Abstract. This paper is devoted to studying the existence of positive solutions of the problem:

$$\begin{cases} -\Delta u = \frac{u^p}{|x|^a} + h(x,u,\nabla u), & \text{in}\Omega, \\ u = 0, & \text{on } \partial\Omega, \end{cases} \tag{$*$}$$

where $\Omega \subset \mathbb{R}^N (N \geq 3)$ is an open bounded smooth domain with boundary $\partial\Omega$, and $1 < p < \frac{N-a}{N-2}$, $0 < a < 2$. Under suitable conditions of $h(x,u,\nabla u)$, we get *a priori* estimates for the positive solutions of problem ($*$). By making use of these estimates and topological degree theory, we further obtain some existence results for the positive solutions of problem ($*$) when $1 < p < \frac{N-a}{N-2}$.

Keywords: *a priori* estimates, Hardy term, positive solutions.

2020 Mathematics Subject Classification: 35B45, 35A21, 35B09.

1 Introduction

Let $\Omega \subset \mathbb{R}^N (N \geq 3)$ be an open bounded smooth domain with boundary $\partial\Omega$. We consider the following elliptic problem with Hardy term:

$$\begin{cases} -\Delta u = \frac{u^p}{|x|^a} + h(x,u,\nabla u), & \text{in } \Omega, \\ u = 0, & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where $0 < a < 2, 1 < p < \frac{N-a}{N-2}$. We mainly focus on the existence of solutions for problem (1.1). It is worth pointing out that problem (1.1) occurs in various branches of mathematical physics and biological models. Theoretically, when $a = 0$, there is no Hardy term in problem (1.1). As is known to all, that the processing without a Hardy term is much simpler than the processing with a Hardy term. When $h(x,u,\nabla u) = h(x,u)$, which means, no gradient terms appear in problem (1.1), in this case, problem (1.1) is reduced to the following problem:

$$\begin{cases} -\Delta u = u^p + h(x,u), & \text{in } \Omega, \\ u = 0, & \text{on } \partial\Omega, \end{cases} \tag{1.2}$$

[✉]Corresponding author. Email: smilexiejunhui@hotmail.com

problem of this type was raised as an important issue in the survey paper [14]. For the existence of solutions to problem of this type, it was studied by many authors with different methods and techniques: upper and lower solution method, mountain pass theorem, *a priori* estimates, fixed points theorem and so on. We recall the papers [2,7,13,15,24] and the references therein. In [7], Figueiredo, Gossez and Ubilla concerned with the existence of solutions based on weak upper and lower solution method. Besides, Ambrosetti and Rabinowitz proposed the mountain pass theorem in [2], and proved the existence of nontrivial solutions. In [13], the author concerned the existence and regularity of solutions based on *a priori* estimates and blow up method by imposing suitable conditions on the coefficients and $h(x,u)$. It is worth mentioning that when $h(x,u)=0$, problem (1.2) becomes:

$$\begin{cases} -\Delta u = u^p, & \text{in } \Omega, \\ u = 0, & \text{on } \partial\Omega. \end{cases} \tag{1.3}$$

There are a lot of work related to this subject. For the existence of solutions, we refer to the pioneering work of [5,9,10,22]. It is well known that the Sobolev exponent $2^* = \frac{2N}{N-2}$ serves as the dividing number for existence and non-existence of solutions to (1.3); please see [5] and [9]. It is pointed out that the proof in [5] is based on Pohozaev identity and moving planes method. While in [10], the proof is based on a scaling argument reminiscent to that used in the theory of Minimal Surfaces to get *a priori* bounds.

As for the problem (1.1) containing gradients term, variational methods can not directly be applied for the problem generally. Thus, some other methods are proposed, we refer to [1,8,19,25] and the references therein. Specifically, for the following problem:

$$\begin{cases} -\Delta u = h(x,u,\nabla u), & \text{in } \Omega, \\ u = 0, & \text{on } \partial\Omega. \end{cases} \tag{1.4}$$

The authors in [8] obtained the existence of positive solution through an iterative method based on mountain-pass techniques. In [1], the existence of solutions are obtained for this problem with convection term by using the Galerkin methods. It should be noted in particular that, the method Gidas and Spruck proposed in [10] is also applicable to the case with gradients term.

Recently, great attention has been focused on the study of the existence and non-existence solutions of the Hardy–Hénon equation:

$$-\Delta u = |x|^a u^p, \quad \text{in } \Omega. \tag{1.5}$$

Traditionally, the equation (1.5) is called Hardy (Hénon, or Lane–Emden) equation for $a < 0 (a > 0,\ a = 0)$. It is shown in [11] that for $a < -2, 1 < p < \frac{N+a}{N-2}$, equation (1.5) has no positive solutions in $\mathbb{R}^N$. Besides, in [21], Reichel and Zou proved that equation (1.5) do not admit any classical solutions in $\mathbb{R}^N$ if $1 < p < \frac{N+2+2a}{N-2}$ and $a > -2$. The non-existence results of Reichel and Zou was revisited by Phan and Souplet in [18], and a new proof of non-existence of bounded solutions in the case $N = 3$ is provided by using the technique introduced in [23]. For the Dirichlet boundary value problem of (1.5), Ni obtained the existence of multiplicity bounded positive solutions by using the upper and lower solution and approximation methods in [16]. Particularly, in [27], Zhu studied the following Hénon equation with perturbation terms in the unit ball B of $\mathbb{R}^N (N > 4)$:

$$\begin{cases} -\Delta u = |x|^\alpha |u|^{p-2} u + h(x), & \text{in } B, \\ u = 0, & \text{on } \partial B. \end{cases} \tag{1.6}$$

By applying the perturbation method in the unit sphere, the author obtained an infinite number of mutually different solutions to problem (1.6). The difficulty with this problem lies in the existence of the Hardy term, so we need to overcome the difficulties brought about by the Hardy term. It is worth pointing out that, in [27], the technique for handling $|x|^a$ is to impose special symmetry restrictions on u; the authors in [18] deal with the Hardy term $|x|^a$ by a change of variables and a doubling-rescaling argument. These methods provide us with good ideas for dealing with Hardy term.

In this paper, we focus on the existence of positive solutions for the problem (1.1) with Hardy term. Through the well-known Liouville-type theorem (see [10, 18]), a change of variable and doubling-rescaling argument (see [20]). We firstly get the decay estimates of the solutions, then we derive *a priori* bounds for positive solutions of problem (1.1). Motivated by the works above, we can show the existence of solutions combined with the topological degree theory under some assumptions.

Firstly, we propose the definition of weak solution.

Definition 1.1. We say that $u \in H_0^1(\Omega)$ is a weak solution of problem (1.1) if

$$\int_\Omega \nabla u \cdot \nabla \varphi dx = \int_\Omega \frac{u^p}{|x|^a} \varphi dx + \int_\Omega h(x, u, \nabla u)\varphi dx, \qquad \forall \varphi \in C_0^\infty(\Omega).$$

Throughout this paper, we always denote by $\|.\|_q$ the norm of $L^q(\Omega)$ for any $q \geq 1$, which means $\|u\|_q = \|u\|_{L^q(\Omega)} = (\int_\Omega |u|^q dx)^{\frac{1}{q}}$, $1 \leq q < \infty$, and $\|u\|_\infty = \|u\|_{L^\infty(\Omega)} = \sup_\Omega |u|$, $q = \infty$.

Next, we introduce the assumptions required for this paper, to this end, we first introduce the following eigenvalue problem:

$$\begin{cases} -\Delta \varphi = \lambda \varphi, & \text{in } \Omega, \\ \varphi = 0, & \text{on } \partial\Omega, \end{cases} \tag{1.7}$$

we denote by $\lambda_1(\Omega)$ the first eigenvalue of problem (1.1). Then we give the following hypotheses on $h(x, u, \nabla u)$:

(H_1) For $m > 0$, $h(x, m, \zeta)$ is Hölder continuous and $h(x, m, \zeta) \geq 0$.

(H_2) If $1 < p < \frac{N-a}{N-2}$, we assume that there exists a positive constant λ_0 such that $\lim_{m\to\infty} \frac{h(x,m,\zeta)}{m^p} = 0$, $\lim_{m\to 0} \frac{h(x,m,\zeta)}{m} = \lambda_0$, and $|h(x, m, \zeta)| \leq C(1 + m^p + \zeta^b)$ for $m > 0$, $1 < b < \frac{2p}{p+1} < p < \frac{N-a}{N-2}$, appropriate constant $C > 0$.

Remark 1.2. If $1 < p < \frac{N-a}{N-2}$, then $h(x, u, \nabla u) = \lambda_0 u + \frac{|u|^{b-1}u|\nabla u|^2}{1+|\nabla u|^2}$ satisfies (H_1) and (H_2).

Now, we are turning to state the main results.

Theorem 1.3. *Let $N \geq 3, 0 < a < 2$ and $1 < p < \frac{N+2}{N-2}$. There exists a constant $\bar{C} = \bar{C}(N, p, a) > 0$ such that the following hold:*

(1) Any nonnegative solution of problem (1.1) in $\Omega = \{x \in \mathbb{R}^N; 0 < |x| < \rho\} (\rho > 0)$ satisfies that:

$$|u(x)| \leq \bar{C}|x|^{-\frac{2-a}{p-1}} \quad \textit{and} \quad |\nabla u(x)| \leq \bar{C}|x|^{-\frac{p+1-a}{p-1}}, \qquad 0 < |x| < \frac{\rho}{2}.$$

(2) Any nonnegative solution of problem (1.1) in $\Omega = \{x \in \mathbb{R}^N; |x| > \rho\}$ $(\rho > 0)$ satisfies that:

$$|u(x)| \leq \bar{C}|x|^{-\frac{2-a}{p-1}} \quad \textit{and} \quad |\nabla u(x)| \leq \bar{C}|x|^{-\frac{p+1-a}{p-1}}, \qquad |x| > 2\rho.$$

The proof of Theorem 1.3 is based on a change of variable and a generalization of a doubling-rescaling arguments; see [18].

Theorem 1.4. *Assume that* $1 < p < \frac{N-a}{N-2}$, $0 < a < 2$, *and that* (H_1) *and* (H_2) *hold with* $\lambda_0 < \lambda_1(\Omega)$. *Then there exist two universal positive constants* $\widetilde{C}$ *and* $\widehat{C}$ *such that for any positive solution* $u \in C^2(\Omega\backslash\{0\}) \cap C(\overline{\Omega})$ *of problem* (1.1), *there holds* $\widetilde{C} \le \|u\|_{C(\Omega)} \le \widehat{C}$.

The proof of Theorem 1.4 is based on the well-known blow up technique introduced by Gidas and Spruck (see [10]) and adopted by Phan (see [18]).

Therefore, according to Theorem 1.4 and the Leray–Schauder degree theory, we can get the existence of positive solutions to problem (1.1).

Theorem 1.5. *Assume that* $1 < p < \frac{N-a}{N-2}$, $0 < a < 2$, $\frac{u^p}{|x|^a} + h(x,u,\nabla u) \in L^k$, *where* $k < \min\{\frac{N}{a}, \frac{N(p-1)}{(p+1-a)b}\}$, (H_1) *and* (H_2) *hold, then problem* (1.1) *has at least one solution.*

The rest of paper is organized as follows. In Section 2, we give some preliminaries. In Section 3, we concern the decay estimates of solutions. Section 4 is devoted to the proof of Theorem 1.4, in which we establish *a priori* estimates to problem (1.1) by blow up technique. In Section 5, we prove the existence of solutions for problem (1.1) by topology degree theory and give the proof of Theorem 1.5.

2 Preliminaries

In this section, we will give some lemmas which will be used to prove the main results.

Lemma 2.1. *Let* $u(x)$ *be a nonnegative* C^2 *solution of the following equation:*

$$-\Delta u = u^p, \qquad x \in \mathbb{R}^N,$$

where $N > 2, 1 < p < \frac{N+2}{N-2}$. *Then* $u(x) \equiv 0$.

Lemma 2.2. *Let* $\mathbb{R}^N_+$ *be the half space* $\{x = (x_1, x_2, \dots, x_N) \in \mathbb{R}^N : x_N > 0\}$. *Suppose that* $u(x)$ *is a nonnegative* $C^2(\mathbb{R}^N_+) \bigcap C^0(\{x \in \mathbb{R}^N : x_N \ge 0\})$ *solution of the following problem:*

$$\begin{cases} -\Delta u = u^p, & x \in \mathbb{R}^N_+, \\ u = 0, & x_N = 0, \end{cases}$$

where $1 < p < \frac{N+2}{N-2}$. *Then* $u(x) \equiv 0$.

Remark 2.3. Lemma 2.1 and Lemma 2.2 follow directly from [10, Theorem 1.2, Theorem 1.3].

Lemma 2.4 ([18])**.** *Let* $N \ge 2$, $a > -2$, $p > 1$. *If* $p < min\{p_s, p_s(a)\}$ *or* $p \le \frac{N+a}{N-2}$, $p_s = \frac{N+2}{N-2}$, $p_s(a) = \frac{N+2+2a}{N-2}$. *Then the following equation:*

$$-\Delta u = |x|^a u^p$$

has no positive solution in $\mathbb{R}^N$.

Lemma 2.5 (Hardy's inequality [4])**.** *Assume* $N \ge 3$ *and* $r > 0$. *Suppose that* $u \in H^1(B(0,r))$. *Then* $\frac{u}{|x|} \in L^2(B(0,r))$, *with the estimate*

$$\int_{B(0,r)} \frac{u^2}{|x|^2} dx \le \int_{B(0,r)} \left(|Du|^2 + \frac{u^2}{r^2}\right) dx.$$

Lemma 2.6 ([20])**.** *Let (X,d) be a complete metric space, $\emptyset \neq D \subset \Sigma \subset X$ with Σ closed. Furthermore, assume that $M : D \to (0,\infty)$ is bounded on compact subsets of D, and fix a real $K > 0$. If $y \in D$ is such that*

$$M(y)\,\mathrm{dist}(y,\Gamma) > 2k, \qquad \Gamma = \Sigma \backslash D,$$

then there exists $x \in D$ such that

$$M(x)\,\mathrm{dist}(x,\Gamma) > 2k, \qquad M(x) \geq M(y),$$

and

$$M(z) \leq 2M(x) \quad \text{for all} \quad z \in D \cap \overline{B\big(x,kM^{-1}(x)\big)}.$$

Lemma 2.7 (Leray–Schauder [3])**.** *Assume that X is a real Banach space, Ω is a bounded, open subset of X and $\Phi : [a,b] \times \overline{\Omega} \to X$ is given by $\Phi(\lambda,u) = u - T(\lambda,u)$ with T a compact map. Define*

$$T_\lambda(u) = T(\lambda,u), \quad u \in X,$$

$$\Phi_\lambda = I - T_\lambda, \quad \lambda \in [a,b],$$

$$\Sigma = \{(\lambda,u) \in [a,b] \times \overline{\Omega} : \Phi(\lambda,u) = 0\},$$

and note $\Sigma_\lambda = \{u \in \overline{\Omega} : (\lambda,u) \in \Sigma\}$. We also suppose that,

$$\Phi(\lambda,u) = u - T(\lambda,u) \neq 0, \qquad \forall (\lambda,u) \in [a,b] \times \partial\Omega.$$

If $\deg(\Phi_a,\Omega,0) \neq 0$, then we have,

(1) $\Phi(\lambda,u) = u - T(\lambda,u) = 0$ has a solution $u \in X$ in Ω for every $a \leq \lambda \leq b$.

(2) Furthermore, there exists a compact connected set $\mathcal{C} \subset \Sigma$ such that

$$\mathcal{C} \cap (\{a\} \times \Sigma_a) \neq \emptyset, \mathcal{C} \cap (\{b\} \times \Sigma_b) \neq \emptyset.$$

3 Decay estimates

In this section, we concern the decay estimates of solutions to the problem (1.1). We need the following lemma, which is an extensive of [20, Theorem 6.1] and [18, Lemma 2.1].

Lemma 3.1. *Let $N \geq 3, 1 < p < \frac{N+2}{N-2}, \alpha \in (0,1]$. Assume in addition that $c(x) \in C^\alpha(\overline{B_1})$ satisfies that,*

$$\|c(x)\|_{C^\alpha(\overline{B_1})} \leq C_1 \quad \text{and} \quad c(x) \geq C_2, \quad x \in \overline{B_1}, \tag{3.1}$$

for some $C_1, C_2 > 0$, where $B_1 = \{x \in \mathbb{R}^N; |x| < 1\}$. Then there exists a constant C, depending only on α, C_1, C_2, p, N such that, for any nonnegative classical solution u of

$$-\Delta u = \frac{u^p}{c(x)} + h(x,u,\nabla u), \quad x \in \overline{B_1}, \tag{3.2}$$

u satisfies that,

$$|u(x)|^{\frac{p-1}{2}} + |\nabla u(x)|^{\frac{p-1}{p+1}} \leq C\big(1 + \mathrm{dist}^{-1}(x,\partial B_1)\big), \qquad x \in B_1.$$

Proof. Arguing by contradiction. Denote $N_k = |u_k|^{\frac{p-1}{2}} + |\nabla u_k|^{\frac{p-1}{p+1}}$. We suppose that there exist a sequence of c_k, u_k, y_k verifying that (3.1), (3.2), and $N_k(y_k) > 2k\big(1 + \operatorname{dist}^{-1}(y_k, \partial B_1)\big) > 2k \operatorname{dist}^{-1}(y_k, \partial B_1)$. By Lemma 2.6, there exists x_k such that

$$N_k(x_k) \geq N_k(y_k), \qquad N_k(x_k) > 2k \operatorname{dist}^{-1}(x_k, \partial B_1).$$

and

$$N_k(z) \leq 2N_k(x_k), \quad \text{for all } z \text{ satisfying } |z - x_k| \leq kN_k^{-1}(x_k).$$

Consequently, we have that,

$$\lambda_k = N_k^{-1}(x_k) \to 0, \qquad k \to +\infty, \tag{3.3}$$

due to $N_k(x_k) \geq N_k(y_k) > 2k$. Next we let

$$v_k(y) = \lambda_k^{\frac{2}{p-1}} u_k(x_k + \lambda_k y), \qquad \widetilde{c_k}(y) = c_k(x_k + \lambda_k y),$$

noting that $|v_k(0)|^{\frac{p-1}{2}} + |\nabla v_k(0)|^{\frac{p-1}{p+1}} = 1$,

$$|v_k(y)|^{\frac{p-1}{2}} + |\nabla v_k(y)|^{\frac{p-1}{p+1}} \leq 2, \qquad |y| \leq k, \tag{3.4}$$

and

$$\begin{aligned} -\Delta v_k &= -\lambda_k^{\frac{2p}{p-1}} \Delta u_k(x_k + \lambda_k y) \\ &= \lambda_k^{\frac{2p}{p-1}} \left(\frac{u_k^p(x_k + \lambda_k y)}{c_k(x_k + \lambda_k y)} + h\big(x_k + \lambda_k y, u_k(x_k + \lambda_k y), \nabla u_k(x_k + \lambda_k y)\big) \right) \\ &= \frac{v_k^p}{c_k(x_k + \lambda_k y)} + \lambda_k^{\frac{2p}{p-1}} h(x_k + \lambda_k y, \lambda_k^{-\frac{2}{p-1}} v_k, \lambda_k^{-\frac{p+1}{p-1}} \nabla v_k) \\ &= \frac{v_k^p}{\widetilde{c_k}(y)} + \lambda_k^{\frac{2p}{p-1}} h(x_k + \lambda_k y, \lambda_k^{-\frac{2}{p-1}} v_k, \lambda_k^{-\frac{p+1}{p-1}} \nabla v_k). \end{aligned} \tag{3.5}$$

So we see that v_k satisfies the following equation:

$$-\Delta v_k = \frac{v_k^p}{\widetilde{c_k}(y)} + \lambda_k^{\frac{2p}{p-1}} h\Big(x_k + \lambda_k y, \lambda_k^{-\frac{2}{p-1}} v_k, \lambda_k^{-\frac{p+1}{p-1}} \nabla v_k\Big) \tag{3.6}$$

where $|y| \leq k$. According to the condition (H_2) on $h(x, u, \nabla u)$, it implies that,

$$\lambda_k^{\frac{2p}{p-1}} h(x_k + \lambda_k y, \lambda_k^{-\frac{2}{p-1}} v_k, \lambda_k^{-\frac{p+1}{p-1}} \nabla v_k) \leq C, \quad |y| \leq k,$$

for k large enough, we deduce that there exist a subsequence of v_k converges in $C^1_{loc}(\mathbb{R}^N)$ to a function $v(y) > 0$. Fix $y \in \mathbb{R}^N$ and denote $\mu_k = \lambda_k^{-\frac{2}{p-1}} v_k(y)$, $\xi_k = v_k^{-\frac{p+1}{2}} \nabla v_k(y)$, we may write that,

$$\lambda_k^{\frac{2p}{p-1}} h(x_k + \lambda_k y, \lambda_k^{-\frac{2}{p-1}} v_k, \lambda_k^{-\frac{p+1}{p-1}} \nabla v_k) = v_k^p \mu_k^{-p} h(x_k + \lambda_k y, \mu_k, \mu_k^{\frac{p+1}{2}} \xi_k).$$

Obviously, $\mu_k \to \infty$ as $k \to +\infty$ and ξ_k is bounded. Besides, if $\{x_k\}$ is bounded, condition (H_2) implies that,

$$v_k^p(y) \mu_k^{-p} h(x_k + \lambda_k y, \mu_k, \mu_k^{\frac{p+1}{2}} \xi_k) \to 0, \qquad k \to +\infty. \tag{3.7}$$

On the other hand, due to (3.1), we have $C_2 \le \widetilde{c_k} \le C_1$, and for each $R > 0$ and $k > k_0(R)$ large enough, the following holds:

$$|\widetilde{c_k}(y) - \widetilde{c_k}(z)| \le C_1 |\lambda_k (y - z)|^\alpha \le C_1 |y - z|^\alpha, \qquad |y|, |z| \le R. \tag{3.8}$$

Therefore, by the Arzelà–Ascoli theorem; see [26], there exists $\widetilde{c}$ in $C(\mathbb{R}^N)$, with $\widetilde{c} \ge C_2$ such that, after extracting a subsequence, $\widetilde{c_k} \to \widetilde{c}$ in $C_{loc}(\mathbb{R}^N)$. Now for each $R > 0$ and $1 < q < \infty$, by (3.4), (3.6) and interior elliptic L^q estimates, the sequence v_k is uniformly bounded in $W^{2,q}(B_R)$. Using standard embeddings and interior elliptic Schauder estimates, after extracting a subsequence, we may assume that $v_k \to v$ in $C^2_{loc}(\mathbb{R}^N)$. Moreover, (3.3) and (3.8) imply that $|\widetilde{c_k}(y) - \widetilde{c_k}(z)| \to 0$ as $k \to +\infty$, so that the function $\widetilde{c}$ is actually a constant $C > 0$. Therefore, we have that,

$$\frac{v_k^p}{\widetilde{c_k}(y)} \to C v^p, \qquad k \to +\infty. \tag{3.9}$$

According to (3.7) and (3.9), it follows that $v > 0$ is a classical solution of

$$-\Delta v = C v^p, \qquad y \in \mathbb{R}^N$$

and satisfying $|v(0)|^{\frac{p-1}{2}} + |\nabla v(0)|^{\frac{p-1}{p+1}} = 1$, this contradicts the Liouville-type theorem. □

By Lemma 3.1, we are ready to prove the decay estimates of solutions to problem (1.1) as follows.

Proof of Theorem 1.3. Assume either $\Omega = \{x \in \mathbb{R}^N; 0 < |x| < \rho\}$ and $0 < |x_0| < \frac{\rho}{2}$, or $\Omega = \{x \in \mathbb{R}^N; |x| > \rho\}$ and $|x_0| > 2\rho$. We denote $R_0 = \frac{1}{2}|x_0|$, and observe that, for all $y \in B_1$, $\frac{|x_0|}{2} < |x_0 + R_0 y| < \frac{3|x_0|}{2}$, so that $x_0 + R_0 y \in \Omega$ in either case. Let us thus define that,

$$U(y) = R_0^{\frac{2-a}{p-1}} u(x_0 + R_0 y).$$

Therefore,

$$\begin{aligned} -\Delta U(y) &= -R_0^{\frac{2p-a}{p-1}} \Delta u(x_0 + R_0 y) \\ &= R_0^{\frac{2p-a}{p-1}} \left(\frac{u^p(x_0 + R_0 y)}{|x_0 + R_0 y|^a} + h\big(x_0 + R_0 y, u(x_0 + R_0 y), \nabla u(x_0 + R_0 y)\big) \right) \\ &= \frac{U^p(y)}{|\frac{x_0}{R_0} + y|^a} + R_0^{\frac{2p-a}{p-1}} h\Big(x_0 + R_0 y, R_0^{-\frac{2-a}{p-1}} U(y), R_0^{-\frac{p+1-a}{p-1}} \nabla U(y)\Big) \\ &= \frac{U^p(y)}{c(y)} + R_0^{\frac{2p-a}{p-1}} h\Big(x_0 + R_0 y, R_0^{-\frac{2-a}{p-1}} U(y), R_0^{-\frac{p+1-a}{p-1}} \nabla U(y)\Big), \end{aligned} \tag{3.10}$$

where $c(y) = |\frac{x_0}{R_0} + y|^a$. Then U is a solution of

$$-\Delta U(y) = \frac{U^p(y)}{c(y)} + R_0^{\frac{2p-a}{p-1}} h\Big(x_0 + R_0 y, R_0^{-\frac{2-a}{p-1}} U(y), R_0^{-\frac{p+1-a}{p-1}} \nabla U(y)\Big), \qquad y \in B_1.$$

Notice that $|y + \frac{x_0}{R_0}| \in [1, 3]$ for all $y \in \overline{B_1}$ and $\|c(y)\|_{C^1(\overline{B_1})} \le C(a)$ according to Lemma 3.1, where $C(a)$ is a constant depending on a. Applying Lemma 3.1 again, we have that $|U(0)| + |\nabla U(0)| \le C$. Hence,

$$|u(x_0)| \le \bar{C} R_0^{-\frac{2-a}{p-1}}, \qquad |\nabla u(x_0)| \le \bar{C} R_0^{-\frac{p+1-a}{p-1}},$$

which yields the desired conclusion. □

4 *A priori* estimates

We will show *a priori* bounds for the positive solutions to problem (1.1) in this section. Owing to the well-known Liouville-type results (Lemma 2.1, Lemma 2.2 and Lemma 2.4), we can get *a priori* estimates. Now, we are ready to prove Theorem 1.4.

Proof of Theorem 1.4. To get the lower bound, we argue by contradiction. Assume that $\|u\|_{C(\Omega)} < \widetilde{C}$ holds for any $\widetilde{C} > 0$. Therefore, there exists a sequence solution $\{u_k\}$ of problem (1.1) such that

$$M_k = \sup_{x\in\Omega} u_k(x) \to 0, \quad \text{as } k \to +\infty.$$

Multiplying the first equation of problem (1.1) by u_k, and integrating the result over Ω, by Hölder inequality, Young's inequality with ε and Hardy's inequality, then we have that

$$\begin{aligned}
\int_\Omega |\nabla u_k|^2 dx &= \int_\Omega \frac{u_k^{p+1}}{|x|^a} + u_k h(x,u_k,\nabla u_k) dx \\
&= \int_\Omega \frac{u_k^a}{|x|^a}\cdot u_k^{p+1-a} dx + \int_\Omega u_k h(x,u_k,\nabla u_k) dx \\
&\le \Big(\int_\Omega \frac{u_k^2}{|x|^2}dx\Big)^{\frac{a}{2}} \Big(\int_\Omega u_k^{\frac{2(p+1-a)}{2-a}} dx\Big)^{\frac{2-a}{2}} + C\int_\Omega u_k(1+u_k^p+|\nabla u_k|^b)dx \\
&\le \varepsilon \int_\Omega \frac{u_k^2}{|x|^2}dx + C\Big(\int_\Omega u_k^{\frac{2(p+1-a)}{2-a}} dx + \int_\Omega u_k + u_k^{p+1} + u_k|\nabla u_k|^b\Big)dx \\
&\le C\Bigg[\varepsilon\int_\Omega (|\nabla u_k|^2 + u_k^2)dx + \int_\Omega u_k^{\frac{2(p+1-a)}{2-a}} dx + \int_\Omega u_k dx \\
&\quad + \int_\Omega u_k^{p+1}dx + \Big(\int_\Omega |\nabla u_k|^2 dx\Big)^{\frac{b}{2}}\Big(\int_\Omega u_k^{\frac{2}{2-b}}dx\Big)^{\frac{2-b}{2}}\Bigg] \\
&\le C\Bigg[\varepsilon\int_\Omega |\nabla u_k|^2 dx + \varepsilon\int_\Omega u_k^2 dx + \int_\Omega u_k^{\frac{2(p+1-a)}{2-a}} dx + \int_\Omega u_k dx \\
&\quad + \int_\Omega u_k^{p+1}dx + \varepsilon\int_\Omega |\nabla u_k|^2 dx + \int_\Omega u_k^{\frac{2}{2-b}}dx\Bigg].
\end{aligned} \tag{4.1}$$

Hence,

$$\begin{aligned}
&(1-\varepsilon C)\int_\Omega |\nabla u_k|^2 dx \\
&\le C\Big(\varepsilon\int_\Omega |u_k|^2 dx + \int_\Omega u_k^{\frac{2(p+1-a)}{2-a}} dx + \int_\Omega u_k dx + \int_\Omega u_k^{p+1}dx + \int_\Omega u_k^{\frac{2}{2-b}}dx\Big).
\end{aligned} \tag{4.2}$$

Let $\varepsilon \to 0$, then we have that

$$\begin{aligned}
\|\nabla u_k\|_2^2 &\le C\Big(\|u_k\|_{\frac{2(p+1-a)}{2-a}}^{\frac{2(p+1-a)}{2-a}} + \|u_k\|_1 + \|u_k\|_{p+1}^{p+1} + \|u_k\|_{\frac{2}{2-b}}^{\frac{2}{2-b}}\Big) \\
&\le C\|u_k\|_{C(\Omega)} \\
&= CM_k \to 0, \quad \text{as } k \to +\infty.
\end{aligned} \tag{4.3}$$

Further, let $u_k(x) = M_k U_k(x)$, obviously, $U_k(x)$ satisfies that,

$$\begin{cases} -\Delta U_k = \frac{M_k^{p-1} U_k^p}{|x|^a} + M_k^{-1} h(x, M_k U_k, M_k \nabla U_k), & \text{in } \Omega, \\ U_k > 0, & \text{in } \Omega, \\ U_k = 0, & \text{on } \partial\Omega. \end{cases} \tag{4.4}$$

Owing to

$$\begin{aligned} \int_\Omega |\nabla U_k|^2 dx &= \int_\Omega \left(M_k^{p-1} \frac{U_k^{p+1}}{|x|^a} + U_k \frac{h(x, M_k U_k, M_k \nabla U_k)}{M_k} \right) dx \\ &= \int_\Omega M_k^{p-1} \frac{U_k^a}{|x|^a} U_k^{p+1-a} dx + \int_\Omega U_k \frac{h(x, M_k U_k, M_k \nabla U_k)}{M_k} dx \\ &\leq M_k^{p-1} \Big(\int_\Omega \frac{U_k^2}{|x|^2} dx \Big)^{\frac{a}{2}} \Big(\int_\Omega U_k^{\frac{2(p+1-a)}{2-a}} dx \Big)^{\frac{2-a}{2}} + \int_\Omega U_k^2 \frac{h(x, M_k U_k, M_k \nabla U_k)}{M_k U_k} dx \\ &\leq \left(M_k^{\frac{p-1}{a}} \int_\Omega \frac{U_k^2}{|x|^2} dx \right)^{\frac{a}{2}} \left(M_k^{\frac{p-1}{2-a}} \int_\Omega U_k^{\frac{2(p+1-a)}{2-a}} dx \right)^{\frac{2-a}{2}} + \int_\Omega U_k^2 \frac{h(x, M_k U_k, M_k \nabla U_k)}{M_k U_k} dx \\ &\leq \frac{a}{2} C M_k^{\frac{p-1}{a}} \int_\Omega (U_k^2 + |\nabla U_k|^2) dx + \frac{2-a}{2} M_k^{\frac{p-1}{2-a}} \int_\Omega U_k^{\frac{2(p+1-a)}{2-a}} dx \\ &\quad + \int_\Omega U_k^2 \frac{h(x, M_k U_k, M_k \nabla U_k)}{M_k U_k} dx. \end{aligned} \tag{4.5}$$

By (H_2) and the standard elliptic estimates; see [12], we can easily see that, the subsequence in U_k converges to a positive function v in $C^2(\Omega)$. Moreover, v satisfies

$$\begin{cases} -\Delta v = \lambda_0 v, & \text{in } \Omega, \\ v = 0, & \text{on } \partial\Omega. \end{cases} \tag{4.6}$$

On the other hand, problem (4.6) has no positive solution due to $\lambda_0 < \lambda_1(\Omega)$. This reaches a contradiction. Consequently, there exists a universal constant $\widetilde{C} > 0$ such that for any positive solution u of problem (1.1), we have that,

$$\|u\|_{C(\Omega)} \geq \widetilde{C}. \tag{4.7}$$

To get the upper bound, we also proceed by contradiction. Assume that $\|u\|_{C(\Omega)} > \widehat{C}$ holds. Therefore, there exists a sequence of solutions u_k and a sequence of points $P_k \in \Omega$ such that

$$M_k = \sup_{x \in \Omega} u_k(x) = u_k(P_k) \to \infty, \quad \text{as } k \to +\infty.$$

We may assume that $P_k \to P \in \overline{\Omega}$ as $k \to +\infty$, and we divide the proof into the following two cases:

Case 1. $P \in \Omega \backslash \{0\}$ or $P \in \partial\Omega$. In this case, we rescale the solution as the following:

$$U_k(y) = \lambda_k^{\frac{2}{p-1}} u_k(P_k + \lambda_k y), \qquad \lambda_k = M_k^{-\frac{p-1}{2}}.$$

Therefore, we deduce that,

$$\begin{aligned}
-\Delta U_k(y) &= -\lambda_k^{\frac{2p}{p-1}}\Delta u_k(P_k+\lambda_k y)\\
&= \lambda_k^{\frac{2p}{p-1}}\left(\frac{u_k^p(P_k+\lambda_k y)}{|P_k+\lambda_k y|^a}+h\big(P_k+\lambda_k y,u_k(P_k+\lambda_k y),\nabla u_k(P_k+\lambda_k y)\big)\right)\\
&= \frac{U_k^p(y)}{|P_k+\lambda_k y|^a}+\lambda_k^{\frac{2p}{p-1}}h\big(P_k+\lambda_k y,\lambda_k^{-\frac{2}{p-1}}U_k(y),\lambda_k^{-\frac{p+1}{p-1}}\nabla U_k(y)\big).
\end{aligned} \tag{4.8}$$

Then U_k satisfies that,

$$\begin{cases}
-\Delta U_k=\frac{U_k^p}{|P_k+\lambda_k y|^a}+\lambda_k^{\frac{2p}{p-1}}h\Big(P_k+\lambda_k y,\lambda_k^{-\frac{2}{p-1}}U_k,\lambda_k^{-\frac{p+1}{p-1}}\nabla U_k\Big), & \text{in } \Omega_k,\\
U_k>0, & \text{in } \Omega_k,\\
U_k=0, & \text{on } \partial\Omega_k,
\end{cases} \tag{4.9}$$

where $\Omega_k=\lambda_k^{-1}(\Omega-\{P_k\})$. Notice that $\lambda_k=M_k^{-\frac{p-1}{2}}$, we can deduce that,

$$\begin{aligned}
&\left|\frac{U_k^p}{|P_k+\lambda_k y|^a}+\lambda_k^{\frac{2p}{p-1}}h(P_k+\lambda_k y,\lambda_k^{-\frac{2}{p-1}}U_k,\lambda_k^{-\frac{p+1}{p-1}}\nabla U_k)\right|\\
&\quad=\left|\frac{U_k^p}{|P_k+\lambda_k y|^a}+M_k^{-p}h(P_k+\lambda_k y,M_kU_k,M_k^{\frac{p+1}{2}}\nabla U_k)\right|\\
&\quad\le\left|\frac{U_k^p}{|P_k+\lambda_k y|^a}+C(M_k^{-p}+U_k^p+M_k^{\frac{(p+1)b}{2}-p}|\nabla U_k|^b)\right|\\
&\quad\le C,
\end{aligned} \tag{4.10}$$

and so we find that U_k is a solution of the equation:

$$-\Delta U_k=\frac{U_k^p}{|P_k+\lambda_k y|^a}+\lambda_k^{\frac{2p}{p-1}}h\Big(P_k+\lambda_k y,\lambda_k^{-\frac{2}{p-1}}U_k,\lambda_k^{-\frac{p+1}{p-1}}\nabla U_k\Big)$$

in a rescaled domain Ω_k. Since $U_k(0)=1, 0<U_k\le 1$, by elliptic estimates and standard embedding similar as that in [10], up to a subsequence, without loss of generality, still denoted by U_k, we can deduce that $\{U_k\}$ is convergent in $C_{loc}(\mathbb{R}^N)$. Hence, by the Arzelà–Ascoli theorem and standard diagonal argument, up to a subsequence, there exists a subsequence of $\{U_k\}$ and function $v\in C(\Omega)$, such that $U_k\to v$ uniformly on compact sets of Ω. In addition, v satisfies the equation $-\Delta v=lv^p$, where $1<p<\frac{N-a}{N-2}$, for some $l>0$ either in the whole space $\mathbb{R}^N$, or in a half-space with 0 boundary conditions. Clearly, this contradicts with the Lemma 2.1 and Lemma 2.2.

Case 2. $P=0$. In this case, we rescale the solution according to $U_k(y)=\lambda_k^{\frac{2-a}{p-1}}u_k(P_k+\lambda_k y)$, $\lambda_k=M_k^{-\frac{p-1}{2-a}}$. By a simple calculation, we infer that,

$$\begin{aligned}
-\Delta U_k(y) &= -\lambda_k^{\frac{2p-a}{p-1}}\Delta u_k(P_k+\lambda_k y)\\
&= \lambda_k^{\frac{2p-a}{p-1}}\left(\frac{u_k^p(P_k+\lambda_k y)}{|P_k+\lambda_k y|^a}+h\big(P_k+\lambda_k y,u_k(P_k+\lambda_k y),\nabla u_k(P_k+\lambda_k y)\big)\right)\\
&= \frac{U_k^p(y)}{|\frac{P_k}{\lambda_k}+y|^a}+\lambda_k^{\frac{2p-a}{p-1}}h\big(P_k+\lambda_k y,\lambda_k^{-\frac{2-a}{p-1}}U_k(y),\lambda_k^{-\frac{p+1-a}{p-1}}\nabla U_k(y)\big),
\end{aligned} \tag{4.11}$$

Then U_k satisfies that

$$\begin{cases} -\Delta U_k = \frac{U_k^p}{|\frac{P_k}{\lambda_k}+y|^a} + \lambda_k^{\frac{2p-a}{p-1}} h\Big(P_k + \lambda_k y, \lambda_k^{-\frac{2-a}{p-1}} U_k, \lambda_k^{-\frac{p+1-a}{p-1}} \nabla U_k\Big), & \text{in } \Omega_k, \\ U_k > 0, & \text{in } \Omega_k, \\ U_k = 0, & \text{on } \partial\Omega_k, \end{cases} \tag{4.12}$$

where $\Omega_k = \lambda_k^{-1}(\Omega - \{P_k\})$. Due to $\lambda_k = M_k^{-\frac{p-1}{2-a}}$, we can deduce that

$$\begin{aligned} &\left| \frac{U_k^p}{|\frac{P_k}{\lambda_k} + y|^a} + \lambda_k^{\frac{2p-a}{p-1}} h(P_k + \lambda_k y, \lambda_k^{-\frac{2-a}{p-1}} U_k, \lambda_k^{-\frac{p+1-a}{p-1}} \nabla U_k) \right| \\ &\quad = \left| \frac{U_k^p}{|\frac{P_k}{\lambda_k} + y|^a} + M_k^{-\frac{2p-a}{2-a}} h(P_k + \lambda_k y, M_k U_k, M_k^{\frac{p+1-a}{2-a}} \nabla U_k) \right| \\ &\quad \le \left| \frac{U_k^p}{|\frac{P_k}{\lambda_k} + y|^a} + C(M_k^{-\frac{2p-a}{2-a}} + M_k^{p-\frac{2p-a}{2-a}} U_k^p + M_k^{\frac{(p+1-a)b-(2p-a)}{2-a}} |\nabla U_k|^b) \right| \\ &\quad \le C, \end{aligned} \tag{4.13}$$

and thus we find that U_k is a solution of the following equation:

$$-\Delta U_k = \frac{U_k^p}{|\frac{P_k}{\lambda_k} + y|^a} + \lambda_k^{\frac{2p-a}{p-1}} h\left(P_k + \lambda_k y, \lambda_k^{-\frac{2-a}{p-1}} U_k, \lambda_k^{-\frac{p+1-a}{p-1}} \nabla U_k\right)$$

in a rescaled domain Ω_k containing $B(0, \rho\lambda_k^{-1})$ for some $\rho > 0$. Moreover, it follows from the estimate in Theorem 1.3 that the sequence $\frac{|P_k|}{\lambda_k} = |P_k| u_k^{\frac{p-1}{2-a}}(P_k)$ is bounded. We may thus assume that $\frac{P_k}{\lambda_k} \to x_0 \in \mathbb{R}^N$ as $k \to +\infty$. A similar limiting procedure as in Case 1 then produces a positive solution v of

$$-\Delta v = \frac{v^p}{|y + x_0|^a}, \qquad y \in \mathbb{R}^N, \tag{4.14}$$

where $0 < a < 2$, then by elliptic regularity, we obtain that u_k satisfy a local $W^{2,\widehat{q}}$ bound for $\frac{N}{2} < \widehat{q} < \frac{N}{|a|}$, so a local Hölder bound holds, and this is sufficient to pass the limit to obtain a solution of problem (4.14). After a space shift, this gives a contradiction with Lemma 2.4. Therefore, there exists a positive constant $\widehat{C}$ such that

$$\|u\|_{C(\Omega)} \le \widehat{C}. \tag{4.15}$$

(4.7) and (4.15) yield the desired conclusion of Theorem 1.4 and this completes the proof. □

5 Existence results

This section devotes to proving some existence results to problem (1.1). For the convenience of proving existence results, we consider the following problem with a parameter $t \in [0, 1]$,

$$\begin{cases} -\Delta u = \frac{u^p}{|x|^a} + h(x, u, \nabla u) + t(|u| + \lambda), & \text{in } \Omega, \\ u = 0, & \text{on } \partial\Omega. \end{cases} \tag{5.1}$$

Fortunately, we have proved the boundedness of solutions firstly in Section 4, therefore, in this section, we only need to use the Leray–Schauder topological degree theory (see [3,6,17]) to prove the existence of solutions.

Proof of Theorem 1.5. We always assume that $h(x,u,\nabla u)$ satisfies (H_1) and (H_2). Let $X = C(\Omega)$, we denote that,

$$f(x,u) = \frac{u^p}{|x|^a} + h(x,u,\nabla u).$$

Given $u \in X$ and $t > 0$, let $\phi_t(u) = u$ be the unique solution of the problem (5.1). Then the solution to problem (1.1) is equivalent to a fixed point of the operator $\phi_0(u)$. Since $f \in L^k(\Omega)$ for $k < \min\{\frac{N}{a}, \frac{N(p-1)}{(p+1-a)b}\}$, we have $\phi_t(u) \in W^{2,r}(\Omega)$ for $r \in (\frac{N}{2}, \min\{\frac{N}{a}, \frac{N(p-1)}{(p+1-a)b}\})$. Therefore, $\phi_t : X \to X$ is compact. Observe that the right-hand sides in (5.1) are nonnegative for every $u \in X$, hence, ϕ_t has no fixed point beyond the nonnegative cone $K = \{u' \in X : u' > 0\}$ for any $t \geq 0$.

Let $\|u\|_X = \varepsilon$ for $\varepsilon > 0$ small. Assume $u = \phi_0(u)$, using L^p estimates, we have that,

$$\|u\|_\infty \leq C\|u\|_{2,r} \leq C\|f\|_r \leq C\|u\|_\infty^p,$$

where $\|\cdot\|_{2,r}$ denotes the norm in $W^{2,r}(\Omega)$. Furthermore, We can deduce that,

$$\|u\|_\infty \leq C\|u\|_\infty^p \leq C\varepsilon^{p-1}\|u\|_\infty.$$

This is a contradiction for ε sufficiently small due to the assumption $p > 1$. Hence $u \neq \phi_0(u)$ and the homotopy invariance of the topological degree implies

$$\deg(I - \phi_0, 0, B_\varepsilon) = \deg(I, 0, B_\varepsilon) = 1,$$

where I denotes the identity and $B_\varepsilon = \{u \in X : \|u\|_X < \varepsilon\}$.

Theorem 1.4 immediately implies $\phi_T(u) \neq u$ for T large and $u \in \overline{B_R} \bigcap K$, $\phi_t(u) \neq u$ for $t \in [0,T]$ and $u \in (\overline{B_R} \backslash B_R) \bigcap K$ (where $R > 0$ is lage enough), hence we have that,

$$\deg(I - \phi_0, 0, B_R) = \deg(I - \phi_T, 0, B_R) = 0.$$

Then we can obtain $\deg(I - \phi_0, 0, B_R \backslash \overline{B_\varepsilon}) = -1$, hence, there exist $u \in (B_R \backslash \overline{B_\varepsilon}) \bigcap K$ such that $\phi_0(u) = u$. Finally, the maximum principle implies the positivity of u. □

Abstract. A coupled damped Klein–Gordon–Schrödinger equations are considered where Ω is a bounded domain of $\mathbb{R}^2$, with smooth boundary Γ and ω is a neighbourhood of $\partial\Omega$ satisfying the geometric control condition. The aim of the paper is to prove the existence, uniqueness and uniform decay for the solutions.

Keywords: Klein–Gordon–Schrödinger, localized damping, exponential stability, asymptotic behavior, existence and uniqueness.

2020 Mathematics Subject Classification: 35B40, 35B45, 35Q55.

1 Introduction

The aim of this paper is to study the following KGS system defined in Ω which is a bounded domain in $\mathbb{R}^2$

$$\begin{aligned} i\psi_t + \kappa\Delta\psi + i\alpha b(x)\psi &= \phi\psi\chi(\omega) \in \Omega\times(0,+\infty) \\ \phi_{tt} - \Delta\phi + \phi + \lambda(x)\phi_t &= -\operatorname{Re}\nabla\psi\chi(\omega) \in \Omega\times(0,+\infty) \qquad (1.1)\\ \psi = \phi &= 0, \quad \text{on } \Gamma\times(0,+\infty) \end{aligned}$$

with locally distributed damping and where Γ is a smooth boundary and ω is an open subset of Ω such that $\operatorname{meas}(\omega) > 0$ and satisfying the geometric control condition. Let $\alpha > 0$ and $\chi(\omega)$ to represent the characteristic function, that is $\chi = 1$ in ω and $\chi = 0$ in $\Omega\setminus\omega$. We also consider $b, \lambda \in L^\infty(\Omega)$ to be nonnegative functions such that

$$b(x) \geq b_0 > 0 \quad \text{a.e. in } \omega \quad \text{and} \quad \lambda(x) \geq \lambda_0 > 0 \quad \text{a.e. in } \omega,$$

in order for the nonlinearity ψ to exist where the damping terms

$$i\alpha b(x)\psi, \qquad \lambda(x)\phi_t$$

✉Corresponding author. Email: mpoulou@uniwa.gr

are effective and reciprocally. If the damping is effective in the whole domain, i.e. $b(x) \geq b_0 > 0$ a.e. in Ω and $\lambda(x) \geq \lambda_0 > 0$ a.e. in Ω we can consider $\chi_\omega \equiv 1$ a.e. in Ω. The variable (complex) ψ stands for the dimensionless low frequency electron field, whereas (real) ϕ denotes the dimensionless low frequency density. This system describes the nonlinear interaction between high frequency electron waves and low frequency ion plasma waves in a homogeneous magnetic field, adapted to model the UHH (Upper Hybrid Heating) plasma heating scheme.

UHH is the dominant branch of the general Electron Cyclotron Resonance Heating (ECRH) scheme, which, for tokamaks and stellarators, constitutes a basic method of plasma build-up and heating. Moreover, ECRH is an attractive method to study transport mechanisms, since it allows for a very localised power deposition, thus influencing temperature and current profiles. The UHH scheme consists in injecting electromagnetic waves in the range $100-200GHz$, from the high field side towards the core of the device. Within this frequency range, the incident wave takes on the character of a longitudinal oscillation for the resonant electrons, which become highly energetic. With respect to the physical mechanism involved in the energy damping of the waves, UHH comprises of two stages:

1. Collisionless damping. The energy of the waves is transferred to the resonant electrons, through collisionless mechanisms, e.g. Landau damping. Subsequently, the electrons gain excessive kinetic energy, thus heated.

2. Collisional damping. The excessive electron energy is distributed over electrons and non-resonant ions, through Coulomb collisions, producing bulk heating of the plasma (equipartition).

Collisional damping is very crucial for the success of UHH. If collisions are infrequent, non-thermal distributions will occur, which may result in a reduction in the power delivered to the plasma. Therefore, it is important to determine the operational conditions for the device, under which UHH becomes effective, namely the collisions manage to distribute the excessive electron energy over the species at an exponential rate. The term $Re\nabla\psi$ is a consequence of the different low frequency coupling that was considered, i.e. the polarization drift instead of the ponderomotive force. The system focuses on the vital role of collisions by considering the non-homogeneous polarization drift for the low frequency coupling (see [12]).

By setting $\theta = \phi_t + \epsilon\phi$ where ϵ is a real positive constant to be specified later, the system (1.1) becomes

$$i\psi_t + \kappa\Delta\psi + i\alpha b(x)\psi = \phi\psi\chi(\omega), \tag{1.2}$$

$$\phi_t + \epsilon\phi = \theta, \tag{1.3}$$

$$\theta_t + (\lambda(x) - \epsilon)\theta - \Delta\phi + (1 - \epsilon(\lambda(x) - \epsilon))\phi = -\operatorname{Re}\nabla\psi\chi(\omega) \tag{1.4}$$

satisfying the following initial conditions

$$\psi(x,0) = \psi_0(x), \quad \phi(x,0) = \phi_0(x), \quad \theta(x,0) = \theta_0(x). \tag{1.5}$$

Therefore, one may set the energy equation of the problem by

$$E(t) := \frac{1}{2}\left\{ \|\psi\|^2_{L^2(\Omega)} + \kappa\|\nabla\psi\|^2_{L^2(\Omega)} + \int_\omega \phi|\psi|^2 + \|\phi\|^2_{L^2(\Omega)} + \|\nabla\phi\|^2_{L^2(\Omega)} + \|\phi_t\|^2_{L^2(\Omega)} \right\}. \tag{1.6}$$

Assumption 1.1. *We denote by ω the intersection of Ω with a neighborhood of $\partial\Omega$ in $\mathbb{R}^2$ and we will call it a neighborhood of the boundary of Ω. We assume that $b, \lambda \in L^\infty(\Omega)$ are nonnegative functions such that*

$$b(x) \geq b_0 > 0, \quad \text{a.e. in } \omega, \qquad \lambda(x) \geq \lambda_0 > 0, \quad \text{a.e. in } \omega.$$

In addition, if $b(x) \geq b_0 > 0$ a.e. in Ω then we can consider $\chi_\omega \equiv 1$ in Ω, and if $\lambda(x) \geq \lambda_0 > 0$ a.e. in Ω, then we can consider $\chi_\omega \equiv 1$ in Ω.

Definition 1.2 (Geometric control condition)**.** Let ω geometrically control Ω, i.e there exists $T_0 > 0$, such that every geodesic of Ω travelling with speed 1 and issued at $t = 0$, which enters the set ω in a time $t < T_0$. So, the couple (ω, T_0) satisfies the geometric control condition (GCC, in short) if every geodesic of Ω, traveling with speed 1 and issued at $t = 0$ enters the open set ω before the time T_0.

Assumption 1.3. *We assume that ω satisfies the geometric control condition. The standard example is when ω is a neighbourhood of $\overline{\Gamma(x_0)}$ where*

$$\Gamma(x_0) := \{x \in \Gamma; (x - x_0) \cdot \nu(x) > 0\}$$

and $\nu(x)$ is the unit outward normal at $x \in \Gamma$.

As a consequence of the previous assumption it follows that there exists a couple (ω, T_0), with $T_0 > 0$, such that the following observability inequalities occur:

$$\|\psi_0\|^2_{L^2(\Omega)} \leq \int_0^T \int_\omega |\psi(x,t)|^2 dxdt \tag{1.7}$$

for the following problem

$$\begin{cases} i\psi_t + \Delta\psi = 0 \in \Omega \times (0,T), \\ \psi = 0 \quad \text{on } \Gamma \times (0,T), \\ \psi(0) = \psi_0 \in L^2(\Omega) \end{cases} \tag{1.8}$$

and

$$\|\phi_1\|^2_{L^2(\Omega)} + \|\nabla\phi_0\|^2_{L^2(\Omega)} \leq C \int_0^T \int_\omega |\phi_t(x,t)|^2 dxdt \tag{1.9}$$

with regards to the following problem

$$\begin{cases} \phi_{tt} - \Delta\phi = 0 \in \Omega \times (0,T), \\ \phi = 0 \quad \text{on } \Gamma \times (0,T), \\ \phi(0) = \phi_0 \in H_0^1(\Omega), \\ \phi_t(0) = \phi_1 \in L^2(\Omega) \end{cases} \tag{1.10}$$

for some positive constant $C = C(\omega, T_0)$ and for all $T > T_0$. The proof of (1.8) can be found in [13] and [18] while the proof of (1.10) is established in [3] and [15].

The aim of this work is to generalize the previous results of [21] by considering the damped structure $i\alpha b(x)\psi$ instead of $i\alpha\psi$ for the Schrödinger equation following the ideas of [1, 2]. Due to the right-hand side of the wave equation, i.e. $-\operatorname{Re}\nabla\psi\chi(\omega)$ the energy functional of the system depends upon the integral $\int \phi|\psi|^2$ which introduces a time that is required by the damping to smooth out the differences between the kinetic energies of the resonant electrons and non resonant ions. The presence of the damping terms in both equations of the system does not necessary guarantee that the energy $E(t)$ associated to the system is a non increasing function of the parameter t. Indeed in [12] where $b(x), \lambda(x)$ are effective in the whole of Ω and in [21] where $\lambda(x)$ is effective in ω the energy exponential rate depends upon the parameters of the system and t^*.

Our main task is to investigate the parametric energy decay for the system. Specifically, we seek necessary conditions, dependent on the parameters of the system b_0, λ_0, so that energy decay occurs at an exponential rate and therefore improve previous results by focusing on the ω. This ensures that, under specific plasma conditions, the energy of the coupled ion-electron wave is effectively dissipated to the plasma. In fact in Section 3 we will prove that the energy ia a non increasing function. For this purpose, we make use of the observability inequality for both, the wave and the Schrödinger equations. It is important to mention that the use of the observability inequality instead of the multiplier technique allows us to consider sharp regions ω satisfying the geometric control condition. Indeed, the inequalities given in (1.7) and (1.9) are proved by means of microlocal analysis and produce sharp regions when compared with the multiplier method. The main results of this paper are the following:

Theorem 1.4. *Let* $(\psi_0, \phi_0, \theta_0) \in \{H_0^1(\Omega) \cap H^2(\Omega)\}^2 \times H_0^1(\Omega)$ *and assuming that* $(\lambda_0 - \epsilon) > \frac{2}{3\alpha\kappa b_0}$, $(\lambda_0 - \epsilon), (1 - \epsilon(\lambda_0 - \epsilon)) > 0$ *hold then there exists a unique regular solution of* (1.2)–(1.4) *such that*

$$\begin{aligned} &\psi \in L^\infty(0, \infty; H_0^1(\Omega) \cap H^2(\Omega)), && \psi_t \in L^\infty(0, \infty; L^2(\Omega)), \\ &\phi \in L^\infty(0, \infty; H_0^1(\Omega) \cap H^2(\Omega)), && \phi_t \in L^\infty(0, \infty; H_0^1(\Omega)), \\ &\phi_{tt} \in L^\infty(0, \infty; L^2(\Omega)). \end{aligned}$$

Theorem 1.5. *Let* $(\psi_0, \phi_0, \theta_0) \in (H_0^1(\Omega) \cap H^2(\Omega)) \times H_0^1(\Omega)$ *and the assumptions of Theorem 1.4 hold, then there exists positive constant* C, ν, μ *such that the following decay rate holds*

$$E_\mu(t) \le Ce^{-\nu t} E(0), \qquad \forall\, t \ge 0$$

for every regular solution of the problem (1.1).

Let us recall the following known results. From Poincaré's inequality we have

$$\|u\|_{L^2(\Omega)} \le c \|\nabla u\|_{L^2(\Omega)}, \quad \text{for all } u \in H_0^1(\Omega),$$

and the Gagliardo–Nirenberg inequality for dimension $n = 2$

$$\|u\|_{L^4(\Omega)} \le c \|u\|_{L^2(\Omega)}^{\frac{1}{2}} \|\nabla u\|_{L^2(\Omega)}^{\frac{1}{2}} \quad \text{for all } u \in H_0^1(\Omega). \tag{1.11}$$

Notation: Denote by $H^s(\Omega)$ both the standard real and complex Sobolev spaces on Ω. For *simplicity reasons* sometimes we use H^s, L^s for $H^s(\Omega)$, $L^s(\Omega)$, and $\|\cdot\|$, $(\cdot, \cdot)$ for the norm and the inner product of $L^2(\Omega)$ and $\|\cdot\|_\omega$, $(\cdot, \cdot)_\omega$ for the norm and the inner product of $L^2(\omega)$ respectively as well as $\int dx$ denotes the integration over the domain Ω. Finally, C is a general symbol for any positive constant.

2 Existence and uniqueness

In this section we derive a priori estimates for the solutions of the system (1.1). Let $\{\omega_\nu\}$ be a basis of $H_0^1(\Omega) \cap H^2(\Omega)$ formed by the real eigenfunctions of Δ such that the sequence

$\{\omega_\nu\}$ gives a Hilbert basis of L^2 (i.e. an orthonormal basis of L^2) and let V_m be a subset of $H_0^1(\Omega)\cap H^2(\Omega)$ generated by the first m vectors. Then, let $g_{im}\in\mathbb{C}$ and $h_{im}, k_{im}\in\mathbb{R}$ with

$$\psi_m(t)=\sum_{i=1}^m g_{im}(t)\omega_i, \qquad \phi_m(t)=\sum_{i=1}^m h_{im}(t)\omega_i, \qquad \theta_m(t)=\sum_{i=1}^m k_{im}(t)\omega_i$$

such that $\{(\psi_m(t),\phi_m(t),\theta_m(t))\}$ is the solution to the following Cauchy problem:

$$\begin{cases} i(\psi_{t,m},u)+\kappa(\Delta\psi_m,u)+i\alpha(b(x)\psi_m,u)=(\phi_m\psi_m\chi(\omega),u), \ \forall\ u\in V_m, \\ (\phi_{t,m},z)=(\theta_m,z)-\epsilon(\phi_m,z), \ \forall\ z\in V_m, \\ (\theta_{t,m},v)+((\lambda(x)-\epsilon)\theta_m,v)-(\Delta\phi_m,v)+((1-\epsilon(\lambda(x)-\epsilon))\phi_m,v) \\ \qquad =-\operatorname{Re}(\nabla\psi_m\chi(\omega),v)\ \forall\ v\in V_m, \\ \psi_m(0)=\psi_{0m}\to\psi_0, \quad \phi_m(0)=\phi_{0m}\to\phi_0\in H_0^1(\Omega)\cap H^2(\Omega), \\ \theta(0)=\theta_{0m}\to\theta_0\in H_0^1(\Omega). \end{cases} \tag{2.1}$$

Let $Y=(\psi_m,\phi_m,\theta_m)$ then (2.1) also reads

$$\begin{cases} (\psi_{t,m},u)=i\kappa(\Delta\psi_m,u)+\alpha(b(x)\psi_m,u)-i(\phi_m\psi_m\chi(\omega),u), \ \forall\ u\in V_m, \\ (\phi_{t,m},z)=(\theta_m,z)-\epsilon(\phi_m,z), \forall\ z\in V_m, \\ (\theta_{t,m},v)=-((\lambda(x)-\epsilon)\theta_m,v)+(\Delta\phi_m,v)-((1-\epsilon(\lambda(x)-\epsilon))\phi_m,v) \\ \qquad -\operatorname{Re}(\nabla\psi_m\chi(\omega),v)\ \forall\ v\in V_m, \\ \psi_m(0)=\psi_{0m}\to\psi_0, \quad \phi_m(0)=\phi_{0m}\to\phi_0\in H_0^1(\Omega)\cap H^2(\Omega), \\ \theta(0)=\theta_{0m}\to\theta_0\in H_0^1(\Omega). \end{cases} \tag{2.2}$$

Then the considered matrix is the identity and therefore one may write $Y_t=F(Y)$ with smooth F. Hence the Cauchy–Lipschitz theorem applies straightforward. Since, the approximate system (2.1) is a finite system of ordinary differential equations which has a solution in $[0,t_m[$ the extension of the solution to the whole interval $[0,T]$, for all $T>0$, is a consequence of the first estimate we are going to obtain. Let us consider $u=\overline{\psi_m}$ in the first equation of (2.1). Then by taking the imaginary part we have

$$\frac{1}{2}\frac{d}{dt}\|\psi_m\|^2+\alpha\int b(x)|\psi_m|^2=0 \tag{2.3}$$

and because

$$\int b(x)|\psi_m|^2\ge\int_\omega b(x)|\psi_m|^2\ge b_0\int_\omega|\psi_m|^2 \tag{2.4}$$

almost everywhere in ω we have

$$\frac{1}{2}\frac{d}{dt}\|\psi_m\|^2+\alpha b_0\|\psi_m\|_\omega^2\le 0. \tag{2.5}$$

Finally, multiplying by 2 and integrating over $(0,t)$ for $t\in[0,t_m)$ concludes in

$$\|\psi_m\|^2+2\alpha b_0\int_0^t\|\psi_m(s)\|_\omega^2 ds\le\|\psi_{m0}\|^2. \tag{2.6}$$

Then, since $\psi_{m0}\to\psi_0$ in $H_0^1(\Omega)\cap H^2(\Omega)$ we have

$$(\psi_m)\text{ is bounded in }L^\infty(0,\infty;L^2(\Omega)) \tag{2.7}$$

and for $C_1 = C(\|\psi_0\|) > 0$ we also have

$$\int_0^\infty \|\psi_m(s)\|_\omega^2 ds \leq C_1 = C(\|\psi_0\|). \tag{2.8}$$

Next, taking $u = -\overline{\psi_{t,m}}$ in the first equation of (2.1) and considering the real part produces

$$\frac{\kappa}{2}\frac{d}{dt}\|\nabla\psi_m\|^2 + \alpha Im \int b(x)\psi_m\overline{\psi_{t,m}} = -\operatorname{Re}\int_\omega \phi_m\psi_m\overline{\psi_{t,m}} \tag{2.9}$$

and similarly with (2.4) we have

$$\frac{\kappa}{2}\frac{d}{dt}\|\nabla\psi_m\|^2 + \alpha b_0 Im \int_\omega \psi_m\overline{\psi_{t,m}} \leq -\operatorname{Re}\int_\omega \phi_m\psi_m\overline{\psi_{t,m}}. \tag{2.10}$$

Now, substituting $u = \alpha b_0\psi_m$ in the first equation of (2.1), integrating over ω and taking the real part we have

$$\alpha b_0 \operatorname{Im}\int_\omega \psi_m\overline{\psi_{t,m}} = \alpha\kappa b_0\|\nabla\psi_m\|_\omega^2 + \alpha b_0\int_\omega \phi_m|\psi_m|^2$$

and substituting the expression into (2.10) we obtain

$$\frac{\kappa}{2}\frac{d}{dt}\|\nabla\psi_m\|^2 + \alpha\kappa b_0\|\nabla\psi_m 0_\omega^2 + \alpha b_0\int_\omega \phi_m|\psi_m|^2 \leq -\operatorname{Re}\int_\omega \phi_m\psi_m\overline{\psi_{t,m}}. \tag{2.11}$$

Therefore, by taking into consideration that

$$\frac{d}{dt}\int_\omega \phi_m|\psi_m|^2 = \int_\omega \phi_{t,m}|\psi_m|^2 + 2\int_\omega \phi_m\psi_m\overline{\psi}_{t,m}$$

equation (2.11) becomes

$$\frac{1}{2}\frac{d}{dt}\{\kappa\|\nabla\psi_m\|^2 + \int_\omega \phi_m|\psi_m|^2\} + \alpha\kappa b_0\|\nabla\psi_m\|_\omega^2 + \alpha b_0\int_\omega \phi_m|\psi_m|^2 \leq \frac{1}{2}\operatorname{Re}\int_\omega \phi_{t,m}|\psi_m|^2. \tag{2.12}$$

Continuing with the second equation of the system (2.1), let $v = \theta_m$

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\{\|\theta_m\|^2 + \|\nabla\phi_m\|^2 + (1-\epsilon(\lambda_0-\epsilon))\|\phi_m\|_\omega^2\} + (\lambda_0-\epsilon)\|\theta_m\|_\omega^2 + \epsilon\|\nabla\phi_m\|^2 \\ + \epsilon(1-\epsilon(\lambda_0-\epsilon))\|\phi_m\|_\omega^2 \leq -\operatorname{Re}\int_\omega \nabla\psi_m\theta_m.\end{aligned} \tag{2.13}$$

Then, adding equations (2.12) and (2.13) produces

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\{\kappa\|\nabla\psi_m\|^2 + \int_\omega \phi_m|\psi_m|^2 + \|\theta_m\|^2 + \|\nabla\phi_m\|^2 + (1-\epsilon(\lambda_0-\epsilon))\|\phi_m\|_\omega^2\} \\ &\quad + \alpha\kappa b_0\|\nabla\psi_m\|_\omega^2 + \alpha b_0\int_\omega \phi_m|\psi_m|^2 + (\lambda_0-\epsilon)\|\theta_m\|_\omega^2 + \epsilon\|\nabla\phi_m\|^2 \\ &\quad + \epsilon(1-\epsilon(\lambda_0-\epsilon))\|\phi_m\|_\omega^2 \leq -\operatorname{Re}\int_\omega \nabla\psi_m\theta_m + \frac{1}{2}\operatorname{Re}\int_\omega \phi_{t,m}|\psi_m|^2,\end{aligned} \tag{2.14}$$

where

$$\frac{1}{2}\operatorname{Re}\int_\omega \phi_{t,m}|\psi_m|^2 = \frac{1}{2}\operatorname{Re}\int_\omega \theta_m|\psi_m|^2 - \frac{\epsilon}{2}\operatorname{Re}\int_\omega \phi_m|\psi_m|^2$$

and with the use of $\|u\|_4 \le c\|u\|^{1/2}\ \|\nabla u\|^{1/2}$ we have

$$\left|\int_\omega \theta_m \nabla\psi_m\right| \le \frac{\alpha\kappa b_0}{2}\|\nabla\psi_m\|_\omega^2 + \frac{1}{2\alpha\kappa b_0}\|\theta_m\|_\omega^2$$

$$\left|\frac{1}{2}\int_\omega \theta_m|\psi_m|^2\right| \le \|\theta_m\|_\omega\ \|\psi_m\|_{4,\omega}^2 \le \frac{(\lambda_0-\epsilon)}{4}\|\theta_m\|_\omega^2 + \frac{\alpha\kappa b_0}{4}\|\nabla\psi_m\|_\omega^2 + C.$$

Therefore, equation (2.14) becomes

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\left\{\kappa\|\nabla\psi_m\|^2 + \int_\omega \phi_m|\psi_m|^2 + \|\theta_m\|^2 + \|\nabla\phi_m\|^2 + (1-\epsilon(\lambda_0-\epsilon))\|\phi_m\|_\omega^2\right\}\\ &\quad + \frac{3\alpha\kappa b_0}{4}\|\nabla\psi_m\|_\omega^2 + (\alpha b_0+\epsilon)\int_\omega \phi_m|\psi_m|^2 + \left(\frac{3(\lambda_0-\epsilon)}{4} - \frac{1}{2\alpha\kappa b_0}\right)\|\theta_m\|_\omega^2\\ &\quad + \epsilon\|\nabla\phi_m\|^2 + \epsilon(1+\epsilon(\lambda_0-\epsilon))\|\phi_m\|_\omega^2 \le C\end{aligned} \tag{2.15}$$

for $\frac{3(\lambda_0-\epsilon)}{4} - \frac{1}{2\alpha\kappa b_0} > 0$. Set $\beta_0 = \min\{\frac{3\alpha\kappa b_0}{4}, (\alpha b_0+\epsilon), (\frac{3(\lambda_0-\epsilon)}{4} - \frac{1}{2\alpha\kappa b_0}), \epsilon, (1-\epsilon(\lambda_0-\epsilon))\}$, with $\beta_0 > 0$ and

$$H_0(t) = \kappa\|\nabla\psi_m\|^2 + \int_\omega \phi_m|\psi_m|^2 + \|\theta_m\|^2 + \|\nabla\phi_m\|^2 + (1-\epsilon(\lambda_0-\epsilon))\|\phi_m\|_\omega^2.$$

Hence we have

$$\frac{d}{dt}H_0(t) + \beta_0 H_0(t) \le C. \tag{2.16}$$

Using Gronwall's Lemma we obtain

$$H_0(t) \le \frac{C}{\beta_0}(1-e^{-\beta_0 t}) + H_0(t)e^{-\beta_0 t}$$

and

$$H_0(t) \le H_0(t)e^{-\beta_0 t} + \frac{C}{\beta_0}.$$

Finally, using (1.11) we estimate the following integral

$$\int_\omega \phi_m|\psi_m|^2 \le \frac{\kappa}{2}\|\nabla\psi_m\|^2 + \frac{1}{2}\|\nabla\phi_m\|^2 + C$$

then

$$H_0(t) \ge \frac{\kappa}{2}\|\nabla\psi_m\|^2 + \|\theta_m\|^2 + \frac{1}{2}\|\nabla\phi_m\|^2 + (1-\epsilon(\lambda_0-\epsilon))\|\phi_m\|_\omega^2 - C$$

and finally gives

$$\frac{\kappa}{2}\|\nabla\psi_m\|^2 + \|\theta_m\|^2 + \frac{1}{2}\|\nabla\phi_m\|^2 + (1-\epsilon(\lambda_0-\epsilon))\|\phi_m\|_\omega^2 \le C.$$

Therefore, we have

$$\begin{aligned}&(\psi_m) \text{ is bounded in } L^\infty(0,\infty;H_0^1(\Omega)),\\ &(\theta_m) \text{ is bounded in } L^\infty(0,\infty;L^2(\Omega)),\\ &(\phi_m) \text{ is bounded in } L^\infty(0,\infty;H_0^1(\Omega)).\end{aligned} \tag{2.17}$$

Moving to the next estimate we take the time derivative of the first equation of (2.1) and by choosing $u = \overline{\psi_{t,m}}$ we obtain

$$i(\psi_{tt,m}, \overline{\psi_{t,m}}) + \kappa(\Delta\psi_{t,m}, \overline{\psi_{t,m}}) + i\alpha(b(x)\psi_{t,m}, \overline{\psi_{t,m}}) = (\phi_{t,m}\psi_m\chi(\omega), \overline{\psi_{t,m}}) + (\phi_m\psi_{t,m}\chi(\omega), \overline{\psi_{t,m}}).$$

Taking into consideration the imaginary part we have

$$\frac{1}{2}\frac{d}{dt}\|\psi_{t,m}\|^2 + \alpha\int b(x)|\psi_{t,m}|^2 \leq \int \phi_{t,m}\psi_m\overline{\psi_{t,m}}$$

where since $\|\psi_m\|_\infty \leq c\|\Delta\psi_m\|^{1/2}\|\psi_m\|^{1/2}$ we obtain

$$\left|\int_\omega \phi_{t,m}\psi_m\overline{\psi_{t,m}}\right| \leq \|\phi_{t,m}\|\ \|\psi_m\|_\infty\|\psi_{t,m}\|_\omega \leq \frac{\alpha b_0}{2}\|\psi_{t,m}\|^2_\omega + \frac{\epsilon\kappa}{4}\|\Delta\psi_m\|^2 + C(\|\phi_{t,m}\|, \|\psi_m\|).$$

Therefore, we have

$$\frac{1}{2}\frac{d}{dt}\|\psi_{t,m}\|^2 + \frac{\alpha b_0}{2}\|\psi_{t,m}\|^2_\omega \leq \frac{\epsilon\kappa}{4}\|\Delta\psi_m\|^2 + C(\|\phi_{t,m}\|, \|\psi_m\|). \tag{2.18}$$

Moving to the next energy estimate by choosing $u = \overline{\Delta\psi_{t,m}} + \epsilon\overline{\Delta\psi_m}$ for the first equation of (2.1) and taking the real part we get

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\left\{\kappa\|\Delta\psi_m\|^2 + 2\alpha\,\mathrm{Im}\int b(x)\psi_m\overline{\Delta\psi_m} - 2\,\mathrm{Re}\int_\omega \phi_m\psi_m\overline{\Delta\psi_m}\right\} + \kappa\epsilon\|\Delta\psi_m\|^2 \\
&+ 2\alpha\epsilon\,\mathrm{Im}\int b(x)\psi_m\overline{\Delta\psi_m} - 2\epsilon\,\mathrm{Re}\int_\omega \phi_m\psi_m\overline{\Delta\psi_m} = \alpha\,\mathrm{Im}\int b(x)\psi_{t,m}\overline{\Delta\psi_m} \\
&- \mathrm{Re}\int_\omega \phi_{t,m}\psi_m\overline{\Delta\psi_m} - \mathrm{Re}\int_\omega \phi_m\psi_{t,m}\overline{\Delta\psi_m} + \alpha\epsilon\,\mathrm{Im}\int b(x)\psi_m\overline{\Delta\psi_m} - \epsilon\,\mathrm{Re}\int \phi_m\psi_m\overline{\Delta\psi_m}.
\end{aligned} \tag{2.19}$$

Next, choosing $v = -\Delta\theta$ in the second equation of (2.1) produces

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\left\{\|\Delta\phi_m\|^2 + (1+\epsilon^2)\|\nabla\phi_m\|^2 + \|\nabla\theta_m\|^2 - 2\int \lambda(x)\phi_{t,m}\Delta\phi_m\right\} \\
&\quad + \epsilon\left\{\|\Delta\phi\|^2 + (1+\epsilon^2)\|\nabla\phi\|^2 + \|\nabla\theta_m\|^2 - 2\int \lambda(x)\phi_{t,m}\Delta\phi_m\right\} \\
&\leq -\mathrm{Re}\int_\omega \Delta\psi_m\nabla\theta_m - \epsilon\int \lambda(x)\phi_{t,m}\Delta\phi_m.
\end{aligned} \tag{2.20}$$

Adding (2.18) with (2.19) and (2.20) produces

$$\begin{aligned}
\frac{1}{2}\frac{d}{dt}H_1(t) + \epsilon H_1 = {}& \alpha\,\mathrm{Im}\int b(x)\psi_{t,m}\overline{\Delta\psi_m} \\
& - \mathrm{Re}\int_\omega \phi_{t,m}\psi_m\overline{\Delta\psi_m} - \mathrm{Re}\int_\omega \phi_m\psi_{t,m}\overline{\Delta\psi_m} + \alpha\epsilon\,\mathrm{Im}\int b(x)\psi_m\overline{\Delta\psi_m} \\
& - \epsilon\,\mathrm{Re}\int \phi_m\psi_m\overline{\Delta\psi_m} - \mathrm{Re}\int_\omega \Delta\psi_m\nabla\theta_m - \epsilon\int \lambda(x)\phi_{t,m}\Delta\phi_m \\
& + \left(\epsilon - \frac{\alpha b_0}{2}\right)\|\psi_{t,m}\|^2 + C\|\nabla\phi_m\|^2\|\nabla\psi_m\|^2
\end{aligned}$$

where

$$\begin{aligned}
H_1(t) = {}& \|\psi_{t,m}\|^2 + \kappa\|\Delta\psi_m\|^2 + 2\alpha\,\mathrm{Im}\int b(x)\psi_m\overline{\Delta\psi_m} - 2\,\mathrm{Re}\int_\omega \phi_m\psi_m\overline{\Delta\psi_m} + \|\Delta\phi_m\|^2 \\
& + (1+\epsilon^2)\|\nabla\phi_m\|^2 + \|\nabla\theta_m\|^2 - 2\int \lambda(x)\phi_{t,m}\Delta\phi_m.
\end{aligned}$$

Set

$$
\begin{aligned}
F_1(t) = {} & \alpha \operatorname{Im} \int b(x)\psi_{t,m}\overline{\Delta\psi_m} - \operatorname{Re}\int_\omega \phi_{t,m}\psi_m\overline{\Delta\psi_m} - \operatorname{Re}\int_\omega \phi_m\psi_{t,m}\overline{\Delta\psi_m} \\
& + \alpha\epsilon \operatorname{Im}\int b(x)\psi_m\overline{\Delta\psi_m} - \epsilon\operatorname{Re}\int \phi_m\psi_m\overline{\Delta\psi_m} - \operatorname{Re}\int_\omega \Delta\psi_m\nabla\theta_m \\
& - \epsilon\int \lambda(x)\phi_{t,m}\Delta\phi_m + \frac{\epsilon\kappa}{4}\|\Delta\psi_m\|^2 + \left(\epsilon - \frac{\alpha b_0}{2}\right)\|\psi_{t,m}\|^2 \\
& + C(c_0, R, \epsilon, \kappa, \alpha, b_0, \|\theta_m\|, |\nabla\phi\|).
\end{aligned} \tag{2.21}
$$

Evaluating the terms in H_1 and F_1 we have

$$
\begin{aligned}
\left|\int_\omega \phi_{t,m}\psi_m\overline{\Delta\psi_m}\right| &\le \|\psi_m\|_\infty\|\phi_{t,m}\|\ \|\Delta\psi_m\| \le \frac{\kappa\epsilon}{8}\|\Delta\psi_m\|^2 + C(\kappa,\epsilon,\|\psi_m\|,\|\phi_{t,m}\|), \\
\left|\int_\omega \Delta\psi_m\nabla\theta_m\right| &\le \frac{\kappa\epsilon}{8}\|\Delta\psi_m\|^2 + \frac{2}{\kappa\epsilon}\|\nabla\theta_m\|^2, \\
\left|\int b(x)\psi_m\overline{\Delta\psi_m}\right| &\le \|b(x)\|_\infty\|\psi_m\|\ \|\Delta\psi_m\| \le \epsilon_1\|\Delta\psi_m\|^2 + C(\epsilon_1)(\|\psi_m\|,\|b(x)\|_\infty), \\
\left|\int b(x)\psi_{t,m}\overline{\Delta\psi_m}\right| &\le \|b(x)\|_\infty\|\psi_{t,m}\|\ \|\Delta\psi_m\| \le \frac{\kappa\epsilon}{8}\|\Delta\psi_m\|^2 + C(\kappa,\epsilon,\|b(x)\|_\infty)\|\psi_{t,m}\|^2 \\
\left|\int \phi_m\psi_m\overline{\Delta\psi_m}\right| &\le \|\phi_m\|_4\|\psi_m\|_4\|\Delta\psi_m\| \le \epsilon_2\|\Delta\psi_m\|^2 + C(\epsilon_2)(\|\psi_m\|,\|\phi_m\|,\|\nabla\psi_m\|,\|\nabla\phi_m\|), \\
\left|\int \phi_m\psi_{t,m}\overline{\Delta\psi_m}\right| &\le \|\phi_m\|_\infty\|\psi_{t,m}\|\ \|\Delta\psi_m\| \\
&\le \frac{\kappa\epsilon}{8}\|\Delta\psi_m\|^2 + \frac{\epsilon}{2}\|\Delta\phi_m\|^2 + \frac{\alpha b_0}{4}\|\psi_{t,m}\|^2 + C(\kappa,\epsilon,\alpha,b_0,c,\|\phi_m\|), \\
\left|\int \lambda(x)\phi_t\Delta\phi_m\right| &\le \|\lambda(x)\|_\infty\|\phi_{t,m}\|\ \|\Delta\phi_m\| \le \epsilon_3\|\Delta\phi_m\|^2 + C(\epsilon_3)(\|\lambda(x)\|_\infty,\|\phi_{t,m}\|).
\end{aligned}
$$

Therefore there exists a constant $\beta_1 > 0$ such that

$$
\beta_1 H_1(t) \le F_1 + C(\kappa,\epsilon,\alpha,b_0,\epsilon_1,\epsilon_2,\epsilon_3,\|\lambda(x)\|_\infty,\|b(x)\|_\infty,\|\phi_m\|,\|\psi_m\|,\|\nabla\psi_m\|,\|\nabla\phi_m\|,\|\phi_{t,m}\|)
$$

and

$$
\frac{d}{dt}H_1(t) + \beta_1 H_1(t) \le C. \tag{2.22}
$$

Employing Gronwall's Lemma we finally obtain

$$
\|\psi_{t,m}\|^2 + \|\Delta\psi_m\|^2 + \|\Delta\phi_m\|^2 + \|\nabla\theta_m\|^2 \le C. \tag{2.23}
$$

Hence,

$$
\begin{aligned}
&(\psi_m) \text{ is bounded in } L^\infty(0,\infty; H_0^1(\Omega)\cap H_0^2(\Omega)), \\
&(\theta_m) \text{ is bounded in } L^\infty(0,\infty; H_0^1(\Omega)), \\
&(\phi_m) \text{ is bounded in } L^\infty(0,\infty; H_0^1(\Omega)\cap H_0^2(\Omega)) \\
&(\psi_{t,m}) \text{ is bounded in } L^\infty(0,\infty; L^2(\Omega)).
\end{aligned} \tag{2.24}
$$

Therefore we may extract subsequences $\{\psi_\nu\} \subset \{\psi_m\}$, $\{\phi_\nu\} \subset \{\phi_m\}$ and $\{\theta_\nu\} \subset \{\theta_m\}$ such that

$$\begin{aligned} \psi_\nu &\rightharpoonup \psi \quad \text{for the weak star topology of } L^\infty(0,\infty; H_0^1(\Omega)\cap H_0^2(\Omega)), \\ \theta_\nu &\rightharpoonup \theta \quad \text{for the weak star topology of } L^\infty(0,\infty; H_0^1(\Omega)), \\ \phi_\nu &\rightharpoonup \phi \quad \text{for the weak star topology of } L^\infty(0,\infty; H_0^1(\Omega)\cap H_0^2(\Omega)) \\ \psi_{t,\nu} &\rightharpoonup \psi_t \quad \text{for the weak star topology of } L^\infty(0,\infty; L^2(\Omega)). \end{aligned} \tag{2.25}$$

These convergencies are sufficient to pass to the limit (on a standard manner) in (2.1) which results in

$$\begin{aligned} i\psi_t + \kappa\Delta\psi + i\alpha b(x)\psi &= \phi\psi\chi(\omega) && \text{in } L^\infty(0,\infty;L^2(\Omega)), \\ \phi_{tt} - \Delta\phi + \phi + \lambda(x)\phi_t &= -\operatorname{Re}\nabla\psi\chi(\omega) && \text{in } L^\infty(0,\infty;L^2(\Omega)). \end{aligned} \tag{2.26}$$

From [22, Lemma 4.1, Chapter II] we may derive that

$$\phi \in C(0,\infty; H_0^1(\Omega)\cap H_0^2(\Omega)) \quad \text{and} \quad \phi_t \in C(0,\infty; L^2(\Omega))$$

and since $\psi_t = \frac{1}{i}(-\kappa\Delta\psi - i\alpha b(x)\psi + \phi\psi\chi(\omega)) \in L^\infty(0,\infty;L^2(\Omega)$ using results in [16] we then obtain that

$$\psi \in C(0,\infty; H_0^1(\Omega)\cap H_0^2(\Omega)).$$

Let (ψ_1,ϕ_1) and (ψ_2,ϕ_2) be two solutions of the problem. Then by setting $z = \psi_1 - \psi_2$ and $w = \phi_1 - \phi_2$ the uniqueness of the solutions follows using the same above analysis.

This concludes the proof of Theorem 1.4. □

3 Uniform decay rates

In order to prove the energy decay of the system we derive some useful estimates.

Theorem 3.1. *Assume that Theorem 1.4 holds and let $C^* > 0$ denote a constant such that $|E(0)| \le C^*$. Then there exists a $t^* > 0$ such that for every $t \ge t^*$, $E(0) > 0$.*

Proof. Taking into consideration the assumptions of Theorem 1.4 and the result $\|\psi\| \le \epsilon^*$ for all $t \ge t^* > 0$ we evaluate the integral of the energy functional, that is

$$\left|\int_\omega \phi|\psi|^2 dx\right| \le c\|\phi\|\|\psi\|_4^2 \le \frac{1}{2}\|\phi\|^2 + \frac{c^2(\epsilon^*)^2}{2}\|\nabla\psi\|^2.$$

Therefore we have

$$E(t) \ge \frac{1}{2}\left[\|\psi\|^2 + \left(\kappa - \frac{c^2(\epsilon^*)^2}{2}\right)\|\nabla\psi\|^2 + \|\nabla\phi\|^2 + \|\phi_t\|^2\right], \quad \text{for } t \ge t^* \tag{3.1}$$

which completes the proof by choosing $\kappa > \frac{c^2(\epsilon^*)^2}{2}$. □

Proceeding with the analysis we take the inner product of (1.2) with $\overline{\psi_t + \alpha\psi}$, adding equation (2.3) and following similar steps as the ones for the a priori estimates we have

$$\frac{1}{2}\frac{d}{dt}\left\{\|\psi\|^2 + \kappa\|\nabla\psi\|^2 + \int_\omega \phi|\psi|^2\right\} + \kappa\alpha b_0\|\nabla\psi\|_\omega^2 + \alpha\int b(x)|\psi|^2 + \alpha b_0\int_\omega \phi|\psi|^2 = \frac{1}{2}\int_\omega \phi_t|\psi|^2. \tag{3.2}$$

Next, taking the inner product of (1.1) with ϕ_t gives

$$\frac{1}{2}\frac{d}{dt}\{\|\phi_t\|^2+\|\nabla\phi\|^2+\|\phi\|^2\}+\int\lambda(x)|\phi_t|^2=\operatorname{Re}\int_\omega\nabla\psi\phi_t. \tag{3.3}$$

Adding equations (2.5), (3.2) and (3.3) results in

$$\begin{aligned}E_t(t)+ab_0\|\psi\|_\omega^2+\kappa\alpha b_0\|\nabla\psi\|^2+\alpha\int b(x)|\psi|^2+\int\lambda(x)|\phi_t|^2\\+\alpha b_0\int_\omega\phi|\psi|^2=\frac{1}{2}\int_\omega\phi_t|\psi|^2+\operatorname{Re}\int_\omega\nabla\psi\phi_t.\end{aligned} \tag{3.4}$$

From equation (2.3) we have

$$\frac{1}{2}\frac{d}{dt}\|\psi\|_\omega^2+\alpha\|\psi\|_\omega^2\le 0$$

from which we get

$$\|\psi\|_\omega\le\|\psi(0)\|_\omega e^{-\alpha t}=\epsilon^* \tag{3.5}$$

and therefore since

$$\lim_{t\to\infty}\sup\|\psi\|_\omega=0.$$

Next, evaluating the integrals

$$\begin{aligned}\left|\alpha b_0\int_\omega\phi|\psi|^2\right|&\le\frac{\epsilon^* c\alpha b_0}{2\kappa}\|\phi\|_\omega^2+\frac{\kappa\alpha b_0}{2}\|\nabla\psi\|_\omega^2,\\ \left|\operatorname{Re}\int_\omega\nabla\psi\phi_t\right|&\le\frac{1}{2\epsilon}\int\lambda(x)|\phi_t|^2+\frac{\epsilon}{2\lambda_0}\|\nabla\psi\|_\omega^2,\\ \left|\frac{1}{2}\int_\omega\phi_t|\psi|^2\right|&\le\frac{\epsilon^*}{8\epsilon}\int\lambda(x)|\phi_t|^2+\frac{\epsilon}{2\lambda_0}\|\nabla\psi\|_\omega^2.\end{aligned}$$

Therefore

$$\begin{aligned}E_t(t)\le&-\left(\frac{\kappa\alpha b_0}{2}-\frac{\epsilon}{\lambda_0}\right)\|\nabla\psi\|_\omega^2-\alpha\int b(x)|\psi|^2-\left(1-\frac{1}{2\epsilon}-\frac{\epsilon^*}{8\epsilon}\right)\int\lambda(x)|\phi_t|^2\\&+\frac{\epsilon^* c\alpha b_0}{2\kappa}\|\phi\|_\omega^2-\alpha b_0\|\psi\|_\omega^2.\end{aligned} \tag{3.6}$$

For $\mu>0$ let us define the perturbed energy

$$E_\mu(t)=E(t)+\mu p(t) \tag{3.7}$$

where

$$p(t)=(\psi(t),\psi(t))+(\phi_t(t),\phi(t))_\omega. \tag{3.8}$$

Lemma 3.2. *For $\mu, C>0$ we have that*

$$|E_\mu(t)-E(t)|\le\mu CE(t),\quad \textit{for all } t\ge t^*.$$

Proof. We have

$$|p(t)|\le\|\psi\|^2+\frac{1}{2}\|\phi_t\|^2+\frac{c_1}{2}\|\nabla\phi\|^2\le C^*E(t)$$

which completes the proof. □

Next, by taking the time derivative of $p(t)$ we obtain

$$\begin{aligned} p_t(t) &= 2\,\mathrm{Re}(\psi_t,\psi) + (\phi_{tt},\phi)_\omega + (\phi_t,\phi_t)_\omega \\ &\leq 2\,\mathrm{Re}(\psi_t,\psi) + (\phi_{tt},\phi)_\omega + \frac{1}{\lambda_0}\int_\omega \lambda(x)|\phi_t|^2 \\ &\leq 2\,\mathrm{Re}(\psi_t,\psi) + (\phi_{tt},\phi) + \frac{1}{\lambda_0}\int \lambda(x)|\phi_t|^2 \end{aligned}$$

which with the help of (1.1) we can deduce that

$$p_t(t) \leq\; -2\alpha\int b(x)|\psi|^2 - \|\nabla\phi\|^2 - \|\phi\|^2 + \frac{1}{\lambda_0}\int \lambda(x)|\phi_t|^2 - \int \lambda(x)\phi_t\phi - \mathrm{Re}\int_\omega \nabla\psi\phi. \quad (3.9)$$

Adding equations (3.6)–(3.9) gives

$$\begin{aligned} E_{t,\mu} &= E_t(t) + \mu p_t(t) \\ &\leq -\left(\frac{\kappa\alpha b_0}{2} - \frac{\epsilon}{\lambda_0}\right)\|\nabla\psi\|^2_\omega - \alpha(2\mu+1)\int b(x)|\psi|^2 \\ &\quad - \left(1 - \frac{1}{2\epsilon} - \frac{\epsilon^*}{8\epsilon} - \frac{\mu}{\lambda_0}\right)\int \lambda(x)|\phi_t|^2 \\ &\quad + \frac{\epsilon^* c\alpha b_0}{2\kappa}\|\phi\|^2_\omega - \mu\|\nabla\phi\|^2 - \mu\|\phi\|^2 - \mu\int\lambda(x)\phi_t\phi - \mathrm{Re}\,\mu\int_\omega \nabla\psi\phi - \alpha b_0\|\psi\|^2_\omega, \end{aligned} \quad (3.10)$$

where

$$\begin{aligned} \left|\mu\int_\omega \nabla\psi\phi\right| &\leq \frac{c\mu}{2}\|\nabla\psi\|^2_\omega + \frac{\mu}{2}\|\nabla\phi\|^2, \\ \left|\mu\int \lambda(x)\phi_t\phi\right| &\leq \frac{c\mu\|\lambda\|_\infty}{2}\int \lambda(x)|\phi_t|^2 + \frac{\mu}{2}\|\nabla\phi\|^2 \end{aligned}$$

which concludes in

$$\begin{aligned} E_{t,\mu} &= E_t(t) + \mu p_t(t) \\ &\leq -\left(\frac{\kappa\alpha b_0}{2} - \frac{\epsilon}{\lambda_0} - \frac{c\mu}{2}\right)\|\nabla\psi\|^2_\omega - \alpha(2\mu+1)\int b(x)|\psi|^2 \\ &\quad - \left(1 - \frac{1}{2\epsilon} - \frac{\epsilon^*}{8\epsilon} - \frac{\mu}{\lambda_0} - \frac{c\mu\|\lambda\|_\infty}{2}\right)\int \lambda(x)|\phi_t|^2 - \mu\left(1 - \frac{\epsilon^* c\alpha b_0}{2\kappa\mu}\right)\|\phi\|^2. \end{aligned}$$

Therefore we will require the following expressions to be nonnegative

$$\begin{cases} \frac{\kappa\alpha b_0}{2} - \frac{\epsilon}{\lambda_0} - \frac{c\mu}{2} > 0, \\ 1 - \frac{1}{2\epsilon} - \frac{\epsilon^*}{8\epsilon} - \frac{\mu}{\lambda_0} - \frac{c\mu\|\lambda\|_\infty}{2} > 0, \\ 1 - \frac{\epsilon^* c\alpha b_0}{2\kappa\mu} > 0. \end{cases}$$

Therefore, choosing κ sufficiently large enough such that the following inequality holds

$$2\kappa\lambda_0 > \epsilon^* acb_0(2 + \lambda_0\|\lambda\|_\infty)$$

we may deduce that there exists a k such that

$$E_{t,\mu}(t) \leq -k\left[\int b(x)|\psi|^2 + \int \lambda(x)|\phi_t|^2\right] \quad (3.11)$$

and hence $E_\mu(t)$ would be a non increasing function.

Remark 3.3. The time t^* introduced in the energy decay analysis which is present through the constant ϵ^* has a specific physical meaning. This is the time so that the non-collisional integral $\int \phi|\psi|^2$ is absorbed by the collisional terms (see (3.1)). Therefore, t^* roughly signifies the time required by the collisional damping to smooth out the excessive difference of the kinetic energies of the resonant electrons and the non-resonant ions (equipartition). It is important to note that equation (3.6) is a non increasing function due to the positive term $\|\phi\|_\omega$ which depends heavily on the t^*.

Lemma 3.4. *For all $T > T_0$ there exists a positive constant $C = C(t)$ such that if (ψ, ϕ) is the regular solution of the system (1.1) where $(\psi_0, \phi_0, \phi_1) \in \{H_0^1(\Omega) \cap H^2(\Omega)\}^2 \times H_0^1(\Omega)$ we have*

$$E_\mu(0) \leq C \int_0^T \left[\int b(x)|\psi|^2 + \int \lambda(x)|\phi_t|^2 \right] dt. \tag{3.12}$$

Proof. We will prove this lemma by contradiction. Assume (3.12) is not true and let $(\psi_k(0), \phi_k(0), \phi_{t,k}(0))$ be a sequence of initial data where the corresponding solutions $(\psi_k, \phi_k, \phi_{t,k})$ with $E_{\mu,k}(0)$, uniformly bounded in k satisfy

$$\lim_{k\to+\infty} \frac{E_{\mu,k}(0)}{\int_0^T \left[\int b(x)|\psi_k|^2 + \int \lambda(x)|\phi_{t,k}|^2 \right] dt} = +\infty. \tag{3.13}$$

Since $E_{\mu,k}(t)$ is non increasing and $E_{\mu,k}(0)$ remains bounded we may obtain a subsequence, denoted again as (ψ_k, ϕ_k) for which we have

$$\begin{cases} \psi_k \rightharpoonup \psi \text{ weak star in } L^\infty(0,T;H_0^1(\Omega)), \\ \phi_k \rightharpoonup \phi \text{ weak star in } L^\infty(0,T;H_0^1(\Omega)), \\ \phi_{t,k} \rightharpoonup \phi_t \text{ weak star in } L^\infty(0,T;L^2(\Omega)), \\ \psi_{t,k} \rightharpoonup \psi_t \text{ weak star in } L^\infty(0,T;L^2(\Omega)). \end{cases} \tag{3.14}$$

By compactness results, see [14] we get

$$\begin{aligned} \psi_k \to \psi_k \text{ strongly in } L^\infty(0,T;L^2(\Omega)), \\ \phi_k \to \phi_k \text{ strongly in } L^\infty(0,T;L^2(\Omega)). \end{aligned} \tag{3.15}$$

Now, taking into consideration (3.13) and (3.14) we obtain

$$\begin{aligned} \lim_{k\to+\infty} \int_0^T \int b(x)|\psi_k|^2 dxdt = 0, \\ \lim_{k\to+\infty} \int_0^T \int \lambda(x)|\phi_{t,k}|^2 dxdt = 0. \end{aligned} \tag{3.16}$$

Setting

$$c_k := [E_{\mu,k}(0)]^{1/2} \quad \text{and} \quad \hat{\phi}_k = \frac{1}{c_k}\phi_k, \quad \hat{\psi}_k = \frac{1}{c_k}\psi_k$$

we infer that

$$\hat{E}_{\mu,k}(t) := \frac{E_{\mu,k}(t)}{c_k^2}$$

for which we have

$$\hat{E}_k(0) = 1. \tag{3.17}$$

Taking into consideration the following system

$$\begin{cases} i\hat{\psi}_{t,k} + \kappa\Delta\hat{\psi}_k + i\alpha b(x)\hat{\psi}_k = \hat{\phi}_k\psi_k\chi(\omega), \\ \hat{\phi}_{tt,k} - \Delta\hat{\phi}_k + \hat{\phi}_k + \lambda(x)\hat{\phi}_{t,k} = -\operatorname{Re}\nabla\hat{\psi}_k\chi(\omega), \\ \hat{\psi}_k = \hat{\phi}_k = 0 \in \Gamma\times(0,T), \\ \hat{\psi}_k(0) = \hat{\psi}_{0k},\ \hat{\phi}_k(0) = \hat{\phi}_{0k},\ \hat{\phi}_{t,k}(0) = \hat{\phi}_{1k} \text{ in } \Omega, \\ \hat{\phi}_{t,k} \to 0 \in L^2(0,T;L^2(\omega)) \end{cases} \tag{3.18}$$

and since $E_{\mu,k}(0) = 1$ we may deduce that for a subsequence $(\hat{\psi}_k, \hat{\phi}_k)$ it is true that

$$\begin{cases} \hat{\psi}_k \rightharpoonup \hat{\psi} \text{ weak star in } L^\infty(0,T;H_0^1(\Omega)), \\ \hat{\psi}_k \to \hat{\psi} \text{ strongly in } L^\infty(0,T;L^2(\Omega)), \\ \hat{\psi}_{t,k} \to \hat{\psi}_t \text{ weak star in } L^\infty(0,T;L^2(\Omega)), \\ \hat{\phi}_k \rightharpoonup \hat{\phi} \text{ weak star in } L^\infty(0,T;H_0^1(\Omega)), \\ \hat{\phi}_{t,k} \rightharpoonup \hat{\phi}_t \text{ weak star in } L^\infty(0,T;L^2(\Omega)), \\ \hat{\phi}_k \to \hat{\phi} \text{ strongly in } L^\infty(0,T;L^2(\Omega)). \end{cases} \tag{3.19}$$

From the (3.19), we obtain

$$\begin{aligned} \lim_{k\to+\infty}\int_0^T\int b(x)|\hat{\psi}_k|^2dxdt = 0, \\ \lim_{k\to+\infty}\int_0^T\int \lambda(x)|\hat{\phi}_{t,k}|^2dxdt = 0, \end{aligned} \tag{3.20}$$

and therefore by (3.20) and by the compact embedding $H_0^1(\Omega) \hookrightarrow L^2(\Omega)$

$$\begin{aligned} \lim_{k\to+\infty}\int_0^T\int_\omega |\nabla\hat{\psi}_k|^2dxdt = 0, \\ \lim_{k\to+\infty}\int_0^T\int_\omega |\hat{\phi}_k\psi_k|^2dxdt = 0. \end{aligned} \tag{3.21}$$

Taking into consideration (3.20) and letting the limit $k \to +\infty$ for the system (3.18) we get for the wave equation

$$\begin{cases} \hat{\phi}_{tt} - \Delta\hat{\phi} + \hat{\phi} = 0 \text{ in } \Omega\ \times(0,T), \\ \hat{\phi} = 0 \in \Gamma\times(0,T), \\ \phi_t = 0 \text{ a.e.} \in \omega\times(0,T) \end{cases} \tag{3.22}$$

and for the Schrödinger equation

$$\begin{cases} i\hat{\psi}_t + \kappa\Delta\hat{\psi} = 0, \text{in } \Omega\ \times(0,T), \\ \hat{\psi} = 0 \text{ on } \Gamma\times(0,T). \end{cases} \tag{3.23}$$

Setting $\hat{\phi}_t = v$ equation (3.22) in the distributional sense becomes

$$\begin{cases} v_{tt} - \Delta v = 0 \in D'(\Omega\ \times(0,T)), \\ v = 0 \in \Gamma\times(0,T), \\ v = 0 \text{ a.e.} \in \omega\times(0,T). \end{cases} \tag{3.24}$$

From standard uniqueness results from equation (3.24) we may conclude that $v \equiv 0$, that is $\hat{\phi}_t \equiv 0$. Therefore for a.e. $t \in (0, T)$

$$\begin{cases} -\Delta\hat{\phi} = 0 \in \Omega, \\ \hat{\phi} = 0 \in \Gamma \end{cases} \tag{3.25}$$

which multiplying by $\hat{\phi}$ implies that $\hat{\phi} \equiv 0$. Following a similar procedure for the Schrödinger equation the uniqueness theorem concludes that $\hat{\psi} = 0$ a.e. $\in \Omega$.

In order to achieve a contradiction it is enough to prove that $\hat{E}_{\mu,k}(0) \to 0$ as $k \to +\infty$.

$$\begin{aligned} \hat{E}_{\mu,k}(0) = & \frac{1}{2}\Big\{\int((2\mu+1)|\hat{\psi}(x,0)|^2 + \kappa|\nabla\hat{\psi}(x,0)|^2 + |\hat{\phi}(x,0)|^2 + |\nabla\hat{\phi}(x,0)|^2 + |\hat{\phi}_t(x,0)|^2) \\ & + \int_\omega \phi(x,0)|\hat{\psi}(x,0)|^2 + 2\mu\int_\omega \hat{\phi}_t(x,0)\hat{\phi}(x,0)\Big\} \\ \le & \frac{1}{2}\Big\{\int((2\mu+1)|\hat{\psi}(x,0)|^2 + \left(\kappa + \frac{c}{2}\right)|\nabla\hat{\psi}(x,0)|^2 + \frac{3}{2}|\hat{\phi}(x,0)|^2 \\ & + (\mu c+1)|\nabla\hat{\phi}(x,0)|^2 + (\mu+1)|\hat{\phi}_t(x,0)|^2)\Big\} = E_{\mu,\hat{\psi}_k}(0) + E_{\mu,\hat{\phi}_k}(0). \end{aligned} \tag{3.26}$$

Our aim is to prove that $E_{\mu,\hat{\psi}_k}(0) \to 0$ and $E_{\mu,\hat{\phi}_k}(0) \to 0$ with the help of (1.7) and (1.9). For this purpose let $\hat{\psi}_k = v_k + w_k$ where $\hat{\psi}_k$ is the solution of the system (3.18) and v_k, w_k are the solutions of the following systems respectively,

$$\begin{cases} iv_{t,k} + \kappa\Delta v_k = 0 \in \Omega \times (0,T), \\ v_k = 0 \in \Gamma \times (0,T), \\ v_k(0) = \hat{\psi}_{0,k} \in \Omega \end{cases} \tag{3.27}$$

and

$$\begin{cases} iw_{t,k} + \kappa\Delta w_k = -i\alpha b(x)\hat{\psi}_k + \hat{\phi}_k\psi_k\chi(\omega), \in \Omega \times (0,T), \\ w_k = 0 \in \Gamma \times (0,T), \\ w_k(0) = 0 \in \Omega. \end{cases} \tag{3.28}$$

Similarly for the wave equation we obtain $\hat{\phi}_k = z_k + u_k$ which produces the following problems

$$\begin{cases} z_{tt,k} + \Delta z_k = 0 \in \Omega \times (0,T), \\ z_k = \hat{\phi}_{0k} \in \Gamma \times (0,T), \\ z_k(0) = \hat{\phi}_{0,k} \in \Omega, \\ z_{t,k}(0) = \hat{\phi}_{1k} \in \Omega \end{cases} \tag{3.29}$$

and

$$\begin{cases} u_{tt,k} + \Delta u_k = -\lambda(x)\hat{\phi}_{t,k} - \operatorname{Re}\nabla\hat{\psi}_k\chi(\omega) \in \Omega \times (0,T), \\ u_k = 0 \in \Gamma \times (0,T), \\ u_k(0) = 0 \in \Omega, \\ u_{t,k}(0) = 0 \in \Omega. \end{cases} \tag{3.30}$$

Therefore, it follows that

$$\begin{aligned}\hat{E}_{\mu,k} &\leq E_{\mu,\hat{\psi}_k}(0) + E_{\mu,\hat{\phi}_k}(0) = E_{\mu,v_k}(0) + E_{\mu,z_k}(0) \leq c_1 \int_0^T \int_\omega |v_k|^2 + c_2 \int_0^T \int_\omega |z_{t,k}|^2 \\ &\leq c_1 \Big(\int_0^T \int b(x)|\hat{\psi}_k|^2 + \int_0^T \int_\omega |w_k|^2 \Big) + c_2 \Big(\int_0^T \int \lambda(x)|\hat{\phi}_{t,k}|^2 + \int_0^T \int_\omega |x_k|^2 \Big).\end{aligned} \tag{3.31}$$

From equation (3.28) we have the following integral form

$$\hat{w}_k(t) = S(t)\hat{w}_k(0) + \int_0^T S(t-\tau)F(\tau)d\tau, \tag{3.32}$$

where $S(t)$ is the semigroup generated by

$$\begin{aligned} A : D(A) = H_0^1(\Omega) \cap H^2(\Omega) \subset L^2(\Omega) &\to L^2(\Omega), \\ y &\to Ay = -i\Delta y \end{aligned}$$

and $F(t) = \hat{\phi}_k(t)\psi_k(t)\chi(\omega) - i\alpha b(x)\hat{\psi}_k(t)$. Thus, taking into consideration that $\|S(t)\|_{\mathcal{L}(L^2(\Omega))} \leq C$ we have

$$\|w_k\|^2 \leq c_1\|w_{0,k}\|^2 + c_2\Big(\int_0^T \|F(\tau)\|d\tau\Big)^2 \leq C(\|w_{0k}\|^2 + \|F\|^2_{L^1(0,T;L^2(\Omega))})$$

which with the help of the embedding $L^\infty(0,T;L^2(\Omega)) \to L^1(0,T;L^2(\Omega))$ and $w_k(0) = 0$ produces

$$\begin{aligned}\int_0^T \int_\omega |w_k|^2 &\leq \|w_k\|^2_{L^\infty(0,T;L^2(\Omega))} \\ &\leq C\|F\|^2_{L^1(0,T;L^2(\Omega))} \leq C \int_0^T \int |\hat{\phi}_k\psi_k\chi(\omega) - i\alpha b(x)\hat{\psi}_k|^2.\end{aligned} \tag{3.33}$$

Moving onto the wave equation we have the following integral form expression for the system (3.29)

$$U_k(t) = S(t)U_{0k} + \int_0^T S(t-\tau)F(\tau)d\tau$$

where

$$U_k = \begin{pmatrix} u_k \\ u_{t,k} \end{pmatrix} \quad \text{with} \quad A = \begin{pmatrix} 0 & -I \\ -\Delta & 0 \end{pmatrix} \quad \text{and} \quad F = \begin{pmatrix} 0 \\ -\lambda(x)\hat{\phi}_k - \operatorname{Re}\nabla\hat{\psi}_k\chi(\omega) \end{pmatrix}.$$

Evaluating the following integral

$$\begin{aligned}\int_0^T \int_\omega |u_{t,k}|^2 &\leq \|u_{t,k}\|^2_{L^\infty(0,T;L^2(\Omega))} \\ &\leq C\|F\|^2_{L^1(0,T;L^2(\Omega))} \leq C \int_0^T \int |-\lambda(x)\hat{\phi}_k - \operatorname{Re}\nabla\hat{\psi}_k\chi(\omega)|^2.\end{aligned} \tag{3.34}$$

Therefore, from equation (3.31) we obtain

$$\begin{aligned}\hat{E}_{\mu,k}(t) \leq C\Big(&\int_0^T \int b(x)|\hat{\psi}_k|^2 + \int_0^T \int |\hat{\phi}_k\psi_k\chi(\omega) - i\alpha b(x)\hat{\psi}_k|^2 \\ &+ \int_0^T \int \lambda(x)|\hat{\phi}_{t,k}|^2 + \int_0^T \int |-\operatorname{Re}\nabla\hat{\psi}_k\chi(\omega) - \lambda(x)\hat{\phi}_{t,k}|^2\Big),\end{aligned} \tag{3.35}$$

which taking into consideration (3.20) and (3.21) produces $\hat{E}_{\mu,k}(0) \to 0$ as $k \to +\infty$ and therefore contradicts the expression (3.17). □

Proof of Theorem 1.5. Continuing with the proof of Theorem 1.5 and by taking $T_0 > 0$ large enough from (3.11) we may deduce that

$$E_\mu(T_0) - E_\mu(0) \le -k\left[\int_0^{T_0} b(x)|\psi|^2 + \int \lambda(x)|\phi_t|^2\right] \tag{3.36}$$

and from Lemma 3.4 we also have

$$E_\mu(0) \le C\int_0^{T_0} D(t)$$

where

$$D(t) := \int b(x)|\psi|^2 + \int \lambda(x)|\phi_t|^2.$$

Therefore, we get

$$E_\mu(T_0) \le E_\mu(0) \le C\int_0^{T_0} D(t) \le -\frac{C}{k}E_\mu(T_0) + \frac{C}{k}E_\mu(0),$$

so

$$\left(1+\frac{C}{k}\right)E_\mu(T_0) \le \frac{C}{k}E_\mu(0).$$

Hence,

$$E_\mu(T_0) \le \nu E_\mu(0), \qquad 0 < \nu < 1.$$

Proceeding in a similar way from T to $2T$ and eventually to nT we have

$$E_\mu(nT) \le \nu^n E_\mu(0), \qquad \forall\, T > T_0.$$

Finally, let $t > T_0$ then $t = nT_0 + r$ for $0 \le r \le T_0$ and

$$E_\mu(t) \le E_\mu(t-r) = E_\mu(nT_0) \le \nu^n E_\mu(0) = \nu^{\frac{t-r}{T_0}} E_\mu(0) = e^{\frac{t-r}{T_0}\ln\nu} E_\mu(0).$$

Moreover, by Lemma 3.2 we have

$$E_\mu(t) \le 2E(t) \quad \text{for } t \ge 0$$

therefore

$$E_\mu(t) \le 2E(0)e^{\frac{t-r}{T_0}\ln\nu} \quad \text{for } t \ge 0$$

which completes the proof of Theorem 1.5. □

Abstract. In this paper, we investigate the bifurcation results of the fractional Kirchhoff–Schrödinger–Poisson system

$$\begin{cases} M([u]_s^2)(-\Delta)^s u + V(x)u + \phi(x)u = \lambda g(x)|u|^{p-1}u + |u|^{2_s^*-2}u & \text{in } \mathbb{R}^3, \\ (-\Delta)^t \phi(x) = u^2 & \text{in } \mathbb{R}^3, \end{cases}$$

where $s, t \in (0,1)$ with $2t + 4s > 3$ and the potential function V is a continuous function. We show that the existence of components of (weak) solutions of the above equation associated with the first eigenvalue λ_1 of the problem

$$(-\Delta)^s u + V(x)u = \lambda g(x)u \quad \text{in } \mathbb{R}^3.$$

The main feature of this paper is the inclusion of a potentially degenerate Kirchhoff model, combined with the critical nonlinearity.

Keywords: Kirchhoff–Schrödinger–Poisson system, global bifurcation, first eigenvalue, fractional Laplacian, fixed point, whole space.

1 Introduction and main results

In this paper, we investigate the bifurcation result of the fractional Kirchhoff–Schrödinger–Poisson system

$$\begin{cases} M([u]_s^2)(-\Delta)^s u + V(x)u + \phi u = \lambda g(x)|u|^{p-1}u + |u|^{2_s^*-2}u, & \text{in } \mathbb{R}^3, \\ (-\Delta)^t \phi = u^2 & \text{in } \mathbb{R}^3, \end{cases} \tag{$\mathcal{P}$}$$

where $s, t \in (0,1)$ with $2t + 4s > 3$, $\lambda \in \mathbb{R}$, $p \in (0,1)$, $g(x) \in L^{\frac{6}{5-p}}(\mathbb{R}^3) \cap L^{\frac{3}{2}}(\mathbb{R}^3)$ is a weight function, the non-local coefficient $M : \mathbb{R}_0^+ \to \mathbb{R}^+$ defined by $M(t) = a + bt$, where $a, b \geq 0$, and the Gagliardo semi-norm

$$[u]_s = \left(\int_{\mathbb{R}^3} |(-\Delta)^{\frac{s}{2}} u|^2 dx \right)^{1/2}.$$

✉Corresponding author. Email: xyuming@hit.edu.cn

Here, we assume that $(-\Delta)^s$ is the fractional Laplacian which, up to a normalization constant, is denoted as

$$(-\Delta)^s u(x) = 2 \lim_{\varepsilon \to 0^+} \int_{\mathbb{R}^3 \setminus B_\varepsilon(x)} \frac{u(x)-u(y)}{|x-y|^{3+2s}} dy, \qquad x \in \mathbb{R}^3,$$

for every $u \in C_0^\infty(\mathbb{R}^3)$, where $B_\varepsilon(x)$ is the ball of $\mathbb{R}^3$ centered at $x \in \mathbb{R}^3$ with radius $\varepsilon > 0$.

The Kirchhoff–Schrödinger–Poisson (KSP) system, including ($\mathcal{P}$) as a special model, describes the interaction of a quantum particle with an electromagnetic field. The (KSP) system consisting of a Schrödinger equation coupled with a Poisson equation and a Kirchhoff function has been studied extensively in various settings, such as Euclidean spaces, fractional spaces, and Heisenberg groups, due to its strong applications in physics. Some of the main topics of interest are the existence, multiplicity, and asymptotic behavior as well as the qualitative properties of the (weak) solutions such as regularity, symmetry, and concentration. For more information and references, one can consult the following papers [2,6,8–11,23].

The fractional (KSP) system is a generalization of the (KSP) system that involves fractional derivatives of order s in $(0,1)$. The fractional part of the system introduces new challenges and difficulties involving fractional derivatives and nonlocal and nonlinear properties. Various methods and techniques have been developed to deal with these problems, such as variational methods, the Nehari manifold, Ekeland variational principle, the concentration-compactness principle, and the mountain pass theorem. We refer the readers to [12,16,22,23]. Benci and Fortunato in [3] first introduced the Schrödinger–Poisson system

$$\begin{cases} -\Delta u + V(x)u + \phi u = f(x,u), & \text{in } \mathbb{R}^3, \\ -\Delta \phi = u^2, & \text{in } \mathbb{R}^3, \end{cases}$$

to describe solitary waves with an electronic field. More recently, the authors in [16] used variational methods to obtain nonnegative solutions for an Schrödinger–Choquard–Kirchhoff type fractional p-Laplacian

$$\left(a + b\|u\|_s^{p(\xi-1)}\right)[(-\Delta)_p^s u + V(x)|u|^{p-2}u] = \lambda f(x,u) + \left(\int_{\mathbb{R}^N} \frac{|u|^{p^*_{\nu,s}}}{|x-y|^\mu} dy\right) |u|^{p^*_{\nu,s}-2}u \quad \text{in } \mathbb{R}^N,$$

where the nonlinearity f satisfies super-linear or sub-linear growth conditions and the parameter λ is large or small enough. In particular, it can be seen as a special case of the fractional Kirchhoff–Schrödinger–Poisson system.

On the other hand, bifurcation analysis is an important method of mathematics that studies how the qualitative behavior of solutions changes as a parameter varies, and moreover, a bifurcation point may correspond to the appearance or disappearance of the solutions or a change in their stability or symmetry. For instance, He, in [7], studied the nonhomogeneous semi-linear fractional Schrödinger equation with critical growth

$$\begin{cases} (-\Delta)^s u + u = u^{2_s^*-1} + \lambda(f(x,u)+h(x)), & x \in \mathbb{R}^N, \\ u \in H^s(\mathbb{R}^N), \quad u(x) > 0 & x \in \mathbb{R}^N, \end{cases}$$

where $s \in (0,1)$, $N > 4s$ and $\lambda > 0$ is a parameter. They showed that there exists a positive bifurcation value of the parameter such that the problem has exactly two positive solutions for smaller values, no positive solutions for larger values, and a unique solution at the bifurcation value. Furthermore, many recent works investigate the bifurcation results for the fractional Kirchhoff or Schrödinger or Poisson equation under different assumptions on the potential functions and the non-linearities. Very recently, for $p \in (1,2)$ and λ is small, Ruiz [19] demonstrated the existence of a branch of positive radial solutions to the problem

$$\begin{cases} -\Delta u + u + \lambda \phi u = u_+^p \\ -\Delta \phi = u^2, \quad \lim_{|x|\to+\infty} \phi(x) = 0. \end{cases}$$

After that, in [24], Xu, Qin, and Chen established bifurcation results for positive solutions by using the local and global bifurcation techniques, a priori bounds for elliptic equation, and the properties of the principal eigenvalues to the Kirchhoff-type problem involving sign-changing weight functions

$$\begin{cases} -(a(x) + b(x)\|u\|^2)\Delta u = \lambda m(x) u + h(x) u^p & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases}$$

In [14], the bifurcation results and the regularity for the (weak) solutions of the Schrödinger–Poisson system

$$\begin{cases} -\Delta u + l(x)\phi u = \lambda a(x)|u|^{p-1}u + f(\lambda, x, u), & \text{in } \mathbb{R}^3, \\ -\Delta \phi = l(x) u^2, & \text{in } \mathbb{R}^3 \end{cases}$$

are proved, where a, l are weight functions and f satisfies the subcritical and critical growth condition, respectively.

Motivated by the above works, especially by [19], this paper is dedicated to investigating bifurcation results to the (weak) solutions of the (KSP) system ($\mathcal{P}$), while overcoming the challenges due to the lack of compactness in critical case as well as the degenerate nature of the Kirchhoff coefficient. To our knowledge, no such general results are provided for ($\mathcal{P}$).

More precisely, we put the hypotheses in the following:

- (V_1) $V \in C(\mathbb{R}^3)$ satisfies $\inf_{x\in\mathbb{R}^3} V(x) \geq V_0 > 0$, where $V_0 > 0$ is a constant;
- (V_2) $\text{meas}\{x \in \mathbb{R}^3 : -\infty < V(x) \leq \xi\} < +\infty$ for any $\xi \in \mathbb{R}$;
- $(M_1)'$ $M \in C(\mathbb{R}_0^+)$ satisfies that for any $\tau > 0$, there exists $\kappa = \kappa(\tau) > 0$, such that $M(t) \geq \tau$ for all $t \geq \tau$;
- (g_1) $g \in L^{6/(5-p)}(\mathbb{R}^3) \cap L^{3/2}(\mathbb{R}^3) \cap L^\infty(\mathbb{R}^3)$ and $g(x) \geq 0$ a.e. in $\mathbb{R}^3$.

It is worth stressing that the degenerate case of Kirchhoff nonlinearity is included in the assumption of $(M_1)'$.

Before stating our main results, let us introduce some notations. Firstly, thanks to the Fourier transform, the fractional Sobolev space $H^s(\mathbb{R}^3)$ is defined by

$$H^s(\mathbb{R}^3) = \left\{ u \in L^2(\mathbb{R}^3) : \int_{\mathbb{R}^3} (|\xi|^{2s} + 1)|\widehat{u}|^2 d\xi < \infty \right\},$$

which is equipped with the standard norm and inter product

$$\|u\|_{H^s} = \left(\int_{\mathbb{R}^3} (|\xi|^{2s} + 1)|\widehat{u}|^2 d\xi \right)^{1/2}, \qquad \langle u, v \rangle = \int_{\mathbb{R}^3} (|\xi|^{2s} + 1)\widehat{u}\widehat{v} d\xi.$$

In fact, Plancherel's theorem in [5] guarantees that $\|u\|_2 = \|\widehat{u}\|_2$ and $\||\xi|^s \widehat{u}\|_2 = \|(-\Delta)^{\frac{s}{2}} u\|_2$, and then

$$\|u\|_{H^s} = \left(\int_{\mathbb{R}^3} \left(|(-\Delta)^{\frac{s}{2}} u|^2 + |u|^2 \right) dx \right)^{1/2}, \qquad \langle u, v \rangle = \int_{\mathbb{R}^3} \left((-\Delta)^{\frac{s}{2}} u (-\Delta)^{\frac{s}{2}} v + uv \right) dx.$$

Furthermore, Proposition 3.4 and Proposition 3.6 in [5] imply that

$$\|(-\Delta)^{\frac{s}{2}}u\|_2^2 = \int_{\mathbb{R}^3} |\xi|^{2s}|\widehat{u}(\xi)|^2 d\xi = \frac{1}{C(s)}\iint_{\mathbb{R}^3\times\mathbb{R}^3} \frac{|u(x)-u(y)|^2}{|x-y|^{3+2s}}dxdy.$$

By virtue of [5, Theorem 6.5], the embedding $H^s(\mathbb{R}^3) \hookrightarrow L^p(\mathbb{R}^3)$, with $p \in [2, 2_s^*]$, is continuous, where 2_s^* is the fractional critical Sobolev exponent, defined as $2_s^* = 6/(3-2s)$. Moreover, let $D^s(\mathbb{R}^3) = \{u \in L^{2_s^*}(\mathbb{R}^3) : \int_{\mathbb{R}^3} |(-\Delta)^{\frac{s}{2}}u|^2 dx < \infty\}$ be the completion of $C_0^\infty(\mathbb{R}^3)$ with respect to the norm $[u]_s$. The continuous fractional Sobolev embedding $D^s(\mathbb{R}^3) \hookrightarrow L^{2_s^*}(\mathbb{R}^3)$ yields that there exists a best Sobolev constant

$$S_* = \inf_{u\in D^s(\mathbb{R}(^3)\setminus\{0\}} \frac{\int_{\mathbb{R}(^3} |(-\Delta)^{\frac{s}{2}}u|^2 dx}{(\int_{\mathbb{R}^3} |u|^{2_s^*} dx)^{2/2^*}},$$

so that

$$\|u\|_{2_s^*} \le c[u]_s, \tag{1.1}$$

where $c = S_*^{-1/2}$. In this paper, the main solutions spaces E is the subspace of $H^s(\mathbb{R}^3)$, considered as

$$E = \left\{ u \in H^s(\mathbb{R}^3) : \|u\| = \left(\int_{\mathbb{R}^3} \left(|(-\Delta)^{\frac{s}{2}}u|^2 + V(x)|u|^2\right)dx\right)^{1/2} < \infty \right\}.$$

Obviously, E is a uniformly convex Banach space, see for instance [16].

Now, we state the main results of this paper in the following theorems.

Theorem 1.1. *Suppose that $s, p \in (0,1)$ and the hypotheses (V_1)–(V_2), $(M_1)'$ and (g_1) hold, equation $(\mathcal{P})$ has the unique bifurcation point $(0,0)$, and there exists an unbounded component $\mathcal{C}$ of positive weak solutions emanating from $(0,0)$.*

Notation:

- $\to$ and $\rightharpoonup$ denote the strong convergence and the weak convergence, respectively.
- $L^p(\mathbb{R}^3)$, $1 \le p \le +\infty$, denotes a Lebesgue space, and the norm in $L^p(\mathbb{R}^3)$ is denoted by $\|\cdot\|_p$.
- C, C_i are various positive constants.

2 Preliminaries

In this section, as preparation for proving the main results, we intend to introduce some fundamental notations, definitions and properties which are essential to the fractional setting.

Let $s, t \in (0,1)$, with $2t + 4s > 3$. Then, it follows that the embedding $H^s(\mathbb{R}^3) \hookrightarrow L^{\frac{12}{3+2t}}(\mathbb{R}^3)$ is continuous, due to the fact that $\frac{12}{3+2t} \le \frac{6}{3-2s} = 2_s^*$. For any $u \in H^t(\mathbb{R}^3)$, we define the linear functional $I_u : D^t(\mathbb{R}^3) \to \mathbb{R}$ by

$$I_u(v) = \int_{\mathbb{R}^3} u^2 v dx, \quad \text{for any } v \in D^t(\mathbb{R}^3).$$

Obviously, from the continuous embedding $H^s(\mathbb{R}^3) \hookrightarrow L^{\frac{12}{3+2t}}(\mathbb{R}^3)$ in the above, there exists $C_1 > 0$, such that

$$|I_u(v)| \leq \left(\int_{\mathbb{R}^3} |u^2|^{\frac{6}{3+2t}} dx\right)^{\frac{3+2t}{6}} \left(\int_{\mathbb{R}^3} |v|^{\frac{6}{3-2t}} dx\right)^{\frac{3-2t}{6}} \leq cS_*^{-1/2}\|u\|_{H^t}^2[v]_t = c_0\|u\|_{H^t}^2[v]_t, \tag{2.1}$$

by (1.1) and the Hölder inequality, where $c_0 = cS_*^{-1/2}$. Hence, according to the Lax–Milgram theorem, for any $u \in H^t(\mathbb{R}^3)$, there exists a unique $\phi_u^t \in D^t(\mathbb{R}^3)$ satisfying

$$\int_{\mathbb{R}^3} u^2 v dx = \int_{\mathbb{R}^3} (-\Delta)^{\frac{t}{2}} \phi_u^t (-\Delta)^{\frac{t}{2}} v dx, \quad \text{for any } v \in D^t(\mathbb{R}^3), \tag{2.2}$$

which concludes ϕ_u^t is the (weak) solution of $(-\Delta)^t \phi_u^t = u^2$ in $\mathbb{R}^3$. Consequently, ϕ_u^t can be represented as

$$\phi_u^t = c_t \int_{\mathbb{R}^3} \frac{u^2(y)}{|x-y|^{3-2t}} dy = c_t \frac{1}{|x|^{3-2t}} * u^2, \qquad x \in \mathbb{R}^3,$$

where $c_t = \Gamma(3-2t)/(\pi^{3/2}2^{2t}\Gamma(t))$ is the t-Riesz potential. Together with (2.1), taking ϕ_u^t as a test function of (2.2), we deduce that

$$[\phi_u^t]_t^2 = \int_{\mathbb{R}^3} \phi_u^t u^2 dx \leq c_0\|u\|_{H^t}^2[\phi_u^t]_t, \qquad \int_{\mathbb{R}^3} \phi_u^t u^2 dx \leq c_0^2\|u\|_{H^t}^4. \tag{2.3}$$

Now, substituting ϕ_u^t in problem $(\mathcal{P})$, it follows that the fractional Kirchhoff–Schrödinger–Poisson equation

$$M([u]_s^2)(-\Delta)^s u + V(x)u + \phi_u^t u = \lambda g(x)|u|^{p-1}u + |u|^{2_s^*-2}u \quad \text{in } \mathbb{R}^3.$$

Definition 2.1. We call that $u \in H^s(\mathbb{R}^3)$ is a (weak) *solution* of problem $(\mathcal{P})$, if for any $v \in E$, there holds

$$\int_{\mathbb{R}^3} \left(M([u]_s^2)(-\Delta)^{\frac{s}{2}} u(-\Delta)^{\frac{s}{2}} v + V(x)uv + \phi_u^t uv\right) dx = \lambda \int_{\mathbb{R}^3} g(x)|u|^{p-1}uvdx + \int_{\mathbb{R}^3} |u|^{2_s^*-2}uvdx.$$

Furthermore, if there exist sequences $(\lambda_n)_n \subset \mathbb{R}$ and nontrivial (weak) solutions $(u_n)_n \subset E$ of problem $(\mathcal{P})$, such that $(\lambda_n, u_n)_n \to (\lambda, 0)$ as $n \to \infty$, then $(\lambda, 0)$ is a bifurcation point of problem $(\mathcal{P})$.

For more information on bifurcation, see, for instance [18]. Along this paper, let $(D^s(\mathbb{R}^3))^*$ be the dual space of $D^s(\mathbb{R}^3)$ and for each $u \in D^s(\mathbb{R}^3)$, let a functional $L: D^s(\mathbb{R}^3) \to (D^s(\mathbb{R}^3))^*$ be the weak formulation, defined by

$$\langle L(u), v\rangle = \int_{\mathbb{R}^3} (-\Delta)^{\frac{s}{2}} u (-\Delta)^{\frac{s}{2}} v dx, \quad \text{for any } v \in E.$$

Note that, by using the Hölder inequality,

$$|\langle L(u), v\rangle| \leq [u]_s[v]_s, \qquad \langle L(u), u\rangle = [u]_s^2. \tag{2.4}$$

A simple observation of (2.4) yields that L is a bounded linear operator in $D^s(\mathbb{R}^3)$. Moreover, write for brevity,

$$\langle u, v\rangle_V = \int_{\mathbb{R}^3} V(x)uvdx, \qquad \|u\|_V = \left(\int_{\mathbb{R}^3} V(x)|u|^2 dx\right)^{1/2}, \quad \text{for any } u, v \in E.$$

Of course, arguing as (2.4), it follows that

$$|\langle u, v\rangle_V| \leq \|u\|_V\|v\|_V, \qquad \langle u, u\rangle_V = \|u\|_V^2.$$

Now, we are in the position to state some useful lemmas.

Lemma 2.2 ([13, Proposition 1.3]). *If X is uniformly convex and* (2.4) *holds, then L is of type* (S), i.e. *every sequence $(u_j)_j \in X$ such that*

$$u_j \rightharpoonup u, \qquad \langle L(u_j), u_j - u\rangle \to 0$$

has a subsequence that converges strongly to u in X.

Lemma 2.3 ([21, Lemma 2.3]). *For any $u \in H^s(\mathbb{R}^3)$, the function ϕ_u^t defined in* (2.2) *satisfies the next properties.*

(i_1) *ϕ_u^t is continuous with respect to u.*

(i_2) *$\phi_u^t \geq 0$ in $\mathbb{R}^3$ and $\phi_{\xi u}^t = \xi^2 \phi_u$ for any $\xi > 0$.*

(i_3) *If $u_n \rightharpoonup u$ in E and $u_n \to u$ in $L^p(\mathbb{R}^3)$, with $p \in [2, 2_s^*)$, as $n \to \infty$, then for any $v \in E$*

$$\int_{\mathbb{R}^3} \phi_{u_n}^t(x) u_n(x) v(x) dx = \int_{\mathbb{R}^3} \phi_u^t(x) u(x) v(x) dx + o(1),$$

and

$$\int_{\mathbb{R}^3} \phi_{u_n}^t(x) u_n^2 dx \to \int_{\mathbb{R}^3} \phi_u^t(x) u(x)^2 dx, \quad \text{as } n \to \infty.$$

Lemma 2.4 ([15, Lemma 1.1]). *Assume that $s \in (0,1)$ and (V_1)–(V_2) hold. If $p \in [2, 2_s^*]$, then the embeddings*

$$E \hookrightarrow H^s(\mathbb{R}^3) \hookrightarrow L^p(\mathbb{R}^3)$$

are continuous, with $\min\{1, V_0\}[u]_s \leq \|u\|$, for all $u \in E$. Particularly, there exists a positive constant C_q, such that

$$\|u\|_q \leq C_q \|u\| \quad \text{for all } u \in E.$$

If $q \in [2, 2_s^*)$, the embedding $E \hookrightarrow L^q(\mathbb{R}^3)$ is compact. Furthermore, if $q \in [1, 2_s^*)$, then the embedding $E \hookrightarrow L^q(B_R)$ is compact for any $R > 0$.

Furthermore, to prove the main results, we need the following embedding theorem due to Lemma 2.1 in [4].

Lemma 2.5. *Let $s \in (0,1)$ and $w \in L^{3/2}(\mathbb{R}^3) \cap L^\infty(\mathbb{R}^3)$. Then the embedding*

$$D^s(\mathbb{R}^3) \hookrightarrow L^2(\mathbb{R}^3, w dx)$$

is continuous and compact, and $\|u\|_{2,w} \leq C_w [u]_s$, for all $u \in D^s(\mathbb{R}^3)$, with $C_w = S_*^{-1/2} \|w\|_{3/2}^{1/2} > 0$.

3 The subcritical case

In this section, we shall demonstrate the bifurcation results of the fundamental problem

$$M([u]_s^2)(-\Delta)^s u + V(x) u + \phi_u^t u = \lambda g(x) |u|^{p-1} u \quad \text{in } \mathbb{R}^3, \tag{3.1}$$

which is of significance in substantiating the proof of the main result. To this aim, let us consider the property of the first eigenvalue $\lambda_1(h)$ of the problem

$$(-\Delta)^s u + V(x) u = \lambda h(x) u, \tag{3.2}$$

where $h \in L^{3/2}(\mathbb{R}^3) \cap L^\infty(\mathbb{R}^3)$ is a strictly positive function.

Lemma 3.1. *The eigenvalue problem* (3.2) has the first eigenpair $(\lambda_1(h), u_1)$, where

$$0 < \lambda_1(h) = \min_{v \in E \setminus \{0\}} \frac{\|v\|^2}{\|v\|_{2,h}^2} = \min_{v \in E \setminus \{0\}} \frac{\int_{\mathbb{R}^3}(|(-\Delta)^{\frac{s}{2}} v|^2 + V(x)|v|^2)dx}{\int_{\mathbb{R}^3} h(x)|v|^2 dx},$$

and the first eigenfunction u_1 has one sign. Furthermore, λ_1 is decreasing map with respect to h, i.e. if $0 < h_1 \le h_2 \in L^{3/2}(\mathbb{R}^3) \cap L^\infty(\mathbb{R}^3)$, then $\lambda_1(h_1) \ge \lambda_1(h_2)$.

Proof. Let $(v_k)_k \subset E \setminus \{0\}$ be a minimizing sequence of $\lambda_1(h)$ in Calculus of Variations. It can be normalized so that $\int_{\mathbb{R}^3} h(x)|v_k|^2 dx = 1$, and

$$\lambda_1(h) = \lim_{k \to \infty} \left(\int_{\mathbb{R}^3} |(-\Delta)^{\frac{s}{2}} v_k|^2 dx + \int_{\mathbb{R}^3} V(x)|v_k|^2 dx \right). \tag{3.3}$$

Moreover, the fact that $[|v|]_s \le [v]_s$ for any $v \in E$ guarantees that $(|v_k|)_k$ is also a minimizing sequence, then we can further assume that v_k is positive. Since $\|v_k\|^2$ is a real convergent sequence in (3.3), we have

$$0 \le \|v_k\|^2 \le \lambda_1 + 1.$$

Consequently, the sequence $(v_k)_k$ is bounded in E. The reflexivity of E yields the existence of $0 \le \widehat{v} \in E$ such that $v_k \rightharpoonup \widehat{v}$ in E and $v_k \to \widehat{v}$ a.e. in $\mathbb{R}^3$, up a subsequence if necessary. Thanks to Lemma 2.5, we obtain that

$$\int_{\mathbb{R}^3} h|v_k|^2 dx \to \int_{\mathbb{R}^3} h|\widehat{v}|^2 dx \quad \text{as } k \to \infty. \tag{3.4}$$

Moreover, by the weak lower semi-continuity of the norm $\|\cdot\|$ and by (3.4), it follows that

$$0 \le \|\widehat{v}\| \le \liminf_{k \to \infty} \|v_k\|.$$

Thus, $\lambda_1 = \|\widehat{v}\|^2$ and $\widehat{v}$ is a critical point of $\psi(v) = \|v\|^2 / \|v\|_{2,h}^2$, i.e. for any $v \in E$

$$\int_{\mathbb{R}^3} \left((-\Delta)^{\frac{s}{2}} \widehat{v}\, (-\Delta)^{\frac{s}{2}} v + V(x)\widehat{v}v\right)dx \int_{\mathbb{R}^3} h(x)|\widehat{v}|^2 dx - \int_{\mathbb{R}^3} \left(|(-\Delta)^{\frac{s}{2}} \widehat{v}|^2 + V(x)|\widehat{v}|^2\right)dx \int_{\mathbb{R}^3} h(x)\widehat{v}v dx = 0.$$

In conclusion, $\widehat{v}$ is the first eigenfunction corresponding to λ_1, provided that $\widehat{u} \not\equiv 0$.
Clearly, the definition of λ_1 implies at once that $\lambda_1(h_1) \ge \lambda_1(h_2)$. □

Proposition 3.2. *Let* $P = \{v \in E^* : v \ge 0\}$ *and let* $f(x) \in P$. *If* $(M_1)'$ *and* (V_1)–(V_2) *holds, then equation*

$$M([u]_s^2)(-\Delta)^s u + V(x)u = f(x) \quad \text{in } \mathbb{R}^3 \tag{3.5}$$

has a unique weak solution u in E. Furthermore, the operator $K : E^* \to E$, *defined by* $K(f) = u$, *where u is the unique weak solution of* (3.5), *is continuous.*

Proof. Of course, if $f \equiv 0$, then $u = 0$ is a unique (weak) solution of equation (3.5). Next, put $f \not\equiv 0$ and set $R = [u]_s^2 \ge 0$. Then, the problem (3.5) becomes

$$M(R)(-\Delta)^s u + V(x)u = f(x) \quad \text{in } \mathbb{R}^3. \tag{3.6}$$

Problem (3.6) has a variational structure and $J : E \to \mathbb{R}$, denoted as

$$J(u) = \frac{1}{2} M(R)[u]_s^2 + \int_{\mathbb{R}^3} V(x)|u|^2 dx - \langle f, u \rangle, \quad \text{for all } u \in E,$$

where $\langle \cdot, \rangle$ is the duality of E, is well defined and of class $C^1(E)$. It is easily deduced that the critical point of $J(u)$, defined by u_R, is a (weak) solution of (3.1). We first claim that J is coercive, bounded below, and sequentially weakly lower semi-continuous in E. Indeed, by Lemma 2.4 and $(M_1)'$, the Hölder inequality implies that

$$\begin{aligned} J(u) &\geq \frac{1}{2}M(R)[u]_s^2 + \frac{1}{2}\int_{\mathbb{R}^3} V(x)u^2dx - \|f\|_{E^*}\|u\| \\ &\geq \frac{1}{2}\min\{\kappa, V_0\}\|u\|^2 - C_f\|u\|. \end{aligned}$$

Consequently, $J(u) \to \infty$ as $\|u\| \to \infty$ and so J is coercive in E. Now, for any minimizing sequence $(u_n)_n$ in E, with $J(u_n) \to \inf_{u\in E} J(u)$ as $n \to \infty$, the coerciveness of J guarantees that there exists $K > 0$, such that $\|u_n\| \leq K$. Thus, for all n, it follows from the Hölder inequality that

$$|J(u_n)| \leq \max\left\{1, \frac{1}{2}M(R)\right\} \|u_n\|^2 + C_f\|u_n\| \leq \max\left\{1, \frac{1}{2}M(R)\right\} K^2 + C_fK,$$

which infers that

$$\inf_{u\in E} J(u_n) \geq -\max\left\{1, \frac{1}{2}M(R)\right\} K^2 - C_fK.$$

Hence, J is bounded below. Moreover, if $v_n \rightharpoonup v$ in E, in view of the weakly lower semi-continuity of $\|\cdot\|$,

$$J(v) \leq \liminf_{n\to\infty} \left(\frac{1}{2}M(R)[v_n]_s^2 + \int_{\mathbb{R}^3} V(x)|v_n|^2dx - \langle f, v_n\rangle\right),$$

We thus deduce that J is weakly lower semi-continuous. Consequently, it guarantees the existence of the unique global minimum u_R for the functional J in E, and moreover, u_R is obviously a (weak) solution of equation (3.6).

Next, let us turn to imply that u_R is also a (weak) solution of problem (3.5). Let $R_j \to R$ in $\mathbb{R}_+$ and let $(u_{R_j})_j$ be (weak) solutions of (3.5) with R replaced by R_j. Once again, by $(M_1)'$, the Hölder inequality and Lemma 2.4, we have

$$\min\{\kappa, V_0\}\|u_{R_j}\|^2 \leq M(R_j)[u_{R_j}]_s^2 + \|u_{R_j}\|_V^2 = \langle f, u_{R_j}\rangle \leq C_f\|u_{R_j}\|. \tag{3.7}$$

Thus, $\{u_{R_j}\}$ is bounded in E. The reflexivity of E, Lemmas 2.4 and 2.5 yield that, there exists $u \in E$, such that up to sequences, as $j \to \infty$,

$$(a)\ u_{R_j} \rightharpoonup u \text{ in } E; \quad (b)\ u_{R_j} \to u \text{ in } L^2(\mathbb{R}^3, wdx); \quad (c)\ u_{R_j} \to u \text{ in } L^q(\mathbb{R}^3) \text{ with } q \in [2, 2_s^*). \tag{3.8}$$

Recalling that $R_j \to R$ and $M \in C(\mathbb{R}^3)$ in the hypothesis $(M_1)'$, one has

$$\begin{aligned} &M(R)\int_{\mathbb{R}^3} (-\Delta)^{\frac{s}{2}}u(-\Delta)^{\frac{s}{2}}vdx + \int_{\mathbb{R}^3} V(x)uvdx \\ &= \lim_{j\to\infty}\int_{\mathbb{R}^3} \left(M(R_j)(-\Delta)^{\frac{s}{2}}u_{R_j}(-\Delta)^{\frac{s}{2}}v + V(x)u_{R_j}v\right)dx \\ &= \langle f, v\rangle \quad \text{for any } v \in E, \end{aligned}$$

and so u is also a weak solution of (3.6). Moreover, taking the test function $v = u_R - u$ in the weak form of (3.6) and applying the Hölder inequality, we deduce that

$$\begin{aligned} 0 &= M(R)\langle L(u) - L(u_R), u - u_R\rangle + \langle u - u_R, u - u_R\rangle_V \\ &= M(R)\big([u]_s^2 - \langle L(u), u_R\rangle - \langle L(u_R), u\rangle + [u_R]_s^2\big) + \|u\|_V^2 - \langle u, u_R\rangle - \langle u_R, u\rangle + \|u_R\|_V^2 \\ &\geq M(R)\big([u]_s^2 - 2[u]_s[u_R]_s + [u_R]_s^2\big) + \|u\|_V^2 - 2\|u\|_V\|u_R\|_V + \|u_R\|_V^2 \\ &= M(R)([u]_s - [u_R]_s)^2 + (\|u\|_V - \|u_R\|_V)^2 \geq 0. \end{aligned} \tag{3.9}$$

We thus have $[u]_s^2 = [u_R]_s^2$ and $\|u\|_V = \|u_R\|_V$. Consequently,

$$\langle f, u - u_R\rangle = M(R)\langle L(u) - L(u_R), u - u_R\rangle + \langle u - u_R, u - u_R\rangle_V = 0,$$

and so $u = u_R$ a.e. in $\mathbb{R}^3$ due to the assumption that $f \not\equiv 0$. Hence,

$$u = u_R \quad \text{in } E, \tag{3.10}$$

and $u_{R_j} \rightharpoonup u_R$ in E due to (3.8)-(a). Now, we claim that

$$u_{R_j} \to u_R \quad \text{in } E. \tag{3.11}$$

From (3.8),

$$M(R_j)\left\langle L(u_{R_j}), u_{R_j} - u_R\right\rangle = \langle f, u_{R_j} - u_R\rangle - \int_{\mathbb{R}^3} V(x)u_{R_j}(u_{R_j} - u_R)dx \to 0, \quad \text{as } j \to \infty.$$

Combining with (2.4) and the fact that $D^s(\mathbb{R}^3)$ is a uniformly space, $u_{R_j} \to u_R$ in $D^s(\mathbb{R}^3)$ by applying Lemma 2.2, and moreover $u_{R_j} \to u_R$ in E by using (3.8)–(b). Therefore, the claim holds and the (weak) solution u_R of (3.6) is continuous with respect to R.

Define $h : \mathbb{R} \to \mathbb{R}$ by

$$h(R) = \frac{1}{M(R)}\langle f, u_R\rangle - \|u_R\|_V^2.$$

Note that, according to the continuity of mappings $R \mapsto \frac{1}{M(R)}$ by (M_1) and $R \mapsto u_R$, $h(R)$ is also a continuous mapping. Observe that $h(0) > 0$. In fact, we first claim that u_0, with $R = 0$, is not a constant. Otherwise, $\|u_0\|_V \leq C_d[u_0]_s = 0$ for some $C_d > 0$, due to Lemma 2.4, which implies in particular that $u_0 = 0$ a.e. in $\mathbb{R}^3$. Moreover, since u_0 is the (weak) solution of the problem

$$M(0)(-\Delta)^s u_0 + V(x)u_0 = f$$

and $f \not\equiv 0$, there is a contradiction with $u_0 = 0$ a.e. in $\mathbb{R}^3$. For such u_0,

$$h(0) = \frac{1}{M(0)}\langle f, u_0\rangle - \|u_0\|_V^2 = [u_0]_s^2 > 0.$$

Similarly, by using the same argument of (3.7) that u_R is bounded in E, there exists a positive constant C, such that

$$|h(R)| = \left|\frac{1}{M(R)}\langle f, u_R\rangle - \|u_R\|_V^2\right| \leq \frac{1}{\kappa}C_f\|u_R\| + \|u_R\|_V^2 \leq C_{f,\kappa}\|u_R\| + \|u_R\|^2 \leq C.$$

Now, denote $h_1(R) : \mathbb{R} \to \mathbb{R}$ as $h_1 = h(R) - R$. Combining all facts in the above, there exists $R_1 > C_f$, such that

$$h_1(0) = h(0) > 0 \quad \text{and} \quad h_1(R_1) = h(R_1) - R_1 < 0.$$

The intermediate value theorem yields at once the existence of zero-point for h_1. In other words, there exists $R > 0$, such that

$$R = h(R) = \frac{1}{M(R)}\langle f, u_R\rangle - \|u_R\|_V^2 = [u_R]_s^2.$$

Consequently, u_R is a weak solution of (3.1).

Consider the uniqueness of the (weak) solution of (3.1). Assume at first that there are distinct (weak) solutions $u_1, u_2 \in E$ of (3.1). Let $v = u_1 - u_2$ be the test function for the weak form of (3.1), which follows that

$$(a + b[u_1]_s^2)\,\langle L(u_1), u_1 - u_2\rangle + \langle u_1, u_1 - u_2\rangle_V = \int_{\mathbb{R}^3} f(u_1 - u_2)dx$$

and

$$(a + b[u_2]_s^2)\,\langle L(u_2), u_1 - u_2\rangle + \langle u_2, u_1 - u_2\rangle_V = \int_{\mathbb{R}^3} f(u_1 - u_2)dx$$

being u_1 and u_2 are the (weak) solutions of (3.1), where a, b are the constant given in the definition of Kirchhoff function M. As a consequence,

$$a\,\langle L(u_1) - L(u_2), u_1 - u_2\rangle + bJ_1(u_1, u_2) + \langle u_1 - u_2, u_1 - u_2\rangle_V = 0, \tag{3.12}$$

where

$$J_1(u_1, u_2) = [u_1]_s^2([u_1]_s^2 - \langle L(u_1), u_2\rangle) + [u_2]_s^2([u_2]_s^2 - \langle L(u_2), u_1\rangle).$$

By virtue of the Hölder inequality,

$$\begin{aligned} J_1(u_1, u_2) &\ge [u_1]_s^2([u_1]_s^2 - [u_1]_s[u_2]_s) + [u_2]_s^2([u_2]_s^2 - [u_2]_s[u_1]_s) \\ &\ge ([u_1]_s - [u_2]_s)([u_1]_s^3 - [u_2]_s^3) \ge 0. \end{aligned}$$

Then, clearly, by using the same argument of (3.9), from (3.12), $[u_1]_s = [u_2]_s$ and $\|u_1\|_V = \|u_2\|_V$. Similar to (3.10), it can be concluded that $u_1 = u_2$ in E.

Finally, it remains to prove that the operator K is continuous. Let $(f_j)_j \subset E^*$, $f \in E^*$ satisfy $f_j \to f$ strongly in E^* and $u_j, u \in E$ be the (weak) solutions of (3.1) corresponding to f_j and f, respectively. We only need to prove that $u_j \to u$ in E. Arguing as in the proof of (3.7) and (3.11), we conclude that $u_j \rightharpoonup u$ in E and $u_j \to u$ a.e. in $L^q(\mathbb{R}^3)$, with $q \in [2, 2_s^*)$, up to a sequence if necessary. Consequently,

$$\begin{aligned} M(u_j)\,\langle L(u_j), u_j - u\rangle &= \langle f_j, u_j - u\rangle - \langle u_j, u_j - u\rangle_V \\ &= \langle f_j - f, u_j\rangle + \langle f, u_j - u\rangle - \langle u_j, u_j - u\rangle_V \\ &\to 0, \quad \text{as } j \to \infty, \end{aligned}$$

which yields that $u_j \to u$ in E by Lemma 2.2. This completes the proof. □

We next prove the bifurcation results of (3.1). For any fixed λ, first denote the operator $N_\lambda :\ E \to E^*$ pointwise for all $u, v \in E$ as

$$\langle N_\lambda(u), v\rangle = \int_{\mathbb{R}^3} [\lambda g(x)|u|^{p-1}u - \phi_u^t u]v dx,$$

where $\langle \cdot, \rangle$ is the duality of E. We assert that $N_\lambda(u)$ is a compact operator. Suppose that $(u_j)_j$ is a bounded sequence in E. Lemma 2.4 yields that there exist a subsequence of $(u_j)_j$ (still defined by $(u_j)_j$) and $u \in E$, such that for any $R > 0$, as $j \to \infty$,

$$(a_1)\ u_j \rightharpoonup u \quad \text{in } E \qquad (a_2)\ u_j \to u \quad \text{in } L^q(\mathbb{R}^3),\ \text{with } q \in [2, 2_s^*) \qquad (a_3)\ u_j \to u \quad \text{a.e. in } \mathbb{R}^3. \tag{3.13}$$

By virtue of Lemma 2.3–(i_3), obviously it follows that

$$\sup_{\|v\| \le 1} \int_{\mathbb{R}^3} (\phi_{u_j}^t u_j - \phi_u^t u) v dx \to 0, \quad \text{as } j \to \infty.$$

Further, for all $R > 0$,

$$\begin{aligned} &\sup_{\|v\| \le 1} \left| \int_{\mathbb{R}^3} g(x)(|u_j|^{p-1}u_j - |u|^{p-1}u) dx \right| \qquad (3.14) \\ &\quad \le \sup_{\|v\| \le 1} \left| \int_{B_R} g(x)(|u_j|^{p-1}u_j - |u|^{p-1}u) dx \right| + \sup_{\|v\| \le 1} \left| \int_{\mathbb{R}^3 \setminus B_R} g(x)(|u_j|^{p-1}u_j - |u|^{p-1}u) dx \right|. \end{aligned}$$

Since $g \in L^{6/(5-p)}(\mathbb{R}^3)$, for any $\varepsilon > 0$, there is a constant $R > 0$ so large that

$$\begin{aligned} &\sup_{\|v\| \le 1} \int_{\mathbb{R}^3 \setminus B_R} g(x)(|u_j|^{p-1}u_j - |u|^{p-1}u) v dx \\ &\quad \le \sup_{\|v\| \le 1} \left(\int_{\mathbb{R}^3 \setminus B_R} |g(x)|^{\frac{6}{5-p}} dx \right)^{\frac{5-p}{6}} \left(\int_{\mathbb{R}^3 \setminus B_R} (|u_j|^p + |u|^p)^{\frac{6}{p}} dx \right)^{\frac{p}{6}} \|v\|_6 \\ &\quad \le \sup_{\|v\| \le 1} \|g\|_{L^{\frac{6}{5-p}}(\mathbb{R}^3 \setminus B_R)} 2^{\frac{6}{p}-1} (\|u_j\|_6^p + \|u\|_6^p) \|v\|_6 \\ &\quad \le 2^{\frac{6}{p}-1} c^{p+1} \|g\|_{L^{\frac{6}{5-p}}(\mathbb{R}^3 \setminus B_R)} (\|u_j\|^p + \|u\|^p) \sup_{\|v\| \le 1} \|v\| \\ &\quad \le \varepsilon/2. \end{aligned}$$

On the other hand, note that for all $R > 0$, the embedding $E \hookrightarrow L^q(B_R)$, with $q \in [1, 2_s^*)$, is compact by using Lemma 2.4. Hence, take a subsequence $(u_{j_k})_k \subset (u_j)_j$, such that $u_{j_k} \to u$ in $L^q(B_{R_\varepsilon})$ for all $q \in [1, 2_s^*)$, then up to a further subsequence, still denoted by $(u_{j_k})_k$, we have that $u_{j_k} \to u$ a.e. in B_{R_ε}. Thus, $g(x)|u_{j_k}|^{p+1} \to g(x)|u|^{p+1}$ a.e. in B_{R_ε}. Furthermore, for each measurable subset $B_E \subset B_{R_\varepsilon}$, with the help of (1.1), Lemma 2.4 and the Hölder inequality, we have

$$\int_{B_E} g(x)|u_{j_k}|^{p+1} dx \le \|g\|_{L^{\frac{6}{5-p}}(B_E)} \|u_{j_k}\|_6^{p+1} \le (cC)^{p+1} \|g\|_{L^{\frac{6}{5-p}}(B_E)},$$

being $(u_j)_j$ is bounded in E. Therefore, $(g(x)|u_{j_k}|^{p+1})_k$ is integrable and uniformly bounded in $L^1(B_{R_\varepsilon})$, since $g \in L^{6/(5-p)}(\mathbb{R}^3)$ by the assumption. The Vitali convergence theorem shows that

$$\lim_{k \to \infty} \int_{B_{R_\varepsilon}} g(x)|u_{j_k}|^{p+1} dx = \int_{B_{R_\varepsilon}} g(x)|u|^{p+1} dx, \tag{3.15}$$

and so $g(x)|u_j|^{p+1} \to g(x)|u|^{p+1}$ in $L^1(B_{R_\varepsilon})$, since the sequence $(u_{j_k})_k$ is arbitrary. Therefore,

$$\sup_{\|v\| \le 1} \left| \int_{B_R} g(x)(|u_j|^{p-1}u_j - |u|^{p-1}u) v dx \right| \to 0, \quad \text{as } j \to \infty,$$

and further (3.14) hold. Together with Proposition 3.2, we deduce that the operator $K \circ N_\lambda : E \to E$ is compact. For the fixed λ, let $K_\lambda : E \to E$, defined by

$$K_\lambda = \mathbb{I} - K \circ N_\lambda,$$

where $\mathbb{I}$ is the identity operator. Note that the zeros of K_λ are exactly the (weak) solutions of the problem (3.1).

Having completed all necessary preparations, now, we are ready to show Theorem 3.3.

Theorem 3.3. *Let $s,\ p \in (0,1)$. If (V_1)–(V_2), $(M_1)'$ and (g_1) hold, equation (3.1) has the unique bifurcation point $(0,0)$, and there exists an unbounded component $\mathcal{C}_0$ of (weak) solutions emanating from $(0,0)$.*

Proof. We first let $\lambda < 0$. For a fixed λ, consider the operator $H_1(r,\cdot) : E \to E$ as follows

$$H_1(r,u) = N_\lambda(r(\lambda g(x)|u|^{p-1}u - \phi_u^t u)), \qquad r \in [0,1].$$

We claim that there exists $\delta_1 > 0$, such that

$$u = H_1(r,u), \quad \text{for any } u \in B_{\delta_1}, u \not\equiv 0 \text{ and } r \in [0,1]. \tag{3.16}$$

Conversely, if there exists sequences $(u_n)_n$ and $(r_n)_n$, with $\|u_n\| \to 0$, $u_n \not\equiv 0$ and $r_n \in [0,1]$, such that $u_n = H_1(r_n,u_n)$. In other words, it follows that

$$\int_{\mathbb{R}^3} (M([u_n]_s^2)|(-\Delta)^{\frac{s}{2}} u_n|^2 + V(x)u_n^2 + r_n \phi_{u_n}^t u_n^2)dx = r_n \int_{\mathbb{R}^3} \lambda g(x)|u_n|^{p+1}dx \le 0 \tag{3.17}$$

by the definition of λ. Thanks to (M_1) and (V_1), we get $M([u_n]_s^2)[u_n]_s^2 + \|u_n\|_V^2 \ge 0$, and so $\|u_n\| = ([u_n]_s^2 + \|u_n\|_V^2)^{1/2} = 0$ by Lemma 2.3–(i_2). Of course, this is a contradiction with the assumption that $u_n \not\equiv 0$ in E and the claim is achieved. Therefore, we can choose $\varepsilon \in (0,\delta_1)$, such that

$$\deg(K_\lambda, B_\varepsilon, 0) = \deg(I - H_1(1,\cdot), B_\varepsilon, 0) = \deg(I - H_1(0,\cdot), B_\varepsilon, 0) = \deg(I, B_\varepsilon, 0) = 1 \tag{3.18}$$

by applying the homotopy invariance of H_1.

On the other hand, let $\lambda > 0$ and let $\psi \in E$, with $\psi > 0$. For this fixed λ and for any $r \in [0,1]$, denote $H_2(r,\cdot) : E \to E$ as

$$H_2(r,u) = N_\lambda(\lambda g(x)|u|^{p-1}u - \phi_u^t u + r\psi).$$

We claim that there exists $\delta_2 > 0$, such that $u \neq H_2(r,u)$ for any $u \in B_{\delta_2} \setminus \{0\}$ and for any $r \in [0,1]$. Let us argue by contradiction that if there exists a sequence $(v_j)_j \subset E$, with $v_j > 0$ and $\|v_j\| \to 0$, as $j \to \infty$, such that for any $r_j \in [0,1]$,

$$v_j = H_2(r_j, v_j), \tag{3.19}$$

which yields at once that

$$M([v_j]_s^2)(-\Delta)^s v_j + V(x)v_j + \phi_{v_j}^t v_j = \lambda g(x)|v_j|^{p-1}v_j + r_j\psi(x). \tag{3.20}$$

Moreover, there exists a positive constant C_0, such that $\|v_j\| \le C_0$ and $[v_j]_s \le \|v_j\| \le C_0$, being $\|v_j\| \to 0$ as $j \to \infty$. Furthermore, up to sequence,

$$v_j \to 0 \quad \text{a.e. in } \mathbb{R}^3 \tag{3.21}$$

by Lemma 2.4. Consequently, $M([v_j]_s^2) \le \max\{1, a + bC_0\} := C_0'$, and then

$$\lambda_1(g(x)(\max\{1, M([v_j]_s^2)\})^{-1}) \le \lambda_1((C_0')^{-1}g(x)).$$

For any $\varepsilon > 0$, taking the test function as a first eigenfunction $w_1 > 0$, by virtue of (1.1) and the Hölder inequality, since $g \in L^{6/(5-p)}(\mathbb{R}^3)$ by the assumption (g_1) and v_j is bounded in E, there exists $R_\varepsilon > 0$ so large that for all j

$$\begin{aligned}\int_{\mathbb{R}^3 \setminus B_{R_\varepsilon}} g(x)|v_j|^p w_1 dx &\le \|g\|_{L^{\frac{6}{5-p}}(\mathbb{R}^3 \setminus B_{R_\varepsilon})} \|v_j\|_6^p \|w_1\|_6 \\ &\le c^{p+1}\|g\|_{L^{\frac{6}{5-p}}(\mathbb{R}^3 \setminus B_{R_\varepsilon})} \|v_j\|^p \|w_1\| \le \varepsilon/2.\end{aligned} \tag{3.22}$$

Thus, arguing as the proof of (3.15),

$$\int_{B_{R_\varepsilon}} g(x)|v_j|^p w_1 dx = o(1) \quad \text{as } j \to \infty.$$

Similarly, according to the assumption (g_2), it is easily to see that $g(x)|v_j|w_1 \to 0$ in $L^1(B_{R_\varepsilon})$ as $j \to \infty$ and

$$\int_{\mathbb{R}^3 \setminus B_{R_\varepsilon}} g(x)v_j w_1 dx \le \|g\|_{L^{\frac{3}{2}}(\mathbb{R}^3 \setminus B_{R_\varepsilon})} \|v_j\|_6 \|w_1\|_6 \le c^2 \|g\|_{L^{\frac{3}{2}}(\mathbb{R}^3 \setminus B_{R_\varepsilon})} \|v_j\| \|w_1\| \le \varepsilon, \tag{3.23}$$

being $g \in L^{3/2}(\mathbb{R}^3)$ by the assumption. In conclusion, from (3.21), (3.22) and (3.23), there is R_ε so large that as $j \to \infty$

$$\begin{aligned}&\lambda \int_{\mathbb{R}^3} g(x)|v_j|^p w_1 dx - \lambda_1((C_0')^{-1}g(x)) \int_{\mathbb{R}^3} g(x)v_j w_1 dx - \int_{\mathbb{R}^3} \phi_{v_j} v_j w_1 dx \\ &= \lambda \int_{B_{R_\varepsilon}} g(x)|v_j|^p w_1 dx + \lambda \int_{\mathbb{R}^3 \setminus B_{R_\varepsilon}} g(x)|v_j|^p w_1 dx - \lambda_1((C_0')^{-1}g(x)) \int_{B_{R_\varepsilon}} g(x)v_j w_1 dx \\ &\quad - \lambda_1((C_0')^{-1}g(x)) \int_{\mathbb{R}^3 \setminus B_{R_\varepsilon}} g(x)|v_j| w_1 dx - C\|v_j\|^3 \|w_1\| \\ &\ge \lambda \int_{B_{R_\varepsilon}} g(x)|v_j|^p w_1 dx - \lambda_1((C_0')^{-1}g(x)) \int_{B_{R_\varepsilon}} g(x)|v_j| w_1 dx - C\varepsilon > 0.\end{aligned} \tag{3.24}$$

Since $\psi > 0$, (3.20) and (3.24) yield that as $n \to \infty$, we estimate

$$\begin{aligned}&\lambda_1(g(x)(\max\{1, M([v_j]_s^2)\})^{-1}) \int_{\mathbb{R}^3} g(x)v_j w_1 dx \\ &= \max\{M([v_j]_s^2), 1\} \left(\int_{\mathbb{R}^3} (-\Delta)^{\frac{s}{2}} v_j (-\Delta)^{\frac{s}{2}} w_1 dx + \int_{\mathbb{R}^3} V(x)v_j w_1 dx \right) \\ &\ge M([v_j]_s^2) \int_{\mathbb{R}^3} (-\Delta)^{\frac{s}{2}} v_j (-\Delta)^{\frac{s}{2}} w_1 dx + \int_{\mathbb{R}^3} V(x)v_j w_1 dx \\ &= \lambda \int_{\mathbb{R}^3} \left(g(x)|v_j|^{p-1} v_j w_1 + r_j \psi(x) w_1 - \phi_{v_j}^t v_j w_1 \right) dx \\ &> \lambda_1((C_0')^{-1}g(x)) \int_{\mathbb{R}^3} g(x)v_j w_1 dx,\end{aligned}$$

and so

$$\{\lambda_1(g(x)\max\{1, M([v_j]_s^2)\}^{-1}) - \lambda_1((C_0')^{-1}g(x))\} \int_{\mathbb{R}^3} g(x)v_j w_1 dx > 0.$$

Since $\int_{\mathbb{R}^3} g(x)v_j w_1 dx > 0$, we have $\lambda_1(g(x)\max\{1, M([v_j]_s^2)\}^{-1}) > \lambda_1((C_0')^{-1}g(x))$. This is an obvious absurdum, and we proved the claim.

Hence, choosing $\varepsilon \in (0, \delta_2)$, we can find the homotopy invariance of H_2, i.e.

$$\deg(K_\lambda, B_\varepsilon, 0) = \deg(I - H_2(0,\cdot), B_\varepsilon, 0) = \deg(I - H_2(1,\cdot), B_\varepsilon, 0) = 0. \tag{3.25}$$

It follows from (3.18) and (3.25) that $(0,0)$ is a bifurcation point of ($\mathcal{P}$).

Now, it is sufficient to prove the existence of the unbounded component of (weak) solutions of (3.1). It is important to note that while the classical global bifurcation theorem [17, Theorem 1.3] is relevant to our argument, we cannot apply it directly because the operator K_λ lacks the differentiability at $u = 0$ and of odd-multiplicity eigenvalue. However, by modifying the global bifurcation theorem in Proposition 3.5 of [1] and replacing these conditions with the topological degree proofs for (3.18) and (3.25), we can derive an efficient version of [17, Theorem 1.3] for the assertion below.

For $\lambda_0 \neq 0$, we claim that $(\lambda_0, 0)$ is an isolated (weak) solution of (3.1). Set $\lambda < 0$. Similar to the analysis of (3.17), there are no nontrivial (weak) solutions of equation (3.1). Let $\lambda > 0$. Assume that there exists a sequence of (weak) solutions $(\lambda_n, u_n)_n \subset \mathbb{R} \times E$ of (3.1), such that $\lambda_n \to \lambda_0$ and $\|u_n\| \to 0$, as $n \to \infty$. Hence, arguing as (3.24), for any $\varepsilon > 0$, there exists $N = N(\varepsilon) > 0$, such that for any $n \geq N(\varepsilon)$,

$$\begin{aligned}
&\lambda_1(g(x)(\max\{1, M([v_j]_s^2)\})^{-1}) \int_{\mathbb{R}^3} g(x) v_j w_1 dx \\
&\quad \geq M([v_j]_s^2) \int_{\mathbb{R}^3} (-\Delta)^{\frac{s}{2}} v_j (-\Delta)^{\frac{s}{2}} w_1 dx + \int_{\mathbb{R}^3} V(x) v_j w_1 dx \\
&\quad \geq (\lambda_0 - \varepsilon) \int_{\mathbb{R}^3} g(x) |v_j|^{p-1} v_j w_1 dx - \int_{\mathbb{R}^3} \phi_{v_j}^t v_j w_1 dx \\
&\quad > \lambda_1((C_0')^{-1} g(x)) \int_{\mathbb{R}^3} g(x) v_j w_1 dx,
\end{aligned}$$

which yields an absurdum $\lambda_1(g(x)(\max\{1, M([v_j]_s^2)\})^{-1}) > \lambda_1((C_0')^{-1} g(x))$. Therefore, $(0,0)$ is a unique bifurcation point of equation (3.1).

Furthermore, if $\mathcal{C}_0$ is bounded in $\mathbb{R} \times E$, by [17, Lemma 1.2] there is a bounded open set $\mathcal{O} \subset \mathbb{R} \times E$ such that $(0,0) \in \mathcal{O}$ and $\mathcal{O}$ contains nontrivial solution other than those in $B_\varepsilon \subset E$, with $\varepsilon > 0$ sufficiently small.

Now, we can argue as (1.11) of [17] to conclude that the existence of $\varepsilon > 0$ and values $\underline{\lambda}$ and $\overline{\lambda}$, such that $-\varepsilon < \underline{\lambda} < 0 < \overline{\lambda} < \varepsilon$ and $i(K_{\underline{\lambda}}, 0) = i(K_{\overline{\lambda}}, 0)$. Therefore, owing to (3.18) and (3.25), we have

$$1 = i(K_{\underline{\lambda}}, 0) = i(K_{\overline{\lambda}}, 0) = 0,$$

which is an obvious contradiction. Then, $\mathcal{C}_0$ is an unbounded component. □

4 Main result

To determine the bifurcation results of problem ($\mathcal{P}$), for any fixed λ, we define pointwise for $u, v \in E$, $T_\lambda : E \to E^*$ by

$$\langle T_\lambda(u), v \rangle = \int_{\mathbb{R}^3} \left\{ \lambda g(x) |u|^{p-1} u + |u|^{2_s^* - 2} u - \phi_u^t u \right\} v dx.$$

Suppose that $(u_n)_n \subset E$ is a bounded sequence in E. Then up to a subsequence, (3.13) also holds for some $u \in E$ by the reflexivity of E. Recalling the compactness result for the operator

N_λ, as shown in section 3, it remains to prove that for any $v \in E$,

$$\int_{\mathbb{R}^3} (|u_n|^{2_s^*-2}u_n - |u|^{2_s^*-2}u)v dx \to 0 \quad \text{as } n \to \infty. \tag{4.1}$$

Since $|u_n|^{2_s^*-2}u_n \in L^{(2_s^*)'}(\mathbb{R}^3)$, $v \in E$ and $E \subset L^{2_s^*}(\mathbb{R}^3)$, the definition of weak convergence yields at once that (4.1) is achieved. In conclusion, the operator $K \circ T_\lambda$ is also compact using Proposition 3.2.

Proof of Theorem 1.1. Let $H_\lambda : E \to E$ be defined as $H_\lambda(u) = K \circ T_\lambda(u)$, where K is the operator introduced by Proposition 3.2. Clearly, Theorem 3.3 guarantees the existence of the positive constants ε and δ, such that

$$\deg(K_\lambda, B_\delta, 0) = \begin{cases} 1, & \lambda \in (-\varepsilon, 0), \\ 0, & \lambda \in (0, \varepsilon). \end{cases}$$

We claim that for any λ, with $0 < \lambda < \varepsilon$, there exist δ_1, such that for any $r \in [0,1]$ and for the operator, defined by

$$\langle T_\lambda^r(u), v\rangle = \int_{\mathbb{R}^3} \left\{\lambda g(x)|u|^{p-1}u - \phi_u^t u + r|u|^{2_s^*-2}u\right\} v dx,$$

the problem

$$u - K \circ T_\lambda^r(u) = 0 \tag{4.2}$$

has no (weak) solutions with $\|u\| = \delta_1$. Otherwise, if there exists a sequence of nontrivial (weak) solutions $(u_n)_n$ of (4.2), with $\|u_n\| \to 0$ and $u_n > 0$, then it yields that

$$M([u_n]_s^2)[u_n]_s^2 + \|u_n\|_V^2 + \int_{\mathbb{R}^3} \phi_{u_n}^t u_n^2 dx = \int_{\mathbb{R}^3} \left\{\lambda g(x)|u_n|^p + r|u_n|^{2_s^*}\right\} dx.$$

Thanks to (3.24), taking the test function as the first eigenvalue w_1, we have

$$\begin{aligned} &\lambda_1(g(x)(\max\{1, M([u_n]_s^2)\})^{-1}) \int_{\mathbb{R}^3} g(x)u_n w_1 dx \\ &\quad = M([u_n]_s^2) \int_{\mathbb{R}^3} (-\Delta)^{\frac{s}{2}} u_n (-\Delta)^{\frac{s}{2}} w_1 dx + \int_{\mathbb{R}^3} V(x)u_n w_1 dx \\ &\quad = \int_{\mathbb{R}^3} (\lambda g(x)|u_n|^{p-1}u_n w_1 - \phi_{u_n}^t u_n w_1 + |u_n|^{2_s^*-1} w_1) dx \\ &\quad > \lambda_1((C_0')^{-1} g(x)) \int_{\mathbb{R}^3} g(x) u_n w_1 dx, \end{aligned}$$

which implies an absurdum that $\lambda_1(g(x)(\max\{1, M([u_n]_s^2)\})^{-1}) > \lambda_1((C_0')^{-1}g(x))$. The claim holds. Hence, the homotopy invariance of the topological degree shows that for any $\lambda \in (0,\varepsilon)$ and $R \in (0, \delta_1)$

$$\deg(I - H_\lambda, B_R, 0) = \deg(K_\lambda, B_R, 0) = 0. \tag{4.3}$$

Fix $\lambda < 0$. Applying the same argument of (3.24), it follows that

$$\int_{\mathbb{R}^3} \{\lambda g(x)|u|^{p+1} + |u|^{2_s^*}\} dx \le 0.$$

Now similar to the analysis of (3.17), there are no nontrivial (weak) solutions of (4.2). Consequently, there exist $\varepsilon > 0$ and $\delta > 0$, with $\varepsilon \le \varepsilon_1$ and $\delta \le \delta_1$, such that for any $\lambda \le \varepsilon$ and for any $R \le \delta$

$$\deg(I - H_\lambda, B_R, 0) = \deg(K_\lambda, B_R, 0) = 1. \tag{4.4}$$

By utilizing (4.3) and (4.4), we get $(0,0)$ is a bifurcation point of equation ($\mathcal{P}$). Moreover, similar to the argument in Theorem 3.3, we imply that the existence of an unbounded component $\mathcal{C}$ of weak solutions of ($\mathcal{P}$). □

Abstract. The blow-up method proves its effectiveness to characterize the integrability of the resonant saddles giving the necessary conditions to have formal integrability and the sufficiency doing the resolution of the associated recurrence differential equation using induction. In this work we apply the blow-up method to monodromic singularities in order to solve the center-focus problem. The case of nondegenerate monodromic singularities is straightforward since any real nondegenerate monodromy singularity can be embedded into a complex system with a resonant saddle. Here we apply the method to nilpotent and degenerate monodromic singularities solving the center problem when the center conditions are algebraic.

Keywords: monodromic singularity, blow-up, center problem, formal first integral.

2020 Mathematics Subject Classification: 34C05, 34A05.

1 Introduction

The center-focus problem for systems of differential equations is one of the main unsolved problems in the qualitative theory of differential systems in the plane [23, 26]. For the non-degenerate monodromic singularities the center-focus problem is closely connected with integrability problem, see for instance references [37, 39]. The center-focus problem consists of providing the necessary and sufficient conditions under which a monodromic singularity has a neighborhood filled with periodic orbits. If the monodromic singularity is a non-degenerate singular point, i.e., its linear part has two purely imaginary eigenvalues, then the real differential system can be embedded in the complex plane and the singular point it transformed to a $1 : -1$ resonant saddle singular point, see [15, 16, 29, 30].

Indeed, the $1 : -1$ resonance can be generalized into a $p : -q$ resonance known as a $p : -q$ resonant singular point of a polynomial vector field in $\mathbb{C}^2$, see [19, 44].

✉Corresponding author. Email: jaume.gine@udl.cat

The characterization of the analytic integrability of several families of differential systems with a resonant saddle is studied in several works, see for instance [17–19, 28–30, 44] and references therein.

In order to find the necessary conditions of analytic integrability of a $p : -q$ resonant singular point there exist different algorithms. One of them is based on the transformation of the original system to its normal form through a series of invertible changes of variables [2]. Another algorithm propose directly the formal first integral, see [41,44]. Recently the blow-up method has been introduced to compute the necessary conditions, see [16].

Once the necessary conditions are obtained the second step is to prove their sufficiency. There is no general algorithm that works for all differential systems in order to prove the sufficiency. The sufficiency is guaranteed if, for instance, the system is Hamiltonian or time-reversible. Recall that a time-reversible system is invariant by certain symmetry. The existence of an explicit first integral well-defined in a neighborhood of the singular point guarantees also the existence of a center in a monodromic singular point. This first integral can be found through the knowledge of an integrating factor. The connections between integrating factors an analytic first integrals have been studied by different authors, see [8, 13, 31, 41] and references therein. Finally ad hoc methods to prove the sufficiency are used for some particular families, see for instance [12, 13, 19, 32, 34–36, 40, 44]. All these different algorithms to prove the sufficiency have been useless for certain differential systems. However, in [15] the blow-up method is used to prove the sufficiency doing the resolution of the associated recurrence differential equation using induction and all the open problems of previous works have been solved.

We remark that for an isolated singularity the existence of a formal first integral implies the existence of an analytic first integral, see [10,41]. Consequently, to prove the sufficiency is sufficient to prove the existence of a formal first integral. In [3] the formal integrability was studied through the existence of invariant analytic (sometimes algebraic) curves.

In this paper we use the blow-up method to approach the center-focus problem for nilpotent and degenerate monodromic singularities, also when there exists no formal integral. This method that was successfully applied for resonant saddles and nondegenerate monodromic singularities, is used here to determine necessary conditions. Also, it is also possible to prove the sufficiency when the center is formally integrable. We solve open cases and cases previously studied with very difficult techniques.

2 Blow-up method for monodromic non-degenerate singular points

A monodromic non-degenerate singular point at the origin of a differential system on $\mathbb{R}^2$ takes the form

$$\dot{u} = v + P(u,v), \qquad \dot{v} = -u + Q(u,v), \tag{2.1}$$

where $P(u,v)$ and $Q(u,v)$ are real analytic functions without constant and linear terms. Such singular point is a center, if and only if, the system has a first integral of the form

$$\Phi(u,v) = u^2 + v^2 + \sum_{k+l\geq 3} \phi_{kl} u^k v^l. \tag{2.2}$$

analytically defined around it, see [37,39]. Therefore, the center-focus problem reduces to the case of proving the existence of such analytic first integral. From this result straightforward emerge a method to determine the first necessary conditions to have a center, which consists in proposing a power series of the form (2.2). However the unique general method that enables us to prove the sufficiency for this first necessary conditions is to use the method developed in [15] solving the recurrence differential equation associated to the problem using induction.

The first step to apply the method is to complexify system (2.1) defining the complex variable $x = u + iv$ and system (2.1) becomes the equation $\dot{x} = ix + R(x, \bar{x})$. Considering also its complex conjugate equation we have the system

$$\dot{x} = ix + R(x, \bar{x}), \qquad \dot{\bar{x}} = -i\bar{x} + \bar{R}(x, \bar{x}).$$

If we define $y := \bar{x}$ as a new variable and $\bar{R}$ as a new function we obtain a complex system which is after the change of time $idt = dT$ written as

$$\dot{x} = x + G(x, y), \qquad \dot{y} = -y + H(x, y). \tag{2.3}$$

The power series (2.2) is now transformed into

$$\Psi(x, y) = xy + \sum_{i+j>2} \psi_{ij} x^i y^j,$$

verifying that $\mathcal{X}\Psi = \sum_{i=1} v_{2i+1}(xy)^{2i+2}$, where $\mathcal{X}$ is the vector field associated to system (2.3) and v_{2i+1} are polynomials in the parameters of the system. We note that if all the polynomials v_{2i+1} vanish then the power series $\Psi(x, y)$ is first integral of system (2.3). The singular point at the origin of system (2.3) is $1 : -1$ resonant saddle singular point and the values v_{2i+1} are the so-called *saddle constants*, see [41, 44].

When the $1 : -1$ resonant saddle singular point at the origin is generalized into the $p : -q$ resonant saddle singular point at the origin then the differential system is of the form

$$\dot{x} = p\,x + F_1(x, y), \qquad \dot{y} = -q\,y + F_2(x, y), \tag{2.4}$$

where F_1 and F_2 are analytic functions without constant and linear terms with $p, q \in \mathbb{Z}$ and $p, q > 0$, see [14, 33, 44]. In this case a $p : -q$ resonant saddle singular point is called a resonant center, if an only if, there exists a meromorphic first integral $\Psi = x^q y^p + \sum_{i+j>p+q} \psi_{ij} x^i y^j$ around it. We recall here that if $\Psi(x, y) \in \mathbb{C}[[x, y]]$, i.e, is a formal first integral in a neighborhood of the singularity, then there also exists an analytic first integral.

The blow-up method to detect formal integrability for a resonant singular point works as follows. We perform the blow-up $(x, y) \to (x, z) = (x, y/x)$ to system (2.4) which has a resonant singular point at the origin. So that the origin is replaced by the line $x = 0$, which contains two singular points that correspond to the separatrices of the resonant point at the origin of system (2.4). These two singular points are a $(p + q) : -p$ resonant saddle and a $(p + q) : -q$ resonant saddle that we call p_1 and p_2, respectively. The method is based on the following result.

Theorem 2.1. *The $p : -q$ resonant singular point at the origin of system (2.4) is analytically integrable if, and only if, either p_1 or p_2 is orbitally analytically linearizable.*

The proof is based on the fact that if the $p : -q$ resonant singular has an analytic first integral $\Psi(x, y)$ then both points p_1 or p_2 have also a well-defined analytic first integral given by $\Psi(x, zx)$. The sufficiency follows from Lemma 1 of [19] using the normal orbital form of the $p : -q$ resonant system (2.4) and the first integral of such normal orbital form. From Theorem 2.1 we deduce that the necessary conditions of integrability for the $p : -q$ resonant singular point generate the same ideal that the necessary integrability conditions of the singular points p_1 or p_2.

Hence we apply the blow-up $z = y/x$ and system (2.4) is transformed into the system

$$\dot{z} = -(p+q)z + x\mathcal{F}(x,z), \qquad \dot{x} = p\,x + x^2\mathcal{G}(x,z), \tag{2.5}$$

where $\mathcal{F}(0,0) = 0$ and $x = 0$ is an invariant line of the new system. Next we propose the power series $\tilde{\mathcal{H}} = \sum_{i\geq 1}^{\infty} f_i(z)x^i$, where $f_i(z)$ are arbitrary functions of z (in the case of formal integrability these functions must be polynomials). Let $\bar{\mathcal{X}}$ be the vector field associated to system (2.5). The lower terms of equation $\bar{\mathcal{X}}\tilde{\mathcal{H}} = 0$ give the differential equation for $f_1(z)$ given by $pf_1(z) - (p+q)zf_1'(z) = 0$ whose solution is $f_1(z) = c_1 z^{p/(p+q)}$. Taking into account that $f_1(z)$ must be a polynomial we take $c_1 = 0$ and consequently $f_1(z) = 0$. The power two of terms give the differential equation $2pf_2(z) - (p+q)zf_2'(z) = 0$ and its solution is $f_2(z) = c_2 z^{(2p)/(p+q)}$. Consequently, either $(2p)/(p+q) \in \mathbb{N}$ or we take $c_2 = 0$. Taking into account that $p,q \in \mathbb{Z}$ with $p,q > 0$ it always exists f_{k_0} such that $(k_0 p)/(p+q) \in \mathbb{N}$ (or $(k_0 q)/(p+q) \in \mathbb{N}$ for saddle point p_2). Finally, for each power of x of the equation $\bar{\mathcal{X}}\tilde{H} = 0$ we get the differential equation

$$k\,p\,f_k(z) - (p+q)\,z\,f_k{}'(z) + g_k(z) = 0, \tag{2.6}$$

where $g_k(z)$ depends on some previous functions $f_i(z)$ for $i = k_0, \ldots, k-1$. The solution of differential equation (2.6) is given by

$$f_k(z) = c_k\,z^{\frac{kp}{p+q}} + z^{\frac{kp}{p+q}} \int \frac{z^{-1-\frac{kp}{p+q}}}{p+q}\,g_k(z)\,dz, \tag{2.7}$$

where c_k is an arbitrary constant. From (2.7) it is easy to see that functions f_k in (2.7) are always polynomials except when appear logarithmic terms. If the origin is not a resonant center, always exists a value k_r such that for $k \geq k_r$ the functions $f_i(z)$ for $i \geq k_r$ can have logarithmic terms. In fact, the logarithmic term appears when there is a term s^{-1} in the integral of (2.7). This is the case when

$$-1 - \frac{k_r p}{p+q} + m_k = -1,$$

where m_k is the degree of the polynomial $g_k(s)$. So, we have $k_r = m_k(p+q)/p$. The coefficients of these logarithmic terms are the saddle constants of the original system (2.4).

Vanishing a certain number of saddle constants and checking that some of the next ones are zero we can apply the following procedure. First we apply the induction method to prove that the solution f_k of recursive equation (2.6) is always a polynomial to assure that system (2.5) has a formal first integral. Second, to prove the sufficiency of the original system (2.4) we can apply the following result.

Theorem 2.2. *Assume that system (2.5) has a formal first integral $\tilde{\mathcal{H}}(x,z)$. If the function $\tilde{H} = \tilde{\mathcal{H}}(x,y/x)$ is well-defined at the origin of system (2.4) then this system is analytic integrable in a neighborhood of the origin.*

The idea of the method is to study the connected singular points at infinity and if they are formally integrable and the first integral can be extended up to the origin then the origin is also formally integrable. The reason of why the coordinates $(x, z = y/x)$ are better than the original coordinates (x, y) is double. First because doing the blow-up we introduce x as a invariant curve of the new differential system and then we can propose an expansion passing through the origin in powers of x with coefficients as functions of z. The second is because the in the new variables (x, z) the coefficients functions of z are polynomials with perhaps some logarithmic terms, see [3]. This does not happens in the original variables, where the system may not have any invariant curve and if it does then the coefficient of the expansion do not have to be polynomial.

In this work we apply the same method to nilpotent and degenerate monodromic singularities in order to solve the center-focus problem. For degenerate monodromic singularities there is no general method to approach the center-focus problem. The method shows that the formal integrability of the points at infinity is intimately linked with the center problem at the origin even though the center at the origin is not formally integrable. The method determine center conditions for monodromic singularities which are algebraically solvable. In the following sections we solve several non trivial examples. The method can also be applied to systems that are not formally integrable at the monodromic singular point giving information for studying the center-focus problem.

3 Nilpotent monodromic singularities

In this section we consider different systems with a nilpotent singularity, and we study, using the blow-up method, the center-focus problem of such systems.

Proposition 3.1. *The nilpotent real cubic differential system*

$$\dot{x} = y + Ax^2y + Bxy^2 + Cy^3, \qquad \dot{y} = -x^3 + Px^2y + Kxy^2 + Ly^3. \tag{3.1}$$

is a center if and only if $P = B + 3L = (A + K)L = 0$.

Proof. In [9] was solved the center-focus problem of the nilpotent cubic system (3.1) constructing a Liapunov function and using different methods to prove the sufficiency. Indeed it is well-known that all the centers are analytically (hence formally) integrable, see [7]. Later in [22,27] the center-focus problem of such system is also solved using the fact that all the nilpotent centers are limit of non-degenerate centers. Here, we apply the blow-up method to solve it. Hence, applying the blow-up transformation

$$(x, y) \to (z, y) = (x/y, y) \tag{3.2}$$

system (3.1) becomes

$$\begin{aligned} \dot{z} &= 1 + Cy^2 + By^2z - Ly^2z + Ay^2z^2 - Ky^2z^2 - Py^2z^3 + y^2z^4, \\ \dot{y} &= y^3(L + Kz + Pz^2 - z^3), \end{aligned} \tag{3.3}$$

which has a regular point at the origin. Therefore system (3.3) is analytic integrable at the origin and the recursive differential equation do not generate logarithmic terms. Next, we propose the power series

$$\mathcal{H}(z, y) = \sum_{k=2}^{\infty} f_k(z) y^k. \tag{3.4}$$

We impose that $\dot{\mathcal{H}} = \dot{z}\partial\mathcal{H}/\partial z + \dot{y}\partial\mathcal{H}/\partial y = 0$ and equating to zero each coefficient of power of y we obtain the following recursive differential equation for the functions f_k

$$(k-1)(L+Kz+Pz^2-z^3)f_{k-1} + (C+Bz-Lz+Az^2-Kz^2-Pz^3+z^4)f'_{k-1} + f'_{k+1} = 0. \quad (3.5)$$

Solving for the first values of k we can take $f_k = 0$ for all k odd and for k even we find $f_2 = c_2$, where c_2 is an arbitrary integration constant that we can take $c_2 = 1$, then we have

$$f_4 = \frac{1}{6}(-12Lz - 6Kz^2 - 4Pz^3 + 3z^4) + c_4,$$
$$f_6 = \frac{1}{630}(P_6(z) - 60Pz^7) + c_6.$$

In order to have a polynomial in the original variables (x, y) we must to take $P = 0$. Then f_8 is a polynomial of degree 9 of the form

$$f_8 = \frac{1}{83160}\big(P_8(z) - 3696(B+3L)z^9\big) + c_8.$$

In this case we have to take $B + 3L = 0$. Taking $B = -3L$ then f_{10} is a polynomial of degree 15 given by

$$f_{10} = \frac{1}{83160}\big(P_{10}(z) - 5896800(A+K)Lz^{11}\big) + c_{10}.$$

If $(A+K)L = 0$ we have checked that some of the next f_k for k even are all of degree at most k. Now, we assume that f_s have degree s for $s = 2, 4, \ldots, k-1$ and solving the recursive equation (3.5) we obtain

$$f_{k+1}(z) = -\int (k-1)(L+Kz-z^3)f_{k-1} + (C-4Lz+(A-K)z^2+z^4)f'_{k-1} \quad (3.6)$$

where it is easy to see that the higher terms cancel, that is, if we introduce $f_{k-1}(z) = C_0 + C_1 z + \cdots + C_{k-1}z^{k-1}$ in (3.6) we get a polynomial for f_{k+1} of degree at most $k+1$. Consequently, we have proven the sufficiency since we have a formal first integral at the origin that in the original variables (x, y) is also formal for all the center cases. Here the blow-up method gives straightforward the necessary conditions and the sufficiency for all cases and in a unified method for all the center cases. □

Proposition 3.2. *Consider the nilpotent differential system*

$$\dot{x} = Ax^3 + By, \qquad \dot{y} = Cx^5 + Dx^2y, \quad (3.7)$$

where the unique monodromic condition is $(D-3A)^2 + 12BC < 0$. *It has a center at the origin if and only if* $3A + D = 0$.

Proof. The monodromic and center-focus problem of system (3.7) has been solved in [1]. Indeed, system (3.7) is a $(1,3)$-quasihomogeneous system and consequently, $V(x,y) = Cx^6 - 3Ax^3y + Dx^3y - 3By^2$ is an inverse integrating factor of (3.7). In fact such (p,q)-quasihomogeneous systems of degree r has a unique center condition given by

$$\int \frac{F_r(\varphi)}{G_r(\varphi)} d\varphi = 0 \quad (3.8)$$

where

$$G_r(\varphi) = p\,Q_{p+r}(\cos\varphi, \sin\varphi)\cos\varphi - q\,P_{q+r}(\cos\varphi, \sin\varphi)\sin\varphi,$$
$$F_r(\varphi) = P_{p+r}(\cos\varphi, \sin\varphi)\cos\varphi + Q_{q+r}(\cos\varphi, \sin\varphi)\sin\varphi.$$

using the weighted polar blow-up $(x, y) \to (\rho, \varphi)$ given by $x = r^p \cos\varphi$, $y = r^q \sin\varphi$. Nevertheless, the computation of condition (3.8) is very demanding and sometimes impossible, see [23,24]. However applying the blow-up method we compute the center condition in a straightforward way. We proceed in a similar way as in the previous example. After transformation (3.2) system (3.9) becomes

$$\begin{aligned}\dot{z} &= B + Ay^2z^3 - Dy^2z^3 - Cy^4z^6,\\ \dot{y} &= y^3z^2(D + Cy^2z^3).\end{aligned} \tag{3.9}$$

Since $B \neq 0$ by the monodromic condition we have that the origin of system (3.9) is also a regular point. Therefore system (3.9) has an analytic first integral around its origin. Hence, we look for a power series of the form (3.4). We compute $\dot{\mathcal{H}} = \dot{z}\partial\mathcal{H}/\partial z + \dot{y}\partial\mathcal{H}/\partial y$ for system (3.9) and equating to zero the coefficients of the same power of y yields the following recurrence differential equation

$$(k-4)Cz^5 f_{k-4} + (k-2)Dz^2 f_{k-2} - Cz^6 f'_{k-4} + (Az^3 - Dz^3)f'_{k-2} + Bf'_k = 0.$$

We take $f_k = 0$ for k odd and for k even we can take $f_2(z) = 1$ and

$$\begin{aligned}f_4(z) &= \frac{1}{3B}(-2Dz^3) + c_4,\\ f_6(z) &= \frac{1}{9B^2}(-3BC + 3AD + D^2)z^6 + c_6,\\ f_8(z) &= \frac{1}{27B^3}(P_8(z) - 2(3A + D)(AD - BC)z^9) + c_8,\end{aligned}$$

where P_8 is a polynomial of at most degree 8. In order to have a polynomial in the original variables (x, y) we must to take $(3A + D)(AD - BC) = 0$. So we impose $3A + D = 0$ because the other one is not compatible with the monodromic condition. In this case f_{10} takes the form

$$f_{10}(z) = \frac{1}{3B^2}(24ABc_8z^3 + 36A^2c_6z^6 - 3BCc_6z^6 - 4ACc_4z^9 + 3B^2c_{10}).$$

We can take all $c_4 = c_6 = c_8 = c_{10} = 0$ and then $f_{10}(z) = 0$ and also take $f_k = 0$ for all $k \geq 10$. Next we define

$$\begin{aligned}H &= f_2\Big(\frac{x}{y}\Big)y^2 + f_4\Big(\frac{x}{y}\Big)y^4 + f_6\Big(\frac{x}{y}\Big)y^6 + f_8\Big(\frac{x}{y}\Big)y^8\\ &= y^2 + \frac{2A}{B}x^3y - \frac{C}{3B}x^6,\end{aligned}$$

which is a polynomial first integral of system (3.7) and therefore it has a center at the origin. Here the computation of the necessary condition is straightforward unlike other known methods and our method also gives directly the sufficiency. □

Proposition 3.3. *The nilpotent differential system*

$$\dot{x} = y + x^2, \qquad \dot{y} = -x^3 + cx^4, \tag{3.10}$$

has not any analytic first integral at the origin and it has a center at the origin if and only if $c = 0$.

Proof. First we apply the blow-up transformation (3.2) and system (3.10) becomes

$$\dot{z} = 1 + yz^2 + y^2z^4 - cy^3z^5, \qquad \dot{y} = y^3z^3(-1 + cyz), \tag{3.11}$$

We propose a power series of the form (3.4) and impose that $\dot{\mathcal{H}} = \dot{z}\partial\mathcal{H}/\partial z + \dot{y}\partial\mathcal{H}/\partial y = 0$ for system (3.11) and we get the following recurrence differential equation

$$(k-3)cz^4 f_{k-3} - (k-2)z^3 f_{k-2} - cz^5 f'_{k-3} + z^4 f'_{k-2} + z^2 f'_{k-1} + f'_k = 0$$

and we can, as in previous case, take $f_2(z) = 1$, and $f_3(z) = c_3$,

$$f_4(z) = \frac{1}{2}z^4 + c_4, \qquad f_5(z) = \frac{1}{60}(45c_3z^4 - 24cz^5 - 20z^6) + c_5.$$

However, it is not possible to get a polynomial from f_5 in the original variables (x, y). Therefore the analytic first integral at infinity cannot be extended to the origin of system (3.10). This also implies system (3.10) has not an analytic first integral at the origin. Next we propose a power series of the form

$$\mathcal{V}(z, y) = \sum_{k=1}^{\infty} v_k(z)y^k. \tag{3.12}$$

and we impose that this $\mathcal{V}$ satisfies the equation

$$\dot{z}\partial\mathcal{V}/\partial z + \dot{y}\partial\mathcal{V}/\partial y - (\partial\dot{z}/\partial z + \partial\dot{y}/\partial y)\mathcal{V} = 0, \tag{3.13}$$

which is the equation of the inverse integrating factor. As an inverse integrating factor is not coordinates free (as happens for a first integral) and it is affected by the Jacobian of the transformation when we come back to the original coordinates. In this case the recurrence differential equation is

$$6cz^4v_{k-3} - 7z^3v_{k-2} - 2zv_{k-1} - cz^5v'_{k-3} + z^4v'_{k-2} + z^2v'_{k-1} + v'_k = 0.$$

Without loss of generality we now take $v_1 = 1$. Then $v_2 = z^2 + c_2$, and

$$\begin{aligned} v_3(z) &= \frac{1}{2}(2c_2z^2 + z^4) + c_3, \\ v_4(z) &= \frac{1}{20}(20c_3z^2 + 15c_2z^4 - 8cz^5) + c_4, \\ v_5(z) &= 5\frac{1}{420}(420c_4z^2 + 420c_3z^4 - 252c\,c_2z^5 + 35c_2z^6 + 12cz^7) + c_5. \end{aligned}$$

Taking into account that the inverse integrating factor for system (3.10) is obtained multiplying the power series (3.12) by the Jacobian of the transformation, we have to take $c = 0$ in a polynomial v_5 to ensure that V is polynomial in the original variables (x, y). Then

$$v_6 = \frac{1}{10080}(10080c_5z^2 + 12600c_4z^4 + 1680c_3z^6 + 525c_2z^8) + c_6.$$

Choosing $c_2 = c_3 = c_4 = c_5 = c_6 = 0$ then $v_6 = 0$ and we can choose $v_k = 0$ for all $k \geq 5$. Consequently,

$$\mathcal{V} = v_1\Big(\frac{x}{y}\Big)y + v_2\Big(\frac{x}{y}\Big)y^2 + v_3\Big(\frac{x}{y}\Big)y^3 + v_4\Big(\frac{x}{y}\Big)y^4 = y + x^2 + \frac{x^4}{2y}.$$

The inverse integrating factor of system (3.10) is obtained multiplying $\mathcal{V}$ by the Jacobian of the transformation

$$V = y\mathcal{V} = y^2 + x^2y + \frac{x^4}{2}.$$

For a general monodromic nilpotent singularity the existence of an inverse integrating factor in a neighborhood of singularity does not guarantees the existence of a center at this singularity, but for the nilpotent monodromic singularities with leading term $(y, -x^3)$ this is true, see the result in [6, 20]. System (3.10) with $c = 0$ was studied in [11], where it was proved that there exists no analytic first integral. Consequently, here we have used the blow–up method to find an inverse integrating factor of system (3.10) which gives the condition $c = 0$ implying that system (3.10) has a center at the origin if and only if $c = 0$. □

Proposition 3.4. *Consider the nilpotent differential system*

$$\dot{x} = y + ax^2 + 5xy^2, \qquad \dot{y} = -2x^3 + 3xy^2 - 4y^3, \tag{3.14}$$

where $a \in \mathbb{R}$. The first necessary condition of system (3.14) to have a center is $-98 + 47a^2 + 20a^4 = 0$. Moreover system (3.14) always has a focus at the origin.

Proof. System (3.14) has a monodromic singular point at the origin if and only if $|a| < 2$, see [27]. Applying the blow-up transformation (3.2) system (3.14) takes the form

$$\dot{z} = \ 1 + 9y^2z + ayz^2 - 3y^2z^2 + 2y^2z^4, \qquad \dot{y} = \ -y^3(4 - 3z + 2z^3). \tag{3.15}$$

We propose directly a power series of the form (3.12) and we impose that this $\mathcal{V}$ satisfies the equation (3.13). Recall that the transformation to the original variables (x, y) will be affected by the Jacobian of the transformation. In this case the recurrence differential equation is

$$\big(3(k-3)z - (4k-11) - 2(k-1)z^3\big)v_{k-2} - 2azv_{k-1} + \big(9z - 3z^2 + 2z^4\big)v'_{k-2} + az^2v'_{k-1} + v'_k = 0$$

and we can, as above, take $v_1(z) = 1$, and $v_2(z) = az^2 + c_2$, $v_3(z) = z + ac_2z^2 + z^4 + c_3$

$$\begin{aligned}
v_4(z) &= 5c_2z - \frac{3}{2}c_2z^2 + ac_3z^2 - 4az^3 + \frac{3}{4}az^4 + \frac{3}{2}c_2z^4 + c_4,\\
v_5(z) &= \frac{1}{60}(P_5(z) + 60z^6 - 15a^2z^6 + 10ac_2z^6) + c_5,\\
v_6(z) &= \frac{1}{1680}(P_7(z) - 525az^8 + 210a^3z^8 + 630c_2z^8 - 140a^2c_2z^8) + c_6,
\end{aligned}$$

where $P_i(z)$ are determined polynomials of degree i. Taking into account that in the original variable the inverse integrating factor is $V = y\mathcal{V}$ the coefficient in the term with z^8 in v_6 must be zero. Then, we have $-525a + 210a^3 + 630c_2 - 140a^2c_2 = 0$ which yields

$$c_2 = \frac{3(2a^3 - 5a)}{2(2a^2 - 9)},$$

if $2a^2 - 9 \neq 0$. Recall that if $2a^2 - 9 = 0$ this is not a monodromic case. Next, v_7 has the form

$$v_7(z) = \frac{P_8(z) + (14112 - 9904a^2 - 1376a^4 + 640a^6)z^9}{1680(2a^2 - 9)} + c_7,$$

where $P_8(z)$ is a determined polynomial of degree 8. The coefficient of the term with monomial z^9 must vanish, so,

$$16(-9+2a^2)(-98+47a^2+20a^4)=0.$$

The unique real roots of this polynomial satisfying the monodromic condition $|a|<2$ are $a=\pm 1.153741$. This last numerical value was obtained by Varin in [42] using the Bautin method after doing a generalized polar blow-up. The method developed in [42, 43] is not useful to compute the algebraic condition $-98+47a^2+20a^4=0$. Moreover, with our method we can distinguish between a center and a focus. If we compute more terms of the power series $\mathcal{V}$ the powers in z that must be zero have not a common root. Therefore, the origin of system (3.14) is always a focus. The algebraic necessary center condition $-98+47a^2+20a^4=0$ was also obtained in [27] using a more involved method based in the result that all the nilpotent centers are limit of non-degenerate centers. The fact that, under monodromy the origin of (3.14) is always a focus was also derived in Proposition 26 of [21]. Here we also use that the existence of a formal inverse integrating factor defined around a nilpotent monodromic singularity with leading term $(-y,x^3)$ is a necessary and sufficient condition to have a center at the singularity, see [6, 20]. □

4 Degenerate monodromic singularities

In this section we consider different systems with a degenerate singularity, and using the blow–up method we study the center-focus problem. The examples proposed here show the narrow relation between the center problem and the existence of a first integral for the singular points at infinity. The necessary conditions founded by the method do not always correspond to trivial cases of centers.

Proposition 4.1. *Consider the differential system*

$$\dot{x}=x^2y+ax^5+y^5, \qquad \dot{y}=-xy^2-x^5+bx^4y, \tag{4.1}$$

where a, $b\in\mathbb{R}$. System (4.1) has a center at the origin if and only if $5a+b=0$.

Proof. In [5] it is proved that the origin of system (4.1) is always monodromic. Moreover, system (4.1) has characteristic directions because the homogeneous polynomial $xq_n(x,y)-yp_n(x,y)$, where p_n and q_n are the lower homogeneous terms of system (4.1), has real roots. When the singular point has characteristic directions it is not possible to apply the Bautin method in order to solve the center-focus problem, see [25].

After applying the blow-up transformation (3.2) system (4.1) takes the form

$$\begin{aligned}\dot{z}&=y^2+2z^2+ay^2z^5-by^2z^5+y^2z^6\\ \dot{y}&=-yz(1-by^2z^3+y^2z^4).\end{aligned}\tag{4.2}$$

Now, we look for a power series of the form (3.4) and we compute $\dot{\mathcal{H}}=(\partial\mathcal{H}/\partial z)\dot{z}+(\partial\mathcal{H}/\partial y)\dot{y}$ for system (4.2). We obtain the following recursive differential equation

$$(k-2)z^4(b-z)f_{k-2}-kzf_k+(1+az^5-bz^5+z^6)f'_{k-2}+2z^2f'_k=0$$

Solving for the first values of k we can take $f_k = 0$ for all k odd and for k even we find $f_2 = 0$, $f_4 = z^2 + c_4$ where c_4 is an arbitrary integration constant, and

$$\begin{aligned} f_6 &= \frac{1}{6}(2 - 3az^5 - 3bz^5 + 2z^6) + c_6, \\ f_8 &= -\frac{1}{80}z^3(100a + 20b - 240bc_6 - 25a^2z^5 - 30abz^5 \\ &\quad - 5b^2z^5 + 20az^6 + 4bz^6 - 80zc_8 - 240c_6 z \log z), \end{aligned}$$

where c_6 and c_8 are arbitrary constants. Since f_8 must be a polynomial we have to impose $c_6 = 0$ and since it must be a polynomial in the original variables (x, y) we have to impose that the terms in z^9 vanish, that is, $5a + b = 0$. Under this restrictions we have that

$$f_{10} = c_8 z^2 \left(\frac{2}{3} + 4az^5 + \frac{2}{3}z^6 \right) + c_{10}z^5.$$

Then taking $c_8 = c_{10} = 0$ we get $f_{10} = 0$ and we can choose $f_k = 0$ for all $k \geq 10$. Consequently

$$\mathcal{H} = f_4\left(\frac{x}{y}\right)y^4 + f_6\left(\frac{x}{y}\right)y^6 + f_8\left(\frac{x}{y}\right)y^8 = \frac{x^6}{3} + 2ax^5y + x^2y^2 + \frac{y^6}{3},$$

which is a polynomial first integral of system (4.1). Therefore, when $5a + b = 0$ system (4.1) has a center at the origin. It remains to see that if $5a + b \neq 0$ then system (4.1) has a focus at the origin. From [5, Theorem 2.3] is derived the geometric criteria for proving that if $5a + b \neq 0$ then system (4.1) has a focus at the origin, see Proposition 3.19 in [5]. Here our blow-up method gives straightforward the necessary condition while for applying the geometric criteria the necessary condition is needed. □

Proposition 4.2. *Consider the differential system*

$$\dot{x} = x^2y + ax^3 + y^5, \qquad \dot{y} = -xy^2 + bx^2y - x^3, \tag{4.3}$$

where $a, b \in \mathbb{R}$. System (4.3) has a center at the origin if and only if $3a + b = 0$.

Proof. The origin of system (4.3) is monodromic if and only if, $(a - b)2 - 8 < 0$, see [5]. System (4.3) has also characteristic directions. Applying the blow-up (3.2) system (4.3) takes the form

$$\begin{aligned} \dot{z} &= y^2 + 2z^2 + az^3 - bz^3 + z^4 \\ \dot{y} &= -yz(1 - bz + z^2), \end{aligned} \tag{4.4}$$

after a scaling of time. Now, we compute $\dot{\mathcal{H}} = (\partial\mathcal{H}/\partial z)\dot{z} + (\partial\mathcal{H}/\partial y)\dot{y}$ for system (4.4) where $\mathcal{H}$ is a power series of the form (3.4) and we obtain the following recursive differential equation

$$-5z(1 - bz + z^2)f_k + f'_{k-2} + (2z^2 + az^3 - bz^3 + z^4)f'_k = 0.$$

Doing the computations of the first f_k we must to take $f_2 = f_3 = 0$ in order to be polynomials and

$$f_4 = c_4 e^{-\frac{2(3a+b)\arctan\left(\frac{a-b+2z}{\sqrt{8-(a-b)^2}}\right)}{\sqrt{8-(a-b)^2}}} z^2(2 + z(a - b + z)).$$

where in order to have a polynomial we have to take $3a + b = 0$ and without loss of generality $c_4 = 1$.

Next we must to take $f_5 = 0$ and $f_6 = (2+3z^3(2+4az+z^2)^{3/2}c_6)/3$, and taking $c_6 = 0$ we have $f_6 = 2/3$. Next, $f_7 = 0$ and $f_8 = c_8 z^4(2+4az+z^2)^2$. Then taking $c_8 = 0$ we obtain $f_8 = 0$ and we can choose $f_k = 0$ for all $k \geq 8$. Consequently

$$\mathcal{H} = f_4\Big(\frac{x}{y}\Big)y^4 + f_6\Big(\frac{x}{y}\Big)y^6 + f_8\Big(\frac{x}{y}\Big)y^8 = x^4 + 4ax^3y + 2x^2y^2 + \frac{2y^6}{3},$$

which is a polynomial first integral of system (4.3). Finally to see that for $3a + b \neq 0$ we have a focus at the origin, we use also the geometric criteria developed from [5, Theorem 2.3]. In Proposition 3.16 [5] is that system (4.3) has a focus if $3a + b \neq 0$. As in the example before the blow-up method gives the necessary condition directly. □

Proposition 4.3. *Consider the degenerate differential system*

$$\dot{x} = cx^2y + fxy^2 + dy^3, \qquad \dot{y} = \tilde{c}xy^2 + fy^3 + ax^5. \tag{4.5}$$

If the origin of system (4.5) is monodromic then it is a center if, and only if, $f = 0$.

Proof. In [38] Medvedeva studied the stability problem of the origin of system(4.5). The first non zero focal value of system (4.5) was given in [38] through a complicate and involved method using several blow-up transformations. The monodromy problem for system (4.5) was solved in [5] where the following result was given.

Lemma 4.4. *The origin of system (4.5) is monodromic if and only if one of the following conditions holds:*

a) $d\,a < 0$, $(\tilde{c} - c)(\tilde{c} - 2c) > 0$ *and* $d(\tilde{c} - c) < 0$

b) $d\,a < 0$, $\tilde{c} - c = 0$ *and* $cd > 0$.

c) $d\,a < 0$, $\tilde{c} - 2c = 0$ *and* $ca > 0$.

Applying the blow-up transformation (3.2) to system (4.5), the new differential system takes the form

$$\begin{aligned} \dot{z} &= d + cz^2 - \tilde{c}z^2 - ay^2z^6, \\ \dot{y} &= y\,(\tilde{c}z + ay^2z^5 + f) \end{aligned} \tag{4.6}$$

with the change of time $d\tau = y^2 dt$. From the monodromic condition we know that $d \neq 0$. System (4.6) has a regular point at the origin and consequently, an analytic first integral around the origin and the recursive differential equation do not generate logarithmic terms. Then the question is if this analytic first integral at infinity can be extended to the origin of the original system (4.5). In this case the recursive differential equation is

$$(k-2)az^5 f_{k-2} + k(\tilde{c}z + f)f_k - az^6 f'_{k-2} + (d + cz^2 - \tilde{c}z^2)f'_k = 0.$$

Then if $f_i = 0$ for $i = 1, \ldots, k-2$ we have that the value of f_k is

$$f_k = c_k e^{-\frac{kf\arctan\left(\frac{\sqrt{c-\tilde{c}}\,z}{\sqrt{d}}\right)}{\sqrt{c-\tilde{c}}\sqrt{d}}} (d + (c - \tilde{c})z^2)^{-\frac{k\tilde{c}}{2(c-\tilde{c})}}.$$

In order to have a well defined function in the original variables (x, y) we have to impose $f = 0$. Moreover, under the monodromic condition system (4.5) has a center at the origin since it is invariant with respect to the symmetry $(x, y, t) \to (-x, y, -t)$.

To finish the proof we see that if $f \neq 0$ then system (4.5) has a focus at the origin. We apply the geometrical criteria developed in [5, Theorem 2.3]. Consider the vector field

$$\mathcal{X}_c = (cx^2y + dy^3)\frac{\partial}{\partial x} + (\tilde{c}xy^2 + ax^5)\frac{\partial}{\partial y},$$

which has a center at the origin. Let $\mathcal{X}$ the vector field associated to system (4.5). Then we compute that

$$\mathcal{X} \wedge \mathcal{X}_c = fy^2(ax^6(\tilde{c} - c)x^2y^2 - dy^4)$$

which is semi-definite under the monodromic conditions of Lemma 4.4 and by Theorem 2.3 of [5] if $f \neq 0$ system (4.5) has a focus at the origin. □

Finally we consider the differential system

$$\begin{aligned} \dot{x} &= y^3 + 2ax^3y + 2x(\alpha x^4 + \beta xy^2), \\ \dot{y} &= -x^5 - 3ax^2y^2 + 3y(\alpha x^4 + \beta xy^2), \end{aligned} \tag{4.7}$$

where α, β, $a \in \mathbb{R}$. In [4] it was proven that system (4.7) with $\alpha\beta \neq 0$ is not orbitally reversible nor formally integrable. Moreover there are values of (α, β, a) with $a \neq 0$ and with the monodromic condition $|a| < 1/\sqrt{6}$ such that the origin of system (4.7) is a center. In fact the center condition is not algebraic in the parameters. In [23] it was also identified the center condition using the existence of an inverse integrating factor. Therefore the center problem is not algebraically solvable. As we will see, if we apply the blow-up method proposing a power series verifying the first integral equation we only find the algebraically solvable centers. So we will propose a power series satisfying the inverse integrating equation. Applying the blow-up (3.2) to system (4.7), the new differential system takes the form

$$\begin{aligned} \dot{z} &= 1 + 5ayz^3 + y^2z^6 - y^2z^5\alpha - yz^2\beta \\ \dot{y} &= -y^2z(3az + yz^4 - 3yz^3\alpha - 3\beta), \end{aligned} \tag{4.8}$$

after the scaling of time $d\tau = y^2dt$. Looking for a power series of the form (3.4) and computing the equation that satisfies a first integral we get only the center condition $\alpha = \beta = 0$ (the reader can follow the steps seeing the previous examples). Therefore the analytic first integral at infinity cannot always be extended to the origin of system (4.7). Next, we propose a power series of the form

$$\mathcal{F}(z, y) = y^{k_2} \sum_{k=0}^{\infty} v_k(z)y^k, \tag{4.9}$$

where $k_2 \in \mathbb{Q}$ and we impose that it satisfies the equation of certain inverse integrating factor $\dot{z}\partial\mathcal{F}/\partial z + \dot{y}\partial\mathcal{F}/\partial y = k_1(\partial\dot{z}/\partial z + \partial\dot{y}/\partial y)\mathcal{F}$, where $k_1 \in \mathbb{R}$. The recurrence differential equation is

$$\begin{aligned} &(-(k-2)z^5 - 3k_1z^5 - k_2z^5 + 3(k-2)z^4\alpha - 4k_1z^4\alpha + 3k_2z^4\alpha)v_{k-2} \\ &\quad + (-3(k-1)az^2 - 9ak_1z^2 - 3ak_2z^2 + 3(k-1)z\beta - 4k_1z\beta + 3k_2z\beta)v_{k-1} \\ &\quad + (z^6 - z^5\alpha)v'_{k-2} + (5az^3 - z^2\beta)v'_{k-1} + v'_k = 0 \end{aligned}$$

and we can take $v_0(z) = 1$, and

$$\begin{aligned} v_1(z) &= 3ak_1z^3 + ak_2z^3 + 2k_1z^2\beta - \frac{3}{2}k_2z^2\beta + c_1, \\ v_2(z) &= \frac{1}{6}k_2z^6 + \frac{1}{2}a^2(9k_1^2 + 6k_1(k_2-2) + (k_2-4)k_2)z^6 - \frac{3}{5}k_2z^5\alpha \\ &\quad - \frac{3}{2}c_1z^2\beta - \frac{3}{2}c_1k_2z^2\beta + 2k_1^2z^4\beta^2 + \frac{3}{8}k_2z^4\beta^2 + \frac{9}{8}k_2^2z^4\beta^2 \\ &\quad + \frac{1}{10}az^3\Big(10\,c_1(1+3k_1+k_2) \\ &\quad + (60k_1^2 + 3(7-5k_2)k_2 - k_1(28+25k_2))z^2\beta\Big) \\ &\quad + \frac{1}{10}k1(5z^6 + 8z^5\alpha + 20c_1z^2\beta - 5(1+6k_2)z^4\beta^2) + c_2. \end{aligned}$$

We do not write here the value of $v_3(z)$ due to its length. Now, choosing the values of k_1, k_2, c_1, c_2 and c_3 we impose that $v_3(z) = 0$. One solution is $k_1 = 12/13$ and $k_2 = 16/13$ and $c_1 = c_2 = c_3 = 0$ which implies $v_k = 0$ for all $k \geq 3$. Consequently,

$$\mathcal{F} = y^{k_2}\Big(v_0\Big(\frac{x}{y}\Big) + v_1\Big(\frac{x}{y}\Big)y + v_2\Big(\frac{x}{y}\Big)y^2\Big) = \frac{2x^6 + 12ax^3y^2 + 3y^4}{3y^{36/13}}.$$

The inverse integrating factor for system (3.10) is obtained by multiplying $\mathcal{V} = \mathcal{F}^{\frac{13}{12}}$ by the Jacobian of the transformation and the change of time made, i.e.

$$V = y^3\mathcal{V} = y^3\mathcal{F}^{\frac{13}{12}} = \left(y^2 + x^2y + \frac{x^4}{2}\right)^{\frac{13}{12}}.$$

For a degenerate singular point the existence of an inverse integrating factor defined around the singular point does not guarantee the existence of a center at the singular point. In fact for system (4.7) an extra nonalgebraic condition in the parameters is needed, see [4, 23].

Abstract. In this paper, we consider of the following second-order Hamiltonian system

$$\ddot{u}(t) - L(t)u(t) + \nabla W(t, u(t)) = 0, \qquad \forall t \in \mathbb{R},$$

where $W(t,x)$ is subquadratic at infinity. With a competition condition, we establish the existence of homoclinic solutions by using the variational methods. In our theorem, the smallest eigenvalue function $l(t)$ of $L(t)$ is not necessarily coercive or bounded from above and $W(t,x)$ is not necessarily integrable on $\mathbb{R}$ with respect to t. Our theorem generalizes many known results in the references.

Keywords: Hamiltonian systems, homoclinic solutions, subquadratic potentials, competition condition, variational methods.

2020 Mathematics Subject Classification: 34C37, 35A15, 35B38.

1 Introduction

In this paper, we consider the following Hamiltonian system

$$\ddot{u}(t) - L(t)u(t) + \nabla W(t, u(t)) = 0, \qquad \forall t \in \mathbb{R}, \tag{1.1}$$

where $W \in C^1(\mathbb{R} \times \mathbb{R}^N, \mathbb{R})$, $L \in C\left(\mathbb{R}, \mathbb{R}^{N^2}\right)$ is a symmetric matrix valued function and $\nabla W(t,x)$ denotes the gradient with respect to the x variable. A nontrivial solution $u(t)$ of problem (1.1) is homoclinic if $u(t) \to 0$, $\dot{u}(t) \to 0$ as $t \to \pm\infty$ and $u(t) \not\equiv 0$.

The importance of homoclinic solutions for Hamiltonian systems in studying the dynamic behavior has been recognized. In recent years, many mathematicians used the variational methods to show the existence and multiplicity of homoclinic solutions for systems (1.1) with different growth conditions on $W(t,x)$. In this paper, we only consider the subquadratic cases. In [5], Ding assumed

✉Corresponding author. Email: wudl2008@163.com

(L') letting $l(t) \equiv \inf_{|q|=1}(L(t)q,q)$, there exists $\xi > 1$ such that

$$|t|^{-\xi} l(t) \to +\infty, \quad \text{as } |t| \to +\infty.$$

By (L'), Ding showed a compact embedding theorem from $H^1(\mathbb{R})$ to $L^p(\mathbb{R})$ for $p \in (1,+\infty]$. Under some other subquadratic conditions on $W(t,x)$ with respect to x, Ding obtained the existence and multiplicity of homoclinic solutions for systems (1.1). This result has been generalized by many mathematicians. For example, in [19], Zhang introduced condition

(L'') There exists a constant $l_0 > 0$ such that $l(t) + l_0 \geq 1$ for all $t \in \mathbb{R}$ and

$$\int_{\mathbb{R}} (l(t) + l_0)^{-1} \, dt < \infty. \tag{1.2}$$

By (L''), the embedding $H^1(\mathbb{R}) \hookrightarrow L^1(\mathbb{R})$ is compact. Obviously, (L'') is weaker than (L') and both of these two conditions yield that $l^{-1}(t)$ decays fast at infinity. When $l^{-1}(t)$ has a slow decay at infinity, it is difficult for us to obtain such compact embeddings. In this case, we can consider the decaying rate of $W(t,x)$ at infinity with respect to t. Let us consider the pure power nonlinearities with weight functions, i.e. $W(t,x) = a(t)|x|^\nu (\nu \in (1,2))$. In [23], Zhang and Yuan assumed that $a(t)$ belongs to $L^2(\mathbb{R},\mathbb{R}^+) \cap L^{\frac{2}{2-\nu}}(\mathbb{R},\mathbb{R}^+)$ to make sure the corresponding functional is well defined and show the convergence of the (PS) sequence. This condition is weakened by Sun, Chen and J. Nieto [12] by just requiring $a \in L^{\frac{2}{2-\nu}}(\mathbb{R},\mathbb{R}^+)$. In 2014, Lv and Tang [11] obtained homoclinic solutions for systems (1.1) with more general weight functions where $a \in L^p(\mathbb{R},\mathbb{R})$ for some $p \in \left(1, \frac{2}{2-\nu}\right]$. The readers are referred to [1–3, 6–10, 13–18, 20–22] for more details.

From above papers, we know that, the decaying rates of $l^{-1}(t)$ and $a(t)$ at infinity are important for us in finding homoclinic solutions of (1.1). There is an interesting question that whether systems (1.1) possesses homoclinic solutions when $a(t)$ is unbounded or $l(t)$ is oscillating (which means $\liminf_{|t|\to\infty} l(t) < +\infty$ and $\limsup_{|t|\to\infty} l(t) = +\infty$)? Motivated by the above analysis, we are encouraged to find a twisted condition between $l(t)$ and $a(t)$ which can be stated as follows:

$(W0)$ For $b \in [1,2]$ and $\mu \in (1,2)$, there exist $\gamma \in \left(b, \frac{2b}{2+b-b\mu}\right]$ and $k \in \left[0, \frac{\gamma-b}{b\gamma}\right]$ such that $\frac{a(t)}{(l(t))^k} \in L^\gamma(\mathbb{R})$.

More precisely, we obtain the following theorem.

Theorem 1.1. *Suppose that $(W0)$ holds for $b = 2$ and*

$(L1)$ *one of the following statements holds:*

(i) $L \in C^2(\mathbb{R},\mathbb{R}^{N^2})$ *and* $((L''(t) - \kappa L(t))x, x) \leq 0$ *for all* $|t| \geq \bar{r}_1$ *and* $x \in \mathbb{R}^N$;

(ii) $L \in C^1(\mathbb{R},\mathbb{R}^{N^2})$ *and* $|L'(t)x| \leq \kappa |L(t)x|$ *for all* $|t| \geq \bar{r}_1$ *and* $x \in \mathbb{R}^N$

with some $\kappa > 0$ *and* $\bar{r}_1 > 0$, *where* $L'(t) = (d/dt)L(t)$ *and* $L''(t) = (d^2/dt^2)L(t)$;

$(L2)$ *there exists* $M_0 > 0$ *such that* $l(t) \geq M_0$ *for all* $t \in \mathbb{R}$, *where* $l(t) \equiv \inf_{|u|=1}(L(t)u,u)$;

$(W1)$ $W(t,0) \equiv 0$, *there exists* $a \in C(\mathbb{R},\mathbb{R}^+)$ *such that* $|\nabla W(t,x)| \leq a(t)|x|^{\mu-1}$;

$(W2)$ *there exist* $\lambda \in (1,2)$, $\eta > 0$, $\zeta > 0$ *and open set* $\Omega \subset \mathbb{R}$ *such that*

$$W(t,x) \geq \eta |x|^\lambda, \qquad \forall (t,x) \in \Omega \times \mathbb{R}^N, |x| \leq \zeta.$$

Then system (1.1) possesses at least one nontrivial homoclinic solution.

$(L1)$ is assumed to show all the critical points of corresponding functional for systems

(1.1) are classical homoclinic solutions, which is introduced in [5]. In [11, 13, 18], the authors only considered the homoclinic solutions in sense of $u(t) \to 0$ as $|t| \to \infty$ while we consider the classical ones. To obtain the asymptotic behavior of the solutions at infinity, we can also consider the following condition

$(L3)$ there exist $\delta > 0$, $D > 0$, $q \in [1,2]$ and $r_0 > 0$ such that

$$\int_t^{t+\delta} \hat{l}^q(s)ds \le D$$

for all $|t| \ge r_0$, where $\hat{l}(t) \equiv \sup_{|u|=1}(L(t)u,u)$.

It is easy to see that $(L3)$ holds if all the eigenvalues of $L(t)$ are bounded from above. Then $(L3)$ can be seen as a generalization of the following bounded condition

$(L4)$ there exists $R > 0$ such that

$$(L(t)u,u) \le R|u|^2, \qquad \forall (t,u) \in \mathbb{R} \times \mathbb{R}^N.$$

Then we obtain the following theorem.

Theorem 1.2. *Suppose $(L2)$, $(L3)$, $(W1)$, $(W2)$ and $(W0)$ hold with $b = q$, then system (1.1) possesses at least one nontrivial homoclinic solution.*

Remark 1.3. In our theorems, condition $(W0)$ is a class of competition conditions between a and l. When $0 < \inf_{t\in\mathbb{R}} l(t) \le \sup_{t\in\mathbb{R}} l(t) < \infty$, $(W0)$ reduces to $a(t) \in L^\gamma(\mathbb{R})$, which is required in [12, 13, 18, 22]. There are examples satisfying the conditions of Theorems 1.1 and 1.2 but not the results in [2, 5, 7–14, 16–23].

Example 1.4 (Oscillating example for Theorem 1.1). Let $L(t) = l(t)Id_N$ and $W(t,x) = a(t)|x|^{\frac{8}{5}}$, where

$$l(t) = \begin{cases} \sin(\ln 2) + 1 & \text{for } |t| < 1, \\ t^{\frac{6}{7}}\left(\sin\left(\ln(t^2+1)\right) + 1\right) + 1 & \text{for } |t| \ge 1, \end{cases}$$

$$a(t) = t^{\frac{1}{20}}\left(\sin\left(\ln(t^2+1)\right) + 1\right)^{\frac{3}{10}}$$

and Id_N is the identity matrix of order N. It is easy to see that

$$\liminf_{|t|\to\infty} l(t) = 1, \quad \limsup_{|t|\to\infty} l(t) = +\infty, \quad \liminf_{|t|\to\infty} a(t) = 0 \quad \text{and} \quad \limsup_{|t|\to\infty} a(t) = +\infty.$$

Hence $l(t)$, $a(t)$ are neither coercive nor bounded from above and $l^{-1}(t)$, $(a(t))^p \notin L(\mathbb{R})$ for any $p \in (1,5]$. However, this example satisfies the conditions of Theorem 1.1 with $\gamma = 5$ and $k = \frac{3}{10}$. Here, we only need to show condition $(L1)$ is fulfilled while the other conditions can be easily checked. To check $(L1)$, we show (ii) holds, which can be verified by the following inequality

$$\left(\frac{6}{7}t^{-\frac{1}{7}}\sin\left(\ln(t^2+1)\right) + \frac{2t^{\frac{13}{7}}}{t^2+1}\cos\left(\ln(t^2+1)\right)\right)|x| \le \left(t^{\frac{6}{7}}\left(\sin\left(\ln(t^2+1)\right)+1\right)+1\right)|x|$$

for all $x \in \mathbb{R}^N$ and $|t|$ large enough.

Example 1.5 (Coercive example for Theorem 1.1)**.** There are also examples in which $l(t)$ and $a(t)$ are both coercive. Let $L(t) = \left(t^6+1\right) Id_N$ and $W(t,x) = t^{\frac{2}{5}}|x|^{\frac{3}{2}}$. If we choose $\gamma = 4$ and $k = \frac{1}{4}$, $(W0)$ is fulfilled. Moreover, other conditions of Theorem 1.1 can be easily checked. However this example does not satisfy the results in [2,5,7–14,17–23].

Example 1.6 (Oscillating example for Theorem 1.2)**.** Let

$$g(t) = \begin{cases} 2n^{\frac{8}{9}}\left(n^{\frac{8}{9}}+1\right)|t| - 2n^{\frac{17}{9}}\left(n^{\frac{8}{9}}+1\right), & n \le |t| < n + \frac{1}{2\left(n^{\frac{8}{9}}+1\right)}, \\ -2n^{\frac{8}{9}}\left(n^{\frac{8}{9}}+1\right)|t| + 2n^{\frac{17}{9}}\left(n^{\frac{8}{9}}+1\right) + 2n^{\frac{8}{9}}, & n + \frac{1}{2\left(n^{\frac{8}{9}}+1\right)} \le |t| \le n + \frac{1}{n^{\frac{8}{9}}+1}, \\ 0, & \text{otherwise} \end{cases} \tag{1.3}$$

and

$$m(t) = \begin{cases} 2n^{\frac{1}{72}}\left(n^{\frac{8}{9}}+1\right)|t| - 2n^{\frac{73}{72}}\left(n^{\frac{8}{9}}+1\right), & n \le |t| < n + \frac{1}{2\left(n^{\frac{8}{9}}+1\right)}, \\ -2n^{\frac{1}{72}}\left(n^{\frac{8}{9}}+1\right)|t| + 2n^{\frac{73}{72}}\left(n^{\frac{8}{9}}+1\right) + 2n^{\frac{1}{72}}, & n + \frac{1}{2\left(n^{\frac{8}{9}}+1\right)} \le |t| \le n + \frac{1}{n^{\frac{8}{9}}+1}, \\ 0, & \text{otherwise} \end{cases} \tag{1.4}$$

for all $n \in \mathbb{N} \cup \{0\}$. We see that $g(t), m(t) \ge 0$ and $g \notin L(\mathbb{R})$, $m \notin L(\mathbb{R})$. Let $a(t) = m(t) + e^{-|t|}$ and $L(t) = l(t) Id_N$, where $l(t) = \sqrt{g(t)+1}$. Obviously,

$$\liminf_{|t|\to\infty} l(t) = 1, \quad \limsup_{|t|\to\infty} l(t) = +\infty, \quad \liminf_{|t|\to\infty} a(t) = 0, \quad \limsup_{|t|\to\infty} a(t) = +\infty.$$

Choosing $q = 2$ and $\delta = \frac{1}{4}$, we deduce from the definitions of $\hat{l}$ and g that

$$\begin{aligned} \int_t^{t+\frac{1}{4}} \hat{l}^2(s) ds = \int_t^{t+\frac{1}{4}} l^2(s) ds = \int_t^{t+\frac{1}{4}} (g(s)+1) ds \\ \le \frac{1}{2}\left[\sum_{i=[|t|]-1,[|t|],[|t|]+1} \frac{i^{\frac{8}{9}}}{i^{\frac{8}{9}}+1}\right] + \frac{1}{4} \\ \le \frac{7}{4} \end{aligned}$$

for $|t|$ is large enough. Then $(L3)$ is checked. Moreover, $l^{-1}(t)$, $(a(t))^p \notin L(\mathbb{R})$ for any $p > 1$. Here we only give the proof for $(a(t))^p \notin L(\mathbb{R})$. It follows from the definition of $a(t)$ that

$$\begin{aligned} \int_{\mathbb{R}} a^p(s) ds &\ge \sum_{n=0}^{\infty} \int_n^{n+\frac{1}{2\left(n^{\frac{8}{9}}+1\right)}} m^p(s) ds \\ &= \sum_{n=0}^{\infty} \int_n^{n+\frac{1}{2\left(n^{\frac{8}{9}}+1\right)}} \left(2n^{\frac{1}{72}}\left(n^{\frac{8}{9}}+1\right)s - 2n^{\frac{73}{72}}\left(n^{\frac{8}{9}}+1\right)\right)^p ds \\ &= \sum_{n=0}^{\infty} \frac{n^{\frac{p}{72}}}{2(p+1)\left(n^{\frac{8}{9}}+1\right)} \\ &= +\infty \end{aligned}$$

which implies $(a(t))^p \notin L(\mathbb{R})$ for all $p > 1$. Finally, we show $(W0)$ is fulfilled with $b = q = 2$. Set $W(t,x) = a(t)|x|^{\frac{3}{2}}$. Choosing $\gamma = 4$ and $k = \frac{1}{4}$, from (1.3) and (1.4), we infer that

$$\begin{aligned}
&\int_{\mathbb{R}} \left(\frac{a(s)}{l^{\frac{1}{4}}(s)} \right)^4 ds \\
&\quad = \int_{\mathbb{R}} \frac{a^4(s)}{\sqrt{g(s)+1}} ds \\
&\quad \le \int_{\mathbb{R}} \frac{8\left(m^4(s) + e^{-4|s|}\right)}{\sqrt{g(s)+1}} ds \\
&\quad \le 8\int_{\mathbb{R}} \frac{m^4(s)}{\sqrt{g(s)}} ds + 8\int_{\mathbb{R}} e^{-4|s|} ds \\
&\quad \le 16 \sum_{n=0}^{\infty} n^{-\frac{63}{144}} \int_n^{n+\frac{1}{2\left(n^{\frac{8}{9}}+1\right)}} \left(2n^{\frac{1}{72}} \left(n^{\frac{8}{9}}+1\right) s - 2n^{\frac{73}{72}} \left(n^{\frac{8}{9}}+1\right) \right)^{\frac{7}{2}} ds \\
&\qquad + 16 \sum_{n=0}^{\infty} n^{-\frac{63}{144}} \int_{n+\frac{1}{2\left(n^{\frac{8}{9}}+1\right)}}^{n+\frac{1}{n^{\frac{8}{9}}+1}} \left(-2n^{\frac{1}{72}} \left(n^{\frac{8}{9}}+1\right) s + 2n^{\frac{73}{72}} \left(n^{\frac{8}{9}}+1\right) + 2n^{\frac{1}{72}} \right)^{\frac{7}{2}} ds + 4 \\
&\quad = \frac{32}{9} \sum_{n=0}^{\infty} \frac{n^{-\frac{7}{18}}}{n^{\frac{8}{9}}+1} + 4 \\
&\quad < +\infty.
\end{aligned}$$

Then all the conditions of Theorem 1.2 are satisfied. However, since a is not integrable or bounded, $l(t)$ is not bounded or coercive, our example does not satisfy the theorems in [2, 5, 8, 9, 11–14, 17, 18, 20–23].

2 Proof of Theorem 1.1

Set

$$E := \left\{ u \in H^1(\mathbb{R}, \mathbb{R}^N) : \int_{\mathbb{R}} (|\dot{u}(t)|^2 + (L(t)u(t), u(t)))dt < \infty \right\}$$

with

$$(u,v) = \int_{\mathbb{R}} ((\dot{u}(t), \dot{v}(t)) + (L(t)u(t), u(t)))dt.$$

By $(L2)$, the embedding $E \hookrightarrow L^p\left(\mathbb{R}, \mathbb{R}^N\right)$ is continuous for all $p \in [2, +\infty]$. Hence, for any $p \in [2, +\infty]$,

$$\|u\|_p \le C_p \|u\|, \qquad \forall u \in E \tag{2.1}$$

for some $C_p > 0$. Furthermore, let $I : E \to \mathbb{R}$ be the functional of (1.1) defined by

$$I(u) = \int_{\mathbb{R}} \left(\frac{1}{2}|\dot{u}(t)|^2 + \frac{1}{2}(L(t)u(t), u(t)) - W(t, u(t)) \right) dt. \tag{2.2}$$

First, we give the following useful estimate.

Lemma 2.1. *Let $u \in E$. For any $\theta > 0$ and $q \in [1,2]$, the following inequality holds*

$$|u(t)| \le \theta^{\frac{1}{q^*}-1} \left(\int_t^{t+\theta} |u(s)|^q ds \right)^{\frac{1}{q}} + \theta^{\frac{1}{q^*}} \left(\int_t^{t+\theta} |\dot{u}(s)|^q \, ds \right)^{\frac{1}{q}}, \qquad \forall t \in \mathbb{R}. \tag{2.3}$$

Furthermore, if $u \in C^2(\mathbb{R}, \mathbb{R}^N)$, there holds

$$|\dot{u}(t)| \le \theta^{\frac{1}{q^*}-1} \left(\int_t^{t+\theta} |\dot{u}(s)|^q ds \right)^{\frac{1}{q}} + \theta^{\frac{1}{q^*}} \left(\int_t^{t+\theta} |\ddot{u}(s)|^q \, ds \right)^{\frac{1}{q}}, \qquad \forall t \in \mathbb{R}, \tag{2.4}$$

where $\frac{1}{q} + \frac{1}{q^*} = 1$ ($q^* = +\infty$, if $q = 1$).

Proof. For any $t,\ \tau \in \mathbb{R}$,

$$|u(t)| \le |u(\tau)| + \left| \int_\tau^t \dot{u}(s) ds \right|.$$

Integrating over $[t, t+\theta]$, we get

$$\begin{aligned} \theta |u(t)| &\le \int_t^{t+\theta} |u(\tau)| d\tau + \int_t^{t+\theta} \left| \int_\tau^t \dot{u}(s) ds \right| d\tau \\ &\le \theta^{\frac{1}{q^*}} \left(\int_t^{t+\theta} |u(s)|^q ds \right)^{\frac{1}{q}} + \theta \int_t^{t+\theta} |\dot{u}(s)| \, ds \\ &\le \theta^{\frac{1}{q^*}} \left(\int_t^{t+\theta} |u(s)|^q ds \right)^{\frac{1}{q}} + \theta^{\frac{1}{q^*}+1} \left(\int_t^{t+\theta} |\dot{u}(s)|^q \, ds \right)^{\frac{1}{q}}, \end{aligned}$$

which implies

$$|u(t)| \le \theta^{\frac{1}{q^*}-1} \left(\int_t^{t+\theta} |u(s)|^q ds \right)^{\frac{1}{q}} + \theta^{\frac{1}{q^*}} \left(\int_t^{t+\theta} |\dot{u}(s)|^q \, ds \right)^{\frac{1}{q}}.$$

Then we obtain (2.3). Similarly, we can also obtain (2.4). □

Lemma 2.2. *Suppose $(L2)$, $(W0)$–$(W2)$ hold, then $I \in C^1(E, \mathbb{R})$ and*

$$\langle I'(u), v \rangle = \int_{\mathbb{R}} [(\dot{u}(t), \dot{v}(t)) + (L(t)u(t), v(t)) - (\nabla W(t, u(t)), v(t))] dt. \tag{2.5}$$

Moreover, all the critical points of I are homoclinic solutions of (1.1) if $(L1)$ holds with $b = 2$ or $(L3)$ holds with $b = q$ respectively.

Proof. First, we show that I is well defined. By $(W1)$, we infer that

$$|W(t, u(t))| = \left| \int_0^1 (\nabla W(t, su(t)), u(t)) ds \right| \le \frac{1}{\mu} a(t) |u(t)|^\mu, \qquad \forall (t, u) \in \mathbb{R} \times \mathbb{R}^N. \tag{2.6}$$

First, we consider a general case, i.e. $\gamma \in \left(1, \frac{2}{2-\mu}\right]$ and $k \in \left[0, \frac{\gamma-1}{\gamma}\right)$. For any $\Lambda \subset \mathbb{R}$, it follows from $(W0)$ and (2.1) that

$$\begin{aligned}
&\int_\Lambda a(t)|u(t)|^\mu dt\\
&\quad= \int_\Lambda \frac{a(t)}{(l(t))^k}(l(t))^k|u(t)|^\mu dt\\
&\quad\le \left(\int_\Lambda\left(\frac{a(t)}{(l(t))^k}\right)^\gamma dt\right)^{\frac{1}{\gamma}}\left(\int_\Lambda (l(t))^{\frac{k\gamma}{\gamma-1}}|u(t)|^{\frac{\mu\gamma}{\gamma-1}}dt\right)^{\frac{\gamma-1}{\gamma}}\\
&\quad= \left(\int_\Lambda\left(\frac{a(t)}{(l(t))^k}\right)^\gamma dt\right)^{\frac{1}{\gamma}}\left(\int_\Lambda (l(t))^{\frac{k\gamma}{\gamma-1}}|u(t)|^{\frac{2k\gamma}{\gamma-1}}|u(t)|^{\frac{(\mu-2k)\gamma}{\gamma-1}}dt\right)^{\frac{\gamma-1}{\gamma}}\\
&\quad\le \left(\int_\Lambda\left(\frac{a(t)}{(l(t))^k}\right)^\gamma dt\right)^{\frac{1}{\gamma}}\left[\left(\int_\Lambda l(t)|u(t)|^2dt\right)^{\frac{k\gamma}{\gamma-1}}\left(\int_\Lambda |u(t)|^{\frac{(\mu-2k)\gamma}{\gamma-1-k\gamma}}dt\right)^{\frac{\gamma-1-k\gamma}{\gamma-1}}\right]^{\frac{\gamma-1}{\gamma}}\\
&\quad\le \left(\int_\Lambda\left(\frac{a(t)}{(l(t))^k}\right)^\gamma dt\right)^{\frac{1}{\gamma}} C^{\mu-2k}_{\frac{(\mu-2k)\gamma}{\gamma-1-k\gamma}}\|u\|^\mu. \qquad (2.7)
\end{aligned}$$

When $k=\frac{\gamma-1}{\gamma}$, we have

$$\begin{aligned}
\int_\Lambda a(t)|u(t)|^\mu dt &= \int_\Lambda \frac{a(t)}{(l(t))^{\frac{\gamma-1}{\gamma}}}(l(t))^{\frac{\gamma-1}{\gamma}}|u(t)|^\mu dt\\
&\le \left(\int_\Lambda\left(\frac{a(t)}{(l(t))^{\frac{\gamma-1}{\gamma}}}\right)^\gamma dt\right)^{\frac{1}{\gamma}}\left(\int_\Lambda l(t)|u(t)|^{\frac{\mu\gamma}{\gamma-1}}dt\right)^{\frac{\gamma-1}{\gamma}}\\
&\le \left(\int_\Lambda\left(\frac{a(t)}{(l(t))^{\frac{\gamma-1}{\gamma}}}\right)^\gamma dt\right)^{\frac{1}{\gamma}}\left(\|u\|_\infty^{\frac{\mu\gamma}{\gamma-1}-2}\int_\Lambda l(t)|u(t)|^2dt\right)^{\frac{\gamma-1}{\gamma}}\\
&\le \left(\int_\Lambda\left(\frac{a(t)}{(l(t))^{\frac{\gamma-1}{\gamma}}}\right)^\gamma dt\right)^{\frac{1}{\gamma}}\|u\|_\infty^{\mu-\frac{2(\gamma-1)}{\gamma}}\|u\|^{\frac{2(\gamma-1)}{\gamma}}\\
&\le \left(\int_\Lambda\left(\frac{a(t)}{(l(t))^{\frac{\gamma-1}{\gamma}}}\right)^\gamma dt\right)^{\frac{1}{\gamma}} C_\infty^{\mu-\frac{2(\gamma-1)}{\gamma}}\|u\|^\mu. \qquad (2.8)
\end{aligned}$$

Since $\left(b,\frac{2b}{2+b-b\mu}\right]\subset\left(1,\frac{2}{2-\mu}\right]$ and $\left[0,\frac{\gamma-b}{b\gamma}\right]\subset\left[0,\frac{\gamma-1}{\gamma}\right]$ for all $b\in[1,2]$, (2.7) and (2.8) also hold when $\gamma\in\left(b,\frac{2b}{2+b-b\mu}\right]$ and $k\in\left[0,\frac{\gamma-b}{b\gamma}\right]$.

Choosing $\Lambda=\mathbb{R}$, we see I is well defined. Similar to Lemma 3.1 in [22], one shows $I\in C^1(E,\mathbb{R})$ and (2.5) holds. Finally, we show all the critical points of I are homoclinic solutions for (1.1), i.e. we need to show $u(t)\to 0$ and $\dot{u}(t)\to 0$ as $t\to\pm\infty$ if $u(t)$ is a critical point of I. We can easily deduce from (2.5) that $L(t)u-\nabla W(t,u)$ is the weak derivative of $\dot{u}$. Since $E\subset C^0\left(\mathbb{R},\mathbb{R}^N\right)$(the space of continuous functions), $W\in C^1\left(\mathbb{R}\times\mathbb{R}^N,\mathbb{R}\right)$ and $L\in C\left(\mathbb{R},\mathbb{R}^{N^2}\right)$, we know u is indeed in $C^2(\mathbb{R},\mathbb{R}^N)$. Obviously,

$$\int_t^{t+\theta}|u(s)|^q ds\le\theta^{\frac{2-q}{2}}\left(\int_t^{t+\theta}|u(s)|^2ds\right)^{\frac{q}{2}}\to 0\quad\text{as } |t|\to+\infty \qquad (2.9)$$

and

$$\int_t^{t+\theta}|\dot{u}(s)|^q ds\le\theta^{\frac{2-q}{2}}\left(\int_t^{t+\theta}|\dot{u}(s)|^2ds\right)^{\frac{q}{2}}\to 0\quad\text{as } |t|\to+\infty \qquad (2.10)$$

for any $\theta \in \mathbb{R}$. It follows from (2.3) that $u(t) \to 0$ as $|t| \to +\infty$. In order to prove $\dot{u}(t) \to 0$ as $|t| \to +\infty$, we show a useful estimate as follow. For any $b \in [1,2]$, it follows from $(W0)$ and (2.1) that

$$\begin{aligned}
&\int_{\mathbb{R}} |\nabla W(t,u(t))|^b dt \\
&\quad \le \int_{\mathbb{R}} a^b(t)|u(t)|^{b(\mu-1)} dt \\
&\quad = \int_{\mathbb{R}} \left(\frac{a(t)}{(l(t))^k}\right)^b (l(t))^{bk} |u(t)|^{b(\mu-1)} dt \\
&\quad \le \left(\int_{\mathbb{R}} \left(\frac{a(t)}{(l(t))^k}\right)^\gamma dt\right)^{\frac{b}{\gamma}} \left(\int_{\mathbb{R}} (l(t))^{\frac{bk\gamma}{\gamma-b}} |u(t)|^{\frac{b\gamma(\mu-1)}{\gamma-b}} dt\right)^{\frac{\gamma-b}{\gamma}} \\
&\quad \le \left(\int_{\mathbb{R}} \left(\frac{a(t)}{(l(t))^k}\right)^\gamma dt\right)^{\frac{b}{\gamma}} \left[\left(\int_{\mathbb{R}} l(t)|u(t)|^2 dt\right)^{\frac{bk\gamma}{\gamma-b}} \left(\int_{\mathbb{R}} |u(t)|^{\frac{b\gamma(\mu-1-2k)}{\gamma-b-bk\gamma}} dt\right)^{\frac{\gamma-b-bk\gamma}{\gamma-b}}\right]^{\frac{\gamma-b}{\gamma}} \\
&\quad \le \left(\int_{\mathbb{R}} \left(\frac{a(t)}{(l(t))^k}\right)^\gamma dt\right)^{\frac{b}{\gamma}} C_{\frac{b\gamma(\mu-1-2k)}{\gamma-b-bk\gamma}}^{b(\mu-1-2k)} \|u\|^{b(\mu-1)}. \qquad (2.11)
\end{aligned}$$

Similarly, when $k = \frac{\gamma-b}{b\gamma}$,

$$\begin{aligned}
\int_{\mathbb{R}} |\nabla W(t,u(t))|^b dt &\le \int_{\mathbb{R}} a^b(t)|u(t)|^{b(\mu-1)} dt \\
&= \int_{\mathbb{R}} \left(\frac{a(t)}{(l(t))^{\frac{\gamma-b}{b\gamma}}}\right)^b (l(t))^{\frac{\gamma-b}{\gamma}} |u(t)|^{b(\mu-1)} dt \\
&\le \left(\int_{\mathbb{R}} \left(\frac{a(t)}{(l(t))^{\frac{\gamma-b}{b\gamma}}}\right)^\gamma dt\right)^{\frac{b}{\gamma}} \left(\int_{\mathbb{R}} l(t)|u(t)|^{\frac{b\gamma(\mu-1)}{\gamma-b}} dt\right)^{\frac{\gamma-b}{\gamma}} \\
&\le \left(\int_{\mathbb{R}} \left(\frac{a(t)}{(l(t))^{\frac{\gamma-b}{b\gamma}}}\right)^\gamma dt\right)^{\frac{b}{\gamma}} \left[\|u\|_\infty^{\frac{b\gamma(\mu-1)}{\gamma-b}-2} \int_{\mathbb{R}} l(t)|u(t)|^2 dt\right]^{\frac{\gamma-b}{\gamma}} \\
&\le \left(\int_{\mathbb{R}} \left(\frac{a(t)}{(l(t))^{\frac{\gamma-b}{b\gamma}}}\right)^\gamma dt\right)^{\frac{b}{\gamma}} C_\infty^{b(\mu-1)-\frac{2(\gamma-b)}{\gamma}} \|u\|^{b(\mu-1)}. \qquad (2.12)
\end{aligned}$$

The following proof is divided into two cases.

