and b structures, total coliform and faecal streptococci parameters were inputs as model 1 and model 2. These model structures were run more efficiently and R values were bigger than model 1 and model 2. When model 3 (c and d) compared with model 1 and model 2 it was seen that model 3 c and d structures run better than model 1 c and d especially model 3 c. There was no difference between model 3 c and d. İnciraltı coast was cleaner than Göllüce coast as shown in *Table 3*. Also, there was cleaner than the lake average in terms of total coliform. Therefore microbial modeling was efficiently due to decrease interactions between pollutants. The raising of neuron numbers of hidden layers in the structures had same number of inputs applied in model 3 (İnciraltı coast) was not enhance model efficiency. The raising of neuron numbers of hidden layers in the structures had same number of inputs in the more contaminated coasts (model 1 and model 2) increased the model efficiency. The raising of input's numbers in the all structures in model 3 enhanced the model efficiency.

In Darka Holiday Village "Model 4" inputs and outputs parameters were like other models. In a and b structures RMSE values were less than other models excluding testing value of a structure. For this testing RMSE value R number of whole data set "a" less than other model structures even the smallest R value. Structure b was one of the most efficient running models. When c and d were compared structure d better than c and other d structures of models. Darka Holiday Village was the cleanest coast in the Lake according to *Table 3*. The pollution in Darka coast was caused mainly domestic waste water originating from holiday village not from agriculture (BBB, 2016; Municipality of İznik, 2016). Unlike the clean area of İnciraltı, increasing of neurons in hidden layers raised the performances of the structures in the Model 4 had same and different numbers of inputs.

According to comparison of Orhangazi coast "Model 5" with other models RMSE values of structure b smaller than other model's structures and it could be said that the most effective one. R values of all Model 5 structures were found 0.75 and over. When and b were compared rising of hidden layer number was increased the performance. According to comparison of c and d rising of hidden layer number was not increased the performance. In the Orhangazi area which was one of the most contaminated coasts enhancing of inputs and hidden layer numbers provided better model performance. Orhangazi was one of the places where agriculture and industry were the most intense in Bursa (BBB, 2016). In sites co-contaminated with metals and organic compounds, metal toxicity inhibits the activity of organic degrading microorganisms, impacting both their physiology and ecology, thus reducing the rate of biodegradation of the organic compounds (Said and Lewis, 1991; Roane et al., 2001; Maslin and Maier, 2000). Also, faecal contamination and growth of pathogens were associated with environmental parameters such as rainfall, temperature, wind, sunlight or different hydrometeorological and hydrodynamic variables (WHO, 2010).

Model structures experimented in this study had shown that the results of the statistical model might not always be in linear trend and gave results with a small inaccuracy. In addition, all these experiments had shown that to increase the number of neurons in hidden layer had not increased at every turn the model efficiency. Species and number of the input parameters might be more effective in the coasts where cleaner than the others with lower concentrations. However, when the whole models were examined the increasing of numbers of inputs with neurons in the hidden layers raised the model performances at every trial. Thus the structure of "b" was found as the most efficient structure in the all models.

As a result, it was found that all model structures of the 4 coasts and all data of the lake were successfully. R and RMSE values calculated were in the acceptable range (Soyupak et al., 2003; Brion and Lingireddy, 2003; Yonar and Kılıç, 2014; Mas and Ahlfeld, 2007; Ogwueleka and Ogwueleka, 2010; Radojevic et al., 2013). In water pollution and quality studies when number of data and tests were increased RMSE and MSE values were calculated smaller (Soyupak et al., 2003; Yonar and Kılıç, 2014). *Figure 3* displays the observed time series and forecasted values with the model structures. In addition, the corresponding scatter plots are also presented.

Conclusions

This study is important to support the modeling studies of microbiological parameters and to more effective monitoring can be done by measuring fewer parameters with the predictions made. Because there are limited number of studies in deep lakes this study is original in terms of artificial neural network modeling of coliform bacteria in deep lakes. The ANN structures were successfully used to forecast the faecal coliform concentrations in Göllüce, İnciraltı, Darka, Orhangazi Coasts-Lake İznik. Multilayer feed forward networks were used. This study indicated that a neural network could be used to predict microbial pollution in deep lakes.

In the regions, where point sources of pollution were continuous, the modeling study gave a result with a certain margin of error since they disturb the ecological balance of the environment and therefore change the competitive environment among microorganisms continuously. Besides, the error values (RMSE) of the modeling results of the coasts had more pollution load and pollutant diversity (Göllüce and Orhangazi areas) were found to be higher than the others coasts of Darka and İnciraltı, which are relatively cleaner, since the metabolism of microorganisms was effected by the number and chemical structure of substrates (pollutants), existing in the environment, and depending on this, their rates of growth were affected. *This study showed that the use of artificial neural networks to forecast of microbial pollution of lake coasts where wide variety of contaminants (industrial and domestic) was found might not provide accurate results.*

For this reason summer and winter data could be assessed separately and together, and repeat of the models by increasing the number of data would enhance the model performance. The effect of neural network structure by changing of inputs and neuron's number of hidden layer on model performance was investigated. *This study showed also that increasing the number of inputs together with the neurons in hidden layer raised the performance of each model structure.*

management, it is necessary to simulate pathogen organisms through different statistical and process based dynamic water quality models, using environmental and hydrodynamic parameters in water and in the atmosphere, and compare the model results. Also, different artificial neural network model structures should be applied for different microbiological parameters, and model performances should be examined in the future. In addition to that it will be useful to establish early warning systems, which are very important for public health, on the examined coasts by using the results of the modeling studies. Investigations to improve the knowledge-base of the area would also be of greatest importance to validate coastal and lake models and identify, for example, the role of diffuse sources from animal and agricultural soil origins which could carry human pathogenic bacteria or viruses.

The fact that monitoring and modeling works to protect of Lake İznik has national and international ecological values of in respect to water birds, endemic flora and fauna, tourism, recreation, fishing and agricultural are vitally important for the conservation of natural equilibrium in the world. Consequently continuation and development of modeling studies will be important in the future to provide information to the protection and supervision mechanisms.

Abstract. The growing population poses serious threats not only to forests but also to the overall environment due to fuel and wood consumption used for various purposes. However, converting organic waste into fire bricks could be a useful step towards alternative energy sources. In the present study, fire bricks were prepared using organic waste i.e., cardboard, rice husk, saw dust, cow dung and newspapers. Firstly, the brick manufacturing materials were soaked in water in various ratios and converted into paste with mortar and pestle to make bricks. Secondly, the fire bricks were analyzed for gas emissions, burning time period, flue gas temperature and net efficiency. The results reveal that gas emissions were below the National Environmental Quality Standards (NEQS). Moreover, the results were also compared with a commonly used fuel wood (*Vachellia karroo*) to calculate the statistical variations for various parameters. Thus, the net efficiency range of fire bricks was from 39.7 to 58.9%, significantly higher than that of the fuel wood. The flue gas temperature varied from 230 to 430 °C. Therefore, the bricks were found to have high heat intensity, to be easy to use, and to have needed small space for their storage. Additionally, fire bricks are cost-effective compared to fuel wood. It is concluded that high quality and durable fire bricks can be made while using a combination of rice husk and newspapers (RHNP), rice husk and cardboard (RHCB), sawdust and cardboard (SDCB), cow dung and cardboard (CDCB), cow dung and newspapers (CDNP), sawdust and cow dung (SDCD) in a ratio of 2:3. It is due to all these benefits, that fire bricks were considered eco-friendlier in efficiency than fuel wood.
Keywords: *fire bricks, alternative energy, fuel wood, biomass recycling, waste management*

Introduction

Energy is a crucial and significant factor for socioeconomic development in any country. However, the ever-growing population is putting more pressure on energy sources. It is said that both sufficient and cost effective energy resources are essential for the steady development around the globe. The energy demand is raised with urbanization and industrialization. Thus, fossil fuel is excessively used around the world for urbanization and modernization. Coal, oil and gas meet 80% of the energy requirements of the world, however; contribution of renewable energy resources and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39193932

nuclear power in energy sector is 13.1% and 6.5%, respectively in the total energy demands (IEA, 2007).

Municipal solid waste is being generated in large amounts with low gas emissions threatening the environmental health. In order to collect, store, process, and dispose the municipal solid waste, usually unsuitable practices are being employed. These unfit techniques in turn harm the health of humans, plants and animals. Suitable and secure management of solid waste is deemed necessary, especially in an area which is denser for better environmental health. In developing countries, waste after its collection is generally discarded on land surface without any protection that causes water and air pollution (Dong et al., 2003; Mosler et al., 2006).

Recently, it has been witnessed that the fossil fuel scarcity is increasing with high energy requirements around the world. It is need of the hour to go for environment-friendly and sustainable alternate energy resources. The interest of switching towards alternate energy sources will not only substitute fossil fuels but it is also good for environmental health. Conventional fuel like firewood is rapidly declining which increases dependency on innovative sources of energy for household usage (Kavitha and Joseph, 2007).

Wood and charcoal had been considered as renewable energy sources and agricultural waste is available in sufficient amounts in rural areas. The residues like rice husk, sawdust, corn stover and cotton stalk are best options to be used for cooking purposes at household level. However, the use of these residues without processing is problematic due to their raw form which produces large amounts of smoke, leading to air pollution. Biomass resources when burned in their raw form generate less heat and have low mass to volume ratio. All these factors lead to poor efficiency to use them as fuel (Emerhi, 2011). Moreover, it is not convenient to use, transport and store these agricultural residues in their pure form.

Massive flammable materials are compacted to make them feasible for using as fuel. Thus, this technique is becoming popular around the globe. Fuel bricks have been produced to use not only for household purposes but also for industries. The reason behind the production of fire bricks is to meet the growing energy requirements and to protect the environment from the harms of traditional fuels. At the same time, this technique also manages crop remains in a very efficient way (Vongsaysana, 2009). Moreover, heat efficiency of these crop residues can also be intensified by converting them into fuel bricks (Wilaipon, 2007).

Calorific values of the agricultural and organic residues would increase in brick form due to compaction. The loose agricultural wastes have lower calorific value which is difficult to handle (Oladeji, 2010). For electricity production, industrial use and for cooking food, the use of fire bricks can be a good option (Styles et al., 2008). Therefore, the present study aims to switch traditional use of fuel wood to the high energy efficient and environment-friendly alternative energy sources through agricultural and other organic residue-based fire bricks.

Materials and methods

Study area description

The current study was carried out in the Punjab Province of Pakistan which is renowned for its agricultural based economy. Geographic location of the study area is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39193932

30.183° latitude and 73.06° longitude. All the waste material used in this study was collected and processed for brick development in the district Pakpattan of the province.

Collection and preparation of samples

Cardboard and newspapers were collected from shops. Likewise, rice husk was collected from rice grinding mills and sawdust from carpenter shop. Fresh cow dung was collected from cow farm house. Similarly, rice husk and sawdust were cleaned to remove dirt and undesirable particles. Newspapers were torn into the smallest possible pieces. These pieces were placed in the bucket and soaked in water for 24, 48 and 72 h. *Table 2* shows the effects of soaking time on quality of fire bricks.

These samples were converted into paste while using grinder. The same procedure was repeated for cardboard sample preparation, and cardboard sample was also converted into paste while using crusher. This practice was adopted to check the most suitable combination and quality of sample materials to convert them into smooth bricks. The quality of sampling combinations in different ratios was ranked in three different categories such as good, average and best. Only the best quality rank was proceeded further for analysis. The quality (average, good and best) of the fire bricks was based on the measurement of porosity and dry bulk density of the bricks (*Table 1*). The porosity (n) of a material indicates the storage capacity of a porous medium. It is a fraction of the voids in total volume of the porous medium (*Eq. 1*). The dry bulk density (ρ_b) is calculated from the dry mass of the material and its total volume (*Eq. 2*) (Fetter, 2001).

$$n(\%) = \frac{V_v}{V_t} \times 100 = \frac{V_w}{V_t} \times 100 \qquad \text{(Eq.1)}$$

$$\rho_b (g / cm^3) = \frac{m_s}{V_t} \qquad \text{(Eq.2)}$$

where V_v is the volume of voids which is equal to volume of water V_w in saturated medium, V_t is total volume and m_s is dry mass of the material.

Table 1. *Criteria used for the quality of fire bricks*

Porosity (%)			**Dry bulk density (g/cm^3)**		
Average	Good	Best	Average	Good	Best
35-60	73-90	60-72	0.31-0.5	0.15-0.3	0.1-0.15

Vachellia karroo (formerly known as *Acacia karroo*) is a fast growing tree and is abundantly found in Pakistan, India, Nepal and Africa. It is commonly found along highways, canals, river sides, rangelands and among the major trees considered for agro-forestry in Pakistan. It produces high-density wood (800-890 kg/m^3) which is commonly used for fuel wood besides other beneficial uses. Fuel wood of *Vachelli karroo* was used as control in this study (*Fig. 1a*).

DOI: http://dx.doi.org/10.15666/aeer/1604_39193932

Binder preparation and formation of bricks

Wheat flour was used to prepare binder. Hot water was added into it to prepare its paste. It was assured that no lumps were produced. Binder was muggy, it did strengthen the samples. The volume of binder varies in different types of combinations depending that a homogeneous mixture is formed. Newspaper (NP) paste was taken and placed into brick mould box, levelled and pressed to make it compact. Afterwards, the mould box was emptied in an outdoor dry place under natural conditions. Three NP bricks were made in this way while three cardboard (CB) bricks were also prepared with the same procedure. The rice husk (RH) sample was taken and thoroughly mixed with binder until the paste was obtained. This paste was placed in brick mould box and was levelled. The same procedure was adopted and repeated for the combination of SDNP, SDCB, RHCD, RHNP, RHCB, CDNP, CDCB, and NPCB. *Table 2* shows the sample combinations in different treatments. The ratios of wastes were based on the volume. The same procedure was repeated for various ratios like 1:9, 7:3, 3:2, and 1:4 respectively. Three bricks of each combination were made. A metallic template was used for the formation of bricks. The volume of each prepared brick was 1823 cm^3 with dimensions of 22.86 cm length, 11.43 cm width and 6.98 cm height. The shape of prepared bricks is shown in *Figure 1b, c* and *d*.

Cost-effectiveness measurements of fire bricks

Market prices of the organic wastes (newspaper, sawdust, rice husk, cardboard and cow dung) were collected and then were compared with the market price of hard wood as control. Cost-effectiveness of fire bricks made of organic waste was calculated. Prices were calculated in US dollars. The price for waste material includes labor charges to prepare fuel bricks (2 persons/day and charges are 3.48 USD/day/person). The prices for dry waste are as newspaper 2.61 USD/40 kg, cow dung 0.35 USD/40 kg, cardboard 3.10 USD/40 kg, sawdust 1.66 USD/40 kg, rice husk 2.78 USD/40 kg.

Analysis of fire bricks for gaseous emissions

Combustion analysis was carried out to measure gas emissions from fire bricks. The system contained weight meter, a stove with ceramic lining and chimney. The Testo 350 flue gas analyzer connected to the chimney was used to measure the emissions, flue gas temperature, net efficiency, gross efficiency, and burning period. In present research, the fuel bricks were burned in the stove of ceramic lining. The emissions of burning of fuel bricks were observed in mg/Nm^3 and then compared with National Environmental Quality Standards (NEQS) for stack emissions. NEQS values for CO, Oxides of Nitrogen and Oxides of Sulphure are 800 mg/Nm^3, 600 mg/Nm^3 and 1700 mg/Nm^3, respectively. However, NEQS for smoke number is 2 on Ringleman Scale (GOP, 2016).

Statistical analysis

MS-Excel (2010) was used for statistical analysis. Descriptive statistics such as percentage, average, were applied to process results of density, porosity, gas emissions and cost-effectiveness of fire bricks. ANOVA was performed for different parameters at significance level of 1%. Degree of freedom (df), sum of squares (SS) and mean sum of squares (MSS) were calculated for different source of variation (SoV).

Results and discussion

Fire bricks of individual materials were found to be difficult to form besides their quality remained average. However, when all treatments were used in combinations, it not only improved their quality but also made their formation easy. Bricks of individual materials: newspaper (T1), cardboard (T2) and cow dung (T5) were made. Out of these treatments, bricks with T1 and T2 were of good quality, while T5 fire bricks were of best quality. It was difficult to make fire bricks from treatments T3 (sawdust) and T4 (rice husk) as individual materials due to their physical properties as both were in powder form. Even the quality of fire bricks prepared from sawdust and rice husk in the presence of binder was also very poor. Sawdust and rice husk can be used along with other waste materials in order to make fire bricks. Apparently, the surface of fire bricks was smooth and homogeneous (*Fig. 1*).

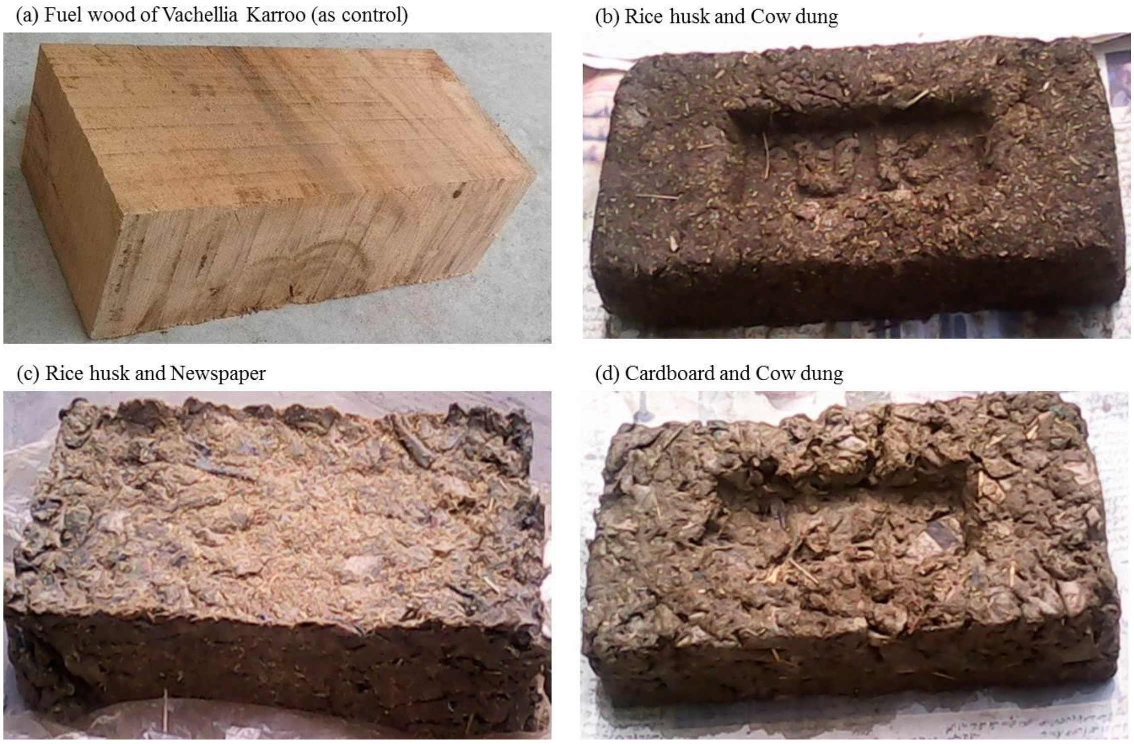

Figure 1. *Fuel wood (as control) and samples of prepared bricks from organic wastes*

It was found that fresh cow dung did not require soaking. Sawdust and rice husk were not soaked because they were used with paste of others. Only newspapers and cardboard were soaked. Various soaking periods were used to create homogeneous moisture in the mixture of materials for formation of bricks. Quality of six combinations (T32-T37) with a soaking period of 72 h was found to be the best, which was further studied (details in *Table 2*).

Amount of carbon monoxide and carbon dioxide in fire brick exhaust

Figure 2 shows the amount of oxygen, CO and CO_2 in the exhaust of fire bricks. Amount of CO varied significantly with treatments from T32 to T37. The lowest CO was observed in T32 (RHNP) and the highest CO emissions were found in T35

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39193932

(CDCB). Emission of CO was within NEQS in case of T32 (RHNP), T33 (RHCB) and T37 (SDCB). Carbon monoxide (CO) emissions were the lowest as 265 mg/Nm^3 in T32 and the highest as 3002 mg/Nm^3 in T35 (*Fig. 2a*) however, NEQS for CO is 800 mg/Nm^3. All values were lower than the ones of NEQS (GOP, 2016) while only T37 (SDCD) emission value meets the ones of NEQS because of their composition. Ishrat and Lakshami (2014) conducted a study at Hyderabad, India to make fuel briquettes from mixture of paper, rice husk and sawdust and emission analysis of combustion of these briquettes was 84.77 mg/Nm^3 CO that is much lower than that of this study.

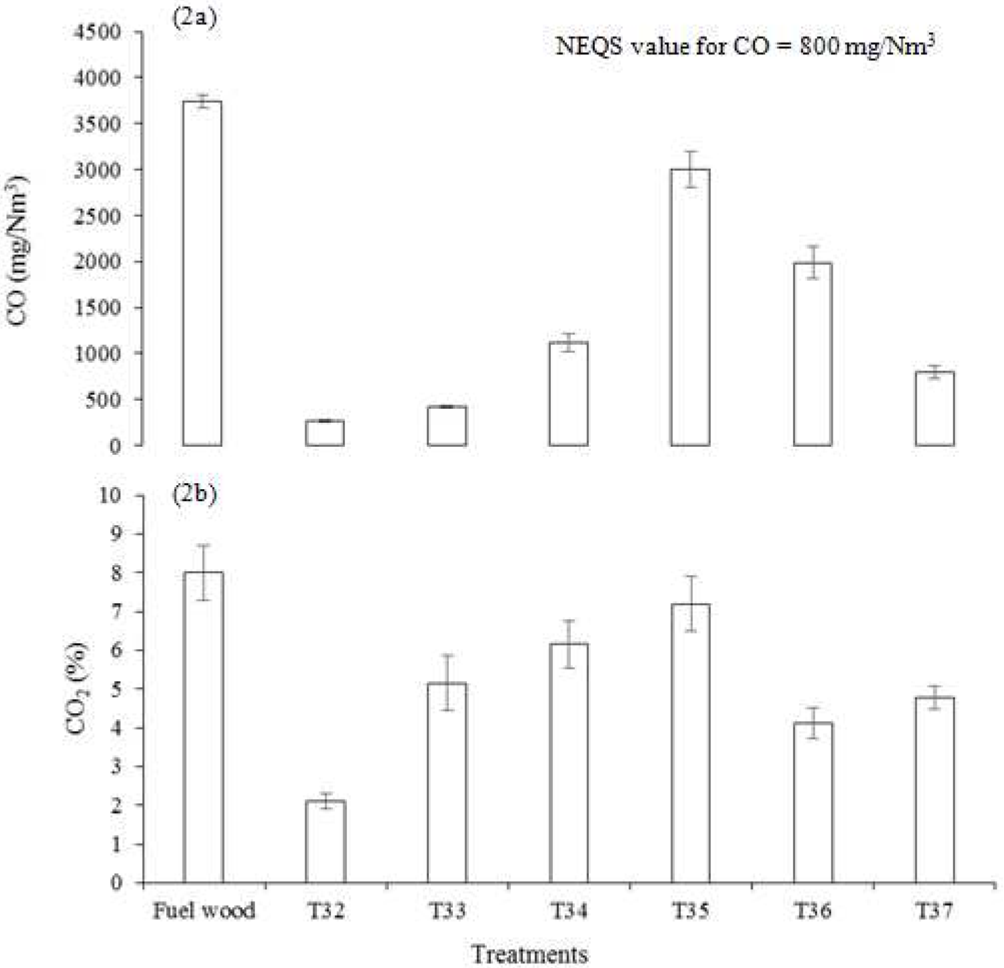

Figure 2. *Amount of CO and CO$_2$ in the fire brick exhaust*

Figure 2b indicates the results of CO_2 emission from fire bricks. It was observed that the highest carbon dioxide emission was seen in T35 (CDCB) and the lowest in T32 (RHNP). Carbon dioxide (CO_2) emission was the lowest 2.1% in T32 and the highest 7.2% in T35. The lower CO_2 emission was due to the combination of biomass NPRH in T32. According to Maia et al. (2014), when biomass fuel bricks were analyzed for emissions of CO_2 the resultant value was 18.56%, which is much higher than that of the present study. In another study, carbon dioxide values were found as 50% for wood chips and paper, and sawdust and paper, and 30% for sugarcane and paper. Evans, S (2014) reported 10 times lower carbon emissions from burning organic residues like

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39193932

branches, twigs and sawdust than in case of fuel wood coals. However, Fernandes et al. (2013) revealed that the biomass briquettes showed a greater release of CO_2 with a peak of 0.48%. Lower oxygen concentration caused higher CO concentration during combustion.

Amount of NO and NO_x in fire brick exhaust

It was observed that NO emission from fire bricks slightly varied from one another. T32 (RHNP) and T35 (CBCD) showed almost similar and the highest emission of NO than others, while T33 (RHCB) showed the lowest emission of NO (*Fig. 3a*). The minimum observed nitric oxide (NO) emission value was 106.7 mg/Nm^3 in T33 and the maximum was 324 mg/Nm^3 in T35. The relevant literature shows 2.45 mg/Nm^3 when biomass fuel bricks were analyzed for NO that is much lower than that of the present study. High nitrogen contents, resulting in an elevated emission of dust and NOx, are still a matter of investigation on the use of herbaceous biomass at small-scale household appliances (Energy Commission of Ghana, 2008).

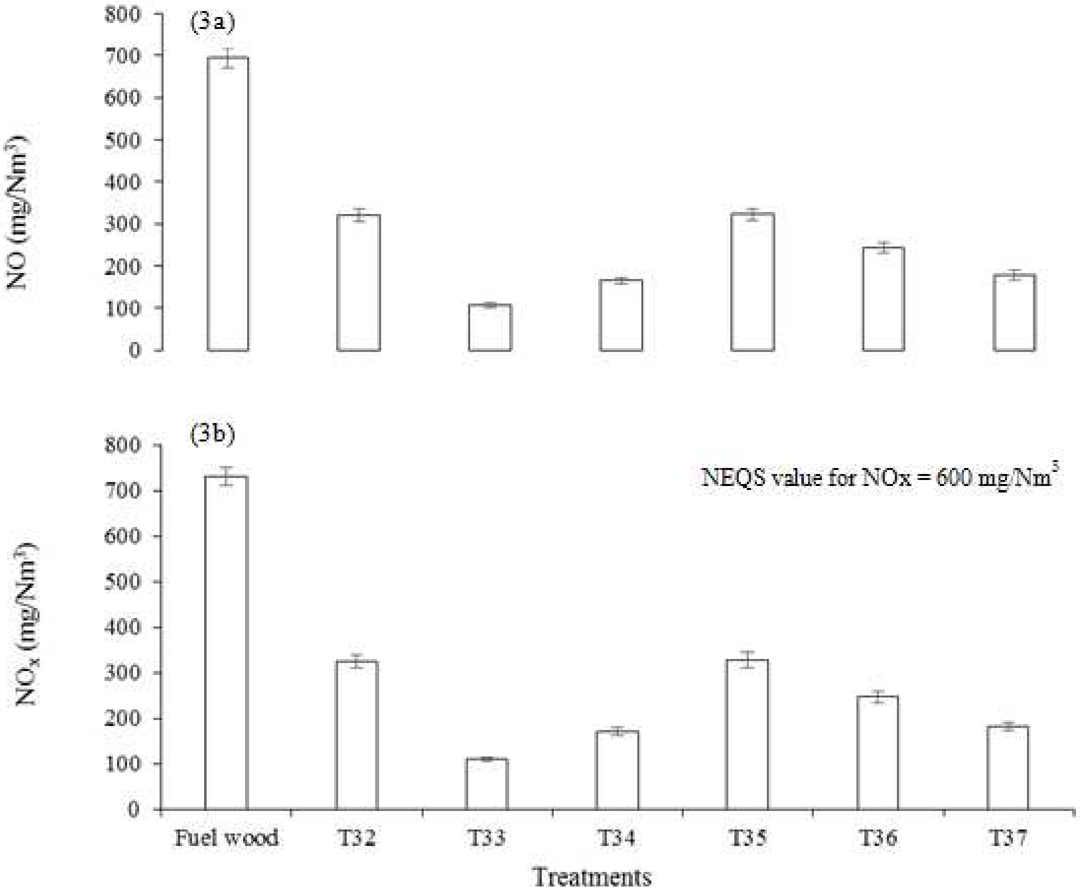

Figure 3. *Amount of NO and NO_x in fire brick exhaust*

Figure 3b shows NOx emissions from fire bricks. It was observed that NOx emissions varied significantly from T32 to T37. The highest NOx emissions (327 mg/Nm^3) were observed in T32 (RHNP) and T35 (CDCB), while T33 (RHCB)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39193932

(3b)

showed the lowest (109.3 mg/Nm^3) NOx emissions. It is stated that all of the NOx emissions during burning the bricks were below those of the NEQS.

Amount of SO_2 in fire brick exhaust

Figure 4 indicates the SO_2 released from burning the fire bricks. It was observed that T35 (CDCB) liberated the highest emissions of SO_2. The lowest emission was observed in T32 (RHNP).

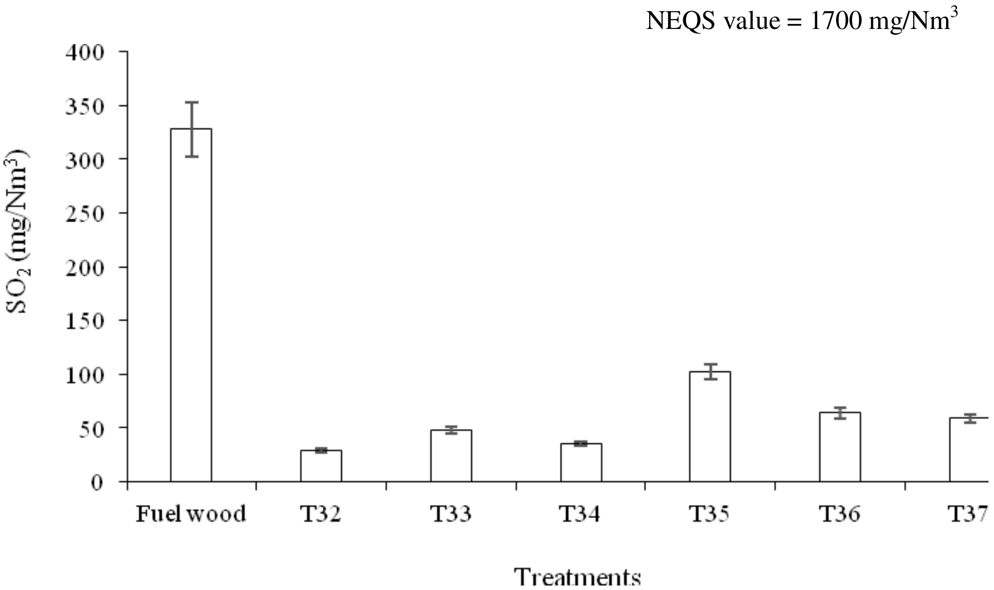

Figure 4. *Amount of SO_2 in fire brick exhaust*

The minimum sulphur dioxide (SO_2) emissions – 29 mg/Nm^3 - were also observed in T32 and the maximum -102.6 mg/Nm^3 - in T35 (*Fig. 4*). Even the maximum observed value was lower than that of the NEQS which is 1700 mg/Nm^3. The reason behind this is the composition of fire bricks. When biomass of fire bricks was analyzed to determine their SO_2 emissions, they were 167.7 mg/Nm^3 (Enweremadu, et al., 2004) which were greater than those of the present study. Less concentration of nitrogen and sulphur was found in fire bricks smoke, which means less polluted atmosphere. This shows that if fire bricks will be used for heat, they will not harm the environment (Enweremadu, et al., 2004). The oxides of nitrogen and sulphur produce nitric and sulphuric acid which cause acid rain (Chaney, 2010).

Combustion of wood and coal as fuel causes air pollution, which in turn damages the health of human beings. One cubic meter of fuel wood release 61-73 kg of CO_2. Longer exposures to the gases such as carbon monoxide (CO), sulphur oxides (SOx) and nitrogen oxide (NOx) cause harm to human health (Raymer, 2006).

Table 3 shows results of the statistical analysis (ANOVA) for different gases in exhaust from burning of different types of fuel bricks. It is clear that there is significant difference between gaseous emissions from burning of fuel bricks. Emission of gases (CO, CO_2, NO, NOx and SO_2) has been significantly reduced for fuel bricks as compared to that of commonly used fuel wood.

* indicates significant difference between treatment

Net efficiency, flue gas temperature and burning time for fire bricks

Figure 5a indicates that the net efficiency of fire bricks slightly varied from T32 to T37. It was observed that the highest net efficiency was found in T37 (SDCD), and the lowest net efficiency was observed with treatment T36 (CDNP). The net efficiency which is the efficiency of solid burned particles of fire bricks was minimum (39.7%) with treatment T36 and maximum 58.9% with T37. In Latvia, a study was conducted to make fire briquettes from woody and non-woody herbaceous resources like grain husk. According to combustion analysis of those fire briquettes, the net energy production was 15.6 to 17.7MJ/Kg.

Flue gas temperature was measured to determine the efficiency of fire bricks. *Figure 5b* shows flue gas temperature while burning the fire bricks. It was observed that flue gas temperature was the highest in case of T35 (CDCB). In case of T36 (CDNP) and T37 (SDCD) same flue gas temperature was found, and it was the lowest for T32 (RHNP). Minimum temperature was 230 °C in T32 and maximum was 450.2 °C. The combustion analysis of flue bricks gave flue gas temperature variation from 331 to 474 °C.

Fernandes et al. (2013) found that carbon, hydrogen and oxygen are the major constituents of biomass fuels. Carbon and hydrogen are oxidized to make CO_2 and H_2O which are responsible for high calorific value of the bricks. According to Ringleman scale, the smoke number indicates the apparent density of smoke, the greater the smoke number the greater the amount of particulate matter in the bricks. Minimum smoke number was 1.4 with treatment T33 (RHCB) and maximum 5.3 with T35 (CDCB) as shown in *Figure 5b*. While the NEQS for smoke number is 2 on the Ringleman scale. Maia et al. (2014) produced banana leaves fuel briquettes and found that in combustion tests, heavy smoke production was attributed to the fact that oxygen was supplied in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39193932

uncontrolled way. Therefore, it is important to provide sufficient oxygen to convert CO to CO_2 and minimize the smoke.

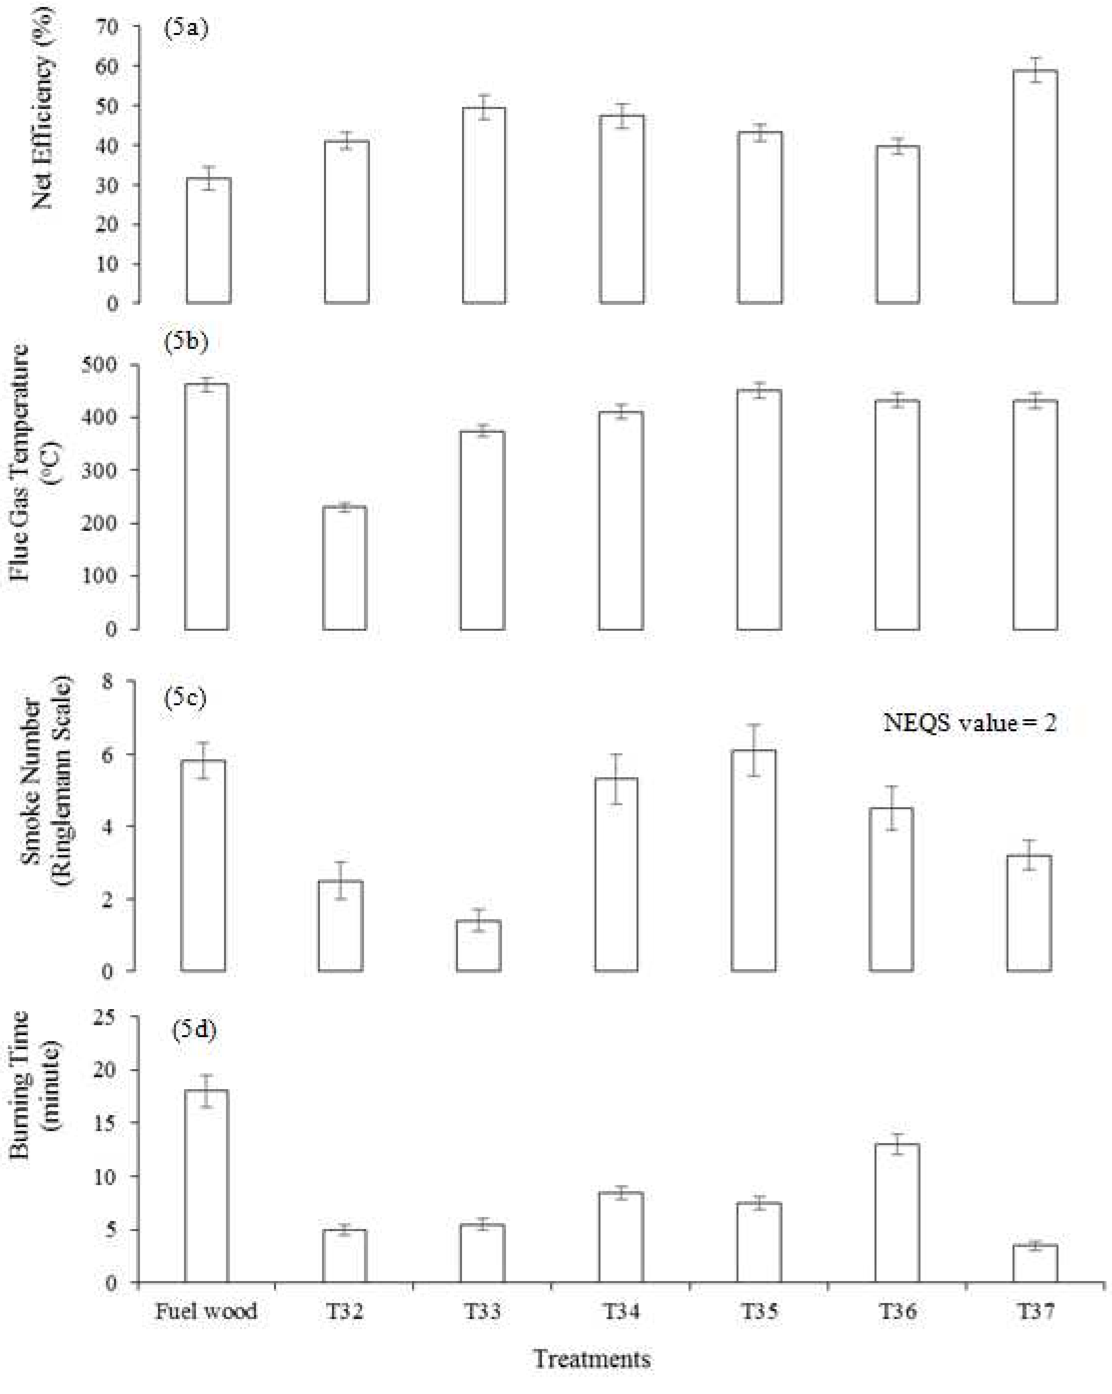

Figure 5. *Net efficiency, flue gas temperature and burning time for fire bricks*

Figure 5d shows burning time or duration of burning of fire bricks. It was observed that burning period was the highest for T36 (CDNP) and the lowest in case of T37 (SDCD). Burning period was observed as the lowest in T37 (4 min) and the highest was 13 min with treatment T36.

DOI: http://dx.doi.org/10.15666/aeer/1604_39193932

Table 4 shows results of statistical analysis of variance (ANOVA) for net efficiency, flue gas temperature and burning time of bricks. It is clear that there is significant difference between treatments for net efficiency, smoke number and burning time. However, there is non-significant difference between treatments in case of flue gas temperature. It shows that there is no effect on flue gas temperature for different types of fuel bricks.

Cost-effectiveness of fire bricks

Cost-effectiveness of the fire bricks manufactured from various organic waste was calculated based on local market prices. The price of fuel bricks prepared from various combinations of these materials is also less than that of the control (fuel wood). The number above bars indicates (%) the fuel bricks prepared from the waste material are less expensive than the control (fuel wood) used as fuel (*Fig. 6*).

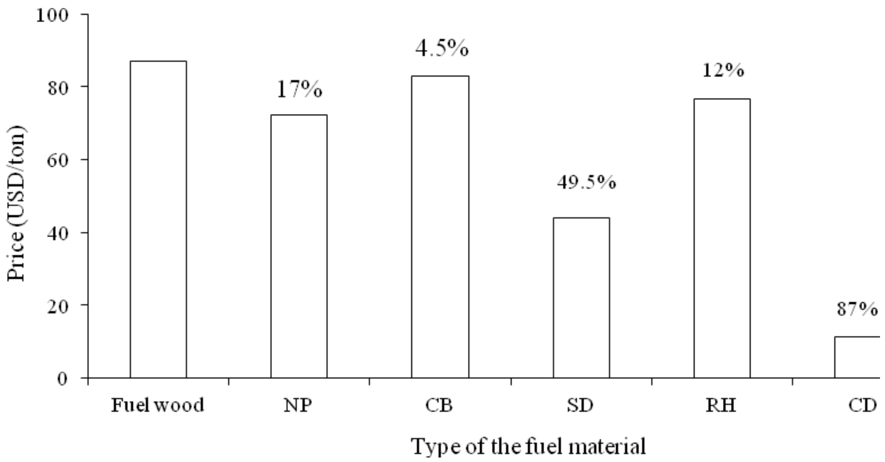

Figure 6. *Cost-effectiveness of using organic waste for manufacturing fire bricks*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39193932

It was assessed that cow dung is 87% cheaper than the fuel wood followed by sawdust that is 49.5% less expensive than the fuel wood.

Conclusion

High quality and durable fire bricks can be made while using a combination of RHNP, RHCB, SDCB, CDCB, CDNP, SDCD in a ratio of 2:3 by volume. Moreover, the fire bricks produced from different organic wastes meet the recommended fuel characteristics as there was no significant difference in the flue gas temperature. The net burning efficiency range of fire bricks ranges from 39.7 to 58.9%, significantly higher than that of the fuel wood. Contrary to fuel wood, fire brick emissions like CO, CO_2, SO_2, NOx are within the permissible limits of NEQS. It is observed that fire bricks are eco-friendly and the use of these bricks will minimize the harmful effects of traditional fuel wood burning which would further minimize pressure on fuel budget of rural households. Fire bricks have the market potential due to their easy way of making, cost effectiveness and environment friendly nature. Similarly, this method recycles the waste into eco-friendly fuel bricks that are more efficient and reduce the burden on wood for energy. These bricks have high durability and can be transported anywhere without any damage to them.

Acknowledgements. Thanks are extended to Health Safety and Environment Consultants and Services, Lahore, Pakistan for providing technical facilities for flue gas analysis from fire bricks.

Abstract. In this study, the combination of high-performance liquid chromatography (HPLC) based isoflavone profiling with multivariate analysis was used to screen specific soybean germplasms from Southwestern China, and simultaneously to investigate the influence of genotype, the geographical environment and the germplasm community size on isoflavone biosynthesis. A total of 144 soybean germplasms were evaluated for 12 isoflavones, which varied markedly due to genotypes and locations. Partial least squares analysis (PLS) results exhibited little variability among the 144 samples of four different locations. Five samples were separated from other genotypes based on the first PLS principal component that had high isoflavones. Daidzin, genistin, malonyldaidzin, malonylgenistin and acetylgenistin were the discriminating metabolites. Later the bidirectional orthogonal projection to latent structures-discriminant analysis (O2PLS-DA) was applied for geographical determination of five specific germplasms samples. Geographical environment influenced mainly acetylgenistin, acetyldaidzin, glycitein and malonylglycitin. Our results suggest that genetic factors play a vital role in the isoflavones biosynthesis of a major community, whereas the environmental factors can effectively regulate the isoflavones accumulation especially in the evaluation of small groups of soybean germplasms. These results demonstrate the use of the HPLC based metabolite profiling combined with multivariate analysis (PLS and O2PLS-DA) as a tool for the determination of specific germplasm, biomarker metabolite and geographical origin.
Keywords: *community size, environment, latitude, multivariate analysis, metabolite*

Introduction

Soybean (*Glycine max* L.) is a highly consumable legume crop on the basis of its nutritional value in the world. Soybean is regarded as a functional food with a variety of beneficial composition, especially in China. Soybeans contain several phytochemicals such as isoflavones, tocopherols, saponins and functional protein that promote and maintain human health (Sugano, 2005). Among all, isoflavones are presented in large amount and have gained more attention globally. Soybean isoflavones are an important secondary plant metabolite, which have variety of physiological activities. Having similar structure of endo-estrogen, isoflavones can exhibit weak estrogen-like activities so as to regulate the hormonal level (Wu et al., 2009). It is reported that isoflavones can reduce the occurrence of breast and prostate cancer, risk of cardiovascular diseases and relieve the osteoporosis and menopausal symptoms (Clubbs and Bomser, 2007; Howes et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39333953

2006; Wu et al., 2009). The major isoflavones can be divided into four groups: malonyl glycosides (malonyldaidzin, malonylgenistin, and malonylglycitin), aglycones (daidzein, genistein, and glycitein), acetyl glycosides (acetyldaidzin, acetylgenistin, and acetylglycitin), and glycosides (daidzin, genistin, and glycitin) (Kim et al., 2014). Each isoflavone has different physiological activities. For example, isoflavone aglycones have stronger biological activities and are absorbed faster, and in greater amounts by the body than corresponding glucosides (Izumi et al., 2000; Setchell et al., 2001). Moreover, daidzein and genistein exhibit high antioxidant activities (Devi et al., 2009; Heim et al., 2002), while genistein has high estrogenic potential, and daidzein has lower estrogenic effects (Kuiper et al., 1998).

Due to benefits described above, much effort has been spent to improve the nutritional quality of soybean by transgenic engineering approaches in recent years. For example, soybean genotype has been engineered to contain lower or higher levels of isoflavones (Lee et al., 2008; Paucar et al., 2010). However, phytochemicals are affected by genotype, weather and geographical sowing location, and they can be varied among soybean germplasms and within germplasm when planted in various geographical regions (Eldridge and Kwolek, 1983). Wang and Murphy observed that isoflavone contents varied across the year, and across growing locations within the same year for single soybean germplasms (Wang and Murphy, 1994). Similar studies confirm the results of previous research by studying multi cultivars over multi years and environment (Hoeck et al., 2000; Lee et al., 2003). However, the effects of germplasm community size on isoflavone biosynthesis are still need to be investigated.

China is regarded as the place of origin of soybean with the history of more than 5,000 years. China has built the largest repository where until 2000, 25,144 soybean germplasms have been collected. Southwestern China was identified as core origin, and most germplasms were provided by Yunnan, Sichuan (including Chongqing) and Guizhou provinces (Xinan et al., 1998). It shows the importance of soybean growth in this region, which provides abundant basic material for the selection and breeding of high quality soybean germplasms.

Although the soybean has been a major crop in Southwest of China, but few studies screened specific soybean germplasm, and investigated the correlation of isoflavone with genotype and geographical environment by metabolomics method previously. Therefore, it was significant to evaluate soybean germplasm from South-western China by using metabolomics method.

In the new era of metabolomics, metabolite profiling combined with chemometrics has become a useful tool for determining phenotypic variations, assessing food quality and identifying metabolic networks in biological systems that can lead to direct breeding strategies (Kim et al., 2014; Park et al., 2013). Thus, in the present study, the combination of HPLC based metabolic profiling with multivariate analysis (PLS and O2PLS-DA) was used to screen the specific isoflavone germplasms, and to investigate the influence of genotype, geographical environment and germplasm community size on isoflavone biosynthesis.

Materials and methods

Plant materials and chemicals

In this study, 144 soybean germplasms were collected from Southwest China in 2014. These germplasms include 102 from Sichuan province, 25 from Chongqing, 15

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39333953

from Guizhou province and 2 from Yunnan province (*Table S1* in the *Appendix*). Geographical locations and detailed information of these soybean germplasms are shown in *Figure 1* and *Table S1,* respectively. HPLC grade acetonitrile was provided by Thermo Fisher scientific inc. (NYSE: TMO). Six of the isoflavone standards (daidzein, gentstein, glycitein, dadzin, genistin and glyctin) were purchased from Weikeqi Biological Technology Co., Ltd. (China). Six external isoflavone standards (malonyldaidzin, malonylgenistin, malonylglycitin, acetyldaidzin, acetylgenistin and acetylglycitin) were purchased from Wako Pure Chemical Industries, Ltd. Japan.

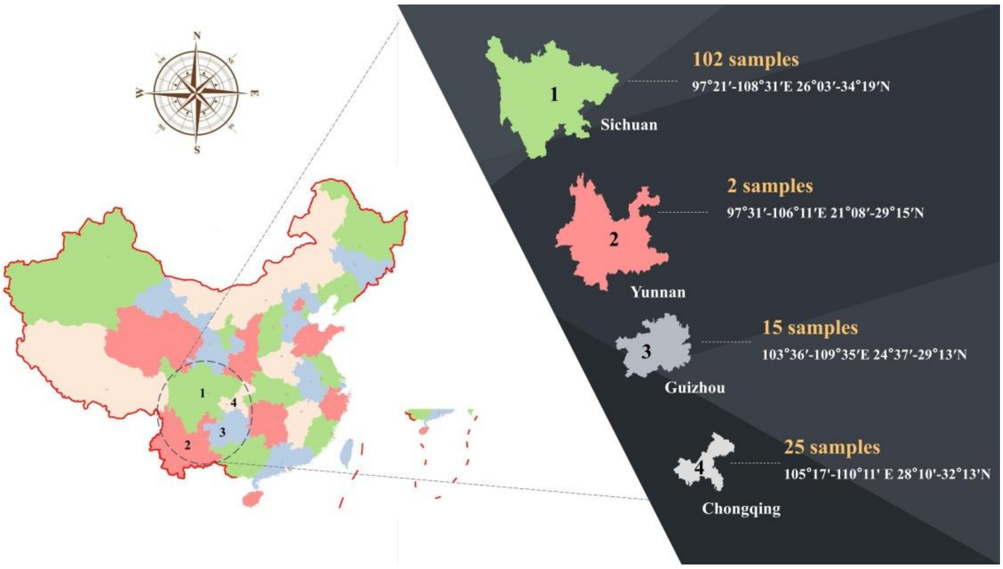

Figure 1. *Geographical locations of soybean germplasms from Southwest China*

Sample preparation

Soybean isoflavones were extracted using a protocol adapted from Liu et al. (2016) with small modifications. All soybeans samples were ground with cyclone miller (Cyclotec 1093 Foss, Denmark), screened through a mesh (size 250 µm) and heated at 40 °C for 24 h. Three extraction replications from soybeans were prepared for each sample. Approximately 200 mg of soya flour was dissolved into 5 mL of a pre chilled MeOH/H_2O (80/20 v: v). The mixture was extracted with ultrasonic for 3 h at 40 °C, and then centrifuged at 11,000 g for 10 min. About 1.5 mL supernatant was filtered through a 0.22 µm organic membrane filter before injecting in a sample bottle. The samples were stored at -20 °C before subjected to HPLC analysis.

Quantification

Agilent 1260 series high performance liquid chromatography (HPLC) system equipped with a mass spectrometric detector (Agilent Quadrupole LC/MS 6120) was used to identified and quantified twelve isoflavones. Three time quantitative HPLC analysis was performed on YMC-Pack ODS-AQ column (4.6 i.d. × 250 mm, RP-18, 5 µm). Previously described chromatographic conditions were used with small modifications (Liu et al., 2016). Linear gradient mobile phase was used, which includes 100% acetonitrile (solution A) and 0.1% acetic acid aqueous (solution B). The linear gradients were as follows: 0 min 15% A, 0~30 min 20% A， 30~60 min 40% A， 60~70

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39333953

min 40% A. The flow rate, column temperature and injection volume were 0.8 ml/min, 30 °C and 5 μL, respectively. The UV detector was set to 260 nm. Selected ion monitoring (SIM) mode was used in the mass spectral acquisition with scan range 100−700 amu. The following conditions were used for mass spectra: desolvation pressure, 35 psig; desolvation temperature, 350 °C; electrospray ionization (ESI), positive ion mode and capillary voltage, 3.8 kV. Nitrogen was used in the ion source and as the collision gas, and the desolvation gas flow rate was 10 L min^{-1}.

Each of the twelve isoflavones was identified by comparing the sample retention times with those of the isoflavone standards. However, the isoflavone concentrations were calculated in absolute term via linear regression.

Statistical analysis

Metabolomics analysis combined with chemometrics was used to investigate the quantification data acquired from HPLC. Partial least squares analysis (PLS) was performed to screen the specific soybean germplasms, and to evaluate the among-groups and within-groups variabilities of multivariate data. Score plot and loading plot were provided by the SIMCA-P 13.0 software (Umetrics, MKS Instruments Inc., Umea, Sweden), the former visualized the variation of all samples by observing the clustering or scattering of the point in score plot and the latter explained which variables contribute most to this difference. Specific soybean germplasms were subjected to O2PLS-DA to evaluate the relationships in terms of similarity or difference among them and predict the geographical origin. Furthermore, score-loading correspondence identified the biomarker metabolites which distinguished the samples from different regions.

Results and discussion

Variation of isoflavone in soybean germplasms

Twelve isoflavones including malonylglycosides (malonyldaidzin, malonylgenistin, and malonylglycitin), aglycones (daidzein, genistein, and glycitein), acetyl glycosides (acetyldaidzin, acetylgenistin, and acetylglycitin), and glycosides (daidzin, genistin, and glycitin) were detected in the 144 soybean germplasms (*Fig. 2*), and then analyzed by SPSS 20.0 to obtain the mean value ± standard error. The total isoflavone levels identified in 144 soybean germplasms are shown in *Table S2* (see *Appendix*). The total isoflavone contents varied significantly among all germplasms due to different genotypes and locations. As shown in *Table S2,* the total isoflavone contents of soybean germplasms varied from 0.612 $mg.g^{-1}$ to 7.635 $mg.g^{-1}$. Among the identified isoflavones, glycosides and malonylglycosides derivatives were observed predominant.

However, in Northern China the total isoflavone contents in cultivated and wild soybean germplasms ranged from 1.462-6.115 $mg.g^{-1}$ and 3.896-7.440 $mg.g^{-1}$, respectively (Cui et al., 2013). The reason for that could be the environmental conditions of Southwest China (Sichuan, Chongqing, Guizhou and Yunnan) are relatively cool and wet compared to Northern China. Therefore, high isoflavone accumulation was shown in this study, because earlier studies in warm and dry environments have shown low isoflavone accumulation (Lozovaya et al., 2005). A similar study has confirmed the change in soy isoflavone content with subtle changes in environmental factors (Caldwell et al., 2005).

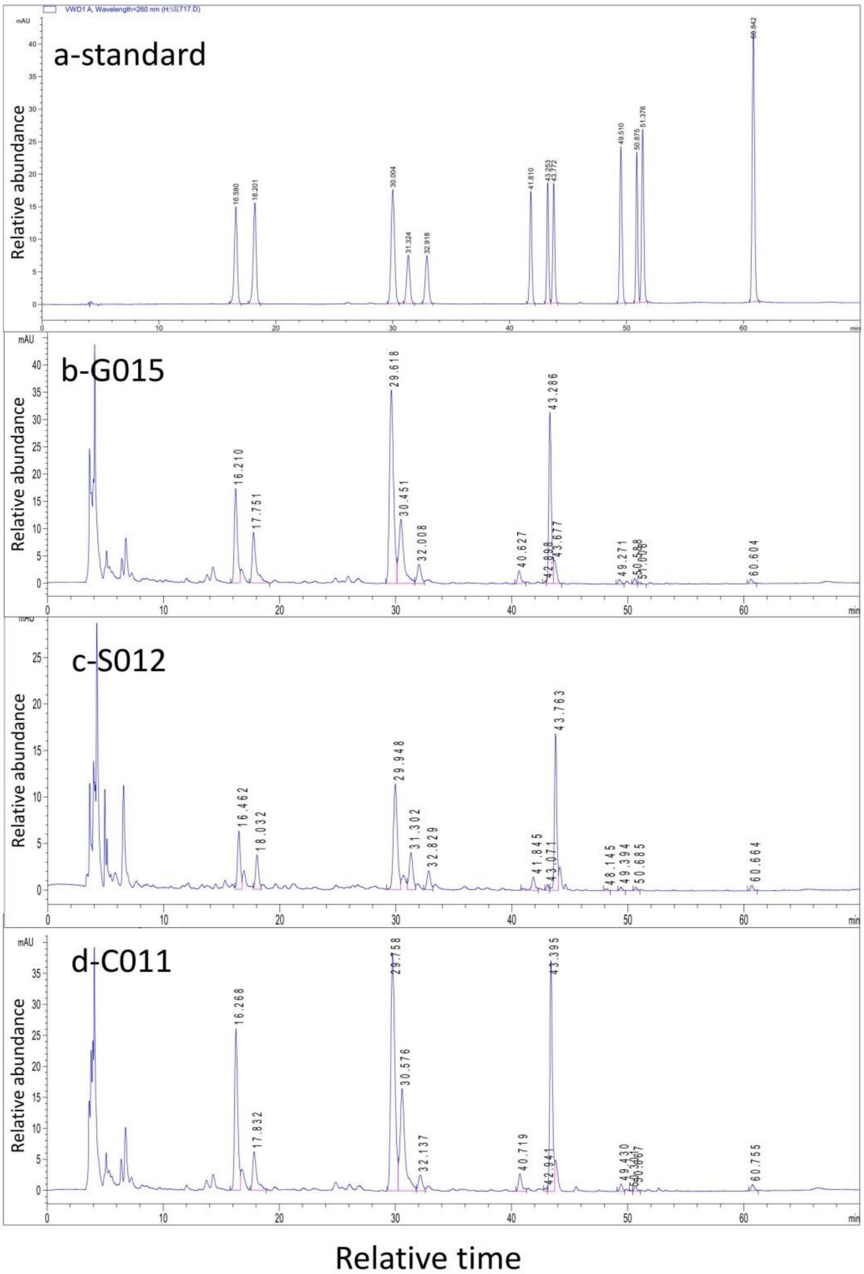

Figure 2. *Total ion chromatograms (TICs) of HPLC analysis of soy isoflavone standards and soybean samples. a, standard chromatogram; b, soybean germplasm "G015" (high MIS, high MIP); c, soybean germplasm "S012" (high MIS, low MIP); d, soybean germplasm "C011" (low MIS, low MIP); Peak assignment: peak 1-daidzin (DG); 2-glycitin (GLG); 3-genistin (GEG); 4-malonyldaidzin (MD); 5-malonylglycitin (MGL); 6-acetyldaidzin (AD); 7-acetylglycitin (AGL); 8-malonylgenistin (MG); 9-daidzein (DE); 10-acetylgeni.stin (AG); 11-glycitein (GLE); 12-genistein (GE); X axis names is Relative time; Y axis names is Relative abundance*

Particularly in recent years, more researches about genotype × environment interaction, especially about the secondary metabolism of plants to investigate the correlation with soybean isoflavones of different varieties and regions. Ge et al. (2011) measured the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39333953

isoflavone of 100 Chinese soybean varieties of different origin, and indicated that the soybean grown in southern China had higher isoflavone content than in northern China. Similar study by Sun et al. (2004) measured the isoflavone content of 249 Chinese soybean varieties, and indicated the great variation among varieties and locations. Moreover, the total isoflavones of wild soybean were noted higher than cultivated soybean (Chune et al., 2010). Undoubtedly, genotype × environment interaction decides the most of the plant secondary metabolism, such as soy isoflavone biosynthesis.

In addition, comparative analysis of total isoflavone contents in soybean genotypes from four different locations showed higher isoflavone contents in samples grown in Chongqing (*Table S2*). This is because, Chongqing is located at a high longitude area, has a subtropical humid climate that promotes isoflavones accumulation in soybean seed. This is consistent with previous study that high longitudes are favourable for isoflavone biosynthesis (Wu et al., 2017).

Screening of germplasm by PLS-DA

HPLC-based isoflavone profiling was conducted to assess the variations in isoflavone contents of various soybean germplasms. Data regarding the 12 isoflavones identified by HPLC analysis were subjected to PLS-DA to identify the differences among soybean germplasms and four different regions of origin (*Fig. 3*).

The PLS-DA score plot showed the profile differences of samples, which are different in genotypes and source of regions (*Fig. 3A*). The corresponding loadings scatter plots of the isoflavone profiling is presented in *Figure 3B*. PLS-DA score plot demonstrated a little variability among samples of four regions of origin. However, five samples (C002, G010, G011, G013 and S075) clearly stood out from other genotypes in PLS component 1 (*Fig. 3A*). Previous studies have indicated the effects of genetic variation on isoflavone biosynthesis (Eldridge and Kwolek, 1983; Wang and Murphy, 1994). In our study, this could confirm that genotype plays an important role in the synthesis of isoflavones. However, PLS could not distinguish the influence of geographical environment.

The corresponding loading plot is used to identify those compounds that can exhibit maximum variability within a population (Kim et al., 2013). The five specific isoflavone germplasms were screened-out from all samples, resulted from their higher scores in component 1 of the PLS-DA. Daidzin, genistin, malonyldaidzin, malonylgenistin and acetylgenistin led to major contribution in component 1, for which the eigenvectors were 0.40, 0.42, 0.39, 0.40 and 0.36, respectively. The loading plot showed that isoflavone contents were higher in these five samples than others. Moreover, daidzin, genistin, malonyldaidzin, malonylgenistin and acetylgenistin were the discriminating metabolites which distinguished the specific isoflavone germplasms from the others. The isoflavone contents were controlled by genotype which contributed to the variation of specific germplasms in component 1 of the PLS-DA. The result is similar to Kim et al. (2014), however more studies confirmed the influence of the both the genotype and the environment on the isoflavones synthesis (Lee et al., 2003; Murphy et al., 2009). Several studies have shown the individual and total isoflavone contents of genotypes at different locations. Hoeck et al. (2000) found the significant differences among locations in one or more years for total and individual isoflavone contents. However, the consistency of the ranking among genotypes for the contents of individual and total isoflavones seems to depend on the magnitude of the differences in their inherent genetic potential for the traits (Zhang et al., 2014; Carter et al., 2018).

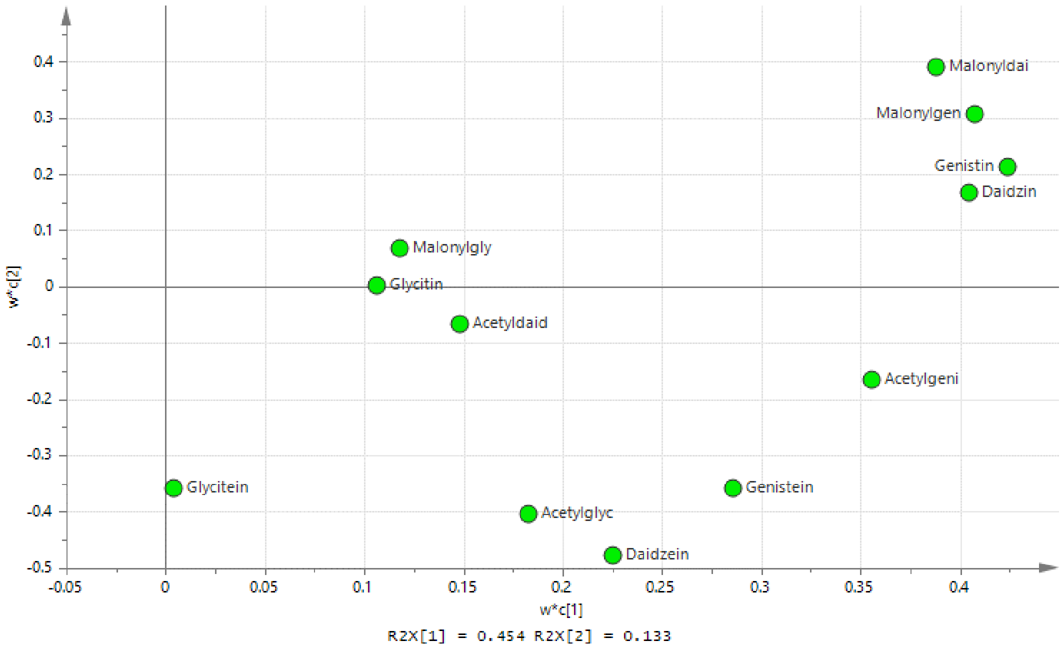
A



B

Figure 3. *PLS-DA score plots (A) and corresponding loadings scatter plots (B) of 144 geographical different soybean seeds*

To further elaborate the differences among 12 isoflavones in different samples, a heat map was created (*Fig. 4*). Different colors indicate the relative concentrations of corresponding metabolites in each sample. Red color indicates higher isoflavone level. The results clearly show that the content of daidzin, genistin, malonyldaidzin, malonylgenistin and acetylgenistin were higher in five specific germplasms (C002,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39333953

G010, G011, G013 and S075) than others. These five specific germplasms had large amount of total isoflavone contents. Moreover, it also shows the daidzin, genistin, malonyldaidzin, malonylgenistin and acetylgenistin as discriminating metabolites which distinguished the specific isoflavone samples from the others.

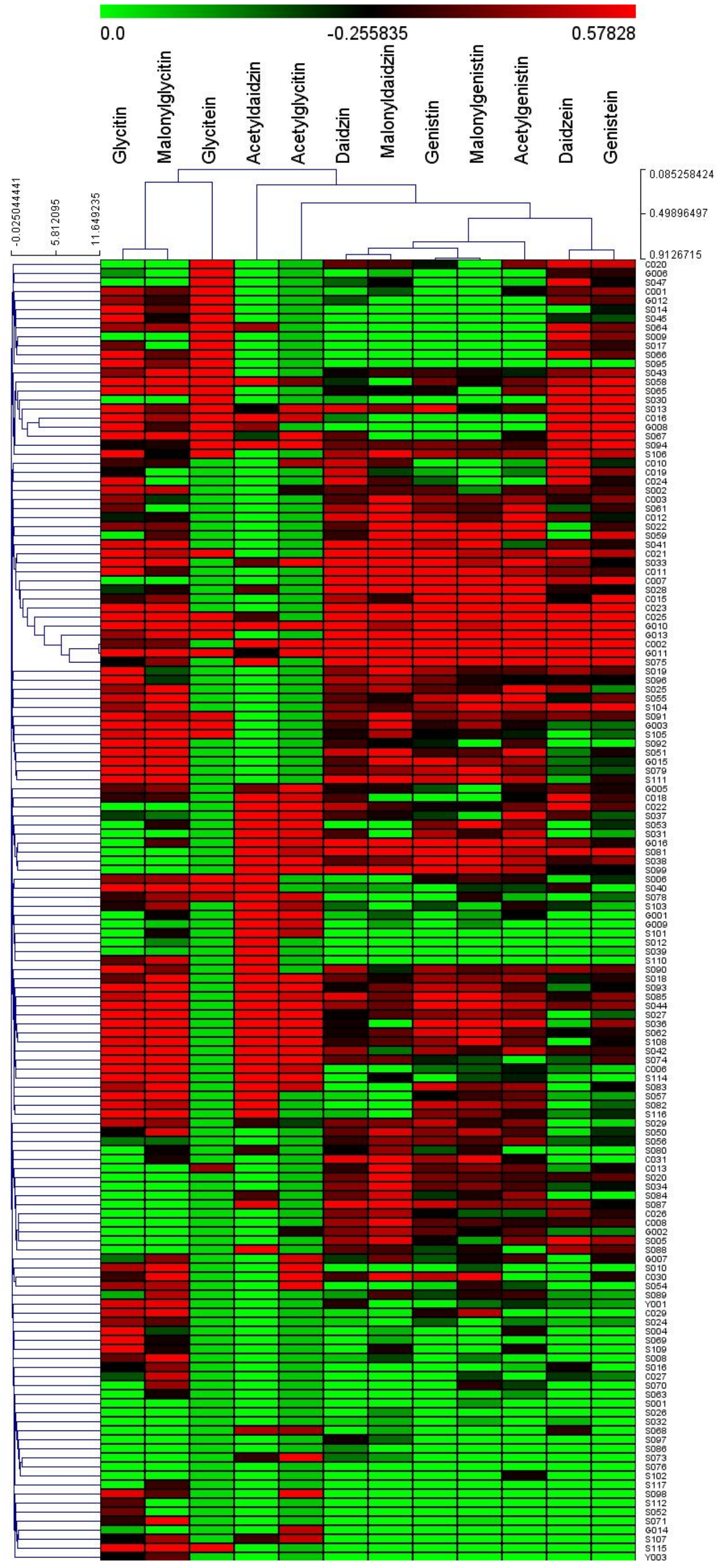


Figure 4. *Heat map and cluster analysis of 12 isoflavones in 144 soybean genotypes*

Geographical determination

O2PLS-DA is a good multivariate projection method, which separates the structured noise in bidirectional way X and Y. O2PLS divides systematic variation into two parts (X and Y). One is regarded as the predictive part which is related to both X and Y (covarying), whereas the other is regarded as parallel part that is not related to orthogonal. As a result, O2PLS improves the interpretation of the predicted model and simplify it as well. It has been reported that O2PLS performed very well for geographical determination of different samples (Consonni et al., 2010). We therefore applied O2PLS-DA for geographical determination of five specific germplasms (*Fig. 5*).

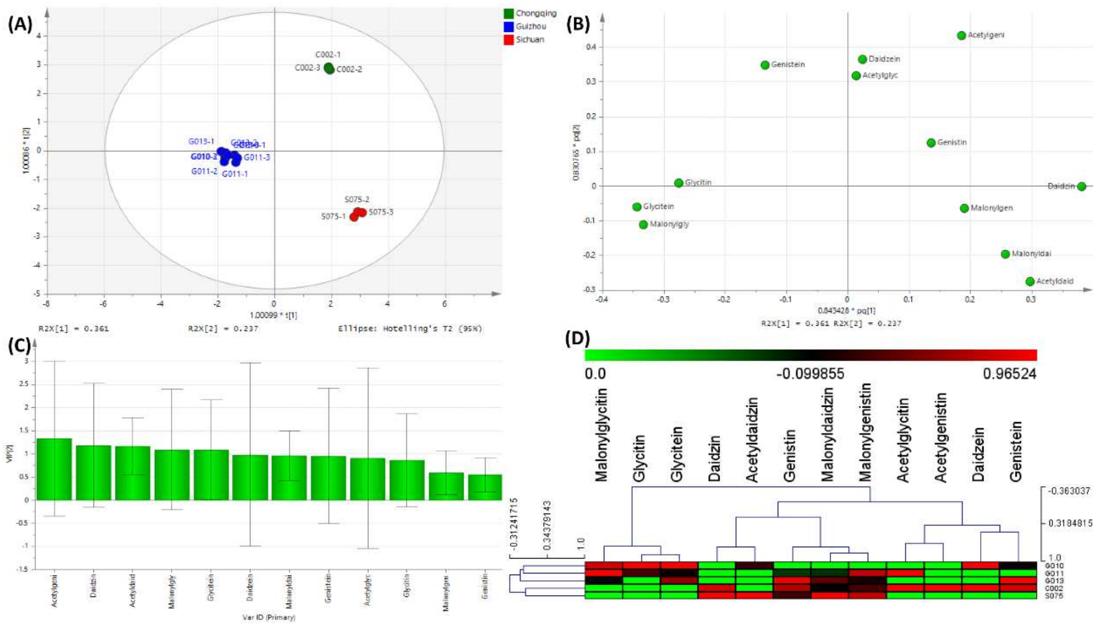

Figure 5. *O2PLS-DA score plots (A) and corresponding loadings scatter plots (B), important features identification (C), and heat map of cluster analysis (D) of 5 geographical different soybean seeds from Chongqing, Guizhou and Sichuan*

These five specific germplasm samples came from clustering and scattering in score scatter plot (*Fig. 5*). The parameters of cross-validation plot, i.e., R2(X) = 0.995, R2(Y) = 0.995, and Q2 = 0.989, indicated a valid model. All samples which had different geographical origins showed a clear separation into three groups: Chongqing, Guizhou and Sichuan (*Fig. 5A*). The different geographical environment led to the sample variations. The score scatter plot indicated that the samples grown in Guizhou were clearly separated from others. This variation was mainly attributed to glycitin, glycitein, and malonylglycitin, of which the corresponding loading scatter plot was negative and contributed mostly to the first O2PLS principal component (*Fig. 5B*). Combining with the VIP value (*Fig. 5C*), glycitein and malonylglycitin with VIP more than 1.0 were determined as biomarker metabolites for soybean seed from Guizhou. In addition, samples from Chongqing (component 2 dimension) and Sichuan (component 2 dimension) were distinguished based on the second O2PLS principal component. The corresponding loading scatter plot was positive for daidzein, acetylglycitin and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39333953

acetylgenistin which contributed most to second O2PLS principal component. As a result, samples from Chongqing were separated from others. Combining the VIP values with the loading plot, the acetylgenistin with VIP more than 1.0 was determined as a biomarker metabolite to distinguish samples of Chongqing from others. However, as the loading plots showed that the acetyldaidzin had a negative loading value and contributed most to second O2PLS principal component. In addition, the VIP value of acetyldaidzin was more than 1.0. This confirmed that acetyldaidzin was a biomarker metabolite that distinguished samples of Sichuan from others.

The results suggest that the content of glycitein and malonylglycitin were higher in samples from Guizhou while the content of acetylgenistin and acetyldaidzin were higher in samples from Chongqing and Sichuan, respectively. Moreover, the comparative analysis of total isoflavone contents in five samples from different locations showed higher isoflavone contents in samples grown in Sichuan province followed by Chongqing (*Table S3* in the *Appendix*). This could be due to the high latitude of both Sichuan and Chongqing areas with favorable environment to promote soybean isoflavone accumulation (*Fig. 1*). It is consistent with earlier study that the geographical latitude of the genotype location plays an important role in separating soybean genotypes with different chemical profiles (Wu et al., 2017). A similar study was conducted by Zhang et al. (2007) in Northern China also confirmed the positive correlation between latitude and soybean isoflavone.

In addition, specific isoflavones were screened from all samples because their genotypes expressed higher isoflavone contents than the others. Therefore, the difference in regions led to the difference of isoflavone contents, which distinguished the five specific samples. It confirmed that geographical environment also influence the isoflavones synthesis besides genotypes. However, the geographical environment could distinguish small community size of specific samples.

A heat map was created to further explain the geographical determination of soybean genotypes based on the targeted isoflavone metabolomics, and to interpret the influence of geographical environment on isoflavone contents (*Fig. 5D*). Samples from different regions clustered different groups in the heat map. However, they were not completely divided into three groups on the base of regions. Samples variability could be distinguished by difference of 12 isoflavones presented in the heat map. As results show, the content of glycitein and malonylglycitin were higher in samples from Guizhou while the content of acetylgenistin and acetyldaidzin were found higher in samples from Chongqing and Sichuan, respectively. The results are the same as the conclusion drawn from O2PLS-DA. It confirmed that glycitein, malonylglycitin, acetylgenistin and acetyldaidzin were biomarker metabolites that could interpret the influence of geographical environment to the isoflavone contents.

Conclusion

In conclusion, the synthesis of isoflavone was affected by both the genotype and the geographical environment. When the community size of germplasm samples was large, the isoflavone contents were mainly subjected to the effect of genotypes which distinguished samples from the others. The genotype mainly influenced the content of daidzin, genistin, malonyldaidzin, malonylgenistin and acetylgenistin. These metabolites differentiated the specific isoflavone germplasms from others. However, the geographical environment also played an important role in distinguishing the small groups of soybean germplasms. Different geographical environments had different influence on the synthesis of isoflavones. The geographical environment affected the acetylgenistin, acetyldaidzin, glycitein and malonylglycitin, which were considered as biomarker metabolites. In addition, these distinguished specific samples from three different regions could be used for future breeding programs.

Abstract. Toxic dyes contaminated aqueous solutions discharged from different industries should be treated before releasing to the environment. In the present study adsorbents manufactured from an easily available waste rice husk (RH) has been used to treat dyes contaminated water. Hereby, two adsorbents, carbon embedded silica (CES) and rice husk ash (RHA) mediated zeolite (Z-RHA) have been synthesized from rice husk by chemical modification, and a comparative study has been performed for decontaminating crystal violet (CV) dye laden aqueous solution. Characterization of the manufactured RHA, CES and Z-RHA has been done by using several techniques like Fourier transform infrared spectroscopy (FTIR), X-ray diffraction (XRD), Scanning electron microscope (SEM), Energy dispersive X-ray (EDX) and Brunauer-Emmett-Teller (BET). The specific surface area for RHA, CES and Z-RHA was 28 m^2/g, 110 m^2/g and 122 m^2/g respectively. Additionally, batch experiments have been performed to evaluate the effect of different parameters like initial concentrations of the adsorbate, initial pH, adsorbent dosages and contact time. The adsorption capacity of the CES and Z-RHA is 18.75 mg/g and 19.28 mg/g respectively, which are satisfactorily higher than the adsorption capacity of their parent material RHA (8.3 mg/g). In the optimization study, the maximum adsorption has been found at the initial concentration of 100 mg/l of the dye, solution pH 8, adsorbent dosages 0.6 mg/50 ml and contact time 10 min. This study stated that the chemically modified adsorbents manufactured from RHA can be an easy solution to remove CV dye from wastewater.
Keywords: *toxic dye removal, polluted water, carbon embedded silica, modified rice husk, zeolite*

Introduction

Nowadays, synthetic dyes are used in different industries like the garment dye industries, textile, plastic, leather, paper, food, mineral processing and cosmetic industries (Dalaran et al., 2011; Kumari et al., 2017). There are more than 10 thousand dyes that are currently used in different industries and the annual production of the dyes all over the world is around 280 thousand tons, which is a huge amount (Mass and Chaudhari, 2005). Alarming amount of dyes are being released into the environment from these industries each year. A small amount of dyes can cause serious pollution of water due to their harmful characteristics such as high visibility, low biodegradability and toxicity (Arenas et al., 2017; O'Neill et al., 1999). Dye-contaminated water can be carcinogenic as well as mutagenic due to their obstruction of light penetration into water which inhibits the photosynthesis activity of aquatic biota (Vakili et al., 2014).

DOI: http://dx.doi.org/10.15666/aeer/1604_39553967

Consequently those dyes can have harmful effects on human beings through aquatic animals and alimentary chain (Secula et al., 2011). Removal of dyes is a great concern not only to protect the environment but also to make it safe for the human health. Among different types of toxic dyes crystal violet (CV) represents one of the mostly used cationic dyes in different industries. The characteristics of the CV dyes are shown in *Table 1*. Cationic dyes are colored organic base salts and they have no water solubilizing agent. Due to these characteristics the cationic dyes are more toxic than the anionic dyes (Loqman et al., 2017; Hao et al., 2000). CV is also known as hexamethyl pararosaniline chloride. There are a lot of established techniques for removing toxic dyes from wastewater approved by different studies such as electrocoagulation, electrochemical oxidation and advanced oxidation process (Arenas et al., 2017). Moreover, the physical treatment like adsorption is very much useful technique to remove toxic compounds from wastewater, if the adsorbents are readily available and cost effective (Banerjee et al., 2017; Lakshmi et al., 2009). There are lots of studies on the activated carbon from different available cheap materials like coconut husk, coconut shell, bamboo ash etc. to reduce toxicity from water or wastewater (Arenas et al., 2017; Yadav et al., 2015; Zhang et al., 2011; Yadanaparthi et al., 2009; Xu et al., 2009). In this study we are using the rice husk ash (RHA) to make zeolite (Z-RHA) and carbon embedded silica (CES) to remove the toxic dye CV from the wastewater. Rice husk (RH) is an easily available material with no price. The amount of the RH is assumed to be approximately twenty percent of the gross weight of grain produced (Arenas et al., 2017). In the disposal point of view, the end material of paddy is very much harmful for environment. RHA has higher efficiency to remove either biodegradable or non-biodegradable toxic pollutants from wastewater due to its highly porous surface and large surface area (Naiya et al., 2009). On the other hand, RHA mainly contained SiO_2 which is very much useful to remove different kinds of heavy metal and dyes after certain modification of them (Lakshmi et al., 2009; Totlani et al., 2012). From the literature review we found that the adsorbents manufactured with modification of rice husk are still not applied on the toxic dye CV. Adsorption study of manufactured RHA mediated Z-RHA and CES on CV dye has been done in the present study. CES is a material made from RHA, with embedding the silica contained by RHA with unburnt carbon. Z-RHA is another manufactured material composed of silica, aluminium and oxygen present in RHA. Finally the adsorption performance of CES and Z-RHA to CV dye removal from aqueous solution has been investigated in this study.

***Table 1.** Properties of CV dye*

Name of the dye	Molecular Structure	Formula	Molecular weight (g mol^{-1})	Ion	Maximum wavelength (nm)
Crystal Violet		$C_{25}H_{30}ClN_3$	407,98	Cationic	590

Materials and methods

Collection of rice husk and preparation of RHA

Rice husk (RH) sample has been collected from the local market of the Qingdao city in Shandong province of China without any cost. Collected RH sample has been sorted to separate from foreign materials like dust, broken parts of rice shoots and roots, stones etc. followed by sieving and washing under running tap water. Finally, after washing with distilled water the RH sample has been dried in room temperature to remove all the extra moisture present on the surface of the husk. In order to remove the metal impurities the sample has been treated with hydrochloric acid. Then the treated sample has been stirred with sodium hydroxide to remove the excess acid. Concurrently, the treated RH has been thoroughly washed again by distilled water to remove both the acid and the alkali from the surface (Arenas et al., 2017). After drying the rice husk, ash has been produced by pyrolyzing the RH at the temperature from 500 to 700 °C for 5 h in a muffle furnace to remove excess organic contents. Consequently, the RHA has been stored in sterile zip-lock bag for further use. Previously, it has been reported that after acid treatment, calcination and pyrolisis of RH, major portion of final material has been represented by silica (Banerjee et al., 2017).

Preparation of Z-RHA

Zeolite RHA has been prepared from the sodium silicate (Na_2SiO_3) obtained by RHA. Firstly, seed and feedstock gel have been prepared by mixing RHA with sodium alluminate ($NaAlO_2$). A homogeneous seed gel has been prepared by mixing Na_2SiO_3 presented in rice husk, with $NaAlO_2$ in distilled water under continuous agitation (Banerjee et al., 2017). Then the prepared gel has been left at ambient temperature up to 24 h for aging. Consequently, homogeneous gel of Al_2O_3:$10SiO_2$ has been formed as seed gel. As well as, feedstock gel has been prepared by following same procedure without any aging. Then the feedstock gel and seed gel have been mixed and stirred vigorously to make a homogeneous mixture and again kept in room temperature for 24 h for aging. Additionally, the aged solution has been crystallized at 100 °C for another 24 h in room temperature. Finally the prepared sample has been washed, dried and stored for further analysis (Goyal et al., 2005).

Preparation of CES

CES has been prepared from the sodium silicate obtained by RHA, after digestion in the solution of NaOH. RHA has been digested with NaOH solution for 1 h at 80 °C temperature to form Na_2SiO_3. Then the alkaline solution has been acidified with phosphoric acid (H_3PO_4) to neutralize the pH and silicic acid has been formed (Totlani et al., 2012). Silicic acid is a chemical compound of silicon, hydrogen and oxygen, also it is the hydrate of SiO_2. Due to heating they lose water to precipitate silica gel as an active form of SiO_2. The partially unburnt carbon present in the RHA has been made a duel substrate like CES including mesoporous silica and partially activated carbon (Totlani et al., 2012). Finally, the samples have been kept at 100 °C for 24 h and preserved for further analysis. The detailed procedure has been reported previously by Shelke et al. (2010).

DOI: http://dx.doi.org/10.15666/aeer/1604_39553967

Characterization of adsorbents

The physico-chemical characteristics of prepared RHA, CES and Z-RHA have been investigated. Gravimetric methods have been used for the proximate analysis. The surface area and the pore size of prepared RHA, CES and Z-RHA have been measured by Brunauer–Emmett–Teller (BET) surface area analyzer. The functional groups present in the adsorbents have been determined by using Fourier transform infrared (FTIR) spectroscopy. To know the structure and orientation of the prepared adsorbents the x-ray diffraction (XRD) analysis has been conducted. The features and the elements present in the prepared adsorbents have been studied by scanning electron microscope (SEM) images and energy dispersive analysis of X-rays (EDX).

Batch kinetic and adsorption studies

In the adsorption study of CV dye, the 1000 mg/l dye solution has been prepared by dissolving 1 gm chemical dye in 1000 ml distilled water. Then the stock solution has been used to make different concentrations (50 mg/l, 100 mg/l, 150 mg/l, 200 mg/l) of dye for further study. 0.5 g of adsorbent (RHA, CES, Z-RHA) has been added into conical flask with different concentrations of dye solutions (Kumari et al., 2017). Then the flasks have been shaken in a rotary shaker at 30 °C temperature and 150 rpm, and the concentrations have been observed after each 10 min. The pH of the samples has been adjusted from 2-10 by adding either 0.1 M HCl or 0.1 M NaOH solutions. The supernatant liquid has been collected carefully from the flasks by using pipette and the concentrations have been measured by comparing the absorbance from spectrophotometer (Setthaya et al., 2017). The percentages of dye removal, and adsorption capacity at equilibrium phase q_e (mg/g) have been calculated as *Equation 1* (Langmuir, 1981):

$$\%\,Dye\,Removal = \frac{\mathrm{Co} - \mathrm{Ce}}{Co} \times 100 \qquad \text{(Eq.1)}$$

where, C_0 denotes initial concentrations and Ce denotes equilibrium concentrations of CV dye (mg/l). Distilled water has been used to blank before each set of the experiments as control. The adsorption capacity of the unit mass of the adsorbents at equilibrium q_e (mg/g) has been calculated by *Equation 2* (Langmuir, 1981):

$$qe = \frac{(\mathrm{Co} - \mathrm{Ce})\ \mathrm{V}}{W} \qquad \text{(Eq.2)}$$

where, V is the volume of the dye solution (ml) and W is the weight of the adsorbent (g) added to the volume V.

Each of the experiment has been done three times for the exact and authenticated value of the measured parameters for kinetic and adsorption studies. For the dosage optimization also three replications per each treatment have been used and the average value of data has been plotted.

Results and discussion

Characterization of synthesized adsorbents

FTIR analysis

The major peaks in the FTIR spectra (*Fig. 1*) for RHA at 3475 cm^{-1}, 2370 cm^{-1}, 1735 cm^{-1}, 1143 cm^{-1}, 810 cm^{-1} and 468 cm^{-1} are representing the presence of the following functional groups Si-OH, O=C=O, C=O, Si-O-Si, C-H and C-Cl in the sample (Kumari et al., 2017). On the other hand the FTIR report for CES sample shows the peaks at 3463 cm^{-1}, 2881 cm^{-1}, 2374 cm^{-1} representing Si-OH, C-H, O=C=O, have broaden. More peaks at 1604 cm^{-1}, 1564 cm^{-1}, 1392 cm^{-1}, 1118 cm^{-1}, 615 cm^{-1} represent C=C, N-O, C-H, C-O, C-Cl respectively (Uddin et al., 2009; Chowdhury et al., 2011; Kumari et al., 2017). Whereas the spectra of Z-RHA sample (*Fig. 1*) show the major peaks at 3363 cm^{-1}, 2374 cm^{-1}, 2137 cm^{-1}, 1666 cm^{-1}, 1371 cm^{-1}, 887 cm^{-1} represent Si-OH, O=C=O, N=N=N, C=O, N-O, C-Cl functional groups respectively (Setthaya et al., 2017). The presence of the polar group on the surface of CES and Z-RHA likely gives the cation exchange capacity for both of them.

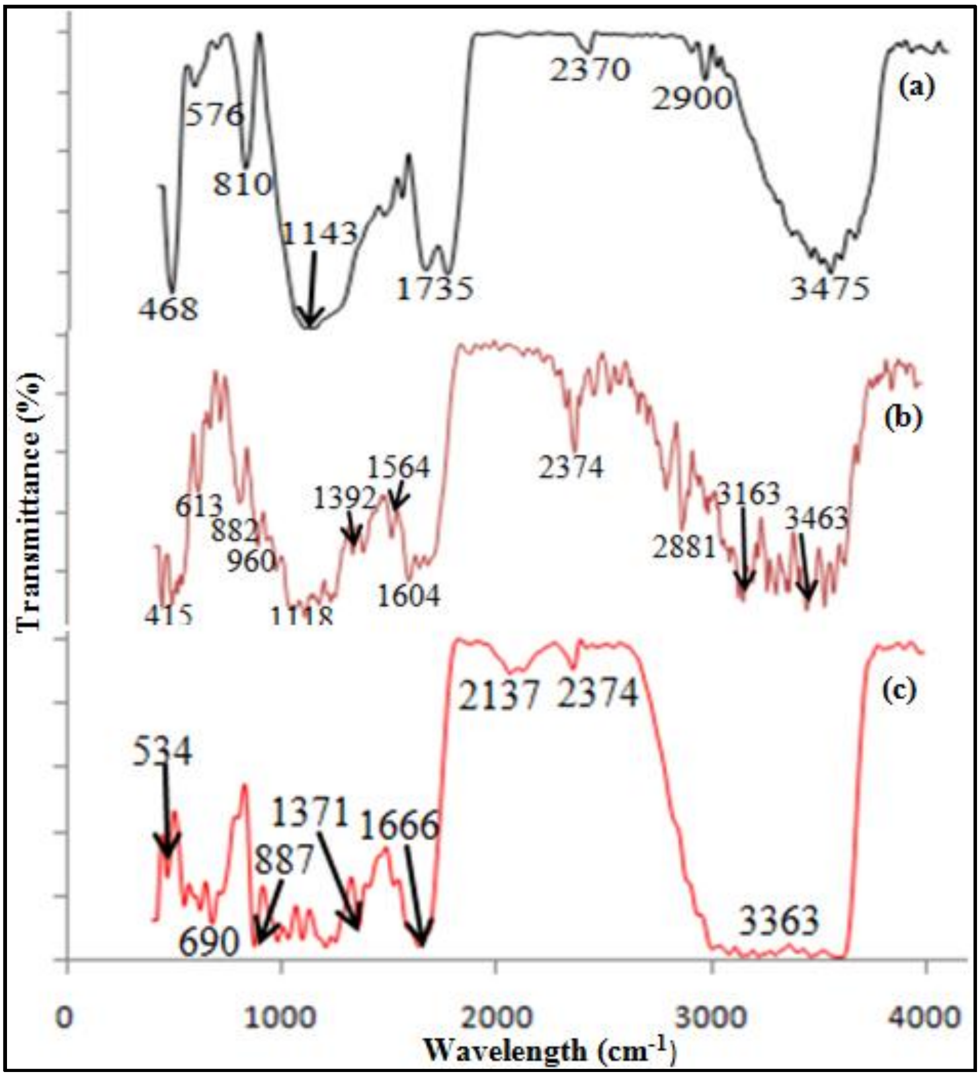

***Figure 1.** FTIR spectra of (a) RHA (b) CES and (c) Z-RHA*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39553967

XRD analysis

The XRD pattern of the RHA, CES and Z-RHA are shown in *Figure 2a, b* and *c* respectively. Both *Figure 2a* and *b* show intense peaks at 23 A° which are indicating the presence of carbon in the samples. As well as *Figure 2b* shows the intense peaks at 33 A° due to the presence of the SiO_2 in CES sample (Kumari et al., 2017). Consequently, XRD pattern for Z-RHA sample shows peaks at 25 A°, 32 A°, and 35 A° (*Fig. 2c*) indicating the presence of AlO_2 and Zeolite ($Na_2Al_2Si_3.3O_{10}.6(H_2O)_7$) (Setthaya et al., 2017; Geetha et al., 2015).

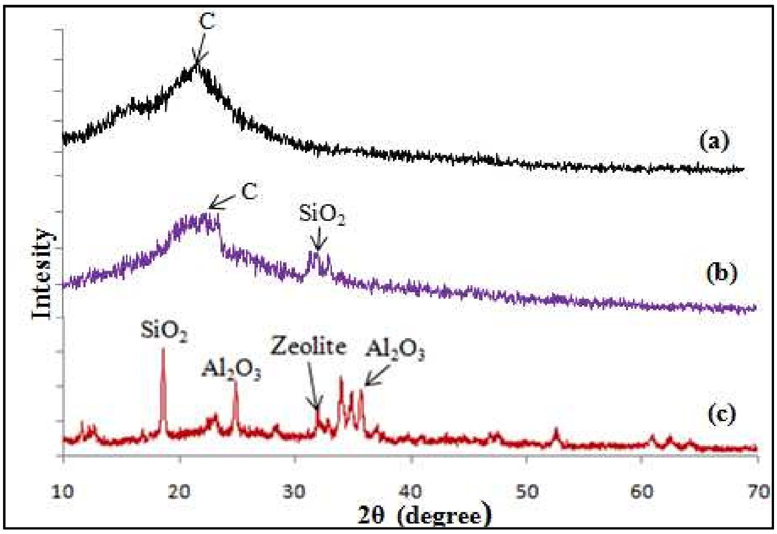

Figure 2. *XRD pattern of (a) RHA (b) CES and (c) Z-RHA*

SEM and EDX

Figure 3a, b and *c* are showing the SEM images of RHA, CES and Z-RHA respectively. Surface structure of the CES and Z-RHA are shown to be more porous than that of the RHA, which is evidence for more adsorption of dyes by CES and Z-RHA compared to their parent material, RHA (Setthaya et al., 2017; Geetha et al., 2015). From the Brunauer–Emmett–Teller (BET) analysis it is also found that the surface area of the RHA, CES and Z-RHA is 28 m^2/g, 110 m^2/g and 122 m^2/g respectively. In EDX analysis of the CES (*Fig. 3e*) sample shows presence of more amount of silica than the RHA (*Fig. 3d*). As well as Z-RHA sample (*Fig. 3f*) shows the presence of Al which is evidence for the presence of zeolite (Banerjee et al., 2017; Loqman et al., 2017; Lee et al., 2017).

Effect of the initial concentrations

In this study it has been found that the concentration of the pollutants plays important role in the adsorption of dyes by synthesized adsorbent. Hence, the amount of removal percentages and adsorption capacity of the materials has been tested with different initial concentrations of dyes. The removal percentages of dye by manufactured adsorbents for different concentrations have been calculated by *Equation 1* and plotted in *Figure 4*. Steep increase has been found, maximum removal percentages for CES (90.69%) and Z-RHA (96.45%) have been noted at the initial concentrations of 100

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39553967

mg/l. Whereas, the maximum removal percentages for RHA (53.66 %) have been achieved comparatively gradually and found at the initial concentrations of 150 mg/l. Adsorption capacity (Qe) has been measured by *Equation 2* and plotted with the initial concentrations of dyes (*Fig. 5*). Hereby, it shows that the adsorption capacity of the adsorbent depends on the initial concentrations of the adsorbate. The initial concentrations of the adsorbate act as a driving force to be adhered to an adsorbent (Menya et al., 2018; Lee et al., 2017; Li et al., 2014). Due to increasing the amount of the adsorbate concentrations the removal percentages as well as the adsorption capacity of the adsorbent materials increased due to the existing driving force (Lee et al., 2017; Li et al., 2014).

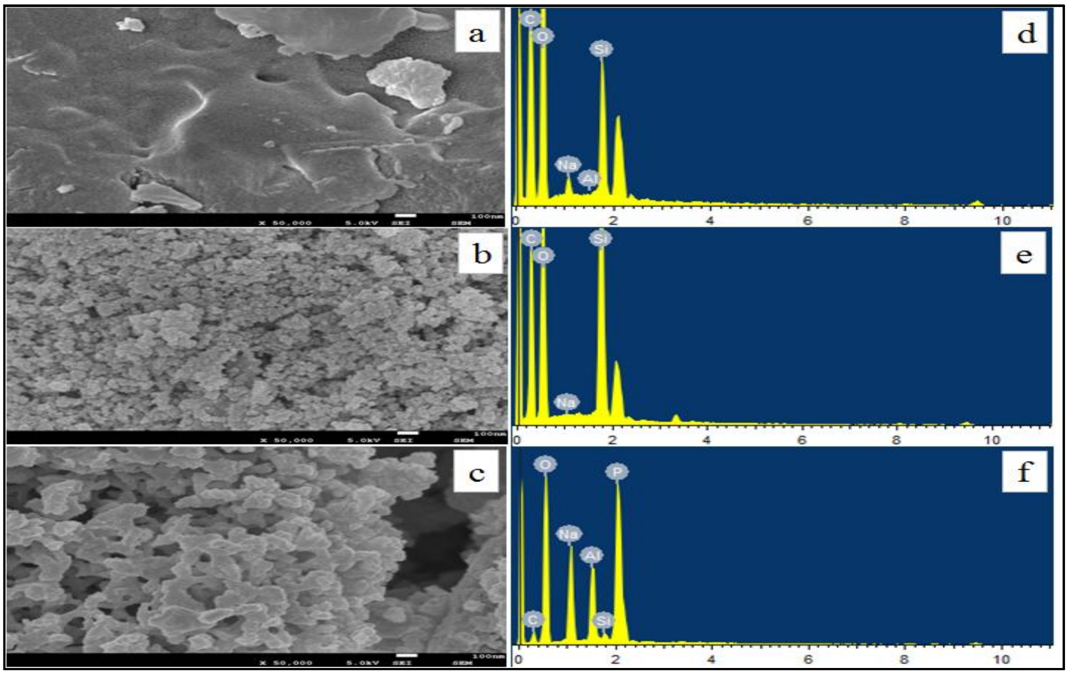

Figure 3. *SEM images of (a) RHA (b) CES and (c) Z-RHA and EDX spectra of (d) RHA (e) CES and (f) Z-RHA*

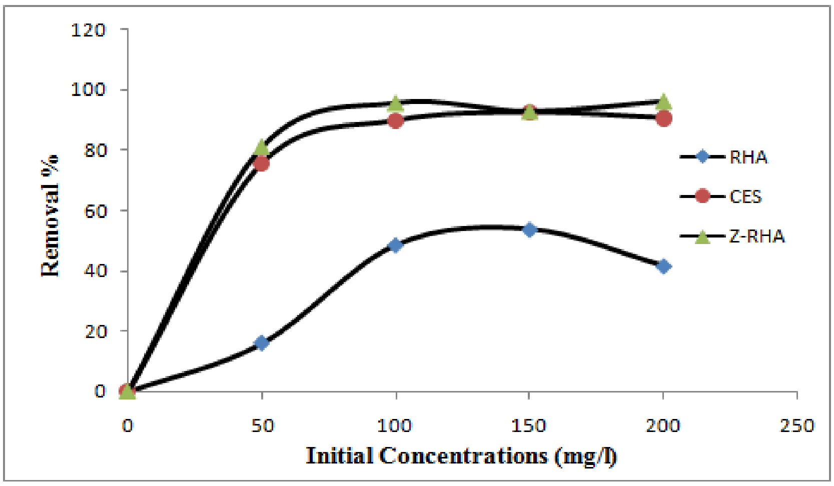

Figure 4. *Effect of the initial concentrations on dyes removal*

DOI: http://dx.doi.org/10.15666/aeer/1604_39553967

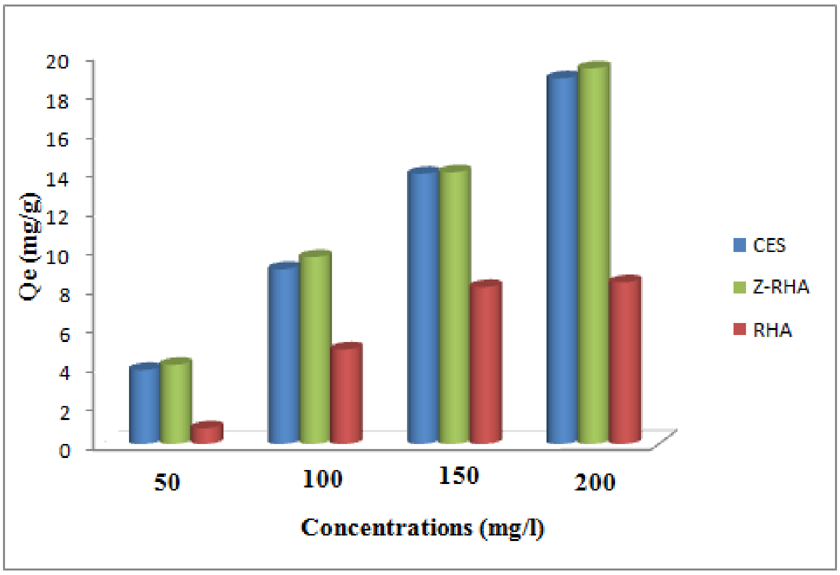

Figure 5. *Adsorption capacities of the adsorbents in different concentrations of dyes*

The maximum adsorbent capacity for RHA, CES and Z-RHA is 8.3 mg/g, 18.78 mg/g and 19.28 mg/g respectively which values are significantly more reasonable compared to those of other investigations (*Table 2*). Different studies have investigated the adsorption capacity of RHA and chemical modified RHA on different heavy metals. Adsorption of CES and Z-RHA on dye like CV is a noble approach which has been investigated in this study. However the adsorption capacity of the manufactured adsorbents is very much reasonable in comparison with other published study.

Effect of pH

The pH of the adsorbate solution is considered a very important parameter in adsorption studies due to two reasons, namely that hydrogen ions have strong competing ability as well as they can ionize the adsorbent surfaces (Rattanapan et al., 2017; Totlani et al., 2012). The change in solution pH may cause to dissociate the functional groups present on the surface of the adsorbent which ultimately affects the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39553967

adsorption processes of the adsorbent. The effect of the pH on dye adsorption using manufactured materials has been studied by varying pH 2 to 10. The data on the removal percentages of dyes with different pH of the solutions plotted in *Figure 6*. It can be concluded that the removal percentages of dyes for CES and Z-RHA show higher removal percentages from the starting up to pH 8, whereas the removal percentage for RHA sample was less at lower pH. These phenomena might happen due to the high surface area of CES and Z-RHA samples rather than the RHA, which may nullify acidic effects during adsorption (Rattanapan et al., 2017; Mor et al., 2016; Totlani et al., 2012).

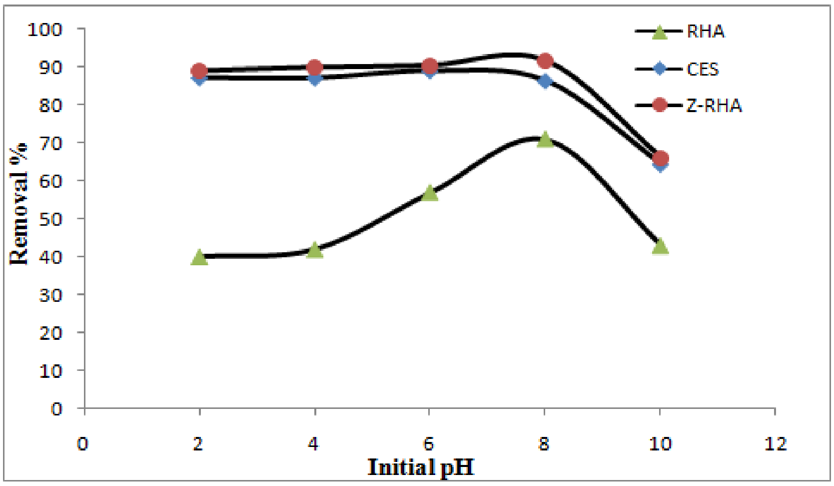

Figure 6. *Effect of the initial pH on dyes' removal*

Effect of dosages

The effect of the different dosages on CV dyes' removal has been studied and plotted in *Figure 8* between removal percentage against the adsorbent dosage 0.2-1.2 mg/50 ml. Usually, the adsorption or removal percentages increase with increasing dosages of adsorbents due to large surface area and consequently, more availability of the vacant sites for adsorption (Rattanapan et al., 2017; Totlani et al., 2012). From *Figure 7,* it is shown that the maximum removal percentages for all materials RHA (62.74%), CES (92.24%) and Z-RHA (94.61%) are at the dosages 0.6 mg/50 ml. After that the removal percentages did not increase with the increase of dosages. This might have happened due to the saturation of the adsorbent in the pollutant solutions (Sawasdee et al., 2017; Kumari et al., 2017; Sharma et al., 2010). Finally it can be concluded from *Figure 8* that the Z-RHA shows more removal efficiency than the other two due to its large surface area.

Effect of contact time

The effect of the contact time on CV dye adsorption has been plotted in *Figure 8*. From *Figure 8* it has been revealed that the adsorption capacity for all of three manufactured adsorbents increases steeply within short time (10 min), and then there is no noticeable increase with time. In this time the adsorption capacities of RHA, CES and Z-RHA are 8.3 mg/g, 18.75 mg/g and 19.28 mg/g respectively. This result can be explained as, at the initial stages of the adsorption the large number of the vacant places

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39553967

are available on the surface of the adsorbents (Yadav et al., 2015; Totlani et al., 2012; Xu et al., 2009). With the increase of the time a repulsive force also starts between the molecules on the adsorbent surface and the bulk phase which is the reason to stop the further adsorption with more lapse time (Singh et al., 2015; Saravanane et al., 2002). The experiment has been carried up to 70 min but no further changes in adsorption have been noticed.

Conclusion

Rice husk is a common waste which is locally available in large quantity with no price. Chemically modified rice husk ash is basically used by many researchers over the world to decontaminate different kinds of the heavy metals but still there has been a lack of research on removal of textile dyes from aqueous solutions. In this study CES and Z-RHA have been synthesized from RHA after chemical modification and applied to remove CV dyes from aqueous solution. The percentages of removal of CV dyes have been found for RHA, CES and Z-RHA are 53.6%, 90.69% and 96.45% respectively. The optimization of adsorption has been studied and maximum adsorption of the adsorbents are found at initial concentration of adsorbate 100 mg/l, solution pH 8, adsorbent dosages 0.6 mg/50 ml and contact time 10 min. FTIR and XRD analyses

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39553967

indicate the presence of silica and aluminum in the CES and Z-RHA which are evident to synthesis of carbon embedded silica and zeolite. From the SEM images it has been also found that the surface of the CES and Z-RHA samples are more rough than that of their parent materials, which evidently adsorb more pollutants than RHA. Thus, from the result of this study it is clear that the chemically modified rice husk can be an alternate solution to treat textile wastewater. Due to the easy availability of the rice husk it has the opportunity to be more popular adsorbent in water treatment and it can help managing the huge amount of rice husk produced as agro waste over the world. Based on this study it can be recommended for future research to examine if the RHA can be further used to remove both anionic and cationic dyes with more chemical modification. Chemically modified RHA adsorbents can possibly be applied in large scale for industrial wastewater treatment which can be a tonic of research for the future researchers.

(Received 22nd Mar 2018; accepted 30th May 2018)

Abstract. Petroleum hydrocarbon (PHC) pollution in marine bays has been one of the critical environmental issues in many countries and regions. Jiaozhou Bay is a semi-closed bay in the fast-growing region in eastern China and has been contaminated by a variety of pollutants after the 1980s. Using investigation data in this bay during 1981-1988, this paper analyzed the temporal, spatial and seasonal changes of PHC. Results showed that PHC contents in surface waters during 1984-1988 were 0.01-0.16 mgL^{-1}, 0.025-0.124 mgL^{-1}, 0.005-0.122 mgL^{-1}, 0.014-0.091 mgL^{-1} and 0.005-0.178 mgL^{-1}, respectively. The pollution level of PHC during 1984-1988 was moderate and was changing with seasons due to the variations of source input. Low values of PHC contents during 1984-1988 were all closed to 0.005 mgL^{-1}, and this value could be considered as the 'background' value of PHC. High values of PHC contents in spring during this period tended to be stable, yet in summer and autumn during this period tended to be increasing. Stream discharge was the major source of PHC, and marine traffic and marine itself were also responsible. The source strengths were still slight/moderate in according to Chinese Sea Water Quality Standard (GB 3097-1997). Stream discharge was one of the major sources of PHC in every year, and the source strengths were increasing along with time. PHC in this bay was mainly input from rainfall runoff. Marine traffic had been one of the important sources since the 1980s, indicated that the oil leaking from marine traffic should be paid attention to. Marine current was also one of the important sources, and the source strengths could be as high as 0.122 mgL^{-1}. Rainfall runoff was the major force of various pollutants to the marine bay, the source input of PHC was also in order of summer > spring > autumn > winter. This was the major reason to explain the seasonal variations of PHC contents in Jiaozhou Bay. The background value of PHC in the marine bay was 0.005 mgL^{-1}, and the increase of PHC contents in the ocean could be calculated as 0.122-0.005 = 0.117 mgL^{-1}. This was the results of the storage of PHC in the ocean. The control and management of anthropogenic source input of PHC in the marine bay were necessary. The outcome of this paper is to identify the major sources, to define the annual change trend and the spatial-seasonal variations, to assess the storage of PHC in the marine bay, and to provide a basis for environmental management decision-making.
Keywords: *spatial, seasonal, annual, pollution, source*

Introduction

Along with the rapid development of industry, agriculture and traffic, a great deal of waste gas, water and residue are generated and discharged to air, soil and water environment (Yang et al., 2002, 2013a). The problem of marine pollution is tending to be more and more serious since the ocean is the "sink" of pollutants (Yang and Miao, 2010; Yang and Gao, 2010). PHC is widely used in industry, agriculture and traffic (Yang et al., 2014). By means of stream discharge, atmospheric deposition and oil spilling, many marine bays have been polluted by PHC and have caused serious environmental problems (Yang et al., 2014, 2015a). Identifying the major anthropogenic sources, the annual change trend and the spatial-seasonal variations is essential to marine environmental protection.

Jiaozhou Bay is a semi-closed bay located in the south of Shandong Peninsula in eastern China and is surrounded by cities of Jiaozhou, Jiaonan and Qingdao in the north, west and east, respectively. This bay has been contaminated after the 1980s, and previous studies showed that this bay has been polluted by various pollutants including Pb (Yang et al., 2008a, 2011a), Hg (Yang et al., 2008b, 2013b), HCH (Yang et al., 2011b, 2015b, 2015c), Cu (Yang et al., 2015d, 2015e). Using investigation data of the bay during 1981-1988, this paper analyzed the temporal, spatial and seasonal changes of PHC. The aim of this paper is to provide a basis for environmental management decision-making.

Materials and methods

Study area

Jiaozhou Bay (120°04′-120°23′ E, 35°55′-36°18′ N) is in the south of Shandong Province, eastern China (*Fig. 1*). It is a semi-closed bay with the total area, average water depth and bay mouth width of 446 km^2, 7 m and 3 km, respectively. There are more than ten inflow rivers such as Haibo River, Licun River, Dagu River, and Loushan River etc., most of which have seasonal features (Yang et al., 2005, 2004).

Data collection

Data on PHC contents in Jiaozhou Bay were provided by North China Sea Environmental Monitoring Center. The investigation was conducted in July, August and October 1984 (*Fig. 1*), April, July and October 1985 (*Fig. 1*), April, July and October 1986 (*Fig. 1*), May, July and November 1987 (*Fig. 1*), and April, July and October 1988 (*Fig. 2*). Surface water samples were collected and measured by the National Specification for Marine Monitoring (China’s State Oceanic Administration, 1991).

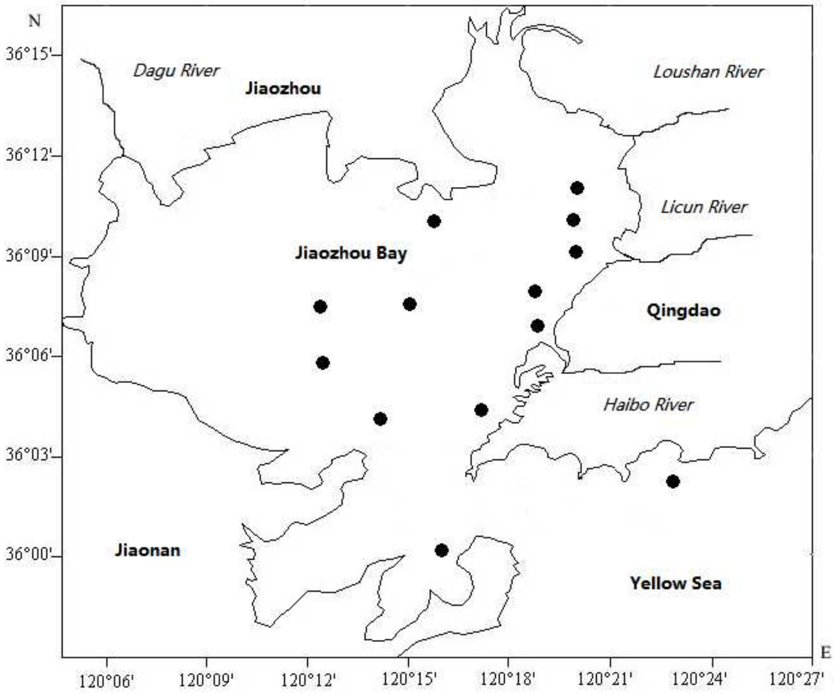

Figure 2. *Geographic location of Jiaozhou Bay and monitoring sites in 1984-1987*

Results and discussion

Annual changes of PHC

PHC contents in surface waters during 1984-1988 were 0.01-0.16 mgL^{-1}, 0.025-0.124 mgL^{-1}, 0.005-0.122 mgL^{-1}, 0.014-0.091 mgL^{-1} and 0.005-0.178 mgL^{-1}, respectively. In the guidelines for PHC in Chinese Sea Water Quality Standard (GB 3097-1997), there are 4 classes of water quality: Class I (and II), III and IV (*Table 1*). PHC contents in surface waters in July, August and October 1984 were 0.050-0.060 mgL^{-1}, 0.090-0.160 mgL^{-1} and 0.010-0.050 mgL^{-1}, and were Class I (and II), Class III and Class I (and II), respectively. PHC contents in surface waters in April, July and October 1985 were 0.025-0.064 mgL^{-1}, 0.059-0.124 mgL^{-1} and 0.010-0.121 mgL^{-1}, belonged to Class I (and II), Class III and Class I (and II), respectively. PHC contents in surface waters in April, July and October 1986 were 0.005-0.066 mgL^{-1}, 0.022-0.122 mgL^{-1} and 0.005-0.017 mgL^{-1}, belonged to Class I to III, Class I to III and Class I (and II), respectively. PHC contents in surface waters in May, July and November 1987 were 0.014-0.060mgL^{-1}, 0.016-0.066 mgL^{-1} and 0.030-0.091 mgL^{-1}, all ranging from Class I to III. PHC contents in surface waters in April, July and October 1988 were 0.014-0.064 mgL^{-1}, 0.005-0.178 mgL^{-1} and 0.022-0.169 mgL^{-1}, all ranging from Class I to III. In general, the pollution level of PHC during 1984-1988 was moderate (*Table 2*) and was changing with seasons due to the seasonal variations of source input.

Table 1. *Guidelines for PHC in Chinese Sea Water Quality Standard (GB 3097-1997)*

Class	I (and II)	III	IV
Guideline	0.05	0.30	0.50

DOI: http://dx.doi.org/10.15666/aeer/1604_39693979

Table 2. *Water quality of PHC in different seasons in Jiaozhou Bay 1984-1988*

Year	Spring	Summer	Autumn
1984	-	I, II, III	I, II, III
1985	I, II, III	I, II, III	I, II, III
1986	I, II, III	I, II, III	I, II
1987	I, II, III	I, II, III	I, II, III
1988	I, II, III	I, II, III	I, II, III

Temporal changes of PHC

In the area of study, April, May and June belong to spring, July, August and September belong to summer, and October, November and December belong to autumn. During 1984-1988, PHC contents in spring, summer and autumn were 0.005-0.066 mgL^{-1}, 0.005-0.178 mgL^{-1} and 0.005-0.169 mgL^{-1}, respectively. According to the high values, PHC contents in different seasons were in order of summer > autumn > spring. The high values of PHC contents in different seasons during 1984-1988 were showed in *Figure 3*. It could be seen that high values of PHC contents in spring during this period tended to be stable, yet in summer and autumn during this period tendes to be increasing. In general, high values of PHC contents during 1984-1988 tended to be increasing. The seasonal changes of PHC contents indicated that the source inputs of PHC in this bay were relative high in summer and autumn yet was relatively low in spring. The reason was that summer and autumn were the wet seasons and a lot of PHC was discharged to Jiaozhou Bay via rainfall-runoff. Meanwhile, the atmospheric deposition of PHC to Jiaozhou Bay was increasing in the wet seasons. In according to the temporal changes of PHC contents in different seasons, it could be found that the pollution levels of PHC tended to be more and more serious along with time. It should be noticed that the low values of PHC contents during 1984-1988 were all closed to 0.005 mgL^{-1}, and this value could be considered as the ‘background’ value of PHC in Jiaozhou Bay. PHC contents in surface waters were directly impacted by source inputs and these trends indicated that the anthropogenic input of PHC was increasing along with the rapid development of industry around this bay, and the source control of PHC was essential to improve the water quality.

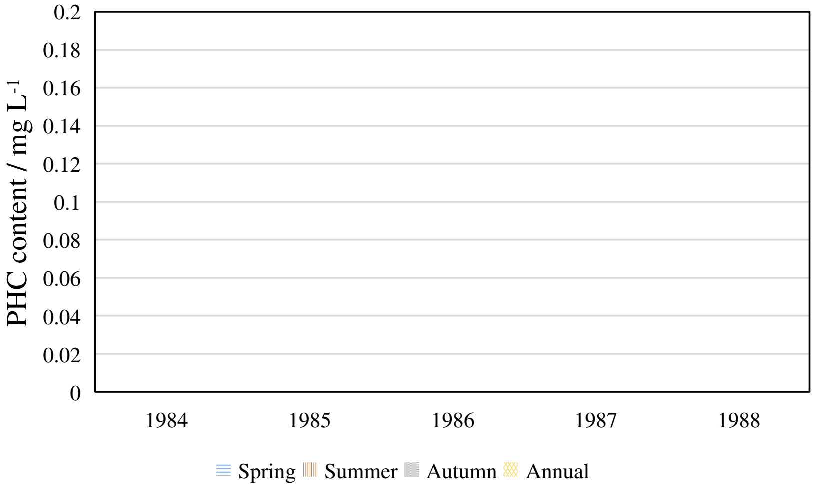

Figure 3. *High values of PHC contents in different seasons in Jiaozhou Bay 1984-1988*

Horizontal distributions of PHC

The contents of PHC in surface waters are mainly impacted by the source input, and the high-value regions are the key evidence to identify the sources. In July, August and October 1984, the high-value regions of PHC contents were in the estuary of the Haibo River (0.060 mgL^{-1}), the estuary of the Loushan River (0.160 mgL^{-1}) and the estuary of the Loushan River (0.050 mgL^{-1}), respectively. In April, July and October 1985, the high-value regions of PHC contents were in the estuary of the Licun River (0.064 mgL^{-1}), the estuary of the Haibo River (0.124 mgL^{-1}) and the estuary of the Licun River (0.121 mgL^{-1}), respectively. In April, July and October 1986, the high-value regions of PHC contents were in the estuary of the Loushan River (0.066 mgL^{-1}), open waters (0.122 mgL^{-1}) and the estuary of the Licun River (0.017 mgL^{-1}), respectively. In May, July and November 1987, the high-value regions of PHC contents were in the southwest coast (0.060 mgL^{-1}), the estuary of the Loushan River (0.066 mgL^{-1}) and the southwest coast (0.091 mgL^{-1}), respectively. In April, July and October 1988, the high-value regions of PHC contents were in the estuary of the Licun River (0.064 mgL^{-1}), the estuary of the Haibo River (0.178 mgL^{-1}) and the estuary of the Haibo River (0.169 mgL^{-1}), respectively.

Sources of PHC

In general, the horizontal distributions of PHC in surface waters are mainly impacted by the source input, and PHC contents are always decreasing along the way from the high-value regions towards areas far away. In July 1984, PHC contents were decreasing from the estuary of Haibo River in the northeast of the bay to the south of the bay (*Fig. 4*), indicating that stream discharge was one of the major sources. In April 1985, PHC contents were decreasing from the estuary of Licun River in the northeast of the bay to the south of the bay (*Fig. 5*), indicating that stream discharge was one of the major sources.

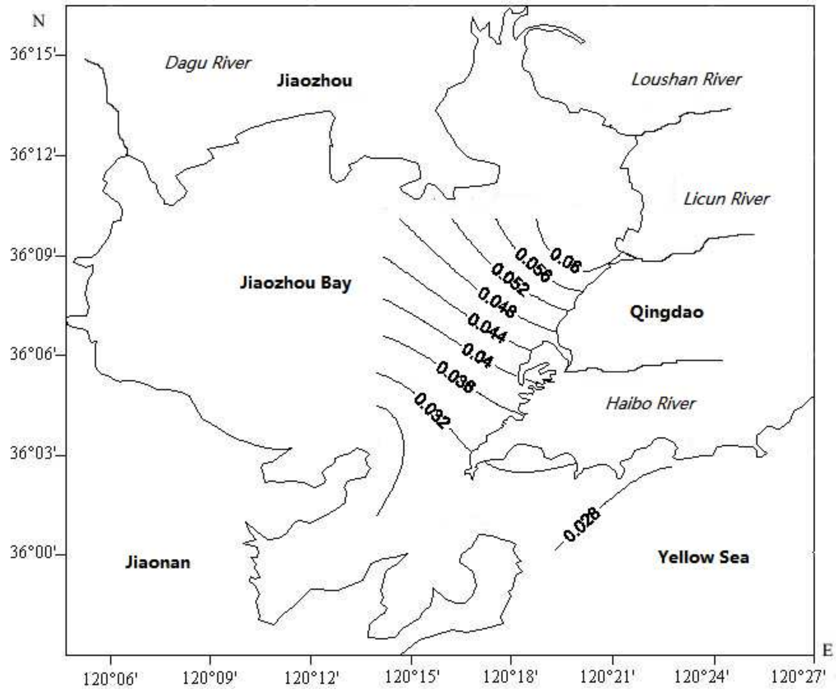

Figure 5. *Horizontal distribution of PHC in surface waters in Jiaozhou Bay in April 1985/mgL*$^{-1}$

In July 1986, PHC contents were decreasing from the open waters to the inside of the bay (*Fig. 6*), indicating that marine current was one of the major sources. In November 1987, PHC contents were decreasing from the southwest coast where there was an important harbour to the northeast of the bay (*Fig. 7*), indicating that marine traffic was one of the major sources.

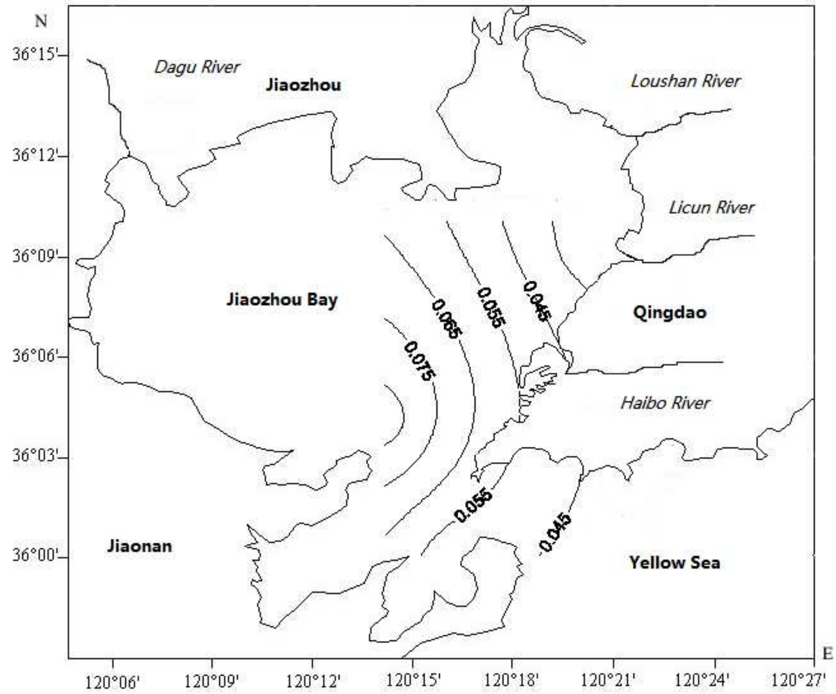

Figure 7. *Horizontal distribution of PHC in surface waters in Jiaozhou Bay in November 1987/mg L^{-1}*

In July 1988, PHC contents were decreasing from the estuary of Haibo River to the center of the bay (*Fig. 8*), indicating that stream discharge was one of the major sources. In general, stream discharge was the major source of PHC, and marine traffic and the sea itself were also responsible (*Table 3*).

Table 3. *Sources and source strengths of PHC in Jiaozhou Bay 1984-1988*

Year	Month	Source	Source strength
	July	Haibo River	0.060
1984	August	Loushan River	0.160
	October	Loushan River	0.050
	April	Licun River	0.064
1985	July	Haibo River	0.124
	October	Licun River	0.121
	April	Loushan River	0.066
1986	July	Marine current	0.122
	October	Licun River	0.017
	May	Marine traffic	0.060
1987	July	Loushan River	0.066
	November	Marine traffic	0.091
	April	Licun River	0.064
1988	July	Haibo River	0.178
	October	Haibo River	0.169

Changes of PHC's sources

In 1984, the major source of PHC in Jiaozhou Bay was stream discharge, whose source strength was 0.05-0.16 mgL^{-1}. In 1985, the major source of PHC in Jiaozhou Bay was stream discharge, whose source strength was 0.064-0.124 mgL^{-1}. In 1986, the major sources of PHC in Jiaozhou Bay were stream discharge and marine current, whose source strength was 0.017-0.066 mgL^{-1} and 0.122 mgL^{-1}, respectively. In 1987, the major sources of PHC in Jiaozhou Bay were stream discharge and marine traffic, whose source strength was 0.066 mg L^{-1} and 0.060-0.091 mg-L^{-1}, respectively. In 1988, the major source of PHC in Jiaozhou Bay was stream discharge, whose source strength was 0.064-0.178 mgL^{-1}. In general, there were three sources of PHC, i.e., stream discharge, marine current and marine, and the source strength was still slight/moderate in according to Chinese Sea Water Quality Standard (GB 3097-1997) (*Table 4*). For annual changes, stream discharge was one of the major sources of PHC in every year, and the source strengths were increasing along with time. Hence, it could be concluded that PHC in this bay was mainly input from rainfall runoff. However, marine traffic had been one of the important sources since the 1980s, indicating that oil leaking from marine traffic should be paid attention to. Furthermore, the marine current was also one of the important sources, and the source strengths could be as high as 0.122 mg L^{-1} during the 1980s. This indicated the ocean had been strongly impacted by anthropogenic source input of PHC. Once the ocean was polluted, the remediation of water quality would be a task and long-term work. As a whole, source control should be promoted.

Table 4. *Pollution levels of PHC's sources in Jiaozhou Bay 1984-1988*

Source	Stream discharge			Marine current	Marine traffic
	Loushan River	Licun River	Haibo River		
Source strength	0.050-0.160	0.017-0.121	0.060-0.178	0.122	0.060-0.091
Pollution level	Slight	Slight	Moderate	Moderate	Slight

DOI: http://dx.doi.org/10.15666/aeer/1604_39693979

During the period of study, the seasonal variation of precipitation was very significant (*Fig. 9*). The maximum and minimum amount of precipitation occurred in summer and winter, respectively. For monthly variations, the amount of precipitation was the lowest in in January (11.8 mm), and was increasing to a relatively high value in April (33.4 mm), and was reaching the maximum amount in August (150.3 mm), and then was decreasing to a relatively low in November (23.4), and finally was reaching the minimum in January in January again. In general, the periods of precipitation were in order of summer > spring > autumn > winter, resulting in a river discharge which was also in order of summer > spring > autumn > winter. Since rainfall runoff was the major force of various pollutants to the marine bay, the source input of PHC was also in order of summer > spring > autumn > winter. This was the major reason for the seasonal variations of PHC contents in Jiaozhou Bay.