Case 1. $(L1)$ holds with $b = 2$. Let $\mathcal{A}$ be the self-adjoint extension of $-(d^2/dt^2) + L(t)$ with $\mathfrak{D}(\mathcal{A}) \subset L^2(\mathbb{R}, \mathbb{R}^N)$. Since we have $(L2)$ and (i)(or (ii)) of $(L1)$, similar to Lemma 2.3 in [5], $\mathfrak{D}(\mathcal{A})$ is continuously embedded in $W^{2,2}(\mathbb{R}, \mathbb{R}^N)$. Making estimates as (2.9) and (2.10), it follows from (2.4) that $\dot{u}(t) \to 0$ as $|t| \to +\infty$ if $u \in \mathfrak{D}(\mathcal{A})$. Subsequently, we show all the critical points of I belong to $\mathfrak{D}(\mathcal{A})$. By (2.11) and (2.12) with $b = 2$, we see $\|\mathcal{A}u\|_{L^2}^2 = \int_{\mathbb{R}} |\nabla W(t,u(t))|^2 dt < \infty$. Then $u \in \mathfrak{D}(\mathcal{A})$, which shows u is a homoclinic solution for (1.1).

Case 2. $(L3)$ holds with $b = q$. Since $u \in C^2(\mathbb{R}, \mathbb{R}^N)$, we deduce from $(L3)$ and (2.4) that

$$|\dot{u}(t)| \le \delta^{\frac{1}{q^*}-1} \left(\int_t^{t+\delta} |\dot{u}(s)|^q ds\right)^{\frac{1}{q}} + \delta^{\frac{1}{q^*}} \left(\int_t^{t+\delta} |\ddot{u}(s)|^q ds\right)^{\frac{1}{q}}.$$

By (2.10), we only need to consider $\int_t^{t+\delta}|\ddot{u}(s)|^q ds$. Similar to Lemma 3.1 in [22], (2.11) and (2.12), for any $\gamma \in \left(q, \frac{2q}{2+q-q\mu}\right]$ and $k \in \left[0, \frac{\gamma-q}{q\gamma}\right]$

$$\begin{aligned}
&\int_t^{t+\delta}|\ddot{u}(s)|^q ds \\
&\le 2^{q-1}\int_t^{t+\delta}\left(|\nabla W(s,u(s))|^q + |L(s)u(s)|^q\right) ds \\
&\le 2^{q-1}M_1\left(\int_t^{t+\delta}\left(\frac{a(s)}{(l(s))^k}\right)^\gamma ds\right)^{\frac{q}{\gamma}}\|u\|^{q(\mu-1)} + 2^{q-1}\int_t^{t+\delta}\left|(L(s)u(s))^T L(s)u(s)\right|^{\frac{q}{2}} ds \\
&= 2^{q-1}M_1\left(\int_t^{t+\delta}\left(\frac{a(s)}{(l(s))^k}\right)^\gamma ds\right)^{\frac{q}{\gamma}}\|u\|^{q(\mu-1)} + 2^{q-1}\int_t^{t+\delta}\left|(u(s))^T L^2(s)u(s)\right|^{\frac{q}{2}} ds \\
&= 2^{q-1}M_1\left(\int_t^{t+\delta}\left(\frac{a(s)}{(l(s))^k}\right)^\gamma ds\right)^{\frac{q}{\gamma}}\|u\|^{q(\mu-1)} + 2^{q-1}\int_t^{t+\delta}\left|(L^2(s)u(s),u(s))\right|^{\frac{q}{2}} ds \\
&\le 2^{q-1}M_1\left(\int_t^{t+\delta}\left(\frac{a(s)}{(l(s))^k}\right)^\gamma ds\right)^{\frac{q}{\gamma}}\|u\|^{q(\mu-1)} + 2^{q-1}\left[\sup_{s\ge t}|u(s)|^q\right]\int_t^{t+\delta}\hat{l}^q(s) ds \\
&\to 0 \quad \text{as } |t|\to+\infty,
\end{aligned}$$

where

$$M_1 = \begin{cases} C^{q(\mu-1-2k)}_{\frac{q\gamma(\mu-1-2k)}{\gamma-q-qk\gamma}}, & k\in\left[0,\frac{\gamma-q}{q\gamma}\right), \\ C_\infty^{q(\mu-1)-\frac{2(\gamma-q)}{\gamma}}, & k=\frac{\gamma-q}{q\gamma}. \end{cases}$$

Thus u is a homoclinic solution for (1.1). □

In the next lemma, we show the functional I satisfies the classical Palais–Smale ((PS) for short) condition. We say that I satisfies the (PS) condition, if any sequence $(u_i)_i$ in E such that

$$(I(u_i))_i \text{ is bounded and } I'(u_i)\to 0,$$

admits a convergent subsequence.

Lemma 2.3. *Under $(L2)$, $(W0)$ and $(W1)$, I satisfies the (PS) condition.*

Proof. Let $\{u_i\}_{i\in\mathbb{N}} \subset E$ be a sequence such that $\{I(u_i)\}_{i\in\mathbb{N}}$ is bounded and $I'(u_i)\to 0$ as $i\to+\infty$. Then there exists $B>0$ such that $|I(u_i)|\le B$. By (2.2), (2.7) and (2.8) with $\Lambda=\mathbb{R}$, we have

$$\|u_i\|^2 = 2I(u_i) + 2\int_{\mathbb{R}} W(t,u_i(t))\,dt \le 2B + \frac{2M_2}{\mu}\left(\int_{\mathbb{R}}\left(\frac{a(t)}{(l(t))^k}\right)^\gamma dt\right)^{\frac{1}{\gamma}}\|u_i\|^\mu,$$

where

$$M_2 = \begin{cases} C^{\mu-2k}_{\frac{(\mu-2k)\gamma}{\gamma-1-k\gamma}}, & k\in\left[0,\frac{\gamma-1}{\gamma}\right), \\ C_\infty^{\mu-\frac{2(\gamma-1)}{\gamma}}, & k=\frac{\gamma-1}{\gamma}, \end{cases}$$

which implies $\{u_i\}_{i\in\mathbb{N}}$ is bounded in E. Hence, there exists $u_0\in E$(up to passing to a subsequence) such that $u_i \rightharpoonup u_0$ in E and

$$\begin{aligned}
&\langle I'(u_i)-I'(u_0), u_i-u_0\rangle \\
&\quad = \|u_i-u_0\|^2 - \int_{\mathbb{R}}\left(\nabla W(t,u_i(t)) - \nabla W(t,u_0(t)), u_i(t)-u_0(t)\right) dt \to 0 \qquad (2.13)
\end{aligned}$$

as $i \to \infty$. Moreover, there exists $M_3 > 0$ such that

$$\sup_{j\in\mathbb{N}} \|u_i\|_\infty \le M_3 \quad \text{and} \quad \|u_0\|_\infty \le M_3. \tag{2.14}$$

For any $\varepsilon > 0$ it follows from $(W0)$ that there exists $T > 0$ such that

$$\left(\int_{|t|>T} \left(\frac{a(t)}{(l(t))^k}\right)^\gamma dt\right)^{\frac{1}{\gamma}} < \varepsilon. \tag{2.15}$$

It follows from $(W0)$ and Sobolev's compact embedding theorem in bounded domain that

$$\begin{aligned}
&\int_{|t|\le T} (\nabla W(t,u_i(t)) - \nabla W(t,u_0(t)), u_i(t) - u_0(t))\, dt \\
&\quad \le \int_{|t|\le T} a(t)\left(|u_i(t)|^{\mu-1} + |u_0(t)|^{\mu-1}\right)|u_i(t) - u_0(t)|\, dt \\
&\quad \le a_0\left(\left(\int_{|t|\le T}|u_i(t)|^\mu\right)^{\frac{\mu-1}{\mu}} + \left(\int_{|t|\le T}|u_0(t)|^\mu\right)^{\frac{\mu-1}{\mu}}\right)\left(\int_{|t|\le T}|u_i(t)-u_0(t)|^\mu\right)^{\frac{1}{\mu}} \\
&\quad \le \varepsilon
\end{aligned} \tag{2.16}$$

for i large enough, where $a_0 = \max_{|t|\le T} a(t)$. By $(W0)$, (2.7) and (2.8) with $\Lambda = \mathbb{R} \setminus [-T, T]$, one has

$$\begin{aligned}
&\int_{|t|>T} (\nabla W(t,u_i(t)) - \nabla W(t,u_0(t)), u_i(t) - u_0(t))\, dt \\
&\quad \le \int_{|t|>T} |\nabla W(t,u_i(t)) - \nabla W(t,u_0(t)\|u_i(t) - u_0(t)| dt \\
&\quad \le \int_{|t|>T} a(t)\left(|u_i(t)|^{\mu-1} + |u_0(t)|^{\mu-1}\right)(|u_i(t)| + |u_0(t)|)\, dt \\
&\quad \le 3\int_{|t|>T} a(t)\left(|u_i(t)|^\mu + |u_0(t)|^\mu\right) dt \\
&\quad \le 3M_2\left(\int_{|t|>T}\left(\frac{a(t)}{(l(t))^k}\right)^\gamma dt\right)^{\frac{1}{\gamma}}\left(\|u_i\|^\mu + \|u_0\|^\mu\right).
\end{aligned} \tag{2.17}$$

By the arbitrariness of ε, (2.15) and (2.17), we obtain

$$\int_{|t|>T} (\nabla W(t,u_i(t)) - \nabla W(t,u(t)), u_i(t) - u_0(t))\, dt \to 0 \quad \text{as } i \to +\infty. \tag{2.18}$$

Together with (2.16), we obtain

$$\int_{\mathbb{R}} (\nabla W(t,u_i(t)) - \nabla W(t,u(t)), u_i(t) - u_0(t))\, dt \to 0 \quad \text{as } i \to +\infty.$$

Consequently, we infer from (2.13) and (2.18) that $\|u_i - u_0\| \to 0$ as $i \to +\infty$. □

Proof of Theorem 1.1. By (2.2), (2.6) and (2.7) with $\Lambda = \mathbb{R}$, for any $u \in E$, we get

$$\begin{aligned}
I(u) &= \frac{1}{2}\|u\|^2 - \int_{\mathbb{R}} W(t,u(t))dt \\
&\ge \frac{1}{2}\|u\|^2 - \frac{1}{\mu}\int_{\mathbb{R}} a(t)|u(t)|^\mu dt \\
&\ge \frac{1}{2}\|u\|^2 - \frac{M_2}{\mu}\left(\int_{\mathbb{R}}\left(\frac{a(t)}{(l(t))^k}\right)^\gamma dt\right)^{\frac{1}{\gamma}}\|u\|^\mu,
\end{aligned}$$

which implies that $I(u) \to +\infty$ as $\|u\| \to +\infty$. Thus I is bounded from below and satisfies the (PS) condition. Then there exists $\bar{u}$ such that $I(\bar{u}) = c = \inf_E I(u)$. We also need to show that $\bar{u} \not\equiv 0$. Letting $\varphi \in C_0^\infty(\Omega, \mathbb{R}^N) \setminus \{0\}$ and $s > 0$, it follows from (2.2) and $(W2)$ that

$$\begin{aligned} I(s\varphi) &= \frac{s^2}{2}\|\varphi\|^2 - \int_{\mathbb{R}} W(t, s\varphi(t))\, dt \\ &= \frac{s^2}{2}\|\varphi\|^2 - \int_{\Omega} W(t, s\varphi(t))\, dt \\ &\leq \frac{s^2}{2}\|\varphi\|^2 - \eta s^\lambda \int_{\Omega} |\varphi(t)|^\lambda\, dt, \end{aligned}$$

which implies $I(s\varphi) < 0$ when $s > 0$ small enough. Then we can deduce that $\inf_E I(u) < 0$, which implies that $\bar{u} \not\equiv 0$. □

Proof of Theorem 1.2. The only difference between Theorems 1.1 and 1.2 is the way to obtain the asymptotic behavior of the solutions for (1.1) at infinity. This has been shown in the proof of Lemma 2.2. The remaining part is similar to Theorem 1.1, we omit it here. □

Abstract. In this paper, we devote ourselves to considering a modified zero energy critical point theory for a specific set of functionals denoted as Φ_μ, defined within the confines of a uniformly convex Banach space. Integrating the nonlinear generalized Rayleigh quotient approach with Ljusternik–Schnirelman category, we establish the nonexistence and multiplicity of zero energy critical points of the involved functionals. In particular, the modified zero energy critical point theory can be applied to more nonlocal problems. Our main results improve and complement the existing results in the related literature.

Keywords: Ljusternik–Schnirelman category, nonlinear generalized Rayleigh quotient, zero energy critical points.

2020 Mathematics Subject Classification: 35A15, 35B33, 35J60.

1 Introduction

In the past decades, researchers have used classical variational methods to deal with various nonlocal problems and obtained various properties of their solutions, such as existence, multiplicity, asymptotic behavior and so on. However, although the classical variational methods have been properly modified, it seems still difficult to be directly effective for some complicated or special nonlocal problems. Based on this situation, the research on new variational methods has aroused increasing interest. It is worth mentioning that in this process, the existence of the number and index theory makes the Ljusternik–Schnirelman category theory more widely used. For more detailed applications of this theory, we refer to [18, 33] and references therein. Along this direction, in this paper we employ the Ljusternik–Schnirelman category theory and the nonlinear generalized Rayleigh (NG-Rayleigh) quotient method to forge a critical point theory at zero energy levels for the energy functional (1.1). By means of this theory, we deal with several kinds of nonlocal problems, and present the nonexistence and multiplicity of their solutions at zero energy levels. More precisely, we consider $\Phi_\mu : X \to \mathbb{R}$

$$\Phi_\mu(u) := \frac{1}{\eta}N(u) - \frac{\mu}{\eta}A(u) - \frac{1}{\beta}B(u) + \frac{1}{\gamma}R(u), \tag{1.1}$$

the setting is within X, a uniformly convex Banach space endowed with the norm $|\cdot|_X$, where $1 < \eta < \gamma < \beta$. Moreover, the functionals N, A, B, and R are considered to be homogeneous, nonnegative, and even, belonging to the class $C^1(X)$.

Throughout this paper, the following assumptions are imposed on the above-mentioned nonnegative even functionals:

($\mathcal{M}_1$) For any $u \in X\backslash\{0\}$, there exists $C > 0$ such that the following inequalities hold:

$$C\|u\|_X^\eta \geq A(u) > 0, \qquad C\|u\|_X^\beta \geq B(u) > 0, \qquad R(u) > 0, \qquad N(u) \geq C^{-1}\|u\|_X^\eta;$$

($\mathcal{M}_2$) $N(tu) = t^\eta N(u), A(tu) = t^\eta A(u), B(tu) = t^\beta B(u), R(tu) = t^\gamma R(u)$, for any $t > 0$;

($\mathcal{M}_3$) If $u_n \rightharpoonup u$ in X, then $A'(u_n) \to A'(u)$ and $B'(u_n) \to B'(u)$ in X^*. Moreover, for any $u_n, u \in X$, it holds that $R'(u_n)(u_n - u) \geq 0$.

($\mathcal{M}_4$) Let N be weakly lower semicontinuous, and there exists $C > 0$ such that for every $u_n, u \in X$, the inequality

$$(N'(u_n) - N'(u))(u_n - u) \geq C(\|u_n\|^{\eta-1} - \|u\|^{\eta-1})(\|u_n\| - \|u\|)$$

holds true.

According to assumption ($\mathcal{M}_1$), we know that $A(u) > 0$ for all $u \in X \setminus \{0\}$. Therefore, $\Phi_\mu(u) = 0$ is equivalent to

$$\mu = \mu_0(u) := \frac{N(u) - \frac{\eta}{\beta}B(u) + \frac{\eta}{\gamma}R(u)}{A(u)}, \quad \text{for any } u \in X \setminus \{0\},$$

where $\mu_0(u)$ is called the Rayleigh quotient, the functional is derived using the NG-Rayleigh quotient approach. For any $u \in X \setminus \{0\}$,

$$\mu_0'(u) = \frac{\Phi'_{\mu_0(u)}(u)}{A(u)} = 0,$$

if and only if $\Phi'_\mu(u) = 0$.

We will search for the critical points of μ_0 by considering the fibering map $t \mapsto \mu_0(tu)$. Obviously, $\mu_0(tu) \in C^2(0,\infty)$ for every $u \in X \setminus \{0\}, u \mapsto \mu_0'(tu) \in C^1(X \setminus \{0\})$ for every $t > 0$. In order to get the critical point of $\mu_0(tu)$, from ($\mathcal{M}_2$) it follows that

$$\mu_0(tu) = \frac{N(u)}{A(u)} - \frac{\eta}{\beta}\frac{B(u)}{A(u)}t^{\beta-\eta} + \frac{\eta}{\gamma}\frac{R(u)}{A(u)}t^{\gamma-\eta}, \quad \text{for any } u \in X \setminus \{0\},\ t > 0.$$

Let

$$\mu_0'(tu) = -(\beta - \eta)\frac{\eta}{\beta}\frac{B(u)}{A(u)}t^{\beta-\eta-1} + (\gamma - \eta)\frac{\eta}{\gamma}\frac{R(u)}{A(u)}t^{\gamma-\eta-1} = 0.$$

Then

$$t_0(u) = \left(\frac{\gamma - \eta}{\beta - \eta}\frac{\beta}{\gamma}\frac{R(u)}{B(u)}\right)^{\frac{1}{\beta-\gamma}},$$

that is $\mu_0'(t_0(u)u) = 0$. Since $\mu_0''(t_0(u)u) < 0$, we obtain that $t_0(u)$ is a non-degenerate global maximum point of $\mu_0(tu)$.

Define

$$\Lambda(u) := \mu_0(t_0(u)u) = \left(\frac{N(u)}{A(u)} - \frac{\eta}{\beta}\frac{B(u)}{A(u)}t_0(u)^{\beta-\eta} + \frac{\eta}{\gamma}\frac{R(u)}{A(u)}t_0(u)^{\gamma-\eta}\right)$$
$$= \frac{N(u)}{A(u)} + C_0\frac{R(u)^{\frac{\beta-\eta}{\beta-\gamma}}}{A(u)B(u)^{\frac{\gamma-\eta}{\beta-\gamma}}},$$

as a NG-Rayleigh quotient. It is obvious that $t_0(u)u$ can be considered as the zero energy critical point of Φ_μ, where $\mu = \Lambda(u)$. One may easily check that $\Lambda \in C^1(X\backslash\{0\})$,

$$\Lambda'(u)v = \frac{A(u)N'(u)v - N(u)A'(u)v}{A(u)^2}$$
$$+ C_0Q(u)\left(\frac{\beta-\eta}{\beta-\gamma}B(u)A(u)R'(u)v - \frac{\gamma-\eta}{\beta-\gamma}R(u)A(u)B'(u)v - B(u)R(u)A'(u)v\right),$$

for every $u \in X\backslash\{0\}, v \in X$, where

$$C_0 = \frac{\eta}{\gamma}\frac{\beta-\gamma}{\beta-\eta}\left(\frac{\gamma-\eta}{\beta-\eta}\frac{\beta}{\gamma}\right)^{\frac{\gamma-\eta}{\beta-\gamma}} > 0, \qquad Q(u) = \frac{R(u)^{\frac{\gamma-\eta}{\beta-\gamma}}}{A(u)^2B(u)^{\frac{\beta-\eta}{\beta-\gamma}}}.$$

To better utilize the Ljusternik–Schnirelman category theory, we first denote $\widetilde{\Lambda}$ as Λ on $S = \{u \in X\backslash\{0\} : \|u\| = 1\}$, where S is considered as a unit sphere in X and is a symmetric C^1 manifold. According to [28, Proposition 2.3], the critical point of $\widetilde{\Lambda}$ is also the critical point of Λ. Since $N(u), A(u), B(u), R(u)$ are even functionals, $\widetilde{\Lambda}$ is also an even functional. Now, let us recall the concept of Krasnoselskii genus. Given a set $F \subset S$, it is closed, nonempty and symmetric. We define

$$\gamma(F) := \inf\{n \in \mathbb{N} : \exists h : F \to \mathbb{R}^n \setminus \{0\} \text{ odd and continuous}\}.$$

to represent the Krasnoselskii genus of F. Setting

$$\mathcal{F}_n = \{F \subset S : F \text{ is compact, symmetric, and } \gamma(F) \geq n\},$$

for every $n \in \mathbb{N}$. Define the critical value of $\widetilde{\Lambda}$:

$$\mu_n := \inf_{F\in\mathcal{F}_n}\sup_{u\in F}\widetilde{\Lambda}, \text{ if } \widetilde{\Lambda} \text{ is bounded from below on } S.$$

It is well-known that the Krasnoselskii genus of the unit sphere in an infinite dimensional Banach space is infinite (cf. [13, Corollary 2.3]), namely, $\gamma(S) = \infty$.

Next, let us sketch some recent advances concerning the zero energy critical point theory. Recently, Quoirin et al. studied qualitative properties of zero energy critical points in [28], which means that at this point, the energy function and its derivatives are both zero. Furthermore, the authors in [28] established a new zero energy critical point theory using the NG-Rayleigh quotient method and Ljusternik–Schnirelman critical theory [2], and effectively applied it to several types of elliptic partial differential equations, resulting in the existence, nonexistence, and multiplicity of zero energy critical points. For more details on the NG-Rayleigh method, we refer to [19, 20] and references therein. Undoubtedly, the zero energy critical point theory established in paper [28] provides us with a new idea and perspective for solving nonlinear partial differential equations. As one of the advantages of this theory, it has a wide range of theoretical applications, that is, it can directly handle many types of nonlinear non-local problems, such as concave-convex problem, Schrödinger–Poisson problem, Kirchhoff-type problem, (p,q)-Laplace problem, and other elliptic problems. As a pioneer paper on zero energy critical point theory, the authors in [28] applied this theory to solve several local and non-local problems. For example, the following p-Laplacian problem with concave and convex nonlinearity was investigated in a bounded domain $\Omega \subset \mathbb{R}^N$:

$$\begin{cases} -\Delta_p u = \mu|u|^{q-2}u + f|u|^{r-2}u, & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.2}$$

where $1 < q < p < r < p^*$, $f, g \in L^\infty(\Omega)$ with $g > 0$ in Ω, Δ_p is p-Laplaian operator, and $f > 0$ in some subdomain $\Omega' \subset \Omega$. With the help of the NG-Rayleigh quotient method and Ljusternik–Schnirelman theory, the authors obtained the existence, non-existence and multiplicity of zero energy solutions for concave and convex problems in [28].

On the other hand, the authors in [28] also considered the properties of the zero energy solution for the Schrödinger-Poisson system, which is physically meaningful. To elaborate, the authors conducted a comprehensive investigation into the intricacies of the following system:

$$\begin{cases} -\Delta u + \omega u + \mu\phi u = |u|^{p-2}u, & \text{in } \mathbb{R}^3, \\ -\Delta u + a^2\Delta^2 u = 4\pi u^2 & \text{in } \mathbb{R}^3, \end{cases} \tag{1.3}$$

where $p \in (2,3), \omega > 0$, and $a \geq 0$. In particular, the authors established the existence, non-existence, multiplicity and sign-changing properties of the zero energy radial solution of system (1.3). Subsequently, Quoirin et al. in [29] established the existence, multiplicity and bifurcation results of the critical points for a class of functionals with prescribed energy along the same technical route as in [28]. The authors first applied the corresponding critical point theory of prescribed energy to eigenvalue problems involving nonhomogeneous perturbations in [29], and its energy functional can be given by:

$$\Phi_\mu(u) = \frac{1}{p}(|\nabla u|_p^p - \mu|u|_p^p) - \frac{1}{r}|u|_r^r,\ u \in W_0^{1,p}(\Omega), \quad \text{where } 1 < r < p^*.$$

The authors made a noteworthy discovery regarding the Schrödinger–Poisson system. Specifically, for $c > 0$ (respectively, $c < 0$) and by choosing $p < r$ (respectively, $p > r$), the study revealed the existence of an infinite number of pairs $(\mu_{n,c}, u_{n,c}) \in \mathbb{R} \times W_0^{1,p}(\Omega) \setminus \{0\}$ satisfying $\Phi_{\mu_{n,c}}(\pm u_{n,c}) = c$ and $\Phi'_{\mu_{n,c}}(\pm u_{n,c}) = 0$. In other words, $\pm u_n$ represent prescribed energy critical points.

The authors next investigated the prescribed energy critical point of the Schrödinger–Bopp–Podolsky problem in [29]. The following represents the energy functional for this particular problem:

$$\Phi_\mu(u) = \frac{1}{2}\int_{\mathbb{R}^3} |\nabla u|^2 dx + \frac{\omega}{2}\int_{\mathbb{R}^3} |u|^2 dx + \frac{\mu}{4}\int_{\mathbb{R}^3} \phi u^2 dx - \frac{1}{p}\int_{\mathbb{R}^3} |u|^p dx, \text{ where } p \in (2,3), \omega > 0.$$

The authors obtained the existence and multiplicity of the critical point with prescribed energy by the critical point theory. Besides, the authors also conducted relevant research on the concave-convex problem in [29], and we will not elaborate on it here.

Motivated by [28, 29], we are interested in making appropriate modifications and extensions according to the existing zero energy critical point theory so that it can be applied to some specific situations. Along this direction, we propose a suitable class of energy functional (1.1). We point out that the purpose of this paper is to address the problem of energy functional (1.1) in the following situation:

$$\Phi'_\mu(u) = 0, \qquad \Phi_\mu(u) = 0.$$

Let $\delta_0 = \inf_{X\setminus\{0\}} \Lambda(u)$. Then the primary result of our article can be stated as:

Theorem 1.1. *Suppose that $(\mathcal{M}_1)$–$(\mathcal{M}_4)$ hold.*

(i) If $\mu < \delta_0$, then there is no critical point having zero energy for the energy functional Φ_μ.

(ii) If $\mu > \delta_0$, then the energy functional Φ_μ has infinitely many zero energy critical points which change sign.

Remark 1.2. At the beginning, we attempt to investigate the qualitative properties for some nonlocal problems in $\mathbb{R}^N$ by employing Theorem 1.1. But the embedding $H^1_r(\mathbb{R}^N) \hookrightarrow L^p(\mathbb{R}^N)$ is compact only for $2 < p < 2^*$, we cannot verify assumption $(\mathcal{M}_3)$ if problems under consideration are involved the critical exponents. Inspired by [28], we give a modified version of Theorem 3.1 in [28], so that we are able to deal with Schrödinger–Poisson systems with critical nonlinearity.

Remark 1.3. In order to deal with Kirchhoff-type problems with critical growth in bounded domains, we follow the idea of proof in Lemma 3.3 of [21] to detour the compact embedding theorem, hence assumption $(\mathcal{M}_3)$ can be verified, which leads to the nonexistence and multiplicity of zero energy critical points for the following Kirchhoff problem with critical nonlinearity.

Notations. Throughout this paper, the following notions are employed:

- Denote $|\cdot|_q$ for the $L^q(\mathbb{R}^N)$-norm for $q \in [1, \infty]$;
- Denote various positive constants by $C, C_0, C_1, C_2, C_3, \ldots$;
- Let $D^{1,2}(\mathbb{R}^3)$ be the completion of $C_0^\infty(\mathbb{R}^3)$ with the norm $\|u\|_{D^{1,2}(\mathbb{R}^3)} = \left(\int_{\mathbb{R}^3} |\nabla u|^2\right)^{\frac{1}{2}}$.

2 Proof of Theorem 1.1

In this proof, we refer to the technical approach demonstrated by [28] to prove Theorem 1.1. In order to supplement and enrich the zero energy critical point theory, we give a modified result, which can be applied to a wider range of nonlocal Lapalcian equations. Based on the Ljusternik–Schnirelman category (see [32, Theorem 5.7]), we only need to prove that $\widetilde{\Lambda}$ satisfies the Palais–Smale condition and is bounded from below on the unit sphere S.

Lemma 2.1. *Assume $(\mathcal{M}_1)$ holds, then $\widetilde{\Lambda}$ is bounded from below on S.*

Proof. From $(\mathcal{M}_1)$, for all $u \in S$,

$$\frac{N(u)}{A(u)} \geq \frac{C^{-1}\|u\|^\eta}{C\|u\|^\eta} = \frac{1}{C^2}, \qquad \frac{R(u)^{\frac{\beta-\eta}{\beta-\gamma}}}{B(u)^{\frac{\gamma-\eta}{\beta-\gamma}} A(u)} > 0.$$

Then

$$\widetilde{\Lambda} = \frac{N(u)}{A(u)} + C_0 \frac{R(u)^{\frac{\beta-\eta}{\beta-\gamma}}}{A(u)B(u)^{\frac{\gamma-\eta}{\beta-\gamma}}} > \frac{1}{C^2}.$$

Therefore, $\widetilde{\Lambda}$ is bounded from below on S. □

A crucial proposition required to validate the Palais–Smale condition for $\widetilde{\Lambda}(u)$ is as follows:

Lemma 2.2. *Assume that* $(u_n) \subset S$, $\widetilde{\Lambda}'(u_n) \to 0$, *then* $\Lambda'(u_n)(u_n - u) \to 0$ *as* $n \to \infty$.

Proof. Since $(u_n) \subset S = \{u \in X \backslash \{0\} : \|u\| = 1\}$, we see that $\|u_n\| = 1$. According to S is weakly closed and (u_n) is bounded in S, we can attain $u_n \rightharpoonup u$ in S. Let $\mathcal{T}_S(u) = \{v \in X : i'(u)v = 0\}$, at the point u, $\mathcal{T}_S(u)$ represents the tangent space to the set S, where $i(u) = \frac{1}{2}\|u\|^2$. Note that, for any $w \in X$ and any $n \in \mathbb{N}$, the pair $(t_n, v_n) \in \mathbb{R} \times \mathcal{T}_S(u_n)$ is uniquely identified, ensuring $w = v_n + t_n u_n$ and subsequently, $i'(u_n)w = i'(u_n)v_n + i'(u_n)t_n u_n$. According to the definition of $\mathcal{T}_S(u)$, we can obtain that $i'(u_n)v_n = 0, i'(u_n)u_n = \|u_n\|^2 = 1$. Therefore, $i'(u_n)w = t_n i'(u_n)u_n = t_n$. Then, (t_n) is bounded, consequently, (v_n) is also bounded. Since $\widetilde{\Lambda}'(u_n) \to 0$, namely, $|\Lambda'(u_n)v_n| \leq \varepsilon_n \|v_n\|$ for any $v_n \in \mathcal{T}_S(u_n)$ with $\varepsilon_n \to 0$, we have $\Lambda'(u_n)v_n \to 0$. According to the Lemma 2.1 of [28] we obtain that $\Lambda'(u_n)u_n = 0$. We conclude that $\Lambda'(u_n)w \to 0$ for any $w \in X$. Taking $w = u_n - u$, we get that $\Lambda'(u_n)(u_n - u) \to 0$, as $n \to \infty$. □

Lemma 2.3. *Assume that* $(\mathcal{M}_1), (\mathcal{M}_3), (\mathcal{M}_4)$ *hold, then* $\widetilde{\Lambda}$ *satisfies the Palais–Smale condition.*

Proof. Choose $(u_n) \subset S$ such that $(\widetilde{\Lambda}(u_n))$ is bounded and $\widetilde{\Lambda}'(u_n) \to 0$, i.e. $|\Lambda'(u_n)v| \leq \varepsilon_n \|v\|$ for any $v \in \mathcal{T}_S(u_n)$, with $\varepsilon_n \to 0$. By Lemma 2.2, together with the fact that $(u_n) \subset S$, $\widetilde{\Lambda}'(u_n) \to 0$, we know that

$$u_n \rightharpoonup u \quad \text{in } S, \qquad \Lambda'(u_n)(u_n - u) \to 0.$$

Then, for any $u_n, u \in S$,

$$\begin{aligned} &\Lambda'(u_n)(u_n - u) \\ &\quad = \frac{A(u_n)N'(u_n)(u_n - u) - N(u_n)A'(u_n)(u_n - u)}{A(u_n)^2} \\ &\qquad + C_0 Q(u_n) \left(\frac{\beta - \eta}{\beta - \gamma} B(u_n)A(u_n)R'(u_n)(u_n - u) \right. \\ &\qquad\qquad - \frac{\gamma - \eta}{\beta - \gamma} R(u_n)A(u_n)B'(u_n)(u_n - u) \\ &\qquad\qquad \left. - B(u_n)R(u_n)A'(u_n)(u_n - u) \right) \to 0. \end{aligned} \tag{2.1}$$

According to $(\mathcal{M}_1)$, we can infer that $A(u_n), B(u_n)$ is bounded, $N(u_n), R(u_n)$ is bounded away from zero. Since $(\widetilde{\Lambda}(u_n))$ is bounded, we know that $Q(u_n)$ is bounded. In the light of (M_3), we can obtain

$$A'(u_n)(u_n - u) \to 0, \qquad B'(u_n)(u_n - u) \to 0.$$

The above analysis leads to the following conclusion:

$$\left(N'(u_n) + R'(u_n)\right)(u_n - u) \to 0.$$

According to $(\mathcal{M}_3)$, we obtain $R'(u_n)(u_n - u) \geq 0$. From $(\mathcal{M}_4)$, we have

$$(N'(u_n) - N'(u))(u_n - u) \geq C(\|u_n\|^{\eta-1} - \|u\|^{\eta-1})(\|u_n\| - \|u\|) \geq 0$$

for every $u_n, u \in S$. Moreover, $u_n \rightharpoonup u$ in S, we have $N'(u)(u_n - u) \to 0$, then $N'(u_n)(u_n - u) \geq 0$. Therefore, we can conclude that $N'(u_n)(u_n - u) \to 0$. Since $(N'(u_n) - N'(u))(u_n - u) \to 0$, we obtain $\|u_n\| \to \|u\|$. Note that X is a reflexive Banach space and $u_n \rightharpoonup u$ in S, which imply that $u_n \to u$ in S. This completes the proof. □

Proof of Theorem 1.1.

(1) We prove that there is no critical point having zero energy when $\mu < \delta_0$. Note that u is a critical point of Λ, if and only if, $t_0(u)u$ is a zero energy critical point of Φ_μ with $\mu = \Lambda(u)$. In other words, this means that

$$\delta_0 = \inf_{X\setminus\{0\}} \Lambda(u) \leq \mu \leq \sup_{X\setminus\{0\}} \Lambda(u),$$

which yields the desired conclusion.

(2) According to Lemma 2.1, we know that $\widetilde{\Lambda}$ is bounded from below on S. Moreover, Lemma 2.3 implied that $\widetilde{\Lambda}$ satisfies the Palais–Smale condition. Note that $\hat{\gamma}(S) = \infty$, we get from Ljusternik–Schnirelman category (see [32, Theorem 5.7]) that there exists a sequence $(u_n) \subset S$ such that $\widetilde{\Lambda}'(u_n) = 0, \widetilde{\Lambda}(u_n) = \mu_n$. Therefore, the energy functional Φ has infinitely many zero energy sign changing critical points $(u_n) \subset S$.

3 Applications of Theorem 1.1

In this section, we shall prove the nonexistence of solutions and the existence of infinitely many solutions for three non-local problems, we confirm that these are just a small part of applications of Theorem 1.1.

3.1 Critical Schrödinger–Poisson system in the whole space

In this subsection, let us consider a Schrödinger–Poisson system with p-Laplacian:

$$\begin{cases} -\Delta_p u + |u|^{p-2}u + \lambda\phi u = |u|^{p^*-2}u + \mu|u|^{p-2}u, & \text{in } \mathbb{R}^3, \\ -\Delta\phi = u^2, & \text{in } \mathbb{R}^3, \end{cases} \tag{3.1}$$

where $\lambda > 0$ is a constant, $12/7 < p < 3$, $p^* := 3p/(3-p)$, and $\Delta_p = \operatorname{div}\left(|\nabla u|^{p-2}\nabla u\right)$ is the p-Laplacian. The p-Laplacian operator appears in nonlinear fluid dynamics, and the range of p is related to the velocity of the fluid and material. For more information on the physical origin of p-Laplacian, we refer to [9]. For any given $u \in W^{1,p}(\mathbb{R}^3)$, there exists a unique

$$\phi_u(x) = \frac{1}{4\pi}\int_{\mathbb{R}^3} \frac{|u(y)|^2}{|x-y|}\mathrm{d}y, \qquad \phi_u \in D^{1,2}\left(\mathbb{R}^3\right),$$

satisfying $-\Delta\phi_u = |u|^2$ (see [17]).

The system (3.1) can be viewed as a perturbation of the system

$$\begin{cases} -\Delta_p u + |u|^{p-2}u + \lambda\phi u = |u|^{q-2}u, & \text{in } \mathbb{R}^3, \\ -\Delta\phi = u^2, & \text{in } \mathbb{R}^3. \end{cases} \tag{3.2}$$

Du, Su and Wang first considered this system in [16], they established the existence of nontrivial solutions through the mountain pass theorem. Systems like (3.2) originate from quantum mechanics models [10, 12, 23], semiconductor theory [24, 25]. They described the interaction between quantum particles and electromagnetic fields. After the seminal work of Benci and Fortunato in [7,8], many researches have been conducted on systems such as (3.2) in the past few decades, as shown in [3,4,6,14,15,22,26,27,31] and their references.

Inspired by the above work, we are committed to studying the existence of solutions for system (3.1) in $\mathbb{R}^3$. Specifically, by using the nonlinear generalized Rayleigh quotient method and Ljusternik–Schnirelman theory, we obtain that there exist infinitely many zero energy sign changing weak solutions.

First of all, we give the variational framework for system (3.1). Let $W^{1,p}(\mathbb{R}^3)$ denote the usual Sobolev space equipped with the norm

$$\|u\| := \left(\int_{\mathbb{R}^3} |\nabla u|^p + |u|^p dx\right)^{\frac{1}{p}}.$$

One may easily get that the corresponding functional of (3.1) is $\Phi_\mu(u) : W^{1,p}(\mathbb{R}^3) \to \mathbb{R}$

$$\Phi_\mu(u) = \frac{1}{p}\int_{\mathbb{R}^3}(|\nabla u|^p + |u|^p)dx - \frac{\mu}{p}\int_{\mathbb{R}^3}|u|^p dx - \frac{1}{p^*}\int_{\mathbb{R}^3}|u|^{p^*}dx + \frac{\lambda}{4}\int_{\mathbb{R}^3}\phi u^2 dx.$$

It is standard to verify that Φ_μ is C^1. Then, for every $u \in W^{1,p}(\mathbb{R}^3)\backslash\{0\}$, we have

$$\mu_0(u) = \frac{\|u\|^p}{|u|_p^p} - \frac{p}{p^*}\frac{|u|_{p^*}^{p^*}}{|u|_p^p} + \frac{\lambda p}{4}\frac{\int_{\mathbb{R}^3}\phi u^2 dx}{|u|_p^p},$$

then

$$\mu_0(tu) = \frac{\|u\|^p}{|u|_p^p} - t^{p^*-p}\frac{p}{p^*}\frac{|u|_{p^*}^{p^*}}{|u|_p^p} + t^{4-p}\frac{\lambda p}{4}\frac{\int_{\mathbb{R}^3}\phi u^2 dx}{|u|_p^p}.$$

Let

$$\mu_0'(tu) = -t^{p^*-p-1}(p^*-p)\frac{p^*}{q}\frac{|u|_{p^*}^{p^*}}{|u|_p^p} + t^{3-p}(4-p)\frac{\lambda p}{4}\frac{\int_{\mathbb{R}^3}\phi u^2 dx}{|u|_p^p} = 0.$$

It is easy to see that

$$t_0(u) = \left(\frac{4-p}{p^*-p}\frac{p^*}{4}\frac{\lambda\int_{\mathbb{R}^3}\phi u^2 dx}{|u|_{p^*}^{p^*}}\right)^{\frac{1}{p^*-4}} > 0,$$

that is $\mu_0'(t_0(u)u) = 0$. Since $\mu_0''(t_0(u)u) < 0$, $t_0(u)$ is a nondegenerate global maximum point of $\mu_0(tu)$. Therefore, we have

$$\Lambda_1(u) = \mu_0(t_0(u)u) = \frac{\|u\|^p}{|u|_p^p} + \frac{p}{4}\frac{p^*-4}{p^*-p}\left(\frac{4-p}{p^*-p}\frac{p^*}{4}\right)^{\frac{4-p}{p^*-4}}\frac{(\lambda\int_{\mathbb{R}^3}\phi u^2 dx)^{\frac{p^*-p}{p^*-4}}}{|u|_p^p|u|_{p^*}^{p^*\frac{4-p}{p^*-4}}}.$$

For simplicity's sake, we call $\widetilde{\Lambda_1}$ the restriction of Λ_1 to S_1, where

$$S_1 = \{u \in W^{1,p}(\mathbb{R}^3)\backslash\{0\} : \|u\| = 1\}.$$

Now it is in a position to state our main result in this section as follows.

Theorem 3.1. *Let* $\delta_1 = \inf_{W^{1,p}(\mathbb{R}^3)\setminus\{0\}} \Lambda_1(u)$.

(i) If $\mu < \delta_1$*, then there is no nontrivial weak solution having zero energy for system* (3.1)*;*

(ii) If $\mu > \delta_1$*, then system* (3.1) *has infinitely many zero energy sign changing weak solutions.*

To prove Theorem 3.1, according to Ljusternik–Schnirelman category, we only need to prove that $\widetilde{\Lambda_1}$ is bounded from below and $\widetilde{\Lambda_1}$ satisfies the Palais-Smale condition.

Lemma 3.2. $\widetilde{\Lambda_1}$ *is bounded from below on* S_1.

Proof. Since the embedding $W^{1,p}(\mathbb{R}^3) \hookrightarrow L^p(\mathbb{R}^3)$ is continuous, there exists $C > 0$ such that $C\|u\|^p \geqslant |u|_p^p$. Because $\frac{12}{7} < p < 3, p^* > 4$, one may check that

$$\widetilde{\Lambda_1}(u) = \frac{\|u\|^p}{|u|_p^p} + \frac{p}{4}\frac{p^*-4}{p^*-p}\left(\frac{4-p}{p^*-p}\frac{p^*}{4}\right)^{\frac{4-p}{p^*-4}} \frac{\left(\lambda\int_{\mathbb{R}^3}\phi u^2 dx\right)^{\frac{p^*-p}{p^*-4}}}{|u|_p^p |u|_{p^*}^{p^*\frac{4-p}{p^*-4}}} > \frac{1}{C}.$$

Therefore, $\widetilde{\Lambda_1}$ is bounded from below on S_1. □

In order to prove that $\widetilde{\Lambda_1}$ satisfies the Palais–Smale condition, we require the following proposition.

Lemma 3.3. *If* $u_n \rightharpoonup u$ *in* S_1*, then for any* $v \in W^{1,p}(\mathbb{R}^3)$ *there holds*

$$\int_{\mathbb{R}^3} |u_n|^{p-2}u_n v dx \to \int_{\mathbb{R}^3} |u|^{p-2}uv dx, \qquad \int_{\mathbb{R}^3} |u_n|^{p^*-2}u_n v dx \to \int_{\mathbb{R}^3} |u|^{p^*-2}uv dx, \qquad n \to \infty.$$

Proof. Since $u_n \rightharpoonup u$ in S_1, we derive that $u_n(x) \to u(x)$ a.e. in $\mathbb{R}^3$. Note that the embedding $W^{1,p}(\mathbb{R}^3) \hookrightarrow L^s(\mathbb{R}^3)$ is continuous for $s \in [p, p^*]$, there exists a positive constant C such that

$$\int_{\mathbb{R}^3} \left||u_n|^{p-2}u_n\right|^{\frac{p}{p-1}} dx \le \int_{\mathbb{R}^3} \left||u_n|^{p-1}\right|^{\frac{p}{p-1}} dx = \int_{\mathbb{R}^3} |u_n|^p dx \le C\|u_n\|^p,$$

$$\int_{\mathbb{R}^3} \left||u_n|^{p^*-2}u_n\right|^{\frac{p^*}{p^*-1}} dx \le \int_{\mathbb{R}^3} \left||u_n|^{p^*-1}\right|^{\frac{p^*}{p^*-1}} dx = \int_{\mathbb{R}^3} |u_n|^{p^*} dx \le C\|u_n\|^{p^*}.$$

Therefore, $\{|u_n|^{p-2}u_n\}$ is bounded in $L^{\frac{p}{p-1}}(\mathbb{R}^3)$ and $\{|u_n|^{p^*-2}u_n\}$ is bounded in $L^{\frac{p^*}{p^*-1}}(\mathbb{R}^3)$. It follows from [34, Proposition 5.4.7] that $|u_n|^{p-2}u_n \rightharpoonup |u|^{p-2}u$ in $L^{\frac{p}{p-1}}(\mathbb{R}^3)$ and $|u_n|^{p^*-2}u_n \rightharpoonup |u|^{p^*-2}u$ in $L^{\frac{p^*}{p^*-1}}(\mathbb{R}^3)$. Thus for any $v \in W^{1,p}(\mathbb{R}^3)$ we have

$$\int_{\mathbb{R}^3} |u_n|^{p-2}u_n v dx \to \int_{\mathbb{R}^3} |u|^{p-2}uv dx, \qquad \int_{\mathbb{R}^3} |u_n|^{p^*-2}u_n v dx \to \int_{\mathbb{R}^3} |u|^{p^*-2}uv dx, \qquad n \to \infty,$$

as required. □

Lemma 3.4 (See [17, Proposition 2.1])**.** *For any* $u \in W^{1,p}(\mathbb{R}^3)$*, the following properties are applicable:*

(1) $\phi_u \ge 0$ *and for any* $t \in \mathbb{R}^+, \phi_{tu} = t^p\phi_u$.

(2) *There exists a positive constant* C *such that*

$$|\nabla\phi_u|_2^2 = \int_{\mathbb{R}^3} \phi_u |u|^p dx \le C\|u\|^{2p}.$$

(3) *In the case of $u_n \rightharpoonup u$ in $W^{1,p}(\mathbb{R}^3)$, it follows that $\phi_{u_n} \rightharpoonup \phi_u$ in $D^{1,2}(\mathbb{R}^3)$ and*

$$\int_{\mathbb{R}^3} \phi_{u_n} u_n^{p-2} u_n \varphi dx \to \int_{\mathbb{R}^3} \phi_u u^{p-2} u \varphi dx, \quad \textit{for any } \varphi \in W^{1,p}(\mathbb{R}^3).$$

Lemma 3.5. *$\widetilde{\Lambda_1}$ satisfies the Palais–Smale condition.*

Proof. Choose a sequence $(u_n) \subset S_1$ such that $(\widetilde{\Lambda_1}(u_n))$ is bounded and $\widetilde{\Lambda_1}'(u_n) \to 0$, that is $|\Lambda_1'(u_n)v| \le \varepsilon_n \|v\|$ for any $v \in \mathcal{T}_{S_1}(u_n)$, with $\varepsilon_n \to 0$. With the help of Lemma 2.2, if there is a sequence $(u_n) \subset S_1$ and $\widetilde{\Lambda_1}'(u_n) \to 0$, we can obtain that $u_n \rightharpoonup u$ in S_1 and $\Lambda_1'(u_n)(u_n - u) \to 0$ as $n \to \infty$. Then, for any $u_n, u \in S_1$,

$$\begin{aligned}
&\Lambda_1'(u_n)(u_n-u) \qquad (3.3)\\
&= p\frac{|u_n|_p^p \int_{\mathbb{R}^3} \left(|\nabla u_n|^{p-2}\nabla u_n \nabla(u_n-u) + |u_n|^{p-2}u_n(u_n-u)\right)dx - \|u_n\|^p \int_{\mathbb{R}^3} |u_n|^{p-2}u_n(u_n-u)dx}{|u_n|_p^{2p}}\\
&\quad + \left(4\frac{p^*-p}{q-4}|u_n|_{p^*}^{p^*}|u_n|_p^p \int_{\mathbb{R}^3} \phi u_n(u_n-u)dx - p^*\frac{4-p}{p^*-4}|u_n|_p^p \int_{\mathbb{R}^3} \phi u_n^2 dx \int_{\mathbb{R}^3} |u_n|^{p^*-2}u_n(u_n-u)dx\right.\\
&\quad \left. - p|u_n|_{p^*}^{p^*} \int_{\mathbb{R}^3} \phi u_n^2 dx \int_{\mathbb{R}^3} |u_n|^{p-2}u_n(u_n-u)dx\right) C_1 Q(u_n) \to 0, \quad \text{as } n \to \infty,
\end{aligned}$$

where

$$C_1 = \lambda \frac{p}{4}\frac{p^*-4}{p^*-p}\left(\frac{4-p}{p^*-p}\frac{p^*}{4}\right)^{\frac{4-p}{p^*-4}}, \qquad Q(u_n) = \frac{\left(\int_{\mathbb{R}^3} \phi u_n^2 dx\right)^{\frac{4-p}{p^*-4}}}{|u_n|_p^{2p} |u_n|_{p^*}^{p^*\frac{p^*-p}{p^*-4}}}.$$

Next, we claim that

$$\int_{\mathbb{R}^3} \left(|\nabla u_n|^{p-2}\nabla u_n \nabla(u_n-u) + |u_n|^{p-2}u_n(u_n-u)\right)dx \to 0, \quad \text{as } n \to \infty.$$

Therefore, we need to show that $|u_n|_{p^*}^{p^*}$, $|u_n|_p^p$, $\int_{\mathbb{R}^3} \phi u_n^2 dx$ and $Q(u_n)$ are bounded and

$$\int_{\mathbb{R}^3} |u_n|^{p-2}u_n(u_n-u)dx \to 0, \quad \int_{\mathbb{R}^3} |u_n|^{p^*-2}u_n(u_n-u)dx \to 0, \quad \int_{\mathbb{R}^3} \phi_{u_n} u_n(u_n-u)dx \to 0$$

as $n \to \infty$. Indeed, since $(u_n) \subset S_1$ and the embedding $W^{1,p}(\mathbb{R}^3) \hookrightarrow L^s(\mathbb{R}^3)$ is continuous for $s \in [p, p^*]$, we can obtain

$$0 < |u_n|_{p^*}^{p^*} \le C\|u_n\|^{p^*} = C, \qquad 0 < |u_n|_p^p \le C_1\|u_n\|^p = C_1.$$

This implied that $|u_n|_{p^*}^{p^*}$ and $|u_n|_p^p$ are bounded. By means of Lemma 3.4, we have

$$0 < \int_{\mathbb{R}^3} \phi u_n^2 dx \le C_2 \|u_n\|^4 = C_2.$$

Then $\int_{\mathbb{R}^3} \phi u_n^2 dx$ is bounded. We can deduce the boundedness of $Q(u_n)$ from the fact that $(\widetilde{\Lambda_1}(u_n))$ is bounded. According to Lemma 3.3, given $v = (u_n - u) \in S_1$, we can attain that

$$\int_{\mathbb{R}^3} \left(|u_n|^{p-2}u_n - |u|^{p-2}u\right)(u_n-u)dx \to 0, \qquad \int_{\mathbb{R}^3} \left(|u_n|^{p^*-2}u_n - |u|^{p^*-2}u\right)(u_n-u)dx \to 0,$$

as $n \to \infty$. Through Lemma 3.4, given $\varphi = u_n - u$, we obtain

$$\int_{\mathbb{R}^3} \left(\phi_{u_n} u_n - \phi_u u\right)(u_n-u)dx \to 0, \qquad n \to \infty.$$

Inasmuch as $u_n \rightharpoonup u$ in S_1, one can conclude that

$$\int_{\mathbb{R}^3} |u_n|^{p-2}u_n(u_n-u)dx \to 0, \int_{\mathbb{R}^3} |u_n|^{p^*-2}u_n(u_n-u)dx \to 0, \int_{\mathbb{R}^3} \phi_{u_n}u_n(u_n-u)dx \to 0,$$

as $n \to \infty$. Therefore, we obtain the following conclusion:

$$\int_{\mathbb{R}^3} \left(|\nabla u_n|^{p-2}\nabla u_n \nabla(u_n-u) + |u_n|^{p-2}u_n(u_n-u)\right) dx \to 0, \quad \text{as } n \to \infty.$$

Notice that $p(u) = \int_{\mathbb{R}^3} |\nabla u|^p + |u|^p dx$, according to the Hölder inequality, one has

$$\begin{aligned}(p'(u_n) - p'(u), u_n - u) &\geq \|u_n\|^p + \|u\|^p - \|u_n\|^{p-1}\|u\| - \|u\|^{p-1}\|u_n\| \\ &= (\|u_n\|^{p-1} - \|u\|^{p-1})(\|u_n\| - \|u\|) \geq 0.\end{aligned}$$

Owing to $u_n \rightharpoonup u$ in S_1, it follows that $(p'(u_n) - p'(u), u_n - u) \to 0$, as $n \to \infty$. Therefore, $\|u_n\| \to \|u\|$ in S_1. According to the uniform convexity of $W^{1,p}(\mathbb{R}^3)$, we can obtain that $u_n \to u$ in S_1. Consequently, there exits a sequence (u_n) such that $u_n \to u$ in S_1 up to a subsequence. Therefore, $\widetilde{\Lambda_1}$ satisfied the Palais–Smale condition. □

Proof of Theorem 3.1.

(i) We prove that there is no critical point having zero energy when $\mu < \delta_1$. A crucial observation is that u being a critical point of Λ_1 is equivalent to $t_0(u)u$ being a zero energy critical point of Φ_μ, where $\mu = \Lambda_1(u)$. In other words, this means that

$$\delta_1 = \inf_{W^{1,p}(\mathbb{R}^3)\setminus\{0\}} \Lambda_1(u) \leq \mu \leq \sup_{W^{1,p}(\mathbb{R}^3)\setminus\{0\}} \Lambda_1(u),$$

which yields the desired conclusion.

(ii) According to Lemma 3.2, we know that $\widetilde{\Lambda_1}$ is bounded from below on S_1. In the meantime, we obtain that $\widetilde{\Lambda_1}$ satisfies the Palais–Smale condition from Lemma 3.5. Note that $\hat{\gamma}(S_1) = \infty$, Ljusternik–Schnirelman category (see[32, Theorem 5.7]) yields that there exists a sequence $(u_n) \subset S_1$ such that $\widetilde{\Lambda_1}'(u_n) = 0, \widetilde{\Lambda_1}(u_n) = \mu_n$. Therefore, the energy functional Φ has infinitely many zero energy critical points $(u_n) \subset S_1$. Since $\widetilde{\Lambda_1}(u)$ is an even functional, $\widetilde{\Lambda_1}'(\pm u_n) = 0, \widetilde{\Lambda_1}(\pm u_n) = \mu_n$. Hence, system (3.1) possesses infinitely many zero energy sign changing weak solutions. □

3.2 Critical Schrödinger–Poisson system in bounded domains

The purpose of this subsection is to study the existence and nonexistence of solutions for a Schrödinger–Poisson system with critical nonlinearity in bounded domains. Here is the system under consideration:

$$\begin{cases} -\Delta u + \lambda\phi|u|^{q-2}u = \mu u - |u|^{2^*-2}u & \text{in } \Omega, \\ -\Delta\phi = |u|^q & \text{in } \Omega, \\ u = \phi = 0 & \text{on } \partial\Omega, \end{cases} \tag{3.4}$$

where $\lambda = -1$, $\Omega \subset \mathbb{R}^N (N \geq 3)$ is a bounded domain with smooth boundary $\partial\Omega$, μ is a real parameter, $1 < N/(N-2) < q < 2N/(N-2) = 2^*$. It is well known that problem (3.4) is equivalent to a nonlocal nonlinear problem related with famous Choquard equations in bounded domains. For more related results, for instance we refer to [1,5,11,30].

Now we start the analysis of problem (3.4). One may easily get that the corresponding functional of (3.4) is as follows:

$$\Phi_\mu(u) = \frac{1}{2}\int_\Omega |\nabla u|^2 dx - \frac{\mu}{2}\int_\Omega |u|^2 dx - \frac{1}{2q}\int_\Omega \phi |u|^q dx + \frac{1}{2^*}\int_\Omega |u|^{2^*} dx, \qquad u \in H_0^1(\Omega).$$

This Hilbert space $H_0^1(\Omega)$ provides a suitable framework for our analysis, capturing the essential properties of functions under consideration. Given the norm

$$\|u\| := \left(\int_\Omega |\nabla u|^2 dx\right)^{\frac{1}{2}}.$$

It is apparent that the functional Φ_μ is C^1. Then, for every $u \in H_0^1(\Omega)\backslash\{0\}$,

$$\mu_0(u) = \frac{\|u\|^2}{|u|_2^2} - \frac{1}{q}\frac{\int_\Omega \phi|u|^q dx}{|u|_2^2} + \frac{2}{2^*}\frac{|u|_{2^*}^{2^*}}{|u|_2^2},$$

$$\mu_0(tu) = \frac{\|u\|^2}{|u|_2^2} - t^{2q-2}\frac{1}{q}\frac{\int_\Omega \phi|u|^q dx}{|u|_2^2} + t^{2^*-2}\frac{2}{2^*}\frac{|u|_{2^*}^{2^*}}{|u|_2^2}.$$

Let $\mu_0'(tu) = 0$, we obtain

$$t_0(u) = \left(\frac{2^*-2}{2q-2}\frac{2q}{2^*}\frac{|u|_{2^*}^{2^*}}{\int_\Omega \phi|u|^q dx}\right)^{\frac{1}{2q-2^*}} > 0,$$

that is $\mu_0'(t_0(u)u) = 0$. In the meantime, on account of $\mu_0''(t_0(u)u) < 0$, we can deduce that $t_0(u)$ is a nondegenerate global maximum point of $\mu_0(tu)$. As a result, we can obtain that

$$\Lambda_2(u) = \mu_0(t_0(u)u) = \frac{\|u\|^2}{|u|_2^2} + \frac{2}{2^*}\frac{2q-2^*}{2q-2}\left(\frac{2^*-2}{2q-2}\frac{2q}{2^*}\right)^{\frac{2^*-2}{2q-2^*}} \frac{(|u|_{2^*}^{2^*})^{\frac{2q-2}{2q-2^*}}}{|u|_2^2(\int_\Omega \phi|u|^q dx)^{\frac{2^*-2}{2q-2^*}}}.$$

For clarity, we call $\widetilde{\Lambda_2}$ the restriction of Λ_2 to S_2, where

$$S_2 = \{u \in H_0^1(\Omega)\backslash\{0\} : \|u\| = 1\}.$$

As for our central discovery in this subsection, it can be phrased as:

Theorem 3.6. *Let* $\delta_2 = \inf_{H_0^1(\Omega)\backslash\{0\}} \Lambda_2(u)$.

(i) If $\mu < \delta_2$*, then there is no nontrivial weak solution having zero energy in system* (3.4);

(ii) If $\mu > \delta_2$*, then system* (3.4) *has infinitely many zero energy sign changing weak solutions.*

As mentioned earlier, to achieve our goal, we only need to prove the boundedness from below of $\widetilde{\Lambda_2}$ on S_2 and verify that $\widetilde{\Lambda_2}$ meets the Palais–Smale condition.

Lemma 3.7. $\widetilde{\Lambda_2}$ *is bounded from below on* S_2.

Proof. According to the embedding theorem, $H_0^1(\Omega) \hookrightarrow L^2(\Omega)$ is continuous, there is a constant $C > 0$ such that $|u|_2^2 \le C\|u\|^2$. Note that $1 < N/(N-2) < q < 2^*$, one may verify that

$$\widetilde{\Lambda_2} = \frac{\|u\|^2}{|u|_2^2} + \frac{2}{2^*}\frac{2q-2^*}{2q-2}\left(\frac{2^*-2}{2q-2}\frac{2q}{2^*}\right)^{\frac{2^*-2}{2q-2^*}} \frac{(|u|_{2^*}^{2^*})^{\frac{2q-2}{2q-2^*}}}{|u|_2^2(\int_\Omega \phi|u|^q dx)^{\frac{2^*-2}{2q-2^*}}} > \frac{1}{C}.$$

That is to say, $\widetilde{\Lambda_2}$ is bounded from below on S_2. □

Lemma 3.8. *$\widetilde{\Lambda_2}$ satisfies the Palais–Smale condition.*

Proof. Choose a sequence $(u_n) \subset S_2$ such that $\widetilde{\Lambda_2}(u_n)$ is bounded and $\widetilde{\Lambda_2}'(u_n) \to 0$. In other words, for any $v \in \mathcal{T}_{S_2}(u_n)$, we have $|\Lambda_2'(u_n)v| \le \varepsilon_n\|v\|$, where $\varepsilon_n \to 0$.

With the assistance of Lemma 2.2, assuming a sequence $(u_n) \subset S_2$ satisfies $\widetilde{\Lambda_2}'(u_n) \to 0$, we can conclude that $u_n \rightharpoonup u$ in S_2 and $\Lambda_2'(u_n)(u_n - u) \to 0$ as $n \to \infty$. Then, for any $u_n, u \in S_2$,

$$\begin{aligned}\Lambda_2'(u_n)(u_n-u) = {}& 2\frac{|u_n|_2^2\int_\Omega \nabla u_n \nabla(u_n-u)dx - \|u_n\|^2\int_\Omega u_n(u_n-u)dx}{|u_n|_2^4} \\ &+ C_2 Q(u_n)\Bigg(2^*\frac{2q-2}{2q-2^*}|u_n|_2^2\int_\Omega \phi|u_n|^q dx \int_\Omega |u_n|^{2^*-2}u_n(u_n-u)dx \\ &- 2q\frac{2^*-2}{2q-2^*}|u_n|_{2^*}^{2^*}|u_n|_2^2\int_\Omega \phi|u_n|^{q-2}u_n(u_n-u)dx \\ &- 2|u_n|_{2^*}^{2^*}\int_\Omega \phi|u_n|^q dx\int_\Omega u_n(u_n-u)dx\Bigg) \to 0,\end{aligned} \tag{3.5}$$

where

$$C_2 = \frac{2}{2^*}\frac{2q-2^*}{2q-2}\left(\frac{2^*-2}{2q-2}\frac{2q}{2^*}\right)^{\frac{2^*-2}{2q-2^*}}, \qquad Q(u_n) = \frac{(|u_n|_{2^*}^{2^*})^{\frac{2^*-2}{2q-2^*}}}{|u_n|_2^4(\int_\Omega \phi|u_n|^q dx)^{\frac{2q-2}{2q-2^*}}}.$$

In order to prove Lemma 3.7, we first verify that $\int_\Omega \nabla u_n \nabla(u_n-u)dx \to 0$, as $n \to \infty$. Therefore, on the one hand, we need to show that $|u_n|_2^2, |u_n|_{2^*}^{2^*}, Q(u_n)$ is bounded. On the other hand, we need to prove

$$\int_\Omega u_n(u_n-u)dx \to 0, \int_\Omega \phi_{u_n}|u_n|^{q-2}(u_n-u)dx \to 0, \quad \text{as } n \to \infty.$$

In fact, we know that $u_n \not\equiv 0$ from $(u_n) \subset S_2$. According to Lemma 3.4, we can obtain

$$0 < \int_\Omega \phi_{u_n}|u_n|^q dx \le C_2\|u_n\|^{2q} = C_2.$$

Therefore, $\int_\Omega \phi_{u_n}|u_n|^q dx$ is bounded. On the basis of the embedding theorem, $H_0^1(\Omega) \hookrightarrow L^s(\Omega)$ is continuous for $2 \le s \le 2^*$, we have

$$0 < |u_n|_2^2 \le C\|u_n\|^2 = C, \qquad 0 < |u_n|_{2^*}^{2^*} \le C\|u_n\|^{2^*} = C,$$

which implied that $|u_n|_2^2$ and $|u_n|_{2^*}^{2^*}$ are bounded. Note that $\widetilde{\Lambda_2}(u_n)$ is bounded, one may check that $Q(u_n)$ is bounded. Thanks to the embedding $H_0^1(\Omega) \hookrightarrow L^2(\Omega)$ is compact, one has

$$\int_\Omega u_n(u_n-u)dx \to 0, \quad \text{as } n \to \infty.$$

With the aid of Lemma 3.4, it holds

$$\int_\Omega \phi_{u_n}|u_n|^{q-2}u_n\varphi dx \to \int_\Omega \phi_u|u|^{q-2}u\varphi dx, \quad \text{for any } \varphi \in H_0^1(\Omega).$$

Let $\varphi = u_n - u$. Then we obtain

$$\int_\Omega \phi_{u_n}|u_n|^{q-2}(u_n-u)dx - \int_\Omega \phi_u|u|^{q-2}(u_n-u)dx \to 0, \quad \text{as } n\to\infty.$$

Since $u_n \rightharpoonup u$ in $H_0^1(\Omega)$, we have $\int_\Omega \phi_u|u|^{q-2}(u_n-u)dx \to 0$. Consequently,

$$\int_\Omega \phi_{u_n}|u_n|^{q-2}(u_n-u)dx \to 0, \quad \text{as } n\to\infty.$$

The analysis leads to the following conclusion:

$$\int_\Omega \nabla u_n\nabla(u_n-u)dx + \int_\Omega |u_n|^{2^*-2}u_n(u_n-u)dx \to 0.$$

In order to obtain $\int_\Omega \nabla u_n\nabla(u_n-u)dx \to 0$, we will use the Hölder inequality to derive

$$\int_\Omega \nabla u_n\nabla(u_n-u)dx \ge 0, \qquad \int_\Omega |u_n|^{2^*-2}u_n(u_n-u)dx \ge 0.$$

For convenience, put $p_1(u) = \int_\Omega |\nabla u|^2dx$, $p_2(u) = \int_\Omega |u|^{2^*}dx$. One may check that

$$(p_1'(u_n) - p_1'(u), u_n-u) = \|u_n\|^2 + \|u\|^2 - \int_\Omega \nabla u_n\nabla u dx - \int_\Omega \nabla u\nabla u_n dx,$$

$$(p_2'(u_n) - p_2'(u), u_n-u) = \|u_n\|_{2^*}^{2^*} + \|u\|_{2^*}^{2^*} - \int_\Omega |u_n|^{2^*-2}u_n u dx - \int_\Omega |u|^{2^*-2}u u_n dx.$$

By virtue of the Hölder inequality, we have

$$\int_\Omega \nabla u_n\nabla u dx \le \left(\int_\Omega |\nabla u|^2dx\right)^{\frac12}\left(\int_\Omega |\nabla u_n|^2dx\right)^{\frac12} = \|u_n\|\|u\|,$$

$$\int_\Omega |u_n|^{2^*-2}u_n u dx \le \left(\int_\Omega |u_n|^{2^*}dx\right)^{\frac{2^*-1}{2^*}}\left(\int_\Omega |u|^{2^*}dx\right)^{\frac{1}{2^*}} = |u_n|_{2^*}^{2^*-1}|u|_{2^*},$$

$$\int_\Omega |u|^{2^*-2}u u_n dx \le \left(\int_\Omega |u|^{2^*}dx\right)^{\frac{2^*-1}{2^*}}\left(\int_\Omega |u_n|^{2^*}dx\right)^{\frac{1}{2^*}} = |u|_{2^*}^{2^*-1}|u_n|_{2^*}.$$

Therefore,

$$(p_1'(u_n) - p_1'(u), u_n-u) \ge (\|u_n\| - \|u\|)(\|u_n\| - \|u\|) \ge 0,$$

$$(p_2'(u_n) - p_2'(u), u_n-u) \ge (\|u_n\|^{2^*-1} - \|u\|^{2^*-1})(\|u_n\| - \|u\|) \ge 0.$$

Since $u_n \rightharpoonup u$ in S_2, we have $(p_1'(u), u_n-u) \to 0, (p_1'(u), u_n-u) \to 0$, as $n\to\infty$. From which it follows that

$$\int_\Omega \nabla u_n\nabla(u_n-u)dx \ge 0, \qquad \int_\Omega |u_n|^{2^*-2}u_n(u_n-u)dx \ge 0.$$

As a result, we can draw the following conclusion:

$$\int_\Omega \nabla u_n\nabla(u_n-u)dx \to 0, \quad \text{as } n\to\infty.$$

Moreover, since $(p_1'(u_n) - p_1'(u), u_n-u) \to 0$, we have $\|u_n\| \to \|u\|$ in S_2. By the uniform convexity of $H_0^1(\Omega)$, we deduce that $u_n \to u$ in S_2. Therefore, $\widetilde{\Lambda_2}$ satisfied the Palais–Smale condition. □

Proof of Theorem 3.6.

(i) We show that there is no critical point having zero energy when $\mu < \delta_2$. Note that u is a critical point of Λ, if and only if, $t_0(u)u$ is a zero energy critical point of Φ_μ with $\mu = \Lambda(u)$, this means the desired conclusion.

(ii) According to Lemma 3.5, we know that $\widetilde{\Lambda_2}$ is bounded from below on S_2. Moreover, $\widetilde{\Lambda_2}$ satisfies the Palais–Smale condition due to Lemma 3.7. Note that $\hat{\gamma}(S_2) = \infty$, it follows from Ljusternik–Schnirelman category (see [32, Theorem 5.7]) that there exists a sequence $(u_n) \subset S_2$ such that $\widetilde{\Lambda_2}'(u_n) = 0, \widetilde{\Lambda_2}(u_n) = \mu_n$. The remainder is the same as the proof of Theorem 3.1, here we omit it. □

3.3 Kirchhoff-type problems with critical growth

Now, let us consider the following Kirchhoff-type problem:

$$\begin{cases} -(a + b\int_\Omega |\nabla u|^2)\Delta u = \mu u + |u|^4 u & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{3.6}$$

where $\Omega \subset \mathbb{R}^3$ is a bounded domain with smooth boundary $\partial\Omega$, $a, b > 0$, μ is a real parameter.

Inspired by the works described above, in this paper we study the existence of zero energy solutions for a class of Kirchhoff problem with critical growth in bounded domains. In recent years, Kirchhoff-type equation is an extension of the classical D'Alembert's wave equation. It was firstly proposed by Kirchhoff in 1883. Various problems of Kirchhoff-type are usually named nonlocal problems in virtue of the appearance of the nonlocal term $a + b\int_\Omega |\nabla u|^2$ and have been extensively investigated up to now. In [28], Quoirin et al. investigated qualitative properties of solutions for a Kirchhoff-type problem with subcritical growth as an application of their zero energy critical point theory. However, their theory seems difficulty to deal with the problem like (3.6) involving the critical exponent. For this purpose, we explore a new strategy (Theorem 1.1) to solve this problem.

As usual, one can get that the corresponding functional of (3.6) is $\Phi_\mu : H_0^1(\Omega) \to \mathbb{R}$:

$$\Phi_\mu(u) = \frac{a}{2}\int_\Omega |\nabla u|^2 dx - \frac{\mu}{2}\int_\Omega |u|^2 dx - \frac{1}{6}\int_\Omega |u|^6 dx + \frac{b}{4}\left(\int_\Omega |\nabla u|^2 dx\right)^2.$$

It is evident that Φ_μ is C^1. Then, according to the previous preliminaries, for every $u \in H_0^1(\Omega)\backslash\{0\}$:

$$\mu_0(u) = \frac{a\|u\|^2}{|u|_2^2} - \frac{1}{3}\frac{|u|_6^6}{|u|_2^2} + \frac{b}{2}\frac{\|u\|^4}{|u|_2^2},$$

$$\mu_0(tu) = \frac{a\|u\|^2}{|u|_2^2} - \frac{t^4}{3}\frac{|u|_6^6}{|u|_2^2} + t^2\frac{b}{2}\frac{\|u\|^4}{|u|_2^2}.$$

Let $\mu_0'(tu) = 0$, we obtain

$$t_0(u) = \left(\frac{3}{4}\frac{b\|u\|^4}{|u|_6^6}\right)^{\frac{1}{2}} > 0,$$

and $t_0(u)$ is a nondegenerate global maximum point of $\mu_0(tu)$ via $\mu_0''(t_0(u)u) < 0$. Therefore, we have

$$\Lambda_3(u) = \frac{a\|u\|^2}{|u|_2^2} + \frac{3}{16}\frac{(b\|u\|^4)^2}{|u|_2^2 |u|_6^6}.$$

For simplicity, we call $\widetilde{\Lambda_3}$ the restriction of Λ_3 to S_3, where

$$S_3 = \{u \in H_0^1(\Omega)\backslash\{0\} : \|u\| = 1\}.$$

The main result we have derived in this section is expressed as:

Theorem 3.9. *Let $\delta_3 = \inf_{H_0^1(\Omega)\backslash\{0\}} \Lambda_3(u)$.*

(i) If $\mu < \delta_3$, then there is no nontrivial weak solution having zero energy in problem (3.6);

(ii) If $\mu > \delta_3$, then problem (3.6) has infinitely many zero energy sign changing weak solutions.

To verify this result, according to Ljusternik–Schnirelman category (see [32, Theorem 5.7]), it is necessary to prove that $\widetilde{\Lambda_3}$ is bounded below and satisfies the Palais–Smale condition.

Lemma 3.10. *$\widetilde{\Lambda_3}$ is bounded from below on S_3.*

Proof. Since the embedding $H_0^1(\Omega) \hookrightarrow L^2(\Omega)$ is continuous, there exists $C > 0$ such that $C\|u\|^2 \geqslant |u|_2^2$. Hence, one can obtain that

$$\widetilde{\Lambda_3}(u) = \frac{a\|u\|^2}{|u|_2^2} + \frac{3}{16}\frac{b\|u\|^4}{|u|_2^2|u|_6^3} > \frac{a}{C},$$

which yields that $\widetilde{\Lambda_3}$ is bounded from below on S_3. □

Lemma 3.11. *If $(u_n) \subset S_3$, then $u_n \rightharpoonup u$ in $H_0^1(\Omega)\backslash\{0\}$ up to a subsequence. Therefore,*

$$\int_{\mathbb{R}^3} |u_n|^4 u_n \varphi dx \to \int_{\mathbb{R}^3} |u|^4 u \varphi dx, \quad as\ n \to \infty,$$

for any $\varphi \in C_0^\infty(\mathbb{R}^3)$.

Proof. We employ the strategy outlined in Lemma 3.3 from [21]. In fact, it is related to a result from the Lebesgue Dominated Convergence Theorem. First we notice that

$$|u_n|^4 u_n \varphi \to |u|^4 u \varphi \quad \text{as } n \to \infty,$$

almost everywhere in the compact support Ω of φ, and

$$||u_n|^4 u_n \varphi \chi_\Omega| \leq |u_n|^5 |\varphi| \chi_\Omega,$$

where χ_Ω represents the characteristic function of Ω. Given that $u_n \to u$ in $L^s_{loc}(\mathbb{R}^3)$ for all $5 < s < 6$, utilizing the Hölder inequality yields

$$\int_\Omega |u_n|^5 |\varphi| dx \leq \left(\int_\Omega |u_n|^s dx\right)^{\frac{5}{s}} \left(\int_\Omega |\varphi|^{\frac{s}{s-5}} dx\right)^{\frac{s-5}{s}},$$

which means that $|u_n|^5 |\varphi| \chi_\Omega \in L^1(\mathbb{R}^3)$. According to Lebesgue dominated convergence theorem, it follows that

$$\int_{\mathbb{R}^3} |u_n|^4 u_n \varphi dx \to \int_{\mathbb{R}^3} |u|^4 u \varphi dx, \quad \text{as } n \to \infty.$$

The proof is now complete. □

Lemma 3.12. *$\widetilde{\Lambda_3}$ satisfied the Palais–Smale condition.*

Proof. Choosing a sequence $(u_n) \subset S_3$ such that $(\widetilde{\Lambda_3}(u_n))$ is bounded and $\widetilde{\Lambda_3}'(u_n) \to 0$, that is $|\Lambda_3'(u_n)v| \leq \varepsilon_n \|v\|$ for any $v \in \mathcal{T}_{S_3}(u_n)$, with $\varepsilon_n \to 0$. In view of Lemma 2.2, if there is a sequence $(u_n) \subset S_3$ and $\widetilde{\Lambda_3}'(u_n) \to 0$, we can acquire that $u_n \rightharpoonup u$ in S_3 and $\Lambda'(u_n)(u_n - u) \to 0$ as $n \to \infty$. Then, for any $u_n, u \in S_3$,

$$\begin{aligned}\Lambda'(u_n)(u_n - u) = 2a &\frac{|u_n|_2^2 \int_\Omega \nabla u_n \nabla(u_n - u)dx - \|u_n\|^2 \int_\Omega u_n(u_n - u)dx}{|u_n|_2^4} \\ &+ \frac{3b}{16} Q(u_n) \left(4|u_n|_2^2 |u_n|_6^6 \int_\Omega |\nabla u_n|^2 dx \int_\Omega \nabla u_n \nabla(u_n - u)dx \right. \\ &\left. - 6\|u_n\|^4 |u|_2^2 \int_\Omega |u_n|^4 u_n(u_n - u)dx - 2\|u_n\|^4 |u_n|_6^6 \int_\Omega u_n(u_n - u)dx \right) \to 0,\end{aligned}$$

as $n \to \infty$, where

$$Q(u_n) = \frac{b\|u_n\|^4}{|u_n|_2^4 (|u_n|_6^6)^{\frac{1}{2}}}.$$

Since $(u_n) \subset S_3$ and the embedding $H_0^1(\Omega) \hookrightarrow L^s(\Omega)$ is continuous for $1 \leq s \leq 6$, there exists a constant $C > 0$ such that

$$0 < |u_n|_2^2 \leq C\|u_n\|^2 = C, \qquad 0 < |u_n|_6^6 \leq C\|u_n\|^6 = C.$$

Therefore, $|u_n|_2^2, |u_n|_6^6$ is bounded. Note that $(\widetilde{\Lambda_3}(u_n))$ is bounded, then $Q(u_n)$ is bounded. Since $u_n \rightharpoonup u$ in $H_0^1(\Omega)$, one can easily deduce from the Sobolev embedding theorem that

$$\int_\Omega u_n(u_n - u)dx \to 0, \quad \text{as } n \to \infty.$$

By means of Lemma 3.11, given $\varphi = u_n - u$, then as $n \to \infty$,

$$\int_\Omega |u_n|^4 u_n(u_n - u)dx - \int_\Omega |u|^4 u(u_n - u)dx \to 0.$$

This yields that

$$\int_\Omega |u_n|^4 u_n(u_n - u)dx \to 0, \quad \text{as } n \to \infty,$$

which leads to the following conclusion:

$$\int_\Omega \nabla u_n \nabla(u_n - u)dx \to 0, \quad \text{as } n \to \infty,$$

which means that $\|u_n\| \to \|u\|$ in S_3. By the uniform convexity of $H_0^1(\Omega)$, it follows that $u_n \to u$ in S_3. In conclusion, $\widetilde{\Lambda_3}$ satisfied the Palais–Smale condition. □

Proof of Theorem 3.9.

(i) We prove that there is no critical point having zero energy when $\mu < \delta_3$. Note that u is a critical point of Λ_3, if and only if, $t_0(u)u$ is a zero energy critical point of Φ_μ with $\mu = \Lambda_3(u)$, this yields the desired conclusion.

(ii) According to Lemma 3.10, it follows that $\widetilde{\Lambda_3}$ is bounded from below on S_3. In the meantime, $\widetilde{\Lambda_3}$ satisfies the Palais–Smale condition as per the Lemma 3.12. Note that $\hat{\gamma}(S_3) = \infty$, Ljusternik–Schnirelman category (see [32, Theorem 5.7]) implied that there exists a sequence $(u_n) \subset S_3$ such that $\widetilde{\Lambda_3}'(u_n) = 0, \widetilde{\Lambda_3}(u_n) = \mu_n$. Analogous to the proof of Theorem 3.1, problem (3.6) possesses infinitely many zero-energy, sign-changing weak solutions. □

Abstract. In this work we mainly prove the following interior gradient estimates in weighted Lorentz spaces

$$g^{-1}\left[\mathcal{M}_1(\mu)\right] \in L^{q,r}_{w,loc}(\Omega) \implies |Du| \in L^{q,r}_{w,loc}(\Omega),$$

where $g(t) = ta(t)$ for $t \geq 0$ and $\mathcal{M}_1(\mu)(x)$ is the first-order fractional maximal function

$$\mathcal{M}_1(\mu)(x) := \sup_{r>0} \frac{r|\mu|(B_r(x))}{|B_r(x)|},$$

for a class of non-homogeneous divergence quasilinear elliptic equations with measure data in the subquadratic case

$$-\operatorname{div}\left[a\left((ADu\cdot Du)^{\frac{1}{2}}\right)ADu\right] = \mu \quad \text{in } \Omega,$$

whose model cases are the classical elliptic p-Laplacian equation with measure data

$$-\operatorname{div}\left(|Du|^{p-2}Du\right) = \mu \quad \text{for } 1 < p < 2$$

and the elliptic p-Laplacian equation with the logarithmic term and measure data

$$-\operatorname{div}\left(|Du|^{p-2}\log\left(1+|Du|\right)Du\right) = \mu \quad \text{for } 1 < p < 2.$$

It deserves to be specially noted that the subquadratic case is a little different from the superquadratic case since as an example, the modulus of ellipticity in the above-mentioned special cases tends to infinity when $|Du| \to 0$ for $1 < p < 2$.

Keywords: weighted, Lorentz, gradient, subquadratic, quasilinear elliptic, measure, data.

1 Introduction

In this paper we mainly study the local gradient estimates in weighted Lorentz spaces for the following non-homogeneous quasilinear elliptic equations with right-hand side measure in divergence form

$$-\operatorname{div}\left[a\left((ADu\cdot Du)^{\frac{1}{2}}\right)ADu\right]=\mu \quad \text{in } \Omega, \tag{1.1}$$

where Ω is a bounded domain in $\mathbb{R}^n$ for $n\geq 2$, μ is a Borel measure with finite mass and $a:[0,\infty)\to[0,\infty)\in C^1[0,\infty)$ satisfies

$$-1<i_a:=\inf_{t>0}\frac{ta'(t)}{a(t)}\leq\sup_{t>0}\frac{ta'(t)}{a(t)}=:s_a<0 \quad \text{for any } t>0. \tag{1.2}$$

Moreover, the symmetric matrix $A(x)=\{a_{ij}(x)\}$ satisfies the following uniformly elliptic condition

$$\Lambda^{-1}|\xi|^2\leq A(x)\xi\cdot\xi\leq\Lambda|\xi|^2 \tag{1.3}$$

for every $\xi\in\mathbb{R}^n$, *a.e.* $x\in\mathbb{R}^n$ and some constant $\Lambda>0$. We remark that if $a(t)=t^{p-2}$ and A is the identity matrix I, then $i_a=s_a=p-2$ for $1<p<2$ and (1.1) is reduced to the classical elliptic p-Laplacian equation with right-hand side measure in divergence form

$$-\operatorname{div}\left(|Du|^{p-2}Du\right)=\mu \quad \text{for } 1<p<2. \tag{1.4}$$

It may be worthwhile to remark that another two natural examples of the functions a are $a(t)=t^{p-2}\log(1+t)$ for $1<p<2$, which makes (1.1) for $A=I$ is equal to

$$-\operatorname{div}\left(|Du|^{p-2}\log\left(1+|Du|\right)Du\right)=\mu,$$

and a more general example (see page 600 in [9] and page 314 in [46]), which is related to (p,q)-growth condition given by appropriate gluing of the monomials.

Define

$$g(t):=ta(t) \tag{1.5}$$

and

$$G(t):=\int_0^t g(\tau)\,d\tau=\int_0^t \tau a(\tau)\,d\tau \quad \text{for } t\geq 0. \tag{1.6}$$

From (1.2) we know that

$$g(t) \text{ is strictly increasing and continuous over } [0,+\infty), \tag{1.7}$$

and then

$$G(t) \text{ is increasing over } [0,+\infty) \text{ and strictly convex with } G(0)=0. \tag{1.8}$$

The partial differential equations involving measure data allow to consider various mathematical models in many interesting phenomena such as the blood flow in the heart [58] and state-constrained optimal control problems [23, 24]. The pointwise estimates of solutions to elliptic PDEs via suitable linear and nonlinear potentials of the right-hand side measure μ

were first investigated by Kilpeläinen & Malý [39,40], in which they obtained the pointwise estimates for u in terms of nonlinear Wolff potentials $W^{\mu}_{\beta,p}$ defined by

$$W^{\mu}_{\beta,p}(x,R) := \int_0^R \left(\frac{|\mu|\,(B(x,\varrho))}{\varrho^{n-\beta p}}\right)^{\frac{1}{p-1}} \frac{d\varrho}{\varrho} \quad \text{for } \beta \in \left(0, \frac{n}{p}\right],$$

where

$$|\mu|(B(x,\varrho)) := \int_{B(x,\varrho)} |\mu(y)|dy.$$

Remarkably, such estimates played an essential role in the nonlinear potential theory (see [38,60]). In more specific terms, Kilpeläinen & Malý [39,40] proved the following estimate

$$|u(x_0)| \leq C(n,p)\left[W^{\mu}_{1,p}(x,R) + \left(\fint_{B(x,R)} |u|^{\gamma} dx\right)^{\frac{1}{\gamma}}\right], \quad \gamma > p-1 \tag{1.9}$$

with $B(x,R) \subseteq \Omega$ for solution to the p-Laplacian equation with right-hand side measure (1.4). Afterwards, Trudinger & Wang [64] used a different approach to prove the pointwise estimate via the nonlinear Wolff potential for the p-Laplacian operators. Later, Duzaar & Mingione [35,51] extended (1.9) to the pointwise estimate at the gradient level

$$|Du(x_0)| \leq C(n,p)\left[\fint_{B(x_0,2R)} |Du|dx + W^{\mu}_{1/p,p}(x,2R)\right]$$

for solutions to the elliptic p-Laplacian equation (1.4) and more general case. In the subsequent papers, for the case $p \geq 2$ Kuusi & Mingione [44,45] made a deep study of the pointwise estimates for gradient

$$|Du(x_0)| \leq C(n,p)\left[\fint_{B(x_0,2R)} |Du|dx + C\left(I_1^{|\mu|}(x_0,2R)\right)^{\frac{1}{p-1}}\right]$$

of solutions to (1.4) and more general case in terms of the linear Riesz potential of the right-hand side $I_1^{|\mu|}(x,R)$ which is defined by

$$I_1^{|\mu|}(x,R) := \int_0^R \frac{|\mu|(B(x,\varrho))}{\varrho^{n-1}}\frac{d\varrho}{\varrho}.$$

In particular, we mention here that Duzaar & Mingione [33] obtained gradient estimates via linear Riesz potentials

$$|Du(x_0)| \leq C\fint_{B(x_0,2R)} |Du|dx + C\left[I_1^{|\mu|}(x_0,2R)\right]^{\frac{1}{p-1}}$$

for solutions of the general case of the elliptic p-Laplacian equation for $2-1/n < p < 2$. We remark that the lower bound $2-1/n$ on the exponent p is to ensure $W^{1,1}$-solutions (see [33]). It deserves to be specially noted that Dong, Nguyen, Phuc & Zhu [32,55,57] also studied the local and global pointwise gradient estimates for solutions to the quasilinear elliptic equation with measure data $-\operatorname{div} A(x,Du) = \mu$ in the case $1 < p \leq 2-1/n$, whose prototype is given by the elliptic p-Laplace equation (1.4). Moreover, an extension of the previous results to a class of general elliptic equations

$$-\operatorname{div}\left[a\left(|Du|\right)Du\right] = \mu$$

including the p-Laplacian equation has been recently given by Baroni [7], in which the author proved the following pointwise gradient estimates via the linear Riesz potential

$$g(|Du(x_0)|) \le Cg\left(\fint_{B(x_0,2R)} |Du|dx\right) + CI_1^{|\mu|}(x_0,2R).$$

Actually, Cianchi & Maz'ya [26–28] have proved Lipschitz regularity and sharp estimates for weak solutions of

$$-\operatorname{div}\left(a\left(|Du|\right)Du\right) = f, \tag{1.10}$$

which is first introduced and studied by Lieberman [46] as the most natural and best generalization of the p-Laplacian equation. In the meanwhile, the authors [5,6,10,21,25,30,31,52,65] also studied regularity estimates of weak solutions for the quasilinear elliptic equations (1.10).

In a general way we call w belongs to the class of the Muckenhoupt weights A_p for some $p > 1$ if $w \in L^1_{loc}(\mathbb{R}^n)$ and $w > 0$ almost everywhere satisfies

$$\left(\fint_{B_r} w(x)dx\right)\left(\fint_{B_r} w(x)^{\frac{-1}{p-1}}dx\right)^{p-1} \le C$$

for any ball B_r in $\mathbb{R}^n$. Moreover, we denote

$$A_\infty := \bigcup_{1<p<\infty} A_p \quad \text{and} \quad w(B_r) := \int_{B_r} w(x)dx.$$

Furthermore, the corresponding weighted Lebesgue space $L^p_w(B_r)$ consists of all functions h which satisfy

$$\|h\|_{L^p_w(B_r)} := \left(\int_{B_r} |h|^p\, w(x)dx\right)^{1/p} < \infty.$$

Now we give the following definition of weighted Lorentz spaces.

Definition 1.1. The weighted Lorentz space $L^{q,r}_w(\Omega)$ for any $0 < q < \infty$ and $0 < r \le \infty$ is the set of all measurable functions h satisfying

$$\|h\|_{L^{q,r}_w(\Omega)} < \infty,$$

where

$$\|h\|_{L^{q,r}_w(\Omega)} := \begin{cases} \left[q\displaystyle\int_0^\infty \lambda^{r-1} w\left(\{x\in\Omega : |h(x)| > \lambda\}\right)^{\frac{r}{q}} d\lambda\right]^{\frac{1}{r}} & \text{for } r<\infty, \\ \displaystyle\sup_{\lambda>0} \lambda\, w\left(\{x\in\Omega : |h(x)| > \lambda\}\right)^{\frac{1}{q}} & \text{for } r=\infty. \end{cases}$$

Actually, the weighted Lebesgue space $L^q_w(\Omega) = L^{q,q}_w(\Omega)$ and Marcinkiewicz space $\mathcal{M}^q(\Omega) = L^{q,\infty}(\Omega)$.

Lemma 1.2 (see [16,19,47,62,63])**.** *Assume that $w \in A_p$ for some $p > 1$. Then there exists a small positive constant $\sigma > 0$ such that*

$$C_1\left(\frac{|B_r|}{|B_R|}\right)^p \le \frac{w(B_r)}{w(B_R)} \le C_2\left(\frac{|B_r|}{|B_R|}\right)^\sigma$$

for any balls $B_r \subset B_R \subset \mathbb{R}^n$, where $C_2 > 1$ and $C_1 > 0$.

There are various kinds of Calderón–Zygmund type estimates for the elliptic equations of p-Laplacican type (see, for example, [3, 8, 17, 29, 41, 47, 48] and the references therein). More to the point, Mingione [50] first proved the local sharp estimates in Lorentz spaces for the solutions to the following p-Laplacian type elliptic equation with measure data

$$-\operatorname{div}\mathbf{a}(x, Du) = \mu \quad \text{in } \Omega. \tag{1.11}$$

Furthermore, Phuc [59] obtained the following global weighted norm inequality in Lorentz spaces for gradients of solutions to (1.11)

$$(\mathcal{M}_1(\mu))^{\frac{1}{p-1}} \in L^{q,r}_w(\Omega) \Longrightarrow |Du| \in L^{q,r}_w(\Omega)$$

for $2 - 1/n < p \le n$, any $q \in (0, +\infty)$ and $r \in (0, +\infty]$, where $\mathcal{M}_1(\mu)(x)$ is the first-order fractional maximal function

$$\mathcal{M}_1(\mu)(x) := \sup_{r>0} \frac{r|\mu|(B_r(x))}{|B_r(x)|}, \quad x \in \mathbb{R}^n.$$

Subsequently, Nguyen & Phuc [54, 56] obtained existence and global regularity estimates for gradients of solutions to quasilinear elliptic equations with measure data, whose prototypes are of the form $-\operatorname{div}\left(|Du|^{p-2}Du\right) = \delta|Du|^q + \mu$ for $1 < p \le 2 - 1/n$. In the meanwhile, Byun, Ok & Park [18] established the corresponding Calderón–Zygmund type estimates for quasilinear elliptic equations (1.11) with variable $p(x)$-growth involving measure data. Moreover, Byun, Cho & Youn [14] studied the existence of distributional solutions and the global Calderón–Zygmund type estimates to nonlinear elliptic problems (1.1) and more general case with the right-hand side Radon measure. Moreover, Avelin, Kuusi & Mingione [4] have investigated a limiting case of Calderón–Zygmund theory for a class of nonlinear elliptic equations modeled on the elliptic p-Laplacian equation with right-hand side measure (1.4). Motivated by the works mentioned above, our purpose of this paper is to establish the local weighted Lorentz gradient estimates for weak solutions of the problem (1.1) with the condition (1.2) in the case $-1/n < i_a \le s_a < 0$. More precisely, we shall prove that

$$g^{-1}\left[\mathcal{M}_1(\mu)\right] \in L^{q,r}_{w,loc}(\Omega) \implies |Du| \in L^{q,r}_{w,loc}(\Omega).$$

We now state the definition of weak solutions.

Definition 1.3. A function $u \in W^{1,G}_{loc}(\Omega)$ (see Definition 2.4) is a local weak solution of (1.1) if for any $\varphi \in W^{1,G}_0(\Omega) \cap L^\infty(\Omega)$ we have

$$\int_\Omega a\left((ADu \cdot Du)^{\frac{1}{2}}\right) ADu \cdot D\varphi dx = \int_\Omega \varphi d\mu.$$

In this work we shall assume that the coefficients of $A = \{a_{ij}\}$ are in the BMO space and their semi-norms are small enough. Higher integrability of solutions to various kinds of elliptic/parabolic PDEs with discontinuous coefficients of VMO/BMO type has been extensively studied by many authors (see [2, 15, 20, 41, 43]). We would like to point out that a function satisfies the small BMO condition if it satisfies the VMO condition. More precisely, we use the following small BMO condition.

Definition 1.4. We say that the matrix A of coefficients is (δ, R)-vanishing if

$$\sup_{0<r\le R}\sup_{x\in\mathbb{R}^n} \fint_{B_r(x)} \left|A(y) - \overline{A}_{B_r(x)}\right| dy \le \delta,$$

where

$$\overline{A}_{B_r(x)} = \fint_{B_r(x)} A(y)\, dy.$$

The main result of this work is stated as follows. First of all, we remark that the following conclusion is stated as a priori estimate for weak solutions. Actually, solutions to measure data problems (very weak solutions) are usually found by approximation procedures. So, they are often called SOLA (Solutions Obtained by Limiting Approximation). We can refer to the relevant existence theory in the papers [11–13, 37, 40]. In the following we shall mention a space $W^{1,f}(\Omega)$, where

$$f(t) := \int_0^t \frac{g(s)}{s} ds,$$

whose definition is just like Section 3.2 in [7]. More precisely, the exact definition of SOLA is given as follows: a function $u \in W^{1,f}_{loc}(\Omega)$ is a local SOLA of (1.1) if

$$\int_\Omega a\left((ADu \cdot Du)^{\frac{1}{2}}\right) ADu \cdot D\varphi dx = \int_\Omega \varphi d\mu$$

holds for any $\varphi \in C_0^\infty(\Omega)$, and moreover there exists a sequence of weak solutions $\{u_k\} \in W^{1,G}_{loc}(\Omega)$ of

$$-\operatorname{div}\left(a\left((ADu_k \cdot Du_k)^{\frac{1}{2}}\right) ADu_k\right) = \mu_k \quad \text{in } \Omega, \tag{1.12}$$

such that $u_k \to u$ in $W^{1,f}_{loc}(\Omega)$, where $\{\mu_k\} \in L^\infty(\Omega)$ converges weakly to μ in the sense of measure. In particular, we shall assume that $-1/n < i_a \le s_a < 0$ in the theorem below just like in the paper of Duzaar & Mingione [33], in which they supposed that $p > 2 - 1/n$ for the elliptic p-Laplacian equations and general case.

Now we shall give a concrete conclusion of this paper.

Theorem 1.5. *Suppose that $\mu \in L^\infty(\Omega)$ and $u \in W^{1,G}_{loc}(\Omega)$ is a local weak solution of (1.1) in $\Omega \supset B_2$ for $-1/n < i_a \le s_a < 0$. Then we have*

$$g^{-1}[\mathcal{M}_1(\mu)] \in L^{q,r}_{w,loc}(\Omega) \Longrightarrow |Du| \in L^{q,r}_{w,loc}(\Omega)$$

for any $q \in (1, \infty)$ and $r \in (0, \infty]$, with the estimate

$$\|Du\|_{L^{q,r}_{w,loc}(B_1)} \le C \int_{B_2} (|Du| + 1)\, dx + C\|g^{-1}[\mathcal{M}_1(\mu))\|_{L^{q,r}_{w,loc}(B_2)},$$

where C is independent of u and μ.

2 Proof of the main result

In this section we shall finish the proof of the main result in this work, Theorem 1.5. First of all, we shall give some definitions on the general Orlicz spaces, which have been extensively studied in the area of analysis (see [1, 53]) and play a crucial role in many fields of mathematics including geometric, probability theory, stochastic analysis, Fourier analysis, partial differential equations and so on (see [61]).

Definition 2.1. A function G belongs to Φ, which consists of all increasing and convex functions $G : [0, +\infty) \to [0, +\infty)$, is said to be a Young function if

$$\lim_{t \to 0+} \frac{G(t)}{t} = \lim_{t \to +\infty} \frac{t}{G(t)} = 0.$$

Additionally, a Young function G is said to $G \in \Delta_2$ if there exists $M > 0$ such that

$$G(2t) \le MG(t) \quad \text{for any } t > 0. \tag{2.1}$$

Moreover, we call a Young function $G \in \nabla_2$ if there exists a number $a > 1$ such that

$$G(t) \le \frac{G(at)}{2a} \quad \text{for any } t > 0. \tag{2.2}$$

Example 2.2.

(1) $G_1(t) = (1+t)\log(1+t) - t \in \Delta_2$, but $G_1(t) \notin \nabla_2$.

(2) $G_2(t) = e^t - t - 1 \in \nabla_2$, but $G_2(t) \notin \Delta_2$.

(3) $G_3(t) = t^p \log(1+t) \in \Delta_2 \cap \nabla_2$ for $p > 1$.

Remark 2.3. Actually, if $G \in \Delta_2 \cap \nabla_2$, then we have

$$G(\theta_1 t) \le K\theta_1^{\beta_1} G(t) \quad \text{and} \quad G(\theta_2 t) \le 2a\theta_2^{\beta_2} G(t) \tag{2.3}$$

for every $t > 0$ and $0 < \theta_2 \le 1 \le \theta_1 < \infty$, where $\beta_1 = \log_2 M \ge \beta_2 = \log_a 2 + 1 > 1$.

Definition 2.4. Assume that G is a Young function. Then the Orlicz class $K^G(\mathbb{R}^n)$ is the set of all measurable functions $f : \mathbb{R}^n \to \mathbb{R}$ satisfying

$$\int_{\mathbb{R}^n} G(|f|)\, dx < \infty.$$

The Orlicz space $L^G(\mathbb{R}^n)$ is the linear hull of $K^G(\mathbb{R}^n)$ and $W^{1,G}(\mathbb{R}^n) := \{f \in L^G(\mathbb{R}^n) \mid Df \in L^G(\mathbb{R}^n)\}$.

Moreover, in this work we need the following crucial lemmas, which will be used in the subsequent proof.

Lemma 2.5 ([1])**.** *Let G be a Young function satisfying $G \in \Delta_2 \cap \nabla_2$. Then*

(1) $K^G(\Omega) = L^G(\Omega)$.

(2) $C_0^\infty(\Omega)$ *is dense in* $L^G(\Omega)$.

(3) $L^{\beta_1}(\Omega) \subset L^G(\Omega) \subset L^{\beta_2}(\Omega) \subset L^1(\Omega)$ *with* $\beta_1 \ge \beta_2 > 1$ *as in* (2.3).

(4) If $f \in L^G(\mathbb{R}^n)$, *then*

$$\int_{\mathbb{R}^n} G(|f|)\, dx = \int_0^\infty |\{x \in \mathbb{R}^n : |f| > \mu\}|\; d\left[G(\mu)\right].$$

(5)

$$st \le \epsilon\, \widetilde{G}(s) + C(\epsilon) G(t) \quad \textit{for any } s, t \ge 0 \textit{ and } \epsilon > 0,$$

where $\widetilde{G}$ *is the conjugate function of* G

$$\widetilde{G}(t) := \sup_{s \ge 0} \{st - G(s)\} \quad \textit{for any } t \ge 0.$$

Now we shall recall the following results, which can be derived from Proposition 2.9 of [26], Lemma 1.9 and Lemma 2.4 of [65] and the change of variable.

Lemma 2.6. *Assume that $a(t)$ satisfies (1.2) for $s_a < 0$ and $G(t) = \int_0^t \tau a(\tau)\, d\tau$ for $t \geq 0$ is defined in (1.6).*

1. *For any $t > 0$ we find that*

$$\theta^{i_a} \leq \frac{a(\theta t)}{a(t)} \leq \theta^{s_a} \quad \text{and} \quad \theta^{2+i_a} \leq \frac{G(\theta t)}{G(t)} \leq \theta^{2+s_a} \quad \text{for any } \theta \geq 1. \tag{2.4}$$

2. *$G(t) \in \nabla_2 \cap \Delta_2$ and $\widetilde{G}(g(t)) \leq CG(t)$ for $t \geq 0$.*
3. *There exist $C = C(n, i_a, s_a) > 0$ and $\epsilon_0 = \epsilon_0(n, i_a, s_a) > 0$ we have*

$$G(|\xi - \eta|) \leq C(\epsilon) \left[a\left((A\xi \cdot \xi)^{\frac{1}{2}} \right) A\xi - a\left((A\eta \cdot \eta)^{\frac{1}{2}} \right) A\eta \right] \cdot (\xi - \eta) + \epsilon G(|\eta|)$$

for any $\xi, \eta \in \mathbb{R}^n$ and small positive constant $\epsilon \in (0, \epsilon_0)$.

Next, we can obtain the following important results for $s_a < 0$.

Lemma 2.7. *Assume that $a(t)$ satisfies (1.2) and $s_a < 0$, $G(t)$ is defined in (1.6) and*

$$V(z) = \sqrt{a(|z|)}z. \tag{2.5}$$

Then for any $\xi, \eta \in \mathbb{R}^n$ there exists $C = C(n, i_a, s_a) > 0$ we have

$$Ca(|\xi| + |\eta|) |\xi - \eta|^2 \leq |V(\xi) - V(\eta)|^2 \leq Ca(|\xi| + |\eta|) |\xi - \eta|^2, \tag{2.6}$$

$$C\sqrt{a(|\xi| + |\eta|)} |\xi - \eta|^2 \leq [V(\xi) - V(\eta)] \cdot (\xi - \eta) \leq C\sqrt{a(|\xi| + |\eta|)} |\xi - \eta|^2 \tag{2.7}$$

and

$$\left[a\left((A\xi \cdot \xi)^{\frac{1}{2}} \right) A\xi - a\left((A\eta \cdot \eta)^{\frac{1}{2}} \right) A\eta \right] \cdot (\xi - \eta) \geq C |V(\xi) - V(\eta)|^2. \tag{2.8}$$

Proof. We first find that

$$\begin{aligned} &V(\xi) - V(\eta) \\ &= \sqrt{a(|\xi|)}\xi - \sqrt{a(|\eta|)}\eta \\ &= (\xi - \eta) \int_0^1 \sqrt{a(|s\xi + (1-s)\eta|)}\, ds \\ &\quad + \frac{1}{2} \int_0^1 \frac{a'(|s\xi + (1-s)\eta|)}{|s\xi + (1-s)\eta|} \frac{1}{\sqrt{a(|s\xi + (1-s)\eta|)}} (s\xi + (1-s)\eta)\, [s\xi + (1-s)\eta] \cdot (\xi - \eta)\, ds. \end{aligned}$$

Then from (1.2) we deduce that

$$\begin{aligned} |V(\xi) - V(\eta)| &\leq |\xi - \eta| \int_0^1 \sqrt{a(|s\xi + (1-s)\eta|)} ds - \frac{i_a}{2} |\xi - \eta| \int_0^1 \sqrt{a(|s\xi + (1-s)\eta|)} ds \\ &= \left(1 - \frac{i_a}{2}\right) |\xi - \eta| \int_0^1 \sqrt{a(|s\xi + (1-s)\eta|)}\, ds. \end{aligned} \tag{2.9}$$

Similarly, we have

$$|V(\xi) - V(\eta)| \geq \left(1 + \frac{i_a}{2}\right) |\xi - \eta| \int_0^1 \sqrt{a(|s\xi + (1-s)\eta|)}\, ds, \tag{2.10}$$

$$[V(\xi)-V(\eta)]\cdot(\xi-\eta)\geq\left(1+\frac{i_a}{2}\right)|\xi-\eta|^2\int_0^1\sqrt{a\left(|s\xi+(1-s)\eta|\right)}\,ds \tag{2.11}$$

and

$$[V(\xi)-V(\eta)]\cdot(\xi-\eta)\leq\left(1-\frac{i_a}{2}\right)|\xi-\eta|^2\int_0^1\sqrt{a\left(|s\xi+(1-s)\eta|\right)}\,ds. \tag{2.12}$$

In view of the facts that $a(t)$ is strictly decreasing and $|s\xi+(1-s)\eta|\leq|\xi|+|\eta|$ for any $0\leq s\leq 1$, we find that

$$\int_0^1\sqrt{a\left(|s\xi+(1-s)\eta|\right)}ds\geq\int_0^1\sqrt{a\left(|\xi|+|\eta|\right)}ds=\sqrt{a\left(|\xi|+|\eta|\right)}, \tag{2.13}$$

which implies that the left-hand inequalities of (2.6) and (2.7) hold true. On the other hand, we define

$$s_0:=\frac{|\xi-\eta_0|}{|\xi-\eta|},$$

where η_0 is the minimum norm point on the line through ξ and η. Without loss of generality we may as well assume that $|\xi|\geq|\eta|>0$. It is easy to check that $s_0\geq\frac{1}{2}$. The following two cases shall be considered separately.

Case 1: $s_0\geq 1$. Then $|s\eta+(1-s)\xi|\geq|s\eta_0+(1-s)\xi|\geq|s0+(1-s)\xi|=(1-s)\,|\xi|\geq\frac{(1-s)}{2}\left(|\xi|+|\eta|\right)$ for any $s\in[0,1]$ and $|\xi|\geq|\eta|>0$. Furthermore, from Lemma 2.6 (1) and the decreasing property of $a(t)$ we conclude that

$$\begin{aligned}\int_0^1\sqrt{a\left(|s\eta+(1-s)\xi|\right)}ds&\leq\int_0^1\sqrt{a\left(\frac{(1-s)}{2}\left(|\xi|+|\eta|\right)\right)}ds\\&\leq C\sqrt{a\left(|\xi|+|\eta|\right)}\int_0^1(1-s)^{\frac{i_a}{2}}ds\\&\leq C\sqrt{a\left(|\xi|+|\eta|\right)}.\end{aligned} \tag{2.14}$$

Case 2: $\frac{1}{2}\leq s_0<1$. Recalling the definition of η_0 and choosing $s=\theta s_0$, we have

$$\begin{aligned}\int_0^1\sqrt{a(|s\eta+(1-s)\xi|)}\mathrm{d}s&\leq 2\int_0^{s_0}\sqrt{a(|s\eta+(1-s)\xi|)}\mathrm{d}s\\&\leq C\int_0^1\sqrt{a(|\theta\eta_0+(1-\theta)\xi|)}\mathrm{d}\theta\\&\leq C\int_0^1\sqrt{a\left((1-\theta)\,|\xi|\right)}d\theta,\end{aligned}$$

in view of the facts that $|\theta\eta_0+(1-\theta)\xi|\geq|\theta 0+(1-\theta)\xi|=(1-\theta)\,|\xi|$ for any $\theta\in[0,1]$ and $a(t)$ is decreasing. Similarly to Case 1, we find that

$$\int_0^1\sqrt{a\left(|s\eta+(1-s)\xi|\right)}ds\leq C\sqrt{a\left(|\xi|+|\eta|\right)}. \tag{2.15}$$

Therefore, from (2.9)–(2.15) we can conclude that the right-hand inequalities of (2.6) and (2.7) are true.

For the sake of clarity and brevity, we may as well assume that $A = I$ in the following proof. First of all, we can compute as follows

$$\xi a(|\xi|) - \eta a(|\eta|) = (\xi - \eta) \int_0^1 a(|s\xi + (1-s)\eta|)\, ds + \int_0^1 \frac{a'(|s\xi + (1-s)\eta|)}{|s\xi + (1-s)\eta|} (s\xi + (1-s)\eta) [s\xi + (1-s)\eta] \cdot (\xi - \eta)\, ds,$$

which implies that

$$\begin{aligned} &[\xi a(|\xi|) - \eta a(|\eta|)] \cdot (\xi - \eta) \\ &\geq |\xi - \eta|^2 \int_0^1 a(|s\xi + (1-s)\eta|)\, ds + i_a \int_0^1 a(|s\xi + (1-s)\eta|) \left| \frac{[s\xi + (1-s)\eta] \cdot (\xi - \eta)}{|s\xi + (1-s)\eta|} \right|^2 ds \\ &\geq (1 + i_a) |\xi - \eta|^2 \int_0^1 a(|s\xi + (1-s)\eta|)\, ds \end{aligned}$$

in view of (1.2). Then similarly to (2.13), we find that

$$\int_0^1 a(|s\xi + (1-s)\eta|)\, ds \geq a(|\xi| + |\eta|),$$

which implies that

$$[\xi a(|\xi|) - \eta a(|\eta|)] \cdot (\xi - \eta) \geq C a(|\xi| + |\eta|) |\xi - \eta|^2. \tag{2.16}$$

Thus, from (2.6) and (2.16) we can obtain (2.8) and then finish the proof. □

For a locally integrable function f in $\mathbb{R}^n$, we define its Hardy–Littlewood maximal function $\mathcal{M}(f)(x)$ as

$$\mathcal{M}(f)(x) := \sup_{r>0} \fint_{B_r(x)} |f(y)|\, dy.$$

If f is not defined outside a bounded domain Ω, then we let f be zero in the above definition if x leaves Ω. Moreover, we can obtain the following basic properties for the Hardy–Littlewood maximal functions.

Lemma 2.8 (see [42]).

1. *If $f \in L^1(\Omega)$, then we have the weak 1-1 estimate*

$$|\{x \in \Omega : (\mathcal{M}f)(x) > \lambda\}| \leq \frac{C_3}{\lambda} \int_\Omega |f(x)|\, dx \quad \text{for some constant } C_3 > 0. \tag{2.17}$$

2. *If $f \in L^G(\Omega)$ for $G \in \Delta_2 \cap \nabla_2$, then we have $\mathcal{M}f \in L^G(\Omega)$ with the estimates*

$$\frac{1}{C} \int_\Omega G(|f|)\, dx \leq \int_\Omega G(\mathcal{M}f)\, dx \leq C \int_\Omega G(|f|)\, dx.$$

In this paper we shall use the following version of the weighted Vitali covering lemma, which will be a crucial ingredient in obtaining our main result.

Lemma 2.9 ([59, Lemma 3.4]). *Assume that E and F are measurable sets, $E \subset F \subset B_1$, and that there exists an $\epsilon > 0$ such that $w(E) < \epsilon w(B_1)$ and that for all $x \in B_1$ and for all $r \in (0,1]$ with $w(E \cap B_r(x)) \geq \epsilon w(B_r(x))$ we have $B_r(x) \cap B_1 \subset F$. Then, we have*

$$w(E) \leq C\epsilon w(F).$$

Moreover, we shall also use the following standard arguments of measure theory.

Lemma 2.10 (see [22,59]). *Assume that $r \in (0,+\infty)$ and f is a nonnegative and measurable function in Ω. Let $m > 1$ be a constant. Then for $0 < q < \infty$ we have*

$$f \in L^{q,r}_w(\Omega) \text{ iff } S := \sum_{i \geq 1} m^{ir} \left[w\left(\left\{ x \in \Omega : f(x) > m^i \right\} \right) \right]^{\frac{r}{q}} < \infty$$

and

$$\frac{1}{C} S \leq \|f\|^r_{L^{q,r}_w(\Omega)} \leq C \left[(w(\Omega))^{\frac{r}{q}} + S \right],$$

where $C > 0$ is a constant depending only on m and w.

Furthermore, we shall prove the following important result, which involves a delicate argument and a new scaling procedure in the subquadratic case $s_a < 0$.

Lemma 2.11. *Assume that $u \in W^{1,G}_{loc}(\Omega)$ is a local weak solution of (1.1) with (1.2) and $B_{2R} \subset \Omega$. If $v \in W^{1,G}(B_{2R})$ is the weak solution of*

$$\begin{cases} \operatorname{div} \left[a\left((ADv \cdot Dv)^{\frac{1}{2}} \right) ADv \right] = 0 & \text{in } B_{2R}, \\ v = u & \text{on } \partial B_{2R}, \end{cases} \tag{2.18}$$

then for any $\epsilon_1 > 0$ there exists a constant $C = C(n, i_a, s_a, \epsilon_1) > 1$ such that

$$\fint_{B_{2R}} |Du - Dv| \, dx \leq C g^{-1} \left(\frac{1}{\epsilon_1} \frac{|\mu|(B_{2R})}{(2R)^{n-1}} \right) + \epsilon_1 \fint_{B_{2R}} |Du| \, dx.$$

Proof. Without loss of generality we may as well assume that $R = 1$ by defining

$$\tilde{u}(x) = R^{-1} u(Rx), \quad \tilde{v}(x) = R^{-1} v(Rx) \quad \text{and} \quad \tilde{\mu}(x) = R\mu(Rx).$$

For $k \geq 1$ we define the following truncation operators (see [33,34,44,49])

$$T_k(s) := \max\{-k, \min\{k, s\}\} \quad \text{and} \quad \Phi_k(s) := T_1(s - T_k(s)), \; s \in \mathbb{R}.$$

Since u and v are weak solutions of (1.1) and (2.18) respectively, then we have

$$\int_{B_2} \left[a\left((ADu \cdot Du)^{\frac{1}{2}} \right) ADu - a\left((ADv \cdot Dv)^{\frac{1}{2}} \right) ADv \right] \cdot D\varphi dx = \int_{B_2} \varphi d\mu \tag{2.19}$$

for any $\varphi \in L^\infty(B_2) \cap W^{1,G}_0(B_2)$. Without loss of generality we may as well assume that

$$|\mu|(B_2) \leq \epsilon_1 \quad \text{and} \quad \fint_{B_2} |Du| dx \leq \frac{1}{\epsilon_1} \tag{2.20}$$

for any small constant $\epsilon_1 \in (0,1)$. If not, we can define

$$\tilde{u}(x) = \frac{u(x)}{\lambda}, \qquad \tilde{v}(x) = \frac{v(x)}{\lambda}, \qquad \tilde{\mu}(x) = \frac{\mu(x)}{g(\lambda)},$$

$$\tilde{a}(t) = \frac{a(\lambda t)}{a(\lambda)} \quad \text{and} \quad \widetilde{G}(t) = \frac{G(\lambda t)}{G(\lambda)},$$

where

$$\lambda = g^{-1}\left(\frac{1}{\epsilon_1}|\mu|(B_2)\right) + \epsilon_1 \fint_{B_2} |Du|dx.$$

Then, $\tilde{a}\,(t)$ satisfies (1.2) and $\tilde{u}(x) \in W^{1,G}_{loc}(\Omega)$ is a local weak solution of

$$-\text{div}\left[\tilde{a}\left((AD\tilde{u}\cdot D\tilde{u})^{\frac{1}{2}}\right)AD\tilde{u}\right] = \tilde{\mu}.$$

Therefore, it is sufficient to prove the following inequality

$$\fint_{B_2} |Du - Dv|\,dx \le C \tag{2.21}$$

under the condition (2.20), where C is independent of ϵ_1. By choosing $\varphi = \Phi_k(u-v) \in L^\infty(B_2)\cap W^{1,G}_0(B_2)$ in (2.19) and using (2.8), we find that

$$\int_{C_k} |V(Du) - V(Dv)|^2\,dx \le C\int_{B_2} |\mu| dx \le C, \tag{2.22}$$

where $C_k := \{x \in B_2 : k < |u(x) - v(x)| \le k+1\}$. In the meantime, from (2.4), (2.6) and Young's inequality we find that

$$\begin{aligned}
|Du - Dv| &\le Ca^{-\frac{1}{2}}\left(|Du| + |Dv|\right)|V(Du) - V(Dv)| \\
&\le Ca^{-\frac{1}{2}}\left(|Du| + |Dv| + 1\right)|V(Du) - V(Dv)| \\
&\le C\left(|Du| + |Dv| + 1\right)^{-\frac{i_a}{2}}|V(Du) - V(Dv)| \\
&\le C\left(|Du - Dv|^{-\frac{i_a}{2}} + |Du|^{-\frac{i_a}{2}} + 1\right)|V(Du) - V(Dv)| \\
&\le C\,|V(Du) - V(Dv)|^{\frac{2}{2+i_a}} + \frac{1}{2}|Du - Dv| \\
&\quad + C|Du|^{-\frac{i_a}{2}}\,|V(Du) - V(Dv)| + |V(Du) - V(Dv)| \\
&\le C\,|V(Du) - V(Dv)|^{\frac{2}{2+i_a}} + \frac{1}{2}|Du - Dv| + C|Du|^{-\frac{i_a}{2}}\,|V(Du) - V(Dv)| + 1
\end{aligned}$$

for $i_a \in (-1/n, 0)$, which implies that

$$|Du - Dv| \le C\,|V(Du) - V(Dv)|^{\frac{2}{2+i_a}} + C|Du|^{-\frac{i_a}{2}}\,|V(Du) - V(Dv)| + 1$$

and then

$$\begin{aligned}
\int_{B_2} |Du - Dv|\,dx &\le C\int_{B_2} |V(Du) - V(Dv)|^{\frac{2}{2+i_a}} + 1dx \\
&\quad + C\left(\int_{B_2} |V(Du) - V(Dv)|^{\frac{2}{2+i_a}}\,dx\right)^{\frac{2+i_a}{2}}\left(\int_{B_2} |Du|dx\right)^{-\frac{i_a}{2}}
\end{aligned} \tag{2.23}$$

by using Hölder's inequality. Moreover, from Hölder's inequality, (2.22) and the definition of C_k we find that

$$\begin{aligned}
\int_{C_k} |V(Du) - V(Dv)|^{\frac{2}{2+i_a}}\,dx &\le C\,|C_k|^{1-\frac{1}{2+i_a}}\left(\int_{C_k} |V(Du) - V(Dv)|^2\,dx\right)^{\frac{1}{2+i_a}} \\
&\le C\,|C_k|^{1-\frac{1}{2+i_a}}\,[|\mu|(B_2)]^{\frac{1}{2+i_a}} \\
&\le C\,[|\mu|(B_2)]^{\frac{1}{2+i_a}}\,\frac{1}{k^{\frac{n}{n-\sigma}(1-\frac{1}{2+i_a})}}\left(\int_{C_k} |u - v|^{\frac{n}{n-\sigma}}\,dx\right)^{1-\frac{1}{2+i_a}}
\end{aligned}$$

for some $\sigma \in (-ni_a, 1) \subset (0,1)$. Therefore, we conclude that

$$\begin{aligned}
&\int_{B_2} |V(Du)-V(Dv)|^{\frac{2}{2+i_a}}\,dx \\
&\le \int_{C_0} |V(Du)-V(Dv)|^{\frac{2}{2+i_a}}\,dx + \sum_{k=1}^{\infty} \int_{C_k} |V(Du)-V(Dv)|^{\frac{2}{2+i_a}}\,dx \\
&\le C\,[|\mu|(B_2)]^{\frac{1}{2+i_a}} \left\{ 1 + \sum_{k=1}^{\infty} \frac{1}{k^{\frac{n}{n-\sigma}(1-\frac{1}{2+i_a})}} \left(\int_{C_k} |u-v|^{\frac{n}{n-\sigma}}\,dx \right)^{1-\frac{1}{2+i_a}} \right\} \\
&\le C\,[|\mu|(B_2)]^{\frac{1}{2+i_a}} \left\{ 1 + \left[\sum_{k=1}^{\infty} \frac{1}{k^{\frac{n(1+i_a)}{n-\sigma}}} \right]^{\frac{1}{2+i_a}} \left(\sum_{k=1}^{\infty} \int_{C_k} |u-v|^{\frac{n}{n-\sigma}}\,dx \right)^{1-\frac{1}{2+i_a}} \right\} \\
&\le C\,[|\mu|(B_2)]^{\frac{1}{2+i_a}} \left\{ 1 + \left(\int_{B_2} |u-v|^{\frac{n}{n-\sigma}}\,dx \right)^{(1-\frac{1}{2+i_a})} \right\} \\
&\le C\,[|\mu|(B_2)]^{\frac{1}{2+i_a}} \left\{ 1 + \left(\int_{B_2} |Du-Dv|\,dx \right)^{\frac{n}{n-\sigma}(1-\frac{1}{2+i_a})} \right\}
\end{aligned} \tag{2.24}$$

by Sobolev's inequality and the fact that

$$\frac{n(1+i_a)}{n-\sigma} > 1,$$

since $\sigma \in (-ni_a, 1)$. Furthermore, from (2.20), (2.23), (2.24) and Young's inequality we obtain

$$\begin{aligned}
\int_{B_2} |Du-Dv|\,dx &\le C + C\,[|\mu|(B_2)]^{\frac{1}{2+i_a}} \left\{ 1 + \left(\int_{B_2} |Du-Dv|\,dx \right)^{\frac{n}{n-\sigma}(1-\frac{1}{2+i_a})} \right\} \\
&\quad + C\,[|\mu|(B_2)]^{\frac{1}{2}} \left(\int_{B_2} |Du|dx \right)^{-\frac{i_a}{2}} \left[1 + \left(\int_{B_2} |Du-Dv|\,dx \right)^{\frac{n}{n-\sigma}(1-\frac{1}{2+i_a})} \right]^{\frac{2+i_a}{2}} \\
&\le C + C\,[|\mu|(B_2)]^{\frac{1}{2+i_a}} \left\{ 1 + \left(\int_{B_2} |Du-Dv|\,dx \right)^{\frac{n}{n-\sigma}(1-\frac{1}{2+i_a})} \right\} \\
&\quad + C \left[[|\mu|(B_2)]^{\frac{1}{2}} \left(\int_{B_2} |Du|dx \right)^{-\frac{i_a}{2}} \right]^{\frac{2}{-i_a}} \\
&\quad + C \left(\int_{B_2} |Du-Dv|\,dx \right)^{\frac{n}{n-\sigma}(1-\frac{1}{2+i_a})} \\
&\le C + C\epsilon_1^{\frac{1+i_a}{-i_a}} + C \left(\int_{B_2} |Du-Dv|\,dx \right)^{\frac{n}{n-\sigma}(1-\frac{1}{2+i_a})} \\
&\le C + C \left(\int_{B_2} |Du-Dv|\,dx \right)^{\frac{n}{n-\sigma}(1-\frac{1}{2+i_a})},
\end{aligned}$$

which implies that (2.21) is true since

$$\frac{n}{n-\sigma}\left(1-\frac{1}{2+i_a}\right) < 1 \quad \text{for } i_a \in \left(-\frac{1}{n}, 0\right).$$

Thus, we finish the proof. □

We now switch to another comparison estimate for solutions to (1.1) and the homogeneous constant coefficient problem.

Lemma 2.12. *Assume that $u \in W^{1,G}_{loc}(\Omega)$ is a local weak solution of (1.1) with $B_R \subset \Omega$ and (1.2). If $w \in W^{1,G}(B_R)$ is the weak solution of*

$$\begin{cases} \operatorname{div}\left[a\left((\overline{A}_{B_R}Dw\cdot Dw)^{\frac{1}{2}}\right)\overline{A}_{B_R}Dw\right]=0 & \text{in } B_R, \\ w=v & \text{on } \partial B_R, \end{cases} \tag{2.25}$$

then for any $\epsilon_1>0$ there exists a constant $C=C(n,i_a,s_a,\epsilon_1)>1$ such that

$$⨍_{B_R}|Du-Dw|\,dx \le Cg^{-1}\left(\frac{1}{\epsilon_1}\frac{|\mu|(B_{2R})}{(2R)^{n-1}}\right)+\epsilon_1⨍_{B_{2R}}|Du|\,dx. \tag{2.26}$$

Proof. If we select the test function $\varphi=v-w$, then after a direct calculation we can show the resulting expression as

$$I_1:=\int_{B_R}a\left((\overline{A}_{B_R}Dw\cdot Dw)^{\frac{1}{2}}\right)\overline{A}_{B_R}Dw\cdot Dwdx=\int_{B_R}a\left((\overline{A}_{B_R}Dw\cdot Dw)^{\frac{1}{2}}\right)\overline{A}_{B_R}Dw\cdot Dvdx=:I_2.$$

Using (1.3) and Lemmas 2.5–2.6, we find that

$$C\int_{B_R}G(|Dw|)\,dx\le I_1=I_2\le\tau\int_{B_R}G(|Dw|)\,dx+C(\tau)\int_{B_R}G(|Dv|)\,dx,$$

which implies that

$$\int_{B_R}G(|Dw|)\,dx\le C\int_{B_R}G(|Dv|)\,dx \tag{2.27}$$

by choosing τ small enough. Moreover, we apply Gehring's lemma (see Theorem 6.7 in [36]) to obtain the reverse Hölder type inequality

$$\left[⨍_{B_R}[G(|Dw|)]^{1+\delta_0}\,dx\right]^{\frac{1}{1+\delta_0}}\le C⨍_{B_{2R}}G(|Dw|)\,dx \tag{2.28}$$

for some positive constant $\delta_0>0$. On the other hand, we can also calculate the result of the expression $I_3=I_4$, where

$$I_3:=\int_{B_R}\left[a\left((ADv\cdot Dv)^{\frac{1}{2}}\right)ADu-a\left((ADw\cdot Dw)^{\frac{1}{2}}\right)ADw\right]\cdot(Dv-Dw)dx,$$
$$I_4:=-\int_{B_R}\left[a\left((ADw\cdot Dw)^{\frac{1}{2}}\right)ADw-a\left((\overline{A}_{B_R}Dw\cdot Dw)^{\frac{1}{2}}\right)\overline{A}_{B_R}Dw\right]\cdot(Dv-Dw)dx.$$

From Lemma 2.6 we find that

$$\epsilon\int_{B_R}G(|Dv|)\,dx+I_3\ge C\int_{B_R}G(|Dv-Dw|)\,dx.$$

Moreover, we first discover

$$\begin{aligned}|I_4|&\le\int_{B_R}a\left((ADw\cdot Dw)^{\frac{1}{2}}\right)|A-\overline{A}_{B_R}|\,|Dw|\,|Dw-Dv|\,dx\\&\quad+\int_{B_R}\left|a\left((ADw\cdot Dw)^{\frac{1}{2}}\right)-a\left((\overline{A}_{B_R}Dw\cdot Dw)^{\frac{1}{2}}\right)\right||\overline{A}_{B_R}Dw|\,|Dw-Dv|\,dx\\&=:I_{41}+I_{42}.\end{aligned}$$

Estimate of I_{41}. From (1.3), Lemma 2.6, Young's inequality and Hölder's inequality we find that

$$\begin{aligned} I_{41} &\le C \int_{B_R} a(|Dw|)\,|Dw|\,\left|A-\overline{A}_{B_R}\right|\,|Dw-Dv|\,dx \\ &\le \frac{\epsilon}{2\Lambda}\int_{B_R} G(|Dw-Dv|)\left|A-\overline{A}_{B_R}\right|dx + C(\epsilon)\int_{B_R}\widetilde{G}\left(a(|Dw|)\,|Dw|\right)\left|A-\overline{A}_{B_R}\right|dx \\ &\le \epsilon\int_{B_R} G(|Dw-Dv|)\,dx + C(\epsilon)\int_{B_R} G(|Dw|)\left|A-\overline{A}_{B_R}\right|dx \\ &\le \epsilon\int_{B_R} G(|Dw-Dv|)\,dx + C(\epsilon)\left\{\int_{B_R}\left[G(|Dw|)\right]^{1+\delta_0}dx\right\}^{\frac{1}{1+\delta_0}}\left[\int_{B_R}\left|A-\overline{A}_{B_R}\right|^{\frac{1+\delta_0}{\delta_0}}dx\right]^{\frac{\delta_0}{1+\delta_0}} \end{aligned}$$

for any $\epsilon > 0$, which implies that

$$\begin{aligned} I_{41} &\le \epsilon\int_{B_R} G(|Dw-Dv|)\,dx + C(\epsilon)\int_{B_{2R}} G(|Dw|)\,dx\left[\int_{B_R}\left|A-\overline{A}_{B_R}\right|dx\right]^{\frac{\delta_0}{1+\delta_0}} \\ &\le \epsilon\int_{B_R} G(|Dw-Dv|)\,dx + C(\epsilon)\delta^{\frac{\delta_0}{1+\delta_0}}\int_{B_{2R}} G(|Dv|)\,dx, \end{aligned}$$

where we used Definition 1.4 and (2.27)–(2.28).

Estimate of I_{42}. (1.2), (1.3), Lemma 2.6 and Lagrange's mean value theorem yield the bound

$$\begin{aligned} I_{42} &\le C\int_{B_R}\left|a'(\zeta)\right|\left|(ADw\cdot Dw)^{\frac{1}{2}} - \left(\overline{A}_{B_R}Dw\cdot Dw\right)^{\frac{1}{2}}\right|\,|Dw|\,|Dw-Dv|\,dx \\ &\le C\int_{B_R}\frac{|a(\zeta)|}{\zeta}\,\frac{\left|A-\overline{A}_{B_R}\right|\,|Dw|^2}{(ADw\cdot Dw)^{\frac{1}{2}} + \left(\overline{A}_{B_R}Dw\cdot Dw\right)^{\frac{1}{2}}}\,|Dw|\,|Dw-Dv|\,dx \\ &\le C\int_{B_R} a(|Dw|)\,|Dw|\,\left|A-\overline{A}_{B_R}\right|\,|Dw-Dv|\,dx, \end{aligned}$$

where ζ is between $(ADw\cdot Dw)^{\frac{1}{2}}$ and $\left(\overline{A}_{B_R}Dw\cdot Dw\right)^{\frac{1}{2}}$ satisfying

$$\Lambda^{-\frac{1}{2}}|Dw| \le \zeta, (ADw\cdot Dw)^{\frac{1}{2}}, \left(\overline{A}_{B_R}Dw\cdot Dw\right)^{\frac{1}{2}} \le \Lambda^{\frac{1}{2}}|Dw|.$$

And then, we have

$$I_{42} \le \epsilon\int_{B_R} G(|Dw-Dv|)\,dx + C(\epsilon)\delta^{\frac{\delta_0}{1+\delta_0}}\int_{B_{2R}} G(|Dv|)\,dx$$

for any $\epsilon > 0$, whose proof is totally similar to that of I_{41}. Thus, we choose ϵ small enough and combine the estimates of I_3 and I_4 to conclude that

$$\begin{aligned} \int_{B_R} G(|Dv-Dw|)\,dx &\le \epsilon\int_{B_R} G(|Dv|)\,dx + C(\epsilon)\delta^{\frac{\delta_0}{1+\delta_0}}\int_{B_{2R}} G(|Dv|)\,dx \\ &\le \epsilon_1^{2+s_a}\int_{B_{2R}} G(|Dv|)\,dx \end{aligned}$$

by selecting ϵ, δ small enough satisfying the last inequality. Since $\theta^{2+i_a}G(t) \le G(\theta t) \le \theta^{2+s_a}G(t)$ for any $\theta \ge 1$ and $t \ge 0$ by (2.4), we find that

$$\theta^{2+i_a}t \le G\left(\theta G^{-1}(t)\right) \le \theta^{2+s_a}t \quad \text{for any } \theta \ge 1,$$

which implies that

$$G^{-1}\left(\theta^{2+i_a}t\right) \le \theta G^{-1}(t) \le G^{-1}\left(\theta^{2+s_a}t\right) \quad \text{for any } \theta \ge 1.$$

In other words, we conclude that

$$\theta^{\frac{1}{2+s_a}} \le \frac{G^{-1}(\theta t)}{G^{-1}(t)} \le \theta^{\frac{1}{2+i_a}} \quad \text{for any } \theta \ge 1. \tag{2.29}$$

From Jensen's inequality and the reverse Hölder's inequality (see Lemma 4.2 in [7]) we deduce that

$$\begin{aligned} G\left(\fint_{B_R} |Dv - Dw| dx\right) &\le C \fint_{B_R} G\left(|Dv - Dw|\right) dx \\ &\le C\epsilon_1^{2+s_a} \fint_{B_R} G\left(|Dv|\right) dx \\ &\le C\epsilon_1^{2+s_a} G\left(\fint_{B_{2R}} |Dv| dx\right), \end{aligned}$$

which implies that

$$\fint_{B_R} |Dv - Dw| dx \le C\epsilon_1 \fint_{B_{2R}} |Dv| dx$$

by using (2.29). Finally, by using Lemma 2.11 and the above inequality we obtain

$$\begin{aligned} \fint_{B_R} |Du - Dw| dx &\le \fint_{B_R} |Du - Dv| dx + \fint_{B_R} |Dv - Dw| dx \\ &\le C g^{-1}\left(\frac{1}{\epsilon_1}\frac{|\mu|(B_{2R})}{(2R)^{n-1}}\right) + C\epsilon_1 \int_{B_R} |Du| dx + C\epsilon_1 \int_{B_{2R}} |Dv| dx \\ &\le C g^{-1}\left(\frac{1}{\epsilon_1}\frac{|\mu|(B_{2R})}{(2R)^{n-1}}\right) + C\epsilon_1 \int_{B_{2R}} |Du| dx + C\epsilon_1 \int_{B_{2R}} |Dv - Du| dx \\ &\le C g^{-1}\left(\frac{1}{\epsilon_1}\frac{|\mu|(B_{2R})}{(2R)^{n-1}}\right) + C\epsilon_1 \int_{B_{2R}} |Du| dx \end{aligned}$$

and then finish the proof. □

Additionally, we can get the following local Lipschitz regularity for the homogeneous constant coefficient problem.

Lemma 2.13 (see [7, Lemma 4.1])**.** *Let $w \in W^{1,G}(\Omega)$ be a weak solution to*

$$\operatorname{div}\left[a\left(\left(\overline{A}_{B_R} Dw \cdot Dw\right)^{\frac{1}{2}}\right) \overline{A}_{B_R} Dw\right] = 0 \quad \text{in } B_R \subset \mathbb{R}^n.$$

Then we can obtain the following De Giorgi type estimate

$$\sup_{B_{R/2}} |Dw| \le C \fint_{B_R} |Dw|\, dx.$$

The following crucial lemma, which shows how the upper level sets of $|Du|$ decay, allows us to build the interior gradient estimates.

Lemma 2.14. *Assume that* $\lambda > 0$. *There is a constant* $N = N(n, i_a, s_a) > 0$ *so that for any* $\epsilon > 0$, *there exists a small* $\delta = \delta(\epsilon) > 0$ *such that if* $u \in W^{1,G}_{loc}(\Omega)$ *is a local weak solution of* (1.1) *in* $B_{6r} \subset \Omega$ *for* $r \in (0,1]$ *with*

$$B_r \cap \left\{x \in B_1 : \mathcal{M}(|Du|)(x) \le \lambda\right\} \cap \left\{x \in B_1 : g^{-1}\left[\mathcal{M}_1(\mu)\right](x) \le \delta\lambda\right\} \neq \emptyset, \tag{2.30}$$

then we have

$$w\left(\left\{x \in B_r : \mathcal{M}(|Du|)(x) > N\lambda\right\}\right) < \epsilon w\left(B_r\right). \tag{2.31}$$

Proof. From (2.30), there exists a point $x_0 \in B_r$ such that

$$\fint_{B_\rho(x_0)} |Du|\, dx \le \lambda \quad \text{and} \quad g^{-1}\left(\rho \fint_{B_\rho(x_0)} d|\mu|\right) \le \delta\lambda \tag{2.32}$$

for all $\rho > 0$. Since $B_{4r} \subset B_{5r}(x_0)$, it follows from (2.32) that

$$\fint_{B_{4r}} |Du|\, dx \le \frac{|B_{5r}(x_0)|}{|B_{4r}|} \cdot \frac{1}{|B_{5r}(x_0)|} \int_{B_{5r}(x_0)} |Du|\, dx \le 2^n\lambda. \tag{2.33}$$

Since $t^{i_a+1}g(1) \le g(t) \le t^{s_a+1}g(1)$ for any $t \ge 1$ by Lemma 2.6, we know that $t^{\frac{1}{s_a+1}} \lesssim g^{-1}(t) \lesssim t^{\frac{1}{i_a+1}}$ for any $t \ge 1$. Similarly, we also see that $t^{\frac{1}{i_a+1}} \lesssim g^{-1}(t) \lesssim t^{\frac{1}{s_a+1}}$ for any $0 < t < 1$. In the same way, we also have

$$g^{-1}\left(4r \fint_{B_{4r}} d|\mu|\right) \le g^{-1}\left(\frac{4r}{5r} \cdot \frac{|B_{5r}(x_0)|}{|B_{4r}|} \cdot 5r \fint_{B_{5r}(x_0)} d|\mu|\right) \le C\delta\lambda.$$

Then we apply Lemma 2.12 to deduce that

$$\begin{aligned}\fint_{B_{3r}} |Du - Dw|\, dx &\le Cg^{-1}\left(\frac{4r}{\epsilon_1} \fint_{B_{4r}} d|\mu|\right) + \epsilon_1 \fint_{B_{4r}} |Du|\, dx \\ &\le C\frac{\delta\lambda}{\epsilon_1^{\frac{1}{i_a+1}}} + C\epsilon_1\lambda\end{aligned}$$

by choosing δ, ϵ_1 small enough satisfying $C\frac{\delta\lambda}{\epsilon_1^{\frac{1}{i_a+1}}} + C\epsilon_1\lambda \le \lambda$ in advance and then

$$\begin{aligned}\|Dw\|_{L^\infty(B_{3r})} &\le C\fint_{B_{4r}} |Dw|\, dx \\ &\le C\fint_{B_{4r}} |Du|\, dx + C\fint_{B_{4r}} |Du - Dw|\, dx \\ &\le N_1\lambda\end{aligned}$$

by Lemma 2.13 and (2.33), for some positive constant $N_1 \ge 1$. Now we shall claim that

$$\left\{x \in B_r : \mathcal{M}(|Du|)(x) > N\lambda\right\} \subset \left\{x \in B_r : \mathcal{M}(|Du - Dw|)(x) > N_1\lambda\right\} \tag{2.34}$$

for $N := \max\{3^n, 2N_1\}$. Actually, we take $x_1 \in \{x \in B_r : \mathcal{M}(|Du - Dw|)(x) \le N_1\lambda\}$. If $0 < \rho < r$, then we find that $B_\rho(x_1) \subset B_{2r}$ and so

$$\begin{aligned}\fint_{B_\rho(x_1)} |Du|\, dx &\le \fint_{B_\rho(x_1)} (|Dw| + |Du - Dw|)\, dx \\ &\le \mathcal{M}(|Du - Dw|)(x_1) + N_1\lambda \\ &\le 2N_1\lambda.\end{aligned}$$

On the other hand, if $\rho \geq r$, then $B_\rho(x_1) \subset B_{3\rho}(x_0)$. From (2.32), we deduce that

$$\fint_{B_\rho(x_1)} |Du|\,dx \leq \frac{|B_{3\rho}(x_0)|}{|B_\rho(x_1)|} \fint_{B_{3\rho}(x_0)} |Du|\,dx \leq 3^n \lambda \leq N\lambda.$$

Thus, the claim (2.34) is true. Then from Lemma 2.8 we estimate

$$\begin{aligned}\frac{1}{|B_r|}\left|\{x \in B_r : \mathcal{M}(|Du|) > N\lambda\}\right| &\leq \frac{1}{|B_r|}\left|\{x \in B_r : \mathcal{M}(|Du - Dw|) > N_1\lambda\}\right| \\ &\leq \frac{C}{N_1\lambda} \fint_{B_{3r}} |Du - Dw|\,dx \\ &\leq C\frac{\delta}{\epsilon_1^{\frac{1}{i_a+1}}} + C\epsilon_1,\end{aligned}$$

which implies that

$$w\left(\{x \in B_r : \mathcal{M}(|Du|) > N\lambda\}\right) \leq C\left(\frac{\delta}{\epsilon_1^{\frac{1}{i_a+1}}} + \epsilon_1\right)^\sigma w(B_r) < \epsilon w(B_r)$$

by Lemma 1.2 and choosing δ, ϵ_1 small enough satisfying the last inequality. Therefore, we finish the final proof of this lemma. □

Now we are ready to finish the proof of the main result, Theorem 1.5.

Proof. Let $u \in W^{1,G}_{loc}(\Omega)$ be the local weak solution of (1.1),

$$E = \{x \in B_1 : \mathcal{M}(|Du|)(x) > N\lambda\lambda_0\}$$

and

$$F = \{x \in B_1 : \mathcal{M}(|Du|) > \lambda\lambda_0\} \cup \left\{x \in B_1 : g^{-1}\left(\mathcal{M}_1(\mu)\right)(x) > \delta\lambda\lambda_0\right\} \quad \text{for any } \lambda \geq 1,$$

where

$$\lambda_0 = \frac{C_3}{N|B_1|}\left(\frac{C_2}{\epsilon}\right)^{\frac{1}{\sigma}} \int_{B_2} |Du| + 1dx. \tag{2.35}$$

It follows from the weak 1-1 estimate that

$$|\{x \in B_1 : \mathcal{M}(|Du|)(x) > N\lambda\lambda_0\}| \leq \frac{C_3}{N\lambda\lambda_0}\int_{B_1} |Du|dx < \left(\frac{\epsilon}{C_2}\right)^{\frac{1}{\sigma}} |B_1|,$$

which implies that

$$w\left(\{x \in B_1 : \mathcal{M}(|Du|)(x) > N\lambda\lambda_0\}\right) < \epsilon w(B_1)$$

by Lemma 1.2. Therefore, we apply Lemma 2.9 and Lemma 2.14 to have

$$w\left(E\right) \leq C\epsilon w\left(F\right). \tag{2.36}$$

Next, we divide into two cases.

Case 1: $r = +\infty$. From (2.36) we conclude that

$$\begin{aligned}\left[w\left(\{x \in B_1 : \mathcal{M}(|Du|)(x) > N\lambda\lambda_0\}\right)\right]^{\frac{1}{q}} &\leq C\epsilon^{\frac{1}{q}}\left[w\left(\{x \in B_1 : \mathcal{M}(|Du|)(x) > \lambda\lambda_0\}\right)\right]^{\frac{1}{q}} \\ &\quad + C\epsilon^{\frac{1}{q}}\left[w\left(\left\{x \in B_1 : g^{-1}\left(\mathcal{M}_1(\mu)\right)(x) > \delta\lambda\lambda_0\right\}\right)\right]^{\frac{1}{q}}\end{aligned}$$

for any $\lambda \geq 1$, which implies that

$$\begin{aligned}\|\mathcal{M}(|Du|)\|_{L^{q,\infty}_w(B_1)} &:= \sup_{\lambda>0} N\lambda\lambda_0 \left[w\left(\{x\in B_1 : \mathcal{M}(|Du|)(x) > N\lambda\lambda_0\}\right)\right]^{\frac{1}{q}} \\ &\le CN\epsilon^{\frac{1}{q}} \sup_{\lambda\ge 1} \lambda\lambda_0 \left[w\left(\{x\in B_1 : \mathcal{M}(|Du|)(x) > \lambda\lambda_0\}\right)\right]^{\frac{1}{q}} + C\lambda_0 \\ &\quad + \frac{CN\epsilon^{\frac{1}{q}}}{\delta} \sup_{\lambda\ge 1} \delta\lambda\lambda_0 \left[w\left(\{x\in B_1 : g^{-1}\left(\mathcal{M}_1(\mu)\right)(x) > \delta\lambda\lambda_0\}\right)\right]^{\frac{1}{q}} \\ &\le C_4\epsilon^{\frac{1}{q}} \|\mathcal{M}(|Du|)\|_{L^{q,\infty}_w(B_1)} + C(\delta,\epsilon)\|g^{-1}\left(\mathcal{M}_1(\mu)\right)\|_{L^{q,\infty}_w(B_1)} + C\lambda_0.\end{aligned}$$

Then, by selecting ϵ small enough such that $C_4\epsilon^{\frac{1}{q}} = 1/2$ and using an approximation argument by choosing $|\nabla u|_k := \min\{\nabla u, k\}$ like the one in [8], we deduce that

$$\begin{aligned}\|Du\|_{L^{q,\infty}_w(B_1)} &\le \|\mathcal{M}(|Du|)\|_{L^{q,\infty}_w(B_1)} \\ &\le C\|g^{-1}\left(\mathcal{M}_1(\mu)\right)\|_{L^{q,\infty}_w(B_1)} + C\lambda_0 \\ &\le C\|g^{-1}\left(\mathcal{M}_1(\mu)\right)\|_{L^{q,\infty}_w(B_1)} + C\int_{B_2} |Du| + 1dx.\end{aligned}$$

Case 2: $0 < r < +\infty$. From (2.36) we find that

$$\begin{aligned}&\left[w\left(\{x\in B_1 : \mathcal{M}(|Du|)(x) > N\lambda\lambda_0\}\right)\right]^{\frac{r}{q}} \\ &\quad = \left[w(E)\right]^{\frac{r}{q}} \le C\epsilon^{\frac{r}{q}}\left[w(F)\right]^{\frac{r}{q}} \\ &\quad \le C\epsilon^{\frac{r}{q}}\left[w\left(\{x\in B_1 : \mathcal{M}(|Du|)(x) > \lambda\lambda_0\}\right)\right]^{\frac{r}{q}} \\ &\quad\quad + C\epsilon^{\frac{r}{q}}\left[w\left(\{x\in B_1 : g^{-1}\left(\mathcal{M}_1(\mu)\right)(x) > \delta\lambda\lambda_0\}\right)\right]^{\frac{r}{q}}.\end{aligned}$$

Actually, by applying an iteration procedure we can also prove

$$\begin{aligned}&\left[w\left(\{x\in B_1 : \mathcal{M}(|Du|)(x) > N^m\lambda_0\}\right)\right]^{\frac{r}{q}} \\ &\quad \le C\epsilon^{\frac{mr}{q}}\left[w\left(\{x\in B_1 : \mathcal{M}(|Du|)(x) > \lambda_0\}\right)\right]^{\frac{r}{q}} \\ &\quad\quad + C\sum_{i=1}^{m}\epsilon^{\frac{ir}{q}}\left[w\left(\{x\in B_1 : g^{-1}\left(\mathcal{M}_1(\mu)\right)(x) > N^{m-i}\delta\lambda_0\}\right)\right]^{\frac{r}{q}}.\end{aligned} \tag{2.37}$$

Now we select ϵ small enough satisfying $N^r\epsilon^{\frac{r}{q}} < 1$ and then apply Lemma 2.10 to observe that

$$\begin{aligned}&\sum_{m=1}^{\infty} N^{mr}\lambda_0^r\left[w\left(\{x\in B_1 : \mathcal{M}(|Du|)(x) > N^m\lambda_0\}\right)\right]^{\frac{r}{q}} \\ &\le C\sum_{m=1}^{\infty} N^{mr}\lambda_0^r \sum_{i=1}^{m}\epsilon^{\frac{ir}{q}}\left[w\left(\{x\in B_1 : g^{-1}\left(\mathcal{M}_1(\mu)\right)(x) > N^{m-i}\delta\lambda_0\}\right)\right]^{\frac{r}{q}} \\ &\quad + C\sum_{m=1}^{\infty} N^{mr}\epsilon^{\frac{mr}{q}}\lambda_0^r\left[w\left(\{x\in B_1 : \mathcal{M}(|Du|)(x) > \lambda_0\}\right)\right]^{\frac{r}{q}} \\ &\le \frac{C}{\delta^r}\sum_{i=1}^{\infty}\epsilon^{\frac{ir}{q}}N^{ir}\sum_{m=i}^{\infty} N^{(m-i)r}\delta^r\lambda_0^r\left[w\left(\{x\in B_1 : g^{-1}\left(\mathcal{M}_1(\mu)\right)(x) > N^{m-i}\delta\lambda_0\}\right)\right]^{\frac{r}{q}} \\ &\quad + C\lambda_0^r\sum_{m=1}^{\infty} N^{mr}\epsilon^{\frac{mr}{q}} \\ &\le C\|g^{-1}\left(\mathcal{M}_1(\mu)\right)\|^r_{L^{q,r}_w(B_1)} + C\lambda_0^r < +\infty,\end{aligned}$$

which implies that

$$\|Du\|_{L^{q,r}_w(B_1)} \le \|\mathcal{M}(|Du|)\|_{L^{q,r}_w(B_1)} \le C\|g^{-1}\left(\mathcal{M}_1(\mu)\right)\|_{L^{q,r}_w(B_1)} + C\int_{B_2}|Du|+1dx.$$

Thus, this finishes the proof of the main result in this work. □

Acknowledgments

The author wishes to thank the anonymous reviewer for many valuable comments and suggestions to improve the expressions.

Communicated by Josef Diblík

Abstract. An exact solution of an initial value problem for the Susceptible–Exposed–Infectious–Recovered–Deceased (SEIRD) epidemic model is derived, and various properties of the exact solution are obtained. It is shown that the parametric form of the exact solution satisfies some linear differential system including a positive solution of an Abel differential equation of the second kind. In this paper Abel differential equations play an important role in establishing the exact solution of the SEIRD differential system, in particular the number of infected individuals can be represented in a simple form by using a positive solution of an initial value problem for an Abel differential equation. Uniqueness of positive solutions of an initial value problem to SEIRD differential system is also investigated, and it is shown that the exact solution is a unique solution in the class of positive solutions.

Keywords: exact solution, SEIRD epidemic model, initial value problem, linear differential system, Abel differential equation, uniqueness of positive solutions.

2020 Mathematics Subject Classification: 34A34.

1 Introduction

Recently there is an increasing interest in mathematical approach to the epidemic models. Since the pioneering work of Bernoulli [2], a vast literature and research papers has been published so far (cf. [4,5,9]), and studies of epidemic models have become one of the important areas in mathematical biology. In particular we mention Kermack and McKendrick [11] in which the Susceptible-Infectious-Recovered (SIR) epidemic model was proposed. Exact solutions of epidemic models have been investigated in recent years. We refer to Bohner, Streipert and Torres [3], Harko, Lobo and Mak [10] and Shabbir, Khan and Sadiq [16] and Yoshida [19] for SIR epidemic models, to Yoshida [18] for Susceptible–Infectious–Recovered–Deceased (SIRD) epidemic models, and to Yoshida [20] for Susceptible-Exposed-Infectious-Recovered (SEIR) epidemic models.

[1]Corresponding author. Email: norio.yoshidajp@gmail.com

The Susceptible–Exposed–Infectious–Recovered–Deceased (SEIRD) epidemic models have been an important and interesting subject to study (cf. [6, 12–15, 17]). However, there appears to be no known results about exact solutions of SEIRD epidemic models. The objective of this paper is to establish an exact solution of an initial value problem for SEIRD epidemic model. Our method is an adaptation of that used in Yoshida [20], and is based on the existence of unique positive solution of an initial value problem for Abel differential equations of the second kind. We refer the reader to Abel [1] and Davis [8] for Abel differential equations. Uniqueness of positive solutions of an initial value problem to SEIRD differential system is also studied, and we find that the exact solution is a unique solution in the class of positive solutions.

We study the Susceptible–Expose–Infectious–Recovered–Deceased (SEIRD) epidemic model

$$\frac{dS(t)}{dt} = -\beta S(t)I(t), \tag{1.1}$$

$$\frac{dE(t)}{dt} = \beta S(t)I(t) - \delta E(t), \tag{1.2}$$

$$\frac{dI(t)}{dt} = \delta E(t) - \gamma I(t) - \mu I(t), \tag{1.3}$$

$$\frac{dR(t)}{dt} = \gamma I(t), \tag{1.4}$$

$$\frac{dD(t)}{dt} = \mu I(t) \tag{1.5}$$

for $t > 0$, where β, γ, δ and μ are positive constants. The initial condition to be considered is the following:

$$S(0) = \tilde{S}, \quad E(0) = \tilde{E}, \quad I(0) = \tilde{I}, \quad R(0) = \tilde{R}, \; D(0) = \tilde{D}. \tag{1.6}$$

It is assumed throughout this paper that:

(A_1) $\tilde{I} > 0$;

(A_2) $\tilde{S} > \frac{\delta \tilde{E}}{\beta \tilde{I}}$;

(A_3) $\tilde{E} > \frac{\gamma+\mu}{\delta}\tilde{I}$;

(A_4) $\tilde{R} \geq 0$;

(A_5) $\tilde{D} \geq 0$ and $\tilde{D}$ satisfies

$$N - \tilde{R} > \tilde{S}e^{(\beta/\mu)\tilde{D}} + \tilde{D};$$

(A_6) $\tilde{S} + \tilde{E} + \tilde{I} + \tilde{R} + \tilde{D} = N$ (positive constant).

In Section 2 we obtain a parametric solution of an initial value problem for SEIRD differential system, and in Section 3 we derive an exact solution of an initial value problem for SEIRD differential system. Section 4 is devoted to various properties of the exact solution of SEIRD differential system. In Section 5 we show that there exists one, and only one, solution of an initial value problem for SEIRD differential system in the class of positive solutions.

2 Parametric solution of an initial value problem for SEIRD differential system

In this section we show that a positive solution of the initial value problem (1.1)–(1.6) can be represented in a parametric form.

Since

$$\frac{d}{dt}\left(S(t)+E(t)+I(t)+R(t)+D(t)\right)=\frac{dS(t)}{dt}+\frac{dE(t)}{dt}+\frac{dI(t)}{dt}+\frac{dR(t)}{dt}+\frac{dD(t)}{dt}=0$$

by (1.1)–(1.5), we obtain

$$S(t)+E(t)+I(t)+R(t)+D(t)=k \qquad (t\geq 0)$$

for some constant k. The hypothesis (A_6) implies

$$k=S(0)+E(0)+I(0)+R(0)+D(0)=\tilde{S}+\tilde{E}+\tilde{I}+\tilde{R}+\tilde{D}=N,$$

and therefore

$$S(t)+E(t)+I(t)+R(t)+D(t)=N \qquad (t\geq 0).$$

We state the following important lemma.

Lemma 2.1. *If* $(S(t),E(t),I(t),R(t),D(t))$ *is a solution of the SEIRD differential system* (1.1)–(1.5) *such that* $S(t)>0$ *for* $t>0$*, then*

$$D''(t)+(\delta+\gamma+\mu)D'(t)=\delta\mu\left(N-\tilde{R}+\frac{\gamma}{\mu}\tilde{D}-\tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)D(t)}-\left(1+\frac{\gamma}{\mu}\right)D(t)\right) \tag{2.1}$$

for $t>0$.

Proof. We see from (1.1) and (1.5) that

$$D'(t)=\mu I(t)=\mu\left(\frac{S'(t)}{-\beta S(t)}\right)=-\frac{\mu}{\beta}(\log S(t))',$$

and integrating the above on $[0,t]$ gives

$$D(t)-\tilde{D}=-\frac{\mu}{\beta}(\log S(t)-\log\tilde{S}).$$

Hence we obtain

$$\log S(t)=-\frac{\beta}{\mu}(D(t)-\tilde{D})+\log\tilde{S}$$

and therefore

$$S(t)=\exp\left(\log\tilde{S}-\frac{\beta}{\mu}D(t)+\frac{\beta}{\mu}\tilde{D}\right)=\tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)D(t)}. \tag{2.2}$$

It follows from (1.5) that $I(t)=D'(t)/\mu$, and hence $I'(t)=D''(t)/\mu$. Therefore, (1.3) implies that

$$\begin{aligned}E(t)&=\frac{1}{\delta}(I'(t)+(\gamma+\mu)I(t))\\&=\frac{1}{\delta}\left(\frac{D''(t)}{\mu}+(\gamma+\mu)\frac{D'(t)}{\mu}\right)\\&=\frac{1}{\delta\mu}\left(D''(t)+(\gamma+\mu)D'(t)\right).\end{aligned} \tag{2.3}$$

It is obvious that

$$R'(t) = \gamma I(t) = \gamma \frac{D'(t)}{\mu} = \frac{\gamma}{\mu} D'(t),$$

and hence

$$R(t) = \frac{\gamma}{\mu} D(t) + k$$

for some constant k. Letting $t = 0$ yields

$$k = \tilde{R} - \frac{\gamma}{\mu} \tilde{D},$$

and therefore

$$R(t) = \frac{\gamma}{\mu} D(t) + \tilde{R} - \frac{\gamma}{\mu} \tilde{D}. \tag{2.4}$$

We observe, using (1.5), (2.2)–(2.4), that

$$\begin{aligned}
\frac{D'(t)}{\mu} &= I(t) \\
&= N - S(t) - E(t) - R(t) - D(t) \\
&= N - \tilde{S} e^{(\beta/\mu)\tilde{D}} e^{-(\beta/\mu)D(t)} - \frac{1}{\delta\mu}\left(D''(t) + (\gamma+\mu)D'(t)\right) - \frac{\gamma}{\mu} D(t) - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - D(t)
\end{aligned}$$

which implies

$$\frac{1}{\delta\mu} D''(t) + \left(\frac{1}{\mu} + \frac{\gamma+\mu}{\delta\mu}\right) D'(t) = N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S} e^{(\beta/\mu)\tilde{D}} e^{-(\beta/\mu)D(t)} - \left(1 + \frac{\gamma}{\mu}\right) D(t).$$

Multiplying the above by $\delta\mu$ yields the desired identity (2.1). □

By a *solution* of the SEIRD differential system (1.1)–(1.5) we mean a vector-valued function $(S(t), E(t), I(t), R(t), D(t))$ of class $C^1(0,\infty) \cap C[0,\infty)$ which satisfies (1.1)–(1.5). Associated with every continuous function $f(t)$ on $[0,\infty)$, we define

$$f(\infty) := \lim_{t\to\infty} f(t).$$

Lemma 2.2. *Let $(S(t), E(t), I(t), R(t), D(t))$ be a solution of the SEIRD differential system (1.1)–(1.5) such that $S(t) > 0$, $E(t) > 0$, $I(t) > 0$ and $R(t) > 0$ for $t > 0$. Then there exists the limit $D(\infty)$.*

Proof. Since $I(t) > 0$ for $t > 0$, it follows from (1.5) that $D'(t) = \mu I(t) > 0$ for $t > 0$, and therefore $D(t)$ is increasing on $[0,\infty)$. It is easy to see that $D(t)$ is bounded from above in light of

$$D(t) = N - S(t) - E(t) - I(t) - R(t) < N \ (t > 0).$$

Hence there exists the limit $D(\infty)$. □

Theorem 2.3. *Let $(S(t), E(t), I(t), R(t), D(t))$ be a solution of the initial value problem (1.1)–(1.6) such that $S(t) > 0$, $E(t) > 0$, $I(t) > 0$ and $R(t) > 0$ for $t > 0$. Then the solution*

$(S(t), E(t), I(t), R(t), D(t))$ *can be represented in the following parametric form:*

$$S(\varphi(u)) = \tilde{S}e^{(\beta/\mu)\tilde{D}}u, \tag{2.5}$$

$$E(\varphi(u)) = \tilde{E}e^{-\delta\varphi(u)} + \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-\delta\varphi(u)} \int_u^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(v)}dv, \tag{2.6}$$

$$\begin{aligned} I(\varphi(u)) = {} & N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}u + \frac{\gamma+\mu}{\beta}\log u - \tilde{E}e^{-\delta\varphi(u)} \\ & - \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-\delta\varphi(u)} \int_u^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(v)}dv, \end{aligned} \tag{2.7}$$

$$R(\varphi(u)) = -\frac{\gamma}{\beta}\log u + \tilde{R} - \frac{\gamma}{\mu}\tilde{D}, \tag{2.8}$$

$$D(\varphi(u)) = -\frac{\mu}{\beta}\log u \tag{2.9}$$

for $e^{-(\beta/\mu)D(\infty)} < u \le e^{-(\beta/\mu)\tilde{D}}$, *where*

$$t = \varphi(u) = \int_u^{e^{-(\beta/\mu)\tilde{D}}} \frac{d\xi}{\xi\psi(\xi)}, \tag{2.10}$$

with $\psi(u)$ *satisfying the Abel differential equation of the second kind*

$$\psi'\psi - \frac{\delta+\gamma+\mu}{u}\psi = -\delta\,\frac{\beta N - \beta\tilde{R} + ((\beta\gamma)/\mu)\tilde{D} - \beta\tilde{S}e^{(\beta/\mu)\tilde{D}}u + (\gamma+\mu)\log u}{u} \tag{2.11}$$

for $e^{-(\beta/\mu)D(\infty)} < u < e^{-(\beta/\mu)\tilde{D}}$, *and the following conditions*

$$\begin{aligned} \psi\big(e^{-(\beta/\mu)\tilde{D}}\big) &= \beta\tilde{I}, \\ \lim_{u\to e^{-(\beta/\mu)D(\infty)}+0} \psi(u) &= 0, \\ \psi(u) > 0 \quad & \text{in } (e^{-(\beta/\mu)D(\infty)}, e^{-(\beta/\mu)\tilde{D}}]. \end{aligned}$$

Proof. Since $D'(t) = \mu I(t) > 0$ for $t > 0$ in view of (1.5), we find that $D(t)$ is increasing on $[0, \infty)$. Then there exists the limit $D(\infty)$ by Lemma 2.2. It is easy to check that $u = u(t) = e^{-(\beta/\mu)D(t)}$ is decreasing on $[0, \infty)$, $e^{-(\beta/\mu)D(\infty)} < u \le e^{-(\beta/\mu)\tilde{D}}$ and $\lim_{t\to\infty} u(t) = e^{-(\beta/\mu)D(\infty)}$. Hence there exists the inverse function $\varphi(u) \in C^1(e^{-(\beta/\mu)D(\infty)}, e^{-(\beta/\mu)\tilde{D}})$ of $u = u(t)$ such that

$$t = \varphi(u) \qquad \left(e^{-(\beta/\mu)D(\infty)} < u \le e^{-(\beta/\mu)\tilde{D}}\right),$$

$\varphi(u)$ is decreasing in $(e^{-(\beta/\mu)D(\infty)}, e^{-(\beta/\mu)\tilde{D}}]$, $\lim_{u\to e^{-(\beta/\mu)D(\infty)}+0} \varphi(u) = \infty$, and $\varphi\big(e^{-(\beta/\mu)\tilde{D}}\big) = 0$. Substituting $t = \varphi(u)$ into (2.1) in Lemma 2.1 yields

$$\begin{aligned} & D''(\varphi(u)) + (\delta+\gamma+\mu)D'(\varphi(u)) \\ & \quad = \delta\mu\left(N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)D(\varphi(u))} - \left(1 + \frac{\gamma}{\mu}\right)D(\varphi(u))\right) \end{aligned} \tag{2.12}$$

for $e^{-(\beta/\mu)D(\infty)} < u < e^{-(\beta/\mu)\tilde{D}}$. Differentiating both sides of $u = e^{-(\beta/\mu)D(\varphi(u))}$ with respect to u yields

$$\begin{aligned} 1 &= -\frac{\beta}{\mu}D'(\varphi(u))\varphi'(u)e^{-(\beta/\mu)D(\varphi(u))} \\ &= -\frac{\beta}{\mu}D'(\varphi(u))\varphi'(u)u, \end{aligned}$$

and therefore

$$D'(\varphi(u)) = -\frac{\mu}{\beta}\frac{1}{\varphi'(u)u}. \tag{2.13}$$

Since $D'(t) \in C^1(0,\infty)$ by means of (1.5) and $\varphi(u) \in C^1(e^{-(\beta/\mu)D(\infty)}, e^{-(\beta/\mu)\tilde{D}})$, we see that $D'(\varphi(u)) \in C^1(e^{-(\beta/\mu)D(\infty)}, e^{-(\beta/\mu)\tilde{D}})$, and consequently $1/(\varphi'(u)u) \in C^1(e^{-(\beta/\mu)D(\infty)}, e^{-(\beta/\mu)\tilde{D}})$. We differentiate (2.13) with respect to u to obtain

$$D''(\varphi(u))\varphi'(u) = -\frac{\mu}{\beta}\left(\frac{1}{\varphi'(u)u}\right)',$$

and hence

$$D''(\varphi(u)) = -\frac{\mu}{\beta}\left(\frac{1}{\varphi'(u)u}\right)'\frac{1}{\varphi'(u)}. \tag{2.14}$$

It is obvious that

$$D(\varphi(u)) = -\frac{\mu}{\beta}\log u \tag{2.15}$$

in light of $u = e^{-(\beta/\mu)D(\varphi(u))}$. Combining (2.12)–(2.15), we get

$$\begin{aligned} -\frac{\mu}{\beta}\left(\frac{1}{\varphi'(u)u}\right)'\frac{1}{\varphi'(u)} + (\delta+\gamma+\mu)\left(-\frac{\mu}{\beta}\frac{1}{\varphi'(u)u}\right) \\ = \delta\mu\left(N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}u - \left(1+\frac{\gamma}{\mu}\right)\left(-\frac{\mu}{\beta}\log u\right)\right) \end{aligned}$$

or

$$\begin{aligned} \frac{\mu}{\beta}\left(-\frac{1}{\varphi'(u)u}\right)'\left(-\frac{1}{\varphi'(u)u}\right) - \frac{\mu}{\beta}\frac{\delta+\gamma+\mu}{u}\left(-\frac{1}{\varphi'(u)u}\right) \\ = -\delta\mu\frac{1}{u}\left(N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}u + \frac{\mu}{\beta}\left(1+\frac{\gamma}{\mu}\right)\log u\right). \end{aligned} \tag{2.16}$$

Letting

$$\psi(u) := -\frac{1}{\varphi'(u)u}, \tag{2.17}$$

we observe that $\psi(u)$ satisfies (2.11). Since $t = \varphi(u) > 0$ for $e^{-(\beta/\mu)D(\infty)} < u < e^{-(\beta/\mu)\tilde{D}}$, we see from (1.5), (2.13) and (2.17) that

$$\psi(u) = \frac{\beta}{\mu}D'(\varphi(u)) = \beta I(\varphi(u)) > 0$$

in $(e^{-(\beta/\mu)D(\infty)}, e^{-(\beta/\mu)\tilde{D}})$. If we define

$$\begin{aligned} \psi\left(e^{-(\beta/\mu)\tilde{D}}\right) &:= \lim_{u\to e^{-(\beta/\mu)\tilde{D}}-0}\psi(u) = \frac{\beta}{\mu}\lim_{u\to e^{-(\beta/\mu)\tilde{D}}-0}D'(\varphi(u)) \\ &= \frac{\beta}{\mu}\lim_{t\to+0}D'(t) = \frac{\beta}{\mu}\mu I(0) = \beta\tilde{I} > 0, \end{aligned}$$

then $\psi(u)$ is a positive continuous function in $(e^{-(\beta/\mu)D(\infty)}, e^{-(\beta/\mu)\tilde{D}}]$. It follows from (2.17) that

$$t = \varphi(u) = \int_{e^{-(\beta/\mu)\tilde{D}}}^{u}\varphi'(\xi)d\xi = \int_{u}^{e^{-(\beta/\mu)\tilde{D}}}\frac{d\xi}{\xi\psi(\xi)},$$

and therefore (2.10) holds. Since $\lim_{u\to e^{-(\beta/\mu)D(\infty)}+0} \varphi(u) = \infty$, it is necessary that $\lim_{u\to e^{-(\beta/\mu)D(\infty)}+0} \psi(u) = 0$.

Now we establish the representation formulae (2.5)–(2.9). We see from (2.2) and (2.15) that

$$\begin{aligned} S(\varphi(u)) &= \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)D(\varphi(u))} = \tilde{S}e^{(\beta/\mu)\tilde{D}}u, \\ D(\varphi(u)) &= -\frac{\mu}{\beta}\log u, \end{aligned}$$

which are the desired representations (2.5) and (2.9). Combining (1.1) with (1.2) yields the first order linear differential equation

$$E'(t) + \delta E(t) = -S'(t)$$

which implies

$$E(t) = \tilde{E}e^{-\delta t} - e^{-\delta t}\int_0^t e^{\delta\xi}S'(\xi)d\xi. \tag{2.18}$$

Differentiating (2.2), we obtain

$$S'(t) = -\frac{\beta}{\mu}\tilde{S}e^{(\beta/\mu)\tilde{D}}D'(t)e^{-(\beta/\mu)D(t)}. \tag{2.19}$$

Substitution of (2.19) into (2.18) gives

$$E(t) = \tilde{E}e^{-\delta t} + \frac{\beta}{\mu}\tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-\delta t}\int_0^t e^{\delta\xi}D'(\xi)e^{-(\beta/\mu)D(\xi)}d\xi. \tag{2.20}$$

By changing the variables $D(\xi) = s$, we obtain

$$\begin{aligned} J := \int_0^t e^{\delta\xi}D'(\xi)e^{-(\beta/\mu)D(\xi)}d\xi &= \int_{\tilde{D}}^{D(t)} e^{\delta D^{-1}(s)}e^{-(\beta/\mu)s}ds \\ &= \int_{\tilde{D}}^{D(t)} e^{\delta\varphi(e^{-(\beta/\mu)s})}e^{-(\beta/\mu)s}ds \\ &= \frac{\mu}{\beta}\int_{D(t)}^{\tilde{D}} e^{\delta\varphi(e^{-(\beta/\mu)s})}\left(e^{-(\beta/\mu)s}\right)' ds \end{aligned}$$

in view of $D^{-1}(s) = \varphi(e^{-(\beta/\mu)s})$. Letting $v = e^{-(\beta/\mu)s}$ yields

$$J = \frac{\mu}{\beta}\int_{e^{-(\beta/\mu)D(t)}}^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(v)}dv. \tag{2.21}$$

Combining (2.20) with (2.21), we are led to

$$E(t) = \tilde{E}e^{-\delta t} + \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-\delta t}\int_{e^{-(\beta/\mu)D(t)}}^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(v)}dv. \tag{2.22}$$

Substituting $t = \varphi(u)$ into (2.22), we arrive at (2.6). We observe, using (2.4), that

$$R(\varphi(u)) = \frac{\gamma}{\mu}D(\varphi(u)) + \tilde{R} - \frac{\gamma}{\mu}\tilde{D} = -\frac{\gamma}{\beta}\log u + \tilde{R} - \frac{\gamma}{\mu}\tilde{D},$$

which is equal to (2.8). Since $I(\varphi(u)) = N - S(\varphi(u)) - R(\varphi(u)) - D(\varphi(u)) - E(\varphi(u))$, (2.7) follows from (2.5), (2.6), (2.8) and (2.9). □

Corollary 2.4. *Let $(S(t), E(t), I(t), R(t), D(t))$ be a solution of the initial value problem (1.1)–(1.6) such that $S(t) > 0$, $E(t) > 0$, $I(t) > 0$ and $R(t) > 0$ for $t > 0$. Then we obtain the following relations:*

$$S(t) = \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)D(t)}, \tag{2.23}$$

$$E(t) = \tilde{E}e^{-\delta t} + \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-\delta t}\int_{e^{-(\beta/\mu)D(t)}}^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta D^{-1}(-(\mu/\beta)\log v)}dv, \tag{2.24}$$

$$I(t) = N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)D(t)} - \frac{\gamma+\mu}{\mu}D(t) - \tilde{E}e^{-\delta t} - \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-\delta t}\int_{e^{-(\beta/\mu)D(t)}}^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta D^{-1}(-(\mu/\beta)\log v)}dv, \tag{2.25}$$

$$R(t) = D(t) + \tilde{R} - \frac{\gamma}{\mu}\tilde{D} \tag{2.26}$$

for $t \geq 0$.

Proof. It is easy to see that

$$u = \varphi^{-1}(t) = e^{-(\beta/\mu)D(t)}, \tag{2.27}$$

$$\varphi(v) = D^{-1}(-(\mu/\beta)\log v) \tag{2.28}$$

in the proof of Theorem 2.3. Combining (2.5)–(2.8), (2.27) and (2.28), we are led to (2.23)–(2.26). □

3 Exact solution of an initial value problem for SEIRD differential system

In this section we establish an exact solution of an initial value problem for SEIRD differential system (1.1)–(1.5) by utilizing Theorem 2.3 in Section 2.

The following lemma follows from a result of Yoshida [18, Lemma 3] by replacing $\tilde{R}, \tilde{D}, \gamma, \mu$ by $\tilde{D}, \tilde{R}, \mu, \gamma$, respectively.

Lemma 3.1. *Under the hypothesis* (A_5), *the transcendental equation*

$$x = \frac{\mu}{\gamma+\mu}N - \frac{\mu}{\gamma+\mu}\tilde{R} + \frac{\gamma}{\gamma+\mu}\tilde{D} - \frac{\mu}{\gamma+\mu}\tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)x}$$

has a unique solution $x = \alpha$ such that

$$\tilde{D} < \alpha < N$$

(*cf.* Figure 3.1).

We assume that the following hypothesis

(A_7) $\tilde{S} < \frac{\gamma+\mu}{\beta}e^{(\beta/\mu)(\alpha-\tilde{D})}$

holds in the rest of this paper. We note that (A_7) is equivalent to the following

(A_7') $\frac{\gamma+\mu}{\beta} > N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \frac{\gamma+\mu}{\mu}\alpha$

in view of $\tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)\alpha} = N - \tilde{R} + (\gamma/\mu)\tilde{D} - ((\gamma+\mu)/\mu)\alpha$.

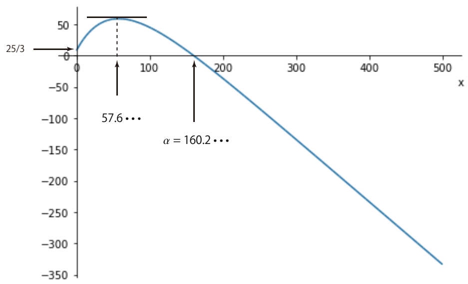

Figure 3.1: Variation of $(\mu/(\gamma+\mu))N - (\mu/(\gamma+\mu))\tilde{R} + (\gamma/(\gamma+\mu))\tilde{D} - (\mu/(\gamma+\mu))\tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)x} - x$ for $N = 1000, \tilde{S} = 950, \tilde{R} = 0, \tilde{D} = 0, \beta = 0.2/1000$, $\gamma = 0.05$ and $\mu = 0.01$. In this case we find that $(\mu/(\gamma+\mu))(N-\tilde{S}) = 25/3$ and $0 < \alpha = 160.2\ldots < 1000$.

Remark 3.2. Combining (A_2) with (A_3), we have

$$\tilde{S} > \frac{\delta\tilde{E}}{\beta\tilde{I}} > \frac{\gamma+\mu}{\beta}.$$

Lemma 3.3. *There exists a unique positive solution $w(x)$ of the initial value problem for the Abel differential equation*

$$w'w + \frac{\beta(\delta+\gamma+\mu)}{\mu}w = \frac{\beta\delta}{\mu}\left(\beta N - \beta\tilde{R} + \frac{\beta\gamma}{\mu}\tilde{D} - \beta\tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)x} - \frac{\beta(\gamma+\mu)}{\mu}x\right) \quad (\tilde{D} < x < \alpha), \tag{3.1}$$

subject to the initial condition

$$w(\tilde{D}) = \beta\tilde{I}. \tag{3.2}$$

Proof. Let

$$f(x) := N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)x} - \frac{\gamma+\mu}{\mu}x.$$

Since $f'(x) = 0$ for

$$x = \tilde{x} = \frac{\mu}{\beta}\log\left(\frac{\beta}{\gamma+\mu}\tilde{S}e^{(\beta/\mu)\tilde{D}}\right),$$

we see that $\tilde{D} < \tilde{x} < \alpha$ by means of (A_7) and Remark 3.2, and that $f'(x) > 0$ for $\tilde{D} < x < \tilde{x}$ and $f'(x) < 0$ for $\tilde{x} < x < \alpha$. Hence, $f(x)$ is increasing in $[\tilde{D}, \tilde{x})$ and decreasing in $(\tilde{x}, \alpha)$. Since $f(\tilde{D}) = N - \tilde{R} - \tilde{S} - \tilde{D} = \tilde{E} + \tilde{I} > 0$ and $\lim_{x\to\alpha-0} f(x) = 0$ by Lemma 3.1, it follows that $f(x) \in C[\tilde{D}, \alpha)$, $f(x) > 0$ in $[\tilde{D}, \alpha)$ and $\lim_{x\to\alpha-0} f(x) = 0$. Therefore there exists a unique positive solution $w(x)$ of the initial value problem (3.1), (3.2) by a result of Yoshida [20, Theorem 3] (*cf.* Figure 3.2). □

Lemma 3.4. *There exists a unique positive solution $\psi(u)$ of the initial value problem for the Abel differential equation*

$$\psi'\psi - \frac{\delta+\gamma+\mu}{u}\psi = -\delta\frac{\beta N - \beta\tilde{R} + ((\beta\gamma)/\mu)\tilde{D} - \beta\tilde{S}e^{(\beta/\mu)\tilde{D}}u + (\gamma+\mu)\log u}{u} \quad (e^{-(\beta/\mu)\alpha} < u < e^{-(\beta/\mu)\tilde{D}}) \tag{3.3}$$

with the initial condition

$$\psi\left(e^{-(\beta/\mu)\tilde{D}}\right) = \beta\tilde{I} \tag{3.4}$$

(*cf*. Figure 3.3).

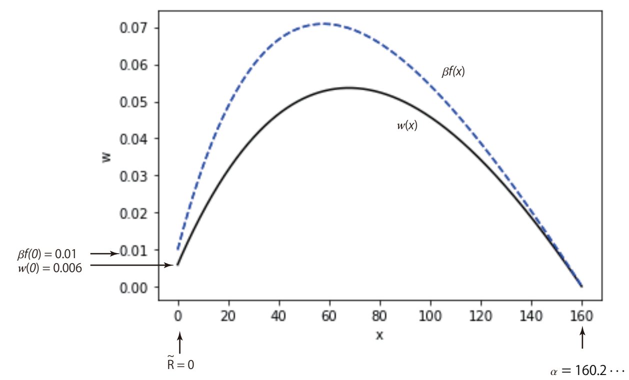

Figure 3.2: Variations of $\beta f(x)$ (dashed curve), and $w(x)$ (solid curve) obtained by the numerical integration of the initial value problem (3.1), (3.2), for $N = 1000, \tilde{S} = 950, \tilde{E} = 20, \tilde{I} = 30, \tilde{R} = \tilde{D} = 0, \beta = 0.2/1000, \gamma = 0.05, \delta = 0.2, \mu = 0.01$ and $\alpha = 160.2\ldots$ In this case we obtain $\beta f(0) = \beta N - \beta\tilde{S} = 0.01$ and $w(0) = \beta\tilde{I} = 0.006$.

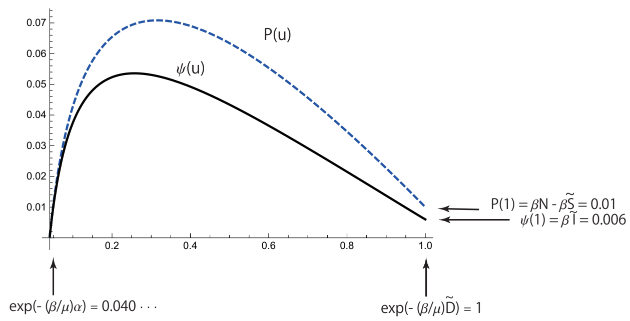

Figure 3.3: Variations of $P(u) := \beta N - \beta\tilde{R} + ((\beta\gamma)/\mu)\tilde{D} - \beta\tilde{S}e^{(\beta/\mu)\tilde{D}}u + (\gamma + \mu)\log u$ (dashed curve) and $\psi(u)$ (solid curve) obtained by the numerical integration of the initial value problem (3.3), (3.4) for $N = 1000, \tilde{S} = 950, \tilde{E} = 20, \tilde{I} = 30, \tilde{R} = \tilde{D} = 0, \beta = 0.2/1000, \gamma = 0.05, \delta = 0.2, \mu = 0.01$ and $\alpha = 160.2\ldots$ In this case we get $e^{-(\beta/\mu)\alpha} = 0.040\ldots$, $e^{-(\beta/\mu)\tilde{D}} = 1$, $P(1) = \beta N - \beta\tilde{S} = 0.01$ and $\psi(1) = \beta\tilde{I} = 0.006$.

Proof. Let $w(x)$ be a unique positive solution of the initial value problem (3.1), (3.2). We define $\psi(u)$ by

$$\psi(u) := w\left(-\frac{\mu}{\beta}\log u\right)$$

and find that

$$\psi'(u) = w'\left(-\frac{\mu}{\beta}\log u\right)\left(-\frac{\mu}{\beta}\frac{1}{u}\right),$$

and hence

$$
\begin{aligned}
\psi'(u)\psi(u) &= -\frac{\mu}{\beta}\frac{1}{u}w'\left(-\frac{\mu}{\beta}\log u\right)w\left(-\frac{\mu}{\beta}\log u\right) \\
&= -\frac{\mu}{\beta}\frac{1}{u}\Bigg[-\frac{\beta(\delta+\gamma+\mu)}{\mu}w\left(-\frac{\mu}{\beta}\log u\right) \\
&\quad +\frac{\beta\delta}{\mu}\left(\beta N-\beta\tilde{R}+((\beta\gamma)/\mu)\tilde{D}-\beta\tilde{S}e^{(\beta/\mu)\tilde{D}}u+(\gamma+\mu)\log u\right)\Bigg] \\
&= \frac{\delta+\gamma+\mu}{u}\psi(u)-\delta\,\frac{\beta N-\beta\tilde{R}+((\beta\gamma)/\mu)\tilde{D}-\beta\tilde{S}e^{(\beta/\mu)\tilde{D}}u+(\gamma+\mu)\log u}{u}
\end{aligned}
$$

for $e^{-(\beta/\mu)\alpha} < u < e^{-(\beta/\mu)\tilde{D}}$ by means of (3.1). Hence $\psi(u)$ satisfies (3.3). It is easily seen from (3.2) that

$$\psi\left(e^{-(\beta/\mu)\tilde{D}}\right) = w(\tilde{D}) = \beta\tilde{I}$$

and therefore (3.4) is satisfied. The uniqueness of $\psi(u)$ follows from that of $w(x)$. It can be shown that

$$\psi(u) > 0 \text{ in } (e^{-(\beta/\mu)\alpha}, e^{-(\beta/\mu)\tilde{D}}] \tag{3.5}$$

since $\psi(u) = w\big(-(\mu/\beta)\log u\big)$ and $w(x) > 0$ in $[\tilde{D}, \alpha)$. □

Lemma 3.5. *The unique positive solution $\psi(u)$ of the initial value problem* (3.3), (3.4) *satisfies the following relation*

$$
\begin{aligned}
\psi(u) &= \beta N-\beta\tilde{R}+\frac{\beta\gamma}{\mu}\tilde{D}-\beta\tilde{S}e^{(\beta/\mu)\tilde{D}}u+(\gamma+\mu)\log u \\
&\quad -\beta\left(\tilde{E}e^{-\delta\varphi(u)}+\tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-\delta\varphi(u)}\int_u^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(v)}dv\right)
\end{aligned} \tag{3.6}
$$

for $e^{-(\beta/\mu)\alpha} < u \le e^{-(\beta/\mu)\tilde{D}}$, where

$$\varphi(u) := \int_u^{e^{-(\beta/\mu)\tilde{D}}} \frac{d\xi}{\xi\psi(\xi)}. \tag{3.7}$$

Conversely, the function $\psi(u)$ satisfying (3.5), (3.6) *is a solution of the initial value problem* (3.3), (3.4).

Proof. We note that (3.6) is some kind of integral equation of $\psi(u)$, in light of (3.7). Let $\psi(u)$ be the unique positive solution of the problem (3.3), (3.4), and define $z(u)$ by

$$z(u) := \psi(u) - P(u), \tag{3.8}$$

where

$$P(u) = \beta N-\beta\tilde{R}+\frac{\beta\gamma}{\mu}\tilde{D}-\beta\tilde{S}e^{(\beta/\mu)\tilde{D}}u+(\gamma+\mu)\log u. \tag{3.9}$$

Dividing (3.3) by $\psi(u)$, we obtain

$$
\begin{aligned}
\psi'(u) &= \frac{\delta+\gamma+\mu}{u}-\delta\,\frac{P(u)}{u\psi(u)} = \frac{\gamma+\mu}{u}-\delta\,\frac{P(u)-\psi(u)}{u\psi(u)} \\
&= \frac{\gamma+\mu}{u}+\delta\,\frac{z(u)}{u\psi(u)}.
\end{aligned} \tag{3.10}
$$

On the other hand, differentiating (3.8) yields

$$\psi'(u) = -\beta\tilde{S}e^{(\beta/\mu)\tilde{D}} + \frac{\gamma+\mu}{u} + z'(u). \tag{3.11}$$

Combining (3.10) with (3.11), we get

$$z'(u) - \frac{\delta}{u\psi(u)}z(u) = \beta\tilde{S}e^{(\beta/\mu)\tilde{D}}$$

or

$$z'(u) + \delta\varphi'(u)z(u) = \beta\tilde{S}e^{(\beta/\mu)\tilde{D}} \tag{3.12}$$

which is a linear differential equation of first order. It is clear that

$$\begin{aligned} z\big(e^{-(\beta/\mu)\tilde{D}}\big) &= \psi\big(e^{-(\beta/\mu)\tilde{D}}\big) - \left(\beta N - \beta\tilde{R} + \frac{\beta\gamma}{\mu}\tilde{D} - \beta\tilde{S} - \frac{\beta(\gamma+\mu)}{\mu}\tilde{D}\right) \\ &= \beta\tilde{I} - \beta\big(N - \tilde{R} - \tilde{S} - \tilde{D}\big) \\ &= -\beta\tilde{E}. \end{aligned} \tag{3.13}$$

Now we solve the initial value problem (3.12), (3.13). Multiplying (3.12) by $e^{\delta\varphi(u)}$ yields

$$\big(e^{\delta\varphi(u)}z(u)\big)' = \beta\tilde{S}e^{(\beta/\mu)\tilde{D}}e^{\delta\varphi(u)}$$

and then integrating the above on $[u, e^{-(\beta/\mu)\tilde{D}}]$ gives

$$z\big(e^{-(\beta/\mu)\tilde{D}}\big) - e^{\delta\varphi(u)}z(u) = \beta\tilde{S}e^{(\beta/\mu)\tilde{D}}\int_u^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(v)}dv.$$

Taking account of (3.13), we obtain

$$z(u) = -\beta\left(\tilde{E}e^{-\delta\varphi(u)} + \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-\delta\varphi(u)}\int_u^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(v)}dv\right). \tag{3.14}$$

Combining (3.8) with (3.14), we observe that $\psi(u)$ satisfies (3.6) for $e^{-(\beta/\mu)\alpha} < u < e^{-(\beta/\mu)\tilde{D}}$. If $u = e^{-(\beta/\mu)\tilde{D}}$, then $\psi\big(e^{-(\beta/\mu)\tilde{D}}\big) = \beta\tilde{I}$ by (3.4) and the right hand side of (3.6) with $u = e^{-(\beta/\mu)\tilde{D}}$ is equal to $\beta N - \beta\tilde{R} + ((\beta\gamma)/\mu)\tilde{D} - \beta\tilde{S} - (\beta(\gamma+\mu)/\mu)\tilde{D} - \beta\tilde{E} = \beta\tilde{I}$. Therefore (3.6) holds for $u = e^{-(\beta/\mu)\tilde{D}}$.

Conversely we suppose that the function $\psi(u)$ satisfies (3.5), (3.6), and let $e^{-(\beta/\mu)\alpha} < u < e^{-(\beta/\mu)\tilde{D}}$. Differentiating (3.6) with respect to u yields

$$\begin{aligned} \psi'(u) = &-\beta\tilde{S}e^{(\beta/\mu)\tilde{D}} + \frac{\gamma+\mu}{u} - \beta\tilde{E}e^{-\delta\varphi(u)}\big(-\delta\varphi'(u)\big) \\ &-\beta\tilde{S}e^{(\beta/\mu)\tilde{D}}\left(e^{-\delta\varphi(u)}\big(-\delta\varphi'(u)\big)\int_u^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(v)}dv - 1\right) \\ = &\frac{\gamma+\mu}{u} - \beta\delta\tilde{E}e^{-\delta\varphi(u)}\frac{1}{u\psi(u)} \\ &-\beta\delta\tilde{S}e^{(\beta/\mu)\tilde{D}}\frac{1}{u\psi(u)}e^{-\delta\varphi(u)}\int_u^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(v)}dv. \end{aligned} \tag{3.15}$$

It follows from (3.6) that

$$-\beta\tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-\delta\varphi(u)}\int_u^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(v)}dv = \psi(u) - P(u) + \beta\tilde{E}e^{-\delta\varphi(u)}. \tag{3.16}$$

We combine (3.15) with (3.16) to obtain

$$\begin{aligned}\psi'(u) &= \frac{\gamma+\mu}{u} - \beta\delta\tilde{E}e^{-\delta\varphi(u)}\frac{1}{u\psi(u)} + \delta\,\frac{\psi(u)-P(u)+\beta\tilde{E}e^{-\delta\varphi(u)}}{u\psi(u)}\\ &= \frac{\gamma+\mu}{u} - \delta\,\frac{P(u)-\psi(u)}{u\psi(u)}\\ &= \frac{\delta+\gamma+\mu}{u} - \delta\,\frac{P(u)}{u\psi(u)}\end{aligned}$$

and consequently, $\psi(u)$ satisfies (3.3) for $e^{-(\beta/\mu)\alpha} < u < e^{-(\beta/\mu)\tilde{D}}$. It is easy to see from (3.6) that

$$\begin{aligned}\psi\big(e^{-(\beta/\mu)\tilde{D}}\big) &= \beta N - \beta\tilde{R} + ((\beta\gamma)/\mu)\tilde{D} - \beta\tilde{S} - (\beta(\gamma+\mu)/\mu)\tilde{D} - \beta\tilde{E}\\ &= \beta N - \beta\tilde{R} - \beta\tilde{D} - \beta\tilde{S} - \beta\tilde{E}\\ &= \beta(N - \tilde{R} - \tilde{D} - \tilde{S} - \tilde{E}) = \beta\tilde{I}\end{aligned}$$

in view of $\varphi\big(e^{-(\beta/\mu)\tilde{D}}\big) = 0$, and therefore (3.4) is satisfied. □

Proposition 3.6. *Let $\psi(u)$ be the unique positive solution of the initial value problem* (3.3), (3.4)*, then we obtain the following inequalities*:

$$\beta N - \beta\tilde{R} + \frac{\beta\gamma}{\mu}\tilde{D} - \beta\tilde{S}e^{(\beta/\mu)\tilde{D}}u + (\gamma+\mu)\log u > \psi(u) > 0, \tag{3.17}$$

$$\begin{aligned}&\beta N - \beta\tilde{R} + \frac{\beta\gamma}{\mu}\tilde{D} - \beta\tilde{S}e^{(\beta/\mu)\tilde{D}}u + (\gamma+\mu)\log u\\ &\quad > \beta\left(\tilde{E}e^{-\delta\varphi(u)} + \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-\delta\varphi(u)}\int_u^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(v)}dv\right) > 0\end{aligned} \tag{3.18}$$

for $e^{-(\beta/\mu)\alpha} < u \le e^{-(\beta/\mu)\tilde{D}}$.

Proof. Since $\psi(u) > 0$ in $(e^{-(\beta/\mu)\alpha}, e^{-(\beta/\mu)\tilde{D}}]$, the relation (3.6) in Lemma 3.5 means

$$\begin{aligned}&\beta N - \beta\tilde{R} + \frac{\beta\gamma}{\mu}\tilde{D} - \beta\tilde{S}e^{(\beta/\mu)\tilde{D}}u + (\gamma+\mu)\log u\\ &\quad > \beta\left(\tilde{E}e^{-\delta\varphi(u)} + \tilde{S}e^{(\beta/\gamma)\tilde{R}}e^{-\delta\varphi(u)}\int_u^{e^{-(\beta/\gamma)\tilde{R}}} e^{\delta\varphi(v)}dv\right)\end{aligned}$$

for $e^{-(\beta/\mu)\alpha} < u \le e^{-(\beta/\mu)\tilde{D}}$. It is clear that

$$\tilde{E}e^{-\delta\varphi(u)} + \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-\delta\varphi(u)}\int_u^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(v)}dv > 0 \tag{3.19}$$

for $e^{-(\beta/\mu)\alpha} < u \le e^{-(\beta/\mu)\tilde{D}}$, and therefore (3.18) follows. Since (3.19) holds, the relation (3.6) implies that

$$\beta N - \beta\tilde{R} + \frac{\beta\gamma}{\mu}\tilde{D} - \beta\tilde{S}e^{(\beta/\mu)\tilde{D}}u + (\gamma+\mu)\log u > \psi(u) > 0$$

for $e^{-(\beta/\mu)\alpha} < u \le e^{-(\beta/\mu)\tilde{D}}$, which is the desired inequality (3.17). □

Proposition 3.7. *Let $\psi(u)$ be the unique positive solution of the initial value problem* (3.3), (3.4)*, then we see that*

$$\lim_{u \to e^{-(\beta/\mu)\alpha}+0} \psi(u) = 0, \tag{3.20}$$

$$\lim_{u \to e^{-(\beta/\mu)\alpha}+0} \left(\tilde{E}e^{-\delta\varphi(u)} + \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-\delta\varphi(u)} \int_u^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(v)}dv \right) = 0 \tag{3.21}$$

(*cf*. Figure 3.4).

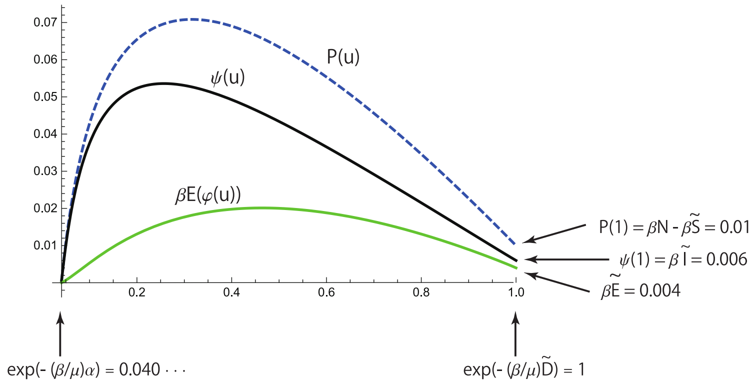

Figure 3.4: Variations of $P(u) = \beta N - \beta\tilde{R} + ((\beta\gamma)/\mu)\tilde{D} - \beta\tilde{S}e^{(\beta/\mu)\tilde{D}}u + (\gamma + \mu)\log u$ (dashed curve), $\beta E(\varphi(u))$ (green curve), and $\psi(u)$ (solid curve) obtained by the numerical integration of the initial value problem (3.3), (3.4) for $N = 1000, \tilde{S} = 950, \tilde{E} = 20, \tilde{I} = 30, \tilde{R} = \tilde{D} = 0, \beta = 0.2/1000, \gamma = 0.05, \delta = 0.2, \mu = 0.01$ and $\alpha = 160.2\ldots$ In this case we have $e^{-(\beta/\mu)\alpha} = 0.040\ldots$, $e^{-(\beta/\mu)\tilde{D}} = 1$, $P(1) = \beta N - \beta\tilde{S} = 0.01$, $\psi(1) = \beta\tilde{I} = 0.006$ and $\beta\tilde{E} = 0.004$. Moreover, $\lim_{u \to e^{-(\beta/\mu)\alpha}+0} P(u) = 0$, $\lim_{u \to e^{-(\beta/\mu)\alpha}+0} \psi(u) = 0$, and $\lim_{u \to e^{-(\beta/\mu)\alpha}+0} \beta E(\varphi(u)) = \lim_{u \to e^{-(\beta/\mu)\alpha}+0} (P(u) - \psi(u)) = 0$.

Proof. Since

$$\begin{aligned}
&\lim_{u \to e^{-(\beta/\mu)\alpha}+0} \left(\beta N - \beta\tilde{R} + \frac{\beta\gamma}{\mu}\tilde{D} - \beta\tilde{S}e^{(\beta/\mu)\tilde{D}}u + (\gamma + \mu)\log u \right) \\
&= \lim_{x \to \alpha - 0} \beta \left(N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)x} - \frac{\gamma + \mu}{\mu}x \right) = 0
\end{aligned}$$

by Lemma 3.1, Proposition 3.6 implies that (3.20) and (3.21) hold by taking the limit as $u \to e^{-(\beta/\mu)\alpha} + 0$ in (3.17) and (3.18). □

Lemma 3.8. *Let $\psi(u)$ be the unique positive solution of the initial value problem* (3.3), (3.4)*. Then there exists the inverse function $\varphi^{-1}(t) \in C^1(0, \infty)$ of the function*

$$t = \varphi(u) = \int_u^{e^{-(\beta/\mu)\tilde{D}}} \frac{d\xi}{\xi\psi(\xi)} \tag{3.22}$$

for $e^{-(\beta/\mu)\alpha} < u \leq e^{-(\beta/\mu)\tilde{D}}$, such that $\varphi^{-1}(t)$ is decreasing on $[0, \infty)$, $\varphi^{-1}(0) = e^{-(\beta/\mu)\tilde{D}}$ and $\lim_{t \to \infty} \varphi^{-1}(t) = e^{-(\beta/\mu)\alpha}$.

Proof. We easily see that $\varphi(u) \in C^1(e^{-(\beta/\mu)\alpha}, e^{-(\beta/\mu)\tilde{D}})$, $\varphi(u)$ is decreasing in $(e^{-(\beta/\mu)\alpha}, e^{-(\beta/\mu)\tilde{D}}]$ and $\varphi(e^{-(\beta/\mu)\tilde{D}}) = 0$. We divide (3.3) by $(\delta+\gamma+\mu)\psi(u)^2$ to obtain

$$\frac{1}{u\psi(u)} = \frac{\delta}{\delta+\gamma+\mu}\frac{P(u)}{u\psi(u)^2} + \frac{1}{\delta+\gamma+\mu}\frac{\psi'(u)}{\psi(u)}, \tag{3.23}$$

and therefore

$$\begin{aligned}\varphi(u) &= \int_u^{e^{-(\beta/\mu)\tilde{D}}} \frac{d\xi}{\xi\psi(\xi)} \\ &= \frac{\delta}{\delta+\gamma+\mu}\int_u^{e^{-(\beta/\mu)\tilde{D}}} \frac{P(\xi)}{\xi\psi(\xi)^2}d\xi + \frac{1}{\delta+\gamma+\mu}\int_u^{e^{-(\beta/\mu)\tilde{D}}} \frac{\psi'(\xi)}{\psi(\xi)}\,d\xi \\ &\geq \frac{1}{\delta+\gamma+\mu}\big(\log(\beta\tilde{I}) - \log\psi(u)\big),\end{aligned} \tag{3.24}$$

where $P(u)$ is defined by (3.8). We see that $\lim_{u\to e^{-(\beta/\mu)\alpha}+0}\log\psi(u) = -\infty$ in view of (3.20), and that $\lim_{u\to e^{-(\beta/\mu)\alpha}+0}\varphi(u) = \infty$ by taking the limit as $u \to e^{-(\beta/\mu)\alpha}+0$ in (3.24). Hence there exists the inverse function $\varphi^{-1}(t)$ which has the desired properties. □

The following is our main theorem.

Theorem 3.9. *The function* $(S(t), E(t), I(t), R(t), D(t))$ *defined by*

$$S(t) = \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t), \tag{3.25}$$

$$E(t) = \tilde{E}e^{-\delta t} + \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-\delta t}\int_{\varphi^{-1}(t)}^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(v)}dv, \tag{3.26}$$

$$\begin{aligned}I(t) = {}& N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t) + \frac{\gamma+\mu}{\beta}\log\varphi^{-1}(t) - \tilde{E}e^{-\delta t} \\ & - \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-\delta t}\int_{\varphi^{-1}(t)}^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(v)}dv,\end{aligned} \tag{3.27}$$

$$R(t) = -\frac{\gamma}{\beta}\log\varphi^{-1}(t) + \tilde{R} - \frac{\gamma}{\mu}\tilde{D}, \tag{3.28}$$

$$D(t) = -\frac{\mu}{\beta}\log\varphi^{-1}(t) \tag{3.29}$$

is a solution of the initial value problem (1.1)–(1.6), *where* $\varphi(u)$ *and* $\varphi^{-1}(t)$ *are given in Lemma* 3.8.

Proof. First note that

$$\begin{aligned}(\varphi^{-1}(t))' &= \frac{1}{\varphi'(u)}\Big|_{u=\varphi^{-1}(t)} = -u\psi(u)\Big|_{u=\varphi^{-1}(t)} \\ &= -\varphi^{-1}(t)\psi(\varphi^{-1}(t)) = -\beta\varphi^{-1}(t)I(t)\end{aligned} \tag{3.30}$$

by taking account of (3.6) and (3.27). We see from (3.25) and (3.30) that

$$\begin{aligned}S'(t) &= \tilde{S}e^{(\beta/\mu)\tilde{D}}(\varphi^{-1}(t))' \\ &= -\beta\tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t)I(t) \\ &= -\beta S(t)I(t)\end{aligned} \tag{3.31}$$

and therefore (1.1) follows. A direct calculation yields

$$\begin{aligned}
E'(t) = & -\delta\tilde{E}e^{-\delta t} \\
& + \tilde{S}e^{(\beta/\mu)\tilde{D}}\left(-\delta e^{-\delta t}\int_{\varphi^{-1}(t)}^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(v)}dv + e^{-\delta t}\left(-e^{\delta t}\left(\varphi^{-1}(t)\right)'\right)\right) \\
= & -\delta\tilde{E}e^{-\delta t} - \delta\tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-\delta t}\int_{\varphi^{-1}(t)}^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(v)}dv - \tilde{S}e^{(\beta/\mu)\tilde{D}}\left(\varphi^{-1}(t)\right)' \\
= & -\delta E(t) + \beta S(t)I(t)
\end{aligned} \tag{3.32}$$

in view of (3.26) and (3.31), and hence (1.2) is satisfied. An easy computation shows that

$$\begin{aligned}
I'(t) = & -\tilde{S}e^{(\beta/\mu)\tilde{D}}\left(\varphi^{-1}(t)\right)' + \frac{\gamma+\mu}{\beta}\frac{\left(\varphi^{-1}(t)\right)'}{\varphi^{-1}(t)} \\
& - \left(\tilde{E}e^{-\delta t} + \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-\delta t}\int_{\varphi^{-1}(t)}^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(v)}dv\right)' \\
= & \beta S(t)I(t) + \frac{\gamma+\mu}{\beta}(-\beta I(t)) - E'(t) \\
= & \beta S(t)I(t) - (\gamma+\mu)I(t) - \left(-\delta E(t) + \beta S(t)I(t)\right) \\
= & \delta E(t) - \gamma I(t) - \mu I(t)
\end{aligned} \tag{3.33}$$

in view of (3.30)–(3.32). Thus, (1.3) holds. It is easily seen from (3.30) that

$$R'(t) = -\frac{\gamma}{\beta}\frac{\left(\varphi^{-1}(t)\right)'}{\varphi^{-1}(t)} = -\frac{\gamma}{\beta}(-\beta I(t)) = \gamma I(t)$$

which is the equation (1.4). Similarly we obtain

$$D'(t) = -\frac{\mu}{\beta}\frac{\left(\varphi^{-1}(t)\right)'}{\varphi^{-1}(t)} = -\frac{\mu}{\beta}(-\beta I(t)) = \mu I(t)$$

which is the desired equation (1.5). It is easy to see that

$$\begin{aligned}
S(0) &= \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(0) = \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)\tilde{D}} = \tilde{S}, \\
E(0) &= \tilde{E} + \tilde{S}e^{(\beta/\mu)\tilde{D}}\int_{\varphi^{-1}(0)}^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(v)}dv = \tilde{E}, \\
I(0) &= N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S} + \frac{\gamma+\mu}{\beta}\left(-\frac{\beta}{\mu}\tilde{D}\right) - \tilde{E} \\
&= N - \tilde{R} - \tilde{S} - \tilde{D} - \tilde{E} = \tilde{I}, \\
R(0) &= -\frac{\gamma}{\beta}\left(-\frac{\beta}{\mu}\tilde{D}\right) + \tilde{R} - \frac{\gamma}{\mu}\tilde{D} = \tilde{R}, \\
D(0) &= -\frac{\mu}{\beta}\left(-\frac{\beta}{\mu}\tilde{D}\right) = \tilde{D}
\end{aligned}$$

in light of $\varphi^{-1}(0) = e^{-(\beta/\mu)\tilde{D}}$. Therefore, (1.6) is satisfied. □

Theorem 3.10. *Let* $(S(t), E(t), I(t), R(t), D(t))$ *be the exact solution* (3.25)–(3.29) *of the initial value problem* (1.1)–(1.6)*. Then,* $(\hat{S}(u), \hat{E}(u), \hat{I}(u), \hat{R}(u), \hat{D}(u))$ *defined by*

$$\left(\hat{S}(u), \hat{E}(u), \hat{I}(u), \hat{R}(u), \hat{D}(u)\right) := \left(S(\varphi(u)), E(\varphi(u)), I(\varphi(u)), R(\varphi(u)), D(\varphi(u))\right)$$

satisfies the linear differential system

$$\frac{d\hat{S}(u)}{du} = \frac{\hat{S}(u)}{u}, \tag{3.34}$$

$$\frac{d\hat{E}(u)}{du} - \frac{\delta}{u\psi(u)}\hat{E}(u) = -\frac{\hat{S}(u)}{u}, \tag{3.35}$$

$$\frac{d\hat{I}(u)}{du} - \frac{\gamma+\mu}{\beta}\frac{1}{u} = -\frac{\delta}{u\psi(u)}\hat{E}(u), \tag{3.36}$$

$$\frac{d\hat{R}(u)}{du} = -\frac{\gamma}{\beta}\frac{1}{u}, \tag{3.37}$$

$$\frac{d\hat{D}(u)}{du} = -\frac{\mu}{\beta}\frac{1}{u} \tag{3.38}$$

for $u \in (e^{-(\beta/\mu)\alpha}, e^{-(\beta/\mu)\tilde{D}})$*, and the initial condition*

$$\hat{S}\left(e^{-(\beta/\mu)\tilde{D}}\right) = \tilde{S}, \tag{3.39}$$

$$\hat{E}\left(e^{-(\beta/\mu)\tilde{D}}\right) = \tilde{E}, \tag{3.40}$$

$$\hat{I}\left(e^{-(\beta/\mu)\tilde{D}}\right) = \tilde{I}, \tag{3.41}$$

$$\hat{R}\left(e^{-(\beta/\mu)\tilde{D}}\right) = \tilde{R}. \tag{3.42}$$

$$\hat{D}\left(e^{-(\beta/\mu)\tilde{D}}\right) = \tilde{D}. \tag{3.43}$$

Proof. It follows from (3.30) that

$$\hat{I}(u) = I(\varphi(u)) = \frac{1}{\beta}\psi(u). \tag{3.44}$$

Since $S(t)$ satisfies (1.1), we obtain

$$S'(\varphi(u)) = -\beta S(\varphi(u))I(\varphi(u)) = -\beta\hat{S}(u)\hat{I}(u).$$

Therefore we arrive at

$$\begin{aligned}\frac{d\hat{S}(u)}{du} &= \frac{dS(t)}{dt}\Big|_{t=\varphi(u)}\varphi'(u) = S'(\varphi(u))\left(-\frac{1}{u\psi(u)}\right)\\ &= \left(-\beta\hat{S}(u)\hat{I}(u)\right)\left(-\frac{1}{u\psi(u)}\right)\\ &= \frac{\hat{S}(u)}{u}\end{aligned}$$

in light of (3.44), and hence (3.34) holds. Using (1.2) and (3.44), we get

$$\begin{aligned}\frac{d\hat{E}(u)}{du} &= \frac{dE(t)}{dt}\Big|_{t=\varphi(u)}\varphi'(u) = E'(\varphi(u))\left(-\frac{1}{u\psi(u)}\right)\\ &= \left(\beta\hat{S}(u)\hat{I}(u) - \delta\hat{E}(u)\right)\left(-\frac{1}{u\psi(u)}\right)\\ &= -\frac{\hat{S}(u)}{u} + \frac{\delta}{u\psi(u)}\hat{E}(u),\end{aligned}$$

which is equal to (3.35). We observe, using (1.3), that

$$
\begin{aligned}
\frac{d\hat{I}(u)}{du} &= \frac{dI(t)}{dt}\Big|_{t=\varphi(u)} \varphi'(u) \\
&= \left(\delta\hat{E}(u) - \gamma\hat{I}(u) - \mu\hat{I}(u)\right)\left(-\frac{1}{u\psi(u)}\right) \\
&= -\delta\frac{\hat{E}(u)}{u\psi(u)} + (\gamma+\mu)\frac{\hat{I}(u)}{u\psi(u)} \\
&= -\frac{\delta}{u\psi(u)}\hat{E}(u) + \frac{\gamma+\mu}{\beta}\frac{1}{u},
\end{aligned}
$$

and therefore (3.36) follows. We are led to

$$
\begin{aligned}
\frac{d\hat{R}(u)}{du} &= \frac{dR(t)}{dt}\Big|_{t=\varphi(u)} \varphi'(u) = R'(\varphi(u))\left(-\frac{1}{u\psi(u)}\right) \\
&= \gamma\hat{I}(u)\left(-\frac{1}{u\psi(u)}\right) \\
&= -\frac{\gamma}{\beta}\frac{1}{u}
\end{aligned}
$$

by use of (1.4) and (3.44). Thus (3.37) is obtained. Similarly we have

$$
\begin{aligned}
\frac{d\hat{D}(u)}{du} &= \frac{dD(t)}{dt}\Big|_{t=\varphi(u)} \varphi'(u) = D'(\varphi(u))\left(-\frac{1}{u\psi(u)}\right) \\
&= \mu\hat{I}(u)\left(-\frac{1}{u\psi(u)}\right) \\
&= -\frac{\mu}{\beta}\frac{1}{u},
\end{aligned}
$$

which is the desired equation (3.38). It is easily seen that

$$
\begin{aligned}
\hat{S}\left(e^{-(\beta/\mu)\tilde{D}}\right) &= S\left(\varphi\left(e^{-(\beta/\mu)\tilde{D}}\right)\right) = S(0) = \tilde{S}, \\
\hat{E}\left(e^{-(\beta/\mu)\tilde{D}}\right) &= E\left(\varphi\left(e^{-(\beta/\mu)\tilde{D}}\right)\right) = E(0) = \tilde{E}, \\
\hat{I}\left(e^{-(\beta/\mu)\tilde{D}}\right) &= I\left(\varphi\left(e^{-(\beta/\mu)\tilde{D}}\right)\right) = I(0) = \tilde{I}, \\
\hat{R}\left(e^{-(\beta/\mu)\tilde{D}}\right) &= R\left(\varphi\left(e^{-(\beta/\mu)\tilde{D}}\right)\right) = R(0) = \tilde{R}, \\
\hat{D}\left(e^{-(\beta/\mu)\tilde{D}}\right) &= D\left(\varphi\left(e^{-(\beta/\mu)\tilde{D}}\right)\right) = D(0) = \tilde{D}.
\end{aligned}
$$

Hence, (3.39)–(3.43) are satisfied. □

Theorem 3.11. *Solving the initial value problem* (3.34)–(3.43)*, we obtain the parametric solution* (2.5)–(2.9) *for* $e^{-(\beta/\mu)\alpha} < u \le e^{-(\beta/\mu)\tilde{D}}$.

Proof. Since (3.34) is equivalent to

$$\frac{d}{du}\left(\frac{1}{u}\hat{S}(u)\right) = 0,$$

we have

$$\hat{S}(u) = ku$$

for some constant k. We see from (3.39) that

$$\hat{S}\left(e^{-(\beta/\mu)\tilde{D}}\right) = ke^{-(\beta/\mu)\tilde{D}} = \tilde{S}$$

which implies

$$k = \tilde{S}e^{(\beta/\mu)\tilde{D}}.$$

Therefore we obtain

$$\hat{S}(u) = \tilde{S}e^{(\beta/\mu)\tilde{D}}u. \tag{3.45}$$

It follows from (3.45) that

$$-\frac{\hat{S}(u)}{u} = -\tilde{S}e^{(\beta/\mu)\tilde{D}}$$

and hence (3.35) reduces to

$$\frac{d\hat{E}(u)}{du} - \frac{\delta}{u\psi(u)}\hat{E}(u) = -\tilde{S}e^{(\beta/\mu)\tilde{D}} \tag{3.46}$$

which can be rewritten as

$$\frac{d\hat{E}(u)}{du} + \delta\varphi'(u)\hat{E}(u) = -\tilde{S}e^{(\beta/\mu)\tilde{D}}. \tag{3.47}$$

Multiplying (3.47) by $e^{\delta\varphi(u)}$ gives

$$\frac{d}{du}\left(e^{\delta\varphi(u)}\hat{E}(u)\right) = -\tilde{S}e^{(\beta/\mu)\tilde{D}}e^{\delta\varphi(u)},$$

and an integration of the above on $[u, e^{-(\beta/\gamma)\tilde{R}}]$ yields

$$\hat{E}(u) = e^{-\delta\varphi(u)}\left(\tilde{E} + \tilde{S}e^{(\beta/\mu)\tilde{D}}\int_u^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(v)}dv\right),$$

which is equal to (2.6). Multiplying (3.36) by β, we have

$$\frac{d(\beta\hat{I}(u))}{du} - \frac{\gamma+\mu}{u} = -\frac{\beta\delta}{u\psi(u)}\hat{E}(u). \tag{3.48}$$

Define $z(u)$ by

$$z(u) := \beta\hat{I}(u) - \left(\beta N - \beta\tilde{R} + ((\beta\gamma)/\mu)\tilde{D} - \beta\tilde{S}e^{(\beta/\mu)\tilde{D}}u + (\gamma+\mu)\log u\right),$$

then we obtain

$$\frac{dz(u)}{du} = \frac{d(\beta\hat{I}(u))}{du} + \beta\tilde{S}e^{(\beta/\mu)\tilde{D}} - \frac{\gamma+\mu}{u}. \tag{3.49}$$

Combining (3.48) with (3.49), we get

$$\begin{aligned}\frac{dz(u)}{du} &= \beta\tilde{S}e^{(\beta/\mu)\tilde{D}} - \frac{\beta\delta}{u\psi(u)}\hat{E}(u)\\ &= -\beta\left(-\tilde{S}e^{(\beta/\mu)\tilde{D}} + \frac{\delta}{u\psi(u)}\hat{E}(u)\right).\end{aligned} \tag{3.50}$$

It follows from (3.46) and (3.50) that

$$\frac{dz(u)}{du} = -\beta \frac{d\hat{E}(u)}{du},$$

and therefore

$$z(u) = -\beta\hat{E}(u) + k$$

for some constant k. Since

$$\begin{aligned} z\big(e^{-(\beta/\mu)\tilde{D}}\big) &= \beta\hat{I}\big(e^{-(\beta/\mu)\tilde{D}}\big) - \big(\beta N - \beta\tilde{R} - \beta\tilde{S} - \beta\tilde{D}\big) \\ &= \beta\tilde{I} - \big(\beta N - \beta\tilde{R} - \beta\tilde{S} - \beta\tilde{D}\big) = -\beta\tilde{E} \end{aligned}$$

and $-\beta\hat{E}\big(e^{-(\beta/\mu)\tilde{D}}\big) = -\beta\tilde{E}$, we see that $k = 0$, and therefore $z(u) = -\beta\hat{E}(u)$, i.e.,

$$\beta\hat{I}(u) = \big(\beta N - \beta\tilde{R} + ((\beta\gamma)/\mu)\tilde{D} - \beta\tilde{S}e^{(\beta/\mu)\tilde{D}}u + (\gamma+\mu)\log u\big) - \beta\hat{E}(u),$$

which is equivalent to (2.7). Solving (3.37) yields

$$\hat{R}(u) = -\frac{\gamma}{\beta}\log u + k$$

for some constant k. The initial condition (3.42) implies

$$\hat{R}\left(e^{-(\beta/\mu)\tilde{D}}\right) = -\frac{\gamma}{\beta}\log e^{-(\beta/\mu)\tilde{D}} + k = \frac{\gamma}{\mu}\tilde{D} + k = \tilde{R}$$

and hence $k = \tilde{R} - (\gamma/\mu)\tilde{D}$. Hence we obtain

$$\hat{R}(u) = -\frac{\gamma}{\beta}\log u + \tilde{R} - \frac{\gamma}{\mu}\tilde{D}.$$

Similarly we find that

$$\hat{D}(u) = -\frac{\mu}{\beta}\log u. \qquad \square$$

Remark 3.12. Let $I(t)$ be given by (3.27). Then $I(t)$ can be represented in the simple form

$$I(t) = \frac{1}{\beta}\psi\big(\varphi^{-1}(t)\big)$$

by taking account of (3.6) and (3.27).

4 Various properties of solution

This section is devoted to various properties of solution by investigating the exact solution of the initial value problem (1.1)–(1.6).

Theorem 4.1. *Let $D(t)$ be given by (3.29). Then we find that $D(\infty) = \alpha$,*

$$D(\infty) = N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)D(\infty)} - \frac{\gamma}{\mu}D(\infty), \tag{4.1}$$

and that $D(t)$ is an increasing function on $[0,\infty)$ such that

$$\tilde{D} \le D(t) < \alpha = D(\infty).$$

Proof. We easily see that

$$\begin{aligned} D(\infty) = \lim_{t\to\infty} D(t) &= \lim_{t\to\infty} -\frac{\mu}{\beta}\log \varphi^{-1}(t) \\ &= \lim_{u\to e^{-(\beta/\mu)\alpha}+0} -\frac{\mu}{\beta}\log u \\ &= \alpha. \end{aligned}$$

Since $\alpha = D(\infty)$, the identity (4.1) follows from the definition of α (see Lemma 3.1). In light of $e^{-(\beta/\mu)\alpha} < \varphi^{-1}(t) \le e^{-(\beta/\mu)\tilde{D}}$, we obtain

$$-\frac{\mu}{\beta}\log e^{-(\beta/\mu)\tilde{D}} \le D(t) < -\frac{\mu}{\beta}\log e^{-(\beta/\mu)\alpha}$$

or

$$\tilde{D} \le D(t) < \alpha = D(\infty).$$

It is easy to check that $D(t)$ is increasing on $[0,\infty)$ in view of the fact that $\varphi^{-1}(t)$ is decreasing on $[0,\infty)$. □

Theorem 4.2. *Let $S(t)$ be given by (3.25). Then we deduce that*

$$S(\infty) = \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)D(\infty)}, \tag{4.2}$$

and that $S(t)$ is a decreasing function on $[0,\infty)$ such that

$$\tilde{S} \ge S(t) > \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)\alpha} = S(\infty).$$

Proof. The identity (4.2) follows from

$$\begin{aligned} S(\infty) = \lim_{t\to\infty} S(t) &= \lim_{t\to\infty} \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t) \\ &= \lim_{u\to e^{-(\beta/\mu)\alpha}+0} \tilde{S}e^{(\beta/\mu)\tilde{D}}u \\ &= \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)\alpha} \\ &= \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)D(\infty)}. \end{aligned}$$

Since $e^{-(\beta/\mu)\alpha} < \varphi^{-1}(t) \le e^{-(\beta/\mu)\tilde{D}}$, we have

$$\tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)\alpha} < \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t) \le \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)\tilde{D}}.$$

Therefore we get

$$\tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)\alpha} < S(t) \le \tilde{S}.$$

Since $\varphi^{-1}(t)$ is decreasing on $[0,\infty)$, we observe that $S(t)$ is also decreasing on $[0,\infty)$. □

Theorem 4.3. *Let $R(t)$ be given by (3.28). Then we conclude that*

$$R(\infty) = \frac{\gamma}{\mu}D(\infty) + \tilde{R} - \frac{\gamma}{\mu}\tilde{D}, \tag{4.3}$$

and that $R(t)$ is an increasing function on $[0,\infty)$ such that

$$\tilde{R} \le R(t) < R(\infty).$$

Proof. We obtain

$$\begin{aligned} R(\infty) = \lim_{t\to\infty} R(t) &= \lim_{t\to\infty}\left(-\frac{\gamma}{\beta}\log\varphi^{-1}(t) + \tilde{R} - \frac{\gamma}{\mu}\tilde{D}\right) \\ &= \lim_{u\to e^{-(\beta/\mu)\alpha}+0}\left(-\frac{\gamma}{\beta}\log u + \tilde{R} - \frac{\gamma}{\mu}\tilde{D}\right) \\ &= \frac{\gamma}{\mu}\alpha + \tilde{R} - \frac{\gamma}{\mu}\tilde{D} \\ &= \frac{\gamma}{\mu}D(\infty) + \tilde{R} - \frac{\gamma}{\mu}\tilde{D}. \end{aligned}$$

Since $e^{-(\beta/\mu)\alpha} < \varphi^{-1}(t) \le e^{-(\beta/\mu)\tilde{D}}$, we get

$$\frac{\gamma}{\mu}\tilde{D} + \tilde{R} - \frac{\gamma}{\mu}\tilde{D} \le R(t) < \frac{\gamma}{\mu}\alpha + \tilde{R} - \frac{\gamma}{\mu}\tilde{D},$$

or

$$\tilde{R} \le R(t) < \frac{\gamma}{\mu}D(\infty) + \tilde{R} - \frac{\gamma}{\mu}\tilde{D} = R(\infty).$$ □

Theorem 4.4. *Let $E(t)$ be given by (3.26). Then we find that*

$$E(\infty) = 0,$$
$$E(t) > 0 \quad \text{on } [0,\infty),$$

and $E(t)$ has the maximum $\max_{t\ge 0} E(t)$ at some $t = T_1 \in \{T;\, E'(T) = 0\}$, where

$$\begin{aligned} E'(T) = &\left(\frac{\delta}{\beta} + \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(T)\right)\psi(\varphi^{-1}(T)) \\ &- \delta\left(N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(T) + \frac{\gamma+\mu}{\beta}\log\varphi^{-1}(T)\right). \end{aligned}$$

Proof. We easily check that

$$\begin{aligned} E(\infty) &= \lim_{t\to\infty} E(t) \\ &= \lim_{u\to e^{-(\beta/\mu)\alpha}+0}\left(\tilde{E}e^{-\delta\varphi(u)} + \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-\delta\varphi(u)}\int_u^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(v)}dv\right) \\ &= 0 \end{aligned}$$

in light of of (3.20) in Proposition 3.7. Since $e^{-(\beta/\mu)\alpha} < \varphi^{-1}(t) \le e^{-(\beta/\mu)\tilde{D}}$ $(t \ge 0)$ and $\hat{E}(u) > 0$ for $e^{-(\beta/\mu)\alpha} < u \le e^{-(\beta/\mu)\tilde{D}}$ (cf. (3.19)), it is easily seen that $E(t) = \hat{E}(\varphi^{-1}(t)) > 0$ on $[0,\infty)$. The hypothesis (A_2) implies that the right differential derivative $E'_+(0)$ is positive because

$$E'_+(0) = \lim_{t\to+0} E'(t) = \lim_{t\to+0}\left(\beta S(t)I(t) - \delta E(t)\right) = \beta\tilde{S}\tilde{I} - \delta\tilde{E} > 0.$$

Since the definition of $E'_+(0)$ implies

$$0 < E'_+(0) = \lim_{t\to+0}\frac{E(t) - E(0)}{t} = \lim_{t\to+0}\frac{E(t) - \tilde{E}}{t},$$

we see that for $\varepsilon = (1/2)E'_+(0) > 0$ there exists a number $\delta_\varepsilon > 0$ such that

$$\left|\frac{E(t) - \tilde{E}}{t} - E'_+(0)\right| < \frac{1}{2}E'_+(0)$$

holds for $0 < t < \delta_\varepsilon$, and hence

$$\frac{1}{2}E'_+(0) < \frac{E(t) - \tilde{E}}{t}$$

or

$$E(t) > \tilde{E} + \frac{1}{2}E'_+(0)t > \tilde{E}$$

holds for $0 < t < \delta_\varepsilon$. Since $E(\infty) = 0$, there exists a number $\tilde{T}$ such that $E(\tilde{T}) = \tilde{E}$ and $E(t) \le \tilde{E}$ for $t \ge \tilde{T}$. Therefore there exists $\max_{0\le t\le \tilde{T}} E(t) = E(T_1)$ $(> \tilde{E})$ at some $t = T_1$ $(< \tilde{T})$. Since $E(t) \le \tilde{E}$ for $t \ge \tilde{T}$, we observe that $\max_{t\ge 0} E(t) = \max_{0\le t\le \tilde{T}} E(t) = E(T_1)$. It is obvious that $E'(T_1) = 0$. It can be shown from (3.25)–(3.27) and (3.44) that

$$\begin{aligned}
E'(t) &= -\delta E(t) + \beta S(t)I(t) \\
&= -\delta E(t) + \tilde{S}e^{(\beta/\gamma)\tilde{R}}\varphi^{-1}(t)\psi(\varphi^{-1}(t)) \\
&= -\delta\left(N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t) + \frac{\gamma+\mu}{\beta}\log\varphi^{-1}(t) - I(t)\right) \\
&\quad + \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t)\psi(\varphi^{-1}(t)) \\
&= \left(\frac{\delta}{\beta} + \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t)\right)\psi(\varphi^{-1}(t)) \\
&\quad - \delta\left(N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t) + \frac{\gamma+\mu}{\beta}\log\varphi^{-1}(t)\right). \qquad (4.4)
\end{aligned}$$

□

Remark 4.5. If u_1 is a unique solution of the equation

$$\left(\frac{\delta}{\beta} + \tilde{S}e^{(\beta/\mu)\tilde{D}}u\right)\psi(u) = \delta\left(N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}u + \frac{\gamma+\mu}{\beta}\log u\right),$$

then we get

$$T_1 = \varphi(u_1) = \int_{u_1}^{e^{-(\beta/\mu)\tilde{D}}} \frac{d\xi}{\xi\psi(\xi)}$$

in view of (3.22) (*cf.* Figure 4.1).

In case $E'(T_1) = 0$, we obtain $\beta S(T_1)I(T_1) = \delta E(T_1)$ by (1.2), and therefore $E(T_1) = (\beta/\delta)S(T_1)I(T_1)$. Hence, in Theorem 4.4 we see that

$$\max_{t\ge 0} E(t) = E(T_1) = \frac{\beta}{\delta}S(T_1)I(T_1).$$

Letting

$$\Psi(u) := \left(\frac{\delta}{\beta} + \tilde{S}e^{(\beta/\mu)\tilde{D}}u\right)\psi(u),$$

we observe that $\Psi(u)$ is a solution of the initial value problem for the Abel differential equation

$$\begin{aligned}
&\Psi'(u)\Psi(u) - \frac{\tilde{S}e^{(\beta/\mu)\tilde{D}}}{(\delta/\beta) + \tilde{S}e^{(\beta/\mu)\tilde{D}}u}\Psi(u)^2 - \frac{\delta+\gamma+\mu}{u}\left(\frac{\delta}{\beta} + \tilde{S}e^{(\beta/\mu)\tilde{D}}u\right)\Psi(u) \\
&= -\delta\left(\frac{\delta}{\beta} + \tilde{S}e^{(\beta/\mu)\tilde{D}}u\right)^2 \\
&\quad \times \frac{\beta N - \beta\tilde{R} + ((\beta\gamma)/\mu)\tilde{D} - \beta\tilde{S}e^{(\beta/\mu)\tilde{D}}u + (\gamma+\mu)\log u}{u} \qquad (4.5)
\end{aligned}$$

for $e^{-(\beta/\mu)\alpha} < u \le e^{-(\beta/\mu)\tilde{D}}$, with the initial condition

$$\Psi\left(e^{-(\beta/\mu)\tilde{D}}\right) = \beta\left(\frac{\delta}{\beta} + \tilde{S}\right)\tilde{I}. \tag{4.6}$$

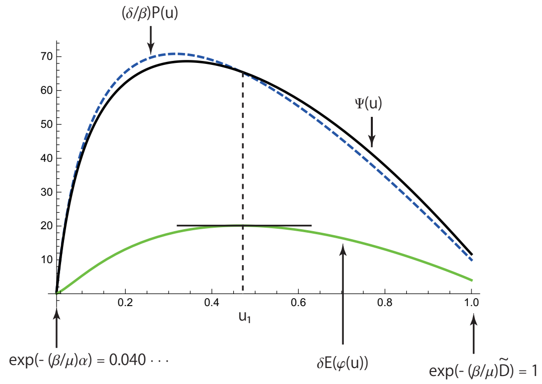

Figure 4.1: Variations of $(\delta/\beta)P(u) = \delta(N - \tilde{R} + (\gamma/\mu)\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}u + ((\gamma+\mu)/\beta)\log u)$ (dashed curve), $\delta E(\varphi(u))$ (green curve) and $\Psi(u)$ (solid curve) obtained by the numerical integration of the initial value problem (4.5), (4.6) for $N = 1000, \tilde{S} = 950, \tilde{E} = 20, \tilde{I} = 30, \tilde{R} = \tilde{D} = 0, \beta = 0.2/1000, \gamma = 0.05$, $\delta = 0.2$ and $\mu = 0.01$. In this case we see that there exists a unique u_1 such that $(\delta/\beta)P(u_1) = \Psi(u_1)$, and that T_1 is calculated by $T_1 = \varphi(u_1) = \int_{u_1}^{1} \frac{d\xi}{\xi\psi(\xi)}$, where $\psi(u)$ is a unique positive solution of the initial value problem $\psi'\psi - \frac{0.26}{u}\psi = -0.2\,\frac{0.2-0.19u+0.06\log u}{u}$ $(0.040\ldots < u < 1)$, $\psi(1) = 0.006$.

Theorem 4.6. *Let $I(t)$ be given by (3.27). Then we see that*

$$I(\infty) = 0,$$
$$I(t) > 0 \quad \text{on } [0,\infty),$$

and $I(t)$ has the maximum $\max_{t\ge 0} I(t)$ at some $t = T_2 \in \{T;\ I'(T) = 0\}$, where

$$I'(T) = -\frac{\delta+\gamma+\mu}{\beta}\psi(\varphi^{-1}(T)) + \delta\left(N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(T) + \frac{\gamma+\mu}{\beta}\log\varphi^{-1}(T)\right).$$

Proof. It follows from (3.20) and (3.30) that

$$\begin{aligned} I(\infty) &= \lim_{t\to\infty} I(t) = \lim_{t\to\infty}\frac{1}{\beta}\psi(\varphi^{-1}(t)) \\ &= \lim_{u\to e^{-(\beta/\mu)\alpha}+0}\frac{1}{\beta}\psi(u) \\ &= 0. \end{aligned}$$

Since $e^{-(\beta/\mu)\alpha} < \varphi^{-1}(t) \le e^{-(\beta/\mu)\tilde{D}}$ $(t \ge 0)$ and $\psi(u) > 0$ for $e^{-(\beta/\mu)\alpha} < u \le e^{-(\beta/\mu)\tilde{D}}$, we find that $I(t) = (1/\beta)\psi(\varphi^{-1}(t)) > 0$ on $[0,\infty)$. The hypothesis (A_3) implies that the right differential derivative $I'_+(0)$ is positive because

$$I'_+(0) = \lim_{t\to+0} I'(t) = \lim_{t\to+0}\left(\delta E(t) - \gamma I(t) - \mu I(t)\right) = \delta\tilde{E} - (\gamma+\mu)\tilde{I} > 0,$$

and therefore there exists a number $\delta_1 > 0$ such that $I(t) > \tilde{I}$ in $(0, \delta_1)$ as in the proof of Theorem 4.3. Since $I(\infty) = 0$, we can use the same arguments as in the proof of Theorem 4.3 to conclude that there exists the maximum $\max_{t\geq 0} I(t) = I(T_2)$ for some T_2. Then $I'(T_2) = 0$, and we obtain

$$\begin{aligned} I'(t) &= \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t)\psi(\varphi^{-1}(t)) - \frac{\gamma+\mu}{\beta}\psi(\varphi^{-1}(t)) - E'(t) \\ &= \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t)\psi(\varphi^{-1}(t)) - \frac{\gamma+\mu}{\beta}\psi(\varphi^{-1}(t)) \\ &\quad - \left[\left(\frac{\delta}{\beta} + \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t)\right)\psi(\varphi^{-1}(t))\right. \\ &\quad \left. -\delta\left(N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t) + \frac{\gamma+\mu}{\beta}\log\varphi^{-1}(t)\right)\right] \\ &= -\frac{\delta+\gamma+\mu}{\beta}\psi(\varphi^{-1}(t)) \\ &\quad + \delta\left(N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t) + \frac{\gamma+\mu}{\beta}\log\varphi^{-1}(t)\right) \end{aligned}$$

in light of (3.30), (3.33), (3.44) and (4.4). □

Remark 4.7. In case u_2 is a unique solution of the equation

$$\frac{\delta+\gamma+\mu}{\beta}\psi(u) = \delta\left(N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}u + \frac{\gamma+\mu}{\beta}\log u\right),$$

then we get

$$T_2 = \varphi(u_2) = \int_{u_2}^{e^{-(\beta/\mu)\tilde{D}}} \frac{d\xi}{\xi\psi(\xi)}$$

(*cf.* Figure 4.2). If $I'(T_2) = 0$, (1.3) implies that $\delta E(T_2) = (\gamma+\mu)I(T_2)$, and in Theorem 4.6 we see that

$$\max_{t\geq 0} I(t) = I(T_2) = \frac{\delta}{\gamma+\mu}E(T_2).$$

Theorem 4.8. *The function $E(t) + I(t)$ has the maximum*

$$\max_{t\geq 0}\,(E(t)+I(t)) = \tilde{S} + \tilde{E} + \tilde{I} - \frac{\gamma+\mu}{\beta}\left(1 + \log\tilde{S} - \log\frac{\gamma+\mu}{\beta}\right)$$

at

$$t = T_3 := \varphi\left(\frac{\gamma+\mu}{\beta\tilde{S}e^{(\beta/\mu)\tilde{D}}}\right) = \int_{(\gamma+\mu)/(\beta\tilde{S}e^{(\beta/\mu)\tilde{D}})}^{e^{-(\beta/\mu)\tilde{D}}} \frac{d\xi}{\xi\psi(\xi)} = S^{-1}\left(\frac{\gamma+\mu}{\beta}\right).$$

Moreover, $E(t) + I(t)$ is increasing in $[0, T_3)$ and is decreasing in (T_3, ∞).

Proof. We see from (3.26) and (3.27) that

$$E(t) + I(t) = N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t) + \frac{\gamma+\mu}{\beta}\log\varphi^{-1}(t). \tag{4.7}$$

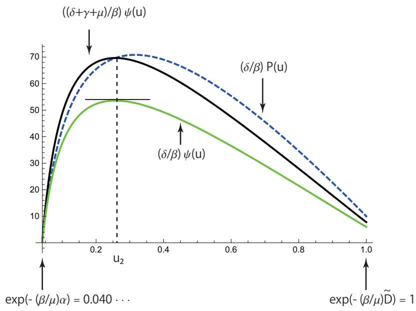

Figure 4.2: Variations of $(\delta/\beta)P(u) = \delta(N - \tilde{R} + (\gamma/\mu)\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}u + ((\gamma + \mu)/\beta)\log u)$ (dashed curve), $((\delta+\gamma+\mu)/\beta)\psi(u)$ (solid curve), and $(\delta/\beta)\psi(u)$ (green curve) obtained by the numerical integration of the initial value problem (4.5), (4.6) for $N = 1000, \tilde{S} = 950, \tilde{E} = 20, \tilde{I} = 30, \tilde{R} = \tilde{D} = 0, \beta = 0.2/1000, \gamma = 0.05$, $\delta = 0.2$ and $\mu = 0.01$. In this case we find that there exists a unique u_2 such that $(\delta/\beta)P(u_2) = ((\delta+\gamma+\mu)/\beta)\psi(u_2)$, and that T_2 is calculated by $T_2 = \varphi(u_2) = \int_{u_2}^{1} \frac{d\xi}{\xi\psi(\xi)}$, where $\psi(u)$ is the unique positive solution of the same initial value problem as in Figure 4.1.

Differentiating (4.7) with respect to t gives

$$\begin{aligned} E'(t) + I'(t) &= -\tilde{S}e^{(\beta/\mu)\tilde{D}}\left(\varphi^{-1}(t)\right)' + \frac{\gamma+\mu}{\beta}\frac{\left(\varphi^{-1}(t)\right)'}{\varphi^{-1}(t)} \\ &= \left(-\tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t) + \frac{\gamma+\mu}{\beta}\right)\frac{\left(\varphi^{-1}(t)\right)'}{\varphi^{-1}(t)} \\ &= \left(-S(t) + \frac{\gamma+\mu}{\beta}\right)\frac{\left(\varphi^{-1}(t)\right)'}{\varphi^{-1}(t)}. \end{aligned}$$

Since

$$\frac{\left(\varphi^{-1}(t)\right)'}{\varphi^{-1}(t)} = -\psi\left(\varphi^{-1}(t)\right) < 0$$

by (3.30), we observe that $E'(t) + I'(t) = 0$ for

$$t = T_3 = \varphi\left(\frac{\gamma+\mu}{\beta\tilde{S}e^{(\beta/\mu)\tilde{D}}}\right) = S^{-1}\left(\frac{\gamma+\mu}{\beta}\right).$$

Note that

$$e^{-(\beta/\mu)\alpha} < \frac{\gamma+\mu}{\beta\tilde{S}e^{(\beta/\mu)\tilde{D}}} = \frac{\gamma+\mu}{\beta\tilde{S}}e^{-(\beta/\mu)\tilde{D}} < e^{-(\beta/\mu)\tilde{D}}$$

in view of (A_7) and Remark 3.2. In light of (3.22) we obtain

$$T_3 = \varphi\left(\frac{\gamma+\mu}{\beta\tilde{S}e^{(\beta/\mu)\tilde{D}}}\right) = \int_{(\gamma+\mu)/(\beta\tilde{S}e^{(\beta/\mu)\tilde{D}})}^{e^{-(\beta/\mu)\tilde{D}}} \frac{d\xi}{\xi\psi(\xi)} = S^{-1}\left(\frac{\gamma+\mu}{\beta}\right).$$

It is easy to check that $E'(t) + I'(t) > 0$ [resp. < 0] if and only if $t < T_3$ [resp. $> T_3$], because $\varphi^{-1}(t)$ is decreasing on $[0, \infty)$. Therefore we conclude that $E(t) + I(t)$ is increasing in $[0, T_3)$

and is decreasing in (T_3, ∞). It can be shown that

$$\begin{aligned}
\max_{t\geq 0} \big(E(t)+I(t)\big) &= N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(T_3) + \frac{\gamma+\mu}{\beta}\log\varphi^{-1}(T_3) \\
&= N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}\frac{\gamma+\mu}{\beta\tilde{S}e^{(\beta/\mu)\tilde{D}}} + \frac{\gamma+\mu}{\beta}\log\left(\frac{\gamma+\mu}{\beta\tilde{S}e^{(\beta/\mu)\tilde{D}}}\right) \\
&= N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \frac{\gamma+\mu}{\beta} + \frac{\gamma+\mu}{\beta}\left(\log\frac{\gamma+\mu}{\beta} - \log\tilde{S} - \frac{\beta}{\mu}\tilde{D}\right) \\
&= \tilde{S} + \tilde{E} + \tilde{I} - \frac{\gamma+\mu}{\beta}\left(1 + \log\tilde{S} - \log\frac{\gamma+\mu}{\beta}\right). \qquad \square
\end{aligned}$$

Remark 4.9. Since $u_3 = (\gamma+\mu)/\big(\beta\tilde{S}e^{(\beta/\mu)\tilde{D}}\big) = ((\gamma+\mu)/(\beta\tilde{S}))e^{-(\beta/\mu)\tilde{D}}$ is a unique solution of the equation

$$\left(N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}u + \frac{\gamma+\mu}{\beta}\log u\right)' = 0,$$

we obtain

$$T_3 = \varphi(u_3) = \int_{((\gamma+\mu)/(\beta\tilde{S}))e^{-(\beta/\mu)\tilde{D}}}^{e^{-(\beta/\mu)\tilde{D}}} \frac{d\xi}{\xi\psi(\xi)}$$

(*cf.* Figure 4.3).

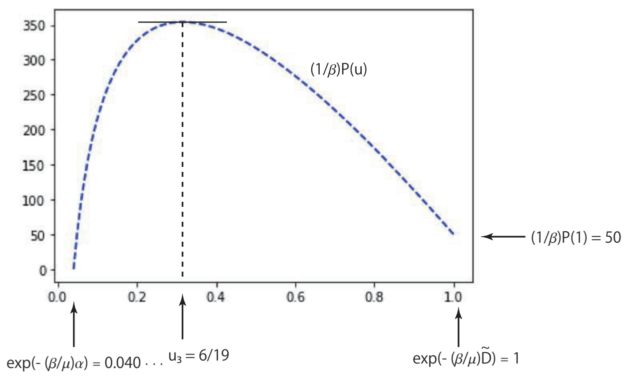

Figure 4.3: Variation of $(1/\beta)P(u) = N - \tilde{R} + (\gamma/\mu)\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}u + ((\gamma+\mu)/\beta)\log u$ (dashed curve) for $N = 1000, \tilde{S} = 950, \tilde{I} = 30, \tilde{E} = 20, \tilde{R} = 0, \beta = 0.3/1000, \gamma = 0.1$ and $\delta = 0.2$. In this case we observe that there exists a unique $u_3 = 6/19$ such that $(1/\beta)P'(u_3) = 0$, and that T_3 is calculated by $T_3 = \varphi(u_3) = \int_{6/19}^{1} \frac{d\xi}{\xi\psi(\xi)} = 41.9\ldots$, where $\psi(u)$ is the unique positive solution of the same initial value problem as in Figure 4.1.

Theorem 4.10. *The following relation holds:*

$$S(\infty) = \tilde{S} + \tilde{E} + \tilde{I} + \frac{\gamma+\mu}{\beta}\log\frac{S(\infty)}{\tilde{S}}.$$

Proof. Since $E(\infty) = I(\infty) = 0$, we obtain

$$\begin{aligned} S(\infty) &= N - R(\infty) - D(\infty) \\ &= N - \left(\frac{\gamma}{\mu}D(\infty) + \tilde{R} - \frac{\gamma}{\mu}\tilde{D}\right) - D(\infty) \\ &= N - \tilde{R} - \tilde{D} + \frac{\gamma+\mu}{\beta}\left(\frac{\beta}{\mu}\tilde{D} - \frac{\beta}{\mu}D(\infty)\right) \\ &= \tilde{S} + \tilde{E} + \tilde{I} + \frac{\gamma+\mu}{\beta}\log\left(e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)D(\infty)}\right) \\ &= \tilde{S} + \tilde{E} + \tilde{I} + \frac{\gamma+\mu}{\beta}\log\frac{S(\infty)}{\tilde{S}} \end{aligned}$$

by use of (4.2) and (4.3). □

Theorem 4.11. *We find that*

$$S'(\infty) = E'(\infty) = I'(\infty) = R'(\infty) = D'(\infty) = 0.$$

Proof. Since $E(\infty) = I(\infty) = 0$, we see from (1.1)–(1.5) that

$$\begin{aligned} S'(\infty) &= -\beta S(\infty)I(\infty) = 0, \\ E'(\infty) &= \beta S(\infty)I(\infty) - \delta E(\infty) = 0, \\ I'(\infty) &= \delta E(\infty) - \gamma I(\infty) - \mu I(\infty) = 0, \\ R'(\infty) &= \gamma I(\infty) = 0, \\ D'(\infty) &= \mu I(\infty) = 0. \end{aligned}$$

□

Remark 4.12. The hypothesis (A_5) is satisfied if $\tilde{D} = 0$, since $N > \tilde{S} + \tilde{R}$.

Remark 4.13. It follows from Theorems 4.1–4.6 that $S(t) > 0, E(t) > 0, I(t) > 0$ for $t \geq 0$ and $R(t) > 0, D(t) > 0$ for $t > 0$ (*cf.* Figure 4.4).

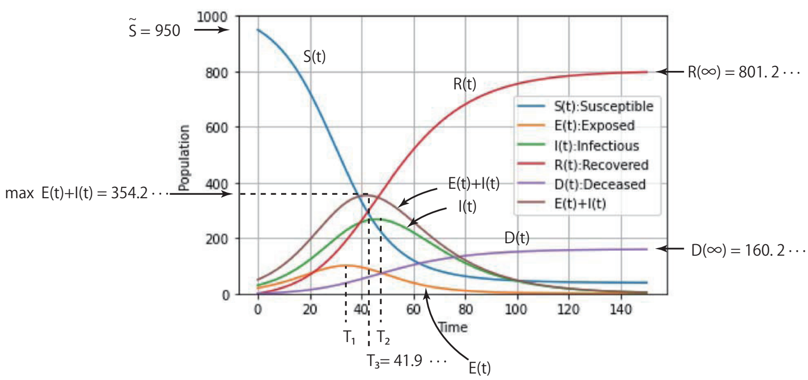

Figure 4.4: Variations of $S(t)$, $E(t)$, $I(t)$, $R(t)$, $D(t)$ and $E(t) + I(t)$ obtained by the numerical integration of the initial value problem (1.1)–(1.6) for $N = 1000, \tilde{S} = 950, \tilde{E} = 20, \tilde{I} = 30, \tilde{R} = 0, \tilde{D} = 0, \beta = 0.2/1000, \gamma = 0.05$, $\delta = 0.2$ and $\mu = 0.01$.

Remark 4.14. We note that

$$E'_+(0) + I'_+(0) = \beta \tilde{S} \tilde{I} - (\gamma + \mu) \tilde{I},$$

and that $E'_+(0) + I'_+(0) \leq 0$ is equivalent to $\tilde{S} \leq (\gamma + \mu)/\beta$. Let $E'_+(0) + I'_+(0) \leq 0$ be satisfied, and let $P(u)$ be given by (3.9). Then we see that

$$\frac{1}{\beta} P'(u) = -\tilde{S} e^{(\beta/\mu)\tilde{D}} + \frac{\gamma + \mu}{\beta} \frac{1}{u} = 0$$

at $u = ((\gamma + \mu)/(\beta \tilde{S})) e^{-(\beta/\mu)\tilde{D}}$ $(\geq e^{-(\beta/\mu)\tilde{D}})$ and that $(1/\beta)P(u)$ is increasing in $\left(e^{-(\beta/\mu)\alpha}, e^{-(\beta/\mu)\tilde{D}}\right]$, $\lim_{u \to e^{-(\beta/\mu)\alpha}+0} (1/\beta)P(u) = 0$ and $(1/\beta)P\left(e^{-(\beta/\mu)\tilde{D}}\right) = \tilde{E} + \tilde{I} > 0$. Since $\varphi^{-1}(t)$ is decreasing on $[0, \infty)$, $\varphi^{-1}(0) = e^{-(\beta/\mu)\tilde{D}}$ and $\lim_{t \to \infty} \varphi^{-1}(t) = e^{-(\beta/\mu)\alpha}$, we conclude that $E(t) + I(t) = (1/\beta)P\left(\varphi^{-1}(t)\right)$ is decreasing on $[0, \infty)$, $E(0) + I(0) = \tilde{E} + \tilde{I}$, and $E(\infty) + I(\infty) = 0$ (*cf.* Figure 4.5).

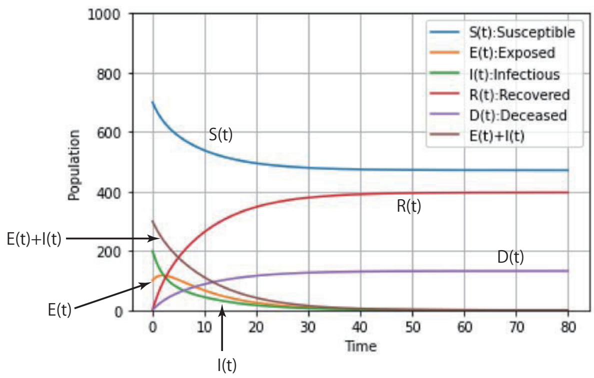

Figure 4.5: Variations of $S(t)$, $E(t)$, $I(t)$, $R(t)$, $D(t)$ and $E(t) + I(t)$ obtained by the numerical integration of the initial value problem (1.1)–(1.6) for $N = 1000, \tilde{S} = 700, \tilde{E} = 100, \tilde{I} = 200, \tilde{R} = 0, \tilde{D} = 0, \beta = 0.3/1000, \gamma = 0.3$, $\delta = 0.2$ and $\mu = 0.1$. In this case we find that $E'_+(0) = 22 > 0$, $I'_+(0) = -60 < 0$ and $E'_+(0) + I'_+(0) = -38 < 0$.

Remark 4.15. The function $D(t)$ given by (3.29) is a positive and increasing solution of the initial value problem for (2.1) with the initial conditions $D(0) = \tilde{D}$ and $D'_+(0) = \mu \tilde{I}$. In fact, it follows from Theorem 4.1 that $D(t)$ is an increasing function such that $D(t) > 0$ for $t > 0$. Since

$$\begin{aligned} D'(t) &= -\frac{\mu}{\beta} \frac{\left(\varphi^{-1}(t)\right)'}{\varphi^{-1}(t)} = -\frac{\mu}{\beta}\left(-\psi(\varphi^{-1}(t))\right) = \frac{\mu}{\beta}\psi(\varphi^{-1}(t)), \\ D''(t) &= -\frac{\mu}{\beta}\varphi^{-1}(t)\psi'(\varphi^{-1}(t))\psi(\varphi^{-1}(t)) \end{aligned}$$

in light of (3.30), we arrive at

$$\begin{aligned}
&D''(t) + (\delta+\gamma+\mu)D'(t) \\
&\quad = -\frac{\mu}{\beta}\varphi^{-1}(t)\left(\psi'(\varphi^{-1}(t))\psi(\varphi^{-1}(t)) - (\delta+\gamma+\mu)\frac{\psi(\varphi^{-1}(t))}{\varphi^{-1}(t)}\right) \\
&\quad = -\frac{\mu}{\beta}\varphi^{-1}(t)\left(-\delta\frac{\beta N - \beta\tilde{R} + ((\beta\gamma)/\mu)\tilde{D} - \beta\tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t) + (\gamma+\mu)\log\varphi^{-1}(t)}{\varphi^{-1}(t)}\right) \\
&\quad = \delta\mu\left(N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t) + \frac{\gamma+\mu}{\beta}\log\varphi^{-1}(t)\right) \\
&\quad = \delta\mu\left(N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)D(t)} - \frac{\gamma+\mu}{\mu}D(t)\right)
\end{aligned}$$

in view of (3.3). It is easy to check that $D(0) = -(\mu/\beta)\log\varphi^{-1}(0) = -(\mu/\beta)\log e^{-(\beta/\mu)\tilde{D}} = \tilde{D}$ and

$$\begin{aligned}
D'_+(0) &= \lim_{\varepsilon\to+0} D'(\varepsilon) = \lim_{\varepsilon\to+0}\frac{\mu}{\beta}\psi(\varphi^{-1}(\varepsilon)) \\
&= \frac{\mu}{\beta}\psi(\varphi^{-1}(0)) = \frac{\mu}{\beta}\psi(e^{-(\beta/\mu)\tilde{D}}) = \frac{\mu}{\beta}\beta\tilde{I} = \mu\tilde{I}.
\end{aligned}$$

Remark 4.16. Let $D(t)$ be given by (3.29). Then the functions $S(t), E(t), I(t)$ and $R(t)$ given by (2.23)–(2.26) reduce to (3.25)–(3.28), respectively, since

$$e^{-(\beta/\mu)D(t)} = \varphi^{-1}(t), \qquad t = D^{-1}(-(\mu/\beta)\log\varphi^{-1}(t)) \quad \text{and} \quad \varphi(v) = D^{-1}(-(\mu/\beta)\log v).$$

Remark 4.17. If we suppose the hypothesis

(A'_4) $\tilde{R} \geq 0$ and $\tilde{R}$ satisfies

$$N - \tilde{D} > \tilde{S}e^{(\beta/\gamma)\tilde{R}} + \tilde{R},$$

then the transcendental equation

$$y = \frac{\gamma}{\gamma+\mu}N - \frac{\gamma}{\gamma+\mu}\tilde{D} + \frac{\mu}{\gamma+\mu}\tilde{R} - \frac{\gamma}{\gamma+\mu}\tilde{S}e^{(\beta/\gamma)\tilde{R}}e^{-(\beta/\gamma)y} \tag{4.8}$$

has a unique solution $y = \alpha_*$ such that

$$\tilde{R} < \alpha_* < N$$

(see Yoshida [18, Lemma 3]). Since the equation (4.8) reduces to the transcendental equation in Lemma 3.1 by the transformation $y = \tilde{R} - (\gamma/\mu)(\tilde{D} - x)$, we find that $\alpha_* = \tilde{R} - (\gamma/\mu)(\tilde{D} - \alpha)$. We define

$$\varphi_*(w) := \int_w^{e^{-(\beta/\gamma)\tilde{R}}} \frac{d\xi}{\xi\psi_*(\xi)}$$

for $e^{-(\beta/\gamma)\alpha_*} < w \leq e^{-(\beta/\gamma)\tilde{R}}$, where $\psi_*(\xi)$ is a unique positive solution of the initial value problem

$$\begin{aligned}
&\psi'_*(\xi)\psi_*(\xi) - \frac{\delta+\mu+\gamma}{\xi}\psi_*(\xi) \\
&\qquad = -\delta\,\frac{\beta N - \beta\tilde{D} + ((\beta\mu)/\gamma)\tilde{R} - \beta\tilde{S}e^{(\beta/\gamma)\tilde{R}}\xi + (\mu+\gamma)\log\xi}{\xi} \\
&\qquad\quad (e^{-(\beta/\gamma)\alpha_*} < \xi < e^{-(\beta/\gamma)\tilde{R}}), \\
&\psi_*(e^{-(\beta/\gamma)\tilde{R}}) = \beta\tilde{I}.
\end{aligned}$$

It follows from the transformation

$$\xi = e^{-(\beta/\gamma)\tilde{R}}e^{(\beta/\mu)\tilde{D}}u$$

that

$$\varphi_*(w) = \int_{e^{(\beta/\gamma)\tilde{R}}e^{-(\beta/\mu)\tilde{D}}w}^{e^{-(\beta/\mu)\tilde{D}}} \frac{du}{u\psi_*(e^{-(\beta/\gamma)\tilde{R}}e^{(\beta/\mu)\tilde{D}}u)},$$

where $e^{-(\beta/\mu)\alpha} < e^{(\beta/\gamma)\tilde{R}}e^{-(\beta/\mu)\tilde{D}}w \le e^{-(\beta/\mu)\tilde{D}}$. It is easy to check that $\psi_*(e^{-(\beta/\gamma)\tilde{R}}e^{(\beta/\mu)\tilde{D}}u)$ is a solution of the initial value problem (3.3), (3.4), and therefore

$$\psi_*\big(e^{-(\beta/\gamma)\tilde{R}}e^{(\beta/\mu)\tilde{D}}u\big) = \psi(u)$$

by the uniqueness of solutions of the initial value problem (3.3), (3.4). Hence we obtain

$$\varphi_*(w) = \varphi\big(e^{(\beta/\gamma)\tilde{R}}e^{-(\beta/\mu)\tilde{D}}w\big). \tag{4.9}$$

Let $\varphi_*^{-1}(t)$ and $\varphi^{-1}(t)$ be the inverse functions of

$$t = \varphi_*(w), \quad t = \varphi\big(e^{(\beta/\gamma)\tilde{R}}e^{-(\beta/\mu)\tilde{D}}w\big),$$

respectively, then we see that

$$\varphi_*^{-1}(t) = e^{-(\beta/\gamma)\tilde{R}}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t) \quad (0 \le t < \infty). \tag{4.10}$$

It is easy to see that the hypothesis (A_7) is equivalent to

(A_8) $\tilde{S} < \dfrac{\mu+\gamma}{\beta}e^{(\beta/\gamma)(\alpha_*-\tilde{R})}$.

Let $\big(S_*(t), E_*(t), I_*(t), R_*(t), D_*(t)\big)$ be the exact solution of the initial value problem (1.1)–(1.6) by starting our arguments utilizing (1.4) instead of (1.5). Then we get

$$\begin{aligned}
S_*(t) &= \tilde{S}e^{(\beta/\gamma)\tilde{R}}\varphi_*^{-1}(t),\\
E_*(t) &= \tilde{E}e^{-\delta t} + \tilde{S}e^{(\beta/\gamma)\tilde{R}}e^{-\delta t}\int_{\varphi_*^{-1}(t)}^{e^{-(\beta/\gamma)\tilde{R}}} e^{\delta\varphi_*(v)}dv,\\
I_*(t) &= N - \tilde{D} + \frac{\mu}{\gamma}\tilde{R} - \tilde{S}e^{(\beta/\gamma)\tilde{R}}\varphi_*^{-1}(t) + \frac{\mu+\gamma}{\beta}\log\varphi_*^{-1}(t)\\
&\qquad - \tilde{E}e^{-\delta t} - \tilde{S}e^{(\beta/\gamma)\tilde{R}}e^{-\delta t}\int_{\varphi_*^{-1}(t)}^{e^{-(\beta/\gamma)\tilde{R}}} e^{\delta\varphi_*(v)}dv,\\
R_*(t) &= -\frac{\gamma}{\beta}\log\varphi_*^{-1}(t),\\
D_*(t) &= -\frac{\mu}{\beta}\log\varphi_*^{-1}(t) + \tilde{D} - \frac{\mu}{\gamma}\tilde{R}.
\end{aligned}$$

We observe, using (4.10), that

$$\begin{aligned}
S_*(t) &= \tilde{S}e^{(\beta/\gamma)\tilde{R}}\varphi_*^{-1}(t) = \tilde{S}e^{(\beta/\gamma)\tilde{R}}\big(e^{-(\beta/\gamma)\tilde{R}}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t)\big)\\
&= \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t) = S(t).
\end{aligned}$$

It follows from (4.9) and (4.10) that

$$\int_{\varphi_*^{-1}(t)}^{e^{-(\beta/\gamma)\tilde{R}}} e^{\delta\varphi_*(v)}dv = \int_{e^{-(\beta/\gamma)\tilde{R}}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t)}^{e^{-(\beta/\gamma)\tilde{R}}} \exp\left(\delta\varphi\left(e^{(\beta/\gamma)\tilde{R}}e^{-(\beta/\mu)\tilde{D}}v\right)\right)dv$$
$$= e^{-(\beta/\gamma)\tilde{R}}e^{(\beta/\mu)\tilde{D}} \int_{\varphi^{-1}(t)}^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(w)}dw$$

and hence

$$E_*(t) = \tilde{E}e^{-\delta t} + \tilde{S}e^{(\beta/\gamma)\tilde{R}}e^{-\delta t}\int_{\varphi_*^{-1}(t)}^{e^{-(\beta/\gamma)\tilde{R}}} e^{\delta\varphi_*(v)}dv$$
$$= \tilde{E}e^{-\delta t} + \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-\delta t}\int_{\varphi^{-1}(t)}^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(w)}dw = E(t). \tag{4.11}$$

Since

$$N - \tilde{D} + \frac{\mu}{\gamma}\tilde{R} - \tilde{S}e^{(\beta/\gamma)\tilde{R}}\varphi_*^{-1}(t) + \frac{\mu+\gamma}{\beta}\log\varphi_*^{-1}(t)$$
$$= N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t) + \frac{\gamma+\mu}{\beta}\log\varphi^{-1}(t),$$

we deduce that $I_*(t) = I(t)$ in view of (4.11). It is easy to see that

$$R_*(t) = -\frac{\gamma}{\beta}\log\varphi_*^{-1}(t)$$
$$= -\frac{\gamma}{\beta}\left(-\frac{\beta}{\gamma}\tilde{R} + \frac{\beta}{\mu}\tilde{D} + \log\varphi^{-1}(t)\right)$$
$$= -\frac{\gamma}{\beta}\log\varphi^{-1}(t) + \tilde{R} - \frac{\gamma}{\mu}\tilde{D} = R(t),$$

and that

$$D_*(t) = -\frac{\mu}{\beta}\log\varphi_*^{-1}(t) + \tilde{D} - \frac{\mu}{\gamma}\tilde{R}$$
$$= -\frac{\mu}{\beta}\left(-\frac{\beta}{\gamma}\tilde{R} + \frac{\beta}{\mu}\tilde{D} + \log\varphi^{-1}(t)\right) + \tilde{D} - \frac{\mu}{\gamma}\tilde{R}$$
$$= -\frac{\mu}{\beta}\log\varphi^{-1}(t) = D(t).$$

Consequently we conclude that

$$\left(S_*(t), E_*(t), I_*(t), R_*(t), D_*(t)\right) \equiv \left(S(t), E(t), I(t), R(t), D(t)\right) \quad \text{on } [0,\infty).$$

Remark 4.18. The hypotheses (A_4') and (A_5) are equivalent to

(A_4'') $0 \le \tilde{R} < \dfrac{\gamma}{\beta}\log\left(1 + (\tilde{E}/\tilde{S}) + (\tilde{I}/\tilde{S})\right)$;

(A_5') $0 \le \tilde{D} < \dfrac{\mu}{\beta}\log\left(1 + (\tilde{E}/\tilde{S}) + (\tilde{I}/\tilde{S})\right)$,

respectively.

5 Uniqueness of positive solutions

This section is devoted to the uniqueness of positive solutions of the initial value problem (1.1)–(1.6). As a consequence we conclude that the exact solution (3.25)–(3.29) is the unique solution in the class of positive solutions.

A solution $(S(t), E(t), I(t), R(t), D(t))$ of the SEIRD differential system (1.1)–(1.5) is said to be *positive* if $S(t) > 0, E(t) > 0, I(t) > 0, R(t) > 0$ and $D(t) > 0$ for $t > 0$.

Theorem 5.1. *Let* $(S_i(t), E_i(t), I_i(t), R_i(t), D_i(t))$ $(i = 1, 2)$ *be solutions of the initial value problem* (1.1)–(1.6) *such that* $S_i(t) > 0, E_i(t) > 0, I_i(t) > 0, R_i(t) > 0$ *for* $t > 0$. *Then we find that*

$$(S_1(t), E_1(t), I_1(t), R_1(t), D_1(t)) \equiv (S_2(t), E_2(t), I_2(t), R_2(t), D_2(t)) \quad \text{on } [0, \infty). \tag{5.1}$$

Proof. First we note that $D_i(t) > 0$ for $t > 0$ $(i = 1, 2)$ since $D_i'(t) = \mu I_i(t) > 0$ for $t > 0$ and $D_i(0) = \tilde{D} \geq 0$. It follows from Lemma 2.1 that $D_i(t)$ $(i = 1, 2)$ satisfies (2.1) and the initial condition

$$D_i(0) = \tilde{D}, \qquad \lim_{\varepsilon \to +0} D_i'(\varepsilon) = \mu \tilde{I}$$

in view of (1.5) and (1.6). It is easy to see that

$$\boldsymbol{z}_i(t) := \big(D_i(t), D_i'(t)\big) \qquad (i = 1, 2)$$

are positive solutions of the initial value problem

$$\begin{aligned} \boldsymbol{y}'(t) &= \boldsymbol{f}(\boldsymbol{y}(t)), \qquad t > 0, \\ \boldsymbol{y}_+(0) &= \lim_{\varepsilon \to +0} \boldsymbol{y}(\varepsilon) = (\tilde{D}, \mu \tilde{I}), \end{aligned}$$

where $\boldsymbol{f}(\boldsymbol{y})$ is a function defined by

$$\boldsymbol{f}(\boldsymbol{y}) = \left(y_2, -(\delta + \gamma + \mu) y_2 + +\delta\mu \left(N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S} e^{(\beta/\mu)\tilde{D}} e^{-(\beta/\mu) y_1} - \left(1 + \frac{\gamma}{\mu}\right) y_1\right)\right)$$

for $\boldsymbol{y} = (y_1, y_2)$ such that $y_1 > 0$ and $y_2 > 0$. Since

$$\begin{aligned} \frac{\partial \boldsymbol{f}}{\partial y_1}(\boldsymbol{y}) &= \left(0, \beta\delta\tilde{S} e^{(\beta/\mu)\tilde{D}} e^{-(\beta/\mu) y_1} - \delta(\gamma + \mu)\right), \\ \frac{\partial \boldsymbol{f}}{\partial y_2}(\boldsymbol{y}) &= (1, -(\delta + \gamma + \mu)), \end{aligned}$$

we obtain

$$\left| \frac{\partial \boldsymbol{f}}{\partial y_k}(\boldsymbol{y}) \right| \leq \max \left\{ \beta\delta\tilde{S} e^{(\beta/\mu)\tilde{D}} + \delta(\gamma + \mu), 1 + (\delta + \gamma + \mu) \right\} \ (\equiv K) \ (k = 1, 2)$$

for $\boldsymbol{y} = (y_1, y_2)$ such that $y_1 > 0$ and $y_2 > 0$, where the magnitude of a vector $\boldsymbol{y}$, denoted by $|\boldsymbol{y}|$, is defined by

$$|\boldsymbol{y}| = |y_1| + |y_2| \quad \text{for } \boldsymbol{y} = (y_1, y_2) \in \mathbb{R}^2.$$

Therefore, $\boldsymbol{f}(\boldsymbol{y})$ satisfies a Lipschitz condition on $(0, \infty) \times (0, \infty)$ with Lipschitz constant K (see Coddington [7, p.248, Theorem 1]). Since

$$\boldsymbol{z}_i'(t) = \boldsymbol{f}(\boldsymbol{z}_i(t)), \qquad t > 0 \qquad (i = 1, 2),$$

integrating the above on $[\varepsilon, t]$ $(\varepsilon > 0)$ and then taking the limit as $\varepsilon \to +0$ yield

$$\boldsymbol{z}_i(t) - \lim_{\varepsilon \to +0} \boldsymbol{z}_i(\varepsilon) = \int_0^t \boldsymbol{f}(\boldsymbol{z}_i(s))ds, \qquad t > 0,$$

and we observe, using $\lim_{\varepsilon \to +0} \boldsymbol{z}_i(\varepsilon) = (\tilde{D}, \mu\tilde{I})$, that

$$\boldsymbol{z}_i(t) = (\tilde{D}, \mu\tilde{I}) + \int_0^t \boldsymbol{f}(\boldsymbol{z}_i(s))ds, \qquad t > 0.$$

Therefore we obtain

$$\boldsymbol{z}_1(t) - \boldsymbol{z}_2(t) = \int_0^t (\boldsymbol{f}(\boldsymbol{z}_1(s)) - \boldsymbol{f}(\boldsymbol{z}_2(s)))\, ds, \qquad t > 0$$

and hence

$$|\boldsymbol{z}_1(t) - \boldsymbol{z}_2(t)| \leq K \int_0^t |\boldsymbol{z}_1(s) - \boldsymbol{z}_2(s)|\, ds, \qquad t > 0$$

since $\boldsymbol{f}(\boldsymbol{y})$ satisfies a Lipschitz condition with Lipschitz constant K. Defining

$$W(t) := \int_0^t |\boldsymbol{z}_1(s) - \boldsymbol{z}_2(s)|\, ds,$$

we obtain

$$W'(t) - KW(t) \leq 0, \qquad t > 0,$$

or

$$\left(e^{-Kt}W(t)\right)' \leq 0, \qquad t > 0.$$

Since $e^{-Kt}W(t) \leq W(0) = 0$ $(t \geq 0)$, we see that $W(t) \leq 0$ $(t \geq 0)$. Hence

$$|\boldsymbol{z}_1(t) - \boldsymbol{z}_2(t)| \leq KW(t) \leq 0, \qquad t > 0,$$

which yields

$$\boldsymbol{z}_1(t) = \boldsymbol{z}_2(t), \qquad t > 0.$$

Therefore we conclude that

$$D_1(t) \equiv D_2(t) \quad \text{on } (0, \infty).$$

Since $D_1(0) = D_2(0) = \tilde{D}$, we observe that

$$D_1(t) \equiv D_2(t) \quad \text{on } [0, \infty).$$

It follows from Corollary 2.4 that $S_i(t)$ $(i = 1, 2)$ can be represented by

$$S_i(t) = \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-(\beta/\mu)D_i(t)}$$

for $t \geq 0$. Since $D_1(t) = D_2(t)$ for $t \geq 0$, we deduce that $S_1(t) = S_2(t)$ for $t \geq 0$. Similarly we find that $E_1(t) = E_2(t)$ $(t \geq 0)$, $I_1(t) = I_2(t)$ $(t \geq 0)$ and $R_1(t) = R_2(t)$ $(t \geq 0)$. Consequently we conclude that (5.1) holds. □

Theorem 5.2. *Assume that the hypotheses* (A$_1$)–(A$_7$), (A$'_4$) *hold. The function* $(S(t), E(t), I(t), R(t), D(t))$ *given by*

$$\begin{aligned}
S(t) &= \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t) = \tilde{S}e^{(\beta/\gamma)\tilde{R}}\varphi_*^{-1}(t),\\
E(t) &= \tilde{E}e^{-\delta t} + \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-\delta t}\int_{\varphi^{-1}(t)}^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi(v)}dv\\
&= \tilde{E}e^{-\delta t} + \tilde{S}e^{(\beta/\gamma)\tilde{R}}e^{-\delta t}\int_{\varphi_*^{-1}(t)}^{e^{-(\beta/\gamma)\tilde{R}}} e^{\delta\varphi_*(v)}dv,\\
I(t) &= N - \tilde{R} + \frac{\gamma}{\mu}\tilde{D} - \tilde{S}e^{(\beta/\mu)\tilde{D}}\varphi^{-1}(t) + \frac{\gamma+\mu}{\beta}\log\varphi^{-1}(t)\\
&\quad - \tilde{E}e^{-\delta t} - \tilde{S}e^{(\beta/\mu)\tilde{D}}e^{-\delta t}\int_{\varphi^{-1}(t)}^{e^{-(\beta/\mu)\tilde{D}}} e^{\delta\varphi_*(v)}dv\\
&= N - \tilde{D} + \frac{\mu}{\gamma}\tilde{R} - \tilde{S}e^{(\beta/\gamma)\tilde{R}}\varphi_*^{-1}(t) + \frac{\mu+\gamma}{\beta}\log\varphi_*^{-1}(t)\\
&\quad - \tilde{E}e^{-\delta t} - \tilde{S}e^{(\beta/\gamma)\tilde{R}}e^{-\delta t}\int_{\varphi_*^{-1}(t)}^{e^{-(\beta/\gamma)\tilde{R}}} e^{\delta\varphi_*(v)}dv,\\
R(t) &= -\frac{\gamma}{\beta}\log\varphi^{-1}(t) + \tilde{R} - \frac{\gamma}{\mu}\tilde{D} = -\frac{\gamma}{\beta}\log\varphi_*^{-1}(t),\\
D(t) &= -\frac{\mu}{\beta}\log\varphi^{-1}(t) = -\frac{\mu}{\beta}\log\varphi_*^{-1}(t) + \tilde{D} - \frac{\mu}{\gamma}\tilde{R}
\end{aligned}$$

is a positive solution of the initial value problem (1.1)–(1.6)*, and is unique in the class of positive solutions.*

Proof. Combining Theorem 3.9, Remarks 4.13 and 4.17, we see that $(S(t), E(t), I(t), R(t), D(t))$ given above is a positive solution of the initial value problem (1.1)–(1.6). Uniqueness of positive solutions follows from Theorem 5.1. □

Abstract. We discuss the Lagrange stability for a class of impulsive Duffing equation with time-dependent polynomial potentials. More precisely, we prove that under suitable impulses, all the solutions of the impulsive Duffing equation (with low regularity in time) are bounded for all time and that there are many (positive Lebesgue measure) quasi-periodic solutions clustering at infinity.

Keywords: boundedness, quasi-periodic solution, Moser's twist theorem, impulsive Duffing equation.

2020 Mathematics Subject Classification: 34C25, 34B15, 34D15.

1 Introduction

The stability theory plays a central role in differential equations for its practical value in real world applications. It is well known that the longtime behavior of a time-dependent nonlinear ordinary differential equation can be very intricate. For instance, the well-known Duffing equation,

$$\ddot{x} + \delta\dot{x} + \alpha x + \beta x^3 = \gamma\cos(\omega t),$$

is an example of dynamical system that exhibits chaotic behavior.

The generalized Duffing-type equation arises in a large class of practically important applied problems in mathematics, physical science and engineering such as the cubic–quintic Duffing oscillatory [9] and the Helmholtz–Duffing oscillator [8], which takes the form of

$$\ddot{x} = \sum_{j\in K} a_j\, x^j(t), \quad K \subset \mathbf{N} \text{ is finite.}$$

See [35] and the references therein for more details.

1.1 Lagrange stability of Duffing-type equation

In contrast to "Lyapunov stability" that is related to the chaotic nature of the system, we pay special interest in this paper to the Lagrange stability of nonlinear systems, which means that all the solutions stay bounded for all time. The Lagrange stability refers roughly to the stability against the escape of a body from the system. We refer to the classical monograph [14] for more details about the Lagrange stability.

The study of Lagrange stability of Duffing-type equation dates back to Littlewood [16], Moser [20,21] and Morris [19]. In 1987, Dieckerhoff and Zehnder studied the Lagrange stability for the generalized Duffing-type equation with time-dependent polynomial potentials

$$\ddot{x} + x^{2n+1} + \sum_{i=0}^{2n} x^i p_i(t) = 0, \quad n \geq 1, \tag{1.1}$$

where $p_i \in C^\nu(\mathbf{T^1})$ $(0 \leq i \leq 2n)$ are 1-periodic with $\mathbf{T^1} = \mathbf{R}/\mathbf{Z}$, and proved that every solution $x(t)$ of (1.1) is bounded for all time, i.e., the solution $x(t)$ exists for all $t \in \mathbf{R}$ and $\sup_{t\in\mathbf{R}}(|x(t)| + |\dot{x}(t)|) < \infty$, if ν is the smallest integer satisfying

$$v > 1 + \frac{4}{n} + [\log_2 n] \to \infty \quad \text{as } n \to \infty.$$

There exist a lot of papers [12,15,17,18,32–34] devoting to the relaxation of the smoothness of p_i in (1.1) with respect to the t-variable when studying the Lagrange stability. However, there is an example in [31] showing that a continuous coefficient would result in an unbounded solution.

As we know, a abrupt change at certain instant during the evolution process falls into the scope of the impulsive dynamical system [1,13], which appear widely in applied mathematics. The appearance of impulse forces may cause complicated dynamic phenomenons and bring difficulties to study. There are many studies on the existence of periodic solutions of impulsive differential equations [2,7,10,22–24] via different approaches. See also [11,26] for the periodic solution of impulsive Duffing-type equation.

However, there are only few results on the Lagrange stability and the existence of quasi-periodic solutions for impulsive differential equations (see [3–5,25,30]). Coming back to the Duffing-type equation (1.1), the term $\sum_{i=0}^{2n} x^i p_i(t)$ can be regarded as the perturbation of $\ddot{x} + x^{2n+1} = 0$ (up to some transformations). Then the Lagrange stability of (1.1) show that all solutions of nonlinear equation $\ddot{x} + x^{2n+1} = 0$ is bounded under a periodic perturbation. It is very natural to ask the following question:

"what happens when the nonlinear equation $\ddot{x} + x^{2n+1} = 0$ is subject to both periodic perturbation and an impulse at the same time?"

Choosing different impulsive functions may have different effects on the solutions. It is also not surprising that an offhand choice of impulse force would destroy the Lagrange stability even though the coefficients p_i are sufficiently smooth. To establish the Lagrange stability of impulsive Duffing-type equation, one needs to be careful on the impulse such that the Poincaré map can be well organized in order to apply Moser's twist theorem after some symplectic transformations. We mention some progress in this respect. In 2019, [30] proved the boundedness of solutions and the existence of quasi-periodic solutions for the impulsive

Duffing equation

$$\begin{cases} \ddot{x} + x^{2n+1} + \sum_{i=0}^{2n} x^i p_i(t) = 0, \quad t \neq t_j, \quad n \geq 1, \\ \Delta x(t_j) := x(t_j^+) - x(t_j^-) = I_j(x(t_j^-), \dot{x}(t_j^-)), \\ \Delta \dot{x}(t_j) := \dot{x}(t_j^+) - \dot{x}(t_j^-) = J_j(x(t_j^-), \dot{x}(t_j^-)), \quad j = \pm 1, \pm 2, \dots \end{cases} \tag{1.2}$$

with the *low regularity in time*

$$p_i(t) \in C^\gamma(\mathbf{T^1}), \quad \gamma > 2 - \frac{1}{n},$$

and with the general sequences of impulsive functions $I_j, J_j : \mathbf{R^2} \to \mathbf{R}$, where $\mathbf{T^1} := \mathbf{R}/\mathbf{Z}$. Moreover, the following restricted conditions are needed: for $j = 1, \dots, k$,

(i) the jumps $I_j(x, y) = o(1)$ as $x^2 + y^2 \to +\infty$;

(ii) the jump map $\Phi_j : (x, y) \to (x, y) + (I_j(x, y), J_j(x, y))$ is an area-preserving homeomorphism,

which enables us to apply Moser's twist theorem. See [30, Remark 2.1] for the comparison of different types of impulse forces and their roles when studying the Lagrange stability.

For the particular case of cubic Duffing-type equation, [25] extended the Morris's boundedness result [19] to the impulsive Duffing equation

$$\begin{cases} \ddot{x} + x^3 + p(t) = 0, \quad t \neq t_j, \\ \Delta x(t_j) := x(t_j^+) - x(t_j^-) = I(x(t_j^-), \dot{x}(t_j^-)), \\ \Delta \dot{x}(t_j) := \dot{x}(t_j^+) - \dot{x}(t_j^-) = J(x(t_j^-), \dot{x}(t_j^-)), \quad j = \pm 1, \pm 2, \dots, \end{cases}$$

where $0 < t_1 < 1, t_{j+1} = t_j + 1$ for $j = \pm 1, \pm 2, \cdots$ and $p(t)$ is 1-periodic and integrable.

In 2020, [3] proposed some concrete and simple impulse forces, which do not satisfy the above conditions (i) and (ii), and proved the Lagrange stability and the existence of quasi-periodic solutions for the impulsive Duffing-type equation

$$\begin{cases} \ddot{x} + x^{2n+1} + \sum_{i=0}^{n} x^i p_i(t) = 0, \quad t \neq t_j, \quad n \geq 1, \\ \Delta x(t_j) = (\gamma_j - 1)\ x(t_j^-), \\ \Delta \dot{x}(t_j) = (\gamma_j^{n+1} - 1)\ \dot{x}(t_j^-)), \quad j = \pm 1, \pm 2, \dots, \end{cases} \tag{1.3}$$

where $\gamma_j > 0$ are some constants and the coefficients $p_i \in C^\infty(\mathbf{T^1})$ for technical simplicity.

In this paper, we pay special attention to the *sharp regularity* of the coefficients $p_i(t)$ in the Duffing-type equation, together with the impulse forces given by (1.3), to establish the Lagrange stability. More precisely, we will prove the Lagrange stability and the existence of quasi-periodic solutions for (1.3) with low regularity in time

$$p_i(t) \in C^\gamma(\mathbf{T^1}) \quad (i = 0, \dots, n), \quad \gamma > 1 - \frac{1}{n}.$$

1.2 Main result

To formulate our main result we have to introduce some notations and hypotheses. Let $\mathbf{R}, \mathbf{C}, \mathbf{N}$ and $\mathbf{Z}$ be the sets of all real numbers, complex numbers, natural numbers and integers, respectively. Denote by $\mathcal{T}$ the impulsive time sequence $\{t_j\}, j = \pm 1, \pm 2, \dots$, and denote by $\mathcal{A}$ the set of indexes j. We assume that the following condition **(H)** holds true.

(H) There exists a positive integer k such that $0 < t_1 < t_2 < \cdots < t_k < 1$, and that t_j's, γ_j's are 1-periodic in j in the sense that $t_{j+k} = t_j + 1, \gamma_{j+k} = \gamma_j$ for $j \le -(k+1)$ or $j \ge 1$; $t_{j+k+1} = t_j + 1, \gamma_{j+k+1} = \gamma_j$ for $-k \le j \le -1$.

The main result in this paper is the following theorem.

Theorem 1.1. *Suppose that condition* (**H**) *holds and that for each* $0 \le i \le n$*, there is* $p_i(t) \in C^\gamma(\mathbf{T^1})$ *with* $\gamma > 1 - \frac{1}{n}$*. In addition, assume that*

$$\prod_{j=1}^{k} \gamma_j = 1. \tag{1.4}$$

Then the time-1 map $\widetilde{P} : (x, \dot{x})_{t=0} \mapsto (x, \dot{x})_{t=1}$ *of* (1.3) *possesses many* (*positive Lebesgue measure*) *invariant closed curves whose radiuses tend to infinity, and thus every solution* $x(t)$ *of* (1.3) *is bounded for all time, i.e. it exists for all* $t \in \mathbf{R}$ *and*

$$\sup_{t\in\mathbf{R}} (|x(t)| + |\dot{x}(t)|) \le \widetilde{C} < +\infty,$$

where $\widetilde{C} = \widetilde{C}(x(0), \dot{x}(0))$ *depends on the initial data* $(x(0), \dot{x}(0))$.

Remark 1.2. In equation (1.3), the jump maps $\Phi_j : (x, y) \mapsto (x, y) + ((\gamma_j - 1)x, (\gamma_j^{n+1} - 1)y)$ are homeomorphisms which are not area-preserving (when $\gamma_j \ne 1$), and $|I_j(x, y)| = |(\gamma_j - 1)x| = O(|x|)$ (when $\gamma_j \ne 1$). Thus, the conditions (i) and (ii) mentioned above in [30] are not satisfied.

Remark 1.3. Equation (1.1) can be written as a Hamiltonian system with the Hamiltonian function $H = h_0(x, y) + R(x, y, t)$. It is essential to regard R as a relatively small perturbation with respect to h_0. See [15] for the detail. Otherwise, the stability might have been violated even without the impulse. Note also that the Duffing-type equation in (1.3) is simpler than (1.1) since the terms $p_i(t)x^i$ $(n + 1 \le i \le 2n)$ are absent. For the general case of equation (1.1) under the impulse given by (1.3), we refer to [3] for some discussions on the obstruction when establishing the Lagrange stability.

Remark 1.4. When using KAM theory to (1.2), one of the main difficulties is the estimation of "small property condition" of Moser's twist theorem. In [30], the difficult was overcome when the smoothness in time $p_i \in C^\gamma(\mathbf{T^1})$ with $\gamma > 2 - \frac{1}{n}$ is used. However, for equation (1.3), we observe that the *smoothness* can be relaxed to $C^\gamma(\mathbf{T^1})$ with $\gamma > 1 - \frac{1}{n}$, which is closely related to the almost sharp result in [34]. Our method is also based on the approximation techniques used in [34].

The paper is organized as follows. In Section 2, we establish the global existence of solutions for impulsive differential equations (1.3) and construct the associated time-one map. In Section 3, we introduce the action-angle variables and apply a preliminary symplectic transformation such that (1.3) becomes a nearly integrable Hamiltonian system. In Section 4, we introduce the approximate lemma to approximate the smooth periodic function by a real analytic function. In Section 5, we take further symplectic transformations such that Moser's twist theorem can be applied. In Section 6, we establish some estimates for the impulsive functions after the transformation. Finally, in Section 7, we prove Theorem 1.1 by employing Moser's twist theorem.

2 Global existence of solutions and time-one map

In this section, we establish the global existence of solutions for impulsive differential equations (1.3) and construct the associated time-one map. We begin with the general impulsive differential equation

$$\begin{cases} \dot{u} = F(t,u), \quad t \neq t_j, \\ \Delta u(t_j) := u(t_j^+) - u(t_j) = L_j(u(t_j)), \quad j \in \mathcal{A} \end{cases} \tag{2.1}$$

with the initial value condition

$$u(\tau^+) = u_0, \tag{2.2}$$

where $\tau \in \mathbf{R}, u_0 \in \mathbf{R^m}, m \in \mathbf{N}$, and where $u(\tau^+) = u(\tau)$ if $\tau \notin \mathcal{T}$. Suppose that

($\mathbf{H_1}$) The function $F : \mathbf{R} \times \mathbf{R^m} \mapsto \mathbf{R^m}$ is continuous, locally Lipschitz in the second variable.

($\mathbf{H_2}$) The function F is 1-periodic in the first variable. There exists a positive integer k such that $0 < t_1 < t_2 < \cdots < t_k < 1$, $t_{j+k} = t_j + 1$, $L_{j+k}(\cdot) = L_j(\cdot)$ for $j \leq -(k+1)$ or $j \geq 1$; $t_{j+k+1} = t_j + 1$, $L_{j+k+1}(\cdot) = L_j(\cdot)$ for $-k \leq j \leq -1$.

($\mathbf{H_3}$) The impulsive functions $L_j : \mathbf{R^m} \to \mathbf{R^m}$ are continuous for all $j \in \mathcal{A}$.

Lemma 2.1 ([30, Lemma 3.2]). *Assume that the conditions* ($\mathbf{H_1}$)–($\mathbf{H_3}$) *hold and that every jump equation*

$$u = v + L_j(v), \quad u \in \mathbf{R^m}, \qquad j = 1, \dots, k, \tag{2.3}$$

has a unique solution with respect to $v \in \mathbf{R^m}$. Assume in addition that all the solutions of the unforced equation $\dot{u} = F(t,u)$ exist for all $t \in \mathbf{R}$. Then the following conclusions hold true.

(a) *For any $\tau \in \mathbf{R}, u_0 \in \mathbf{R^m}$, there is a unique solution $u = u(t;\tau,u_0)$ of (2.1) satisfying the initial value condition (2.2), and it exists for all $t \in \mathbf{R}$.*

(b) *If the equation $\dot{u} = F(t,u)$ is conservative and the impulsive maps $\aleph_j : u \mapsto u + L_j(u) (j \in \mathcal{A})$ are homeomorphisms of $\mathbf{R^m}$, then for $t \in \mathbf{R} \setminus \mathcal{T}$, the map $Q_t : u_0 \mapsto u(t;\tau,u_0)$ is also a homeomorphism.*

(c) *The solution satisfies the elastic property. That is, for any $b_0 > 0$, there is $r_{b_0} > 0$ such that the inequality $|u_0| \geq r_{b_0}$ implies $|u(t;\tau,u_0)| \geq b_0$, for $t \in (\tau, \tau+1]$.*

In order to deduce a global existence result of the impulsive Duffing equation (1.3), by letting $y = \dot{x}$ and noting that $x(t_j^-) = x(t_j), y(t_j^-) = y(t_j)$, we can rewrite equation (1.3) as an equivalent system of the form

$$\begin{cases} \dot{x} = y, \quad t \neq t_j, \\ \dot{y} = -x^{2n+1} - \sum_{i=0}^{n} p_i(t) x^i, \quad t \neq t_j; \\ \Delta x(t_j) = I_j(x(t_j), y(t_j)) = (\gamma_j - 1) x(t_j), \\ \Delta y(t_j) = J_j(x(t_j), y(t_j)) = (\gamma_j^{n+1} - 1) y(t_j), \quad j = 1, 2, \dots, k. \end{cases} \tag{2.4}$$

For (2.4), each jump map

$$\widetilde{\aleph}_j : \begin{cases} u = x + I_j(x,y), \\ v = y + J_j(x,y), \quad j = 1, \dots, k \end{cases} \tag{2.5}$$

is a homeomorphism on $\mathbf{R}^2$. Note also that every solution $(x(t), y(t))$ of the unforced Duffing equation

$$\begin{cases} \dot{x} = y, \\ \dot{y} = -x^{2n+1} - \sum_{i=0}^{n} p_i(t) x^i \end{cases}$$

satisfying the initial value condition $(x(t_0), y(t_0)) = (x_0, y_0)$ is unique and exists for all $t \in \mathbf{R}$. Then using the implicit function theorem and Lemma 2.1, we obtain the following corollary.

Corollary 2.2. *Suppose that condition* $(\mathbf{H})$ *holds and that for each* $0 \le i \le n, p_i(t) \in C^\gamma(\mathbf{T}^1)$ *with* $\gamma > 1 - \frac{1}{n}$. *Then the following statements hold.*

(a) *For any* $\tau \in \mathbf{R}$, $(x_0, y_0) \in \mathbf{R}^2$, *there is a unique solution*

$$(x(t), y(t)) = (x(t; \tau, x_0, y_0), y(t; \tau, x_0, y_0))$$

of (2.4) *satisfying the initial condition* $x(\tau^+) = x_0, y(\tau^+) = y_0$, *which exists for all* $t \in \mathbf{R}$.

(b) *The map* $Q_t : (x_0, y_0) \mapsto (x(t; \tau, x_0, y_0), y(t; \tau, x_0, y_0))$ *is continuous in* (x_0, y_0) *for* $t \in \mathbf{R} \setminus \mathcal{T}$.

(c) *The solution satisfies the elastic property. More precisely, for any* $b_0 > 0$, *there is* $r_{b_0} > 0$ *such that the inequalities* $|x_0| \ge r_{b_0}, |y_0| \ge r_{b_0}$ *implies that* $|x(t; \tau, x_0, y_0)| \ge b_0$ *and* $|y(t; \tau, x_0, y_0)| \ge b_0$ *for* $t \in (\tau, \tau + 1]$.

In order to deduce the time-one map of impulsive Duffing equation (2.4), we denote by $(x(t), y(t)) = (x(t; x_0, y_0), y(t; x_0, y_0))$ the solution of (2.4) satisfying the initial condition $(x(0), y(0)) = (x_0, y_0)$. Let

$$\begin{aligned}
\widetilde{P}_0 &: (x_0, y_0) \mapsto (x(t_1), y(t_1)) := (x_1, y_1), \\
\Phi_1 &: (x_1, y_1) \mapsto (x_1 + I_1(x_1, y_1), y_1 + J_1(x_1, y_1)) = (x(t_1^+), y(t_1^+)) := (x_1^+, y_1^+), \\
\widetilde{P}_1 &: (x_1^+, y_1^+) \mapsto (x(t_2), y(t_2)) := (x_2, y_2), \\
\Phi_2 &: (x_2, y_2) \mapsto (x_2 + I_2(x_2, y_2), y_2 + J_2(x_2, y_2)) = (x(t_2^+), y(t_2^+)) := (x_2^+, y_2^+), \\
&\vdots \\
\widetilde{P}_{k-1} &: (x_{k-1}^+, y_{k-1}^+) \mapsto (x(t_k), y(t_k)) := (x_k, y_k), \\
\Phi_k &: (x_k, y_k) \mapsto (x_k + I_k(x_k, y_k), y_k + J_k(x_k, y_k)) = (x(t_k^+), y(t_k^+) := (x_k^+, y_k^+), \\
\widetilde{P}_k &: (x_k^+, y_k^+) \mapsto (x(1), y(1)).
\end{aligned}$$

Then the time-one map $\widetilde{P} : (x_0, y_0) \mapsto (x(1), y(1))$ of (2.4) can be expressed by

$$\widetilde{P} = \widetilde{P}_k \circ \Phi_k \circ \cdots \circ \widetilde{P}_1 \circ \Phi_1 \circ \widetilde{P}_0.$$

Remark 2.3. Under the condition $(\mathbf{H})$, since the impulsive maps $\Phi_j : (x, y) \mapsto (x, y) + (I_j(x, y), J_j(x, y))$, $(j = 1, 2, \ldots, k)$ are homeomorphisms on $\mathbf{R}^2$, the time-one map $\widetilde{P}$ of (2.4) is also a homeomorphism on $\mathbf{R}^2$.

From Corollary 2.2 and Remark 2.3, we have the following result.

Corollary 2.4. *Suppose that the condition* $(\mathbf{H})$ *holds and that for each* $0 \le i \le n$ *there is* $p_i(t) \in C^\gamma(\mathbf{T}^1)$ *with* $\gamma > 1 - \frac{1}{n}$. *Then the time-one map* $\widetilde{P}$ *of* (2.4) *is a homeomorphism on* $\mathbf{R}^2$. *Moreover, for any* $b_0 > 0$, *there is* $r_{b_0} > 0$ *such that the inequalities* $|x_0| \ge r_{b_0}, |y_0| \ge r_{b_0}$ *implies that* $|x(1; x_0, y_0)| \ge b_0$ *and* $|y(1; x_0, y_0)| \ge b_0$.

3 Action-angle variables

In this section, we introduce the action-angle variables and apply a preliminary symplectic transformation such that (1.3) becomes a nearly integrable Hamiltonian system. The transformations are standard for the Duffing equation and can be found in [6,30,34] for instance. Let

$$x = AX, \tag{3.1}$$

$$Y = A^{-n}\dot{X} = A^{-n-1}\dot{x} = A^{-n-1}y, \tag{3.2}$$

$$\Delta X(t_j) = X(t_j^+) - X(t_j), \quad \Delta Y(t_j) = Y(t_j^+) - Y(t_j). \tag{3.3}$$

Then we see from equation (1.3) that

$$\begin{cases} \dot{X} = \frac{\partial H^*}{\partial Y}, \quad t \neq t_j, \\ \dot{Y} = -\frac{\partial H^*}{\partial X}, \quad t \neq t_j, \\ \Delta X(t_j) = (\gamma_j - 1)X(t_j) := \tilde{I}_j(X(t_j), Y(t_j)), \\ \Delta Y(t_j) = (\gamma_j^{n+1} - 1)Y(t_j) := \tilde{J}_j(X(t_j), Y(t_j)), \end{cases} \tag{3.4}$$

where $j = 1, 2, \ldots, k$ and

$$H^*(X, Y, t) = A^n \left(\frac{1}{2}Y^2 + \frac{1}{2(n+1)}X^{2(n+1)} \right) + \sum_{i=0}^{n} \frac{p_i(t)}{i+1} A^{i-n-1} X^{i+1}. \tag{3.5}$$

The similar formulation of (3.4) can be also found in Section 5 in [30].

Consider the auxiliary Hamiltonian system

$$\dot{X} = \frac{\partial H_0^*}{\partial Y}, \quad \dot{Y} = -\frac{\partial H_0^*}{\partial X}, \tag{3.6}$$

where

$$H_0^*(X, Y) = \frac{1}{2}Y^2 + \frac{1}{2(n+1)}X^{2(n+1)}.$$

Let $(X_0(t), Y_0(t))$ be the solution of (3.6) with initial $(X_0(0), Y_0(0)) = (1, 0)$. Then this solution is clearly periodic. Let T_0 be its minimal positive period. By the energy conservation, we have

(s_1) $(n+1)Y_0^2(t) + X_0^{2n+2}(t) \equiv 1$;

(s_2) $X_0(-t) = X_0(t)$, $Y_0(-t) = -Y_0(t)$;

(s_3) $\dot{X}_0(t) = Y_0(t)$, $\dot{Y}_0(t) = -X_0^{2n+1}(t)$;

(s_4) $X_0(t + T_0) = X_0(t)$, $Y_0(t + T_0) = Y_0(t)$.

We construct the following symplectic transformation

$$\Psi_0 : X = c^\alpha \lambda^\alpha X_0(\theta T_0), \quad Y = c^\beta \lambda^\beta Y_0(\theta T_0), \tag{3.7}$$

where $\alpha = \frac{1}{n+2}$, $\beta = 1 - \alpha = \frac{n+1}{n+2}$, $c = \frac{1}{\alpha T_0}$ and $(\lambda, \theta) \in \mathbf{R}^+ \times \mathbf{T}^1$ is the action-angle variables. By calculation, the Jacobian determinant det $\frac{\partial(X,Y)}{\partial(\theta,\lambda)} = 1$. Then the transformation Ψ_0 is indeed symplectic.

By (3.7), we have

$$\lambda = \frac{1}{c}[X^{2n+2} + (n+1)Y^2]^{\frac{n+2}{2n+2}}. \tag{3.8}$$

We claim that there exists the inverse function $\widetilde{X}_0^{-1}$ such that $\theta = \widetilde{X}_0^{-1}(c^{-\alpha}\lambda^{-\alpha}X)$. Indeed, from (3.7) we have $X_0(\theta T_0) = c^{-\alpha}\lambda^{-\alpha}X$. In the case of $\theta \in [0, \frac{1}{2}]$, by ($s_3$) we get $\frac{dX_0(\theta T_0)}{d\theta} = T_0 Y_0(\theta T_0) < 0$. Thus, we have

$$\theta = T_0^{-1} X_0^{-1}(c^{-\alpha}\lambda^{-\alpha}X).$$

In the case of $\theta \in (\frac{1}{2}, 1)$, by using (3.7), ($s_2$) and ($s_4$), we have

$$X = c^\alpha \lambda^\alpha X_0(\theta T_0) = c^\alpha \lambda^\alpha X_0(-\theta T_0) = c^\alpha \lambda^\alpha X_0((1-\theta)T_0).$$

Let $\xi = 1 - \theta$ and we have $\frac{dX_0(\xi T_0)}{d\xi} = T_0 Y_0(\xi T_0) < 0$ for $\xi \in (0, \frac{1}{2})$. Then we get $\xi = T_0^{-1} X_0^{-1}(c^{-\alpha}\lambda^{-\alpha}X)$ and thus

$$\theta = 1 - T_0^{-1} X_0^{-1}(c^{-\alpha}\lambda^{-\alpha}X).$$

From (3.4), we have that for $j = 1, 2, \ldots, k$

$$\begin{cases} X(t_j^+) = X(t_j) + \tilde{I}_j(X(t_j), Y(t_j)) = \gamma_j X(t_j), \\ Y(t_j^+) = Y(t_j) + \tilde{J}_j(X(t_j), Y(t_j)) = \gamma_j^{n+1} Y(t_j). \end{cases} \tag{3.9}$$

Then using (1.3), (3.7)–(3.9), we have that

$$\begin{aligned} \Delta\lambda(t_j) &= \lambda(t_j^+) - \lambda(t_j) \\ &= \frac{1}{c}[X^{2n+2}(t_j^+) + (n+1)Y^2(t_j^+)]^{\frac{n+2}{2n+2}} - \lambda(t_j) \\ &= \frac{1}{c}\{[X(t_j) + \widetilde{I}_j(X(t_j), Y(t_j))]^{2n+2} + (n+1)[Y(t_j) + \widetilde{J}_j(X(t_j), Y(t_j))]^2\}^{\frac{n+2}{2n+2}} - \lambda(t_j) \\ &= \frac{1}{c}\{[\gamma_j X(t_j)]^{2n+2} + (n+1)[\gamma_j^{n+1} Y(t_j)]^2\}^{\frac{n+2}{2n+2}} - \lambda(t_j) \\ &= \frac{1}{c}\{\gamma_j^{2n+2}[X^{2n+2}(t_j) + (n+1)Y^2(t_j)]\}^{\frac{n+2}{2n+2}} - \lambda(t_j) \\ &= \gamma_j^{n+2}\lambda(t_j) - \lambda(t_j) = (\gamma_j^{n+2} - 1)\lambda(t_j) \\ &=: J_j^*(\lambda(t_j), \theta(t_j)) \end{aligned} \tag{3.10}$$

for $j = 1, 2, \ldots, k$.

By using (3.7), we have that for $j = 1, 2, \ldots, k$ there is

$$X(t_j) = c^{\frac{1}{n+2}} \lambda^{\frac{1}{n+2}}(t_j) X_0(\theta(t_j)T_0), \qquad Y(t_j) = c^{\frac{n+1}{n+2}} \lambda^{\frac{n+1}{n+2}}(t_j) X_0(\theta(t_j)T_0), \tag{3.11}$$

and

$$X(t_j^+) = c^{\frac{1}{n+2}} \lambda^{\frac{1}{n+2}}(t_j^+) X_0(\theta(t_j^+)T_0), \qquad Y(t_j^+) = c^{\frac{n+1}{n+2}} \lambda^{\frac{n+1}{n+2}}(t_j^+) X_0(\theta(t_j^+)T_0). \tag{3.12}$$

Then using (3.10) and (3.12) we have that for $j = 1, 2, \ldots, k$,

$$\begin{aligned} X(t_j^+) &= c^{\frac{1}{n+2}}[\lambda(t_j) + J_j^*(\lambda(t_j), \theta(t_j))]^{\frac{1}{n+2}} X_0(\theta(t_j^+)T_0) \\ &= c^{\frac{1}{n+2}}[\lambda(t_j) + (\gamma_j^{n+2} - 1)(\lambda(t_j)]^{\frac{1}{n+2}} X_0(\theta(t_j^+)T_0) \\ &= \gamma_j c^{\frac{1}{n+2}} \lambda^{\frac{1}{n+2}}(t_j) X_0(\theta(t_j^+)T_0). \end{aligned} \tag{3.13}$$

Combining $\gamma_j > 0$, (3.9), (3.12) and (3.13), we have that for $j = 1, 2, \ldots, k$,

$$X(t_j) = c^{\frac{1}{n+2}} \lambda^{\frac{1}{n+2}}(t_j) X_0(\theta(t_j^+)T_0). \tag{3.14}$$

Similarly, by (1.3), (3.9), (3.10) and (3.12), we have that for $j = 1, 2, \dots, k$,

$$Y(t_j^+) = \gamma_j^{n+1} c^{\frac{n+1}{n+2}} \lambda^{\frac{n+1}{n+2}}(t_j) Y_0(\theta(t_j^+)T_0) = \gamma_j^{n+1} Y(t_j),$$

and thus

$$Y(t_j) = c^{\frac{n+1}{n+2}} \lambda^{\frac{n+1}{n+2}}(t_j) Y_0(\theta(t_j^+)T_0). \tag{3.15}$$

By (3.11), (3.14) and (3.15), we have $\theta(t_j^+) = \theta(t_j)$. Then, for $j = 1, 2, \dots, k$,

$$\Delta\theta(t_j) = \theta(t_j^+) - \theta(t_j) = 0 := I_j^*(\lambda(t_j), \theta(t_j)). \tag{3.16}$$

As a result, under the transformation Ψ_0, system (3.4) is changed into

$$\begin{cases} \dot{\theta} = \frac{\partial H}{\partial \lambda}, & t \neq t_j, \\ \dot{\lambda} = -\frac{\partial H}{\partial \theta}, & t \neq t_j, \\ \Delta\theta(t_j) = I_j^*(\lambda(t_j), \theta(t_j)), \\ \Delta\lambda(t_j) = J_j^*(\lambda(t_j), \theta(t_j)), & j = 1, 2, \dots, k, \end{cases} \tag{3.17}$$

where $I_j^*(\lambda(t_j), \theta(t_j)) = 0$, $J_j^*(\lambda(t_j), \theta(t_j)) = (\gamma_j^{n+2} - 1)\lambda(t_j)$ and $H(\lambda, \theta, t) = H_0(\lambda) + R(\lambda, \theta, t)$ with

$$H_0(\lambda) = d \cdot A^n \cdot \lambda^{\frac{2(n+1)}{n+2}}, \qquad d = \frac{1}{2(n+1)} c^{\frac{2(n+1)}{n+2}}$$

and

$$R(\lambda, \theta, t) = \sum_{i=0}^{n} \frac{p_i(t)}{i+1} A^{i-n-1} (c^\alpha X_0(\theta T_0))^{i+1} \lambda^{\alpha(i+1)}.$$

4 Approximation lemma

In this section, we make use of the Jackson–Moser–Zehnder approximate lemma (see [28,29,34] for the detail) to approximate the smooth periodic function R by a real analytic periodic function R_ε. Some estimates of R_ε and the remainder $R^\varepsilon = R - R_\varepsilon$ are also given for the later application.

Let $\mathbf{T}^1_\varepsilon = \{t \in \mathbf{C}/\mathbf{Z} : |\mathrm{Im}\, t| < \varepsilon\}$ for any $\varepsilon > 0$. By the Jackson–Moser–Zehnder lemma (see Lemma 6.1 in [30]), for each $p_i \in C^\gamma(\mathbf{T^1})$, $i = 0, 1, \dots, n$, and any $\varepsilon > 0$, there is a real analytic function (a complex value function $f(t)$ of complex variable t in some domain in $\mathbf{C}$ is called real analytic if it is analytic in the domain and is real for real argument t) $p_{i,\varepsilon}(t)$ from $\mathbf{T}^1_\varepsilon$ to $\mathbf{C}$ such that

$$\sup_{t \in \mathbf{T^1}} |p_{i,\varepsilon}(t) - p_i(t)| \leq C\varepsilon^\gamma \|p_i\|_{C^\gamma}$$

and

$$\sup_{t \in \mathbf{T}^1_\varepsilon} |p_{i,\varepsilon}(t)| \leq C\|p_i\|_{C^\gamma}.$$

Write

$$R(\lambda, \theta, t) = R_\varepsilon(\lambda, \theta, t) + R^\varepsilon(\lambda, \theta, t),$$

where

$$R_\varepsilon(\lambda, \theta, t) = \sum_{i=0}^{n} \frac{1}{i+1} A^{i-n-1} c^{\frac{i+1}{n+2}} X_0^{i+1}(\theta T_0) \lambda^{\frac{i+1}{n+2}} p_{i,\varepsilon}(t),$$

$$R^{\varepsilon}(\lambda,\theta,t)=\sum_{i=0}^{n}\frac{1}{i+1}A^{i-n-1}c^{\frac{i+1}{n+2}}X_0^{i+1}(\theta T_0)\lambda^{\frac{i+1}{n+2}}(p_i(t)-p_{i,\varepsilon}(t)).$$

Then, we have

$$H=H_0(\lambda)+R_{\varepsilon}(\lambda,\theta,t)+R^{\varepsilon}(\lambda,\theta,t), \tag{4.1}$$

where

$$H_0(\lambda)=d\cdot A^n\cdot\lambda^{\frac{2(n+1)}{n+2}},\qquad d=\frac{1}{2(n+1)}c^{\frac{2(n+1)}{n+2}}. \tag{4.2}$$

We introduce two definitions.

Definition 4.1. Given constants p and q, for a complex valued function $f=f(\lambda,\theta,t,A)$: $(\lambda,\theta,t)\in[1,+\infty)\times\mathbf{T^1}\times\mathbf{T}^1_{\varepsilon}\to\mathbf{C}$, where $A\gg1$ is a large constant, we say that

$$f=O_{\varepsilon}(A^p\lambda^q),$$

if f is C^{∞} in $(\lambda,\theta)\in[1,+\infty)\times\mathbf{T^1}$ and is analytic in $t\in\mathbf{T}^1_{\varepsilon}$ and for all nonnegative integers k and l, there is

$$\sup_{(\theta,t)\in\mathbf{T^1}\times\mathbf{T}^1_{\varepsilon}}|(D_{\lambda})^k(D_{\theta})^l f(\lambda,\theta,t,A)|<C_{k,l}A^p\lambda^{q-k},\quad\lambda\gg1,$$

where $C_{k,l}$ is a constant depending on k and l.

Definition 4.2. Given constants p and q, for a function $f=f(\lambda,\theta,t,A)$: $(\lambda,\theta,t)\in[1,+\infty)\times\mathbf{T^1}\times\mathbf{T^1}\to\mathbf{R}$, where $A\gg1$ is a large constant, we say that

$$f=O(A^p\lambda^q),$$

if f is C^{∞} in $(\lambda,\theta)\in[1,+\infty)\times\mathbf{T^1}$ and C^1 in $t\in\mathbf{T^1}$ and for all nonnegative integers k and l, there is

$$\sup_{(\theta,t)\in\mathbf{T^1}\times\mathbf{T^1}}|(D_{\lambda})^k(D_{\theta})^l f(\lambda,\theta,t,A)|<C_{k,l}A^p\lambda^{q-k},\quad\lambda\gg1,$$

where $C_{k,l}$ is a constant depending on k and l.

Lemma 4.3.

(i) *If* $f_1=O(A^{p_1}\lambda^{q_1}), f_2=O(A^{p_2}\lambda^{q_2})$, *then* $f_1\cdot f_2=O(A^{p_1+p_2}\lambda^{q_1+q_2})$;

(ii) *If* $f=O(A^p\lambda^{q_1}), g(\lambda)=O(\lambda^{q_2})$ *satisfy* $|g(\lambda)|\ge c\lambda^{q_2}$ *for* $\lambda\ge\lambda_0$, *and* $c>0, q_2>0$, *then* $f^*(\lambda,\theta,t):=f(g(\lambda),\theta,t)=O(A^p\lambda^{q_1q_2})$;

(iii) *If* $f=O(A^p\lambda^q), u=O(A^p\lambda^{q_1}), v=O(A^p\lambda^{q_2})$ *and* $q_1<1, q_2<0$, *then* $f^{**}(\lambda,\theta,t):=f(\lambda+u,\theta+v,t)=O(A^p\lambda^q)$.

Proof. (i). Since

$$(D^k_{\lambda}D^l_{\theta})(f_1\cdot f_2)=\sum_{i=0}^{k}\sum_{j=0}^{l}C^i_kC^j_l(D^{k-i}_{\lambda}D^{l-j}_{\theta}f_1)\cdot(D^i_{\lambda}D^j_{\theta}f_2),$$

by Definition 4.2, it follows that

$$f_1\cdot f_2=O(A^{p_1+p_2}\lambda^{q_1+q_2}).$$

(ii). Note that $(D_\lambda^k D_\theta^l) f(g(\lambda),\theta,t)$ is a sum of the terms

$$(D_\theta^l D_g^p f(g(\lambda),\theta,t)) \cdot (D_\lambda^{m_1} g) \cdot (D_\lambda^{m_2} g) \cdots (D_\lambda^{m_p} g)$$

with $\sum_{i=1}^p m_i = k$. Direct computation leads to the estimate

$$\sup_{(\theta,t)\in\mathbf{T}^1\times\mathbf{T}^1} |(D_\lambda^k)(D_\theta^l) f(g(\lambda),\theta,t))| \le C_{k,l} A^p \lambda^{q_1 q_2 - k},$$

and consequently

$$f^*(\lambda,\theta,t)) = f(g(\lambda),\theta,t)) = O(A^p \lambda^{q_1 q_2}).$$

(iii). We observe that $(D_\lambda^k)(D_\theta^l) f(\lambda+u,\theta+v,t)$ is a sum of the terms

$$D_\theta^l [(D_\phi^q D_\mu^p f(\mu,\phi))(D_\lambda^{m_1}\mu)(D_\lambda^{m_2}\mu)\cdots(D_\lambda^{m_p}\mu)(D_\lambda^{n_1}\phi)(D_\lambda^{n_2}\phi)\cdots(D_\lambda^{n_q}\phi)],$$

where $\mu = \lambda + u,\ \phi = \theta + v,\ 0 \le p+q \le k,\ \sum_{i=1}^p m_i + \sum_{i=1}^q n_i = k$, and

$$\begin{aligned} &D_\theta^l [(D_\phi^q D_\mu^p f(\mu,\phi))(D_\lambda^{m_1}\mu)(D_\lambda^{m_2}\mu)\cdots(D_\lambda^{m_p}\mu)(D_\lambda^{n_1}\phi)(D_\lambda^{n_2}\phi)\cdots(D_\lambda^{n_q}\phi)] \\ &\quad = \sum_{i=1}^{l} C_l^i (D_\theta^i D_\phi^q D_\mu^p f(\mu,\phi)) \cdot D_\theta^{l-i}[D_\lambda^{m_1}\mu)\cdots(D_\lambda^{m_p}\mu)(D_\lambda^{n_1}\phi)\cdots(D_\lambda^{n_q}\phi)], \end{aligned}$$

where $D_\theta^i D_\phi^q D_\mu^p f(\mu,\phi)$ is a sum of the terms

$$(D_\phi^{q+\tilde{q}} D_\mu^{p+\tilde{p}} f(\mu,\phi))(D_\theta^{\tilde{m}_1}\mu)(D_\theta^{\tilde{m}_2}\mu)\cdots(D_\theta^{\tilde{m}_p}\mu)(D_\theta^{\tilde{n}_1}\phi)(D_\theta^{\tilde{n}_2}\phi)\cdots(D_\theta^{\tilde{n}_q}\phi),$$

with $0 \le \tilde{p} + \tilde{q} \le i,\ \sum_{j=1}^{\tilde{p}} \tilde{m}_j + \sum_{j=1}^{\tilde{q}} \tilde{n}_j = i$. Noting that $u = O(A^p \lambda^{q_1})$, $v = O(A^p \lambda^{q_2})$, $q_1 < 1, q_2 < 0$, we have

$$\sup_{(\theta,t)\in\mathbf{T}^1\times\mathbf{T}^1} |(D_\lambda^k)(D_\theta^l) f(\lambda+u,\theta+v,t)| \le C_{k,l} A^p \lambda^{q-k}.$$

As a result, we obtain

$$f^{**}(\lambda,\theta,t) = f(\lambda+u,\theta+v,t) = O(A^p \lambda^q).$$ □

Let $\varepsilon = A^{-\nu}$, where $\nu > 0$ will be specified later. By Definition 4.1 and Definition 4.2, we have

$$R_\varepsilon(\lambda,\theta,t) = O_\varepsilon\big(A^{-1}\lambda^{\frac{n+1}{n+2}}\big), \tag{4.3}$$

$$R^\varepsilon(\lambda,\theta,t) = O\big(A^{-1-\nu\gamma}\lambda^{\frac{n+1}{n+2}}\big). \tag{4.4}$$

In the following, we will omit the constant d in $H_0(\lambda)$ (see (4.2)) without loss of generality.

5 Some transformations

Firstly, we look for a series of symplectic transformations $\Psi_1,\dots,\Psi_N$ such that $H^N := H \circ \Psi_1 \circ \cdots \circ \Psi_N = H_0^N + O(\varepsilon_0)$, $\varepsilon_0 = A^{-\delta}$, $\delta > 0$. The following lemma is similar to Lemma 7.1 in [30] and we refer to [30] for the proof.

Lemma 5.1. *Let $H(\lambda,\theta,t)$ be the same as (4.1). For $A \gg 1$, $\lambda \gg 1$, then there is a symplectic diffeomorphism Ψ_1 depending periodically on t of the form*

$$\Psi_1 : \begin{cases} \lambda = \tilde{\mu} + u_1(\tilde{\mu},\tilde{\phi},t), \\ \theta = \tilde{\phi} + v_1(\tilde{\mu},\tilde{\phi},t), \end{cases}$$

with $u_1 = O_\varepsilon\big(A^{-1-n}\tilde{\mu}^{\frac{1}{n+2}}\big)$ and $v_1 = O_\varepsilon\big(A^{-1-n}\tilde{\mu}^{-\frac{n+1}{n+2}}\big)$. Moreover the transformed Hamiltonian vector field $\Psi_1(X_H) = X_{H^1}$ is of the form

$$H^1(\tilde{\mu},\tilde{\phi},t) = H_0^1(\tilde{\mu},t) + \widetilde{R}_\varepsilon^1(\tilde{\mu},\tilde{\phi},t) + R^\varepsilon \circ \Psi_1(\tilde{\mu},\tilde{\phi},t),$$

where

$$H_0^1(\tilde{\mu},t) = H_0(\tilde{\mu}) + [R_\varepsilon](\tilde{\mu},t), \quad H_0 = dA^n \cdot \tilde{\mu}^{\frac{2(n+1)}{n+2}},$$

$$[R_\varepsilon] = O_\varepsilon\Big(A^{-1}\tilde{\mu}^{\frac{n+1}{n+2}}\Big), \quad \tilde{R}_\varepsilon^1(\tilde{\mu},\tilde{\phi},t) = O_{\frac{\varepsilon}{2}}\left(A^{-2-n}\right) + O_{\frac{\varepsilon}{2}}\Big(A^{u-1-n}\tilde{\mu}^{\frac{1}{n+2}}\Big),$$

$$R^\varepsilon \circ \Psi_1(\tilde{\mu},\tilde{\phi},t) = O\left(A^{-1-v\gamma}\tilde{\mu}^{\frac{n+1}{n+2}}\right).$$

Let

$$\tau > 0, \quad \nu < n(1+\tau), \tag{5.1}$$

and

$$\lambda \in \left[c_1 A^{(n+2)\tau}, c_2 A^{(n+2)\tau}\right], \quad c_2 > c_1 > 0.$$

Repeating the symplectic diffeomorphism in Lemma 5.1 for N times, we get N symplectic transformations $\Psi_1,\dots,\Psi_N$ such that

$$H^N(\mu,\phi,t) = H \circ \Psi_1 \circ \cdots \circ \Psi_N = H_0^N(\mu,t) + R_\varepsilon^N(\mu,\phi,t),$$

where

$$\mu \in \left[c_1 A^{(n+2)\tau}, c_2 A^{(n+2)\tau}\right], \quad c_2 > c_1 > 0,$$

$$H_0^N(\mu,t) = H_0(\mu) + H_1(\mu,t),$$

$$H_0 = d \cdot A^n \cdot \mu^{\frac{2(n+1)}{n+2}}, \quad H_1 = O_{\frac{\varepsilon}{2^N}}\left(A^{-1}\mu^{\frac{n+1}{n+2}}\right),$$

$$R_\varepsilon^N = O_{\frac{\varepsilon}{2^N}}\left(A^{-1-N(1+n)}\mu^{\frac{n+1-N(n+1)}{n+2}}\right) + O_{\frac{\varepsilon}{2^N}}\left(A^{-1+N(v-n)}\mu^{\frac{n+1-Nn}{n+2}}\right) + O\Big(A^{-1-\nu\gamma}\mu^{\frac{n+1}{n+2}}\Big).$$

Now the corresponding unforced equation in (3.17) can be changed into

$$\begin{cases} \dot{\phi} = \frac{\partial H^N}{\partial \mu} = \frac{\partial H_0(\mu)}{\partial \mu} + \frac{\partial H_1(\mu,t)}{\partial \mu} + \frac{\partial R_\varepsilon^N(\mu,\phi,t)}{\partial \mu}, \\ \dot{\mu} = -\frac{\partial H^N}{\partial \phi} = -\frac{\partial R_\varepsilon^N(\mu,\phi,t)}{\partial \phi}, \end{cases} \tag{5.2}$$

where

$$\frac{\partial H_0(\mu)}{\partial \mu} = d \cdot \frac{2n+2}{n+2} A^n \mu^{\frac{n}{n+2}}$$

and we omit the constant $d \cdot \frac{2n+2}{n+2}$ for simplicity in the following arguments. Define the diffeomorphism

$$\Psi: \quad \rho = \frac{\partial \mu^{\frac{2n+2}{n+2}}}{\partial \mu} = \frac{2n+2}{n+2}\mu^{\frac{n}{n+2}}, \qquad \phi = \phi, \tag{5.3}$$

and we get

$$\dot{\rho} = \frac{n(2n+2)}{(n+2)^2} \mu^{\frac{-2}{n+2}} \dot{\mu}.$$

Then we have

$$\dot{\rho} = O\left(A^{-1-N(n+1)} \mu^{\frac{n-1-N(n+1)}{n+2}}\right) + O\left(A^{-1+N(\nu-n)} \mu^{\frac{n-1-Nn}{n+2}}\right) + O\left(A^{-1-\nu\gamma} \mu^{\frac{n-1}{n+2}}\right),$$

$$\dot{\phi} = \rho + r(\rho,t) + O\left(A^{-1-N(n+1)} \mu^{\frac{-1-N(n+1)}{n+2}}\right) + O\left(A^{-1-N(\nu-n)} \mu^{\frac{-1-Nn}{n+2}}\right) + O\left(A^{-1-\nu\gamma} \mu^{\frac{-1}{n+2}}\right),$$

where $r(\rho,t) = \frac{\partial H_1(\mu,t)}{\partial \mu}$ with $\mu = \left(\frac{n+2}{2n+2}\rho\right)^{\frac{n+2}{n}}$. Thus

$$r(\rho,t) = O\left(A^{-1} \mu^{\frac{-1}{n+2}}\right) = O\left(A^{-1}\left(\frac{n+2}{2n+2}\rho\right)^{-\frac{1}{n}}\right) = O\left(A^{-1}\rho^{-\frac{1}{n}}\right).$$

Noting that $\mu \in [c_1 A^{(n+2)\tau}, c_2 A^{(n+2)\tau}]$, we have

$$\rho \in \left[c_1 \frac{2n+2}{n+2} A^{n\tau}, c_2 \frac{2n+2}{n+2} A^{n\tau}\right]. \tag{5.4}$$

It follows that

$$\dot{\rho} = O\left(A^{-1-N(n+1)+[n-1-N(n+1)]\tau}\right) + O\left(A^{-1+N(\nu-n)+(n-1-Nn)\tau}\right) + O\left(A^{-1-\nu\gamma+(n-1)\tau}\right),$$

$$\dot{\phi} = \rho + r(\rho,t) + O\left(A^{[-1-N(n+1)](1+\tau)}\right) + O\left(A^{-1+N(\nu-n)+(-1-Nn)\tau}\right) + O\left(A^{-1-\nu\gamma-\tau}\right).$$

When $N \gg 1$ and $\nu < n(1+\tau)$, we have

$$-1 + N(\nu-n) + (n-1-Nn)\tau = N[\nu - n(1+\tau)] + (n-1)\tau - 1 < 0,$$
$$-1 + N(\nu-n) + (-1-Nn)\tau = N[\nu - n((1+\tau)] - (1+\tau) < 0.$$

When $N \gg 1$ and $\tau > 0$, we have

$$-1 - N(n+1) + [n-1-N(n+1)]\tau < 0, \quad [-1-N(n+1)](1+\tau) < 0.$$

Note that $-1-\nu\gamma-\tau < -1-\nu\gamma+(n-1)\tau < n-1-\nu\gamma+(n-1)\tau$. Let

$$n - 1 - \nu\gamma + (n-1)\tau < 0, \tag{5.5}$$

Then, by (5.1) and (5.5), we have

$$\frac{(n-1)(1+\tau)}{\gamma} < \nu < n(1+\tau). \tag{5.6}$$

Since $\gamma > 1 - \frac{1}{n}$, we have $(n-1)/\gamma < n$. Then, when $\tau > 0$ and $\nu \in \left(\frac{(n-1)(1+\tau)}{\gamma}, n(1+\tau)\right)$, there is $\delta > 0$ and (5.2) can be changed into

$$\begin{cases} \dot{\phi} = \rho + r(\rho,t) + f(\rho,\phi,t) = \rho + r(\rho,t) + O(A^{-\delta}), \\ \dot{\rho} = g(\rho,\phi,t) = O(A^{-\delta}), \end{cases} \tag{5.7}$$

where $\phi \in \mathbf{T^1}, r(\rho,t) = O(A^{-1}\rho^{-\frac{1}{n}})$ and $\rho \in [c_3 A^{n\tau}, c_4 A^{n\tau}]$ for $c_4 > c_3 > 0$ given by (5.4).

Next we compute the transformed impulsive forces in (3.17). Based on the symplectic transformation Ψ_1 in Lemma 5.1, we see from the implicit function theorem that

$$\tilde{\mu} = \lambda + u(\lambda,\theta,t), \qquad \tilde{\phi} = \theta + v(\lambda,\theta,t).$$

Under the symplectic transformation Ψ_1, we see that the jumps $\Delta\theta(t_j)$ and $\Delta\lambda(t_j)$ in (3.17) can be changed into

$$\begin{cases} \Delta\tilde{\phi}(t_j) := \tilde{\phi}(t_j^+) - \tilde{\phi}(t_j) = \tilde{I}_j^*(\tilde{\mu}(t_j),\tilde{\phi}(t_j)), \\ \Delta\tilde{\mu}(t_j) := \tilde{\mu}(t_j^+) - \tilde{\mu}(t_j) = \tilde{J}_j^*(\tilde{\mu}(t_j),\tilde{\phi}(t_j)), \end{cases} \tag{5.8}$$

where $j = 1,2,\ldots,k$.

In the same way, under the symplectic transformation Ψ_2, the jumps $\Delta\tilde{\phi}(t_j)$ and $\Delta\tilde{\mu}(t_j)$ can be changed into new forms

$$\begin{cases} \Delta\bar{\phi}(t_j) := \bar{\phi}(t_j^+) - \bar{\phi}(t_j) = \bar{I}_j^*(\bar{\mu}(t_j),\bar{\phi}(t_j)), \\ \Delta\bar{\mu}(t_j) := \bar{\mu}(t_j^+) - \bar{\mu}(t_j) = \bar{J}_j^*(\bar{\mu}(t_j),\bar{\phi}(t_j)), \end{cases} \tag{5.9}$$

where $j = 1,2,\ldots,k$. Repeating this procedure by the symplectic transformations $\Psi_1,\ldots,\Psi_N$, the jumps in (3.17) are finally changed into

$$\begin{cases} \Delta\phi(t_j) := \phi(t_j^+) - \phi(t_j) = I_j^{**}(\mu(t_j),\phi(t_j)), \\ \Delta\mu(t_j) := \mu(t_j^+) - \mu(t_j) = J_j^{**}(\mu(t_j),\phi(t_j)), \end{cases} \tag{5.10}$$

where $j = 1,2,\ldots,k$. Combining (5.2) and (5.10), we see that (3.17) can be transformed into

$$\begin{cases} \dot{\phi} = \frac{\partial H_0(\mu)}{\partial \mu} + \frac{\partial H_1(\mu,t)}{\partial \mu} + \frac{\partial R_\varepsilon^N(\mu,\phi,t)}{\partial \mu}, \\ \dot{\mu} = -\frac{\partial R_\varepsilon^N(\mu,\phi,t)}{\partial \phi}, \quad t \neq t_j; \\ \Delta\phi(t_j) = I_j^{**}(\mu(t_j),\phi(t_j)), \\ \Delta\mu(t_j) = J_j^{**}(\mu(t_j),\phi(t_j)), \quad j = 1,2,\ldots,k. \end{cases} \tag{5.11}$$

Similarly, under Ψ defined by (5.3), system (5.11) can be transformed into

$$\begin{cases} \dot{\phi} = \rho + r(\rho,t) + f(\rho,\phi,t) = \rho + r(\rho,t) + O(A^{-\delta}), \\ \dot{\rho} = g(\rho,\phi,t) = O(A^{-\delta}), \quad t \neq t_j; \\ \Delta\phi(t_j) = I_j^{**1}(\rho(t_j),\phi(t_j)), \\ \Delta\rho(t_j) = J_j^{**1}(\rho(t_j),\phi(t_j)), \quad j = 1,2,\ldots,k, \end{cases} \tag{5.12}$$

where $\phi \in \mathbf{T^1}, r(\rho,t) = O(A^{-1}\rho^{-\frac{1}{n}})$ and $\rho \in [c_3 A^{n\tau}, c_4 A^{n\tau}]$.

It should be pointed out that, although we have not been able to formulate explicitly $I_j^{**1}(\rho(t_j),\phi(t_j))$ and $J_j^{**1}(\rho(t_j),\phi(t_j))$, we can implicitly express them. We will calculate the estimates of the impulsive functions $I_j^{**1}(\rho(t_j),\phi(t_j))$ and $J_j^{**1}(\rho(t_j),\phi(t_j))$ in next section.

6 Some estimates

In this section, we will establish some estimates for impulsive functions $I_j^{**1}(\rho,\phi)$ and $J_j^{**1}(\rho,\phi)$. To this end, we first give the estimates of $I_j^{**}(\mu,\phi)$ and $J_j^{**}(\mu,\phi)$. In this whole section and in the sequel, all the occurrences of j mean $j = 1,2,\ldots,k$.

Lemma 6.1. *Assume that the conditions in Theorem 1.1 are satisfied. Let $\mu(t_j)=\mu, \phi(t_j)=\phi$. We have the following estimates*

$$I_j^{**}(\mu,\phi)=O(A^{-1-n}\mu^{-\frac{n+1}{n+2}}),$$
$$J_j^{**}(\mu,\phi)=(\gamma_j^{n+2}-1)\mu+f_j(\mu,\phi)$$

with $f_j(\mu,\phi)=O(A^{-1-n}\mu^{\frac{1}{n+2}})$, where $I_j^{**}(\mu,\phi)$ and $J_j^{**}(\mu,\phi)$ are given by (5.10).

Proof. For $(\lambda,\theta)\in[c_1A^{(n+2)\tau},c_2A^{(n+2)\tau}]\times\mathbf{T^1}$, from Lemma 5.1, the symplectic diffeomorphism Ψ_1 is of the form

$$\Psi_1:\lambda=\tilde{\mu}+u_1(\tilde{\mu},\tilde{\phi},t),\qquad \theta=\tilde{\phi}+v_1(\tilde{\mu},\tilde{\phi},t),\tag{6.1}$$

where $(\tilde{\mu},\tilde{\phi})\in[c_1A^{(n+2)\tau},c_2A^{(n+2)\tau}]\times\mathbf{T^1}, u_1=O(A^{-1-n}\tilde{\mu}^{\frac{1}{n+2}}), v_1=O(A^{-1-n}\tilde{\mu}^{-\frac{n+1}{n+2}})$. By the implicit function theorem, we have

$$\tilde{\mu}=\lambda+u(\lambda,\theta,t),\qquad \tilde{\phi}=\theta+v(\lambda,\theta,t),\tag{6.2}$$

where $|u|<CA^{-1-n}\lambda^{\frac{1}{n+2}}$ and $|v|<CA^{-1-n}\lambda^{-\frac{n+1}{n+2}}$.

Next we show that

$$u=O\left(A^{-1-n}\lambda^{\frac{1}{n+2}}\right),\qquad v=O\left(A^{-1-n}\lambda^{-\frac{n+1}{n+2}}\right).\tag{6.3}$$

Indeed, we see from Lemma 5.1 that

$$\begin{cases}\lambda=\tilde{\mu}+\frac{\partial S_1}{\partial\theta}=\tilde{\mu}+\nu(\tilde{\mu},\theta,t),\\ \tilde{\phi}=\theta+\frac{\partial S_1}{\partial\tilde{\mu}}=\theta+g(\tilde{\mu},\theta,t),\end{cases}\tag{6.4}$$

where

$$\nu(\tilde{\mu},\theta,t)=O\left(A^{-1-n}\tilde{\mu}^{\frac{1}{n+2}}\right),\qquad g(\tilde{\mu},\theta,t)=O\left(A^{-1-n}\tilde{\mu}^{-\frac{n+1}{n+2}}\right).$$

From (6.2) and (6.4) we know

$$u=-\nu(\lambda+u,\theta,t).\tag{6.5}$$

If $\tilde{\mu}$ and λ are large, then $|D_{\tilde{\mu}}\nu|\le 1/2$, so that u is uniquely determined by the contraction principle. Moreover, the implicit function theorem implies that u is C^∞ with respect to $(\lambda,\theta)\in[c_1A^{(n+2)\tau},c_2A^{(n+2)\tau}]\times\mathbf{T^1}$. We claim that

$$u=O\left(A^{-1-n}\lambda^{\frac{1}{n+2}}\right).\tag{6.6}$$

Indeed, applying $(D_\lambda)^l$ to equation (6.5), the right hand side is a sum of the terms

$$(D_{\tilde{\mu}}^p)(D_\lambda^{j_1}(\lambda+u))(D_\lambda^{j_2}(\lambda+u))\cdots(D_\lambda^{j_p}(\lambda+u)),\tag{6.7}$$

with $1\le p\le l$ and $\sum_{i=1}^p j_i=l$. The highest order term is the one with $p=1$, namely $(D_{\tilde{\mu}}\nu)D_\lambda^n u$. Note that $|u|<CA^{-1-n}\lambda^{\frac{1}{n+2}}$. Assuming that for $j\le n-1$ the estimates $|D_\lambda^j u|<CA^{-1-n}\lambda^{\frac{1}{n+2}-j}$ hold true, then inductively, from (6.4) and (6.5) we can conclude that the same estimate holds true for $j=n$. In fact, from (6.4) we have

$$|D_{\tilde{\mu}}^p\nu|<CA^{-1-n}\lambda^{\frac{1}{n+2}-p},$$

which yields

$$|(1-D_{\tilde{\mu}}\nu)D_{\lambda}^{l}u| \leq CA^{-1-n}\lambda^{\frac{1}{n+2}-p}\lambda^{1-j_1}\cdots\lambda^{1-j_p} < CA^{-1-n}\lambda^{\frac{1}{n+2}-l}.$$

It follows that

$$|D_{\lambda}^{l}u| < CA^{-1-n}\lambda^{\frac{1}{n+2}-l}.$$

The estimates of $(D_\theta)^j(D_\lambda)^i u$ can be proved similarly. Thus, the claim (6.6) is valid. Similarly, one also has

$$v = O\left(A^{-1-n}\lambda^{-\frac{n+1}{n+2}}\right).$$

Under the symplectic transformation Ψ_1, the jumps $\Delta\theta(t_j)$ and $\Delta\lambda(t_j)$ in (3.17) can be changed into $\tilde{I}_j^*(\tilde{\mu}(t_j),\tilde{\phi}(t_j))$ and $\tilde{J}_j^*(\tilde{\mu}(t_j),\tilde{\phi}(t_j))$ (see (5.8)). Then using (3.17), (5.8), (6.1) and (6.2), we have

$$\begin{aligned}
\tilde{I}_j^*(\tilde{\mu}(t_j),\tilde{\phi}(t_j)) &= \tilde{\phi}(t_j^+) - \tilde{\phi}(t_j)\\
&= \theta(t_j^+) + v(\lambda(t_j^+),\theta(t_j^+),t_j) - \theta(t_j) - v(\lambda(t_j),\theta(t_j),t_j)\\
&= I_j^*(\lambda(t_j),\theta(t_j)) + v(\lambda(t_j) + J_j^*(\lambda(t_j),\theta(t_j)),\theta(t_j)\\
&\quad + I_j^*(\lambda(t_j),\theta(t_j)),t_j) - v(\lambda(t_j),\theta(t_j),t_j)\\
&= v[\gamma_j^{n+2}(\tilde{\mu}(t_j) + u_1(\tilde{\mu}(t_j),\tilde{\phi}(t_j),t_j)),\tilde{\phi}(t_j) + v_1(\tilde{\mu}(t_j),\tilde{\phi}(t_j),t_j),t_j]\\
&\quad - v[\tilde{\mu}(t_j) + u_1(\tilde{\mu}(t_j),\tilde{\phi}(t_j),t_j),\tilde{\phi}(t_j) + v_1(\tilde{\mu}(t_j),\tilde{\phi}(t_j),t_j),t_j],\\
\tilde{J}_j^*(\tilde{\mu}(t_j),\tilde{\phi}(t_j)) &= \tilde{\mu}(t_j^+) - \tilde{\mu}(t_j)\\
&= \lambda(t_j^+) + u(\lambda(t_j^+),\theta(t_j^+),t_j) - \lambda(t_j) - u(\lambda(t_j),\theta(t_j),t_j)\\
&= J_j^*(\lambda(t_j),\theta(t_j)) + u(\lambda(t_j) + J_j^*(\lambda(t_j),\theta(t_j)),\theta(t_j)\\
&\quad + I_j^*(\lambda(t_j),\theta(t_j)),t_j) - u(\lambda(t_j),\theta(t_j),t_j)\\
&= (\gamma_j^{n+2}-1)\lambda(t_j) + u(\gamma_j^{n+2}\lambda(t_j),\theta(t_j),t_j) - u(\lambda(t_j),\theta(t_j),t_j)\\
&= (\gamma_j^{n+2}-1)\tilde{\mu}(t_j) + (\gamma_j^{n+2}-1)u_1(\tilde{\mu}(t_j),\tilde{\phi}(t_j),t_j)\\
&\quad + u(\gamma_j^{n+2}(\tilde{\mu}(t_j) + u_1(\tilde{\mu}(t_j),\tilde{\phi}(t_j),t_j)),\tilde{\phi}(t_j) + v_1(\tilde{\mu}(t_j),\tilde{\phi}(t_j),t_j),t_j)\\
&\quad - u(\tilde{\mu}(t_j) + u_1(\tilde{\mu}(t_j),\tilde{\phi}(t_j),t_j),\tilde{\phi}(t_j) + v_1(\tilde{\mu}(t_j),\tilde{\phi}(t_j),t_j),t_j)\\
&=: (\gamma_j^{n+2}-1)\tilde{\mu}(t_j) + \tilde{f}_j(\tilde{\mu}(t_j),\tilde{\phi}(t_j)).
\end{aligned}$$

It follows from

$$\begin{aligned}
u_1 &= O\left(A^{-1-n}\tilde{\mu}^{\frac{1}{n+2}}\right), \qquad v_1 = O\left(A^{-1-n}\tilde{\mu}^{-\frac{n+1}{n+2}}\right),\\
u &= O\left(A^{-1-n}\tilde{\mu}^{\frac{1}{n+2}}\right), \qquad v = O\left(A^{-1-n}\tilde{\mu}^{-\frac{n+1}{n+2}}\right)
\end{aligned}$$

and Lemma 4.3 that

$$\tilde{I}_j^*(\tilde{\mu}(t_j),\tilde{\phi}(t_j)) = O\left(A^{-1-n}\tilde{\mu}^{-\frac{n+1}{n+2}}\right), \qquad \tilde{f}_j(\tilde{\mu}(t_j),\tilde{\phi}(t_j)) = O\left(A^{-1-n}\tilde{\mu}^{\frac{1}{n+2}}\right). \tag{6.8}$$

Similarly, under the symplectic transformation Ψ_2, the jumps $\tilde{I}_j^*(\tilde{\mu}(t_j),\tilde{\phi}(t_j))$ and $\tilde{J}_j^*(\tilde{\mu}(t_j),\tilde{\phi}(t_j))$ can be changed into $\bar{I}_j^*(\bar{\mu}(t_j),\bar{\phi}(t_j))$ and $\bar{J}_j^*(\bar{\mu}(t_j),\bar{\phi}(t_j))$ (see (5.9)). Moreover, there are

$$\bar{I}_j^*(\bar{\mu}(t_j),\bar{\phi}(t_j)) = O\left(A^{-1-n}\bar{\mu}^{-\frac{n+1}{n+2}}\right)$$

and

$$\bar{J}_j^*(\bar{\mu}(t_j),\bar{\phi}(t_j)) = (\gamma_j^{n+2}-1)\bar{\mu}(t_j) + \bar{f}_j(\bar{\mu}(t_j),\bar{\phi}(t_j))$$

with

$$\bar{f}_j(\bar{\mu}(t_j),\bar{\phi}(t_j)) = O\Big(A^{-1-n}\bar{\mu}^{\frac{1}{n+2}}\Big).$$

Finally, by repeating this procedure and noting the fact that $\Psi = \Psi_m \circ \Psi_{m-1} \circ \cdots \circ \Psi_1$ transforms (3.17) into (5.11), we have

$$I_j^{**}(\mu(t_j),\phi(t_j)) = O\Big(A^{-1-n}\bar{\mu}^{-\frac{n+1}{n+2}}\Big)$$

and

$$J_j^{**}(\mu(t_j),\phi(t_j)) = (\gamma_j^{n+2}-1)\mu(t_j) + f_j(\mu(t_j),\phi(t_j))$$

with $f_j(\mu(t_j),\phi(t_j)) = O\big(A^{-1-n}\mu^{\frac{1}{n+2}}\big)$. This completes the proof of Lemma 6.1. □

Lemma 6.2. *Under the assumptions of Theorem 1.1, we have*

$$I_j^{**1}(\rho(t_j),\phi(t_j)) = O\Big(A^{-1-n}\rho^{-\frac{n+1}{n}}\Big),$$

and

$$J_j^{**1}(\rho(t_j),\phi(t_j)) = (\gamma_j^{n}-1)\rho(t_j) + \tilde{g}_j(\rho(t_j),\phi(t_j))$$

with $\tilde{g}_j(\rho(t_j),\phi(t_j)) = O\big(A^{-1-n}\rho^{-\frac{1}{n}}\big)$, *where* $I_j^{**1}(\rho(t_j),\phi(t_j))$ *and* $J_j^{**1}(\rho(t_j),\phi(t_j))$ *are given by (5.12).*

Proof. By (5.3), (5.12), Lemma 6.1 and Taylor's formula, we have

$$\begin{aligned} I_j^{**1}(\rho(t_j),\phi(t_j)) &= \phi(t_j^+) - \phi(t_j) = I_j^{**}(\mu(t_j),\phi(t_j)) \\ &= I_j^{**}\left(\left(\frac{n+2}{2n+2}\rho(t_j)\right)^{\frac{n+2}{n}},\phi(t_j)\right) \end{aligned}$$

and

$$\begin{aligned} J_j^{**1}(\rho(t_j),\phi(t_j)) &= \rho(t_j^+) - \rho(t_j) = \frac{2n+2}{n+2}\mu^{\frac{n}{n+2}}(t_j^+) - \rho(t_j) \\ &= \frac{2n+2}{n+2}[\mu(t_j) + J_j^{**}(\mu(t_j),\phi(t_j))]^{\frac{n}{n+2}} - \rho(t_j) \\ &= \frac{2n+2}{n+2}[\mu(t_j) + (\gamma_j^{n+2}-1)\mu(t_j) + f_j(\mu(t_j),\phi(t_j))]^{\frac{n}{n+2}} - \rho(t_j) \\ &= \frac{2n+2}{n+2}[\gamma_j^{n+2}\mu(t_j)]^{\frac{n}{n+2}}\left(1 + \frac{f_j(\mu(t_j),\phi(t_j))}{\gamma_j^{n+2}\mu(t_j)}\right)^{\frac{n}{n+2}} - \rho(t_j) \\ &= \gamma_j^n\rho(t_j)\left[1 + \frac{n}{n+2}\frac{f_j(\mu(t_j),\phi(t_j))}{\gamma_j^{n+2}\mu(t_j)}\left(1+\xi\frac{f_j(\mu(t_j),\phi(t_j))}{\gamma_j^{n+2}\mu(t_j)}\right)^{-\frac{2}{n+2}}\right] - \rho(t_j) \\ &= (\gamma_j^n-1)\rho(t_j) + \frac{\rho^{-\frac{2}{n}}(t_j) f_j\left(\left(\frac{n+2}{2n+2}\rho(t_j)\right)^{\frac{n+2}{n}},\phi(t_j)\right)}{\frac{n+2}{n}\left(\frac{n+2}{2n+2}\right)^{\frac{n+2}{n}}\gamma_j^2} \\ &\quad \times \left(1+\xi\frac{f_j\left(\left(\frac{n+2}{2n+2}\rho(t_j)\right)^{\frac{n+2}{n}},\phi(t_j)\right)}{\gamma_j^{n+2}\left(\frac{n+2}{2n+2}\rho(t_j)\right)^{\frac{n+2}{n}}}\right)^{-\frac{2}{n+2}} \end{aligned}$$

$$=: (\gamma_j^n - 1)\rho(t_j) + \tilde{g}_j(\rho(t_j), \phi(t_j))$$

by (6.8), where $\xi \in (0,1)$. Then by Lemma 4.3 and Lemma 6.1, we have

$$I_j^{**1}(\rho(t_j), \phi(t_j)) = O\Big(A^{-1-n}\rho^{\frac{n+2}{n}\cdot(-\frac{n+1}{n+2})}\Big) = O\Big(A^{-1-n}\rho^{-\frac{n+1}{n}}\Big),$$

$$\tilde{g}_j(\rho(t_j), \phi(t_j)) = O\Big(\rho^{-\frac{2}{n}}A^{-1-n}\rho^{\frac{n+2}{n}\cdot\frac{1}{n+2}}\Big) = O\Big(A^{-1-n}\rho^{-\frac{1}{n}}\Big).$$

This completes the proof of Lemma 6.2. □

7 Proof of Theorem 1.1

The following two lemmas are similar to Lemma 9.2 in [30] and Lemma 6.2 in [3], respectively. We refer to [30] and [3] for the proofs. Let $(\rho(t), \phi(t)) = (\rho(t,\rho,\phi), \phi(t,\rho,\phi))$ be the solution of (5.12) with the initial value $(\rho(0), \phi(0)) = (\rho, \phi)$. Let $\phi_1 = \phi(1), \rho_1 = \rho(1)$.

Lemma 7.1. *If all conditions of Theorem 1.1 hold, then the time one map Φ^1 of the flow Φ^t of (5.12) takes the form of*

$$\Phi^1 : \begin{cases} \phi_1 = \phi + \alpha(\rho) + F(\rho,\phi), \\ \rho_1 = \rho + G(\rho,\phi). \end{cases}$$

Moreover, $\dot{\alpha}(\rho) > 0$ and for any non-negative integers r, s with $r + s \le 5$,

$$\left|\frac{\partial^{r+s}F(\rho,\phi)}{\partial\rho^r\partial\phi^s}\right|, \quad \left|\frac{\partial^{r+s}G(\rho,\phi)}{\partial\rho^r\partial\phi^s}\right| < CA^{-\varepsilon_0},$$

where $\varepsilon_0 = \min(\tau,\delta) > 0$, $(\rho,\phi) \in [c_3A^{n\tau}, c_4A^{n\tau}] \times \mathbf{T^1}$, $c_4 > c_3 > 0$, $A \gg 1$, $\tau > 0$, $\delta > 0$.

Lemma 7.2. *Assume that the conditions of Theorem 1.1 are satisfied, then the time-1 map Φ^1 of (4.1) has the intersection property on $\Omega = \{(\rho,\phi) \mid \rho$ large enough, $\phi \in \mathbf{T^1}\}$, i.e. if Γ is an embedded circle in Ω homotopic to a circle $\rho =$ const. in Ω, then $\Phi^1(\Gamma)\bigcap\Gamma \neq \emptyset$. In particular, Φ^1 has the intersection property on $\Omega = \{(\rho,\phi) \mid c_3A^{n\tau} \le \rho \le c_4A^{n\tau}, \phi \in \mathbf{T^1}\}$, where $c_4 > c_3 > 0, \tau > 0$.*

Now let us state Moser's twist theorem. Let $\mathcal{D}$ be an annulus given by

$$\mathcal{D} \ : \ a \le r \le b, \quad 0 < a < b.$$

For convenience, we introduce for a function $h \in C^l(\mathcal{D})$ the norm

$$|h|_l = \sup_{\mathcal{D},\, m+n\le l}\left|\frac{\partial^{m+n}}{\partial r^m\partial\theta^n}\right|.$$

Theorem 7.3 (Moser's twist theorem). *Let $\alpha(r) \in C^l$ and $|\partial_r\,\alpha(r)| \ge \nu > 0$ on the annulus $\mathcal{D}$ for some l with $l \ge 5$, and ε be a positive number. Then there exists a $\delta > 0$ depending on $\varepsilon, l, \alpha(r)$, such that any area-preserving mapping*

$$M : \begin{cases} \theta_1 = \theta + 2\pi\alpha(r) + f(r,\theta), \\ r_1 = r + g(r,\theta) \end{cases}$$

of $\mathcal{D}$ into $\mathbf{R^2}$ with $f, g \in C^l$ and

$$|f|_l + |g|_l \le \nu\,\delta$$

possesses an invariant curve of the form

$$r = c + u(\xi), \qquad \theta = \xi + v(\xi)$$

in $\mathcal{D}$ where u, v are continuously differentiable, of period 2π and satisfy

$$|u|_1 + |v|_1 < \varepsilon,$$

and c is a constant in (a, b). Moreover, the induced mapping of this curve is given by

$$\xi \to \xi + \omega,$$

where ω is incommensurable with 2π, and satisfies infinitely many conditions

$$\left| \frac{\omega}{2\pi} - \frac{p}{q} \right| \geq \gamma q^{-\tau}$$

with some positive γ, τ, for all integers $q > 0$, p. In fact, each choice of ω in the range of $\alpha(r)$ and satisfying the above inequalities give rise to such an invariant curve.

Moser's twist theorem above can be found in [21, pp. 50–54] (see also [27]). It should be pointed out that the δ does not depend on ν. It should be also noted that the period 2π can be replaced by any period T. In addition, "any area-preserving mapping" can be relaxed to "any mapping which has intersection property".

We are now in a position to prove Theorem 1.1. From Lemma 7.1 and Lemma 7.2, by Moser's twist theorem, Φ^1 has an invariant curve $\widetilde{\Gamma}$ in the annulus $(\rho, \phi) \in [c_3 A^{n\tau}, c_4 A^{n\tau}] \times \mathbf{T^1}$, $c_4 > c_3 > 0$, $A \gg 1$, $\tau > 0$. It follows that the time-one map of the original system has an invariant curve $\widetilde{\Gamma}_{A_0}$. Choosing a sequence $A_0 = A_{m0} \to \infty$ as $m \to \infty$, we have that there are countable many invariant curves $\widetilde{\Gamma}_{A_{m0}}$, clustering at ∞. Therefore any solution of the original system is bounded. This completes the proof of Theorem 1.1.

Remark 7.4. Any solutions starting from the invariant curves $\widetilde{\Gamma}_{A_{m0}}$ $(m = 1, 2, \dots)$ are quasi-periodic with frequencies $(1, \omega_m)$ in time t, where $(1, \omega_m)$ satisfies Diophantine conditions and $\omega_m > C A_{m0}^{n\tau}$. Actually, the frequencies can form a positive Lebesgue set in $\mathbf{R}$.

Abstract. In this paper, we study the existence of multi-bump solutions for the following Schrödinger–Bopp–Podolsky system with steep potential well:

$$\begin{cases} -\Delta u + (\lambda V(x) + V_0(x))u + K(x)\phi u = |u|^{p-2}u, & x \in \mathbb{R}^3, \\ -\Delta\phi + a^2\Delta^2\phi = K(x)u^2, & x \in \mathbb{R}^3, \end{cases}$$

where $p \in (4,6), a > 0$ and λ is a parameter. We require that $V(x) \geq 0$ and has a bounded potential well $\Omega = V^{-1}(0)$. Combining this with other suitable assumptions on Ω, V_0 and K, when λ is large enough, we obtain the existence of multi-bump-type solutions u_λ by using variational methods.

Keywords: Schrödinger–Bopp–Podolsky system, penalization method, variational methods.

1 Introduction and main results

In this paper, we investigate the existence of multi-bump solutions for the following problem with steep potential well:

$$\begin{cases} -\Delta u + (\lambda V(x) + V_0(x))u + K(x)\phi u = |u|^{p-2}u, & x \in \mathbb{R}^3, \\ -\Delta\phi + a^2\Delta^2\phi = K(x)u^2, & x \in \mathbb{R}^3, \end{cases} \tag{1.1}$$

where $p \in (4,6), a > 0$ and λ is a parameter.

To illustrate the significance of this article, we first introduce some background about Schrödinger–Bopp–Podolsky system. As mentioned in [10], problem (1.1) is a version of

✉Corresponding author. Emails: wangli.423@163.com (Li Wang), wj2746154229@163.com (Jun Wang), wangjixiu127@aliyun.com (Jixiu Wang)

the Schrödinger–Bopp–Podolsky system, which is a Schrödinger equation coupled with a Bopp–Podolsky equation. It is worth mentioning that, Podolsky's theory is a second-order gauge theory for the electromagnetic field developed by Bopp [7], independently by Podolsky–Schwed [14]. For some more details about the Bopp–Podolsky equation, we refer to [5, 6, 15] and the references therein.

If $a = V_0(x) = 0, \lambda = K(x) = 1$, system (1.1) gives back the classical Schrödinger–Poisson system as follows:

$$\begin{cases} -\Delta u + V(x)u + \phi u = f(x,u), & x \in \mathbb{R}^3, \\ -\Delta \phi = u^2, & x \in \mathbb{R}^3, \end{cases}$$

which has been first introduced by D'Aprile–Mugnai [9]. The authors studied the existence of radially symmetric solitary waves by using the variational approach method for the above question when $V(x)$ is a constant. In this system, the potential function V is regarded as an external potential, u and ϕ represent the wave functions associated with the particle and electric potential respectively. For more details on the physical aspects of this system, we refer the readers to [4, 8] and the references therein.

In the last decades, the classical Schrödinger–Poisson system has been widely studied under variant assumptions on V and f. By using variational methods, the existence, nonexistence, and multiplicity results are obtained in many papers. For example, when $f(u) = |u|^{p-1}u$ with $p \in (3, 5)$, Cerami and Vaira in [8] studied the following Schrödinger–Poisson system:

$$\begin{cases} -\Delta u + u + K(x)\phi(x)u = a(x)f(u), & x \in \mathbb{R}^3, \\ -\Delta \phi = K(x)u^2, & x \in \mathbb{R}^3. \end{cases}$$

Without requiring any symmetry property on $K(x)$ and $a(x)$, they proved the existence of the positive ground state and bound state solutions by minimizing energy functional restricted to a Nehari manifold when $K(x)$ and $a(x)$ satisfy different assumptions. After that, Sun et al. in [18] extended the result to a general nonlinear term.

Note that, the steep potential well has been introduced by Bartsch and Wang [3] in the study of nonlinear Schrödinger equation. Our assumptions on V are similar to [11], in which Ding and Tanaka have proven the existence of multi-bump-type solutions for nonlinear Schrödinger equations. After that, more and more researchers have studied multi-bump-type solutions, we refer the readers to the papers [1, 12, 19]. In particular, Zhang and Ma in [21] considered the following system with steep potential well

$$\begin{cases} -\Delta u + (\lambda a(x) + a_0(x))u + K(x)\phi u = |u|^{p-2}u, & x \in \mathbb{R}^3, \\ -\Delta \phi = K(x)u^2, & x \in \mathbb{R}^3, \end{cases} \tag{1.2}$$

they obtained the existence of multi-bump solutions for (1.2) by using variational methods. Compared with [21], although our paper also studies the existence of multi-bump solutions, it studies a new system which has great significance.

If $a \neq 0$, system (1.1) is a Schrödinger–Bopp–Podolsky system. Based on variational methods, D'Avenia–Siciliano [10] first proved the existence and nonexistence results which depended on the parameters p and q to system

$$\begin{cases} -\Delta u + \omega u + q^2\phi u = |u|^{p-2}u, & x \in \mathbb{R}^3, \\ -\Delta \phi + \varepsilon^2\Delta^2\phi = 4\pi u^2, & x \in \mathbb{R}^3. \end{cases} \tag{1.3}$$

Later, for $p \in (2,3]$, Siciliano–Silva [17] obtained the existence and nonexistence of solutions to system (1.3) by means of the fiber map approach and the Implicit Function Theorem. Note that, the authors in [10] and [17] merely considered system (1.3) with subcritical growth, so Liu and Chen in [13] filled the gaps. More precisely, they studied the existence, nonexistence, and asymptotic behavior of ground state solutions to system (1.3) which involves a critical nonlinearity.

Recently, Wang et al. in [20] considered Schrödinger–Bopp–Podolsky system with general nonlinear term:

$$\begin{cases} -\Delta u + \omega u + q^2 \phi u = f(u), & x \in \mathbb{R}^3, \\ -\Delta \phi + \varepsilon^2 \Delta^2 \phi = 4\pi u^2, & x \in \mathbb{R}^3, \end{cases} \tag{1.4}$$

where f is a continuous, superlinear, and subcritical nonlinearity. They proved the existence and multiplicity of sign-changing solutions of system (1.4) by using the method of invariant sets of descending flow incorporated with minimax arguments. In addition, the asymptotic behavior of sign-changing solutions was also established.

Motivated by all results mentioned above, it is quite natural to ask, does the system (1.1) have multi-bump solutions? In the present paper, we give an affirmative answer.

In this paper, we make the following assumptions:

- (V_1) $V(x) \in C\left(\mathbb{R}^3, \mathbb{R}^+\right)$ and $\Omega := \operatorname{int} V^{-1}(0)$ is a non-empty bounded set with smooth boundary. Moreover, there is a positive constant M_0 such that the measure of the set $A = \left\{x \in \mathbb{R}^3 : V(x) \le M_0\right\}$ is finite.
- (V_2) There is a $V_0(x) \in C\left(\mathbb{R}^3, \mathbb{R}\right)$ and a constant $M_1 > 1$ such that $|V_0(x)| \le M_1(V(x) + 1)$.
- (V_3) Ω possesses m connected components $\Omega_1, \ldots, \Omega_m$ such that $\overline{\Omega_j} \cap \overline{\Omega \backslash \Omega_j} = \emptyset$, and $\inf_{u \in H_0^1(\Omega_j), |u|_2 = 1} \int_\Omega \left[|\nabla u|^2 + V_0(x) u^2\right] \mathrm{d}x > 0$ for $j = 1, 2, \ldots, m$.

Now, we say something about (V_1): although A and M_0 in (V_1) are not explicitly mentioned in the article, they are used in the proof of Proposition 2.4. Note that the proof of Proposition 2.4 is very similar to Corollary 1.4 in [11], so it is omitted. In [11], Corollary 1.4 is proven by using Proposition 1.1, but the proof of Proposition 1.1 requires the use of A and M_0 to ensure the vanishing of the energy outside the sphere. Please see [11] for details. Therefore, the role of (V_1) is to ensure that Proposition 2.4 holds in our manuscript.

We also assume that

- (K) $K \in L^\infty\left(\mathbb{R}^3\right), K(x) \ge 0$ and $K \not\equiv 0$.

The main result of this paper reads as follows:

Theorem 1.1. *Assume that $(V_1), (V_2), (V_3)$ and (K) hold. Then, for any small $\nu > 0$ and any non-empty subset J of $\{1, 2, \ldots, m\}$, there exist $\Lambda = \Lambda(\nu)$ and $k(\nu) > 0$ such that, when $\lambda > \Lambda$ and $|K|_\infty \le k(\nu)$, (1.1) has a solution $u_\lambda \in H^1\left(\mathbb{R}^3\right)$ satisfying*

$$\left| \int_{\Omega_j} \left[|\nabla u_\lambda|^2 + (\lambda V(x) + V_0(x)) u_\lambda^2\right] \mathrm{d}x - \left(\frac{1}{2} - \frac{1}{p}\right)^{-1} c\left(\Omega_j\right) \right| \le \nu, \qquad j \in J$$

and

$$\int_{\mathbb{R}^3 \backslash \Omega_J} \left[|\nabla u_\lambda|^2 + (\lambda V(x) + V_0(x)) u_\lambda^2\right] \mathrm{d}x \le \nu,$$

where $\Omega_J = \bigcup_{j \in J} \Omega_j, c\left(\Omega_j\right)$ are some constants. Moreover, for any sequence of solutions $\{u_{\lambda_n}\}$ with $\lambda_n \to \infty$, going if necessary to a subsequence, u_{λ_n} converges strongly in $H^1\left(\mathbb{R}^3\right)$ to a function u satisfying $u(x) = 0$ for $x \in \mathbb{R}^3 \backslash \Omega_J$.

Remark 1.2. The constant $c\left(\Omega_j\right)$ in Theorem 1.1 is the least energy of all the nontrivial solutions for the following boundary value problem

$$-\Delta u + V_0(x)u = |u|^{p-2}u \quad \text{in } \Omega_j,\, u|_{\partial\Omega_j} = 0.$$

Hence under the assumption of (V_3), $c\left(\Omega_j\right) > 0$.

This paper is organized as follows. In Section 2, we give some variational frameworks. After that, we introduce a modified functional and verify the Palais–Smale condition. In Sections 4 and 5, we give some results on the Nehari manifold and the proof of Theorem 1.1 respectively.

2 Variational frameworks

We consider the following functional space

$$E := \left\{ u \in H^1\left(\mathbb{R}^3\right) : \int_{\mathbb{R}^3} V(x)u^2 \mathrm{d}x < \infty \right\}$$

with the inner product

$$(u,v)_E := \int_{\mathbb{R}^3} \left[\nabla u \nabla v + (V(x)+1)uv\right] \mathrm{d}x,$$

and the corresponding norm is $\|u\|_E = (u,u)_E^{1/2}$. It is easy to see that $(E, \|\cdot\|_E)$ is a Hilbert space and the embedding $E \hookrightarrow H^1\left(\mathbb{R}^3\right)$ is continuous. For any open set $D \subset \mathbb{R}^3$, we also define

$$E(D) = \left\{ u \in H^1(D) : \int_D V(x)u^2 \mathrm{d}x < \infty \right\},$$

$$\|u\|_{E(D)} = \int_D \left[|\nabla u|^2 + (V(x)+1)u^2\right] \mathrm{d}x.$$

Note that $\|\cdot\|_{E(D)}$ is equivalent to $\|\cdot\|_{H^1(D)}$ when D is bounded.

Now, we define $\mathcal{D}$ be the completion of $C_0^\infty\left(\mathbb{R}^3\right)$ with respect to the norm $\|\cdot\|_{\mathcal{D}}$ induced by the scalar product

$$(u,v)_{\mathcal{D}} = \int_{\mathbb{R}^3} \left(\nabla u \nabla v + a^2 \Delta u \Delta v\right) \mathrm{d}x.$$

Then $\mathcal{D}$ is a Hilbert space, which is continuously embedded into $D^{1,2}\left(\mathbb{R}^3\right)$ and consequently into $L^6(\mathbb{R}^3)$. We denote that $L^q(\mathbb{R}^3)$ is the usual Lebesgue space with the standard norm $\|u\|_q := \left(\int_{\mathbb{R}^3} |u|^q \mathrm{d}x\right)^{\frac{1}{q}}$, $1 \le q < \infty$.

Proposition 2.1 (see [10]). *The space $\mathcal{D}$ is continuously embedded into $L^\infty(\mathbb{R}^3)$.*

By using the Lax–Milgram theorem, for every fixed $u \in E$, there exists a unique solution $\phi_u^a \in \mathcal{D}$ of the second equation in system (1.1). In order to explicitly write such solution (see [15]), we consider that

$$\mathcal{K}(x) = \frac{1 - e^{\frac{-|x|}{a}}}{|x|}.$$

As for $\mathcal{K}$, we have the following fundamental properties from [10].

Proposition 2.2 (see [10]). *For all $y \in \mathbb{R}^3, \mathcal{K}(\cdot - y)$ solves in the sense of distributions*

$$-\Delta\phi + a^2\Delta^2\phi = 4\pi\delta_y.$$

Moreover,

(i) *if $f \in L^1_{loc}\left(\mathbb{R}^3\right)$ and for a.e. $x \in \mathbb{R}^3$, the map $y \in \mathbb{R}^3 \to \frac{f(y)}{|x-y|}$ is summated, then $\mathcal{K} * f \in L^1_{loc}\left(\mathbb{R}^3\right)$;*

(ii) *if $f \in L^p\left(\mathbb{R}^3\right)$ with $1 \leqslant p < \frac{3}{2}$, then $\mathcal{K} * f \in L^q\left(\mathbb{R}^3\right)$ for $q \in \left(\frac{3p}{3-2p}, +\infty\right]$.*

In both cases $\mathcal{K} * f$ solves

$$-\Delta\phi + a^2\Delta^2\phi = 4\pi f.$$

Then if we fix $u \in E$, the unique solution in $\mathcal{D}$ of the second equation in system (1.1) can be expressed by

$$\phi_u^a = \mathcal{K} * (Ku^2) = \frac{1}{4\pi}\int_{\mathbb{R}^3} \frac{1 - e^{\frac{-|x-y|}{a}}}{|x-y|} K(y)u^2(y)\mathrm{d}y.$$

Now, let us summarize some properties of ϕ_u^a.

Proposition 2.3 (see [10]). *For every $u, v \in E$, the following statements are correct.*

(i) $\phi_u^a \geqslant 0$.

(ii) *For each $t > 0, \phi_{tu}^a = t^2\phi_u^a$.*

(iii) *If $u_n \rightharpoonup u$ in E, then $\phi_{u_n}^a \rightharpoonup \phi_u^a$ in $\mathcal{D}$.*

(iv) $\|\phi_u^a\|_{\mathcal{D}} \leqslant C\|u\|^2_{\frac{12}{5}} \leqslant C\|u\|_E^2$ *and* $\int_{\mathbb{R}^3} \phi_u^a|u|^2\,\mathrm{d}x \leqslant C\|u\|^4_{\frac{12}{5}} \leqslant C\|u\|_E^4$.

By using the classical reduction argument, system (1.1) can be reduced to a single equation:

$$-\Delta u + (\lambda V(x) + V_0(x))\,u + K(x)\phi_u^a u = |u|^{p-2}u, \qquad x \in \mathbb{R}^3. \tag{2.1}$$

From now on, the solutions of system (1.1) are equal to the solutions of equation (2.1). It is easy to see that the solutions of equation (2.1) can be regarded as critical points of the energy functional $I_\lambda : E \to \mathbb{R}$ defined by

$$I_\lambda(u) = \frac{1}{2}\int_{\mathbb{R}^3} \left(|\nabla u|^2 + (\lambda V(x) + V_0(x))\,u^2\right)\mathrm{d}x + \frac{1}{4}\int_{\mathbb{R}^3} K(x)\phi_u^a u^2\mathrm{d}x - \frac{1}{p}\int_{\mathbb{R}^3} |u|^p\mathrm{d}x.$$

According to (V_1) and (V_3), it is easy to check that I_λ is a well defined C^1 functional in E. Moreover, $\forall\varphi \in E$, we have

$$\left\langle I'_\lambda(u), \varphi\right\rangle = \int_{\mathbb{R}^3}(\nabla u\nabla\varphi + (\lambda V(x) + V_0(x))\,u\varphi)\mathrm{d}x + \int_{\mathbb{R}^3} K(x)\phi_u^a u\varphi\mathrm{d}x - \int_{\mathbb{R}^3} |u|^{p-2}u\varphi\mathrm{d}x.$$

By assumption (V_3), there exist smoothly bounded open sets $\Omega'_1, \Omega'_2, \ldots, \Omega'_m \subset \mathbb{R}^3$ such that $\overline{\Omega_j} \subset \Omega'_j$ and $\overline{\Omega'_i} \cap \overline{\Omega'_j} = \emptyset$ for $i \neq j$. In the following proposition, which is one of the keys of our argument, we will give the positivity of the operator $-\Delta + (\lambda V(x) + V_0(x))$ acting on the space $E(D)$, where D is one of the following sets:

$$D = \mathbb{R}^3, \qquad \Omega'_j\ (j = 1, 2, \ldots, k), \quad \text{or} \quad \mathbb{R}^3 \setminus \bigcup_{j\in J} \Omega'_j \qquad (J \subset \{1, 2, \ldots, k\}).$$

Now, we define a norm $\|\cdot\|_{\lambda,D}$ on $E(D)$ for $\lambda \geq \Lambda_1$ by

$$\|u\|_{\lambda,D}^2 = \int_D \left[|\nabla u|^2 + (\lambda V(x) + V_0(x))\, u^2\right] \mathrm{d}x.$$

We write $\|\cdot\|_\lambda = \|\cdot\|_{\lambda,\mathbb{R}^3}$ for simplicity. From Corollary 1.3 in [11], we can get that there exist $C_{1,\lambda}, C'_{1,\lambda} > 0$ such that

$$C_{1,\lambda}\|u\|_{E(D)} \leq \|u\|_{\lambda,D} \leq C'_{1,\lambda}\|u\|_{E(D)} \quad \text{for } u \in E(D).$$

Proposition 2.4. (see [11]) *There exist $\delta_0, \nu_0 > 0$ such that for any set D and $u \in E(D)$*

$$\delta_0\|u\|_{\lambda,D}^2 \leq \|u\|_{\lambda,D}^2 - (p-1)\nu_0\|u\|_{L^2(D)}^2 \quad \text{for } \lambda \geq \Lambda_1.$$

3 Compactness condition

Since I_λ given in Section 2 does not satisfy the Palais–Smale condition easily, we modify it and establish the compactness conditions in this section. For $t \in \mathbb{R}$ and ν_0 given in Proposition 2.4, set

$$f(t) = \begin{cases} |t|^{p-2}t, & \text{if } |t| \leq \nu_0^{\frac{1}{p-2}}, \\ \nu_0 t, & \text{if } |t| \geq \nu_0^{\frac{1}{p-2}}, \end{cases}$$

and $F(t) = \int_0^t f(s)\mathrm{d}s$. Let $J \subset \{1, 2, \ldots, k\}$ and $\chi_J : \mathbb{R}^3 \to [0,1]$ be the characteristic function of $\Omega'_J := \bigcup_{j\in J}\Omega'_j$. We consider the penalized nonlinearity

$$g(x,t) = \chi_J(x)|t|^{p-2}t + (1-\chi_J(x))\, f(t).$$

Setting $G(t) = \int_0^t g(s)\mathrm{d}s$, we define $J_\lambda : E \to \mathbb{R}$ by

$$J_\lambda(u) = \frac{1}{2}\int_{\mathbb{R}^3} \left(|\nabla u|^2 + \left(\lambda V(x) + V_0(x) u^2\right)\right) \mathrm{d}x + \frac{1}{4}\int_{\mathbb{R}^3} K(x)\phi_u^a u^2 \mathrm{d}x - \int_{\mathbb{R}^3} G(x,u)\mathrm{d}x.$$

By using a standard method, one can see that J_λ is of class C^1 and its nontrivial critical points are nontrivial solutions of

$$-\Delta u + (\lambda V(x) + V_0(x))\, u + K(x)\phi_u^a(x) u = g(x,u) \quad \text{in } \mathbb{R}^3.$$

Since $f(t) = |t|^{p-2}t$ for $|t| \leq \nu_0^{\frac{1}{p-2}}$, a critical point u of J_λ solves the original problem (1.1) when it satisfies $|u(x)| \leq \nu_0^{\frac{1}{p-2}}$ for all $x \in \mathbb{R}^3 \backslash \Omega'_J$.

Next, we verify the Palais–Smale condition of J_λ. First of all, the following lemma can give the boundedness of the $(PS)_c$ sequence of J_λ.

Lemma 3.1. *For any $(PS)_c$ sequence $\{u_n\}_n \subset E$ of J_λ, there exists a positive constant $M(c)$ which is independent of $\lambda \geq \Lambda_1$ such that*

$$\limsup_{n\to\infty} \|u_n\|_\lambda^2 \leq M(c).$$

Proof. Due to $\{u_n\}_n$ is the $(PS)_c$ sequence of J_λ, we have

$$J_\lambda(u_n) - \frac{1}{p}\langle J'_\lambda(u_n), u_n\rangle = c + o(1) + \varepsilon_n \|u_n\|_\lambda,$$

where $\varepsilon_n \to \infty$ as $n \to \infty$. Then by using the fact $F(t) - \frac{1}{p}f(t)t \le (\frac{1}{2} - \frac{1}{p})\nu_0 t^2$ for $t \in \mathbb{R}$ and $\int_{\mathbb{R}^3} K(x)\phi_{u_n}^a u_n^2 \mathrm{d}x \ge 0$, we get

$$\begin{aligned}
c + o(1) + \varepsilon_n \|u_n\|_\lambda &= J_\lambda(u_n) - \frac{1}{p}\langle J'_\lambda(u_n), u_n\rangle \\
&= \left(\frac{1}{2} - \frac{1}{p}\right)\|u_n\|_\lambda^2 + \left(\frac{1}{4} - \frac{1}{p}\right)\int_{\mathbb{R}^3} K(x)\phi_{u_n}^a u_n^2 \mathrm{d}x \\
&\quad - \int_{\mathbb{R}^3\setminus\Omega'_J}\left(F(u_n) - \frac{1}{p}f(u_n)u_n\right)\mathrm{d}x - \int_{\Omega'_J}\left(F(u_n) - \frac{1}{p}f(u_n)u_n\right)\mathrm{d}x \\
&= \left(\frac{1}{2} - \frac{1}{p}\right)\|u_n\|_\lambda^2 + \left(\frac{1}{4} - \frac{1}{p}\right)\int_{\mathbb{R}^3} K(x)\phi_{u_n}^a u_n^2 \mathrm{d}x \\
&\quad - \int_{\mathbb{R}^3\setminus\Omega'_J}\left(F(u_n) - \frac{1}{p}f(u_n)u_n\right)\mathrm{d}x \\
&\ge \left(\frac{1}{2} - \frac{1}{p}\right)\|u_n\|_\lambda^2 - \left(\frac{1}{2} - \frac{1}{p}\right)\nu_0\|u_n\|_{L^2}^2.
\end{aligned}$$

Using Proposition 2.4, we obtain

$$\left(\frac{1}{2} - \frac{1}{p}\right)\delta_0\|u_n\|_\lambda^2 \le c + o(1) + \varepsilon_n\|u_n\|_\lambda.$$

Hence, $\|u_n\|_\lambda$ is bounded as $n \to \infty$ and

$$\limsup_{n\to\infty}\|u_n\|_\lambda^2 \le M(c).$$ □

Now we have the following fact.

Lemma 3.2. *When $c > 0$, there exists $\Lambda_1 > 0$, such that J_λ satisfies the Palais–Smale condition at level c on E for $\lambda \ge \Lambda_1$ large enough.*

Proof. By using Lemma 3.1, we know that any $(PS)_c$-sequence $\{u_n\}_n$ is bounded in E. So, going if necessary to a subsequence, we may assume that

$$\begin{aligned}
u_n &\rightharpoonup u \quad \text{in } E \text{ and } H^1(\mathbb{R}^3), \\
u_n &\to u \quad \text{in } L^q_{\mathrm{loc}}(\mathbb{R}^3),\ 1 \le q < 6, \\
u_n &\to u \quad \text{a.e. in } \mathbb{R}^3.
\end{aligned}$$

Now we prove that $u_n \to u$ in E. Firstly, it is easy to check that $J'_\lambda(u) = 0$. In fact, by Proposition 2.3, we know that $\phi_{u_n}^a \rightharpoonup \phi_u^a$ in $\mathcal{D}$. For any $\varphi \in C_0^\infty(\mathbb{R}^3)$, since $K(x)u\varphi \in L^{\frac{6}{5}}(\mathbb{R}^3)$, we have

$$\int_{\mathbb{R}^3} K(x)u\varphi\left(\phi_{u_n}^a - \phi_u^a\right)\mathrm{d}x \to 0 \quad \text{as } n \to \infty.$$

Similarly,

$$\begin{aligned}
\int_{\mathbb{R}^3} K(x)\varphi\phi_{u_n}^a(u_n - u)\mathrm{d}x &\le |K|_\infty\|\varphi\|_3\|\phi_{u_n}^a\|_6\|u_n - u\|_{L^2(\Omega_\varphi)} \\
&\le C\|u_n - u\|_{L^2(\Omega_\varphi)} \\
&\to 0
\end{aligned}$$

as $n \to \infty$, where Ω_φ is the support of φ. Consequently,

$$\begin{aligned}&\int_{\mathbb{R}^3}\left(K(x)\phi_{u_n}^a u_n\varphi - K(x)\phi_u^a u\varphi\right)\mathrm{d}x\\&\quad=\int_{\mathbb{R}^3}K(x)u\varphi\left(\phi_{u_n}^a-\phi_u^a\right)\mathrm{d}x+\int_{\mathbb{R}^3}K(x)\varphi\phi_{u_n}^a\left(u_n-u\right)\mathrm{d}x\\&\quad\to 0\end{aligned}$$

as $n \to \infty$, thus we see that

$$\begin{aligned}\langle J_\lambda'(u_n)-J_\lambda'(u),\varphi\rangle &= \langle J_\lambda'(u_n),\varphi\rangle-\langle J_\lambda'(u),\varphi\rangle\\&=\int_{\mathbb{R}^3}(\nabla u_n\nabla\varphi+(\lambda V(x)+V_0(x))\,u_n\varphi)\mathrm{d}x+\int_{\mathbb{R}^3}K(x)\phi_{u_n}^a u_n\varphi\mathrm{d}x\\&\quad-\int_{\mathbb{R}^3}(\nabla u\nabla\varphi-(\lambda V(x)+V_0(x))\,u\varphi)\mathrm{d}x-\int_{\mathbb{R}^3}K(x)\phi_u^a u\varphi\mathrm{d}x\\&\quad-\int_{\mathbb{R}^3}g(x,u_n)\varphi\mathrm{d}x+\int_{\mathbb{R}^3}g(x,u)\varphi\mathrm{d}x\\&=o(1).\end{aligned}$$

So $J_\lambda'(u)=0$. Then we have

$$\begin{aligned}&\langle J_\lambda'\left(u_n\right)-J_\lambda'(u),u_n-u\rangle\\&\quad=\langle J_\lambda'\left(u_n\right),u_n-u\rangle-\langle J_\lambda'(u),u_n-u\rangle\\&\quad=\|u_n-u\|_\lambda^2+\int_{\mathbb{R}^3}\left(K(x)\phi_{u_n}^a u_n\left(u_n-u\right)-K(x)\phi_u^a u\left(u_n-u\right)\right)\mathrm{d}x\\&\qquad-\int_{\mathbb{R}^3\backslash\Omega_J'}\left(f\left(u_n\right)-f(u)\right)\left(u_n-u\right)\mathrm{d}x-\int_{\Omega_J'}\left(|u_n|^{p-2}u_n-|u|^{p-2}u\right)\left(u_n-u\right)\mathrm{d}x\\&\quad=\|u_n-u\|_\lambda^2+\int_{\mathbb{R}^3}K(x)\phi_{u_n}^a\left(u_n-u\right)^2\mathrm{d}x+\int_{\mathbb{R}^3}K(x)\left(\phi_{u_n}^a-\phi_u^a\right)u\left(u_n-u\right)\mathrm{d}x\\&\qquad-\int_{\mathbb{R}^3\backslash\Omega_J'}\left(f\left(u_n\right)-f(u)\right)\left(u_n-u\right)\mathrm{d}x-\int_{\Omega_J'}\left(|u_n|^{p-2}u_n-|u|^{p-2}u\right)\left(u_n-u\right)\mathrm{d}x\\&\quad=o(1)\end{aligned}$$

as $n\to\infty$. Because of $\max_{x\in\mathbb{R}}|f'(x)|\le(p-1)\nu_0$, by using the Mean Value Theorem, we get that

$$\int_{\mathbb{R}^3\backslash\Omega_J'}\left(f\left(u_n\right)-f(u)\right)\left(u_n-u\right)\mathrm{d}x\le(p-1)\nu_0\left\|u_n-u\right\|_2^2.$$

Noting that $u_n\to u$ in $L^p_{\mathrm{loc}}(\mathbb{R}^3)$, so we have

$$\int_{\Omega_J'}\left(|u_n|^{p-2}u_n-|u|^{p-2}u\right)\left(u_n-u\right)\mathrm{d}x=o(1)\quad\text{as } n\to\infty.$$

We also remark that $u_n\rightharpoonup u$ in $L^3\left(\mathbb{R}^3\right)$. Thus, by the uniqueness of limit, we have $|u_n-u|^{\frac{6}{5}}\rightharpoonup 0$ in $L^{\frac{5}{2}}\left(\mathbb{R}^3\right)$. Then according to $K\in L^\infty(\mathbb{R}^3)$ and $|u|^{\frac{6}{5}}\in L^{\frac{5}{3}}\left(\mathbb{R}^3\right)$, we obtain

$$\begin{aligned}\int_{\mathbb{R}^3}K(x)\left(\phi_{u_n}^a-\phi_u^a\right)u\left(u_n-u\right)\mathrm{d}x&\le|K|_\infty\|\phi_{u_n}^a-\phi_u^a\|_6\left(\int_{\mathbb{R}^3}|u|^{\frac{6}{5}}|u_n-u|^{\frac{6}{5}}\mathrm{d}x\right)^{\frac{5}{6}}\\&=o(1)\quad\text{as } n\to\infty.\end{aligned}$$

Combining all these and the fact $\int_{\mathbb{R}^3} K(x)\phi_{u_n}^a (u_n - u)^2 \, dx \geq 0$, by using Proposition 2.4, we have

$$\delta_0 \|u_n - u\|_\lambda^2 \leq \|u_n - u\|_\lambda^2 - (p-1)\nu_0 \|u_n - u\|_2^2 + \int_{\mathbb{R}^3} K(x)\phi_{u_n}^a (u_n - u)^2 \, dx \leq o(1)$$

as $n \to \infty$, which completes the proof. □

Following the spirit of Lemma 3.2, we have

Lemma 3.3. *Suppose the sequences $\lambda_n \to \infty$ as $n \to \infty$ and $\{u_n\}_n$ in E satisfy*

$$J_{\lambda_n}(u_n) \leq c, \qquad \|\nabla J_{\lambda_n}(u_n)\|_{\lambda_n} \to 0.$$

Then, after passing to a subsequence, we have:

- (a) *$u_n \rightharpoonup u$ in E for some $u \in E$;*
- (b) *$u \equiv 0$ in $\mathbb{R}^3 \backslash \Omega_J$, and $u_j = u|_{\Omega_j} \in H_0^1(\Omega_j)$ solves $-\Delta v + V_0(x)v + K(x)\phi_u^a v = |v|^{p-2}v$ in Ω_j weakly for $j \in J$;*
- (c) *$\|u_n - u\|_{\lambda_n} \to 0$, consequently $u_n \to u$ in $H^1(\mathbb{R}^3)$;*
- (d) *For $n \to \infty$, u_n also satisfies:*
  - (1) $\int_{\mathbb{R}^3} \lambda_n V(x) u_n^2 dx \to 0$;
  - (2) $\int_{\mathbb{R}^3 \backslash \Omega_J'} \left(|\nabla u_n|^2 + (\lambda_n V(x) + V_0(x)) u_n^2\right) dx \to 0$;
  - (3) $\int_{\Omega_j'} \left(|\nabla u_n|^2 + (\lambda_n V(x) + V_0(x)) u_n^2\right) dx \to \int_{\Omega_j} \left(|\nabla u|^2 + V_0(x)u^2\right) dx, j = 1, \ldots, m.$

Proof. By a similar method of Lemma 3.1, we obtain that $\{u_n\}_n$ is bounded in E and $H^1(\mathbb{R}^3)$. So we could assume that for some $u \in E$,

$$\begin{aligned} u_n &\rightharpoonup u \quad \text{in } E \text{ and } H^1(\mathbb{R}^3), \\ u_n &\to u \quad \text{in } L^q_{\text{loc}}(\mathbb{R}^3),\ 1 \leq q < 6, \\ u_n &\to u \quad \text{a.e in } \mathbb{R}^3. \end{aligned}$$

Let $C_m = \left\{x \in \mathbb{R}^3 : V(x) \geq \frac{1}{m}\right\}$. When n large enough such that $\lambda_n \leq 2(\lambda_n - \lambda_1)$, we have that

$$\begin{aligned} \int_{C_m} u_n^2 dx &\leq \frac{m}{\lambda_n} \int_{\mathbb{R}^3} \lambda_n V(x) u_n^2 dx \\ &\leq \frac{2m}{\lambda_n} \int_{\mathbb{R}^3} (\lambda_n - \lambda_1) V(x) u_n^2 dx \\ &\leq \frac{2m}{\lambda_n} \int_{\mathbb{R}^3} (\lambda_n - \lambda_1) V(x) u_n^2 dx + \frac{2m}{\lambda_n} \|u_n\|_{\lambda_1}^2 \\ &= \frac{2m}{\lambda_n} \int_{\mathbb{R}^3} \left(|\nabla u_n|^2 + (\lambda_n V(x) + V_0(x)) u_n^2\right) dx \\ &= \frac{2m}{\lambda_n} \|u_n\|_{\lambda_n}^2 \to 0 \quad \text{as } n \to \infty. \end{aligned}$$

Therefore, $u(x) = 0$ a.e. in $\bigcup_m C_m = \mathbb{R}^3 \backslash \overline{\Omega}$. For any $\varphi \in C_0^\infty(\Omega_j), j \in J$, we get

$$\langle J_{\lambda_n}'(u_n), \varphi \rangle = \int_{\Omega_j} \left(\nabla u_n \nabla \varphi + V_0(x) u_n \varphi + K(x)\phi_{u_n}^a u_n \varphi - |u_n|^{p-2} u_n \varphi\right) dx.$$

Due to $K(x)u\varphi \in L^{\frac{6}{5}}\left(\mathbb{R}^3\right), \Phi\left(u_n\right) \rightharpoonup \Phi(u)$ in $\mathcal{D}$ and $u_n \to u$ in $L^q_{\mathrm{loc}}\left(\mathbb{R}^3\right)$ for $1 \le q < 6$, for $n \to \infty$, we have

$$\begin{aligned}\int_{\Omega_j}\left(K(x)\phi^a_{u_n}u_n\varphi - K(x)\phi^a_u u\varphi\right)\mathrm{d}x &= \int_{\Omega_j} K(x)\phi^a_{u_n}\left(u_n-u\right)\varphi \mathrm{d}x + \int_{\Omega_j} K(x)\left(\phi^a_{u_n}-\phi^a_u\right)u\varphi \mathrm{d}x \\ &\to 0.\end{aligned}$$

Similar to the proof of Lemma 3.2, we have $\langle J'_{\lambda_n}(u_n) - J'_{\lambda_n}(u), \varphi\rangle \to 0$. Thus it follows from $\langle J'_{\lambda_n}\left(u_n\right), \varphi\rangle \to 0$ that

$$\int_{\Omega_j}\left(\nabla u \nabla \varphi + V_0(x)u\varphi + K(x)\phi^a_u u\varphi - |u|^{p-2}u\varphi\right)\mathrm{d}x = 0.$$

As a result, for $j \in J, u_j = u|_{\Omega_j} \in H^1_0\left(\Omega_j\right)$ solves $-\Delta v + V_0(x)v + K(x)\phi^a_u v = |v|^{p-2}v$ in Ω_j weakly. When $j \in \{1,2,\ldots,m\} \setminus J$, let $\varphi = u$, then we get

$$\int_{\Omega_j}\left(|\nabla u|^2 + V_0(x)u^2 + K(x)\phi^a_u u^2 - f(u)u\right)\mathrm{d}x = 0.$$

Because of $\varphi = u \in C^\infty_0\left(\Omega_j\right)$, we have

$$\int_{\Omega'_j}\left(|\nabla u|^2 + V_0(x)u^2 + K(x)\phi^a_u u^2 - f(u)u\right)\mathrm{d}x = 0.$$

From Proposition 2.4, $f(t)t \le \nu_0 t^2$ for $t \in \mathbb{R}$ and the fact that $K(x)\phi^a_u u^2 \ge 0$, we have

$$\begin{aligned}\delta_0\|u\|^2_{\Lambda_1,\Omega'_j} &\le \|u\|^2_{\Lambda_1,\Omega'_j} - (p-1)\nu_0\|u\|^2_{L^2\left(\Omega'_j\right)} \\ &\le \|u\|^2_{\Lambda_1,\Omega'_j} - \nu_0\|u\|^2_{L^2\left(\Omega'_j\right)} \\ &\le \int_{\Omega'_j}\left(|\nabla u|^2 + a_0(x)u^2 + K(x)\phi^a_u u^2 - f(u)u\right)\mathrm{d}x \\ &= 0.\end{aligned}$$

So that, $u = 0$ in Ω_j when $j \in \{1,2,\ldots,m\} \setminus J$ and we get (b).

In order to prove (c), we use the following fact:

$$\begin{aligned}o(1) &= \langle J'_{\lambda_n}\left(u_n\right) - J'_{\lambda_n}(u), u_n - u\rangle \\ &= \langle J'_{\lambda_n}\left(u_n\right), u_n - u\rangle - \langle J'_{\lambda_n}(u), u_n - u\rangle \\ &= \|u_n - u\|^2_{\lambda_n} + \int_{\mathbb{R}^3}\left(K(x)\phi^a_{u_n}u_n\left(u_n-u\right) - K(x)\phi^a_u u\left(u_n-u\right)\right)\mathrm{d}x \\ &\quad - \int_{\mathbb{R}^3\setminus\Omega'_J}\left(f\left(u_n\right)-f(u)\right)\left(u_n-u\right)\mathrm{d}x - \int_{\Omega'_J}\left(\left|u_n\right|^{p-2}u_n - |u|^{p-2}u\right)\left(u_n-u\right)\mathrm{d}x \\ &= \|u_n - u\|^2_{\lambda_n} + \int_{\mathbb{R}^3}K(x)\phi^a_{u_n}\left(u_n-u\right)^2\mathrm{d}x + \int_{\mathbb{R}^3}K(x)\left(\phi^a_{u_n}-\phi^a_u\right)u\left(u_n-u\right)\mathrm{d}x \\ &\quad - \int_{\mathbb{R}^3\setminus\Omega'_J}\left(f\left(u_n\right)-f(u)\right)\left(u_n-u\right)\mathrm{d}x - \int_{\Omega'_J}\left(\left|u_n\right|^{p-2}u_n - |u|^{p-2}u\right)\left(u_n-u\right)\mathrm{d}x.\end{aligned}$$

Similar to the proof of Lemma 3.2, we also have

$$\int_{\mathbb{R}^3\setminus\Omega'_J}\left(f\left(u_n\right)-f(u)\right)\left(u_n-u\right)\mathrm{d}x \le (p-1)\nu_0\left\|u_n-u\right\|^2_2,$$

$$\int_{\Omega'_J}\left(\left|u_n\right|^{p-2}u_n - |u|^{p-2}u\right)\left(u_n-u\right)\mathrm{d}x = o(1) \quad \text{as } n \to \infty$$

and

$$\int_{\mathbb{R}^3} K(x)\left(\phi_{u_n}^a-\phi_u^a\right) u\left(u_n-u\right) \mathrm{d}x=o(1) \quad \text{as } n \rightarrow \infty.$$

So we have

$$\delta_0\left\|u_n-u\right\|_{\lambda_n}^2 \leq\left\|u_n-u\right\|_{\lambda_n}^2-(p-1) \nu_0\left\|u_n-u\right\|_2^2+\int_{\mathbb{R}^3} K(x) \phi_{u_n}^a\left(u_n-u\right)^2 \mathrm{d}x \leq o(1).$$

This completes the proof of (c).

For (d), we use (c) and for sufficiently large $n, \lambda_n \leq 2\left(\lambda_n-\lambda_1\right)$. Then as $n \rightarrow \infty$, we have

$$\begin{aligned}
\frac{1}{2} \int_{\mathbb{R}^3} \lambda_n V(x) u_n^2 \mathrm{d}x \leq \int_{\mathbb{R}^3}\left(\lambda_n-\lambda_1\right) V(x) u_n^2 \mathrm{d}x & =\int_{\mathbb{R}^3}\left(\lambda_n-\lambda_1\right) V(x)\left(u_n-u\right)^2 \mathrm{d}x \\
& \leq \int_{\mathbb{R}^3}\left(\lambda_n-\lambda_1\right) V(x)\left(u_n-u\right)^2 \mathrm{d}x+\left\|u_n-u\right\|_{\lambda_1}^2=\left\|u_n-u\right\|_{\lambda_n}^2 \rightarrow 0.
\end{aligned}$$

Thus (1) in (d) is obtained. It is easy to show that (2), (3) in (d) also follows immediately from (1) in (d) and (c), and we obtain the conclusion. □

Lemma 3.4. *For any fixed $c>0$, there exists $\Lambda_c \geq \Lambda_1$ such that if u_λ is a critical point of J_λ satisfying $\left|J_\lambda\left(u_\lambda\right)\right| \leq c$ for $\lambda \geq \Lambda_c$, then $\left|u_\lambda\right| \leq \nu_0^{\frac{1}{p-2}}$ on $\mathbb{R}^3 \backslash \Omega_J^{\prime}$, ν_0 is defined in Proposition 2.4. In particular, u_λ solves the original problem (1.1).*

Proof. Since $u_\lambda \in E$ is a critical point of J_λ with $\left|J_\lambda\left(u_\lambda\right)\right| \leq c, u_\lambda$ is bounded in E uniformly for $\lambda \geq \Lambda_1$. And it satisfies the equation

$$-\Delta u_\lambda+\left(\lambda V(x)+V_0(x)\right) u_\lambda+K(x) \phi_{u_\lambda}^a u_\lambda=g\left(x, u_\lambda\right) \quad \text{in } \mathbb{R}^3.$$

Due to Lemma 5.1 in [2], $H_\lambda^{-1}:=\left(-\Delta+\left(\lambda V(x)+V_0(x)\right)\right)^{-1}$ is a well-defined bounded operator from $L^s\left(\mathbb{R}^3\right)$ to $L^r\left(\mathbb{R}^3\right)$ provided $1 \leq s \leq r \leq+\infty$ and $\frac{1}{s}-\frac{1}{r} \leq \frac{2}{3}$. And there exists a constant $C_{r, s}>0$ (independent of λ sufficiently large) such that

$$\left\|H_\lambda^{-1} g\right\|_r \leq C_{r, s}\|g\|_s, \qquad g \in L^s\left(\mathbb{R}^3\right).$$

Let $\chi_{\lambda, 0}$ be the characteristic function of the set $\left\{x \in \mathbb{R}^3:\left|u_\lambda(x)\right| \leq 1\right\}$ and define $v_{\lambda, 0}=\chi_{\lambda, 0} u_\lambda$, $w_{\lambda, 0}=u_\lambda-v_{\lambda, 0}=\left(1-\chi_{\lambda, 0}\right) u_\lambda$. Setting $l_{\lambda, 0}=g\left(\cdot, v_{\lambda, 0}\right)-K(\cdot) \phi_{u_\lambda}^a v_{\lambda, 0}$ and $h_{\lambda, 0}=g\left(\cdot, w_{\lambda, 0}\right)-K(\cdot) \phi_{u_\lambda}^a w_{\lambda, 0}$, we have $g\left(\cdot, u_\lambda\right)=l_{\lambda, 0}+h_{\lambda, 0}$. Since u_λ is bounded in $E, \phi_{u_\lambda}^a$ is bounded in L^{∞}. Thus, $l_{\lambda, 0}$ is bounded in $L^{\infty}\left(\mathbb{R}^3\right)$ uniformly in λ. Moreover, $h_{\lambda, 0}$ is bounded uniformly for λ in $L^{\frac{6}{p-1}}\left(\mathbb{R}^3\right)$. In fact,

$$\begin{aligned}
\left|\phi_{u_\lambda}^a(x)\right| & \leq \frac{1}{4 \pi}\left|\int_{\mathbb{R}^3} \frac{K(y)}{|x-y|} u_\lambda^2(y) \mathrm{d}y\right| \\
& \leq c|K|_{\infty}\left(\int_{B_1(x)} \frac{u_\lambda^2(y)}{|x-y|} \mathrm{d}y+\int_{B_1^c(x)} \frac{u_\lambda^2(y)}{|x-y|} \mathrm{d}y\right) \\
& \leq c|K|_{\infty}\left(\left(\int_{B_1(x)} \frac{1}{|x-y|^2} \mathrm{~d}y\right)^{1/2}\left(\int_{B_1(x)} u_\lambda^4 \mathrm{~d}y\right)^{1/2}\right. \\
& \quad\left.+\left(\int_{B_1^c(x)} \frac{1}{|x-y|^4} \mathrm{~d}y\right)^{1/4}\left(\int_{B_1^c(x)}\left|u_\lambda\right|^{8/3} \mathrm{~d}y\right)^{4/3}\right) \\
& \leq c^{\prime}|K|_{\infty}.
\end{aligned}$$

In the set $|u_\lambda| \leq 1$, we have $|w_{\lambda,0}| = 0$; and in the set $|u_\lambda| > 1$, we have $|w_{\lambda,0}| = |u_\lambda - v_{\lambda,0}| = |(1-\chi_{\lambda,0})\, u_\lambda| = |u_\lambda| > 1$. So we have

$$\begin{aligned}
\left(\int_{\mathbb{R}^3} |w_{\lambda,0}|^{\frac{6}{p-1}}\ \mathrm{d}x\right)^{\frac{p-1}{6}} &= \left(\int_{\{x:|u_\lambda|\leq 1\}} |w_{\lambda,0}|^{\frac{6}{p-1}}\ \mathrm{d}x + \int_{\{x:|u_\lambda|>1\}} |w_{\lambda,0}|^{\frac{6}{p-1}}\ \mathrm{d}x\right)^{\frac{p-1}{6}} \\
&\leq \left(0 + \int_{\{x:|u_\lambda|>1\}} |w_{\lambda,0}|^{6}\ \mathrm{d}x\right)^{\frac{p-1}{6}} \\
&= \left(\int_{\mathbb{R}^3} |w_{\lambda,0}|^{6}\ \mathrm{d}x\right)^{\frac{p-1}{6}}.
\end{aligned}$$

Therefore, combining this with Minkowski inequality, we have

$$\begin{aligned}
\|h_{\lambda,0}\|_{\frac{6}{p-1}} &\leq \|g(\cdot, w_{\lambda,0})\|_{\frac{6}{p-1}} + \left\|K(\cdot)\phi^a_{u_\lambda} w_{\lambda,0}\right\|_{\frac{6}{p-1}} \\
&\leq \left(\int_{\mathbb{R}^3} |u_\lambda|^6\ \mathrm{d}x\right)^{\frac{p-1}{6}} + |K|_\infty \left|\phi^a_{u_\lambda}\right|_\infty \left(\int_{\mathbb{R}^3} |w_{\lambda,0}|^{\frac{6}{p-1}}\ \mathrm{d}x\right)^{\frac{p-1}{6}} \\
&\leq \left(\int_{\mathbb{R}^3} |u_\lambda|^6\ \mathrm{d}x\right)^{\frac{p-1}{6}} + |K|_\infty \left|\phi^a_{u_\lambda}\right|_\infty \left(\int_{\mathbb{R}^3} |w_{\lambda,0}|^{6}\ \mathrm{d}x\right)^{\frac{p-1}{6}} \\
&\leq C\,\|u_\lambda\|_E^{p-1}.
\end{aligned}$$

Now we define $v_{\lambda,1} = H_\lambda^{-1} l_{\lambda,0}$ and $w_{\lambda,1} = H_\lambda^{-1} h_{\lambda,0}$ so that $u_\lambda = v_{\lambda,1} + w_{\lambda,1}$. Then, there exists $C_2 > 0$ such that

$$|v_{\lambda,1}|_\infty \leq C_2 \quad \text{and} \quad \|w_{\lambda,1}\|_{p_1} \leq C_2$$

uniformly in λ; here $p_1 = \infty$ if $p_0 = \frac{6}{p-1} > \frac{3}{2}$, and p_1 is arbitrarily close to and less than $\frac{3p_0}{3-2p_0}$ if $p_0 \leq \frac{3}{2}$. In the case $p_0 > \frac{3}{2}$ we are done. In the case $p_0 \leq \frac{3}{2}$, we have $5 \leq p < 6$. Thus, we can assume that there is a positive constant $\delta \leq 1$ such that $p = 6 - \delta$. Let $\chi_{\lambda,1}$ be the characteristic function of the set

$$A_\lambda = \left\{x \in \mathbb{R}^3 : |w_{\lambda,1}(x)| \leq C_2 + 1\right\}.$$

Setting

$$\begin{aligned}
\bar{v}_{\lambda,1} &= \chi_{\lambda,1} u_\lambda = \chi_{\lambda,1}\left(v_{\lambda,1} + w_{\lambda,1}\right), \\
\bar{w}_{\lambda,1} &= u_\lambda - \bar{v}_{\lambda,1} = \left(1 - \chi_{\lambda,1}\right)\left(v_{\lambda,1} + w_{\lambda,1}\right), \\
l_{\lambda,1} &= g\left(\cdot, \bar{v}_{\lambda,1}\right) - K(\cdot)\phi^a_{u_\lambda}\bar{v}_{\lambda,1}, \\
h_{\lambda,1} &= g\left(\cdot, \bar{w}_{\lambda,1}\right) - K(\cdot)\phi^a_{u_\lambda}\bar{w}_{\lambda,1}.
\end{aligned}$$

We see that $|l_{\lambda,1}|_\infty$ is bounded uniformly in λ. In addition, since the measure of the set A_λ^c is finite and $\|w_{\lambda,1}\|_{p_1} \leq C_2$, we have $h_{\lambda,1}$ is bounded in $L^{\frac{p_1}{p-1}}(\mathbb{R}^3)$. Now repeating the above argument with $v_{\lambda,2} = H_\lambda^{-1} l_{\lambda,1}$ and $w_{\lambda,2} = H_\lambda^{-1} h_{\lambda,1}$, we obtain a constant $C_3 > 0$ such that

$$|v_{\lambda,2}|_\infty \leq C_3 \quad \text{and} \quad \|w_{\lambda,1}\|_{p_2} \leq C_3,$$

where $p_2 = \infty$ if $\bar{p}_1 = \frac{p_1}{p-1} > \frac{3}{2}$, and p_2 is arbitrarily close to and less than $\frac{3\bar{p}_1}{3-2\bar{p}_1}$ if $\bar{p}_1 \leq \frac{3}{2}$. Using the assumption $p = 6 - \delta, 0 < \delta \leq 1$ and after a finite number of such steps we get a uniform bounded for $|u_\lambda|_\infty$.

According to the definition of g and uniform boundedness of $\left|\phi^a_{u_\lambda}\right|_\infty$, we obtain that $A(x) = \frac{g(x,u_\lambda(x))}{u_\lambda(x)} + K(x)\phi^a_{u_\lambda}$ is bounded in $L^\infty(\mathbb{R})$. Moreover, the negative part of $W_\lambda =$

$\lambda V + V_0 - A$ is bounded uniformly in λ. It follows from Theorem A.2.1 in [16] that the norm of W_λ^- in the Kato class K_3 is bounded uniformly in λ. Therefore, Theorem C.1.2 in [16] implies that there is a constant $C(r)$ which is independent of λ such that

$$|u_\lambda(x)| \leq C(r) \int_{B_r(x)} |u_\lambda| \, \mathrm{d}x,$$

where $B_r(x)$ is a ball in $\mathbb{R}^3$ centered at x with radius r. From Lemma 3.3(b), as $n \to \infty$

$$u_\lambda \to 0 \quad \text{in } L^2\left(\mathbb{R}^3 \backslash \overline{\Omega}\right).$$

Thus, choosing $r = \frac{1}{2}\operatorname{dist}\left(\Omega, \mathbb{R}^3 \backslash \Omega'\right)$, we have uniformly in $x \in \mathbb{R}^3 \backslash \Omega'$,

$$\begin{aligned} |u_\lambda(x)| &\leq C(r) \int_{B_r(x)} |u_\lambda| \, \mathrm{d}x \\ &\leq C(r) \left(\operatorname{meas} B_r(x)\right)^{\frac{1}{2}} |u_\lambda|_{2, B_r(x)} \\ &\leq C(r) \left(\operatorname{meas} B_r(x)\right)^{\frac{1}{2}} |u_\lambda|_{2, \mathbb{R}^3 \backslash \Omega} \\ &\to 0 \quad \text{as } \lambda \to \infty. \end{aligned}$$

□

4 Nehari manifold and minimax arguments

Consider the following nonlinear problems for $j \in J$,

$$\begin{cases} -\Delta u + V_0(x) u = |u|^{p-2} u, & \text{in } \Omega_j, \\ u = 0, & \text{on } \partial\Omega_j \end{cases}$$

and

$$\begin{cases} -\Delta u + \left(\lambda V(x) + V_0(x)\right) u = |u|^{p-2} u, & \text{in } \Omega_j', \\ \dfrac{\partial u}{\partial n} = 0, & \text{on } \partial\Omega_j' \end{cases}$$

with their corresponding functionals

$$\begin{aligned} I_j(u) &= \frac{1}{2} \int_{\Omega_j} \left(|\nabla u|^2 + V_0(x) u^2\right) \mathrm{d}x - \frac{1}{p} \int_{\Omega_j} |u|^p \mathrm{d}x; \qquad H_0^1\left(\Omega_j\right) \to \mathbb{R}, \\ I_{\lambda,j}(u) &= \frac{1}{2} \int_{\Omega_j'} \left(|\nabla u|^2 + \left(\lambda V(x) + V_0(x)\right) u^2\right) \mathrm{d}x - \frac{1}{p} \int_{\Omega_j'} |u|^p \mathrm{d}x; \qquad H^1\left(\Omega_j'\right) \to \mathbb{R}. \end{aligned}$$

It is easy to check that both I_j and $I_{\lambda,j}$ possess the mountain pass geometry and satisfy the (PS) condition. On the other hand, the infimum of I_j and $I_{\lambda,j}$ on their Nehari manifold

$$\begin{aligned} \mathcal{N}_j &= \left\{u \in H_0^1\left(\Omega_j\right) \backslash \{0\} : \left(\nabla I_j(u), u\right) = 0\right\}, \\ \mathcal{N}_{\lambda,j} &= \left\{u \in H^1\left(\Omega_j'\right) \backslash \{0\} : \left(\nabla I_{\lambda,j}(u), u\right) = 0\right\} \end{aligned}$$

are achieved by some $\omega_j \in \mathcal{N}$ and $\omega_{\lambda,j} \in \mathcal{N}_{\lambda,j}$ respectively. By a standard argument, we can see that $\omega_j, \omega_{\lambda,j}$ are critical points of I_j and $I_{\lambda,j}$ separately. The critical values $c_j = I_j\left(\omega_j\right)$ and $c_{\lambda,j} = I_{\lambda,j}\left(\omega_{\lambda,j}\right)$ are equal to the mountain pass value of their corresponding functional. Moreover, we also have the following lemma (see Lemma 3.1 in [11] and (3.8) for details).

Lemma 4.1. *The following statements hold:*

(a) *there is a* $\rho > 0$ *such* $0 < \rho \leq c_{\lambda,j} \leq c_j$ *for* $\lambda \geq \Lambda_1$ *sufficiently large;*

(b) $c_j = \max\limits_{r>0} I_j\left(rw_j\right), c_{\lambda,j} = \max\limits_{r>0} I_{\lambda,j}\left(rw_{\lambda,j}\right)$*;*

(c) $c_{\lambda,j} \to c_j$ *as* $\lambda \to \infty$*;*

(d)

$$c_j = \inf\left\{I_j(v) : v \in H_0^1\left(\Omega_j\right), \int_{\Omega_j} |v|^p \mathrm{d}x = \left(\frac{1}{2} - \frac{1}{p}\right)^{-1} c_j\right\},$$
$$c_{\lambda,j} = \inf\left\{I_{\lambda,j}(v) : v \in H^1\left(\Omega_j'\right), \int_{\Omega_j'} |v|^p \mathrm{d}x = \left(\frac{1}{2} - \frac{1}{p}\right)^{-1} c_{\lambda,j}\right\}.$$

In the following, we give a minimax argument for $J_\lambda(u)$. First of all, we fix $R \geq 2$ such that

$$\begin{aligned} &I_j\left(R\omega_j\right) < 0, \\ &R^2 \left\|w_j\right\|_{\lambda,\Omega_j'}^2 = R^p \left|w_j\right|_p^p \geq 2\left(\frac{1}{2} - \frac{1}{p}\right)^{-1} c_j \end{aligned} \tag{4.1}$$

for all $j \in J$. By relabeling the indices, we could assume $J = \{1, 2, \ldots, l\}$ $(l \leq m)$. We define $\gamma_0 : [0,1]^l \to E$,

$$\gamma_0\left(t_1, t_2, \ldots, t_l\right)(x) = \sum_{j=1}^{l} t_j R\omega_j(x), \tag{4.2}$$

$$\Gamma_J = \left\{\gamma \in C\left([0,1]^l, E\right); \gamma\left(t_1, t_2, \ldots, t_l\right) = \gamma_0\left(t_1, t_2, \ldots, t_l\right), \left(t_1, t_2, \ldots, t_l\right) \in \partial\left([0,1]^l\right)\right\}$$

and

$$b_{\lambda,J} = \inf_{\gamma \in \Gamma_J} \max_{t \in [0,1]^l} J_\lambda(\gamma(t)).$$

Obviously, $\Gamma_J \neq \emptyset$ since $\gamma_0 \in \Gamma_J$. Thus $b_{\lambda,j}$ is well defined.

According to Lemma 3.3 in [11], by using a topological degree argument we can get the following conclusion.

Lemma 4.2. *For any* $\gamma \in \Gamma_J$*, there is a* $t_\gamma \in [0,1]^l$ *such that for* $j \in J$

$$\int_{\Omega_j'} \left|\gamma\left(t_\gamma\right)(x)\right|^p \mathrm{d}x = \left(\frac{1}{2} - \frac{1}{p}\right)^{-1} c_{\lambda,j}.$$

Lemma 4.3. $\sum_{j=1}^{l} c_{\lambda,j} \leq b_{\lambda,J} \leq \sum_{j=1}^{l} c_j + \mu$*, where*

$$\mu = \frac{R^4}{4} \sum_{j=1}^{l} \int_{\Omega_j} K(x) \phi^a_{\sum_{j=1}^{l} \omega_j}\left(\omega_j\right)^2 \mathrm{d}x. \tag{4.3}$$

Proof. According to Lemma 4.2, for any $\gamma \in \Gamma_J$, we have

$$\max_{t \in [0,1]^l} J_\lambda(\gamma(t)) \geq J_\lambda\left(\gamma\left(t_\gamma\right)\right) \geq J_{\lambda,\mathbb{R}^3 \backslash \Omega_J'}\left(\gamma\left(t_\gamma\right)\right) + \sum_{j=1}^{l} J_{\lambda,\Omega_j'}\left(\gamma\left(t_\gamma\right)\right),$$

where $J_{\lambda,\Omega_j'}(u)$ is defined by

$$J_{\lambda,\Omega_j'}(u)=\frac{1}{2}\int_{\Omega_j'}\left(|\nabla u|^2+\left(\lambda V(x)+V_0(x)u^2\right)\right)\mathrm{d}x+\frac{1}{4}\int_{\Omega_j'}K(x)\phi_u^a u^2\mathrm{d}x-\int_{\Omega_j'}G(x,u)\mathrm{d}x.$$

And the definition of $J_{\lambda,\mathbb{R}^3\backslash\Omega_j'}(u)$ is similar. According to Proposition 2.4 and the fact that $|G(x,t)|\le\frac{1}{2}\nu_0 t^2$ when $x\in\mathbb{R}^3\backslash\Omega_J'$, we get that

$$J_{\lambda,\mathbb{R}^3\backslash\Omega_j'}(u)\ge 0\quad\text{for } u\in E \text{ and } j\in J.$$

By using $\int_{\Omega_j'}K(x)\phi_u^a u^2\mathrm{d}x\ge 0$ and Lemma 4.1(d) we obtain

$$\begin{aligned}\max_{t\in[0,1]^l}J_\lambda(\gamma(t))&\ge\sum_{j=1}^{l}J_{\lambda,\Omega_j'}\left(\gamma\left(t_\gamma\right)\right)\ge\sum_{j=1}^{l}I_{\lambda,j}\left(\gamma\left(t_\gamma\right)\right)\\&\ge\sum_{j=1}^{l}\inf\left\{I_{\lambda,j}(v):v\in H^1\left(\Omega_j'\right),\int_{\Omega_j'}|v|^p\mathrm{d}x=\left(\frac{1}{2}-\frac{1}{p}\right)^{-1}c_{\lambda,j}\right\}\\&=\sum_{j=1}^{l}c_{\lambda,j}.\end{aligned}$$

According to the arbitrary choice of γ, we have $\sum_{j=1}^{l}c_{\lambda,j}\le b_{\lambda,J}$. On the other hand,

$$\begin{aligned}b_{\lambda,J}&\le\max_{t\in[0,1]^l}J_\lambda\left(\gamma_0(t)\right)\\&=\max_{t\in[0,1]^l}\sum_{j=1}^{l}I_j\left(t_jR\omega_j\right)+\frac{1}{4}\sum_{j=1}^{l}\int_{\Omega_j}K(x)\phi^a_{\sum_{j=1}^{l}t_jR\omega_j}\left(t_jR\omega_j\right)^2\mathrm{d}x\\&\le\sum_{j=1}^{l}c_j+\frac{R^4}{4}\sum_{j=1}^{l}\int_{\Omega_j}K(x)\phi^a_{\sum_{j=1}^{l}\omega_j}\left(\omega_j\right)^2\mathrm{d}x.\end{aligned}$$

Thus, we get the conclusion. □

In the following, we denote $\sum_{j=1}^{l}c_j$ by c_J. It is easy to see that, for $\gamma\in\Gamma_J,\gamma(t)=\gamma_0(t)$ on $\partial[0,1]^l$. So, for $t=(t_1,t_2,\ldots,t_l)\in\partial[0,1]^l$, one has

$$J_\lambda(\gamma(t))=J_\lambda\left(\gamma_0(t)\right)\le\sum_{j=1}^{l}I_j\left(t_jR\omega_j\right)+\frac{R^4}{4}\sum_{j=1}^{l}\int_{\Omega_j}K(x)\phi^a_{\sum_{j=1}^{l}\omega_j}\left(\omega_j\right)^2\mathrm{d}x.$$

Choosing k small enough such that

$$\frac{R^4}{4}\sum_{j=1}^{l}\int_{\Omega_j}K(x)\phi^a_{\sum_{j=1}^{l}\omega_j}\left(\omega_j\right)^2\mathrm{d}x\le\frac{1}{2}\min_{j\in J}c_j$$

when $|K|_\infty\le k$. Due to Lemma 4.1(b), $I_j\left(t_jR\omega_j\right)\le c_j$ for $j\in J$. But on the other hand, because of $t=(t_1,t_2,\ldots,t_l)\in\partial[0,1]^l$, there must be some $j_0\in J,t_{j_0}\in\{0,1\}$. Thus $I_{j_0}\le 0$. Hence

$$J_\lambda(\gamma(t))\le\sum_{j=1}^{l}c_j-c_{j_0}+\frac{1}{2}\min_{j\in J}c_j\le\sum_{j=1}^{l}c_j-\frac{1}{2}\rho.$$

By Lemma 4.3 and $c_{\lambda,j}\to c_j$ for $j\in J$, we have $b_{\lambda,j}\ge\sum_{j=1}^{l}c_j-\frac{1}{4}\rho$ when λ is sufficiently large. Combining this and the Palais-Smale condition of J_λ, we conclude that $b_{\lambda,J}$ is a critical value of J_λ by using a standard deformation argument. Therefore, we have

Corollary 4.4. *There exists $k>0$ such that when $|K|_\infty\le k, b_{\lambda,J}$ is a critical value of J_λ for large λ.*

5 Proof of Theorem 1.1

In this section, we find the so-called multi-bump solution u_λ.

Firstly, we define

$$D_\lambda^\nu = \left\{ u \in E : \|u\|_{\lambda,\mathbb{R}^3\backslash\Omega_J'} \le \nu, \left| \|u\|_{\lambda,\Omega_j'} - \sqrt{\left(\frac{1}{2}-\frac{1}{p}\right)^{-1} c_j} \right| \le \nu, \quad j \in J \right\},$$

and

$$J_\lambda^c = \{u \in E : J_\lambda(u) \le c\}.$$

Then we have

Lemma 5.1. *For $0 < \nu < \frac{1}{3}\min_{j\in J}\sqrt{\left(\frac{1}{2}-\frac{1}{p}\right)^{-1} c_j}$, there exist $k_1(\nu) > 0$ and $\sigma_0 > 0$, such that for $\lambda \ge \Lambda_1$ sufficiently large and $u \in \left(D_\lambda^{2\nu}\backslash D_\lambda^\nu\right) \cap J_\lambda^{c_J+\mu}$ we have*

$$\|\nabla J_\lambda(u)\|_\lambda \ge \sigma_0 \tag{5.1}$$

when $|K|_\infty < k(\nu)$. Here

$$\mu = \frac{R^4}{4}\sum_{j=1}^{l}\int_{\Omega_j} K(x)\phi^a_{\sum_{j=1}^l \omega_j}(\omega_j)^2\,\mathrm{d}x$$

is defined in (4.3).

Proof. If the conclusion is false, we can assume that there exists $u_n \in \left(D_{\lambda_n}^{2\nu}\backslash D_{\lambda_n}^\nu\right) \cap J_\lambda^{c_J+\mu}$ such that $\|\nabla J_{\lambda_n}(u_n)\|_{\lambda_n} \to 0, \lambda_n \to \infty$.

Since $(u_n) \subset J_{\lambda_n}^{c_J+\mu}$, according to Lemma 3.3, we have for some $u \in E$, $\|u_n - u\|_{\lambda_n} \to 0$ and

$$\begin{aligned} c_J + \mu &\ge \lim_{n\to\infty} J_{\lambda_n}(u_n) \\ &= \frac{1}{2}\int_{\Omega_J}\left(|\nabla u|^2 + V_0(x)u^2\right)\mathrm{d}x + \frac{1}{4}\int_{\Omega_J} K(x)\phi_u^a u^2 - \frac{1}{p}\int_{\Omega_J}|u|^p\mathrm{d}x \\ &= \sum_{j\in J}\frac{1}{2}\int_{\Omega_j}\left(|\nabla u|^2 + V_0(x)u^2\right)\mathrm{d}x + \frac{1}{4}\int_{\Omega_j} K(x)\phi_u^a u^2\mathrm{d}x - \frac{1}{p}\int_{\Omega_j}|u|^p\mathrm{d}x, \end{aligned}$$

where $u \equiv 0$ in $\mathbb{R}^3\backslash\Omega_J$, and $u_j = u|_{\Omega_j} \in H_0^1(\Omega_j)$ is the weak solutions of $-\Delta v + V_0(x)v + K(x)\phi_u^a v = |v|^{p-2}v$ in Ω_j for $j \in J$. Hence, if $u_j \ne 0, j \in J$ and $t_j u_j \in \mathcal{N}_j$, we have

$$\begin{aligned} &\frac{1}{2}\int_{\Omega_j}\left(|\nabla u_j|^2 + V_0(x)u_j^2\right)\mathrm{d}x + \frac{1}{4}\int_{\Omega_j} K(x)\phi_u^a u_j^2\mathrm{d}x - \frac{1}{p}\int_{\Omega_j}|u_j|^p\,\mathrm{d}x \\ &\quad = \max_{t>0}\frac{t^2}{2}\int_{\Omega_j}\left(|\nabla u_j|^2 + V_0(x)u_j^2\right)\mathrm{d}x + \frac{t^4}{4}\int_{\Omega_j} K(x)\phi_u^a u_j^2\mathrm{d}x - \frac{t^p}{p}\int_{\Omega_j}|u_j|^p\,\mathrm{d}x \\ &\quad \ge \frac{t_j^2}{2}\int_{\Omega_j}\left(|\nabla u_j|^2 + V_0(x)u_j^2\right)\mathrm{d}x + \frac{t_j^4}{4}\int_{\Omega_j} K(x)\phi_u^a u_j^2\mathrm{d}x - \frac{t_j^p}{p}\int_{\Omega_j}|u_j|^p\,\mathrm{d}x \\ &\quad \ge I_j(t_j u_j) \ge c_j. \end{aligned}$$

Thus, we have two possibilities:

(1) there exist some $j_0 \in J$ such $u_{j_0} = u|_{\Omega_{j_0}} = 0$;

(2) $\frac{1}{2}\int_{\Omega_j}\left(|\nabla u_j|^2+V_0(x)u_j^2\right)\mathrm{d}x+\frac{1}{4}\int_{\Omega_j}K(x)\phi_u^a u_j^2\mathrm{d}x-\frac{1}{p}\int_{\Omega_j}|u_j|^p\,\mathrm{d}x\in[c_j,c_j+\mu]$.

When (1) occurs, by Lemma 3.3(d) we obtain

$$\left|\|u_n\|_{\lambda_n,\Omega'_{j_0}}-\sqrt{\left(\frac{1}{2}-\frac{1}{p}\right)^{-1}c_{j_0}}\right|\to\sqrt{\left(\frac{1}{2}-\frac{1}{p}\right)^{-1}c_{j_0}}\geq 3\nu,$$

which contradicts to the assumption $u_n\in D^{2\nu}_{\lambda_n}\backslash D^{\nu}_{\lambda_n}$.

If (2) occurs, by Lemma 3.3(b), it is easy to check

$$\begin{aligned}&\left(\frac{1}{2}-\frac{1}{p}\right)\int_{\Omega_j}\left(|\nabla u_j|^2+V_0(x)u_j^2\right)\mathrm{d}x+\left(\frac{1}{4}-\frac{1}{p}\right)\int_{\Omega_j}K(x)\phi_u^a u_j^2\mathrm{d}x\\&\quad=\frac{1}{2}\int_{\Omega_j}\left(|\nabla u_j|^2+V_0(x)u_j^2\right)\mathrm{d}x+\frac{1}{4}\int_{\Omega_j}K(x)\phi_u^a u_j^2\mathrm{d}x-\frac{1}{p}\int_{\Omega_j}|u_j|^p\,\mathrm{d}x.\end{aligned}$$

Thus,

$$\left(\frac{1}{2}-\frac{1}{p}\right)\int_{\Omega_j}\left(|\nabla u|^2+V_0(x)u^2\right)\mathrm{d}x+\left(\frac{1}{4}-\frac{1}{p}\right)\int_{\Omega_j}K(x)\phi_u^a u^2\mathrm{d}x\in\left[c_j,c_j+\mu\right].$$

Since $\|u\|_E\leq M\,(c_J+\mu)$, we can choose $k_1(\nu)>0$ such that for $j\in J$,

(1) $\mu\leq 1$ and $\sqrt{\left(\frac{1}{2}-\frac{1}{p}\right)^{-1}(c_j+\mu)}\leq\sqrt{\left(\frac{1}{2}-\frac{1}{p}\right)^{-1}c_j}+\nu$;

(2) $\left[\left(\frac{1}{2}-\frac{1}{p}\right)^{-1}c_j-\left(\frac{1}{2}-\frac{1}{p}\right)^{-1}\left(\frac{1}{4}-\frac{1}{p}\right)\int_{\Omega_j}K(x)\phi_u^a u^2\mathrm{d}x\right]^{1/2}\geq\sqrt{\left(\frac{1}{2}-\frac{1}{p}\right)^{-1}c_j}-\nu$, when $|K|_\infty<k_1(\nu)$.

Hence we have $\left|\left(\int_{\Omega_j}(|\nabla u|^2+V_0(x)u^2)\mathrm{d}x\right)^{1/2}-\sqrt{\left(\frac{1}{2}-\frac{1}{p}\right)^{-1}c_j}\right|\leq\nu$. By Lemma 3.3 again we get that $u_n\in D^{2\nu}_{\lambda_n}$ as n is large, which is a contradiction. □

Lemma 5.2. *For $0<\nu<\frac{1}{3}\min_{j\in J}\left(\frac{1}{2}-\frac{1}{p}\right)c_j$, there exists $k(\nu)>0$, such that for $\lambda\geq\Lambda_1$ sufficiently large,* (1.1) *possesses a solution satisfying $u_\lambda\in D^\nu_\lambda$ when $|K|_\infty<k(\nu)$.*

Proof. If the conclusion is false, we assume that J_λ has no critical point in $D^\nu_\lambda\cap J_\lambda^{c_J+\mu}$, here μ is defined as that in Lemma 5.1. Since J_λ satisfies the Palais–Smale condition (see Lemma 3.2), there is a constant $\sigma_\lambda>0$ such that

$$\|\nabla J_\lambda(u)\|_\lambda\geq\sigma_\lambda,\qquad u\in D^\nu_\lambda\cap J_\lambda^{c_J+\mu}.$$

By (5.1) there holds, for $\lambda\geq\Lambda_1$ and $|K|_\infty\leq k_1(\nu)$,

$$\|\nabla J_\lambda(u)\|_\lambda\geq\sigma_0,\qquad u\in\left(D^{2\nu}_\lambda\backslash D^\nu_\lambda\right)\cap J_\lambda^{c_J+\mu}.$$

Combining these, we could define a Lipschitz continuous function $\theta:E\to[0,1]$ such that $\theta(u)=1$ for $u\in D^{3\nu/2}_\lambda;\theta(u)=0$ for $u\notin D^{2\nu}_\lambda$. Then, the vector field

$$V:J_\lambda^{c_J+\mu}\to E,V(u)=-\theta(u)\frac{\nabla J_\lambda(u)}{\|\nabla J_\lambda(u)\|_\lambda}$$

is well defined and Lipschitz continuous. And moreover

$$\|V(u)\|_\lambda\leq 1,\qquad u\in E. \tag{5.2}$$

Now we consider the associated gradient flow $\eta : [0,+\infty) \times J_\lambda^{c_J+\mu} \to J_\lambda^{c_J+\mu}$ defined by

$$\frac{\mathrm{d}}{\mathrm{d}s}\eta = V(\eta), \qquad \eta(0,u) = u.$$

By a standard argument, one can show that

$$\frac{\mathrm{d}}{\mathrm{d}s} J_\lambda(\eta(s,u)) = -\theta(u) \left\| \nabla J_\lambda(u) \right\|_\lambda \leq 0 \tag{5.3}$$

and

$$\eta(s,u) = u, \qquad s \geq 0, \quad u \in J_\lambda^{c_J+\mu} \backslash D_\lambda^{2\nu}. \tag{5.4}$$

Recalling $\gamma_0 \in \Gamma_J$, a path which is defined by (4.2). Because of (4.1), we have that

$$\gamma_0(t) \notin D_\lambda^{2\nu}, \qquad t \in \partial[0,1]^l.$$

Therefore, by using (5.4), we have

$$\eta\left(s,\gamma_0(t)\right) = \gamma_0(t), \qquad t \in \partial[0,1]^l.$$

Thus, $\eta\left(s,\gamma_0(\cdot)\right) \in \Gamma_J$ for any $s \geq 0$.

Since $\operatorname{supp}\gamma_0 \subset \bigcup_{j\in J}\overline{\Omega_j}$ for $t \in [0,1]^l$, thus $J_\lambda\left(\gamma_0(t)\right)$ and $\|\gamma_0(t)\|^2_{\lambda,\Omega_j'}$ do not depend on $\lambda \geq 0$. Considering about

$$m_0 = \max\left\{ J_\lambda(u) : u \in \gamma_0\left([0,1]^l\right) \backslash D_\lambda^\nu \right\}, \tag{5.5}$$

we also have that m_0 does not depend on $\lambda \geq 0$. Furthermore, we claim that there exists $k(\nu) > 0$ such that

$$m_0 < c_J \tag{5.6}$$

when $|K|_\infty \leq k(\nu)$. In fact, for any $u = \sum_{j=1}^l t_j R\omega_j \in \gamma_0\left([0,1]^l\right) \backslash D_\lambda^\nu$, there must exists some $j_0 \in J$ such that

$$\left| t_{j_0} R \left\|\omega_{j_0}\right\|_{\lambda,\Omega_j'} - \sqrt{\left(\frac{1}{2} - \frac{1}{p}\right)^{-1} c_{j_0}} \right| > \nu.$$

According to the definition of ω_{j_0}, we know that $\|\omega_{j_0}\|^2_{\lambda,\Omega_j'} = \left(\frac{1}{2} - \frac{1}{p}\right)^{-1} c_{j_0}$. Thus, $\left|t_{j_0}R - 1\right| > \left(\frac{1}{2} - \frac{1}{p}\right)^{\frac{1}{2}} c_{j_0}^{-\frac{1}{2}}\nu$. So there exists $\delta(\nu) > 0$ such that

$$\frac{t_{j_0}^2 R^2}{2} \int_{\Omega_j} \left(\left|\nabla\omega_{j_0}\right|^2 + V_0(x)\omega_{j_0}^2\right) \mathrm{d}x - \frac{t_{j_0}^p R^p}{p} \int_{\Omega_j} \left|\omega_{j_0}\right|^p \mathrm{d}x < c_{j_0} - \delta(\nu).$$

And consequently,

$$\begin{aligned} J_\lambda(u) &= \sum_{j=1}^l I_j\left(t_j R\omega_j\right) + \frac{1}{4}\sum_{j=1}^l \int_{\Omega_j} K(x)\phi_u^a \left(t_j R\omega_j\right)^2 \mathrm{d}x \\ &< \sum_{j=1}^l c_j - \delta(\nu) + \frac{R^4}{4}\sum_{j=1}^l \int_{\Omega_j} K(x)\phi^a_{\sum_{j=1}^l \omega_j} \omega_j^2 \mathrm{d}x. \end{aligned}$$

Obviously, there is a $k(\nu) > 0$ such that

$$\frac{R^4}{4}\sum_{j=1}^{l}\int_{\Omega_j} K(x)\phi^a_{\sum_{j=1}^{l}\omega_j}\omega_j^2 dx < \frac{1}{2}\delta(\nu) \quad \text{for } |K|_\infty \le k(\nu).$$

Thus, $J_\lambda(u) < c_J - \frac{1}{2}\delta(\nu)$ and we show the claim.

Next, we prove that there is $k(\nu) > 0$ such that for some $S > 0$ and $|K|_\infty < k(\nu)$,

$$\max_{t\in[0,1]^l} J_\lambda\left(\eta\left(S,\gamma_0(t)\right)\right) \le \max\left\{m_0, c_J - \frac{1}{4}\sigma_0\nu\right\}. \tag{5.7}$$

If this is true, according to Lemma 4.3 and $\eta\left(S,\gamma_0(\cdot)\right) \in \Gamma_J$ we have

$$\sum_{j=1}^{l} c_{\lambda,j} \le b_{\lambda,J} \le \max_{t\in[0,1]^L} J_\lambda\left(\eta\left(S,\gamma_0(t)\right)\right) \le \max\left\{m_0, c_J - \frac{1}{4}\sigma_0\nu\right\} < c_J,$$

which contradicts to the fact $\sum_{j=1}^{l} c_{\lambda,j} \to c_J$. Thus, we obtain the lemma.

Next, we want to prove (5.7). Setting $u = \gamma_0(t) \in E$, if $u \notin D_\lambda^\nu$, because of (5.3) and (5.5), $J_\lambda(\eta(s,u)) \le J_\lambda(u) \le m_0$ for all $s \ge 0$. If $u \in D_\lambda^\nu$, we consider two possibilities:

(1) $\eta(s,u) \in D_\lambda^{3\nu/2}$ for all $s \in [0,S]$;

(2) $\eta(s,u) \in \partial D_\lambda^{3\nu/2}$ for some $s_0 \in [0,S]$.

When (1) occurs, we have $\theta(\eta(s,u)) = 1$ and $\|\nabla J_\lambda(\eta(s,u))\|_\lambda \ge \min\{\sigma_0,\sigma_\lambda\}$ when $|K|_\infty \le k_1(\nu)$ and $\lambda \ge \Lambda_1$ (see Lemma 5.1). Thus, setting $S = \frac{\sigma_0\nu}{2\min\{\sigma_0,\sigma_\lambda\}}$, by (5.3)

$$\begin{aligned} J_\lambda(\eta(S,u)) &= J_\lambda(u) + \int_0^S \frac{d}{ds} J_\lambda(\eta(s,u))ds \\ &= J_\lambda(u) - \int_0^S \theta(\eta(s,u))\left\|\nabla J_\lambda(\eta(s,u))\right\|_\lambda ds \\ &\le c_J + \mu - S\min\{\sigma_0,\sigma_\lambda\} \\ &= c_J + \mu - \frac{1}{2}\sigma_0\nu. \end{aligned} \tag{5.8}$$

When (2) occurs, there exist $0 < s_1 < s_2 \le S$ such that

$$\begin{aligned} &\eta\left(s_1,u\right) \in \partial D_\lambda^\nu, \\ &\eta\left(s_2,u\right) \in \partial D_\lambda^{3\nu/2}, \\ &\eta(s,u) \in D_\lambda^{3\nu/2}\backslash D_\lambda^\nu, s \in \left(s_1,s_2\right]. \end{aligned} \tag{5.9}$$

So we have, for some $j_0 \in J$,

$$\left\|\eta\left(s_2,u\right)\right\|_{\lambda,\mathbb{R}^3\backslash\Omega'_J} = \frac{3}{2}\nu \quad \text{or} \quad \left|\left\|\eta\left(s_2,u\right)\right\|_{\lambda,\Omega'_{j_0}} - \sqrt{\left(\frac{1}{2}-\frac{1}{p}\right)^{-1} c_{j_0}}\right| = \frac{3}{2}\nu.$$

We only see the latter case and the former one can be dealt with by a similar method. Following from (5.9), we have

$$\left|\left\|\eta\left(s_1,u\right)\right\|_{\lambda,\Omega'_{j_0}} - \sqrt{\left(\frac{1}{2}-\frac{1}{p}\right)^{-1} c_{j_0}}\right| \le \nu,$$

$$
\begin{aligned}
\|\eta(s_2,u)-\eta(s_1,u)\|_{\lambda,\Omega'_{j_0}} &\geq \left| \|\eta(s_2,u)\|_{\lambda,\Omega'_{j_0}} - \sqrt{\left(\frac{1}{2}-\frac{1}{p}\right)^{-1} c_{j_0}} \right| \\
&\quad - \left| \|\eta(s_1,u)\|_{\lambda,\Omega'_{j_0}} - \sqrt{\left(\frac{1}{2}-\frac{1}{p}\right)^{-1} c_{j_0}} \right| \\
&\geq \frac{1}{2}\nu.
\end{aligned}
$$

This implies $\|\eta(s_2,u)-\eta(s_1,u)\|_{\lambda} \geq \frac{1}{2}\nu$.

According to (5.2), $\left\|\frac{\mathrm{d}}{\mathrm{d}s}\eta\right\|_{\lambda} = \|V(\eta)\|_{\lambda} \leq 1$. Hence

$$
\frac{1}{2}\nu \leq \|\eta(s_2,u)-\eta(s_1,u)\|_{\lambda} \leq \left\| \int_{s_1}^{s_2} \frac{\mathrm{d}\eta}{\mathrm{d}s}\mathrm{d}s \right\|_{\lambda} \leq \int_{s_1}^{s_2} \left\| \frac{\mathrm{d}\eta}{\mathrm{d}s} \right\|_{\lambda} \mathrm{d}s \leq s_2 - s_1.
$$

According to (5.1), we have

$$
\begin{aligned}
J_\lambda(\eta(S,u)) &= J_\lambda(u) - \int_0^S \theta(\eta(s,u)) \,\|\nabla J_\lambda(\eta(s,u))\|_\lambda \,\mathrm{d}s \\
&\leq c_J + \mu - \int_{s_1}^{s_2} \sigma_0 \mathrm{d}s \\
&\leq c_J + \mu - \frac{1}{2}\sigma_0\nu.
\end{aligned} \tag{5.10}
$$

Then, we can choose $k(\nu) > 0$ such that $\mu \leq \frac{1}{4}\sigma_0\nu$ if $|K|_\infty \leq k(\nu)$. Combining with (5.8) and (5.10) we get (5.7). And hence J_λ possesses a critical point u_λ in D_λ^ν for $\lambda \geq \Lambda_1$ and $|K|_\infty \leq k(\nu)$. According to Lemma 3.4, we know that u_λ is a solution of (1.1). □

Proof of Theorem 1.1. Setting $u_{\lambda_n}(\lambda_n \to \infty)$ be a sequence of solutions of (1.1) obtained by the procedure above. Then, they are critical points of J_{λ_n} with critical value bounded by $c_J + \mu$. According to Lemma 3.3, we get the conclusion. □

Received 30 May 2023, appeared 8 February 2024
Communicated by Miklós Horváth

Abstract. This paper deals with necessary and sufficient conditions for weak and strong minimizers of functionals $\Phi(u) = \int_a^b f(x, u(x), u'(x))\, dx$, where $u \in C^1([a, b], \mathbb{R}^N)$. We first derive conditions which are simpler than the known ones, and then apply them to several particular problems, including stability problems in the elasticity theory. In particular, we solve some open problems in [A. Majumdar, A. Raisch, Stability of twisted rods, helices and buckling solutions in three dimensions, *Nonlinearity* **27**(2014), 2841–2867] by finding optimal conditions for the stability of a naturally straight Kirchhoff rod under various types of endpoint constraints.

Keywords: minimizer, natural boundary conditions, conjugate points, field of extremals, elastica.

2020 Mathematics Subject Classification: 49K05, 74K10, 74G65, 34B15.

1 Introduction

This paper deals with necessary and sufficient conditions for local minimizers of one-dimensional variational problems for vector-valued functions. We consider the functional

$$\Phi : C^1([a, b], \mathbb{R}^N) \to \mathbb{R} : u \mapsto \int_a^b f(x, u(x), u'(x))\, dx, \tag{1.1}$$

where $-\infty < a < b < \infty$, $u = (u_1, u_2, \dots, u_N)$, and the Lagrangian[1]

$$f : [a, b] \times \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{R} : (x, u, p) \mapsto f(x, u, p)$$

is sufficiently smooth ($f \in C^3$ or $f \in C^2$). We also fix a function $u^0 \in C^1([a, b], \mathbb{R}^N)$ and (possibly empty) subsets $I_a^{\mathcal{D}}, I_b^{\mathcal{D}}$ of the index set $I := \{1, 2, \dots, N\}$, and we look for conditions guaranteeing that u^0 is a local minimizer of Φ in the set

$$\mathcal{M} := \{u \in C^1([a, b], \mathbb{R}^N) : (u_i - u_i^0)(a) = 0 \text{ for } i \in I_a^{\mathcal{D}},\ (u_i - u_i^0)(b) = 0 \text{ for } i \in I_b^{\mathcal{D}}\}. \tag{1.2}$$

✉ Email: quittner@fmph.uniba.sk

[1] As in [8, pp. 11–12], by u we denote both the functions $[a, b] \to \mathbb{R}^N$ and the independent variable in $\mathbb{R}^N$, and by p we denote the last argument of f; see also similar notation $L(t, x(t), \dot{x}(t))$ vs. $L(t, x, v)$ in [15], for example.

This means that at $x = a$ we consider Dirichlet endpoint constraints for the components u_i with $i \in I_a^{\mathcal{D}}$, while the endpoints of the remaining components u_j with $j \in I \setminus I_a^{\mathcal{D}}$ are free; similarly for $x = b$. It is well known (see Proposition 2.1) that if u^0 is a local minimizer of this problem, then u^0 has to satisfy the natural boundary conditions

$$\frac{\partial f}{\partial p_j}(a, u^0(a), (u^0)'(a)) = 0 \quad \text{for } j \notin I_a^{\mathcal{D}} \quad \text{and} \quad \frac{\partial f}{\partial p_j}(b, u^0(b), (u^0)'(b)) = 0 \quad \text{for } j \notin I_b^{\mathcal{D}}.$$

We say that u^0 is a weak (or strong, resp.) local minimizer if there exists $\varepsilon > 0$ such that $\Phi(u^0) \leq \Phi(u)$ for any $u \in \mathcal{M}$ satisfying $\|u - u^0\|_{C^1} < \varepsilon$ (or $\|u - u^0\|_C < \varepsilon$, resp.), where $\|\cdot\|_{C^1}$ and $\|\cdot\|_C$ are the usual norms in C^1 and C, respectively (see Definition 2.2 and the subsequent comments for more details). If u^0 is a steady state of a mechanical system with potential energy Φ, and u^0 is a weak (or strong) local minimizer of Φ, then u^0 is stable with respect to perturbations which are small in C^1 (or C), respectively. On the other hand, if u^0 is not a minimizer, then u^0 is unstable.

If $I_a^{\mathcal{D}} = I_b^{\mathcal{D}} = I$, i.e. if one considers the Dirichlet endpoint constraints for all components and both ends, then necessary and sufficient conditions for u^0 to be a minimizer belong to the classical results in the calculus of variations, see [5,7,8], for example. They are based on the Jacobi theory (conjugate points) or the Weierstrass theory (field of extremals and excess function). In the general case such conditions are also known (see [15,16] and the references therein, and cf. also [17]); however, they use the notion of a *coupled point* which is more complicated than the classical notion of a *conjugate point*. This might be the reason why – as far as the author is aware – that general theory has not yet been applied in the elasticity theory, for example. In the scalar case, another approach to problems with variable endpoints (and a special class of Lagrangians) can be found in [12] but the conditions there are even more complicated than those in [15,16]. Reference [12] has been cited by several papers dealing with problems in the elasticity theory: Some of those papers use the complicated theory in [12] for scalar problems with special Lagrangians (see [10], for example), some use various ad-hoc estimates to obtain at least partial results in the vector-valued case (when the theory in [12] does not seem to apply, see [11], for example) and some refrain from considering variable endpoints because of the complexity of the theory in [12], see [3], for example, where the authors write: "…the application of the conjugate point test with nonclamped ends is a delicate issue …". Difficulties arising in a scalar problem with variable endpoints have also been analyzed in [14], for example.

The main purpose of this paper is to derive simple conditions for u^0 to be a minimizer, and to show how they can be applied to particular problems.

In Section 3 we derive necessary and sufficient conditions for weak minimizers by modifying the Jacobi theory (see Theorem 3.4 and also Remark 7.1 for the comparison of our conditions with those in [15,16]). In Section 4 we use the results from Section 3 to find optimal conditions for the stability of a naturally straight Kirchhoff rod under various types of endpoint constraints. The reasons for this particular application are the following:

- We show that our general results can easily be applied to vector-valued problems in the elasticity theory.
- We solve some open problems (and correct an erroneous result) in [11].
- We show how the choice of endpoint constraints influences the stability of the rod.

In Section 5 we use the Weierstrass theory to derive conditions for weak, strong and global minimizers, see Theorem 5.2. In this case we restrict our applications in Section 6 to the scalar case $N = 1$. The reason for this restriction is the following: If $N = 1$ and the Lagragian f is independent of its first variable x, then the phase plane analysis of the corresponding Du Bois-Reymond equation yields a very simple and efficient way to prove (or disprove) the existence of a suitable field of extremals; hence it is sufficient to verify the nonnegativity of the excess function in order to check our conditions. In particular, this approach does not require the verification of sufficient conditions based on the Jacobi theory and it can be used even if we do not know an explicit formula for u^0. In Section 6 we first determine the stability of a planar weightless inextensible and unshearable rod (see Example 6.3). This problem has already been analyzed in [1,10], for example, but our analysis is simpler than that in [10] and more complete than that in [1]. The notions of weak and strong minimizers are equivalent for functionals Φ in Section 4 and Example 6.3 (see Remark 4.2(vi) and Proposition 2.3, respectively). To illustrate various interesting features of minimizers in a more general case and demonstrate the applicability of our theory, in Example 6.5 we consider Lagrangians of the form $f(u, p) = u^2 + g(p)$, where g is a double-well function. In particular, the corresponding functional can possess both strong (even global) minimizers and minimizers which are weak but not strong.

Some of our results in the scalar case $N = 1$ have been obtained in the Master thesis [2].

2 Preliminaries

Throughout this paper we will use the symbols $\Phi, f, u^0, a, b, N, I, I_a^{\mathcal{D}}$ and $I_b^{\mathcal{D}}$ introduced in the Introduction. The partial derivatives of f will be denoted by $f_x, f_{u_i}, f_{p_i}, f_{p_i p_j}, \dots$

Given $\mathfrak{f} \in \{f, f_x, f_{u_i}, f_{p_i}, f_{p_i p_j}, \dots\}$, we will use the notation[2]

$$\mathfrak{f}^0(x) := \mathfrak{f}(x, u^0(x), (u^0)'(x)).$$

If $x \in \{a, b\}$ and W is a space of functions $[a, b] \to \mathbb{R}^N$, then we set

$$\begin{aligned} I_x^{\mathcal{N}} &:= I \setminus I_x^{\mathcal{D}}, \\ \mathbb{R}^N_{\mathcal{D},x} &:= \{\xi \in \mathbb{R}^N : \xi_i = 0 \text{ for } i \in I_x^{\mathcal{D}}\}, \\ \mathbb{R}^N_{\mathcal{N},x} &:= \{\xi \in \mathbb{R}^N : \xi_i = 0 \text{ for } i \in I_x^{\mathcal{N}}\}, \\ W_{\mathcal{D},x} &:= \{v \in W : v(x) \in \mathbb{R}^N_{\mathcal{D},x}\}, \\ W_{\mathcal{D}} &:= W_{\mathcal{D},a} \cap W_{\mathcal{D},b}. \end{aligned}$$

In particular, if $W = C^1 = C^1([a, b], \mathbb{R}^N)$, then

$$C^1_{\mathcal{D}} = \{v \in C^1([a, b], \mathbb{R}^N) : v_i(a) = 0 \text{ for } i \in I_a^{\mathcal{D}},\ v_i(b) = 0 \text{ for } i \in I_b^{\mathcal{D}}\} \tag{2.1}$$

is the space of C^1-test functions. (Notice that the set $\mathcal{M}$ in (1.2) satisfies $\mathcal{M} = u^0 + C^1_{\mathcal{D}}$.)

The norm in a general Banach space X will be denoted by $\|\cdot\|_X$; the norm in $W^{1,2}$ will also be denoted by $\|\cdot\|_{1,2}$. In particular, if $X = C^1 = C^1([a, b], \mathbb{R}^N)$ or $X = C = C([a, b], \mathbb{R}^N)$, then $\|u\|_{C^1} = \max_{x\in[a,b]} |u(x)| + \max_{x\in[a,b]} |u'(x)|$ or $\|u\|_C = \max_{x\in[a,b]} |u(x)|$, respectively, where $|u(x)|$ denotes the Euclidean norm of $u(x) \in \mathbb{R}^N$. We also set $B_\varepsilon := \{\xi \in \mathbb{R}^N : |\xi| < \varepsilon\}$.

[2]The superscript 0 in $\mathfrak{f}^0$ denotes evaluation of $\mathfrak{f}$ along the reference arc u^0; cf. similar notation $\hat{L}(t) = L(t, \hat{x}(t), \dot{\hat{x}}(t))$ in [15] or $\bar{\mathfrak{f}}(x) = \mathfrak{f}(x, u(x), u'(x))$ in [8, formulas (30), (39) in Section 2.3, pp. 114–116]. The advantages of our notation will become evident in Section 6: See the notation introduced in Theorem 6.1.

We will assume that u^0 is a critical point of Φ in the set $u^0 + C^1_{\mathcal{D}}$, i.e. $\Phi'(u^0)h = 0$ for any test function $h \in C^1_{\mathcal{D}}$, where Φ' denotes the Fréchet derivative of Φ. The following proposition is well known, but for the reader's convenience we explain the idea of its proof in the Appendix.

Proposition 2.1. *Let $f \in C^1$ and let u^0 be a critical point of Φ in $u^0 + C^1_{\mathcal{D}}$. Then u^0 is an extremal (i.e. it satisfies the Euler equations $\frac{d}{dx}(f^0_{p_i}) = f^0_{u_i}$, $i = 1, 2, \dots, N$), and u^0 also has to satisfy the natural boundary conditions*

$$f^0_{p_j}(a) = 0 \ \text{for} \ j \in I^{\mathcal{N}}_a \quad \text{and} \quad f^0_{p_j}(b) = 0 \ \text{for} \ j \in I^{\mathcal{N}}_b. \tag{2.2}$$

If $f_{p_i} \in C^1$ for $i = 1, 2, \dots, N$, and the strengthened Legendre condition

$$(\exists c^0 > 0) \qquad \sum_{i,j=1}^{N} f^0_{p_i p_j}(x)\xi_i\xi_j \geq c^0|\xi|^2, \qquad \xi \in \mathbb{R}^N, \ x \in [a,b], \tag{2.3}$$

is true, then $u^0 \in C^2$.

It is known that the Legendre condition (i.e. condition (2.3) with $c^0 = 0$) is necessary for u^0 to be a minimizer, but even the strengthened Legendre condition is not sufficient, in general. Assuming that

$$f \in C^3 \text{ satisfies (2.3), where } u^0 \in C^1([a,b], \mathbb{R}^N) \text{ is an extremal satisfying (2.2),} \tag{2.4}$$

and denoting $\sum_k = \sum_{k=1}^N$, we set

$$\Psi(h) := \int_a^b \mathfrak{F}(x, h(x), h'(x))\, dx, \quad h \in W^{1,2}([a,b], \mathbb{R}^N), \tag{2.5}$$

where

$$\mathfrak{F} = \mathfrak{F}(x,u,p) := \sum_{i,j} \Big(f^0_{p_i p_j}(x) p_i p_j + f^0_{p_i u_j}(x) p_i u_j + f^0_{u_i p_j}(x) u_i p_j + f^0_{u_i u_j}(x) u_i u_j \Big). \tag{2.6}$$

If $h \in C^1$, then $\Psi(h) = \Phi''(u^0)(h,h)$, i.e. Ψ is the second variation of Φ at u^0. In addition, if $h \in C^2$, then integration by parts yields

$$\Psi(h) = \int_a^b \sum_i (\mathcal{A}_i h) h_i \, dx + \sum_i (\mathcal{B}_i h) h_i \Big|_a^b, \tag{2.7}$$

where

$$\mathcal{A}_i h := -\frac{d}{dx}(\mathcal{B}_i h) + \mathcal{C}_i h, \quad \mathcal{B}_i h := \sum_j \Big(f^0_{p_i p_j} h'_j + f^0_{p_i u_j} h_j \Big), \quad \mathcal{C}_i h := \sum_j \Big(f^0_{u_i p_j} h'_j + f^0_{u_i u_j} h_j \Big). \tag{2.8}$$

Set also

$$\mathcal{A}h := (\mathcal{A}_1 h, \dots, \mathcal{A}_N h), \quad \mathcal{B}h := (\mathcal{B}_1 h, \dots \mathcal{B}_N h), \quad f_p := (f_{p_1}, \dots, f_{p_N}), \quad f_u = (f_{u_1}, \dots, f_{u_N}).$$

The (vector-valued) second-order linear differential equation $\mathcal{A}h = 0$ is called the *Jacobi* equation (for Φ and u^0): it will play a fundamental role in the study of positive definiteness of Ψ. Notice also that the Jacobi equation is the Euler equation for functional Ψ. More precisely, by using the symmetry relations $f_{p_i p_j} = f_{p_j p_i}$, $f_{p_i u_j} = f_{u_j p_i}$ and $f_{u_i u_j} = f_{u_j u_i}$ we obtain

$$\mathfrak{F}_{p_i}(x, h(x), h'(x)) = 2\mathcal{B}_i h(x), \quad \mathfrak{F}_{u_i}(x, h(x), h'(x)) = 2\mathcal{C}_i h(x), \tag{2.9}$$

hence

$$2\mathcal{A}_i h(x) = -\frac{d}{dx}\mathfrak{F}_{p_i}(x,h(x),h'(x)) + \mathfrak{F}_{u_i}(x,h(x),h'(x)). \tag{2.10}$$

Notice also that, given $h, w \in W^{1,2}$, (2.9) and the symmetry of the second-order derivatives of f mentioned above imply

$$\begin{aligned}\Psi'(h)w &= \int_a^b \sum_i \big(\mathfrak{F}_{p_i}(x,h(x),h'(x))w_i'(x) + \mathfrak{F}_{u_i}(x,h(x),h'(x))w_i(x)\big)\,dx \\ &= 2\int_a^b \sum_i \big(\mathcal{B}_i h\cdot w_i' + \mathcal{C}_i h\cdot w_i\big)\,dx = 2\int_a^b \sum_i \big(\mathcal{B}_i w\cdot h_i' + \mathcal{C}_i w\cdot h_i\big)\,dx = \Psi'(w)h.\end{aligned} \tag{2.11}$$

Definition 2.2. Let $w \in \mathcal{M}$, where $\mathcal{M}$ is a subset of $C^1([a,b],\mathbb{R}^N)$. The function w is called a *weak* or *strong local minimizer* in $\mathcal{M}$ if there exists $\varepsilon > 0$ such that $\Phi(v) \geq \Phi(w)$ for any $v \in \mathcal{M}$ satisfying $\|v-w\|_{C^1} < \varepsilon$ or $\|v-w\|_C < \varepsilon$, respectively.

Let $w \in \mathcal{N}$, where $\mathcal{N}$ is a subset of $W^{1,2}([a,b],\mathbb{R}^N)$. The function w is called a *local minimizer* in $\mathcal{N}$ if there exists $\varepsilon > 0$ such that $\Phi(v) \geq \Phi(w)$ for any $v \in \mathcal{N}$ satisfying $\|v\|_{1,2} < \varepsilon$.

If the inequalities $\Phi(v) \geq \Phi(w)$ in the definitions above are strict for $v \neq w$, then the minimizer w is called *strict*.

Since the adjectives *weak* and *strong* are not meaningful in the case of global minimizers, we often omit the word “local” in the notions of weak and strong local minimizers. Each strong minimizer is a weak minimizer but the opposite is not true, in general. For example, if $N = 1$ and $f(x,u,p) = p^2 + p^3$, then $u^0 \equiv 0$ is a weak but not strong minimizer of Φ in $u^0 + C^1_{\mathcal{D}}$ for any choice of $a, b, I_a^{\mathcal{D}}$ and $I_b^{\mathcal{D}}$ (see also Example 6.5 for a less trivial example). On the other hand, the following Proposition 2.3 and Remark 4.2(vi) show that in some cases the notions of weak and strong minimizers are equivalent. The choice of the class of Lagrangians in Proposition 2.3 is motivated by Example 6.3, where we consider the stability of a planar rod. Proposition 2.3 is true for any choice of $a, b, I_a^{\mathcal{D}}$ and $I_b^{\mathcal{D}}$; its proof is postponed to the Appendix.

Proposition 2.3. *Let $N = 1$ and $f(x,u,p) = (p-K)^2 + g(u)$, where $K \in \mathbb{R}$ and $g \in C^1(\mathbb{R})$. If $u^0 \in C^1$ is a weak minimizer, then it is a strong minimizer.*

The following proposition is a consequence of well known facts (see [5,8], for example). The assumptions in that proposition are much stronger than necessary, but the proposition will be sufficient for our purposes (see Remark 4.2(vi), Section 6 and the proof of Proposition 3.5).

Proposition 2.4.

(i) Let $f \in C^k$, $k \geq 2$.

If $u^0 \in C^1$ is a critical point of Φ in $u^0 + C^1_{\mathcal{D}}$ and (2.3) is true, then $u^0 \in C^k$ and u^0 satisfies the Du Bois-Reymond equation

$$\frac{d}{dx}\big(f^0 - (u^0)'\cdot f^0_p\big) = f^0_x \quad \text{in } [a,b]. \tag{2.12}$$

Conversely, if $u^0 \in C^2$ satisfies (2.12) and $(u^0)' \neq 0$ a.e., then u^0 is an extremal.

(ii) Let $f \in C^1$ satisfy the growth condition $(1+|p|)|f_p| + |f_u| \leq M(|u|)(1+|p|)^2$, where $M : [0,\infty) \to [0,\infty)$ is nondecreasing. Then $\Phi \in C^1(W^{1,2})$. In addition, if $u^0 \in W^{1,2}$ is a local minimizer of Φ in $u^0 + W^{1,2}_{\mathcal{D}}$, then there exists $C \in \mathbb{R}^N$ such that

$$f^0_p(x) = \int_a^x f^0_u(\xi)\,d\xi + C \quad \text{for a.e. } x \in [a,b].$$

3 Jacobi theory

In this section we will prove necessary and sufficient conditions for weak minimizers by modifying the classical Jacobi theory. Throughout this section we assume (2.4).

The following proposition is well known, but for the reader's convenience we provide its proof in the Appendix.

Proposition 3.1. *Assume* (2.4) *and let* Ψ *be defined by* (2.5).

(i) If Ψ *is positive definite in* $W^{1,2}_{\mathcal{D}}$*, then* u^0 *is a strict weak minimizer in* $u^0 + C^1_{\mathcal{D}}$.

(ii) If $\Psi(h) < 0$ *for some* $h \in W^{1,2}_{\mathcal{D}}$*, then* u^0 *is not a weak minimizer in* $u^0 + C^1_{\mathcal{D}}$.

We will consider the scalar case first. Assume that

$$h \text{ is a nontrivial solution of the Jacobi equation } \mathcal{A}h = 0. \tag{3.1}$$

Then the following classical result for problems with Dirichlet endpoint constraints is well known.

Theorem 3.2. *Assume* (2.4) *with* $N = 1$ *and* (3.1)*. Let* $I^{\mathcal{N}}_a = I^{\mathcal{N}}_b = \emptyset$ *and* $h(a) = 0$.

(i) If $h(y) = 0$ *for some* $y \in (a, b)$*, then* u^0 *is not a weak minimizer.*

(ii) If $h(y) \neq 0$ *for any* $y \in (a, b]$*, then* u^0 *is a strict weak minimizer.*

Our analogue in the case of variable endpoints is the following theorem.

Theorem 3.3. *Assume* (2.4) *with* $N = 1$ *and* (3.1)*. Let* $I^{\mathcal{N}}_a = I^{\mathcal{N}}_b = \{1\}$ *and* $\mathcal{B}h(a) = 0$.

(i) If $h(y) = 0$ *for some* $y \in (a, b]$ *or* $\mathcal{B}h(b)h(b) < 0$*, then* u^0 *is not a weak minimizer.*

(ii) If $h(y) \neq 0$ *for any* $y \in (a, b]$ *and* $\mathcal{B}h(b)h(b) > 0$*, then* u^0 *is a strict weak minimizer.*

In fact, a slight generalization of Theorem 3.3(ii) has been proved in [2]: The initial condition $\mathcal{B}h(a) = 0$ can be replaced with $\mathcal{B}h(a)h(a) \leq 0$. Unfortunately, the method of the proof in [2] does not seem to be easily extendable to the vector-valued case.

Theorems 3.2 and 3.3 are special cases of the following general theorem.

Theorem 3.4. *Assume* (2.4)*. Let* $h^{(1)}, \dots, h^{(N)}$ *be linearly independent solutions of the Jacobi equation* $\mathcal{A}h = 0$ *satisfying the initial conditions* $h(a) \in \mathbb{R}^N_{\mathcal{D},a}$*,* $\mathcal{B}h(a) \in \mathbb{R}^N_{\mathcal{N},a}$*. Set*

$$D(x) := \det(h^{(1)}(x), \dots, h^{(N)}(x)), \quad H := \operatorname{span}(h^{(1)}, \dots, h^{(N)}), \quad H_0 := \{h \in H : h(b) = 0\}.$$

(i) *If* $D(x) = 0$ *for some* $x \in (a, b)$ *or*

$$I^{\mathcal{N}}_b \neq \emptyset \;\; \text{and} \;\; \mathcal{B}h(b) \cdot h(b) < 0 \text{ for some } h \in H_{\mathcal{D},b},$$

then u^0 *is not a weak minimizer.*

(ii) *If* $D \neq 0$ *in* $(a, b]$ *and*

$$\text{either} \;\; I^{\mathcal{N}}_b = \emptyset \;\; \text{or} \;\; \mathcal{B}h(b) \cdot h(b) > 0 \text{ for any } h \in H_{\mathcal{D},b} \setminus \{0\},$$

then u^0 *is a strict weak minimizer.*

(iii) *Let* $D \neq 0$ *in* (a,b), $D(b) = 0$ *(hence* $H_0 \neq \{0\}$*), and* $I_b^{\mathcal{N}} \neq \emptyset$. *If*

$$\text{there exists } h \in H_0 \text{ such that } \mathcal{B}_i h(b) \neq 0 \text{ for some } i \in I_b^{\mathcal{N}}, \tag{3.2}$$

then u^0 *is not a weak minimizer. If* $I_b^{\mathcal{D}} = \emptyset$, *then* (3.2) *is always true.*

The proof of Theorem 3.4 is based on a modification of the classical Jacobi theory, and this is also true in the case of the corresponding proof in [16]. However, our conditions in Theorem 3.4 are simpler than those in [15,16], see Remark 7.1 in the Appendix.

In order to prove Theorem 3.4, we need some preparation. Given $y \in (a,b]$, let

$$X_y := \{h \in W^{1,2}([a,b],\mathbb{R}^N) : h(a) \in \mathbb{R}^N_{\mathcal{D},a},\ h(x) = 0 \text{ for } x \geq y\}$$

be endowed with the norm $\|h\|_{X_y} := (\int_a^b \sum_{i,j} f^0_{p_ip_j} h'_i h'_j \, dx)^{1/2}$ (which is equivalent to the standard norm in $W^{1,2}$ for $h \in X_y$ due to (2.3) and the boundary condition $h(b) = 0$), and let S_y denote the unit sphere in X_y. If $\tilde{y} \in (y,b]$, then $X_y \subset X_{\tilde{y}}$, hence $S_y \subset S_{\tilde{y}}$. Set also

$$\lambda_1 = \lambda_1(y) := \inf_{h \in S_y} \Psi(h) = 1 + \inf_{h \in S_y} \hat{\Psi}(h), \tag{3.3}$$

where

$$\hat{\Psi}(h) := \int_a^b \sum_{i,j} \Big(f^0_{p_iu_j} h'_i h_j + f^0_{u_ip_j} h_i h'_j + f^0_{u_iu_j} h_i h_j \Big)\, dx.$$

Since $S_y \subset S_{\tilde{y}}$ if $y < \tilde{y}$, the function λ_1 is nonincreasing. In addition, one can easily show that λ_1 is continuous, and the estimate

$$\begin{aligned} |h(x)| &= \Big| \int_x^y h'(\xi)\, d\xi \Big| \leq \Big(\int_x^y |h'(\xi)|^2 \, d\xi \Big)^{1/2} \sqrt{y-x} \\ &\leq \frac{1}{\sqrt{c^0}} \Big(\int_a^b \sum_{i,j} f^0_{p_ip_j} h'_i h'_j \, d\xi \Big)^{1/2} \sqrt{y-a} = \frac{1}{\sqrt{c^0}} \sqrt{y-a} \end{aligned}$$

for $h \in S_y$ and $x \in (a,y)$ implies $\lim_{y \to a+} \lambda_1(y) = 1$.

Proposition 3.5. *Let* D *be as in Theorem 3.4 and* $y \in (a,b]$.

(i) *If* $\lambda_1(y) = 0$, *then* $D(y) = 0$ *and* $\lambda_1(z) < 0$ *for* $z \in (y,b]$. *If* $D(y) = 0$, *then* $\lambda_1(y) \leq 0$.

(ii) *If* $h \in X_b$, *then* $\Psi(h) \geq \lambda_1(b)\|h\|^2_{X_b}$. *If* $\lambda_1(b) < 0$, *then there exists* $h \in X_b$ *such that* $\Psi(h) < 0$.

Proof. Let $\lambda_1(y) = 0$ and let B_y denote the closed unit ball in X_y. Since $\hat{\Psi}$ is weakly sequentially continuous, there exists $h_y \in B_y$ such that $\hat{\Psi}(h_y) = \inf_{B_y} \hat{\Psi} = -1$. We have $h_y \in S_y$ (otherwise $th_y \in B_y$ for some $t > 1$, and $\hat{\Psi}(th_y) = t^2 \hat{\Psi}(h_y) < \inf_{B_y} \hat{\Psi}$, which yields a contradiction). Since $\Psi(h_y) = \inf_{S_y} \Psi = 0$, h_y is a global minimizer of Ψ in X_y. Notice that $\mathfrak{F} \in C^1$ satisfies the growth condition

$$(1+|p|)|\mathfrak{F}_p(x,u,p)| + |\mathfrak{F}_u(x,u,p)| \leq C(1+|p|)(|u|+|p|) \leq 2C(1+|u|^2)(1+|p|^2),$$

where C depends only on the sup-norm of $f^0_{p_ip_j}, f^0_{p_iu_j}, f^0_{u_ip_j}, f^0_{u_iu_j}$, hence Proposition 2.4(ii) and (2.9) imply

$$2\mathcal{B}_i h_y(x) = \mathfrak{F}_{p_i}(x, h_y(x), h'_y(x)) = \int_a^x \mathfrak{F}_{u_i}(\xi, h_y(\xi), h'_y(\xi))\, d\xi + c_i = \int_a^x 2\mathcal{C}_i h_y \, d\xi + c_i \tag{3.4}$$

for a.e. $x \in [a,y]$. Since the right-hand side of (3.4) is a continuous function of x, $f \in C^3$ and (2.3) is true (hence the matrix $f^0_{p_ip_j}$ is invertible and the inverse matrix is a continuous function of x), we see that the restriction of h_y to $[a,y]$ is C^1. Denote this restriction by $\bar h_y$ and set $C^1_y := \{w \in C^1([a,y]) : w(a) \in \mathbb{R}^N_{\mathcal{D},a},\ w(y) = 0\}$, $\Psi_y(h) = \int_a^y \mathfrak{F}(x,h(x),h'(x))\,dx$. Then $\bar h_y$ is a critical point of Ψ_y in $\bar h_y + C^1_y = C^1_y$. Now Proposition 2.1, (2.10) and (2.9) imply that $\bar h_y$ is C^2, it satisfies the Jacobi equation $\mathcal{A}h = 0$ in $[a,y]$ and the natural boundary conditions $\mathcal{B}h(a) \in \mathbb{R}^N_{\mathcal{N},a}$. Since we also have $h_y(a) \in \mathbb{R}^N_{\mathcal{D},a}$, there exists $\alpha \in \mathbb{R}^N \setminus \{0\}$ such that $h_y = \sum_k \alpha_k h^{(k)}$ on $[a,y]$, where $h^{(k)}$ are as in Theorem 3.4. Since $h_y(y) = 0$, we have $D(y) = 0$.

Next assume on the contrary that $\lambda_1(y) = 0 = \lambda_1(z)$ for some $z \in (y,b]$. Then the minimizer h_y is a global minimizer of Ψ in X_z. Similarly as above we deduce that $h_y \in C^2([a,z])$ and h_y solves the Jacobi equation in $[a,z]$. Consequently, $h_y(y) = h'_y(y) = 0$, which yields a contradiction with the uniqueness of solutions of the initial value problem for the Jacobi equation.

Next assume that $D(y) = 0$. Then there exists $\alpha = (\alpha_1,\dots,\alpha_N) \in \mathbb{R}^N \setminus \{0\}$ such that $h := \sum_k \alpha_k h^{(k)}$ satisfies $h(y) = 0$, hence if we set $\tilde h(x) := h(x)$ for $x \le y$ and $\tilde h(x) := 0$ otherwise, then $\tilde h \in X_y$. In addition, using $\mathcal{A}_i h = 0$, $\mathcal{B}_i h(a) \in \mathbb{R}^N_{\mathcal{N},a}$, $h(a) \in \mathbb{R}^N_{\mathcal{D},a}$ and $h(y) = 0$ we obtain

$$\Psi(\tilde h) = \int_a^b \mathfrak{F}(x,\tilde h(x),\tilde h'(x))\,dx = \int_a^y \mathfrak{F}(x,h(x),h'(x))\,dx = \int_a^y \sum_i (\mathcal{A}_i h)h_i\,dx + \sum_i (\mathcal{B}_i h)h_i\Big|_a^y = 0,$$

hence $\lambda_1(y) \le 0$.

If $h \in X_b \setminus \{0\}$, then $\Psi(h) = \|h\|^2_{X_b}\Psi(h/\|h\|_{X_b}) \ge \lambda_1(b)\|h\|^2_{X_b}$ by the definition of λ_1. If $\lambda_1(b) < 0$, then the definition of λ_1 implies the existence of $h \in S_b$ such that $\Psi(h) < 0$. □

Proof of Theorem 3.4. We will show that

$$\text{the assumptions in (i) (or (iii)) imply } \Psi(h) < 0 \text{ for some } h \in W^{1,2}_{\mathcal{D}}, \tag{3.5}$$

while

$$\text{the assumptions in (ii) guarantee that } \Psi \text{ is positive definite in } W^{1,2}_{\mathcal{D}}, \tag{3.6}$$

hence the assertions in Theorem 3.4 will follow from Proposition 3.1.

(i) If $D(x) = 0$ for some $x \in (a,b)$, then Proposition 3.5(i) implies $\lambda_1(x) \le 0$ and $\lambda_1(b) < 0$, hence Proposition 3.5(ii) implies the existence of $h \in X_b \subset W^{1,2}_{\mathcal{D}}$ such that $\Psi(h) < 0$.

If $I^{\mathcal{N}}_b \ne \emptyset$ and $\mathcal{B}h(b) \cdot h(b) < 0$ for some $h \in H_{\mathcal{D},b} \subset W^{1,2}_{\mathcal{D}}$, then $\mathcal{A}h = 0$, $h_i(a) = 0$ for $i \in I^{\mathcal{D}}_a$ and $\mathcal{B}_i h(a) = 0$ for $i \in I^{\mathcal{N}}_a$, hence (2.7) implies

$$\Psi(h) = \mathcal{B}h \cdot h\Big|_a^b = \mathcal{B}h(b) \cdot h(b) < 0.$$

(ii) Assume that $D \ne 0$ in $(a,b]$. Then Proposition 3.5 implies $\lambda_1(b) > 0$ and $\Psi(h) \ge \lambda_1(b)\|h\|^2_{X_b}$ for $h \in X_b$. If $I^{\mathcal{N}}_b = \emptyset$, then $X_b = W^{1,2}_{\mathcal{D}}$, hence we are done.

Next assume that $I^{\mathcal{N}}_b \ne \emptyset$ and $\mathcal{B}\tilde h(b) \cdot \tilde h(b) > 0$ for any $\tilde h \in H_{\mathcal{D},b} \setminus \{0\}$ (hence $\mathcal{B}\tilde h(b) \cdot \tilde h(b) \ge c_1\|\tilde h\|^2_{1,2}$ for some $c_1 > 0$ due to $\dim H_{\mathcal{D},b} < \infty$), and let $h \in W^{1,2}_{\mathcal{D}}$ be fixed. Since $D(b) \ne 0$, there exists $\alpha \in \mathbb{R}^N$ such that $\tilde h := \sum_k \alpha_k h^{(k)}$ satisfies $\tilde h(b) = h(b)$. In particular, $\tilde h \in H_{\mathcal{D},b}$. Set $\hat h := h - \tilde h$. Then $\hat h \in X_b$, hence $\Psi(\hat h) \ge \lambda_1(b)\|\hat h\|^2_{X_b}$. In addition, $\Psi(\tilde h) = \mathcal{B}\tilde h(b) \cdot \tilde h(b) \ge c_1\|\tilde h\|^2_{1,2}$. Since Ψ is a quadratic functional, we have $\Psi''(\tilde h)(\hat h,\hat h) = 2\Psi(\hat h)$ and $\Psi''' = 0$. Using (2.11) and integration by parts we also obtain

$$\Psi'(\hat h)\tilde h = \Psi'(\tilde h)\hat h = 2\int_a^b \mathcal{A}\tilde h \cdot \hat h\,dx + 2\mathcal{B}\tilde h \cdot \hat h\Big|_a^b = 0,$$

hence there exists $c > 0$ such that

$$\Psi(h) = \Psi(\tilde{h} + \hat{h}) = \Psi(\tilde{h}) + \Psi'(\tilde{h})\hat{h} + \frac{1}{2}\Psi''(\tilde{h})(\hat{h}, \hat{h}) = \Psi(\tilde{h}) + \Psi(\hat{h}) \geq c\|h\|_{1,2}^2.$$

(iii) Let $h \in H_0$ and $\mathcal{B}_i h(b) \neq 0$ for some $i \in I_b^{\mathcal{N}}$. Then $\mathcal{A}h = 0$, $h(a) \in \mathbb{R}^N_{\mathcal{D},a}$, $\mathcal{B}h(a) \in \mathbb{R}^N_{\mathcal{N},a}$ and $h(b) = 0$, hence

$$\Psi(h) = \int_a^b \mathcal{A}h \cdot h\,dx + \mathcal{B}h \cdot h\Big|_a^b = 0.$$

Notice also that $h \neq 0$ due to $\mathcal{B}_i h(b) \neq 0$. Since $D \neq 0$ in (a, b), $D(b) = 0$, $\lim_{y \to a+} \lambda_1(y) = 1$ and λ_1 is continuous and nonincreasing, Proposition 3.5(i) implies $\lambda_1(b) = 0$, hence h is a global minimizer of Ψ in X_b. Choose $\tilde{h} \in C^1_{\mathcal{D}}$ with $\tilde{h}(a) = 0$, $\tilde{h}_j(b) = \delta_{ij}$ for $j = 1, 2, \ldots, N$. Then

$$\Psi'(h)\tilde{h} = 2\int_a^b \mathcal{A}h \cdot \tilde{h}\,dx + 2\mathcal{B}h \cdot \tilde{h}\Big|_a^b = 2\mathcal{B}_i h(b) \neq 0,$$

hence

$$\Psi(h + \varepsilon\tilde{h}) = \varepsilon\Psi'(h)\tilde{h} + o(\varepsilon) < 0$$

provided $|\varepsilon|$ is small enough and $\varepsilon\mathcal{B}_i h(b) < 0$.

If $I_b^{\mathcal{D}} = \emptyset$ and $h \in H_0 \setminus \{0\}$, then $\mathcal{A}h = 0$ and $h(b) = 0$, hence the uniqueness of the initial value problem for the Jacobi equation implies the existence of $i \in I_b^{\mathcal{N}} = I$ such that $\mathcal{B}_i h(b) \neq 0$. □

Remark 3.6.

(i) If Ψ is positive semidefinite but not positive definite, then there exists $h^* \in W^{1,2}_{\mathcal{D}} \setminus \{0\}$ such that $0 = \Psi(h^*) = \inf_{W^{1,2}_{\mathcal{D}}} \Psi$ and h^* can be determined from our analysis. For example, if $N = 1$ and $I_a^{\mathcal{D}} = I_b^{\mathcal{D}} = \emptyset$ (cf. Theorem 3.3), then h^* is a positive (or negative) solution of the Jacobi equation satisfying $\mathcal{B}h^*(a) = \mathcal{B}h^*(b) = 0$. If Φ depends smoothly on a parameter θ, u^0 is a critical point of Φ for any θ, and u^0 is (or is not, respectively) a weak minimizer for $\theta > \theta^*$ (or $\theta < \theta^*$, respectively), then the critical parameter θ^* corresponds to the case where h^* exists. (Such situation occurs, for example, in the study of stability of a twisted rod in Section 4.) In this case one can expect bifurcation for the problem $\Phi'(u) = 0$ at $\theta = \theta^*$ in the direction of h^*, cf. [6, Theorem 5.6].

(ii) Let $h^{(k)}$, $k = 1, 2, \ldots, N$, be as in Theorem 3.4, $\xi \in \mathbb{R}^N$ and $h^\xi := \sum_k \xi_k h^{(k)}$. Set $\mathfrak{A} := (a_{kl})_{k,l=1}^N$, where $a_{kl} = \mathcal{B}h^{(k)}(b) \cdot h^{(l)}(b)$, and

$$\Xi_{\mathcal{D}} := \{\xi \in \mathbb{R}^N : h^\xi(b) \in \mathbb{R}^N_{\mathcal{D},b}\}.$$

Then $\mathcal{B}h^\xi(b) \cdot h^\xi(b) = \mathfrak{A}\xi \cdot \xi$, i.e. the condition $\mathcal{B}h(b) \cdot h(b) > 0$ for any $h \in H_{\mathcal{D},b} \setminus \{0\}$ in Theorem 3.4(ii), for example, is equivalent to $\mathfrak{A}\xi \cdot \xi > 0$ for any $\xi \in \Xi_{\mathcal{D}} \setminus \{0\}$. In particular, if $I_b^{\mathcal{D}} = \emptyset$ (and $D(b) \neq 0$), then that condition is equivalent to the positive definiteness of the matrix $\mathfrak{A}$. Notice also that $a_{kl} = a_{lk}$ due to $2a_{kl} = \Psi'(h^{(k)})h^{(l)}$ and $\Psi'(h^{(k)})h^{(l)} = \Psi'(h^{(l)})h^{(k)}$.

(iii) Assertions (3.6) or (3.5) show that some of the assumptions in Theorem 3.4 are sufficient for the positivity or the negativity of Ψ, respectively. We will show that those assumptions are also necessary, at least in some cases.

Let Ψ be positive definite in $W^{1,2}_{\mathcal{D}}$. Since $X_b \subset W^{1,2}_{\mathcal{D}}$, Ψ is also positive definite in X_b and Proposition 3.5(i) implies $D \neq 0$ in $[a,b]$. If $I^{\mathcal{N}}_b \neq \emptyset$ and $h \in H_{\mathcal{D},b} \setminus \{0\}$, then $h \in W^{1,2}_{\mathcal{D}}$, $\mathcal{B}h(a) \in \mathbb{R}^N_{\mathcal{N},a}$, $\mathcal{A}h = 0$, hence

$$0 < \Psi(h) = \int_a^b \mathcal{A}h \cdot h\,dx + \mathcal{B}h \cdot h\Big|_a^b = \mathcal{B}h(b) \cdot h(b),$$

so that the assumptions in Theorem 3.4(ii) are satisfied. This fact and (3.6) show that the positive definiteness of Ψ in $W^{1,2}_{\mathcal{D}}$ and the assumptions of Theorem 3.4(ii) are equivalent.

Let $\Psi(\bar{h}) < 0$ for some $\bar{h} \in W^{1,2}_{\mathcal{D}}$ and

$$I^{\mathcal{D}}_b = \emptyset \quad \text{or} \quad I^{\mathcal{N}}_b = \emptyset. \tag{3.7}$$

Assume that the assumptions of Theorem 3.4(i) are not satisfied. Then $D \neq 0$ in (a,b) (hence $\lambda_1(b) \geq 0$ due to Proposition 3.5(i)) and either $I^{\mathcal{N}}_b = \emptyset$ or $\mathcal{B}h(b) \cdot h(b) \geq 0$ for any $h \in H_{\mathcal{D},b}$. If $I^{\mathcal{N}}_b = \emptyset$, then $W^{1,2}_{\mathcal{D}} = X_b$, hence $\Psi \geq 0$ in $W^{1,2}_{\mathcal{D}}$, which is a contradiction. Consequently, $I^{\mathcal{N}}_b \neq \emptyset$, $\mathcal{B}h(b) \cdot h(b) \geq 0$ for any $h \in H_{\mathcal{D},b}$ and $I^{\mathcal{D}}_b = \emptyset$ (due to (3.7)). If $D(b) \neq 0$, then there exists $\tilde{h} \in H_{\mathcal{D},b}$ such that $\tilde{h}(b) = \bar{h}(b)$. Set $\hat{h} := \bar{h} - \tilde{h} \in X_b$. Then similarly as in the proof of Theorem 3.4(ii) we obtain

$$0 > \Psi(\bar{h}) = \Psi(\tilde{h} + \hat{h}) = \Psi(\tilde{h}) + \Psi(\hat{h}) \geq \mathcal{B}\tilde{h}(b) \cdot \tilde{h}(b) + \lambda_1(b)\|\hat{h}\|^2_{X_b} \geq 0,$$

which is a contradiction. Consequently, $D(b) = 0$. Since $I^{\mathcal{D}}_b = \emptyset$ implies (3.2), all assumptions of Theorem 3.4(iii) are satisfied. These considerations and (3.5) show that if (3.7) is true, then the condition $\Psi(\bar{h}) < 0$ for some $\bar{h} \in W^{1,2}_{\mathcal{D}}$ is satisfied if and only if the assumptions of Theorem 3.4(i) or the assumptions of Theorem 3.4(iii) are satisfied. □

4 Stability of a twisted rod

In this section we use Theorem 3.4 in order to determine the stability of an unbuckled state of an inextensible, unshearable, isotropic Kirchhoff rod. Under suitable assumptions the strain energy of the rod is given by

$$\Phi(u) = \int_0^1 \left(\frac{A}{2}\big((u_1')^2 + (u_2')^2 \sin^2 u_1\big) + \frac{C}{2}(u_3' + u_2' \cos u_1)^2 + FL^2 \sin u_1 \cos u_2 \right) dx,$$

where u_1, u_2, u_3 are so called Euler angles describing the orientation of the director basis, $A, C > 0$ are constants, L is the rod-length and $F \in \mathbb{R}$ is an external terminal load; the rod is oriented horizontally (along the x axis), see [11, (9)]. The unbuckled state is given by $u^0(x) := (\frac{\pi}{2}, 0, 2\pi Mx)$ where M is a twist parameter. Notice that u^0 is an extremal satisfying the natural boundary conditions $f^0_{p_i}(x) = 0$ for $i = 1,2$ and $x = 0,1$. The stability of u^0 was studied in [11] under the Dirichlet boundary conditions $u_3(x) = u_3^0(x)$ for $x = 0,1$, and one of the following sets of boundary conditions for u_1, u_2:

$$u_1(0) = u_1(1) = \pi/2, \qquad u_2(0) = u_2(1) = 0, \tag{4.1}$$

$$u_1(0) = u_1(1) = \pi/2, \qquad u_2'(0) = u_2'(1) = 0, \tag{4.2}$$

$$u_1'(0) = u_1'(1) = 0, \qquad u_2'(0) = u_2'(1) = 0. \tag{4.3}$$

The results in [11] are essentially optimal in case (4.1), but the results in cases (4.2) and (4.3) are only partial, leaving several open problems. Notice that the Neumann boundary conditions are not the same as the natural boundary conditions in general (see [13] for related issues), but one can easily show (see Proposition 7.2 and Remark 7.3 in the Appendix) that the problem of stability of u^0 considered in [11] in cases (4.2) and (4.3) is equivalent to the question whether u^0 is a weak minimizer of Φ in $u^0 + C^1_{\mathcal{D}}$ with $I_0^{\mathcal{N}} = I_1^{\mathcal{N}} = \{2\}$ and $I_0^{\mathcal{N}} = I_1^{\mathcal{N}} = \{1,2\}$, respectively; hence we can use Theorem 3.4 in order to solve those problems. In fact, we will consider all possible subsets $I_0^{\mathcal{N}}, I_1^{\mathcal{N}}$ of $\{1,2\}$, and in each case we will find the borderline between the stability and instability (i.e. between the situations when u^0 is and is not a weak minimizer, respectively). On the other hand, we will always assume $3 \in I_0^{\mathcal{D}} \cap I_1^{\mathcal{D}}$, i.e. we will always consider the Dirichlet boundary conditions for the third component u_3.

In order to have a more graphic notation, given $I_0^{\mathcal{N}}, I_1^{\mathcal{N}} \subset \{1,2\}$, we denote the corresponding case by $\binom{c_0^1 c_1^1}{c_0^2 c_1^2}$, where $c_j^i = \mathcal{N}$ if $i \in I_j^{\mathcal{N}}$, $c_j^i = \mathcal{D}$ if $i \in I_j^{\mathcal{D}}$, $i = 1,2$, $j = 0,1$. For example, $\binom{\mathcal{D}\mathcal{D}}{\mathcal{N}\mathcal{N}}$ corresponds to the case $I_0^{\mathcal{N}} = I_1^{\mathcal{N}} = \{2\}$, i.e. (4.2), and $\binom{\mathcal{N}\mathcal{N}}{\mathcal{N}\mathcal{N}}$ corresponds to the case $I_0^{\mathcal{N}} = I_1^{\mathcal{N}} = \{1,2\}$, i.e. (4.3). Set also

$$\alpha := \frac{2\pi CM}{A}, \quad \beta := -\frac{FL^2}{A}, \quad \gamma := \sqrt{\left|\beta - \frac{1}{4}\alpha^2\right|}, \quad \delta := \frac{\alpha}{2}, \quad \theta := \frac{2\gamma\delta}{\gamma^2 + \delta^2}. \tag{4.4}$$

We will show that we may assume $\alpha > 0$, and for any $\binom{c_0^1 c_1^1}{c_0^2 c_1^2}$ with $c_j^i \in \{\mathcal{D}, \mathcal{N}\}$ we will find a function $g = g^{c_0^1 c_1^1}_{c_0^2 c_1^2} : (0,\infty) \to \mathbb{R} : \alpha \mapsto \beta$ which describes the borderline between stability and instability. In the particular cases (4.1), (4.2) and (4.3) we will also use the notation

$$g_D := g^{\mathcal{D}\mathcal{D}}_{\mathcal{D}\mathcal{D}}, \quad g_M := g^{\mathcal{D}\mathcal{D}}_{\mathcal{N}\mathcal{N}}, \quad \text{and} \quad g_N := g^{\mathcal{N}\mathcal{N}}_{\mathcal{N}\mathcal{N}},$$

respectively (the notation g_M reflects the fact that case (4.2) is called "Mixed" in [11, (13)]).

Proposition 4.1. *Let u^0 be as above, $\alpha > 0$, and let $I_0^{\mathcal{N}}, I_1^{\mathcal{N}} \subset \{1,2\}$ be fixed. Then there exists a continuous function $g : (0,\infty) \to \mathbb{R}$ having the properties mentioned above, i.e. if $\beta > g(\alpha)$ (or $\beta < g(\alpha)$, resp.), then u^0 is a strict weak minimizer (or is not a weak minimizer, resp.).*

(i) *Let $I_0^{\mathcal{D}} \cap \{1,2\} \neq \emptyset \neq I_1^{\mathcal{D}} \cap \{1,2\}$. Then*

$$g^{\mathcal{D}\mathcal{D}}_{\mathcal{N}\mathcal{D}} = g^{\mathcal{D}\mathcal{D}}_{\mathcal{D}\mathcal{N}} = g^{\mathcal{D}\mathcal{N}}_{\mathcal{D}\mathcal{D}} = g^{\mathcal{N}\mathcal{D}}_{\mathcal{D}\mathcal{D}}, \quad g^{\mathcal{D}\mathcal{N}}_{\mathcal{N}\mathcal{D}} = g^{\mathcal{N}\mathcal{D}}_{\mathcal{D}\mathcal{N}}, \quad g^{\mathcal{D}\mathcal{D}}_{\mathcal{N}\mathcal{N}} = g^{\mathcal{N}\mathcal{N}}_{\mathcal{D}\mathcal{D}} (= g_M), \tag{4.5}$$

$$\left.\begin{aligned} g_D(\alpha) &= \frac{\alpha^2}{4} - \pi^2, \quad g^{\mathcal{D}\mathcal{D}}_{\mathcal{N}\mathcal{D}}(\alpha) = \frac{\alpha^2}{4} - \frac{\pi^2}{4}, \\ g^{\mathcal{D}\mathcal{N}}_{\mathcal{N}\mathcal{D}}(\alpha) &= (k + \tfrac{1}{2})\pi(\alpha - (k + \tfrac{1}{2})\pi) \ \text{ if } \alpha \in [2k\pi, 2(k+1)\pi], \quad k = 0,1,2,\ldots, \\ g_M(\alpha) &= k\pi(\alpha - k\pi) \qquad\qquad \text{ if } \alpha \in [(2k-1)\pi, (2k+1)\pi],\ k = 0,1,2,\ldots. \end{aligned}\right\} \tag{4.6}$$

(ii) *Let either $I_0^{\mathcal{D}} \cap \{1,2\} = \emptyset$ or $I_1^{\mathcal{D}} \cap \{1,2\} = \emptyset$. Then*

$$g^{\mathcal{N}\mathcal{D}}_{\mathcal{N}\mathcal{D}} = g^{\mathcal{D}\mathcal{N}}_{\mathcal{D}\mathcal{N}}, \quad g^{\mathcal{N}\mathcal{N}}_{\mathcal{N}\mathcal{D}} = g^{\mathcal{N}\mathcal{N}}_{\mathcal{D}\mathcal{N}}, \quad g^{\mathcal{N}\mathcal{D}}_{\mathcal{N}\mathcal{N}} = g^{\mathcal{D}\mathcal{N}}_{\mathcal{N}\mathcal{N}}, \tag{4.7}$$

$$g_N(\alpha) = \inf\Big\{\beta \geq \frac{1}{2}\alpha^2 : (1-\theta^2)\cosh(2\gamma) + \theta^2\cos(2\delta) = 1\Big\} \in \Big[\frac{1}{2}\alpha^2, \alpha^2\Big],$$

$$g^{\mathcal{ND}}_{\mathcal{ND}}(\alpha) = \begin{cases} \sup\{\beta \in (\frac{1}{4}\alpha^2, \frac{1}{2}\alpha^2) : (\alpha^2 - 2\beta)\cosh(2\gamma) = 2\beta\} & \text{if } \alpha > 2, \\ \frac{1}{4}\alpha^2 & \text{if } \alpha = 2, \\ \sup\{\beta \in (\frac{1}{4}(\alpha^2-\pi^2), \frac{1}{4}\alpha^2) : (\alpha^2 - 2\beta)\cos(2\gamma) = 2\beta\} & \text{if } \alpha \in (0,2), \end{cases}$$

$$g^{\mathcal{NN}}_{\mathcal{ND}}(\alpha) = \inf\{\beta \geq \beta_\alpha : (\gamma^2 - \delta^2)\sinh(2\gamma) = 2\gamma\delta\sin(2\delta)\}, \quad \beta_\alpha := \begin{cases} \frac{1}{2}\alpha^2 & \text{if } \alpha \leq \pi, \\ g^{\mathcal{ND}}_{\mathcal{ND}}(\alpha) & \text{if } \alpha > \pi, \end{cases}$$

$$g^{\mathcal{ND}}_{\mathcal{NN}}(\alpha) = \begin{cases} \inf\{\beta \geq g^{\mathcal{ND}}_{\mathcal{ND}}(\alpha) : (\gamma^2 - \delta^2)\sinh(2\gamma) = -2\gamma\delta\sin(2\delta)\} & \text{if } \alpha \geq \alpha_0, \\ \inf\{\beta \geq g^{\mathcal{ND}}_{\mathcal{ND}}(\alpha) : \xi_1^2 \sin\xi_2\cos\xi_1 = \xi_2^2\sin\xi_1\cos\xi_2\} & \text{if } \alpha \in (\frac{1}{2}\pi, \alpha_0), \\ 0 & \text{if } \alpha \in (0, \frac{1}{2}\pi], \end{cases}$$

where $\xi_i := -\frac{1}{2}\alpha \pm \gamma$ *and* $\alpha_0 > 0$ *is defined by* $\alpha_0 = 2\sin\alpha_0$.

Remark 4.2. (i) If u^0 is a weak minimizer of Φ with given $I_0^{\mathcal{N}}, I_1^{\mathcal{N}}$ (and the borderline function g), then it remains a weak minimizer if we replace $I_x^{\mathcal{N}}$ with any subset of $I_x^{\mathcal{N}}$ for $x = 0, 1$, since the set $C^1_{\mathcal{D}}$ becomes smaller. Therefore the new borderline function $\tilde{g}$ has to satisfy $\tilde{g} \leq g$. In particular, $g_D \leq g \leq g_N$ for any borderline function g, $g^{\mathcal{ND}}_{\mathcal{ND}} \leq \min(g^{\mathcal{NN}}_{\mathcal{ND}}, g^{\mathcal{ND}}_{\mathcal{NN}})$, and $g^{\mathcal{ND}}_{\mathcal{ND}}(\alpha) \geq g^{\mathcal{DD}}_{\mathcal{ND}}(\alpha) = \frac{1}{4}(\alpha^2 - \pi^2)$. We also have $g_N(\alpha) \leq \alpha^2$ since the Cauchy inequality implies that the corresponding functional Ψ is positive definite for $\beta > \alpha^2$.

(ii) If $\alpha \in (0, \alpha_0)$ is fixed, then the function $\Xi(\beta) := \xi_1^2\sin\xi_2\cos\xi_1 - \xi_2^2\sin\xi_1\cos\xi_2$ appearing in the formula for $g^{\mathcal{ND}}_{\mathcal{NN}}$ in Proposition 4.1 has a unique root β^* in in the interval $[g^{\mathcal{ND}}_{\mathcal{ND}}(\alpha), \frac{1}{4}\alpha^2)$: This follows from our proof, since any root in that interval corresponds to the case when the corresponding functional Ψ is positive semidefinite but not positive definite, and the form of Ψ guarantees that, given α, this can happen only for one β. Consequently,

$$g^{\mathcal{ND}}_{\mathcal{NN}}(\alpha) = \sup\Big\{\beta < \frac{1}{4}\alpha^2 : \xi_1^2\sin\xi_2\cos\xi_1 = \xi_2^2\sin\xi_1\cos\xi_2\Big\} \quad \text{if } \alpha \in (0, \alpha_0).$$

In addition, our proof implies that if $\beta^* > g^{\mathcal{ND}}_{\mathcal{ND}}(\alpha)$, then Ξ changes sign at β^*. Similarly, if $\alpha > \alpha_0$ (or $\alpha > 0$, resp.), then the function $(\gamma^2 - \delta^2)\sinh(2\gamma) + 2\gamma\delta\sin(2\delta)$ (or $(\gamma^2 - \delta^2)\sinh(2\gamma) - 2\gamma\delta\sin(2\delta)$, resp.) has a unique root β^* in the interval $[g^{\mathcal{ND}}_{\mathcal{ND}}(\alpha), \infty)$ (or $[\beta_\alpha, \infty)$, resp.), and it changes sign at β^* if $\beta^* > g^{\mathcal{ND}}_{\mathcal{ND}}(\alpha)$ (or $\beta^* > \beta_\alpha$, resp.). In addition, the estimates in (i) guarantee that that root β^* satisfies $\beta^* \leq g_N(\alpha) \leq \alpha^2$. Analogous statements are true in the case of g_N.

(iii) Our definition of α and β in (4.4) implies that the borderline function g_M was estimated above and below in [11, Proposition 6] by functions

$$\overline{g_M}(\alpha) := \max(0, \alpha^2 - \pi^2) \quad \text{and} \quad \underline{g_M}(\alpha) := \pi^2(\alpha^2 - \pi^2)/(\alpha^2 + \pi^2),$$

respectively, see Figure 4.1. Let us also mention that the upper bound $\overline{g_N}(\alpha) := \frac{1}{4}\alpha^2$ for $g_N(\alpha)$ in [11, Proposition 5] is incorrect: The error is explained below.