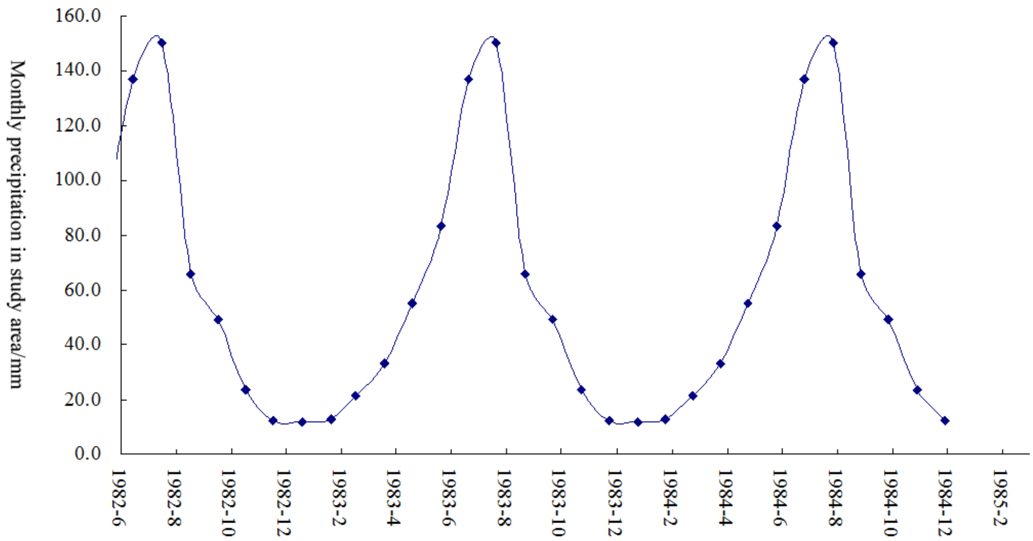

Figure 9. *Monthly precipitation in study area/mm*

Storage of PHC

In general, precipitation determined the river discharge, river discharge determined the source input of PHC, resulting in the seasonal variations of PHC in Jiaozhou Bay waters. By means of the continuous source input of PHC from river discharged, and the continuous accumulation of PHC in waters, a great deal of PHC was stored in Jiaozhou Bay, resulting in the increasing trend of PHC contents in waters. However, in 1987, PHC contents in waters were mainly impacted bay source input of marine traffic, resulting in different seasonal distribution patterns. In case of little source input, the background value of PHC in this bay was 0.005 mgL^{-1}, while in case of source input from marine current, the high-value was 0.122 mgL^{-1}. In consideration that the background value of PHC was 0.005 mgL^{-1} and the background value of PHC in marine was mgL^{-1}, the increase of PHC contents in the ocean could be calculated as 0.122-0.005 = 0.117 mgL^{-1}. This was the results of the storage of PHC in the ocean. Furthermore, a block diagram model was provided to demonstrate that PHC contents in marine waters were increasing continuously by means of continuous source input (*Fig. 10*). Hence, the control and management of anthropogenic source input of PHC in the marine bay were necessary.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

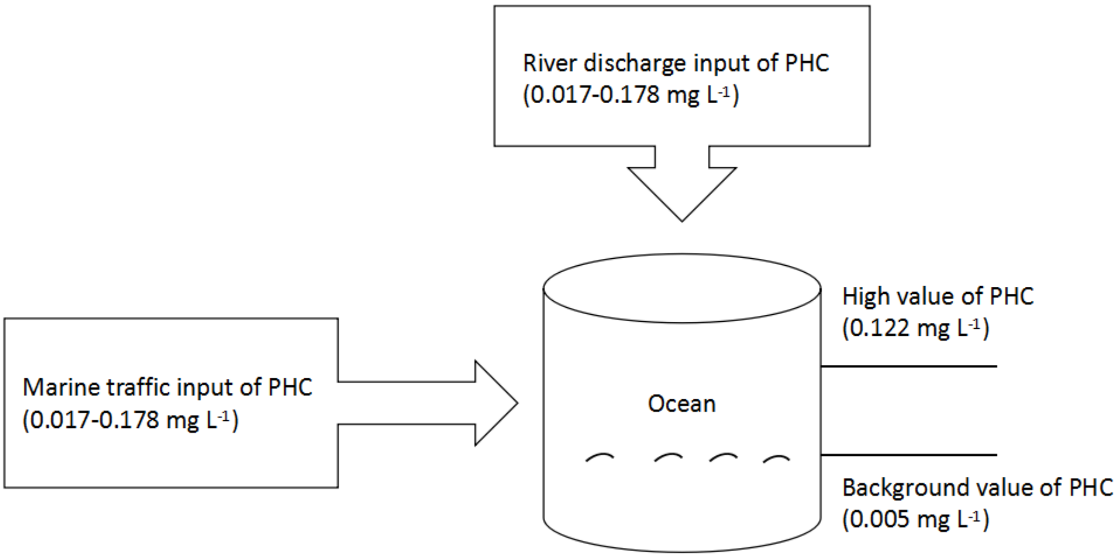

Figure 10. *Block diagram model for the influence of PHC input on marine PHC content*

Conclusion

PHC during 1984-1988 was 0.01-0.16 mgL^{-1}, 0.025-0.124 mgL^{-1}, 0.005-0.122 mgL^{-1}, 0.014-0.091 mgL^{-1} and 0.005-0.178 mgL^{-1}, respectively. The pollution level of PHC during 1984-1988 was moderate and was changing with seasons due to the seasonal variations of source input. Low values of PHC contents during 1984-1988 were all closed to 0.005 mgL^{-1}, and these values could be considered as the 'background' values of PHC in Jiaozhou Bay. High values of PHC contents in spring during this period tends to be stable, yet in summer and autumn during this period were tending to be increasing. The pollution levels of PHC tends to be more and more serious along with time, and the source control of PHC is essential to improve the water quality.

The sources of PHC in Jiaozhou Bay during 1984-1988 were identified. Stream discharge was the major source of PHC, and marine traffic and marine were also responsible. The source strengths were still slight/moderate in according to Chinese Sea Water Quality Standard (GB 3097-1997). Stream discharge was one of the major sources of PHC in every year, and the source strengths were increasing along with time. PHC in this bay was mainly input from rainfall runoff. Marine traffic had been one of the important sources since the 1980s, indicated that oil leaking from marine traffic should be paid attention to. Marine current was also one of the important sources, and the source strengths could be as high as 0.122 mgL^{-1} during the 1980s. Source control should be promoted.

Rainfall runoff was the major force of various pollutants to the marine bay, the source input of PHC was also in order of summer > spring > autumn > winter. This was the major reason for the seasonal variations of PHC contents in Jiaozhou Bay. The background value of PHC was 0.005 mgL^{-1} and that in marine was mgL^{-1}, the increase of PHC contents in the ocean could be calculated as 0.122-0.005 = 0.117 mgL^{-1}. This was the results of the storage of PHC in the ocean. Furthermore, a block diagram model was provided to demonstrate that PHC contents in marine waters were increasing continuously by means of continuous source input. Hence, the control and management of anthropogenic source input of PHC in the marine were necessary.

Abstract. The aim of this study is to assess soil conditioners' effects on the colour intensity of lawn grass. The field experiment was conducted in the experimental facility between 2013 and 2015 in Poland. The following grass species were used in the experiment (factor B): *Lolium perenne*, *Festuca rubra*, and *Poa pratensis*. Another experimental factor tested in the research was soil conditioners (factor A) as Substral, Humus Active Papka, Eko-Użyźniacz, UGmax. At the end of each growing season between 2013 and 2015 the colour of grasses was assessed in accordance with the methodology using a 9-point rating scale. This assessment was conducted in three seasons: spring, summer, and autumn. In all seasons of the year smooth-stalked meadow-grass had the most favourable colour when treated with Substral in spring and summer seasons, and with Eko-Użyźniacz in autumn. Comparing all soil conditioners, grass treated with UGmax had the best colour. From a practical point of view, of all grass species tested in the study, perennial ryegrass had the smallest, most favourable, colour variation during the whole period.
Keywords: *leaf-blade greenness, lawns, soil conditioners, turf grasses, growing season*

Introduction

Green spaces positively affect human well-being and mental state not only in dwelling areas but also in workplaces. In addition, to some degree they satisfy inhabitants' aesthetic needs. Regardless of the purpose of a green area, grass is the basic plant to cover the ground in a lawn (Grabowski et al., 2003a; Prończuk and Żurek, 2008; Pooya et al., 2013; Knot et al., 2017). With its richness of species and forms, grass has an amazing ability to adapt to changing weather conditions and different ways of its use (Wolski, 2003; Knot et al., 2017). A lawn should be composed of several species of grass, complementing each other in terms of their properties. Selection of those species should depend on habitat conditions and on the lawn's user capacity to provide means to meet maintenance requirements (Salehi and Khosh-Khui, 2004; Czeluściński et al., 2017). Each species of grass has a unique role in the environment, as well as in human life and economic activity (Pooya et al., 2013; Knot et al., 2017). In Poland there are some 160 species of grass, but out of this considerable number only 16 of them are suitable to plant lawns (Grabowski et al., 2003a; Prończuk and Żurek, 2008). The most common grass species used for extensive lawns include: red fescue (*Festuca rubra*), smooth-stalked meadow-grass (*Poa pratensis*), and perennial ryegrass (*Lolium perenne*). These species have a varied degree of leaf-blade greenness. In general, red fescue, as opposed to the other two

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39813992

species, is a dark green plant. Naturally, an important element in determining the appearance of a lawn is its colour (Jankowski et al., 2012a, b; Braun et al., 2016), which can change under the influence of the weather, habitat, and other conditions. Difficulty in maintaining a proper grass colour under adverse moisture conditions or with insufficient nutrients in the soil can cause a loss of a lawn's natural greenness and, consequently, its attractiveness can be significantly reduced. Green is a calming and beneficial colour for the human eye, positively affecting mental health. In degraded areas there is a much higher rate of people suffering because of the direct action of pollutants, but there is also a significant increase in mental health problems resulting from stress caused by a lack of contact with nature (Stępczak, 1997; Salehi et al., 2004; Knot et al., 2017).

As a result of the presence of green spaces, negative effects of long lasting droughts can be reduced. However, longer periods with little rainfall lead to a change of lawn colour from green to yellow, with some grass leaves turning discoloured (Prończuk and Żurek, 2008; Braun et al., 2016). When adequate care and conditions cannot be provided, an application of soil conditioners before setting up a lawn can be a good solution. The quality of the turf with its colour depends to a large extent on a frequent application of plant nutrients which can stimulate quality and colour of the grass (Jankowski et al., 2010, 2011a, b, c). Additionally, leaf colour, apart from leaf fineness, is an indicator most often assessed in lawns. Grass with narrow dark green leaves looks the best (Jankowski et al., 2012a), and this is the colour most desired by lawn users. Plant physiological processes can be modified by mineral compounds stimulating plant growth. Soil conditioners are based on natural substances such as plant or humus extracts and phytohormones (Hamza and Suggars, 2001). Those bio fertilizers demonstrate a positive impact on grass metabolism, stimulate life processes, and reduce the effects of adverse environmental conditions (drought, salinity, temperature fluctuations) and pathogens (Chen et al., 2004; Gąbka and Wolski, 2008). Soil conditioner application contributes to the decomposition of organic matter. This is a very important effect due to the release of mineral forms, which are an important source of nutrients for arable crops (Hamza and Suggars, 2001; Chen et al., 2004; Calvo et al., 2014). Soil conditioners used instead of mineral fertilizers can play an essential role in grass ecological maintenance, and the aim of this study is to assess their effects on the colour intensity of lawn grass.

Materials and methods

Experimental design

Set up in 2012 the field experiment was conducted in Poland in the experimental facility of the University of Natural Sciences and Humanities in Siedlce (52°12' N, 22°28' E) between 2013 and 2015. The research was carried out as a mini-plot experiment, in the split plot design with three replications and the plot area of 1 m^2. The following grass species were used in the experiment (factor B): *Lolium perenne* - variety Info, *Festuca rubra* - variety Nil, and *Poa pratensis* - variety Alicja. They were sown on their own, each of them at the rate of 28 $g \cdot m^2$. Another experimental factor tested in the research was soil conditioners (factor A).

Soil conditioners used in the experiment improve soil properties, according to the Institute of Soil Science and Plant Cultivation (IUNG) in Puławy. The composition of the soil conditioners used in the research is presented in *Table 1*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39813992

Table 1. *Composition of soil conditioners applied in the experiment*

Soil conditioner	Macronutrients (g·kg^{-1})						Micronutrients (mg·kg^{-1})					Microorganism and others
	N	P	K	Ca	Mg	Na	Mn	Fe	Zn	Cu	Mo	
Substral (S)	220	21.8	83		12.06		12	50	12.5	12.5	1	-
g·m^{-2}	4.4	0.44	1.66									
Humus Active Papka (HAP)	0.2	1.3	4.6	3.0	0.5	-	15	500	3	1	-	Active humus with useful microorganisms
g·m^{-2}	0.05	0.33	1.15									
Eko-Użyźniacz (EU)	0.6	0.3	0.7	-	-	-	-	-	-	-	-	Endo micorhiza, fungi, bacteria, enzymes of earthworms
g·m^{-2}	0.06	0.03	0.07									
Ugmax (UG)	1.2	0.2	2.9	-	0.1	0.2	0.3	-	-	-	-	Lactic acid bacteria, photosynthetic bacteria, *Azotobacter*, *Pseudomonas,* yeast, *Actinomycetes*
g·m^{-2}	0.03	0.01	0.07									

The UGmax soil conditioner is an extract from compost, containing macronutrients (N, P, K, Mg, Na) and micronutrients (Mn). It also contains lactic acid bacteria, photosynthetic bacteria, *Azotobacter*, *Pseudomonas*, yeast, and *Actinomycetes*. The micro-organisms in the conditioner have a capacity of processing organic and natural fertilizers into compost and humus. These processes are conducive not only to the production of humus but also to improving soil structure, which in turn has a positive effect on water balance in the soil. In addition, the UGmax soil conditioner increases disease resistance, keeping plants healthy, but it also stimulates the development of the root system and supports the biological reduction of molecular nitrogen.

Humus Active Papka contains macronutrients (N, P, K, Ca, Mg), trace elements (Mn, Fe, Zn, Cu), and active humus with useful microorganisms. According to the manufacturer Humus Active, among other beneficial effects, positively affects plant health as well as soil structure, and releases nutrients not readily available to plants.

Eko-Użyźniacz is extracted from bovine vermicompost and contains the main macronutrients (N, P, K), micro-organisms, and enzymes related to metabolism of earthworms. This soil conditioner stimulates biological life in soil degraded chemically, mechanically, or biologically, and increases plant resistance to different stress factors.

Soil conditioners were applied annually in spring (mid May) in the following doses: UGmax – 25 ml m^{-2} (0.6 l in 250 l of water), Eko-Użyźniacz - 100 ml m^{-2} (10 l in 100 l of water), and Humus Active Papka - 250 ml m^{-2} (0.2 l for 10 l of water). In turn, Substral, a slow release fertilizer used on lawns, was used in the quantity of 20 g m^{-2}. The tested fertilizers were used in doses recommended by the manufacturer.

At the end of each growing season between 2013 and 2015 an assessment of grass based on the methods described by Domański (1998) was carried out. Among other

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39813992

things its colour was assessed in accordance with the methodology using a 9-point rating scale (*Table 2*). This assessment was conducted in three seasons: spring, summer, and autumn. In each year of the research spring assessment was made around 20 May, summer assessment around 20 August, and autumn assessment around 10 October.

The experiment was set up on the soil developed from loamy sand, belonging to anthropogenic soils of the culture-earth order, and of the type of hortisole (Systematics of Polish Soils, 2011). Chemical analysis showed that the soil was of neutral pH (pH = 6.8), with assimilable phosphorus in a form of $H_2 PO_4$ - standing at 170 mg·kg^{-1}, magnesium Mg^{2+} at 84 mg·kg^{-1}, potassium K^+ at 114 mg·kg^{-1}, total nitrogen N at 1.3 g·kg^{-1}, and organic carbon at 13.5 g·kg^{-1} DM.

Table 2. *Lawn grass colour rating with a scale of 1 to 9 according to Domański (1998)*

Rating	Grass colour
1	Bare ground with no grass
2	Dry grass
3	Yellowish to brownish green
4	Yellowish green with discolouration
5	Greyish green
6	Bluish green
7	Light green
8	Lush green
9	Dark green

Statistical analysis

The test results were evaluated statistically with the analysis of variance. Tukey's test ($P \leq 0.5$) was used to find significantly different means of the effects of experimental factors and their interaction. Based on lawn colour ratings, standard deviation and coefficient of variation were calculated for separate seasons, years, and soil conditioners.

Weather conditions

Meteorological data between 2013 and 2015 were obtained from the Hydrological and Meteorological Station in Siedlce (about 4 km from experimental station). In order to determine the temporal variation of meteorological elements and their effects on vegetation, Sielianinov's hydrothermal coefficient was calculated on the basis of monthly rainfall (P) and the monthly total air temperature (Σt), using the formula: $K=P/0.1\ \Sigma t$ (Skowera and Puła, 2004).

In assessing temperature and moisture conditions ten-scale classification of Sielianinov's hydrothermal coefficient (K) was used, which, according to Skowera and Puła (2004), has the following ranges:

$K \leq 0.4$ extremely dry (ed);

$0.4 < K \leq 0.7$ very dry (vd);

$0.7 < K \leq 1.0$ dry (d);

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39813992

1.0 < K ≤ 1.3 quite dry (qd);
1.3 < K ≤ 1.6 optimal (o);
1.6 < K ≤ 2.0 quite wet (qw);
2.0 < K ≤ 2.5 wet (w);
2.5 < K ≤ 3.0 very wet (vw);
K > 3.0 extremely wet (ew).

The values of Sielianinov's hydrothermal coefficient for individual months of the experiment are shown in *Table 3*. It was assumed that the conditions were extreme when coefficient values were below 0.7 and above 2.5 (Skowera and Puła, 2004).

Optimal temperature and moisture conditions were only in April 2014 and in September 2015. In the remaining months of all the growing seasons the weather conditions were not as favourable, varying from extremely dry in August 2015 to extremely wet in May 2013. Throughout the experiment the best conditions occurred at the beginning of each growing season. It can be concluded that the most difficult period for plants was in 2015, when, apart from May and the end of the growing season, the weather conditions ranged from quite dry to extremely dry.

Table 3. *Sielianinov's hydrothermal coefficient (K) during the growing season*

Years	Month

Results

One of the most important characteristics rated in lawn quality assessment is its colour. In the present study, assessment done in spring seasons (*Table 4*) proved that grass colour was dependent on the species, the type of soil conditioner, and meteorological conditions.

Comparing soil conditioner effects it was observed that in spring grass was the most intensely green (7.86^o) on plots where Substral was applied, being the least intensely green as a result of Eko-Użyźniacz (6.05^o) or Humus Active Papka (6.08^o) application. Despite that, statistical analysis showed that differences between colour ratings of lawns treated with different kinds of soil conditioner were not significant.

Similarly, the differences between the colour ratings of grass species were not statistically significant either, although smooth-stalked meadow-grass and red fescue had slightly more intense colour than perennial ryegrass, with their ratings of 6.97^o and 6.94^o, which is bright green.

The forms of soil conditioners affected the colour of different grass species to a different extent. It was observed that Substral application resulted in leaf blades with the darkest shade of green for all grass species, but smooth-stalk meadow-grass was of the most intense colour (8.13^o). In spring seasons, out of all conditioners UGmax application resulted in the most favourable colour of leaf blades in all species, with the average rating of above 7, indicating light green colour. Throughout all growing seasons it turned out that in the spring, grass was the greenest in 2015, with the rating of 7.45^o, as the average score of all three types of soil conditioners.

Grass colour considerably improved in summer seasons compared with spring periods (*Table 5*). The results indicated that in summer seasons grass treated with Substral (8.95°) and UGmax (8.84°) had dark green colour, with lawns treated with those two soil conditioners having the most favourable appearance. Grass colour in plots with Eko-Użyźniacz and Humus Active Papka was rated considerably lower, with a score statistically different from the ratings of the other two soil conditioners.

Comparing the colours of different grass species, it was observed that in summer seasons there was no statistically significant difference between them, with the average rating of above 8 for all species, although red fescue had the best colour (8.23°). Grass strongly responded with increased greenness of leaf blades to the application of Substral and UGmax, which was proved by comparing average colour ratings of the three grass species treated with those two conditioners. Those ratings were over 8.8° for both soil conditioners, indicating dark green colour.

Additionally, the weather conditions in summer seasons affected colour intensity of the grass tested in the study. In the 2014 and 2015 growing seasons grass had the most intense dark green colour (above 8.8°), while in 2013 it was much lighter, with the rating of 6.62°, indicating bluish green. The difference in grass colour between all the above growing seasons was statistically significant.

ns – not significant

During autumn seasons quite variable grass colours were observed (*Table 6*). Comparing the types of soil conditioners, Eko-Użyźniacz application resulted in the best colour of grass (6.51°). Grass fertilised with Substral had the least favourable colour during in the autumn (5.87°). However, the differences between the effects of different conditioners were not statistically significant. Contrary to that, there were significant differences between grass species in their shades of green in autumn seasons. Perennial ryegrass had the best colour, with the rating of 7.07°, which was significantly better than for other species of grass.

The grass had the best dark-green colour in 2013 with the rating of above 8.7 as the average of the effects of all conditioners. High rainfall in September 2013 had a huge impact on grass colour, but in the autumn of 2014 and 2015 grass had significantly lower colour rating. The difference in colour ratings between the grass in autumn of 2013 and of the other two years was statistically significant. Comparing the average colour ratings of grass species in all growing seasons (*Table 7*) it was found that perennial ryegrass had the most advantageous colour (7.22°). Taking into account the type of applied soil conditioner, perennial ryegrass treated with Substral (7.89°) and smooth-stalked meadow-grass treated with Humus Active Papka had the highest colour rating of 6.07°.

DOI: http://dx.doi.org/10.15666/aeer/1604_39813992

Grass treated with Substral had the most favourable lush green colour, with the rating of 7.56°, as the average for all the species, but when it was treated with Humus Active Papka the rating was the lowest, with blue shade of green (6.46°).

Comparing the three years of research, without a division into seasons of the year, it was observed that the grass had the highest colour rating in 2013 (7.23°) and the lowest in 2014 (6.79°). The coefficient of variation of grass colours calculated during the research (*Table 8*) indicated that during the whole research period perennial ryegrass had the smallest variation of the intensity of greenness, and, at the same time, it was characterised by the highest average colour rating of 7.22°, which is light green colour.

Table 8. *Standard deviation and coefficient of variation of grass colour*

Species	Min. value of colour rating	Max. value of colour rating	Mean values of colour rating	Standard deviation	Coefficient of variation
Smooth-stalked meadow-grass	2.8	9	6.94	2.35	33.86
Perennial ryegrass	3.7	9	7.22	1.77	24.52
Red fescue	1.8	9	6.86	2.38	34.69

Coefficient of variation: 0–20% small variation, 20–40% moderate variation, 40–60% large variation, >60% very large variation

Discussion

In this study the differences between the colour ratings of grass species in spring were not significant, although smooth-stalked meadow-grass and red fescue had slightly more intense colour than perennial ryegrass. But in the studies, of Starczewski and Affek-Starczewska (2011) the cultivars of perennial ryegrass were characterized by the most intensive green at the beginning of the growing season (vivid green in May), and the least favorable in the summer month (grey, dirty green) than other species.

In summer seasons the best green colour had red fescue, but not significant to the other species. In this study in autumn seasons, there were significant differences between grass species in their shades of green but perennial ryegrass had the best colour. Also in the studies by Grabowski et al. (1999) and Jankowski et al. (1999) cultivars of perennial ryegrass achieved the highest marks of colour assessment in autumn periods.

Comparing the average colour ratings of grass species in all growing seasons, it was found that perennial ryegrass had the most advantageous colour. In regard to soil conditioner effects it was observed that in spring and in summer grass was the most intensely green on plots where Substral was applied, being the least intensely green as a result of Eko-Użyźniacz or Humus Active Papka application. According to Jankowski et al. (2012a) the colour of a lawn is an unstable characteristic, depending, among others, on habitat conditions, the content of macro- and micronutrients in the soil, and on their availability for plants. Soil conditioners make absorption of nutrients easier, which affects metabolism of plants (Calvo et al., 2014). Studies conducted by Talar-Krasa and Świerszcz (2015) confirm stimulating properties of humic acids present in soil conditioners on plant growth and development as well as grass colour. In the case of the colour of the species studied in the present experiment, application of soil conditioners resulted in a significant increase in leaf blade greenness. In the spring and in summer the best green colour was after Substral application.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39813992

Comparing the types of soil conditioners in autumn, Eko-Użyźniacz application resulted in the best colour of grass. Also in the study of Wiśniewska-Kadżajan (2013) the intensity of the green colour of turf lawns has improved with the increase of the applied dose of mushrooms substrate. According to Jankowski et al. (2012b) the type and amount of fertilizers applied had a big impact on the intensity of the colour. In the other study of Jankowski et al. (2011d) a significantly better effect of fertilizer Sierrablen on the colour of monoculture turfs was observed as compared with Trawovit Komplet.

As the average for all the species, grass treated with Substral had the most favourable lush green colour, but when it was treated with Humus Active Papka the rating was the lowest, with blue shade of green. Braun et al. (2016) studied the stability of dark-green colour of grass leaves over the entire period of vegetation together with greenness durability into late autumn, and observed that it was also dependent on the application of proper fertilizers.

The weather conditions in spring, summer and autumn seasons of each experimental year affected colour intensity of the grass tested in the study. Also the results of Wiśniewska-Kadżajan (2013) clearly indicate that the colour of turf lawns strongly affected by weather conditions.

Throughout all growing seasons it turned out that in the spring, grass was the greenest in 2015, in summer in 2014 and 2015 but in autumn in 2013. In the studies by other authors (Jankowski et al., 1999; Grabowski et al., 1999, 2003b) a similar tendency was noticeable at the assessment of lawn colour.

For example, in autumn period high rainfall in September 2013 had a huge impact on grass colour. In the other study of Jankowski et al. (2011d), the lawn colour was also largely dependent on the meteorological conditions. The results obtained indicate that more favorable weather conditions in 2003 had an effect on more intensive and more desirable colour of lawns. The intensity of green colour of leaf blades of lawn turfs in 2003 was to a large extend affected by the most even distribution of precipitation during the growing period.

In the literature concerning lawn turfs there are few studies on the assessment of their colouring. Consequently, it is difficult to relate the results of the present study to other authors.

Conclusion

In the study grass colour varied over the growing seasons in relation to the grass species (smooth-stalked meadow-grass, perennial ryegrass, red fescue) and the soil conditioner applied. Of all the bio products, Substral application resulted in the most favourable grass colour when used in spring and summer, and Eko-Użyźniacz when applied in autumn. This means that differences in the effects of soil conditioners in different seasons under different weather conditions were difficult to evaluate. However, those results also indicate an interaction between the types of soil conditioner and the meteorological conditions in their effect on grass colour. In all seasons of the year smooth-stalked meadow-grass had the most favourable colour when treated with Substral in spring and summer seasons, and with Eko-Użyźniacz in autumn. Comparing all soil conditioners, grass treated with UGmax had the best colour. This conditioner is composed not only of minerals, but also contains such micro-organisms as lactic acid bacteria, photosynthetic bacteria, *Azotobacter*, *Pseudomonas*, yeast, and *Actinomycetes.*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39813992

From a practical point of view, of all grass species tested in the study, perennial ryegrass had the smallest, most favourable, colour variation during the whole period. In regard to obtained results for future studies should be recommended UGmax for lawn fertilization as well as the other new soil conditioners.

(Received 3rd Apr 2018; accepted 13th Jun 2018)

Abstract. The analysis of land use/land cover (LULC) change has always been a topic of interest in land dynamics research. The majority of previous studies used the conventional method of "net change" analysis to show spatiotemporal LULC transitions. However, such analysis failed to indicate whether the transition is clearly systematic or due to an apparently random process. Hence, this study aimed to identify the most prominent signals of landscape transitions over the last three decades, using the landscapes of East African Rift Valley Region. We used Remote Sensing and GIS to quantify and map the changes in LULC for 1986 and 2016, and then the two maps compared to produce transition matrices. Results show that net change and swap change accounted for 43% and 57% of total change on the landscape respectively. Accordingly, 6% of scattered acacia woodland and 5% of bush land have been converted to agricultural land, whereas 7% and 3% of scattered acacia woodland have been degraded towards grazing land and bush land respectively. These changes were found to be clearly systematic and hence indicate the dominant and prominent signals of landscape transformation. Hence, future land use policies need to consider such prominent signals of LULC change in order to plan an integrated approach to safeguard the fragile ecosystems of the region, while searching for alternative livelihood options.
Keywords: *gain, loss, net change, persistence, swap change*

Introduction

Anthropogenic-induced changes in land use/land cover (LULC) have occurred in the past, is presently ongoing, and is likely to continue in the future, with its related ecological, environmental and socioeconomic impacts worldwide (MEA, 2005; FAO, 2016). Unregulated LULC change for example has brought local, regional and global impact on biotic life, soil, hydrological balance, climate and ecological processes (Lambin et al., 2003; MEA, 2005; Yan et al., 2016; Rai et al., 2017). In addition, LULC change has threatened regional food supply, livelihood systems, and global sustainability (Reid et al., 2000). Such impacts of LULC change are more serious in developing countries where economic, political and sociocultural backgrounds further aggravate the complexity of the dynamics (Kalacska et al., 2017). These entire concerns make the analysis of land dynamics always been a topic of interest in researches at various fields and levels (Manandhar et al., 2010; Li et al., 2017; Yirsaw et al., 2017),

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39934014

which have spawned a flurry of research on its extent, drivers and consequences in recent decades globally.

Based on causative factors, the transitions in LULC could be classified as ‘random’ or ‘systematic’ (Pontius et al., 2004; Briones and Sepúlveda-Varas, 2017). Random transitions are those influenced by accidental or unique processes of change (Tucker et al., 1991; Geist and Lambin, 2002; Lambin et al., 2003). These transitions are usually caused by the interaction of land use factors such as: spontaneous migration, internal conflicts, changes in microeconomic conditions or loss of ownership to land resources (Lambin et al., 2003; Braimoh and Vlek, 2005). On the other hand, systematic transitions are those which occur due to regular or common processes of change. They tend to evolve in a consistent, progressive or gradual manner driven by natural population growth, increase in commercialization, border development, lack of public awareness on the environment or changes in institutions governing access to natural resources (Lambin et al., 2003; Geist et al., 2006).

Pontius et al. (2004) and Alo and Pontius Jr (2008) pointed out that though a conventional cross-tabulation matrix is a fundamental starting point in the analysis of LULC change, several related research works failed to analyze the matrix based on its various components, and thus failed to gain as much insight as possible concerning the potential processes that determine a pattern of landscape changes. This is because the majority of earlier landscape change studies used a ‘net change’ to compare a spatiotemporal LULC change trends between two different periods. However, though a net change indicates a definite change on the landscape, the absence of net change does not necessarily indicate the absence of change on the landscape. This is ascribed to the fact that the net change fails to capture a gross gain of a land category in one location with a gross loss of the same category in other location (Manandhar et al., 2010). This type of simultaneous loss and gain for a land category in spatial allocation is termed as the ‘swapping’ component of a change (Pontius et al., 2004; Braimoh, 2006; Briones and Sepúlveda-Varas, 2017). In addition, since the dominant landscape change signal is usually that of persistence, net change undermines the total change on the landscape, and hence fails to indicate the most prominent signals of LULC changes (Versace et al., 2008).

Due to such important limitations of ‘net change’, scientists recommend extending of the usual way of land transition matrices analysis beyond reporting net change, to gain an in-depth information that is important for detecting the most important signals of landscape changes (Braimoh, 2006; Manandhar et al., 2010). Pontius et al. (2004) strongly recommended detecting the most prominent signals of change, and ultimately linking pattern to process when analyzing LULC changes. Similarly, Geist et al. (2006) pointed the importance of considering two fundamental steps in any study of land dynamics. These are detecting changes in the landscape first, and then ascribing that change to some set of casual factors. The importance of addressing systematic and random LULC transitions has been further evidenced by recent studies (Burmeister and Schanze, 2016; Zewdie and Csaplovics, 2016; Briones and Sepúlveda-Varas, 2017). Linking the studies of changes in landscape pattern to the processes underlying helps to better understand the mechanisms of change; generate predictions about future rates of change, identify potential vulnerable places to change, and to design appropriate policy responses (Lambin, 1997; Nagendra et al., 2004; Alo and Pontius Jr, 2008).

Ethiopia is one of the typical countries in the sub-Saharan Africa confronted with the multidirectional impacts of extensive and rapid LULC dynamics since the beginning of the twentieth century (Kindu et al., 2013; Lemenih and Kassa, 2014). For example,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39934014

empirical studies shown that deforestation in Ethiopian highlands has changed the landscape from 40% of forest cover in 1900 to 3.2% cover in 1980 (Dessie and Kleman, 2007; Eshetu, 2014), though some unpublished sources reported an increase in forest coverage of the country since 2000. On the other hand, significant increase in agricultural lands in expense of losses in forestlands, woodlands and grasslands has been reported in arid and semi-arid areas of the country including the Central Rift Valley (CRV) Lakes Region (Muzein, 2006; Garedew et al., 2009; Temesgen et al., 2013; Meshesha et al., 2014; Ariti et al., 2015; Zewdie and Csaplovics, 2016). In addition, in recent years, expansion in built-up areas has also been accelerated in Ethiopia since the government change and subsequent land use policy reforms in 1991 (Meire et al., 2013). Nonetheless, among such previous land dynamics studies in different parts of the country, only study by Zewdie and Csaplovics (2016) in north western Ethiopia, addressed random and systematic transition analysis. In addition, these studies did not emphasize the degree of landscape categories persistence relative to gross losses and gains. Hence, this study is aimed at: 1) detecting and mapping spatiotemporal LULC changes for the years 1986 and 2016; 2) analyzing LULC change matrices according to their various components (net change, persistence, gross gain/loss and swap); and 3) identifying systematic and random transitions, and the most prominent signals of LULC changes, and relating this to some possible causative factors, taking the CRV lakes region of Ethiopia as ideal case study site. This way of analysis helps in linking patterns to process and in designing appropriate policy interventions aimed at reducing the adverse effects of spectacular LULC changes in developing countries like East Africa.

Materials and methods

The study area

The study site, also known as Ziway-Shalla basin, is one of the four sub basins under the Rift Valley Lakes Basin, located about 170 km south of the capital city, Addis Ababa, Ethiopia. It is geographically found in the limits of 7°20'–8°00'N latitude and 38°20'– 38°50'E longitude (*Fig. 1*). The study area belongs to the main African Rift system (Benvenuti et al., 2002). The African Rift originates from Aden Junction (Arabian Plate) in the Middle East and continues in the direction of south-west, traversing longitudinally eastern African countries such as Djibouti, Eritrea, Ethiopia, Kenya, Uganda, and Tanzania (JICA, 2012). The CRV is part of the Main Ethiopian Rift system (Molin and Corti, 2015) which is topographically characterized by a depression zone with steep marginal faults along its eastern and western edges (JICA, 2012). Altitude ranges from 1554 to 2069 m a.s.l. and bounded by north-western and south-eastern highlands (Hengsdijk and Jansen, 2006). The total area of the basin is about 13,401 km^2 (JICA, 2012). It is situated in the current regional administrative boundaries of Southern Nations, Nationalities and Peoples (SNNP) and Oromia (*Fig. 1*).

The climate in CRV lakes region varies markedly with altitude and season (Jansen et al., 2007). It is characterized by warm and wet summer (June to September) and dry, cold and windy winter (October to May). The climate of the main valley in the central portion is dominantly semi-arid, whereas that of highland portion is sub-humid (Fritzsche et al., 2007). Based on the data obtained from National Meteorological Agency (NMA), Ziway Station, mean annual rainfall is about 739 mm, while mean monthly minimum and maximum temperatures are 14 and 27 °C respectively (*Fig. 2*),

DOI: http://dx.doi.org/10.15666/aeer/1604_39934014

and this figure significantly varies throughout the basin depending on elevation. In general, the region is highly vulnerable to climate change as it encompasses a dryland zone which has been repeatedly hit by drought (Jansen et al., 2007; Biazin and Sterk, 2013).

Soil in CRV lakes region is largely derived from recent volcanic rocks (Itanna, 2005). It is generally shallow in depth, and texture ranges between loamy sand and sandy loam that readily compacts and is susceptible to crusting, and also sensitive to drought (Biazin et al., 2011). The soil is weak in its physical structure (Abdelkadir and Yimer, 2011; Temesgen et al., 2013). Above all, the area is known for its highly fragile ecosystems subjected to high natural and anthropogenic-induced pressures. One of such human-induced pressures on environment among others in the region is the rapid changes in LULC.

Based on interpolation of 1994 and 2007 national census (CSA, 1994 and 2007), the total population for two Districts in the study area, namely Adami Tulu-Jido Kombolcha and Arsi Negele, is 155 382 in 1986, 319 484 in 2000 and 521 124 in 2016, which indicates a sharp increase in population growth in the region. According to Melka et al. (2015), more than 85% of rural farmers in the study area mainly practice mixed farming, predominantly rain-fed, while the rest practice agro-pastoral livelihood system. The major field crops are maize, wheat, ‘teff’ (*Eragrostis tef*), barley, lentil, horse bean, chickpea and field pea (Hengsdijk and Jansen, 2006), whereas acacia woodland dominates the vegetation type of the region. Due to erratic nature of rainfall and poor farming system, agricultural productivity is still low and subsistent in the region (Garedew et al., 2009). With such highly variable climate and soil moisture stress, feeding the ever-growing population becomes a major challenge to government rural poverty reduction program in the region.

Data sources

Satellite imageries and field survey are the two main data sources used for this study (*Table 1*). For the purpose of temporal LULC change detection of 1986 and 2016, cloud-free Landsat5 Thematic Mapper (TM) and Landsat8 Operational Land Imager (OLI) imageries were respectively used after downloading from online United States Geological Survey (USGS) data base archive (http://glovis.usgs.gov). Satellite imagery from the same season of the year (January to February) was used to minimize discrepancies in reflectance caused by seasonal vegetation fluxes and sun angle differences. In addition, Google earth service, topographic map and administrative map of the study area were used for boundary delineation, navigation purpose, support in ground truthing and training site establishment.

Table 1. *Data used and sources*

Data source	Path/Row	Resolution	Analysis period and date of acquisition
Landsat5 Thematic Mapper (TM)	168/055	30 m	1986 (21/01/1986)

Sketch map/GCPs/Ground observation/Key informants			Field work in 2017

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39934014

Field survey was carried out from January to May 2017 to collect information about households' socioeconomic background, historical LULC change, driving forces, impacts and adaptation strategies of farmers who were knowledgeable about LULC dynamics during the respective study period (1986-2016). Focus group discussions with five to ten participants per group were carried out in a total of eight Kebeles (Villages) randomly selected from two adjacent study Woredas (Districts) (five at Adami Tulu-Jido Kombolcha District and three at Arsi Negele District) (*Fig. 1*). Additional land use information also gathered from at least one elder key informant (age at least 60) from each village. Ground control points (GCP) were collected through interpretation of topographic map, Google earth, focus group discussion/key informants' interview, and visual observation carried out during field verification.

Image processing and LULC classification

Landsat images were pre-processed for geometric and atmospheric corrections using 30 m by 30 m Aster Global Digital Elevation Model (ASTGM) of the study area, and the commonly used dark subtraction technique respectively (Jensen, 1996). Each image was georectified to Universal Transverse Mercator (UTM) WGS 1984 Zone 37 North coordinates using ground control points collected during field work (Hall et al., 1991; Wijedasa et al., 2012). A first-order affine transformation and nearest-neighbour resampling method was applied for LULC classification (Jensen, 1996), resulting in a root mean square error (RMSE) below 15 m for all Landsat images. The procedure involved radiometric rectification of the 1986 image to the 2016 image, followed by a tasseled cap orthogonal transformation of the original six bands in each image in to three new dimensional spaces, corresponding to soil brightness, green vegetation and moisture indices (Hall et al., 1991). Apart from yielding relevant training data for LULC classification, the transformation also improved visual discrimination of LULC types. Ground-truth GPS points recorded in the field were used for training of the 2016 imagery, to determine the LULC classes during the image classification process, and to assess the accuracy of the classification.

LULC classification was carried out using the supervised maximum likelihood algorithm approach which is generally recognized as the popular classifier technique (Booth and Oldfield, 1989; Liu and Zhou, 2004; Verburg et al., 2004; Lillesand et al., 2014). It requires prior knowledge of the area to set training sites and use of spectral information contained in individual pixels to generate LULC classes. Accordingly, we classified the LULC categories of the study area into: dense and scattered acacia woodlands, grass/grazing land, agricultural land, shrub/bush land, water body, marsh/swampy area and bare land. The operational definition of each LULC category is given in *Table 2*.

Accuracy assessment was done using a separate set of points randomly generated using a stratified random sampling approach to determine the precision of the classified image (Jensen, 1996) which is important for post-classification change detection analysis (Liu and Zhou, 2004). The reference points were transferred to a GIS software program, in which they were overlaid with the classified images. A field check was made to test the accuracy of the reference points. The accuracy of a classification was assessed by comparing the classification with some reference data that was believed to reflect accurately the true LULC classes. The overall accuracy was measured by counting the number of pixels classified consistently in the satellite image and on the ground and dividing this by the total number of sample pixels in each class. The post-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39934014

classification comparison (PCC) change detection technique was used for change detection analysis (Jensen, 1996). This was done by comparison of independently produced classified images, by properly coding the classification results of 1986 and 2016, from which a change map that indicates a complete matrix of change was produced (Singh, 1989). Actual change was obtained by a direct comparison between classified image from 1986 with that obtained for 2016 and results described by LULC change in percentage.

Table 2. *Operational definitions of different LULC types of CRV lakes region of Ethiopia*

LULC type	General description
Dense acacia woodland	Acacia dominated woodlands where the trees cover approximately more than 40% of the ground surface. It also includes other dense broad-leaved tress like riverine forests and plantations
Scattered acacia woodland	Acacia dominated woodlands where the trees cover approximately between 10-40% of the ground surface and the open areas under the tree canopy covered with grasses and herbs
Agricultural land	Areas used for rain-fed and irrigated cultivation (small or large scale, seasonal or perennial), including fallow plots and a complex unit, i.e. cultivated land mixed with bushes, trees and rural homesteads
Grass/grazing land	Grass being the dominant plants with the canopy of scattered acacia trees approximately covering less than 10%
Water body	Lakes, reservoirs/ponds, rivers and streams
Swampy/marshy land	Permanently waterlogged areas covered by long grasses, other aquatic plants, and mainly found near lakes and river banks
Bush/shrub land	Land covered by scattered small trees, bushes and shrubs (less than 5 m in height) and occasionally found mixed with grass
Bare land	Surface not covered by any type of vegetation, mainly including: sands, rock outcrops, cattle tracks, or exposed soils not used by any of the above LULC types

The LULC transition matrix

For the simplicity of explanation of the analysis methods used for LULC transition in this study, the general cross-tabulation matrix for comparison of two maps from two different points in time (1986 and 2016) was adopted from the initial work of Pontius et al. (2004). In a cross-tabulation matrix, the rows display the classes of 1986 and the columns display the classes of 2016. Entries on the diagonal indicate ‘persistence’, proportion of the landscape that did not undergo change during 1986-2016, and it usually dominates most landscape changes (Pontius et al., 2004). Persistence helps to compute two types of changes: gross gains and gross losses (Pontius et al., 2004). The gains are the differences between the column totals and persistence, whereas losses are the differences between row totals and persistence.

LULC persistence, net change and swap

Persistence is simply the proportion of the landscape that did not undergo change during the respective study period, represented by entries on the diagonal of a cross-tabulation matrix. Swap, as elaborated by Pontius et al. (2004), is a change attributed to location which implies simultaneous gain and loss of a land class on the landscape. Thus, the computation of swap requires the pairing of each pixel that loses with a pixel

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39934014

those gains. The amount of swap (S_j) of land class j is defined as two times the minimum of the gain and the loss (*Eq. 1*) as in Pontius et al. (2004).

For each class j in cross-tabulation matrix, the absolute value of net change during 1986-2016 is simply calculated as $|C_{+j} - C_{j+}|$. *Equation 2* defines the absolute value of the net change, denoted N_j, for class j as the maximum of the gain and loss minus the minimum of the gain and loss (Braimoh, 2006). This net change is the remaining unpaired gain or loss after all gains and losses have been paired to compute the amount of swap. *Equation 3* shows that one can express total change (T_j) for each category as either the sum of the net change and swap or the sum of the gains and losses as in Pontius et al. (2004) and Braimoh (2006).

$$S_j = 2\min\left(C_{j+} - C_{jj}, C_{+j} - C_{jj}\right) \quad \text{(Eq.1)}$$

$$N_j = \mathrm{Max}\left(C_{j+} - C_{jj}, C_{+j} - C_{jj}\right) - \mathrm{Min}\left(C_{j+} - C_{jj}, C_{+j} - C_{jj}\right) = \left|C_{+j} - C_{j+}\right| \quad \text{(Eq.2)}$$

$$T_j = D_j + S_j = \mathrm{Max}\left(C_{j+} - C_{jj}, C_{+j} - C_{jj}\right) + \mathrm{Min}\left(C_{j+} - C_{jj}, C_{+j} - C_{jj}\right) \quad \text{(Eq.3)}$$

In addition to these indices of land change, other important indicators of LULC vulnerability to transition (Ouedraogo et al., 2011; Zewdie and Csaplovics, 2016) like: gross loss to persistence ratio (l/p) which assesses the exposure of a land cover for a change, gross gain to persistence ratio (g/p) which evaluates the gain of land cover in comparison to its 1986 size, net change to persistence ratio (n/p), the tendency of land classes to undergo change, and gain to loss ratio (g/l) were analyzed based on baseline data in in cross-tabulation matrix.

Identification of dominant signals of LULC changes

Even though the analysis of persistence, swap, gross gain and gross loss is very important, still it fails to inform whether systematic transitions exist or not among the land classes, as this general analysis fails to examine the dynamics among the off-diagonal entries of cross-tabulation matrix. In other words, it fails to identify the dominant signals of land change. To relate the concept of ‘random’ and ‘systematic’ LULC transitions to land change transition matrix, it is important to define the terms in terms of statistical concept of Chi-square test as explained by Pontius et al. (2004). Statistically, a landscape transition is said to be ‘random’ if a LULC class gains from other categories in proportion to the availability of those other losing classes, or if a class loses to other class in proportion to the size of those other gaining classes (Pontius et al., 2004; Braimoh, 2006; Versace et al., 2008; Ouedraogo et al., 2011), and any large deviation from these proportions is referred to as ‘systematic’ transitions.

The identification of systematic inter-category transitions generally consists of four steps. The *first step* computes the expected gain, g_{ij} for each class under a random process of gain using the formula given in *Equation 4* (Pontius et al., 2004). *Equation 4* assumes that the gain of each class and the proportion of each class in 2016 are given a priori. The gain is then distributed in each column among the off-diagonal entries in the column according to their relative proportions in 1986. This makes the gain fairly random.

$$g_{ij} = \left(C_{+j} - C_{jj}\right)\left(\frac{C_{i+}}{100 - C_{j+}}\right), \forall i \neq j \quad \text{(Eq.4)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39934014

The *second step* computes the differences between the observed proportions and the expected proportions under a random process of gain (Pontius et al., 2004). Large positive or negative deviations from zero indicate systematic inter-category transitions rather than random transitions occurring between two LULC classes. The higher a positive difference between the observed proportion and the expected proportion under a random process of gain for the transition between class 1 and class 2, the larger the area affected by systematic gain of 2 from 1. The higher a negative difference between the observed proportion and the expected proportion under a random process of gain for the transition between class 1 and 2, the higher the tendency of class 2 to avoid gaining systematically from class 1.

The *third step* computes the expected loss, l_{ij} under a random process of loss using the formula in *Equation 5* (Pontius et al., 2004). *Equation 5* assumes the loss of each class is fixed, and distributes the loss in each row across the other classes relative to their proportions in 2016. The *fourth* and the *last step* compute the differences between the observed and the expected proportions under a random process of loss (Pontius et al., 2004). Similarly, large positive and negative deviations from zero indicate systematic inter-category transitions rather than random transitions occurring between two LULC types. In general, according to Alo and Pontius Jr (2008), to arrive at a conclusive evidence of a dominant signal of landscape transformation, class 1 must systematically gain from class 2, and class 2 must systematically lose to class 1 simultaneously.

$$l_{ij} = (C_{i+} - C_{ii})\left(\frac{C_{+j}}{100 - C_{+i}}\right), \forall i \neq j \quad \text{(Eq.5)}$$

Results

Accuracy assessment

Results of the overall classification accuracy, producer accuracy, user accuracy and kappa statistics for each LULC class, derived from the error matrix, were used to determine the degree of accuracy of the LULC classification (*Table 3*). The lowest producer accuracy of 61% and 60% were obtained for bare land and swampy/marsh land classes for 1986 and 2016 respectively. On the other hand, an overall accuracy of greater than 90% was obtained for both study periods which could be acceptable for proceeding to further data analysis in this study. The lowest producer accuracy assessment value obtained for bare land in 1986 could be due to classification error with grazing land, as both could share similar spectral signature especially in arid landscapes (Zhang et al., 2015). Similarly, it is difficult to differentiate between swampy and water body, and scattered and dense acacia woodlands in some circumstances due to absence of clear cut boundaries between these classes which could also be possible source of classification error.

Major LULC transitions

From the analysis of results, we observed an increase in human pressure and a decrease in natural and semi-natural landscapes in CRV lakes region of Ethiopia. Spatiotemporal pattern of LULC change in the study area for 1986 and 2016 is shown in *Figure 3,* while *Table 4* summarizes the 1986 and 2016 proportion, gain, loss, swap, net

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39934014

change and total change of each LULC class. The largest portion of the landscape has been covered by water body in both 1986 (31%) and 2016 (29%), whereas dense acacia woodland and swampy/marshy land covered the least percentage (<3%) during both periods.

Table 3. *Accuracy assessment results of LULC classification*

LULC type	1986		2016	
	Producer accuracy	**User accuracy**	**Producer accuracy**	**User accuracy**
Agricultural land	88.24	85.71	90.20	93.88
Scattered acacia woodland	100.00	96.36	95.65	91.67
Bare land	61.11	84.62	76.92	83.33
Bush/Shrub land	92.59	80.65	94.12	80.00
Dense acacia woodland	75.00	90.00	66.67	66.67
Grass/Grazing land	75.86	75.86	96.77	92.31
Swampy/Marshy land	90.91	90.91	60.00	85.71
Water body	100.00	100.00	97.40	98.68
Overall accuracy	90.63		92.58	
Kappa Statistics	0.89		0.91	

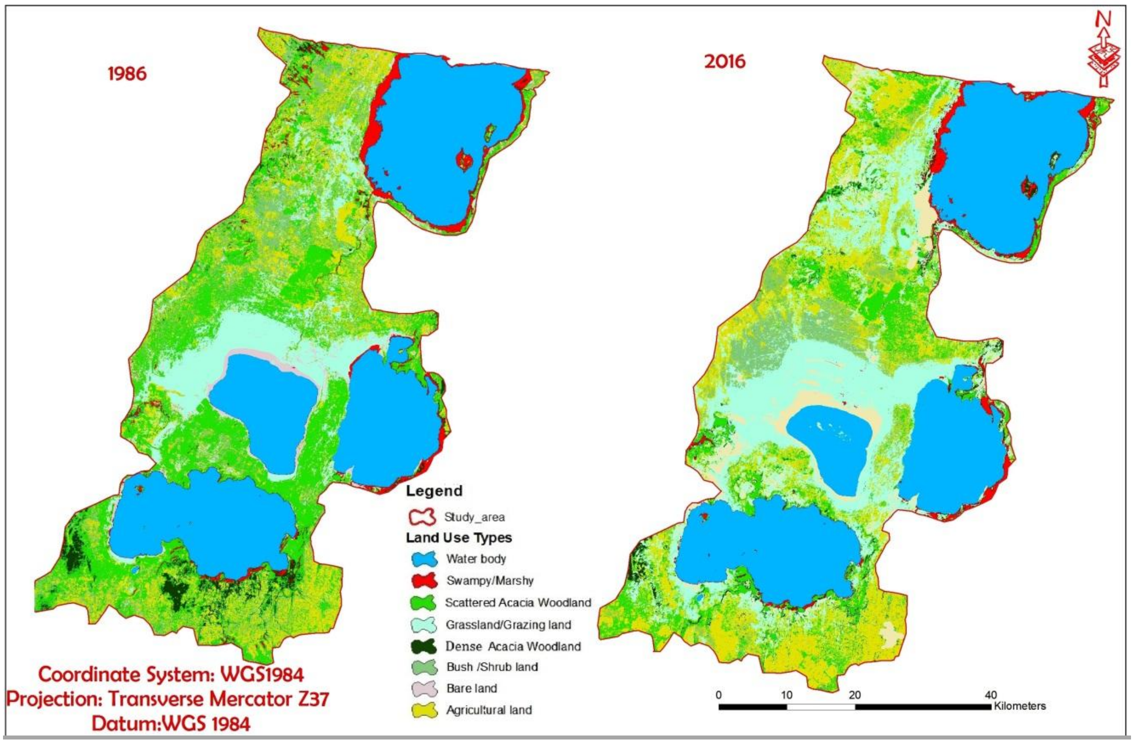

Figure 3. *LULC maps for the years 1986 and 2016*

Over the last three decades, grass/grazing land, agricultural land and bare land have increased by 124%, 42% and 34% respectively, whereas scattered acacia woodland, bush/shrub land and swampy/marshy land have declined by 52%, 50% and 31% respectively (*Table 4*). Scattered acacia woodland, which was the second in terms of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39934014

proportion in 1986 (23%), declined by about half percentage in 2016 (11%). Due to this, scattered acacia woodland experienced the highest area loss (18%) followed by bush/shrub land (11%) during the same period. On the other hand, grazing land, which was only 11% in 1986, has shown an increment and took the second position in terms of area percentage proportion in 2016 (25%). Hence, grazing land experienced the highest gain in over 17% of the landscape followed by agricultural land (14%) during the study period. The gain-to-loss ratio was also highest (5.2) for grazing land, indicating that grazing land experienced five times more gain than loss. In general, total change occurred in about 48% of the landscape during the study period while the rest, 52%, persisted (*Table 4*).

Table 4. *Landscape changes (%)*

LULC types	Total 1986	Total 2016	Persistence	Gain	Loss	Total change	Swap	Absolute value of net change
Agricultural land	13.94	19.85	6.15	13.70	7.79	21.50	15.59	5.91
Scattered acacia woodland	22.87	11.08	5.15	5.93	17.72	23.65	11.86	11.79
Bare land	3.79	5.08	0.59	4.50	3.21	7.71	6.41	1.29
Bush/Shrub land	11.90	5.92	1.20	4.72	10.70	15.42	9.43	5.98

Water body	30.97	28.96	28.80	0.16	2.17	2.34	0.32	2.01
Total	100.00	100.00	51.59	48.41	48.41	48.41	27.45	20.96

Net change and swap changes

Results showed both swap changes and net changes occurred for most of LULC categories in the study area. The summary for changes attributed to net change and swap is given in *Table 4*. Changes in all land categories except for water body consists both swap and net changes, whereas change in dense acacia woodland is nearly a pure swap type. This is to mean that for dense acacia woodland the net change is zero, and hence each cell gained can be paired with each cell lost. The change attributed to quantitative net change is highest for grazing land (about 68% of total change for grazing land); followed by scattered acacia woodland (about 50% of its total change). Net change overall accounted for 43% of total change on the landscape. On the other hand, the change attributed to location (swap) is highest for agricultural land (72% of total change for its whole area), followed by scattered acacia woodland (50% of its total change). Swap of land change dynamics overall accounted for 57% of total landscape change in the study area.

Persistence of LULC classes

We observed all LULC categories showed relative persistence during the study period which is in consistent with the usual trend in most LULC change studies. About

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39934014

52% of landscape remained unchanged during the study period (*Fig. 4* and *Table 4*). The proportion of different LULC classes that were unchanged between 1986 and 2016 are also shown in the diagonal cells of *Table 5*. Water body experienced the highest resistance to change during the study period. About 93% of landscape occupied by water body in 1986 remained unchanged in 2016.

Total 2016	19.85	11.08	5.08	5.92	2.23	24.81	2.07	28.96	100.00	48.41
Gain	13.70	5.93	4.50	4.72	1.73	17.05	0.62	0.16	48.41	

Bush/shrub land on the other hand showed the lowest persistence in 1.20% of the landscape. As shown in *Table 6,* the loss-to-persistence ratio (l/p) for all classes is greater than 1 except for grazing land and water body. This indicates all land classes except grazing land and water body showed a higher tendency to lose than to persist. The highest (8.88) and lowest (0.08) l/p ratio was obtained for bush/shrub land and water body classes respectively. On the other hand, the gain-to-persistence ratio (g/p) is greater than 1 for all classes except aquatic habitats (*Table 6*), indicating that these land classes experienced more gain than persistence. Bare land experienced the highest g/p ratio (7.68), whereas water body and swampy/marshy lands experienced the least values.

Table 6. *Gain to persistence (g/p), loss to persistence (l/p), net change to persistence (n/p) and gain to loss (g/l) ratios of LULC classes*

LUC class	Gain to persistence (g/p)	Loss to persistence (l/p)	Net change to persistence (n/p)	Gain to loss (g/l)

Water body	0.01	0.08	-0.07	0.07

Systematic and random LULC transitions

Results have clearly showed that systematic as well as random LULC transitions occurred in the study area during 1986 to 2016. In *Table 7a,* the off-diagonal numbers

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39934014

represent expected values of the gain in LULC categories at the given persistence under a random process of change. The difference between the observed proportions (*Table 5*) and the expected proportions (*Table 7a*) is given in *Table 7b*. The observed value for gain is greater than the corresponding expected value for all land classes except for swampy and water body (*Fig. 5*). Relatively large positive values in *Table 7b* indicates systematic gain transitions. Hence, agricultural land systematically gained from both bush land (3.16%) and scattered acacia wood land (2.62%) transitions. Similarly scattered acacia woodland gained systematically from both agricultural land (1.35%) and bush land (1.05%) transitions. In addition, grazing land systematically gained from both scattered acacia woodland (2.30%) and bare land (1.48%). Bush land also systematically gained from scattered acacia wood land (1.33%). On the other hand, grazing land, agricultural land, scattered acacia woodland and bush land, all systematically avoided gaining from water bodies (indicated by large negative values in *Table 7b*), which also mean that water body avoided systematically losing to these LULC categories.

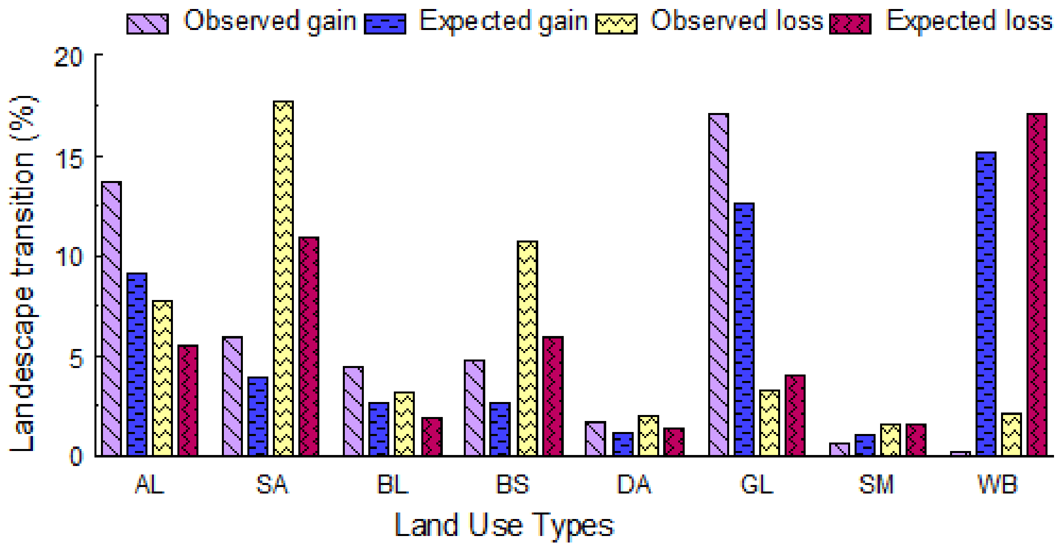

Figure 5. *Observed and expected LULC gross gains and losses for 1986-2016 (%): AL = agricultural land, SA = scattered acacia woodland, BL = bare land, BS = bush/shrub land, DA = dense acacia woodland, GL = grass/grazing land, SM = swampy/marshy land, and WB = water body*

The values for expected losses under a random process of loss are given in *Table 8a,* whereas the differences between the observed and expected losses are given in *Table 8b*. Relatively large positive values (>0) in *Table 8b* indicate systematic loss transitions. Accordingly, scattered acacia woodland systematically loses to agricultural land (**2.31**%), grazing land (**1.74**%) and bush land classes (**1.37**%). Similarly bush land systematically loses to agricultural land (**2.80**%), agricultural land systematically loses to scattered acacia woodland (**1.35**%), bare land systematically loses to grazing land (**1.37**%) and water body systematically loses to bare land (**1.07**%). On the other hand, scattered acacia woodland, bush land, agricultural land and grazing land systematically avoided losing to water bodies which is indicated by relatively large and negative values in *Table 8b*.

In general, major interclass systematic gains and losses observed for this study can be summarized as follows (*Fig. 4* and *Table 5*). About 6% of scattered acacia woodland and 5% of bush land has been converted to agricultural land, whereas about 7% and 3% of scattered acacia woodland has been respectively degraded and shifted to grazing land and bush/shrub lands during the study period. On the other hand, there has been an increase in vegetation biomass from agricultural land and bush land to scattered acacia woodland in over 2% of the landscape from each class. Similarly, there has been a vegetation restoration from bare land to grass land via ecological succession on lake retreat areas in over 2% of the landscape during the study period.

Discussions

Our result indicated that there has been an increased pressure from anthropogenic-induced LULC dynamics in the study region during the last three decades. This is evidenced by substantial gains/losses observed for major LULC categories during the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39934014

study period (*Table 4*). For instance, expansion in agricultural land, grazing land and bare land by 124%, 42% and 34% respectively are among the changes attributed to gain, whereas decline in acacia woodlands and bush/shrub lands by 52% and 50% respectively are the major changes attributed to loss. Gain in grazing land is mainly due to land transition from lake retreat bare lands, particularly of Lake Abijata, that gradually shifts to grass/grazing land through ecological succession (Biazin and Sterk, 2013; Temesgen et al., 2013). With current rate of retreat, studies predicted that Lake Abijata will totally dry within coming 50 years (Temesgen et al., 2013). The other probable source for gain in grazing land is that in most cases acacia woodlands have been subjected to free access of firewood extraction and charcoal making by the community in rural Ethiopia, which gradually degrade the trees and shifts the land to either bush/shrub lands or open grazing areas. Coupled with natural pressures (frequent draught and fragile ecosystems), overgrazing is one basic proximate forcing factor behind high land degradation (critical water and wind erosion) observed during field work in CRV lakes region.

Agricultural land expansion in the region on the other hand is mainly in expense of losses in acacia woodlands and bush/shrub lands. Gain in agricultural land is associated with continual expansion of agricultural frontier as population increase (Garedew et al., 2009; Ariti et al., 2015), as population growth is the main underlying driver behind LULC change in developing countries like sub-Saharan Africa (Braimoh, 2006; Ouedraogo et al., 2011). This indicates agricultural land, bush/shrub land as well as grazing land targeted mainly the peculiar acacia woodland vegetation of the region for their gains. The result is in consistent with the results of previous LULC change studies in the region (Biazin and Sterk, 2013; Temesgen et al., 2013; Ariti et al., 2015) who reported agricultural land expansion as root cause for woodland vegetation decline in the region. Study by Zewdie and Csaplovics (2016) in dry lands of north western Ethiopia, an area with comparable agro ecological condition, also reported similar results. However, study by Braimoh (2006) and Ouedraogo et al. (2011) in western Sub-Saharan Africa reported decline in closed woodland mainly due to logging activities than due to crop land expansion. These studies also reported the systematic conversion of grazing land to crop land which is different from the case of our study. The loss in agricultural land observed for this study might be due to fallowing and abandonment of highly degraded farm lands as confirmed during field verification.

The other principal LULC change observed for this study is the substantial loss in acacia woodlands and bush/shrub land of the region (*Table 4*). Proximate causes for loss in scattered acacia woodland and bush/shrub land is most likely deforestation for firewood, charcoal making, and cultivation land expansion, owing to population pressure, and partly due to recent agricultural investment expansion in the region (Biazin and Sterk, 2013; Temesgen et al., 2013). The government of Ethiopia targeted the CRV lakes region as one potential agricultural investment zone due to its accessible lake water for irrigation and the proximity to Addis Ababa for ease of agricultural products export. Overgrazing pressure from pastoralist herds seasonally coming from neighbouring Districts in search of pasture grass is also another main factor for degradation of both woodlands and bush/shrub lands. Slight gain observed in scattered acacia woodland on the other hand could be associated with either degradation of dense acacia woodlands or government rehabilitation initiatives of degraded lands from either abandon agricultural lands or bush/shrub lands through area closure in recent years. This indicates part of the degraded and abandoned agricultural lands could shift to scattered acacia woodlands, following regeneration of remnant acacia trees after rehabilitation treatment like area closure. Currently the government has given strong attention to implement degraded land rehabilitation program, mainly through social mobilization, throughout the country though such practices are criticized for effectiveness and sustainability in most cases.

Analysis for changes attributed to persistence, net change and swap was another objective for this study. Results indicated that changes at landscape level are more attributed to swap (57% of total change) than to net change (43% of total change). However, the majority of LULC classes showed the tendency to persist (52%) than to change during the same period (*Table 4* and *Fig. 4*). Persistence is the resistance of the landscape to resist change and it usually dominates most landscape changes (Pontius et al., 2004). In line to this fact, our result also showed that the majority of the landscape area persisted than to change. It is normal to see more persistence than change in LULC change analysis (Pontius et al., 2004). Our result also showed that the overall percent

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_39934014

change attributed to location (swap) is greater than the change attributed to net change at landscape level. This indicates the importance of analyzing swap beyond net change analysis in order to see the changes attributed to location which otherwise overlooked by 'net change' analysis alone (Pontius et al., 2004; Braimoh, 2006).

Finally, our result also identified systematic and random LULC changes occurred during the study period by comparing the observed change to the expected change arising from chance for any given degree of persistence (*Table 7b* and *8b*). Accordingly, the gain in agricultural land from scattered acacia wood land and bush/shrub land is systematic. This implies when agricultural land gains, new agricultural land tends to gain systematically from these classes (Braimoh, 2006). Similarly, scattered acacia woodland systematically gained from agricultural lands and bush/shrub lands; and both bush/shrub land and grazing lands systematically gained from scattered acacia woodland. This implies there is a systematic exchange of land portion among some LULC classes. On the other hand, the scattered acacia woodland systematically losing to agricultural land, bush/shrub land and grazing lands, whereas by reverse, agricultural land systematically losing to scattered acacia woodlands. In addition, bush/shrub lands systematically losing to agricultural land, and water body systematically losing to bare land. All the rest gain/loss observed in this study is depicted as random changes. However, it should be noted that a change is random does not necessarily downplay its worth as factors for random change could also lead to systematic change and vice versa (Braimoh, 2006). *Figure 5* shows that the observed value for gain/loss is greater than the corresponding expected value for all land classes, except for swampy/marshy and water body. According to Braimoh (2006), the expected gain or loss could be different from the observed gain or loss due to various reasons: like changes in spatial determinants of land use distribution, such as population growth, soil suitability and the opening up of new roads, or it could be due to competition between LULC types.

This study might have limitations, for instance by using Landsat data, changes that are below pixel size might have been missed. Hence, in order to generate more information from the method, first, it is important to use algorithms that reduce map errors (Verburg et al., 2004; Alba, 2014; Agarwal et al., 2002) as accuracy assessment alone may not warrant for absence of map errors. For example, it is recommended to use other modeling algorithms like agent based modeling and spatial land change models for better results. Second, it might be important performing the method at multiple map resolutions in order to measure the sensitivity of the results to changes in map scale (Pontius et al., 2004). In addition, the similarity in spectral signature of some LULC classes could be another source of classification error in this study.

Conclusions

This study followed an approach that moves from broad to more detailed level of analysis and tried to highlight the importance of an in depth analysis of systematic and random LULC transition beyond the conventional net change analysis. It also indicated the importance of focusing on most prevalent systematic process of land change. Hence, future studies in the fields of geography and landscape ecology need to incorporate this method since existing popular methods fail to segregate LULC change according to its different components and thus fail to gain maximum insight in to the processes driving these changes.

Our result clearly shown that, there have been active LULC dynamics in CRV lakes region of Ethiopia for the period of 1986 to 2016. From the concrete data of systematic gains and losses, we conclude that there have been most dominant and prominent signals of change in terms of conversion, degradation and restoration of LULC in CRV lakes region of Ethiopia. The majority of land conversion as well as degradation signals targeted the acacia woodlands of the region. To arrive at a conclusive evidence of a dominant signal of landscape transformation, class 1 must systematically gain from class 2, and class 2 must systematically lose to class 1 simultaneously. Accordingly, the conversion of both scattered acacia woodlands and bush/shrub lands to agricultural land; the degradation of scattered acacia woodlands towards bush/shrub lands and grass/grazing lands; and the restoration in vegetation biomass from agricultural land and bare land towards scattered acacia woodland and grazing land respectively are found to be clearly systematic, and hence indicates the dominant signals of landscape transformation in this study. All the rest transitions are found to be either random or not fully systematic.

The result of this study implicates the continued land degradation in developing countries, particularly East Africa, where the livelihood of the majority of population is directly dependent on natural resources. The loss in acacia woodlands and bush/shrub lands either by conversion or through degradation, calls for means to reduce such adverse pressures. The decline in water bodies and shift to bare land, particularly of Lake Abijata, requires urgent watershed management measures on its catchment area. Increased land use intensity due to increased population pressure calls for agricultural intensification related policies to prevent crop land expansion on fragile lands. The pressure on woodlands from firewood extraction and charcoal making requires availing affordable alternative energy source technologies to poor households. The restoration in vegetation biomass requires further study to know where and how it occurs, how long it takes and factors underlying it. Future studies also need to investigate the local and national level drivers behind; and the impacts imposed by such continued LULC changes to rural livelihood, natural ecosystem and biodiversity in the region. In general, future land use policies need to consider such prominent signals of land change in order to plan an integrated approach to safeguard the fragile acacia woodland ecosystems while searching for alternative livelihood options to feed the ever growing population in the region.

Acknowledgements. The authors are indebted to thank the National Natural Sciences Foundation of China (Fund No. 41571176) and The 111 Project (Fund No. B17024) by State Administration of Foreign Experts Affairs and Ministry of Education of China for financial support and encouragement in conducting this study. We are grateful to thank the Chinese government Scholarship Council (CSC) for giving a chance for the first author to pursue his PhD study in China. Special thanks also go to all the staff members of Agricultural Office of the Dugda, Adami Tulu-Jido Kombolcha and Arsi Negele districts who helped during field data collection and all the rural farmers of the three districts who took part during the survey. We are also grateful to thank the anonymous reviewers for their helpful comments and suggestions on earlier draft of this manuscript.

Abstract. The objective of the paper was the determination of values of selected habitat conditions optimal for *Oxycoccus palustris Pers.* on peatlands in the central part of East Poland in the aspect of provision of proper conditions in ecological cultivations of the plant. The obtained results showed a broad range of ecological tolerance towards the analysed physical-chemical properties of the habitat, however not the exceeding values typical of the occupied habitat, as evidenced by the relatively common occurrence of the species. Statistical analyses of the study results showed that important factors causing variability in the abundance and therefore condition of the population of the species at particular study sites include: P_{total}, $P\text{-}PO_4$, and DOC (dissolved organic carbon). Ranges of values of the factors optimal for the functioning of the *O. palustris* population on the studied habitats were specified (P_{total} = 0.17 - 0.36; P-PO4 = 0.1 and DOC = 33.81 – 55.90 [mg dm^{-3}]).
Keywords: *small cranberry, herbs, physical-chemical properties, phytotherapy*

Introduction

The medicinal effect of active natural substances of plants on the patient's organism and the complex provision of easily available biofactors (e.g. vitamins, enzymes, or micro- and macroelements) in phytotherapy constitutes a desirable alternative for synthetic pharmacology, related to unhealthy side effects and dangerous polypharmacy (Nowiński, 1983; Brinkmann et al., 2007; Buettner et al., 2009; Drozd, 2012; Oliveira et al., 2012; Skotnicka, 2013; Senderski, 2015).

One of the most valued herbal plants obtained from nature and to a lower degree from cultivation is small cranberry (*Oxycoccus palustris* Pers.). In morphological terms, it is a shrub from the ericaceous family (*Ericaceae*) with delicate, creeping shoots reaching a height of 100 cm. It has small, leathery, evergreen leaves with elliptical shape. The flowers usually grow by 3-4 on long stalks. They are pink with petals folded downwards. The fruit is a spherical, multi-seed, juicy, red berry. It blooms in the moderate climate from June to August. The fruit matures in September, remaining on the shoot until early spring. It occurs in the countries of North and Central Europe, North Asia, and North America, and in Poland on wetlands related to ombrogenic peatlands (Jaquemart, 1997; Arnal et al., 2008; Senderski, 2015).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40154028

In terms of life strategy, *Oxycoccus palustris* is a perennial chamephyte preferring sites on organogenic soils characteristic of raised or transitional bogs, oligotrophic, with a lower reaction and parameters of circumboreal climate, moisturised, with moderate light conditions (Jaquemart, 1997; Zarzycki and Korzeniak, 2002; Senderski, 2015).

The herbal resource is the cranberry fruit containing many bioactive substances, i.e. acids: benzoic, citric, malic, gallic, quinic, ascorbic; anthocyanins, carotenoids, flavonoids, pectins, tannins, carbohydrates, mineral substances, including iodine salts, and leaves containing glycoside arbutin (Česonienė et al., 2006; Adamczak et al., 2009; Lyutikova and Turov, 2011; Senderski, 2015). Extracts from cranberry fruit are applied as a refreshing and immunosuppressive agent, and as auxiliary medicine in urinary infections. The leaves are used as astringent and disinfectant, and to stop bleeding (Jepson and Craig, 2008; Ruzik-Kuklińska, 2010; Senderski, 2015).

Herbal plants at natural sites of occurrence, in the conditions of low human pressure, show a natural content and proportion of biologically active components translating into high quality herbal resources (Lyutikova and Turov, 2011). Medicinal products manufactured in accordance with the rules of Good Manufacturing Practice (GMP) from such plants meet the optimum assumptions of the natural herbal medicine pursuant to the guidelines of WHO (Borkowski, 1994; Drozd, 2012). Due to the above, an alternative worth considering can be ecological cultivations conducted under conditions adjusted to the natural preferences of plants.

The objective of this paper was the determination of optimal values of selected habitat conditions important for the proper functioning of *Oxycoccus palustris* in the peatlands of the central part of East Poland in the aspect of provision of proper conditions in ecological cultivations of the plant. The lack of available source texts regarding the qualitative analysis of the habitat factors of cranberry at natural sites of its occurrence is an additional argument for undertaking this research.

Material and methods

Fieldwork

The research was conducted in the area of peatlands of the central part of East Poland included in the Łęczna-Włodawa Lakeland (Polesie Podleskie). After preliminary reconnaissance, six representative sites were selected with plant species composition characteristic of the analysed region, where the presence of the population of *O. palustris* was observed within or near the Poleski National Park: lake-peatland complexes: Lake Bikcze (B), Lake Karaśne (K), Lake Długie (D), Lake Moszne (M), forest peatland Blizionki (BZ) and Dekowina (DK) – *Figure 1*.

Research areas (plots) of 100 m^2 (10 m × 10 m) were designated at study sites. Their phytocoenoses were characterised by variable contribution of *O. palustris*. In the vegetation season 2011, to confirm the correctness of the selection of study sites, the species composition of phytocoenoses of the plots was determined with consideration of percent contribution of particular species of vascular plants.

Piezometers were installed in the central part of the sites (perforated PVC pipe with a length of 1 m and diameter of 10 cm, dug into the ground) for sampling peatland water. Each year (in the years 2011-2013) in the vegetative season (from March to April), water was sampled from the piezometers seven times, and transported to the laboratory. Water reaction and electrolytic conductivity were also measured *in situ* by means of portable multiparameter meters.

Laboratory analysis

Laboratory analyses of the sampled piezometric waters were performed at the Central Agroecological Laboratory of the University of Life Sciences in Lublin (CLA) by means of certified methods. They covered 14 physical-chemical properties of peatland waters: reaction (pH), electrolytic conductivity (CON), dissolved organic carbon content (DOC), content of nitrogen fractions: total nitrogen (N_{total}), ammonia nitrogen ($N\text{-}NH_4$), nitrates ($N\text{-}NO_3$), nitrites ($N\text{-}NO_2$), and content of phosphorus fractions: total phosphorus (P_{total}), phosphates ($P\text{-}PO_4$), and concentration of sulphates ($S\text{-}SO_4$) and basic cations: potassium (K), sodium (Na), calcium (Ca), and magnesium (Mg).

Data analysis

The coefficient of species similarity of the phytocoenoses of plots was calculated by means of the Jaccard's method. It provided the basis for the classification analysis as the distance measure with the application of the classification algorithm of minimum variance (Ward clustering) for the species composition, and algorithm of complete linkage for habitats.

For the purpose of comparison of distributions of the values of the analysed properties in particular habitats, due to the lack of normality of their distribution and non-uniformity of variance within data sets, a non-parametric Kruskal-Wallis test was applied.

The ranges of values of selected environmental factors with statistical testing are presented graphically in the form of box-plots presenting particular properties of empirical distributions for two groups of study sites: B+BZ (sites with a low %

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40154028

contribution of occurrence of *O. palustris*) and M+K+D+DK (sites with a high % contribution of occurrence of *O. palustris*).

All the obtained values were analysed by means of direct ordinance methods. Based on the obtained value of gradient length (1.56), redundancy analysis (RDA) was applied. Selection of environmental variables was performed, adopting the absolute value of the correlation coefficient > 0.6 as the rejection criterion (Zuur et al., 2007).

All statistical analyses were performed using packages: vegan (version 2.4-2), nortest, MASS and ggdendro in R environmental (R Core Team, 2015; Oksanen et al., 2016).

Results and discussion

The specificity of habitat conditions of the peatlands of Polesie Podlaskie in the central part of East Poland, involving specific microclimate, rich water relations, and relatively low human pressure, determines the possibilities of occurrence of many species of environmentally valuable plants that are also useful for man, including herbs.

Oxycoccus palustris is a native species of utility peatland plants occurring quite commonly in the Łęczna-Włodawa Lakeland, as confirmed by field reconnaissance research performed in the years 2011-2013.

Other species of cranberry, i.e. *Oxycoccus microcarpus* and *O. macrocarpus*, are domesticated anthropophytes. They are slightly less common in nature, but more frequently cultivated (Stobnicka and Gniewosz, 2010). They were not observed at the selected natural study sites.

Due to its characteristic sweet-bitter taste and attractive colour, the fruit of all three species of cranberry has been used for culinary purposes for centuries (jams, confitures, juices, addition to sauces or beverages). It has also been an important component of phytotherapy, with effectiveness confirmed by traditional application and pharmacological studies (Hong and Wrolstad, 1986; Rodowski, 2001; Stobnicka and Gniewosz, 2010; Senderski, 2015).

The culinary and medicinal usefulness of cranberry is also manifested by the popularity of harvesting the herbal resource from nature, the common cultivation of popular cultivars, particularly the big fruit cranberries, e.g. Ben Lear, Bergman, Pilgrim, or Stevens (Mazur et al., 2009), as well as the popularity of sale of ready food products and herbal medicines (Stobnicka and Gniewosz, 2010).

Similarly as the content of bioactive substances and mass of the resource during vegetation in the case of herbs, the abundance of the population of many plant species can be determined by the variability of the environment. The effect of climatic (e.g. temperature, day light duration, precipitation) and soil-habitat factors, i.e. reaction, fertility, water relations, soil structure, content of organic substances, or content of different elements in the soil solution, and biocoenotic relations determine both the individual development and the abundance of individuals in the population (Stackevičiené and Labokas, 2000; Falińska, 2004; Kazimierczak et al., 2010; Lyuticova and Turov, 2011; Senderski, 2015; Usmanov et al., 2016; Serafin et al., 2017).

Observations conducted in the years 2011-2013 showed that in spite of the relatively common occurrence, the abundance of the population of small cranberry on peatlands in the central part of East Poland differs from site to site. In the case of the selected sites representative of the region, numerous populations of the species occurred in the area of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40154028

lake-peatland complexes Karaśne, Dekowina, Moszne, and Długie (K, DK, M, and D – group I), where their contribution in phytocoenoses of the analysed areas varied from 10% (D) to 30% (K). In the remaining study areas, the contribution of *O. palustris* in phytocoenoses was considerably lower (from 2% - B to 4% - BZ – group II).

A total of 43 spermatophytes (description *Fig. 2*) from 19 botanical families were identified in the assemblages of both groups of sites, in different phytocoenotic configurations. Species such as *Carex rostrata*, *Equisetum limosum*, *Betula pubescens*, as well as *Comarum palustre* and *Menyanthes trifoliata* – herbs subject to simultaneous habitat research (Serafin et al., 2017; and unpublished data) – occurred constantly, although with different percent contributions at all of the study sites.

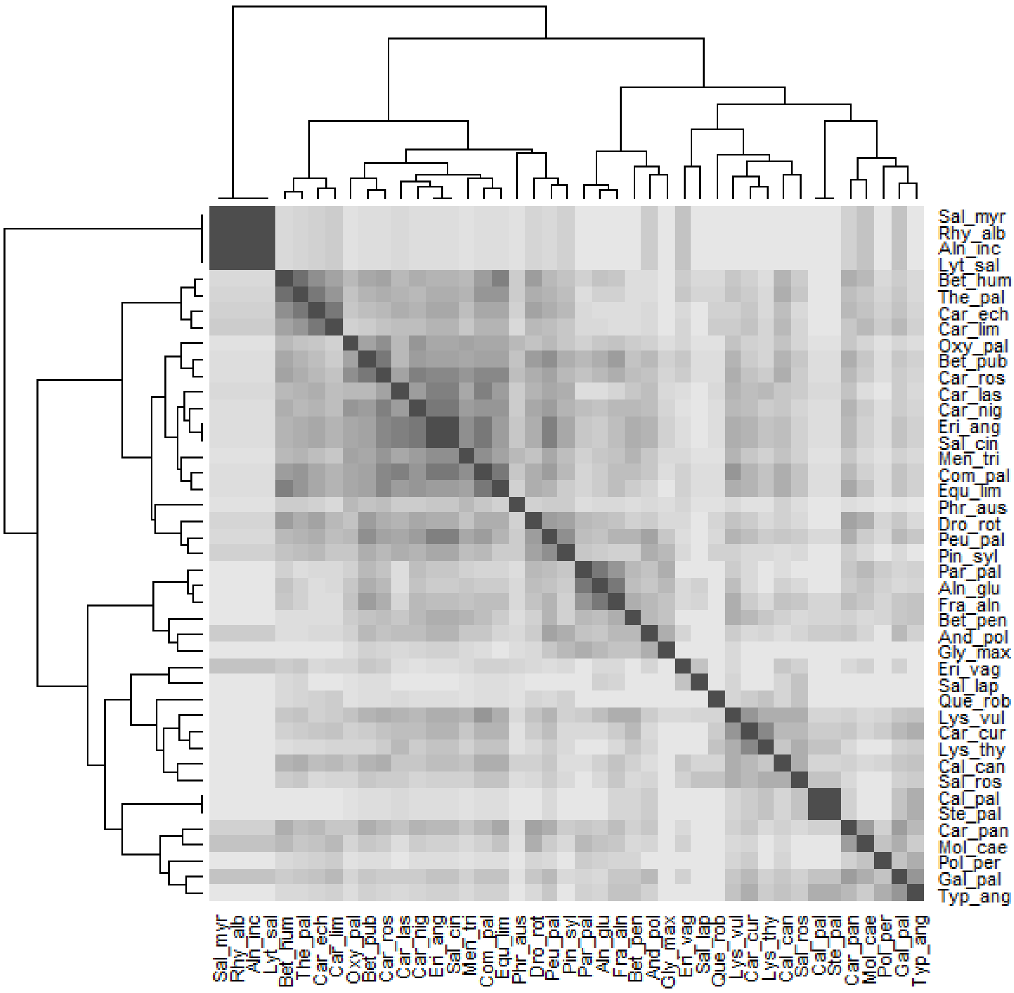

Figure 2. *Dendrogram and heatmap of hierarchical cluster analysis of 43 species based on Jaccard's coefficient and Ward method.* ***Species composition of phytozenoses****: Alnus glutinosa, Alnus incana, Andromeda polifolia, Betula humilis, Betula pendula, Betula pubescens, Calamagrostis canescens, Calla palustris, Carex curta, Carex echinata, Carex lasiocarpa, Carex limosa, Carex nigra, Carex panacea, Carex rostrata, Comarum palustre, Drosera rotundifolia, Equisetum limosum, Eriophorum angustifolium, Eriophorum vaginatum, Frangula alnus, Galium palustre, Glyceria maxima, Lysimachia thyrsiflora, Lysimachia vulgaris, Lythrum salicaria, Menyanthes trifoliata, Molinia caerulea, Oxycoccus palustris, Quercus robur, Parnassia palustris, Peucedanum palustre, Phragmites australis, Pinus sylvestris, Polygonum persicaria, Rhynchospora alba, Salix cinerea, Salix lapponum, Salix myrtilloides, Salix rosmarinifolia, Stellaria palustris, Thelypteris palustris, Typha angustifolia*

DOI: http://dx.doi.org/10.15666/aeer/1604_40154028

The combination of the classic dendrogram and heatmap, for which colour intensity is directly proportionate to the degree of similarity, permitted a more thorough classification analysis of the species composition. Here, a division covering four assemblages of plant species occurs (*Fig. 2*). They were also analysed in phytosociological terms.

Assemblage I – includes species *Alnus incana, Lythrum salicaria, Rhynchospora alba*, and *Salix myrtilloides*, grouped together due to their single occurrence at individual sites (*Fig. 3*). Assemblage II – includes species showing a stronger tendency of joint occurrence at the same sites than the remaining species in other groups: *Betula humilis, Comarum palustre, Equisetum limosum, Eriophorum angustifolium, Menyanthes trifoliata, Peucedanum palustre,* (class: *Scheuchzerio-Caricetea* – fens and transitional bogs); *Betula pubescens*, *Drosera rotundifolia, Oxycoccus palustris, Pinus sylvestris* (class: *Oxycocco-Sphagnetea* – raised bogs), *Phragmites australis, Salix cinerea, Thelypteris palustris* (class: *Alnetea glutinosae* – marshy forests with black alder and thickets), and *Carex echinata, Carex lasiocarpa, Carex limosa, Carex nigra*, and *Carex rostrata* (*Fig. 3*) with variable phytosociological association. This assemblage includes the analysed species *Oxycoccus palustris.* Associations III and IV include species with variable phytosociological associations, with a weaker tendency of joint occurrence (according to Zarzycki and Korzeniak, 2002).

The Jaccard's coefficient of species similarity of the analysed phytocoenoses rarely and inconsiderably exceeded the value of 0.5, which suggests variability of the flora between both groups of sites and within each of the groups (Serafin et al., 2017).

Somewhat more complete information is provided by the classification analysis with the Jaccard's coefficient as the similarity measure, performed for sites (*Fig. 3*).

In spite of the typological similarity, characteristic of the peatlands of the central part of East Poland, in the case of the classification of sites, a division into three groups is designated: I- D, M, B – sites with high similarity of species composition; II- DK, K – sites showing mutual similarity of species composition and considerably lower towards group I; III- BZ – site with the lowest similarity of species composition towards the remaining groups (*Fig. 3*).

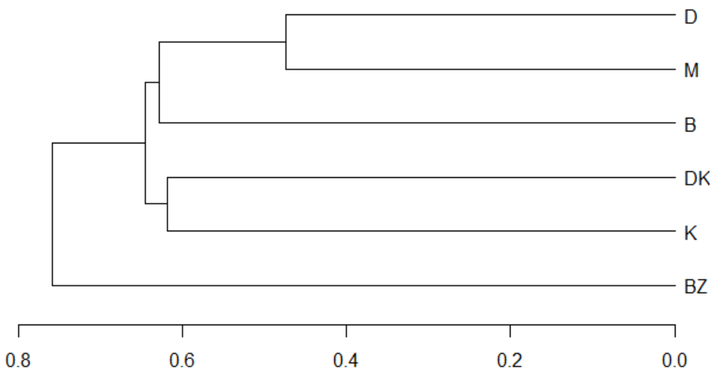

Figure 3. *Dendrogram of hierarchical cluster analysis of 6 phytocoenoses based on Jaccard's coefficient and complete linkage method*

Group 1 includes sites within active, typologically similar lake-peatland complexes (lakes: Długie (D), Moszne (M), and Bikcze - B), which determines their species similarity. Group 2 includes sites variable in terms of genesis – peatland complex not

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40154028

directly related to a water body – Dekowina (DK) and lake-peatland complex Karaśne (K), where the final stages of ecological succession occur leading to complete overgrowing of the water body – perhaps the common basis for species similarity in the group. The site in group 3, namely the Blizionki range (BZ), is a small area remaining after a shallow water body, which although typologically corresponds with preferences of the analysed species, is characterised by the lowest species similarity towards the remaining groups. In combination with the low % contribution of occurrence of *O. palustris*, this encourages searching the explanation of the fact in the abiotic properties of the habitat.

In phytosociological terms, the presented plant species compositions are dominated by species from classes: *Scheuchzerio-Caricetea, Alnetea glutinosae*, and *Oxycocco-Sphagnetea* closely associated with the ombrogenic habitats of raised and transitional bogs (Matuszkiewicz, 2001). This confirms the adequacy of selection of the study sites. Small cranberry is a species characteristic of shrub-peat assemblages from class: *Oxycocco-Sphagnetea* occurring on raised bogs, in acidic oligotrophic and dystrophic habitats fed primarily or exclusively by precipitation waters (Matuszkiewicz, 2001).

The botanical and the phytosociological analyses, however, do not constitute a significant factor affecting the greater abundance of phytocoenoses in small cranberry (classification of sites in relation to a higher % share of *O. palustris* does not correspond to the classification of maximum species similarity). Therefore, the other factors favoring a better condition of the studied species should be found.

Therefore, values of the physical-chemical properties of the habitat, analysed in groundwaters in the years 2011-2013, provide a more complete image of habitat preferences of the analysed species, additionally determining the ranges of its ecological tolerance towards the analysed physical-chemical factors based on its variable population abundance (*Table 1*).

Table 1. *Values of physical-chemical factors of piezometric waters at study sites on peatlands in the central part of East Poland (Polesie Podlaskie) with preliminary statistical analysis (Serafin et al., 2017).* N_{total}, $N\text{-}NH_4$, $N\text{-}NO_3$, $N\text{-}NO_2$, P_{total}, $P\text{-}PO_4$, $S\text{-}SO_4$, *DOC, Na, K, Ca, Mg [mg dm*$^{-3}$*], CON [*$\mu S\ cm^{-1}$*]*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40154028

Due to considerable deviations of individual results, mean values of the majority of factors (e.g. Na, Ca, DOC, CON, N_{total}, P_{total}, $S\text{-}SO_4$,) sometimes exceeded the range of typical observation distribution. The fact determined the somewhat misleading image of the intensity of a given property irrespective of the group of sites (*Table 1*), however not the exceeding values typical of the preferred habitat (following Zarzycki and Korzeniak, 2002).

The ranges of values of some of the factors (i.e. N_{total}, $P\text{-}PO_4$, DOC, and to a lower degree K and Ca) depending on the group of sites variable in terms of population abundance of the analysed species were sometimes incoherent, additionally influencing the broader amplitude of environmental valency for the small cranberry. For the group of sites with a higher percent contribution of the analysed species (M+K+D+DK), lower values in comparison to a group with its low contribution (B+BZ) were observed for P_{total}, $P\text{-}PO_4$, and DOC, and higher for Ca and Mg ions, respectively (*Fig. 4*).

Values of the remaining factors (e.g. Na, $S\text{-}SO_4$, N_{total}, CON, etc.) were characterised by similar ranges in reference to two designated groups of sites, therefore they had no limiting effect (compare *Fig. 4*).

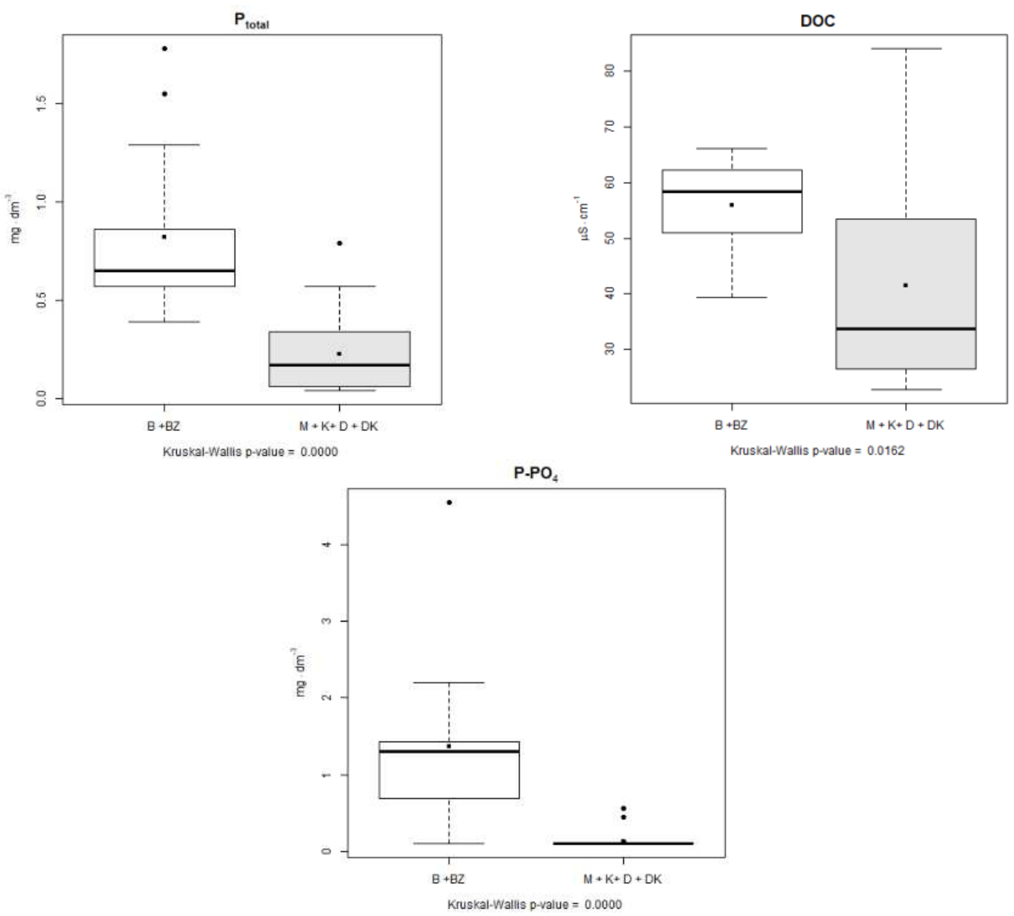

Figure 4. *Distribution of values of the investigated physical-chemical factors of piezometric groundwater which may have a limiting effect on the studied population at the study sites in the period 2011-2013. The x axis label provides the p-value derived by the Kruskal-Wallis test. The horizontal line across the central region of the box represents the median. The mean value of the data is marked by a filled square. Any observation not included between the whiskers is considered as an outlier and represented by a filled circle*

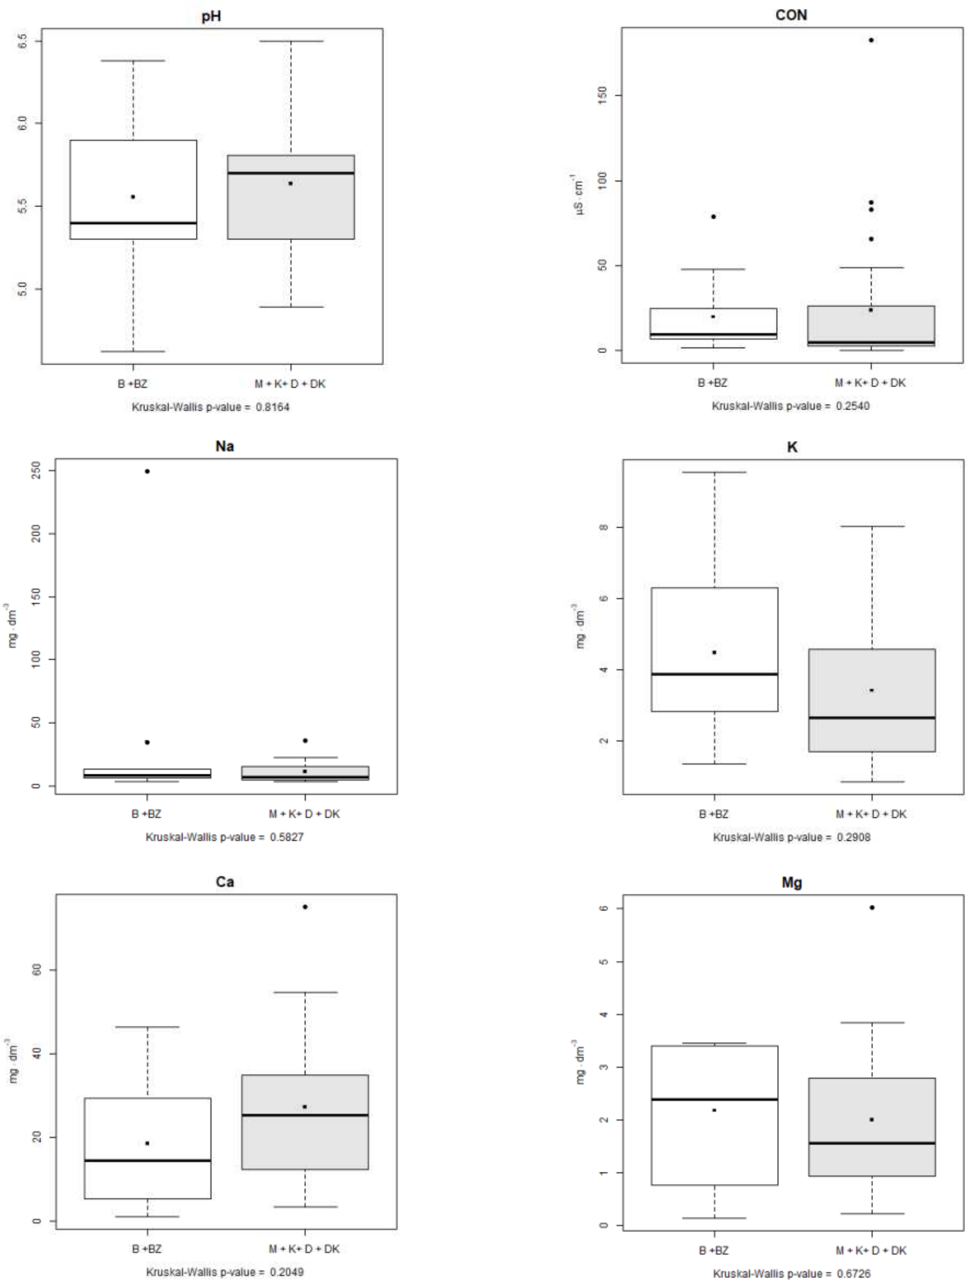
http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40154028

A non-parametric Kruskal-Wallis test was performed to verify the variation in the distribution of values of the investigated parameters at particular sites. Statistically significant differences were only observed in the case of distribution of values of three factors: P_{total}, P-PO_4, and DOC (*Fig. 4*), which may have a limiting effect on the population size of *O. palustris*. The reduced values of the above parameters may be particularly considered a condition favouring higher occurrence of the studied species. Statistics of distribution of values of the factors (upper and lower quartile) therefore suggest ranges optimal for the functioning of the population of the studied species: P_{total} = 0.17 - 0.36; P-PO_4 = 0.1, and DOC = 33.81 - 55.90 [mg·dm^{-3}]. In the case of factors N_{total}, N-NO_2, N-NO_3, N-NH_4, S-SO_4, pH, CON as well as Mg, Ca, Na and K, the distribution of each of the factors was found to be invariant in relation to the sites studied (*Figs. 4* and *5*).



http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40154028

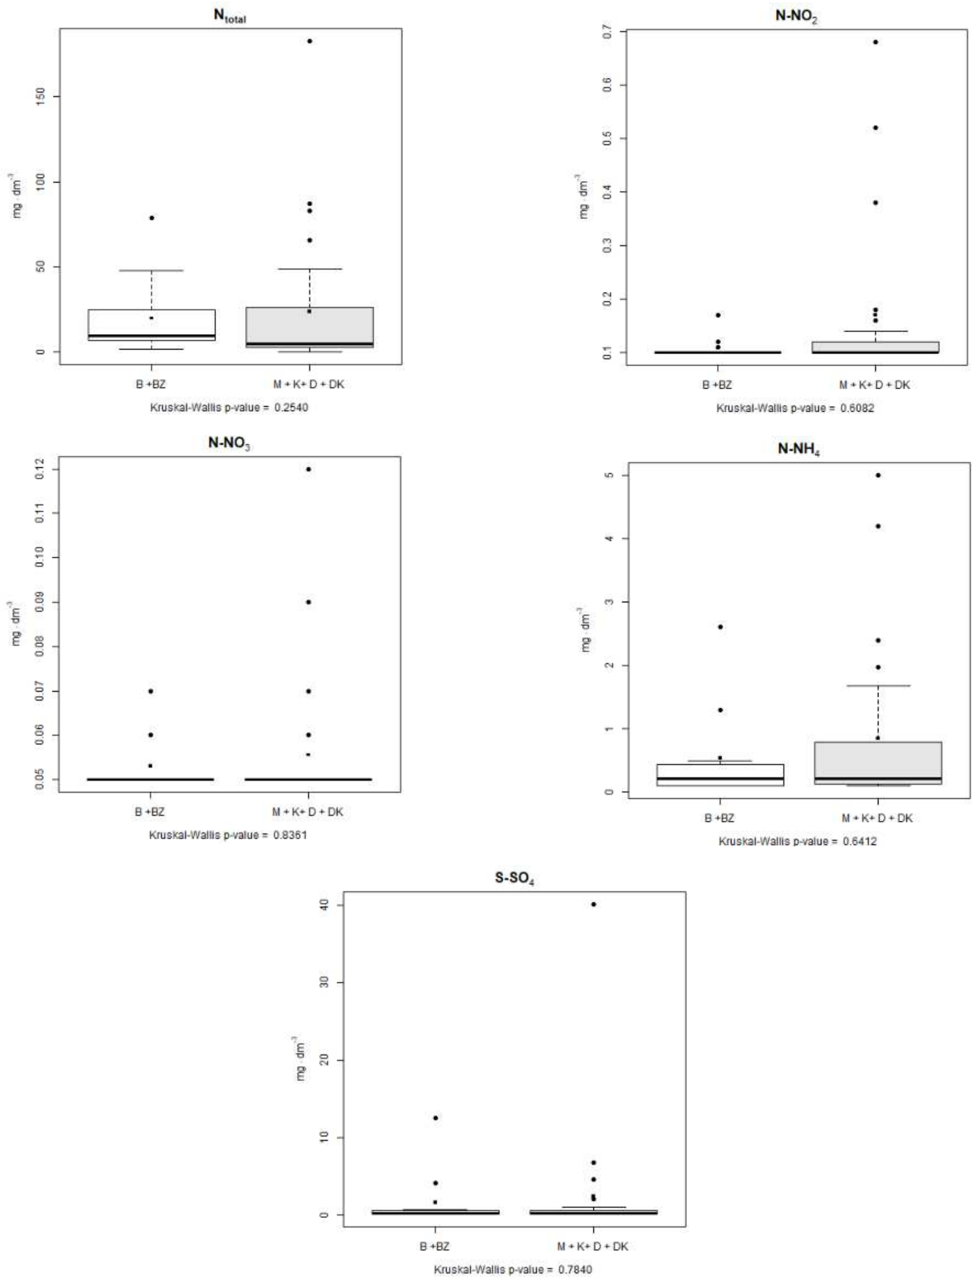


Figure 5. *Distribution of values of the other investigated physical-chemical factors of piezometric groundwater at the study sites in the period 2011-2013*

For comparison, simultaneous research conducted in the area for another species of herbal plant *Menyanthes trifoliata* showed that although both species prefer the same type of habitat, factors determining better condition of the population of the latter include: higher level of N_{total}, P_{total}, and low values of pH and CON. Values of the remaining analysed factors, invariant in relation to different sites, had no limiting effect for the occurrence of the species (Serafin et al., 2017).

The next stage of the analysis employed direct ordination methods. The ordination analysis included 34 species (species characterised by the occurrence of single

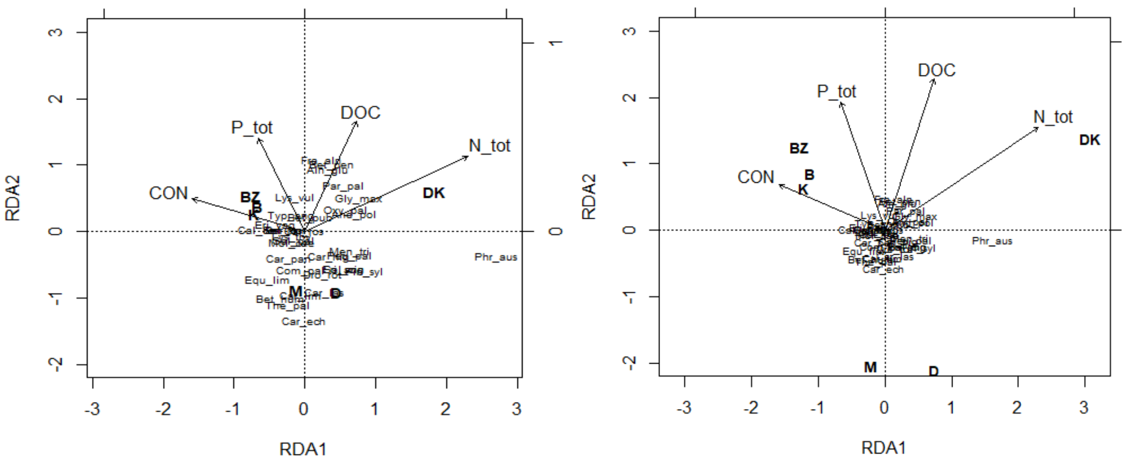
http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40154028

individuals at only one or two sites were excluded), 6 study sites, and 14 environmental variables.

The data set was first subject to detrended correspondence analysis (DCA) which showed a first-axis gradient length of 1.16 in standard deviation units. Therefore, we decided to apply redundancy analysis (RDA) using the rda function in the vegan package (Oksanen et al., 2016).

Prior to the analysis, redundant environmental variables (with linear correlation coefficient |r| > 0.6) were omitted to avoid collinear rite (Blanchet et al., 2008). For this reason and also taking into account the Kruskal-Wallis test results, we carried out RDA with 4 selected environmental explanatory variables: P_{total}, N_{total}, DOC and CON. Before performing further analyses, environmental data were log-transformed (using $\log(y + 1)$) and standardised to meet the assumption of normality. Furthermore, we decided to apply Hellinger transformation to the species data (Legendre and Gallagher, 2001).

RDA results were used to produce ordination diagrams with scaling = 1 and scaling = 2 (*Fig. 6a* and *b,* respectively). All environmental variables accounted for 78.58% of the total variation. The first two RDA axes explained 53.86% of the total variation in the species data (RDA1 = 35.17%, RDA2 = 18.69%). The distances between the sites were approximate Euclidean distances (*Fig. 6a*). Therefore, sites ordinated closer together (like B, K, BZ and also D, M) can be expected to have a similar species composition and similar values of environmental variables. In this context, site DK is not similar to any of the other sites. Moreover, DK is characterised by high level of N_{total} (*Fig. 6b*). Sites B, K, BZ are characterised by high CON and P_{total} levels. Variable N_{total} appeared to be associated to the positive part of axis 1. CON occupies the opposite part of the axis. The second axis is positively correlated with DOC and P_{total}.



(a) scaling = 1 (b) scaling = 2

Figure 6. *Triplot of the RDA with fitted site scores, species and environmental variables as arrows*

The triplot (*Fig. 6b*) indicates a positive correlation between N_{total} and DOC, and a similar magnitude correlation between CON and P_{total}, and between P_{total} and DOC. We found a near-zero correlation between DOC and CON, as well as between as P_{total} and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40154028

N_{total}. In terms of species-environment associations, we observed that the studied species *Oxycoccus palustris* was strongly positively associated with N_{total}.

The habitat research and statistical analyses concerning selected physical-chemical parameters of peatland waters confirm the relatively broad spectrum of ecological tolerance for small cranberry. This is manifested by the common occurrence of the species on peatlands in East Poland. Nonetheless, the condition of its population can be determined by different habitat and biocoenotic factors determining the growth and development of the population, and therefore its abundance at different sites. More abundant occurrence of *O. palustris* in places with reduced human impact allows for the presumption that due to the evolutionally developed optimum habitat preferences, the composition and content of biologically active substances in its organs are more natural. Obtaining the herbal resource from such natural sites in accordance with the rules of Good Manufacturing Practice permits the production of natural herbal medicines pursuant to the guidelines of WHO (Borkowski, 1994; Drozd, 2012). In many cases, it is impossible to determine which biologically active compound has medicinal importance. Therefore, the properties of the herbal resource such as natural composition and the natural composition of medicinal factors, confirmed by the traditional application and effective treatment, seem to be of importance.

In the case of harvesting the herbal resource from nature, area restrictions exist, and sometimes also legal restrictions related to forms of nature protection areas. Ecological cultivations retaining optimum natural values of physical-chemical properties of habitats seem to be an excellent alternative, particularly in reference to conventional cultivations (Serafin et al., 2017) dominated by other species of cranberry more seldom occurring in nature (Stobnicka and Gniewosz, 2010).

The consequence of the habitat research will be the laboratory analysis of the content of biologically active substances obtained from the therapeutic raw material of small cranberry at all study sites for comparative purposes, and the perspective of the experiment of organic cultivation of this species in conditions optimised by these study results.

Conclusions

1. In the area of peatlands of Central-East Poland, *Oxycoccus palustris* is a species with a broad range of ecological tolerance in reference to the majority of the analysed physical-chemical habitat properties.
2. Values of the analysed habitat parameters, although variable depending on the study site, did not exceed values typical of preferences of the species, which translated into its common occurrence.
3. Lower values of concentration of important habitat parameters in ranges: $P_{total} = 0.17 - 0.36$; $P\text{-}PO_4 = 0.1$, and $DOC = 33.81 - 55.90$ [$mg \cdot dm^{-3}$] can be considered as a condition favourable for proper functioning of individuals of the analysed species.

Abstract. Forest road constructions have been investigated in terms of damage to trees below road construction areas and in stream beds. In this study, constructing a road using a bulldozer and environmental damages caused by this technique were investigated in the forested regions of Antalya in Turkey. Decision variables were collected from 52 cross sections in a road section that was selected as a sample. In these cross sectional areas, the number of damaged and undamaged trees was determined in each cross section. Another damage type, the damage in stream beds was investigated based on deposits of excavated materials dumped during the forest road construction operation. The slope in this research area varied between 25–80%. Moreover, the maximum and the minimum length of fill areas in different cross sections was found to be approximately between 2 and 16 m. In this study, the rate of bending damage to trees below the road construction areas was 26.3%, and the rate of wounding damage was 6.1%. The number of damaged trees in various gradient was also determined in the study area. Along the chosen road section, debris were found to cover the stream bed in some areas. The wounding of tree barks was serious in this forest region although there was also significant damage caused by bark beetles.
Keywords: *road, tree damages, cross section, stream bed*

Introduction

Forest roads are necessary to provide access to forests for general management, maintenance, timber extraction, recreation (Ryan et al., 2004), regeneration, production (Demir and Hasdemir, 2005), and fire and pest control (Tehrani et al., 2015). Forest roads are associated with economic growth and national wealth. However, they have various direct and indirect effects on their adjacent environment (Tehrani et al., 2015). Construction of a forest road network is considered as the key element for a successful forest management (Krc and Begus, 2013). Planning a forest road network depends on social requirements since such roads provide access to forest villages, rural settlements and recreational areas (Acar and Eker, 2003). When forest roads are routed, construction methods and equipment selection directly affect their economical, functional and ecological efficiency (Ozturk et al., 2010). A proper design and routing of forest roads will reduce the need for major repairs and save on maintenance costs over time (Edwards, 2011).

Forest roads also have major environmental impacts. The environmental impacts of forest road constructions vary according to conditions of a terrain, that is whether it is a

DOI: http://dx.doi.org/10.15666/aeer/1604_40294038

rocky, loose rock, soil, gentle or steeper terrain, and so forth. In addition, in general, environmental damage may increase depending on situations such as stands (average tree diameters, average tree lengths, stand ages, canopy closures, etc.), choice of machines, tree species, and road construction techniques. Building forest roads involves removal of vegetation and soil, thus favoring run-offs, pollution of streams, and the risk of erosion and mass movement on steeper terrains (Edwards, 2011; Hernandez-Diaz et al., 2015). Moreover, stream beds can fill up with excavated materials, which is very concerning in terms of freshwater ecology, fish health, and rerouted stream beds.

Various types of bulldozers and excavators are generally used in forest road construction operations in Turkey. Bulldozers are commonly preferred on terrains with gentle to moderate hillside slopes and on soil and loose rock grounds. However, in steep and rocky terrain conditions, the efficiency of bulldozers diminishes, and excessive environmental damages may occur because of the difficulty to keep excavated materials alongside the road (Ozturk, et al., 2009).

In this study, a forest road construction was investigated in the southern part of Turkey. The construction was carried out by using a bulldozer. Environmental damages to trees and to the stream bed caused by the forest road construction were investigated. In addition, productivity and cost of the bulldozer were evaluated, and some suggestions were offered.

Materials and methods

Study area

The study area is selected from the office zone Gursu Forest Enterprise in Kas Forest Management in Antalya (*Fig. 1*). In this enterprise, dominant commercial tree species include *Pinus brutia*, *Cedrus libani* and *Juniperus* sp. The elevation ranges from 500 m to 1200 m with ground slopes of 25% to 80%. The study area consists of Type B forest roads with a density of 16 m/ha. Total length of the sample road examined in this study was about 1575 m with an average road width of 5 m. The study area is located on the Taurus Mountainous, which is the largest and most important karst region in Turkey. Due to immediate penetration of rainfall and snowmelt into the rock crack system, surface soil formation very slowly occurs along the cracks and statification surfaces of the limestone. In this study area, the road alignment consists of soil and losses rock.

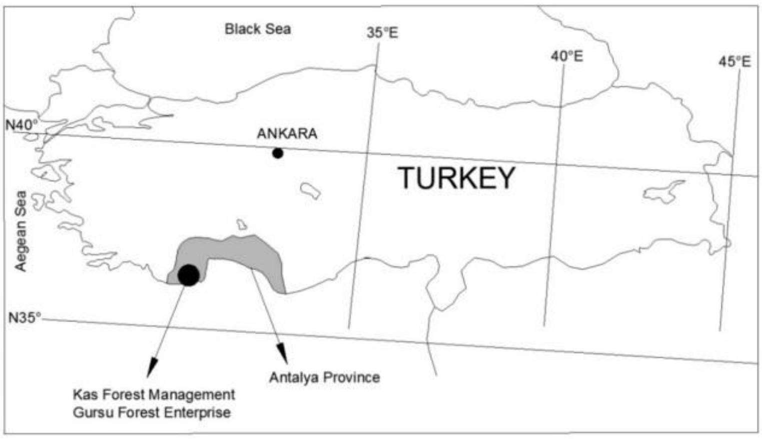

Figure 1. *The location of the study area in Antalya region*

The equipment specifications

Komatsu D85ex type bulldozer was used in forest road construction operations. This bulldozer is a very strong machine and it is suitable for forest road operations on soil and loose rock region. The technical specifications of the bulldozer are shown in *Table 1*.

Table 1. *Technical features of the Komatsu D85ex (Anonymous, 2015)*

Specifications		Values
Bulldozer weight		21220 kg
Operating weight		28100 kg
Engine model		SAA6D125E-5
Engine type		4 cycle, water cooled, direct injection
Engine power		266 HP
Maximum travel speed	Forward	10.1 km/h
	Reverse	13.0 km/h
Blade capacity		7.0 m³
Minimum turning radius		1.99 m
Fuel tank		490 l
Bulldozer height		3330 mm
Bulldozer length		5795 mm
Bulldozer width		3635 mm
Ground pressure		73.6 kPa

Methods

The area and the trees in it during the forest road construction were measured to determine and investigate the damage caused by the excavated materials. Also, environmental damages to the stream bed caused by the excavated materials were investigated. In this study, primarily, the cross sections were determined along the forest road. Every cross section included different variables. These variables include cut-slope height (Ch), cut-slope width (Crw), road width (Road + Ditch) (Rw), fill-slope width (Frw), fill-slope length (Fl), road construction zone width (Czw), cut slope length (Cl) and ground slope (S) (*Fig. 2*).

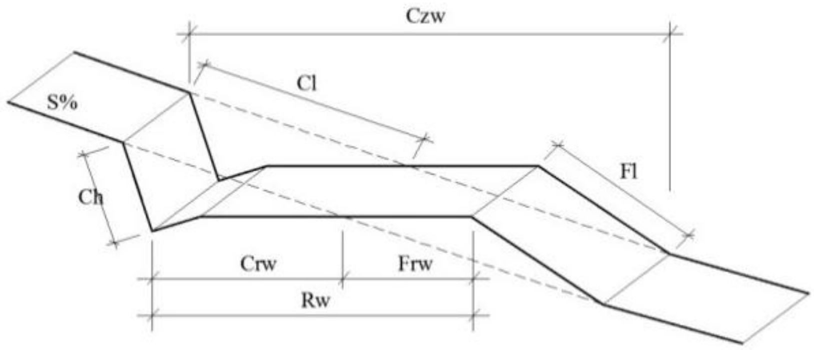

Figure 2. *The decision variables measured from each cross section along the forest road*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40294038

In this study, surveying instruments such as a steel tape, a measuring batten, clinometers, an altimeter, and a compass were used in the research area. Along the 1,575 m of road section, decision variables were collected from 52 cross sections, which were 30 m apart from each other. The number of damaged and undamaged trees were determined in each cross section as a gradient group. The types of damage such as bending of a tree and wounding of tree bark were also observed. Using the data that were collected, distribution of damage types in relation to the construction techniques associated with the bulldozer and the effect of positional values of damaged trees were investigated. The data were entered into a spread-sheet program to compute simple statistics such as arithmetic averages and standard deviations. The average excavation speeds and productivities of the bulldozer were found throughout the forest road operation. Every cross section was shown in percent slopes, differently for cut-slopes and fill-slopes. The shapes of the cross sections were measured, and the difference between the lengths of cut-slopes and fill-slopes was shown.

Results and discussion

In the first stage of the road construction operation, the trees on the route were cut, and removed. In this route, 386 m^3 of logs were extracted from 452 fallen trees that were collected from a single cross section that was selected as a sample along the construction zone. The trees that were cut were mostly *Pinus brutia*. The results indicated that the total amount of excavated materials along the roadway was 12,195.00 m^3, The percentages of soil, loose rock and soft rock of those materials were 59%, 36% and 5%, respectively. The average operation time of the bulldozer was 8 h per day. The research was conducted in August 2015. The research area is very hot in the summer season, which affected the forest road operation.

Cross sections

In this study, the data from the cross sections were collected on the sample road. In this region, the types of materials on the ground are soil and loose rock along the forest road construction route. The excavation operation using the bulldozer was easy because the amount of rock on the ground was very small. *Table 2* lists the values of the specific variables measured from the cross sections.

Table 2. *The values of decision variables measured on the cross sections*

Variables	Symbol	Average	Standard deviation	Max. values	Min. values
Ground slope (%)	S	58.8	17.73	80	25
Cut-slope height (m)	Ch	3.51	1.43	7.8	1.7
Cut length on road width (m)	Crw	4.31	1.10	6.5	2.9
Fill length on road width (m)	Frw	2.34	1.79	8.5	0.5
Road width (m)	Rw	6.56	1.72	12.0	4.2
Cut-slope length (m)	Cl	6.55	1.85	10.8	3.9
Fill-slope length (m)	Fl	5.67	3.82	16.2	1.9
Construction zone width (m)	Czw	11.32	3.40	19.5	6.9

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40294038

The average construction zone width was 11.32 m; therefore, the sample road section affected approximately 1.78 ha of the forested area (11.32 m × 1,575 m = 17,829 m² = 1.78 ha) during the road construction activity.

In this study, the rates of cut-slopes in the forest road were mostly between 3/1 and 5/1 depending on the cut-slope heights and road widths. Excavated materials were scattered down the side of the roadway, and the fill-slope lengths varied between 1.9 and 16.2 m depending on the fill-slope gradients. The gradient of study area was found to be between 25 and 80%.

Environmental damages on trees and stream bed

Some of the cross sections did not have any damaged trees, whereas the others had damaged trees (*Fig. 3*). The damaged trees usually had bending and wounding damages (*Figs. 4* and *5*). The number and rate of the damaged trees in the study area is shown in *Table 3*.

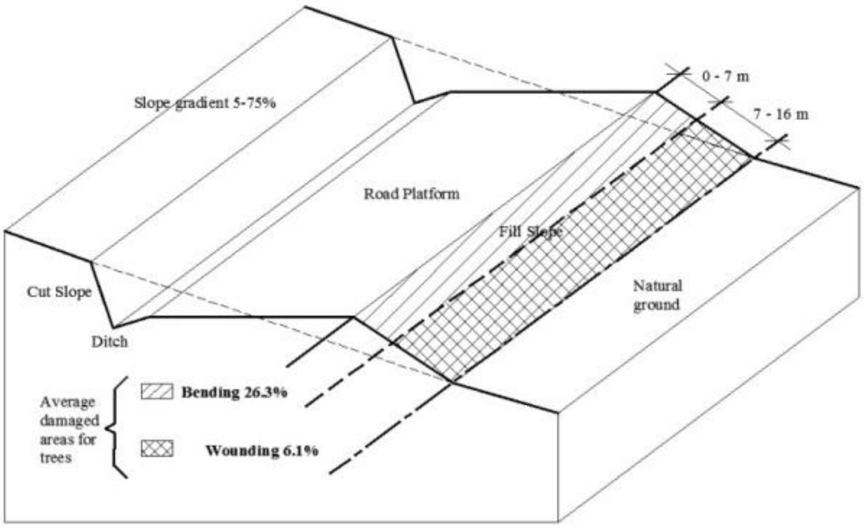

Figure 3. *Determination of cross sections along the road alignment*

Figure 4. *Bending damages of trees*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40294038

Figure 5. *Wounding damages of trees*

The wounding of the tree barks is a very serious issue for this forest region. For many years, bark beetles have been devastating this region. The damage caused by bark beetles is denser especially on *Pinus brutia*. The environmental damage may be increased in these regions due to bark beetles. In addition, direct economic losses are rising due to the timber quality lowered by bark beetles.

Table 3. *Number and rate of damaged trees in study areas*

Cross section number	Distance (m)	Average of grade fill slope (%)	Total number of trees	Number of bending trees	Number of wounding trees	Average of distance rolling (m)	Bending percent (%)	Wounding percent (%)
1	30	65	24	6	-	9	25	0
2	30	65	29	9	1	9.5	31	3.4
3	30	75	65	20	3	22	30.8	4.6
4	30	70	22	8	2	9.5	36.4	9
5	30	45	5	-	-	5.5	0	0
6	30	72	38	14	5	18.5	36.8	13.2
7	30	63	20	4	1	7.5	20	5
8	30	55	18	8	3	6	44.4	16.6
9	30	40	13	2	-	4.5	15.4	0
10	30	58	22	5	2	8	22.7	9
Ort.	20	60.8	26	8	2	10	26.3	6.1

The number of damaged trees in the steep and gentle terrain was found to be greater. In 25–80% of the sloped areas, there were an average of 8 bent trees and 2 wounded trees. In addition, in the cross sections, the average number of undamaged trees was counted to be 26. Along the forest road, the average gradient was found to be 61%. The amount of excavated materials along the road alignment and the slope gradient are also important. The length of fill-slopes increases with increasing slope gradients, and consequently, the damage grows. When the sliding and rolling distance of excavated materials increase, the environmental damages to trees and to the river basin are increased.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40294038

All the excavated materials were dumped down the side of the roadway by the bulldozer. As the second type of environmental damage, the stream bed was filled with excavated materials. In this case, the direction of the stream flow was diverted. This change was very serious in terms of freshwater ecology, fish health, and rerouted stream beds (*Fig. 6*).

Figure 6. *The fill with excavated material of stream bed*

Filling stream beds with excavated materials increases the risk of erosion in this area especially in the rainy season. The main reason for dumping excavated materials over the stream bed was the fact that the forest road was very close to the stream. A buffer zone should be allowed between a road and a stream so that the stream can be protected from excavated materials. According to Akgül, the width of a buffer zone should be increased depending on the slope rate. The width of a buffer zone ranges between 25 and 150 m on productive forest areas (Akgül, 2012). Stream beds are protected from flow of sediments by buffer zones, and thus, the speed of rainwater is reduced in such areas (Wenger, 1999; Wood and Armitage, 1997).

Productivity and cost of bulldozer

The production rate of the bulldozer is generally computed as the length of constructed road per hour. In this study, the average productivity of the bulldozer in soil, loose rock and soft rock were found to be 221.41, 125.00 and 86.5 m^3/h, respectively (*Table 4*).

The average slopes of soil, loose rock and soft rock in the study area were 55, 66 and 63%, respectively. The total road construction cost of the Gürsu region was 14,750.00 US$, with a unit cost of 9,370.00 US$/km. The fuel consumption of Komatsu D85ex bulldozer varied between 18–20 l/h.

In this study, the average zone width of the constructed sample road was 11.32 m. The amount of forest area impacted along the road was 1.78 ha. A study conducted in the Antalya region reported that a road construction operation in the same region resulted in a zone width of 12.18 m (Wood and Armitage, 1997). Another study conducted by Ozturk (Ozturk, et al., 2010) — in which a bulldozer was used — in the Bolu region of Turkey indicated that the average zone width of the construction was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40294038

7.27 m, and the ground type was soil. Ozturk also reported a construction zone width of 7.47 m on loose rock in the Eskişehir region of Turkey (Ozturk, et al., 2009).

Table 4. *Productivity of bulldozer at different excavated materials*

Cross section number	Excavated materials ground type	Average slope (%)	Distance of between cross sections (m)	Productivity of bulldozer (m^3/hr)
1	Soil	55	25	221.41
2	Loose rock	66	25	125.00
3	Soft rock	63	30	86.50

There are two types of environmental damages caused by forest road constructions. These are damages to trees and damages to stream beds. The tree damages include bending and wounding of trees. The damages to stream beds include the filling of stream beds with excavated materials. In this study, in the 25–80% ground slopes, 26.3% of the trees below the forest road construction zone were bent, and 6.1% of the trees were wounded. In a similar study conducted by Tunay (Tunay and Melemez, 2004) in Antalya, 55% of trees under the forest road construction zone in a terrain with a ground slope of 51% were damaged. In a similar region, Ozturk (Ozturk, et al., 2010) reported that the types of damages that were identified on trees included bending, crushing and wounding in a karstic region. The rate of total damage including all three types was 23% in the 46–90% ground slope. Another study conducted by Caliskan in the Trabzon region of Turkey revealed that 44% of trees were damaged in soil, loose rock and rock areas of a terrain that had a ground slope of 59% (Caliskan, 2013). Damage types in those areas included bending, crushing and wounding. Although the area in this study was a sloping area, the number of trees that were damaged was less than those that were observed in the other studies. The reason might be that the types of ground were mostly soil and loose rock. The soil load usually bends trees. The rate of wounding observed on the trees was less. In this study, dumping the excavated materials on the stream bed was a more serious problem for the environment. It appears, the risk of erosion will increase in this road area in the consequent years.

In this study, the cut-slope rates ranged from 3/1 to 5/1, and the fill-slope rate was 2/3. Kramer indicated that a cut-slope rate of 3/1 is the most appropriate rate especially for steep terrains (Kramer, 2001).

Conclusion

In this study, constructing a road using a bulldozer were evaluated in soil and loose rock areas by considering economic and environmental requirements. The following are recommended:

- Bulldozers should be used in forested areas with less than 45% ground slope. Environmental damage is increased in areas where slope is higher.
- A buffer zone should be maintained between a forest road and a stream. The buffer zone protects the stream bed from excavated materials.
- Damaged trees should be removed from sensitive areas where bark beetles are abundant. Especially the wounded trees will increase the number of bark beetles. This situation is very dangerous for sensitive forest areas.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40294038

- Cut-slope rates should be 3/1 or 5/1 on mountainous areas. Lower rates such as 1/1 or 2/1 will increase construction zone widths of forest roads.
- Bulldozer operators should be well trained to improve the efficiency of construction activities, which affect economical and environmental aspects.

PUBLIC AWARENESS AND PERCEPTIONS OF CLIMATE CHANGE: DIFFERENCES IN CONCERN ABOUT CLIMATE CHANGE IN THE WEST MEDITERRANEAN REGION OF TURKEY

KORKMAZ, M.

Department of Forest Economics, Faculty of Forestry, Suleyman Demirel University
32260 Isparta, Turkey

(Received 7th Apr 2018; accepted 13th Jun 2018)

Abstract. This study was aimed at determining perception and awareness levels about climate change in three city centers located in the West Mediterranean Region of Turkey and identified differences in public perceptions and knowledge about regional climate change. The study utilized a questionnaire method to obtain data. The results found that approximately half of the participants had inadequate climate change knowledge. In particular, knowledge levels regarding climate change adaptation were comparatively low. Women were more concerned about climate changed compared to men. Additionally, primary and high school graduates and married individuals were also more concerned. Age and income were not determining variables. There were no significant differences in terms of gender, age, income and educational status apart from marital status as to whether or not adaptation to climate change will be achieved. There are varying levels of awareness among the public regarding climate change, and thus it is especially important to organize outreach programs supported by media to increase climate change adaptation knowledge levels. Institutions need to improve their ability to promote public awareness and knowledge about climate change in order to reach a larger proportion of the public.
Keywords: *global warming, public opinion, adaptation, Turkey*

Introduction

Climate change is a key agenda item for a majority of countries due to the increased visibility of general ecological problems, developments in science and technology, and related studies by ecological economists since the 1970s. It is forecasted that important consequences, such as melting of icebergs, rising sea levels, and severe weather events may directly or indirectly impact human life and health, socioeconomic sectors and ecological systems (IPCC, 2013). It is now generally and widely agreed that global warming is accelerating in present-day conditions due to human-induced effects and that climate change is reaching a level that affects the future of society (Cook, 2013; MacCracken, 2001; IPCC, 2001). The fifth assessment report of the *Intergovernmental Panel on Climate Change* confirms changes in the frequency and intensity of some extreme events such as weather and ocean temperatures, precipitation changes, rising sea levels and drought, floods and storms (IPCC, 2014).

Policymakers face the challenge of combating climate change and determining strategies for optimal adaptation and rational policies. Strategies that focus on maintaining the healthy and effective functioning of climate-change-resistant ecosystems and managing and conserving water, land and biological resources are fundamentally important to coping with the impacts of climate change. While efforts to hinder and prevent this process continue at an international level, work aimed at implementing adaptation in societies around the world are also underway (IPCC, 1990,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40394050

1995, 2007; WB, 2008; EC, 2009). National climate legislation and strategies have been formed in most United Nations member countries (Dubash et al., 2013).

In terms of general public awareness about climate change, visible changes such as an increase in temperatures and a decrease in precipitation are effective in impacting public perceptions (Rankoana, 2016). The most striking aspect of climate change perception is personal experience with negative natural phenomena, which is a strong determinant of individual risk perception (Frondel et al., 2017). According to many academic researchers, climate change policies have been insufficient to sensitize people in society to the meaning and importance of the problem and in particular for mobilizing people to take action (Westerhoff and Robinson, 2013: Randall, 2009; Lejano et al., 2013). The risk perception of the public regarding the possible consequences of climate change is of great importance. Apart from shaping climate policies, risk perception also plays a central role in adaptation and reduction initiatives (Lujala et al., 2015). Therefore, there is a need for more data determinants that influence people's perceptions of climate change.

Turkey is one of the countries that is most affected by climate change due to global warming. The complex climate structure in Turkey, which is surrounded by the sea on three sides, a fragmented topography, and orographic features means that different areas in Turkey will be affected to varying degrees (Ozturk, 2002). The *Turkey Climate Change Adaptation Strategy and Course of Action* policy aims to reduce the impact of climate change and adapt to global warming. Importantly, public awareness levels and institutional capacity must be increased in Turkey (MEU, 2010). Very few empirical studies have considered how the public in Turkey interprets and respond to climate change. This study investigates perceptions, concerns, and adaptation to climate change by residents of three city centers in the West Mediterranean Region of Turkey.