(iv) The function $\hat{g}(\alpha) := \frac{1}{2}\alpha^2$ is a good approximation of functions g in Proposition 4.1(ii) for α large, see Table 4.1 and Figure 4.2. The functions $g^{\mathcal{ND}}_{\mathcal{NN}}, g^{\mathcal{NN}}_{\mathcal{ND}}$ oscillate between g_N and $g^{\mathcal{ND}}_{\mathcal{ND}}$, they intersect each other whenever $\alpha = k\pi$, $k = 1, 2, \ldots$, and then their common values equal $\hat{g}(\alpha)$ (and also $g_N(\alpha)$ if k is even). Similarly, $\min(g^{\mathcal{ND}}_{\mathcal{NN}}(\alpha), g^{\mathcal{NN}}_{\mathcal{ND}}(\alpha)) = g^{\mathcal{ND}}_{\mathcal{ND}}(\alpha)$ if $\alpha = (k + \frac{1}{2})\pi$, $k = 0, 1, 2, \ldots$. Similar behavior of functions $\tilde{g}(\alpha) = \frac{1}{4}\alpha^2$ and g_M, $g^{\mathcal{DN}}_{\mathcal{ND}}$, $g^{\mathcal{DD}}_{\mathcal{ND}}$ can be observed in Figure 4.1. The formulas for functions g in Proposition 4.1(ii) can

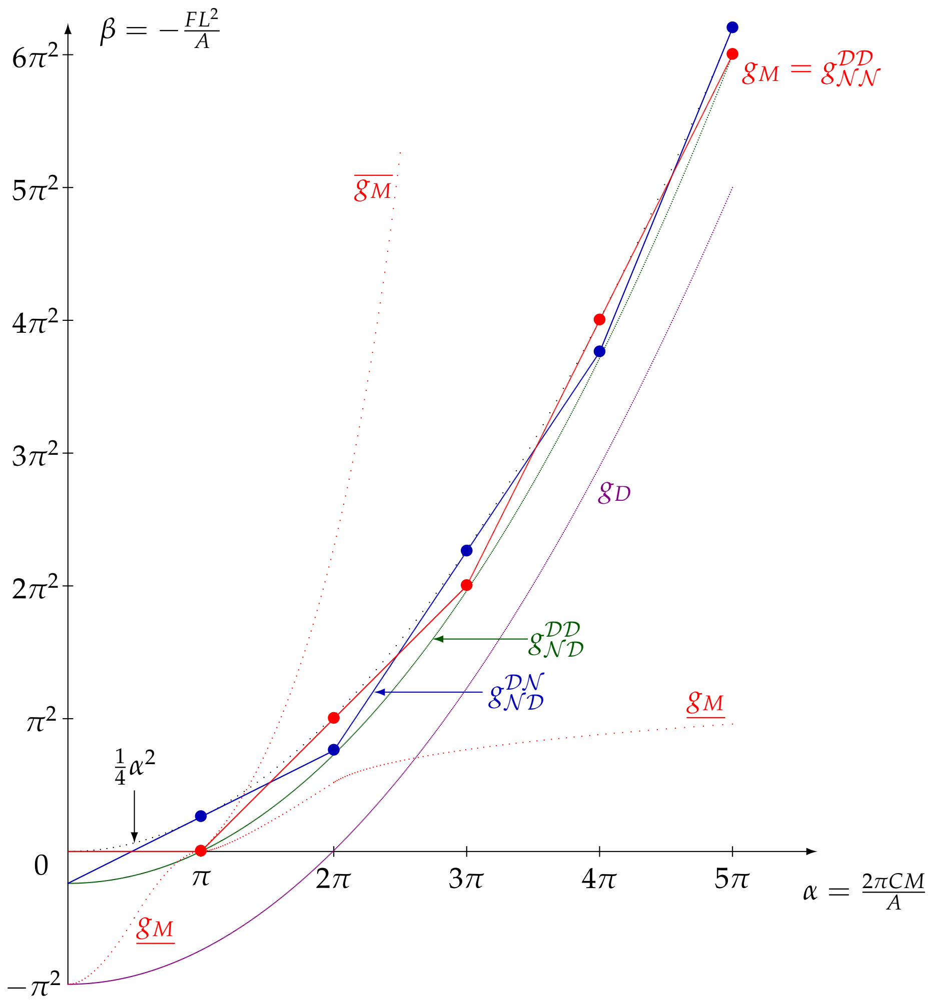

Figure 4.1: The case $I_0^{\mathcal{D}} \cap \{1,2\} \neq \emptyset \neq I_1^{\mathcal{D}} \cap \{1,2\}$.

be used in the numerical computations of g, but they also can be used in the study of the asymptotic or qualitative behavior of g. For example, they imply that $\lim_{\alpha \to 0+} \frac{g_N(\alpha)}{\alpha^2} = 1$, $\lim_{\alpha\to\infty}(\hat{g} - g^{\mathcal{ND}}_{\mathcal{ND}})(\alpha) = 0$, $g^{\mathcal{ND}}_{\mathcal{ND}}$ is $C^1 \setminus C^2$ at $\alpha = 2$, and g_N is $C \setminus C^1$ at $\alpha = 2k\pi$, $k = 1, 2 \ldots$.

(v) Numerical computations determining the borderlines for stability could be used also if we did not know the formulas for functions g in Proposition 4.1. If $\beta_0 < \beta_1$ and the problem with parameters (α_0, β_0) or (α_0, β_1) is unstable or stable, respectively, then one can set $\beta_2 := (\beta_0 + \beta_1)/2$ and numerically solve the Jacobi equations with suitable initial conditions and parameters (α_0, β_2) (by the Euler method, for example). If that problem is stable or unstable, then one can set $\beta_3 := (\beta_0 + \beta_2)/2$ or $\beta_3 := (\beta_2 + \beta_1)/2$, respectively, and solve the problem with parameters (α_0, β_3) etc. In fact, we used such general approach to compute the numerical values of functions g_N and $g^{\mathcal{ND}}_{\mathcal{ND}}$ first, and we verified a posteriori that the computed critical parameters correspond to the critical values determined by Proposition 4.1.

(vi) Let u^0 be a weak minimizer. Then a straightfoward modification of the proof of Proposition 2.3 shows that u^0 is also a strong minimizer. In fact, assume first that there exist $v^k \in W^{1,2}_{\mathcal{D}}$ such that $r_k := \|v^k\|_{1,2} \to 0$ and $\Phi(u^0 + v^k) < \Phi(u^0)$. Since $\Phi \in C^1(W^{1,2})$ is weakly sequentially lower semicontinuous, we can find a minimizer u^k of Φ in $\{u \in u^0 + W^{1,2}_{\mathcal{D}} : \|u - u^0\|_{1,2} \leq r_k\}$ and Lagrange multipliers $\lambda_k \leq 0$ such that $\Phi'(u^k)h = \lambda_k \Theta'(u^k)h$ for any

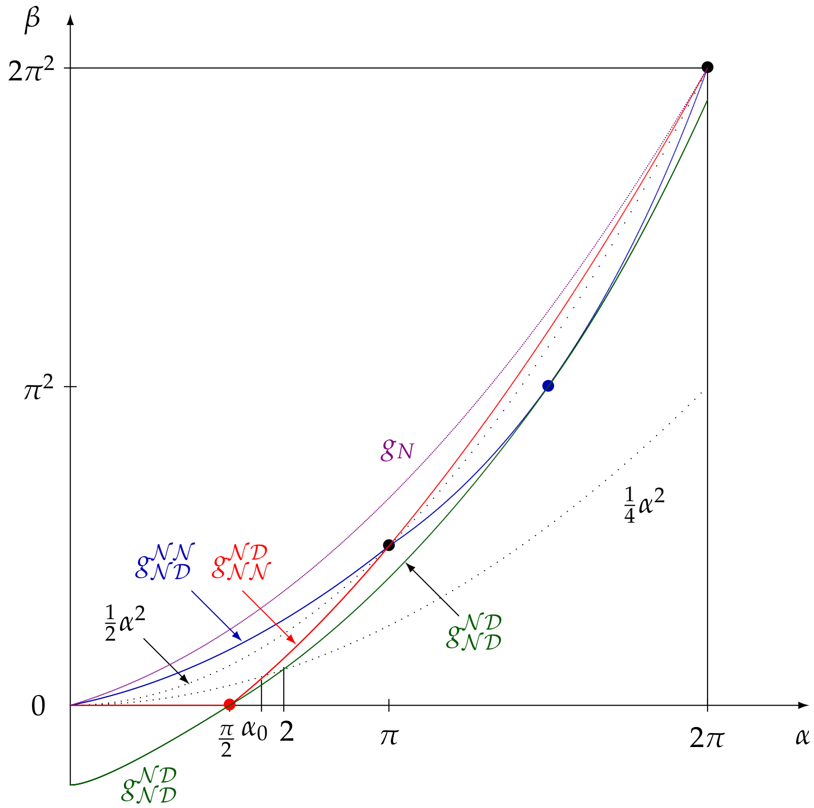

Figure 4.2: The case $I_0^{\mathcal{D}} \cap \{1,2\} = \emptyset$.

$h \in W^{1,2}_{\mathcal{D}}$, where $\Theta(u) = \|u - u^0\|^2_{1,2}$. The arguments in [5, Section 2.6] guarantee that $u^k \in C^2$ and u^k satisfy the Euler equations $(F_p^k(x))' = F_u^k(x)$, where $F_p^k(x) := F_p(\lambda_k, x, u^k(x), (u^k)'(x))$ (similarly F_u^k) and $F(\lambda, x, u, p) := f(x, u, p) - \lambda(|p - (u^0)'(x)|^2 + |u - u^0(x)|^2)$. These equations, the particular form of f, u^0, the positive definiteness of F^k_{pp} and the convergence $u^k \to u^0$ in $W^{1,2}$ guarantee that $\{u^k\}$ is a Cauchy sequence in $W^{2,1}$, hence in C^1, thus $u^k \to u^0$ in C^1. However, this contradicts our assumption that u^0 is a weak minimizer. Consequently, u^0 is a local minimizer in $u^0 + W^{1,2}_{\mathcal{D}}$. Next assume that there exist $v^k \in C^1_{\mathcal{D}}$ such that $\|v^k\|_C \to 0$ and $\Phi(u^0 + v^k) < \Phi(u^0)$. Then it is not difficult to show that there exists $c > 0$ such that $0 > \Phi(u^0 + v^k) - \Phi(u^0) \geq c\|v^k\|^2_{1,2} + o(1)$, hence $\|v^k\|_{1,2} \to 0$, which yields a contradiction and concludes the proof. □

Proof of Proposition 4.1. Notice that u^0 is a critical point of Φ for any choice of $I_0^{\mathcal{N}}, I_1^{\mathcal{N}} \subset \{1,2\}$. By Proposition 3.1, we have to determine the positivity of functional Ψ in $W^{1,2}_{\mathcal{D}}$. We have $\Psi(h) = \Psi_1(h_1, h_2) + \Psi_2(h_3)$, where

$$\Psi_1(h_1, h_2) = A \int_0^1 \big((h_1')^2 + (h_2')^2 - 2\alpha h_2' h_1 + \beta(h_1^2 + h_2^2)\big)\, dx, \quad \Psi_2(h_3) = C \int_0^1 (h_3')^2\, dx.$$

Since the positivity of Ψ does not change if we replace α by $-\alpha$ (consider $-h_1$ instead of h_1), we may assume $\alpha \geq 0$. Since the case $\alpha = 0$ is trivial, we assume $\alpha > 0$. Since Ψ_2 is positive definite in $W_0^{1,2}([0,1])$, it is sufficient to study the positivity of the functional

$$\tilde{\Psi}(h_1, h_2) := \frac{1}{2A}\Psi_1(h_1, h_2) = \frac{1}{2}\int_0^1 \big((h_1')^2 + (h_2')^2 - 2\alpha h_2' h_1 + \beta(h_1^2 + h_2^2)\big)\, dx \tag{4.8}$$

Table 4.1: Numerical values of functions g and $\Delta_{\max} := g_N - g_{\mathcal{N}\mathcal{D}}^{\mathcal{N}\mathcal{D}}$ if $I_0^{\mathcal{D}} \cap \{1,2\} = \emptyset$.

in the space

$$\tilde{W}_{\mathcal{D}} := \{h \in W^{1,2}([0,1],\mathbb{R}^2) : h_i(j) = 0 \text{ for } i \in I_j^{\mathcal{D}},\ i = 1,2,\ j = 0,1\}. \tag{4.9}$$

In fact, Ψ is positive definite (or semidefinite, resp.) in $W_{\mathcal{D}}^{1,2}$ if and only if $\tilde{\Psi}$ is positive definite (or semidefinite, resp.) in $\tilde{W}_{\mathcal{D}}$. Therefore, in what follows, we will apply the Jacobi theory from Section 3 to the functional $\tilde{\Psi}$ with $\alpha > 0$. Notice that the assumptions in Theorem 3.4 depend only on the corresponding functional Ψ, and the conclusions can also be formulated in terms of Ψ, see (3.5), (3.6). We will use Theorem 3.4 in this way. More precisely, we will use assertions (3.5), (3.6) (with Ψ and $W_{\mathcal{D}}^{1,2}$ replaced by $\tilde{\Psi}$ and $\tilde{W}_{\mathcal{D}}$, respectively) to determine the positivity of $\tilde{\Psi}$ (hence the positivity of Ψ) and then we will use Proposition 3.1 (with $\Psi(h) = \Psi(h_1, h_2, h_3)$) to conclude that u^0 is (or is not) a minimizer of Φ.

Notice that the index sets for functional $\tilde{\Psi}$ satisfy $\tilde{I}_j^{\mathcal{D}} = I_j^{\mathcal{D}} \cap \{1,2\}$ and $\tilde{I}_j^{\mathcal{N}} = I_j^{\mathcal{N}} \cap \{1,2\} = I_j^{\mathcal{N}}$ for $j = 1,2$, hence we will use the notation $I_j^{\mathcal{N}}$ instead of $\tilde{I}_j^{\mathcal{N}}$. Similarly, the corresponding operators $\tilde{\mathcal{B}}_i$, $i = 1,2$ (cf. (2.8)), satisfy $\tilde{\mathcal{B}}_i(h_1,h_2) = \mathcal{B}_i(h_1,h_2,0)$ for $i = 1,2$, and – without fearing confusion – we will use the notation $\mathcal{B}_i h$ instead of $\tilde{\mathcal{B}}_i h$ and $\mathcal{B}h := (\mathcal{B}_1 h, \mathcal{B}_2 h)$ if $h = (h_1, h_2)$ and $i = 1,2$. The same applies to operators $\mathcal{C}_i$ and $\mathcal{A}_i$. Since

$$\mathcal{B}_1 h = h_1', \quad \mathcal{B}_2 h = -\alpha h_1 + h_2', \quad \mathcal{C}_1 h = \beta h_1 - \alpha h_2', \quad \mathcal{C}_2 h = \beta h_2, \tag{4.10}$$

the corresponding system of Jacobi equations is

$$\left.\begin{aligned} h_1'' + \alpha h_2' - \beta h_1 = 0, \\ h_2'' - \alpha h_1' - \beta h_2 = 0, \end{aligned}\right\} \quad \text{in } (0,1), \tag{4.11}$$

and the initial conditions for $h^{(1)}, h^{(2)}$ in Theorem 3.4 (with $N = 2$) are $h_i(0) = 0$ if $i \in \tilde{I}_0^{\mathcal{D}}$ and $i = 1,2$, $h_1'(0) = 0$ if $1 \in I_0^{\mathcal{N}}$, and $h_2'(0) = \alpha h_1(0)$ if $2 \in I_0^{\mathcal{N}}$.

The existence of continuous borderline functions g follows from the form of $\tilde\Psi$. Notice that if the index sets $\tilde I_0^{\mathcal D}$ and $\tilde I_1^{\mathcal D}$ are nonempty, then $h_1h_2(0) = h_1h_2(1) = 0$ for any $h \in \tilde W_{\mathcal D}$, hence

$$\int_0^1 h_2'h_1\,dx = -\int_0^1 h_1'h_2\,dx. \tag{4.12}$$

Identity (4.12) shows that the value of $\tilde\Psi$ does not change if we replace h_1 with h_2 and α with $-\alpha$. In general, the value of $\tilde\Psi$ does not change if we replace h_i with $\tilde h_i(x) = h_i(1-x)$ and α with $-\alpha$. These two observations guarantee (4.5) and (4.7).

Let us first consider the cases in Proposition 4.1(i), i.e. $\tilde I_0^{\mathcal D} \neq \emptyset \neq \tilde I_1^{\mathcal D}$. Then (4.12) guarantees $\int_0^1 2h_2'h_1\,dx = \int_0^1 (h_2'h_1 - h_1'h_2)\,dx$ and the Cauchy inequality implies that

$$\tilde\Psi \text{ is positive definite if } \alpha^2 < 4\beta. \tag{4.13}$$

Hence it is sufficient to study the case $\alpha^2 \geq 4\beta$.

Case $\binom{\mathcal{DD}}{\mathcal{DD}}$ has already been solved in [11, Proposition 3], but Theorem 3.4 enables us to to show $g_D(\alpha) = \frac{\alpha^2}{4} - \pi^2$ in a simpler way. Assume $\alpha^2 > 4\beta$. We can set $h^{(1)}(x) = (\sin\xi_1 x - \sin\xi_2 x, \cos\xi_1 x - \cos\xi_2 x)$ and $h^{(2)}(x) = (-\cos\xi_1 x + \cos\xi_2 x, \sin\xi_1 x - \sin\xi_2 x)$, where $\xi_{1,2} = -\frac12\alpha \pm \gamma$. The function D in Theorem 3.4 satisfies $D(x) = 2 - 2\cos(\xi_1 - \xi_2)x$, hence $D \neq 0$ in $(0,1]$ if and only if $|\xi_1 - \xi_2| < 2\pi$, i.e. if $\beta > g_D(\alpha)$. Consequently, if $\beta > g_D(\alpha)$, then u^0 is a strict weak minimizer (this remains true also if $4\beta = \alpha^2$ due to the monotonicity of $\tilde\Psi$ with respect to β), and if $\beta < g_D(\alpha)$, then u^0 is not a weak minimizer.

The remaining cases in Proposition 4.1(i) are $\binom{\mathcal{DD}}{\mathcal{ND}}$, $\binom{\mathcal{DN}}{\mathcal{ND}}$, and $\binom{\mathcal{DD}}{\mathcal{NN}}$. Assume $\alpha^2 > 4\beta$. Since $I_0^{\mathcal N} = \{2\}$, the initial conditions for $h^{(1)}, h^{(2)}$ in Theorem 3.4 are $h_1(0) = 0$ and $h_2'(0) = 0$. One can easily check that we can set $h^{(i)}(x) := (\sin\xi_i x, \cos\xi_i x)$, $i = 1,2$, where $\xi_{1,2} := -\frac12\alpha \pm \gamma$. The function D in Theorem 3.4 satisfies

$$D(x) = \sin(\xi_1 - \xi_2)x = \sin 2\gamma x = \sin\sqrt{\alpha^2 - 4\beta}\,x,$$

hence

$$\text{if } \alpha^2 - 4\beta > \pi^2, \text{ then } D(x) = 0 \text{ for some } x \in (0,1), \tag{4.14}$$

$$\text{if } 0 < \alpha^2 - 4\beta < \pi^2, \text{ then } D(x) \neq 0 \text{ in } (0,1]. \tag{4.15}$$

Theorem 3.4(i) (more precisely, assertion (3.5)) and (4.14) imply that

$$\tilde\Psi \text{ is not positive semidefinite if } \alpha^2 - 4\beta > \pi^2. \tag{4.16}$$

Let $I_1^{\mathcal N} = \emptyset$. If $0 < \alpha^2 - 4\beta < \pi^2$, then (4.15) and Theorem 3.4(ii) (more precisely, assertion (3.6)) guarantee that $\tilde\Psi$ is positive definite. If $0 = \alpha^2 - 4\beta < \pi^2$ and we replace β by $\tilde\beta := \beta - \varepsilon$ with $\varepsilon > 0$ small, then $0 < \alpha^2 - 4\tilde\beta < \pi^2$, hence the modified functional $\tilde\Psi^{\tilde\beta}$ (with β replaced by $\tilde\beta$) is positive definite, and the monotonicity of $\tilde\Psi$ with respect to β implies that $\tilde\Psi$ is positive definite as well. These facts together with (4.13) and (4.16) imply $g^{\mathcal{DD}}_{\mathcal{ND}}(\alpha) = \frac{\alpha^2}{4} - \frac{\pi^2}{4}$.

If $I_1^{\mathcal N} = \{2\}$ and $\alpha^2 > 4\beta$, then $H_{\mathcal D,b} = \{\tilde h \in \operatorname{span}(h^{(1)}, h^{(2)}) : \tilde h_1(1) = 0\}$ is spanned by $h := \sin\xi_2 h^{(1)} - \sin\xi_1 h^{(2)}$. We have

$$B := \mathcal{B}h(1)\cdot h(1) = h_2'(1)h_2(1) = (\xi_2 - \xi_1)\sin(\xi_2 - \xi_1)\sin\xi_1\sin\xi_2$$

and, assuming $\alpha \in [(2k-1)\pi, (2k+1)\pi]$, $k = 0,1,2,\dots$, $\alpha > 0$, we have $B > 0$ or $B < 0$ if and only if β is greater or less than $k\pi(\alpha - k\pi)$, respectively. Notice that

$$\alpha^2/4 \geq k\pi(\alpha - k\pi) \geq (\alpha^2 - \pi^2)/4. \tag{4.17}$$

These facts, Theorem 3.4(ii) and (4.13) imply that $\tilde{\Psi}$ is positive definite if $\beta > k\pi(\alpha - k\pi)$, $\beta \neq \alpha^2/4$. The assumption $\beta \neq \alpha^2/4$ can be removed by the same argument as above (by considering $\tilde{\beta} = \beta - \varepsilon$). If $\beta < k\pi(\alpha - k\pi)$, then $\alpha^2 > 4\beta$ due to (4.17), hence $B < 0$ and Theorem 3.4(i) imply that $\tilde{\Psi}$ is not positive semidefinite. Consequently, the formula for $g_M = g^{\mathcal{DD}}_{\mathcal{NN}}$ in (4.6) is true.

If $I_1^{\mathcal{N}} = \{1\}$, then we can use the same arguments as in the case $I_1^{\mathcal{N}} = \{2\}$ to show that the formula for $g^{\mathcal{DN}}_{\mathcal{ND}}$ in (4.6) is true. In particular, if $\alpha^2 > 4\beta$, then $H_{\mathcal{D},b} = \{\tilde{h} \in \text{span}(h^{(1)}, h^{(2)}) : \tilde{h}_2(1) = 0\}$ is spanned by $h := \cos\xi_2 h^{(1)} - \cos\xi_1 h^{(2)}$ and we have

$$B := \mathcal{B}h(1) \cdot h(1) = h_1'(1)h_1(1) = (\xi_1 - \xi_2)\sin(\xi_1 - \xi_2)\cos\xi_1\cos\xi_2,$$

hence assuming $\alpha \in [2k\pi, 2(k+1)\pi]$, $k = 0, 1, 2, \ldots$, we obtain $B > 0$ or $B < 0$ if and only if β is greater or less than $(k + \frac{1}{2})\pi(\alpha - (k + \frac{1}{2})\pi)$, respectively.

Next consider the cases in Proposition 4.1(ii), i.e. $\binom{\mathcal{ND}}{\mathcal{ND}}$, $\binom{\mathcal{NN}}{\mathcal{ND}}$, $\binom{\mathcal{ND}}{\mathcal{NN}}$ and $\binom{\mathcal{NN}}{\mathcal{NN}}$. Since $I_0^{\mathcal{N}} = \{1, 2\}$, the initial conditions for $h^{(1)}, h^{(2)}$ in Theorem 3.4 are $h_1'(0) = 0$ and $h_2'(0) = \alpha h_1(0)$. We will distinguish the following four subcases:

(ii-1) $\beta = \frac{1}{2}\alpha^2$,

(ii-2) $\beta = \frac{1}{4}\alpha^2$,

(ii-3) $\beta > \frac{1}{4}\alpha^2$ and $\beta \neq \frac{1}{2}\alpha^2$,

(ii-4) $\beta < \frac{1}{4}\alpha^2$.

(ii-1) Assume that $\beta = \frac{1}{2}\alpha^2$. We will show that $\tilde{\Psi}$ is positive definite (hence u^0 is a strict weak minimizer) in case $\binom{\mathcal{ND}}{\mathcal{ND}}$ and $\tilde{\Psi}$ is not positive semidefinite (hence u^0 is not a weak minimizer) in case $\binom{\mathcal{NN}}{\mathcal{NN}}$ if $\alpha \neq 2k\pi$. In addition, in case $\binom{\mathcal{NN}}{\mathcal{ND}}$, u^0 is or is not a weak minimizer if $\alpha \in ((2k-1)\pi, 2k\pi)$ or $\alpha \in (2k\pi, (2k+1)\pi)$, respectively, and the opposite is true in case $\binom{\mathcal{ND}}{\mathcal{NN}}$.

Recall that $\delta = \alpha/2$. If we set

$$\begin{aligned} h^{(1)}(x) &:= (e^{\delta x}(\cos(\delta x) - \sin(\delta x)), e^{\delta x}(\cos(\delta x) + \sin(\delta x))), \\ h^{(2)}(x) &:= (e^{-\delta x}(\cos(\delta x) + \sin(\delta x)), e^{-\delta x}(-\cos(\delta x) + \sin(\delta x))), \end{aligned}$$

then we obtain $D \equiv -2$, hence $\tilde{\Psi}$ is positive definite in case $\binom{\mathcal{ND}}{\mathcal{ND}}$ due to Theorem 3.4(ii).

Considering case $\binom{\mathcal{NN}}{\mathcal{NN}}$, one can check that the matrix $\mathfrak{A} = (a_{kl})$ in Remark 3.6(ii) satisfies

$$a_{11} = 4\delta e^{2\delta}\sin^2\delta, \quad a_{22} = -4\delta e^{-2\delta}\sin^2\delta, \quad a_{12} = a_{21} = -4\delta\sin\delta\cos\delta.$$

If $\delta \neq k\pi$, then choosing $\xi := (0, 1)$ and $h := \sum_{k=1}^2 \xi_k h^{(k)} = h^{(2)} \in H_{\mathcal{D},1} = H$ we obtain $\mathcal{B}h(1) \cdot h(1) = \mathfrak{A}\xi \cdot \xi = a_{22} < 0$, i.e. $\tilde{\Psi}$ is not positive semidefinite due to Theorem 3.4(i). Notice also that $\mathcal{B}h(0) = 0$, hence

$$\tilde{\Psi}(h) = \mathcal{B}h \cdot h\Big|_0^1 < 0. \tag{4.18}$$

If $\delta = k\pi$, then $\mathfrak{A} = 0$ (degenerate case). Already these facts contradict [11, Proposition 5] which claims the stability for $\beta > \frac{1}{4}\alpha^2$. In fact, the authors of [11] mention in their proof that

"We have not used any integration by parts . . . ", but they seem to use [11, (35)–(37)], and [11, (35)] does use an integration by parts requiring the boundary conditions $h_1h_2(0) = h_1h_2(1)$.

In case $\binom{\mathcal{ND}}{\mathcal{NN}}$ we set

$$h := e^{-\delta}(\cos\delta + \sin\delta)h^{(1)} - e^{\delta}(\cos\delta - \sin\delta)h^{(2)}.$$

Since at least one of the numbers $h_1^{(1)}(1)$ and $h_1^{(2)}(1)$ is non-zero, we have $\dim H_{\mathcal{D},1} \le 1$. Since $h_1(1) = 0$, we obtain $H_{\mathcal{D},1} = \mathrm{span}(h)$, and

$$\mathcal{B}h(1)\cdot h(1) = \mathcal{B}_2 h(1)\cdot h_2(1) = (-\alpha h_1 + h_2')(1)\cdot h_2(1) = 2\alpha\sin\alpha$$

due to $h_2(1) = 2$ and $h_2'(1) = \alpha\sin\alpha$. Consequently, $\mathcal{B}h(1)\cdot h(1) > 0$ if $\alpha \in (2k\pi, (2k+1)\pi)$ and $\mathcal{B}h(1)\cdot h(1) < 0$ if $\alpha \in ((2k-1)\pi, 2k\pi)$, so that our assertion follows from Theorem 3.4(ii) and Theorem 3.4(i), respectively.

Similarly, in case $\binom{\mathcal{NN}}{\mathcal{ND}}$ we set

$$h := e^{-\delta}(\cos\delta - \sin\delta)h^{(1)} + e^{\delta}(\cos\delta + \sin\delta)h^{(2)}.$$

Then $h_2(1) = 0$ and $H_{\mathcal{D},1} = \mathrm{span}(h)$;

$$\mathcal{B}h(1)\cdot h(1) = \mathcal{B}_1 h(1)\cdot h(1) = h_1'(1)h_1(1) = -2\alpha\sin\alpha \tag{4.19}$$

due to $h_1(1) = 2$ and $h_1'(1) = -\alpha\sin\alpha$. The rest of the proof is the same as in case $\binom{\mathcal{ND}}{\mathcal{NN}}$. Notice also that (similarly as in the case of (4.18)), (4.19) implies

$$\tilde{\Psi}(h) = \mathcal{B}h\cdot h\Big|_0^1 < 0 \tag{4.20}$$

provided $\alpha \in (2k\pi, (2k+1)\pi)$.

(ii-2) Assume that $\beta = \frac{1}{4}\alpha^2$. Set $\xi := -\frac{1}{2}\alpha$ and

$$\begin{aligned} h^{(1)}(x) &:= (\sin(\xi x) - \xi x\cos(\xi x), \cos(\xi x) + \xi x\sin(\xi x)),\\ h^{(2)}(x) &:= (\cos(\xi x) - \xi x\sin(\xi x), -\sin(\xi x) - \xi x\cos(\xi x)). \end{aligned}$$

Notice that the function D in Theorem 3.4 satisfies $D(x) = \xi^2x^2 - 1$, hence $D < 0$ in $[0,1]$ if $\alpha < 2$, and $D(x) = 0$ for some $x \in (0,1)$ if $\alpha > 2$. This shows that $\frac{1}{4}\alpha^2 < g_{\mathcal{ND}}^{\mathcal{ND}}(\alpha) \le \min\big(g_{\mathcal{ND}}^{\mathcal{NN}}(\alpha), g_{\mathcal{NN}}^{\mathcal{ND}}(\alpha), g_N(\alpha)\big)$ if $\alpha > 2$, i.e. u^0 cannot be a weak minimizer in any case.

Let $\alpha < 2$. Then u^0 is a strict weak minimizer in case $\binom{\mathcal{ND}}{\mathcal{ND}}$. Next consider case $\binom{\mathcal{NN}}{\mathcal{NN}}$. If $\beta = \alpha^2/2$, then (4.18) implies that $\tilde{\Psi}$ is not positive semidefinite. The monotonicity of $\tilde{\Psi}$ with respect to β shows that $\tilde{\Psi}$ cannot be positive semidefinite if $\beta = \alpha^2/4$ either, hence u_0 is not a weak minimizer. The same arguments show that u_0 is not a weak minimizer in case $\binom{\mathcal{NN}}{\mathcal{ND}}$, see (4.20). It remains to consider case $\binom{\mathcal{ND}}{\mathcal{NN}}$. Set

$$h := (\cos\xi - \xi\sin\xi)h^{(1)} - (\sin\xi - \xi\cos\xi)h^{(2)},$$

so that $h_1(1) = 0$. Then the restriction $\alpha < 2$ implies $h_2(1) = 1 - \xi^2 > 0$. Since $h_2'(1) = -\xi^2 + \xi\sin(2\xi)$, we see that $h_2'(1)h_2(1) > 0$ only if $\alpha < \alpha_0$, where α_0 is defined by $\alpha_0 = 2\sin\alpha_0$ ($\alpha_0 \approx 0.6\pi$).

(ii-3) Assume $\beta > \frac{1}{4}\alpha^2$, $\beta \neq \frac{1}{2}\alpha^2$, and set

$$\varphi(x) := e^{\gamma x}(\gamma^2 - \delta^2), \quad \psi_\pm(x) := e^{-\gamma x}(\gamma \pm \delta)^2.$$

Then we can take

$$\begin{aligned} h^{(1)}(x) &:= [(\varphi(x) + \psi_+(x))(\cos(\delta x) + \sin(\delta x)), (\varphi(x) + \psi_+(x))(-\cos(\delta x) + \sin(\delta x))], \\ h^{(2)}(x) &:= [(\varphi(x) + \psi_-(x))(\cos(\delta x) - \sin(\delta x)), (\varphi(x) + \psi_-(x))(\cos(\delta x) + \sin(\delta x))], \end{aligned}$$

and an easy computation yields

$$D(x) = 4(\gamma^2 - \delta^2)\Big((\gamma^2 - \delta^2)\cosh(2\gamma x) + \gamma^2 + \delta^2\Big). \tag{4.21}$$

The function D does not vanish in $(0, 1]$ if and only if $\gamma > \delta$ (i.e. $\beta > \frac{1}{2}\alpha^2$), or $\gamma < \delta$ and $\cosh(2\gamma) < \frac{\gamma^2+\delta^2}{\delta^2-\gamma^2}$. The last inequality can be written in the form

$$(\alpha^2 - 2\beta)\cosh(2\gamma) < 2\beta. \tag{4.22}$$

In case $\binom{\mathcal{NN}}{\mathcal{NN}}$, one has to consider the numbers a_{kl} in Remark 3.6(ii):

$$\begin{aligned} a_{11} &= 2\gamma(\varphi^2 - \psi_+^2)(1) + 2\delta(\varphi + \psi_+)^2(1)\cos(2\delta), \\ a_{22} &= 2\gamma(\varphi^2 - \psi_-^2)(1) - 2\delta(\varphi + \psi_-)^2(1)\cos(2\delta), \\ a_{12} = a_{21} &= -2\delta(\varphi + \psi_+)(\varphi + \psi_-)(1)\sin(2\delta). \end{aligned}$$

If $\gamma > \delta$ (i.e. $\beta > \frac{1}{2}\alpha^2$), then

$$a_{11}(\gamma + \delta)^{-2} + a_{22}(\gamma - \delta)^{-2} = 8(\gamma^2 + \delta^2)(\gamma - \theta\delta\cos(2\delta))\sinh(2\gamma) > 0,$$

hence the matrix $\mathfrak{A}$ is positive definite if and only if $a_{11}a_{22} > a_{12}^2$, which is equivalent to

$$(1 - \theta^2)\cosh(2\gamma) + \theta^2\cos(2\delta) > 1. \tag{4.23}$$

We used the assumption $\beta > \frac{1}{2}\alpha^2$ in order to derive (4.23), but this is not restrictive, since we know that u^0 can only be a weak minimizer of our problem in case $\binom{\mathcal{NN}}{\mathcal{NN}}$ when $\beta > \frac{1}{2}\alpha^2$. Hence in this case the condition (4.23) determines the domain of stability.

In cases $\binom{\mathcal{NN}}{\mathcal{ND}}$ and $\binom{\mathcal{ND}}{\mathcal{NN}}$, we set

$$h := (\varphi(1) + \psi_-(1))(\cos\delta + \sin\delta)h^{(1)} + (\varphi(1) + \psi_+(1))(\cos\delta - \sin\delta)h^{(2)}$$

and

$$h := (\varphi(1) + \psi_-(1))(\cos\delta - \sin\delta)h^{(1)} - (\varphi(1) + \psi_+(1))(\cos\delta + \sin\delta)h^{(2)},$$

respectively. Then $h_2(1) = 0$, $h_1(1) = D(1)$,

$$\mathcal{B}h(1) \cdot h(1) = h_1'h_1(1) = 4\gamma(\gamma^2 - \delta^2)D(1)\big((\gamma^2 - \delta^2)\sinh(2\gamma) - 2\gamma\delta\sin(2\delta)\big),$$

and $h_1(1) = 0$, $h_2(1) = -D(1)$,

$$\mathcal{B}h(1) \cdot h(1) = h_2'h_2(1) = 4\gamma(\gamma^2 - \delta^2)D(1)\big((\gamma^2 - \delta^2)\sinh(2\gamma) + 2\gamma\delta\sin(2\delta)\big),$$

respectively, where D is as in (4.21). Consequently, assuming that D does not vanish in $[0,1]$ (i.e. (4.22) is true), the stability conditions are

$$(\gamma^2-\delta^2)\sinh(2\gamma)-2\gamma\delta\sin(2\delta)>0 \tag{4.24}$$

and

$$(\gamma^2-\delta^2)\sinh(2\gamma)+2\gamma\delta\sin(2\delta)>0, \tag{4.25}$$

respectively. Notice that if $\beta=\frac{1}{2}\alpha^2$ (hence $\gamma=\delta$), then (4.24) and (4.25) are equivalent to the corresponding stability conditions in case (ii-1).

(ii-4) If $\beta<\frac{1}{4}\alpha^2$, then we can set

$$\begin{aligned} h^{(1)}(x) &:= (\xi_2\sin(\xi_1x)-\xi_1\sin(\xi_2x),\xi_2\cos(\xi_1x)-\xi_1\cos(\xi_2x)),\\ h^{(2)}(x) &:= (\xi_1\cos(\xi_1x)-\xi_2\cos(\xi_2x),-\xi_1\sin(\xi_1x)+\xi_2\sin(\xi_2x)), \end{aligned}$$

where $\xi_{1,2}=-\frac{1}{2}\alpha\pm\gamma$, and we obtain

$$D(x)=-2\beta+(\alpha^2-2\beta)\cos(2\gamma x). \tag{4.26}$$

If $\alpha^2-4\beta\geq\pi^2$, then D changes sign in $[0,1]$. Hence the condition $D>0$ in $[0,1]$ is equivalent to

$$\alpha^2-4\beta<\pi^2 \quad\text{and}\quad (\alpha^2-2\beta)\cos(2\gamma)>2\beta. \tag{4.27}$$

It is not difficult to check (cf. case (ii-2)) that if $\alpha<2$ or $\alpha>2$, then (4.27) or (4.22), respectively, is the (essentially optimal) sufficient condition for the stability in our problem in case $\binom{\mathcal{ND}}{\mathcal{ND}}$. If $\alpha=2$, then that sufficient condition is $\beta>1$.

Case (ii-2) shows that it remains to consider only case $\binom{\mathcal{ND}}{\mathcal{NN}}$ and $\alpha<\alpha_0$. Take

$$h:=(\xi_1\cos\xi_1-\xi_2\cos\xi_2)h^{(1)}-(\xi_2\sin\xi_1-\xi_1\sin\xi_2)h^{(2)}.$$

Then $h_1(1)=0$, $h_2(1)=-D(1)$ (where D is as in (4.26)), and

$$h_2'(1)=(\xi_1^2\sin\xi_2\cos\xi_1-\xi_2^2\sin\xi_1\cos\xi_2)(\xi_2-\xi_1).$$

Assuming $D>0$ in $[0,1]$ (i.e. (4.27)), the condition $h_2'h_2(1)>0$ is equivalent to

$$\xi_1^2\sin\xi_2\cos\xi_1>\xi_2^2\sin\xi_1\cos\xi_2. \tag{4.28}$$

Since $\xi_1=0$ if $\beta=0$, (4.28) can only be true if $\beta>0$. It is not difficult to see that $g^{\mathcal{ND}}_{\mathcal{NN}}(\alpha)=0$ for $\alpha\leq\frac{1}{2}\pi$ and $g^{\mathcal{ND}}_{\mathcal{NN}}(\alpha_0)=\frac{1}{4}\alpha_0^2$. If $\alpha>\alpha_0$, then (4.25) determines $g^{\mathcal{ND}}_{\mathcal{NN}}(\alpha)$.

The formulas for functions g in Proposition 4.1(ii) follow from the stability conditions (4.22), (4.23), (4.24), (4.25), (4.27), (4.28). □

Remark 4.3. Consider case $\binom{\mathcal{DD}}{\mathcal{NN}}$. We have $g^{\mathcal{DD}}_{\mathcal{NN}}(\alpha)=g_M(\alpha)>g^{\mathcal{DD}}_{\mathcal{ND}}(\alpha)$ except for $\alpha=\alpha_k:=(2k-1)\pi$, $k=1,2,\dots$. If $\alpha=\alpha_k$ and $\beta=g_M(\alpha)=g^{\mathcal{DD}}_{\mathcal{ND}}(\alpha)$, then the function D in Theorem 3.4 satisfies $D\neq0$ in $(0,1)$, $D(1)=0$, hence condition (3.2) cannot be satisfied (otherwise (3.5) would imply $\tilde\Psi(\bar h)<0$ for some $\bar h\in\tilde W_{\mathcal{D}}$, so that $\tilde\Psi(\bar h)<0$ also if β is slightly greater than $g_M(\alpha)$, which is a contradiction). For example, if $k=2$ (i.e. $\alpha=3\pi$, $\beta=2\pi^2$), then our proof shows that H_0 is spanned by $h(x):=(-\sin(\pi x)-\sin(2\pi x),\cos(\pi x)+\cos(2\pi x))$ and $\mathcal{B}_2h(1)=h_2(1)=h_1(1)=0$ which violates (3.2). This degeneracy seems to be also responsible for the non-smooth behavior of g_M at $\alpha=\alpha_k$. □

5 Field of extremals

In this section we modify the Weierstrass theory to provide necessary and sufficient conditions for weak, strong and global minimizers. Recall that $B_\varepsilon := \{\xi \in \mathbb{R}^N : |\xi| < \varepsilon\}$.

Definition 5.1. Let $f \in C^2$, $\tilde{\varepsilon} > 0$, and let $u^0 \in C^2$ be an extremal. The image $\mathcal{P}$ of a C^1-diffeomorphism $P : [a,b] \times B_{\tilde{\varepsilon}} \to [a,b] \times \mathbb{R}^N : (x,\alpha) \mapsto (x, \varphi(x,\alpha))$ is called a *field of extremals for* u^0 if $\varphi_x \in C^1$, $\varphi(\cdot,\alpha)$ is an extremal for each α, and $\varphi(\cdot,0) = u^0$. The *slope* of the field of extremals $\mathcal{P}$ is defined as $\psi : \mathcal{P} \to \mathbb{R}^N : (x,v) \mapsto \varphi_x(x,\alpha(x,v))$, where $\alpha(x,v)$ is defined by $\varphi(x,\alpha(x,v)) = v$.

It is known that in the case of the Dirichlet boundary conditions, the existence of a field of extremals $\varphi(x,\alpha)$ satisfying the self-adjointness condition (5.1), and the nonnegativity of the excess function

$$E(x,u,p,q) := f(x,u,q) - f(x,u,p) - (q-p) \cdot f_p(x,u,p)$$

for suitable (x,u,p,q) imply that u^0 is a strong minimizer. In addition, the existence of the field is guaranteed by the sufficient condition for the weak minimizer in Theorem 3.4(ii). In the general case we have the following analogue (see Theorem 6.1 for a simpler version in the scalar case $N = 1$):

Theorem 5.2. *Let $f \in C^2$, $\varepsilon > 0$, and let $u^0 \in C^2$ be an extremal satisfying (2.2).*

(i) *Let there exist a field of extremals $\mathcal{P}$ for u^0 satisfying the conditions*

$$\frac{\partial f_{p_i}(a,v,\psi(a,v))}{\partial v_j} = \frac{\partial f_{p_j}(a,v,\psi(a,v))}{\partial v_i} \quad \text{whenever} \;\; i,j \in I,\ v - u^0(a) \in B_\varepsilon, \tag{5.1}$$

$$f_p(a,v,\psi(a,v)) \cdot (v - u^0(a)) \le 0, \qquad \text{whenever} \;\; v - u^0(a) \in \mathbb{R}^N_{\mathcal{D},a} \cap B_\varepsilon, \tag{5.2}$$

$$f_p(b,v,\psi(b,v)) \cdot (v - u^0(b)) \ge 0, \qquad \text{whenever} \;\; v - u^0(b) \in \mathbb{R}^N_{\mathcal{D},b} \cap B_\varepsilon, \tag{5.3}$$

where ψ denotes the slope of the field. Assume also

$$E(x,v,\psi(x,v),q) \ge 0 \quad \text{for all} \;\; ((x,v),q) \in \mathcal{P} \times \mathbb{R}^N. \tag{5.4}$$

Then u^0 is a strong minimizer.

If (5.4) is only true for all $(x,v) \in \mathcal{P}$ and $q = q(x,v)$ satisfying $|q - \psi(x,v)| \le \eta$ for some $\eta > 0$, then u^0 is a weak minimizer.

If the field is global (i.e. $\mathcal{P} = [a,b] \times \mathbb{R}^N$) and (5.1), (5.2), (5.3) are true with B_ε replaced by $\mathbb{R}^N$, then u^0 is a global minimizer.

(ii) *Assume $I^{\mathcal{D}}_a = \emptyset$ and let there exist a field of extremals satisfying (5.1). If the reversed inequality "$\ge$" is true in (5.2), and the reversed strict inequality "$<$" is true in (5.3) for $v = u^0(b) + tw^0$, where $t \in (0,1)$ and $w^0 \in \mathbb{R}^N_{\mathcal{D},b}$ is fixed, then u_0 is not a weak minimizer.*

(iii) *Assume (2.4) and let the sufficient conditions for a weak minimizer in Theorem 3.4(ii) be satisfied. If $I^{\mathcal{D}}_a = \emptyset$ or $I^{\mathcal{N}}_a = \emptyset$ or*

$$\left.\begin{array}{l} f_{p_i}(a,u,p) \text{ for } i \in I^{\mathcal{D}}_a \text{ does not depend on } u_j, p_j \text{ with } j \notin I^{\mathcal{D}}_a, \\ f_{p_i u_j} = f_{p_j u_i} \text{ for } i,j \in I^{\mathcal{D}}_a, \end{array}\right\} \tag{5.5}$$

then a field of extremals satisfying (5.1), (5.2), (5.3) exists.

Remark 5.3. The well known Weierstrass necessary condition for minimizers asserts that the inequality $E(x,u^0(x),(u^0)'(x),q)\geq 0$ for all $q\in\mathbb{R}^N$ or $q=q(x)$ satisfying $|q-(u^0)'(x)|\leq\eta$ is necessary for u^0 to be a strong or weak minimizer, respectively, hence the nonnegativity conditions on E in Theorem 5.2 are not far from optimal. Similarly, Theorem 5.2(ii) shows that the sufficient conditions (5.2)–(5.3) in Theorem 5.2(i) are also necessary in some sense, at least if $I_a^{\mathcal{D}}=\emptyset$. □

The proof of part (iii) of Theorem 5.2 is quite technical and, in addition, we will not need that part in our examples (since we will prove the existence of the field required by Theorem 5.2(i)–(ii) by other arguments). Therefore the proof of part (iii) is postponed to the Appendix.

In what follows we assume that

$$\begin{aligned}&f\in C^2,\ u^0\in C^2 \text{ is an extremal,}\\&\mathcal{P}\text{ is a field of extremals for } u^0 \text{ with slope } \psi, \text{ and (5.1) is true.}\end{aligned}\tag{5.6}$$

Given $v\in C^1([a,b],\mathbb{R}^N)$ such that $\operatorname{graph}(v):=\{(x,v(x)):x\in[a,b]\}\subset\mathcal{P}$, we define the Hilbert invariant integral

$$I(v):=\int_a^b\big[f\big(x,v(x),\psi(x,v(x))\big)+\big(v'(x)-\psi(x,v(x))\big)\cdot f_p\big(x,v(x),\psi(x,v(x))\big)\big]\,dx.$$

The following proposition is well known, but for the reader's convenience we provide its proof in the Appendix.

Proposition 5.4. *Assume* (5.6). *Then there exists* $S\in C^2(\mathcal{P})$ *such that*

$$\begin{aligned}&I(v)=S(b,v(b))-S(a,v(a))\quad\textit{for any}\ \ v\in C^1([a,b],\mathbb{R}^N)\ \ \textit{with}\ \ \operatorname{graph}(v)\subset\mathcal{P},\\&S_v(x,v)=f_p(x,v,\psi(x,v))\quad\textit{for any}\ \ (x,v)\in\mathcal{P}.\end{aligned}\tag{5.7}$$

Proof of Theorem 5.2. (i) Let $u-u^0\in C^1_{\mathcal{D}}$, $\operatorname{graph}(u)\subset\mathcal{P}$, and let S be the function from Proposition 5.4. If u is close to u^0 in the sup-norm, then the assumptions (5.2)–(5.3) guarantee

$$S(a,u(a))-S(a,u^0(a))=\int_0^1 S_v(a,u^0(a)+t(u(a)-u^0(a)))\cdot(u(a)-u^0(a))\,dt\leq 0,$$

and similarly $S(b,u(b))-S(b,u^0(b))\geq 0$, hence $I(u^0)\leq I(u)$ due to Proposition 5.4. This fact and assumption (5.4) imply

$$\Phi(u)-\Phi(u^0)=\Phi(u)-I(u^0)\geq\Phi(u)-I(u)=\int_a^b E(x,u(x),\psi(x,u(x)),u'(x))\,dx\geq 0,$$

hence u^0 is a strong minimizer. The remaining assertions in (i) are obvious.

(ii) Choose $t_k\to 0+$ and let α_k be such that $\varphi(b,\alpha_k)=u^0(b)+t_kw^0$. Then $u^k:=\varphi(\cdot,\alpha_k)\to u^0$ in C^1, $u^k-u^0\in C^1_{\mathcal{D}}$ due to $I_a^{\mathcal{D}}=\emptyset$ and $w^0\in\mathbb{R}^N_{\mathcal{D},b}$, and, similarly as in (i), we obtain

$$\Phi(u^k)=I(u^k)=S(b,u^k(b))-S(a,u^k(a))<S(b,u^0(b))-S(a,u^0(a))=I(u^0)=\Phi(u^0),$$

hence u^0 is not a minimizer. □

6 Scalar examples with variable endpoints

Throughout this section (except for Remark 6.4) we assume $N = 1$ and $I_a^{\mathcal{D}} = I_b^{\mathcal{D}} = \emptyset$. Since we will often use Theorem 5.2, let us first reformulate it in this special case. Notice that the extremals in the field of extremals satisfy $\varphi_\alpha(x,\alpha) \neq 0$, hence we can assume $\varphi_\alpha > 0$ without loss of generality.

Theorem 6.1. *Let $N = 1$, $I_a^{\mathcal{D}} = I_b^{\mathcal{D}} = \emptyset$, $f \in C^2$ and let $u^0 \in C^2$ be an extremal satisfying* (2.2)*.*

(i) *Let there exist a field of extremals $\mathcal{P} = \{(x,\varphi(x,\alpha)) : x \in [a,b],\ \alpha \in (-\varepsilon,\varepsilon)\}$ for u^0 satisfying the conditions $\varphi_\alpha > 0$ and*

$$f_p^\alpha(a)\alpha \leq 0 \leq f_p^\alpha(b)\alpha, \qquad \alpha \in (-\varepsilon,\varepsilon), \tag{6.1}$$

where $f_p^\alpha(x) := f_p(x,\varphi(x,\alpha),\varphi_x(x,\alpha))$. Assume also

$$E(x,v,\psi(x,v),q) \geq 0 \quad \text{for all} \ \ ((x,v),q) \in \mathcal{P}\times\mathbb{R}. \tag{6.2}$$

Then u^0 is a strong minimizer.

If (6.2) *is only true for all $(x,v) \in \mathcal{P}$ and $q = q(x,v)$ satisfying $|q - \psi(x,v)| \leq \eta$ for some $\eta > 0$, then u^0 is a weak minimizer.*

If $\mathcal{P} = [a,b]\times\mathbb{R}$, then u^0 is a global minimizer.

(ii) *Let there exist a field of extremals satisfying $\varphi_\alpha > 0$. If, for $\alpha > 0$ or $\alpha < 0$, the reversed inequalities in* (6.1) *are true and one of them is strict (for example, if $f_p^\alpha(a) \geq 0 > f_p^\alpha(b)$ for $\alpha > 0$), then u_0 is not a weak minimizer.*

(iii) *Assume* (2.4) *and let the sufficient conditions for a weak minimizer in Theorem 3.3(ii) be satisfied. Then a field of extremals satisfying $\varphi_\alpha > 0$ and* (6.1) *exists.*

Remark 6.2. If $f_{up}^0 = 0$ and we set $P := f_{pp}^0$, $Q := f_{uu}^0$, then $\Psi(h) = \int_a^b (P(h')^2 + Qh^2)\,dx$ and the Jacobi equation has the form $-\frac{d}{dx}(Ph') + Qh = 0$. Notice also that if $P, Q > 0$, then Ψ is positive definite in $W^{1,2}$. Consequently, Remark 3.6(iii) implies that the sufficient conditions for a weak minimizer in Theorem 3.3(ii) are satisfied and Theorem 6.1(iii) implies the existence of a field of extremals satisfying $\varphi_\alpha > 0$ and (6.1). □

In the following examples we will consider Lagrangians $f = f(u,p)$ and we will use the phase plane analysis for the Du Bois-Reymond equation $f^0 - (u^0)'f_p^0 = C$.

Example 6.3. The study of the deformation of a planar weightless inextensible and unshearable rod (satisfying suitable boundary conditions) leads to the minimization of the functional

$$\Phi(u) = \int_0^1 \Big(\frac{1}{2}(u'-K)^2 + M\cos u\Big)\,dx, \qquad u \in C^1([0,1]), \tag{6.3}$$

where $K \in \mathbb{R}$, $M > 0$, and u denotes the angle between the tangent to the rod and a suitable vertical, see [10, (97)] and cf. also [1]. Functional Φ possesses multiple critical points, i.e. extremals satisfying the natural boundary conditions $u'(0) = u'(1) = K$; see [10] for their detailed analysis. Their stability was also analyzed in [10], but that analysis based on the approach from [12] is unnecessarily complicated. Somewhat simpler arguments were used in [1], but those arguments cannot be used for all critical points. We will show that Theorems 3.3 and 6.1 yield a very simple way to determine the stability of any critical point.

Proposition 2.3 implies that u^0 is a weak minimizer of Φ if and only if it is a strong minimizer. Therefore we will only speak about minimizers. Notice also that $f_{pp} = 1$ and the excess function satisfies $E(x,u,p,q) = \frac{1}{2}(q-p)^2 \geq 0$. Proposition 2.4 guarantees that any critical point of Φ is C^∞ and satisfies the Du Bois-Reymond equation $(u')^2 = 2M\cos u + C$, where C is a constant. Conversely, any non-constant solution of the Du Bois-Reymond equation is an extremal.

We consider the phase plane (u,v), where $v = u'$, and set

$$\phi_C := \{(u,v) : v^2 = 2M\cos u + C\}, \qquad C \in (-2M,\infty)$$

(see Figure 6.1). The considerations above show that given any non-constant critical point u^0, there exists $C^0 > -2M$ such that $(u^0(x),(u^0)'(x)) \in \phi_{C^0}$ for $x \in [0,1]$, $(u^0)'(0) = (u^0)'(1) = K$. On the other hand, if $(A_0,K),(A_1,K) \in \Phi_{C^0}$ for some $C^0 \in (2M,\infty)$, $A_0 \neq A_1$, and $u^0 \in C^1$ satisfies $(u^0(x),(u^0)'(x)) \in \phi_{C^0}$ for $x \in [0,1]$, $(u^0(0),(u^0)'(0)) = (A_0,K)$ and $(u^0(b),(u^0)'(b)) = (A_1,K)$ for some $b > 0$, then u^0 is a critical point if and only if $b = 1$ (the value of b is uniquely determined in this case since $(u^0)' \neq 0$). Similar assertion is true if $C^0 \in (-2M,2M]$ ($K \neq 0$ if $C^0 = 2M$), but this time one can have $(u^0(b),(u^0)'(b)) = (A_1,K)$ for multiple values of b (since u^0 need not be monotone), and one has to allow $A_1 = A_0$.

The phase plane analysis can be used to find critical points of Φ (see [2] for a particular case), but since those critical points are known (see [10], for example), we will restrict ourselves to the determination of their stability. More precisely, considering the case $K \geq 0$ (the case $K \leq 0$ being symmetric), we will show the following: A critical point of Φ is a minimizer if and only if either $u^0(x) \equiv (2k+1)\pi$ for some integer k or u^0 is a part of curve ϕ_{C^0} with $C^0 > 2M$ and $(u^0)''(0) < 0 < (u^0)''(1)$.

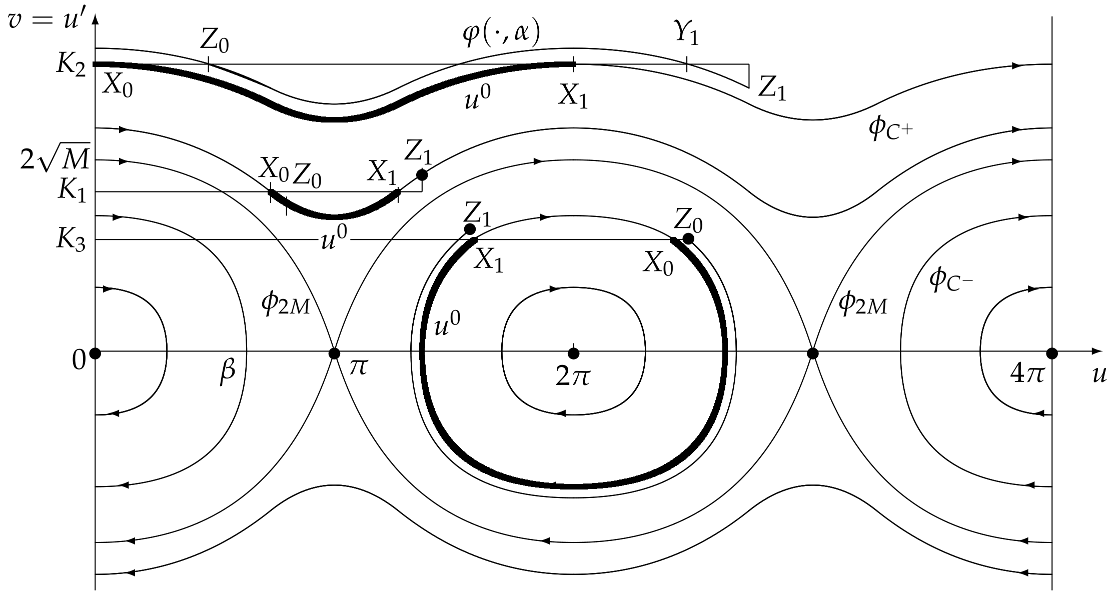

Figure 6.1: Phase plane and extremals for Example 6.3 and $0 \leq u \leq 4\pi$; $C^- < 2M < C^+$, $Z_i = (\varphi(i,\alpha),\varphi_x(i,\alpha))$, $i = 0,1$, $Y_1 = (A_1+\alpha,K)$, $X_i = (A_i,K) = (u^0(i),(u^0)'(i))$, $i = 0,1$.

Let us first consider a critical point u^0 being a part of curve ϕ_{C^0} with $C^0 > 2M$, and let (A_i,K) be as above. For symmetry reasons we may assume $K > 0$. Notice that $u'' = -M\sin u$,

$|(u^0)''(0)| = |(u^0)''(1)|$, and that $u^0(x)$ can also be defined (as an extremal, hence a part of ϕ_{C^0}) for $x \notin [0,1]$.

If $(u^0)''(0) < 0 < (u^0)''(1)$ (i.e. $u^0(0) \in (2k\pi, (2k+1)\pi)$ and $u^0(1) \in ((2m+1)\pi, (2m+2)\pi)$ for some $m \geq k$; see the extremal u^0 with $(u^0)'(0) = K_1$ in Figure 6.1), then $\varphi(x,\alpha) := u^0(x+\alpha)$, $x \in [0,1]$, $\alpha \in (-\varepsilon, \varepsilon)$, is a field of extremals for u^0 satisfying (6.1), hence Theorem 6.1(i) guarantees that u^0 is a minimizer. If $(u^0)''(0) > 0 > (u^0)''(1)$, then the same argument and Theorem 6.1(ii) show that u^0 is not a minimizer.

Next assume that $(u^0)''(0) \cdot (u^0)''(1) \geq 0$. We will show that u^0 is not a minimizer.

Assume $(u^0)''(0) < 0$, or $(u^0)''(0) = 0$ and $(u^0)'''(0) < 0$ (the cases $(u^0)''(0) > 0$, or $(u^0)''(0) = 0$ and $(u^0)'''(0) > 0$ are analogous). We necessarily have $A_1 = A_0 + 2k_0\pi$ for some $k_0 \in \{1, 2, \dots\}$. Let $\varphi(\cdot,\alpha)$ (with $|\alpha|$ being small) be the extremal with initial values $Z_0 := (\varphi(0,\alpha), \varphi_x(0,\alpha)) = (A_0 + \alpha, K)$ (see the extremal u^0 with $(u^0)'(0) = K_2$ in Figure 6.1). Then φ is a field of extremals for u^0, and $\varphi(\cdot,\alpha)$ is a part of the curve ϕ_{C^α}, where C^α is close to C^0, $C^\alpha > C^0$ if $\alpha > 0$.

Let $\alpha > 0$ be small. If u^1 and u^2 are extremals in ϕ_{C^0} and ϕ_{C^α}, respectively, and $u^1(0) = u^2(0) = 0$, then $u^1(b_1) = u^2(b_2) = 2\pi$ for some $0 < b_1 < b_2$ (due to $(u^2)' > (u^1)'$ whenever $u^2 = u^1$). This fact and the 2π-periodicity of the problem guarantee that $\varphi(b,\alpha) = A_1 + \alpha$ for some $b < 1$, hence $\varphi_x(1,\alpha) < (u^0)'(1)$, and Theorem 6.1(ii) implies that u^0 is not a minimizer.

Next consider the case $C^0 \in (-2M, 2M]$ and $K \geq 0$; $K \neq 0$ if $C^0 = 2M$. If $K > 0$ and $(u^0)''(0) > 0 > (u^0)''(1)$, then the same arguments as above guarantee that u^0 is not a minimizer. If $K = 0$ or $(u^0)''(0) < 0 < (u^0)''(1)$ (hence $A_1 < A_0$) or $(u^0)''(0) \cdot (u^0)''(1) \geq 0$ (hence $A_0 = A_1 = 2k\pi$), then choosing $\varphi(\cdot,\alpha)$ to be an extremal satisfying initial conditions $(\varphi(0,\alpha), \varphi_x(0,\alpha)) = (A_0 + \alpha, K)$ we see from the phase plane that $\varphi(\cdot,\alpha)$ and u^0 intersect in $(0,1)$ for any $\alpha \neq 0$ small (if, for example, $(u^0)''(0) < 0 < (u^0)''(1)$ and $\alpha > 0$ is small, then there exists $y \in (0,1)$ such that $\varphi(y,\alpha) = \min \varphi(\cdot,\alpha) < \min u^0$, and the inequalities $\varphi(0,\alpha) > u^0(0)$, $\varphi(y,\alpha) < u^0(y)$ imply that $\varphi(\cdot,\alpha)$ and u^0 intersect in $(0,y)$; see the extremal u^0 with $(u^0)'(0) = K_3$ in Figure 6.1). Consequently, $h := \varphi_x(\cdot,0)$ is a solution of the Jacobi equation satisfying $h(0) = 1$, $h'(0) = 0$, $h(y) = 0$ for some $y \in (0,1]$, and Theorem 3.3 guarantees that u^0 is not a minimizer.

Similar considerations as above can be used in the case of constant extremals $k\pi$, but we will use a different argument: If $u^0 \equiv (2k+1)\pi$, then $P = 1$, $Q = -M\cos u^0 = M$, and the solution $h(x) = e^{\sqrt{M}x} + e^{-\sqrt{M}x}$ of the Jacobi equation satisfies $h > 0$, $h'(0) = 0$, $h'(1) > 0$, hence u^0 is a minimizer. If $u^0 \equiv 2k\pi$, then $P = 1$, $Q = -M$ and the solution $h(x) = \cos(\sqrt{M}x)$ of the Jacobi equation satisfies $h(0) > 0$, $h'(0) = 0$ and either $h(x) = 0$ for some $x \in (0,1]$ or $h'(1) < 0$, hence u^0 is not a minimizer. □

Remark 6.4. The author of [9] considers the functional Φ in (6.3) with $K = 0$, $[a,b] = [-1/2, 1/2]$ (instead of $[a,b] = [0,1]$), and the Dirichlet boundary conditions $u(-1/2) = u(1/2) = 0$, see [9, (6)]. He considers the extremal u^0 satisfying $u^0(0) = \beta$ and $(u^0)'(0) = 0$, i.e. the extremal passing through the point $(\beta, 0)$ in Figure 6.1, and he provides explicit formulas for this extremal, its field of extremals φ and the derivative φ_α (see [9, (8),(9),(13),(14) and (16)]; functions u^0, φ and φ_α are denoted by θ, y and $\partial y/\partial\gamma$, respectively). The nonnegativity of the excess function then implies that u^0 is a strong minimizer. In [9, Introduction], the author claims that "Based on the Jacobian test, potential energy of Euler elasticas ... was proved to hold a weak minimum value...", but "...it is an open problem to find sufficient conditions for the potential energy for these Euler elasticas to hold a strong minimum." However, Proposition 2.3 shows that weak and strong minimizers of functional Φ in (6.3) are equivalent. In addition, Theorem 5.2(iii) implies that the positive definiteness of the second variation ψ in

$W_0^{1,2}(-1/2, 1/2)$ (i.e. the sufficient condition for a weak minimizer) guarantees the existence of the required field φ, hence the technical construction of the field in [9] is not necessary even if we do not consider Proposition 2.3. $\square$

Example 6.5. Consider the functional $\Phi(u) = \int_a^b f(u, u')\, dx$ in $C^1([a, b])$, where $f(u, p) = g(p) + u^2$ and g is a double-well function. More precisely, we will consider the following two cases (see Figure 6.2):

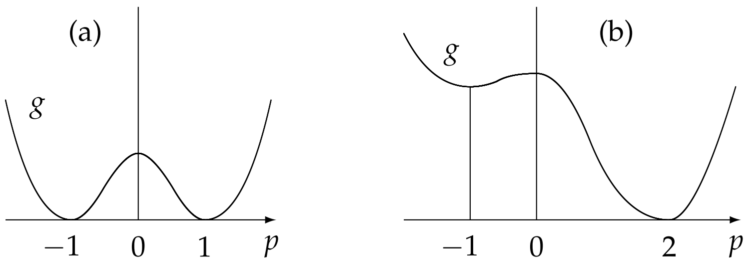

Figure 6.2: Graphs of g in the symmetric and non-symetric cases.

(a) $g(p) = (p^2 - 1)^2$ (hence $g'(p) = 4p(p^2 - 1)$, $g''(p) = 4(3p^2 - 1)$),
(b) $g(p) = \frac{1}{4}p^4 - \frac{1}{3}p^3 - p^2 + \frac{8}{3}$ (hence $g'(p) = (p + 1)p(p - 2)$, $g''(p) = 3p^2 - 2p - 2$).
Let us consider the symmetric case (a) first. The Du Bois-Reymond equation has the form

$$u^2 = C + h(u'), \qquad \text{where} \quad h(p) := 3p^4 - 2p^2,$$

see Figures 6.3 and 6.4 for the graph of h and the phase plane (u, u'), respectively. All minimizers have to satisfy $u'(a), u'(b) \in \{0, \pm 1\}$; the only constant extremal is $u \equiv 0$. Functional Φ does not possess local maximizers since $\Phi''(u^0)(1, 1) > 0$ for any u^0.

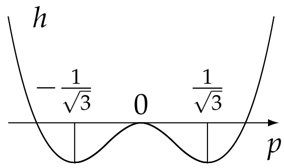

Figure 6.3: Graph of h in the symmetric case.

Since $f_{pp}(u, p) = 4(3p^2 - 1)$, the extremals in the region $|u'| \leq 1/\sqrt{3}$ (satisfying $(u^0)'(a) = (u^0)'(b) = 0$) cannot be local minimizers. The extremal u^* with $(u^*)'(a) = 1$ and $\min(u^*)' = 1/\sqrt{3}$ (see Figure 6.4) satifies $u^*(b^*) = 1$ for some $b^* > a$. If $b \in (a, b^*)$, then there exists a unique extremal u^0 satisfying $(u^0)'(a) = (u^0)'(b) = 1$ (and a unique extremal u^1 satisfying $(u^1)'(a) = (u^1)'(b) = -1$); in addition $(u^0)' > 1/\sqrt{3}$ (and $(u^1)' < -1/\sqrt{3}$). Since $P, Q > 0$ and the excess function $E = (q - p)^2((q + p)^2 + 2(p^2 - 1))$ considered as a function of q changes sign if $|p| < 1$, Remarks 6.2 and 5.3 show that the extremals u^0, u^1 are weak but not strong minimizers. (Remark 6.2 also guarantees the existence of a field of extremals, but this fact is not needed here: The Weierstrass necessary condition for strong minimizers in Remark 5.3 does not require the existence of a field of extremals.) Notice also that $\inf \Phi = 0$ is not attained (neither in C^1, nor in $W^{1,4}$): A minimizing sequence in C^1 can be obtained by suitable smooth approximation of piecewise C^1-functions u_ε satisfying $|u_\varepsilon'| = 1$ a.e. and $|u_\varepsilon| \leq \varepsilon$.

Next consider the nonsymmetric case (b). The Du Bois-Reymond equation has the form

$$u^2 = C + h(u'), \qquad \text{where} \quad h(p) := \frac{3}{4}p^4 - \frac{2}{3}p^3 - p^2,$$

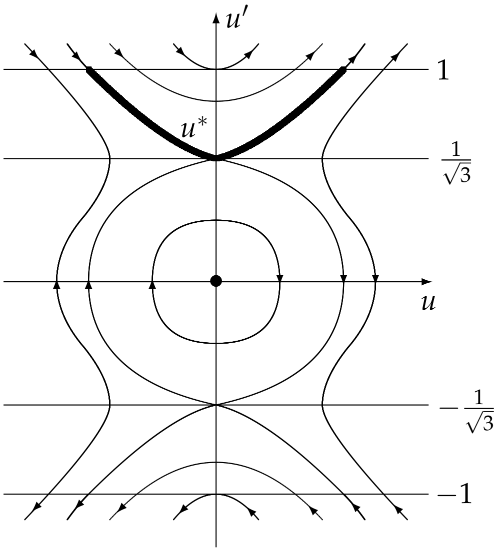

Figure 6.4: Phase plane in the symmetric case.

see Figures 6.5 and 6.6 for the graph of h and the phase plane (u, u'), respectively. All minimizers have to satisfy $u'(a), u'(b) \in \{0, -1, 2\}$; the only constant extremal is $u \equiv 0$.

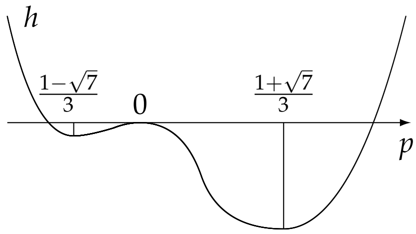

Figure 6.5: Graph of h in the non-symmetric case.

Since $f_{pp}(u, p) = 3p^2 - 2p - 2$, similarly as in case (a) we see that the extremals in the region $u' \in [\frac{1-\sqrt{7}}{3}, \frac{1+\sqrt{7}}{3}]$ are neither local minimizers nor local maximizers. The extremal u^* with $(u^*)'(a) = 2$ and $\min(u^*)' = \frac{1+\sqrt{7}}{3}$ (see Figure 6.6) satisfies $u^*(b^*) = 2$ for some $b^* > a$. If $b \in (a, b^*)$, then there exists a a unique extremal u^0 satisfying $(u^0)'(a) = (u^0)'(b) = 2$ and, as above, this extremal is a weak local minimizer. However, now $E = \frac{1}{12}(q-p)^2((\sqrt{3}(q+p) - \frac{2}{\sqrt{3}})^2 + 6p^2 - 4p - 13\frac{1}{3}) \geq 0$ for all q if $p \leq p_1$ or $p \geq p_2$, where $p_1 = \frac{1}{3}(1-\sqrt{21}) < -1$, $p_2 = \frac{1}{3}(1+\sqrt{21}) \in (\frac{1}{3}(1+\sqrt{7}), 2)$, and Remark 6.2 guarantees the existence of a field of extremals satisfying $\varphi_\alpha > 0$ and (6.1), hence u^0 is a strong local minimizer provided $\min(u^0)' > p_2$ (and it is not if $\min(u^0)' < p_2$). In fact, if $\min(u^0)' > p_2$, then Proposition 6.6 below shows the existence of a global field of extremals for u^0 satisfying the assumptions of Theorem 6.1(i), with slope $\psi > p_2$, hence u^0 is a global minimizer.

An analogous analysis as in the case $u' > \frac{1+\sqrt{7}}{3}$ shows that the extremals in the region $u' < \frac{1-\sqrt{7}}{3}$ are weak but not strong local minimizers. □

Proposition 6.6. *Let Φ and p_2 be as in Example 6.5(b), and let u^0 be a critical point of Φ satisfying $\min(u^0)' > p_2$. Then there exists a global field of extremals for u^0 satisfying the assumptions of Theorem 6.1(i), with slope $\psi > p_2$.*

Proof. Assume first $\alpha \geq 0$. Then we choose the extremals $u^\alpha := \varphi(\cdot, \alpha)$ in the global field such

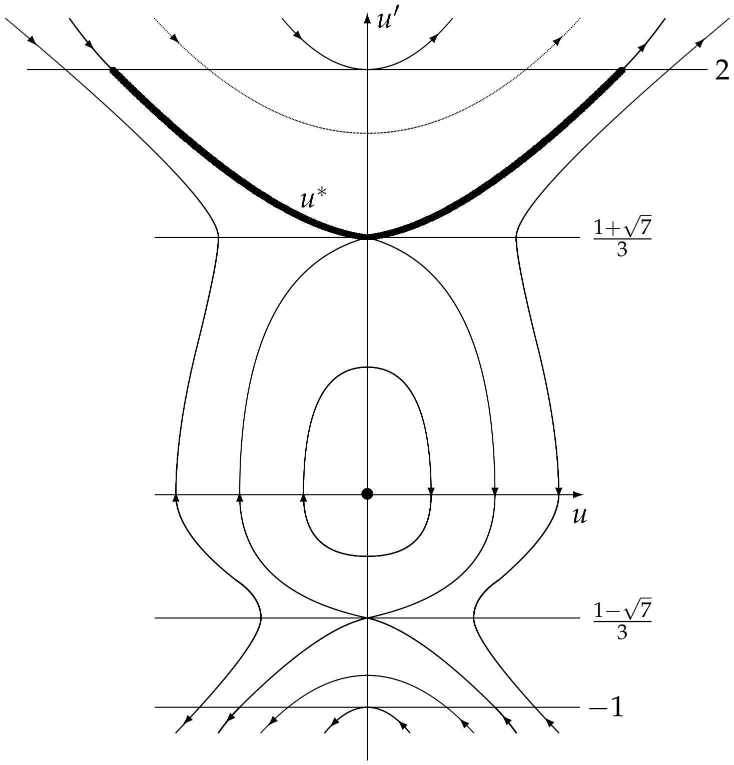

Figure 6.6: Phase plane in the non-symmetric case.

that $\varphi(\cdot,\alpha)$ is the solution of the Du Bois-Reymond equation with $(\varphi(a,\alpha),\varphi_x(a,\alpha)) = A(\alpha)$, where $A(\alpha) = (A_1(\alpha), A_2(\alpha)) : (0,\infty) \to \mathbb{R}^2$ is smooth,

$$A(\alpha) = \begin{cases} (u^0(a+\alpha),(u^0)'(a+\alpha)) & \text{if } \alpha \le b-a-\varepsilon, \\ (u^0(b)+\alpha-(b-a),2) & \text{if } \alpha \ge b-a+\varepsilon, \end{cases} \tag{6.4}$$

$$A_1'(\alpha) \ge 1, \quad A_2'(\alpha) > 0 \quad \text{for } \alpha \in (b-a-\varepsilon, b-a+\varepsilon), \text{ where } \varepsilon \in (0,(b-a)/2), \tag{6.5}$$

see Figure 6.7. Notice that $A_1'(b-a-\varepsilon) = (u^0)'(b-\varepsilon) > p_2 > 1$, $A_2'(b-a-\varepsilon) = (u^0)''(b-\varepsilon) > 0$, $A_1'(b-a+\varepsilon) = 1$, $A_2'(b-a+\varepsilon) = 0$, $A_1(b-a+\varepsilon) - A_1(b-a-\varepsilon) > 2\varepsilon$ (since $A_1(b-a+\varepsilon) = u^0(b)+\varepsilon$, $A_1(b-a-\varepsilon) = u^0(b-\varepsilon)$, $u^0(b) - u^0(b-\varepsilon) = (u^0)'(b-\theta\varepsilon)\varepsilon > p_2\varepsilon$), $A_2(b-a+\varepsilon) > A_2(b-a-\varepsilon)$, so that (6.5) can be satisfied.

Let us show that $\varphi_\alpha > 0$. Since $\varphi(x,\alpha) = u^0(x+\alpha)$ for $\alpha \le b-a-\varepsilon$ and $(u^0)' > 0$, we may assume $\alpha > b-a-\varepsilon$, hence $\varphi > 0$. Set $w(x,\alpha) = \varphi_\alpha(x,\alpha)$. Then (6.4)–(6.5) imply $w(a,\alpha) \ge 1$. Let h^{-1} denote the inverse of the increasing function $h|_{(p_2,\infty)}$. Since $\varphi(\cdot,\alpha)$ solves the Du Bois-Reymond equation, there exists $C(\alpha)$ such that $\varphi(x,\alpha)^2 = C(\alpha) + h(\varphi_x(x,\alpha))$. Consequently,

$$w_x = \frac{\partial}{\partial x}(\varphi_\alpha) = \frac{\partial}{\partial \alpha}(\varphi_x) = \frac{\partial}{\partial \alpha}(h^{-1}(\varphi^2 - C(\alpha)) = \underbrace{(h^{-1})'(\varphi^2 - C(\alpha))}_{>0}[2\varphi w - C'(\alpha)]. \tag{6.6}$$

If $w_x(a,\alpha) > 0$ (which is true for $\alpha < b-a+\varepsilon$ due to (6.4)–(6.5)), then $\varphi_x > 0$ and (6.6) guarantee $w_x(x,\alpha) > 0$ for $x > a$, hence $w(x,\alpha) \ge w(a,\alpha) \ge 1$. If $w_x(a,\alpha) = 0$ (which is true for $\alpha \ge b-a+\varepsilon$ due to (6.4)), then $(2\varphi w)(a,\alpha) = C'(\alpha)$ and

$$\frac{d}{dx}(2\varphi w - C'(\alpha))(a,\alpha) = 2\varphi_x w + 2\varphi w_x = 2\varphi_x w > 2p_2 > 0$$

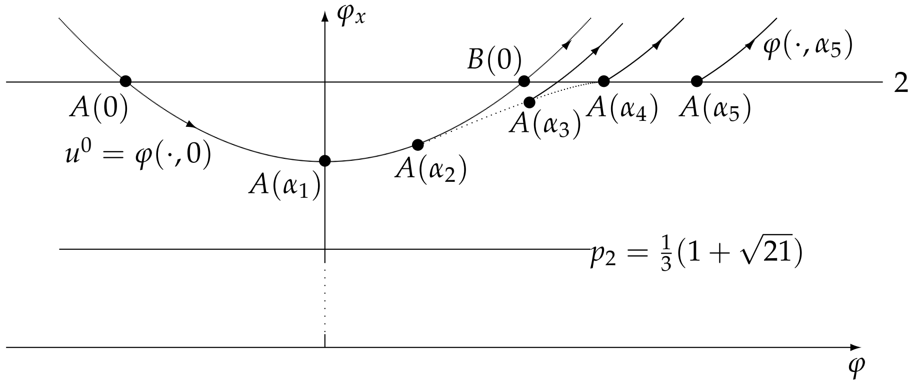

Figure 6.7: Global field of extremals: $A(\alpha) = (\varphi(a,\alpha),\varphi_x(a,\alpha))$, $B(\alpha) = (\varphi(b,\alpha),\varphi_x(b,\alpha))$, $(b-a)/2 = \alpha_1 < b-a-\varepsilon = \alpha_2 < \alpha_3 < \alpha_4 = b-a+\varepsilon < \alpha_5$.

hence $w_x(x,\alpha) > 0$ for $x > a$ close to a, and (6.6) implies $w_x(x,\alpha) > 0$ for all $x > a$. As before, this implies $w(x,\alpha) \geq 1$.

If $\alpha < 0$, then the choice of $\varphi(\cdot,\alpha)$ is symmetric: The extremal $\varphi(\cdot,\alpha)$ solves the Du Bois-Reymond equation in $[a,b]$ and $(\varphi(b,\alpha),\varphi_x(b,\alpha)) = B(\alpha) := (-A_1(-\alpha),A_2(-\alpha))$.

As an alternative to the technical construction of the global field above, we could also set $(\varphi(a,\alpha),\varphi_x(a,\alpha)) = A(\alpha)$, where

$$A(\alpha) = \begin{cases} (u^0(a+\alpha),(u^0)'(a+\alpha)) & \text{if } 0 \leq \alpha \leq b-a, \\ (u^0(b)+\alpha-(b-a),2) & \text{if } \alpha > b-a, \end{cases}$$

and analogously for $\alpha < 0$. Then the field $\varphi(\cdot,\alpha)$ is not sufficiently smooth if $|\alpha| = b-a$, but a simple generalization of Theorem 6.1 shows that this does not matter. In fact, denote $v^{\pm} := \varphi(\cdot,\pm(b-a))$. Let $u \in C^1([a,b])$; we want to show $\Phi(u) \geq \Phi(u^0)$. Approximating u suitably, we may assume that the set $\{x \in [a,b] : u(x) = v^+(x) \text{ or } u(x) = v^-(x)\}$ is finite. Set $\tilde{u} := \max(v^-,\min(v^+,u))$ and approximate $\tilde{u}$ by a sequence of C^1-functions u^k such that $\operatorname{graph}(u^k) \subset \mathcal{P}_1 := \{(x,\varphi(x,\alpha)) : x \in [a,b],\ |\alpha| \leq b-a\}$ and $u^k \to \tilde{u}$ in $W^{1,4}$. Then Theorem 6.1 shows that $\Phi(u^k) \geq \Phi(u^0)$, hence $\Phi(\tilde{u}) \geq \Phi(u^0)$ due to the continuity of Φ in $W^{1,4}$. Let $[x_1,x_2]$ be any maximal interval where $\tilde{u} = v^+$ (i.e. $u \geq v^+$) or $\tilde{u} = v^-$. Notice that either $x_1 = a$ or $u(x_1) = v^{\pm}(x_1)$, and either $x_2 = b$ or $u(x_2) = v^{\pm}(x_2)$. Denote $\Phi_{x_1}^{x_2}(u) = \int_{x_1}^{x_2} f(x,u(x),u'(x))\,dx$. Then the proof of Theorem 6.1 shows $\Phi_{x_1}^{x_2}(u) \geq \Phi_{x_1}^{x_2}(v^+)$ (if $u \geq v^+$ in $[x_1,x_2]$) or $\Phi_{x_1}^{x_2}(u) \geq \Phi_{x_1}^{x_2}(v^-)$, hence $\Phi(u) \geq \Phi(\tilde{u}) \geq \Phi(u^0)$. □

7 Appendix

Proof of Proposition 2.1. We will consider only the special case $N = 1$, $I_a^{\mathcal{D}} = \emptyset$, $I_b^{\mathcal{N}} = \emptyset$, but the arguments in our proof can also be used in the general case.

If $h \in C_{\mathcal{D}}^1 = \{\varphi \in C^1([a,b]) : \varphi(b) = 0\}$, then integration by parts yields

$$\begin{aligned} 0 = \Phi'(u^0)h &= \int_a^b (f_p^0(x)h'(x) + f_u^0(x)h(x))\,dx \\ &= gh\Big|_a^b + \int_a^b (f_p^0(x) - g(x))h'(x)\,dx, \end{aligned} \tag{7.1}$$

where $g(x) := \int_a^x f_u^0(\xi)\,d\xi$ is C^1. Considering test functions h with compact support in (a,b), the Du Bois-Reymond Lemma and (7.1) yield the existence of a constant C such that $f_p^0(x) = g(x) + C$, hence $f_p^0 \in C^1$ and the Euler equation $\frac{d}{dx}(f_p^0) = f_u^0$ is satisfied. This equation and the choice of h with $h(a) = 1$ in (7.1) imply

$$\begin{aligned} 0 = \Phi'(u^0)h &= \int_a^b (f_p^0(x)h'(x) + f_u^0(x)h(x))\,dx \\ &= f_p^0 h\Big|_a^b + \int_a^b \Big(-\frac{d}{dx}(f_p^0(x)) + f_u^0(x)\Big)h(x)\,dx = -f_p^0(a), \end{aligned}$$

which concludes the proof of the first part. If $f_p \in C^1$ and $f_{pp}^0 \geq c^0 > 0$, then the function $F(x,p) := f_p(x, u^0(x), p) - g(x) - C$ is C^1, $F(x, (u^0)'(x)) = 0$, $F_p(x, (u^0)'(x)) > 0$, hence the Implicit Function Theorem implies $u^0 \in C^2$. □

Proof of Proposition 2.3. The proof is based on an idea due to [4].

Let $u^0 \in C^1$ be a weak minimizer of Φ in $u^0 + C^1_{\mathcal{D}}$. Assume first that there exist $v^k \in W^{1,2}_{\mathcal{D}}$, $k = 1, 2, \dots$, such that $r_k := \|v^k\|_{1,2} \to 0$ and $\Phi(u^0 + v^k) < \Phi(u^0)$. Since Φ is weakly lower semicontinuous in $W^{1,2}$, there exists a minimizer u^k of Φ in the set $\{u \in u^0 + W^{1,2}_{\mathcal{D}} : \|u - u^0\|_{1,2} \leq r_k\}$, hence $\Phi(u^k) \leq \Phi(u^0 + v^k) < \Phi(u^0)$. Set $\Theta(u) := \|u - u^0\|^2_{1,2}$. Then there exists a Lagrange multiplier λ_k such that $\Phi'(u^k)h = \lambda_k \Theta'(u^k)h$ for any $h \in W^{1,2}_{\mathcal{D}}$ (where the derivatives are considered in $W^{1,2}$). Since $\Phi'(u^k)(u^k - u^0) \leq 0$, we have $\lambda_k \leq 0$. Standard theory implies that $u^0, u^k \in C^2$ solve the Euler equation

$$2(1 - \lambda_k)(u^k)'' = g'(u^k) - 2\lambda_k((u^0)'' + u^k - u^0),$$

which shows that the sequence u^k is bounded in C^2. Since $u^k \to u^0$ in $W^{1,2}$, the boundedness in C^2 implies $u^k \to u^0$ in C^1 which contradicts the fact, that u^0 is a weak minimizer. Consequently, u^0 is a local minimizer in $u^0 + W^{1,2}_{\mathcal{D}}$.

Next assume that there exist $v^k \in C^1_{\mathcal{D}}$ such that $\|v^k\|_C \to 0$ and $\Phi(u^0 + v_k) < \Phi(u^0)$. Since $\Phi'(u^0)h = \int_a^b (2((u^0)' - K)h' + g'(u^0)h)\,dx = 0$ for $h \in C^1_{\mathcal{D}}$, we have

$$\begin{aligned} 0 < \Phi(u^0) - \Phi(u^0 + v^k) &= \int_a^b [((u^0)' - K)^2 - ((u^0)' + (v^k)' - K)^2]\,dx + o(1) \\ &= -\int_a^b (v^k)'[(v^k)' + 2((u^0)' - K)]\,dx + o(1) \\ &= -\|v^k\|^2_{1,2} + \int_a^b g'(u^0)v^k\,dx + o(1) = -\|v^k\|^2_{1,2} + o(1), \end{aligned}$$

hence $v^k \to 0$ in $W^{1,2}$, which yields a contradiction. Consequently, u^0 is a strong minimizer. □

Proof of Proposition 3.1. Assume that $\Psi(h) \geq c\|h\|^2_{1,2}$ for some $c > 0$ and all $h \in W^{1,2}_{\mathcal{D}}$ and recall that $\Psi(h) = \Phi''(u^0)(h,h)$ if $h \in C^1$. If u^1 is close u^0 in C^1 and Ψ^1 denotes the functional Ψ with u^0 replaced by u^1, then one can easily check that $\Psi^1(h) = \Phi''(u^1)(h,h) \geq \frac{c}{2}\|h\|^2_{1,2}$ for $h \in C^1_{\mathcal{D}}$, and the Mean Value Theorem implies the existence of $\theta \in (0,1)$ such that

$$\Phi(u^0 + h) - \Phi(u^0) = \frac{1}{2}\Phi''(u^0 + \theta h)(h,h) \geq \frac{c}{4}\|h\|^2_{1,2}$$

whenever $h \in C^1_{\mathcal{D}}$ is small enough. Consequently, u^0 is a strict weak minimizer in $u^0 + C^1_{\mathcal{D}}$.

If $\Psi(h) < 0$ for some $h \in W^{1,2}_{\mathcal{D}}$, then the density of $C^1_{\mathcal{D}}$ in $W^{1,2}_{\mathcal{D}}$ and the continuity of Ψ in $W^{1,2}_{\mathcal{D}}$ guarantee the existence of $\tilde{h} \in C^1_{\mathcal{D}}$ such that $0 > \Psi(\tilde{h}) = \Phi''(u^0)(\tilde{h}, \tilde{h})$, which shows that u^0 is not a weak minimizer $u^0 + C^1_{\mathcal{D}}$. □

Proof of Theorem 5.2(iii). First assume that $I_a^{\mathcal{N}} = \emptyset$. If $I_b^{\mathcal{N}} = \emptyset$, then the assertion is well known (see [7] or [8], for example), hence we may assume $I_b^{\mathcal{N}} \neq \emptyset$. Our assumptions imply $D \neq 0$ in $(a,b]$ and $\mathcal{B}h(b) \cdot h(b) > 0$ for any $h \in H_{\mathcal{D},b} \setminus \{0\}$. We may also assume that f is defined and of class C^3 in an open neighbourhood of $\{(x, u^0(x), (u^0)'(x)) : x \in [a,b]\}$ in $\mathbb{R} \times \mathbb{R}^N \times \mathbb{R}^N$ (see [2] for a detailed proof if $N = 1$). Consequently, there exists $\varepsilon > 0$ small such that u^0 can be extended (as an extremal) for $x \in [a-\varepsilon, a]$, f^0 satisfies (2.3) in $[a-\varepsilon, b]$, and the solutions $h^{(k)}$, $k = 1, 2, \dots, N$ of the Jacobi equation in $[a-\varepsilon, b]$ with initial conditions $h^{(k)}(a-\varepsilon) = 0$, $(h_i^{(k)})'(a-\varepsilon) = \delta_{ik}$, satisfy $D > 0$ in $(a-\varepsilon, b]$ and $\mathcal{B}h(b) \cdot h(b) > 0$ for any $h \in H_{\mathcal{D},b} \setminus \{0\}$ due to the continuous dependence of solutions of ODEs on initial values. Let $\varphi(\cdot, \alpha)$ be the extremal satisfying the initial conditions $\varphi(a-\varepsilon, \alpha) = u^0(a-\varepsilon)$, $\varphi_x(a, \alpha) = (u^0)'(a-\varepsilon) + \alpha$. The arguments in [7, 8] guarantee that such extremals define a field of extremals for u^0 (in $[a,b]$) satisfying (5.1). Condition (5.2) is empty, hence we only have to show that (5.3) is true. Thus assume that $v - u^0(b) \in \mathbb{R}^N_{\mathcal{D},b} \cap B_\varepsilon \setminus \{0\}$. We have $v = \varphi(b, \alpha)$ for some α small. Set $h^\alpha := \sum_k \alpha_k h^{(k)}$. If $i \in I_b^{\mathcal{D}}$, then $0 = \varphi_i(b, \alpha) - u_i^0(b) = h_i^\alpha(b) + o(\alpha)$, hence $h^\alpha = h^{\tilde\alpha} + o(\alpha)$ for some $h^{\tilde\alpha} \in H_{\mathcal{D},b} \setminus \{0\}$ and $\tilde\alpha = \alpha + o(\alpha)$. Since our assumptions imply $\mathcal{B}h^{\tilde\alpha}(b) \cdot h^{\tilde\alpha}(b) = \sum_{i \in I_b^{\mathcal{N}}} \mathcal{B}_i h^{\tilde\alpha}(b) h_i^{\tilde\alpha}(b) > 0$, we also have

$$
\begin{aligned}
f_p(b, v, \psi(b,v)) \cdot (v - u^0(b)) &= \sum_{i \in I_b^{\mathcal{N}}} f_{p_i}(b, \varphi(b,\alpha), \varphi_x(b,\alpha))(\varphi_i(b,\alpha) - u_i^0(b)) \\
&= \sum_{i \in I_b^{\mathcal{N}}} \big(\mathcal{B}_i h^\alpha(b) + o(\alpha)\big)\big(h_i^\alpha(b) + o(\alpha)\big) \\
&= \sum_{i \in I_b^{\mathcal{N}}} \big(\mathcal{B}_i h^{\tilde\alpha}(b) + o(\tilde\alpha)\big)\big(h_i^{\tilde\alpha}(b) + o(\tilde\alpha)\big) > 0.
\end{aligned}
$$

Next assume $I_a^{\mathcal{D}} = \emptyset$. Since our proof in this case uses similar arguments as in the case $I_a^{\mathcal{N}} = \emptyset$ (and a very detailed proof in the case $N = 1$ can be found in [2]), we will be brief. Given $\alpha \in \mathbb{R}^N$ small and $v = v(\alpha) := u^0(a) + \alpha$, the Implicit Function Theorem implies the existence of a unique $w = w(\alpha) \in \mathbb{R}^N$ close to $(u^0)'(a)$ such $f_p(a, v(\alpha), w(\alpha)) = 0$. Let $\varphi(\cdot, \alpha)$ be the extremal satisfying the initial conditions $\varphi(a, \alpha) = v(\alpha)$, $\varphi_x(a, \alpha) = w(\alpha)$. We claim that such extremals $\varphi(\cdot, \alpha)$ define the required field. In fact, the function P in Definition 5.1 is a C^1-diffeomorphism and $\varphi_x \in C^1$ due to the differentiability of solutions of ODEs on initial values and the fact that $h^{(k)} := \frac{\partial \varphi}{\partial \alpha_k}(\cdot, 0)$, $k = 1, \dots, N$, are linearly independent solutions of the Jacobi equation $\mathcal{A}h = 0$ satisfying the initial conditions $\mathcal{B}h(a) = 0$, hence $\det(h^{(1)}, \dots, h^{(N)}) \neq 0$ in $[a,b]$ due to our assumptions. Properties (5.1) and (5.2) follow from $f_p(a, v, \psi(a,v)) = 0$ and the proof of (5.3) is the same as in the case $I_a^{\mathcal{N}} = \emptyset$.

Finally assume (5.5). Let $h^{(1)}, \dots, h^{(N)}$ be solutions of the Jacobi equation $\mathcal{A}h = 0$ in $[a,b]$ satisfying the initial conditions

$$
\begin{aligned}
&h_i^{(k)}(a) = \eta\delta_{ik} \quad &&\text{for } k \in I_a^{\mathcal{D}}, i \in I, \quad &&(h_i^{(k)})'(a) = \delta_{ik} \quad &&\text{for } k \in I, i \in I_a^{\mathcal{D}}, \\
&h_i^{(k)}(a) = \delta_{ik} \quad &&\text{for } k \in I_a^{\mathcal{N}}, i \in I, \quad &&\mathcal{B}_i h^{(k)}(a) = 0 \quad &&\text{for } k \in I, i \in I_a^{\mathcal{N}},
\end{aligned}
$$

where $\eta \in [0,1]$. If $\zeta \geq 0$ is small, then

$$
\begin{aligned}
&h_i^{(k)}(a+\zeta) = (\eta+\zeta)\delta_{ik} + o(\zeta) \qquad &&\text{if } k, i \in I_a^{\mathcal{D}}, \\
&h_i^{(k)}(a+\zeta) = \delta_{ik} + O(\zeta) &&\text{otherwise,}
\end{aligned}
$$

hence $D(x) := \det(h^{(1)}(x), \dots, h^{(N)}(x)) > 0$ for $x \in [a, a+\zeta]$ and $\eta \in (0,1]$. If $\eta = 0$, then our assumptions imply $D(x) > 0$ for $x \in [a+\zeta, b]$ and $\mathcal{B}h(b) \cdot h(b) > 0$ for any $h := \sum_k \beta_k h^{(k)}$

satisfying $h_i(b) = 0$ for $i \in I_b^{\mathcal{D}}$ and $h \not\equiv 0$. Those properties remain true for $\eta > 0$ small and we fix such $\eta > 0$. Set $v_i(\alpha) = u_i^0(a) + \eta\alpha_i$ if $i \in I_a^{\mathcal{D}}$, $v_i(\alpha) = u_i^0(a) + \alpha_i$ if $i \in I_a^{\mathcal{N}}$ and $w_i(\alpha) = (u_i^0)'(a) + \alpha_i$ if $i \in I_a^{\mathcal{D}}$. The Implicit Function Theorem guarantees that there exist unique $w_i(\alpha)$ for $i \in I_a^{\mathcal{N}}$ (close to $(u_i^0)'(a)$) such that $f_{p_i}(a, v(\alpha), w(\alpha)) = 0$ for $i \in I_a^{\mathcal{N}}$ and α small. Let $\varphi(\cdot, \alpha)$ be extremals satisfying the initial conditions $\varphi(a, \alpha) = v(\alpha)$, $\varphi_x(a, \alpha) = w(\alpha)$. Then $\varphi_{\alpha_k}(a, 0) = h^{(k)}(a)$ and $\varphi_{x\alpha_k}(a, 0) = (h^{(k)})'(a)$, which shows that these extremals define a field of extremals for α small. The same arguments as above guarantee that properties (5.2),(5.3) are satisfied. Let us show that (5.1) is true. If $i, j \in I_a^{\mathcal{N}}$, then this follows from $f_{p_i}(a, v, \psi(a, v)) = f_{p_j}(a, v, \psi(a, v)) = 0$. Let $i \in I_a^{\mathcal{D}}$. If $j \in I_a^{\mathcal{N}}$, then the left-hand side in (5.1) is zero due to $f_{p_i u_j} = f_{p_i p_j} = 0$. If $j \in I_a^{\mathcal{D}}$, then that left-hand side equals $f_{p_i u_j}(a, v, \psi(a, v)) + \sum_{k \in I} f_{p_i p_k}(a, v, \psi(a, v))\psi_{k, v_j}(a, v)$. Since $f_{p_i u_j} = f_{p_j u_i}$, $f_{p_i p_k}(a, v, \psi(a, v)) = 0$ for $k \in I_a^{\mathcal{N}}$ and $\psi_{k, v_j}(a, v) = \frac{1}{\eta}\delta_{kj}$ if $k \in I_a^{\mathcal{D}}$, we see that that left-hand side equals to the right-hand side. □

Proof of Proposition 5.4. If $w = (w_1, \dots, w_N)$ depends on θ, then we denote $w_{i,\theta} := \frac{\partial w_i}{\partial \theta}$. By differentiating the identity $\varphi_x(x, \alpha) = \psi\big(x, \varphi(x, \alpha)\big)$ we obtain

$$\varphi_{j,xx} = \psi_{j,x} + \sum_k \psi_{j,v_k}\varphi_{k,x} = \psi_{j,x} + \sum_k \psi_{j,v_k}\psi_k.$$

If we substitute this relation into the Euler equations

$$\sum_j (f_{p_i p_j}\varphi_{j,xx} + f_{p_i u_j}\varphi_{j,x}) + f_{p_i x} - f_{u_i} = 0,$$

(where the arguments of the derivatives of f and φ are $\big(x, \varphi(x, \alpha), \varphi_x(x, \alpha)\big)$ and (x, α), respectively), then we obtain

$$\sum_j \Big(f_{p_i p_j}\big(\psi_{j,x} + \sum_k \psi_{j,v_k}\psi_k\big) + f_{p_i u_j}\psi_j\Big) + f_{p_i x} - f_{u_i} = 0, \tag{7.2}$$

where the arguments of the derivatives of f and ψ are $\big(x, v, \psi(x, v)\big)$ and (x, v), respectively. For $(x, v) \in \mathcal{P}$ we set

$$\begin{aligned} V(x, v) &:= f\big(x, v, \psi(x, v)\big) - f_p\big(x, v, \psi(x, v)\big) \cdot \psi(x, v), \\ W(x, v) &:= f_p\big(x, v, \psi(x, v)\big). \end{aligned} \tag{7.3}$$

We claim that

$$(W_{i,v_j} - W_{j,v_i})(x, v) = \frac{\partial f_{p_i}(x, v, \psi(x, v))}{\partial v_j} - \frac{\partial f_{p_j}(x, v, \psi(x, v))}{\partial v_i} = 0, \quad i, j \in I. \tag{7.4}$$

In fact, if f and φ are of class C^3, then setting $v = \varphi(x, \alpha)$ and $\psi(x, v) = \varphi_x(x, \alpha)$ in (7.4), the Euler equations imply that the d/dx-derivative of the resulting expression vanishes, hence the conclusion follows from (5.1). Such argument can also be used without the additional smoothness assumptions on f, φ, see the proof of [8, Proposition 6.1.1.4].

Now (7.4) and (7.2) imply $V_v = W_x$. This fact and (7.4) guarantee the existence of $S \in C^2(\mathcal{P})$ such that $S_x = V$ and $S_v = W$. Finally,

$$\begin{aligned} I(v) &= \int_a^b (V + W \cdot v')\,dx = \int_a^b (S_x + S_v \cdot v')\,dx = \int_a^b \frac{d}{dx} S\big(x, v(x)\big)\,dx \\ &= S\big(b, v(b)\big) - S\big(a, v(a)\big). \end{aligned}$$

□

Remark 7.1. Necessary and sufficient conditions for weak minimizers in [15, 16] are formulated in terms of (semi-)coupled points and seem to be more complicated than our conditions. In order to compare them, let us consider the scalar case with variable endpoints (i.e. $I_a^{\mathcal{D}} = I_b^{\mathcal{D}} = \emptyset$), and let h be the solution of the Jacobi equation satisfying the initial conditions $h(a) = 1$, $\mathcal{B}h(a) = 0$. Let us also denote $Q := f^0_{uu}$. Then our sufficient condition for a weak minimizer in Theorem 3.3 is equivalent to

$$h(y) \neq 0 \ \text{ for } \ y \in (a, b] \quad \text{and} \quad \mathcal{B}h(b) > 0, \tag{7.5}$$

while the sufficient condition for a weak minimizer in [15, 16] is equivalent to

$$-\mathcal{B}h(y) \neq \Big(\int_y^b Q\Big)h(y) \ \text{ for } \ y \in (a, b] \quad \text{and} \quad \int_a^b Q > 0. \tag{7.6}$$

The proofs of the sufficiency guarantee that (7.5) is equivalent to (7.6). Let us show this equivalence directly: For simplicity, consider just Lagrangians of the form $2f(x, u, p) = p^2 + Q(x)u^2$. Then $\mathcal{B}h = h'$ and the Jacobi equation has the form $h'' = Qh$. Let h be the solution of this equation with initial conditions $h(a) = 1$, $h'(a) = 0$.

First assume that (7.5) is true. Then integration by parts yields

$$\int_a^b Q = \int_a^b \frac{h''}{h} = \frac{h'}{h}\Big|_a^b + \int_a^b \frac{(h')^2}{h^2} > 0. \tag{7.7}$$

Assume to the contrary that $-h'(y) = (\int_y^b Q)h(y)$ for some $y \in (a, b]$. Then

$$-\int_y^b Q = \frac{h'(y)}{h(y)} = \frac{h'}{h}\Big|_a^y = \int_a^y \Big(\frac{h''}{h} - \frac{(h')^2}{h^2}\Big) = \int_a^y \Big(Q - \frac{(h')^2}{h^2}\Big). \tag{7.8}$$

Now (7.8) and (7.7) imply

$$\int_a^b Q = \int_a^y \frac{(h')^2}{h^2} < \frac{h'}{h}\Big|_a^b + \int_a^b \frac{(h')^2}{h^2} = \int_a^b Q,$$

which yields a contradiction.

Next assume that (7.5) fails, i.e. either $h(y) = 0$ for some $y \in (a, b]$ or $h'(b) \leq 0$, and assume also to the contrary (7.6) is true. If $h(y) = 0$ for some $y \in (a, b]$ and $h > 0$ on $[a, y]$, then $h'(y) < 0$, hence

$$-h'(a) = 0 < \Big(\int_a^b Q\Big)h(a),$$
$$-h'(y) > 0 = \Big(\int_y^b Q\Big)h(y),$$

so that there exists $z \in (a, y)$ such that $-h'(z) = (\int_z^b Q)h(z)$, which yields a contradiction. If $h > 0$ and $h'(b) \leq 0$, then

$$-h'(a) = 0 < \Big(\int_a^b Q\Big)h(a),$$
$$-h'(b) \geq 0 = \Big(\int_b^b Q\Big)h(b),$$

so that there exists $z \in (a, b]$ such that $-h'(z) = (\int_z^b Q)h(z)$ and we arrive at contradiction again.

The proof above shows that if y_1 is the first (= smallest) zero of h, then the smallest solution z_1 of the equation $-h'(z) = \big(\int_z^b Q\big)h(z)$ satisfies $z_1 < y_1$. The inequality $z_1 \leq y_1$ also follows from the proof of Theorem 3.4 and the corresponding proof in [16]. In fact, those proofs show that y_1 and z_1 correspond to the zeroes of the continuous nonincreasing functions $\lambda_1(y) = \inf_{S_y}\Psi$ and $\tilde\lambda_1(z) = \inf_{\tilde S_z}\Psi$, respectively, where S_y is the unit sphere in X_y (see (3.3)) and $\tilde S_z$ is the unit sphere in $\tilde X_z = \{h \in W^{1,2}([a,b]) : h(x) = h(z) \text{ for } x \geq z\}$. Since $X_y \subset \tilde X_y$ and the norm in X_y is equivalent to the norm in $W^{1,2}$, we have $\tilde\lambda_1 \leq \max\{C\lambda_1, 0\}$. □

The following proposition is motivated by [11] and Section 4. Given $u^0 \in C^1([a,b],\mathbb{R}^N)$, we will use the following notation (cf. (1.2)):

$$\begin{aligned}\mathcal{M} &:= u^0 + C^1_{\mathcal{D}} = \{u \in C^1([a,b]) : (u_i - u_i^0)(x) = 0 \text{ for } i \in I_x^{\mathcal{D}} \text{ and } x \in \{a,b\}\},\\ \mathcal{M}_{\mathcal{N}} &:= \{u \in \mathcal{M} : u_i'(x) = 0 \text{ for } i \in I_x^{\mathcal{N}} \text{ and } x \in \{a,b\}\}.\end{aligned}$$

Proposition 7.2. *Let $f \in C^1$ and let u^0 be a weak minimizer of Φ in $\mathcal{M}_{\mathcal{N}}$. Then u^0 is a weak minimizer in $\mathcal{M}$. Conversely, if u is a weak minimizer in $\mathcal{M}$ and $u^0 \in \mathcal{M}_{\mathcal{N}}$, then u^0 is a weak minimizer in $\mathcal{M}_{\mathcal{N}}$.*

Proof. For simplicity, we will prove the assertion only in the special case $N = 1$, $I_a^{\mathcal{D}} = \emptyset$, $I_b^{\mathcal{N}} = \emptyset$, but it will be clear from the proof that our arguments can also be used in the general case.

Hence assume first that u^0 is a weak minimizer of Φ in

$$\mathcal{M}_{\mathcal{N}} = \{u \in C^1([a,b]) : (u - u^0)(b) = 0,\ u'(a) = 0\}.$$

Then there exists $\varepsilon > 0$ such that u^0 is a (global) minimizer of Φ in the set

$$\mathcal{M}^\varepsilon_{\mathcal{N}} := \{u \in \mathcal{M}_{\mathcal{N}} : \|u - u^0\|_{C^1} < \varepsilon\}.$$

We will show that u^0 is a (global) minimizer in the set $\mathcal{M}^{\varepsilon/4}$, where

$$\mathcal{M}^\varepsilon := \{u \in \mathcal{M} : \|u - u^0\|_{C^1} < \varepsilon\},$$

hence u^0 is a weak minimizer of Φ in $\mathcal{M} = \{u \in C^1([a,b]) : (u - u^0)(b) = 0\}$.

Fix $u \in \mathcal{M}^{\varepsilon/4}$. Since $(u^0)'(a) = 0$, given $k \in \mathbb{N}$, there exists $\delta_k \in (0, 1/k)$ such that

$$|(u^0)'(x)| < 1/k \quad \text{for } x \in J_k := [a, a + \delta_k].$$

Since $\|u - u^0\|_{C^1} < \varepsilon/4$, we also have $|u'(x)| < \varepsilon/4 + 1/k$ for $x \in J_k$. Consequently, we can modify the function u in J_k such that the modified function $u^k \in C^1([a,b])$ satisfies $u^k = u$ on $[a + \delta_k, b]$, $(u^k)'(a) = 0$ and $|(u^k)'(x)| < \varepsilon/4 + 1/k$ for $x \in J_k$ (for example, we can choose $(u^k)'(x) = u'(\delta_k)(x - a)/(\delta_k - a)$ for $x \in J_k$). Then

$$|(u^k)' - (u^0)'| \leq |(u^k)'| + |(u^0)'| < \varepsilon/4 + 2/k \quad \text{on } J_k$$

and the Mean Value Theorem implies

$$|u^k - u^0| \leq |u^k - u| + |u - u^0| < \max_{J_k} |(u^k - u)'|\delta_k + \varepsilon/4 < (\varepsilon/2 + 2/k)/k + \varepsilon/4 \quad \text{on } J_k,$$

hence $u^k \in \mathcal{M}^\varepsilon_{\mathcal{N}}$ for k large, which implies $\Phi(u^k) \geq \Phi(u^0)$. Since $\Phi(u^k) \to \Phi(u)$, we have $\Phi(u) \geq \Phi(u^0)$.

The converse assertion is trivial. □

Remark 7.3. In [11, Propositions 5 and 6] the authors consider the function u^0 and the functional Φ from our Section 4, and they provide conditions guaranteeing that u^0 is a weak minimizer subject to the Neumann boundary conditions for some of its components (see (4.3) and (4.2) above). Proposition 7.2 shows that the Neumann boundary conditions do not play any role in such assertions, i.e. u^0 remains a weak minimizer if we replace "the Neumann boundary conditions" with "no boundary conditions". Consequently (see Proposition 2.1), u^0 then has to satisfy the corresponding natural boundary conditions (instead of the Neumann boundary conditions). The Neumann boundary conditions are different from the natural boundary conditions in general, but the first two components of the function u^0 in Section 4 satisfy both the Neumann and the natural boundary conditions. □

Abstract. The authors investigate the multiplicity of solutions to a quasilinear periodic boundary value problem with impulsive effects. They use variational methods and some critical points theorems for smooth functionals, due to Ricceri, that are defined on reflexive Banach spaces. They obtain the existence of at least three solutions to the problem. The applicability of the results is illustrated with an example.

Keywords: three solutions, quasilinear periodic, boundary value problem, impulsive effects, variational methods.

2020 Mathematics Subject Classification: 34B15, 34C25, 70H12.

1 Introduction

We study the existence of at least three distinct classical solutions to the quasilinear periodic boundary value problem with impulsive effects

$$\begin{cases} -p(x')x'' + \alpha(t)x = \lambda f(t,x) + \mu g(t,x), & t \neq t_j, \quad \text{a.e. } t \in [0,1], \\ \Delta(h'(u'(t_j))) = I_j(u(t_j)), & j = 1,2,\dots,m, \\ x(1) - x(0) = x'(1) - x'(0) = 0, \end{cases} \tag{$P^{f,g}_{\lambda,\mu}$}$$

where $f : [0,1] \times \mathbb{R} \to \mathbb{R}$ and $g : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ are L^1-Carathéodory functions, $\lambda > 0$ and $\mu \geq 0$ are parameters, $0 = t_0 < t_1 < \cdots < t_m < t_{m+1} = 1$, $I_j : \mathbb{R} \to \mathbb{R}$, $j = 1,\dots,m$, are continuous functions, $\Delta(h'(u'(t_j))) = h'(u'(t_j^+)) - h'(u'(t_j^-))$ with $h'(u'(t_j^\pm)) = \lim_{t\to t^\pm} h'(u'(t))$, and

$$h(y) = \int_0^y \left(\int_0^\tau p(\xi)d\xi \right) d\tau \quad \text{for every } y \in \mathbb{R}.$$

Recall that a function $h : [0,1] \times \mathbb{R} \to \mathbb{R}$ is an L^1-Carathéodory function if it satisfies:

(a) $x \mapsto h(t,x)$ is measurable for every $x \in \mathbb{R}$;

✉ sh.heidarkhani@razi.ac.ir

(b) $t \mapsto h(t,x)$ is continuous for a.e. $x \in [0,1]$;

(c) for every $\varepsilon > 0$ there exists a function $l_\varepsilon \in L^1([0,1])$ such that

$$\sup_{|x|\leq\varepsilon} |h(t,x)| \leq l_\varepsilon(t) \quad \text{for a.e. } t \in [0,1].$$

In this paper, and without further mention, we always assume that:

(Q_1) $p : \mathbb{R} \to (0,\infty)$ is continuous and nondecreasing on $[0,\infty)$, and there exist $M \geq m > 0$ such that

$$m \leq p(x) \leq M \quad \text{for all } x \in \mathbb{R}; \tag{1.1}$$

(Q_2) $\alpha \in C([0,1])$ and there exist $\alpha_1 \geq \alpha_0 > 0$ such that

$$\alpha_0 \leq \alpha(t) \leq \alpha_1 \quad \text{for all } t \in [0,1]; \tag{1.2}$$

(Q_3) $I_j : \mathbb{R} \to \mathbb{R}$ is nondecreasing and $I_j(0) = 0$ for $j = 1,\ldots,m$.

In recent years, impulsive differential equations have played an important role in modern applied mathematical models of real processes arising in phenomena studied in physics, ecology, biological systems, biotechnology, and industrial robotics. Many authors have applied variational methods to study the existence of multiple solutions of impulsive systems of the form (1.1) or its variations, and we refer the reader to [2–4, 6, 7, 12, 17, 20] and references cited therein for some recent results. For example, Bonanno and Livrea [3] studied the existence and multiplicity of solutions to the periodic boundary value problem

$$\begin{cases} -x'' + A(t)x = \lambda b(t)\nabla G(x), & t \in [0,T], \\ x(T) - x(0) = x'(T) - x'(0) = 0, \end{cases}$$

where $A(t) = (a_{i,j}(t))_{n\times n}$ is a positive definite matrix for all $t \in [0,T]$, $a_{i,j} \in C([0,T],\mathbb{R})$, $G \in C^1(\mathbb{R}^n,\mathbb{R})$, and $b \in L^1([0,T])\backslash\{0\}$ that is nonnegative a.e. In [6], by using a three critical points theorem due to Bonanno and Marano, the existence of at least three solutions to a quasilinear second order differential equation was discussed. Using the symmetric mountain pass theorem and genus properties of critical point theory, Shen and Liu [17] investigated the existence of infinitely many solutions to the second-order quasilinear periodic boundary value problem with impulsive effects

$$\begin{cases} -u(t)'' + b(t)u(t) - (|u(t)|^2)''u(t) = f(t,u), & t \in J, \\ \Delta(u'(t_j)) = I_j(u(t_j)), & j = 1,2,\ldots,m, \\ u(T) = u(0), \; u'(T) = u'(0), \end{cases}$$

where $b \in L^\infty(0,T;\mathbb{R})$ and $f : [0,T] \times \mathbb{R} \to \mathbb{R}$ is continuous. Using variational methods, Heidarkhani and Moradi [7] discussed the existence of at least one weak solution and infinitely many weak solutions to $(P^{f,g}_{\lambda,\mu})$ with $\mu = 0$ and $I_j \equiv 0$ for $j = 1,2,\ldots,m$.

Motivated by the above studies, in this paper, we establish new criteria to guarantee that the problem $(P^{f,g}_{\lambda,\mu})$ has at least three classical solutions for appropriate values of the parameters λ and μ. It is worth stressing that we only assume g to be a L^1-Carathéodory function which permits us to use variational methods. In addition, we obtain multiplicity results for two cases: (i) if the nonlinearity f is asymptotically quadratic, and (ii) if it is subquadratic as $|u| \to \infty$. Our approach is based on variational methods and a three critical points theorem due to Ricceri [14].

The remainder of this paper is organized as follows. Section 2 contains some preliminary lemmas, and Section 2.1 contains our main results and their proofs.

2 Preliminaries

Our main tool is a theorem of Ricceri [14, Theorem 2] which is recalled in Lemma 2.1 below. In what follows, we let X be a real Banach space, and as in [14], we let $\mathcal{W}_X$ denote the class of all functionals $\Phi : X \to \mathbb{R}$ having the property: If $\{u_n\}$ is a sequence in X converging weakly to $u \in X$ with $\liminf_{n\to\infty} \Phi(u_n) \leq \Phi(u)$, then $\{u_n\}$ has a subsequence converging strongly to u. For example, if X is uniformly convex and $g : [0, \infty) \to \mathbb{R}$ is a continuous and strictly increasing function, then the functional $u \to g(\|u\|)$ belongs to the class $\mathcal{W}_X$.

Lemma 2.1. *Let X be a separable and reflexive real Banach space, let $\Phi : X \to \mathbb{R}$ be a coercive, sequentially weakly lower semicontinuous C^1-functional belonging to $\mathcal{W}_X$ that is bounded on bounded subsets of X and whose derivative admits a continuous inverse on X^*. Let $J : X \to \mathbb{R}$ be a C^1-functional with a compact derivative and assume that Φ has a strict local minimum u_0 with $\Phi(u_0) = J(u_0) = 0$. Finally, set*

$$\rho = \max\left\{0, \limsup_{\|u\|\to\infty} \frac{J(u)}{\Phi(u)}, \limsup_{u\to u_0} \frac{J(u)}{\Phi(u)}\right\}, \quad \sigma = \sup_{u\in\Phi^{-1}((0,\infty))} \frac{J(u)}{\Phi(u)},$$

and assume that $\rho < \sigma$. Then for each compact interval $[c, d] \subset (1/\sigma, 1/\rho)$ (with the conventions that $1/0 = \infty$ and $1/\infty = 0$), there exists $R > 0$ with the property: for every $\lambda \in [c, d]$ and every C^1-functional $\Psi : X \to \mathbb{R}$ with compact derivative, there exists $\gamma > 0$ such that for each $\mu \in [0, \gamma]$, the equation

$$\Phi'(u) = \lambda J'(u) + \mu\Psi'(u)$$

has at least three solutions in X whose norms are less than R.

We refer the reader to the papers [5, 8–10, 18, 19] in which Lemma 2.1 was successfully used to ensure the existence of at least three solutions to boundary value problems.

The following two results of Ricceri are taken from [15, Theorem 1] and [16, Proposition 3.1], respectively.

Lemma 2.2. *Let X be a reflexive real Banach space, $I \subseteq \mathbb{R}$ be an interval, and let $\Phi : X \to \mathbb{R}$ be a sequentially weakly lower semicontinuous C^1 functional that is bounded on bounded subsets of X, and whose derivative admits a continuous inverse on X^*. Let $J : X \to \mathbb{R}$ be a functional with a compact derivative and assume that*

$$\lim_{\|x\|\to\infty} (\Phi(x) - \lambda J(x)) = \infty, \quad \textit{for all } \lambda \in I,$$

and that there exists $\rho \in \mathbb{R}$ such that

$$\sup_{\lambda\in I} \inf_{x\in X} (\Phi(x) - \lambda(\rho - J(x))) < \inf_{x\in X} \sup_{\lambda\in I} (\Phi(x) - \lambda(\rho - J(x))).$$

Then there exist a nonempty open set $A \subseteq I$ and a positive number R with the property: for every $\lambda \in A$ and every C^1 functional $\Psi : X \to \mathbb{R}$ with compact derivative, there exists $\delta > 0$ such that, for each $\mu \in [0, \delta]$, the equation

$$\Phi'(u) - \lambda J'(u) - \mu \Psi'(u) = 0$$

has at least three solutions in X whose norms are less than R.

Lemma 2.3. *Let X be a nonempty set and let Φ and Ψ be two real functions on X. Assume that there exist $r > 0$ and $x_0, x_1 \in X$ such that*

$$\Phi(x_0) = J(x_0) = 0, \quad \Phi(x_1) > r, \quad \text{and} \quad \sup_{x \in \Phi^{-1}(-\infty, r]} J(x) < r\frac{J(x_1)}{\Phi(x_1)}.$$

Then for each ρ satisfying

$$\sup_{x \in \Phi^{-1}(-\infty, r]} J(x) < \rho < r\frac{J(x_1)}{\Phi(x_1)},$$

we have

$$\sup_{\lambda \geq 0} \inf_{x \in X} (\Phi(x) - \lambda(\rho - J(x))) < \inf_{x \in X} \sup_{\lambda \geq 0} (\Phi(x) - \lambda(\rho - J(x))).$$

We refer the reader to the paper of Sun *et al.* [18] in which Lemma 2.2 was successfully employed to ensure the existence of at least three solutions to boundary value problems.

To construct an appropriate function space and apply critical point theory, we introduce the following notations and results to be used in the proofs of our main results.

Let us define the Banach space E by

$$E = \left\{u : [0, 1] \to \mathbb{R} \,|\, u \text{ is absolutely continuous, } u(1) = u(0),\ u' \in L^2([0, 1]\right\},$$

equipped with the norm

$$\|u\| = \left(\int_0^1 \left(|u'|^2 + |u|^2\right) dt \right)^{\frac{1}{2}}.$$

Clearly, E is a Hilbert space with the dual space E^*.

For every $u \in E$, we define

$$\Phi(u) = \int_0^1 h(u'(t))dt + \frac{1}{2}\int_0^1 \alpha(t)|u(t)|^2 dt + \sum_{j=1}^{m} \int_0^{u(t_j)} I_j(\zeta) \mathrm{d}\zeta, \tag{2.1}$$

$$J(u) = \int_0^1 F(t, u(t))dt, \tag{2.2}$$

and

$$\Psi(u) = \int_0^1 G(t, u(t))dt, \tag{2.3}$$

where

$$F(t, x) = \int_0^x f(t, s)ds \quad \text{and} \quad G(t, x) = \int_0^x g(t, s)ds \quad \text{for all } x \in \mathbb{R}.$$

Standard arguments show that $I_\lambda := \Phi - \mu\Psi - \lambda J$ is a Gâteaux differentiable functional whose Gâteaux derivative at the point $u \in E$ is given by

$$\begin{aligned}(\Phi' - \mu\Psi' - \lambda J')(u)(v) = &\int_0^1 h'(u'(t))v'(t)dt + \int_0^1 \alpha(t)u(t)v(t)dt \\ &+ \sum_{j=1}^{m} I_j(u(t_j))v(t_j) - \lambda \int_0^1 f(t, u(t))v(t)dt \\ &- \mu \int_0^1 g(t, u(t))v(t)dt, \quad \text{for all } v \in E.\end{aligned}$$

Furthermore, from the definition of Φ, we see that it is sequentially weakly lower semicontinuous.

Definition 2.4. By a weak solution of the problem ($P^{f,g}_{\lambda,\mu}$), we mean a function $u \in E$ such that

$$\int_0^1 h'(u'(t))v'(t)dt + \int_0^1 \alpha(t)u(t)v(t)dt + \sum_{j=1}^{m} I_j(u(t_j))v(t_j) - \lambda \int_0^1 f(t,u(t))v(t)dt - \mu \int_0^1 g(t,u(t))v(t)dt = 0,$$

for every $v \in E$.

By a classical solution of the problem ($P^{f,g}_{\lambda,\mu}$), we mean a function $u \in E$ such that $u(t)$ satisfies the equation in ($P^{f,g}_{\lambda,\mu}$) for a.e. $t \in [0,1] \setminus \{t_1, \dots, t_m\}$ and both the impulse condition and the boundary condition in ($P^{f,g}_{\lambda,\mu}$) hold.

Clearly, a critical point $u \in E$ of the functional I_λ is a weak solution of the problem ($P^{f,g}_{\lambda,\mu}$). Next , we show that u is indeed a classical solution.

Lemma 2.5. *If $u \in E$ is a critical point of I_λ, then u is a classical solution of* ($P^{f,g}_{\lambda,\mu}$).

Proof. Let $u \in E$ be a critical point for I_λ. Then, for any $v \in E$, it follows that

$$\begin{aligned} 0 &= \int_0^1 h'(u'(t))v'(t)dt + \int_0^1 \alpha(t)u(t)v(t)dt + \sum_{j=1}^{m} I_j(u(t_j))v(t_j) \\ &\quad - \lambda \int_0^1 f(t,u(t))v(t)dt - \mu \int_0^1 g(t,u(t))v(t)dt \\ &= \sum_{j=0}^{m+1} h'(u'(t))v(t)\Big|_{t=t_j^+}^{t_{j+1}^-} + \sum_{j=1}^{m} I_j(u(t_j))v(t_j) \\ &\quad - \int_0^1 [(h'(u'(t)))' - \alpha(t)u(t) + \lambda f(t,u(t)) + \mu g(t,u(t))]v(t)dt \\ &= \sum_{j=1}^{m} [-\Delta(h'(u'(t_j))) + I_j(u(t_j))]v(t_j) + h'(u'(1))v(1) - h'(u'(0))v(0) \\ &\quad - \int_0^1 [(h'(u'(t)))' - \alpha(t)u(t) + \lambda f(t,u(t)) + \mu g(t,u(t))]v(t)dt. \end{aligned}$$

That is, we have

$$\sum_{j=1}^{m} [-\Delta(h'(u'(t_j))) + I_j(u(t_j))]v(t_j) + h'(u'(1))v(1) - h'(u'(0))v(0) - \int_0^1 [(h'(u'(t)))' - \alpha(t)u(t) + \lambda f(t,u(t)) + \mu g(t,u(t))]v(t)dt = 0 \quad \text{for all } v \in E. \tag{2.4}$$

Without loss of generality, we assume that $v \in C_0^\infty(t_j, t_{j+1})$ and $v(t) = 0$ for $t \in [0, t_j] \cup [t_{j+1}, 1]$. Then, substituting into (2.4) gives

$$(h'(u'(t)))' - \alpha(t)u(t) + \lambda f(t,u(t)) + \mu g(t,u(t)) = 0 \quad \text{a.e. } t \in (t_j, t_{j+1}).$$

Thus, in view of the fact that $(h'(u'(t)))' = p(u'(t))u''(t)$, we see that u satisfies the equation in $(P^{f,g}_{\lambda,\mu})$. Now, by (2.4), we have

$$\sum_{j=1}^{m}[-\Delta(h'(u'(t_j))) + I_j(u(t_j))]v(t_j) + h'(u'(1))v(1) - h'(u'(0))v(0) = 0 \tag{2.5}$$

for all $v \in E$. Next we shall show that u satisfies the impulsive condition in $(P^{f,g}_{\lambda,\mu})$. If this is not the case, without loss of generality, we assume that there exists $j \in \{1, \dots, m\}$ such that

$$-\Delta(h'(u'(t_j))) + I_j(u(t_j)) \neq 0.$$

Let

$$v(t) = \prod_{i=0,\, i\neq j}^{m+1}(t - t_i).$$

Then,

$$\begin{aligned}
&\sum_{k=1}^{m}[-\Delta(h'(u'(t_k))) + I_k(u(t_k))]v(t_k) + h'(u'(1))v(1) - h'(u'(0))v(0)\\
&\quad= \sum_{k=1}^{m}[-\Delta(h'(u'(t_k))) + I_k(u(t_k))]\prod_{i=0,\, i\neq j}^{m+1}(t_k - t_i)\\
&\qquad + h'(u'(1))\prod_{i=0,\, i\neq j}^{m+1}(t_{m+1} - t_i) - h'(u'(0))\prod_{i=0,\, i\neq j}^{m+1}(t_0 - t_i)\\
&\quad= [-\Delta(h'(u'(t_j))) + I_j(u(t_j))]\prod_{i=0,\, i\neq j}^{m+1}(t_k - t_i) \neq 0,
\end{aligned}$$

which contradicts (2.5). Thus, u satisfies the impulse condition in $(P^{f,g}_{\lambda,\mu})$. Similarly, we can show that u satisfies the boundary condition in $(P^{f,g}_{\lambda,\mu})$. Therefore, u is a solution of $(P^{f,g}_{\lambda,\mu})$. □

We will also need the following lemma in the proof of our main result.

Lemma 2.6. *Let $S : E \to E^*$ be the operator defined by*

$$S(u)(v) = \int_0^1 h'(u'(t))v'(t)dt + \int_0^1 \alpha(t)u(t)v(t)dt + \sum_{j=1}^{m} I_j(u(t_j))v(t_j)$$

for every $u, v \in E$. Then S admits a continuous inverse on E^*.

Proof. For any $u \in E$, from conditions (Q_1)–(Q_3), it follows that

$$\begin{aligned}
S(u)(u) &= \int_0^1 h'(u'(t))u'(t)dt + \int_0^1 \alpha(t)|u(t)|^2dt + \sum_{j=1}^{m} I_j(u(t_j))u_i(t_j)\\
&\geq \min\{m, \alpha_0\}\|u\|^2,
\end{aligned}$$

which implies that S is coercive. Now, for any $u, v \in E$, we have

$$\begin{aligned}\langle S(u)-S(v), u-v\rangle &= \int_0^1 (h'(u'(t))-h'(v'(t)))(u'(t)-v'(t))dt \\ &+\int_0^1 \alpha(t)(u(t)-v(t))^2 dt \\ &+\sum_{j=1}^{m}\left(I_j(u(t))-I_j(v(t))\right)(u(t)-v(t)) \\ &\geq \min\{m,\alpha_0\}\|u-v\|^2.\end{aligned}$$

Thus, S is strongly monotone. Moreover, since E is reflexive, if $u_n \to u$ strongly in E as $n \to \infty$, it can be shown that $S(u_n) \to S(u)$ weakly in E^* as $n \to \infty$. Hence, S is demicontinuous. By [21, Theorem 26.A(d)], the inverse operator S^{-1} of S exists and is continuous. □

2.1 Main result

In this section, we state and prove our main results. Let

$$\lambda_1 = \inf_{u\in E\setminus\{0\}}\left\{\frac{\int_0^1 h(u'(t))dt+\frac{1}{2}\int_0^1 \alpha(t)|u(t)|^2 dt+\sum_{j=1}^{m}\int_0^{u(t_j)} I_j(\zeta)\mathrm{d}\zeta}{\int_0^1 F(t,u(t))\mathrm{d}t} : \int_0^1 F(t,u(t))\mathrm{d}t>0\right\}$$

and

$$\lambda_2 = \frac{1}{\max\{0,\ \lambda_0,\ \lambda_\infty\}},$$

where

$$\lambda_0 = \limsup_{u\to 0}\frac{\int_0^1 F(t,u(t))\mathrm{d}t}{\int_0^1 h(u'(t))dt+\frac{1}{2}\int_0^1 \alpha(t)|u(t)|^2 dt+\sum_{j=1}^{m}\int_0^{u(t_j)} I_j(\zeta)\mathrm{d}\zeta}$$

and

$$\lambda_\infty = \limsup_{\|u\|\to \infty}\frac{\int_0^1 F(t,u(t))\mathrm{d}t}{\int_0^1 h(u'(t))dt+\frac{1}{2}\int_0^1 \alpha(t)|u(t)|^2 dt+\sum_{j=1}^{m}\int_0^{u(t_j)} I_j(\zeta)\mathrm{d}\zeta}.$$

Theorem 2.7. *Assume that*

($\mathcal{A}_1$) *there exists a constant $\varepsilon > 0$ such that*

$$\max\left\{\limsup_{u\to 0}\frac{\max_{t\in[0,1]} F(t,u)}{|u|^2},\ \limsup_{|u|\to\infty}\frac{\max_{t\in[0,1]} F(t,u)}{|u|^2}\right\} < \varepsilon;$$

($\mathcal{A}_2$) *there exists a function $w \in E$ such that*

$$\int_0^1 h(w'(t))dt+\frac{1}{2}\int_0^1 \alpha(t)|w(t)|^2 dt+\sum_{j=1}^{m}\int_0^{w(t_j)} I_j(\zeta)\mathrm{d}\zeta \neq 0$$

and

$$\frac{8\varepsilon}{\min\{m,\alpha_0\}} < \frac{\int_0^1 F(t,w(t))\mathrm{d}t}{\int_0^1 h(w'(t))dt+\frac{1}{2}\int_0^1 \alpha(t)|w(t)|^2 dt+\sum_{j=1}^{m}\int_0^{w(t_j)} I_j(\zeta)\mathrm{d}\zeta}.$$

Then for each compact interval $[c,d] \subset (\lambda_1, \lambda_2)$, there exists $R > 0$ such that for every $\lambda \in [c,d]$ and every L^1-Carathéodory function $g : [0,1] \times \mathbb{R} \to \mathbb{R}$, there exists $\gamma > 0$ such that for every $\mu \in [0,\gamma]$, the problem $(P^{f,g}_{\lambda,\mu})$ has at least three classical solutions whose norms in E are less than R.

Remark 2.8. Under conditions $(\mathcal{A}_1)$ and $(\mathcal{A}_2)$, it is true that $\lambda_1 < \lambda_2$ as is shown in the proof of Theorem 2.7 given below.

Proof of Theorem 2.7. Our aim is to apply Lemma 2.1 to the problem $(P^{f,g}_{\lambda,\mu})$. Take $X = E$; clearly, X is a separable and uniformly convex Banach space. From [13, Proposition 1.1] and its proof with $T = 1$ and $p = q = 2$, we have

$$\max_{t\in[0,1]} |u(t)| \le 2\|u\| \quad \text{for all } u \in X. \tag{2.6}$$

Let the functionals Φ, J, and Ψ be as given in (2.1)–(2.3). The functional Φ is C^1, and by Lemma 2.6, its derivative admits a continuous inverse on X^*. Moreover, Φ is sequentially weakly lower semicontinuous since Φ' is monotone (see the proof of Lemma 2.6). Since

$$\int_0^1 h(u'(t))dt = \int_0^1 \left(\int_0^{u'(t)} \left(\int_0^{\tau} p(\xi)d\xi \right) d\tau \right) dt,$$

from (1.1) and (1.2), it follows that

$$\begin{aligned}
\frac{1}{2}\min\{m,\alpha_0\}\|u\|^2 &\le \frac{m}{2}\int_0^1 |u'(t)|^2dt + \frac{\alpha_0}{2}\int_0^1 |u(t)|^2dt + \sum_{j=1}^m \int_0^{u(t_j)} I_j(\zeta)\mathrm{d}\zeta \\
&\le \Phi(u) \\
&\le \frac{M}{2}\int_0^1 |u'(t)|^2dt + \frac{\alpha_1}{2}\int_0^1 |u(t)|^2dt + \sum_{j=1}^m \int_0^{u(t_j)} I_j(\zeta)\mathrm{d}\zeta \\
&\le \frac{1}{2}\max\{M,\alpha_1\}\|u\|^2 + \sum_{j=1}^m \int_0^{u(t_j)} I_j(\zeta)\mathrm{d}\zeta
\end{aligned} \tag{2.7}$$

for every $u \in X$. We then have

$$\lim_{\|u\|\to+\infty} \Phi(u) = \infty,$$

i.e., Φ is coercive. Now, let A be a bounded subset of X. Then there exist a constant $c > 0$ such that $\|u\| \le c$ for all $u \in A$. From (2.6), $\max_{t\in[0,1]} |u(t)| \le 2c$ for all $u \in A$. Thus, by the continuity of each I_j, we see that there exists $K > 0$ such that $\left|\sum_{j=1}^m \int_0^{u(t_j)} I_j(\zeta)\mathrm{d}\zeta\right| < K$ for all $u \in A$. Then, by (2.7), we have

$$\Phi(u) \le \frac{1}{2}\max\{M,\alpha_1\}\|c\|^2 + K,$$

so Φ is bounded on each bounded subset of X.

To prove that $\Phi \in \mathcal{W}_X$, define

$$\Phi_1(u) = \int_0^1 h(u'(t))dt \quad \text{and} \quad \Phi_2(u) = \frac{1}{2}\int_0^1 \alpha(t)|u(t)|^2dt + \sum_{j=1}^m \int_0^{u(t_j)} I_j(\zeta)\mathrm{d}\zeta$$

for all $u \in X$. Then,

$$\Phi(u) = \Phi_1(u) + \Phi_2(u) \quad \text{for all } u \in X.$$

As in (2.7), we have

$$\Phi_1(u) \geq d(u) := \frac{m}{2}\int_0^1 |u'(t)|^2 dt \quad \text{for all } u \in X. \tag{2.8}$$

Let $\{u_k\}$ be a sequence in X and let $u \in X$ be such that $u_k \rightharpoonup u$ and $\liminf_{k\to\infty} \Phi(u_k) \leq \Phi(u)$. To show that $\{u_k\}$ has a subsequence strongly converging to u, assume, to the contrary, that $\{u_k\}$ does not have such a subsequence. Then, there exist $\epsilon > 0$ and a subsequence $\{u_{k_n}\}$ of $\{u_k\}$ such that

$$\left\| \frac{u_{k_n} - u}{2} \right\| \geq \epsilon \quad \text{for all } n \in \mathbb{N}.$$

Note that $\{u_{k_n}\}$ converges uniformly to u by [13, Proposition 1.2]. Then, in view of the definition of $\|\cdot\|$, there exists $\epsilon_1 > 0$ such that

$$d\left(\frac{u_{k_n} - u}{2}\right) \geq \epsilon_1 \quad \text{for all } n \in \mathbb{N}.$$

Thus, from (2.8)

$$\Phi_1\left(\frac{u_{k_n} - u}{2}\right) \geq \epsilon_1 \quad \text{for all } n \in \mathbb{N}. \tag{2.9}$$

Now, the sequentially weakly lower semicontinuity of Φ implies that $\liminf_{n\to\infty} \Phi(u_{k_n}) = \Phi(u)$. Hence, there exists a subsequence $\{w_\ell\} = \{u_{k_{n_\ell}}\}$ of $\{u_{k_n}\}$ such that

$$\lim_{\ell\to\infty} \Phi(w_\ell) = \Phi(u).$$

Since $\{w_\ell\}$ converges uniformly to u and I_j, $j = 1\ldots, m$, are continuous, we see that

$$\lim_{\ell\to\infty} \Phi_2(w_\ell) = \Phi_2(u),$$

and so

$$\lim_{\ell\to\infty} \Phi_1(w_\ell) = \Phi_1(u). \tag{2.10}$$

It is clear that Φ_1 is sequentially weakly lower semicontinuous and that $(w_\ell + u)/2 \rightharpoonup u$ as $\ell \to \infty$. Then,

$$\Phi_1(u) \leq \liminf_{\ell\to\infty} \Phi_1\left(\frac{w_\ell + u}{2}\right). \tag{2.11}$$

By simple calculations and the nondecreasing nature of p, we have that for $y > 0$,

$$\begin{aligned} h''(\sqrt{y}) &= \frac{1}{4}y^{-1}p(\sqrt{y}) - \frac{1}{4}y^{-3/2}\int_0^{\sqrt{y}} p(\xi)d\xi \\ &\geq \frac{1}{4}y^{-1}p(\sqrt{y}) - \frac{1}{4}y^{-3/2}\sqrt{y}p(\sqrt{y}) = 0. \end{aligned}$$

Hence, $h(\sqrt{y})$ is convex. Moreover, $h(y)$ is continuous, strictly increasing for $y \geq 0$, and $h(0) = 0$. Thus, from [11, Theorem 2.1], we have

$$\frac{1}{2}\Phi_1(w_\ell) + \frac{1}{2}\Phi_1(u) \geq \Phi_1\left(\frac{w_\ell + u}{2}\right) + \Phi_1\left(\frac{w_\ell - u}{2}\right) \quad \text{for all } \ell \in \mathbb{N}.$$

Taking limit superior as $\ell \to \infty$ and using (2.8), (2.9), and (2.10) in the above inequality, we obtain

$$\Phi_1(u) - \epsilon_1 \geq \limsup_{\ell\to\infty} \Phi_1\left(\frac{w_\ell + u}{2}\right),$$

which contradicts (2.11). This shows that $\{u_k\}$ has a subsequence converging strongly to u. Therefore, $\Phi \in \mathcal{W}_X$.

The functionals J and Ψ are C^1-functionals with compact derivatives. Moreover, Φ has a strict local minimum 0 with $\Phi(0) = J(0) = 0$. Therefore, the regularity assumptions on Φ, J, and Ψ, as required in Lemma 2.1, are satisfied. In view of $(\mathcal{A}_1)$, there exist τ_1, τ_2 with $0 < \tau_1 < \tau_2$ such that

$$F(t,u) \le \varepsilon |u|^2 \tag{2.12}$$

for every $t \in [0,1]$ and every u with $|u| \in [0,\tau_1) \cup (\tau_2, \infty)$. Since $F(t,u)$ is continuous on $[0,1] \times \mathbb{R}$, $F(t,u)$ is bounded on $[0,1] \times [\tau_1, \tau_2]$. Thus, we can choose $\eta > 0$ and $v > 2$ such that

$$F(t,u) \le \varepsilon |u|^2 + \eta |u|^v$$

for all $(t,u) \in [0,1] \times \mathbb{R}$. Then, from (2.6), we have

$$J(u) \le 4\varepsilon \|u\|^2 + \eta 2^v \|u\|^v \tag{2.13}$$

for all $u \in X$. Hence, from (2.7) and (2.13), we have

$$\limsup_{|u| \to 0} \frac{J(u)}{\Phi(u)} \le \frac{8\varepsilon}{\min\{m, \alpha_0\}}. \tag{2.14}$$

Moreover, by (2.12), for each $u \in X \setminus \{0\}$,

$$\begin{aligned} \frac{J(u)}{\Phi(u)} &= \frac{\int_{|u| \le \tau_2} F(t,u(t))\mathrm{d}t}{\Phi(u)} + \frac{\int_{|u| > \tau_2} F(t,u(t))dt}{\Phi(u)} \\ &\le \frac{\sup_{t \in [0,1], |u| \in [0,\tau_2]} F(t,u)}{\Phi(u)} + \frac{4\varepsilon \|u\|^2}{\Phi(u)} \\ &\le \frac{\sup_{t \in [0,1], |u| \in [0,\tau_2]} F(t,u)}{\frac{1}{2}\min\{m, \alpha_0\} \|u\|^2} + \frac{8\varepsilon}{\min\{m, \alpha_0\}}. \end{aligned}$$

Therefore,

$$\limsup_{\|u\| \to \infty} \frac{J(u)}{\Phi(u)} \le \frac{8\varepsilon}{\min\{m, \alpha_0\}}. \tag{2.15}$$

In view of (2.14) and (2.15), we have

$$\rho = \max\left\{0, \limsup_{\|u\| \to \infty} \frac{J(u)}{\Phi(u)}, \limsup_{u \to 0} \frac{J(u)}{\Phi(u)}\right\} \le \frac{8\varepsilon}{\min\{m, \alpha_0\}}. \tag{2.16}$$

Condition $(\mathcal{A}_2)$ together with (2.16) yield

$$\begin{aligned} \sigma &= \sup_{u \in \Phi^{-1}((0,\infty))} \frac{J(u)}{\Phi(u)} = \sup_{X \setminus \{0\}} \frac{J(u)}{\Phi(u)} \\ &\ge \frac{\int_0^1 F(t,w(t))dt}{\Phi(w(t))} = \frac{\int_0^1 F(t,w(t))dt}{\frac{1}{2}\max\{M, \alpha_1\}\|u\|^2 + \sum_{j=1}^m \int_0^{w(t_j)} I_j(\zeta)d\zeta} \\ &> \frac{8\varepsilon}{\min\{m, \alpha_0\}} \ge \rho. \end{aligned}$$

Thus, all the conditions of Lemma 2.1 are satisfied. With $\lambda_1 = 1/\sigma$ and $\lambda_2 = 1/\rho$, by Lemmas 2.1 and 2.5, for each compact interval $[c,d] \subset (\lambda_1, \lambda_2)$, there exists $R > 0$ such that for every $\lambda \in [c,d]$ and every L^1-Carathéodory function $g : [0,1] \times \mathbb{R} \to \mathbb{R}$, there exists $\gamma > 0$ such that for each $\mu \in [0,\gamma]$, the problem $(P^{f,g}_{\lambda,\mu})$ has at least three classical solutions whose norms in X are less than R. □

The following result is another application of Lemma 2.1.

Theorem 2.9. *Assume that*

$$\max_{u\in E}\left\{\limsup_{u\to 0}\frac{\max_{t\in[0,1]}F(t,u)}{|u|^2},\ \limsup_{|u|\to\infty}\frac{\max_{t\in[0,1]}F(t,u)}{|u|^2}\right\}\le 0 \tag{2.17}$$

and

$$\sup_{u\in E}\frac{\int_0^1 F(t,u(t))\mathrm{d}t}{\int_0^1 h(u'(t))dt+\frac{1}{2}\int_0^1\alpha(t)|u(t)|^2dt+\sum_{j=1}^m\int_0^{u(t_j)}I_j(\zeta)d\zeta}>0. \tag{2.18}$$

Then for each compact interval $[c,d] \subset (\lambda_1, \infty)$, there exists $R > 0$ such that for every $\lambda \in [c,d]$ and every L^1-Carathéodory function $g : [0,1] \times \mathbb{R} \to \mathbb{R}$, there exists $\gamma > 0$ such that for each $\mu \in [0,\gamma]$, the problem $(P^{f,g}_{\lambda,\mu})$ has at least three classical solutions whose norms in E are less than R.

Proof. For any $\varepsilon > 0$, (2.17) implies that there exist τ_1 and τ_2 with $0 < \tau_1 < \tau_2$ such that

$$F(t,u) \le \varepsilon |u|^2$$

for every $t \in [0,1]$ and every u with $|u| \in [0,\tau_1) \cup (\tau_2, \infty)$. Since $F(t,u)$ is continuous on $[0,1] \times \mathbb{R}$, $F(t,u)$ is bounded on $[0,1] \times [\tau_1, \tau_2]$. Thus, as before, we can choose $\eta > 0$ and $v > 2$ so that

$$F(t,u) \le \varepsilon|u|^2 + \eta|u|^v$$

for all $(t,u) \in [0,1] \times \mathbb{R}$. Then, by the same process as in the proof of Theorem 2.7, we obtain (2.14) and (2.15). Since ϵ is arbitrary, (2.14) and (2.15) give

$$\max\left\{0,\ \limsup_{\|u\|\to+\infty}\frac{J(u)}{\Phi(u)},\ \limsup_{u\to 0}\frac{J(u)}{\Phi(u)}\right\}\le 0.$$

Then, with ρ and σ defined as in Lemma 2.1, we have $\rho = 0$, and by (2.18), we have $\sigma > 0$. In this case, $\lambda_1 = 1/\sigma$ and $\lambda_2 = \infty$. Thus, by Lemma 2.1 the theorem is proved. □

Remark 2.10. In condition $(\mathcal{A}_2)$ of Theorem 2.7, if we choose

$$w_0(t)=\begin{cases}\sigma, & t\in[0,1/4],\\ 2\sigma t+\sigma/2, & t\in[1/4,1/2],\\ -2\sigma t+5\sigma/2, & t\in[1/2,3/4],\\ \sigma, & t\in[3/4,1],\end{cases} \tag{2.19}$$

where $\sigma > 0$, then $w_0 \in E$, and $(\mathcal{A}_2)$ now takes the form

$(\widehat{\mathcal{A}_2})$ there exists a positive constant σ such that

$$\frac{1}{4}h(2\sigma)+\frac{1}{4}h(-2\sigma)+\frac{1}{2}\int_0^1 \alpha(t)|w_0(t)|^2dt+\sum_{j=1}^{m}\int_0^{w_0(t_j)} I_j(\zeta)d\zeta \neq 0$$

and

$$\frac{8\varepsilon}{\min\{m,\alpha_0\}}<\frac{\int_0^1 F(t,w_0(t))dt}{\frac{1}{4}h(2\sigma)+\frac{1}{4}h(-2\sigma)+\frac{1}{2}\int_0^1 \alpha(t)|w_0(t)|^2dt+\sum_{j=1}^{m}\int_0^{w_0(t_j)} I_j(\zeta)d\zeta}.$$

Next, we point out some results in which the function f is separable. To be precise, we consider the problem

$$\begin{cases} -p(x')x''+\alpha(t)x=\lambda\theta(t)f(x)+\mu g(t,x), & t\neq t_j, \quad \text{a.e. } t\in[0,1],\\ \Delta(h'(u'(t_j)))=I_j(u(t_j)), \quad j=1,2,\dots,m, \\ x(1)-x(0)=x'(1)-x'(0)=0, \end{cases} \qquad (\phi^{\theta}_{\lambda,\mu})$$

where $\theta:[0,1]\to\mathbb{R}$ is a nonzero function with $\theta\in L^1([0,1])$, $f:\mathbb{R}\to\mathbb{R}$ is a continuous function, and $g:[0,1]\times\mathbb{R}\to\mathbb{R}$ is an L^1-Carathéodory function. Let $F(t,x)=\theta(t)F(x)$ for every $(t,x)\in[0,1]\times\mathbb{R}$, where

$$F(x)=\int_0^x f(\xi)d\xi \quad \text{for all } x\in\mathbb{R}.$$

The following existence results are then consequences of Theorem 2.7.

Theorem 2.11. *Assume that*

$(\mathcal{A}_3)$ *there exists a constant $\varepsilon>0$ such that*

$$\sup_{t\in[0,1]}\theta(t)\cdot\max\left\{\limsup_{u\to 0}\frac{F(u)}{|u|^2},\limsup_{|u|\to\infty}\frac{F(u)}{|u|^2}\right\}<\varepsilon;$$

$(\mathcal{A}_4)$ *there exists a positive constant σ such that*

$$\frac{1}{4}h(2\sigma)+\frac{1}{4}h(-2\sigma)+\frac{1}{2}\int_0^1 \alpha(t)|w_0(t)|^2dt+\sum_{j=1}^{m}\int_0^{w_0(t_j)} I_j(\zeta)d\zeta \neq 0$$

and

$$\frac{8\varepsilon}{\min\{m,\alpha_0\}}<\frac{f(w_0(t))\int_0^1 \theta(t)dt}{\frac{1}{4}h(2\sigma)+\frac{1}{4}h(-2\sigma)+\frac{1}{2}\int_0^1 \alpha(t)|w_0(t)|^2dt+\sum_{j=1}^{m}\int_0^{w_0(t_j)} I_j(\zeta)d\zeta},$$

where w_0 is defined by (2.19).

Then for each compact interval $[c,d]\subset(\lambda_3,\lambda_4)$, where λ_3 and λ_4 are the same as λ_1 and λ_2, but with $\int_0^1 F(t,u(t))dt$ replaced by $\int_0^1 \theta(t)F(u(t))dt$, there exists $R>0$ such that for every $\lambda\in[c,d]$ and every L^1-Carathéodory function $g:[0,1]\times\mathbb{R}\to\mathbb{R}$, there exists $\gamma>0$ such that for each $\mu\in[0,\gamma]$, the problem $(\phi^{\theta}_{\lambda,\mu})$ has at least three classical solutions whose norms in E are less than R.

Theorem 2.12. *Assume that there exists a positive constant σ such that*

$$\frac{1}{4}h(2\sigma)+\frac{1}{4}h(-2\sigma)+\frac{1}{2}\int_0^1 \alpha(t)|w_0(t)|^2dt+\sum_{j=1}^{m}\int_0^{w_0(t_j)} I_j(\zeta)d\zeta>0$$

and

$$\int_0^1 \theta(t)F(w_0(t))dt>0, \tag{2.20}$$

where w_0 is given by (2.19). In addition, assume that

$$\limsup_{u\to 0}\frac{F(u)}{|u|^2}=\limsup_{|u|\to\infty}\frac{F(u)}{|u|^2}=0. \tag{2.21}$$

Then for each compact interval $[c,d]\subset(\lambda_3,\infty)$, where λ_3 is the same as λ_1 but with $\int_0^1 F(t,u(t))\mathrm{d}t$ replaced by $\int_0^1 \theta(t)F(u(t))\mathrm{d}t$, there exists $R>0$ such that for every $\lambda\in[c,d]$ and every L^1-Carathéodory function $g:[0,1]\times\mathbb{R}\to\mathbb{R}$, there exists $\gamma>0$ such that for each $\mu\in[0,\gamma]$, the problem $(\phi^{\theta}_{\lambda,\mu})$ has at least three classical solutions whose norms in E are less than R.

Proof. From (2.21), we easily see that $(\mathcal{A}_3)$ is satisfied for every $\varepsilon>0$. Moreover, using (2.20), by choosing $\varepsilon>0$ small enough, $(\mathcal{A}_4)$ will hold. Hence, the conclusion of this theorem follows from Theorem 2.11. □

As an example in which the hypotheses of Theorem 2.12 are satisfied, we have the following.

Example 2.13. Let $p(x)=4-\cot(x)$ for each $x\in\mathbb{R}$, $\alpha(t)=\theta(t)=1$ for every $t\in[0,1]$, $m=1$, $t_1=1/5$, $I_1(x)=x^3$ for each $x\in\mathbb{R}$, and

$$f(x)=\begin{cases}4x^3, & |x|\le 1,\\ 4x, & 1<|x|\le 2,\\ 8, & |x|\ge 2.\end{cases}$$

Then, it is easy to check that

$$F(x)=\begin{cases}x^4, & |x|\le 1,\\ 2x^2-1, & 1<|x|\le 2,\\ 8x-9, & x>2,\\ 8x+23, & x<-2.\end{cases}$$

By choosing $\sigma=1$, $w_0(t)$ becomes

$$w_0(t)=\begin{cases}1, & t\in[0,1/4],\\ 2t+1/2, & t\in[1/4,1/2],\\ -2t+5/2, & t\in[1/2,3/4],\\ 1, & t\in[3/4,1].\end{cases}$$

It is trivial to verify that

$$\frac{1}{4}h(2\sigma)+\frac{1}{4}h(-2\sigma)+\frac{1}{2}\int_0^1 \alpha(t)|w_0(t)|^2dt+\sum_{j=1}^{m}\int_0^{w_0(t_j)} I_j(\zeta)d\zeta>0,$$

$$\int_0^1 \theta(t)F(w_0(t))dt > 0,$$

and

$$\lim_{u\to 0}\frac{F(u)}{|u|^2} = \lim_{|u|\to\infty}\frac{F(u)}{|u|^2} = 0.$$

Hence, by Theorem 2.12, for each compact interval $[c,d] \subset (0,\infty)$, there exists $R > 0$ such that for every $\lambda \in [c,d]$ and every L^1-Carathéodory function $g : [0,1]\times\mathbb{R} \to \mathbb{R}$, there exists $\gamma > 0$ such that for each $\mu \in [0,\gamma]$, the problem

$$\begin{cases} -p(x')x'' + x = \lambda f(x) + \mu g(t,x), & t \neq \frac{1}{5}, \quad \text{a.e. } t \in [0,1],\\ \Delta(h'(u'(\frac{1}{5}))) = I_1(u(\frac{1}{5})), \\ x(1) - x(0) = x'(1) - x'(0) = 0, \end{cases}$$

has at least three classical solutions whose norms in E are less than R.

The following theorem is a consequences of Lemma 2.3.

Theorem 2.14. *Assume that there exist three positive constants $1 \le \zeta < 2$, θ, and σ, with*

$$\theta < \sqrt{\frac{1}{4}h(2\sigma) + \frac{1}{4}h(-2\sigma) + \frac{31\alpha_0\sigma^2}{48}}, \tag{2.22}$$

such that

($\mathcal{B}_1$) *$f(t,x) \ge 0$ for every $(t,x) \in \big([0,1/4]\times[0,\sigma]\big) \cup \big([3/4,1]\times[0,\sigma]\big) \cup \big([1/4,3/4]\times[\sigma,3\sigma/2]\big)$;*

($\mathcal{B}_2$) $$\frac{\int_0^1 \sup_{|u|\le\theta} F(t,u)dt}{\theta^2} < \frac{\min\{m,\alpha_0\}}{8}\,\frac{\int_{\frac{1}{4}}^{\frac{3}{4}} F(t,\sigma)dt}{\frac{1}{4}h(2\sigma) + \frac{1}{4}h(-2\sigma) + \frac{31\alpha_1\sigma^2}{48} + \sum_{j=1}^m \int_0^{w_0(t_j)} I_j(\zeta)\mathrm{d}\zeta};$$

($\mathcal{B}_3$) *there exists $p > 0$ and a positive constant q such that*

$$|F(t,u)| \le p|u|^{\zeta} + q \quad \textit{for all } (t,u) \in [0,1]\times\mathbb{R};$$

($\mathcal{B}_4$) *there exists $l > 0$ and a positive constant $\varrho \in \mathbb{R}$ such that*

$$G(t,u) \le lu^{\zeta} + \varrho \quad \textit{for all } (t,u) \in [0,1]\times\mathbb{R}.$$

Then there exist a nonempty open set $A \subset [0,\infty)$ and a positive number $R > 0$ such that for every $\lambda \in A$ and every L^1-Carathéodory function $g : [0,1]\times\mathbb{R} \to \mathbb{R}$, there exists $\delta > 0$ such that for each $\mu \in [0,\delta]$, the problem ($P^{f,g}_{\lambda,\mu}$) has at least three classical solutions whose norms in E are less than R.

Proof. Since the embeddings $E \hookrightarrow L^q$ $(q \ge 1)$ and $E \hookrightarrow L^\infty$ are compact (see Adams and Fournier [1]), there exists a positive constant C such that

$$|u|_{L^q([0,1])} \le C\|u\|.$$

For any $\lambda \ge 0$ and $u \in E$, from (Q_3), $(\mathcal{B}_3)$, and $(\mathcal{B}_4)$, we have

$$\begin{aligned} \Phi(u) - \lambda\Psi(u) &\ge \frac{1}{2}\min\{m,\alpha_0\}\|u\|^2 - \lambda\int_0^1 [F(t,u(t)) + \frac{\mu}{\lambda}G(t,u(t))]dt \\ &\ge \frac{1}{2}\min\{m,\alpha_0\}\|u\|^2 - \lambda\left(\int_0^1 p|u|^{\zeta}dt + q\right) - \mu\left(l\int_0^1 |u(t)|^{\zeta}dt + \varrho\right) \\ &\ge \frac{1}{2}\min\{m,\alpha_0\}\|u\|^2 - \lambda pC_0\|u\|^{\zeta} - \mu lC_1\|u\|^{\zeta} - \lambda q - \mu\varrho. \end{aligned}$$

Since $\zeta < 2$,

$$\lim_{\|u\|\to+\infty} \Phi(u) - \lambda\Psi(u) = \infty \quad \text{for all } \lambda > 0.$$

Let w_0 be defined by (2.19) with σ given in the theorem. Now, $\min_{t\in[\frac{1}{4},\frac{3}{4}]}\{w_0(t)\} = \sigma$ and $\max_{t\in[\frac{1}{4},\frac{3}{4}]}\{w_0(t)\} = \frac{3\sigma}{2}$, so

$$\begin{aligned} J(w_0) &= \int_0^{\frac{1}{4}}\int_0^{\sigma} f(t,\xi)d\xi dt + \int_{\frac{1}{4}}^{\frac{3}{4}}\int_0^{w_0(t)} f(t,\xi)d\xi dt + \int_{\frac{3}{4}}^{1}\int_0^{\sigma} f(t,\xi)d\xi dt \\ &\geq \int_{\frac{1}{4}}^{\frac{3}{4}}\int_0^{\sigma} f(t,\xi)d\xi dt = \int_{\frac{1}{4}}^{\frac{3}{4}} F(t,\sigma)dt. \end{aligned}$$

Moreover, simple calculations show that

$$\begin{aligned} \Phi(w_0) &= \frac{1}{4}h(2\sigma) + \frac{1}{4}h(-2\sigma) + \frac{1}{2}\int_0^1 \alpha(t)|w_0(t)|^2dt + \sum_{j=1}^{m}\int_0^{w_0(t_j)} I_j(\zeta)d\zeta \\ &\leq \frac{1}{4}h(2\sigma) + \frac{1}{4}h(-2\sigma) + \frac{\alpha_1}{2}\int_0^1 |w_0(t)|^2dt + \sum_{j=1}^{m}\int_0^{w_0(t_j)} I_j(\zeta)\mathrm{d}\zeta \\ &= \frac{1}{4}h(2\sigma) + \frac{1}{4}h(-2\sigma) + \frac{31\alpha_1\sigma^2}{48} + \sum_{j=1}^{m}\int_0^{w_0(t_j)} I_j(\zeta)\mathrm{d}\zeta \end{aligned} \tag{2.23}$$

and

$$\begin{aligned} \Phi(w_0) &= \frac{1}{4}h(2\sigma) + \frac{1}{4}h(-2\sigma) + \frac{1}{2}\int_0^1 \alpha(t)|w_0(t)|^2dt + \sum_{j=1}^{m}\int_0^{w_0(t_j)} I_j(\zeta)d\zeta \\ &\geq \frac{1}{4}h(2\sigma) + \frac{1}{4}h(-2\sigma) + \frac{\alpha_0}{2}\int_0^1 |w_0(t)|^2dt \\ &= \frac{1}{4}h(2\sigma) + \frac{1}{4}h(-2\sigma) + \frac{31\alpha_0\sigma^2}{48}. \end{aligned} \tag{2.24}$$

Let $r = \frac{\min\{m,\alpha_0\}}{8}\theta^2$. Then, from (2.22) and (2.24), we have $\Phi(w_0) > r$. From the definition of Φ, (2.6), and (2.7), it follows that

$$\begin{aligned} \Phi^{-1}(-\infty, r] &= \{x \in E : \ \Phi(x) \leq r\} \\ &\subseteq \left\{x \in E : \ \max_{t\in[0,1]} |x(t)| \leq \sqrt{\frac{8r}{\min\{m,\alpha_0\}}}\right\} \\ &\subseteq \left\{x \in E : \ \max_{t\in[0,1]} |x(t)| \leq \theta\right\}. \end{aligned}$$

Therefore,

$$\sup_{u\in\Phi^{-1}((-\infty,r])} J(u) \leq \int_0^1 \sup_{|u|\leq\theta} F(t,u)dt.$$

Thus, from $(\mathcal{B}_2)$ and (2.23), we have

$$r\frac{J(w_0)}{\Phi(w_0)} = \frac{r}{\Phi(w_0)}\left(\int_0^1 F(t,w_0(t))dt\right)$$
$$\geq \frac{\frac{\min\{m,\alpha_0\}}{8}\theta^2\left(\int_{\frac{1}{4}}^{\frac{3}{4}} F(t,\sigma)dt\right)}{\frac{1}{4}h(2\sigma)+\frac{1}{4}h(-2\sigma)+\frac{31\alpha_1\sigma^2}{48}+\sum_{j=1}^{m}\int_0^{w_0(t_j)} I_j(\zeta)d\zeta}$$
$$> \int_0^1 \sup_{|u|\leq\theta} F(t,u)dt \geq \sup_{u\in\Phi^{-1}((-\infty,r])} J(u).$$

We can then fix ρ so that

$$\sup_{u\in\Phi^{-1}((-\infty,r])} J(u) < \rho < r\frac{J(w_0)}{\Phi(w_0)}.$$

From Lemma 2.3, we obtain

$$\sup_{\lambda\geq 0}\inf_{u\in E}(\Phi(u)-\lambda(\rho-J(u))) < \inf_{u\in E}\sup_{\lambda\geq 0}(\Phi(u)-\lambda(\rho-J(u))).$$

Hence, by Lemma 2.2, for each compact interval $[c,d]\subset(\lambda_1,\lambda_2)$, there exists $R>0$ such that for every $\lambda\in[c,d]$, and every L^1-Carathéodory function $g:[0,1]\times\mathbb{R}\to\mathbb{R}$ there exists $\delta>0$ such that, for each $\mu\in[0,\delta]$, $\Phi'(u)-\lambda J'(u)-\mu\Psi'(u)=0$ has at least three solutions in E. Hence, the problem $(P^{f,g}_{\lambda,\mu})$ has at least three classical solutions whose norms are less than R. □

2.2 Results and discussion

In this paper we investigate the existence of multiple solutions to a quasilinear periodic boundary value problem with impulsive effects. The main technique of proof involves variational methods and critical points theorems for smooth functionals. We obtain the existence of at least three solutions to the problem. The applicability of the results are illustrated by an example.

Communicated by Gabriele Bonanno

Abstract. We study the problem $-\Delta u = \lambda u - u^{-1}$ with a Neumann boundary condition; the peculiarity being the presence of the singular term $-u^{-1}$. We point out that the minus sign in front of the negative power of u is particularly challenging, since no convexity argument can be invoked. Using bifurcation techniques we are able to prove the existence of solution (u_λ, λ) with u_λ approaching the trivial constant solution $u = \lambda^{-1/2}$ and λ close to an eigenvalue of a suitable linearized problem. To achieve this we also need to prove a generalization of a classical two-branch bifurcation result for potential operators. Next we study the radial case and show that in this case one of the bifurcation branches is global and we find the asymptotical behavior of such a branch. This results allows to derive the existence of multiple solutions u with λ fixed.

Keywords: singular elliptic equation, positive solutions, radial solutions, variational bifurcation, two branches.

2020 Mathematics Subject Classification: 34B16, 35J20, 58E07.

1 Introduction

In the last decades several authors have studied semilinear elliptic problems with singular nonlinear term (with respect to the unknown function u). The model problem is the following:

$$\begin{cases} -\Delta u = \gamma u^{-q} + f(x,u) & \text{in } \Omega, \\ u > 0 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where $q > 0$ $\gamma \neq 0$ and f is a non linear term with standard growth conditions. Existence and multiplicity of solutions to problem (1.1) are usually investigated in terms of the behavior of f and the sign of γ.

A main aspect to be taken into account is the variational nature of (1.1): formally speaking solutions u of (1.1) are expected to be critical points of the functional

$$I(u) := \frac{1}{2}\int_\Omega |\nabla u|^2\,dx - \frac{\gamma}{1-q}\int_\Omega u^{1-q}\,dx - \int_\Omega F(x,u)\,dx,$$

✉Corresponding author. Email: claudio.saccon@unipi.it

defined on $W_0^{1,2}(\Omega)$ and restricted to $\{u \geq 0\}$, where $F(x,s)$ is a primitive in s of $f(x,s)$ (if $q = 1$ a logarithm should be introduced). Unfortunately the presence of the singular term makes it problematic to give a rigorous formulation of the above ideas.

The majority of the known results concern the case $\gamma > 0$, where the term $u \mapsto -\frac{\gamma}{1-q}u^{1-q}$ is convex in the interval $]0, +\infty[$. This fact helps a lot, whether one tries to directly deal with I (by using some nonsmooth-critical-point theory) or to use an approximation scheme (by a sequence $I_n \to I$, I_n being $\mathcal{C}^1$ on $W_0^{1,2}(\Omega)$). For instance, if $f = 0$, the problem has a unique weak solution $\bar{u}$ in $W_0^{1,2}(\Omega)$ when $0 < q < 3$ and the solution is a minimizer for I. This result can be extended for all $q > 0$ dropping the request that $\bar{u} \in W_0^{1,2}(\Omega)$ (see [5, 9]). For a small non exhaustive list of multiplicity results for solutions of this kind of problems see [1, 3, 7, 11, 13–15, 17, 18, 26, 27] (and the references therein).

If we turn to $\gamma < 0$ the literature is scarcer: to the author's knowledge the main results are contained in [6, 12, 22, 27, 28]. In this situation solutions are "attracted" from the value zero and tend to develop "dead cores", so the formulation (1.1) needs to be modified in order to admit non strictly positive solutions. For instance the only solution for the case $f = 0$ is $u = 0$ (as one can easily see by multiplying the equation by u). Moreover a direct variational approach using the functional I seems difficult for the moment and the usual approach goes by perturbation methods.

We have found particularly interesting the paper [22] by Montenegro and Silva, where the authors use perturbation methods and show that there exist two nontrivial solutions when $\gamma = -1$, $0 < q < 1$, $f(x,u) = \mu u^p$, with $q < p <$ and $\mu > 0$ big enough. If we pass to $q = 1$, simple tests in the radial case suggest that the Dirichlet problem only has the trivial solution. As we said before solutions starting from zero are "forced to stick" at zero and not allowed to "emerge" (in contrast with the case of $q < 1$). On this respect see Remark 4.9.

For this reasons, in the case $q = 1$, we are lead to replace the Dirichlet condition with a Neumann one. In particular we have considered the problem

$$\begin{cases} -\Delta u = \lambda u - \dfrac{1}{u} & \text{in } \Omega, \\ u > 0 & \text{in } \Omega, \\ \nabla u \cdot \nu = 0 & \text{on } \partial\Omega \end{cases} \tag{1.2}$$

where Ω is a bounded smooth open subset of $\mathbb{R}^N$ and ν denotes the unit normal defined on $\partial\Omega$. This corresponds to the problem of [22] with $q = p = 1$ (with Neumann condition).

In case $N = 1$ (1.2) is closely related to a problem studied by Del Pino, Manásevich, and Montero in 1992 (see [10]) who deal with an ODE, in the periodic case, with a more general, non autonomous, singular term $f(u,x)$ (singular in u and T-periodic in x). Using topological degree arguments they prove for instance that the equation:

$$-\ddot{u} = \lambda u - \frac{1}{u^\alpha}, \qquad u(x) > 0, \qquad u(x+T) = u(x),$$

where $\alpha \geq 1$, has a solution provided $\lambda \neq \frac{\mu_k}{4}$ for all k. Here μ_k denote the eigenvalues of a suitable linearized problem which arises in a natural way from the problem. In this case, which has a variational structure, the results of [10] can be derived from the existence of two global bifurcation branches which originate from trivial solutions of the linearized problem.

In this paper we present two types of results concerning problem (1.2). In Theorem (2.1) of Section 2 we prove the existence of two local bifurcation branches $(u_{1,\rho}, \lambda_{1,\rho})$ and $(u_{2,\rho}, \lambda_{2,\rho})$ of solutions of (1.2), such that $(u_{i,\rho}, \lambda_{1,\rho}) \to (\hat{u}, \hat{\lambda})$, as $\rho \to 0$, where $\hat{\lambda}/2$ is an eigenvalue of

$-\Delta$ with Neumann condition and $\hat{u}$ is the constant function: $\hat{u} \equiv \hat{\lambda}^{-1/2}$. The proof of (2.1) heavily relies on a variant of the well known abstract results on the existence of two bifurcation branches in the variational case (see [4, 19, 20, 25]). To the author surprise such a variant (see Theorem (3.1) seems not to be present in the literature so its proof is carried on in Section 3. It has to be said that proving (3.1) requires some additional technicalities compared to the standard version. Indeed in [4, 20] the proof goes by studying a suitable perturbed function f_ρ on the unit sphere S, while in our case S has to be replaced by a sphere-like set S_ρ also varying with ρ. This requires to construct suitable projections to show that all S_ρ's are homeomorphic to $S_0 = S$ (for ρ small). Apart from this the proof of (3.1) follows the ideas of [2].

In Section 4 we study the radial case in dimension $N = 2$ (the same could be probably done for $N \geq 3$) using ODE techniques and a continuation argument for the nodal regions of the solutions. In this way, following the ideas of [24], we are able to prove that one of the two branches (u_ρ, λ_ρ) is global and bounded in λ_ρ. This is done by proving that nodal regions of u_ρ cannot collapse along the branch and that $\lambda_\rho \to \bar{\lambda}$ as $\|u_\rho\| \to +\infty$, where $\bar{\rho}$ is an eigenvalue of another suitable linear problem. In this way – in the radial case – we can find a lower estimate in the number of solutions for a fixed λ, by counting the number of branches that cross λ.

2 A local bifurcation result for the singular problem

Let Ω be a bounded open subset of $\mathbb{R}^N$ with smooth boundary.

Theorem 2.1. *Let $\hat{\mu} > 0$ be an eigenvalue of the following Neumann problem:*

$$\begin{cases} -\Delta u = \mu u & \text{in } \Omega, \\ \nabla u \cdot \nu = 0 & \text{on } \partial\Omega, \end{cases} \tag{2.1}$$

(ν denotes the normal to $\partial\Omega$).

Then there exists $\rho_0 > 0$ such that for all $\rho \in \,]0, \rho_0[$ there exist two distinct pairs $(u_{1,\rho}, \lambda_{1,\rho})$ and $(u_{2,\rho}, \lambda_{2,\rho})$ such that, for $i = 1, 2$:

$$(u_{i,\rho}, \lambda_{i,\rho}) \text{ are solutions of (1.2)}, \; u_{i,\rho} \to \frac{1}{\sqrt{\mu/2}} \quad (\text{in } W^{1,2}(\Omega)\,)\,, \; \lambda_{i,\rho} \xrightarrow{\rho \to 0} \frac{\hat{\mu}}{2}.$$

Proof. We start by introducing some changes of variables. First of all notice that, for all $\lambda > 0$, Problem (1.2) has the constant solution $u(x) = \frac{1}{\sqrt{\lambda}}$. If we seek for solutions of the form $u = \frac{1}{\sqrt{\lambda}} + z$ we easily end up with the equivalent problem on z:

$$\begin{cases} -\Delta z = 2\lambda z - h_\lambda(z) & \text{in } \Omega, \\ \sqrt{\lambda} z > -1 & \text{in } \Omega, \\ \nabla z \cdot \nu = 0 & \text{on } \partial\Omega, \end{cases} \tag{2.2}$$

where $h_\lambda : \,]-\frac{1}{\sqrt{\lambda}}, +\infty[\, \to \mathbb{R}$ is defined by

$$h_\lambda(s) = \frac{\lambda\sqrt{\lambda}s^2}{1 + \sqrt{\lambda}s}.$$

Now we consider another simple transformation: $v := \sqrt{\lambda}z$, so that (2.2) turns out to be equivalent to

$$\begin{cases} -\Delta v = 2\lambda\left(v - \frac{1}{2}h_1(v)\right) & \text{in } \Omega, \\ v > -1 & \text{in } \Omega, \\ \nabla v \cdot \nu = 0 & \text{on } \partial\Omega. \end{cases} \tag{2.3}$$

Now choose s_0 with $0 < s_0 < 1/2$ and a $\mathcal{C}^\infty$ cutoff function $\eta : \mathbb{R} \to [0,1]$ such that $\eta(s) = 1$ for $|s| \le s_0$, $\eta(s) = 0$, for $|s| \ge 2s_0$. Define $\tilde{h}_1 : \mathbb{R} \to \mathbb{R}$ by

$$\tilde{h}_1(s) := \eta(s)\, h_1(s) \tag{2.4}$$

($\tilde{h}_1(s)$ is given the value zero for $s = -1$). Then $\tilde{h}_1 \in \mathcal{C}_0^\infty(\mathbb{R};\mathbb{R})$, $\tilde{h}_1'(0) = h_1''(0) = 0$, $\tilde{h}_1 = h_1$ on $[-s_0, s_0]$. Denote by $\tilde{H}_1 : \mathbb{R} \to \mathbb{R}$ the primitive function for $\tilde{h}_1$ (i.e. $\tilde{H}_1' = \tilde{h}_1$) such that $\tilde{H}_1(0) = 0$.

Now we apply the bifurcation theorem (3.1) with $\mathbb{H} := W^{1,2}(\Omega)$. $\mathbb{L} = L^2(\Omega)$, $\mathcal{H} = 0$, $\hat{\lambda} = \mu$, $\mathcal{H}_1(v) := \frac{1}{2}\int_\Omega \tilde{H}_1(v)\,dx$. In this way we get that there exists $\rho_0 > 0$ such that for all $\rho \in]0, \rho_0[$ there are two distinct pairs $(v_{1,\rho}, \mu_{1,\rho})$ and $(v_{2,\rho}, \mu_{2,\rho})$ which are *weak* solutions of

$$\begin{cases} -\Delta v = \mu\left(v - \frac{1}{2}\tilde{h}_1(v)\right) & \text{in } \Omega, \\ \nabla v \cdot \nu = 0 & \text{on } \partial\Omega \end{cases} \tag{2.5}$$

and such that

$$v_{i,\rho} \xrightarrow{\rho \to 0} 0 \quad (\text{in } W^{1,2}(\Omega)), \qquad \mu_{i,\rho} \xrightarrow{\rho \to 0} \mu_k, \qquad i = 1,2. \tag{2.6}$$

We claim the there exists a constant K such, for any $\mu \in [\hat{\mu}_k - 1, \hat{\mu}_k + 1]$ and any weak solution v of (2.5), v is bounded and:

$$\|v\|_\infty \le K\mu \left\| v - \frac{1}{2}\tilde{h}_1(v) \right\|_2 . \tag{2.7}$$

For this we use a standard bootstrap argument using the fact that the function $k(s) = (s - \frac{1}{2}\tilde{h}_1(s))$, appearing on the right hand side of (2.5), verifies

$$|k(s)| \le M|s| \qquad \forall s \in \mathbb{R} \tag{2.8}$$

for a suitable M (since $\tilde{h}_1'$ is bounded). Assume that v is a solution, i.e. $-\Delta v = \mu k(v)$, and $v \in L^q(\Omega)$ for some $q > 1$ (for sure this is true for $q = 2^*$). Then, by (2.8), $k(v) \in L^q(\Omega)$. From the standard Calderón–Zygmund theory (see e.g. Section 9.6 in [16]), we have $v \in W^{2,q}(\Omega)$. Then, using the Sobolev embedding Theorem, either $v \in L^{q_1}(\Omega)$ with $q_1 \le \frac{Nq}{N-2q}$ (if $2q \le N$) or $v \in \mathcal{C}^{0,\alpha}$ with $\alpha > 0$ (in the case $2q > N$). Iterating this argument a finite number of times we get the conclusion. Notice that we could go further and prove that v is $\mathcal{C}^\infty$ and is a classical solution.

Using (2.6) and (2.7) we get that $v_{i,\rho} \to 0$ in $L^\infty(\Omega)$ as $\rho \to 0$, so $|v_{i,\rho}| < s_0$, $i = 1,2$, for ρ_0 small. This implies that $\tilde{h}_1(v_{i,\rho}) = h_1(v_{i,\rho})$, and $v_{i,\rho}$ actually solve (2.3) with $\lambda_{i,\rho} := \frac{\mu_{i,\rho}}{2}$. Going backwards and setting $u_{i,\rho} := \frac{1}{\sqrt{\lambda_{i,\rho}}} + \sqrt{\lambda_{i,\rho}}v_{i,\rho}$, we find the desired solutions of (1.2).

□

3 A variant for the two bifurcation branches theorem for potential operators

Let $\mathbb{L}$ and $\mathbb{H}$ be two Hilbert spaces such that $\mathbb{H} \subset \mathbb{L}$ with a compact embedding $i : \mathbb{H} \to \mathbb{L}$. We use the notations $\|\cdot\|$, $\langle \cdot, \cdot \rangle$ and $\|\cdot\|_{\mathbb{L}}$, $\langle \cdot, \cdot \rangle_{\mathbb{L}}$ to indicate the norms and inner products in $\mathbb{H}$ and $\mathbb{L}$ respectively. Let $A : \mathbb{H} \to \mathbb{H}$ be a bounded linear symmetric operator such that

$$\langle Au, u \rangle \geq \nu \|u\|^2 - M \|u\|_{\mathbb{L}}^2 \qquad \forall u \in \mathbb{H} \tag{3.1}$$

where $\nu > 0$ and M are two constants. We say that $\lambda \in \mathbb{R}$ is an "eigenvalue for A" if there exists $e \in \mathbb{H} \setminus \{0\}$ with

$$\langle Ae, v \rangle = \lambda \langle e, v \rangle_{\mathbb{L}} \qquad \forall v \in \mathbb{H}$$

which corresponds to say that:

$$Ae = \lambda i^* e.$$

In this case we say that e is an "eigenvector" corresponding to λ.

It is well known that there exists a sequence (λ_n) of eigenvalues of A with $\lambda_n \leq \lambda_{n+1}$, $\lambda_n \to +\infty$, such that the corresponding eigenvectors generate $\mathbb{H}$. It is convenient to agreee that $\lambda_0 = -\infty$. We can suppose that for any $k \geq 1$ we are given an eigenvector e_k relative to λ_k with $\|e_n\|_{\mathbb{L}} = 1$, and

$$\langle e_n, e_m \rangle = \langle e_n, e_m \rangle_{\mathbb{L}} = 0 \quad \text{if } n \neq m.$$

If $\lambda \in \mathbb{R}$ we define

$$E_\lambda^- := \text{span}\{e_i : \lambda_i < \lambda\}, \quad E_\lambda^0 := \text{span}\{e_i : \lambda_i = \lambda\}, \quad E_\lambda^+ := \overline{\text{span}\{e_i : \lambda_i > \lambda\}}^{(\mathbb{H})}$$

($E_\lambda^0 = \{0\}$ if λ is not an eigenvalue). If $\lambda_n \leq \lambda \leq \lambda_{n+1}$ it is clear that

$$\sup_{\left\{u \in E_\lambda^- : \|u\|_{\mathbb{L}} = 1\right\}} \langle Au, u \rangle \leq \lambda_n, \qquad \inf_{\{u \in E^+\lambda : \|u\|_{\mathbb{L}} = 1\}} \langle Au, u \rangle \geq \lambda_{n+1},$$

while $\langle Au, u \rangle = \lambda$, if $u \in E_\lambda^0$.

Theorem 3.1 (Bifurcation). *Let $\mathcal{H} \in \mathcal{C}^1(\mathbb{H}; \mathbb{R})$, $\mathcal{H}_1 \in \mathcal{C}^1(\mathbb{L}; \mathbb{R})$ be such that*

$$\begin{aligned} &\mathcal{H}(0) = 0, \qquad \nabla \mathcal{H}(0) = 0, \qquad \lim_{u \to 0} \frac{\|\nabla \mathcal{H}(u)\|_{\mathbb{L}}}{\|u\|_{\mathbb{L}}} = 0 \\ &\mathcal{H}_1(0) = 0, \qquad \nabla_{\mathbb{L}} \mathcal{H}_1(0) = 0, \qquad \lim_{u \to 0} \frac{\|\nabla_{\mathbb{L}} \mathcal{H}_1(u)\|_{\mathbb{L}}}{\|u\|_{\mathbb{L}}} = 0. \end{aligned} \tag{3.2}$$

Notice that we are using the symbol ∇ to denote the gradient with respect to the inner product in $\mathbb{H}$ and $\nabla_{\mathbb{L}}$ for the corresponding gradient in $\mathbb{L}$.

Let $\hat{\lambda}$ be an eigenvalue for A. Then, for any $\rho > 0$ small, there exist $(u_{1,\rho}, \lambda_{1,\rho})$ and $(u_{2,\rho}, \lambda_{2,\rho})$ which solve the problem

$$Au + \nabla \mathcal{H}(u) = \lambda i^* \left(u + \nabla_{\mathbb{L}} \mathcal{H}_1(u)\right), \qquad u \neq 0, \tag{3.3}$$

such that $u_{1,\rho} \neq u_{2,\rho}$ and

$$u_{1,\rho} \xrightarrow{\mathbb{H}} 0, \qquad u_{2,\rho} \xrightarrow{\mathbb{H}} 0, \qquad \lambda_{1,\rho} \to \hat{\lambda}, \qquad \lambda_{2,\rho} \to \hat{\lambda} \quad \text{as } \rho \to 0. \tag{3.4}$$

Proof. We adapt the proof of Lemma 3.4 in [2]. Let $\hat{\lambda} = \lambda_i = \lambda_k$ with $\lambda_{i-1} < \lambda_i$ and $\lambda_k < \lambda_{k+1}$. We define $f : \mathbb{H} \to \mathbb{R}$ and $g : \mathbb{L} \to \mathbb{R}$ by

$$f(u) := \frac{1}{2} \langle Au, u \rangle + \mathcal{H}(u), \qquad g(u) := \frac{1}{2} \|u\|_{\mathbb{L}}^2 + \mathcal{H}_1(u).$$

Let $\mathcal{C} := \{u \in \mathbb{L} : 1 < \|u\|_{\mathbb{L}} < 2\}$. Moreover, if $0 < \rho < 1$ we define

$$f_\rho(u) := \frac{1}{\rho^2} f(\rho u), \qquad g_\rho(u) := \frac{1}{\rho^2} g(\rho u),$$
$$\mathcal{H}_\rho(u) := \frac{1}{\rho^2} \mathcal{H}(\rho u), \qquad \mathcal{H}_{1,\rho}(u) := \frac{1}{\rho^2} \mathcal{H}_1(\rho u),$$
$$\mathcal{S}_\rho := \{u \in \mathcal{C} : g_\rho(u) = 1\}.$$

In fact $f_\rho(u) = \frac{1}{2} \langle Au, u \rangle + \mathcal{H}_\rho(u)$ and $g_\rho(u) = \frac{1}{2} \|u\|_{\mathbb{L}}^2 + \mathcal{H}_{1,\rho}(u)$.

Since the result we are proving only involves the behaviour of $\mathcal{H}, \mathcal{H}_1$ near zero, we are allowed to modify $\mathcal{H}$ and $\mathcal{H}_1$ outside of a small ball around the origin. More precisely using (3.2) we can find R in $]0, 1/3[$ such that

$$\|\nabla \mathcal{H}(u)\| \leq \frac{\nu}{8} \|u\| \ \forall u \text{ with } \|u\| < 3R, \quad \|\nabla_{\mathbb{L}} \mathcal{H}_1(u)\| \leq \frac{1}{2} \|u\|_1 \ \forall u \text{ with } \|u\|_1 < 3R, \tag{3.5}$$

and define $\tilde{\mathcal{H}}(u) := \eta(\|u\|)\mathcal{H}(u)$, $\tilde{\mathcal{H}}_1(u) := \eta(\|u\|_1)\mathcal{H}_1(u)$, where $\eta : [0, +\infty[\to [0, 1]$ is a cutoff function with $\eta(s) = 1$ for $0 \leq s \leq R$, $\eta(s) = 0$ for $s \geq 3R$, and $\eta'(s) \leq 1$. Now since

$$\tilde{\mathcal{H}}(u) = \mathcal{H}(u) \quad \forall u \text{ with } \|u\| < R, \qquad \tilde{\mathcal{H}}_1(u) = \mathcal{H}_1(u) \quad \forall u \text{ with } \|u\|_{\mathbb{L}} < R,$$

then the conclusion of Theorem 3.1 holds for $\mathcal{H}, \mathcal{H}_1$ if and only if it holds for $\tilde{\mathcal{H}}, \tilde{\mathcal{H}}_1$. Indeed the first component u_ρ of a bifucation branch (for any of the two problems) eventually verifies $\|u_\rho\| < R$ and $\|u_\rho\|_1 < R$. So from now on we replace $\mathcal{H}$ with $\tilde{\mathcal{H}}$ and $\mathcal{H}_1$ with $\tilde{\mathcal{H}}_1$, maintaining the same notation. With simple computations we can deduce from (3.5) that the redefined functions verify:

$$\text{(a)} \quad |\nabla \mathcal{H}(u)| \leq \frac{\nu}{4} \|u\| \ \forall u \in \mathbb{H}, \qquad \text{(b)} \quad |\nabla_{\mathbb{L}} \mathcal{H}_1(u)| \leq \|u\|_{\mathbb{L}} \ \forall u \in \mathbb{L}. \tag{3.6}$$

From (a) in (3.6) we get

$$|\mathcal{H}(u)| \leq \frac{\nu}{4} \|u\|^2 \Rightarrow |\mathcal{H}_\rho(u)| \leq \frac{\nu}{4} \|u\|^2 \qquad \forall u \in \mathbb{H}, \forall \rho \in [0, 1]. \tag{3.7}$$

Using (3.1) and (3.7) we get that:

$$\|u\|^2 \leq \frac{4}{\nu} \left(f_\rho(u) + M \|u\|_{\mathbb{L}}^2 \right). \tag{3.8}$$

From (3.2) and (3.8) we easily get that, if $c \in \mathbb{R}$ and $\rho \to 0$:

$$\begin{aligned} &\sup_{u \in \mathcal{C}, f_\rho(u) \leq c} |\mathcal{H}_\rho(u)| \to 0, &&\sup_{u \in \mathcal{C}} |\mathcal{H}_{1,\rho}(u)| \to 0, \\ &\sup_{u \in \mathcal{C}, f_\rho(u) \leq c} \|\nabla \mathcal{H}_\rho(u)\| \to 0, &&\sup_{u \in \mathcal{C}} \|\nabla_{\mathbb{L}} \mathcal{H}_{1,\rho}(u)\|_{\mathbb{L}} \to 0. \end{aligned} \tag{3.9}$$

So if we extend the definition to $\rho = 0$ by letting $f_0(u) := \frac{1}{2}\langle Au, u\rangle$ and $g_0(u) := \frac{1}{2}\|u\|_{\mathbb{L}}^2$, then $(\rho, u) \mapsto f_\rho(u)$ is continuous on $[0, +\infty[\times\mathbb{H}$ and $(\rho, u) \mapsto g_\rho(u)$ is continuous on $[0, +\infty[\times\mathbb{L}$. We also define $\mathcal{S}_\rho$ for $\rho = 0$:

$$\mathcal{S}_0 := \{u \in \mathbb{L} : g_0(u) = 1\} = \left\{u \in \mathbb{L} : \|u\|_{\mathbb{L}}^2 = 2\right\}.$$

Notice that the critical values of f_0 on $\mathcal{S}_\rho$ are precisely the eigenvalues λ_n.

We claim that there exist $\bar\rho >$ such that the $\mathbb{L}$-closure of $\mathcal{S}_\rho$ is contained in $\mathcal{C}$ for all $\rho \in]0, \bar\rho]$ in other terms $\mathcal{S}_\rho$ is closed for $\rho > 0$ small. Indeed if the claim were false there would exist two sequences (ρ_n) and (u_n) such that $\rho_n \to 0$, $\rho_n \to 0$, $g_{\rho_n}(u_n) = \frac{\|u_n\|_{\mathbb{L}}^2}{2} + \frac{\mathcal{H}_1(\rho_n u_n)}{\rho^2} = 1$, and $\|u_n\|_{\mathbb{L}} \in \{1, 2\}$. From (3.2) we would have $\frac{\mathcal{H}_1(\rho_n u_n)}{\rho_n^2} = \frac{\mathcal{H}_1(\rho_n u_n)}{\|\rho_n u_n\|_{\mathbb{L}}^2}\|u_n\|_{\mathbb{L}}^2 \to 0$, so $\|u_n\|_{\mathbb{L}} \to \sqrt{2}$ which yields a contradiction for n large.

Let us split $\mathbb{H}$ as $\mathbb{H} = \mathbb{X}_1 \oplus \mathbb{X}_2 \oplus \mathbb{X}_3$, where

$$\mathbb{X}_1 := E_{\hat\lambda}^-, \qquad \mathbb{X}_2 := E_{\hat\lambda}^0, \qquad \mathbb{X}_3 := E_{\hat\lambda}^+$$

and consider the orthogonal projections $\Pi_i : \mathbb{H} \to \mathbb{X}_i$. $i = 1, 2, 3$. We also denote $\Pi_{13} := \Pi_1 + \Pi_3$. Given $\rho \in [0, \bar\rho]$ and $\delta \in]0, 1[$, we set

$$\mathcal{C}_\delta := \{u \in \mathcal{C} : \|\Pi_2(u)\|_{\mathbb{L}} \geq \delta\}, \qquad \mathcal{S}_{\rho,\delta} := \mathcal{S}_\rho \cap \mathcal{C}_\delta.$$

Since $\mathcal{S}_\rho$ is closed, then $S_{\rho,\delta}$ is a smooth manifold with boundary, the boundary being

$$\Sigma_{\rho,\delta} := \left\{u \in \mathcal{S}_\rho : \|\Pi_2(u)\|_{\mathbb{L}} = \delta\right\}.$$

Notice that $\mathcal{S}_{0,\delta} \neq \emptyset$ ($\delta < 1$). Let us indicate by $\bar f_\rho$ the restriction of f_ρ on $\mathcal{S}_{\rho,\delta}$.

We will use the notion of lower critical point for $\bar f_\rho$ (see [2,21] and the references therein): u is (lower) critical for $\bar f_\rho$ if and only there exist $\lambda, \mu \in \mathbb{R}$ such that $\mu \geq 0$, $\mu = 0$ if $\|\Pi_2(u)\|_{\mathbb{L}} > \delta$, and

$$\langle Au, v\rangle + \langle\nabla\mathcal{H}_\rho(u), v\rangle = \lambda\langle u + \nabla_{\mathbb{L}}\mathcal{H}_{1,\rho}(u), v\rangle_{\mathbb{L}} + \mu\langle\Pi_2(u), v\rangle_{\mathbb{L}} \quad \forall v \in \mathbb{H}. \tag{3.10}$$

Define $\Gamma : \mathcal{C}_\delta \times [1/2, 2] \to \mathcal{C}_\delta$ and $\varphi : [0, \bar\rho] \times \mathcal{C}_\delta \times [1/2, 2] \to \mathbb{R}$ by

$$\begin{aligned}\Gamma(u, t) &:= \frac{\delta\Pi_2(u)}{\|\Pi_2(u)\|_{\mathbb{L}}} + t\left(u - \frac{\delta\Pi_2(u)}{\|\Pi_2(u)\|_{\mathbb{L}}}\right)\\ &= t\Pi_{13}(u) + (\delta + t(\|\Pi_2(u)\|_{\mathbb{L}} - \delta))\frac{\Pi_2(u)}{\|\Pi_2(u)\|_{\mathbb{L}}},\\ \varphi(\rho, u, t) &:= g_\rho(\Gamma(u, t)).\end{aligned}$$

With easy computations:

$$\begin{aligned}\varphi(0, u, t) &= \frac{1}{2}\left(t^2\|\Pi_{13}(u)\|_{\mathbb{L}}^2 + (\delta + t(\|\Pi_2(u)\|_{\mathbb{L}} - \delta))^2\right)\\ &= \frac{1}{2}\left(t^2(\|u\|_{\mathbb{L}}^2 - 2\delta\|\Pi_2(u)\|_{\mathbb{L}} + \delta^2) + 2\delta t(\|\Pi_2(u)\|_{\mathbb{L}} - \delta) + \delta^2\right).\end{aligned}$$

Since $1 < \|u\|_{\mathbb{L}} < 2$ and $\|\Pi_2(u)\|_{\mathbb{L}} \geq \delta$, we have

$$\frac{t^2}{2} - 2\delta t^2 \leq \varphi(0, u, t) \leq \left(2 + \frac{\delta^2}{2}\right)t^2 + 2\delta t + \frac{\delta^2}{2}.$$

In particular:

$$2-2\delta \le \varphi(0,u,2), \qquad \varphi(0,u,1/2) \le \frac{1}{2}+\frac{\delta^2}{8}+\delta+\frac{\delta^2}{2} < \frac{1}{2}+2\delta.$$

We can choose $\delta_0 > 0$ so that $2-2\delta > 3/2$ and $\frac{1}{2}+2\delta < 3/4$ for all $\delta \in]0,\delta_0]$. From now on we consider $0<\delta\le\delta_0$. By (3.9), up to shrinking $\bar\rho$, we have

$$\sup_{u\in\mathcal{C}_\delta} \varphi(\rho,u,1/2) < 1, \qquad \inf_{u\in\mathcal{C}_\delta} \varphi(\rho,u,2) > 1 \qquad \forall \rho\in[0,\bar\rho].$$

Moreover,

$$\frac{\partial}{\partial t}\varphi(0,u,t) = t(\|u\|_{\mathbb{L}}^2 - 2\delta\,\|\Pi_2(u)\|_{\mathbb{L}} + \delta^2) + \delta(\|\Pi_2(u)\|_{\mathbb{L}} - \delta) \ge t(1-4\delta)$$

so, up to shrinking δ_0, we have $\frac{\partial}{\partial t}\varphi(0,u,t) \ge \frac{1}{4}$ for all $t\ge\frac{1}{2}$. Up to further shrinking $\bar\rho>0$ (again we use (3.9)), we have that $\rho\in[0,\bar\rho]$, $\delta\in]0,\delta_0]$, $u\in\mathcal{C}_\delta$ imply

$$\varphi(\rho,u,1/2)<1, \quad \varphi(\rho,u,2)>1, \quad \frac{\partial}{\partial t}\varphi(\rho,u,t)\ge\frac{1}{8} \quad \forall t\in[1/2,2].$$

We can therefore conclude that for all $u\in[0,\bar\rho]$ and $u\in\mathcal{C}_\delta$ there exists a unique $\bar t=\bar t(\rho,u)$ in $[1/2,2]$ such that $\varphi(\rho,u,\bar t(u,\rho))=1$, that is $\Gamma(u,\bar t(\rho,u))\in\mathcal{S}_{\rho,\delta}$. It is easy to check that $\bar t:[0,\bar\rho]\times\mathcal{C}_\delta\to[1/2,2]$ is continuous and so is $\Phi:[0,\bar\rho]\times\mathcal{C}_\delta\to\mathcal{S}_{\rho,\delta}$ defined by $\Phi(\rho,u):=\Gamma(u,\bar t(\rho,u))$. Notice that

$$t\in[1/2,2],\ u\in\mathcal{C}_\delta,\ \|\Pi_2(u)\|_{\mathbb{L}}=\delta \ \Rightarrow\ \|\Pi_2(\Gamma(u,t))\|_{\mathbb{L}}=\delta.$$

Therefore $\Phi(\rho,\cdot)$ maps $\{u\in\mathcal{C}_\delta, \|\Pi_2(u)\|_{\mathbb{L}}=\delta\}$ into $\Sigma_{\rho,\delta}$. Also notice that $\Phi(\rho,u)\circ\Phi(0,u)=u$ whenever $u\in\mathcal{S}_{\rho,\delta}$ and $\Phi(0,u)\circ\Phi(\rho,u)=u$ whenever $u\in\mathcal{S}_{0,\delta}$. We have thus proven that $\Phi(\rho,\cdot)|_{S_{0,\delta}}$ is a homeomorphism from $(S_{0,\delta},\Sigma_{0,\delta})$ to $(S_{\rho,\delta},\Sigma_{\rho,\delta})$ whose inverse is $\Phi(0,\cdot)|_{S_{\rho,\delta}}$.

Now let

$$a'_\rho := \sup_{(\mathbb{X}_1\oplus\mathbb{X}_2)\cap\Sigma_{\rho,\delta}} f_\rho \qquad a''_\rho := \inf_{(\mathbb{X}_2\oplus\mathbb{X}_3)\cap\mathcal{S}_{\rho,\delta}} f_\rho \tag{3.11}$$

$$b'_\rho := \sup_{(\mathbb{X}_1\oplus\mathbb{X}_2)\cap\mathcal{S}_{\rho,\delta}} f_\rho \qquad b''_\rho := \inf_{(\mathbb{X}_2\oplus\mathbb{X}_3)\cap\Sigma_{\rho,\delta}} f_\rho. \tag{3.12}$$

Notice that, by definition, $a''_\rho \le b'_\rho$. For $\rho=0$ it is easy to see that

$$a'_0 = \lambda_{i-1} + \frac{\delta^2}{2}(\hat\lambda-\lambda_{i-1}) < \hat\lambda = a''_0 = b'_0 = \hat\lambda < \lambda_{k+1} - \frac{\delta^2}{2}(\lambda_{k+1}-\hat\lambda) = b''_0$$

(recall that $0<\delta<1$). Let $\varepsilon_0>0$ with $\varepsilon_0<\hat\lambda-\lambda_{i-1}$. We claim that, if $\delta^2(\hat\lambda-\lambda_{i-1})<2\varepsilon_0$, then

$$\text{there exists no } u\in\Sigma_{0,\delta} \text{ with } u \text{ lower critical for } \bar f_0 \text{ and } \lambda_{i-1}+\varepsilon_0\le f_0(u). \tag{3.13}$$

By contradiction assume that such a u exists; then there exist $\lambda\in\mathbb{R}$ and $\mu\ge0$ such that (3.10) holds. Let $u_i=\Pi_i(u)$, $i=1,2,3$. Taking $v=u_2$ in (3.10) (with $\rho=0$) yields

$$\hat\lambda\,\|u_2\|_{\mathbb{L}}^2 = \langle Au_2,u_2\rangle = \langle Au,u_2\rangle = \lambda\,\langle u,u_2\rangle_{\mathbb{L}} + \mu\,\langle u_2,u_2\rangle_{\mathbb{L}} = (\lambda+\mu)\,\|u_2\|_{\mathbb{L}}^2.$$

Since $\|u_2\|_{\mathbb{L}} = \delta > 0$, we have $\lambda + \nu = \hat{\lambda}$, so $\lambda = \hat{\lambda} - \nu \le \hat{\lambda}$. Taking $v = u_3$:

$$\lambda_{k+1} \|u_3\|^2 \le \langle Au_3, u_3 \rangle = \langle Au, u_3 \rangle = \langle \lambda u + \mu u_2, u_3 \rangle = \lambda \|u_3\|_{\mathbb{L}}^2 \le \hat{\lambda} \|u_3\|_{\mathbb{L}}^2 .$$

Since $\lambda_{k+1} < \hat{\lambda}$, we have $u_3 = 0$. Then $u \in \mathbb{X}_1 \oplus \mathbb{X}_2 \cap \Sigma_{0,\delta}$, which implies

$$f_0(u) \le a_0' = \lambda_{i-1} + \frac{\delta^2}{2}(\hat{\lambda} - \lambda_{i-1}) < \lambda_{i-1} + \varepsilon_0$$

which gives a contradiction. Hence the claim is proven. Notice that (3.13) implies that the only critical value λ_0 of $\bar{f}_0$, with $\lambda_{i-1} + \varepsilon_0 \le \lambda_0 \le \lambda_{k+1} - \varepsilon_0$, is $\lambda_0 = \hat{\lambda}$. Indeed assume u_0 to be a critical point with $\bar{f}_0(u_0) = \lambda_0$: then, by (3.13), $u_0 \notin \Sigma_{0,\delta}$ so (3.10) holds with $\mu = 0$ which easily implies $\lambda_0 = \hat{\lambda}$.

From now on we fix $\varepsilon_0 > 0$ such that $5\varepsilon_0 < \min(\hat{\lambda} - \lambda_{i-1}, \lambda_{k+1} - \hat{\lambda})$ and $\delta > 0$ such that $\delta^2(\hat{\lambda} - \lambda_{i-1}) \le \varepsilon_0$ (so (3.13) holds with $\varepsilon_0/2$). Using (3.9) we can derive that, given $\varepsilon \in]0, \varepsilon_0]$ there exists $\rho(\varepsilon) \in]0, \bar{\rho}]$ such that, if $\rho \in]0, \rho(\varepsilon)]$:

$$\begin{aligned} a_\rho' &\le \lambda_{i-1} + \varepsilon_0 < \hat{\lambda} - 4\varepsilon < \hat{\lambda} - \varepsilon \le a_\rho'' \le \inf_{\mathbb{X}_2 \cap \mathcal{S}_{\rho,\delta}} f_\rho \\ &\le \sup_{\mathbb{X}_2 \cap \mathcal{S}_{\rho,\delta}} f_\rho \le b_\rho' \le \hat{\lambda} + \varepsilon < \hat{\lambda} + 4\varepsilon < \lambda_{k+1} - \varepsilon_0 \le b_\rho''; \end{aligned} \tag{3.14}$$

$$\begin{gathered} \text{there are no } u \in \Sigma_{\rho,\delta} \text{ with } u \text{ lower critical for } \bar{f}_\rho \text{ and} \\ f_\rho(u) \in [\lambda_{i-1} + \varepsilon_0, \lambda_{k+1} - \varepsilon_0]\,; \end{gathered} \tag{3.15}$$

$$\begin{gathered} \text{there are no } u \in \mathcal{S}_{\rho,\delta} \text{ with } u \text{ lower critical for } \bar{f}_\rho \text{ and} \\ f_\rho(u) \in \left[\lambda_{i-1} + \varepsilon_0, \hat{\lambda} - \varepsilon\right] \cup \left[\hat{\lambda} + \varepsilon, \lambda_{k+1} - \varepsilon_0\right]; \end{gathered} \tag{3.16}$$

$$\left|f_0(u) - f_\rho(\Phi(\rho, u))\right| < \varepsilon \qquad \forall u \in \mathcal{S}_{0,\delta} \text{ with } f_0(u) \le \lambda_{k+1} - \varepsilon_0; \tag{3.17}$$

$$\left|f_\rho(u) - f_0(\Phi(0, (u))\right| < \varepsilon \qquad \forall u \in \mathcal{S}_{\rho,\delta} \text{ with } f_\rho(u) \le \lambda_{k+1} - \varepsilon_0. \tag{3.18}$$

To prove (3.17) and (3.18) we use (3.8). If $\sigma \in [\varepsilon, 4\varepsilon]$, set $A_\rho^\sigma := \bar{f}_\rho^{\hat{\lambda}/2-\sigma}$, $B_\rho^\sigma := \bar{f}_\rho^{\hat{\lambda}/2+\sigma}$ i.e.:

$$A_\rho^\sigma = \left\{u \in S_{\rho,\delta} : f_\rho(u) \le \hat{\lambda}/2 - \sigma\right\}, \qquad B_\rho^\sigma = \left\{u \in S_{\rho,\delta} : f_\rho(u) \le \hat{\lambda}/2 + \sigma\right\}.$$

Moreover set $\tilde{A}_\rho^\sigma := \Phi(\rho, A_0^\sigma)$, $\tilde{B}_\rho^\sigma := \Phi(\rho, B_0^\sigma)$, $\hat{A}_\rho^\sigma := \Phi(0, A_\rho^\sigma)$, $\hat{B}_\rho^\sigma := \Phi(0, B_\rho^\sigma)$. From (3.17) and (3.18) (remind that $\Phi(\rho, \cdot)^{-1} = \Phi(0, \cdot)$) we get

$$\begin{aligned} &A_0^{4\varepsilon} \subset \Phi(0, A_\rho^{3\varepsilon}) \subset A_0^{2\varepsilon} \subset \Phi(0, A_\rho^{\varepsilon}), \qquad B_0^{\varepsilon} \subset \Phi(0, B_\rho^{2\varepsilon}) \subset B_0^{3\varepsilon}\Phi(0, B_\rho^{4\varepsilon}), \\ &A_\rho^{4\varepsilon} \subset \Phi(\rho, A_0^{3\varepsilon}) \subset A_\rho^{2\varepsilon} \subset \Phi(\rho, A_0^{\varepsilon}), \qquad B_\rho^{\varepsilon} \subset \Phi(\rho, B_0^{2\varepsilon}) \subset B_\rho^{3\varepsilon}\Phi(\rho, B_0^{4\varepsilon}). \end{aligned}$$

The above inclusions give rise to the following diagram in homology:

$$\begin{array}{ccccccc} H_q(B_\rho^\varepsilon, A_\rho^{4\varepsilon}) & \xrightarrow{i_1^*} & H_q(\tilde{B}_\rho^{2\varepsilon}, \tilde{A}_\rho^{3\varepsilon}) & \xrightarrow{i_2^*} & H_q(B_\rho^{3\varepsilon}, A_\rho^{2\varepsilon}) & \xrightarrow{i_3^*} & H_q(\tilde{B}_\rho^{4\varepsilon}, \tilde{A}_\rho^{\varepsilon}) \\ \downarrow \phi_1^* & & \phi_2^* \uparrow & & \downarrow \phi_3^* & & \phi_2^* \uparrow \\ H_q(\hat{B}_\rho^\varepsilon, \hat{A}_\rho^{4\varepsilon}) & \xrightarrow{j_1^*} & H_q(B_0^{2\varepsilon}, A_0^{3\varepsilon}) & \xrightarrow{j_2^*} & H_q(\hat{B}_\rho^{3\varepsilon}, \hat{A}_\rho^{2\varepsilon}) & \xrightarrow{j_3^*} & H_q(B_0^{4\varepsilon}, A_0^{\varepsilon}) \end{array}$$

where i_1, i_2, i_3, j_1, j_2, j_3 are embeddings and ϕ_1, ϕ_3 are restrictions of $\Phi(0, \cdot)$, while ϕ_2, ϕ_4 are restrictions of $\Phi(\rho, \cdot)$. It is clear that ϕ_i^* are isomorphisms. Notice that $i_2 \circ \phi_2 \circ j_1 \circ \phi_1$ is the embedding of $(B_\rho^\varepsilon, A_\rho^{4\varepsilon})$ in $(B_\rho^{3\varepsilon}, A_\rho^{2\varepsilon})$ and $j_3 \circ \phi_3 \circ i_2 \circ \phi_2$ is the embedding of $(B_0^{2\varepsilon}, A_0^{3\varepsilon})$ in $(B_0^{4\varepsilon}, A_0^{\varepsilon})$.

Since there are no critical values for $\bar{f}_0$ in $[\hat{\lambda}-4\varepsilon, \hat{\lambda}-\varepsilon] \cup [\hat{\lambda}+\varepsilon, \hat{\lambda}+4\varepsilon]$ (see (3.16)), then the pair $(B_\rho^\varepsilon, A_\rho^{4\varepsilon})$ is a deformation retract of the pair $(B_\rho^{3\varepsilon}, A_\rho^{2\varepsilon})$, so $i_2^* \circ \phi_2^* \circ j_1^* \circ \phi_1^*$ is an isomorphism. For analogous reasons $j_3^* \circ \phi_3^* \circ i_2^* \circ \phi_2^*$ is an isomorphism. It follows that $i_2^* \circ \phi_2^* : H_q(B_0^{2\varepsilon}, A_0^{3\varepsilon}) \to H_q(B_\rho^{3\varepsilon}, A_\rho^{2\varepsilon})$ is an isomorphism.

From the definitions (3.11) and (3.12) we have the inclusions:

$$(\mathcal{S}_{0,\delta} \cap (\mathbb{X}_1 \oplus \mathbb{X}_2), \Sigma_{0,\delta} \cap (\mathbb{X}_1 \oplus \mathbb{X}_2)) \subset (B_\rho^{3\varepsilon}, A_\rho^{2\varepsilon}) \subset (\mathcal{S}_{0,\delta} \setminus \mathbb{X}_3, \mathcal{S}_{\rho,\delta} \setminus (\mathbb{X}_2 \oplus \mathbb{X}_3))$$

which allow to repeat the arguments of [2] (see also the proof of Lemma 2.3 in [21]). To estimate the relative category:

$$\mathrm{cat}_{(B_\rho^{3\varepsilon}, A_\rho^{2\varepsilon})}(B_\rho^{3\varepsilon}) \geq 2 \qquad \forall \rho \in \,]0, \rho(\varepsilon)].$$

This implies that $\bar{f}_\rho$ hat at least two critical points $\bar{u}_{1,\rho}$, $\bar{u}_{2,\rho}$ with $\hat{\lambda}-3\varepsilon \leq f_\rho(\bar{u}_{i,\rho}) \leq \hat{\lambda}+2\varepsilon$. We have $\|\bar{u}_{i,\rho}\|_{\mathbb{L}}^2/2 + \mathcal{H}_{1,\rho}(\bar{u}_{i,\rho}) = 1$ and

$$\left\langle A\bar{u}_{i,\rho} + \nabla\mathcal{H}_\rho(\bar{u}_{i,\rho}), v\right\rangle = \lambda_{i,\rho}\left\langle \bar{u}_{i,\rho} + \nabla_{\mathbb{L}}\mathcal{H}_{1,\rho}(\bar{u}_{i,\rho}), v\right\rangle_{\mathbb{L}} \qquad \forall v \in \mathbb{H} \tag{3.19}$$

for a suitable Lagrange multiplier $\lambda_{i,\rho} \in \mathbb{R}$ (there is no μ, due to (3.15)). Taking $v = \bar{u}_{i,\rho}$ in (3.19):

$$\begin{aligned}
[\hat{\lambda}-2\varepsilon, \hat{\lambda}+3\varepsilon] \ni \bar{f}(\bar{u}_{i,\rho}) &= \frac{1}{2}\left\langle A\bar{u}_{i,\rho}, \bar{u}_{i,\rho}\right\rangle + \mathcal{H}_\rho(\bar{u}_{i,\rho}) \\
&= \mathcal{H}_\rho(\bar{u}_{i,\rho}) - \frac{1}{2}\left\langle \nabla\mathcal{H}_\rho(\bar{u}_{i,\rho}), \bar{u}_{i,\rho}\right\rangle + \frac{\lambda_{i,\rho}}{2}\left(\|\bar{u}_{i,\rho}\|_{\mathbb{L}}^2 + \left\langle \nabla_{\mathbb{L}}\mathcal{H}_{1,\rho}(\bar{u}_{i,\rho}), \bar{u}_{i,\rho}\right\rangle_{\mathbb{L}}\right) \\
&= \underbrace{\mathcal{H}_\rho(\bar{u}_{i,\rho}) - \frac{\left\langle \nabla\mathcal{H}_\rho(\bar{u}_{i,\rho}), \bar{u}_{i,\rho}\right\rangle}{2}}_{:=C_1(\rho)} + \lambda_{i,\rho}\left(1 + \underbrace{\left(\frac{\left\langle \nabla_{\mathbb{L}}\mathcal{H}_{1,\rho}(\bar{u}_{i,\rho}), \bar{u}_{i,\rho}\right\rangle_{\mathbb{L}}}{2} - \mathcal{H}_{1,\rho}(\bar{u}_{i,\rho})\right)}_{:=C_2(\rho)}\right)
\end{aligned}$$

By using (3.9) we obtain $C_1(\rho) \to 0$, $C_2(\rho) \to 0$, so for $\rho(\varepsilon)$ small enough we have $|\lambda_{i,\rho} - \hat{\lambda}| < 4\varepsilon$. We have thus proven that $\lambda_{1,\rho} \to \hat{\lambda}$ as $\rho \to 0$. Let $u_{i,\rho} := \rho\bar{u}_{1,\rho}$. Clearly $u_{i,\rho} \xrightarrow{\mathbb{L}} 0$ as $\rho \to 0$. By multiplying (3.19) by ρ and using the definitions of $\mathcal{H}_\rho$ and $\mathcal{H}_{1,\rho}$ we get that $(u, \lambda) = (u_{i,\rho}, \lambda_{i,\rho})$ verify (3.3). Taking the scalar product with $u_{i,\rho}$ in (3.3) gives $\left\langle Au_{i,\rho}, u_{i,\rho}\right\rangle \to 0$. Then, by (3.1), we have $u_{i,\rho} \xrightarrow{\mathbb{H}} 0$. □

4 A global bifurcation result for radial solutions

We consider the case $N = 2$ and $\Omega = B(0, R) = \left\{x \in \mathbb{R}^2 : \|X\| < R\right\}$. We look for radial solutions for Problem (2.2), i.e. $z(x, y) = w(\|(x, y)\|)$. Actually with similar arguments we could have considered the general case $N \geq 2$. Given $R > 0$, it is therefore convenient to introduce the Hilbert space

$$E := \left\{w : [0, R] \to \mathbb{R} : \int_0^R \rho\dot{w}^2\, d\rho < +\infty\right\}$$

endowed with $(v, w)_E := \int_0^R \rho\dot{v}\dot{w}\, d\rho + \int_0^R \rho v w\, d\rho$ and for $\lambda > 0$ the set

$$W_\lambda := \left\{w \in E : 1 + \sqrt{\lambda}w(\rho) > 0\right\}, \qquad \mathcal{W} := \left\{(w, \lambda) \in \mathbb{R} \times E : \lambda > 0, w \in W_\lambda\right\}.$$

It is clear that $\|w\|_\infty \le C\|w\|_E$, for a suitable constant C, so W is open in E and $\mathcal{W}$ is open in $\mathbb{R} \times E$. As well known the search for radial solutions leads to the equation

$$\begin{cases} \ddot{w} + \dfrac{\dot{w}}{\rho} = -\lambda w - \dfrac{\lambda w}{1+\sqrt{\lambda w}} =: f_\lambda(w), \\ \dot{w}(0) = \dot{w}(R) = 0. \end{cases} \tag{4.1}$$

By the above we mean that

$$(w,\lambda) \in \mathcal{W}, \qquad \int_0^R \rho \dot{w}\dot{\delta}\, d\rho = \int_0^R \rho f_\lambda(w)\delta\, d\rho \qquad \forall v \in E. \tag{4.2}$$

It is standard to check that "weak solutions", i.e. solutions to (4.2) actually solve (4.1) in a classical sense.

It is clear that $(0,\lambda)$ is a solution for (4.1) for any $\lambda \in \mathbb{R}$. We call "nontrivial " solution a pair (w,λ) with $w \neq 0$ such that (4.1) holds.

Remark 4.1. If (w,λ) is a nontrivial solution then $\lambda > 0$. To see this it suffices to multiply (4.1) by u and integrate over $[0,R]$. Actually this property is true in the general case (not just in the radial problem).

We shall use the following simple inequality.

Remark 4.2. Let $0 < a < b < +\infty$. We have

$$\frac{b-a}{b} \le \ln\left(\frac{b}{a}\right) \le \frac{b-a}{a}. \tag{4.3}$$

We have indeed

$$\ln\left(\frac{b}{a}\right) = \ln\left(1 + \frac{b-a}{a}\right) \le \frac{b-a}{a}$$

and

$$\ln\left(\frac{b}{a}\right) = -\ln\left(\frac{a}{b}\right) = -\ln\left(1+\frac{a-b}{b}\right) \ge -\frac{a-b}{b} = \frac{b-a}{b}.$$

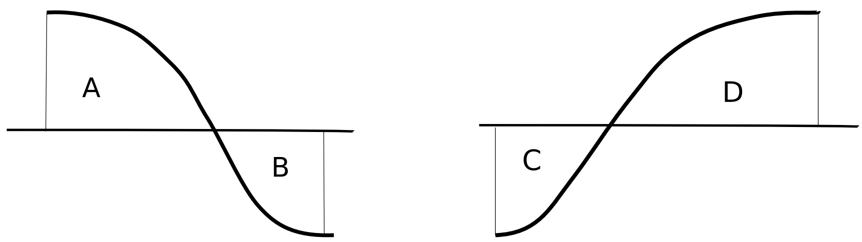

Figure 4.1: The different cases

Now let us suppose that a solution (w,λ) exists so we can find some properties and estimates on w. Arguing as in the proof of Lemma 2.2 in [8] we have that either $w = 0$ or $[0,R]$ can be split as the union of a finite number of subintervals $[r_{1,i}, r_{2,i}]$, $i = 1\ldots,k$, where w has one of the following behaviors (see Figure 4.1, we are skipping the index i):

(A) $w(r_1) > 0$, $\dot{w}(r_1) = 0$, $\dot{w} < 0$ in $]r_1, r_2]$, and $w(r_2) = 0$;

(B) $w(r_1) = 0$, $\dot{w} < 0$ in $[r_1, r_2[$, $\dot{w}(r_2) = 0$, and $w(r_2) < 0$;

(C) $w(r_1) < 0$, $\dot{w}(r_1) = 0$, $\dot{w} > 0$ in $]r_1, r_2]$, and $w(r_2) = 0$;

(D) $w(r_1) = 0$, $\dot{w} > 0$ in $[r_1, r_2[$, $\dot{w}(r_2) = 0$, and $w(r_2) > 0$.

So let $w : [r_1, r_2] \to \mathbb{R}$ be as in one of the above cases. Multiplying (4.1) by $\dot{w}$ gives

$$\frac{1}{2}\ddot{w}\dot{w}' + \frac{\dot{w}^2}{\rho} = \frac{d}{d\rho}F_\lambda(w)$$

where

$$F_\lambda(s) = \ln(1 + \sqrt{\lambda}s) - \sqrt{\lambda}s - \frac{\lambda}{2}s^2.$$

Let $p := \dot{w}^2$, the previous equation can be written as

$$\frac{1}{2}\dot{p} + \frac{p}{\rho} = \frac{d}{d\rho}F_\lambda(w)$$

which is equivalent to

$$\frac{d}{d\rho}(\rho^2 p) = 2\rho^2\frac{d}{d\rho}F_\lambda(w)\rho^2 = 2\rho^2\frac{d}{d\rho}F_1\left(\sqrt{\lambda}w\right).$$

We integrate between ρ_1 and ρ_2, where $r_1 \le \rho_1 \le \rho_2 \le r_2$:

$$\rho_2^2 p(\rho_2) - \rho_1^2 p(\rho_1) = 2\rho_2^2 F_\lambda(w(\rho_2)) - 2\rho_1^2 F_\lambda(w(\rho_1)) - \int_{\rho_1}^{\rho_2} 4\sigma F_\lambda(w(\sigma))\, d\sigma.$$

Notice that F_λ is increasing on $\left]-\frac{1}{\sqrt{\lambda}}, 0\right[$ and decreasing on $]0, +\infty[$, so

$\sigma \mapsto F_\lambda(w(\sigma))$ is increasing (decreasing) in cases (A) and (C) (in cases (B) and (D)).

We hence get, in cases (A) and (C):

$$-2(\rho_2^2 - \rho_1^2)F_\lambda(w(\rho_2)) \le -\int_{\rho_1}^{\rho_2} 4\sigma F_\lambda(w(\sigma))\, d\sigma \le -2(\rho_2^2 - \rho_1^2)F_\lambda(w(\rho_1))$$

while in cases (B) and (D):

$$-2(\rho_2^2 - \rho_1^2)F_\lambda(w(\rho_1)) \le -\int_{\rho_1}^{\rho_2} 4\sigma F_\lambda(w(\sigma))\, d\sigma \le -2(\rho_2^2 - \rho_1^2)F_\lambda(w(\rho_2)).$$

So in cases (A) and (C) we have

$$2\rho_1^2(F_\lambda(w(\rho_2)) - F_\lambda(w(\rho_1)) \le \rho_2^2 p(\rho_2) - \rho_1^2 p(\rho_1) \le 2\rho_2^2(F_\lambda(w(\rho_2)) - F_\lambda(w(\rho_1)) \tag{4.4}$$

and in cases (B) and (D):

$$2\rho_2^2(F_\lambda(w(\rho_2)) - F_\lambda(w(\rho_1)) \le \rho_2^2 p(\rho_2) - \rho_1^2 p(\rho_1) \le 2\rho_1^2(F_\lambda(w(\rho_2)) - F_\lambda(w(\rho_1)). \tag{4.5}$$

Now we estimate $w(\rho)$ – we need to take into account all the four cases (A), (B), (C), (D).

Case (A). We rename $\bar{\rho} := r_1$, $\rho_0 := r_2$ and let $h := w(\bar{\rho}) > 0$. We use (4.4) with $\rho_1 = \bar{\rho}$ and $\rho_2 = \sigma \in [\bar{\rho}, \rho_0]$:

$$2\bar{\rho}^2(F_\lambda(w(\sigma)) - F_\lambda(h)) \le \sigma^2\dot{w}(\sigma)^2 \le 2\sigma^2(F_\lambda(w(\sigma)) - F_\lambda(h)).$$

Then we take the square root and divide:

$$\sqrt{2}\frac{\bar{\rho}}{\sigma} \leq \frac{-\dot{w}(\sigma)}{\sqrt{F_\lambda(w(\sigma)) - F_\lambda(h)}} \leq \sqrt{2}$$

and now we integrate between $\bar{\rho}$ and $\rho \in [\bar{\rho}, \rho_0]$ getting

$$\sqrt{2}\bar{\rho}\ln\left(\frac{\rho}{\bar{\rho}}\right) \leq -\Phi_{\lambda,h}(w(\rho)) + \Phi_{\lambda,h}(h) \leq \sqrt{2}(\rho - \bar{\rho})$$

where $\Phi_{\lambda,h} : [0,h] \to \mathbb{R}$ is defined by

$$\Phi_{\lambda,h}(s) := \int_0^s \frac{d\xi}{\sqrt{F_\lambda(\xi) - F_\lambda(h)}}$$

(it is simple to check the the integral converges at $\xi = h$). So we deduce

$$\Phi^{-1}_{\lambda,h}\left(\Phi_{\lambda,h}(h) - \sqrt{2}\,(\rho - \bar{\rho})\right) \leq w(\rho) \leq \Phi^{-1}_{\lambda,h}\left(\Phi_{\lambda,h}(h) - \sqrt{2}\bar{\rho}\ln\left(\frac{\rho}{\bar{\rho}}\right)\right)$$

which we prefer to write as

$$\Phi^{-1}_{\lambda,h}\left(\Phi_{\lambda,h}(h) + \sqrt{2}\,(\bar{\rho} - \rho)\right) \leq w(\rho) \leq \Phi^{-1}_{\lambda,h}\left(\Phi_{\lambda,h}(h) + \sqrt{2}\bar{\rho}\ln\left(\frac{\bar{\rho}}{\rho}\right)\right). \tag{4.6}$$

In particular, taking $\rho = \rho_0$, which gives $w(\rho_0) = 0$, (and using (4.3)) we have

$$\sqrt{2}\frac{\bar{\rho}}{\rho_0}(\rho_0 - \bar{\rho}) \leq \sqrt{2}\bar{\rho}\ln\left(\frac{\rho_0}{\bar{\rho}}\right) \leq \Phi_{\lambda,h}(h) \leq \sqrt{2}\,(\rho_0 - \bar{\rho}). \tag{4.7}$$

Moreover taking $\rho_1 = \bar{\rho}$ and $\rho_2 = \rho_0$ in (4.4) we have:

$$\sqrt{2}\frac{\bar{\rho}}{\rho_0}\sqrt{-F_\lambda(h))} \leq -\dot{w}(\rho_0) \leq \sqrt{2}\sqrt{-F_\lambda(h))} \tag{4.8}$$

Case (B). We rename $\rho_0 := r_1$, $\bar{\rho} := r_2$ and let $h := w(\bar{\rho}) < 0$. We use (4.5) with $\rho_1 = \sigma \in [\rho_0, \bar{\rho}]$ and $\rho_2 = \bar{\rho}$:

$$2\bar{\rho}^2(F_\lambda(h) - F_\lambda(w(\sigma))) \leq -\sigma^2\dot{w}(\sigma)^2 \leq 2\sigma^2(F_\lambda(h) - F_\lambda(w(\sigma))).$$

We change sign and proceed as in case (A):

$$2\sigma^2(F_\lambda(w(\sigma)) - F_\lambda(h)) \leq \sigma^2\dot{w}(\sigma)^2 \leq 2\bar{\rho}^2(F_\lambda(w(\sigma)) - F_\lambda(h))).$$

Take the square root and divide:

$$\sqrt{2} \leq \frac{-\dot{w}(\sigma)}{\sqrt{F_\lambda(w(\sigma)) - F_\lambda(h)}} \leq \sqrt{2}\frac{\bar{\rho}}{\sigma}.$$

Integrate on $[\rho, \bar{\rho}_0]$:

$$\sqrt{2}(\bar{\rho} - \rho) \leq -\Phi_{\lambda,h}(h) + \Phi_{\lambda,h}(w(\rho)) \leq \sqrt{2}\bar{\rho}\ln\left(\frac{\bar{\rho}}{\rho}\right)$$

defining $\Phi_{\lambda,h} : [h, 0] \to \mathbb{R}$ as in case (A). Applying $\Phi^{-1}_{\lambda,h}$ we get that (4.6) holds in case (B) too. In particular, taking $\rho = \rho_0$ (and using (4.3)):

$$\sqrt{2}(\bar{\rho} - \rho_0) \le -\Phi_{\lambda,h}(h) \le \sqrt{2}\bar{\rho} \ln\left(\frac{\bar{\rho}}{\rho_0}\right) \le \sqrt{2}\frac{\bar{\rho}}{\rho_0}(\bar{\rho} - \rho_0) \tag{4.9}$$

and taking $\rho_1 = \rho_0$ and $\rho_2 = \bar{\rho}$ in (4.5) we have

$$\sqrt{2}\sqrt{-F_\lambda(h))} \le -\dot{w}(\rho_0) \le \sqrt{2}\frac{\bar{\rho}}{\rho_0}\sqrt{-F_\lambda(h))} \tag{4.10}$$

Case (C). We rename $\bar{\rho} := r_1$, $\rho_0 := r_2$ end let $h := w(\bar{\rho}) < 0$. Using (4.4) with $\rho_1 = \bar{\rho}$ and $\rho_2 = \sigma \in [\bar{\rho}, \rho_0]$ we obtain the same inequality of case (A). After taking the square root and dividing:

$$\sqrt{2}\frac{\bar{\rho}}{\sigma} \le \frac{\dot{w}(\sigma)}{\sqrt{F_\lambda(w(\sigma)) - F_\lambda(h)}} \le \sqrt{2}.$$

We integrate between $\bar{\rho}$ and $\rho \in [\bar{\rho}, \rho_0]$ getting

$$\sqrt{2}\bar{\rho} \ln\left(\frac{\rho}{\bar{\rho}}\right) \le \Phi_{\lambda,h}(w(\rho)) - \Phi_{\lambda,h}(h) \le \sqrt{2}(\rho - \bar{\rho})$$

with $\Phi_{\lambda,h} : [h, 0] \to \mathbb{R}$ defined as above. So we deduce

$$\Phi^{-1}_{\lambda,h}\left(\Phi_{\lambda,h}(h) + \sqrt{2}\bar{\rho} \ln\left(\frac{\rho}{\bar{\rho}}\right)\right) \le w(\rho) \le \Phi^{-1}_{\lambda,h}\left(\Phi_{\lambda,h}(h) + \sqrt{2}\,(\rho - \bar{\rho})\right). \tag{4.11}$$

In particular, taking $\rho = \rho_0$ (and using (4.3)):

$$\sqrt{2}\frac{\bar{\rho}}{\bar{\rho}_0}(\rho_0 - \bar{\rho}) \le \sqrt{2}\bar{\rho} \ln\left(\frac{\rho_0}{\bar{\rho}}\right) \le -\Phi_{\lambda,h}(h) \le \sqrt{2}\,(\rho_0 - \bar{\rho})\,. \tag{4.12}$$

Moreover taking $\rho_1 = \bar{\rho}$ and $\rho_2 = \rho_0$ in (4.4) we have

$$\sqrt{2}\frac{\bar{\rho}}{\rho_0}\sqrt{-F_\lambda(h))} \le \dot{w}(\rho_0) \le \sqrt{2}\sqrt{-F_\lambda(h))}. \tag{4.13}$$

Case (D). We rename $\rho_0 := r_1$, $\bar{\rho} := r_2$ and let $h := w(\bar{\rho}) > 0$. Using (4.5) with $\rho_1 = \sigma \in [\rho_0, \bar{\rho}]$ and $\rho_2 = \bar{\rho}$ we obtain the same inequalities of case (B). When we take the square root and divide:

$$\sqrt{2} \le \frac{\dot{w}(\sigma)}{\sqrt{F_\lambda(w(\sigma)) - F_\lambda(h)}} \le \sqrt{2}\frac{\bar{\rho}}{\sigma}.$$

Integrate on $[\rho, \bar{\rho}_0]$:

$$\sqrt{2}(\bar{\rho} - \rho) \le \Phi_{\lambda,h}(h) - \Phi_{\lambda,h}(w(\rho)) \le \sqrt{2}\bar{\rho} \ln\left(\frac{\bar{\rho}}{\rho}\right)$$

with the usual definition of $\Phi_{\lambda,h} : [h, 0] \to \mathbb{R}$. Applying $\Phi^{-1}_{\lambda,h}$ we obtain that (4.11) holds in case (D) too. In particular, taking $\rho = \rho_0$ (and using (4.3)):

$$\sqrt{2}\,(\bar{\rho} - \rho_0) \le \Phi_{\lambda,h}(h) \le \sqrt{2}\bar{\rho} \ln\left(\frac{\bar{\rho}}{\bar{\rho}_0}\right) \le \sqrt{2}\frac{\bar{\rho}}{\rho_0}(\bar{\rho} - \rho_0) \tag{4.14}$$

and taking $\rho_1 = \rho_0$ and $\rho_2 = \bar{\rho}_0$ in (4.5) we have

$$\sqrt{2}\sqrt{-F_\lambda(h))} \le \dot{w}(\rho_0) \le \sqrt{2}\frac{\bar{\rho}}{\rho_0}\sqrt{-F_\lambda(h))}. \tag{4.15}$$

Now we have

$$\sqrt{2}\Phi_{\lambda,h}(h) = \int_0^h \frac{d\xi}{\sqrt{F(\sqrt{\lambda}\xi) - F(\sqrt{\lambda}h)}} = \int_0^1 \frac{h\, d\sigma}{\sqrt{F(\sigma\sqrt{\lambda}h) - F(\sqrt{\lambda}h)}} = \frac{1}{\sqrt{\lambda}}\bar{\Phi}(\sqrt{\lambda}h)$$

where

$$\bar{\Phi}(s) := \int_0^1 \frac{s\, d\sigma}{\sqrt{F(\sigma s) - F(s)}} = \operatorname{sgn}(s)\int_0^1 \sqrt{\frac{s^2}{F(\sigma s) - F(s)}}\, d\sigma.$$

With simple computations:

$$\lim_{s\to 0} \frac{s^2}{F(\sigma s) - F(s)} = \frac{1}{1-\sigma^2}, \qquad \lim_{s\to +\infty} \frac{s^2}{F(\sigma s) - F(s)} = \frac{2}{1-\sigma^2},$$

and

$$\lim_{s\to -1^-} \frac{s^2}{F(\sigma s) - F(s)} = 0.$$

So we deduce that (see Figure 4.2)

$$\lim_{h\to 0^+} \Phi_{\lambda,h}(h) = \frac{\pi}{2\sqrt{2\lambda}}, \qquad \lim_{h\to +\infty} \Phi_{\lambda,h}(h) = \frac{\pi}{2\sqrt{\lambda}}, \tag{4.16}$$

$$\lim_{h\to 0^-} \Phi_{\lambda,h}(h) = -\frac{\pi}{2\sqrt{2\lambda}}, \qquad \lim_{h\to -1^+} \Phi_{\lambda,h}(h) = 0. \tag{4.17}$$

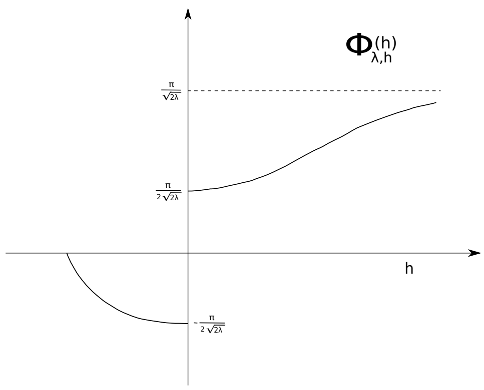

Figure 4.2: Graph of $\Phi_{\lambda,h}(h)$

To state the main result we need some notation, which we take from [8,23]. For $k \in \mathbb{N}$, $k \ge 1$, we consider

$$\begin{aligned}
\mathcal{S} &:= \{(w,\lambda) \in \mathcal{W} : (w,\lambda) \text{ is a solution to (4.1)}\} \\
\mathcal{S}_k^+ &:= \{(w,\lambda) \in \mathcal{S} :\ w \text{ has } k \text{ nodes in }]0,R[, w(0) > 0\}, \\
\mathcal{S}_k^- &:= \{(w,\lambda) \in \mathcal{S} :\ w \text{ has } k \text{ nodes in }]0,R[, w(0) < 0\}.
\end{aligned}$$

We also consider the two eigenvalue problems:

$$\ddot{w} + \frac{\dot{w}}{\rho} = -\mu w, \qquad \dot{w}(0) = \dot{w}(R) = 0. \tag{4.18}$$

$$\ddot{v} + \frac{\dot{v}}{\rho} = -\nu v, \qquad \dot{v}(0) = 0, v(R) = 0. \tag{4.19}$$

It is clear that $w \neq 0$ and $\mu \neq 0$ solve (4.18) if and only if, for some integer $k \geq 1$,

$$\mu = \mu_k := \left(\frac{y_k}{R}\right)^2 \tag{4.20}$$

where y_k denotes the k-th nontrivial zero of J_0' and J_0 is the first Bessel function, and

$$w = \alpha w_k, \quad \alpha \in \mathbb{R}, \qquad w_k(\rho) := J_0\left(\frac{y_k}{R}\rho\right). \tag{4.21}$$

For the sake of completeness we can agree that $\mu_0 = 0$ and $w_0(\rho) = J_0(0)$. In the same way $v \neq 0$ and ν solve (4.19) if and only if, for some integer $k \geq 1$:

$$\nu = \nu_k := \left(\frac{z_k}{R}\right)^2 \tag{4.22}$$

where z_k is the k-th zero of J_0 and

$$v = \alpha v_k, \quad \alpha \in \mathbb{R}, \qquad v_k(\rho) := J_0\left(\frac{z_k}{R}\rho\right). \tag{4.23}$$

Notice that $\nu_k < \mu_k < \nu_{k+1}$ for all k.

Theorem 4.3. *Let $\mu_k > 0$ be an eigenvalue for (4.18). Then $\mathcal{S}_k^+$ is a connected set and*

- $(0, \mu_k/2) \in \overline{\mathcal{S}_k^+}$;
- $0 < \inf\{\lambda \in \mathbb{R} : \exists w \in E \text{ with } (w,\lambda) \in \mathcal{S}_k^+\}$;
- $\sup\{\lambda \in \mathbb{R} : \exists w \in E \text{ with } (w,\lambda) \in \mathcal{S}_k^+\} < +\infty$;
- *$\mathcal{S}_k^+$ is unbounded and contains a sequence (w_n, λ_n) such that $\|w_n\|_E \to \infty$ and*

$$\lim_{n\to\infty} \lambda_n = \begin{cases} \mu_{k/2} & \text{if } k \text{ is even,} \\ \nu_{(k+1)/2} & \text{if } k \text{ is odd.} \end{cases} \tag{4.24}$$

Figure 4.3 somehow illustrates Theorem (4.3).

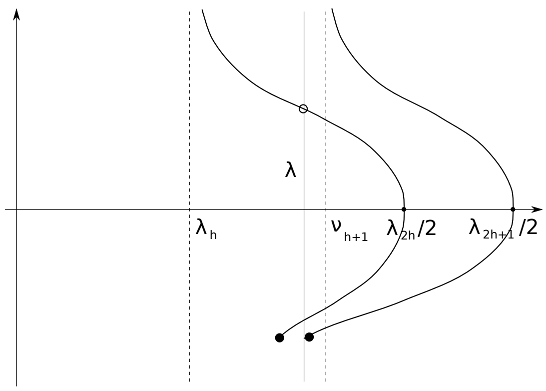

Figure 4.3: Bifurcation diagram

The proof of (4.3) will be obtained from some preliminary statements.

Remark 4.4. If $(w, \lambda) \in \mathcal{S}^+$ (resp. $(w, \lambda) \in \mathcal{S}^+$), and $0 = \rho_0 < \rho_1, \dots, \rho_k < \rho_{k+1=R}$, $\rho_1, \dots, \rho_k$ being the nodal points of w, then

$$\rho_{i+1} - \rho_i \geq \ (\leq) \ \frac{\pi}{4\sqrt{\lambda}} \quad \text{for } i \text{ even} \quad (\text{resp. for } i \text{ odd}). \tag{4.25}$$

This is easily seen using the right hand sides of the inequalities (4.7), (4.12), and (4.16).

Lemma 4.5. *For any integer k there esist two constants $\underline{\lambda}_k$ and $\overline{\lambda}_k$ such that*

$$(w, \lambda) \in \mathcal{S}_k^+ \cup \mathcal{S}_k^- \Rightarrow 0 < \underline{\lambda}_k \leq \lambda \leq \overline{\lambda}_k < +\infty. \tag{4.26}$$

Proof. Take any subinterval $[r_1, r_2]$ as in cases (A)–(D) and consider the first eigenvalue $\bar{\mu} = \bar{\mu}(r_1, r_2)$ for the mixed type boundary condition

$$\begin{cases} -(\rho \dot{w})' = \mu w \quad \text{on }]r_1, r_2[\\ \dot{w}(r_1) = 0, w(r_2) = 0 \qquad (\text{resp. } w(r_1) = 0, \dot{w}(r_2) = 0) \end{cases}$$

in cases (A), (C) (resp. cases (C), (D)). We can choose an eigenfunction $\bar{e}$ corresponding to $\bar{\mu}$ so that $z\bar{e} > 0$ in $]r_1, r_2[$. Multiplying (4.1) by $\bar{e}$ and integrating over $[r_1, r_2]$ yields

$$\bar{\mu} \int_{r_1}^{r_2} \rho z \bar{e} \, d\rho = \lambda \int_{r_1}^{r_2} \rho z \bar{e} \left(1 + \frac{1}{1 + \sqrt{\lambda z}} \right) d\rho.$$

This implies:

$$\lambda \int_{r_1}^{r_2} \rho z \bar{e} \, d\rho \leq \bar{\mu} \int_{r_1}^{r_2} \rho z \bar{e} \, d\rho \leq 2\lambda \int_{r_1}^{r_2} \rho z \bar{e} \, d\rho$$

which gives $\frac{\bar{\mu}}{2} \leq \lambda \leq \bar{\mu}$. Now since $]r_1, r_2[\subset]0, R[$ we have $\bar{\mu} \geq \bar{\mu}[0, R]$. On the other side since w has k nodal points we can choose r_1, r_2 such that $r_2 - r_1 \geq R/k$, which implies $\bar{\mu} \leq \sup_{b-a=R/k} \bar{\mu}(a, b) < +\infty$. This proves (4.26). □

Lemma 4.6. *Let (w_n, λ_n) be a sequence in $\mathcal{S}_k^+$. Then we can consider $0 < \rho_{1,n} < \dots < \rho_{k,n} < R$ to be the nodes of w_n and set $\rho_{0,n} := 0$, $\rho_{k+1,n} := R$; in ths way $wn(\rho) > 0$ on $]\rho_1, \rho_{i+1}[$ if i is even and $wn(\rho) < 0$ on $]\rho_1, \rho_{i+1}[$ if i is odd. The following facts are equivalent:*

(a)
$$\lim_{n \to \infty} \sup_{\rho \in [0,R]} w_n(\rho) = +\infty;$$

(b)
$$\lim_{n \to \infty} \inf_{\rho \in [0,R]} (1 + \lambda_n w_n(\rho)) = 0;$$

(c)
$$\lim_{n \to \infty} \sup_{\rho \in [\rho_{i,n}, \rho_{i+1,n}]} w_n(\rho) = +\infty \quad \textit{if i is even;}$$

(d)
$$\lim_{n \to \infty} \inf_{\rho \in [\rho_{i,n}, \rho_{i+1,n}]} (1 + \lambda_n w_n(\rho)) = 0 \quad \textit{if i is odd;}$$

(e)
$$\lim_{n \to \infty} \rho_{1+1,n} - \rho_{i,n} = 0 \quad \textit{if i is odd;}$$

Moreover, if any of the above holds, then (4.24) holds.

Proof. We can assume, passing to a subsequence that $\lambda_n \to \hat{\lambda} \in [\underline{\lambda}_k, \overline{\overline{\lambda}}_k]$. First notice that for all i even (corresponding to $w > 0$) we have

$$\rho_{i+1,n} - \rho_{i,n} \geq \frac{\pi}{4\sqrt{\underline{\lambda}_k}}$$

as we can infer from (4.7) or (4.14) and the behaviour of $\Phi_{\lambda,h}(h)$ in (4.16).

Let

$$h_{i,n} := \max_{\rho_{i,n} \le \rho_{i+1,n}} w(\rho) \text{ for } i \text{ even}, \qquad h_{i,n} := \min_{\rho_{i,n} \le \rho_{i+1,n}} w(\rho) \text{ for } i \text{ odd}.$$

Then for any i even:

$$h_{i,n} \to +\infty \Leftrightarrow \Phi_{\lambda_n, h_{i,n}}(h_{i,n}) \to \frac{\pi}{2\sqrt{\hat{\lambda}}} \Leftrightarrow \dot{w}(\rho_{i,n}) \to +\infty \Leftrightarrow \dot{w}(\rho_{i+1,n}) \to -\infty.$$

This can be deduced from (4.16), (4.8), and (4.15). In the same way, using (4.17), (4.10), and (4.13) we get that, for i odd:

$$1 + \sqrt{\lambda_n} h_{i,n} \to 0 \Leftrightarrow \Phi_{\lambda_n, h_{i,n}}(h_{i,n}) \to 0 \Leftrightarrow \dot{w}(\rho_{i,n}) \to -\infty \Leftrightarrow \dot{w}(\rho_{i+1,n}) \to +\infty.$$

Now we prove our claims. Let $\bar{i} \in \{0, \dots, k\}$ with $\bar{i}$ even (resp. odd) and suppose that $h_{\bar{i},n} \to +\infty$ (resp. $1 + \sqrt{\lambda_n} h_{\bar{i},n} \to 0$). Then $F_{\lambda_n}(h_{\bar{i},n}) \to +\infty$ (resp. $F_{\lambda_n}(h_{\bar{i},n}) \to -\infty$) and by (4.8), (4.15) ((4.10), (4.13)) we get that

$$\dot{w}_n(\rho_{\bar{i},n}) \to +\infty, \ \dot{w}_n(\rho_{\bar{i}+1,n}) \to -\infty \quad (\dot{w}_n(\rho_{\bar{i},n}) \to -\infty, \ \dot{w}_n(\rho_{\bar{i}+1,n}) \to +\infty)$$

which in turn implies

$$F_{\lambda_n}(h_{\bar{i}-1,n}) \to -\infty \text{ (resp. } +\infty), \ F_{\lambda_n}(h_{\bar{i}+1,n}) \to -\infty \text{ (resp. } +\infty)$$

(with the obvious exceptions when $\bar{i} - 1 < 0$ or $\bar{i} + 1 > k$). So we get

$$1 + \sqrt{\lambda_n} h_{\bar{i}-1,n} \to 0 \ (h_{\bar{i}-1,n} \to +\infty), \ 1 + \sqrt{\lambda_n} h_{\bar{i}+1,n} \to 0 \ (h_{\bar{i}+1,n} \to +\infty).$$

This shows that the property $|F_\lambda(h_{i,n})| \to +\infty$ "propagates" from the i-th interval to the previous and to the next one. From this it is easy to deduce that (a)–(d) are all equivalent. To prove that they are equivalent to (e) just use (4.7), (4.9), (4.12), (4.14), depending on the case, noticing that $\rho_{1,n} \ge \frac{\pi}{4\pi\underline{\lambda}_k}$, as from (4.25) (this would not be possible if we were considering $\mathcal{S}_k^-$).

Finally suppose that (w_n, λ_n) verifies any of (a)–(e). Then $\|w_n\|_\infty \to +\infty$. Let $\hat{w}_n := \frac{w_n}{\|w_n\|_\infty}$. We can suppose that $\hat{w}_n \rightharpoonup \hat{w}$ in E and that

$$\rho_{1,n} \to \rho_1, \ \rho_{2j-1,n} \to \rho_j, \ \rho_{2j,n} \to \rho_j \ 1 \le j \le k/2, \ \rho_{k,n} \to R \text{ if } k \text{ is odd},$$

where $0 = \rho_0 < \rho_1 < \cdots < \rho_h < \rho_h + 1 = R$ and $h = \lfloor k/2 \rfloor$ (so $\rho_1 = R$ when $k = 1$). It is not difficult to prove that $\hat{w}(\rho) > 0$ in $]\rho_i, \rho_{i+1}[$ if $i = 0, \dots, h$, $\hat{w}(\rho_1) = \cdots = \hat{w}(\rho_h) = 0$, $\hat{w}'(0) = 0$ and $\hat{w}'(R) = 0$ is k is even while $\hat{w}(R) = 0$ is k is odd. Moreover for any $i = 0, \dots, h$:

$$-(\rho \hat{w}')' = \hat{\lambda} \hat{w} \quad \text{on }]\rho_i, \rho_{i+1}[$$

Now we can rearrange $\hat{w}$ defining $\tilde{w} := \sum_{j=0}^h (-1)^j \alpha_j \hat{w} \mathbb{1}_{[\rho_j, \rho_{j+1}]}$, where $\alpha_1 = 1$ and $\alpha_j \hat{w}'_-(\rho_j) = \alpha_{j+1} \hat{w}'_+(\rho_j)$, $j = 1, \dots, h$. In this way $(\hat{\lambda}, \tilde{w})$ is an eigenvalue – eigenfunction pair relative for problem (4.21) if k is even and of (4.23) if k is odd. Since $\tilde{w}$ has $h = k/2$ nodal points for k even and $h + 1 = (k+1)/2$ if k is odd, then (4.24) holds. □

Proof of Theorem 4.3. If $\varepsilon \in]0, 1[$ we set

$$\mathcal{O}_\varepsilon := \left\{ (w, \lambda) \in E : \varepsilon < \lambda < \varepsilon^{-1}, 1 + \sqrt{\lambda} w(\rho) > \varepsilon, w(\rho) < \varepsilon^{-1} \ \forall \rho \in [0, R] \right\}.$$

Clearly $\mathcal{O}_\varepsilon$ is an open set with $\mathcal{O}_\varepsilon \subset \mathcal{W}$. Moreover, $(\mu_{k/2}, 0) \in \mathcal{O}_\varepsilon$ if ε is sufficiently small. Define $\tilde{h}_{\lambda,\varepsilon}$ as in (2.4) with $s_0 = \varepsilon$ and let $\tilde{h}_\lambda(s) := \tilde{h}_1(\sqrt{\lambda}s)$. Using [23] we get there that there exists a pair $(w_\varepsilon, \lambda_\varepsilon)$ in $\partial\mathcal{O}_\varepsilon$, with w_ε having k nodal points, which solves Problem (4.1) with $\tilde{h}_{\varepsilon,\lambda} := \tilde{h}_\varepsilon(\lambda, \cdot)$ instead of h_λ. Since $(w, \lambda) \in \partial\mathcal{O}_\varepsilon \Rightarrow \tilde{h}_\varepsilon(w, \lambda) = h_\lambda(w)$, we get that $(w_\varepsilon, \lambda_\varepsilon) \in \mathcal{S}_k^+$. For ε small we have $\varepsilon < \underline{\lambda}_k \leq \overline{\lambda}_k < \varepsilon^{-1}$ so we get $w_\varepsilon \in \partial\left\{1 + \sqrt{\lambda_\varepsilon}w > \varepsilon, w < \varepsilon^{-1}\right\}$ i.e. there exists a point $\rho_\varepsilon \in [0, R]$ such that

$$\text{either} \quad 1 + \sqrt{\lambda_\varepsilon}w_\varepsilon(\rho_\varepsilon) = \varepsilon \quad \text{or} \quad w_\varepsilon(\rho_\varepsilon) = \varepsilon^{-1}.$$

We can find a sequence $\varepsilon_n \to 0$ such that the corresponding $(w_n, \lambda_n) := (w_{\varepsilon_n}, \lambda_{\varepsilon_n})$ verify one of the above properties for all $n \in \mathbb{N}$. If the first one holds for all n, then (w_n, λ_n) verifies (b) of Lemma (4.6); in the second case (w_n, λ_n) verifies (a) of Lemma (4.6). Then by Lemma (4.6) $\|w_n\|_\infty \to \infty$ and (4.24) holds. This proves the theorem. □

Remark 4.7. As a consequence of Theorem (4.3) we get that for any $h \geq 1$ integer and any λ strictly between λ_h and $\lambda_{2h}/2$ there exists u such that (u, λ) solves Problem (1.2). The same is true for all λ strictly between ν_h and $\lambda_{2h-1}/2$.