Materials and methods

Study area

Many of the problems caused by climate change have a tremendous effect on cities. The economic and social aspects of these problems must be tackled alongside the environmental implications (Albayrak and Atasayan, 2017). National strategies must be reorganized to a local level to improve the adaptation ability of cities against increasing risks (Warmsler et al., 2013). Over the last thirty years, the western and southern regions of Turkey have suffered from droughts due to Mediterranean precipitation patterns (Turkes, 2012). As such, this study focused on city centers (Antalya, Isparta, and Burdur) of the Western Mediterranean Region of Turkey (*Fig. 1*). The comparison of precipitation and average temperature of the study area between 1970 and 2017 was shown in *Figure 2*.

Data collection and analysis

Data were collected using a questionnaire approach. The multiple-choice questions in the questionnaire used a Likert scale. The questionnaire consists of two parts. The first part gathers profile information regarding the participants and the second part consists of questions designed to determine their level of perception and awareness about climate change. The questionnaire was conducted in face to face in the aforementioned three city centers. In order to determine the views of a group of participants with a 5%

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40394050

sampling error, the sample size was calculated by the formula (*Eq. 1*) below (Bas, 2010):

$$n = \frac{t^2 Npq}{(N-1)d^2 + t^2 pq} \qquad \text{(Eq.1)}$$

where:

n sampling size,
t t value (1.96 for 95% confidence level),
N population size,
p,q probability of availability of the mass to be measured in the main mass,
D sampling error accepted (5%).

Figure 1. *Study area*

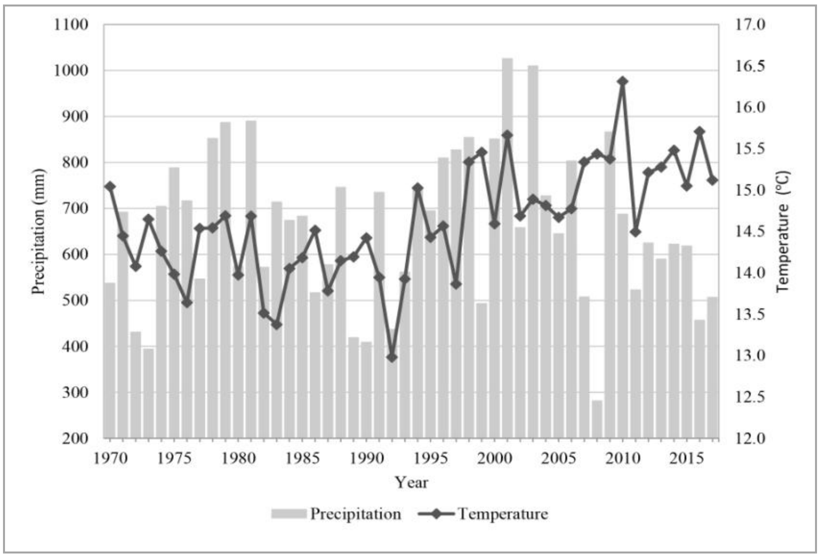

Figure 2. *Temperature and precipitation change between years 1970 and 2017 in study area*

Based on the above formula, the sample size needs to include 383 questionnaires. This study obtained 406 questionnaire forms in three cities (175 in Antalya, 118 in Isparta and 113 in Burdur) that were filled out and analyzed to increase the reliability of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40394050

the study. In the questionnaire applications, a systematic random sampling procedure was used. Quotas were set on age, gender, education and city population. In this context, participants were selected to represent the whole population in the study area. The internal consistency (Cronbach's alpha) coefficient of the scaled statements was determined to be 0.910. Since the internal consistency coefficient was greater than 0.8, the scale was highly reliable as a statistic.

The data obtained from the questionnaires were evaluated using statistical methods. The answers given in the first stage were analyzed using the SPSS package program to convert to percentage ratios. The Shapiro-Wilk test, the most effective method of testing the hypothesis for normality, was used to determine whether or not the questionnaire data was parametric. It was determined that 95% of the data did not have normal distribution ($p < 0.05$), meaning that it is not parametric. As such, non-parametric tests were used in the data analysis. In order to check for discrepancies among socio-demographic features (age, gender, education, etc.) while determining the views of individuals participating in the questionnaires on climate change concerns and their thoughts on climate change adaptation, several statistical methods were employed, including: for bivariate features the Mann-Whitney U test (Macfarland and Yates, 2016) and for more than two variables the Kruskal-Wallis H test (Corder and Foreman, 2014).

Results and discussion

Participant profile characteristics

Participant profile characteristics are provided in *Table 1*. A majority of the participants were young and middle-aged. Approximately one third were women. The majority were university graduates. About 60% of participants were single. The proportion with moderate and low incomes was 93.6%.

Opinions regarding climate impacts and perceptions about climate change

Since climate change is an important threat, it is helpful to determine the level of knowledge and awareness in the community, in particular regarding causes, effects, how to tackle the problem, and adaptation. *Figure 3* shows that while all participants have some knowledge about climate change, about roughly half do not have enough information. The levels of knowledge in the areas of climate change and adaptation are relatively low. Ochieng and Koske (2013), Semenza (2008), Michail et al. (2007) and Papadimitriou (2004) concluded that knowledge on climate change is inadequate, which is a finding similar to our study.

Figure 3 shows that all of the people living in the cities inside the research area are aware of climate change. Although some are at low knowledge levels, almost everybody has some information on causes, impacts, how to tackle climate change, and how to adapt to it. The most important reason for this is that climate change is largely associated with changes in the air. When asked, “What is the first concept you think of when you hear the words climate change?” the most popular answers were shifting seasons (41.1%) and global warming (20.4%). Natural disasters (17.5%) and weather deterioration (7.6%) follow closely (*Fig. 4*). In studies aimed at determining perception about global warming conducted by Steentjes et al. (2017) in France, Germany, Norway and England, global warming and seasonal change were also the first concepts to come to mind. In addition, emissions, environmental pollution, and air pollution, which are the driving forces of climate change, lag behind. Such awareness supports the idea that emotional and empirical learning is more effective than intellectual-based learning to change attitudes towards climate change issues (Lujala et al., 2015).

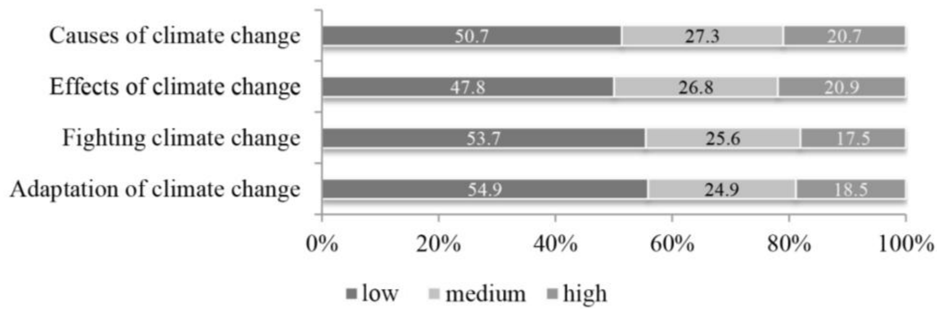

Figure 3. *Knowledge level on climate change (n = 406, only values > 5%)*

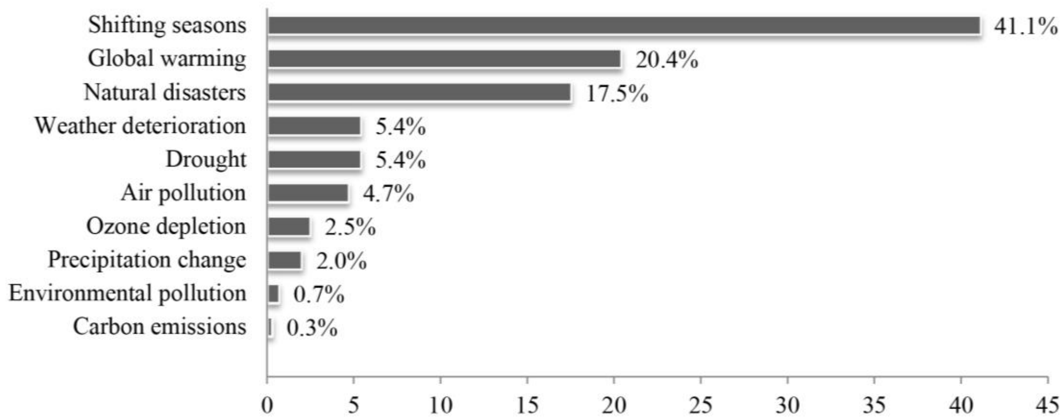

Figure 4. *What first comes to mind when you hear the phrase “climate change”?*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40394050

Findings on the results of climate change can be found in *Figure 5*. The vast majority of respondents indicate that climate change will cause many negative consequences, ranging from melting of glaciers to high temperatures. The level of awareness for melting of glaciers was higher (40.4%) than other impacts. Sea level rise was considered relatively important at a lower level. Unlike other concepts, about 6% of participants indicated that this is not important. The most important effect of climate change shown in *Figure 5* is the risk of extreme temperatures and drought. In our study, 75.8% of respondents in Turkey believed that heat and drought in the Mediterranean basin have increased and believe that this will continue in the future.

Schmidt et al. (2013) did a comparative analysis of 27 different countries and determined that climate change is covered in the media of countries at varying levels and that the attention of the media to carbon-dependent countries, which are committed under the Kyoto Protocol, is particularly high. The findings of this research also support this. In our study, 72% of the respondents said that they were provided information and awareness about climate change through the media. The distribution of effective media tools is internet (29%), TV (27%), and newspapers and magazines (16%). Since climate change is a global phenomenon, such platforms can affect societies around the world. Importantly, the prominence of the media is clearly evident.

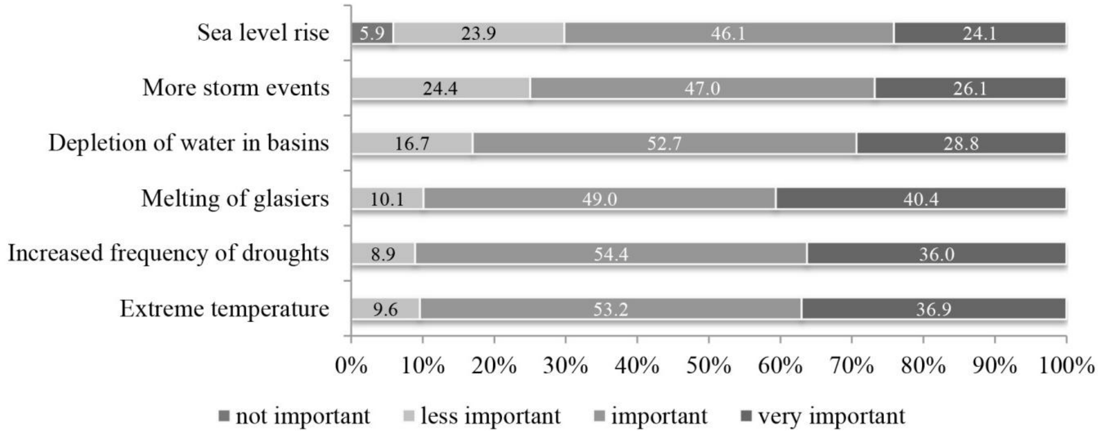

Figure 5. *Climate change impacts (n = 406, only values > 5%)*

Opinions regarding concerns about climate change

Public perceptions of climate change vary internationally. For example, people in France are more worried than those in Germany and Norway, while people in the United Kingdom are less concerned (Steentjes et al., 2017). Public perceptions also fluctuate over time. Social research shows that in the U.S., concern about climate change has fallen considerably since 2008 (Scruggs and Benegal, 2012). However, in many parts of the world in general, concerns over climate change have increased in recent years (Capstick et al., 2015).

Among the people participating in our study, women are generally more worried than men (*Table 2*). Similarly, Shi et al. (2016) also found that women in Germany and the United Kingdom were more worried than men. Recent research suggests that knowledge of climate change has limited impact on shaping climate change concerns (Malka et al., 2009; Kahan et al., 2012; Kellstedt et al., 2008). However, if measured in an area-specific and multidimensional manner, we see that knowledge is indeed an

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40394050

important driving force for climate change concerns, even when we control for human values. Likewise, different information dimensions play different roles in shaping the concerns of climate change. In some studies, women were found to have more knowledge than men (McCright, 2010). For this reason, the increased levels of anxiety in women compared to men can be explained by the varying levels of knowledge.

Worldwide, educational attainment is the most powerful determinant of climate change awareness. While understanding the anthropogenic cause of climate change is the strongest determinant of climate change risk perceptions, especially in Latin America and Europe, the perception of local temperature change is the strongest determinant in many African and Asian countries. However, public awareness and other important factors related to risk perceptions underscore the need to develop specific climate communication strategies for each country (Lee et al., 2015).

Ultimately, basic education is vital for public climate literacy, local dimensions of climate change, public participation, and support for climate action. In this study, statistically significant differences were determined between university graduates and others by educational level (*Table 2*). This difference can be explained by the high level of awareness among university students. Similarly, Yayar et al. (2014) found that level of education has a positive effect on awareness. Additionally, married people are more worried than single people (*Table 2*). The main reason for this is the concern that the children of married participants will continue to live in this world. Shi et al. (2016) found that elderly adults in the UK are less concerned about climate change compared to young people. On the contrary, no difference was found according to age groups in our study ($p > 0.05$). Similarly, income was not a variable with significant differences (*Table 2*).

Table 2. *Statistical relations on concern about climate change according to socio-economic characteristics*

Perceptions of adaptation to climate change

The *Intergovernmental Panel on Climate Change (IPCC) Fourth Assessment Report* (IPCC, 2007) indicated that harmonization studies are of great importance in managing climate change impacts and are the only means of counteracting climate change.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40394050

Importantly, this is the sole reason precautions were taken for climate change adaptation in the past. This emphasizes the importance of adopting a strategic approach at regional and national levels as well as at the global scale. It is vital to ensure harmony between the various sectors and levels of management to ensure that measures are taken in a timely and more effective manner to address climate change adaptation.

In recent years, creating awareness in the public about climate change in Turkey has been about lowering emission levels for compliance with the effects of climate change while adaptation to the results of climate change has been very low. The situation is similar in NGOs, which are mainly active in the management of ecosystem services (MEO, 2010).

In this study, overall, only a few demographic variables were significantly related to adaptation to climate change. Accordingly, married and unmarried people have different opinions about adaptation to climate change ($p < 0.05$). Married participants stated that more adaptation can be achieved. This can be explained by the positive perceptions that married people have developed for their concern about climate change. There were no statistically significant differences ($p > 0.05$) in terms of gender, age, income and educational status (*Table 3*). Although nearly half of the participants have low knowledge levels, there are positive opinions that climate change can be harmonized to a large extent. In other words, in this study there is wide participation (57.4%) in the idea that climate change is an important subject of adaptation. Meanwhile, however, the subject is characterized by different perceptions, interpretations, and evaluations contradicting each other in many respects. For individuals with high climate change awareness, adaptation capacity was also higher (Marshall et al., 2013).

Table 3. *Statistical relations of ideas on adaptation to climate change according to socio-economic characteristics*

Characteristic		n	Test results		
Gender	Female Male	149 257	MW-U* = 18434.0	Z = -0.730	p = 0.465
Age	18-25 26-45 46-65 > 65	158 142 98 8	X^{2**} = 3.254	df = 3	p = 0.354
Marital status	Married Single	150 256	MW-U = 16707.0	Z = -2.271	**p = 0.023*****
Monthly Income	≤ 1400 TRY 1401-5000 TRY > 5000 TRY	115 265 26	X^2 = 1.831	df = 2	p = 0.400
Education	Graduate Primary, secondary or high school	161 245	MW-U = 19236.0	Z = -0.491	p = 0.623

*Mann Whitney U test, **Kruskal Wallis H test, ***p < .05

Such an understanding about the different levels of awareness, knowledge and support among various demographics is important in terms of supporting policies and strategies for harmonization. Those who indicate that they can be adapted have the perception that *"we will have to change our lifestyle"*, *"new technologies will be produced"* and *"we will learn to live with a warmer climate"*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40394050

One of the most important ways to adapt to the effects of climate change is to protect natural ecosystems. One of the most vulnerable sources of climate change is forest ecosystems (Detten and Faber, 2013). Withana et al. (2007) found that there is a perception that forest fires resulting from climate change will increase. In our work, there was a high perception, with 85% holding the view that forest fires will increase in the Mediterranean basin. According to public perceptions, the most important causes of climate change are air pollution (26%), deforestation (23%) and ozone depletion (15%). In this context, forests are considered as one of the most important approaches to adaptation, as forests are important resources for climate change. The survey indicated that 91.4% of respondents underline that more afforestation is needed. However, 92.6% of the respondents indicated that they would invest in alternative energy sources (wind, solar, geothermal etc.).

Conclusions

In this study, the most important determinants of concern for climate change were gender, educational status, and marital status. Age and income levels were not determinants of concern. These results are a resource for developing climate change policies and actions to increase perception and awareness regarding climate change. Governments should promote changes in perception by increasing the level of consciousness and awareness of nature, in particular about the risks of climate change and how to better manage risk factors. The greater the awareness in the community regarding the effects of climate change, the easier it will be to eliminate risks and improve adaptation.

We found that about half of the participants have little knowledge about climate change. In particular, the levels of knowledge on adaptation are relatively lower. The success of policies and actions by governments and environmental agencies to mitigate and adapt to climate change depends on support by the public. This support is closely related to public perception and awareness. In Turkey, although climate change awareness raising activities from civil society organizations have increased, the effectiveness of the NGOs working in this area is inadequate. A significant number of NGOs have focused on mitigation activities and active management of ecosystem services, but they are few in number. Importantly, many NGOs need to be aware of climate change mitigation as “mitigation” and that awareness raising is needed regarding “adaptation”. While there is considerable public awareness about climate change, it is especially important to promote programs supported by media to raise the level of knowledge regarding climate change adaptation. Increasing the capacity of institutions to address this important issue is keys. In summary, it is necessary to increase public awareness in Turkey regarding climate change.

EFFECT OF DIFFERENT FERTILIZER TREATMENTS ON BOTANICAL COMPOSITION, HERBAGE YIELD AND HERBAGE QUALITY IN THE EASTERN ANATOLIA REGION PASTURE OF TURKEY

CACAN, E.

Department of Crop and Animal Production, Vocational School of Genc, University of Bingol Bingol, Turkey
(e-mail: erdalcacan@gmail.com; phone: +90-505-844-5280; fax: +90-426-411-2083)

(Received 13th Apr 2018; accepted 13th Jun 2018)

Abstract. This study was carried out to reveal the effect of different doses of nitrogen, phosphorus and combinations of these doses on the botanical composition, herbage yield and herbage quality in the Eastern Anatolia Region pasture of Turkey. In the study 0, 5, 10, 15 kg da^{-1} nitrogen, 0, 4, 8, 12 kg da^{-1} phosphorus doses and different combinations of these fertilizers (5-4, 5-8, 5-12, 10-4, 10-8, 10-12, 15-4, 15-8, 15-12 kg da^{-1}) were used and the study was conducted over a natural pasture section of Research and Application Center of Bingol University. Experiments were conducted between the years 2014-2017 for 4 years in randomized blocks factorial experimental design with 3 replications and 2 factors. Weight-based botanical composition, green herbage yield, dry herbage yield, crude protein yield, acid detergent fiber (ADF), neutral detergent fiber (NDF) and relative feed values (RFV) were investigated. Present findings revealed that fertilizer treatments (nitrogen and phosphorus doses and combinations) increased legume ratio in botanical composition, green herbage yields, dry herbage yields, crude protein yields and relative feed values and reduced ADF and NDF ratios systematically during the first three years of the experiments. The greatest green herbage yield (758.9 kg da^{-1}), dry herbage yield (458.6 kg da^{-1}) and crude protein yield (63.7 kg da^{-1}) were obtained from 10 kg da^{-1} nitrogen and 8 kg da^{-1} phosphorus treatments. As compared to the control plot, the plot with 10-8 kg da^{-1} N-P treatment had about 115.7% greater green herbage yield and 154.4% greater dry herbage yield. Therefore, 10 kg da^{-1} nitrogen and 8 kg da^{-1} phosphorus treatments could be recommended for fertilization programs to be applied in pastures of Bingol province and the Eastern Anatolia pastures with the similar ecological conditions.
Keywords: *pasture, nitrogen, phosphorus, crude protein yield, relative feed value*

Introduction

Meadow and pastures are commonly used in animal feeding in Turkey. Misuse of pastures for years, excessive and uncontrolled grazing practices have made soil surfaces barren, resulted in serious soil erosion over these surfaces and ultimately resulted in significant yield and quality losses. Then pastures were not able to meet the feed needs of the present animals. Therefore, pastures should urgently be reclaimed to make them sufficient again to meet forage needs of livestock. Fertilization is among the significant methods used for pasture reclamation.

Fertilizers are the primary inputs used in modern agriculture to improve yield levels (Ergene, 1997). They can alone provide about 40% yield increase in agricultural production activities and thus may provide significant contributions to food safety (Karaman, 2012). With the efficient use of fertilizers, about 50-70% yield increase can be achieved for nitrogen and 10-15% for phosphorus (IFA, 1999). Fertilization has versatile impacts on meadow and pastures. Fertilizers can improve herbage yield and quality, provide regular distribution of herbage throughout the grazing periods, ease the establishment of seed-propagated seedlings and enrich the taste of herbage (Altin, 1992; Heady and Child, 1994).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40514063

However, economic analyses should be performed to assess the economy of fertilization practices (level of yield increase achieved with the fertilizer quantity applied per unit area). For this purpose, the economic limit of the fertilizer to be applied should be well identified. The price of the product obtained with additional fertilizer should be greater or at least equal to the price of utilized fertilizer plus the price of other practices performed during fertilization. Otherwise, fertilizer use will not be economic (Sezen, 1995).

In previous studies carried out in Turkey and the other countries, it was stated that pasture vegetation could benefit from precipitations more efficiently, vegetation herbage quantity and quality could be improved with fertilization practices. With reclamation practices, pastures regain their previous statuses and may provide sufficient and quality herbage. To have expected benefits from the fertilizers, economic analyses should be performed, proper fertilizer types and doses should be well identified.

Previous studies also revealed that pasture class was improved from poor or risky to healthy with fertilization practices (Dasci et al., 2009), pasture herbage quality and quantities were improved with fertilization practices (Celik et al., 2001; Hatipoglu et al., 2001; Hatipoglu et al., 2005; Gur, 2007; Balabanli et al., 2010; Andic et al., 2001; Budakli and Carpici, 2011), crude protein of pasture hay was improved (Andic et al., 2001; Hatipoglu et al., 2005; Balabanli et al., 2010; Budakli and Carpici, 2011), ADF (Budakli and Carpici, 2011) and NDF ratios (Balabanlı et al., 2010) decreased and relative feed values increased with fertilization practices.

This study was conducted in Bingol province of Turkey to investigate the effects of different nitrogen doses combined with different phosphorus doses on botanical composition, herbage yield and quality of pastures and to determine proper fertilizer doses for Eastern Anatolia pastures and the other pastures with similar ecological conditions.

Materials and methods

Location, soil and climate

The studies were carried out in the province of Bingol. Bingol province is located in the Eastern Anatolia Region of Turkey. Experiments were set up in April of 2014 over the Research and Application Center of Bingol University about 15 km from Bingol province with an altitude of 1088 m (38.81256°N - 40.53551°E). The map of Turkey and a few photographs of the study area are given in *Figure 1*. Experiments were conducted between the years 2014-2017 for 4 years.

Meteorological data of the research site were received from Bingol Provincial Directorate of Meteorology. As it can be seen from *Table 1,* annual variations in temperature and relative humidity values were similar to each other, but precipitations of the years 2014 and 2017 were lower than the other years.

Soil samples were taken from 0-30 cm soil profile of different sections of the research site. Soil analyses were performed at laboratories of Soil Science and Plant Nutrition Department of Bingol University Agricultural Faculty. Soil analyses revealed that experimental soils were clay-loam in texture. Soils were slightly acidic (pH = 6.266), unsaline (0.014%), poor in organic matter (1.09%) and lime (0.41%) and sufficient in potassium (20.27 kg da^{-1}) and phosphorus (7.60 kg da^{-1}).

Trial design and treatments

Effects of four different nitrogen doses (0, 5, 10, 15 kg da^{-1}), four different phosphorus doses (0, 4, 8, 12 kg da^{-1}) and combination of these doses (5-4, 5-8, 5-12, 10-4, 10-8, 10-12, 15-4, 15-8, 15-12 kg da^{-1}) on herbage yield and quality of pasture

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40514063

vegetation were investigated in this study. Urea (46% N) as nitrogen source and triple super phosphate (43-44% P_2O_5) as phosphorus source were used. The chemical composition of urea is H_2N-CO-NH_2 and chemical composition of the triple super phosphate is $Ca(H_2PO_4)_2.H_2O$. For each treatment and combination, plot size was arranged as 2 x 6 = 12 m^2. Experiments were conducted in randomized blocks with three replications and factorial experimental design with 2 factors. Phosphorus treatments were applied at the beginning of October in which effective precipitations started and nitrogen treatments were applied in April of each year. In the same way nitrogen application for combinations was carried out in April and phosphorus application in October.

Measurements

Vegetation was harvested from randomly placed 33 × 33 cm frame sections (3 frames for each plot) of each plot at earing stage of the dominant vegetation plants at the last week of May. Harvested herbage was weighted to get green herbage weight. Then, samples were dried at 78 °C for 24 h and weighted to get dry herbage weights. Dry weights were used to get dry herbage yields. The dry herbage obtained from the frames was divided into three groups, namely legumes, grasses and other family plants. The rates of botanical composition according to weight were obtained by dividing the dry herbage yield values of plant groups determined in each frame into the total dry herbage yield determined in said frames.

Dried samples were ground and subjected to crude protein, ADF (acid detergent fiber), NDF (neutral detergent fiber) and related quality analyses with the aid of NIRS (Near Infrared Spectroscopy - Foss Model 6500) device at Science and Technology Implementation and Research Center of Dicle University (Basaran et al., 2011; Mut et al., 2010; Cinar and Hatipoglu, 2015). Crude protein ratios were used to get crude protein yield per decare. ADF and NDF values were used to get relative feed value (RFV = (88.9 - (0.779 × %ADF)) × (120 / %NDF) / 1.29 (Van Dyke and Anderson, 2000; Morrison, 2003).

Statistics

Experimental data were subjected to variance analysis with JMP statistical software in accordance with randomized blocks factorial experimental design with three replications and two factors. Means were separated with Tukey's HSD (honest significant difference) test (Steel and Torrie, 1980; Kalayci, 2005).

Results

Botanical composition (%)

Annual botanical composition of pastures with different nitrogen and phosphorus doses are presented in *Figure 2*. As it can be seen from *Figure 2,* fertilizer doses applied to pastures increased the ratio of legumes in botanical composition in the second and third year, but legume ratio decreased again in the fourth year. Phosphorus fertilizer was the primary reason for the increasing legume ratio of the pasture in 2015 and 2016. Since lower precipitation levels were received in 2014 and 2017, legume ratio of those years were lower than the other years. The pasture was dominantly a graminae pasture with about 93.50% graminae species.

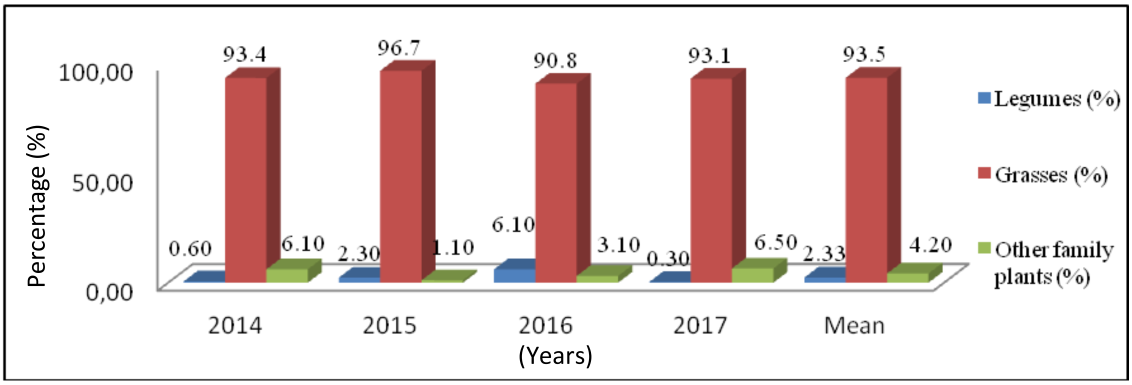

Figure 2. *The botanical composition of the pasture area (%)*

Green and dry herbage yields (kg da^{-1})

Green herbage yields and averages from the pastures treated with nitrogen and phosphorus doses for 4 years are provided in *Table 2* and dry herbage yields and averages are provided in *Table 3*. The effects of nitrogen and phosphorus treatments on green and dry herbage yields were found to be significant and the differences in green and dry herbage yields of the years were also significant (1%). As the average of 4 years, the greatest green herbage yield (758.9 kg da^{-1}) and the greatest dry herbage yield (458.6 kg da^{-1}) were obtained from the plots with 10 kg da^{-1} N and 8 kg da^{-1} P treatments; the lowest green herbage yield (351.8 kg da^{-1}) and the lowest dry herbage yield (180.3 kg da^{-1}) were obtained from the control treatment (0-0 kg da^{-1}).

With fertilization treatments for 4 years, average green herbage yield increased from 351.8 kg da^{-1} to 600.2 kg da^{-1} and the average dry herbage yield increased from 180.3 kg da^{-1} to 321.3 kg da^{-1}. Such values revealed that applied fertilizer doses resulted in 70.6% increase in green herbage yields and 78.2% increase in dry herbage yields. However, considering the plot with the greatest yields (10 kg da^{-1} N and 8 kg da^{-1} P), such an increase as compared to control (0-0 kg da^{-1}) was 115.7% in green herbage yield and 154.4% in dry herbage yield.

**$P < 0.01$, CV(%): 21.3

With regard to yields of the years, the greatest green herbage and dry herbage yields were obtained from 2015 and 2016 and the lowest green herbage and dry herbage yields were obtained from 2014 and 2017. Lower precipitation levels of the years 2014 and 2017 were the primary reason of such lower yields in those years. Since 2014 was the first year of the experiments and thus the impacts of fertilizers did not showed up and the precipitations in March and April were lower than the other years, the lowest yields were observed in 2014.

As compared to control treatments (0-0 kg da^{-1}), all nitrogen and phosphorus treatments had greater yields (*Fig. 3*). However, only 10-0 kg da^{-1}, 5-12 kg da^{-1}, 10-4 kg da^{-1}, 10-8 kg da^{-1}, 10-12 kg da^{-1}, 15-4 kg da^{-1}, 15-8 kg da^{-1} and 15-12 kg da^{-1} nitrogen and phosphorus treatments had yield values greater than general average (321.3 kg da^{-1}). Therefore while preparing fertilization plans, cost-benefit analysis should be performed and one of those treatments should be selected.

Crude protein yield (kg da^{-1})

Crude protein ratios and averages of pasture plots treated with different nitrogen and phosphorus doses are provided in *Table 4*. The effects of nitrogen and phosphorus treatments on crude protein yields were found to be significant and the differences in crude protein yields of the years were also significant (1%). The greatest crude protein yield (63.7 kg da^{-1}) was obtained from 10 kg N and 8 kg P treatments and the lowest crude protein yield (23.8 kg da^{-1}) was obtained from the control plot (0-0 kg da^{-1}).

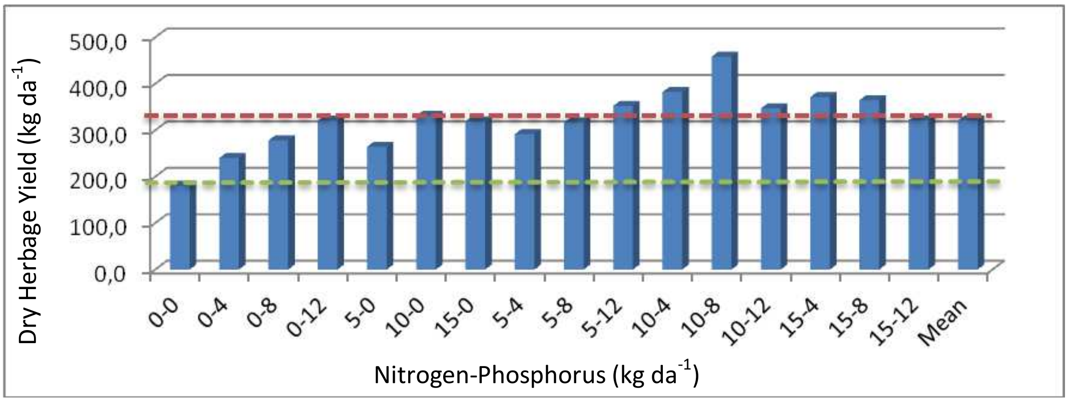

Figure 3. *The dry herbage yield of the pasture parcels (kg da^{-1})*

Considering the crude protein yields of the years, the greatest value (80.9 kg da^{-1}) was obtained in 2016 and the lowest value (26.2 kg da^{-1}) was obtained in 2014. As it was in green herbage and dry herbage yields, the lowest crude protein yield was observed in the first year of the experiments, crude protein yields then systematically increased in the second and third year and decreased again the fourth year. Since crude

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40514063

protein yield is obtained by multiplying dry herbage yield with crude protein ratio, crude protein yields were higher at doses and years with greater dry herbage yields.

As compared to control plots, nitrogen and phosphorus-treated plots had greater crude protein yields (*Fig. 4*). However, only 10-0 kg da^{-1}, 15-0 kg da^{-1}, 5-12 kg da^{-1}, 10-4 kg da^{-1}, 10-8 kg da^{-1}, 10-12 kg da^{-1}, 15-4 kg da^{-1}, 15-8 kg da^{-1} and 15-12 kg da^{-1} nitrogen and phosphorus treatments had crude protein yields greater than the general average (47.9 kg da^{-1}).

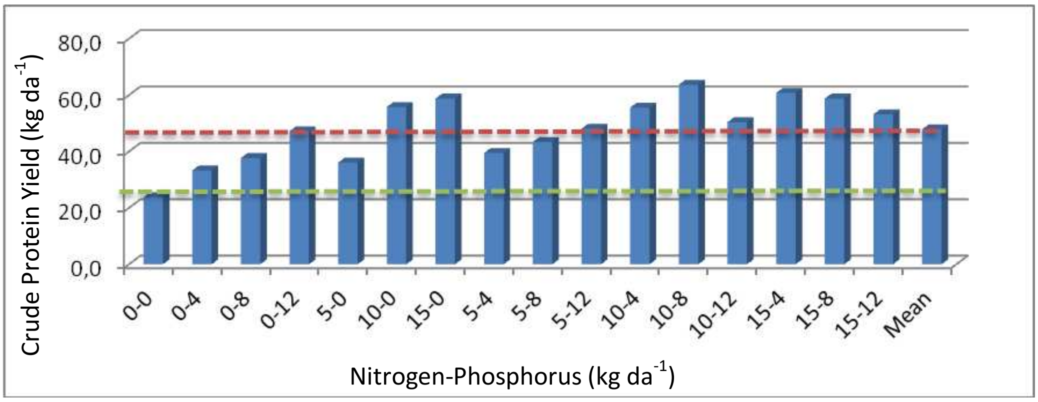

***Figure 4.** The crude protein yield of the pasture parcels (kg da^{-1})*

ADF and NDF ratios (%)

ADF ratios and averages of pasture plots with different nitrogen and phosphorus treatments are provided in *Table 5* and NDF ratios and averages are provided in *Table 6*. The effects of nitrogen and phosphorus treatments on ADF and NDF ratios were not found to be significant. However, the differences in ADF and NDF ratios of the years were found to be significant (1%).

Relative feed value

Relative feed values (RFV) and averages of the pasture plots treated with different nitrogen and phosphorus doses are provided in *Table 7*. The effects of different nitrogen and phosphorus treatments on relative feed values were not found to be significant, but the differences in relative feed values of the years were significant (1%). Relative feed values varied between 100.7-112.6 with an average value of 105.3.

With regard to ADF and NDF ratios of the years, it was observed that ADF and NDF ratios systematically decreased, thus relative feed values increased in the first three years. However, in the fourth year, ADF and NDF ratios started to increase, thus relative feed values get into decreasing trend again.

Discussion

Fertilizer doses increased weight-based ratios of the legumes in botanical composition. However, legume ratios decreased in 2014 and 2017 with lower precipitation levels than the other years. Phosphorus fertilizers were reported to increase legume ratios in botanical composition (Hatipoglu et al., 2001; Polat et al., 2007; Kacorzyk and Glab, 2017). However, phosphorus fertilization was recommended for pastures with less than 10% legume ratio in botanical composition (Altin et al., 2005).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40514063

Since the legume ratio in present botanical composition was 2.33%, phosphorus fertilization was not necessary for these pasture plots. Phosphorus supplementation not only meets the phosphorus needs of the plants, but also improves nitrogen efficiency (Black, 1968 and Whitehead, 1995). Therefore, phosphorus fertilizers to be made to enrich the botanical composition should be applied together with nitrogenous fertilizers.

With the fertilizer treatments, green and dry herbage yields increased from the first year, increases went on in the second and third year. However, in the fourth year, both green and dry herbage yields started to decrease again. There are two reasons of these trends. The first one was the lower precipitations of the first and the forth years than the other years. The second one was limited yield increase potential of fertilizers. It is normal to expect a yield increase with fertilizers, but such an increase will not be infinite. Yields reach to a peak value and then a stable yield levels expected. In present study, yields reached to a peak value in the third year, but a table peak levels were not attained in the fourth year because of lower precipitations. Kacorzyk and Glab (2017) carried out a study over the pastures for 10 years and indicated significant relationships between climate factors (temperature and precipitation) and yield parameters and reported lower yields in years with lower temperature and precipitation levels.

It was reported in previous studies that nitrogen and phosphorus fertilizations increased herbage yields of the pastures (Polat et al., 2007), nitrogen treatments alone increased dry matter yields (Aydin and Uzun, 2005; Balabanli et al., 2010; Budakli and Carpici, 2011), nitrogen treatments increased herbage yields of a pasture (with an average yields of 151.5 kg da^{-1}) three folds (Celik et al., 2001). It was reported in previous studies that fertilizers increased dry herbage yield of a pasture from 166.3 kg da^{-1} to 386.4 kg da^{-1} (Hatipoglu et al., 2005), increased green herbage yields from

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40514063

538.5 kg da^{-1} to 1228.5 kg da^{-1} and dry herbage yields from 337.6 kg da^{-1} to 808.0 kg da^{-1} (Gur, 2007), increased green herbage yields by 189.5% and dry herbage yields by 163.3% (Altin et al., 2010).

The greatest yields in present study were obtained from 10 kg da^{-1} nitrogen and 8 kg da^{-1} phosphorus treatments. Similarly, Cinar et al. (2005) in a tree-year study reported the greatest yield levels for 10 kg da^{-1} nitrogen and 5 kg da^{-1} phosphorus treatments, Hatipoglu et al. (2005) and Dasci et al. (2009) recommended 10 kg da^{-1} nitrogen treatments. Altin et al. (2005) recommended 7.5-10 kg da^{-1} nitrogen and 5-10 kg da^{-1} phosphorus treatments for high-altitude Eastern Anatolia pastures. Present findings comply with all those earlier ones.

The crude protein yield of control (0-0 kg da^{-1}) plot (23.8 kg da^{-1}) increased to 47.9 kg da^{-1} with fertilizer treatments. Since crude protein yield is obtained by multiplying dry herbage yield with crude protein ratio, the variations in crude protein yields were similar with the variations in dry herbage yields. The crude protein yields were almost doubled (101.3%) with fertilizer treatments. It was reported in previous studies that nitrogenous fertilizers increased crude protein yields (Andic et al., 2001; Polat et al., 2007; Balabanli et al., 2010; Budakli Carpici, 2011).

It was reported in previous studies that phosphorus fertilizers did not have significant effects on ADF and NDF ratios (Budakli Carpici, 2011; Budakli Carpici et al., 2012), nitrogenous fertilizers combined with phosphorus and potassium reduced ADF and NDF ratios (Balabanli et al., 2010) and increasing nitrogen doses decreased ADF ratios of the herbage (Budakli Carpici, 2011). In present study, effects of fertilizer treatments on ADF, NDF ratios and RFV were not found to be significant. Therefore, great variations in ADF, NDF ratios and RFV should not be expected from one-year fertilization plans. Thusly, Heady and Child (1994) reported that fertilizers did not improved chemical composition of the herbage, but increased freshness and leaf ratios and stay-green durations of the herbage. However, multi-year studies may reveal significant variations in ADF, NDF ratios and RFV of pasture herbage.

Conclusion

Present nitrogen and phosphorus treatments increased legume ratio in botanical composition, and also systematically increased green herbage yields, dry herbage yields, crude protein yields and relative feed values and reduced ADF and NDF ratios during the initial three years. There was a direct relationship between the precipitations and herbage yields, the lower values were observed in 2014 and 2017 with lower precipitations than the other years.

The effects of nitrogen and phosphorus doses on ADF, NDF ratios and relative feed values of the years were found to be significant, however, the effects of fertilizer treatments with the same year were not found to be significant. Therefore, significant changes in ADF, NDF ratios and relative feed values should not be expected from one-year fertilization programs.

Nitrogen and phosphorus treatments generally yielded greater values than the control plots. However, cost-benefit analyses should be performed while preparing fertilization programs and the doses yielding greater values than the general averages should be selected.

In present study, the greatest green herbage yield, dry herbage yield and crude protein yield were obtained from 10 kg nitrogen and 8 kg phosphorus treatments.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40514063

Therefore, this combination (10-8 kg da^{-1} N-P) could be recommended for fertilization programs to be applied over the pastures of Eastern Anatolia region or over the pastures with similar ecological conditions.

The effects of applied nitrogen and phosphorus doses on plant nutrients and soil structure were not investigated in this study. Therefore, it is suggested to investigate the effects of recommended 10 kg da^{-1} nitrogen and 8 kg da^{-1} phosphorus doses on the plant nutrients and the soil structure in the future.

Abstract. Citrus is a conventionally produced fruit crop in extensive agricultural areas in Mediterranean-type agroecosystems. The use of rootstocks for citrus fruits is necessary for profitable production under some limiting factors, such as climactic factors, bad soil conditions, and diseases. In addition, the use of the citrus rootstocks provides a large number of choices to growers to increase fruit quality and yield, obtain early fruiting, uniform cropping and high-density planting, avoid juvenility, and control tree size. The aim of the present study was to evaluate the effects of several citrus rootstocks on the fruit yield, quality, physiological changes in leaves and leaf mineral composition of Rio Red grapefruit. Thus, seasonal changes in the leaf chlorophyll concentration, PSII efficiency (Fv / Fm), stomatal conductance (g_S), leaf temperature, leaf mineral nutrient, fruit yield and fruit quality traits of the Rio Red grapefruit variety grafted onto six commonly used rootstocks (Carrizo citrange, citremon, sour orange, Swingle citrumelo, Troyer citrange and Volkameriana) in citriculture were evaluated. The physiological responses of fully expanded young leaves to rootstocks were significantly affected by seasonal changes. Two-way ANOVA indicated significant main effects of rootstock and season and their interaction ($p \leq 0.05$) on the leaf Chl concentration. Leaf Chl concentrations were lowest in April for all rootstocks. The PSII efficiency slightly decreased in the leaves of Rio Red grafted onto Volkameriana in February. The rootstocks significantly affected seasonal changes in the leaf stomatal conductance. The highest g_S was recorded in October in the leaves of a Rio Red variety grafted onto the Volkameriana rootstock. Significant rootstock effects on leaf Ca, Mg, Mn, Zn and Cu concentrations were observed in the Rio Red variety. The highest leaf Zn concentration (ppm) was recorded in plants on Volkameriana, whereas the lowest Zn concentrations were recorded in plants on Troyer citrange. There were no significant rootstock effects on leaf N, P, K and Fe concentrations. The rootstocks significantly affected the fruit yield of the Rio Red variety in the 2013 and 2014 harvest years. The highest fruit yield was observed in Rio Red grafted onto Carrizo citrange in 2013, whereas it was highest in plants on Troyer citrange in 2014. The fruit weight (g), fruit diameter (mm), total soluble solids (%), juice content (%) and juice color (hue^o) of Rio Red grapefruit were significantly affected by the rootstocks.
Keywords: *stomatal conductance, chlorophyll concentration, fruit quality, fruit juice color*

Introduction

The citrus growing areas of Turkey are situated in the northern hemisphere of the citrus belt. Turkey has very suitable ecological conditions and a high potential for citrus production; in fact, 4.293.007 t of citrus fruit was produced in Turkey in 2016 (TUIK, 2017). The eastern Mediterranean Region produces 80% of Turkey's total citrus fruit and 99% of its total grapefruit. In recent years, there has been a large increase in the exportation of citrus fruits, especially grapefruit. For example, Turkey produced 253.120 t of grapefruit in 2016 (TUIK, 2017) and exported 183.329 t of grapefruit in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40654080

same year (AKIB, 2017). Star Ruby is the dominant grapefruit variety of Turkey. It is followed Rio Red, which is the latest variety and was derived from ‘Redblush’ by bud irradiation.

Rootstocks have a substantial role in the development of the citrus industry. It is necessary to use rootstocks for citrus fruits to have profitable production under some limiting factors, such as climate, bad soil conditions, and diseases. In addition to these factors, the use of citrus rootstocks provides a large amount of choices to growers, enabling growers to, among other things, increase fruit quality and yield, obtain early fruiting and uniform cropping, avoid juvenility, control the tree size and perform high-density planting (Tuzcu et al., 2005). Choosing a rootstock is an important decision, and local climatic and soil conditions are important factors in rootstock selection. Although any citrus variety can be used as a rootstock, some of them are better suited to specific conditions than the others (Davies and Albrigo, 1994; Lawrence and Bridges, 1974).

Citrus rootstocks have a large impact on scion growth, fruit quality and yield (Castle, 1987; Georgiou, 2002; Forner-Giner et al., 2003; Castle et al., 2009; Hussain et al., 2013). In addition, scion behavior depends in part on the rootstock-induced effects on leaf gas exchange (González-Mas et al., 2009) and chlorophyll content (Garci-Sanchez et al., 2002). The influence of rootstocks on scion photosynthetic capacity may play a key role in citrus plant performances in terms of vigor, crop load, and fruit characteristics and should be considered (Jover, 2012). In the grafted tree, rootstock type affects many traits such as leaf mineral elements (Jr et al., 2003; Toplu et al., 2008). Rootstocks directly affect the ability of plants to uptake water and nutrients from soil. Plant nutrient concentrations in scion cultivars may differ, even though they are grown under the same conditions. For this reason, it is important to determine the effects of rootstocks on plant nutrient statuses to optimize fertilization programs.

Sour orange is the main rootstock (approximately 85%) used in citrus growing in Turkey, because of the high soil clay content and high pH (causing to iron, zinc and manganese chlorosis) of many soils in the country. Trees on sour orange produce excellent quality fruit but are susceptible to citrus tristeza virus (CTV) and poor compatibility with some citrus cultivars; in some cases, these trees produce low fruit yields compared to trees with other rootstocks (Castle et al., 2010; Shafieizargar et al., 2012). To address these problems, researchers and citrus growers have made an effort to look for alternative rootstocks. In the selection of a suitable rootstock, its adaptability to soil conditions and interactive effects with the scion cultivar have to be carefully considered (Shafieizargar et al., 2012). Given that rootstocks are unlike genotypes and modify growth, fruit production, photosynthetic capacity and leaf mineral composition, the present study aimed to determine the effect of several citrus rootstocks on the fruit yield, quality and leaf mineral composition of Rio Red grapefruit. In addition, the rootstock effects on the photosynthetic performance of the scion were assessed based on leaf chlorophyll concentration (Chl), chlorophyll fluorescence, stoma conductance and gas exchange measurements.

Materials and methods

Plant material and growing conditions

‘Rio Red’ grapefruit which is a normal appearing grapefruit (shape and rind texture) variety with attractive dark pink flesh was grafted on the following rootstocks: local sour orange (*Citrus aurantium* L.), ‘Troyer’ and ‘Carrizo’ citranges (*Citrus sinensis*

Osb. × *Poncirus trifoliata* (L.) Raf.), Volkameriana (*Citrus volkameriana* Tan. and Pasq.), Swingle citrumelo (*Citrus paradisi* Macf. x *Poncirus trifoliata*), and Citremon (*Citrus limon* x *Poncirus trifoliata).* The grafted trees were planted in 1997 with 8 × 8 m spacing at the Research Station of Cukurova University, Agricultural Faculty, Citrus Experiment Station, Adana (Latitude, 35°23' N; Longitude, 36°50' E, altitude 27 m), Turkey. A completely randomized experimental design was used, with five replicates for each combination. In the experimental area, the soil was a clay-loam (57% clay, 21% silt, and 22% sand, containing 12% CaCO3), and the soil pH was in the range of 7.39-7.46 at a depth of 0-90 cm and considered slightly alkaline. The salt content of the soil was 0.22 EC (mmhos cm-1). The area has a mean maximum and a mean minimum temperature of 26 and 14.5 °C, respectively, and an average annual rainfall of 465 mm (*Fig. 1*). The trees were irrigated weekly from May to October using drip irrigation. Nitrogen (N) was applied as Ammonium nitrate at a rate of 1.5 kg N tree^{-1} (2/3 in mid-February and 1/3 in mid-May), phosphorus (P) was applied as triple superphosphate at a rate of 1 kg P tree^{-1} (December) and potassium was applied as potassium nitrate (K) at a rate of 1 kg K tree^{-1} (January).

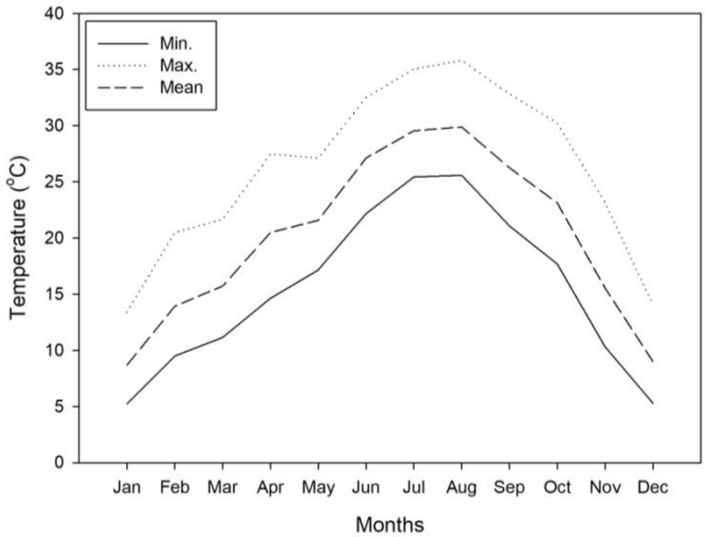

Figure 1. *Minimum, maximum and mean temperature data of the experimental field in 2016*

Fruit yield and quality

Rio Red grapefruit is mid to late-season in maturity with juicy and well pigmented flesh. The effects of different rootstocks on fruit yield were evaluated in 2013 and 2015. Each year, the fruit yield of each tree was determined during the harvesting period. Fruits were harvested at the optimum harvest time (at the end of December or at the beginning of January). The yield per tree (kg/tree) was obtained by weighing the harvested fruit.

A random sample of 25 grapefruits was evaluated for fruit quality analysis. The fruit samples were weighed, the fruit diameter at the equator was measured with a digital caliper, and the rind thickness was measured after cutting the fruit in half with a digital caliper (Mitutoyo CD-15CPX, Mitutoyo America Corporation, USA). The fruit samples were weighed and juiced using a standard juicer; then, the juice was weighed and expressed as a percentage of the total fruit weight. The total soluble solids (TSS) values

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40654080

were determined with a portable refractometer (FG-103/113) using a few drops of juice. The total acidity (TA) of the juice was determined by titrating 5 ml of the juice sample with 0.1 N sodium hydroxide (NaOH) and phenolphthalein as the indicator. Fruit juice color determinations were made at 25 ± 1 °C using a Hunterlab Colorflex (Hunterlab, Reston, Virginia, USA). This spectrophotometer uses an illuminant D65 and a 10° observer as references. A sample cup for the reflectance measurements was used (5.9 cm internal diameter × 3.8 cm height) with a path length of light of 10 mm. The results were expressed as the Hue angle [hab = arc tg (b*/a*)], which is determined as starting at the +a* axis and is expressed in degrees; 0% is +a* (red), 90% is +b* (yellow), 180% is -a* (green), and 270% is -b* (blue).

Leaf chlorophyll concentration and photosystem II efficiency

The leaf chlorophyll concentration was estimated using a portable SPAD meter (Minolta, Japan), and the chlorophyll fluorescence parameter ((*Fv' / Fm'*) = quantum yield in light-adapted leaves) was measured with a portable fluorometer (FluorPen FP100, Photon System Instruments Ltd, Drasov, Czech Republic). The evaluations of the chlorophyll concentration and fluorescence measurements were taken in six periods between 2015 and 2016. The same leaves were used to estimate the leaf chlorophyll (Chl) concentrations and PSII efficiency, based on the quantum yield of light-adapted leaves (*Fv' / Fm'*), The chlorophyll concentration and maximum chlorophyll fluorescence efficiency readings for the light-adapted leaves were measured on 10 fully expanded young leaves (third and fourth leaves from the shoot apex) of each replicate at the four chosen time points. Measurements were performed before midday (08^{00}-11^{00} h).

Leaf stomatal conductance measurements (g_s) and leaf temperature (°C)

After the leaf chlorophyll concentration and fluorescence measurements, the same leaves were analyzed by a portable SC-1 leaf porometer (Meter Group, Inc. USA) to estimate leaf stomatal conductance (mmol $m^{-2}s^{-1}$) and leaf temperature (°C). The stomatal conductance evaluations were conducted in five periods between 2015 and 2016. The stomatal conductance efficiency of leaves in the light-adapted stage was measured on 10 fully expanded young leaves (third and fourth leaves from the shoot apex) from each replicate at the four chosen time points (*Fig. 2*). Measurements were performed before midday (08^{00}-11^{00} h).

Figure 2. *A general view of the examined orchard and stomatal conductance measurements by porometer*

Leaf mineral content

Leaf samples were taken from the fruitless shoots in autumn for the analysis of plant nutri-elements in 2015, according to Chapman (1960). The leaves were washed in a detergent solution, rinsed several times in distilled water, and then dried at 70 °C for 48 h using a thermoventilated oven. The dried leaves were ground (<0.5 mm) and ashed in a muffle furnace at 550 °C for 8 h. The ash samples were digested in HNO_3-$HClO_4$ (3:1 v/v) and filtered through a blue band paper filter (Kacar, 1972). In the extract solutions, sodium (Na), potassium (K), magnesium (Mg), iron (Fe), manganese (Mn) and copper (Cu) concentrations were determined by inductively coupled plasma-atomic emission spectrometry (ICP-AES, Varian Liberty Series II), and the concentrations of phosphorus (P) were determined by UV-VIS spectrophotometry (Barton, 1948). The leaf total nitrogen (N) content was determined by the semi-micro Kjeldahl method (Lees, 1971).

Statistical analysis

Data were subjected to two-way analysis of variance (ANOVA), and significant differences between means were evaluated using Tukey's multiple range test at $p \leq 0.05$ and $p \leq 0.01$. All statistical analyses were performed by using SAS v9.00 statistics software procedures (SAS, 2006), and SigmaPlot® version 11.00 was used for the data presentation.

Results

Fruit yield and quality

Rootstocks significantly affected the cumulative yield. The highest cumulative yield of the Rio Red grapefruit in the three-year period was obtained from the trees on Carrizo and Troyer citrange, followed by those on Swingle citrumelo. Trees on Citremon, sour orange and *Volkameriana* had the lowest cumulative yield (*Fig. 3*). There were statistically significant differences in the fruit yield per tree between rootstocks, except for in 2015 (*Fig. 3*).

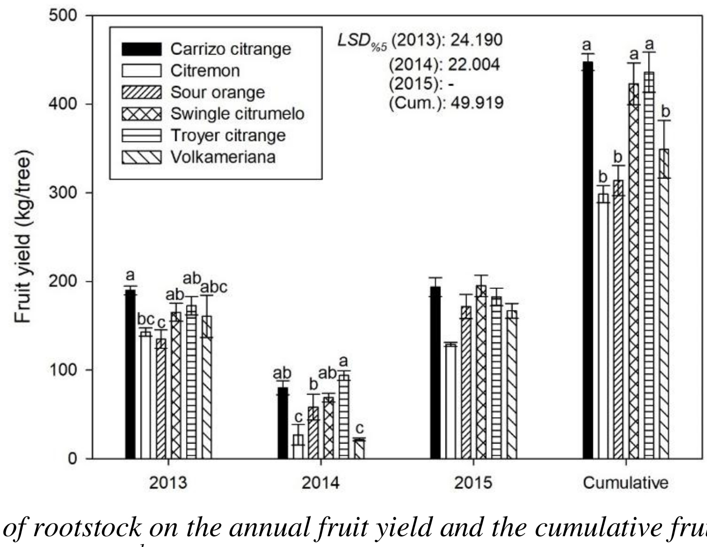

Figure 3. *Effect of rootstock on the annual fruit yield and the cumulative fruit yield over three consecutive years (kg tree^{-1}) of 'Rio Red' grapefruit. Error bars represent ± standard error*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40654080

In 2013, the highest yield was obtained from trees on Carrizo citranges, followed by trees on Troyer citrange and Swingle citrumelo. In 2014, the highest yield was obtained from trees on Troyer citrange, followed by trees on Carrizo citrange and Swingle citrumelo. In 2013, the lowest yield was obtained from trees on sour orange, followed by those on Citremon; in 2014, the lowest yield was obtained from trees on Volkameriana and Citremon, followed by those on Sour orange.

According to the results obtained from this study, Carrizo and Troyer citranges followed by Swingle citrumelo generally had the highest fruit yields during the three-year study period. The lowest yield was found for the trees on Citremon (*Fig. 3*).

The present study showed rootstocks had a significant effect ($p \leq 0.05$) on the fruit weight, fruit diameter, TSS and juice content of ‘Rio Red’ grapefruit (*Table 1*). The effects of rootstocks on the rind thickness, TA and TSS/TA ratio were not statistically significant, and all of the rootstocks gave similar values (*Table 1*). Fruits from trees on sour orange were significantly heavier than those on the other rootstocks, followed by fruits from trees on Swingle citrumelo and Troyer citrange. The lightest fruits were obtained from the trees on Citremon. The fruits from the trees on Troyer citrange had the highest fruit diameters. Trees on Citremon produced fruit with a small diameter. Rootstock had a significant effect on the total soluble solids (TSS). The highest TSS was detected in the fruits from the trees on *Swingle citrumelo* rootstock and the lowest TSS in the juice was obtained from the trees on Volkameriana. There were significant differences among the juice contents of fruits with different rootstocks. The juice content was the highest for fruits from trees on *Swingle citrumelo* and the lowest for fruits on other rootstocks.

Table 1. *Effects of rootstocks on the fruit quality parameters of ‘Rio Red’ grapefruit*

Rootstock	Fruit weight (g)	Fruit Diameter (mm)	Rind thickness (mm)	TSS (%)	TA (%)	TSS/TA	Juice content (%)
Carrizo	354.35 bcd	93.30 ab	6.76	9.50 ab	2.70	3.54	33.95 b
Citremon	335.15 d	90.85 b	6.80	9.58 ab	2.51	3.85	30.29 b
Sour orange	445.60 a	99.14 ab	7.23	8.93 b	2.47	3.67	29.73 b
Swingle	418.40 ab	98.36 ab	6.85	9.95 a	2.69	3.71	42.56 a
Troyer	415.10 abc	101.94 a	7.24	9.40 ab	2.64	3.56	31.84 b
Volkameriana	344.47 cd	94.98 ab	7.70	7.87 c	2.24	3.52	31.73 b
Prob>F	*0.0155*	*0.0362*	*0.6066*	*0.0062*	*0.1403*	*0.8517*	*0.0374*
LSD%5	*62.369*	*8.730*	-	*0.904*	-	-	*7.165*

The fruit juice color was significantly affected by rootstock ($p \leq 0.05$) (*Fig. 2*), and the juice hue^{o} values ranged between 43.11 and 51.84. The juice from trees on Carrizo citrange had the lowest hue^{o} (most red), followed by the juice from trees on Swingle citrumelo. The highest hue^{o} values were obtained from the trees on Sour orange and Volkameriana (*Fig. 4*).

Leaf chlorophyll concentration and fluorescence measurements (PSII efficiency)

The SPAD measurements were used as an estimate of leaf chlorophyll concentration because there is a positive linear relationship between these two parameters ($r^2 > 0.8$, Jifon et al., 2005). Two-way analysis of variance (ANOVA) indicated a significant main effect of rootstocks, sample date and their interaction ($p \leq 0.05$) on the Chl concentration (*Table 2*).

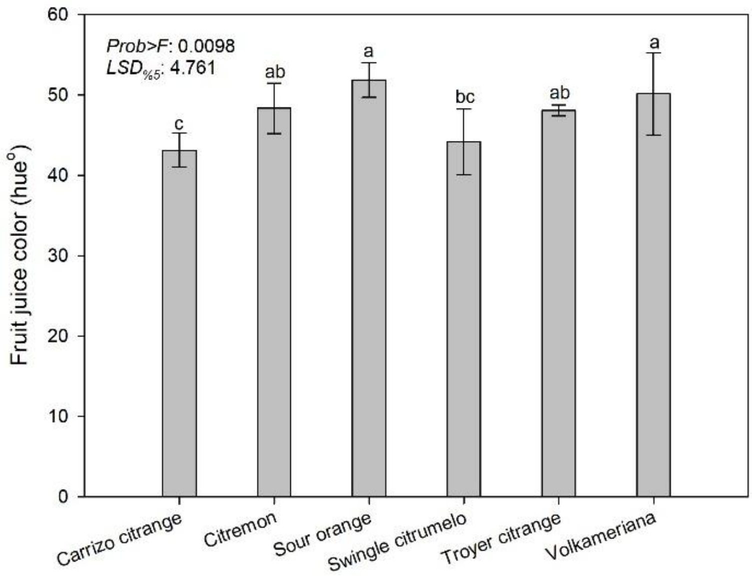

***Figure 4.** Effects of different rootstocks on the fruit juice color of 'Rio Red' grapefruit. Error bars represent ± standard error*

***Table 2.** Results of two-way analysis of variance (ANOVA) of the effects of rootstock (R) and season (S) and their interaction (R × S) for the dependent variables considered. Numbers represent F values. *p < 0.05*

Dependent variable	Independent variable		
	S	**R**	**S x R**
SPAD	296.73*	5.17*	1.84*
Fv'/Fm'	134.14*	4.29*	3.90*
g_s	250.27*	14.27*	6.80*
Leaf temperature	196.23*	4.08*	10.33*

As shown in *Figure 5a,* in the present study, the leaf chlorophyll concentration ranged between 36.20 and 72.25. Rootstocks significantly affected the leaf chlorophyll (Chl) concentration. The scion leaves of shoots grafted onto Troyer citrange and Volkameriana had the lowest Chl concentrations, whereas the leaves of shoots budded on to Citremon and Swingle citrumelo had the highest Chl concentration for nearly all periods. In terms of Chl measurements, statistically significant differences were found between the measurement periods. The lowest Chl was observed in April 2015 and 2016. The highest Chl was observed in February and October every year. According to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40654080

the interaction between the rootstocks and the sampling date, Troyer citrange has the lowest value of Chl in all periods (*Fig. 5a*).

At the end of the experiment, the PS II efficiency ranged between 0.503 and 0.737. Two-way analysis of variance (ANOVA) indicated a significant main effect of rootstocks and sampling date and their interaction ($p \leq 0.05$) on the PS II efficiency (*Table 2*). Rootstocks significantly affected the PS II efficiency of Rio Red grapefruit. The maximum quantum yield of PSII was the smallest in the leaves of shoots grafted onto Volkameriana and Troyer citrange; the highest maximum quantum yield of PSII was observed in the leaves of shoots grafted onto Sour orange and Citremon (*Fig. 5b*). In terms of measurement period and the maximum quantum yield of PSII, in 2015 and 2016, the highest values were in July and October, followed by those in April. The smallest values were observed in February 2015 and 2016.

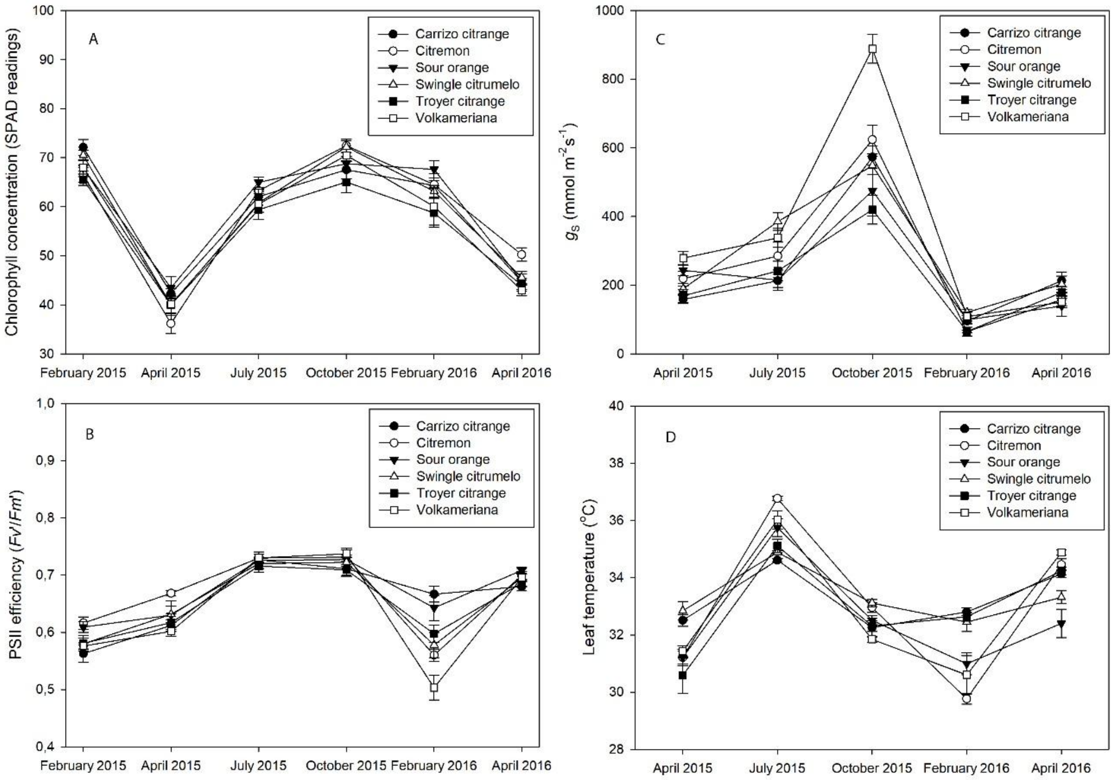

Figure 5. *Rootstock effects on the Chlorophyll concentration (A), PSII efficiency (B), stomatal conductance (C), and leaf temperature (D) of 'Rio Red' grapefruit. Error bars represent ± standard error*

Leaf stomatal conductance measurements (g_s) and leaf temperature (^oC)

As shown in *Table 2* in the present study, two-way analysis of variance (ANOVA) indicated a significant main effect of rootstocks and sampling date and their interaction ($p \leq 0.05$) on the leaf stomatal conductance and leaf temperature (°C). There were also significant differences among rootstocks in terms of leaf stomatal conductance (g_S). The highest leaf stomatal conductance values were recorded in the trees on Volkameriana in almost all measurement periods. The lowest g_S values were recorded in the leaves of shoots on Troyer citrange, followed by those in the leaves of shoots on Carrizo. In terms of measurement period, the highest *gs* was recorded in October 2015; the lowest g_S was recorded in February 2016, followed by April 2016. According to the interaction between the rootstocks and the sampling date, Troyer citrange had the lowest *gs* value in all periods (*Fig. 5c*). When all the measurement periods were examined, a decrease in leaf temperature due to the decrease in air temperature was clearly identified in the leaves of the trees grafted onto the Volkameriana and Citremon rootstocks. Decreases in stoma conductance were observed during periods when leaf temperature increased (*Fig. 5d*).

Leaf nutrients concentration

Leaf macro nutrients

The impact of rootstocks on the macronutrient concentrations of Rio Red leaves were significant, except for the N, P and K values (*Table 3*). There was no significant difference between the leaf N-K contents and rootstocks, but high N and K contents in the leaves of trees grafted onto the Volkameriana rootstock were found. The Ca and Mg contents in the leaves were affected by rootstocks. The leaf Ca content was significantly highest in trees on sour orange, while it was the lowest in trees on Volkameriana, followed by trees on Troyer citrange. The magnesium (Mg) contents of the trees on the Troyer and Carrizo citranges were significantly higher than those of trees on all other rootstocks, while the minimum Mg contents were recorded in trees on Volkameriana and Swingle citrumelo.

Table 3. *Rootstock effects on the leaf mineral nutrients of 'Rio Red' grapefruit*

Rootstock	%N	% P	% K	% Ca	% Mg	ppm Fe	ppm Mn	ppm Zn	ppm Cu
Carrizo	2.42	0.11	0.74	5.13 ab	0.34 a	85.70	46.10 cd	24.86 bc	13.82 a
Citrumelo	2.50	0.11	0.88	5.03 ab	0.32 c	71.54	48.53 bc	26.12 b	11.35 ab
Sour orange	2.56	0.10	0.76	5.35 a	0.25 b	73.17	51.17 ab	25.27 bc	12.67 a

Prob>F	*0.6518*	*0.1466*	*0.1477*	*0.0244*	*0.0001*	*0.6620*	*0.0002*	*0.0005*	*0.0230*
LSD%5	-	-	-	*0.560*	*0.022*	-	*2.786*	*1.381*	*2.781*

Leaf micro nutrients

The concentration of micro-nutrients in the leaves of the Rio Red grapefruit cultivar was also significantly affected by rootstock-scion combinations, except for Fe (*Table 3*). The Rio Red/Volkameriana combination accumulated the highest scion leaf Mn and Zn concentrations, but the lowest concentrations of these micronutrients were recorded in the Rio Red/Troyer citrange combination. The leaf Cu content was significantly highest in trees on the Carrizo and Troyer citrange, Swingle citrumelo and sour orange rootstocks, while it was the lowest in trees on the Volkameriana rootstock, followed by the Citremon rootstock.

Discussion

Yield is the leading agronomic property for producers (Koepke and Dhingra, 2013) Most horticultural characters, such as tree growth, yield and quality, are influenced by rootstocks (Davies and Albrigo, 1994). In this study, rootstocks induced significant changes in fruit yield and some quality parameters. The highest cumulative yield of the 'Rio Red' grapefruit in the study period of three consecutive years (2013, 2014 and 2015 seasons) was obtained from the trees on the Carrizo and Troyer citranges and the Swingle citrumelo. Trees on the Citremon, Sour orange and Volkameriana rootstocks had the lowest cumulative yield. Previous studies have found that Carrizo citrange has positive effects on the fruit yield of Redblush and Marsh seedless grapefruits (Fallahi, 1992; Yalcın and Hızal, 1994; Tuzcu ve Toplu, 1999). In addition, in their study of Marsh seedless grapefruits, Mehrotra et al. (1999) reported that the Carrizo citrange rootstock had positive effects on yield. Despite these results, Ramin and Alirezanezhad (2005) reported that Volkameriana was the most productive rootstock for Marsh seedless and Redblush grapefruit. Volkameriana is a productive rootstock, and trees on Volkameriana may show high productivity. In this study, the low yield of trees on Volkameriana was probably due to the extremely low winter temperatures in the 2014 and 2015 seasons. The results obtained for sour orange productivity are in agreement with those of Louzada et al. (2008), who reported that 'Rio Red' trees on sour orange had the lowest yields compared to the other rootstocks evaluated, except for Goutou sour orange. In addition, Sharma et al. (2016) reported that sour orange was a low-yield rootstock for the Redblush grapefruit variety. Yield is controlled by rootstocks in fruit crops (Bassal, 2009) and the rootstocks induced changes in yield depending on the crop and type of rootstocks (Whiting et al., 2005). Based on the results of the current study on Rio Red grapefruit scions, Carrizo and Troyer citranges are very promising alternative rootstocks.

Fruit size is a valuable trait for both producers and consumers. Fruit size is one of the most important factors affecting the marketability of fresh citrus fruits, and medium- to large-sized fruits contribute maximum consumer returns in fresh markets. The present study showed rootstocks had significant effects on the fruit weight. The heaviest fruits were obtained from the trees on Sour orange, followed by the trees on Swingle citrumelo and Troyer citrange, while the Citremon rootstock produced the lightest fruit. Fruit diameter was significantly affected by rootstocks, and fruits from the trees on Troyer citrange had the highest fruit diameters. The trees on Citremon produced fruit with a small diameter. The results obtained in the present study are in agreement with those described in a previous report by Sharma et al. (2016), who studied the effects of rootstocks on the fruit quality of Marsh seedless grapefruit and indicated that Marsh seedless on Troyer citrange produced the heaviest fruit. Similar results have been reported for Redblush (Fallahi et al., 1989; Yalcin and Hizal; 1994), Marsh seedless (Mehrotra et al., 1999), and Lane Late (Emmanouilidou and Kyriacou, 2017), for which the highest fruit weights were recorded from trees on Carrizo and Troyer citranges. In their study of Marsh seedless grapefruit, Economides and Gregoriou (1993) concluded that the largest and heaviest fruits were produced by trees on the rough lemon group, Palestine sweet lime, Rangpur lime, Carrizo citrange and *C. volkameriana*. The TSS contents were higher in fruits from trees on Swingle and lower in fruits from trees on Volkameriana, followed by sour orange. The juice content per unit weight was higher for trees on Swingle citrumelo and lower for those on *C. volkameriana*. These results are in agreement with those of previous work, in which the fruits with the highest TSS contents were from trees on Swingle citrumelo (Economides and Gregoriou, 1993; McCollum et al., 2002), and the lowest TSS contents were from trees on Volkameriana (Fallahi and Rodney, 1992; Stuchi et al., 2002; Ramin and Alirezanezhad, 2005; Emmanouilidou and Kyriacou, 2017). Variations in juice content due to rootstocks have also been reported in citrus (Economides and Gregoriou, 1993; Sharma et al., 2016). Fruit quality characters are important variables, as grapefruit is grown for fresh consumption and processed for its deep red coloration (Castle, 2012), which is highly influenced by the rootstock (Forner-Giner et al., 2003). Carrizo citrange and Swingle citrumelo produced fruit with more color, and the lowest color values were obtained from the trees on Sour orange and Volkameriana. Other researchers have also reported (Tuzcu et al., 1999; García-Sánchez et al., 2006; Bassal, 2009) that the fruits with the best color values were obtained from trees grafted on citranges.

Chlorophyll fluorescence is very useful to study the effects of environmental stresses on photosynthesis in plants (Bron et al., 2004). The maximum quantum yield of PSII was the smallest in the leaves of shoots grafted onto Volkameriana and Troyer citrange. Pestana et al. (2001) indicated that the chlorophyll fluorescence parameters of 'Newhall' orange grafted on 'Troyer' citrange slightly decreased under Fe-deprived conditions. González-Mas et al. (2009) reported clear decreases in the leaf chlorophyll fluorescence parameters of Navelina orange trees grafted onto Carrizo citrange growing in calcareous soil. In addition, Pestana et al. (2001) indicated that the chlorophyll fluorescence parameters of Newhall orange grafted onto Troyer citrange were slightly decreased under Fe-deprived conditions.

Our results demonstrate that rootstocks significantly affected leaf chlorophyll (Chl) concentrations. The scion leaves of shoots grafted onto Troyer citrange and Volkameriana had the lowest Chl concentrations, whereas the leaves of shoots budded onto Citremon and Swingle citrumelo had the highest Chl concentrations for nearly all periods. The results obtained in the present study are in agreement with those described in a previous report by Aboutalebi et al. (2012), who reported that rootstocks had significant effects on the leaf chlorophyll content of Valencia orange. In addition, González-Mas et al. (2009) indicated that the leaf Chl concentration of Navelina orange grafted on Carrizo citrange and grown in the calcareous soils of the Mediterranean region was lower than those of the other rootstocks evaluated. Considering the soil of the study area had 12%$CaCO_3$ and a slightly high pH level, the decreases in the leaf Chl concentrations of Rio Red grafted onto Troyer citranges are in agreement with the results of González-Mas et al. (2009).

There were also significant differences between the rootstocks in terms of leaf stomatal conductance (g_s). The highest the g_s value was recorded in the trees grafted onto Volkameriana; the lowest g_S values were recorded in the leaves of shoots on 'Troyer' citrange followed by the leaves of shoots on Carrizo. Chouliaras et al. (2004) indicated that gs was significantly reduced in two orange cultivars on Swingle citrumelo. Similarly, Incesu et al. (2015) reported that 'Valencia' scion grafted on 'Swingle' citrumelo had a significantly lower stomatal conductance (mol m^{-2} s^{-1}) that scion grafted onto other rootstocks grown in calcareous soil. Fe deficiency has a noticeable effect on the g_s of leaves because of the importance of Fe in many enzyme systems and in energy transfer during photosynthesis. Trees that were not affected by the calcareous soil had higher chlorophyll contents and photosynthesis values, which were associated with increased g_s values, as previously observed (Flexas et al., 2001; Afrousheh et al., 2010). Regarding the measurement periods, g_s values decreased in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40654080

periods when the leaf temperature became too high (>35 °C). The highest response of stoma conductance to changes in leaf temperature was detected for the Citremon and Volkameriana rootstocks. This may be due to the lemon hybridization of both rootstocks. In citrus plants, the optimum temperature for g_s is ≈ 30 °C (Khari and Hall, 1976). In addition, Ribeiro et al. (2004) indicated that the g_s values of sweet orange seedlings decreased as leaf temperature increased.

Rootstock had a meaningful impact on nutrient absorption, and the nutrient uptake efficiency varied with rootstock (Parvaneh et al., 2011). Taylor and Dimsey (1993) indicated that rootstock type and scion cultivar had different effects on the mineral element concentrations of scion leaves. In our experiment, there was no significant difference between the leaf N-K contents and rootstocks, but considerably high N and K contents in the leaves of the trees grafted onto the Volkameriana rootstock were observed. Barakat et al. (2013) reported that Volkamer lemon generally produced significantly higher N, P, K and Mg contents compared to sour orange. Georgiou (2000) showed that P and K in Nova mandarin leaves were induced by the Volkamer lemon rootstock. Similar results have been detected for Ca in previous studies, and higher Ca contents have been reported for trees on sour orange than for trees on other rootstocks (Toplu et al., 2008; Barakat et al., 2013; Dubey and Sharma, 2016). Citrange rootstocks produced higher concentrations of leaf Mg. These findings are in agreement with those of Taylor and Dimsey (1993) in Valencia and Navel oranges, Toplu et al. (2008) in Rhode Red Valencia and Valencia late, and Dubey and Sharma (2016) in Kagzi Kalan lemon.

Rootstocks significantly influenced the leaf Mn, Zn and Cu contents. The lower foliar Mn in trees on Troyer citrange reported by Iyengar et al. (1982), Toplu et al., (2008), Dubey and Sharma, (2016) is also supported by our results. Similar to previous studies, trees on Volkameriana had sufficient levels of leaf Zn, which were significantly higher than those in trees on Troyer citrange (Platt, 1981; Fallahi and Rodney, 1992). When compared to the budding of trees on Volkameriana, the budding of trees on citranges and other trifoliate orange hybrids accumulated the highest leaf Cu contents in Rio Red. This result is compatible with the findings of Fallahi and Rodney (1992). Differences in leaf nutrient concentrations might be due to the alteration of root morphology and hydraulic conductance due to scion morphology and physiology (Save et al., 2000; Sharma et al., 2016).

Conclusion

In this study, we evaluated the influences of rootstock on the fruit yield, quality, leaf mineral composition and photosynthetic performances of ‘Rio Red’, which is an economically important grapefruit cultivar in Turkey. The results indicated that rootstock had significant effects on the evaluated variables. Fruit yield and quality were affected by the use of rootstocks. Carrizo and Troyer citrange and Swingle citrumelo rootstocks achieved the highest cumulative yields and improved the quality of fruits. The fruits with the lowest quality were obtained from trees on Volkameriana. In addition, fruit juice color is an important variable because grapefruit is grown for fresh consumption and processed because of its deep red color. Carrizo citrange produced fruit with more color than the fruit of other rootstocks. Rootstocks had different abilities to utilize plant nutrient elements; considering the yield, fruit quality and mineral nutrient uptake, Carrizo and Troyer citranges are suitable rootstocks for Rio Red

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40654080

grapefruit grown under Mediterranean region conditions. Based on the chlorophyll content, gas exchange and the chlorophyll fluorescence parameters, “Rio Red” scion grafted onto the ‘Troyer’ and Carrizo citranges were affected by calcareous soil. On the other hand, trees on the sour orange rootstocks were shown to perform much better in calcareous soil. Considering its overall performance and its CTV resistance, Carrizo is a promising rootstock alternative to Sour orange, particularly in calcareous soils.

(Received 19th Apr 2018; accepted 13th Jun 2018)

Abstract. Mangrove sediment and mangrove plant *Soneratia caseolaris* in Songkhla Lake, Thailand have been increasingly threatened by trace metal pollution. Mangroves receive trace metal pollution from upstream areas and the sea. However, little is known about the mangrove plant's capacity to uptake and store trace metals. In this study, the concentrations of As, Cd, Pb and Zn in mangrove plant parts (leaf, root, and bark) of *Sonneratia caseolaris* and sediments were determined. Sediment and plant samples were digested using total metal concentration procedure and ICPMS techniques. It was found that the maximum values of total concentrations of As in mangrove sediments were classified as heavily polluted according to USEPA. The highest concentrations of As and Zn were found to be in bark whereas Cd and Pb in the root. The fractions of all the metals were measured using BCR techniques and their results revealed that the bioavailability fraction was greater than the residual fraction. The order of the amounts of trace metals present in the fractions was as follows; As: Oxidizable > Reducible > Residual > Exchangeable and the order of Cd: Exchangeable > Reducible > Oxidizable > Residual. Both BCF and TF values showed limited accumulation of these elements in their aboveground parts and thus presented a low food chain hazard except at Phawong and U-Taphao canals.
Keywords: *BCR techniques, coastal lagoon, BCF, TF, food chain*

Introduction

Mangrove forest is a group of trees and shrubs and commonly found in coastal areas. Mangrove is like a connection place between land and sea and important to the ecosystem especially to the aquatic population. Mangroves are an important food source of aquatic fauna in the tidal areas. In addition, the elongated root system makes it possible to trap sediment and trap pollutants such as trace metals. Generally, mangrove increases metal accumulation in sediments by modifying the soil acidity, redox potential, organic contents and salinity (Zhou et al., 2010; Sekomo et al., 2011) and subsequently reduces metal exposure to adjacent aquatic environment (Nath et al., 2013). Active uptake requires metabolic energy and takes place against a chemical gradient. The rate of heavy metals uptake is corresponding with its available pool at the root surface (Lanno et al., 2004). For example, when As, Cd and Pb are present in soluble forms in pore water, plant roots are able to take up great amounts of these metals. The uptake rates increase as concentration in the solutions increase. The plant uptake is also affected by temperature. According to Pendias and Pendias (2001), a higher ambient temperature influences a greater uptake of trace metals by plants.

It is widely recognized that the adverse impact of heavy metals does not simply depend on their concentrations but critically on their bioavailable fraction of the total metal

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40814095

concentration in sediment (Kim et al., 2015; Tokalioglu et al., 2000). Toxicological bioavailability is defined as a bioaccumulation effect of heavy metals within plants. Among various pollutants, trace metals with persistence, non-biodegradation, toxicity and bioavailability pose a major threat to the mangrove biodiversity and human health (Liu et al., 2014). Mangroves have the capacity to contain trace metals by accumulating them in their sediments and plant tissues (MacFarlane et al., 2003). Accumulation of these metals also can cause potential problems to animals and human through food chain interaction (Hosani and Anouti, 2014).

Soneratia caseolaris is one of the mangrove trees found in Songkhla lake, Thailand and a lead or pioneer species. In the Outer Section of Songkhla Lake, *Soneratia caseolaris* is generally found at the mouth of the Phawong canal and U-Taphao canal and Kuannieng District, the Middle Section of Songkhla Lake is found in Kukhut non hunting areas as well. In the Songkhla Lake, there were several studies on trace metal contamination in the mangrove sediment but little is known about heavy metal uptake by mangrove plant (*Sonneratia caseolaris*). Therefore, the aims of this study were to determine the bioavailability of As, Cd, Pb and Zn in mangrove sediments of the Songkhla Lake using modified European Community Bureau of Reference (BCR) sequential extraction procedure and to analyze the accumulation of trace metals (As, Cd, Pb and Zn) in mangrove sediment and mangrove plant parts (leaves, root, bark) of *Sonneratia caseolaris.*

Material and method

Study area

The Songkhla Lake is a shallow coastal lagoon located in the southern part of Thailand and occupies approximately 1,042 km^2 formed by an interaction of land and ocean processes over geological time (Sompongchaiyakul and Sirinawin, 2007). The lake is divided into 4 sections; Thale Noi, Inner Section, Middle Section and Outer Section. The salinity ranges from fresh water in Thale Noi to saline water in the Outer Section. The Outer Section is connected to the Gulf of Thailand through a deep and narrow outlet at Songkhla city. The system receives runoff and wastewater from the surrounding watershed. The runoff carries sediment onto the lakes, which will be transported through the lake by the general movement of water towards the Gulf of Thailand. According to the EmSong Project (1998), the average residence time of the water mass in the Inner, Middle and Outer Lakes is 55, 28 and 15 days respectively. The average sediment accumulation rate of in the lake is 2.5-3.5 mm/year and at some places it is higher than 15 mm/year (Sojisuporn, 2005). The average depth of Inner, Middle and Outer Lakes is 2, 1.5 and 1.5 meters, respectively. The lake is facing problems of environmental degradation due to urban expansion and industrialization. Sources of pollutants to the lake system include municipal wastes from Hat Yai and Songkhla cities, industrial wastes mainly related to the rubber industries, seafood processing industries, mining activities and pollution from boats in Songkhla harbour (Sompongchayakul and Sirinawin, 2007; Pradit et al., 2010).

Sample collection and preparation

The sediment cores were collected from 4 stations (*Fig. 1*) which were located in the Middle Section (station 1: Kukhut non hunting area) and in the Outer Section (station 2: Kuannieng, station 3: Phawong canal and station 4: U-Taphao canal). The selected station

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40814095

based on the appearance of *Soneratia caseolaris* was found in the Middle Section (Kukhut non hunting area; station 1) and in the Outer Section of the lake (Kuannieng, Phawong and U-Taphao canals). The survey was carried out in November, 2016.

The surface of mangrove sediment (0-10 cm) was taken from the active root zone using a Plexiglas tube (5 cm diameter and 30 cm length) by pushing into the bottom sediment with 3 replicates for each station. After that the sediment cores were sectioned 5 cm (1 core got 2 pieces) and then packed into a plastic zip lock, labeled and put in to a plastic container before being transported to the laboratory.

Mangrove plant*; Sonneratia caseolaris* samples consisted of root, bark and leaf. The leaves (old leave = yellow colour, mature leave = green colour and young leaves) were collected by hand pick (in total about 30 leaves per stations) whereas roots (about 10 roots per station) and barks (about 5 pieces; each piece about 3 × 5 cm) were collected using a ceramic knife. The plant samples were stored in clean plastic bags. The 200 g wet sample (plant and sediment) of each station was put on tray and then oven dried at 50 °C, homogenized and grinded in a mortar and sieved through a 1 mm nylon sieve and then stored in plastic zip locked bags with label and kept in desiccators prior to further analysis.

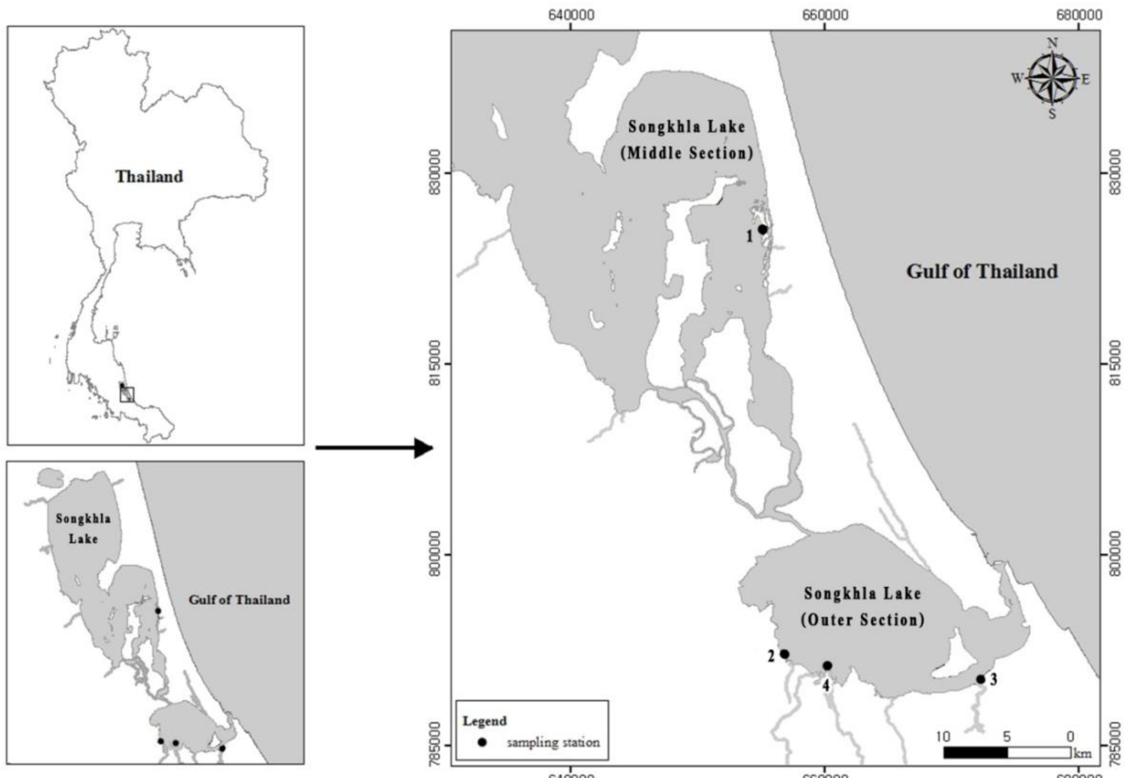

***Figure 1.** Map of sampling station in Songkhla Lake (station 1: Kukhut non hunting area; station 2: Kuannieng; station 3: Phawong canal; station 4: U-Taphao canal)*

Sample analysis

The bulk sediment samples (about 0.1 g) were totally digested in an acid mixture (5 ml HCl: 8 ml HNO_3: 2 ml HF) and analyzed for trace metals, according to the published methodologies of Noriki et al. (1980) Chojnacka et al. (2004) and Loring and Rantala (1992), with some modifications (the Teflon vessels were heated in an oven instead of a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40814095

microwave until complete digestion of the sample occurred). The amounts of trace metals (As, Cd, Pb and Zn) were measured by ICP-MS (Perkin Elmer Elan 9000). The sediment certified reference material; SRM 1646/estuarine sediment was similarly analyzed to validate the accuracy of the analytical procedure .The analytical values were within 90 %of the certified values, which demonstrated the validity of the methods applied. Plant sample was digested in a closed teflon vessel. Sample of 0.5 g was dissolved in 5 ml of HNO_3 (Chojnacka et al., 2004). Concentrations of As, Cd, Pb and Zn in digested samples were then determined by Inductively Coupled Plasma Mass Spectrometry (ICPMS). Standard reference material for plant (Peach Leaves: NIST 1547) was digested following the same procedure and analyzed for metal concentrations to validate accuracy and precision of the analysis.

Sequential extraction of mangrove sediment was performed using the revised BCR protocol (Rauret et al., 1999) briefly describes as follows:

Step 1 (Fraction 1: Exchangeable and acid soluble fractions): 40 ml of 0.11 mol/l acetic acid was added to 1 g of the air-dried sediment sample in a 50 ml polyethylene centrifuge tube. The tube was shaken for 16 h at room temperature at a speed of 23 ± 1 rpm. The extract was separated from the solid residue by centrifugation (3000 rpm for 20 min), decanted into a polyethylene bottle and stored at 4 °C. The residue was washed by shaking with 20 ml of distilled water for 15 min and centrifuging after which the supernatant was discarded.

Step 2 (Fraction 2: Reducible fraction): 40 ml of 0.5 mol/l hydroxylamine hydrochloride (adjusted to pH 1.5 by addition of a fixed amount of HNO_3) was added to the residue from step 1, and the extraction performed as in step 1 above.

Step 3 (Fraction 3: Oxidizable fraction): 10 ml of 8.8 mol/l hydrogen peroxide was added in aliquots to the residue from step 2. The vessel was covered loosely and the contents were digested at room temperature for 1 h with occasional agitation. It was then placed in a water bath and digested at 85 °C until the volume was reduced to less than 3 ml. Another 10 ml of the hydrogen peroxide was added, and further heated to near dryness. Thereafter, 50 ml of 1.0 mol/l ammonium acetate (adjusted to pH 2 with HNO_3) was added, and the extraction was performed as in the previous steps.

Step 4 (Fraction 4: Residual fraction): The residue from step 3 was transferred into a suitable vessel and the metal content was determined by microwave-assisted digestion with *aqua regia* .This step was for analyzing the metals content in their primary and secondary minerals.

The trace element (As, Cd and Pb) content of each fraction was analyzed using ICP-MS model Perkin Elmer Elan 9000.

Data analysis and statistical

Two comparative measures were chosen to assess the trace metals uptake and distribution within the plant. Bioconcentration factor (BCF) and translocation factor (TF) was calculated using the following equations:

$$\mathrm{BCF} = [\text{plant tissue}] \,/\, [\text{sediment}]$$

$$\mathrm{TF} = [\text{shoot}] \,/\, [\text{root}] \quad (\mathrm{TF} > 1\text{: high mobility})$$

where [ ] is metal concentration in μg/g.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40814095

In order to evaluate the degree of trace metal amount in the mangrove sediments of mangrove ecosystem, ecological risk assessment was conducted using the Håkanson, ecological risk index (R_I) (*Eqs. 1* and *2;* Håkanson, 1980).

$$R_I = \sum Er^i = \sum Tr^i Cf^i \qquad \text{(Eq.1)}$$

$$Cf^i = C_o^i / C_n^i \qquad \text{(Eq.2)}$$

where:
R_I = the sum of all risk factors for heavy metals in sediments
Er^i = the monomial potential ecological risk factor
Tr^i = the toxicity coefficient which represents the toxic response factor for a given metal. The value of Tr for As, Cd, Pb and Zn is 10, 30, 5 and 1 respectively
Cf^i = the contamination factor
Co^i = the concentration of metal in the sediment of mangrove ecosystem
Cn^i = the background value of heavy mental in coastal sediment

Statistic analysis

The data analysis using ANOVA to detect if any significant difference in mean exited between the mangrove sediment and plant parts. Duncan's new multiple range test (DMRT) was used to describe the differences between the variables (sediment and plant parts). Significance was set at 95% confidence level. Correlation was used to clarify the relationship between sediment fractions and metal accumulation in plant parts.

Results

Sediment characteristic in mangrove sediment

The metal concentrations in sediments from of Songkhla Lake (*Table 1*) ranged from 20.4 (station 1) - 50.5 (station 2) µg/g dry weight for As, 0.006 (station 4) -0.182 (station 3) µg/g dry weight, for Cd, 48.8 (station 4) -78.8 (station 1) µg/g dry weight, for Pb and 48.6 (station 4) -126.6 (station 1) µg/g dry weight, for Zn. The amounts of As, Zn and Pb were highest at Kuannieng (station 2) whereas Cd was highest at Phawong canal (station 3). The amounts of Zn, Cd and Pb were lowest at mouth of U-Taphao canal (station 4) whereas As was lowest at Kukhut (station 1). Besides that the results of the selected physical properties of sediment and water samples were summarized in *Table 1*. The pH in water ranged from 7.03 – 7.85 and in sediment ranged from 6.71-7.53. Salinity ranged between 8 ppt (station1) – 20 ppt (station 2).

Table 1. *Trace metals, physical properties of sediment and water in Songkhla Lake*

Station	pH water	Salinity (ppt)	pH sed	Eh (mV)	As	Zn	Cd	Pb
					µg/g dry weight (in sed.)			
St.1	7.33	8	7.53	-292	20.35	86.5	0.0759	59.8

Accumulation of trace metals in Sonneratia caseolaris

Accumulation of trace metals (As, Cd, Pb and Zn) in *Sonneratia caseolaris* is shown in *Table 2* and summarized as below:

As: The amount of As ranged from 0.20-4.72 µg/g dry weight. It was found that the concentration of As was highest in the barks (4.72 µg/g dry weight) at U-Taphao Canal (station 4), followed by roots (1.51 µg/g dry weight) and old leaves (1.03 µg/g dry weight).

Cd: The amount of Cd ranged from 0.003-0.041 µg/g dry weight. The result revealed that the concentration of Cd was highest in root (0.041 µg/g dry wt.) at Phawong canal (station 3), followed by old leaves (0.033 µg/g dry weight), green leaves (0.029 µg/g dry weight) and barks (0.029 µg/g dry weight).

Pb: The amount of Pb ranged from 0.18-6.76 µg/g dry weight. It was found that the concentration of Pb was highest in the root (6.76 µg/g dry wt.) at U-Taphao canal (station 4), followed by bark (4.12 µg/g dry weight) and old leaves (2.74 µg/g dry weight).

Zn: The amount of Zn ranged from 2.66-35.80 µg/g dry weight. The result showed that concentration of Zn was highest in the bark (35.80 µg/g dry wt.) at Kuannieng (station 2), followed by young leaves (17.10 µg/g dry weight) and root (16.58 µg/g dry weight).

Overall the amounts of trace metals were in order Zn > Pb > As > Cd.

Trace metal speciation in mangrove sediment

The speciation of As, Cd and Pb in the mangrove sediment samples from the Songkhla Lake using the BCR protocol were presented in *Figure 2*.

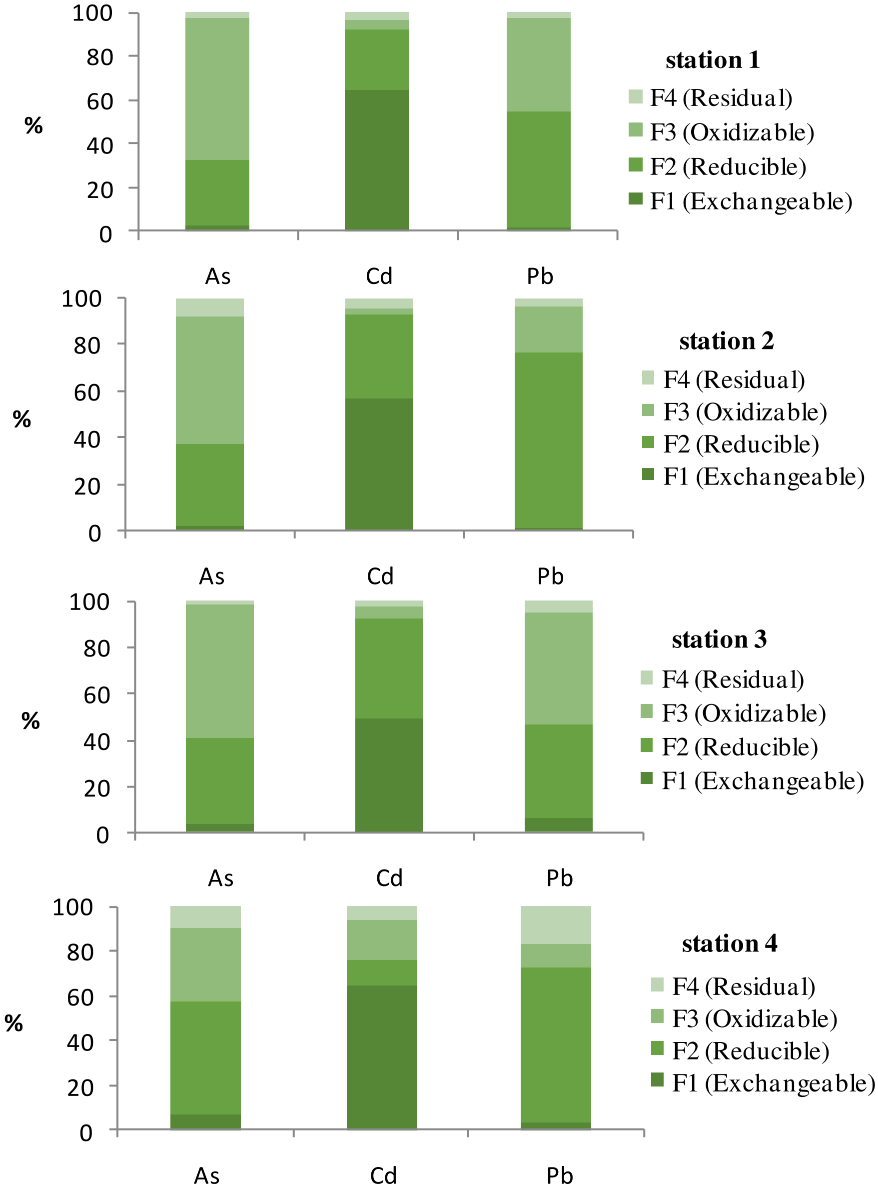

Figure 2. *The speciation distribution of As, Cd and Pb in mangrove sediments in Songkhla Lake, Southern Thailand*

The results of the sequential extraction for overall stations were as follows:

Exchangeable and acid soluble fraction (F1): Cd (49.58% - 64.33%) was found dominant in the acid-soluble fraction (F1), associated with exchangeable cations and carbonates for all the stations.

Reducible Fraction (F2): Pb (40.89% - 74.81%) was found dominant in F2 in all the stations except station 3 .This fraction is readily available with medium mobility and may be released into the environment under unstable anoxic conditions.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40814095

Oxidizable fraction (F3): As (32.47% - 64.76%) was found dominant in F3 at all the stations except station 4 .Metals bound to organic matter are reasonable stable in nature however under strong oxidizing conditions such as currents, dredging, flooding and tides the organic matter can be degraded, hence leading to a release of heavy metals bound to this component (Sarkar et al., 2014; MacFarlane and Burchett, 2000).

Residual fraction (F4): Pb (2.60% - 16.49%) was found highest in F4. The residual solid normally consists of mainly primary and secondary minerals that retained heavy metals within their crystal structure. They are regarded as immobile and unavailable fraction.

As: Oxidizable (F3) > Reducible (F2) > Residual (F4) > Exchangeable (F1)
Cd :Exchangeable (F1) > Reducible (F2) > Oxidizable (F3) > Residual (F4)
Pb: Reducible (F2) > Oxidizable (F3) > Residual (F4) > Exchangeable (F1)

Bioaccumulation factors (BAF) and transfer factors (TF)

The bioconcentration factor (BCF) of *Sonneratia caseolaris* in different plant parts was varied as As>Cd>Zn> Pb. The BAF of Zn, As, Cd and Pb was shown in *Table 3*. The bioconcentration factor (BCF) was always below 1 for all the trace metals and all the stations except As (1.06) in old leave at Phawong canal (station 3) and Cd in old leave (1.02) at the U-Taphao canal (station 4). These results suggested that *Sonneratia caseolaris* showed the limited uptake of Zn and Pb (BCF < 1) but surprisingly not for As and Cd which BCF > 1 in old leave was found in Phawongcanal (station 3) and U-Taphao canal (station 4).

Table 3. *Bioconcentration factor (BCF) of Zn, As, Cd and Pb in Sonneratia caseolaris of Songkhla Lake*

Station	Plant part	Zn	As	Cd	Pb

Y = young leave, M = mature leave (green colour), O = old leave (yellow colour)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40814095

The translocation factor (TF) of *Sonneratia caseolaris* in different plant parts varied as Cd >As>Zn> Pb (*Table 4*). The TF value of Zn ranged 0.16 -1.47 µg/g dry weight; As ranged 0.02-2.55 µg/g dry weight; Cd ranged 0.10-7.60 µg/g dry weight; Pb ranged 0.03-1.48 µg/g dry weight. The TF of these metals was above 1 at some stations and below 1 at other stations. At U-Taphao canal (station 4) TF value was above 1 for Zn, As, and Cd. TF value of As and Cd in old leave was greater than one at station 4 and 1. TF value of Pb in old leave was greater than one at station 2. TF value in bark was greater than 1 for Zn at station 1 and 4; As at station 4; Cd at station 1 and 4; Pb at station 2. Thus the result revealed that this plant species was effectively transferring Cd to the aerial parts. The TF of Pb was always below 1 (except station 2 in bark and station 3 in old leave), which might be described as having moderate mobility for this metal.

Table 4. *Translocation factor (TF) for mangrove plant parts*

Ecological risk index of heavy metals in mangrove sediments of different areas

The potential ecological risk index of single element E^i_r shown in *Table 5* indicated that As and Zn were classified as moderate level whereas Cd and Pb were classified as low level. As shown in *Table 5*, the ecological risk indexes (R_I) of trace metals in the mangrove sediments from different part of Songkhla Lake showed that Kuannieng (station 2) and Phawong canal (station 3) were classified as moderate level whereas Kukhut nonhunting area (station 1) and U-Taphao canal (station 4) were classified as low level.

Comparison of trace metal concentration with Sediment Quality Guidelines (SQGs)

Several sediment quality guidelines (SQGs) for the assessment of sediment quality using chemical and biological effect databases have been established. These SQGs are

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40814095

summarized in *Table 6*. NOAA presents ERL (effects range low) and ERM (effects range mean) guidelines for estuarine and marine environments which represent the 10th and 50th percentiles of adverse biological effects (NOAA, 1999). The MacDonald et al. (2000) SQGs for freshwater environments have a lower TEC (threshold effects concentration) and an upper PEC (probable effect concentration) at which toxicity to bottom dwelling organisms are predicted to be unlikely and probable, respectively. The US-EPA has also made classifications (non-polluted, moderately polluted, heavily polluted based on toxicity tests (Baudo et al., 1990; Filgueiras et al., 2004). Regional background values assessed from core sediment samples were reported by Choi et al. (2008) and offshore sediments in the Gulf of Thailand by Shazili et al. (1999). Background levels varied from 55-115 µg/ g dry weitht for Zn, from 5-9 µg/g dry weight for As, from 0.03-0.2 µg/g dry weight for Cd, from 15-30 µg/g dry weight for Pb.

Table 5. *Ecological risk index of trace metals in mangrove sediments of Songkhla Lake*

E_r^i	Potential ecological risk for single regulator	R_I	Ecological risk for all factors
<40	Low	$R_I < 95$	Low (L)
$40 \leq E_r^i \leq 80$	**Moderate**	$95 \leq R_I \leq 190$	Moderate (M)
$80 \leq E_r^i \leq 160$	Considerable	$190 \leq R_I < 380$	Considerable (C)
$160 \leq E_r^i \leq 320$	High	$R_I \leq 380$	Very high (V)
$E_r^i \geq 320$	Very high		

Sites	E_r^i				R_I
	Zn	As	Cd	Pb

Zn	<90	90-200	>200	150	410	120	460	48.6-126.6

TEC: threshold effect concentration, PEC: probable effect concentration, ERL: effects range low, ERM: effects range mean

Sediment quality guidelines (SQGs) were recognized as appropriate thresholds to reveal adverse effects of heavy metals in sediments for plants, animals and human health. SQGs were applied to our study to determine the overall pollution status in sediments of Songkhla Lake. The amount of As and Pb was above the background value. Our study showed that highest amount of As at Kuannieng (station 2) of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40814095

Songkhla Lake exceeded the ERL value; TEC value was classified as heavily polluted probably affected the health of plants and organisms. Pb levels from both sites exceeded the ERL and TEC value and were regarded as heavily polluted at Kuannieng (station 2) and classified as moderately polluted for stations 1, 3, and 4. Cd level was classified as lower than ERL and TEC. Zn was classified as moderately polluted and exceeded TEC value.

The comparison of trace metals in mangrove sediment and plant parts

Our result revealed that the total concentration of all metals (As, Zn, Pb, Cd) in mangrove sediment no statiscally significant difference among the stations ($p > 0.05$). For the comparison of the trace metal concentrations between plant parts of *Soneratia caseolaris*, all the values show variations among the stations. The post hoc Duncan-Test showed no significantly different accumulation in barks ($p > 0.05$) whereas roots and leaves were significantly different ($p < 0.05$). The comparison of the metal contamination in the different sediment fractions revealed the low metal concentration in residual fraction and high in bioavailability fractions. The post hoc Duncan-Test showed among the stations showed no significant difference in residual fraction ($p > 0.05$) whereas the other fractions (Exchangeable, Reducible and Oxidizble) were significantly different ($p < 0.05$).

Correlation between fractionation of heavy metals in sediment and accumulation in plant parts

The accumulation in various parts of *Soneratia caseoralis* was investigated to determine the relationship between the fractionation and plant's uptake as showed in *Table 7*. Fraction 1 (Exchangeable) was significantly negative correlated with accumulation in leaves (young, green, old). The result indicated that Fraction 2 (Reducible) was showed positive correlation with root ($r = 0.634$, $p < 0.05$), bark ($r = 0.682$, $p < 0.05$) leaves (Y: $r = 0.678$, $p < 0.05$; O: $r = 0.712$, $p < 0.05$). Higher Fraction 2 resulted in higher plant uptake. Fraction 3 (oxidizable) had moderate correlation ($r = 0.585$, $p < 0.05$) and Fraction 4 (Residual) had high correlation with plant uptake in root ($r = 0.749$, $p < 0.05$) and bark ($r = 0.776$, $p < 0.05$). High correlation was found between young leave and green leave ($r = 0.661$, $p < 0.05$) and between green leave and old leave ($r = 0.933$, $p < 0.05$).

Table 7. *Correlation between fractionation of trace metals in sediment and accumulation in plant parts*

	Fraction1	Fraction2	Fraction3	Fraction4	Root	Bark	Leaf_Y	Leaf_M	Leaf_O

Discussion

In this study, the samples were collected during the heavy rainy season and therefore several large freshwater bodies flowed into the lake and lessened the salinity of the lake water. However, the metal concentrations in the collected mangrove sediment samples in our study area as compared to the sediment quality guideline revealed that the As concentration was still higher than that of the quality guideline by 2-4 times and classified as heavily polluted. Comparison of our data regarding the metal concentrations (As, Cd, Pb and Zn) with the previous data from the other studies of Songkhla lake as well as other areas in the world was illustrated in *Table 8*. The maximum values of As and Pb at the Outer Section of Songkhla Lake previously reported by Pradit et al. (2010, 2013) were considerably lower than those of this study. Especially, As levels in Songkhla Lake were much higher than those found in Pattani bay (Pradit et al., 2016), Seitu Wetland (Pradit et al., 2016), Sundarban Wetland (Chowdhury et al., 2015) and at Kelantan Delta reported by Baruddin (2017). This result is certainly supported by Sompongchaiyakul and Sirinawin (2007), Pradit et al. (2010, 2013); who reported that concentrations of As, and Pb were ascending owing to rapid urban and industrial expansion. Outer Section of Songkhla Lake receives municipal wastes from two large and rapidly expanding cities of Songkhla and Hatyai as well as agricultural and industrial discharges transported by U-Taphao canal (Sompongchaiyakul and Sirinawin, 2007). The mean concentration values of As and Pb of this study were similar to the result of Pradit et al. (2010) but higher than those of Pradit et al. (2013). It is well accepted that the mangrove area is considered as a sink of trace metals and therefore the mangrove sediment samples of this study possesses the higher amounts of trace metals than those of the lake sediment reported by Pradit et al. (2013). Although the total concentration of metal is an appropriate indicator of contamination assessment, it does not provide enough information about bioavailability and toxicity of heavy metals (Zhong et al., 2011).

Chemical fractionation differentiates metals of natural origin from those derived from anthropogenic sources. The bioavailability fractions (exchangeable, oxidizable and reducible) of As, Cd and Pb in mangrove sediments of this study were greater than 90%whereas the residual fraction of these elements was very low. Thus, it was probably concluded that mangrove area in this study had high bioavailability. This may suggest that there was considerable anthropogenic input to the Songkhla Lake as compared to the low bioavailability of As (about 30%) reported by Baruddin et al. (2017). This was probably caused by different mangrove plant types. Our sampling area was *S. caseolaris* habitat whereas Baruddin et al. (2017) was *R. mucronata.*

In our study Pb seemedto be accumulated in plant parts. This was concordant with the study of Toledo-Bruno et al. (2016) in Mangrove forest reserve in Mindanao, Philippines discovering of *Sonneratia alba* being Pb-hyperaccumulator. Our study Pb was highest in root and well agreed with the study of Nazli and Hashim (2010).

Plants may be passive receptors of heavy metals, but they also exert control over uptake or rejection of some elements by appropriate physiological reactions. To illustrate this point, based on *Table 3,* the BAF values for all the studied heavy metals were always less than 1, which indicated that *Soneratia caseolaris* exhibited restricted metal sediment-root uptake for non-essential heavy metals similar to BAF of *R. mucronata* in the Outer Section of Songkhla Lake (Barrudin et al., 2017)

Conclusion

The anthropogenic inputs of As and Pb were high in the mangrove sediments of the lake especially at Kuannieng (station 2). As and Zn were found highest concentration in bark whereas Cd and Pb were found highest concentration in root. The BCF and TF values proposed that *Sonneratia caseolaris* showed limited (BCF < 1, and TF > 1) accumulation of As, Cd, Pb and Zn in their aboveground parts and thus presented a low food chain hazard except As and Cd at Phawong canal (station 3) and U-Taphao canal (station 4). The potential ecological risk index of single element indicated that As was classified as moderate risk level. The concentration of As should be concerned and regularly monitored.

(Received 9th Feb 2018; accepted 12th Jun 2018)

Abstract. In modern agriculture, mepiquat chloride (pix) as a synthetic growth regulator, is considered as an important management tool for reducing stress damage in Cotton seed. In the present study, the effects of the growth regulator, pix were investigated on the physiological and biochemical characteristics in new cultivars of cotton in response to salinity stress in Golestan province, Iran. The experiment was carried out in a completely randomized design enriched with 10 gr. L^{-1} Pix and 15 ds.m^{-1} salt (sodium chloride) in Petri dish with three cultivars (*Latif*, *Kashmar* and *Sahel*). The physiological and biochemical parameters of seedlings were measured after 4 days. The use of Pix in saline conditions resulted in a significant increase in germination percentage, radicle length, dry and fresh weights, phenolic compounds, as well as proline and glycine betaine content in the *Latif* and *Kashmar* cultivars ($p \leq 0.05$). The amount of Na^+ ion absorption was lower in *Kashmar* and *Latif* cultivars compared with the *Sahel* cultivar while the amount of K^+ and Ca^{2+} ions absorption was increased in the two mentioned cultivars compared to the Sahel cultivar. This study showed that the effects of stress were reduced after treating the seeds with Pix, especially in the *Kashmar* and *Latif* cultivars during the seedling stage.
Keywords: *salt stress, mepiquat chloride, synthetic growth regulator, enzyme activity, ion accumulation, osmotic regulator, Malvaceae*

Introduction

Cotton (*Gossypium spp.*) is a flowering plant which belongs to the Malvaceae family. Today, it has gained importance both economically and commercially with regard to the production of fibers, raw material for textiles, the oil industry, food (Ozarslan, 2002) and various other materials for consumption. For a long time, salinity has been one of the major environmental problems faced by humankind (Jaleel et al., 2009) and is the basic limiting factor for production in arid and semi-arid inlands (Munns et al., 2002; Ashraf and Foolad, 2005). Like many areas of the world, Iran has a hot and dry climate and more than half of its cultivation lands has been transformed into saline and sodic soils (Jamali et al., 2015). Salinity stress affects the physiological and bio-chemical features of the plant and disrupting the osmotic balance (Kook et al., 2009) can lead to severely decreased plant growth and reduced amount of production (Koca et al., 2007).

Salinity stress and increasing Na^+ concentration cause a decrease in essential absorption including K^+ and calcium, and a reduction of enzyme activity and membrane structure (Demir Kaya et al., 2006; Netondo et al., 2004). An irreparable damage is caused by the plant through the production of reactive oxygen species (ROS) (Koca et al., 2007). Also, plants in saline areas are faced with water deficit in addition to the salinity stress. This affects plant metabolic reactions such as photosynthesis, respiration, and protein synthesis (Pal et al., 2004; Meloni et al., 2003). The effect of salinity is different in different periods of plant growth. Germination is the most critical stage of plant growth (Khan et al., 2002; Khan and Panda, 2008) including cotton (Weiping et al., 2009; Mer, 2000; Prado, 2000) so that germination can be prevented by increasing salinity (Sosa et al., 2005; McDonald, 2000; Godfery et al., 2004).

Each plant with more resistance can have a better growth during the later stages (Gulzar, 2001). The investigation showed that an increase in salinity caused a decrease in plant height, leaf surface, fresh and dry weight, as well as radicle and plumule length in the studied cultivars of cotton (Saranga et al., 2004; Noor et al., 2001). Even in susceptible (*Sahel*) and resistant (*Siokra*) cultivars of cotton, salinity also causes shortening in radicle and plumule length (Rezaei et al., 2005). An important effect of stress in plants is the overproduction of reactive oxygen species (ROS) in chloroplasts and mitochondria (Mittler, 2002; Masood et al., 2006).

The accumulation of secondary metabolites is one of the possible responses of plants to the changes in osmotic potential of the environment (Hasegawa et al., 2000). Plants accumulate compatible solution such as proline (Mansour et al., 2005a) and glycine betaine in the cell osmotic regulation (Rhodes and Hanson, 1993) to counteract the harmful effects of salt.

Glycine betaine is increased in plant as consistent and effective osmolytes under stressful conditions (Ashraf and Foolad, 2007), particularly under salinity stress (McNell et al., 2001). Increasing glycine betaine has been observed in response to salinity stress in spinach, cabbage, tomato, potato, Rice and sorghum (Yang et al., 2003). Also, increase in water salinity resulted in an increase in glycine betaine in two cotton cultivars (*Aria-Anubam and LRA - 5166*) (Desingh and Kanagaraj, 2007). Proline is the amino acid that is accumulated under salinity stress as active osmotic regulator; it is widely used in higher plants (Abraham et al., 2003) and causes membrane stability and affects the membrane process.

Another effect of salinity stress on plants is the disruption of important nutrient balance including K^+ and Ca^{2+} (Renault, 2005). K^+ is an essential cytoplasmic element and is considered to be an important element in saline conditions as a result of its role in regulating osmosis and the competition effect. Also, several reports have emphasized the beneficial effects of Ca^{2+} in reducing the effects of salinity and in most cases these effects are related to restoring the plasma membrane, health maintenance and cohesion in roots and shoots (Nedjimi and Daoud, 2009; Kaya et al., 2002; Tuna et al., 2007). Various methods are used to reduce salinity in cotton. These include the use of growth regulators, selection and the cultivation of resistant genotypes. Pix as a synthetic growth regulator in Cotton seed is considered as an important management tool for reducing stress damage in modern agriculture (Jost et al., 2006; Niakan et al., 2012). Pix with the common name, mepiquat chloride, is composed of 4.2% N, N-dimethylpiperidinium chloride and a multi-component composition of Ammonia (it inhibits the synthesis of Gibberellic acid) (Stewart, 2005). The colonization of seeds with Pix before planting is an appropriate method of reducing salinity which can increase the length of roots with changes in seed physiology and impressing cell wall in the early stages of germination. Studies have shown that a significantly higher seed germination was observed in seeds treated with Pix compared to the control (Niakan et al., 2012).

It has been found that plants primed with Pix are shorter, denser and darker than plants that are not stained with it (Stewart, 2005). The use of Pix leads to the absorption of more phosphorus and nitrogen (Oosterhuis and Robertson, 2000) and the concentration of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40974114

magnesium, phosphorus, and nitrogen in the root is more compared to the control group (Osterhuis and Robertson, 2000; Zhang et al., 2001). The literature review revealed that the use of Pix at high concentrations of salt resulted in improved germination and an increase in physiological characteristics such as root length, fresh and dry weight and increased biochemical properties such as catalase activity and the amount of phenol (Alishah et al., 2012).

The objective of this study was to investigate the effect of Pix (mepiquat chloride) on the salinity resistance of the new cultivars of cotton (*Gossypium hirsutum* L.) in Gorgan area, Golestan province, Iran.

Materials and methods

Plant material

Delinted cottonseed (*Gossypium hirsutum* L.) from three cultivars (*Kashmir*, *Latif* and *Sahel*) was prepared in the Cotton Research Center of Iran, Gorgan city, Golestan Province, (36° 50' North and 54° 26' East) which is located in the North East of Iran.

The experimental design was completely randomized with priming Pix (10%) and salt (15 $ds.m^{-1}$) in the Petri dish with three mentioned cultivars (*Latif*, *Kashmar* and *Sahel*) at the germination stage. In addition, four treatments (Pix, salinity, Pix and salinity and control) were studied with four replications from three cultivars in 48 Petri dishes.

Sahel cultivar was considered as control (grown in northern areas and most areas of Iran) and two new cultivars of *Latif* and *Kashmar* were used as treatments that were developed and recorded in the year 2015 in the Cotton Research Institute of Iran through crop breeding. Cotton seeds priming was performed with10 gr. L^{-1} (gram/liter) Pix for 5 h at 25 °C. Thereafter, 3 milliliters (ml) of distilled water was added to the control and 3 ml of water soluble salt (sodium chloride) (EC: 15 $ds.m^{-1}$) was added to salt treatment and the seeds were covered with a filter paper, and were placed in a germinator for 4 days at 27 °C. Moreover, the following physiological and biochemical parameters were measured: percentage of germination, root length, fresh and dry weight, the phenolic compounds, glycine betaine, proline, the concentration of Na^+ ions, K^+, and calcium.

Assessment of germination percentage: The germination of seeds was calculated after 4 days by *Equation 1*. It should be noted that seeds with radicle length of 1 mm or more were considered as germinated seeds (Weston et al., 2004).

$$PG = 100\ n/N \qquad \text{(Eq.1)}$$

where N is the total number of seeds, n is the number of germinated seeds and PG is the Percentage of Germination.

Measuring the length of radicle seedlings: The radicle length of the seedling (mm) was measured (4 days) after the initial radicle emergence.

Measurement of the fresh and dry weight of seedlings: Seedlings from each treatment (4 repetitions) were randomly selected and their fresh weight was measured using a Digital Scale (gram). To determine the dry weight, seedlings from each treatment (4 repetitions) were placed in the oven at 90 °C for 24 h, followed by weighing.

Assessment of proline (Bates et al., 1973): 0.2 gr of frozen seedlings was homogenized in 3% sulfosalicylic acid, and the homogenate was centrifuged at 10000 rpm (revolutions per minute). The supernatant was used for the estimation of proline content. The reaction mixture (2 ml acid ninhydrin and 2 ml of glacial acetic acid) was heated at 100 °C for 1 h.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40974114

The reaction mixture was extracted with 4 ml of toluene and absorbance was read at 520 nm.

Phenolic compounds assay (Matta and Giai, 1969): The samples were boiled in 10 ml alcohol 80% for 15 min and then, centrifuged for 15 min at 3000 *g*. 5 ml of diluted foline (1:3) and 10 ml of saturation Na_2CO_3 were added to 5 ml of this solution. Samples were incubated at 25 °C for 10 min and then, centrifuged for 15 min at 4000 *g*. Supernatant absorption was determined at 640 nm. The standard curve of catechol was used to determine the content of phenolic compounds (milligram / gram dry weight: mg. g^{-1} FW).

Measurement of glycine betaine content (Sairam et al., 2004): 0.5 gr dried powder of seeds was distilled in 20 ml water and shaken at 25 °C. The samples were filtered by filter paper and diluted with an equal ratio of sulfuric acid 2 N. 2 ml was separated and mixed with 8.0 ml of iodide - cold iodine K^+ (Lugols). The solution was placed in a refrigerator for 16 h and was centrifuged at 3000 rpm for 30 min. 1 ml of the upper phase was separated and dissolved with 9 ml of 2,1-dichloroethane. The samples were vertex and after 2.5 h, its absorption was read at 365 nm and then, the glycine betaine content (micromol / gram dry weight: µmol/g DW) was calculated using *Equation 2*.

$$C = \text{Abs} \times 0.00017 + 0.014636 \qquad \text{(Eq.2)}$$

Measurement of Na^+ and K^+ (Williams and Twine, 1960): 1 gr of fresh material was placed in the oven at 80 °C for 48 h. Thereafter, it was put in an electric furnace at 600 °C for 6 h. Subsequently, after weighting, the ashes was dissolved in 1 ml of hydrochloric acid 6 N, using a stirrer. Next, the samples were filtered and diluted with distilled water to a volume of 50 cc. Then, the amount of Na^+ and K^+ were determined using a flame photometer and a standard curve (gram / gram dry weight: g. g^{-1} DW).

Measurement of Ca^{2+} ions (Manteghi et al., 1987): 10 ml mineral extraction plant was poured into Erlenmeyer flasks and then, 2 ml NaOH 4 normal was added and 3.0 gr Murexide powder was added. Then, the titration was performed using EDTA 0.01 normal to change its color to purple. This process was performed in the presence of calcium chloride solution as control. The value of Ca^{2+} as gram per gram of dry matter was calculated using the formula (g. g^{-1} DW).

Statistical analysis

The data was represented as mean ± standard deviation (SD). The experiment was conducted using a completely randomized design with Four replicates (n = 4) having twenty seeds of each replicate. The data were statistically treated by one-way analysis of variance (ANOVA) and the mean values were compared using Duncan's test at $P < 0.05$ to establish significant differences between each treatment and control.

Results

Pix, salinity effect and their influence on the germination percentage, radicle length, fresh and dry weight

The results showed that germination percentage and radicle length were reduced under salinity stress in three cultivars compared with the control. Also, the use of Pix resulted in a significant increase in germination percentage compared with the control in all three

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40974114

cultivars and among them, the rate of increase of *Latif* and *Kashmar* cultivars was more than that of the *Sahel* cultivar (*Fig. 1*).

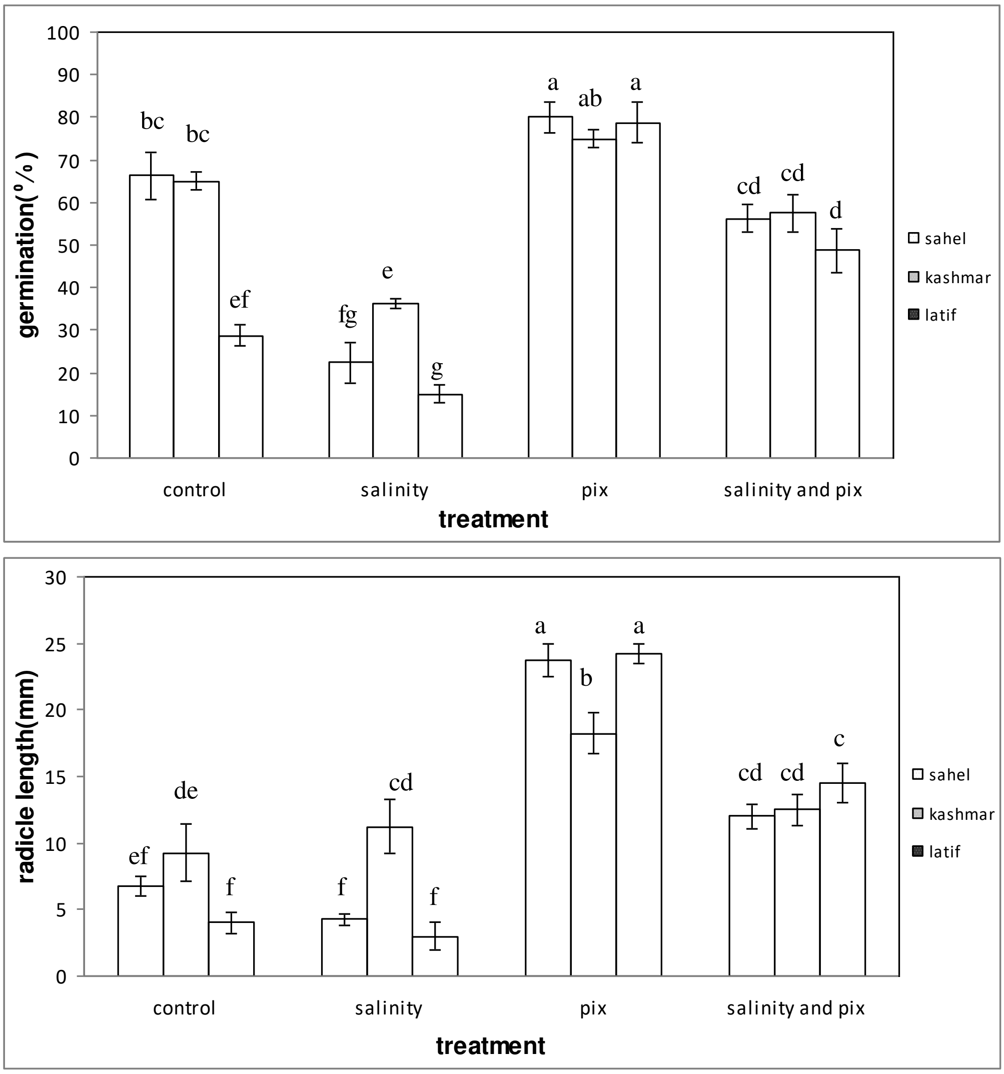

Figure 1. *Effect of Pix, salinity and their interaction on the percentage of germination and radicle length. *Average with the same letters was not statistically significant (p ≥ 0.05)*

Figure 2 shows that Sahel cultivar is sensitive to salinity and its fresh weight and dry weight decreased under salt stress but the use of Pix was very useful for salt stress tolerance. On the other hand, the fresh and dry weights of *Latif* cultivar were increased under Pix treatment alone as well as Pix and salinity combination treatments.

Effect of Pix, salinity and their interaction on the amount of seed phenol in new cultivars of cotton seedlings

The results showed that the phenolic compounds in Sahel cultivar treated with Pix presented a significant increase compared with the control treatment. Also, the phenolic compounds in all the treatments were increased in Latif and Kashmar cultivars in comparison with the control (*Fig. 3*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40974114

Effect of Pix, salinity and their interaction on the glycine-betain content

Figure 4 shows that the use of Pix and salinity combination caused an increase in the glycine betaine content in the three cultivars. Despite the fact that the Sahel cultivar is sensitive to salt stress, the highest glycine betaine content belonged to this cultivar.

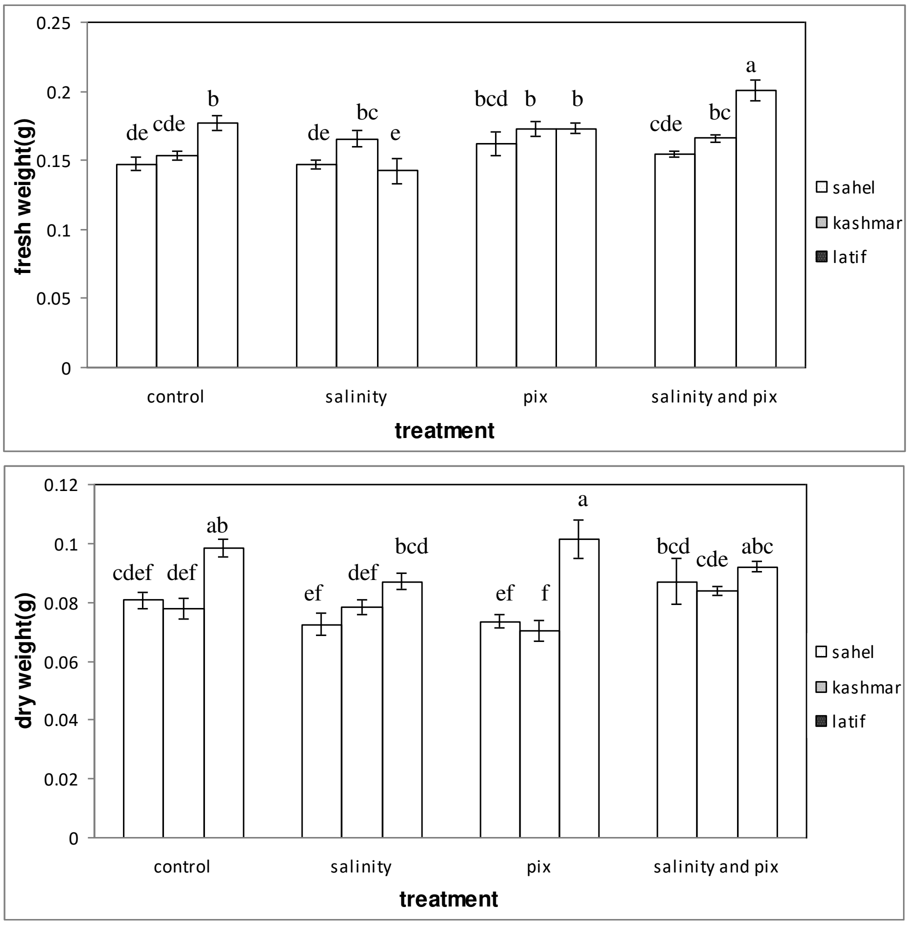

Figure 2. *Effect of Pix, salinity and their interaction on the fresh and dry weights*

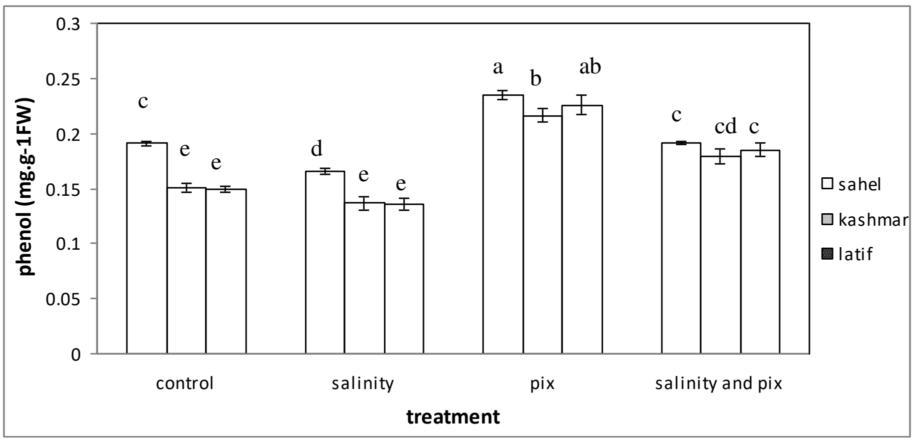

Figure 3. *Effect of Pix, salinity and their interaction on the amount in phenol of new cultivars of cotton seedlings*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40974114

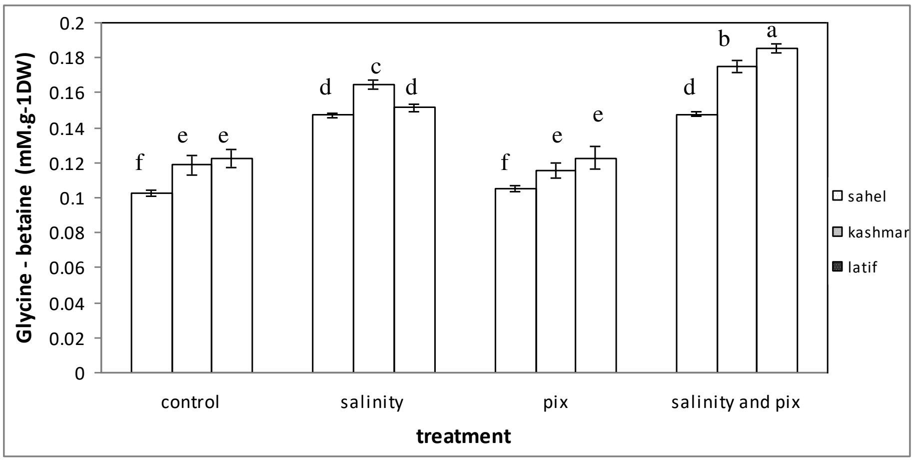

Figure 4. *Effect of Pix, salinity and their interaction on the amount of Glycine - betaine in new cultivars of cotton seedlings*

Effect of Pix, salinity and their interaction on the amount of proline

The results showed that the proline content had a significant increase in all three cultivars in the different treatments compared with the control treatment, but the proline content in cultivars of Kashmar and Latif was more compared to the sensitive cultivar of Sahel (*Fig. 5*).

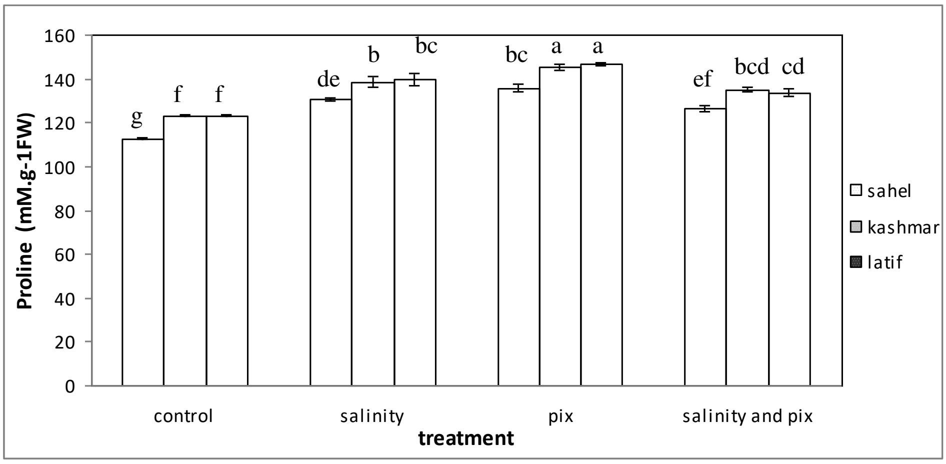

Figure 5. *The effect of Pix, salinity and their interaction on the amount of proline in new cultivars of cotton seedlings*

Effect of Pix, salinity and their interaction on the amount of Na^+ and K^+ in new cultivars of cotton seedlings

The results of this research showed that the amount of Na^+ in all three cultivars in different treatments had a significant increase compared with the control treatment. The amount of Na^+ in Latif and Kashmar cultivars was less than in the Sahel cultivar. Also, the amount of K^+ caused a significant decrease in the Sahel cultivar in all three treatments compared to the control treatment (*Figs. 6* and *7*).

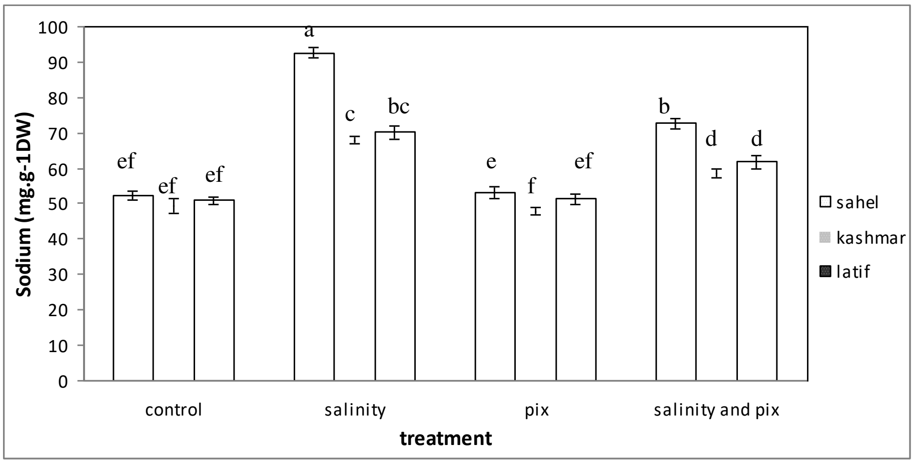

Figure 6. *The effect of Pix, salinity and their interaction on the amount of* Na^+ *of new cultivars of cotton seedlings*

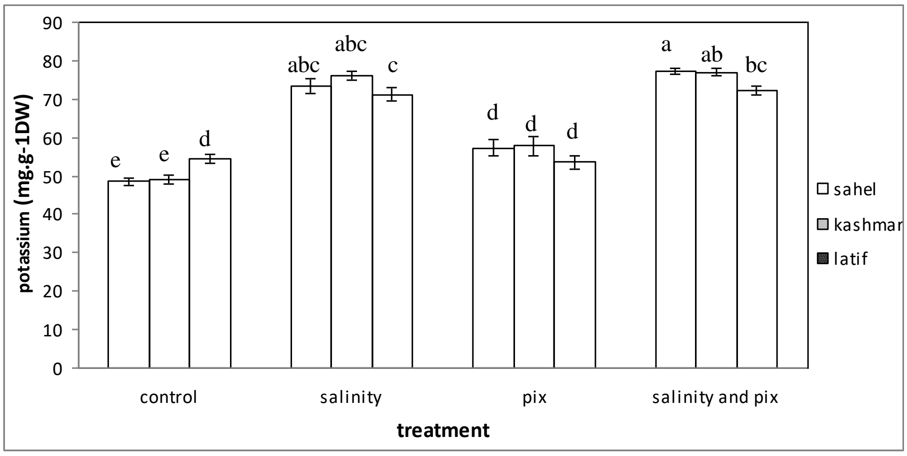

Figure 7. *The effect of Pix, salinity and their interaction on the amount of* K^+ *in new cultivars of cotton seedlings*

Effect of Pix, salinity and their interaction on the amount of Ca^{2+} *in new cultivars of cotton seedlings*

Compared to the control treatment, the results indicated that the amount of Ca^{2+} had a significant increase in all three cultivars in different treatments (*Fig. 8*).

Discussion

Previous studies showed that the length of root and stem was significantly reduced under salinity (Habib et al., 2014; Pervaiz et al., 2007; Noor et al., 2001; Ibrahim et al., 2007; Weiping et al., 2009; Rezaei et al., 2005). Moreover, the fresh and dry weight of the root and stem was reduced in cotton cultivar (Habib et al., 2014; Ibrahim et al., 2007; Saleh, 2011). In addition, the results of previous studies showed that salinity stress resulted in a decrease in germination percentage and growth parameters of cotton seedling in S*epid 2* cultivar. Also, priming with Pix improved injuries that were caused

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40974114

by salinity on these parameters (Alishah et al., 2012). The most important effect of Pix on cotton was longitudinal growth prevention (Singh, 2010). Pix can cause changes in seed physiology and affect the cell wall. Reviews on the germination percentage showed that seeds treated with Pix had significantly higher germination percentage compared with the control (Niakan et al., 2012). The findings revealed that at high concentrations of salt, the use of Pix resulted in improved germination and increased physiological characteristics including root length, as well as fresh and dry weight (Alishah et al., 2012). Regarding the obtained results, there was an increase in the dry weight of the seedlings due to an increase in the length of the radicle when Pix was used. The priming of seeds with Pix before planting can be a suitable method in cotton production that leads to increase in root length in the early stages of germination.

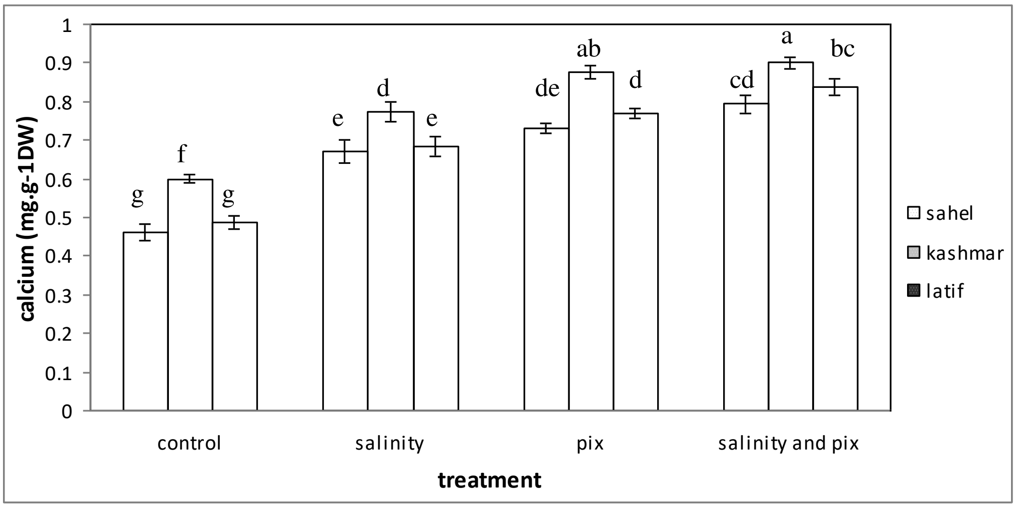

Figure 8. *The effect of Pix, salinity and their interaction on the amount of Ca^{2+} in new cultivars of cotton seedlings*

Phenolic compounds are different secondary metabolites that exist in large quantities in plant tissues until the plant can cope against reactive oxygen species, these compounds play an antioxidant role and protect plants from the oxidizing action of malicious free radicals (Grace and Logon, 2000; Zhu, 2000). Previous researches showed that salinity stress in barley seedlings leads to a decrease in phenolic compounds, flavonoids and growth (Ali and Abbas, 2003). Tamer and Abdel-al (2012) in their research findings on the content of the phenolic compounds of barley seedlings under the NaCl -salinity stress showed that the content of phenolic compounds was reduced. These findings are based on the fact that the reduction of phenolic compounds in the *Sahel* cultivar under salinity stress was consistent with the results of the present study.

The results showed that the amount of phenolic compounds increased in *Kashmar* and *Latif* Cultivars subjected to Pix and salinity along with Pix treatments. This issue indicated that seed treatment with Pix in saline or non-saline conditions caused the increase of phenolic compounds that were resistant to stress. The first step in the phenylpropanoids metabolism was deamination of L-phenylalanine of cinnamic acid by phenylalanine ammonia-lyase (PAL) (Iijima et al., 2004; Achnine et al., 2004). PAL is an enzyme intermediate between the primary and secondary metabolism of

phenylpropanoids (Adams, 2001). Metabolites that occur as a result of PAL activity are classified as phenolic derivatives. The results of this study demonstrated that the amount of glycine - betaine increased in all three treatments in the *Sahel* cultivar compared to the control treatment.

In plants, osmotic adjustment takes place through the production of various types of compatible organic solvents and some inorganic ions. These materials may insulate the injuries of plant cells through osmotic stress by modulating and maintaining membrane fluidity and stability of proteins or enzymes (Bohnert and Jensen, 1996).

Glycine betaine is one of the most abundant compatible organic substances in plants (Weibing and Rajashekar, 1999). In many plants, such as spinach, barley, wheat and sorghum, there is an increase in glycine betaine in response to various stresses (Rhodes and Hanson, 1993; Yang et al., 2003; McNell et al., 2001; Hellman et al., 2000; Ashraf and Foolad, 2007; McNell et al., 2001; Gorham et al., 2000).

Glycine betaine is naturally accumulated in some plants whereas in others, it is not produced even under stress condition (Ashraf and Foolad, 2007). However, it appears that the moderating role of glycine betaine depends on many factors including product type, time, its application, and the environmental conditions (Makela et al., 1998). The glycine betaine concentration is changing in different species and are used as an osmotic regulator (Agastian et al., 2000).

An investigation revealed that an increase in the different levels of glycine betaine in cotton under salinity is different in some variety compared to other varieties that accumulate higher amounts of proline and glycine betaine (Desingh and Kanagaraj, 2007).

With increasing salinity in two cotton cultivars, (*Aria- Anubam and LRA - 5166*), the amount of glycine betaine increased in both cultivars (Desingh and Kanagaraj, 2007).

The results of this study showed that the amount of glycine betaine in the seedling was significantly increased as compared to the control. This combination is one of the physiological resistances against salinity in the early stages of germination.

Studies have shown that the osmotic stress injuries caused by salinity and NaCl can be reduced with the use of glycine betaine and this issue depends on the concentration and time of conducting this research (Ashraf, 2009). Interestingly, plants under salinity stress are divided into three categories of plants with resistance strategy via proline or glycine betaine or both (Larher et al., 1996). It appears that *Kashmar* and *Latif* cultivars are the apparently tolerant ones in the salinity treatment and showed increase in the glycine betaine. Hence, they could be regarded among plants that act with Resistance strategy through the accumulation of glycine betaine. Proline is an amino acid which is widely accumulated in higher plants under salinity and drought stress as an osmotic regulator (Abraham et al., 2003; Rontein et al., 2002; Rontein et al., 2002; Fahramand et al., 2014; Ashraf and Harris, 2004; Mansour et al., 2005b) and substantially contributes to osmotic cytoplasm adjustment, and to the stability of the membrane and membrane process.

The results showed that salinity increased the amount of proline in alfalfa (Parida et al., 2004), cotton (Desingh and Kanagaraj, 2007; Mirghasemi et al., 2010), as well as different ecotypes of fox berry plant in the germination stage (Nad Ali et al., 2014). Some studies have indicated that salinity stress causes the excessive accumulation of proline in the *Sayochra* cultivar of cotton and show that this cultivar follows the proline accumulation strategy in salt tolerance (Kumar, 1987). Regarding the increase in proline and glycine betaine content in *Kashmar* and *Latif* cultivars that are apparently tolerant

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40974114

in salinity treatment; therefore, an increase in these compounds in the cell relieves stress for osmotic moderation. *Kashmar* and *Latif* cultivars accumulate proline and glycine betaine that can be considered part of the plants that act through resistance strategy.

In this research, the use of Pix in saline condition caused a decrease in seedling proline content, as compared to the treatment of Pix and saline treatment. It is possible that the decrease in the amount of proline in saline conditions is as a result of the activation of the enzyme proline oxidase that has a role in the conversion of proline to glutamate. Glutamate is used in the biosynthesis of other amino acids for protein synthesis (Mundree et al., 2002).

Even at low concentrations, Na^+ ions are toxic inside the plant and limit the metabolic activity while K^+ ion is known as one of the macronutrients essential for membrane maintenance and enzyme activity. The high concentrations of Na^+ results in the reduced absorption of other nutrients into the soil (Silber bush and Ben-Asher, 2001). Na^+ ions occupy k^+ transfer channels in the plasma membrane of root cells, thereby preventing the absorption of K^+ (Tester and Davenport, 2003) and lead to reduced absorption of other essential elements (Kaymakanova and Stoeva, 2008).

A research of resistant and susceptible genotypes of cotton to salt indicated that the amount of Na^+ was significantly increased under salinity condition and resulted in a decrease in the amount of K^+ (Habib et al., 2014). The ratio of K^+ to Na^+ has been proposed as a success indicator in salt resistance. The terrestrial life of plants depends on high-affinity K^+ uptake systems and benefits from high-affinity Na^+ uptake systems. In plants, both systems have received extensive attention during recent years and a clear insight of their functions is emerging. Some plant HAK transporters mediate high-affinity K^+ uptake in yeast, mimicking K^+ uptake in roots, while other members of the same family may be K^+ transporters in the tonoplast. In parallel with the HAK transporters, some HKT transporters mediate high-affinity Na^+ uptake without cotransporting K^+. HKT transporters have two functions: (i) to take up Na^+ from the soil solution to reduce K^+ requirements when K^+ is a limiting factor, and (ii) to reduce Na^+ accumulation in leaves by both removing Na^+ from the xylem sap and loading Na^+ into the phloem sap (Rodriguez and Rubio, 2006). Although there is no data available on the presence of HAK in Cotton but perhaps, there are effective mechanisms to increase transcription of these proteins that may be due to the adjusting effect of K^+ to maintain osmotic salinity stress (Yokoi, 2002; Rodrıguez and Rubio, 2006). The results indicated that in the sensitive cultivar of *Sahel*, the number of Na^+ ions is higher in plants than in the other two cultivars, *Latif* and *Kashmar*. Therefore, there is more damage to plants. However, the Na^+ content was increased in the *Latif* and *Kashmar* cultivars as compared to the control, but this increase was less compared to the sensitive *Sahel* cultivar. Indeed, the number of ions in the plant was reduced when treatment with Pix and the amount of damage was decreased, as well. It can be said that in the sensitive cultivar of *Sahel*, K^+ was not increased but this amount was increased in *Latif* and *Kashmar* cultivars. This result is encouraging and shows that two cultivars of *Kashmar* and *Latif* were resistant to salinity and thus, the amount of K^+ was increased in order to reduce the losses of the Na^+ adsorption.

As a result of the importance of Ca^{2+} permeability and the properties of selective membranes, high levels of Na^+ to Ca^{2+} ions in tissues can cause changes in the cell activities (Ashraf, 2004; Mahmoud, 2009). Ca^{2+} is the main component of the wall and preserve the integrity of the plasma membrane and maintains coherence in roots and shoots during stress (Ashraf, 2004; Mahmoud, 2009; Ashraf et al., 2008).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_40974114

Ca^{2+} is an immobile element which remains during the growing season in older tissues, and transfers carbohydrates, facilitates the absorption of nitrogen and reduces the harmful effects of Na^{+} (Ashraf, 2008). Cell wall formation and its development is impossible without Ca^{2+} (Taiz and Zeiger, 1998). Research has shown that Ca^{2+} plays a significant role in the salinity resistance of cotton and it will reduce the toxic effect of Na^{+} with a decrease of Ca^{2+} (Cramer et al., 2002). Pix cause an increase in the concentration of Ca^{2+} ion in the tissues and K^{+} ion at the root. Pix controls the vegetative and reproductive growth by reducing the concentration of gibberellic acid in the plant and reducing the length of internodes (Havargi, 2007; Jonathan, 2006; Joseph, 2006). The results showed that the amount of Ca^{2+} in each cultivar was increased with increasing salinity compared to the control, but this increase was more in *Latif* and especially, *Kashmar* cultivars. This suggests that the mechanism of Ca^{2+} ion to reduce Na^{+} ion was used in these two cultivars under stress conditions compared to the *Sahel* cultivar. Therefore, these two cultivars, and especially *Kashmar* cultivar, are considered as the resistant cultivar to salinity.

The results of this research indicated that *Latif* and especially, *Kashmar* cultivars are considered as resistant cultivars to salt stress. The results of this study showed that growth parameters including germination percentage and radicle length in the *Latif* and especially, *Kashmar* cultivars had a significant increase compared to the sensitive cultivar of *Sahel*. Considering the amount of dry and fresh weight of these two cultivars in particular, *Latif* cultivar was higher than *Sahel* cultivar.

The number of phenolic compounds, proline and glycine betaine in these two cultivars have increased with increasing salinity compared to the control and *Sahel* cultivar. Also, in these two cultivars, the amount of Na^{+} ion absorption was lower than that of the *Sahel* cultivar while the absorption amount of K^{+} and Ca^{2+} ions increased compared to that of the *Sahel* cultivar and control treatment. In Pix treatment as well as Pix and salinity treatment, phenolic compounds and proline increased in the two cultivars of *Kashmar* and *Latif* compared to the controls and *Sahel* cultivar. In Pix and salinity treatments, the amount of proline was increased in salinity treatment and control. The Na^{+} absorption ratio in the *Latif* and *Kashmar* cultivars was decreased in salinity and Pix treatment compared to the salinity treatment. Pix and salinity treatment cause increase in uptake of K^{+} compared to salinity treatment in the *Kashmar* cultivar. Indeed, in Pix and salinity treatment, the amount of Ca^{2+} in all cultivars, especially *Kashmar* and *Latif* was higher compared to the salinity treatment. Therefore, it can be concluded that priming seeds with Pix can lead to a decrease in salinity, especially in resistant cultivars. The *Latif* cultivar and especially, *Kashmar* cultivar showed more resistance to the salinity; hence both are considered as resistant cultivars. Indeed, the priming of seed with Pix has a significant effect on increasing resistance to salinity in these cultivars.

As reported in *Figure 9,* Na^{+} in the aerial parts was reduced through priming of *Kashmar* cultivar with Pix and therefore, the number of these toxic ions decreased. Interestingly, it would occur due to the number of reasons including low absorption of Na^{+} by the roots, reflux Na^{+} from root seedlings, inhibition of Na^{+} transport to the aerial parts and the choice of K^{+} and Ca^{2+} as well as the removal of Na^{+}. Increasing the amount of glycine betaine, proline and phenolic compounds in the seedlings of *Kashmar* cultivars along with reducing the amount of Na^{+} ions in the aerial parts of plants cause less damage of the membrane system and better ion balance in these cultivars. These factors result in an increase in the germination, radicle length, fresh and

DOI: http://dx.doi.org/10.15666/aeer/1604_40974114

dry weight in the seedlings of *Kashmar* cultivar and finally, had better performance than other cultivars (*Fig. 9*).

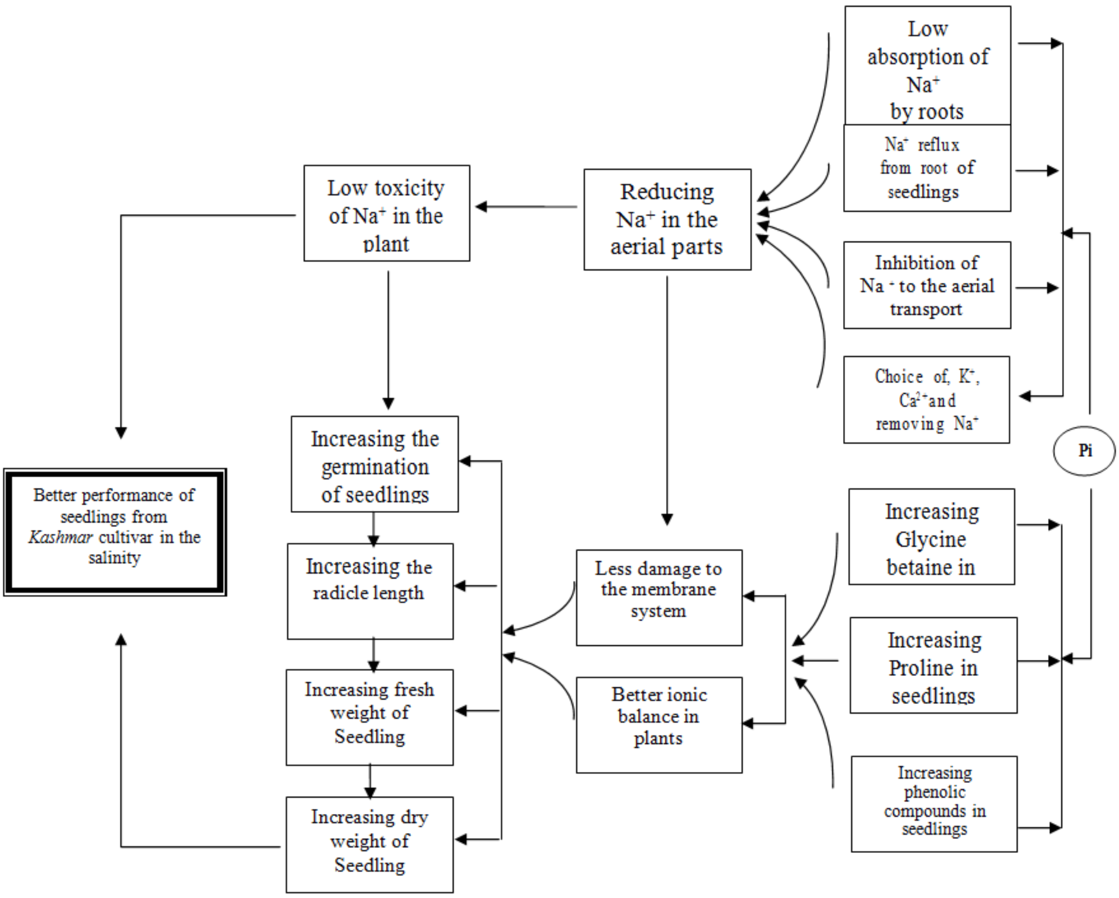

Figure 9. *The effect of Pix on the resistance of salinity in Kashmar cultivar at seedling stage*

Conclusion

The manipulation of cotton plant architecture using plant growth regulators such as Pix can be an agronomic strategy for obtaining high yields. The results indicated that priming Pix improved the physiological and biochemical parameters of cotton (especially in the Kashmar and Latif cultivars) in terms of salinity.

The NaCl stress caused changes in physiological and biochemical traits and reduced germination percentage, radicle length, dry and fresh weight, phenolic compounds, proline and glycine betaine in the Latif and Kashmar cultivars, whereas the treatment of cottonseed with mepiquat chloride in saline stress resulted in significant increase in these parameters. The amount of Na^+ in all three cultivars in different treatments had a significant increase compared to the control treatment.

The amount of Na^+ ion absorption was lower in Kashmar and Latif cultivars compared to the Sahel cultivar while the amount of K^+ and Ca^{2+} ions absorption was increased in the two mentioned cultivars compared to the Sahel cultivar.

It appears that Pix treatment in NaCl stress can be one of the tolerance mechanisms in cotton (especially in the Kashmar and Latif cultivars) which requires further research.

Considering the fact that in the present study, cotton seed priming with Pix was used, it is recommended that this experiment be carried out with a Pix spray on the plant. Also, the morphological and genetic parameters of the plant in vegetative and reproductive stages, as well as the final yield of the plant should be investigated. Also, given the fact that in the current and traditional agriculture system, cotton is pruned to prevent it from extra growth, it is recommended that the relationship between Pix level and pruning should be investigated.

Abstract. With activated carbon as carrier and sodium persulfate as oxidant, the preparation conditions of catalyst and the optimal reaction conditions of sodium persulfate advanced oxidation are studied. The study shows that the catalytic performance of manganese in sodium persulfate advanced oxidation treatment of pickle wastewater is the best. The optimum preparation conditions of the catalyst are as follows: at 30 °C, the carrier is soaked in 0.15 mol/L manganese nitrate solution for 2 h and calcined for 2 h at 400 °C. The optimum reaction conditions: the amount of oxidant, dosage of catalyst, reaction pH and reaction time are kept at 1 mmol/L, 10 g/L, 4 and 75 min respectively. and the reaction temperature is set to 30 °C. Under the optimal reaction conditions, the removal rate of chemical oxygen demand (COD) can reach 84%. According to the analysis of BET, FT-IR and X ray diffraction, manganese has been successfully loaded onto the carrier. Meanwhile, the activity of catalyst is affected by physical factors such as specific surface area, aperture and pore volume.
Keywords: *advanced oxidation, characterization analysis, catalyzer, reaction conditions, preparation conditions, COD*

Introduction

As a kind of flavour food, pickle has the effect of reducing blood fat and enhancing immunity (Bao et al., 2011), and it is welcomed by the majority of consumers. With the rapid expansion of the scale of production, environmental pollution caused by a large amount of salt pickle wastewater has been aggravated. Its main pollution components are plant fiber, plant amino acids, organic acids, alcohols, salts, and inorganic salts of metals such as calcium and magnesium. Therefore, they are characterized by high chemical oxygen demand (COD), high nitrogen and phosphorus and so on. The direct discharge of pickle wastewater will pollute the local soil and water, which will cause serious eutrophication of water and salinization of the soil (Zhao et al., 2011). Therefore, the effective solution to the problem of pickle wastewater has been paid more and more attention.

At present, the methods commonly used in the treatment of high salinity, high COD are biochemical method (Wang et al., 2002; Qin et al., 2006; Chen et al., 2011), membrane separation method (Jin et al., 2009; Zhao et al., 2011) and ion exchange method (Bao et al., 2010; Yuan, 2012). The ability of microorganism to treat pollutants is reduced, because of the salt in pickle water, so the effect of traditional biochemical method is not ideal. On the basis of biological method, salt tolerant microorganism has been studied in the treatment of high salt wastewater, but there are still some shortcomings such as long taming time and the fact that it is easily affected by change of salinity (Bao et al., 2010). Ion exchange and membrane separation are ideal treatment methods for high COD and high salinity wastewater, but there is also poor resistance to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41154127

organic pollutants, frequent membrane replacement, high treatment cost and large amount of auxiliary reagents during processing, which are likely to cause extra pollution.

The persulfate advanced oxidation technology is widely used in the field of wastewater treatment, and the strong oxidation of sulfate radical ($SO_4^{-}\cdot$) is used to deal with harmful substances in water (Wang and Cheng, 2017; Zhang, 2017; Shao et al., 2017). During the treatment, $S_2O_8^{2-}$ is converted to $SO_4^{-}\cdot$ (E_0 = 2.5v-3.1v), which is equivalent to or even higher than the redox potential of HO· (E_0 = 2.7V-2.8V), resulting in the oxidation and decomposition of most organic pollutants. In this paper, persulfate advanced oxidation process was used to treat the wastewater of pickled cabbage, and the optimal preparation conditions of the catalyst are explored.

Materials and methods

Experimental reagents and instruments

Reagents and materials: sulfuric acid (AR), sodium persulfate (AR), powder activated carbon, potassium dichromate (PT), mercury sulfate (AR), ammonium ferrous sulfate (AR), silver sulfate (AR), silver nitrate (AR), ferric nitrate, zinc nitrate, manganese nitrate, nickel nitrate, copper nitrate, pH paper, distillation water, Pickle wastewater taken from the pickle plant in Xin Fan Town, the main index of wastewater is shown in *Table 1*.

Table 1. *Pickle wastewater quality indicators*

Project	Content
COD	2500~3000 mg/L
pH	4.0~6.0
Turbidity	300~400
Salt content	0.5%~2%
SS	800~1000 mg/L

Equipment and instruments: electronic balance, COD125 digestion instrument, THZ-82B gas bath constant temperature oscillator, DHG-9240A electrothermal constant temperature blower drying box, SZ-93 automatic double water distiller, SX2-5-12 electric furnace, constant temperature magnetic stirrer B11-2, Automatic multi station specific surface, micropore and mesoporous pore analyzer (BELSORP-max), X- ray diffractometer (EMPYREAN X), Fourier infrared spectrometer (Nicolet 6700).

Method of experiment and analysis

Preparation of catalyst

The activated carbon is placed in the beaker, soaked in distilled water, fully stirred and washed until the effluent is clarified, and then dried at 105 °C in the oven. A certain amount of activated carbon after pretreatment was soaked in a certain concentration of nitrate solution and placed in the air bath constant temperature oscillator for a period of time. Then filtering out, and the catalyst is made by drying and calcination.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41154127

The impregnation conditions and calcination conditions in the process of catalyst preparation were explored through experiments #1 and #2.

(1) Experiment #1

At 30 °C, activated carbon, as a carrier, is immersed in different concentrations of ferric nitrate, zinc nitrate, manganese nitrate, nickel nitrate, copper nitrate for 2 h. The calcination temperature is 400 °C, and the calcination time is 2 h. The catalyst is prepared to deal with pickle wastewater, the reaction temperature is maintained at 30 °C, the pH value is about 5, sodium persulfate dosage was 1 mmol/L, reaction time is 2 h.

(2) Experiment #2

According to the data of Experiment 1, the best immersing solution is used and immersing time is 2 h. The calcination temperature is adjusted to 200, 300, 400, 500, 600 °C, and the calcination time is 2 h; The calcination temperature is adjusted to the best calcination temperature and the calcination time is changed from 1 to 6 h.

Method of optimizing reaction conditions

Under the condition of normal pressure, 100 ml pickle wastewater is placed in a conical bottle, then a certain amount of sodium persulfate and a certain amount of catalyst is added. Finally, the conical bottle is placed in a constant temperature reactor.

The reaction conditions, such as the amount of oxidant, the amount of catalyst, pH, reaction temperature and time, were explored and optimized through experiments #3 ~ #6.

(1) Experiment #3

The optimal conditions of catalysis are determined for the treatment of pickle wastewater based on Experiment #1 and #2. In this part, the dosage of oxidant is changed, while the other reaction conditions are kept. In other words, the reaction temperature is maintained at 30 °C, the pH value is about 5, and the reaction time is 2 h.

(2) Experiment #4

First, the dosage of oxidant is adjusted to be the best, then the dosage of the optimized catalyst is changed, while the other reaction conditions were maintained at 30 °C, the pH value is about 5, and the reaction time is 2 h.

(3) Experiment #5

First, the dosage of oxidant and catalyst are adjusted to be the best, then the pH value of the reaction system was changed while the other reaction conditions are maintained.

(4) Experiment #6

The experiment is carried out by adjusting pH, oxidant dosage, catalyst dosage to the best condition. the reaction temperature and reaction time are changed from 20°C to 45 °C and from 0min to 120 min. The treatment effect of wastewater was determined once every 15 min at different temperatures.

Analysis of results

The components of pickle wastewater is complex. The main components are plant fibre, plant amino acids, organic acids, alcohols, salts, calcium and magnesium ions etc. Therefore, in this experiment, the effect of COD removal rate was used as the evaluation index. The determination of COD was determined by potassium dichromate method (GB11914 - 89). The calculation is based on *Equation 1:*

$$COD_{Removal\ rate} = \frac{(COD_{inlet} - COD_{effuent}) \cdot 100\%}{COD_{inlet}} \quad \text{(Eq.1)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41154127

The specific surface area and pore size distribution of activated carbon carrier and catalyst are analyzed by BELSORP-max (full automatic multistation ratio surface, micropore and mesoporous pore analyzer).

The Nicolet 6700 infrared spectrometer was used to analyze the catalyst and the active carbon carrier, and the characteristic peak change mechanism of the material was analyzed by the EZOMNC software.

The crystal structure of catalyst and carrier activated carbon was determined and qualitatively analyzed by EMPYREAN X ray diffraction analyzer, and the variation of characteristic peak of the material was analyzed by JADE6.0 software.

Results and discussion

Optimization of the catalyst preparation conditions

Determination of active components and impregnation concentration

After the Experiment #1, the COD value of the effluent is measured, the results are shown in *Figure 1*.

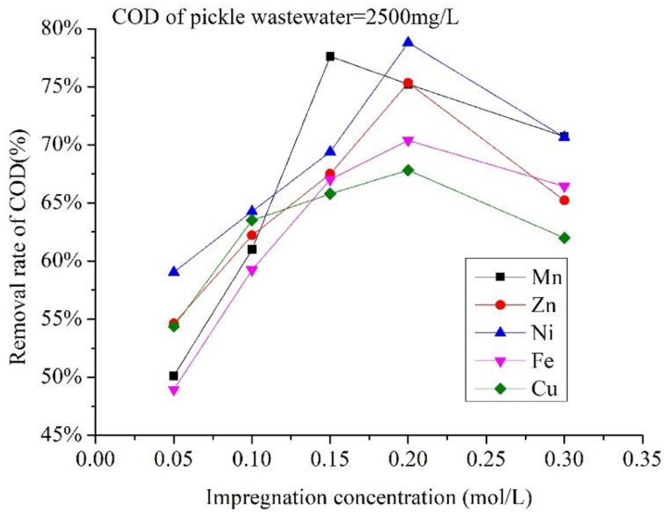

Figure 1. *Treatment effect of different active component catalysts*

As shown in *Figure 1,* the COD removal rate of all catalysts are above 35%. In contrast, the catalytic activity of activated carbon immersed 0.2 mol/L nickel nitrate is the highest, and the removal rate of COD reached 78.80%, the second highest is the catalyst which is immersed in 0.15 mol/L manganese nitrate, reaching 77.61%. This is due to the strong adsorption capacity of activated carbon. In the process of immersion, the active component of nitrate enters its pore structure. During the reaction, the generation of $SO_4^{-\cdot}$ and related chain reactions are accelerated by the transition metals in the carrier, increasing the number of $SO_4^{-\cdot}$ in the reaction system, and the rate of $SO_4^{-\cdot}$ propagation is also increased. When the immersing concentration is too large, the activity of the catalyst decreases. Because in this situation, the active components in the carrier pore will be saturated. The accumulation of active components on the surface of the carrier will lead to uneven distribution, and the active sites will be obscured. The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41154127

efforts between the catalytic efficiency of manganese and nickel is about 1%, but the concentration of manganese nitrate solution is lower and the price is cheaper. Based on experimental data and economic considerations, 0.15 mol/L manganese nitrate is used as the immersing solution, and immersing time is 2 h.

The effect of calcination conditions on the activity of catalyst

After the Experiment #2, the effect of calcination time and calcination temperature on the activity of the catalyst were tested. The results of the test are shown in *Figure 2*(a and b).

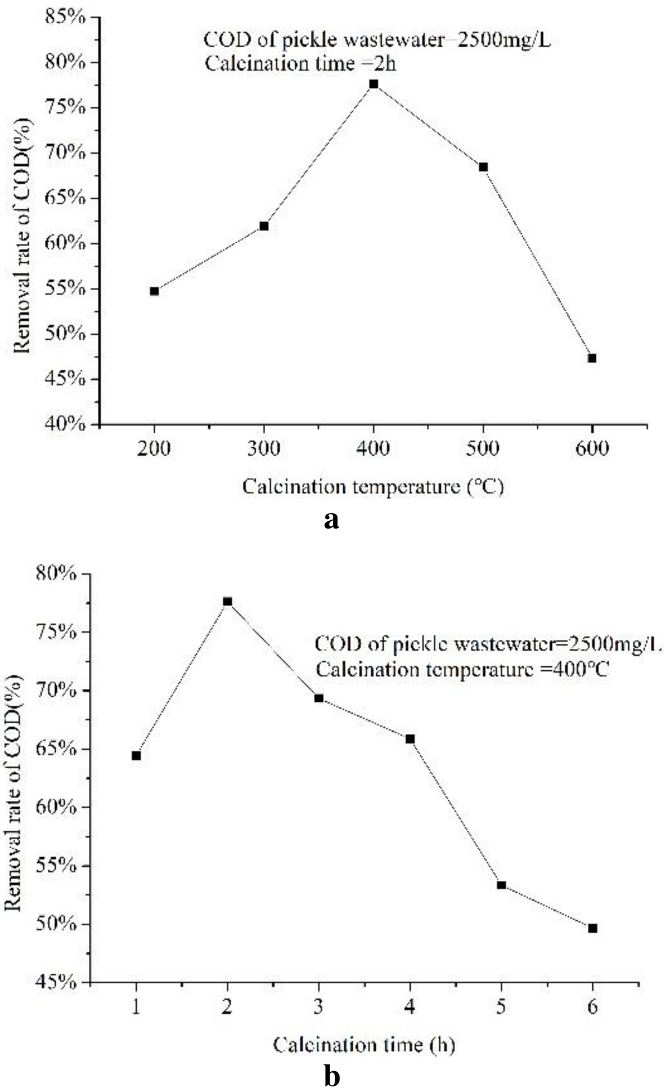

Figure 2. *The effect of calcination temperature on the activity of catalyst (a). The effect of calcination time on the activity of catalyst (b)*

As shown in *Figure 2a,* the activity of the catalyst increases with the calcination temperature when the calcination time is 2 h and the calcination temperature is changed during 200 °C to 400 °C. This is because at a lower temperature, the nitrate on the carrier is not completely decomposed, and the activity of the catalyst is increased by

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41154127

raising the calcination temperature. The effect is best at 400 °C, and the removal rate is 77.61%. When the calcination temperature continues to rise, obvious sintering phenomenon will appear, and it leads to the decrease of the specific surface area and the decrease of the activity of the catalyst. From *Figure 2b*, it reveals that the calcination time is 0 h, that is, unroasted, the treatment effect is not good. In contrast, after calcination, the activity increased significantly, This is not only due to the transformation of manganese nitrate into manganese oxide, but proper calcination can also make the surface of the carrier structure is more stable. When the calcination time is 2 h, the removal rate of COD is the largest. The activity of catalyst decreases with increasing calcination time, because the sintering phenomenon occurs, and the pore structure collapses and the specific surface area decreases.

Optimization of reaction conditions

Influence of the amount of oxidant on the treatment effect

Through the Experiment #3, the effect of the catalyst on the treatment effect was tested. The results of the test are shown in *Figure 3*.

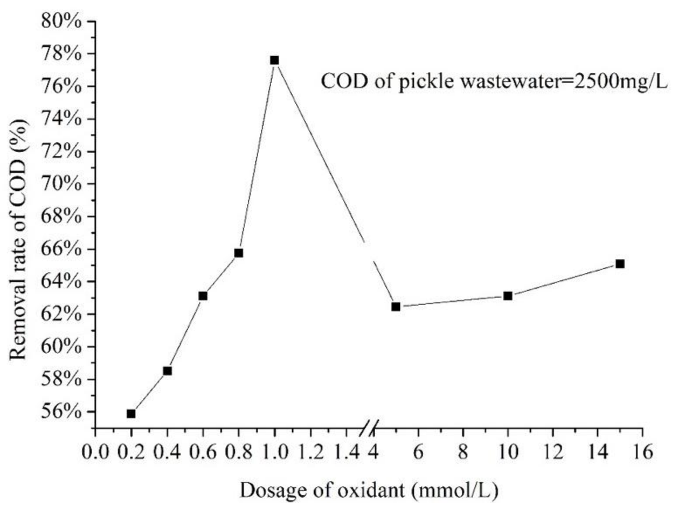

Figure 3. *The effect of the amount of oxidizing agent on the treatment effect*

As shown in *Figure 3,* with the increase of the amount of oxidant, the removal rate of COD increases first and then decreases. When the dosage is 1 mmol/L, the removal rate is 77.61%. When the dosage of sodium persulfate continues to increase, the removal rate of COD will decrease. When the sodium persulfate dosage is 5 mmol/L, the removal rate is 62.46%. The reason for this phenomenon is that with the increase of oxidants, the conversion of persulfate to $SO_4^{-\cdot}$ is accelerated under the action of catalyst, and the $SO_4^{-\cdot}$ content is increased. Its strong oxidizing property is used to decompose organic matter in the waste water and the concentration of COD is reduced. When the dosage of oxidant continues to increase, in the reaction system, a large number of $S_2O_8^{2-}$ will be quenched with $SO_4^{-\cdot}$ (Yang et al., 2010; Liang and Su, 2009), which leads to the decrease of $SO_4^{-\cdot}$ content. At the same time, $SO_4^{-\cdot}$ will also be self coupled. The oxidant utilization is declined by these two factors. Therefore, the dosage of the oxidant in the subsequent experiment was determined to be 1 mmol/L.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41154127

Influence of catalyst dosage on treatment effect

Through the Experiment #4, the effect of the oxidant on the reaction was tested. The results of the test are shown in *Figure 4*.

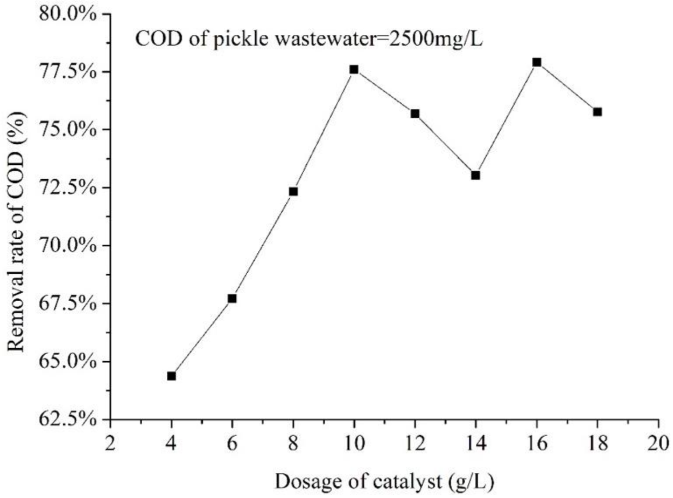

Figure 4. *The effect of catalyst dosage on treatment effect*

As shown in *Figure 4,* with the increase of the amount of catalyst, the removal rate of COD increases first and then tends to be stable. The removal rate of COD in the wastewater increases with the increase of dosage, and the removal rate is up to 77.61% when the dosage is 10 g/L. This is due to the increase of the active site with the addition of the catalyst. The contact probability of the reactant and the active site will increase. The generation of $SO_4^{-}\cdot$ and the reaction of chain reaction were accelerated, resulting in the increase of $SO_4^{-}\cdot$ content, which resulted in higher reaction efficiency and increased COD removal rate. When the dosage of catalyst is more than 10 g, the removal rate of COD always fluctuates around 75%, and the change tends to be stable. When the amount of dosage is 4~18 g/L, the removal rate of COD is all above 64%. Therefore, in the comprehensive economic consideration, the dosage of the subsequent experimental catalyst is determined to be 10 g/L.

Influence of reaction system pH on reaction effect

Through the Experiment #5, the effect of the reaction pH was tested. The results of the test are shown in *Figure 5:* As the pH value of the reaction system increases, the removal rate of COD increases first and then decreases. When pH is 2, the removal rate of COD is 72.34%, and when pH is adjusted to 4, the removal rate of COD increases to 85.81%, and then continues to increase pH value, the COD removal rate will decrease. When pH is alkaline (pH > 8), the removal rate of COD is less than 75%, and when pH is 12, the removal rate of COD is only 52.78%. When pH is medium / strong alkaline (pH > 8), the removal rate of COD is less than 75%, and when pH is 12, the removal rate of COD is only 52.78%. It can be seen that the pH reaction system has great influence on the reaction effect, and this is due to the fact that the mechanism of advanced oxidation reaction system for sodium persulfate in acidic or alkaline condition

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41154127

is completely different. When pH is acidic, the $SO_4^{-\cdot}$ in the reaction system is stable (Couttenye et al., 2002), and it can play a role in the process of oxidation.

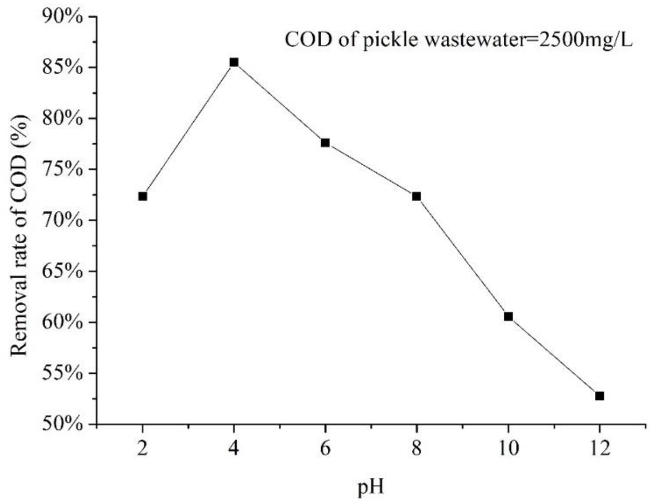

Figure 5. *The effect of reaction system pH on treatment effect*

When the reaction system is alkaline, in the reaction system, $SO_4^{-\cdot}$ Will react with H_2O and OH^-, and the chemical equations are as follows:

$$SO_{4^-}\cdot + H_2O \rightarrow HSO_{4^-} + \cdot OH$$

$$SO_{4^-}\cdot + OH^- \rightarrow SO_4^{2-} + \cdot OH$$

At this time, the hydroxyl radicals (·OH) were involved in the oxidation. However, there was a lot of Cl^- in the pickle wastewater, and Cl^- has quenching effect on ·OH, so that ·OH have been quenched before oxidized, resulting in a sharp decrease in COD removal rate.

Based on the above experimental data and analysis, when the reaction pH changes during 4 to 7, the COD removal rate is kept at a high level. In order to find the best reaction effect, the subsequent pH will be 4.

Influence of reaction temperature and reaction time on the treatment effect

The results of the Experiment #6 are shown in *Figure 6:* From the reaction time, the reaction in the first 15 min is very fast, and the COD removal rate can reach 63.69%. Then, the reaction rate will slow down from 15 to 75 min, and the reaction will tend to be stable after 75 min. From the reaction temperature, when the temperature rises from 20 °C to 30 °C, the removal rate of COD increases from about 72% to about 84%, and the reaction effect is obviously better. When the temperature is higher than 30 °C, the increase of temperature also plays a role in the improvement of the treatment effect but is not obvious, and the change tends to be stable. From the aspect of kinetics, when the temperature is increased, the mass transfer process between reactants and products in liquid phase and active sites is accelerated, which improves the reaction efficiency and increases the removal rate of COD. As the temperature continues to rise, the “forward”

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41154127

effect of temperature continues, but from the aspect of thermodynamics, the oxidation process of the organic matter and the adsorption process on the surface of the catalyst are both exothermic. From this point of view, the increase of temperature is not conducive to the oxidation and adsorption. Therefore, when the temperature is higher than a certain temperature, the removal rate increases little. Therefore, considering the energy saving and economy, the reaction time is 75 min, the optimum reaction temperature is 30 °C. From the experimental data, the oxidation process has a good tolerance for temperature.

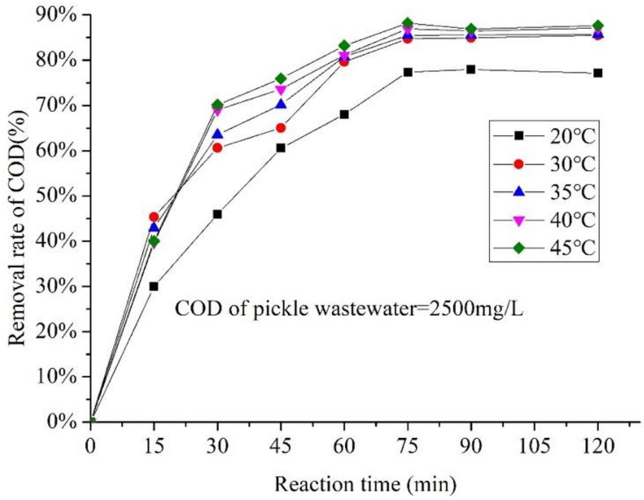

Figure 6. *The effect of reaction temperature and reaction time on the treatment effect*

Characterization and analysis of catalyst

Specific surface area/aperture analysis

In order to further explore the influence of immersion and calcination on the structure of the catalyst, the BET specific surface area of the prepared catalyst was tested. In the experiment, the liquid nitrogen was used as the adsorbent and the desorption curve is shown in *Figure 7,* and the results of the BET test are shown in *Table 2*.

As shown in *Figure 7,* the adsorption curve and the desorption curve coincide in p/p 0 < 0.4, and at p/p 0 > 0.4, the desorption curve is higher than the adsorption curve, then it is closed again at about p/p 0 = 1.0, forming a hysteresis loop. It affects the pore structure of the catalyst and is related to the network properties of the pores. According to the characteristics of this curve, the nitrogen desorption isotherm curve of the catalyst should be summed up as type IV curve, and the pore structure of the catalyst is mainly mesoporous and microporous. According to *Table 2*, it reveals that the specific surface area and pore structure of the carrier changed after impregnation and calcination. The specific surface area of the catalyst increases, the total volume of the micropores increases, but the average pore size and the mean pore volume decrease. This is due to the calcination which can open the inner pores of the active carbon, so the micropores are increased. But, after calcination, manganese nitrate becomes manganese oxide, and it blocks the partial pore structure of the carrier, resulting in the decrease of the average

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41154127

pore volume. And it also reflects the active components being successfully loaded onto the catalyst carrier.

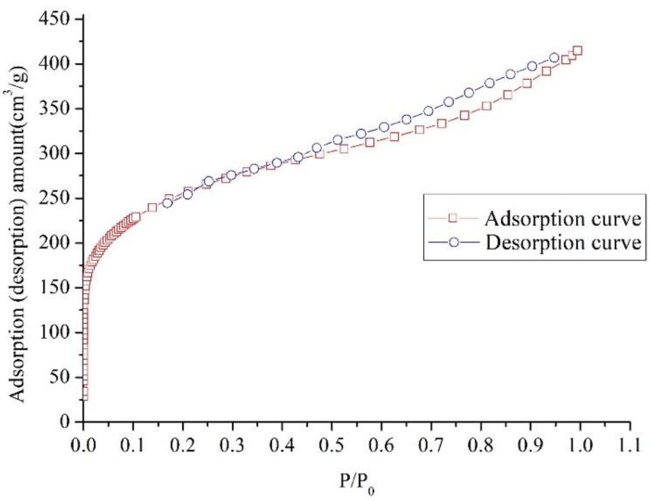

Figure 7. *Catalyst for nitrogen adsorption desorption isotherm*

Table 2. *Catalyst BET analysis*

Name	Impregnation condition	Calcination condition	Specific surface area (m^2/g)	Aperture (nm)	Pore volume (cm^3/g)	Total volume of micropores (cm^3/g)
Carrier AC	--	--	463.81	3.733	0.424	0.1874

Fourier infrared spectroscopic analysis

Fourier infrared spectroscopy (FT-IR) was used to analyze the changes in the chemical groups of the active carbon of the carrier before and after the load. The results of the experiment are as shown in *Figure 8*.

Figure 8 shows that the carrier activated carbon has absorption peak at 3404.64 cm^{-1}, 2921.88 cm^{-1}, 2844.86 cm^{-1}, 1618.52~1316.82 cm^{-1}, 1162.62~1029.14 cm^{-1}, 896.26 cm^{-1}, 775.70~471.78 cm^{-1}. Among them, a wider absorption peak appeared at 3404.64 cm^{-1}, and it is caused by the hydrogen bond vibration in -OH, indicating the presence of a large number of hydroxyl groups in the samples. 2921.88 cm^{-1} and 2844.86 cm^{-1} indicate the presence of phenolic group (O-H); There are several smaller absorption peaks in the 1618.52~1316.82 cm^{-1} interval, which may be related to the telescopic vibration of C=O and the presence of nitro compounds and carboxyl groups. The absorption peak in the 1162.62~1029.14 cm^{-1} interval indicates that there are also ethers (=C-O-C, C-O-C) in the activated carbon. The continuous and weak absorption peaks in the 500~1000 interval may be caused by the bending vibration of -OH and C-H. Compared with the carrier activated carbon, the overall transmittance of the Mn/AC catalyst was reduced. Among them, the hydroxyl, carboxyl and phenolic hydroxyl groups all increased. All kinds of oxygen-containing functional groups greatly enhanced the polarity of the catalyst surface and enhanced the adsorption capacity. At the same

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41154127

time, the peak of the absorption peak of the catalyst at 516 cm^{-1} and 565 cm^{-1} is due to the telescopic vibration of the Mn-O metal bond (Li, 2015a; Li, 2015b). This shows that after the carrier activated carbon impregnated, manganese is successfully loaded, and after calcination, manganese and manganese oxides are formed.

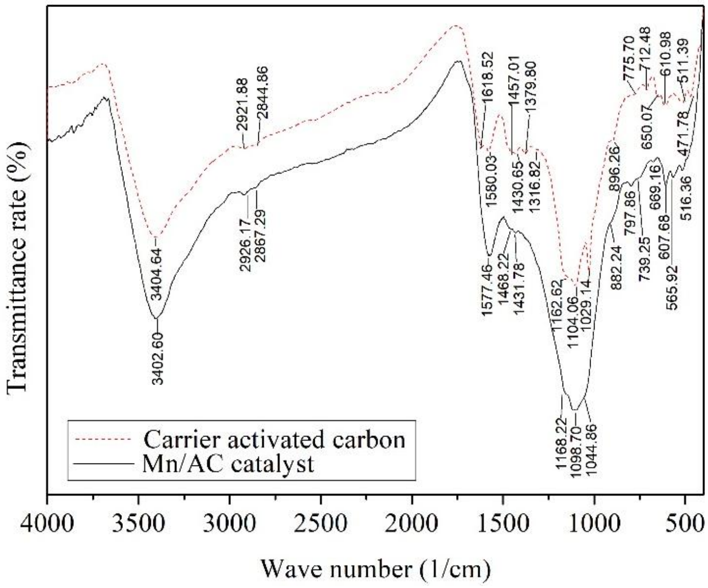

Figure 8. *Comparison of infrared spectra of active carbon of carrier before and after load*

X-ray diffraction analysis

X-ray diffraction was used to analyze the active carbon of the carrier before and after the load. By comparing the variation of the characteristic peaks, the changes in the crystals of the related material before and after the load can be found. The results of the experiment are as shown in *Figure 9*.

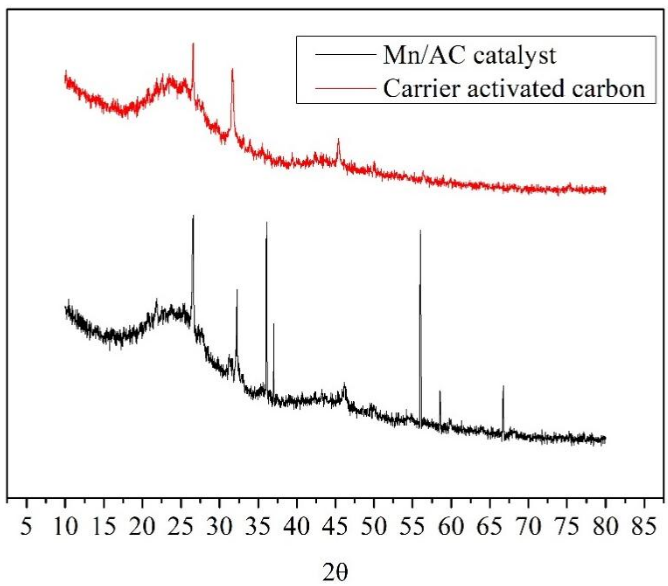

Figure 9. *The Xrd pattern of activated carbon before and after load*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41154127

As shown in *Figure 9,* some sharp peaks of sharp diffraction are found in the carrier after treatment. The peak diffraction angle 2θ is 32.31°, 36.09°, 37.12°, 56.02°, 59.84°, 66.76°. Compared with the JCPDS standard card (30-0820), the diffraction peaks at 37.12°, 56.02°, and 66.76° indicate that MnO_2 is formed in the carrier. Compared with the JCPDS standard card (24-0734), the diffraction peaks of 2θ at 32.31°, 36.09° and 59.84° conformed to the characteristic peaks of Mn_3O_4. The characteristic peak pointed out that the manganese oxide formed the crystal, but the figure of merit (FOM) was not high, which may be related to the background peak and the sample processing conditions during the measurement. Through the comparison of the XRD diagram, it is shown that the manganese oxide has been successfully loaded with activated carbon.

Conclusion

(1) Experiments show that the manganese in sodium persulfate advanced oxidation treatment of pickle wastewater for the catalytic performance is the best. In the preparation of the catalyst, the selection of the suitable impregnation concentration can make the active component into the carrier gap and get the uniform distribution. The selection of the appropriate calcination time and temperature can efficiently convert the active component into the corresponding metal oxide, and the sintering phenomenon is controlled. Based on the experimental data, the optimum preparation conditions of the catalyst are as follows: at 30 °C, the carrier is soaked in 0.15 mol/L manganese nitrate solution for 2h and calcined for 2h at 400 °C.

(2) The prepared catalyst was used for advanced oxidation treatment of wastewater. The effects of oxidant dosage, catalyst dosage, reaction pH, reaction temperature and reaction time on the reaction effect were studied. The optimum reaction conditions: the dosage of oxidant is 1 mmol/L, and the amount of catalyst is 10 g/L, and the reaction pH is 4, and the reaction time is 75 min, and the reaction temperature is set to 30 °C. The COD can be removed 84% when the best preparation conditions of catalyst and the best reaction conditions is used in the advanced oxidation treatment of pickle wastewater.

(3) According to the BET analysis, it is found that compared with the carrier activated carbon, the specific surface area of the carrier is increased. The pore structure of the carrier material be improved by the formation of micropores. This may be the cause of the calcination. The activity of the catalyst is influenced by the specific surface area, aperture, pore volume and other physical factors.

(4) According to Fourier transform infrared spectroscopy analysis, the hydroxyl, carboxyl and phenolic hydroxyl groups on the activated carbon were increased. The oxygen functional groups greatly improve the adsorption capacity and activity of the catalyst. At the same time, the characteristic peaks of the telescopic vibration of the Mn-O metal bond were found in the catalyst. This shows that after the carrier activated carbon impregnation and calcination, the Mn has been successfully loaded.

(5) According to the X ray diffraction analysis, it was found that the catalyst showed a characteristic peak of MnO_2 and Mn_3O_4 compared with the carrier activated carbon. This shows that the carrier activated carbon has successfully loaded the manganese element, which is in accordance with the results of the FT-IR analysis.

(6) Follow up studies can focus on the following aspects: first, further study on the regeneration of the catalyst should be carried out in order to provide a basis for actual operation and economic analysis; second, in order to apply this method to practical engineering, it is necessary to further expand the scale of experiments.

(Received 26th Mar 2018; accepted 12th Jun 2018)

Abstract. Defining the characteristics of rainfall distribution is the key for many engineering applications such as road design, flood damage mitigation measures, and planning and management of water resources. Since Makkah Al-Mukarramah area is of utmost importance in Saudi Arabia, studying the characteristics of rainfall distribution is necessary. This research aims at investigating rainfall data to define the best rainfall distributions and its characteristics in the study area via rainfall frequency analysis. Different statistical analyses such as log-normal distribution, normal distribution, extreme value type I distribution, Pearson type III distribution, and log-Pearson type III distribution were preformed on more than 20 stations having annual rainfall data over ten years. The results showed the best probability distributions, and rainfall predictions at various return periods for the study area. 36% of rainfall stations follow three parameters log-normal distribution, 27% of stations follow log-Pearson type III distribution, 14% of stations follow Pearson type III distribution,9% of stations follow GEV distribution,9% of stations follow two parameters log-normal distribution and 5% follow Gumbel Type I.
Keywords: *arid and semiarid zones, frequency analysis, rainfall modelling, stochastic analysis*

Introduction

Rainfall is considered the most important factor in hydrology, and nearly most or all of the natural and unnatural activities depend on rainfall, and rainfall initiates various types of work, like water resource management, agriculture and forestry, flood protection and many other (Mahdavi et al., 2010). Predicted changes in precipitation in the future are needed for studying of the consequences of the climatic changes around the world which represent input to the hydrological cycles. And due to lack of randomization in the meteorological and hydrological data, they can be analyzed statistically using frequency data analysis of rainfall and flood. Due to these reasons, it is easy to use statistical distribution in many studies like those dealing with water structure design, water resources and watershed management and parameter estimation in the hydrological cycle (Subyani, 2011; Mashat and Basset, 2011). One of the essential things is the determination and fitting of the best distribution to the data. The analysis of frequency means relating the ultimate events magnitude to their occurrence frequency by the use of the probability distribution (Chow et al., 1988). Rainfall measurements would enhance the feasibility of flood protection works, and will also lead to successful managing of runoff water, and such data analysis will help in preventing floods and droughts (Bahrawi, 2009). It can also be applied in the management and design of most engineering works that deal with water resources like the design of reservoirs, the control of floods and drainage systems, methods to conserve soil and water. Rainfall data are needed to provide the base for all these types of design works.

Makkah Al-Mukarramah area is one of the most developed areas in Saudi Arabia. The annual average rainfall of Makkah Al-Mukarramah area exceeds 100 mm (Bahrawi et al., 2016). There is an increasing need for water for economic development. Autumn and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41294144

winter are the major rainy seasons, and steep terrains of the study area often cause short time of concentration and extremely rapid creation of wadis during the precipitation-runoff process. It results in flash flood dangers. In order to reduce losses arising from these kinds of floods, an appropriate hydrologic design is very important. Rainfalls are not evenly distributed spatially and temporally (Mahdavi et al., 2010). Makkah Al-Mukarramah climate is affected by various air masses from Mediterranean (cyclone type) during winter season to monsoon type in summer season. The mechanisms of the movement of these air masses is explained in details in the literature (Mahdavi et al., 2010; Subyani, 2011; Mashat and Basset, 2011).

This particular research intends to study the rainfall distribution characteristics of the Makkah Al-Mukarramah area, through utilizing various statistical tests of probability distributions such as the normal distribution, log-normal distribution, extreme value type, I distribution, Pearson type III distribution, and log-Pearson type III distribution all these distributions are mentioned as suitable and practical in the literature (Kite, 1977). Rainfall gauging data from stations of Makkah Al-Mukarramah province were used to investigate the fitness of statistical distributions (*Fig. 1*). Twenty-two stations providing annual rainfall data over more than 30 years were chosen in order to execute the frequency analysis (Subyani, 2011). For determination of the best fitting distribution to maximum daily rainfall the Relative residual mean square (RRMS) is used. Shuqiu (1993) suggested in her research, that: "Nearly all rainfall stations at the same region can easily certainly not be characterized simply by only an individual probability distribution, supposing these types of stations to fit to a specific probability distribution and type a cluster." nearly all the stations in the similar regions categorized a varied cluster in agreement with their probability distributions. In case important characteristics among clusters persisted, such as a particular part of the stations being similar to rainfall characteristics and consequently fit to the exact same probability distribution, these characteristics might result from the stations of a cluster and have a special connection to a particular daily rainfall data. Subyani (2011) used annual maximum rainfalls from 8 rainfall stations in order to obtain rainfall frequency analysis. The author utilized the statistical distribution methods like Gumbel's extreme value distribution and Log Pearson Type III distribution for maximization of the daily rainfall data over 24-40 years, and he found that the best fitting for prediction of the rainfall occurrence in future is Gumbels model.

The areas with heavy annual rainfall within Saudi Arabia extend along the southwestern Red Sea Coast and North-Eastern coast and then moves over the middle region of the Saud Arabia. Hasanean and Almazroui (2015) mentioned that within Saudi Arabia, the very heavy precipitation areas were along the southwestern coast and the South West to North East inclined precipitation band, which moves over the middle region of Saudi Arabia. However, the annual average rainfall of the Makkah Al-Mukarramah area exceeds about 140 mm mean annual rainfall, generally there is a big gap between rainfalls, which usually has wide uncertainly spatially and temporally (Subyani, 2011; Shuqiu, 1993).

Materials and methods

Study area

Saudi Arabia is divided into 13 districts. Makkah Al-Mukarramah region is one of the most important districts. It has 22 recording rainfall gauges (*Fig. 1*). Makkah Al-Mukarramah region has actually a dry climate with extremely high temperature values during the day, and minimal rainfall that is inconsistent (Mahdavi et al., 2010; Subyani, 2011). There are either wadis during the entire 12 months, or the rain might just occur in the type of one or two abundant outbursts that may cause actual flooding. Data from different sources, which is usually climatological, was provided by the Ministry of Water and Electricity in Saudi Arabia. Spatially, the mountainous area has additional rainfalls compared to the regular area, and the sloping ground would definitely result from the water preservation potential of watershed to decline dramatically (Subyani, 2011). A large portion of rainfalls will become runoff and discharges quickly, causing damage to infrastructure. Types of these sources had a continuous and timely based record (*Table 1*). The rainfall data with valid documentation obtained and examined from these types of gauging stations, considerably increased in the past 20 years. Some other stations either had very few records of daily data or records with total sum of daily data.

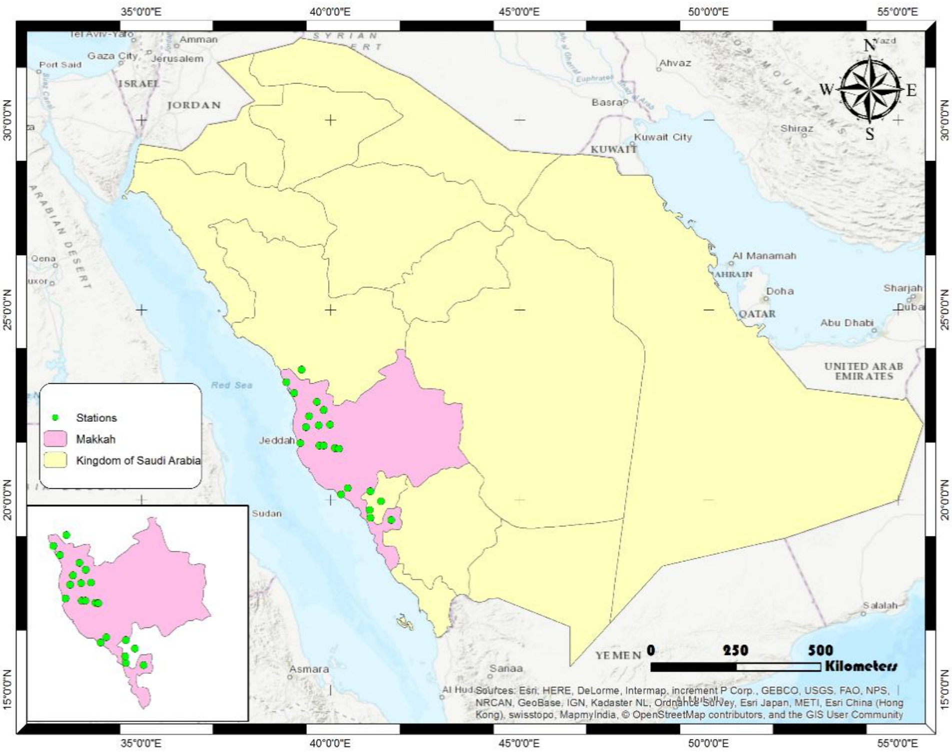

Figure 1. Stations in the Kingdom of Saudi Arabia and Makkah Al-Mukarramah Region

Data

Saudi Arabia has an arid environment characterized by extreme heat during the day, abrupt drop in temperature at night. Rainfall in the region of Makkah Al-Mukarramah is low and erratic. *Figure 2* shows the average monthly rainfall depth for the rainfall stations in the study area from (1966 to 2013). The figure shows that the spatial variation of rainfall is influenced by the topographic features. The rainfall depth increases with the elevation (which is called the orographic effect). The orographic rainfall is due to the mechanical raising of the clouds over mountain boundaries (Linsley et al., 1982). The stations near the coastal zone receive less rainfall in comparison with the stations in mountainous areas. (see e.g. station J108, J111, J134, J140 at coastal plain, and stations J113, J116, J131, J137 at the mountains). It is obvious

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41294144

from *Figure 2* that most rainfall occurs in October, November, December and January (winter season), and out of the winter season there is a lot of rainfall in March and April. May, June, July, August and September have low rainfall. There is no specific pattern spatially and temporally in every region. This behaviour is evident from *Figure 2* since in every month there is a high variation of rainfall depth in all stations.

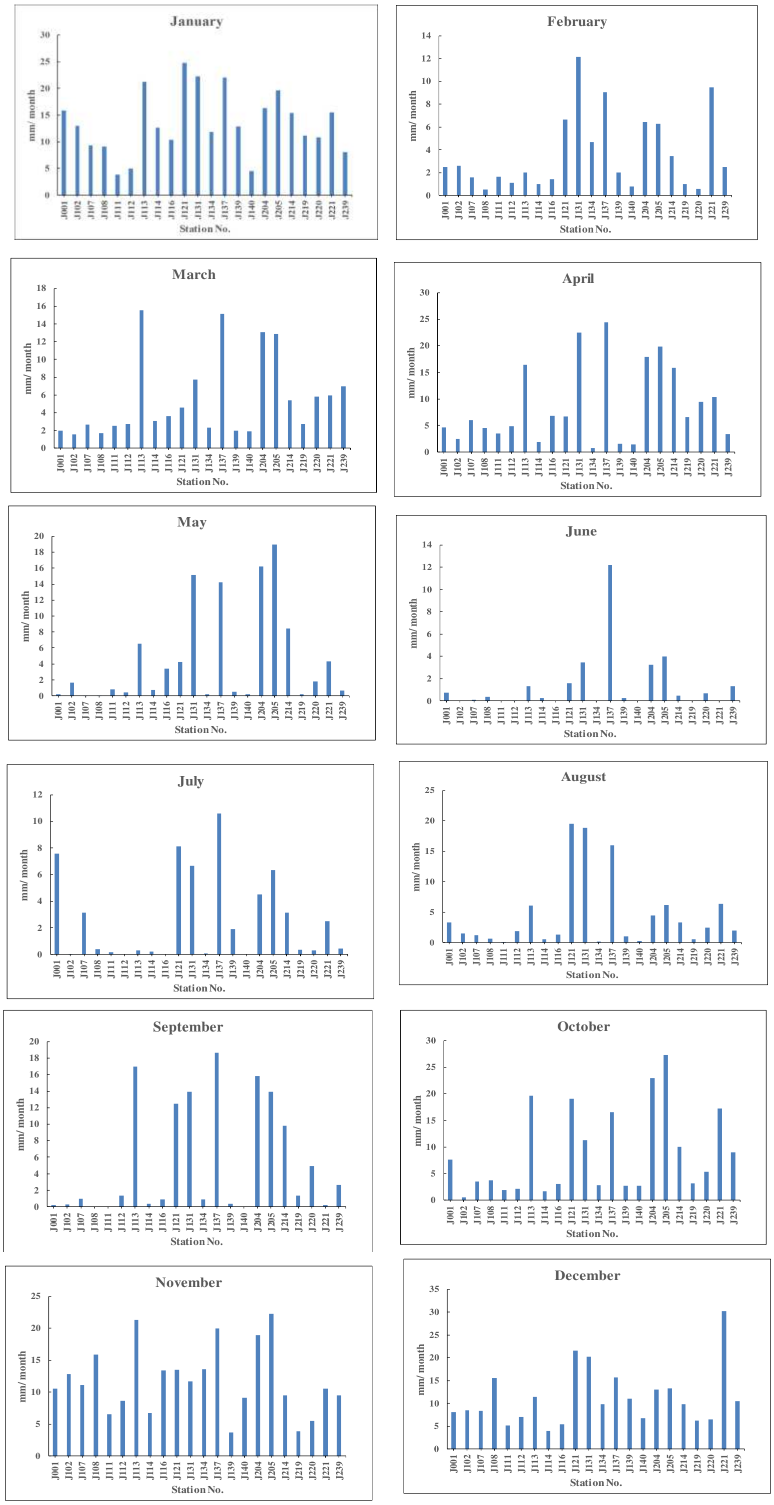

Figure 2. *Average monthly rainfall depth*

Continuous rainfall data were collected from 1966 to 2013, from the rainfall gauge network that covers the Makkah Al-Mukarramah region. The data collected for each station includes the station number, station symbol, years of records, coordinates, and number of storms (*Table 1, Fig. 3*). Maximum daily rainfall, storms are collected from the 22 stations covering the study area (*Table 1*). *Figure 3* shows samples of time series for maximum daily rainfall data at some stations in the study area. The figures show high variations in the rainfall data over the station history. Some years show no rainfall.

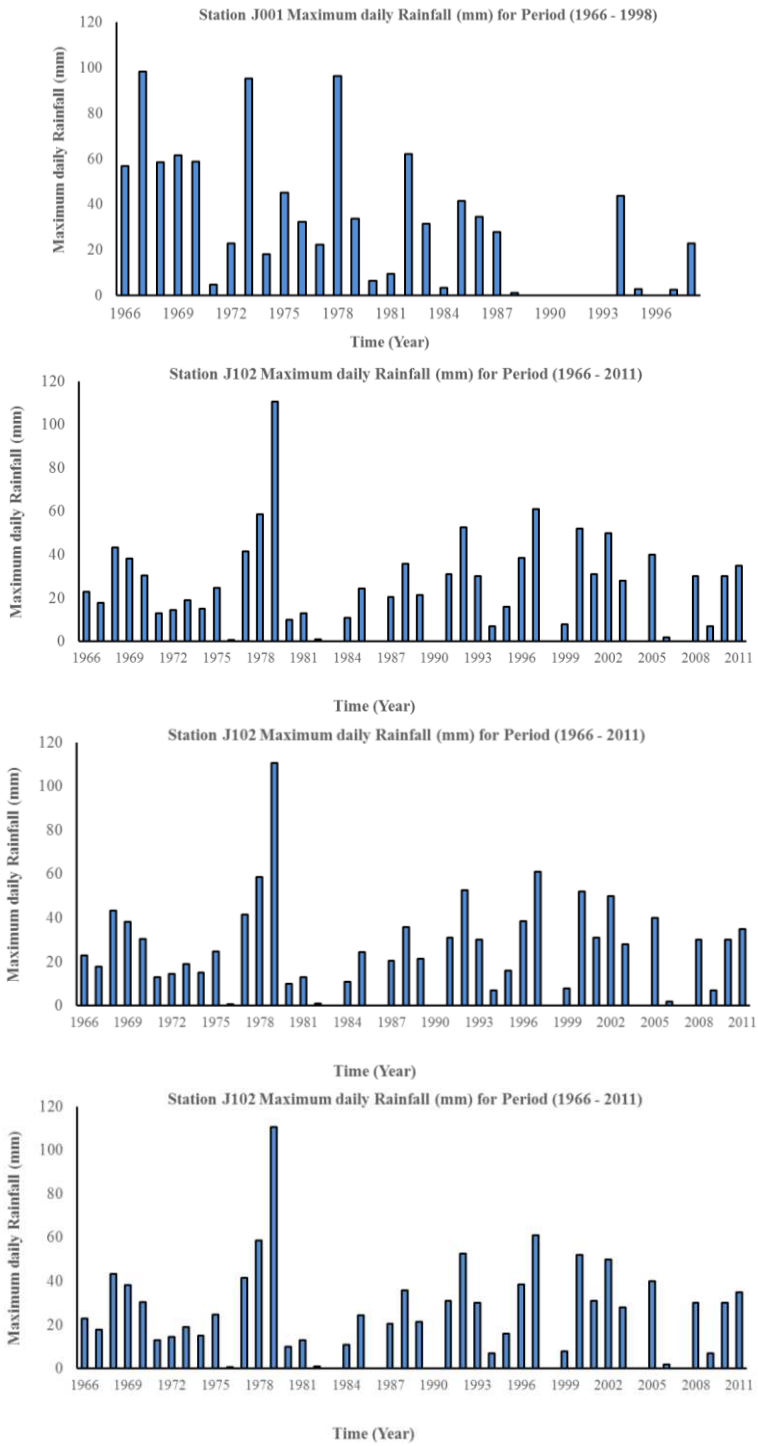

Figure 3. *Sample of maximum daily rainfall depth time series of some stations, namely J001, J102 and J108*

Research method

Frequency analysis

Hydrologic Frequency Analysis is the method used for evaluation of the probability of the hydrologic events, which are averaged out in statistical viewpoints, either greater

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41294144

than or of a specific magnitude within a certain area, that will occur within a certain period. The frequency analysis methods used in this study are as follows.

The equation (*Eq. 1*) of frequency analysis is

$$Q_T = M + K_T S \tag{Eq.1}$$

where Q_T is the hydrologic quantity (rainfall depth in the current study) with the return period T; M is the mean of hydrological data; S is the standard deviation of hydrological data; and K_T is the frequency factor, a function of the return period and probability distribution Kite (1977) has calculated K_T for the Gumbel distribution for the lognormal distribution and for the gamma distribution. The followings are short descriptions of the probability distributions used in the analysis:

Two-parameter lognormal distribution (LN2)

The lognormal distribution is used at a larger stage for the analysis of environmental extremes. The probability density function of the two-parameter lognormal distribution is calculated as *Equation 2:*

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma x} \exp\{ -\frac{1}{2}(\frac{\ln x - \mu}{\sigma})^2 \} \tag{Eq.2}$$

μ is a location parameter, and σ is a scale parameter.

The magnitude of the event with return period T = 1/p can be estimated from *Equation 3:*

$$\ln x_T = \mu + \sigma Z_p \tag{Eq.3}$$

where Z_p is the standard normal variate with exceedance probability p.

Three-parameter lognormal distribution (LN3)

The three-parameter lognormal distribution which is in fact the two-parameter distribution is represented as *Equation 4:*

$$f(x) = \frac{1}{(x - x_0)\sigma\sqrt{2\pi}} \exp\{ -\frac{1}{2}(\frac{\ln(x - x_0) - \mu}{\sigma})^2 \} \tag{Eq.4}$$

μ is the location parameter and ð is the scale parameter, while X_0 controls the shape of the distribution.

The event magnitude for the return period T = 1/p is calculated according to *Equation 5:*

$$\ln(x_T - x_0) = \mu + \sigma Z_p \tag{Eq.5}$$

where z_p is the standard normal variate with exceedance probability p.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41294144

Pearson Type III distribution (P3)

The Pearson Type III distribution is one of a large family of probability distributions developed by Pearson (Price and Harrison, 1975). Both the exponential and gamma distributions are special cases of the Pearson Type III distribution.

The distribution function is (*Eq. 6*):

$$f(x)=\frac{(x-x_0)^{\gamma-1}\exp\left\{\frac{-(x-x_0)}{\beta}\right\}}{\beta^{\gamma}\,\Gamma(\gamma)} \quad \text{(Eq.6)}$$

The X_0 which constitutes a lower bound controls locations, β controls the scale and γ controls the shape. And due to difficulty in calculating the magnitude of the event with return period T using hand calculation, the best and simplest way is to make estimations of the T-year event from the means of the sample, the standard deviation and a factor K_T (*Eq. 6*)

$$x_T=\bar{x}+\sigma K_T \quad \text{(Eq.7)}$$

The factor K_T varies with return period T and sample skewness γ, and can be read from tables (Tables 9-2 and 13-4 in Mahdavi et al., 2010, for example).

Log-Pearson Type III distribution (LP3)

Log-Pearson Type III distribution is in fact refers to Pearson Type III distribution, and it is represented as *Equation 8:*

$$f(x)=\frac{\ln(x-x_0)^{\gamma-1}\exp\left\{\frac{-\ln(x-x_0)}{\beta}\right\}}{\beta^{\gamma}\,\Gamma(\gamma)} \quad \text{(Eq.8)}$$

The X_0 which constitutes a lower bound controls location, β controls the scale and γ controls the shape. And the best and simplest way is to make estimations of the T-year event from Pearson Type III distribution.

Generalized extreme value distribution (GEV)

The generalized extreme-value (GEV) distribution was introduced by Jenkinson (1955, 1969) and Mahdavi et al. (2010) initiated the distribution based on the, Generalized Extreme Value (GEV) for annual rainfall data, and thus brought together a number of distributions into Gumbel's value, and thus the function is (*Eq. 9*):

$$F(x) = \exp\text{-}\,[1 - k(\frac{x - u}{\alpha})\,]^{1/k} \quad \text{(Eq.9)}$$

and the magnitude with Gumbel reduced variate y can be determined from *Equation 10:*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41294144

$$x = u + \alpha\left(\frac{1 - e^{-ky}}{k}\right) \qquad \text{(Eq.10)}$$

$$where \quad u + \frac{\alpha}{k} \leq x < \infty \quad if \;\; k < 0$$

$$-\infty < x \leq u + \frac{\alpha}{k} \quad if \;\; k > 0$$

μ and α represent parameters, a location parameter and a scale parameter, and K represents the shape of the distribution. When K becomes zero the general extreme value will be reduced to extreme value 1 distribution, and when K becomes negative then the general extreme value will be type 2 without an upper limit, and when K is positive then the general extreme value becomes 3 with an upper limit of $\mu + \alpha/k$.

Results and discussions

It was indicated from the relative frequency distribution that Log Pearson type III distribution initiated the best probability distribution (Mahdavi et al., 2010). *Figure 4* shows the annual average rainfall depth of the stations in the study area. It is obvious that there is high variation between the different stations (minimum is 10 mm and maximum 45 mm) the highest annual rainfall depth is observed in station J205 and lowest rainfall station is J140. The standard deviation rainfall of the stations is shown in *Figure 5*.

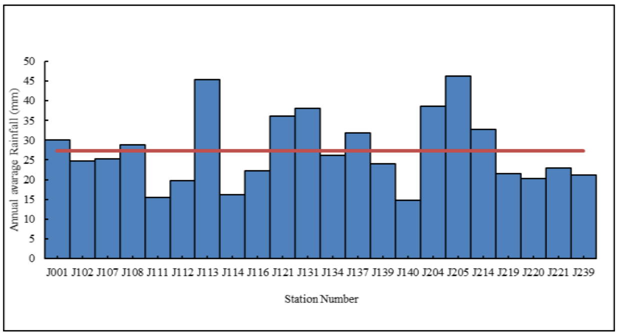

Figure 4. *Annual average rainfall depth of the stations in the study area*

Frequency analysis

In order to determine common characteristic rainfall distribution of the study area frequency analysis is applied using various distributions, of which, three parameters log-normal distribution, two parameters log-normal distribution, log Pearson type III distribution, Pearson type III distribution, and Gumbel extreme value distribution, with rainfall data recorded through 22 stations over 30 years. Results showed that the 3 par

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41294144

log-normal distribution is the best probability distribution, occupying 36% of the total number of stations (as shown in *Figure 8a, b, c* and *Table 2*).

The best distributions were chosen dependent on the root-mean-square error measure, RMSE (Mahdavi et al., 2010). RMSE values for the different distributions explain the mean inconsistency between the predictable value and the measured one. *Table 2.* shows the best fitting distributions depending upon the minimum RMSE as given by italicization in the table. The best probability distribution is presented in *Figure 8a, b, c*.

Figure 8. *(a, b, c) Rainfall depth, frequency analysis at the stations in the study area based on the best probability distribution assigned from Table 2 and the corresponding confidence interval*

Table 3 shows the maximum and minimum values of the expected rainfall depth for study area under different return periods. The table shows that the variation between the minimum, and maximum is very high depending on the location of the stations where the stations over the mountain area have high expected rainfall depth. However, stations at low plain area have low expected rainfall depth. The eastern part of the study area has no stations. Therefore, the contouring extrapolated values for these areas which need to be validated by ground stations. It is recommended to have extra rainfall stations in this area to get more reliable mapping. *Table 4* shows the percentage of each distribution of the rainfall stations. The table shows that 36% of the rainfall stations follow three parameters log-normal distribution, 27% of the stations follow log-Pearson type III distribution, 14% of the stations follow Pearson type III distribution, 9% of the stations follow GEV distribution, 9% of the stations follow two parameters log-normal distribution and 5% follow Gumbel Type I.

Table 3. *Expected maximum and minimum rainfall depth for Makkah Al-Mukarramah region at different return periods*

Return period years	Minimum rainfall depth (mm)	Maximum rainfall (mm)
5	27.08	69.17
10	42.41	94.91
25	57.47	132.98
50	62.41	165.36
100	65.76	208.85
200	68.1	282.15

Table 4. *The percentage of the best distributions over Makkah Al-Mukarramah region from all stations*

Distribution type	% per all stations
Gumbel type I	5%
GEV	9%
Two-parameter log-normal	9%
Three parameters log-normal	36%
Pearson type III	14%
Log-pearson type III	27%

Moreover, *Figure 9* displays a color contour map of the expected rainfall depth at different return periods from 2 to 200 years over Makkah Al-Mukarramah region. The maps show the locations of expected high and low rainfall depth in the region. This can be useful in the flood analysis in these areas. Locations of maximum rainfall have a high risk of flooding while locations of minimum rainfall have a low risk of flooding.

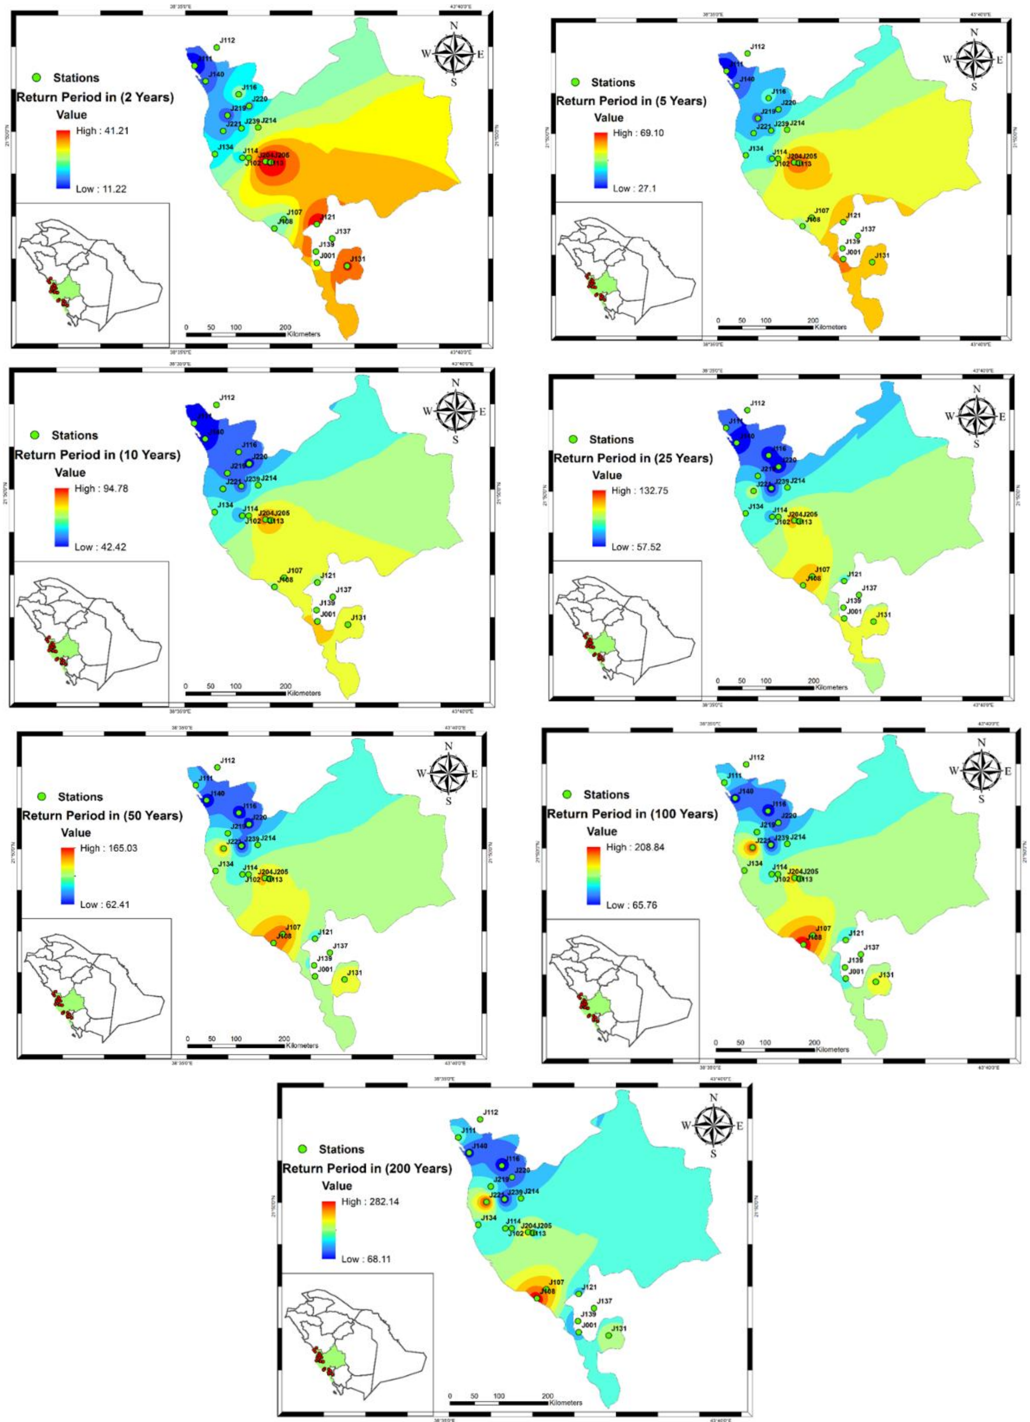

Figure 9. *Mapping rainfall depth for different return periods (5, 10, 25, 50, 100, 200 years) over Makkah Al-Mukarramah region*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41294144

Conclusion

From the results of five frequency distributions applied in this study, it is suggested that the best frequency distribution obtained for Makkah Al-Mukarramah area is the three Parameter Log-Normal distribution, which occupies 36% of the total number of stations, followed by the log-Pearson Type III and Pearson type III distribution which accounts for 27% and 14% of the total station number, respectively. From the results of the frequency analysis, three Parameter Log-Normal distribution is the primary distribution pattern for this study site. By increasing the number of years and data and employing different methods for the analysis, it is believed that more accurate results could be obtained. Outcomes revealed that the three Parameter Log-Normal distribution, conducted the best in the probability distribution, fitting 36% of the total station data.

Abstract. This paper used data on land use, normalized difference vegetation index, digital elevation model, temperature and precipitation, and urban distribution to analyse the impacts of climate change, urban expansion and the Grain for Green project implementation on land use and land cover change in the Loess Plateau between 1980 and 2015 based on a single factor and comprehensive factor analysis. The aim of this paper is to explore the spatial expression of human activities under the influence of urban expansion, climate change, and the implementation of the Grain for Green project. The results indicated that climate change dominated among the influencing factors of land use and land cover change in the Loess Plateau, accounting for 93.65% of the total, with a surface-like distribution. It was followed by urban expansion, accounting for 5.46% of the total, with a point-like distribution. The impact of the Grain for Green project implementation accounted for 0.64%, with a patchy distribution. However, due to the low resolution, the quantitative assessment results regarding the role of the Grain for Green project implementation was lower, while for climate change and urban expansion, results were higher.
Keywords: *NDVI, temperature, precipitation, correlation coefficient, buffer analysis*

Introduction

Land use and land cover change (LUCC) is an important component of global environmental change research and was one of the core programs for the International Geosphere-Biosphere Programme (IGBP) and International Human Dimensions Programme (IHDP) joint research between 1994 to 2005 (Liu et al., 2010). The Global land project (GLP) replaced the LUCC research program and became the global land system research program during 2005-2015. It inherited the content of the LUCC program and now focuses more on land system dynamics, change results and integrated sustainability analysis and simulation (Milne et al., 2009). Through preliminary LUCC studies, scholars have confirmed the role of LUCC in the earth surface system, and LUCC has become important data and background information for any land-related research (Liu et al., 2014a).

The main influencing factors of the LUCC process are climatic factors and human activities. Climatic factors affect LUCC process mainly through the influence of land surface vegetation, and human activities mainly impact LUCC by affecting land use on

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41454163

the earth's surface (Chen et al., 2014; Song et al., 2014). In terms of climatic factors, arid and semi-arid regions, ecologically fragile and sensitive areas are affected by climate change and dramatic changes in LUCC (Guan et al., 2015; Li et al., 2015a; Lu et al., 2016), especially with changes in precipitation and increases in temperature that increase the amount of glacial meltwater, which leads to greater water volume and improved vegetation growth conditions. These changes would promote the development of regional LUCC in a more sustainable direction, which is conducive to improved regional ecological and environmental conditions (Niu et al., 2013; Wang and Wang, 2013; Liu et al., 2014b). Human activities include agricultural reclamation, urban expansion, ecological construction and the implementation of environmental protection policies. The primary tropical rainforest areas in the world face degradation of surface vegetation caused by agricultural reclamation. Tropical rainforests and ecosystems have been severely damaged by this, which has had a serious negative effect on global environmental change (Malhi et al., 2014; Chen et al., 2016). In the arid region of northwestern China, Xinjiang also faces a large amount of land reclamation. Despite the increase in the amount of water in the region caused by global warming, reclamation of and extraction of surface water and groundwater in large quantities require the supervision and scientific management of government departments, in order to prevent terrestrial salinization and water scarcity caused by over-consumption (Feng et al., 2016; Wei et al., 2017). In terms of urban expansion, in countries that have experienced centuries of industrialization such as Europe and the United States, the pace of urban expansion has been effectively kept in check and even halted (Theobald, 2005; Seto et al., 2012). In the emerging economies of the world, such as China with its rapid economic development, the process of urbanization is accelerating, orderly and disorderly urban expansion has had a significant impact on the earth's surface and LUCC. Various types of land use and land cover in the area around the city are gradually replaced by urban lands, which leads to the simplification and homogenization of LUCC structure and the gradual loss of spatial heterogeneity in specific areas (Li et al., 2013; Chuai et al., 2015; Wang et al., 2016). With regard to the implementation of the government's ecological construction and protection policies, China has made a great deal of effort. It has successively implemented the construction of the "Three Norths" shelterbelt, closing hillsides for afforestation and prohibiting grazing activities, as well as the implementing the Grain for Green project (GGP) to restore farmlands to forest land and grassland (Li et al., 2015b; Jiang et al., 2016; Li et al., 2016). The GGP has a wide scope of work, a large resident population, significant funds and positive environmental impacts. The vegetation on the land surface has been restored and improved, and the vegetation coverage has continuously increased (Deng et al., 2014; Liu et al., 2017). The first round of GGP was started in 2000 and completed in 2008, and the second round was implemented in 2015. Through subsidies, the implementation of GGP has promoted farmers to voluntarily give up the cultivation of farmland in steeper regions.

The Loess Plateau is a major environmentally fragile and sensitive area in China and also a hotspot for research. The impacts of climate change, urban expansion and the implementation of the GGP on LUCC are well known in the region (Su and Fu, 2013; Chen et al., 2015; Xie et al., 2016). However, most studies have focused on one or two factors, while the quantitative study of three factors has not been done. This paper analyzes and quantitatively evaluates the impacts of climate change, urban expansion and the implementation of the GGP on LUCC in the Loess Plateau, using data on land

DOI: http://dx.doi.org/10.15666/aeer/1604_41454163

use, normalized difference vegetation index (NDVI), digital elevation model (DEM), temperature, precipitation and urban distribution from 1980 to 2015. It provides scientific support for the protection and utilization of the environmental resources of the Loess Plateau.

Materials and methods

Study area

The Loess Plateau is located in the centre and western region of China, east of the Taihang Mountains, west Wuqiaoling Mountains and Riyue Mountains, and south of the Qinling Mountains, north of the Great Wall. The geographical coordinates are 100°50′-114°12′E and 33°40′-41°18′N, and it encompasses the provinces or autonomous regions of Qinghai, Gansu, Ningxiang, Inner Mongolia, Shaanxi, Shanxi and Henan, with a total area of 63.2×104 km^2. The area mainly has a temperate continental monsoon climate, with cold and dry winters and hot and rainy summers. The average annual precipitation is about 460 mm, which decreases in a southeast-northwest direction. The southeast is a semi-humid zone, the middle is a semi-arid zone, and the northwest is an arid zone. The Loess Plateau is between 85-5210 m above sea level, rising from east to west and is the largest loess accumulation area in the world (*Fig. 1a*).

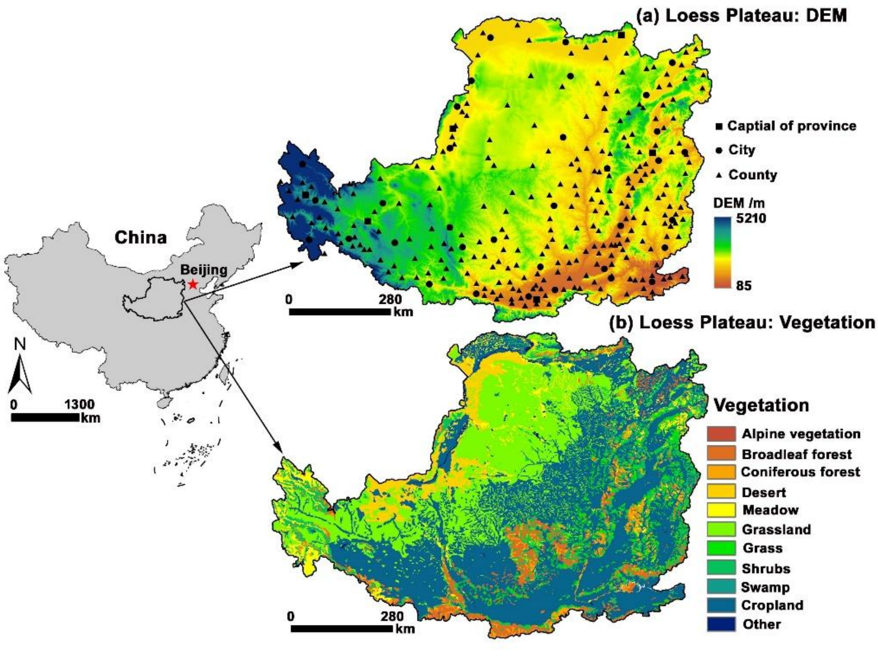

Figure 1. *Digital elevation model and vegetation type distribution in the Loess Plateau*

Loess is an Aeolian product with a loose texture and strong erodibility. In summer, concentrated precipitation and complex terrain are the important factors influencing soil water erosion in the middle and eastern parts, while the northwestern part of the plateau experiences severe soil wind erosion. Vegetation and water distribution are closely related and have a southeast-northwest distribution, mainly including coniferous forests, broadleaf forests, shrub lands, deserts, grasslands grass, meadows, swamps, alpine vegetation and cropland (CVEB of CAS, 2001) (*Fig. 1b*). The Loess Plateau is located

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41454163

in the middle of the Yellow River basin. The rivers in the territory include the Huangshui, Qingshui, Kuye, Wuding, Yanhe, Beiluo, Jinghe, Weihe and Fenhe Rivers. The Loess Plateau has a long history of development and is one of the more densely populated areas in China, which means that the original vegetation on the surface has been greatly damaged and reclaimed for cultivated lands. China's reform and opening up, rapid economic development led to a heavy urban expansion in the region. In addition, climate change, especially temperature rise and increased frequency of extreme precipitation, has caused changes in the surface vegetation in the area, while GGP has also impacted land use and land cover in the Loess Plateau. Scientific analysis of this process can provide a basis for the adjustment and restriction of human activities within the Loess Plateau.

Data

The data used in this study included: (1) land use raster data for China with a spatial resolution of 1km in 1980, 1990, 2000 and 2015, in which land use was divided into six types: cultivated land, forest land, grassland, water body, construction land and unutilized land. (2) China's annual average temperature and precipitation raster data had a spatial resolution of 1km from 1980 to 2015. The data was generated by interpolating daily observation data from more than 2400 weather stations throughout the country using ANUSPLINE software. (3) An SRTM (Shuttle Radar Topography Mission) digital elevation model (DEM) had a spatial resolution of 90m. (4) Vector boundaries of the Loess Plateau and point data for provincial capitals, cities and counties were also included. These datasets were provided by Data Center for Resources and Environmental Sciences, Chinese Academy of Sciences (RESDC) (http://www.resdc.cn). (5) Third generation Global Inventory Monitoring and Modelling System NDVI from Advanced Very High-Resolution Radiometer sensors (GIMMS AVHRR NDVI3g) data from 1982 to 2015 with a spatial resolution of 0.05° were downloaded from http://ecocast.arc.nasa.gov/data/pub/gimms/3g.v1/.

Data from (1), (2) and (5) above were used to obtain land use, temperature and precipitation; and NDVI in the Loess Plateau was extracted in ArcGIS software based on the vector boundaries. The NDVI and DEM data were resampled to 1 km resolution.

Methods

Single factor analysis

(1) Vegetation NDVI trends and *F* test

The trend analysis used a linear regression model to analyze the temporal and spatial change process and the possible future change direction of NDVI in the Loess Plateau, as well as to reflect the linear change trend and spatial distribution in the study period. It is calculated as follows (Xu, 2014):

$$Y = aX + b \tag{Eq.1}$$

$$a = \frac{\sum_{i=1}^{n} x_i y_i - n\bar{x}\bar{y}}{\sum_{i=1}^{n} x_i^2 - n\bar{x}^2} \tag{Eq.2}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41454163

$$b = \bar{y} - a\bar{x} \tag{Eq.3}$$

where: Y is the NDVI value or spatial distribution data; X is the year 1982-2015; a is a coefficient; b is a constant; $\bar{x}$ and $\bar{y}$ are the average values of X and Y. Positive or negative values of a reflect a linear increase or decrease of vegetation NDVI.

For the linear regression model using the F test for significance, the formula is as follows (Xu, 2014):

$$F = U / [Q / (n-2)] \tag{Eq.4}$$

where: $Q = \sum_{i=1}^{n}(y_i - \hat{y}_i)^2$, $U = \sum_{i=1}^{n}(\hat{y}_i - \bar{y})^2$; $\hat{y}$ is the fitted value of y calculated using values for a, b and x; and the other parameters are the same as in the previous formula. In an F test threshold table, when α = 0.05, the critical value is 4.15. This means that a linear trend is significant when $F > 4.15$, and not significant otherwise.

(2) Impact analysis of climate change on NDVI

The correlation coefficient was used to identify the relationship between climate change and vegetation change, and the formula is as follows (Xu, 2014):

$$r = \frac{\sum_{i=1}^{n}(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^{n}(x_i - \bar{x})^2}\sqrt{\sum_{i=1}^{n}(y_i - \bar{y})^2}} \tag{Eq.5}$$

where: x and y are NDVI and temperature and precipitation, respectively. The r value ranges between [-1, 1], where r = 0 means that the two variables are irrelevant. The closer the value of r is to -1, the stronger the negative correlation. The closer it is to 1, the stronger the positive correlation. In the correlation coefficient threshold table, when α = 0.05, the critical value of r is 0.3494. That is, a correlation coefficient value of $|r|>0.3494$ is significant, and not significant otherwise.

(3) Impact analysis of urban expansion on LUCC

The impacts of urban expansion on LUCC were mainly concentrated in areas near cities and decreased with distance from cities. A buffer analysis method was used to generate a 30 km buffer around the provincial capitals and cities at intervals of 2 km. Counties adopted 1 km intervals within 10 km and 2 km intervals in the range of 10 km to 20 km. The average NDVI values and changes were analyzed within the buffer zones from 1982 to 2015. The limits of urban expansion affecting vegetation were identified, and that boundary was used as the criterion for the impact of urban expansion on LUCC process, after which the relative change rate of land use within and outside the boundary was calculated. The formula is as follows:

$$Area\_avg_{blct} = \frac{A_{blct}}{Urban_{nc}} \tag{Eq.6}$$

$$RC = \left(\frac{Areaavg_{blc(t+1)}}{SArea_{b(t+1)}} - \frac{Area\_avg_{blct}}{SArea_{bt}}\right) \times 100\% \tag{Eq.7}$$

where: RC is the relative change rate, %; $Area\_avg_{blct}$ and $Area\_avg_{blc(t+1)}$ represent the average area of l land use type within buffer b of city c (or provincial capital/county) at time t and t+1, respectively, km^2; $SArea_{bt}$ denotes the total area of all land use types in buffer b at time t, km^2; A_{blct} represents the area of l land use type in buffer b of city c (or provincial capital/county) at time t, km^2; $Urban_{nc}$ represents the number of city c (or provincial capital/county).

(4) Impact analysis of GGP on LUCC

The implementation of GGP was mainly aimed at areas with slope>=25°, and the influence on LUCC as also considered to be mainly distributed in the area of >=25°. Statistics on land use and NDVI changes in the region of >=25° in the Loess Plateau before and after 2000 were used to determine the impact of GGP on LUCC. Land use statistics were calculated using the change rate method:

$$R_{tsl} = \frac{Area_{tsl}}{SumA_{tl}} \times 100\% \quad \text{(Eq.8)}$$

$$CR = R_{(t+1)sl} - R_{tsl} \quad \text{(Eq.9)}$$

where: CR is the change rate, %; R_{tsl} and $R_{(t+1)sl}$ represent the percentage of land use type l on slope s at time t and $t+1$, respectively, %; $Area_{tsl}$ denotes the area of land use type l on slope s at time t, km^2; $SumA_{tl}$ denotes the area of land use type l at time t, km^2.

Comprehensive factor analysis

Based on the single factor analysis above, the change in LUCC in the Loess Plateau from 1980 to 2015 and the impacts of climate change, urban expansion, and the implementation of GGP on LUCC were obtained. However, it was still necessary to quantitatively determine the role of each factor in the LUCC process and their spatial distributions through comprehensive mapping of multiple influencing factors. This analysis involved land use, F test results for the NDVI change process, and correlation coefficients between NDVI and temperature and precipitation. It also involved analysis results for the impact of urban expansion and the implementation of GGP. The calculated method was as follows:

(1) Land use (*LD*): Based on the land use classification of the Loess Plateau in 2015, the values of construction land, cultivated land, and water body were assigned to 4, 3, 1, respectively, and the values of forest land, grassland, and unutilized land were assigned to 2.

(2) F test results of the NDVI change process (*FT*): The values for significant and not significant decreases were assigned to 4 and 3, respectively, and the respective values for not significant and significant increases were assigned to 2 and 1.

(3) Correlation coefficients between NDVI and temperature (*TE*) and precipitation (*PE*): The values for significant and not significant negative correlation were assigned to 4 and 3, respectively, and positive and significant positive correlation values were assigned to 2 and 1, respectively.

(4) The impact of urban expansion (*UP*): Within the range of urban expansion for the provincial capitals, cities, and counties in 2015, the value of construction land was assigned to 4, farmland, forest land, grassland, water body and unutilized land were assigned to 3, and values outside the range were assigned to 2.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41454163

(5) The impact of GGP (*IGGP*): The value of construction land in the region with slope >= 25° in 2015 was assigned to 4. The value of cultivated land converted into forest land and grassland between 2000 and 2015 was assigned to 3. The value of cultivated land in the region with slope >= 25° in 2015 was assigned to 2. All other values were assigned to 1.

(6) Comprehensive evaluation results: The formula was as follows:

$$CE = LD \times 100000 + FT \times 10000 + TE \times 1000 + PE \times 100 + UP \times 10 + IGGP \quad \text{(Eq.10)}$$

where:

CE is the comprehensive evaluation of the results.

CE ranged between 111111 and 444444 and was composed of six digits. From left to right, the first digit indicated land use, the second indicated the *F* test result for NDVI change, the third indicated the correlation between NDVI and temperature, the fourth indicated the correlation between NDVI and precipitation, the fifth indicated urban expansion, and the sixth indicated GGP. The larger the value of *CE*, the greater the impact of urban expansion was, while the smaller the value, the less affected the area was by human activities and the greater the impact of climate change was.

The specific classification method was as follows, according to the area statistics for each type and spatial mapping:

(1) If the six digits of the CE contained the number 4, it was divided into the area impacted by urban expansion.

(2) If the six digits of the CE contained the number 1 but did not contain the number 4, and the 6th number was not 3, it was divided into the area impacted by climate change.

(3) If the 6th digit of the CE was 3, it was divided into the area impacted by GGP implementation.

(4) The parts not assigned to the above areas were divided into the area impacted by other factors.

Results

The LUCC process in the Loess Plateau

Land use change process

The statistics for land use in the Loess Plateau showed that (*Table 1*) the land use structure generally remained stable with grassland, cultivated land, and forest land dominating between 1980 and 2015 and accounting for 41.80%, 32.34%, and 15.02% of the total area, respectively. However, grassland and cultivated land decreased by 0.57% and 0.59%, respectively, while forest land increased by 0.41% over the study period. In addition, the largest increase was in construction land at 1.08%.

The amount and rate of land use change were different at different periods. Between 1980 and 2015, the area of cultivated land, grassland, water body, and unutilized land decreased greatly, while the area of forest land and construction land increased greatly. Due to the large area of the Loess Plateau, although the area changed was large, it made up a relatively small proportion of the total area. The decrease in grassland was the largest at 5.45%, and the increase in construction land was the highest at 51.54%. Between 1980 and 2000, the area of forest land, grassland, water body, and unutilized

http://www.aloki.hu • ISSN 1589 1623 (Print) • ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41454163

land decreased, and the area of cultivated land and construction land increased. During this period the decrease in water body was the largest at 9.00%, and the increase in construction land was highest at 11.97%. Between 2000 and 2015, the area of farmland, grassland, and unutilized land decreased greatly, while the area of forest land, water body and construction land greatly increased. During this period, the decrease in the cultivated land was the largest at 2.74%, and the increase in construction land was the highest at 35.34%.

Table 1. *Area and change rate of land use type between 1980 and 2015*

Type	Year	Farmland	Forest land	Grassland	Waterbody	Construction land	Unutilized land
Area (km^2) / percentage (%)	1980	205530/32.51	94959/15.02	264254/41.80	9718/1.54	13229/2.09	44562/7.05

Amount (km^2/a) and rate (%/a) of annual change	1980-2000	98.4/0.05	-2.5/-0.003	-90.1/-0.03	-43.8/-0.45	79.2/0.60	-41.4/-0.09
	2000-2015	-378.5/-0.18	175.1/0.18	-119.4/-0.05	23.0/0.26	349.0/2.36	-49.1/-0.11
	1980-2015	-106.0/-0.05	73.6/0.08	-102.7/-0.04	-15.1/-0.16	194.8/1.47	-44.7/-0.10

Between 1980 and 2015, the annual reduction in cultivated land and grassland was the largest, with the largest increase in construction land. The rate of annual change in grassland was the largest decrease and change in construction land was the largest increase. Between 1980 and 2000, the annual increase in cultivated land and construction land was the largest, and the annual decrease in grassland and the unutilized land was the largest. The largest decrease in the rate of annual change was in the waterbody, and the largest increase in the rate of annual change was in construction land. Between 2000 and 2015, the annual reduction in farmland was the largest, and the largest increase was in construction land. The rate of annual change in the cultivated land was the largest decrease, and the largest increase was in construction land during 2000-2015.

The above analysis showed that the land use structure of the Loess Plateau was stable between 1980 and 2015, but overall the area of cultivated land and grassland decreased, and the area of construction land and forest land increased. The area of farmland increased prior to 2000 and decreased after 2000, and the decrease was 2.89 times greater than the increase. The area of forest land change was opposite than that of farmland, where the area of increase was 52.52 times the area of decrease. Grassland area continued to decrease, and construction land continued to increase during 1980-2000 and 2000-2015. The change in farmland and forest land was clearly impacted by the implementation of GGP. The increase in construction land was affected by urban expansion caused by rapid social and economic development in the region. As the area of grassland continued to decrease, it may have been related to cultivated land occupied prior to 2000. However, the subsequent reduction was not consistent with the area increase caused by GGP implementation.

NDVI change process

Equations 1, 2, 3, and *4* were used to obtain the spatial and temporal change rate of NDVI and *F* test results (*Fig. 2*). From 1982 to 2015, the NDVI in the Loess Plateau increased significantly and ($y = 0.002x - 3.824$, $R^2 = 0.653$, $P < 0.001$) with a linear growth rate of 0.02/10a. However, it could be divided into two stages: before and after 2000. Both stages showed a significant linear increase; however, the growth rate of the first stage was slower ($y = 0.001x - 1.797$, $R^2 = 0.246$, $P < 0.05$), and the linear growth rate was 0.01/10a. In the latter stage, the growth rate was faster ($y = 0.005x - 10.359$, $R^2 = 0.840$, $P < 0.001$), and the linear growth rate was 0.05/10a, which was five times the growth rate of the previous stage (*Fig. 2a*).

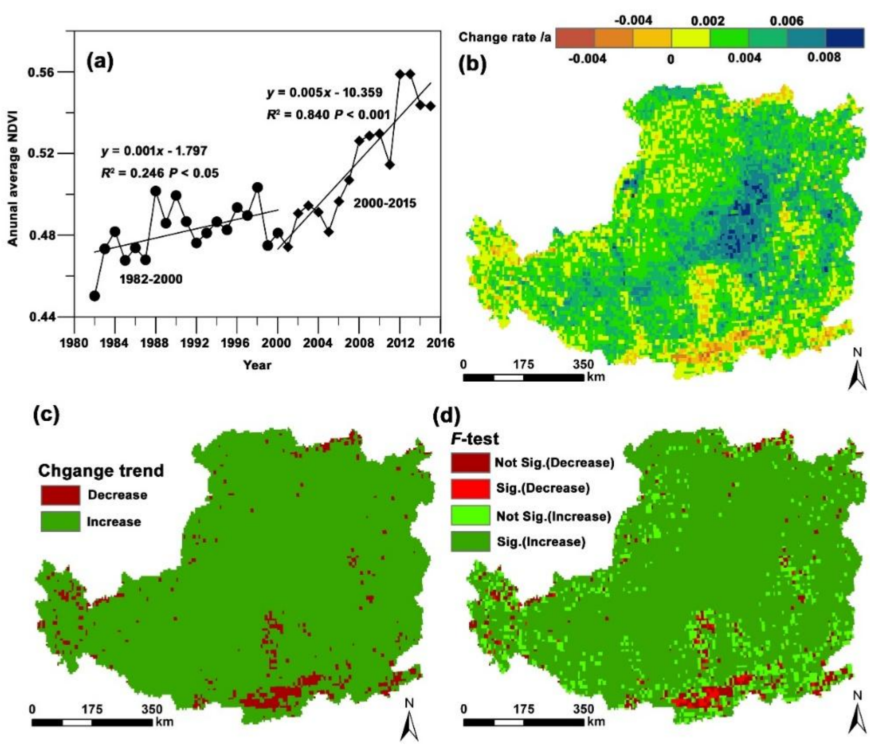

Figure 2. *Spatial and temporal distribution of NDVI change. (a) Temporal change process; (b) change rate; (c) change trend; (d) F test results of change trend*

The linear change rate and change trend of NDVI indicated that (*Fig. 2b* and *c*): the linear growth trend in the Loess Plateau from 1982 to 2015 accounted for 94.86%, while the decreasing trend only accounted for 5.14%. In the growth trend, the change rate was mostly concentrated between 0-0.006/a, accounting for 87.51%, of which 0.002-0.004/a accounted for 40.68%. The spatial growth rate and trend were widely distributed, the growth rate was greater with the land closer to the centre part of the Loess Plateau, while smaller with the land farther from the centre. Where the trend was decreasing, the areas with negative change rates were mainly located in the marginal zone, especially in the southern part of the study area, and the distribution around the western, northern and eastern areas was scattered.

The *F* test results for NDVI change indicated that (*Fig. 2d*), there was significant growth in the Loess Plateau from 1982 to 2015 that accounted for 83.82% of the total

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41454163

area, while not significant growth accounted for 11.04%, and was mainly in the marginal areas of the Loess Plateau. Areas with significant and not significant reduction trend distributions were small, accounting for only 0.93% and 4.21%, respectively, and were concentrated in the southern area, scattered around the eastern, western, and northern margins of the region.

The above analysis indicated that the NDVI of the Loess Plateau generally increased linearly from 1982 to 2015, during which time the NDVI growth rate after 2000 was affected by the implementation of GGP and was five times faster than before 2000. The NDVI of the Loess Plateau was dominated by a significant growth trend. The closer to the middle of the region, the higher the growth rate, and vice versa. The decreased trend was concentrated in the southern part of the region, scattered around the eastern, western, and northern margins.

The impact of climate change on NDVI

The LUCC process is made up of two parts: land use and land cover change. The former is mainly affected by human activities and reflects the macroeconomic pattern of human activities. The latter is affected not only by human activities but also by climate change. Human activities affect land cover by changing the land use, while climate change changes the hydrothermal conditions to affect the distribution of surface vegetation. The land cover change in this paper was represented by NDVI.

From 1961 to 2014, the temperature in the Loess Plateau increased, while the precipitation fluctuate decreased (Yan, 2015), and the frequency of precipitation intensity and extreme precipitation increased (Wang et al., 2014a, b). *Equation 5* was used to obtain the correlation between NDVI and both temperature and precipitation (*Fig. 3*). It shows that there were clear correlations between NDVI and annual temperature and precipitation in the Loess Plateau from 1982 to 2015 (*Fig. 3*). The correlation between NDVI and annual temperature was positive, accounting for 82.22% of the total, with a significant positive correlation area accounting for 25.91% of that and a significant negative correlation area accounting for only 1.77%. The positive and significant positive correlation distribution was consistent with the change trend (*Fig. 2c*), and mainly distributed in the centre of the region. The significant positive correlations were found in the centre and northern parts of the region and in the southern part of the region from west to east. The negative and significantly negative correlations were concentrated in the southern, western, and southwestern parts of the region.

From 1982 to 2015, the positive and significantly positive correlations between NDVI and precipitation accounted for 84.84%, and the significantly positive correlation area accounted for 23.63%, while the significant negative correlation area accounted for only 0.44%. In terms of spatial distribution, positive and significantly positive correlations were concentrated in a large area of the centre region. Significantly positive correlations were mainly located in the north, northwest, and southwest, while negative correlations were mainly distributed in the southeast, southwest, and northwest, as well as the centre regions with a scattered distribution.

The above analysis indicated that vegetation changes in most parts of the Loess Plateau from 1982 to 2015 were affected by temperature and precipitation, and the correlations with temperature and precipitation were mainly positive, in which significantly positive correlations were greater than 20%. It showed that climate change had the dominant effect on vegetation change in the Loess Plateau. However, human

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41454163

activities in the Loess Plateau were intense, and the changes in vegetation in some areas were completely dominated by human activities.

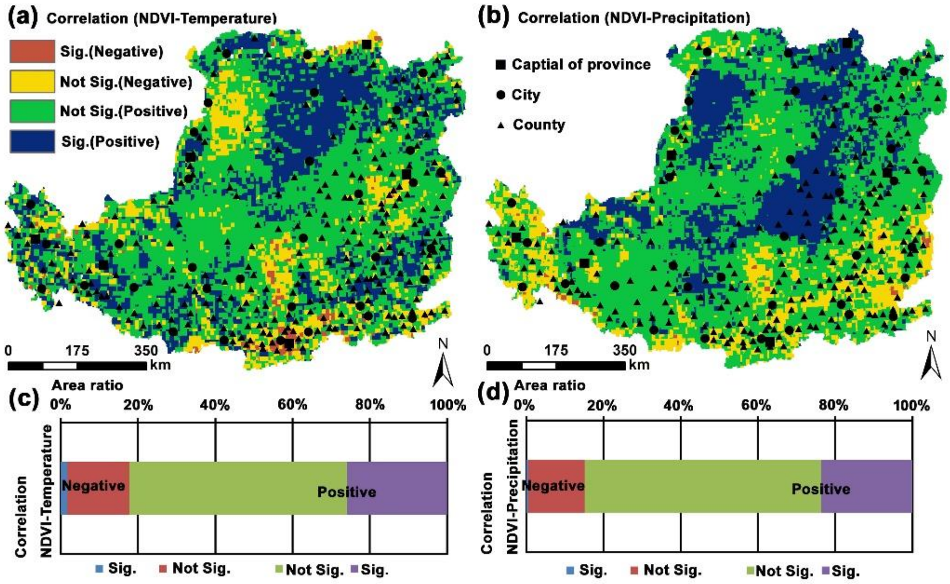

Figure 3. *Distribution of correlations and area ratios between NDVI and temperature and precipitation. (a) Correlation between NDVI and temperature; (b) correlation between NDVI and precipitation; (c) statistical results of correlation between NDVI and temperature; (d) statistical results of correlation between NDVI and precipitation*

The impact of urban expansion on LUCC

The impact of urban expansion on LUCC process was analyzed from two aspects, namely the process of NDVI change and the process of land use change. The average NDVI from 1982 to 2015 in different buffer zones was calculated in provincial capitals, cities and counties, respectively (*Fig. 4a, c* and *e*). By determining the buffer distance corresponding to the inflection point of the average NDVI value, the relative change rates for land use types between 1982-2015 before and after the inflection point were calculated according to *Equations 6* and *7* (*Fig. 4b, d,* and *f*).

Urban expansion was one of the most important characteristics of the current LUCC process. Because the administrative level of the city directly affects urban expansion, the cities of the Loess Plateau were divided into three categories: provincial capitals, cities, and counties.

Within the 30 km buffer zone of the provincial capitals, the inflection point for average NDVI change occurred at 18 km. NDVI had rapid and significant linear growth before the inflection point and stabilized after the inflection point (*Fig. 4a*). From 1982 to 2015, there were clear differences in land use change within the 18 km and 18-30 km buffer zones of the provincial capitals. For the former, the decrease in farmland and the increase in construction land were higher than those in the latter by 9.9 and 3.6 times, respectively (*Fig. 4b*). 18 km can, therefore, be used as the urban expansion boundary for provincial capitals in the Loess Plateau.

Within the 30 km buffer zone, the average NDVI inflection point occurred at 14 km, and the buffer was divided into 0-14 km and 14-30 km. The average NDVI value had a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41454163

significant linear increase, but the linear growth of the former is 5.6 times than the latter (*Fig. 4c*). From 1982 to 2015, land use in the 14 km and 14-30 km buffer zones of cities also had clear differences, where cultivated land was reduced, and construction land increased in the former by 3.6 times, and the same value was only 2.7 times in the latter (*Fig. 4d*). This demonstrated that 14 km could be used as the urban expansion boundary of cities in the Loess Plateau.