Remark 4.8. The above proof fails if we follow the bifurcation branch (w_ρ, λ_ρ) with $w_\rho(0) < 0$. In this case it seems possible that the branch tends to a point $(\tilde{\lambda}, \tilde{w})$ where $\sqrt{\tilde{\lambda}}\tilde{w}(0) = -1$ (but $\sqrt{\tilde{\lambda}}\tilde{w}(0) > -1$ for $\rho > 0$). This phenomenon, if true, would be worth studying.

Remark 4.9. The computations of this section show that, if Ω is the ball, then there are no solutions for the Dirichlet problem. It is indeed impossible to construct a (nontrivial) solution (w, λ) for (4.1) with $w(R) = 0$.

Abstract. In this manuscript previous results [*Nonlinearity* **25**(2012), 905–930] are extended to a non-autonomous 3D Navier–Stokes–Voigt model in which a forcing term contains memory effects. Under suitable assumptions on the function driving the delay time, the existence and uniqueness of weak solution are proved. Existence and relationships among pullback attractors in several phase-spaces are analyzed for two possible choices of the attracted universes, namely, the standard one of fixed bounded sets, and another one given by a tempered condition. Some regularity results for these attractors are also established. Compactness and attraction norms are strengthened. Since the model does not have a regularizing effect, obtaining asymptotic compactness for the associated process is a more involved task. Our proofs rely on a sharp use of the energy equality, an energy method, bootstrapping arguments and by using bi-space attractors results.

Keywords: 3D Navier–Stokes–Voigt equations, delay terms, pullback attractors, bi-space attractors.

1 Introduction and setting of the problem

Let $\Omega \subset \mathbb{R}^3$ be a bounded domain with smooth enough (e.g. C^2) boundary $\partial\Omega$. We consider an arbitrary initial time $\tau \in \mathbb{R}$, and the following non-autonomous functional Navier–Stokes–

✉ Corresponding author. Email: julia.gluengo@upm.es

Voigt problem:

$$\begin{cases} \dfrac{\partial}{\partial t}(u-\alpha^2\Delta u) - \nu\Delta u + (u\cdot\nabla)u + \nabla p = f(t) + g(t,u_t) \quad \text{in } \Omega\times(\tau,\infty), \\ \operatorname{div} u = 0 \quad \text{in } \Omega\times(\tau,\infty), \\ u = 0 \quad \text{on } \partial\Omega\times(\tau,\infty), \\ u(x,\tau) = u^\tau(x), \quad x\in\Omega, \\ u(x,\tau+s) = \phi(x,s), \quad x\in\Omega,\ s\in(-h,0), \end{cases} \tag{1.1}$$

where $\nu > 0$ is the kinematic viscosity, $\alpha > 0$ is a characterizing parameter of the elasticity of the fluid, $u = (u_1, u_2, u_3)$ is the velocity field of the fluid, p is the pressure, f is a non-delayed external force field, g is another external force containing some hereditary characteristics, and u^τ and $\phi(x, s-\tau)$ are the initial data in τ and $(\tau - h, \tau)$ respectively, where $h > 0$ is the time of memory effect. For each $t \geq \tau$, we denote by u_t the function defined a.e. on $(-h, 0)$ by the relation $u_t(s) = u(t+s)$, a.e. $s \in (-h, 0)$.

The Navier–Stokes–Voigt (NSV for short in the sequel) model of viscoelastic incompresible fluid, introduced by Oskolkov in [29], gives an approximate description of the Kelvin-Voigt fluid (see [22, 30]), and was proposed as a regularization of the 3D-Navier–Stokes equations for the purpose of direct numerical simulations in [2]. The extra regularizing term $-\alpha^2\Delta u_t$ changes the parabolic character of the equation, making it a well-posed (forward and backward) problem in 3D, but one does not observe any immediate smoothing of the solution, as expected in parabolic PDEs. Moreover, the generated semigroup is only asymptotically compact, similarly to damped hyperbolic systems. One of the studied topics about the problem is the inviscid question in some different senses. It is also worth observing that, when $\nu = 0$, the inviscid equation that one recovers is the simplified Bardina subgrid scale model of turbulence. The relationship between the original and inviscid models was also addressed in [2]. On other hand, some questions on the inviscid regularization were used for the study of a 2D surface quasi-geostrophic model in [21].

With respect to the non-delayed NSV model, the long-time behaviour of the solutions has been studied by different authors. Namely, in the autonomous case, the existence of a global compact attractor was proved by Kalantarov and Titi in [20]. Other related results have been also analyzed, as the Gévrey regularity of the global attractor (again for the autonomous model) when the force term is analytic of Gévrey type (see [19]), and the establishment of similar statistical properties (and invariant measures) as for the 3D-Navier–Stokes equations (cf. [23, 31]). Moreover, in the non-autonomous case, the existence of minimal pullback attractors in both V and $D(A)$ norms, and some regularity properties of these attractors, were obtained in [14]. We may also cite in this non-autonomous framework the paper [40], where the existence of uniform attractor for a NSV model is studied.

On the other hand, in many physical experiments, the inclusion of measurement devices to control properties of fluids (such as temperature, velocity, etc.) may incorporate additional external forces to the model including also delay effects (e.g. for a wind-tunnel model). In this sense, the study of 2D-Navier–Stokes models with delay terms – existence, uniqueness, stationary solutions, exponential decay, existence of attractors, et cetera – was initiated in the references [6–8] and, after that, many different questions, as dealing with unbounded domains, and models (for instance in three dimensions for modified terms) have been addressed (e.g., cf. [15, 17, 26, 28, 36] among others). In the past years, the asymptotic behaviour of the Navier–Stokes–Voigt equations with delays or with memory have been studied in [3, 12, 24, 34, 35, 38]. It is worth pointing out that, in [24], the authors establish the existence of pullback attractors in V norm for a three dimensional NSV model when the forcing term containing the delay is sublinear and only continuous. Since the uniqueness of solution is not guaranteed under these assumptions, they use the theory of multi-valued dynamical systems and similar arguments as in [28] for the proof of the asymptotic compactness of the process. In this work, we suppose more restrictive conditions on the delay operator that assure the uniqueness of solution, so we can apply the classical results of Dynamical Systems. However, in contrast with [24], we modify the phase-space enlarging the set of initial conditions. Moreover, for the associated single-valued process, we are able to obtain the existence of minimal pullback attractors, with richer compactness sections and not only in (roughly speaking) V norm, but also in $D(A)$ norm. Moreover, some regularity properties of these attractors are also successfully established. This analysis is carried out by applying similar techniques as in [14], but with the necessary modifications caused by the inclusion of a delay term.

As commented before, the difference between this model and the *standard* 2D-Navier–Stokes model is that there exists a regularizing effect in the 2D-Navier–Stokes model, while not here. For 2D-Navier–Stokes a continuous energy method can be applied thanks to the extra estimates that hold in higher norms (e.g., cf. [28]), which does not seem to hold for the NSV model. Some of the proofs in the previously cited references about NSV (e.g., cf. [20]) rely on splitting the problem in two, one with exponential decay, and the other with good asymptotic properties in the domain of a suitable fractional power of the Stokes operator. However, similarly as in [14], we will provide a simpler proof, which does not require the above mentioned technicalities, but a sharp use of the energy equality, and the energy method used by Rosa in [32]. Moreover, it is worth pointing out that our results in Section 3 do not use the regularity assumption on $\partial\Omega$ at all, and the force term may take values in V' instead of in L^2 as appears in [20].

The structure of the paper is the following. In Section 2 we recall some definitions of classical functional spaces to state our problem in an abstract form, basic properties and estimates of the involved operators. We also obtain a result on the existence, uniqueness and regularity of the weak solution for problem (1.1). We start Section 3 with a brief recall of the main definitions on the theory of minimal pullback attractors and bi-space attractors for non-autonomous dynamical systems within the framework of universes. Then, we prove the existence of pullback attractors in (roughly speaking) V norm and for two choices of the attracted universes, namely, the standard one of fixed bounded sets, and secondly, one given by a tempered growth condition. We also establish some relations among these families and improve compactness and attraction norm results. In Section 4, extra regularity for the obtained attractors will be deduced by using a bootstrapping argument that involves fractional powers of the Stokes operator. Finally, in Section 5, the problem of attraction in $D(A)$ norm is studied although it is more involved (namely it fits out from the standard theoretical results). Indeed under suitable assumptions, all attractors are proved to coincide.

2 Existence and uniqueness of solution

In this section we prove existence, uniqueness and regularity of the solutions to problem (1.1). These results will be obtained in a similar way as in [14], but with the necessary changes due to the inclusion of a delay term. We begin by stating the problem in an abstract setting, and to do so we recall several definitions of functional spaces, operators and some of their properties (for the details see [37]).

To start with, we consider the usual spaces in the variational theory of Navier–Stokes equations: H, the closure of $\mathcal{V} = \{u \in (C_0^\infty(\Omega))^3 : \operatorname{div} u = 0\}$ in $(L^2(\Omega))^3$ with norm $|\cdot|$, and inner product $(\cdot,\cdot)$, and V, the closure of $\mathcal{V}$ in $(H_0^1(\Omega))^3$ with norm $\|\cdot\|$, and inner product $((\cdot,\cdot))$, that is, the L^2-product of gradients, thanks to the Poincaré inequality.

We will use $\|\cdot\|_*$ for the norm in V' and $\langle\cdot,\cdot\rangle$ for the duality $\langle V', V\rangle$. We consider every element $h \in H$ as an element of V', given by the equality $\langle h, v\rangle = (h, v)$ for all $v \in V$. It follows that $V \subset H \subset V'$, where the injections are dense and compact.

Let us define the linear continuous operator $A : V \to V'$ as $\langle Au, v\rangle = ((u, v))$ for all $u, v \in V$, and we denote $D(A) = \{u \in V : Au \in H\}$. By the regularity of $\partial\Omega$, one has that $D(A) = (H^2(\Omega))^3 \cap V$, and $Au = -P\Delta u$ for all $u \in D(A)$ is the Stokes operator (P is the ortho-projector from $(L^2(\Omega))^3$ onto H). On $D(A)$ we consider the norm $|\cdot|_{D(A)}$ defined by $|u|_{D(A)} = |Au|$. Observe that on $D(A)$ the norms $\|\cdot\|_{(H^2(\Omega))^3}$ and $|\cdot|_{D(A)}$ are equivalent, and $D(A)$ is compactly and densely injected in V. We will also denote by $\{w_j\}_{j\geq 1} \subset D(A)$ a Hilbert basis of H formed by normalized eigenfunctions of the Stokes operator A, with corresponding eigenvalues $\{\lambda_j\}_{j\geq 1}$ being $0 < \lambda_1 \leq \lambda_2 \leq \ldots$ and $\lim_{j\to\infty} \lambda_j = \infty$. Recall that the first eigenvalue of A satisfies

$$\lambda_1 = \inf_{v \in V\setminus\{0\}} \frac{\|v\|^2}{|v|^2}. \tag{2.1}$$

For the fractional powers of A, we have the following inclusions with continuous injection (cf. [33, Chapter III, Lemmas 2.4.2 and 2.4.3]):

$$D(A^\beta) \subset (L^{6/(3-4\beta)}(\Omega))^3, \quad \forall\, 0 \leq \beta < 3/4, \tag{2.2}$$

$$D(A^{3/4}) \subset (L^p(\Omega))^3, \qquad \forall\, 1 \leq p < \infty, \tag{2.3}$$

and

$$D(A^\beta) \subset (L^\infty(\Omega))^3, \quad \forall\, 3/4 < \beta \leq 1. \tag{2.4}$$

Now, we define

$$b(u, v, w) = \sum_{i,j=1}^{3} \int_\Omega u_i \frac{\partial v_j}{\partial x_i} w_j \, dx,$$

for every functions $u, v, w : \Omega \to \mathbb{R}^3$ for which the right-hand side is well defined. In particular, b has sense for all $u, v, w \in V$, and is a continuous trilinear form on $V \times V \times V$, i.e., there exists a constant $C_1 > 0$ such that

$$|b(u, v, w)| \leq C_1 \|u\| \|v\| \|w\|, \quad \forall u, v, w \in V. \tag{2.5}$$

Important properties concerning b are that

$$\begin{aligned} b(u, v, w) &= -b(u, w, v), \quad \forall u, v, w \in V, \\ b(u, v, v) &= 0, \quad \forall u, v \in V, \end{aligned} \tag{2.6}$$

and, using Agmon inequality (e.g. cf. [10]), we can assure that there exists a constant $C_2 > 0$ such that

$$|b(u, v, w)| \leq C_2 |Au|^{1/2} \|u\|^{1/2} \|v\| |w|, \quad \forall u \in D(A), v \in V, w \in H. \tag{2.7}$$

For any $u \in V$, we will use $B(u)$ to denote the element of V' given by $\langle B(u), w\rangle = b(u, u, w)$ for all $w \in V$. Thus, by (2.5),

$$\|B(u)\|_* \leq C_1 \|u\|^2, \quad \forall u \in V, \tag{2.8}$$

and in particular, by (2.7) and the identification of H' with H, if $u \in D(A)$, then $B(u) \in H$, with

$$|B(u)| \le C_2 |Au|^{1/2} \|u\|^{3/2}, \quad \forall u \in D(A). \tag{2.9}$$

In fact, from (2.4), one also deduces that if $u \in D(A^\beta)$ with $3/4 < \beta \le 1$, then $B(u) \in H$, and more exactly

$$|B(u)| \le C_{(\beta)} |A^\beta u| \|u\|, \quad \forall u \in D(A^\beta), \quad \forall\, 3/4 < \beta \le 1. \tag{2.10}$$

Analogously, if $0 \le \beta < 3/4$, from (2.2) one obtains that if $u \in D(A^\beta) \cap V$, $B(u) \in D(A^{\beta - 3/4})$, and more exactly

$$|A^{\beta-3/4} B(u)| \le C_{(\beta)} |A^\beta u| \|u\|, \quad \forall u \in D(A^\beta) \cap V, \quad \forall\, 0 \le \beta < 3/4. \tag{2.11}$$

Finally, in the case $\beta = 3/4$, from (2.3) one can see that if $u \in D(A^{3/4})$, then $B(u) \in D(A^{-\delta})$ for all $\delta > 0$, and more exactly

$$|A^{-\delta} B(u)| \le C_{(3/4,\delta)} |A^{3/4} u| \|u\|, \quad \forall u \in D(A^{3/4}), \quad \forall \delta > 0.$$

Now, we establish some appropriate assumptions on the term in (1.1) containing the delay.

Let $(X, \|\cdot\|_X)$ be a Banach space. We will denote $C_X = C([-h,0]; X)$, the space of continuous functions from $[-h, 0]$ into X, with the norm $\|\varphi\|_{C_X} = \max_{s \in [-h,0]} \|\varphi(s)\|_X$, and $L^2_X = L^2(-h, 0; X)$, where the norm will be denoted by $\|\cdot\|_{L^2_X}$. On the delay operator from (1.1), we consider that is well defined as $g : \mathbb{R} \times C_H \to (L^2(\Omega))^3$, and it satisfies the following assumptions:

(I) for all $\xi \in C_H$, the function $\mathbb{R} \ni t \mapsto g(t, \xi) \in (L^2(\Omega))^3$ is measurable,

(II) $g(t, 0) = 0$, for all $t \in \mathbb{R}$,

(III) there exists $L_g > 0$ such that for all $t \in \mathbb{R}$, and for all $\xi, \eta \in C_H$,

$$|g(t, \xi) - g(t, \eta)| \le L_g |\xi - \eta|_{C_H},$$

(IV) there exists $C_g > 0$ such that for all $\tau \le t$, and for all $u, v \in C([\tau - h, t]; H)$,

$$\int_\tau^t |g(s, u_s) - g(s, v_s)|^2 \, ds \le C_g^2 \int_{\tau - h}^t |u(s) - v(s)|^2 \, ds.$$

Examples of fixed, variable and distributed delay operators can be found, for instance, in [6, Section 3], [8, Sections 3.5 and 3.6], and [17, Section 3], and we omit them here just for the sake of brevity.

Observe that (I)–(III) imply that given $T > \tau$ and $u \in C([\tau - h, T]; H)$, the function $g_u : [\tau, T] \to (L^2(\Omega))^3$ defined by $g_u(t) = g(t, u_t)$ for all $t \in [\tau, T]$, is measurable and, in fact, belongs to $L^\infty(\tau, T; (L^2(\Omega))^3)$. Then, thanks to (IV), the mapping

$$\mathcal{G} : u \in C([\tau - h, T]; H) \to g_u \in L^2(\tau, T; (L^2(\Omega))^3)$$

has a unique extension to a mapping $\widetilde{\mathcal{G}}$ which is uniformly continuous from $L^2(\tau - h, T; H)$ into $L^2(\tau, T; (L^2(\Omega))^3)$. From now on, we will denote $g(t, u_t) = \widetilde{\mathcal{G}}(u)(t)$ for each $u \in L^2(\tau - h, T; H)$, and thus property (IV) will also hold for all $u, v \in L^2(\tau - h, T; H)$.

Since it will be used to deduce some estimates for the solutions of (1.1), we study the autonomous equation $u + \alpha^2 Au = \varphi$. From the Lax–Milgram lemma, we know that for each $\varphi \in V'$ there exists a unique $u_\varphi \in V$ such that $u_\varphi + \alpha^2 Au_\varphi = \varphi$. Therefore, the mapping

$$\mathcal{C} : u \in V \mapsto u + \alpha^2 Au \in V'$$

is linear and bijective, with $\mathcal{C}^{-1}\varphi = u_\varphi$. Moreover, by the definition of $D(A)$, we also have that $\mathcal{C}^{-1}(H) = D(A)$. Now, reasoning as in [14], we obtain that

$$\|u_\varphi\| \leq \alpha^{-2}\|\varphi\|_*, \quad \forall\varphi \in V', \tag{2.12}$$

and

$$|Au_\varphi| \leq 2\alpha^{-2}|\varphi|, \quad \forall\varphi \in H. \tag{2.13}$$

Let us consider that $u^\tau \in V$, $\phi \in L^2_H$, and $f \in L^2_{loc}(\mathbb{R}; V')$.

Definition 2.1. A weak solution to (1.1) is a function u that belongs to $L^2(\tau - h, T; H) \cap L^2(\tau, T; V)$ for all $T > \tau$, such that $u(\tau) = u^\tau$, $u(t) = \phi(t - \tau)$ a.e. $t \in (\tau - h, \tau)$, and satisfies

$$\frac{d}{dt}(u(t) + \alpha^2 Au(t)) + \nu Au(t) + B(u(t)) = f(t) + g(t, u_t), \quad \text{in } \mathcal{D}'(\tau, \infty; V'). \tag{2.14}$$

Observe that if u is a weak solution to (1.1), then $u(t) + \alpha^2 Au(t) \in L^2(\tau, T; V')$ for all $T > \tau$, and by (2.8), $\frac{d}{dt}(u(t) + \alpha^2 Au(t)) \in L^1(\tau, T; V')$ for all $T > \tau$. Therefore, by using (2.12) and reasoning as in [14], we can deduce that $u \in C([\tau, \infty); V)$, whence the initial datum $u(\tau) = u^\tau$ has full sense, and $u' \in L^2(\tau, T; V)$ for all $T > \tau$.

Furthermore, the following energy equality holds:

$$\frac{1}{2}\frac{d}{dt}(|u(t)|^2 + \alpha^2\|u(t)\|^2) + \nu\|u(t)\|^2 = \langle f(t), u(t)\rangle + (g(t, u_t), u(t)), \quad \text{a.e. } t > \tau. \tag{2.15}$$

Concerning the existence and uniqueness of weak solution to (1.1), we have the following result.

Theorem 2.2. *Let $f \in L^2_{loc}(\mathbb{R}; V')$, and $g : \mathbb{R} \times C_H \to (L^2(\Omega))^3$ satisfying (I)–(IV), be given. Then, for each $\tau \in \mathbb{R}$, $u^\tau \in V$ and $\phi \in L^2_H$, there exists a unique weak solution $u = u(\cdot; \tau, u^\tau, \phi)$ of (1.1).*

Moreover, if $f \in L^2_{loc}(\mathbb{R}; (L^2(\Omega))^3)$ and $u^\tau \in D(A)$, then u has the following regularity

$$u \in C([\tau, \infty); D(A)), \quad u' \in L^2(\tau, T; D(A)) \text{ for all } T > \tau, \tag{2.16}$$

and a.e. $t > \tau$ satisfies

$$\frac{1}{2}\frac{d}{dt}(\|u(t)\|^2 + \alpha^2|Au(t)|^2) + \nu|Au(t)|^2 + (B(u(t)), Au(t)) = (f(t) + g(t, u_t), Au(t)). \tag{2.17}$$

Proof. Uniqueness. Consider two weak solutions $u^{(1)}$ and $u^{(2)}$ to problem (1.1), corresponding to the same initial data, and denote $\hat{u} = u^{(1)} - u^{(2)}$. Observe that by (2.5) and (2.6),

$$\begin{aligned}|b(u^{(1)}(s), u^{(1)}(s), \hat{u}(s)) - b(u^{(2)}(s), u^{(2)}(s), \hat{u}(s))| &= |b(\hat{u}(s), u^{(1)}(s), \hat{u}(s))| \\ &\leq C_1\|u^{(1)}(s)\|\|\hat{u}(s)\|^2.\end{aligned}$$

Then, from the equation satisfied by $\hat{u}$ and the energy equality, it follows that

$$\begin{aligned}|\hat{u}(t)|^2 &+ \alpha^2\|\hat{u}(t)\|^2 + 2\nu\int_\tau^t \|\hat{u}(s)\|^2\,ds\\ &= -2\int_\tau^t b(\hat{u}(s),u^{(1)}(s),\hat{u}(s))\,ds + 2\int_\tau^t (g(s,u_s^{(1)}) - g(s,u_s^{(2)}),\hat{u}(s))\,ds\\ &\le 2C_1\int_\tau^t \|u^{(1)}(s)\|\|\hat{u}(s)\|^2\,ds + 2\int_\tau^t |g(s,u_s^{(1)}) - g(s,u_s^{(2)})||\hat{u}(s)|\,ds\end{aligned}$$

for all $t \ge \tau$. Now, by the Young inequality and the assumption (IV) on g, taking into account that $\hat{u}(s) = 0$ for $s \in (\tau - h, \tau)$, we obtain that

$$\begin{aligned}|\hat{u}(t)|^2 &+ \alpha^2\|\hat{u}(t)\|^2 + 2\nu\int_\tau^t \|\hat{u}(s)\|^2\,ds\\ &\le 2C_1\int_\tau^t \|u^{(1)}(s)\|\|\hat{u}(s)\|^2\,ds + \int_\tau^t |g(s,u_s^{(1)}) - g(s,u_s^{(2)})|^2\,ds + \int_\tau^t |\hat{u}(s)|^2\,ds\\ &\le 2C_1\int_\tau^t \|u^{(1)}(s)\|\|\hat{u}(s)\|^2\,ds + \lambda_1^{-1}(C_g^2+1)\int_\tau^t \|\hat{u}(s)\|^2\,ds\end{aligned}$$

for all $t \ge \tau$, and in particular

$$\|\hat{u}(t)\|^2 \le \alpha^{-2}\big(2C_1 + \lambda_1^{-1}(C_g^2+1)\big)\int_\tau^t \big(\|u^{(1)}(s)\| + 1\big)\|\hat{u}(s)\|^2\,ds$$

for all $t \ge \tau$. Thus, from the Gronwall lemma, we conclude uniqueness.

Existence. We will follow a Galerkin scheme similarly as in [14, Theorem 4]. Let $\{w_j\}_{j\ge1} \subset D(A)$ be the Hilbert basis of H formed by normalized eigenfunctions of the Stokes operator A introduced before.

For each integer $m \ge 1$, we pose the approximate problems of finding $u^m \in V_m := \mathrm{span}[w_1,\dots,w_m]$ with $u^m(t) = \sum_{j=1}^m \gamma_{m,j}(t)w_j$, where the coefficients $\gamma_{m,j}$ are required to satisfy the system

$$\begin{aligned}&\frac{d}{dt}(u^m(t) + \alpha^2 Au^m(t), w_j) + \nu((u^m(t),w_j)) + b(u^m(t),u^m(t),w_j)\\ &\quad = \langle f(t),w_j\rangle + (g(t,u_t^m),w_j), \quad \text{a.e. } t > \tau, \quad 1 \le j \le m,\end{aligned} \tag{2.18}$$

and the initial conditions

$$u^m(\tau) = P_m u^\tau \quad \text{and} \quad u^m(\tau+s) = P_m\phi(s) \quad \text{a.e. } s \in (-h,0),$$

where P_m is the orthogonal projector from H onto V_m. Observe that, by the choice of the basis $\{w_j\}_{j\ge1}$, the restriction $P_{m|_V}$ of P_m to V belongs to $\mathcal{L}(V)$, $\|P_{m|_V}\|_{\mathcal{L}(V)} \le 1$ for all $m \ge 1$, and $\lim_{m\to\infty}\|u^\tau - P_m u^\tau\| = 0$.

The above system of ordinary functional differential equations with finite delay fulfills the conditions for existence and uniqueness of local solution (see for example [18]).

Next, we will deduce a priori estimates that in particular assure that the solutions u^m do exist for all time $t \in [\tau - h, \infty)$.

Multiplying each equation in (2.18) by $\gamma_{m,j}(t)$ and summing from $j = 1$ to $j = m$, we obtain that a.e. $t > \tau$,

$$\begin{aligned}\frac{d}{dt}(|u^m(t)|^2 + \alpha^2\|u^m(t)\|^2) + 2\nu\|u^m(t)\|^2 &= 2\langle f(t),u^m(t)\rangle + 2(g(t,u_t^m),u^m(t))\\ &\le \nu\|u^m(t)\|^2 + \nu^{-1}\|f(t)\|_*^2 + |g(t,u_t^m)|^2 + |u^m(t)|^2,\end{aligned}$$

where we have used (2.6) to remove the nonlinear term b, and the Young inequality.

By integrating in time, from the assumptions on the delay operator g, in particular we deduce that

$$
\begin{aligned}
&|u^m(t)|^2 + \alpha^2 \|u^m(t)\|^2 \\
&\quad \leq |P_m u^\tau|^2 + \alpha^2 \|P_m u^\tau\|^2 + \nu^{-1} \int_\tau^t \|f(s)\|_*^2\, ds + C_g^2 \int_{\tau-h}^t |u^m(s)|^2\, ds + \int_\tau^t |u^m(s)|^2\, ds \\
&\quad \leq |u^\tau|^2 + \alpha^2 \|u^\tau\|^2 + C_g^2 \|\phi\|_{L^2_H}^2 + \nu^{-1} \int_\tau^t \|f(s)\|_*^2\, ds + \lambda_1^{-1}(C_g^2 + 1) \int_\tau^t \|u^m(s)\|^2\, ds
\end{aligned}
$$

for all $t \geq \tau$, and any $m \geq 1$. Now, by the Gronwall lemma we conclude that the sequence $\{u^m\}_{m\geq 1}$ is bounded in $C([\tau, T]; V)$ for all $T > \tau$. Moreover, since $u^m_\tau = P_m \phi$ converges to ϕ in $L^2(-h, 0; H)$, in particular, thanks to (IV), the sequence $\{g(\cdot, u^m_\cdot)\}_{m\geq 1}$ is bounded in $L^2(\tau, T; (L^2(\Omega))^3)$ for all $T > \tau$.

Now from (2.8), (2.18) and by the choice of the basis, we obtain that $v^m = \mathcal{C} u^m$ satisfies

$$
\|(v^m)'(t)\|_* \leq \nu \|u^m(t)\| + C_1 \|u^m(t)\|^2 + \|f(t)\|_* + \lambda_1^{-1/2} |g(t, u^m_t)|, \quad \text{a.e. } t > \tau,
$$

which implies that the sequence $\{dv^m/dt\}_{m\geq 1}$ is bounded in $L^2(\tau, T; V')$ for all $T > \tau$. Therefore, taking into account that $du^m/dt = \mathcal{C}^{-1}(dv^m/dt)$, we have that the sequence $\{du^m/dt\}_{m\geq 1}$ is bounded in $L^2(\tau, T; V)$ for all $T > \tau$.

Thus, by the compactness of the injection of V into H and the Ascoli–Arzelà theorem, we deduce that there exist a subsequence $\{u^{m'}\}_{m'\geq 1} \subset \{u^m\}_{m\geq 1}$ and a function $u \in W^{1,2}(\tau, T; V)$ for all $T > \tau$, with $u_\tau = \phi$, such that

$$
\begin{cases}
u^{m'} \overset{*}{\rightharpoonup} u \text{ weakly-star in } L^\infty(\tau, T; V), \\
u^{m'} \to u \text{ strongly in } C([\tau, T]; H), \\
u^{m'} \to u \text{ a.e. in } \Omega \times (\tau, T), \\
g(\cdot, u^{m'}_\cdot) \to g(\cdot, u_\cdot) \text{ strongly in } L^2(\tau, T; (L^2(\Omega))^3), \\
\dfrac{du^{m'}}{dt} \rightharpoonup \dfrac{du}{dt} \text{ weakly in } L^2(\tau, T; V), \\
\dfrac{dv^{m'}}{dt} = \mathcal{C}\left(\dfrac{du^{m'}}{dt}\right) \rightharpoonup \mathcal{C}\left(\dfrac{du}{dt}\right) \text{ weakly in } L^2(\tau, T; V'),
\end{cases}
\tag{2.19}
$$

for all $T > \tau$.

Now, using the same reasoning as in [14], we can obtain that $B(u^{m'}) \rightharpoonup B(u)$ weakly in $L^2(\tau, T; V')$, for all $T > \tau$. So, from all the convergences above, we can take limits in (2.18) and conclude that u satisfies (2.14).

Notice also that $u(\tau) = \lim_{m'\to\infty} u^{m'}(\tau) = \lim_{m'\to\infty} P_{m'} u^\tau = u^\tau$. Thus, u is the weak solution to (1.1).

Finally, the regularity property (2.16) and the identity (2.17) follow from the corresponding results proved in [14, Theorem 4] and the fact that, if $f \in L^2_{loc}(\mathbb{R}; (L^2(\Omega))^3)$, then the function $f(\cdot) + g(\cdot, u_\cdot)$ belongs to $L^2_{loc}(\tau, \infty; (L^2(\Omega))^3)$. □

Remark 2.3. Observe that in the above proof, using the uniqueness of solution to the problem, for any $T > \tau$ we have that the whole sequence of the Galerkin approximations $\{u^m\}$ converges to u in $C([\tau, T]; H)$. Actually, all the convergences in (2.19), except the third one, hold for the whole sequence. Analogously, one also deduces that for any $t \in [\tau, T]$, $u^m(t) \rightharpoonup u(t)$ weakly in V.

In addition, if $u^\tau \in D(A)$ and $f \in L^2_{loc}(\mathbb{R}; (L^2(\Omega))^3)$, then for any $T > \tau$ the sequence $\{u^m\}$ converges to u in $C([\tau, T]; V)$, and weakly-star in $L^\infty(\tau, T; D(A))$, for any $t \in [\tau, T]$, $u^m(t) \rightharpoonup u(t)$ in $D(A)$, and the sequence $\{du^m/dt\}$ converges to du/dt weakly in $L^2(\tau, T; D(A))$.

Remark 2.4. (i) The solution depends continuously on the initial data in the strong topology of $V \times L^2_H$. Moreover, when $f \in L^2_{loc}(\mathbb{R}; (L^2(\Omega))^3)$, the solution depends continuously on the initial data in the strong topology of $D(A) \times L^2_V$. Indeed, this can be proved similarly to the proof of uniqueness of weak solution to (1.1), considering the difference of two solutions and using the Gronwall lemma.

(ii) The existence and uniqueness part of Theorem 2.2 do not need any regularity assumption on the boundary of the domain. In fact, this assumption is only required for the additional regularity results.

3 Existence of minimal pullback attractors in V norm

Before to start, let us recall some abstract definitions and results on pullback attractors and bi-space attractors theories. In fact, abstract existence results are omitted for the sake of brevity. For instance, they can be found in [4, 5, 13, 27] for pullback attractors (and references therein) and in [11] for bi-space pullback attractors (see also [1, 9, 39] for the autonomous bi-space attractors theory). They will be applied to a suitable dynamical system associated to (1.1), or to a restricted version involving more regularity or because of better properties.

Consider given a metric space (X, d_X), and let us denote $\mathbb{R}^2_d = \{(t, \tau) \in \mathbb{R}^2 : \tau \leq t\}$.

A process $\mathcal{U}$ on X is a mapping $\mathbb{R}^2_d \times X \ni (t, \tau, x) \mapsto \mathcal{U}(t, \tau)x \in X$ such that $\mathcal{U}(\tau, \tau)x = x$ for any $(\tau, x) \in \mathbb{R} \times X$, and $\mathcal{U}(t, r)(\mathcal{U}(r, \tau)x) = \mathcal{U}(t, \tau)x$ for any $\tau \leq r \leq t$ and all $x \in X$.

A process $\mathcal{U}$ is said to be continuous if for any pair $\tau \leq t$, the mapping $\mathcal{U}(t, \tau) : X \to X$ is continuous. It is said to be closed if for any $\tau \leq t$, and any sequence $\{x_n\} \subset X$, if $x_n \to x \in X$ and $\mathcal{U}(t, \tau)x_n \to y \in X$, then $\mathcal{U}(t, \tau)x = y$. It is clear that every continuous process is closed.

Let us denote by $\mathcal{P}(X)$ the family of all nonempty subsets of X, and consider a family of nonempty sets $\widehat{D}_0 = \{D_0(t) : t \in \mathbb{R}\} \subset \mathcal{P}(X)$.

The process $\mathcal{U}$ is pullback $\widehat{D}_0$-asymptotically compact if for any $t \in \mathbb{R}$ and any sequences $\{\tau_n\} \subset (-\infty, t]$ and $\{x_n\} \subset X$ satisfying $\tau_n \to -\infty$ and $x_n \in D_0(\tau_n)$ for all n, the sequence $\{\mathcal{U}(t, \tau_n)x_n\}$ is relatively compact in X.

A process $\mathcal{U}$ on X being pullback $\widehat{D}_0$-asymptotically compact possesses a family of nonempty compact subsets of X, namely the atomized structure for the asymptotic behavior, the omega-limit family $\Lambda_X(\widehat{D}_0) = \{\Lambda_X(\widehat{D}_0, t) : t \in \mathbb{R}\}$ with

$$\Lambda_X(\widehat{D}_0, t) = \bigcap_{s \leq t} \overline{\bigcup_{\tau \leq s} \mathcal{U}(t, \tau) D_0(\tau)}^X.$$

It pullback attracts in X norm to $\widehat{D}_0$ (cf. [13, Proposition 3.4]), i.e.

$$\lim_{\tau \to -\infty} \mathrm{dist}_X(\mathcal{U}(t, \tau)D_0(\tau), \Lambda_X(\widehat{D}_0, t)) = 0, \qquad \forall t \in \mathbb{R},$$

where $\mathrm{dist}_X(\cdot, \cdot)$ denotes the Hausdorff semi-distance in X. In fact, it is the minimal family of closed sections in X that attracts $\widehat{D}_0$. Moreover, if $\mathcal{U}$ is also a closed process on X, then (cf. [13, Proposition 3.5]) it is invariant, i.e. $\mathcal{U}(t, \tau)\Lambda_X(\widehat{D}_0, \tau) = \Lambda_X(\widehat{D}_0, t)$ for all $\tau \leq t$.

Let be given $\mathcal{D}$ a nonempty class of families parameterized in time $\widehat{D} = \{D(t) : t \in \mathbb{R}\} \subset \mathcal{P}(X)$. The class $\mathcal{D}$ will be called a universe in $\mathcal{P}(X)$.

Definition 3.1. A process $\mathcal{U}$ on X is said to be pullback $\mathcal{D}$-asymptotically compact if it is $\widehat{D}$-asymptotically compact for any $\widehat{D} \in \mathcal{D}$.

It is said that $\widehat{D}_0 = \{D_0(t) : t \in \mathbb{R}\} \subset \mathcal{P}(X)$ is pullback $\mathcal{D}$-absorbing for $\mathcal{U}$ on X if for any $t \in \mathbb{R}$ and any $\widehat{D} \in \mathcal{D}$, there exists a $\tau_0(t, \widehat{D}) \leq t$ such that $\mathcal{U}(t,\tau)D(\tau) \subset D_0(t)$ for all $\tau \leq \tau_0(t, \widehat{D})$.

The suitable combination of the above two ingredients leads to

Definition 3.2. Given a metric space X, a universe $\mathcal{D}$ in $\mathcal{P}(X)$, and a process $\mathcal{U}$ on X, a family $\mathcal{A}_{\mathcal{D}} = \{\mathcal{A}_{\mathcal{D}}(t) : t \in \mathbb{R}\}$ is called a pullback $\mathcal{D}$-attractor for $\mathcal{U}$ if (i) $\mathcal{A}_{\mathcal{D}}(t)$ is compact in X for any $t \in \mathbb{R}$, (ii) $\mathcal{A}_{\mathcal{D}}$ pullback $\mathcal{D}$-attracts in X and (iii) it is invariant (i.e. $\mathcal{U}(t,\tau)\mathcal{A}_{\mathcal{D}}(\tau) = \mathcal{A}_{\mathcal{D}}(t)$ for any $\tau \leq t$).

Besides, it is said the minimal pullback $\mathcal{D}$-attractor for $\mathcal{U}$ on X if given any family $\widehat{C} = \{C(t) : t \in \mathbb{R}\} \subset \mathcal{P}(X)$ of closed sets that pullback $\mathcal{D}$-attracts under $\mathcal{U}$, then $\mathcal{A}_{\mathcal{D}}(t) \subset C(t)$.

Without minimality, pullback attractors are not unique in general (cf. [27]). Minimality involves uniqueness and a clear candidate, after the definition of omega-limit families. Namely, the following result is well-known.

Theorem 3.3 (cf. [13, Theorem 3.11])**.** *Consider a closed process $\mathcal{U} : \mathbb{R}^2_d \times X \to X$, a universe $\mathcal{D}$ in $\mathcal{P}(X)$, and a family $\widehat{D}_0 = \{D_0(t) : t \in \mathbb{R}\} \subset \mathcal{P}(X)$ which is pullback $\mathcal{D}$-absorbing for $\mathcal{U}$, and assume also that $\mathcal{U}$ is pullback $\widehat{D}_0$-asymptotically compact. Then, the family $\mathcal{A}_{\mathcal{D}} = \{\mathcal{A}_{\mathcal{D}}(t) : t \in \mathbb{R}\}$ defined by $\mathcal{A}_{\mathcal{D}}(t) = \overline{\bigcup_{\widehat{D} \in \mathcal{D}} \Lambda_X(\widehat{D}, t)}^X$ is the minimal pullback $\mathcal{D}$-attractor for $\mathcal{U}$ in X.*

Remark 3.4. Under the assumptions of Theorem 3.3, the family $\mathcal{A}_{\mathcal{D}}$ satisfies $\mathcal{A}_{\mathcal{D}}(t) \subset \Lambda_X(\widehat{D}_0, t)$ for any $t \in \mathbb{R}$. Actually, if $\widehat{D}_0 \in \mathcal{D}$, then $\mathcal{A}_{\mathcal{D}} = \Lambda_X(\widehat{D}_0)$. Moreover, if $\mathcal{A}_{\mathcal{D}} \in \mathcal{D}$, then it is the unique family of closed subsets in $\mathcal{D}$ that satisfies (ii)–(iii) in Definition 3.2. A sufficient condition for $\mathcal{A}_{\mathcal{D}} \in \mathcal{D}$ is to have that $\widehat{D}_0 \in \mathcal{D}$, the set $D_0(t)$ is closed for all $t \in \mathbb{R}$, and the family $\mathcal{D}$ is inclusion-closed (i.e., if $\widehat{D} \in \mathcal{D}$, and $\widehat{D}' = \{D'(t) : t \in \mathbb{R}\} \subset \mathcal{P}(X)$ with $D'(t) \subset D(t)$ for all t, then $\widehat{D}' \in \mathcal{D}$).

We will denote $\mathcal{D}_F(X)$ the universe of fixed nonempty bounded subsets of X, i.e., the class of all families $\widehat{D}$ of the form $\widehat{D} = \{D(t) = D : t \in \mathbb{R}\}$ with D a fixed nonempty bounded subset of X.

Now, it is easy to conclude the following result.

Corollary 3.5 (cf. [27, Corollaries 20 and 21])**.** *Under the assumptions of Theorem 3.3, if $\mathcal{D}$ contains $\mathcal{D}_F(X)$, then the minimal pullback attractor $\mathcal{A}_{\mathcal{D}_F(X)}$ also exists and $\mathcal{A}_{\mathcal{D}_F(X)}(t) \subset \mathcal{A}_{\mathcal{D}}(t)$ for all $t \in \mathbb{R}$. Moreover, if for some $T \in \mathbb{R}$, the set $\cup_{t \leq T} D_0(t)$ is bounded, then $\mathcal{A}_{\mathcal{D}_F(X)}(t) = \mathcal{A}_{\mathcal{D}}(t)$ for all $t \leq T$.*

Comparison results with different universes are also possible if the process $\mathcal{U}$ is well-posed in several metric spaces with a connection between them. Namely, Theorem 3.15 in [13] allows us to gain additional regularity about attractors. For the sake of brevity, we omit such statement. Nevertheless, we will recall another one with previous definitions, which will be analogously useful for our results (this is inspired from another study, cf. [25, Section 5]).

Theory of bi-space attractors (cf. [1,9,39] for autonomous setting and the references therein) is close to the previous results but joining extra regularity of the solution operator involving two spaces. Since our context is non-autonomous, we borrow some of these results from [11], settled in this framework also for closed processes. Consider given two metric spaces (X_i, d_{X_i}), $i = 1, 2$ (not necessarily related) and a process $\mathcal{U}$ on X_1. It is said (cf. [11, Definition 2.12]) that $\mathcal{U}$ is (X_1, X_2) closed if for any $\tau \leq t$ and $\{x_n\} \subset X_1 \cap X_2$ with $\mathcal{U}(t,\tau)x_n \in X_1 \cap X_2$, if $x_n \to x$ in X_2 and $\mathcal{U}(t,\tau)x_n \to y \in X_2$, then $x \in X_1$ and $\mathcal{U}(t,\tau)x = y$.

Given a parameterized-in-time family $\widehat{D}_0 \subset \mathcal{P}(X_1)$, a process $\mathcal{U}$ on X_1 is said (X_1, X_2) pullback $\widehat{D}_0$-asymptotically compact (cf. [11, Definition 2.4]) if for any $t \in \mathbb{R}$, sequence $\{\tau_n\} \subset (-\infty, t]$ and $\{x_n\} \subset X_1$ with $\tau_n \to -\infty$ and $x_n \in D_0(\tau_n)$, the sequence $\{\mathcal{U}(t,\tau_n)x_n\}$ is relatively compact in X_2. Analogously to Definition 3.1, a process $\mathcal{U}$ on X_1 is said to be (X_1, X_2) pullback $\mathcal{D}$-asymptotically compact if it is (X_1, X_2) pullback $\widehat{D}$-asymptotically compact for any $\widehat{D} \in \mathcal{D}$.

We may run parallel the construction of a family with the desired properties of minimal pullback attractor for a universe $\mathcal{D}$ in $\mathcal{P}(X_1)$, provided that for any $\widehat{D} = \{D(s) : s \in \mathbb{R}\} \in \mathcal{D}$ and $t \in \mathbb{R}$ there exists $s_{\widehat{D},t} \leq t$ such that $\mathcal{U}(t,s)D(s) \subset X_2$ for all $s \leq s_{\widehat{D},t}$ (cf. [11, (2.2)]). In this case, data comes from X_1 and the arrival attracting space is X_2 with its corresponding metric [11, Definition 2.2].

Definition 3.6. Let be given a process $\mathcal{U}$ on X_1 and a universe $\mathcal{D}$ in $\mathcal{P}(X_1)$. The family $\widehat{\mathcal{A}}_{\mathcal{D}} = \{\widehat{\mathcal{A}}_{\mathcal{D}}(t) : t \in \mathbb{R}\}$ is called a (X_1, X_2) pullback $\mathcal{D}$-attractor if (i) $\widehat{\mathcal{A}}_{\mathcal{D}}(t) \subset X_1 \cap X_2$ is a nonempty compact set in X_2 for each $t \in \mathbb{R}$, (ii) it is pullback $\mathcal{D}$-attracting using the Hausdorff semidistance in X_2 and (iii) it is invariant. Besides, it is said minimal if for any other family $\widehat{C}$ of nonempty closed time-sections with values in X_2 and pullback $\mathcal{D}$-attracting in X_2, then $\widehat{\mathcal{A}}_{\mathcal{D}}(t) \subset \widehat{C}(t)$ for any $t \in \mathbb{R}$.

Similarly to Theorem 3.3, we may ensure the existence of the minimal (X_1, X_2) pullback $\mathcal{D}$-attractor under rather general conditions (cf. [11, Theorem 2.16]).

Theorem 3.7. *Let be given two metric spaces X_i, $i = 1, 2$, a process $\mathcal{U}$ on X_1, and a universe $\mathcal{D}$ in $\mathcal{P}(X_1)$. Suppose that there exists a family $\widehat{\mathcal{B}}_0$ in $\mathcal{P}(X_1)$ that is pullback $\mathcal{D}$-absorbing, such that for any $t \in \mathbb{R}$ there exists $s_{\widehat{\mathcal{B}}_0,t} \leq t$ such that $\mathcal{U}(t,s)\widehat{\mathcal{B}}_0(s) \subset X_2$ for any $s \leq s_{\widehat{\mathcal{B}}_0,t}$. If the process $\mathcal{U}$ is (X_1, X_2) closed and (X_1, X_2) pullback $\widehat{\mathcal{B}}_0$-asymptotically compact, then there exists $\widehat{\mathcal{A}}_{\mathcal{D}}$ the minimal (X_1, X_2) pullback $\mathcal{D}$-attractor for $\mathcal{U}$, and it is given by $\widehat{\mathcal{A}}_{\mathcal{D}}(t) = \overline{\cup_{\widehat{D}\in\mathcal{D}}\Lambda_{X_2}(\widehat{D}, t)}^{X_2} \subset \Lambda_{X_2}(\widehat{\mathcal{B}}_0, t)$.*

Remark 3.8. If $X_2 \subset X_1$ with continuous injection, the following consequences are immediate: (i) A process $\mathcal{U}$ on X_1 that is X_1 closed, it is also (X_1, X_2) closed. (ii) Given a universe $\mathcal{D}$ in $\mathcal{P}(X_1)$ and a process $\mathcal{U}$ (X_1, X_2) pullback $\mathcal{D}$-asymptotically compact, then $\Lambda_{X_1}(\widehat{D}) = \Lambda_{X_2}(\widehat{D})$ for any $\widehat{D} \in \mathcal{D}$ thanks to the minimality properties of omega-limit families and that a compact set in X_2 is compact in X_1. (iii) A process $\mathcal{U}$ that has a (X_1, X_2) pullback $\mathcal{D}$-attractor $\widehat{\mathcal{A}}_{\mathcal{D}}$, it also has a (X_1, X_1) pullback $\mathcal{D}$-attractor $\mathcal{A}_{\mathcal{D}}$ just using the embedding $X_2 \subset X_1$ (same arguments of minimality and compact sets than in (ii), even using different clousures). In this case we make an abuse of notation, identifying both families without any extra notation, gaining extra regularity in X_2 for the sections of the attractor.

In view of Theorem 2.2 and Remark 2.4 (i), we will apply the above abstract results in the phase-space $X = V \times L^2_H$, which is a Hilbert space with the norm $\|(u^\tau, \phi)\|^2_X = \|u^\tau\|^2 + \|\phi\|^2_{L^2_H}$ for a pair $(u^\tau, \phi) \in X$.

The first consequence after the Theorem 2.2 and Remark 2.4 (i) is the following

Corollary 3.9. *Let $f \in L^2_{loc}(\mathbb{R}; V')$, and $g : \mathbb{R} \times C_H \to (L^2(\Omega))^3$ satisfying (I)–(IV), be given. Then, the bi-parametric family of maps $S(t,\tau) : V \times L^2_H \to V \times L^2_H$, with $\tau \leq t$, given by*

$$S(t,\tau)(u^\tau, \phi) = (u(t; \tau, u^\tau, \phi), u_t(\cdot; \tau, u^\tau, \phi)), \tag{3.1}$$

where $u = u(\cdot;\tau,u^\tau,\phi)$ *is the unique weak solution to* (1.1)*, defines a continuous process on* $V \times L^2_H$.

We will need the following continuity result for the process S in a weak sense.

Proposition 3.10. *Let* $f \in L^2_{loc}(\mathbb{R};V')$, $g : \mathbb{R} \times C_H \to (L^2(\Omega))^3$ *satisfying (I)–(IV), and* $\tau < t$ *be given. Then, for any sequence such that*

$$(u^{\tau,n},\phi^n) \rightharpoonup (u^\tau,\phi) \quad \text{weakly in } V \times L^2_V$$

and

$$\frac{d\phi^n}{ds} \rightharpoonup \frac{d\phi}{ds} \quad \text{weakly in } L^2_V,$$

the following convergences hold for the sequence of solutions $u(\cdot;\tau,u^{\tau,n},\phi^n)$ *towards the solution* $u(\cdot;\tau,u^\tau,\phi)$*:*

$$\begin{aligned}
&u(\cdot;\tau,u^{\tau,n},\phi^n) \overset{*}{\rightharpoonup} u(\cdot;\tau,u^\tau,\phi) && \text{weakly-star in } L^\infty(\tau,t;V),\\
&u(\cdot;\tau,u^{\tau,n},\phi^n) \to u(\cdot;\tau,u^\tau,\phi) && \text{strongly in } C([\tau-h,t];H),\\
&u(t;\tau,u^{\tau,n},\phi^n) \rightharpoonup u(t;\tau,u^\tau,\phi) && \text{weakly in } V,\\
&u(\cdot;\tau,u^{\tau,n},\phi^n) \rightharpoonup u(\cdot;\tau,u^\tau,\phi) && \text{weakly in } L^2(\tau-h,t;V).
\end{aligned} \tag{3.2}$$

Proof. Taking into account that $\{\phi^n\}$ is bounded in $W^{1,2}(-h,0;V) \subset C([-h,0];V)$, and the compactness of the injection of V into H, by the Ascoli–Arzelà theorem we deduce that $\phi^n \to \phi$ strongly in C_H. Therefore, the *a priori* estimates obtained for the Galerkin approximations in Theorem 2.2 also hold for the sequence of solutions $\{u(\cdot;\tau,u^{\tau,n},\phi^n)\}$, and then all the convergences in (3.2) hold. Finally, the fact that the whole sequence satisfies the above convergences is a consequence of the uniqueness of solution for the problem (cf. Remark 2.3). □

Now, we introduce an additional assumption on g in order to obtain some asymptotic estimates for the solutions to (1.1).

(V) Assume that $\nu\lambda_1 > C_g$, and that there exists a value $0 < \sigma < 2(\nu - \lambda_1^{-1}C_g)(\lambda_1^{-1} + \alpha^2)^{-1}$ such that for every $u \in L^2(\tau-h,t;H)$,

$$\int_\tau^t e^{\sigma s}|g(s,u_s)|^2\,ds \le C_g^2 \int_{\tau-h}^t e^{\sigma s}|u(s)|^2\,ds, \quad \forall t \ge \tau.$$

Lemma 3.11. *Consider given* $f \in L^2_{loc}(\mathbb{R};V')$ *and* $g : \mathbb{R} \times C_H \to (L^2(\Omega))^3$ *satisfying conditions (I)–(V). Then, for any* $(u^\tau,\phi) \in V \times L^2_H$*, the following estimate holds for the solution* u *to* (1.1) *for all* $t \ge \tau$,

$$\|u(t)\|^2 \le \alpha^{-2}\max\{\lambda_1^{-1}+\alpha^2, C_g\}e^{\sigma(\tau-t)}\|(u^\tau,\phi)\|^2_{V\times L^2_H} + \alpha^{-2}\varepsilon^{-1}\int_\tau^t e^{\sigma(s-t)}\|f(s)\|_*^2\,ds, \tag{3.3}$$

where

$$\varepsilon = 2\nu - \sigma(\lambda_1^{-1}+\alpha^2) - 2\lambda_1^{-1}C_g > 0. \tag{3.4}$$

Proof. By the energy equality (2.15) and the Young inequality, we have

$$\begin{aligned}
&\frac{d}{dt}(|u(t)|^2 + \alpha^2\|u(t)\|^2) + 2\nu\|u(t)\|^2\\
&\quad \le \varepsilon\|u(t)\|^2 + \varepsilon^{-1}\|f(t)\|_*^2 + C_g|u(t)|^2 + C_g^{-1}|g(t,u_t)|^2, \quad \text{a.e. } t > \tau.
\end{aligned}$$

Thus,

$$\frac{d}{dt}(e^{\sigma t}|u(t)|^2 + \alpha^2 e^{\sigma t}\|u(t)\|^2) + e^{\sigma t}\big(2\nu - \varepsilon - \sigma(\lambda_1^{-1} + \alpha^2) - \lambda_1^{-1}C_g\big)\|u(t)\|^2 \\ \le e^{\sigma t}\varepsilon^{-1}\|f(t)\|_*^2 + e^{\sigma t}C_g^{-1}|g(t,u_t)|^2, \quad \text{a.e. } t > \tau,$$

and therefore, integrating in time above and using property (V), we obtain

$$e^{\sigma t}(|u(t)|^2 + \alpha^2\|u(t)\|^2) + \big(2\nu - \varepsilon - \sigma(\lambda_1^{-1} + \alpha^2) - \lambda_1^{-1}C_g\big)\int_\tau^t e^{\sigma s}\|u(s)\|^2\,ds \\ \le e^{\sigma\tau}(\lambda_1^{-1} + \alpha^2)\|u^\tau\|^2 + \varepsilon^{-1}\int_\tau^t e^{\sigma s}\|f(s)\|_*^2\,ds + C_g\int_{\tau-h}^t e^{\sigma s}|u(s)|^2\,ds \\ \le e^{\sigma\tau}\left((\lambda_1^{-1} + \alpha^2)\|u^\tau\|^2 + C_g\int_{-h}^0 |\phi(s)|^2\,ds\right) + \varepsilon^{-1}\int_\tau^t e^{\sigma s}\|f(s)\|_*^2\,ds + \lambda_1^{-1}C_g\int_\tau^t e^{\sigma s}\|u(s)\|^2\,ds$$

for all $t \ge \tau$, and from this last inequality and (3.4), in particular we deduce (3.3). □

From now on, being $\sigma > 0$ given in (V), we will assume that $f \in L^2_{loc}(\mathbb{R}; V')$ satisfies

$$\int_{-\infty}^0 e^{\sigma s}\|f(s)\|_*^2\,ds < \infty. \tag{3.5}$$

At the light of the previous result, we now define an appropriate concept of (tempered) universe for problem (1.1).

Definition 3.12. Denote by $\mathcal{D}_\sigma(V \times L^2_H)$ the class of all families of nonempty subsets $\widehat{D} = \{D(t) : t \in \mathbb{R}\} \subset \mathcal{P}(V \times L^2_H)$ such that

$$\lim_{\tau\to-\infty}\left(e^{\sigma\tau}\sup_{(v,\varphi)\in D(\tau)}\|(v,\varphi)\|^2_{V\times L^2_H}\right) = 0.$$

According to the notation introduced in the previous section, we will denote by $\mathcal{D}_F(V \times L^2_H)$ the universe of fixed bounded sets in $V \times L^2_H$. Observe that trivially $\mathcal{D}_F(V \times L^2_H) \subset \mathcal{D}_\sigma(V \times L^2_H)$ and that $\mathcal{D}_\sigma(V \times L^2_H)$ is inclusion-closed.

Remark 3.13. Although from Lemma 3.11 it is easy to see that the family $\{\overline{B}_{V\times L^2_H}(0,\rho_\sigma(t)) : t \in \mathbb{R}\} \subset \mathcal{P}(V \times L^2_H)$ is pullback $\mathcal{D}_\sigma(V \times L^2_H)$-absorbing for the process S, where

$$\rho_\sigma^2(t) = 1 + \alpha^{-2}\varepsilon^{-1}(1 + \lambda_1^{-1}he^{\sigma h})e^{-\sigma t}\int_{-\infty}^t e^{\sigma s}\|f(s)\|_*^2\,ds,$$

we will need, in order to apply Proposition 3.10, to obtain a different pullback $\mathcal{D}_\sigma(V \times L^2_H)$-absorbing family.

Lemma 3.14. *Assume that $g : \mathbb{R} \times C_H \to (L^2(\Omega))^3$ fulfills conditions (I)–(V), and $f \in L^2_{loc}(\mathbb{R}; V')$ satisfies (3.5). Then, for any $t \in \mathbb{R}$ and $\widehat{D} \in \mathcal{D}_\sigma(V \times L^2_H)$, there exist $\tau_1(\widehat{D}, t, h) < t - 2h$ and functions $\{\rho_i\}_{i=1}^2$ such that for any $\tau \le \tau_1(\widehat{D}, t, h)$ and any $(u^\tau, \phi) \in D(\tau)$, it holds*

$$\|u(r;\tau,u^\tau,\phi)\|^2 \le \rho_1^2(t), \quad \forall\, r \in [t-2h, t], \tag{3.6}$$

$$\int_{t-h}^t \|u'(\theta;\tau,u^\tau,\phi)\|^2\,d\theta \le \rho_2^2(t), \tag{3.7}$$

where

$$\rho_1^2(t) = 1 + \alpha^{-2}\varepsilon^{-1}e^{-\sigma(t-2h)}\int_{-\infty}^{t} e^{\sigma s}\|f(s)\|_*^2\,ds, \tag{3.8}$$

$$\rho_2^2(t) = 4\alpha^{-4}h\rho_1^2(t)\left(\nu^2 + C_1^2\rho_1^2(t) + 2\lambda_1^{-2}C_g^2\right) + 4\alpha^{-4}\int_{t-h}^{t}\|f(s)\|_*^2\,ds, \tag{3.9}$$

and ε is given by (3.4).

Proof. Let $\tau_1(\widehat{D}, t, h) < t - 2h$ be such that

$$\alpha^{-2}\max\{\lambda_1^{-1}+\alpha^2, C_g\}e^{-\sigma(t-2h)}e^{\sigma\tau}\|(u^\tau,\phi)\|^2_{V\times L^2_H} \le 1 \quad \forall\, \tau \le \tau_1(\widehat{D},t,h),\ (u^\tau,\phi)\in D(\tau).$$

Consider fixed $\tau \le \tau_1(\widehat{D}, t, h)$ and $(u^\tau, \phi) \in D(\tau)$. The estimate (3.6) follows directly from (3.3), using the increasing character of the exponential.

Now, from (2.8), (2.14), (2.1) and the fact that A is an isometric isomorphism, we obtain that $v = Cu$ satisfies

$$\|v'(\theta)\|_* \le \nu\|u(\theta)\| + C_1\|u(\theta)\|^2 + \|f(\theta)\|_* + \lambda_1^{-1/2}|g(\theta,u_\theta)|, \quad \text{a.e. } \theta > \tau,$$

and therefore,

$$\|v'(\theta)\|_*^2 \le 4\nu^2\|u(\theta)\|^2 + 4C_1^2\|u(\theta)\|^4 + 4\|f(\theta)\|_*^2 + 4\lambda_1^{-1}|g(\theta,u_\theta)|^2, \quad \text{a.e. } \theta > \tau.$$

Integrating in time and using properties (II) and (IV), we deduce

$$\int_{t-h}^{t}\|v'(\theta)\|_*^2\,d\theta \le 4\nu^2\int_{t-h}^{t}\|u(\theta)\|^2\,d\theta + 4C_1^2\int_{t-h}^{t}\|u(\theta)\|^4\,d\theta$$
$$+ 4\int_{t-h}^{t}\|f(\theta)\|_*^2\,d\theta + 4\lambda_1^{-2}C_g^2\int_{t-2h}^{t}\|u(\theta)\|^2\,d\theta,$$

whence, by (2.12) and (3.6), the estimate (3.7) follows. □

Remark 3.15. Observe that $\lim_{t\to-\infty} e^{\sigma t}\rho_1(t) = 0$.

Corollary 3.16. *Under the assumptions of Lemma 3.14, the family $\widehat{D}_\sigma = \{D_\sigma(t) : t \in \mathbb{R}\} \subset \mathcal{P}(V \times L^2_H)$ defined by*

$$D_\sigma(t) = \left\{(w,\psi) \in V\times L^2_V : \exists \frac{d\psi}{ds} \in L^2_V,\ \|(w,\psi)\|_{V\times L^2_V} \le \widetilde{\rho}_\sigma(t),\ \left\|\frac{d\psi}{ds}\right\|_{L^2_V} \le \rho_2(t)\right\} \tag{3.10}$$

is pullback $\mathcal{D}_\sigma(V\times L^2_H)$-absorbing for the process S on $V\times L^2_H$ defined by (3.1), where $\widetilde{\rho}_\sigma(t)$ satisfies

$$\widetilde{\rho}_\sigma^2(t) = (1+h)\rho_1^2(t), \tag{3.11}$$

with $\rho_1(t)$ and $\rho_2(t)$ given by (3.8) and (3.9) respectively. Moreover, $\widehat{D}_\sigma \in \mathcal{D}_\sigma(V\times L^2_H)$.

Now, we prove that the process S is $(V\times L^2_H, V\times C_H)$ pullback $\widehat{D}_\sigma$-asymptotically compact. To this end, we will apply an energy method used by Rosa (cf. [32], see also [26] and [14]), which does not require any additional estimates on the solutions in higher norms in contrast with the *energy continuous method* (e.g., cf. [28]), or the method used in [20] with the fractional powers of the operator A. Our proof here relies on a sharp use of the differential equality that leads to the existence of an absorbing family, the use of weak limits in $V\times L^2_V$ in a diagonal argument, and the convergences established in Proposition 3.10.

Lemma 3.17. *Under the assumptions of Lemma 3.14, the process S defined by (3.1) is $(V \times L^2_H, V \times C_H)$ pullback $\widehat{D}_\sigma$-asymptotically compact, where $\widehat{D}_\sigma = \{D_\sigma(t) : t \in \mathbb{R}\}$ is defined in Corollary 3.16.*

Proof. Let us consider $t \in \mathbb{R}$, a sequence $\{\tau_n\} \subset (-\infty, t]$ with $\tau_n \to -\infty$, and a sequence $\{(u^{\tau_n}, \phi^n)\}$ with $(u^{\tau_n}, \phi^n) \in D_\sigma(\tau_n)$ for all n. We must prove that the sequence

$$\{S(t,\tau_n)(u^{\tau_n}, \phi^n)\} = \{(u(t;\tau_n,u^{\tau_n},\phi^n), u_t(\cdot;\tau_n,u^{\tau_n},\phi^n))\}$$

is relatively compact in $V \times C_H$.

First, we check the asymptotic compactness in the first component of S. By Corollary 3.16, for each integer $k \geq 0$, there exists $\tau_{\widehat{D}_\sigma}(k) \leq t-k$ such that $S(t-k,\tau)D_\sigma(\tau) \subset D_\sigma(t-k)$ for all $\tau \leq \tau_{\widehat{D}_\sigma}(k)$. From this and a diagonal argument, we can extract a subsequence $\{(u^{\tau_{n'}}, \phi^{n'})\} \subset \{(u^{\tau_n}, \phi^n)\}$ such that

$$S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}) \rightharpoonup (w^k,\psi^k) \quad \text{weakly in } V \times L^2_V, \tag{3.12}$$

$$\frac{d}{ds}u_{t-k}(\cdot;\tau_{n'},u^{\tau_{n'}},\phi^{n'}) \rightharpoonup \frac{d}{ds}\psi^k \quad \text{weakly in } L^2_V, \tag{3.13}$$

for all integer $k \geq 0$, where $(w^k,\psi^k) \in D_\sigma(t-k)$.

Now, applying Proposition 3.10 on each fixed interval $[t-k,t]$, we deduce that

$$\begin{aligned}
(w^0,\psi^0) &= (V \times L^2_V) - \text{weak} \lim_{n'\to\infty} S(t,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}) \\
&= (V \times L^2_V) - \text{weak} \lim_{n'\to\infty} S(t,t-k)S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}) \\
&= S(t,t-k)\left[(V \times L^2_V) - \text{weak} \lim_{n'\to\infty} S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'})\right] \\
&= S(t,t-k)(w^k,\psi^k).
\end{aligned}$$

From (3.12) with $k=0$, we obtain in particular that $\|w^0\| \leq \liminf_{n'\to\infty}\|u(t;\tau_{n'},u^{\tau_{n'}},\phi^{n'})\|$. We will prove now that it also holds that

$$\limsup_{n'\to\infty}\|u(t;\tau_{n'},u^{\tau_{n'}},\phi^{n'})\| \leq \|w^0\|, \tag{3.14}$$

which combined with the weak converge of $u(t;\tau_{n'},u^{\tau_{n'}},\phi^{n'})$ to w^0 in V, will imply the convergence in the strong topology of V.

Observe that, as we already used in Lemma 3.11, for any $\tau \in \mathbb{R}$ and $(u^\tau,\phi) \in V \times L^2_H$, the solution $u(\cdot;\tau,u^\tau,\phi)$, for short denoted $u(\cdot)$, satisfies the differential equality

$$\begin{aligned}
\frac{d}{dt}(e^{\sigma t}|u(t)|^2 + \alpha^2 e^{\sigma t}\|u(t)\|^2) &= \sigma e^{\sigma t}|u(t)|^2 + \alpha^2\sigma e^{\sigma t}\|u(t)\|^2 - 2\nu e^{\sigma t}\|u(t)\|^2 \\
&\quad + 2e^{\sigma t}\langle f(t),u(t)\rangle + 2e^{\sigma t}(g(t,u_t),u(t)), \quad \text{a.e. } t > \tau.
\end{aligned} \tag{3.15}$$

Since in particular $0 < \sigma < 2\nu(\lambda_1^{-1}+\alpha^2)^{-1}$, notice that $[\cdot]$, with $[v]^2 = (2\nu - \alpha^2\sigma)\|v\|^2 - \sigma|v|^2$, defines an equivalent norm to $\|\cdot\|$ in V.

We integrate the above expression in the interval $[t-k,t]$ for the solutions $u(\cdot;\tau_{n'},u^{\tau_{n'}},\phi^{n'})$

with $\tau_{n'} \leq t-k$, which yields

$$
\begin{aligned}
&|u(t;\tau_{n'},u^{\tau_{n'}},\phi^{n'})|^2 + \alpha^2\|u(t;\tau_{n'},u^{\tau_{n'}},\phi^{n'})\|^2 \\
&\quad = |u(t;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}))|^2 + \alpha^2\|u(t;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}))\|^2 \\
&\quad = e^{-\sigma k}\left(|u(t-k;\tau_{n'},u^{\tau_{n'}},\phi^{n'})|^2 + \alpha^2\|u(t-k;\tau_{n'},u^{\tau_{n'}},\phi^{n'})\|^2\right) \\
&\qquad + 2\int_{t-k}^{t} e^{\sigma(s-t)}\langle f(s),u(s;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}))\rangle\,ds \\
&\qquad + 2\int_{t-k}^{t} e^{\sigma(s-t)}(g(s,u_s(\cdot;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}))),u(s;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'})))\,ds \\
&\qquad - \int_{t-k}^{t} e^{\sigma(s-t)}[u(s;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}))]^2\,ds. \qquad (3.16)
\end{aligned}
$$

On other hand, by (3.12), (3.13) and Proposition 3.10, we deduce that

$$u(\cdot;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'})) \rightharpoonup u(\cdot;t-k,w^k,\psi^k) \quad \text{weakly in } L^2(t-k,t;V).$$

From this, as $e^{\sigma(\cdot-t)}f(\cdot) \in L^2(t-k,t;V')$, it yields

$$
\begin{aligned}
\lim_{n'\to\infty}&\int_{t-k}^{t} e^{\sigma(s-t)}\langle f(s),u(s;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}))\rangle\,ds \\
&= \int_{t-k}^{t} e^{\sigma(s-t)}\langle f(s),u(s;t-k,w^k,\psi^k)\rangle\,ds.
\end{aligned}
$$

Since $\int_{t-k}^{t} e^{\sigma(s-t)}[v(s)]^2\,ds$ defines an equivalent norm in $L^2(t-k,t;V)$, we also deduce from above that

$$\int_{t-k}^{t} e^{\sigma(s-t)}[u(s;t-k,w^k,\psi^k)]^2\,ds \leq \liminf_{n'\to\infty}\int_{t-k}^{t} e^{\sigma(s-t)}[u(s;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}))]^2\,ds.$$

Finally, again by (3.12), (3.13) and Proposition 3.10, it holds that

$$u(\cdot;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'})) \to u(\cdot;t-k,w^k,\psi^k) \quad \text{strongly in } L^2(t-k-h,t;H),$$

and therefore,

$$
\begin{aligned}
\lim_{n'\to\infty}&\int_{t-k}^{t} e^{\sigma(s-t)}(g(s,u_s(\cdot;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}))),u(s;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'})))\,ds \\
&= \int_{t-k}^{t} e^{\sigma(s-t)}(g(s,u_s(\cdot;t-k,w^k,\psi^k)),u(s;t-k,w^k,\psi^k))\,ds \qquad (3.17)
\end{aligned}
$$

From (3.16)–(3.17), taking into account (3.12) with $k=0$, the compactness of the injection of V into H, and (3.10), we conclude that

$$
\begin{aligned}
&|w^0|^2 + \alpha^2\limsup_{n'\to\infty}\|u(t;\tau_{n'},u^{\tau_{n'}},\phi^{n'})\|^2 \\
&\quad \leq e^{-\sigma k}(\lambda_1^{-1}+\alpha^2)\tilde{\rho}_\sigma^2(t-k) + 2\int_{t-k}^{t} e^{\sigma(s-t)}\langle f(s),u(s;t-k,w^k,\psi^k)\rangle\,ds \\
&\qquad + 2\int_{t-k}^{t} e^{\sigma(s-t)}(g(s,u_s(\cdot;t-k,w^k,\psi^k)),u(s;t-k,w^k,\psi^k))\,ds \\
&\qquad - \int_{t-k}^{t} e^{\sigma(s-t)}[u(s;t-k,w^k,\psi^k)]^2\,ds.
\end{aligned}
$$

Now, taking into account that $w^0 = u(t; t-k, w^k, \psi^k)$, integrating again in (3.15), we obtain

$$|w^0|^2 + \alpha^2\|w^0\|^2 = e^{-\sigma k}(|w^k|^2 + \alpha^2\|w^k\|^2) + 2\int_{t-k}^t e^{\sigma(s-t)}\langle f(s), u(s; t-k, w^k, \psi^k)\rangle\, ds$$
$$+ 2\int_{t-k}^t e^{\sigma(s-t)}(g(s, u_s(\cdot; t-k, w^k, \psi^k)), u(s; t-k, w^k, \psi^k))\, ds$$
$$- \int_{t-k}^t e^{\sigma(s-t)}[u(s; t-k, w^k, \psi^k)]^2\, ds.$$

Comparing the above two expressions, in particular we conclude that

$$|w^0|^2 + \alpha^2 \limsup_{n'\to\infty} \|u(t; \tau_{n'}, u^{\tau_{n'}}, \phi^{n'})\|^2 \le e^{-\sigma k}(\lambda_1^{-1} + \alpha^2)\tilde{\rho}_\sigma^2(t-k) + |w^0|^2 + \alpha^2\|w^0\|^2.$$

But from Remark 3.15 and (3.11), we have that $\lim_{k\to\infty} e^{-\sigma k}\tilde{\rho}_\sigma^2(t-k) = 0$, so (3.14) holds, and we conclude that

$$u(t; \tau_{n'}, u^{\tau_{n'}}, \phi^{n'}) \to w^0 \quad \text{strongly in } V.$$

Finally, we prove the asymptotic compactness in the second component of S. From (3.12) and (3.13) with $k = 0$, we have that

$$u_t(\cdot; \tau_{n'}, u^{\tau_{n'}}, \phi^{n'}) \rightharpoonup \psi^0 \qquad \text{weakly in } L^2_V,$$
$$\frac{d}{ds}u_t(\cdot; \tau_{n'}, u^{\tau'_n}, \phi^{n'}) \rightharpoonup \frac{d}{ds}\psi^0 \quad \text{weakly in } L^2_V.$$

Thus, by applying the Ascoli–Arzelà theorem, we can deduce that there exists a subsequence (relabelled the same) such that $u_t(\cdot; \tau_{n'}, u^{\tau_{n'}}, \phi^{n'})$ converges to ψ^0 in C_H. So, the proof is finished. □

As a consequence of the above results, we obtain the existence of minimal pullback attractors for the process S on $V \times L^2_H$ defined by (3.1).

Theorem 3.18. *Assume that $g : \mathbb{R} \times C_H \to (L^2(\Omega))^3$ fulfills conditions (I)–(V), and $f \in L^2_{loc}(\mathbb{R}; V')$ satisfies (3.5). Then, there exist the $(V \times L^2_H, V \times C_H)$ minimal pullback $\mathcal{D}_\sigma(V \times L^2_H)$ and $\mathcal{D}_F(V \times L^2_H)$-attractors $\{\mathcal{A}_{\mathcal{D}_\sigma(V\times L^2_H)}(t) : t \in \mathbb{R}\}$ and $\{\mathcal{A}_{\mathcal{D}_F(V\times L^2_H)}(t) : t \in \mathbb{R}\}$ respectively, both belonging to $\mathcal{D}_\sigma(V \times L^2_H)$, which means that they have compact sections in $V \times C_H$ and pullback attracts in this norm, and the following relations hold:*

$$\mathcal{A}_{\mathcal{D}_F(V\times L^2_H)}(t) \subset \mathcal{A}_{\mathcal{D}_\sigma(V\times L^2_H)}(t) = \Lambda_{V\times C_H}(\widehat{D}_\sigma, t), \quad \forall\, t \in \mathbb{R}. \tag{3.18}$$

Moreover, if f satisfies the stronger requirement

$$\sup_{r\le 0}\left(e^{-\sigma r}\int_{-\infty}^r e^{\sigma s}\|f(s)\|_*^2\, ds\right) < \infty, \tag{3.19}$$

then both attractors coincide, i.e.,

$$\mathcal{A}_{\mathcal{D}_F(V\times L^2_H)}(t) = \mathcal{A}_{\mathcal{D}_\sigma(V\times L^2_H)}(t), \quad \forall\, t \in \mathbb{R}. \tag{3.20}$$

Proof. The process S is continuous on $V \times L^2_H$ by Corollary 3.9. By Remark 3.8, S is $(V \times L^2_H, V \times C_H)$ closed. There exists a pullback absorbing family $\widehat{D}_\sigma \in \mathcal{D}_\sigma(V \times L^2_H)$ by Corollary 3.16, and the process S is $(V \times L^2_H, V \times C_H)$ pullback $\widehat{D}_\sigma$-asymptotically compact by

Lemma 3.17. The existence of $\mathcal{A}_{\mathcal{D}_\sigma(V\times L^2_H)}$ and $\mathcal{A}_{\mathcal{D}_F(V\times L^2_H)}$ follows from Theorem 3.7 (actually Theorem 3.3 and Corollary 3.5 could also be applied, but using the bi-space attractors theory we strengthen compactness and attraction norm).

Moreover, the inclusion relation in (3.18) follows from Corollary 3.5.

The fact that $\mathcal{A}_{\mathcal{D}_\sigma(V\times L^2_H)}$ belongs to $\mathcal{D}_\sigma(V\times L^2_H)$ is due to Remark 3.4, since the pullback absorbing family $\widehat{D}_\sigma \in \mathcal{D}_\sigma(V\times L^2_H)$ has closed sections and this universe is inclusion-closed.

Finally, the equality (3.20) is a consequence of Corollary 3.5, since $D_\sigma(t) \subset \overline{B}_{V\times L^2_V}(0,\widetilde{\rho}_\sigma(t))$ for all $t\in\mathbb{R}$, and the assumption (3.19) is equivalent to have that $\sup_{t\le T}\widetilde{\rho}_\sigma(t)$ is bounded for any $T\in\mathbb{R}$. □

Just splitted for the sake of clarity, with the same arguments as above, we obtain the following result, which relates the above attractors for the universes $\mathcal{D}_F(V\times L^2_H)\subset\mathcal{D}_\sigma(V\times L^2_H)$ with new ones for the universes $\mathcal{D}_F(V\times C_H)\subset\mathcal{D}_\sigma(V\times C_H)$.

Corollary 3.19. *Under the assumptions of Theorem 3.18 there exist the minimal pullback attractors $\mathcal{A}_{\mathcal{D}_F(V\times C_H)}$ and $\mathcal{A}_{\mathcal{D}_\sigma(V\times C_H)}$, both belonging to $\mathcal{D}_\sigma(V\times C_H)$, all time sections are compact subsets in $V\times C_H$, they attract in $V\times C_H$ norm, and the following relations hold:*

$$\mathcal{A}_{\mathcal{D}_F(V\times C_H)}(t)\subset\mathcal{A}_{\mathcal{D}_F(V\times L^2_H)}(t)\subset\mathcal{A}_{\mathcal{D}_\sigma(V\times C_H)}(t)=\mathcal{A}_{\mathcal{D}_\sigma(V\times L^2_H)}(t),\quad \forall\, t\in\mathbb{R}.$$

Proof. Observe that S is well-defined on $V\times C_H$ by Theorem 2.2 and closed by Remark 2.4 (i). Observe that $\widehat{D}_\sigma\subset\mathcal{P}(V\times C_H)$. Then the existence of attractors and its inclusion in $\mathcal{D}_\sigma(V\times C_H)$ follows from Theorem 3.3 and Remark 3.4.

The equality relation of pullback $\mathcal{D}_\sigma(V\times C_H)$ and $\mathcal{D}_\sigma(V\times L^2_H)$-attractors follows from [13, Theorem 3.15]. Indeed, observe that after an elapsed time h, by (3.3), $S(\cdot+h,\cdot)$ maps elements from $\mathcal{D}_\sigma(V\times L^2_H)$ into $\mathcal{D}_\sigma(V\times C_H)$.

The rest of inclusions follows from Corollary 3.5 or by minimality arguments. □

Remark 3.20. The stronger attraction and compactness properties of these results also apply to several previous ones concerning asymptotic behavior of PDE with delays (e.g., cf. [16]).

Remark 3.21. Observe that by the invariance of the minimal pullback attractors under the process S, and the regularity of the solutions, it is clear that the second component of any time section of $\mathcal{A}_{\mathcal{D}_\sigma(V\times L^2_H)}$ and $\mathcal{A}_{\mathcal{D}_F(V\times L^2_H)}$ lives in C_V. In fact, denoting $R^2_\sigma(t)=2\rho^2_1(t)$, from (3.6) it holds that

$$\mathcal{A}_{\mathcal{D}_\sigma(V\times L^2_H)}(t)\subset\overline{B}_{V\times C_V}(0,R_\sigma(t)),\quad\forall\, t\in\mathbb{R}.$$

4 Regularity of the pullback attractors

The main goal of this paragraph is to provide some extra regularity for the attractors obtained in the previous section. This will be obtained by a bootstrapping argument, and making the most out of a representation of the solutions to the problem splitting it in two parts, the linear part with an exponential decay, and the nonlinear part with good enough estimates. In order to achieve these results, we will use the fractional powers of the Stokes operator, introduced in Section 2.

Observe that for every $\tau\in\mathbb{R}$, $(u^\tau,\phi)\in V\times L^2_H$, $f\in L^2_{loc}(\mathbb{R};V')$, and $g:\mathbb{R}\times C_H\to(L^2(\Omega))^3$ satisfying (I)–(IV), by Theorem 2.2, there exists a unique weak solution u to problem (1.1). Moreover, let us point out that the following representation of the solution holds:

$$u(t;\tau,u^\tau,\phi)=y(t;\tau,u^\tau,\phi)+z(t;\tau,0,0),\quad\forall\, t\ge\tau,$$

where $y = y(\cdot;\tau,u^\tau,\phi)$ and $z = z(\cdot;\tau,0,0)$ are solutions of

$$\begin{cases} y \in C([\tau,\infty);V) \cap L^2(\tau-h,T;H) \text{ for all } T > \tau, \\ \dfrac{d}{dt}(y(t)+\alpha^2 Ay(t)) + \nu Ay(t) = 0, \quad \text{in } \mathcal{D}'(\tau,\infty;V'), \\ y(\tau) = u^\tau, \\ y(t) = \phi(t-\tau) \quad \text{a.e. } t \in (\tau-h,\tau) \end{cases} \tag{4.1}$$

and

$$\begin{cases} z \in C([\tau,\infty);V) \cap L^2(\tau-h,T;H) \text{ for all } T > \tau, \\ \dfrac{d}{dt}(z(t)+\alpha^2 Az(t)) + \nu Az(t) = f(t) + g(t,u_t) - B(u(t)), \quad \text{in } \mathcal{D}'(\tau,\infty;V'), \\ z(\tau) = 0, \\ z(t) = 0 \quad \text{a.e.} t \in (\tau-h,\tau) \end{cases} \tag{4.2}$$

respectively.

The existence and uniqueness of weak solution to (4.1) and to (4.2) can be obtained reasoning as in the proof of Theorem 2.2.

For the problem (4.1) we have the following result.

Lemma 4.1. *For any $\tau \in \mathbb{R}$, $(u^\tau,\phi) \in V \times L^2_H$ and σ fulfilling that $0 < \sigma < 2(\nu - \lambda_1^{-1}C_g)(\lambda_1^{-1} + \alpha^2)^{-1}$, the solution $y = y(\cdot;\tau,u^\tau,\phi)$ of (4.1) satisfies*

$$\|y(t)\|^2 \le \alpha^{-2}(\lambda_1^{-1}+\alpha^2)e^{\sigma(\tau-t)}\|(u^\tau,\phi)\|^2_{V\times L^2_H} \quad \textit{for all } t \ge \tau. \tag{4.3}$$

Proof. It is analogous to the proof of (3.3), and we omit it. □

For the study of the problem (4.2), we will make use of the following lemma.

Lemma 4.2. *Let me given $F \in L^2_{loc}(\mathbb{R};D(A^{-\beta}))$ with $0 \le \beta \le 1/2$, $\tau \in \mathbb{R}$ and σ fulfilling that $0 < \sigma < 2(\nu - \lambda_1^{-1}C_g)(\lambda_1^{-1}+\alpha^2)^{-1}$. Then, the problem*

$$\begin{cases} z \in C([\tau,\infty);V) \cap L^2(\tau-h,T;H) \textit{ for all } T > \tau, \\ \dfrac{d}{dt}(z(t)+\alpha^2 Az(t)) + \nu Az(t) = F(t), \quad \textit{in } \mathcal{D}'(\tau,\infty;V'), \\ z(\tau) = 0, \\ z(t) = 0 \quad \text{a.e. } t \in (\tau-h,\tau) \end{cases}$$

has a unique solution z, which also satisfies $z \in C([\tau,\infty);D(A^{1-\beta}))$, and

$$|A^{1-\beta}z(t)|^2 \le \alpha^{-2}\varepsilon^{-1}\int_\tau^t e^{\sigma(s-t)}\left|A^{-\beta}F(s)\right|^2 ds \quad \textit{for all } t \ge \tau,$$

where ε is given by (3.4).

Proof. It can be done analogously as in [14, Lemma 26] with $z = 0$ in $(\tau-h,\tau)$. □

Now we can prove the following regularity result for the pullback attractors in V norm.

Theorem 4.3. *Consider given $g : \mathbb{R} \times C_H \to (L^2(\Omega))^3$ satisfying conditions (I)–(V). Assume that $f \in L^2_{loc}(\mathbb{R}; D(A^{-\beta}))$ for some $0 \le \beta \le 1/2$, and that*

$$\sup_{r\le 0} \int_{r-1}^{r} \|f(s)\|_*^2 ds < \infty. \tag{4.4}$$

Then:

(1) If f also satisfies

$$\int_{-\infty}^{0} e^{\sigma s} |A^{-\beta} f(s)|^2 ds < \infty, \tag{4.5}$$

and

$$\begin{cases} \sup_{r\le 0} \int_{r-1}^{r} |A^{-1/4-\beta} f(s)|^2 ds < \infty, & \text{if } 0 < \beta < 1/4, \\ \sup_{r\le 0} \int_{r-1}^{r} |A^{-\delta} f(s)|^2 ds < \infty & \text{for some } 0 < \delta < 1/4, \text{ if } \beta = 0, \end{cases} \tag{4.6}$$

then, for any $t_1 < t_2$, the pullback attractor $\mathcal{A}_{\mathcal{D}_\sigma(V\times L^2_H)} = \mathcal{A}_{\mathcal{D}_F(V\times L^2_H)}$ fulfills that

$$\bigcup_{t_1\le t\le t_2} \mathcal{A}_{\mathcal{D}_\sigma(V\times L^2_H)}(t) = \bigcup_{t_1\le t\le t_2} \mathcal{A}_{\mathcal{D}_F(V\times L^2_H)}(t) \text{ is a bounded subset of } D(A^{1-\beta}) \times C_{D(A^{1-\beta})}. \tag{4.7}$$

(2) If f also satisfies

$$\sup_{r\le 0} \int_{r-1}^{r} |A^{-\beta} f(s)|^2 ds < \infty, \tag{4.8}$$

then, for any $t_2 \in \mathbb{R}$, it holds that

$$\bigcup_{t\le t_2} \mathcal{A}_{\mathcal{D}_\sigma(V\times L^2_H)}(t) = \bigcup_{t\le t_2} \mathcal{A}_{\mathcal{D}_F(V\times L^2_H)}(t) \text{ is a bounded subset of } D(A^{1-\beta}) \times C_{D(A^{1-\beta})}. \tag{4.9}$$

Proof. Let us fix $t \in \mathbb{R}$ and $(v,\psi) \in \mathcal{A}_{\mathcal{D}_\sigma(V\times L^2_H)}(t) = \mathcal{A}_{\mathcal{D}_F(V\times L^2_H)}(t)$. By Remark 3.21 and (4.4), we see that

$$\bigcup_{r\le t} \mathcal{A}_{\mathcal{D}_\sigma(V\times L^2_H)}(r) \subset \overline{B}_{V\times C_V}(0, \widetilde{R}_\sigma(t)), \tag{4.10}$$

where $\widetilde{R}_\sigma^2(t) = 2 + 2\alpha^{-2}\varepsilon^{-1}e^{2\sigma h} \sup_{r\le t}(e^{-\sigma r}\int_{-\infty}^{r} e^{\sigma s}\|f(s)\|_*^2 ds)$, with ε given by (3.4).

Let $\{\tau_n\}_{n\ge 1} \subset (-\infty, t-h]$ be a sequence with $\tau_n \to -\infty$ as $n \to \infty$. By the invariance of $\mathcal{A}_{\mathcal{D}_\sigma(V\times L^2_H)}$, for each $n \ge 1$ there exists $(u^{\tau_n}, \phi^n) \in \mathcal{A}_{\mathcal{D}_\sigma(V\times L^2_H)}(\tau_n)$ such that $(v,\psi) = S(t,\tau_n)(u^{\tau_n},\phi^n)$, and therefore,

$$(v,\psi) = Y(t,\tau_n)(u^{\tau_n},\phi^n) + Z(t,\tau_n)(0,0),$$

where

$$Y(t,\tau_n)(u^{\tau_n},\phi^n) = (y(t;\tau_n,u^{\tau_n},\phi^n), y_t(\cdot;\tau_n,u^{\tau_n},\phi^n))$$

and

$$Z(t,\tau_n)(0,0) = (z(t;\tau_n,0,0), z_t(\cdot;\tau_n,0,0))$$

are continuous processes on $V \times L^2_H$ associated to problems (4.1) and (4.2), respectively.

From (4.3) and (4.10) we deduce that $\|Y(t,\tau_n)(u^{\tau_n},\phi^n)\|_{V\times C_V} \to 0$ as $n \to \infty$. Thus,

$$\lim_{n\to\infty} \|Z(t,\tau_n)(0,0) - (v,\psi)\|_{V\times C_V} = 0. \tag{4.11}$$

Let us denote $(u^n(r), u^n_r(\cdot)) = S(r, \tau_n)(u^{\tau_n}, \phi^n)$ for $r \geq \tau_n$ and $n \geq 1$. By (4.10) and the invariance of $\mathcal{A}_{\mathcal{D}_\sigma(V\times L^2_H)}$,

$$(u^n(r), u^n_r(\cdot)) \in \mathcal{A}_{\mathcal{D}_\sigma(V\times L^2_H)}(r) \subset \overline{B}_{V\times C_V}(0, \widetilde{R}_\sigma(t)), \quad \forall \tau_n \leq r \leq t, \quad \forall n \geq 1. \tag{4.12}$$

Now we distinguish three cases.

Case 1. If $1/4 \leq \beta \leq 1/2$.

In this case, from (2.11), the continuous injection of V in $D(A^{3/4-\beta})$ and (4.12), we deduce that

$$\begin{aligned} |A^{-\beta}B(u^n(r))| &\leq C_{(3/4-\beta)}|A^{3/4-\beta}u^n(r)|\|u^n(r)\| \\ &\leq \widetilde{C}_{(3/4-\beta)}\|u^n(r)\|^2 \\ &\leq \widetilde{C}_{(3/4-\beta)}\widetilde{R}^2_\sigma(t), \quad \forall \tau_n \leq r \leq t, \quad \forall n \geq 1. \end{aligned}$$

Thus, if we assume (4.5), from Lemma 4.2, condition (V) on g, and the continuous injection of H in $D(A^{-\beta})$, we obtain that

$$\begin{aligned} |A^{1-\beta}z(\theta;\tau_n,0,0)|^2 &\leq 3\alpha^{-2}\varepsilon^{-1}e^{\sigma h}\left(\int_{-\infty}^t e^{\sigma(s-t)}|A^{-\beta}f(s)|^2\,ds + \sigma^{-1}\widetilde{C}^2_{(3/4-\beta)}\widetilde{R}^4_\sigma(t)\right. \\ &\quad \left. + \int_{\tau_n}^t e^{\sigma(s-t)}|A^{-\beta}g(s,u^n_s)|^2\,ds\right) \\ &\leq 3\alpha^{-2}\varepsilon^{-1}e^{\sigma h}\left(\int_{-\infty}^t e^{\sigma(s-t)}|A^{-\beta}f(s)|^2\,ds + \sigma^{-1}\widetilde{C}^2_{(3/4-\beta)}\widetilde{R}^4_\sigma(t)\right. \\ &\quad \left. + C_\beta C_g^2\lambda_1^{-1}\left(\int_{\tau_n-h}^{\tau_n} e^{\sigma(s-t)}\|\phi^n(s-\tau_n)\|^2\,ds + \int_{\tau_n}^t e^{\sigma(s-t)}\|u^n(s)\|^2\,ds\right)\right) \end{aligned}$$

for all $\theta \in [t-h, t]$, and then, from (4.12), we deduce that

$$\|Z(t,\tau_n)(0,0)\|^2_{D(A^{1-\beta})\times C_{D(A^{1-\beta})}} \leq M^2_{\sigma,\beta}(t), \tag{4.13}$$

where

$$M^2_{\sigma,\beta}(t) = 6\alpha^{-2}\varepsilon^{-1}e^{\sigma h}\left(\int_{-\infty}^t e^{\sigma(s-t)}|A^{-\beta}f(s)|^2\,ds + \sigma^{-1}\widetilde{C}^2_{(3/4-\beta)}\widetilde{R}^4_\sigma(t) + 2C_\beta C_g^2\lambda_1^{-1}\sigma^{-1}\widetilde{R}^2_\sigma(t)\right).$$

From (4.11), (4.13) and the weak lower semi-continuity of the norm, we deduce that (v,ψ) belongs to $\overline{B}_{D(A^{1-\beta})\times C_{D(A^{1-\beta})}}(0, M_{\sigma,\beta}(t))$, and therefore (4.7) holds.

Moreover, if f satisfies (4.8), then (4.9) holds, and more exactly,

$$\bigcup_{t\leq t_2} \mathcal{A}_{\mathcal{D}_\sigma(V\times L^2_H)}(t) \subset \overline{B}_{D(A^{1-\beta})\times C_{D(A^{1-\beta})}}(0, \widetilde{M}_{\sigma,\beta}(t_2)), \quad \text{for all } t_2 \in \mathbb{R}, \tag{4.14}$$

where

$$\begin{aligned} \widetilde{M}^2_{\sigma,\beta}(t_2) = 6\alpha^{-2}\varepsilon^{-1}e^{\sigma h}\Bigg(&\sup_{t\leq t_2}\int_{-\infty}^t e^{\sigma(s-t)}|A^{-\beta}f(s)|^2 ds \\ &+ \sigma^{-1}\widetilde{C}^2_{(3/4-\beta)}\widetilde{R}^4_\sigma(t_2) + 2C_\beta C_g^2\lambda_1^{-1}\sigma^{-1}\widetilde{R}^2_\sigma(t_2)\Bigg). \end{aligned}$$

Case 2. If $0 < \beta < 1/4$.

In this case, if f satisfies (4.6), as $1/4 < 1/4+\beta < 1/2$, from (4.14) we have that

$$\bigcup_{r\le t}\mathcal{A}_{\mathcal{D}_\sigma(V\times L^2_H)}(r)\subset \overline{B}_{D(A^{3/4-\beta})\times C_{D(A^{3/4-\beta})}}(0,\widetilde{M}_{\sigma,1/4+\beta}(t)).$$

Thus, by (2.11) and (4.12), we obtain that

$$\begin{aligned}|A^{-\beta}B(u^n(r))| &\le C_{(3/4-\beta)}|A^{3/4-\beta}u^n(r)|\|u^n(r)\|\\ &\le C_{(3/4-\beta)}\widetilde{M}_{\sigma,1/4+\beta}(t)\widetilde{R}_\sigma(t),\quad \forall\tau_n\le r\le t,\quad \forall n\ge 1.\end{aligned}$$

Thus, if we assume (4.5), from Lemma 4.2 we deduce that

$$\|Z(t,\tau_n)(0,0)\|^2_{D(A^{1-\beta})\times C_{D(A^{1-\beta})}}\le R^2_{\sigma,\beta}(t), \tag{4.15}$$

where

$$R^2_{\sigma,\beta}(t)=6\alpha^{-2}\varepsilon^{-1}e^{\sigma h}\bigg(\int_{-\infty}^t e^{\sigma(s-t)}|A^{-\beta}f(s)|^2\,ds \\ +\sigma^{-1}C^2_{(3/4-\beta)}\widetilde{M}^2_{\sigma,1/4+\beta}(t)\widetilde{R}^2_\sigma(t)+2C_\beta C_g^2\lambda_1^{-1}\sigma^{-1}\widetilde{R}^2_\sigma(t)\bigg).$$

Again, from (4.11), (4.15) and the weak lower semi-continuity of the norm, we deduce that (v,ψ) belongs to $\overline{B}_{D(A^{1-\beta})\times C_{D(A^{1-\beta})}}(0,R_{\sigma,\beta}(t))$, and therefore (4.7) holds.

Moreover, if f satisfies (4.8), then (4.9) holds, and more exactly,

$$\bigcup_{t\le t_2}\mathcal{A}_{\mathcal{D}_\sigma(V\times L^2_H)}(t)\subset \overline{B}_{D(A^{1-\beta})\times C_{D(A^{1-\beta})}}(0,\widetilde{R}_{\sigma,\beta}(t_2)),\quad \text{for all } t_2\in\mathbb{R}, \tag{4.16}$$

where

$$\widetilde{R}^2_{\sigma,\beta}(t_2)=6\alpha^{-2}\varepsilon^{-1}e^{\sigma h}\bigg(\sup_{t\le t_2}\int_{-\infty}^t e^{\sigma(s-t)}|A^{-\beta}f(s)|^2\,ds \\ +\sigma^{-1}C^2_{(3/4-\beta)}\widetilde{M}^2_{\sigma,1/4+\beta}(t_2)\widetilde{R}^2_\sigma(t_2)+2C_\beta C_g^2\lambda_1^{-1}\sigma^{-1}\widetilde{R}^2_\sigma(t_2)\bigg).$$

Case 3. If $\beta=0$.

In this case, if f satisfies (4.6), as $0<\delta<1/4$, from (4.16) we see that

$$\bigcup_{r\le t}\mathcal{A}_{\mathcal{D}_\sigma(V\times L^2_H)}(r)\subset \overline{B}_{D(A^{1-\delta})\times C_{D(A^{1-\delta})}}(0,\widetilde{R}_{\sigma,\delta}(t)).$$

So, by (2.10) and (4.12), we deduce that

$$\begin{aligned}|B(u^n(r))| &\le C_{(1-\delta)}|A^{1-\delta}u^n(r)|\|u^n(r)\|\\ &\le C_{(1-\delta)}\widetilde{R}_{\sigma,\delta}(t)\widetilde{R}_\sigma(t),\quad \forall\tau_n\le r\le t,\quad \forall n\ge 1.\end{aligned}$$

Thus, if we assume (4.5), from Lemma 4.2 we deduce that

$$\|Z(t,\tau_n)(0,0)\|^2_{D(A)\times C_{D(A)}}\le R^2_{\sigma,\delta,0}(t) \tag{4.17}$$

where

$$R^2_{\sigma,\delta,0}(t)=6\alpha^{-2}\varepsilon^{-1}e^{\sigma h}\bigg(\int_{-\infty}^t e^{\sigma(s-t)}|f(s)|^2\,ds+\sigma^{-1}C^2_{(1-\delta)}\widetilde{R}^2_{\sigma,\delta}(t)\widetilde{R}^2_\sigma(t)+2C_g^2\lambda_1^{-1}\sigma^{-1}\widetilde{R}^2_\sigma(t)\bigg).$$

Again, from (4.11), (4.17) and the weak lower semi-continuity of the norm, we deduce that

$$(v, \psi) \in \overline{B}_{D(A)\times C_{D(A)}}(0, R_{\sigma,\delta,0}(t)),$$

and therefore (4.7) holds.

Moreover, if f satisfies (4.8), then (4.9) holds, and more exactly,

$$\bigcup_{t\le t_2} \mathcal{A}_{\mathcal{D}_\sigma(V\times L^2_H)}(t) \subset \overline{B}_{D(A)\times C_{D(A)}}(0, \widetilde{R}_{\sigma,\delta,0}(t_2)), \text{ for all } t_2 \in \mathbb{R},$$

where

$$\widetilde{R}^2_{\sigma,\delta,0}(t_2) = 6\alpha^{-2}\varepsilon^{-1}e^{\sigma h}\left(\sup_{t\le t_2}\int_{-\infty}^{t} e^{\sigma(s-t)}|f(s)|^2\,ds \right.$$
$$\left. + \sigma^{-1}C^2_{(1-\delta)}\widetilde{R}^2_{\sigma,\delta}(t_2)\widetilde{R}^2_{\sigma}(t_2) + 2C_g^2\lambda_1^{-1}\sigma^{-1}\widetilde{R}^2_\sigma(t_2)\right). \quad \square$$

5 Attraction in $D(A)$ norm

By the previous results, when $f \in L^2_{loc}(\mathbb{R};(L^2(\Omega))^3)$, the restriction to $D(A)\times L^2_V$ of the process S defined by (3.1) is a process on $D(A)\times L^2_V$. Now, we will prove that under suitable assumptions on f and g, we can obtain the existence of minimal pullback attractors for S on $D(A)\times L^2_V$ and even more.

Proposition 5.1. *Assume that $f \in L^2_{loc}(\mathbb{R};(L^2(\Omega))^3)$, and $g : \mathbb{R}\times C_H \to (L^2(\Omega))^3$ satisfying (I)–(IV), are given. Then, the restriction to $D(A)\times L^2_V$ of the bi-parametric family of maps $S(t,\tau)$, with $\tau \le t$, given by (3.1), is a continuous process on $D(A)\times L^2_V$.*

Proof. It is a consequence of Theorem 2.2 and Remark 2.4 (i). □

As in the previous section, we will need the following continuity result for the process S in a weak sense.

Proposition 5.2. *Let $f \in L^2_{loc}(\mathbb{R};(L^2(\Omega))^3)$, $g : \mathbb{R}\times C_H \to (L^2(\Omega))^3$ satisfying (I)–(IV), and $\tau < t$ be given. Then, for any sequence such that*

$$(u^{\tau,n}, \phi^n) \rightharpoonup (u^\tau, \phi) \text{ weakly in } D(A)\times L^2_{D(A)}$$

and

$$\frac{d\phi^n}{ds} \rightharpoonup \frac{d\phi}{ds} \text{ weakly in } L^2_{D(A)},$$

the following convergences hold for the sequence of solutions $u(\cdot;\tau,u^{\tau,n},\phi^n)$ towards the solution $u(\cdot;\tau,u^\tau,\phi)$:

$$u(\cdot;\tau,u^{\tau,n},\phi^n) \overset{*}{\rightharpoonup} u(\cdot;\tau,u^\tau,\phi) \text{ weakly-star in } L^\infty(\tau,t;D(A)),$$

$$u(\cdot;\tau,u^{\tau,n},\phi^n) \to u(\cdot;\tau,u^\tau,\phi) \text{ strongly in } C([\tau-h,t];V),$$

$$u(t;\tau,u^{\tau,n},\phi^n) \rightharpoonup u(t;\tau,u^\tau,\phi) \text{ weakly in } D(A),$$

$$u(\cdot;\tau,u^{\tau,n},\phi^n) \rightharpoonup u(\cdot;\tau,u^\tau,\phi) \text{ weakly in } L^2(\tau-h,t;D(A)).$$

Proof. It can be done analogously to that of Proposition 3.10. □

For the obtention of a pullback absorbing family for the process S restricted to $D(A) \times L^2_V$, we first have the following result.

Lemma 5.3. *Suppose that $f \in L^2_{loc}(\mathbb{R}; (L^2(\Omega))^3)$ satisfies (4.4) and that $g : \mathbb{R} \times C_H \to (L^2(\Omega))^3$ fulfills conditions (I)–(V). Then, for any $\tau \in \mathbb{R}$, $(u^\tau, \phi) \in D(A) \times L^2_V$, and $0 < \underline{\sigma} < \sigma/3$, the solution $u = u(\cdot; \tau, u^\tau, \phi)$ of (1.1) satisfies*

$$|Au(t)|^2 \leq \alpha^{-2} \max\{\lambda_1^{-1} + \alpha^2, C_g\} e^{\sigma(\tau - t)} \|(u^\tau, \phi)\|^2_{D(A)\times L^2_V} + 2\alpha^{-2}\varepsilon^{-1} \int_\tau^t e^{\sigma(s-t)} |f(s)|^2\, ds$$
$$+ 4\alpha^{-2} C_\varepsilon C^3_{\underline{\sigma}} (\sigma - 3\underline{\sigma})^{-1} \left(e^{-3\underline{\sigma}(t-\tau)} \|(u^\tau, \phi)\|^6_{V \times L^2_H} + M^3_{t,\underline{\sigma}} \right) \tag{5.1}$$

for all $t \geq \tau$, where $\varepsilon > 0$ is given by (3.4),

$$C_\varepsilon = 27 C_2^4 (2\varepsilon^3)^{-1}, \tag{5.2}$$

$$C_{\underline{\sigma}} = \alpha^{-2} \max\left\{ \max\{\lambda_1^{-1} + \alpha^2, C_g\}, \left(2\nu - \underline{\sigma}(\lambda_1^{-1} + \alpha^2) - 2\lambda_1^{-1} C_g\right)^{-1} \right\}, \tag{5.3}$$

and

$$M_{t,\underline{\sigma}} = \sup_{r \leq t} \int_{-\infty}^r e^{\underline{\sigma}(s-r)} \|f(s)\|^2_* ds. \tag{5.4}$$

Proof. From Lemma 3.11, we have that

$$\|u(s)\|^2 \leq C_{\underline{\sigma}} \left(e^{\underline{\sigma}(\tau - s)} \|(u^\tau, \phi)\|^2_{V \times L^2_H} + M_{t,\underline{\sigma}} \right), \quad \forall \tau \leq s \leq t. \tag{5.5}$$

On the other hand, by (2.17),

$$\frac{d}{dt}(e^{\sigma t}\|u(t)\|^2 + \alpha^2 e^{\sigma t}|Au(t)|^2) + 2\nu e^{\sigma t}|Au(t)|^2 + 2e^{\sigma t}(B(u(t)), Au(t))$$
$$= \sigma e^{\sigma t}\|u(t)\|^2 + \alpha^2 \sigma e^{\sigma t}|Au(t)|^2 + 2e^{\sigma t}(f(t) + g(t, u_t), Au(t)), \quad \text{a.e. } t > \tau.$$

Thus, taking into account that $\|u(t)\|^2 \leq \lambda_1^{-1}|Au(t)|^2$,

$$2|\,(B(u(t)), Au(t))\,| \leq 2C_2 \|u(t)\|^{3/2} |Au(t)|^{3/2}$$
$$\leq C_\varepsilon \|u(t)\|^6 + \frac{\varepsilon}{2}|Au(t)|^2,$$
$$2|\,(f(t), Au(t))\,| \leq \frac{\varepsilon}{2}|Au(t)|^2 + \frac{2}{\varepsilon}|f(t)|^2,$$

and

$$2|(g(t, u_t), Au(t))| \leq \frac{C_g}{\lambda_1}|Au(t)|^2 + \frac{\lambda_1}{C_g}|g(t, u_t)|^2,$$

we deduce that

$$e^{\sigma t}(\|u(t)\|^2 + \alpha^2|Au(t)|^2) + (2\nu - \varepsilon - \sigma(\lambda_1^{-1} + \alpha^2) - \lambda_1^{-1}C_g) \int_\tau^t e^{\sigma s}|Au(s)|^2\, ds$$
$$\leq e^{\sigma\tau}(\lambda_1^{-1} + \alpha^2)|Au^\tau|^2 + 2\varepsilon^{-1} \int_\tau^t e^{\sigma s}|f(s)|^2\, ds + \lambda_1 C_g \int_{\tau - h}^t e^{\sigma s}|u(s)|^2\, ds$$
$$+ C_\varepsilon \int_\tau^t e^{\sigma s}\|u(s)\|^6\, ds$$
$$\leq e^{\sigma\tau}\left((\lambda_1^{-1} + \alpha^2)|Au^\tau|^2 + C_g\|\phi\|^2_{L^2_V}\right) + 2\varepsilon^{-1} \int_\tau^t e^{\sigma s}|f(s)|^2\, ds + \lambda_1^{-1} C_g \int_\tau^t e^{\sigma s}|Au(s)|^2\, ds$$
$$+ C_\varepsilon \int_\tau^t e^{\sigma s}\|u(s)\|^6\, ds$$

for all $t \geq \tau$.

From this inequality, since the choice of ε makes the term $\int_\tau^t e^{\sigma s}|Au(s)|^2\,ds$ disappear, using (5.5) we easily obtain (5.1). □

Definition 5.4. For any $\sigma, \underline{\sigma} > 0$, consider the universe $\mathcal{D}_\sigma(D(A) \times L^2_V) \cap \mathcal{D}_{\underline{\sigma}}(V \times L^2_H)$ formed by the class of all families of nonempty subsets $\widehat{D} = \{D(t) : t \in \mathbb{R}\} \subset \mathcal{P}(D(A) \times L^2_V)$ such that

$$\lim_{\tau\to-\infty}\left(e^{\sigma\tau}\sup_{(v,\varphi)\in D(\tau)}\|(v,\varphi)\|^2_{D(A)\times L^2_V}\right) = \lim_{\tau\to-\infty}\left(e^{\underline{\sigma}\tau}\sup_{(v,\varphi)\in D(\tau)}\|(v,\varphi)\|^2_{V\times L^2_H}\right) = 0.$$

Accordingly to the notation introduced in Section 3, $\mathcal{D}_F(D(A) \times L^2_V)$ will denote the class of families $\widehat{D} = \{D(t) = D : t \in \mathbb{R}\}$ with D a fixed nonempty bounded subset of $D(A) \times L^2_V$. Observe that the universe $\mathcal{D}_\sigma(D(A) \times L^2_V) \cap \mathcal{D}_{\underline{\sigma}}(V \times L^2_H)$, which is inclusion-closed, contains the universe $\mathcal{D}_F(D(A) \times L^2_V)$.

Remark 5.5. Under the additional assumption

$$\int_{-\infty}^0 e^{\sigma s}|f(s)|^2\,ds < \infty, \tag{5.6}$$

from Lemma 5.3 it is easy to see that, for $0 < \underline{\sigma} < \sigma/3$, the family $\{\overline{B}_{D(A)\times L^2_V}(0, \widetilde{R}_{\sigma,\underline{\sigma}}(t)) : t \in \mathbb{R}\} \subset \mathcal{P}(D(A) \times L^2_V)$ is pullback $\mathcal{D}_\sigma(D(A) \times L^2_V) \cap \mathcal{D}_{\underline{\sigma}}(V \times L^2_H)$-absorbing for the process S on $D(A) \times L^2_V$, where

$$\widetilde{R}^2_{\sigma,\underline{\sigma}}(t) = 1 + 2\alpha^{-2}\varepsilon^{-1}(1+\lambda_1^{-1}he^{\sigma h})e^{-\sigma t}\int_{-\infty}^t e^{\sigma s}|f(s)|^2\,ds + (1+\lambda_1^{-1}h)4\alpha^{-2}C_\varepsilon C^3_{\underline{\sigma}}(\sigma-3\underline{\sigma})^{-1}M^3_{t,\underline{\sigma}}.$$

However, in order to apply Proposition 5.2, we need to obtain a different pullback $\mathcal{D}_\sigma(D(A) \times L^2_V) \cap \mathcal{D}_{\underline{\sigma}}(V \times L^2_H)$-absorbing family.

Lemma 5.6. *Assume that $f \in L^2_{loc}(\mathbb{R}; (L^2(\Omega))^3)$ satisfies (4.4) and (5.6), and $g : \mathbb{R} \times C_H \to (L^2(\Omega))^3$ fulfills conditions (I)–(V). Then, for $0 < \underline{\sigma} < \sigma/3$ and for any $t \in \mathbb{R}$ and $\widehat{D} \in \mathcal{D}_\sigma(D(A) \times L^2_V) \cap \mathcal{D}_{\underline{\sigma}}(V \times L^2_H)$, there exist $\tau_2(\widehat{D}, t, h) < t - 2h$ and functions $\{\rho_i\}_{i=3}^4$ such that for any $\tau \leq \tau_2(\widehat{D}, t, h)$ and any $(u^\tau, \phi) \in D(\tau)$, it holds*

$$|Au(r;\tau,u^\tau,\phi)|^2 \leq \rho_3^2(t), \quad \forall r \in [t-2h, t], \tag{5.7}$$

$$\int_{t-h}^t |Au'(\theta;\tau,u^\tau,\phi)|^2\,d\theta \leq \rho_4^2(t), \tag{5.8}$$

where

$$\rho_3^2(t) = 1 + 2\alpha^{-2}\varepsilon^{-1}e^{-\sigma(t-2h)}\int_{-\infty}^t e^{\sigma s}|f(s)|^2\,ds + 4\alpha^{-2}C_\varepsilon C^3_{\underline{\sigma}}(\sigma-3\underline{\sigma})^{-1}M^3_{t,\underline{\sigma}}, \tag{5.9}$$

$$\rho_4^2(t) = 16\alpha^{-4}h\rho_3^2(t)\left(\nu^2 + C_2^2\lambda_1^{-3/2}\rho_3^2(t) + 2\lambda_1^{-2}C_g^2\right) + 16\alpha^{-4}\int_{t-h}^t |f(s)|^2\,ds, \tag{5.10}$$

where $\varepsilon, C_\varepsilon, C_{\underline{\sigma}}$ and $M_{t,\underline{\sigma}}$ are given by (3.4), (5.2), (5.3) and (5.4), respectively.

Proof. Let $\tau_2(\widehat{D}, t, h) < t - 2h$ be such that

$$\alpha^{-2}\max\{\lambda_1^{-1}+\alpha^2, C_g\}e^{-\sigma(t-2h)}e^{\sigma\tau}\|(u^\tau,\phi)\|^2_{D(A)\times L^2_V}$$
$$+ 4\alpha^{-2}C_\varepsilon C^3_{\underline{\sigma}}(\sigma-3\underline{\sigma})^{-1}e^{-3\underline{\sigma}(t-2h)}e^{3\underline{\sigma}\tau}\|(u^\tau,\phi)\|^6_{V\times L^2_H} \leq 1 \quad \forall\tau \leq \tau_2(\widehat{D},t,h),\ (u^\tau,\phi) \in D(\tau).$$

Consider fixed $\tau \leq \tau_2(\widehat{D}, t, h)$ and $(u^\tau, \phi) \in D(\tau)$. The estimate (5.7) follows directly from (5.1), using the increasing character of the exponential.

Now, from (2.9), (2.14) and (2.1), we obtain that $v = \mathcal{C}u$ satisfies

$$\begin{aligned}|v'(\theta)| &\leq \nu|Au(\theta)| + C_2|Au(\theta)|^{1/2}\|u(\theta)\|^{3/2} + |f(\theta)| + |g(\theta, u_\theta)| \\ &\leq \nu|Au(\theta)| + C_2\lambda_1^{-3/4}|Au(\theta)|^2 + |f(\theta)| + |g(\theta, u_\theta)|, \quad \text{a.e. } \theta > \tau,\end{aligned}$$

and therefore,

$$|v'(\theta)|^2 \leq 4\nu^2|Au(\theta)|^2 + 4C_2^2\lambda_1^{-3/2}|Au(\theta)|^4 + 4|f(\theta)|^2 + 4|g(\theta, u_\theta)|^2, \quad \text{a.e. } \theta > \tau.$$

Integrating in time above and using properties (II) and (IV) on g, we deduce

$$\begin{aligned}\int_{t-h}^t |v'(\theta)|^2\, d\theta \leq 4\nu^2 \int_{t-h}^t |Au(\theta)|^2\, d\theta + 4C_2^2\lambda_1^{-3/2} \int_{t-h}^t |Au(\theta)|^4\, d\theta \\ + 4\int_{t-h}^t |f(\theta)|^2\, d\theta + 4\lambda_1^{-2}C_g^2 \int_{t-2h}^t |Au(\theta)|^2\, d\theta,\end{aligned}$$

whence, by (2.13) and (5.7), the estimate (5.8) follows. □

Corollary 5.7. *Under the assumptions of Lemma 5.6, for $0 < \underline{\sigma} < \sigma/3$, the family $\widehat{D}_{\sigma,\underline{\sigma}} = \{D_{\sigma,\underline{\sigma}}(t) : t \in \mathbb{R}\} \subset \mathcal{P}(D(A) \times L_V^2)$ defined by*

$$\begin{aligned}D_{\sigma,\underline{\sigma}}(t) = \Big\{(w, \psi) \in D(A) \times L^2_{D(A)} : \exists \frac{d\psi}{ds} \in L^2_{D(A)}, \\ \|(w, \psi)\|_{D(A)\times L^2_{D(A)}} \leq R_{\sigma,\underline{\sigma}}(t), \left\|\frac{d\psi}{ds}\right\|_{L^2_{D(A)}} \leq \rho_4(t)\Big\}\end{aligned} \tag{5.11}$$

is pullback $\mathcal{D}_\sigma(D(A) \times L_V^2) \cap \mathcal{D}_{\underline{\sigma}}(V \times L_H^2)$-absorbing for the process S on $D(A) \times L_V^2$ defined by (3.1), (and therefore $\mathcal{D}_F(D(A) \times L_V^2)$-absorbing too), where $R_{\sigma,\underline{\sigma}}(t)$ satisfies

$$R^2_{\sigma,\underline{\sigma}}(t) = (1 + h)\rho_3^2(t), \tag{5.12}$$

with $\rho_3(t)$ and $\rho_4(t)$ given by (5.9) and (5.10) respectively.

Now, we prove that the process S is $(D(A) \times L_V^2, D(A) \times C_V)$ pullback $\mathcal{D}_\sigma(D(A) \times L_V^2) \cap \mathcal{D}_{\underline{\sigma}}(V \times L_H^2)$-asymptotically compact. We will apply, under the natural necessary changes, the same energy method used in the proof of Lemma 3.17.

Lemma 5.8. *Assume that $f \in L^2_{loc}(\mathbb{R}; (L^2(\Omega))^3)$ satisfies (4.4) and (5.6), and $g : \mathbb{R} \times C_H \to (L^2(\Omega))^3$ fulfills conditions (I)–(V). Then, for any $0 < \underline{\sigma} < \sigma/3$, the restriction to $D(A) \times L_V^2$ of the process S defined by (3.1) is $(D(A) \times L_V^2, D(A) \times C_V)$ pullback $\mathcal{D}_\sigma(D(A) \times L_V^2) \cap \mathcal{D}_{\underline{\sigma}}(V \times L_H^2)$-asymptotically compact.*

Proof. Let us fix $0 < \underline{\sigma} < \sigma/3$. Let be given $\widehat{D} \in \mathcal{D}_\sigma(D(A) \times L_V^2) \cap \mathcal{D}_{\underline{\sigma}}(V \times L_H^2)$, $t \in \mathbb{R}$, a sequence $\{\tau_n\} \subset (-\infty, t]$ with $\tau_n \to -\infty$, and a sequence $\{(u^{\tau_n}, \phi^n)\}$ with $(u^{\tau_n}, \phi^n) \in D(\tau_n)$ for all n. We must prove that the sequence

$$\{S(t, \tau_n)(u^{\tau_n}, \phi^n)\} = \{(u(t; \tau_n, u^{\tau_n}, \phi^n), u_t(\cdot; \tau_n, u^{\tau_n}, \phi^n))\}$$

is relatively compact in $D(A) \times C_V$.

First, we check the asymptotic compactness in the first component of S. By Corollary 5.7, for each integer $k \geq 0$, there exists $\tau_{\widehat{D}}(k) \leq t-k$ such that $S(t-k,\tau)D(\tau) \subset D_{\sigma,\underline{\sigma}}(t-k)$ for all $\tau \leq \tau_{\widehat{D}}(k)$. From this and a diagonal argument, we can extract a subsequence $\{(u^{\tau_{n'}},\phi^{n'})\} \subset \{(u^{\tau_n},\phi^n)\}$ such that

$$S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}) \rightharpoonup (w^k,\psi^k) \quad \text{weakly in } D(A)\times L^2_{D(A)}, \tag{5.13}$$

$$\frac{d}{ds}u_{t-k}(\cdot;\tau_{n'},u^{\tau_{n'}},\phi^{n'}) \rightharpoonup \frac{d}{ds}\psi^k \qquad \text{weakly in } L^2_{D(A)}, \tag{5.14}$$

for all integer $k \geq 0$, where $(w^k,\psi^k) \in D_{\sigma,\underline{\sigma}}(t-k)$.

Now, applying Proposition 5.2 on each fixed interval $[t-k,t]$, we deduce that

$$\begin{aligned}(w^0,\psi^0) &= (D(A)\times L^2_{D(A)}) - \text{weak} \lim_{n'\to\infty} S(t,\tau_{n'})(u^{\tau_{n'}},\phi^{n'})\\ &= (D(A)\times L^2_{D(A)}) - \text{weak} \lim_{n'\to\infty} S(t,t-k)S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'})\\ &= S(t,t-k)\left[(D(A)\times L^2_{D(A)}) - \text{weak} \lim_{n'\to\infty} S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'})\right]\\ &= S(t,t-k)(w^k,\psi^k).\end{aligned}$$

From (5.13) with $k=0$, we obtain in particular that $|Aw^0| \leq \liminf_{n'\to\infty}|Au(t;\tau_{n'},u^{\tau_{n'}},\phi^{n'})|$. We will prove now that it also holds that

$$\limsup_{n'\to\infty}|Au(t;\tau_{n'},u^{\tau_{n'}},\phi^{n'})| \leq |Aw^0|, \tag{5.15}$$

which combined with the weak converge of $u(t;\tau_{n'},u^{\tau_{n'}},\phi^{n'})$ to w^0 in $D(A)$, will imply the convergence in the strong topology of $D(A)$.

Observe that, as we already used in Lemma 5.3, for any $\tau \in \mathbb{R}$ and $(u^\tau,\phi) \in D(A)\times L^2_V$, the solution $u(\cdot;\tau,u^\tau,\phi)$, for short denoted $u(\cdot)$, satisfies the differential equality

$$\begin{aligned}\frac{d}{dt}(e^{\sigma t}\|u(t)\|^2+\alpha^2 e^{\sigma t}|Au(t)|^2) &= \sigma e^{\sigma t}\|u(t)\|^2+\alpha^2\sigma e^{\sigma t}|Au(t)|^2-2\nu e^{\sigma t}|Au(t)|^2\\ &\quad -2e^{\sigma t}(B(u(t)),Au(t))+2e^{\sigma t}(f(t)+g(t,u_t),Au(t))\end{aligned} \tag{5.16}$$

a.e. $t > \tau$. Since in particular $0 < \sigma < 2\nu(\lambda_1^{-1}+\alpha^2)^{-1}$, notice that $[[\cdot]]$, with $[[v]]^2 = (2\nu-\alpha^2\sigma)|Av|^2-\sigma\|v\|^2$, defines an equivalent norm to $|\cdot|_{D(A)}$ in $D(A)$.

We integrate the above expression in the interval $[t-k,t]$ for the solutions $u(\cdot;\tau_{n'},u^{\tau_{n'}},\phi^{n'})$ with $\tau_{n'} \leq t-k$, which yields

$$\begin{aligned}&\|u(t;\tau_{n'},u^{\tau_{n'}},\phi^{n'})\|^2+\alpha^2|Au(t;\tau_{n'},u^{\tau_{n'}},\phi^{n'})|^2\\ &\quad = \|u(t;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}))\|^2+\alpha^2|Au(t;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}))|^2\\ &\quad = e^{-\sigma k}\left(\|u(t-k;\tau_{n'},u^{\tau_{n'}},\phi^{n'})\|^2+\alpha^2|Au(t-k;\tau_{n'},u^{\tau_{n'}},\phi^{n'})|^2\right)\\ &\qquad +2\int_{t-k}^t e^{\sigma(s-t)}(f(s),Au(s;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'})))\,ds\\ &\qquad +2\int_{t-k}^t e^{\sigma(s-t)}(g(s,u_s(\cdot;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}))),Au(s;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'})))\,ds\\ &\qquad -2\int_{t-k}^t e^{\sigma(s-t)}(B(u(s;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}))),Au(s;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'})))\,ds\\ &\qquad -\int_{t-k}^t e^{\sigma(s-t)}[[u(s;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}))]]^2\,ds.\end{aligned} \tag{5.17}$$

From (5.13), (5.14) and Proposition 5.2, in particular we have that

$$u(\cdot;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}))\to u(\cdot;t-k,w^k,\psi^k)\quad \text{strongly in } C([t-k,t];V), \tag{5.18}$$

and also

$$u(\cdot;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}))\rightharpoonup u(\cdot;t-k,w^k,\psi^k)\quad \text{weakly in } L^2(t-k,t;D(A)). \tag{5.19}$$

Then, it is not difficult to see that

$$\begin{aligned}\lim_{n'\to\infty}&\int_{t-k}^t e^{\sigma(s-t)}(B(u(s;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}))),Au(s;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'})))\,ds\\ &=\int_{t-k}^t e^{\sigma(s-t)}(B(u(s;t-k,w^k,\psi^k)),Au(s;t-k,w^k,\psi^k))\,ds.\end{aligned} \tag{5.20}$$

On other hand, as $e^{\sigma(\cdot-t)}f(\cdot)\in L^2(t-k,t;(L^2(\Omega))^3)$, it yields

$$\begin{aligned}\lim_{n'\to\infty}&\int_{t-k}^t e^{\sigma(s-t)}(f(s),Au(s;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'})))\,ds\\ &=\int_{t-k}^t e^{\sigma(s-t)}(f(s),Au(s;t-k,w^k,\psi^k))\,ds.\end{aligned}$$

Moreover, from (5.18), in particular we also have that

$$u(\cdot;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}))\to u(\cdot;t-k,w^k,\psi^k)\quad \text{strongly in } L^2(t-k-h,t;H),$$

which jointly with (5.19), implies that

$$\begin{aligned}\lim_{n'\to\infty}&\int_{t-k}^t e^{\sigma(s-t)}(g(s,u_s(\cdot;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}))),Au(s;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'})))\,ds\\ &=\int_{t-k}^t e^{\sigma(s-t)}(g(s,u_s(\cdot;t-k,w^k,\psi^k)),Au(s;t-k,w^k,\psi^k))\,ds\end{aligned}$$

Finally, as $\int_{t-k}^t e^{\sigma(s-t)}[[v(s)]]^2\,ds$ defines an equivalent norm in $L^2(t-k,t;D(A))$, we also deduce from above that

$$\begin{aligned}&\int_{t-k}^t e^{\sigma(s-t)}[[u(s;t-k,w^k,\psi^k)]]^2\,ds\\ &\qquad\le \liminf_{n'\to\infty}\int_{t-k}^t e^{\sigma(s-t)}[[u(s;t-k,S(t-k,\tau_{n'})(u^{\tau_{n'}},\phi^{n'}))]]^2\,ds.\end{aligned} \tag{5.21}$$

From (5.17), (5.20)–(5.21), taking into account (5.13) with $k=0$, the compactness of the injection of $D(A)$ into V, and (5.11), we conclude that

$$\begin{aligned}\|w^0\|^2&+\alpha^2\limsup_{n'\to\infty}|Au(t;\tau_{n'},u^{\tau_{n'}},\phi^{n'})|^2\\ &\le e^{-\sigma k}(\lambda_1^{-1}+\alpha^2)R^2_{\sigma,\underline{\sigma}}(t-k)+2\int_{t-k}^t e^{\sigma(s-t)}(f(s),Au(s;t-k,w^k,\psi^k))\,ds\\ &\quad+2\int_{t-k}^t e^{\sigma(s-t)}(g(s,u_s(\cdot;t-k,w^k,\psi^k)),Au(s;t-k,w^k,\psi^k))\,ds\\ &\quad-2\int_{t-k}^t e^{\sigma(s-t)}(B(u(s;t-k,w^k,\psi^k)),Au(s;t-k,w^k,\psi^k))\,ds\\ &\quad-\int_{t-k}^t e^{\sigma(s-t)}[[u(s;t-k,w^k,\psi^k)]]^2\,ds.\end{aligned}$$

Now, taking into account that $w^0 = u(t; t-k, w^k, \psi^k)$, integrating again in (5.16), we obtain

$$\begin{aligned}\|w^0\|^2 + \alpha^2|Aw^0|^2 = e^{-\sigma k}(\|w^k\|^2 + \alpha^2|Aw^k|^2) + 2\int_{t-k}^{t} e^{\sigma(s-t)}(f(s), Au(s; t-k, w^k, \psi^k))\, ds \\ + 2\int_{t-k}^{t} e^{\sigma(s-t)}(g(s, u_s(\cdot; t-k, w^k, \psi^k)), Au(s; t-k, w^k, \psi^k))\, ds \\ - 2\int_{t-k}^{t} e^{\sigma(s-t)}(B(u(s; t-k, w^k, \psi^k)), Au(s; t-k, w^k, \psi^k))\, ds \\ - \int_{t-k}^{t} e^{\sigma(s-t)}[[u(s; t-k, w^k, \psi^k)]]^2\, ds.\end{aligned}$$

Comparing the above two expressions, we conclude that

$$\|w^0\|^2 + \alpha^2 \limsup_{n'\to\infty} |Au(t; \tau_{n'}, u^{\tau_{n'}}, \phi^{n'})|^2 \le e^{-\sigma k}(\lambda_1^{-1} + \alpha^2)R^2_{\sigma,\underline{\sigma}}(t-k) + \|w^0\|^2 + \alpha^2|Aw^0|^2.$$

But from (5.9) and (5.12), we have that $\lim_{k\to\infty} e^{-\sigma k} R^2_{\sigma,\underline{\sigma}}(t-k) = 0$, so (5.15) holds, and we conclude that

$$u(t; \tau_{n'}, u^{\tau_{n'}}, \phi^{n'}) \to w^0 \quad \text{strongly in } D(A).$$

Finally, we prove the asymptotic compactness in the second component of S. From (5.13) and (5.14) with $k = 0$, we have that

$$\begin{aligned} u_t(\cdot; \tau_{n'}, u^{\tau_{n'}}, \phi^{n'}) &\rightharpoonup \psi^0 \quad \text{weakly in } L^2_{D(A)}, \\ \frac{d}{ds}u_t(\cdot; \tau_{n'}, u^{\tau'_{n}}, \phi^{n'}) &\rightharpoonup \frac{d}{ds}\psi^0 \quad \text{weakly in } L^2_{D(A)}. \end{aligned}$$

Thus, by applying the Ascoli–Arzelà theorem, we can deduce that there exists a subsequence (relabeled the same) such that $u_t(\cdot; \tau_{n'}, u^{\tau_{n'}}, \phi^{n'})$ converges to ψ^0 in C_V. So, the proof is finished. □

Remark 5.9. Since $S : \mathbb{R}^2_d \times D(A) \times L^2_V \to D(A) \times L^2_V$ is a continuous process, by the regularity properties established in Theorem 2.2 and Remark 2.4 (i), $S : \mathbb{R}^2_d \times D(A) \times C_V \to D(A) \times C_V$ is a well-defined closed process. In particular, $\{\Lambda_{D(A)\times C_V}(\widehat{D}, t)\}_{t\in\mathbb{R}}$ is meaningful for any $\widehat{D} \in \mathcal{D}_\sigma(D(A) \times L^2_V) \cap \mathcal{D}_{\underline{\sigma}}(V \times L^2_H)$ by Lemma 5.8. Actually, by the embedding $C_V \subset L^2_V$, recalling Remark 3.8 (ii), it holds that $\Lambda_{D(A)\times C_V}(\widehat{D}, t) = \Lambda_{D(A)\times L^2_V}(\widehat{D}, t)$ for any $t \in \mathbb{R}$, which is therefore invariant for S.

In general, the pullback absorbing family $\widehat{D}_{\sigma,\underline{\sigma}}$ defined by (5.11) does not belong to the universe $\mathcal{D}_\sigma(D(A) \times L^2_V) \cap \mathcal{D}_{\underline{\sigma}}(V \times L^2_H)$, and we do not know whether or not S is pullback $\widehat{D}_{\sigma,\underline{\sigma}}$-asymptotically compact. Thus, we cannot apply Theorem 3.3 nor Theorem 3.7 to the family $\widehat{D}_{\sigma,\underline{\sigma}}$. Nevertheless, collecting the proved results, we may construct *by hand* a minimal pullback $\mathcal{D}_\sigma(D(A) \times L^2_V) \cap \mathcal{D}_{\underline{\sigma}}(V \times L^2_H)$-attractor in a better norm than the natural one for the phase-space $D(A) \times L^2_V$, namely in the $D(A) \times C_V$ norm.

Theorem 5.10. *Assume that $f \in L^2_{loc}(\mathbb{R}; (L^2(\Omega))^3)$ satisfies (4.4) and (5.6), and $g : \mathbb{R} \times C_H \to (L^2(\Omega))^3$ fulfills conditions (I)–(V). Then, for any $0 < \underline{\sigma} < \sigma/3$, the family $\mathcal{A}_{\sigma,\underline{\sigma}} = \{\mathcal{A}_{\sigma,\underline{\sigma}}(t) : t \in \mathbb{R}\}$, given by*

$$\mathcal{A}_{\sigma,\underline{\sigma}}(t) = \overline{\bigcup_{\widehat{D}\in\mathcal{D}_\sigma(D(A)\times L^2_V)\cap\mathcal{D}_{\underline{\sigma}}(V\times L^2_H)} \Lambda_{D(A)\times C_V}(\widehat{D}, t)}^{D(A)\times C_V}, \quad \forall t \in \mathbb{R},$$

satisfies the following properties:

(a) $\lim_{\tau\to-\infty} dist_{D(A)\times C_V}(S(t,\tau)D(\tau),\mathcal{A}_{\sigma,\underline{\sigma}}(t)) = 0$ *for all* $t\in\mathbb{R}$ *and any* $\widehat{D}\in\mathcal{D}_\sigma(D(A)\times L^2_V)\cap\mathcal{D}_{\underline{\sigma}}(V\times L^2_H)$ *(pullback attraction).*

(b) $\mathcal{A}_{\sigma,\underline{\sigma}}(t)$ *is compact in* $D(A)\times C_V$ *for all* $t\in\mathbb{R}$.

(c) *It is minimal in the sense that if* $\widehat{C}=\{C(t):t\in\mathbb{R}\}\subset\mathcal{P}(D(A)\times C_V)$ *(resp.* $\widehat{C}=\{C(t):t\in\mathbb{R}\}\subset\mathcal{P}(D(A)\times L^2_V)$*) is a family of closed subsets of* $D(A)\times C_V$ *(resp.* $D(A)\times L^2_V$*) such that* $\lim_{\tau\to-\infty} dist_{D(A)\times C_V}(S(t,\tau)D(\tau),C(t))=0$ *(resp.* $\lim_{\tau\to-\infty} dist_{D(A)\times L^2_V}(S(t,\tau)D(\tau),C(t))=0$*) for all* $t\in\mathbb{R}$ *and any* $\widehat{D}\in\mathcal{D}_\sigma(D(A)\times L^2_V)\cap\mathcal{D}_{\underline{\sigma}}(V\times L^2_H)$*, then* $\mathcal{A}_{\sigma,\underline{\sigma}}(t)\subset C(t)$ *for all* $t\in\mathbb{R}$.

(d) $S(t,\tau)\mathcal{A}_{\sigma,\underline{\sigma}}(\tau)=\mathcal{A}_{\sigma,\underline{\sigma}}(t)$ *for all* $\tau\le t$ *(invariance).*

In particular, $\mathcal{A}_{\sigma,\underline{\sigma}}$ *is the* $(D(A)\times L^2_V, D(A)\times C_V)$ *minimal pullback* $\mathcal{D}_\sigma(D(A)\times L^2_V)\cap\mathcal{D}_{\underline{\sigma}}(V\times L^2_H)$*-attractor for the process* $S:\mathbb{R}^2_d\times D(A)\times L^2_V\to D(A)\times L^2_V$.

Proof. It suffices to check (a)–(d).

Claim (a). The pullback $D(A)\times C_V$-attraction property is an easy consequence of Lemma 5.8 (see also Remark 5.9).

Claim (b). Consider a sequence $\{y^n\}\subset\mathcal{A}_{\sigma,\underline{\sigma}}(t)$. We will extract a converging subsequence $\{y^{n'}\}\subset\{y^n\}$ with $D(A)\times C_V-\lim_{n'} y^{n'}\in\mathcal{A}_{\sigma,\underline{\sigma}}(t)$.

By definition of $\mathcal{A}_{\sigma,\underline{\sigma}}(t)$ we may consider a sequence $\{x^n\}_n$ with $x^n\in\Lambda_{D(A)\times C_V}(\widehat{D}_n,t)$, where $\widehat{D}_n\in\mathcal{D}_\sigma(D(A)\times L^2_V)\cap\mathcal{D}_{\underline{\sigma}}(V\times L^2_H)$, with $\mathrm{dist}_{D(A)\times C_V}(x^n,y^n)<1/n$. For each $n\in\mathbb{N}$, this means that there exist sequences $\{z^{m,n}\}_m$ and $\{\tau^n_m\}_m$ with $\lim_m\tau^n_m=-\infty$, $z^{m,n}\in D_n(\tau^n_m)$ and $x^n=D(A)\times C_V-\lim_m S(t,\tau^n_m)z^{m,n}$. We may consider $m(n)$ such that

$$\mathrm{dist}_{D(A)\times C_V}(x^n,S(t,\tau^n_{m(n)})z^{m(n),n})<1/n,\quad\forall n\ge 1.$$

It is obvious that we are done if we obtain a subsequence $\{x^{n'}\}$ converging in $D(A)\times C_V$ since $\mathcal{A}_{\sigma,\underline{\sigma}}(t)$ is closed in $D(A)\times C_V$ and then $\lim_{n'}y^{n'}=\lim_{n'}x^{n'}\in\mathcal{A}_{\sigma,\underline{\sigma}}(t)$.

Now we rearrange the arguments of Lemma 5.8. For each integer $k\ge 0$, by the absorbing property established in Corollary 5.7, there exists $\tau_{\widehat{D}_n}(k)\le t-k$ such that

$$S(t-k,\tau)D_n(\tau)\subset D_{\sigma,\underline{\sigma}}(t-k),\quad\forall\tau\le\tau_{\widehat{D}_n}(k).$$

From this and a diagonal argument we can extract subsequences (the notation $\tau^{n'}_{m(n')}$ and $z^{m(n'),n'}$ is shorten for simplicity) $\{\tau_{n'}\}$ and $\{z^{n'}\}$ with $\tau_{n'}\to-\infty$ and $z^{n'}\in D_{n'}(\tau_{n'})$ such that

$$S(t-k,\tau_{n'})z^{n'}\rightharpoonup(w^k,\psi^k)\quad\text{weakly in } D(A)\times L^2_{D(A)},\text{ for all } k\ge 0,$$

where $(w^k,\psi^k)\in D_{\sigma,\underline{\sigma}}(t-k)$.

Now we can repeat verbatim the arguments from Lemma 5.8 to conclude that

$$D(A)\times C_V-\lim_{n'}S(t,\tau_{n'})z^{n'}=(w^0,\psi^0)$$

which is also the limit of $x^{n'}$ and $y^{n'}$, so $\mathcal{A}_{\sigma,\underline{\sigma}}(t)$ is relatively compact and closed, therefore compact in $D(A)\times C_V$.

Claim (c). The minimality among the families of closed subsets in $D(A)\times C_V$ is obvious, since $\mathcal{A}_{\sigma,\underline{\sigma}}(t)$ is the closure of omega-limit sets in this topology. For the case of $D(A)\times L^2_V$, observe that the omega-limit sets in this topology are those obtained in the $D(A) \times C_V$ topology (see Remark 5.9 (ii)). Besides, from (b), we have that $\mathcal{A}_{\sigma,\underline{\sigma}}(t)$ is compact in $D(A) \times C_V$, and therefore also compact (in particular closed) in $D(A) \times L^2_V$. So the minimality argument is analogous.

Claim (d). We prove it by double inclusion. Let us first check that $\mathcal{A}_{\sigma,\underline{\sigma}}$ is negatively invariant, that is,

$$\mathcal{A}_{\sigma,\underline{\sigma}}(t) \subset S(t,\tau)\mathcal{A}_{\sigma,\underline{\sigma}}(\tau), \quad \forall \tau \le t. \tag{5.22}$$

Consider $y \in \mathcal{A}_{\sigma,\underline{\sigma}}(t)$. Then $y = D(A) \times C_V - \lim_n y^n$ with $y^n \in \Lambda_{D(A)\times C_V}(\widehat{D}_n, t)$, where $\widehat{D}_n \in \mathcal{D}_\sigma(D(A) \times L^2_V) \cap \mathcal{D}_{\underline{\sigma}}(V \times L^2_H)$. As long as each $\Lambda_{D(A)\times C_V}(\widehat{D}_n, t)$ is invariant for the process S, there exists $x^n \in \Lambda_{D(A)\times C_V}(\widehat{D}_n, \tau)$ with $y^n = S(t,\tau)x^n$. Observe that $\mathcal{A}_{\sigma,\underline{\sigma}}(\tau)$ is compact (proved previously in (b)) in $D(A) \times C_V$. Therefore there exists a subsequence $\{x^{n'}\} \subset \{x^n\}$ with $D(A) \times C_V - \lim_{n'} x^{n'} = x \in \mathcal{A}_{\sigma,\underline{\sigma}}(\tau)$. In particular, by the $D(A) \times L^2_V$ continuity of $S(t,\tau)$ (in fact, it is also continuous in $D(A) \times C_V$) it holds that $y^{n'} = S(t,\tau)x^{n'}$ converges to $S(t,\tau)x$ in $D(A) \times L^2_V$. So, by the uniqueness of the limit, $y = S(t,\tau)x$ and (5.22) holds.

Let us check the converse inclusion

$$S(t,\tau)\mathcal{A}_{\sigma,\underline{\sigma}}(\tau) \subset \mathcal{A}_{\sigma,\underline{\sigma}}(t), \quad \forall \tau \le t.$$

Fix $\tau \le t$ and $x \in \mathcal{A}_{\sigma,\underline{\sigma}}(\tau)$. Then $x = D(A) \times C_V - \lim_n x^n$ with $x^n \in \Lambda_{D(A)\times C_V}(\widehat{D}_n, \tau)$, where $\widehat{D}_n \in \mathcal{D}_\sigma(D(A) \times L^2_V) \cap \mathcal{D}_{\underline{\sigma}}(V \times L^2_H)$. Using again the invariance property $\Lambda_{D(A)\times C_V}(\widehat{D}_n, t) = S(t,\tau)\Lambda_{D(A)\times C_V}(\widehat{D}_n, \tau)$, denote $y^n := S(t,\tau)x^n$. As long as $S(t,\tau)$ is continuous in $D(A) \times C_V$,

$$\mathcal{A}_{\sigma,\underline{\sigma}}(t) \supset \Lambda_{D(A)\times C_V}(\widehat{D}_n, t) \ni y^n = S(t,\tau)x^n \to S(t,\tau)x,$$

and since $\mathcal{A}_{\sigma,\underline{\sigma}}(t)$ is closed in $D(A) \times C_V$, we obtain that $S(t,\tau)x \in \mathcal{A}_{\sigma,\underline{\sigma}}(t)$, which concludes the positive invariance of $\mathcal{A}_{\sigma,\underline{\sigma}}$. □

Remark 5.11. Observe that [14, Theorem 35] can be improved analogously as we have proceeded here. The notation $X_{\sigma,\underline{\sigma}}$ coined in [14] -in a context without delay effects- for the analogous role of $\mathcal{A}_{\sigma,\underline{\sigma}}$ here, was used because at that moment we did not realize that this family already had compact sections and therefore it was the minimal pullback attractor (in several topologies).

Under the additional assumption

$$\sup_{r\le 0} \int_{r-1}^{r} |f(s)|^2 ds < \infty, \tag{5.23}$$

the pullback absorbing family $\widehat{D}_{\sigma,\underline{\sigma}}$ defined by (5.11) does belong to $\mathcal{D}_\sigma(D(A) \times L^2_V) \cap \mathcal{D}_{\underline{\sigma}}(V \times L^2_H)$, whence now we can apply Theorem 3.3, and actually we have the following result.

Theorem 5.12. *Assume that $f \in L^2_{loc}(\mathbb{R}; (L^2(\Omega))^3)$ satisfies (5.23), and $g : \mathbb{R} \times C_H \to (L^2(\Omega))^3$ fulfills conditions (I)–(V). Then, for any $0 < \underline{\sigma} < \sigma/3$,*

$$\mathcal{A}_{\sigma,\underline{\sigma}} = \mathcal{A}_{\mathcal{D}_F(V\times L^2_H)}.$$

Actually, $\mathcal{A}_{\mathcal{D}_F(V\times L^2_H)}$ is the unique family of closed subsets in $D(A) \times L^2_V$ in the universe $\mathcal{D}_\sigma(D(A) \times L^2_V) \cap \mathcal{D}_{\underline{\sigma}}(V \times L^2_H)$ that is invariant for S and pullback $\mathcal{D}_\sigma(D(A) \times L^2_V) \cap \mathcal{D}_{\underline{\sigma}}(V \times L^2_H)$-attracting.

Proof. Consider a fixed value $\underline{\sigma} \in (0, \sigma/3)$.

Observe that under the above assumption on f, the family $\widehat{D}_{\sigma,\underline{\sigma}} = \{D_{\sigma,\underline{\sigma}}(t) : t \in \mathbb{R}\}$ defined by (5.11)–(5.12) belongs to $\mathcal{D}_\sigma(D(A) \times L^2_V) \cap \mathcal{D}_{\underline{\sigma}}(V \times L^2_H)$.

Let us prove the equality $\mathcal{A}_{\sigma,\underline{\sigma}} = \mathcal{A}_{\mathcal{D}_F(V \times L^2_H)}$ by double inclusion.

By Theorem 5.10, $\mathcal{A}_{\sigma,\underline{\sigma}}$ is well defined, and indeed, $\mathcal{A}_{\sigma,\underline{\sigma}}(t) \subset D_{\sigma,\underline{\sigma}}(t)$ for any $t \in \mathbb{R}$. By (5.23), for any fixed $t \in \mathbb{R}$, the set $\bigcup_{s \le t} D_{\sigma,\underline{\sigma}}(s)$ is bounded in $D(A) \times L^2_{D(A)}$ since $\sup_{s \le t} R^2_{\sigma,\underline{\sigma}}(s) < \infty$. In particular, from the invariance of $\mathcal{A}_{\sigma,\underline{\sigma}}$, we conclude that

$$\mathcal{A}_{\sigma,\underline{\sigma}}(t) \subset \mathcal{A}_{\mathcal{D}_F(V \times L^2_H)}(t), \quad \forall t \in \mathbb{R}.$$

On the other hand, again by (5.23), from Theorem 4.3 we have that for any $\tau \in \mathbb{R}$, $\bigcup_{r \le \tau} \mathcal{A}_{\mathcal{D}_F(V \times L^2_H)}(r)$ is a bounded subset of $D(A) \times L^2_V$, and therefore,

$$\operatorname{dist}_{D(A) \times L^2_V}(\mathcal{A}_{\mathcal{D}_F(V \times L^2_H)}(t), \mathcal{A}_{\sigma,\underline{\sigma}}(t)) \le \operatorname{dist}_{D(A) \times L^2_V}(S(t,\tau) \bigcup_{r \le \tau} \mathcal{A}_{\mathcal{D}_F(V \times L^2_H)}(r), \mathcal{A}_{\sigma,\underline{\sigma}}(t)),$$

where the right-hand side goes to zero as $\tau \to -\infty$. So we conclude that

$$\mathcal{A}_{\mathcal{D}_F(V \times L^2_H)}(t) \subset \mathcal{A}_{\sigma,\underline{\sigma}}(t).$$

The final statement about uniqueness is a direct consequence of Remark 3.4. □

Remark 5.13. Observe that, in particular, if $f \in L^2_{loc}(\mathbb{R}; (L^2(\Omega))^3)$ satisfies (5.23), by Corollary 3.5 the minimal pullback attractor $\mathcal{A}_{\mathcal{D}_F(D(A) \times L^2_V)}$ does exist, and it also coincides with the family $\mathcal{A}_{\mathcal{D}_F(V \times L^2_H)}$. They have compact sections in $D(A) \times C_V$ and pullback attract in this metric. Moreover, from Theorem 4.3 we have that

$$\bigcup_{t \le t_2} \mathcal{A}_{\sigma,\underline{\sigma}}(t) = \bigcup_{t \le t_2} \mathcal{A}_{\mathcal{D}_F(V \times L^2_H)}(t) \text{ is a bounded subset of } D(A) \times C_{D(A)} \text{ for any } t_2 \in \mathbb{R}.$$

Abstract. In this paper we define the notion of slow divergence integral along sliding segments in regularized planar piecewise smooth systems. The boundary of such segments may contain diverse tangency points. We show that the slow divergence integral is invariant under smooth equivalences. This is a natural generalization of the notion of slow divergence integral along normally hyperbolic portions of curve of singularities in smooth planar slow–fast systems. We give an interesting application of the integral in a model with visible-invisible two-fold of type VI_3. It is related to a connection between so-called Minkowski dimension of bounded and monotone "entry-exit" sequences and the number of sliding limit cycles produced by so-called canard cycles.

Keywords: sliding limit cycles, piecewise smooth systems, regularization function, slow divergence integral, Minkowski dimension.

2020 Mathematics Subject Classification: 34E15, 34E17, 34C40.

1 Introduction

The notion of slow divergence integral [6, Chapter 5] has proved to be an important tool to study lower and upper bounds of limit cycles in smooth planar slow–fast systems (see e.g. [5–7, 10, 11] and references therein). In this paper by "smooth", we mean differentiable of class C^∞. One of the main goals of this paper is to define the slow divergence integral in regularized planar piecewise smooth (PWS) systems with sliding and to prove its invariance under smooth equivalences (by smooth equivalence we mean smooth coordinate change and a multiplication by a smooth positive function). This is a natural generalization of [25] where the slow divergence integral is defined only for a PWS two-fold bifurcation of type visible-invisible called VI_3 and the switching boundary is a straight line (for more details about two-fold singularity VI_3 see [28] and Sections 2 and 3). In this paper we define the slow

divergence integral along sliding segments with a regular sliding vector field [16] (Section 2.1), and extend it to tangency points when only one vector field is tangent to switching boundary (Section 2.3), two-fold singularities of sliding type VV_1, II_1, VI_2 and VI_3 [28], and to a visible-invisible two-fold singularity when the sliding vector field vanishes at the two-fold point (Section 2.2).

Consider a smooth planar slow–fast system

$$X_{\epsilon,\lambda} = f_\lambda Y_\lambda + \epsilon Q_\lambda + O(\epsilon^2)$$

defined on open set $V \subset \mathbb{R}^2$, where $0 < \epsilon \ll 1$ is the singular perturbation parameter, $\lambda \sim \lambda_0 \in \mathbb{R}^l$, f_λ is a smooth family of functions and Y_λ and Q_λ are smooth families of vector fields. We suppose that $X_{0,\lambda}$ has a curve of singularities C_λ for all $\lambda \sim \lambda_0$ (Fig. 1.1). We further assume that $\nabla f_\lambda(p) \neq (0,0)$ for all $p \in \{(x,y) \in V \mid f_\lambda(x,y) = 0\}$ and that Y_λ has no singularities for each $\lambda \sim \lambda_0$. Then we have $C_\lambda = \{f_\lambda = 0\}$ and C_λ is a smooth family of 1-dimensional manifolds.

The orbits of the flow of $X_{0,\lambda}$ are located inside the leaves of a smooth 1-dimensional foliation $\mathcal{F}_\lambda$ on V tangent to Y_λ ($\mathcal{F}_\lambda$ is called the fast foliation of $X_{0,\lambda}$). If $p \in C_\lambda$, then $DX_{0,\lambda}(p)$ has one eigenvalue equal to zero, with eigenspace T_pC_λ, and the other one equal to $\operatorname{div} X_{0,\lambda}(p)$ (i.e., the trace of $DX_{0,\lambda}(p)$) with eigenspace $T_pl_{\lambda,p}$ ($l_{\lambda,p}$ is the leaf through p). We say that $p \in C_\lambda$ is normally hyperbolic if $\operatorname{div} X_{0,\lambda}(p) \neq 0$ (attracting when $\operatorname{div} X_{0,\lambda}(p) < 0$ and repelling when $\operatorname{div} X_{0,\lambda}(p) > 0$). We can define the notion of slow vector field on normally hyperbolic segments of C_λ. Let $p \in C_\lambda$ be a normally hyperbolic singularity and let $\bar{Q}_\lambda(p) \in T_pC_\lambda$ be the projection of $Q_\lambda(p)$ on T_pC_λ in the direction of $T_pl_{\lambda,p}$. $\bar{Q}_\lambda$ is called the slow vector field and its flow the slow dynamics. The time variable of the slow dynamics is the slow time $\bar{t} = \epsilon t$ where t is the time variable of the flow of $X_{\epsilon,\lambda}$. We point out that the classical definition of the slow vector field using center manifolds is equivalent to this definition. For more details see [6, Chapter 3].

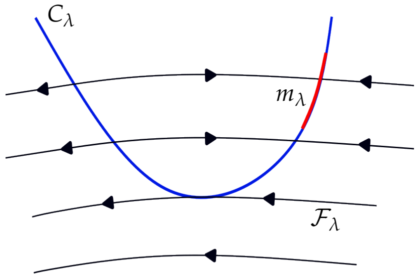

Figure 1.1: The dynamics of $X_{0,\lambda}$ with the curve of singularities C_λ (blue) and the fast foliation $\mathcal{F}_\lambda$. A normally hyperbolic segment $m_\lambda \subset C_\lambda$ (red) along which the slow divergence integral can be defined.

We define now the notion of slow divergence integral (see [6, Chapter 5]). If $m_\lambda \subset C_\lambda$ is a normally hyperbolic segment not containing singularities of $\bar{Q}_\lambda$, then the slow divergence integral along m_λ is defined by

$$I(m_\lambda) = \int_{\bar{t}_1}^{\bar{t}_2} \operatorname{div} X_{0,\lambda}(z_\lambda(\bar{t}))d\bar{t} \tag{1.1}$$

where $z_\lambda : [\bar{t}_1, \bar{t}_2] \to \mathbb{R}^2$, $z'_\lambda(\bar{t}) = \bar{Q}_\lambda(z_\lambda(\bar{t}))$ and $z_\lambda(\bar{t}_1)$ and $z_\lambda(\bar{t}_2)$ are the end points of m_λ (we parameterize m_λ by $\bar{t}$). This definition is independent of the choice of parameterization z_λ of

m_λ and the slow divergence integral is invariant under smooth equivalences (see [6, Section 5.3]).

If both eigenvalues of the linear part of $X_{0,\lambda}$ at $p \in C_\lambda$ are zero, then we say that p is a (nilpotent) contact point between C_λ and $\mathcal{F}_\lambda$. The slow divergence integral can also be defined along parts of C_λ that contain contact points, using its invariance under smooth equivalences and normal forms near contact points (see [6, Section 5.5]).

We come now to a natural question: can we define the notion of slow divergence integral if we replace the slow–fast system $X_{\epsilon,\lambda}$ with a regularized planar PWS system? In Section 2 we give a positive answer to the question. Instead of $X_{0,\lambda}$ we consider a λ-family of planar PWS systems (2.1) defined in Section 2. The switching boundary Σ_λ defined after (2.1) plays the role of the curve of singularities C_λ, and the Filippov sliding vector field Z_λ^{sl} on sliding subsets of Σ_λ (see (2.2)) plays the role of the slow vector field $\bar{Q}_\lambda$ on normally hyperbolic portions of C_λ (see Proposition 2.1). The function that will be integrated (Definition 2.2 in Section 2.1) is the divergence of a smooth slow–fast vector field visible in the scaling chart of a cylindrical blow-up applied to regularized PWS system (2.4) (for more details see [25] and the proof of Proposition 2.1). The notion of slow divergence integral in the PWS setting is well-defined when the sliding vector field Z_λ^{sl} has no singularities (see Definition 2.2).

We show that the slow divergence integral from Definition 2.2 is invariant under smooth equivalences (see Theorem 2.4 in Section 2.1).

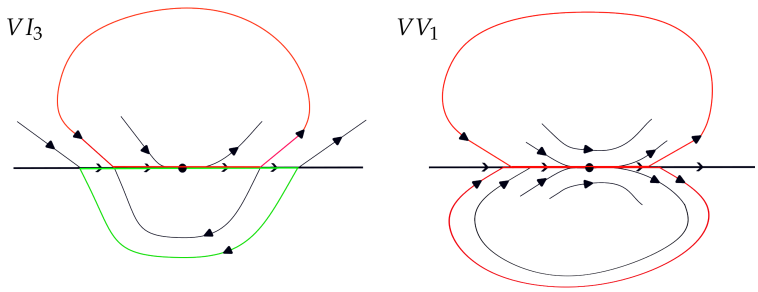

Figure 1.2: Limit periodic sets in planar PWS systems through two-fold points with sliding (the VI_3 case and the VV_1 case). They can be located in a region with invisible fold point (green) or in a region with visible fold point (red).

In Sections 2.2 and 2.3 we define the slow divergence integral near tangency points, as already mentioned above (tangency points in Σ_λ play the role of contact points between C_λ and $\mathcal{F}_\lambda$). We use the invariance of the slow divergence integral under smooth equivalence. The extension of the slow divergence integral to tangency points has proved to be crucial when we study the number of sliding limit cycles (i.e., isolated closed orbits with sliding segments) of a regularized planar PWS system produced by so-called canard limit periodic sets or canard cycles (for more details see [25]). In [25] only the VI_3 case has been studied, with canard cycles located in the region with invisible fold point (see the green closed curve in Fig. 1.2). Canard cycles contain both stable and unstable sliding portions of the discontinuity manifold (often called switching boundary). For example, it has been proved in [25] that the number of sliding limit cycles (produced by the canard cycles) of regularized quadratic PWS systems is unbounded.

A canard cycle can also be located in a region with visible fold point (for example, red closed curves in Fig. 1.2), and again the slow divergence integral associated to the segment of the switching boundary contained in the canard cycle plays an important role when studying sliding limit cycles (see [24]).

Besides sliding cycles, crossing limit cycles can exist for PWS systems and for example J. Llibre and co-workers have obtained upper bounds for a number of classes [13, 29, 32]. See also [2, 4, 17, 18, 20, 21, 30, 31] and references therein.

Section 3 is devoted to applications of the slow divergence integral from Section 2. In Section 3 we focus on the model used in [25] (visible-invisible two-fold VI_3) and read upper bounds of the number of sliding limit cycles and type of bifurcations near so-called generalized canard cycles (Fig. 3.1) from fractal properties of a bounded and monotone sequence in $\mathbb{R}$ defined using the slow divergence integral and the notion of slow relation function (see Section 3.1). The main advantage of this fractal approach is that, instead of computing the multiplicity of zeros of the slow divergence integral (like in [25]), it suffices to find the Minkowski dimension [14] of the sequence. There is a bijective correspondence between the multiplicity and the Minkowski dimension (see Section 4). A similar fractal approach has been used in [8, 22, 23, 26] where one deals with smooth slow–fast systems. See also [12, 35] and the references therein. We point out that there exist simple formulas for numerical computation of the Minkowski dimension of the sequence (see e.g. [23]). In Section 3.2 we state the main fractal results (Theorems 3.4–3.6), and in Section 4 we prove them.

For the sake of readability, in this paper we work in $\mathbb{R}^2$ using the Euclidean metric. We believe that the notion of slow divergence integral in regularized PWS systems on a smooth surface could also be defined. We point out that the slow divergence integral [6] is defined for slow–fast systems on a smooth surface.

2 The slow divergence integral in PWS systems with sliding

First we recall the basic definitions in PWS theory [9, 19] (switching boundary, sliding set, crossing set, sliding vector field, tangency point, two-fold singularity, etc.). Then we define the notion of slow divergence integral of a regularized PWS system along a sliding segment (not containing singularities of the sliding vector field) and prove that the integral is invariant under smooth equivalences (see Section 2.1). In Section 2.2 we extend the definition of the slow divergence integral to segments consisting of a stable sliding region, an unstable sliding region and a two-fold singularity between them. If the two-fold singularity is visible-invisible, then we assume that the sliding vector field is regular or has a hyperbolic singularity in the two-fold point. In Section 2.3 we define the slow divergence integral near a tangency point where the tangency (quadratic or more degenerate) appears only in one vector field.

Consider a λ-family of PWS systems in the plane

$$\dot{z} = \begin{cases} Z_\lambda^+(z) & \text{for } z \in \Sigma_\lambda^+, \\ Z_\lambda^-(z) & \text{for } z \in \Sigma_\lambda^-, \end{cases} \tag{2.1}$$

where $z = (x, y)$, $\lambda \sim \lambda_0 \in \mathbb{R}^l$ and the switching boundary is a smooth λ-family of 1-dimensional manifolds Σ_λ given by

$$\Sigma_\lambda = \{z \in \mathbb{R}^2 \mid h_\lambda(z) = 0\} \cap V,$$

with an open set V and a smooth family of functions h_λ such that $\nabla h_\lambda(z) \neq (0, 0)$, $\forall z \in \Sigma_\lambda$. The switching boundary Σ_λ separates the open set $\Sigma_\lambda^+ = \{z \in V \mid h_\lambda(z) > 0\}$ from the open set $\Sigma_\lambda^- = \{z \in V \mid h_\lambda(z) < 0\}$. We assume that the λ-family of vector fields $Z_\lambda^+ = (X_\lambda^+, Y_\lambda^+)$ (resp. $Z_\lambda^- = (X_\lambda^-, Y_\lambda^-)$) is smooth in the closure of the λ-family Σ_λ^+ (resp. Σ_λ^-). In this paper "smooth" means "C^∞-smooth".

The subset $\Sigma_\lambda^{sl} \subset \Sigma_\lambda$ consisting of all points $z \in \Sigma_\lambda$ such that

$$Z_\lambda^+(h_\lambda)(z) Z_\lambda^-(h_\lambda)(z) < 0$$

is called the sliding set, where $Z_\lambda^\pm(h_\lambda)(z) := \nabla h_\lambda(z) \cdot Z_\lambda^\pm(z)$ is the Lie-derivative of h_λ with respect to the vector field $Z_\lambda^\pm$ at z. A sliding point $z \in \Sigma_\lambda^{sl}$ is stable (resp. unstable) if $Z_\lambda^+(h_\lambda)(z) < 0$ and $Z_\lambda^-(h_\lambda)(z) > 0$ (resp. $Z_\lambda^+(h_\lambda)(z) > 0$ and $Z_\lambda^-(h_\lambda)(z) < 0$). We write $\Sigma_\lambda^{sl} = \Sigma_\lambda^s \cup \Sigma_\lambda^u$ where Σ_λ^s (resp. Σ_λ^u) is the set of all stable (resp. unstable) sliding points. In Σ_λ^s (resp. Σ_λ^u) the vector fields $Z_\lambda^\pm$ point toward (resp. away from) the switching boundary. We call the set $\Sigma_\lambda^{cr} \subset \Sigma_\lambda$ of all points $z \in \Sigma_\lambda$ such that

$$Z_\lambda^+(h_\lambda)(z) Z_\lambda^-(h_\lambda)(z) > 0$$

the crossing set.

At each point $z \in \Sigma_\lambda^{cr}$ the orbit of (2.1) crosses the switching boundary Σ_λ (it is the concatenation of the orbit of Z_λ^+ and the orbit of Z_λ^- through z). Along the sliding set Σ_λ^{sl}, the flow is given by the Filippov sliding vector field [16]

$$Z_\lambda^{sl}(z) = \frac{1}{(Z_\lambda^+ - Z_\lambda^-)(h_\lambda)} \left(Z_\lambda^+(h_\lambda) Z_\lambda^- - Z_\lambda^-(h_\lambda) Z_\lambda^+ \right)(z), \; z \in \Sigma_\lambda^{sl}. \tag{2.2}$$

The sliding vector field Z_λ^{sl} defined in (2.2) is tangent to Σ_λ^{sl}, i.e., $Z_\lambda^{sl}(z)$ is equal to the convex combination $\tau Z_\lambda^+(z) + (1-\tau) Z_\lambda^-(z)$ with

$$\tau = \tau_\lambda(z) = \frac{-Z_\lambda^-(h_\lambda)}{(Z_\lambda^+ - Z_\lambda^-)(h_\lambda)}(z) \in]0,1[. \tag{2.3}$$

We say that $z \in \Sigma_\lambda^{sl}$ is a pseudo-equilibrium of (2.1) if $Z_\lambda^{sl}(z) = 0$.

A point $z \in \Sigma_\lambda$ where $Z_\lambda^+(h_\lambda)(z) = 0$ or $Z_\lambda^-(h_\lambda)(z) = 0$ is a PWS singularity called tangency. We say that $z \in \Sigma_\lambda$ is a fold singularity (or a fold point) of Z_λ^+ (resp. Z_λ^-) if $Z_\lambda^+(h_\lambda)(z) = 0$ and $(Z_\lambda^+)^2(h_\lambda)(z) \neq 0$ (resp. $Z_\lambda^-(h_\lambda)(z) = 0$ and $(Z_\lambda^-)^2(h_\lambda)(z) \neq 0$). The fold point is visible if $(Z_\lambda^+)^2(h_\lambda)(z) > 0$ (resp. $(Z_\lambda^-)^2(h_\lambda)(z) < 0$) and invisible if $(Z_\lambda^+)^2(h_\lambda)(z) < 0$ (resp. $(Z_\lambda^-)^2(h_\lambda)(z) > 0$).

We say that $z \in \Sigma_\lambda$ is a two-fold singularity if z is a fold point of both $Z_\lambda^\pm$. A two-fold singularity $z \in \Sigma_\lambda$ is said to be visible-visible (VV) if z is visible in both $Z_\lambda^\pm$, invisible-invisible (II) if z is invisible in both $Z_\lambda^\pm$, and visible-invisible (VI) if z is visible in Z_λ^+ and invisible in Z_λ^- or visible in Z_λ^- and invisible in Z_λ^+. Following [28], there exist 7 (generic) cases for two-fold singularities taking into account the direction of the flow of $Z_\lambda^\pm$ and Z_λ^{sl}: 2 visible-visible cases (denoted by VV_1 and VV_2 in [28]), 2 invisible-invisible cases (II_1 and II_2) and 3 visible-invisible cases (VI_1, VI_2 and VI_3). For more details we refer to [1,19,27,28]. In Section 2.2 we define the notion of slow divergence integral near two-fold singularities of sliding type (VV_1, II_1, VI_2 and VI_3). The four sliding cases are illustrated in Fig. 2.2. We also treat a visible-invisible two-fold singularity where the sliding vector field points toward (or away from) the two-fold singularity on both sides (Fig. 2.3).

We consider a regularized PWS system [25]

$$\dot{z} = \phi(h_\lambda(z)\epsilon^{-1}) Z_\lambda^+(z) + (1 - \phi(h_\lambda(z)\epsilon^{-1})) Z_\lambda^-(z) \tag{2.4}$$

where $0 < \epsilon \ll 1$ and $\phi : \mathbb{R} \to \mathbb{R}$ is a smooth regularization function. We assume that ϕ is strictly monotone, i.e.,

$$\phi'(u) > 0 \quad \text{for all } u \in \mathbb{R}, \tag{2.5}$$

and ϕ has the following asymptotics for $u \to \pm\infty$:

$$\phi(u) \to \begin{cases} 1 & \text{for } u \to \infty, \\ 0 & \text{for } u \to -\infty. \end{cases} \tag{2.6}$$

Moreover, we assume that ϕ is smooth at $\pm\infty$ in the following sense: The functions

$$\phi_+(u) := \begin{cases} 1 & \text{for } u = 0, \\ \phi(u^{-1}) & \text{for } u > 0, \end{cases} \quad \phi_-(u) := \begin{cases} \phi(-u^{-1}) & \text{for } u > 0, \\ 0 & \text{for } u = 0, \end{cases}$$

are smooth at $u = 0$.

Using the asymptotics of ϕ given in (2.6), the system (2.4) becomes the PWS system (2.1) in the limit $\epsilon \to 0$. Combining this with the fact that ϕ is smooth at $\pm\infty$, we have that, for z kept in any fixed compact set in $V \setminus \Sigma_\lambda$, the right hand side of (2.4) is an $o(1)$-perturbation of the right hand side of (2.1) where $o(1)$ is a smooth function in (z, ϵ, λ) and tends to 0 as $\epsilon \to 0$, uniformly in (z, λ). Thus, the PWS system (2.1) describes the dynamics of (2.4), for $\epsilon > 0$ small, as long as z is kept uniformly away from Σ_λ.

Near Σ_λ^{sl}, the dynamics of (2.4), with $0 < \epsilon \ll 1$, is given by Proposition 2.1 (see also [33]).

2.1 Definition and invariance of the slow divergence integral

Proposition 2.1. *Suppose that the PWS system (2.1) has a stable (resp. unstable) sliding point $p \in \Sigma_{\lambda_0}^{sl}$. Then, for each $0 < \epsilon \ll 1$ and $\lambda \sim \lambda_0$, (2.4) has a locally invariant manifold near p with foliation by stable (resp. unstable) fibers, and the reduced dynamics on this manifold (when $\epsilon \to 0$) is given by sliding vector field Z_λ^{sl} defined in (2.2).*

Proof. Without loss of generality, we can assume that $\frac{\partial h_{\lambda_0}}{\partial y}(p) \neq 0$. Then the switching boundary Σ_λ (locally near p) is the graph of a smooth function $y = f_\lambda(x)$. Using $h_\lambda(x, y) = \epsilon \tilde{y}$, the system (2.4) multiplied by $\epsilon > 0$ becomes a slow–fast system

$$\begin{aligned} \dot{x} &= \epsilon \left(\phi(\tilde{y}) X_\lambda^+(x, f_\lambda(x)) + (1 - \phi(\tilde{y})) X_\lambda^-(x, f_\lambda(x)) + O(\epsilon \tilde{y}) \right), \\ \dot{\tilde{y}} &= \phi(\tilde{y}) Z_\lambda^+(h_\lambda)(x, f_\lambda(x)) + (1 - \phi(\tilde{y})) Z_\lambda^-(h_\lambda)(x, f_\lambda(x)) + O(\epsilon \tilde{y}). \end{aligned} \tag{2.7}$$

When $\epsilon = 0$, the curve of singularities of (2.7) is given by $\tilde{y} = \phi^{-1}(\tau_\lambda(x, f_\lambda(x)))$ where τ_λ is defined in (2.3). Each singularity $(x, \phi^{-1}(\tau_\lambda(x, f_\lambda(x))))$ is semi-hyperbolic with the nonzero eigenvalue equal to the divergence of the vector field (2.7), with $\epsilon = 0$, computed in that singularity:

$$(Z_\lambda^+ - Z_\lambda^-)(h_\lambda)(x, f_\lambda(x)) \phi' \left(\phi^{-1}(\tau_\lambda(x, f_\lambda(x))) \right). \tag{2.8}$$

The reason why the eigenvalue in (2.8) is nonzero is because $Z_\lambda^+(h_\lambda) Z_\lambda^-(h_\lambda) < 0$ and $\phi' > 0$ (see (2.5)). The curve of singularities is attracting (resp. repelling) if p is a stable (resp. unstable) sliding point. The result follows now from Fenichel's theory [15]. Notice that the reduced dynamics of (2.7) along the curve of singularities is given by the vector field

$$\left(\tau_\lambda X_\lambda^+ + (1 - \tau_\lambda) X_\lambda^- \right)(x, f_\lambda(x)). \tag{2.9}$$

We divided the x-component in (2.7) by ϵ and let $\epsilon \to 0$ with $\tilde{y} = \phi^{-1}(\tau_\lambda(x, f_\lambda(x)))$. We get the same expression (2.9) if we use the definition of the slow vector field introduced in Section 1. This completes the proof. □

Following [6, Chapter 5] or Section 1 in the smooth slow–fast system (2.7) one can define the notion of slow divergence integral along normally hyperbolic curve of singularities $\tilde{y} = \phi^{-1}(\tau_\lambda(x, f_\lambda(x)))$ when the sliding vector field in (2.9) has no singularities: it is the integral of the divergence in (2.8) where the variable of integration is the time variable of the flow of the sliding vector field. This is our motivation for the definition of the notion of slow divergence integral of regularized PWS system (2.4) (see also [25]).

Definition 2.2 (Slow divergence integral). Let $m_\lambda \subset \Sigma_\lambda^{sl}$ be a bounded segment (Fig. 2.1) not containing pseudo-equilibria of the PWS system (2.1). Let $z_\lambda : [t_1, t_2] \to \mathbb{R}^2$ be a solution of $z'(t) = Z_\lambda^{sl}(z(t))$ where $z_\lambda(t_1)$ and $z_\lambda(t_2)$ are the end points of m_λ (z_λ is a parameterization of m_λ). Then we define the slow divergence integral of regularized PWS system (2.4) associated to m_λ as

$$I(m_\lambda) = \int_{t_1}^{t_2} E_\lambda(z_\lambda(t))dt \tag{2.10}$$

where

$$E_\lambda(z) = (Z_\lambda^+ - Z_\lambda^-)(h_\lambda)(z)\phi'\left(\phi^{-1}(\tau_\lambda(z))\right), \qquad z \in \Sigma_\lambda^{sl}.$$

Remark 2.3. Note that the definition of the slow divergence integral given by (2.10) is independent of the choice of z_λ. Indeed, if $\hat{z}_\lambda$ is another solution to $z'(t) = Z_\lambda^{sl}(z(t))$ and $p \in m_\lambda$, then there exist $\tilde{t} \in [t_1, t_2]$ and $\bar{t}$ such that $z_\lambda(\tilde{t}) = \hat{z}_\lambda(\bar{t}) = p$. Then we have $z_\lambda(t) = \hat{z}_\lambda(t + \bar{t} - \tilde{t})$ due to uniqueness of solutions. Now, we get

$$\int_{t_1+\bar{t}-\tilde{t}}^{t_2+\bar{t}-\tilde{t}} E_\lambda(\hat{z}_\lambda(s))ds = \int_{t_1}^{t_2} E_\lambda(z_\lambda(t))dt,$$

where we use the change of variable $s = t + \bar{t} - \tilde{t}$.

If m_λ is stable (resp. unstable), then $I(m_\lambda)$ is negative (resp. positive).

The slow divergence integral from Definition 2.2 is invariant under smooth equivalences (Theorem 2.4.1 and Theorem 2.4.2). Theorem 2.4.3 tells us how to compute $I(m_\lambda)$ for an arbitrary parameterization of m_λ (see also [6, Proposition 5.3]).

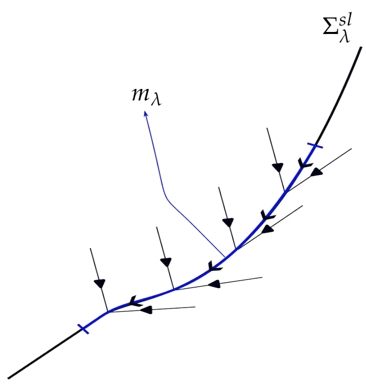

Figure 2.1: A segment $m_\lambda \subset \Sigma_\lambda^{sl}$ (blue).

Theorem 2.4 (Invariance of the slow divergence integral). *Let us denote the family of vector field in (2.4) by $Z_{\epsilon,\lambda}$ and let $m_\lambda \subset \Sigma_\lambda^{sl}$ be as in Definition 2.2. The following statements are true.*

1. *Let $T : V_w \to V_z \subset V$ ($w \mapsto z = T(w)$) be a smooth coordinate transformation, with open sets $V_w, V_z \subset \mathbb{R}^2$. Let $I(m_\lambda)$ be the slow divergence integral of $Z_{\epsilon,\lambda}$ along $m_\lambda \subset V_z$. Then the slow divergence integral $I(T^{-1}(m_\lambda))$ of the pullback of the vector field $Z_{\epsilon,\lambda}|_{V_z}$ along $T^{-1}(m_\lambda) \subset V_w$ is equal to $I(m_\lambda)$.*

2. *Let g be a smooth strictly positive function defined in a neighborhood of m_λ. Then the slow divergence integral of $Z_{\epsilon,\lambda}$ along m_λ is equal to the slow divergence integral of the equivalent vector field $g.Z_{\epsilon,\lambda}$ along m_λ.*

3. *Let $p_\lambda : [v_1, v_2] \to \mathbb{R}^2$ be a parameterization of m_λ. Then we have*

$$I(m_\lambda) = \int_{v_1}^{v_2} \frac{E_\lambda(p_\lambda(v))dv}{|\tilde{p}_\lambda(v)|},$$

where $\tilde{p}_\lambda$ is a smooth λ-family of nowhere zero functions satisfying

$$Z_\lambda^{sl}(p_\lambda(v)) = \tilde{p}_\lambda(v) p'_\lambda(v).$$

Proof. Statement 1. The pullback of the vector field $Z_{\epsilon,\lambda}|_{V_z}$ can be written as

$$T^*(Z_{\epsilon,\lambda}|_{V_z})(w) = \phi(h_\lambda \circ T(w)\epsilon^{-1})W_\lambda^+(w) + (1 - \phi(h_\lambda \circ T(w)\epsilon^{-1}))W_\lambda^-(w)$$

where $W_\lambda^\pm(w) = DT(w)^{-1}(Z_\lambda^\pm \circ T)(w)$. It is not difficult to see that the Lie-derivative of $h_\lambda \circ T$ with respect to the vector field $W_\lambda^\pm$ is given by

$$W_\lambda^\pm(h_\lambda \circ T)(w) = Z_\lambda^\pm(h_\lambda)(T(w)). \tag{2.11}$$

Using (2.11) and Definition 2.2 we find that the slow divergence integral of $T^*(Z_{\epsilon,\lambda}|_{V_z})$ along $T^{-1}(m_\lambda)$ is given by

$$I(T^{-1}(m_\lambda)) = \int_{t_1}^{t_2} E_\lambda(T(w_\lambda(t)))dt$$

where $w_\lambda : [t_1, t_2] \to T^{-1}(m_\lambda)$ is a solution of $w'(t) = W_\lambda^{sl}(w(t))$ (the Filippov sliding vector field along $T^{-1}(m_\lambda)$ is given by $W_\lambda^{sl}(w) = DT(w)^{-1}Z_\lambda^{sl}(T(w))$). Since $T \circ w_\lambda : [t_1, t_2] \to m_\lambda$ is a solution to $z'(t) = Z_\lambda^{sl}(z(t))$, the result follows.

Statement 2. From Definition 2.2 it follows that the slow divergence integral of $g.Z_{\epsilon,\lambda}$ along m_λ is equal to

$$I(m_\lambda) = \int_{\hat{t}_1}^{\hat{t}_2} E_\lambda(\hat{z}_\lambda(\hat{t}))g(\hat{z}_\lambda(\hat{t}))d\hat{t} \tag{2.12}$$

where $\hat{z}_\lambda : [\hat{t}_1, \hat{t}_2] \to m_\lambda$ and $\hat{z}'_\lambda(\hat{t}) = g(\hat{z}_\lambda(\hat{t}))Z_\lambda^{sl}(\hat{z}_\lambda(\hat{t}))$. We make in the integral in (2.12) the change of variable $t = \rho(\hat{t}) = \int_{\hat{t}_1}^{\hat{t}} g(\hat{z}_\lambda(v))dv$ with $\hat{t} \in [\hat{t}_1, \hat{t}_2]$. Then we have

$$\int_{\hat{t}_1}^{\hat{t}_2} E_\lambda(\hat{z}_\lambda(\hat{t}))g(\hat{z}_\lambda(\hat{t}))d\hat{t} = \int_0^{\rho(\hat{t}_2)} E_\lambda(\hat{z}_\lambda \circ \rho^{-1}(t))dt.$$

Since $(\hat{z}_\lambda \circ \rho^{-1})'(t) = Z_\lambda^{sl}((\hat{z}_\lambda \circ \rho^{-1})(t))$, $t \in [0, \rho(\hat{t}_2)]$, this integral is the slow divergence integral of $Z_{\epsilon,\lambda}$ associated to m_λ. This completes the proof of Statement 2.

Statement 3. The proof of Statement 3 is similar to the proof of Statement 2. □

Remark 2.5. It follows directly from Definition 2.2 that the slow divergence integral of $-Z_{\epsilon,\lambda}$ along m_λ is equal to the slow divergence integral of $Z_{\epsilon,\lambda}$ along m_λ multiplied by -1.

We will use the invariance of the slow divergence integral under smooth equivalences in Section 2.2 and Section 2.3.

If $m_\lambda \subset \Sigma_\lambda^{sl}$ contains pseudo-equilibria, then the slow divergence integral associated to m_λ is not well-defined.

2.2 The slow divergence integral near two-fold singularities

In this section we suppose that the sliding vector field Z_λ^{sl}, given by (2.2), is defined around a two-fold singularity. Our goal is to define the notion of slow divergence integral near such a two-fold singularity. Since the slow divergence integral (2.10) is invariant under smooth equivalences (Theorem 2.4), we use a normal form of (2.1), locally near the two-fold singularity, in which $h_\lambda(x,y) = y$ and the two-fold point corresponds to the origin $p = (0,0)$. Notice that such normal form coordinates exist because $\nabla h_\lambda(z) \neq (0,0)$, $\forall z \in \Sigma_\lambda$, in (2.1).

Using $h_\lambda(x,y) = y$ the two-fold p satisfies

$$Z_\lambda^\pm(h_\lambda)(0) = Y_\lambda^\pm(0) = 0, \quad (Z_\lambda^\pm)^2(h_\lambda)(0) = X_\lambda^\pm(0)\partial_x Y_\lambda^\pm(0) \neq 0, \tag{2.13}$$

and the sliding vector field Z_λ^{sl} near p can be written as

$$X_\lambda^{sl}(x) = \frac{\det Z_\lambda(x)}{(Y_\lambda^- - Y_\lambda^+)(x,0)} \tag{2.14}$$

where

$$\det Z_\lambda(x) := (X_\lambda^+ Y_\lambda^- - X_\lambda^- Y_\lambda^+)(x,0).$$

Remark 2.6. The notation $\det Z_\lambda$ comes from [1]. In [25] a similar notation has been used for $-(X_\lambda^+ Y_\lambda^- - X_\lambda^- Y_\lambda^+)$.

Since we assumed that the sliding vector field X_λ^{sl} is defined around the two-fold p, we find that $X_\lambda^+(0)X_\lambda^-(0) > 0$ if the folds have the same visibility (visible-visible or invisible-invisible) and $X_\lambda^+(0)X_\lambda^-(0) < 0$ if the folds have opposite visibility. We have $p \in \partial\Sigma_\lambda^s \cap \partial\Sigma_\lambda^u$. These properties follow directly from (2.13) and the definition of visible and invisible folds (see [1, Lemma 2.8]), and imply that $\partial_x(Y_\lambda^- - Y_\lambda^+)(0) \neq 0$ and $\partial_x Y_\lambda^+(0)\partial_x Y_\lambda^-(0) < 0$.

Using $\partial_x(Y_\lambda^- - Y_\lambda^+)(0) \neq 0$ it is clear that the sliding vector field in (2.14) has a removable singularity in $x = 0$ and

$$X_\lambda^{sl}(x) = \nu + O(x), \quad \nu = \frac{(\det Z_\lambda)'(0)}{\partial_x(Y_\lambda^- - Y_\lambda^+)(0)}. \tag{2.15}$$

From [1, Lemma 2.9] and [1, Corollary 2.10] it follows that $\nu \neq 0$ and $\operatorname{sgn}(\nu) = \operatorname{sgn}(X_\lambda^+(0))$ if the folds have the same visibility (VV_1 and II_1 in Fig. 2.2), and that $\nu \neq 0$ and $\operatorname{sgn}(\nu) = -\operatorname{sgn}\left(X_\lambda^+(0)(\det Z_\lambda)'(0)\right)$ if the folds have opposite visibility and $(\det Z_\lambda)'(0) \neq 0$ (VI_2 and VI_3 in Fig. 2.2). *If the folds have opposite visibility, we assume that $\nu \neq 0$ in (2.15) or $x = 0$ is a hyperbolic singularity of the sliding vector field X_λ^{sl} (or, equivalently, $x = 0$ is a zero of multiplicity 1 or 2 of the function $\det Z_\lambda$).* We refer to Fig. 2.3 (the multiplicity of the zero $x = 0$ of $\det Z_\lambda$ is 2).

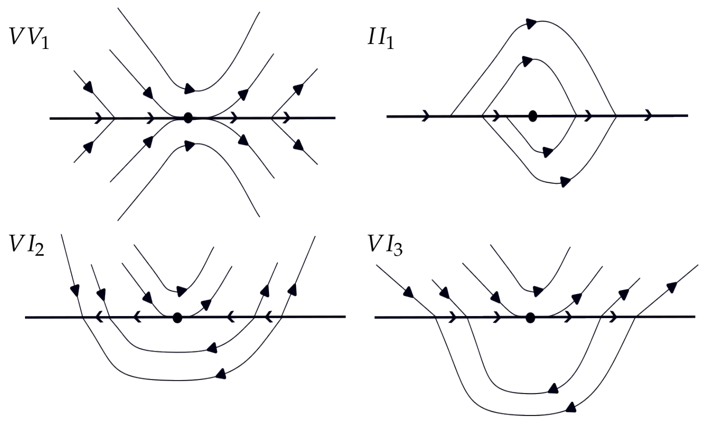

Figure 2.2: The different types of two-fold singularities with sliding: the folds in VV_1 and II_1 have the same visibility, while the folds in VI_2 and VI_3 have opposite visibility.

From $\partial_x(Y_\lambda^- - Y_\lambda^+)(0) \neq 0$ and $\partial_x Y_\lambda^+(0)\partial_x Y_\lambda^-(0) < 0$ it follows that the function τ_λ defined in (2.3) has the following property when $x \to 0$:

$$\lim_{x\to 0} \tau_\lambda(x,0) = \lim_{x\to 0} \frac{-Y_\lambda^-}{Y_\lambda^+ - Y_\lambda^-}(x,0) = \frac{\partial_x Y_\lambda^-(0)}{\partial_x(Y_\lambda^- - Y_\lambda^+)(0)} \in]0,1[. \tag{2.16}$$

Let us now compute the slow divergence integral along $[x_0, x_1]$, with $0 < x_0 < x_1$. We assume that x_1 is small enough such that $[x_0, x_1]$ does not contain any singularities of the sliding vector field X_λ^{sl}. We use Theorem 2.4.3. We take $p_\lambda(x) = (x, 0)$, $x \in [x_0, x_1]$, in Theorem 2.4.3. Then we have

$$\tilde{p}_\lambda(x) = \frac{\det Z_\lambda(x)}{(Y_\lambda^- - Y_\lambda^+)(x,0)},\ E_\lambda(p_\lambda(v)) = (Y_\lambda^+ - Y_\lambda^-)(x,0)\phi'\left(\phi^{-1}\left(\tau_\lambda(x,0)\right)\right).$$

This implies

$$I([x_0,x_1]) = \int_{x_0}^{x_1} \frac{|Y_\lambda^- - Y_\lambda^+|(Y_\lambda^+ - Y_\lambda^-)(x,0)}{|\det Z_\lambda|(x)} \phi'\left(\phi^{-1}\left(\frac{-Y_\lambda^-}{Y_\lambda^+ - Y_\lambda^-}(x,0)\right)\right) dx. \tag{2.17}$$

Finally, we define the slow divergence integral along $[0, x_1]$ (the left end point of $[0, x_1]$ is the two-fold point).

Definition 2.7. Let $m_\lambda = [0, x_1]$. Then the slow divergence integral along m_λ is defined as

$$I(m_\lambda) = \lim_{x_0 \to 0+} I([x_0, x_1])$$

where $I([x_0, x_1])$ is given in (2.17).

Remark 2.8. Notice that the function $x \mapsto \phi'\left(\phi^{-1}\left(\tau_\lambda(x,0)\right)\right)$ in (2.17) can be defined at $x = 0$ such that this function is smooth and positive on the segment m_λ (see (2.5), (2.6) and (2.16)). If the folds have the same visibility, then $I(m_\lambda)$ is well-defined (finite) because $\nu \neq 0$ in (2.15). Since we assume that the multiplicity of the zero $x = 0$ of $\det Z_\lambda$ does not exceed 2 when the folds have opposite visibility, $I(m_\lambda)$ is finite.

Remark 2.9. The slow divergence integral along $m_\lambda = [x_0, 0]$, with $x_0 < 0$, can be defined in a similar way: $I(m_\lambda) = \lim_{x_1 \to 0-} I([x_0, x_1])$ where $I([x_0, x_1])$ has the same form (2.17).

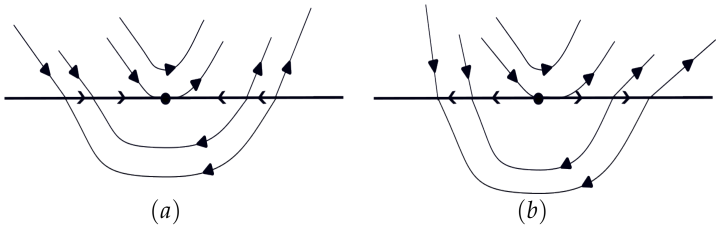

Figure 2.3: Non-generic visible-invisible two-fold singularities. The (extended) sliding vector field has a hyperbolic singularity at the two-fold points. (a) The sliding vector field points toward the two-fold singularity. (b) The sliding vector field points away from the two-fold singularity.

2.3 The slow divergence integral near one-sided tangency points

In this section we define the slow divergence integral near a tangency point $p \in \partial\Sigma_\lambda^s \cup \partial\Sigma_\lambda^u$ where both vectors $Z_\lambda^\pm(p)$ are nonzero and precisely one of them is tangent to Σ_λ at p (see e.g. Fig. 2.4). Like in Section 2.2, the switching boundary Σ_λ is locally given by $h_\lambda(x,y) = y$ and $p = (0,0)$. Since we suppose that $p \in \partial\Sigma_\lambda^s \cup \partial\Sigma_\lambda^u$, there is a side of p (without loss of generality we take $x > 0$) where the sliding vector field is defined, and given by (2.14). If the (nonzero) vector $Z_\lambda^+(0)$ (resp. $Z_\lambda^-(0)$) is tangent to Σ_λ, then $X_\lambda^+(0) \neq 0$, $Y_\lambda^+(0) = 0$ and $Y_\lambda^-(0) \neq 0$ (resp. $X_\lambda^-(0) \neq 0$, $Y_\lambda^-(0) = 0$ and $Y_\lambda^+(0) \neq 0$) and

$$X_\lambda^{sl}(x) = X_\lambda^+(0) + O(x) \quad \left(\text{resp. } X_\lambda^{sl}(x) = X_\lambda^-(0) + O(x)\right). \tag{2.18}$$

Since $X_\lambda^+(0) \neq 0$ (resp. $X_\lambda^-(0) \neq 0$), the sliding vector field X_λ^{sl} in (2.18) is regular near $x = 0$. Thus, the segment $[x_0, x_1]$, with $0 < x_0 < x_1$, does not contain any singularities of X_λ^{sl} if x_1 is small enough and we can define the slow divergence integral along $[x_0, x_1]$ exactly in the same way as in Section 2.2. The slow divergence integral is given by (2.17) and we use the same notation $I([x_0, x_1])$.

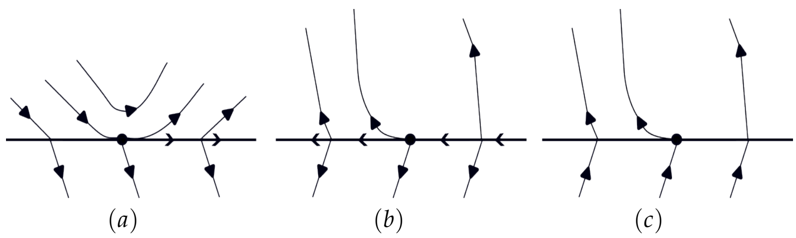

Figure 2.4: (a) The sliding vector field is defined on one side of the tangency point. (b) The sliding vector field is defined on both sides of the tangency point. (c) A crossing region around the tangency point (in this case the slow divergence integral near the tangency point is not defined).

We can now define the slow divergence integral near the tangency point p.

Definition 2.10. Let $m_\lambda = [0, x_1]$. Then the slow divergence integral along m_λ is defined as

$$I(m_\lambda) = \lim_{x_0 \to 0+} I([x_0, x_1]).$$

Remark 2.11. The slow divergence integral $I(m_\lambda)$ from Definition 2.10 is well-defined. Indeed, $\lim_{u\to\pm\infty}\phi'(u) = 0$ (due to the smoothness of ϕ at $\pm\infty$ given after (2.6)). Moreover, we have (a) $\lim_{u\to 1-}\phi^{-1}(u) = +\infty$, (b) $\lim_{u\to 0+}\phi^{-1}(u) = -\infty$ (see (2.6)) and finally (c) $\frac{-Y_\lambda^-}{Y_\lambda^+ - Y_\lambda^-}(x,0)$ tends to 1 (resp. 0) as $x\to 0+$ when $Z_\lambda^+(0)$ (resp. $Z_\lambda^-(0)$) is tangent to Σ_λ. It follows from (a), (b) and (c) that the integrand in (2.17) can be defined at $x=0$ (0 for $x=0$) and that the integrand is continuous on the segment m_λ. This implies that $I(m_\lambda)$ is well-defined.

3 Limit cycles and fractal analysis through visible-invisible two-fold VI_3

3.1 Model and assumptions

We consider a PWS system (2.1) where we assume that $\lambda\sim\lambda_0\in\mathbb{R}$, and $h_\lambda(x,y) = y$ (the switching boundary is the line $y=0$).

Assumption A. Suppose that there are $\eta_- < 0$ and $\eta_+ > 0$ such that the PWS system (2.1) for $\lambda=\lambda_0$ has stable sliding for all $x\in[\eta_-,0[$ (i.e., $Y_{\lambda_0}^+(x,0) < 0$ and $Y_{\lambda_0}^-(x,0) > 0$ for $x\in[\eta_-,0[$) and unstable sliding for all $x\in]0,\eta_+]$ (i.e., $Y_{\lambda_0}^+(x,0) > 0$ and $Y_{\lambda_0}^-(x,0) < 0$ for $x\in]0,\eta_+]$). Moreover, we assume that the Filippov sliding vector field X_λ^{sl} given by (2.14) is positive for $x\in[\eta_-,\eta_+]\setminus\{0\}$ and $\lambda=\lambda_0$.

Assumption A implies that $Y_{\lambda_0}^\pm(0) = 0$ and the origin $z=0$ is therefore a tangency point (see Section 2). We assume that $z=0$ for $\lambda=\lambda_0$ is a two-fold singularity. Moreover, we suppose that the two-fold singularity is visible from "above" and invisible from "below", i.e., the orbit of $Z_{\lambda_0}^+$ through $z=0$ is contained within $y>0$ near $z=0$, and the orbit of $Z_{\lambda_0}^-$ through $z=0$ is not contained within $y<0$ (Section 2).

Assumption B. We assume that the origin $z=0$ in the PWS system (2.1) is a visible-invisible two-fold for $\lambda=\lambda_0$: $Y_{\lambda_0}^\pm(0)=0$ and

$$\begin{cases} X_{\lambda_0}^+(0) & >0, \\ \partial_x Y_{\lambda_0}^+(0) & >0, \end{cases} \quad \begin{cases} X_{\lambda_0}^-(0) & <0, \\ \partial_x Y_{\lambda_0}^-(0) & <0. \end{cases} \tag{3.1}$$

Additionally, we assume that $(\det Z_{\lambda_0})'(0) < 0$ where $\det Z_\lambda$ is defined in (2.14).

Remark 3.1. From (3.1) it follows that $\partial_x(Y_{\lambda_0}^- - Y_{\lambda_0}^+)(0) < 0$. This, together with $(\det Z_{\lambda_0})'(0) < 0$ and (2.15), implies that $X_{\lambda_0}^{sl}(0) > 0$. Thus, $X_{\lambda_0}^{sl}(x) > 0$ for all $x\in[\eta_-,\eta_+]$ (see Assumption A).

Assumption B and the Implicit Function Theorem imply the existence of smooth λ-families of fold singularities $z_+ = (x_+(\lambda),0)$ from above and fold singularities $z_- = (x_-(\lambda),0)$ from below, for $\lambda\sim\lambda_0$, with $x_\pm(\lambda_0)=0$. The following assumption deals with non-zero velocity of the collision between z_+ and z_- for $\lambda=\lambda_0$ at the origin $z=0$:

$$x_+'(\lambda_0) - x_-'(\lambda_0) = \left(-\frac{\partial_\lambda Y_{\lambda_0}^+}{\partial_x Y_{\lambda_0}^+} + \frac{\partial_\lambda Y_{\lambda_0}^-}{\partial_x Y_{\lambda_0}^-}\right)(0) \neq 0$$

where $\partial_\lambda Y_{\lambda_0}^\pm$ means the partial derivative of $Y_\lambda^\pm$ w.r.t. λ, computed in $\lambda=\lambda_0$.

Assumption C. We assume that

$$\partial_\lambda Y_\lambda^- \partial_x Y_\lambda^+ \neq \partial_\lambda Y_\lambda^+ \partial_x Y_\lambda^- \tag{3.2}$$

at $(z, \lambda) = (0, \lambda_0)$.

We consider a regularized PWS system (2.4) with $h_\lambda(x, y) = y$:

$$\dot{z} = \phi(y\epsilon^{-2}) Z_\lambda^+(z) + (1 - \phi(y\epsilon^{-2})) Z_\lambda^-(z) \tag{3.3}$$

where $0 < \epsilon \ll 1$ and $\phi : \mathbb{R} \to \mathbb{R}$ is a smooth regularization function that satisfies the assumptions given after (2.4). More precisely, we have

Assumption D. We suppose that ϕ satisfies (2.5) and (2.6) and that ϕ is smooth at $\pm\infty$.

It is more convenient to write ϵ^{-2} in (3.3) instead of ϵ^{-1} so that we can directly use results from [25] (see Section 4).

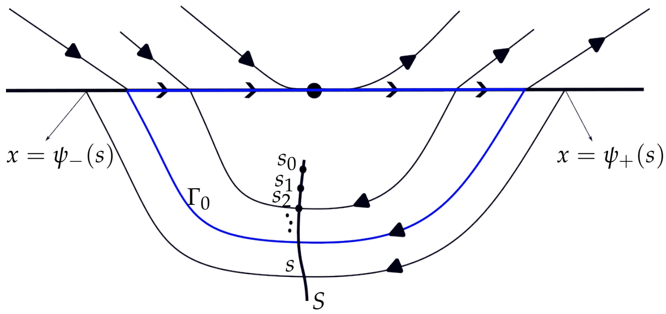

Figure 3.1: A fractal sequence $(s_n)_{n\in\mathbb{N}}$ near the canard cycle Γ_0.

Let S be an open section transversally cutting orbits of Z_λ^-, parametrized by a regular parameter $s \sim 0$ (Fig. 3.1). We assume that s increases as we approach the origin $z = 0$. For $\lambda = \lambda_0$, let Γ_s be the limit periodic set consisting of the orbit of $Z_{\lambda_0}^-$ connecting $(\psi_+(s), 0)$ and $(\psi_-(s), 0)$, and the segment $[\psi_-(s), \psi_+(s)] \subset \{y = 0\}$ (Fig. 3.1). We suppose that $[\psi_-(s), \psi_+(s)] \subset [\eta_-, \eta_+]$ for all $s \sim 0$. In [25] Γ_s is called a canard cycle. From the chosen parameterization of S it follows that $\psi_-'(s) > 0$ and $\psi_+'(s) < 0$. Following [25, Section 3], to study the number of limit cycles of (3.3) produced by Γ_s for $(\epsilon, \lambda) \sim (0, \lambda_0)$ one can use the slow divergence integral associated to the segment $[\psi_-(s), \psi_+(s)]$:

$$I(s) = \int_{\psi_-(s)}^{\psi_+(s)} \frac{(Y_{\lambda_0}^+ - Y_{\lambda_0}^-)^2(x,0)}{-\det Z_{\lambda_0}(x)} \phi' \left(\phi^{-1} \left(\frac{-Y_{\lambda_0}^-}{Y_{\lambda_0}^+ - Y_{\lambda_0}^-}(x,0) \right) \right) dx. \tag{3.4}$$

Remark 3.2. In (3.4) we use Definition 2.7 and Remark 2.9. Note that

$$I(s) = I(m_{\lambda_0}) + I(\tilde{m}_{\lambda_0})$$

where $m_{\lambda_0} = [0, \psi_+(s)]$ and $\tilde{m}_{\lambda_0} = [\psi_-(s), 0]$.

Remark 3.3. We suppose that Assumptions A through D are satisfied and write

$$\lambda = \lambda_0 + \epsilon\widetilde{\lambda}$$

with $\widetilde{\lambda} \sim 0$. We say that the cyclicity of the canard cycle Γ_0 inside (3.3) is bounded by $N \in \mathbb{N}$ if there exist $\epsilon_0 > 0$, $\delta_0 > 0$ and a neighborhood $\mathcal{U}$ of 0 in the $\widetilde{\lambda}$-space such that (3.3) has at most N limit cycles, each lying within Hausdorff distance δ_0 of Γ_0, for all $(\epsilon, \widetilde{\lambda}) \in]0, \epsilon_0] \times \mathcal{U}$. We call the smallest N with this property the cyclicity of Γ_0 and denote it by $\text{Cycl}(\Gamma_0)$.

If the slow divergence integral I in (3.4) has a simple zero at $s = 0$, then $\text{Cycl}(\Gamma_0) = 2$ and, for each small $\epsilon > 0$, the $\widetilde{\lambda}$-family in (3.3) undergoes a saddle-node bifurcation of limit cycles near Γ_0 when we vary $\widetilde{\lambda} \sim 0$. Under the same assumption on I, there is a smooth function $\widetilde{\lambda} = \widetilde{\lambda}(\epsilon)$, $\widetilde{\lambda}(0) = 0$, such that (3.3) with $\lambda = \lambda_0 + \epsilon\widetilde{\lambda}(\epsilon)$ has a unique (hyperbolic) limit cycle Hausdorff close to Γ_0 for each small $\epsilon > 0$.

If I has a zero of multiplicity $m \geq 1$ at $s = 0$, then $\text{Cycl}(\Gamma_0) \leq m + 1$. When $I(0) < 0$ (resp. $I(0) > 0$), then $\text{Cycl}(\Gamma_0) = 1$, and the limit cycle is hyperbolic and attracting (resp. repelling).

We refer the reader to [25, Theorem 3.1] and [25, Remark 3.4].

We say that the canard cycle Γ_0 is balanced if $s = 0$ is a zero of $I(s)$ defined in (3.4) ($I(0) = 0$). If Γ_0 is balanced, then there exists a unique function $G(s)$ satisfying $G(0) = 0$, $G'(0) > 0$ and

$$\int_{\psi_-(s)}^{\psi_+(G(s))} \frac{(Y^+_{\lambda_0} - Y^-_{\lambda_0})^2(x,0)}{-\det Z_{\lambda_0}(x)} \phi'\left(\phi^{-1}\left(\frac{-Y^-_{\lambda_0}}{Y^+_{\lambda_0} - Y^-_{\lambda_0}}(x,0)\right)\right) dx = 0 \tag{3.5}$$

for $s \sim 0$. This follows from the Implicit Function Theorem because $I(0) = 0$, $\psi'_-(s) > 0$, $\psi'_+(s) < 0$ and the integrand in (3.4) is negative for $x < 0$ and positive for $x > 0$ (see Assumptions A and D). We call G defined by (3.5) the slow relation function.

Assumption E. We suppose that Γ_0 is balanced and that $s = 0$ is an isolated zero of $I(s)$, meaning that $s = 0$ has a small neighborhood $]-\tilde{s}, \tilde{s}[$ ($\tilde{s} > 0$) that does not contain any other zero of $I(s)$.

Assumption E implies that I is either negative or positive for $s > 0$ (I is continuous). Using the above mentioned property of the integrand in (3.4) it can be easily seen that $0 < G(s) < s$ for $s > 0$ when I is negative and $G(s) > s$ for $s > 0$ when I is positive. Let $s_0 > 0$ be small and fixed. Thus, if I is negative (resp. positive), then the orbit of s_0

$$U_0 = \{s_0, s_1, s_2, \dots\} \tag{3.6}$$

defined by $s_{n+1} = G(s_n)$ (resp. $s_{n+1} = G^{-1}(s_n)$), $n \geq 0$, tends monotonically to the fixed point $s = 0$ of G. We want to study the Minkowski dimension of U_0.

Let us first define the notion of Minkowski (or box) dimension (see [14,34] and references therein). Let $U \subset \mathbb{R}^N$ be a bounded set. We define the δ-neighborhood of U:

$$U_\delta = \{x \in \mathbb{R}^N \mid d(x, U) \leq \delta\},$$

and denote by $|U_\delta|$ the Lebesgue measure of U_δ. The lower u-dimensional Minkowski content of U, for $u \geq 0$, is defined by

$$\mathcal{M}^u_*(U) = \liminf_{\delta \to 0} \frac{|U_\delta|}{\delta^{N-u}},$$

and analogously the upper u-dimensional Minkowski content $\mathcal{M}^{*u}(U)$ (we replace $\liminf_{\delta\to 0}$ with $\limsup_{\delta\to 0}$). We define lower and upper Minkowski dimensions of U:

$$\underline{\dim}_B U = \inf\{u \geq 0 \mid \mathcal{M}^u_*(U) = 0\}, \qquad \overline{\dim}_B U = \inf\{u \geq 0 \mid \mathcal{M}^{*u}(U) = 0\}.$$

We have $\underline{\dim}_B U \leq \overline{\dim}_B U$ and, if $\underline{\dim}_B U = \overline{\dim}_B U$, we call it the Minkowski dimension of U, and denote it by $\dim_B U$.

The upper Minkowski dimension is finitely stable. More precisely,

$$\overline{\dim}_B(U_1 \cup U_2) = \max\{\overline{\dim}_B U_1, \overline{\dim}_B U_2\},\ U_1, U_2 \subset \mathbb{R}^N.$$

If $U_1 \subset U_2$, then $\underline{\dim}_B U_1 \leq \underline{\dim}_B U_2$ and $\overline{\dim}_B U_1 \leq \overline{\dim}_B U_2$ ($\underline{\dim}_B$ and $\overline{\dim}_B$ are monotonic).

Furthermore, if $0 < \mathcal{M}_*^d(U) \leq \mathcal{M}^{*d}(U) < \infty$ for some d, then we say that U is Minkowski nondegenerate. In this case we have necessarily that $d = \dim_B U$. Recall also that the notion of being Minkowski nondegenerate is invariant under bi-Lipschitz maps. Namely, if Φ is a bi-Lipschitz map and U is Minkowski nondegenerate, then $\Phi(U)$ is also Minkowski nondegenerate (see [36, Theorem 4.1]).

We use these properties in Section 4.2.

Following [12], $\dim_B U_0$ exists, it is independent of the choice of $s_0 > 0$ and can take only the following discrete set of values: $0, \frac{1}{2}, \frac{2}{3}, \frac{3}{4}, \ldots, 1$ (see also Theorem 4.1). The set U_0 is defined in (3.6).

3.2 Statement of results

In this section we consider the family (3.3) that satisfies Assumptions A through E and assume that $\lambda = \lambda_0 + \epsilon\widetilde{\lambda}$ with $\widetilde{\lambda} \sim 0$.

Theorem 3.4. *Let $s_0 > 0$ be small and fixed and let U_0 be the orbit of s_0 defined in (3.6). If $\dim_B U_0 = 0$, then the following statements hold.*

1. *(λ unbroken) There exists a smooth function $\widetilde{\lambda} = \widetilde{\lambda}(\epsilon)$, $\widetilde{\lambda}(0) = 0$, such that (3.3) with $\lambda = \lambda_0 + \epsilon\widetilde{\lambda}(\epsilon)$ has a unique (hyperbolic) limit cycle Hausdorff close to Γ_0 for each small $\epsilon > 0$.*

2. *(λ broken) We have that $\mathrm{Cycl}(\Gamma_0) = 2$ and, for every small $\epsilon > 0$, the $\widetilde{\lambda}$-family (3.3) undergoes a saddle-node bifurcation of limit cycles Hausdorff close to Γ_0.*

Theorem 3.4 will be proved in Section 4.1.

Theorem 3.5. *Let U_0 be the orbit of s_0 defined in (3.6), for a small $s_0 > 0$. If $\dim_B U_0 < 1$, then* $\mathrm{Cycl}(\Gamma_0) \leq \frac{2-\dim_B U_0}{1-\dim_B U_0}$.

Theorem 3.5 will be proved in Section 4.1.

Theorem 3.6. *Let U_0 be the orbit of s_0 defined in (3.6), for a small $s_0 > 0$, and $\dim_B U_0 = 0$. The following statements are true.*

1. *For $\widetilde{\lambda} = \widetilde{\lambda}(\epsilon)$ given in Theorem 3.4.1 and for each small $\epsilon > 0$, the Minkowski dimension of any spiral trajectory accumulating (in forward or backward time) on the unique limit cycle of (3.3) near Γ_0 is equal to 1.*

2. *For each small $\epsilon > 0$, the Minkowski dimension of any spiral trajectory accumulating (in forward or backward time) on the limit cycle of multiplicity 2 of (3.3), born in a saddle-node bifurcation of limit cycles Hausdorff close to Γ_0, is equal to $\frac{3}{2}$ and moreover, the spiral is Minkowski nondegenerate.*

Theorem 3.6 will be proved in Section 4.2. A small (Hausdorff) neighborhood of Γ_0 in which we consider spiral trajectories in Theorem 3.6.1 or Theorem 3.6.2 does not shrink to Γ_0 as $\epsilon \to 0$ (see Section 4.2).

4 Proof of Theorems 3.4–3.6

4.1 Proof of Theorems 3.4–3.5

Let $\tilde{s} > 0$ be small and fixed. Suppose that F is a smooth function on $[0, \tilde{s}[$, $F(0) = 0$ and $0 < F(s) < s$ for all $s \in]0, \tilde{s}[$. We define $H(s) := s - F(s)$ and the orbit of $s_0 \in]0, \tilde{s}[$ by H:

$$U := \{s_n = H^n(s_0) \mid n = 0, 1, \dots\}$$

where H^n denotes n-fold composition of H. It is clear that s_n tends monotonically to zero. We say that the multiplicity of the fixed point $s = 0$ of H is equal to m if $s = 0$ is a zero of multiplicity m of F ($F(0) = \dots = F^{(m-1)}(0) = 0$ and $F^{(m)}(0) \neq 0$). If $F^{(n)}(0) = 0$ for each $n = 0, 1, \dots$, then we say that the multiplicity of $s = 0$ of H is ∞.

Theorem 4.1 ([12])**.** *Let F be a smooth function on $[0, \tilde{s}[$, $F(0) = 0$ and $0 < F(s) < s$ for each $s \in]0, \tilde{s}[$. Let $H = \mathrm{id} - F$ and let U be the orbit of $s_0 \in]0, \tilde{s}[$ by H. Then $\dim_B U$ is independent of the initial point s_0 and, for $1 \leq m \leq \infty$, the following bijective correspondence holds:*

$$m = \frac{1}{1 - \dim_B U} \tag{4.1}$$

where m is the multiplicity of $s = 0$ of H (if $m = \infty$, then $\dim_B U = 1$).

If we denote by Φ the integrand in (3.4) and (3.5), then we have

$$I(s) = \int_{\psi_-(s)}^{\psi_+(s)} \Phi(x)dx = \int_{\psi_-(s)}^{\psi_+(G(s))} \Phi(x)dx + \int_{\psi_+(G(s))}^{\psi_+(s)} \Phi(x)dx = \int_{\psi_+(G(s))}^{\psi_+(s)} \Phi(x)dx$$

where in the last step we use (3.5). From $\psi_+'(s) < 0$, $\Phi(x) > 0$ for $x > 0$ and The Fundamental Theorem of Calculus it follows that there exists a negative smooth function $\Psi(s)$ such that

$$I(s) = \Psi(s)(s - G(s)).$$

This implies that $s = 0$ is a zero of multiplicity m of $I(s)$ if and only if $s = 0$ is a zero of multiplicity m of $s - G(s)$.

We will first suppose that the orbit U_0 in (3.6) is generated by the slow relation function G. If $\dim_B U_0 = 0$, then Theorem 4.1, with $H = G$, implies that the multiplicity of the fixed point $s = 0$ of G is 1. Thus, we have that $s = 0$ is a simple zero of I and Theorem 3.4.1 (resp. Theorem 3.4.2) follows directly from [25, Theorem 3.1] (resp. [25, Remark 3.4]). See also Remark 3.3. If $\dim_B U_0 < 1$, then the multiplicity of $s = 0$ of G is equal to $\frac{1}{1 - \dim_B U_0}$ (see (4.1)). Thus, $s = 0$ is a zero of multiplicity $\frac{1}{1 - \dim_B U_0}$ of I and [25, Remark 3.4]) implies that

$$\mathrm{Cycl}(\Gamma_0) \leq 1 + \frac{1}{1 - \dim_B U_0} = \frac{2 - \dim_B U_0}{1 - \dim_B U_0}.$$

This completes the proof of Theorem 3.5.

If U_0 is generated by G^{-1}, Theorem 3.4 and Theorem 3.5 can be proved in the same way as above (we use Theorem 4.1 with $H = G^{-1}$ and the fact that G and G^{-1} have the same multiplicity of the fixed point $s = 0$).

4.2 Proof of Theorem 3.6

The Minkowski dimension of spiral trajectories accumulating on a hyperbolic or non-hyperbolic limit cycle of planar vector fields (without parameters) has been studied in [35,37]. We prove Theorem 3.6 for spiral trajectories in a Hausdorff neighborhood of the canard cycle Γ_0 that does not shrink to Γ_0 as $\epsilon \to 0$.

We will first prove Theorem 3.6.1. We assume that $\dim_B U_0 = 0$ and $\widetilde{\lambda}(\epsilon)$ is given in Theorem 3.4.1. Let $\bar{V}$ be a fixed neighborhood of Γ_0. Then the unique limit cycle of (3.3) with $\widetilde{\lambda} = \widetilde{\lambda}(\epsilon)$ is located in $\bar{V}$ for each $\epsilon > 0$ small enough (see [25]). For such fixed $\epsilon > 0$, let Γ be any spiral trajectory in $\bar{V}$ accumulating on the limit cycle (in the forward time if the limit cycle is attracting or in the backward time if the limit cycle is repelling). We write $\Gamma = \tilde{\Gamma} \cup \bar{\Gamma}$ where $\bar{\Gamma}$ is the part of Γ sufficiently close to the limit cycle (we can apply the results of [35,37]) and $\tilde{\Gamma}$ is the rest of Γ (of finite length). It is clear that $\dim_B \tilde{\Gamma} = 1$ and $\overline{\dim}_B \bar{\Gamma} \geq 1$. Since $\underline{\dim}_B \leq \overline{\dim}_B$, $\underline{\dim}_B$ is monotonic and $\overline{\dim}_B$ is finitely stable (see Section 3.1), we have

$$\underline{\dim}_B \bar{\Gamma} \leq \underline{\dim}_B (\tilde{\Gamma} \cup \bar{\Gamma}) \leq \overline{\dim}_B (\tilde{\Gamma} \cup \bar{\Gamma}) = \max\{\overline{\dim}_B \tilde{\Gamma}, \overline{\dim}_B \bar{\Gamma}\} = \overline{\dim}_B \bar{\Gamma}. \tag{4.2}$$

Since the limit cycle is hyperbolic (see Theorem 3.4.1), [35, Theorem 10] implies that $\dim_B \bar{\Gamma} = \underline{\dim}_B \bar{\Gamma} = \overline{\dim}_B \bar{\Gamma} = 1$. Using (4.2) we obtain $\dim_B \Gamma = 1$. This completes the proof of Theorem 3.6.1.

The first part of Theorem 3.6.2 can be proved in the same way as Theorem 3.6.1. Since the non-hyperbolic limit cycle is generated by a saddle-node bifurcation of limit cycles we have $\dim_B \bar{\Gamma} = \underline{\dim}_B \bar{\Gamma} = \overline{\dim}_B \bar{\Gamma} = \frac{3}{2}$ (see [35, Theorem 10] and [37, Theorem 1]). To prove the claim about Minkowski nondegeneracy; first observe that $\mathcal{M}^{3/2}(\tilde{\Gamma}) = 0$ since $\dim_B(\tilde{\Gamma}) = 1 < 3/2$ so that this part does not affect the upper and lower Minkowski content of $\Gamma = \tilde{\Gamma} \cup \bar{\Gamma}$; hence, it is enough to show that $\bar{\Gamma}$ is Minkowski nondegenerate. To see this, we observe that $\bar{\Gamma}$ can be partitioned into finitely many pieces $\bar{\Gamma}_i$; $i = 1, \dots, k$ such that each $\bar{\Gamma}_i$ is bi-Lipschitz equivalent to $[0,1[\times U$ by the Lipschitz flow-box Theorem [3]. Note also that $\dim_B U = 1/2$ and it is Minkowski nondegenerate which implies that $[0,1[\times U$ is also Minkowski nondegenerate; see the proof of [37, Theorem 4(b)]. Finally, the finite stability of Minkowski dimension and of Minkowski nondegeneracy now complete the proof exactly as in the proof of [37, Theorem 4(b)].

Abstract. In this paper, we consider the radially symmetric spacelike solutions of a nonlinear Dirichlet problem for the prescribed mean curvature spacelike equation in a Friedmann–Lemaître–Robertson–Walker spacetime. By using a conformal change of variable, this problem can be translated an equivalent problem in the Minkowski spacetime. By using the lower and upper solution method, fixed point, a priori bounds and topological degree method, we obtain the existence, nonexistence and multiplicity of radially symmetric spacelike solutions.

Keywords: topological degree, radially symmetric spacelike solutions, Dirichlet problem, prescribed mean curvature spacelike equation, Friedmann–Lemaître–Robertson–Walker spacetime.

2020 Mathematics Subject Classification: 34B15, 35A01, 35J93.

1 Introduction

Let $I \subseteq \mathbb{R}$ be an open interval in $\mathbb{R}$ with the metric $-dt^2$. Denote by $\mathcal{M}$ the $(N+1)$-dimensional product manifold $I \times \mathbb{R}^N$ with $N \geq 1$ endowed with the Lorentzian metric

$$g = -dt^2 + f^2(t)dx^2,$$

where $f \in C^\infty(I)$, $f > 0$, is called the *scale factor* or *warping function* in the related literature. Clearly, $\mathcal{M}$ is a Lorentzian warped product with base $(I, -dt^2)$, fiber $(\mathbb{R}^N, dx^2)$ and warping function f, we refer it as a Friedmann–Lemaître–Robertson–Walker (FLRW) spacetime. In the fiber space $(\mathbb{R}^N, dx^2)$, the metric dx^2 is an arbitrary Riemannian metric in a Generalized FLRW spacetime. In cosmology, the FLRW spacetime is the accepted model for a spatially homogeneous and isotropic Universe. In this context, the warping function $f(t)$ is interpreted as the radius of the Universe at time t, and the sign of its derivative indicates if the Universe

✉ Corresponding author. Email: xmannwnu@126.com

is expanding or contracting at given time, for more details of FLRW spacetime, we refer the reader to [11,21,22,27,34–37] and the references therein. Observe that for the particular case $f(t) \equiv 1$ we recover the Minkowski spacetime.

Given $f \in C^\infty(I)$, $f > 0$, for each $u \in C^\infty(\Omega)$, where Ω is a domain of $\mathbb{R}^N$, such that $u(\Omega) \subseteq I$, we can consider its graph $M = \{(x, u(x)) : x \in \Omega\}$ in the FLRW spacetime $\mathcal{M}$. The graph is spacelike whenever

$$|\operatorname{grad} u| < f(u) \quad \text{in } \Omega, \tag{1.1}$$

where $\operatorname{grad} u$ is the gradient of u in $\mathbb{R}^N$ and $|\cdot|$ denotes the Euclidean norm in $\mathbb{R}^N$, in this case, the unit timelike normal vector field in the same time orientation of ∂_t is given by

$$A = \frac{f(u)}{\sqrt{f(u) - |\operatorname{grad} u|^2}} \left(\frac{1}{f^2(u)} \operatorname{grad} u + \partial_t \right),$$

and the corresponding mean curvature associated to A, is defined by

$$\frac{1}{N} \left\{ \operatorname{div} \left(\frac{\operatorname{grad} u}{f(u)\sqrt{f^2(u) - |\operatorname{grad} u|^2}} \right) + \frac{f'(u)}{\sqrt{f^2(u) - |\operatorname{grad} u|^2}} \left(N + \frac{|\operatorname{grad} u|^2}{f^2(u)} \right) \right\},$$

where div denotes the divergence operator of $\mathbb{R}^N$, $f'(u) := f' \circ u$, it can be seen as a quasilinear elliptic operator Q, because of (1.1). We are interested in the existence of spacelike graphs with a prescribed mean curvature function in the FLRW spacetime $\mathcal{M}$. The general problem of the curvature prescription is, given a function $H : I \times \mathbb{R}^N \to \mathbb{R}$, to obtain solutions of the quasilinear elliptic equation

$$Q(u) = H(u, x), \quad |\operatorname{grad} u| < f(u) \quad \text{in } \Omega, \tag{1.2}$$

and (1.2) is called the prescribed mean curvature spacelike equation in FLRW spacetime. Specially relevant is the case when H is constant, then it is called the prescribed constant mean curvature spacelike equation (if $H = 0$ it is also called the maximal spacelike graph equation).

In the recent years, most of the efforts have been directed to the prescribed mean curvature spacelike equation in Minkowski spacetime ($f(t) \equiv 1$), in this context, we mention the seminal work of R. Bartnik and L. Simon [1], E. Calabi [8], S.-Y. Cheng and S.-T. Yau [10] and A. E. Treibergs [39], in these papers, the spacelike graphs having the property that their mean curvature is zero or constant are considered. More recently, Dirichlet problems for prescribed mean curvature spacelike equation in Minkowski spacetime have been widely concerned by many scholars, and their attention is mainly focused on their positive solutions, we refer the reader to [3–6,12–16,23,24,28–32,41,42] and the references therein. In particular, based on the detailed analysis of time map, some exact multiplicity of positive solutions have been obtained in [24,42], for the radially symmetric solutions on a ball, some existence, nonexistence and multiplicity results have been established in [4,5], and some bifurcation results have been obtained in [14,28] via bifurcation technique, and when Ω is a general domain in $\mathbb{R}^N$, some existence and bifurcation results have been obtained in the papers [13,15,16,31]. In addition to, these concern discrete problems associated with the prescribed mean curvature spacelike equation in Minkowski spacetime, we refer the reader to [7,9,25,26] and the references therein.

In comparison with the study in Minkowski spacetime, the number of references devoted to the prescribed mean curvature spacelike equation in FLRW spacetime is appreciably lower. Only in the recent years, C. Bereanu, D. de la Fuente, A. Romero and P. J. Torres [2,20] have considered the existence and multiplicity of radially symmetric spacelike solutions of the Dirichlet problem by using the Schauder fixed point Theorem with approximation process, J. Mawhin and P. J. Torres [33, 38] have provided some sufficient conditions for the existence of radially symmetric spacelike solutions of the Neumann problem by the Leray–Schauder degree theory, G. Dai, A. Romero and P. J. Torres [17–19] have obtained the existence and multiplicity of radially symmetric spacelike positive solutions of the equation with 0-Dirichlet boundary condition on a ball and studied the global structure of the solution set via the Rabinowitz's global bifurcation method. Xu and Ma [40] have considered the differential and difference problems associated with the discrete approximation of radially symmetric spacelike solutions of the Dirichlet problem, by using lower and upper solutions, they proved the existence of solutions of the corresponding differential and difference problems, and based on the ideas of a prior bound showed the solutions of the discrete problem converge to the solutions of the continuous problem.

In this paper we are concerned with the mixed boundary value problem

$$\begin{cases} -(r^{N-1}\phi(v'))' = \lambda N r^{N-1}\left[\dfrac{f'(\varphi^{-1}(v))}{\sqrt{1-v'^2}} - f(\varphi^{-1}(v))H(\varphi^{-1}(v),r)\right], & r\in(0,R),\\ |v'|<1, \quad r\in(0,R), \\ v'(0)=v(R)=0, \end{cases} \tag{1.3}$$

where $\phi(s) = \frac{s}{\sqrt{1-s^2}}$, and $\phi : (-1,1) \to \mathbb{R}$ is an increasing homeomorphism with $\phi(0) = 0$, such an ϕ is called *singular*, λ is a positive parameter, R is a positive constant, $f \in C^\infty(I)$ and $f > 0$, I is an open interval in $\mathbb{R}$, $\varphi(s) = \int_0^s \frac{dt}{f(t)}$, φ^{-1} is the inverse function of φ, $H : I\times[0,R] \to \mathbb{R}$ is a continuous function. The aim of this paper is to investigate the intervals of the λ in which the (1.3) has zero, one or two positive radial solutions.

This study mainly motivated by the numerical approximation of radially symmetric spacelike solutions of the nonlinear Dirichlet problem for the prescribed mean curvature spacelike equation in FLRW spacetime:

$$\begin{cases} \operatorname{div}\left(\frac{\operatorname{grad} u}{f(u)\sqrt{f^2(u)-|\operatorname{grad} u|^2}}\right) + \frac{f'(u)}{\sqrt{f^2(u)-|\operatorname{grad} u|^2}}\left(N + \frac{|\operatorname{grad} u|^2}{f^2(u)}\right) = NH(u,|x|) & \text{in } \mathcal{B},\\ |\operatorname{grad} u| < f(u) \quad \text{in } \mathcal{B}, \\ u = 0 \quad \text{on } \partial\mathcal{B}, \end{cases} \tag{1.4}$$

where $\mathcal{B} = \{x\in\mathbb{R}^N : |x| < R\}$, $f\in C^\infty(I)$, $f>0$ and $H : I\times[0,+\infty)\to\mathbb{R}$ is the prescribed mean curvature function. We follow the method developed in [20], let us define the function $\varphi : I\to\mathbb{R}$ by $\varphi(s) = \int_0^s \frac{dt}{f(t)}$, and φ is an increasing diffeomorphism from I onto $J := \varphi(I)$ such that $\varphi(0) = 0$. Doing the change $v = \varphi(u)$ and taking radial coordinates, we can reduce the Dirichlet problem (1.4) to the mixed boundary value problem (1.3) with $\lambda = 1$, and the solutions of (1.3) with $\lambda = 1$ are just the radially symmetric spacelike solutions of (1.4).

We say that a function $v\in C^1[0,R]$ is a solution of (1.3) if $\|v'\|_\infty < 1$, $r^{N-1}\phi(v')\in C^1[0,R]$, and (1.3) is satisfied. For (1.3), since the graph associate to v is spacelike, i.e. $\|v'\|_\infty < 1$, we deduce that $\|v\|_\infty < R$, this implies the image of nonnegative v is in $[0,R]$, therefore, when discussing the nonnegative solutions of (1.3), we always assume $\varphi^{-1}([0,R]) \subset I$, which is equivalent to

$$I_f R := \left[0, \int_0^R f(\varphi^{-1}(s))ds\right] \subset I.$$

In Section 2, we present a lower and upper solution result for continuous problem (1.3) with $\lambda = 1$. In Section 3, we give some notations and fixed point reformulation of (1.3) with $\lambda = 1$ and prove all possible solutions and their first differences have a prior bounds, based on this, we calculate some topological degrees. Using the results of these two parts and the estimate of the first derivative of a concave function, in Section 4, we show that there is a $\Lambda > 0$ such that problem (1.3) has zero, at least one or at least two positive solutions when $\lambda \in (0, \Lambda)$, $\lambda = \Lambda$, $\lambda > \Lambda$. Finally in Section 5, for the convenience of readers and integrity of the paper, we give the detailed derivation process of problem (1.3) with $\lambda = 1$.

The main result is as follows.

Theorem 1.1. *Assume that* $I_f R \subset I$ *and* $f'(t) \geq 0$, $H(t,r) < \frac{f'}{f}(t)$ *for all* $r \in [0, R]$, $t \in I_f R$ *and assume also that*

$$\begin{cases} \lim\limits_{t \to 0^+} \frac{N f'(t)}{\varphi(t)} = f_0, \\ \lim\limits_{t \to 0^+} \frac{N f(t) H(t,r)}{\varphi(t)} = H_0, \\ f_0 - H_0 = 0. \end{cases} \tag{A_{fH}}$$

Then there is a $\Lambda > \frac{2NM_0}{R^3}$ *such that problem* (1.3) *has zero, at least one or at least two positive solutions when* $\lambda \in (0, \Lambda)$, $\lambda = \Lambda$, $\lambda > \Lambda$.

Notations: The space $C := C[0, R]$ will be endowed with the usual sup-norm $\|\cdot\|_\infty$ and $C^1 := C^1[0, R]$ will considered with the norm $\|u\| = \|u\|_\infty + \|u'\|_\infty$. $C^1_M := \{u \in C^1 : u'(0) = u(R) = 0\}$ is the closed subspace of C^1. For $u_0 \in C^1_M$, we set $B(u_0, \rho) := \{u \in C^1_M : \|u\| < \rho\}$ $(\rho > 0)$ and B_ρ is used to represent $B(0, \rho)$.

2 Lower and upper solutions

In this section, we develop the lower and upper solution method for the mixed boundary value problem

$$\begin{cases} -\left(r^{N-1}\phi(v')\right)' = N r^{N-1}\left[\dfrac{f'(\varphi^{-1}(v))}{\sqrt{1 - v'^2}} - f(\varphi^{-1}(v)) H(\varphi^{-1}(v), r)\right], & r \in (0, R), \\ |v'| < 1, \quad r \in (0, R), \\ v'(0) = v(R) = 0. \end{cases} \tag{2.1}$$

Definition 2.1. A lower solution α of (2.1) is a function $\alpha \in C^1$ such that $\|\alpha'\|_\infty < 1$, $r^{N-1}\phi(\alpha') \in C^1$, $I_f R \subset I$ and

$$-(r^{N-1}\phi(\alpha'))' \leq N r^{N-1}\left[\frac{f'(\varphi^{-1}(\alpha))}{\sqrt{1 - \alpha'^2}} - f(\varphi^{-1}(\alpha)) H(\varphi^{-1}(\alpha), r)\right], \quad r \in (0, R), \quad \alpha(R) \leq 0.$$

An upper solution β of (2.1) is a function $\beta \in C^1$ such that $\|\beta'\|_\infty < 1$, $r^{N-1}\phi(\beta') \in C^1$, $I_f R \subset I$ and

$$-(r^{N-1}\phi(\beta'))' \geq N r^{N-1}\left[\frac{f'(\varphi^{-1}(\beta))}{\sqrt{1 - \beta'^2}} - f(\varphi^{-1}(\beta)) H(\varphi^{-1}(\beta), r)\right], \quad r \in (0, R), \quad \beta(R) \geq 0.$$

Such a lower or an upper solution is called strict if the above inequalities are strict.

Theorem 2.2. *Assume that $I_f R \subset I$ and $f'(t) \geq 0$, $H(t,r) < \frac{f'}{f}(t)$ for all $r \in [0,R]$, $t \in I_f R$. If (2.1) has a lower solution α and an upper solution β such that $\alpha(r) \leq \beta(r)$ for all $r \in [0,R]$, then (2.1) has at least one solution v such that $\alpha(r) \leq v(r) \leq \beta(r)$ for all $r \in [0,R]$.*

Proof. Let $\gamma : [0,R] \times \mathbb{R} \to \mathbb{R}$ be the continuous function defined by

$$\gamma(r,v) = \begin{cases} \alpha(r), & \text{if } v < \alpha(r), \\ v, & \text{if } \alpha(r) \leq v \leq \beta(r), \\ \beta(r), & \text{if } v > \beta(r). \end{cases}$$

We consider the modified problem

$$\begin{cases} (r^{N-1}\phi(v'))' + Nr^{N-1}\Big[\dfrac{f'(\varphi^{-1}(\gamma(r,v)))}{\sqrt{1-v'^2}} \\ \qquad -H(\varphi^{-1}(\gamma(r,v)),r)f(\varphi^{-1}(\gamma(r,v))) - v + \gamma(r,v)\Big] = 0, \quad r \in (0,R), \\ |v'| < 1, \quad r \in (0,R), \\ v'(0) = 0 = v(R). \end{cases} \tag{2.2}$$

It follows from [2] that the problem (2.2) has at least one solution.

We show that if v is a solution (2.2), then $\alpha(r) \leq v(r) \leq \beta(r)$ for all $r \in [0,R]$. This will conclude the proof.

Suppose by contradiction that there is some $r_0 \in [0,R]$ such that

$$\max_{[0,R]}[\alpha - v] = \alpha(r_0) - v(r_0) > 0.$$

If $r_0 \in (0,R)$, then $\alpha'(r_0) = v'(r_0)$ and there are sequences $\{r_k\}$ in $(0,r_0)$ converging to r_0 such that $\alpha'(r_k) - v'(r_k) \geq 0$. Since ϕ is an increasing homeomorphism then we can have

$$r_k^{N-1}\phi(v'(r_k)) - r_0^{N-1}\phi(v'(r_0)) \leq r_k^{N-1}\phi(\alpha'(r_k)) - r_0^{N-1}\phi(\alpha'(r_0)),$$

which means

$$(r_0^{N-1}\phi(\alpha'(r_0)))' \leq (r_0^{N-1}\phi(v'(r_0))'.$$

Therefore, since α is a lower solution of (2.1) we have

$$\begin{aligned} &(r_0^{N-1}\phi(\alpha'(r_0)))' \\ &\quad \leq (r_0^{N-1}\phi(v'(r_0)))' \\ &\quad = Nr_0^{N-1}\left[-\frac{f'(\varphi^{-1}(\alpha(r_0)))}{\sqrt{1-(\alpha'(r_0))^2}} + H(\varphi^{-1}(\alpha(r_0)),r_0)f(\varphi^{-1}(\alpha(r_0))) + v(r_0) - \alpha(r_0)\right] \\ &\quad < Nr_0^{N-1}\left[-\frac{f'(\varphi^{-1}(\alpha(r_0)))}{\sqrt{1-(\alpha'(r_0))^2}} + H(\varphi^{-1}(\alpha(r_0)),r_0)f(\varphi^{-1}(\alpha(r_0)))\right] \\ &\quad \leq (r_0^{N-1}\phi(\alpha'(r_0)))', \end{aligned}$$

but this a contradiction.

If $\max_{[0,R]}[\alpha - v] = \alpha(R) - v(R) > 0$, then by definition of lower solutions, we obtain a contradiction again. If $\max_{[0,R]}[\alpha - v] = \alpha(0) - v(0) > 0$, then there exists $r_1 \in (0,R]$ such that $\alpha(r) - v(r) > 0$ for all $r \in [0,r_1]$ and $\alpha'(r_1) - v'(r_1) \leq 0$. It follows that

$$(r_1^{N-1}\phi(\alpha'(r_1)))' \leq (r_1^{N-1}\phi(v'(r_1)))'.$$

Note that $I_f R \subset I$ and $f'(t) \geq 0$ for all $t \in I_f R$. By using the fact and integrating (2.2) from 0 to r_1, we have that

$$\begin{aligned} r_1^{N-1}\phi(\alpha'(r_1)) &\leq r_1^{N-1}\phi(v'(r_1)) \\ &< N\int_0^{r_1} r^{N-1}\left[-\frac{f'(\varphi^{-1}(\alpha(r)))}{\sqrt{1-(v'(r))^2}} + H(\varphi^{-1}(\alpha(r)),r)f(\varphi^{-1}(\alpha(r)))\right]dr \\ &\leq N\int_0^{r_1} r^{N-1}\left[-\frac{f'(\varphi^{-1}(\alpha(r)))}{\sqrt{1-(\alpha'(r))^2}} + H(\varphi^{-1}(\alpha(r)),r)f(\varphi^{-1}(\alpha(r)))\right]dr \\ &\leq r_1^{N-1}\phi(\alpha'(r_1)). \end{aligned}$$

But this is a contradiction. Hence, $\alpha(r) \leq v(r)$ for all $r \in [0, R]$. Analogously, we can show that $v(r) \leq \beta(r)$ for all $r \in [0, R]$. □

Remark 2.3. The Theorem 2.2 still holds for $f(t) \equiv 1$.

3 Fixed point, a priori bounds and degree

In this section, we consider problems of type

$$\begin{cases} (r^{N-1}\phi(v'))' + r^{N-1}g(r, v, v') = 0, & r \in (0, R), \\ |v'| < 1, \quad r \in (0, R), \\ v'(0) = v(R) = 0, \end{cases} \tag{3.1}$$

where $N \geq 1$ is an integer, $R > 0$ is a constant, and we also assume that

(A_ϕ) $\phi : (-1, 1) \to \mathbb{R}$ is an odd, increasing homeomorphism;

(A_g) $g : [0, R] \times [0, \alpha) \times (-1, 1) \to [0, +\infty)$ is a continuous function with $0 < \alpha \leq +\infty$.

Recall, by a solution of (3.1) we mean a function $v \in C^1$ with $\|v'\|_\infty < 1$, such that $r^{N-1}\phi(v') \in C^1$ and (3.1) is satisfied.

Setting

$$\sigma(r) := 1/r^{N-1},$$

we introduce the linear operators

$$S : C \to C, \quad Sv(r) = \sigma(r)\int_0^r t^{N-1}v(t)\,dt \quad (r \in [0, R]), \quad Sv(0) = 0;$$

$$K : C \to C^1, \quad Kv(r) = \int_r^R v(t)\,dt \quad (r \in [0, R]).$$

It is easy to see the standard argument that K is bounded and that S is compact by the Arzelà–Ascoli theorem. This means that the nonlinear operator $K \circ \phi^{-1} \circ S : C \to C^1$ is compact. Moreover, for a given function $h \in C$, the problem

$$(r^{N-1}\phi(v'))' + r^{N-1}h(r) = 0, \quad r \in (0, R), \quad |v'| < 1, \quad v'(0) = v(R) = 0$$

has a unique solution

$$v = K \circ \phi^{-1} \circ S \circ h.$$

Next, let N_g be the Nemytskii operator associated with g, i.e.,

$$N_g : C \to C, \quad N_g = g(\cdot, v(\cdot), v'(\cdot)).$$

Noticing that N_g is continuous and maps a bounded set to a bounded set. So problem (3.1) has the following reformulation about fixed points.

Lemma 3.1. *A function $v \in C^1_M$ is a solution of problem (3.1) if and only if the compact nonlinear operator*

$$\mathcal{N}_g : C^1_M \to C^1_M, \quad \mathcal{N}_g = K \circ \phi^{-1} \circ S \circ N_g$$

has a fixed point, and furthermore the fixed point of $\mathcal{N}_g$ satisfies

$$\|v'\|_\infty < 1, \quad \|v\|_\infty < R \tag{3.2}$$

and

$$d_{LS}[I - \mathcal{N}_g, B_\rho, 0] = 1 \quad \textit{for all } \rho \geq (R+1).$$

Proof. Since the range of ϕ^{-1} is $(-1,1)$, the inequality (3.2) holds. Next, consider the compact homotopy

$$\mathcal{H} : [0,1] \times C^1_M, \quad \mathcal{H}(\tau, \cdot) = \tau \mathcal{N}_g$$

and

$$\mathcal{H}([0,1] \times C^1_M) \subset B_{(R+1)}.$$

Then, from the invariance under homotopy of the Leray–Schauder degree it follows that

$$d_{LS}[I - \mathcal{H}(0,\cdot), B_\rho, 0] = d_{LS}[I - \mathcal{H}(1,\cdot), B_\rho, 0] = d_{LS}[I - \mathcal{N}_g, B_\rho, 0] = 1,$$

for all $\rho \geq (R+1)$. □

In view of Theorem 2.2 and Remark 2.3, we have the following result.

Lemma 3.2. *Assume that (3.1) has a lower solution α and an upper solution β such that $\alpha(r) \leq \beta(r)$ for all $r \in [0,R]$, and let $\Omega_{\alpha,\beta} := \{v \in C^1_M : \alpha \leq v \leq \beta\}$. Assume also that (3.1) has an unique solution v_0 in $\Omega_{\alpha,\beta}$ and there exists $\rho_0 > 0$ such that $\overline{B}(v_0, \rho_0) \subset \Omega_{\alpha,\beta}$. Then*

$$d_{LS} = [I - \mathcal{N}_g, B(v_0, \rho), 0] = 1 \quad \textit{for all } 0 < \rho \leq \rho_0,$$

where $\mathcal{N}_g$ is the fixed point operator associated to (3.1).

Proof. Let $\mathcal{N}_g$ be the fixed point operator associated with (3.1). The proof of Theorem 2.2 shows that any fixed point v of $\mathcal{N}_g$ is contained in $\Omega_{\alpha,\beta}$, and this means that v_0 is the unique fixed of $\mathcal{N}_g$ and there exists $\rho_0 > 0$ such that $\overline{B}(v_0, \rho_0) \subset \Omega_{\alpha,\beta}$. From Lemma 3.1 and the excision property of the Leray–Schauder degree there is

$$d_{LS}[I - \mathcal{N}_g, B(v_0, \rho_0), 0] = 1,$$

which is

$$d_{LS}[I - \mathcal{N}_g, B(v_0, \rho), 0] = 1 \quad \text{for all } 0 < \rho \leq \rho_0.$$

□

Lemma 3.3. *Assume that (A_ϕ), (A_g) and*

(A_g') *$g(r, v, v') > 0$ for all $(r, v, v') \in (0, R] \times (0, \alpha) \times (-1, 1)$.*

Let v be a nontrivial solution of (3.1). Then $v > 0$ on $[0, R)$ and v is strictly decreasing.

Proof. Let's first integrate both sides of (3.1) from 0 to r, which is

$$v'(r) = -\phi^{-1}\left(\frac{1}{r^{N-1}}\int_0^r s^{N-1}g(s, v, v')ds\right). \tag{3.3}$$

Then integrate both sides of (3.3) from r to R to get

$$v(r) = \int_r^R \phi^{-1}\left(\frac{1}{t^{N-1}}\int_0^t s^{N-1}g(s, v, v')ds\right) dt. \tag{3.4}$$

So if $g(r, v, v') > 0$, we have $v > 0$ on $[0, R)$ and v is strictly decreasing. □

In the next lemma we assume that g is sublinear with respect to ϕ at zero.

Lemma 3.4. *Assume that conditions (A_ϕ), (A_g) and (A'_g) hold. Assume also that*

$$\lim_{s\to 0^+} \frac{g(r, s, s')}{\phi(s)} = 0 \quad \textit{uniformly for } r \times s' \in [0, R] \times (-1, 1) \tag{3.5}$$

and

$$\liminf_{s\to 0^+} \frac{\phi(\sigma s)}{\phi(s)} > 0 \quad \textit{for all } \sigma > 0. \tag{3.6}$$

Then there exists $\rho_0 > 0$ such that

$$d_{LS}[I - \mathcal{N}_g, B_\rho, 0] = 1 \quad \textit{for all } 0 < \rho \leq \rho_0.$$

Proof. Using (3.6) we can find $\varepsilon > 0$ such that

$$R\varepsilon/N < \liminf_{s\to 0} \frac{\phi(s/R)}{\phi(s)}. \tag{3.7}$$

Using (3.5) we can find $s_\varepsilon > 0$ such that

$$g(r, s, s') \leq \varepsilon\phi(s) \quad \text{for all } (r, s, s') \in [0, R] \times [0, s_\varepsilon] \times (-1, 1). \tag{3.8}$$

Next, we consider the compact homotopy

$$\mathcal{H} : [0, 1] \times C^1_M \to C^1_M, \quad \mathcal{H}(\tau, v) = \tau\mathcal{N}_g(v).$$

Let's we say have $\rho_0 > 0$ such that

$$v \neq \mathcal{H}(\tau, v) \quad \text{for all } (\tau, v) \in [0, 1] \times (\overline{B}_{\rho_0} \setminus \{0\}). \tag{3.9}$$

In fact, suppose there exists

$$v_k = \tau_k\mathcal{N}_g(v_k), \quad \tau_k \in [0, 1],$$

where $v_k \in C^1_M \setminus \{0\}$, $k \in \mathbb{N}$, $\|v_k\| \to 0$. From the previous lemma, v is strictly monotonically decreasing and strictly positive on $[0, R)$.

Asuming $\|v_k\| \leq s_\varepsilon$, $k \in \mathbb{N}$, we can see from (3.8)

$$g(r, v_k(r), v'_k(r)) \leq \varepsilon\phi(\|v_k\|_\infty) \quad \text{for all } r \in [0, R],\ k \in \mathbb{N}.$$

Then for any $k \in \mathbb{N}$, there is

$$\begin{aligned}\|v_k\|_\infty &\leq \int_0^R \phi^{-1}\left(\sigma(t)\int_0^t r^{N-1}g(r,v_k,v_k')dr\right)dt \\ &\leq R\phi^{-1}\left(\frac{\varepsilon R}{N}\phi(\|v_k\|_\infty)\right).\end{aligned}$$

That is, there is

$$\frac{\phi\left(\frac{\|v_k\|_\infty}{R}\right)}{\phi(\|v_k\|_\infty)} \leq \frac{\varepsilon R}{N}.$$

This contradicts (3.7) and so (3.9) is true. That is, for any $\rho \in (0, \rho_0]$, there is

$$d_{LS}[I - \mathcal{H}(1,\cdot), B_\rho, 0] = d_{LS}[I - \mathcal{N}_g, B_\rho, 0] = d_{LS}[I - \mathcal{H}(0,\cdot), B_\rho, 0] = d_{LS}[I, B_\rho, 0] = 1. \qquad \square$$

4 Proof of main result

First of all there is an important lemma before the main result of this paper.

Lemma 4.1. *Let $k \in (0,1)$, $\beta_0 \in (0, \frac{1-k}{8}R)$ be given. Let $I_{k,\beta_0} := [\frac{4\beta_0}{1-k}, R - \frac{4\beta_0}{1-k}]$. Then*

$$\frac{R}{2} \in I_{k,\beta_0}$$

and

$$|v'(s)| \leq 1-k, \quad \forall v \in \mathcal{A}, \quad \forall s \in I_{k,\beta_0},$$

where $\mathcal{A} := \{\, v \mid v$ is concave in $[0,R]$, $v'(0) < 1$, $v'(R) > -1$, $\|v\|_\infty \leq 4\beta_0\}$.