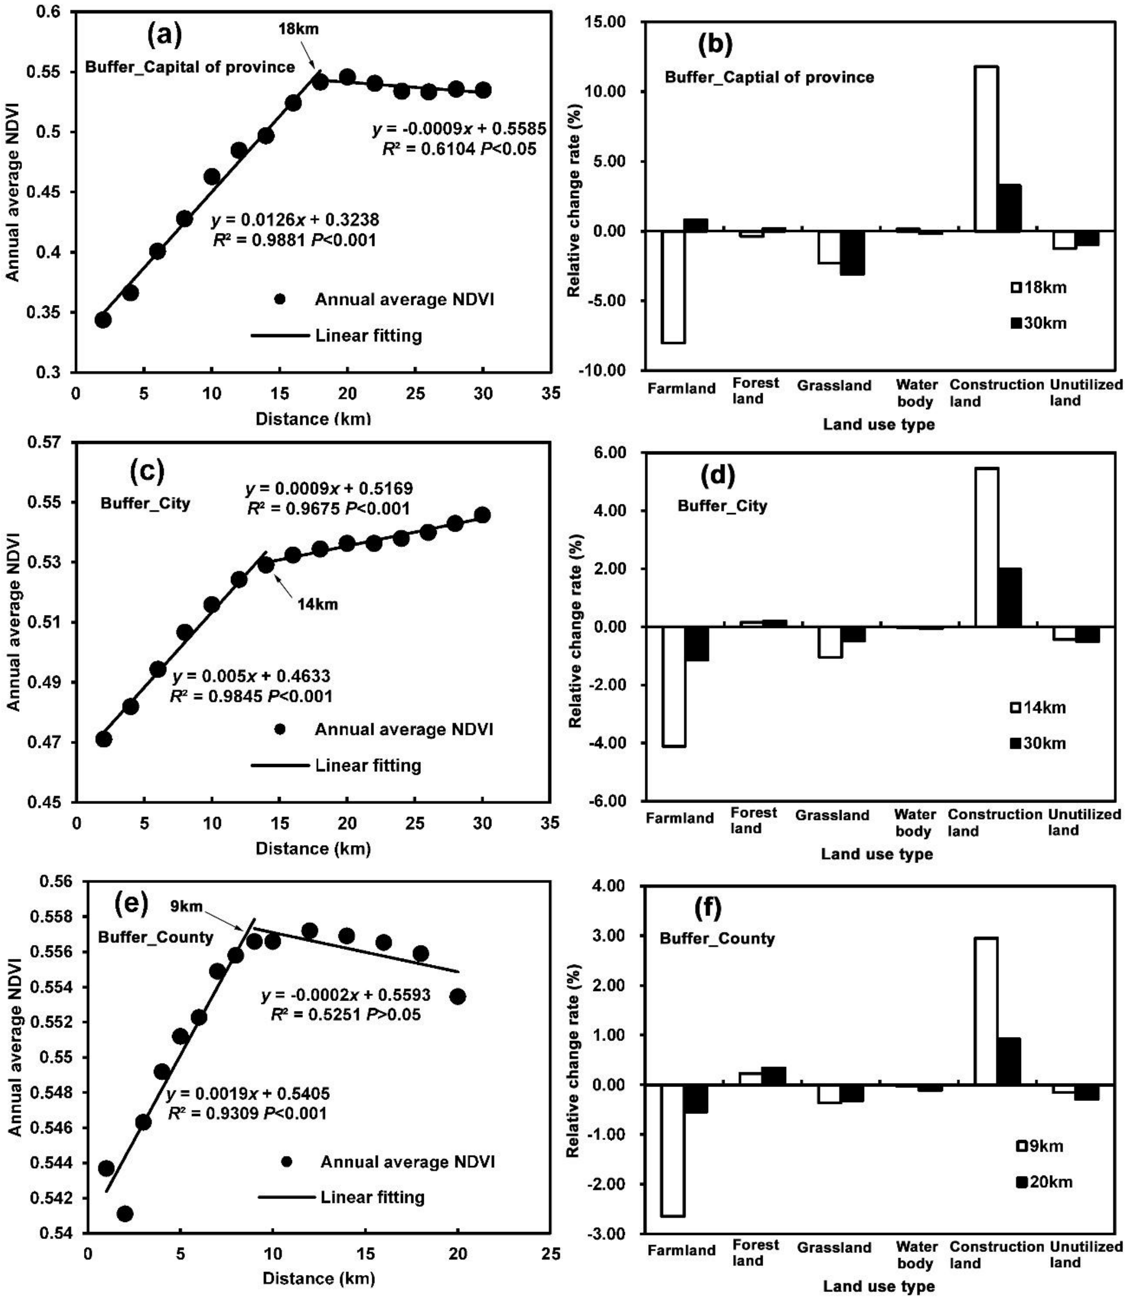

Figure 4. *Annual average NDVI changes (1982-2015) and land use change ratios (1980-2015) for different administrative buffers. (a) Average NDVI change in provincial capitals from 1982 to 2015; (b) relative change rate in land use in provincial capitals from 1980 to 2015; (c) average NDVI change in cities from 1982 to 2015; (d) relative change rate of land use in cities from 1980 to 2015; (e) average NDVI change in counties capitals from 1982 to 2015; (f) relative change rates of land use in counties from 1980 to 2015*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41454163

Within the 20 km buffer zone, the NDVI inflection point appeared at 9 km. Prior to that, there was a significant linear NDVI growth, and the change rate in the 0-9 km buffer was higher than in 9-30 km (*Fig. 4e*). From 1982 to 2015, there was an obvious difference in land use between 9 km and 9-30 km buffer zone in counties, where farmland decreased, and construction increased in the former by 4.8 times and increased 3.2 times in the latter (*Fig. 4f*). That indicated that 9 km could be used as the urban expansion boundary of counties in the Loess Plateau.

The above analysis indicated that the urban expansion boundaries for provincial capitals, cities, and counties in the Loess Plateau were 18 km, 14 km and 9 km, respectively. Within the boundaries, the rapid reduction of cultivated land and the rapid increase of construction land were observed, while outside the boundary the reduction in cultivated land and the increase in construction land were far below the limit.

The impact of GGP on LUCC

Due to its fragile environment, the Loess Plateau is a key region for the implementation of the GGP, which focused on areas with slope >= 25°. The percentage of each land use type across the total region, annual average NDVI values for the Loess Plateau from 1980 (1982) to 2015, and accompanying statistics are calculated according to *Equations 8* and *9* (*Fig. 5*).

Taking the time of GGP implementation as the dividing point, the study period was divided into 1980 (1982)-2000 and 2000-2015. Between 1980 and 2015, the proportion of cultivated land to total cultivated land in the Loess Plateau >= 25° increased slightly, and the proportion of forest land and construction land decreased, while grassland increased (*Fig. 5a*). Correspondingly, the annual average NDVI value in the area >=25°from 1982 to 2015, was generally higher than the area <25°; however, the linear increase in the area >=25° was not significant, while the linear increase in the area <25° was significant (*Fig. 5b*). This indicated that the higher slopes limited human activities and maintained better vegetation conditions, while lower slope vegetation was also improved. Between 2000 and 2015, the GGP was implemented, and the proportion of cultivated land >=25° of the Loess Plateau decreased (*Fig. 5c*). The NDVI in >=25° also showed a faster increase from 2000 to 2015 than from 1982 to 2015; moreover, and the linear growth rate also exceeded the area of <25° (*Fig. 5d*). This showed that the implementation of the GGP greatly promoted the improvement of vegetation in the higher gradient.

Between 1980 and 2000, on the whole, the proportion of farmland decreased, and the proportion of grassland increased in the area of >=25° (*Fig. 5e*). At the same time, both areas of slope >=25° and slope <25° had a significant linear increase in annual NDVI from 1982 to 2015, and the linear growth rate was similar. However, the linear growth rate in the area of >=25° was higher than that of <25°, which directly reflected the process of land use and land cover change in high slope areas driven by policy (*Fig. 5f*).

Quantitative assessment of LUCC process driving factors

According to *Equation 10,* the impacts of climate change, urban expansion, and GGP implementation on LUCC was assessed quantitatively using comprehensive methods in the Loess Plateau between 1980 and 2015, based on the results of land use change, *F* test results for NDVI change trends, and the correlations between NDVI and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41454163

temperature and precipitation, as well as urban expansion and GGP implementation (*Fig. 6*).

It indicated that among the influencing factors of LUCC, climate change was the main factor and accounted for 93.65%, followed by urban expansion (accounting for 5.46%), and the implementation of GGP (accounting for 0.64%) in the Loess Plateau between 1980 and 2015 (*Fig. 6*). The role of climate change on the LUCC process was characterized by a wide range of impacts, and areas that could not be covered by human activities, and agricultural production activities, which were still controlled by climate factors. The impacts of climate change on LUCC process had surface-like characteristics.

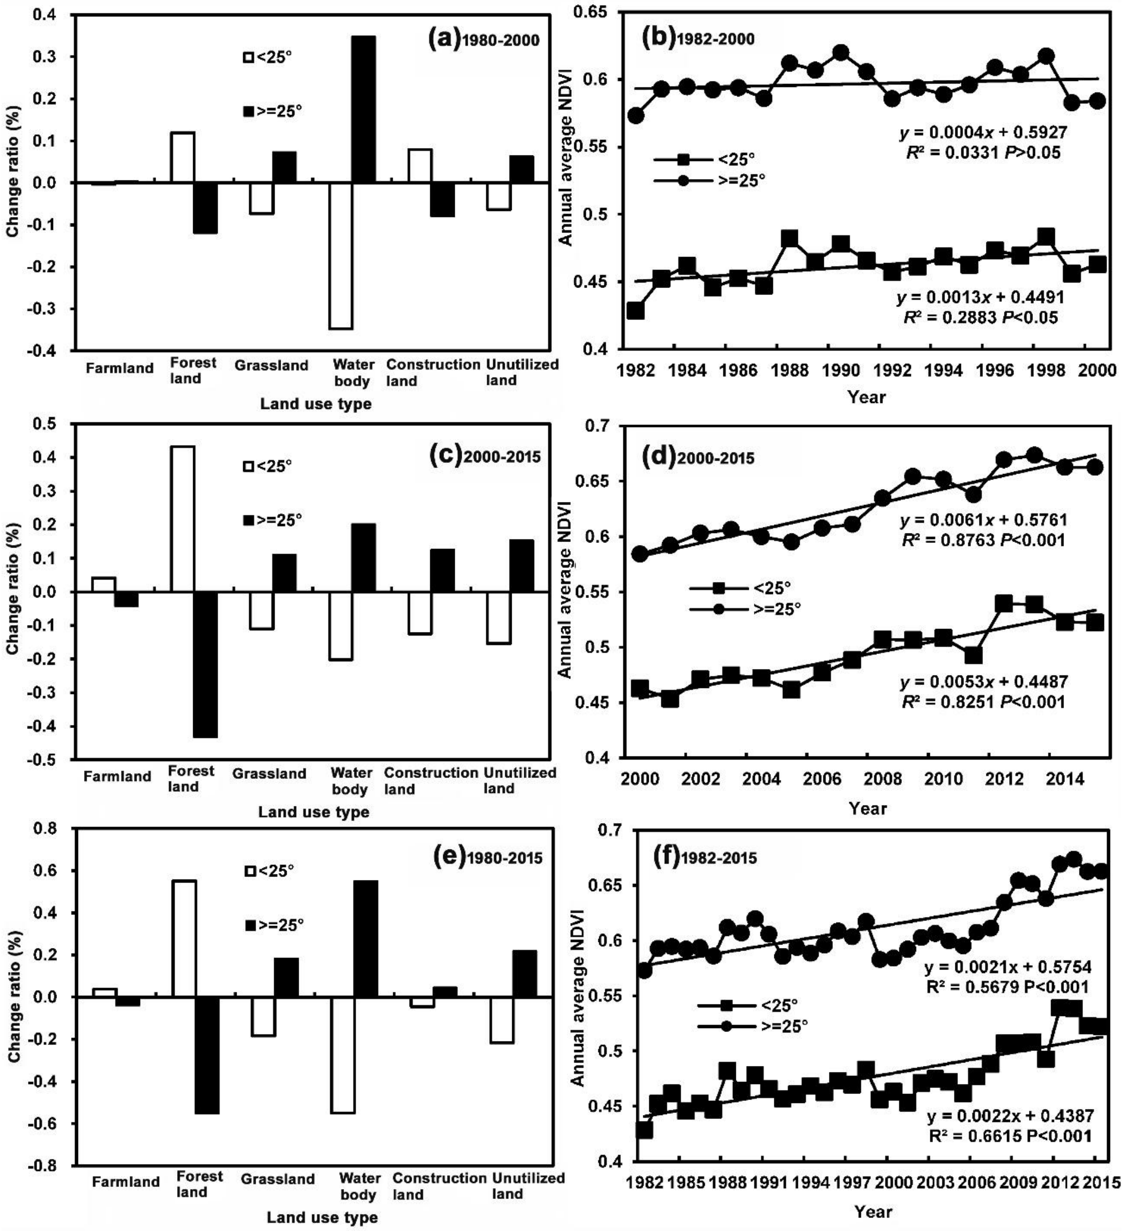

***Figure 5.** The change process of land use and NDVI in different slop area. (a) land use change between 1980 and 2000; (b) NDVI change from 1982 to 2000; (c) land use change between 2000 to 2015; (d) NDVI change from 2000 to 2015; (e) land sue change between 1980 to 2014; (f) NDVI change from 1982 to 2015*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41454163

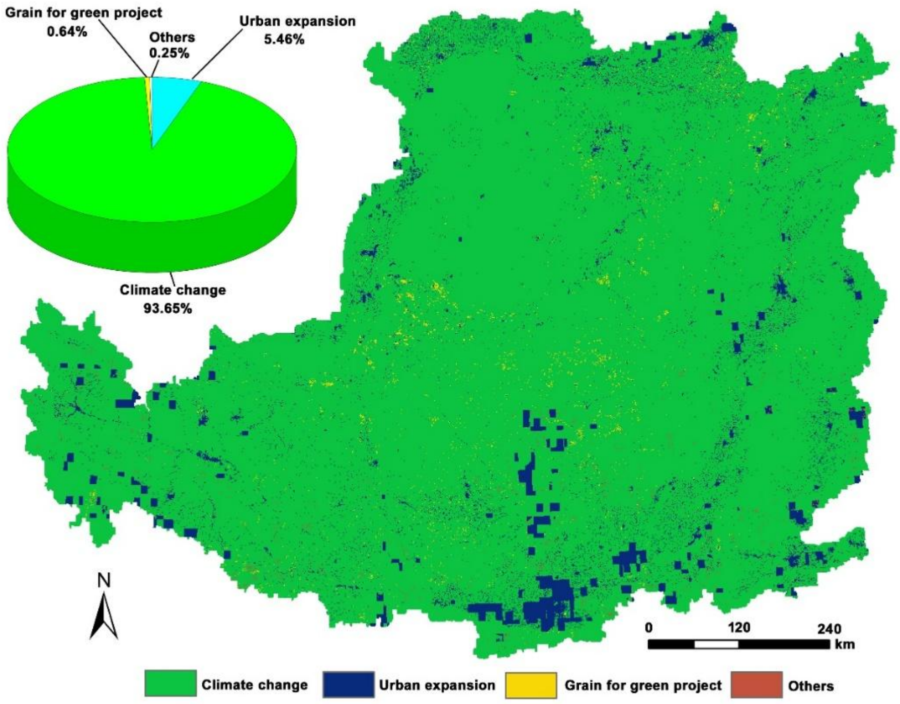

***Figure 6.** The evaluation results for the impacts of climate change, urban expansion, and the grain for green project on LUCC in the Loess Plateau*

Urban expansion was the main driving force for human activities in the LUCC in the Loess Plateau between 1980 and 2015. It reflected the rapid social and economic development and the continued influx of population, and the rapid urbanization process in the Loess Plateau, especially in the southern region where large amounts of farmland, forest land, and grassland, were converted into construction land. The impact of urban expansion on LUCC had point-like characteristics. The impacts of GGP on LUCC were relatively scattered, and related to project implementation and the distribution characteristics in areas with slope >=25°, and were generally patchy in distribution.

Discussion

The LUCC process in other countries or regions is mainly affected by urban expansion, deforestation induced by the behavior of farmers, and industrial activities (such as forest development), while the Loess Plateau region of China is unique. Research on the impacts of climate change, urban expansion, and the implementation of GGP on the LUCC process in the Loess Plateau has attracted the attention of many scholars (Theobald, 2005; Chen et al., 2014; Song et al., 2014), but the focus has been on one or two elements, and less on the LUCC process under the combined action of 3 elements. Although quantitative analysis of influencing factors has been carried out, spatial expression was not achieved and maintained half-quantitative methods, which were also the main approach in the current study on the impact of climate change and human activities on the process of natural geographical elements. The research methods and conclusions presented here provide a reference for similar research in other countries or regions.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41454163

The basic framework for quantitative assessment and spatial expression of the impacts of climate change, urban expansion and GGP on LUCC has already been initiated, but some problems remain. The first is data issues, including NDVI and DEM data. The NDVI data used in this paper were GIMMS NDVI from 1982 to 2015, with a spatial resolution of 0.05° and 1 km by resampling. However, it is clear that resampling did not solve the problem of low spatial resolution (*Fig. 6*). The current time-series NDVI data were mainly GIMMS NDVI and SPOT/MODIS NDVI, but the latter time is short. SPOT NDVI and MODIS NDVI started in 1998 and 2000, respectively, and for the study of climate change, the timeframe is slightly shorter. DEM data was at 90 m resolution and resampled to a 30 m resolution to extract the slope for the analysis of GGP impacts. However, because the NDVI and land use data were 1 km, it was difficult using the extracted slope for analysis of NDVI and land use. As a whole, quantitative assessment results on the role of GGP implementation were lower, while climate change and urban expansion results were higher.

The second problem was the division of quantitative assessment results. In the article, the analysis method for comprehensive factor was subjective, and the classification of results was too simple, only distinguishing the different functions and spatial distribution, but not distinguishing the spatial distribution of their strengths and weaknesses within the same classification. The third problem was the application of the quantitative assessment results. The Loess Plateau is a typical fragile area in China with serious soil erosion problems, and the vegetation cover is reduced from southeast to northwest, while rapid social and economic development drives large significant urban expansion. Research needs to be conducted on the natural spatial and temporal geographical processes, based on spatial mapping of climate change and human activities (such as urban expansion and GGP).

Conclusion

Based on a quantitative assessment of the impacts of climate change, urban expansion, and the implementation of GGP on LUCC in the Loess Plateau, the following conclusions were obtained:

(1) The land use structure of the Loess Plateau was stable, and the area of cultivated land and grassland was reduced, while the area of construction land and forestland increased. The area of cultivated land increased prior to 2000 and decreased afterwards, with a decrease that was 2.89 times the increase. Construction land continued to increase. NDVI had an increasing linear trend in general. After 2000, the NDVI growth rate was five times that of the rate before 2000. The significant increasing trend was concentrated in the middle part of the region, and the decrease was concentrated in the south of the region.

(2) The NDVI changes in most parts of the Loess Plateau were positively correlated with changes in air temperature and precipitation, and significant positive correlations were all greater than 20%, which indicated that climate change had a dominant effect on vegetation changes in the Loess Plateau, but changes in vegetation in some areas were completely affected by human activities.

(3) The boundaries of provincial capitals, cities and counties in the Loess Plateau were 18 km, 14 km and 9 km respectively. The rapid reduction of cultivated land and the rapid increase of construction land were shown within those boundaries. The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41454163

reduction in cultivated land and the increase in construction land outside the boundaries were far below the threshold values.

(4) In the area of >=25°, the proportion of cultivated land decreased, the proportion of grassland increased, and the linear growth rate of NDVI was clearly higher than those areas <25°, which directly showed that the driving effect was GGP implementation.

(5) Among the influencing factors of LUCC in the Loess Plateau, climate change was dominant, accounting for 93.65% of the total, with a surface-like distribution. It was followed by urban expansion, accounting for 5.46% of the total, with a point-like distribution. The impact of GGP accounted for 0.64% and had a patchy distribution.

(Received 2nd Apr 2018; accepted 12th Jun 2018)

Abstract. The Loess Plateau in the northern Shaanxi Province is one of the areas with serious soil erosion in China. Affected by the implementation of the Grain for Green project, land use types and vegetation status have changed considerably. To assess the impacts of these changes on soil erosion has important theoretical and practical significance. Taking the Wuding River Basin and Luohe River Basin in northern Shaanxi as examples, land use data, normalized difference vegetation index, and daily rainfall data, as well as digital elevation model, soil type data, combined with the revised universal soil loss equation, the change of the soil erosion modulus were analyzed. The results showed that: (1) the implementation of the Grain for Green project has promoted the conversion of farmland to grassland and forest land (concentrated in 2000-2005). In 2000-2014, the change rate of land use and NDVI in the areas with a slope ≥ 25° were higher than those areas with a slope < 25° and across the entire basin. Affected by this, the change rate of the soil erosion modulus difference value at areas with a slope ≥ 25° was higher than that at areas with a slope < 25°. (2) The soil erosion modulus of both basins increased from 2000 to 2014. Without considering the impact of changed precipitation, the soil erosion modulus of both basins showed a decreasing. This proves that the implementation of the GGP, converting farmland into forest land and grassland, has improved the vegetation coverage and reduced soil erosion.
Keywords: *RUSLE, rainfall, vegetation, slope, northern Shaanxi Province*

Introduction

Soil erosion is a worldwide eco-environmental problem and has a close relationship with agricultural production (Montgomery, 2007). As one of the main soil erosion regions in China and the world, the Loess Plateau is affected by the terrain, soil, precipitation, surface vegetation cover, and human activities. To reduce soil erosion, the Chinese government has formulated and implemented the Grain for Green project (GGP), which aims to reduce the soil erosion via improving the vegetation cover. Combined with the check-dam project built in the 1970s, soil erosion on the Loess Plateau will be comprehensively managed.

The GGP is an important environmental construction and restoration project in China and involves 1,897 administrative units at the national level, in 25 provinces and autonomous regions across the country. The Loess Plateau is a key area for implementing the GGP and has drawn considerable attention from scholars (Sun et al., 2013; Jiao et al., 2014). Soil erosion has been studied from the micro-slope scale to the whole Loess Plateau, and slope soil erosion research discussed the effects of land use change on soil surface roughness, soil organic matter, and slope micro-topography

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41654181

evolution on soil erosion (Hu et al., 2014; Liu et al., 2014; Li et al., 2015, 2017). Studies on channel soil erosion focus on the role of the check-dam construction in the ecological environment as well as socio-economic, water, and sediment reduction effects in the basin (Wang et al., 2014a; Feng et al., 2016; Zhao et al., 2017). Soil erosion in small watersheds has been studied, as well as the effects of land cover change on soil erosion and ecological and economic sustainability (Zhao et al., 2014; Zhang et al., 2016; Dong et al., 2017). The change of soil erosion in the basins before and after the implementation of the GGP also has been analyzed (Wang et al., 2014b; Liu et al., 2015; Li et al., 2016). Overall, studies on the Loess Plateau focus on climate change, vegetation change, and soil erosion change scenarios, with potential governance prospects (Gao et al., 2016; Xie et al., 2016; Gao et al., 2017; Jiang et al., 2018).

At the core area of the Loess Plateau in northern Shaanxi, a hilly-gully area, the implementation of the GGP has played an important role in the improvement of the regional ecological environment. The impact of GGP implementation on soil erosion is the key evaluation content, with a large number of reports. However, comparative analyses of multiple basins are scarce. The Wuding River and the Luohe River are the major rivers on the Loess Plateau in northern Shaanxi. Solid knowledge on the impacts of the GGP on different basins in terms of soil erosion would be used for assess the effectiveness and direction of future implementations.

Materials and methods

Study sites

The Wuding River Basin (WDRB) and Luohe River Basin (LHRB) were selected as study sites (*Fig. 1*). The two basins are located in the areas Yulin and Yan'an, on the Loess Plateau, in the northern part of the province Shaanxi, China (LPNSC). The area is the core area of the Loess Plateau, with a complex topography and severe soil erosion. The dominant vegetation types are temperate forest, temperate grassland, and temperate desert, from south to north. Due to the long history of human activities, the surface in other regions is dominated by artificial vegetation, except for the forest vegetation in the south. The climate is characterized as temperate continental monsoon climate, with hot and rainy summers and cold and dry winters. The inherent characteristics of loess and the undulating surface conditions, as well as the concentrated precipitation in summer and autumn, lead to serious soil erosion in the region.

The Wuding River is the first tributary of the Yellow River. It is located in the northern part of the LPNSC and is mainly distributed in the territory of Yulin. The northwestern part of the basin is flat and sandy and belongs to the southern margin of the Mu Us Desert, while the southwestern part contains the source of the Wuding River and has a higher elevation; similar to the southeastern part, it is a hilly-gully region. The WDRB is the key basin for soil erosion control on the Loess Plateau. Since the 1970s, more than 10,000 check dams have been built in the basin, with the aim to treat channel soil erosion. Slope vegetation restoration and construction approaches have been adopted since 1999. Large areas of sloping farmland have been turned into forest land and grassland via the GGP implementation, with major land use changes, resulting in improved slope vegetation coverage and increased ecological value; in addition, annual runoff and sediment erosion also decreased.

The Luohe River is mainly located in the area around Yan'an, in the southern part of the LPNSC. It flows into the Weihe River and is a secondary tributary of the Yellow

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41654181

River. The vegetation cover in the LHRB is high, and temperate steppe and forest areas are distributed in the northwestern and southern regions of the basin, respectively. As a consequence of GGP implementation, land use in the basin has undergone considerable changes. Compared with the Yanhe River Basin, which is also located in the LPNSC, studies on the Wuding River and the Luohe River are scarce. This paper, therefore, focused on the WDRB and LHRB, analyzing temporal and spatial changes in soil erosion with the implementation of the GGP.

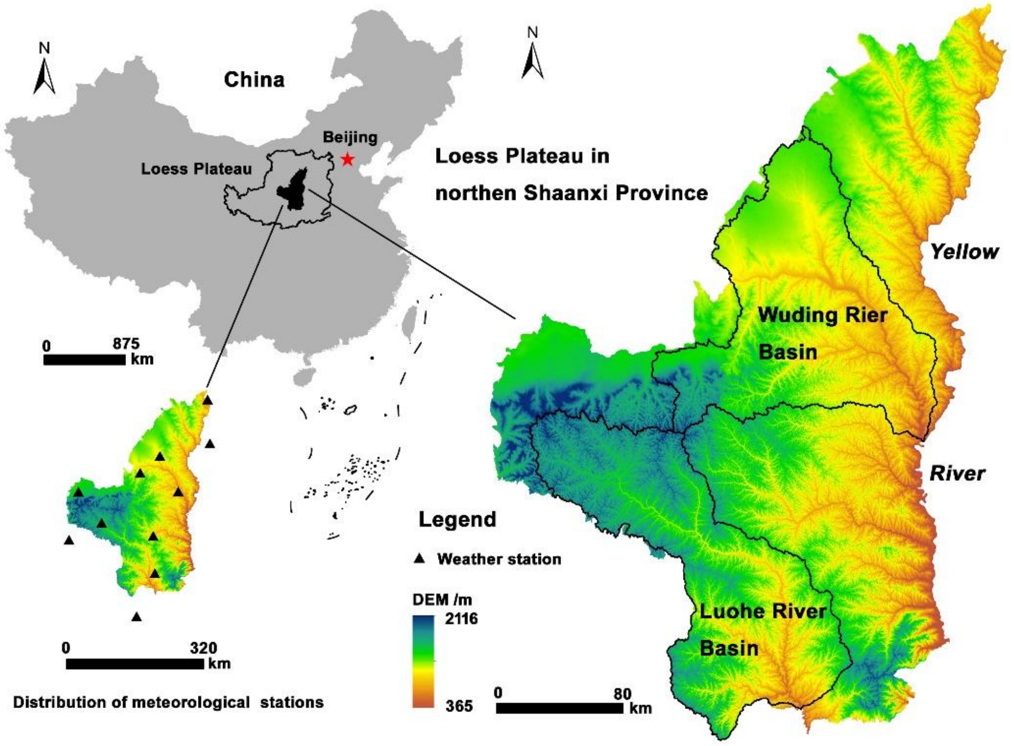

Figure 1. *Study sites and the distribution of meteorological stations*

Data

The research data included the following: (1) daily rainfall data, obtained from 11 meteorological stations in and around the basin from 2000 to 2014 (*Fig. 1*), were provided by the China Meteorological Data Network (http://data.cma.cn); the stations were Yulin, Dingbian, Wuqi, Hengshan, Suide, Yan'an, Hequ, Xingxian, Luochuan, Huanxian, and Yaozhou; (2) ASTER DEM (Digital Elevation Model) data of 30 m resolution, collected from the National Science Data Mirroring Website of the Computer Network Information Center, Chinese Academy of Science (http://www.gscloud.cn); (3) soil type distribution, using a 1:50,000 map; (4) 250 m resolution and 16d synthesized Normalized Difference Vegetation Index (NDVI) from the Moderate Resolution Imaging Spectroradiometer (MODIS) from 2000 to 2014, downloaded from http://lpdaac.usgs.gov; (5) land use data for the province Shaanxi for the years 2000, 2005, and 2010, at a scale of 1:100,000, collected from the "Remote Sensing Survey and Assessment of the Ten Years of National Ecological Environment Change (2000-2010)". All data were resampled to 30-m resolution for calculation and statistical analysis.

Methods

The Revised Universal Soil Loss Equation (RUSLE) is a mature and widely used calculation method of the soil erosion modulus, using the following formula (*Eq. 1;* Renard et al., 1991):

$$A = R \times K \times L \times S \times C \times P \tag{Eq.1}$$

where
A is the soil erosion modulus, t/(km^2·a);
R is the rainfall erosivity factor, (MJ·mm)/(hm^2·h·a);
K is the soil erodibility factor;
L is the slope length factor;
S is the slope factor;
C is the vegetation cover factor; and
P is the soil and water conservation factor.

Rainfall erosivity factor (R)

The R factor is the indicator for evaluating the impact of rainfall on soil separation and transportation. Annual rainfall erosivity is calculated (*Eqs. 2, 3* and *4*) using daily rainfall data as proposed in Zhang et al. (2002, 2003) and Xie et al. (2000):

$$R_i = a\sum_{j=1}^{n} D_j^b \tag{Eq.2}$$

$$a = 21.586b^{-7.1891} \tag{Eq.3}$$

$$b = 0.8363 + 18.144D_{d12}^{-1} + 24.455D_{y12}^{-1} \tag{Eq.4}$$

where
R_i is the rainfall erosivity in the i year (MJ·mm)/(hm^2·h·a);
D_j is the erosive rainfall on the jth day, mm;
n is the total time of erosive rainfall in a year, d;
D_{d12} is the multi-year average daily rainfall of daily rainfall ≥ 12 mm/d, mm;
D_{y12} is the multi-year average annual rainfall of daily rainfall ≥ 12 mm/d, mm; and
a and b are the model parameters.

Soil erodibility factor (K)

The K factor is the indicator to evaluate soil erosion probability when rainfall erosivity has occurred. The calculated method has been proposed by Sharpley and Williams (1990), using *Equation 5:*

$$\begin{aligned} K = &\{0.2 + 0.3\exp[0.0256M(1 - F/100)]\} \times (F/(F+M))^{0.3}[1.0 - 0.25T(T + \\ &\exp(3.72 - 2.95T)] \times \{1.0 - 0.7\delta/[\delta + \exp(-5.51 + 22.9\delta)]\} \end{aligned} \tag{Eq.5}$$

where
M is the mass fraction of sand, %;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41654181

F is the mass fraction of silt, %;
N is the mass fraction of clay, %;
T is the mass fraction of soil organic carbon, %; and
$\Delta = 1\text{-}M/100$;
The K value is needed to use the international system units through multiplication by 0.1317.

Topographical factor (LS)

Slope length and slope (*LS*) are the topographical factors mainly reflecting the effects of topography on soil erosion. The formulae are expressed as follows (*Eqs. 6, 7, 8, 9* and *10;* Moore and Wilson, 1992; Liu et al., 1994; Renard et al., 1997):

$$L = (\lambda / 22.13)^{\alpha} \quad \text{(Eq.6)}$$

$$\alpha = \frac{\beta}{\beta + 1} \quad \text{(Eq.7)}$$

$$\beta = (\sin\theta / 0.0896) / [3.0 \times (\sin\theta)^{0.8} + 0.56] \quad \text{(Eq.8)}$$

$$S = \begin{cases} 10.8\sin\theta + 0.03, \theta < 9\% \\ 16.8\sin\theta - 0.50, 9\% \le \theta < 14\% \\ 21.9\sin\theta - 0.96, \theta \ge 14\% \end{cases} \quad \text{(Eq.9)}$$

$$LS = L \times S \quad \text{(Eq.10)}$$

where
λ is the slope length, calculated using the hydrological analysis module in the ArcMap on the basis of 30 m resolution DEM;
α is the slope length index;
θ is the slope in %, obtained by the surface analysis tool in ArcMap and based on 30 m DEM;
The *LS* value is calculated by multiplying L by the S value, according to the *Equations 6, 7, 8* and *9*.

Vegetation cover factor (C)

The C factor is the vegetation index, which is calculated based on MODIS NDVI data; the formula is expressed as follows (*Eqs. 11* and *12;* Li and Zheng, 2012):

$$NDVI_A = 0.18 \times NDVI_M + 0.131 \quad \text{(Eq.11)}$$

$$C = \exp[-c \times \frac{NDVI_A}{d - NDVI_A}] \quad \text{(Eq.12)}$$

where
The c value is 2, and the d value is 1;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41654181

$NDVI_A$ and $NDVI_M$ represent the AVHRR (Advanced Very High Resolution Radiometer) NDVI and MODIS NDVI data, respectively.

Soil and water conservation factor (P)

Use the calculation method (*Eq. 13*) proposed by Lufafa et al. (2002):

$$P = 0.2 + 0.03\theta \tag{Eq.13}$$

The results of the soil erosion modulus and various factors in the WDRB and LHRB in LPNSC were calculated using RUSLE (*Fig. 2*).

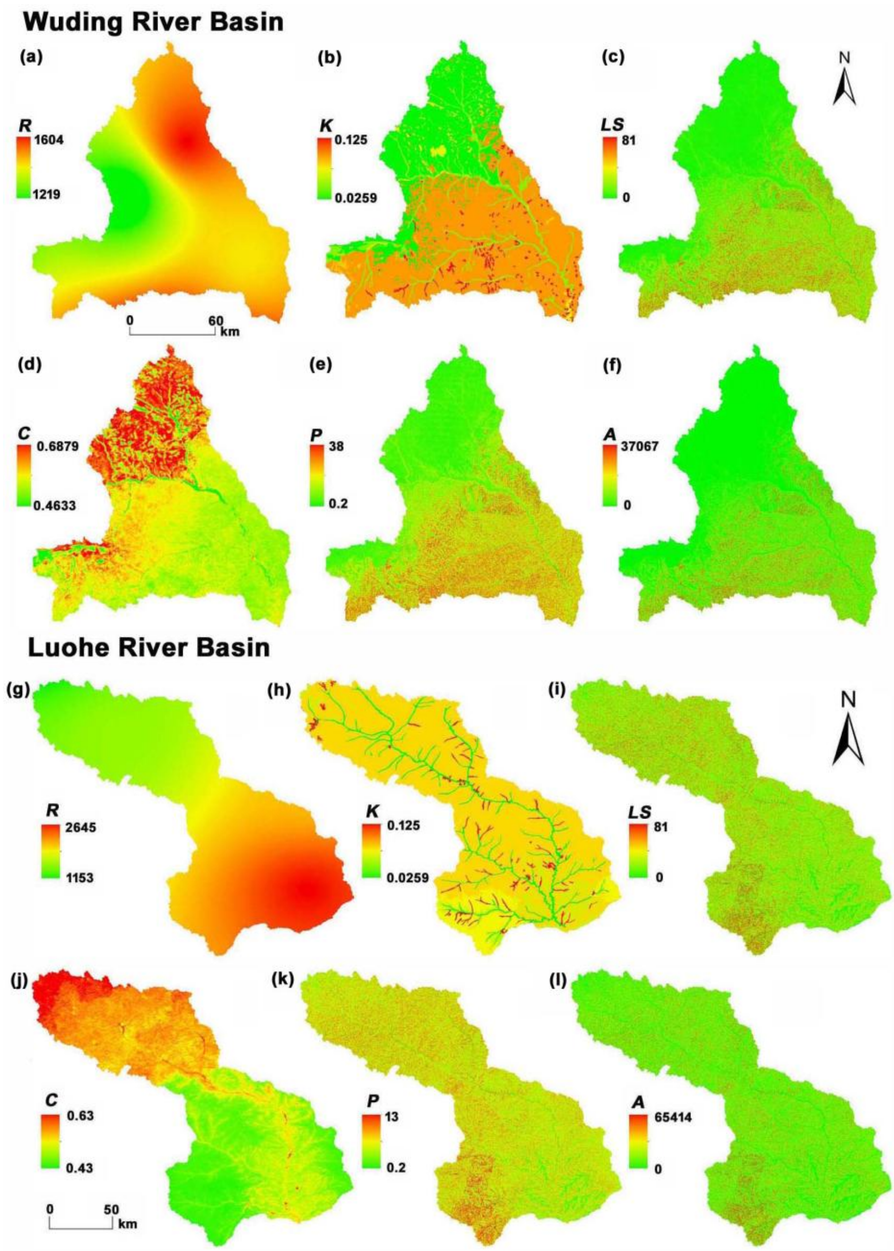

Figure 2. *Results of soil erosion modulation and its factors in the Wuding River Basin and Luohe River Basin. The maps present average values (2000 to 2014) for rainfall erosivity (R; (MJ·mm)/(hm·h·a)), vegetation cover factor (C), and soil erosion modulus (A; t/(km^2·a))*

Results

Impacts of GGP implementation on land use and NDVI change

Land use and NDVI change

The main land use types in the WDRB were grassland, farmland, and idle land. Affected by the implementation of the GGP, land use in the basin underwent major changes between 2000 and 2010. In general, the areas of farmland and idle land decreased, while other land use types increased. The large reduction in farmland area and the large increase in grassland area indicate that a large amount of farmland was turned into grassland. In addition, the farmland area decreased, while grassland areas increased between 2000 and 2005; the changes were higher than those between 2005 and 2010, indicating that in the WDRB, the impact of GGP implementation on land use change was concentrated in the years between 2000 and 2005 (*Fig. 3a*). Despite the largest reduction and increase in farmland and grassland areas, respectively, between 2000 and 2010, construction land also increased, namely by 162.18%. This reflects the ongoing and considerable growth of the urban area as well as of industrial and mining land (*Fig. 3b*).

The main land use types in the LHRB were forest land, grassland, and farmland. As a consequence of the implementation of the GGP between 2000 and 2010, farmland areas declined mostly, while grassland areas considerably increased, followed by forested land. Such changes were concentrated in the period 2000-2005, while between 2005 and 2010, only slight changes occurred (*Fig. 3c*). Adhering to the main objectives of the GGP, farmland areas were transformed into forests and grasslands. Compared with the year 2000, 19.52% of the farmland was reduced in 2010, while construction land increased more than forest and grassland, reaching 39.58% (*Fig. 3d*).

The impact of GGP implementation on land use changes was concentrated between 2000 and 2005, resulting in a large reduction in farmland and a large increase in grassland. However, there was a lower forest land area in the WDRB, and the farmland was converted into grassland, while in the LHRB, farmland was mainly converted into the forest. Furthermore, in the WDRB, the construction land increased more than in the LHRB, reflecting the economic and social development.

The NDVI is an important indicator of the level of surface vegetation. The vegetation in the WDRB was dominated by temperature grassland, and that in the LHRB was dominated by temperature forest. The NDVI value was higher in the LHRB compared to the WDRB. However, affected by the implementation of the GGP, the average annual NDVI of the WDRB increased from 0.3103 to 0.5038 (61.38%) from 2000 to 2014, while the NDVI in the LHRB increased from 0.6052 to 0.7233 (19.52%) in the same period; both trends were linear. The growth rates were 0.0128/a and 0.0083/a, respectively, above the significance level of 0.001, which indicates that the NDVI in the two basins will continue to increase (*Fig.3e*).

Land use and NDVI change at different slopes

Areas with a slope $\geq 25°$ were the main objectives in the GGP implementation. Changes in land use and NDVI in regions $< 25°$ and $\geq 25°$ were calculated, and the effects of the implementation of the GGP were compared. The results are shown in *Figure 4*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41654181

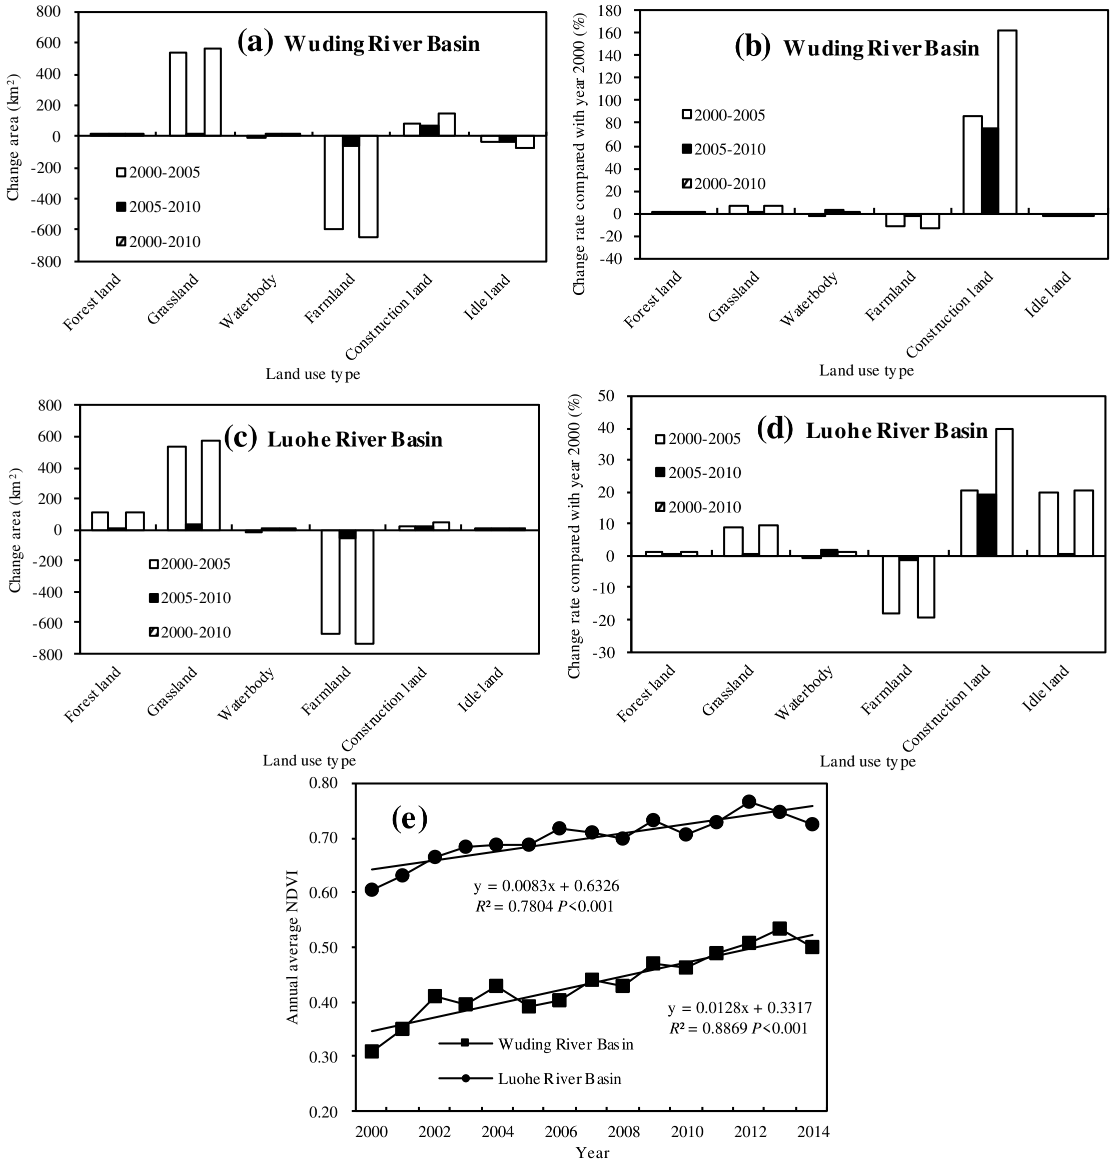

Figure 3. *The area of land use change, change rate compared between year 2000 and 2010, and change trend of annual average NDVI from 2000 to 2014 in the Wuding River Basin and Luohe River Basin. Figure (a) and (b) show the areas of land use change in different periods for Wuding River Basin during 2000-2010 and the percentage of change area compared with 2000, respectively. Figure (c) and (d) show the areas of land use change in different periods for Luohe River Basin during 2000-2010 and the percentage of change area compared with 2000, respectively. Figure (e) shows the annual average NDVI change trend for Wuding River Basin and Luohe River Basin from 2000 to 2014*

Land use change at different slopes can also cause changes in NDVI. In the WDRB, the NDVI value of the area with slopes ≥ 25° was higher than that of the area with slopes < 25°. The NDVI of both regions showed a linear increase from 2000 to 2014, with linear growth rates of 0.0157/a and 0.0127/a, respectively. These results indicate that the growth rate of NDVI in areas ≥ 25° was higher than that in areas < 25°, and the NDVI in the two regions is expected to continue to increase in the future (*Fig. 4e*). The situation in the LHRB was similar to that in the WDRB. The NDVI value in the ≥ 25°

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41654181

region was higher than that in the < 25° region, and all showed a linear increase; linear growth rates were 0.0078/a and 0.0084/a, respectively. Based on these results, we assume that the NDVI growth rate in areas < 25° was higher than that in areas ≥ 25°, which may be related to the better vegetation coverage in the LHRB and the effects of GGP implementation (*Fig. 4f*).

DOI: http://dx.doi.org/10.15666/aeer/1604_41654181

Soil erosion modulus change at different slopes

The soil erosion modulus at different slopes as well as the anomalies for each year were calculated (*Fig. 5*). The annual average soil erosion modulus for both sites from 2000 to 2014 at a slope < 25° was lower than that of the slope ≥ 25°. Annual average soil erosion modulus in the area of < 25° in the WDRB was only 277.26 t/(km^2·a), while that in the ≥ 25° region was 4,362.99 t/(km^2·a). In the LHRB, the annual average soil erosion modulus in the < 25° region was 1,335.96 t/(km^2·a), while in the region ≥ 25°, this value was 5,109.25 t/(km^2·a). Based on the results, the slope of an area had a impact on land use change. However, for any area, the slope was fixed and relatively small. The vegetation attached to the slope surface was affected by climatic changes and human activities, such as GGP implementation.

The decrease in farmland and the increase in grassland and forest land were concentrated in 2000-2005. Given the changes in land use and soil erosion modulus at different slopes (*Figs. 4* and *5*), the soil erosion modulus of the WDRB from 2000 to 2007 (except for 2001) was lower than the average value from 2000 to 2014, while after 2008 (except for 2010), the soil erosion modulus increased and was higher than the multi-year average value (*Fig. 5a*). This can be explained by the relatively sparse precipitation in the WDRB in 2000-2005 and affected by the implementation of the GGP. The surface vegetation coverage increased and the soil erosion modulus decreased; but under extreme precipitation in the following period, the soil erosion modulus increased (Wang et al., 2014c, d).

Vegetation coverage in the LHRB was relatively high, especially in the southeast of the basin. Therefore, GGP implementation further increased the level of vegetation cover in the basin and caused the decline of the soil erosion modulus. The soil erosion modulus anomalies for most years were negative from 2000 to 2014, which indicated that the inter-annual precipitation variability increased, resulting in an extremely high soil modulus. Therefore, the mean value from 2000 to 2014 also increased, and most of the year's anomalies showed a negative value (*Fig. 5b*).

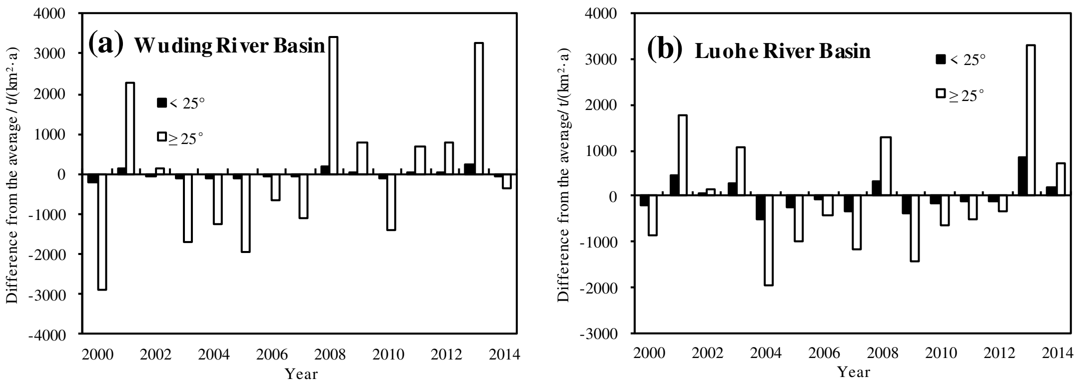

Figure 5. *Differences between annual soil erosion modulus and the average value between 2000 and 2014 at different slopes in the Wuding River Basin and Luohe River Basin*

Temporal and spatial changes of soil erosion modulus

Annual sediment transport data of the Baijiachuan hydrological station in the WDRB and the Zhuangtou hydrological station in the LHRB were obtained by the Yellow River Water Resource and Sediment Bulletin. The multi-year average soil erosion modulus of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41654181

the WDRB in LPNSC, from 2000 to 2014, was 457.90 t/(km^2·a), slightly higher than the average soil erosion modulus of 419.30 t/(km^2·a) measured by the Baijiachuan hydrological station, while the soil erosion modulus in the LHRB was 1,843 t/(km^2·a), slightly lower than the 2,150 t/(km^2·a) measured by the Zhuangtou hydrological station. The estimated soil erosion modulus was higher in the WDRB in LPNSC, while in the LHRB, the estimated values were lower; however, the overall difference was relatively low.

Temporal changes

Soil erosion in LPNSC is serious, but there are obvious differences in soil erosion levels between the different watersheds. *Figure 6* showed that, in general, the soil erosion modulus in the LHRB was higher than that in the WDRB, and the multi-year average soil erosion modulus was different. This mainly reflects the dominant role of precipitation in the soil erosion process. The LHRB is located in the southern part of the northern Shaanxi Province, and annual precipitation is higher than that in the WDRB in the northern part of the northern Shaanxi Province. Moreover, the climatic conditions and the vegetation coverage in the LHRB are relatively better than those in the WDRB. Therefore, the soil erosion modulus in the LHRB was higher than that in the WDRB, which can be attributed to the difference in precipitation. From 2000 to 2014, the soil modulus in the LHRB and the WDRB showed a fluctuating increase, and the linear increase rate of the soil erosion modulus in the LHRB was higher than that in the WDRB, although the linear fitting results were insignificant ($P > 0.05$), reflecting the inconsistency of the soil erosion change in both sites.

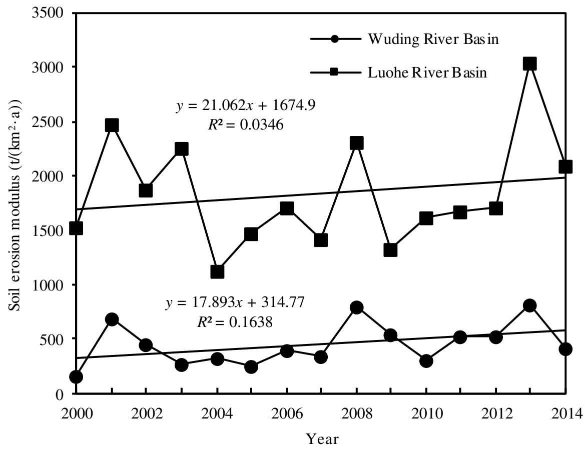

Figure 6. *Changes in annual average soil erosion modulation in the Wuding River Basin and Luohe River Basin*

Spatial change process

The linear change rate, the linear change trend, and the *F* test results for LHRB and WDRB were calculated by the linear trend method, using data from 2000 to 2014. The results are shown in *Figure 7*.

The linear change rate of the soil erosion modulus in the WDRB from 2000 to 2014 ranged between -230 and 1756 t/km^2 per year; higher values were mainly distributed in the southeast of the basin and in the southern part of the hilly-gully area, while the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41654181

northwestern and western parts belong to the southern margin of the Mu Us Sandy Land, with low-lying land, less rainfall, less soil erosion, and a relatively small change rate in soil modulus (*Fig. 7a*). The linear change rate was higher than 0 and lower than 0, which means that the soil erosion modulus in WDRB increased and decreased from 2000 to 2014. The changing trend of the soil erosion modulus mainly increased, accounting for 99.6% of the total basin area, while decreases accounted for 0.45%, concentrated in the northern part of the basin (*Fig. 7b*). The *F* test results showed that the linear change of the soil erosion modulus in the WDRB was mainly insignificant, accounting for 79.3% of the total basin area, while the area with a trend of significant change accounted for 20.7%, concentrated in the south-east of the basin. The soil erosion modulus of the hilly-gully region of the Loess Plateau, located in the southeast of the WDRB, continues to increase, with a critical soil erosion situation (*Fig. 7c*).

The linear change rate of the soil erosion modulus in the LHRB ranged between -584 and 992 t/km^2 per year, which was smaller than that in the WDRB; however, both rates are still relatively high. High values were mainly concentrated in the middle area and the central southwest of the watershed (*Fig. 7d*). The northern part of the LHRB is a loess hilly-gully region, which is dominated by grassland and showed serious soil erosion. The central and southern parts were covered by temperate forest, with a relatively high vegetation coverage and low soil erosion low (*Fig. 2I*). Overall, there was an increasing change, accounting for 73.3% of the total area of the basin, while the decreasing accounting for 26.7%, mainly in the southeastern and northern parts of the basin (*Fig. 7e*). The results of the *F* test showed that the linear change of the soil erosion modulus in the LHRB was mainly insignificant, accounting for 99.3%, while a significant trend was sparsely distributed along the northern margins in the basin (*Fig. 7f*).

Impacts of GGP implementation on soil erosion

To assess the impacts of GGP implementation on soil erosion, it is assumed that the soil erodibility factor (*K*), the topography factor (*LS*), and the soil and water conservation factor (*P*) are fixed, while the rainfall erosivity factor (*R*) and the vegetation cover factor (*C*) varied over the years. In terms of the *R* and *C* factor, the former was not controllable, while the latter could be affected by GGP implementation. When *R* is fixed, the erosive forces in 2000 would remain unchanged from 2000 to 2014, only the impact of the *C* factor (NDVI) on soil erosion would be considered. The results are shown in *Figure 8*.

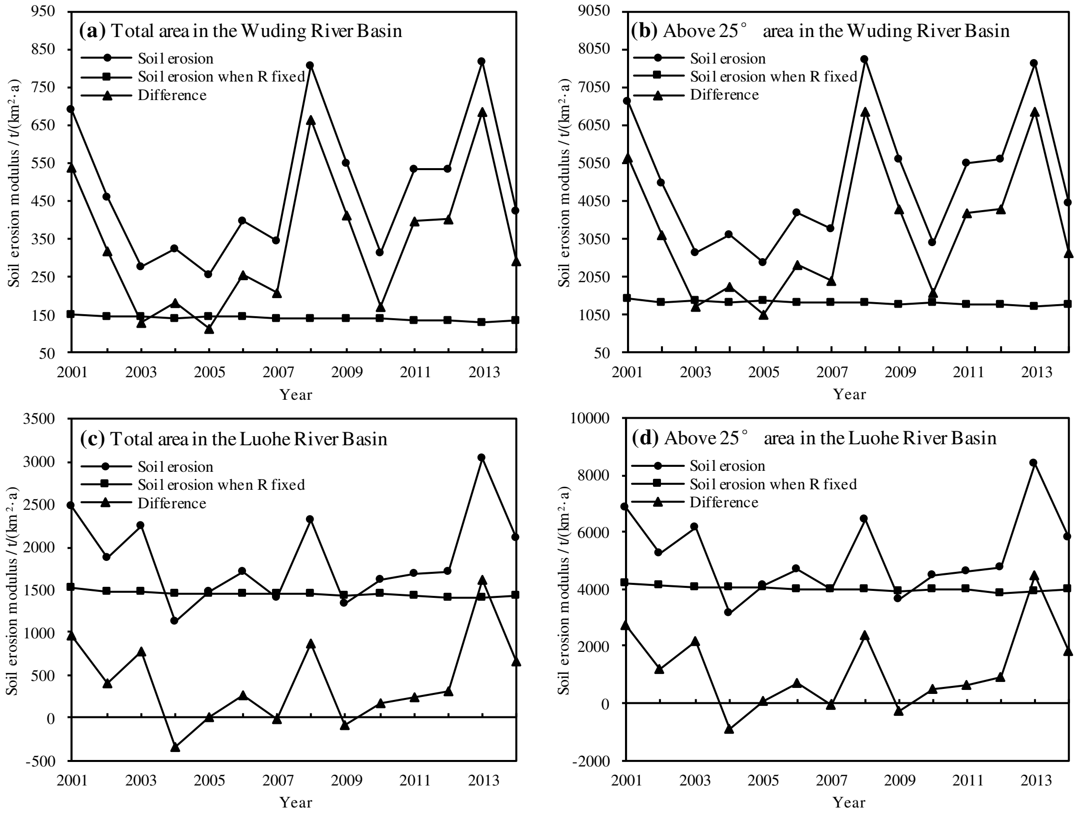

Figure 8. *Soil erosion modulus change in the entire region and areas with a slope ≥ 25 °, with fixed R values, and the difference between soil erosion modulus in actual and when R fixed in 2000, from 2001 to 2014 in the Wuding River Basin and Luohe River Basin*

The soil erosion modulus in both WDRB and LHRB during 2000-2014 increased. When the change of rainfall erosivity was not taken into account, the soil erosion in the two basins was only affected by the surface vegetation changes. The soil erosion modulus in both basins showed decline (*Fig. 8a* and *c*). The ≥ 25° regions were the key areas for GGP implementation, and the soil erosion modulus at these regions also showed reduction (*Fig. 8b* and *c*). At areas with a slope ≥ 25°, the soil erosion modulus in the two basins was 9.5 times and 2.7 times higher than the total soil erosion modulus, respectively, which indicated that the implementation of GGP had reduced the soil erosion modulus by changing the surface vegetation coverage. However, it should also be noted that in the natural state, the soil erosion modulus increased from 2000 to 2014,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41654181

which means that the increase in the soil erosion modulus caused by precipitation changes far exceeded the reduction caused by the implementation of the GGP.

Discussion

Using the WDRB and LHRB as examples, the implementation of the GGP changed the land use types and affected the vegetation status (reflected by changes in NDVI), thereby reducing soil erosion. However, there are a large number of factors influencing soil erosion, which is a quite complex process.

In the RUSLE model, the soil erodibility factor is mainly affected by the organic matter content in the soil and the mechanical composition of soil particles. The GGP implementation in the first stage (2000-2008) has caused obvious changes in soil organic matter content (Zhu et al., 2014; Xie et al., 2016). The soil erodibility factor changes over time, and under objective conditions, the use of a year-by-year soil erodibility factor to calculate the soil erosion modulus will be closer to the actual situation.

Positive soil erosion modulus values in the WDRB and LHRB from 2000 to 2014 were six and five years, respectively. However, the overall increase in soil erosion in the two basins indicates that severe soil erosion will occur within a few years, caused by heavy precipitation (*Fig.9*). The role of precipitation in soil erosion is obvious. The construction of check dams for channel treatment and the implementation of the GGP for slope vegetation treatment have already been performed. However, with the increase of the frequency of extreme precipitation caused by climate change, the changes in soil erosion in the basins require further research.

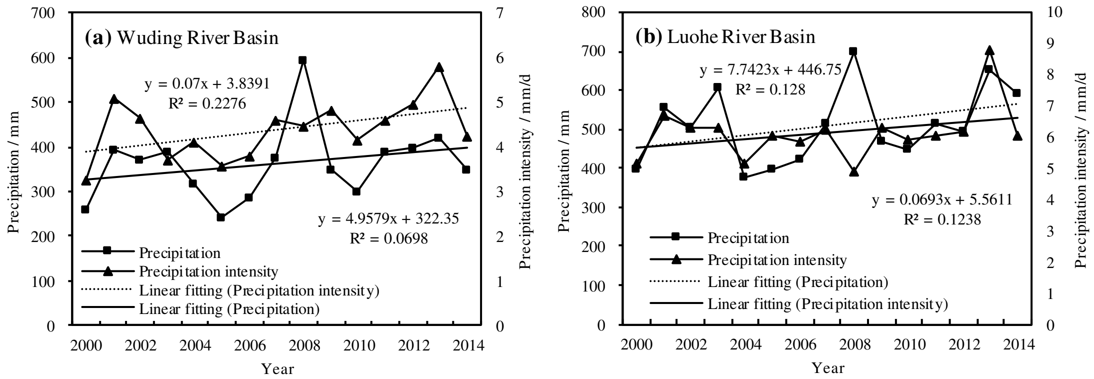

Figure 9. *Precipitation and precipitation intensity change from 2000 to 2014 in the Wuding River Basin and Luohe River Basin*

Conclusions

(1) The implementation of the GGP (2000-2008) promoted the conversion of farmland to grassland and forest land (concentrated in 2000-2005) in the WDRB and LHRB. In 2000-2014, the NDVI values increased by 61.38 and 19.52% in the WDRB and LHRB, respectively, and showed a linear increase; the change rates of land use and NDVI in the area with a slope ≥ 25° were higher than those in < 25° areas and throughout the basin. The change range of soil erosion modulus difference value at a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41654181

slope ≥ 25° was higher than that at a slope < 25°, and the negative value reflected the role of the GGP, while the positive value reflected the rainfall impact.

(2) The soil erosion modulus values of both basins increased from 2000 to 2014, and the average soil erosion modulus and its growth rate in the LHRB were higher than those in the WDRB, which is mainly due to the difference in rainfall. The soil erosion modulus in both basins mainly showed an increase and areas with increase were mainly distributed in the southeastern region of the WDRB (20.7%), and the northern of the LHRB (only 0.7%).

(3) Without considering the impact of changed precipitation, the soil erosion modulus of both basins from 2000 to 2014 showed a decrease; the linear decline rate of the soil erosion modulus in the region with a slope ≥ 25° was 9.7 and 2.5 times than that of the whole basin in the WDRB and LHRB, respectively. This proves that the implementation of the GGP, converting farmland into forest land and grassland, has improved the vegetation coverage (especially in areas with a slope ≥ 25°) and consequently reduced soil erosion.

This paper analyzed the process by which soil erosion in the Wuding River Basin and Luohe River Basin in northern Shaanxi Province of China has changed based on the RUSLE. However, the research lacks support from measured data. Future studies should obtain hydrological monitoring data and compare this with the results calculated by RUSLE.

(Received 27th Apr 2018; accepted 20th Jun 2018)

Abstract. Wetlands are points of interest for social scientists as much as they are for naturalists. Due to their ecological importance, they have been in contact with human communities throughout the history and as a result of this, they also became ecosystems that shape cultural periods. The main reason for choosing wetlands in this study was that Turkey is rich in wetlands as a result of its geographical location. On the other hand, in order to have a sustainable environment, significant steps should be taken in preserving and developing the wetlands. In the scope of this study; the significant wetlands in the immediate vicinity of Sivas were used as material with a holistic view. These wetlands are located to the north of Sivas are Hafik Lake (Koçhisar Lake), Lota Lakes and Tödürge Lake (Demiryurt Lake). The images representing the condition of the study area together with the necessary information and the score card, were submitted to the experts for their evaluation. The aim of this study was to find out wetlands of landscape photographs in terms of potential differences (water property size, plant existence, topographic diversity, neighbors views, natural elements, cultural existence) and was to develop sustainable recreational areas in terms of visual preferences. The results were evaluated with a Q-sort analysis. Suggestions are offered about the visual landscaping quality and the development and preservation of recreational application potential within the scope of sustainable landscaping.
Keywords: *wetlands, landscape quality, q-sort analysis, expert opinion, sustainable landscape*

Introduction

In modern societies, environmental consciousness started with the “Urban ecology” in 1970s, as a result of the worldwide environmental crisis. It continued developing in 1980s (Özgüner, 2003) and in the Rio Conference of Environment and Development held in 1992, the notion of “Sustainability” came up for the first time. Within the scope of this notion, with the aim of having sustainable cities and ecological balance, developing and preserving urban ecosystems gradually became significant. This tendency named as ecological approach in landscape designing and administration, brought a different point of view to the applications of our day (Erdoğan Onur, 2012; Ankaya and Gülgün, 2009; Türkyılmaz et al., 2007; Gülgün et al., 2009).

Wetlands, as one of the most fertile ecosystems of the world, have been the focus of human settlement choices for thousands of years (Tırıl, 2006). Throughout the history, it has been seen that the first settlement areas of humans were concentrated on places that can be defined as wetlands like deltas, floodplains, lakesides or riversides. The water elements that can be listed within the extent of wetlands are swamps, peat bogs, floodplains, rivers, lakes, salt marshes, mangroves, sea grass beds, corals, seaside areas with a depth of no more than 6 m during tides, shore wetlands and man-made areas like water treatment pools and dams. Wetlands have direct and indirect usage values. Direct usage value examples can be; salt production, aquaculture production, reed harvesting, agriculture and stock breeding,

DOI: http://dx.doi.org/10.15666/aeer/1604_41834197

being used as grazing or timber supply, being used as drinking, municipal or irrigation water, being used for transportation or tourism activities. It is crucial to establish a planned recreational usage in order to develop tourism opportunities and create a sustainable environmental value.

Many methods can be used to evaluate and improve wetlands recreationally. In this study, Q sort analysis was used to analyze the visual quality and to determine the important criteria of each wetland. Q- sort analysis or Q factor analysis as it is named in the foreign literature, is a relatively new tool not only as approach but particularly following the quite recent rediscovery of its usefulness in those fields where psychometric knowledge of individuals have thorough implications (Pitt and Sube, 1979; Kramer et al., 2003).

Review of literature

It is an undisputable fact that the increase in water existence and water surface in terms of recreational activities are important factors in raising the preferability and attractiveness of an area. In many studies (Schroeder, 1982; Arriaza et al., 2004; Özhancı and Yılmaz, 2011; Bolca et al., 2007) it was mentioned that the existence of water positively affects the aesthetic landscaping quality (Aşur, 2017). Despite the various initiatives in Turkey on the preservation and sustainability of the wetland views, especially in the Eastern Anatolia and Southeastern Anatolia regions, these landscapes are under the threat of existing financial activities as well as regional and local development plans prioritizing financial improvement (Baylan et al., 2013).

There were studies showing that areas with architectural aspects compatible with the nature in terms of vegetation, fabric, color and form together with characterizing the aesthetic and visual aspects of water in landscaping; increase the visual quality and are preferable to the users in recreational objectives (Özhancı and Yılmaz, 2011; Özgeriş and Karahan, 2015). According to Ak (2010) visual quality studies should be used as an important leading tool in planning and designing rural and urban areas in terms of the visual data created by the changes in physical environment. They should also be used in forming some of the administrative policies. Criteria for monitoring and defining the landscaping in survey forms used in reviewing the visual landscaping evaluation as published in the Scotland Natural Heritage Environmental Evaluation guidebook (SNH, 2013): Visible physical components: land form, land cover, utilities on the land, water existence, forest land, coppices, woodlands, agricultural areas, animals, settlements, other usages of the land (like area or city parks), linear features (highways or coastal line) or point features (like castles of monuments). In order to reveal the landscaping quality of an area, a visual landscaping evaluation should be conducted. To determine the visual landscaping evaluation parameters, these parameters were grouped under cognitive/emotional/biophysical titles according to studies conducted on the visual perception, preference and evaluation of the landscaping. according to Clay and Daniel (2000), Wu et al. (2006), Arriaza et al. (2004), Sevenant and Antrop (2009), Uzun and Müderrisoğlu (2011), Jahany et al. (2012), SNH (2013), Huang (2014). Biophysical parameters were evaluated as visual field width, form of clarity limits, silhouettes, land silhouette, width, slope, exposure (to sun), land form, relief, land cover, adjacent view, cultural variables, vegetation, richness in species and water existence.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41834197

The categories were obtained using the Q-sort method like described by Pitt and Zube (1979). In particular, participants were asked to sort the 74 landscape photographs into 5 classes of urbanization. As each person's interpretation of urbanization may vary, we used a more objective criterion to perform the sorting: the presence of built area in the image. For the sorting task, the participants were presented with all photographs on a desk and were asked to first remove the 12 scenes which they thought were least characterized by built area. These landscapes were classified as 'Rural'. The second task consisted of picking out the 12 scenes in which they thought the most built area was present (Urban'). For the remaining 50 photographs these two steps were repeated but at each time selecting 16 photographs instead of 12 (respectively 'Semirural' and 'Semi-urban').

Fairweather and Swaffield (2001): This paper reported on an interpretative study of visitor experiences of landscape in Kaikoura, New Zealand and focuses on how these experiences vary among different groups. Photographs representing different landscape experiences were Q sorted by a non-random sample of both overseas and New Zealand visitors. The data were factor analyzed to yield five groups each describing a distinct visitor experience, and the results were interpreted on the basis of the photographs most and least liked, and the comments made about them by the people interviewed. The eco-tourist experience is characterized by being close to marine mammals in a spectacular setting.

Naspetti et al. (2016): Visual Q methodology is particularly suited for the assessment of such perceived impact of photovoltaic systems. A selection (concourse) of landscape images with photovoltaic elements was collected and used during this Q-sort analysis. The final Q sample included 54 images of various photovoltaic plants in urban and rural settings. The P set was composed of 34 participants, including landscape and photovoltaic professionals. This analysis identified three distinctive factors that are representative of the different viewpoints on the integration of photovoltaic systems within the urban and rural landscapes. We conclude with a discussion of the wider land-use policy implications of this analysis.

According to Dupont et al. (2017), the remaining 18 landscape scenes formed the last 'Mixed' class and used Q-sort analysis. Scores of for each photograph were summed across participants and an average urbanization score was calculated. These means determined to which class of urbanization each photograph was assigned. However, a number of photographs seemed to balance between two categories (scores close to e.g., 1.5, 2.5 etc.) and could therefore not be unequivocally assigned to one class.

Q-Sort analysis method was used for this study and the mentioned wetlands which were considered to be important in the close vicinity of Sivas were; Hafik Lake (Koçhisar Lake), Ulaş Lake, Gürün Gökpınar Lake and Tödürge Lake (Demiryurt Lake). The aim of this study was to evaluate the visual landscaping quality and recreational usage potential of the wetlands with different sizes and located to the north of Sivas-Hafik highway. Therefore some parameters were examined (water property size, plant existence, topographic diversity, neighbors views, natural elements, cultural existence). A second aim of our study, these wetlands was to bring suggestions to protect in sustainable landscape.

Material and method

Material

The study material consisted of the wetlands in the immediate surroundings of Sivas (*Fig. 1*). They are wetlands with different sizes and located to the north of Sivas – Hafik highway: Hafik Lake (Koçhisar Lake), Gürün Gökpınar Lake, Ulaş Lake and Tödürge Lake (Demiryurt Lake). Photographs of these wetlands were taken with a digital camera between 11.00 and 17.00 h. When images were taken, active uses are taken into consideration and areas that people observe individually were taken as basis. In order to allow for the assessment of the areas from all angles, 48 photographs were taken and a total of 16 images (4 photographs for each wetland) were selected for selection.

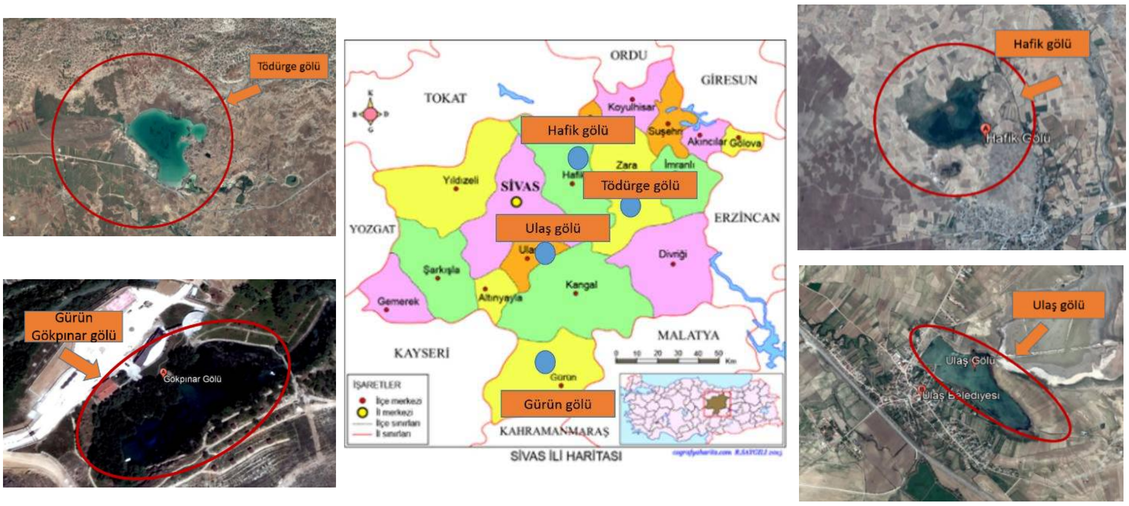

Figure 1. *Satellite images of wetlands in the study and Sivas map (Turkey)*

Gökpınar Lake is located in Gürün County. It is used as a recreational area. Gökpınar (Gürün) Lake has a surface area of 3.000 m^2 and the trout facilities established on the brook flowing from the lake is a source of livelihood for the people living in the area (*Table 1*). Gökpınar has its name because of its structure resembling an aquarium, its water being soft and cold, its color being turquois and azure blue. On the other hand; Hafik Lake is 36 km far from Sivas city center and it is a karst lake. It has a surface area of 7.5 km and its volume is 2.250.000 m^3. It has eutrophic characteristics and has an average depth of 2 m (Çepken, 2008). Ulaş Lake is located in Ulaş County. It has a surface area of 0, 79943 km. It has been recently put into service as a recreational area by the local administration.

Tödürge is a mildly salty lake located on the upper Kızılırmak basin. It is on the Sivas – Erzurum highway, 50 km far from Sivas, between the counties Hafik and Zara. There is a village with the same name in about 1-km distance. The word “Tödürge” is a changed version of the name belonging to one of the old Turkish tribes; Dodurga (*Table 2*).

The surface area of Tödürge Lake is 5 km^2 and it is fed by the waters emerging from the bottom, springs in the surrounding area and Acısu brook. Tödürge Lake is not very deep in the sides and its average depth is 20 m. In its deepest spot, it is

DOI: http://dx.doi.org/10.15666/aeer/1604_41834197

around 45 m deep. It flows into Kızılırmak with an outgoing channel from the west side. The average depth of the lake is 4 m and there are small reeds on its shores. Keşan Island located to the east of the lake is a favorite spot for cranes. To the west, there are large meadows used as grazing for the cattle.

DOI: http://dx.doi.org/10.15666/aeer/1604_41834197

Method

The data obtained from the questionnaires of every 30 experts for each of the 16 images were recorded and separated for 4 wetlands. Then the biophysical parameters of the visual landscape were studied, evaluated (*Table 3*) and scored numerically (very beautiful +2, beautiful +1, ordinary 0, ugly -1, and very ugly -2). The results of this study were set in a separate table. The number of experts are obtained in light of the data of landscape architects living in Sivas according to UCTEA Chamber of Landscape Architects. The score of each landscape characteristic got based on experts' opinions, was calculated. High score of each wetland suggests photo's desirability and higher priorities of public preferences. In order to calculate the score of each photograph, the following method was used: Scoring was done for each building according to five point Likert scale as +2, +1, 0, -1, -2 and the recreationally significant areas are designated by a Q-Sort analysis formula was used and the resulted findings are listed in *Tables 4, 5, 6, 7, 8, 9* and *10.*

$$N = \sum_{i=1}^{5} n_i (3 - i)$$

Total points of every photo = N
The number of selectors with the quality of very beautiful = n1
The number of selectors with the quality of beautiful = n2
The number of selectors with the quality of ordinary= n3
The number of selectors with the quality of ugly = n4
The number of selectors with the quality of very ugly = n5 (Golchin et al., 2012).

Table 3. *Evaluation chart according to visual landscape biophysical parameters Çakcı (2007), Uzun and Müderrisoğlu (2011), SNH (2013)*

Points Criteria	+2	+1	0	-1	-2
Water property size	Very dominant and clear water surface	Water surface is very visible but non-clear water	Water surface obvious	Water surface is obvious and dirty	The physical quality and appearance of the water is very bad, dirty
Plant existence	Very various	Various	Little variety	Not various	No vegetation
Topographic diversity	Very clear	Clear	Little clear	Not clear	Not at all clear
Neighbors views	Very clear	Clear	In the middle	Little clear	Not at all clear
Natural elements	Natural elements are very dominant	Natural elements dominant	Natural and structural elements are balanced	Structural elements dominant	Structural elements are very dominant
Cultural existence	Near, varied and clear	Near, less varieties	Far away, less clear	Far away, not clear	Not available

DOI: http://dx.doi.org/10.15666/aeer/1604_41834197

Results and discussion

Following the study conducted, 6 parameters on the visual landscaping character and general expert opinion were evaluated with a Q-Sort analysis. In light of the data gathered, it is seen that Gürün Lake had the first place in “attractiveness”. Tödürge Lake also had an important point. As seen in *Table 4,* 2 out of 4 wetlands in different locations had high points. While it is significant that recreational area works of Ulaş Lake continues, the area also must be protected against destruction. The *Table 4* indicated Gürün Lake had 48 points as the general view of expert. Also Tödürge Lake had 39 point second rank in terms of general view.

Table 4. *The general view of visual landscape value assessment by experts in working area of lakes*

The number of the photo selectors of different qualities (from 30 experts) - the general view						
Photo name	**Very Beautiful n1**	**Beautiful n2**	**Ordinary n3**	**Ugly n4**	**Very ugly n5**	**Photo points N**
Tödürge Lake-(TL)	12	16	1	1	0	39
Hafik Lake (HL)	2	12	9	6	1	8
Gürün Gökpınar Lake GL)	19	10	1	0	0	48
Ulaş Lake (UL)	0	11	15	4	0	7

Gökpınar Lake which is one of the important picnic areas of Sivas, has a depth of 15 m. Its water is quite clean and clear. The lake is famous for its trout and it is fed by the waters emerging from the bottom. There are motels and restaurants on the lakeshore and the opportunity of boating on the lake affected its scoring positively (*Table 4; Figs. 2* and *3*). Ulaş Lake is located in Ulaş County. It used to be idle but after the work conducted by Ulaş Municipality, the lake became active again and there was a picnic area constructed on its shore. There are gazebos installed around the lake for the visitors, however the wetland is not under adequate protective measures.

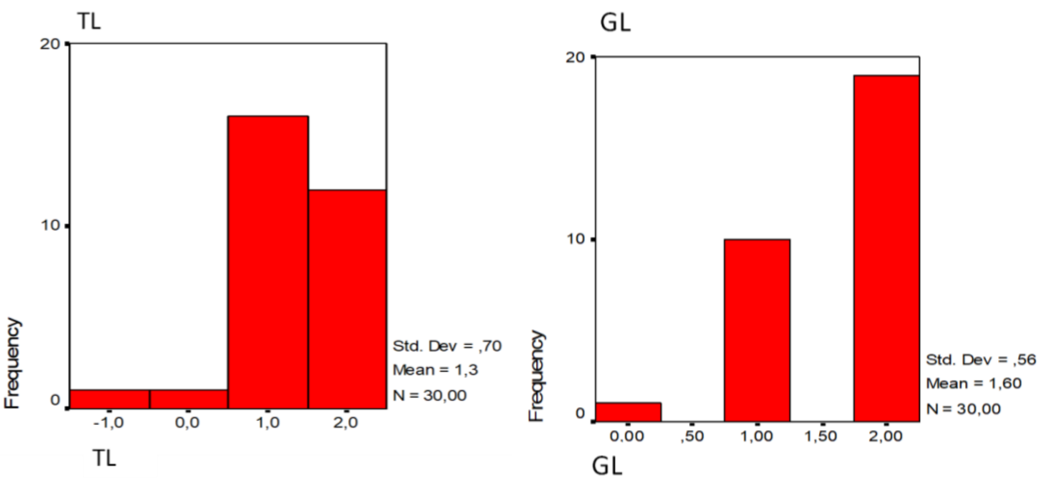

Figure 2. *Standard deviation values of general opinion evaluation by experts of visual landscape value of Tödürge, Gürün Lakes*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41834197

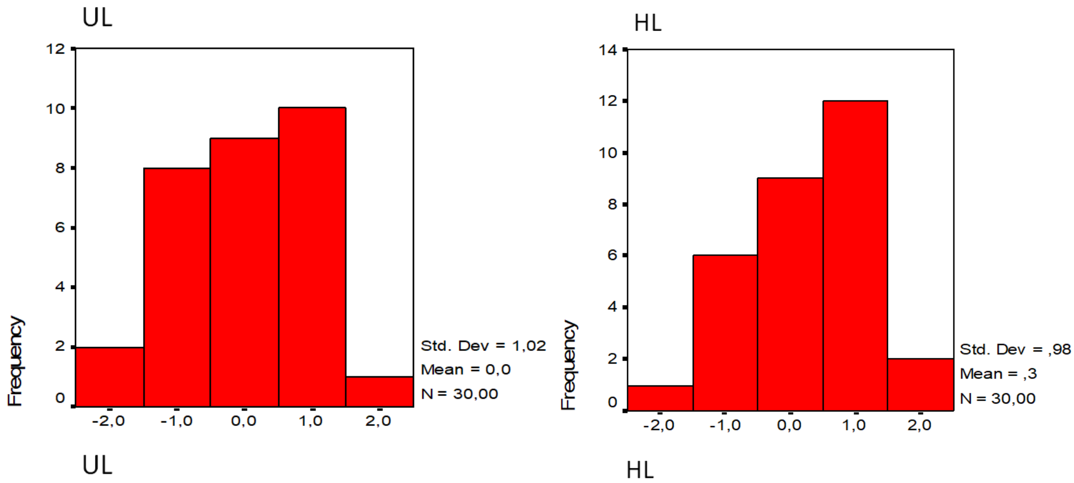

Figure 3. *Standard deviation values of general opinion evaluation by experts of visual landscape value of Ulaş and Hafik Lakes*

When the parameter of water existence was reviewed; Tödürge Lake being on the migration route of the birds and coming in the first place according to area size (4.340 ha) support the result of Q-Sort analysis. As seen on *Table 5,* Tödürge Lake had the highest point in terms of water existence. When we look at Gürün Lake on the other hand, it was seen that running water being used as drinking water supply by the locals was a significant advantage. It was remarkable that the water was clean, healthy and cold at the same time. The effects of this situation could also be seen on the scoring. Hafik and Ulaş lakes had close points. None of the 4 wetlands had negative point in terms of water quality and wetland distinctiveness (*Table 5*).

Table 5. *The visual landscaping items of the lakes assessment according to the "Parameter of water presence"*

The number of the photo selectors of different qualities (from 30 experts) - water presence							
Photo name	**Very beautiful n1**	**Beautiful n2**	**Ordinary n3**	**Ugly n4**	**Very ugly n5**	**Photo score N**	**Standard dev.**
Tödürge Lake-(TL)	12	18	0	0	0	42	,49827
Hafik Lake (HL)	11	14	3	2	0	34	,86037
Gürün Gökpınar Lake (GL)	12	15	3	0	0	39	,65126
Ulaş Lake (UL)	9	15	4	2	0	31	,85029

When the plant existence parameter was reviewed; it was seen that the points of Gürün, Ulaş and Tödürge lakes were close to one another. Ulaş Lakes' Wetland was registered as "Wetland of National Importance" on 10 July 2016. The area is 79.943 decares big. Ulaş Lakes are small and shallow lakes located to the southeast of Sivas. They are 37 km far from Sivas. There are 48 families, 188 types, 338 species and 345 taxa around Ulaş Lakes and their surroundings. 57 out of 338 detected species are endemic. Gurun Lake also had a decent point (45) (*Table 6*).

Table 6. *The visual landscaping items of the lakes assessment according to the "Parameter of plant existence"*

The number of the photo selectors of different qualities (from 30 experts) - plant							
Photo name	**Very Beautiful n1**	**Beautiful n2**	**Ordinary n3**	**Ugly n4**	**Very ugly n5**	**Photo score N**	**Standard dev.**
Tödürge Lake-(TL)	12	17	1	0	0	41	,55605
Hafik Lake (HL)	2	13	11	4	0	13	,81720
Gürün Gökpınar Lake (GL)	17	11	2	0	0	45	,62972
Ulaş Lake (UL)	18	7	4	1	0	42	,85501

When the topographical variety parameter was evaluated; it was seen that the area is rich in topographical variety. It was especially important that there were mountains with different heights that shape up the land view. According to the results of the analysis, Gürün Lake was in the first place in terms of variety. Hafik and Ulaş lakes also had decent points (*Table 7*).

Table 7. *The study area consists of visual landscaping items of the lakes assessment according to the "Parameter of topographic diversity"*

The number of the photo selectors of different qualities (from 30 experts) - topographic diversity							
Photo name	**Very beautiful n1**	**Beautiful n2**	**Ordinary n3**	**Ugly n4**	**Very ugly n5**	**Photo score N**	**Standard dev.**
Tödürge Lake-(TL)	2	19	7	2	0	21	,70221
Hafik Lake (HL)	13	14	3	0	0	40	,66089
Gürün Gökpınar Lake (GL)	18	11	1	0	0	47	,56832
Ulaş Lake (UL)	6	19	5	0	0	31	,61495

When the neighboring view parameter was reviewed; it was seen that plant diversity and topographical diversity, positively affect the view. Existence of settlements close to the wetland was limiting the view and is also a threat to the area. According to the analysis results; Gürün Lake was in the first place as it had clean and unique water as well as natural beauties in its surroundings. Hafik, Tödürge and Ulaş Lakes also had decent points (*Table 8*).

Table 8. *The study area consists of visual landscaping items of the lakes assessment according to the "Parameter of neighbors views"*

Photo name	**Very beautiful n1**	**Beautiful n2**	**Ordinary n3**	**Ugly n4**	**Very ugly n5**	**Photo score N**	**Standard dev.**
Tödürge Lake-(TL)	6	20	4	0	0	32	,58329
Hafik Lake (HL)	10	16	4	0	0	36	,66436
Gürün Gökpınar Lake (GL)	20	10	0	0	0	50	,47946
Ulaş Lake (UL)	3	17	8	2	0	21	,74971

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41834197

When the natural elements parameter was reviewed; it was seen that for all three wetlands, natural elements were apparent. The existence of a settlement in close vicinity of Ulaş Lake showed that there was a balance between natural element and structures. In case the city started to become a concrete jungle without the notion of sustainable environmentalism, destruction and pollution in wetlands were thought to happen (*Table 9*).

Table 9. *The visual landscaping items of the lakes assessment according to the "Parameter of natural elements"*

The number of the photo selectors of different qualities (from 30 experts) - natural elements							
Photo name	**Very beautiful n1**	**Beautiful n2**	**Ordinary n3**	**Ugly n4**	**Very ugly n5**	**Photo score N**	**Standard dev.**
Tödürge Lake-(TL)	12	16	2	0	0	40	,60648
Hafik Lake (HL)	13	15	2	0	0	41	,61495
Gürün Gökpınar Lake (GL)	20	10	0	0	0	50	,47946
Ulaş Lake (UL)	1	18	8	3	0	17	,72793

When the cultural existence parameters are reviewed; it was seen that the presence of a historical past surrounding the wetlands had significant effects. There are social facilities belonging to Sivas Cumhuriyet University on the east coast of Tödürge Lake, on a hill overviewing the it. Also, to the north of Tödürge Lake, there is a historical settlement named Tepecik Mound.

When Hafik Lake was evaluated; it was seen that during the drilling excavation on Pılır Mound, the existence of lake houses built on wooden poles nailed to the bottom of the lake was detected and it was concluded that this settlement dated back to Neolithic, Catholic and First Bronze Age. Pılır Mound was the only example of settlement style formed by the lake houses called Palafit in our country. Other examples of these houses were discovered in the Zurich Lake and the Lakes of the Alps in Switzerland (Sivas Provincial Directorate of Culture and Tourism). These historical past effects also affected the result of the analysis. Hafik Lake and Tödürge Lake had the highest points (*Table 10*).

Table 10. *The visual landscaping items of the lakes assessment according to the "Parameter of cultural elements"*

Results and suggestions

It is a known fact that building a city causes pressure and destruction on the natural environment. Yet, in order to minimize the destruction, it is important to make guiding plans for benefiting from natural areas within the limits of preservation – utilization balance and determining the limits for structuring (Aşur, 2017; Aşur and Alphan, 2017; Meriç and Çağırankaya, 2013). In wetlands, many physical factors come into play dominantly and it is easier for users to see the interactions between physical and biological environments.

In the studies conducted on wetlands; asides from using wetlands as recreational areas (Osborn and Spofford, 1972; Troost and Altman, 1972), the advantages of using them for educational purposes and their suitability for local, national and global environmental problems were researched. It was also aimed to teach basic ecological concepts and develop motivations that would help stir the feelings of curiosity and attention about environment by making first-hand observations.

City of Sivas which was the subject of this study, had wetlands with various sizes. These could be listed as the Hafik Lake (Koçhisar Lake) located to the north of Sivas – Hafik highway, Gürün Gökpınar Lake, Ulaş Lake and Tödürge Lake (Demiryurt Lake). Among these wetlands, reed field properties of Sivas – Ulaş wetland and Hafik wetland are under threat because of their being in a close distance to the city center. All four of the wetlands, particularly Tödürge Lake and Gürün Lake, receive many visitors coming with recreational purposes. Even though they were relatively far from the city center, their natural structures have started being subject to depredation. It was suggested that the restoration works on the areas of Sivas Hafik Lake and Ulaş Lake were increased and the location should be open to visitors with arrangements compatible to the nature of the area.

Each lake discussed within the scope of this study were reviewed under 7 different parameters regarding the wetlands and the lakes with the highest point in each parameter are designated (*Table 11*).

Table 11. *The highest values of examined the parameters in the wetlands*

Parameters	Wetland name	Point
General view of experts	Gürün Lake	48
Water property size	Tödürge Lake	42
Plant existence	Gürün Lake	45
Topographic diversity	Gürün Lake	47
Neighbors views	Gürün Lake	50
Natural elements	Gürün Lake	50
Cultural existence	Hafik Lake	50

Table 11 can be summarized as follows: In neighboring view, natural elements, topographical diversity and plant existence parameters, Gürün Lake had the highest point by a narrow margin. In cultural existence parameter, Hafik Lake had the highest point. In water existence parameter, Tödürge Lake had the highest point. The result of the evaluation conducted according to the general view of the experts, the overall highest point belongs to Gürün Lake.

In order to preserve these beautiful and natural structures existing in Sivas and many other cities alike; shore protection plans should be constituted in order to prevent the destruction caused by the structuring done against building codes and pollution of solid wastes and waste waters. It is suggested that by staying within the limits of Shore Protection Act No. 3621; public-minded facilities on recreation, culture, sports, entertainment, relaxation, health and social life should be established and the natural habitat areas should be protected. Each of the wetlands located in the city of Sivas and its immediate surroundings of shore areas, have high ornithological importance thanks to the significant potential as wetlands and being on the important bird migration routes. Among these wetlands, Kızılırmak Delta has international preservation status. Ulaş and Tödürge Lakes are designated as RAMSAR areas. Sivas has visual landscaping resources and to preserve the landscaping quality of wetlands in Sivas and maintain ecological sustainability, local authorities of Directorate General for Nature Conservation and National Parks and Turkish Republic Ministry of Forestry and Water Affairs should have precedence in the development of human resources and corporate capacity. Studies conducted should be supported with awareness raising activities done by local decision makers and local community, together with preparing integrated wetland administration plans. One of the most important conditions of preserving the wetland sceneries of Sivas was considered to be corporate collaborations aimed at the protection of wetland areas' visual landscaping quality.

Abstract. To further study the effect of ozone stress on growth and yield formation of rice (*Oryza sativa*), we conducted an experiment with rice by using Free Air gas Concentration Enrichment (FACE) facility stored in paddy field in China. A conventional indica cultivar Yangdao 6 and a super hybrid indica cultivar II you 084 were grown at current or elevated ozone concentration (target at 50% above current, E-O_3) under low (LD, 16 hills m^{-2}), medium (MD, 24 hills m^{-2}) or high planting density (HD, 32 hills m^{-2}) from tillering until maturity. The increase of O_3 had no significant effect on phenology and plant height of Yangdao 6, but greatly accelerated phenology development and reduced plant height of II you 084. Ozone stress significantly reduced dry matter production of rice in mid and late stage, and finally, decreased the biomass of Yangdao 6 and II you 084 by 17.6% and 25.4% respectively. Ozone stress had no significant effect on harvest index of Yangdao 6 but reduced it of II you 084 by 9.0%. The increase of O_3 had no significant effect on the panicle number per area of rice. Ozone stress had no significant effect on the spikelet number per panicle of Yangdao 6, but significantly reduced that of II you 084 by 22.0%. Ozone stress decreased spikelets per area, filled grain percentage, and filled grain weight of rice, and eventually reduced grain yield of Yangdao 6 and II you 084 by 15.9% and 27.3% respectively. Variance analysis showed that the impacts of ozone stress on II you 084 were bigger than Yangdao 6, which were proved by the significant ozone by cultivar interactions for biomass, harvest index, spikelet number per panicle, spikelet number per area, filled grain percentage, filled grain weight. Week interactions of ozone by cultivar by planting density were detected: The effects of ozone stress on biomass and grain yield of Yangdao 6 were decreased with the increase of planting density. The above results showed that the increase of O_3 depressed the dry matter production of rice, and then decreased the yield, and the response of super hybrid rice varieties to ozone is greater than that of conventional varieties. The selection of high-yielding conventional varieties combined with relatively high planting density can minimize the yield loss in the future high ozone conditions.
Keywords: *rice, ozone, plant density, yield formation*

Introduction

In recent decades, due to the aggravation of human activities, the use of a large number of fossil fuels and nitrogenous fertilizers and the emission of automobile tail gas, the concentrations of NOx and VOCs in the atmosphere have increased dramatically, resulting in the increasing concentration of ozone in the atmosphere near the ground. According to observations, the concentration of O_3 in the troposphere of the Northern Hemisphere is increasing at an annual rate of 1% (WMO, 1991), even more in some industrial areas (Logan, 1985). It is reported that the average ozone concentration in the troposphere of the earth has risen rapidly from less than 10 nl/L before the industrial revolution (Volz and Kley, 1988) to about 50 ml/L in 2000 (Fiscus et al., 2005). According to Fuhrer et al.'s (1997) study, the ozone concentration has exceeded 25% of sensitive crops' injury concentration (40 nl/L). It is estimated that nearly a quarter of the countries and regions in the world now face the threat of O_3 concentration

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41994215

of more than 60 nl/L in summer (Fowler et al., 1999). It is estimated that by 2050, the concentration of O_3 in the troposphere will increase by 20% to 25% (IPCC, 2007), and by 2100 by 40% to 60% (Morgan et al., 2006; Sitch et al., 2007; Meehl et al., 2007). The pessimistic estimate is that the concentration of O_3 in the troposphere will rise to 80 nl/ L by 2100 (Fiscus et al., 2005).

The response of rice growth and yield formation under ozone stress has been widely reported (Yang et al., 2008; Ainsworth, 2008). The results showed that the response of yield to ozone stress varies greatly due to the control equipment of the experiment (Maggs et al., 1995), materials (Kobayashi et al., 1995; Maggs and Ashmore, 1998; Zheng et al., 1998; Jin et al., 2000; Li et al., 2017), the concentration of O_3 treatment materials (Bai et al., 2002; Jin et al., 2001; Feng et al., 2003) and the treatment period (Asakaw et al., 1981; Heagle et al., 1991). But does the response of rice growth and yield formation to the increase of ozone concentration vary with other environment or cultivation factors? Due to the limitation of the air chamber's narrow test space, there are few reports in this aspect. Because of the large experimental space and long duration, FACE platform provides an opportunity to study the interaction between ozone and other factors (Long and Ainsworth, 2005; Lie et al., 2014; Peng et al., 2016). In recent years, the influence of ozone and other factors, especially N, on rice (Luo et al., 2012, 2013) or wheat (Chen et al., 2011a, b) has been studied by FACE platform. As a common cultivation measure, could planting density regulate rice growth and yield formation under high ozone concentration? And does this regulation vary from variety to variety? There have been no previous reports, which is more realistic for the future development of strategies for rice production under higher surface ozone concentrations. According to the experimental materials, most of the previous studies focused on conventional rice varieties, but less on hybrid rice and even less on super hybrid rice. As has been reported in the past, the yield response of rice varieties and hybrid rice varieties to ozone stress was more significant (Shi et al., 2009; Wang et al., 2012; Luo et al., 2013). But what is the difference between the growth and yield response of super rice under ozone stress and other types of varieties? Is the yield loss similar or even greater to hybrid rice? In order to solve these problems, the effect of ozone stress on growth, development and yield formation under different densities were analyzed by using China O_3-FACE platform and conventional indica rice of Yangdao 6 and Super hybrid rice of II you 084 in order to provide some guidance for rice production strategies and high-yield cultivation measures under the condition of high ozone concentration in the future.

Materials and methods

Ozone-FACE platform

The experiment was conducted on the China O_3-FACE platform, which was located at Xiaoji town, Jiangdu County, Jiangsu province, China (119°45' E, 32°35' N). The site, at 5 m above the sea level in elevation, sits in the subtropical marine climatic zone. Throughout the period of 113 days from June 21 to October 17 for the experiment in 2012, mean daily temperature was 24.5 °C, mean daily integral solar radiation (or PAR) was 13.9 MJ m^{-2}, and mean daytime (6:00–18:00) vapor pressure deficit was 0.67 kPa (Tang et al., 2011). This site has been in continuous cultivation for more than 1000 years with rice–wheat or rice–rapeseed rotation. Detailed descriptions of the soil properties for the site can be found in our previous publication (Shi et al., 2009).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41994215

Details of the design and performance of this O_3-FACE system are provided by Tang et al. (2011). In brief, The FACE system has eight 240 m^2 plots, of which four replicate plots were exposed to elevated ozone concentration (hereinafter called E-O_3 plots) and four equal size plots were in current ozone concentration (current ambient ozone concentration, C-O_3 plots). Any one of the E-O_3 plots was separated from other plots by at least 70 m to avoid cross contamination. The quantity and direction of the ozone release for each E-O_3 plot was controlled by a proportional integral derivative algorithm for computer feedback that compares achieved ozone concentration to the target ozone concentration of 1.5 times current ozone concentration (simulating the predicted ozone concentration at the end of the century) with an ozone monitor (model 49i, Thermo Environmental Instruments, MA, USA), a data logger-controller, an anemometer and a wind vane. Current ozone concentration at canopy height was monitored with separate O_3 analyzers in two of the C- O_3 plots at a 2-min interval. Every 10 min, a control computer accessed all the data logger-controllers in C- O_3 and E- O_3 plots to collect the latest ozone concentration. A mixed gas consisting of about 5% ozone and 95% O_2 was produced by an ozone generator (KCF-BT0.2, Jiangsu Koner Ozone Co., Ltd, Yangzhou, China). The mixed gas was released in a stream of compressed air into the plots through the ABS pipes positioned at about 50 cm above the canopy. In the ambient plots, plants were grown under ambient ozone conditions without the ring structures. The ozone fumigation began on 1st July and continued throughout the rice season until harvest, from 9:00 am to 16:00 pm every day, only suspended in these conditions, such as ozone concentration in the control cycle lower than 20 nL/L, leafs moistened by rain and dew, ozone analysis device correction, and equipment overhaul, so the actual mean ozone concentration in FACE cycle during the entire growing season of rice was higher approximately 27% than that in the control cycle. *Figure 1* shows the seasonal change in daily 7-h mean ozone concentration for C-O_3 and E-O_3 plots.

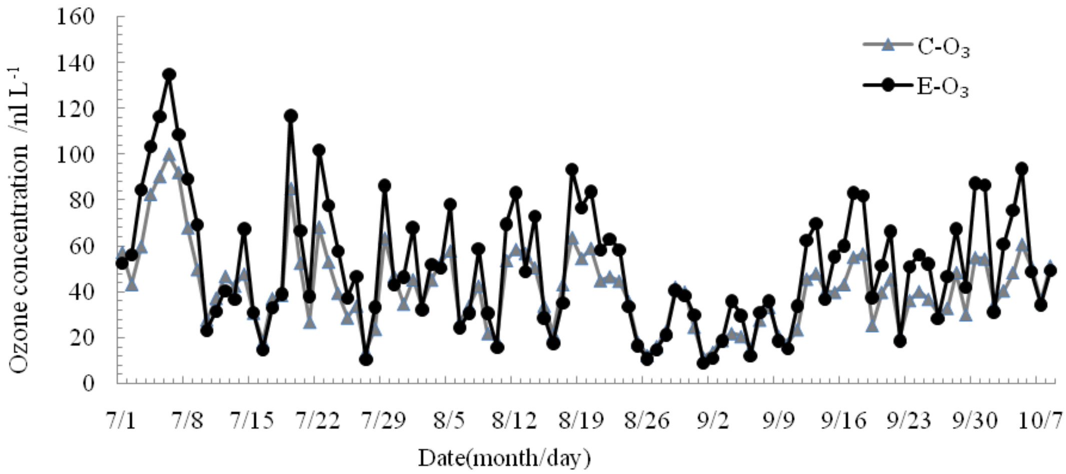

Figure 1. *The change of day time 7-h average ozone concentration during ozone fumigation. C-O_3: Current O_3 concentration; E-O_3: Elevated O_3 concentration; The same below*

Plant material and cultivation

The rice varieties are conventional indica Yangdao 6 (the variety features can not be separated from their offspring) and super hybrid indica II you 084 (the variety that was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41994215

produced by cross breeding, and had heterosis in yield). Rice seeds were sown on 21 May; the seedlings were grown under current air and were manually transplanted into the C-O_3 and E-O_3 plots with one seedling per hill on 21 June 2012. Nitrogen (N) was supplied as urea (N = 46%) and compound chemical fertilizer ($N:P_2O_5:K_2O$ = 15:15:15) at a rate of 15 g N/m^2. Of the total N, 50% was applied as the basal dressing on 20 June, 10% was top-dressed on 7 July and 40% top-dressed on 7 August. Both phosphorus (P) and potassium (K) were applied as compound chemical fertilizer at equal rates of 7 g/m^2 as the basal dressing at 1 d before transplanting. Standard cultivation practices as commonly performed in the area were followed in all experimental plots. In brief, the paddy fields were submerged with water of about 3 cm in depth from 21 June to 4 July, and then the fields were subjected to wet–dry cycles through natural drainage and intermittent irrigation. At 10 d before harvest, irrigation was terminated to allow paddy fields to dry for final harvesting. Pesticides and fungicides were applied when necessary throughout the experiment.

Experimental treatment

This trial was a split plot experiment, in which ozone concentration was the main plot, and the treatment of varieties and transplanting density was the split plot, repeated each treatment four times, so there were 12 treatments and 48 plots in total. The transplanting density was determined as three densities including low density (16 hills/m^2, planting spacing 25 cm), medium density (24 hills/m^2, planting spacing 16.7 cm × 5 cm), and high density (32 hills/m^2, planting spacing 12.5 cm × 25 cm).

Plant phenology, plant height and tillering dynamics

The date for heading (50% of plant headed) and grain maturity was recorded in each subplot. Plant height and tiller numbers were measured for fixed 10 hills in each treatment at 5–10 days intervals until heading. The productive tiller ratio (%) was expressed as the panicle number per square meter/ the maximum tiller number per square meter × 100.

Dry matter production

Eight plants (hills) were randomly selected at tillering, jointing, heading and maturity stage. The samples were separated into green and senescent leaf, stem (including leaf sheath), and panicle (when applicable). Each plant organ was dried in an oven at 105 °C for 30 min, then at 80 °C until dry weight was constant. The dry matter accumulation and distribution among different organs during each growth period were calculated. The dry weight per stem at heading stage (%) was expressed as the dry weight per plant at heading stage / the stem number per plant. The ratio of spikelet number to stem dry weight (number/g^1) was expressed as the spikelet number per panicle/the dry weight per plant at heading stage.

Grain yield and yield components

Actual grain yield was determined of all the plants (60 hills) from a 4, 3, and 2 m^2 patch in each LD (low density), MD (medium density) and HD (high density) subplot, respectively. The grains were air dried and weighted to obtain actual grain yield. Grain yield components, i.e. the number of panicles per square meter, the number of spikelets

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41994215

per panicle, filled grain percentage, and individual grain mass, were determined at crop maturity with six hills of plants in each subplot. Grains were soaked in tap water (specific gravity = 1.0) and the number of sunken and floated grains was counted to determine the filled grain percentage. The sunken (filled) grains were oven-dried at 80 °C until constant weight achieved. low, medium and high density.

Statistical analysis

A split-plot design was employed with [O_3] as main-plot treatment, varieties and planting density as the split-plot treatment. Analysis of variance (ANOVA) was performed using the software Statistical Product and Service Solutions (SPSS Inc., Chicago, IL, USA) to determine the main effects of [O_3], variety, planting density and the effects of their interaction. Treatments were compared by Tukey's test and differences were declared statistically significant if $p < 0.05$.

Results

Plant phenology and plant height

O_3 treatment had no significant effects on phenology development and plant height of Yangdao 6. However, high concentration of O_3 advanced the heading stage of II you 084 by 3 days and the mature stage by 7 days (*Table 1; Fig. 2*). High concentration O_3 decreased the plant height of Yangdao 6, but did not reach the significant level, and decreased the height of II you 084 by 0.5%, 1.3% and 6.7% ($p < 0.05$) and 7.8% ($p < 0.05$) after transplanting at 23, 45, 66 and 113 d (*Fig. 3*). The results of variance analysis showed that the interaction between O_3 and varieties had a weak interaction effects on plant heights at the mature stage of rice ($p = 0.16$).

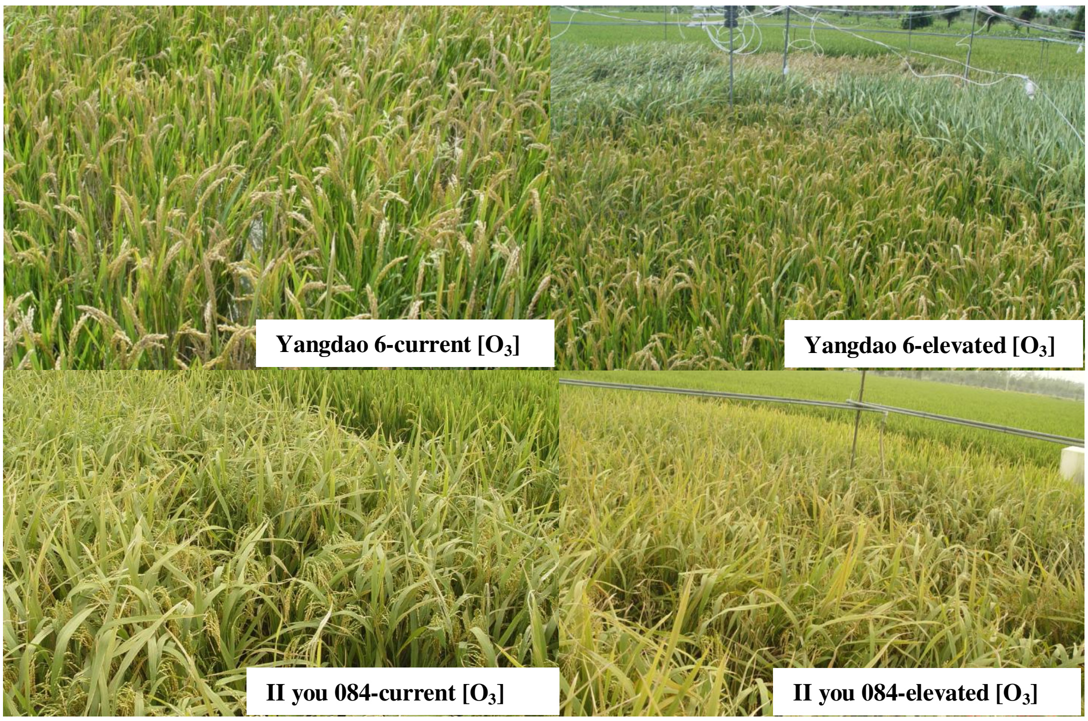

Figure 2. *Ozone stress had no impact on growth stage of Yangdao 6, but obviously accelerated phonological development of II you-084*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41994215

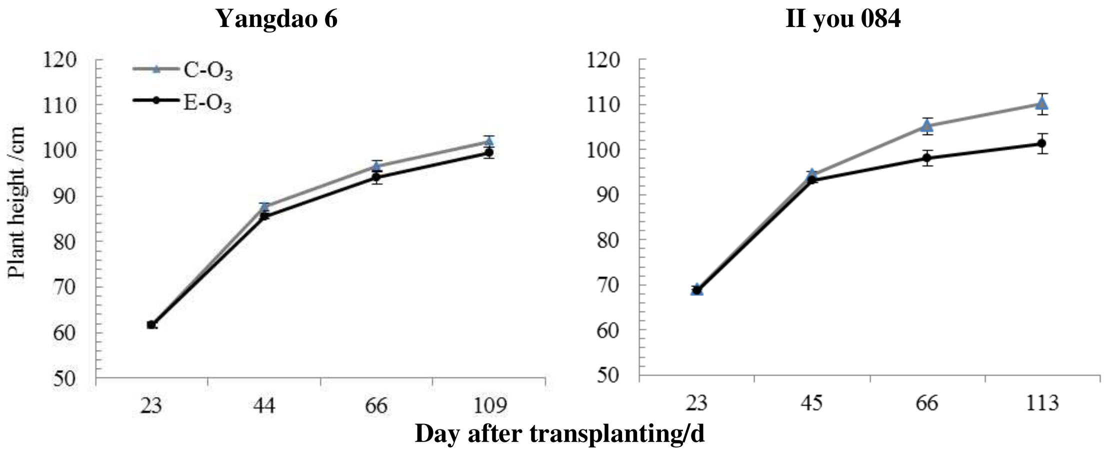

Figure 3. *Effects of ozone concentration on plant height at different growth stage of Yangdao 6 and II you 084*

Table 1. *Effects of surface ozone concentration and plant density on growth stage of rice varieties*

Cultivar	O_3 treatment	Growth stage/mouth/day		Growth period/days		
		Heading stage	Maturity	Transplanting to heading	Heading to maturity	Transplanting to maturity
Yangdao 6	C-O_3	8/28	10/16	68	49	117
	E-O_3	8/28	10/16	68	49	117
II you 084	C-O_3	8/29	10/19	69	51	120
	E-O_3	8/26	10/12	66	47	113

Dry matter production and biomass

High concentration of O_3 reduced the biomass of Yangdao 6 by 17.6% (*$p < 0.01$*), among which 23.5%, 20.1% and 9.3% were decreased at low, medium and high density respectively, with all reaching a significant level. The elevated ozone concentration decreased the biomass of II you 084 by 25.4% (*$p < 0.01$*), among which 29.2%, 25.6% and 22.0% were significantly decreased respectively (*Fig. 4*). The effects of ozone multiplied by varieties and ozone multiplied by density on biomass of rice reached the significant level of 0.05 and 0.1 respectively.

The biomass of rice was closely related to the dry matter production in each growth stage. High concentration of O_3 reduced the dry matter production of Yangdao 6 from tillering to jointing, jointing to heading, heading to maturity stage by 1.8%, 29.2% (*$p < 0.01$*) and 19.0% (*$p < 0.05$*) respectively, and decreased II you 084 with the same stage by 8.6% (*$p < 0.05$*), 13.6% ($p < 0.1$) and 46.5% (*$p < 0.01$*) respectively (*Table 2*). The analysis of variance showed that the interaction of ozone and varieties had a significant effect on the biomass from heading to maturity of rice. The high concentration of O_3 had no significant effect on the harvest index of Yangdao 6 but decreased it of II you 084 by 9% (*$p < 0.05$*) (*Fig. 5*). Variance analysis showed that the effect of ozone multiplied by varieties on harvest index of rice reached 0.1 significant level.

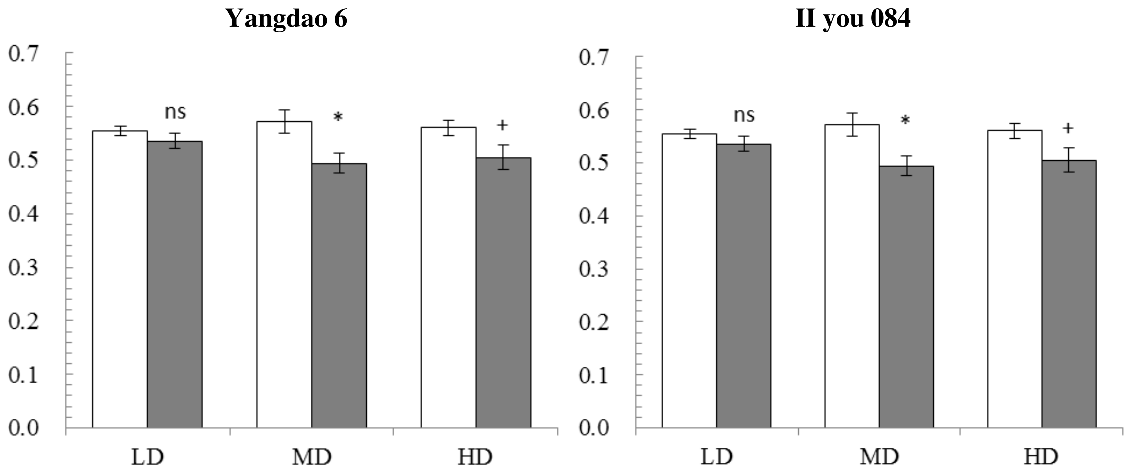

***Figure 5.** Effects of surface ozone concentration and plant density on harvest index of Yangdao 6 and Ⅱ-you 084. ANOVA: Cultivar (p > 0.1); Density (p > 0.1); Ozone (P < 0.1); O_3 × Cultivar (P < 0.1); O_3 × Density (p > 0.1); Cultivar × Density (p > 0.1); O_3 × Cultivar × Density (p > 0.1)*

Grain yield and yield components

O_3 treatment decreased the grain yield of Yangdao 6 by 142.0 g/m^2, which was 15.9% (*p < 0.01*) reduction compared to the control, with the decrease of 23.5% (*p < 0.01*), 14% (*p < 0.1*) and 9.9% (*p < 0.1*) under low, medium and high density. The O_3 stress reduced the yield of II you 084 by 278.5 g/m^2, which was 27.3% (*p < 0.01*) reduction compared to the control, with the significant decrease of 26.9%, 25.0% and 30.0% respectively under low, medium and high density (*Fig. 6*). Variance analysis showed that the interaction of O_3 and varieties had a significant effect on rice yield, and the interaction of three factors of O_3, varieties and density had a weak interaction effect on the rice yield (*p = 0.20*), which show that the effect of O_3 on the grain yield of Yangdao 6 decreased with the increase of density.

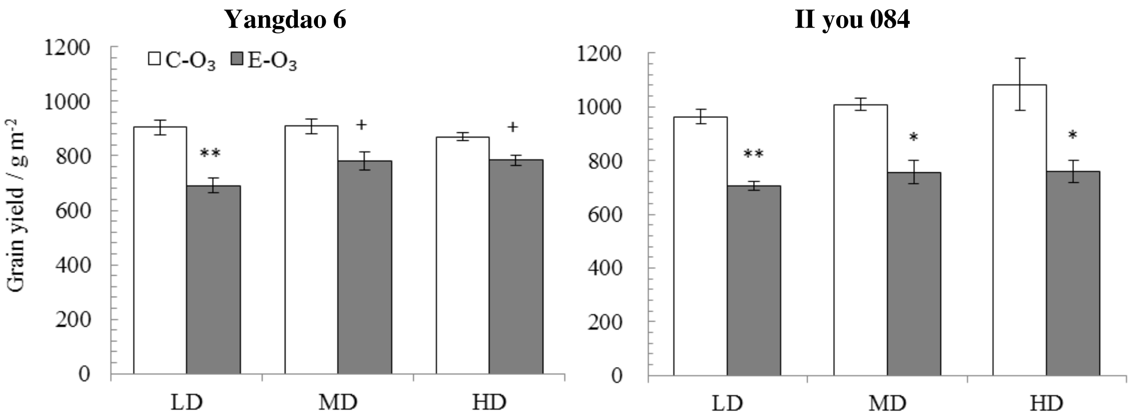

***Figure 6.** Effects of surface ozone concentration and plant density on grain yield of Yangdao 6 and Ⅱ you 084. ANOVA: Cultivar (P < 0.05); Density (p > 0.1); Ozone (P < 0.01); O_3 × Cultivar (P < 0.01); O_3 × Density (p > 0.1); Cultivar × Density (p > 0.1); O_3 × Cultivar × Density (p > 0.1)*

The high concentration of O_3 had no significant effects on the spike number per unit area of Yangdao 6 and II you 084. But from the composition of the spike number, the elevated ozone concentration significantly decreased the maximum tiller number of rice by 8.5%, increased productive tiller ratio of rice by 6.6% (*$p < 0.05$*) (*Fig. 7*). O_3 stress had no significant effect on the spikelet number per panicle of Yangdao 6 but decreased it of II you 084 by 22. 0% (*$p < 0.01$*), with the significant decrease of 15.7%, 27.6% and 21.9% under low, medium and high density (*Table 3*). Analyzing from the composition of the spikelet number per panicle, the increase of O_3 concentration decreased the dry weight per stem at heading stage of Yangdao 6 by 11.1% (*$p < 0.05$*) but increased the ratio of spikelet number to stem dry weight of Yangdao 6 by 13.2 g (*$p < 0.05$*). High concentration of O_3 reduced the dry weight per stem at heading stage and the ratio of spikelet number to stem dry weight of II you 084 by 12.7% (*$p < 0.05$*) and 10.7% (*$p < 0.05$*) respectively (*Fig. 8*). Ozone stress reduced the spikelet number per unit area of Yangdao 6 by 4.8% (*$p > 0.05$*), and decreased it of II you 084 by 21.7% (*$p < 0.01$*) on average, among which 20.3%, 26.0% and 18.8% were significantly decreased respectively under low, medium and high density (*Table 3*). High concentration of O_3 reduced the filled grain percentage of Yangdao 6 and II you 084 by 6.4% (*$p < 0.05$*) and 11.9% (*$p < 0.01$*) respectively. The filled grain weight of Yangdao 6 and II you 084 were decreased by 2.3% (*$p < 0.05$*) and 4.7% (*$p < 0.01$*) respectively to ozone stress (*Table 3*).

Discussion

Phenology and plant height

Previous studies in gas chambers showed that the phenology of rice was unchanged or shortened under ozone stress (Yang et al., 2008). Our study found that O_3 treatment, which is 25% higher than the ambient concentration, had no significant effects on phenology development of Yangdao 6, conventional rice. However, the heading date and maturity stage of super hybrid rice II you 084 were 3 days and 7 days earlier respectively under O_3 treatment (*Table 1; Fig. 2*). The effect on the super hybrid rice was similar to that of hybrid rice “Shanyou 63” under FACE condition (Shi et al., 2009; Wang et al., 2012). It was inferred that the effect of high O_3 concentration on phenology of hybrid rice or super hybrid rice in the future may be more significant than that of conventional rice. Many studies on plant height showed that the increase of ozone concentration generally reduced the plant height of rice, and the decline varied with varieties (Abhijit and Agrawal, 2012; Hiroko et al., 2012; Shi et al., 2009). This research showed that O_3 treatment had no significant effect on the plant height of Yangdao 6 but decreased the plant height of II you 084 by7.8%. From the dynamic response of high sensitive variety II you 084, the effect of ozone stress on the plant

DOI: http://dx.doi.org/10.15666/aeer/1604_41994215

height gradually increased with the plant growth process (*Fig. 3*), showing a certain cumulative effect.

Dry matter production and biomass

Previous studies showed that high concentration of ozone significantly inhibited the dry matter production of rice, but the degree of influence varied greatly with different treatment concentration, variety and environment (Kobayashi et al., 1995; Jin et al., 2001; Pang et al., 2009; Hiroko et al., 2012). This result showed that the increase of ozone concentration decreased the biomass of rice by 22%, in which Yangdao 6 and II you 084 were decreased by 17% and 25% respectively (*Fig. 4*). It showed that the loss of biomass of super hybrid rice may be higher than that of conventional rice under high ozone concentration in the future. According to different densities, the response of biomass of the two varieties to O_3 stress decreased with the increase of density, especially Yangdao 6. Our study also showed that high concentration of ozone had little effect on the dry matter production of rice in the early stage of growth, but significantly decreased it in the middle and late stages of rice (*Table 2*). This indicated that the decline of the final productivity of rice under ozone stress was mainly related to the inhibition of growth in the middle and later growth period, especially in the later stage.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41994215

Under ozone stress, the decrease of dry matter production from heading to maturity stage of II you 084 (-47%) was significantly larger than that of Yangdao 6 (-19%) (*Table 2*), which obviously resulted in the decrease of the final biomass of II you 084 was greater than that of Yangdao 6. According to the difference of different densities, there was significant interaction between ozone and density on the dry matter production during the reproductive growth stage (jointing to maturity) of Yangdao 6. The response of dry matter production of Yangdao 6 to ozone stress decreased with the increase of density. The meta-analysis of Ainsworth (2008) on the gas chamber showed that the ozone concentration of 61 nl/L decreased the harvest index of rice by 5%, compared with the filtered air (n = 19). Our results showed that high O_3 concentration had no significant effect on the harvest index of Yangdao 6, significantly reduced it of II you 084 by 9% (*Fig. 5*), and the difference of response between two varieties reached a significant level.

Yield components

Previous studies on yield components of rice show that O_3 stress had no significant effect on panicle number per unit area (Ainsworth, 2008). There were also studies showing that the panicle number per unit area of rice decreased under ozone stress, which was due to the decrease of tiller capability (Walid et al., 1995) or the decrease of productive tiller percentage (Maggs and Ashmore, 1998). This study showed that high concentration ozone had no significant effect on panicle number per unit area of conventional indica rice Yangdao 6 and super hybrid rice II you 084. Analyzing the constituent factors of panicle number per unit area, the increase of O_3 concentration resulted in an average decrease of the maximum tiller number 9% and 7% increase in productive tiller percentage (*Fig. 7*). It indicated that the tiller capability was decreased, and the productive tiller percentage was increased under the ozone stress, which may be the main reason for the no significant change of panicle number per unit area. The majority of previous studies showed that the spikelet number per panicle of rice was decreased with ozone stress, and the decline was due to different ozone treatment (Kats et al., 1985; Jin et al., 2001; Feng et al., 2003; Bhatia et al., 2011) or different varieties (Shi et al., 2009; Wang et al., 2012; Hiroko et al., 2012). This study showed that high concentration ozone had no significant effect on the spikelet number per panicle of Yangdao 6, but significantly reduced it of II you 084 by 22% (*Table 3*). Ozone stress both decreased the dry weight per stem at heading stage and the ratio of spikelet number to stem dry weight of Yangdao 6, which resulted in a significant decrease in the spikelet number per panicle of Yangdao 6. Ozone stress significantly reduced the dry weight per stem at heading stage of II you 084, meanwhile, increased the ratio of spikelet number to stem dry weight. As a result, the spikelet number per panicle of II you 084 was not significantly changed. According to the differences among different densities, ozone multiplied by varieties and density also had significant interaction effects on the spikelet number per panicle of rice ($p = 0.02$). It showed that the effect of O_3 on the spikelet number per panicle of II you 084 had no significant differences between different densities. For Yangdao 6, the high concentration of O_3 decreased the spikelet number per panicle by 9% at low density, but increased slightly (+5%, $p > 0.05$).

The spikelet number per unit area of rice represents the yield capacity. The meta-analysis of Ainsworth (2008) on the gas chamber showed that the ozone concentration of 62 nl/L decreased the spikelet number per unit area of rice by 20%, compared with the filtered air (n = 15). This study showed that high concentration of O_3 significantly

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41994215

reduced the spikelet number per unit area of rice by 14%, among which 5% and 9.3% were decreased of Yangdao 6 and II you 084 respectively with significant differences among varieties. Combined with the change of the spikelet number per panicle, the effect of ozone stress on the spikelet number per unit area was mainly due to the influence of the spikelet number per panicle.

The filled grain percentage and filled grain weight reflected the grain filling ability of rice. Previous studies showed that high concentration of ozone reduced the filled grain percentage of rice. This study also showed that ozone stress decreased the filled grain percentage of Yangdao 6 and II you 084 by 6% and 12% respectively, and the effect on the II you 084 was significantly greater than that of Yang Rice No. 6. The meta-analysis of Ainsworth (2008) on the gas chamber showed that the ozone concentration of 83 nl/L decreased filled grain weight of rice by 5%, compared with the filtered air (n = 22). The meta-analysis of Feng (2009) showed that current ozone concentration (31-50 nl/L) decreased filled grain weight of rice by 3.1%, compared with the filtered air. Recent FACE experiments in China showed that the filled grain weight of rice decreased with the increase of ozone stress, and the decline was due to different varieties or years (Shi et al., 2009; Wang et al., 2012). The results of this study showed that O_3 stress reduced the filled grain weight of Yangdao 6 and II you 084 respectively 2% and 5%, and the effect of O_3 stress on the filled grain weight of Yangdao 6 decreased with the increasing density.

Grain yields

Previous studies had mostly shown that the increase of atmospheric ozone concentration significantly decreased the rice yield, and the decline was related to the control equipment of the experiment (Maggs et al., 1995), materials (Kobayashi et al., 1995; Maggs and Ashmore, 1998; Zheng et al., 1998; Jin et al., 2000), the concentration of O_3 treatment (Asakawa et al., 1981; Heagle et al., 1991; Bai et al., 2002) and the treatment period (Morikawa et al., 1980; Asakawa et al., 1981; Chen et al., 2007). The meta-analysis of Ainsworth (2008) on the gas chamber showed that the ozone concentration of 61 nl/L significantly decreased yield of rice by 14%, compared with the filtered air. Our results showed that the grain yield of rice was decreased 235 g/m^2 at high O_3 concentration, with the significant decrease of 25%, in which Yangdao 6 and II you 084 were decreased 16% and 27% respectively (*Fig. 6*), and the interaction between ozone and varieties reached a significant level. Combined with previous research results (Shi et al., 2009; Pang et al., 2009; Wang et al., 2012), it was inferred that compared with conventional rice, although hybrid rice and super hybrid rice have some yield advantages at present, the yield loss of them may be more significant in the future under the condition of high O_3 concentration. From the perspective of yield components, the effect of ozone stress on yield of Yangdao 6 was mainly related to the decrease of filled grain percentage, followed by the decrease of the filled grain weight. That was, ozone stress mainly affects the fertilization process and filling process of Yangdao 6. The main reason for the effect of ozone stress on the yield of II you 084 was the decrease of the spikelet number per area and filled grain percentage, then the filled grain weight. Ozone stress not only affected the spikelet formation of II you 084, but also affected the fertilization process and grain filling process, and the effect of the latter was significantly greater than that of Yangdao 6, so the loss of yield was more obvious. In terms of dry matter production and distribution, high concentration of ozone reduced the photosynthetic production of Yangdao 6 but had no significant effects on the proportion

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_41994215

of photosynthesis to grain. Analyzing the effect on II you 084, on the one hand, ozone stress significantly decreased the biomass (the decrease was significantly higher than that of Yangdao 6), but also significantly reduced the distribution of dry matter in the grain, thus making the decline of grain yield of II you 084 more significant.

The results showed that there was a weak interaction effect among ozone, varieties and density on yield. There were no significant differences in the effect of O_3 stress on the yield of II you 084 among different densities. However, the yield-loss of Yangdao 6 to high ozone concentration decreased significantly with the increase of density (at low, medium and high density, the yield was decreased 24%, 14% and 10% respectively). According to the factors of yield composition, the effect of ozone on the spikelet number per panicle, yield capacity and filled grain weight of Yangdao 6 decreased with the increase of density. However, the effects of ozone stress on the yield components of II you 084 had no significant differences among different densities. Analyzing from dry matter production, effects of ozone on dry matter production at reproductive stage of Yangdao 6 decreased with the increase of density, and the effects on biomass and yield showed the same trend among different densities. Effects of ozone stress on II you 084 had no significant difference among different densities.

Conclusion

The results showed that the loss of rice yield under the condition of high O_3 concentration was caused by the decline of grain filling ability (conventional rice) or both the decrease of yield storage capacities and grain filling ability (super hybrid rice). The ozone stress effect of hybrid rice varieties was significantly higher than that of conventional rice varieties. Secondly, proper increase of planting density can alleviate the ozone stress effect of conventional rice varieties to some extent. Therefore, under the background of high ozone concentration in the future, we can first select high-yielding conventional rice varieties with strong ozone resistance by properly increasing planting density, thus slowing down the production loss to a certain extent. Limited to the conditions, only two varieties and three densities were studied in our research. Further researches on the interaction of ozone with more varieties and more cultivation measures should be further expanded in the future.

(Received 24th Apr 2018; accepted 20th Jun 2018)

Abstract. Sixteen dairy ewes 1 to 2 months pregnant and weighing 50.4 ± 1.02 kg on average were randomly assigned to one of the four treatments, four animals to each treatment: 1) control, 2) yucca saponin (YE, 0.1%), 3) pomegranate peel (PP, 15%), or 4) thyme oil (TO, 0.1%). Total gas production from the fresh manure was measured and the contents of CH_4, N_2O, and CO_2 were determined. Digestibility in vivo and nitrogen balance were also determined. Feed intake and body weight were not affected whereas some properties of the manure (dry matter, total N, ADF, and NDF but neither ash nor pH) were affected by the composition of the feed. Total manure production and the emissions of CH_4 and CO_2 expressed as parts per million per millilitre of manure were similar in all the four treatments whereas the content of N_2O was higher in the control. Supplementing the rations with tannin, saponin, or thyme oil reduced N_2O emissions from the manure.
Keywords: *methane, carbon dioxide, nitrous oxide, livestock wastes, food by-products*

Introduction

Livestock waste is an important source of greenhouse gases (GHG). Manure contributes directly to emissions of nitrous oxide (N_2O) – which has a global warming potential 298 times that of CO_2 (Mosier et al., 1998) – by stimulating nitrification and denitrification (Tang et al., 2016). Methane (CH_4) is also emitted during anaerobic fermentation of organic matter, especially during the storage of manure. The amount of GHG released from manure depends on the nitrogen (N) and carbon (C) content of the manure, the duration over which it is stored, the animal, and the diet. Increasing concern about mitigating the adverse effects of climate change has led to greater interest in reducing the emissions of GHG from all sources including manure from ruminants.

Pomegranate is grown on a large scale (about a million trees) in south-eastern Turkey, especially in Şanlıurfa province, and its productivity has remained high over several decades (TUIK, 2014). Local production and consumption of pomegranate have greatly increased in recent years (8000 tonnes a year) which, in turn, have led to greater quantities of pomegranate peel (PP) and seeds. The peel is a waste product of processing the fruit for juice for human consumption. Pomegranate is reported to contain up to 48% peel (Zarei et al., 2011), which is rich in hydrolysable tannins and saponin. Ullah et al. (2012) estimated the crude fibre content of PP at 21% ± 0.6%, and Feizi et al. (2005) estimated its crude protein content at 11.4%. Pomegranate peel containing tannins and saponin may improve N utilization efficiency and thereby

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42174228

decrease the N content of manure, which, in turn, may affect N_2O emissions because less N is available to the denitrifying bacteria that use the manure as substrate. The addition of saponins from PP can thus modify the C and N contents of sheep manure.