Proof. Let $a = 1-k$, $b = \frac{4\beta_0}{1-k}$, then

$$0 < a < 1, \quad b \in \left(0, \frac{R}{2}\right), \quad I := I_{k,\beta_0} = [b, R-b].$$

Since $v \in C^1[0,R]$, v is concave in $[0,R]$ and v' is decreasing. If there exists $s \in I$ such that $|v'(s)| > 1-k = a$, then $v'(s) > a$ or $v'(s) < -a$. If $v'(s) < -a$, then $\frac{v(s)-v(R)}{s-R} = v'(t)$, for some $t \in (s,R)$. So we have $\frac{v(s)}{s-R} \leq v'(s) < -a$. Therefore $v(s) > a(R-s) \geq ab = 4\beta_0 \geq \|v\|_\infty$. This is a contradiction. Analogously, we can get a contradiction for other case. $\square$

Proof of Theorem 1.1. Let us say

$$S_j := \{\lambda > 0 : (1.3) \text{ at least } j \text{ positive solutions}\}, \quad (j = 1,2).$$

1. *The existence of* Λ.

Let $\lambda > 0$ and v be a positive solution of (1.3). Firstly, using hypothesis (A_{fH}), we have: $\forall \varepsilon_0 > 0$, $\exists\, \delta_1$, for $|\varphi^{-1}(v) - 0| < \delta_1$, there can be $\left|\frac{Nf'(\varphi^{-1}(v))}{v} - f_0\right| < \varepsilon_0$. For the above ε_0, $\exists\, \delta_2$, when $|\varphi^{-1}(v) - 0| < \delta_2$, there is $\left|\frac{Nf(\varphi^{-1}(v))H(\varphi^{-1}(v),r)}{v} - H_0\right| < \varepsilon_0$.

Secondly, integrating (1.3) from 0 to $r \in (0, R]$ and using that v is a positive solution of (1.3) such that we obtain

$$\begin{aligned} -r^{N-1}\phi(v') &= \int_0^r \lambda t^{N-1}\left(\frac{Nf'(\varphi^{-1}(v))}{\sqrt{1-v'^2}} - Nf(\varphi^{-1}(v))H(\varphi^{-1}(v),t)\right)dt \\ &< \lambda \int_0^r t^{N-1}\left(\frac{f_0 v}{\sqrt{1-v'^2}} - H_0 v\right)dt \\ &= \lambda \int_0^r t^{N-1}\left(\frac{f_0 v}{\sqrt{1-v'^2}} - f_0 v\right)dt. \end{aligned}$$

Using Lemma 4.1, let $k = a_0$, $\beta_0 = \frac{(1-a_0)\eta}{8}R \in (0, \frac{1-a_0}{8}R)$, a_0 is the constant that satisfies the definition and $\eta \in (0,1)$ is the given constant, then there is $I = [\frac{\eta}{2}R, R - \frac{\eta}{2}R]$. Hence, $\|v\|_\infty \le \frac{(1-a_0)\eta}{2}R$, $|v'(s)| \le 1 - a_0$, for all $s \in I$.

Therefore,

$$\begin{aligned} -r^{N-1}\phi(v') &< \lambda \int_0^r t^{N-1}\left(\frac{f_0 v}{\sqrt{1-v'^2}} - f_0 v\right)dt \\ &\le \lambda \int_0^r t^{N-1} f_0 \frac{(1-a_0)\eta}{2} R\left(\frac{1}{\sqrt{1-(1-a_0)^2}} - 1\right)dt \\ &\le \lambda M R \int_0^r t^{N-1} dt \\ &= \frac{\lambda M R r^N}{N}, \end{aligned}$$

where $M = f_0 \frac{(1-a_0)\eta}{2}\left(\frac{1}{\sqrt{1-(1-a_0)^2}} - 1\right)$.

Therefore, there is

$$-v'(r) \le -\frac{v'(r)}{\sqrt{1-v'^2}} < \frac{\lambda M R r}{N}. \tag{4.1}$$

Integrating (4.1) from 0 to R we obtain

$$v(0) < \frac{\lambda M R^3}{2N}. \tag{4.2}$$

Next, using $v(0) > 0$, we obtain

$$\lambda > \frac{2NM_0}{R^3},$$

where $M_0 := v(0)/M$.

We know from [18] that the problem (1.3) has at least one positive solution for $\lambda > 0$. Specially, $S_1 \neq \emptyset$ and we can define

$$\Lambda = \Lambda(R) := \inf S_1.$$

Clearly, we have $\Lambda \ge \frac{2NM_0}{R^3}$. We claim that $\Lambda \in S_1$. Indeed, let $\lambda_k \subset S_1, \lambda_k \to \Lambda$ $(k \to \infty)$. Since $v_k \in C^1_M$, v_k is positive on $[0, R)$, then

$$v_k = K \circ \phi^{-1} \circ S \circ \left(\lambda_k\left(\frac{Nf'(\varphi^{-1}(v_k))}{\sqrt{1-v_k'^2}} - Nf(\varphi^{-1}(v_k))H(\varphi^{-1}(v_k), r)\right)\right).$$

Using (3.2) and the Arzelà–Ascoli theorem can have $v \in C$ and has a subsequence such that $\{v_k\} \to v$. So, it follows that $v \geq 0$ and

$$v = K \circ \phi^{-1} \circ S \circ \left(\Lambda \left(\frac{Nf'(\varphi^{-1}(v))}{\sqrt{1-v'^2}} - Nf(\varphi^{-1}(v))H(\varphi^{-1}(v), r) \right) \right).$$

With (4.2), we can see that there is a constant $c_1 > 0$ such that $v_k(0) > c_1$, $\forall k \in \mathbb{N}$. This ensures that $v(0) \geq c_1$, according to Lemma 3.3, has $v > 0$ on $[0, R)$. Hence, $\Lambda \in S_1$. Obviously, $\Lambda > \frac{2NM_0}{R^3}$.

Next, let $\lambda_0 > \Lambda$, where λ_0 is arbitrary. Here $\lambda_0 \in S_1$ is proved by Theorem 2.2. Let v_1 be a positive solution for (1.3) corresponding to $\lambda = \Lambda$. It is now easy to know that v_1 is a lower solution to problem (1.3) when $\lambda = \lambda_0$. Construct the upper solution, let $H > 0$, $\widetilde{R} > R$, while considering the problem

$$\left(r^{N-1} \frac{v'}{\sqrt{1-v'^2}} \right)' + r^{N-1} H = 0, \quad v'(0) = v(\widetilde{R}) = 0. \tag{4.3}$$

By integrating the above formula, we get

$$v(r) = \frac{N}{H} \left[\sqrt{1 + \frac{H^2}{N^2}\widetilde{R}^2} - \sqrt{1 + \frac{H^2}{N^2} r^2} \right].$$

For fixed $\lambda_2 > \lambda_0$, let v_2 is the solution of problem (4.3) corresponding to $H = \lambda_2 M \widetilde{R}$. By $v_2(R) > 0$ and

$$\lambda_0 \left(\frac{Nf'(\varphi^{-1}(v_2))}{\sqrt{1-v_2'^2}} - Nf(\varphi^{-1}(v_2))H(\varphi^{-1}(v_2), r) \right) \leq \lambda_2 M \widetilde{R}, \quad r \in [0, R].$$

Then we can see that v_2 is an upper solution of problem (1.3) when $\lambda = \lambda_0$, then

$$v_2(R) = N \left[\sqrt{\frac{1}{(\lambda_2 M \widetilde{R})^2} + \frac{\widetilde{R}^2}{N^2}} - \sqrt{\frac{1}{(\lambda_2 M \widetilde{R})^2} + \frac{R^2}{N^2}} \right].$$

Then there is $v_1(0) < v_2(R)$ when $\widetilde{R}$ is sufficiently large. Consider that v_1, v_2 is strictly decreasing, then there is $v_1 < v_2$ on $[0, R]$. Thus, from Theorem 2.2 we know that $\lambda_0 \in S_1$, therefore $S_1 \in [\Lambda, \infty]$.

2. *Multiplicity.*

Let $\lambda_0 > \Lambda$. Let us prove $\lambda_0 \in S_2$ by Lemma 3.1, 3.2, 3.4. Let v_1, v_2 be constructed as above. When $\lambda = \lambda_0$, let v_0 be a solution to problem (1.3) such that $v_1 \leq v_0 \leq v_2$, i.e., $v_0 \in \Omega_{v_1, v_2} := \{v_0 \in C^1_M : v_1 \leq v_0 \leq v_2\}$.

First, we claim that exists $\varepsilon > 0$ with $\overline{B}(v_0, \varepsilon) \subset \Omega_{v_1, v_2}$. For all $r \in [0, R]$, there is

$$\begin{aligned}
v_2(r) &= \int_r^{\widetilde{R}} \phi^{-1} \left(\sigma(t) \int_0^t s^{N-1} \lambda_2 M \widetilde{R} ds \right) dt \\
&> \int_r^R \phi^{-1} \left(\sigma(t) \int_0^t s^{N-1} \lambda_2 \left(\frac{Nf'(\varphi^{-1}(v_2))}{\sqrt{1-v_2'^2}} - Nf(\varphi^{-1}(v_2))H(\varphi^{-1}(v_2), s) \right) ds \right) dt \\
&\geq \int_r^R \phi^{-1} \left(\sigma(t) \int_0^t s^{N-1} \lambda_0 \left(\frac{Nf'(\varphi^{-1}(v_0))}{\sqrt{1-v_0'^2}} - Nf(\varphi^{-1}(v_0))H(\varphi^{-1}(v_0), s) \right) ds \right) dt \\
&= v_0(r).
\end{aligned}$$

Therefore, there exists $\varepsilon_2 > 0$ such that $v \le v_2$ for all $v \in \overline{B}(v_0, \varepsilon_2)$. Similarly on $[0, R/2]$ there is $v_1 < v_0$. Therefore $\varepsilon_1' > 0$ can be found such that

$$v \in C^1_M \text{ and } \|v - v_0\|_\infty \le \varepsilon_1' \Rightarrow v \ge v_1 \text{ on } [0, R/2]. \tag{4.4}$$

On the other hand, we have

$$-v_0' = \phi^{-1} \circ S \circ \lambda_0 \left(\frac{Nf'(\varphi^{-1}(v_0))}{\sqrt{1 - {v_0'}^2}} - Nf(\varphi^{-1}(v_0))H(\varphi^{-1}(v_0), r) \right)$$

and

$$-v_1' = \phi^{-1} \circ S \circ \Lambda \left(\frac{Nf'(\varphi^{-1}(v_1))}{\sqrt{1 - {v_1'}^2}} - Nf(\varphi^{-1}(v_1))H(\varphi^{-1}(v_1), r) \right),$$

yielding $v_0' < v_1'$ on $[R/2, R]$. So we can find a sufficiently small $\varepsilon_1 \in (0, \varepsilon_1')$ such that $v' < v_1'$ on $[R/2, R]$, where $v \in \overline{B}(v_0, \varepsilon_1)$. It follows from $v_0(R) = 0 = v(R)$ that for all $v \in \overline{B}(v_0, \varepsilon_1)$ has $v > v_1$ on [0,R]. Considering (4.4), we claim $\varepsilon \in (0, \min\{\varepsilon_1, \varepsilon_2\})$. Next, if the problem (1.3) has a second solution in Ω_{v_1, v_2}, then the proof of the multiplicity is completed.

If not, using Lemma 3.2 we get

$$d_{LS}[I - \mathcal{N}_{\lambda_0}, B(v_0, \rho), 0] = 1 \quad \text{for all } 0 < \rho \le \varepsilon,$$

where $\mathcal{N}_{\lambda_0}$ is the fixed point operator associated to (1.3) with $\lambda = \lambda_0$.

In addition, using Lemma 3.1 we have

$$d_{LS}[I - \mathcal{N}_{\lambda_0}, B_\rho, 0] = 1 \quad \text{for all } \rho \ge (R + 1).$$

From Lemma 3.4 one has

$$d_{LS}[I - \mathcal{N}_{\lambda_0}, B_\rho, 0] = 1 \quad \text{for all sufficiently small } \rho.$$

When ρ_1, ρ_2 is sufficiently small and $\rho_3 \ge R + 1$ such that $\overline{B}(v_0, \rho_1) \cap \overline{B}_{\rho_2} = \emptyset$ and $\overline{B}(v_0, \rho_1) \cup \overline{B}_{\rho_2} \subset B_{\rho_3}$. Then, from the additivity-excision property of the Leray–Schauder degree it follows that

$$d_{LS}[I - \mathcal{N}_{\lambda_0}, B_{\rho_3} \setminus [\overline{B}(v_0, \rho_1) \cup \overline{B}_{\rho_2}], 0] = -1,$$

which, together with the existence property of the Leray–Schauder degree, imply that $\mathcal{N}_{\lambda_0}$ has a fixed point $\widetilde{v}_0 \in B_{\rho_3} \backslash [\overline{B}(v_0, \rho_1) \bigcup \overline{B}_{\rho_2}]$. We infer that (1.3) has a second positive solution, and the proof is complete. □

Appendix: derivation process of problem (1.3)

To the best of our knowledge, problem (1.3) was first given in [20], but they did not given derivation process. For the convenience of readers and integrity of the paper, here we give the detailed derivation.

Without loss of generality, let us consider the radially symmetric spacelike solutions of the Dirichlet problem with the mean curvature operator in FLRW spacetime

$$\begin{cases} \operatorname{div}\left(\frac{\operatorname{grad} u}{f(u)\sqrt{f^2(u) - |\operatorname{grad} u|^2}} \right) + \frac{f'(u)}{\sqrt{f^2(u) - |\operatorname{grad} u|^2}} \left(N + \frac{|\operatorname{grad} u|^2}{f^2(u)} \right) = NH(u, |x|) & \text{in } B(R), \\ |\operatorname{grad} u| < f(u) & \text{in } B(R), \\ u = 0 & \text{on } \partial B(R), \end{cases} \tag{A.1}$$

where $B(R) = \{x \in \mathbb{R}^N : |x| < R\}$ and $N \geq 1$.

Step 1. If $N = 1$.

Then (A.1) reduces to

$$\begin{cases} \left(\dfrac{u'}{f(u)\sqrt{f^2(u) - u'^2}}\right)' + \dfrac{f'(u)}{\sqrt{f^2(u) - u'^2}}\left(1 + \dfrac{u'^2}{f^2(u)}\right) = H(u, |x|), \quad x \in (0, R), \\ |u'| < f(u), \quad x \in (0, R), \\ u'(0) = u(R) = 0. \end{cases} \tag{A.2}$$

In fact (A.2) can be converted to the following

$$\begin{cases} \left(\dfrac{1}{f(u)} \cdot \dfrac{u'}{f(u)\sqrt{1 - \left(\frac{u'}{f(u)}\right)^2}}\right)' + \dfrac{f'(u)(f^2(u) + u'^2)}{f^3(u)\sqrt{1 - \left(\frac{u'}{f(u)}\right)^2}} = H(u, |x|), \quad x \in (0, R), \\ |u'| < f(u), \quad x \in (0, R), \\ u'(0) = u(R) = 0. \end{cases} \tag{A.3}$$

Let $v(r) = \varphi(u(x))$ and $r = |x|$. Then

$$v'(r) = \varphi'(u)u'(x) = \frac{u'(x)}{f(u(x))}, \quad \left(\varphi(s) = \int_0^s \frac{dt}{f(t)}\right),$$

and accordingly,

$$u(x) = \varphi^{-1}(v(r)), \quad u'(x) = f(u(x))v'(r). \tag{A.4}$$

Since

$$\begin{aligned} &\left(\frac{1}{f(u)} \cdot \frac{u'}{f(u)\sqrt{1 - \left(\frac{u'}{f(u)}\right)^2}}\right)' + \frac{f'(u)(f^2(u) + u'^2)}{f^3(u)\sqrt{1 - \left(\frac{u'}{f(u)}\right)^2}} \\ &= \frac{-f'(u)u'}{f^2(u)} \cdot \frac{u'}{f(u)\sqrt{1 - \left(\frac{u'}{f(u)}\right)^2}} + \frac{1}{f(u)} \cdot \left(\frac{u'}{f(u)\sqrt{1 - \left(\frac{u'}{f(u)}\right)^2}}\right)' \\ &\quad + \frac{f'(u)}{f(u)\sqrt{1 - \left(\frac{u'}{f(u)}\right)^2}} + \frac{f'(u)u'^2}{f^3(u)\sqrt{1 - \left(\frac{u'}{f(u)}\right)^2}} \\ &= \frac{1}{f(u)} \cdot \left(\frac{u'}{f(u)\sqrt{1 - \left(\frac{u'}{f(u)}\right)^2}}\right)' + \frac{f'(u)}{f(u)\sqrt{1 - \left(\frac{u'}{f(u)}\right)^2}}. \end{aligned} \tag{A.5}$$

Then, this fact together with (A.4), problem (A.3) can be converted to the following

$$\begin{cases} -\left(\dfrac{v'}{\sqrt{1 - v'^2}}\right)' = \dfrac{f'(\varphi^{-1}(v))}{\sqrt{1 - v'^2}} - f(\varphi^{-1}(v))H(\varphi^{-1}(v), r), \quad r \in (0, R), \\ |v'| < 1, \quad r \in (0, R), \\ v'(0) = v(R) = 0. \end{cases} \tag{A.6}$$

Step 2. If $N \geq 2$.

Given $u(x),\ x = (x_1, \ldots, x_N)$.

Let $v(r) = \varphi(u(x))$ and $r = |x| = \left(\sum_{i=1}^{N} x_i^2\right)^{\frac{1}{2}}$. Then

$$\frac{\partial r}{\partial x_i} = \frac{1}{2}\left(\sum_{i=1}^{N} x_i^2\right)^{-\frac{1}{2}} 2x_i = \frac{x_i}{r}. \tag{A.7}$$

$$\frac{\partial v}{\partial x_i} = v'(r)\frac{\partial r}{\partial x_i} = v'(r)\cdot\frac{x_i}{r} = \varphi'(u)\cdot\frac{\partial u}{\partial x_i} = \frac{1}{f(u)}\cdot\frac{\partial u}{\partial x_i}.$$

Hence

$$\frac{\partial u}{\partial x_i} = f(u)\cdot v'(r)\cdot\frac{x_i}{r}. \tag{A.8}$$

Since

$$\operatorname{grad} u = \left(\frac{\partial u}{\partial x_1}, \ldots, \frac{\partial u}{\partial x_N}\right),$$

then

$$|\operatorname{grad} u|^2 = \sum_{i=1}^{N}\left(\frac{\partial u}{\partial x_i}\right)^2 = \sum_{i=1}^{N}\left(f(u)\cdot v'(r)\cdot\frac{x_i}{r}\right)^2 = (f(u)v'(r))^2\sum_{i=1}^{N}\left(\frac{x_i}{r}\right)^2 = (f(u)v'(r))^2, \tag{A.9}$$

that is

$$\left(\frac{|\operatorname{grad} u|}{f(u)}\right)^2 = (v'(r))^2,$$

and accordingly, from this and (A.8), we have that

$$\begin{aligned}
&\operatorname{div}\left(\frac{\operatorname{grad} u}{f(u)\sqrt{f^2(u) - |\operatorname{grad} u|^2}}\right) + \frac{f'(u)}{\sqrt{f^2(u) - |\operatorname{grad} u|^2}}\left(N + \frac{|\operatorname{grad} u|^2}{f^2(u)}\right)\\
&= \operatorname{div}\left(\frac{1}{f(u)}\cdot\frac{\operatorname{grad} u}{f(u)\sqrt{1 - \left(\frac{|\operatorname{grad} u|}{f(u)}\right)^2}}\right) + \frac{f'(u)(Nf^2(u) + |\operatorname{grad} u|^2)}{f^3(u)\sqrt{1 - \left(\frac{|\operatorname{grad} u|}{f(u)}\right)^2}}\\
&= \operatorname{div}\left(\frac{1}{f(u)}\cdot\frac{\operatorname{grad} u}{f(u)\sqrt{1-(v'(r))^2}}\right) + \frac{f'(u)(Nf^2(u) + (f(u)v'(r))^2)}{f^3(u)\sqrt{1-(v'(r))^2}}\\
&= \sum_{i=1}^{N}\frac{\partial}{\partial x_i}\left(\frac{1}{f(u)}\cdot\frac{1}{f(u)\sqrt{1-(v'(r))^2}}\cdot f(u)\cdot v'(r)\cdot\frac{x_i}{r}\right)\\
&\quad + \frac{f'(u)(Nf^2(u) + (f(u)v'(r))^2)}{f^3(u)\sqrt{1-(v'(r))^2}}\\
&= \sum_{i=1}^{N}\frac{\partial}{\partial x_i}\left(\frac{1}{f(u)}\cdot\frac{v'(r)}{\sqrt{1-(v'(r))^2}}\cdot\frac{x_i}{r}\right) + \frac{f'(u)(Nf^2(u) + (f(u)v'(r))^2)}{f^3(u)\sqrt{1-(v'(r))^2}}.
\end{aligned} \tag{A.10}$$

From now on, let us fixed the notation $\phi(s) = \frac{s}{\sqrt{1-s^2}}$.

From (A.7), (A.8), it follows that

$$\begin{aligned}
&\frac{\partial}{\partial x_i}\left(\frac{1}{f(u)}\cdot\frac{v'(r)}{\sqrt{1-(v'(r))^2}}\cdot\frac{x_i}{r}\right)\\
&\quad=\frac{-f'(u)\cdot f(u)\cdot v'(r)\cdot\frac{x_i}{r}}{f^2(u)}\cdot\phi(v'(r))\cdot\frac{x_i}{r}\\
&\qquad+\frac{1}{f(u)}\left[\phi'(v'(r))\cdot\frac{x_i}{r}\cdot\frac{x_i}{r}+\phi(v'(r))\cdot\frac{r-x_i\cdot\frac{x_i}{r}}{r^2}\right]\\
&\quad=\frac{-f'(u)\cdot v'(r)\cdot\left(\frac{x_i}{r}\right)^2}{f(u)}\cdot\phi(v'(r))\\
&\qquad+\frac{1}{f(u)}\phi'(v'(r))\cdot\left(\frac{x_i}{r}\right)^2+\frac{1}{f(u)}\cdot\phi(v'(r))\cdot\frac{r^2-x_i^2}{r^3}.
\end{aligned}\tag{A.11}$$

Hence

$$\begin{aligned}
&\sum_{i=1}^{N}\frac{\partial}{\partial x_i}\left(\frac{1}{f(u)}\cdot\frac{v'(r)}{\sqrt{1-(v'(r))^2}}\cdot\frac{x_i}{r}\right)\\
&\qquad=\frac{-f'(u)\cdot v'(r)}{f(u)}\cdot\phi(v'(r))+\frac{1}{f(u)}\phi'(v'(r))+\frac{1}{f(u)}\cdot\phi(v'(r))\cdot\frac{N-1}{r}.
\end{aligned}\tag{A.12}$$

From this and (A.10), we have that

$$\begin{aligned}
&\operatorname{div}\left(\frac{\operatorname{grad}u}{f(u)\sqrt{f^2(u)-|\operatorname{grad}u|^2}}\right)+\frac{f'(u)}{\sqrt{f^2(u)-|\operatorname{grad}u|^2}}\left(N+\frac{|\operatorname{grad}u|^2}{f^2(u)}\right)\\
&=\frac{-f'(u)\cdot v'(r)}{f(u)}\cdot\phi(v'(r))+\frac{1}{f(u)}\phi'(v'(r))+\frac{1}{f(u)}\cdot\phi(v'(r))\cdot\frac{N-1}{r}\\
&\quad+\frac{Nf'(u)}{f(u)\sqrt{1-(v'(r))^2}}+\frac{f'(u)v'(r)}{f(u)}\cdot\phi(v'(r))\\
&=\frac{1}{f(u)}\phi'(v'(r))+\frac{1}{f(u)}\cdot\phi(v'(r))\cdot\frac{N-1}{r}+\frac{Nf'(u)}{f(u)\sqrt{1-(v'(r))^2}}\\
&=NH(u,r).
\end{aligned}\tag{A.13}$$

Hence, we have

$$\phi'(v'(r))+\frac{N-1}{r}\phi(v'(r))=-\frac{Nf'(u)}{\sqrt{1-(v'(r))^2}}+Nf(u)H(u,r),$$

multiplying both sides of the equation by r^{N-1}, we get that

$$r^{N-1}\phi'(v'(r))+(N-1)r^{N-2}\phi(v'(r))=Nr^{N-1}\left[-\frac{f'(u)}{\sqrt{1-(v'(r))^2}}+f(u)H(u,r)\right],$$

that is

$$-(r^{N-1}\phi(v'(r)))'=Nr^{N-1}\left[\frac{f'(u)}{\sqrt{1-(v'(r))^2}}-f(u)H(u,r)\right].\tag{A.14}$$

From this and the fact

$$u(x)=\varphi^{-1}(v(r)),$$

problem (A.1) can be converted to

$$\begin{cases} -\left(r^{N-1}\phi(v')\right)' = Nr^{N-1}\left[\dfrac{f'(\varphi^{-1}(v))}{\sqrt{1-v'^2}} - f(\varphi^{-1}(v))H(\varphi^{-1}(v),r)\right], \quad r\in(0,R), \\ |v'|<1, \quad r\in(0,R), \\ v'(0)=v(R)=0. \end{cases} \tag{A.15}$$

Abstract. In the present paper, we further study the asymptotical behavior of the following higher order nonlinear difference equation

$$x(n+1) = ax(n) + bf(x(n)) + cf(x(n-k)), \qquad n = 0, 1, \dots$$

where a, b and c are constants with $0 < a < 1, 0 \leq b < 1, 0 \leq c < 1$ and $a + b + c = 1$, $f \in C[[0, \infty), [0, \infty)]$ with $f(x) > 0$ for $x > 0$, and k is a positive integer, which has been recently studied in: On global attractivity of a higher order difference equation and its applications [*Electron. J. Qual. Theory Diff. Equ.* **2022**, No. 2, 1–14 pp]. We obtain some new sufficient conditions for the global attractivity of positive solutions of the equation, and show the applications of these results to some population models..

Keywords: higher order nonlinear difference equation, positive equilibrium, global attractivity, population model.

2020 Mathematics Subject Classification: 39A10, 92D25.

1 Introduction

Consider the following higher order nonlinear difference equation

$$x(n+1) = ax(n) + bf(x(n)) + cf(x(n-k)), \qquad n = 0, 1, \dots, \tag{1.1}$$

where a, b and c are constants with $0 < a < 1, 0 \leq b < 1, 0 \leq c < 1$ and $a + b + c = 1$, $f \in C[[0, \infty), [0, \infty)]$ with $f(x) > 0$ for $x > 0$ and k is a positive integer. The case when the sum of the main coefficients of a higher order difference equation is equal to one is of a great interest and has been studied a lot see, e.g., [1,2,19–23] and the related references therein. One of the reasons is that such difference equations frequently model some processes in nature or society. Recently, asymptotic behavior of positive solutions of Eq. (1.1) has been studied in [1]. Among other results, the following one was presented therein.

✉Corresponding author. Email: qian@math.msstate.edu

Theorem A. *Assume that $f(x)$ has a unique positive fixed point $\bar{x}$ and satisfies the negative feedback condition*

$$(x-\bar{x})(f(x)-x)<0, \qquad x>0,\ x\neq\bar{x}. \tag{1.2}$$

Suppose also $ax+bf(x)$ is increasing, and $f(x)$ is L-Lipschitz with

$$c\frac{1-a^{k+1}}{c+a^k b}L\leq 1. \tag{1.3}$$

Then every positive solution $\{x(n)\}$ of Eq. (1.1) converges to $\bar{x}$ as $n\to\infty$.

In addition, by using a different approach, a new result on the global attractivity of positive solutions of Eq. (1.1) was obtained in [2] for the special case that f is unimodal, that is, $f(x)=xg(x)$ where $g\in C[[0,\infty),[0,\infty)]$ is decreasing.

In the present paper, we are still interested in the study of global attractivity of positive solutions of Eq. (1.1), but for the case that f is decreasing, and furthermore for the case that f is an S-map, that is, $f:[0,\infty)\to[0,\infty)$ is three times differentiable with $(Sf)(x)<0$ and $f'(x)<0$ for $x>0$ where S is the Schwarzian derivative

$$(Sf)(x)=\frac{f'''(x)}{f'(x)}-\frac{3}{2}\left(\frac{f''(x)}{f'(x)}\right)^2.$$

Clearly, if we let

$$x(-k),x(-k+1),\dots,x(0) \tag{1.4}$$

be $k+1$ given nonnegative numbers with $x(0)>0$, then Eq. (1.1) has a unique positive solution with initial condition (1.4).

In the next section, we establish two sufficient conditions on the global attractivity of positive solutions of Eq. (1.1) under the conditions that f is a decreasing function and f is an S-map, respectively. Our results can be applied to several difference equations derived from mathematical biology. We show these applications in Section 3.

In the following discussion,we always assume that f is decreasing. In addition, for the sake of convenience, we adopt the notation $\prod_{i=m}^{n}s(i)=1$ and $\sum_{i=m}^{n}s(i)=0$ whenever $\{s(n)\}$ is a real sequence and $m>n$.

2 Main results

Since f is decreasing, f has a unique positive fixed point $\bar{x}$ and satisfies the negative feedback condition (1.2). Hence by Lemma 2.1 in [1], every positive solution $\{x(n)\}$ of Eq. (1.1) is bounded and persistent.

In the following, we establish two sufficient conditions for every positive solution of Eq. (1.1) to converge to $\bar{x}$ as $n\to\infty$. By an argument similar to that in the proof of Theorem 2.2 in [1], we know that every nonoscillatory solution of Eq. (1.1) converges to $\bar{x}$. Hence we need to obtain conditions for every oscillatory solution of Eq. (1.1) to converge to $\bar{x}$ also.

The following lemma on the asymptotic behavior of oscillatory solutions of Eq. (1.1) is needed in the proof of our main results.

Lemma 2.1. *Assume that $ax+bf(x)$ is increasing and let $\{x(n)\}$ be a positive solution of Eq. (1.1) which oscillates about $\bar{x}$. Then for any nonnegative integer $m\geq 0$, there is a positive integer N_m such that*

$$u(2m)\leq x(n)\leq u(2m+1) \quad \textit{for } n\geq N_m \tag{2.1}$$

where $\{u(n)\}$ is defined by

$$\begin{cases} u(n) = c\frac{1-a^{k+1}}{c+a^k b} f(u(n-1)) + \frac{a^k(b+ac)}{c+a^k b}\bar{x}, \ n = 1,2,\dots, \\ u(0) = \frac{a^k(b+ac)}{c+a^k b}\bar{x}. \end{cases} \tag{2.2}$$

Proof. Let $y(n) = x(n) - \bar{x}$. Then $\{y(n)\}$ satisfies the equation

$$y(n+1) = ay(n) + b(f(y(n)+\bar{x}) - \bar{x}) + c(f(y(n-k)+\bar{x}) - \bar{x}) \tag{2.3}$$

and $\{y(n)\}$ oscillates about zero.

Let $y(i)$ and $y(j)$ be two consecutive members of the solution $\{y(n)\}$ such that

$$y(i) \geq 0, y(j+1) \geq 0 \quad \text{and} \quad y(n) < 0 \quad \text{for } i+1 \leq n \leq j. \tag{2.4}$$

and let

$$y(r) = \min\{y(i+1), y(i+2), \dots, y(j)\}.$$

Then by an argument similar to that in the proof of Theorem 2.2 in [1] (the increasing property of $ax + bf(x)$ is needed in the proof) we may show that

$$r - (i+1) \leq k \tag{2.5}$$

and

$$y(r) \geq \frac{1-a}{c+a^k b} a^r \sum_{n=i}^{r-1} \frac{c}{a^{n+1}} [f(y(n-k)+\bar{x}) - f(\bar{x})]. \tag{2.6}$$

Noting $f(y(n-k)+\bar{x}) \geq 0, f(\bar{x}) = \bar{x}$ and (2.5), we see that

$$y(r) \geq -\bar{x}\frac{1-a}{c+a^k b} a^r \sum_{n=i}^{r-1} \frac{c}{a^{n+1}} = -\bar{x}\frac{1-a}{c+a^k b} c \left(\frac{1-a^{r-i}}{1-a}\right) \geq -c\bar{x}\frac{1-a^{k+1}}{c+a^k b}$$

and so it follows that

$$y(n) \geq -c\bar{x}\frac{1-a^{k+1}}{c+a^k b}, \qquad i \leq n \leq j.$$

Since $y(i)$ and $y(j)$ are two arbitrary members of the solution with property (2.4), we see that there is a positive integer N_0' such that

$$y(n) \geq -c\bar{x}\frac{1-a^{k+1}}{c+a^k b} \stackrel{\text{def}}{=} z(0), \qquad n \geq N_0'. \tag{2.7}$$

Next, let $y(i)$ and $y(j)$ be two consecutive members of the solution $\{y(n)\}$ with $N_0' + k \leq i < j$ such that

$$y(i) \leq 0, \ y(j+1) \leq 0 \quad \text{and} \quad y(n) > 0 \quad \text{for } i+1 \leq n \leq j \tag{2.8}$$

and

$$y(t) = \max\{y(i+1), y(i+2), \dots, y(j)\}.$$

Then by a similar argument, we may show that

$$t - (i+1) \leq k \tag{2.9}$$

and

$$y(t) \le \frac{1-a}{c+a^k b} a^t \sum_{n=i}^{t-1} \frac{c}{a^{n+1}} [f(y(n-k)+\bar{x}) - f(\bar{x})]. \tag{2.10}$$

Since

$$z(0)+\bar{x} = \left(1 - c\frac{1-a^{k+1}}{c+a^k b}\right)\bar{x} = \frac{a^k(b+ac)}{c+a^k b}\bar{x} > 0,$$

$f(z(0)+\bar{x})$ is well-defined. Since $z(0) < 0$ (see (2.7)) and f is decreasing, we see that

$$f(y(n-k)+\bar{x}) \le f(z(0)+\bar{x}) \quad \text{for } n \ge N_0' + k.$$

Hence, it follows from (2.9) and (2.10) that

$$y(t) \le \frac{1-a}{c+a^k b} a^t \sum_{n=i}^{t-1} \frac{c}{a^{n+1}} [f(z(0)+\bar{x}) - f(\bar{x})] \le c\frac{1-a^{k+1}}{c+a^k b}[f(z(0)+\bar{x}) - \bar{x}],$$

which yields

$$y(n) \le c\frac{1-a^{k+1}}{c+a^k b}[f(z(0)+\bar{x}) - \bar{x}], \qquad i \le n \le j.$$

Since $y(i)$ and $y(j)$ are two arbitrary members of the solution with property (2.8), we see that there is a positive integer $N_0 > N_0'$ such that

$$y(n) \le c\frac{1-a^{k+1}}{c+a^k b}[f(z(0)+\bar{x}) - \bar{x}] \stackrel{\text{def}}{=} z(1), \qquad n \ge N_0.$$

Then, by an easy induction, we see that for each $m \ge 0$, there is a positive integer N_m such that

$$z(2m) \le y(n) \le z(2m+1) \quad \text{for } n \ge N_m, \tag{2.11}$$

where $\{z(n)\}$ is defined by

$$\begin{cases} z(n) = c\frac{1-a^{k+1}}{c+a^k b}[f(z(n-1)+\bar{x}) - \bar{x}], & n = 1,2,\dots, \\ z(0) = -c\bar{x}\frac{1-a^{k+1}}{c+a^k b}. \end{cases} \tag{2.12}$$

Let $u(n) = z(n) + \bar{x}, n = 0,1,\dots$ Then (2.11) and (2.12) become (2.1) and (2.2), respectively. The proof is complete. □

Theorem 2.2. *Assume that $ax + bf(x)$ is increasing and*

$$\frac{c(1-a^{k+1})}{a^k(b+ac)\bar{x}}(xf(x))' > -1, \qquad x > 0. \tag{2.13}$$

Then every positive solution $\{x(n)\}$ of Eq. (1.1) tends to its positive equilibrium $\bar{x}$ as $n \to \infty$.

Proof. As indicated at the beginning of the section, every nonoscillatory solution of Eq. (1.1) converges to $\bar{x}$. Hence we only need to show that every oscillatory solution converges to $\bar{x}$ also. To this end, let $\{x(n)\}$ be an oscillatory solution of Eq. (1.1). Then by Lemma 2.1, $\{x(n)\}$ satisfies (2.1). Since $u(0) \le u(1)$, from (2.2) and the monotonicity of f it is not difficult to see that $\{u(2m)\}$ is increasing, $\{u(2m+1)\}$ is decreasing and $u(2m) \le \bar{x} \le u(2m+1)$, $m = 0,1,\dots$ Hence,

$$\lim_{m\to\infty} u(2m) = l \le \bar{x} \quad \text{and} \quad \lim_{m\to\infty} u(2m+1) = L \ge \bar{x}$$

exist, and l and L satisfy the equations

$$\begin{cases} l = c\frac{1-a^{k+1}}{c+a^k b} f(L) + \frac{a^k(b+ac)}{c+a^k b}\bar{x} \\ L = c\frac{1-a^{k+1}}{c+a^k b} f(l) + \frac{a^k(b+ac)}{c+a^k b}\bar{x}. \end{cases} \tag{2.14}$$

We now show that $l = L = \bar{x}$. To this end, let

$$g(x) = c\frac{1-a^{k+1}}{c+a^k b} x f(x) + \frac{a^k(b+ac)}{c+a^k b}\bar{x}x, \qquad x > 0$$

and observe that

$$g'(x) = c\frac{1-a^{k+1}}{c+a^k b}(xf(x))' + \frac{a^k(b+ac)}{c+a^k b}\bar{x}, \qquad x > 0.$$

In view of (2.13), we see that $g'(x) > 0$. However, it follows from (2.14) that $g(l) = g(L) = lL$. Hence $l = L = \bar{x}$ and so $\lim_{n\to\infty} u(n) = \bar{x}$. Then from (2.1) we see that $x(n) \to \bar{x}$ as $n \to \infty$. The proof is complete. □

For the proof of the next theorem, we need the following lemma which is extracted from [12].

Lemma 2.3. *Consider the following difference equation*

$$x(n+1) = h(x(n)), \qquad n = 0, 1, \ldots \tag{2.15}$$

where $h : [0,\infty) \to [0,\infty)$ is an S-map. Assume that $\bar{x}$ is the unique fixed point of h and $|h'(\bar{x})| \leq 1$. Then $\bar{x}$ is a global attractor of all solutions of Eq. (2.15).

Theorem 2.4. *Assume that $ax + bf(x)$ is increasing and f is an S-map with*

$$c\frac{1-a^{k+1}}{c+a^k b} f'(\bar{x}) \geq -1. \tag{2.16}$$

Then every positive solution $\{x(n)\}$ of Eq. (1.1) tends to its positive equilibrium $\bar{x}$ as $n \to \infty$.

Proof. We only need to show that every oscillatory solution of Eq. (1.1) converges to $\bar{x}$. Let $\{x(n)\}$ be an oscillatory solution. Then $\{x(n)\}$ satisfies (2.1). Hence, to show that $x(n) \to \bar{x}$ as $n \to \infty$ it suffices to show that $u(n) \to \bar{x}$ as $n \to \infty$. To this end, let

$$h(x) = c\frac{1-a^{k+1}}{c+a^k b} f(x) + \frac{a^k(b+ac)}{c+a^k b}\bar{x}.$$

Clearly, $h : [0,\infty) \to [0,\infty)$, $\bar{x}$ is the unique fixed point of h, $h'(x) = c\frac{1-a^{k+1}}{c+a^k b} f'(x) < 0$ and $(Sh)(x) = (Sf)(x) < 0$ for $x > 0$. Hence, h is an S-map. In addition, (2.16) yields $|h'(\bar{x})| \leq 1$. Therefore, all the conditions assumed in Lemma 2.3 are satisfied and so $u(n) \to \bar{x}$ as $n \to \infty$. Then it follows that $x(n) \to \bar{x}$ as $n \to \infty$. The proof is complete. □

Remark 2.5. By comparing Theorems 2.2 and 2.4 with Theorem A, we see that when f is a decreasing function, the condition (2.13) is different from the condition (1.3); while when f is an S-map, the condition (2.16) is better than the condition (1.3).

3 Applications

In this section, we apply our results obtained in the last section to some difference equations derived from mathematical biology.

Consider the following system of difference equations

$$\begin{cases} x(n+1) = (1-\epsilon)f(x(n)) + \epsilon y(n), \\ y(n+1) = (1-\epsilon)y(n) + \epsilon f(x(n)), \qquad n = 0,1,\ldots, \\ x(0) \geq 0,\ y(0) \geq 0,\ x(0)+y(0) > 0, \end{cases} \tag{3.1}$$

where $0 < \epsilon < 1$ is a positive constant and $f \in C[[0,\infty),[0,\infty)]$ with $f(x) > 0$ for $x > 0$. Sys. (3.1) is a population model proposed by Newman et al. [18] which assumes symmetric dispersal between active population $x(n)$ and refuge population $y(n)$. The chaotic behavior of positive solutions of Sys. (3.1) is studied in [18] by numerical simulations, whereas in [3] various properties of solutions of (3.1) are studied and several results on the asymptotic behavior of solutions of (3.1) are obtained. Recently, a sufficient condition on the global stability of positive solutions of (3.1) is obtained in [1].

Notice that Sys. (3.1) can be converted into the second order difference equation

$$x(n+1) = (1-\epsilon)x(n) + (1-\epsilon)f(x(n)) + (2\epsilon-1)f(x(n-1)), \qquad n = 0,1,\ldots \tag{3.2}$$

When f is decreasing and $\epsilon \geq 1/2$, Eq. (3.2) is in the form of (1.1) and f has a unique positive fixed point $\bar{x}$. Clearly, $\bar{x}$ is the unique positive equilibrium of Eq. (3.2) and $(\bar{x},\bar{x})$ is the unique positive equilibrium of Sys. (3.1).

By Theorems 2.2 and 2.4, we may have the following result on the global attractivity of positive solutions of Sys. (3.1).

Corollary 3.1. *Assume that $1/2 \leq \epsilon < 1$, f is decreasing and $x + f(x)$ is increasing. Suppose also that either $xf(x)$ is differentiable with*

$$\frac{(2\epsilon-1)(2-\epsilon)}{2(1-\epsilon)^2\bar{x}}(xf(x))' > -1, \qquad x > 0 \tag{3.3}$$

or f is an S-map with

$$(2-\epsilon)(2-1/\epsilon)f'(\bar{x}) \geq -1. \tag{3.4}$$

Then every positive solution $(x(n),y(n))$ of Sys. (3.1) tends to its positive equilibrium $(\bar{x},\bar{x})$ as $n \to \infty$.

Proof. As indicated above, Sys. (3.1) can be converted into (3.2) which is in the form of Eq. (1.1) with $a = b = 1-\epsilon, c = 2\epsilon - 1$ and $k = 1$. By the assumption, $ax + bf(x) = (1-\epsilon)(x + f(x))$ is increasing. In addition, noting

$$\frac{c(1-a^{k+1})}{a^k(b+ac)} = \frac{(2\epsilon-1)(2-\epsilon)}{2(1-\epsilon)^2} \tag{3.5}$$

and

$$c\frac{1-a^{k+1}}{c+a^kb} = (2-\epsilon)(2-1/\epsilon) \tag{3.6}$$

we see that when (3.5) or (3.6) holds, (2.13) or (2.16) holds respectively. Then by Theorems 2.2 and 2.4, every positive solution $\{x(n)\}$ of Eq. (3.2) converges to $\bar{x}$ as $n \to \infty$. Then from (3.1) we see that

$$\epsilon y(n) = x(n+1) - (1-\epsilon)f(x(n)) \to \bar{x} - (1-\epsilon)f(\bar{x}) \quad \text{as } n \to \infty,$$

which yields

$$y(n) \to \bar{x} \quad \text{as } n \to \infty.$$

Hence, it follows that every positive solution $(x(n), y(n))$ of Sys. (3.1) converges to $(\bar{x}, \bar{x})$. The proof is complete. □

Next, consider the following difference equation in the form

$$x(n+1) = \alpha x(n) + \beta g(x(n)) + \gamma g(x(n-k)), \qquad n = 0, 1, \dots, \tag{3.7}$$

where $0 < \alpha < 1, \beta \geq 0$ and $\gamma \geq 0$ with $\beta + \gamma > 0$ are constants, $g \in C[[0,\infty),[0,\infty)]$ and k is a positive integer, observe that it can be written as

$$x(n+1) = \alpha x(n) + \frac{\beta(1-\alpha)}{\beta+\gamma}\left[\frac{\beta+\gamma}{1-\alpha}g(x(n))\right] + \frac{\gamma(1-\alpha)}{\beta+\gamma}\left[\frac{\beta+\gamma}{1-\alpha}g(x(n-k))\right], \tag{3.8}$$

which is in the form of (1.1) with

$$a = \alpha, \qquad b = \frac{\beta(1-\alpha)}{\beta+\gamma}, \qquad c = \frac{\gamma(1-\alpha)}{\beta+\gamma} \quad \text{and} \quad f(x) = \frac{\beta+\gamma}{1-\alpha}g(x).$$

Assume that $\bar{x}$ is the unique positive fixed point of $f(x)$, that is, $\bar{x}$ is the only positive number satisfying

$$g(\bar{x}) = \frac{1-\alpha}{\beta+\gamma}\bar{x}.$$

Clearly $\bar{x}$ is the unique positive equilibrium of Eq. (3.7). Observing that

$$\frac{c(1-a^{k+1})}{a^k(b+ac)\bar{x}} = \frac{\gamma(1-\alpha^{k+1})}{\alpha^k(\beta+\alpha\gamma)\bar{x}}$$

and

$$c\frac{1-a^{k+1}}{c+a^k b}f'(\bar{x}) = \frac{\gamma(1-\alpha^{k+1})(\beta+\gamma)}{(1-\alpha)(\gamma+\alpha^k\beta)}g'(\bar{x}),$$

we see that the following corollary on the global attractivity of $\bar{x}$ is a direct consequence of Theorems 2.2 and 2.4.

Corollary 3.2. *Assume that g is decreasing and $\alpha x + \beta g(x)$ is increasing. Let $\bar{x}$ be the unique positive equilibrium of Eq. (3.7) and suppose that either $xg(x)$ is differentiable with*

$$\frac{\gamma(1-\alpha^{k+1})}{\alpha^k(\beta+\alpha\gamma)\bar{x}}(xg(x))' > -1 \tag{3.9}$$

or g is an S-map with

$$\frac{\gamma(1-\alpha^{k+1})(\beta+\gamma)}{(1-\alpha)(\gamma+\alpha^k\beta)}g'(\bar{x}) \geq -1. \tag{3.10}$$

Then every positive solution of Eq. (3.7) tends to $\bar{x}$ as $n \to \infty$.

When $\gamma = 0$, Eq. (3.7) reduces to

$$x(n+1) = \alpha x(n) + \beta g(x(n)), \qquad n = 0, 1, \dots \tag{3.11}$$

Clearly, (3.9) is automatically satisfied since the left side is 0. From Corollary 3.2 we know that when g is decreasing and $\alpha x + \beta g(x)$ is increasing, every positive solution $\{x(n)\}$ of Eq. (3.11) tends to its positive equilibrium $\bar{x}$ as $n \to \infty$ where $\bar{x}$ is the unique positive number satisfying $\bar{x} = \frac{\beta}{1-\alpha} g(\bar{x})$.

When $\beta = 0$, Eq. (3.7) reduces to

$$x(n+1) = \alpha x(n) + \gamma g(x(n-k)), \qquad n = 0, 1, \dots, \tag{3.12}$$

which includes several discrete models derived from mathematical biology. For instance, when $g(x) = \frac{1}{1+x^p}$ where p is a positive constant, Eq. (3.12) is a discrete analogue of a model that has been used to study blood cells production [13]; when $g(x) = e^{-qx}$ where q is a positive constant, Eq. (3.12) is a discrete version of a model of the survival of red blood cells in an animal [25]. Due to its theoretical interest and applications, asymptotic behavior of positive solutions of Eq. (3.12) and some related forms have been studied by numerous authors, see, for example, [1, 2, 4–11, 13–25] and the references cited therein. As a special case of Eq. (3.7), our results can be applied to Eq. (3.12) also.

In the following, we discuss the global attractivity of positive solutions of Eq. (3.7) when $g(x) = \frac{1}{1+x^p}$ and $g(x) = e^{-qx}$ where p and q are positive constants, respectively. When $g(x) = \frac{1}{1+x^p}$, Eq. (3.7) becomes

$$x(n+1) = \alpha x(n) + \frac{\beta}{1+x^p} + \frac{\gamma}{1+x^p(n-k)}, \qquad n = 0, 1, \dots \tag{3.13}$$

Clearly, g is decreasing and has a unique positive number $\bar{x}$ satisfying $g(\bar{x}) = \frac{1-\alpha}{\beta+\gamma}\bar{x}$ which is the only positive equilibrium of Eq. (3.13). When $\beta = 0$, $\alpha x + \beta g(x) = \alpha x$ is increasing; when $\beta > 0$ and $p \geq 1$, noting

$$g'(x) = \frac{-px^{p-1}}{(1+x^p)^2}$$

and

$$g''(x) = \frac{-px^{p-2}((p-1)-(p+1)x^p)}{(1+x^p)^3}$$

we see that $g'(x)$ takes minimum at $x^* = (\frac{p-1}{p+1})^{1/p}$ and

$$g'(x^*) = -\frac{1}{4p}(p-1)^{1-1/p}(1+p)^{1+1/p}.$$

Hence, if $p \geq 1$ and

$$\frac{\beta}{4p}(p-1)^{1-1/p}(1+p)^{1+1/p} \leq \alpha, \tag{3.14}$$

then

$$(\alpha x + \beta g(x))' \geq \alpha + \beta g'(x^*) = \alpha - \frac{\beta}{4p}(p-1)^{1-1/p}(1+p)^{1+1/p} \geq 0$$

and so $\alpha x + \beta g(x)$ is increasing.

Next, observe that

$$(xg(x))' = \frac{1+(1-p)x^p}{(1+x^p)^2}$$

and

$$(xg(x))'' = \frac{px^{p-1}((p-1)x^p-(p+1))}{(1+x^p)^3}.$$

We see that when $p \le 1$, $(xg(x))' > 0$ and so (3.9) is true; when $p > 1$, $(xg(x))'$ has minimum at $x^* = \left(\frac{p+1}{p-1}\right)^{1/p}$. Hence in this case,

$$(xg(x))' \ge (xg(x))'|_{x=x^*} = -\frac{(p-1)^2}{4p}. \tag{3.15}$$

Clearly, if

$$\frac{\gamma(1-\alpha^{k+1})}{\alpha^k(\beta+\alpha\gamma)\bar{x}}\left(-\frac{(p-1)^2}{4p}\right) > -1,$$

that is,

$$\frac{\gamma(1-\alpha^{k+1})}{\alpha^k(\beta+\alpha\gamma)\bar{x}}\frac{(p-1)^2}{4p} < 1, \tag{3.16}$$

then by noting (3.15) we know that (3.9) is satisfied. Furthermore, by a simple calculation, we find that for $p > 1$,

$$(Sg)(x) = \frac{g'''(x)}{g'(x)} - \frac{3}{2}\left(\frac{g''(x)}{g'(x)}\right)^2 = \frac{1}{2}(1-p)(1+p)x^{-2} < 0, \qquad x > 0,$$

that is, g is an S-map. In addition, by noting

$$g'(\bar{x}) = -\frac{p\bar{x}^{p-1}}{(1+\bar{x}^p)^2} = -p\bar{x}^{p-1}g^2(\bar{x}) = -p\bar{x}^{p-1}\left(\frac{1-\alpha}{\beta+\gamma}\bar{x}\right)^2 = -p\left(\frac{1-\alpha}{\beta+\gamma}\right)^2\bar{x}^{p+1}$$

we see that if

$$\frac{\gamma(1-\alpha^{k+1})(\beta+\gamma)}{(1-\alpha)(\gamma+\alpha^k\beta)}\left(-p\left(\frac{1-\alpha}{\beta+\gamma}\right)^2\bar{x}^{p+1}\right) \ge -1,$$

that is,

$$\frac{\gamma(1-\alpha)(1-\alpha^{k+1})}{(\beta+\gamma)(\gamma+\alpha^k\beta)}p\bar{x}^{p+1} \le 1, \tag{3.17}$$

then (3.10) is satisfied. Hence, by Corollary 3.2, we have the following conclusion: every positive solution of Eq. (3.13) tends to its positive equilibrium $\bar{x}$ as $n \to \infty$ if one of the following holds

(i) $p \le 1$ and $\beta = 0$;

(ii) $p \ge 1$, (3.14) and (3.16) hold;

(iii) $p > 1$, (3.14) and (3.17) hold.

When $f(x) = \frac{1}{1+x^p}$, Sys. (3.1) becomes

$$\begin{cases} x(n+1) = \frac{1-\epsilon}{1+x^p(n)} + \epsilon y(n), \\ y(n+1) = (1-\epsilon)y(n) + \frac{\epsilon}{1+x^p(n)}, \qquad n = 0,1,\ldots, \\ x(0) \ge 0,\ y(0) \ge 0,\ x(0)+y(0) > 0, \end{cases} \tag{3.18}$$

and it can be converted into Eq. (3.13) with $\alpha = \beta = 1-\epsilon, \gamma = 2\epsilon - 1$ and $k = 1$. Since $\alpha = \beta$, (3.14) reduces to

$$\frac{1}{4p}(p-1)^{1-1/p}(1+p)^{1+1/p} \leq 1. \tag{3.19}$$

Hence, when $p \geq 1$ and (3.19) holds, $x + f(x)$ is increasing. Note that $f(x) = g(x)$. From (3.15), (3.17) and the above discussion, we know that when $p \geq 1$,

$$(xf(x))' \geq -(p-1)^2/(4p) \tag{3.20}$$

and

$$f(\bar{x}) = -p\left(\frac{1-\alpha}{\beta+\gamma}\right)^2 \bar{x}^{p+1} = -p\bar{x}^{p+1}. \tag{3.21}$$

Clearly, (3.20) implies that if

$$\frac{(2\epsilon-1)(2-\epsilon)}{2(1-\epsilon)^2\bar{x}}\left(-\frac{(p-1)^2}{4p}\right) > -1,$$

that is,

$$\frac{(2\epsilon-1)(2-\epsilon)}{2(1-\epsilon)^2\bar{x}}\frac{(p-1)^2}{4p} < 1, \tag{3.22}$$

then (3.5) is satisfied, and (3.21) implies that if

$$(2-\epsilon)(2-1/\epsilon)(-p\bar{x}^{p+1}) \geq -1,$$

that is,

$$(2-\epsilon)(2-1/\epsilon)p\bar{x}^{p+1} \leq 1, \tag{3.23}$$

then (3.6) is satisfied. In addition, from the above discussion, we know that when $p > 1$, f is an S-map. Hence, by Corollary 3.1, we have the following conclusion: when $1/2 \leq \epsilon < 1$, every positive solution of Sys. (3.18) converges to its positive equilibrium $(\bar{x}, \bar{x})$ as $n \to \infty$ if either $p \geq 1$, (3.19) and (3.22) hold, or $p > 1$, (3.19) and (3.23) hold.

Example 3.3. Consider the equation

$$x(n+1) = (1/2)x(n) + (3/4)\frac{1}{1+x^2(n)} + (1/4)\frac{1}{1+x^2(n-3)}, \qquad n = 0, 1, \ldots, \tag{3.24}$$

which is in the form of Eq. (3.7) with $\alpha = 1/2, \beta = 3/4, \gamma = 1/4, k = 3$ and $g(x) = 1/(1+x^2)$. Note that $\bar{x} = 1$ is the unique positive equilibrium of Eq. (3.24). Since $p = 2$,

$$\frac{\beta}{4p}(p-1)^{1-1/p}(1+p)^{1+1/p} = (3/4)(1/8)3^{3/2} < 1/2 = \alpha,$$

that is, (3.14) is satisfied. In addition, observing that

$$\frac{\gamma(1-\alpha^{k+1})}{\alpha^k(\beta+\alpha\gamma)\bar{x}}\frac{(p-1)^2}{4p} = \frac{(1/4)(1-(1/2)^4)}{(1/2)^3((3/4)+(1/2)(1/4))}\cdot\frac{1}{8} = \frac{15}{56} < 1$$

we see that (3.16) is satisfied. Hence, from the above discussion, we know that every positive solution of Eq. (3.24) tends to its positive equilibrium $\bar{x} = 1$ as $n \to \infty$.

Example 3.4. Consider the system

$$\begin{cases} x(n+1) = \frac{7/15}{1+x^3(n)} + (8/15)y(n), \\ y(n+1) = (7/15)y(n) + \frac{8/15}{1+x^3(n)}, & n = 0,1,\dots, \\ x(0) \geq 0,\ y(0) \geq 0,\ x(0)+y(0) > 0, \end{cases} \tag{3.25}$$

which is in the form of Sys. (3.18) with $\epsilon = 8/15$ and $f(x) = 1/(1+x^3)$. Since $p = 3$,

$$\frac{1}{4p}(p-1)^{1-1/p}(p+1)^{1+1/p} = (1/12)2^{2/3}4^{4/3} < 1,$$

that is, (3.19) is satisfied. In addition, we know that f is an S-map. Sys. (3.25) has the unique positive equilibrium $(\bar{x}, \bar{x})$ where $\bar{x}$ is the unique positive fixed point of f. Observing $\bar{x}(1+\bar{x}^3) = 1$, we see that $\bar{x} < 1$. Then it follows that

$$(2-\epsilon)(2-1/\epsilon)p\bar{x}^{p+1} \leq (2-8/15)(2-15/8)3 = 11/20 < 1$$

and so (3.22) is satisfied. Hence, from the above discussion, we know that every positive solution of Sys. (3.25) tends to its positive equilibrium $(\bar{x}, \bar{x})$ as $n \to \infty$.

When $g(x) = e^{-qx}$, Eq. (3.7) becomes

$$x(n+1) = \alpha x(n) + \beta e^{-qx(n)} + \gamma e^{-qx(n-k)}, \qquad n = 0,1,\dots. \tag{3.26}$$

Since g is decreasing, there is a unique positive number $\bar{x}$ satisfying $g(\bar{x}) = \frac{1-\alpha}{\beta+\gamma}\bar{x}$. Clearly $\bar{x}$ is the only positive equilibrium of Eq. (3.26). Noting

$$(\alpha x + \beta g(x))' = (\alpha x + \beta e^{-qx})' = \alpha - q\beta e^{-qx}$$

we see that $\alpha x + \beta e^{-qx}$ is increasing when

$$\alpha \geq q\beta. \tag{3.27}$$

In addition, observing that

$$(xg(x))' = (1-qx)e^{-qx} \text{ and } (xg(x))'' = q(qx-2)e^{-qx}$$

we find that $(xg(x))'$ takes minimum when $x = 2/q$ and so

$$(xg(x))' \geq (xg(x))'|_{x=q/2} = -e^{-2}. \tag{3.28}$$

Hence, if

$$\frac{\gamma(1-\alpha^{k+1})}{\alpha^k(\beta+\alpha\gamma)\bar{x}}(-e^{-2}) > -1,$$

that is,

$$\frac{\gamma(1-\alpha^{k+1})}{\alpha^k(\beta+\alpha\gamma)\bar{x}} < e^2, \tag{3.29}$$

then (3.9) is satisfied. Furthermore, by a simple calculation, we find that

$$(Sg)(x) = \frac{g'''(x)}{g'(x)} - \frac{3}{2}\left(\frac{g''(x)}{g'(x)}\right)^2 = -(1/2)q^2 < 0, \qquad x > 0,$$

that is, g is an S-map. In addition, by noting

$$g'(\bar{x}) = -qe^{-q\bar{x}} = -q\frac{1-\alpha}{\beta+\gamma}\bar{x} \tag{3.30}$$

we see that if

$$\frac{\gamma(1-\alpha^{k+1})(\beta+\gamma)}{(1-\alpha)(\gamma+\alpha^k\beta)}\left(-q\frac{1-\alpha}{\beta+\gamma}\bar{x}\right) \geq -1$$

that is,

$$\frac{\gamma(1-\alpha^{k+1})}{\gamma+\alpha^k\beta}q\bar{x} \leq 1, \tag{3.31}$$

then (3.10) is satisfied. Hence, by Corollary 3.2, we have the following conclusion: if (3.27) holds and either (3.29) or (3.31) holds also, then every positive solution of Eq. (3.26) tends to its positive equilibrium as $n \to \infty$.

When $f(x) = e^{-qx}$, Sys. (3.1) is

$$\begin{cases} x(n+1) = (1-\epsilon)e^{-qx(n)} + \epsilon y(n), \\ y(n+1) = (1-\epsilon)y(n) + \epsilon e^{-qx(n)}, \qquad n = 0, 1, \ldots, \\ x(0) \geq 0,\ y(0) \geq 0,\ x(0)+y(0) > 0, \end{cases} \tag{3.32}$$

and it can be converted into Eq. (3.26) with $\alpha = \beta = 1-\epsilon, \gamma = 2\epsilon - 1$ and $k = 1$. Since $\alpha = \beta$, (3.27) reduces to $q \leq 1$. Noting $f(x) = g(x)$, from (3.28), (3.30) and the above discussion, we know that

$$(xf(x))' \geq -e^{-2} \tag{3.33}$$

and

$$f'(\bar{x}) = -qe^{-q\bar{x}} = -q\frac{1-\alpha}{\beta+\gamma}\bar{x} = -q\bar{x}. \tag{3.34}$$

Clearly, (3.33) implies that if

$$\frac{(2\epsilon-1)(2-\epsilon)}{2(1-\epsilon)^2\bar{x}}(-e^{-2}) > -1,$$

that is,

$$\frac{(2\epsilon-1)(2-\epsilon)}{2(1-\epsilon)^2\bar{x}} < e^2, \tag{3.35}$$

then (3.5) is satisfied, and if

$$(2-\epsilon)(2-1/\epsilon)(-q\bar{x}) \geq -1,$$

that is,

$$(2-\epsilon)(2-1/\epsilon)q\bar{x} \leq 1, \tag{3.36}$$

then (3.6) is satisfied. Hence, by Corollary 3.1, we have the following conclusion on the global attractivity of positive solutions of Sys. (3.32): if $q \leq 1$ and either (3.35) or (3.36) holds, then every positive solution of Sys. (3.32) tends to its positive equilibrium $(\bar{x}, \bar{x})$ as $n \to \infty$.

Example 3.5. Consider the equation

$$x(n+1) = (2/3)x(n) + (1/3)e^{-2x(n)} + (1/4)e^{-2x(n-3)}, \qquad n = 0, 1, \ldots \tag{3.37}$$

which is in the form of Eq. (3.26) with $\alpha = 2/3, \beta = 1/3, \gamma = 1/4, k = 3$ and $g(x) = e^{-2x}$. Noting $q = 2$, we see that (3.27) is satisfied. Let $\bar{x}$ be the unique positive equilibrium of Eq. (3.37). Then $\bar{x}$ satisfies $\bar{x}e^{2\bar{x}} = 7/4$. By noting $(1/2)e^{2(1/2)} < 7/4$, we see that $\bar{x} > 1/2$ and so it follows that

$$\frac{\gamma(1-\alpha^{k+1})}{\alpha^k(\beta+\alpha\gamma)\bar{x}} < \frac{(1/4)(1-(2/3)^4)}{(2/3)^3((1/3)+(2/3)(1/4))(1/2)} = \frac{65}{24} < e^2,$$

that is, (3.29) holds. Hence, from the above discussion, we know that every positive solution of Eq. (3.37) converges to its positive equilibrium $\bar{x}$ as $n \to \infty$.

Example 3.6. Consider the system

$$\begin{cases} x(n+1) = (2/5)e^{-(1/2)x(n)} + (3/5)y(n), \\ y(n+1) = (2/5)y(n) + (3/5)e^{-(1/2)x(n)}, \qquad n = 0, 1, \dots, \\ x(0) \geq 0,\ y(0) \geq 0,\ x(0) + y(0) > 0, \end{cases} \tag{3.38}$$

which is in the form of Sys. (3.32) with $\epsilon = 3/5$ and $f(x) = e^{-(1/2)x}$. Note that $q = 1/2 < 1$. Sys. (3.38) has the unique positive equilibrium $(\bar{x}, \bar{x})$ where $\bar{x}$ is the unique positive fixed point of f. Noting $\bar{x}e^{(1/2)\bar{x}} = 1$, we see that $\bar{x} < 1$. Then it follows that

$$(2-\epsilon)(2-1/\epsilon)q\bar{x} \leq (2-3/5)(2-5/3)(1/2) = 7/30 < 1$$

and so (3.36) is satisfied. Hence, from the above discussion, we know that every positive solution of Sys. (3.38) tends to its positive equilibrium $(\bar{x}, \bar{x})$ as $n \to \infty$.

Abstract. This paper is concerned with the existence of positive solutions for asymptotically periodic quasilinear Schrödinger equations. By using a Nehari-type constraint and Moser iteration, we get the existence results which is a complement to the ones in Chu and Liu [*Nonlinear Anal. Real World Appl.* **44**(2018), 118–127]. Moreover, we consider a new reformative asymptotic processes of the potential function and the nonlinearity term is only locally defined.

Keywords: quasilinear Schrödinger equation, L^∞-estimate, asymptotically periodic, Nehari manifold.

2020 Mathematics Subject Classification: 35A15, 35D30, 35B09.

1 Introduction and main results

We are concerned with the existence of solutions for the following quasilinear Schrödinger equation

$$-\Delta u + V(x)u - \frac{u}{2\sqrt{1+u^2}}\Delta(\sqrt{1+u^2}) = \lambda h(u), \qquad x \in \mathbb{R}^N, \tag{1.1}$$

which models the self-channeling of a high-power ultrashort laser in matter (see [2]).

The main mathematical difficulty with problem (1.1) is caused by the quasilinear term $\frac{u}{2\sqrt{1+u^2}}\Delta(\sqrt{1+u^2})$, the natural functional corresponding to problem (1.1) maybe not well defined for all $u \in H^1(\mathbb{R}^N)$. To overcome this difficulty, various arguments have been developed, such as a change of variables (see [1,4,5,11,15,17]) and a perturbation method (see [3]). Chu and Liu [1] proved that (1.1) has a positive solution by using the monotonicity trick and a priori estimate in the radial space. It is a little surprising that no condition is assumed on the nonlinear term $h(u)$ near infinity. For the periodic potential, there are references [4,5], they discussed the following equation

$$-\Delta u + V(x)u - [\Delta(1+u^2)^{\alpha/2}]\frac{\alpha u}{2(1+u^2)^{(2-\alpha)/2}} = h(x,u), \tag{1.2}$$

✉Corresponding author. Email: xueyanfang2015@163.com

where α is a parameter. Jalilian [4] considered equation (1.2) with $1.36 < \alpha \leq 2$ and proved that (1.2) had infinitely many geometrically distinct solutions. Then, Li [5] extended the results to $1 \leq \alpha \leq 2$ and proved the existence of a ground state solution for equation (1.2). Shen and Wang [11] studied the well potential and got the standing wave solutions for (1.1) with subcritical or critical growth by using Resonance Theorem and Hahn–Banach Theorem. For the steep potential well, one can see [15], the authors obtained the existence of a ground state solution by using the Mountain Pass Theorem, and considered the concentration behavior of the solution. In [17], the authors considered the constant potential and obtained the existence and multiplicity of radial and nonradial normalized solutions for problem (1.1) when h satisfies the well-known Berestycki–Lions condition. As far as we know, there are no results concerning problem (1.1) with the asymptotically periodic potential except [16].

However, the related semilinear equation with the asymptotically periodic condition has been extensively studied, see [6,8,13,18] and their references. We would like to point out that in reference [6,8], they discussed the asymptotically periodic potential and given reformative conditions which unify the asymptotic processes of V, h at infinity. The asymptotic processes is weaker than those in [13,18].

In the present paper, we borrow an idea from [1,6] to discuss problem (1.1) with the asymptotically periodic potential. Denote

$$\mathcal{F}_0 := \left\{ k(x) : \forall \epsilon > 0,\ \lim_{|y|\to\infty} \mathrm{meas}\{x \in B_1(y) : |k(x)| \geq \epsilon\} = 0 \right\}.$$

Then, we give some assumptions on the potential $V(x)$ and the nonlinear term $h(s)$.

(V) $0 \leq V(x) \leq V_0(x) \in L^\infty(\mathbb{R}^N)$, $V(x) - V_0(x) \in \mathcal{F}_0$, $\inf_{x\in\mathbb{R}^N} V_0(x) > 0$ and $V_0(x)$ satisfies $V_0(x+z) = V_0(x)$ for all $x \in \mathbb{R}^N$ and $z \in \mathbb{Z}^N$.

The function $h \in C(\mathbb{R}, \mathbb{R})$ satisfies

(h_1) there exist $p > 2$, $\delta \in (0,1)$ such that the function $s \mapsto \frac{h(s)}{s^{p-1}}$ is nondecreasing and $h(s) > 0$ on $(0, \delta]$.

(h_2) there exists $q \in (2, 2^*)$ such that $\liminf_{s\to 0^+} \frac{H(s)}{s^q} > 0$, where $H(s) = \int_0^s h(t)dt$ and $2^* = \frac{2N}{N-2}$ is the Sobolev critical exponent.

Now we state our main result.

Theorem 1.1. *Suppose that conditions (V) and (h_1), (h_2) are satisfied, then there is $\lambda_1 > 0$ such that problem (1.1) possesses a positive solution for $\lambda \geq \lambda_1$.*

Remark 1.2. (1) We emphasize that no condition is assumed on the nonlinear term $h(u)$ near infinity in Theorem 1.1. In all these previous works for problem (1.1), among other assumptions, the authors always assume that the nonlinear term $h(u)$ has growth conditions near infinity except [1]. However, Chu and Liu [1] investigated quasi-linear Schrödinger equations in the radial space. They had the compactness and got certain solutions easily. In our cases, we do not have compact embedding. Due to the lack of compact embedding, the existence of ground states of problem (1.1) becomes rather complicated. we borrow an idea from [6] to overcome this difficulty.

(2) Our results also can be seen as the extension of semilinear poroblem in [6] to the quasilinear one.

(3) For simplicity, we will abbreviate $\int_{\mathbb{R}^N} k(x)dx$ as $\int_{\mathbb{R}^N} k(x)$.

Notation: In this paper, we use the following notations.

- $H^1(\mathbb{R}^N)$ is the usual Hilbert space endowed with the norm

$$\|u\|_H^2 = \int_{\mathbb{R}^N} \Big(|\nabla u|^2 + u^2\Big).$$

- $L^s(\mathbb{R}^N)$ is the usual Banach space endowed with the norm

$$\|u\|_s^s = \int_{\mathbb{R}^N} |u|^s, \quad \forall s \in [1, +\infty).$$

- $\|u\|_\infty = \operatorname{ess\,sup}_{x\in\mathbb{R}^N} |u(x)|$ denotes the usual norm in $L^\infty(\mathbb{R}^N)$.
- $E = \{u \in H^1(\mathbb{R}^N) : \int_{\mathbb{R}^N} V(x)u^2 < \infty\}$ is endowed with the norm

$$\|u\|^2 = \int_{\mathbb{R}^N} \Big(|\nabla u|^2 + V(x)u^2\Big).$$

- $B_r(y) := \{x \in \mathbb{R}^N : |x - y| < r\}$.
- $C, C_1, C_2, \dots$ denote various positive (possibly different) constants.

2 Some preliminary results

We note that the solutions of problem (1.1) are the critical points of the functional

$$J_h(u) = \frac{1}{2}\int_{\mathbb{R}^N} \left[\left(1 + \frac{u^2}{2(1+u^2)}\right)|\nabla u|^2\right] + \frac{1}{2}\int_{\mathbb{R}^N} V(x)u^2 - \lambda \int_{\mathbb{R}^N} H(u).$$

Variational methods cannot be applied directly to find weak solutions of problem (1.1), since the natural associated functional $J_h(u)$ is not well defined in general in the space E. To overcome this difficulty, we borrow an idea from Shen and Wang [10].

Let $F(u) := \int_0^u f(t)dt$, where f is defined by

$$f(t) = \sqrt{1 + \frac{t^2}{2(1+t^2)}}. \tag{2.1}$$

After the change of variables $u = F^{-1}(v)$ from J, we get a new variational functional

$$I_h(v) = \frac{1}{2}\int_{\mathbb{R}^N} (|\nabla v|^2 + V(x)|F^{-1}(v)|^2) - \lambda \int_{\mathbb{R}^N} H(F^{-1}(v)).$$

Since f is a nondecreasing positive function, we obtain $|F^{-1}(v)| \le \frac{|v|}{f(0)} = |v|$. From this and the conditions of h, it is clear that I_h is well defined in E and $I_h \in C^1(E, \mathbb{R})$ (see [2, 10, 11] for details). Now, we give another equation

$$-\operatorname{div}\left[\left(1 + \frac{u^2}{2(1+u^2)}\right)\nabla u\right] + V(x)u + \frac{u}{2(1+u^2)^2}|\nabla u|^2 = \lambda h(u), \tag{2.2}$$

which is equivalent to (1.1). In fact, we only need to show that

$$-\text{div}\left[\left(1+\frac{u^2}{2(1+u^2)}\right)\nabla u\right]+\frac{u}{2(1+u^2)^2}|\nabla u|^2=-\Delta u-\frac{u}{2\sqrt{1+u^2}}\Delta(\sqrt{1+u^2}).$$

By a direct calculation, we obtain

$$\begin{aligned}
&-\text{div}\left[\left(1+\frac{u^2}{2(1+u^2)}\right)\nabla u\right]+\frac{u}{2(1+u^2)^2}|\nabla u|^2\\
&=-\text{div}\nabla u-\frac{u^2}{2(1+u^2)}\text{div}\nabla u-\nabla u\cdot\nabla\frac{u^2}{2(1+u^2)}+\frac{u}{2(1+u^2)^2}|\nabla u|^2\\
&=-\Delta u-\frac{u^2}{2(1+u^2)}\Delta u-\frac{u}{2(1+u^2)^2}|\nabla u|^2\\
&=-\Delta u-\frac{u}{2\sqrt{1+u^2}}\left(\frac{u}{\sqrt{1+u^2}}\text{div}\nabla u+\nabla u\cdot\nabla\frac{u}{\sqrt{1+u^2}}\right)\\
&=-\Delta u-\frac{u}{2\sqrt{1+u^2}}\Delta(\sqrt{1+u^2}).
\end{aligned}$$

If u is a weak solution of problem (1.1), then it is also a weak solution of (2.2) and should satisfy

$$\int_{\mathbb{R}^N}\left[\left(1+\frac{u^2}{2(1+u^2)}\right)\nabla u\cdot\nabla\varphi+\frac{u}{2(1+u^2)^2}|\nabla u|^2\varphi+V(x)u\varphi-\lambda h(u)\varphi\right]=0, \tag{2.3}$$

for all $\varphi\in C_0^\infty(\mathbb{R}^N)$. Let $\varphi=\frac{\psi}{f(u)}$, then, it can be checked that (2.3) is equivalent to the following equality

$$\int_{\mathbb{R}^N}\left(\nabla v\cdot\nabla\psi+V(x)\frac{F^{-1}(v)}{f(F^{-1}(v))}\psi-\lambda\frac{h(F^{-1}(v))}{f(F^{-1}(v))}\psi\right)=0. \tag{2.4}$$

Therefore, in order to find the solutions of problem (1.1), it suffices to study the existence of solutions of the following equation

$$-\triangle v+V(x)\frac{F^{-1}(v)}{f(F^{-1}(v))}=\lambda\frac{h(F^{-1}(v))}{f(F^{-1}(v))},\qquad x\in\mathbb{R}^N. \tag{2.5}$$

Now, we summarize the properties of F^{-1}, f.

Lemma 2.1. *The functions F^{-1}, f satisfy the following properties:*

(1) $1\le f(t)\le\sqrt{\frac{3}{2}}$ *for all* $t\in\mathbb{R}$;

(2) $1\le\frac{F^{-1}(t)f(F^{-1}(t))}{t}\le 6-2\sqrt{6}$ *for all* $t\in\mathbb{R}, t\neq 0$;

(3) $\sqrt{\frac{2}{3}}|t|\le|F^{-1}(t)|\le|t|$ *for all* $t\in\mathbb{R}$;

(4) $\frac{F^{-1}(t)}{t}\to 1$ *as* $t\to 0$;

(5) $\frac{F^{-1}(t)}{t}\to\sqrt{\frac{2}{3}}$ *as* $t\to\infty$;

(6) $0\le\frac{f'(t)t}{f(t)}\le 5-2\sqrt{6}$ *for all* $t\in\mathbb{R}$;

(7) *The function* $\frac{t}{f(t)F(t)}$ *is strictly decreasing for all* $t \geq 0$*;*

(8) *The function* $\frac{t^\mu}{f(t)F(t)}$*,* $\mu \in (2, p)$ *is strictly increasing for all* $t \geq 0$*.*

Proof. The proof of the items (1)–(6) have been proved in [11], we only need to prove items (7)(8). Let $l_1(t) = \frac{t}{f(t)F(t)}$. Since $f(t)$ is strictly increasing in $(0, +\infty)$, one has

$$0 \leq F(t) = \int_0^t f(s)ds < tf(t). \tag{2.6}$$

Then using item (6) and (2.6), we obtain

$$l'(t) = \frac{F(t) - tf(t) - \frac{f'(t)t}{f(t)}F(t)}{f(t)F^2(t)} \leq \frac{F(t) - tf(t)}{f(t)F^2(t)} < 0.$$

The above inequality proves item (7).

Let $l_\mu(t) = \frac{t^\mu}{f(t)F(t)}$, $l_0(t) = [\mu - (5 - 2\sqrt{6})]F(t) - tf(t)$. It is following from item (6) that

$$l_0'(t) = (\mu F(t) - tf(t))' = f(t)\left(\mu - (6 - 2\sqrt{6}) - \frac{f'(t)t}{f(t)}\right) > 0.$$

We can get that $l_0(t)$ is strictly increasing in $(0, +\infty)$ and $l_0(t) > l_0(0) = 0$ for $t > 0$. Then, using item (6) again, we obtain

$$l_\mu'(t) = \frac{t^{\mu-1}}{f(t)F^2(t)}\left[\mu F(t) - tf(t) - \frac{f'(t)t}{f(t)}F(t)\right] \geq \frac{t^{\mu-1}}{f(t)F^2(t)}l_0(t) > 0.$$

The above inequality proves item (8). □

Lemma 2.2 ([8])**.** *Suppose that condition* (V) *is satisfied. Then, the norms* $\|\cdot\|_H$ *and* $\|\cdot\|$ *are equivalent in the space E and the embedding* $E \hookrightarrow L^\alpha(\mathbb{R}^N)$ *is continuous for any* $\alpha \in [2, 2^*]$*.*

Lemma 2.3 ([12])**.** *Let E be a real Banach space and* $I \in C^1(E, \mathbb{R})$*. Let S be a closed subset of E which disconnects E in distinct connected components* E_1*,* E_2*. Suppose further that* $I(0) = 0$ *and*

(1) $0 \in E_1$ *and there is* $\alpha > 0$ *such that* $I|_S \geq \alpha > 0$*.*

(2) *there is* $\rho > 0$*,* $e \in E_2$*,* $\|e\| > \rho$*, such that* $I(e) < 0$*.*

Then I possesses a sequence $\{u_n\} \subset E$ *satisfying*

$$I(u_n) \to c \geq \alpha, \qquad (1 + \|u_n\|)\|I'(u_n)\| \to 0, \tag{2.7}$$

where $c \geq \alpha > 0$ *given by*

$$c = \inf_{\gamma \in \Gamma} \max_{t \in [0,1]} I(\gamma(t)), \qquad \Gamma = \{\gamma \in C([0,1], E) : \gamma(0) = 0, \gamma(1) = e\}.$$

We call the sequence $\{u_n\}$ that satisfies (2.7) ia a $(C)_c$ sequence of the functional I.

Lemma 2.4. *Assume that condition* (V) *holds. If* $\{u_n\}$ *is bounded in E and* $u_n \to 0$ *in* $L^\alpha_{\text{loc}}(\mathbb{R}^N)$ *for* $\alpha \in [2, 2^*)$*, one has*

$$A_{n1} := \int_{\mathbb{R}^N} (V(x) - V_0(x)) |F^{-1}(u_n)|^2 = o_n(1).$$

Proof. When $k(x) \in \mathcal{F}_0$, for any $\epsilon > 0$, there exists $R_\epsilon > 0$ such that

$$\int_{|k(x)|\geq \epsilon} u^2 \leq C_0 \int_{B_{R_\epsilon+1}(0)} u^2 + C_1 \epsilon^{2/N} \|u\|_H^2, \qquad \forall u \in E, \tag{2.8}$$

where C_0, C_1 are positive constants and independent on ϵ. Inequality (2.8) has already been proved in [8], we omit it here.

Let $k(x) := V(x) - V_0(x) \in \mathcal{F}_0$, then, $|k(x)| \leq 2|V_0(x)| \leq 2\|V_0\|_\infty$, by using Lemma 2.1-(3) and (2.8), we have

$$\begin{aligned} |A_{n1}| &\leq \int_{\mathbb{R}^N} |k(x)||F^{-1}(u_n)|^2 \leq \int_{\mathbb{R}^N} |k(x)u_n^2| \\ &= \int_{|k(x)|\geq\epsilon} |k(x)u_n^2| + \int_{|k(x)|<\epsilon} |k(x)u_n^2| \\ &\leq 2\|V_0\|_\infty \left[C_0 \int_{B_{R_\epsilon+1}(0)} u_n^2 + C_1 \epsilon^{\frac{2}{N}} \|u_n\|_H^2 \right] + \epsilon \int_{\mathbb{R}^N} |u_n|^2 \\ &= o_n(1) + C_2 \epsilon^{\frac{2}{N}} + C_3 \epsilon. \end{aligned}$$

Let $\epsilon \to 0$, Lemma 2.4 holds. □

Lemma 2.5. *Assume that condition (V) holds, $\{u_n\} \subset E$ is bounded, $|z_n| \to +\infty$. Then for any $\varphi \in C_0^\infty(\mathbb{R}^N)$, one has*

$$B_{n1} := \int_{\mathbb{R}^N} (V(x) - V_0(x)) \frac{F^{-1}(u_n)}{f(F^{-1}(u_n))} \varphi(x - z_n) = o_n(1).$$

Proof. Since $\varphi \in C_0^\infty(\mathbb{R}^N)$, we get that

$$\int_{B_{R_\epsilon+1}(0)} |\varphi(x - z_n)|^2 = o_n(1). \tag{2.9}$$

Let $k(x) := V(x) - V_0(x) \in \mathcal{F}_0$, by using Lemma 2.1-(3), (2.8), (2.9) and the Hölder inequality, we have

$$\begin{aligned} |B_{n1}| &\leq \int_{|k|\geq\epsilon} \left| \frac{k(x)F^{-1}(u_n)}{f(F^{-1}(u_n))} \varphi(x - z_n) \right| + \int_{|k|<\epsilon} \left| \frac{k(x)F^{-1}(u_n)}{f(F^{-1}(u_n))} \varphi(x - z_n) \right| \\ &\leq 2\|V_0\|_\infty \int_{|k|\geq\epsilon} |u_n \varphi(x - z_n)| + \epsilon \int_{|k|<\epsilon} |u_n \varphi(x - z_n)| \\ &\leq 2\|V_0\|_\infty \|u_n\|_2 \left(\int_{|k|\geq\epsilon} |\varphi(x - z_n)|^2 \right)^{1/2} + \epsilon \|u_n\|_2 \|\varphi\|_2 \\ &\leq C_4 \left(C_0 \int_{B_{R_\epsilon+1}(0)} |\varphi(x - z_n)|^2 + C_1 \epsilon^{2/N} \|\varphi\|_H^2 \right)^{1/2} + C_5 \epsilon \\ &= o_n(1) + C_6 \epsilon^{1/N} + C_5 \epsilon. \end{aligned}$$

Let $\epsilon \to 0$, Lemma 2.5 is proved. □

3 Proof of Theorem 1.1

By assumptions (h_1) and (h_2), we get that $p \leq q$ and

$$|h(s)s| \leq C|s|^p, \qquad \forall |s| \leq \delta.$$

Then, we need to modify $h(u)$ to prove our main results. Set

$$g(s) := \begin{cases} 0, & s \le 0, \\ h(s), & 0 < s \le \delta, \\ C_1 s^{p-1}, & s > \delta. \end{cases}$$

We can fix $C_1 > 0$ such that $g \in C(\mathbb{R}, \mathbb{R}^+)$. According to the definition of g, and we can get the following lemma easily.

Lemma 3.1. *Suppose that (h_1) is satisfied. Then*

(1) $\lim_{s\to+\infty} \frac{G(s)}{s^2} = +\infty$, *where* $G(s) = \int_0^s g(t)dt$.

(2) *there exists $C > 0$ such that $|g(s)s| \le C|s|^p$ and $|G(s)| \le C|s|^p$ for all $s \in \mathbb{R}$.*

(3) *there exists $\mu \in (2, p)$ such that the function $s \mapsto \frac{g(s)}{s^{\mu-1}}$ is strictly increasing on $(0, +\infty)$.*

Let us consider the modified equation of problem (2.5) given by

$$-\triangle v + V(x)\frac{F^{-1}(v)}{f(F^{-1}(v))} = \lambda \frac{g(F^{-1}(v))}{f(F^{-1}(v))}, \qquad x \in \mathbb{R}^N. \tag{3.1}$$

We note that the solutions of problem (3.1) are the critical points of the functional

$$I(v) = \frac{1}{2}\int_{\mathbb{R}^N} (|\nabla v|^2 + V(x)|F^{-1}(v)|^2) - \lambda \int_{\mathbb{R}^N} G(F^{-1}(v)).$$

In order to prove our results, we need the periodic problem as follow

$$-\triangle v + V_0(x)\frac{F^{-1}(v)}{f(F^{-1}(v))} = \lambda \frac{g(F^{-1}(v))}{f(F^{-1}(v))}, \qquad x \in \mathbb{R}^N, \tag{3.2}$$

whose corresponding energy functional is denoted as

$$I_0(v) = \frac{1}{2}\int_{\mathbb{R}^N} \left[|\nabla v|^2 + V_0(x)|F^{-1}(v)|^2\right] - \int_{\mathbb{R}^N} G(x, F^{-1}(v)).$$

Define

$$\mathcal{N} = \{u \in E : \langle I'(u), u\rangle = 0, u \ne 0\}, \qquad \mathcal{N}_0 = \{u \in E : \langle I_0'(u), u\rangle = 0, u \ne 0\},$$

$$c = \inf_{u\in\mathcal{N}} I(u), \qquad c_0 = \inf_{u\in\mathcal{N}_0} I_0(u).$$

Then we can deduce the following lemma.

Lemma 3.2. *Suppose that conditions (V) and $(h_1), (h_2)$ hold, then for each $u \in E$, $u \ne 0$, there is a unique $t_u > 0$ such that $t_u u \in \mathcal{N}$. Moreover, the maximum of $I(tu)$ for $t \ge 0$ is achieved at t_u.*

Proof. By Lemma 2.1-(3), Lemma 3.1-(2) and the Sobolev inequality, one has

$$\int_{\mathbb{R}^N} G(F^{-1}(tu)) \le C\int_{\mathbb{R}^N} |F^{-1}(tu)|^p \le Ct^p \int_{\mathbb{R}^N} u^p \le Ct^p\|u\|^p. \tag{3.3}$$

It follows from Lemma 2.1-(3), (3.3) and Lemma 2.2 that

$$\begin{aligned}\Psi(t) := I(tu) &= \frac{1}{2}\int_{\mathbb{R}^N}\left[|\nabla(tu)|^2 + V(x)|F^{-1}(tu)|^2\right] - \lambda\int_{\mathbb{R}^N} G(F^{-1}(tu))\\ &\geq \frac{t^2}{2}\int_{\mathbb{R}^N}|\nabla u|^2 + \frac{t^2}{3}\int_{\mathbb{R}^N} V(x)u^2 - \lambda C t^p\|u\|^p\\ &\geq \frac{t^2}{3}\|u\|^2 - \lambda C t^p\|u\|^p.\end{aligned}$$

Therefore, we can get $\Psi(t) > 0$ whenever $t > 0$ is small enough.

Let $\Omega = \{x \in \mathbb{R}^N : u(x) > 0\}$, then thanks to Lemma 3.1-(1), Lemma 2.1-(3)(5) and the Fatou Lemma, we can deduce that

$$\limsup_{t\to\infty}\frac{\Psi(t)}{t^2} \leq \frac{1}{2}\|u\|^2 - \lambda\liminf_{t\to\infty}\int_\Omega \frac{G(F^{-1}(tu))}{|F^{-1}(tu)|^2}\cdot\frac{|F^{-1}(tu)|^2}{(tu)^2}\cdot u^2 = -\infty.$$

Hence, $\Psi(t) \to -\infty$ as $t \to \infty$ and Ψ has a positive maximum.

The condition $\Psi'(t) = 0$ is equivalent to

$$\int_{\mathbb{R}^N}|\nabla u|^2 = \int_{\mathbb{R}^N}\left[\frac{\lambda g(F^{-1}(tu))}{tuf(F^{-1}(tu))} - \frac{V(x)F^{-1}(tu)}{f(F^{-1}(tu))tu}\right]u^2.$$

Let

$$Z(s) := \frac{g(s)}{f(s)F(s)} - \frac{V(x)s}{f(s)F(s)}.$$

By Lemma 3.1-(3) and Lemma 2.1-(7)(8), $s \mapsto Z(s)$ is strictly increasing for $s > 0$, so there is a unique $t_u > 0$ such that $\Psi'(t_u) = 0$. The conclusion is true since $\Psi'(t) = t^{-1}\langle I'(tu), tu\rangle$. □

Lemma 3.3. *Suppose that (V) and (h_1), (h_2) hold. Then*

(i) there exists $\rho > 0$ such that $\|u\| \geq \rho$ for all $u \in \mathcal{N}$.

(ii) the functional I is bounded from below on $\mathcal{N}$ by a positive constant.

Proof. (i) For any $u \in \mathcal{N}$, By Lemma 3.1-(1)(2), Lemma 2.2-(1)(3) and the Sobolev inequality, we have

$$\begin{aligned}\frac{2}{3}\|u\|^2 &\leq \int_{\mathbb{R}^N}|\nabla u|^2 + \int_{\mathbb{R}^N} V(x)\frac{F^{-1}(u)}{f(F^{-1}(u))}u = \lambda\int_{\mathbb{R}^N}\frac{g(F^{-1}(u))}{f(F^{-1}(u))}u\\ &\leq \lambda C\int_{\mathbb{R}^N} u^p \leq \lambda C\|u\|^p.\end{aligned}$$

Hence, there exists $\rho > 0$ independent of u such that $\|u\| \geq \rho$.

(ii) It follows from (3.3) and Lemma 2.1-(3) that

$$\begin{aligned}I(u) &= \frac{1}{2}\int_{\mathbb{R}^N}|\nabla u|^2 + \frac{1}{2}\int_{\mathbb{R}^N} V(x)|F^{-1}(u)|^2 - \lambda\int_{\mathbb{R}^N} G(F^{-1}(u))\\ &\geq \frac{1}{3}\|u\|^2 - \lambda C\|u\|^p.\end{aligned}$$

Since $p > 2$, there exists $\sigma > 0$ such that $I(u) \geq \frac{\sigma^2}{4} > 0$ for $\|u\| = \sigma > 0$. For any $v \in \mathcal{N}$, there exists $t_1 > 0$ such that $t_1\|v\| = \sigma$. By Lemma 3.1-(1)(2), we obtain

$$I(v) \geq I(t_1 v) \geq \frac{\sigma^2}{4}.$$

This completes the proof. □

Lemma 3.4. *Suppose that conditions (V) and $(h_1), (h_2)$ are satisfied. If $u \in \mathcal{N}$ and $I(u) = c$, then u is a ground state solution of problem* (3.1) *(see [8, 16]).*

It follows from [16] that the periodic problem (3.2) has a positive ground state solution u. From Lemma 3.2, there is a unique $t_u > 0$ such that $t_u u \in \mathcal{N}$. Moreover, the maximum of $I(tu)$ for $t \geq 0$ is achieved at t_u. Thanks to $V(x) \leq V_0(x)$, we obtain

$$c \leq I(t_u u) \leq I_0(t_u u) \leq I_0(u) = c_0, \tag{3.4}$$

hence $c \leq c_0$. Thanks to Lemma 3.3-(ii), we can also get $c > 0$.

As the argument in [14, Theorem 4.2], we obtain the following lemma due to Lemmas 3.1–3.3.

Lemma 3.5. *Suppose that (V) holds, h satisfies $(h_1), (h_2)$, then*

$$c = \inf_{u \in \mathcal{N}} I(u) = \inf_{u \in E} \max_{t > 0} I(tu) = \inf_{\gamma \in \Gamma} \max_{t \in [0,1]} I(\gamma(t)),$$

where $\Gamma = \{\gamma \in C([0,1], E) : \gamma(0) = 0, I(\gamma(t)) < 0\}$.

The above lemma is also valid for functional I_0.

Next, we will give the boundedness of the Cerami sequences.

Lemma 3.6. *Suppose that conditions (V) and $(h_1), (h_2)$ hold. Let $\{u_n\} \subset E$ be a $(C)_c$ sequence for the functional I. Then $\{u_n\}$ is bounded in E .*

Proof. Suppose by contradiction that $\{u_n\} \subset E$ be a sequence such that $\|u_n\| \to \infty$, $I(u_n) \to c$ and $(1 + \|u_n\|)\|I'(u_n)\| \to 0$. Set $v_n := \frac{u_n}{\|u_n\|}$, then, there is a $v \in E$ such that $v_n \rightharpoonup v$ in E, $v_n \to v$ in $L^2_{\text{loc}}(\mathbb{R}^N)$ and $v_n(x) \to v(x)$ a.e. in $\mathbb{R}^N$.

If $v \neq 0$, let $\Omega_* = \{x \in \mathbb{R}^N : v(x) > 0\}$, then $\operatorname{meas} \Omega_* > 0$. For a.e. $x \in \Omega_*$, one has

$$u_n(x) \to +\infty \quad \text{as } \|u_n\| \to +\infty,$$

since $v_n(x) = \frac{u_n(x)}{\|u_n\|} \to v(x) > 0$ for a.e. $x \in \Omega_*$, from Lemma 2.1-(5) and the fact that $F^{-1}(t)$ is strictly increasing, we can deduce that for a.e. $x \in \Omega_*$,

$$F^{-1}(u_n) \to +\infty \quad \text{as } \|u_n\| \to +\infty.$$

It follows from Lemma 2.1-(3)(5) and Lemma 3.1-(1) that

$$\begin{aligned}
0 &= \limsup_{n\to\infty} \frac{I(u_n)}{\|u_n\|^2} \\
&\leq \limsup_{n\to\infty} \frac{\frac{1}{2}\|u_n\|^2 - \lambda \int_{\mathbb{R}^N} G(F^{-1}(u_n))}{\|u_n\|^2} \\
&= \frac{1}{2} - \lambda \liminf_{n\to\infty} \int_{\Omega_*} \left(\frac{G(F^{-1}(u_n))}{|F^{-1}(u_n)|^2} \cdot \frac{|F^{-1}(u_n)|^2}{u_n^2} \cdot v_n^2 \right) \\
&= -\infty.
\end{aligned}$$

A contradiction, thus $v = 0$. Define

$$\beta := \limsup_{n\to\infty} \sup_{z \in \mathbb{R}^N} \int_{B_1(z)} v_n^2 dx.$$

If $\beta = 0$, by the Lions lemma [14, Lemma 1.21], we get $v_n \to 0$ in $L^p(\mathbb{R}^N)$ for $p \in (2, 2^*)$. It follows from Lemma 3.1-(2) and Lemma 2.1-(3) that

$$\int_{\mathbb{R}^N} G(F^{-1}(tv_n)) \leq C \int_{\mathbb{R}^N} |F^{-1}(tv_n)|^p \leq Ct^p \int_{\mathbb{R}^N} |v_n|^p = o_n(1), \tag{3.5}$$

for any $t \geq 0$. Especially, set $t = 4\sqrt{c}$, we obtain

$$\int_{\mathbb{R}^N} G(F^{-1}(4\sqrt{c}v_n)) = o_n(1). \tag{3.6}$$

By Lemma 2.1-(4), one has $F^{-1}(4\sqrt{c}v_n) \to 4\sqrt{c}v_n$, since $4\sqrt{c}v_n \to 0$ a.e. in $\mathbb{R}^N$. Then, we can deduce that

$$\int_{\mathbb{R}^N} V(x) \left[(4\sqrt{c}v_n)^2 - [F^{-1}(4\sqrt{c}v_n)]^2 \right] = o_n(1). \tag{3.7}$$

Setting

$$k(x,s) = \lambda \frac{g(F^{-1}(s))}{f(F^{-1}(s))} - V(x) \frac{F^{-1}(s)}{f(F^{-1}(s))} + V(x)s,$$

and

$$K(x,s) := \int_0^s k(x,t)dt = \lambda G(F^{-1}(s)) - \frac{1}{2} V(x) |F^{-1}(s)|^2 + \frac{1}{2} V(x) s^2.$$

Then,

$$I(u) = \frac{1}{2} \int_{\mathbb{R}^N} [|\nabla u|^2 + V(x)u^2] - \int_{\mathbb{R}^N} K(x,u). \tag{3.8}$$

Thanks to (3.6) and (3.7), we can obtain that

$$\begin{aligned} \int_{\mathbb{R}^N} K(x, 4\sqrt{c}v_n) = \lambda \int_{\mathbb{R}^N} G(F^{-1}(4\sqrt{c}v_n)) \\ + \frac{1}{2} \int_{\mathbb{R}^N} V(x) \left[(4\sqrt{c}v_n)^2 - [F^{-1}(4\sqrt{c}v_n)]^2 \right] = o_n(1). \end{aligned}$$

By the continuity of I, there exists $t_n \in [0,1]$ such that $I(t_n u_n) = \max_{0 \leq t \leq 1} I(tu_n)$. Since $\|u_n\| \to \infty$, we have $\frac{4\sqrt{c}}{\|u_n\|} \leq 1$ when n is large enough. Hence, one has

$$\begin{aligned} I(t_n u_n) + o_n(1) &\geq I\left(\frac{4\sqrt{c}}{\|u_n\|} u_n \right) + o_n(1) = I(4\sqrt{c}v_n) + o_n(1) \\ &= 8c\|v_n\|^2 - \int_{\mathbb{R}^N} K(x, 4\sqrt{c}v_n) + o_n(1) \\ &= 8c + o_n(1). \end{aligned}$$

Note that $I(u_n) \to c$, so $0 < t_n < 1$ and $\langle I'(t_n u_n), t_n u_n \rangle = 0$ when n is large enough. By Lemma 3.1-(3) and Lemma 2.1-(7)(8), the function

$$\frac{k(x,s)}{s} = \frac{\lambda g(F^{-1}(s))}{f(F^{-1}(s))s} - V(x) \frac{F^{-1}(s)}{f(F^{-1}(s))s} + V(x)$$

is strictly increasing for $s > 0$. Since $\{u_n\}$ is a Cerami sequence of I and the monotonicity of $\frac{k(x,s)}{s}$, we can conclude

$$
\begin{aligned}
c &= I(u_n) + o_n(1) \\
&= I(u_n) - \frac{1}{2}\langle I'(u_n), u_n\rangle + o_n(1) \\
&= \int_{\mathbb{R}^N} \left(\frac{1}{2}k(x,u_n)u_n - K(x,u_n)\right) + o_n(1) \\
&\geq \int_{\mathbb{R}^N} \left(\frac{1}{2}k(x,t_nu_n)t_nu_n - K(x,t_nu_n)\right) + o_n(1) \\
&= I(t_nu_n) - \frac{1}{2}\langle I'(t_nu_n), t_nu_n\rangle + o_n(1) \\
&= I(t_nu_n) + o_n(1) \\
&\geq 8c + o_n(1),
\end{aligned}
$$

which is a contradiction for $c > 0$.

If $\beta > 0$, by the definition of β, there is $z_n \in \mathbb{R}^N$ such that

$$\frac{\beta}{2} < \int_{B_1(z_n)} v_n^2.$$

If z_n is bounded, there exists $R > 0$ such that

$$\frac{\beta}{2} < \int_{B_R(0)} v_n^2,$$

which is a contradiction with $v_n \to 0$ in $L^2_{\mathrm{loc}}(\mathbb{R}^N)$.

If z_n is unbounded, up to a subsequence, $|z_n| \to \infty$. Let $w_n(x) := v_n(x+z_n) = \frac{u_n(x+z_n)}{\|u_n\|}$, we have

$$\frac{\beta}{2} < \int_{B_1(0)} w_n^2. \tag{3.9}$$

There is a function $w \in E$ such that $w_n \rightharpoonup w$ in E, $w_n \to w$ in $L^2_{\mathrm{loc}}(\mathbb{R}^N)$ and $w_n(x) \to w(x)$ a.e. in $\mathbb{R}^N$. Moreover, by (3.9), one has $w(x) \neq 0$. Define $\Omega_{**} = \{x \in \mathbb{R}^N : w(x) > 0\}$, then $meas\Omega_{**} > 0$ and for a.e. $x \in \Omega_{**}$, we have

$$u_n(x+z_n) \to +\infty \quad \text{as } \|u_n\| \to +\infty.$$

Since $F^{-1}(t)$ is strictly increasing for $t \geq 0$, by Lemma 2.1-(5), we can conclude that for a.e. $x \in \Omega_{**}$,

$$F^{-1}(u_n(x+z_n)) \to +\infty \quad \text{as } \|u_n\| \to +\infty.$$

Then, from Lemma 3.1-(1) and Lemma 2.1-(5), one has

$$
\begin{aligned}
&\liminf_{n\to\infty} \frac{\int_{\mathbb{R}^N} G(F^{-1}(u_n))}{\|u_n\|^2} \\
&\quad = \liminf_{n\to\infty} \frac{\int_{\mathbb{R}^N} G(F^{-1}(u_n(x+z_n)))}{\|u_n\|^2} \\
&\quad \geq \liminf_{n\to\infty} \int_{\Omega_{**}} \frac{G(F^{-1}(u_n(x+z_n)))}{|F^{-1}(u_n(x+z_n))|^2} \frac{|F^{-1}(u_n(x+z_n))|^2}{(u_n(x+z_n))^2} w_n^2 \\
&\quad = +\infty.
\end{aligned}
$$

Combining the above inequality with Lemma 2.1-(3), we have

$$\begin{aligned} 0 &= \limsup_{n\to\infty} \frac{I(u_n)}{\|u_n\|^2} \\ &\le \frac{1}{2} - \lambda \liminf_{n\to\infty} \frac{1}{\|u_n\|^2} \int_{\mathbb{R}^N} G(F^{-1}(u_n)) \\ &= -\infty, \end{aligned}$$

this contradiction finished the proof. □

Lemma 3.7. *Suppose that conditions* (V) *and* $(h_1), (h_2)$ *hold. Then problem* (3.1) *has a positive ground state solution.*

Proof. It follows from Lemma 3.3-(ii) and (3.44) that

$$0 < c \le c_0.$$

If $c = c_0$, we can get from (3.4) that

$$c_0 = c \le I(t_u u) \le I_0(t_u u) \le I_0(u) = c_0.$$

Then $t_u u$ is a positive ground solution of problem (3.1).

If $0 < c < c_0$, we see that I satisfies the mountain pass geometry from the proof of Lemma 3.2. Then, we can get a Cerami sequence $\{u_n\}$ on level c due to Lemma 2.3. Applying Lemma 3.6, the $(C)_c$ sequence is bounded. Then, we may get, up to a subsequence, $u_n \rightharpoonup u$ in E, $u_n \to u$ in $L^2_{\mathrm{loc}}(\mathbb{R}^N)$ and $u_n(x) \to u(x)$ a.e. in $\mathbb{R}^N$. By using the Lebesgue dominated convergence theorem, through the standard discussion, we can get that

$$0 = \langle I'(u_n), \phi\rangle + o_n(1) = \langle I'(u), \phi\rangle,$$

for any $\phi \in C_0^\infty(\mathbb{R}^N)$, i.e. u is a weak solution of problem (3.1).

(i) The case $u \ne 0$. Since u is a weak solution of problem (3.1), $I(u) \ge c$ and $u \in \mathcal{N}$. By (3.8), the monotonicity of $\frac{k(x,s)}{s}$ and the Fatou lemma, one has

$$\begin{aligned} c &= I(u_n) + o_n(1) \\ &= I(u_n) - \frac{1}{2}\langle I'(u_n), u_n\rangle + o_n(1) \\ &= \int_{\mathbb{R}^N} \left(\frac{1}{2}k(x,u_n)u_n - K(x,u_n)\right) + o_n(1) \\ &\ge \int_{\mathbb{R}^N} \left(\frac{1}{2}k(x,u)u - K(x,u)\right) + o_n(1) \\ &= I(u) - \frac{1}{2}\langle I'(u), u\rangle \\ &= I(u). \end{aligned}$$

Hence, $I(u) = c$ and $I'(u) = 0$, which implies that u is a ground state solution of problem (3.1). Moreover, we could deduce that u is a positive solution by applying the strongly maximum principle.

(ii) The case $u = 0$. Define

$$\beta := \limsup_{n\to\infty} \sup_{z\in\mathbb{R}^N} \int_{B_1(z)} u_n^2.$$

If $\beta = 0$, by the Lions lemma [14, Lemma 1.21], we get $u_n \to 0$ in $L^\alpha(\mathbb{R}^N)$ for $\alpha \in (2, 2^*)$. It is similar to the proof of (3.5), we can deduce

$$\int_{\mathbb{R}^N} G(F^{-1}(u_n)) \le o_n(1). \tag{3.10}$$

Combining (3.10) with Lemma 2.1-(3), we obtain

$$\begin{aligned} c &= I(u_n) + o_n(1) \\ &\le \frac{1}{2}\|u_n\|^2 - \lambda \int_{\mathbb{R}^N} G(F^{-1}(u_n)) = o_n(1). \end{aligned}$$

A contradiction, thus $\beta > 0$. By the definition of β, up to a subsequence, there exist $R > 0$ and $z_n \in \mathbb{Z}^N$ such that

$$\int_{B_R(0)} u_n^2(x + z_n) = \int_{B_R(z_n)} u_n^2(x) > \frac{\beta}{2}.$$

If z_n is bounded, there is $R' > 0$ such that

$$\int_{B_{R'}(0)} u_n^2 \ge \int_{B_R(z_n)} u_n^2 > \frac{\beta}{2},$$

which contradicts with $u_n \to u = 0$ in $L^2_{\text{loc}}(\mathbb{R}^N)$. Thus, z_n is unbounded, going if necessary to a subsequence, $|z_n| \to \infty$. Let $w_n(x) := u_n(x + z_n)$, then there exists a function $w \in E\backslash\{0\}$ such that $w_n \rightharpoonup w$ in E, $w_n \to w$ in $L^2_{\text{loc}}(\mathbb{R}^N)$ and $w_n(x) \to w(x)$ a.e. in $\mathbb{R}^N$. It follows from Lemma 2.5 that, for any $\varphi \in C_0^\infty(\mathbb{R}^N)$, we have

$$\begin{aligned} 0 &= \langle I'(u_n), \varphi(x - z_n)\rangle + o_n(1) \\ &= \int_{\mathbb{R}^N} \nabla u_n \cdot \nabla \varphi(x - z_n) + \int_{\mathbb{R}^N} V(x) \frac{F^{-1}(u_n)}{f(F^{-1}(u_n))} \varphi(x - z_n) \\ &\quad - \lambda \int_{\mathbb{R}^N} \frac{g(F^{-1}(u_n))}{f(F^{-1}(u_n))} \varphi(x - z_n) + o_n(1) \\ &= \int_{\mathbb{R}^N} \nabla u_n \cdot \nabla \varphi(x - z_n) + \int_{\mathbb{R}^N} V_0(x) \frac{F^{-1}(u_n)}{f(F^{-1}(u_n))} \varphi(x - z_n) \\ &\quad - \lambda \int_{\mathbb{R}^N} \frac{g(F^{-1}(u_n))}{f(F^{-1}(u_n))} \varphi(x - z_n) + o_n(1) \\ &= \int_{\mathbb{R}^N} \nabla w_n \cdot \nabla \varphi + \int_{\mathbb{R}^N} V_0(x) \frac{F^{-1}(w_n)}{f(F^{-1}(w_n))} \varphi - \lambda \int_{\mathbb{R}^N} \frac{g(F^{-1}(w_n))}{f(F^{-1}(w_n))} \varphi + o_n(1) \\ &= \int_{\mathbb{R}^N} \nabla w \cdot \nabla \varphi + \int_{\mathbb{R}^N} V_0(x) \frac{F^{-1}(w)}{f(F^{-1}(w))} \varphi - \lambda \int_{\mathbb{R}^N} \frac{g(F^{-1}(w))}{f(F^{-1}(w))} \varphi \\ &= \langle I_0'(w), \varphi\rangle, \end{aligned}$$

i.e. w is a weak solution of the periodic problem (3.2).

On the one hand, it follows from Lemmas 2.4–2.5 that

$$\begin{aligned} c &= I(u_n) - \frac{1}{2}\langle I'(u_n), u_n\rangle + o_n(1) \\ &= \frac{1}{2} \int_{\mathbb{R}^N} V(x)|F^{-1}(u_n)|^2 - \frac{1}{2} \int_{\mathbb{R}^N} V(x) \frac{F^{-1}(u_n)}{f(F^{-1}(u_n))} u_n \\ &\quad + \lambda \int_{\mathbb{R}^N} \frac{g(F^{-1}(u_n))}{2f(F^{-1}(u_n))} u_n - \lambda \int_{\mathbb{R}^N} G(F^{-1}(u_n)) + o_n(1) \end{aligned}$$

$$
\begin{aligned}
&= \frac{1}{2}\int_{\mathbb{R}^N} V_0(x)|F^{-1}(u_n)|^2 - \frac{1}{2}\int_{\mathbb{R}^N} V_0(x)\frac{F^{-1}(u_n)}{f(F^{-1}(u_n))}u_n \\
&\quad + \lambda\int_{\mathbb{R}^N} \frac{g(F^{-1}(u_n))}{2f(F^{-1}(u_n))}u_n - \int_{\mathbb{R}^N} G(F^{-1}(u_n)) + o_n(1) \\
&= \frac{1}{2}\int_{\mathbb{R}^N} V_0(x)\left[|F^{-1}(w_n)|^2 - \frac{F^{-1}(w_n)}{f(F^{-1}(w_n))}w_n\right] \\
&\quad + \lambda\int_{\mathbb{R}^N} \left[\frac{g(F^{-1}(w_n))}{2f(F^{-1}(w_n))}w_n - G(F^{-1}(w_n))\right] + o_n(1) \\
&= \frac{1}{2}\int_{\mathbb{R}^N} V_0(x)\left[|F^{-1}(w)|^2 - \frac{F^{-1}(w)}{f(F^{-1}(w))}w\right] \\
&\quad + \lambda\int_{\mathbb{R}^N} \left[\frac{g(F^{-1}(w))}{2f(F^{-1}(w))}w - G(F^{-1}(w))\right] \\
&= I_0(w) - \frac{1}{2}\langle I_0'(w), w\rangle \\
&= I_0(w) \geq c_0,
\end{aligned}
$$

which is a contradiction with $c \leq c_0$. Hence, the case $u = 0$ cannot happen, this completes the proof. □

Lemma 3.8. *Suppose that (V) and (h_1) hold. If u is a critical point of I, then $u \in L^\infty(\mathbb{R}^N)$. Moreover, there is a constant $C > 0$ independent of λ such that*

$$
\|u\|_\infty \leq C\lambda^{\frac{1}{2^*-p}}\left(\int_{\mathbb{R}^N} |\nabla u|^2\right)^{\frac{2^*-2}{2(2^*-p)}}.
$$

Proof. For all $k > 0$, we set

$$
u_k(x) = \begin{cases} u(x), & \text{if } |u(x)| \leq k, \\ \pm k, & \text{if } \pm u(x) > k. \end{cases}
$$

We use $\varphi_k = |u_k|^{2(\beta-1)}u$ with $\beta > 1$ as a test function and calculate $\langle I'(u), \varphi_k\rangle = 0$, namely,

$$
\begin{aligned}
&\int_{\mathbb{R}^N} |u_k|^{2(\beta-1)}|\nabla u|^2 + 2(\beta-1)\int_{\mathbb{R}^N} |u_k|^{2(\beta-2)}uu_k\nabla u\cdot\nabla u_k \\
&\qquad + \int_{\mathbb{R}^N} V(x)\frac{F^{-1}(u)}{f(F^{-1}(u))}|u_k|^{2(\beta-1)}u = \lambda\int_{\mathbb{R}^N} \frac{g(F^{-1}(u))}{f(F^{-1}(u))}|u_k|^{2(\beta-1)}u. \quad (3.11)
\end{aligned}
$$

According to the facts that $u^2|\nabla u_k|^2 \leq u_k^2|\nabla u|^2$, $\beta > 1$, and the Sobolev inequality, we obtain

$$
\begin{aligned}
&\beta^2\int_{\mathbb{R}^N} \left(|u_k|^{2(\beta-1)}|\nabla u|^2 + 2(\beta-1)|u_k|^{2(\beta-2)}uu_k\nabla u\cdot\nabla u_k\right) \\
&\quad \geq \int_{\mathbb{R}^N} |u_k|^{2(\beta-1)}|\nabla u|^2 + \int_{\mathbb{R}^N} (\beta-1)^2|u_k|^{2(\beta-2)}u^2|\nabla u_k|^2 \\
&\qquad + \int_{\mathbb{R}^N} 2(\beta-1)|u_k|^{2(\beta-2)}uu_k\nabla u\cdot\nabla u_k \\
&\quad = \int_{\mathbb{R}^N} \left|\nabla\left(|u_k|^{\beta-1}u\right)\right|^2 \\
&\quad \geq C\left(\int_{\mathbb{R}^N} \left||u_k|^{\beta-1}u\right|^{2^*}\right)^{\frac{2}{2^*}}, \quad (3.12)
\end{aligned}
$$

By Lemma 2.1-(1)(3) and Lemma 3.1-(2), we have

$$\int_{\mathbb{R}^N} \frac{g(F^{-1}(u))}{f(F^{-1}(u))}|u_k|^{2(\beta-1)}u \leq \int_{\mathbb{R}^N} g(F^{-1}(u))|u_k|^{2(\beta-1)}u \leq C\int_{\mathbb{R}^N} |u|^p|u_k|^{2(\beta-1)}. \tag{3.13}$$

Using Lemma 2.1-(1)(3) again, we can obtain

$$\int_{\mathbb{R}^N} V(x)\frac{F^{-1}(u)}{f(F^{-1}(u))}|u_k|^{2(\beta-1)}u \geq \frac{2}{3}\int_{\mathbb{R}^N} V(x)|u_k|^{2(\beta-1)}u^2 \geq 0. \tag{3.14}$$

By (3.11)–(3.14) and the Hölder inequality, we have

$$\begin{aligned}
&\left(\int_{\mathbb{R}^N} \left||u_k|^{\beta-1}u\right|^{2^*}\right)^{\frac{2}{2^*}} \\
&\quad \leq C\beta^2\lambda\int_{\mathbb{R}^N}(|u|^{p-2}|u_k|^{2(\beta-1)}u^2) \\
&\quad \leq C\beta^2\lambda\left(\int_{\mathbb{R}^N}|u|^{2^*}\right)^{\frac{p-2}{2^*}}\left(\int_{\mathbb{R}^N}\left||u_k|^{2(\beta-1)}u^2\right|^{\frac{2^*}{2^*-p+2}}\right)^{\frac{2^*-p+2}{2^*}}.
\end{aligned}$$

Then, let $k \to \infty$, we obtain

$$\|u\|_{\beta\cdot 2^*} \leq (C\beta^2\lambda)^{\frac{1}{2\beta}}\left(\int_{\mathbb{R}^N}|\nabla u|^2\right)^{\frac{p-2}{4\beta}}\|u\|_{\frac{2\cdot 2^*\beta}{2^*-p+2}}. \tag{3.15}$$

Set

$$\beta_m = \left(\frac{2^*-p+2}{2}\right)^{m+1}, \qquad m = 0, 1, \ldots$$

Then we get

$$\frac{2\cdot 2^*\beta_m}{2^*-p+2} = 2^*\beta_{m-1}.$$

It follows from (3.15) that

$$\begin{aligned}
\|u\|_{\beta_m\cdot 2^*} &\leq (C\beta_m^2\lambda)^{\frac{1}{2\beta_m}}\left(\int_{\mathbb{R}^N}|\nabla u|^2\right)^{\frac{p-2}{4\beta_m}}\|u\|_{\frac{2\cdot 2^*\beta_m}{2^*-p+2}} \\
&= (C\lambda)^{\frac{1}{2\beta_m}}\beta_m^{\frac{1}{\beta_m}}\left(\int_{\mathbb{R}^N}|\nabla u|^2\right)^{\frac{p-2}{4\beta_m}}\|u\|_{\beta_{m-1}\cdot 2^*}.
\end{aligned}$$

According to the Moser iteration, we obtain

$$\|u\|_{\beta_m\cdot 2^*} \leq (C\lambda)^{\sum_{i=0}^m \frac{1}{2\beta_i}}\prod_{i=0}^m \beta_i^{\frac{1}{\beta_i}}\left(\int_{\mathbb{R}^N}|\nabla u|^2\right)^{\frac{p-2}{4}\sum_{i=0}^m\frac{1}{\beta_i}}\|u\|_{2^*}. \tag{3.16}$$

Since $\beta_0 = \left(\frac{2^*-p+2}{2}\right) > 1$ and $\beta_i = \beta_0^{i+1}$, we get

$$\sum_{i=0}^m \frac{1}{\beta_i} = \sum_{i=0}^m \frac{1}{\beta_0^{i+1}}, \qquad \prod_{i=0}^m \beta_i^{\frac{1}{\beta_i}} = \prod_{i=0}^m(\beta_0^{i+1})^{\frac{1}{\beta_0^{i+1}}} = (\beta_0)^{\sum_{i=0}^m\frac{i+1}{\beta_0^{i+1}}}.$$

We can see

$$\sum_{i=0}^\infty \frac{i+1}{\beta_0^{i+1}} = \beta^* < +\infty, \quad \sum_{i=0}^\infty \frac{1}{\beta_0^{i+1}} = \frac{2}{2^*-p}.$$

Then, letting $m \to \infty$ in (3.16), we obtain that $u \in L^\infty(\mathbb{R}^N)$ and

$$\begin{aligned}\|u\|_\infty &\le C\lambda^{\frac{1}{2^*-p}} \beta_0^{\beta_*} \left(\int_{\mathbb{R}^N} |\nabla u|^2 \right)^{\frac{p-2}{2(2^*-p)}} \|u\|_{2^*} \\ &\le C\lambda^{\frac{1}{2^*-p}} \left(\int_{\mathbb{R}^N} |\nabla u|^2 \right)^{\frac{2^*-2}{2(2^*-p)}}. \end{aligned} \tag{3.17}$$

This lemma is proved. □

Proof of Theorem 1.1. According to Lemma 3.7, equation (3.1) has a ground state solution u and $u \in \mathcal{N}$. By (3.8), Lemma 3.3-(i) and the Sobolev embedding, we have

$$\begin{aligned} c &= I(u) - \frac{1}{\mu}\langle I'(u), u\rangle \\ &= \left(\frac{1}{2} - \frac{1}{\mu}\right) \int_{\mathbb{R}^N} (|\nabla u|^2 + V(x)u^2) + \int_{\mathbb{R}^N} [\frac{1}{\mu} k(x,u)u - K(x,u)] \\ &\ge \left(\frac{1}{2} - \frac{1}{\mu}\right) \|u\|^2. \end{aligned} \tag{3.18}$$

We can choose $v \in E \cap L^\infty(\mathbb{R}^N)$ such that $\|v\|_\infty < 1$. By (h_2) and (3) of Lemma 2.1, there exists a positive constant C_1 independent of λ such that

$$G(F^{-1}(tv)) \ge C_1 |F^{-1}(tv)|^q \ge C|tv|^q, \quad t \in [0,1].$$

Meanwhile, there exists $\lambda_0 > 0$ such that $I(v) < 0$ for $\lambda \ge \lambda_0$. It follows from the definition of c, Lemma 3.1-(2) and Lemma 2.1-(3) that

$$\begin{aligned} c &\le \max_{t\in[0,1]} I(tv) \\ &\le \max_{t\in[0,1]} \frac{t^2}{2} \int_{\mathbb{R}^N} (|\nabla v|^2 dx + V(x)v^2) - \lambda \int_{\mathbb{R}^N} G(F^{-1}(tv)) \\ &\le \max_{t\in[0,1]} \frac{t^2}{2} \|v\|^2 - Ct^q \lambda \int_{\mathbb{R}^N} |v|^q \\ &\le C\lambda^{-\frac{2}{q-2}}. \end{aligned} \tag{3.19}$$

Combining (3.17), (3.18) with (3.19), one has

$$\|u\|_\infty \le C\lambda^{\frac{1}{2^*-p}} \|u\|^{\frac{2^*-2}{2^*-p}} \le C\lambda^{\frac{1}{2^*-p}} \lambda^{\frac{1}{2-q}\cdot\frac{2^*-2}{2^*-p}}.$$

Since $p, q \in (2, 2^*)$, there exists $\lambda_1 \ge \lambda_0$ such that

$$\|u\|_\infty \le C\lambda_1^{\frac{(2^*-q)}{(2^*-p)(2-q)}} \le \delta.$$

Therefore, by the definition of g, we can obtain that u is also a positive solution of equation (2.5) for $\lambda \ge \lambda_1$. This ends the proof. □

Abstract. This paper deals with the oscillation problems for nonlinear differential equations of the form $(r(t)|x'|^{p(t)-2}x')' + c(t)f(x) = 0$ involving $p(t)$-Laplacian. The Leighton–Wintner type oscillation criteria are established without any conditions on the limit of $p(t)$. In addition, we discuss the applications to partial differential equations. Some examples are given to illustrate our results.

Keywords: oscillation, second-order differential equation, $p(t)$-Laplacian, quasilinear differential equation, Emden–Fowler differential equation, Riccati technique.

2020 Mathematics Subject Classification: 34C10, 34C15, 35J60.

1 Introduction

In this paper, we consider the second-order nonlinear differential equation

$$\Big(r(t)|x'|^{p(t)-2}x'\Big)' + c(t)f(x) = 0, \quad t \geq t_0 \in \mathbb{R}, \tag{1.1}$$

where $r(t) > 0$, $c(t)$, and $p(t) > 1$ are continuous functions, and $f(u)$ is a continuous function satisfying the condition $uf(u) > 0$ for $u \neq 0$.

A function $x(t)$ is said to be a *solution* of equation (1.1) defined on $[t_0, \tau) \subset \mathbb{R}$, if $x(t)$ and the quasiderivative $r(t)|x'(t)|^{p(t)-2}x'(t)$ are continuously differentiable and $x(t)$ satisfies equation (1.1) on $[t_0, \tau)$. A nontrivial solution $x(t)$ of equation (1.1) is said to be a *singular solution of the first kind*, if there exists a number $T_x > t_0$ such that $x(t) \equiv 0$ for $t \geq T_x$. It is said to be a *singular solution of the second kind* if $\tau < \infty$, which means that $x(t)$ is nonextendable to the right, i.e.,

$$\limsup_{t\to\tau-} \big(|x(t)| + |x'(t)|\big) = \infty$$

✉ Corresponding author. Email: kfujimoto@riko.shimane-u.ac.jp

holds. It is said to be a *proper* solution if $x(t)$ is nonsingular. Furthermore, a proper solution $x(t)$ of equation (1.1) can be divided into the following two types. It is called *oscillatory*, if there exists a sequence $\{t_n\}$ of $[t_0,\infty)$ such that $x(t_n) = 0$ and $t_n \to \infty$ as $n \to \infty$. Otherwise, it is called *nonoscillatory*.

A great deal of papers have been devoted to the oscillation problems for the quasilinear differential equation

$$\left(r(t)|x'|^{p-2}x'\right)' + c(t)|x|^{p-2}x = 0 \tag{1.2}$$

involving the classical p-Laplacian. It is easy to see that the constant multiple of a solution of equation (1.2) is also a solution, but the sum of solutions is not always a solution. In this point of view, equation (1.2) is known as a *half-linear* differential equation (see [1,8]). With this advantage, we can introduce the generalized trigonometric functions and Sturm's separation and comparison theorems as basic tools for p-Laplacian. Moreover, the global existence and uniqueness of solutions of equation (1.2) are guaranteed for initial-value problem, i.e., all nontrivial solutions of equation (1.2) are proper. For example, various results for the oscillation problems for equation (1.2) can be found in [1,7–9,14–17,22] and the references cited therein. Especially, the so-called Leighton–Wintner type oscillation criterion has been obtained as follows.

Theorem A ([1,8])**.** *Suppose that*

$$\int_{t_0}^{\infty}\left(\frac{1}{r(t)}\right)^{1/(p-1)} dt = \infty \quad \textit{and} \quad \int_{t_0}^{\infty} c(t)\,dt = \infty.$$

Then, all nontrivial solutions of equation (1.2) *are oscillatory.*

The differential operator in equation (1.1) is called $p(t)$*-Laplacian*, which is a generalization of p-Laplacian. It is also known as the one-dimensional version of the partial differential operator $p(\mathbf{x})$-Laplacian, which appears in mathematical models of various research fields such as nonlinear elasticity theory, electrorheological fluids, and image processing (see [4,13,18]). For example, oscillation problems for quasilinear elliptic partial differential equations with $p(\mathbf{x})$-Laplacian are considered in [23–25]. In particular, sufficient conditions are obtained under which all radial solutions of the equation

$$\operatorname{div}\left(|\nabla u|^{p(\mathbf{x})-2}\nabla u\right) + \frac{1}{|\mathbf{x}|^{\theta(\mathbf{x})}}|u|^{q(\mathbf{x})-2}u = 0 \quad \text{in } \Omega$$

are oscillatory in [25] under certain conditions on the limits of p, θ, and q, where $\Omega = \{\mathbf{x} \in \mathbb{R}^N \mid |x| > r_0\}$ with the Euclidean norm. The proof is based on radialization technique with ordinary differential equation involving $p(t)$-Laplacian. In this way, there has been an increasing interest in the study of asymptotic behavior of solutions for ordinary differential equations involving $p(t)$-Laplacian. For instance, those results can be found in [3,5,6,10–12,19–21]. In [10], a kind of comparison theorem is proved to the oscillation problems for equation (1.1). In addition, the existence of proper solutions and singular solutions of equation (1.1) is treated in [3].

However, we point out that the solution space of the equation

$$\left(r(t)|x'|^{p(t)-2}x'\right)' + c(t)|x|^{p(t)-2}x = 0 \tag{1.3}$$

involving $p(t)$-Laplacian does not have homogeneity unlike equation (1.2). Hence, to the best of our knowledge, generalized trigonometric functions and Sturm's separation and comparison theorems are not obtained for equation (1.3). Hence, not a few results do not rule out the coexistence of oscillatory and nonoscillatory solutions. Moreover, the literature on $p(t)$-Laplacian often assumes certain conditions on the limit of $p(t)$. For example, the log-Hölder decay condition is assumed in [12, 25], i.e., there exist $p > 1$, and $M > 0$ such that

$$t^{|p-p(t)|} < M$$

for t sufficiently large. This implies that $p(t) \to p > 1$ as $t \to \infty$.

The purpose of this paper is to establish Leighton–Wintner type oscillation criteria for equation (1.1). This paper is organized as follows. In Section 2, we give two oscillation criteria. In Section 3, we deal with the existence of proper solutions. Finally, we consider an application to partial differential equations in Section 4.

2 Oscillation problem

In this section, we give Leighton–Wintner type oscillation criteria for equation (1.1).

Theorem 2.1. *Assume that $f(u)$ is a smooth function satisfying $f'(u) \geq 0$ for $u \in \mathbb{R}$. Suppose that for any $L > 0$,*

$$\int_{t_0}^{\infty} \left(\frac{L}{r(t)}\right)^{1/(p(t)-1)} dt = \infty \quad \text{and} \quad \int_{t_0}^{\infty} c(t)\, dt = \infty. \tag{2.1}$$

Then, all proper solutions of equation (1.1) are oscillatory.

Proof. Suppose, toward a contradiction, that equation (1.1) has a positive solution. That is to say, there exists $t_1 \geq t_0$ such that $x(t) > 0$ for $t \geq t_1$. Let

$$w(t) = \frac{r(t)|x'(t)|^{p(t)-2}x'(t)}{f(x(t))}.$$

Then, we have

$$w'(t) = -c(t) - \frac{r(t)|x'(t)|^{p(t)}f'(x(t))}{(f(x(t)))^2}.$$

Integrating both sides of this equality from t_1 to $t \geq t_1$, we get

$$w(t) = w(t_1) - \int_{t_1}^{t} c(s)\, ds - \int_{t_1}^{t} \frac{r(s)|x'(s)|^{p(s)}f'(x(s))}{(f(x(s)))^2}\, ds.$$

From (2.1) and $f'(u) \geq 0$ ($u \in \mathbb{R}$), there exists $t_2 \geq t_1$ such that

$$\int_{t_2}^{t} c(s)\, ds \geq 0$$

and $w(t) < 0$ for $t \geq t_2$, which implies $x'(t) < 0$ for $t \geq t_2$.

Integrating both sides of equation (1.1) from t_2 to $t \geq t_2$, we get

$$\begin{aligned} -r(t)|x'(t)|^{p(t)-1} &= r(t)|x'(t)|^{p(t)-2}x'(t) \\ &= r(t_2)|x'(t_2)|^{p(t_2)-2}x'(t_2) - \int_{t_2}^{t} c(s)f(x(s))\, ds \\ &= r(t_2)|x'(t_2)|^{p(t_2)-2}x'(t_2) - f(x(t)) \int_{t_2}^{t} c(s)\, ds \\ &\quad + \int_{t_2}^{t} f'(x(s))x'(s) \int_{t_2}^{s} c(\tau)\, d\tau\, ds \\ &\leq r(t_2)|x'(t_2)|^{p(t_2)-2}x'(t_2) = -r(t_2)|x'(t_2)|^{p(t_2)-1}. \end{aligned}$$

Hence, we have

$$-x'(t) \geq \left(\frac{K}{r(t)}\right)^{\frac{1}{p(t)-1}}$$

for $t \geq t_2$, where $K = r(t_2)|x'(t_2)|^{p(t_2)-1} > 0$. Thus, by (2.1) we obtain

$$x(t) \leq x(t_2) - \int_{t_2}^{t} \left(\frac{K}{r(s)}\right)^{\frac{1}{p(s)-1}} ds \to -\infty$$

as $t \to \infty$, which is a contradiction to the positivity of $x(t)$. □

We also prove the following criterion.

Theorem 2.2. *Assume that $c(t) > 0$ for $t \geq t_0$ and there exists a smooth function $g(u)$ such that $ug(u) > 0$ ($u \neq 0$), $g'(u) \geq 0$, and $|f(u)| \geq |g(u)|$ ($u \in \mathbb{R}$). Suppose that (2.1) holds for any $L > 0$. Then, all proper solutions of equation (1.1) are oscillatory.*

Proof. Suppose, toward a contradiction, that equation (1.1) has a positive solution $x(t)$. That is to say, there exists $t_1 \geq t_0$ such that $x(t) > 0$ for $t \geq t_1$. Hence, $x(t)$ satisfies

$$\left(r(t)|x'(t)|^{p(t)-2}x'(t)\right)' + C(t)g(x(t)) = 0, \quad t \geq t_1, \tag{2.2}$$

where $C(t) = c(t)f(x(t))/g(x(t))$. We note that $C(t)$ is continuous because $x(t) > 0$ for $t \geq t_1$ and $ug(u) > 0$ for $u \neq 0$. Since $|f(u)| \geq |g(u)|$ ($u \in \mathbb{R}$), we see that $C(t) \geq c(t)$, and therefore, we get

$$\int_{t_0}^{\infty} C(t)\,dt \geq \int_{t_0}^{\infty} c(t)\,dt = \infty.$$

Proceeding in the same manner as the proof of Theorem 2.1 with (2.2), we see that the assertion holds. □

Remark 2.3. Although the positivity of $c(t)$ is required, we don't need the monotonicity and the smoothness of $f(u)$ in Theorem 2.2.

We consider the special case that $f(u) = |u|^{\lambda-2}u$, where $\lambda > 1$ is a constant. Then, equation (1.1) becomes the equation

$$\left(r(t)|x'|^{p(t)-2}x'\right)' + c(t)|x|^{\lambda-2}x = 0. \tag{2.3}$$

In the rest of this paper, for simplicity, we focus on equation (2.3). By Theorem 2.1, we give the following corollary.

Corollary 2.4. *Suppose that (2.1) holds for any $L > 0$. Then, all proper solutions of equation (2.3) are oscillatory.*

3 Existence of proper solutions

In order to deal with the asymptotic behavior of solutions, we must pay attention to the existence of singular solutions. In fact, for example, when $p(t) \equiv p > 1$ and $r(t) \equiv 1$, equation (2.3) becomes the generalized Emden–Fowler type differential equation

$$\left(|x'|^{p-2}x'\right)' + c(t)|x|^{\lambda-2}x = 0. \tag{3.1}$$

It is known that if $p > \lambda$ (resp., $p < \lambda$) then equation (3.1) has a singular solution of the first (resp., second) kind for certain $c(t)$ (see [2, Theorem 4]).

In this section, we consider the existence of proper solutions of equation (2.3). According to [3], the following theorem is proved.

Theorem B ([3]). *Suppose that $p(t)$ and $(r(t))^{1/(p(t)-1)}$ are continuously differentiable, $p(t)$ is nondecreasing, and $c(t)$ is positive. Then, every nontrivial solutions of equation (2.3) is proper.*

Using Corollary 2.4 and Theorem B, we obtain the following corollary.

Corollary 3.1. *Assume that $p(t)$ and $(r(t))^{1/(p(t)-1)}$ are continuously differentiable, $p(t)$ is nondecreasing, and $c(t)$ is positive. Suppose that (2.1) holds for any $L > 0$. Then, all nontrivial solutions of equation (2.3) are oscillatory.*

We propose an example of Corollary 3.1.

Example 3.2. Let $t_0 = 1$, $r(t) \equiv 1$, $c(t) = 1/t$, and $p(t) = 3 - 1/t$. Then, equation (2.3) becomes

$$\left(|x'|^{3-1/t}x'\right)' + \frac{1}{t}|x|^{\lambda-2}x = 0. \tag{3.2}$$

From Corollary 3.1, all nontrivial solutions of equation (3.2) are oscillatory. Figure 3.1 indicates the solution is proper and oscillatory.

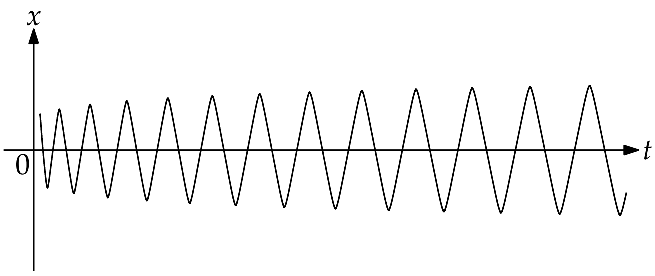

Figure 3.1: A solution $x(t)$ of equation (3.2) with $x(1) = 3$, $x'(1) = 0$, and $\lambda = 5$.

We next consider the case when $p(t)$ does not have monotonicity. For equation (2.3), the following propositions are derived from [3, Theorems 2.1, 2.2].

Proposition 3.3. *Suppose that $p(t) \le \lambda$ for $t \in [t_0, \infty)$. Then, equation (2.3) has no singular solutions of the first kind.*

Proposition 3.4. *Suppose that $p(t) \ge \lambda$ for $t \in [t_0, \infty)$. Then, equation (2.3) has no singular solutions of the second kind.*

In the case when $c(t)$ is negative, then the following result is given from Proposition 3.4.

Theorem 3.5. *Suppose that $p(t) \ge \lambda$ and $c(t) < 0$ for $t \in [t_0, \infty)$. Then, equation (2.3) has proper solutions.*

Proof. Let $x(t)$ be a solution of equation (2.3) satisfying the initial condition $x(t_0) > 0$ and $x'(t_0) > 0$. Since $c(t)$ is negative, we can find $T > t_0$ such that

$$\left(r(t)|x'(t)|^{p(t)-2}x'(t)\right)' = -c(t)|x(t)|^{\lambda-2}x(t) > 0$$

for $t \in [t_0, T)$, which implies that $r(t)|x'(t)|^{p(t)-2}x'(t)$ is positive increasing for $t \in [t_0, T)$. Hence, $x'(t)$ is positive for any $t \in [t_0, \infty)$, and therefore, $x(t)$ is a positive increasing solution. From Proposition 3.4, we see that $x(t)$ is proper. □

However, it is clear that (2.1) does not hold and equation (2.3) has no oscillatory solutions under the assumptions of Theorem 3.5.

In view of Propositions 3.3 and 3.4, we see that all nontrivial solutions of equation (2.3) are proper when $p(t) \equiv \lambda$. Otherwise, we cannot exclude the possibilities of the existence of singular solutions by using these propositions. To illustrate this problem, we introduce an example of Corollary 2.4 and Propositions 3.3, 3.4.

Example 3.6. Let $t_0 = 1$, $r(t) \equiv 1$, $c(t) = 1/t$, and $p(t) = \sin t + 5/2$. Then, equation (2.3) becomes

$$\left(|x'|^{\sin t + 1/2} x'\right)' + \frac{1}{t}|x|^{\lambda - 2}x = 0. \tag{3.3}$$

In the case of $\lambda \geq 7/2$, equation (3.3) has no singular solution of the first kind, as stated in Proposition 3.3. However, we cannot rule out the possibility that equation (3.3) has singular solutions of the second kind. In fact, keen spikes can be observed in Figure 3.2. On the other hand, when $1 < \lambda \leq 3/2$, equation (3.3) has no singular solution of the second kind according to Proposition 3.4. However, we cannot exclude the possibility that equation (3.3) has singular solutions of the first kind. We can identify the points in Figure 3.3 where the derivative of the solution is zero, even though they are not extrema. In the case of $3/2 < \lambda < 7/2$, there are possibilities that equation (3.3) has singular solutions of the first/second kind. In any cases, it can be derived from Corollary 2.4 that all proper solutions of equation (3.3) are oscillatory.

In the case of $p(t) \not\equiv \lambda$, the existence of proper solutions of equation (2.3) is proved by Theorem 4.1 in [3] under the additional assumption $\liminf_{t\to\infty} p(t) > 1$. However, in order to apply this result, the condition

$$\int_{t_0}^{\infty} |c(t)|\, dt < \infty$$

is also required, which is the opposite case of (2.1). It is an open problem if equation (2.3) has proper solutions under $p(t) \not\equiv \lambda$ and (2.1).

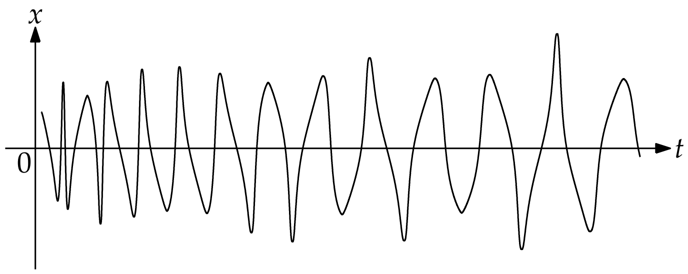

Figure 3.2: A solution $x(t)$ of equation (3.3) with $x(1) = 3$, $x'(1) = 0$, and $\lambda = 4$.

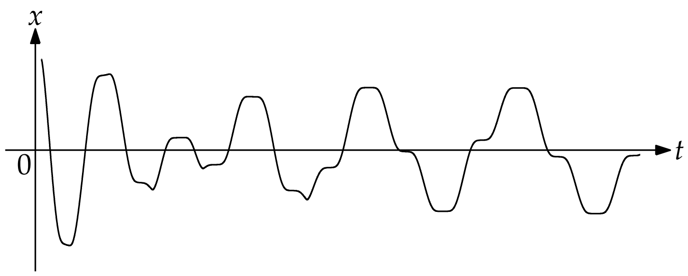

Figure 3.3: A solution $x(t)$ of equation (3.3) with $x(1) = 1$, $x'(1) = 0$, and $\lambda = 3/2$.

4 Applications

In this section, we propose an application to partial differential equations. Let us consider the quasilinear differential equation

$$\operatorname{div}\left(|\nabla u|^{p(\mathbf{x})-2}\nabla u\right)+F(\mathbf{x})|u|^{\lambda-2}u=0 \quad \text{in } \Omega, \tag{4.1}$$

where $\Omega=\{\mathbf{x}\in\mathbb{R}^N \mid |x|>r_0\}$. If u is a radially symmetric function, i.e., $u(\mathbf{x})=y(t)$, $t=|\mathbf{x}|$, we can write equation (4.1) as

$$\left(t^{N-1}|y'|^{p(t)-2}y'\right)'+t^{N-1}F(t)|y|^{\lambda-2}y=0 \quad \text{for } t>r_0. \tag{4.2}$$

We say that a radially symmetric solution $u(\mathbf{x})$ of (4.1) is oscillatory if it keeps neither positive nor negative, that is, the solution $y(t)$ of equation (4.2) corresponding to $u(\mathbf{x})$ is oscillatory. Using Corollary 2.4, we obtain the following theorem.

Theorem 4.1. *Suppose that for any $L>0$,*

$$\int_{t_0}^{\infty}\left(\frac{L}{t^{N-1}}\right)^{1/(p(t)-1)}dt=\infty \quad \textit{and} \quad \int_{t_0}^{\infty}t^{N-1}F(t)\,dt=\infty.$$

Then, all radially symmetric solutions of equation (4.1) are oscillatory.

Example 4.2. Let $N\in\mathbb{N}$, $F(t)=1/t^N$, and $p(t)=\sin t+N+3/2$. Then, equation (4.2) becomes

$$\left(t^{N-1}|y'|^{\sin t+N-1/2}y'\right)'+\frac{1}{t}|y|^{\lambda-2}y=0 \text{ for } t>r_0 \tag{4.3}$$

and it is easy to see that $\int_{r_0}^{\infty}t^{N-1}F(t)\,dt=\infty$. In addition, we have $1/(p(t)-1)\le 2/(2N-1)$. Hence, it is obvious that

$$\int_{r_0}^{\infty}\left(\frac{L}{t^{N-1}}\right)^{1/(p(t)-1)}dt=\infty$$

when $N=1$. In the case of $N\ge 2$, since $L/t^{N-1}\to 0$ as $t\to\infty$, we can find $r_1\ge r_0$ such that $L/t^{N-1}<1$. Hence, we have

$$\begin{aligned}\int_{r_1}^{t}\left(\frac{L}{s^{N-1}}\right)^{1/(p(s)-1)}ds &\ge \int_{r_1}^{t}\left(\frac{L}{s^{N-1}}\right)^{2/(2N-1)}ds = L^{2/(2N-1)}\int_{r_1}^{t}s^{-2(N-1)/(2N-1)}\,ds\\ &=(2N-1)L^{2/(2N-1)}\left(t^{1/(2N-1)}-r_1^{1/(2N-1)}\right)\to\infty\end{aligned}$$

as $t\to\infty$. From Theorem 4.1, all radially symmetric solutions of equation (4.1) are oscillatory.

Abstract. In this work, we give a variation of parameters formula for nonautonomous linear impulsive differential equations with piecewise constant arguments of generalized type. We cover several cases of differential equations with deviated arguments investigated before as particular cases. We also give some examples showing the applicability of our results.

Keywords: variation of parameters formula, piecewise constant argument, linear functional differential equations, DEPCAG, IDEPCAG.

2020 Mathematics Subject Classification: 34A36, 34A37, 34A38, 34K34, 34K45.

1 Introduction

Occasionally, natural phenomena must be modeled using differential equations that may have discontinuous solutions, such as a piecewise constant, or the impulsive effect must be present. Some examples of such modeling can be found in the works of S. Busenberg and K. Cooke [7] (where the authors modeled vertical transmission diseases) and L. Dai and M. C. Singh [12] (oscillatory motion of spring-mass systems subject to piecewise constant forces such $Ax([t])$ or $A\cos([t])$). The last work studied the motion of mechanisms modeled by

$$mx''(t) + kx_1 = A\sin\left(\omega\left[\frac{t}{T}\right]\right),$$

where $[\cdot]$ is the greatest integer function. (See [11]).

In the 70's, A. Myshkis [15] studied differential equations with deviating arguments ($h(t) \leq t$, such as $h(t) = [t]$ or $h(t) = [t-1]$). The Ukrainian mathematician M. Akhmet generalized those systems, introducing differential equations of the form

$$y'(t) = f(t, y(t), y(\gamma(t))), \tag{1.1}$$

where $\gamma(t)$ is a *piecewise constant argument of generalized type*. In order to define such γ, let $(t_n)_{n\in\mathbb{Z}}$ and $(\zeta_n)_{n\in\mathbb{Z}}$ such that $t_n < t_{n+1}, \forall n \in \mathbb{Z}$ with $\lim_{n\to\infty} t_n = \infty$, $\lim_{n\to-\infty} t_n = -\infty$ and $\zeta_n \in [t_n, t_{n+1}]$. Then, $\gamma(t) = \zeta_n$, if $t \in I_n = [t_n, t_{n+1})$. I.e., $\gamma(t)$ is a step function. An elementary example of such functions is $\gamma(t) = [t]$ which is constant in every interval $[n, n+1[$ with $n \in \mathbb{Z}$ (see (1.3)).

If a piecewise constant argument is used, the interval I_n is decomposed into an advanced and delayed subintervals $I_n = I_n^+ \bigcup I_n^-$, where $I_n^+ = [t_n, \zeta_n]$ and $I_n^- = [\zeta_n, t_{n+1}]$. This class of differential equations is known as *Differential Equations with Piecewise Constant Argument of Generalized Type* (*DEPCAG*). They have continuous solutions, even though γ is discontinuous. If we assume continuity of the solutions of (1.1), integrating from t_n to t_{n+1}, we define a finite-difference equation, so we are in the presence of a hybrid dynamic (see [3,17]).

For example, taking $\gamma(t) = \left[\frac{t+l}{h}\right]h$ with $0 \leq l < h$, we have

$$\left[\frac{t+l}{h}\right]h = nh, \text{ when } t \in I_n = [nh-l, (n+1)h-l).$$

Then, we see that $\gamma(t) - t \geq 0 \Leftrightarrow t \leq nh$ and $\gamma(t) - t \leq 0 \Leftrightarrow t \geq nh$. Hence, we have

$$I_n^+ = [nh-l, nh], \quad I_n^- = [nh, (n+1)h-l].$$

Now, if an impulsive condition is defined at $\{t_n\}_{n\in\mathbb{Z}}$, we are in the presence of the *Impulsive differential equations with piecewise constant argument of generalized type* (*IDEPCAG*) (see [2]),

$$\begin{aligned} x'(t) &= f(t, x(t), x(\gamma(t))), \qquad t \neq t_n \\ \Delta x(t_n) &:= x(t_n) - x(t_n^-) = J_n(x(t_n^-)), \qquad t = t_n, \quad n \in \mathbb{N}, \end{aligned} \tag{1.2}$$

where $x(t_n^-) = \lim_{t\to t_n^-} x(t)$, and J_n is the impulsive operator (see [18]).

When the piecewise constant argument used in a differential equation is explicit, it will be called DEPCA (IDEPCA if it has impulses).

An elementary and illustrative example of IDEPCA

Consider the scalar IDEPCA

$$\begin{aligned} x'(t) &= (\alpha-1)x([t]), \qquad t \neq n \\ x(n) &= \beta x(n^-), \qquad t = n, \quad n \in \mathbb{N}. \end{aligned} \tag{1.3}$$

where $\alpha, \beta \in \mathbb{R}$, $\beta \neq 1$.

If $t \in [n, n+1)$ for some $n \in \mathbb{Z}$, equation (1.3) can be written as

$$x'(t) = (\alpha-1)x(n). \tag{1.4}$$

In the following, we will assume $t_0 = 0$. Now, integrating on $[n, n+1)$ from n to t we see that

$$x(t) = x(n)(1 + (\alpha-1)(t-n)). \tag{1.5}$$

Next, assuming continuity at $t = n+1$, we have

$$x((n+1)^-) = \alpha x(n).$$

Applying the impulsive condition to the last expression, we get the following *finite-difference equation*

$$x((n+1)) = (\alpha\beta)x(n).$$

Its solution is

$$x(n) = (\alpha\beta)^n x(0). \tag{1.6}$$

Finally, applying (1.6) in (1.5) we have

$$x(t) = (\alpha\beta)^{[t]} (1 + (\alpha - 1)(t - [t]))x(0). \tag{1.7}$$

Remark 1.1. From (1.7), we can conclude that the underlying dynamic is of mixed type. The discrete and the continuous parts of the system are dependent. For example, A stable continuous part (associated with the coefficient α) can be unstabilized by the discrete part (associated with the parameter β). See [18].

In the next table, we describe some of the behavior of the solutions of (1.7):

Behavior of solutions	**Condition**
$\lvert x(t)\rvert \xrightarrow{t\to\infty} 0$ exponentially.	$\lvert\alpha\beta\rvert < 1$ and $\alpha\beta \neq 0$.
$x(t)$ is constant.	$\alpha\beta = 0$ or $\alpha = \beta = 1$
$x(t)$ is oscillatory.	$\alpha\beta < 0$
$x(t)$ is piecewise constant.	$\alpha = 1$
$\lvert x(t)\rvert$ is piecewise constant and $x(t) \xrightarrow{t\to\infty} +\infty$.	$\alpha = 1$ and $\lvert\beta\rvert > 1$
$x(t)$ is piecewise constant and $x(t) \xrightarrow{t\to\infty} 0$.	$\alpha = 1$ and $0 < \beta < 1$
$\lvert x(t)\rvert \xrightarrow{t\to\infty} +\infty$ exponentially.	$\lvert\alpha\beta\rvert > 1$.

Table 1.1: Behavior of solutions of (1.7)

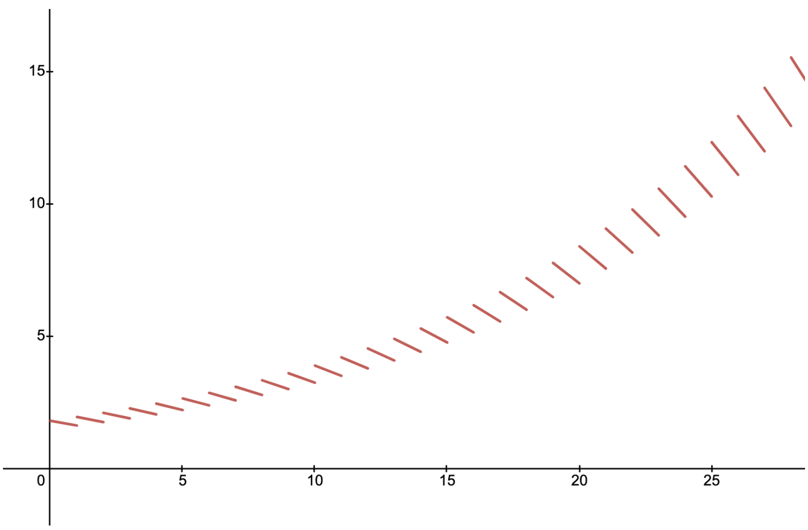

Figure 1.1: Solution of (1.3) with $\alpha = 0.9$, $\beta = 1.2$, $x_0 = 1.8$.

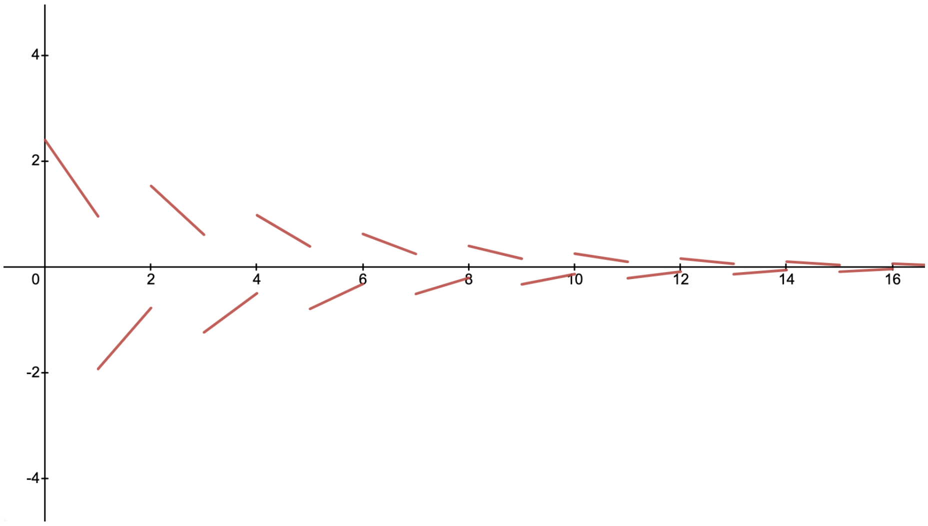

Figure 1.2: solution of (1.3) with $\alpha = 0.4$, $\beta = -2$, $x_0 = 2.4$.

1.1 Why study IDEPCAG?: impulses in action

Example 1.2. Let the following scalar linear DEPCA

$$x'(t) = a(t)(x(t) - x([t])), \qquad x(\tau) = x_0, \tag{1.8}$$

and the scalar linear IDEPCA

$$\begin{array}{ll} z'(t) = a(t)\left(z(t) - z([t])\right), & t \neq k \\ z(k) = c_k z(k^-), & t = k, \quad k \in \mathbb{Z}, \end{array} \tag{1.9}$$

where $a(t)$ is a continuous locally integrable function and $(c_k)_{k\in\mathbb{N}}$ a real sequence such that $c_k \notin \{0, 1\}$, for all $k \in \mathbb{N}$. As $\gamma(t) = [t]$, we have $t_k = k = \zeta_k = k$ if $t \in [k, k+1)$, $k \in \mathbb{Z}$.

The solution of (1.8) is $x(t) = x_0$, $\forall t \geq \tau$. I.e., all the solutions are constant (see [17]).

On the other hand, as we will see, the solution of (1.9) is

$$z(t) = \left(\prod_{j=k(\tau)+1}^{k(t)} c_j\right) z(\tau), \qquad t \geq \tau,$$

where $k(t) = k$ is the only integer such that $t \in [k, k+1]$.

Hence, all the solutions are nonconstant if $c_j \neq 1$ and $c_j \neq 0$, for all $j \geq k(\tau)$. This example shows the differences between DEPCA and IDEPCA systems. The discrete part of the system can greatly impact the whole dynamic, determining the qualitative properties of the solutions.

1.2 Fundamental matrices and variation of parameters formulas: an overview

1.2.1 The fundamental matrix of a DEPCA system

In [9], K. L. Cooke and J. Wiener were the first to obtain a fundamental matrix for a scalar *DEPCA*'s using the delayed piecewise constant arguments $\gamma(t) = [t]$, $\gamma(t) = [t-1]$, $\gamma(t) = [t-n]$ and $\gamma(t) = t - n[t]$. Also, they considered the very interesting scalar DEPCA

$$x'(t) = a(t)x(t) + \sum_{i=0}^{n} a_i(t)x([t-i]), \qquad a_n \neq 0,$$

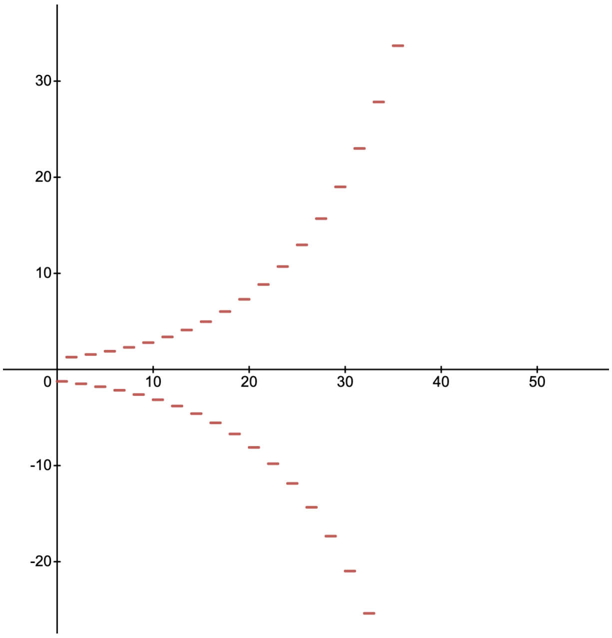

Figure 1.3: Solution of (1.9) with $c_k = -1.1$ and $z(0) = -1.2$

and

$$x'(t) = ax(t) + \sum_{i=1}^{n} a_i x(t - i[t]).$$

Also, in [19], S. M. Shah and J. Wiener studied the DEPCA

$$x'(t) = a(t)x(t) + \sum_{i=0}^{n} a_i(t)x([t+i]), \qquad a_n \neq 0, \quad n \geq 2.$$

Then, in [8], K. L. Cooke and J. Wiener studied the mixed-type piecewise constant argument $\gamma(t) = 2\left[\frac{t+1}{2}\right]$ and considered the DEPCA

$$z'(t) = az(t) + bz(2[(t+1)/2]).$$

Additionally, in [22], J. Wiener and A. R. Aftabizadeh considered the mixed-type piecewise constant argument $\gamma(t) = m\left[\frac{t+k}{m}\right]$ where $0 < k < m$, $k, m, n \in \mathbb{Z}^+$, and they studied the DEPCA

$$w'(t) = aw(t) + bw(m[(t+k)/m]).$$

1.2.2 Variation of parameters formula for a DEPCA

In [13] (1991), N. Jayasree and S. G. Deo were the first to consider the advanced and delayed parts of the solutions studying the equation

$$z'(t) = az(t) + bz(2[(t+1)/2]) + f(t),$$

obtaining a variation of parameters formula for this DEPCA, in terms of the homogeneous linear DEPCA associated:

$$\begin{aligned} z(t) = y(t) &+ \sum_{j=0}^{[(t+1)/2]-1} \lambda^{-1}(1) \int_{2j}^{2j+1} \Psi(t,2j)\phi(2j+1,s)f(s)ds \\ &- \sum_{j=1}^{[(t+1)/2]} \lambda^{-1}(1) \int_{2j}^{2j-1} \Psi(t,2j)\phi(2j-1,s)f(s)ds \\ &+ \int_{2[(t+1)/2]}^{t} \phi(t,s)f(s)ds, \end{aligned}$$

where

$$\lambda(t) = \exp(at)\left(1+a^{-1}b\right) - a^{-1}b,$$

ϕ and Ψ are the fundamental solutions of $x'(t) = ax(t)$ and $y'(t) = ay(t) + by(2[(t+1)/2])$ respectively.

In [14] (2001), Q. Meng and J. Yan obtained a variation of parameters formula for the differential equation

$$x'(t) + a(t)x(t) + b(t)x(g(t)) = f(t) \quad \text{for } t > 0,$$

where $a(t), b(t)$ and $f(t)$ are locally integrable functions on $[0,\infty)$, $g(t)$ is a piecewise constant function defined by $g(t) = np$ for $t \in [np-l,(n+1)p-l)$ with $n \in \mathbb{N}$ and p, l positive constants such that $p > l$. The authors studied the oscillation and asymptotic stability properties of the solutions.

In [1] (2008), M. Akhmet considered the DEPCAG for systems

$$z'(t) = A(t)z(t) + B(t)z(\gamma(t)) + F(t), \tag{1.10}$$

$$w'(t) = A(t)w(t) + B(t)w(\gamma(t)) + g\left(t, w(t), w(\gamma(t))\right), \tag{1.11}$$

where $A(t), B(t) \in C(\mathbb{R})$ are $n \times n$ real valued uniformly bounded on $\mathbb{R}$ matrices, $g(t,x,y) \in C(\mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^n)$ is an $n \times 1$ Lipschitz real valued function with $g(t,0,0) = 0$, $\gamma(t)$ is a piecewise constant argument of generalized type. The author found the following variation of parameters formula

$$\begin{aligned} w(t) = W(t,t_0)w_0 &+ W(t,t_0)\int_{t_0}^{\zeta_i} X(t_0,s)g(s,w(s),w(\gamma(s)))ds \\ &+ \sum_{k=i}^{j-1} W(t,t_{k+1}) \int_{\zeta_k}^{\zeta_{k+1}} X(t_{k+1},s)g(s,w(s),w(\gamma(s)))ds \\ &+ \int_{\zeta_j}^{t} X(t,s)g(s,w(s),w(\gamma(s)))ds, \end{aligned}$$

where $j = j(t)$ is the only $j \in \mathbb{Z}$ such that $t_{j(t)} \le t \le t_{j(t)+1}$, $t_k \le \zeta_k \le t_{k+1}$, $t_i \le t_0 \le t_{i+1}$, X is the fundamental matrix of

$$x'(t) = A(t)x(t),$$

and W is the fundamental matrix of the homogeneous linear DEPCAG

$$y'(t) = A(t)y(t) + B(t)y(\gamma(t)).$$

Later, in [17] (2011), M. Pinto gave a new DEPCAG variation of parameters formula. This time, the author considered the delayed and advanced intervals defined by the general piecewise constant argument

$$
\begin{aligned}
z(t) = W(t,t_0)z_0 + \underbrace{W(t,t_0)\int_{t_0}^{\zeta_i} X(t_0,s)g(s,z(s),z(\gamma(s)))ds}_{I_k^+} \\
+ \sum_{k=i+1}^{j} \underbrace{W(t,t_k)\int_{t_k}^{\zeta_k} X(t_k,s)g(s,z(s),z(\gamma(s)))ds}_{I_k^+} \\
+ \sum_{k=i}^{j-1} \underbrace{W(t,t_{k+1})\int_{\zeta_k}^{t_{k+1}} X(t_{k+1},s)g(s,z(s),z(\gamma(s)))ds}_{I_k^-} \\
+ \underbrace{\int_{\zeta_j}^{t} X(t,s)g(s,z(s),z(\gamma(s)))ds,}_{I_k^-}
\end{aligned}
$$

where $t_i \le t_0 \le t_{i+1}$ and $t_{j(t)} \le t \le t_{j(t)+1}$.

In the DEPCAG theory, decomposing the interval I_n into the advanced and delayed subintervals is critical. As we will see, it is necessary for the forward or backward continuation of solutions.

1.2.3 Variation of parameters formula for an IDEPCA: the impulsive effect applied

For the IDEPCA case, In [16] (2012), G. Oztepe and H. Bereketoglu studied the scalar IDEPCA

$$
\begin{aligned}
x'(t) &= a(t)(x(t) - x([t+1])) + f(t), \qquad x(0) = x_0, \quad t \neq n \in \mathbb{N} \\
\Delta x(n) &= d_n, \qquad t = n, \quad n \in \mathbb{N}.
\end{aligned} \tag{1.12}
$$

They proved the convergence of the solutions to a real constant when $t \to \infty$, and they showed the limit value in terms of x_0, using a suitable integral equation. They concluded the following expression for the solutions of (1.12)

$$
\begin{aligned}
x(t) = {} & \exp\left(\int_{[t]}^{t} a(u)du\right) x([t]) + \left(1 - \exp\left(\int_{[t]}^{t} a(u)du\right)\right) x([t+1]) \\
& + \int_{[t]}^{t} \exp\left(\int_{s}^{t} a(u)du\right) f(s)ds,
\end{aligned}
$$

where

$$
x([t]) = x_0 + \sum_{j=0}^{[t]-1} \left(\int_{j}^{j+1} \exp\left(-\int_{j}^{s} a(u)du\right) f(s)ds + \exp\left(-\int_{j}^{j+1} a(u)du\right) d_{j+1}\right).
$$

For the IDEPCA case, in [6] (2023), K-S. Chiu and I. Berna considered the following impulsive differential equation with a piecewise constant argument

$$
\begin{aligned}
y'(t) &= a(t)y(t) + b(t)y\left(p\left[\frac{t+l}{p}\right]\right), \quad y(\tau) = c_0, \qquad t \neq kp - l \\
\Delta y(kp - l) &= d_k y(kp - l^-), \qquad t = kp - l, \quad k \in \mathbb{Z},
\end{aligned} \tag{1.13}
$$

and

$$y'(t) = a(t)y(t) + b(t)y\left(p\left[\frac{t+l}{p}\right]\right) + f(t), \qquad y(\tau) = c_0, \quad t \neq kp - l$$
$$\Delta y(kp-l) = d_k y(kp - l^-), \qquad t = kp - l, \quad k \in \mathbb{Z}, \tag{1.14}$$

where $a(t) \neq 0$, $b(t)$ and $f(t)$ are real-valued continuous functions, $p < l$ and $d_k \in \mathbb{R} - \{1\}$. The authors obtained criteria for the existence and uniqueness, a variation of parameters formula, a Gronwall–Bellman inequality, stability and oscillation criteria for solutions for (1.13) and (1.14).

To our knowledge, there is no variation formula for impulsive differential equations with a generalized constant argument. As we have shown, some authors have studied just some particular cases before.

2 Aim of the work

We will get a variation of parameters formula associated with *IDEPCAG* system

$$\begin{array}{ll} x'(t) = A(t)x(t) + B(t)x(\gamma(t)) + F(t), & t \neq t_k \\ \Delta x|_{t=t_k} = C_k x(t_k^-) + D_k, & t = t_k, \end{array} \tag{2.1}$$

extending the particular case treated in [6] and the general results of the DEPCAG case studied in [17] to the IDEPCAG context.

3 Preliminaires

Let $\mathcal{PC}(X,Y)$ be the set of all functions $r : X \to Y$ which are continuous for $t \neq t_k$ and continuous from the left with discontinuities of the first kind at $t = t_k$. Similarly, let $\mathcal{PC}^1(X,Y)$ the set of functions $s : X \to Y$ such that $s' \in \mathcal{PC}(X,Y)$.

Definition 3.1 (DEPCAG solution)**.** A continuous function $x(t)$ is a solution of (1.1) if:

(i) $x'(t)$ exists at each point $t \in \mathbb{R}$ with the possible exception at the times t_k, $k \in \mathbb{Z}$, where the one side derivative exists.

(ii) $x(t)$ satisfies (1.1) on the intervals of the form (t_k, t_{k+1}), and it holds for the right derivative of $x(t)$ at t_k.

Definition 3.2 (IDEPCAG solution)**.** A piecewise continuous function $y(t)$ is a solution of (1.2) if:

(i) $y(t)$ is continuous on $I_k = [t_k, t_{k+1})$ with first kind discontinuities at t_k, $k \in \mathbb{Z}$, where $y'(t)$ exists at each $t \in \mathbb{R}$ with the possible exception at the times t_k, where lateral derivatives exist (i.e. $y(t) \in \mathcal{PC}^1([t_k, t_{k+1}), R^n)$).

(ii) The ordinary differential equation

$$y'(t) = f(t, y(t), y(\zeta_k))$$

holds on every interval I_k, where $\gamma(t) = \zeta_k$.

(iii) For $t = t_k$, the impulsive condition

$$\Delta y(t_k) = y(t_k) - y(t_k^-) = J_k(y(t_k^-))$$

holds. I.e., $y(t_k) = y(t_k^-) + J_k(y(t_k^-))$, where $y(t_k^-)$ denotes the left-hand limit of the function y at t_k.

Let the IDEPCAG system:

$$\begin{aligned} x'(t) &= f(t, x(t), x(\gamma(t))), \qquad && t \neq t_k \\ x(t_k) - x\left(t_k^-\right) &= J_k(x(t_k^-)), && t = t_k, \\ x(\tau) &= x_0, \end{aligned} \tag{3.1}$$

where $f \in C([\tau, \infty) \times \mathbb{R}^n \times \mathbb{R}^n, \mathbb{R}^n)$, $J_k \in C(\{t_k\}, \mathbb{R}^n)$ and $(\tau, x_0) \in \mathbb{R} \times \mathbb{R}^n$.

Let the following hypotheses hold:

(H1) Let $\eta_1, \eta_2 : \mathbb{R} \to [0, \infty)$ locally integrable functions and $\lambda_k \in \mathbb{R}^+$, $\forall k \in \mathbb{Z}$; such that

$$\begin{aligned} \|f(t, x_1, y_1) - f(t, x_2, y_2)\| &\leq \eta_1(t) \|x_1 - x_2\| + \eta_2(t) \|y_1 - y_2\|, \\ \left\|J_k(x_1(t_k^-)) - J_k(x_2(t_k^-))\right\| &\leq \lambda_k \left\|x_1\left(t_k^-\right) - x_2\left(t_k^-\right)\right\|. \end{aligned}$$

where $\|\cdot\|$ is some matricial norm.

(H2)
$$\overline{\nu} = \sup_{k \in \mathbb{Z}} \left(\int_{t_k}^{t_{k+1}} (\eta_1(s) + \eta_2(s))\, ds \right) < 1.$$

In the following, we mention some useful results: an integral equation associated with (2.1) and two Gronwall–Bellman type inequalities necessary to prove the uniqueness and stability of solutions.

3.1 An integral equation associated to (3.1)

Theorem 3.3 ([4, Lemma 4.2]). *a function $x(t) = x(t, \tau, x_0)$, $\tau \in \mathbb{R}^+$ is a solution of* (3.1) *on* $\mathbb{R}^+$ *if and only if satisfies:*

$$x(t) = x_0 + \int_\tau^t f(s, x(s), x(\gamma(s)))ds + \sum_{\tau < t_k \leq t} J_k\left(x\left(t_k^-\right)\right),$$

where

$$\begin{aligned} \int_\tau^t f(s, x(s), x(\gamma(t)))ds = \int_\tau^{t_1} f(s, x(s), x(\zeta_0))\, ds + \sum_{j=1}^{k(t)-1} \int_{t_j}^{t_{j+1}} f(s, x(s), x(\zeta_j))ds \\ + \int_{t_{k(t)}}^t f\left(s, x(s), x\left(\zeta_{k(t)}\right)\right) ds, \end{aligned}$$

3.2 First IDEPCAG Gronwall–Bellman type inequality

Lemma 3.4 ([20], [4, Lemma 4.3]). *Let I an interval and $u, \eta_1, \eta_2 : I \to [0, \infty)$ such that u is continuous (with possible exception at $\{t_k\}_{k \in \mathbb{N}}$), η_1, η_2 are continuous and locally integrable functions, $\eta : \{t_k\} \to [0, \infty)$ and $\gamma(t)$ a piecewise constant argument of generalized type such that $\gamma(t) = \zeta_k$, $\forall t \in I_k = [t_k, t_{k+1})$ with $t_k \leq \zeta_k \leq t_{k+1}$ $\forall k \in \mathbb{N}$. Assume that $\forall t \geq \tau$*

$$u(t) \leq u(\tau) + \int_\tau^t (\eta_1(s)u(s) + \eta_2(s)u(\gamma(s)))\, ds + \sum_{\tau < t_k \leq t} \eta(t_k)u(t_k^-)$$

and

$$\widehat{\vartheta}_k = \int_{t_k}^{\zeta_k} (\eta_1(s) + \eta_2(s))\,ds \le \widehat{\vartheta} := \sup_{k\in\mathbb{N}} \widehat{\vartheta}_k < 1. \tag{3.2}$$

hold. Then, for $t \ge \tau$, we have

$$u(t) \le \left(\prod_{\tau<t_k\le t}(1+\eta(t_k))\right)\exp\left(\int_\tau^t\left(\eta_1(s)+\frac{\eta_2(s)}{1-\widehat{\vartheta}}\right)ds\right)u(\tau), \tag{3.3}$$

$$u(\zeta_k) \le (1-\vartheta)u(t_k) \tag{3.4}$$

$$u(\gamma(t)) \le (1-\vartheta)^{-1}\left(\prod_{\tau<t_k\le t}(1+\eta_3(t_j))\right)\exp\left(\int_\tau^t\left(\eta_1(s)+\frac{\eta_2(s)}{1-\widehat{\vartheta}}\right)ds\right)u(\tau). \tag{3.5}$$

3.3 Second IDEPCAG Gronwall–Bellman type inequality

Lemma 3.5 ([5, 20])**.** *Let I an interval and $u, \eta_1, \eta_2 : I \to [0,\infty)$ such that u is continuous (with possible exception at $\{t_k\}_{k\in N}$), η_1, η_2 are continuous and locally integrable functions, $\eta : \{t_k\} \to [0,\infty)$ and $\gamma(t)$ a piecewise constant argument of generalized type such that $\gamma(t) = \zeta_k$, $\forall t \in I_k = [t_k, t_{k+1})$ with $t_k \le \zeta_k \le t_{k+1}$ $\forall k \in \mathbb{N}$. Assume that $\forall t \ge \tau$*

$$u(t) \le u(\tau) + \int_\tau^t (\eta_1(s)u(s) + \eta_2(s)u(\gamma(s)))ds + \sum_{\tau<t_k\le t}\eta(t_k)u(t_k^-) \tag{3.6}$$

and

$$\varrho_k = \int_{t_k}^{\zeta_k}\left(\eta_2(s)e^{\int_s^{\zeta_k}\eta_1(r)dr}\right)ds \le \varrho := \sup_{k\in\mathbb{N}}\varrho_k < 1. \tag{3.7}$$

Then, for $t \ge \tau$, we have

$$\begin{aligned} u(t) \le & \left(\prod_{\tau<t_k\le t}(1+\eta(t_k))\right) \\ & \cdot \exp\left(\frac{1}{1-\vartheta}\sum_{j=k(\tau)+1}^{k(t)}\int_{t_{j-1}}^{t_j}\eta_2(s)\exp\left(\int_{t_{j-1}}^{\zeta_{j-1}}\eta_1(r)dr\right)ds\right. \\ & \left. + \frac{1}{1-\vartheta}\int_{t_{k(t)}}^t \eta_2(s)\exp\left(\int_{t_{k(t)}}^{\zeta_{k(t)}}\eta_1(r)dr\right)ds + \int_\tau^t \eta_1(s)ds\right)u(\tau). \end{aligned} \tag{3.8}$$

3.4 Existence and uniqueness for (3.1)

Theorem 3.6 (Uniqueness [4, Theorem 4.5])**.** *Consider the I.V.P for (2.1) with $y(t,\tau,y(\tau))$. Let (H1)–(H2) hold. Then, there exists a unique solution y for (2.1) on $[\tau,\infty)$. Moreover, every solution is stable.*

Lemma 3.7 (Existence of solutions in $[\tau, t_k)$ [4, Lemma 4.6])**.** *Consider the I.V.P for (2.1) with $y(t,\tau,y(\tau))$. Let (H1)–(H2) hold. Then, for each $y_0 \in \mathbb{R}^n$ and $\zeta_k \in [t_{k-1}, t_k)$ there exists a solution $y(t) = y(t,\tau,y(\tau))$ of (2.1) on $[\tau, t_r)$ such that $y(\tau) = y_0$.*

Theorem 3.8 (Existence of solutions in $[\tau,\infty$ [4, Theorem 4.7])**.** *Let (H1)–(H2) hold. Then, for each $(\tau, y_0 \in \mathbb{R}_0^+ \times \mathbb{R}^n$, there exists $y(t) = y(t,\tau,y_0)$ for $t \ge \tau$, a unique solution for (2.1) such that $y(\tau) = y_0$.*

4 Variation of parameters formula for IDEPCAG

In this section, we will construct a variation of parameters formula for the IDEPCAG system

$$\begin{aligned} y'(t) &= A(t)y(t) + B(t)y(\gamma(t)) + F(t), && t \neq t_k \\ \Delta y|_{t=t_k} &= C_k y(t_k^-) + D_k, && t = t_k \end{aligned} \tag{4.1}$$

where $y \in \mathbb{R}^{n\times 1}, t \in \mathbb{R}, F(t) \in \mathbb{R}^{n\times 1}$ is a real valued continuous matrix, $A(t), B(t) \in \mathbb{R}^{n\times n}$ are real valued continuous locally integrable matrices, $C_k, D_k \in \mathbb{R}^{n\times n}$, $(I + C_k)$ invertible $\forall k \in \mathbb{Z}$, where $I_{n\times n} = I$ is the identity matrix and $\gamma(t)$ is a generalized piecewise constant argument. This time, we will consider the advanced and the delayed intervals in our approach.

First, we will find the *fundamental matrix* for the linear IDEPCAG

$$\begin{aligned} w'(t) &= A(t)w(t) + B(t)w(\gamma(t)), && t \neq t_k \\ \Delta w|_{t=t_k} &= C_k w(t_k^-), && t = t_k. \end{aligned} \tag{4.2}$$

Then, we will give the variation of parameters formula for (4.1).

Let $\Phi(t,s)$, $t, s \in \mathbb{R}$, with $\Phi(t,t) = I$ the transition (Cauchy) matrix of the ordinary system

$$x'(t) = A(t)x(t), \qquad t \in I_k = [t_k, t_{k+1}). \tag{4.3}$$

We will assume the following hypothesis:

(H3) Let

$$\rho_{k^+}(A) = \exp\left(\int_{t_k}^{\zeta_k} \|A(u)\|\, du\right), \qquad \rho_{k^-}(A) = \exp\left(\int_{\zeta_k}^{t_{k+1}} \|A(u)\|\, du\right),$$

$$\rho_k(A) = \rho_{k^+}(A)\cdot\rho_{k^-}(A), \qquad \nu_k^{\pm}(B) = \rho_k^{\pm}(A)\ln\rho_k^{\pm}(B),$$

and assume that

$$\rho(A) = \sup_{k\in\mathbb{Z}} \rho_k(A) < \infty, \qquad \nu^{\pm}(B) = \sup_{k\in\mathbb{Z}} \nu_k^{\pm}(B) < \infty.$$

Consider the following matrices

$$J(t,\tau) = I + \int_\tau^t \Phi(\tau,s)B(s)ds, \qquad E(t,\tau) = \Phi(t,\tau)J(t,\tau), \tag{4.4}$$

where

$$\nu_k^{\pm}(B) < \nu^{\pm}(B) < 1. \tag{4.5}$$

Remark 4.1. It is important to notice the following facts:

a) As a consequence of (H3), $J(t_k,\zeta_k)$ and $J(t_{k+1},\zeta_k)$ are invertible $\forall k \in \mathbb{Z}$, and

$$\left\|J^{-1}(t_k,\zeta_k)\right\| \leq \sum_{k=0}^{\infty}\left[\nu^+(B)\right]^k = \frac{1}{1-\nu^+(B)}, \qquad \|J(t_k,\zeta_k)\| \leq 1 + \nu^+(B), \tag{4.6}$$

$$\left\|J^{-1}(t_{k+1},\zeta_k)\right\| \leq \sum_{k=0}^{\infty}\left[\nu^-(B)\right]^k = \frac{1}{1-\nu^-(B)}, \qquad \|J(t_{k+1},\zeta_k)\| \leq 1 + \nu^-(B). \tag{4.7}$$

Additionally, setting $t_0 := \tau$, we will assume that $J^{-1}(\tau,\gamma(\tau))$ exists.

b) Also, due to (H3) and the Gronwall inequality, we have

$$|\Phi(t)| \leq \rho(A),$$

(see [17]).

4.1 The fundamental matrix of the linear homogeneous IDEPCAG

We adopt the following convention:

$$\overleftarrow{\prod_{k=j}^{j+p}} T_k = T_{j+p} \cdot T_{j+p-1} \cdot \ldots \cdot T_j.$$

Also, we will assume $\gamma(\tau) := \tau$ if $\gamma(\tau) < \tau$, where $k(\tau)$ is the only $k \in \mathbb{Z}$ such that $\tau \in I_{k(\tau)} = [t_{k(\tau)}, t_{k(\tau)+1})$. We will adopt the following notation:

$$\prod_{j=r+1}^{r} A_j = 1, \qquad \sum_{j=r+1}^{r} A_j = 0.$$

Let the system

$$\begin{array}{ll} w'(t) = A(t)w(t) + B(t)w(\gamma(t)), & t \neq t_k \\ w(t_k) = (I + C_k)\, w(t_k^-), & t = t_k \\ w_0 = w(\tau). & \end{array} \tag{4.8}$$

We will construct the fundamental matrix for system (4.8).
Let $t, \tau \in I_k = [t_k, t_{k+1})$ for some $k \in \mathbb{Z}$. In this interval, we are in the presence of the ordinary system

$$w'(t) = A(t)w(t) + B(t)w(\zeta_k).$$

So, the unique solution can be written as

$$w(t) = \Phi(t,\tau)w(\tau) + \int_\tau^t \Phi(t,s)B(s)w(\zeta_k)ds. \tag{4.9}$$

Keeping in mind $I_k^+ = [t_k, \zeta_k]$, evaluating the last expression at $t = \zeta_k$ we have

$$w(\zeta_k) = \Phi(\zeta_k,\tau)w(\tau) + \int_\tau^{\zeta_k} \Phi(\zeta_k,s)B(s)w(\zeta_k)ds. \tag{4.10}$$

Hence, we get

$$\left(I + \int_{\zeta_k}^{\tau} \Phi(\zeta_k,s)B(s)ds\right) w(\zeta_k) = \Phi(\zeta_k,\tau)w(\tau).$$

I.e.

$$w(\zeta_k) = J^{-1}(\tau,\zeta_k)\Phi(\zeta_k,\tau)w(\tau). \tag{4.11}$$

Then, by the definition of $E(t,\tau) = \Phi(t,\tau)J(t,\tau)$, we have

$$w(\zeta_k) = E^{-1}(\tau,\zeta_k)w(\tau). \tag{4.12}$$

Now, from (4.9) working on $I_k^- = [\zeta_k, t_{k+1})$, considering $\tau = \zeta_k$, we have

$$\begin{aligned} w(t) &= \Phi(t,\zeta_k)w(\zeta_k) + \int_{\zeta_k}^t \Phi(t,s)B(s)w(\zeta_k)ds \\ &= \Phi(t,\zeta_k)\left(I + \int_{\zeta_k}^t \Phi(\zeta_k,s)B(s)ds\right) w(\zeta_k). \end{aligned}$$

I.e.,

$$w(t) = E(t,\zeta_k)w(\zeta_k). \tag{4.13}$$

So, by (4.12), we can rewrite (4.13) as

$$w(t) = E(t,\zeta_k)E^{-1}(\tau,\zeta_k)w(\tau). \tag{4.14}$$

Then, setting

$$W(t,s) = E(t,\gamma(s))E^{-1}(s,\gamma(s)), \quad \text{if } t,s \in I_k = [t_k, t_{k+1}), \tag{4.15}$$

we have the solution for (4.8) for $t \in I_k$

$$w(t) = W(t,\tau)w(\tau). \tag{4.16}$$

Next, if we consider $\tau = t_k$ and assuming left side continuity of (4.16) at $t = t_{k+1}$, we have

$$w(t_{k+1}^-) = W(t_{k+1}, t_k)w(t_k).$$

Then, applying the impulsive condition to the last equation, we get

$$\begin{aligned} w(t_{k+1}) &= (I + C_{k+1})\, w(t_{k+1}^-) \\ &= (I + C_{k+1})\, W(t_{k+1}, t_k)w(t_k). \end{aligned}$$

This expression corresponds to a finite-difference equation. Then, by solving it, we get

$$w(t_{k(t)}) = \left(\overset{\leftarrow}{\prod_{j=k(\tau)+1}^{k(t)-1}} (I + C_{j+1})\, W(t_{j+1}, t_j) \right) w\left(t_{k(\tau)+1}\right). \tag{4.17}$$

Finally, by (4.16) and the impulsive condition, we have

$$w(t_{k(\tau)+1}) = (I + C_{k(\tau)+1})W(t_{k(\tau)+1}, \tau)w(\tau).$$

Hence, considering $\tau = t_k$ in (4.16) and applying (4.17) we get

$$\begin{aligned} w(t) &= W(t, t_{k(t)}) \left(\overset{\leftarrow}{\prod_{j=k(\tau)+1}^{k(t)-1}} (I + C_{j+1})\, W(t_{j+1}, t_j) \right) \left(I + C_{k(\tau)+1}\right) W(t_{k(\tau)+1}, \tau)w(\tau) \\ &= W(t,\tau)w(\tau), \quad \text{for } t \in I_{k(t)} \text{ and } \tau \in I_{k(\tau)}. \end{aligned} \tag{4.18}$$

The last equation is the solution of (4.8) on $[\tau, t)$.

We call the expression

$$W(t,\tau) = W(t, t_{k(t)}) \left(\overset{\leftarrow}{\prod_{j=k(\tau)+1}^{k(t)-1}} (I + C_{j+1})\, W(t_{j+1}, t_j) \right) \left(I + C_{k(\tau)+1}\right) W(t_{k(\tau)+1}, \tau) \tag{4.19}$$

the fundamental matrix for (4.8) for $t \in I_{k(t)}$ and $\tau \in I_{k(\tau)}$.

Remark 4.2. We use the decomposition of $I_k = I_k^+ \cup I_k^-$ to define W. In fact, we can rewrite (4.19) in terms of the advanced and delayed parts using (4.15):

$$\begin{aligned} W(t,\tau) = E(t,\zeta_{k(t)})E^{-1}(t_{k(t)},\zeta_{k(t)}) &\left(\overset{\leftarrow}{\prod_{j=k(\tau)+1}^{k(t)-1}} (I + C_{j+1})\, E(t_{j+1},\zeta_j)E^{-1}(t_j,\zeta_j) \right) \\ &\cdot \left(I + C_{k(\tau)+1}\right) E(t_{k(\tau)+1}, \gamma(\tau))E^{-1}(\tau,\gamma(\tau)), \qquad \zeta_j = \gamma(t_j) \end{aligned}$$

for $t \in I_{k(t)}$ and $\tau \in I_{k(\tau)}$.

Remark 4.3.

a) Considering $B(t) = 0$, we recover the classical fundamental matrix of the impulsive linear differential equation (see [18]).

b) If $C_k = 0, \forall k \in \mathbb{Z}$, we recover the DEPCAG case studied by M. Pinto in [17].

c) If we consider $\gamma(t) = p[\frac{t+l}{p}]$, with $p < l$, we recover the IDEPCA case studied by K.-S. Chiu in [6].

4.2 The variation of parameter formula for IDEPCAG

Let the IDEPCAG

$$\begin{aligned} &y'(t) = A(t)y(t) + B(t)y(\gamma(t)) + F(t), && t \neq t_k, \\ &y(t_k) = (I + C_k)y(t_k^-) + D_k, && t = t_k, \\ &y_0 = y(\tau). \end{aligned} \tag{4.20}$$

If $\tau, t \in I_k = [t_k, t_{k+1})$, then the unique solution of (4.20) is

$$y(t) = \Phi(t,\tau)y(\tau) + \int_\tau^t \Phi(t,s)B(s)y(\zeta_k)ds + \int_\tau^t \Phi(t,s)f(s)ds.$$

Then, if $\tau = \zeta_k$, we have

$$\begin{aligned} y(t) &= \Phi(t,\zeta_k)y(\zeta_k) + \int_{\zeta_k}^t \Phi(t,s)B(s)y(\zeta_k)ds + \int_{\zeta_k}^t \Phi(t,s)f(s)ds \\ &= \Phi(t,\zeta_k)\left(I + \int_{\zeta_k}^t \Phi(\zeta_k,s)B(s)ds\right)y(\zeta_k) + \int_{\zeta_k}^t \Phi(t,s)f(s)ds \\ &= \Phi(t,\zeta_k)J\,(t,\zeta_k)\,y(\zeta_k) + \int_{\zeta_k}^t \Phi(t,s)f(s)ds, \end{aligned}$$

i.e.

$$y(t) = E(t,\zeta_k)y(\zeta_k) + \int_{\zeta_k}^t \Phi(t,s)f(s)ds. \tag{4.21}$$

Now, if we consider $t = \tau$ in (4.21) we have

$$y(\tau) = E(\tau,\zeta_k)y(\zeta_k) + \int_{\zeta_k}^\tau \Phi(\tau,s)f(s)ds,$$

and, by $(H3)$, we get the following estimation for $y(\zeta_k)$

$$y(\zeta_k) = E^{-1}(\tau,\zeta_k)\left(y(\tau) + \int_\tau^{\zeta_k} \Phi(\tau,s)f(s)ds\right). \tag{4.22}$$

Then, applying (4.22) in (4.21) we obtain

$$y(t) = E(t,\zeta_k)E^{-1}(\tau,\zeta_k)\left(y(\tau) + \int_\tau^{\zeta_k} \Phi(\tau,s)f(s)ds\right) + \int_{\zeta_k}^t \Phi(t,s)f(s)ds,$$

i.e.,

$$y(t) = W(t,\tau)y(\tau) + \int_\tau^{\zeta_k} W(t,\tau)\Phi(\tau,s)f(s)ds + \int_{\zeta_k}^t \Phi(t,s)f(s)ds, \qquad \tau, t \in I_k. \tag{4.23}$$

Next, taking the left-side limit to the last expression, we have

$$y(t_{k+1}^-) = W(t_{k+1},\tau)\left(y(\tau) + \int_\tau^{\zeta_k} \Phi(\tau,s)f(s)ds\right) + \int_{\zeta_k}^{t_{k+1}} \Phi(t_{k+1},s)f(s)ds. \tag{4.24}$$

Applying the impulsive condition, we get

$$y(t_{k+1}) = (I + C_{k+1})\, y(t_{k+1}^-) + D_{k+1},$$

or

$$\begin{aligned} y(t_{k+1}) = &\ (I + C_{k+1})\, W(t_{k+1},\tau)\left(y(\tau) + \int_\tau^{\zeta_k} \Phi(\tau,s)f(s)ds\right) \\ &+ \int_{\zeta_k}^{t_{k+1}} (I + C_{k+1})\, \Phi(t_{k+1},s)f(s)ds + D_{k+1}. \end{aligned}$$

Therefore, considering $\tau = t_k$ in the last expression we have

$$\begin{aligned} y(t_{k+1}) = &\ (I + C_{k+1})\, W(t_{k+1},t_k)\left(y(t_k) + \int_{t_k}^{\zeta_k} \Phi(t_k,s)f(s)ds\right) \\ &+ \int_{\zeta_k}^{t_{k+1}} (I + C_{k+1})\, \Phi(t_{k+1},s)f(s)ds + D_{k+1}, \end{aligned}$$

or

$$y(t_{k+1}) = W_k\left(y(t_k) + \alpha_k^+\right) + \alpha_k^- + \beta_k,$$

which corresponds to a non-homogeneous linear difference equation, where

$$\begin{aligned} W_k &= (I + C_{k+1})W(t_{k+1},t_k), \\ \alpha_k^+ &= \int_{t_k}^{\zeta_k} \Phi(t_k,s)f(s)ds, \\ \alpha_k^- &= \int_{\zeta_k}^{t_{k+1}} (I + C_{k+1})\, \Phi(t_{k+1},s)f(s)ds, \\ \beta_k &= D_{k+1}. \end{aligned}$$

Recalling that

$$W(t_{k(t)},\tau) = \left(\overset{\leftarrow}{\prod_{j=k(\tau)+1}^{k(t)-1}} \left(I + C_{j+1}\right) W(t_{j+1},t_j)\right)\left(I + C_{k(\tau)+1}\right) W(t_{k(\tau)+1},\tau),$$

we get the discrete solution of (4.20):

$$\begin{aligned} y(t_{k(t)}) = &\left(\overset{\leftarrow}{\prod_{j=k(\tau)+1}^{k(t)-1}} \left(I + C_{j+1}\right) W(t_{j+1},t_j)\right)(I + C_{k(\tau)+1})W(t_{k(\tau)+1},\tau)y(\tau) \\ &+ \int_\tau^{\zeta_{k(\tau)}} W\left(t_{k(t)},\tau\right)\Phi(\tau,s)f(s)ds \\ &+ \sum_{r=k(\tau)+1}^{k(t)-1}\left(\overset{\leftarrow}{\prod_{j=r}^{k(t)-1}} \left(I + C_{j+1}\right) W(t_{j+1},t_j)\right)\int_{t_r}^{\zeta_r} \Phi(t_r,s)f(s)ds \\ &+ \sum_{r=k(\tau)}^{k(t)-1}\left(\overset{\leftarrow}{\prod_{j=r+1}^{k(t)-1}} (I + C_{j+1})W(t_{j+1},t_j)\right)\int_{\zeta_r}^{t_{r+1}} (I + C_{r+1})\Phi(t_{r+1},s)f(s)ds \\ &+ \sum_{r=k(\tau)}^{k(t)-1}\left(\overset{\leftarrow}{\prod_{j=r+1}^{k(t)-1}} (I + C_{j+1})W(t_{j+1},t_j)\right) D_{r+1}, \end{aligned}$$

or, written in terms of (4.19),

$$
\begin{aligned}
y(t_{k(t)}) &= W(t_{k(t)},\tau)y(\tau) + \int_{\tau}^{\zeta_{k(\tau)}} W\left(t_{k(t)},\tau\right)\Phi(\tau,s)f(s)ds \\
&+ \sum_{r=k(\tau)+1}^{k(t)-1}\int_{t_r}^{\zeta_r} W(t_{k(t)},t_r)\Phi(t_r,s)f(s)ds \\
&+ \sum_{r=k(\tau)}^{k(t)-1}\int_{\zeta_r}^{t_{r+1}} W(t_{k(t)},t_{r+1})(I+C_{r+1})\Phi(t_{r+1},s)f(s)ds \\
&+ \sum_{r=k(\tau)}^{k(t)-1} W(t_{k(t)},t_{r+1})D_{r+1}.
\end{aligned}
\tag{4.25}
$$

Now, considering $\tau = t_k$ in (4.23) we have

$$
y(t) = W(t,t_{k(t)})y(t_{k(t)}) + \int_{t_{k(t)}}^{\zeta_{k(t)}} W(t,t_{k(t)})\Phi(t_{k(t)},s)f(s)ds + \int_{\zeta_{k(t)}}^{t} \Phi(t,s)f(s)ds.
$$

Finally, replacing $y(t_{k(t)})$ by (4.25) and rewriting in terms of (4.19), we get the variation of parameters formula for IDEPCAG (4.20):

$$
\begin{aligned}
y(t) &= W(t,\tau)y(\tau) \\
&+ \int_{\tau}^{\zeta_{k(\tau)}} W(t,\tau)\Phi(\tau,s)f(s)ds + \sum_{r=k(\tau)+1}^{k(t)}\int_{t_r}^{\zeta_r} W(t,t_r)\Phi(t_r,s)f(s)ds \\
&+ \sum_{r=k(\tau)}^{k(t)-1}\int_{\zeta_r}^{t_{r+1}} W(t,t_{r+1})\left(I+C_{r+1}\right)\Phi(t_{r+1},s)f(s)ds \\
&+ \int_{\zeta_{k(t)}}^{t} \Phi(t,s)f(s)ds + \sum_{r=k(\tau)+1}^{k(t)} W(t,t_r)D_r, \quad \text{for } t\in[\tau,t_{k(t)+1}),
\end{aligned}
\tag{4.26}
$$

where W is the fundamental matrix of (4.8).

4.2.1 Green type matrix for IDEPCAG

If we define the following Green matrix type for IDEPCAG:

$$
\widetilde{W}(t,s) = \begin{cases} W^{+}(t,s), & \text{if } t_r \le s \le \gamma(s) \\ W^{-}(t,s), & \text{if } \gamma(s) < s \le t_{r+1}, \end{cases}
\tag{4.27}
$$

where

$$
W^{+}(t,s) = W(t,t_r)\Phi(t_r,s), \quad \text{if } \ t_r \le s \le \gamma(s),\ s<t,
\tag{4.28}
$$

and

$$
W^{-}(t,s) = \begin{cases} W(t,t_{r+1})\left(I+C_{r+1}\right)\Phi(t_{r+1},s), & \text{if } \gamma(s) \le s < t_{r+1},\ t>s,\ t\le t_{k+1}, \\ \Phi(t,s), & \text{if } \gamma(t) < s \le t < t_{r+1}. \end{cases}
\tag{4.29}
$$

Hence, we can see that

$$\int_{\tau}^{t} W^{+}(t,s)f(s)ds = \int_{\tau}^{\zeta_{k(\tau)}} W(t,\tau)\Phi(\tau,s)f(s)ds + \sum_{r=k(\tau)+1}^{k(t)} \int_{t_r}^{\zeta_r} W(t,t_r)\Phi(t_r,s)f(s)ds,$$

$$\int_{\tau}^{t} W^{-}(t,s)f(s)ds = \sum_{r=k(\tau)}^{k(t)-1} \int_{\zeta_r}^{t_{r+1}} W(t,t_{r+1})\left(I+C_{r+1}\right)\Phi(t_{r+1},s)f(s)ds + \int_{\zeta_{k(t)}}^{t} \Phi(t,s)f(s)ds.$$

So, we have

$$\widetilde{W}(t,s) = W^{+}(t,s) + W^{-}(t,s).$$

In this way, (4.26) can be expressed as

$$y(t) = W(t,\tau)y(\tau) + \int_{\tau}^{t} \widetilde{W}(t,s)f(s)ds + \sum_{r=k(\tau)+1}^{k(t)} W(t,t_r)D_r. \tag{4.30}$$

4.3 Some special cases of (4.20)

In the following, we present some r cases for (4.20).

1. Let $\gamma^{-}(t) = t_k$ and $\gamma^{+}(t) = t_{k+1}$, for all $t \in I_k = [t_k, t_{k+1})$. I.e., we are considering the completely delayed and advanced general piecewise constant arguments. Then, taking in account Remark 4.2, the solution of (4.20) for both cases $y_{-}(t)$ and $y_{+}(t)$ respectively are:

$$y_{-}(t) = W_{-}(t,\tau)y(\tau) + \sum_{r=k(\tau)}^{k(t)-1} \int_{t_r}^{t_{r+1}} W_{-}(t,t_{r+1})\left(I+C_{r+1}\right)\Phi(t_{r+1},s)f(s)ds + \int_{t_{k(t)}}^{t} \Phi(t,s)f(s)ds + \sum_{r=k(\tau)+1}^{k(t)} W_{-}(t,t_r)D_r, \tag{4.31}$$

where

$$W_{-}(t,\tau) = E(t,t_{k(t)})\left(\overset{\leftarrow}{\prod_{j=k(\tau)+1}^{k(t)-1}} \left(I+C_{j+1}\right)E(t_{j+1},t_j)\right)\cdot\left(I+C_{k(\tau)+1}\right)E(t_{k(\tau)+1},\tau), \tag{4.32}$$

and

$$y_{+}(t) = W_{+}(t,\tau)y(\tau) + \int_{\tau}^{t_{k(\tau)+1}} W_{+}(t,\tau)\Phi(\tau,s)f(s)ds + \sum_{r=k(\tau)+1}^{k(t)} \int_{t_r}^{t_{r+1}} W_{+}(t,t_r)\Phi(t_r,s)f(s)ds - \int_{t}^{t_{k(t)+1}} \Phi(t,s)f(s)ds + \sum_{r=k(\tau)+1}^{k(t)} W_{+}(t,t_r)D_r, \tag{4.33}$$

where

$$W_+(t,\tau) = E(t,t_{k(t)+1})E^{-1}(t_{k(t)},t_{k(t)+1}) \left(\overleftarrow{\prod_{j=k(\tau)+1}^{k(t)-1}} \left(I + C_{j+1}\right) E^{-1}(t_j,t_{j+1}) \right) \cdot \left(I + C_{k(\tau)+1}\right) E^{-1}(\tau,t_{k(\tau)+1}),$$

for $t \in I_{k(t)}$ and $\tau \in I_{k(\tau)}$, recalling that $\gamma(\tau) := \tau$ if $\gamma(\tau) < \tau$.

2. Let the IDEPCAG

$$\begin{aligned} w'(t) &= B(t)w(\gamma(t)), && t \neq t_k \\ w(t_k) &= (I + C_k)w(t_k^-), && t = t_k \\ w_0 &= w(\tau). \end{aligned} \tag{4.34}$$

We see that $\Phi(t,s) = I, E(t,s) = J(t,s)$ and $J(t,s) = I + \int_s^t B(u)du$, where I is the identity matrix. Hence the fundamental matrix for (4.34) is given by

$$W(t,\tau) = J(t,\zeta_{k(t)})J^{-1}(t_{k(t)},\zeta_{k(t)}) \left(\overleftarrow{\prod_{j=k(\tau)+1}^{k(t)-1}} \left(I + C_{j+1}\right) J(t_{j+1},\zeta_j)J^{-1}(t_j,\zeta_j) \right) \cdot \left(I + C_{k(\tau)+1}\right) J(t_{k(\tau)+1},\gamma(\tau))J^{-1}(\tau,\gamma(\tau)), \qquad \zeta_j = \gamma(t_j).$$

for $t \in I_{k(t)}$ and $\tau \in I_{k(\tau)}$.

This case is very important because it is used for the approximation of solutions of differential equations considering $\gamma(t) = \left[\frac{t}{h}\right] h$, with $h > 0$ fixed.

3. Let the IDEPCAG

$$\begin{aligned} w'(t) &= Aw(t) + Bw(\gamma(t)), && t \neq t_k \\ w(t_k) &= (I + C)w(t_k^-), && t = t_k \\ w_0 &= w(\tau), \end{aligned} \tag{4.35}$$

and

$$\begin{aligned} y'(t) &= Ay(t) + By(\gamma(t)) + f(t), && t \neq t_k \\ y(t_k) &= (I + C)y(t_k^-) + D_k, && t = t_k \\ y_0 &= y(\tau), \end{aligned} \tag{4.36}$$

where A^{-1} exist. By $(H3)$, we know that $J(t,\tau) = I + \int_\tau^t e^{A(\tau-s)}B\,ds$ is invertible, for $\tau, t \in I_k = [t_k, t_{k+1})$. Moreover, following [17], we see that

$$\begin{aligned} J(t,\tau) &= I + \int_\tau^t e^{A(\tau-s)}Bds \\ &= I + e^{A\tau}\left(\int_\tau^t (-A)e^{-As}ds\right)(-A^{-1})B \\ &= I + A^{-1}\left(I - e^{A(\tau-t)}\right)B. \end{aligned} \tag{4.37}$$

Then, as $E(t,\tau) = \Phi(t,\tau)J(t,\tau)$, we have

$$E(t,\tau) = e^{A(t-\tau)}\left(I + A^{-1}\left(I - e^{-A(t-\tau)}\right)B\right). \tag{4.38}$$

In light of the last calculations, we define

$$\begin{aligned}\widetilde{E}(t) &= e^{At}\left(I + A^{-1}\left(I - e^{-At}\right)B\right)\\ \eta_k^+ &= \zeta_k - t_k, \qquad \eta_k^- = t_{k+1} - \zeta_k, \quad k \in \mathbb{Z},\\ \eta(t) &= t - \gamma(t).\end{aligned}$$

Recalling that

$$\widehat{W}(t,s) = \widetilde{E}(t-\gamma(s))\widetilde{E}^{-1}(\eta(s)), \quad \text{if } t,s \in I_k = [t_k, t_{k+1}), \tag{4.39}$$

the solution of (4.35) is

$$w(t) = \widehat{W}(t,\tau)w(\tau),$$

where

$$\widehat{W}(t,\tau) = \widetilde{E}(\eta(t))\widetilde{E}^{-1}(-\eta_{k(t)}^+)\left(\overset{\leftarrow}{\prod_{j=k(\tau)+1}^{k(t)-1}}(I+C)\widetilde{E}(\eta_j^-)\widetilde{E}^{-1}(-\eta_j^+)\right) \tag{4.40}$$

$$\cdot (I+C)\widetilde{E}(\eta_{k(\tau)+1}^-)\widetilde{E}^{-1}(\eta(\tau)), \tag{4.41}$$

is the fundamental matrix for (4.35) with $t \in I_{k(t)}$ and $\tau \in I_{k(\tau)}$.

The solution for (4.36) is given by

$$\begin{aligned}y(t) = {} & \widetilde{E}(\eta(t))\widetilde{E}^{-1}(-\eta_{k(t)}^+)\left(\overset{\leftarrow}{\prod_{j=k(\tau)+1}^{k(t)-1}}(I+C)\widetilde{E}(\eta_j^-)\widetilde{E}^{-1}(-\eta_j^+)\right)\\ & \cdot (I+C)\widetilde{E}(\eta_{k(\tau)+1}^-)\widetilde{E}^{-1}(\eta(\tau))\left(y(\tau) + \int_\tau^{\zeta_{k(\tau)}} e^{A(\tau-s)}f(s)ds\right)\\ & + \widetilde{E}(\eta(t))\widetilde{E}^{-1}(-\eta_{k(t)}^+)\\ & \cdot\left\{\sum_{r=k(\tau)+1}^{k(t)}\left(\overset{\leftarrow}{\prod_{j=r}^{k(t)-1}}(I+C)\widetilde{E}(\eta_j^-)\widetilde{E}^{-1}(-\eta_j^+)\right)\int_{t_r}^{\zeta_r} e^{A(t_r-s)}f(s)ds\right.\\ & + \sum_{r=k(\tau)}^{k(t)-1}\left(\overset{\leftarrow}{\prod_{j=r+1}^{k(t)}}(I+C)\widetilde{E}(\eta_j^-)\widetilde{E}^{-1}(-\eta_j^+)\right)\int_{\zeta_r}^{t_{r+1}}(I+C)e^{A(t_{r+1}-s)}f(s)ds\\ & \left.+ \sum_{r=k(\tau)}^{k(t)-1}\left(\overset{\leftarrow}{\prod_{j=r+1}^{k(t)}}(I+C)\widetilde{E}(\eta_j^-)\widetilde{E}^{-1}(-\eta_j^+)\right)D_r\right\}\\ & + \int_{\zeta_{k(t)}}^t e^{A(t-s)}f(s)ds.\end{aligned} \tag{4.42}$$

Also, if $\eta = \eta_k^+ = \eta_k^-$, $k \in \mathbb{Z}$, $\widehat{E} = (I+C)\widetilde{E}(\eta)\widetilde{E}^{-1}(-\eta)$, the solution of (4.35) is

$$w(t) = \widehat{W}(t,\tau)w(\tau),$$

where

$$\widehat{W}(t,\tau) = \widetilde{E}(\eta(t))\widetilde{E}^{-1}(-\eta_{k(t)}^+)\widehat{E}^{k(t)-k(\tau)-1}(I+C)\widetilde{E}(\eta)\widetilde{E}^{-1}(\eta(\tau)),$$

is the fundamental matrix for (4.35) with $t \in I_{k(t)}$ and $\tau \in I_{k(\tau)}$.
The solution for (4.36) is given by

$$\begin{aligned} y(t) &= \widetilde{E}(\eta(t))\widetilde{E}^{-1}(-\eta^{+}_{k(t)})\widehat{E}^{k(t)-k(\tau)-1}(I+C)\widetilde{E}(\eta^{-}_{k(\tau)+1})\widetilde{E}^{-1}(\eta(\tau)) \\ &\cdot \left(y(\tau) + \int_{\tau}^{\zeta_{k(\tau)}} e^{A(\tau-s)} f(s)ds\right) \\ &+ \widetilde{E}(\eta(t))\widetilde{E}^{-1}(-\eta^{+}_{k(t)}) \cdot \left\{ \sum_{r=k(\tau)+1}^{k(t)} \widehat{E}^{k(t)-r} \int_{t_r}^{\zeta_r} e^{A(t_r-s)} f(s)ds \right. \\ &+ \left. \sum_{r=k(\tau)}^{k(t)-1} \widehat{E}^{k(t)-r} \int_{\zeta_r}^{t_{r+1}} (I+C)e^{A(t_{r+1}-s)} f(s)ds + \sum_{r=k(\tau)+1}^{k(t)} \widehat{E}^{k(t)-r} D_r \right\} \\ &+ \int_{\zeta_{k(t)}}^{t} e^{A(t-s)} f(s)ds. \end{aligned} \tag{4.43}$$

Remark 4.4.

1. We recover the variation of parameters concluded in [17] when $D_r = C_r = 0$.
2. Also, our result implies the variation of constant formulas given in section 1.2

5 Some examples of linear IDEPCAG systems

In [16], H. Bereketoglu and G. Oztepe studied the following linear IDEPCAG

$$\begin{aligned} &z'(t) = A(t)\left(z(t) - z(\gamma(t))\right) + f(t), && t \neq t_k \\ &z(t_k) = z(t_k^-) + D_k, && t = t_k. \\ &z(\tau) = z_0 \end{aligned} \tag{5.1}$$

where $\gamma(t)$ is some piecewise constant argument of generalized type, $A(t)$ is a continuous locally integrable matrix, $D : \mathbb{N} \to \mathbb{R}$ is such that $D_k \neq 0, \forall k \in \mathbb{N}$. The authors originally considered the cases $\gamma_1(t) = [t+1]$, and $\gamma_2(t) = [t-1]$. Hence, $t_k = k, \zeta_{1,k}k = k+1$ and $\zeta_{2,k} = k-1$, respectively.

Let $\Phi(t)$ be the fundamental matrix of the ordinary differential system

$$x'(t) = A(t)x(t). \tag{5.2}$$

It is well known that $\Phi^{-1}(t)$ is the fundamental matrix of the adjoint system associated with (5.2). So, it satisfies

$$\left(\Phi^{-1}\right)'(t) = -\Phi^{-1}(t)A(t).$$

Therefore, we have

$$\begin{aligned} J(t,t_k) &= I - \int_{t_k}^{t} \Phi(t_k,s)A(s)ds \\ &= I + \Phi(t_k)\left(\int_{t_k}^{t} -\Phi^{-1}(s)A(s)ds\right) \\ &= I + \Phi(t_k)\left(\Phi^{-1}(t) - \Phi^{-1}(t_k)\right) \\ &= \Phi(t_k,t) \\ &= \Phi^{-1}(t,t_k), \end{aligned}$$

$E(t,t_k) = \Phi(t,t_k)J(t,t_k) = \Phi(t,t_k)\Phi^{-1}(t,t_k) = I$, and, as a result of last estimations, for $t,t' \in I_k$, we have $W(t,t') = I$. Hence, the linear homogeneous IDEPCAG (is a DEPCAG because $C_k = 0$) system

$$\begin{aligned} w'(t) &= A(t)\left(w(t) - w(\gamma(t))\right), && t \neq t_k \\ w(t_k) &= w(t_k^-) && t = t_k. \\ w(\tau) &= w_0, \end{aligned} \tag{5.3}$$

has the constant solution $w(t) = w(\tau)$.

Finally, for the variation of parameters formula (4.26), the solution for (5.1) is

$$\begin{aligned} y(t) = y(\tau) &+ \int_{\tau}^{\zeta_{k(\tau)}} \Phi(\tau,s)f(s)ds + \sum_{r=k(\tau)+1}^{k(t)} \int_{t_r}^{\zeta_r} \Phi(t_r,s)f(s)ds \\ &+ \sum_{r=k(\tau)}^{k(t)-1} \int_{\zeta_r}^{t_{r+1}} \Phi(t_{r+1},s)f(s)ds + \int_{\zeta_{k(t)}}^{t} \Phi(t,s)f(s)ds + \sum_{r=k(\tau)+1}^{k(t)} D_r, \end{aligned}$$

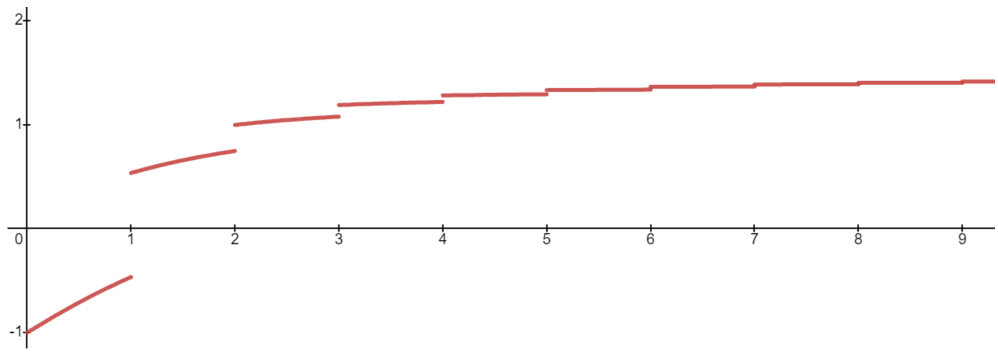

Figure 5.1: Solution of (5.1) with $\gamma(t) = [t] + 7/10$, $D_r = 1/r^2$, $A(t) = 1/(t+1)$, $f(t) = \exp(-t)$ and $y(0) = y_0 = -1$.

Remark 5.1. This is the IDEPCAG case for the well-known differential equation studied by K. L Cooke and J. A. Yorke in [10]. The authors investigated the following delay differential equation (DDE):

$$x'(t) = g(x(t)) - g(x(t-L)),$$

where $x(t)$ denotes the number of individuals in a population, the number of births is $g(x(t))$, and L is the constant life span of the individuals in the population. Then, the number of deaths $g(x(t-L))$. Since the difference $g(x(t)) - g(x(t-L)]$ means the change of the population. Therefore $x'(t)$ corresponds to the growth of the population at instant t.

In (5.3), we considered $g(x(t)) = A(t)x(t)$ and the constant delay in the Cooke–Yorke equation is regarded as a piecewise constant argument $\gamma(t)$. Notice that if D_r is summable and $f(t) = 0\ \forall t \geq \tau$, then the solution of (5.1) tends to the constant

$$y_\infty = y(\tau) + \sum_{t_r \geq t_{k(\tau)+1}} D_r, \quad \text{as } t \to \infty,$$

no matter what $\gamma(t)$ was used. For further about asymptotics in IDEPCAG, see [4].

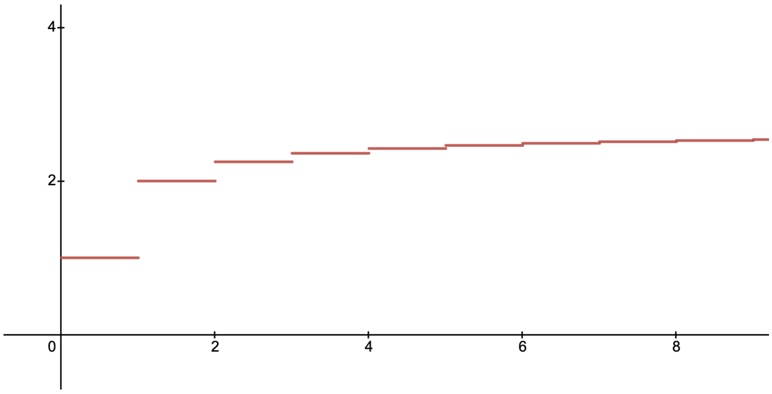

Figure 5.2: Solution of (5.1) with $D_k = 1/k^2,\ f(t) = 0$ and $z(0) = 1$.

Let us consider the following IDEPCA

$$\begin{aligned} &z'(t) = \sin(2\pi t) z\left(\left[\tfrac{t}{h}\right]h + \beta h\right) + 1, && t \neq kh, \quad k \in \mathbb{N}, \\ &z(kh) = \left(-\frac{1}{2}\right) z(kh^-) + \frac{1}{2}, && t = kh, \\ &z(0) = z_0, \end{aligned} \tag{5.4}$$

where $h > 0$, $0 \leq \beta \leq 1$.

It is easy to see that $t_k = kh,\ \zeta_k = (k+\beta)h,\ k \in \mathbb{N}$ and

$$I_k^+ = [kh, (k+\beta)h], \quad I_k^- = [(k+\beta)h, (k+1)h).$$

We see that

$$\begin{aligned} &\nu_k^+(\sin(2\pi t)) \leq \beta h < 1, \quad \text{if } h \text{ is small enough}, \\ &\nu_k^-(\sin(2\pi t)) \leq (1-\beta)h < 1, \quad \text{if } h \text{ is small enough}, \\ &E(t,\tau) = 1 + \int_\tau^t \sin(2\pi s) ds. \end{aligned}$$

The fundamental matrix of the homogeneous equation associated with (5.4) is

$$\begin{aligned} W(t,0) = &\left(1 + \int_{[t/h]h+\beta h}^{t} \sin(2\pi s)\, ds\right)\left(1 + \int_{[t/h]h+\beta h}^{[t/h]h} \sin(2\pi s)\, ds\right)^{(-1)} \\ &\cdot \left(-\frac{1}{2}\right)^{[t/h]} \left(\prod_{j=0}^{[t/h]-1} \left(1 + \int_{(j+\beta)h}^{(j+1)h} \sin(2\pi s)\, ds\right)\left(1 + \int_{(j+\beta)h}^{jh} \sin(2\pi s)\, ds\right)^{(-1)}\right). \end{aligned}$$

Hence, the solution of (5.4) is

$$\begin{aligned} z(t) = W(t,0)z_0 + \left(-\frac{1}{2}\right)(1-\beta)\, h \sum_{r=0}^{[t/h]-1} W(t,(r+1)\,h) + (t - ([t/h]h + \beta h)) \\ + W(t,0)\,\beta h + \beta h \sum_{r=1}^{[t/h]} W(t, rh) + \left(-\frac{1}{2}\right)\sum_{r=0}^{[t/h]-1} W(t,(r+1)\,h). \end{aligned}$$

The piecewise constant used in this example was introduced in [21] to study the approximation of solutions of differential equations (under some stability assumptions and taking $h \to 0$.)

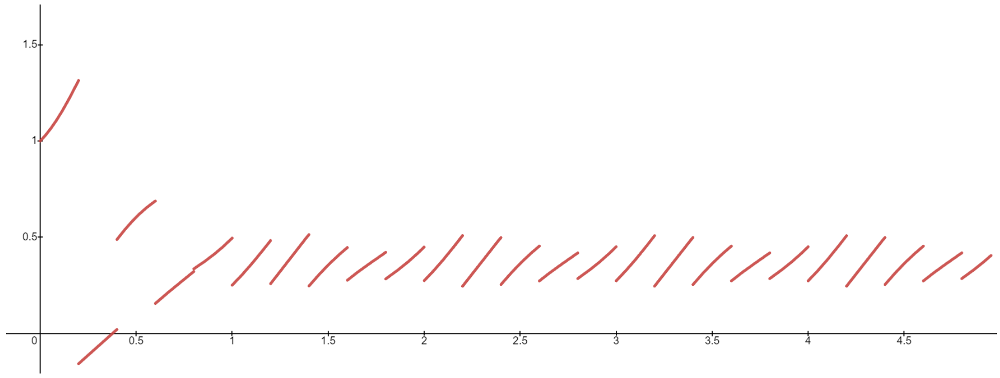

Figure 5.3: Solution of (5.4) with $h = \beta = 0, 2$.

6 Conclusions

In this work, we gave a variation of parameters formula for impulsive differential equations with piecewise constant arguments. We analyzed the constant coefficients case and gave several examples of formulas applied to some concrete piecewise constant arguments. We extended some cases treated before and showed the effect of the impulses in the dynamic.

Communicated by Patrizia Pucci

Abstract. This paper examines a class of fractional p-Kirchhoff systems driven by a nonlocal integro-differential operator with singular nonlinearity. By making use of Nehari manifold techniques, the existence of two nontrivial solutions is established. Our results extend those in Xiang et al. [*Nonlinearity* **29**(2016), 3186–3205] for the corresponding subcritical case.

Keywords: p-Kirchhoff system, singular nonlinearity, Nehari manifold.

2020 Mathematics Subject Classification: 35A15, 35J60.

1 Introduction

We look for nontrivial solutions of the following fractional p-Kirchhoff system

$$\begin{cases} \left(\sum\limits_{i=1}^{k}[u_i]_{s,p}^p\right)^{\theta-1}(-\Delta)_p^s u_j(x)=\lambda_j|u_j|^{q-2}u_j+\sum\limits_{i\neq j}\beta_{ij}|u_i|^{1-m}|u_j|^{-m} & \text{in } \Omega,\\ u_j=0 & \text{in } \mathbb{R}^N\setminus\Omega, \end{cases} \tag{1.1}$$

where

$$[u_j]_{s,p}=\left(\iint_{\mathbb{R}^N\times\mathbb{R}^N}\frac{|u_j(x)-u_j(y)|^p}{|x-y|^{N+ps}}dxdy\right)^{\frac{1}{p}}, \qquad j=1,2,\dots,k,\ k\geq 2,$$

$\theta\geq 1$, $N>ps$ with $s\in(0,1)$, $0<m<1$, $0<2-2m<\theta p<q<p_s^*=\frac{Np}{N-sp}$, $\Omega\subset\mathbb{R}^N$ is a bounded domain with Lipschitz boundary, $\lambda_j>0$ is a parameter, $\beta_{ij}>0$ for all $1\leq i<j\leq k$, $\beta_{ij}=\beta_{ji}$ for $i\neq j$, $j=1,2,\dots,k$, and $(-\Delta)_p^s$ is the fractional p-Laplace operator which may be defined along any $v\in C_0^\infty(\mathbb{R}^N)$ as

$$(-\Delta)_p^s v=2\lim_{\delta\to 0^+}\int_{\mathbb{R}^N\setminus B_\delta(x)}\frac{|v(x)-v(y)|^{p-2}(v(x)-v(y))}{|x-y|^{N+ps}}dy \quad \text{for } x\in\mathbb{R}^N,$$

where $B_\delta(x)$ denotes the ball in $\mathbb{R}^N$ of radius δ centered at x. For more details on the fractional p-Laplacian, we can see [8] and the references therein.

In [9], a steady-state Kirchhoff variational model in bounded regular domains of $\mathbb{R}^N$ was proposed by Fiscella and Valdinoci. In fact, problem (1.1) is a fractional version of Kirchhoff model. Specifically, Kirchhoff proposed the following model

$$\rho \frac{\partial^2 u}{\partial t^2} - \left(\frac{p_0}{h} + \frac{E}{2L} \|\nabla u\|^2_{L^2([0,L])} \right) \frac{\partial^2 u}{\partial x^2} = f(x,u), \tag{1.2}$$

where ρ, p_0, h, E, L are constants. As we all know, this model extends the classical D'Alambert wave equation. Set $M(y) = p_0/h + (E(2L))y$ with $y \geq 0$. If $M(0) = 0$, we call problem (1.2) degenerate, otherwise, it is called non-degenerate if $M(0) > 0$. For $M(0) = 0$, it has a very important physical significance, that is, the base tension of the string is equal to zero. Clearly, in this paper, we are concerned about the situation of degradation in the fractional p-Laplacian setting. We refer the interested reader to [2,6,12,13] for some related results.

In recent years, with the application of nonlocal operators in real life or engineering fields becoming more and more obvious, such as bridge survey, population model, image processing, etc., the fractional Laplacian operator has received extensive attention. Most recently, Sousa in [14] studied a class of fractional p-Laplacian differential operators with variable exponents. The author obtained the existence of a positive solution for the investigated fractional system of the Kirchhoff type by using the method of sub- and super- solutions, via technical assumptions on the nonlinearity. In [19] Zuo et al. considered a variational approach based on the scaling function method to solve optimization problems. Precisely, in [18] Zhao et al. studied a p-fractional Schrödinger–Kirchhoff equation with electromagnetic fields and the Hardy–Littlewood–Sobolev nonlinearity. They used the concentration-compactness principles and improved techniques to obtain Palais–Smile condition at level c. By variational methods, they obtained the existence and multiplicity of solutions. For more literature about the results for nonlocal fractional Laplacian operators and related nonlocal integro-differential equations, we can also refer to [1,7,17] and the references therein.

On the other hand, there are a lot of literature on the equation or system with singular nonlinearity. Consider the following semilinear problem

$$\begin{cases} (-\Delta)^s u = \lambda k(x) u^{-\gamma} + M u^q & \text{in } \Omega, \\ u|_{\partial\Omega} = 0, u > 0 & \text{in } \Omega, \end{cases}$$

where $n > 2s$, $M \geq 0$, $0 < s < 1$, $\gamma > 0$, $\lambda > 0$, $1 < q < 2^*_s - 1$. The weights $k : \Omega \to \mathbb{R}$ are assumed to be nonnegative and (essentially) bounded. In [3], the authors studied the existence of distributional solutions for small λ using the uniform estimates of $\{u_n\}$ which are solutions of the regularized problems with singular term $u^{-\gamma}$ replaced by $(u + \frac{1}{m})^{-\gamma}$. This was extended for the p-fractional Laplace operator by Canino et al. in [5]. Assuming $0 < \gamma < 1$, Ghanmi and Saoudi [10] studied the existence of at least two solutions for singular equations with a positively homogeneous function by making use of variational methods. For fractional Laplacian system involving singular nonlinearity, the work [11] dealt with

$$\begin{cases} (-\Delta)^s u = \lambda a(x)|u|^{q-2}u + \frac{1-\alpha}{2-\alpha-\beta} c(x)|u|^{-\alpha}|v|^{1-\beta} & x \in \Omega, \\ (-\Delta)^s v = \mu b(x)|v|^{q-2}u + \frac{1-\alpha}{2-\alpha-\beta} c(x)|u|^{1-\alpha}|v|^{-\beta} & x \in \Omega, \\ u = v = 0 & x \in \mathbb{R}^N \setminus \Omega, \end{cases}$$

where $\lambda, \mu \in (0, \infty)$, $0 < \alpha, \beta < 1$, $N > 2s$, $1 < q < 2 < 2^*_s = \frac{2N}{N-2s}$, $s \in (0,1)$, and $a, b, c \in C(\overline{\Omega})$ are nonnegative functions. With the help of Nehari manifold, the authors obtained two nontrivial solutions to this system.

Inspired by above papers, the main purpose of this paper is to extend the following work [16]

$$\begin{cases} \left(\sum_{i=1}^{k}[u_i]_{s,p}^{p}\right)^{\theta-1}(-\Delta)_p^s u_j(x)=\lambda_j|u_j|^{q-2}u_j+\sum_{i\neq j}\beta_{ij}|u_i|^m|u_j|^{m-2}u_j & \text{in } \Omega,\\ u_j=0 & \text{in } \mathbb{R}^N\setminus\Omega. \end{cases} \tag{1.3}$$

In [16], when $1<q<\theta p<2m<p_s^*$, the authors obtained two distinct solutions to system (1.3). We try to study whether it is possible to get similar result when replacing $\sum_{i\neq j}\beta_{ij}|u_i|^{1-m}|u_j|^{-m}$ in the place of $\sum_{i\neq j}\beta_{ij}|u_i|^m|u_j|^{m-2}u_j$. The main difficulties in dealing with this problem come from the singular nonlinearity, i.e. $0<m<1$. To our best knowledge, our result for the fractional p-Kirchhoff system with singular nonlinearity is new.

Before describing main result, we recall some necessary definitions. For convenience, we denote by $|u|_r:=\|u\|_{L^r(\mathbb{R}^N)}$ the norm of Lebesgue space $L^r(\Omega)$ with $r\geq 1$. Define $W^{s,p}(\Omega)$ as a linear space of Lebesgue measurable functions from $\mathbb{R}^N$ to $\mathbb{R}$ such that the restriction to Ω of any function u in $W^{s,p}(\Omega)$ belongs to $L^p(\Omega)$ and

$$\iint_{\mathbb{R}^N\times\mathbb{R}^N}\frac{|u(x)-u(y)|^p}{|x-y|^{N+ps}}dxdy<\infty.$$

Equip $W^{s,p}(\Omega)$ with the norm

$$\|u\|_{W^{s,p}(\Omega)}=|u|_p+\left(\iint_{\mathbb{R}^N\times\mathbb{R}^N}\frac{|u(x)-u(y)|^p}{|x-y|^{N+ps}}dxdy\right)^{\frac{1}{p}}.$$

Obviously, $W^{s,p}(\Omega)$ is a Banach space. We shall consider the following closed linear subspace

$$W_0^{s,p}(\Omega)=\left\{u\in W^{s,p}(\Omega):u(x)=0 \text{ a.e. in } \mathbb{R}^N\setminus\Omega\right\}.$$

Moreover, we have that

$$\|u_j\|_{W_j}=\left(\iint_{\mathbb{R}^N\times\mathbb{R}^N}\frac{|u_j(x)-u_j(y)|^p}{|x-y|^{N+ps}}dxdy\right)^{\frac{1}{p}}$$

is an equivalent norm of $W_j=W_0^{s,p}(\Omega)$. It follows from the fractional Sobolev inequality that

$$S=\inf_{u_j\in W_j}\left(\frac{\|u_j\|_{W_j}}{|u_j|_{p_s^*}}\right)^p. \tag{1.4}$$

In this paper we will work in the reflexive Banach space $W=W_1\times\cdots\times W_k$ endowed with the norm

$$\|\mathbf{u}\|_W=\left(\|u_1\|_{W_1}^p+\cdots+\|u_k\|_{W_k}^p\right)^{\frac{1}{p}},\qquad \forall\mathbf{u}=(u_1,\ldots,u_k)\in W.$$

The variational functional of system (1.1) is

$$J(\mathbf{u})=\frac{1}{\theta p}\|\mathbf{u}\|_W^{\theta p}-\frac{1}{q}\sum_{j=1}^{k}\lambda_j|u_j|_q^q-\frac{1}{1-m}\sum_{j=1}^{k}\sum_{i<j}\beta_{ij}|u_iu_j|_{1-m}^{1-m}, \tag{1.5}$$

for $\mathbf{u} = (u_1, \dots, u_k) \in W$. Note that $J \notin C^1(W, \mathbb{R})$, and classical variational methods are not applicable. Moreover, we say that function $\mathbf{u} = (u_1, \dots, u_k) \in W$ is a weak solution of system (1.1), if

$$\|\mathbf{u}\|_W^{(\theta-1)p} \sum_{j=1}^{k} \iint_{\mathbb{R}^N \times \mathbb{R}^N} \frac{|u_j(x) - u_j(y)|^{p-2}(u_j(x) - u_j(y))(w_j(x) - w_j(y))}{|x-y|^{n+ps}} dxdy$$
$$= \sum_{j=1}^{k} \lambda_j \int_\Omega |u_j|^{q-2} u_j w_j dx + \sum_{j=1}^{k} \sum_{i \neq j} \beta_{ij} \int_\Omega |u_i|^{1-m} |u_j|^{-m} w_j dx,$$

for any $\mathbf{w} = (w_1, \dots, w_k) \in W$. It is easy to see that solutions of system (1.1) correspond to the critical points of J.

Set

$$\Lambda = \frac{\theta p - 2 + 2m}{q - \theta p} \left(\frac{q - 2 + 2m}{q - \theta p} \right)^{\frac{2-2m-q}{\theta p - 2 + 2m}} \left(\sum_{j=1}^{k} \sum_{i<j} \beta_{ij} \right)^{\frac{\theta p - q}{\theta p - 2 + 2m}} |\Omega|^{\frac{(2m-2+q)(\theta p - p_s^*)}{p_s^*(\theta p - 2 + 2m)}} S^{\frac{\theta(2m-2+q)}{\theta p - 2 + 2m}},$$

$$\Lambda_0 = \left(\frac{\theta p}{2 - 2m} \right)^{\frac{\theta p - q}{\theta p - 2 + 2m}} \Lambda,$$

$$\Theta_\Lambda = \left\{ (\lambda_1, \lambda_2, \dots, \lambda_k) \in (\mathbb{R}^+)^k : 0 < \left(\sum_{j=1}^{k} \lambda_j^{\frac{\theta p}{\theta p - q}} \right)^{\frac{\theta p - q}{\theta p}} < \Lambda \right\}$$

and

$$\Theta_{\Lambda_0} = \left\{ (\lambda_1, \lambda_2, \dots, \lambda_k) \in (\mathbb{R}^+)^k : 0 < \left(\sum_{j=1}^{k} \lambda_j^{\frac{\theta p}{\theta p - q}} \right)^{\frac{\theta p - q}{\theta p}} < \Lambda_0 \right\}.$$

Obviously, $\Theta_{\Lambda_0} \subset \Theta_\Lambda$. Our main result is the following.

Theorem 1.1. *Suppose that $(\lambda_1, \lambda_2, \dots, \lambda_k) \in \Theta_{\Lambda_0}$. Then system (1.1) has two distinct solutions.*

The remainder of this paper is organized as follows. In Section 2, we state some preliminary results. Section 3 is devoted to the proof of Theorem 1.1.

2 Preliminaries

In this section, we state some basic results. Define the constraint set (Nehari maniflod)

$$\mathcal{N} = \{\mathbf{u} \in W \backslash \{0\} : \langle J'(\mathbf{u}), \mathbf{u} \rangle = 0\}.$$

Thus, $\mathbf{u} \in \mathcal{N}$ if and only if

$$\|\mathbf{u}\|_W^{\theta p} = \sum_{j=1}^{k} \lambda_j \int_\Omega |u_j|^q dx + 2 \sum_{j=1}^{k} \sum_{i<j} \beta_{ij} \int_\Omega |u_i u_j|^{1-m} dx. \tag{2.1}$$

Fix $\mathbf{u} \in W$ and define the function of the form $K_\mathbf{u} : t \to J(t\mathbf{u})$ for $t > 0$. Such maps are famous fibering maps, which were discussed by Brown and Wu in [4]. Precisely,

$$K_\mathbf{u}(t) = J(t\mathbf{u}) = \frac{t^{\theta p}}{\theta p} \|\mathbf{u}\|_W^{\theta p} - \frac{t^q}{q} \sum_{j=1}^{k} \lambda_j \int_\Omega |u_j|^q dx - \frac{t^{2-2m}}{1-m} \sum_{j=1}^{k} \sum_{i<j} \beta_{ij} \int_\Omega |u_i u_j|^{1-m} dx.$$

Therefore,

$$K'_{\mathbf{u}}(t) = t^{\theta p-1}\|\mathbf{u}\|_W^{\theta p} - t^{q-1}\sum_{j=1}^{k}\lambda_j\int_\Omega |u_j|^q dx - 2t^{1-2m}\sum_{j=1}^{k}\sum_{i<j}\beta_{ij}\int_\Omega |u_iu_j|^{1-m}dx$$

and

$$K''_{\mathbf{u}}(t) = (\theta p-1)t^{\theta p-2}\|\mathbf{u}\|_W^{\theta p} - (q-1)t^{q-2}\sum_{j=1}^{k}\lambda_j\int_\Omega |u_j|^q dx$$
$$- 2(1-2m)t^{-2m}\sum_{j=1}^{k}\sum_{i<j}\beta_{ij}\int_\Omega |u_iu_j|^{1-m}dx.$$

Lemma 2.1. *Let $\mathbf{u} \in W\backslash\{0\}$ and $t > 0$. Then $t\mathbf{u} \in \mathcal{N}$ if and only if $K'_{\mathbf{u}}(t) = 0$.*

Proof. Note that

$$tK'_{\mathbf{u}}(t) = \|t\mathbf{u}\|_W^{\theta p} - \sum_{j=1}^{k}\lambda_j\int_\Omega |tu_j|^q dx - 2\sum_{j=1}^{k}\sum_{i<j}\beta_{ij}\int_\Omega |tu_itu_j|^{1-m}dx.$$

By (2.1), we can easily draw the conclusion of the lemma. □

Using methods similar to those used in [15], we split $\mathcal{N}$ into three sets. Accordingly, we define

$$\mathcal{N}^+ = \{t\mathbf{u} \in W : K'_{\mathbf{u}}(t) = 0, K''_{\mathbf{u}}(t) > 0\} = \{\mathbf{u} \in \mathcal{N} : K''_{\mathbf{u}}(1) > 0\};$$
$$\mathcal{N}^- = \{t\mathbf{u} \in W : K'_{\mathbf{u}}(t) = 0, K''_{\mathbf{u}}(t) < 0\} = \{\mathbf{u} \in \mathcal{N} : K''_{\mathbf{u}}(1) < 0\};$$
$$\mathcal{N}^0 = \{t\mathbf{u} \in W : K'_{\mathbf{u}}(t) = 0, K''_{\mathbf{u}}(t) = 0\} = \{\mathbf{u} \in \mathcal{N} : K''_{\mathbf{u}}(1) = 0\}.$$

In the next, we state some basic properties of submanifold.

Lemma 2.2. *Let $\mathbf{u}_0$ be a local minimizer for J such that $\mathbf{u}_0 \notin \mathcal{N}^0$. Then $\mathbf{u}_0$ is a critical point for J.*

Proof. Since $\mathbf{u}_0$ is a local minimizer of J on $\mathcal{N}$, it is a solution of the optimization problem

$$\text{minimize } J \text{ subject to } F(\mathbf{u}) = 0,$$

where

$$F(\mathbf{u}) = \|\mathbf{u}\|_W^{\theta p} - \sum_{j=1}^{k}\lambda_j\int_\Omega |u_j|^q dx - 2\sum_{j=1}^{k}\sum_{i<j}\beta_{ij}\int_\Omega |u_iu_j|^{1-m}dx.$$

Then, applying the theory of Lagrange multipliers, we can find a $\mu \in \mathbb{R}$ such that $J'(\mathbf{u}_0) = \mu F'(\mathbf{u}_0)$ which implies

$$0 = \langle J'(\mathbf{u}_0), \mathbf{u}_0\rangle = \mu\langle F'(\mathbf{u}_0), \mathbf{u}_0\rangle.$$

Further, from $\mathbf{u}_0 \in \mathcal{N}$ and $\mathbf{u}_0 \notin \mathcal{N}^0$ it is easy to know $\langle F'(\mathbf{u}_0), \mathbf{u}_0\rangle \neq 0$. So we obtain $\mu = 0$ and the proof is complete. □

Lemma 2.3. *The functional J is coercive and bounded below on $\mathcal{N}$.*

Proof. For any $\mathbf{u} \in \mathcal{N}$, by (1.4), (2.1), the Young and Hölder inequalities, we obtain

$$\begin{aligned}
J(\mathbf{u}) &= \left(\frac{1}{\theta p} - \frac{1}{q}\right) \|\mathbf{u}\|_W^{\theta p} - \left(\frac{1}{1-m} - \frac{2}{q}\right) \sum_{j=1}^{k} \sum_{i<j} \beta_{ij} |u_i u_j|_{1-m}^{1-m} \\
&\geq \left(\frac{1}{\theta p} - \frac{1}{q}\right) \|\mathbf{u}\|_W^{\theta p} - \frac{1}{2}\left(\frac{1}{1-m} - \frac{2}{q}\right) \sum_{j=1}^{k} \sum_{i<j} \beta_{ij} \left(|u_i|_{2-2m}^{2-2m} + |u_j|_{2-2m}^{2-2m}\right) \\
&\geq \left(\frac{1}{\theta p} - \frac{1}{q}\right) \|\mathbf{u}\|_W^{\theta p} - \frac{1}{2}\left(\frac{1}{1-m} - \frac{2}{q}\right) \sum_{j=1}^{k} \sum_{i<j} \beta_{ij} |\Omega|^{\frac{p_s^*+2m-2}{p_s^*}} S^{\frac{2m-2}{p}} \|\mathbf{u}\|_W^{2-2m},
\end{aligned}$$

which together with $2-2m < \theta p$ yields that J is coercive and bounded below on $\mathcal{N}$. □

Set

$$I_{\mathbf{u}}(t) = t^{\theta p - q} \|\mathbf{u}\|_W^{\theta p} - 2t^{2-2m-q} \sum_{j=1}^{k} \sum_{i<j} \beta_{ij} \int_\Omega |u_i u_j|^{1-m} dx.$$

Clearly, $t\mathbf{u} \in \mathcal{N}$ if and only if

$$I_{\mathbf{u}}(t) = \sum_{j=1}^{k} \lambda_j \int_\Omega |u_j|^q dx. \tag{2.2}$$

Moreover, $I_{\mathbf{u}}$ satisfies the following properties.

Lemma 2.4. *Suppose that* $\mathbf{u} \in W\backslash\{0\}$. *One has*

(i) the function $I_{\mathbf{u}}$ *possesses a unique maximum at*

$$t = t_{max} = \left(\frac{2(q-2+2m) \sum_{j=1}^{k} \sum_{i<j} \beta_{ij} \int_\Omega |u_i u_j|^{1-m} dx}{(q-\theta p)\|\mathbf{u}\|_W^{\theta p}} \right)^{\frac{1}{\theta p - 2 + 2m}};$$

(ii) $I'_{\mathbf{u}}(t) > 0$ *for* $t \in (0, t_{max})$ *and* $I'_{\mathbf{u}}(t) < 0$ *for* $t \in (t_{max}, +\infty)$;

(iii) $\lim_{t\to 0^+} I_{\mathbf{u}}(t) = -\infty$, $\lim_{t\to+\infty} I_{\mathbf{u}}(t) = 0$.

Proof. Note that

$$I'_{\mathbf{u}}(t) = (\theta p - q) t^{\theta p - q - 1} \|\mathbf{u}\|_W^{\theta p} - 2(2-2m-q) t^{1-2m-q} \sum_{j=1}^{k} \sum_{i<j} \beta_{ij} \int_\Omega |u_i u_j|^{1-m} dx.$$

Set $I'_{\mathbf{u}}(t) = 0$. Obviously, $I'_{\mathbf{u}}(t_{max}) = 0$ and $I''_{\mathbf{u}}(t_{max}) < 0$, with unique

$$t_{max} = \left(\frac{2(q-2+2m) \sum_{j=1}^{k} \sum_{i<j} \beta_{ij} \int_\Omega |u_i u_j|^{1-m} dx}{(q-\theta p)\|\mathbf{u}\|_W^{\theta p}} \right)^{\frac{1}{\theta p - 2 + 2m}}.$$

Moreover, it is easy to see that (ii) and (iii) follow from the structure of $I_{\mathbf{u}}$. □

Lemma 2.5. *Suppose that* $t\mathbf{u} \in \mathcal{N}$. *Then* $t\mathbf{u} \in \mathcal{N}^+$ *or* $(\mathcal{N}^-)$ *if and only if* $I'_u(t) > 0$ *or* (< 0).

Proof. If $t\mathbf{u} \in \mathcal{N}$, by (2.1), we get

$$K''_{\mathbf{u}}(t) = (\theta p - q)t^{\theta p - 2}\|\mathbf{u}\|_W^{\theta p} - 2(2-2m-q)t^{-2m}\sum_{j=1}^{k}\sum_{i<j}\beta_{ij}\int_{\Omega}|u_i u_j|^{1-m}dx.$$

Note that

$$t^{1-q}I'_{\mathbf{u}}(t) = K''_{\mathbf{u}}(t),$$

which yields that $t\mathbf{u} \in \mathcal{N}^+$ or $(\mathcal{N}^-)$ if and only if $I'_u(t) > 0$ or (< 0). □

Lemma 2.6. *Suppose that* $\mathbf{u} \in W\backslash\{0\}$. *Then for* $(\lambda_1, \lambda_2, \dots, \lambda_k) \in \Theta_\Lambda$, *there exist* $t^+, t^- > 0$ *such that* $t^+ < t_{max} < t^-$, $t^+\mathbf{u} \in \mathcal{N}^+$, $t^-\mathbf{u} \in \mathcal{N}^-$ *and*

$$J(t^+\mathbf{u}) = \inf_{0\le t\le t_{max}} J(t\mathbf{u}), \qquad J(t^-\mathbf{u}) = \sup_{t\ge 0} J(t\mathbf{u}).$$

Proof. By (1.4), the Young and Hölder inequalities, we have

$$\begin{aligned}
I_{\mathbf{u}}(t_{max}) &= \frac{\theta p - 2 + 2m}{q - \theta p}\left(\frac{q-2+2m}{q-\theta p}\right)^{\frac{2-2m-q}{\theta p - 2 + 2m}} \frac{\left(2\sum_{j=1}^{k}\sum_{i<j}\beta_{ij}\int_\Omega |u_i u_j|^{1-m}dx\right)^{\frac{\theta p - q}{\theta p - 2 + 2m}}}{\left(\|\mathbf{u}\|_W^{\theta p}\right)^{\frac{2-2m-q}{\theta p - 2+2m}}} \\
&\ge \frac{\theta p - 2 + 2m}{q - \theta p}\left(\frac{q-2+2m}{q-\theta p}\right)^{\frac{2-2m-q}{\theta p - 2 + 2m}} \frac{\left(\sum_{j=1}^{k}\sum_{i<j}\beta_{ij}|\Omega|^{\frac{p_s^*+2m-2}{p_s^*}}S^{\frac{2m-2}{p}}\|\mathbf{u}\|_W^{2-2m}\right)^{\frac{\theta p - q}{\theta p - 2 + 2m}}}{\left(\|\mathbf{u}\|_W^{\theta p}\right)^{\frac{2-2m-q}{\theta p - 2+2m}}} \\
&= \frac{\theta p - 2 + 2m}{q - \theta p}\left(\frac{q-2+2m}{q-\theta p}\right)^{\frac{2-2m-q}{\theta p - 2 + 2m}} \left(\sum_{j=1}^{k}\sum_{i<j}\beta_{ij}|\Omega|^{\frac{p_s^*+2m-2}{p_s^*}}S^{\frac{2m-2}{p}}\right)^{\frac{\theta p - q}{\theta p - 2 + 2m}} \|\mathbf{u}\|_W^{q}.
\end{aligned}$$

It follows from $(\lambda_1, \lambda_2, \dots, \lambda_k) \in \Theta_\Lambda$ that

$$\begin{aligned}
0 &< \sum_{j=1}^{k}\lambda_j\int_\Omega |u_j|^q dx \le |\Omega|^{\frac{p_s^*-q}{p_s^*}}\sum_{j=1}^{k}\lambda_j|u_j|_{p_s^*}^q \\
&\le |\Omega|^{\frac{p_s^*-q}{p_s^*}}S^{-\frac{q}{p}}\sum_{j=1}^{k}\lambda_j\|u_j\|_{W_j}^q \le |\Omega|^{\frac{p_s^*-q}{p_s^*}}S^{-\frac{q}{p}}\left(\sum_{j=1}^{k}\lambda_j^{\frac{\theta p}{\theta p - q}}\right)^{\frac{\theta p - q}{\theta p}}\left(\sum_{j=1}^{k}\|u_j\|_{W_j}^{\theta p}\right)^{\frac{q}{\theta p}} \\
&\le |\Omega|^{\frac{p_s^*-q}{p_s^*}}S^{-\frac{q}{p}}\left(\sum_{j=1}^{k}\lambda_j^{\frac{\theta p}{\theta p - q}}\right)^{\frac{\theta p - q}{\theta p}}\|\mathbf{u}\|_W^q < I_{\mathbf{u}}(t_{max}),
\end{aligned}$$

which implies that there exist $t^+, t^- > 0$ such that $t^+ < t_{max} < t^-$,

$$I_{\mathbf{u}}(t^+) = \sum_{j=1}^{k}\lambda_j\int_\Omega |u_j|^q dx = I_{\mathbf{u}}(t^-),$$

$I'_{\mathbf{u}}(t^+) > 0$ and $I'_{\mathbf{u}}(t^-) < 0$. Then, by (2.2) and Lemma 2.5, we obtain $t^+\mathbf{u} \in \mathcal{N}^+$ and $t^-\mathbf{u} \in \mathcal{N}^-$. Combining Lemma 2.4 and

$$K'_{\mathbf{u}}(t) = t^{q-1}\left(I_{\mathbf{u}}(t) - \sum_{j=1}^{k}\lambda_j\int_\Omega |u_j|^q dx\right),$$

we get that $J(t\mathbf{u})$ is strictly decreasing on $(0,t^+)$, strictly increasing on (t^+,t^-) and strictly decreasing on $(t^-,+\infty)$. Hence

$$J(t^+\mathbf{u}) = \inf_{0\le t\le t_{max}} J(t\mathbf{u}), \qquad J(t^-\mathbf{u}) = \sup_{t\ge 0} J(t\mathbf{u}).$$

The proof is completed. □

Lemma 2.7. *Suppose that* $(\lambda_1,\lambda_2,\dots,\lambda_k)\in\Theta_\Lambda$. *Then* $\mathcal{N}^0=\emptyset$.