Another recent trend has been to use the oil from aromatic plants directly instead of extracting essential oils from such plants, because extraction is difficult and not particularly efficient. Many plant essential oils stimulate rumen fermentation at high concentrations. Thyme (*Thymus vulgaris*) oil is an antioxidant (Seung-Joo et al., 2005) and contains about 15% essential oil (soluble in alcohol or steam). However, in vivo investigation is necessary to determine whether these oils can be used successfully to inhibit rumen methanogens with lasting effects on emissions from manure without any adverse effects on digestion.

Another possible candidate to control the production of GHG from manure is the extract of yucca, which contains two active components: a glyco component that binds ammonia and a fraction of steroidal saponins, which has the properties of a surfactant. Saponins also seem to have shown some potential in reducing enteric CH_4 production (Pal et al., 2015). However, the effects of tannins from PP, thyme oil (TO), and yucca extract (YE) on the production of GHG (CH_4, CO_2, and N_2O) from manure and the overall nutritional effects of PP, TO, and YE are unknown—which is why the present study sought to observe the effects of PP, YE, and TO on the emissions of the above three GHG from sheep manure under routine farming practices such as open-air stool administration.

Material and methods

Animals and experimental groups

Research on animals was conducted according to institutional committee on animal use (ethical document number: KSU-2013/08-3). The experiments took place between 2 and 10 April 2014 at the Sanliurfa province in the Southeast Anatolian Region of Turkey, which lies on 37°9’32.9364 latitude and 38°47’48.8724 longitude. The mean air temperature was 17 °C and the maximum was 27 °C. As a source of tannins, sun-dried PP was collected from pomegranate-processing plants in Şanliurfa City and ground fine enough to pass through a 3 to 5 cm sieve. The other source of forage was lucerne hay cut into 3 to 5 cm long pieces.

A total of 16 adult fat-tailed Awassi ewes 1 to 2 months pregnant, 2 to 3 years old, and weighing 50.4 kg ± 1.02 kg on average were randomly assigned to one of the four treatments (4 ewes in each treatment serving as 4 replicates). Each ewe was kept in a 1.5 m × 1.5 m pen. The sheep were housed in individual cages and had free access to fresh water throughout the study. They were fed separately *ad libitum* with a total mixed ration (TMR) containing a mixture of a concentrate and lucerne hay. The four treatments were as follows: 1-) control, (only the basal diet); 2-) YE, (the basal diet supplemented with YE at the rate of 1.5 kg of YE per tonne of the ratio; 3-) PP, or 15% of ratio (that is, 150 kg of the mix per tonne of the ratio; or a mix of 38% PP and 62% lucerne hay as forage sources, w/w); and 4-) TO, (the basal diet supplemented with TO at the rate of 1 liter per ton of the ratio). While determining the amounts to be included in the ration, PP was used as feed material and TO and YE were considered as extract. The amount of PP was designed to not exceed 20% in the direction of other studies (Shabtay et al., 2008). The amounts of TO and YE were determined based on the manufacturer's recommendation.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42174228

The diets were so designed that all the four treatments were equal in terms of the number of calories and the amount of N over the duration of the experiment, and were also comparable in terms of the proportions of macronutrients and energy:proteins balance (*Table 1*). All rations were set to be a standard milk ration as recommended by the US National Research Council (NRC, 2007).

The experiment, including a 10 day adaptation period, lasted for 17 days. Each ewe was weighed at the beginning and at the end of the adaptation period. Feed intake was monitored over this period. Feed intake and feed refused (amount of feed left untouched) were recorded before the morning feed and weighed after one week during the adaptation period, the total feed intake being the difference between the total amounts of feed offered and refused.

Sampling of manure and gases

No bedding was used in the experiment; therefore, the manure contained nothing other than feces and urine. Samples of manure for analyzing the gases were collected after leaving the sheep one day on sheets of canvas. During the collection period, urine was not separated from feces, and total manure produced by individual animals was weighed after collecting it from the canvas sheets on which the ewe stood. The manure from each ewe was sampled three times in a day through the 3-day collection periods at

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42174228

the beginning, middle and end of the data collection period and fresh weights (kilograms per day) and pH were recorded immediately after collection.

To measure total gas production, specially designed glass bottles (250 ml each) were connected to the sampling device in such a way that its neck was joined to the side of the bottle. The joints were sealed with parafilm. Representative samples of manure (100 g or 150 g) from each animal were placed in these bottles, which were stored in a dryer maintained at 35 to 40 °C for 1 h. Total gas emitted from the feces was tried to be measured with by gas pressure. For this reason, we had left a certain volume empty (50 ml) in bottle for measuring pressure volume dependent. The gas from the 150 grams of fecal matter placed in the bottles was determined and recalculated in proportion to the daily total feces. Total gas from the manure produced in 1 h was measured in grams and estimated from the barometric pressure using *Equation 1* (Petrucci et al., 2010):

$$\left[m = \frac{PV}{RT} \right] \tag{Eq.1}$$

where m is the total gas produced (g), P is the atmospheric pressure (Pa), V is the volume (50 ml or cm^3), R is the national gas constant value, and T is the temperature (°K). However, after sampling the gases, oxygen was allowed to enter the bottles by opening them and the sampling process was repeated several times so as to represent normal conditions (open-air stool administration). The manure samples were kept in sealed bottles and the gases were sampled three times a day by drawing the gas sample through a sealed syringe: the amounts of CH_4, N_2O, and CO_2 in these samples were measured later with gas chromatography. (SRI Instruments-European Greenhouse Gas Chromatograph (GC) System ®). Samples were introduced to the injection port via plastic syringes. 3 m Hayesep D packed column was used for CO_2 and CH_4 analysis and 3m Hayesep D column was used for N_2O analysis. Operating conditions for the GC were as follows: injector temperature 95 °C, column temperature 85 °C, and detector temperature 320 to 350 °C for GC.

Feces and feed analysis

After drying, the manure samples were analyzed following the standard AOAC procedures (AOAC, 1998), and NDF and ADF were analyzed using an ANKOM fibre analyzer (ANKOM Technologies, Macedon, NY, USA) using the methods of Van Soest et al. (1991). The samples were dried in an oven for dry matter analysis and then ashed.

The same methods were used for feed analysis. Additionally, ground pomegranate peels was treated with a condensed tannin (CT) solution (95 ml n-butanol, 5 ml HCl (35%), 0.05 g Fe_2SO_4) and the amount of CT was estimated by taking the absorbance values in the spectrophotometer (Makkar et al., 1995).

Apparent digestibility in vivo

Total manure produced by each animal was collected every day at 08:30 and urine was separated from the samples of manure collected for gas measurements by filtration. As the studies were done in female sheep, it was difficult to separate stools and urine. Because the feces of the sheep were in a pelletized structure, the urine was very small and the effect of urine was very insignificant.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42174228

The digestibility was calculated as follows: digestibility (%) = (A−B) / A, where A is the organic matter or N content of the feed (the input) and B is the organic matter or N content of the faeces (the output). The data were analysed following the completely randomized design with one-way analysis of variance using the generalized linear model (GLM) (SPSS, 2013). The only factor was the difference in the rations. The treatments means were compared using the Tukey's-b multiple range test (TMRT).

Results

Compared to the control, none of the other three treatment groups showed any significant differences ($p > 0.05$) in feed intake, change in live weight, or feed conversion ratio at the end of the trial (*Table 2*).

Table 2. *Effect of diet on some performance parameters of Awassi ewes*

*Fresh weight. PP: pomegranate peel, SEM: standard error of mean, LWC: overall live weight change, DLWC: daily live weight change, FCR: feed conversion ratio

The manure, however, showed significant differences between the treatments in terms of dry matter, nitrogen, ADF, and NDF (*Table 3*). Especially in terms of N content, the three treatment groups were significantly different from the control, the PP group recording the lowest values of N, followed by the yucca group.

Table 3. *Properties of manure as affected by diet*

*Metabolic energy intake (Mcal/day). OM: organic matter, ADF: acid detergent fibre, NDF: neutral detergent fibre, PP: pomegranate peel, SEM: standard error of mean. Different letters in the same row show significant differences ($P \leq 0.05$) between treatments

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42174228

Adding YE, TO, or PP to the diets reduced the N content of the manure compared to that from the control, pointing to the higher in vivo N digestibility (*Table 3*). In other words, N excretion in the manure was significantly ($p < 0.05$) higher in the control. The daily average N excretion in the total manure was 15.8 g with YE, 5.8 g with PP, and 13.9 g with TO (*Table 3*). All the three additives improved in vivo digestibility of N significantly, which is consistent with the above figures. However, YE decreased the in vivo digestibility of organic matter (OM) significantly ($p < 0.05$; *Table 3*). The digestibility of N was maximum in TO, although the manure of ewes fed with TO was rich in N.

Finally, neither daily gas production nor CH_4 and CO_2 content per milliliter varied between the four groups. Overall, YE in the diet led to greater quantities of manure and lower emissions of N_2O than those in the control (*Table 4*).

Table 4. *Gaseous emissions from manure*

Discussion

Manure production and feed intake are often related. Manure output usually increases as the concentration of dietary fiber increases. However, the content of dietary fiber in all the diets was broadly similar although slightly greater in YE and PP (*Table 2*), and the higher manure production can be generally attributed to the high ADF content of the manure (*Table 3*) and low digestibility of ADF in YE and PP. The increased fiber content of the manure in YE and PP was probably due to the higher fiber content of these two treatments (*Table 3*). Weiss and St. Pierre (2010) suggested that diets with a high concentration of by-products are usually less digestible than typical forage, and that cows often consume more dry matter when their diets are rich in the by-products, which means that the manure output is also greater. In PP, ADF content was 51.8% and NDF content was 55.7%; as a result of such high content, feed supplemented with PP increased the total manure production compared to that in the control group in the current study. High manure production by ewes fed with YE was probably due to the unknown response of sheep to YE or, more specifically, to the steroidal saponin in YE, but Li and Power (2015) found no correlation between yucca saponin and manure output. Although feed intake was not affected by the treatments ($p > 0.05$), it was higher in PP and YE than that in the control and TO (*Table 2*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42174228

In the present study, greater production of manure may also have been associated with a very low rate of digestion of dry matter as a result of the increased tannin or saponin content in PP and YE (*Table 3*)—it is well known that ADF concentration is negatively correlated to digestibility (Niyigena et al., 2016).

Ewes in the control, YE, and PP groups lost weight towards the end of the experiment but no valid inference can be drawn in this case because the differences between the all groups were not statistically significant: perhaps sheep in all groups lost weight simply because they were older (2 to 3 years old). Transient diarrheal events in PP groups and in some other groups may have also caused this.

Our hypothesis was that GHG production can be lowered by additives to the feed, and our results point to greater loss of N from the manure of ewes in the control and TO (*Table 3*) and significantly decreased N_2O emissions from the manure in all the three additives. We speculate that the lower emissions were due to the lower N content of the manure as a result of greater N binding and inhibition of N transformation.

Yucca extract decreased the digestibility of OM in vivo significantly ($p < 0.05$; *Table 3*). These differences between the groups seem to be related to the diet or to the effect of saponin, depending on the source (YE or PP). For example, Lu and Jorgensen (1987) reported increased digestibility of OM and cellulose in sheep fed with lucerne saponins. However, in the present experiment, PP, YE, and TO as dietary supplements increased the digestibility of N (*Table 3*) and may have been increased its availability. This resulted in lower production of N_2O and lower overall emissions (*Table 4*). Earlier research has shown that saponin-rich feed supplements reduce the population of ciliate protozoa in vitro and in vivo (Makkar et al., 1998; Valdez et al., 1986; Cieslak et al., 2013).

A decrease in the ruminal population of protozoa may increase the flow of microbial N from rumen and improve N utilization efficiency, which was reflected in the greater digestibility of N and lower production of N_2O (*Table 3*). According to Makkar et al. (1998), this may also be due to lower protein degradation with tannins or from ammonia binding of *Yucca schidigera*. The digestibility of N was also higher in TO, although the manure too was richer in N, probably because of decreased total manure production in this group.

None of the additives (PP, YE, or TO) had any impact on total gas production or on the production of CH_4 or CO_2, but all the three had an impact on manure production, DM, ADF, NDF, and pH when compared with the control group (*Tables 3* and *4*). After defecation, the emissions are dominated by N_2O and CO_2, probably because of the oxygenated environment. Wulf et al. (2002) suggest that after field application of organic manure, GHG emissions are dominated by N_2O and NH_3, and CH_4 is only of minor importance. On the other hand, when manure is stored, CH_4 emissions may be considerably greater because OM is degraded to CH_4 during anaerobic fermentation. The present experiment offered no anaerobic environment, and the oxygen-rich environment under which the manure was stored in the present study showed that emissions of CH_4 and of CO_2 from manure may be independent of the rumen environment and that the methane-producing bacteria may be inhibited by the oxygen-rich environment. Johnson et al. (2000) suggested that CH_4 emissions from the excreta of grazing cattle amount to only 1% of the CH_4 emissions from anaerobic conditions. Therefore, in ruminant production systems, CH_4 emissions from excreta are often ignored. Emissions of CO_2 from manure depend on storage conditions and were the highest from the mouldy manure towards the later stages of the present experiment.

Although only a few studies have been conducted so far on CH_4 emissions from manure outdoors, our results reinforce the view that such manure is not a major source of methane and poses no risk to the environment.

Emissions of nitrogenous gases have also been linked to the pH of the manure. For example, Zaman et al. (2009) suggested that an increase in pH and NH_4 concentration could trigger NH_3 emissions during storage and after field application. Our results show a strong influence of PP on N_2O emissions: the lowest emissions of N_2O were seen in that treatment. The lower emissions from PP and YE were probably due to the lower contents of mineral N in the manure (*Table 4*). The concentration of steroidal saponins was 4.4% in YE (Wina et al., 2005). Generally, saponins have been found to have no effect on dry matter consumption (Valdez et al., 1986). However, saponins in YE effectively suppressed ruminal protozoa by interacting with cholesterol in the cell membrane (Wina et al., 2005). A decrease in protozoa may have increased the rate of fermentation of high-forage diets by increasing the populations of bacteria and fungi in the rumen. In ruminants, YE is believed to decrease ammonia in the rumen (Sheng Sun et al., 2017), and a reduction in rumen protozoa may have a positive effect, including N conservation, by altering the rumen flora in favour of bacteria and fungi. Makkar et al. (1999) also demonstrated such conservation of N in the rumen. These mechanisms may have contributed to the difference in the N content of the manure between YE and the control and the lower N_2O emissions in YE. The higher N_2O emissions from the control were probably due to the higher output of mineral N (*Table 3*). Conversely, the high N content but low emissions from TO may be due to the higher concentration of oil in that ration, leading to the N being fixed and thus less amenable to digestion. The lower moisture content of the manure in the TO group may also be responsible for the lower emissions of N_2O from that group (*Table 3*).

Although tannin levels had no effect on the emissions of CH_4 from the manure, PP, which is rich in tannins, decreased the amount of N lost through emissions compared to that in the control. Nauman et al. (2017) suggest that moderate levels of condensed tannins in the rumen protect dietary proteins from degradation by microorganisms, thereby increasing protein flow through the intestines.

The contents of crude protein and the amount of ammonia released from manure are interrelated. However, tannins have been shown to make plant proteins less degradable by binding with them (Nauman et al., 2017). It is well known that PP contains large amounts of tannin; these tannins, by binding to the proteins, slow down proteolysis and thus the degradation of proteins (Garipoğlu and Uçar, 2015). Fayed et al. (2012) reported similar observations for PP and found that rabbit feed that contained PP was low in digestible nutrients (crude protein and ether extract) than that without PP. The present study shows that additives such as PP and YE are an effective component of the strategy for reducing N_2O emissions from ruminants given protein-rich diets (as starter diets and diets aimed at faster growth).

Under experimental conditions, cases of diarrhea were considerably fewer in ewes fed with PP than those in the other groups. In rats suffering from diarrhea, feeding with extracts of pomegranate seeds reduced fluid accumulation in the intestines by decreasing the quantity of faeces and gastrointestinal motility (Aghsaghali et al., 2011), both of which may have contributed to lowering N_2O emissions. However, on the basis of daily manure production, N_2O emissions per animal were lower in all the three groups compared to those in the control group. In the current study, gas production was expressed as parts per million (in milligrams) of total faecal matter (manure) per hour.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42174228

The production was then apportioned into that of specific gases (CH_4, CO_2, and N_2O) and expressed in the same units but per animal. Both daily manure output and total gas production increased, especially in YE, but the production of nitrogenous gases also decreased markedly in YE ($p < 0.05$). The other two additives (PP and TO) also had significant effects on N_2O emissions but the control group did not (*Fig. 1*), and neither YE nor TO had any effect on daily emissions of CO_2 and CH_4 (*Table 4*).

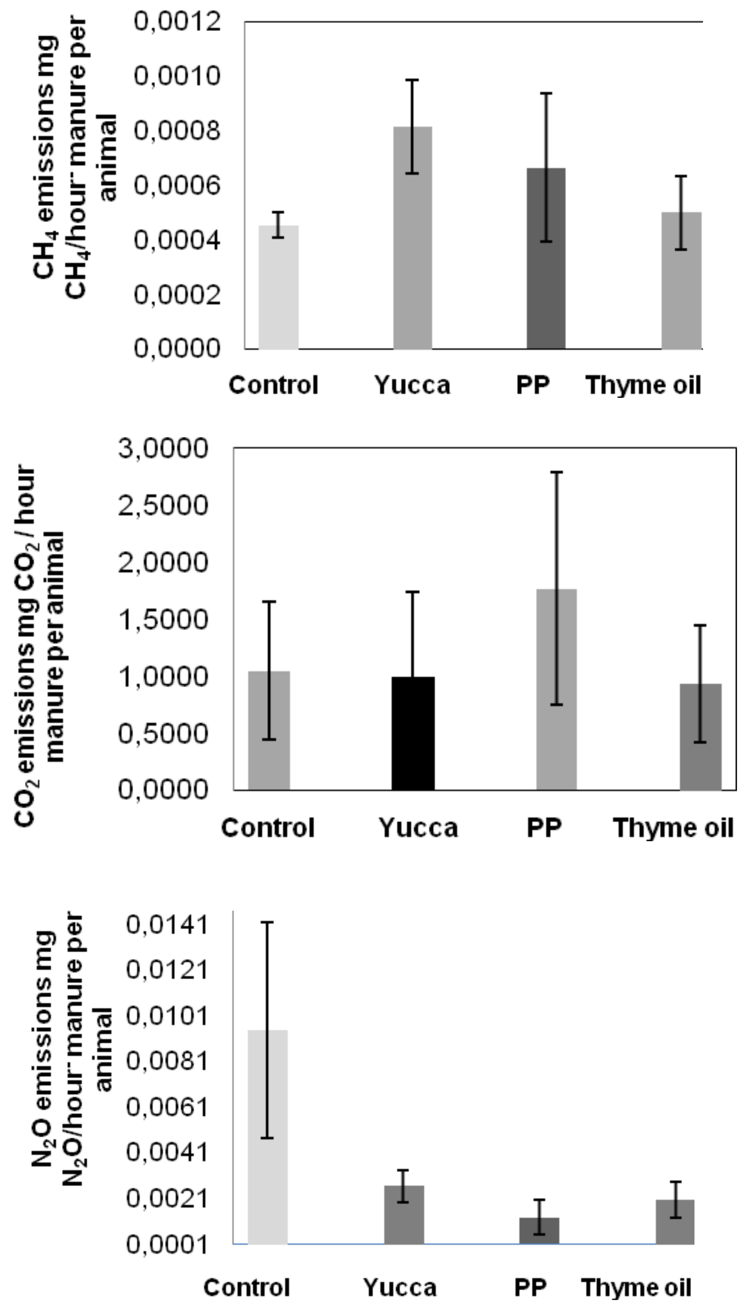

Figure 1. *Emissions of greenhouse gases from manure per hour as affected by diet. The four groups did not differ significantly in terms of CH_4 and CO_2 emissions but differed relatively in terms of N_2O emissions*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42174228

Thus, some by-products of the food industry have a potential as animal feedstuff that can reduce N_2O emissions. Reducing the emissions of GHG from ruminants can put such by-products to better use and help in mitigating the adverse impacts of climate change at the same time. On the other hand, PP is widely used in folk medicine for the treatment of a variety of diseases including diarrhoea, and no metabolic disorders were observed in ewes when hay was mixed with 15% PP (*Table 1*). Therefore, lucerne hay can be safely mixed with 15% dried PP; the effect of increasing this proportion should be assessed through further experiments. We advise that the feces produced in farm should be urgently evaluated as biogas or fertilizer. Otherwise it would be an important source of N_2O and CO_2 gases particularly but not CH_4 due to the oxygenated conditions.

Conclusion

We found that the use of CT-containing PP as 38% of the Lucerne hay as roughage feed was a good choice for sheep production. Supplementing the rations with tannin, saponin, or thyme oil reduced N_2O emissions from the manure. PP, YE or TO were good choices to reduce fecal emission of nitrogen-based gases. But they did not effectively reduce the production of enteric CH_4 in the rumen and energy loss through CH_4 for the Lucerne hay-based.

Abstract. In Vietnam as in other developing countries, firewood, including biomass is very important in rural areas as the main energy source and a part of the subsistence livelihood for ethnic minority communities. Rangers still carry out patrol activity for reducing the firewood collection inside nature reserve areas. However, before this study, little research had been conducted in the buffer zone of Pu Hu nature reserve (NR). The study was conducted to obtain an understanding of household firewood used, and the factors which influence firewood consumption. The methodology included questionnaires, observing household practices, and in-depth interviews with village leaders and local rangers with patrol activity currency. A survey of 248 households was conducted in five villages including households from all three ethnic minorities living in the area, who were found to require firewood as a primary resource. Firewood consumption was greatest among the Thai minority families (187.62 kg/household/month), followed by the Muong and Mong minorities (112.61 and 101.96 kg/household/month, respectively). Economic development was the most important factor in the demand for firewood because of consumption for household businesses. An important finding from this research was that the respondents indicated that rangers did not patrol frequently nor did they strictly enforce the regulations prohibiting the collection of firewood. A well-managed firewood resource could support minority households' requirements, improve fire-efficiency, and contribute to natural reserve objectives through ranger's efforts.
Keywords: *firewood consumption, ethnic minority, household, patrol, rangers, reserve*

Introduction

Since the time a human lit the very first fire, biomass resources have contributed to providing energy for millions of people (Kimemia and Annegarn, 2011). Particularly, in developing countries, forest resources are intensively used by remote communities, even inside nature reserves, and play important roles in their livelihoods (Kumar and Shahabuddin, 2005; Kim et al., 2016). Forest extraction, including timber, hunting, firewood, and grazing, either for direct use or business, has been regarded as a critical issue confronted by management in protecting forest resources (Hegde and Enters, 2000). Sources of firewood are one of society's oldest requirements (Lindroos, 2011), and a vital source of household energy in rural areas essential in the preparation of many staple foods (Biran et al., 2004; Mon et al., 2012). The reality of demands for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42294249

traditional biomass in the form of firewood from forest resources is and will continue to be crucial for energy management and for ethnic people (Ektvedt, 2011; Maes and Verbist, 2012) and pressure on forests due to the continuous loss of biomass will also continue (Chettri et al., 2002).

Forests are one of the most important sources of firewood (Sassen et al., 2015) and are the main and the most frequently used energy source in remote areas in developing and poor countries (Kim et al., 2016; Reyes et al., 2018). Nearly 3 billion people continue to use fuelwood in their daily lives (He et al., 2009) as the first choice of energy for cooking and heating rooms (Felix, 2015) and it is also used for heating water or conducting traditional businesses within households (Nyambane et al., 2014; Wang et al., 2015; Schueftan et al., 2016). However, the distribution of forest resources for traditional use as fuelwood is increasingly affecting biodiversity and decreasing forest cover (Maes and Verbist, 2012). Sassen et al. (2015) found that the amount of dead wood or resident natural forest was affected by fuelwood collection for up to 1000 m inside the boundary of parks in upland Uganda and local villagers who live near to protected tropical forests particularly depend on those forests as their primary source of firewood.

Similarly, in Vietnam, most households depend on firewood to satisfy their demand for energy. Firewood is collected from farms, community and private forests, and private plantations as either live or dead wood (Nyambane et al., 2014) where tree by-products such as pruned branches from bamboo plantations, agricultural waste, and dry plantation wood are collected (Nyambane et al., 2014). Firewood, in Vietnam and other countries is considered as being a free commodity, which may be collected without cost other than that associated with the gatherer's own personal efforts (Kim et al., 2016). In the buffer zone of Pu Hu nature reserve (NR), the collection of firewood is strictly regulated through restrictions on wood-cutting (Nyambane et al., 2014). The scale of the households' requirement for and use of firewood is a critical issue that confronts forest management (Wang et al., 2015). This is particularly critical in mountainous regions, where limited energy sources lead to high pressure on scarce natural resources (Rantala et al., 2004; Mislimshoeva et al., 2014).

People's requirement for firewood as a basic source of energy is causing serious deforestation problems in various developing countries (Fox, 1984). The increased demand for firewood threatens the habitat of many wildlife species (Carey and Gill, 1980) in protected areas, and there is a need for an improved understanding of the use of the resource to enable conservation strategies to be better adapted to local livelihoods (Abbot and Mace, 1999). Ormsby and Kaplin (2005) found that even though residents were mostly aware of a NR's existence they were unfamiliar with its goals resulting in a problematic relationship between NRs and human communities {Formatting Citation}. This means that even with increased time devoted to patrolling or more severe penalties, law enforcement practice alone is unlikely to safeguard protected areas because there are no alternative supplies of firewood which can be used by local people (Abbot and Mace, 1999).

There have been few studies of firewood consumption conducted in Vietnam. The FAO (2017) reported that the firewood and energy sectors were estimated to have extracted around 5 million tons of fuelwood in 2016 consisting of charcoal, chips, residues, and pellets. The daily firewood demand for traditional pig production in Hue province has also been estimated to lie somewhere between 6.1 and 21.3 kg (Lan et al., 2002; Kien and Harwood, 2017).

Wasted agricultural residues are a very abundant source of biomass (Tung, 2009) and are traditionally burned as firewood as a source of energy in Vietnam (Khoa et al., 1999). Nonetheless, available data on firewood consumption in different areas in Vietnam is lacking (Kim et al., 2016), and there has been relatively little research attention devoted to the assessment of firewood use for daily needs in the buffer zone of Pu Hu NR. In fact, there is little information available regarding firewood extraction and use by minority n the buffer zone of the protected area around the NR, or in Vietnam generally. Firewood extraction by ethnic minorities may be having an impact on conservation on the area studied in the research described in this paper. Moreover, the effects of firewood collection and law enforcement practices related to natural resources are frequently not fully investigated nor understood (Brown et al., 2009)

To gain a better understanding relating to these issues, research was conducted on firewood extraction in the buffer zone of Pu Hu NR, Vietnam. The aims of this study were to identify (1) different forms of firewood consumption based on location and ethnic minority; and (2) to foster cooperation between ethnic minority households and NR rangers. The final objective was to support forest management's efforts to adjust their law enforcement practices to take into account ethnic minority households' demands for forest resources.

Materials and methods

Research site

Pu Hu NR, located in Quan Hoa and Muong Lat districts in Thanh Hoa province in northeast Vietnam, was established in 1999 as a NR by the government of Vietnam and is one of the largest in this province covering around 28.000 ha. It is managed by the Pu Hu management board in Quan Hoa district and is located in a mountainous area (latitude 20°30' to 20°40'N and longitude 104°40' to 105°05'E) (*Fig. 1*). It is home to a number of endangered animals, and rare plant species. Following the establishment of the NR, all extraction activity by people living in the area of the NR was made illegal. However, even after the NR was established, the extraction of folder and fuelwood has been informally allowed although people are not allowed to enter the NR without official permission. Communities living around Pu Hu NR practice subsistence farming based on the cultivation of crops and supplement those crops by the exploitation of non-timber forest production (NTFPs), raising livestock and by the cultivation of bamboo (Thapa and Chapman, 2010). The biggest management issues include the relatively unrestricted extraction of forest resources by local residents from the surrounding area (Allendorf and Allendorf, 2012). The major forest resource use focused on in this case study is the requirement for firewood as a source of energy for the ethnic minority households in the area..

This study was conducted during the cold season, extending from November 2017 to March 2018 in the buffer zone of the Pu Hu NR, where there are 24,569 residents in 5,694 households living in 61 villages in 11 communes in two districts (Muong Lat and Quan Hoa). Most local people practice farming, cultivating crops such as paddy, maize, manioc, and vegetables. There has also some forestry activities including the extraction of both timber and non-timber products. Other occupations include harvesting bamboo, retailing and working as hired labor.

Data collection

Data on firewood use was collected in fieldwork using a questionnaire, observation and face-to-face interviews between November 2017 and February 2018. For the buffer zone of Pu Hu, over 90% of the households from different minorities in 5 villages in 5 communes were sampled and interviewed as well as being observed in their daily firewood collecting activity. Household surveys and Interviews were carried out in between 40 and 80 households per village and were conducted either by one of the researchers or by the village leader, based on visiting each household. By preference the head of each family was interviewed, who either completed the questionnaire or answered the questions asked by the interviewer, the answers to which were then filled in on the questionnaire by the interviewer. In most cases the head of household was male and it was a more difficult to interview women among the ethnic minorities because they were mostly illiterate or felt ashamed at being asked questions. If the head of the household was not available a willing member of the household was selected (Thapa and Chapman, 2010). Before the interviews took place there was a meeting in the village with a head of the village who was a key-informant, to gain an understanding of the background of changes. It had taken place in the area in the past as well as obtaining background information on socio-economic conditions, village size, and the distribution and number of households and the size of their families, and a list of households was obtained.

The researcher also interviewed a number of Pu Hu NR rangers in order to gain an understanding of the situation regarding the collecting of firewood, and to gain an

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42294249

understanding the law enforcement regime relating to firewood collection in the buffer zone, as well as to discuss the government's firewood programme.

The questionnaire was formulated in English then translated into Vietnamese (Sousa-Silva et al., 2016) and consisted of a mixture of open-ended and closed-ended questions in three parts: the first relating to the respondent's socio-economic situation (*Table 1*), the second to establish the household's requirement for firewood, and the third to gain an understanding of the household's perspective relating to the NR rangers' activities.

Table 1. *Description of socio-economic aspects from survey*

Social-economic parameter	Classification	Description
Gender		
Age (years)		
House size		
Number of families		
Household income (per month)	Wealthy	(≥ 76 USD)
	Average	(51–75 USD)
	Close to poor	(31–50 USD)
	Poor	(≤ 30 USD)
Education level of the leader of household	Tertiary education	Upper 12 years of education
	High school	10–12 years of education in high school
	Secondary school	6–9 years of education in secondary school
	Primary school	1–5 years of education in primary school
	No formal education	Not educated in school
Occupation of person interviewed in household	Full-time farming	Working in the field all the time
	Part-time farming	Doing some other job in addition

Data analysis

Data relating to the households' income levels, firewood use, and the purposes for which firewood was used by the households in the selected villages were collected from interviews. Data on the firewood consumption situation by the different ethnic minority households were summed and averages and percentages for each minority were computed (Kim et al., 2016). Data analysis was performed using the SPSS version 20 software package and Microsoft Excel. Both descriptive and statistical data analyses were performed. The calculation of sample means, standard errors, medians, minimum and maximum values, and frequency distributions was conducted.

Inferential statistical analysis was used to discover the relationships among the relevant variables. Because the data was not normally distributed, the Mann–Whitney U test for two variables and the Kruskal–Wallis test for more than two variables were used in SPSS, to analyze the data with any significant differences expressed at the 0.05 level (or higher where indicated in the text). The estimated volume of firewood consumed by the three ethnic minorities in the five villages was computed based on the data from the questionnaires.

Results

Background information established from the survey of households

Three-quarters of the 248 interviewees (75%) were male and the age of the interviewees ranged from 20 to 75 years with the median age, 36 years (*Table 2*). the largest age group, represented was 20–35 years with 48% of the respondents. The average house size was 144.6 m^2, varying between 23 and 450 m^2 and more than half the houses (54%) were below 100 m^2. The mean number of persons in each household was five, ranging from 3 to 12 members and more than half of the households (56.5%) had between five and eight persons. Regarding the income situation of the households, around 64% fell within the poor level, whilst those close to poor or with an average living standard accounted for 19.4 and 7.7% of the households surveyed, respectively. More than half of the interviewees in the households (57.3%) had had secondary school level education (five years and four years of education in the primary school and secondary school, respectively). Based on occupation, 87.9% of the interviewees in the households were full-time farmers.

Table 2. *Summary of socio-economic respondents based on the survey*

Social-economic situation	Categories	Frequency (n)	Proportion (%)
Gender	Male	186	75.0
	Female	62	25.0
Age (years)	20–35	118	47.6
	36–50	95	38.6
	51–65	29	11.7
	66–75	6	2.4

DOI: http://dx.doi.org/10.15666/aeer/1604_42294249

There were significant differences in socio-economic conditions among the household in the Pu Hu buffer zone with income earned by the three ethnic minorities different, at the $p < 0.001$ level. The Thai ethnic minority earned the highest average net annual income of 64.67 ± 51.80 USD/person/month, while the lowest income was 21.98 ± 12.33 USD/person/month for the Mong minority. Further, there were moderately low but significant correlations between the socio-economic data and firewood consumption. The total amount of firewood used was correlated with house-size, number of persons, and income based on Spearman rank order correlations (rs) of 0.24, ($p < 0.01$), 0.24 ($p < 0.01$) and 0.30 ($p < 0.01$) respectively for the communities.

Location of firewood collection areas for daily use

All the ethnic minority households used firewood baskets carried as headloads as illustrated in *Figure 2,* and they frequently carried large loads supported by both their backs and heads as reported by Sassen et al. (2015) in research in protected areas in Uganda. Additionally, 65% of the respondents transported firewood-using motorbikes, and some households also used bicycles.

a b c

***Figure 2**. Photographs of typical headloads in the field (a) Muong; (b) Thai; (c) Mong. (Source: Pu Hu NR and author)*

When asked about the main natural forest resources used by their household, all the respondents stated that their family as a source of energy used firewood daily. Of the respondent households, 74 and 163 were involved in harvesting timber and NTFP respectively. There were three sources of firewood collected as a daily activity: Pu Hu NR, private forest, and agricultural land. The three minorities mainly collected firewood in forestland (Mong: 28%, Muong: 12% and Thai 18%; see *Fig. 3*). In the Pu Hu NR, the Mong minority was the main group who collected firewood accounting for about 10% of the firewood they extracted (*Fig. 3*), while the percentage of firewood collected by other minorities was less than 2%.

Furthermore, for daily cooking and boiling water as shown in *Table 3*, the Thai ethnic minority households required the greatest amount of firewood (36.02 ± 10.08 kg) while the Mong and Muong minorities used less for these purposes (31.51 ± 17.25 and 22.57 ± 11.59 kg, respectively). Similarly, the amount of firewood used for heating was significantly different among the ethnic minorities (*Table 3; Fig. 4*). The amount of firewood used by the Thai minority (21.00 ± 11.54 kg) was nearly double that used by the Mong minority (12.88 ± 4.34 kg) with the Muong minority being the second highest (15.01 ± 7.80 kg). The average firewood used for this purpose was 15.17 ± 7.97 kg/month/household.

There was a significant difference in the monthly amount of firewood used for livestock, with the lowest mean firewood consumed for this purpose of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42294249

26.48 ± 18.27 kg/month/household being found in the Mong minority. It was only around a third and a fifth that used by the Muong and Thai minorities, respectively, even though only 75% of the Muong households used firewood for livestock whereas all the Mong households used firewood for that purpose. The mean amount of firewood used by all three ethnic minorities for their livestock was 63.17 ± 48.26 kg/day/household.

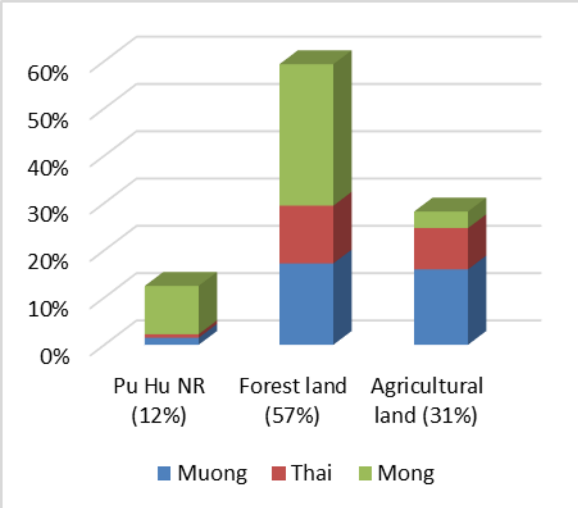

***Figure 3.** Location of firewood collection by three-ethnic minority households (%)*

***Table 3.** Percentage of households using firewood for different purposes and mean monthly volume consumed*

Category of firewood use by ethnic minority	Percentage of households interviewed using firewood for this purpose	Mean monthly volume (kg/household)
Cooking and boiling water		
Muong	100%	22.57 ± 11.59
Thai	100%	36.02 ± 10.08
Mong	100%	31.51 ± 17.25
Heating		
Muong	91%	15.01 ± 7.80
Thai	94%	21.00 ± 11.54
Mong	100%	12.88 ± 4.34
Livestock		
Muong	75%	87.07 ± 31.00
Thai	94%	125.22 ± 31.49
Mong	100%	26.48 ± 18.27
Making wine		
Muong	36%	18.31 ± 10.49
Thai	29%	34.53 ± 26.91
Mong	99%	31.37 ± 8.57
Bamboo drying		
Muong	18%	24.64 ± 18.24
Thai	10%	40.00 ± 12.25
Mong	Not used	

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

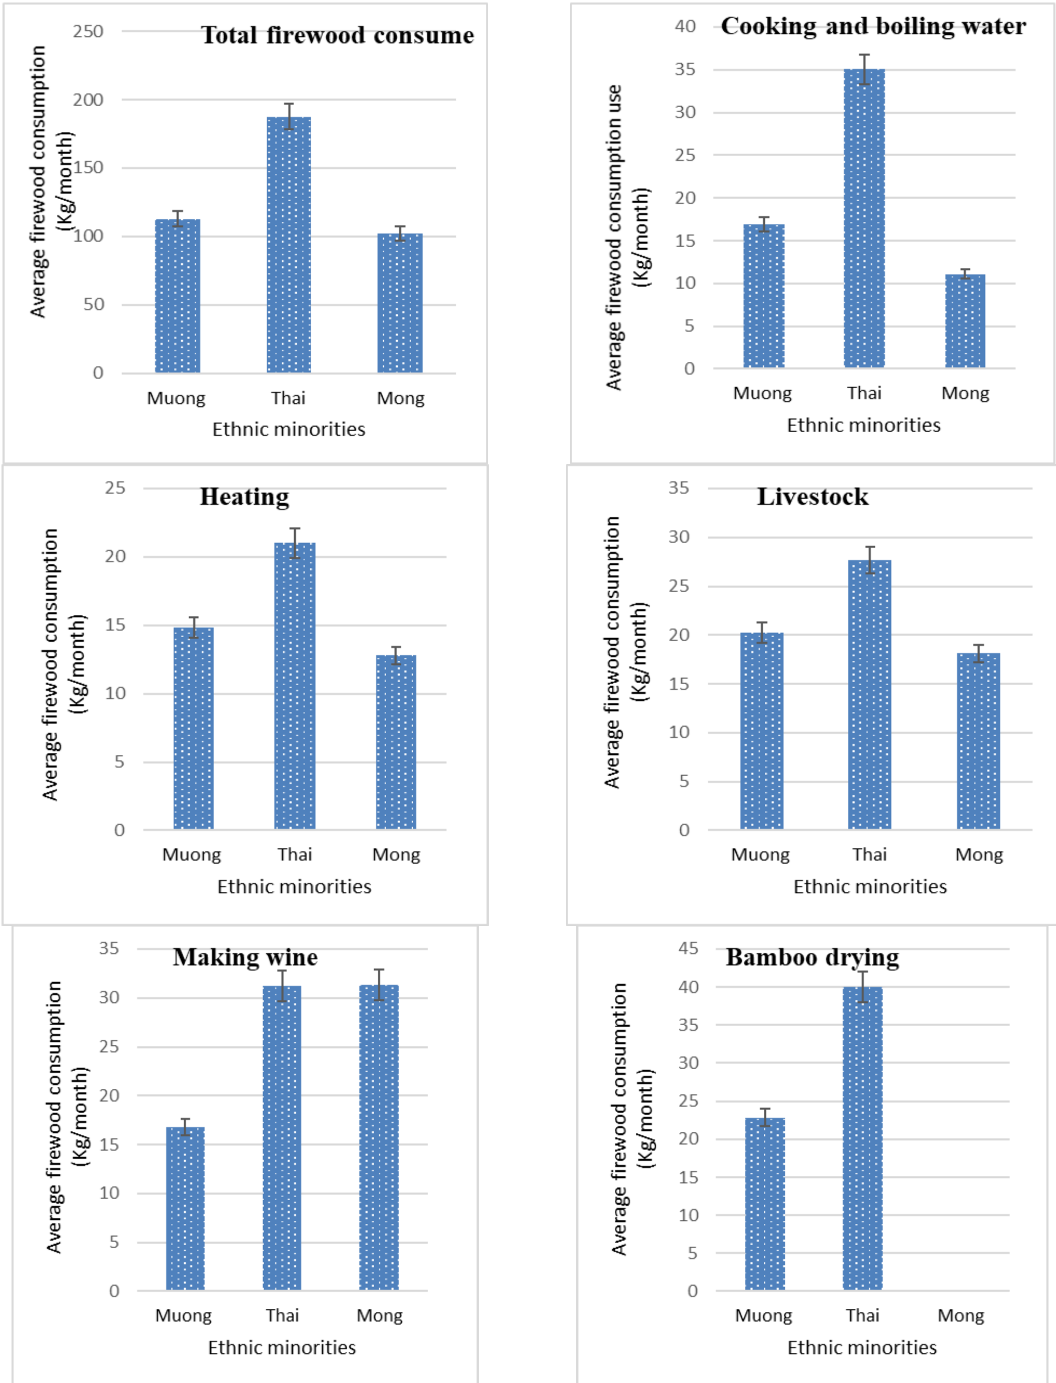

Figure 4. *The estimated monthly weight of firewood used in total and for different purposes*

Further, the Thai minority households used a significantly higher monthly amount of firewood for making wine (34.53 ± 26.91 kg) than the Mong minority (31.37 ± 8.57), whereas the Muong households used only around half the amount used by Thai households for that purpose. Moreover, only around 30% of the Muong Thai households used firewood for this purpose and the number was more than three times that among the Mong households. The average firewood used for this purpose was 29.48 ± 12.71 kg/month/household.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42294249

It was found that none of the Mong households used firewood for drying bamboo but almost twice as many Muong households used firewood for this purpose than Thai households. Nevertheless, the amount of firewood used in the Thai households (40.00 ± 12.25 kg) was higher than that used in the Muong households (24.64 ± 18.24 kg) with the average firewood used for drying bamboo being 28.68 ± 17.94 kg/month/day.

The average firewood used by the three ethnic minorities combined was 123.19 ± 60.49 kg/month/household. However, the Thai households consumed the highest amount of firewood per month (187.62 ± 67.23 kg), while the Muong and Mong households consumed broadly similar amounts of firewood (112.61 ± 58.03 and 101.97 ± 34.57 kg, respectively - see *Fig. 4*). Furthermore, the use of firewood by the Thai households for all purposes of daily living was the highest among the three ethnic minority households. However, the amount of firewood used for heating, livestock and bamboo drying in the Muong households was higher than that of the Mong households and overall, the monthly firewood used by each household among the three minorities was significantly different ($H = 67.06$; $p < 0.01$) as was the personal firewood consumption ($H = 20.82$; $p < 0.01$).

Interestingly, averaging the observed November to February consumption rates and extrapolating from that across the total number of individuals (i.e., 30 kg/person × 12 months). The approximately 360 kg per person of firewood is consumed by the Muong minority during a year while the firewood used by the Thai and Mong minorities was lower at 324 kg/year and 240 kg/year.

Ranger activity in the villages

When interviewed, nearly half the Muong and 72% of the Mong said that they occasionally saw rangers patrolling whereas about 65% of the Thai minority interviewed said that they sometimes met rangers patrolling (*Fig. 5*). Interestingly, a very low percentage of Muong people (1%) generally met rangers while collecting firewood while nobody in the other ethnic minorities generally saw rangers patrolling. When asked what happened when they met a ranger, the main proportion experienced being talked to by the ranger (Muong 55%, Thai 49%, and Mong 85%). The rangers rarely, arrested people in the three ethnic minorities with only 2% of the Thai people reporting having been arrested.

Figure 6 details the communication between the minority households and local rangers with the main percentage (58%) of Muong and Mong households having had communication with rangers, but 67% of the respondents in Thai households having no communication with rangers (*Fig. 6*). Interestingly, the quality of advice from the rangers reported by almost all the Thais (94%) was normal while the percentage of 'normal' advice to the Mong (48%) and Muong (45%) was lower.

There were similar percentages of the three minorities who considered that the rangers provide technical support for forest development. But the percentages of Mong and Thai who considered forest policy to be appropriate (70% and 50%, respectively) was higher than that among the Muong households, many of whom (62%) suggested that the rangers should come to their villages regularly (*Fig. 7*). With regard to the improvement of forest development, the largest number of Muong and Thai households wanted support for forest activities (58% and 62%, respectively, while most Mong households felt that the best way to improve forest development was by the selection of good village leaders.

Discussion

Firewood use relative to social aspects

Firewood was found to be the main energy source for residents in the Pu Hu buffer zone and is likely to remain an important natural resource because it is essential for human activity (Wangchuk et al., 2014). Overall, the firewood consumed by the three ethnic minorities was significantly correlated with households' economic indicators, house-size, and the number of persons in the family (Démurger and Fournier, 2011; Wang et al., 2015). It was found that all the households had forest land and agricultural land, and almost all the households conducted farming as their daily activity. The forest land which makes up the core zone of the NR is far from the area occupied by the households and thus the collection of firewood is difficult and time-consuming and is mainly carried out by the women in the family (Abbot and Mace, 1999; Maes and Verbist, 2012; Tabuti et al., 2003). This study showed that the household size based on the number members of the family had a relationship with the firewood used and this finding was similar to the results of previous studies (Marquez-Reynoso et al., 2017; Win et al., 2018).

Firewood collection and requirement

In the present work, it was found that firewood is a vital resource in the villages adjacent to the Pu Hu buffer zone (Cardoso et al., 2013). The requirement for firewood is more common, compared to timber and NTFP because firewood is used as the major fuel (Kim et al., 2016). Firewood collection on forest land appears to be more intense than in agricultural land in the region as previously found by Sassen et al. (2015) in the forest of Mt Elgon National Park (Uganda) and the implementing of a buffer zone is a way to reduce some of the pressure on NRs (Naughton-Treves et al., 2007). However, local people (nearly 70%) mainly collected firewood from the forest areas including in forestland both inside and adjacent to the NR. This activity puts pressure on forest resources and is likely to lead to serious deforestation (Fox, 1984; Agurto Adrianzén, 2013). In Pu Hu NR, the percentage of household firewood collected in the NR used by the Mong (about 10%) was the highest among the three minorities. Even though Pu Hu NR is a protected area it makes a highly important contribution to the livelihood of households in the area as similarly found by Kim et al. (2016) in considering Ke Go NR in Vietnam. Moreover, as found by Thapa and Chapman (2010) who conducted research in Bardia National Park, Nepal when farming areas and the collection of resources is very important, local people may not be deterred by measures to deter them from using a protected area. However, the study conducted in Indonesia by Pattanayak et al. (2004) reported that households extracted firewood from a local NR forest and their own fields. To collect firewood in the NR, individuals interviewed in this study said people walked over 2 km taking from 3 h to half of the day to cut and collect a full head-load of wood (Win et al., 2018). The distance between households and the protected areas is a challenge and discouraged most local people from entering the NR to harvest firewood.

The estimated yearly quantities of firewood consumed were around 300 kg per household among the three ethnic minorities living in the Pu Hu buffer zone which was very similar to the household requirement in the Budongo Forest Reserve, Uganda of 316 kg firewood (Tweheyo et al., 2005). Mislimshoeva et al. (2014) found a per household consumption of 355 kg year in the Western Pamirs and Bhatt and Sachan

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42294249

(2004) suggested that 174 kg of firewood was used per year by each household in communities in northeast India. Further, Kim et al. (2016) reported a consumption of about 165 kg per household in the neighbouring province of Nghe An.

Firewood use was highest among the Muong minority (1.03 kg/capita/day), followed by the Thais (0.89 kg/capita/day) and Mong (0.67 kg/capita/day), irrespective of their socio-economic status. Comparatively more firewood is used by tribal minorities in Arunachal Pradesh and Garos in northeast India with 3.1 and 5.0 kg/capita/day, respectively (Maikhuri, 1991). Sassen et al. (2015) found that people consumed an average of between 2.14 and 3.88 kg of fuel-wood per capita per year in Mount Elgon national park in Uganda.

In common with the present study, Victor and Victor (2002) and Kim et al. (2016) reported that the average firewood consumption was highest for business activities such as raising livestock. The Thai and Muong minorities are more focused on developing their economic status, and therefore their requirement for firewood was found to be higher for this purpose than for others in similar research conducted in Vietnam by Kim et al. (2016). The livestock business plays a crucial role in household income structure and pig and cattle raising is important to the livelihoods of various minorities living in rural areas (Kim et al., 2016). Based on economic development, the Mong minority generally had lower household incomes, and therefore their priority use of firewood was for cooking and boiling water. Moreover, the Mong people also live in more inaccessible and higher areas than the Thai and Muong minorities.

Connection between households and forest rangers

It is undeniable that firewood is important for a sustainable livelihood among rural people without access to other sources of energy (Kimemia and Annegarn, 2011). Households among the ethnic minorities in the Pu Hu buffer zone mainly used firewood as their source of energy and the main areas for collecting firewood are the forest and agricultural land which are accessible to everybody in the adjacent villages (Kim et al., 2016). Thus, It seems that firewood will remain an important source of energy for the ethnic minority households (Nansaior et al., 2011). Law enforcement is inefficient because the number of effective patrol days is low compared with the potential number of scout working days as reported by Bell and Mcshane-Calzi (1986). A different situation was found by Sassen et al. (2015) in Uganda, where the official allowance per household under forest protection agreements was one headload, twice per week. However, in this study it was observed that although officially excluded, local people have been permitted to collect firewood from the NR area. Rangers at Pu Hu NR said that firewood was collected from both inside the NR and from adjacent forestland, but that they do not consider this a major issue because the volume of firewood taken is not great. This finding is in agreement with those of Kimemia and Annegarn (2011) and Abbot and Mace (1999) in studies in South Africa and Lake Malawi National Park, respectively. Based on the reports of the minority Muong and Mong they patrolling efforts are sporadic and when they encountered the rangers while collecting firewood they would talk to the farmers rather than arresting them.

Most of the respondents considered that the quality of the rangers' advice was normal and there was communication between rangers and some of the people in all three ethnic minorities. Effective communication is necessary because this enables a flow of helpful information about the forest and its management, which is necessary to formulate the authority's management policy (Wang et al., 2015). Insufficient

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42294249

communication between rangers and local people might cause negative behavior related to illegal activity inside and outside the NR (Obua et al., 1998). It is notable that more than half of the Muong minority community interviewed expressed the view that the rangers should conduct regularly patrols in their villages, while most of the Mong minority considered it more important for the rangers to implement appropriate forest policy. Due to improvement of forest management, around 80% of Mong respondents focused on having a good village leader, whereas the other ethnic minorities both indicated that the forest development policy was more important

Conclusion

Forests are still a major source of firewood for ethnic minority households in Pu Hu buffer zone and provide them with substantial economic benefits (Wangchuk et al., 2014). In this study, the patterns of household firewood use were analyzed for the three minorities in the Pu Hu buffer zone, namely the Muong, the Thai and the Mong, using primary data obtained during research in villages located adjacent to the Pu Hu NR. The paper also analyzed the relevant factors that influence household firewood consumption, including the number of household members, and house-size. A comparison by way of a descriptive analysis of households of the three minorities was presented and their firewood requirements were established as being the major demand which they make of local natural resources (Behera et al., 2015). In the study location, the Thai minority households tended to consume more firewood than other minorities. However, the percentage of firewood collected by the Mong households in the nature reserve was the greatest among the three minorities and whilst the Thai minority constitute the largest ethnic group, it is the Mong minority who have the traditional culture of collecting firewood in Pu Hu NR. Thus, NR rangers had to talk to them and demand that they reduce their collection of firewood in the NR when they met them while patrolling. In view of this situation, the management of the NR should focus on the firewood needs of the Mong households, for instance by improving their knowledge of forest protection, enhancing reforestation, reducing the risk of forest fires, and contributing to conservation (Wangchuk et al., 2014).

In the long-term, the best way of dealing with this problem would be to provide greater subsidies for the use of electric power for personal consumers, as a way of reducing pressure on the forests in buffer zone (Naughton-Treves et al., 2007). In the short-term, it is suggested that the widespread introduction of improved-design cooking stoves (both in terms of firing efficiency and heating conductibility) to replace the traditional three-stone cooking rings used by local people, is pursued as a matter of urgency (Kim et al., 2016). On the other hand, rangers should regularly patrol and carry out their responsibility of forest protection, even though in practice, there is little extraction of firewood from the NR. To enhance the sustainable management of resources, firewood harvesting by minorities could be controlled by rangers in this location as part of their duty to ensure that it is carried out in a manner that does not create ecological impacts. Moreover, the park management should convince villagers to find ways of working without resorting to illegal resource extraction, which in the long term would be the best way of preventing ecological damage in the Pu Hu NR (Thapa and Chapman, 2010). Further, upcoming research should consider on patrolling rangers efforts in each location that could be influent local’s behavior and firewood collection.

Acknowledgements. We would like to thank Thailand's Education Hub for Southern Region of ASEAN Countries (TEH-AC), the Graduate School of Sustainable Energy Management, and the Faculty of Environmental Management of Prince of Songkla University, Thailand for supporting this research. We are grateful to the local people in the households of the three ethnic minorities in the Pu Hu buffer zone for assistance in the field and for contributing and sharing their knowledge about firewood consumption. Further, we greatly appreciate the help of the rangers in all the forest stations and the Department of Science and International Cooperation in the Pu Hu NR for their support, advice and assistance during the field survey. Mostly, we would like to thank Mr. Le Khac Dong who fully designed, analyzed and reviewed our manuscript and research.

APPENDIX

Household survey questionnaire

I. General information

Date:	Village: ……………	
Name: …………………; Age ………....	Ethnic: …………..; Education: …………	
Gender: ……………;	Number of family: …… / Children: ………………..	
Household size: ………… m^2,	Estimated income: …………………..VND/month	
Living–years in buffer zone: ..... year		
Cultivated working time	☐ Full-time	☐ Part-time
Land use of family	☐ Agriculture	☐ Forest
	☐ Plantation	☐ Other

II. Firewood aspect

1. What is your requirement from the forest?

a. [ ] Firewood b. [ ] Timber c. [ ] None-timber d. [ ] Other, ….

Why?…………………………………………………………………………………..

2. Do your family use firewood? Yes ☐ No ☐
3. How long has your family used firewood? ……… Years

What reason for?……………………………………………………………………….

- Where do you collect firewood?

a. [ ] Pu Hu forest b. [ ] Household forest c. [ ] Agriculture land d. [ ] Buy d. [ ] Other

For the purpose of…

a. [ ] Cooking b. [ ] Heating c. [ ] Boiling water d. [ ] Drying bamboo

e. [ ] Wine f. [ ] Livestock g. [ ] Other……………..

4. What do you usually do when you collect firewood? ……………………………
5. How do you transport firewood from field to house?

a. [ ] Head b. [ ] Bicycle c. [ ] Motorbike d. [ ] Other, …..

6. How important is firewood as energy consuming in your family?

a. [ ] Unimportant b. [ ] Little important c. [ ] Medium d. [ ] Important e. [ ] Very important

7. Why is firewood your main energy consumption?

a. [ ] Cheap b. [ ] Nature c. [ ] Efficiency d. [ ] Other, …..

8. Do you sell firewood? Yes ☐; No ☐

Why? ………………………………………………………………………………

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42294249

9. Can you estimate firewood consume per day?

Cooking and heating (…….person/day)	……………………kg/baskets
Heating	……………………kg/baskets
Livestock	……………………kg/baskets
Wine	……………………kg/baskets
Bamboo drying	……………………kg/baskets
Other	……………………kg/baskets

10. There is a different quantity of firewood if compared to 10 years before?

a. [ ] Yes b. [ ] No

Why? ………….……………………………………………………………………

11. Do you select plant species for firewood? Yes ☐ ; No ☐

12. What kind of species for firewood do you prefer? ……………………………..

13. Do you think about improving firewood?

a. [ ] Yes b. [ ] No

If yes? What?

…………………..…………………………………………………………………

14. Do you think what government should support for energy consumption?

…………………..…………………………………………………………………

15. Do you see ranger's patrolling when collected firewood?

a. [ ] Rarely b. [ ] Occasionally c. [ ] Sometimes d. [ ] Generally e. [ ] Always

What happens?

a. [ ] Ignore b. [ ] Talking c. [ ] Arrest d. [ ] Other, ……

16. Do you know forester communicated households?

a. [ ] Yes b. [ ] No c. [ ] Don't know

17. If yes, how good is the communication of forester and household?

a. [ ] Very bad b. [ ] Bad c. [ ] Normal d. [ ] Good e. [ ] Very good

18. Can you estimate the quality of firewood advice?

a. [ ] Very bad b. [ ] Bad c. [ ] Normal d. [ ] Good e. [ ] Very good

19. Do you think household agree on firewood advice?

a. [ ] Yes b. [ ] Not much c. [ ] No d. [ ] Don't know

20. Do you receive firewood's advice from forester? ☐ Yes ☐ No

21. How do you know the communication between household and forester?

- Forester:
  a. Usually go to and contact to commune ☐
  b. Support of technical and information on forest development ☐
  c. Propagandized policy ☐
  d. Others ………………………………………..………………………
- Family requirement:
  a. Suggested forest protection and development ☐
  b. Require the excellent leader ☐

Household Survey Questionnaire

I. Thông tin chung

Ngày:	Tên thôn: ……………	
Họ và tên: …………………; Tuổi ………...	Dân tộc: ……………; trình độ học vấn: …………	
Giới tính: ……………;	Số khẩu: ………………….. / Số con: ………………..	
Diện tích nhà: ………… m^2,	Ước tính thu nhập: …………………..VND/Tháng	
Số năm sống trong vùng đệm KBT: ..... năm		
Thời gian làm nương	☐ Thời gian chính	☐ Bán thời gian
Các loại đất sử dụng gia đình có	☐ Nông nghiệp	☐ Đất rừng
	☐ Đất trồng cây công nghiệp	☐ Đất khác

II. Quá trình củi

1. Theo anh/chị nhu cầu nào trong gia đình đang cần hơn?

a. [ ] Củi | b. [ ] Gỗ | c. [ ] Lâm sản phụ | d. [ ] Khác, ….

Tại sao? …..……………………………………………………………………..

2. Gia đình anh/chị có dùng củi trong gia đình bạn không? Có ☐ Không ☐
3. Gia đình Anh/chị dùng củi đốt trong thời gian (hoặc không)? ……… năm

Nguyên nhân nào anh/chị quyết định như vậy? …………………………………….

- Anh chị lấy thu gom củi ở vùng nào?

a. [ ] Rừng Pu Hu b. [ ] Đất rừng nhà c. [ ] Đất nông ghiệp d. [ ] Mua d. [ ] Khác

- Mục đích sử dụng củi

a. [ ] Nấu ăn b. [ ] Sưởi ấm c. [ ] Nấu nước d. [ ] Sấy măng

e. [ ] Nấu rượn f. [ ] Chăn nuôi g. [ ] Khác……………..

4. Hoạt động nào anh/chị thường kết hợp với việc lấy củi? ....……………………………………
5. Làm thế nào anh/chị vận chuyển củi về nhà? (chọn một lúc nhiều phương án)

a. [ ] Đi bộ/gùi b. [ ] Xe đạp c. [ ] xe máy d. [ ] Khác, …..

6. Gia đình Anh/chị có quan trọng vấn đề nhiên liệu củi đốt trong thời gian qua?

a. [ ] Không quan trọng b. [ ] Ít quan trọng c. [ ] Bình thường d. [ ] Quan trọng e. [ ] Rất quang trọng

7. Tại sao củi đốt lại là nguồn năng lượng cho gia đình?

a. [ ] Rẻ b. [ ] Có sẵn c. [ ] Có hiệu quả d. [ ] Khác, …..

8. Anh/chị có bán củi nấu không? Có ☐; Không ☐

Tại sao? ……………………………………………………………………………

9. Nếu anh/chị ước tính lượng củi dùng trong 1 ngày?

Nấu ăn và nấu nước (……..người/ngày)	…………………….. kg/bế
Sưởi ấm	…………………….. kg/bế
Nấu chăn nuôi (…..….lợn+….. bò + ……..)	…………………….. kg/bế
Nấu rượn (………./ bó/kg; chai/lít ……….)	…………………….. kg/bế
Sấy măng (……….măng/kg)	…………………….. kg/bế
Khác: ………………………………………………	…………………….. kg/bế

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42294249

10. Nếu anh/chị so sánh gia đình có so với 10 năm về trước, có sự khác biệt về số lượng củi đun?

a. [ ] Có b. [ ] Không

Tại sao? ……………………………………………………………………………………

11. Anh/chị có lựa chọn các loài cây làm củi đốt không? Có ☐ ; Không ☐
12. Loại cây nào anh/chị yêu thích dùng củi trong gia đình? ………………………………………………………………………...……………..
13. Anh/chị có nghĩ cần phải có cải thiện nguồn cung cấp củi?

a. [ ] Có b. [ ] Không

Nếu có? Điều gì anh/chị nghĩ cần phải nâng cao nguồn cung cấp củi?

………………..…………………………………………………………………………

14. Hoạt động nhà nước nên hỗ trợ anh/chị thay đổi việc sử dụng năng lượng?

Liệt kê………..……………………………………………………………………….

15. Anh/chị có nhìn thấy cán bộ kiểm lâm tuần tra rừng trong khi đi vào khu bảo tồn thu gom củi đốt?

a. [ ] Hiếm khi b. [ ] Thỉnh thoảng c. [ ] Thường xuyên d. [ ] Liên tục e. [ ] Rất nhiều

Điều gì sẽ xảy ra ?

a. [ ] Bỏ qua b. [ ] Nói chuyện c. [ ] Bị bắt lại d. [ ] Khác, ……

16. Anh/chị có nghĩ đã có liên lạc giữa các hộ và cán bộ Lâm nghiệp trong thời gian qua?

a. [ ] Có b. [ ] Không c. [ ] Không biết

17. Nếu có, anh/chị cho biết mức độ liên lạc giữa các chủ hộ gia đình với KBT?

a. [ ] Rất xấu b. [ ] Xấu c. [ ] Bình thường d. [ ] Tốt e. [ ] Rất tốt

18. Anh/chị đánh giá chất lượng hỗ trợ trong hoạt động của cán bộ kiểm lâm về củi đốt?

a. [ ] Rất xấu b. [ ] Xấu c. [ ] Bình thường d. [ ] Tốt e. [ ] Rất tốt

19. Hộ gia đình có chấp nhận những tư vấn của cán bộ kiểm lâm về củi đốt?

a. [ ] Có b. [ ] Không nhiều c. [ ] Không d. [ ] Không biết

20. Anh/chị có được hỗ trợ tư vấn trong sử dụng củi từ cán bộ KBT?

☐ Có ☐ Không

21. Theo anh/chị cho biết làm thế nào mức độ kết nối liên lạc hộ gia đình với KBT?

- Cán bộ lâm nghiệp:
  a. Thường xuyên xuống và liên lạc với cộng đồng ☐
  b. Cung cấp hỗ trợ kỹ thuật và thông tin về phát triển rừng ☐
  c. Tuyên truyền chính sách ☐
- Hộ gia đình:
  a. Đề xuất các vấn đề liên quan đến lĩnh vực bảo vệ và phát triển ☐
  b. Cần có ban lãnh đạo/trưởng thôn uy tín ☐

(Received 17th Sep 2017; accepted 24th May 2018)

Abstract. To locate the loci controlling physiological traits of barley in seedling stage, an experiment was conducted under drought stress and normal irrigation in greenhouse as a completely randomized design with two replications in Iran in 2016. For this purpose, the populations of Cebad Capa (C. Capa) × Susptrit (S) and Vada (V) × Susptrit (S) with their parents were separately cultivated under drought stress condition and normal irrigation. 112 and 89 Recombinant Inbred Lines respectively resulted from V × S and C. Capa × S were used. Susptrit was used as drought tolerant cultivar and Vada and Cebada Capa were selected as sensitive cultivars. In this experiment Chlorophyll content (CC), relative water content (RWC), shoot dry weight (SDW) and leaf temperature (LT) were measured. For each population and environment, QTL (Quantitative Trait Loci) analysis was done based on composite interval mapping on the lines separately. The results showed the effect of genotype was significant for all traits. 43 locations covering QTLs were identified in both populations and both environments. 15 QTLs were located for C. Capa × S under drought stress. The identified QTLs under drought stress were identified as three QTLs for RWC on chromosomes 4 and 5, six QTLs for chlorophyll content as two QTLs for CC-30%FC and two QTLs for CC-50%FC on chromosomes 3 and 7, two QTLs for CC-20%FC on chromosomes 4 and 7, three QTLs for SDW on chromosomes 1 and 6, and three QTLs for LT on chromosomes 4, 6, and 7. In contrast, two QTLs on chromosomes 3 and 6 were detected under normal irrigation for SDW. In addition, 13 QTLs were located for V×S under drought stress. 10 QTLs were observed for chlorophyll content as three QTLs for CC-50%FC on chromosomes 3 and 7, three QTLs for CC-30%FC on chromosomes 1, 2, and 5, four QTLs for CC-20%FC on chromosomes 2, 3 and 6. For RWC, there were identified two QTLs on chromosomes 4 and 6, while a QTL was recorded for SDW on chromosomes 6. Our study showed stable QTLs within and between populations, which it can be used in selection process by markers.
Keywords: *barley, drought stress, mapping, physiological traits, quantitative trait loci*

Introduction

Barley (*Hordeum vulgare* L.), is a major cereal grain grown in temperate climates globally and the fourth most widely grown small-grain cereal in the world (Ashida et al., 2007). It was one of the first cultivated grains, particularly in Eurasia as early as 13,000 years ago. Barley has been used as animal fodder, as a source of fermentable material for beer and certain distilled beverages, and as a component of various healthy

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42514263

foods. It is used in soups and stews, and in barley bread of various cultures. It has high flexibility to various environmental conditions especially for water deficient condition (Ceccarelli, 1987). Assessing the grain yield in areas with intensive stress is the most common method to describe the adaptation of plants under stress conditions (Blum, 1988). Different traits of plants are corresponded to drought stress, but the traits indicating the relative water capacity (RWC) can reveal useful findings for water stress shortage. RWC has been reported as a useful parameter in drought stress by Peltonen-Saino and Mäkelä (1995) and Teulat et al. (2003). Gutierrez-Rodriguez et al. (2004) found that there was a significant relationship between chlorophyll content, photosynthesis rate and yield of wheat genotypes cultivated in normal irrigation and water deficit treatments, so the chlorophyll content could be a representative of photosynthesis capacity. Although the analization of some traits could be time consuming, using DNA markers were efficient method for identify QTLs, and selection programmed by marker assisted selection (MAS). Especially in the case of drought stress by identifying certain loci for tolerating sensitive genotypes based on MAS procedure. Molecular methods make a way to produce the drought tolerant cultivars with high capacity of water uptake (Hammam Mohammed, 2004). Many gene loci controlling traits are associated with drought tolerance and they have been evaluated by relative performance of strains (Mackill, 2003). Chen et al. (2004) showed that in barley, *eibi1* gene was caused strong sensitivity to drought condition. Hammam Mohammed (2004) used a new approach based on advanced backcross in barley to identify QTLs for osmotic adjustment, relative water content, carbon isotope discrimination, dry matter yield and seed yield in dry conditions in the greenhouse. Molecular markers were useful and efficient to identifying the controlling factors associated with drought stress and introducing the improved cultivars. Seedling stage as a critical phase in plant establishment is very important in plant growth. Moreover, assessment of traits in early stages which are linked to the adult stage can facilitate early selection of desirable genotypes. Direct selection might not have adequate proficiency for improving yield under drought conditions due to low heritability, polygenic control, presence of epistasis, QTL × environment interactions (QTL × E), and complex mechanisms of drought tolerance. So, in drought tolerance improvement programs, finding molecular markers associated to chromosomal regions which control drought tolerance traits could accelerate breeding programs and raise the selection efficiency (Cattivelli et al., 2002). Determining the number of QTLs controlling quantitative traits is a crucial attempt in plant molecular breeding (Cooper et al., 2009). QTL analysis makes association between continuous variation of the phenotype and genotypic variation of any concerned loci (Collard et al., 2005). Identifying QTLs make possibilities to accomplish MAS programs (Emberini et al., 2009). Climate changes and global warming is a main challenge in present-day agriculture, which are considered as a risk factor for crop plants. Hence, further researches are necessary to obtain the appropriate varieties using molecular breeding. The present study was conducted to determining QTLs associated with some physiological traits involved in drought stress as well as estimating the effects of the QTLs in barley.

Material and methods

A total of 112 recombinant inbred lines (RILs) of Vada × Susptrit and 89 RILs of Cebad Capa × Susptrit were selected. The Susptrit was drought tolerant cultivar,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42514263

whereas Cebada Capa and Vada were sensitive cultivars (Nguyen, 2012). Population of V × S derived from Vada × Susptrit included 112 lines, where its genetic map with 450 markers consisted of 420 amplified fragment length polymorphism (AFLP) and 24 simple sequence repeats (SSR) markers (Jafary et al., 2006) and also population of C. Capa ×S from Cebad Capa × Susptrit consisted of 89 lines with 459 markers included 481 AFLP and 14 SSR markers (Jafary et al., 2008) (*Table 1*).

Table 1. *Characteristics of two barley populations used in this study. "Gene" is related to two morphologic markers include naked vs cowered seed, and two row vs six row ear, also "other markers" indicate restricted fragment length polymorphysm (RFLP) markers*

Populations			**Markers**				
Population	**Type**	**Number of lines**	**AFLP**	**SSR**	**Gene**	**Other markers**	**Total**
V × S	RIL	112	420	24	2	4	450
CC × S	RIL	89	481	14	0	0	459

This study was performed under a completely randomized design in a greenhouse, controled by average temperature 25 °C and moisture 70% in Iran in 2016. The lines of both populations were separately cultivated in 15 × 25-cm plastic pots. Because of uniformity of the greenhouse environment and soil bedding, each experiment was conducted under a completely randomized design with two replications was. In both populations and parent cultivars, 5 sound seeds were selected and after disinfected with 70% Ethilic Alcohol, they were cultivated in plastic pots filled with field soil and sand as 1:1 v/v. The thinning led to reduce of three seedlings per pot. All pots were irrigated uniformly until 4-leaf stage. Standard Hoagland nutrient solution (*Table 2*) was used in two stages (2-leaf and 4-leaf stages) 200 ml per pot in both stages. The drought stress was imposed at the 4-leaf stage by stopping the irrigation for stress experiments, while irrigated experiments was maintained well-watered. Drought stress was applied up to 20% of field capacity (FC). In this stage all traits were measured in both experiments.

Table 2. *Chemical compounds and those concentrations consist of standard Hoagland nutrient solution, used in this study*

Chemical compound	**Chemical formula**	**Concentration (g l^{-1})**
Calcium nitrate	$Ca(NO_3)_2.4H_2O$	3
Potassium nitrate	$K(NO_3)_2$	1.25
Magnesium sulphate	$MgSO_4$	1.1
Ammonium mono phosphate	$(NH4)_3PO_4$	0.3

Measured traits

Chlorophyll content (CC): Chlorophyll content of barley leaves was tested in drought stress during the stress period in 3 stages at 50% FC, 30% FC and 20% FC using SPAD (MINOLTA). In normal experiments, one step was measured. To measure the chlorophyll content of the leaves, the last fully developed leaves and the middle part of the leaves were used. This trait was measured in each of the 3 plants per pot, and average amount was used for further analysis.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42514263

Relative water content (RWC): Several pieces of the last developing barley leaves were used based on Barr and Weatherley (1962). Sampling was done after 11 AM. Fresh weight of leaf samples was measured immediately. All samples were transported to the laboratory in a tank containing ice bricks. Then, the leaf samples immediately immersed in separate containers containing a sufficient amount of distilled water and were incubated at 25 °C. Turgid weight (TW) was measured after 48 h. Then, the leaf samples envelopes for 24 h in an oven at 75 °C, the dry weight (DW) of leaf samples were immediately recorded. Finally, RWC was calculated according to *Equation 1:*

$$RWC\% = \left[\frac{FW - DW}{TW - DW}\right] \times 100 \qquad \text{(Eq.1)}$$

Shoot dry weight (SDW): The shoots of three plants in per pot were harvested and dried at 75 °C for 24 h and then were weighted and average of three plants were recorded.

Leaf temperature (LT): LT was measured in populations of C. Capa × S. The infrared thermometer was used and measurements were taken on the last well developed leaves on every 3 plants in each pot and their averages were recorded.

Statistical analysis

Analysis of variance and calculation of descriptive statistics were performed using software SPSS 22.

QTL analysis

QTL analysis software was used for MapQTL 5. This analysis was performed using the automatic cofactor selection (ACS) and the method of multiple-QTL mapping (MQM). To determine LOD threshold, permutation test was used. In order to map the chromosomal software MapChart 2.2 was applied.

Results

Analysis of variance (ANOVA)

Analysis of variance showed that there was significant difference (P ≤ 0.01) between different genotypes (*Tables 3* and *4*).

The effects of the environment and genotype × environment on all traits in both crosses were significant. In addition, a significant genetic diversity between the traits was observed. Discriptive statistics of traits in parents and RILs of two populations in drought stress and irrigation experiments, were showed in *Tables 5* and *6,* respectively.

Identified QTLs in C. Capa × S population under normal irrigation (control)							
SDW	3	53-62	3.56	11.9	E42M55-329#3-126	E39M54-305-113	-0.036
SDW	6	126-141	3.7	13.3	E37M50-532-24	E32M55-102-15	-0.031

There were found a total of 15 QTLs for this population under drought stress. The percentage of phenotypic variance explained by QTLs under drought stress was observed as 7.6, 14.8 and 14.4 for SDW, RWC, LT, respectively. Phenotypic variance ranged from 8 for CC-20%FC to 14.4 for CC-30%FC. There were located 15 QTLs for C. Capa × S under drought stress on chromosomes 1, 3, 4, 5, 6 and 7. RWC had three QTLs on chromosomes 4 and 5, controlling of only 36.90% of its phenotypic variance. Also, six QTLs, as two for CC-30%FC and CC-50%FC on chromosomes 3 and 7 controlling of 25.4% and 24.7%, respectively, and two for CC-20%FC on chromosomes 4 and 7 with 17.9%. SDW covered three QTLs on chromosomes 1 and 6, which controls 31.8% of its phenotypic variance. There were identified three QTLs on chromosomes 4, 6 and 7 with 36% of phenotypic variance. For C. Capa × S under normal irrigation, two QTLs were found just for SDW on chromosomes 3 and 6 with controlling of 25.2%, where QTLs were in 53-62 and 126-141 closed to E42M55-329#3-126 and E37M50-532-24 on the left, and E39M54-305-113 and E32M55-102-15 on the right. The highest LOD in C. Capa × S was observed in CC-30%FC as 2.5, whereas the lowest LOD was recorded in LT as 4.58 in drought stress. In normal irrigating, LOD ranged from 3.56 (for SDW) to 3.7 for (SDW). Increased effect for C. Capa × S ranged from - 0.018 (for SWD) up to 3.84 (for RWC). Three QTLs on

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42514263

chromosomes 1 and 6 for SDW was observed. It has the highest control and impact by closing to E33M55-63-76 and E35M61-269#6-67. RWC with one QTL and LOD of 4.01 in 20–35 closing to E33M61-110-309 and E33M54-313#5-374 reached a 3.52-increasing effect. 1.52-increasing effect in CC-50%FC with LOD of 4.07 was recorded for chlorophyll content. Decreasing effect of -0.031 with LOD 3.70 closing to E37M50-532-24 and E32M55-102-15 was observed in SDW under normal irrigation. Allelic effect for RWC, CC-50%FC, CC-30%FC, CC-20%FC, SDW, and LT was positive. In contrast, allelic effect was negative for SDW and LT under drought stress and SDW under normal irrigation.

13 QTLs for V × S under a piece of drought stress and normal irrigation were identified (*Tables 8* and *9*).

Table 8. *Identified QTLs in V × S under drought stress in 4-leaf stage of barley*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42514263

Phenotypic variance explained by QTLs ranged from 5.6 (for CC-20%FC) to 15.9 (for CC-50%FC). Chlorophyll content had the maximum number of QTLs ranging from 5.6 (for C-20%FC) to 15.9 (for CC-50%FC). There was observed 13 QTLs for V×S under drought stress located on all chromosomes. 10 QTLs were identified for chlorophyll content, three were observed for CC-50%FC on chromosomes 3 and 7 explaining 38% of phenotypic variances, and three belongs to chromosomes 1, 2 and 5 with 33.3%, four on chromosomes 2, 3 and 6 with 30.4%, and two were determined on chromosomes 4 and 6 with 21.5%. SDW had a QTL on chromosome 6 covering of 12.8% of its phenotypic variance. Two QTLs were identified on chromosomes 1 and 7 explaining 19.9% of its phenotypic variance, where they were respectively in 0-10 and 49-60 closing to E37M50-401-60 and E36M50-316-37 on the left, and E42M51-232-63 and E38M55-128-39#7 on the right. The highest and lowest LOD in V × S ranged from 2.61 for CC-20%FC to 5.17 for CC-50%FC under drought stress. In contrast, LOD was in a 3.24-5.24 range under normal irrigation. Increasing effect in normal irrigation in V × S ranged from 2.91 for RWC to 3.35 for RWC. The maximum and minimum increasing effect in V × S was recorded as 4.91 and 1.43 for RWC and CC-50%FC, respectively.

One QTL was observed on chromosome 6 for SDW with LOD 3.23 closing to E39M48-310-364 and E38M61-128#1-363. On the other hand, the highest phenotypic variance for RWC was 15.4% with LOD 5.24 in the vicinity of Bmag0136-38 and E39M55-150-332 (*Table 9*). Negative allelic effect was obtained for CC-50%FC, CC-30%FC, CC-20%FC, and SDW under drought stress and also RWC and CC was under normal irrigation.

In C. Capa × S under drought stress, there were found great-effect QTLs. For example, a QTL in the vicinity of E33M61-110-309, E33M54-313#5-374, E41M40-304#5-41, E42M51-68-410 on chromosomes 5 for RWC, a QTL closing to E33M54-338-152 and E42M55-329#3-126 on chromosomes 3 for CC-50%FC and CC-30%FC, a QTL in the vicinity of E33M55-63-76 and E35M61-269#6-67 for SDW, a QTL in the vicinity of E32M61-166#4-462 and E36M50-155#4-464 on chromosome 4 for LT. Moreover, the greatest QTL was observed in the vicinity of E37M50-532-24 and E32M55-102-15 on chromosome 6. In V×S under drought stress, a QTL in the vicinity of P17M54-205-301 and E39M61-370-298#4 on chromosome 4 for RWC, some QTLs closing to E38M55-322-389#3 and E33M54-446-351 on chromosomes 3 for CC-50%FC, and a QTL in the vicinity of E38M54-241-172#2 and E35M48-318-186#2 on chromosome 2 for CC-30%FC, and a QTL in the vicinity of E39M48-310-364 and E38M61-128#1-363 on chromosome 6 for SDW. In contrast, in V×S under normal irrigation, major QTLs in the vicinity of Bmag0136-382, E39M55-150-332, E38M55-322-389#3 and Bmag0136-382 on chromosome 3 for RWC, and a great QTL neighbouring to E36M50-316-37 and E38M55-128-39#7 on chromosome 7 had the maximum impacts.

Chromosomal map, the number and the type of populations have been presented in *Figure 1*. Highlighted area on QTLs relates to significant LOD. The areas shown by continuous lines belong to start and end of LOD curve. QTLs in the linkage disequilibrium with same allelic effect had a positive correlation. In contrast, a negative correlation was observed for QTLs in the linkage disequilibrium with different allelic effects. QTLs of CC-50%FC and CC-30%FC on chromosome 3, and QTLs CC-30%FC and CC-20%FC on chromosome 7 were mapped as a linkage disequilibrium.

Discussion

Statistical parameters diversity of traits in both crosses and both environmental conditions (normal and stress) showed that the difference between parents for some traits were significant, shows parents in two extremes. The aggressor separation (positive genetic progress) for the best parent and line was observed. Significant genetic progress in a positive direction and negative indicated that there are increasing and decreasing alleles in parental. For assessing the stability of QTLs, the society should be investigated in different genetic and environmental conditions. In our study, most QTLs mapped to control physiological traits were stable in different conditions and crosses, a finding that agrees with previous studies (Liu et al., 2015; Srividhya et al., 2011). Finding the chromosomal areas controlling the traits is a starting point to use the QTLs in order to improve of the agricultural products. In our study, some genes showed different reactions in various environments based on different sizes and numbers of QTLs. Hence, repeating the experiments in different environments is important, because some QTLs are specialized to given environments. QTL × E was indicated as a change in the number of QTLs in different environments or their effects in different environments (Yadav et al., 2003). The QTLs have been reported under drought stress in different studies such as resistance to premature senescence in sorghum (Tuinstra et al., 1997; Crasta et al., 1999), yield in corn (Ribaut and Ragot, 2007), and RWC in barley (Teulat et al., 2001, 2003).

The overlap of traits and identified QTLs on chromosomes may be occurred. In our study, C. Capa × S and V × S were conducted in both drought and normal conditions and parent S was same in both crosses. It was observed for RWC in C. Capa × S under drought stress, and in V×S in both drought stress and normal irrigation on chromosome 4. For CC-50%FC in both V × S and C. Capa × S identified QTLs were observed on chromosomes 3 and 7. It was occurred for SDW on chromosome 6. It can be mentioned that according to mutuality of parent S in two crosses, the corresponding QTLs have overlapping areas. QTLs of linkage disequilibrium in the vicinity of each other may reveal a strong correlation between traits. For example, it was observed for RWC, CC-50%FC, and SDW. The presence of a QTL corresponds to growth in *Q7HB* and *Q7 HC* has been reported (Teulat et al., 1997a). The analysis of linkage disequilibrium QTLs can correspond to phenotypic and genotypic correlation. In addition, six QTLs for chlorophyll content in *Q4HA, Q2H, Q7HC, Q7HB, Q5HC,* and *Q4HC* were mapped in barley (Thisi et al., 2000). This trend was recorded for PHS of barley (Han et al., 2003) and yield of barley (Siahsar and Narouei, 2010). Cluster genes of different traits can make overlap QTLs. Traits controlling the yield should be determined and transfer to high-performance genotypes (Cattivelli et al., 2002). Yang et al. (2007) found a locus under drought stress and five loci under normal irrigation by studying chlorophyll fluorescence of wheat. Baum et al. (2003) identified different QTLs using RAPD and RFLP markers on chromosomes 2, 3, 6 and 7.

Stability of RWC is a significant trait in yield efficiency, which is considered as an eminent factor in tolerance to drought stress (Rezapour Fard et al., 2015). Chen et al. (2010) reported three QTLs for RWC located on chromosomes 1, 2 and 6 in barley under drought stress. 3 QTLs for RWC under early short time drought stress were recorded in barley on chromosomes 2 and 5 (Wójcik‑Jagła et al., 2013).

Castro et al. (2008) in QTL analysis of phenological traits for population deriving from *BCD47* and Baronesses showed that the parental lines of mapped population have a same growth profile. However, their offspring showed transgressive segregation. In

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42514263

the present study, there were found different QTLs whether their location was different or their allelic effect was variable. Drought stress influences physiological traits, which results in creating diversity and instability in QTLs. According to overlapping between QTLs places and mutual parent in both two crosses, we indicated that the QTLs have sufficient stability. The allelic effect in C. Capa × S for RWC, CC-50%FC, CC-30%FC, CC-20%FC, SDW and LT was positive under drought stress, whereas it was negative for SDW and LT and SDW under normal irrigation. It shows alleles which decrease SDW and LT, they increase SDW, LT, RWC and CC. A negative allelic effect was observed for CC-50%FC, CC-50%FC, CC-30%FC, CC-20%FC and SDW under drought stress and for RWC and CC under normal irrigation. It indicates the alleles which decrease some traits, they can increase others. To understand the controlling areas with more traits is derived from linkage, pleiotropic effect or cluster genes; the high density map is needed (Golshani and Fakheri, 2015). These traits can also easily stabilize through the selection in primary generations of genotypes (Ehdaei and Waines, 1989). QTLs obtained for C. Capa × S and V × S were stable in most different places. So it can be used in similar findings to select by markers. Due to the controlling of the traits by some loci with high effects, the stability of QTLs is. Stable QTLs relatively stabilize genetic controlling of traits, which cope with QTL × E.

Conclusions

Our study showed, there was a significant diversity in two different populations in terms of physiological traits of barley in normal and drought stress conditions. QTLs were distributed on all 7 chromosomes which most of them observed on chromosome 3. Several overlapping regions among QTLs were observed within and between of two populations, that can be related to common parent S in both crosses. QTLs were observed in both positive and negative direction, indicated that there are increasing and decreasing alleles in parents. Stable QTLs were identified, especially for chlorophyll content in different soil moisture conditions. Some QTLs showed different reactions in various environments based on different sizes and numbers. Hence, repeating the experiments in different environments is important, because some QTLs are specialized to unique environments. In both populations, the most QTLs, were related to chlorophyll content, that it seems the trait is more affected from drought stress in barley.

We recommend that the QTLs identified in this study, can be applied in order to marker assisted selection (MAS) and also gene pyramiding, which finally resulted in appropriate genotypes of barley under drought stress. Also chlorophyll content can be used as an important trait in QTL studies under drought stress in barley.

Abstract. The present study deciphers the impacts of urban planning and role of socio-economic determinants on the perception about urban vegetation. The residents inhabiting the planned (Islamabad) and the semi-planned (Rawalpindi) urban centres were the study population. Both urban areas, lying in close proximity, face rapid transformations in LULC due to urbanization. Despite their closeness, such variants as discrepancies in the standards of urban-planning and socio-economic characteristics of inhabitants make them apt study-sites. The inhabitants' perception was tapped regarding the importance of urban vegetation, temporal and spatial changes and their impacts. The majority concurred to its efficacy, a substantial proportion observed transformations in it over time while a reasonable number perceived these changes as negative and unwelcome. Such socio-economic determinants as location, education, gender, ownership status of residence and income of respondents were studied, deploying Statistical analyses (KW). Responses varied, with location and income weighing-in more heavily. Pair-wise comparison (WRST) further vindicated the results. Urbanization is sure to tarnish the environmental sustainability of both cities. Synchronized efforts from all stake-holders are a must.

Introduction

Life on the planet Earth is dependent on constant support and productivity of Ecosystems Services (ES) (De Groot et al., 2002). The biophysical processes and ecological systems have profound effects on the natural and social systems (Pickett et al., 2001; Alberti et al., 2003; Rockström et al., 2009; Collins et al., 2011). Since the early stages of social and societal organization, the human perception regarding the role of ecological products in their lives, witnessed many transformations in response to spatial-temporal changes.

The researchers acknowledge that human perception and interactions with the ecological resources are significantly influenced by the contextual settings (Ward Thompson et al., 2005; Nasar, 2008; Jim and Shan, 2013). The nature of these interactions significantly transform with the awareness about the benefits of these resources. In present times, these benefits are acknowledged as ES, the contributions of ecological resources towards human wellbeing (Costanza et al., 1997, 2014; De Groot et

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42654287

al., 2002). The ES are grouped into four categories i.e. provisioning, regulating, supportive and cultural (Millennium Ecosystem Assessment, 2005a; Rodríguez et al., 2006; De Groot et al., 2010).

It has been opined that the paradigm of human wellbeing is dependent upon the cumulative contribution of four types of capitals in a given geographical setting. These capitals are recognized as; the natural capital (natural resources), the human capital (human resources), the built capital (physical infrastructure) and the social capital which includes the social norms and institutions (Chiesura and De Groot, 2003; Mulder et al., 2006; Vemuri and Costanza, 2006). The human, built and social capitals have reflective effects on the contributions of natural capital towards human prosperity. The previous studies observed a symbiotic relationship between vibrant ecosystems and the quality of human life (Millennium Ecosystem Assessment, 2005b; Elmqvist et al., 2013; Gómez-Baggethun and Barton, 2013; Luederitz et al., 2015).

Thus, the evaluation of ES, in a given spatial setting, demands inclusion of trans-disciplinary perspectives based upon contextual requirements. These assessments are also indispensable for postulating sustainable measures to enhance the performance of eco-capital i.e. ecological resources e.g. natural and manmade vegetative covers.

The previous studies have stressed on the evaluation of ecosystem services based upon holistic appraisal about the contextual demands (Millennium Ecosystem Assessment, 2003; Heal Geoffrey et al., 2005; Troy and Wilson, 2006). Thus, the identification of socio-economic factors are needed to ensure the sustainability of ecology and environment (Holling, 2001; Ostrom et al., 2001; Anton et al., 2010; Castro et al., 2011; Colding, 2013; Jim and Shan, 2013; Mcphearson et al., 2014; Kaczorowska et al., 2016; Sutton and Anderson, 2016). This realization is a precondition for sustainable development and warrants a coordinated research effort across the disciplinary divides. In response to these demands, the understanding of linkages between man and the natural environment have begun to gain momentum (Costanza and Folke, 1997; Egoh et al., 2007).

The socio-cultural transformations in a society have noteworthy impacts on the ecological resources and their performance. Agricultural activities have magnified the role of ecological resources in the wellbeing of human society (Goldblatt, 2013; Hannigan, 2014). Agricultural revolution also supported the phenomenon of permanent settlements. The urban centers are the culmination of these earlier settlements. These settlements are classified into three major types on the basis of their physical structure i.e planned, unplanned and semi planned urban settlements. Planned cities are built and progress according to a 'Master Plan', thus, displaying a perfect equilibrium of infrastructure for urban social life and ecological sustainability. While, the unplanned cities reflect no formal structure and design to achieve these goals. As compared to these types of urban settlements, the semi-planned urban settlements, grow haphazardly i.e. without any specific design or form but in the subsequent stages, its expansion and development might be regulated with planning and management instruments.

The 21st century is being labeled as the 'urban century' due to the alarming concentration of human population in the urban areas (Benko and Strohmayer, 2014; Nersesian, 2014). The researchers supported the notions that the proportion of global population living in the urban areas is increasing (Elmqvist et al., 2013; Nations, 2014; Luederitz et al., 2015; Green et al., 2016; Larondelle and Lauf, 2016). The uncontrolled urbanization and socio-economic transformations in the urban-based activities are held responsible for unregulated land use/ land cover changes (LULC), loss of urban

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42654287

biodiversity, weather and climatic abnormalities and compromises over urban ecological managements (Grimm et al., 2008; Mcdonald et al., 2008; Seto et al., 2012; Wamsler et al., 2013; Luederitz et al., 2015; Green et al., 2016; Kaczorowska et al., 2016; Schetke et al., 2016). Veeman and Politylo (2003) and Corburn (2017) opined that the ecological degradations in the urban areas are also accountable for rising vunerabilities among the economically deprived and socially marginalized segments of society. The pressures on urban ecological resources will intensify in magnitude and complexity (Grimm et al., 2008; United-Nations, 2014; Schetke et al., 2016). Thus, the uncontrolled urbanization and ecological deteriorations in urban areas are the real challenges of the present times (Marten, 2001; Solecki et al., 2013; Sutton and Anderson, 2016) and synchronization of these two realities is incumbent for the social, economic, ecological and environmental sustainability of urban areas (Luederitz et al., 2015). The assessment of human perception about the ecological resources in a given urban milieu is, thus, a precondition for ensuring wellbeing of urban areas (Mcintyre et al., 2008; Jim and Shan, 2013; Rapoport, 2016). The developing nations are less equipped and hence less prepared to address these challenges (Schetke et al., 2016; Jim, 2013). This lack of preparedness in the developing regions is a potent threat for their urban ecological assets and social life (Morinière, 2012; Schetke et al., 2016).

The phenomena of permanent settlements in Pakistan emerged during the phase of Indus Valley Civilization (Kenoyer et al., 2013) and these settlements were urban in structure and character. The inhabitants were acquainted with the benefits of healthy environment. The subsequent socio-economic and structural transformations in this region such as canalization of the Indus Plain (Shiva, 2016) and more economic opportunities in the big cities stimulated the rural population to migrate towards these urban areas as they were already facing a paucity of basic facilities in their native rural areas. Thus, it triggered an uncontrolled urbanization of certain regions at the cost of their ecological environment. The resulting degradation in ecological resources has added stress for the urban social life in these settlements. The occurrences of erratic weather extremities such as urban heat waves and smog in winter have become a common phenomenon of big cities. These undesirable phenomena are thought to be associated with hyperactive urbanization and urban ecological degradation. Grimm et al. (2008), Wu (2008) and Qureshi et al. (2010b) anticipated that in future the process of urbanization will more accelerate in the developing countries.

The reorientation of policy to reverse the ensuing urban environmental/ecological degradation demands scientifically-based research initiatives (Kaplan and Kaplan, 1989; Jim and Shan, 2013). The inclusion of stakeholder’s perception about the urban ecological resources in research and management initiatives is a prerequisite for ensuring ecological integrity and social wellbeing in the urban areas (Elkington, 1997; Sutton and Anderson, 2016).

Pakistan is among those countries where the research regarding urban environment is in its embryonic stages. Therefore, an increased focus on urban studies is required towards the assessments of urban environment and its ecological resources. In response to these demands, the research focusing on urban vegetative resources got impetus in Pakistan during the last decade. Most of the earlier research concerning urban vegetation was carried out in the contextual settings of the coastal city-Karachi. The studies such as Qureshi et al. (2010a, b, 2013) and Schetke et al. (2016) were designed to decipher the impacts and nature of relationship between urban social life and vegetative cover. However, the physical and human geography of Karachi is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42654287

diametrically different from the urban settlements of Pothwar Plateau such as Islamabad and Rawalpindi.

In the similar time period, the researchers also tried to investigate the potentials of ecological resources and impacts of urbanization on the environmental sustainability of Islamabad and Rawalpindi. However, these studies such as Malik and Husain (2006), Jabeen et al. (2009) and Ali and Malik (2010a, b) were either inclined towards plant sciences are the studies such as Adeel (2010), Ali et al. (2011), Butt et al. (2015) and Hassan et al. (2016) were designed to decipher the impacts of urbanization on LULC changes.

Whereas, the evaluation of human perception about ecological resources is a requirement for ensuring integrated management of urban environment (Breuste, 2008; Qureshi and Breuste, 2010; Qureshi et al., 2010b). In this respect, it is apt to note that human interaction and perception about urban environment is significantly determined by societal perception about ecological resources, economic status, technological advancements, standards of urban planning, and management of existing vegetative covers in the urban regions.

The current study was designed to evaluate the impacts of socio-economic factors on the perception of urban residents about urban greenery in the planned (Islamabad) and semi-planned (Rawalpindi) urban settlements. The study hypothesizes that urban planning and socio-economic status of the inhabitants significantly influence the awareness about urban greenery.

Method

Study area

The study context is located between 72°55”E to 73°10”E and from 33°30” N to 33°45” N and comprises urban and peri-urban areas of twin cities, Islamabad and Rawalpindi. Islamabad owes its development to an administrative decision in 1959 (Maria and Imran, 2006) and was designed to serve as the capital city of Pakistan (Doxiadis, 1965). The green landscape of Islamabad was mainly inhabited by government employees besides some rural population in the vicinity. The older city of Rawalpindi, on the other hand, is a sprawling urban settlement with no formal design and infrastructure. It has less developed green areas and which are typically less taken care of.

In the recent times, the structural and social transformations in this region are responsible for the phenomena of rural to urban migration. The educated and resourceful migrants prefer to shift in Islamabad for better opportunities and peaceful urban social life. While, the economic, environmental and social migrants with less financial support find an abode in urban centers such as Rawalpindi. Resultantly, the density of human population in both urban centers is rapidly increasing (*Fig. 1*).

The impacts of population growth in the study area have become more visible over the period of the last ten years in the form of unregulated urban expansion. *Figure 2* depicts the spatial-temporal transformations in the LULC of the study area.

The quantitative and qualitative changes in the LULC of the study area from 2005 to 2016 have been condensed in *Figure 3* for comparison and brevity.

These urban centers are located in close proximity but their contrasting socio-ecological contextual settings and level of urban planning make it a suitable context for conducting this study of human perception. *Figure 4* indicates that the respondents were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42654287

selected from across the study area with the intent of representing the socio-economic heterogeneities of the study population.

Data collection

The data about socio-economic characteristics of respondents and their views about urban vegetation was retrieved through questionnaire method. The questionnaire was designed for deciphering the effects of socio-economic factors on the perception of respondents about urban vegetation in planned and semi planned urban areas. For this purpose, a structured questionnaire based upon literature review and feedbacks of the pilot survey was prepared.

The questionnaire is composed of two sections. The first section was designed to collect information about the economic and demographic characteristics of the respondents. The second part of the questionnaire deals with the views of the respondents about the urban vegetative cover of the study area. The respondents were required to select an option from the given format for depicting their views (*Appendix 1*). The questionnaire with a brief introduction about the scope and significance of the study was translated in the Urdu language for clarity and convenience of the respondents.

The residents, who were living within the metropolitan limits of Islamabad and Rawalpindi for the last ten years, were the target population. In the contextual setting of Pakistan, the head of a household significantly influences the socio-economic status and orientations of the other family members. Thus, the designated head of the family by National Database and Registration Authority (NADRA) was requested to participate in the survey as a respondent.

The sub-division of the study area into neighborhoods is a reliable sampling technique for representing social, economic and ecological heterogeneities of urban areas (Dupont, 2004). The technique was relied upon and deployed. The initial respondent from each selected locality was contacted through convenience sampling method. The rest of the respondents from the same neighborhood were approached with the help of the initial respondent on the principle of the snowballing or chain-referral sampling (Etikan et al., 2016; Marcus et al., 2017).

Vollmer et al. (2015) stressed on the recording of the geo-coordinates for each data point as these information are helpful in portraying the fine scale heterogeneities of a study area. The geographic coordinates were noted down on the questionnaire at the residence of each potential respondent (*Appendix 2*).

The questionnaires were retrieved from the respondents after one week of delivery. On the whole, 531 questionnaires out of the distributed 800 were collected, returning an average of (66.37%). The process was concluded during the months of July & August 2016.

The questionnaires with incomplete records were discarded during the scrutiny. On the whole, 250 questionnaires each, from both urban centers were selected. The initial data entries were made by the researchers in Microsoft Excel (Version 2016) for subsequent processing and analysis in R (R Version 3.4.2) program language and Geographic Information System (GIS). A portion of this data set is being used in this study.

Data analysis

Three questions about urban vegetation were asked from the respondents. The respondents were grouped on the basis of their residential location i.e. Islamabad and Rawalpindi for inter-city comparison. In the next stage, the respondents were classified and their responses were segregated on the basis of gender, education, residential status of dwellings, monthly income, and age for evaluating the role of these predictor variables in opinion building (*Table 1*).

Table 1. *The socio-economic and demographic characteristics of respondents*

Respondents	Islamabad (%)	Rawalpindi (%)
Gender		
Male	178 (71.2%)	174 (69.6%)
Female	72 (28.8%)	76 (30.4%)
Education		
Uneducated	3 (1.2%)	7 (2.8%)
Up to matric	24 (9.6%)	60 (24%)

DOI: http://dx.doi.org/10.15666/aeer/1604_42654287

The responses and attributes of the respondents were subsequently cross-tabulated for subsequent statistical analysis (*Appendix 3*).

Keeping in view the non-parametric nature of data the Kruskal-Wallis (KW) test was performed to discover the significant variations between the responses on the basis of predictor variables. In the next stage, pair -wise comparisons were carried out with the help of Wilcoxon Rank Sum Test (WRST) for those predictive variables in which the significant differences were observed in the initial KW test. The findings of WRST helped in deciphering the intra-group variations in responses. The findings were tabulated for assessments and comparisons.

Results

Perception about the usefulness of urban vegetation

The role and value of ecological contributions in a contextual setting is determined by human perception (Bixler and Floyd, 1997; Jim and Shan, 2013). The urban surroundings and socio-economic factors such as gender, education, residential status of dwellings, monthly income, and age, markedly influence the human perception about urban vegetation. The outcomes of the study (90% respondents agreed or strongly agreed; 4.8% responded "disagree or strongly disagree" while 5.20% stayed neutral) vindicate that the contributions of urban ecological resources stand acknowledged across the study area. However, the statistical findings (KW $\chi^2 = 5.90$; df = 1; $p < 0.02$) pointed out the significant differences between the responses of residents from both cities about the usefulness of urban vegetation.

The findings of KW based upon the predictor variables such as Education (KW $\chi2$ 30; df 4; $p < 0.01$), Income (KW $\chi230$; df 4; $p < 0.01$), Age (KW $\chi220$; df 3; $p < 0.01$) and Residential status (KW χ^2 10; df 4; $p < 0.02$) indicated that these predictor variables also have a significant influence on the perception of respondents regarding the usefulness of urban vegetation (*Table 2*). However, the test statistics (KW χ^2 0.3; df 1; $p > 0.05$) indicate that the Gender of respondent has a less significant role in this connection.

Table 2. *The findings of Kruskal-Wallis (KW) test based upon of socio-economic variables*

Kruskal-Wallis (KW) test and views of respondents									
	Chi square value			**Degree of freedom (df)**			**P value**		
Predictor variables	**UVBR**	**VCC**	**ICUV**	**UVBR**	**VCC**	**ICUV**	**UVBR**	**VCC**	**ICUV**
Gender	0.3	0.5	4	1	1	1	0.6	0.5	0.05
Education	30	10	4	4	4	4	0.0000006	0.05	0.4
Residential status	10	10	7	4	4	4	0.02	0.03	0.2
Income	30	20	20	4	4	4	0.000002	0.001	0.0001
Age	20	20	1	3	3	3	0.0007	0.001	0.8

Urban Vegetation is Beneficial for Residents (UVBR); Vegetation Cover Changes (VCC); Impacts of Changes in Urban Vegetation (ICUV)

The predictor variables identified in KW as responsible for significant differences were further tested for pair-wise comparison by WRST. The findings ($p < 0.05$) of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42654287

WRST based upon educational background revealed significant differences in the responses between the lesser or uneducated and educated respondents (*Appendix 4a*). This clearly implies that the level of education has significant bearings on the human perception about the benefits of natural capital. The ownership status of the dwelling is another important socio-economic indicator and meaningfully influences the opinions of people about the benefits of urban ecology. The marked variations ($p < 0.05$) among the views of respondents residing in different categories of accommodations were also observed in the findings of WRST (*Appendix 4b*).

The age-based comparison of WRST among different age groups (*Appendix 4c*) revealed significant differences ($p < 01$) between the responses of the most senior age group (61 years and above) with all other age groups (up to 20 years; 21-40 years; 41-60 years). The significant variations in views were not found between all the other categories of age groups. The income of respondents was also observed to be an influential factor in shaping the perception of respondents about the usefulness of urban vegetation. The pair wise comparison of income based categories in (*Appendix 4d*) indicated that the two lowest income groups (Up to Rs. 25000, Rs. 25001 to 50000) have a significantly different perception about the importance of urban greenery ($p < 01$) than the respondents from three higher income categories (Rs. 50001 to 75000, Rs. 75001 to 100000, and Rs. 100001 and above).

Perception of respondents about change in urban vegetation

The respondents were enquired about the vegetation cover changes in the study area. The majority of the respondents (69.20%) observed that the vegetative cover of Islamabad and Rawalpindi is changing and 12.80% reported that they do not perceive any visible change in it. Whereas, the remaining 18% of respondents have no considered opinion about the phenomenon.

However, the test statistics (KW χ^2 5.26; df 1; $p < 0.02$) identified the significant variations in the responses of inhabitants from both urban centers regarding the changes in vegetation cover. The significant variations in the responses were also found on the basis of socio-economic factors such as Education (KW χ^2 10; df 4; $p < 0.05$), Residential status (KW χ^2 10; df 4; $p < 0.03$), Income (KW χ^2 20; df 4; $p < 0.001$) and Age (KW χ^2 20; df 3; $p < 0.001$). However, the role of Gender was found negligible in this regard (KW χ^2 0.5; df 1; $p > 0.5$) (*Table 2*).

The subsequent findings of WRST ($p < 0.05$) revealed meaningful variations among the different categories of respondents on the basis of education (*Appendix 5a*)**.** In this connection, significant differences ($p < 0.05$) were also observed in the opinions of respondents living in the rented dwellings with those who are living in government residences or in their personal abodes (*Appendix 5b*). These statistical findings infer that the ownership status of dwelling influences the opinions of people about changes in urban vegetation.

The significant differences in the opinions ($p < 0.01$) about the phenomenon were also observed in the findings of WRST between the responses of age group (61years and above) with all other ages based categories (*Appendix 5c*). While, the Income based pair wise comparison based upon WRST indicated that the lowest income group (up to Rs. 25000) had a significantly different perception ($p < 0.01$) about the changes in vegetation cover of the study area than all the other income based categories of respondents (*Appendix 5d*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42654287

Impacts of vegetative cover changes and respondents

The changes in the vegetative cover of the study area were negatively perceived by the majority (55.80%) of respondents. The significant differences in views regarding the impacts of these changes were also observed on the basis of residential location i.e. Islamabad or Rawalpindi (KW χ^2 7.37; df 1; $p < 0.01$) and socio-economic factors such as Gender (KW χ^2 4; df 1; $p < 0.05$) and Income (KW χ^2 20; df 4; $p < 0.01$). However, the test statistics based upon KW in (*Table 2*) depicted that the predictor variables such as Education, Residential status and Age of respondents have an ineffective influence on the views of residents in the study context.

The (KW) findings revealed that the gender of respondents had, yet, a different type of influence on perceptions regarding outcomes of change in the urban vegetative cover of the study area (*Table 2*).

The succeeding findings based upon WRST suggested that the economic status of urban residents has significant bearings on their views about the consequences of changes in vegetation cover (*Appendix 6e*). The pair wise findings of WRST based upon categories of education (*Appendix 6b*) pointed towards significant variations in perception about the impacts of changes ($p < 0.05$) between uneducated and higher educated respondents. However, such differences were found to be insignificant between uneducated and moderately educated respondents.

Discussion

The study evaluated socio-economic impacts and role of urban planning in shaping the perceptions of urban residents about ecological resources. The study was carried out in the contextual setting of Islamabad and Rawalpindi in Pakistan. The findings of the study establish that the process of urbanization is gaining momentum. The previous studies (Ali and Malik, 2010b; Ali et al., 2011; Ghafoor Chaudhry et al., 2014) returned similar conclusions. The critical findings of the study also formulate that urbanization through LULC changes is responsible for transformations in the ecology of the study area. These findings give credibility to the assertions of Ali and Malik (2010b) and Faeth et al. (2011) that urbanization causes and stimulates changes in the urban vegetation.

The majority (90%) of the respondents affirmed the positive contributions of urban ecological resources. The finding is in line with the opinions of Kaplan and Kaplan (1989) and Qureshi et al. (2010b) that urban residents acknowledge the importance of ecological contributions.

However, the findings divulge that the residential location and socio-economic characteristics of the study population are accountable for significant variations in views about the various aspects of urban vegetation. The outcomes of subsequent analysis vindicate the assertions that human perspectives about vegetative cover are significantly influenced by the level of education (Tidball and Krasny, 2011; Rupprecht and Byrne, 2014), ownership status of the inhabitant (Van Heezik et al., 2013; Shakeel and Conway, 2014), age (Lee and Maheswaran, 2011), income (Lee and Maheswaran, 2011; Majumdar et al., 2011) and gender (Gidlöf-Gunnarsson and Öhrström, 2010; Lee and Maheswaran, 2011).

The statistical findings based on empirical data validate the differences in the views of respondents from both urban centers about the transformation in vegetative cover. These variations in opinions are attributable to quantitative and qualitative differences in socio-ecological settings of both cities. The urban vegetative cover, city structure, level of urban planning and management of urban ecological resources in Islamabad and Rawalpindi are inherently different. The former urban settlement is comparatively greener, broader in structure, more planned and administered by a well-structured and resourceful organization. As compared to it, Rawalpindi is a semi planned city, a victim of compromised environmental governance and unregulated and disorderly urban expansion.

However, this acknowledgement of change in urban vegetation is not homogenous among the different socio-economic segments of the study population. The summary statistics of data illustrate significant heterogeneities among the opinions of respondents on the basis of their awareness and sensitivity. The socio-economic trajectories of respondents were found influential in shaping their perception regarding changes in urban vegetation. These observations are in line with the previous assertions (Faeth et al., 2011; Kowarik, 2011) that socio-economic factors suggestively influence the human perception about changes in urban vegetative cover.

The variations in views about the impacts of changes on the basis of gender, support the previous findings (Gidlöf-Gunnarsson and Öhrström, 2010; Lee and Maheswaran, 2011) that the gender of respondents influences the human perception about human-environment relationships. In conservative social settings of the developing world, unequal exposures between male and female, is responsible for differences in normative knowledge about urban vegetation. Thus, it offers a plausible explanation for reported dissimilarities in views.

The study also substantiates the notions of reported findings (Jim and Shan, 2013; Mcguirk, 2013) that income, a proxy variable for economic status of individuals, not only determines socio-economic standings of the individuals but also significantly influences their propensities towards ecological resources. It is the considered opinion of the authors of this study that in the present age of consumerism and knowledge based economy the role of income and education is becoming more influential in shaping the perception of respondents regarding urban ecological resources.

Conclusions

The present study evaluated the role of urban planning and socio-economic factors i.e. gender, education, residential status of dwellings, monthly income, and age, in shaping the perception of respondents about ecological resources in the study area. The findings of the study indicate that the level of urban planning, exposure to ecological resources, socio-economic and demographic characteristics of the urban population have significant bearings on their orientations towards green infrastructure of urban areas. The study also points towards the growing urbanization and rapid transformations in LULC of the study area. The resultant impacts of these intrusions may adversely impact the performance and sustainability of the urban environment in both cities. The synchronized efforts of researchers, opinion builders, policy makers, concerned institutions and proactive participation of urban residents are required for integrated management and sustainability of the urban environment. In this connection further research is needed for evaluating the orientation of spatial and temporal changes in the LULC of the study area. The use of Remote Sensing (RS) data with the help of Geographic Information System (GIS) techniques seems to be a pragmatic option for measuring these trends. The findings of this study also signify the role and importance

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42654287

of environmental management for the sustainability of urban green resources. Therefore, further investigations are also required for assessing the role and performance of institutions responsible for the environmental management of the study area. The holistic appraisal about such dimensions of environmental management are imperative for a healthy, green urban infrastructure.

Acknowledgements. The authors of this manuscript are highly indebted to anonymous reviewers for their invaluable suggestions and comments for improving the orientation and quality of the manuscript.

APPENDIX

Appendix 1. *Questionnaire*

Date		GPS Coordinates	
		LAT.	LONG.

1	Location of respondent	(a) Islamabad
		(b) Rawalpindi
2	Year of birth	
3	Gender	(a) Male
		(b) Female
4	Highest education level	
5	Monthly household income	
6	Do you have any knowledge about ecosystem?	Yes
		No
7	What is the ownership status of your Dwelling?	(a) Personal
		(b) Official
		(c) Rented
		(d) Allotted
		(e) any other

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42654287

8	Do you think that urban vegetative cover is beneficial for urban residents?	(a) Strongly disagree
		(b) Disagree
		(c) Agree
		(d) Strongly agree
		(e) Don't know
9	In your opinion, have the vegetative cover between your work place and home have changed in the past 10 years?	(a) Strongly disagree
		(b) Disagree
		(c) Agree
		(d) Strongly agree
		(e) Don't know
10	What is your opinion about the impacts of these changes in vegetative cover?	(a) Positive change
		(b) Negative change
		(c) Don't know

Appendix 2. *Latitude/longitude coordinates of the respondents*

Abstract. The aim of this study was to determine the performances of yield and factors affecting the yield of 9 soybean lines and 2 standard soybean varieties grown in the soybean production seasons of 2012 and 2013 under semi-arid climatic conditions. The results indicated that performances of yield and other characteristics of soybean varieties/lines obtained in both trial seasons were significantly different from each other. The average temperature of experimental site in the first plant growing season was higher than that of the second year. The difference in temperatures between two growing seasons adversely influenced the yield, parameters affecting the yield and some quality parameters. Negative relationship between soybean yield and the temperature, an environmental factor that cannot be controlled during the growing season of the soybean, was obtained.
Keywords: *soybean, heat stress, plant and environment interactions*

Introduction

Soybean (*Glycine max*) is an important industrial legume as human and animal feed in the world with an average of 18-22% oil, 38-56% vegetable protein in its seeds. Soybean is the most widely grown oilseed in the world as a main or second crop (USDA, 2018). The annual plant of soybean is a vertically branching plant and has pile root system that allows the use of water and nutrition in deeper soil profile (Baydar and Erbaş, 2014). Soybean that has a symbiosis with a special *Rhizobium japonicum* bacteria, is an extremely important plant in terms of improving the physical and chemical quality of soils. Soybean is consumed as soybean oil and soybean flour in human nutrition as well as in preparation of human foods such as dough products, baby foods, confectionery products, non-allergic milk and dairy products, special dietary products, artificial meat products and dry/cold instant (Öner, 2006). Soybean is used in many other sectors as in producing insecticides. Wax, soap, oil lamps, biodiesel, glue, paper raincoats and plastic materials are also produced using soybean. Soybean pulp contains 40-46% protein, 1-6% oil, 30-31% carbohydrates and 5-6% cellulose, thus is utilized as a good source of protein and fiber in livestock feeding (Singh and Shivakumar, 2010). Since soybean is extensively used in human nutrition, numerous researches have been conducted to determine the effects of soybean products on human health. The results revealed that individuals fed by soybean and soy products have a reduced risk of developing different types of cancers and soybean has a protective effect against cancers and also has positive effect in prevention of many other diseases

(menopause, cholesterol, osteoporosis, cardiovascular and chronic diseases-coronary heart diseases) (Uesugi et al., 2013; Lovati et al., 1987; Messina, 1999; Xiao, 2008; Brouns, 2002).

Soybean is originated from China. Domestication and cultivation of soybean by humans in China dates from about the 11th century BC or a little earlier according to oldest records (Hymowitz and Shurtleff, 2005). Soybean is introduced from the ancient world to the new world in the middle of 17th century and gained its worldwide importance at the beginning of the 20th century. The arrival to Turkey coincides with World War I (Arıoğlu, 2007).

The soybean planted area in the world 2016 was estimated at 121 million hectares and soybean production was 335 million tons (www.fao.org). The consumption of soybean per person is 40.64 kg year^{-1} based on the assumption that the entire soybean production in the world is consumed by humans. But a large part of the produced soybean is used in animal feeding. Soybean is suitable for growing in both temperate and tropical climates with diverse environmental conditions (Hasanuzzaman et al., 2016). However, soybean production in Turkey is only 150 thousand tons in 34 thousand hectares. Despite the appropriate climate, soil and water resources to produce higher amounts in Turkey and the importance of soybean in human and animal nutrition as well as a raw material in industry, Turkey imports significant amount of soybean and processed soy products. Soybean is ranked 4th in Turkey among the imported agricultural products with 1,073,757 tons and ranked 3rd with 1.08674 million tons as processed soybean (www.fao.org). For this reason, studies on the cultivation and adaptation of soybean varieties are of great importance to increase the soybean production in the country.

Abiotic stress or extreme environmental conditions such as soil salinity, long term drought, low and high temperatures, nutrient deficiency or toxicity of heavy metals etc. may cause significant reduction in quality traits and yield of soybean varieties (Jumrani and Bhatia, 2018; Shah and Paulsen, 2003; Hasanuzzaman et al., 2016). Also many researchers have examined the effects of environmental factors on yield and quality. It has been shown that environmental factors significantly affect yield and quality in soybean cultivation (Piper and Boote, 1999; Thomas et al., 2003; Kumar et al., 2003; Pipolo et al., 2004). This study was carried out in semi-arid climatic conditions to determine oil and protein ratios of soybean seeds, yield and factors influencing the yield in different soybean genotypes.

Material and method

The study was conducted during the main soybean crop production season in 2012 and 2013. In the study, 2 standard soybean varieties (Ataem-7 and Türksoy) and 9 advanced soybean lines (6, 11, 17, 24, 27, 834, 1021 and 1022) were used as material. Standard varieties used as materials in the experiment were used because they conformed to the local conditions. The lines used in this study were the crossbreeds of the parents shown in *Table 1* and were obtained in 1999.

The field experiments were carried out in the Gündaş research station of GAP Agricultural Research Institute during soybean growing seasons in 2012 and 2013. The Gündaş station is located at 360 44’ 05.22 N and 380 48’ 49.76 E within the borders of Akçakale town of Sanliurfa province, Turkey (*Fig. 1*). The summers are dry and hot, and the winters are relatively warm. The average temperature in July and August is

40 °C, while during some nights the temperature goes above 30 °C (https://mevbis.mgm.gov.tr, 2017).

Figure 1. *The area of trial*

Some physical and chemical characteristics of the soil samples taken from the experimental fields are given in *Table 2*. The experimental fields were similar in terms of soil water saturation (%), soil pH level, soil salinity (EC ds m^{-1}), calcium carbonate (%), plant available phosphorus (P_2O_5, kg ha^{-1}), potassium (K_2O, kg ha^{-1}) and soil organic matter content (*Table 2*).

Table 2. *Soil properties of trial areas*

Years	Water saturation rate (%)	pH	Ec ds/m	Lime RATE (%)	Phosphorus P_2O_5 (kg ha^{-1})	Potassium K_2O (kg ha^{-1})	Organic matter rate (%)

2013	69	7.47	0.89	24.3	51.9	3000	2.45

The meteorological data indicated that the temperatures in 2012 were generally higher than those of 2013. The average temperatures of June, July and August which are the vegetative and generative development periods of the soybean, was warmer in 2012 (*Table 3*).

*Long term average (1929-2017)

The experiments were established in a randomized block design with three replicates on May 08 and May 06 in 2012 and 2013, respectively. Each plot was 6 m long and plants were grown in 4 rows with a 70-cm row and a 5-cm inter-plant (intra row) spacing. Irrigation, hoeing, and all other cultural practices have been uniformly applied to all the experimental plots to minimize the experimental error. Plants were harvested between 01 and 11, October in 2012, and 05 and 10, October in 2013. *Rhizobium japonicum* bacterial inoculation was not carried out during planting. Data were recorded for grain yield (kg ha^{-1}), plant height, first pod height, number of pods per plant, 1000-grain weight. Seed oil and protein ratios which are important quality characteristics were also determined.

The data were subjected to analyses of variance using JMP (JMP is a division of SAS that produces interactive statistical discovery software) statistic software package and average values for each of the traits were grouped according to LSD test.

Results

The mean values of properties examined for varieties/lines used as materials in the experiment and the groups obtained for the values of 2012 are presented in *Table 4*.

The grain yields (kg ha^{-1}) for different soybean varieties/lines were statistically significant at $p < 0.01$ level and the 1000-grain weight significant at $p < 0.05$ level. However, the values for plant height, the first pod height, the number of pods per plant, the oil and protein ratio among the different soybean varieties/lines were not statistically different. The yield of varieties / lines ranged from 2044.30 to 2950.00 kg ha^{-1}. The highest yield was obtained as 2950.00 kg ha^{-1} with the line 11, while the lowest yield was obtained as 2044.30 kg ha^{-1} with line 6. The plant height of varieties/lines varied between 110.27 and 125.70 cm. The highest plant height was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42894298

125.70 cm with line 1022, while the lowest plant height was 110.27 cm with line 17. The first pod height values ranged from 18.00 (Türksoy variety) to 28.77 cm (line 6). The highest number was obtained from the Türksoy variety (28.77 cm) and the lowest value was obtained from the line 6 (18.00 cm). The highest value number of pods per plant was obtained from Ataem-7 as 55.67 pods/plant, and the lowest value was obtained from line 1022 as 40.37 pods/plant. The highest 1000-grain weight (222.67 g) was occurred with line 1022 and the lowest weight (146.67 g) was obtained with line 17. The oil rate values of varieties/lines varied between 15.44 and 18.18%. The highest oil ratio (18.18%) was found in line 1022, while the lowest oil ratio (15.44%) in line 13. The highest protein ratio (37.46%) was obtained with line 13 and the lowest protein ratio (34.73%) in line 24.

The mean values of properties examined and the groups obtained for varieties/lines 2012 are presented in *Table 4*. The values of grain yield (kg ha^{-1}), plant height (cm), number of pods per plant (pod $plant^{-1}$) and 1000-grain weight (g), and oil ratio (%) were significantly different ($p < 0.01$) among the different soybean varieties/lines. The difference in the first pod height was significant at $p < 0.05$ level. The differences in protein values among varieties/lines were not statistically significant in 2013. The grain yield of varieties/lines was ranged from 2892.90 (line 24) to 4464.30 kg ha^{-1}(line 11). The plant height of varieties/lines was between 100.93 cm (line 834) and 116.47 cm (line 27). The highest first pod height value (21.07 cm) was obtained for line 17, while the lowest value (16.00 cm) was occurred with line 27. Line 11 yielded the highest number of pods per plant (75.47) whereas the lowest number of pods per plant was obtained for line 834 as 42.73 pods $plant^{-1}$. The highest 1000-grain weight (207.67 g) was found with line 1022 and the lowest 1000-grain weight (163.33 g) was obtained with line 834. The oil rate among varieties/lines was ranged from 18.49% (line 13) to 22.56% (line 1021). The highest protein content was obtained with line 13 (37.43%) and the lowest was in line 1021 (34.30%).

Discussion

In the second year of the experiment, grain yields and oil ratios of all varieties/lines were higher, whereas plant lengths were lower compared to the first year of the study. The first pod height values of varieties were lower except for line 13 which was significantly higher than in the first year of the experiment. The number of pod per plant in the second season was lower in Ataem-7 variety and line 834 compared to the first growing season of the study. The 1000-grain weights of lines 13, 834, 1022 and 6 in 2012 were lower compared to the second year, while it was similar for line 11, and higher for Ataem-7 and Türksoy varieties and lines of 27, 17, 24 and 1021. The protein ratios of Türksoy and Ataem-7 varieties and 27 and 24 lines increased in the second year and decreased in other varieties/lines.

Grain yield

The average soybean yield in 2012 (249.20 kg da^{-1}) was lower than that of 2013 (394.32 kg da^{-1}). The average, maximum, minimum and total temperatures during the growing season of 2012 (June, July, August) were higher than those of 2013 (*Table 3*). Higher temperatures during the vegetative and generative periods in 2012 compared to those of 2013 resulted in lower grain yields of varieties/lines in 2012. Increasing temperature causes water stress (Jumrani and Bhatia, 2018; Pipolo et al., 2004; Shah

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42894298

and Paulsen, 2003) which negatively affects the fertilization of the flowers, and also causes flowers to fall down. Eventually, significant losses occur in grain yield of crops (Dornbos and Mullen, 1992).

Relationship between grain yield and yield components

A correlation test was conducted to determine the relationship between the grain yield and the factors affecting the yield of soybean varieties/lines (*Tables 5* and *6*). Although not statistically significant in the first year, there was a negative correlation between the grain yield and plant height, the 1000-grain weight, the oil ratio and the protein ratio, and a positive relationship between yield and the first pod height. However, a statistically significant positive correlation was found between yield and number of plant pods. In the second year, a statistically non-significant positive relationship was found between the grain yield and the plant height, the first pod height, the number of pods per plant, the 1000-grain weight, the oil ratio and the protein ratio. The positive correlations between grain yield and the first pod height and the pod number per plant revealed that increases in the first pod height and the number of plant pods resulted in considerable increases in grain yields. The height of first pod and the number of pods per plant are important factors positively affecting the yield and both have been considerably changed with variation in temperature between the experimental years (*Table 7*). Due to the higher temperatures, the first pod height was higher in the first year compared to that in the second year.

Despite the decreasing number of pods per plant compared to the second year due to the high temperature, the grain size remained unchanged and therefore the 1000-grain weight was not significantly decreased compared to the first year. Higher temperatures in the first year caused decline in the number of grains per pod and this had a negative impact on grain yield. A negative correlation between the 1000-grain weight and the grain yield may actually be attributed to the decline in the number of grains per pod. In summary, a decrease in the number of grains per pod in the first year resulted an increase of the 1000-grain weight, while an increase in the number of the grains per pod caused a lower the 1000-grain weight. Also Ionescu et al. (2016) has reported that the relationship between the number of capsules in the plant and the 1000-grain weight is negative. Therefore, the grain yield depending on the number of the pod per plant is assumed to have a negative relationship with the weight of the 1000 grain.

Oil and protein ratio (%)

Environmental factors as well as genetic characteristics of genotypes are also effective in influencing the chemical content of soybean (Jumrani and Bhatia, 2018; Shah and Paulsen, 2003). The oil and protein ratios of the soybean are as important as the grain yield. The oil and protein ratios of both years are given in *Table 4*. The oil ratio of varieties/lines were between 15.44 and 18.18% in the first year and it was between 18.49 and 22.56% in the second year (*Table 4*). Similar to the oil ratio, the grain yield was also lower in 2012 compared to that in 2013. Differences in oil ratios of genotypes between two growing seasons are related to responses of genotypes to environmental factors. Some researchers have reported similar results (Piper and Boote, 1999 and Wang, et al., 2015). In other words, the high temperatures during the growing season in 2012 caused the oil ratio of grains to significantly decrease in parallel with the grain yield. The difference between the average protein ratios of the two years is not significant, though the protein ratio of the first year is relatively higher than that of the second year. Also, Kumar et al. (2006) has similarly found that the mean air temperature during bean development showed a significant positive correlation with protein and a negative correlation with oil. The results revealed that the protein ratio of the grain does not react to the temperature as in the grain yield and the oil ratio of the grain (*Table 7*). The correlation test showed that the oil and protein ratios of the soybean grains had significant negative relationships ($p < 0.05$ and $p < 0.01$ in the first

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42894298

and second years, respectively). Similar to our findings, Johnson et al. (1955) also reported a significant negative relationship between oil and protein rates of soybean grains.

Conclusion

A two-year field experiment (2012-2013) was conducted to determine the performances of two standard soybean varieties and 11 soybean lines under semi-arid climate conditions by evaluating the yield, factors affecting the yield and some quality traits. Performance of yield and other characteristics of soybean varieties/lines differed between two growing seasons. The average temperature of the study area during the growing season in the first year was higher than that of the second year. The higher temperature in the first growing season had a negative impact on the yield, the factors affecting the soybean yield and the oil ratio of the soybean grain. A negative relationship between oil ratio and protein ratio of the soybean grains is one of the most important findings of the study. In conclusion, the yields of soybean varieties/genotypes have been negatively affected by the extreme temperature, one of the most important environmental factors.

Acknowledgements. This study was conducted by the supports of General Directorate of Agricultural Research and Politics affiliated to the Turkish Republic Ministry of Food, Agriculture and Livestock within the scope of Soybean Breeding Project (TAGEM/TA/09/05/01/0014). Soybean line 11 was registered as GAPSOY-16 in 2016 by the Directorate of Seed Registration and Certification Center affiliated to the Ministry of Food, Agriculture and Livestock of Turkey.

Abstract. Present experiment was performed to determine the effect of salinity stress on canola (*Brassica napus* L.) using the parameters of inorganic nutrients, malondialdehyde (MDA) and leaf proline content and the activity of antioxidant enzymes. Four canola cultivars viz., Oscar, Ac Excel, Cyclone and Dunkled and two levels of salt (0 mmol/L NaCl, 120 mmol/L NaCl) were used. Root fresh and dry weight of four canola cultivars markedly declined due to salinity stress. Salt stress significantly increased leaf proline content in four canola cultivars and higher values were recorded in cultivar Dunkled and Ac Excel than those in Cyclone and Oscar. Salt stress significantly enhanced antioxidant enzyme activities including SOD, POD and CAT in all canola cultivars. SOD showed highest value in Cyclone and Dunkled, POD in Ac Excel, Cyclone and Dunkled while CAT in Ac Excel and Dunkled. Malondialdehyde (MDA) showed variable response in all canola cultivars under saline conditions. Shoot and root (Na^+, Cl^-, K^+, and Ca^{2+}) were significantly affected under salt regimes. Salt stress increased Na^+ content in root and shoot in canola cultivars. High shoot Na^+ was found in Oscar and Cyclone, root Na^+ in Oscar, Ac Excel and Cyclone. Value of K^+ and Ca^{2+} in shoot and root was markedly reduced under saline conditions. It is concluded that high salt tolerance of canola cultivar "Dunkled" could be accredited due to exclusion of Na^+ and accumulation of K^+ ions, enhanced leaf free proline content and also antioxidant enzyme CAT activity.
Keywords: *oilseed crop, salt stress, enzyme assay, biomass production, Na^+ and K^+*

Introduction

Stresses including biotic and abiotic limits life forms all over the world. Abiotic stresses such as drought, salinity, waterlogging, low light intensity, and extreme in temperature inhibit plant growth and development like biomass production. Overall, agriculture productivity markedly reduces by salinity stress (Khodary, 2004; Ashrafuzzaman et al., 2002). Salinity, as a major abiotic stress in crop species, disrupts homeostasis, water potential, ion distribution and induces inhibition of growth and oxidative changes as a secondary stress. Formation and accumulation of reactive oxygen species (ROS) can be induced by salinity stress (Erdal et al., 2011). Reactive oxygen species include singlet oxygen, hydroxyl radicals and hydrogen peroxide which destroy mitochondria and DNA. Enzymatic as well as non-enzymatic antioxidant defence mechanisms reduce the accumulation of reactive oxygen species by detoxifying free radicals (Siddiqi et al., 2011). The activities of antioxidant enzymes, such as catalase, peroxidase, superoxide dismutase and ascorbate have a key role in the removal of reactive oxygen species (Anderson et al., 1995).

Canola (*Brassica napus* L.) is a moderately salt tolerant oilseed crop which is mostly cultivated for edible oil purpose (Francois, 1994). In literature, it is widely reported that requirements of canola oil as oilseed crop has increased since the last four decades due to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42994309

increased awareness about health benefits of canola. Attention increased to cultivate canola in soils where salinity issues already exist (Ashraf and McNeilly, 2004). To improve salt tolerant crop, it is necessary to increase the productivity of saline soils, different approaches have been proposed by various plant scientists (Ashraf et al., 2008).