Proof. Arguing by contradiction, we assume that $\mathcal{N}^0\neq\emptyset$. Then for $\mathbf{u}\in\mathcal{N}^0$, we have by (2.1) that

$$\begin{aligned}0 = K''_{\mathbf{u}}(1) &= (\theta p - q)\|\mathbf{u}\|_W^{\theta p} - 2(2-2m-q)\sum_{j=1}^k\sum_{i<j}\beta_{ij}\int_\Omega |u_iu_j|^{1-m}dx\\ &= (\theta p + 2m - 2)\|\mathbf{u}\|_W^{\theta p} - (q+2m-2)\sum_{j=1}^k \lambda_j\int_\Omega |u_j|^q dx.\end{aligned}$$

Hence, by (1.4), the Young and Hölder inequalities, we get

$$\begin{aligned}\|\mathbf{u}\|_W^{\theta p} &= \frac{2(2-2m-q)}{\theta p - q}\sum_{j=1}^k\sum_{i<j}\beta_{ij}\int_\Omega |u_iu_j|^{1-m}dx\\ &\le \frac{2-2m-q}{\theta p - q}\sum_{j=1}^k\sum_{i<j}\beta_{ij}|\Omega|^{\frac{p_s^*+2m-2}{p_s^*}} S^{\frac{2m-2}{p}}\|\mathbf{u}\|_W^{2-2m},\end{aligned}$$

which implies that

$$\|\mathbf{u}\|_W \le \left(\frac{2-2m-q}{\theta p - q}\sum_{j=1}^k\sum_{i<j}\beta_{ij}|\Omega|^{\frac{p_s^*+2m-2}{p_s^*}} S^{\frac{2m-2}{p}}\right)^{\frac{1}{\theta p - 2 + 2m}}. \tag{2.3}$$

Moreover, by (1.4) and the Hölder inequality, we get

$$\begin{aligned}\|\mathbf{u}\|_W^{\theta p} &= \frac{q+2m-2}{\theta p + 2m - 2}\sum_{j=1}^k \lambda_j\int_\Omega |u_j|^q dx\\ &\le \frac{q+2m-2}{\theta p + 2m - 2}|\Omega|^{\frac{p_s^*-q}{p_s^*}} S^{-\frac{q}{p}}\left(\sum_{j=1}^k \lambda_j^{\frac{\theta p}{\theta p - q}}\right)^{\frac{\theta p - q}{\theta p}}\|\mathbf{u}\|_W^q,\end{aligned}$$

which implies that

$$\|\mathbf{u}\|_W \ge \left(\frac{q+2m-2}{\theta p + 2m - 2}|\Omega|^{\frac{p_s^*-q}{p_s^*}} S^{-\frac{q}{p}}\left(\sum_{j=1}^k \lambda_j^{\frac{\theta p}{\theta p - q}}\right)^{\frac{\theta p - q}{\theta p}}\right)^{\frac{1}{\theta p - q}}. \tag{2.4}$$

Combining (2.3) and (2.4), we obtain

$$\begin{aligned}&\left(\sum_{j=1}^k \lambda_j^{\frac{\theta p}{\theta p - q}}\right)^{\frac{\theta p - q}{\theta p}}\\ &\quad\ge \frac{\theta p - 2 + 2m}{q - \theta p}\left(\frac{q-2+2m}{q-\theta p}\right)^{\frac{2-2m-q}{\theta p - 2 + 2m}}\left(\sum_{j=1}^k\sum_{i<j}\beta_{ij}\right)^{\frac{\theta p - q}{\theta p - 2 + 2m}}|\Omega|^{\frac{(2m-2+q)(\theta p - p_s^*)}{p_s^*(\theta p - 2 + 2m)}} S^{\frac{\theta(2m-2+q)}{\theta p - 2 + 2m}},\end{aligned}$$

which contradicts

$$0 < \left(\sum_{j=1}^{k} \lambda_j^{\frac{\theta p}{\theta p - q}} \right)^{\frac{\theta p - q}{\theta p}} < \Lambda.$$

This ends the proof. □

3 Proof of Theorem 1.1

By Lemmas 2.3 and 2.7, for $(\lambda_1, \lambda_2, \ldots, \lambda_k) \in \Theta_\Lambda$, we obtain $\mathcal{N} = \mathcal{N}^+ \cup \mathcal{N}^-$ and J is bounded from below on $\mathcal{N}^+$ and $\mathcal{N}^-$. Set

$$\alpha^+ = \inf_{\mathbf{u} \in \mathcal{N}^+} J(\mathbf{u}) \quad \text{and} \quad \alpha^- = \inf_{\mathbf{u} \in \mathcal{N}^-} J(\mathbf{u}).$$

Lemma 3.1. $\alpha^+ < 0$.

Proof. For $\mathbf{u} \in \mathcal{N}^+$, we have $K'_{\mathbf{u}}(1) = 0$ and $K''_{\mathbf{u}}(1) > 0$. Then

$$(\theta p - q)\|\mathbf{u}\|_W^{\theta p} > 2(2 - 2m - q) \sum_{j=1}^{k} \sum_{i<j} \beta_{ij} \int_\Omega |u_i u_j|^{1-m} dx.$$

This yields that

$$\begin{aligned} J(\mathbf{u}) &= \left(\frac{1}{\theta p} - \frac{1}{q}\right) \|\mathbf{u}\|_W^{\theta p} - \left(\frac{1}{1-m} - \frac{2}{q}\right) \sum_{j=1}^{k} \sum_{i<j} \beta_{ij} |u_i u_j|_{1-m}^{1-m} \\ &\leq \left[\left(\frac{1}{\theta p} - \frac{1}{q}\right) - \left(\frac{1}{1-m} - \frac{2}{q}\right) \frac{q - \theta p}{2(q - 2 + 2m)} \right] \|\mathbf{u}\|_W^{\theta p} \\ &= \frac{(\theta p - q)(\theta p - 2 + 2m)}{(2 - 2m) q \theta p} \|\mathbf{u}\|_W^{\theta p} < 0, \end{aligned}$$

due to $0 < 2 - 2m < \theta p < q$. Therefore $\alpha^+ < 0$ follows from the definition α^+. □

Lemma 3.2. *The minimization problem*

$$\alpha^+ = \inf_{\mathbf{u} \in \mathcal{N}^+} J(\mathbf{u})$$

is achieved at a point $\mathbf{u}^+ \in \mathcal{N}^+$.

Proof. Let $\{\mathbf{u}_n\}$ be a minimizing sequence of the minimization problem, i.e. $\{\mathbf{u}_n\} \subset \mathcal{N}^+$ and $\lim_{n\to\infty} J(\mathbf{u}_n) = \alpha^+$. By Lemma 2.3, it is easy to see that $\{\mathbf{u}_n\}$ is bounded, we can find a $\mathbf{u}^+$ such that $\mathbf{u}_n \rightharpoonup \mathbf{u}^+$ weakly in W, $\mathbf{u}_n \to \mathbf{u}^+$ strongly in $L^r(\Omega)$, $1 \leq r < p_s^*$. Now, we prove

$$\lim_{n\to\infty} \sum_{j=1}^{k} \sum_{i<j} \beta_{ij} \int_\Omega |(\mathbf{u}_n)_i (\mathbf{u}_n)_j|^{1-m} dx = \sum_{j=1}^{k} \sum_{i<j} \beta_{ij} \int_\Omega |(\mathbf{u}^+)_i (\mathbf{u}^+)_j|^{1-m} dx \tag{3.1}$$

and

$$\lim_{n\to\infty} \sum_{j=1}^{k} \lambda_j \int_\Omega |(\mathbf{u}_n)_j|^q dx = \sum_{j=1}^{k} \lambda_j \int_\Omega |(\mathbf{u}^+)_j|^q dx. \tag{3.2}$$

By the Vitali theorem, we claim that

$$\lim_{n\to\infty} \int_\Omega |(\mathbf{u}_n)_i (\mathbf{u}_n)_j|^{1-m} dx = \int_\Omega |(\mathbf{u}^+)_i (\mathbf{u}^+)_j|^{1-m} dx.$$

In fact, by the Young inequality, we have

$$\int_\Omega |(\mathbf{u}_n)_i(\mathbf{u}_n)_j|^{1-m}dx \le \frac{1}{2}\int_\Omega |(\mathbf{u}_n)_i|^{2-2m}dx + \frac{1}{2}\int_\Omega |(\mathbf{u}_n)_j|^{2-2m}dx.$$

By the Sobolev embedding theorem and boundedness of $\{(\mathbf{u}_n)_i\}$, we can find a constant $C > 0$ such that $|(\mathbf{u}_n)_i|_{p_s^*} \le C$. Moreover, it follows from the Hölder inequality that

$$\int_\Omega |(\mathbf{u}_n)_i|^{2-2m}dx \le |\Omega|^{\frac{p_s^*+2m-2}{p_s^*}} |(\mathbf{u}_n)_i|_{p_s^*}^{2-2m}. \tag{3.3}$$

From (3.3), for every $\epsilon > 0$, setting

$$\delta = \left(\frac{\epsilon}{C^{2-2m}}\right)^{\frac{p_s^*}{p_s^*+2m-2}},$$

when $A \subset \Omega$ with meas $A < \delta$, we obtain

$$\int_A |(\mathbf{u}_n)_i|^{2-2m}dx \le |A|^{\frac{p_s^*+2m-2}{p_s^*}} C^{2-2m} < \epsilon.$$

Similarly, $\int_A |(\mathbf{u}_n)_j|^{2-2m}dx < \epsilon$. This yields that

$$\left\{\int_\Omega |(\mathbf{u}_n)_i(\mathbf{u}_n)_j|^{1-m}dx, n \in \mathbb{N}\right\}$$

is equi-absolutely-continuous. Thus, our claim is true. This implies that (3.1) holds. On the other hand, for $1 \le j \le k$, it follows from the Hölder inequality and $\mathbf{u}_n \to \mathbf{u}^+$ strongly in $L^q(\Omega)$ that

$$\begin{aligned}\int_\Omega \big||(\mathbf{u}_n)_j|^q - |(\mathbf{u}^+)_j|^q\big|\,dx &= q\int_\Omega (|(\mathbf{u}^+)_j| + \tau(|(\mathbf{u}_n)_j - (\mathbf{u}^+)_j|))^{q-1}|(\mathbf{u}_n)_j - (\mathbf{u}^+)_j|dx \\ &\le q|(\mathbf{u}_n)_j + (\mathbf{u}^+)_j|_q^{q-1}|(\mathbf{u}_n)_j - (\mathbf{u}^+)_j|_q \\ &\le C|(\mathbf{u}_n)_j - (\mathbf{u}^+)_j|_q \to 0,\end{aligned}$$

as $n \to \infty$, where $\tau \in (0,1)$ and $C > 0$ denotes various constants. Therefore,

$$\lim_{n\to\infty}\int_\Omega \big||(\mathbf{u}_n)_j|^q - |(\mathbf{u}^+)_j|^q\big|\,dx = 0, \qquad \forall j \in \{1,2,,\dots k\},$$

which implies that (3.2) holds. Furthermore, we can prove that $\mathbf{u}_n \to \mathbf{u}^+$ strongly in W. Arguing by contradiction, we assume $\mathbf{u}_n \nrightarrow \mathbf{u}^+$ strongly in W. Then,

$$\|\mathbf{u}^+\|_W^{\theta p} < \lim_{n\to\infty}\inf \|\mathbf{u}_n\|_W^{\theta p}.$$

By Lemma 2.6, there exists $t^+ > 0$ such that $t^+\mathbf{u}^+ \in \mathcal{N}^+$. Then, for $\mathbf{u}_n \in \mathcal{N}^+$, one has

$$\begin{aligned}&\lim_{n\to\infty} K'_{\mathbf{u}_n}(t^+) \\ &= \lim_{n\to\infty}\left((t^+)^{\theta p-1}\|\mathbf{u}_n\|_W^{\theta p} - (t^+)^{q-1}\sum_{j=1}^k \lambda_j\int_\Omega |(\mathbf{u}_n)_j|^q dx - 2(t^+)^{1-2m}\sum_{j=1}^k\sum_{i<j}\beta_{ij}\int_\Omega |(\mathbf{u}_n)_i(\mathbf{u}_n)_j|^{1-m}dx\right) \\ &> (t^+)^{\theta p-1}\|\mathbf{u}^+\|_W^{\theta p} - (t^+)^{q-1}\sum_{j=1}^k \lambda_j\int_\Omega |(\mathbf{u}^+)_j|^q dx - 2(t^+)^{1-2m}\sum_{j=1}^k\sum_{i<j}\beta_{ij}\int_\Omega |(\mathbf{u}^+)_i(\mathbf{u}^+)_j|^{1-m}dx \\ &= K'_{\mathbf{u}^+}(t^+) = 0.\end{aligned}$$

This yields $K'_{\mathbf{u}_n}(t^+) > 0$ for large enough n. Note that $K'_{\mathbf{u}_n}(1) = 0$ for each n and $K'_{\mathbf{u}_n}(t) < 0$ for $t \in (0,1)$. It follows that $t^+ > 1$. Moreover, from that fact that $K_{\mathbf{u}^+}(t)$ is decreasing on $(0, t^+)$, we have

$$J(t^+\mathbf{u}^+) \le J(\mathbf{u}^+) < \lim_{n\to\infty} J(\mathbf{u}_n) = \alpha^+,$$

which contradicts the fact that $\alpha^+ = \inf_{\mathbf{u}\in\mathcal{N}^+} J(\mathbf{u})$. Thus, we conclude that $\mathbf{u}_n \to \mathbf{u}^+$ strongly in W. By $K'_{\mathbf{u}_n}(1) = 0$ and $K''_{\mathbf{u}_n}(1) > 0$, we get that $K'_{\mathbf{u}^+}(1) = 0$ and $K''_{\mathbf{u}^+}(1) \ge 0$. Note that $\mathcal{N}^0 = \emptyset$. Then $K''_{\mathbf{u}^+}(1) > 0$, which implies $\mathbf{u}^+ \in \mathcal{N}^+$. Above all, by $J(\mathbf{u}^+) = \inf_{\mathbf{u}\in\mathcal{N}^+} J(\mathbf{u}) < 0$, $\mathbf{u}^+$ is a minimizer of J on $\mathcal{N}^+$. The proof is completed. □

Lemma 3.3. *Suppose that $(\lambda_1, \lambda_2, \ldots, \lambda_k) \in \Theta_{\Lambda_0}$. Then $\alpha^- > \alpha_0$ for some $\alpha_0 > 0$.*

Proof. For $\mathbf{u} \in \mathcal{N}^-$, we have $K'_{\mathbf{u}}(1) = 0$ and $K''_{\mathbf{u}}(1) < 0$. Then

$$(\theta p - 2 + 2m)\|\mathbf{u}\|_W^{\theta p} < (q - 2 + 2m)\sum_{j=1}^{k} \lambda_j \int_\Omega |u_j|^q dx.$$

By (1.4) and the Hölder inequality, we have

$$\sum_{j=1}^{k} \lambda_j \int_\Omega |u_j|^q dx \le |\Omega|^{\frac{p_s^* - q}{p_s^*}} S^{-\frac{q}{p}} \left(\sum_{j=1}^{k} \lambda_j^{\frac{\theta p}{\theta p - q}}\right)^{\frac{\theta p - q}{\theta p}} \|\mathbf{u}\|_W^q.$$

Hence,

$$\|\mathbf{u}\|_W > \left[\frac{q - 2 + 2m}{\theta p - 2 + 2m} |\Omega|^{\frac{p_s^* - q}{p_s^*}} S^{-\frac{q}{p}} \left(\sum_{j=1}^{k} \lambda_j^{\frac{\theta p}{\theta p - q}}\right)^{\frac{\theta p - q}{\theta p}}\right]^{\frac{1}{\theta p - q}}. \tag{3.4}$$

Then we obtain

$$\begin{aligned}
J(\mathbf{u}) &= \left(\frac{1}{\theta p} - \frac{1}{q}\right)\|\mathbf{u}\|_W^{\theta p} - \left(\frac{1}{1-m} - \frac{2}{q}\right)\sum_{j=1}^{k}\sum_{i<j} \beta_{ij} |u_i u_j|_{1-m}^{1-m} \\
&\ge \left(\frac{1}{\theta p} - \frac{1}{q}\right)\|\mathbf{u}\|_W^{\theta p} - \frac{1}{2}\left(\frac{1}{1-m} - \frac{2}{q}\right)\sum_{j=1}^{k}\sum_{i<j} \beta_{ij} |\Omega|^{\frac{p_s^* + 2m - 2}{p_s^*}} S^{\frac{2m-2}{p}} \|\mathbf{u}\|_W^{2-2m} \\
&= \|\mathbf{u}\|_W^{2-2m}\left[\left(\frac{1}{\theta p} - \frac{1}{q}\right)\|\mathbf{u}\|_W^{\theta p - 2 + 2m} - \frac{1}{2}\left(\frac{1}{1-m} - \frac{2}{q}\right)\sum_{j=1}^{k}\sum_{i<j} \beta_{ij} |\Omega|^{\frac{p_s^* + 2m - 2}{p_s^*}} S^{\frac{2m-2}{p}}\right] \\
&> \|\mathbf{u}\|_W^{2-2m}\Bigg\{\left(\frac{1}{\theta p} - \frac{1}{q}\right)\left[\frac{q - 2 + 2m}{\theta p - 2 + 2m} |\Omega|^{\frac{p_s^* - q}{p_s^*}} S^{-\frac{q}{p}} \left(\sum_{j=1}^{k} \lambda_j^{\frac{\theta p}{\theta p - q}}\right)^{\frac{\theta p - q}{\theta p}}\right]^{\frac{\theta p - 2 + 2m}{\theta p - q}} \\
&\quad - \frac{1}{2}\left(\frac{1}{1-m} - \frac{2}{q}\right)\sum_{j=1}^{k}\sum_{i<j} \beta_{ij} |\Omega|^{\frac{p_s^* + 2m - 2}{p_s^*}} S^{\frac{2m-2}{p}}\Bigg\} \ge \alpha_0 > 0,
\end{aligned}$$

thanks to $(\lambda_1, \lambda_2, \ldots, \lambda_k) \in \Theta_{\Lambda_0}$ and (3.4). □

Lemma 3.4. *The minimization problem*

$$\alpha^- = \inf_{\mathbf{u}\in\mathcal{N}^-} J(\mathbf{u})$$

is achieved at a point $\mathbf{u}^- \in \mathcal{N}^-$.

Proof. Let $\{\mathbf{u}_n\}$ be a minimizing sequence of the minimization problem, i.e. $\{\mathbf{u}_n\} \subset \mathcal{N}^-$ and $\lim_{n\to\infty} J(\mathbf{u}_n) = \alpha^-$. By Lemma 2.3, it is easy to see that $\{\mathbf{u}_n\}$ is bounded, we can find a $\mathbf{u}^-$ such that $\mathbf{u}_n \rightharpoonup \mathbf{u}^-$ weakly in W, $\mathbf{u}_n \to \mathbf{u}^-$ strongly in $L^r(\Omega)$, $1 \le r < p_s^*$. Similar to Lemma 3.2, we have

$$\lim_{n\to\infty} \sum_{j=1}^{k} \sum_{i<j} \beta_{ij} \int_\Omega |(\mathbf{u}_n)_i (\mathbf{u}_n)_j|^{1-m} dx = \sum_{j=1}^{k} \sum_{i<j} \beta_{ij} \int_\Omega |(\mathbf{u}^-)_i (\mathbf{u}^-)_j|^{1-m} dx$$

and

$$\lim_{n\to\infty} \sum_{j=1}^{k} \lambda_j \int_\Omega |(\mathbf{u}_n)_j|^q dx = \sum_{j=1}^{k} \lambda_j \int_\Omega |(\mathbf{u}^-)_j|^q dx.$$

Furthermore, we can prove that $\mathbf{u}_n \to \mathbf{u}^-$ strongly in W. Arguing by contradiction, we assume $\mathbf{u}_n \not\to \mathbf{u}^-$ strongly in W. Then,

$$\|\mathbf{u}^-\|_W^{\theta p} < \lim_{n\to\infty} \inf \|\mathbf{u}_n\|_W^{\theta p}.$$

By Lemma 2.6, there exists $t^- > 0$ such that $t^-\mathbf{u}^- \in \mathcal{N}^-$. Thus, since $\{\mathbf{u}_n\} \subset \mathcal{N}^-$ and $J(t\mathbf{u}_n) \le J(\mathbf{u}_n)$, for all $t > 0$ we have

$$J(t^-\mathbf{u}^-) < \lim_{n\to\infty} J(t^-\mathbf{u}_n) \le \lim_{n\to\infty} J(\mathbf{u}_n) = \alpha^-,$$

which contradicts the fact that $\alpha^- = \inf_{\mathbf{u}\in\mathcal{N}^-} J(\mathbf{u})$. Thus, we conclude that $\mathbf{u}_n \to \mathbf{u}^-$ strongly in W. By $K'_{\mathbf{u}_n}(1) = 0$ and $K''_{\mathbf{u}_n}(1) < 0$, we get that $K'_{\mathbf{u}^-}(1) = 0$ and $K''_{\mathbf{u}^-}(1) \le 0$. Note that $\mathcal{N}^0 = \emptyset$. Then $K''_{\mathbf{u}^+}(1) < 0$, which implies $\mathbf{u}^- \in \mathcal{N}^+$. Above all, by $J(\mathbf{u}^-) = \inf_{\mathbf{u}\in\mathcal{N}^-} J(\mathbf{u})$, $\mathbf{u}^-$ is a minimizer of J on $\mathcal{N}^-$. The proof is completed. □

Proof of Theorem 1.1. For all $(\lambda_1, \lambda_2, \dots, \lambda_k) \in \Theta_{\Lambda_0}$, by Lemmas 3.2 and 3.4, we conclude that there exist $\mathbf{u}^+ \in \mathcal{N}^+$ and $\mathbf{u}^- \in \mathcal{N}^-$ satisfying $J(\mathbf{u}^+) = \inf_{\mathbf{u}\in\mathcal{N}^+} J(\mathbf{u})$ and $J(\mathbf{u}^-) = \inf_{\mathbf{u}\in\mathcal{N}^-} J(\mathbf{u})$. In view of Lemma 2.2, $\mathbf{u}^+$ and $\mathbf{u}^-$ are two solutions of system (1.1). Moreover, since $J(\mathbf{u}^+) = J(|\mathbf{u}^+|)$ and $|\mathbf{u}^+| \in \mathcal{N}^+$ and similarly $J(\mathbf{u}^-) = J(|\mathbf{u}^-|)$ and $|\mathbf{u}^-| \in \mathcal{N}^+$, so we may assume $\mathbf{u}^\pm \ge 0$. Since $\mathcal{N}^+ \cap \mathcal{N}^- = \emptyset$, two solutions of system (1.1) are distinct. And by Lemmas 3.1 and 3.3, we have $J(\mathbf{u}^+) < 0$ and $J(\mathbf{u}^-) > 0$. Hence we provided the existence of two nontrivial nonnegative solutions to our system (1.1). □

Abstract. Consider the class **QS** of all non-degenerate planar quadratic differential systems and its subclass **QSP** of all its systems possessing an invariant parabola. This is an interesting family because on one side it is defined by an algebraic geometric property and on the other, it is a family where limit cycles occur. Note that each quadratic differential system can be identified with a point of $\mathbb{R}^{12}$ through its coefficients. In this paper, we provide necessary and sufficient conditions for a system in **QS** to have at least one invariant parabola. We give the global "bifurcation" diagram of the family **QS** which indicates where a parabola is present or absent and in case it is present, the diagram indicates how many parabolas there could be, their reciprocal position and what kind of singular points at infinity (simple or multiple) as well as their multiplicities are the points at infinity of the parabolas. The diagram is expressed in terms of affine invariant polynomials and it is done in the 12-dimensional space of parameters.

Keywords: quadratic vector fields, affine invariant polynomials, invariant algebraic curve, invariant parabola.

1 Introduction and statement of main results

We consider here differential systems of the form

$$\frac{dx}{dt} = P(x,y), \qquad \frac{dy}{dt} = Q(x,y), \tag{1.1}$$

where $P, Q \in \mathbb{R}[x,y]$, i.e. P, Q are polynomials in x, y over $\mathbb{R}$ and their associated vector fields

$$X = P(x,y)\frac{\partial}{\partial x} + Q(x,y)\frac{\partial}{\partial y}.$$

We call *degree* of a system (1.1) the integer $m = \max(\deg P, \deg Q)$. In particular we call *quadratic* a differential system (1.1) with $m = 2$. We denote here by **QS** the whole class of real quadratic differential systems.

✉ Email: nicolae.vulpe@math.usm.md

Quadratic systems appear in the modelling of many natural phenomena described in different branches of science, in biological and physical applications and applications of these systems became a subject of interest for the mathematicians. Many papers have been published about quadratic systems, see for example [19] for a bibliographical survey.

Here we always assume that the polynomials P and Q are coprime. Otherwise doing a rescaling of the time, systems (1.1) can be reduced to linear or constant systems. Quadratic systems under this assumption are called *non-degenerate quadratic systems*.

Let V be an open and dense subset of $\mathbb{R}^2$, we say that a nonconstant differentiable function $H : V \to \mathbb{R}$ is a first integral of a system (1.1) on V if $H(x(t), y(t))$ is constant for all of the values of t for which $(x(t), y(t))$ is a solution of this system contained in V. Obviously H is a first integral of systems (1.1) if and only if

$$X(H) = P\frac{\partial H}{\partial x} + Q\frac{\partial H}{\partial y} = 0,$$

for all $(x, y) \in V$. When a system (1.1) has a first integral we say that this system is integrable.

The knowledge of the first integrals is of particular interest in planar differential systems because they allow us to draw their phase portraits.

On the other hand given $f \in \mathbb{C}[x, y]$ we say that the curve $f(x, y) = 0$ is an *invariant algebraic curve* of systems (1.1) if there exists $K \in \mathbb{C}[x, y]$ such that

$$P\frac{\partial f}{\partial x} + Q\frac{\partial f}{\partial y} = Kf.$$

The polynomial K is called the *cofactor* of the invariant algebraic curve $f = 0$. When $K = 0$, f is a polynomial first integral.

Let us suppose that $f(x, y) = 0$ is of degree n:

$$f(x, y) = c_{00} + c_{10}x + c_{01}y + \cdots + c_{n0}x^n + c_{n-1,1}x^{n-1}y + \cdots + c_{0n}y^n$$

with $\hat{c} = (c_{00}, \ldots, c_{0n}) \in \mathbb{C}^N$ where $N = (n+1)(n+2)/2$. We note that the equation $\lambda f(x, y) = 0$ where $\lambda \in \mathbb{C}^* = \mathbb{C}\backslash\{0\}$ yields the same locus of complex points in the plane as the locus induced by $f(x, y) = 0$. So, a curve of degree n defined by $\hat{c}$ can be identified with a point $[\hat{c}] = [c_{00} : c_{10} : \cdots : c_{0n}]$ in $P_{N-1}(\mathbb{C})$. We say that a sequence of degree n curves $f_i(x, y) = 0$ converges to a curve $f(x, y) = 0$ if and only if the sequence of points $[\hat{c}_i] = [c_{i00} : c_{i10} \cdots : c_{i0n}]$ converges to $[\hat{c}] = [c_{00} : c_{10} : \cdots : c_{0n}]$ in the topology of $P_{N-1}(\mathbb{C})$.

We observe that if we rescale the time $t' = \lambda t$ by a positive constant λ the geometry of the systems (1.1) does not change. So for our purposes we can identify a system (1.1) of degree m with a point in $[a_{10}, a_{10}, \ldots, b_{0m}]$ in $\mathbb{S}^{M-1}(\mathbb{R})$ with $M = (m+1)(m+2)$.

We compactify the space of all the polynomial differential systems of degree m on $\mathbb{S}^{M-1}$ with $M = (m+1)(m+2)$ by multiplying the coefficients of each systems with $1/\big(\sum(a_{ij}^2 + b_{ij}^2)\big)^{1/2}$.

Definition 1.1. We say that an invariant curve $\mathcal{L} : f(x, y) = 0$, $f \in \mathbb{C}[x, y]$ for a polynomial system (S) of degree m has *multiplicity* r if there exists a sequence of real polynomial systems (S_k) of degree m converging to (S) in the topology of $\mathbb{S}^{M-1}$, $M = (m+1)(m+2)$, such that each (S_k) has r distinct invariant curves $\mathcal{L}_{1,k} : f_{1,k}(x, y) = 0, \ldots, \mathcal{L}_{r,k} : f_{r,k}(x, y) = 0$ over $\mathbb{C}$, $\deg(f) = \deg(f_{i,k}) = n$, converging to $\mathcal{L}$ as $k \to \infty$, in the topology of $P_{N-1}(\mathbb{C})$, with $N = (n+1)(n+2)/2$ and this does not occur for $r+1$.

The motivation for studying the systems in the quadratic class is not only because of their usefulness in many applications but also for theoretical reasons, as discussed by Schlomiuk and Vulpe in the introduction of [20]. The study of non–degenerate quadratic systems could be done using normal forms and applying the invariant theory.

Systematic work on quadratic differential systems possessing an invariant conic began towards the end of the XX-th century and the beginning of this century. Quadratic systems having an invariant ellipse as a limit cycle were investigated by Y.-X. Qin [18]; the necessary and sufficient conditions on the coefficients of a quadratic system and also on the coefficients of a conic so as to have the conic as an invariant curve of the system were presented by Druzhkova [8]; Cairó and Llibre in [4] have investigated the Darboux integrability of the quadratic systems having invariant algebraic conics; Oliveira, Rezende and Vulpe [14] provided necessary and sufficient conditions for a system in **QS** to have at least one invariant hyperbola in terms of its coefficients and the necessary and sufficient affine invariant conditions for a system in **QS** so as to have the ellipse as an invariant curve of the system were presented by Oliveira, Rezende, Schlomiuk and Vulpe [16]. In [15] the authors classified the family of quadratic systems possessing an invariant hyperbola in terms of configurations of hyperbolas and presence or absence of invariant lines. This is an invariant classification, independent of specific normal forms. A similar classification in the case of an invariant ellipse is done in [13].

In this work we consider non-degenerate quadratic differential systems possessing an invariant parabola. We denote this family by **QSP**. Our goal in this paper is to obtain a characterization of systems in **QSP** in terms of invariant polynomials. Thus our equalities and inequalities in the bifurcation diagram splitting the parameter space into regions and subsets with distinct dynamics, will not be expressed in terms of coefficients of a fixed normal form or several such forms, coefficients which do not have any geometrical meaning and are rigidly tied to these normal forms. They will be expressed in terms of invariant polynomials which are very supple objects that can be easily be computed by a computer for any specific normal form and allowing us also to easily pass from one normal form to any other.

It is known that the coordinates of an infinite singular point p of a quadratic system (S) are defined by a linear factor in the factorization of the invariant polynomial $C_2(x,y) = yp_2(x,y) - xq_2(x,y)$ over $\mathbb{C}$. Here $p_2(x,y)$ and $q_2(x,y)$ are the corresponding quadratic homogeneous parts of (S). The multiplicity m of the singularity p has two components (see the concepts and notations introduced in [11]). If we denote them by (m^∞, m^f) (i.e. $m = m^\infty + m^f$) then m^∞ (respectively, m^f) is the maximum number of infinite (respectively, finite) singularities which can split from p, in small perturbations of the systems. In this case the number m^∞ coincides with the multiplicity of the linear factor of $C_2(x,y)$ which defines p.

Definition 1.2. By the direction of an invariant parabola of a quadratic system (S) we mean the direction of its axis of symmetry which intersects the invariant line $Z = 0$ at an infinite singular point p of (S) with the multiplicity (m^∞, m^f). We say that this direction of the invariant parabola is simple (respectively, double; triple) if $m^\infty = 1$ (respectively 2; 3). We denote this parabola by $\cup$ (respectively $\overset{2}{\cup}$; $\overset{3}{\cup}$). Moreover, if the infinite invariant line $Z = 0$ is filled up with singularities then we denote by $\overset{\infty}{\cup}$ the invariant parabola which is tangent to the line $Z = 0$ at a non-isolated singular point.

In order to distinguish the invariant parabolas that a quadratic system could have we use the following notations:

- $\cup$ for a simple invariant parabola;

- $\Cup$ for two simple invariant parabolas in the same direction (they could intersect);
- $\cup\subset$ for two simple invariant parabolas in different directions;
- $\boldsymbol{\cup}^2$ for one double invariant parabola;
- $\overset{2}{\cup}$ for one simple invariant parabola in double direction;
- $\overset{3}{\cup}$ for one simple invariant parabola in triple direction;
- $\overset{\infty}{\cup}$ for one simple invariant parabola when the line at infinity is filled up with singularities;
- $\overset{2}{\cup}\subset$ for two simple invariant parabola: one in a double direction and one in a simple direction;
- $\Cup\subset$ for three simple invariant parabolas: two in one direction and one in another direction;
- $\overset{2}{\cup}\overset{2}{\Cup}$ for three real invariant parabolas in the same double direction;
- $\overset{2}{\cup}\overset{2}{\Cup}{}^c$ for one real and two complex invariant parabolas in the same double direction;
- $\overset{2}{\cup}\overset{2}{\boldsymbol{\cup}}{}^2$ for one simple and one double real invariant parabolas in the same double direction;
- $\overset{2}{\boldsymbol{\cup}}{}^3$ for a triple real invariant parabola in a double direction;
- $\infty\overset{2}{\cup}$ for a 1-parameter family of invariant parabolas in the same double direction;
- $\infty\overset{3}{\cup}$ for a 1-parameter family of invariant parabolas in the same triple direction.

Our main results are stated in the following theorem.

Main Theorem. (A) *The condition $\chi_1 = \chi_2 = 0$ is necessary for a non-degenerate quadratic system to possess at least one invariant parabola.*

$(\boldsymbol{B})$ *Assume that for a non-degenerate quadratic system (S) the condition $\chi_1 = \chi_2 = 0$ holds. Then this system possesses at least one invariant parabola if and only if the corresponding conditions indicated below are satisfied, respectively. Furthermore in the case of the existence of an invariant parabola this systems could be brought via an affine transformation and time rescaling to one of the canonical forms presented below, correspondingly:*

$\boldsymbol{\alpha})$ *For $\eta > 0$ the system (S) could only possess one of the following sets of invariant parabolas: $\cup$, $\Cup$, $\boldsymbol{\cup}^2$, $\cup\subset$, $\Cup\subset$. Moreover (S) has one of the above sets of parabolas if and only if the corresponding conditions provided by the diagram given in Figure 1 are satisfied. Furthermore the system (S) with an invariant parabola could be brought via an affine transformation and time rescaling to the following canonical form*

$$\dot{x} = m + nx - \frac{1}{2}(1+g)y + gx^2 + xy, \quad \dot{y} = 2mx + 2ny + (g-1)xy + 2y^2 \qquad (S_{\boldsymbol{\alpha}})$$

possessing the invariant parabola $\Phi(x,y) = x^2 - y$.

$\boldsymbol{\beta}$) *For $\eta < 0$ the system (S) could only possess one of the following sets of invariant parabolas: $\cup$, $\Cup$, $\mathbf{U}^2$. Moreover (S) has one of the above sets of parabolas if and only if the corresponding conditions provided by the diagram given in Figure 1 are satisfied. Furthermore the system (S) with an invariant parabola could be brought via an affine transformation and time rescaling to the following canonical form*

$$\dot{x} = m + \frac{2n-1}{2}\,x - \frac{g}{2}\,y + gx^2 - xy, \quad \dot{y} = 2mx + 2ny - x^2 + gxy - 2y^2 \qquad (S_{\boldsymbol{\beta}})$$

possessing the invariant parabola $\Phi(x, y) = x^2 - y$.

$\boldsymbol{\gamma}$) *For $\eta = 0$ and $\widetilde{M} \neq 0$ the system (S) could only possess one of the following sets of invariant parabolas: $\cup$, $\Cup$, $\mathbf{U}^2$, $\overset{2}{\cup}$, $\overset{2}{\cup}\subset$, $\overset{2}{\cup}\overset{2}{\Cup}$, $\overset{2}{\cup}\overset{2}{\Cup}{}^c$, $\overset{2}{\cup}\overset{2}{\mathbf{U}}{}^2$, $\overset{2}{\mathbf{U}}{}^3$, $\infty\overset{2}{\cup}$.*

Moreover (S) has one of the above sets of parabolas if and only if the corresponding conditions provided by the diagram given in Figure 1 are satisfied. Furthermore the system (S) with invariant parabola could be brought via an affine transformation and time rescaling to one of the following two normal forms:

$$\dot{x} = m + nx - gy/2 + gx^2 + xy, \quad \dot{y} = 2mx + 2ny + gxy + 2y^2, \ g \in \{0, 1\} \qquad (S^1_{\boldsymbol{\gamma}})$$

possessing the invariant parabola $\Phi(x, y) = x^2 - y$, or

$$\dot{x} = 2mx + 2ny + (h-1)xy, \quad \dot{y} = n - (h+1)x/2 + my + hy^2 \qquad (S^2_{\boldsymbol{\gamma}})$$

possessing the invariant parabola $\Phi(x, y) = y^2 - x$.

$\boldsymbol{\delta}$) *For $\eta = \widetilde{M} = 0$ and $C_2 \neq 0$ the system (S) could only possess one of the following sets of invariant parabolas: $\overset{3}{\cup}$, $\infty\overset{3}{\cup}$. Moreover (S) has one of the above sets of parabolas if and only if the corresponding conditions provided by the diagram given in Figure 1 (the branch $C_2 \neq 0$) are satisfied. Furthermore the system (S) with an invariant parabola could be brought via an affine transformation and time rescaling to the following canonical form*

$$\dot{x} = m + (2n-1)x/2 - gy/2 + gx^2, \quad \dot{y} = 2mx + 2ny - x^2 + gxy \qquad (S_{\boldsymbol{\delta}})$$

possessing the invariant parabola $\Phi(x, y) = x^2 - y$.

$\boldsymbol{\theta}$) *For $\eta = \widetilde{M} = C_2 = 0$ the system (S) could only possess an invariant parabola $\overset{\infty}{\cup}$. Moreover (S) has this invariant parabola if and only if the corresponding conditions provided by the diagram given in Figure 1 (the branch $C_2 = 0$) are satisfied. Furthermore the system (S) with an invariant parabola could be brought via an affine transformation and time rescaling to the following canonical form*

$$\dot{x} = m + nx - y/2 + x^2, \quad \dot{y} = 2mx + 2ny + xy \qquad (S_{\boldsymbol{\theta}})$$

possessing the invariant parabola $\Phi(x, y) = x^2 - y$.

The paper is organized as follows. In Section 2 we construct the invariant polynomials which are responsible for the existence of an invariant parabola and obtain the ten equations relating the coefficients of a quadratic system with those of an invariant parabola. In Section 3 we give the proof of the Main Theorem constructing the conditions for the existence of invariant parabolas as well as the corresponding canonical systems.

2 The construction of the invariant polynomials

Consider real quadratic systems of the form

$$\begin{aligned} \frac{dx}{dt} &= p_0 + p_1(x,y) + p_2(x,y) \equiv P(x,y), \\ \frac{dy}{dt} &= q_0 + q_1(x,y) + q_2(x,y) \equiv Q(x,y), \end{aligned} \tag{2.1}$$

with homogeneous polynomials p_i and q_i $(i = 0, 1, 2)$ of degree i in x, y:

$$\begin{aligned} &p_0 = a_{00}, \quad && p_1(x,y) = a_{10}x + a_{01}y, \quad && p_2(x,y) = a_{20}x^2 + 2a_{11}xy + a_{02}y^2, \\ &q_0 = b_{00}, \quad && q_1(x,y) = b_{10}x + b_{01}y, \quad && q_2(x,y) = b_{20}x^2 + 2b_{11}xy + b_{02}y^2. \end{aligned}$$

It is known that on the set of quadratic systems acts the group $Aff(2,\mathbb{R})$ of affine transformations on the plane (cf. [21]). For every subgroup $G \subseteq Aff(2,\mathbb{R})$ we have an induced action of G on **QS**. We can identify the set **QS** of systems (2.1) with a subset of $\mathbb{R}^{12}$ via the map **QS** $\longrightarrow \mathbb{R}^{12}$ which associates to each system (2.1) the 12-tuple $\tilde{a} = (a_{00}, a_{10}, a_{01}, a_{20}, a_{11}, a_{02}, b_{00}, b_{10}, b_{01}, b_{20}, b_{11}, b_{02})$ of its coefficients. We associate to this group action polynomials in x, y and parameters which behave well with respect to this action, the GL-comitants (GL-invariants), the T-comitants (affine invariants) and the CT-comitants. For their definitions as well as their detailed constructions we refer the reader to the paper [21] (see also [1]).

2.1 Main invariant polynomials associated with invariant parabolas

We single out the following five polynomials, basic ingredients in constructing invariant polynomials for systems (2.1):

$$\begin{aligned} C_i(\tilde{a},x,y) &= yp_i(x,y) - xq_i(x,y), \ (i = 0,1,2), \\ D_i(\tilde{a},x,y) &= \frac{\partial p_i}{\partial x} + \frac{\partial q_i}{\partial y}, \ (i = 1,2). \end{aligned} \tag{2.2}$$

As it was shown in [23] these polynomials of degree one in the coefficients of systems (2.1) are GL-comitants of these systems. Let $f, g \in \mathbb{R}[\tilde{a}, x, y]$ and

$$(f,g)^{(k)} = \sum_{h=0}^{k} (-1)^h \binom{k}{h} \frac{\partial^k f}{\partial x^{k-h} \partial y^h} \frac{\partial^k g}{\partial x^h \partial y^{k-h}}.$$

The polynomial $(f,g)^{(k)} \in \mathbb{R}[\tilde{a}, x, y]$ is called *the transvectant of index k of (f,g)* (cf. [9,17])).

Proposition 2.1 (see [24]). *Any GL-comitant of systems (2.1) can be constructed from the elements (2.2) by using the operations: $+$, $-$, $\times$, and by applying the differential operation $(*,*)^{(k)}$.*

Remark 2.2. We point out that the elements (2.2) generate the whole set of GL-comitants and hence also the set of affine comitants as well as the set of T-comitants.

We construct the following GL-comitants of the second degree with respect to the coefficients of the initial systems

$$\begin{aligned} &T_1=(C_0,C_1)^{(1)}, \quad T_2=(C_0,C_2)^{(1)}, \quad T_3=(C_0,D_2)^{(1)},\\ &T_4=(C_1,C_1)^{(2)}, \quad T_5=(C_1,C_2)^{(1)}, \quad T_6=(C_1,C_2)^{(2)},\\ &T_7=(C_1,D_2)^{(1)}, \quad T_8=(C_2,C_2)^{(2)}, \quad T_9=(C_2,D_2)^{(1)}. \end{aligned} \tag{2.3}$$

Using these GL-comitants as well as the polynomials (2.2) we construct the additional invariant polynomials. In order to be able to calculate the values of the needed invariant polynomials directly for every canonical system we shall define here a family of T-comitants expressed through C_i $(i=0,1,2)$ and D_j $(j=1,2)$:

$$\begin{aligned}
\hat{A} =\ & \left(C_1, T_8-2T_9+D_2^2\right)^{(2)}/144,\\
\widehat{D} =\ & \Big[2C_0(T_8-8T_9-2D_2^2)+C_1(6T_7-T_6-(C_1,T_5)^{(1)}+6D_1(C_1D_2-T_5)-9D_1^2C_2\Big]/36,\\
\widehat{E} =\ & \Big[D_1(2T_9-T_8)-3\,(C_1,T_9)^{(1)}-D_2(3T_7+D_1D_2)\Big]/72,\\
\widehat{F} =\ & [6D_1^2(D_2^2-4T_9)+4D_1D_2(T_6+6T_7)+48C_0\,(D_2,T_9)^{(1)}-9D_2^2T_4+288D_1\widehat{E}\\
& -24\left(C_2,\widehat{D}\right)^{(2)}+120\left(D_2,\widehat{D}\right)^{(1)}-36C_1\,(D_2,T_7)^{(1)}+8D_1\,(D_2,T_5)^{(1)}\Big]/144,\\
\widehat{B} =\ & \Big\{16D_1\,(D_2,T_8)^{(1)}\,(3C_1D_1-2C_0D_2+4T_2)+32C_0\,(D_2,T_9)^{(1)}\,(3D_1D_2-5T_6+9T_7)\\
& +2\,(D_2,T_9)^{(1)}\left(27C_1T_4-18C_1D_1^2-32D_1T_2+32\,(C_0,T_5)^{(1)}\right)\\
& +6(D_2,T_7)^{(1)}[8C_0(T_8-12T_9)-12C_1(D_1D_2+T_7)+D_1(26C_2D_1+32T_5)+C_2(9T_4+96T_3)]\\
& +6\,(D_2,T_6)^{(1)}\,[32C_0T_9-C_1(12T_7+52D_1D_2)-32C_2D_1^2]+48D_2\,(D_2,T_1)^{(1)}\,(2D_2^2-T_8)\\
& -32D_1T_8\,(D_2,T_2)^{(1)}+9D_2^2T_4\,(T_6-2T_7)-16D_1\,(C_2,T_8)^{(1)}\,(D_1^2+4T_3)\\
& +12D_1\,(C_1,T_8)^{(2)}\,(C_1D_2-2C_2D_1)+6D_1D_2T_4\,(T_8-7D_2^2-42T_9)\\
& +12D_1\,(C_1,T_8)^{(1)}\,(T_7+2D_1D_2)+96D_2^2\Big[D_1\,(C_1,T_6)^{(1)}+D_2\,(C_0,T_6)^{(1)}\Big]\\
& -16D_1D_2T_3\,(2D_2^2+3T_8)-4D_1^3D_2\,(D_2^2+3T_8+6T_9)+6D_1^2D_2^2\,(7T_6+2T_7)\\
& -252D_1D_2T_4T_9\Big\}/(2^83^3),\\
\widehat{K} =\ & (T_8+4T_9+4D_2^2)/72, \quad \widehat{H}=(8T_9-T_8+2D_2^2)/72.
\end{aligned}$$

These polynomials in addition to (2.2) and (2.3) will serve as bricks in constructing affine invariant polynomials for systems (2.1).

The following 42 affine invariants $A_1,\ldots,A_{42}$ form the minimal polynomial basis of affine invariants up to degree 12. This fact was proved in [2] by constructing $A_1,\ldots,A_{42}$ using the above bricks.

$$\begin{aligned}
A_1 &= \hat{A}, & A_{22} &= \frac{1}{1152}[\![C_2,\widehat{D})^{(1)},D_2)^{(1)},D_2)^{(1)},D_2)^{(1)}D_2)^{(1)},\\
A_2 &= (C_2,\widehat{D})^{(3)}/12, & A_{23} &= [\![[\widehat{F},\widehat{H})^{(1)},\widehat{K})^{(2)}/8,\\
A_3 &= [\![C_2,D_2)^{(1)},D_2)^{(1)},D_2)^{(1)}/48, & A_{24} &= [\![C_2,\widehat{D})^{(2)},\widehat{K})^{(1)},\widehat{H})^{(2)}/32,\\
A_4 &= (\widehat{H},\widehat{H})^{(2)}, & A_{25} &= [\![\widehat{D},\widehat{D})^{(2)},\widehat{E})^{(2)}/16,\\
A_5 &= (\widehat{H},\widehat{K})^{(2)}/2, & A_{26} &= (\widehat{B},\widehat{D})^{(3)}/36,
\end{aligned}$$

$$
\begin{aligned}
A_6 &= (\widehat{E},\widehat{H})^{(2)}/2, & A_{27} &= [\![\widehat{B},D_2)^{(1)},\widehat{H})^{(2)}/24,\\
A_7 &= [\![[C_2,\widehat{E})^{(2)},D_2)^{(1)}/8, & A_{28} &= [\![C_2,\widehat{K})^{(2)},\widehat{D})^{(1)},\widehat{E})^{(2)}/16,\\
A_8 &= [\![\widehat{D},\widehat{H})^{(2)},D_2)^{(1)}/8, & A_{29} &= [\![\widehat{D},\widehat{F})^{(1)},\widehat{D})^{(3)}/96,\\
A_9 &= [\![\widehat{D},D_2)^{(1)},D_2)^{(1)},D_2)^{(1)}/48, & A_{30} &= [\![C_2,\widehat{D})^{(2)},\widehat{D})^{(1)},\widehat{D})^{(3)}/288,\\
A_{10} &= [\![\widehat{D},\widehat{K})^{(2)},D_2)^{(1)}/8, & A_{31} &= [\![\widehat{D},\widehat{D})^{(2)},\widehat{K})^{(1)},\widehat{H})^{(2)}/64,\\
A_{11} &= (\widehat{F},\widehat{K})^{(2)}/4, & A_{32} &= [\![\widehat{D},\widehat{D})^{(2)},D_2)^{(1)},\widehat{H})^{(1)},D_2)^{(1)}/64,\\
A_{12} &= (\widehat{F},\widehat{H})^{(2)}/4, & A_{33} &= [\![\widehat{D},D_2)^{(1)},\widehat{F})^{(1)},D_2)^{(1)},D_2)^{(1)}/128,\\
A_{13} &= [\![C_2,\widehat{H})^{(1)},\widehat{H})^{(2)},D_2)^{(1)}/24, & A_{34} &= [\![\widehat{D},\widehat{D})^{(2)},D_2)^{(1)},\widehat{K})^{(1)},D_2)^{(1)}/64,\\
A_{14} &= (\widehat{B},C_2)^{(3)}/36, & A_{35} &= [\![\widehat{D},\widehat{D})^{(2)},\widehat{E})^{(1)},D_2)^{(1)},D_2)^{(1)}/128,\\
A_{15} &= (\widehat{E},\widehat{F})^{(2)}/4, & A_{36} &= [\![\widehat{D},\widehat{E})^{(2)},\widehat{D})^{(1)},\widehat{H})^{(2)}/16,\\
A_{16} &= [\![\widehat{E},D_2)^{(1)},C_2)^{(1)},\widehat{K})^{(2)}/16, & A_{37} &= [\![\widehat{D},\widehat{D})^{(2)},\widehat{D})^{(1)},\widehat{D})^{(3)}/576,\\
A_{17} &= [\![\widehat{D},\widehat{D})^{(2)},D_2)^{(1)},D_2)^{(1)}/64, & A_{38} &= [\![C_2,\widehat{D})^{(2)},\widehat{D})^{(2)},\widehat{D})^{(1)},\widehat{H})^{(2)}/64,\\
A_{18} &= [\![\widehat{D},\widehat{F})^{(2)},D_2)^{(1)}/16, & A_{39} &= [\![\widehat{D},\widehat{D})^{(2)},\widehat{F})^{(1)},\widehat{H})^{(2)}/64,\\
A_{19} &= [\![\widehat{D},\widehat{D})^{(2)},\widehat{H})^{(2)}/16, & A_{40} &= [\![\widehat{D},\widehat{D})^{(2)},\widehat{F})^{(1)},\widehat{K})^{(2)}/64,\\
A_{20} &= [\![C_2,\widehat{D})^{(2)},\widehat{F})^{(2)}/16, & A_{41} &= [\![C_2,\widehat{D})^{(2)},\widehat{D})^{(2)},\widehat{F})^{(1)},D_2)^{(1)}/64,\\
A_{21} &= [\![\widehat{D},\widehat{D})^{(2)},\widehat{K})^{(2)}/16, & A_{42} &= [\![\widehat{D},\widehat{F})^{(2)},\widehat{F})^{(1)},D_2)^{(1)}/16.
\end{aligned}
$$

In the above list, the bracket "$[\![$" is used in order to avoid placing the otherwise necessary up to five parentheses "(".

Using the elements of the minimal polynomial basis given above we construct the affine invariant polynomials

$$
\begin{aligned}

2.2 Preliminary results involving the use of polynomial invariants

Considering the GL-comitant $C_2(\tilde{a},x,y) = yp_2(\tilde{a},x,y) - xq_2(\tilde{a},x,y)$ as a cubic binary form of x and y we calculate

$$\eta(\tilde{a}) = \text{Discrim}[C_2,\xi], \quad \widetilde{M}(\tilde{a},x,y) = \text{Hessian}[C_2],$$

where $\xi = y/x$ or $\xi = x/y$. Following [23] (see also [21]) we have the next lemma.

Lemma 2.3. *The number of distinct roots (real and imaginary) of the polynomial $C_2(\tilde{a},x,y)$ is determined by the following conditions:*

(i) 3 *real if* $\eta > 0$*;*

(ii) 1 *real and* 2 *imaginary if* $\eta < 0$*;*

(iii) 2 *real (1 double) if* $\eta = 0$ *and* $\widetilde{M} \neq 0$*;*

(iv) 1 *real (triple) if* $\eta = \widetilde{M} = 0$ *and* $C_2 \neq 0$*;*

(v) ∞ *if* $\eta = \widetilde{M} = C_2 = 0$.

Moreover, for each one of these cases the quadratic systems (2.1) *can be brought via a linear transformation to one of the following canonical systems* $(\mathbf{S}_I)$–$(\mathbf{S}_{IV})$*:*

$$\begin{cases} \dot{x} = a + cx + dy + gx^2 + (h-1)xy, \\ \dot{y} = b + ex + fy + (g-1)xy + hy^2; \end{cases} \qquad (\mathbf{S}_I)$$

$$\begin{cases} \dot{x} = a + cx + dy + gx^2 + (h+1)xy, \\ \dot{y} = b + ex + fy - x^2 + gxy + hy^2; \end{cases} \qquad (\mathbf{S}_{II})$$

$$\begin{cases} \dot{x} = a + cx + dy + gx^2 + hxy, \\ \dot{y} = b + ex + fy + (g-1)xy + hy^2; \end{cases} \qquad (\mathbf{S}_{III})$$

$$\begin{cases} \dot{x} = a + cx + dy + gx^2 + hxy, \\ \dot{y} = b + ex + fy - x^2 + gxy + hy^2, \end{cases} \qquad (\mathbf{S}_{IV})$$

$$\begin{cases} \dot{x} = a + cx + dy + x^2, \\ \dot{y} = b + ex + fy + xy. \end{cases} \qquad (\mathbf{S}_V)$$

Some important necessary conditions for a quadratic system to possess invariant parabolas are provided by the next lemma.

Lemma 2.4. *If a quadratic system* (2.1) *possesses an invariant parabola then the conditions* $\chi_1 = \chi_2 = 0$ *hold.*

Proof. Assume that a quadratic system (2.1) possesses an invariant parabola. It is known that via an affine transformation this parabola could be brought to the canonical form $y = x^2$. Then as it was proved in [5] this quadratic system can be written in the form

$$\dot{x} = c(y - x^2) + (a + bx + gy) + ex, \quad \dot{y} = d(y - x^2) + 2x(a + bx + gy) + 2ey^2,$$

where a, b, c, d, g, h, e are real parameters. A straightforward calculation gives $\chi_1 = \chi_2 = 0$ for the above systems and this completes the proof of the lemma. □

Assume that a conic

$$\Phi(x,y) \equiv p + qx + ry + sx^2 + 2vxy + uy^2 = 0 \tag{2.4}$$

is an affine algebraic invariant curve for quadratic systems (2.1), which we rewrite in the form:

$$\begin{aligned} \frac{dx}{dt} &= a + cx + dy + gx^2 + 2hxy + ky^2 \equiv P(x,y), \\ \frac{dy}{dt} &= b + ex + fy + lx^2 + 2mxy + ny^2 \equiv Q(x,y). \end{aligned} \tag{2.5}$$

Remark 2.5. Following [10] we construct the determinant

$$\Delta = \begin{vmatrix} s & v & q/2 \\ v & u & r/2 \\ q/2 & r/2 & p \end{vmatrix},$$

associated to the conic (2.4). By [10] this conic is irreducible (i.e. the polynomial Φ defining the conic is irreducible over $\mathbb{C}$) if and only if $\Delta \neq 0$.

According to definition of an invariant curve (see page 2) considering the cofactor $K = Ux + Vy + W \in \mathbb{R}[x,y]$ the following identity holds:

$$\frac{\partial \Phi}{\partial x} P(x,y) + \frac{\partial \Phi}{\partial y} Q(x,y) = \Phi(x,y)(Ux + Vy + W).$$

This identity yields a system of 10 equations for determining the 9 unknown parameters p, q, r, s, u, v, U, V, W:

$$\begin{aligned} Eq_1 &\equiv s(2a_{20} - U) + 2b_{20}v = 0, \\ Eq_2 &\equiv 2v(a_{20} + 2b_{11} - U) + s(4a_{11} - V) + 2b_{20}u = 0, \\ Eq_3 &\equiv 2v(2a_{11} + b_{02} - V) + u(4b_{11} - U) + 2a_{02}s = 0, \\ Eq_4 &\equiv u(2b_{02} - V) + 2a_{02}v = 0, \\ Eq_5 &\equiv q(a_{20} - U) + s(2a_{10} - W) + 2b_{10}v + b_{20}r = 0, \\ Eq_6 &\equiv r(2b_{11} - U) + q(2a_{11} - V) + 2v(a_{10} + b_{01} - W) + 2(a_{01}s + b_{10}u) = 0, \\ Eq_7 &\equiv r(b_{02} - V) + u(2b_{01} - W) + 2a_{01}v + a_{02}q = 0, \\ Eq_8 &\equiv q(a_{10} - W) + 2(a_{00}s + b_{00}v) + b_{10}r - pU = 0, \\ Eq_9 &\equiv r(b_{01} - W) + 2(b_{00}u + a_{00}v) + a_{01}q - pV = 0, \\ Eq_{10} &\equiv a_{00}q + b_{00}r - pW = 0. \end{aligned} \tag{2.6}$$

According to [6] (see also [3]) we have the next lemma.

Lemma 2.6. *Suppose that a polynomial system (1.1) of degree n has the invariant algebraic curve $f(x,y) = 0$ of degree m. Let P_n, Q_n and f_m be the homogeneous components of P, Q and f of degree n and m, respectively. Then the irreducible factors of f_m must be factors of $yP_n - xQn$.*

3 The proof of the Main Theorem

Assuming that a quadratic system (2.5) has an invariant parabola (2.4) by Lemma 2.4 we conclude that for this system the conditions $\chi_1 = \chi_2 = 0$ have to be fulfilled.

In what follows considering Lemma 2.3 we examine each one of the families of quadratic systems provided by this lemma.

3.1 Systems with three real infinite singularities

In this case according to Lemma 2.3 systems (2.5) via a linear transformation could be brought to the following family of systems

$$\frac{dx}{dt} = a + cx + dy + gx^2 + (h-1)xy, \qquad\qquad (3.1)$$
$$\frac{dy}{dt} = b + ex + fy + (g-1)xy + hy^2,$$

for which we have $C_2(x,y) = xy(x-y)$. Therefore the infinite singularities are located at the intersections of the lines $x = 0$, $y = 0$ and $x - y = 0$ with the line $Z = 0$ at infinity. So by Lemma 2.6 it is clear that if a parabola is invariant for these systems, then its homogeneous quadratic part has one of the following forms: $(i)\ kx^2$, $(ii)\ ky^2$, $(iii)\ k(x-y)^2$, where k is a real nonzero constant. Obviously we may assume $k = 1$ (otherwise instead of conic (2.4) we could consider $\Phi(x,y)/k = 0$).

According to Lemma 2.4 for the existence of an invariant parabola for a system (3.1) the condition $\chi_1 = 0$ is necessary. For the above systems we calculate

$$\chi_1 = 2(g-2)(h-2)(1+g+h) \qquad\qquad (3.2)$$

and therefore the condition $\chi_1 = 0$ is equivalent to $(g-2)(h-2)(1+g+h) = 0$.

On the other hand we have the following lemma.

Lemma 3.1. *Assume that a system (3.1) possesses an invariant parabola. Then its quadratic homogeneous part is of the form x^2 (respectively, y^2; $(x-y)^2$) only if the condition $h - 2 = 0$ (respectively, $g - 2 = 0$; $g + h + 1 = 0$) holds.*

Proof. Assume that a system (3.1) possesses an invariant parabola of the form $\Phi(x,y) = p + qx + ry + x^2$ with $r \neq 0$ (otherwise we get a reducible conic). Then considering equations (2.6) we obtain

$$s = 1,\ \ v = u = 0,\ \ Eq_2 = -2 + 2h - V = 0\ \Rightarrow\ V = 2(h-1).$$

Therefore we have $Eq_7 = (2-h)r = 0$ and since $r \neq 0$ this implies $h - 2 = 0$. So the statement of the lemma is true in this case.

If the system possesses an invariant parabola of the form $\Phi(x,y) = p + qx + ry + y^2$ with $q \neq 0$ then considering equations (2.6) we obtain

$$s = v = 0,\ \ u = 1,\ \ Eq_3 = -2 + 2g - U = 0\ \Rightarrow\ U = 2(g-1).$$

In this case we obtain $Eq_5 = (2-g)q = 0$ and due to $q \neq 0$ we get $g - 2 = 0$.

Assume now a system (3.1) possesses an invariant parabola of the form $\Phi(x,y) = p + qx + ry + (x-y)^2$ with $q + r \neq 0$. Then we have

$$s = 1,\ v = -1,\ u = 1,\ \ Eq_1 = 2g - U,\ Eq_4 = 2h - V$$

and therefore the equations $Eq_1 = 0$ and $Eq_4 = 0$ yield $U = 2g$ and $V = 2h$, respectively. Then we calculate $Eq_5 + Eq_6 + Eq_7 = -(1+g+h)(q+r) = 0$ and due to the condition $q + r \neq 0$ we get $1 + g + h = 0$ and this completes the proof of Lemma 3.1. □

Considering (3.2) it is clear that the condition $\chi_1 = 0$ implies either $h = 2$ or $g = 2$ or $h = -(1+g)$. On the other hand for systems (3.1) we have

$$\begin{aligned} \zeta_1 &= 2(g-2)(3+g) \quad \text{in the case } h = 2;\\ \zeta_1 &= 2(h-2)(3+h) \quad \text{in the case } g = 2;\\ \zeta_1 &= 2(g-2)(3+g) \quad \text{in the case } h = -(1+g) \end{aligned}$$

and therefore we conclude that if $\chi_1 = 0$ then the condition $\zeta_1 = 0$ imposes the vanishing of one more factor of the polynomial χ_1.

Remark 3.2. If $(h-2)(g-2)(1+g+h) = 0$ then without losing generality we may assume $h = 2$. Furthermore if two of these factors vanish simultaneously (i.e. $\zeta_1 = 0$) then we may assume $h = 2$ and $g = 2$.

Indeed assume $h - 2 \neq 0$ and suppose first that $g = 2$. We observe that the change

$$(x, y, a, b, c, d, e, f, g, h) \mapsto (y, x, b, a, e, d, f, c, h, g)$$

conserves systems (3.1) and hence the condition $g = 2$ is transformed into $h = 2$.

Admit now that the condition $1 + g + h = 0$ is fulfilled. Then applying to these systems the transformation

$$x_1 = x - y, \quad y_1 = -y$$

and arrive at the systems

$$\dot{x}_1 = a_1 + c_1x_1 + g_1x_1^2 + (h_1 - 1)x_1y_1, \quad \dot{y}_1 = b_1 + f_1y_1 + (g_1 - 1)x_1y_1 + h_1y_1^2$$

where (we are interested only in homogeneous quadratic parts)

$$g_1 = g, \quad h_1 = 1 - g - h, \Rightarrow \; g = g_1, \quad h = 1 - g_1 - h_1.$$

Therefore we obtain $1 + h_1 + g_1 = 1 + (1 - g - h) + g = 2 - h$ and hence via the above transformation the condition $1 + g + h = 0$ is reduced to the condition $h - 2 = 0$.

Assume now that two of the factors $(h-2)(g-2)(1+g+h)$ vanish. Then as it was shown above we may assume $h = 2$. In this case other two factors become $g - 2$ and $g + 3$. Supposing $h = 2$ and $g = -3$ systems (3.1) become

$$\dot{x} = a + cx + dy - 3x^2 + xy, \quad \dot{y} = b + ex + fy - 4xy + 2y^2,$$

which via the transformation $x_1 = x$, $y_1 = x - y$ can be brought to the systems

$$\dot{x}_1 = a_1 + c_1x_1 + d_1y_1 + 2x_1^2 + x_1y_1, \quad \dot{y}_1 = b_1 + e_1x_1 + f_1y_1 + x_1y_1 + 2y_1^2.$$

It remains to observe that these systems have the form (3.1) with $h = 2$ and $g = 2$ and we conclude that the statement of Remark 3.2 is valid.

Considering Lemma 3.1 and Remark 3.2 we conclude that for determining the conditions for the existence and the number of invariant parabolas for systems (3.1) it is sufficient to examine when the invariant parabolas have the forms $\Phi(x, y) = p + qx + ry + x^2$ and $\Phi(x, y) = p + qx + ry + y^2$. Moreover as it is mentioned above systems (3.1) could have invariant parabolas only in one direction (if $\chi_1 = 0$ and $\zeta_1 \neq 0$) and they could have invariant parabolas in two directions (if $\chi_1 = 0$ and $\zeta_1 = 0$). In what follows we examine each one of these two possibilities.

3.1.1 The possibility $\chi_1 = 0$ and $\zeta_1 \neq 0$

Then we may assume $h = 2$ and by Lemma 3.1 systems (3.1) could have invariant parabolas of the form $\Phi(x,y) = p + qx + ry + x^2$. Applying the translation $(x,y) \mapsto \big(x - d,\ y - c + 2dg\big)$ systems (3.1) can be brought to the systems

$$\dot{x} = a + gx^2 + xy, \quad \dot{y} = b + ex + fy + (g-1)xy + 2y^2. \tag{3.3}$$

Coefficient conditions for systems (3.3) to possess invariant parabolas

Lemma 3.3. *A system (3.3) possesses either one or two invariant parabolas or a double invariant parabola of the form $\Phi(x,y) = p + qx + ry + x^2$ $(r \neq 0)$ if and only if $\Omega_1 = 0$ and the corresponding set of conditions are satisfied, respectively:*

$(\mathcal{A}_1)$ $g(g+1) \neq 0,\ 2g+1 \neq 0,\ \mathcal{D}_1 \neq 0,\ \mathcal{G}_1 \neq 0 \Rightarrow \cup$;

$(\mathcal{A}_2)$ $g(g+1) \neq 0,\ 2g+1 \neq 0,\ \mathcal{D}_1 = 0,\ a \neq 0,\ \mathcal{F}_1 \neq 0 \Rightarrow \Cup$;

$(\mathcal{A}_3)$ $g(g+1) \neq 0,\ 2g+1 \neq 0,\ \mathcal{D}_1 = 0,\ a \neq 0,\ \mathcal{F}_1 = 0 \Rightarrow \cup^2$;

$(\mathcal{A}_4)$ $g(g+1) \neq 0,\ 2g+1 \neq 0,\ \mathcal{D}_1 = 0,\ a = 0,\ f \neq 0 \Rightarrow \cup$;

$(\mathcal{A}_5)$ $g = -1/2,\ \mathcal{D}_1 \neq 0,\ a \neq 0 \Rightarrow \cup$;

$(\mathcal{A}_6)$ $g = -1/2,\ \mathcal{D}_1 = 0,\ b \neq 0,\ e^2 - 2b \neq 0 \Rightarrow \Cup$;

$(\mathcal{A}_7)$ $g = -1/2,\ \mathcal{D}_1 = 0,\ b \neq 0,\ e^2 - 2b = 0 \Rightarrow \cup^2$;

$(\mathcal{A}_8)$ $g = -1/2,\ \mathcal{D}_1 = 0,\ b = 0,\ e \neq 0 \Rightarrow \cup$;

$(\mathcal{A}_9)$ $g = 0,\ b = a,\ e \neq 0,\ a \neq 0 \Rightarrow \cup$;

$(\mathcal{A}_{10})$ $g = -1,\ b = 0,\ e + f \neq 0,\ a \neq 0 \Rightarrow \cup$,

where

$$\begin{aligned}
\Omega_1 &= 2b^2(1+2g)^2 - b\big[4a(1+g)(1+2g)(1+3g) - (e-fg)(e+f+fg)\big] \\
&\quad + a(1+g)\big[2a(1+g)(1+3g)^2 - (e-2fg)(e+f+fg)\big]; \\
\mathcal{D}_1 &= e + f(g+1);\ \ \mathcal{G}_1 = a - b + 4ag - 2bg + 3ag^2;\ \ \mathcal{F}_1 = 8ag(1+g) - f^2(1+2g).
\end{aligned} \tag{3.4}$$

Proof. Considering the equations (2.6) and the form of invariant parabola $\Phi(x,y) = p + qx + ry + x^2$ with $r \neq 0$ we obtain

$$\begin{gathered}
s = 1,\ v = u = 0,\ U = 2g,\ V = 2,\ W = -gq, \\
Eq_1 = Eq_2 = Eq_3 = Eq_4 = Eq_5 = Eq_7 = 0.
\end{gathered}$$

Calculating the remaining equations we obtain

$$\begin{aligned}
&Eq_6 = -q - r - gr, \qquad Eq_8 = 2a - 2gp + gq^2 + er, \\
&Eq_9 = -2p + fr + gqr, \qquad Eq_{10} = aq + gpq + br.
\end{aligned}$$

It is clear that the equations $Eq_6 = 0$ implies $q = -(1+g)r$ and then $Eq_9 = 0$ gives us $p = r(f - gr - g^2 r)/2$. Therefore calculations yield

$$\begin{aligned}
Eq_8 &= g(1+g)(1+2g)r^2 + (e - fg)r + 2a, \\
Eq_{10} &= r\big[g^2(1+g)^2 r^2 - fg(1+g)r - 2(a - b + ag)\big]/2 \equiv r\Psi/2
\end{aligned} \tag{3.5}$$

and since $r \neq 0$ the equation $Eq_{10} = 0$ is equivalent to $\Psi = 0$.

According to [12, Lemmas 11, 12] the equations $Eq_8 = 0$ and $\Psi = 0$ have a common solution of degree 2 with respect to the parameter r if and only if

$$Res_r^{(0)}(Eq_8, \Psi) = Res_r^{(1)}(Eq_8, \Psi) = 0$$

where $Res_r^{(1)}$ is the subresultant of order one and $Res_r^{(0)}$ is the subresultant of order zero which coincide with standard resultant (for detailed definition see [12], formula (19)). We calculate

$$\begin{aligned} Res_r^{(1)}(Eq_8, \Psi) &= -g^2(1+g)^2(e+f+fg) \equiv -g^2(1+g)^2\mathcal{D}_1, \\ Res_r^{(0)}(Eq_8, \Psi) &= 2g^2(g+1)^2\Omega_1. \end{aligned}$$

So we examine three possibilities: $g(g+1) \neq 0$, $g = 0$ and $g = -1$.

***1:* The possibility** $g(g+1) \neq 0$**.** Considering (3.4) we observe that the polynomial Ω_1 is quadratic with respect to the parameter b if $2g+1 \neq 0$. So we discuss two cases: $2g+1 \neq 0$ and $2g+1 = 0$.

***1.1:* The case** $2g+1 \neq 0$**.** We observe that due to the condition $g(g+1) \neq 0$ the subresultant of order one $Res_r^{(1)}(Eq_8, \Psi)$ vanishes if and only if $\mathcal{D}_1 = 0$. So we consider two subcases: $\mathcal{D}_1 \neq 0$ and $\mathcal{D}_1 = 0$.

1.1.1: *The subcase* $\mathcal{D}_1 \neq 0$. Then the invariant parabola exists if and only if $\Omega_1 = 0$ and therefore we have to examine the solutions of the equation $\Omega_1 = 0$. In this case we calculate

$$\text{Discrim}[\Omega_1, b] = -(e+f+fg)^2\big[8ag(1+g)(1+2g) - (e-fg)^2\big] \equiv -\mathcal{D}_1^2\mathcal{E}$$

and hence the equation $\Omega_1 = 0$ has real solutions with respect to the parameter b if and only if either $\mathcal{D}_1 = 0$ or $\mathcal{E} \leq 0$. However since the condition $\mathcal{D}_1 \neq 0$ holds it remains to examine the condition $\mathcal{E} \leq 0$.

In this case setting $\mathcal{E} = -w^2 \leq 0$ we calculate

$$a = \frac{(e-fg)^2 - w^2}{8g(g+1)(2g+1)} \tag{3.6}$$

and then we obtain:

$$\Omega_1 = \frac{B_+B_-}{32g^2(1+2g)^2},$$

where

$$B_\pm = 8bg(1+2g)^2 + (fg - e + \varepsilon w)\big[e(1+g) - fg(3+5g) + \varepsilon w(1+3g)\big], \quad \varepsilon = \pm 1.$$

Then the condition $\Omega_1 = 0$ gives us

$$b = \frac{(e - fg - \varepsilon w)}{8g(1+2g)^2}\big[e(1+g) - fg(3+5g) + \varepsilon w(1+3g)\big] \tag{3.7}$$

where $\varepsilon = 1$ if $B_+ = 0$ and $\varepsilon = -1$ if $B_- = 0$. In this case we obtain that the polynomials Eq_8 and $\Psi(e, f, g, r)$ have the common factor $\zeta = 2g(1+g)(1+2g)r + e - fg - \varepsilon w$ which is linear with respect to the parameter r. Setting $\zeta = 0$ we get

$$r = -\frac{e - fg - \varepsilon w}{2g(1+g)(1+2g)}$$

and we arrive at the family of systems

$$\begin{aligned} \dot{x} &= \frac{(e-fg)^2 - w^2}{8g(g+1)(2g+1)} + gx^2 + xy, \\ \dot{y} &= \frac{(e-fg-\varepsilon w)}{8g(1+2g)^2}\big[e(1+g) - fg(3+5g) + \varepsilon w(1+3g)\big] + ex + fy + (g-1)xy + 2y^2. \end{aligned} \tag{3.8}$$

This family of systems possess the following invariant parabola

$$\begin{aligned} \Phi(x,y) = &-\frac{(e-fg-\varepsilon w)(e+2f+3fg-\varepsilon w)}{8g(1+g)(1+2g)^2} \\ &+ \frac{e-fg-\varepsilon w}{2g(1+2g)}\,x - \frac{e-fg-\varepsilon w}{2g(1+g)(1+2g)}\,y + x^2. \end{aligned} \tag{3.9}$$

We observe that this conic is reducible if and only if $e - fg + \varepsilon w = 0$.

Considering (3.6) and (3.7) we get

$$w^2 = -8ag(1+g)(1+2g) + (e-fg)^2$$

and then we obtain

$$\begin{aligned} b = \frac{1}{8g(1+2g)^2}\big[(e-fg)(e+eg-3fg-5fg^2) - 2\varepsilon wg(e+f+fg) - (1+3g)w^2\big] \;\Rightarrow \\ 4b(1+2g)^2 - 4a(1+g)(1+2g)(1+3g) + (e+f+fg)(e-fg-\varepsilon w) = 0. \end{aligned}$$

Since $\mathcal{D}_1 = (e+f+fg) \neq 0$ we solve the last equation with respect to εw and we obtain

$$\varepsilon w = \frac{1}{e+f+fg}\big[4b(1+2g)^2 - 4a(1+g)(1+2g)(1+3g) + (e-fg)(e+f+fg)\big].$$

Then calculations yield

$$r = -\frac{e-fg-\varepsilon w}{2g(1+g)(1+2g)} = -\frac{2(a-b+4ag-2bg+3ag^2)}{g(1+g)(e+f+fg)} = -\frac{2\,\mathcal{G}_1}{g(1+g)(e+f+fg)} \neq 0.$$

This completes the proof of the statement $(\boldsymbol{A_1})$ of Lemma 3.3.

Since systems (3.8) are in the class defined by the condition $\eta > 0$, according to the statement $\boldsymbol{\alpha})$ of Main Theorem we have to prove that these systems could be brought via a transformation to the canonical form $(S_{\boldsymbol{\alpha}})$.

Indeed as $g(1+g)(1+2g) \neq 0$ we apply to the parabola (3.9) the translation

$$x = x_1 - \frac{e-fg-\varepsilon w}{4g(1+2g)}, \quad y = y_1 - \frac{e+3eg+fg(3+5g)-(1+3g)\varepsilon w}{8g(1+2g)} \tag{3.10}$$

and we get a simpler form of this parabola:

$$\widetilde{\Phi}(x_1,y_1) = x_1^2 - \frac{e-fg-\varepsilon w}{2g(1+g)(1+2g)}\,y_1.$$

On the other hand applying the same translation to the family of systems (3.8) we arrive at the systems

$$\begin{aligned}\dot{x}_1 =& \frac{(e-fg-\varepsilon w)\big[fg(1-g)(3+5g)+e(1+10g+13g^2)+(g-1)(1+3g)\varepsilon w\big]}{32g^2(1+g)(1+2g)^2}-\\ & \frac{fg(3+g)+e(1+7g)-(1+7g)\varepsilon w}{8g(1+2g)}x_1-\frac{e-fg-\varepsilon w}{4g(1+2g)}y_1+gx_1^2+x_1y_1,\\ \dot{y}_1 =& \frac{fg(1-g)(3+5g)+e(1+10g+13g^2)+(g-1)(1+3g)\varepsilon w}{8g(1+2g)}x_1-\\ & \frac{fg(3+g)+e(1+7g)-(1+7g)\varepsilon w}{4g(1+2g)}y_1+(g-1)x_1y_1+2y_1^2.\end{aligned} \tag{3.11}$$

Observation 3.4. We remark that simultaneously applying the same translation on systems (3.8) and on the corresponding invariant parabola (3.9) we arrive at systems (3.11). We point out that the linear parts of these systems together with the coefficients of the transformed parabola $\widetilde{\Phi}(x_1,y_1)$ suggest us the new notations for the simplification of the canonical forms.

Indeed due to the condition $g(1+g)(1+2g)(e-fg-\varepsilon w)\neq 0$ we could set the following new notations:

$$\begin{gathered}k=\frac{e-fg-\varepsilon w}{2g(1+g)(1+2g)},\quad n=-\frac{fg(3+g)+e(1+7g)-(1+7g)\varepsilon w}{8g(1+2g)},\\ m=\frac{fg(1-g)(3+5g)+e(1+10g+13g^2)+(g-1)(1+3g)\varepsilon w}{16g(1+2g)}\quad\Rightarrow\\ e=gk-g^3k+2m+n-gn,\quad f=-\frac{(1+g)(1+7g)k-4n}{2},\\ w=-\frac{g(1+g)(1+3g)k-2(2m+n+gn)}{2\varepsilon}\end{gathered}$$

where $k\neq 0$ due to $e-fg+\varepsilon w\neq 0$. Then we arrive at the following family of systems:

$$\begin{aligned}\dot{x}_1 &= km+nx_1-\frac{k}{2}(g+1)y_1+gx_1^2+xy,\\ \dot{y}_1 &= 2mx_1+2ny_1+(g-1)x_1y_1+2y_1^2.\end{aligned}$$

which possess the invariant parabola $\Phi(x_1,y_1)=x_1^2-ky_1,\quad k\neq 0$.

Remark 3.5. If $k\neq 0$ then due to a rescaling we may assume $k=1$ in the above systems as well as in the invariant parabola.

Indeed since $k\neq 0$ via the rescaling $(x_1,y_1,t_1)\mapsto(kx_1,ky_1,t/k)$ and setting $m/k=m$ and $n/k=n$ we may assume $k=1$ in the above systems. At the same time applying this rescaling to the above parabola we get $\Phi(x_1,y_1)=k^2(x_1^2-y_1)$ and we conclude that the parabola $\widetilde{\Phi}(x_1,y_1)=x_1^2-y_1$ also in invariant for the above systems.

Therefore due to this remark we get the canonical systems $(S_{\boldsymbol{\alpha}})$ provided by the statement $\boldsymbol{\alpha})$ of Main Theorem.

1.1.2: *The subcase* $\mathcal{D}_1=0$. Then $e=-f(1+g)$ and therefore we obtain:

$$\Omega_1=2\big[a(1+g)(1+3g)-b(1+2g)\big]^2=2\mathcal{G}_1^2$$

and since $2g+1 \neq 0$ the condition $\Omega_1 = 0$ implies

$$b = \frac{a(1+g)(1+3g)}{1+2g}.$$

Therefore we determine that in this case the polynomials Eq_8 and Eq_{10} have the following common factor

$$\tilde{\phi} = 2a - f(1+2g)r + g(1+g)(1+2g)r^2.$$

We observe that $\tilde{\phi}$ is quadratic in r with the discriminant

$$\text{Discrim}[\tilde{\phi}, r] = -(1+2g)\left[8ag(1+g) - f^2(1+2g)\right]$$

and setting this discriminant equal to be w^2 we obtain

$$a = \frac{f^2(1+2g)^2 - w^2}{8g(1+g)(1+2g)}. \tag{3.12}$$

Then we arrive at the following expressions for the polynomials Eq_8 and Eq_{10}:

$$Eq_8 = \frac{H_+ H_-}{4g(1+g)(1+2g)}, \quad Eq_{10} = \frac{rH_+ H_-}{8(1+2g)^2},$$

where

$$H_\pm = f(1+2g) - 2g(1+g)(1+2g)r \pm w.$$

Therefore the equations $Eq_8 = Eq_{10} = 0$ imply $H_+H_- = 0$. If $H_+ = 0$ we determine

$$r = \frac{f + 2fg + w}{2g(1+g)(1+2g)} \equiv r^+$$

and we obtain the parabola

$$\Phi_1(x,y) = \frac{f^2(1+2g)^2 - w^2}{8g(g+1)(2g+1)^2} - \frac{f+2fg+w}{2g(1+2g)}\,x + \frac{f+2fg+w}{2g(g+1)(2g+1)}\,y + x^2.$$

In the case $H_- = 0$ we obtain

$$r = \frac{f + 2fg - w}{2g(1+g)(1+2g)} \equiv r^-$$

and we get the parabola

$$\Phi_2(x,y) = \frac{f^2(1+2g)^2 - w^2}{8g(g+1)(2g+1)^2} - \frac{f+2fg-w}{2g(1+2g)}\,x + \frac{f+2fg-w}{2g(g+1)(2g+1)}\,y + x^2.$$

Both these parabolas are invariant for the following family of systems:

$$\begin{aligned} \dot{x} &= \frac{f^2(1+2g)^2 - w^2}{8g(1+g)(1+2g)} + gx^2 + xy, \\ \dot{y} &= \frac{(3g+1)\left[f^2(1+2g)^2 - w^2\right]}{8g(2g+1)^2} - f(g+1)x + fy + (g-1)xy + 2y^2). \end{aligned} \tag{3.13}$$

We observe that both parabolas $\Phi_i(x,y) = 0$ $(i = 1,2)$ exist (i.e. are not reducible) if and only if $r^+ r^- \neq 0$ and this is equivalent to

$$(f + 2fg + w)(f + 2fg - w) = f^2(1+2g)^2 - w^2 \neq 0$$

and considering (3.12) this is equivalent to $a \neq 0$.

On the other hand if only one of the factors vanishes we have $a = 0$ and

$$r^+ + r^- = (f + 2fg + w) + (f + 2fg - w) = 2f(1 + 2g) \neq 0$$

and due to $1 + 2g \neq 0$ we obtain that the above condition is equivalent to $f \neq 0$. Therefore for $a = 0$ and $f \neq 0$ we could have only one parabola.

We determine that in the case $w = 0$ we obtain $\Phi_1(x, y) = \Phi_2(x, y)$, i.e. the parabolas coalesce when w tends to zero and we obtain a double parabola. On the other hand considering (3.12) for $w = 0$ we obtain to

$$a - \frac{f^2(1 + 2g)}{8g(1 + g)} = \frac{8ag(1 + g) - f^2(1 + 2g)}{8g(1 + g)} = \frac{\mathcal{F}_1}{8g(1 + g)}$$

and we conclude that these invariant parabolas coalesce if and only if $\mathcal{F}_1 = 0$.

Thus we conclude that the statements $(\boldsymbol{A_2})$, $(\boldsymbol{A_3})$ and $(\boldsymbol{A_4})$ of Lemma 3.3 are proved.

Next we observe that the family of systems (3.13) is a subfamily of (3.8) defined by the condition $e = -f(1 + g)$ (i.e. $\mathcal{D}_1 = 0$). Moreover considering (3.9) for $e = -f(1 + g)$ we obtain:

$$\Phi(x, y) = \frac{f^2(1 + 2g)^2 - w^2}{8g(g + 1)(2g + 1)^2} - \frac{f + 2fg + \varepsilon w}{2g(1 + 2g)}\, x + \frac{f + 2fg + \varepsilon w}{2g(g + 1)(2g + 1)}\, y + x^2$$

and we observe that for $\varepsilon = 1$ (respectively $\varepsilon = -1$) the above parabola coincides with the invariant parabola $\Phi_1(x, y) = 0$ (respectively $\Phi_2(x, y) = 0$) of systems (3.13).

So taking the invariant parabola $\Phi_1(x, y) = 0$ (obtained for $e = -f(1 + g)$ and $\varepsilon = 1$) we could apply the same translation (3.10) in this particular case and we arrive at the subfamily of systems (3.11) defined by the conditions $e = -f(1 + g)$ and $\varepsilon = 1$ which possess the following invariant parabola

$$\widetilde{\Phi}_1(x_1, y_1) = x_1^2 + \frac{(f + 2fg + w)}{2g(1 + g)(1 + 2g)}\, y_1.$$

Since in the considered case we have only three free parameters, we set only two new parameters as follows:

$$k = -\frac{f + 2fg + w}{2g(1 + g)(1 + 2g)}, \quad n = \frac{f + 5fg + 6fg^2 + w + 7gw}{8g(1 + 2g)} \quad \Rightarrow$$
$$f = -\frac{k + 8gk + 7g^2k + 4n}{2}, \quad w = \frac{(1 + 2g)(k + 4gk + 3g^2k + 4n)}{2}.$$

In this case after an additional rescaling (to force $k = 1$, see Remark 3.5) we arrive at the subfamily of systems $(S_{\boldsymbol{\alpha}})$ defined by the condition

$$m = (1 + 3g)(1 + 4g + 3g^2 + 2n)/4.$$

***1.2:* The case** $2g + 1 = 0$**.** Then $g = -1/2$ and evaluating Ω_1 and $\mathcal{D}_1$ we obtain

$$\Omega_1 = \left[2b(2e + f)^2 + a(a - 4e^2 - 6ef - 2f^2)\right]/8 = 0, \quad \mathcal{D}_1 = (2e + f)/2. \tag{3.14}$$

So we discuss two subcases: $\mathcal{D}_1 \neq 0$ and $\mathcal{D}_1 = 0$.

1.2.1: *The subcase* $\mathcal{D}_1 \neq 0$. Then $2e+f \neq 0$ and then the condition $\Omega_1 = 0$ gives us

$$b = -\frac{a(a-4e^2-6ef-2f^2)}{2(2e+f)^2}.$$

In this case the polynomials Eq_8 and Eq_{10} have the common factor $4a+(2e+f)r$. Therefore the equations $Eq_8 = Eq_{10} = 0$ imply $r = -4a/(2e+f)$ and we arrive at the family of systems

$$\begin{aligned} \dot{x} &= a - x^2/2 + xy, \\ \dot{y} &= -\frac{a(a-4e^2-6ef-2f^2)}{2(2e+f)^2} + ex + fy - 3xy/2 + 2y^2, \end{aligned} \tag{3.15}$$

which possess the invariant parabola

$$\Phi(x,y) = \frac{2a(a-2ef-f^2)}{(2e+f)^2} + \frac{2a}{2e+f}\,x - \frac{4a}{2e+f}\,y + x^2. \tag{3.16}$$

Evidently this conic is irreducible if and only if $a \neq 0$. This completes the proof of the statement $(\boldsymbol{A_5})$ of Lemma 3.3.

Next we show that systems (3.15) could be brought via a transformation to the canonical form $(S_{\boldsymbol{\alpha}})$. Indeed since $2e+f \neq 0$ we apply to parabola (3.16) the translation

$$x = x_1 - \frac{a}{2e+f}, \quad y = y_1 + \frac{a-4ef-2f^2}{4(2e+f)}.$$

which brings this parabola to the form $\widetilde{\Phi}(x_1,y_1) = x_1^2 - \dfrac{4a}{2e+f}\,y_1$.

On the other hand considering Observation 3.4 we apply the same translation to systems (3.15) and we set the following new notations (suggested by the above parabola and the linear parts of the transformed systems):

$$\begin{aligned} k &= \frac{4a}{2e+f}, \quad n = -\frac{(-5a+4ef+2f^2)}{4(2e+f)}, \quad m = \frac{-3a+16e^2+20ef+6f^2}{16(2e+f)} \quad \Rightarrow \\ a &= -\frac{k(k-32m-8n)}{32}, \quad e = \frac{-3k+16m+12n}{8}, \quad f = \frac{5k-16n}{8}. \end{aligned}$$

Then after an additional rescaling (to force $k = 1$, see Remark 3.5) we arrive at the subfamily of systems $(S_{\boldsymbol{\alpha}})$ defined by the condition $g = -1/2$.

1.2.2: *The subcase* $\mathcal{D}_1 = 0$. This implies $f = -2e$ and considering (3.14) we have

$$\Omega_1 = a^2/8 = 0 \;\Rightarrow\; a = 0.$$

Therefore we obtain

$$Eq_8 = 0, \quad Eq_{10} = r(32b - 8er + r^2)/32 \equiv r\phi(b,e,r)/32 = 0.$$

Since $r \neq 0$ and $\text{Discrim}[\phi, r] = 64(e^2-2b)$ we must have $e^2 - 2b \geq 0$ and we set $e^2 - 2b = w^2 \geq 0$, i.e. $b = (e^2-w^2)/2$. Then we obtain

$$\phi = (4e - r - 4w)(4e - r + 4w) \equiv \varphi_1\varphi_2 = 0.$$

If $\varphi_1 = 0$ we obtain $r = 4(e-w) \neq 0$ and we obtain the parabola

$$\Phi_1'(x,y) = -2(e^2-w^2) - 2(e-w)x + 4(e-w)y + x^2 \tag{3.17}$$

which is invariant for the family of systems

$$\dot{x} = -x^2/2 + xy,$$
$$\dot{y} = (e^2 - w^2)/2 + ex - 2ey - 3xy/2 + 2y^2. \tag{3.18}$$

In the case $\varphi_2 = 0$ we obtain $r = 4(e + w) \neq 0$ and we obtain the parabola

$$\Phi_2'(x, y) = -2(e^2 - w^2) - 2(e + w)x + 4(e + w)y + x^2$$

which is invariant for the same family of systems (3.18).

We observe that both invariant parabolas exist only for $(e - w)(e + w) = e^2 - w^2 \neq 0$ and since $b = (e^2 - w^2)/2$ we obtain that the condition $b \neq 0$ must hold.

On the other hand we could have only one invariant parabola in the case when one of the factors vanishes, i.e. $(e - w)(e + w) = 0$. So we calculate

$$(e - w) + (e + w) = 2e$$

and we conclude that in the case $b = 0$ and $e \neq 0$ systems (3.18) possess only one invariant parabola.

We determine that in the case $w = 0$ we obtain $\Phi_1'(x, y) = \Phi_2'(x, y)$, i.e. the parabolas coalesce when w tends to zero and we obtain a double parabola. On the other hand considering the relation $e^2 - 2b = w^2$ for $w = 0$ we obtain $e^2 - 2b = 0$ and hence in the case $b \neq 0$ we have two distinct invariant parabolas if $e^2 - 2b \neq 0$ and one double invariant parabola if $e^2 - 2b = 0$.

Thus we conclude that the statements $(\boldsymbol{A_6})$, $(\boldsymbol{A_7})$ and $(\boldsymbol{A_8})$ of Lemma 3.3 are proved.

Next we show that systems (3.18) could be brought via a transformation to the canonical form $(S_{\boldsymbol{\alpha}})$. Indeed we apply to parabola (3.17) the translation

$$x = x_1 + e - w, \quad y = y_1 + (3e + w)/4$$

which brings this parabola to the form $\widetilde{\Phi}(x_1, y_1) = x_1^2 + 4(e - w)\, y_1$.

On the other hand considering Observation 3.4 we apply the same translation to systems (3.18) and we set the following new notations (suggested by the above parabola and the linear parts of the transformed systems):

$$k = -4(e - w), \quad n = (-e + 5w)/4 \quad \Rightarrow$$
$$e = (-5k + 16n)/16, \quad w = (-k + 16n)/16.$$

Then after an additional rescaling (to force $k = 1$) we arrive at the subfamily of systems $(S_{\boldsymbol{\alpha}})$ defined by the conditions $g = -1/2$ and $m = (1 - 8n)/32$.

***2:* The possibility $g = 0$.** Then considering (3.5) we obtain

$$Eq_8 = 2a + er = 0, \quad Eq_{10} = (b - a)r = 0.$$

and since $r \neq 0$ we obtain $b = a$. We discuss two cases: $e \neq 0$ and $e = 0$.

***2.1:* The case $e \neq 0$.** Then we get $r = -2a/e$ and we arrive at the family of systems

$$\dot{x} = a + xy, \quad \dot{y} = a + ex + fy - xy + 2y^2, \tag{3.19}$$

which possess the invariant parabola

$$\Phi(x,y) = -\frac{af}{e} + \frac{2a}{e}x - \frac{2a}{e}y + x^2 \tag{3.20}$$

and clearly this conic is irreducible if and only if the condition $a \neq 0$ holds.

***2.2:* The case** $e = 0$**.** Then the equation $Eq_8 = 0$ gives us $a = 0$ and then the equation $Eq_{10} = br = 0$ implies $b = 0$. However in this case we get the degenerate system:

$$\dot{x} = xy, \quad \dot{y} = y(f - x + 2y).$$

So a system (3.3) with $g = 0$ possesses an invariant parabola if and only if the condition $ea \neq 0$ is satisfied. This completes the proof of the statement $(\boldsymbol{A_9})$ of Lemma 3.3.

Now we look for a transformation to brings systems (3.19) to the canonical form (S_{α}). For this we apply to parabola (3.20) the translation

$$x = x_1 - a/e, \quad y = y_1 - \frac{a+ef}{2e}$$

which brings this parabola to the form $\widetilde{\Phi}(x_1, y_1) = x_1^2 - \frac{2a}{e}y_1$.

On the other hand considering Observation 3.4 we apply the same translation to systems (3.15) and we set the following new notations (suggested by the above parabola and the linear parts of the transformed systems):

$$k = \frac{2a}{e}, \quad m = \frac{a + 2e^2 + ef}{4e}, \quad n = -\frac{a+ef}{2e} \quad \Rightarrow$$
$$a = k(2m+n)/2, \quad e = 2m+n, \quad f = -(k+4n)/2.$$

Then after an additional rescaling (to force $k = 1$) we arrive at the subfamily of systems (S_{α}) defined by the condition $g = 0$.

***3:* The possibility** $g = -1$**.** Then considering (3.5) we obtain

$$Eq_8 = 2a + (e+f)r = 0, \quad Eq_{10} = br = 0.$$

and since $r \neq 0$ we obtain $b = 0$. We discuss two cases: $e + f \neq 0$ and $e + f = 0$.

***3.1:* The case** $e + f \neq 0$**.** Then we get $r = -2a/(e+f)$ and we arrive at the family of systems

$$\dot{x} = a - x^2 + xy, \quad \dot{y} = ex + fy - 2xy + 2y^2, \tag{3.21}$$

which possess the invariant parabola

$$\Phi(x,y) = -\frac{af}{e+f} - \frac{2a}{e+f}y + x^2. \tag{3.22}$$

if $a(e+f) \neq 0$.

***3.2:* The case** $e + f = 0$**.** Then $f = -e$ and the equation $Eq_8 = 0$ gives us $a = 0$. Since $b = 0$ this leads to the degenerate system:

$$\dot{x} = -x(x-y), \quad \dot{y} = (e-2y)(x-y).$$

Thus we have proved that a system (3.3) with $g = -1$ possesses an invariant parabola if and only if the condition $a(e+f) \neq 0$ holds. This completes the proof of the statement $(\boldsymbol{A_{10}})$.

Next we show that systems (3.21) could be brought via a transformation to the canonical form (S_α). Indeed we apply to parabola (3.22) the translation

$$x = x_1, \quad y = y_1 - f/2$$

which brings this parabola to the form $\widetilde{\Phi}(x_1, y_1) = x_1^2 - \dfrac{2a}{e+f}\, y_1$.

On the other hand considering Observation 3.4 we apply the same translation to systems (3.15) and we set the following new notations (suggested by the above parabola and the linear parts of the transformed systems):

$$k = \frac{2a}{e+f}, \quad m = \frac{e+f}{2}, \quad n = -\frac{f}{2} \quad \Rightarrow$$
$$a = km, \quad e = 2(m+n), \quad f = -2n.$$

Then after an additional rescaling (to force $k = 1$) we arrive at the subfamily of systems (S_α) defined by the conditions $g = -1$.

Since all the cases are examined we deduce that Lemma 3.3 is proved. □

Invariant conditions: the case $\eta > 0$ and $\zeta_1 \neq 0$ Next we determine the affine invariant conditions for a system with $\eta > 0$ and $\zeta_1 \neq 0$ to possess an invariant parabola. According to Lemma 2.4 in this case the condition $\chi_1 = 0$ is necessary.

We prove the following theorem.

Theorem 3.6. *Assume that for a non-degenerate arbitrary quadratic system the conditions $\eta > 0$, $\chi_1 = 0$ and $\zeta_1 \neq 0$ are satisfied. Then this system could possess invariant parabolas only in one direction. More exactly it could only possess one of the following sets of invariant parabolas: $\cup$, $\Cup$ and $\cup^2$. Moreover this system has one of the above sets of parabolas if and only if $\chi_2 = 0$ and one of the following sets of conditions are satisfied, correspondingly:*

$(\mathcal{A}_1)$ $\zeta_2 \neq 0, \zeta_3 \neq 0, \zeta_4 \neq 0, \mathcal{R}_1 \neq 0 \Rightarrow \cup$;
$(\mathcal{A}_2)$ $\zeta_2 \neq 0, \zeta_3 \neq 0, \zeta_4 = 0, \mathcal{R}_2 \neq 0, \zeta_5 \neq 0 \Rightarrow \Cup$;
$(\mathcal{A}_3)$ $\zeta_2 \neq 0, \zeta_3 \neq 0, \zeta_4 = 0, \mathcal{R}_2 \neq 0, \zeta_5 = 0 \Rightarrow \cup^2$;
$(\mathcal{A}_4)$ $\zeta_2 \neq 0, \zeta_3 \neq 0, \zeta_4 = 0, \mathcal{R}_2 = 0, \zeta_5 \neq 0 \Rightarrow \cup$;
$(\mathcal{A}_5)$ $\zeta_2 \neq 0, \zeta_3 = 0, \zeta_4 \neq 0, \mathcal{R}_1 \neq 0 \Rightarrow \cup$;
$(\mathcal{A}_6)$ $\zeta_2 \neq 0, \zeta_3 = 0, \zeta_4 = 0, \mathcal{R}_2 \neq 0\ \zeta_5 \neq 0 \Rightarrow \Cup$;
$(\mathcal{A}_7)$ $\zeta_2 \neq 0, \zeta_3 = 0, \zeta_4 = 0, \mathcal{R}_2 \neq 0, \zeta_5 = 0 \Rightarrow \cup^2$;
$(\mathcal{A}_8)$ $\zeta_2 \neq 0, \zeta_3 = 0, \zeta_4 = 0, \mathcal{R}_2 = 0, \zeta_5 \neq 0 \Rightarrow \cup$;
$(\mathcal{A}_9)$ $\zeta_2 = 0, \ \zeta_6 \neq 0, \mathcal{R}_1 = 0, \mathcal{R}_2 \neq 0 \Rightarrow \cup$.

Proof. Assume that for an arbitrary non-degenerate quadratic system the condition $\eta > 0$ holds. Then according to Lemma 2.3 this system could be brought via a linear transformation to the family of systems (3.1). Forcing the condition $\chi_1 = 0$ to be fulfilled for these systems we get $(h-2)(g-2)(1+g+h) = 0$. Considering Remark 3.2 we may assume $h = 2$ and after an additional translation we arrive at the family of systems (3.3), i.e. at the systems

$$\dot{x} = a + gx^2 + xy, \quad \dot{y} = b + ex + fy + (g-1)xy + 2y^2. \tag{3.23}$$

For these systems we calculate

$$\zeta_1 = 2(g-2)(3+g), \quad \chi_2 = 384(g-2)(3+g)\Omega_1$$

and since $\zeta_1 \neq 0$ the condition $\chi_2 = 0$ is equivalent to $\Omega_1 = 0$.

Following the statements $(\mathcal{A}_1)$–$(\mathcal{A}_4)$ of the theorem for systems (3.23) we calculate:

$$\zeta_2 = 4g(g+1),\ \zeta_3 = 8(2g+1)^2,\ \zeta_4 = -(g-2)(3+g)\mathcal{D}_1/8,$$
$$\mathcal{R}_1 = 30(g-2)(3+g)(a-b+4ag-2bg+3ag^2) = 30(g-2)(3+g)\mathcal{G}_1.$$

We discuss two cases: $\zeta_2 \neq 0$ and $\zeta_2 = 0$.

***1:* The case $\zeta_2 \neq 0$.** Then $g(g+1) \neq 0$ and taking into account Lemma 3.3 we have to consider the condition $2g+1 \neq 0$ which is equivalent to $\zeta_3 \neq 0$.

***1.1:* The subcase $\zeta_3 \neq 0$.**

Then we have $2g+1 \neq 0$ and due to $\zeta_1 \neq 0$ (i.e. $(g-2)(3+g) \neq 0$) the condition $\zeta_4 \neq 0$ is equivalent to $\mathcal{D}_1 \neq 0$. So we examine two possibilities: $\zeta_4 \neq 0$ and $\zeta_4 = 0$.

1.1.1: *The possibility $\zeta_4 \neq 0$.* Then we have $\mathcal{D}_1 \neq 0$ and we observe that the condition $\mathcal{R}_1 \neq 0$ is equivalent to $\mathcal{G}_1 \neq 0$ since $\zeta_1 \neq 0$. Therefore all the conditions provided by the statement $(\boldsymbol{A_1})$ of Lemma 3.3 are satisfied and by this lemma systems (3.23) possess one invariant parabola.

1.1.2: *The possibility $\zeta_4 = 0$.* In this case due to $\zeta_1 \neq 0$ we obtain $\mathcal{D}_1 = 0$ and considering (3.4) we get:

$$\mathcal{D}_1 = e + f(1+g) = 0 \quad \Rightarrow \quad e = -f(1+g).$$

Then for systems (3.23) we obtain

$$\Omega_1 = 2\big[a(1+g)(1+3g) - b(1+2g)\big]^2$$

and due to the condition $1+2g \neq 0$ the condition $\Omega_1 = 0$ yields

$$b = \frac{a(1+g)(1+3g)}{1+2g}.$$

Therefore for systems (3.23) with the parameters e and b above determined we calculate

$$\zeta_5 = -\frac{19}{1+2g}(g-2)(3+g)\left[8ag(1+g) - f^2(1+2g)\right] = -\frac{19}{1+2g}(g-2)(3+g)\mathcal{F}_1.$$

So due to the condition $\zeta_1 \neq 0$ (i.e. $(g-2)(3+g) \neq 0$ we obtain that the condition $\mathcal{F}_1 = 0$ is equivalent to $\zeta_5 = 0$.

We determine that in the case under examination the condition $a \neq 0$ is equivalent to $\mathcal{R}_2 \neq 0$, which for systems (3.23) has the value

$$\mathcal{R}_2 = -\frac{a(g-2)(3+g)(8+27g+27g^2)}{4(1+2g)}.$$

Indeed first we observe that $\mathrm{Discrim}[8+27g+27g^2, g] = -135 < 0$ and secondly we have $(g-2)(3+g)(1+2g) \neq 0$ due to the condition $\zeta_1\zeta_3 \neq 0$. So considering Lemma 3.3 we conclude that systems (3.23) possess two parabolas if the conditions

$$\chi_1 = \chi_2 = 0,\ \zeta_1 \neq 0,\ \zeta_2 \neq 0,\ \zeta_3 \neq 0,\ \zeta_4 = 0,\ \mathcal{R}_2 \neq 0$$

hold. Moreover by Lemma 3.3 these invariant parabolas are distinct if $\zeta_5 \neq 0$, i.e. $\mathcal{F}_1 \neq 0$ (see statement $(\boldsymbol{A_2})$) and they coalesce (obtaining a double parabola) if $\zeta_5 = 0$, i.e. $\mathcal{F}_1 = 0$ (see statement $(\boldsymbol{A_3})$).

Assume now that the condition $\mathcal{R}_2 = 0$ (i.e. $a = 0$) holds. Then for systems (3.23) with $\mathcal{D}_1 = 0$ and $\Omega_1 = 0$ we calculate

$$\zeta_5 = 19f^2(g-2)(3+g)$$

and since $(g-2)(3+g) \neq 0$ (due to $\zeta_1 \neq 0$) we conclude that the condition $f \neq 0$ is equivalent to $\zeta_5 \neq 0$. So we get the conditions provided by Lemma 3.3 (see statement $(\boldsymbol{A_4})$) and therefore we have one simple invariant parabola.

***1.2:* The subcase $\zeta_3 = 0$.** Then $1+2g = 0$, i.e. $g = -1/2$ and for systems (3.23) calculations yield:

$$\zeta_1 = -25/2,\ \zeta_2 = -1,\ \zeta_4 = 25(2e+f)/64 = 25\mathcal{D}_1/32,$$
$$\chi_2 = -300\big[2b(2e+f)^2 + a(a-4e^2-6ef-2f^2)\big].$$

So considering Lemma 3.3 (see statements $(\boldsymbol{A_5})$–$(\boldsymbol{A_8})$) we discuss two possibilities: $\zeta_4 \neq 0$ and $\zeta_4 = 0$.

1.2.1:* *The possibility $\zeta_4 \neq 0$. Then $2e+f \neq 0$ and the condition $\chi_2 = 0$ gives us

$$b = -\frac{a(a-4e^2-6ef-2f^2)}{2(2e+f)^2}.$$

So according to Lemma 3.3 (see statements $(\boldsymbol{A_5})$) systems (3.23) with $g = -1/2$ and the above given value of the parameter b possess one invariant parabola if in addition the condition $a \neq 0$ holds. It remains to observe that this condition is governed by the invariant polynomial $\mathcal{R}_1$ because for these systems we have $\mathcal{R}_1 = 375a/8$.

1.2.2:* *The possibility $\zeta_4 = 0$. Then we have $\mathcal{D}_1 = 0$ which implies $f = -2e$ and then we obtain $\chi_2 = -300a^2 = 0$, i.e. $a = 0$. As a result we arrive at the family of systems

$$\dot{x} = -x^2/2 + xy, \quad \dot{y} = b + ex - 2ey - 3xy/2 + 2y^2 \tag{3.24}$$

for which we calculate

$$\zeta_1 = -25/2,\ \zeta_2 = -1,\ \zeta_3 = \zeta_4 = \mathcal{R}_1 = 0,\ \ \mathcal{R}_2 = -125b/16,\ \zeta_5 = 475(2b-e^2).$$

So considering the statements $(\boldsymbol{A_6})$ and $(\boldsymbol{A_7})$ of Lemma 3.3 we deduce that in the case $\mathcal{R}_2 \neq 0$ (i.e. $b \neq 0$) systems (3.24) possess two distinct invariant parabolas if $\zeta_5 \neq 0$ and one double invariant parabola if $\zeta_5 = 0$.

Assuming $\mathcal{R}_2 = 0$ (i.e. $b = 0$) considering the value of the invariant polynomial ζ_5 given above we get $\zeta_5 = -475e^2$ and hence the condition $e \neq 0$ is equivalent to $\zeta_5 \neq 0$.

So we get the conditions provided by the statement $(\boldsymbol{A_8})$ of Lemma 3.3 and therefore systems (3.24) possess one simple invariant parabola.

***2:* The case $\zeta_2 = 0$.** Then we have $g(g+1) = 0$, i.e. either $g = 0$ or $g = -1$. We discuss each one of these possibilities.

2.1:* *The possibility $g = 0$. Then for for systems (3.23) we calculate

$$\chi_2 = -2304(a-b)(2a-2b-e^2-ef),\ \mathcal{R}_1 = -180(a-b).$$

According to the statement $(\boldsymbol{A_9})$ of Lemma 3.3 for the existence of invariant parabola the condition $b = a$ is necessary, i.e. we must have $\mathcal{R}_1 = 0$ and this implies $\chi_2 = 0$. Setting $b = a$ we obtain

$$\zeta_6 = e/2,\ \ \mathcal{R}_2 = 12a$$

and considering the statements (A_9) the condition $\zeta_6\mathcal{R}_2 \neq 0$ must be satisfied for the existence of an invariant parabola.

2.2: *The possibility* $g = -1$. In this case for systems (3.23) we obtain

$$\chi_2 = -2304b(2b + e^2 + ef), \; \mathcal{R}_1 = -180b.$$

Considering the statement (A_{10}) of Lemma 3.3 we deduce that for the existence of an invariant parabola the condition $b = 0$ is necessary, i.e. we must have $\mathcal{R}_1 = 0$ and this implies $\chi_2 = 0$. Setting $b = 0$ we calculate

$$\zeta_6 = -(e + f)/2, \;\; \mathcal{R}_2 = -12a$$

and therefore by the statements (A_{10}) the condition $\zeta_6\mathcal{R}_2 \neq 0$ must be satisfied for the existence of an invariant parabola.

We observe that in both cases $g = 0$ and $g = -1$ we have obtained the same invariant conditions $\mathcal{R}_1 = 0$ and $\zeta_6\mathcal{R}_2 \neq 0$. This completes the proof of the statement $(\boldsymbol{\mathcal{A}_9})$ of Theorem 3.6 as well as the proof of Theorem 3.6. □

3.1.2 The possibility $\chi_1 = \zeta_1 = 0$

Next we consider the case when systems (3.1) could possess invariant parabolas in two directions. Then two factors of χ_1 from (3.2) vanish. According to Remark 3.2 we could consider $h = 2 = g$ and due to the translation $(x, y) \mapsto (x - d, y - e)$ (forcing $d = e = 0$) we arrive at the family of systems

$$\dot{x} = a + cx + 2x^2 + xy, \quad \dot{y} = b + fy + xy + 2y^2. \tag{3.25}$$

Coefficient conditions for systems (3.25) to possess invariant parabolas. By Lemma 3.1 systems (3.25) could possess invariant parabolas either of the form $\Phi(x, y) = p + qx + ry + x^2$ $(r \neq 0)$ or of the form $\Phi(x, y) = p + qx + ry + y^2$ $(q \neq 0)$. We prove the following lemma.

Lemma 3.7. *A system (3.25) possesses either one or two invariant parabolas or a double invariant parabola of the indicated form if and only if the corresponding set of conditions are satisfied, respectively:*

$(\boldsymbol{B})$ $\Phi(x, y) = p + qx + ry + x^2 \quad \Leftrightarrow \quad \Omega_1' = 0$ *and either*

- $(\boldsymbol{B_1})$ $\mathcal{D}_1' \neq 0, \mathcal{G}_1' \neq 0 \Rightarrow$ *one invariant parabola; or*
- $(\boldsymbol{B_2})$ $\mathcal{D}_1' = 0, a \neq 0, \mathcal{F}_1' \neq 0 \Rightarrow$ *two invariant parabolas; or*
- $(\boldsymbol{B_3})$ $\mathcal{D}_1' = 0, a \neq 0, \mathcal{F}_1' = 0 \Rightarrow$ *one double invariant parabola; or*
- $(\boldsymbol{B_4})$ $\mathcal{D}_1' = 0, a = 0, c \neq 0 \Rightarrow$ *one invariant parabola.*

$(\boldsymbol{B'})$ $\Phi(x, y) = p + qx + ry + y^2 \quad \Leftrightarrow \quad \Omega_2' = 0$ *and either*

- $(\boldsymbol{B_1'})$ $\mathcal{D}_2' \neq 0, \mathcal{G}_2' \neq 0 \Rightarrow$ *one invariant parabola; or*
- $(\boldsymbol{B_2'})$ $\mathcal{D}_2' = 0, b \neq 0, \mathcal{F}_2' \neq 0 \Rightarrow$ *two invariant parabolas; or*
- $(\boldsymbol{B_3'})$ $\mathcal{D}_2' = 0, b \neq 0, \mathcal{F}_2' = 0 \Rightarrow$ *one double invariant parabola; or*
- $(\boldsymbol{B_4'})$ $\mathcal{D}_2' = 0, b = 0, f \neq 0 \Rightarrow$ *one invariant parabola.*

where

$$\begin{aligned}
&\Omega_1' = 50b^2 + b(109c^2 - 420a - 53cf - 6f^2) + 3(6a - c^2 + cf)(49a - 6c^2 - cf + 2f^2);\\
&\mathcal{D}_1' = 13c - 3f;\;\; \mathcal{G}_1' = 21a - 5b - 10c^2 + 5cf;\\
&\mathcal{F}_1' = 15a - 15b - 2c^2 + 2f^2;\\
&\Omega_2' = 50a^2 + a(109f^2 - 420b - 53cf - 6c^2) + 3(6b - f^2 + cf)(49b - 6f^2 - cf + 2c^2);\\
&\mathcal{D}_2' = 13f - 3c;\;\; \mathcal{G}_2' = 21b - 5a - 10f^2 + 5cf;\\
&\mathcal{F}_2' = 15b - 15a - 2f^2 + 2c^2.
\end{aligned} \tag{3.26}$$

Proof. Considering the equations (2.6) we examine each one of the statements of the above lemma.

(B) $\Phi(x,y) = p + qx + ry + x^2$ with $r \neq 0$. In this case we obtain

$$s = 1,\; v = u = 0,\; U = 4,\; V = 2,\; W = 2(c - q),$$
$$Eq_1 = Eq_2 = Eq_3 = Eq_4 = Eq_5 = Eq_7 = 0.$$

Calculating the remaining equations we have

$$Eq_6 = -q - 3r,\;\; Eq_8 = 2a - 4p - cq + 2q^2,$$
$$Eq_9 = -2p - 2cr + fr + 2qr,\;\; Eq_{10} = aq - 2cp + 2pq + br.$$

It is clear that the equations $Eq_6 = 0$ implies $q = -3r$ whereas $Eq_9 = 0$ gives us $p = -r(2c - f + 6r)/2$. Therefore calculations yield

$$Eq_8 = 2a + (7c - 2f)r + 30r^2,$$
$$Eq_{10} = r\big[b - 3a + 2c^2 - cf + 3(4c - f)r + 18r^2\big] \equiv r\Psi'(a,b,c,f,r)$$

and since $r \neq 0$ the equation $Eq_{10} = 0$ is equivalent to $\Psi' = 0$.

According to [12, Lemmas 11,12] the equations $Eq_8 = 0$ and $\Psi' = 0$ have a common solution of degree 2 with respect to the parameter r if and only if

$$Res_r^{(0)}\,(Eq_8, \Psi') = Res_r^{(1)}\,(Eq_8, \Psi) = 0$$

where $Res_r^{(1)}$ is the subresultant of order one and $Res_r^{(0)}$ is the subresultant of order zero which coincide with standard resultant (for detailed definition see [12], formula (19)). We calculate

$$Res_r^{(1)}\,(Eq_8, \Psi) = 18(13c - 3f) \equiv 18\mathcal{D}_1', \quad Res_r^{(0)}\,(Eq_8, \Psi) \;\; = 18\Omega_1'.$$

So we examine two possibilities: $\mathcal{D}_1' \neq 0$ and $\mathcal{D}_1' = 0$.

1: **The possibility** $\mathcal{D}_1' \neq 0$**.** Therefore the equations $Eq_8 = 0$ and $\Psi' = 0$ could have a unique common solution with respect to the parameter r and for this it is necessary and sufficient $\Omega_1' = 0$. So we have to examine the solutions of the equation $\Omega_1' = 0$. In this case we calculate

$$\text{Discrim}[\Omega_1', b] = -(13c - 3f)^2(240a - 49c^2 + 28cf - 4f^2) \equiv -\mathcal{D}_1'^2\mathcal{E}'$$

and hence the equation $\Omega_1' = 0$ has real solutions with respect to the parameter b if and only if either $\mathcal{D}_1' = 0$ or $\mathcal{E}' \leq 0$. However since the condition $\mathcal{D}_1' \neq 0$ holds it remains to examine the condition $\mathcal{E}' \leq 0$. In this case setting $\mathcal{E}' = -w^2 \leq 0$ we calculate

$$a = \frac{(7c - 2f)^2 - w^2}{240} \tag{3.27}$$

and then we obtain $\Omega_1' = (E_+E_-)/3200$, where

$$E_\pm = 400b + 93c^2 - 16cf - 52f^2 + 4\varepsilon(13c - 3f)w + 7w^2, \quad \varepsilon = \pm 1.$$

Then the condition $\Omega_1' = 0$ gives us

$$b = -\frac{1}{400}(3c + 2f + \varepsilon w)(31c - 26f + 7\varepsilon w) \tag{3.28}$$

where $\varepsilon = 1$ if $E_+ = 0$ and $\varepsilon = -1$ if $E_- = 0$. In this case we obtain that the polynomials Eq_8 and $\Psi(c, f, r)$ have the common factor $\zeta = (7c - 2f + 60r - \varepsilon w)$ which is linear with respect to the parameter r. Setting $\zeta = 0$ we get

$$r = \frac{2f - 7c + \varepsilon w}{60}$$

and we arrive at the family of systems

$$\begin{aligned} \dot{x} &= \frac{(7c - 2f)^2 - w^2}{240} + cx + 2x^2 + xy, \\ \dot{y} &= -\frac{(3c + 2f + \varepsilon w)(31c - 26f + 7\varepsilon w)}{400} + fy + xy + 2y^2. \end{aligned} \tag{3.29}$$

This family of systems possess the following invariant parabola

$$\Phi(x, y) = \frac{(7c - 2f - \varepsilon w)(13c - 8f + \varepsilon w)}{1200} + \frac{(7c - 2f - \varepsilon w)}{20}x - \frac{(7c - 2f - \varepsilon w)}{60}y + x^2. \tag{3.30}$$

We observe that this conic is reducible if and only if $7c - 2f - \varepsilon w = 0$.

Considering (3.27) and (3.28) we get

$$w^2 = -240a + (7c - 2f)^2$$

and then we obtain

$$\begin{gathered} b = -\frac{1}{400}\big[(31c - 26f)(3c + 2f) + 4(13c - 3f)\varepsilon w + 7w^2\big] \;\Rightarrow \\ 100b - 420a + 109c^2 - 53cf - 6f^2 + (13c - 3f)\varepsilon w = 0. \end{gathered}$$

Since $\mathcal{D}_1' = 13c - 3f \neq 0$ we solve the last equation with respect to εw and we obtain

$$\varepsilon w = \frac{1}{13c - 3f}\big(420a - 100b - 109c^2 + 53cf + 6f^2\big).$$

Then calculations yield

$$r = \frac{(-7c + 2f + \varepsilon w)}{60} = \frac{21a - 5b - 10c^2 + 5cf}{3(13c - 3f)} = \frac{\mathcal{G}_1'}{3(13c - 3f)} \neq 0.$$

This completes the proof of the statement $(\boldsymbol{B_1})$ of Lemma 3.3.

Next we show that systems (3.29) could be brought via a transformation to the canonical form $(S_{\boldsymbol{\alpha}})$. Indeed we apply to parabola (3.30) the translation

$$x = x_1 + \frac{2f - 7c + \varepsilon w}{40}, \quad y = y_1 + \frac{31c - 26f + 7\varepsilon w}{80}.$$

which brings this parabola to the form $\widetilde{\Phi}(x_1, y_1) = x_1^2 + \dfrac{2f - 7c + \varepsilon w}{60} y_1$.

On the other hand considering Observation 3.4 we apply the same translation to systems (3.29) and we set the following new notations (suggested by the above parabola and the linear parts of the transformed systems):

$$k = -\frac{2f - 7c + \varepsilon w}{60}, \quad m = -\frac{31c - 26f + 7\varepsilon w}{160}, \quad n = \frac{11c - 2f + 3\varepsilon w}{16} \quad \Rightarrow$$
$$c = 6k - 2m + n, \quad f = \frac{3k - 16m + 4n}{2}, \quad \varepsilon w = -21k + 2m + 3n.$$

Then after an additional rescaling (to force $k = 1$) we arrive at the subfamily of systems $(S_{\boldsymbol{\alpha}})$ defined by the conditions $g = 2$.

2: The possibility $\mathcal{D}_1' = 0$. Then $f = 13c/3$ and therefore we obtain:

$$\Omega_1' = 2(63a - 15b + 35c^2)^2/9$$

and hence the condition $\Omega_1' = 0$ implies

$$b = 7(9a + 5c^2)/15.$$

Therefore we determine that in this case the polynomials Eq_8 and Eq_{10} have the following common factor

$$\phi' = 6a - 5cr + 90r^2.$$

We observe that ϕ' is quadratic in r with the discriminant

$$\text{Discrim}[\phi', r] = -5(432a - 5c^2)$$

and setting this discriminant equal to be w^2 we obtain

$$a = \frac{25c^2 - w^2}{2160}. \tag{3.31}$$

Then we arrive at the following expressions for the polynomials Eq_8 and Eq_{10}:

$$Eq_{10} = \frac{3r}{5} Eq_8 = \frac{r(5c - 180r + w)(5c - 180r - w)}{1800} = \frac{rU_+U_-}{1800}.$$

Therefore the equations $Eq_8 = Eq_{10} = 0$ imply $U_+U_- = 0$. If $U_+ = 0$ we determine

$$r = \frac{5c + w}{180} \equiv r^+$$

and we obtain the parabola

$$\Phi_1'(x, y) = \frac{(65c - w)(5c + w)}{10800} - \frac{5c + w}{60} x + \frac{5c + w}{180} y + x^2. \tag{3.32}$$

In the case $U_- = 0$ we obtain

$$r = \frac{5c + w}{180} \equiv r^-$$

and we get the parabola

$$\Phi_2'(x, y) = \frac{(65c + w)(5c - w)}{10800} - \frac{5c - w}{60} x + \frac{5c - w}{180} y + x^2.$$

Both these parabolas are invariant for the following family of systems:

$$\dot{x} = \frac{25c^2 - w^2}{2160} + cx + 2x^2 + xy, \quad \dot{y} = \frac{7(1225c^2 - w^2)}{3600} + \frac{13c}{3}y + xy + 2y^2. \tag{3.33}$$

We observe that both parabolas $\Phi_i'(x,y) = 0$ $(i = 1,2)$ exist (i.e. are not reducible) if and only if $r^+r^- \neq 0$ and this is equivalent to

$$(5c + w)(5c - w) = 25c^2 - w^2$$

and considering (3.31) this is equivalent to $a \neq 0$.

On the other hand if only one of the factors vanishes we have $a = 0$ and

$$r^+ + r^- = (5c + w) + (5c - w) = 10c \neq 0.$$

Therefore for $a = 0$ and $c \neq 0$ we could have only one parabola.

We determine that in the case $w = 0$ we obtain $\Phi_1'(x,y) = \Phi_2'(x,y)$, i.e. the parabolas coalesce when w tends to zero and we obtain a double parabola. On the other hand considering (3.31) for $w = 0$ we obtain

$$a - \frac{25c^2}{2160} = \frac{432a - 5c^2}{432} = -\frac{9}{432}\mathcal{F}_1'$$

and we conclude that these invariant parabolas coalesce if and only if $\mathcal{F}_1' = 0$.

Thus we conclude that the statements $(\boldsymbol{B_2})$, $(\boldsymbol{B_3})$ and $(\boldsymbol{B_4})$ of Lemma 3.7 are proved.

Next we show that systems (3.33) could be brought via a transformation to the canonical form $(S_{\boldsymbol{\alpha}})$. Indeed we could apply to parabola (3.32) the translation

$$x = x_1 + \frac{5c + w}{120}, \quad y = y_1 - \frac{7(35c - w)}{240}$$

which brings this parabola to the form $\widetilde{\Phi}(x_1, y_1) = x_1^2 + \dfrac{5c + w}{180}y_1$.

On the other hand considering Observation 3.4 we apply the same translation to systems (3.29) and we set the following new notations (suggested by the above parabola and the linear parts of the transformed systems):

$$k = -\frac{5c + w}{180}, \quad n = \frac{7c + 3w}{48} \quad \Rightarrow \quad c = -3(45k + 4n)/2, \quad w = 15(21k + 4n)/2.$$

Then after an additional rescaling (to force $k = 1$) we arrive at the subfamily of systems $(S_{\boldsymbol{\alpha}})$ defined by the conditions $g = 2$ and $m = 7(21k + 2n)/4$.

$(\boldsymbol{B'})$ $\Phi(x,y) = p + qx + ry + y^2$ with $q \neq 0$ otherwise we get a reducible conic. It is not too difficult to detect that this case can be brought to the case $(\boldsymbol{B})$ if we apply two changes: one in systems (3.25) and another in the formula of conic (2.4). More precisely the change

$$(x, y, a, b, c, f) \mapsto (y, x, b, a, f, c) \tag{3.34}$$

conserves systems (3.25) whereas the change

$$(x, y, p, q, r, s, v, u) \to (y, x, p, r, q, u, v, s)$$

conserves the conic (2.4). We observe that the second change transfers the parabola $\Phi(x,y) = p + qx + ry + x^2$ to the parabola $\Phi(x,y) = p + qx + ry + y^2$ and at the same time the first change transfers the conditions $(\boldsymbol{B_i})$, $i = 1,2,3,4$ from the statement $(\boldsymbol{B})$ of Lemma 3.7 to the conditions $(\boldsymbol{B_i'})$, $i = 1,2,3,4$ from the statement $(\boldsymbol{B'})$ of the same lemma, correspondingly. Since the conditions of the statement $(\boldsymbol{B})$ are proved, we conclude that the conditions of the statement $(\boldsymbol{B'})$ of Lemma 3.7 are also valid. This completes the proof of Lemma 3.7. □

We point out that Theorem 3.6 provides the necessary and sufficient conditions for the existence of invariant parabolas for an arbitrary quadratic systems with the conditions $\eta > 0$, $\chi_1 = 0$ and $\zeta_1 \neq 0$. As it was mentioned earlier (see page 16) the condition $\zeta_1 \neq 0$ does not allow this system to possess invariant parabolas in two directions.

Invariant conditions: the case $\eta > 0$ and $\zeta_1 = 0$ Next we consider the class of quadratic systems for which the conditions $\eta > 0$ and $\zeta_1 = 0$, which could possess invariant parabolas in two directions.

We prove the following theorem.

Theorem 3.8. *Assume that for a non-degenerate arbitrary quadratic system the conditions $\eta > 0$ and $\chi_1 = \zeta_1 = 0$ are satisfied. Then this system could possess invariant parabolas in one or two directions. More exactly it could only possess one of the following sets of invariant parabolas: $\cup$, $\Cup$, $\cup^2$, $\cup\subset$ and $\Cup\subset$. Moreover this system has one of the above sets of invariant parabolas if and only if $\chi_3 = 0$ and one of the following sets of conditions are satisfied, correspondingly:*

$(\mathcal{B}_1)$ $\chi_4 \neq 0,\ \zeta_7 \neq 0,\ \mathcal{R}_3 \neq 0 \Rightarrow \cup;$
$(\mathcal{B}_2)$ $\chi_4 \neq 0,\ \zeta_7 = 0,\ \mathcal{R}_4 \neq 0,\ \zeta_8 \neq 0 \Rightarrow \Cup;$
$(\mathcal{B}_3)$ $\chi_4 \neq 0,\ \zeta_7 = 0,\ \mathcal{R}_4 \neq 0,\ \zeta_8 = 0 \Rightarrow \cup^2;$
$(\mathcal{B}_4)$ $\chi_4 \neq 0,\ \zeta_7 = 0,\ \mathcal{R}_4 = 0 \Rightarrow \cup;$
$(\mathcal{B}_5)$ $\chi_4 = 0,\ \zeta_5 \neq 0,\ \zeta_9 \neq 0 \Rightarrow \cup\subset;$
$(\mathcal{B}_6)$ $\chi_4 = 0,\ \zeta_5 \neq 0,\ \zeta_9 = 0,\ \zeta_{10} \neq 0 \Rightarrow \cup;$
$(\mathcal{B}_7)$ $\chi_4 = 0,\ \zeta_5 = 0,\ \zeta_6 \neq 0 \Rightarrow \Cup\subset.$

Proof. As it was shown earlier (see page 29) if for a quadratic system with three real infinite singularities the conditions $\chi_1 = \zeta_1 = 0$ are satisfied, then via an affine transformation and time rescaling this system can be brought to the form (3.25). Thus in what follows we consider the family of quadratic systems

$$\dot{x} = a + cx + 2x^2 + xy, \quad \dot{y} = b + fy + xy + 2y^2. \tag{3.35}$$

Considering (3.26) for these systems we calculate

$$\chi_1 = \chi_2 = \zeta_1 = 0, \;\; \chi_3 = 2^4 3^4 5^3 83 \cdot 491\, \Omega_1' \Omega_2', \;\; \chi_4 = 123750(\Omega_1' + \Omega_2')$$

and therefore the condition $\chi_3 = 0$ yields $\Omega_1'\Omega_2' = 0$, i.e. one of the necessary conditions provided either by the statement $(\boldsymbol{B})$ of Lemma 3.7 or by the statement $(\boldsymbol{B'})$ of this lemma is satisfied. We discuss two cases: $\chi_4 \neq 0$ and $\chi_4 = 0$.

1: **The case $\chi_4 \neq 0$.** Then $\Omega_1' + \Omega_2' \neq 0$ and we conclude that only one of the polynomials Ω_1' or Ω_2' vanishes. Considering the change (3.34) we may assume without losing generality that the conditions $\Omega_1' = 0$ and $\Omega_2' \neq 0$ are fulfilled.

On the other hand for systems (3.35) we calculate

$$\zeta_7 = 105750\big(\mathcal{D}_2'\Omega_1' + \mathcal{D}_1'\Omega_2'\big), \quad \mathcal{R}_3 = 5134081342500\big(\mathcal{G}_2'\Omega_1' + \mathcal{G}_1'\Omega_2'\big).$$

Therefore since $\Omega_1' = 0$ and $\Omega_2' \neq 0$ we obtain that the condition $\mathcal{D}_1' = 0$ is equivalent to $\zeta_7 = 0$. Moreover in this case the condition $\mathcal{R}_3 \neq 0$ is equivalent to $\mathcal{G}_1' \neq 0$. So we discuss two subcases: $\zeta_7 \neq 0$ and $\zeta_7 = 0$.

1.1: **The subcase $\zeta_7 \neq 0$.** Then $\mathcal{D}_1' \neq 0$ and by Lemma 3.7 (see statement $(\boldsymbol{B_1})$) we deduce that systems (3.25) possess one invariant parabola if and only if $\mathcal{G}_1' \neq 0$. Due to $\Omega_1' = 0$ and

$\Omega'_2 \neq 0$ this condition is equivalent to $\mathcal{R}_3 \neq 0$ and we conclude that the statement $(\boldsymbol{\mathcal{B}_1})$ of Theorem 3.8 is proved.

***1.2:* The subcase $\zeta_7 = 0$.** This implies $\mathcal{D}'_1 = 13c - 3f = 0$, i.e. $f = 13c/3$ and then we get

$$\Omega'_1 = 2(63a - 15b + 35c^2)^2/9 = 0 \;\Rightarrow\; b = 7(9a + 5c^2)/15.$$

So we arrive at the family of systems

$$\dot{x} = a + cx + 2x^2 + xy, \quad \dot{y} = \frac{7}{15}(9a + 5c^2) + \frac{13c}{3}y + xy + 2y^2, \tag{3.36}$$

for which we calculate

$$\zeta_8 = -(432a - 5c^2)/9 = \mathcal{F}'_1, \quad \mathcal{R}_4 = 15600a.$$

We observe that the condition $\mathcal{R}_4 \neq 0$ is equivalent to $a \neq 0$ and therefore by Lemma 3.7 in the case $\mathcal{R}_4 \neq 0$ systems (3.36) possess two distinct parabolas in one direction (see statement $(\boldsymbol{B_2})$) if $\zeta_8 \neq 0$ and they possess one double invariant parabola (see statement $(\boldsymbol{B_3})$) if $\zeta_8 = 0$. This means that the statements $(\boldsymbol{\mathcal{B}_2})$ and $(\boldsymbol{\mathcal{B}_3})$ of Theorem 3.8 are proved.

Assume now that the condition $\mathcal{R}_4 = 0$ holds. Then $a = 0$ and for systems (3.36) we have $\chi_4 = 110000c^4 \neq 0$. Then according to the statement $(\boldsymbol{B_4})$ of Lemma 3.7 we conclude that these systems possess one invariant parabola and therefore the statements $(\boldsymbol{\mathcal{B}_4})$ of Theorem 3.8 is valid.

***2:* The case $\chi_4 = 0$.** Then we get $\Omega'_1 = \Omega'_2 = 0$ and since for systems (3.35) we have

$$\begin{aligned} \zeta_5 &= 25(13c - 3f)(13f - 3c)/4 = 25\mathcal{D}'_1\mathcal{D}'_2/4, \\ \zeta_9 &= -990000(21a - 5b - 10c^2 + 5cf)(5a - 21b - 5cf + 10f^2) = 990000\mathcal{G}'_1\mathcal{G}'_2, \\ \zeta_{10} &= 5(8a + 8b - 5c^2 + 5cf - 5f^2)/4 = 5(\mathcal{G}'_1 + \mathcal{G}'_2)/8. \end{aligned} \tag{3.37}$$

We examine two subcases: $\zeta_5 \neq 0$ and $\zeta_5 = 0$.

***2.1:* The subcase $\zeta_5 \neq 0$.** Then $\mathcal{D}'_1\mathcal{D}'_2 \neq 0$ and by Lemma 3.7 (see statements $(\boldsymbol{A'_1})$ and $(\boldsymbol{B'_1})$) we have one invariant parabola in the direction $x = 0$ if $\mathcal{G}'_1 \neq 0$ and one in the direction $y = 0$ if $\mathcal{G}'_2 \neq 0$. So considering (3.37) we examine two possibilities: $\zeta_9 \neq 0$ and $\zeta_9 = 0$.

2.1.1: *The possibility $\zeta_9 \neq 0$.* This implies $\mathcal{G}'_1\mathcal{G}'_2 \neq 0$ and by Lemma 3.7 in this case we have one invariant parabola in one direction and another invariant parabola in other direction. So the statement $(\boldsymbol{\mathcal{B}_5})$ of Theorem 3.8 is proved.

2.1.2: *The possibility $\zeta_9 = 0$.* Then we have $\mathcal{G}'_1\mathcal{G}'_2 = 0$, i.e. at least one of the factors vanishes. Considering (3.37) we conclude that both factors vanish if and only if $\zeta_{10} = 0$. In this case $\mathcal{G}'_1 = \mathcal{G}'_2 = 0$ and by Lemma 3.7 (see statements $(\boldsymbol{B_1})$ and $(\boldsymbol{B'_1})$) systems (3.25) could not possess any invariant parabolas.

On the other hand in the case $\zeta_{10} \neq 0$ we have $\mathcal{G}'_1 + \mathcal{G}'_2 \neq 0$ and since $\mathcal{G}'_1\mathcal{G}'_2 = 0$, by Lemma 3.7 we have one invariant parabola (either in direction $y = 0$ if $\mathcal{G}'_1 = 0$ or in direction $x = 0$ if $\mathcal{G}'_2 = 0$. This means that the statement $(\boldsymbol{\mathcal{B}_6})$ of Theorem 3.8 is valid.

***2.2:* The subcase $\zeta_5 = 0$.** In this case we get $\mathcal{D}'_1\mathcal{D}'_2 = 0$. On the other hand we obtain $\mathcal{D}'_1 + \mathcal{D}'_2 = 10(c + f)$ and hence both $\mathcal{D}'_1$ and $\mathcal{D}'_2$ vanish if and only if $c + f = 0$ and this condition is governed by the invariant polynomial $\zeta_6 = -(c + f)/2$. So we discuss two possibilities: $\zeta_6 \neq 0$ and $\zeta_6 = 0$.

2.2.1: *The possibility* $\zeta_6 \neq 0$. Then only one of the polynomials $\mathcal{D}'_1$ or $\mathcal{D}'_2$ vanishes and due to the change $(x, y, a, b, c, f) \mapsto (y, x, b, a, f, c)$ without losing generality we may assume that for systems (3.25) the condition $\mathcal{D}'_1 = 0$ holds. Considering (3.26) this condition implies $f = 13c/3$ and then we obtain

$$\Omega'_1 = 2(63a - 15b + 35c^2)^2/9 = 0 \Rightarrow b = 7(9a + 5c^2)/15.$$

Therefore we calculate

$$\Omega'_2 = 8(144a + 5c^2)(2704a + 5c^2)/225, \quad \zeta_6 = -8c/3 \neq 0$$

and the condition $\Omega'_2 = 0$ gives us either $a = -5c^2/144 \neq 0$ or $a = -5c^2/2704 \neq 0$ (due to $\zeta_6 \neq 0$). In this case we get either

$$\mathcal{F}'_1 = 20c^2/9 \neq 0, \quad \mathcal{G}'_2 = -120c^2 \neq 0$$

if $a = -5c^2/144$ or

$$\mathcal{F}'_1 = 980c^2/1521 \neq 0, \quad \mathcal{G}'_2 = -13720c^2/117 \neq 0$$

if $a = -5c^2/2704$. So considering the statements $(\boldsymbol{B_2})$ and $(\boldsymbol{B'_1})$ of Lemma 3.7 we conclude that systems (3.25) possess two distinct invariant parabolas in the direction $x = 0$ and one invariant parabola in the direction $y = 0$. This means that the statement $(\boldsymbol{\mathcal{B}_7})$ of Theorem 3.8 is valid.

2.2.2: *The possibility* $\zeta_6 = 0$. This condition implies $\mathcal{D}'_1 = \mathcal{D}'_2 = 0$ and considering (3.26) we obtain $c = f = 0$. Then we obtain

$$\Omega'_1 = 2(21a - 5b)^2, \quad \Omega'_2 = 2(5a - 21b)^2$$

and evidently the conditions $\Omega'_1 = \Omega'_2 = 0$ imply $a = b = 0$. Therefore we arrive at the following homogeneous system

$$\dot{x} = x(2x + y), \quad \dot{y} = y(x + 2y)$$

that could not possess any invariant parabola.

Since all the possibilities are examined we conclude that Theorem 3.8 is proved. □

3.2 Systems with one real and two complex infinite singularities

In this case according to Lemma 2.3 systems (2.5) could be brought via a linear transformation to the following family of systems

$$\begin{aligned} \frac{dx}{dt} &= a + cx + dy + gx^2 + (h+1)xy, \\ \frac{dy}{dt} &= b + ex + fy - x^2 + gxy + hy^2. \end{aligned} \tag{3.38}$$

For these systems we calculate

$$C_2(x, y) = x(x^2 + y^2), \quad \chi_1 = -2(2 + h)\left[g^2 + (h-3)^2\right] \tag{3.39}$$

and by Lemma 2.6 we conclude that the above systems could have invariant parabolas only of the form $\Phi(x, y) = p + qx + ry + x^2$ with $r \neq 0$ (otherwise we get a reducible conic).

On the other hand according to Lemma 2.4 for a system (3.38) to possess an invariant parabola the condition $\chi_1 = 0$ is necessary. Considering (3.39) this condition implies either $h = -2$ or $g = 0 = h - 3$. We claim that in the second case systems (3.38) could not possess any invariant parabola.

Indeed, assuming $g = 0$ and $h = 3$ and using a translation we may assume $c = d = 0$ and we arrive at the family of systems

$$\dot{x} = a + 4xy, \quad \dot{y} = b + ex + fy - x^2 + 3y^2. \tag{3.40}$$

Considering equations (2.6) and the form of the parabola $\Phi(x, y) = p + qx + ry + x^2$ with $r \neq 0$, for systems (3.40) we have

$$s = 1,\ v = u = 0,\ Eq_2 = 8 - V, Eq_7 = r(3 - V).$$

Evidently the conditions $Eq_2 = 0$ and $Eq_7 = 0$ imply $r = 0$, i.e. the conic $\Phi(x, y) = p + qx + ry + x^2$ with $r = 0$ is reducible and this completes the proof of our claim.

For systems (3.38) we calculate

$$\zeta_1 = -2\big[(h-3)(1+h)(2h-1) + g^2(3+2h)\big]$$

and clearly the conditions $g = 0$ and $h = 3$ imply $\zeta_1 = 0$. On the other hand for $h = -2$ we get $\zeta_1 = 2(25 + g^2) \neq 0$ and therefore the condition $h + 2 = 0$ is equivalent to $\chi_1 = 0$ and $\zeta_1 \neq 0$. So we have the next remark.

Remark 3.9. If a system (3.38) possesses an invariant parabola then the conditions $\chi_1 = 0$ and $\zeta_1 \neq 0$ are necessary.

According to this remark we assume that the conditions $\chi_1 = 0$ and $\zeta_1 \neq 0$ are fulfilled for systems (3.38). Then the condition $h = -2$ holds and due to a translation we may consider $c = d = 0$. So we arrive at the family of systems

$$\dot{x} = a + gx^2 - xy, \quad \dot{y} = b + ex + fy - x^2 + gxy - 2y^2. \tag{3.41}$$

3.2.1 Coefficient conditions for systems (3.41) to possess invariant parabolas

We prove the following lemma.

Lemma 3.10. *A system (3.41) possesses either one or two invariant parabolas or a double invariant parabola of the form $\Phi(x, y) = p + qx + ry + x^2$ if and only if $\widetilde{\Omega} = 0$ and the corresponding set of conditions are satisfied, respectively:*

(E_1) $\widetilde{\mathcal{D}} \neq 0, \widetilde{\mathcal{G}} \neq 0 \Rightarrow$ *one invariant parabola;*

(E_2) $\widetilde{\mathcal{D}} = 0, b \neq 0, \widetilde{\mathcal{F}} \neq 0 \Rightarrow$ *two invariant parabolas;*

(E_3) $\widetilde{\mathcal{D}} = 0, b \neq 0, \widetilde{\mathcal{F}} = 0 \Rightarrow$ *one double invariant parabola;*

(E_4) $\widetilde{\mathcal{D}} = 0, b = 0, f \neq 0 \Rightarrow$ *one invariant parabola,*

where

$$\begin{aligned}
&\widetilde{\Omega} = 2a^2(1+3g^2)^2 + a\big[8bg(1+3g^2) - (e-fg)(f+eg+2fg^2)\big] + b(8bg^2 + f^2g^2 - e^2),\\
&\widetilde{\mathcal{D}} = e - fg, \quad \widetilde{\mathcal{G}} = a + 2bg + 3ag^2,\\
&\widetilde{\mathcal{F}} = 608(b+ag)(25+g^2) + 25(49e^2 + 76f^2) - fg(850e + 299fg).
\end{aligned} \tag{3.42}$$

Proof. Considering equations (2.6) and the form of the parabola $\Phi(x,y) = p + qx + ry + x^2$ with $r \neq 0$ for systems (3.41) we obtain

$$s = 1,\ v = u = 0,\ U = 2g,\ V = -2,\ W = -gq - r,$$
$$Eq_1 = Eq_2 = Eq_3 = Eq_4 = Eq_5 = Eq_7 = 0,\ \ Eq_6 = q - gr.$$

Therefore the condition $Eq_6 = 0$ gives us $q = gr$ and calculations yield:

$$Eq_9 = 2p + r(f + r + g^2 r) = 0 \ \Rightarrow \ p = -r(f + r + g^2 r)/2$$

and then we obtain

$$Eq_8 = 2a + (e + fg)r + 2g(1 + g^2)r^2,$$
$$Eq_{10} = \frac{r}{2}\big[2(b + ag) - f(1 + g^2)r - (1 + g^2)^2 r^2\big] \equiv \frac{r}{2}\widetilde{\Psi}(a, b, f, g, r).$$

Since $r \neq 0$ the equation $Eq_{10} = 0$ is equivalent to $\widetilde{\Psi} = 0$.

According to [12, Lemmas 11,12] the equations $Eq_8 = 0$ and $\widetilde{\Psi} = 0$ have a common solution of degree 2 with respect to the parameter r if and only if

$$Res_r^{(0)}\,(Eq_8, \widetilde{\Psi}) = Res_r^{(1)}\,(Eq_8, \widetilde{\Psi}) = 0$$

where $Res_r^{(1)}$ is the subresultant of order one and $Res_r^{(0)}$ is the subresultant of order zero which coincide with the standard resultant (for detailed definition see [12], formula (19)). We calculate

$$Res_r^{(1)}\,(Eq_8, \widetilde{\Psi}) = (1 + g^2)^2(e - fg) \equiv (1 + g^2)^2\widetilde{\mathcal{D}},$$
$$Res_r^{(0)}\,(Eq_8, \widetilde{\Psi}) = 2(1 + g^2)^2\widetilde{\Omega}.$$

We observe that the subresultant of order one $Res_r^{(1)}\,(Eq_8, \widetilde{\Psi})$ vanishes if and only if $\widetilde{\mathcal{D}} = 0$. So we consider two cases: $\widetilde{\mathcal{D}} \neq 0$ and $\widetilde{\mathcal{D}} = 0$.

***1:* The case $\widetilde{\mathcal{D}} \neq 0$.** Then the invariant parabola exists if and only if $\widetilde{\Omega} = 0$ and therefore we have to examine the solutions of the equation $\widetilde{\Omega} = 0$. We calculate

$$\mathrm{Discrim}[\widetilde{\Omega}, a] = (e - fg)^2\big[8b(1 + g^2)(1 + 3g^2) + (f + eg + 2fg^2)^2\big] \equiv \widetilde{\mathcal{D}}^2\widetilde{\mathcal{E}}$$

and hence the equation $\widetilde{\Omega} = 0$ has real solutions in the parameter a if and only if either $\widetilde{\mathcal{D}} = 0$ or $\widetilde{\mathcal{E}} \geq 0$. However since the condition $\widetilde{\mathcal{D}} \neq 0$ holds it remains to examine the condition $\widetilde{\mathcal{E}} \geq 0$.

In this case setting $\widetilde{\mathcal{E}} = w^2 \geq 0$ we calculate

$$b = -\frac{(f + eg + 2fg^2)^2 - w^2}{8(1 + g^2)(1 + 3g^2)} \tag{3.43}$$

and then we obtain

$$\widetilde{\Omega} = \frac{G_+ G-}{8(1 + g^2)^2(1 + 3g^2)^2},$$

where

$$G_\pm = 4a(1 + g^2)(1 + 3g^2)^2 - (f + eg + 2fg^2 + \varepsilon w)(e + 2eg^2 + fg^3 - \varepsilon gw),\ \ \varepsilon = \pm 1.$$

Then the condition $\widetilde{\Omega} = 0$ gives us

$$a = \frac{(f + eg + 2fg^2 + \varepsilon w)(e + 2eg^2 + fg^3 - \varepsilon wg)}{4(1 + g^2)(1 + 3g^2)^2}, \tag{3.44}$$

where $\varepsilon = 1$ if $G_+ = 0$ and $\varepsilon = -1$ if $G_- = 0$. In this case we obtain that the polynomials Eq_8 and $\widetilde{\Psi}$ have the common factor $\zeta = 2(1+g^2)(1+3g^2)r + f + eg + 2fg^2 + \varepsilon w$ which is linear with respect to the parameter r. Setting $\zeta = 0$ we get

$$r = -\frac{f + eg + 2fg^2 + \varepsilon w}{2(1+g^2)(1+3g^2)}$$

and we arrive at the family of systems

$$\begin{aligned} \dot{x} &= \frac{(f + eg + 2fg^2 + \varepsilon w)(e + 2eg^2 + fg^3 - g\varepsilon w)}{4(1+g^2)(1+3g^2)^2} + gx^2 - xy, \\ \dot{y} &= -\frac{(f + eg + 2fg^2)^2 - w^2}{8(1+g^2)(1+3g^2)} + ex + fy + gxy - 2y^2. \end{aligned} \tag{3.45}$$

This family of systems possess the following invariant parabola

$$\begin{aligned} \Phi(x,y) = &\frac{(f - eg + 4fg^2 - \varepsilon w)(f + eg + 2fg^2 + \varepsilon w)}{8(1+g^2)(1+3g^2)^2} - \frac{g(f + eg + 2fg^2 + \varepsilon w)}{2(1+g^2)(1+3g^2)^2}\,x \\ &- \frac{f + eg + 2fg^2 + \varepsilon w}{2(1+g^2)(1+3g^2)}\,y + x^2. \end{aligned} \tag{3.46}$$

We observe that this conic is reducible if and only if $f + eg + 2fg^2 + \varepsilon w = 0$.

Considering (3.43) we get

$$w^2 = 8b(1+g^2)(1+3g^2) + (f + eg + 2fg^2)^2$$

and then from (3.44) we obtain

$$\begin{aligned} a = \frac{1}{4(1+g^2)(1+3g^2)^2}\big[(f + eg + 2fg^2)(e + 2eg^2 + fg^3) + (e - fg)(1+g^2)\varepsilon w - gw^2\big] \;\Rightarrow \\ 8bg(1+3g^2) + 4a(1+3g^2)^2 - (e - fg)(f + eg + 2fg^2) - (e - fg)\varepsilon w = 0. \end{aligned}$$

Since $\widetilde{\mathcal{D}} = (e - fg) \neq 0$ we solve the last equation with respect to εw and we obtain

$$\varepsilon w = \frac{1}{e - fg}\big[4b(1+2g)^2 - 4a(1+g)(1+2g)(1+3g) + (e - fg)(e + f + fg)\big].$$

Then calculations yield

$$r = -\frac{f + eg + 2fg^2 + \varepsilon w}{2(1+g^2)(1+3g^2)} = -\frac{2(a + 2bg + 3ag^2)}{(e - fg)(1+g^2)} = -\frac{2\,\widetilde{\mathcal{G}}}{(e - fg)(1+g^2)} \neq 0.$$

This completes the proof of the statement $(\boldsymbol{E_1})$ of Lemma 3.10.

Next we show that systems (3.45) could be brought via a transformation to the canonical form $(S_{\boldsymbol{\beta}})$. Indeed we could apply to parabola (3.46) the translation

$$x = x_1 + \frac{g(f + eg + 2fg^2 + \varepsilon w)}{4(1+g^2)(1+3g^2)}, \quad y = y_1 + \frac{f(2 + 9g^2 + 6g^4) - (2 + 3g^2)(eg + \varepsilon w)}{8(1+g^2)(1+3g^2)},$$

which brings this parabola to the form $\widetilde{\Phi}(x_1, y_1) = x_1^2 - \dfrac{f + eg + 2fg^2 + \varepsilon w}{2(1+g^2)(1+3g^2)}\,y_1$.

On the other hand considering Observation 3.4 we apply the same translation to systems (3.45) and we set the following new notations (suggested by the above parabola and the linear parts of the transformed systems):

$$k = \frac{f+eg+2fg^2+\varepsilon w}{2(1+g^2)(1+3g^2)}, \quad n = \frac{g(4e-fg+7eg^2+2fg^3)+(4+7g^2)\varepsilon w}{8(1+g^2)(1+3g^2)},$$
$$m = \frac{(2+3g^2)(4e-fg+7eg^2+2fg^3)-3g(2+g^2)\varepsilon w}{16(1+g^2)(1+3g^2)} \quad \Rightarrow$$
$$e = \frac{gk-2g^3k+4m+2gn}{2}, \quad f = \frac{4k+7g^2k-4n}{2}, \quad w = \frac{2n-2gm+3g^2n}{\varepsilon}.$$

Then after an additional rescaling (to force $k=1$) we arrive at the family of systems (S_{β}).

2: The case $\widetilde{\mathcal{D}}=0$. Then $e-fg=0$ and we have $e=fg$. Therefore we obtain:

$$\widetilde{\Omega} = 2(a+2bg+3ag^2)^2$$

and the condition $\widetilde{\Omega}=0$ implies

$$a = -\frac{2bg}{1+3g^2}.$$

Therefore we determine that in this case the polynomials Eq_8 and Eq_{10} have the following common factor

$$\tilde{\phi} = 2b - f(1+3g^2)r - (1+g^2)(1+3g^2)r^2.$$

We observe that $\tilde{\phi}$ is quadratic in r with the discriminant

$$\text{Discrim}[\tilde{\phi}, r] = (1+3g^2)(8b+f^2+8bg^2+3f^2g^2)$$

and clearly the condition $(8b+f^2+8bg^2+3f^2g^2) \geq 0$ must hold. Setting

$$8b+f^2+8bg^2+3f^2g^2 = (1+3g^2)w^2 \geq 0,$$

we obtain

$$b = -\frac{(1+3g^2)(f^2-w^2)}{8(1+g^2)}. \tag{3.47}$$

Then we arrive at the following expressions for the polynomials Eq_8 and Eq_{10}:

$$Eq_8 = \frac{gM_+M_-}{2(1+g^2)}, \quad Eq_{10} = -\frac{rM_+M_-}{8}, \quad M_{\pm} = f+2r+2g^2r \pm w.$$

Therefore the equations $Eq_8 = Eq_{10} = 0$ imply $M_+M_- = 0$.

If $M_+ = 0$ we determine

$$r = -\frac{f+w}{2(1+g^2)} \equiv r^+$$

and we obtain the parabola

$$\Phi_1(x,y) = \frac{(f-w)(f+w)}{8\,(g^2+1)} - \frac{g(f+w)}{2\,(g^2+1)}\,x - \frac{f+w}{2\,(g^2+1)}\,y + x^2. \tag{3.48}$$

In the case $M_- = 0$ we obtain

$$r = -\frac{f-w}{2(1+g^2)} \equiv r^-$$

and we get the parabola

$$\Phi_2(x,y) = \frac{(f-w)(f+w)}{8\,(g^2+1)} - \frac{g(f-w)}{2\,(g^2+1)}\,x - \frac{f-w}{2\,(g^2+1)}\,y + x^2.$$

Both these parabolas are invariant for the following family of systems:

$$\begin{aligned} \dot{x} &= \frac{g(f^2-w^2)}{4(1+g^2)} + gx^2 - xy, \\ \dot{y} &= -\frac{(1+3g^2)(f^2-w^2)}{8(1+g^2)} + fgx + fy + gxy - 2y^2. \end{aligned} \tag{3.49}$$

We observe that both parabolas $\Phi_i(x,y) = 0$ $(i = 1,2)$ exist (i.e. are not reducible) if and only if $r^+r^- \neq 0$ and this is equivalent to

$$(f-w)(f+w) = f^2 - w^2$$

and considering (3.47) this is equivalent to $b \neq 0$.

On the other hand if only one of the factors vanishes we have $b = 0$ and

$$r^+ + r^- = (f-w) + (f+w) = 2f \neq 0$$

i.e. $f \neq 0$. Therefore for $b = 0$ and $f \neq 0$ we could have only one parabola.

We determine that in the case $w = 0$ we obtain $\Phi_1(x,y) = \Phi_2(x,y)$, i.e. the parabolas coalesced when w tends to zero and we obtain a double parabola. On the other hand considering (3.47) for $w = 0$ we obtain to

$$b + \frac{f^2(1+3g^2)}{8(1+g^2)} = \frac{8b(1+g^2) + f^2(1+3g^2)}{8(1+g^2)} = \frac{(1+3g^2)}{608(25+g^2)(1+g^2)}\,\widetilde{\mathcal{F}}$$

and we conclude that these invariant parabolas coalesce if and only if $\widetilde{\mathcal{F}} = 0$. So the statements $(\boldsymbol{E_2})$–$(\boldsymbol{E_4})$ of Lemma 3.10 are valid.

As all the cases are examined we conclude that Lemma 3.10 is proved. □

Next we show that systems (3.49) could be brought via a transformation to the canonical form (S_{β}). Indeed we could apply to parabola (3.48) the translation

$$x = x_1 + \frac{g(f+w)}{4(1+g^2)}, \quad y = y_1 + \frac{f(2+g^2) - (2+3g^2)w}{8(1+g^2)}.$$

which brings this parabola to the form $\widetilde{\Phi}(x_1,y_1) = x_1^2 - \dfrac{f+w}{2(1+g^2)}\,y_1$.

On the other hand considering Observation 3.4 we apply the same translation to systems (3.49) and we set the following new notations (suggested by the above parabola and the linear parts of the transformed systems):

$$k = \frac{f+w}{2(1+g^2)}, \quad n = \frac{3fg^2 + 4w + 7g^2w}{8(1+g^2)} \quad \Rightarrow \quad f = \frac{4k + 7g^2k - 4n}{2}, \quad w = \frac{4n - 3g^2k}{2}.$$

Then after an additional rescaling (to force $k = 1$) we arrive at the subfamily of systems (S_{β}) defined by the conditions $m = 3g(1 + 3g^2 - 2n)/4$.

3.2.2 Invariant conditions: the case $\eta < 0$

Next using Lemma 3.10 we shall construct the equivalent affine invariant conditions for a system with $\eta < 0$ to possess an invariant parabola.

We prove the following theorem.

Theorem 3.11. *Assume that for a non-degenerate arbitrary quadratic system the conditions $\eta < 0$, $\chi_1 = 0$ and $\zeta_1 \neq 0$ are satisfied. Then this system could possess invariant parabolas only in one (real) direction. More exactly it could only possess one of the following sets of invariant parabolas: $\cup$, $\Cup$ and $\bigcup^2$. Moreover this system has one of the above sets of invariant parabolas if and only if $\chi_2 = 0$ and one of the following sets of conditions are satisfied, correspondingly:*

$(\mathcal{E}_1)$ $\zeta_4 \neq 0$, $\mathcal{R}_1 \neq 0$ $\Rightarrow \cup$;
$(\mathcal{E}_2)$ $\zeta_4 = 0$, $\mathcal{R}_7 \neq 0$, $\zeta_5 \neq 0$ $\Rightarrow \Cup$;
$(\mathcal{E}_3)$ $\zeta_4 = 0$, $\mathcal{R}_7 \neq 0$, $\zeta_5 = 0$ $\Rightarrow \bigcup^2$;
$(\mathcal{E}_4)$ $\zeta_4 = 0$, $\mathcal{R}_7 = 0$, $\zeta_5 \neq 0$ $\Rightarrow \cup$.

Proof. According to Remark 3.9 for a system (3.38) to possess an invariant parabola the conditions $\chi_1 = 0$ and $\zeta_1 \neq 0$ are necessary. As it was shown earlier (see page 37) if for a quadratic system with one real and two complex infinite singularities the conditions $\chi_1 = 0$ and $\zeta_1 \neq 0$ are satisfied, then via an affine transformation and time rescaling this system can be brought to the form (3.41). Thus in what follows we consider the family of quadratic systems

$$\dot{x} = a + gx^2 - xy, \quad \dot{y} = b + ex + fy - x^2 + gxy - 2y^2, \tag{3.50}$$

for which considering (3.42) we calculate.

$$\begin{aligned} &\chi_1 = 0, \quad \zeta_1 = 2(25+g^2), \quad \chi_2 = 384(25+g^2)\,\widetilde{\Omega}, \\ &\zeta_4 = -(25+g^2)\,\widetilde{\mathcal{D}}/8, \quad \mathcal{R}_1 = -30(25+g^2)\,\widetilde{\mathcal{G}}. \end{aligned} \tag{3.51}$$

Evidently the condition $\chi_2 = 0$ is equivalent to $\widetilde{\Omega} = 0$ and we consider two cases: $\zeta_4 \neq 0$ and $\zeta_4 = 0$.

1: **The case $\zeta_4 \neq 0$.** Then we have $\widetilde{\mathcal{D}} \neq 0$ and according to Lemma 3.10 in this case a quadratic system possesses an invariant parabola if and only if the condition $\widetilde{\mathcal{G}} \neq 0$ holds. According to (3.51) this condition is governed by the invariant polynomial $\mathcal{R}_1$. So we conclude that the statement $(\mathcal{E}_1)$ of Theorem 3.11 is valid.

2: **The case $\zeta_4 = 0$.** This implies $\widetilde{\mathcal{D}} = 0$ and considering (3.42) we get $e = fg$. Then for systems (3.50) we calculate

$$\chi_2 = 768(25+g^2)(a+2bg+3ag^2)^2 = 0 \;\Rightarrow\; a = -\frac{2bg}{1+3g^2}$$

and in this case we obtain:

$$\zeta_5 = \widetilde{\mathcal{F}}/4, \quad \mathcal{R}_7 = -64480b.$$

We examine two possibilities: $\mathcal{R}_7 \neq 0$ and $\mathcal{R}_7 = 0$.

2.1: **The possibility $\mathcal{R}_7 \neq 0$.** In this case we get $b \neq 0$. We observe that the condition $\zeta_5 = 0$ is equivalent to $\widetilde{\mathcal{F}} = 0$ and according to Lemma 3.10 due to $b \neq 0$ we get two invariant parabolas for $\zeta_5 \neq 0$ and one double invariant parabola if $\zeta_5 = 0$.

Thus the statements $(\mathcal{E}_2)$ and $(\mathcal{E}_3)$ of Theorem 3.11 are valid.

***2.2:* The possibility $\mathcal{R}_7 = 0$.** This implies $b = 0$ and for systems (3.50) with $e = fg$ we calculate

$$\chi_2 = 768a^2(25+g^2)(1+3g^2)^2, \quad \zeta_5 = 19(f^2+8ag)(25+g^2).$$

Therefore the condition $\chi_2 = 0$ gives us $a = 0$ and then we obtain $\zeta_5 = 19f^2(25+g^2)$. So the condition $f \neq 0$ is equivalent to $\zeta_5 \neq 0$ and considering the statement $(\boldsymbol{E_4})$ of Lemma 3.10 we conclude that the statement $(\mathcal{E}_4)$ of Theorem 3.11 is valid and this completes the proof of this theorem. □

3.3 Systems with two real distinct infinite singularities

In this case, according to Lemma 2.3, the conditions $\eta = 0$ and $\widetilde{M} \neq 0$ hold and systems (2.5) could be brought via a linear transformation and the additional change $(x, y, a, b, c, d, e, f, g, h) \mapsto (y, x, b, a, f, e, d, c, h, g)$ to the following family of systems

$$\begin{aligned} \frac{dx}{dt} &= a + cx + dy + gx^2 + (h-1)xy, \\ \frac{dy}{dt} &= b + ex + fy + gxy + hy^2. \end{aligned} \tag{3.52}$$

For these systems we calculate

$$C_2(x,y) = -xy^2, \quad \chi_1 = 2g^2(h-2)$$

and by Lemma 2.6 we conclude that the above systems could have invariant parabolas either of the form $\Phi(x,y) = p + qx + ry + x^2$ with $r \neq 0$ (otherwise we get a reducible conic) or of the form $\Phi(x,y) = p + qx + ry + y^2$ with $q \neq 0$.

According to Lemma 2.4 for the existence of an invariant parabola for a system (3.52) the condition $\chi_1 = 0$ is necessary, i.e. $g(h-2) = 0$. We prove the following lemma.

Lemma 3.12. *Assume that a system (3.52) possesses an invariant parabola. Then its quadratic homogeneous part is of the form x^2 (respectively, y^2) only if the condition $h = 2$ (respectively, $g = 0$) holds.*

Proof. Assume that a system (3.52) possesses an invariant parabola of the form $\Phi(x,y) = p + qx + ry + x^2$ with $r \neq 0$ (otherwise we get a reducible conic). Then considering equations (2.6) we obtain

$$s = 1, \quad v = u = 0, \quad Eq_2 = -2 + 2h - V = 0 \ \Rightarrow \ V = 2(h-1).$$

Therefore we have $Eq_7 = -(h-2)r = 0$ and since $r \neq 0$ this implies $h = 2$. So the statement of the lemma is true in this case.

If the system possesses an invariant parabola of the form $\Phi(x,y) = p + qx + ry + y^2$ with $q \neq 0$ then considering equations (2.6) we obtain

$$s = v = 0, \quad u = 1, \quad Eq_3 = 2g - U = 0 \ \Rightarrow \ U = 2g.$$

In this case we obtain $Eq_5 = -gq = 0$ and due to $q \neq 0$ we get $g = 0$. This completes the proof of the lemma. □

Considering Lemma 3.12 we conclude that for determining the conditions for the existence and the number of invariant parabolas for systems (3.52) it is necessary and sufficient to examine the two possibilities: the existence of invariant parabolas of the form $\Phi(x,y) = p+qx+ry+x^2$ $(r \neq 0)$ and of the form $\Phi(x,y) = p+qx+ry+y^2$ $(q \neq 0)$. By Lemma 3.12 in the first case the condition $h=2$ holds whereas in the second we have $g=0$.

Taking into account that for systems (3.52) we have

$$\chi_1 = 2g^2(h-2), \quad \mu_0 = g^2 h$$

we conclude that the case $h-2=0$ is equivalent to $\chi_1 = 0$ and $\mu_0 \neq 0$ whereas the case $g=0$ is equivalent to $\chi_1 = \mu_0 = 0$. In what follows we examine each one of this two possibilities.

3.3.1 The possibility $\chi_1 = 0$ and $\mu_0 \neq 0$

Then we have $g \neq 0$ and $h=2$ and by Lemma 3.12 systems (3.52) could have invariant parabolas only of the form $\Phi(x,y) = p+qx+ry+x^2$ with $r \neq 0$. Applying the transformation $(x,y) \mapsto (x/g-d,\ y-c+2dg)$ we impose the conditions $g=1$ and $c=d=0$ to be fulfilled and we arrive at the family of systems

$$\dot{x} = a + x^2 + xy, \quad \dot{y} = b + ex + fy + xy + 2y^2. \tag{3.53}$$

Coefficient conditions for systems (3.53) to possess invariant parabolas. We prove the following lemma.

Lemma 3.13. *A system (3.53) possesses either one or two invariant parabolas or a double invariant parabola of the form $\Phi(x,y) = p+qx+ry+x^2$ $(r \neq 0)$ if and only if $\Upsilon_1 = 0$ and the corresponding set of conditions are satisfied, respectively:*

(H_1) $\mathfrak{D}_1 \neq 0,\ \mathfrak{G}_1 \neq 0 \Rightarrow \cup$;

(H_2) $\mathfrak{D}_1 = 0,\ a \neq 0,\ \mathfrak{F}_1 \neq 0 \Rightarrow \Cup$;

(H_3) $\mathfrak{D}_1 = 0,\ a \neq 0,\ \mathfrak{F}_1 = 0 \Rightarrow \cup^2$;

(H_4) $\mathfrak{D}_1 = 0,\ a = 0,\ e \neq 0 \Rightarrow \cup$.

where

$$\begin{aligned} &\Upsilon_1 = 8b^2 - b(24a - e^2 + f^2) + a(18a - e^2 + ef + 2f^2); \\ &\mathfrak{D}_1 = e + f; \quad \mathfrak{G}_1 = 3a - 2b; \quad \mathfrak{F}_1 = 4a - e^2. \end{aligned} \tag{3.54}$$

Proof. Considering the equations (2.6) and the form of invariant parabola $\Phi(x,y) = p+qx+ry+x^2$ with $r \neq 0$ for systems (3.53) we obtain

$$\begin{aligned} &s = 1,\ v = u = 0,\ U = 2,\ V = 2,\ W = -q, \\ &Eq_1 = Eq_2 = Eq_3 = Eq_4 = Eq_5 = Eq_7 = 0. \end{aligned}$$

Then we have

$$Eq_6 = -q - r = 0, \ \ Eq_9 = -2p + fr + qr = 0 \ \Rightarrow \ q = -r,\ p = r(f-r)/2$$

and calculations yield

$$Eq_8 = 2a + (e-f)r + 2r^2, \ \ Eq_{10} = -\frac{r}{2}\big[2(a-b) + fr - r^2)\big] \equiv -\frac{r}{2}\Psi_1(a,b,f,r).$$

Since $r \neq 0$ the equation $Eq_{10} = 0$ is equivalent to $\Psi_1 = 0$.

According to [12, Lemmas 11,12] the equations $Eq_8 = 0$ and $\Psi_1 = 0$ have a common solution of degree 2 with respect to the parameter r if and only if

$$Res_r^{(0)}(Eq_8, \Psi_1) = Res_r^{(1)}(Eq_8, \Psi_1) = 0$$

where $Res_r^{(1)}$ is the subresultant of order one and $Res_r^{(0)}$ is the subresultant of order zero which coincide with the standard resultant (for detailed definition see [12], formula (19)). We calculate

$$Res_r^{(1)}(Eq_8, \Psi_1) = (e+f) \equiv \mathfrak{D}_1, \quad Res_r^{(0)}(Eq_8, \Psi_1) = 2\Upsilon_1.$$

So we consider two possibilities: $\mathfrak{D}_1 \neq 0$ and $\mathfrak{D}_1 = 0$.

1: **The possibility $\mathfrak{D}_1 \neq 0$.** Then the invariant parabola exists if and only if $\Upsilon_1 = 0$ and therefore we have to examine the solutions of the equation $\Upsilon_1 = 0$. In this case we calculate ??

$$\text{Discrim}[\Upsilon_1, b] = -(e+f)^2(16a - e^2 + 2ef - f^2) \equiv -\mathfrak{D}_1^2\mathcal{E}$$

and hence due to $\mathfrak{D}_1 \neq 0$ the equation $\Upsilon_1 = 0$ has real solutions with respect to the parameter b if and only if $\mathcal{E} \leq 0$. Then setting $\mathcal{E} = -w^2 \geq 0$ we calculate

$$a = \frac{(e-f)^2 - w^2}{16} \tag{3.55}$$

and then we obtain:

$$\Upsilon_1 = \frac{N_+N_-}{128},$$

where

$$N_\pm = 32b - e^2 + 6ef - 5f^2 + 2(e+f)\varepsilon w + 3w^2, \quad \varepsilon = \pm 1.$$

Then the condition $\Upsilon_1 = 0$ gives us

$$b = \frac{1}{32}(e - 5f - 3\varepsilon w)(e - f + \varepsilon w) \tag{3.56}$$

where $\varepsilon = 1$ if $N_+ = 0$ and $\varepsilon = -1$ if $N_- = 0$. In this case we obtain that the polynomials Eq_8 and $\Psi_1(e, f, g, r)$ have the common factor $\zeta = e - f + 4r + \varepsilon w$ which is linear with respect to the parameter r. Setting $\zeta = 0$ we get

$$r = -\frac{e - f + \varepsilon w}{4}$$

and we arrive at the family of systems

$$\begin{aligned} \dot{x} &= \frac{(e-f)^2 - w^2}{16} + x^2 + xy, \\ \dot{y} &= \frac{1}{32}(e - 5f - 3\varepsilon w)(e - f + \varepsilon w) + ex + fy + xy + 2y^2. \end{aligned} \tag{3.57}$$

This family of systems possess the following invariant parabola

$$\Phi(x, y) = -\frac{(e - f + \varepsilon w)(e + 3f + \varepsilon w)}{32} + \frac{e - f + \varepsilon w}{4}x - \frac{e - f + \varepsilon w}{4}y + x^2. \tag{3.58}$$

We observe that this conic is reducible if and only if $e - f + \varepsilon w = 0$.

Considering (3.55) we get

$$w^2 = -16a + (e-f)^2$$

and then we obtain

$$b = \frac{1}{32}\big[(e-5f)(e-f) - 2(e+f)\varepsilon w - 3w^2\big] \;\Rightarrow$$
$$16b - 24a + (e+f)(e-f+\varepsilon w) = 0.$$

Since $\mathfrak{D}_1 = e+f \neq 0$ we solve the last equation with respect to εw and we obtain

$$\varepsilon w = \frac{1}{e+f}\big(24a - 16b - e^2 + f^2\big).$$

Then calculations yield

$$r = -\frac{e-f+\varepsilon w}{4} = -\frac{2(3a-2b)}{e+f} = -\frac{2\,\mathfrak{G}_1}{e+f} \neq 0.$$

This completes the proof of the statement $(\boldsymbol{H_1})$ of Lemma 3.13.

Next we show that systems (3.57) could be brought via a transformation to the canonical form $(S^1_{\boldsymbol{\gamma}})$. Indeed we could apply to parabola (3.58) the translation

$$x = x_1 - \frac{e-f+\varepsilon w}{8}, \quad y = y_1 - \frac{3e+5f+3\varepsilon w}{16},$$

which brings this parabola to the form $\widetilde{\Phi}(x_1, y_1) = x_1^2 - \dfrac{e-f+\varepsilon w}{4}\, y_1$.

On the other hand considering Observation 3.4 we apply the same translation to systems (3.57) and we set the following new notations (suggested by the above parabola and the linear parts of the transformed systems):

$$k = \frac{e-f+\varepsilon w}{4}, \quad n = -\frac{7e+f+7\varepsilon w}{16}, \quad m = \frac{13e-5f-3\varepsilon w}{32} \quad \Rightarrow$$
$$e = -k+2m-n, \quad f = -\frac{7k+4n}{2}, \quad w = \frac{3k-4m-2n}{2\varepsilon}.$$

Then after an additional rescaling (to force $k=1$) we arrive at the subfamily of systems $(S^1_{\boldsymbol{\gamma}})$ defined by the conditions $g=1$.

***2:* The possibility** $\mathfrak{D}_1 = 0$**.** Considering (3.54) we have $f = -e$ and then we calculate

$$\Upsilon_1 = 2(3a-2b)^2 = 0 \;\Rightarrow\; b = 3a/2.$$

Therefore we determine that in this case the polynomials Eq_8 and Eq_{10} have the following common factor

$$\phi_1 = a + er + r^2.$$

We observe that $\tilde{\phi}$ is quadratic in r with the discriminant Discrim$[\phi_1, r] = -4a + e^2$ and setting Discrim$[\phi_1, r] = w^2$ we obtain

$$a = \frac{e^2 - w^2}{4}. \tag{3.59}$$

Then we arrive at the following expressions for the polynomials Eq_8 and Eq_{10}:

$$Eq_8 = \frac{S_+S_-}{2}, \quad Eq_{10} = r\frac{S_+S_-}{8}, \quad S_\pm = (e + 2r \pm w).$$

Therefore the equations $Eq_8 = Eq_{10} = 0$ imply $S_+S_- = 0$. If $S_+ = 0$ we determine

$$r = -\frac{e+w}{2} \equiv r^+$$

and we obtain the parabola

$$\Phi_1(x,y) = \frac{e^2-w^2}{8} + \frac{e+w}{2}x - \frac{e+w}{2}y + x^2. \tag{3.60}$$

In the case $S_- = 0$ we obtain

$$r = -\frac{e-w}{2} \equiv r^-$$

and we get the parabola

$$\Phi_2(x,y) = \frac{e^2-w^2}{8} + \frac{e-w}{2}x - \frac{e-w}{2}y + x^2.$$

Both these parabolas are invariant for the following family of systems:

$$\dot{x} = \frac{e^2-w^2}{4} + x^2 + xy, \quad \dot{y} = \frac{3(e^2-w^2)}{8} + ex - ey + xy + 2y^2. \tag{3.61}$$

We observe that both parabolas $\Phi_i(x,y) = 0$ $(i = 1,2)$ exist (i.e. are not reducible) if and only if $r^+r^- \neq 0$ and this is equivalent to

$$(e+w)(e-w) = e^2 - w^2 \neq 0.$$

Considering (3.59) this is equivalent to $a \neq 0$.

On the other hand if only one of the factors vanishes we have $a = 0$ and

$$r^+ + r^- = (e+w) + (e-w) = 2e \neq 0$$

and we obtain that the above condition is equivalent to $e \neq 0$. Therefore for $a = 0$ and $e \neq 0$ we could have only one parabola and we have no parabolas for $a = e = 0$.

We determine that in the case $w = 0$ we obtain $\Phi_1(x,y) = \Phi_2(x,y)$, i.e. the parabolas coalesce when w tends to zero and we obtain a double parabola. On the other hand considering (3.59) for $w = 0$ we obtain

$$a - \frac{e^2-w^2}{4} = \frac{4a-e^2}{4} = \frac{\mathfrak{F}_1}{4}$$

and we conclude that these invariant parabolas coalesce if and only if $\mathfrak{F}_1 = 0$.

Thus we conclude that the statements $(\boldsymbol{H_2})$,$(\boldsymbol{H_3})$ and $(\boldsymbol{H_4})$ of Lemma 3.13 are proved. □

Next we show that systems (3.61) could be brought via a transformation to the canonical form (S^1_γ). Indeed we could apply to parabola (3.60) the translation

$$x = x_1 - (e+w)/4, \quad y = y_1 + (e-3w)/8,$$

which brings this parabola to the form $\widetilde{\Phi}(x_1,y_1) = x_1^2 - \dfrac{e+w}{2}y_1$.

On the other hand considering Observation 3.4 we apply the same translation to systems (3.61) and we set the following new notations (suggested by the above parabola and the linear parts of the transformed systems):

$$k = (e+w)/2, \;\; n = -(3e+7w)/8 \;\; \Rightarrow \;\; e = (7k+4n)/2, \;\; w = -(3k+4n)/2.$$

Then after an additional rescaling (to force $k = 1$) we arrive at the subfamily of systems (S^1_γ) defined by the conditions $g = 1$ and $m = 3(3+2n)/4$.

Invariant conditions: the case $\eta = 0$, $\widetilde{M} \neq 0$ and $\mu_0 \neq 0$. Next using Lemma 3.13 we shall construct the equivalent affine invariant conditions for a system with $\eta = 0$, $\widetilde{M} \neq 0$ and $\mu_0 \neq 0$ to possess an invariant parabola.

We prove the following theorem.

Theorem 3.14. *Assume that for a non-degenerate arbitrary quadratic system the conditions $\eta = 0$, $\widetilde{M} \neq 0$, $\chi_1 = 0$ and $\mu_0 \neq 0$ are satisfied. Then this system could possess invariant parabolas only in one (simple) direction. More exactly it could only possess one of the following sets of invariant parabolas: ∪, ⩌ and $\bigcup^2$. Moreover this system has one of the above sets of invariant parabolas if and only if $\chi_2 = 0$ and one of the following sets of conditions are satisfied, correspondingly:*

$(\mathcal{H}_1)$ $\zeta_4 \neq 0$, $\mathcal{R}_1 \neq 0$ $\Rightarrow$ ∪;

$(\mathcal{H}_2)$ $\zeta_4 = 0$, $\mathcal{R}_2 \neq 0$, $\zeta_5 \neq 0$ $\Rightarrow$ ⩌;

$(\mathcal{H}_3)$ $\zeta_4 = 0$, $\mathcal{R}_2 \neq 0$, $\zeta_5 = 0$ $\Rightarrow$ $\bigcup^2$;

$(\mathcal{H}_4)$ $\zeta_4 = 0$, $\mathcal{R}_2 = 0$, $\zeta_5 \neq 0$ $\Rightarrow$ ∪.

Proof. Assume that quadratic system the conditions $\eta = 0$ and $\widetilde{M} \neq 0$ are fulfilled. Then via a linear transformation this system can be brought to the canonical form (3.52). According to Lemma 2.4 for a system (3.52) to possess an invariant parabola the conditions $\chi_1 = \chi_2 = 0$ are necessary. Moreover it was shown earlier (see page 44) that a system (3.52) with $\chi_1 = 0$ and $\mu_0 \neq 0$ via an affine transformation ant time rescaling can be brought to the form (3.53). Thus in what follows we consider the family of quadratic systems

$$\dot{x} = a + x^2 + xy, \quad \dot{y} = b + ex + fy + xy + 2y^2. \tag{3.62}$$

Considering (3.54) for these systems we calculate.

$$\chi_1 = 0, \quad \chi_2 = 384\mathrm{Y}_1, \quad \zeta_4 = -\mathfrak{D}_1/8, \quad \mathcal{R}_1 = 30\mathfrak{G}_1. \tag{3.63}$$

Evidently the condition $\chi_2 = 0$ is equivalent to $\mathrm{Y}_1 = 0$ and we consider two cases: $\zeta_4 \neq 0$ and $\zeta_4 = 0$.

1: **The case $\zeta_4 \neq 0$.** Then we have $\mathfrak{D}_1 \neq 0$ and according to Lemma 3.13 in this case a quadratic system possesses an invariant parabola if and only if the condition $\mathfrak{G}_1 \neq 0$ holds. According to (3.63) this condition is governed by the invariant polynomial $\mathcal{R}_1$. So we conclude that the statement $(\mathcal{H}_1)$ of Theorem 3.14 is valid.

2: **The case $\zeta_4 = 0$.** This implies $\mathfrak{D}_1 = 0$ and considering (3.54) we get $f = -e$. Then for systems (3.62) we calculate

$$\chi_2 = 768(3a - 2b)^2 = 0 \;\Rightarrow\; b = 3a/2$$

and in this case we obtain:

$$\zeta_5 = -19(4a - e^2) = -19\mathfrak{F}_1, \quad \mathcal{R}_2 = -27a/2.$$

We examine two possibilities: $\mathcal{R}_2 \neq 0$ and $\mathcal{R}_2 = 0$.

2.1: **The subcase $\mathcal{R}_2 \neq 0$.** In this case we get $a \neq 0$. We observe that the condition $\zeta_5 = 0$ is equivalent to $\mathfrak{F}_1 = 0$ and according to Lemma 3.13 due to $b \neq 0$ (because $a \neq 0$) we get two invariant parabolas for $\zeta_5 \neq 0$ and one double invariant parabola if $\zeta_5 = 0$.

Thus the statements $(\mathcal{H}_2)$ and $(\mathcal{H}_3)$ of Theorem 3.14 are valid.

2.2: The subcase $\mathcal{R}_2 = 0$. This implies $a = 0$ and for systems (3.62) with $f = -e$ and $a = b = 0$ we calculate

$$\zeta_5 = 19e^2.$$

So the condition $e \neq 0$ is equivalent to $\zeta_5 \neq 0$ and considering Lemma 3.13 we conclude that the statement $(\mathcal{H}_4)$ of Theorem 3.14 is valid. This completes the proof of Theorem 3.14. □

3.3.2 The possibility $\chi_1 = \mu_0 = 0$

In this case considering the conditions $\chi_1 = 2g^2(h-2) = 0$ and $\mu_0 = g^2 h$ for systems (3.52) we obtain $g = 0$ and by Lemma 3.12 these systems could have invariant parabolas of the form $\Phi(x,y) = p + qx + ry + y^2$ with $q \neq 0$ and if in addition $h = 2$ then they could have invariant parabolas of the form $\Phi(x,y) = p + qx + ry + x^2$ with $r \neq 0$.

So we consider the family of systems

$$\dot{x} = a + cx + dy + (h-1)xy, \quad \dot{y} = b + ex + fy + hy^2. \tag{3.64}$$

Coefficient conditions for systems (3.64) to possess invariant parabolas. We prove the following lemma.

Lemma 3.15. *A system (3.64) could only possess one of the following sets of invariant parabolas:* $\cup$, $\overset{2}{\cup}$, $\overset{2}{\cup}\subset$, $\overset{2}{\cup}\overset{2}{\mathbb{U}}$, $\overset{2}{\cup}\overset{2}{\mathbb{U}}^c$, $\overset{2}{\cup}\overset{2}{\bigcup}^2$, $\overset{2}{\bigcup}^3$ *and* $\infty\overset{2}{\cup}$. *Moreover this system has one of the above sets of invariant parabolas if and only if the corresponding set of conditions are satisfied, respectively:*

- $(\boldsymbol{K_1})$ $h+1 \neq 0$, $3h+1 \neq 0$, $h \neq 0$, $h-2 \neq 0$, $\Upsilon_2 = 0$, $e \neq 0 \Rightarrow \overset{2}{\cup}$;
- $(\boldsymbol{K_2})$ $h = 2$, $\Upsilon_3 \neq 0$, $\Upsilon_2 = 0$, $e \neq 0 \Rightarrow \overset{2}{\cup}$;
- $(\boldsymbol{K_3})$ $h = 2$, $\Upsilon_3 = 0$, $\Upsilon_2 \neq 0$, $e(a-cd) \neq 0 \Rightarrow \cup$;
- $(\boldsymbol{K_4})$ $h = 2$, $\Upsilon_3 = 0$, $\Upsilon_2 = 0$, $e(4c-f) \neq 0 \Rightarrow \overset{2}{\cup}\subset$;
- $(\boldsymbol{K_5})$ $h = 0$, $\Upsilon_2 = 0$, $ef \neq 0 \Rightarrow \overset{2}{\cup}$;
- $(\boldsymbol{K_6})$ $h = -1/3$, $c = 2f$, $\mathfrak{D}_2 > 0$, $e \neq 0 \Rightarrow \overset{2}{\cup}\overset{2}{\mathbb{U}}$;
- $(\boldsymbol{K_7})$ $h = -1/3$, $c = 2f$, $\mathfrak{D}_2 < 0$, $e \neq 0 \Rightarrow \overset{2}{\cup}\overset{2}{\mathbb{U}}^c$;
- $(\boldsymbol{K_8})$ $h = -1/3$, $c = 2f$, $\mathfrak{D}_2 = 0$, $\mathfrak{F}_2 \neq 0$, $e \neq 0 \Rightarrow \overset{2}{\cup}\overset{2}{\bigcup}^2$;
- $(\boldsymbol{K_9})$ $h = -1/3$, $c = 2f$, $\mathfrak{D}_2 = 0$, $\mathfrak{F}_2 = 0$, $e \neq 0 \Rightarrow \overset{2}{\bigcup}^3$;
- $(\boldsymbol{K_{10}})$ $h = -1$, $e = 0$, $\mathfrak{G}_2 \neq 0$, $\mathfrak{H}_2 \neq 0$, $c - f \neq 0 \Rightarrow \overset{2}{\cup}$;
- $(\boldsymbol{K_{11}})$ $h = -1$, $e = 0$, $\mathfrak{G}_2 = 0$, $\mathfrak{H}_2 \neq 0$, $c - f = 0 \Rightarrow \infty\overset{2}{\cup}$,

where

$$\begin{aligned}
\Upsilon_2 &= aeh(1+3h)^3 - b(1+h)(1+3h)^2(f+2ch-fh) - (f+ch+fh)\big[2c^2h(1+h) \\
&\quad - cf(1+h)(5h-1) + de - 2f^2 + 6deh + 9deh^2 + 2f^2h^2\big]; \quad \Upsilon_3 = b + 2c^2 - de - cf; \\
\mathfrak{D}_2 &= 256b^3 + 576b^2(de+f^2) + 432b(de+f^2)^2 - 324a^2e^2 - 972ade^2f \\
&\quad + 27(de-2f^2)^2(4de+f^2); \quad \mathfrak{F}_2 = 4b + 3de + 3f^2; \quad \mathfrak{G}_2 = 2a + cd, \quad \mathfrak{H}_2 = 4b - c^2 + 2cf.
\end{aligned} \tag{3.65}$$

Proof. Considering the equations (2.6) and the form of invariant parabola $\Phi(x,y) = p + qx + ry + y^2$ with $q \neq 0$ we obtain

$$\begin{gathered} s = v = 0,\ u = 1,\ U = 0,\ V = 2h,\ W = 2f - hr, \\ Eq_1 = Eq_2 = Eq_3 = Eq_4 = Eq_5 = Eq_7 = 0,\ Eq_6 = 2e - (h+1)q. \end{gathered} \tag{3.66}$$

So we have to consider two possibilities: $h + 1 \neq 0$ and $h + 1 = 0$.

1: **The possibility** $h + 1 \neq 0$**.** Then equation $Eq_6 = 0$ gives us $q = \dfrac{2e}{1+h}$ and since $q \neq 0$ we get $e \neq 0$. Therefore we calculate:

$$Eq_8 = \frac{e\big[2c - 4f + (1+3h)r\big]}{1+h}$$

and we have to examine two cases: $1 + 3h \neq 0$ and $1 + 3h = 0$.

1.1: **The case** $1 + 3h \neq 0$**.** Then due to $e \neq 0$ the equation $Eq_8 = 0$ implies $r = -\dfrac{2(c-2f)}{1+3h}$ and calculations yield:

$$\begin{aligned} Eq_9 &= \frac{2}{(1+h)(1+3h)^2}\big[de(1+3h)^2 + b(1+h)(1+3h)^2 + (c-2f)(1+h)(f+2ch-fh) \\ &\quad - h(1+h)(1+3h)^2 p\big], \\ Eq_{10} &= \frac{2}{(1+h)(1+3h)}\big[ae(1+3h) - b(c-2f)(1+h) - (1+h)(f+ch+fh)p\big]. \end{aligned} \tag{3.67}$$

We observe that both equations are linear with respect to parameter p and we calculate

$$Res_p(Eq_9, Eq_{10}) = -\frac{4}{(1+h)(1+3h)^3}\,\Upsilon_2 = 0.$$

Considering (3.65) we observe that Υ_2 is linear with respect to the parameter a with the coefficient $eh(1+3h)^3$ where $e(1+3h) \neq 0$. So we consider two subcases: $h \neq 0$ and $h = 0$.

1.1.1: *The subcase* $h \neq 0$. Then the condition $\Upsilon_2 = 0$ gives us

$$\begin{aligned} a = {} & \frac{1}{eh(1+3h)^3}\big[b(1+h)(1+3h)^2(f+2ch-fh) \\ & + (f+ch+fh)(de + cf - 2f^2 + 2c^2h + 6deh - 4cfh \\ & + 2c^2h^2 + 9deh^2 - 5cfh^2 + 2f^2h^2)\big] \equiv a' \end{aligned} \tag{3.68}$$

and then we calculate

$$Eq_9 = \frac{2}{(1+h)(1+3h)^2}\Psi(b,c,d,e,f,h), \quad Eq_{10} = \frac{2(f+ch+fh)}{h(1+h)(1+3h)^3}\Psi(b,c,d,e,f,h),$$

where

$$\Psi = b(1+h)(1+3h)^2 - h(1+h)(1+3h)^2 p + de(1+3h)^2 + (c-2f)(1+h)(f+2ch-fh).$$

Therefore the condition $Eq_9 = Eq_{10} = 0$ implies $\Psi = 0$ and we get

$$p = \frac{2}{h(1+h)(1+3h)^2}\big[b(1+h)(1+3h)^2 + de(1+3h)^2 + (c-2f)(1+h)(f+2ch-fh)\big] \equiv p'. \tag{3.69}$$

Thus we arrive at the family of systems

$$\dot{x} = a' + cx + dy + (h-1)xy, \quad \dot{y} \ = b + ex + fy + hy^2, \ \ e \neq 0, \tag{3.70}$$

where a' is given in (3.68). These systems possess the following invariant parabola:

$$\Phi = p' + \frac{2e}{h+1}x - \frac{2(c-2f)}{3h+1}y + y^2, \quad e \neq 0, \tag{3.71}$$

where p' is given in (3.69).

We recall that according to Lemma 3.12 in the case $h-2=0$ systems (3.64) could possess invariant parabolas of the form $\Phi(x,y) = p + qx + ry + x^2$. So we discuss two cases: $h-2 \neq 0$ and $h-2=0$.

1.1.1.1: *The possibility* $h-2 \neq 0$. Then by Lemma 3.12 systems (3.64) could not possess invariant parabolas in the second direction.

So we proved that in the case $(h+1)(3h+1)h(h-2)e \neq 0$ and $\Upsilon_2 = 0$ systems (3.64) possess an invariant parabola of the form $\Phi(x,y) = p + qx + ry + y^2$.

Thus the proof of the statement $(\boldsymbol{K_1})$ of Lemma 3.15 is completed.

Next we show that systems (3.70) could be brought via a transformation to the canonical form (S^2_{γ}). Indeed we could apply to parabola (3.71) the translation

$$x = x_1 - \frac{1}{2eh(1+3h)^2}\big[de(1+3h)^2 + b(1+h)(1+3h)^2 + (c-2f)(1+h)(f+ch+fh)\big],$$
$$y = y_1 + \frac{c-2f}{1+3h},$$

which brings this parabola to the form $\widetilde{\Phi}(x_1,y_1) = y_1^2 + \dfrac{2e}{1+h}x_1$.

On the other hand considering Observation 3.4 we apply the same translation to systems (3.61) and we set the following new notations (suggested by the above parabola and the linear parts of the transformed systems):

$$k = -\frac{2e}{1+h}, \quad m = \frac{f+2ch-fh}{1+3h}, \quad n = \frac{h+1}{4eh(1+3h)^2}\big[de(1+3h)^2 -$$
$$b(h-1)(1+3h)^2 - (c-2f)(h-1)(f+ch+fh)\big] \quad \Rightarrow$$
$$c = \frac{f(h-1)+(1+3h)m}{2h}, \ d = \frac{(h-1)(f^2-m^2) - 4h(bh-b-2hkn)}{2h(1+h)k}, \ e = -\frac{(1+h)k}{2}.$$

Then after an additional rescaling (to force $k=1$) we arrive at the family of systems (S^2_{γ}).

1.1.1.2: *The possibility* $h-2=0$. In this case we examine the conditions for the existence of the invariant parabolas of the form $\Phi(x,y) = p + qx + ry + x^2$ $(r \neq 0)$.

Considering the equations (2.6) for systems (3.64) we obtain

$$s = 1, \ v = u = 0, \ U = 0, \ V = 2, \ W = 2c,$$
$$Eq_1 = Eq_2 = Eq_3 = Eq_4 = Eq_5 = Eq_7 = 0, \ Eq_6 = 2d - q.$$

Therefore the equation $Eq_6 = 0$ gives us $q = 2d$ and then calculations yield:

$$Eq_9 = 2d^2 - 2p - 2cr + fr = 0 \ \Rightarrow \ p = (2d^2 - 2cr + fr)/2.$$

In this case we obtain

$$Eq_8 = 2(a - cd) + er, \quad Eq_{10} = 2d(a - cd) + (b + 2c^2 - cf)r$$

and we claim that the condition $e \neq 0$ must hold in order to have an invariant parabola. Indeed suppose $e = 0$. Then $Eq_8 = 0$ gives us $a = cd$ and therefore due to $r \neq 0$ from $Eq_{10} = 0$ we get $b = c(f - 2c)$ and this leads to the following degenerate systems

$$\dot{x} = (d + x)(c + y), \; \dot{y} = -(2c - f - 2y)(c + y).$$

So $e \neq 0$ and we obtain

$$r = -2(a - cd))/e \neq 0.$$

In this case calculations yield

$$Eq_{10} = -2(a - cd)(b + 2c^2 - de - cf)/e = -2(a - cd)\Upsilon_3/e \tag{3.72}$$

and due to $a - cd \neq 0$ we obtain that $Eq_{10} = 0$ is equivalent to $\Upsilon_3 = 0$. Therefore we discuss two cases: $\Upsilon_3 \neq 0$ and $\Upsilon_3 = 0$.

a) *The case* $\Upsilon_3 \neq 0$. Then systems (3.64) could not possess invariant parabolas of the form $\Phi(x, y) = p + qx + ry + x^2$ ($r \neq 0$). However these systems could have invariant parabolas of the form $\Phi(x, y) = p + qx + ry + y^2$ ($q \neq 0$) and for this it is sufficient to force the conditions $\Upsilon_2 = 0$ and $e \neq 0$. Indeed the condition $h = 2$ implies $(h + 1)(3h + 1)h \neq 0$ and as it was shown above (see p. ***1.1.1:***) in the case $\Upsilon_2 = 0$ and $e \neq 0$ we arrive at the family of systems (3.70) possessing the invariant parabola (3.71) in this particular case with $h = 2$.

Thus we conclude that the statement $(\boldsymbol{K_2})$ of Lemma 3.15 is proved.

b) *The case* $\Upsilon_3 = 0$. Considering (3.65) the condition $\Upsilon_3 = 0$ gives us $b = -2c^2 + de + cf$. Then from (3.72) we get $Eq_{10} = 0$ and we arrive at the following systems

$$\dot{x} = a + cx + dy + xy, \quad \dot{y} = -2c^2 + de + cf + ex + fy + 2y^2, \; e \neq 0, \tag{3.73}$$

possessing the invariant parabola

$$\Phi = \frac{a(2c - f) - d(2c^2 - de - cf)}{e} + 2dx - \frac{2(a - cd)}{e}y + x^2, \quad e(a - cd) \neq 0. \tag{3.74}$$

Next we show that systems (3.73) could be brought via a transformation to the canonical form (S^1_γ). Indeed we could apply to parabola (3.74) the translation

$$x = x_1 - d, \quad y = y_1 + \frac{2c - f}{2}.$$

which brings this parabola to the form $\widetilde{\Phi}(x_1, y_1) = x_1^2 - \dfrac{2(a - cd)}{e}y_1$.

On the other hand considering Observation 3.4 we apply the same translation to systems (3.73) and we set the following new notations (suggested by the above parabola and the linear parts of the transformed systems):

$$k = \frac{2(a - cd)}{e}, \;\; m = \frac{e}{2}, \;\; n = \frac{4c - f}{2} \quad \Rightarrow$$
$$a = cd + km, \; e = 2m, \; f = 2(2c - n).$$

Then after an additional rescaling (to force $k=1$) we arrive at the subfamily of systems (S^1_{γ}) defined by the condition $g=0$.

Next we examine the possibility of the existence besides the parabola (3.74) another parabola of the form $\Phi(x,y)=p+qx+ry+y^2$ $(q\neq 0)$. As it was mentioned earlier the condition $h=2$ implies $(h+1)(3h+1)h\neq 0$ and according to the statement $(\boldsymbol{K_1})$ of Lemma 3.15 to have such a parabola the condition $\Upsilon_2=0$ is necessary. So we examine two possibilities: $\Upsilon_2\neq 0$ and $\Upsilon_2=0$.

b.1) *The possibility* $\Upsilon_2\neq 0$. In this case by the statement $(\boldsymbol{K_1})$ we could not have parabola of the form $\Phi(x,y)=p+qx+ry+y^2$ $(q\neq 0)$ and hence in the case under consideration we have a single parabola (3.74).

Thus we deduce that the conditions provided by the statement $(\boldsymbol{K_3})$ of Lemma 3.15 are valid.

b.2) *The possibility* $\Upsilon_2=0$. As it was shown above (see p. ***b)***) for $h=2$ and $\Upsilon_3=0$ systems (3.64) can be brought to the form (3.73). For these systems we calculate

$$\Upsilon_2=2(576c^3+343ae-343cde-432c^2f+108cf^2-9f^3).$$

So due to $e\neq 0$ we obtain

$$a=\frac{1}{343e}\big[c(343de-576c^2)+9f(48c^2-12cf+f^2)\big]$$

and we arrive at the family of systems

$$\begin{aligned}\dot{x}&=\frac{1}{343e}\big[c(343de-576c^2)+9f(48c^2-12cf+f^2)\big]+cx+dy+xy,\\ \dot{y}&=-2c^2+de+cf+ex+fy+2y^2,\quad e\neq 0,\end{aligned}\tag{3.75}$$

possessing the following two invariant parabolas:

$$\begin{aligned}\Phi_1&=d^2-\frac{9(2c-f)(4c-f)^3}{343e^2}+2dx+\frac{18(4c-f)^3}{343e^2}\,y+x^2,\quad e(4c-f)\neq 0;\\ \Phi_2&=\frac{1}{147}(60cf-141c^2+98de+3f^2)+\frac{2e}{3}\,x-\frac{2(c-2f)}{7}\,y+y^2,\quad e\neq 0.\end{aligned}\tag{3.76}$$

So the conditions provided by the statement $(\boldsymbol{K_4})$ of Lemma 3.15 are valid.

Next we show that systems (3.75) could be brought via a transformation to the canonical form (S^2_{γ}). Indeed we could apply to parabola $\Phi_2=0$ from (3.76) the translation

$$x=x_1+\frac{9(4c-f)^2-98de}{98e},\quad y=y_1+\frac{c-2f}{7}$$

which brings this parabola to the form $\widetilde{\Phi}(x_1,y_1)=y_1^2+\dfrac{2e}{3}\,x_1$.

On the other hand considering Observation 3.4 we apply the same translation to systems (3.75) and we set the following new notations (suggested by the above parabola and the linear parts of the transformed systems):

$$k=-\frac{2e}{3},\quad m=\frac{4c-f}{7}\quad\Rightarrow\quad c=\frac{f+7m}{4},\quad e=-\frac{3k}{2}.$$

Then after an additional rescaling (to force $k=1$) we arrive at the the subfamily of systems (S^2_{γ}) defined by the conditions $h=2$ and $n=-3m^2/2$.

1.1.2: *The subcase* $h = 0$. In this case considering (3.67) we obtain

$$Eq_9 = 2(b + de + cf - 2f^2), \quad Eq_{10} = 2(ae - bc + 2bf - fp)$$

and clearly the condition $Eq_9 = 0$ gives us $b = -de - cf + 2f^2$. We observe that the equation $Eq_{10} = 0$ is linear with respect to the parameter p with the coefficient f. So we discuss two possibilities: $f \neq 0$ and $f = 0$.

1.1.2.1: *The possibility* $f \neq 0$. Then the condition $Eq_{10} = 0$ implies

$$p = \left[ae + (c - 2f)(de + cf - 2f^2)\right]/f$$

and we arrive at the family of systems

$$\dot{x} = a + cx + dy - xy, \quad \dot{y} = -de - cf + 2f^2 + ex + fy, \;\; ef \neq 0, \tag{3.77}$$

possessing the following invariant parabola:

$$\Phi = \frac{1}{f}\left[ae + (c - 2f)(de + cf - 2f^2)\right] + 2ex - 2(c - 2f)y + y^2, \quad ef \neq 0. \tag{3.78}$$

On the other hand for $h = 0$ we have

$$\Upsilon_2 = -f(b + de + cf - 2f^2)$$

and since $f \neq 0$ we conclude that the condition $\Upsilon_2 = 0$ is equivalent to $b + de + cf - 2f^2 = 0$.

1.1.2.2: *The possibility* $f = 0$. Then considering (3.67) for $h = f = 0$ we obtain

$$Eq_9 = 2(b + de) = 0, \quad Eq_{10} = 2(ae - bc) = 0$$

and due to $e \neq 0$ (since $q \neq 0$) this implies $b = -de$ and $a = -cd$. However in this case we get the degenerate systems

$$\dot{x} = -(d - x)(c - y), \quad \dot{y} = -e(d - x).$$

Thus we have proved that for the existence of invariant parabola of systems (3.64) with $h = 0$ the conditions $\Upsilon_2 = 0$ and $ef \neq 0$ must hold and we deduce that the conditions provided by the statement $(\boldsymbol{K_5})$ of Lemma 3.15 are valid.

Next we show that systems (3.77) could be brought via a transformation to the canonical form (S^2_γ). Indeed we could apply to parabola (3.78) the translation

$$x = x_1 - \frac{a + cd - 2df}{2f}, \quad y = y_1 + c - 2f,$$

which brings this parabola to the form $\widetilde{\Phi}(x_1, y_1) = y_1^2 + 2e\,x_1$.

On the other hand considering Observation 3.4 we apply the same translation to systems (3.77) and we set the following new notations (suggested by the above parabola and the linear parts of the transformed systems):

$$k = -2e, \;\; m = f, \;\; n = \frac{a + cd}{4f} \quad \Rightarrow$$
$$a = -cd + 4mn, \;\; e = -k/2, \;\; f = m.$$

Then after an additional rescaling (to force $k = 1$) we arrive at the the subfamily of systems (S^2_γ) defined by the conditions $h = 0$.

1.2: **The case** $1 + 3h = 0$**.** Then $h = -1/3$ and considering (2.6) and (3.66) we calculate $Eq_6 = 2/3(3e - q) = 0$ which implies $q = 3e \neq 0$. Therefore calculations yield:

$$Eq_8 = 3e(c - 2f), \quad Eq_9 = (6b + 9de + 2p - 3fr - r^2)/3$$

and since $e \neq 0$ the equation $Eq_8 = 0$ implies $c = 2f$ and from $Eq_9 = 0$ we obtain

$$p = \frac{1}{2}\big[r^2 + 3fr - 3(2b + 3de)\big].$$

Then we obtain

$$Eq_{10} = -\frac{1}{6}\big[r^3 + 9fr^2 - 3(4b + 3de - 6f^2)r - 18(ae + 2bf + 3def)\big] \equiv -\frac{1}{6}\Psi(r)$$

and we conclude that if r_0 is a solution of the equation $Eq_{10} = 0$ (i.e. $\Psi(r_0) = 0$) then systems

$$\dot{x} = a + 2fx + dy - 4xy/3, \quad \dot{y} = b + ex + fy - y^2/3, \quad e \neq 0 \tag{3.79}$$

possess the invariant parabola

$$\Phi_0(x, y) = (r_0^2 + 3fr_0 - 6b - 9de)/2 + 3ex + r_0 y + y^2. \tag{3.80}$$

On the other hand we calculate

$$\Psi'_r = 3(r^2 + 6fr - 4b - 3de + 6f^2), \quad \Psi''_r = 6(3f + r),$$
$$\text{Discrim}[\Psi, r] = 27\mathcal{D}_2, \quad \text{Res}_r(\Psi'_r, \Psi''_r) = -108\mathcal{F}_2,$$

and we conclude that systems (3.79) has the following invariant parabolas of the form (3.80):

- if $\mathcal{D}_2 > 0 \Rightarrow$ three real distinct invariant parabolas;
- if $\mathcal{D}_2 < 0 \Rightarrow$ one real and two complex invariant parabolas;
- if $\mathcal{D}_2 = 0$, $\mathcal{F}_2 \neq 0 \Rightarrow$ one simple and one double real invariant parabolas;
- if $\mathcal{D}_2 = 0$, $\mathcal{F}_2 = 0 \Rightarrow$ one triple real invariant parabolas.

So we conclude that the conditions provided by the statements $(\boldsymbol{K_6})$–$(\boldsymbol{K_9})$ of Lemma 3.15 are valid.

Next we show that systems (3.79) could be brought via a real transformation to the canonical form (S^2_γ). Indeed we could apply to parabola (3.80) with $r_0 \in \mathbb{R}$ the translation

$$x = x_1 + \frac{12b + 18de - 6fr_0 - r_0^2}{12e}, \quad y = y_1 - r_0/2,$$

which brings this parabola to the form $\widetilde{\Phi}(x_1, y_1) = y_1^2 + 3e\,x_1$.

On the other hand applying the same translation to systems (3.79) we arrive at the systems

$$\begin{aligned}
\dot{x}_1 &= -\frac{1}{8e}\Psi(r_0) + \frac{2}{3}(3f + r_0)x_1 - \frac{1}{9e}(12b + 9de - 6fr_0 - r_0^2)y_1 - \frac{4}{3}x_1y_1,\\
\dot{y}_1 &= \frac{1}{6}(12b + 9de - 6fr_0 - r_0^2) + ex_1 + \frac{1}{3}(3f + r_0)y_1 - \frac{1}{3}y_1^2.
\end{aligned}$$

We recall that $\Psi(r_0) = 0$ and we set the following new notations (suggested by the above parabola and the linear parts of the above systems):

$$k = -3e, \quad m = \frac{3f + r_0}{3}, \quad n = -\frac{12b + 9de - 6fr_0 - r_0^2}{18e} \quad \Rightarrow$$
$$b = \frac{3dk + 6kn + 6mr_0 - r_0^2}{12}, \; e = -\frac{k}{3}, \; f = \frac{3m - r_0}{3}.$$

Then after an additional rescaling (to force $k = 1$) we arrive at the subfamily of systems (S_{γ}^2) defined by the conditions $h = -1/3$.

***2:* The possibility $h + 1 = 0$.** Then $h = -1$ and considering (3.66) for $h = -1$ we have $Eq_6 = 2e = 0$, i.e. $e = 0$. Then taking into account (2.6) calculations yield:

$$Eq_8 = q(c - 2f - r), \quad Eq_9 = 2b + 2p + dq - fr - r^2$$

and since $q \neq 0$ the condition $Eq_8 = 0$ implies $c - 2f - r = 0$ and this gives us $r = c - 2f$. Then from $Eq_9 = 0$ we obtain $p = (c^2 - 2b - 3cf + 2f^2 - dq)/2$ and we obtain

$$Eq_{10} = \frac{1}{2}\big[(c - f)(4b - c^2 + 2cf) + (2a + cd)q\big]. \tag{3.81}$$

We observe that for systems (3.64) we have $\mathcal{G}_2 = 2a + cd$ and therefore we have to consider two cases: $\mathcal{G}_2 \neq 0$ and $\mathcal{G}_2 = 0$.

***2.1:* The case $\mathcal{G}_2 \neq 0$.** Then $2a + cd \neq 0$ and the equation $Eq_{10} = 0$ implies

$$q = -\frac{(c - f)(4b - c^2 + 2cf)}{2a + cd}$$

and we obtain the parabola

$$\begin{gathered}\Phi = \frac{-2ab + ac^2 - 3acf + 2af^2 + bcd - 2bdf}{2a + cd} - \frac{(c - f)(4b - c^2 + 2cf)}{2a + cd}x + (c - 2f)y + y^2, \\ (2a + cd)(c - f)\left(4b - c^2 + 2cf\right) \neq 0 \Leftrightarrow \mathfrak{G}_2\mathfrak{H}_2(c - f) \neq 0,\end{gathered} \tag{3.82}$$

which is invariant for the family of systems

$$\dot{x} = a + cx + dy - 2xy, \quad \dot{y} = b + fy - y^2. \tag{3.83}$$

So we conclude that the conditions provided by the statement $(\boldsymbol{K_{10}})$ of Lemma 3.15 are valid.

Next we show that systems (3.83) could be brought via a transformation to the canonical form (S_{γ}^2). Indeed we could apply to parabola (3.82) the translation

$$x = x_1 - \frac{2a - cd + 2df}{4(c - f)}, \quad y = y_1 - \frac{c - 2f}{2},$$

which brings this parabola to the form $\widetilde{\Phi}(x_1, y_1) = y_1^2 - \dfrac{(c - f)(4b - c^2 + 2cf)}{2a + cd}x_1$.

On the other hand considering Observation 3.4 we apply the same translation to systems (3.83) and we set the following new notations (suggested by the above parabola and the linear parts of the transformed systems):

$$k = \frac{(c - f)(4b - c^2 + 2cf)}{2a + cd}, \quad m = c - f, \quad n = \frac{2a + cd}{4(c - f)} \quad \Rightarrow$$
$$a = (4mn - cd)/2, \quad b = (2cm - c^2 + 4kn)/4, \; f = c - m.$$

Then after an additional rescaling (to force $k = 1$) we arrive at the the subfamily of systems (S_{γ}^2) defined by the conditions $h = -1$.

2.2: **The case $\mathcal{G}_2 = 0$.** In this case $2a + cd = 0$, i.e. $a = -cd/2$ and considering (3.81) the equation $Eq_{10} = 0$ yields

$$(c - f)(4b - c^2 + 2cf) = 0 \quad \Rightarrow \quad (c - f)\mathfrak{H}_2 = 0.$$

If $\mathfrak{H}_2 = 0$ then we get $b = c(c - 2f)/4$ and this leads to degenerate systems:

$$\dot{x} = -(d - 2x)(c - 2y)/2, \quad \dot{y} = (c - 2y)(c - 2f + 2y)/4.$$

So the condition $\mathfrak{H}_2 \neq 0$ is necessary and then we have $c - f = 0$. So we get $f = c$ which leads to the family of systems

$$\dot{x} = -cd/2 + cx + dy - 2xy, \quad \dot{y} = b + cy - y^2 \tag{3.84}$$

possessing the following family of invariant parabolas:

$$\Phi = -(2b + dq)/2 + qx - cy + y^2, \quad q \in \mathbb{R}, \quad q \neq 0. \tag{3.85}$$

Next we show that systems (3.84) could be brought via a transformation to the canonical form (S^2_γ). Indeed we could apply to parabola (3.85) the translation

$$x = x_1 + \frac{4b + c^2 + 2dq}{4q}, \quad y = y_1 + \frac{c}{2},$$

which brings this parabola to the form $\widetilde{\Phi}(x_1, y_1) = y_1^2 + q\,x_1$.

On the other hand considering Observation 3.4 we apply the same translation to systems (3.84) and we set the following new notations (suggested by the above parabola and the linear parts of the transformed systems):

$$k = -q, \quad m = c - f, \quad n = -\frac{4b + c^2}{4q} \quad \Rightarrow$$
$$b = (4kn - c^2)/4, \quad q = -k \neq 0.$$

Then after an additional rescaling (to force $k = 1$) we arrive at the subfamily of systems (S^2_γ) defined by the conditions $h = -1$ and $m = 0$. Moreover we observe that this subfamily of systems possess the following family of invariant parabolas:

$$\Phi = -n(1 + q) + qx + y^2, \quad q \in \mathbb{R}, \quad q \neq 0.$$

Evidently for $q = -1$ we get the parabola $y^2 - x = 0$.

Thus the the condition provided by the statement $(\boldsymbol{K_{11}})$ of Lemma 3.15 are valid and this completes the proof of the Lemma 3.15. □

Invariant conditions: the case $\eta = 0$, $\widetilde{M} \neq 0$ and $\mu_0 = 0$. Next we consider the class of quadratic systems for which the conditions $\eta = 0$, $\widetilde{M} \neq 0$, $\mu_0 = 0$, which by Lemma 3.12 could possess invariant parabolas in two directions.

We prove the following theorem.

Theorem 3.16. *Assume that for a non-degenerate arbitrary quadratic system the conditions $\eta = 0$, $\widetilde{M} \neq 0$, $\chi_1 = \mu_0 = 0$ are satisfied. Then this system could possess invariant parabolas in two directions. More exactly it could only possess one of the following sets of invariant parabolas: $\cup$, $\overset{2}{\cup}$, $\overset{2}{\cup}\subset$, $\overset{2}{\cup}\overset{2}{\mathbb{U}}$, $\overset{2}{\cup}\overset{2}{\mathbb{U}}^c$, $\overset{2}{\cup}\overset{2}{\boldsymbol{\cup}}{}^2$, $\overset{2}{\boldsymbol{\cup}}{}^3$ and $\infty\overset{2}{\cup}$. Moreover this system has one of the above sets of invariant parabolas if and only if one of the following sets of conditions are satisfied, correspondingly:*

$$(\mathcal{K}_1)\ \zeta_{11}\zeta_{12}\zeta_{13}\zeta_{14}\neq 0,\ \mathcal{R}_5\neq 0,\ \begin{cases}\zeta_{15}\neq 0, \zeta_{16}=0\\ or\ \zeta_{15}=\zeta_{17}=0,\end{cases} \Rightarrow \overset{2}{\cup};$$

$$(\mathcal{K}_2)\ \zeta_{11}=0,\ \mathcal{R}_3\neq 0,\ \zeta_{16}=0,\ \mathcal{R}_5\neq 0 \Rightarrow \overset{2}{\cup};$$

$$(\mathcal{K}_3)\ \zeta_{11}=0,\ \mathcal{R}_3=0,\ \zeta_{16}\neq 0,\ \mathcal{R}_6\neq 0 \Rightarrow \cup;$$

$$(\mathcal{K}_4)\ \zeta_{11}=0,\ \mathcal{R}_3=0,\ \zeta_{16}=0,\ \zeta_8\neq 0 \Rightarrow \overset{2}{\cup}\subset;$$

$$(\mathcal{K}_5)\ \zeta_{12}=0,\ \zeta_{16}=0,\ \zeta_8\neq 0 \Rightarrow \overset{2}{\cup};$$

$$(\mathcal{K}_6)\ \zeta_{13}=0,\ \zeta_8=0,\ \zeta_{18}>0,\ \mathcal{R}_5\neq 0 \Rightarrow \overset{2}{\cup}\overset{2}{\Cup};$$

$$(\mathcal{K}_7)\ \zeta_{13}=0,\ \zeta_8=0,\ \zeta_{18}<0,\ \mathcal{R}_5\neq 0 \Rightarrow \overset{2}{\cup}\overset{2}{\Cup}^c;$$

$$(\mathcal{K}_8)\ \zeta_{13}=0,\ \zeta_8=0,\ \zeta_{18}=0,\ \mathcal{R}_5\neq 0,\ \chi_3\neq 0 \Rightarrow \overset{2}{\cup}\overset{2}{\cup}^2;$$

$$(\mathcal{K}_9)\ \zeta_{13}=0,\ \zeta_8=0,\ \zeta_{18}=0,\ \mathcal{R}_5\neq 0, \chi_3=0 \Rightarrow \overset{2}{\cup}^3;$$

$$(\mathcal{K}_{10})\ \zeta_{14}=0,\ \zeta_{19}\neq 0,\ \zeta_{20}\neq 0,\ \mathcal{R}_5=0,\ \zeta_{21}\neq 0 \Rightarrow \overset{2}{\cup};$$

$$(\mathcal{K}_{11})\ \zeta_{14}=0,\ \zeta_{19}=0,\ \zeta_{20}\neq 0,\ \mathcal{R}_5=0,\ \zeta_{21}=0 \Rightarrow \infty\overset{2}{\cup}.$$

Proof. Assume that quadratic system the conditions $\eta=0$ and $\widetilde{M}\neq 0$ are fulfilled. Then via a linear transformation this system can be brought to the canonical form (3.52). According to Lemma 2.4 for a system (3.52) to possess an invariant parabola the conditions $\chi_1=\chi_2=0$ are necessary. Moreover it was shown earlier (see page 49) that a system (3.52) with $\chi_1=\mu_0=0$ via an affine transformation and time rescaling can be brought to the form (3.64). Thus in what follows we consider the family of quadratic systems

$$\dot{x}=a+cx+dy+(h-1)xy,\quad \dot{y}=b+ex+fy+hy^2. \tag{3.86}$$

***1:* The statement $(\mathcal{K}_1)$.** Considering (3.65) for these systems we calculate

$$\begin{aligned}\chi_1=\chi_2=0,\ \ \zeta_{11}=-4(h-2)y^2,\ \ \zeta_{12}=4hy^2,\ \ \zeta_{13}=(1+3h)y^2,\ \ \zeta_{14}=(1+h)^2y^2,\\ \zeta_{15}=(h-1)^2y^2/4,\ \ \zeta_{16}=45e^3(h-1)^2\Upsilon_2/8,\ \ \mathcal{R}_5=32e.\end{aligned} \tag{3.87}$$

The condition $\zeta_{11}\neq 0$ implies $h-2\neq 0$ and according to Lemma 3.12 systems (3.64) could not possess invariant parabolas of the form $\Phi(x,y)=p+qx+ry+x^2$.

On the other hand evidently the condition $\zeta_{12}\zeta_{13}\zeta_{14}\neq 0$ is equivalent to $(1+h)(1+3h)h\neq 0$ and the condition $\mathcal{R}_5\neq 0$ is equivalent to $e\neq 0$. So considering the statement $(\boldsymbol{K_1})$ of Lemma 3.15 it remains to determine in invariant form the condition which is equivalent to $\Upsilon_2=0$. We consider two cases: $\zeta_{15}\neq 0$ and $\zeta_{15}=0$.

***1.1:* The case $\zeta_{15}\neq 0$.** Then $h-1\neq 0$ and due to $\mathcal{R}_5\neq 0$ (i.e. $e\neq 0$) we conclude that the condition $\Upsilon_2=0$ is equivalent to $\zeta_{16}=0$ and hence the statement $(\mathcal{K}_1)$ of Theorem 3.16 is valid in this case.

***1.2:* The case $\zeta_{15}=0$.** Then $h=1$ and we obtain

$$\Upsilon_2=-4(16bc+c^3-16ae+4cde+8def-4cf^2),\quad \zeta_{17}=13824e^2\Upsilon_2.$$

Therefore due to $e\neq 0$ we conclude that the condition $\Upsilon_2=0$ is equivalent to $\zeta_{17}=0$ and this completes the proof of the statement $(\mathcal{K}_1)$ of Theorem 3.16.

2: **The statements $(\mathcal{K}_2)$–$(\mathcal{K}_4)$.** For systems (3.86) the condition $\zeta_{11} = 0$ gives us $h = 2$. In this case we calculate

$$\mathcal{R}_3 = -503139971565000\, e^4(b + 2c^2 - de - cf) = -503139971565000\, e^4 Y_3,$$
$$\mathcal{R}_5 = 32e, \ \ \mathcal{R}_6 = 8925(a - cd)e^4/4, \ \ \zeta_{16} = 45e^3 Y_2/8, \ \ \zeta_8 = e(4c - f).$$

Therefore the condition $\mathcal{R}_5 \neq 0$ is equivalent to $e \neq 0$ and for $e \neq 0$ the condition $\mathcal{R}_3 = 0$ (respectively $\zeta_{16} = 0$) is equivalent with $Y_3 = 0$ (respectively $Y_2 = 0$). So in the case $\mathcal{R}_3 \neq 0$ we deduce that the conditions of the statements $(\mathcal{K}_2)$ provides the conditions of the statements$(\boldsymbol{K_2})$ of Lemma 3.15.

Assume now $\mathcal{R}_3 = 0$. We observe that the condition $\mathcal{R}_6 \neq 0$ (respectively $\zeta_8 \neq 0$) implies $e(a - cd) \neq 0$ (respectively $e(4c - f) \neq 0$), i.e. in both cases we have $e \neq 0$. Then the condition $\mathcal{R}_3 = 0$ is equivalent to Y_3 and the condition $\zeta_{16} = 0$ is equivalent to $Y_2 = 0$.

Thus considering Lemma 3.15 we conclude that in the case $\zeta_{16} \neq 0$ (respectively $\zeta_{16} = 0$) we get the conditions provided by the statement $(\boldsymbol{K_3})$ (respectively $(\boldsymbol{K_4})$) of this lemma. So the invariant conditions provided by the statements statements $(\mathcal{K}_2)$–$(\mathcal{K}_4)$ of Theorem 3.16 are valid.

3: **The statement $(\mathcal{K}_5)$.** Considering (3.87) the condition $\zeta_{12} = 0$ implies $h = 0$ and we calculate:

$$\zeta_{16} = 45e^3 Y_2/8, \ \ \zeta_8 = ef.$$

Clearly the condition $\zeta_8 \neq 0$ implies $ef \neq 0$ and then the condition $\zeta_{16} = 0$ is equivalent to $Y_2 = 0$. So we get the conditions provided by the statement $(\boldsymbol{K_5})$ of Lemma 3.15 and this implies the validity of the statement $(\mathcal{K}_5)$ of Theorem 3.16.

4: **The statements $(\mathcal{K}_6)$–$(\mathcal{K}_9)$.** Considering (3.87) we observe that the condition $\zeta_{13} = 0$ implies $h = -1/3$ and we calculate:

$$\mathcal{R}_5 = 32e, \ \ \zeta_8 = -2e(c - 2f)/3.$$

So the condition $\mathcal{R}_5 \neq 0$ implies $e \neq 0$ and then the condition $\zeta_8 = 0$ yields $c = 2f$. In this case we have

$$\zeta_{18} = 64/2187\, e^2\, \mathfrak{D}_2, \ \ \chi_3 = -\frac{15792269387776}{729}\, e^4\, \mathfrak{F}_2^2$$

and hence the condition $\zeta_{18} = 0$ is equivalent to $\mathfrak{D}_2 = 0$ and for $\zeta_{18} \neq 0$ we have $\mathrm{sign}(\zeta_{18}) = \mathrm{sign}(\mathfrak{D}_2)$. Moreover the condition $\chi_3 = 0$ is equivalent to $\mathfrak{F}_2 = 0$.

Thus we obtain that in the case $\mathcal{R}_5 \neq 0$, $\zeta_8 = 0$ and $\zeta_{18} > 0$ (respectively $\zeta_{18} < 0$) then we arrive at the conditions provided by the statement $(\mathcal{K}_6)$ (respectively $(\mathcal{K}_7)$) of Lemma 3.15.

In the case $\zeta_{18} = 0$ (i.e. $\mathfrak{D}_2 = 0$) we obtain the conditions provided by the statement $(\mathcal{K}_8)$ if $\chi_3 \neq 0$ and by the statement $(\mathcal{K}_9)$ if $\chi_3 = 0$ (i.e. $\mathfrak{F}_2 = 0$). This proves the validity of the statements $(\mathcal{K}_6)$–$(\mathcal{K}_9)$ of Theorem 3.16.

5: **The statements $(\mathcal{K}_{10})$, $(\mathcal{K}_{11})$.** From (3.87) we obtain that the condition $\zeta_{14} = 0$ implies $h = -1$ and then we have $\mathcal{R}_5 = 32e$. So the condition $\mathcal{R}_5 = 0$ implies $e = 0$ and we calculate

$$\zeta_{19} = 6(2a + cd)y^4 = 6\mathfrak{G}_2, \ \ \zeta_{20} = 8(4b - c^2 + 2cf)y^2 = 8\mathfrak{H}_2 y^2, \ \ \zeta_{21} = 2(c - f)y^3.$$

So we observe that for $\zeta_{19} \neq 0$, $\zeta_{20} \neq 0$ and $\zeta_{21} \neq 0$ we arrive at the conditions provided by the statement $(\boldsymbol{K_{10}})$ of Lemma 3.15. In the case $\zeta_{19} = 0$, $\zeta_{20} \neq 0$ and $\zeta_{21} = 0$ we get the conditions provided by the statement $(\boldsymbol{K_{11}})$ of the same lemma.

Thus we conclude that the statements $(\mathcal{K}_{10})$ and $(\mathcal{K}_{11})$ of Theorem 3.16 are valid and this completes the proof of this theorem. □

3.4 Systems with a unique infinite singular point which is real

In this case according to Lemma 2.3 systems (2.5) via a linear transformation could be brought to the following family of systems

$$\frac{dx}{dt} = a + cx + dy + gx^2 + hxy, \quad \frac{dy}{dt} = b + ex + fy - x^2 + gxy + hy^2. \tag{3.88}$$

For these systems we calculate

$$C_2(x,y) = x^3, \ \ \chi_1 = -2h^3$$

and by Lemma 2.6 we conclude that the above systems could have invariant parabolas only of the form $\Phi(x,y) = p + qx + ry + x^2$ with $r \neq 0$ (otherwise we get a reducible conic).

According to Lemma 2.4 for a system (3.88) to possess an invariant parabola the condition $\chi_1 = 0$ is necessary and this implies $h = 0$. Moreover we may assume $e = 0$ due to the translation $x \to x + e/2$, $y \to y$ and we arrive at the family of systems

$$\frac{dx}{dt} = a + cx + dy + gx^2, \quad \frac{dy}{dt} = b + fy - x^2 + gxy. \tag{3.89}$$

3.4.1 Coefficient conditions for systems (3.89) to possess invariant parabolas.

We prove the following lemma.

Lemma 3.17. *A system* (3.89) *could only possess one of the following sets of invariant parabolas:* $\overset{3}{\cup}$ *and* $\infty\overset{3}{\cup}$. *Moreover this system has one of the above sets of invariant parabolas if and only if the corresponding set of conditions are satisfied, respectively:*

$(\boldsymbol{L_1})$ $g \neq 0$, $\Upsilon_4 = 0$, $d \neq 0 \Rightarrow \overset{3}{\cup}$;

$(\boldsymbol{L_2})$ $g = 0$, $d = 0$, $c - f \neq 0$, $f(2c - f) \neq 0 \ \Rightarrow \overset{3}{\cup}$;

$(\boldsymbol{L_3})$ $g = 0$, $d = 0$, $f = c \neq 0 \ \Rightarrow \infty\overset{3}{\cup}$,

where

$$\Upsilon_4 = 27bdg^4 - 9ag^3(d - cg + 2fg) - (2d + cg - 2fg)(d - cg - fg)(2d - 2cg + fg). \tag{3.90}$$

Proof. Considering equations (2.6) and the form of the parabola $\Phi(x,y) = p + qr + ry + x^2$ with $r \neq 0$ (otherwise we get a reducible conic), for systems (3.89) we obtain

$$s = 1, \ v = u = 0, \ U = 2g, \ V = 0, \ W = 2c - gq - r, \ Eq_6 = 2d - gr$$

and clearly we have to discuss two possibilities: $g \neq 0$ and $g = 0$.

***1:* The possibility** $g \neq 0$. Then the equation $Eq_6 = 0$ yields $r = 2d/g \neq 0$ and we calculate:

$$Eq_8 = 2(a - gp) + q(2d - cg)/g + gq^2 = 0 \ \Rightarrow \ p = \frac{a}{g} - \frac{q(cg - 2d)}{2g^2} + \frac{q^2}{2}.$$

Then we obtain

$$Eq_9 = d(4d - 4cg + 2fg + 3g^2q)/g^2$$

and since $dg \neq 0$ the equation $Eq_8 = 0$ gives us

$$q = 2(2cg - 2d - fg)/(3g^2)$$

and finally we calculate the last equation $Eq_{10} = 0$:

$$\begin{aligned} Eq_{10} &= \frac{2}{27g^5}\big[27bdg^4 - 9ag^3(d - cg + 2fg) - (2d + cg - 2fg)(d - cg - fg)(2d - 2cg + fg)\big] \\ &= \frac{2}{27g^5}\Upsilon_4. \end{aligned}$$

Since $dg \neq 0$ the equation $Eq_{10} = 0$ gives us

$$b = \frac{1}{27dg^4}\big[9ag^3(d - cg + 2fg) + (2d + cg - 2fg)(d - cg - fg)(2d - 2cg + fg)\big] \equiv b_0$$

and we arrive at the family of systems

$$\dot{x} = a + cx + dy + gx^2, \quad \dot{y} = b_0 + fy - x^2 + gxy \tag{3.91}$$

possessing the invariant parabola

$$\Phi(x,y) = \frac{9ag^3 - (2d + cg - 2fg)(2d - 2cg + fg)}{9g^4} - \frac{2(2d - 2cg + fg)}{3g^2}x + \frac{2d}{g}y + x^2. \tag{3.92}$$

This completes the proof of the statement $(\boldsymbol{L_1})$ of Lemma 3.17.

Next we show that systems (3.91) could be brought via a transformation to the canonical form (S_δ). Indeed we could apply to parabola (3.92) the translation

$$x = x_1 - \frac{2cg - 2d - fg}{3g^2}, \quad y = y_1 + \frac{8d^2 - 2d(5c - f)g + g^2(2c^2 + cf - f^2 - 9ag)}{18dg^3},$$

which brings this parabola to the form $\widetilde{\Phi}(x_1, y_1) = x_1^2 + \dfrac{2d}{g}y_1$.

On the other hand considering Observation 3.4 we apply the same translation to systems (3.91) and we set the following new notations (suggested by the above parabola and the linear parts of the transformed systems):

$$\begin{gathered} k = -\frac{2d}{g},\ n = -\frac{-d + cg - 2fg}{3g},\ m = -\frac{16d^2 - 2d(7c - 5f)g - g^2(2c^2 + cf - f^2 - 9ag)}{36dg^2} \Rightarrow \\ a = \frac{4c^2 - 8ck - 5k^2 - 4n^2 + 4k(8gm + 3n)}{16g},\ d = -\frac{gk}{2},\ f = \frac{2c + k + 6n}{4}. \end{gathered}$$

Then after an additional rescaling (to force $k = 1$) we arrive at the family of systems (S_δ).

***2:* The possibility** $g = 0$. Then the equation $Eq_6 = 0$ yields $d = 0$ and we calculate:

$$Eq_9 = r(f - 2c + r)$$

and due to $r \neq 0$ we get $r = 2c - f \neq 0$. Then calculations yield:

$$Eq_8 = 2a + (c - f)q, \quad Eq_{10} = 2bc - bf - fp + aq$$

and we have to examine two cases: $c - f \neq 0$ and $c - f = 0$.

***2.1:* The case** $c - f \neq 0$**.** Then the equation $Eq_8 = 0$ gives us $q = -2a/(c-f)$ and then we obtain

$$Eq_{10} = \frac{2bc^2 - 2a^2 - 3bcf + bf^2}{c - f} - fp.$$

We claim that for the existence of an invariant parabola the condition $f \neq 0$ must hold. Indeed supposing $f = 0$ we obtain $Eq_{10} = 2(bc - a^2)/c$ and then the condition $Eq_{10} = 0$ implies $b = a^2/c$. However in this case we arrive at the degenerate systems

$$\dot{x} = a + cx, \quad \dot{y} = \frac{(a - cx)(a + cx)}{c^2}$$

and this completes the proof of our claim.

So we have $f \neq 0$ and then the condition $Eq_{10} = 0$ gives us

$$p = \frac{-2a^2 + 2bc^2 - 3bcf + bf^2}{f(c - f)}$$

and we arrive at the parabola

$$\Phi(x, y) = \frac{2bc^2 - 2a^2 - 3bcf + bf^2}{f(c - f)} - \frac{2a}{c - f}x + (2c - f)y + x^2, \;\; f(c - f)(2c - f) \neq 0, \quad (3.93)$$

which is invariant for the family of systems:

$$\dot{x} = a + cx, \quad \dot{y} = b + fy - x^2. \quad (3.94)$$

This completes the proof of the statement $(\boldsymbol{L_2})$ of Lemma 3.17.

Next we show that systems (3.94) could be brought via a transformation to the canonical form (S_δ). Indeed we could apply to parabola (3.93) the translation

$$x = x_1 + \frac{a}{c - f}, \quad y = y_1 - \frac{bc^2 - a^2 - 2bcf + bf^2}{(c - f)^2 f},$$

which brings this parabola to the form $\widetilde{\Phi}(x_1, y_1) = x_1^2 + (2c - f)\,y_1$.

On the other hand considering Observation 3.4 we apply the same translation to systems (3.95) and we set the following new notations (suggested by the above parabola and the linear parts of the transformed systems):

$$k = f - 2c, \; m = -\frac{a}{c - f}, \; n = \frac{f}{2} \quad \Rightarrow \quad a = -\frac{m(k + 2n)}{2}, \; c = \frac{2n - k}{2}, \; f = 2n.$$

Then after an additional rescaling (to force $k = 1$) we arrive at the subfamily of systems (S_δ) defined by the condition $g = 0$.

***2.2:* The case** $c - f = 0$**.** Then we set $f = c$ and the equation $Eq_8 = 0$ gives us $a = 0$ and we obtain

$$Eq_{10} = c(b - p) = 0.$$

In this case $r = 2c - f = c \neq 0$ and hence the condition $Eq_{10} = 0$ implies $p = b$. Therefore we obtain the family of systems

$$\dot{x} = cx, \quad \dot{y} = b + cy - x^2, \quad (3.95)$$

which possess the family of the invariant parabolas depending on one parameter q.

$$\Phi(x, y) = b + qx + cy + x^2, \;\; c \neq 0. \quad (3.96)$$

This completes the proof of the Lemma 3.17. □

Next we show that systems (3.95) could be brought via a transformation to the canonical form (S_δ). Indeed we could apply to parabola (3.96) the translation

$$x = x_1 - \frac{q}{2}, \quad y = y_1 - \frac{4b - q^2}{4c},$$

which brings this parabola to the form $\widetilde{\Phi}(x_1, y_1) = x_1^2 + c\,y_1$.

On the other hand considering Observation 3.4 we apply the same translation to systems (3.95) and we set the following new notations (suggested by the above parabola and the linear parts of the transformed systems):

$$k = -c, \ m = \frac{q}{2} \ \Rightarrow \ c = -k, \ q = 2m.$$

Then after an additional rescaling (to force $k = 1$) arrive at the subfamily of systems (S_δ) defined by the conditions $g = 0$ and $n = -1/2$.

3.4.2 Invariant conditions: the case $\eta = \widetilde{M} = 0$ and $C_2 \neq 0$

Next, using Lemma 3.17 we shall construct the equivalent affine invariant conditions for a system with $\eta = \widetilde{M} = 0$ and $C_2 \neq 0$ to possess an invariant parabola.

We prove the following theorem.

Theorem 3.18. *Assume that for a non-degenerate arbitrary quadratic system the conditions $\eta = \widetilde{M} = 0$, $\chi_1 = 0$ and $C_2 \neq 0$ are satisfied. Then this system could only possess one of the following sets of invariant parabolas: $\overset{3}{\cup}$ and $\infty\overset{3}{\cup}$. Moreover this system has one of the above sets of invariant parabolas if and only if one of the following sets of conditions are satisfied, correspondingly:*

$(\boldsymbol{\mathcal{L}_1})$ $\quad \zeta_{14} \neq 0, \zeta_{22} = 0, \mathcal{R}_2 \neq 0 \quad \Rightarrow \overset{3}{\cup}$;

$(\boldsymbol{\mathcal{L}_2})$ $\quad \zeta_{14} = 0, \zeta_{20} = 0, \zeta_{23} \neq 0, \zeta_{24} \neq 0 \quad \Rightarrow \overset{3}{\cup}$;

$(\boldsymbol{\mathcal{L}_3})$ $\quad \zeta_{14} = 0, \zeta_{20} = 0, \zeta_{23} = 0, \zeta_{24} \neq 0 \quad \Rightarrow \infty\overset{3}{\cup}$.

Proof. Assume that quadratic system the conditions $\widetilde{M} = 0$ and $C_2 \neq 0$ are fulfilled. Then via a linear transformation this system can be brought to the canonical form (3.88). According to Lemma 2.4 for a system (3.88) to possess an invariant parabola the conditions $\chi_1 = \chi_2 = 0$ are necessary. Moreover it was shown earlier (see page 60) that a system (3.88) with $\chi_1 = 0$ via an affine transformation ant time rescaling can be brought to the form (3.89). Thus in what follows we consider the family of quadratic systems

$$\frac{dx}{dt} = a + cx + dy + gx^2, \quad \frac{dy}{dt} = b + fy - x^2 + gxy. \tag{3.97}$$

1: **The statement $(\boldsymbol{\mathcal{L}_1})$.** Considering (3.90) for these systems we calculate

$$\chi_1 = \chi_2 = 0, \ \ \zeta_{14} = g^2x^2, \ \ \zeta_{22} = 9d^3g^3\mathrm{Y}_4, \ \ \mathcal{R}_2 = 9d^2g^4/4 \tag{3.98}$$

and clearly the condition $\zeta_{14} \neq 0$ is equivalent to $g \neq 0$ and in this case the condition $\mathcal{R}_2 \neq 0$ gives us $d \neq 0$. Therefore we conclude that for $\zeta_{14}\mathcal{R}_2 \neq 0$ the condition $\zeta_{22} = 0$ is equivalent to $\mathrm{Y}_4 = 0$.

2: **The statement $(\mathcal{L}_2)$.** From (3.98) evidently the condition $\zeta_{14} = 0$ implies $g = 0$ and then we calculate

$$\zeta_{23} = -2(c-f)^2, \quad \zeta_{20} = -12d^2x^2.$$

Therefore the condition $\zeta_{20} = 0$ is equivalent to $d = 0$ whereas $\zeta_{23} \neq 0$ implies $c - f \neq 0$. So for $\zeta_{20} = 0$ we get $d = 0$ and then we calculate

$$\zeta_{24} = 24f(2c-f)x^3$$

and hence the condition $\zeta_{24} \neq 0$ is equivalent to $f(2c-f) \neq 0$. Since the condition $\zeta_{23} \neq 0$ is equivalent to $c - f \neq 0$, considering Lemma 3.17 we conclude that the statement $(\mathcal{L}_2)$ of Theorem 3.18 is proved.

3: **The statement $(\mathcal{L}_3)$.** Since the condition $\zeta_{23} = -2(c-f)^2 = 0$ gives us $f = c$ for systems (3.97) with $g = d = 0$ and $f = c$ we calculate $\zeta_{24} = 24c^2x^3$ and clearly the condition $\zeta_{24} \neq 0$ is equivalent to $c \neq 0$. This completes the proof of Theorem 3.18. □

3.5 Systems with infinite line filled up with singularities

According to Lemma 2.3 in the case $C_2 = 0$ systems (2.5) via a linear transformation could be brought to the systems $(\mathbf{S}_V)$ for which in addition we may assume $e = f = 0$ due to a translation. So we consider the following family of quadratic systems

$$\frac{dx}{dt} = a + cx + dy + x^2, \quad \frac{dy}{dt} = b + xy. \tag{3.99}$$

We prove the following lemma.

Lemma 3.19. *A non-degenerate quadratic system (3.99) could only have invariant parabola of the form $\Phi(x,y) = p + qx + ry + x^2$ with $r \neq 0$. Moreover it possesses an invariant parabola of this form if and only if the following conditions hold:*

$$d \neq 0, \ \Upsilon_5 = 9ac - 2c^3 + 27bd = 0.$$

Proof. Suppose that these systems possess an invariant parabola

$$\Phi(x,y) \equiv p + qx + ry + sx^2 + 2vxy + uy^2 = 0$$

with $v^2 - su = 0$ and $u \neq 0$, i.e. its quadratic part is not of the form sx^2. Then clearly we may assume $u = 1$ and then we obtain $s = v^2$, i.e. we get the parabola

$$\Phi(x,y) \equiv p + qx + ry + (vx+y)^2 = 0, \tag{3.100}$$

for which the condition $q \neq rv$ must hold, otherwise we get a reducible conic.

Considering equations (2.6) and the form of the parabola (3.100) with $q \neq rv$, for systems (3.99) we obtain

$$s = v^2, \ u = 1, \ Eq_3 = 2 - U - 2vV, \ Eq_4 = -V$$

and evidently the equations $Eq_3 = 0$ and $Eq_4 = 0$ imply $V = 0$ and $U = 2$. Then calculations yield

$$Eq_5 = -q + 2cv^2 - v^2W = 0, \ \ Eq_6 = -r + 2cv + 2dv^2 - 2vW = 0, \ \ Eq_7 = 2dv - W = 0$$

and we get

$$W = 2dv, \;\; q = 2v^2(c - dv), \;\; r = 2v(c - dv) \;\Rightarrow\; q = rv.$$

So we obtain a reducible conic.

Thus we have proved that if systems (3.99) possess an invariant parabola then it is necessary of the form

$$\Phi(x, y) \equiv p + qx + ry + sx^2 = 0$$

with $s \neq 0$ and $r \neq 0$, otherwise we get a reducible conic. Then we may assume $s = 1$ and again, considering the ten equations (2.6) and the above parabola, for systems (3.99) we obtain

$$s = 1, \; u = v = 0, \;\; Eq_1 = 2 - U = 0, \;\; Eq_2 = -V = 0 \;\Rightarrow\; V = 0, \; U = 2$$

and then calculations yield:

$$Eq_5 = 2c - q - W = 0, \;\; Eq_6 = 2d - r = 0 \;\Rightarrow\; r = 2d \neq 0, \; W = 2c - q.$$

Therefore evaluating the remaining equations we obtain

$$Eq_8 = 2a - 2p - cq + q^2, \;\; Eq_9 = d(3q - 4c), \;\; Eq_{10} = 2bd - 2cp + aq + pq.$$

Since $d \neq 0$ (due to $r \neq 0$) the equation $Eq_9 = 0$ gives us $q = 4c/3$ and then from $Eq_8 = 0$ we get $p = (9a + 2c^2)/9$. In this case we obtain

$$Eq_{10} = \frac{2}{27}(9ac - 2c^3 + 27bd) = \frac{2}{27}\Upsilon_5 = 0.$$

Since $d \neq 0$ the condition $\Upsilon_5 = 0$ implies $b = \dfrac{c}{27d}(2c^2 - 9a)$ and we arrive at the systems

$$\dot{x} = a + cx + dy + x^2, \quad \dot{y} = \frac{c}{27d}(2c^2 - 9a) + xy \tag{3.101}$$

which possess the following invariant parabola:

$$\Phi(x, y) = \frac{1}{9}\left(9a + 2c^2\right) + \frac{4c}{3}x + 2dy + x^2, \;\; d \neq 0. \tag{3.102}$$

This complete the proof of the Lemma 3.19. □

Evaluating for systems (3.99) the invariant polynomials ζ_5 and ζ_{22} we obtain

$$\zeta_5 = -891d^2/4, \;\; \zeta_{22} = 9d^3(9ac - 2c^3 + 27bd) = 9d^3\Upsilon_5.$$

So the condition $d \neq 0$ is equivalent to $\zeta_5 \neq 0$ and in this case the condition $\Upsilon_5 = 0$ is equivalent to $\zeta_{22} = 0$. Therefore considering Lemma 3.19 we conclude that the following theorem is valid.

Theorem 3.20. *Assume that for a non-degenerate quadratic system the condition $C_2 = 0$ holds. Then this system possesses an invariant parabola (which is unique) if and only if the conditions $\zeta_5 \neq 0$ and $\zeta_{22} = 0$ hold.*

In order to determine a simpler canonical form of systems (3.101) we apply to these systems as well as to parabola (3.102) the translation

$$x = x_1 - \frac{2c}{3}, \quad y = y_1 - \frac{9a - 2c^2}{18d}.$$

Then we could set the following new notations:

$$k = -2d, \ m = -\frac{9a - 2c^2}{36d}, \ n = -\frac{c}{3} \ \Rightarrow$$
$$a = 2(km + n^2), \ c = -3n, \ d = -\frac{k}{2},$$

where $k \neq 0$ due to $d \neq 0$. Then we arrive at the family of systems

$$\dot{x}_1 = km + nx_1 - \frac{k}{2}y_1 + x_1^2, \quad \dot{y}_1 = 2mx_1 + 2ny_1 + x_1y_1,$$

which possess the invariant parabola

$$\Phi(x_1, y_1) = x_1^2 - ky_1, \quad k \neq 0.$$

Finally applying the rescaling $(x_1, y_1, t_1) \mapsto (kx, ky, t/k)$ we arrive at the systems

$$\dot{x} = m + nx - y/2 + x^2, \quad \dot{y} = 2mx + 2ny + xy,$$

which possess the invariant parabola $\Phi(x, y) = x^2 - y$.

As all the cases are investigated we conclude that the Main Theorem is proved.

Abstract. In this paper, we study the following Schrödinger–Hardy system

$$\begin{cases} -\Delta_{\mathbb{G}} u - \mu \frac{\psi^2}{r(\xi)^2} u = F_u(\xi, u, v) & \text{in } \Omega, \\ -\Delta_{\mathbb{G}} v - \nu \frac{\psi^2}{r(\xi)^2} v = F_v(\xi, u, v) & \text{in } \Omega, \\ u = v = 0 & \text{on } \partial\Omega, \end{cases}$$

where Ω is a smooth bounded domain on Carnot groups $\mathbb{G}$, whose homogeneous dimension is $Q \geq 3$, $\Delta_{\mathbb{G}}$ denotes the sub-Laplacian operator on $\mathbb{G}$, μ and ν are real parameters, $r(\xi)$ is the natural gauge associated with fundamental solution of $-\Delta_{\mathbb{G}}$ on $\mathbb{G}$, ψ is the geometrical function defined as $\psi = |\nabla_{\mathbb{G}} r|$, and $\nabla_{\mathbb{G}}$ is the horizontal gradient associated with $\Delta_{\mathbb{G}}$. The difficulty is not only the nonlinearities F_u and F_v without Ambrosetti–Rabinowitz condition, but also the hardy terms and the structure on Carnot groups. We obtain the existence of nonnegative solution for this system by mountain pass theorem in a new framework.

Keywords: Schrödinger–Hardy system, without Ambrosetti–Rabinowitz condition, Carnot groups, mountain pass theorem.

1 Introduction and main results

In this paper, we consider the following Schrödinger–Hardy system

$$\begin{cases} -\Delta_{\mathbb{G}} u - \mu \frac{\psi^2}{r(\xi)^2} u = F_u(\xi, u, v) & \text{in } \Omega, \\ -\Delta_{\mathbb{G}} v - \nu \frac{\psi^2}{r(\xi)^2} v = F_v(\xi, u, v) & \text{in } \Omega, \\ u = v = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where Ω is a smooth bounded domain on Carnot groups $\mathbb{G}$, whose homogeneous dimension is $Q \geq 3$, $\Delta_{\mathbb{G}}$ denotes the sub-Laplacian operator on $\mathbb{G}$, μ and ν are real parameters, $r(\xi)$ is

✉ Corresponding author. Email: fangyumath@163.com

the natural gauge associated with fundamental solution of $-\Delta_{\mathbb{G}}$ on $\mathbb{G}$, ψ is the geometrical function defined as $\psi = |\nabla_{\mathbb{G}} r|$, and $\nabla_{\mathbb{G}}$ is the horizontal gradient associated with $\Delta_{\mathbb{G}}$. The difficulty in this paper is not only the nonlinearities F_u and F_v without Ambrosetti–Rabinowitz condition, but also the hardy terms and the structure on Carnot groups.