Major objectives of the present research work were to explore the response of canola cultivars to salt stress through their antioxidant enzymes, leaf proline and nutrients content at vegetative growth stage.

Materials and methods

Objective of the present investigation were to determine the effect of salt stress on canola (*Brassica napus* L.) cultivars. Pot experiment was performed in the Botanical Garden, Department of Botany, University of Gujrat, Pakistan. Seeds of four canola cultivars were acquired from Ayub Agriculture Research Institute (AARI), Faisalabad, Pakistan. Seeds were treated using sodium hypochlorite (5% NaClO) solution for surface sterilization for 5 min. Seeds were rinsed with double distilled water after the process of sterilization. Plastic pots (24 cm diameter) were filled with 10 kg fresh river washed sand. Eight (8) healthy seeds were sown in each plastic pot. Each pot was irrigated with Hoagland nutrition (2 L) solution. Thinning was done to maintain five plants in each pot after ten days. Treatment of the experiment was control (0 mmol/L NaCl) and salt stress (120 mmol/L NaCl). After twenty days of initiation seed germination, salt treatment was started with full strength Hoaglands nutrient solution. Objective of the Hoagland nutrient solution application to plants is to maintain mineral nutrients requirements. Step wise salt treatment was given by adding 40 mmol/L NaCl on a daily basis to maintain final salinity level. Also, distilled water (250 ml) was applied on a daily basis to each pot to avoid evaporation loss. Data of the followings attributes were noted after the start of seven weeks of salt treatment.

Biomass production

One plant from each replicate was removed and separated into their respective shoot and root. Samples of shoot and root were oven dried at 65 °C for five (05) days and their dry weight was recorded by using an analytical balance.

Malondialdehyde (MDA)

Method of Carmak and Horst (1991) was followed for the determination of leaf malondialdehyde (MDA) contents. Fresh leaf sample (0.5 g) was grinded, trichloroacetic acid (10 ml) was added and then that mixture was centrifuged for 10 min at 12,000 × g. Four ml of 0.5% thiobarbituric acid prepared in 20% trichloroacetic acid was added in 1 ml of the supernatant. After that reaction mixture was placed in water bath at 90 °C for three min. These samples were again centrifuged for 10 min at 12,000 × g. Absorbance of the samples was noted at two wavelengths 532 and 600 nm with a spectrophotometer (U2020 IRMECO).

Antioxidant enzyme activities

Fresh leaf sample (0.5 g) was grinded in 0.5 ml phosphate buffer for the measurement of antioxidant enzyme activities. Homogenate was centrifuged at 15,000 × g for 15 min at 4 °C. Values of superoxide dismutase, peroxidase and catalase was determined using the supernatant. Superoxide dismutase activity was determined by enzymatic photoreduction of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42994309

nitroblue tetrazolium (NBT) following the method of Giannopolitis and Ries (1977). Reaction mixture of 3 ml contained methionine (13 mmol/L), riboflavin (1.3 µmol L^{-1}), phosphate buffer and NBT (50 µmol L^{-1}). In test tube 20–50 µL enzyme extract was homogenized. Under white fluorescent light, solution mixture was illuminated. Catalase and peroxidase activities were determined using the method of Chance and Maehly, 1995. Solution mixture was prepared containing guaiacol (20 mmol/L), hydrogen peroxide (40 mmol/L), phosphate buffer (50 mmol/L phosphate) and enzyme extract (0.1 ml). Catalase activity was determined using hydrogen peroxide (5.9 mmol/L), phosphate buffer (50 mmol/L) and 0.1 ml enzyme extract. To determine catalase activity, enzyme extract was mixed with reaction mixture and absorbance was recorded at 240 nm after every 20 sec. Concentration of protein was determined using the method of Bradford (1976).

Determination of free proline

Method of Bates et al. (1973) with some amendments was used for the measurement of leaf proline content. 0.5 g of fresh leaf sample was grinded and extracted using sulfosalicylic acid (3%). Filtrate of the reaction mixture was obtained using filter paper (Whatman No. 2). Two ml of filtrate was added in the test tube with 2 ml of acidic ninhydrin solution and 2 ml of glacial acetic acid and further homogenized. Then it was heated in water bath at 75 °C for 60 min. After that mixture was placed in ice water bath for the termination of reaction. Toluene (4 ml) was added to the reaction mixture to isolate proline as supernatant. Absorbance of the proline supernatant was recorded at 520 nm using a spectrophotometer. Only toluene was used as a blank.

Nutrient analysis

Method of Wolf (1982) was followed for the determination of different nutrient contents. Dried sample (0.1 g) was grinded and digested in H_2SO_4 and H_2O_2 for the determination of nutrients (Na^+, K^+ and Ca^{2+}). Sulphuric acid (2.5 ml) was added in the digestion tube and further tubes were incubated overnight at room temperature. Then hydrogen peroxide (1 ml) was added to each digestion tube. Tubes was set in digestion block and heated to 350 °C until fumes were produced. Heating continued for a further 30 min and after that digestion tubes were removed from the digestion block. Appearance of colorless material in the digestion tube is the indication of completed digestion. Using deionized water, volume of the digestion material was made to 50 ml. Values of Na^+, K^+ and Ca^{2+} were determined with a flame photometer (PFP-7 ELE, Jenway Instrument Co. Ltd, Stone, UK).

Experimental design and statistical analysis

Experiment was set as a completely randomized design (CRD) with four replicates. Two factorial experiments consist of two levels of salt treatment and four canola cultivar. The data obtained were analyzed statistically by using Analysis of Variance (ANOVA) technique using the MSTAT- C computer package (MSTAT Development Team, 1989).

Results

Growth parameter

Salinity in the rooting growth medium markedly reduced root fresh and dry weight in four canola cultivars. A notable variation was recorded in this set. Maximum value of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42994309

root fresh weight was found in cultivar “Oscar and Dunkled” and minimum in “Ac excel and Cyclone” while root dry weight showed highest value in “Dunkled” as compared to all other canola cultivar under saline regimes (*Fig. 1*). Analysis of variance of the data showed that salt stress significantly reduced the root fresh and dry weight of four canola cultivars and a clear variable response was recorded (*Table 1*).

Leaf proline and MDA content

Addition of salinity in the root zone significantly increased leaf proline content in all canola cultivar. A significant variation was found in this regard. Highest value of leaf proline was found in “Ac excel and Dunkled” as compared to other cultivar under salt regimes (*Fig. 1*).

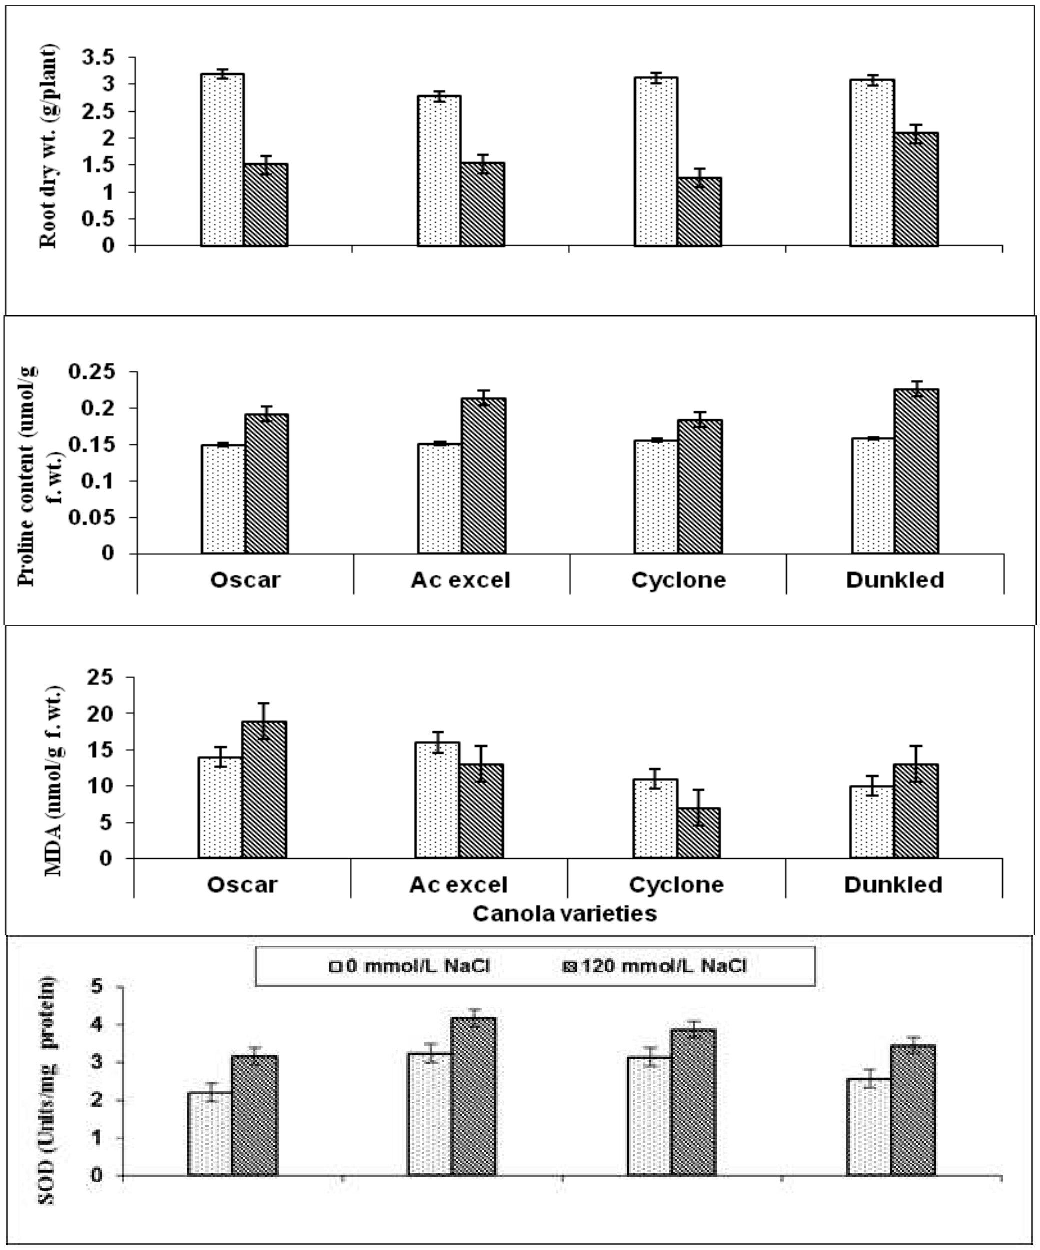

Figure 1. *Fresh and dry weight of root, leaf proline and malondialdehyde (MDA) content of four canola cultivars when treated to salinity stress for 48 days*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42994309

Addition of salt to rooting growth medium showed variable response in malondialdehyde (MDA) values in four canola cultivars. Cultivar "Oscar and Dunkled" showed increased while Ac excel and Cyclone showed decreased values of MDA under saline conditions (*Fig. 1*). Analysis of variance of the data showed that salt level and cultivars showed significant result in the set of leaf proline and MDA content (*Table 1*).

Nutrient analysis

Salinity in the growth medium increased Na^+ content in shoot and root of four canola cultivars. A variable response was noted in this attribute. Cultivar "Oscar and Cyclone" showed higher values in shoot Na^+ content while Ac Excel, Oscar and Cyclone in root Na^+ under saline conditions (*Fig. 2*).

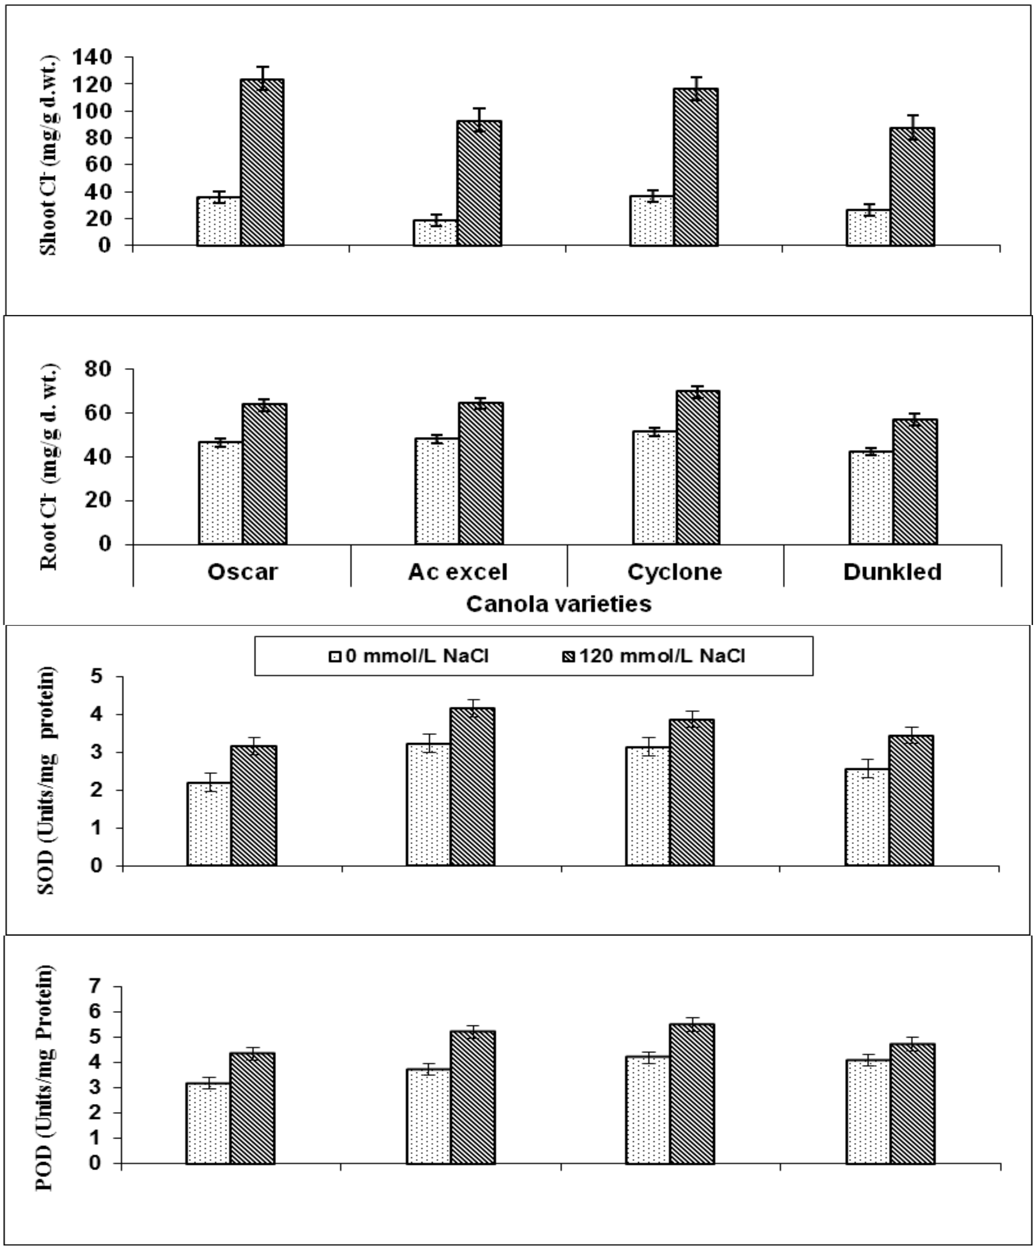

Figure 2. *Shoot and root Na^+ and Cl^- of four canola cultivars when treated to salt stress for 48 days.*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42994309

Addition of salinity in the rooting medium highly increased the values of root and shoot chloride (Cl^-) in four canola cultivars. A clear variation was found in this attribute. Higher conc. of chloride was found in the shoot of Oscar and Cyclone and root of Oscar, Ac Excel and Cyclone than those of other cultivars as compared to control (*Fig. 2*).

Increasing salinity in the rooting medium significantly decreased values of K^+ in four canola cultivars. A variable response was found in this set of parameter. Less reduction of shoot K^+ was found in Ac excel and Cyclone while root K^+ in Oscar, Ac excel and Cylone under saline conditions (*Fig. 3*). Salt stress significantly decreased Ca^{2+} in shoot and root in all canola cultivars. Less variation was observed in shoot Ca^{2+}. Less reduction in shoot Ca^{2+} was noted in Cyclone while in root Ca^{2+} in Oscar and Cyclone under salt regimes (*Fig. 3*). Analysis of variance of the data showed that salt level and cultivars showed significant result in the parameters of shoot and root Na+, Cl^-, K^+ and Ca^{2+} (*Tables 2* and *3*).

Antioxidant enzyme activities

Values of antioxidant enzyme activity (SOD, POD. CAT) were increased in four canola cultivars under saline conditions. A notable variation was found in these parameters. Higher value of SOD was found in cultivar “Cyclone and Ac excel” than in “Oscar and Ac excel” under salt stress. POD showed higher value in Ac excels and Cyclone while lower in Ac excel and Oscar under salinity stress. Less reduction in catalase activity was found in Oscar as compared to Ac excel, Cyclone and Dunkled under salt regimes (*Fig. 4*). ANOVA of data showed that salt level, cultivar and salt level × cultivar interaction showed significant results in the value of antioxidant enzyme activities (SOD, POD. CAT) (*Table 4*).

Discussion

To explore variation at inter and intra-cultivar level is a prime importance for a breeding program needing crop improvement for different abiotic stresses including salinity (Munns, 2007). Results of the present research work are in accordance with the finding of different researchers where biomass production (root fresh and dry weight) were significantly reduced in different crops e.g., mangrove plant (Parida et al., 2004), tomato (Foolad and Lin, 1997) and safflower (Siddiqi et al., 2011).

Salinity stress has severe damaging effect on plants through ion toxicity or nutrient imbalance which occur due to higher accumulation of sodium and chloride in differentparts of plant in different plants (Munns et al., 2002; Ashraf, 2004). Higher quantity of salinity (NaCl) in soil or water hinders the uptake of different essential nutrients, such as potassium and calcium due to which plants face the problem of nutrient deficiency (Parida et al., 2004; Siddiqi et al., 2011). In the present investigation, accumulation of salt in the rooting zone medium markedly increased the concentration of Na^+ and Cl^- while decreased that of K^+ and Ca^{2+} in four canola cultivars. In literature, it is reported that low accumulation of Na^+ and high K^+ showed salt tolerant cultivars of the different crop species such as barley (Wei et al., 2003) and safflower (Siddiqi et al., 2011). Plant vacuoles maintained the balance of various nutrients due to accumulation

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_42994309

of active osmolyte through osmotic adjustment. Of different osmolytes, proline is the essential one which amasses in various plants under saline conditions (Ashraf, 1994; Abbas et al., 2010). Present investigation showed that salt-stress increased the concentration of proline in the leaf of all canola cultivars. These results are in accordance with earlier findings where accumulation of proline under salt stress conditions has a key contribution to salt tolerance of various plant species (Maggio et al., 2002; Abbas et al., 2010). Furthermore, it is clearly reported in literature that proline accumulates more in salt-sensitive than in salt-tolerant cultivars (Ozturket al., 2012; Abbas et al., 2010).

Abiotic stresses including salt stress generate reactive oxygen species in plants (Turkyilmaz et al., 2014; Flowers et al., 2010). Plants have ability to counterpoise salinity-induced reactive oxygen species with the help of various antioxidant enzyme activities. In literature, it is reported that activities of antioxidant enzymes have a key role in salt tolerance of plant in different plant species. Findings of the present research work showed that addition of salinity in the growth medium increased the values of superoxide dismutase, peroxidase and catalase in all canola cultivars. Our results are in agreement with the findings on different crops such as wheat, safflower, finger millet and tomato where antioxidant enzymes produced under salinity stress (Raza et al., 2007; Ediga et al., 2013; Shalata et al., 2001).

In the present research work, values of MDA showed variable response in all canola cultivars under saline conditions, which are in accordance with the findings in the case of e.g. wheat (Ashraf et al., 2010), and finger millet (Ediga et al., 2013).

Conclusion

It is concluded that salt stress significantly increased sodium (Na^+), chloride (Cl^-) and leaf proline content of root and shoot, and enhanced the activities of SOD, POD and CAT, while it decreased the values of potassium (K^+) and calcium (Ca^{2+}). Overall, tolerance of canola to salt stress could be accredited to exclusion of Na^+ and Cl^-, higher accretion of K^+ and free leaf proline boosting antioxidant enzyme activities in canola cultivars.

(Received 23rd Mar 2018; accepted 12th Jun 2018)

Abstract. Vertical hydraulic conductivity (K_v) of riverbed is an important variable exerting impact on the exchange of water and salts between riverbeds and the surrounding underground water systems. However, there is little detailed information on the spatial variations of the riverbed K_v, and there is hardly any information on its timing variations. Time changes in the amount of K_v of the riverbed reveal the need for further studies as a potentially significant controlling factor in temporal variations in the amount and spatial patterns of water fluxes and solutes between groundwater and surface waters. With this in view, this study adopted a time series analysis approach to investigate the hydraulic conductivity measured over a year from January 2016 to January 2017 on a weekly basis for a downstream point of the Gorgan Ziarat River, Iran. The researchers first began to verify the hydraulic conductivity data, which was a downward trend during this period, from the particle size distribution of the riverbed for several times over the course of a year. Then, after identifying the existing data trends, autocorrelation and partial autocorrelation coefficients were determined. Finally, an ARMA model (1,1) was identified as the superior model. The mean squared error was used to evaluate the selected model. Moreover, Pert-Manto test was used to test the validity and reliability of the model.
Keywords: *riverbed, downstream, particle size, time series analysis, ARMA models*

Introduction

Hydraulic conductivity (K_v) of streambed is regarded as one of the most important controlling variables in the exchange of water and minerals between the rivers and the surrounding groundwater systems (Saenger et al., 2005; Storey et al., 2003). Variations in the location of K_v of the streambed may lead to increase in the water exchange rate between one stream and the Hyporheic region of the bed, which can lead to changes in the durability of the minerals and further cause intermixture in this area (Cardenas et al., 2004). Little information is available about the way such aspects of the exchange between the streambed and groundwater may be affected by the temporal changes of the K_v of the streambed.

Hydraulic conductivity (K_v) of streambed is an effective variable in the exchange of water and minerals between the rivers and the surrounding groundwater systems. There exists little information about the environmental changes of the K_v of the streambed and almost no information on its temporal changes. The environmental and temporal

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43114327

variation of K_v of a river in North Carolina during a one-year period was studied using 487 field measurements (Genereux et al., 2008).

The temporal changes of streambed's K_v determine further studies as a potential controlling factor in the temporal changes of amount and environmental patterns of water and the minerals between the groundwater and surface water. Using the available information, it seems appropriate to consider the streambed's K_v as a dynamic feature which is dynamic both in terms of time and location.

A pilot area (11.42 km in length) in Pajaro River located in the central beach of California was studied using the average reach and special point-based methods in order to determine the rate of leakage in the bed (Hatch et al., 2010). These data were utilized to assess the variation in the hydraulic conductivity of the streambed over time, as a function of the canal and changes are related to sedimentation.

The point-by-point leakage rate, which was determined using the time series analysis of the thermal records of the streambed, shows leakage rates of 1.4 meters per day (moving to the lower parts and into the center). The leakage rates had changes in time and place, such that the leakage mostly is occurred in lower end of the reach and during summer and fall.

These results show that the interaction models of surface and groundwater can benefit from the relationships between the stream, sediment load and the hydraulic features of the streambed (Hatch et al., 2010).

In the study accomplished by Min et al. (2013), the scholars have focused on the spatial changes of the vertical hydraulic conductivity of a stream in a meandering river of China. They observed that the change in the vertical hydraulic conductivity of the stream along the reach of the river was remarkable and high amounts of K_v is related to part of the canals with more deep water.

The evaluation of the 14 methods to determine the permeability was conducted through indirect measurement. The estimation of the value of hydraulic conductivity (K_v) was done based on the distribution curve of particle measurement (Fenza et al., 2017). All the methods were evaluated with regard to certainty, by comparing the measured parameters and the results obtained from the permeation experiments. The findings demonstrated that the amounts of K_v obtained from the distribution curves are smaller than the measured data, which could be due to the different depth of sediment sampling during the experimental analyses.

In this study, we analyzed the hydraulic conductivity during a one-year period. We tried to study the hydraulic conductivity of one area of a river during 52 weeks starting from January 20, 2017 and to see if we can come up with a formula to estimate the hydraulic conductivity during one year. Moreover, we extracted samples from the streambed at five different time intervals and sent them to the laboratory to analyze the changes in the grain size during the one-year time period. In addition, using experimental formulas, we measured the hydraulic conductivity and compared them with the data obtained using the stable permeation method. We reached an overall analysis about the interaction between the surface and groundwater.

Materials and methods

Study area

Ziyarat River, originating from Alborz mountain range, is located in Golestan Province, which is a northeastern area in Iran (*Fig. 1*). It flows to the north and after

36 km, and merges into Gharesoo River. The drainage basin in upstream is about 100 km^2 with dimensions of 19.64 km in length and 5.11 km in width. The mean of water abstraction rate at stream gauge is about 10.5 m^2. The study area is located in a temperate climate. The mean of annual precipitation is equal to 601 mm, and mean temperature is 13.4 °C. The variation in seasonal precipitation is distinctive and not uniform. The temperature of stream water varies from 19.04 to 29.2 °C. Although, the weather is rainier in winter, the majority of floods occur from August to November. The streambed sediments were alluvial coarse, sand-gravel, and clay and silt in downstream. The highest height of Ziyarat stream gauge is equal to 3068 m and the beginning of main river is 2620 m. The length of the river to Naharkhoran is 21 km with the slop average rate of 10.1% and the remainder of river to Ghorbanabad is 15 km with the slop average rate of 4.6%.

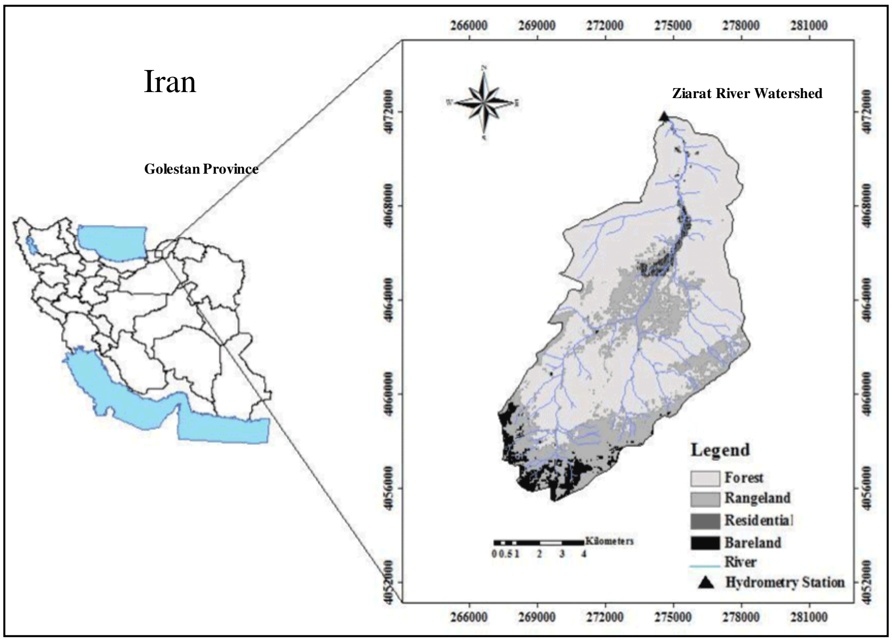

Figure 1. *The location of the study area along the Ziarat River*

The geographical position of the study area is shown based on latitude and longitude and the UTM coordinates system. It is evident that, most rivers stemming from the Alborz Mountain Range, are similar in terms of morphology and slope. Therefore, studying any of them can help us get familiar with other rivers of the same kind. In other words, the results of the study could be generalized to other rivers with alluvial bed. The area under study was located in downstream in Ghorbanabad, with a slope around 2%. The position of the area, as identified by the UTM system, is X:271732,Y:4089803 (*Fig. 2*).

Since the interaction between the surface and groundwater in the bed rivers has been widely investigated and is considered significant, in this study, we examine the potential of groundwater layers in the downstream, as they satisfy the needs of human beings for water through wells. Another reason for selecting this part of the river is the decrease in the hydraulic conductivity of this area due to being located in the downstream. This results in sediments with small grain size consisted of silt which act like an

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43114327

impermeable layer. In addition, studying the downstream is an undeniable necessity, as this area is under the danger of flood during summer and this natural disaster overfills the streambed with sediments consisted of mud which thickens the impermeable layer in the bed of the river.

Figure 2. *The location of the test point on the map*

The high frequency of flood occurrence in the summer for this region is due to the fact that this area is located adjacent to the Alborz Mountains, within south zone and it is also close to the Caspian Sea, in the north zone, as a result the high heat leads to evaporation and the formation of rainy clouds due to the high volume of water evaporation during summer season. Hence, the reduction in the temperature renders this volume of water evaporation into the intensive rains. Moreover, due to the high heat of soil and secrecy of humid heat air in the soil holes, the intensive rains during summer reason cannot permeate into the soil holes and the accumulated water will flow which will lead to formation of flood.

Methods

Vertical hydraulic conductivity

Falling-head test method

A falling-head test is conducted by rapidly raising the water level in the control well and subsequently measuring the falling water level. Slug-in test is another term for falling-head test. In the previous studies, a field permeameter method has been adopted for measuring vertical hydraulic conductivity (see e.g. Chen, 2005; Genereux et al., 2008; Song et al., 2010; Dong et al., 2012). The purpose of this method is to determine the streambed hydraulic conductivity (K_v), and, as it is illustrated in *Figure 3,* it operates by vertically inserting a pipe into the streambed, filling the pipe with water, and calculating the amount of decline of the water level inside the pipe. After repeating this process for a few times, the K_v can be measured using this rate. In the present study, steel standpipe with an inner diameter of 4.8 cm and length of 120 cm was used. The pipe was injected into the sediments of the streambed and it was ensured that the length of the sediment column was almost equal to 40 cm. A sensor (Onset HOBO Water

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43114327

Level-U20L-Series) with an accuracy of 1 mm was also employed to measure the water levels. Water was added during the test at the top of the pipe to create a hydraulic head. Then, the head was passed to fall in the pipe. In the current research, a water-level declining interval of 1 cm was used to record the hydraulic head and time. The hydraulic head estimations were obtained more than 3 times. To measure the K_v value using *Equation 1* proposed by Hvorslev (1951), all pairs of measured data of hydraulic head and time were used.

$$K_v = \frac{\frac{\pi D}{11m}+L_v}{t_2-t_1} ln(h_1/h_2) \quad \text{(Eq.1)}$$

Where D denotes the inner diameter of the pipe, m denotes the square root of the ratio of the horizontal conductivity K_h represents the vertical conductivity K_v (i.e., $m=\sqrt{\frac{Kh}{Kv}}$), L_v refers to the length of the sediment column, h_1 and h_2 are hydraulic head inside the pipe measured at times t_1 and t_2, respectively. Overall, K_h is greater than K_v. An adopted Hvorslev (1951) solution has been proposed by Chen (2004) and Song et al. (2009) in order to specify the K_v when L_v is greater than D (*Eq. 2*):

$$K_v = \frac{L_v}{t_2-t_1} ln(h_1/h_2) \quad \text{(Eq.2)}$$

However, the error in K_v from the formula provided by the modified formula of Hvorslev (1951). *Equation 2* is related to the ratio (L_v/ D) of the estimated sediment length (L_v) to the inner diameter (D) of the steel pipe. When $1 < m < 5$, if the ratio (L_v/D) is greater than 5, the error of the adopted estimation will be less than 5% (Chen, 2004).

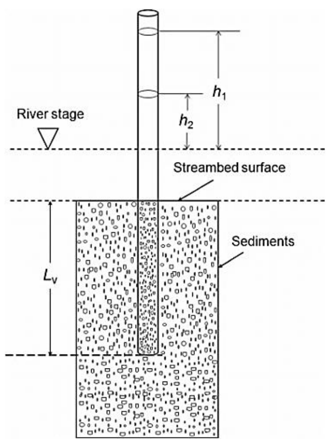

Figure 3. *Schematic diagram showing an in situ permeameter test to determine streambed*

The values of hydraulic conductivity were calculated weakly for this section of the river, in a regular manner and these values were analyzed in such a way that almost 52 values for hydraulic conductive were recorded during 52 weeks.

Verification of the hydraulic conductivity

Researchers have made a lot of efforts and introduced the grain size analysis of the particles in the sediments of the streambed for the autocorrelation of the parameters that have a direct relationship with the hydraulic conductivity (K_v) (Hazen, 1982; Rosas et al., 2014). Therefore, the hydraulic conductivity analysis of the streambed should be regarded as one of the methods to obtain the vertical hydraulic conductivity. Accordingly, the best method for sampling from the sediments of the bed is the vertical hydraulic conductivity to verify the process of sampling in the horizontal hydraulic conductivity (K_v)

Sampling from the sediments of the streambed

Since the present research aims at conducting a time history analysis on the hydraulic conductivity of a point of riverbed within one year, so the grain size of riverbed soil can be regarded as a proper parameter which has a high correlation with hydraulic conductivity. Therefore, a specific section of the river channel associated with river bed (at the afore-mentioned geographical length and width of X: 271732, Y: 4089803, in accordance with UTM coordination system) was opted and the results obtained for this section were compared with the values recorded for hydraulic conductivity of that section.

Since the sediments were soft in that part of the river, this task was done easily and the only point was ensuring that the device was operating properly.

A steel pipe was inserted 50 cm into the hyporheic zone in the bed of the river. A plastic pipe (40 cm) made of Polyvinyl chloride (PVC) was inserted into this steel pipe where the particles of the sediments pile up. There was leather cover above the open part of the pipe which disconnected the pipe from the surrounding atmosphere. The sediments accumulate in the pipe remain unchanged and will not fall when the pipe is pulled out from the bed (Song et al., 2009).

These samples were sent to the soil mechanics laboratory of Golestan Province. The grain size experiment was conducted carefully and it was noted that the smallest grain was .075 and the largest one was 10 mm. The particles smaller than .075 were identified as silt and clay and those between .075 and 2.0 were classified as sand. The grains larger than 2.0 were identified as gravel (Song et al., 2010).

Results

Grain size analysis

Grain size is the main controlling factor for streambed hydraulic conductivity (Song et al., 2010). Sampling from the sediments was accomplished in five sessions after obtaining the hydraulic conductivity. So, the analysis of grain size was done in weeks 1, 6, 26, 47 and 52.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43114327

Indeed, the primary objective of this research was to extract sediment from intended section, middle section and endpoint section of the riverbed within the first week, 26-th week and 52-end week, respectively. This project was defined for grading analysis. That is, these three extractions within the above-mentioned weeks were pre-defined, while the research team decided to perform random sampling method on the riverbed particles within 6-th and 47-th weeks too. In fact, this mode of week selections meets the requirements of purposive and random sampling method.

The curve of grain size is depicted by *Figure 5*. This study attempted to analyze the changes in the sediments of the streambed during the three time intervals. It is evident that during 1 and 6 weeks, the curves of the grain size are quite similar and this was expected, since the hydraulic conductivity for these two weeks were the same. During the middle stages of the study, the curve of the grain size tended to the left in such a way that the percentage of sand increased and the percentage of gravel decreased. These variation in the grain size occurred with a decrease in the hydraulic conductivity. During weeks of 47 and 52, the percentage of silt and clay increased and the percentage of gravel decreased. As it was expected, the hydraulic conductivity decreased to a great extent. The percentages of silt, clay and sand of the sediments for these five specimens are given in *Table 1*. It is evident that due to the occurrence of floods during summer in this region, which caused great changes in the morphology of the streambed, the hydraulic conductivity of the bed started to decrease noticeably from 26-th week. The increase in the percentage of silt and clay is evident in the samples taken from 26-th week. d_{50} in *Table 3* refers to the average diameter of particles of the sediments in millimeter the weight of which is less than 50% of the overall particles.

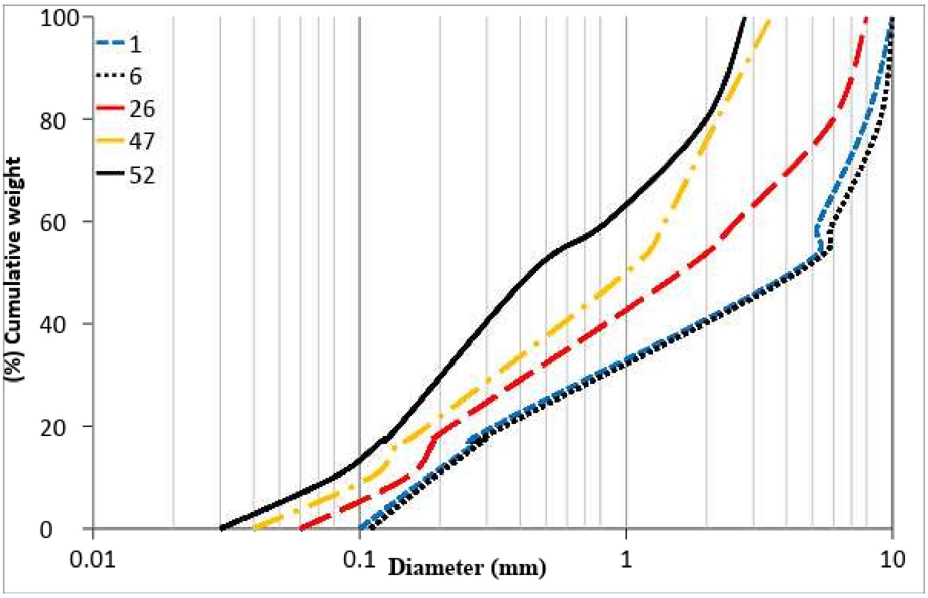

Figure 5. *Curve of grading distribution of the sediment fines of riverbed within selected five weeks*

The first step in the analysis of time series data is drawing the variable values during the period under investigation. This is influential in identifying the trends of the data which need to be extracted from the data before doing the analysis. *Figure 6* shows the values of the K_v index during the 52 weeks period which was analyzed by MINITAB 18

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43114327

Software. To determine the trend of the data, which is a descending trend, as the diagram demonstrates, the different visual functions, the second step and the S curve were evaluated. The results indicate that the S curve exhibited the best fitness for the trend of the data. The functional format of this curve is shown in *Equation 3*:

$$y_t = \frac{\alpha}{\beta + \gamma(\delta^t)} \tag{Eq.3}$$

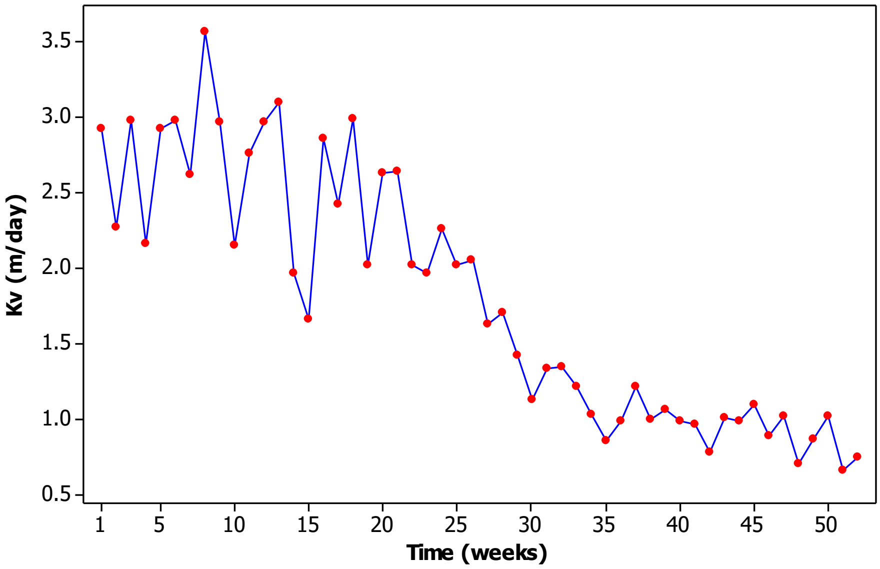

***Figure 6.** Time series diagram of K_v within 52 weeks*

***Table 3.** Grading distribution of 5 samples of particles within riverbed over a year*

Sample number	Sample 1	Sample 2	Sample 3	Sample 4	Sample 5
Per week	1	6	26	47	52
% < 2 mm	40.4	41.5	52.2	78.6	80.4
% < 0.075 mm (silt and clay %)	0	0	2.1	6.3	8.1
Average median grain size d_{50} (mm)	4.1	4.2	1.4	1	0.42

The α, β, γ, *and* δ parameters were estimated by the data and the values of the y_t trend were subtracted from the main values of the data. The remaining data from this section will be analyzed as the detrended data using the time series models. The values of the trend under this function are shown over the main values of the data. As it can be seen in *Figure 7, Equation 4* obtained from the fitness analysis is as follows:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43114327

$$y_t = \frac{100}{5.43+23.69(1.033^t)} \quad \text{(Eq.4)}$$

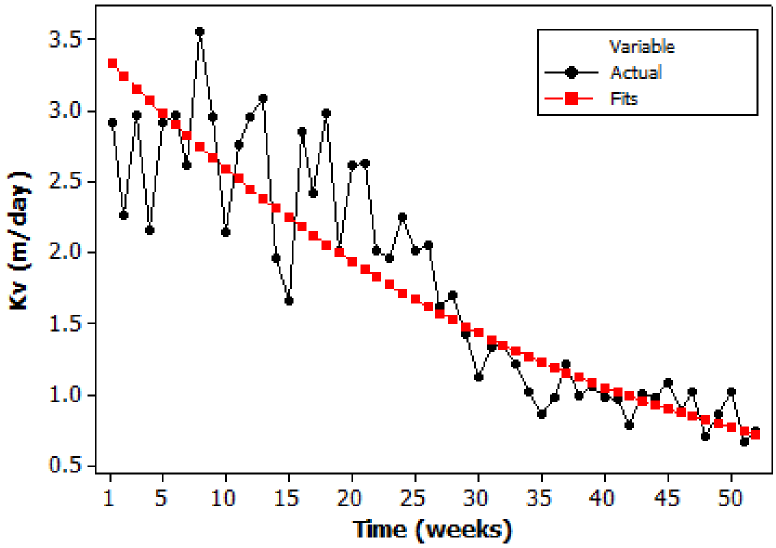

Figure 7. *Identifying the time series trend (K_v) under S curve*

After identifying the trends in the time series data, the first step in recognizing the model is to determine the values of autocorrelation. For this purpose, the values of ACF and PACF were calculated and drawn for the ACF and PACF of detrended data of 13 intervals which were identified automatically with reference to the length of the data. *Figures 8* and *9* show the values of ACF and PACF of detrended data (K_v), respectively.

As can be seen in *Figures 8* and *9,* the values of autocorrelation and partial autocorrelation of the data were insignificant only in the first interval which is an indication the fact that ARMA model with (1,1) parameters is fitted. To analyze the values more accurately, the statistics of their significance level which have the Student's t-distribution are also given in *Table 4*.

6	-0.08194	-0.47	-0.27918	-2.01	16.15
7	-0.0496	-0.29	-0.04806	-0.35	16.3
8	0.159692	0.92	0.179708	1.3	17.93
9	-0.07248	-0.41	-0.17439	-1.26	18.27
10	-0.04918	-0.28	-0.02614	-0.19	18.43
11	-0.14704	-0.83	-0.05485	-0.4	19.91
12	-0.0151	-0.08	0.065661	0.47	19.93
13	0.055656	0.31	-0.00882	-0.06	20.15

According to the results given in *Table 5,* it is evident that in the first interval both ACF and PACF were significant. The value of Ljung-Box, which was found to be equal to 5.03, shows the suitability of the first interval for the self-recursion sections and the average dynamic model.

To determine the optimum model among all the possible models which have parameters equal to the suggested values in the diagrams of ACF and PACF, the average square values of the model errors in data prediction were taken into account. Accordingly, models with different parameters were fitted for the data and the average square values of the model errors were compared and contrasted. In addition, since estimating the time series models results in error values in the model, the primary

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43114327

assumptions of the models (normality, equal variance, and independence) need to be checked. Among all the fitted models, most did not have desirable models as far as the primary assumptions were concerned. The statistics of the Ljung-Box test were also evaluated to check the information in the model error and, accordingly the model which significantly caused pure noises was selected. The ARMA model (1,1) consisted of one self-recursion term and one term of dynamic average.

Validation of the model

Taking into account the details of the model fitness, it can be seen that the self-recursion term in the first step of the time series model and the dynamic average component of the model were significant, so the index of K_v is significantly affected by the first interval. After fitting the model, determining the accuracy of the selected pattern is necessary. The root-mean-square error (RMSE) was used in this model. The mean square error for this model was found to be equal to .1357, which, compared to other estimated models, had an acceptable value. The criterion of the root-mean-square error (RMSE) was estimated based on *Equation 5*.

$$RMSE = \left[\frac{\sum_{i=1}^{n}(P_i - O_i)^2}{n}\right]^{1/2} \quad \text{(Eq.5)}$$

In *Equation 5*, n refers to the number of cases given to the model. Oi and Pi refer to the values of measurement and estimation, respectively.

Discussion

Checking the suitability of the model

One of the methods to analyze the residuals is analyzing the diagrams of the residuals. Accordingly, the first step is to check the normality of the residuals. *Figure 10a* shows that the error components are normally distributed. The histogram (*Fig. 10c*) also depicts that the residuals are normally distributed. The distribution of error values versus the fitted values shows that the expanded and contracted trends do not exist in this diagram. Accordingly, the error statements were independent from each other.

In order to determine the equal variance of the error components, the values of error were plotted based on the order of their occurrence (*Fig. 10b*). In this figure, it seems that the primary statements of error have more variance but this variance has not been different over time. Therefore, it is possible to consider the converting models like the MSM model as more suitable for these data than the ARMA or ARIMA models.

ARIMA model is considered as one of the best prediction models used for short-term time series analysis (Chang et al., 2012). In addition, the Holt-Winters time series analysis can be used when there exist seasonal or cyclic variation. Costa et al. (2015) have attempted to estimate the water qualitative parameters using Holt-Winters model whose findings have demonstrated the model efficiency. However, it is should be noted that models like Holt-Winters lead to greater error, compared to ARIMA Model. The diagram of the residuals versus time show that they are around zero with a fixed variance (*Fig. 10d*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43114327

The Pert-Manto test

A more formal method to examine the suitability of the model is the Pert-Manto test. This test is given at the end of all the outputs of the model fitness. This method is known as the Ljung-Box Test in the statistical software. The significance level of Ljung-Box statistics in this model is greater than the .05 error for the intervals of 12, 24, 36, and 48 (*Table 5*). This shows that there were not significant variations in the error statements for the modelling and the assumption that the residuals were not correlated, is confirmed. The primary assumptions of the error statements in the model are checked in *Figure 10*. *Figure 11* illustrates the fit values of K_v in the model in contrast to their real values. It seems that the obtained time series model can suitably explain the trend and changes existent in the data.

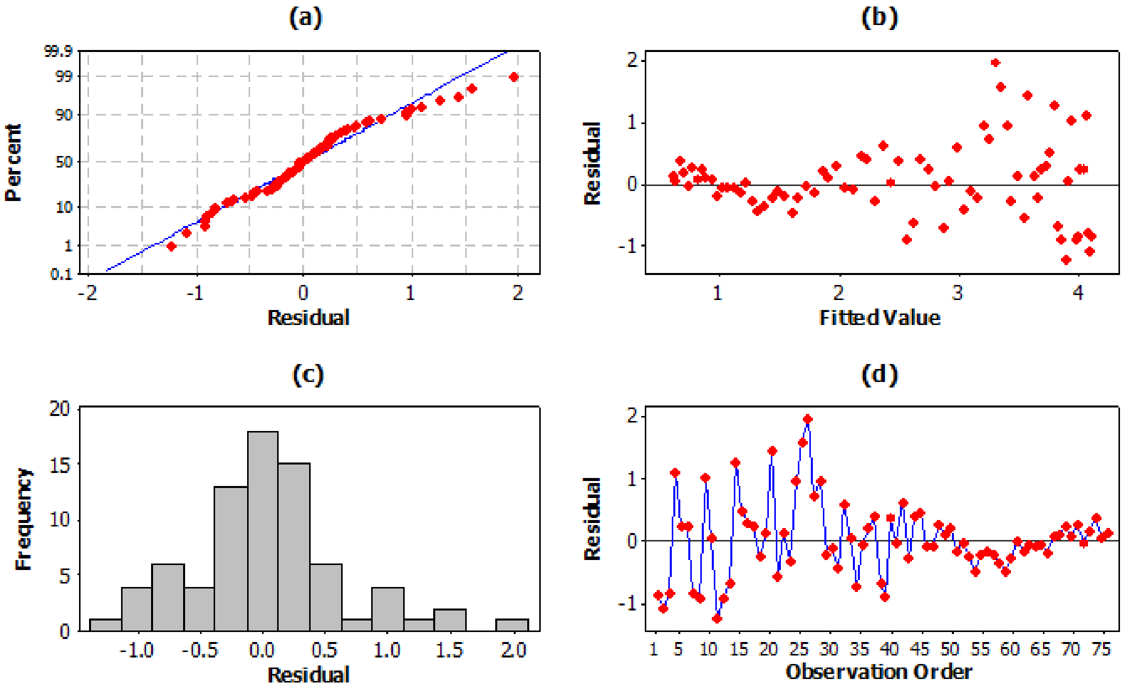

Figure 10. *Primary assumptions of model error terms.* ***a*** *Normality diagram.* ***b*** *Residual versus fitted values.* ***c*** *Histogram diagram.* ***d*** *Residual versus time*

Table 5. *Results of Ljung-Box test*

Delay time	12	24	36	48
Chi Square	14.2	29	32.6	37
Freedom degree	9	21	33	45
P-Value	0.117	0.114	0.486	0.797

To determine the goodness of fit and ensure that error statements of the model do not have any information, the diagrams of ACF and PACF were plotted for the components of the model error (*Figs. 12* and *13*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43114327

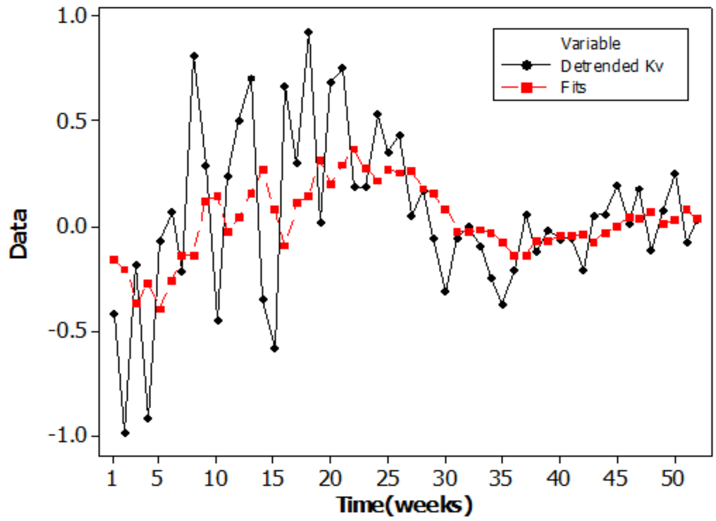

Figure 11. *Fitted values versus detrended real values of K_v*

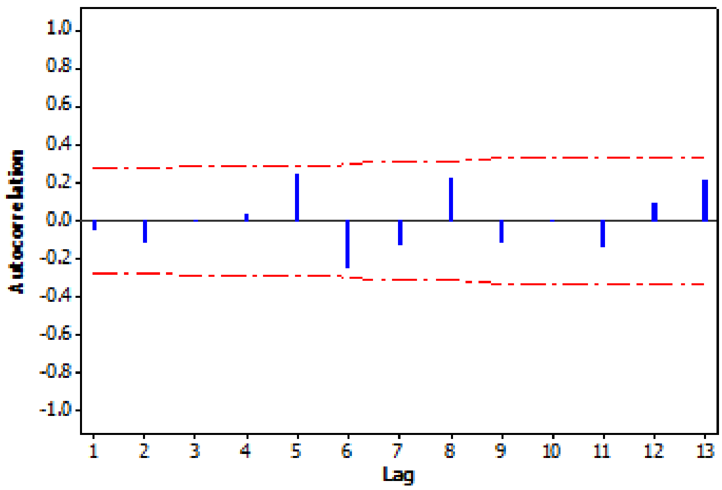

Figure 12. *Values of ACF function for model error elements*

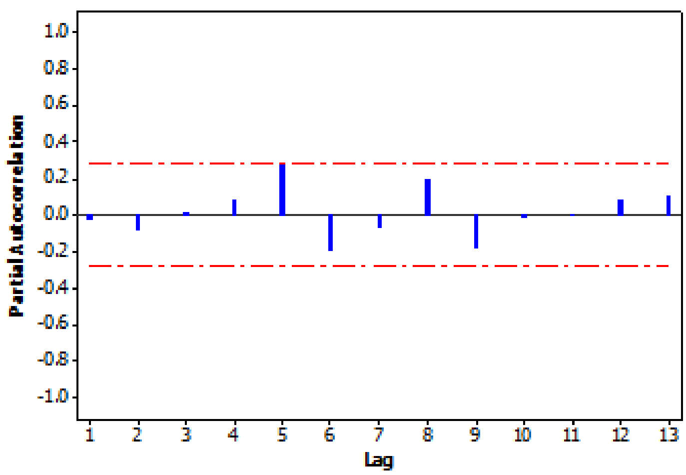

Figure 13. *Values of PACF function for model error elements*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43114327

The results showed that in all the intervals, these two indices were significant and the errors obtained from the model were around zero and no further information was available for modelling. Therefore, the assumption of independence of the residuals was accepted.

With reference to the suitable fitness of the model, the predicted values of K_v which were added to the trend values in the next steps and show the main predicted values for the K_v index during the following 52 weeks. *Figure 14* shows the predicted values by the model for K_v. However, with a closer examination and analysis of the impact and role of major factors on K_v, such a prediction is not very optimistic. Therefore, considering the next flood and its effect on the river bed layers, it is likely to expect quite surprising results on the time series model so that the flood phenomenon can be considered as a direct shocking factor for the time series model.

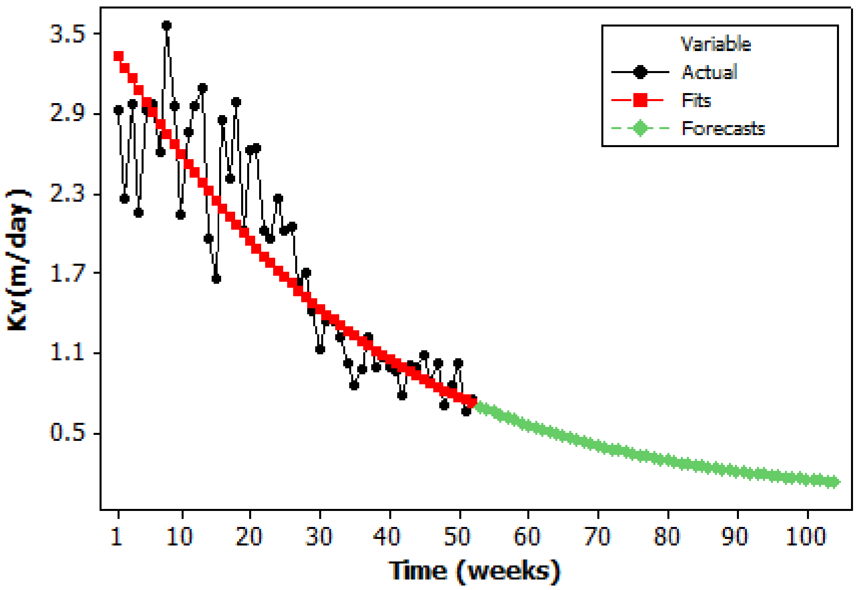

Figure 14. *Identifying the time series trend (K_v) for the next 52 weeks*

Unfortunately, there is little information about time series analysis of the hydraulic conductivity of the riverbed. For instance, Genereux et al. (2008) have focused on West Bear River, located at North Carolina, USA and the significant variation of the river within all 46 zones with 262 interval were measured in bimonthly manner. However, it is worth noting the investigation of hydraulic conductivity per two months cannot yield promising results and the resulted trend cannot be desirable in terms of predicting the hydraulic conductivity, while in our research, the measurements were done every 7 days. Wu et al. (2015) found that, after the flood season, the influence of bed-form on streambed K_v values was small, compared to that of the flood season. In the present study, it was observed that bed form of the river has a great impact on the hydraulic conductivity values prior to flood occurrence, and this finding is in line with that of Wu et al. (2015). It can be deduced that the impermeable layer consisted of silt and clay particles emerging within the river bed after flood, can affect everything, while the impact of other factors on the values of hydraulic conductivity is negligible (e.g. bedform).

It should be pointed out that the estimation of hydraulic conductivity of a specific zone of a river within a time can yield useful information on the exchange rate of surface and subsurface water. Moreover, time series analysis is a cost-effective solution for estimating the hydraulic conductivity. So the behavior of specific zone of a riverbed can provide us with relatively general information about river. For instance in the present paper, the influence of flood on degradation intensity of hydraulic conductivity was revealed and it can be inferred that the flood encompasses the riverbed with impermeable layer comprised of silt and clay particles, as a result the exchange rate of surface and subsurface water will decrease.

Conclusion

The time series analysis of hydraulic conductivity is one of the new methods to predict the trend of estimating the interaction between the surface and groundwater which helps human beings protect the rivers against natural disasters. Consequently, this study conducted a time series analysis to examine the hydraulic conductivity of one part of the downstream in Ziarat River in Gorgan, Iran. First, the data of hydraulic conductivity were verified and after identifying the trends, the values of autocorrelation and partial autocorrelation were determined. Finally, the ARMA model (1,1) was identified as the best model, but some external variables like flood were effective in the variation of hydraulic conductivity which led to evident changes in the morphology of the streambed and noticeably reduced the hydraulic conductivity. A look at the weather forecasts for this region shows the occurrence of flood in late July or August, but due to the inaccurate prediction of the flood, a variable that reduces the hydraulic conductivity is impossible. Considering the growing impact of major factors on K_v such as flood, It can be mentioned that predicting the hydraulic conductivity is difficult so it is suggested that time series analysis be performed in a period of 3 to 5 years. The obtained results can be generalized to other rivers of the same type, which have the same morphological conditions or annually experience one or more flood.

DETERMINATION OF THE MOST SUITABLE ECOTOURISM ACTIVITIES WITH THE ANALYTIC HIERARCHY PROCESS: A CASE STUDY OF BALAMBA NATURAL PARK, TURKEY

ÇELIK, D.

Programme of Landscape and Ornamental Plants, Vocational High School, Bartın University 74100 Bartın, Turkey
(e-mail: dcelik@bartin.edu.tr; phone: +90-378-227-9939/147; fax: +90-378-227-8875)

(Received 29th Mar 2018; accepted 12th Jun 2018)

Abstract. Ecotourism can be defined as tourism conserving the existing natural and socio-cultural structure, considering the balance between conservation and utilization, promoting the sustainability of natural resources, encouraging tourism activities, and developing the economic structure of the local community. Natural parks are areas where local and foreign tourists may join ecotourism activities due to their natural and cultural landscape potentials. Balamba Natural Park (BNP) located in the city of Bartin in Turkey, was chosen as a research area due to its natural landscape values and easy accessibility. The research method is composed of the following steps; data acquirement, field analysis, Analytical Hierarchy Process (AHS), Strengths, Weaknesses, Opportunities, and Threats (SWOT) Analysis, evaluation of findings, and conclusion and recommendations. This study aimed to determine the most suitable ecotourism activities in the existing potentials BNP. As a result, the study concluded that ecotourism activities such as botanical tourism, trekking, photo safaris, bicycle safaris and bird/butterfly watching could be implemented in the BNP.
Keywords: *natural and cultural landscape, nature conservation, land use, collaborative planning, Bartın*

Introduction

According to Hector Ceballos-Lascurain, ecotourism is a sightseeing tour of flora and fauna for touristic purposes and for observance and monitoring of cultural activities in natural areas that have not been interfered with by human beings (Cheia, 2013). This definition of ecotourism has recently become even more comprehensive. Ecotourism can be defined as responsible travel aimed at promoting the expansion of conservation awareness among both tourists and local residents, as well as conserving natural and cultural areas, maintaining sustainability, and raising the economic level of local communities (Gössling, 1999; Ceylan, 2004; Kuvan and Akan, 2005; Jaafar and Maideen, 2012; ESTA, 2016; Wishitemia et al., 2015; Verdugo et al., 2016; TIES, 2017). Briefly, the definition of ecotourism includes fundamental issues/characteristics such as natural and cultural areas, conservation, benefits for local residents, education, sustainability, ethics and awareness (Fennell, 2001).

With flora-fauna richness, aesthetic and natural beauty, water resources, active and passive recreational opportunities, the natural conservation areas and forests, where ecotourism activities are realized, have several potentials (Toskay, 1989). Ecotourism activities have several influences on the natural and cultural environment. However, the negative effect of these activities are at the lowest level, and the positive effects are at the highest level (Nyaupane and Thapa, 2004). In addition, ecotourism activities may contribute to the conservation of natural resources by providing economic support in this manner (Lopez and Monteros, 2002). Ecotourism may also accommodate several nature-based activities. Botanical tourism, mountain tourism, photo safaris, wildlife observation, cave tourism, adventure tourism, boating, and walking through forests or in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43294355

nature could be provided as examples. Furthermore, cultural tourism activities are also included within ecotourism activities (Erdoğan, 2003; Hussin et al., 2015).

There are various activities related to ecotourism in Turkey. For example, with the aim to develop ecotourism, the improvement of protected wildlife reserves, national parks and similar conservation areas and activities related to the protection of natural, cultural and aesthetic values, were included in the Five-Year Development Plans (EFYDP, 2000). In addition, ecotourism sites and the Tourism Strategies of Turkey were identified by the Ministry of Culture and Tourism, and the importance of issues such as sustainable use of natural and cultural resources and increasing the level of social consciousness and awareness were emphasized (TTS2023, 2007; EPD, 2017). In Turkey, as is the case in many countries, the national parks, protected wildlife reserves, etc., have been mostly utilized for ecotourism purposes (ESR, 2012). The definition of a natural park, from a legal dimension, was established with Turkey's National Parks Law No. 2873, and the authorized organizations were determined in this field (NPL, 2016.). According to the 2018 official data provided by the General Directorate of Nature Conservation and National Parks within the Ministry of Forestry and Water Affairs, there are 214 natural parks in our country (PA, 2018). Indeed, one of these parks is Balamba Natural Park. In terms of landscape potentials, BNP has the power to be an important centre of attraction in Bartın Province and the immediate surrounding areas. Therefore, the purpose of this study was to attain answers to the following questions: what are the existing landscape potentials of BNP? And, what are the most suitable ecotourism activities to utilize these potentials? This study also foresaw that any activities held in BNP should be assessed within the scope of ecotourism in terms of not harming nature, ensuring environmental sustainability, and providing economic benefits to the local community.

Material and methods

Study area

The main material in the study was BNP itself. BNP was located at 41°37'39.62" N and 32°21'47.59" E. Based on the 1/5000 scale master plan, there were residential areas in the southern and north-western areas in BNP and agricultural lands in the northern and eastern areas. The park covered an area of 13,105 ha. BNP was located in the eastern side of the central district in Bartın Province, at a distance of 2.2 km from the city centre, and on the Bartın–Karabuk Highway (*Fig. 1*). The park was located at an altitude of 13-30 m. Approximately 31.5% of the park had north-east-facing slopes, and 30% was considered to be within the range of the 10-20% slope group. It is located within the first degree earthquake zone. The First Revision Development Plan for the park was created in 2006. In this context, the Plan was aimed at protecting the natural resources and recreational potential of the area, developing without destroying the existing values, and ensuring sustainable development (Anonymous, 2006). While the Park Balamba was once used as an in-forest-recreational-ground, the land was converted from this status into a natural park, in accordance with the provisions from Article 3 of the National Parks Law No. 2873, dated 11.07.2011 (BNP, 2017).

Since BNP was located in Bartın city centre, it was selected as a research area and had a landscape potential to serve the communities in the city and in the immediate surrounding areas and also presented high local recognition and accessibility. In addition, this park was located in Bartın Province, which was previously selected for its

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43294355

potential in terms of biological diversity and ecotourism development in the Black Sea Region within the scope of Turkey's Tourism Strategy, 2023 (TTS2023, 2007).

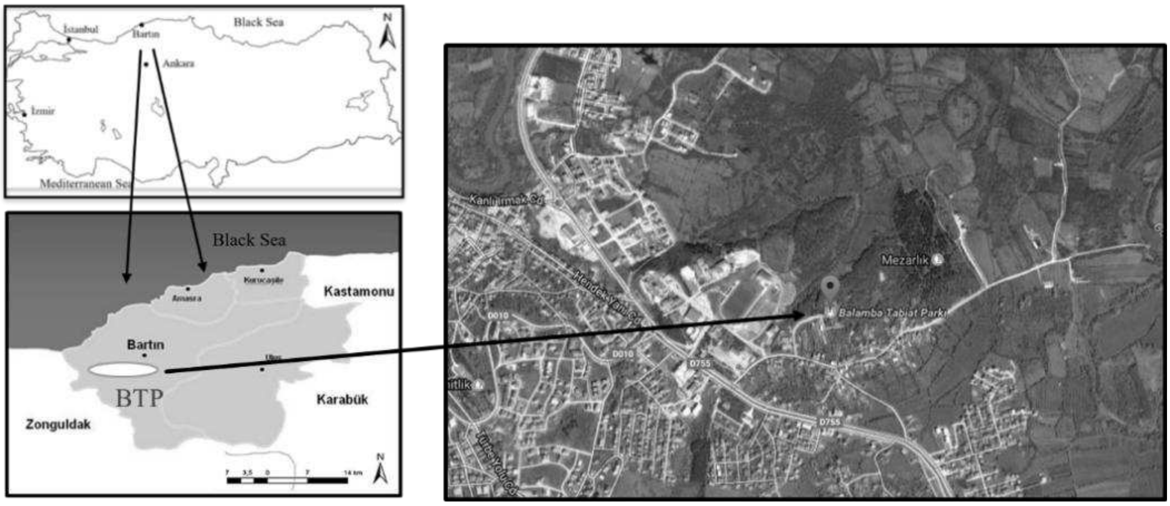

Figure 1. *Maps of the location of Bartın Province and BNP*

Methods

The methods in this research were developed by analysing studies in the literature (Saaty, 1994; Akpınar, 1995; Scholl, 2005; Timor, 2011; Akpınar Külekçi and Bulut, 2013; Yılmaz and Surat, 2015). The research was conducted within a six-stage method. These stages included literature review and data retrieval; land analysis and observation; administration of a questionnaire using AHP with the participation of experts among the relevant stakeholders; a SWOT (Strengths, Weaknesses Opportunities, Threats) analysis; evaluation of findings; and the conclusion and recommendations.

In the first stage, a national and international literature review was conducted on the topics of natural parks, AHP, BNP, ecotourism, etc., and the necessary required data were obtained through interviews at the related institutions and organizations. In the second stage, field analyses and observations were performed, and the current situation was determined by taking photographs when visiting the area of interest during different seasons.

In the third stage, a public survey was conducted by interviewing the stakeholders and experts who were considered relevant, such as representatives from the Bartın Provincial Directorate of Forestry and Water Affairs, Bartın Provincial Directorate of Culture and Tourism, Kure Mountains National Park Directorate, Bartın Municipality, Bartın University, Bartın Provincial Directorate of Environment and Urbanism, Bartın Provincial Representative of the Chamber of Landscape Architects, the Grand Astra Hotel (tourism enterprise) and a specialized tour agency. A total of nine experts participated in the questionnaire, including various professionals such as a landscape architect, forest engineer, art historian, archaeologist, construction engineer, tourism operator, botanist, and wilderness guide. The questionnaire made it possible to determine the most suitable ecotourism activity among the potential activities. Questionnaires were conducted by the author using the AHP method in June 2017. The AHP method was used for the ranking process and selecting the alternatives in accordance with multiple criteria. Questionnaires were administered to more specialized

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43294355

persons. In the fields of sensitive areas, education, health, planning, tourism, architecture, etc., the most suitable location, ecotourism activity, and selection of project or education methods, etc., were available for use by different professional disciplines (Saaty, 1977; Akpınar, 1995; Saaty and Vargas, 2006; Akten et al., 2009; Daşdemir and Güngör, 2010; Akpınar Külekçi and Bulut, 2012; Medjoudj et al., 2012; İmren et al., 2017; Chen et al., 2014; Yılmaz and Surat, 2015). In addition, with the use of the AHP method together with GIS (Geographic Information System), selection of the most suitable area can be achieved for planning green spaces in urban areas, selection of the most suitable solid waste area, and determination of the most suitable marina location, etc. (Lin et al., 2008; Gumusay et al., 2016; Şener et al., 2011).

The AHP method, developed by Saaty, allows us to use both qualitative and quantitative attributes. In the AHP, the factors within the scope of the goal and the sub-factors belonging to these key factors are determined first. Thus, the AHP decision hierarchy is established (Scholl, 2005). Subsequently, a binary comparison is made between the factors. The significance level or weights of the factors are determined. The consistency rate (CR) of the questionnaires is checked. If the CR is less than 0.10, the identified values are considered valid and acceptable (Saaty, 1994; Akpinar, 1995; Timor, 2011).

During the fourth stage, a SWOT analysis of the area was conducted based on the results of the field analyses, observation, the questionnaire data and literature review. SWOT analysis is a method used to determine the strengths and weaknesses of the studied environment, organization, technique, city, period, etc., and to identify opportunities and threats originating from internal and external environments. The objective of this technique is to develop strategies to obtain the maximum benefit from the strengths and opportunities available and to reduce the effect of the weaknesses and keep threats to a minimum. While the strengths and opportunities have a positive effect; the weaknesses and threats result in a negative effect. There are strong and weak aspects, which may be mostly under our control, in the internal environment. However, the external environment contains opportunities and threats, which are factors usually outside of our control. The possibilities to convert weaknesses, such as political, economic, sociocultural, and technological factors, into strengths have been carried out via SWOT analysis, and efforts are underway to remove the threats (Gürlek, 2002). SWOT analysis is also used for determining the current state and development of strategies on issues such as tourism, utilization of natural resources, sustainable development, conservation areas, and the energy and economic sectors (Ghinolfi et al., 2014; Scolozzi et al., 2014; Ghorbani et al., 2015; Açıksöz et al., 2016; Njoh, 2017).

In the fifth stage, the findings were analysed and evaluated from the perspective of the discipline of the landscape architecture profession by relating the findings to issues such as ecotourism and collaborative planning. In the sixth stage, however, the obtained results regarding the most suitable ecotourism activities for the existing potential were presented, and recommendations were formed.

Results

The current field usage

The current situation of the BNP was determined by field studies and observations. The park is under the influence of both the Black Sea climate, which is hot in summer and cool in winter seasons, and a forest ecosystem. The BNP is entered by a single

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43294355

access point. At this entrance, there are fees for vehicles and visitors. In the entrance area, there are a parking lot, a water-well, a rural-casino, an amphitheater, a information desk, a basketball court, children's playgrounds, and pergolas. There are also 40 picnic tables, 30 barbecues and 6 fountains that are located in suitable places throughout the area. The 2-meters-wide walking trail and 1153-m-long and 4-m-wide existing forest road, of which both were decided in the 1st Revision of the BNP Development Plan, are still in use at the present time. There are tennis courts and areas for fitness equipment on the walking trail. In the park, there are also four natural water channels for drainage, especially for the rainy periods against rain falls. Bridges are constructed for passing over these water channels. Today, the use of park continues as a picnic area and walking area, and as well as photographing area for weddings.

Questionnaire results

Using the AHP method with the expert group, a questionnaire was conducted to determine the ecotourism activity that best suits the current landscape potentials of BNP. The AHP full-hierarchy model generated for BNP is shown in *Figure 2*.

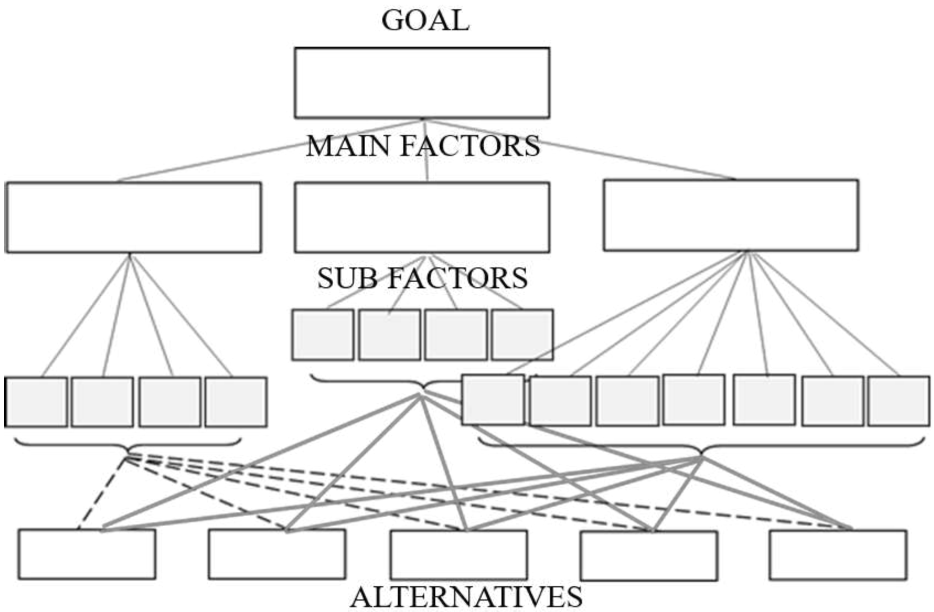

Figure 2. *Full AHP Hierarchy modes for BNP*

The purpose of this questionnaire was to make a classification between the main factors, sub-factors, and alternatives. For this purpose, 19 questions containing the key factors, sub-factors and alternatives were asked to the experts. The natural and cultural landscaping potentials were considered when determining the main factors and sub-factors. These factors were identified based on the literature review (Akpınar, 1995; Akten et al., 2009) performed on BNP-related studies and field analyses. While the main factors were composed of 3 variables, the sub-factors consisted of 15 variables, and the alternatives included 5 variables. The main factors consisted of the following variables: natural factors, socio-cultural and economic factors, and factors related to targets and policies regarding land usage. The main factors, sub-factors and alternatives are presented in *Table 1*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43294355

The Expert Choice (EC) software program was utilized for calculations and use of the AHP method. When the data obtained from the AHP were analysed, binary comparisons were also performed between the main factors and sub-factors. By using this program, the significance levels and weights of the factors, as well as the weight scores of the alternatives/ecotourism activities for each factor were determined. The questionnaires were determined to be meaningful since their consistency rates were identified as below 0.1. In addition, sensitivity analysis was also performed on the main factors. The survey results via use of the AHP are summarized below.

Table 1. *Main factors, sub-factors and alternatives used in the questionnaire*

Main factors	Sub-factors	Alternatives
Natural Factors (NF)	Climate	• Botanical tourism • Trekking • Bird/butterfly watching • Photo safari • Bicycle safari
	Flora/fauna	
	Topography	
	Geographical location	
Socio-cultural and economic factors (SCEF)	Transportation	
	Economic status of visitors	
	Demographic structure of visitors	
	Existence of nearby attraction centres	
Factors related to land use targets and policies (FRLUTP)	Biodiversity conservation	
	Satisfaction of recreational needs	
	Preservation of visual landscape potentials	
	City branding	
	Diversification of tourism activities	
	Increase in business opportunities	
	Improvement of infrastructure	

For the binary comparison between the factors, experts were asked to generate an assessment in accordance with the basic scale listed in *Table 2*.

Table 2. *The significance levels and their definitions used in the binary comparison among criteria (Saaty and Vargas, 2006)*

Significance level	Definition
1	Equal importance
3	Moderate importance
5	Strong importance
7	Very strong importance
9	Extreme importance
2, 4, 6, 8	Intermediate levels

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43294355

Based on the existing potentials, which were obtained from the experts, a binary comparison matrix, in which each main factor was compared with the others for determination of the most suitable ecotourism activities, is presented in *Table 3*.

Table 3. *The binary comparison matrix of the main factors*

	NF	SCEF	FRLUTP
NF	1	4	3
SCEF	1/4	1	1/2
FRLUTP	1/3	2	1

In *Table 3*, factors in rows were compared to factors in columns. These comparisons were presented as questions in the questionnaire form. The natural factors were scored with 4 points when compared to the sociocultural and economic factors and 3 points when compared to the factors related to targets and policies for land usage. In this case, the natural factors had priority for significance at the outset.

According to *Figure 3,* when the main factors, which were assumed to be effective for selecting the ecotourism activities by experts, were classified based on their weight ratios, 'natural factors' was ranked as the factor with the highest weight ratio (0.625).

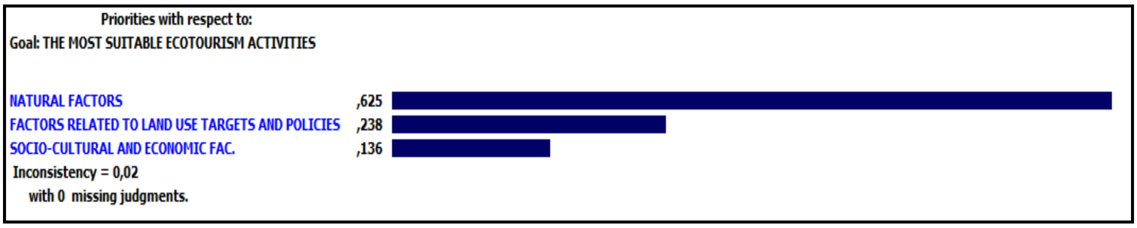

Figure 3. *The weight ratios for the main factors*

The sub-factor of flora/fauna was rated with the highest score by the experts. The binary comparisons among the sub-factors of the natural factors are also shown in *Figure 4.* According to *Figure 4,* the significance levels of the sub-factors of the natural factors were ranked as follows: flora/fauna, climate, topography, and geographical location.

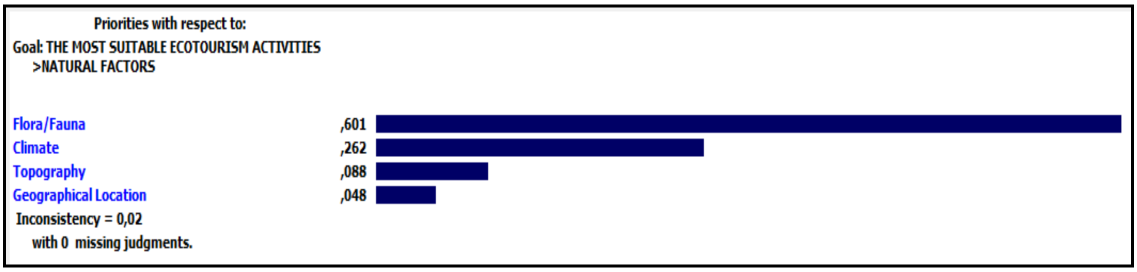

Figure 4. *The weight ratios of the sub-factors related to natural factors*

As a result of the binary comparison of natural factors with alternatives, botanic tourism had the highest weight ratio (0.338) (*Fig. 5*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43294355

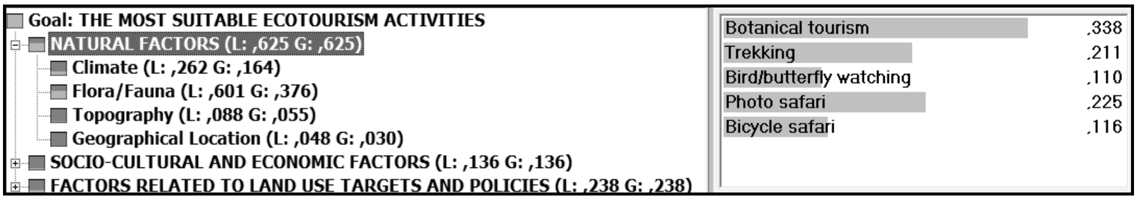

Figure 5. *The weight ratios of the ecotourism activities based on the natural factors*

Trekking had the highest weight ratio based on the binary comparison of climate and topography sub-factors with alternatives. When the flora/fauna and geographical location sub-factors were compared with alternatives, however, botanical tourism received the highest weight ratio.

The sub-factor of transportation was rated with the highest score (weight ratio 0.542) by the experts. According to *Figure 6* the significance levels of the sub-factors belonging to the socio-cultural and economic factors were ranked as follows: transportation, demographic structure of visitors, existence of nearby attraction centres, and economic status of visitors.

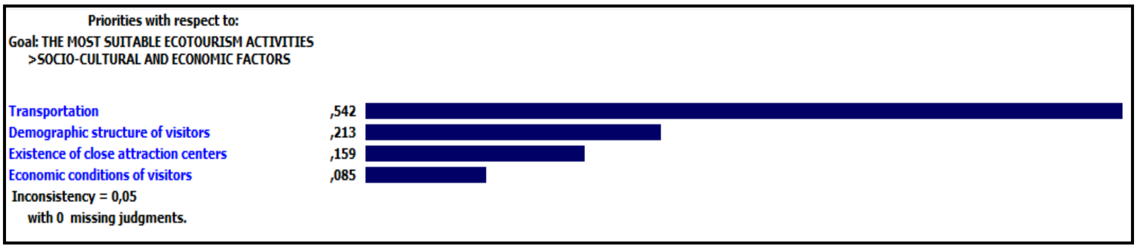

Figure 6. *The weight ratios of the sub-factors related to socio-cultural and economic factors*

As a result of the binary comparison of socio-cultural and economic factors with alternatives, trekking was identified as the highest weight ratio (0.507) (*Fig. 7*).

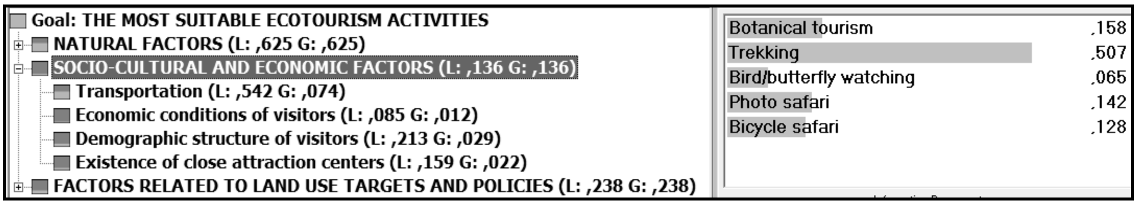

Figure 7. *The weight ratios of the ecotourism activities based on the socio-cultural and economic factors*

The binary comparison of alternatives with sub-factors, such as transportation, economic status of visitors, demographic structure of visitors, and the existence of nearby attraction centres, resulted in the identification of trekking as the activity with the highest weight ratio.

The binary comparison among the sub-factors of the main factor related to land use targets and policies is shown in *Figure 8*. The sub-factor of conservation of biodiversity was rated with the highest score (0.401) by the experts. Others were ranked in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43294355

following order: diversification of tourism activities, city branding, improvement of infrastructure, preservation of visual landscape potentials, increase in business opportunities, and satisfaction of recreational needs.

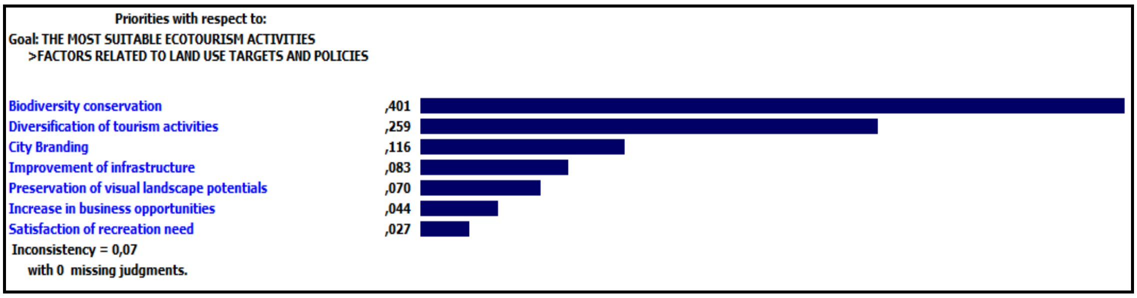

Figure 8. *The weight ratios of the sub-factors of the main factor related to land use targets and policies*

As a result of the binary comparison of alternatives with the factors related to land use targets and policies, botanical tourism received the highest weight ratio (0.330) (*Fig. 9*).

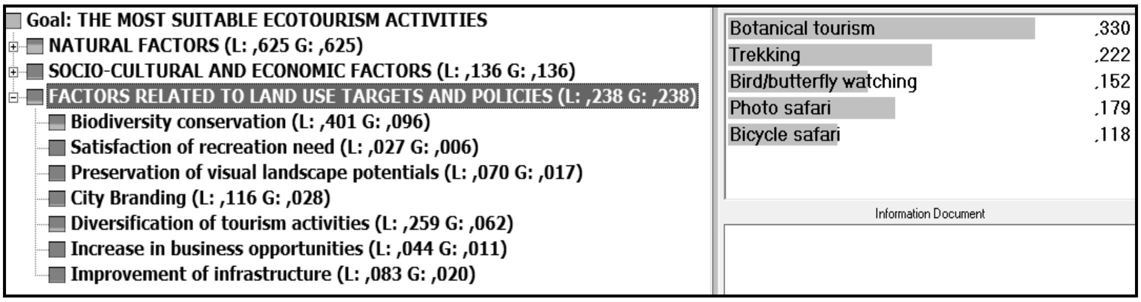

Figure 9. *The weight ratios of the ecotourism activities based on the factors related to land use targets and policies*

When the binary comparison was performed among the alternatives and the sub-factors, such as biodiversity conservation, satisfaction of recreational needs, city branding and increase in business opportunities, botanical tourism obtained the highest weight ratio. In the case of the binary comparison among the alternatives and the sub-factors, such as preservation of visual landscape potentials and diversification of tourism activities, trekking resulted in the highest weight ratio. The bicycle safari, however, received the highest weight ratio as a result of the binary comparison of alternatives with the sub-factor of improvement of infrastructure.

The sum of the weight ratios for all of the criteria was ‘1’. Hence, the comparison was consistent since the resulting rate was CR < 0.1.

The sensitivity analysis performed on the main factors is presented in *Figure 10*. While the natural factors had a 62.5% significance level, botanical tourism was in the top position with a significance level of 31.3%.

When the significance levels of socio-cultural and economic factors were increased from 13.6% to 65.2%, the order of the alternatives did not change. Additionally, trekking still remained in the leading position (*Fig. 11*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43294355

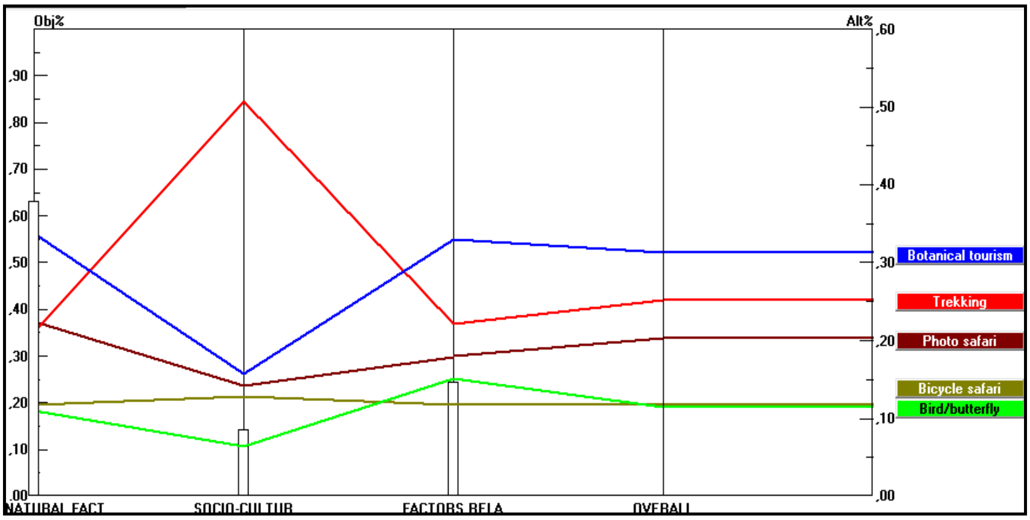

Figure 10. *The sensitivity analysis of the main factors*

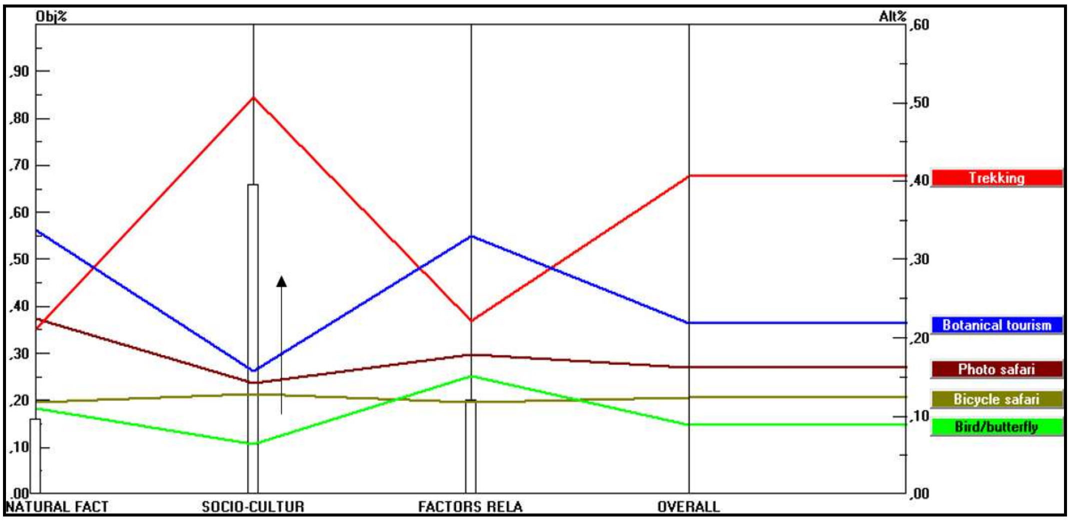

Figure 11. *Significance level of socio-cultural and economic factors*

Botanical tourism was also ranked the highest when the significance level of factors related to land use targets and policies was increased from 23.8% to 61.3% (*Fig. 12*). Hence, botanical tourism had a preferential significance level for BNP.

SWOT analysis

Field analyses and observations were made via visiting the field in different seasons. The current situation was determined by photo shoots. In addition, literature review was performed. In this context, the following studies and reports were analyzed; the 1st Revision of Development Plan and Report for the BNP prepared by the Bartın Provincial Directorate of Environment and Forest (Anonymous, 2006); the ‘Strategic Goals and Provincial Development Plan’ prepared by the Bartın Provincial Directorate of Planning and Coordination (Anonymous, 2008); the ‘Bartın Province Tourism Action Plan’ for 2012–2016 period prepared by the Bartın Provincial Directorate of Culture

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43294355

and Tourism (Anonymous, 2011); the ‘Strategic Plan’ for 2015–2019 period prepared by the Bartın Municipality (Anonymous, 2014); the ‘Regional Plan’ for 2010–2013 period prepared by the Western Black Sea Development Agency (Anonymous, 2009); and the article themed on the importance of open green areas in branding of Bartın Province (Çelik, 2017; *Table 4*). With this analysis, the strengths and weaknesses and opportunities and threats of BNP were determined. The study also determined how strengths and opportunities might be assessed and how weaknesses could be converted into strengths as well as what could be undertaken to remove the threats.

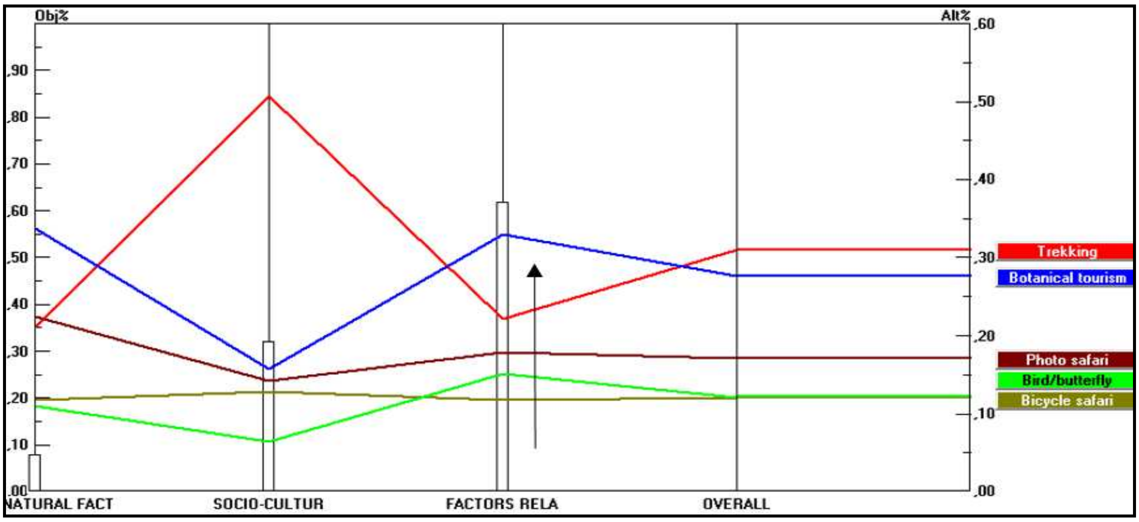

Figure 12. *Significance level of factors related to land use targets and policies*

As a result of the field analysis, the following issues were determined the strengths of BNP: absence of any residential areas and no deterioration of natural structures due to less frequent use, preparation of an in-progress development plan for the Park, presence of potential recreational activities, the existence of a safe environment, close proximity to important routes such as the Bartın-Karabuk Highway, and the famous destinations such as Amasra, Inkumu, Yedigoller, which have favourable climatic conditions and rich floral as well as faunal diversity, and finally, the absence of a property problem. As a result of the scientific research project (No.2016-FEN-A-001-author included) conducted in BNP, researchers determined that the Park contained a total of 50 families, 115 genera and 130 taxa. These aspects might be important forces for implementing ecotourism activities and for contributing positively to city branding as well as local and regional economic development. Again as a result of the surveys and observations, the positive reaction of the local community to development of the tourism sector, enthusiasm for environmental protection by both the local community and tourists, lack of agriculture and livestock activities, and tourist attraction potential of Bartın Province were considered opportunities in BNP. However, insufficient urban equipment and walking/running road information signage, lack of timely landscape maintenance and repair work, and insufficient promotional activity for BNP were considered weaknesses in the area. The absence of an application-oriented landscape project in this field of study, the lack of adequate investment activity in the tourism sector, and the increasing use of ecotourism activities that caused complications for biodiversity conservation were also listed as threats.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43294355

Table 4. *The SWOT analysis related to ecotourism*

INTERNAL ANALYSIS	STRENGTHS	• Suitable climate conditions for ecotourism activities • Rich floral and faunal diversity • Existence of an in-progress Development Plan for BNP • Natural Park status • High potential landscape value, visually • Close proximity to Bartın city centre • Easy intracity and intercity transportation • Presence of a forest ecosystem • Close proximity to important destinations such as Safranbolu, and Yedigoller • Location in a secure area
	WEAKNESSES	• Insufficient promotional activity for BNP • Lack of infrastructure (information desks, buffets, urban equipment, etc.) • Lack of maintenance for tennis courts, volleyball courts and conditioning places • Lack of timely landscape maintenance and repair work • Lack of trekking trails maintained with desired plate stones and grass joints
EXTERNAL ANALYSIS	OPPORTUNITIES	• Local community's positive reaction to development of the tourism sector • Safety of Bartın as a secure city • Areas for souvenirs and shopping • Local community's positive reaction to environmental protection and BNP • Tourism brand potential of Bartın Province • Traditional handicrafts and food, existence of historical buildings, and development of ecotourism activities and business opportunities • Possibility for improvements in infrastructure • Possibility of diversifying and extending tourism activities throughout the year • Possibility of satisfying the recreational needs of the community • Possibility for conservation of visual landscape potentials • Perception of Bartın Province as a natural beauty • Location of Bartın in close proximity to Ankara and Istanbul cities
	CONSTRAINTS/THREATS	• Lack of application-oriented landscape projects • Wedding parties in the area • Possibility of the pressure for extensive use • Placement of newly added informational signboards for flora and fauna in a way that disrupts the existing integrity • Lack of an adequate amount of tour agents to contribute to the advertisement of Bartın Province • Lack of an adequate level of touristic events and activities in Bartın Province • Possibility of encountering difficulties in biodiversity conservation due to increasing demand for ecotourism activities • Lack of quality service and professionalism in the accommodation facilities in Bartın • Lack of infrastructure opportunities in Bartın Province (parks, parking areas, banks, post offices, social facilities, etc.) • Insufficient promotion and marketing activities for Bartın and its surroundings

Discussion

Various studies have been conducted both in national and international literature to identify the natural and cultural potentials of national parks, natural conservation areas, and natural parks and to determine the most suitable recreational or ecotourism activities for these potentials. Similar or different aspects of this research with the other conducted studies were summarized below. For example, in a study based on the socio-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43294355

economic and cultural structure of a local community in Ol Donyo Sapuk National Park in Kenya, the research noted that ecotourism would contribute to economic development at the local and regional scale (Owino et al., 2012). This result was also supported by Yunus et al. (2013). In a survey study conducted for a Malaysian National Park, researchers emphasized that the implementation of ecotourism would be appropriate for increasing the income level of a local community and for achieving land use conservation. Similarly, the conservative use of natural resources, maintenance of sustainability, and engaging in ecotourism activities to accelerate local development were also predicted for BNP. This study also determined that ecotourism activities would be primary contributors to the socio-economic structure of Bartın's local residents.

When studying the Iron Gates Natural Park in Romania, Boengiu (2012) initially examined the available resources and infrastructure in order to determine the development potential for tourism. As a result, the study stated that attractive natural resources and natural monuments had potential values for tourism. In addition, Öztürk (2005) investigated the natural and cultural landscape potential of Kastamonu-Bartın Kure Mountains National Park on the basis of recreation and ecotourism concepts and determined the most suitable activities for ecotourism. These included activities such as wildlife viewing, trekking, photography, etc. Using SWOT analysis, Orhan and Karahan (2010) identified Uzundere's natural and cultural landscape potentials and determined the relevant ecotourism activities. In this context, religious tourism, trips to Tortum Waterfall and Ruins, picnicking, and festivals were listed as promising tourism activities. Similar to these studies, the current potentials of BNP were determined using SWOT analysis. However, the proposed ecotourism activities for BNP were varied. BNP had the potential for activities such as trekking, botanical tourism, photo safaris, bicycle safaris, etc.

In a study conducted by Nahuelhual et al. (2013) on a local level in southern Chile, the researchers noted that the unprecedented natural beauty had recreational potential. Additionally, Aminzadeh and Ghorashi (2007) investigated the relationship between recreational activities and aesthetic and ecological potentials in their research, which was conducted in Siangtan Forest Park in Iran. As a result, they indicated that recreational activities attracted attention in areas of natural beauty instead of in designed spaces. Similarly, this research concluded that BNP also had rich flora. As a result of the floristic studies conducted in BNP, a total of 130 taxa were identified. The park contains recreational potential due to its natural landscape values. With organized events, tourists and local residents will receive benefits from these recreational and ecotourism activities.

Within the context of landscape planning/restoration, alternative land uses following mining activities were determined by Akpınar (1995) using the AHP method. These alternatives were also prioritized. The priority order of ecotourism activities in the Yusufeli District of Artvin Province was also determined using the AHP method from Yılmaz and Surat (2015). According to the AHP analysis results, a nature exploration walk was identified as the ecotourism activity with the highest priority value. Similarly, BNP questionnaire data obtained from the experts were utilized in the AHP method, and the ecotourism activities, which could be implemented in BNP, were determined. The priority order of the ecotourism activities was determined; thus, botanical tourism was the top ranked activity. Other important activities identified were trekking, photo safaris, bicycle safaris, and bird/butterfly watching.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43294355

To select the most suitable ecotourism activity in the Oltu and Olur Districts in Erzurum Province, a questionnaire was conducted using the AHP Method. The study emphasized that the ecotourism activities would contribute to promotion of the region (Akpınar Külekçi and Bulut, 2012). This result also aligns with the conclusion that ecotourism contributes to the promotion and branding of Bartın Province.

In a study conducted by Jalani (2012) in the Puerto Princesa Subterranean River National Park, the research stated that the local communities would receive new employment opportunities and their economic conditions would prosper due to ecotourism activities. In addition, the study concluded that city development would increase through ecotourism activities. These findings paralleled the results of the research performed in BNP. This study also concluded that the ecotourism activities in BNP would generate new employment opportunities for the local community and increase residents' economic incomes as well as the quality of urban infrastructure.

The existing natural and cultural values of the Karapinar District in Konya Province were determined using SWOT analysis. As a result, planning, management and monitoring requirements were emphasized in order to ensure the long-term sustainability of ecotourism (Önder and Polat, 2004). Similarly, the SWOT analysis technique was also used to determine the existing natural and cultural resources of Oltu District in Erzurum Province for the ecotourism potential. The research stated that development of ecotourism policies at regional and national scales was required to avoid harming the natural biota (Akpınar Külekçi and Bulut, 2013). The SWOT analysis performed for BNP also presented similar results. Ecotourism may be used as a tool for sustainable economic development at local, regional and national levels. In the tourism industry, attention should be given to planning, implementation, supervision and monitoring as well as to compliance with necessary laws and regulations.

Güngör and Polat (2017) stated that the local community in Konya was intensively using the urban parks for picnicking. They indicated that the visitor capacity of these parks could be at risk under such high pressure, and environmental pollution might increase to the degree that other visitors might feel uncomfortable. Therefore, the authors emphasized that allowing picnics and recreational activities, etc. in the forest area near the city might reduce this overuse pressure. Similar to that result, BNP has the characteristic of being a potential area for use as an alternative to publicly open green spaces in the city centre. By engaging in recreational events or ecotourism activities in BNP, both local communities and tourists will contribute to reducing pressure on publicly open green spaces in the city centre. There are one hundred and four parks in Bartın city. These parks are different sizes, and including playground areas, sporting areas, hiking trail, etc. These urban open green areas have been extensively used in Bartın (Anonymous, 2014).

Conclusions

In conclusion; with the aim of determining the existing landscape characteristics of the BNP, literature reviews, field analyses and observations were performed. Literature reviews and data obtained for Bartın city were analyzed for the BNP. In this context, data were obtained regarding geographical location, transportation status, topographical and geological structures, climatic characteristics, flora and fauna characteristics, historical development, technical and social infrastructure, tourism and recreation relations.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43294355

Questionnaire were also conducted to an expert group in order to determine the most suitable ecotourism activities in the identified landscape potentials. The surveys were analyzed using the AHP method. Experts recommended ecotourism activities in the following order such as botanical tourism, trekking, photo safari, bike safari, bird/butterfly watching in line with the current potentials of the BNP. Ecotourism may be used as a tool for conservation, and sustainable use of landscape values for the BNP.

The ecotourism activities have the power to contribute to economy and local tourism sector. Thus, it will be possible to diversify tourism activities and spread them throughout the year. Ecotourism activities also have a strong effect on the economy and contribute to positively activating the local tourism sector. Thus, diversification of tourism activities and extending the activities throughout the whole year is possible.

In this context, the following recommendations were developed for ecotourism-oriented use of BNP:

- Initially, the visitor capacity of the park should be identified,
- Structural and botanical landscape design projects should be prepared to include disadvantaged groups,
- These projects should be conducted by a multi-disciplinary team,
- After the implementation of a project, landscape maintenance and repair work should be performed by a certain level of experts,
- Training activities should be planned to elevate the environmental protection awareness level,
- Tourism infrastructure should be developed in Bartın city centre,
- Promotional activities for Bartın and BNP should be increased.

In this process, it is very important to compel stakeholders to work together such as those from the public and private sectors, universities and NGOs (Non-Governmental Organizations) without any conflicting authorities. Planning, implementation, supervision controls should also be implemented, and compliance with laws and regulations should be considered.

Acknowledgements. This article relied on scientific research project No. 2016-FEN-A-001, entitled ‘Assessment of Balamba Natural Park Landscape Potential in terms of Ecotourism’. The floristic research in the project was completed by Assoc. Prof. Zafer Kaya and Asst. Prof. Cevdet Gumus. I thank them for their contributions and participation in the project.

APPENDIX

Questionnaire

Determination of the priority with the analytic hierarchy process

This questionnaire aimed to determine the most suitable ecotourism activities in the existing potentials Balamba Natural Park (BNP).

Table A1. *The significance levels and their definitions used in the binary comparison among criteria (Saaty and Vargas, 2006)*

Significance level	Definition
1	Equal importance
3	Moderate importance
5	Strong importance
7	Very strong importance
9	Extreme importance
2, 4, 6, 8	Intermediate levels

The binary comparison matrix of the main factors

Natural factors	9	8	7	6	5	4	3	2	1	2	3	4	5	6	7	8	9	Socio-cultural and economic factors
	9	8	7	6	5	4	3	2	1	2	3	4	5	6	7	8	9	Factors related to land use targets and policies

1- *What is the relative significance of the following* ***main factors*** *in relation to the purpose of determining the most suitable ecotourism activity according to the existing potentials?*

Socio-cultural and economic factors	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Factors related to land use targets and policies

2- *What is the relative significance of the following the sub-factors related to natural factors in relation to the purpose of determining the most suitable ecotourism activity according to the existing potentials?*

Climate	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Flora/fauna
	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Topography
	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Geographical location

Flora/fauna	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Topography
	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Geographical location

Topography	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Geographical location

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43294355

***3-** What is the relative significance of the following **the sub-factors related to socio-cultural and economic factors** in relation to the purpose of determining the most suitable ecotourism activity according to the existing potentials?*

Transportation	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Economic status of visitors
	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Demographic structure of visitors
	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Existence of nearby attraction centres

Economic status of visitors	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Demographic structure of visitors
	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Existence of nearby attraction centres

Demographic structure of visitors	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Existence of nearby attraction centres

***4-** What is the relative significance of the following **the sub-factors of land use targets and policies** in relation to the purpose of determining the most suitable ecotourism activity according to the existing potentials?*

Biodiversity conservation	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Satisfaction of recreational needs
	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Preservation of visual landscape potentials
	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	City branding
	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Diversification of tourism activities
	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Increase in business opportunities
	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Improvement of infrastructure

Satisfaction of recreational needs	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Preservation of visual landscape potentials
	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	City branding
	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Diversification of tourism activities
	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Increase in business opportunities
	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Improvement of infrastructure

Preservation of visual landscape potentials	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	City branding
	9	8	7	6	5	4	3	2	**1**	2	3	4	5	6	7	8	9	Diversification of tourism activities

Abstract. The abundance of Collembola families were studied in three localities with four different land-use types: forest, agroforestry, grassland and corn crop, all located in the Santa Marta Range, Los Tuxtlas Biosphere Reserve, Veracruz, Mexico. Samples of litter and soil were collected in each land use during the dry season, February and March 2005, and processed by Berlese-Tullgren funnels. In addition, physical and chemical parameters of soil were measured. A nested MANOVA was applied to evaluate land-use and site effect on edaphic parameters, and a nested ANOVA was used to evaluate their effect on the Collembola abundance. In addition to this, a Cluster Analysis (CA) and Canonical Correspondence Analysis (CCA) were used. Besides, Shannon diversity index was calculated. A total of 1,088 collembolans from seven families were gathered, with the most abundant being Isotomidae, Entomobryidae and Hypogastruridae. The nested MANOVA and ANOVA revealed significant effect of the site and land-use on the soil parameters and Collembola abundance, respectively. CA formed two main groups based mainly on sites and biotopes. The CCA, showed that abundance of Onychiuridae and Odontellidae are related with altitude, Na and Cation Exchange Capacity (CEC). Diversity was higher in forest than in corn crop and grassland. The corn crop showed a higher incidence of Isotomidae and Entomobryidae than the other sites. Thus, the changes in the Collembola community at family level can be useful to recognize the quality of soil in different land uses.
Keywords: *bioindicators, canonical correspondence analysis, Entomobryidae, Hypogastruridae, Isotomidae*

Introduction

Land-use change is the main factor determining patterns of biodiversity of soil organisms (Bengtsson, 2002; Martins da Silva et al., 2015). Thus, the need to highlight the fact that disturbances caused by human land-use practices can affect biodiversity positively or negatively, usually having a loss of species (Bengtsson et al., 2000; Cuchta et al., 2012) is important to land management. Understanding the impact that changes in land-use practices has on the environment biodiversity is essential for the implementation of effective measures to preserve biodiversity in human-disturbed landscapes (Niemelä, 2000; Gisladottir and Stocking, 2005; Wu and Cho, 2007). Therefore, since Collembola is highly sensitive to changes in soil conditions, they have been used as bioindicators to follow the evolution of several types of edaphic systems

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43574373

(Fiera, 2009; Muturi, 2009; Paul et al., 2011; Ponge et al., 2003; Sousa et al., 2004, 2006). Some species, as *Mesaphorura krausbaueri*, have also been proposed as possible indicators of soil fertility; they have been considered pioneer in secondary succession on cultivated soil (Dunger, 1986). Other species, such as *Protaphorura armata*, have been considered in the study of the effects that pollution from human activities have on biological and ecological processes such as reproduction, mortality and population growth (Bengtsson et al., 1983, 1985a, b). Furthermore, the important role that Collembola play in the edaphic process makes them a useful tool in identifying the modification and quality of the soil ecosystems (Rusek, 1998; Culliney, 2013). They can be used at a species and even at a family levels, as has been shown in studies of the subtropical forest floor in Manipur, India (Waikhom et al., 2006) and those carried out in areas with *Araucaria* forest in Brazil (Baretta et al., 2008) have demonstrated. It has been shown that data sets built at the family systematic rank can also detect the effects of disturbance with little loss of information and can be a preliminary tool for describing patterns and successions in human-disturbed soil ecosystems (Caruso and Migliorini, 2006).

Veracruz State is recognized for its high biodiversity, and high rate of endemism as well as its contribution to global diversity, and the ongoing conservation of the tropical forest. The State takes the first place in the species richness of many groups, including Collembola (Palacios-Vargas et al., 2000, 2004). Nevertheless, as most of the State is in the tropics, its territory is experiencing severe and rapid change in land-use, increasing the alarm at the deforestation rate and original vegetation loss (Phillips, 1997; Dalrymple, 2006).

The deforestation of tropical rain forest at Los Tuxtlas region has been particularly high in the last five decades, mainly due to the conversion of forest land in pastures and corn fields, that is the dominant land use at this region (Flint et al., 2000). Adding, the region was transformed severely to gain cattle pastures and only about 21% of the original forest vegetation remains unspoiled (Gutiérrez-García and Ricker, 2011).

The change in use modifies the biogeochemical cycles of the soil at local, regional and global scales, and also produces important effects in the diversity and role of soil organisms. Many studies on this subject have been developed in the tropics (Lemessa et al., 2015; Smith et al., 2015; Peña-Peña and Irmler, 2016). Although Collembola is one of the major components of the soil biota, the evaluation of human activities' effect on Collembola assemblages has not been reviewed recently in Mexico (Lavèlle et al., 1981; Palacios-Vargas, 1985; Villalobos, 1989, 1990; Miranda and Palacios-Vargas, 1992; Mendoza, 1995; Mendoza et al., 1999). Palacios-Vargas and Castaño-Meneses (2014) compiled recently the information about importance of Collembola as bioindicators in different environments. There are evidences that Collembola richness and abundance show modifications in agroecosystems according to the quality of irrigation, moreover some edaphic parameters, such as pH, organic matter and exchangeable cations are altered as well (Cutz-Pool et al., 2007).

The main purpose of this study is to evaluate the effects of four land-use types: corn crop, grassland, agroforestry and forest on the Collembola family abundance patterns in three sites. Besides, this article will explore the relationships of these organisms to some soil variables. We hypothesize that agricultural and livestock practices produce negative effects on the Collembola diversity and abundance, and changes in the composition and dominance of Collembola families, suggest that some families can be as indicators of

DOI: http://dx.doi.org/10.15666/aeer/1604_43574373

land use and agricultural practices, and can be a useful tool in management and conservation programs.

Materials and methods

Study site

The St. Marta Range (SMR), is located at the East of Veracruz (extreme coordinates: 18° 15′ 18′′ N; 94° 40′ 95′′ W) in Los Tuxtlas Biosphere Reserve (*Fig. 1*), Mexico. SMR comprises 20,000 hs in the Soteapan and Mecayapan municipalities. The highest peaks are the volcanoes Santa Marta (1720 m), San Martín Tuxtla (1680 m), and San Martín Pajapan (1180 m) (Ramírez, 1999). The climate of Los Tuxtlas region is tropical, hot and humid in the lowlands (below 300 m) and medium altitudes (300-700 m). It turns semi-warm at higher elevation (700-1700 m). The rainfall is abundant in the area, close to 5,000 mm in the lowlands though this could increase in elevated places. Overall annual average temperature can reach 26 °C falling to 18 °C (Soto and Gama, 1997). Among the most important types of vegetation are high evergreen tropical forest, medium evergreen tropical forest, cloud forest, pine forest, oak forest and savanna (Castillo-Campos and Laborde, 2004). Unfortunately, the region of Los Tuxtlas has been deforested severely, mainly to gain cattle pastures, and only about 21% of the original forest vegetation remains unspoiled (Gutiérrez-García and Ricker, 2011).

Sample collection

Sampling of fauna was carried out in February and March 2005 during the dry season (which runs from January to April in the area). Three sites with different altitude and vegetal cover percentages were sampled: San Fernando (SF; range 740-1145 m asl; 50% vegetal cover), López Mateos (LM; 191-357 m asl; 75% vegetal cover) and Venustiano Carranza (VC; 160-380 m asl; 25% vegetal cover) on the slopes of the Santa Marta Volcano in the biosphere reserve of Los Tuxtlas. In each site, we sampled four land-use types: forest (Fr), agroforestry (Ag), grassland (Gr) and corn crop (Cc). Sampling methodology and extraction of soil fauna followed that recommended by Franklin and Morais (2008). We chose 5 points in each land-use at random. Beside, we sampled litter (Li) and soil at 0-5 cm (So1) and 5-10 cm (So2) being 15 samples a total: 5 of Li, 5 of So1 and 5 of So2 for each site/land-use. Samples were taken in the same core: first, we removed the litter then we took the first 5 cm, and finally the following 5 cm. In this way, the total of samples per site was 60, being 180 the sample total in all three sites. For sampling, a metal cylinder was used: 5 cm diameter and 5 cm height. Samples of Li, So1 and So2 were taken in a vertical profile fashion in each point.

Fauna extraction was by Berlese funnels with electric light bulb 40 W/funnel for five days. All fauna was first fixed in formalin 5% and then was preserved in 70% alcohol.

In addition to faunal sampling, soil samples were analyzed to obtain some soil parameters; pH was measured in a solution of $CaCl_2$ extract (1:2.5); moisture percentage; particle-size distribution (clay, sand and silt) was determined by hydrometer method (Bouyoucos, 1962); Mg^+ and Ca^+ were extracted by 1 M ammonium acetate pH7 and quantified by EDTA, whereas Na^+ and K^+ were evaluated using a flame photometer (Page et al., 1982); also Cationic Exchange Capacity (CEC) and porosity were recorded.

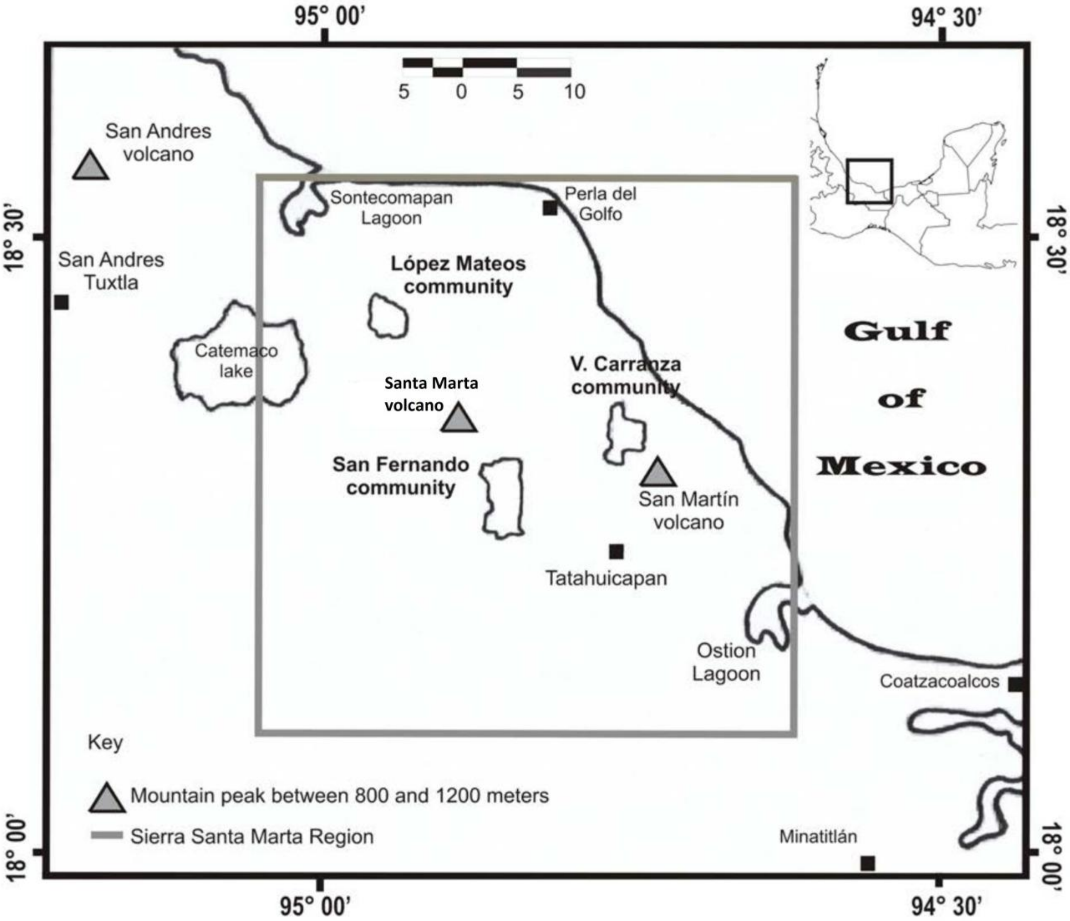

Figure 1. *Location of the three study sites, López Mateos, San Fernando and Venustiano Carranza in St. Marta Range (grey frame), in Los Tuxtlas Biosphere Reserve*

Statistical analysis

A nested multiple analysis of variance (MANOVA) was applied with two hierarchized level, land-use nested within sites, and sites, to evaluate the effect of these factors on all the physical and chemical soil variables. A nested analysis of variance (ANOVA) with three hierarchized levels, depth strata nested within land-uses; land-use nested within sites, and sites, to evaluate their effect on the Collembola abundance transformed as $\log_{10}(x + 1)$ to meet homoscedasticity and normality (Zar, 1999). A post hoc multiple comparisons with Bonferroni paired test (Zar, 1999) was performed when significant effects were found. Statistical analyses were performed using Statistica 6.0 (StatSoft, 2006). A Cluster analysis (CA) on a Bray-Curtis similarity matrix and using the unweighted pair-group average (UPGMA) amalgamation rule was performed on all data including site, land-use type and biotope: litter and soil at two depth levels in order to explore the faunal relationships. The analysis were made using PC-ORD v. 5.0. A Canonical Correspondence Analysis (CCA) was used to explore the influence of soil variables on faunal composition by using CANOCO 4.5 (Ter Braak and Smilauer, 1998). A Montecarlo test with 500 permutations was used to evaluate the significance of axes. Also Shannon diversity index (*H*) was calculated using the abundance of family level of taxa.

Results

Nested MANOVA showed significant effect of site (λ = 0.04, $F_{18,\ 164}$ = 37.13, p < 0.01) and land use nested in site (λ = 0.11, $F_{81,538.9}$ = 2.66, p < 0.01) on physical and chemical soil parameters. Means and 95% confidence intervals (CI) for all variables are shown in *Table 1*.

Moisture content was higher in the four SF land uses than in other localities, with no differences among them. We observed significant differences between SF corn and grass with the four LM land uses, in addition to this, there were differences between SF agroforestry and LM corn. The four SF land uses differ from VC agroforestry and corn

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43574373

land use. The SF corn and grass vary form VC grass and forest. The sand and Na contents showed similar patterns, observing the highest averages in the four LM land uses. Both parameters, sand and sodium, were lower in SF and VC than in LM with no significant differences among them. We observed significant differences in sand content among the four LM land uses with the four SF and VC land uses. Sodium showed differences among LM agroforestry, grass and forest compared to the four SF and VC land uses. There were also differences between corn with agroforestry and forest in LM. Porosity was very homogeneous among the four land uses of the three sites. We observed differences only among SF grass compared with LM agroforestry and forest, and between SF grass and forest. The silt content did not show defined patterns between land uses and sites. The pH of VC grass, agroforestry and forest was different to LM corn, grass and forest, so were SF agroforestry and corn; we found differences between LM agroforestry and VC grass as well. Potassium content was higher in LM grass and forest. We identified important differences in the potassium levels among LM grass and the four land uses of SF and VC. Magnesium was also homogeneous among the four land uses of the three sites; we found some differences among LM and SF forests and the VC four land uses. The CEC was also very similar among the four land uses of the three sites. We recorded differences in CEC between LM forest with VC agroforestry, grass and forest, also between LM and VC grasses, SF agroforestry with VC grass and forest, and SF corn and VC grass. Calcium content also showed few important differences in such levels among land uses most of them correlated with CEC. The clay contents were significantly lower in the four LM land uses than those of SF and VC, among these, there were no differences. We observed significant differences in clay levels among LM agroforestry, corn and forest with all land uses of both SF and VC.

The nested ANOVA showed significant effect of site ($F_{2,\,154} = 13.86$, $P < 0.001$), and land-use nested within site ($F_{6,\,154} = 2.54$, $P < 0.05$) but not for depth strata nested by land-use ($F_{8,154} = 1.09$, $P > 0.05$) on Collembola abundance. The Bonferroni paired test detected significant differences among LM with SF and VC. For land-use nested by site, we identified differences among corn crop in LM with corn crop, grassland and forest in SF and VC. Other differences were found among corn crop and agroforestry in LM, grassland in SF and both grassland and forest in LM, and grassland and forest in VC. Means and 95% confidence intervals (CI) for Collembola abundance are shown in *Table 2*.

A total of 1,088 springtails of seven families were obtained from the three sites (LM, SF and VC). The most abundant families were Isotomidae (37%), Entomobryidae (27%) and Hypogastruridae (24%) (*Fig. 2a*). The number of Neanuridae and Odontellidae recorded was far less, under1% each (*Fig. 2*). LM had more than half of the total amount of Collembola (54%), while SF and VC had 25% and 21%, respectively (*Fig. 2b*). Abundance was higher in Gr and lower in Ag (*Fig. 2c*). In soil biotope the abundance was higher in So1 (40% in the first 5 cm deep) than in So2 (34%), with the lowest occurring in litter (26%) (*Fig. 2d*). All families were recorded in LM while Neanuridae was absent in SF and VC (*Fig. 3a*). We found all families in soil in both So1 and So2, however Neanuridae was absent in litter (*Fig. 3b*). In land-use types, all families were found in Gr, although Neanuridae was absent in Ag and Fr; Odontellidae also was absent in Cc (*Fig. 3c*). Shannon index showed a higher diversity in LM, mainly this fact comes from agroforestry and forest; however, we identified the highest diversity in SF forest. In biotopes, the highest diversity was observed in litter and both depth level of soil of forest (*Table 2*).

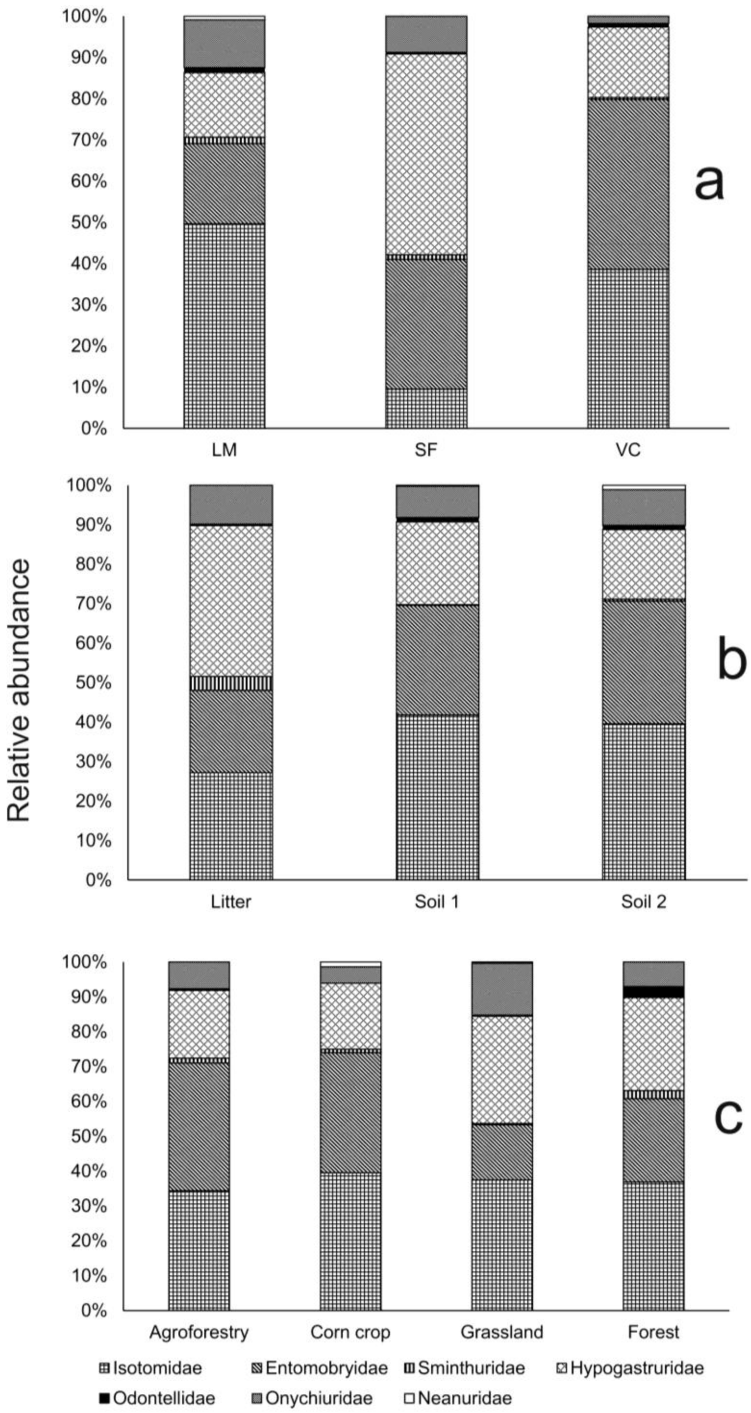

Figure 3. *Relative composition of Collembola assemblages in sites a), biotopes b), and land-use types c). LM, López Mateos; SF, San Francisco and CV, Venustiano Carranza*

In the CA, almost all the samples of LM and VC tended to form one high group (Gr1), while those of SF formed a second high group (Gr2, *Fig. 4*). In the first group, soil samples of all the land-use types from VC tended to be close forming a sub-cluster. The litter samples of all land use of VC had low abundance of Collembola and they were dispersed in Gr2.

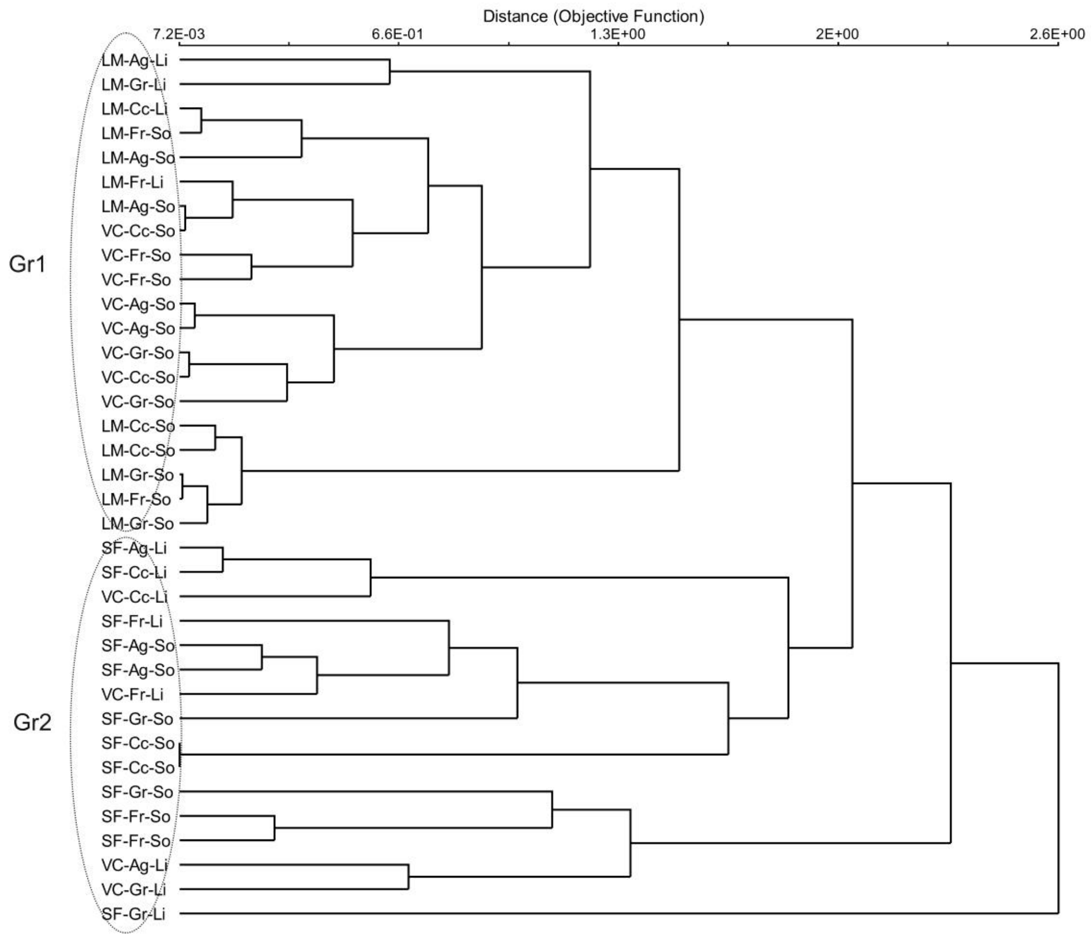

Figure 4. *Classification dendrogram showing faunal relationships of Collembola assemblages based on a Bray-Curtis similarity matrix and UPGMA amalgamation rule using all the samples including sites, biotopes and land-use types*

The CCA analysis (*Fig. 5*) showed that canonical axes 1 and 2 together explain 84% of the variance in family composition of Collembola. Correlation coefficients between ordination axes and environmental variables, rather than canonical coefficients, were used to infer the importance of each parameter in predicting the family composition. More related land uses were Cc and Gr and in our analysis, they were opposite located to Fr (*Fig. 5*). Corn crop and forest axes (although opposed) exerted the strongest influence on Collembola abundance. Odontellidae were more related to forest axis and soil moisture. Sand, porosity and the presence of silt and clay are also important in determining the distribution of Collembola abundance. We represented these variables by longer arrows in *Figure 5*. The first two exerted an opposite effect on each other but sand was an important determinant of abundance of both Sminthuridae and Onychiuridae. We mainly recorded the abundance of these two families in all the land uses of LM except Sminthuridae in Ag, in which higher records of sodium and sand were obtained. Neanuridae seems to be related to the corn crop of LM because only a few specimens of this family were found in this land use. Samples of all the land uses from VC and LM were well separated in the plane generated by the first two axes; however, samples of SF crossed between LM and VC. Samples of Ag and Cc from SF were more related to VC-Cc and samples of Fr and Gr from SF to LM-Fr and LM-Ag.

Discussion

Abundance patterns of the Collembola from SMR correlates with most of those reported in literature. Such correlation lies in the fact that the dominant families in soil and litter are Isotomidae, Entomobryidae and Hypogastruridae, although some types of soils can contain great populations of other families such as Onychiuridae (Lavèlle et al., 1981) or Neanuridae (Garita-Cambronero et al., 2006).

The estimation of Collembola density (individuals/m^2) for the grassland of SMR was 3,361 m^2, similar to that registered by Lavèlle et al. (1981) from the grassland of the Laguna Verde region, Veracruz (3,005 – 4,383 m^2). The estimated density of 2,834 m^2 for the forest of SMR is lower than that reported by the same author from the tropical rain forest of Laguna Verde region (6,257-7,025 m^2). Collembola density for the agroforestry of SMR was 2,685 m^2 and for that of the corn crop was 4,232 m^2. In agricultural zones of tropical regions, densities of 60,600 m^2 have been registered (Culik et al., 2002), which represent important differences within this study. Meanwhile, in the litter of SMR a density of 2,506 m^2 could be expected and for the first 5 cm deep of the soil of 3,925 m^2 and for the next 5 cm deep 3,168 m^2. Isotomidae, accounting for 37%, dominated the Collembolan assemblage in the study area. Particularly, Isotomidae accounted for 65% in the forest, and 40%, 37% and 34% for corn crop, grassland and agroforestry, respectively.

Luanga-Reyrel and Deconchat (1999) reported similar results for oak coppice forests in France and Muturi et al. (2009) for Embu, Kenia. Dominant Isotomidae species represented high reproductive rate and adaptive ability. The feature has allowed some of the genera to colonize forests and open micro-habitats.

In general, Collembola density was higher in the land uses subjected to a greater impact such as corn crop and grass. It is possible that this fact is related to a higher incidence of individuals from one or a few dominant species of Isotomidae and Entomobryidae.

The land-use practices have an important effect on the soil biodiversity and they are usually associated with the loss of species and a reduction of biodiversity (Bengtsson et al., 2000). The results of this study are compatible with this assertion. The lowest diversity of Collembola was recorded in both grassland and agroforestry of Venustiano Carranza (VC) and corn crop of San Fernando and from litter of grassland use type. Opposite to this, the highest diversity was found in the forest of SF, the most unspoiled site. This fact is consistent with the hypothesis of finding greater diversity in the most conserved sites such as the forest that represents our control use type. The next most diverse land use was agroforestry of López Mateos. It is possible that the intensity and duration of practices in agroforestry of LM produce few fluctuations in the original Collembola assemblage.

On the other hand, the highest abundance of collembolans was recorded (in decreasing order) at corn crop, grassland and forest of LM, most of them pertaining to the Isotomidae family. All families were recorded in the four land uses of LM, except Odontellidae which was absent in corn crop. On the contrary, the lower densities of colembolans were recorded in grassland of VC and forest of SF. In grassland of VC diversity was 0.78 because only three families were present, Isotomidae, Entomobryidae and Hypogastruridae unlike the diversity of forest of SF (1.51) because six families out of seven were present. We discovered Neanuridae only in López Mateos, in corn crop and grassland, but in very low densities. Additionally, Odontellidae was a rare family, only recorded in the three land uses of LM and both forest of SF and VC in very low densities. The low densities of Odontellidae and Neanuridae throughout the land uses did not show a clear pattern, so their role as reliable bioindicators is here uncertain despite the fact that some authors have mentioned them as important bioindicators of edaphic conditions. Mendoza et al. (1999) reported incidence of Odontellidae (*Superodontella*) in a recovery land with corn crop from a tropical site in Balún Canán, Chiapas, Mexico. Perhaps the presence of Odontellidae in a recovery soil could be considered as an indicator of restoration.

About Collembola distribution on biotopes, it seems clear that, with rare exceptions, soil contains a greater abundance and diversity of Collembola than litter as has been reported for other tropical forests (Gómez-Anaya et al., 2010) but in this study the diversity of litter was little higher than that of both soil layers. In LM the highest diversity was recorded in the soil of forest and the lowest in the litter of forest, this could be because this biotope was scarce and variable. In litter the abundance of springtails can be extremely variable, due to the different levels of the accumulation of litter on the ground depending on many factors: slope, soil relief, vegetable cover. Especially, abundance in litter depends largely on precipitation and moisture level. In biotopes of land uses the lowest abundance of Collembola was recorded in the litter of agroforestry and the highest abundance in the deepest layer of soil (So2) of corn crop. The accumulation of litter in some grassland systems can be high because of an increase

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43574373

of the number of herbaceous plants (Sánchez et al., 2007). Litter accumulation in grassland of SMR was more variable than in the other land uses and may correlate to the lower Collembola abundance recorded. In relation to the higher Collembola abundance in corn crop, the species composition is likely to be represented only by one or few species of Isotomidae and/or Entomobryidae, the most abundant families recorded, that find by peculiar temporal microhabitat conditions, e.g. moisture, favorable to maintain high populations. Agricultural stubble is mainly represented by cornstalk debris, that can be either highly variable or a very homogeneous medium depending on the type of management used. Under humid conditions stubble can generate a fungal mycelium-rich medium during the decaying cycle which provides abundant food for sustain high populations of Isotomidae (pers. obs. J. A. Gómez). Particularly in the two layers of soil abundance was higher in the deepest layer So2 (0-5 cm deep) in the corn crop and then in the first layer of soil of the forest. This shows a contrast between the site of greatest intensity of use and the control one. Composition of families shows that most of the Collembola collected from So1 of forest soil were epiedaphic forms of the Isotomidae family. Similar dominance of Isotomidae have been reported from other tropical site used in a corn cultivation (Mendoza et al., 1999) in Balún Canal, Chiapas. In corn crop soil, the abundance of Collembola was very similar between the two soil layers, 4073 m^2 and 4465 m^2 for So1 and So2, respectively. This is because the variation in depth between the two layers of soil was minimal and the land preparation promote a more homogeneous edaphic vertical profile in characteristics e.g. moisture, sand, clay, silt, porosity and therefore the vertical distribution of Collembola was similar. However, this was only for abundance distribution since in composition there was no Sminthuridae in So1 and no Odontellidae in either soil layers.

It is a fact that some soil physicochemical properties are modified by different agricultural practices and grazing. For example, silt content has been reported to tend to increase in the grassland and farmland (Evrendilek et al., 2004). Particularly, silt content was higher in cropland and grassland in SRM in which higher Isotomidae and Entomobryidae were registered (see CCA *Fig. 5*). Contrary, porosity is another property that tends to decrease in soils with grassland and agricultural management and increases in preserved soil, like forest, as this study proved. Apparently, the clay content also tends to decrease with soil management even though our study showed to be higher in the grassland (Evrendilek et al., 2004). The highest abundances of Isotomidae and Entomobryidae seem to be correlated mainly to corn crop cultivation practices, agroforestry and grazing but not to the preserved forest. Undoubtedly, the different land-use practices tend to transform the physicochemical properties of soil and thus to modify assemblages structure of wildlife that inhabits it.

Among Poduromorpha some species of Hypogastruridae, Neanuridae, Odontellidae and Onychiuridae have been regarded as reliable indicators of perturbation (Barbercheck et al., 2009; Ponge et al., 2003; Van Straalen, 1998). Nevertheless, contrary to expectations, there was Neanuridae recorded in the corn crop and grassland of LM but absent in the tropical rain forest of the same site. Whereas, Odontellidae was absent in the most land-use types, except in forest, the most unspoiled site, in Santa Marta Range. It is feasible that, Neanuridae and Odontellidae could be more sensitive than other Collembola to human influence.

As a group, Collembola has shown to be an efficient bioindicator of the effects of land-use mainly in aspects of incorporation of Nitrogen and pesticides in soils, as well as in the evaluation of the quality of grassland environments (Hodkinson and Jackson,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43574373

2005). Several families are more or less sensitive to the pollution of the environment. It is of great value to detect the assemblages of microarthropods at family level, those of Collembola, to provide an efficient tool to determining the quality and health of altered soils (Garita-Cambronero et al., 2006). We consider that a family level of quantification can give an effective indication to the different human impacts on soils such as the different land-use types in Santa Marta.

Conclusions

According to our results, it can be concluded that the differential land use by practices such as corn crop, grazing and agroforestry in St. Marta Region (Los Tuxtlas) produces significant changes in abundance and diversity of the Collembola families in leaf litter and soil when compared to a barely modified forest. These changes occurred in the three sites as well as in the two biotopes, leaf litter and soil, of the four land uses. Collembola showed a reduction in diversity and abundance in those land uses subjected to a more intensive use such as corn crop, grazing and agroforestry. On the other hand, as expected, the Collembola were more diverse and abundant in the land use that experiences less intensity as the forest. The higher abundance of Isotomidae and Entomobryidae recorded in corn crop can be probably associated with the soil management in agricultural soils, with more humidity due the crop requirements, and promote mycelial growth, and that is exploited for those Collembola families increasing their abundances. A detailed study of the taxonomy of these two families would, undoubtedly, reveal that relatively a few opportunistic epiedaphic species are dominant in corn crop and that a reduction in diversity is always constant consequence that can be verified in any place where the intensity of land use is increased. Odontellidae and Neanuridae were rare families because of their abundance, however, their incidence/absence patterns are not clear here and their value as bioindicators was not possible to be highlighted. Nonetheless, some authors have proposed that some Collembola species with higher bioindicator value are in these families. Apparently, they tend to disappear with farming practices and grazing. They are probably sensitive to the use of agrochemical and pesticides used in agriculture and cattle farming. Particularly we think that the Odontellidae, which were not registered in the corn crop in St. Marta, could be used as good bioindicators. It is recommended to observe their abundance and/or presence-absence in soils subjected to intense use. Finally, the use of higher taxonomic categories other than species is recommended, as in this case the family level, in rapid assessments to detect coarse quantitative/qualitative changes introduced by human impact. Our results suggest that the changes in dynamic community of Collembola can be used as indicator of modified soil use and quality.

Acknowledgements. This work was conducted within the project "Conservation and Sustainable Management of Below-Ground Biodiversity (CSM-BGBD)" which is coordinated by the Tropical Soil Biology and Fertility Institute of CIAT (TSBF-CIAT). Financial support was provided by the Global Environment Facility (GEF) and by the United Nations Environment Program (UNEP). We also are indebted to Dr. Isabelle Barois, Dr. José A. García-Pérez and Biól. Martín De Los Santos for their support in the fieldwork. Professor Luis Parra Pantoja gave important grammatical revision to the manuscript. The final manuscript was reviewed by Andy Murray (www.chaosofdelight.org).

Abstract. Disposal of industrial wastewater is a current issue of urbanization. However, this problem can be sorted out by using wastewater as an alternate source of irrigation after the addition of some amendment. The present study was performed at the Shakarganj Sugar Research Institute (SSRI) Jhang, Pakistan to determine the influence of different combinations of distillery spent wash (DSW) and NPK fertilizers on growth, yield and nutrient uptake of wheat crop. The experiment was composed of different combinations of DSW and NPK (0:0, 0:100, 25:75, 50:50, 75:25, 100:0). The results revealed that the application of different combinations of DSW and NPK significantly improved the growth, yield, and nutrient uptake in wheat crop. The maximum improvement in growth attributes (LAI, LAD, CGR and TDM) was recorded with the application of 25:75% DSW and NPK fertilizers. Similarly, application of 25:75% DSW and NPK improved the plant height, fertile tillers, 1000 grain weight, biological yield grain yield nitrogen uptake, phosphorus uptake and potassium uptake up to 32.88%, 37.5%, 38.87%, 34.61%, 78.42%, 62.42%, 92.55% and 73.25% respectively, over the control. In conclusion, application of 25:75% DSW and NPK was proven superior to other combinations in terms of growth, yield and nutrient uptake.
Keywords: *wheat, spent wash, yield, grain, N. P. K.*

Introduction

The imperious issue of water scarcity has devastating impacts on the economic growth, livelihoods and environmental supremacy around the globe. The rapid increase in industrialization excretes immense amount of waste water, as demands for fresh water is amplifying day by day, therefore, waste water often seen as a valuable asset, thus it can be a prime alternate source to irrigate the crops (Noori et al., 2013). Additionally, the agricultural crops also require a huge quantity of water for their growth and development. Therefore, the use of waste water in agriculture will solve both problems, and will improve the environmental quality and crop yield. Moreover, the use of waste water can improve the soil physical and chemical properties, soil nutrition status (Kiziloglu et al., 2007) and crop growth, yield as well as quality (Nagajyothi et al., 2009; Nath et al., 2009). Therefore, the wise use of waste water would be helpful in water conservation, nutrient recycling, reduction of water pollution and input application (Thapliyal et al., 2009; Vasudevan et al., 2010).

The sugar industry plays a pivotal part in the economic development of Pakistan. There are 88 sugar mills in Pakistan (PSMA, 2014). These mills have limited capacity to store and to treat this spent wash, therefore, much of the spent wash is disposed into surrounding areas of mills. The poor handling and management of DSW create the problems of water pollution and deterioration of soil health (Chhonkar et al., 2000).

DSW is a by-product of sugar industry, it is purely of plant origin and contains appreciable amount of macro nutrients (N, P, K, Mg, Ca, and S), micronutrients (Fe, Zn and Mn) and organic matter, and therefore it can be a valuable fertilizer when applied to soil along with irrigation water (Vadivel et al., 2014). Likewise, DSW also contains a significant amount of growth promoting substances, i.e. auxins and gibberellins, which further increases its value as a fertilizer. The higher amount of calcium in DSW has the potential to reclaim the sodic soil, similarly to gypsum effect (Suganya and Rajannan, 2009).

The application of DSW not only controls the water pollution, but also improves the crop growth and productivity (Suganya and Rajannan, 2009). The application of DSW substantially improved the yield of sugarcane crop (Haron et al., 2004), rice and wheat yield (Pathak et al., 1998), and ground nut owing to improvements in soil quality and nutrient uptake (Ramana et al., 2001). Moreover, the use of DSW appreciably improved the crop productivity without affecting the soil fertility (Ramana et al., 2001).

The land application of DSW improved the microbial biomass, and enzymatic activities, which increased the mineralization of organic matter, thus improved the uptake and availability of nutrients (Mahimairaja et al., 2004). The judicious application of DSW enhanced the nutrient uptake in root vegetables (Chandraju et al., 2008), top vegetables (Basvaraju and Chandraju, 2008), leafy vegetables (Chandraju et al., 2007) and pulses (Chandraju et al., 2008).

The conjunctive application of synthetic fertilizers along with the organic fertilizers further improves the growth, yield and quality of crops. The combined application of DSW and NPK fertilizers, improved the growth, yield and nutrient uptake in sugar cane crop (Sharma, 2013). Likewise, the application of diluted DSW and NPK fertilizers improved the soil health, growth and yield and quality of sugarcane crop (Kaloi et al., 2017). On the basis of these facts, the present investigation was carried out to determine the suitable combination of spent wash and inorganic fertilizers, which has the best effect on growth, yield and nutrient uptake in wheat crop.

Materials and methods

Study site and experimental design

A Field study was conducted for two consecutive years (2013-14, 2014-15) at the farm of Shakarganj Mills Farms, Jhang, (longitude 73·8°E, latitude 31·8°N, and altitude 184·4 m asl) Pakistan to investigate the influence of different combination of distillery spent wash and NPK fertilizers on growth, yield and quality of wheat crop. The study site comes under sub-tropical region, moreover, the prevailing conditions during both growing seasons are given in *Figure 1*. Composite soil samples were taken from the site in order to determine the different physical and chemical properties of soil. The soil samples were analyzed by standard procedures of Homer and Pratt (1961). The soil was sandy loam, containing 0.74% organic matter, 0.058% nitrogen (N), 4.63 ppm phosphorus (P), 121 ppm potassium (K), and has a pH of 7.94. The experiment was laid out in randomized complete block design having four replications.

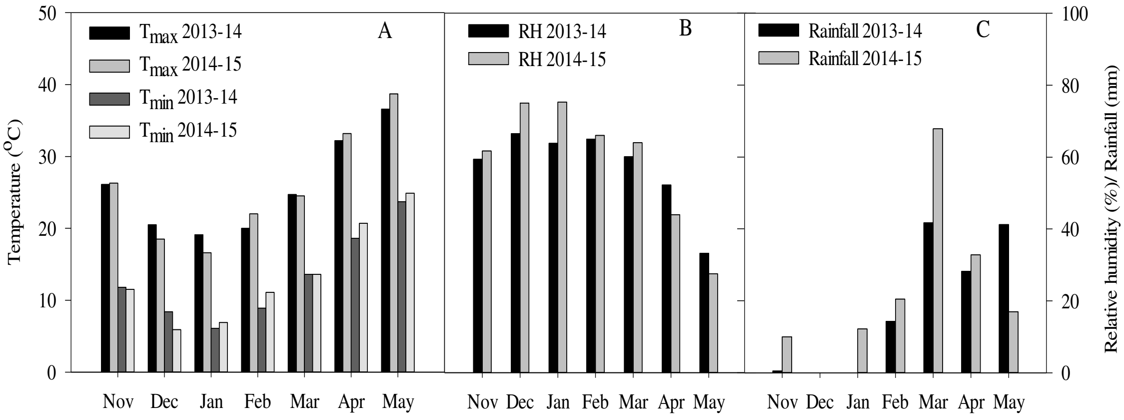

Figure 1. *Prevailed climatic conditions during the growing seasons. A: Maximum and minimum temperature during 2013-14 and 2014-15, B: Relative humidity during 2013-14 and 2014-15, C: Rainfall during 2013-14 and 2014-15*

Collection of spent wash and analysis

Spent wash (SW) was collected from distillery of Shakarganj Mills. The spent wash samples were preserved in polycarbonyl sterilized air-free containers, after that they were transported into the laboratory and kept in refrigerator at 4 °C till use. The different components of spent wash like pH, total solids, N, P, K, Ca, Mg, Na, BOD and COD (*Table 1*) were determined by the standard procedures of AWWA and WEF (1998).

Table 1. *Characteristics of spent wash used in study*

EC (dS m^{-1})	7.7	Total Na (mg L^{-1})	223
pH	4.1	Total P (mg L^{-1})	75
Organic matter (%)	1.25	Total N (mg L^{-1})	410
BOD (mg L^{-1})	232	Total K (mg L^{-1})	2303
COD (mg L^{-1})	6109	HCO3 (mg L^{-1})	101
Total Ca (mg L^{-1})	124	Indole acetic acid (mg L^{-1})	41
Total Mg (mg L^{-1})	63	Gibberellic acid (mg L^{-1})	3119

Treatment and crop husbandry

The study was composed of the following treatments: T_1: 0%DSW+0%NPK, T_2: 0%DSW+100%NPK, T_3: 25%DSW+75%NPK, T_4: 50%DSW+50%NPK, T_5: 75%DSW+25%NPK and T_6: 100%DSW+0%NPK. The seed bed was prepared as recommended by the department of agriculture, Punjab, Pakistan (Govt. of Punjab, 2013-14). The recommended rates of NPK for wheat crop were, 120:90:60 kg ha^{-1} and they were applied in the form of urea, diammonium phosphate and sulphate of potash. All the P and K fertilizers were applied at the time of sowing, while N was applied in two splits, i.e., at sowing and with first irrigation. The spent wash was applied with the first irrigation to the plots according to treatments. The distance between the sugarcane distillery and field was 1387 m. The Punjab-2011 was used as test cultivars and sown in 23 cm apart lines by manual drill. During, both the growing seasons' five irrigations

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43754385

were applied to the wheat crop. All the management practices were kept uniform in order to get good production.

Collection of growth and yield data

Leaf area was measured by leaf area meter (Model: Licor 3000), whereas the leaf area index (LAI) was measured by the standard procedures of Watson (1947). Similarly, the leaf area duration (LAD) and crop growth rate (CRG) was measured by standard methods (Hunt, 1947). The unit area was selected to determine the number of fertile and un-fertile tillers, whereas, twenty plants were selected from each plot to determine the different yield and yield components (Chattha et al., 2017). At harvest grain and biological yield of each plot were measured and later on converted to ton per hectare basis mathematically (Chattha et al., 2017).

Chemical analysis

At harvesting, grain samples were collected from each plot, for analysis of grain NPK. The collected grain samples were dried in over at 72 °C until constant weight, after that they were grinded and sieved. The grinded samples were digested by adding di-acid mixture (H_2SO_4 and H_2O_2 in 2:1 ratio). The grain N contents were determined by standard procedure of nitrogen Chapman and Parker (1961), whereas the P contents were measured by the Olsen et al. (1954) methods. Moreover, K was determined by flame photometer by using standard curve (Chapman and Parker, 1961).

Statistical analysis

In combined analysis the interaction of year (2013-14 and 2014-15) and treatments were found non-significant, therefore, the data was pooled for both years (2013-14 and 2014-15) and an average of two years was taken. The collected data regarding growth, yield and chemical analysis were analyzed by using analysis of variance technique and treatment means were compared by least significant difference test (Steel et al., 1997).

Results

Influence of different combinations of spent wash and NPK fertilizers on growth attributes of wheat crop

Different combinations of distillery spent wash (DSW) and NPK fertilizers significantly improved the growth attributes of wheat (*Triticum aestivum* L.) crop as compared to control (No DS and NPK) (*Fig. 1*). Crop attained maximum leaf area index (LAI) 75 days after sowing (DAS) with highest LAI value under the application of 25%DSW+50%NPK fertilizers, that was comparable to the application of 50%DSW+50%NPK, whereas the non-application of both DSW and NPK fertilizers remarkably decreased the LAI. Nonetheless a declining trend in LAI was recorded 75 DAS, whereas this declining trend was more pronounced when no DSW or NPK were applied followed by a 100% DSW application, whereas the minimum declining trend was found with the use of 25% DSW+75% NPK (*Fig. 3*). Likewise, the effect of different combinations of DSW and NPK fertilizers was also significant on LAD, CGR and TDM. Crop attained maximum LAD and CGR 60-75 DAS, and this maximum LAD and CGR was recorded with the use of 25% DSW and 75% NPK, followed

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43754385

closely by the application of 50%DSW+50%NPK whereas the lowest LAD and CGR was recorded with no DSW and NPK application (*Fig. 3*). Similarly, TDM also increased with different combination of DSW and NPK, however, the highest TDM was recorded with the use of 25% DSW+75% NPK, whereas no application of DSW and NPK fertilizers remarkably reduced the TDM (*Fig. 3*).

Influence of different combinations of spent wash and NPK fertilizers on root growth and flag leaf length of wheat crop

The influence of different combinations of DSW and NPK on root length and flag leaf length was substantiated (*Table 2*). The maximum root length (13.10 cm) and flag leaf length (18.1 cm) were recorded with application of 25% DSW and 75% NPK fertilizers, however, it was similar to application of 50% DSW and 50% NPK, meanwhile the lowest root length (7.5 cm) and flag leaf length (11.20 cm) were recorded when no DSW or NPK were applied, nonetheless it was also comparable with application of 100% DSW.

Table 2. *Effect of different combinations of DSW and NPK fertilizers on growth and attributes of wheat crop*

Treatments	Root length (cm)	Flag leaf length (cm)	Plant height (cm)	No. of fertile tillers (m^2)
Control	7.50c	11.20d	73.00d	226.67c

Influence of different combinations of spent wash and NPK fertilizers on yield attributes of wheat crop

Distillery spent wash and inorganic fertilizers significantly increased the yield attributes of wheat crop as compared to alone application of DSW, whereas the yield attributes considerably decreased when no DSW or NPK were applied (*Tables 2* and *3*). A significant increase in plant height was recorded with the use of DSW and NPK fertilizers compared to control. The application of 25%DSW and 75%NPK exhibited maximum improvement in plant height of wheat crop up to 32.88% over the control, nonetheless, it was comparable with 50%DSW+50%NPK and 100% DSW, whereas a substantial reduction in plant height was recorded under control treatment. Likewise, the effect of DSW and NPK on fertile and unfertile tillers was also significant. Maximum fertile tillers (311.67) was found with 25%DSW and 70% NPK, followed by 50%DSW+50%NPK, similarly, minimum fertile tillers were recorded in the control treatment. Additionally, minimum number of unfertile tiller (13.33) were counted from plot fed with 25%+75%NPK that was the same with the application of

DOI: http://dx.doi.org/10.15666/aeer/1604_43754385

50%DSW+50%NPK, moreover, the maximum unfertile tillers (26.67) were found in the control treatment. Regarding the 1000 grain weight combination of 50%DSW+50%NPK increased the 1000 grain weight up to 26.24% that was the same with the application of 25%DSW+75%NPK, whereas lowest 1000 grain weight was recorded with no DSW + NPK. Similarly, different levels of DSW and NPK fertilizers also had a significant effect on the biological yield and grain yield (*Table 3*). Similarly, up to 36.18% and 78.42% increase in biological and grain yield was found with the application of 25%DSW+75%NPK, compared to control, however it was at par with the application of 50%DSW+50%NPK.

Table 3. *Effect of different combinations of DSW and NPK fertilizers on yield attributes of wheat crop*

Influence of different combinations of spent wash and grain NPK uptake and grain NPK concentration

The results revealed that the application of different combinations of DSW+NPK and alone DSW, NPK and control treatment had considerable effects on the nutrient uptake in wheat crop (*Fig. 2*). The maximum increase in nitrogen uptake was found with 25%+75%NPK application, i.e. 69.18% over the control, and similar trend was found with 50%DSW+50NPK application. Moreover, minimum nitrogen uptake was found in the control treatment. A significant increase in phosphorus uptake was found with the use of 25%DSW+75%NPK treatment, i.e. 92.70% over the respective control (no DSW and no NPK application). Furthermore, K uptake also increased by application of DSW and NPK and maximum increase of 73.26% in K uptake was found by 25%DSW+75%NPK, followed by 50%DSW+50%NPK that was similar to 100%DSW, meanwhile the minimum K uptake was found in control (No DSW+ No NPK). Similarly, different combinations of DSW+NPK fertilizers also had the considerable effect on the grain NPK concentration (*Fig. 2*). Maximum grain nitrogen concentration (2.8%), phosphorus concentration (0.49%) and potassium concentration (1.05%) was recorded with application of 25%DSW+75%NPK, however, it was comparable with 50%DSW+50%NPK, whereas the minimum grain nitrogen (1.10%) phosphorus (0.24%) potassium (0.40%) was observed in the control treatment.

Discussion

The rapid growth of the population substantially increased the quantity of industries around the globe. These industries excrete a huge amount of waste water, which is continuously deteriorating our environment. As the fresh water resources are declining and the demand of fresh water is increasing day by day due to blooming population, waste water usage in agriculture for irrigation purposes may offer a solution to this

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43754385

problem. Moreover, this waste also contains undesirable substances which can deteriorate the soil health, crop yield and environmental quality. However, the use of this water along with certain amendments can reduce its negative impacts on soil health, crop, environment and microbial activities. The application of NPK fertilizers along with DSW is a viable strategy to reduce the negative impacts of DSW on soil and crop. The present study determines the effectiveness of different combinations of DSW along with NPK fertilizers on the growth, yield, and nutrient uptake in wheat (*Triticum aestivum* L.) crop. The results revealed that the application of different combinations of DSW+NPK significantly improved the growth attributes, i.e. LAI, LAD, CGR, TDM, as compared to alone application of DSW and no application of DSW and NPK (*Fig. 3*).

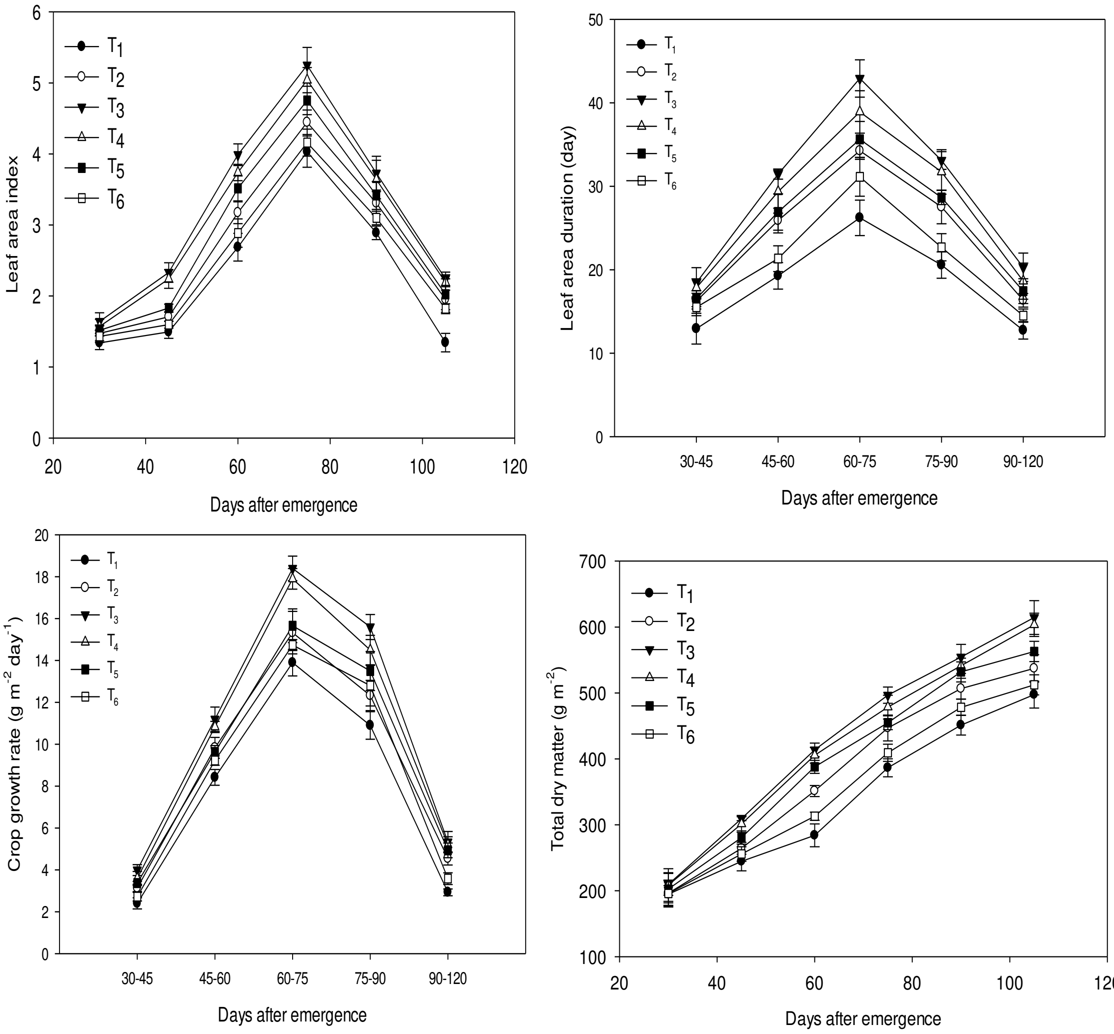

Figure 3. *Influence of different combinations of DSW and NPK fertilizers on LAI, LAD, CGR and TDM*

The increase in growth attributes of wheat crop (LAI, LAD) at lower concentration of DSW might be due to improved root length, which resulted in better absorption of nutrient and water thereby improved the growth attributes. Likewise, the maximum CGR and TDM were found with application of 25%DSW+75%NPK. This improvement in CGR and TDM can be due to increased flag leaf length; therefore, the plants having longer flag leaf absorbed more

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43754385

light, that resulted in production of more assimilates; thus produced more CGR and TDM. Similarly, Ramana et al. (2001) and Nandy et al. (2002) reported that application of DSW at lower concentrations significantly improved the growth attributes of rice and maize crop due to better availability of nutrients. Similarly, the reduction in growth attributes of wheat crop at higher concentration of DSW might be due to the presences of higher quantity of organic matter and BOD, which resulted in depletion of soil oxygen and accumulation of carbon dioxide in soil (Rath et al., 2010).

Likewise, the DSW+NPK also improved the root length, flag leaf length and plant height of wheat crop. The improvement in root length, flag leaf length, by application of the lower concentration of DSW, can be due to the presence of decreased amount of salts. Therefore, the application of DSW has substantially improved microbial activities which improved the decomposition of organic matter thus improved the nutrient uptake and therefore the plant growth. These results are supported by previous findings of Rajkishore and Vignesh (2012), who found that application of DSW at lower concentration substantially improved the microbial activities, therefore, increased the nutrient uptake and availability and thereby improved plant growth. Similarly, the various combinations of DSW and inorganic fertilizers had considerable effects on the yield and yield attributes of wheat crop (*Table 3*). The improvement in yield attributes of wheat crop by lower doses of DSW might be due to the improvement of soil properties, which resulted in better availability of nutrient and thereby improved the growth attributes. Moreover, the lower dose of DSW and application of higher dose of NPK might have increased the concentration of nutrients in soil solutions that overcome the toxic effects of heavy metals. Conversely, higher concentration of DSW might have increased the salt accumulation in the root which resulted in higher osmotic pressure within the root zone. This increase in osmotic pressure can substantially reduce the nutrient uptake, thereby, reduced the crop yield and yield components. These results are in line with previous findings of earlier researchers who reported that application of DSW at lower concentration remarkably improved the growth, yield and yield attributes (Mahimairaja and Bolan, 2004; Chandraju et al., 2008; Chidankumar et al., 2009). Similarly, Rath et al. (2010) reported that application of higher concentration of DSW significantly decreased the growth, and yield of sugarcane crop.

The results showed that conjunctive application of DSW+NPK fertilizers considerably improved the nutrient uptake in wheat crop (*Fig. 2*). The increase in nutrient uptake by DSW+NPK might be due to the presence of appreciable amounts of nutrients in DSW and improvement in soil conditions due to DSW application. Similar results were reported by many researchers who reported that application of DSW improved the uptake of nutrients (Chandraju et al., 2008; Chidankumar et al., 2008; Basvaraju and Chandraju, 2008). Moreover, the application of DSW remarkably improved grain NPK concentration. The improvement in grain NPK concentration by lower DSW might be due to the counter effect of beneficial nutrients, reduction in metal toxicity, and improvement of microbial activity that produces chelate and hormones, which improved growth, yield and nutrient uptake in wheat crop.

Conclusion

Distillery spent wash contains many important nutrients; therefore, it can be used to grow the crops along with inorganic fertilizers. This study implies that combination of 25%DSW+75%NPK could be a viable strategy, and it can remarkably improve the growth, yield, and quality of wheat crop.

(Received 11th Dec 2017; accepted 13th Jun 2018)

Abstract. The aim of this study was to assess the effect of air pollution on road side fruit plants (*Prunus avium* L.) palynology. Flower samples were collected from polluted (1-2 m away from the edge of Quetta to Hunna Urak road) and for the comparison from non-polluted sites (250-300 m away from the same collection site). During the investigation different pollen parameters including pollen umbers/production, pollen size, pollen tube growth, pollen viability, pollen regularity and pollen protein contents were used through different methods. Results indicated that pollen grains of *Prunus avium* L. were very sensitive to automobile air pollution. Consequences showed significant reduction in numbers and sizes of pollen grains, pollen tube length and pollen viability of polluted site with respect to the control site. Maximum irregularity in pollen morphology and low pollen protein contents were also recorded from the polluted site. Moreover, results also designated that vehicular pollution increases the resting period of pollen grains for 1 to 3 h. So the different attributes of pollen grains can be used as sensitive bioindicators of adverse factors in botanical environment and this leads to the idea that reduction in the development and potential of pollen grains in response to various poisonous environmental pollutants can be exploited as a good index of air purity.
Keywords: *sweet cherry, road side contamination, flowers, soil and statistical analysis*

Introduction

Growing *human* population and technologies are producing one of the important problems which we are facing today i.e., air pollution. Plant fertility and precise insemination of plant mostly depend on the pollen grains. In severe air pollution conditions, the fertility of plant decreases because of the straight and subsidiary effects on the propagative mechanism. Air pollution due to vehicle exhaust causes irregularity in anthers, decreases the number and masculine infertility (Rezanejad, 2007). The chemical pollutants produced by industries and traffic emissions not only put damaging effects on morphological and physiological parameters of plants but also comprise alterations and chromosomal impairment. According to Pfahler (1981) these irregularities are contingent on ecological and hereditary issues and may eventually go to alteration in propagative capability of plant species. Between several features that add to air contamination,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43874399

locomotive emissions are problems of growing dimensions. Vehicular emissions enhance large quantities of dust particulate matters, smolder, toxic gases, heavy metals and biological molecules in the environment all over the world. All these air contaminants produced adverse effects on the health of humans, animals and vegetation (Rezaei et al., 2010; Atkinson et al., 2012). Majd et al. (2004) reported that air pollution due to automobile emission enhances pollen allergenicity and increases the problem of asthma among people residing along road sides. According to Shannigrahi et al. (2004) outdoor vegetation growing is the main and primary target of all types of air contamination.

Several investigations have indicated vehicular emission effects on plant leaves stomatal apertures, viability of pollen and development of plants (Iannotti et al., 2000; Verma et al., 2006; Leghari et al., 2015). Other researchers such as Iannotti et al. (2000), Duro et al. (2013), Kaur et al. (2016) indicated that air pollution mainly effects the size, shape, viability and exine sculpturing of pollen grains. Kaur et al. (2016) also reported that developed pollen grains when released from the flower buds in the contaminated air absorbed humidity and some pollutants, which influenced their viability henceforth plants reproductive system. The pollutants such as heavy metals, fluorides, pesticides gather on the pollen grains surfaces and make them lively and sensitive bioindicators of atmospheric pollution (Noori et al., 2009; Yousefi et al., 2011). To perceive and assess the poisonous materials in the atmosphere, biomonitoring techniques can be engaged.

In the current ages several researchers of diverse fields give their attention to the application of palynology in various fields. In palynology the development of pollen grains, pollen grain viability and pollen tube evolution are the superficial bio-pointers of adverse atmospheric pollution. Vehicular traffic adds up different kinds of contaminants like heavy metals, polyaromatic hydrocarbons, gaseous toxins etc. to the atmosphere. Pollen grains of different plants have been found to be sensitive to these pollutants, which show varied effects on their viability, and size and hence can be used as bioindicators of air pollution (Kaur and Nagpal, 2017). This research directed to the knowledge that the downcast growth and developmental potential of pollen in reply to many poisonous environmental pollutants released by traffic can be introduced as a good directory of air cleanliness. This current research study, therefore, was carried out to understand the harshness of vehicular exhaust pollution on the fruit plant at Quetta, Balochistan and delivers some reasonable ideas to decrease vehicular contamination. The present study was conducted on *Prunus avium* L. through different attributes of pollen grains.

Materials and methods

Study area

A heavily trafficked road from Quetta city to Urak valley (*Fig. 1*) located in Balochistan, Pakistan was selected in order to evaluate the effect of air pollutants released by vehicles on *Prunus avium* L. fruit crop pollen grains. The road between Quetta city and Urak valley is about 21 km segment and lined on either side with wild roses, medicinally important plants and fruit orchards. Peaches, plums, apricots, cherries and apples of many varieties are grown in this valley. There is no industry on this road and the major source of pollution is from the vehicular emissions. One beautiful water fall is located at the end of Urak valley which makes an interesting picnic spot. The surrounding area of this picnic spot is full of orchards of apple, sweet cherry and apricot, gathering large number of visitors from all over the country to visit the beautiful valley especially during pleasant summer/flowering season. Before sampling in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43874399

target area, a walk through survey of the study area was made and on the basis of small and large vehicular traffic density, the emissions were expected very high along the road sites.

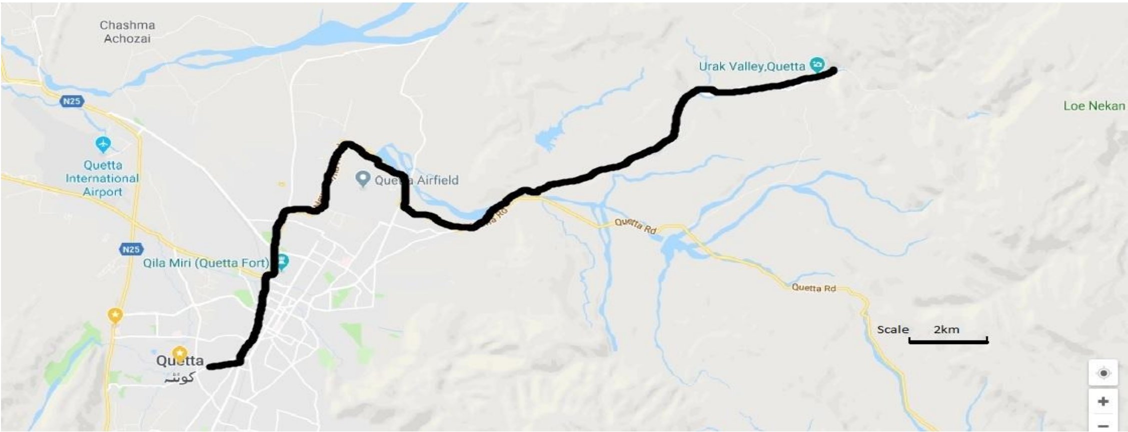

Figure 1. *Google roads map of study area. (Black colour showing road from Quetta city to Urak valley)*

Climate of the study area

Study area (Quetta district) lies between 300-03’ and 300-27’ N and 660-44’ and 670-18’ E. It is situated at an altitude of 1,700 m above sea level. The weather is extremely dry and mean relative humidity of this area mostly remains in range of 15-25% throughout the year. The winter is very cold and the minimum temperature ranges between, -15 to -7 °C and summer is relatively mild and the maximum temperature ranges between 32 to 35 °C, July is generally the hottest month. The district lies outside the range of the monsoon currents and the rainfall is scanty and irregular. The long term 127 year average annual rainfall for Quetta city is 220 mm (BARDC annual report 2017), whereas in the Hanna Urak area, the average is about 312 mm which is mostly recorded in winter months (December –March). (Source: Directorate of Minerals G.O.B Quetta 2017).

Plant material collected

For the investigation of vehicular exhaust emission effects on physiological parameters of pollen grains such as; production, viability and size of pollen along with germination rate and growth of pollen tube, flower samples were collected from polluted (1-2 m away from the edge of the heavily trafficked road) and comparatively non-polluted areas (about 250-300 m away from the same collection site) having the same soil characteristics (*Table 1*) during the year 2017, as was carried out by Ma et al. (2009). Five sampling sites on the heavily trafficked road were designated after a walk through inspection of various sites and on the basis of assessment of traffic density, level of visible auto emissions fumes/smoke, road dust. Collection of flowers for anther was done by random selection of 5 plants from the polluted (P) and control (C) sites separately at each location from the base, middle and upper portion of the plant around all four sides (north, south, east and west) for the accuracy. The average of the results obtained was used for statistical analysis

DOI: http://dx.doi.org/10.15666/aeer/1604_43874399

and interpretation of results. The flower sample collection was done on the same day and time from both sites (polluted and control).

Determination of pollen grain count/production per anther

For the investigation of pollen grain count/production 36 normal anthers were taken from each plant species of *Prunus avium* L. and put into a 1.5 ml Eppendorf tube at 25 °C, 1 ml of 50 $g^{\cdot}$ L^{-1} sodium polyphosphate solution was added, and the tube was capped and shaken. Small quantities of the pollen suspension were placed in a hemocytometer counting chamber and the chamber was placed on different microscopic stages to count the number of pollen grains. The number of pollen grains in one anther was calculated as the number of pollen grains per square area × 10 × 36 × 1000)/36, with three replications (Shi et al., 2015).

Analysis of pollen grains regularity and size

Regularity of pollen grains was evaluated on the basis of percentage of well-regulated and normal pollen grains. At least 500 pollen grains were investigated from each site (polluted and control). Pollen size was determined by micrometry method. A visual micrometer was fixed on light microscope and measurements of pollen grain size were determined under the magnification of 400×, as per procedure carried out by (Kaur and Nagpal, 2017). A minimum of 500 pollen grains were examined from each plant species. The investigation was repeated thrice and an average was expressed in µm (Iyer and Bholay, 2015).

Pollen viability

Pollen grain viability were examined by using 2, 3, 5 - triphenyl tetrazolium chloride (TTC) staining technique by small alterations as described by Iannotti et al. (2000). By adding 1% solution of TTC in 60% sucrose solution, TTC strain was made stain and saved in dark bottles for the process (making slides). Ten anthers from ten randomly selected appropriate size flower buds of the respective plant species were removed by a shrill needle and placed on a glass slide for examination adding one drop of TTC. After removing air bubbles, the slides were covered by cover slip and airtight by didutylphathalate xylene (DPX) and hatched in the daylight for 2-3 h. These slides were prepared with-in no time after sampling from both sites (polluted and control). Prepared slides were examined under light microscope at the exaggeration of 400× separately. Pollen grain viability was determined by noting/counting the viable and non-viable pollen grains under following categories: the yellowish pollen grains with shrunken configuration were designated as non-viable, whereas the red marked and deep pink pollen grains,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43874399

which were rounded in shape, were counted as viable pollen grains. At least 500 pollen grains were studied by each plant (separately from polluted and control sites) and the experiment was repeated for three times and an average was calculated (Kaur and Nagpal, 2017). Further the viability of pollen grains was also tested by the germination of pollen grains (Iyer and Bholay, 2015) and percentage of viable pollen grains was calculated by the following formula:

$$\text{Pollen viability}\,(\%) = \frac{\text{Number of viable pollen grains}}{\text{Total number of counted pollen grains}} \times 100$$

Rate of pollen grain germination and pollen tube growth

Pollen grains propagation probability and pollen tube growth was determined by marking the different stages of pollen grain development on flower buds of different sizes. At the same time open flowers were pulled and the succeeding flowers series were marked as; F-0, F-24, F-48 and F-72, where; F-0 was designated for flower bud at the time of dehiscence of anthers, F-24 was for flower buds needed 24 h to open, F-48 was for the flower buds required 48 h to open and F-72 was for the flower buds required 72 h to open. Potential of pollen grains germination, the in-vitro experiment was performed by the method of standing drop in Brewbaker and Kwack's culture medium in the laboratory of Botany department in suitable relative humidity (Brewbaker and Kwack, 1963). Pollen germination and tube growth rate were noted by setting the cultures in one hour intervals that was extended for 12 h. The germination tests were conducted in triplicates and average data were displayed in the results.

Rate of decrease in pollen grain propagation and pollen tube growth

It contracts by the capability of the pollen grains to persist feasible in the detached successive flowers under natural conditions after the dehiscence of the anthers. The decreasing rate of pollen grain germination and pollen tube development was also deliberated time to time throughout storing via setting cultures medium at 3 h intermissions. These cultures were sustained for 15 h (Nair and Rastogi, 1963).

Determination and analysis of protein

Protein contents from *Prunus avium* L. pollen grains were determined by the methods used by Rezanejad (2007). Pollen extracts were made by incubating pollen grains in 0.1 M phosphate buffered saline (PBS) pH 7.4 in 15% quantity through inspiring at 4-8 °C for 8 h. Postponements were centrifuged at 10000 × *g* for 50 min and the supernatants were removed. Protein concentration in pollen grain extracts was recorded in 595 nm as per method of Bradford (1976). Sample protein and standard protein were unglued via SDS-PAGE patterns at 80 V continuous powers for 1-2 h at 15 °C, similar to the modified procedure of Laemmli (1970). Proteins were detected by using a mixture of methanole; acetic; distilled water (1:1:8) with Coomassie brilliant blue R 250.

DOI: http://dx.doi.org/10.15666/aeer/1604_43874399

Soil analysis

The soil samples were collected from the areas, where under investigated plant species were grown (polluted and control sites) and examined to know the range of soil pH, electrical conductivity (E.C.), contents of organic matters (O.M.) and soil texture. Electrical conductivity and pH were determined by using the conductivity and pH meters respectively. Soil texture and soil organic matter were determined by using Atomic absorption spectrophotometer as the methods described by ICARDA (2001).

Vehicle count

The vehicles passing along the selected road were counted for 12 peak hours from 8 am to 8 pm for three consecutive times of the season at 5 sites each on target study road. Busses, trucks, vans, cars, motor bikes, rickshaws, container and loaders were counted and classified into three groups (2 and 3-wheelers, 4-wheeler and ≥ 6-wheelers (Leghari et al., 2013; Kalid et al., 2017).

Statistical analysis

All the observation of investigated parameters were calculated as an average and standard deviation. T-test of significance was used for the statistical analysis of data by using self-coded software on Microsoft excel 2007. Comparison between two means (polluted and control) was also intended for the determination of relative stimulatory and inhibitory effects of air pollution on the different attributes (Iyer and Bholay, 2015).

Results and discussion

The rapid increase in automobile activities and industrial processes, are the main causes of environmental pollution which have adverse effects on plant growth, fertility and productivity. In several contents it has been recommended that the pollen grains have capacity as bioindicators of environmental pollution. In this study, observations recorded show that the plants growing along the road side exhibited considerable damage to their pollen grains in response to automobile exhaust emission as compared to the control site while having the same soil characteristics (*Table 1*). All results regarding the pollen grains parameters are illustrated in *Figure 2a-j* and *Tables 2 to 5*.

In this study the consequences of pollen production, pollen size, pollen viability and pollen regularity are shown in *Fig. 2a, b, c, d, e,* respectively. Statistics exhibited slightly to significant ($p < 0.05$) decrease in pollen grains production, pollen size (breadth and length), pollen regularity and pollen viability at polluted site as compared to the non-polluted site. The number of pollen grains per flower from polluted site was found 38551.2, whereas pollen numbers were found 40819.2 from control site which is significantly ($p < 0.05$) high (*Fig. 2a*). During the study of pollen grain size; pollen breadth before and after the dehiscence from anther was noted 35 and 47 µm at control site, while at polluted site its breadth decreased by 20 and 31 µm respectively. Similarly pollen length: before and after dehiscence from anther was 45 and 60 µm at control site, whereas it decreased by 32 and 46 µm at the polluted site. Pollen size and length showed slightly to significantly ($p < 0.05$) reduction at polluted site (*Fig. 2b*). Slightly significant ($p < 0.05$) differences in pollen viability were also found between polluted and control sites samples. The percentage of pollen viability at polluted site was recorded 76.2% (T.T.C method) and 78.7% (germination method) with respect to the control site samples 85.6 and 85.5 %, respectively (*Fig. 2c, d*). The data shown in *Figure 2e* indicate that air pollution has significant effect on pollen structure. The air pollution caused a significant ($p < 0.05$) increased number of irregular and breakable pollen grains with respect to control site pollen grains. At control site sample 90% pollen grains were regular, while at polluted site pollen grains regularity reduced with the percentage of 70%. So the data disclosed in *Fig. 2a-e* indicate that the investigated plant species exhibited inhibition in its production of pollen grains, pollen viability, pollen regularity and pollen size due to auto exhaust pollution. Therefore, palynology of any plant can be used as vehicular pollution indicators. Similar results regarding inhibition in pollen production, pollen viability, and pollen size and pollen regularity were also reported by Iyer and Bholay (2015) and Rezanejad (2009). Pollen grain fertility reduction due to vehicular emission was also reported by Bharadwaj and Chauhan (1998) and this effect extends to the heredities development of plants and generative ecology which was highly influenced by the pollen grains propagation (Jain et al., 1997). Rezanejad (2007) also verified that air contamination produced abnormality in anthers, decrease of pollen grains, pollen numbers and male infertility of *Spartium junceum* L. (Spanish broom).

Effects of vehicular emission on pollen grains in the form of reduction in pollen germination and pollen tube length considerably affect the yield of plants. Many other researchers, including Gottardini et al. (2004), Higashitani (2013), Rezanejad (2013), Paupiere et al. (2014), have concluded that the vehicular emission and other atmospheric generated pollutants significantly influence the pollen grain production, pollen size, structure and its viability of different plant species. Kaur and Nagpal (2017) reported inversely proportion between number of traffic and pollen viability for *Alstonia scholaris, Nerium oleander* and *Tabernaemontana divaricata* at selected study sites.

Results presented in *Table 4* indicate that vehicular pollution increases the resting period of pollen grains in examined plant species of F-series by 1, 2 and 3 h, because the pollen grains of *Prunus avium* L. were pretentious due to the perpetuation of the resting time of F-series from 1 to 3 h at polluted site sample. At polluted site the pollen grains started their growth after 3 h and at 4th hour the growth was recorded only 164 µm as compared to control site sample 453.2 µm, while on the other hand pollen grain started its growth at 152.2 µm within one hour at control site. These results indicate that the pollen grains were under the stress of vehicular pollution. Data in

DOI: http://dx.doi.org/10.15666/aeer/1604_43874399

Table 4 also shows that the pollen grains of *Prunus avium* L. exhibited no propagation in F-24 series at all in both sites samples, including polluted and control. The results of this study are in conformity with observation recorded by Iyer and Bholay (2015) who found serious effects of air pollution on pollen grains of *Peltophorum ferrugineum.* They found resting period elongation to 5 h in F-series along with no germination in F-24 series due to air pollution.

(C: control site or non-polluted site, P: polluted site, ns: non-significant, *: slightly significant, **: significant)*

Observations about the rate of decrease in pollen grains germination and pollen tube length in F-series of successive flowers are displayed in *Tables 2* and *3*. These consequences show reverse proportion to the storage period in F-series of successive flowers. At 0 h, rate of decrease in pollen grain germination was 95.3 and 67.46 µm for control and polluted site respectively, while at 15^{th} hour the rate of decrease was 55.7 and 21.4 µm, respectively (*Table 2*). Total decrease rate of pollen grains germination after 15 h was 39.6 µm (control) and 46.06 µm (polluted site) with respect to the 0 hour (*Fig. 2g*). The total decreasing percentage was 41.55 and 68.27%, at control and polluted site samples respectively (*Fig. 2i*). Similarly the pollen tube length at 0 h was 814.8 µm (control site) and 710.1 µm (polluted site) in successive flowers, while at 15 h it was decreased by 452.3 and 215.3 µm respectively (*Table 3*). The total decreased rate of pollen tube length at 15 h was 362.5 and 494.8 µm for control and polluted sites respectively (*Fig. 2g*) with respect to 0 hour. The total decreasing percentage in pollen tube length at control and polluted sample after 15 h was 44.49 and 69.68 %, respectively (*Fig. 2j*). Observations reported by Iyer and Bholar (2015) in *Peltophorum ferrugineum* are also coinciding with our results. Significant reduction in both parameters was also noted for each interval of time (0 to 15 h), respectively in the samples of polluted site with respect to the control site (*Fig. 2h*). From these results, it is concluded that the low rate of pollen grains propagation and pollen tube length in the plant species was might be due to greater rate of air pollution in city area. The decrease or inhibition in pollen grain germination and pollen tube length through auto exhaust pollution was also reinforced by other researchers, Farkhondeh (2009) who also found reduction in pollen of *Thuja orientalis* L. (Cupressaceae). Similarly destructive properties of automobile pollutants on vegetation have long been documented (Carhart,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_43874399

1995; Agrawal and Tiwari, 1997; Singh et al., 2002; Byers et al., 2008; Mashitha and Pise, 2008; Leghari et al., 2013; Laghari et al., 2015) and can be utilized as a bioindicator of air pollution.

Data about soluble protein contents in pollen grain extract is shown in *Figure 2f*. These results conclude that the total contents of protein in polluted site sample was low (5.8 mg/g dw) as compared to the control site sample (7.0 mg/g dw). The results also indicate that as exposing time to the air pollution increased the level of protein contents decrease, which was non-significant. After 20 days at control site sample the pollen protein concentration was recorded at 6.6 mg/g dw but in control site sample it was only 5 mg/g dw (*Fig. 2f*). Similar results were revealed by Hjelmroos et al. (1994) and Parui et al. (1998) who found decrease in Bet v 1 concentration in air contaminated sample. Our results indicate that the difference in protein contents between the sample of polluted and non-polluted sites was non-significant. Similarly, non-significant variation was also noted by Rezanejad (2007) in soluble pollen proteins of *Spartium junceum* L. (Fabaceae) in the samples of polluted and control sites. Observations reported by several other researchers are found in confirmation to our results. Helender et al. (1997) did not perceive any important changes in the bands of protein of control and polluted site samples. Investigation on *lagerstroemia indica* exhibited reduction in total protein concentration and succeeding lower intensity of proteins in air contaminated conditions (Rezanejad et al., 2003).

Conclusion

This study concludes that the pollen grains are sensitive to air pollution. Vehicular exhaust pollutants prolonged the resting period of pollen grain of F-series by 1 to 3 h in the species study. *Prunus avium* L. exhibited potentiality of pollen grain germination only in F-series and showed no germination at all in F-24 series. Air pollution inhibited pollen tube length, pollen structure, viability and growth of pollen tube and their growth was also found inversely proportionate to the storage time. It is concluded that air contamination seems proficient in altering the pollen grain fertility, development, viability and biochemical and physiological properties of the airborne pollen, therefore imperiling fertilization, reproduction ability, seed setting, plant breeding and possibly allergencity. So it may be concluded that pollen grains can give significant data about the organic impact of air impurities and can be used as decent applicants as bioindicators of environmental pollution. This type of research may be supportive in exploration of tolerance or sensitivity level of different roadside plant species against air pollution.

Abstract. The favorable effects of exogenously applied brassinosteroids and zinc micronutrient on plant growth performance and seed development have been extensively outlined in many studies. Nevertheless, almost no published document is available on the effects of 24-epibrassinolide and nano-zinc oxide on tomato seed quality and osmotic stress tolerance of the resulted seedlings. In this study, the effects of 24-epibrassinolide (0, 15 and 30 mg.ha^{-1} EBL) and nano-zinc oxide (0, 600 and 1200 ppm N-ZnO), which were exogenously applied on tomato mother plants, on seed germination parameters and stress tolerance capability of the produced seedlings under osmotic stress conditions (water potential of 0, -0.1 and -0.2 MPa stimulated by PEG-6000) were investigated. According to obtained results, the water potential of -0.2 MPa resulted in the lowest seed germinability and seedling growth performance with the highest amount of proline, hydrogen peroxide, malondialdehyde and activity of catalase and peroxidase, compared to non-stress control. All the foliar treatments resulted in decreased H_2O_2 and MDA content, especially EBL_2+N-ZnO_2. In addition, foliar application of EBL and N-ZnO enhanced the activity of antioxidative enzymes and ameliorated the inhibitory effects of osmotic stress on tomato seedling growth, except for percentage and rate of germination.
Keywords: *antioxidant system, brassinosteroids, micronutrients, seed quality, water potential*

Introduction

Tomato is the second most important vegetable crop next to potato worldwide (Eevera and Vanangamudi, 2006), and also it is highly popular in Northwest of Iran. According to the Food and Agriculture Organization (FAO), in 2016, around 4.7 million hectares of world farms allocated to tomatoes, which included about 177 million tons of annual production of fresh fruit (Anonymous, 2016). Tomato is mainly cultivated in tropical and sub-tropical countries, preferably in Mediterranean regions, which is mostly encountered by the varying environmental fluctuations. Among these adverse conditions, soil drying in seedbed is one of the critical problems that negatively influence seed germination and subsequent seedling growth (George, 2009; Chandrasekaran et al., 2017). The reduction in soil water potential results in disorder in seed germination by decreasing the imbibition rate (Eisvand et al., 2010). Individual seeds have to cross a threshold water potential in order to develop enzyme activity and lower their puncture force. The endosperm weakening opposite the radicle tip

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_44014417

determines the threshold water potential for germination, which determines the rate and extent of germination (Finch-Savage, 2013).

In normal conditions, the reactive oxygen species (ROS) and antioxidant enzymes are produced in plant cells in a stable equilibrium (Gill and Tuteja, 2010), while under abiotic stresses, the balance can be overcome, mediating an accumulation of ROS and inducing oxidative damage (Mignolet-Spruyt et al., 2016). Lipid peroxidation as a main destructive event occurs due to increased ROS production and is detected by malondialdehyde accumulation in plant cells (Petrov et al., 2015). The antioxidant defense including the antioxidative enzymes (such as catalase and peroxidase) and metabolites is exploited by plant cells to cope with ROS attack (Gill and Tuteja, 2010). Catalase converts hydrogen peroxide (H_2O_2) into water and molecular oxygen (DeLay, 2017). Peroxidase can also detoxify H_2O_2 using various compounds as electron donor (Puthur, 2016). In addition, some researchers have introduced proline as an antioxidant molecule, proposing its role as ROS scavenger along with compatible osmolyte (Hossain et al., 2014; Rejeb et al., 2014). Under osmotic stress condition, the high capacity of antioxidant system is essential for plants to scavenge ROS and then avoid oxidative stress (Uzilday et al., 2014).

To ensure optimum stand establishment in soils with low water content, high-quality seeds must be used to achieve rapid and uniform seedling emergence, which may improve the resources use efficiency of established seedlings (Copeland and McDonald, 2012; Taiz et al., 2015). High-quality, also known as high-vigor seed lot has a great potential for rapid and uniform seed germination and successful seedling emergence under stressful conditions (Ellis and Roberts, 1981; Rehman et al., 1999; de Figueiredo et al., 2003). In all horticultural plants, including tomato, the high-quality seeds are the most important input in an efficient plant production system. So that, the low-quality seeds result in the poor stand establishment and consequently lower the crop productivity, especially under abiotic stresses (Rashid and Singh, 2000; Elias et al., 2006; George, 2009).

Seed quality consists of the physiological, physical and health attributes and is influenced by the growth conditions of the mother plant, which is well known as ‘maternal effect’ (Sangkram and Noomhorm, 2002; Pfeifer et al., 2011). In tomato plant, the fruit as a surrounding environment directly transfers the external conditions to the developing seeds. In this respect, the phytohormones and the mineral nutrients that reach the seeds play a key role in plant cell metabolism and ultimately improve the quality of produced seeds (Srivastava and Handa, 2005). Overall, the internal concentrations of plant growth regulators such as brassinosteroids and nutritional status of the plant, especially after adequate supply of micronutrients during the formation and development of seeds on the mother plant, are so vital. Some researchers have previously reported the production of high-quality seeds in plants exogenously treated with brassinosteroids and zinc (Biesaga-Koscielniak et al., 2014; Laware and Raskar, 2014).

Brassinosteroids are the sixth group of phytohormones, which have different physiological effects on seed and seedling tissues including the stimulation of cell elongation and division, the regulation of enzymes activity and the promotion of seed germination (Özdemir et al., 2004). Previous researchers have reported that these compounds alleviate the detrimental impacts of environmental hazards such as drought, on plant performance (Prusakova et al., 2000; Vardhini et al., 2010). In this regard, Yuan et al. (2010) demonstrated that the exogenous application of 24-epibrassinolide

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_44014417

mediated drought tolerance in tomato plants through reducing malondialdehyde and hydrogen peroxide and increasing the activity of antioxidant enzymes. The micronutrient element of Zinc (Zn) plays a fundamental role in plant metabolism (Marschner, 2011) and biosynthesis of RNA, DNA and proteins (Welch, 2001). Although zinc is required in small amounts (5-100 ppm), its complete lack or insufficiency may influence the important physiological aspects of plant growth (Baybordi, 2006) including antioxidative enzymes and some regulatory metabolites (Cakmak, 2000). Supplemental zinc can alleviate the negative impacts of oxidative damage on plant metabolism (Tavallali et al., 2010). For example, zinc can help maintain sulfhydryl groups of cell membrane, which are easily oxidized by ROS (Rengel, 1995; Rengel and Wheal, 1997).

Already, some efforts have been made to produce high-quality seeds by employing certain agronomic techniques. The aim of the present research was to evaluate the osmotic stress tolerance capability (as an indicator of seed quality) of tomato seeds harvested from mother plants subjected to 24-epibrassinolide and nano-zinc oxide at the flowering stage. In the present experiment, seed germinability and seedling growth indices were measured and the antioxidative enzyme activities, hydrogen peroxide, malondialdehyde and proline accumulation in tomato seedlings were determined. This work is important as it demonstrates the collaborative role of brassinosteroid and zinc micro-element in providing osmotic stress tolerance and creating awareness of the potential for tomato plants to be cultivated in arid and semi-arid areas.

Materials and methods

The present experiment was conducted during 2015-2016 growing season in the Department of Agronomyand Plant Breeding, Faculty of Agriculture and Natural Resoursec at the University of Mohaghegh Ardabili, Ardabil, Iran. The seed lot of tomato (*Solanum lycopersicum* L.) cv. Y was obtained from SPCRI (Seed and Plant Certification and Registration Institute, Karaj). The viability and moisture content of prepared seeds were about 98% and 8%, respectively. All chemicals used in this research were purchased from Merck and Sigma-Aldrich.

Tomato seeds were sown in nursery beds of 0.5 m × 0.5 m, rich in loam and provided with shade and regular watering for seed germination. After 25 days of growth in the nursery, tomato plantlets were carefully transferred to the main field. The farm soil characteristics are listed in *Table 1*. The fertilizer application was 180 kg N, 150 kg P_2O_5 and 150 kg K per hectare. Tomato seedlings were transplanted in 3 rows in each plot at spacing of 45 cm × 120 cm, giving a total of 1500 plants per experimental unit. The final crop density was around 18,500 plants per hectare. A factorial experiment was conducted based on randomized complete block design (RCBD) with three replications. Experimental factors were foliar treatment combinations [control (only water), 15 $mg.ha^{-1}$ of 24-epibrassinolide (EBL_1), 30 $mg.ha^{-1}$ of 24-epibrassinolide (EBL_2), 600 ppm of nano-zinc oxide (N-ZnO_1), 1200 ppm of nano-zinc oxide (N-ZnO_2), EBL_1 + N-ZnO_1, EBL_1 + N-ZnO_2, EBL_2 + N-ZnO_1, EBL_2 + N-ZnO_2] and osmotic stress levels (0, -0.1 and -0.2 MPa). After complete vegetative growth in the field, foliar treatments with 24-epibrassinolide (EBL) and nano-zinc oxide (N-ZnO) were imposed at the flowering stage. Tween-20 (0.1%) was used as surfactant to enhance the effectiveness of foliar spray. The foliar applications were made with a portable field sprayer at 150 kPa pressure with 1000 l of liquid applied per hectare.

Available K ($mg.kg^{-1}$)	230
Zn ($mg.kg^{-1}$)	0.994

After harvesting the fully ripe fruits, the seeds were extracted by fermentation method (at 25 °C for 24 h) and then dried to moisture content of about 8%. The quality of obtained seeds was assayed under osmotic stress condition. In order to create the different water stress levels (0, -0.1 and -0.2 MPa) in seed germination mediums, PEG-6000 was used. The standard germination test of the processed seeds was conducted according to the rules approved by the International Seed Testing Association (ISTA, 2008). In brief, after 10 min of surface sterilization with sodium hypochlorite 1%, four replicates of 50 seeds were incubated in alternating temperatures (25/30 °C) for 14 days. The daily counting of the number of germinated seeds (>2 mm radicle protrusion) continued until the end of the 14th day. In each experimental unit, the standard germination percentage and dry weight and length of seedlings were measured. The germination rate was calculated using the formula of Ellis and Roberts (1981). The vigor index (VI) was calculated using the following equation: VI = seedling length × germination percentage.

Free proline content in tomato seedlings was determined using ninhydrin reagent according to the most used method described by Bates et al. (1973). Malondialdehyde (MDA) content was measured by thiobarbituric acid reaction (Heath and Packer, 1968), with slight modifications. Fresh seedlings (0.1 g each) were homogenized in 1 ml of 0.1% (w/v) trichloroacetic acid (TCA) and the homogenates were centrifuged at 5000 × g for 10 min at 4 °C. In the following, 400 µl of the supernatant was added into1 ml of 0.5% (w/v) thiobarbituric acid. The obtained mixture was incubated at a temperature of 95 °C in a water bath for 30 min. After centrifugation at 10000 × g for 10 min, the absorbance of the supernatant was measured at 532 and 600 nm in a spectrophotometer. To calculate the concentration of MDA, the related extinction coefficient (0.155 $\mu M^{-1}.cm^{-1}$) was used and the values were expressed as $\mu mol.g^{-1}$ F.W. Hydrogen peroxide was quantified by the method of Hung et al. (2005). Fresh seedlings (0.1 g each) were homogenized in 1 ml of 0.1% (w/v) TCA. The obtained mixture was centrifuged at 10000 × g for 10 min, at 4 °C, then 0.5 ml of supernatant was added to 0.5 ml of 10 mM potassium phosphate buffer (pH = 7) and 1 ml of 1 mM potassium iodide. The absorbance was read at a wavelength of 390 nm. The amount of hydrogen peroxide in each sample was calculated using the specific extinction coefficient (0.28 $\mu M^{-1}.cm^{-1}$) and the values were expressed in units of $\mu mol.g^{-1}$ F.W. Catalase (CAT) and peroxidase (POD) activities in tomato seedlings were assayed using the methods of Aebi (1984) and MacAdam et al. (1992), respectively.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_44014417

After conducting the normality test of obtained data, two-way analysis of variance (ANOVA) for randomized complete block design was done using SAS 9.4 software and the means were compared by least significant difference (LSD) test at 5% probability level and the figures were created with Microsoft Excel 2013.

Results

In the present study, tomato plants were exogenously treated with different combinations of 24-epibrassinolide (EBL) and nano-zinc oxide (N-ZnO) at the flowering stage and then the harvested seed lots were subjected to osmotic stress (OS). Finally, germination percentage and rate, seedling length, dry weight and vigor index, proline, malondialdehyde and H_2O_2 content and catalase and peroxidase activity in the seedlings were estimated. In general, the main effects and interaction of two experimental factors: (1) foliar application of EBL+N-ZnO and (2) osmotic stress were statistically significant ($P \leq 5\%$) in all measured characteristics, but germination percentage and rate which had the main effects, were significant (*Table 2*).

The effect of osmotic stress on the germination percentage and rate of seeds produced from tomato mother plants exogenously treated with EBL and N-ZnO are shown in *Table 3*. Overall, the promotive influence of foliar application of EBL and N-ZnO on the germination percentage and rate were observed. The treatment, EBL_1 (15 $mg.ha^{-1}$), had no significant difference from control ($P > 5\%$) in percentage germination. The sole applications of EBL and N-ZnO were statistically the same in the rate of germination. The highest germination percentage and rate were recorded when EBL_2 + N-ZnO_2 was applied in the mother plants, compared to control in which only the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_44014417

distilled water was sprayed. The germination percentage and rate was significantly decreased with increased levels of osmotic stress. So that, the maximum reduction in germination percentage (about 5%) and rate (approximately 72%) were observed in water potential of -0.2 MPa compared with control.

Table 3. *Germination percentage and rate of seeds harvested from tomato plants subjected to exogenous EBL and N-ZnO in response to osmotic stress*

Similar letters indicate no significant difference at $p \leq 5\%$

Changes in the length, dry weight and vigor index of tomato seedlings in response to treatment compounds almost followed the same trend (*Fig. 1 A-C*). Overall, the foliar treatments of EBL and N-ZnO significantly increased the seedling growth parameters, compared to untreated control (only water spray). On the other hand, the inhibitory effect of osmotic stress on the growth performance of tomato seedlings was intensified by decreasing the water potential. The highest values of seedling length (*Fig. 1A*), dry weight (*Fig. 1B*) and vigor index (*Fig. 1C*) were recorded in treatment combination of EBL_2+$N\text{-}ZnO_2$ under non-stress condition. The lowest length, dry weight and vigor index of tomato seedlings belonged to both $N\text{-}ZnO_1$ (600 ppm of nano-zinc oxide) and untreated control, when -0.2 MPa water potential was created in the growth medium. Notably, when the osmotic stress was amplified in seedling growth medium (-0.2 MPa water potential), the effectiveness of exogenously applied brassinosteroid and zinc was relatively maintained in comparison with the mild water deficit condition (-0.1 MPa water potential).

The free proline content in tomato seedlings was significantly influenced by osmotic stress levels ($P \leq 0.05$). In an osmotic potential of -0.2 MPa, the accumulation of proline was increased approximately by 15% compared to non-stress control. In general, the foliar treatments had negligible but significant positive effects on the proline amount ($P > 0.05$). On the other hand, the interaction between the two experimental factors was statistically significant. The proline content was considerably elevated in response to concomitant application of 24-epibrassinolide and nano-zinc oxide under both osmotic stress levels, so that the highest proline accumulation occurred in treatment combination of EBL_2+$N\text{-}ZnO_2$ under water potential of -0.2 MPa (*Fig. 2*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_44014417

The tomato seedlings showed the higher H_2O_2 accumulation under osmotic stress compared to the corresponding control, especially when the osmotic potential of the culture medium was -0.2 MPa (*Fig. 3*). Under both non-stress and osmotic stress conditions, foliar sprayed EBL+N-ZnO combination had more significant reduction in the H_2O_2 accumulation compared to sole application of EBL and/or N-ZnO. The lowest H_2O_2 content was clearly observed in EBL_2+N-ZnO_2 (30 mg.ha^{-1} EBL and 1200 ppm N-ZnO) under non-stress condition. Among the sole applications of 24-epibrassinolide (EBL_1 and EBL_2) and nano-zinc oxide (N-ZnO_1 and N-ZnO_2), 30 mg.ha^{-1} brassinosteroid (EBL_2) showed more decrease in hydrogen peroxide amount.

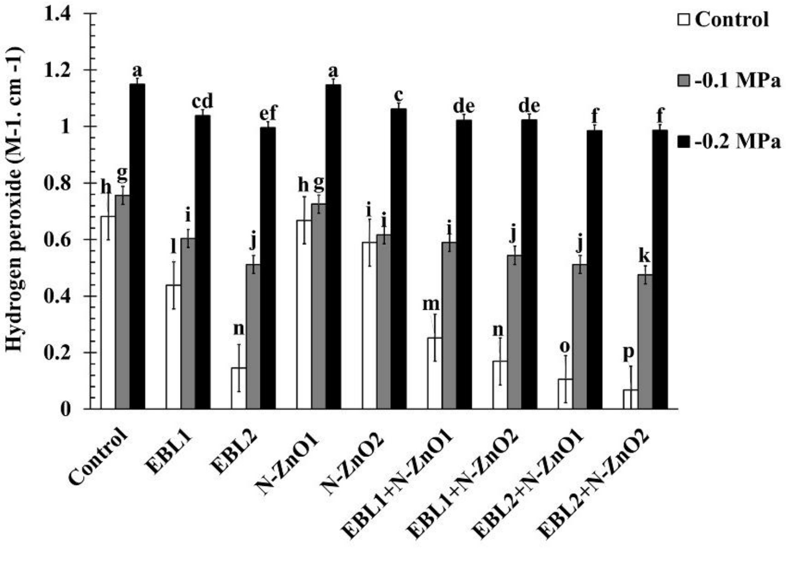

Figure 3. *Changes in the H_2O_2 content of seedling in response to foliar spray treatments (EBL and N-ZnO) applied on tomato mother plants and osmotic stress applied in the germination medium of produced seeds. Similar letters indicate no significant difference at $P \leq 5\%$. LSD value was 0.0328*

The osmotic stress led to a significant increase in malondialdehyde (MDA) content in tomato seedlings compared to corresponding control (*Fig. 4*). The greatest accumulation of MDA was recorded in tomato seedlings untreated with EBL and N-ZnO under osmotic stress level of -0.2 MPa. Among the sole applications of brassinosteroid and zinc, EBL_2 (30 mg.ha^{-1}) indicated more reduction in MDA content. Overall, the osmotic stress-induced MDA production was further restricted when EBL+N-ZnO combinations were exogenously applied, instead of using them alone. The lowest accumulation of malondialdehyde was observed in EBL_2 + N-ZnO_2 treatment under all three levels of osmotic stress.

As shown in *Figure 5,* the catalase activity in tomato seedlings was significantly increased under osmotic stress condition (-0.1 and -0.2 MPa) compared to control, and the foliar treatments relatively enhanced the CAT activity. The highest activity of catalase (about 3-fold of control) was observed in water potential of -0.2 MPa when 30 mg.ha^{-1} EBL and 1200 ppm N-ZnO were concomitantly applied.

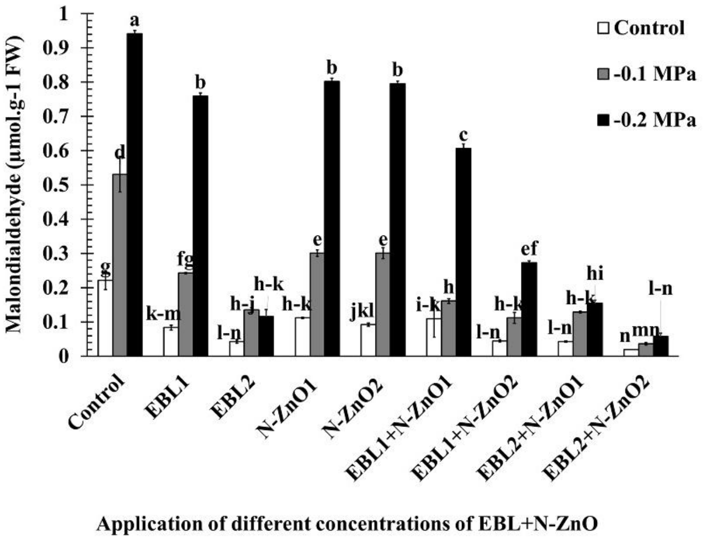

Figure 4. *Changes in the MDA content of seedling in response to foliar spray treatments (EBL and N-ZnO) applied on tomato mother plants and osmotic stress applied in the germination medium of produced seeds. Similar letters indicate no significant difference at P ≤ 5%. LSD value was 0.0509*

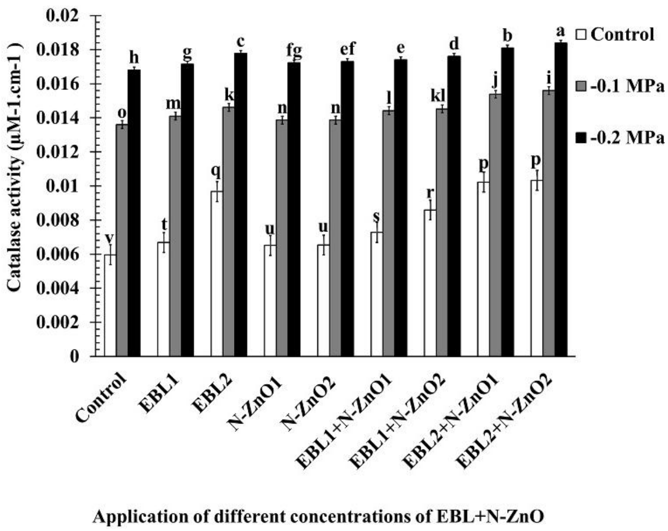

Figure 5. *Changes in the activity of CAT in response to foliar spray treatments (EBL and N-ZnO) applied on tomato mother plants and osmotic stress applied in the germination medium of produced seeds. Similar letters indicate no significant difference at P ≤ 5%. LSD value was 0.0001*

Under non-stress conditions, foliar sprayed EBL and N-ZnO did not have any significant effect on the peroxidase activities (*Fig. 6*). Under osmotic stress, the activities of POD in tomato seedlings were obviously increased, whereas the application of 24-epibrassinolide and nano-zinc oxide negligibly but significantly promoted the increase. Like the CAT enzyme, the highest activity of POD (more than two fold of control) was recorded in treatment combination of EBL_2 + N-ZnO_2 under water potential of -0.2 MPa.

Discussion

Promotive effects of brassinosteroid and zinc micronutrient on seed quantity and quality of field crops has already been mentioned by some authors (Hayat et al., 2001; Biesaga-Koscielniak et al., 2014; Laware and Raskar, 2014). According to previous studies, exogenous application of 24-epibrassinolide (Özdemir et al., 2004) and nano-zinc oxide (Prasad et al., 2012) at germination stage can lead to improved seed germinability and subsequent seedling growth. To the best of our knowledge, almost no research has been conducted to evaluate the effects of foliar spray of EBL and N-ZnO on seed germination and subsequent seedling performance under osmotic stress condition in seed lots produced from tomato mother plants. In the present research, the results showed that osmotic stress resulted in a delayed and decreased germination, which was not improve by foliar application of EBL and N-ZnO in tomato plants (*Table 2*). The results are in good agreement with previous investigations which reported osmotic stress-induced reduction in the seed germinability (PENG et al., 2013; Bhatt et al., 2015). Rajabi et al. (2013) stated that interruption in water absorption by seed could affect the metabolic activities related to germination process under osmotic stress condition. On the other hand, foliar spray of EBL and N-ZnO combinations at the flowering stage could enhance the percentage and rate of germination in the obtained seeds (*Table 2*). Brassinosteroids have a similar role as gibberellin in the germination process and enhances the germinability of seeds by reducing and/or increasing their biosynthesis and sensitivity to abscisic acid and/or gibberellin, respectively (Erik et al., 1996; Steber and McCourt, 2001; Zhang et al., 2009; Divi and Krishna, 2010). Similar results have reported that exogenous application of zinc in safflower (Movahhedy-Dehnavy et al., 2009) and soybean (Sedghi et al., 2013) increased the germination of produced seeds under drought stress conditions. Zinc micro-element is required for the biosynthesis of auxin (IAA) through the tryptamine pathway (Haslett et al., 2001), and has a promotive effect on the cell division (Alloway, 2004). Therefore, it can be

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_44014417

concluded that Zn-mediated increase in the seed germination parameters can be originated from the signaling of IAA and the proliferation of cells.

According to the present results, the tomato seedling performance (measured as seedling length, dry weight and vigor index) was adversly affected when osmotic stress was intensified in the culture medium of harvested seeds. As seen in *Figure 1,* 30 $mg.ha^{-1}$ EBL along with 1200 ppm N-ZnO (treatment combination of EBL_2 + N-ZnO_2) may to a great extent compensate for the drought-induced inhibition in tomato seedling growth. The results of the current study are consistent with the recent study (Khripach et al., 1998) in which the growth performance of seedlings was improved when the mother plants was treated with 24-epibrassinolide and the harvested seeds were exposed to low water potentials. Prasad et al. (2012) demonstrated that the foliar spray of nano-zinc oxide caused a significant increase in seedling length and dry weight, compared to the control. Boonchuay et al. (2013) found that foliar application of zinc resulted in higher seedling vigor index in seed lots obtained from exogenously treated mother plants. Overall, nanoparticles provide an efficient means to distribute agro-chemicals including fertilizers, in a controlled fashion (Agrawal and Rathore, 2014). So, plants can rapidly absorb slow-release nano-fertilizers and surely cause the saving of fertilizer consumption and minimize environmental pollution (Mura et al., 2013; Bindraban et al., 2015). It should be noted that the hormone (24-epibrassinolide) application was more efficient than the micronutrient (nano-zinc oxide), when only one of them was used alone, compared to EBL+N-ZnO co-application.

In consistency with the results of this experiment, many researchers reported that osmotic stress increases the accumulation of free proline in tomato seedlings (Calvo-Polanco et al., 2016; Sun et al., 2016). Kishor et al. (2014) stated that the proline accumulation has a positive and direct relationship with increasing the tolerance to water deficit stress in plants, as was evident in the current study (*Fig. 2*). Further increase in proline amount leads to preventing ROS attack and subsequently reducing the cell membrane damage. In addition, drought tolerance is increased by proline-induced osmotic adjustment (Szabados and Savouré, 2010). On the other hand, exogenous EBL and N-ZnO, exogenously applied in tomato mother plants during anthesis, promotes the production of free proline in seedlings under low water potential (*Fig. 2*). In this regard, Behnamnia et al. (2009) reported that 24-epibrassinolide increased the proline content in tomato leaves under limited water access. It has commonly been assumed that, EBL can promote free proline biosynthesis through inducing the expression of genes responsible for the related enzymes (Talaat and Shawky, 2013) and regulating the synthesis of nucleic acids (Bajgaz, 2000). As an important cofactor, Zinc has a key role in the production and activity of several enzymes (Bagci et al., 2007), particularly those involved in the main pathway of proline biosynthesis, i.e. glutamate pathway which is dominant in higher plants (Delaney et al., 1993). So, it seems that great increase in the proline content of tomato seedlings in response to exogenous application of EBL and N-ZnO at the flowering stage can help maintain an efficient osmotic homeostasis into the cell (by increasing proline and other compatible osmolytes), and therefore induce the osmotic stress tolerance in seedlings.

In this study, the hydrogen peroxide (*Fig. 3*) and malondialdehyde (*Fig. 4*) accumulation was clearly observed in leaves in response to low water potential imposed to seedlings from harvested tomato seeds. There is strong evidence that osmotic stress can result in the accumulation of ROS including hydrogen peroxide and MDA, as an indicator of lipid peroxidation, in different plant tissues (Todorova et al., 2016). As previous studies

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_44014417

have emphasized, the overproduction of toxic ROS in plant cells under stress can mainly damage the lipid-containing components of cell (Tavallali et al., 2010) and then cause the plasma membrane disintegrity that increases the permeabilization (Anjum, 2015). As found in the present experiment, osmotic stress-induced accumulation of H_2O_2 and MDA in seedlings was significantly declined as a result of foliar treatment of tomato mother plants with 24-epibrassinolide and nano-zinc oxide (*Figs. 3* and *4*). Several researchers reported the decline in H_2O_2 and MDA content of leaves due to 24-epibrassinolide application (Yuan et al., 2010; Talaat and Shawky, 2013). Brassinosteroid hormones may prevent the membrane damage caused by lipid peroxidation through influencing fatty acid composition and regulating the expression of genes (Khripach et al., 1998; Cao et al., 2005). In addition, Zn reduced ROS generation by indirect activation of antioxidant system (Grewal and Wiliams, 2000; Bagci et al., 2007).

Higher plants evolutionary have an antioxidant defense mechanism for scavenging reactive oxygen species, and efficient modulation of this defense system is essential for plants to tolerate the stress-iduced oxidative damage (Mittova et al., 2015). In the present study, antioxidative enzymes including catalase (*Fig. 5*) and peroxidase (*Fig. 6*) showed a significant increase in tomato seedlings under osmotic stress conditions, which were effective in alleviating the adverse impact of ROS and subsequently preventing lipid peroxidation. Foliar application of EBL and N-ZnO resulted in increased activity of both CAT and POD, especially when no osmotic stress was imposed on tomato seedlings. This may also imply that CAT plays more important role than POD in scavenging excessive hydrogen peroxide in osmotic stress condition. This is in consistency with the same report in silicon-supplemented tomato seedlings exposed to water deficit stress (Shi et al., 2014). Yuan et al. (2010) reported that the use of epibrassinolide induced tolerance to drought in tomato via reducing malondialdehyde and hydrogen peroxide and increasing the activity of antioxidant enzymes. Researchers believe that brassinosteroids increase the resistance of plants to ROS-mediated oxidative damage through the modulation of expression of genes encoding antioxidative enzymes (Goda et al., 2002; Cao et al., 2005). Zinc is effective in the induction of gene expression responsible for the synthesis of proteins and antioxidant enzymes and in some cases, is also considred a cofactor for these enzymes (Grewal and Wiliams, 2000; Bagci et al., 2007; Alharby et al., 2016).

Conclusion

Finally, it could be concluded that seeds produced from tomato plants, which were treated with 24-epibrassinolide and nano-zinc oxide, showed higher tolerance to osmotic stress. So that seed germination indices, seedling growth performance and activity of antioxidative enzymes were significantly increased by preventing the accumulation of toxic ROS and MDA as the main peroxidative products. Although, both two applied concentrations of 24-epibrassinolide and nano-zinc oxide showed the promotive effects on osmotic stress tolerance in tomato seedlings, the combined treatment of 30 $mg.ha^{-1}$ 24-epibrassinolide and 1200 ppm nano-zinc oxide (EBL_2+N-ZnO_2), had higher tolerance capability. Based on the current findings, foliar application of 24-epibrassinolide and nano-zinc oxide with the optimal concentrations at the flowering stage is highly recommended. On the other hand, it is recommended that researchers investigate the effects of optimal concentrations of 24-epibrassinolide and nano-zinc oxide on different developmental stages of tomato seeds and report their results in order to complete the results of current study.

(Received 14th Feb 2018; accepted 24th May 2018)

Abstract. The most important climate parameters in dendrochronological investigation are air temperature and dynamics of precipitation in certain periods. In the research time from 2005 to 2016 3 species and 2 hybrids: *Larix sibirica, L. decidua, L. kaempheri, L. x gmelinii* and *L. x eurolepis* were evaluated in the Botanical Garden of Klaipėda University, that is situated in the western part of Lithuania. This region can be characterized with high precipitation in the summer season, warm air temperature in winter and the lowest temperature values are in the summer season. According to research data the precipitation in autumn season influenced the highest radial growths of all observed Larix (r from 0,33 to 0,78), but average air temperature in this season had no influence (r from -0,19 to 0,50), similarly temperature had no influence in the spring season either (r from -0,12 to -0,76, $p<0.001$). 62 % of *L. sibirica* was influenced by precipitation but 22 % of L. *decidua* by air temperature in the autumn season. The average radial growth of hibrid larches, namely *L. x gmelinii* and *L. x eurolepis* was 1.3 – 1.5 times lower compared with *L. sibirica* and *L. decidua* . *L. x gmelinii* and *L. x eurolepis* were also positively influenced by precipitation in the autumn season.
Keywords: *botanic garden, Larix, average temperature, precipitation, season, radial growth*

Introduction

Tree rings analysis is widely used in modern forest lumbering, climate change research and in forest monitoring studies (Worbes, 2004). Most important climate parameters in dendrochronological investigation are air temperature and dynamics of precipitation content in certain periods (Xue et al., 2016). In Lithuanian conditions the formation of annual tree rings is mostly influenced by air temperature in active vegetation period (April – September) and precipitation in the summer time (Stravinskienė, 2002). Climate is a major environmental factor affecting the phenotype of trees and a critical agent of natural selection that has molded among-population genetic variation. Population response functions describe the environmental effect of planting site climate on the performance of a single population, whereas transfer functions describe among-population genetic variation molded by natural selection for climate. Although these approaches are widely used to predict the responses of trees to climate change, both have limitations (Wang et al., 2010). The rapid rate of change coupled with the large absolute amount of change are expected to have profound effects on terrestrial ecosystems at all hierarchical levels: from vegetation zones (Tchebakova et al., 2005), to ecosystems (Guisan et al., 1995), species (Fujiwara and Box, 1999), and to populations within species (Rehfeldt et al., 1999, 2002; Tchebakova et al., 2005).

Larch (*Larix*) belongs to the Pinaceae family and is one of the most abundant coniferous genera of the northern hemisphere. The larches - Larix P. Mill. - of the world are usually grouped into 10 species that are widely distributed in Eurasia and North America (Hora, 1981; Krüssmann, 1985; Schmidt, 1995; Farjon, 2010; Ide et al., 2016). Some species

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_44194430

dominate at the northern limits of boreal forests and others occur above subalpine forests (Gower and Richards, 1990). Larch cannot grow in the shade. It prefers moist soil. The plant can tolerate maritime exposure, they cannot tolerate atmospheric pollution (http://www.pfaf.org). Geographic races have developed in many widely distributed larch species, and these often exhibit marked differences in growth rates and other characteristics (Rudolf, 1974; Bednarova et al., 2013). The European larch includes at least 5 geographic races (often considered to be subspecies or varieties) that roughly coincide with major distributional groups of the species. European larch (*Larix decidua*, Miller, 1768) is endemic to Europe and is characterized by a disjunctive distribution (Wagner, 2013). European seed sources perform similarly in northeastern United States as in Great Britain, Germany and Italy (Dylis, 1981). Some varieties of Dahurian larch that is confined to definite areas appear to be geographic races. The native western larch specimens from more continental climates with lower humidity are doing poorly. European larch compared with other species can be characterized with faster growth. Natural habitat of European larch is relatively small and covers mainly the European mountainous regions (Busetto et al., 2010). The rapid growth of larch, high productivity and sustainability are achieved when soil and climatic conditions are in accordance with the biological requirements. The dry weather, hot summers and cold winters are important conditions for larch (Тимофеев, 1961). *Larix sibirica* is common in the lowland taiga of West Siberia, where it forms the northern limit of trees alternately with *Picea obovata* and with *Pinus sylvestris*. Larrix also occurs in the mountains (from 500 m to 2,400 m a.s.l.). It grows on a great variety of soils, from peat bogs to well drained, sandy or rocky soils, where it has its optimum, that is in very cold climate (min. temp. -55 °C), continental or subarctic, dry, with very long winters. There are stands on peat or on mountains above the steppe (Altai Mts.), but more common it is mixed with *Pinus sylvestris*, *P. sibirica*, *Picea obovata*, *Abies sibirica* and broad-leaved trees such as *Betula pendula* and *Populus* spp (Farjon, 2013). Japanese larch (*Larix kaempferi*) is one of the most important timber species in the sub-Alpine region and northern area of Japan (Zhu et al., 1998). *Larix gmelinii* (Rupr.) is one of the most economically important species in boreal forests (Zyryanova et al., 2007). It is a deciduous needleleaf conifer that is adapted to growing in very harsh climates and is widely distributed over a range from 40° N to 72° N and 110° E to 130° E (Zhu et al., 1998). It is the dominant tree species in the Greater Khingan Mountains forest ecosystem in northern China (Farjon, 1990; Fu et al., 1999).

Introduction of European larch (*Larix decidua* Mill.) in Lithuania launched in the middle of the XIX century as a valuable industrial and decorative species. In forestries of the country larch began to grow 160 years ago, and now grow such forest stand in south part of Lithuania in Alytus district (Navasaitis, 2004). As in natural habitats, in Lithuania larches resistant to cold, and not affected by winter (Pūkienė and Bitvinskas, 2000). In Lithuania European larch mainly grows in mixed stands associated with Norway spruce (*Picea abies*), stone pine (*Pinus cembra*), Swiss pine (*Pinus mugo*), European beech (*Fagus sylvatica*) or silver fir (*Abies alba*) but can also occur in pure stands (Navasaitis, 2004).

The stem radial growth of trees in any year integrates the effects of the climate during the previous and current year (Zhang and Chen, 2015; Jiang et al., 2016). Tree radial growth is influenced by environmental factors (e.g., temperature, precipitation, and competition) and conditions within the individual tree (Zhang and Chen, 2015). Tree-ring records are often used to investigate the responses of tree growth to historical climate variations, to predict the effects of future climate change on tree growth, and to understand the spatial and temporal patterns of tree-growth variability of forest ecosystems (Thuiller et al., 2005; Tardif et al., 2006; Metsaranta et al., 2008). Stem sensitivity growth rate is an important indicator for the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_44194430

assessment to increasing annual radial gain and their connection with environmental conditions (Karpavičius, 2004). Reasearch of Larix genus growing intensity is important to climate changes context in botanical gardens, because there ussualy carry out evaluating of plants acclimatization. This is important to preserve biological diversity and educate the society. Many people may have a conceptual grasp of climate change, but may not know what climate effects to expect in the region, and what impacts climate change may have on their day-to-day environment. As the urgency and significance of climate change continues to mount, new approaches are needed for interpreting and visualizing climate change for the public that is tangible and approachable. Botanical gardens have made longstanding contributions to climate change research, particularly with respect to temperature and its effects on the timing of plant flowering and leaf out by participating in phenological networks of botanical gardens, monitoring standardized plantings in phenological gardens, and studying and examining herbarium specimens and historical photographs (Primack and Miller-Rushing, 2009).

The aim of this work is to evaluate *Larix* Mill genus plant radial growth in the context of climate parameter changes in the Botanical Garden of Klaipėda University located in the west part of Lithuania (coastal zone).

Material and methods

Study area and object

The Botanical Garden of Klaipėda University is located in Western Lithuania, in the northern part of the city of Klaipėda, in the valley of the Dane River. It was established in 1993, since 2002 it has dendrological park status. In general, the width of the area is 9.3 ha, and collections of ornamental plants are established here. The most important purpose of the Botanical Garden is the conservation of the genetic resources of herbaceous and woody ornamental and medicinal plants in the collections. It is a unique plant introduction centre, where climatic conditions differ from other parts of Lithuania, because of having higher air temperature, more precipitation, and a longer plant-vegetation period. Therefore, these are favourable conditions for plant adaptation. Since 2005, Botanical Garden is a member of the International Phenological Gardens (IPG).

In the Dendrological section of the Botanical Garden 10 taxa of Larix P. Mill. are growing. For research 3 species and 2 hybrids of larches were evaluated: *Larix sibirica, L. decidua, L. kaempheri, L. x gmelinii* and *L. x eurolepis* (3 individuals from every taxa). The age of the evaluated larix were different: *L. sibirica* was 19, *L. decidua* was 14, *L. kaempheri* was 13, *L. x gmelinii* was 14, *L. x eurolepis* was 10 years old. In this research radial growth of stems were compared during the period of 2005-2016.

All plants were growing in the same soil type, namely FLc-ar (Fluvisol Areni-Calcicaric). The texture of soil at 0.30 m: 84.8% sand, 9.4% dust, 5.8% clay. The soil pH is 6.2, mobile phosphorus concentration is 581 mg/kg, mobile potassium concentration is 135 mg/kg, total nitrogen – 0.114 mg/L, biohumus content is 2.05%.

Dendrochronological investigation

Dendrochronological investigation of larch tree stems was done by the methodological recommendation of Stravinskienė, 2005. Experimental bore was carried out in March from 2015-2017 with Pressler borer. 1.30 m height was bored from tree root mouth, to the same north-east direction. In total 15 trees were bored. For the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_44194430

evaluation measuring system LINTAB was used with computer programme WinTSAP 0.30 (F. Rinn Engineering Office and Distribution, Heidelberg, Germany), the accuracy of the measurement was 0.001 mm. The quality and synchronity of dating between lines of radial growth was measured by COFECHA 3.00 programme. Non synchronic examples remained undetermined.

Meteorological data

The average monthly and annual data of climate factors (air temperature and precipitation) was supplied by the Lithuanian Hydrometeorological Service (LHS) under the Ministry of Environment, Department of Klaipėda. Distance between LHS and Klaipėda University Botanical Garden is approximately 3 km. Data were presented from 2005 to 2016. In this period in January –June precipitation content was from 30 to 50 mm per month in average, but in July – December 100 mm and more per month (*Fig. 1*). During the period of 2005-2016 negative air temperatures usually are fixed in January and February (from -1.5 to -1.8 °C respectively), the highest annual air temperature in this period was in June – September months (from 14.6 to 18.9 °C) (*Fig. 2*).

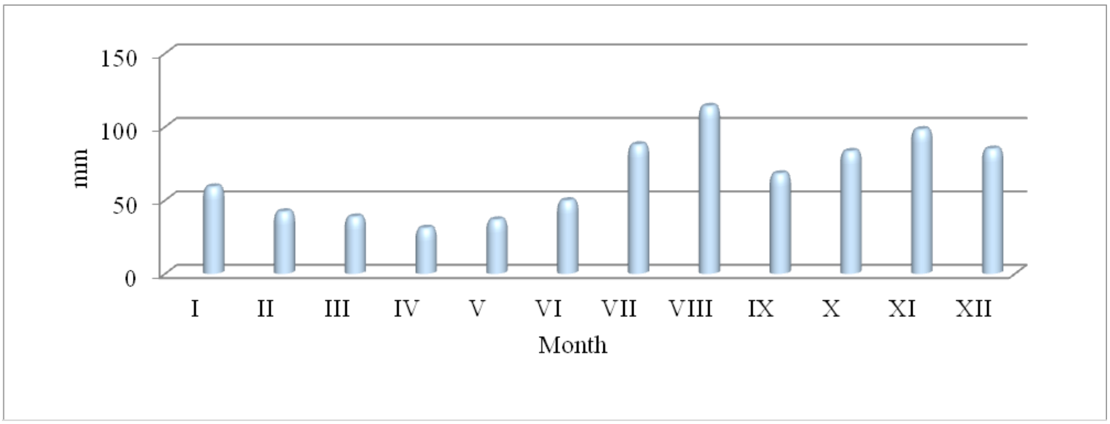

Figure 1. *Distribution of precipitation (mm), average in 2005-2016. Data of Klaipėda meteorological station*

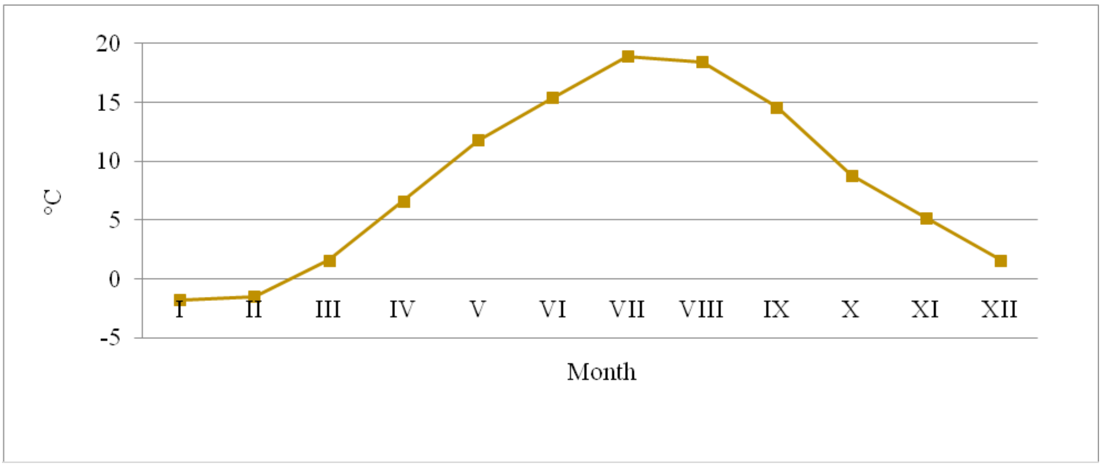

Figure 2. *Average air temperature (°C) in 2005-2016. (Data of Klaipėda meteorological station)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_44194430

Statistical analysis

The experimental data were processed using statistical package SPSS version 17.0. Interrelationship between radial growth (width of tree – ring) and precipitation and air temperature were estimated. Correlation (r) and regression (R) was considered significant when $P < 0.05$.

Results

Annual air temperature and precipitation and humidity are important factors in plants growing rate and productivity. The values and linear trend of means of annual precipitation and air temperature in four seasons are presented in *Figure 3* and *4*. The total precipitation was the highest in the summer time (3014.5 mm). In other seasons this indicator was 1273.5 mm, 2890 mm and 2145.9 mm in the spring, in the autumn and in the winter, respectively.

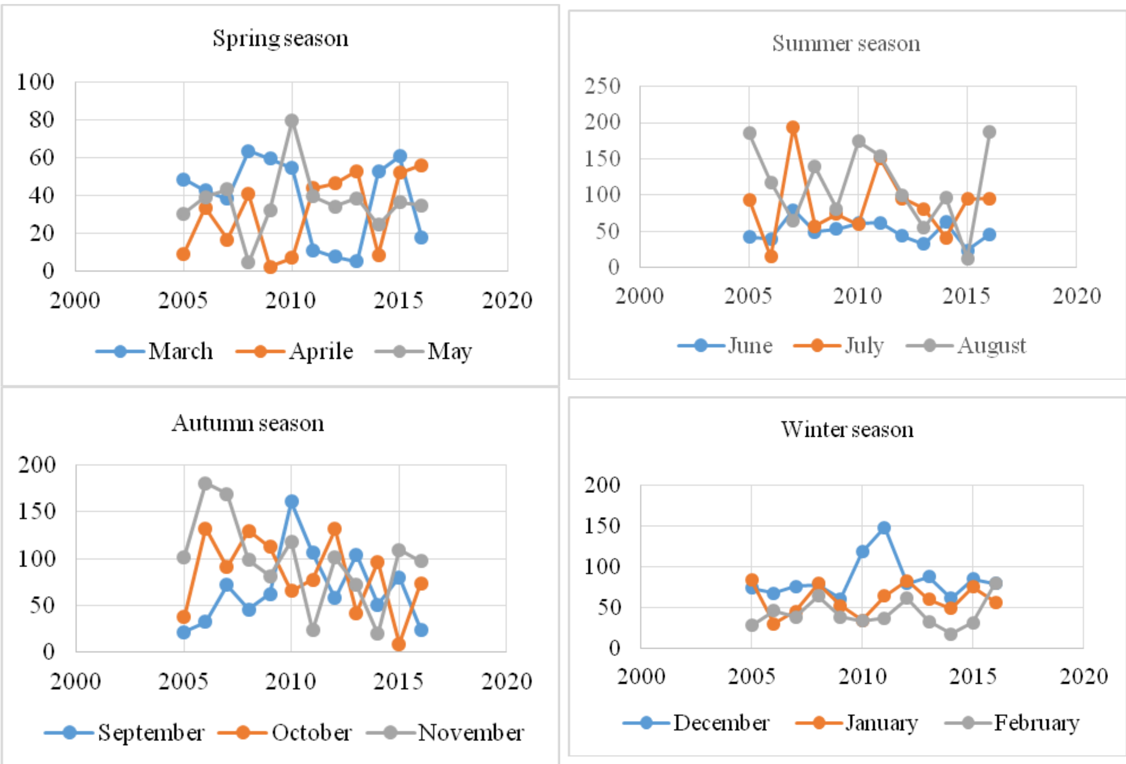

Figure 3. *Distribution of precipitation (mm) in seasons. (Klaipėda, 2005-2016)*

In the period of 2005 – 2016 the highest precipitation in spring was in 2010 and 2015 years (respectively 141.6 mm and 149. 4 mm). The lowest amount of precipitation was in 2014 (86.1 mm). The exclusive summer season was in 2015, when precipitation was only 130.5 mm and in 2011 when it was over 366.5 mm. In the autumn season the highest precipitation was 345.4 mm (2006) and the lowest - 97.6 mm (2016), in the winter season the highest content 248.5 mm (2011) and the lowest 135.9 mm (2016) .

If range of temperatures per season (*Fig. 4*) are compared, the highest temperature in spring was in 2014 (8.1 °C) and the lowest in 2005 (4.9 °C). The summer and autumn

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_44194430

seasons haven't important fluctuations per period. Temperature in the summer is in average 17.5 °C (from 16.8 °C in 2012 to 18.4 °C in 2010) and in the autumn it was the lowest in 2010 (8 °C) and the highest in 2011 (10.3 °C). Winter season was mutable per period: temperature ranged from - 5.4 (2010) to 2.3 °C (2015), but mostly was about 0 °C, in average it was -0.7 °C per period.

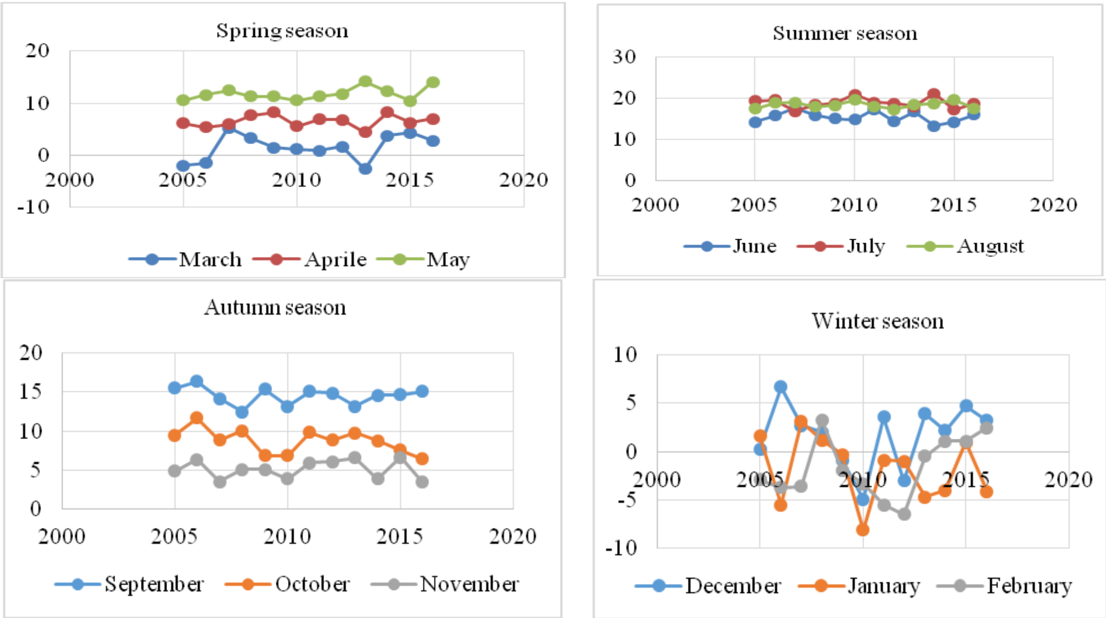

Figure 4. *Distribution of average air temperature (°C) in seasons. (Klaipėda, 2005-2016)*

All larches growing rapidly are lush and vital. *L. sibirica* is the oldest in the Botanical Garden, it is 19 years old and the diameter of its stem is 40 cm. *L. decidua* and *L. x gmelinii* are 14 years old and their average stem diameter is 30 cm. The meteorological conditions (precipitation and air temperature) individually influenced the radial growth rate of different Larix species in separate years (*Table 1*).

For observing plants per period was investigate, unequal growth of stem rings (*Fig. 5*). Per period the highest radial growth of *L. sibirica* was in 2006 and 2012 years – 11.5 mm, but the lowest in 2014 only 4.5 mm. Very similar tendencies can be observed in L. *decidua*: the highest radial growth (11.5 mm) was in 2006 year and the lowest (3.7 mm) in 2013. *L. kaempferi* growth rate in 2014 was 10.00 mm (its highest increase) and the lowest – 5 mm determine in 2013, 2015 and 2016 as well. In *L. x gmelinii and L. x eurolepis* the highest value of this indicator was 9.3 mm in 2008 and 7.3 mm in 2011, but the lowest in 2016 to both species, 4.3 mm and 3.0 mm, respectively. Statisticaly significant and negative correlation (*Table 2*) between radial growth and precipitation was found mostly in the spring season related to *L. sibirica, L. kaempferi, L. x gmelinii* and *L. x eurolepis,* but in the summer and winter seasons it can be related to *L. decidua.* Positive, but statistically unreliable correlation between mentioned parameters in all species of larch was determined only in the autumn season. Statistically significant and negative correlation between radial growth and air temperature in *L. sibirica* was established in the spring, summer and winter seasons, in *L. decidua* only in the spring season, in *L. kaempferi* in the autumn and winter seasons, in hybrids of *L. x gmelinii* and *L. x eurolepis* in the spring and autumn seasons. Very similar and statistically significant dependences

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_44194430

are also shown regression coefficients (*Table 3*). To be noted, that statistically more significant relationships (r and R) in the investigated larches were determined between radial growth and temperature than between radial growth and precipitation. Thus, a tendency that annual air temperature makes more influence on the width of tree rings than annual precipitation can be observed. However, according to research data, in autumn season on the radial growth of *L. sibirica* precipitation positive affected by 62% (y = 0.0245x + 2.6459; R^2 = 0.6216), of *L. x eurolepis* – by 53% (y = 0.0148x + 1.7703; R^2 = 0.5256) and of *L. x gmelinii* – by 39% (y = 0.0119x + 3.6817; R^2 = 0.3925).

Discussion

Larch cannot grow in the shade. It prefers moist soil. The plant can tolerate maritime exposure, they cannot tolerate atmospheric pollution (http://www.pfaf.org). In the Klaipėda University Botanical Garden are favourable conditions for larches to grow and cultivate. In the optimal conditions the climatic factors correlation with annual rings of trees radial gains are negligible, however in worse growing conditions a higher increasing effect on the formation of annual radial rings is noticed (Läänelaid, 1996). In the research period from 2005 – 2016 in the Botanical Garden of Klaipėda University the radial growth ranged from 3 to 11.5 mm in average (*Fig. 5*). The highest precipitation (*Fig. 3*) was in 2007 (925 mm), 2010 (966 mm) and 2011 (917.5 mm) and the lowest in 2014 (581.6 mm), the temperature (*Fig. 4*) had its highest value in 2008 and 2015, 9.1 and 9.0 °C, respectively and the lowest in 2010, only 6.7 °C. For larches in Lithuanian conditions active vegetation begins in the middle of April and ends in the middle of October, in this period air temperature usually ranges from 12.0 to 15.8 °C, in average perennial air temperature was 12,8 °C. Winter and spring seasons air temperature for Larix radial growth is very important too (Karpavičius and Kaselytė, 2000). In Klaipėda, costal area it is noticed, that in spring and winter seasons air temperature and precipitation are unequal, but in summer season they are smooth. Average temperature in summer season is 17.5 °C (in the spring, autumn and winter seasons were 6.7°C; 9.7°C and -0.7 °C, respectively). By the evaluation of data of larches in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_44194430

the spring season statistically significant correlation between tree-ring width and precipitation (*Table 2*) be found for all Larix except for *L. decidua.* The correlation and regression between tree-ring and precipitation in autumn season was statistically insignificant for all Larix (*Table 2, 3*). If compared in the winter season, the statistically significant correlation between tree-ring width and precipitation were only true for *L. decidua* (P<0.001) and *L. kaempferi* (P<0.05)*,* but tree-ring width and air temperature only for *L. sibirica* (P<0.001) and *L. kaempferi* (P<0.001). In the spring and winter seasons precipitation was 1273.5 mm and 2145.9 mm, respectively.

The annual hybrid larix radial growth in Estonia was 3.5 mm, the highest value was 13 mm. The high rings width of young age of larix show that it is hybrid and had good environmental conditions (Sander and Läänelaid, 2007). In Poland, the annual radial growth showed more dependence from the amount of precipitation in summer season (Oleksyn and Fritts, 1991). Evaluating all larches in the Botanical Garden, only *L. decidua* in the summer season showed significant negative correlation (*Table 2*). In the summer season height regression between tree-ring width and precipitation for all larix too, but statistically significant value was only for *L. decidua* (P<0.001). The influence of precipitation on the radial growth of larch across Lithuania is usually positive but more variable than the relationships with air temperature (Karpavičius and Kaselytė, 2000).

Temperature requirements of European larch regarding the onset of individual phenological stages were evaluated based on the sums of air temperatures above 0 °C and of effective air temperatures higher than +5 °C (Bednarova et al., 2013). Efficient growth and good adaptation of European larch and *Larix deciduas* subsp. *Polonica* in Lithuania can be associated with the northern habitat border. The increased air moisture, relatively warm winters and cool summers are factors that European larch can much better endure. In addition, European larch grows very rapidly during the growing season, it takes up much more water than other conifers and larch is one of the most sun-loving tree species (Karpavičius, 2004). In Lithuanian climate conditions the L. *decidue* radial growth is mostly influenced by the warm and dry summer season (Karpavičius, 2004). Sensitivity of growth rate of *L. decidua* was 0.35 ± 0.01 (Karpavičius, 2004). European larch grows very rapidly during the growing season, it takes up much more water than other conifers and larch is one of the most sun-loving tree species. Average radial growth of L. *decidua* pursue 2.18 ± 0.04 mm. The period of 1850 – 2007 was a distinguished time when 70 – 90% from all evaluating trees average radial growth was bigger compared with multi – annual average. It is observed that more wood gained in years with warm spring and warm winter (Stravinskienė and Erlickytė, 2003; Vitas and Žeimavičius, 2006; Vitas, 2011). In west Lithuania due the research period the radial growth fluctuate from 6.25 ± 0.02 mm of *L. decidua*, 8.46 ± 0.02 mm – L. *sibirica*, 7.45 ± 0.02 mm – *L. kaempferi,* 6.75 ± 0.01 mm – *L. x gmelinii* and 5 ± 0.01 mm – L. *x eurolepis.* The Botanical Garden is good environmental condition for Larix to grow and in west Lithuania climate parameters as temperature and precipitation are favorable too.

Conclusions

1. According to research data in the west Lithuania (costal area) the highest precipitation per evaluating period was in the summer time 3014.5 mm, the lowest in the spring, 1273.5 mm. The mutable temperature per period was in the winter season from -5.4 to 2.3 °C. The air conditions for growing of *Larix* genus is good but for some species is a too big amount of precipitation.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_44194430

2. After the evaluation of 5 taxa of larches, it was established, that on the radial growth the climate parameters (precipitation and air temperature) in separate seasons influenced the larches individually. Hybrid larches *L. x gmelinii* and *L. x eurolepis* average radial growth was 1.3 – 1.5 times lower compared with *L. sibirica* and *L. decidua*. It means, that lower radial width are for pure species rather than for hybrids.
3. Positive, but statistically unreliable correlation between radial growth and precipitation in all species of larch was only in the autumn season. Usually autumn precipitation can more influencing on the growing quality in next year.
4. Noted, that more statistically significant relationships (r and R) in the investigated larches was determined between radial growth and temperature than between radial growth and precipitation. Thus, there is a tendency that annual air temperature makes more influence on the width of tree – rings than annual precipitation.

(Received 20th Mar 2018; accepted 25th May 2018)

Abstract. The aim of this study was to discover the geneic basis of drought tolerance, a double haploid mapping population, Drought Mapping Population 5 (DR. M.P. 5) was assessed for drought tolerance in hexaploid wheat (*Triticum aestivum* L.) under control and drought stress condition. The germplasm was planted under control and stress conditions. The yield and yield components were recorded. QTLs were detected by linking morphological data with genotypic data. Five drought tolerant wheat lines were found based on a thousand-grain weight, ranging from 49 to 62 g. Novel Quantitative Trait Loci (QTLs) for spike length and grain per spike were identified during the present study. The novel QTLs are of great importance as these may be helpful in finding such regions in genome, which are responsible for drought tolerance contributing characteristics. The D genome is the main allele which denote drought tolerance to hexapoloid wheat while A and B genome in durum contribute the stress tolerant characteristics.
Keywords: *SSR, DNA polymorphism, interval mapping, multiple QTL mapping, clustering of QTL*

Introduction

Abiotic stress, such as drought not only interferes with the growth of plants (Tuberosa and Salvi, 2006) but also triggers several changes even at cellular level (Holmberg and Bulow, 1998). Further, it reduces nodes and internodes number; which reduces the height of plant (Ahmed et al., 2007). Drought prevails in Asian countries, and its severity can be observed in the arid and semi-arid areas, creating massive losses to their agricultural economics (Huaqi et al., 2002). Drought stress affects the rate of transpiration and ultimately plants may start wilting. Particularly in wheat, the developmental stages are also affected by drought (Wahid et al., 2007). Usually plants grow normally under favorable conditions, but if plants are exposed to any kind of stress, then it is natural that they complete their life cycle rapidly and escape the stress (Fischer, 1985; Hossain et al., 2009, 2011, 2012a, b, c, Hakim et al., 2012; Nahar et al., 2010). Further in moisture-affected areas, late sowing results in yield reduction of wheat and as a result, early sowing

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_44314453

is the common practice in drought prone areas such as Pakistan, India and Bangladesh to avoid drought and heat stress (Mahboob et al., 2005; Din and Singh, 2005).

Common wheat (*Triticum aestivum* L.) is originated from three different genomes. Each genome has three groups of chromosomes: A, B and D. The genome size of the hexplaoid is 16×10^9 bp per chromosome (Bennett and Smith, 1976). As wheat is a major staple food and its intake is growing day by day, there will be approximately a double quantity of wheat grain required by the next fifty years (Rajaram, 2001; Mujeeb-Kazi and Rajaram, 2002). To meet the increasing demand, genetic resources can play a vital role both locally as well as globally, ultimately supporting agricultural economies worldwide (Rajaram, 2001). Significant work was accomplished in the past by synthesizing the bread wheat by crossing durum and *Ae. tauschii* (2n = 14) and then duplicating its chromosome Mujeeb-Kazi (2000). By crossing the *T. turgidum* (2n = 28) with a variety of *Ae. tauschii,* stress tolerance was ultimately enhanced in synthetic wheat. *Ae. tauschii* is the D genome donor and enhances drought tolerance in bread wheat (Del Blanco et al., 2000, 2001; Schmidt et al., 2005). Hexaploid wheat is the most essential cereal crop in the world and the chief staple food of Pakistan. It is paramount to increase the production of wheat by 70% globally to meet the nutritional demands by 2050 (Ray et al., 2013). As wheat is the staple of Pakistan, it occupies the central position in the agricultural policies of the country. Wheat contains 55% carbohydrate, which equals to 20% food calories. Pakistan is ranked ninth in wheat production. The bread wheat production was noted in 2010 to 2012 as 23.3, 25 and 23.5 million tons respectively (GOP, 2012). According to the Pakistan Bureau of Statistics, the world wheat production in 2016-17 was 749 million tons. Pakistan's statistical data of wheat reveal that the amount of cultivated land is 9.05 m ha, the total production is 25 million tons and the yield is 2.78 tons/ha (GOP, 2017).

DNA polymorphisms play a crucial role in unveiling Simple Sequence Repeats (SSRs) derived from Triticeae. The genomic relationship among various traits in wheat was identified by using SSR (Dreisigacker et al., 2004; Sun et al., 1998). For QTL analysis, a linkage map is required and by linking the genotypic and phenotypic data, QTLs can be find out (McCouch and Doerge, 1995). SSR markers could be used to measure agronomic traits of concern, which minimize the cost and time of quantitative trait loci analyses (Young, 1996; Ijaz and Khan, 2009). The current research was planned for QTL mapping in drought mapping population 5 (DR MP 5) by linking the genotypic and phenotypic data.

Material and methods

Plant material

The mapping population consists of two parents that is Opata and SH349 and eighty-four individuals of doubled haploids. The pedigree is Opata // Decoy (DOY) / *Ae. tauschii* (*Ae. squarrosa*) {458}. *Ae. tauschii* was assigned 458 accession number. Opata (bread wheat) is a high yielding cultivar and is drought sensitive while SH349 is synthetic hexaploid wheat and has drought tolerance properties.

Soil type and agriculture practices

These eighty-four individuals with parents were planted at the Wheat Wide Crosses Program in the National Agriculture Research Center (NARC) in Islamabad, Pakistan. Two treatments were control (fully irrigated) and a drought stress treatment was in a tunnel. To protect it from precipitation, plot for stress treatment was sheltered with plastic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_44314453

sheets sustained on iron rods of the tunnel. Water was suspended at flowering in the middle of March. The site of experiment originates from the upland part of potohar, confined in Gujranwala type soil series (Location 6; Rashid et al., 1994). This soil is comprised of well-drained, deep and temperately fine-textured units. It is non-saline, somewhat calcareous; its pH is 8.1 with 0.24 dS/m electrical conductivity (EC). In order to provide ample nutrition, standard agronomical practices were carried out.

Healthy seeds were selected for sowing. Seeds were surface sterilized by using 1% mercuric chloride for 5-7 minutes and, then washed carefully with distilled water. Petri plates were used for seeds germination in the dark for two days on wet filter paper while monitoring temperature. The healthy seedlings were shifted to jiffies containing humus for auxiliary growth. The seedlings of equal height (six days old) were transferred to the field and tunnel. Drought stress was enforced at pre-anthesis period, where water was withheld for 70-90 days. For control treatment, regular mode of irrigation was maintained. Soil humidity was checked by using the Time-Domain Reflectometer (TDR), a soil moisture meter. The control showed a 25% soil moisture, which dropped to 13% under the drought-stressed conditions.

Experimental design

RCBD (Randomized Complete Block Design) was applied in tunnel as well as in field for control and drought treatment observations. Each row was two meters long. A distance of 30 cm was maintained for inter row spacing. After sowing, the yield and yield components were recorded during the experiment such as Plant height (measured in cm) (PH), Days to heading (DH), (measured in numbers), Days to physiological maturity (DPM), (measured in numbers), Spike length (measured in cm) (SL), Grain per spike (G/S) and Thousand Grain weight (measured in gm) (TGW). Statistical analysis was performed through the software Statistica.

Extraction, polymerization and electrophoresis of DNA

Fatima et al. (2014) published the map under consideration; it was of a double haploid mapping population (DR. M.P.5). According to that published data, the DNA of parental lines (Opata and SH349) and the whole mapping population were extracted (Sharp et al., 1988). Fresh leaves were used for this purpose. The extracted DNA was stored at -20 °C. The florimeter was used for the quantification of DNA. (The Qubit fluorometer is a small instrument used for quantification of DNA, RNA, and protein and used in many different applications.) The Qubit fluorometer uses fluorescent dyes to determine the concentration of nucleic acids and proteins in a sample. The robotic station was used for the normalization of DNA at 20 ng/µl. The robotic station is a fully automatic system, which is used to dilute the DNA samples with more accuracy and speed.

The SSR markers are used for the genotyping of parental lines and for the whole mapping population. The SSR markers were selected based on the literature cited. The SSR were selected in such a way that they cover the entire genome of the wheat. 174 SSRs were used during the present study. By using PCR, the parental line genomes were amplified and after this, parental peaks were identified by using capillary sequencer. The selected polymorphic markers were used to detect the polymorphism in the entire mapping population. Seventy-nine polymorphic SSRs genomic loci were applied overall mapping population to detect the QTLs. The following markers were used, WMC (Gupta et al., 2002); GWM (Roder et al., 1998); MGBE and TaPGAM (Xue et al., 2008), STS-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1604_44314453

PSR (Xue et al., 2008), SWES (Peng and Lapitan, 2005), BARC (Song et al., 2005), MAG (Xue et al., 2008), CFD (Guyomarc'h et al., 2002) and CFA (Sourdille et al., 2003). The mixture, which was used for PCR, consisted of DNA, dNTPs, buffer, forward and reverse primer, DMSO, water and DNA taq polymerase. Roder et al. (1998) prescribed conditions were followed for PCR reaction. Alleles having difference of at least two base pairs with reference to amplified product were selected for polymorphic marker. The difference up to one base pair is difficult to predict so it is ignored during analysis (Jones et al., 1997). The Capillary electrophoresis is an analytical technique that separates ions based on their electrophoretic mobility with the use of an applied voltage, is a better instrument to find out polymorphism than the gel electrophoresis. Highest quality data can be obtained at low cast per sample. Fluorescent primers such as FAM, HEX, NED and TET were used to see the peaks and peaks were recorded at 500 nm absorbance maximum. The GeneMapper 4 was used to separate the electropherograms. To save time and money, primers were run simultaneously, which have different colors of electropherograms.

The JoinMap 4 software (Van Ooijen and Voorips, 2004) was used to construct the map with a minimum LOD value 4 by using the Kosambi mapping function. This map was developed by taking Opata and SH349 as having contrasting characteristics of interest. This map was constructed by using 79 PCR based polymorphic genomic loci. Chi-square test was used for all loci for verification of goodness of fit to an estimated value 1:1. Sixteen linkage groups were obtained. Previous published wheat maps were used to associate the linkage groups to the chromosomes of wheat (Somers et al., 2004).

Statistical analysis and QTL detection

Analysis of variance, frequency distribution and Pearson correlation were determined by using Statistix. Genotypes, which have α0.5 values, were differentially different from each other and significant interaction was found between the treatments and the genotypes. The JoinMap4 and the MapQTL 5 were used to analyze the molecular diagnostics (Van Ooijen, 2004). The generated data were entered on an Excel sheet as As (parent A type) and Bs (parent B type). To construct the linkage map, JoinMap4 was used and data was analyzed (Van Ooijen and Voorips, 2004). The computer program MapQTL 5 was used to link the morphho-physiological and genotypic data to find out QTLs. Corel draw 4 and Map chart were used to draw the QTLs on chromosomes. Permutation test was used to check the LOD value. Threshold levels were determined by using $P < 0.05$ for the comparison of 1000 data permutations which is suitable for assessing critical thresholds at $\alpha = 0.10$, and $\alpha = 0.05$ (Churchill and Doerge, 1994). First, Interval Mapping (IM) was used to find the major QTLs. After finding the major QTLs, Multiple QTL Mapping (MQM) was applied to find more precise results.

Results

Phenotypic analysis of drought tolerance

The phenotypic data for yield and yield components was recorded (*Fig. 1*). Opata, SH349 and the DHs displayed high phenotypic variation for these traits. Opata and SH349 performed distinctly in all observations. Throughout the study, certain characters reduced under water stress e.g. the PH reduced by 15.26%, the SL reduced by 15%, the number of G/S reduced by 62.34% and the TGW reduced by 35.80% respectively.

Correlations

Significant correlation was found between (DH) and (DPM) with r-value = 0.7613 (*Table 1*). Further significant correlation was found between (DH) and (DPM) with r = 0.8210 value under water stress condition that indicates delay in heading that leads to delay in days to physiological maturity. The PH is a genetically controlled character and varies with environmental conditions and genotype. Under water stress condition PH has significant and positive correlation with DH and DPM with values r = 0.2276 and 0.3766. The SL has positive and significant correlation with DPM with a value r = 0.2570. Values r = 0.2644, 0.4340 and 0.5608 were found for spike length, DH and DPM under drought stress. Values for correlation, r = 0.4688 and 0.2149 were recorded for G/S, PH and SL respectively. Values r = 0.2389, 0.4330, 0.3791 and 0.5354 were found for DPM, PH, SL and G/S.

QTLs detected by interval mapping (IM)

Interval mapping was used to detect QTL and data are shown in *Table 2* and *Figure 2*. Four QTLs for DH were detected in the field experiments with LOD values 7.69, 3.89, 1.91 and 2.00 respectively on the 6A chromosome. A QTL for DPM was detected by interval mapping in field experiments, located on 1B having a LOD score 3.06 with very high phenotypic variation i.e. 80.4% and allele contributed by SH349 for this QTL. LOD values 2.31 and 2.43 were found for two QTLs located on the 6A and the 7B chromosomes for G/S. A QTL was detected by interval mapping having a LOD value 2.14 under drought stress condition on 5A chromosome. Under control conditions, a QTL having LOD value 2.02 was detected on 6A chromosome for SL.