In the context of stratified groups, the problem has been intensively studied in last decades, starting with the pioneering papers [21,22]. In particular, a number of literatures are related to Heisenberg group, such as [4,15,16,23,35,36] and references therein. Only few results concern the general Carnot setting. For related topics, see [2,3,11,31,37] and references therein.

We mention that Ferrara et al. [17] obtained the existence of a weak solution for the following problem

$$\begin{cases} -\Delta_{\mathbb{G}} u = \lambda f(\xi, u) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

where Ω is a bounded domain of $\mathbb{G}$, $\lambda > 0$ is a real parameter, and f is a subcritical nonlinearity. For critical exponent subelliptic problem,

$$\begin{cases} -\Delta_{\mathbb{G}} u = |u|^{2^*-2}u + f & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.2}$$

with $2^* = \frac{2Q}{Q-2}$. When $f = 0$, problem (1.2) does not admit any nonnegative non trivial solution on star-shaped domain, see [21, 22]. If Ω is a bounded domain of $\mathbb{G}$, Loiudice [27] established the existence of positive and sign changing solutions for $f = \lambda u$, extending the famous Brezis–Nirenberg results [8] to the subelliptic Carnot setting. Subsequently, by Nehari manifold and Ekeland variational principle, Loiudice [32] considered the general non-homogeneous problem (1.2) and proved the existence of at least two positive solutions, provided that non-homogeneous term f satisfies suitable assumptions.

Concerning the problem for sub-Laplacian operator involving critical Hardy–Sobolev nonlinearity

$$\begin{cases} -\Delta_{\mathbb{G}} u = \frac{\psi^{\alpha}}{r(\xi)^{\alpha}}|u|^{2^*(\alpha)-2}u + \lambda u & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

where $\Omega \subset \mathbb{G}$ is a bounded domain, $0 < \alpha < 2$, $2^*(\alpha) = \frac{2(Q-\alpha)}{Q-2}$ is the critical Sobolev–Hardy exponent, Loiudice [29] proved that if $\lambda = 0$, there is no nonnegative nontrivial solutions when Ω is a bounded star-shaped domain about the origin with respect to dilations of the group. Also, the existence of solution was established provided that $\lambda > 0$.

For more general nonlinearity with Hardy type potential, that is

$$\begin{cases} -\Delta_{\mathbb{G}} u - \mu\frac{\psi^2}{r(\xi)^2}u = f(\xi, u) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.3}$$

where Ω is an open subset of $\mathbb{G}$, $0 \in \Omega$, $0 \le \mu < (\frac{Q-2}{2})^2$, the function f satisfies $f(\xi, u) \le C(|u| + |u|^{2^*-1})$, $\forall(\xi, u) \in \Omega \times \mathbb{R}$ and $C > 0$ is a constant. By L^p regularity of solutions and Moser's iteration, Loiudice [30] showed that any positive solution of (1.3) has a stronger singularity as $\mu \to (\frac{Q-2}{2})^2$. When f is a purely critical nonlinearity, that is $f(u) = |u|^{2^*-2}u$, the behavior of solutions at origin shows the decay of solution at infinity by Kelvin transform on $\mathbb{R}^n$ in Euclidean setting. However, this technique fails in Carnot group, because there does not exist a suitable inversion with good conformal properties. We point out this technique is true for a special subclass of stratified groups, that is the Iwasawa-type groups $\mathbb{H}$. Loiudice [28] showed that if $u \in \mathcal{S}_0^1(\Omega)$ is a solution to

$$-\Delta_{\mathbb{H}} u - \mu \frac{\psi^2}{r(\xi)^2} u = |u|^{2^*-2} u \quad \text{in } \Omega,$$

there is $C_1 > 0$ such that

$$|u(\xi)| \le C_1 r(\xi)^{-\sqrt{\mu_{\mathbb{H}}} - \sqrt{\mu_{\mathbb{H}} - \mu}}, \quad \text{for } r(\xi) \text{ large.}$$

Moreover, if u is positive, there exists $C_2 > 0$ such that

$$|u(\xi)| \ge C_2 r(\xi)^{-\sqrt{\mu_{\mathbb{H}}} - \sqrt{\mu_{\mathbb{H}} - \mu}}, \quad \text{for } r(\xi) \text{ large,}$$

where $\mathcal{S}_0^1(\Omega)$ is the Folland–Stein space, defined as the completion of $C_0^\infty(\Omega)$ with respect to the norm

$$\|u\|_{\mathcal{S}_0^1(\Omega)} = \Big(\int_\Omega |\nabla_{\mathbb{G}} u|^2 d\xi \Big)^{\frac{1}{2}},$$

and $\mu_{\mathbb{H}} = (\frac{Q-2}{2})^2$ is the best constant in Hardy inequality on Iwasawa-type groups,

$$\mu_{\mathbb{H}} \int_{\mathbb{H}} \psi^2 \frac{|u|^2}{r(\xi)^2} d\xi \le \int_{\mathbb{H}} |\nabla_{\mathbb{H}} u|^2 d\xi, \quad \forall u \in C_0^\infty(\mathbb{H}),$$

and it is never attained, some more details can be seen in [5, 10]. Moreover, this result was extended to the whole Carnot groups in [33] by using different methods, and Loiudice investigated the existence and nonexistence for subelliptic Brezis–Nirenberg type problem as follows

$$\begin{cases} -\Delta_{\mathbb{G}} u - \mu \frac{\psi^2}{r(\xi)^2} u = u^{2^*-1} + \lambda u & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases}$$

Concerning the results in the whole Carnot group, Zhang [39] considered the following equation

$$-\Delta_{\mathbb{G}} u = \lambda \frac{\psi^\alpha}{r(\xi)^\alpha} |u|^{2^*(\alpha)-2} u + \beta f(\xi) |u|^{p-2} u \quad \text{in } \mathbb{G},$$

where λ, $\beta > 0$ are parameters, $0 < \alpha \le 2$, Zhang proved the existence and multiplicity of solutions by variational methods and the theory of genus. Concerning multiple Hardy nonlinearities, Zhang [38] proved the attainability of best Sobolev–Hardy constant of

$$S_{\mu,\alpha} = \inf_{u \in \mathcal{S}^1(\mathbb{G}) \setminus \{0\}} \frac{\int_{\mathbb{G}} |\nabla_{\mathbb{G}} u|^2 d\xi - \mu \int_{\mathbb{G}} \frac{\psi(\xi)^2}{r(\xi)^2} |u|^2 d\xi}{\Big(\int_{\mathbb{G}} \frac{\psi(\xi)^\alpha}{r(\xi)^\alpha} |u|^{2^*(\alpha)} d\xi \Big)^{\frac{2}{2^*(\alpha)}}}.$$

Moreover, as an application, by variational methods and local compactness of Palais–Smale sequences, Zhang obtained the existence of nontrivial weak solution to the following singularity sub-elliptic equation and system

$$-\Delta_{\mathbb{G}} u - \mu \frac{\psi(\xi)^2}{r(\xi)^2} u = \frac{\psi(\xi)^\alpha}{r(\xi)^\alpha} |u|^{2^*(\alpha)-2} u + \frac{\psi(\xi)^\beta}{r(\xi)^\beta} |u|^{2^*(\beta)-2} u \quad \text{in } \mathbb{G},$$

and

$$\begin{cases} -\Delta_{\mathbb{G}}u-\mu\frac{\psi(\xi)^2}{r(\xi)^2}u=\frac{\psi(\xi)^\alpha}{r(\xi)^\alpha}|u|^{2^*(\alpha)-2}u+\frac{\lambda\eta}{\eta+\theta}\frac{\psi(\xi)^\alpha}{r(\xi)^\alpha}|u|^{\eta-2}u|v|^\theta & \text{in } \mathbb{G}, \\ -\Delta_{\mathbb{G}}v-\mu\frac{\psi(\xi)^2}{r(\xi)^2}v=\frac{\psi(\xi)^\alpha}{r(\xi)^\alpha}|v|^{2^*(\alpha)-2}v+\frac{\lambda\eta}{\eta+\theta}\frac{\psi(\xi)^\alpha}{r(\xi)^\alpha}|u|^{\eta}|v|^{\theta-2}v & \text{in } \mathbb{G}, \end{cases}$$

where $0\le\alpha,\ \beta<2$ and $\eta,\ \theta>1$ with $\eta+\theta=2^*(\alpha)$, $\lambda>0$ is a parameter. Further, the problems with Hardy potential have been considered by [24] and [6,7,34,35] for Hardy nonlinearity in Heisenberg group. In particular, we mention that Bordoni and Pucci [6] first proved the existence of nontrivial nonnegative solutions of the Schrödinger system including multiple critical nonlinearities and Hardy potentials in Heisenberg groups.

In order to deal with (1.1), we introduce the Sobolev-type inequality: there exists a positive constant $C>0$ such that

$$\int_\Omega |u|^{2^*}d\xi\le C\Big(\int_\Omega|\nabla_{\mathbb{G}}u|^2d\xi\Big)^{\frac{2^*}{2}},\quad \forall u\in C_0^\infty(\Omega), \tag{1.4}$$

where 2^* is the critical exponent for $\Delta_{\mathbb{G}}$, the embedding $\mathcal{S}_0^1(\Omega)\hookrightarrow L^q(\Omega)$ is compact for $1\le q<2^*$ but only continuous for $q=2^*$, and the Hardy-type inequality is: for every $u\in C_0^\infty(\Omega)$, there holds

$$\Big(\frac{Q-2}{2}\Big)^2\Big(\int_\Omega\frac{\psi^2}{r(\xi)^2}|u|^2d\xi\Big)\le\int_\Omega|\nabla_{\mathbb{G}}u|^2d\xi, \tag{1.5}$$

where $\big(\frac{Q-2}{2}\big)^2$ is the optimal constant but never attained (see [12,20]). (1.5) is first proved by Garofalo and Lanconelli [20] in Heisenberg group, then, D'Ambrosio [12] extended this result to all Carnot groups. Moreover, the best Hardy constant $\mathcal{K}>0$ of (1.5) is given by

$$\mathcal{K}=\inf_{u\in\mathcal{S}_0^1(\Omega),u\neq0}\frac{\|u\|^2_{\mathcal{S}_0^1(\Omega)}}{\|u\|_\psi^2}\quad\text{with}\quad \|u\|_\psi^2=\int_\Omega\frac{\psi^2}{r(\xi)^2}|u|^2d\xi. \tag{1.6}$$

Now, let us define a suitable solution space $W=\mathcal{S}_0^1(\Omega)\times\mathcal{S}_0^1(\Omega)$, which is a separable, reflexive Banach space and endowed with the norm

$$\|(u,v)\|=\Big(\|u\|^2_{\mathcal{S}_0^1(\Omega)}+\|v\|^2_{\mathcal{S}_0^1(\Omega)}\Big)^{\frac12}, \tag{1.7}$$

we denote

$$\|(u,v)\|_p=\Big(\int_\Omega|(u,v)|^pd\xi\Big)^{\frac1p}=\Big(\int_\Omega|(u^2+v^2)^{\frac12}|^pd\xi\Big)^{\frac1p},$$

for $1\le p<\infty$, and let

$$\lambda^*=\inf_{(u,v)\in W\setminus\{(0,0)\}}\frac{\|(u,v)\|^2}{\|(u,v)\|_2^2}>0.$$

Throughout the paper, we assume that $F(\xi,u,v):\Omega\times\mathbb{R}^2\to\mathbb{R}$ is continuous, $F(\xi,0,0)=0$ in Ω, and it satisfies the following assumptions.

(f_1) The partial derivatives F_u, $F_v\in C(\Omega\times\mathbb{R}^2)$, $F(\xi,u,v)\ge0$ in $\Omega\times\mathbb{R}^2$. Moreover, for each $\xi\in\Omega$,

$$F_u(\xi,u,v)=0\begin{cases}\text{if } u\le0 \text{ and } v\in\mathbb{R},\\ \text{if } v\le0\text{ and } u\in\mathbb{R}.\end{cases}$$

(f_2) There exists $s \in (2, 2^*)$ and $\lambda \in [0, \lambda^*)$, then for each $\epsilon > 0$, there is a constant $C_\epsilon > 0$ such that

$$|F_w(\xi, w)| \leq (\lambda + \epsilon)|w| + C_\epsilon |w|^{s-1},$$

for every $(\xi, w) \in \Omega \times \mathbb{R}^2$, $w = (u, v)$, $|w| = \sqrt{u^2 + v^2}$, where $F_w = (F_u, F_v)$.

(f_3) $\lim\limits_{|w|\to\infty} \frac{2F(\xi,w)}{|w|^2} = \infty$, uniformly in Ω.

(f_4) For any $w = (u, v) \in \mathbb{R}^+ \times \mathbb{R}^+$ and $0 < \tau < 1$, there exists a nonnegative function $g \in L^1(\Omega)$ and a constant $C_F \geq 1$ such that $H(\xi, \tau w) \leq C_F H(\xi, w) + g(\xi)$, where $H(\xi, w) = F_w(\xi, w)w - 2F(\xi, w)$.

The main result can be stated as follows.

Theorem 1.1. *Assume that F satisfies (f_1)–(f_4). Then (1.1) has at least a nonnegative solution $(u, v) \in W$ for any μ, $\nu \in (-\infty, \mathcal{K})$ such that*

$$\Theta - \frac{2\lambda}{\lambda^*} > 0, \tag{1.8}$$

where $\lambda \in [0, \lambda^*)$, $\Theta = \min\left\{1 - \frac{\mu^+}{\mathcal{K}}, 1 - \frac{\nu^+}{\mathcal{K}}\right\}$, $\mu^+ = \max\{0, \mu\}$ and $\nu^+ = \max\{0, \nu\}$.

In this paper, the main difficulty is that the energy functional does not satisfy Palais–Smale condition since the nonlinearities F_u and F_v loss the Ambrosetti–Rabinowitz condition, see also [14, 25, 26]. It should be mentioned that the (f_4) plays an important role in proving the boundless of Palais–Smale sequence.

The rest of the paper is organized as follows. In Section 2, we recall the main notations and definitions related to the Carnot groups, and present some preparatory results. In Section 3, we prove that the energy functional satisfies the mountain pass geometry structures. In Section 4, we obtain the compactness theorem and prove the main result. Finally, we show two lemmas in Section 5.

2 The functional setting of Carnot groups

We briefly recall the definitions and notations related to the Carnot groups functional setting. For a complete treatment, we refer to [5, 18, 19].

2.1 The Carnot groups

A Carnot group is a homogeneous group, denoted as $\mathbb{G} = (\mathbb{R}^n, \circ, \mathfrak{F})$, whose Lie algebra $\mathfrak{g}$ is stratified, that is, $\mathfrak{g} = \bigoplus_{i=1}^r V_i$, where $r > 0$ is a integer number and called the *step* of $\mathbb{G}$, $\mathfrak{g}$ is the Lie algebra of left invariant vector fields on $\mathbb{G}$, V_i is a linear subspace of $\mathfrak{g}$, $i = 1, \ldots, r$, and satisfies

$$\begin{aligned}
&\dim V_i = n_i, \text{ for } i = 1, \ldots, r, \\
&[V_1, V_i] = V_{i+1}, \text{ for } 1 \leq i \leq r-1, \text{ and } [V_1, V_r] = \{0\}.
\end{aligned}$$

From these, we can see that $[V_1, V_i]$ stands for the subspace of $\mathfrak{g}$ generated by the commutators $[X, Y]$ with $X \in V_1$, $Y \in V_i$.

In fact, $(\mathbb{R}^n, \circ)$ is a Lie group equipped with a family of group automorphisms (namely *dilatations*) $\mathfrak{F} := \{\delta_\eta\}_{\eta>0}$ such that, for every $\eta > 0$, the map

$$\delta_\eta : \prod_{i=1}^{r} \mathbb{R}^{n_i} \to \prod_{i=1}^{r} \mathbb{R}^{n_i},$$

shows that $\delta_\eta(\xi^{(1)}, \ldots, \xi^{(r)}) = (\eta\xi^{(1)}, \eta^2\xi^{(2)}, \ldots, \eta^r\xi^{(r)})$, where $\xi^{(i)} \in \mathbb{R}^{n_i}$, $i = 1, \ldots, r$, and $\sum_{i=1}^{r} n_i = n$. The structure $\mathbb{G} = (\mathbb{R}^n, \circ, \mathfrak{F})$ is called a *homogeneous group*, and $Q = \dim_h \mathbb{G} := \sum_{k=1}^{r} k n_k$ is called the *homogeneous dimension* of $\mathbb{G}$. In this paper, we pay attention to $\dim_h \mathbb{G} \geq 3$. In particular, $\mathbb{G}$ is the Euclidean space provided that $\dim_h \mathbb{G} \leq 3$, i.e. $\mathbb{G} = (\mathbb{R}^{\dim_h \mathbb{G}}, +)$.

Let $\{X_j\}_{j=1}^{n_1}$ be a basis of V_1, then the associated subelliptic operator $\Delta_{\mathbb{G}}$ is given by

$$\Delta_{\mathbb{G}} := \sum_{j=1}^{n_1} X_j^2,$$

which is the second order differential operator on $\mathbb{G}$. Here, n_1 is the dimension of the first step, moreover, the subelliptic gradient is $\nabla_{\mathbb{G}} := (X_1, X_2, \ldots, X_{n_1})$. As proved in [18], there exists a suitable homogeneous norm $r(\xi)$, called *gauge norm*, such that $\Gamma(\xi) = \frac{C}{r(\xi)^{Q-2}}$ is the fundamental solution of $-\Delta_{\mathbb{G}}$, where $C > 0$ is a constant. By definition, a homogeneous norm is any continuous function from $\mathbb{G}$ to $[0, +\infty)$ such that for $\eta > 0$, $\xi \in \mathbb{G}$, $r(\delta_\eta(\xi)) = \eta r(\xi)$, $r(\xi^{-1}) = r(\xi)$, $r(\xi) = 0$ if and only if $\xi = 0$.

2.2 Functional setting and preliminary results

In this subsection, we present some useful results and comments, (1.1) has a variational structure and the Euler–Lagrange functional $I_{\mu,\nu} : W \to \mathbb{R}$ is given by

$$I_{\mu,\nu}(u,v) = \frac{1}{2}\|u\|^2_{\mathcal{S}_0^1(\Omega)} + \frac{1}{2}\|v\|^2_{\mathcal{S}_0^1(\Omega)} - \frac{\mu}{2}\|u\|^2_\psi - \frac{\nu}{2}\|v\|^2_\psi - \int_\Omega F(\xi, u, v)d\xi,$$

for all $u, v \in W$. Indeed, $I_{\mu,\nu}$ is well defined and be of class $C^1(W)$ under the assumptions (f_1) and (f_2). A function $(u, v) \in W$ is a weak solution of (1.1) if holds

$$\langle u, \Phi\rangle + \langle v, \Psi\rangle - \mu\langle u, \Phi\rangle_\psi - \nu\langle v, \Psi\rangle_\psi = \int_\Omega \Big(F_u(\xi, u, v)\Phi + F_v(\xi, u, v)\Psi\Big)d\xi,$$

for every $(\Phi, \Psi) \in W$, where

$$\langle u, \Phi\rangle = \int_\Omega (\nabla_{\mathbb{G}} u, \nabla_{\mathbb{G}} \Phi)d\xi, \qquad \langle v, \Psi\rangle = \int_\Omega (\nabla_{\mathbb{G}} v, \nabla_{\mathbb{G}} \Psi)d\xi,$$
$$\langle u, \Phi\rangle_\psi = \int_\Omega \frac{\psi^2}{r(\xi)^2} u\Phi d\xi, \qquad \langle v, \Psi\rangle_\psi = \int_\Omega \frac{\psi^2}{r(\xi)^2} v\Psi d\xi.$$

Moreover, for all $(u, v) \in W$, there holds

$$\langle I'_{\mu,\nu}(u, v), (\Phi, \Psi)\rangle = \langle u, \Phi\rangle + \langle v, \Psi\rangle - \mu\langle u, \Phi\rangle_\psi - \nu\langle v, \Psi\rangle_\psi - \int_\Omega \Big(F_u(\xi, u, v)\Phi + F_v(\xi, u, v)\Psi\Big)d\xi, \quad \text{for every } (\Phi, \Psi) \in W.$$

Therefore, the weak solutions of (1.1) are exactly the critical points of $I_{\mu,\nu}$.

Lemma 2.1. *The embedding* $W \hookrightarrow L^q(\Omega) \times L^q(\Omega)$ *is continuous for* $1 \le q \le 2^*$ *and* $\|(u,v)\|_q \le C_q'\|(u,v)\|$ *for all* $(u,v) \in W$ *and* $C_q' > 0$ *is a constant.*

Proof. From [19], we know that $\mathcal{S}_0^1(\Omega) \hookrightarrow L^q(\Omega)$ for $1 \le q \le 2^*$, thus, there is $C_q > 0$ such that

$$\|u\|_q \le C_q\|u\|_{\mathcal{S}_0^1(\Omega)} \quad \text{and} \quad \|v\|_q \le C_q\|v\|_{\mathcal{S}_0^1(\Omega)}.$$

Moreover, by (f_2), (1.7) and a fact $a+b \le \sqrt{2(a^2+b^2)}$ for each $a,b \in \mathbb{R}$, there holds

$$\begin{aligned}\|(u,v)\|_q &= \|\sqrt{u^2+v^2}\|_q \le \|\sqrt{(u+v)^2}\|_q \le \|u\|_q + \|v\|_q \\ &\le C_q(\|u\|_{\mathcal{S}_0^1(\Omega)} + \|v\|_{\mathcal{S}_0^1(\Omega)}) \le C_q\sqrt{2(\|u\|^2_{\mathcal{S}_0^1(\Omega)} + \|v\|^2_{\mathcal{S}_0^1(\Omega)})} = C_q'\|(u,v)\|.\end{aligned}$$

This proof is finished. □

Lemma 2.2 ([1])**.** *Let* $\{(u_k,v_k)\} \subset W$ *be such that* $(u_k,v_k) \rightharpoonup (u,v)$ *weakly in* W *as* $k \to \infty$*, then up to a subsequence,* $(u_k,v_k) \to (u,v)$ *a.e. in* Ω *as* $k \to \infty$*.*

Lemma 2.3. *Let* $\Omega \subset \mathbb{G}$ *be a smooth bounded domain, then, the embedding* $W \hookrightarrow L^q(\Omega) \times L^q(\Omega)$ *is compact when* $1 \le q < 2^*$*.*

Proof. From [19], it holds that $S_0^1(\Omega) \hookrightarrow L^q(\Omega)$ is compact for $1 \le q < 2^*$, that is, if $\{u_k\}$ and $\{v_k\}$ are bounded sequences in $S_0^1(\Omega)$, then there exist $u, v \in W$ such that,

$$u_k \to u \quad \text{and} \quad v_k \to v \quad \text{in} \quad L^q(\Omega).$$

Hence, if $\{(u_k,v_k)\} \subset W$ be a bounded sequence, we have

$$\|(u_k,v_k) - (u,v)\|_q \le \|u_k - u\|_q + \|v_k - v\|_q \to 0.$$

It follows that $\{(u_k,v_k)\}$ strongly in $L^q(\Omega) \times L^q(\Omega)$. □

In the following, we recall the definition of Cerami sequence and Cerami condition.

Definition 2.4. Let $X = (X, \|\cdot\|)$ be a Banach space, X' denotes its dual space, the functional $I : X \to \mathbb{R}$ be of $C^1(X)$.

(i) Cerami sequence: A sequence $u_k \in X$ is called a Cerami sequence if for every $u_k \in X$, $I(u_k)$ is bounded and $(1 + \|u_k\|)\|I'(u_k)\|_{X'} \to 0$ as $k \to \infty$. In particular, $\|I'(u_k)\|_{X'} \to 0$ as $k \to \infty$.

(ii) Cerami condition: A functional I satisfies the Cerami condition if any Cerami sequence associated with I has a strongly convergent subsequence in X.

3 Mountain pass structure

In this section, the results concern the existence of Palais–Smale sequence for $I_{\mu,\nu}$.

Lemma 3.1 ([9])**.** *Let* E *be a real Banach space,* $\mathcal{I} \in C^1(E)$ *with* $\mathcal{I}(0) = 0$*. There are constants* $\rho, \tau > 0$ *and* $e \in E$ *with* $\|e\|_E > \rho$ *such that*

$$\inf_{\|u\|_E = \rho} \mathcal{I}(u) \ge \tau \quad \text{and} \quad \mathcal{I}(e) < 0.$$

Then there is a Cerami sequence $\{u_k\} \subset E$ *such that*

$$\mathcal{I}(u_k) \to c, \quad (1 + \|u_k\|_E)\|I'(u_k)\|_E \to 0,$$

where

$$c := \inf_{\gamma\in\Gamma} \max_{t\in[0,1]} \mathcal{I}(\gamma(t)) \geq \tau,$$

and

$$\Gamma = \{\gamma \in C([0,1], E) : \gamma(0) = 0, \gamma(1) = e\}.$$

The number c is called mountain pass level. If the functional $\mathcal{I}$ *satisfies the Cerami condition at the minimax level c, then c is a critical value of* $\mathcal{I}$ *in E.*

We first show that the energy functional $\mathcal{I}_{\mu,\nu}$ satisfies the geometric structure required by Lemma 3.1.

Lemma 3.2. *Assume that* (f_2) *holds, then there exist* ζ, $\rho > 0$ *such that*

$$I_{\mu,\nu}(u,v) \geq \zeta, \quad \text{if } \|(u,v)\| = \rho.$$

Proof. Let us set $\chi = \min\{(1 - \frac{\mu^+}{\mathcal{K}}), (1 - \frac{\nu^+}{\mathcal{K}})\}$ and from (f_2), we have

$$\begin{aligned}
I_{\mu,\nu}(u,v) &= \frac{1}{2}\|u\|^2_{\mathcal{S}^1_0(\Omega)} + \frac{1}{2}\|v\|^2_{\mathcal{S}^1_0(\Omega)} - \frac{\mu}{2}\|u\|^2_{\psi} - \frac{\nu}{2}\|v\|^2_{\psi} - \int_\Omega F(\xi,u,v)d\xi \\
&\geq \frac{1}{2}\|u\|^2_{\mathcal{S}^1_0(\Omega)}\Big(1 - \frac{\mu^+}{\mathcal{K}}\Big) + \frac{1}{2}\|v\|^2_{\mathcal{S}^1_0(\Omega)}\Big(1 - \frac{\nu^+}{\mathcal{K}}\Big) \\
&\quad - \int_\Omega \Big(\frac{1}{2}(\lambda+\epsilon)|(u,v)|^2 + \frac{1}{s}C_\epsilon|(u,v)|^s\Big)d\xi \\
&\geq \frac{\chi}{2}(\|u\|^2_{\mathcal{S}^1_0(\Omega)} + \|v\|^2_{\mathcal{S}^1_0(\Omega)}) - \frac{1}{2}(\lambda+\epsilon)\|(u,v)\|^2_2 - \frac{1}{s}C_\epsilon\|(u,v)\|^s_s \\
&\geq \frac{\chi}{2}\|(u,v)\|^2 - \frac{1}{2\lambda^*}(\lambda+\epsilon)\|(u,v)\|^2 - \frac{1}{s}C_\epsilon C_s\|(u,v)\|^s \\
&= \frac{1}{2}\Big(\chi - \frac{\lambda+\epsilon}{\lambda^*} - \frac{2}{s}C_\epsilon C_s\|(u,v)\|^{s-2}\Big)\|(u,v)\|^2,
\end{aligned}$$

where $C_s > 0$ is a constant, $\mathcal{K}$ is given in (1.6) and $s \in (2, 2^*)$. Thus, if ρ is small enough such that

$$\chi - \frac{\lambda+\epsilon}{\lambda^*} - \frac{2}{s}C_\epsilon C_s\rho^{s-2} > 0,$$

it holds $I_{\mu,\nu}(u,v) \geq \frac{1}{2}(\chi - \frac{\lambda+\epsilon}{\lambda^*} - \frac{2}{s}C_\epsilon C_s\rho^{s-2})\rho^2 = \zeta > 0$ for all $(u,v) \in W$ with $\|(u,v)\| = \rho$. We obtain this lemma. □

Lemma 3.3. *Suppose that* (f_3) *holds, then there exists* $(\tilde{u},\tilde{v}) \in W$ *with* $\|(\tilde{u},\tilde{v})\| > \rho$ *such that* $I_{\mu,\nu}(\tilde{u},\tilde{v}) < 0$.

Proof. It suffices to prove that for a fixed $(u_0,v_0) \in W$, $I_{\mu,\nu}(tu_0,tv_0) \to -\infty$ as $t \to +\infty$. We assume that $(u,v) \in W$ with compact support $\mathbf{D_c}$. From (f_3), there are constants c_1, c_2, $\delta > 0$, such that for $|u|$, $|v| > \delta$, one has

$$F(\xi,u,v) \geq c_1|(u,v)|^2 \geq c_1|(u,v)|^2 - c_2, \quad \text{for } (u,v) \in W.$$

Now, choosing arbitrarily $(u_0, v_0) \in W$ with $u_0, v_0 > 0$, and $\|(u_0, v_0)\| = 1$, hence, for all $t > 0$, we set $\mu^- = \min\{0, \mu\}$ and $\nu^- = \min\{0, \nu\}$, then

$$\begin{aligned} I_{\mu,\nu}(tu_0, tv_0) &\leq \frac{t^2}{2}\Big(\|u_0\|^2_{\mathcal{S}^1_0(\Omega)} + \|v_0\|^2_{\mathcal{S}^1_0(\Omega)} - \mu\|u_0\|^2_\psi - \nu\|v_0\|^2_\psi\Big) - \int_\Omega \Big(c_1|(tu_0, tv_0)|^2 - c_2\Big)d\xi \\ &\leq \frac{t^2}{2}\Big(\|u_0\|^2_{\mathcal{S}^1_0(\Omega)} + \|v_0\|^2_{\mathcal{S}^1_0(\Omega)} + |\mu^-|\|u_0\|^2_\psi + |\nu^-|\|v_0\|^2_\psi - 2c_1\|(u_0, v_0)\|^2_2\Big) + c_2|\mathbf{D_c}|. \end{aligned}$$

If c_1 is large enough, there holds

$$0 < \|u_0\|^2_{\mathcal{S}^1_0(\Omega)} + \|v_0\|^2_{\mathcal{S}^1_0(\Omega)} + |\mu^-|\|u_0\|^2_\psi + |\nu^-|\|v_0\|^2_\psi < 2c_1\|(u_0, v_0)\|^2_2.$$

Therefore, we have $I_{\mu,\nu}(tu_0, tu_0) \to -\infty$ as $t \to \infty$. Setting $(\tilde{u}, \tilde{v}) = (t_0u_0, t_0u_0) \in W$, such that $\|(\tilde{u}, \tilde{v})\| > \rho$ and $I_{\mu,\nu}(\tilde{u}, \tilde{v}) < 0$. We obtain this lemma. □

4 Cerami sequence and existence of solutions

4.1 Cerami sequence

In this section, we give an analysis of Cerami sequence and prove that $I_{\mu,\nu}$ satisfies Cerami condition.

Lemma 4.1. *Assume that (f_1)–(f_4) hold, then for each μ, $\nu \in (-\infty, \mathcal{K})$, any Cerami sequence of $I_{\mu,\nu}$ is bounded in W.*

Proof. Let $\{(u_k, v_k)\} \subset W$ be a Cerami sequence of $I_{\mu,\nu}$, then, there exists $\mathcal{L} > 0$ independent of k such that

$$|I_{\mu,\nu}(u_k, v_k)| \leq \mathcal{L} \quad \text{for all } k, \quad (1 + \|(u_k, v_k)\|)I'_{\mu,\nu}(u_k, v_k) \to 0 \quad \text{as } k \to \infty. \tag{4.1}$$

Thus, there is $\tau_k > 0$ and $\tau_k \to 0$ as $k \to \infty$, such that

$$|\langle I'_{\mu,\nu}(u_k, v_k), (\Phi, \Psi)\rangle| \leq \frac{\tau_k\|(\Phi, \Psi)\|}{1 + \|(u_k, v_k)\|}, \quad \forall(\Phi, \Psi) \in W. \tag{4.2}$$

Let us set $(\Phi, \Psi) = (u_k, v_k)$, then

$$\begin{aligned} &\Big|\langle u_k, u_k\rangle + \langle v_k, v_k\rangle - \mu\langle u_k, u_k\rangle_\psi - \nu\langle v_k, v_k\rangle_\psi - \int_\Omega \Big(F_u(\xi, u_k, v_k)u_k + F_v(\xi, u_k, v_k)v_k\Big)d\xi\Big| \\ &\quad = |\langle I'_{\mu,\nu}(u_k, v_k), (u_k, v_k)\rangle| \leq \frac{\tau_k\|(u_k, v_k)\|}{1 + \|(u_k, v_k)\|} \leq \tau_k \leq C, \end{aligned}$$

that is

$$\begin{aligned} &- \|u_k\|^2_{\mathcal{S}^1_0(\Omega)} - \|v_k\|^2_{\mathcal{S}^1_0(\Omega)} + \mu\|u_k\|^2_\psi + \nu\|v_k\|^2_\psi \\ &\qquad + \int_\Omega \Big(F_u(\xi, u_k, v_k)u_k + F_v(\xi, u_k, v_k)v_k\Big)d\xi \leq C. \end{aligned} \tag{4.3}$$

Now, we prove that (u_k, v_k) is bounded in W. Suppose, by contradiction, $\|(u_k, v_k)\| \to \infty$ as $k \to \infty$. We define a sequence as $(w_k, z_k) = \frac{(u_k, v_k)}{\|(u_k, v_k)\|}$, then, $\|(w_k, z_k)\| = 1$. By Lemmas 2.2 and 2.3, there exists $(w, z) \in W$ such that

$$\begin{aligned} &(w_k, z_k) \rightharpoonup (w, z) \quad \text{weakly in } W, \\ &(w_k, z_k) \to (w, z) \quad \text{strongly in } L^q(\Omega) \times L^q(\Omega) \quad \text{for } q \in [1, 2^*), \\ &(w_k, z_k) \to (w, z) \quad \text{a.e. in } \Omega. \end{aligned} \tag{4.4}$$

We divide the argument into several steps.

Step 1: We prove $w \geq 0$ and $z \geq 0$ *a.e.* in Ω. Let us set $w_k^- = \min\{0, w_k\}$ and $z_k^- = \min\{0, z_k\}$, then (w_k^-, z_k^-) is bounded because (w_k, z_k) in W is bounded. We choose $(\Phi, \Psi) = (w_k^-, z_k^-)$ in (4.2), it follows that

$$o(1) = \frac{|\langle I'_{\mu,\nu}(u_k, v_k), (w_k^-, z_k^-)\rangle|}{\|(u_k, v_k)\|} \quad \text{for } \|(u_k, v_k)\| \to \infty.$$

Therefore, from (f_1), the elementary inequality $|a^- - b^-|^2 \leq (a-b)(a^- - b^-)$, $(a, b \in \mathbb{R})$, (1.5) and a fact that $\mu, \nu < \mathcal{K}$, one has

$$\begin{aligned}
o(1) &= \frac{1}{\|(u_k, v_k)\|}\Big(\langle u_k, w_k^-\rangle + \langle v_k, z_k^-\rangle - \mu\langle u_k, w_k^-\rangle_\psi - \nu\langle v_k, z_k^-\rangle_\psi \\
&\quad - \int_\Omega \Big(F_u(\xi, u_k, v_k)w_k^- + F_v(\xi, u_k, v_k)z_k^-\Big)d\xi\Big) \\
&= \frac{1}{\|(u_k, v_k)\|^2}\Big(\langle u_k, u_k^-\rangle + \langle v_k, v_k^-\rangle - \mu\langle u_k, u_k^-\rangle_\psi - \nu\langle v_k, v_k^-\rangle_\psi\Big) \\
&\quad - \int_\Omega \frac{\Big(F_u(\xi, u_k, v_k)u_k^- + F_v(\xi, u_k, v_k)v_k^-\Big)}{\|(u_k, v_k)\|^2} d\xi \\
&= \frac{1}{\|(u_k, v_k)\|^2}\Big(\langle u_k, u_k^-\rangle + \langle v_k, v_k^-\rangle - \mu\langle u_k, u_k^-\rangle_\psi - \nu\langle v_k, v_k^-\rangle_\psi\Big) \\
&\geq \frac{1}{\|(u_k, v_k)\|^2}\Big(\|u_k^-\|^2_{\mathcal{S}_0^1(\Omega)} + \|v_k^-\|^2_{\mathcal{S}_0^1(\Omega)} - \mu\|u_k^-\|^2_\psi - \nu\|v_k^-\|^2_\psi\Big) \\
&\geq \Big(1 - \frac{\mu^+}{\mathcal{K}}\Big)\|w_k^-\|^2_{\mathcal{S}_0^1(\Omega)} + \Big(1 - \frac{\nu^+}{\mathcal{K}}\Big)\|z_k^-\|^2_{\mathcal{S}_0^1(\Omega)}.
\end{aligned}$$

It follows that

$$\|w_k^-\|_{\mathcal{S}_0^1(\Omega)} \to 0 \quad \text{and} \quad \|z_k^-\|_{\mathcal{S}_0^1(\Omega)} \to 0.$$

Hence, $(w_k^-, z_k^-) \to (0, 0)$ in W as $k \to \infty$, $(w_k^-, z_k^-) = (0, 0)$ *a.e* in Ω, by the definition of w_k^- and z_k^-, we get that $w \geq 0$ and $z \geq 0$ *a.e.* in Ω.

Step 2: We prove $(w, z) = (0, 0)$ *a.e* in Ω. Let us set $\mathbf{D}_+ = \{\xi \in \Omega : w > 0 \text{ or } z > 0\}$ and $\mathbf{D_0} = \{\xi \in \Omega : (w, z) = (0, 0)\}$. Assume that the Haar measure of $\mathbf{D}_+$ is positive. From the assumption that $\|(u_k, v_k)\| \to \infty$, we have

$$|(u_k, v_k)| = \|(u_k, v_k)\||(w_k, z_k)| \to \infty \quad a.e. \text{ in } \mathbf{D}_+.$$

Then, from (f_3), we get

$$\lim_{k\to\infty} \frac{F(\xi, u_k, v_k)}{\|(u_k, v_k)\|^2} = \lim_{k\to\infty} \frac{F(\xi, u_k, v_k)|(w_k, z_k)|^2}{|(u_k, v_k)|^2} = \infty \quad a.e. \text{ in } \mathbf{D}_+. \tag{4.5}$$

Moreover, by Fatou's lemma and (4.5), there holds

$$\begin{aligned}
\liminf_{k\to\infty} \int_\Omega \frac{F(\xi, u_k, v_k)}{\|(u_k, v_k)\|^2} d\xi &\geq \int_\Omega \liminf_{k\to\infty} \frac{F(\xi, u_k, v_k)}{\|(u_k, v_k)\|^2} d\xi \\
&= \int_\Omega \liminf_{k\to\infty} \frac{F(\xi, u_k, v_k)|(w_k, z_k)|^2}{|(u_k, v_k)|^2} d\xi = \infty \quad a.e. \text{ in } \mathbf{D}_+.
\end{aligned} \tag{4.6}$$

On the other hand, from (4.1), a fact that $\|u_k\|^2_{\mathcal{S}^1_0(\Omega)} \leq \|(u_k, v_k)\|^2$, $\|v_k\|^2_{\mathcal{S}^1_0(\Omega)} \leq \|(u_k, v_k)\|^2$ and (1.5), we get

$$\begin{aligned}\int_\Omega F(\xi, u_k, v_k)d\xi &\leq \frac{1}{2}\|u_k\|^2_{\mathcal{S}^1_0(\Omega)} + \frac{1}{2}\|v_k\|^2_{\mathcal{S}^1_0(\Omega)} - \frac{\mu}{2}\|u_k\|^2_\psi - \frac{\nu}{2}\|v_k\|^2_\psi + \mathcal{L} \\ &\leq \|(u_k, v_k)\|^2 + \frac{|\mu^-|}{2\mathcal{K}}\|(u_k, v_k)\|^2 + \frac{|\nu^-|}{2\mathcal{K}}\|(u_k, v_k)\|^2 + \mathcal{L} \quad \text{for } k \in \mathbb{N},\end{aligned}$$

where we have used a fact that $\|(u_k, v_k)\| \geq 1$ because the hypothesis $(u_k, v_k) \to \infty$. Hence

$$\limsup_{k\to\infty} \int_\Omega \frac{F(\xi, u_k, v_k)}{\|(u_k, v_k)\|^2} d\xi \leq 1 + \frac{|\mu^-|}{2\mathcal{K}} + \frac{|\nu^-|}{2\mathcal{K}} + \frac{Z}{\|(u_k, v_k)\|^2},$$

it contradicts with (4.6). Hence, the measure of $\mathbf{D}_+$ is zero, that is $(w, z) = (0, 0)$ *a.e* in Ω.

Step 3: We prove that $\{(u_k, v_k)\} \subset W$ is bounded. Choosing τ_k is the smallest value of $\tau \in [0, 1]$ such that $I_{\mu,\nu}(\tau_k u_k, \tau_k v_k) = \max_{0\leq\tau\leq1} I_{\mu,\nu}(\tau u_k, \tau v_k)$. For $\Lambda > 0$, we set $(W_k, Z_k) = \sqrt{2\Lambda}(w_k, z_k) = \sqrt{2\Lambda}\frac{(u_k, v_k)}{\|(u_k, v_k)\|}$, then, by (4.4) and Step 2, we obtain

$$\lim_{k\to\infty}(W_k, Z_k) = \lim_{k\to\infty}\sqrt{2\Lambda}(w_k, z_k) = \sqrt{2\Lambda}(w, z) = \sqrt{2\Lambda}(0, 0), \tag{4.7}$$

in $L^q(\Omega) \times L^q(\Omega)$ for $q \in [1, 2^*)$. By (f_1), (f_2), (4.7) and let $\epsilon = 1$, it holds

$$\begin{aligned}0 \leq \int_\Omega F(\xi, W_k, Z_k)d\xi &\leq \int_\Omega \Big((\lambda + 1)|(W_k, Z_k)| + C_1|(W_k, Z_k)|^s\Big)d\xi \\ &\leq (\lambda + 1)\|(W_k, Z_k)\|_1 + C_1\|(W_k, Z_k)\|^s_s \to 0, \quad \text{as } k \to \infty,\end{aligned}$$

for $s \in (2, 2^*)$, that is

$$\lim_{k\to\infty}\int_\Omega F(\xi, W_k, Z_k)d\xi = 0. \tag{4.8}$$

From $\|(u_k, v_k)\| \to \infty$, we assume that there is $k_0 \geq k$, such that $\frac{\sqrt{2\Lambda}}{\|(u_k, v_k)\|} \in (0, 1)$, then

$$\begin{aligned}I_{\mu,\nu}(\tau_k u_k, \tau_k v_k) &\geq I_{\mu,\nu}\left(\sqrt{2\Lambda}\frac{u_k}{\|(u_k, v_k)\|}, \sqrt{2\Lambda}\frac{v_k}{\|(u_k, v_k)\|}\right) \\ &\geq \Lambda\|w_k\|^2(1 - \frac{\mu^+}{\mathcal{K}}) + \|z_k\|^2(1 - \frac{\nu^+}{\mathcal{K}}) - \int_\Omega F(\xi, W_k, Z_k)d\xi \\ &\geq \Lambda\chi(\|w_k\|^2 + \|z_k\|^2) - \int_\Omega F(\xi, W_k, Z_k)d\xi \\ &\geq \frac{1}{2}\Lambda\chi - \int_\Omega F(\xi, W_k, Z_k)d\xi,\end{aligned}$$

where χ is defined in Lemma 3.2, $\|w_k\|^2_{\mathcal{S}^1_0(\Omega)} + \|z_k\|^2_{\mathcal{S}^1_0(\Omega)} = 1$ because $\|(w_k, z_k)\| = 1$. By (4.8), there is $k_1 \geq k_0$ such that $\int_\Omega F(\xi, W_k, Z_k)d\xi \leq \frac{1}{2}\Lambda\chi$ for $k \geq k_1$. It follows that

$$\lim_{k\to\infty} I_{\mu,\nu}(\tau_k u_k, \tau_k v_k) = \infty. \tag{4.9}$$

Since $0 < \tau_k < 1$, by (f_4), one has

$$\int_\Omega H(\xi, \tau_k u_k, \tau_k v_k)d\xi \leq C_F\int_\Omega H(\xi, u_k, v_k)d\xi + \int_\Omega g(\xi)d\xi. \tag{4.10}$$

From the facts that $I_{\mu,\nu}(0,0)=0$, $I_{\mu,\nu}(u_k,v_k)\to c\in\mathbb{R}$, (4.9), and $\tau_k\in(0,1)$, there holds

$$\begin{aligned}0=\tau_k\frac{d}{d\tau}I_{\mu,\nu}(\tau u_k,\tau v_k)\Big|_{\tau=\tau_k}&=\langle I'_{\mu,\nu}(\tau_k u_k,\tau_k v_k),(\tau_k u_k,\tau_k v_k)\rangle\\&=\|\tau_k u_k\|^2_{\mathcal{S}^1_0(\Omega)}+\|\tau_k v_k\|^2_{\mathcal{S}^1_0(\Omega)}-\mu\|\tau_k u_k\|^2_\psi-\nu\|\tau_k v_k\|^2_\psi\\&\quad-\int_\Omega\Big(F_u(\xi,\tau_k u_k,\tau_k v_k)\tau_k u_k+F_v(\xi,\tau_k u_k,\tau_k v_k)\tau_k v_k\Big)d\xi.\end{aligned}$$

By (f_4) and (4.10), it follows that

$$\begin{aligned}&\|\tau_k u_k\|^2_{\mathcal{S}^1_0(\Omega)}+\|\tau_k v_k\|^2_{\mathcal{S}^1_0(\Omega)}-\mu\|\tau_k u_k\|^2_\psi-\nu\|\tau_k v_k\|^2_\psi\\&=\int_\Omega\Big(F_u(\xi,\tau_k u_k,\tau_k v_k)\tau_k u_k+F_v(\xi,\tau_k u_k,\tau_k v_k)\tau_k v_k\Big)d\xi\\&=2\int_\Omega F(\xi,\tau_k u_k,\tau_k v_k)d\xi+\int_\Omega H(\xi,\tau_k u_k,\tau_k v_k)d\xi\\&\le 2\int_\Omega F(\xi,\tau_k u_k,\tau_k v_k)d\xi+C_F\int_\Omega H(\xi,u_k,v_k)d\xi+\int_\Omega g(\xi)d\xi.\end{aligned}\tag{4.11}$$

From (4.9) and (4.11), one has

$$\begin{aligned}2I_{\mu,\nu}(\tau_k u_k,\tau_k v_k)&=\|\tau_k u_k\|^2_{\mathcal{S}^1_0(\Omega)}+\|\tau_k v_k\|^2_{\mathcal{S}^1_0(\Omega)}-\mu\|\tau_k u_k\|^2_\psi-\nu\|\tau_k v_k\|^2_\psi\\&\quad-2\int_\Omega F(\xi,\tau_k u_k,\tau_k v_k)d\xi\\&\le C_F\int_\Omega H(\xi,u_k,v_k)d\xi+\int_\Omega g(\xi)d\xi\to\infty\quad\text{as } k\to\infty.\end{aligned}$$

Hence, we deduce that

$$\frac{1}{C_F}\Big(-C+\int_\Omega H(\xi,u_k,v_k)d\xi\Big)\to\infty\quad\text{as } k\to\infty.\tag{4.12}$$

On the other hand, by (4.1), (f_4) and (4.3), we have

$$\begin{aligned}\tilde{\mathcal{L}}&\ge 2I_{\mu,\nu}(u_k,v_k)\\&=\|u_k\|^2_{\mathcal{S}^1_0(\Omega)}+\|v_k\|^2_{\mathcal{S}^1_0(\Omega)}-\mu\|u_k\|^2_\psi-\nu\|v_k\|^2_\psi-2\int_\Omega F(\xi,u_k,v_k)d\xi\\&=\|u_k\|^2_{\mathcal{S}^1_0(\Omega)}+\|v_k\|^2_{\mathcal{S}^1_0(\Omega)}-\mu\|u_k\|^2_\psi-\nu\|v_k\|^2_\psi\\&\quad-\int_\Omega\Big(F_u(\xi,u_k,v_k)u_k+F_v(\xi,u_k,v_k)v_k\Big)d\xi+\int_\Omega H(\xi,u_k,v_k)d\xi\\&\ge -C+\int_\Omega H(\xi,u_k,v_k)d\xi,\end{aligned}\tag{4.13}$$

where $\tilde{\mathcal{L}}$ is a positive constant. Since $C_F\ge 1$ in (f_4) and by (4.13), we obtain

$$\frac{1}{C_F}\Big(-C+\int_\Omega H(\xi,u_k,v_k)d\xi\Big)\le -C+\int_\Omega H(\xi,u_k,v_k)d\xi\le\tilde{\mathcal{L}}.$$

This contradicts with (4.12), it follows that $\{(u_k,v_k)\}\subset W$ is a bounded Cerami sequence. We finish the proof of this lemma. □

In the following, we verify that $I_{\mu,\nu}$ satisfies the Cerami condition at level c.

Lemma 4.2. *Assume that* (f_2) *with* $\epsilon = 1$ *holds. Then, for all* μ, $\nu \in (-\infty, \mathcal{K})$, $I_{\mu,\nu}$ *satisfies the Cerami condition in* W.

Proof. Assume that $\{(u_k, v_k)\} \subset W$ is a Cerami sequence of $I_{\mu,\nu}$. Then, by Lemma 4.1, we know that $\{(u_k, v_k)\}$ is bounded. Then, up to subsequence, from (1.5), Lemmas 2.2 and 2.3, for $1 \le q < 2^*$, there exists $(u, v) \in W$ such that

$$
\begin{aligned}
(u_k, v_k) \rightharpoonup (u, v) \ \text{ in } W, \quad \|u_k - u\|_{\mathcal{S}_0^1(\Omega)} \to \bar{a}, \ \ \|v_k - v\|_{\mathcal{S}_0^1(\Omega)} \to \check{a}, \\
u_k \rightharpoonup u \ \text{ in } L^2(\Omega, \psi^2 r^{-2}), \ \ \|u_k - u\|_\psi \to \acute{a}, \\
v_k \rightharpoonup v \ \text{ in } L^2(\Omega, \psi^2 r^{-2}), \ \ \|v_k - v\|_\psi \to \grave{a}, \\
(u_k, v_k) \to (u, v) \ \text{ in } L^q(\Omega) \times L^q(\Omega), \quad (u_k, v_k) \to (u, v) \ \text{ a.e in } \Omega, \\
\nabla_{\mathbb{G}} u_k \rightharpoonup \nabla_{\mathbb{G}} u \ \text{ in } L^2(\Omega, \mathbb{R}^{2n}), \quad \nabla_{\mathbb{G}} v_k \rightharpoonup \nabla_{\mathbb{G}} v \ \text{ in } L^2(\Omega, \mathbb{R}^{2n}), \\
\nabla_{\mathbb{G}} u_k \rightharpoonup \vartheta \ \text{ in } L^2(\Omega, \mathbb{R}^{2n}), \quad \nabla_{\mathbb{G}} v_k \rightharpoonup \varsigma \ \text{ in } L^2(\Omega, \mathbb{R}^{2n}),
\end{aligned}
\tag{4.14}
$$

where $\vartheta, \varsigma \in L^2(\Omega, \mathbb{R}^{2n})$ are two vector field functions in Ω, and $\bar{a}$, $\acute{a}$, $\check{a}$, $\grave{a}$ are four nonnegative numbers.

From (4.14), we conclude that

$$
\int_\Omega \frac{\psi^2}{r(\xi)^2} u_k \Phi d\xi \to \int_\Omega \frac{\psi^2}{r(\xi)^2} u \Phi d\xi \quad \text{and} \quad \int_\Omega \frac{\psi^2}{r(\xi)^2} v_k \Psi d\xi \to \int_\Omega \frac{\psi^2}{r(\xi)^2} v \Psi d\xi, \tag{4.15}
$$

for $(\Phi, \Psi) \in W$. We choose $\epsilon = 1$ in (f_2), and by Hölder inequality, then

$$
\begin{aligned}
&\int_\Omega \Big| \Big(F_u(\xi, u_k, v_k) - F_u(\xi, u, v) \Big) (u_k - u) \\
&\qquad + \Big(F_v(\xi, u_k, v_k) - F_v(\xi, u, v) \Big) (v_k - v) \Big| d\xi \\
&= \int_\Omega \Big| F_w(\xi, w_k)(w_k - w) - F_w(\xi, w)(w_k - w) \Big| d\xi \\
&\le \int_\Omega \Big((\lambda + 1)(|w_k| + |w|)|w_k - w| + C_1(|w_k|^{s-1} + |w|^{s-1})|w_k - w| \Big) d\xi \\
&\le C_\lambda (\|w_k - w\|_2 + \|w_k - w\|_s) \to 0 \quad \text{as } k \to \infty,
\end{aligned}
\tag{4.16}
$$

where $C_\lambda > 0$ is a suitable constant. From (4.1), it holds that $I'_{\mu,\nu}(u_k, v_k) \to 0$ in W' as $k \to \infty$, then for every $(\Phi, \Psi) \in W$, we have

$$
\begin{aligned}
0 \leftarrow & \langle I'_{\mu,\nu}(u_k, v_k), (\Phi, \Psi) \rangle \\
= & \int_\Omega (\nabla_{\mathbb{G}} u_k, \nabla_{\mathbb{G}} \Phi) d\xi + \int_\Omega (\nabla_{\mathbb{G}} v_k, \nabla_{\mathbb{G}} \Psi) d\xi - \mu \int_\Omega \frac{\psi^2}{r(\xi)^2} u_k \Phi d\xi - \nu \int_\Omega \frac{\psi^2}{r(\xi)^2} v_k \Psi d\xi \\
& - \int_\Omega \Big(F_u(\xi, u_k, v_k) \Phi + F_v(\xi, u_k, v_k) \Psi \Big) d\xi.
\end{aligned}
\tag{4.17}
$$

Subsequently, we prove that the (PS) sequence satisfies compactness condition by means of the Brézis–Lieb lemma.

From (4.17) and Lemma A.1 (it shows that (u_k, v_k) satisfies the Brézis–Lieb lemma's condition, see in the Appendix), one has

$$
\nabla_{\mathbb{G}} u_k \to \nabla_{\mathbb{G}} u \quad \text{and} \ \ \nabla_{\mathbb{G}} v_k \to \nabla_{\mathbb{G}} v \quad a.e. \text{ in } \ \Omega, \tag{4.18}
$$

and by (4.14), there holds $\nabla_{\mathbb{G}} u_k \rightharpoonup \vartheta$ and $\nabla_{\mathbb{G}} v_k \rightharpoonup \varsigma$ in $L^2(\Omega, \mathbb{R}^{2n})$. Hence, from Proposition A.7 in [1], we obtain $\nabla_{\mathbb{G}} u = \vartheta$ and $\nabla_{\mathbb{G}} v = \varsigma$ a.e. in Ω. It yields that $\nabla_{\mathbb{G}} u_k \rightharpoonup \nabla_{\mathbb{G}} u$ and $\nabla_{\mathbb{G}} v_k \rightharpoonup \nabla_{\mathbb{G}} v$ in $L^2(\Omega, \mathbb{R}^{2n})$, therefore, for any $(\Phi, \Psi) \in W$, one has

$$\int_\Omega (\nabla_{\mathbb{G}} u_k, \nabla_{\mathbb{G}} \Phi) d\xi \to \int_\Omega (\nabla_{\mathbb{G}} u, \nabla_{\mathbb{G}} \Phi) d\xi \quad \text{and} \quad \int_\Omega (\nabla_{\mathbb{G}} v_k, \nabla_{\mathbb{G}} \Phi) d\xi \to \int_\Omega (\nabla_{\mathbb{G}} v, \nabla_{\mathbb{G}} \Phi) d\xi.$$

It follows $\langle u_k, u\rangle \to \|u\|^2_{\mathcal{S}^1_0(\Omega)}$, $\langle u, u_k\rangle \to \|u\|^2_{\mathcal{S}^1_0(\Omega)}$ and $\langle v_k, v\rangle \to \|v\|^2_{\mathcal{S}^1_0(\Omega)}$, $\langle v, v_k\rangle \to \|v\|^2_{\mathcal{S}^1_0(\Omega)}$. Moreover, by (4.15) and (4.16), the weak limit $w = (u, v)$ is a critical point of $I_{\mu,\nu}$ in W. From (4.14) and (4.18), the Brézis–Lieb lemma holds that

$$\|u_k\|^2_{\mathcal{S}^1_0(\Omega)} = \|u_k - u\|^2_{\mathcal{S}^1_0(\Omega)} + \|u\|^2_{\mathcal{S}^1_0(\Omega)} + o(1), \quad \|v_k\|^2_{\mathcal{S}^1_0(\Omega)} = \|v_k - v\|^2_{\mathcal{S}^1_0(\Omega)} + \|v\|^2_{\mathcal{S}^1_0(\Omega)} + o(1),$$
$$\|u_k\|^2_\psi = \|u_k - u\|^2_\psi + \|u\|^2_\psi + o(1), \quad \|v_k\|^2_\psi = \|v_k - v\|^2_\psi + \|v\|^2_\psi + o(1).$$

Consequently, one has

$$\begin{aligned} o(1) &= \langle I'_{\mu,\nu}(w_k) - I'_{\mu,\nu}(w), w_k - w\rangle \\ &= \|u_k\|^2_{\mathcal{S}^1_0(\Omega)} + \|u\|^2_{\mathcal{S}^1_0(\Omega)} + \|v_k\|^2_{\mathcal{S}^1_0(\Omega)} + \|v\|^2_{\mathcal{S}^1_0(\Omega)} - \langle u_k, u\rangle - \langle u, u_k\rangle - \langle v_k, v\rangle - \langle u, u_k\rangle \\ &\quad - \mu\Big(\|u_k\|^2_\psi + \|u\|^2_\psi - \langle u_k, u\rangle_\psi - \langle u, u_k\rangle_\psi\Big) \\ &\quad - \nu\Big(\|v_k\|^2_\psi + \|v\|^2_\psi - \langle v_k, v\rangle_\psi - \langle v v_k\rangle_\psi\Big) + o(1) \\ &= \|u_k\|^2_{\mathcal{S}^1_0(\Omega)} - \|u\|^2_{\mathcal{S}^1_0(\Omega)} + \|v_k\|^2_{\mathcal{S}^1_0(\Omega)} - \|v\|^2_{\mathcal{S}^1_0(\Omega)} - \mu(\|u_k\|^2_\psi - \|u\|^2_\psi) \\ &\quad - \nu(\|v_k\|^2_\psi - \|v\|^2_\psi) + o(1) \\ &= \|u_k - u\|^2_{\mathcal{S}^1_0(\Omega)} + \|v_k - v\|^2_{\mathcal{S}^1_0(\Omega)} - \mu\|u_k - u\|^2_\psi - \nu\|v_k - v\|^2_\psi + o(1). \end{aligned}$$

From (4.14) and above equality, it follows that

$$\begin{aligned} \bar{a}^2 + \breve{a}^2 &= \lim_{k\to\infty} \|u_k - u\|^2_{\mathcal{S}^1_0(\Omega)} + \lim_{k\to\infty} \|v_k - v\|^2_{\mathcal{S}^1_0(\Omega)} \\ &= \mu \lim_{k\to\infty} \|u_k - u\|^2_\psi + \nu \lim_{k\to\infty} \|v_k - v\|^2_\psi \\ &= \mu \acute{a}^2 + \nu \grave{a}^2. \end{aligned} \tag{4.19}$$

Thus, when either $\mu^+ + \nu^+ = 0$ or $\acute{a} + \grave{a} = 0$, we get $(u_k, v_k) \to (u, v)$ in W as $k \to \infty$ and finish the proof about compactness condition for (PS) sequence of I_ϵ. In order to achieve this aim, we assume by contradiction, that is $\mu^+ + \nu^+ > 0$ and $\acute{a} + \grave{a} > 0$.

(1) If either $\mu^+ + \grave{a} = 0$ or $\nu^+ + \acute{a} = 0$, then either $\acute{a} > 0$ and $\bar{a} = 0$, or $\grave{a} > 0$ and $\breve{a} = 0$. However, all of cases are impossible because the nonnegative of norm in (4.14).

(2) If either $\mu^+ + \acute{a} = 0$ or $\nu^+ + \grave{a} = 0$, then either $\grave{a} > 0$, $\nu^+ > 0$ and $\breve{a}^2 \le \nu^+ \grave{a}^2 < \mathcal{K}\grave{a}^2 \le \breve{a}^2$, or $\acute{a} > 0$, $\mu^+ > 0$ and $\bar{a}^2 \le \mu^+ \acute{a}^2 < \mathcal{K}\acute{a}^2 \le \bar{a}^2$, it appears a contradiction.

(3) $\mu^+ > 0$, $\nu^+ > 0$, $\acute{a} > 0$ and $\grave{a} > 0$, from (4.19) and (1.5), we get

$$\bar{a}^2 + \breve{a}^2 = \mu\acute{a}^2 + \nu\grave{a}^2 < \mathcal{K}\acute{a}^2 + \mathcal{K}\grave{a}^2 \le \bar{a}^2 + \breve{a}^2,$$

and a contradiction arises. From above discussions, we get $\acute{a} + \grave{a} = 0$, that is $(u_k, v_k) \to (u, v)$ in W as $k \to \infty$, from (4.19), the proof of this lemma is finished. □

4.2 The existence of solution

In this part, we study the existence of nonnegative solution for (1.1).

Proof of Theorem 1.1. From Lemmas 3.2 and 3.3, we know that $I_{\mu,\nu}$ satisfies the mountain pass geometry structures. Moreover, the Cerami condition holds by Lemma 4.2. Therefore, for every $(\Phi, \Psi) \in W$, there exists $(u,v) \in W$, $(u,v) \neq (0,0)$ such that

$$\langle u, \Phi\rangle + \langle v, \Psi\rangle - \mu\langle u, \Phi\rangle_\psi - \nu\langle v, \Psi\rangle_\psi = \int_\Omega \Big(F_u(\xi,u,v)\Phi + F_v(\xi,u,v)\Psi\Big)d\xi.$$

Now, we prove that (u,v) is nonnegative. Let us set $\Phi = u^- = \min\{0,u\}$ and $\Psi = v^- = \min\{0,v\}$, then, from (f_1), (1.6) and (1.8), one has

$$\begin{aligned} 0 &= \int_\Omega \Big(F_u(\xi,u,v)u^- + F_v(\xi,u,v)v^-\Big)d\xi \\ &= \langle u, u^-\rangle + \langle v, v^-\rangle - \mu\langle u, u^-\rangle_\psi - \nu\langle v, v^-\rangle_\psi \\ &\geq (1 - \frac{\mu^+}{\mathcal{K}})\|u^-\|^2_{\mathcal{S}^1_0(\Omega)} + (1 - \frac{\nu^+}{\mathcal{K}})\|v^-\|^2_{\mathcal{S}^1_0(\Omega)} \geq 0. \end{aligned}$$

Thus, $u^- = 0$ and $v^- = 0$ a.e. in Ω, that is $u \geq 0$ and $v \geq 0$ a.e. in Ω, it shows that any solution of (1.1) is nonnegative. We finish the proof. □

A Appendix

In this section, we give a proof for the following lemma.

Lemma A.1. *Let (u_k, v_k) and (u,v) belongs to W and satisfying*

(i) $(u_k, v_k) \rightharpoonup (u,v)$ *in* W,

(ii) $(u_k, v_k) \to (u,v)$ *a.e. in* Ω,

(iii) $I'_{\mu,\nu}(u_k, v_k) \to 0$ *strongly in* W',

(iv) ϑ, $\varsigma \in \Omega$ *are two vector field functions with* ϑ, $\varsigma \in L^2(\Omega, \mathbb{R}^{2n})$ *such that* $\nabla_{\mathbb{G}} u_k \rightharpoonup \vartheta$ *and* $\nabla_{\mathbb{G}} v_k \rightharpoonup \varsigma$ *in* $L^2(\Omega, \mathbb{R}^{2n})$*, then, it holds*

$$\nabla_{\mathbb{G}} u_k \to \nabla_{\mathbb{G}} u \quad \text{and} \quad \nabla_{\mathbb{G}} v_k \to \nabla_{\mathbb{G}} v \quad \text{a.e. in } \Omega. \tag{A.1}$$

Proof. Let function $\beta_R \in C_0^\infty(\Omega)$ with $R > 0$, such that $0 \leq \beta_R \leq 1$ in Ω and $\beta_R \equiv 1$ in B_R. For every $z \in \mathbb{R}$, we define

$$\varrho_\epsilon(z) = \begin{cases} z, & \text{if } |z| < \epsilon, \\ \epsilon\dfrac{z}{|z|}, & \text{if } |z| \geq \epsilon. \end{cases}$$

We set $\phi_k = \beta_R \varrho_\epsilon \circ (u_k - u)$ and $\varphi_k = \beta_R \varrho_\epsilon \circ (v_k - v)$, thus, by Lemma 2.1, there holds ϕ_k,

$\varphi_k \in W^{1,2}(\Omega)$. Let $\Phi = \phi_k$ and $\Psi = \varphi_k$ in (4.17), then

$$\begin{aligned}
&\int_\Omega \beta_R\Big((\nabla_{\mathbb{G}}u_k - \nabla_{\mathbb{G}}u, \nabla_{\mathbb{G}}\Big(\varrho_\epsilon\circ(u_k-u)\Big)\Big)d\xi \\
&\qquad + \int_\Omega \beta_R\Big(\nabla_{\mathbb{G}}v_k - \nabla_{\mathbb{G}}v, \nabla_{\mathbb{G}}\Big(\varrho_\epsilon\circ(v_k-v)\Big)\Big)d\xi \\
&= -\int_\Omega \varrho_\epsilon\circ(u_k-u)(\nabla_{\mathbb{G}}u_k, \nabla_{\mathbb{G}}\beta_R)d\xi - \int_\Omega \beta_R\Big(\nabla_{\mathbb{G}}u, \nabla_{\mathbb{G}}\Big(\varrho_\epsilon\circ(u_k-u)\Big)\Big)d\xi \\
&\qquad - \int_\Omega \varrho_\epsilon\circ(v_k-v)(\nabla_{\mathbb{G}}v_k, \nabla_{\mathbb{G}}\beta_R)d\xi - \int_\Omega \beta_R\Big(\nabla_{\mathbb{G}}v, \nabla_{\mathbb{G}}\Big(\varrho_\epsilon\circ(v_k-v)\Big)\Big)d\xi \\
&\qquad + \langle I'_{\mu,\nu}(u_k,v_k),(\phi_k,\varphi_k)\rangle + \mu\int_\Omega \frac{\psi^2}{r(\xi)^2}u_k\phi_k d\xi + \nu\int_\Omega \frac{\psi^2}{r(\xi)^2}v_k\varphi_k d\xi \\
&\qquad + \int_\Omega \Big(F_u(\xi,u_k,v_k)\phi_k + F_v(\xi,u_k,v_k)\varphi_k\Big)d\xi. \qquad \text{(A.2)}
\end{aligned}$$

Now, we prove the each term in (A.2).

(1) We choose that $\tilde{\beta}_R$ be the support of β_R and contained in a suitable ball of Ω, since $|\varrho_\epsilon\circ(u_k-u)\nabla_{\mathbb{G}}\beta_R| \to 0$ in $L^2(\tilde{\beta}_R)$ and $|\varrho_\epsilon\circ(v_k-v)\nabla_{\mathbb{G}}\beta_R| \to 0$ in $L^2(\tilde{\beta}_R)$, and by (4.14), $\nabla_{\mathbb{G}}u_k \rightharpoonup \vartheta$ in $L^2(\Omega,\mathbb{R}^{2n})$, $\nabla_{\mathbb{G}}v_k \rightharpoonup \varsigma$ in $L^2(\Omega,\mathbb{R}^{2n})$, then

$$\int_\Omega \varrho_\epsilon\circ(u_k-u)(\nabla_{\mathbb{G}}u_k,\nabla_{\mathbb{G}}\beta_R)d\xi \to 0 \quad \text{and} \quad \int_\Omega \varrho_\epsilon\circ(v_k-v)(\nabla_{\mathbb{G}}v_k,\nabla_{\mathbb{G}}\beta_R)d\xi \to 0.$$

(2) Since $\nabla_{\mathbb{G}}\Big(\varrho_\epsilon\circ(u_k-u)\Big)$ in $L^2(\Omega,\mathbb{R}^{2n})$, $\nabla_{\mathbb{G}}\Big(\varrho_\epsilon\circ(v_k-v)\Big)$ in $L^2(\Omega,\mathbb{R}^{2n})$, $\nabla_{\mathbb{G}}u_k \in L^2(\Omega,\mathbb{R}^{2n})$, $\nabla_{\mathbb{G}}v_k \in L^2(\Omega,\mathbb{R}^{2n})$. From Lemma 2.1, $u_k \rightharpoonup u$ and $v_k \rightharpoonup v$ in W, one has

$$\int_\Omega \beta_R\Big(\nabla_{\mathbb{G}}u, \nabla_{\mathbb{G}}(\varrho_\epsilon\circ(u_k-u))\Big)d\xi \to 0 \quad \text{and} \quad \int_\Omega \beta_R\Big(\nabla_{\mathbb{G}}v, \nabla_{\mathbb{G}}(\varrho_\epsilon\circ(v_k-v))\Big)d\xi \to 0.$$

(3) From $I'_{\mu,\nu}(u_k,v_k) \to 0$ in W' and $(\varphi_k,\phi_k) \rightharpoonup 0$ in W as $k\to\infty$, we have

$$\langle I'_{\mu,\nu}(u_k,v_k),(\varphi_k,\phi_k)\rangle \rightharpoonup 0.$$

(4) For simplicity, we denote

$$M_k = \mu\frac{\psi^2}{r(\xi)^2}u_k + F_u(\xi,u_k,v_k), \quad N_k = \nu\frac{\psi^2}{r(\xi)^2}v_k + F_v(\xi,u_k,v_k), \qquad \text{(A.3)}$$

by $0 \le \beta_R \le 1$ in Ω, the definition of ϕ_k, φ_k and $\varrho_\epsilon(z)$, Lemma A.2, there holds

$$\begin{aligned}
\int_\Omega (M_k\varphi_k + N_k\phi_k)d\xi &\le \int_{\tilde{\beta}_R}\Big(|M_k|\cdot|\varrho_\epsilon\circ(u_k-u)| + |N_k|\cdot|\varrho_\epsilon\circ(v_k-v)|\Big)d\xi \\
&\le \epsilon\int_{\tilde{\beta}_R}(|M_k|+|N_k|)d\xi \le \epsilon C_R,
\end{aligned}$$

where $C_R > 0$ is a constant. Moreover

$$\begin{aligned}
&\beta_R\Big(\nabla_{\mathbb{G}}u_k - \nabla_{\mathbb{G}}u, \nabla_{\mathbb{G}}(\varrho_\epsilon\circ(u_k-u))\Big) \ge 0, \\
&\beta_R\Big(\nabla_{\mathbb{G}}v_k - \nabla_{\mathbb{G}}v, \nabla_{\mathbb{G}}(\varrho_\epsilon\circ(v_k-v))\Big) \ge 0 \quad \textit{a.e.} \text{ in } \Omega. \qquad \text{(A.4)}
\end{aligned}$$

Furthermore

$$\begin{aligned}
&\int_{B_R} \beta_R\Big(\nabla_{\mathbb{G}}u_k - \nabla_{\mathbb{G}}u, \nabla_{\mathbb{G}}\Big(\varrho_\epsilon \circ (u_k - u)\Big)\Big)d\xi \\
&\qquad + \int_{B_R} \beta_R\Big(\nabla_{\mathbb{G}}v_k - \nabla_{\mathbb{G}}v, \nabla_{\mathbb{G}}\Big(\varrho_\epsilon \circ (v_k - v)\Big)\Big)d\xi \\
&\quad \leq \int_{\Omega} \beta_R\Big(\nabla_{\mathbb{G}}u_k - \nabla_{\mathbb{G}}u, \nabla_{\mathbb{G}}\Big(\varrho_\epsilon \circ (u_k - u)\Big)\Big)d\xi \\
&\qquad + \int_{\Omega} \beta_R\Big(\nabla_{\mathbb{G}}v_k - \nabla_{\mathbb{G}}v, \nabla_{\mathbb{G}}\Big(\varrho_\epsilon \circ (v_k - v)\Big)\Big)d\xi.
\end{aligned}$$

From (1)–(4) and a fact that $\beta_R \equiv 1$ in B_R, then (A.2) becomes

$$\begin{aligned}
&\limsup_{k\to\infty} \Bigg[\int_{B_R} \Big(\nabla_{\mathbb{G}}u_k - \nabla_{\mathbb{G}}u, \nabla_{\mathbb{G}}\Big(\varrho_\epsilon \circ (u_k - u)\Big)\Big)d\xi \\
&\qquad + \int_{B_R} \Big(\nabla_{\mathbb{G}}v_k - \nabla_{\mathbb{G}}v, \nabla_{\mathbb{G}}\Big(\varrho_\epsilon \circ (v_k - v)\Big)\Big)d\xi\Bigg] \\
&\quad \leq \limsup_{k\to\infty} \Bigg[\int_{\Omega} \Big(\nabla_{\mathbb{G}}u_k - \nabla_{\mathbb{G}}u, \nabla_{\mathbb{G}}\Big(\varrho_\epsilon \circ (u_k - u)\Big)\Big)d\xi \\
&\qquad + \int_{\Omega} \Big(\nabla_{\mathbb{G}}v_k - \nabla_{\mathbb{G}}v, \nabla_{\mathbb{G}}\Big(\varrho_\epsilon \circ (v_k - v)\Big)\Big)d\xi\Bigg] \leq \epsilon C_R.
\end{aligned} \tag{A.5}$$

Subsequently, let $g_k = g_{u,k} + g_{v,k}$ with $g_{u,k} = \big(\nabla_{\mathbb{G}}u_k - \nabla_{\mathbb{G}}u, \nabla_{\mathbb{G}}(u_k - u)\big)$ and $g_{v,k} = \big(\nabla_{\mathbb{G}}v_k - \nabla_{\mathbb{G}}v, \nabla_{\mathbb{G}}(v_k - v)\big)$. We will show that g_k is nonnegative and bounded in $L^1(\Omega)$.

Firstly, if we assume that g_k is negative, it appears a contradiction with (A.4), thus, g_k is nonnegative. Secondly, since $\nabla_{\mathbb{G}}u_k$ is bounded in $L^2(\Omega, \mathbb{R}^{2n})$, and by (4.14), we know that $\nabla_{\mathbb{G}}v_k$ is bounded in $L^2(\Omega, \mathbb{R}^{2n})$. Therefore

$$0 \leq \int_{\Omega} g_k(\xi)d\xi \leq \|\nabla_{\mathbb{G}}u_k - \nabla_{\mathbb{G}}u\|_2^2 + \|\nabla_{\mathbb{G}}v_k - \nabla_{\mathbb{G}}v\|_2^2 \leq C_0, \tag{A.6}$$

where C_0 is a suitable constant and independent of k.

We select $t \in (0,1)$ and divide the ball B_R into four parts,

$$\begin{aligned}
B^\epsilon_{u,k}(R) &= \{\xi \in B_R : |u_k(\xi) - u(\xi)| \leq \epsilon\}, &\quad \tilde{B}^\epsilon_{u,k}(R) &= B_R \setminus B^\epsilon_{u,k}(R), \\
B^\epsilon_{v,k}(R) &= \{\xi \in B_R : |v_k(\xi) - v(\xi)| \leq \epsilon\}, &\quad \tilde{B}^\epsilon_{v,k}(R) &= B_R \setminus B^\epsilon_{v,k}(R).
\end{aligned}$$

Since $\nabla_{\mathbb{G}}\big(\varrho_\epsilon \circ (u_k - u)\big) = \nabla_{\mathbb{G}}(u_k - u)$ in $B^\epsilon_{u,k}(R)$ and $\nabla_{\mathbb{G}}\big(\varrho_\epsilon \circ (v_k - v)\big) = \nabla_{\mathbb{G}}(v_k - v)$ in $B^\epsilon_{v,k}(R)$, and from (A.6), we get

$$\begin{aligned}
\int_{B_R} g_k^t d\xi &\leq \int_{B_R} g_{u,k}^t d\xi + \int_{B_R} g_{v,k}^t d\xi \\
&= \int_{B^\epsilon_{u,k}(R)} g_{u,k}^t d\xi + \int_{\tilde{B}^\epsilon_{u,k}(R)} g_{u,k}^t d\xi + \int_{B^\epsilon_{v,k}(R)} g_{v,k}^t d\xi + \int_{\tilde{B}^\epsilon_{v,k}(R)} g_{v,k}^t d\xi \\
&\leq \Big(\int_{B^\epsilon_{u,k}(R)} g_{u,k} d\xi\Big)^t |B^\epsilon_{u,k}(R)|^{1-t} + \Big(\int_{\tilde{B}^\epsilon_{u,k}(R)} g_k d\xi\Big)^t |\tilde{B}^\epsilon_{u,k}(R)|^{1-t} \\
&\quad + \Big(\int_{B^\epsilon_{v,k}(R)} g_{v,k} d\xi\Big)^t |B^\epsilon_{v,k}(R)|^{1-t} + \Big(\int_{\tilde{B}^\epsilon_{v,k}(R)} g_k d\xi\Big)^t |\tilde{B}^\epsilon_{v,k}(R)|^{1-t} \\
&\leq (\epsilon C_R)^t \Big(|B^\epsilon_{u,k}(R)|^{1-t} + |\tilde{B}^\epsilon_{v,k}(R)|^{1-t}\Big) + C_0^t \Big(|B^\epsilon_{u,k}(R)|^{1-t} + |\tilde{B}^\epsilon_{v,k}(R)|^{1-t}\Big).
\end{aligned}$$

Moreover, the definition of $B^{\epsilon}_{u,k}(R)$ and $B^{\epsilon}_{v,k}(R)$ follows that, $|\tilde{B}^{\epsilon}_{u,k}(R)|$ and $|\tilde{B}^{\epsilon}_{v,k}(R)|$ tends to 0 as k goes to ∞. Thus, $0 \le \limsup_{k\to\infty} \int_{B_R} g_k^t d\xi \le (\epsilon C_R)^t |B_R|^{1-t}$, which means that $g_k^t \to 0$ as $\epsilon \to 0$ in $L^1(B_R)$. Hence, $g_k \to 0$ a.e. in Ω for R is arbitrary, then, (A.1) is valid from Lemma 3 in [13]. □

Finally, the following result shows that the hardy term is bounded in W.

Lemma A.2. *Let $\{(u_k, v_k)\} \subset W$ be a bounded sequence and Ω_0 represent a compact set of Ω, M_k and N_k are given in* (A.3)*. Then there is a constant $C(\Omega_0) > 0$ such that*

$$\sup_k \int_{\Omega_0} (|M_k| + |N_k|) d\xi \le C(\Omega_0).$$

Proof. Since $\psi = |\psi| \le 1$ and the Jacobian determinant is r^4, thus, $\psi^2 r^{-2}$ be of class $L^1_{loc}(\Omega)$, by (1.5), one has

$$\int_{\Omega_0} \left(\left(\frac{\psi}{r}\right)^2 |u_k| + \left(\frac{\psi}{r}\right)^2 |v_k| \right) d\xi \le \left\| \frac{\psi}{r} \right\|_2 \sup_k \|u_k\|_\psi + \left\| \frac{\psi}{r} \right\|_2 \sup_k \|v_k\|_\psi = C_2(\Omega_0),$$

where $C_2(\Omega_0)$ is a positive constant depending on Ω_0. Moreover, from (f_2), it holds

$$\begin{aligned}
&\int_{\Omega_0} \Big| F_u(\xi, u_k, v_k) + F_v(\xi, u_k, v_k) \Big| d\xi \\
&\le \sqrt{2} \int_{\Omega_0} \left| \frac{\sqrt{H_u^2(\xi, u_k, v_k) + H_v^2(\xi, u_k, v_k)}}{2} \right| d\xi \\
&\le \sqrt{2} \int_{\Omega_0} \Big| (\lambda + 1) |(u_k, v_k)| + C_\epsilon |(u_k, v_k)|^{s-1} \Big| d\xi \\
&\le \sqrt{2} \Big((\lambda + 1) \sup_k \|(u_k, v_k)\|_{2^*} |\Omega_0|^{\frac{1}{t}} + C_\epsilon |\Omega_0|^{2^*-2+1} \sup_k \|(u_k, v_k)\|_{2^*}^{2-1} \Big) = C_3(\Omega_0),
\end{aligned}$$

where $t > 1$ and $t = \frac{2^*}{2^*-1}$ is the Lebesgue exponent for $s \in (2, 2^*)$. From above argument, we get $\sup_k \int_{\Omega_0} (|M_k| + |N_k|) d\xi \le C(\Omega_0)$, the proof of this lemma is completed. □

Abstract. In this paper, we study a generalized Schrödinger–Poisson system in a bounded domain of $\mathbb{R}^3$ and involving an asymptotically linear nonlinearity. We prove the existence of positive solutions using bifurcation theory.

Keywords: bifurcation theory, positive solutions, Schrödinger–Poisson system, topological degree.

2020 Mathematics Subject Classification: 35A01, 35A16, 35B09, 35B32.

1 Introduction

This paper is concerned with the existence of solutions for the problem

$$\begin{cases} -\Delta u + \phi(x)u = \lambda f(u) \text{ in } \Omega, \\ -\Delta\phi(x) = g(u) \text{ in } \Omega, \\ u > 0 \text{ in } \Omega, \\ \phi > 0 \text{ in } \Omega, \\ u(x) = \phi(x) = 0 \quad \text{on} \quad \partial\Omega, \end{cases} \tag{P}$$

where $0 < \lambda$ is a parameter, $\Omega \subset \mathbb{R}^3$ is a bounded domain with smooth boundary $\partial\Omega$, $f \in C^1([0,\infty),\mathbb{R})$ and $g \in C(\mathbb{R},[0,\infty))$.

When the function $g(t) = t^2$, this system represents the well known Schrödinger–Poisson (or Schrödinger–Maxwell) equations, that have been widely studied in the recent past. This equation appears in the mean field approach for the Hartree–Fock model and as a nonlinear Schrödinger equation that takes into account the electrostatic field generated by the wave, see [7, 10, 14, 15].

Recently, many authors have studied the existence, non-existence and multiplicity of solutions of the problem

$$\begin{cases} -\Delta u + \lambda\phi(x)u = z(u) \text{ in } \Omega, \\ -\Delta\phi(x) = u^2 \text{ in } \Omega, \\ u(x) = \phi(x) = 0 \quad \text{on} \quad \partial\Omega, \end{cases}$$

✉ Email: ricardoalveslima8@gmail.com

where z is a superlinear function; see for example [1,3,8,9,11,13] and the references therein. To prove their results they used the reduction argument and then employed variational methods. It is worth pointing out that in the proof of Theorem 2.1 of [13] the authors used the Leray–Schauder degree to prove the existence of a positive solution when the parameter λ is small enough. Also, in the references of the papers mentioned above the reader will find many works dealing with Schrödinger–Poisson systems where $\Omega = \mathbb{R}^3$.

Motivated by the papers above and Ambrosetti and Hess [4], we are interested in studying system (P) when f is asymptotically linear and g satisfies some suitable assumptions. Specifically, we introduce the following assumptions:

(F_1) $f \in C^1([0,\infty),\mathbb{R})$, $f(0) = 0$ and $m_0 = \lim_{t\to 0^+} \frac{f(t)}{t} > 0$ (namely $m_0 = f'_+(0)$);

(F_2) There exist $m_\infty > 0$, a function h and a constant C such that

$$f(t) = m_\infty t + h(t), \text{ where } h \in C^{0,1}(\mathbb{R}^+,\mathbb{R}) \text{ and } |h(t)| \le C, \forall t \in \mathbb{R}^+ (\mathbb{R}^+ = [0,\infty));$$

(G_1) $g(t) = t^{2p}$, where $0 < p < 2$;

(G_2) $g \in C(\mathbb{R},(0,\infty))$ and there exist the limit $\lim_{t\to\infty} g(t) = g(\infty)$ and a constant $c > 0$ such that $0 < g(t) < c$ for all $t \in \mathbb{R}$.

Some examples of functions satisfying the above assumptions are as follows.

Example 1.1.

(a) The function $f(t) = t - t^{10}, t \ge 0$, satisfies (F_1).

(b) The function $f(t) = t - arctg(t^2), t \ge 0$, satisfies (F_1) and (F_2).

(c) The function $f(t) = t, t \ge 0$, satisfies (F_1) and (F_2).

(e) The function $g(t) = \frac{t^2}{1+t^2} + 1, t \in \mathbb{R}$, satisfies (G_2).

(g) The function $g(t) = \frac{|t|}{1+t^2} + 1, t \in \mathbb{R}$, satisfies (G_2).

As we can see, the function f is allowed to change sign. Before stating our main results, we need some definitions and notations. First, we introduce the Banach space

$$X = C(\overline{\Omega},\mathbb{R})$$

endowed with the norm $\|u\| = \sup_{x\in\overline{\Omega}} |u(x)|$ for $u \in X$.

We say that $(\lambda, u, \phi_u) \in \mathbb{R} \times [(H_0^1(\Omega) \times H_0^1(\Omega)) \cap (X \times X)]$ is a solution of (P) if $u > 0$ in Ω, $\phi_u > 0$ in Ω and

$$\int_\Omega \nabla u \nabla \varphi dx + \int_\Omega \phi_u(x) u \varphi dx = \lambda \int_\Omega f(u)\varphi dx, \tag{1.1}$$

$$\int_\Omega \nabla \phi_u \nabla \psi dx = \int_\Omega g(u)\psi dx, \tag{1.2}$$

for all $(\varphi,\psi) \in H_0^1(\Omega) \times H_0^1(\Omega)$. When $u > 0$ in Ω, (u, ϕ_u) is a positive solution. Moreover, we say that (λ, u, ϕ_u) is a weak solution of (P) if $(u, \phi_u) \in H_0^1(\Omega) \times H_0^1(\Omega)$ and it satisfies (1.1)–(1.2). It turns out that weak solutions are solutions provided f has subcritical growth (see Lemma 2.4).

A bifurcation point for (P) is a number $\lambda^* \in \mathbb{R}$ such that there exists a sequence $(\lambda_n, u_n, \phi_{u_n})$ $\in \mathbb{R} \times [(H_0^1(\Omega) \times H_0^1(\Omega)) \cap (X \times X)]$ satisfying the following properties:

(*i*) $\lambda_n \longrightarrow \lambda^*$;

(*ii*) $(\lambda_n, u_n, \phi_{u_n})$ is a solution of (P) with $u_n \neq 0$ and $\|u_n\| \longrightarrow 0$.

We say that $\lambda^* \in \mathbb{R}$ is a bifurcation point from infinity of (P) if there exists a sequence $(\lambda_n, u_n, \phi_{u_n}) \in \mathbb{R} \times [(H_0^1(\Omega) \times H_0^1(\Omega)) \cap (X \times X)]$ satisfying the following properties:

(*i*) $\lambda_n \longrightarrow \lambda^*$;

(*ii*) $(\lambda_n, u_n, \phi_{u_n})$ is a solution of (P) and $\|u_n\| \longrightarrow +\infty$.

It is well known that under the assumption (G_2) there exists a unique solution $\phi_\infty \in H_0^1(\Omega) \cap X$ of the problem

$$\begin{cases} -\Delta u = g(\infty) \text{ in } \Omega, \\ u > 0 \text{ in } \Omega, \\ u = 0 \text{ on } \partial\Omega. \end{cases}$$

Also, there exists a unique solution $\phi_0 \in H_0^1(\Omega) \cap X$ of the problem

$$\begin{cases} -\Delta u = g(0) \text{ in } \Omega, \\ u \geq 0 \text{ in } \Omega, \\ u = 0 \text{ on } \partial\Omega, \end{cases}$$

where $\phi_0 > 0$ in Ω if $g(0) > 0$ holds.

Let us denote by $\lambda_1[\phi_\infty]$ and φ_∞ the first eigenvalue and the positive eigenfunction normalized by $\|\varphi_\infty\| = 1$, respectively, of the eigenvalue problem

$$-\Delta u + \phi_\infty(x) u = \lambda u \text{ in } \Omega,$$

$$u = 0 \text{ on } \partial\Omega.$$

Similarly, let us denote by $\lambda_1[\phi_0]$ and φ_0 the first eigenvalue and the positive eigenfunction normalized by $\|\varphi_0\| = 1$, respectively, of the eigenvalue problem

$$-\Delta u + \phi_0(x) u = \lambda u \text{ in } \Omega,$$

$$u = 0 \text{ on } \partial\Omega.$$

We observe that if $g(0) = 0$ then $\lambda_1[\phi_0]$ and φ_0 are the first eigenvalue and the positive eigenfunction, respectively, of $(-\Delta, H_0^1(\Omega))$.

Now we are ready to state our main results.

Theorem 1.2. *Suppose that* (F_1) *and* (G_1) *hold. Then* $\lambda_0 = \lambda_1[\phi_0]/m_0$ *is the unique bifurcation point of* (P)*. In addition, the continuum* Σ_0 *emanating from* $(\lambda_0, 0)$ *is unbounded. The same conclusion holds under the assumptions* (F_1) *and* (G_2)*.*

Theorem 1.3. *Assume that* (F_2) *and* (G_2) *hold. Then* $\lambda_\infty = \lambda_1[\phi_\infty]/m_\infty$ *is the unique bifurcation point from infinity of* (P)*. Moreover, there exists a subset* Σ_∞ *in* $\mathbb{R} \times X$ *of solutions of* (P) *such that* $\tilde{\Sigma}_\infty = \left\{(\lambda, z) : (\lambda, z/\|z\|^2) \in \Sigma_\infty\right\} \cup \left\{(\lambda_\infty, 0)\right\}$ *is connected and unbounded.*

After a bibliography review, we did not find any paper involving bifurcation theory and problems involving a generalized Schrödinger–Poisson system in a bounded domain as in the problem (P). Inspired by this fact, in the present paper we show that it is possible to apply the Leray–Schauder degree theory and the global bifurcation result due to Rabinowitz [12] to study the existence of solution for (P). To carry out this program, we first use the reduction argument (see [2]), which says that (P) is equivalent to a nonlocal problem (see problem (S)). After, we follow the same methodology as Ambrosetti and Hess [4]. However as we are working with a nonlocal problem it is necessary to do a careful study on some estimates and convergences involving the nonlocal term $\phi_u u$. Also, the calculation of Leray–Schauder degree of some maps involving the nonlocal term $\phi_u u$ must be justified (see Lemma 3.2). The reader is invited to verify that when $g(0) \neq 0$ the bifurcation points of Theorems 1.2 and 1.3 are different from those found in [4]. Moreover, under additional assumptions on f and g we will show that the bifurcation point found in our work is supercritical (the nontrivial solutions branch off on the right of λ_∞), while under the same assumption on f, the bifurcation point found in [4] is subcritical (the branching is on the left of bifurcation point).

Finally, we would like to point out that our results are new even in the case where $g(t) = t^2$ (that is, $p = 1$ in (G_1)), which is the case considered in the papers mentioned above and which allows us to apply variational methods. Indeed, in the papers mentioned above they did not study the existence of bifurcation points for problems of type (P). Also, they did not consider asymptotically linear nonlinearities as in our work. Thus, our work is the first to deal with the existence of bifurcation points and the continuum emanating from these points for Problem (P) with asymptotically linear nonlinearities even in the case when $p = 1$.

The paper is organized as follows. Section 2 is devoted to some preliminaries. In Section 3, we prove Theorem 1.2. In Section 4, we prove Theorem 1.3. In section 5 we will show a result of multiplicity of solutions under additional assumptions on f and g.

Notation. Throughout this paper, we make use of the following notations:

- $L^p(\Omega)$, for $1 \leq p \leq \infty$, denotes the Lebesgue space with usual norm denoted by $|u|_p$.
- $H_0^1(\Omega)$ denotes the Sobolev space endowed with inner product

$$(u, v)_H = \int_\Omega \nabla u \nabla v, \ \forall u, v \in H_0^1(\Omega).$$

  The norm associated with this inner product will be denoted by $\| \ \|_H$.

- $W^{2,k}(\Omega)$ denotes the Sobolev space with norm $\|u\|_{W^{2,k}} = \left(\sum_{|\alpha| \leq 2} \|D^\alpha u\|_k^k\right)^{1/k}$.
- If u is a measurable function, we denote by u^- the negative part of u, which is given by $u^- = \max\{-u, 0\}$.
- The function $d(x, \partial\Omega)$ denotes the distance from a point $x \in \overline{\Omega}$ to the boundary $\partial\Omega$, where $\overline{\Omega} = \Omega \cup \partial\Omega$ is the closure of $\Omega \subset \mathbb{R}^N$.
- $\deg(I - \Psi, \mathcal{W}, 0)$ denotes the Leray–Schauder degree of $I - \Psi$ in $\mathcal{W}$ with respect to 0, where $\mathcal{W} \subset X$ is a bounded open set and $\Psi : \overline{\mathcal{W}} \longrightarrow X$ is a compact operator.
- $B_r(0) \subset X$ denotes the ball centered at $0 \in X$ with radius $r > 0$.
- $c, c_1, c_2, \ldots$ and $C, C_1, C_2, \ldots$ are possibly different positive constants which may change from line to line.

2 Preliminary results

Throughout this paper, unless it is explicitly stated, we will assume that (G_1) or (G_2) holds. In this section we will establish some results that we will need in the next sections.

For all $u \in L^{3/p}(\Omega)$ there exists a unique $\phi_u \in H_0^1(\Omega)$ which solves

$$-\Delta\phi = g(u(x)) \text{ in } \Omega,$$

and there holds

$$\phi_u(x) = \int_\Omega \frac{g(u(y))}{|x-y|}dy.$$

By L^p-theory one has $\phi_u \in W^{2,3/p}(\Omega)$, $0 < p < 2$, and so $\phi_u \in X$ (because $6/p > 3$). Since $g(u) \geq 0$, then by the maximum principle $\phi_u \geq 0$. Moreover, if $u \neq 0$ then $\phi_u > 0$ in Ω. Also, we have the following estimates.

Lemma 2.1. *For every $u \in L^{3/p}(\Omega)$ there holds*

$$\|\phi_u\| \leq C_2|g(u)|_{3/p},$$

for some constant $C_2 > 0$ independent of u. In particular, if $u \in X$, then

$$\|\phi_u\| \leq C\|g(u)\|, \tag{2.1}$$

for some constant $C > 0$ independent of u.

Proof. By L^p-theory one has $\phi_u \in W^{2,3/p}(\Omega)$ and

$$\|\phi_u\|_{W^{2,3/p}} \leq C_1|g(u)|_{3/p},$$

for some constant $C_1 > 0$, which depends only on Ω and p.

Combining this inequality with the embedding of $W^{2,3/p}(\Omega)$ into X we get

$$\|\phi_u\| \leq C_2|g(u)|_{3/p},$$

for some constant $C_2 > 0$, which depends only on Ω and p.

If in addition $u \in X$, then the inequality $|g(u)|_{3/p} \leq |\Omega|^{p/3}\|g(u)\|$ is valid, and therefore

$$\|\phi_u\| \leq C\|g(u)\|,$$

where $C = C_2(\Omega)|\Omega|^{p/3}$. This completes the proof of the lemma. □

We recall that a map $J : X \to X$ is bounded if it maps bounded sets onto bounded sets.

In order to apply Bifurcation Theory we will need the following lemma.

Lemma 2.2. *The map $\mathcal{J} : X \longrightarrow X$ defined by setting $\mathcal{J}(u) = \phi_u$ is continuous and bounded.*

Proof. Let $\{u_n\} \subset X$ be a sequence such that $u_n \to u$ in X. As $\phi_{u_n} - \phi_u \in H_0^1(\Omega)$ satisfies

$$-\Delta(\phi_{u_n} - \phi_u) = g(u_n) - g(u) \textit{ in } \Omega,$$

by elliptic regularity it follows that

$$\|\phi_{u_n} - \phi_u\| \leq C\|g(u_n) - g(u)\|,$$

for some constant $C > 0$ independent of u_n and u. Since $u_n \to u$ in X implies $g(u_n) \to g(u)$ in X, from the last inequality one deduces that $\phi_{u_n} \to \phi_u$ in X. This proves that the map $\mathcal{J}$ is continuous in X.

Finally, the boundedness of $\mathcal{J}$ follows from (2.1), and the proof is completed. □

Our next result establishes the positivity of weak solutions to a variational inequality.

Lemma 2.3. *Let $\phi \in X$ and suppose that $u \in H_0^1(\Omega)$ satisfies*

$$\begin{cases} -\Delta u + \phi(x)u \geq 0 \text{ in } \Omega, \\ u \geq 0 \text{ in } \Omega. \end{cases}$$

Then either $u \equiv 0$, or there exists $\epsilon > 0$ such that $u(x) \geq \epsilon d(x, \partial\Omega)$ in Ω.

Proof. Let $k = \|\phi\|$ and assume that $u \not\equiv 0$. In this case, we get

$$-\Delta u + ku \geq -\Delta u + \phi(x)u \geq 0 \text{ in } \Omega,$$

namely, u satisfies

$$\begin{cases} -\Delta u + ku \geq 0 \text{ in } \Omega, \\ u \gneqq 0 \text{ in } \Omega. \end{cases}$$

This allows us to apply Theorem 3 of Brezis–Nirenberg [6] to deduce that $u(x) \geq \epsilon d(x, \partial\Omega)$ in Ω, for some $\epsilon > 0$. This completes the proof. □

Now, we consider the nonlocal problem

$$\begin{cases} -\Delta u + \phi_u(x)u = z(u) \text{ in } \Omega, \\ u(x) = 0 \text{ on } \partial\Omega, \end{cases} \tag{Q}$$

under the following assumption on $z \in C(\mathbb{R}, \mathbb{R})$:

(H) $|z(t)| \leq c_1 + c_2|t|^q$, where $c_1, c_2 > 0$ are constants and $0 < q < 2^* - 1$.

Lemma 2.4. *Suppose that (H) holds. Then every $u \in H_0^1(\Omega)$ which is a weak solution of (Q) belongs to X.*

Proof. Indeed, $u \in H_0^1(\Omega)$ is a weak solution of the problem

$$-\Delta u = h(x, u) \text{ in } \Omega,$$

where $h(x,t) = z(t) - \phi_u(x)t$. From Lemma 2.2 and (H) one infers that

$$|h(x,t)| \leq c_3 + c_4|t|^q,$$

for all $x \in \Omega, t \in \mathbb{R}$ and some constants $c_3, c_4 > 0$. Thus, a standard bootstrap argument implies that $u \in X$. This completes the proof. □

3 Global bifurcation

The main goal of this section is to prove Theorem 1.2. To do this we need some definitions and auxiliary lemmas.

It is well known that Problem (P) is equivalent to the nonlocal problem

$$\begin{cases} -\Delta u + \phi_u(x)u = \lambda f(u) \text{ in } \Omega, \\ u > 0 \text{ in } \Omega, \\ u(x) = 0 \text{ on } \partial\Omega. \end{cases} \tag{S}$$

We extend the function f to a continuous function $\tilde{f}$ defined on $\mathbb{R}$ in such a way that $\tilde{f}(t) = f(0)$ for all $t < 0$. Then, we can consider the nonlocal problem

$$\begin{cases} -\Delta u + \phi_u(x)u = \lambda \tilde{f}(u) \text{ in } \Omega, \\ u > 0 \text{ in } \Omega, \\ u(x) = 0 \text{ on } \partial\Omega. \end{cases} \tag{$\tilde{S}$}$$

Now we prove the following result.

Lemma 3.1. *Assume that either* (F_1) *or* (F_2) *is satisfied. Then Problems* (S) *and* $(\tilde{S})$ *are equivalent.*

Proof. It is clear that if u is a solution of (S) then it is also a solution of $(\tilde{S})$. Now, we assume that u is a solution of $(\tilde{S})$. Taking u^- as test function in $(\tilde{S})$ we get

$$-\|u^-\|_H^2 - \int_\Omega \phi_u(x)(u^-)^2 = \int_\Omega \lambda f(0)u^-,$$

which implies $\|u^-\|_H = 0$, that is, $u \geq 0$ in Ω. Thus $\tilde{f}(u) = f(u)$ in Ω, and if either (F_1) or (F_2) is satisfied then

$$|\tilde{f}(t)| = |f(t)| \leq c_1|t|, \ \forall t \in [0, \|u\| + 1),$$

and for some constant $c_1 > 0$. Therefore, u satisfies

$$\begin{cases} -\Delta u + (\phi_u(x) + \lambda c_1)u \geq 0 \text{ in } \Omega, \\ u \gneqq 0 \text{ in } \Omega, \\ u(x) = 0 \ \text{ on } \partial\Omega, \end{cases}$$

and from Lemma 2.3 one infers that $u > 0$ in Ω. This completes the proof. □

Due to Lemma 3.1, the proof of Theorems 1.2 and 1.3 is reduced to proving the existence of the bifurcation points of Problem $(\tilde{S})$. To study Problem $(\tilde{S})$ we will transform it into a functional equation. From now on we will denote by K the Green operator of $-\Delta$ on $H_0^1(\Omega)$. It is well known that K is compact as a map from X in itself. From Lemma 2.2 it follows that the map $F_\lambda : X \to X$ given by

$$F_\lambda(u) = \lambda \tilde{f}(u) - \phi_u u$$

is continuous and bounded. As a consequence, the map $T : \mathbb{R} \times X \to X$ defined by $T(\lambda, u) = K(F_\lambda(u))$ is compact and Problem $(\tilde{S})$ is equivalent to the functional equation

$$\Phi(\lambda, u) = 0,$$

where $\Phi(\lambda, u) = u - T(\lambda, u)$ for $(\lambda, u) \in \mathbb{R} \times X$.

The first property of the map Φ that we highlight is the following.

Lemma 3.2. *For every* $\mu \in [0, 1]$ *the function* $u \equiv 0$ *is the unique solution of the problem*

$$\begin{cases} -\Delta u + \mu\phi_u(x)u = 0 \text{ in } \Omega, \\ u \in H_0^1(\Omega) \cap X. \end{cases} \tag{A}$$

In particular,

$$\deg(\Phi(0, \cdot), B_r(0), 0) = 1,$$

for all $r > 0$.

Proof. If u satisfies (A) then,

$$\|u\|_H^2 + \mu \int_\Omega \phi_u u^2 = 0,$$

and this implies that $\|u\|_H = 0$, namely that $u \equiv 0$.

Thus the homotopy $H(\mu, u) = u - \mu T(0, u), (\mu, u) \in [0, 1] \times X$, is admissible on the ball $B_r(0)$, for all $r > 0$. Using the homotopy invariance, it follows that

$$\deg(H(1, \cdot), B_r(0), 0) = \deg(I, B_r(0), 0) = 1,$$

and since $\Phi(0, \cdot) = H(1, \cdot)$, we get $\deg(\Phi(0, \cdot), B_r(0), 0) = 1$. □

Now, let us give the precise definition of bifurcation point of the functional equation $\Phi(\lambda, u) = 0$.

Definition 3.3. We say that λ_* is a bifurcation point of $\Phi(\lambda, u) = 0$ if there exists a sequence $(\lambda_n, u_n) \in \mathbb{R} \times X$, with $u_n \neq 0$, such that $\lambda_n \longrightarrow \lambda_*$, $\|u_n\| \longrightarrow 0$ and $\Phi(\lambda_n, u_n) = 0$.

It turns out that the bifurcation points of $\Phi(\lambda, u) = 0$ are the bifurcation points of ($\tilde{S}$) (and therefore are also the bifurcation points of (P)).

Denoting by

$$\Sigma_\Phi = \{(\lambda, u) \in \mathbb{R} \times X : \Phi(\lambda, u) = 0,\ u \neq 0\},$$

and taking the closure $\overline{\Sigma}_\Phi$ of Σ_Φ, we see that λ_* is a bifurcation point of $\Phi(\lambda, u) = 0$ if and only if $(\lambda_*, 0) \in \overline{\Sigma}_\Phi$.

For each $\lambda \in \mathbb{R}$ fixed, the index of $\Phi_\lambda = \Phi(\lambda, \cdot)$ relative to 0, denoted by $i(\Phi_\lambda, 0)$, is defined by

$$i(\Phi_\lambda, 0) = \lim_{\epsilon \to 0} \deg(\Phi_\lambda, B_\epsilon(0), 0).$$

To prove Theorem 1.2 we have to prove the change of index of $\Phi(\lambda, \cdot)$ as λ crosses $\lambda = \lambda_0$. The proof is based on the following lemmas.

Lemma 3.4. *Let $\Lambda \subset \mathbb{R}^+$ be a compact interval with $\lambda_0 \notin \Lambda$. Then there exists $\epsilon > 0$ satisfying*

$$\Phi(\lambda, u) \neq 0, \qquad \forall \lambda \in \Lambda, \quad \forall 0 < \|u\| \leq \epsilon.$$

Proof. We argue by contradiction assuming that there exists a sequence $(\lambda_n, u_n) \in \Lambda \times X$ satisfying

$$\lambda_n \longrightarrow \lambda \neq \lambda_0, \qquad \|u_n\| \longrightarrow 0,$$
$$\Phi(\lambda_n, u_n) = 0, \qquad u_n > 0.$$

Now, we divide the equation $u_n = K(F_{\lambda_n}(u_n))$ by $\|u_n\|$ to get

$$v_n = K\left(\frac{F_{\lambda_n}(u_n)}{\|u_n\|}\right), \quad \text{where } v_n = \frac{u_n}{\|u_n\|}.$$

We claim that the sequence $\left\{\frac{F_{\lambda_n}(u_n)}{\|u_n\|}\right\}$ is bounded in $\Lambda \times X$. To prove this claim, let $\delta > 0$ such that $|f(t)| \leq (m_0 + 1)|t|$ for all $0 < t < \delta$ (the existence of δ is guaranteed by (F_1)). Since $\|u_n\| \longrightarrow 0$ there exists $n_0 \in \mathbb{N}$ such that $\|u_n\| < \delta$ for all $n > n_0$. From this and (2.1) we deduce that

$$\|F_{\lambda_n}(u_n)\| \leq C(\|u_n\| + \|g(u_n)\|\|u_n\|),$$

for all $n > n_0$ and for some constant $C > 0$ independent of n.

Therefore,

$$\|\frac{F_{\lambda_n}(u_n)}{\|u_n\|}\| \le C(1+\|g(u_n)\|) \le C(1+\max_{t\in[-\delta,\delta]}|g(t)|),$$

for $n > n_0$, which implies that the sequence $\{\frac{F_{\lambda_n}(u_n)}{\|u_n\|}\}$ is bounded in $\Lambda \times X$.

Since K is compact, from $v_n = K(\frac{F_{\lambda_n}(u_n)}{\|u_n\|})$ we deduce that, up to a subsequence, v_n strongly converges to some $v \in X$ with $\|v\| = 1$. Then, by Lemmas 2.1 and 2.2 and (F_1) one infers

$$\frac{F_{\lambda_n}(u_n)}{\|u_n\|} \longrightarrow (\lambda m_0 - \phi_0)v \text{ in } X,$$

and therefore

$$v = K((\lambda m_0 - \phi_0)v).$$

But this says that v is a solution of the problem

$$\begin{cases} -\Delta v + \phi_0(x)v = \lambda m_0 v \text{ in } \Omega, \\ v \ge 0 \ in \ \Omega, \end{cases}$$

and from Lemma 2.3 one infers that $v > 0$ in Ω. As a consequence v is an eigenfunction of norm one associated to λ.

Using φ_0 as a test function in this eigenvalue problem we obtain

$$\lambda_1[\phi_0]\int_\Omega v\varphi_0 = \int_\Omega \nabla v \nabla \varphi_0 dx + \int_\Omega \phi_0 v \varphi_0 dx = \lambda m_0 \int_\Omega v\varphi_0,$$

and we conclude that $\lambda_1[\phi_0] = \lambda m_0$, which is a contradiction and the proof is finished. □

As a consequence of the proof of Lemma 3.4 we obtain the following corollary.

Corollary 3.5. *The unique possible bifurcation point of solutions is* $\lambda = \lambda_0$.

Lemma 3.6. *If* $\lambda < \lambda_0$ *then* $i(\Phi_\lambda, 0) = 1$.

Proof. Fix any $\lambda < \lambda_0$ and take $\Lambda = [0, \lambda]$. For $t \in [0, 1]$, the parameter $t\lambda$ belongs to Λ and from Lemma 3.4 it follows that $\Phi(t\lambda, u) \neq 0$ for all $0 < \|u\| \le \epsilon$, where $\epsilon > 0$ is given by Lemma 3.4. Consider the homotopy $H(t, u) = \Phi(t\lambda, u)$. Using the homotopy invariance, we get

$$\deg(H(1,\cdot), B_\epsilon(0), 0) = \deg(H(0,\cdot), B_\epsilon(0), 0),$$

namely

$$i(\Phi_\lambda, 0) = \deg(\Phi_\lambda, B_\epsilon(0), 0) = \deg(\Phi_0, B_\epsilon(0), 0) = 1,$$

where we have used Lemma 3.2 in the last equality. This completes the proof. □

Lemma 3.7. *For every* $\lambda > \lambda_0$ *there exists* $\delta > 0$ *such that*

$$\Phi(\lambda, u) \neq \tau\varphi_1, \quad \forall 0 < \|u\| \le \delta, \quad \forall \tau \ge 0.$$

Proof. We fix $\lambda > \lambda_0$ and we assume, by contradiction, that there exist sequences $u_n \in X$ and $\tau_n \ge 0$ satisfying $u_n > 0$ in Ω, $\|u_n\| \longrightarrow 0$ and

$$\Phi(\lambda, u_n) = \tau_n \varphi_1,$$

or, equivalently,

$$u_n = K(F_\lambda(u_n)) + \tau_n \varphi_1.$$

Dividing this equation by $\|u_n\|$ one finds

$$v_n = K\left(\frac{F_\lambda(u_n)}{\|u_n\|}\right) + \varphi_1 \frac{\tau_n}{\|u_n\|}, \quad \text{where } v_n = \frac{u_n}{\|u_n\|}.$$

Arguing as in the proof of Lemma 3.4, we see that the sequence $\{\frac{F_\lambda(u_n)}{\|u_n\|}\}$ is bounded in X. Thus, using the compactness of K, we deduce that, up to a subsequence, $K(\frac{F_\lambda(u_n)}{\|u_n\|})$ is convergent and hence $\tau_n/\|u_n\|$ is bounded. Passing again to a subsequence, if necessary, we can assume that $\tau_n/\|u_n\| \longrightarrow \tau \geq 0$ and $u_n/\|u_n\| \longrightarrow v$ with $v \in X$ and $\|v\| = 1$. Arguing as we have done in the proof of Lemma 3.4, it is easy to see that v satisfies

$$\begin{cases} -\Delta v + \phi_0 v = \lambda m_0 v + \tau \lambda_1 \varphi_1 \text{ in } \Omega, \\ v = 0 \text{ on } \partial\Omega, \\ \|v\| = 1. \end{cases}$$

Then, using φ_0 as a test function in this problem we obtain

$$\lambda_1[\phi_0] \int_\Omega v\varphi_0 = \lambda m_0 \int_\Omega v\varphi_0 + \int_\Omega \tau\lambda_1\varphi_1\varphi_0 \geq \lambda m_0 \int_\Omega v\varphi_0,$$

which implies that $\lambda_0 \geq \lambda$, a contradiction. The proof is finished. □

Lemma 3.8. *If $\lambda > \lambda_0$ then $i(\Phi_\lambda, 0) = 0$.*

Proof. If $\lambda > \lambda_0$ then, from Lemma 3.7, we derive that

$$\deg(\Phi_\lambda, B_\delta(0), 0) = \deg(\Phi_\lambda - \tau\varphi_1, B_\delta(0), 0), \quad \forall \tau > 0,$$

where $\delta > 0$ is given by Lemma 3.7.

But, again using Lemma 3.7, the problem

$$\begin{cases} -\Delta w + \phi_w(x) w = \lambda \tilde{f}(w) + \tau\lambda_1\varphi_1 \text{ in } \Omega, \\ w = 0 \text{ in } \partial\Omega, \end{cases}$$

has no nontrivial solution satisfying $0 < \|u\| \leq \delta$. Since, $w = 0$ is not a solution provided that $\tau > 0$, we deduce that

$$i(\Phi_\lambda, 0) = \deg(\Phi_\lambda, B_\delta(0), 0) = \deg(\Phi_\lambda - \tau\varphi_1, B_\delta(0), 0) = 0, \quad \forall \lambda > \lambda_0.$$

This completes the proof. □

Now, we are ready to prove Theorem 1.2.

Proof. (*of Theorem 1.2*) Assume that λ_0 is no bifurcation point. Then there exists $\epsilon > 0$ such that

$$\Phi_\lambda(u) \neq 0, \text{ for all } \lambda \in [\lambda_0 - \epsilon, \lambda_0 + \epsilon] \text{ and } 0 < \|u\| \leq \epsilon.$$

Thus, if we take

$$\lambda_0 - \epsilon < \tilde{\lambda} < \lambda_0 < \hat{\lambda} < \lambda_0 + \epsilon$$

one has

$$\deg(\Phi_{\tilde{\lambda}}, B_\epsilon(0), 0) = \deg(\Phi_{\hat{\lambda}}, B_\epsilon(0), 0),$$

and therefore,

$$i(\Phi_{\tilde{\lambda}}, 0) = i(\Phi_{\hat{\lambda}}, 0),$$

which contradicts Lemmas 3.6 and 3.8. Moreover, from Corollary 3.5 λ_0 is the unique bifurcation point for (P).

As a consequence, one can repeat the arguments carried out in the proof of the Global Bifurcation Theorem due to Rabinowitz [12] to show the existence of Σ_0. This completes the proof. □

4 Bifurcation from infinity

In this section we are going to prove Theorem 1.3. Hereafter we will assume that (F_2) and (G_2) hold. We start with the following definition.

Definition 4.1. We say that λ_∞ is a bifurcation point from infinity of $\Phi(\lambda, u) = 0$ if there exists a sequence $(\lambda_n, u_n) \in \mathbb{R} \times X$ satisfying

$$\lambda_n \longrightarrow \lambda_\infty, \quad \|u_n\| \longrightarrow +\infty, \quad \Phi(\lambda_n, u_n) = 0.$$

It turns out that the bifurcation points from infinity of $\Phi(\lambda, u) = 0$ are the bifurcation points from infinity of ($\tilde{S}$) (and therefore are also the bifurcation points from infinity of (P)).

Following [4], if we make the Kelvin transform

$$z = \frac{u}{\|u\|^2}, \quad \text{with } u \neq 0,$$

we derive that

$$\Phi(\lambda, u) = 0, \;\; u \neq 0 \Leftrightarrow z - \|z\|^2 T\left(\lambda, \frac{z}{\|z\|^2}\right) = 0, \quad z \neq 0.$$

Thus we are led to define the map

$$\tilde{\Phi}(\lambda, z) = \begin{cases} z - \|z\|^2 T(\lambda, \frac{z}{\|z\|^2}), \text{ if } z \neq 0, \\ 0, \text{ if } z = 0. \end{cases}$$

Moreover, using Lemma 2.1 we find that

$$\|z\|^2 \|\phi_{z/\|z\|^2} \frac{z}{\|z\|^2}\| \leq C\|z\|,$$

for all $z \neq 0$ and some constant $C > 0$ independent of z. As a consequence we obtain

$$\lim_{z \to 0} \|z\|^2 \phi_{z/\|z\|^2} \frac{z}{\|z\|^2} = 0.$$

From this limit and assumption on f it readily follows that $\tilde{\Phi}$ is continuous. In particular, $\tilde{\Phi}$ is a compact perturbation of the identity and λ_∞ is a bifurcation point from infinity for $\Phi(\lambda, u) = 0$ if and only if λ_∞ is a bifurcation point for $\tilde{\Phi}(\lambda, z) = 0$. Moreover, arguing as in the proof of Lemma 3.2, we immediately deduce the following property:

$$\deg(\tilde{\Phi}(0, \cdot), B_\epsilon(0), 0) = 1, \text{ for all } \epsilon > 0.$$

The proof of Theorem 1.3 is based on the following lemmas.

Lemma 4.2. *Let $\Lambda \subset [0, \lambda_\infty)$ be any compact interval. Then*

(a) *there exists $r > 0$ such that $\Phi_\lambda(u) \neq 0$, for all $\lambda \in \Lambda$ and $\|u\| \geq r$,*

(b) *λ_∞ is the only possible bifurcation from infinity for $\Phi(\lambda, u) = 0$,*

(c) *$i(\tilde{\Phi}_\lambda, 0) = 1$ for all $\lambda < \lambda_\infty$.*

Proof. (a) We argue by contradiction assuming that there exists a sequence $(\lambda_n, u_n) \in \Lambda \times X$ satisfying

$$\lambda_n \longrightarrow \lambda \neq \lambda_\infty, \quad \|u_n\| \longrightarrow \infty,$$

$$\Phi(\lambda_n, u_n) = 0, \quad u_n > 0.$$

Setting $v_n = \|u_n\|^{-1} u_n$, we find

$$v_n = K\left(\lambda_n \frac{f(u_n)}{\|u_n\|} - \phi_{u_n} v_n\right).$$

By Lemma 2.1 we infer that there exists a constant $C > 0$ such that

$$\left\|\lambda_n \frac{f(u_n)}{\|u_n\|} - \phi_{u_n} v_n\right\| \leq \left[\left\|\lambda_n \left(m_\infty v_n + \frac{h(u_n)}{\|u_n\|}\right)\right\| + \|\phi_{u_n} v_n\|\right] \leq C, \text{ for all } n \in \mathbb{N}.$$

Since K is compact, from $v_n = K(\lambda_n \frac{f(u_n)}{\|u_n\|} - \phi_{u_n} v_n)$ we deduce that, up to a subsequence, v_n strongly converges to some $v \in X$ with $\|v\| = 1$. Note also that v_n converges weakly to v in $H_0^1(\Omega)$ and $v \geq 0$ in Ω. Moreover, there holds

$$\int_\Omega \nabla v_n \nabla \varphi dx + \int_\Omega \phi_{u_n} v_n \varphi dx = \int_\Omega \lambda_n \frac{f(u_n)}{\|u_n\|} \varphi dx, \quad \varphi \in H_0^1(\Omega). \tag{4.1}$$

On the other hand, the boundedness of g and the L^p-theory imply that, up to a subsequence, ϕ_{u_n} converges weakly in $H_0^1(\Omega)$ and strongly in X, to some $\phi \in H_0^1(\Omega) \cap X$. Thus, by the Lebesgue dominated convergence theorem we yield

$$\int_\Omega \nabla v \nabla \varphi dx + \int_\Omega \phi v \varphi dx = \int_\Omega \lambda m_\infty v \varphi dx, \quad \varphi \in H_0^1(\Omega), \tag{4.2}$$

which together with Lemma 2.3 implies that $v > 0$ in Ω. As a consequence we get that $u_n(x) = \|u_n\| v_n(x) \longrightarrow \infty$ for all $x \in \Omega$, and applying the Lebesgue dominated convergence theorem we found that

$$\int_\Omega \nabla \phi \nabla \varphi dx = \int_\Omega g(\infty) \varphi dx, \quad \varphi \in H_0^1(\Omega),$$

namely $\phi = \phi_\infty$.

Finally, using φ_∞ as a test function in (4.2) we obtain

$$\lambda_1[\phi_\infty] \int_\Omega v \varphi_\infty dx = \lambda m_\infty \int_\Omega v \varphi_\infty dx,$$

and we conclude that $\lambda_\infty = \lambda$, which is a contradiction. This contradiction proves (a).

Statement (b) follows immediately from (a). Regarding (c), fix any $\lambda < \lambda_\infty$ and take $\Lambda = [0, \lambda]$. For $t \in [0, 1]$, the parameter $t\lambda$ belongs to Λ and from (a) it follows that $u \neq T(t\lambda, u)$

for all $\|u\| \geq r$. This implies that $\tilde{\Phi}(t\lambda, z) \neq 0$ for all $0 < \|z\| \leq 1/r$. Consider the homotopy $H(t,z) = \tilde{\Phi}(t\lambda, z)$. Using the homotopy invariance, we get

$$\deg(\tilde{\Phi}_\lambda, B_{1/r}(0), 0) = \deg(\tilde{\Phi}_0, B_{1/r}(0), 0),$$

namely

$$i(\tilde{\Phi}_\lambda, 0) = \deg(\tilde{\Phi}_0, B_{1/r}(0), 0) = 1,$$

proving (c).

□

Lemma 4.3. *Let $\lambda > \lambda_\infty$. Then*

(a) *there exists $\epsilon > 0$ such that $\Phi_\lambda(u) \neq \tau\varphi_1$, for all $\tau \geq 0$ and $\|u\| \geq \epsilon$,*

(b) *$i(\tilde{\Phi}_\lambda, 0) = 0$ for all $\lambda > \lambda_\infty$.*

Proof. (a) We fix $\lambda > \lambda_\infty$ and we assume, by contradiction, that there exist $\tau_n \geq 0$ and $\|u_n\| \to \infty$ such that $\Phi_\lambda(u_n) = \tau_n\varphi_1$, namely

$$u_n - \tau_n\varphi_1 = K(\lambda f(u_n) - \phi_{u_n}u_n).$$

Setting $v_n = \|u_n\|^{-1}u_n$, we get

$$v_n - \tau_n\|u_n\|^{-1}\varphi_1 = K\left(\lambda\frac{f(u_n)}{\|u_n\|} - \phi_{u_n}v_n\right),$$

and arguing as in Lemma 4.2, one readily shows that the sequence $\left\{\frac{f(u_n)}{\|u_n\|} - \phi_{u_n}v_n\right\}$ is bounded in X. Thus, using the compactness of K, we deduce that, up to a subsequence,

$$K\left(\lambda\frac{f(u_n)}{\|u_n\|} - \phi_{u_n}v_n\right)$$

is convergent and hence $\tau_n/\|u_n\|$ is bounded. Passing again to a subsequence, if necessary, we can assume that $\tau_n/\|u_n\| \longrightarrow \tau \geq 0$ and $u_n/\|u_n\| \longrightarrow v$ with $v \in X$ and $\|v\| = 1$. Arguing as we have done in the proof of Lemma 4.2, we can deduce that $u_n(x) \to \infty$ for all $x \in \Omega$ and that v satisfies

$$\begin{cases} -\Delta v + \phi_\infty v = \lambda m_\infty v + \tau\lambda_1\varphi_1 \text{ in } \Omega, \\ v = 0 \text{ on } \partial\Omega, \\ \|v\| = 1. \end{cases}$$

Therefore, using φ_∞ as a test function in this problem we obtain

$$\lambda_1[\phi_\infty]\int_\Omega v\varphi_\infty \geq \lambda m_\infty \int_\Omega v\varphi_\infty,$$

and we conclude that $\lambda_\infty \geq \lambda$, which is a contradiction. This proves (a).

(b) Take $\tau = t\|u\|^2$, with $t \in [0,1]$. By (a) it follows that $\Phi_\lambda(u) \neq t\|u\|^2\varphi_1$ for all $\|u\| \geq \epsilon$. This implies

$$\tilde{\Phi}_\lambda(z) \neq t\varphi_1, \quad \forall 0 < \|z\| \leq \frac{1}{\epsilon}, \quad \forall t \in [0,1]. \tag{4.3}$$

Using the homotopy $H(t,z) = \tilde{\Phi}_\lambda(z) - t\varphi_1$ on the ball $B_{1/\epsilon}(0)$ we find

$$i(\tilde{\Phi}_\lambda, 0) = \deg(\tilde{\Phi}_\lambda, B_{1/\epsilon}(0), 0) = \deg(\tilde{\Phi}_\lambda - \varphi_1, B_{1/\epsilon}(0), 0).$$

The latter degree is zero because (4.3), with $t = 1$, implies that $\tilde{\Phi}_\lambda(z) = \varphi_1$ has no solution on $B_{1/\epsilon}(0)$. This proves (b). □

Now, we are ready to prove Theorem 1.3.

Proof of Theorem 1.3. Arguing as in the proof of Theorem 1.2, the Lemmas 4.2 and 4.3 ensure that λ_∞ is the unique bifurcation point for the equation $\tilde{\Phi}(\lambda, z) = 0$, and that from $(\lambda_\infty, 0)$ emanates an unbounded continuum of solutions $\tilde{\Sigma}_\infty = \{(\lambda, z) : \tilde{\Phi}(\lambda, z) = 0\}$ in $\mathbb{R} \times X$. Moreover, $(\lambda, z) \in \tilde{\Sigma}_\infty, z \neq 0$, if and only if $(\lambda, z/\|z\|^2) \in \Sigma_\Phi = \{(\lambda, u) : \Phi(\lambda, u) = 0,\ u \neq 0\}$. We define $\Sigma_\infty = \{(\lambda, z/\|z\|^2) : (\lambda, z) \in \tilde{\Sigma}_\infty, z \neq 0\}$. Therefore, $\Sigma_\infty \subset \Sigma_\Phi$ and

$$\tilde{\Sigma}_\infty = \{(\lambda, z) : (\lambda, z/\|z\|^2) \in \Sigma_\infty\} \cup \{(\lambda_\infty, 0)\}$$

is connected and unbounded. This completes the proof. □

Remark 4.4. The reader can ask why we consider only assumption (G_2) in Theorem 1.3. To answer this question, we recall that in the proof of Lemmas 4.2 and 4.3 the boundedness of the sequence $\{\phi_{u_n} v_n\}$ plays a fundamental role. However, under the assumption (G_1), we have the inequality $\|\phi_{u_n}\| \leq C\|u_n\|^{2q}$, which does not ensure the boundedness of the sequence $\{\phi_{u_n} v_n\}$ as $\|u_n\| \longrightarrow \infty$.

5 Multiplicity of solutions

Throughout this section we will use the same notation as in the previous sections. In this section we will apply Theorems 1.2 and 1.3 to show a result of multiplicity of solutions for (P) under additional assumptions on f and g. Specifically, we introduce the following assumptions:

(F_3) $2^{-1} m_\infty t \leq f(t) \leq m_\infty t$ for all $t \geq 0$ and $f'_+(0) = m_\infty$;

(G_3) $g(\infty) = \lim_{t\to\infty} g(t) = \lim_{t\to 0} g(t)$ and $g(\infty) \leq g(t)$ for all $t \in \mathbb{R}$.

Assume that (G_3) is valid. For every $u \in H_0^1(\Omega)$ we have

$$-\Delta\phi_u = g(u) \geq g(\infty) = -\Delta\phi_\infty \text{ in } \Omega,$$

which implies

$$\phi_u \geq \phi_\infty \text{ in } \Omega. \tag{5.1}$$

Moreover, if we define

$$\tilde{g} = \sup_{t\geq 0} g(t) \quad \text{and} \quad -\Delta\phi_{\tilde{g}} = \tilde{g}, \phi_{\tilde{g}} \in H_0^1(\Omega),$$

we can show that $\phi_u \leq \phi_{\tilde{g}}$ in Ω (using the same argument as above) for all $u \in H_0^1(\Omega)$.

Let us denote by $\lambda_1[\phi_{\tilde{g}}]$ and $\varphi_{\tilde{g}}$ the first eigenvalue and the positive eigenfunction normalized by $\|\varphi_{\tilde{g}}\| = 1$, respectively, of the eigenvalue problem

$$-\Delta u + \phi_{\tilde{g}}(x) u = \lambda u \text{ in } \Omega,$$

$$u = 0 \text{ on } \partial\Omega.$$

Let us point out that under the assumptions (F_1)–(F_3) and (G_2)–(G_3) one has $\lambda_0 = \lambda_\infty$.

Now we have the following lemma.

Lemma 5.1. *Suppose that* (F_3) *and* (G_3) *hold. If Problem* (S) *has a solution, then* $\lambda_0 \le \lambda \le \lambda_{\tilde{g}}$*, where* $\lambda_{\tilde{g}} = 2\lambda_1[\phi_{\tilde{g}}]/m_\infty$.

Proof. Indeed, if u is a solution of (S), then

$$\begin{aligned}\lambda_1[\phi_\infty]\int_\Omega u\varphi_\infty dx &= \int_\Omega \nabla u \nabla \varphi_\infty dx + \int_\Omega \phi_\infty u \varphi_\infty dx \\ &\le \int_\Omega \nabla u \nabla \varphi_\infty dx + \int_\Omega \phi_u u \varphi_\infty dx \quad \text{(by (5.1))} \\ &= \lambda \int_\Omega f(u)\varphi_\infty dx \\ &\le \lambda m_\infty \int_\Omega u\varphi_\infty dx \quad \text{(by } (F_3)).\end{aligned}$$

This now implies $\lambda \ge \lambda_0$.

Similarly,

$$\begin{aligned}2^{-1}m_\infty\lambda \int_\Omega u\varphi_{\tilde{g}} dx &\le \int_\Omega \lambda f(u)\varphi_{\tilde{g}} dx \\ &= \int_\Omega \nabla u \nabla \varphi_{\tilde{g}} dx + \int_\Omega \phi_u u \varphi_{\tilde{g}} dx \\ &\le \int_\Omega \nabla u \nabla \varphi_{\tilde{g}} dx + \int_\Omega \phi_{\tilde{g}} u \varphi_{\tilde{g}} dx \\ &= \lambda_1[\phi_{\tilde{g}}]\int_\Omega u\varphi_{\tilde{g}} dx,\end{aligned}$$

whence we infer that $\lambda_{\tilde{g}} \ge \lambda$. This proves the lemma. □

The main result of this section is the following theorem.

Theorem 5.2. *Assume that* (F_1)–(F_3) *and* (G_2)–(G_3) *hold. Then*

(*a*) $\Sigma_0 = \Sigma_\infty \cup \{(\lambda_\infty, 0)\}$,

(*b*) *there exists* $\epsilon > 0$ *such that Problem* (P) *has at least two solutions for* $\lambda_0 < \lambda < \lambda_0 + \epsilon$.

Proof. (*a*) First of all, let us remark that since $\tilde{\Sigma}_\infty$ is connected and $\tilde{\Sigma}_\infty \cap (\mathbb{R} \times \{0\}) = \{(\lambda_\infty, 0)\}$ then $\tilde{\Sigma}_\infty - \{(\lambda_\infty, 0)\}$ is connected. Now, the map $W : \tilde{\Sigma}_\infty - \{(\lambda_\infty, 0)\} \longrightarrow \Sigma_\Phi$ given by

$$W(\lambda, z) = (\lambda, z/\|z\|^2)$$

is continuous. Thus $W(\tilde{\Sigma} - \{(\lambda_*, 0)\}) = \Sigma_\infty$ is a connected subset of Σ_Φ. Using Lemma 5.1 and that λ_∞ is the unique bifurcation point of $\Phi(\lambda, u) = 0$ and the unique bifurcation point from infinity of $\Phi(\lambda, u) = 0$ we can see that $\overline{\Sigma_\infty} = \Sigma_\infty \cup \{(\lambda_\infty, 0)\}$ (which is a connected subset of Σ_Φ too).

Finally, we will show that $\Sigma_0 = \Sigma_\infty \cup \{(\lambda_\infty, 0)\}$. Clearly, $\Sigma_\infty \cup \{(\lambda_\infty, 0)\} \subset \Sigma_0$. We assume now that $(\lambda, u) \in \Sigma_0 - \{(\lambda_\infty, 0)\}$, namely, $u \ne 0$ and

$$u - T(\lambda, u) = 0.$$

Let us write $(\lambda, u) = (\lambda, z/\|z\|^2)$, where $z = u/\|u\|^2$. Thus, the last equality above can be rewritten as

$$\frac{z}{\|z\|^2} - T(\lambda, z/\|z\|^2) = 0,$$

which implies $(\lambda, u) = (\lambda, z/\|z\|^2) \in \Sigma_\infty$.

Then one finds:

$$\Sigma_0 - \{(\lambda_\infty, 0)\} \subset \Sigma_\infty$$

and as $\Sigma_\infty \subset \Sigma_0$ we conclude that $\Sigma_0 = \Sigma_\infty \cup \{(\lambda_\infty, 0)\}$. This proves (a).

(b) Let $u_\lambda \in \Sigma_0$ and $v_\lambda \in \Sigma_\infty$ be the solutions of (P) obtained in Theorems 1.2 and 1.3, respectively. By using the fact that $\|u_\lambda\| \to 0$ and $\|v_\lambda\| \to \infty$ as $\lambda \to \lambda_0$ and Lemma 5.1, we deduce that there exists $\epsilon > 0$ such that

$$\|u_\lambda\| < 1 < \|v_\lambda\| \quad \text{for } \lambda_0 < \lambda < \lambda_0 + \epsilon.$$

This allows us to conclude that $u_\lambda \neq v_\lambda$, and therefore u_λ and v_λ are two distinct solutions of (P) for $\lambda_0 < \lambda < \lambda_0 + \epsilon$. □

Abstract. In this paper, we study the existence of nodal solutions of some nonlinear boundary value problems for ordinary differential equations of fourth order with a spectral parameter in the boundary condition. To do this, we first study the global bifurcation of solutions from zero and infinity of the corresponding nonlinear eigenvalue problems in classes with a fixed oscillation count. Then, using these global bifurcation results, we prove the existence of solutions of the considered nonlinear boundary value problems with a fixed number of nodes.

Keywords: nonlinear problem, eigenvalue parameter, bifurcation point, nodal solution, component

1 Introduction

In this paper, we consider the existence of nodal solutions to the following nonlinear boundary value problem for ordinary differential equations of fourth order

$$\ell(y) \equiv (p(x)y''(x))'' - (q(x)y'(x))' = \chi r(x)h(y(x)),\ x \in (0,l), \tag{1.1}$$

$$y'(0)\cos\alpha - (py'')(0)\sin\alpha = 0, \tag{1.2}$$

$$y(0)\cos\beta + Ty(0)\sin\beta = 0, \tag{1.3}$$

$$y'(l)\cos\gamma + (py'')(l)\sin\gamma = 0, \tag{1.4}$$

$$(a\lambda + b)y(l) - (c\lambda + d)Ty(l) = 0, \tag{1.5}$$

where $Ty \equiv (py'')' - qy'$, p is a positive twice continuously differentiable function on $[0,l]$, q is a non-negative continuously differentiable function on $[0,l]$, χ is a positive number, $r(x)$ is

✉ Corresponding author. Email: z_aliyev@mail.ru

a positive continuous function on $[0, l]$, α, β, γ, a, b, c, d are real constants such that $\alpha, \beta, \gamma \in [0, \pi/2]$ and $\sigma = bc - ad > 0$. The nonlinear term h has the form $f + g$, where f and g are real-valued continuous on $\mathbb{R}$ functions that satisfy the following conditions:

$$\underline{f}_0, \overline{f}_0, \underline{f}_\infty, \overline{f}_\infty \in \mathbb{R} \quad \text{with} \quad \underline{f}_0 \neq \overline{f}_0, \underline{f}_\infty \neq \overline{f}_\infty, \tag{1.6}$$

where

$$\underline{f}_0 = \liminf_{|s| \to 0} \frac{f(s)}{s}, \qquad \overline{f}_0 = \limsup_{|s| \to 0} \frac{f(s)}{s}, \tag{1.7}$$

$$\underline{f}_\infty = \liminf_{|s| \to +\infty} \frac{f(s)}{s}, \qquad \overline{f}_\infty = \limsup_{|s| \to +\infty} \frac{f(s)}{s}; \tag{1.8}$$

$$sg(s) > 0 \quad \text{for } s \in \mathbb{R} \setminus \{0\}; \tag{1.9}$$

there exist positive constants g_0, $g_\infty \in (0, +\infty)$ such that

$$g_0 = \lim_{|s| \to 0} \frac{g(s)}{s}, \qquad g_\infty = \lim_{|s| \to +\infty} \frac{g(s)}{s}. \tag{1.10}$$

The subject of this paper is to determine the interval of χ, in which there are solutions to problem (1.1)–(1.5) that have a fixed number of simple zeros in $(0, l)$.

It is well known that boundary value problems for ordinary differential equations arise in the study of many different processes of natural science, see [9,10,12,14,17] and the references therein. For example, problem (1.1)–(1.5) arises when studying of bending (of deformation) of a homogeneous rod, in the cross sections of which a longitudinal force acts and at the right end of which the mass is concentrated or on this end a tracking force acts.

Problems similar to (1.1)–(1.5) for ordinary differential equations of second and fourth orders have been considered before in, for example, [8, 11, 13, 16, 18–22, 26–28]. In [8, 11, 18–21, 26], the authors using the global bifurcation results of [1, 2, 7, 8, 11, 18, 23–25] show that there are nontrivial solutions of the considered nonlinear problems, which have the usual nodal properties (unfortunately, there are gaps in the proofs of the main assertions in [11, Theorems 2.2 and 3.1] and [18, Theorem 3.1]). Similar results were obtained in the paper [22] by analytical methods involving the Prüfer angular functions. Should be noted that in [13, 26, 27], problems with local and nonlocal boundary conditions are considered and the existence of positive solutions of these problems is established.

In the present paper, using the global bifurcation results from [1–4, 6] and removing the above gaps (see the proof of Steps 1–3 of Theorem 3.1), we prove the existence of two different solutions to problem (1.1)–(1.5) with a fixed number of nodal points.

The rest of this article is organized as follows. Section 2 provides, which we need in the future, known facts about the unilateral global bifurcation of solutions from zero and infinity of nonlinear eigenvalue problems for fourth-order ordinary differential equations. In Section 3, we determine an interval for a parameter χ, in which there are nodal solutions to problem (1.1)–(1.5). In this case, the proof of the main theorem, i.e. Theorem 3.1 consists of 4 steps. In Step 1, using (1.6), (1.7) and the first condition from (1.10), we find bifurcation intervals from zero and prove the existence of two families of unbounded components of the solution set of problem (1.1)–(1.5) bifurcating from these intervals and contained in classes with a fixed number of nodes. In Step 2, using (1.6), (1.8) and the second condition from (1.10), we find bifurcation intervals from infinity and prove the existence of two families of unbounded components of the set of solutions bifurcating from these intervals and contained in classes with a fixed number of nodes in the neighborhood of these intervals, which either intersect another bifurcation interval, or intersect the line of trivial solutions, or have unbounded projections onto the line of trivial solutions. In Step 3, it is established that the global components of solutions to problem (1.1)–(1.5) bifurcating from intervals infinity are also contained in the corresponding classes with a fixed number of nodes and coincide with the corresponding components of solutions bifurcating from intervals of the line of trivial solutions.

2 Preliminary

We consider the following linear eigenvalue problem

$$\begin{cases} \ell(y)(x) = \lambda r(x) y(x),\ x \in (0,l), \\ y \in (b.c.)_\lambda, \end{cases} . \tag{2.1}$$

where $\lambda \in \mathbb{C}$ is a spectral parameter, $(b.c.)_\lambda$ is a set of functions satisfying the boundary conditions (1.2)–(1.5).

The spectral properties of (2.1) were studied in [15], where, in particular, it was shown that the spectrum of this problem is discrete and consists of an infinitely increasing sequence $\{\lambda_k\}_{k=1}^{\infty}$ of real and simple eigenvalues. Moreover, if $c = 0$, then eigenfunction $y_k(x)$, $k \in \mathbb{N}$, corresponding to the eigenvalue λ_k has exactly $k-1$ simple zeros in $(0,1)$; if $c \neq 0$, then there exists $N \in \mathbb{N}$ such that the eigenfunction $y_k(x)$ corresponding to the eigenvalue λ_k has for $k \leq N$ exactly $k-1$ and for $k > N$ exactly $k-2$ simple zeros in $(0,l)$.

Remark 2.1. Throughout what follows we will assume that the coefficients of boundary conditions are chosen such that the first eigenvalue of problem (2.1) is positive.

Let E be a Banach space $C^3[0,l] \cap BC_0$ with the norm $\|y\|_3 = \sum_{s=0}^{3} \| y^{(s)} \|_\infty$, where $\|y\|_\infty = \max_{x\in[0,l]} |y\,(x)|$ and BC_0 is a set of functions which satisfy the boundary conditions (1.2)–(1.4).

From now on ν will denote an element of $\{+,-\}$ that is, either $\nu = +$ or $\nu = -$.

In a recent paper [4, §2, pp. 4–5], using the Prüfer type transformation for each $k \in \mathbb{N}$ and each ν, the authors constructed sets $\mathcal{S}_k^\nu$ of functions $y \in E$, which have the oscillatory properties of eigenfunctions of the linear problem (2.1) and their derivatives. Note that the sets $\mathcal{S}_k^+$, $\mathcal{S}_k^-$ and $\mathcal{S}_k = \mathcal{S}_k^+ \cup \mathcal{S}_k^-$ are pairwise disjoint open subsets of E. Moreover, it was shown in [1, Lemma 2.2] that if $y \in \partial\mathcal{S}_k^\nu\ (\partial\mathcal{S}_k)$, then y has at least one zero of multiplicity 4 in $(0,l)$.

To study the existence of solutions to problem (1.1)–(1.5) with a fixed number of nodes, consider the following nonlinear eigenvalue problem

$$\begin{cases} \ell(y) = \lambda r(x) y + \tilde{h}(x, y, y', y'', y''', \lambda),\ x \in (0,l), \\ y \in (b.c.)_\lambda. \end{cases} \tag{2.2}$$

Here $\tilde{h}$ has a representation $\tilde{f} + \tilde{g}$, where $\tilde{f}$ and $\tilde{g}$ are real-valued continuous functions on $[0,l] \times \mathbb{R}^5$ that satisfy the following conditions: there exist constants $\tilde{M} > 0$ and sufficiently small $\tau_0 > 0$ such that

$$\left| \frac{\tilde{f}(x,y,s,v,w,\lambda)}{y} \right| \leq \tilde{M},\ (x,y,s,v,w) \in [0,l] \times \mathbb{R}^4,\ 0 < |y| + |s| + |v| + |w|\ \leq \tau_0, \\ y \neq 0,\ \lambda \in \mathbb{R}; \tag{2.3}$$

$$\tilde{g}(x,y,s,v,w,\lambda) = o(|y|+|s|+|v|+|w|) \text{ as } |y|+|s|+|v|+|w| \to 0, \tag{2.4}$$

uniformly in $x \in [0,l]$ and $\lambda \in \Lambda$ for each bounded interval $\Lambda \subset \mathbb{R}$, or there exist constants $\tilde{\tilde{M}} > 0$ and sufficiently large $\varkappa_0 > 0$ such that

$$\left|\frac{\tilde{f}(x,y,s,v,w,\lambda)}{y}\right| \le \tilde{\tilde{M}},\ (x,y,s,v,w) \in [0,l] \times \mathbb{R}^4,\ |y|+|s|+|v|+|w| \ge \varkappa_0,\ y \neq 0,\ \lambda \in \mathbb{R}; \tag{2.5}$$

$$\tilde{g}(x,\,y,\,s,\,v,\,w,\,\lambda) = o(|y|+|s|+|v|+|w|) \text{ as } |y|+|s|+|v|+|w| \to \infty, \tag{2.6}$$

uniformly in $x \in [0,l]$ and $\lambda \in \Lambda$.

If conditions (2.3) and (2.4) are satisfied, then the bifurcation of nontrivial solutions of problem (2.2) from the line of trivial solutions $\mathbb{R} \times \{0\} = \{(\lambda,0) : \lambda \in \mathbb{R}\}$ is considered. In this case, the global bifurcation of nontrivial solutions of problem (2.2) is studied in [4], where the following results are obtained.

Lemma 2.2 ([4, Lemmas 3 and 4]). *Let conditions (2.3) and (2.4) be satisfied. Then for each $k \in \mathbb{N}$ and each ν the set of bifurcation points of (2.2) with respect to the set $\mathbb{R} \times \mathcal{S}_k^\nu$ is nonempty and lies in $\tilde{I}_k \times \{0\}$, where $\tilde{I}_k = \left[\lambda_k - \frac{\tilde{M}}{r_0}, \lambda_k + \frac{\tilde{M}}{r_0}\right]$, $r_0 = \min_{x\in[0,l]} r(x)$.*

For each $k \in \mathbb{N}$ and each ν let $\tilde{D}_k^\nu$ be the union of all the components of the set of nontrivial solutions to problem (2.2) bifurcating from the points of the interval $\tilde{I}_k \times \{0\}$ with respect to $\mathbb{R} \times \mathcal{S}_k^\nu$. Moreover, let $D_k^\nu = \tilde{D}_k^\nu \cup (\tilde{I}_k \times \{0\})$. Note that D_k^ν is connected, but $\tilde{D}_k^\nu$ may not be connected in $\mathbb{R} \times E$.

Theorem 2.3 ([4, Theorem 3]). *Let conditions (2.3) and (2.4) be satisfied. Then for each $k \in \mathbb{N}$ and each ν the set $\tilde{D}_k^\nu$ is nonempty, lies in $\mathbb{R} \times S_k^\nu$ and is unbounded in $\mathbb{R} \times E$.*

In the case when conditions (2.5) and (2.6) are satisfied, then we consider the bifurcation of nontrivial solutions to problem (2.2) from infinity, or rather from the line $\mathbb{R} \times \{\infty\} = \{(\lambda,\infty) : \lambda \in \mathbb{R}\}$. Global bifurcation of nontrivial solutions of problem (2.2) from infinity with respect to the set $\mathbb{R} \times S_k^\nu$ was considered in [3] in the case of $\tilde{f} \equiv 0$. Using the results of [1,3] and [4] following the corresponding arguments in [6], we can obtain the following results.

Lemma 2.4. *Let conditions (2.5) and (2.6) be satisfied. Then for each $k \in \mathbb{N}$ and each ν the set of asymptotic bifurcation points of problem (2.2) with respect to the set $\mathbb{R} \times S_k^\nu$ is nonempty and lies in $\tilde{\tilde{I}}_k \times \{\infty\}$, where $\tilde{\tilde{I}}_k = \left[\lambda_k - \frac{\tilde{\tilde{M}}}{r_0}, \lambda_k + \frac{\tilde{\tilde{M}}}{r_0}\right]$.*

For each $k \in \mathbb{N}$ and each ν let $\tilde{\tilde{D}}_k^\nu$ be the union of all the components of the set of nontrivial solutions to problem (2.2) bifurcating from the points of the interval $\tilde{\tilde{I}}_k \times \{\infty\}$ with respect to the set $\mathbb{R} \times S_k^\nu$. Moreover, let $D_k^{\nu,*} = \tilde{\tilde{D}}_k^\nu \cup \left(\tilde{\tilde{I}}_k \times \{\infty\}\right)$ (in this case we add the points $\{(\lambda,\infty) : \lambda \in \mathbb{R}\}$ to our space $\mathbb{R} \times E$ and define an appropriate topology on the resulting set). Note that $D_k^{\nu,*}$ is connected.

Theorem 2.5. *For each $k \in \mathbb{N}$ and each ν the set $\tilde{\tilde{D}}_k^\nu$ is nonempty and for this set at least one of the following statements holds:*

(i) the set $\tilde{\tilde{D}}_k^\nu$ meets $\tilde{\tilde{I}}_{k'} \times \{\infty\}$ with respect to $\mathbb{R} \times \mathcal{S}_{k'}^{\nu'}$ for some $(k',\nu') \neq (k,\nu)$;

(ii) the set $\tilde{\tilde{D}}_k^\nu$ meets $\mathbb{R} \times \{0\}$ for some $\lambda \in \mathbb{R}$;

(iii) the projection of $\tilde{\tilde{D}}_k^\nu$ on $\mathbb{R} \times \{0\}$ is unbounded.

In addition, if cases (ii) and (iii) are not satisfied for the union $\tilde{\tilde{D}}_k = \tilde{\tilde{D}}_k^+ \cup \tilde{\tilde{D}}_k^-$, then case (i) is satisfied for it with $k' \neq k$.

3 Existence of solutions to problem (1.1)–(1.5) with fixed oscillation count

In this section we will determine the interval of χ, in which there exist nodal solutions of problem (1.1)–(1.5).

Theorem 3.1. *Let $g_0 > -\underline{f}_0$, $g_\infty > -\underline{f}_\infty$, and for some $k \in \mathbb{N}$ one of the following conditions is satisfied:*

$$\frac{\lambda_k}{g_0 + \underline{f}_0} < \chi < \frac{\lambda_k}{g_\infty + \overline{f}_\infty}; \qquad \frac{\lambda_k}{g_\infty + \underline{f}_\infty} < \chi < \frac{\lambda_k}{g_0 + \overline{f}_0}.$$

Then there are two solutions $\tilde{y}_k^+$ and $\tilde{y}_k^-$ of problem (1.1)–(1.5) such that $\tilde{y}_k^+ \in \mathcal{S}_k^+$ and $\tilde{y}_k^- \in \mathcal{S}_k^-$, i.e., $\tilde{y}_k^+$ has either $k-1$ or $k-2$ simple zeros in $(0, l)$ and is positive near $x = 0$, and $\tilde{y}_k^-$ has either $k-1$ or $k-2$ simple zeros in $(0, l)$ and is negative near $x = 0$.

Proof. To prove the theorem, consider the following nonlinear eigenvalue problem

$$\begin{cases} \ell(y)(x) = \lambda \chi r(x) g(y(x)) + \chi r(x) f(y(x)), \ x \in (0, l), \\ y \in (b.c.)_\lambda, \end{cases} \tag{3.1}$$

where $\lambda \in \mathbb{R}$ is an eigenvalue parameter.

Step 1. It follows from the first condition of (1.10) that the function $g(s)$, $s \in \mathbb{R}$, can be represented in the following form

$$g(s) = s g_0 + \rho(s), \tag{3.2}$$

where $\rho(s)$ is a real-valued continuous functions on $\mathbb{R}$ that satisfies the condition

$$\lim_{|s| \to 0} \frac{\rho(s)}{s} = 0. \tag{3.3}$$

Let $\zeta(u) = \max_{|s| \in [0, u]} |\rho(s)|$. It is obvious that the function $\zeta(u)$ is nondecreasing on $[0, +\infty)$.

It follows from (3.3) that for any sufficiently small $\varepsilon > 0$ one can find a sufficiently small $\delta_\varepsilon > 0$ such that for any $s \in \mathbb{R}$ satisfying condition $|s| < \delta_\varepsilon$ we have $|\rho(s)| < \varepsilon |s|$. Then we have

$$\frac{\zeta(u)}{u} < \varepsilon \quad \text{for any } u \in (0, \delta_\varepsilon). \tag{3.4}$$

Since the function $\zeta(u)$ is nondecreasing on $[0, +\infty)$ for any $x \in [0, l]$ we get

$$\frac{|\rho(y(x))|}{\|y\|_3} \leq \frac{\zeta(\|y\|_\infty)}{\|y\|_3} \leq \frac{\zeta(\|y\|_3)}{\|y\|_3}. \tag{3.5}$$

Let $y \in E$ such that $\|y\|_3 < \delta_\varepsilon$. Then by (3.4) we have

$$\frac{\zeta(\|y\|_3)}{\|y\|_3} < \varepsilon,$$

and consequently, for any $x \in [0, l]$ we get

$$\frac{|\rho(y(x))|}{\|y\|_3} < \varepsilon \quad \text{for any } x \in [0, l], \tag{3.6}$$

in view of (3.5). Therefore, it follows from (3.6) that

$$\|\rho(y)\|_\infty = o(\|y\|_3) \quad \text{as } \|y\|_3 \to 0. \tag{3.7}$$

Considering (3.2), the problem (3.1) can be written in the following equivalent form

$$\begin{cases} \ell(y)(x) = \lambda\chi r(x) g_0 y(x) + \chi r(x) f(y(x)) + \lambda\chi r(x)\rho(y(x)),\ x \in (0,l), \\ y \in (b.c.)_\lambda. \end{cases} \tag{3.8}$$

Let $\delta_0 > 0$ be a sufficiently small number. Then it follows from (1.6) and (1.7) that there exists sufficiently small $\sigma_0 \in (0, \tau_0)$ such that

$$\underline{f}_0 - \frac{g_0\delta_0}{2} < \frac{f(s)}{s} < \overline{f}_0 + \frac{g_0\delta_0}{2} \quad \text{for any } s \in \mathbb{R},\ 0 < |s| < \sigma_0. \tag{3.9}$$

Relation (3.9) implies that

$$\left|\frac{f(s)}{s}\right| \le \tilde{M}_0 \quad \text{for any } s \in \mathbb{R},\ \ 0 < |s| < \sigma_0, \tag{3.10}$$

where $\tilde{M}_0 = \max\left\{|\underline{f}_0 - \frac{g_0\delta_0}{2}|, |\overline{f}_0 + \frac{g_0\delta_0}{2}|\right\} > 0$. Then by (3.7) (see also (3.6)) and (3.10) it follows from Lemma 2.2 that for each $k \in \mathbb{N}$ and each ν the set of bifurcation points of (3.8) (or (3.1)) with respect to the set $\mathbb{R} \times \mathcal{S}_k^\nu$ is nonempty. If $(\lambda^*, 0)$ is a bifurcation point of problem (3.8) with respect to $\mathbb{R} \times \mathcal{S}_k^\nu$, then there exists a sequence $\{(\lambda_n^*, y_n^*)\}_{n=1}^\infty \subset \mathbb{R} \times \mathcal{S}_k^\nu$ such that

$$\begin{cases} \ell(y_n^*)(x) = \lambda_n^*\chi r(x) g_0 y_n^*(x) + \chi r(x) f(y_n^*(x)) + \lambda_n^*\chi r(x)\rho(y_n^*(x)),\ x \in (0,l), \\ y_n^* \in (b.c.)_{\lambda_n^*}, \end{cases} \tag{3.11}$$

and

$$(\lambda_n^*, y_n^*) \to (\lambda^*, 0) \quad \text{in } \mathbb{R} \times E \text{ as } n \to \infty. \tag{3.12}$$

Let

$$\varphi_n^*(x) = \begin{cases} -\frac{f(\tilde{y}_n^*(x))}{\tilde{y}_n^*(x)} & \text{if } \tilde{y}_n^*(x) \neq 0, \\ 0 & \text{if } \tilde{y}_n^*(x) = 0. \end{cases} \tag{3.13}$$

Then by (3.13) it follows from (3.11) that for each $n \in \mathbb{N}$ the pair (λ_n^*, y_n^*) is a solution of the following linearizable problem

$$\begin{cases} \frac{1}{\chi r(x) g_0}\,\ell(y)(x) + \frac{1}{g_0}\,\varphi_n^*(x) y(x) = \lambda y(x) + \frac{1}{g_0}\,\lambda\rho(y(x)),\ x \in (0,l), \\ y \in (b.c.)_\lambda. \end{cases} \tag{3.14}$$

In view of (3.12) we can choose $n \in \mathbb{N}$ so large that

$$-\left(\frac{\overline{f}_0}{g_0} + \frac{\delta_0}{2}\right) < \frac{1}{g_0}\varphi_n^*(x) < -\left(\frac{\underline{f}_0}{g_0} - \frac{\delta_0}{2}\right) \quad \text{for any } x \in [0,l], \tag{3.15}$$

in view of (3.9) and (3.13).

It follows from [5, Remark 4.2 and Theorem 4.3] that for each fixed $n \in \mathbb{N}$ the eigenvalues of the linear eigenvalue problem

$$\begin{cases} \frac{1}{\chi r(x) g_0}\,\ell(y)(x) + \frac{1}{g_0}\,\varphi_n^*(x) y(x) = \lambda y(x),\ x \in (0,l), \\ y \in (b.c.)_\lambda, \end{cases} \tag{3.16}$$

are real and simple, and form an infinitely increasing sequence $\{\lambda^*_{k,n}\}_{k=1}^{\infty}$; moreover, the eigenfunction $y^*_{k,n}(x)$, $k \in \mathbb{N}$, corresponding to the eigenvalue $\lambda^*_{k,n}$ lies in $\mathcal{S}_k$.

In view of relation (3.15), by following the arguments in Lemmas 5.1 and 5.3 of [1] we get

$$\tilde{\lambda}_k - \frac{\overline{f}_0}{g_0} - \frac{\delta_0}{2} \leq \lambda^*_{k,n} \leq \tilde{\lambda}_k - \frac{\underline{f}_0}{g_0} + \frac{\delta_0}{2}, \tag{3.17}$$

where $\tilde{\lambda}_k$, $k \in \mathbb{N}$, is a kth eigenvalue of the linear eigenvalue problem

$$\begin{cases} \frac{1}{\chi r(x) g_0}\, \ell(y)(x) = \lambda y(x), \; x \in (0,l), \\ y \in (b.c.)_\lambda. \end{cases} \tag{3.18}$$

Since $(\lambda^*_{k,n}, 0)$ is a unique bifurcation point of problem (3.14) with respect to $\mathbb{R} \times \mathcal{S}_k^\nu$ by (3.12) we can again choose $n \in \mathbb{N}$ so large that

$$\lambda^*_{k,n} - \frac{\delta_0}{2} < \lambda^*_n < \lambda^*_{k,n} + \frac{\delta_0}{2}\,. \tag{3.19}$$

Then it follows from (3.17) and (3.19) that

$$\tilde{\lambda}_k - \frac{\overline{f}_0}{g_0} - \delta_0 < \lambda^*_n < \tilde{\lambda}_k - \frac{\underline{f}_0}{g_0} + \delta_0\,, \tag{3.20}$$

whence, with regard to (3.12), we obtain

$$\tilde{\lambda}_k - \frac{\overline{f}_0}{g_0} - \delta_0 \leq \lambda^* \leq \tilde{\lambda}_k - \frac{\underline{f}_0}{g_0} + \delta_0\,. \tag{3.21}$$

As can be seen from (3.18) that $\lambda_k = \chi g_0 \tilde{\lambda}_k$ for each $k \in \mathbb{N}$. Consequently, it follows from (3.21) that

$$\frac{\lambda_k}{\chi g_0} - \frac{\overline{f}_0}{g_0} - \delta_0 \leq \lambda^* \leq \frac{\lambda_k}{\chi g_0} - \frac{\underline{f}_0}{g_0} + \delta_0\,. \tag{3.22}$$

Since δ_0 is arbitrary small enough, it follows from (3.22) that

$$\frac{\lambda_k}{\chi g_0} - \frac{\overline{f}_0}{g_0} \leq \lambda^* \leq \frac{\lambda_k}{\chi g_0} - \frac{\underline{f}_0}{g_0}\,. \tag{3.23}$$

Thus, (3.23) shows that the bifurcation points of problem (3.1) (or (3.8)) with respect to the set $\mathbb{R} \times \mathcal{S}_k^\nu$ are contained in the interval $I_k^0 \times \{0\}$, where

$$I_k^0 = \left[\frac{\lambda_k}{\chi g_0} - \frac{\overline{f}_0}{g_0}, \frac{\lambda_k}{\chi g_0} - \frac{\underline{f}_0}{g_0}\right].$$

Then, by Theorem 2.3, for each $k \in \mathbb{N}$ and each ν there exists a component $D^\nu_{k,0}$ of the set of solutions of problem (3.1), which contains $I_k^0 \times \{0\}$, lies in $(\mathbb{R} \times \mathcal{S}_k^\nu) \cup (I_k^0 \times \{0\})$ and is unbounded in $\mathbb{R} \times E$.

Step 2. By the second condition in (1.10) we can represent the function $g(s)$, $s \in \mathbb{R}$, as follows:

$$g(s) = s g_\infty + \varrho(s), \tag{3.24}$$

where

$$\lim_{|s|\to+\infty}\frac{\varrho(s)}{s}=0. \tag{3.25}$$

Let $\varsigma(u)=\max_{|s|\in[0,u]}|\varrho(s)|$. It is obvious that the function $\varsigma(u)$ is nondecreasing on $[0,+\infty)$.

In view of (3.25), for any sufficiently small $\varepsilon>0$ there exists a sufficiently large $\Delta_\varepsilon>0$ such that

$$|\varrho(s)|<\frac{1}{2}\,\varepsilon|s| \quad \text{for any } s\in\mathbb{R},\ |s|>\Delta_\varepsilon. \tag{3.26}$$

Let $u\in[\Delta_\varepsilon,\infty)$ be arbitrary. Then we have

$$\varsigma(u)=\max\left\{\max_{|s|\in[0,\Delta_\varepsilon]}|\varrho(s)|,\ \max_{|s|\in[\Delta_\varepsilon,u]}|\varrho(s)|\right\}. \tag{3.27}$$

Let $K_\varepsilon=\max_{|s|\in[0,\Delta_\varepsilon]}|\varrho(s)|$. We will choose $\Delta_{1,\varepsilon}>\Delta_\varepsilon$ so large that $\frac{K_\varepsilon}{\Delta_{1,\varepsilon}}<\frac{1}{2}\,\varepsilon$. Now let $u>\Delta_{1,\varepsilon}$. Then by (3.26) it follows from (3.27) that

$$\begin{aligned}\frac{\varsigma(u)}{u}&=\frac{\max\{K_\varepsilon,\max_{|s|\in[\Delta_\varepsilon,u]}|\varrho(s)|\}}{u}\le\frac{\max\{K_\varepsilon,\frac{1}{2}\,\varepsilon\,u\}}{u}\\&=\max\left\{\frac{K_\varepsilon}{u},\frac{1}{2}\,\varepsilon\right\}\le\max\left\{\frac{K_\varepsilon}{\Delta_{1,\varepsilon}},\frac{1}{2}\,\varepsilon\right\}\le\frac{1}{2}\,\varepsilon<\varepsilon.\end{aligned} \tag{3.28}$$

Since the function $\varsigma(u)$ is nondecreasing on $[0,+\infty)$ for any $x\in[0,l]$ we have

$$\frac{|\varrho(y(x))|}{\|y\|_3}\le\frac{\varsigma(\|y\|_\infty)}{\|y\|_3}\le\frac{\varsigma(\|y\|_3)}{\|y\|_3}. \tag{3.29}$$

If $\|y\|_3>\Delta_{1,\varepsilon}$, then by (3.28) it follows from (3.29) that

$$\frac{|\varrho(y(x))|}{\|y\|_3}<\varepsilon \quad \text{for any } x\in[0,l],$$

which shows that

$$\|\varrho(y)\|_\infty=o(\|y\|_3) \quad \text{as } \|y\|_3\to\infty. \tag{3.30}$$

Taking into account (3.24), we can rewrite the problem (3.1) in the following equivalent form

$$\begin{cases}\ell(y)(x)=\lambda\chi r(x)g_\infty y(x)+\chi r(x)f(y(x))+\lambda\chi r(x)\varrho(y(x)),\ x\in(0,l),\\ y\in(b.c.)_\lambda.\end{cases} \tag{3.31}$$

Using [1, Lemma 5.1], Lemma 2.4, relations (1.6), (1.8), (3.30) and following the above arguments, we can show that if $(\tilde\lambda^*,\infty)$ is an asymptotic bifurcation point of problem (3.1) (or (3.31)), then

$$\tilde\lambda^*\in I_k^\infty=\left[\frac{\lambda_k}{\chi g_\infty}-\frac{\overline{f}_\infty}{g_\infty},\frac{\lambda_k}{\chi g_\infty}-\frac{\underline{f}_\infty}{g_\infty}\right].$$

Hence it follows from Theorem 2.5 that for each $k\in\mathbb{N}$ and each ν there exists a component $D_{k,\infty}^\nu$ of the set of solutions to problem (3.1) containing $I_k^\infty\times\{\infty\}$ and for which at least one of the following statements holds:

(i) the set $D_{k,\infty}^\nu$ meets $I_{k'}^\infty\times\{\infty\}$ with respect to $\mathbb{R}\times\mathcal{S}_{k'}^{\nu'}$ for some $(k',\nu')\neq(k,\nu)$;

(ii) the set $D^{\nu}_{k,\infty}$ meets $\mathbb{R} \times \{0\}$ for some $\lambda \in \mathbb{R}$;

(iii) the projection of $D^{\nu}_{k,\infty}$ on $\mathbb{R} \times \{0\}$ is unbounded.

Step 3. By following the arguments in Theorem 3.3 of [25] we can show that for each $k \in \mathbb{N}$ and each ν, $D^{\nu}_{k,\infty} \backslash (I^{\infty}_k \times \{\infty\}) \subset \mathbb{R} \times \mathcal{S}^{\nu}_k$, and consequently, alternative (i) above for $D^{\nu}_{k,\infty}$ cannot hold. Moreover, if $D^{\nu}_{k,\infty}$ meets $\mathbb{R} \times \{0\}$ for some $\lambda \in \mathbb{R}$, then $\lambda \in I^0_k$. Similarly, if $D^{\nu}_{k,0}$ meets $\mathbb{R} \times \{\infty\}$ for some $\lambda \in \mathbb{R}$, then $\lambda \in I^{\infty}_k$. Hence we conclude that if $D^{\nu}_{k,\infty}$ has a bounded projection on $\mathbb{R} \times \{0\}$, then $D^{+}_{k,0} = D^{+}_{k,\infty}$ and $D^{-}_{k,0} = D^{-}_{k,\infty}$.

Now we show that for each $k \in \mathbb{N}$ and each ν the set $D^{\nu}_{k,\infty}$ has a bounded projection on $\mathbb{R} \times \{0\}$. Indeed, otherwise there exists a sequence $\{(\overline{\lambda}_n, \overline{y}_n)\}_{n=1}^{\infty} \subset (D^{\nu}_{k,\infty} \backslash \mathcal{Q}_{k,\infty}) \subset (\mathbb{R} \times \mathcal{S}^{\nu}_k)$ such that

$$\lim_{n\to\infty} \overline{\lambda}_n = \pm\infty, \tag{3.32}$$

where $\mathcal{Q}_{k,\infty}$ is a some neighborhood of $I^{\infty}_k \times \{\infty\}$.

By (1.6)–(1.10) there exists a positive constants κ_0, κ_1 and κ_2 such that

$$\kappa_0 \leq \frac{g(s)}{s} \leq \kappa_1 \quad \text{and} \quad \left|\frac{f(s)}{s}\right| \leq \kappa_2 \quad \text{for any } s \in \mathbb{R},\ s \neq 0. \tag{3.33}$$

We define the functions $\overline{\varphi}_n(x)$ and $\overline{\phi}_n(x)$, $x \in [0, l]$, as follows:

$$\overline{\varphi}_n(x) = \begin{cases} \frac{g(\overline{y}_n(x))}{\overline{y}_n(x)} & \text{if } \overline{y}_n(x) \neq 0, \\ 0 & \text{if } \overline{y}_n(x) = 0, \end{cases} \qquad \overline{\phi}_n(x) = \begin{cases} -\frac{f(\overline{y}_n(x))}{\overline{y}_n(x)} & \text{if } \overline{y}_n(x) \neq 0, \\ 0 & \text{if } \overline{y}_n(x) = 0. \end{cases} \tag{3.34}$$

Since $\overline{y}_n \in \mathcal{S}^{\nu}_k$ by (3.34) it follows from (3.1) that $\overline{\lambda}_n$ for each $n \in \mathbb{N}$ is kth eigenvalue of the following linear eigenvalue problem

$$\begin{cases} \ell(y)(x) + \chi r(x)\overline{\phi}_n(x)\, y(x) = \lambda \chi r(x)\overline{\varphi}_n(x)\, y(x)),\ x \in (0, l), \\ y \in (b.c.)_{\lambda}. \end{cases} \tag{3.35}$$

By (3.33) from (3.34) we get

$$\kappa_0 \leq \overline{\varphi}_n(x) \leq \kappa_1 \quad \text{and} \quad |\overline{\phi}_n(x)| \leq \kappa_2 \quad \text{for any } x \in [0, l]. \tag{3.36}$$

It is known (see [1, 4]) that problem (3.35) reduces to the spectral problem for the self-adjoint operator in the Hilbert space $H = L_2(0, l) \oplus \mathbb{C}$ with corresponding scalar product. In view of (3.36), by the maximum-minimum property of eigenvalues (see [1, 2]) we obtain that the eigenvalues of problem (3.35) are uniformly bounded from below with respect to $n \in \mathbb{N}$. Consequently, the relation

$$\lim_{n\to\infty} \overline{\lambda}_n = -\infty$$

is not possible. Should be noted that the relation

$$\lim_{n\to\infty} \overline{\lambda}_n = +\infty,$$

is also impossible, since for a sufficiently large n, by [5, Theorem 4.3], the number of zeros of the function $\overline{y}_n$ will be large enough, which contradicts the condition $\overline{y}_n \in \mathcal{S}^{\nu}_k$.

Therefore, for any $k \in \mathbb{N}$ we have

$$D^{+}_{k,0} = D^{+}_{k,\infty} \quad \text{and} \quad D^{-}_{k,0} = D^{-}_{k,\infty}. \tag{3.37}$$

Step 4. It is obvious that any solution to problem (3.1) of the form $(1, y)$ gives a solution y to problem (1.1)–(1.5). In order for problem (1.1)–(1.5) to have a solution y which is contained in $\mathcal{S}_k^\nu$ for some $k \in \mathbb{N}$, by (3.37) it is sufficient that on the real axis $\mathbb{R}$ the interval I_k^0 lies to the left of 1 and the interval I_k^∞ lies to the right of 1, or the interval I_k^0 lies to the right of 1, and the interval I_k^∞ lies to the left of 1.

Let the conditions $g_0 > -\underline{f}_0$ and $g_\infty > -\underline{f}_\infty$ be satisfied. Hence we have $g_\infty > -\overline{f}_\infty$. If the condition $\frac{\lambda_k}{g_0+\underline{f}_0} < \chi < \frac{\lambda_k}{g_\infty+\overline{f}_\infty}$ is satisfied, then we get

$$\frac{\lambda_k}{\chi g_0} - \frac{\underline{f}_0}{g_0} < \frac{\lambda_k}{\frac{\lambda_k}{g_0+\underline{f}_0} g_0} - \frac{\underline{f}_0}{g_0} = \frac{\lambda_k(g_0+\underline{f}_0)}{\lambda_k g_0} - \frac{\lambda_k \underline{f}_0}{\lambda_k g_0} = 1$$

and

$$\frac{\lambda_k}{\chi g_\infty} - \frac{\overline{f}_\infty}{g_\infty} > \frac{\lambda_k}{\frac{\lambda_k}{g_\infty+\overline{f}_\infty} g_\infty} - \frac{\overline{f}_\infty}{g_\infty} = \frac{\lambda_k(g_\infty+\overline{f}_\infty)}{\lambda_k g_\infty} - \frac{\lambda_k \overline{f}_\infty}{\lambda_k g_\infty} = 1.$$

The case in which $\frac{\lambda_k}{g_\infty+\underline{f}_\infty} < \chi < \frac{\lambda_k}{g_0+\overline{f}_0}$ can be considered in a similar way. The proof of this theorem is complete. □

Step 4 of the proof of Theorem 3.1 makes it possible to obtain other conditions for the existence of solutions to problem (1.1)–(1.5) contained in the sets $\mathcal{S}_k^+$ and $\mathcal{S}_k^-$ for some $k \in \mathbb{N}$.

Theorem 3.2. *Let $g_0 > -\underline{f}_0$, $-\overline{f}_\infty < g_\infty \leq -\underline{f}_\infty$, and for some $k \in \mathbb{N}$ the following condition is satisfied:*

$$\frac{\lambda_k}{g_0+\underline{f}_0} < \chi < \frac{\lambda_k}{g_\infty+\overline{f}_\infty}.$$

Then the statement of Theorem 3.1 holds.

Theorem 3.3. *Let $g_0 > -\underline{f}_0$, $g_\infty \leq -\overline{f}_\infty$, and for some $k \in \mathbb{N}$ the following condition is satisfied:*

$$\chi > \frac{\lambda_k}{g_0+\underline{f}_0}.$$

Then the statement of Theorem 3.1 holds.

Theorem 3.4. *Let $-\overline{f}_0 < g_0 \leq -\underline{f}_0$, $g_\infty > -\underline{f}_\infty$, and for some $k \in \mathbb{N}$ the following condition is satisfied:*

$$\frac{\lambda_k}{g_\infty+\underline{f}_\infty} < \chi < \frac{\lambda_k}{g_0+\overline{f}_0}.$$

Then the statement of Theorem 3.1 holds.

Theorem 3.5. *Let $g_0 \leq -\overline{f}_0$, $g_\infty > -\underline{f}_\infty$, and for some $k \in \mathbb{N}$ the following condition is satisfied:*

$$\chi > \frac{\lambda_k}{g_\infty+\underline{f}_\infty}.$$

Then the statement of Theorem 3.1 holds.

The proofs of these theorems are similar to that of Step 4 of Theorem 3.1.

Abstract. We consider a class of degenerate elliptic fully nonlinear equations with applications to Grad equations:

$$\begin{cases} |Du|^{\gamma}\mathcal{M}^{+}_{\lambda,\Lambda}\big(D^2u(x)\big) = f\big(|u \geq u(x)|\big) & \text{in } \Omega \\ u = g & \text{on } \partial\Omega, \end{cases}$$

where $\gamma \geq 1$ is a constant, Ω is a bounded domain in $\mathbb{R}^N$ with $C^{1,1}$ boundary. We prove the existence of a $W^{2,p}$-viscosity solution to the above equation, which degenerates when the gradient of the solution vanishes.

Keywords: fully nonlinear degenerate elliptic equations, viscosity solution, Pucci's extremal operator, Dirichlet boundary value problem.

2020 Mathematics Subject Classification: 35J25, 35J60, 35J70, 35D40.

1 Introduction

We investigate the following degenerate problem:

$$\begin{cases} |Du|^{\gamma}\mathcal{M}^{+}_{\lambda,\Lambda}\big(D^2u(x)\big) = f\big(|u \geq u(x)|\big) & \text{in } \Omega \\ u = g & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where $\gamma \geq 1$ is a constant, Ω is a bounded domain in $\mathbb{R}^N$ with $C^{1,1}$ boundary, $|\cdot|$ denotes the Lebesgue measure in $\mathbb{R}^N$, $f : [0, |\Omega|] \longrightarrow \mathbb{R}$ is a non-decreasing, non-negative continuous function and $u : \Omega \longrightarrow \mathbb{R}$. Here, $\mathcal{M}^{+}_{\lambda,\Lambda}$ is the Pucci's extremal operator. In our setting, by $u \geq u(x)$, we mean,

$$\{\omega \in \Omega : u(\omega) \geq u(x)\}$$

called the superlevel sets of u. We establish the existence of a $W^{2,p}$-viscosity solution (also known as L^p-viscosity solution) to (1.1). It is worth mentioning that the notion of $W^{2,p}$-viscosity solution was defined by Caffarelli et al. [7]. In the case when $\gamma = 0$ in (1.1), the existence of a $W^{2,p}$-viscosity solution is proven by L. Caffarelli and I. Tomasetti [8].

The pioneer contribution in this direction was due to H. Grad [12], who introduced such equations, which appear in plasma physics, called "Grad equations". In their seminal work, Grad examined the following equation in three-dimension:

$$\Delta\Psi = F(V, \Psi, \Psi', \Psi''),$$

where the right hand side (R.H.S.) represents a second-order differential operator acting on $\Psi(V)$ for a surface defined by $\Psi =$ constant. Here, $\Psi'(V)$ represents the derivative with respect to volume and $\Psi(V)$ stands for the inverse function to $V(\Psi)$, denoting the volume enclosed by Ψ. Furthermore, they pointed out the potential for simplifying plasma equations by introducing u^* defined as:

$$u^*(t) := \inf\Big\{s : |u < s| \geq t\Big\}.$$

These equations, also known as Queer Differential Equations in the literature, have a wide range of applications across various fields. One notable application is their appearance in plasma modeling, specifically in analyzing plasma confined within toroidal containers. We refer to [12] for the details. Moreover, these equations exhibit connections in financial mathematics, see [23]. R. Temam [22] pioneered the investigation of problems akin to (1.1) concerning the Laplacian, a direction extensively examined by several researchers. They notably established the existence of solutions to equations having the model structure:

$$\Delta u = g\big(|u < u(x)|, u(x)\big) + f(x),$$

by exploiting the properties of directional derivatives of u^*. For further insights into this topic, we refer the interested readers to the works of J. Mossino and R. Temam [17], as well as those by P. Laurence and E. Stredulinsky [15,16], along with the related references therein.

In all the aforementioned research works, the problem was studied using variational methods. However, in a recent work, L. Caffarelli and I. Tomasetti [8] studied the equation similar to J. Mossino and R. Temam [17] for fully nonlinear uniformly elliptic operators using the viscosity approach. Specifically, they addressed the following problem:

$$\begin{cases} F\big(D^2u(x)\big) = f\big(|u \geq u(x)|\big) & \text{in } \Omega \\ u = g & \text{on } \partial\Omega, \end{cases}$$

where F represents a convex, uniformly elliptic operator. They established the existence of a $W^{2,p}$-viscosity solution u to this problem, satisfying the following estimate:

$$\|u\|_{W^{2,p}(\Omega)} \leq C\big[\|u\|_{\infty,\Omega} + \|g\|_{W^{2,p}(\Omega)} + \|f\big(|u \geq u(x)|\big)\|_{p,\Omega}\big].$$

For further insights into the existence and qualitative questions pertaining to extremal Pucci's equations, we refer to [10,11,18,20,21,24–26] .

Concurrently, equations involving gradient degenerate fully nonlinear elliptic operators have been widely investigated over the past decade. Pioneering works in this direction are attributed to I. Birindelli and F. Demengel. They proved several important results for these operators in a series of papers. These contributions involve comparison principle and Liouville-type results [3], regularity and uniqueness of eigenvalues and eigenfunctions [4,5], $C^{1,\alpha}$ regularity in the radial case [6]. Furthermore, the equations of the form:

$$|Du|^\gamma F(D^2u) = f \quad \text{in } B_1, \tag{1.2}$$

when $\gamma \geq 0$ is a constant and $f \in L^\infty(B_1, \mathbb{R})$, were investigated by C. Imbert and L. Silvestre [13]. In particular, they established the interior $C^{1,\alpha}$ regularity of solutions for equations of the form (1.2). One may also see [19] for insights into variable exponent degenerate mixed fully nonlinear local and nonlocal equations.

Motivated by the above works and recently by the work of L. Caffarelli and I. Tomasetti [8], it is natural to ask the following question:

Question: *Do we have the existence of a viscosity solution to* (1.1)*?*

The aim of this paper is to answer this question affirmatively. The crucial difference to our problem from [8] is due to the fact that $|Du|^\gamma \mathcal{M}^+_{\lambda,\Lambda}(D^2u)$ degenerates along the set of critical points,

$$\mathcal{C} := \{x : Du(x) = 0\}.$$

The problem is challenging due to the following reasons:

(C1) The R.H.S. of (1.1) is a function of measure of superlevel sets. This makes the problem nonlocal.

(C2) The L.H.S. of (1.1) is degenerate. The fundamental theory of L^p-viscosity solutions does not work directly here since it requires the uniform ellipticity of the operator. Also, when $f \in C(\Omega)$, the problem can be discussed in the C-viscosity sense but in the case of discontinuous data, when $f \in L^p(\Omega)$, the problem needs to be treated in the L^p-viscosity sense. We point out that this situation occurs while approximating the R.H.S. of (1.1).

We use the L^p-viscosity solution approach for Monge–Ampère equation as in [1, 8] to (1.1). To handle the above mentioned challenges, we first consider the following approximate problem:

$$\begin{cases} |Du|^\gamma \mathcal{M}^+_{\lambda,\Lambda}\big(D^2u(x)\big) + \varepsilon\Delta u = f\big(|u \geq u(x)|\big) & \text{in } \Omega \\ u = g & \text{on } \partial\Omega, \end{cases} \tag{1.3}$$

for $\varepsilon > 0$. Further, using the approximations in the R.H.S. of the equation and exploiting the results available for uniform elliptic operators, for instance, Theorem 2.5 and Theorem 2.7 (see next), we establish the existence of a viscosity solution to the approximate problem (1.3). This yields the existence of a viscosity solution to (1.1). More precisely, using the idea of Amadori et al. [1], we first get the existence of a $W^{2,p}$-viscosity solution to the approximate problem (1.3) by invoking Theorem 2.1 [8]. We recall that the estimate established in [8] is not adequate to claim the uniform bound on the $W^{2,p}$-viscosity solution of (1.3). To show the existence of a solution to the original problem (1.1), we seek the uniform bound on the solutions of (1.3), which is crucial in approaching $\varepsilon \longrightarrow 0^+$. We invoke the Alexandroff–Bakelman–Pucci (ABP) estimates from Caffarelli et al. [7] to sort this issue. These estimates play a crucial role in obtaining uniform bounds on the $W^{2,p}$-viscosity solutions to (1.3).

Throughout the paper, we consider Ω to be a bounded $C^{1,1}$ domain in $\mathbb{R}^N$, $N \geq 2$.

The main result of this paper is the following:

Theorem 1.1. *Let $\gamma \geq 1$ be a constant. Let $\Omega \subset \mathbb{R}^N$ be a bounded $C^{1,1}$ domain. Let $f \in C\big([0, |\Omega|], \mathbb{R}\big)$ be a non-decreasing, non-negative function and $g \in W^{2,p}(\Omega) \cap C(\overline{\Omega})$, $p > N$. Consider the problem*

$$\begin{cases} |Du|^\gamma \mathcal{M}^+_{\lambda,\Lambda}\big(D^2u(x)\big) = f\big(|u \geq u(x)|\big) & \textit{in } \Omega \\ u = g & \textit{on } \partial\Omega. \end{cases} \tag{1.4}$$

Then, there exists a $W^{2,p}$-viscosity solution of (1.4). Moreover, the solution satisfies the following estimate:

$$\|u\|_{W^{2,p}(\Omega)} \le C\Big(\|u\|_{\infty,\Omega} + \|g\|_{W^{2,p}(\Omega)} + \|f(|u \ge u(x)|)\|_{p,\Omega}\Big),$$

where $C > 0$ is a constant.

Remark 1.2. By Sobolev's embedding theorem we have that the solution is $C^{1,\alpha}(\overline{\Omega})$ regular for any $0 < \alpha < 1$.

The organization of the paper is as follows. In Section 2, we recall the basic definitions and several key results used in the ensuing sections of the paper. Section 3 is devoted to the proof of our main result. Here, we sketch the plan of our proof:

(i) Perturb the left-hand side (L.H.S.), i.e., the operator $|Du|^\gamma \mathcal{M}^+_{\lambda,\Lambda}(D^2u)$ by adding $\varepsilon\Delta u$, for $\varepsilon > 0$. (This makes the problem uniformly elliptic.)

(ii) Fix a Lipschitz function v in the R.H.S. of (1.3).

(iii) Construct a sequence of L^p-functions converging to R.H.S. (for fixed Lipschitz function v) and obtain a sequence of solutions.

(iv) Obtain the existence of solution to equation pertaining $|Du|^\gamma \mathcal{M}^+_{\lambda,\Lambda}(D^2u) + \varepsilon\Delta u$ for fixed Lipschitz function v in the R.H.S.

(v) Use Theorem 2.1 [8] (an application of Schaefer fixed point theorem) to show the existence of a solution to (1.3).

(vi) Establish the existence of a $W^{2,p}$-viscosity solution to (1.4).

2 Preliminaries

We recall that a continuous mapping $F : S^N \longrightarrow \mathbb{R}$ is *uniformly elliptic* if:
For any $A \in \mathcal{S}^N$, where $\mathcal{S}^N$ is the set of all $N \times N$ real symmetric matrices, there exist two positive constants $\Lambda \ge \lambda > 0$ s.t.

$$\lambda\|B\| \le F(A+B) - F(A) \le N\Lambda\|B\| \quad \text{for all positive semi-definite } B \in \mathcal{S}^N,$$

and $\|B\|$ is the largest eigenvalue of B. Here, we have the usual partial ordering: $A \le B$ in $\mathcal{S}^N$ means that $\langle A\xi, \xi\rangle \le \langle B\xi, \xi\rangle$ for any $\xi \in \mathbb{R}^N$. In other words, $B - A$ is positive semidefinite.

Let $S \in \mathcal{S}^N$, then for the given two parameters $\Lambda \ge \lambda > 0$, Pucci's maximal operator is defined as follows:

$$\mathcal{M}^+_{\lambda,\Lambda}(S) := \Lambda \sum_{e_i \ge 0} e_i + \lambda \sum_{e_i < 0} e_i,$$

where $\{e_i\}_{i=1}^N$ are the eigenvalues of S. This operator is uniformly elliptic and subadditive, that is

$$\mathcal{M}^+_{\lambda,\Lambda}(A+B) \le \mathcal{M}^+_{\lambda,\Lambda}(A) + \mathcal{M}^+_{\lambda,\Lambda}(B),$$

for $A, B \in \mathcal{S}^N$. Clearly, for $\lambda = \Lambda = 1$, $\mathcal{M}^+_{\lambda,\Lambda} \equiv \Delta$, the classical Laplace operator.

Next, we recall the notion of a viscosity solution. M. G. Crandall and P.-L. Lions [9] were the first to introduce the concept of a viscosity solution. Now, we recall the definition of *continuous viscosity solution* to the following equation:

$$|Du|^\gamma F(D^2u(x)) = f \quad \text{in } \Omega, \tag{2.1}$$

for $f \in C(\Omega)$.

Definition 2.1 ([3])**.** Let $u : \overline{\Omega} \longrightarrow \mathbb{R}$ be an upper semicontinuous (USC) function in Ω. Then, u is called a *viscosity subsolution* of (2.1) if

$$|D\varphi(x)|^{\gamma} F\big(D^2\varphi(x)\big) \geq f(x),$$

whenever $\varphi \in C^2(\Omega)$ and $x \in \Omega$ is a local maximizer of $u - \varphi$ with $D\varphi \neq \mathbf{0} \in \mathbb{R}^N$.

Definition 2.2 ([3])**.** Let $u : \overline{\Omega} \longrightarrow \mathbb{R}$ be a lower semicontinuous (LSC) function in Ω. Then, u is called a *viscosity supersolution* of (2.1) if

$$|D\psi(x)|^{\gamma} F\big(D^2\psi(x)\big) \leq f(x),$$

whenever $\psi \in C^2(\Omega)$ and $x \in \Omega$ is a local minimizer of $u - \psi$ with $D\psi \neq \mathbf{0} \in \mathbb{R}^N$.

Definition 2.3 ([3])**.** A continuous function u is said to be a *viscosity solution* to (2.1) if it is a supersolution as well as subsolution to (2.1).

Let $h \in L^p(\Omega)$, $g \in W^{2,p}(\Omega) \cap C(\overline{\Omega})$ for $p > N$. Let us consider the problem

$$\begin{cases} |Du|^{\gamma} \mathcal{M}^{+}_{\lambda,\Lambda}(D^2 u) = h & \text{in } \Omega, \\ u = g & \text{on } \partial\Omega. \end{cases} \tag{2.2}$$

We mention that the classical definition of $W^{2,p}$-viscosity solution can not be applied for (2.2), due to the lack of uniform ellipticity. Consider the problem:

$$\begin{cases} |Du|^{\gamma} \mathcal{M}^{+}_{\lambda,\Lambda}\big(D^2 u\big) + \varepsilon \Delta u = h & \text{in } \Omega \\ u = g & \text{on } \partial\Omega, \end{cases} \tag{2.3}$$

for $p \in \mathbb{R}^N$. Motivated by Caffarelli et al. [7] and Ishii et al. [14], we define the L^p-viscosity subsolution (supersolution) to (2.3) as follows.

Definition 2.4. Let u be an USC (respectively, LSC) function on $\overline{\Omega}$. We say that u is an L^p-viscosity subsolution (respectively, supersolution) to (2.3) if $u \leq g$ (resp., $u \geq g$) on $\partial\Omega$ and for all $\phi \in W^{2,p}(\Omega)$,

$$\operatorname{ess}\liminf_{x \longrightarrow y} \big(|D\phi(x)|^{\gamma} \mathcal{M}^{+}_{\lambda,\Lambda}\big(D^2\phi(x)\big) + \varepsilon\Delta\phi(x) - h(x)\big) \geq 0$$

$$\left(\text{resp., } \operatorname{ess}\limsup_{x \longrightarrow y} \big(|D\phi(x)|^{\gamma} \mathcal{M}^{+}_{\lambda,\Lambda}\big(D^2\phi(x)\big) + \varepsilon\Delta\phi(x) - h(x)\big) \leq 0\right),$$

for $y \in \Omega$, the point of local maxima (respectively, minima) to $u - \phi$.

We say that any continuous function u is an L^p-viscosity solution to (2.3) if it is both L^p-viscosity subsolution and supersolution to (2.3). Now, we state a result concerning the existence and uniqueness of $W^{2,p}$-viscosity solution to the operator F under certain hypotheses. The following result is due to N. Winter [27].

Theorem 2.5 ([27, Theorem 4.6]). *Let Ω be a bounded $C^{1,1}$ domain in $\mathbb{R}^N$. Let $F(p,M)$ be a uniformly elliptic operator and convex in M-variable. Also, let $F(0,0) \equiv 0$ in Ω, $f \in L^p(\Omega)$ and $g \in W^{2,p}(\Omega)$ for $p > N$. Then, there exists a unique $W^{2,p}$-viscosity solution to*

$$\begin{cases} F(Du, D^2u) = f & \text{in } \Omega \\ u = g & \text{on } \partial\Omega. \end{cases}$$

Moreover, $u \in W^{2,p}(\Omega)$ and

$$\|u\|_{W^{2,p}(\Omega)} \leq C\Big(\|u\|_{\infty,\Omega} + \|g\|_{W^{2,p}(\Omega)} + \|f\|_{p,\Omega}\Big),$$

for some positive constant C.

Theorem 2.6 ([2, Theorem 1.1]). *Let Ω be a bounded domain with C^2-boundary. Let $\gamma \geq 0$ and F be a uniformly elliptic operator and $f \in C(\overline{\Omega})$, $g \in C^{1,\beta}(\partial\Omega)$ for some $\beta \in (0,1)$. Then, any viscosity solution u of*

$$\begin{cases} |Du|^\gamma F(D^2u) = f & \text{in } \Omega \\ u = g & \text{on } \partial\Omega \end{cases}$$

is in $C^{1,\alpha}$ for some $\alpha = \alpha(\lambda, \Lambda, \|f\|_{\infty,\Omega}, N, \Omega, , \beta)$. Moreover, u satisfies the following estimate

$$\|u\|_{C^{1,\alpha}(\overline{\Omega})} \leq C\left(\|g\|_{C^{1,\beta}(\partial\Omega)} + \|u\|_{\infty,\Omega} + \|f\|_{\infty,\Omega}^{\frac{1}{1+\gamma}}\right),$$

for some positive constant $C = C(\alpha)$.

The following result plays an important role in Step 5 of the proof of our main result.

Theorem 2.7 ([7, Theorem 3.8]). *Let F_i, F be uniformly elliptic and $p > N$. Let $f, f_i \in L^p(\Omega)$. Let $u_i \in C(\Omega)$ be $W^{2,p}$-viscosity subsolutions (supersolutions) to*

$$F_i(D^2u_i) = f_i \quad \text{in } \Omega,$$

for $i = 1, 2, \ldots$ Assume that $u_i \longrightarrow u$ locally uniformly in Ω. Also, assume that if for each $B(x_0, r) \subset \Omega$ and $g \in W^{2,p}(B(x_0,r))$, we have

$$\|\big(F_i(D^2u_i) - f_i(x) - F(D^2(u)) + f(x)\big)^+\|_{p,B(x_0,r)} \longrightarrow 0,$$
$$\Big(\|\big(F_i(D^2u_i) - f_i(x) - F(D^2(u)) + f(x)\big)^-\|_{p,B(x_0,r)} \longrightarrow 0\Big).$$

Then, u is a $W^{2,p}$-viscosity subsolution (supersolution) to

$$F(D^2u) = f \quad \text{in } \Omega.$$

3 Proof of our main result

Proof of Theorem 1.1. The original problem is

$$\begin{cases} |Du|^\gamma \mathcal{M}^+_{\lambda,\Lambda}(D^2u(x)) = f(|u \geq u(x)|) & \text{in } \Omega \\ u = g & \text{on } \partial\Omega. \end{cases} \tag{3.1}$$

Step 1: Perturbing the L.H.S. by adding $\varepsilon\Delta u$. Consider the approximate problem:

$$\begin{cases} |Du|^{\gamma}\mathcal{M}^{+}_{\lambda,\Lambda}(D^2u) + \varepsilon\Delta u = f(|u \geq u(x)|) & \text{in } \Omega \\ u = g & \text{on } \partial\Omega, \end{cases} \tag{3.2}$$

for $\varepsilon > 0$. Since, $Gu := |Du|^{\gamma}\mathcal{M}^{+}_{\lambda,\Lambda}(D^2u) + \varepsilon\Delta u$ is uniformly elliptic, so by Theorem 2.1 [8], we immediately have the existence of a $W^{2,p}$-viscosity solution (say u_ε) to (3.2) satisfying the following estimate:

$$\|u_\varepsilon\|_{W^{2,p}(\Omega)} \leq C\Big(\|u_\varepsilon\|_{\infty,\Omega} + \|g\|_{W^{2,p}(\Omega)} + \|f(|u_\varepsilon \geq u_\varepsilon(x)|)\|_{p,\Omega}\Big).$$

By the above estimate, one can not directly claim the uniform bound on u_ε, which is crucial in order to pass the limit $\varepsilon \longrightarrow 0$ to establish the existence of $W^{2,p}$-viscosity solution to (3.1). To overcome this difficulty, we further approximate problem (3.2).

Step 2: Freeze a Lipschitz function v for the R.H.S.. Next, following the arguments similar to [8], we fix a Lipschitz function v in Ω, and consider $h_v(x) := f(|v \geq v(x)|)$ and reduce to the following problem:

$$\begin{cases} |Du|^{\gamma}\mathcal{M}^{+}_{\lambda,\Lambda}(D^2u) + \varepsilon\Delta u = h_v & \text{in } \Omega \\ u = g & \text{on } \partial\Omega. \end{cases} \tag{3.3}$$

Step 3: Building a sequence of functions in R.H.S. We consider a sequence of functions $\{h_v^i\}_{i=1}^{\infty}$ defined as

$$h_v^i(x) := f\Big(i\int_0^{\frac{1}{i}} |v \geq v(x) - t|dt\Big).$$

We approximate the function

$$h_v(x)\ (= f(|v \geq v(x)|))$$

in the R.H.S. of (3.3) by the sequence of functions $\{h_v^i\}_{i=1}^{\infty}$. Hence, we have the following approximate problem:

$$\begin{cases} |Du|^{\gamma}\mathcal{M}^{+}_{\lambda,\Lambda}(D^2u) + \varepsilon\Delta u = h_v^i & \text{in } \Omega \\ u = g & \text{on } \partial\Omega, \end{cases} \tag{3.4}$$

for $i \geq 1$. Since $\{h_v^i\} \in L^p(\Omega)$. For each i, by Theorem 2.5, we have the existence of a unique $W^{2,p}$-viscosity solution to (3.4).

Lemma 3.1. *There exists a unique $W^{2,p}$-viscosity solution to* (3.4). *Moreover, it satisfies the following estimate:*

$$\|u_\varepsilon^i\|_{W^{2,p}(\Omega)} \leq C\Big(\max_{\partial\Omega} g + \|g\|_{W^{2,p}(\Omega)} + f(|\Omega|)|\Omega|^{\frac{1}{p}}\Big).$$

Proof. By Theorem 2.5, we have the existence of a unique $W^{2,p}$-viscosity solution u_ε^i to (3.4) satisfying the following estimate:

$$\|u_\varepsilon^i\|_{W^{2,p}(\Omega)} \leq C\Big(\|u_\varepsilon^i\|_{\infty,\Omega} + \|g\|_{W^{2,p}(\Omega)} + \|h_v^i\|_{p,\Omega}\Big),$$

Also, it is easy to observe that

$$\|h_v^i\|_{\infty,\Omega} \leq f(|\Omega|), \tag{3.5}$$

and

$$\begin{aligned} \|h_v^i\|_{p,\Omega} &= \left(\int_\Omega |h_v^i(x)|^p dx \right)^{\frac{1}{p}} \\ &\le \|h_v^i\|_{\infty,\Omega} |\Omega|^{\frac{1}{p}} \\ &\le f(|\Omega|)|\Omega|^{\frac{1}{p}}, \end{aligned} \tag{3.6}$$

for each $i \ge 1$. Thus the sequence of functions h_v^i is uniformly bounded. Now, by ABP estimates established in [7], we have

$$\sup_\Omega u_\varepsilon^i \le \sup_{\partial\Omega} u_\varepsilon^i + C\|h_v^i\|_{p,\Omega},$$

and similarly for the $\inf_\Omega u_\varepsilon^i$. For more details, see Proposition 3.3 [7]. Using this along with the estimates (3.5) and (3.6), we have the following:

$$\|u_\varepsilon^i\|_{W^{2,p}(\Omega)} \le \widetilde{C},$$

where $\widetilde{C}$ is a positive constant independent of i and ε. □

Step 4: Establish the existence of solution to (3.3)**.** It further gives that $\{u_\varepsilon^i\}$ is uniformly bounded in $W^{2,p}(\Omega)$ (with respect to i). Now, by reflexivity of $W^{2,p}(\Omega)$, u_ε^i converges weakly in $W^{2,p}(\Omega)$. Moreover, since $p > N/2$. Using the similar arguments as above, we have the existence of a subsequence such that $u_\varepsilon^i \longrightarrow u_{\varepsilon,v}$ in the Lipschitz norm. As a consequence of Theorem 2.7, $u_{\varepsilon,v}$ is a $W^{2,p}$-viscosity solution to (3.3). Moreover, $u_{\varepsilon,v}$ satisfies the following estimate:

$$\|u_{\varepsilon,v}\|_{W^{2,p}(\Omega)} \le C\left(\max_{\partial\Omega} |g| + \|g\|_{W^{2,p}(\Omega)} + \|f(|v \ge v(x)|)\|_{p,\Omega} \right).$$

Step 5: Establish the existence of solution to (3.2)**.** Further, using Theorem 2.1 [8] (an application of Schaefer fixed point theorem), we have the existence of a $W^{2,p}$-viscosity solution to (3.2) for each $0 < \varepsilon < 1$, say u_ε (a Lipschitz fixed point). Moreover, u_ε satisfies the following estimate:

$$\|u_\varepsilon\|_{W^{2,p}(\Omega)} \le C\left(\max_{\partial\Omega} |g| + \|g\|_{W^{2,p}(\Omega)} + \|f(|u_\varepsilon \ge u_\varepsilon(x)|)\|_{p,\Omega} \right). \tag{3.7}$$

Step 6: Establish the existence of solution to (3.1) **on** $\varepsilon \longrightarrow 0$**.** Since u_ε is uniformly bounded in $W^{2,p}(\Omega)$ (with respect to ε) so we have that along some subsequence, u_ε converges weakly in $W^{2,p}(\Omega)$. Moreover, by the Rellich–Kondrasov theorem, along some subsequence $u_\varepsilon \longrightarrow u$ in $C(\overline{\Omega})$ (since $p > N$) to a Lipschitz function u. We further claim that u is an L^p-viscosity solution to (3.1). We use the idea of [1]. We just check the supersolution part. Further, one can check for the subsolution part using the similar arguments. Let, if possible, assume that u is not an L^p-viscosity supersolution to (3.1). Then by definition, there exists a point $x_0 \in \Omega$ and a function $\phi \in W^{2,p}(\Omega)$ with $D\phi \ne 0$ such that $u - \phi$ has local minimum at x_0 and

$$|D\phi|^\gamma \mathcal{M}^+_{\lambda,\Lambda}(D^2\phi) - f(|u \ge u(x_0)|) \ge \alpha \text{ a.e. in some ball } B(x_0, r), \tag{3.8}$$

for some constant $\alpha > 0$. In other words, $u - \phi$ restricted to $\overline{B(x_0, r)}$ has a global strict minima at x_0. Next, using the above information, we get a contradiction by constructing a function $\phi_\varepsilon = \phi - \psi_\varepsilon$ corresponding to u_ε such that

$$|D\phi_\varepsilon|^\gamma \mathcal{M}^+_{\lambda,\Lambda}(D^2\phi_\varepsilon) + \varepsilon\Delta\phi_\varepsilon - f(|u \ge u(x_0)|) \ge \alpha \quad \text{a.e. in } B(x_0, r) \tag{3.9}$$

for small enough $\varepsilon > 0$ and

$$\phi_\varepsilon \longrightarrow \phi \quad \text{uniformly.}$$

Now, since u_ε is an L^p-viscosity solution to (3.2) so (3.9) implies that $u_\varepsilon - \phi_\varepsilon$ can not attain minimum in the ball $B(x_0, r)$. However, since $u_\varepsilon - \phi_\varepsilon$ is continuous and $\overline{B(x_0, r)}$ is compact. Therefore, $u_\varepsilon - \phi_\varepsilon$ attains minimum in $\overline{B(x_0, r)}$. Let it be x_ε. It gives that $x_\varepsilon \longrightarrow x_0$ along some subsequence. It further implies that $x_\varepsilon \in B(x_0, r)$ for small enough ε, which is a contradiction. Thus such a function ϕ constructed in (3.8) does not exist, which proves our claim that u is an L^p-supersolution to (3.1). Similarly, one can check the subsolution part.

Next, we show that u is the limit function of the sequence of functions u_ε as $\varepsilon \longrightarrow 0$. Let if possible, ε_i and $\widetilde{\varepsilon}_i$ be two sequences approaching 0 with u and $\widetilde{u}$ being the corresponding limit functions to the sequences, respectively. Up to subsequences, we may assume that

$$\cdots \leq \widetilde{\varepsilon}_{i+1} \leq \varepsilon_i \leq \widetilde{\varepsilon}_i \leq \varepsilon_{i-1} \leq \cdots .$$

Our aim is to show that $w = u_{\varepsilon_i} - u_{\widetilde{\varepsilon}_{i+1}} \leq 0$. If we show that

$$|Dw|^\gamma \mathcal{M}^+_{\lambda,\Lambda}(D^2 w) + \varepsilon \Delta w \geq 0 \quad \text{in } \Omega \text{ (in } C\text{-viscosity sense)},$$

we are done. As by comparison principle, we would immediately get $w \leq 0$. Therefore, $u_{\varepsilon_i} \leq u_{\widetilde{\varepsilon}_{i+1}}$. Thus, in order to show that

$$w = u_{\varepsilon_i} - u_{\widetilde{\varepsilon}_{i+1}} \leq 0,$$

we only need to show that

$$|Dw|^\gamma \mathcal{M}^+_{\lambda,\Lambda}(D^2 w) + \varepsilon_i \Delta w \geq 0.$$

As shown above, it immediately gives $w \leq 0$. Let us assume the contrary, i.e., there exists some point $x_0 \in \Omega$ such that for some $\varphi \in C^2(\Omega)$, $w - \varphi$ attains local maxima at x_0, i.e., there exists a ball $B(x_0, r)$ such that

$$|D\varphi|^\gamma \mathcal{M}^+_{\lambda,\Lambda}(D^2 \varphi) + \varepsilon_i \Delta \varphi \leq -\alpha \quad \text{in } B(x_0, r),$$

for some $\alpha > 0$ and $w - \varphi = \left(u_{\varepsilon_i} - u_{\widetilde{\varepsilon}_{i+1}}\right) - \varphi = u_{\varepsilon_i} - \left(u_{\widetilde{\varepsilon}_{i+1}} + \varphi\right)$ has a global strict maximum at x_0 in $B(x_0, r)$. Now, consider a function

$$\Psi := \varphi + u_{\widetilde{\varepsilon}_{i+1}}.$$

Clearly, $\Psi \in W^{2,p}(\Omega)$ and touches u_{ε_i} from above at x_0. Also, consider a test function, Φ for

$u_{\widetilde{\varepsilon}_{i+1}}$ touching from below with $|D\Phi(x_0)|$ sufficiently larger than $|D\varphi(x_0)|$. We have

$$
\begin{aligned}
&|D\Psi(x_0)|^{\gamma}\mathcal{M}^{+}_{\lambda,\Lambda}\big(D^2\Psi(x_0)\big)+\varepsilon_i\Delta\Psi(x_0)-f\big(|u\geq u(x_0)|\big)+\alpha\\
&\quad\leq |D\Psi(x_0)|^{\gamma}\big(\mathcal{M}^{+}_{\lambda,\Lambda}\big(D^2\varphi(x_0)\big)+\mathcal{M}^{+}_{\lambda,\Lambda}\big(D^2\Phi(x_0)\big)\big)+\varepsilon_i\Delta\varphi(x_0)\\
&\qquad+\varepsilon_i\Delta\Phi(x_0)-f\big(|u\geq u(x_0)|\big)+\alpha\\
&\quad= |D\Psi(x_0)|^{\gamma}\mathcal{M}^{+}_{\lambda,\Lambda}\big(D^2\varphi(x_0)\big)+\varepsilon_i\Delta\varphi(x_0)+|D\Psi(x_0)|^{\gamma}\mathcal{M}^{+}_{\lambda,\Lambda}\big(D^2\Phi(x_0)\big)\\
&\qquad+\varepsilon_i\Delta\Phi(x_0)-f\big(|u\geq u(x_0)|\big)+\alpha\\
&\quad= |D\varphi(x_0)+D\Phi(x_0)|^{\gamma}\mathcal{M}^{+}_{\lambda,\Lambda}\big(D^2\varphi(x_0)\big)+\varepsilon_i\Delta\varphi(x_0)+\alpha\\
&\qquad+|D\varphi(x_0)+D\Phi(x_0)|^{\gamma}\mathcal{M}^{+}_{\lambda,\Lambda}(D^2\Phi(x_0))+\varepsilon_i\Delta\Phi(x_0)-f\big(|u\geq u(x_0)|\big)\\
&\quad\leq \frac{|D\varphi(x_0)+D\Phi(x_0)|^{\gamma}}{|D\varphi(x_0)|^{\gamma}}\big(-\alpha-\varepsilon_i\Delta\varphi(x_0)\big)+\varepsilon_i\Delta\varphi(x_0)+\alpha\\
&\qquad+\frac{|D\varphi(x_0)+D\Phi(x_0)|^{\gamma}}{|D\Phi(x_0)|^{\gamma}}\big(f\big(|u\geq u(x_0)|\big)-\varepsilon_i\Delta\Phi(x_0)\big)+\varepsilon_i\Delta\Phi(x_0)\\
&\qquad-f\big(|u\geq u(x_0)|\big)\\
&\quad\leq \frac{|D\varphi(x_0)+D\Phi(x_0)|^{\gamma}}{|D\varphi(x_0)|^{\gamma}}\big(-\alpha-\varepsilon_i\Delta\varphi(x_0)\big)+\varepsilon_i\Delta\varphi(x_0)+\alpha\\
&\qquad+2^{\gamma-1}\frac{|D\varphi(x_0)|^{\gamma}+|D\Phi(x_0)|^{\gamma}}{|D\Phi(x_0)|^{\gamma}}\big(f\big(|u\geq u(x_0)|\big)-\varepsilon_i\Delta\Phi(x_0)\big)+\varepsilon_i\Delta\Phi(x_0)\\
&\qquad-f\big(|u\geq u(x_0)|\big)\\
&\quad\leq \big(-\alpha-\varepsilon_i\Delta\varphi(x_0)\big)\left(\frac{|D\varphi(x_0)+D\Phi(x_0)|^{\gamma}}{|D\varphi(x_0)|^{\gamma}}-1\right)\\
&\qquad+\big(f\big(|u\geq u(x_0)|\big)-\varepsilon_i\Delta\Phi(x_0)\big)\left(2^{\gamma-1}\frac{\big(|D\varphi(x_0)|^{\gamma}+|D\Phi(x_0)|^{\gamma}\big)}{|D\Phi(x_0)|^{\gamma}}-1\right),
\end{aligned}
\tag{3.10}
$$

for all large enough $i\in\mathbb{N}$. Note that in the second last step we used the fact that for any positive real numbers a,b and $r\geq 1$, we have

$$|a+b|^r\leq 2^{r-1}\big(|a|^r+|b|^r\big).$$

Further, by the choice of test function Φ made before (3.10), we have

$$\mathcal{M}^{+}_{\lambda,\Lambda}(D^2\Psi)+\varepsilon_i\Delta\Psi-f\big(|u\geq u(x_0)|\big)\leq-\alpha<0,$$

which contradicts the fact that u_{ε_i} is an L^p-viscosity solution to (3.2). Thus we have that $u_{\varepsilon_i}\leq u_{\widetilde{\varepsilon}_{i+1}}$. Letting $i\longrightarrow\infty$, we get $u\leq\widetilde{u}$. Also, following the similar arguments, one can show that $u_{\widetilde{\varepsilon}_{i+1}}\leq u_{\varepsilon_i}$. Thus, we have $\widetilde{u}\leq u$ and hence $u=\widetilde{u}$.
Therefore, we have the existence of a $W^{2,p}$-viscosity solution, u to (3.1). Moreover, by (3.7), we have the following estimate:

$$\|u\|_{W^{2,p}(\Omega)}\leq C\Big(\|u\|_{\infty,\Omega}+\|g\|_{W^{2,p}(\Omega)}+\|f(|u\geq u(x)|)\|_{p,\Omega}\Big).\qquad\square$$

Acknowledgements

My sincere thanks go out to Prof. Jagmohan Tyagi for his constructive remarks and suggestions. Author also thanks the anonymous referee for the insightful review and suggestions, which helped us to improve the quality of this manuscript. The research was financially supported by Council of Scientific & Industrial Research (CSIR) India under the grant no. 09/1031(0005)/2019–EMR–I.

There are no conflict of interests of any type. This manuscript does not use any kind of data.

Abstract. We derive Melnikov type conditions for the persistence of heteroclinic solutions in perturbed slowly varying discontinuous differential equations. Opposite to [*J. Differential Equations* **400**(2024), 314–375] we assume that the unperturbed (frozen) equation has a parametric system of heteroclinic solutions and extend a result in [*SIAM J. Math. Anal.* **18**(1987), 612–629] and [*SIAM J. Math. Anal.* **19**(1988), 1254–1255] to higher dimensional non-Hamiltonian discontinuous singularly perturbed differential equations.

Keywords: discontinuous differential equations, heteroclinic solutions, Melnikov conditions, persistence.

2020 Mathematics Subject Classification: Primary 34C37, Secondary 34C23, 34D15, 37G20.

1 Introduction

Let $h(x,y), f_i(x,y) : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}$, $i = 1, \dots, N+1$, be C^r-functions, $r \geq 2$, bounded on $\mathbb{R}^n \times \mathbb{R}^m$ together with their derivatives, and $c_1 < c_2 < \dots < c_N < c_{N+1}$ be real numbers.

In this paper we study the problem of existence of continuous, piecewise smooth, bounded solutions of a singularly perturbed equation like

$$\begin{aligned} \dot{x} &= f(x,y), \\ \dot{y} &= \varepsilon g(x,y,\varepsilon) \end{aligned} \tag{1.1}$$

where $x \in \mathbb{R}^n$, $y \in \mathbb{R}^m$, $\varepsilon \in \mathbb{R}$, $\varepsilon > 0$ and

$$f(x,y) := \begin{cases} f_i(x,y) & \text{if } c_{i-1} < h(x,y) < c_i, \\ & i = 1, \dots, N \\ f_{N+1}(x,y) & \text{if } h(x,y) > c_N \end{cases} \tag{1.2}$$

✉Corresponding author. Email: michal.feckan@fmph.uniba.sk

where we take for notational simplicity $c_0 = -\infty$. It is assumed that for all $y \in \mathbb{R}^m$, the frozen system

$$\dot{x} = f(x, y) \tag{1.3}$$

has hyperbolic fixed points $x = w_\pm(y)$ with an associated piecewise C^r, heteroclinic solution $u(t, y)$ intersecting transversally the manifolds $\mathcal{S}_i(y) = \{x \mid h(x, y) = c_i\}$. We intend to give a Melnikov like condition guaranteeing that the perturbed system (1.1) has a solution $(x(t, \varepsilon), y(t, \varepsilon))$ such that $\sup_{t\in\mathbb{R}} |x(t, \varepsilon) - u(t, y(t, \varepsilon))| \to 0$ as $\varepsilon \to 0$. This paper has been motivated by [10, 11] where the authors considered a perturbation of a smooth, Hamiltonian, three-dimensional system. The main result of our paper (Theorem 6.2) concerns higher dimension, discontinuous and not necessarily Hamiltonian systems. Moreover the approach in [10, 11] is basically geometrical, while in this paper it is based on Lyapunov–Schmidt reduction.

This paper is a continuation of series of our works [3–6] on the study of existence of bounded solutions for slowly varying discontinuous differential equations. Papers [3–5] deal with the persistence of periodic solutions in case of existence of either a single or a family of periodic solutions for the frozen system (1.3). Next, in [6] generic conditions have been given for persistence of an isolated homoclinic-heteroclinic solution for the frozen system. Thus it is a natural step to study the case when the frozen system possesses a parametric system of bounded-homoclinic-heteroclinic solutions, which is the purpose of this paper.

To prove Theorem 6.2 we use a general result in [6] concerning the characterization of bounded solutions on both the positive and the negative line for the perturbed equation, Then, in [6], this result is used, jointly with a Lyapunov–Schmidt reduction, to write down a bifurcation equation which is the scalar product of certain vectors with the difference at $t = 0$ of the value of these solutions. Now, in [6] the case is considered where this function has a simple zero at $\varepsilon = 0$, while in this paper it is identically zero at $\varepsilon = 0$. This fact makes a big difference and indeed the Melnikov functions obtained in the two cases are quite different.

We now briefly sketch the content of this paper. For the reader convenience and also for the completeness of this paper, we recall necessary results from [6] in Sections 2–5. Namely, Section 2 provides basic assumptions and defines the piecewise smooth heteroclinic solution of the unperturbed system. Section 3 recalls the definition of exponential dichotomy and extends this notion to discontinuous, piecewise linear, systems with jumps at some points; moreover some results concerning existence of bounded solutions on either $t \geq 0$ and $t \leq 0$ are extended to these systems. In Section 4 we construct families of bounded solutions and describes them in terms of some parameters. These solutions are continuous and piecewise smooth and give the bounded solutions we look for, when they assume the same value at $t = 0$. Section 5 defines the discontinuous variational equation.

Our main results are proved in Section 6 where we obtain a Melnikov-type condition assuring that the bifurcation function has a manifold of solutions. Motivated by [8], Section 7, is devoted to the construction of an example of application of the main result of this paper. Although the equation is three-dimensional and Hamiltonian, the vector field is discontinuous and then the results in [8, 10, 11] do not apply.

Finally, in Section 8 we show that the Melnikov function given here extends to the heteroclinic case with finitely many discontinuity points, the Melnikov function given in [5] for the periodic case with two discontinuity points.

In the whole paper we will use the following notation. Given a vector v or a matrix A with v^T, A^T we denote the transpose of v, A.

2 Notation and basic assumptions

Let $\Omega \subset \mathbb{R}^n$ be a bounded domain, $c_1 < \ldots < c_{N+1}$ be real numbers and $h : \Omega \times \mathbb{R}^m \to \mathbb{R}$ be a C^r-functions, $r \geq 2$, with bounded derivatives. For $\ell = 1, \ldots, N+1$, we set

$$\Omega_\ell = \{(x,y) \in \Omega \times \mathbb{R}^m \mid c_{i-1} \leq h(x,y) < c_i\},$$

where we set for simplicity, $c_0 = -\infty$. Then let $f_\ell : \Omega \times \mathbb{R}^m \to \mathbb{R}^n$ be C^r-functions, bounded together with their derivatives in $\Omega \times \mathbb{R}^m$.

First we give the definition of solutions of equation

$$\dot{x} = f_i(x,y), \quad (x,y) \in \Omega_i,\ i = 1, \ldots, N+1 \tag{2.1}$$

we are considering in this paper.

Definition 2.1. A continuous, piecewise smooth function $u(t,y)$ is a solution of equation (2.1) on $t \geq 0$ intersecting transversally the sets $\mathcal{S}_i(y) = \{x \in \Omega \mid h(x,y) = c_i\}$, $i = 1, \ldots, N$, if there exist $\eta > 0$ and C^r-functions bounded together with their derivatives $0 < t_1(y) < \ldots < t_N(y)$ such that the following conditions hold for $1 \leq i \leq N$ (note that we set $t_0(y) = 0$)

$a_1)$ $\dot{u}(t,y) = f_i(u(t,y),y)$ for $t_{i-1}(y) < t < t_i(y)$ and $\dot{u}(t,y) = f_{N+1}(u(t,y),y)$ for $t > t_N(y)$;

$a_2)$ $h(u(t_i(y),y),y) = c_i$, and $h_x(u(t_i(y),y),y)\dot{u}(t_i(y)^\pm,y) > 2\eta$;

$a_3)$ $c_{i-1} < h(u(t,y),y) < c_i$, for $t_{i-1}(y) < t < t_i(y)$ and $h(u(t,y),y) > c_N$, for $t > t_N(y)$.

Similarly, a continuous, piecewise smooth function $u(t,y)$ is a solution of equation (2.1) on $t \leq 0$ intersecting transversally the sets $\mathcal{S}_i(y)$, if there exist $\eta > 0$ and C^r-functions bounded together with their derivatives $t_{-N}(y) < \ldots < t_{-1}(y) < 0$ such that the following conditions hold for any $1 \leq i \leq N$:

$a_1')$ $\dot{u}(t,y) = f_i(u(t,y),y)$ for $t_{-i}(y) < t < t_{-i+1}(y)$ and $\dot{u}(t,y) = f_{N+1}(u(t,y),y)$ for $t < t_{-N}(y)$;

$a_2')$ $h(u(t_{-i}(y),y),y) = c_i$, and $h_x(u(t_{-i}(y),y),y)\dot{u}(t_{-i}(y)^\pm,y) < -2\eta$;

$a_3')$ $c_{i-1} < h(u(t,y),y) < c_i$, for $t_{-i}(y) < t < t_{-i+1}(y)$ and $h(u(t,y),y) > c_N$, for $t < t_{-N}(y)$.

In this paper we assume that a continuous, piecewise smooth solution $u(t,y)$ of equation (2.1) exist, for $t \in \mathbb{R}$, such that the following conditions hold.

$A_1)$ $w_0(y) := u(0,y)$ and its derivatives are bounded functions on $\mathbb{R}^m$ and $w_0(y)$ belongs to an open and bounded subset $B \subset \mathbb{R}^n$ such that $\overline{B} \times \mathbb{R}^m \subset \Omega_1$.

$A_2)$ There exist smooth and bounded functions $w_\pm(y)$ and $\mu_0 > 0$, such that

$$f_{N+1}(w_\pm(y),y) = 0,$$
$$h(w_\pm(y),y) - c_N > \mu_0,$$

for any $y \in \mathbb{R}^m$ and

$$\lim_{t \to \pm\infty} u(t,y) - w_\pm(y) = 0$$

uniformly with respect to $y \in \mathbb{R}^m$.

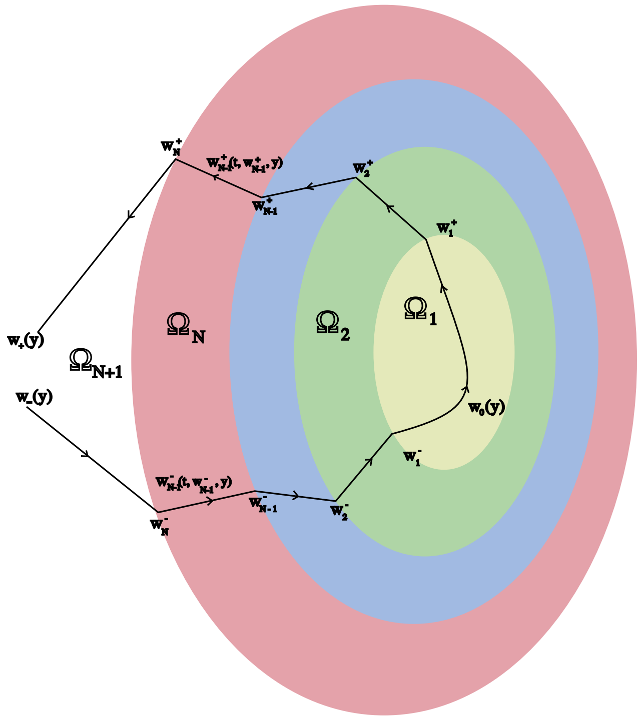

Figure 2.1: The piecewise C^1 bounded solution of (1.3). For simplicity we write $w_j^\pm$ instead of $w_j^\pm(y)$.

A_3) For any $y \in \mathbb{R}^m$, $f_{N+1,x}(w_\pm(y), y)$ have k eigenvalues with negative real parts and $n-k$ eigenvalues with positive real parts, counted with multiplicities and there exists $\delta_0 > 0$ such that all these eigenvalues satisfy

$$|\operatorname{Re}\lambda(y)| > \delta_0.$$

We set

$$t_0(y) = 0, \qquad \forall y \in \mathbb{R}^m.$$

So, we are considering solutions of (2.1) which are contained in $C \times \mathbb{R}^n \subset \Omega \times \mathbb{R}^m$, where C is a compact subset of Ω. Then we may and will assume that $\Omega = \mathbb{R}^n$.

Remark 2.2. i) As in [6], all results in this paper can be easily generalised to the case where the solutions exit transversally Ω_i and enter into either Ω_{i+1} or Ω_{i-1} transversally. We can formalize all of this as follows: there exists $(j_0, \dots, j_M)$ such that given j_i then j_{i+1} is either $j_i - 1$ or $j_i + 1$ and for $t_i(y) < t < t_{i+1}(y)$ we have

$$c_{j_i - 1} < h(u(t,y), y) < c_{j_i}.$$

Moreover

$$|h_x(u(t_i(y), y), y) f_i(u(t_i(y), y), y)| > 2\eta.$$

for any $i = 1, \dots, N$. A similar generalization can be made for $t \le 0$ and all other assumption will be changed accordingly.

ii) From a_2) and a_2') it follows that, for $i = 1, \dots, N$:

$$\frac{\partial}{\partial t} h(u(t,y),y)_{|t=t_i(y)} \geq 0,$$
$$\frac{\partial}{\partial t} h(u(t,y),y)_{|t=0} \geq 0$$

that is

$$h_x(u(t_i(y),y),y) f_{i-1}(u(t_i(y),y),y) \geq 0,$$
$$h_x(u(t_i(y),y),y) f_i(u(t_i(y),y),y) \geq 0.$$

Similarly

$$h_x(u(t_{-i}(y),y),y) f_i(u(t_{-i}(y),y),y) \leq 0;$$
$$h_x(u(t_{-i}(y),y),y) f_{i+1}(u(t_{-i}(y),y),y) \leq 0.$$

So a_2) and a_2') are a kind of transversality assumption on $u(t,y)$.

Let $w_0^{\pm}(y) = u(0,y)$ and set, for $i = 1, \dots, N$:

$$w_i^{\pm}(y) = u(t_{\pm i}(y),y) \in \mathcal{S}_i(y). \tag{2.2}$$

The following result has been proved in [6]

Lemma 2.3. *$w_i^{\pm}(y)$ are C^r-functions bounded together with their derivatives. Moreover $u(t,y)$ and its derivatives with respect to y are bounded uniformly with respect to y, on both $t \geq t_N^+(y)$ and $t \leq t_N^-(y)$.*

Let $i = 1, \dots, N+1$. For $t \geq 0$, let $u_i^+(t,y)$ be the solution of $\dot{x} = f_i(x,y)$ such that $u_i^+(t_{i-1}(y),y) = w_{i-1}^+(y)$. Similarly, let $u_i^-(t,y)$ be the solution of $\dot{x} = f_i(x,y)$ such that $u_i^-(t_{1-i}(y),y) = w_{i-1}^-(y)$. Note that $u_i^{\pm}(t,y)$ is defined for $t \in \mathbb{R}$ and

$$u(t,y) = \begin{cases} u_i^-(t,y) & \text{for } t_{-i}(y) \leq t \leq t_{1-i}(y),\, i = 1, \dots N+1, \\ u_i^+(t,y) & \text{for } t_{i-1}(y) \leq t \leq t_i(y),\, i = 1, \dots, N+1 \end{cases} \tag{2.3}$$

where, for simplicity, we set $t_{-N-1}(y) = -\infty$ and $t_{N+1}(y) = \infty$. Note that

$$u_i^+(t_i(y),y) = u(t_i(y),y) = w_i^+(y) = u_{i+1}^+(t_i(y),y)$$

and similarly,

$$u_i^-(t_{-i}(y),y) = u(t_{-i}(y),y) = w_i^-(y) = u_{i+1}^-(t_{-i}(y),y).$$

3 Exponential dichotomy for piecewise discontinuous systems

A basic tool in this paper is the notion of exponential dichotomy, whose definition we recall here. Let J be either $[a,\infty)$, $(-\infty,a]$, or $\mathbb{R}$ and $A(t)$, $t \in J$, be a $n \times n$ continuous matrix. We say that the linear system

$$\dot{x} = A(t)x, \quad x \in \mathbb{R}^n \tag{3.1}$$

has an exponential dichotomy on J if there exist a projection $P : \mathbb{R}^n \to \mathbb{R}^n$ and constants $\delta > 0$ and $K \geq 1$ such that the fundamental matrix $X(t)$ of (3.1) satisfying $X(a) = \mathbb{I}$, when $J = [a, \infty), (-\infty, a]$, or $X(0) = \mathbb{I}$ when $J = \mathbb{R}$, satisfies

$$|X(t)PX(s)^{-1}| \leq Ke^{-\delta(t-s)}, \quad \text{for } s \leq t, s, t \in J,$$
$$|X(s)(\mathbb{I} - P)X(t)^{-1}| \leq Ke^{-\delta(t-s)}, \quad \text{for } s \leq t, s, t \in J.$$

K and δ are called the constant and the exponent of the exponential dichotomy.

In [6] the notion of exponential dichotomy has been extended to systems with discontinuities.

Let $t_0 < t_1 < \ldots < t_N$ be real numbers, $B_1, \ldots, B_N$ be invertible $n \times n$ matrices and $\mathcal{A}(t)$, $t \geq t_0$ be a piecewise continuous matrix with possible discontinuity jumps at $t = t_1, \ldots, t_N$, that is

$$\mathcal{A}(t) = \begin{cases} A_i(t) & \text{if } t_{i-1} \leq t < t_i, \\ & i = 1, \ldots, N \\ A_{N+1}(t) & \text{if } t \geq t_N \end{cases} \tag{3.2}$$

where $A_i(t)$ is continuous for $t_{i-1} \leq t \leq t_i$, $A_{N+1}(t)$ is continuous for $t \geq t_N$. Note that $\mathcal{A}(t)$ is continuous for $t \geq t_0$, $t \neq t_i$, $i \neq 1, \ldots, N$ and right-continuous at $t = t_i$, $i = 1, \ldots, N$ with possible jumps at $t = t_i$, $i = 1, \ldots, N$ given by the matrix $A_{i+1}(t_i) - A_i(t_i)$.

For $t \geq t_0$ the fundamental matrix of the linear, discontinuous, system

$$\begin{aligned} \dot{x} &= \mathcal{A}(t)x, \\ x(t_i^+) &= B_i x(t_i^-), \qquad i = 1, \ldots, N \end{aligned} \tag{3.3}$$

is defined as

$$X_+(t) = \begin{cases} U_1(t) & \text{if } 0 \leq t < t_1, \\ U_{i+1}(t)U_{i+1}(t_i)^{-1}B_i X_+(t_i^-) & \text{if } t_i \leq t < t_{i+1}, \\ & i = 1 \ldots, N-1 \\ U_{N+1}(t)U_{N+1}(t_N)^{-1}B_N X_+(t_N^-) & \text{if } t \geq t_N, \end{cases}$$

where $U_i(t)$ is the fundamental matrix of the linear systems

$$\dot{x} = A_i(t)x$$

on $\mathbb{R}$, that is $\dot{U}_i(t) = A_i(t)U_i(t)$, $t \in \mathbb{R}$, and $U_i(0) = \mathbb{I}$.

Similarly, if $t_{-N} < \ldots t_{-1} < t_0$ and

$$\mathcal{A}(t) = \begin{cases} A_{N+1}(t) & \text{if } t \leq t_{-N}, \\ A_i(t) & \text{if } t_{-i} < t \leq t_{-i+1}, \\ & i = 1, \ldots, N \end{cases} \tag{3.4}$$

where $A_i(t)$ is continuous for $t_{-i-1} \leq t \leq t_{-i}$ and $A_{N+1}(t)$ is continuous for $t \leq t_{-N}$, the fundamental matrix, for $t \leq t_0$, of the linear, discontinuous, system

$$\begin{aligned} \dot{x} &= \mathcal{A}(t)x, \\ x(t_{-i}^+) &= B_i x(t_{-i}^-) \end{aligned} \tag{3.5}$$

is

$$X_-(t) = \begin{cases} U_1(t) & \text{if } t_{-1} < t \leq 0, \\ U_{i+1}(t)U_{i+1}(t_{-i})^{-1}B_i^{-1}X_-(t_{-i}^+) & \text{if } t_{-i-1} < t \leq t_{-i}, \\ & i = 1, \ldots, N-1 \\ U_{N+1}(t)U_{N+1}(t_{-N})^{-1}B_N^{-1}X_+(t_{-N}^+) & \text{if } t \leq t_{-N}. \end{cases}$$

Note that, on $t \le t_0$, $\mathcal{A}(t)$ is continuous for $t \le t_0$, $t \ne t_{-i}$, $i \ne 1, \dots, N$ and left-continuous at $t = t_{-i}$, $i = 1, \dots, N$ with possible jumps at $t = t_{-i}$, $i = 1, \dots, N$ given by the matrix $A_i(t_{-i}) - A_{-i+1}(t_{-i})$.

Remark 3.1. As a matter of facts, for $t \ge t_0$, we will consider

$$\mathcal{A}(t) = \begin{cases} A_i(t) & \text{if } t_{i-1} \le t \le t_i, \\ & \ i = 1, \dots, N \\ A_{N+1}(t) & \text{if } t \ge t_N \end{cases}$$

and similarly for $t \le t_0$. This may cause a duplicate definition of $\mathcal{A}(t)$ at $t = t_i$, however it will be always clear which one among the functions $A_i(t)$ will be taken into account at that point.

Without loss of generality we may and will assume that $t_0 = 0$.

Note that $X_+(t)$ is continuous for $t \ne t_1, \dots, t_N$ and right-continuous at $t = t_1, \dots, t_N$ and $X_-(t)$ is continuous for $t \ne t_{-1}, \dots, t_{-N}$ and left-continuous at $t = t_{-1}, \dots, t_{-N}$.

It is clear that $\dot{X}_\pm(t) = \mathcal{A}(t)X_\pm(t)$, for any $\pm t \ge 0$, $t \ne t_{\pm 1}, \dots, t_{\pm N}$, $X_\pm(0) = \mathbb{I}$, the identity matrix, and

$$\begin{aligned} X_+(t_i^+) &= B_i X_+(t_i^-), \\ X_-(t_{-i}^+) &= B_i X_-(t_{-i}^-) \end{aligned} \tag{3.6}$$

for any $i = 1, \dots, N$. Actually we can write

$$X_+(t_i) = B_i X_+(t_i^-), \quad X_-(t_{-i}) = B_i^{-1} X_-(t_{-i}^+)$$

since $X_+(t)$ is right-continuous and $X_-(t)$ is left-continuous.

Remark 3.2. Let $\tau \ge 0$ be a fixed number. For $t \ge 0$, $x(t) = X_+(t)X_+(\tau)^{-1}\tilde{x}$ is the right-continuous solution of

$$\begin{cases} \dot{x} = \mathcal{A}(t)x, & \text{for } t \ge 0, t \ne t_1, \dots, t_N \\ x(t_i^+) = B_i x(t_i^-) \\ x(\tau^+) = \tilde{x}. \end{cases} \tag{3.7}$$

Indeed, it is obvious that $\dot{x}(t) = \mathcal{A}(t)x(t)$ for $t \ge 0$, $t \ne t_1, \dots, t_N$ and that $x(t_i^+) = B_i x(t_i^-)$, since $X_+(t_i^+) = B_i X_+(t_i^-)$. Moreover, for any $\tau \ge 0$ we have $x(\tau^+) = X_+(\tau^+)X_+(\tau)^{-1}\tilde{x} = X_+(\tau)X_+(\tau)^{-1}\tilde{x} = \tilde{x}$, since $X_+(t)$ is right-continuous at any $t \ge 0$.

Similarly, for $t \le 0$ and any fixed $\tau \le 0$, $x(t) = X_-(t)X_-(\tau)^{-1}\tilde{x}$ is the left-continuous solution of

$$\begin{cases} \dot{x} = \mathcal{A}(t)x, & \text{for } t \le 0, t \ne t_{-1}, \dots, t_{-N} \\ x(t_{-i}^-) = B_i^{-1} x(t_{-i}^+) \\ x(\tau^-) = \tilde{x}. \end{cases} \tag{3.8}$$

The following results have been proved in [6]:

Lemma 3.3. *Suppose that the linear system*

$$\dot{x} = A_{N+1}(t)x$$

has an exponential dichotomy on $t \ge t_N$ (resp. $t \le t_{-N}$) with constant K, exponent δ and projection $\mathcal{P}_+$ (resp. $\mathcal{P}_-$ when $t \le t_{-N}$). Then, the linear system (3.3) *(resp.* (3.5)*) with $\mathcal{A}(t)$ as in* (3.2) *(resp.*

(3.4)) *has an exponential dichotomy on* $\mathbb{R}_+$, *(resp.* $\mathbb{R}_-$*) with the same exponent* δ, *constant* $\tilde{K} \geq K$ *and projection*

$$\begin{aligned}\tilde{\mathcal{P}}_+ &= X_+(t_N^+)^{-1}\mathcal{P}_+X_+(t_N^+),\\ \tilde{\mathcal{P}}_- &= X_-(t_{-N}^-)^{-1}\mathcal{P}_-X_-(t_{-N}^-).\end{aligned} \tag{3.9}$$

Lemma 3.4. *Let* $\mathcal{A}(t)$ *be either as in* (3.2) *or* (3.4)*. Suppose that the condition of Lemma 3.3 holds and let* $\tilde{\mathcal{P}}_\pm$ *be as in* (3.9)*. where $\tilde{\mathcal{P}}_\pm$ *is as in* (3.9) *and* $0 \leq \tau \in \mathbb{R}$ *is a fixed number. Then, for any* $\xi_+ \in \mathcal{R}\tilde{\mathcal{P}}_+^\tau$ *(resp.* $\xi_- \in \mathcal{N}\tilde{\mathcal{P}}_-^\tau$*) the linear inhomogeneous system*

$$\begin{aligned}\dot{x} &= \mathcal{A}(t)x + k(t),\\ x(t_i^+) &= B_i x(t_i^-), \quad i = 1,\dots,N\\ \tilde{\mathcal{P}}_+^\tau x(\tau) &= \xi_+\end{aligned} \tag{3.10}$$

with $t \geq 0$, *[resp.*

$$\begin{aligned}\dot{x} &= \mathcal{A}(t)x + k(t),\\ x(t_i^-) &= B_i^{-1}x(t_i^+),\\ (\mathbb{I} - \tilde{\mathcal{P}}_-^\tau)x(-\tau) &= \xi_-\end{aligned}$$

when $t \leq 0$*] has the unique right-continuous, [resp. left-continuous when* $t \leq 0$*] bounded solution*

$$\begin{aligned}x(t) = X_+(t)\tilde{\mathcal{P}}_+X_+(\tau)^{-1}\xi_+ &+ \int_\tau^t X_+(t)\tilde{\mathcal{P}}_+X_+(s)^{-1}k(s)ds\\ &- \int_t^\infty X_+(t)(\mathbb{I} - \tilde{\mathcal{P}}_+)X_+(s)^{-1}k(s)ds\end{aligned} \tag{3.11}$$

[resp.

$$\begin{aligned}x(t) = X_-(t)(\mathbb{I} - \tilde{\mathcal{P}}_-)X_-(-\tau)^{-1}\xi_- &+ \int_{-\infty}^t X_-(t)\tilde{\mathcal{P}}_-X_-(s)^{-1}k(s)ds\\ &- \int_t^{-\tau} X_-(t)(\mathbb{I} - \tilde{\mathcal{P}}_-)X_-(s)^{-1}k(s)ds\end{aligned} \tag{3.12}$$

if $t \leq 0$*]. Moreover such a solution satisfies*

$$\sup_{t\geq\tau}|x(t)| \leq K[|\xi_+| + 2\delta^{-1}\sup_{t\geq 0}|k(t)|] \tag{3.13}$$

if $t \geq 0$ *[resp.*

$$\sup_{t\leq-\tau}|x(t)| \leq K[|\xi_-| + 2\delta^{-1}\sup_{t\leq 0}|k(t)|] \tag{3.14}$$

if $t \leq 0$*].*

4 Bounded solutions on the half lines

From A_3) we know that the number of the eigenvalues of $f_{N+1,x}(w_\pm(y),y)$ with negative (and then also positive) real parts, counted with multiplicities, is independent of $y \in \mathbb{R}^m$. Moreover it also follows that all eigenvalues are bounded functions of $y \in \mathbb{R}^m$. Indeed, since $f_{N+1,x}(w_\pm(y),y)$ is bounded, the matrix $\mathbb{I} - \lambda^{-1} f_{N+1,x}(w_\pm(y),y)$ is invertible for $|\lambda| > R$, sufficiently large and independent of y. Hence all eigenvalues have to satisfy $|\lambda| \le R$.

Let δ_0 be any positive number strictly less than $\min\{|\operatorname{Re}\lambda(y)|\}$, where $\lambda(y)$ are the eigenvalues of $f_{N+1,x}(w_\pm(y),y)$. According to [7] the system $\dot{x} = f_{N+1,x}(w_\pm(y),y)x$ has an exponential dichotomy on $\mathbb{R}$ with exponent δ_0 and spectral projection (of rank k)

$$\begin{aligned} P^0_\pm(y) &= \frac{1}{2\pi i}\int_\Gamma (z\mathbb{I} - f_{N+1,x}(w_\pm(y),y))^{-1} dz \\ &= \sum_{Re\lambda(y)<0} \operatorname{Res}((z\mathbb{I} - f_{N+1,x}(w_\pm(y),y))^{-1}, z = \lambda(y)) \end{aligned}$$

where $\operatorname{Res}(F(z), z = z_0)$ is the residual of the meromorphic function $F(z)$ at z_0 and Γ is a closed curve that contains in its interior all eigenvalues of $f_{N+1,x}(w_\pm(y),y)$ with negative real parts, but none of those with positive real parts. Hence $|P^0(y)| \le M$, for any $y \in \mathbb{R}^m$ and some $M \ge 1$.

Now, recalling (2.3), from A_2) and the boundedness of $t_N(y)$, it follows immediately that

$$\lim_{t\to\pm\infty} u^\pm_{N+1}(t,y) = w_\pm(y)$$

uniformly with respect to $y \in \mathbb{R}^m$.

Let $T_+ > \sup_{y\in\mathbb{R}^m} t_N(y)$, $T_- < \inf_{y\in\mathbb{R}^m} t_{-N}(y)$ and take $0 < \delta < \delta_0$. From the roughness of exponential dichotomies (cfr. [7, Proposition 2, p. 34]) the linear systems

$$\dot{x} = f_{N+1,x}(u^+_{N+1}(t+T_+,y),y)x \tag{4.1}$$

and

$$\dot{x} = f_{N+1,x}(u^-_{N+1}(t+T_-,y),y)x \tag{4.2}$$

have an exponential dichotomy on $\mathbb{R}_+$, $\mathbb{R}_-$ resp., uniformly with respect to $y \in \mathbb{R}^m$, with projections $P_+(y)$, resp. $P_-(y)$, of rank k, constant K and exponent δ. Moreover, according to [8, Proposition 2.3], it can be assumed that, for $|y - y_0|$ sufficiently small it results: $\mathcal{N}P_+(y) = \mathcal{N}P_+(y_0)$, $\mathcal{R}P_-(y) = \mathcal{R}P_-(y_0)$ and in this case the projections are smooth with respect to y. Note that, $\mathcal{N}P_+(y) = \mathcal{N}P_+(y_0)$ and $\mathcal{R}P_-(y) = \mathcal{R}P_-(y_0)$ are equivalent to

$$\begin{aligned} P_+(y) &= P_+(y)P_+(y_0), \qquad & P_+(y_0) &= P_+(y_0)P_+(y) \\ P_-(y) &= P_-(y_0)P_-(y), \qquad & P_-(y_0) &= P_-(y)P_-(y_0). \end{aligned} \tag{4.3}$$

Let $U^\pm_i(t,y)$ be the fundamental matrix of

$$\dot{x} = f_{i,x}(u^\pm_i(t,y),y)x$$

in $\mathbb{R}_\pm$ resp., that is

$$\begin{aligned} &\dot{U}^\pm_i(t,y) = f_{i,x}(u^\pm_i(t,y),y)U^\pm_i(t,y), \quad \pm t \ge 0, \\ &U^\pm_i(0,y) = \mathbb{I}. \end{aligned}$$

As in [6] we see that

Lemma 4.1. *For any $\tau \in \mathbb{R}$ the linear system*

$$\dot{x} = f_{N+1,x}(u^+_{N+1}(t,y),y)x, \tag{4.4}$$

resp.

$$\dot{x} = f_{N+1,x}(u^-_{N+1}(t,y),y)x, \tag{4.5}$$

has an exponential dichotomy on $t \geq \tau$, resp. $t \leq \tau$, with exponent δ, constant $\tilde{K}$ independent on y and projections

$$Q_+(y) = U^+_{N+1}(\tau,y)U^+_{N+1}(T_+,y)^{-1}P_+(y)U^+_{N+1}(T_+,y)U^+_{N+1}(\tau,y)^{-1}$$
$$Q_-(y) = U^-_{N+1}(\tau,y)U^-_{N+1}(T_-,y)^{-1}P_-(y)U^-_{N+1}(T_-,y)U^-_{N+1}(\tau,y)^{-1}.$$

In particular, if $\tau = T_+$, resp. $\tau = T_-$, then $Q_+(y) = P_+(y)$, resp. $Q_-(y) = P_-(y)$, and $\tilde{K} = K$.

Finally, the following result holds (see [6, Theorems 4.3, 4.5]).

Theorem 4.2. *There exist $\rho > 0$, bounded C^r-functions*

$$t^*_{-N}(\xi_-,\alpha,\varepsilon) < \ldots < t^*_{-1}(\xi_-,\alpha,\varepsilon) < t^*_0(\xi_-,\alpha,\varepsilon) = 0 < t^*_1(\xi_+,\alpha,\varepsilon) < \ldots < t^*_N(\xi_+,\alpha,\varepsilon)$$

such that, for all $i = 1,\ldots,N$,

$$\lim_{(\xi_+,\varepsilon)\to 0} |t^*_i(\xi_+,\alpha,\varepsilon) - t_i(\alpha)| = 0,$$
$$\lim_{(\xi_-,\varepsilon)\to 0} |t^*_{-i}(\xi_-,\alpha,\varepsilon) - t_{-i}(\alpha)| = 0$$

uniformly with respect to $\alpha \in \mathbb{R}^m$, and continuous, piecewise C^r, solutions of (1.1)

$$(x_\pm(t,\xi_\pm,\alpha,\varepsilon), y_\pm(t,\xi_\pm,\alpha,\varepsilon))$$

defined for $t \geq 0$ and $t \leq 0$ resp., and such that

$$\begin{aligned}
c_{i-1} < h(x_+(t,\xi_+,\alpha,\varepsilon),y_+(t,\xi_+,\alpha,\varepsilon)) < c_i, &\quad \text{for } t^*_{i-1}(\xi_+,\alpha,\varepsilon) < t < t^*_i(\xi_+,\alpha,\varepsilon),\\
h(x_+(t,\xi_+,\alpha,\varepsilon),y_+(t,\xi_+,\alpha,\varepsilon)) > c_N, &\quad \text{for } t > t^*_N(\xi_+,\alpha,\varepsilon),\\
c_{i-1} < h(x_-(t,\xi_-,\alpha,\varepsilon),y_-(t,\xi_-,\alpha,\varepsilon)) < c_i, &\quad \text{for } t^*_{-i}(\xi_-,\alpha,\varepsilon) < t < t^*_{-i+1}(\xi_-,\alpha,\varepsilon),\\
h(x_-(t,\xi_-,\alpha,\varepsilon),y_-(t,\xi_-,\alpha,\varepsilon)) > c_N, &\quad \text{for } t < t^*_{-N}(\xi_-,\alpha,\varepsilon),
\end{aligned}$$

$$\begin{aligned}
h(x_+(t^*_i(\xi_+,\alpha,\varepsilon),\xi_+,\alpha,\varepsilon),y_+(t^*_i(\xi_+,\alpha,\varepsilon),\xi_+,\alpha,\varepsilon)) &= c_i,\\
h(x_-(t^*_{-i}(\xi_-,\alpha,\varepsilon),\xi_-,\alpha,\varepsilon),y_-(t^*_{-i}(\xi_-,\alpha,\varepsilon),\xi_-,\alpha,\varepsilon)) &= c_i,\\
\frac{\partial}{\partial t}h(x_+(t,\xi_+,\alpha,\varepsilon),y_+(t,\xi_+,\alpha,\varepsilon))_{|t=t^*_i(\xi_+,\alpha,\varepsilon)} &> \eta,\\
\frac{\partial}{\partial t}h(x_-(t,\xi_-,\alpha,\varepsilon),y_-(t,\xi_-,\alpha,\varepsilon))_{|t=t^*_{-i}(\xi_-,\alpha,\varepsilon)} &< -\eta,\\
y_\pm(T_\pm,\xi_\pm,\alpha,\varepsilon) &= \alpha,\\
P_+(\alpha)[x(T_+) - u(T_+,\alpha)] &= \xi_+,\\
(\mathbb{I} - P_-(\alpha))[x(T_-) - u(T_-,\alpha)] &= \xi_-
\end{aligned}$$

where $c_0 = -\infty$. Moreover

$$\begin{aligned} \sup_{t\geq 0} |x_+(t,\xi_+,\alpha,\varepsilon) - u(t,y_+(t,\xi_+,\alpha,\varepsilon))| < \rho, \\ \sup_{t\leq 0} |x_-(t,\xi_-,\alpha,\varepsilon) - u(t,y_-(t,\xi_-,\alpha,\varepsilon))| < \rho \end{aligned} \tag{4.6}$$

and

$$\begin{aligned} \sup_{t\geq 0} |x_+(t,\xi_+,\alpha,\varepsilon) - u(t,y_+(t,\xi_+,\alpha,\varepsilon))| \to 0 \quad \textit{as } |\xi_+| + |\varepsilon| \to 0, \\ \sup_{t\leq 0} |x_-(t,\xi_-,\alpha,\varepsilon) - u(t,y_-(t,\xi_-,\alpha,\varepsilon))| \to 0 \quad \textit{as } |\xi_-| + |\varepsilon| \to 0 \end{aligned} \tag{4.7}$$

uniformly with respect to α as well as

$$\lim_{\varepsilon\to 0} y_\pm(0,\xi_\pm,\alpha,\varepsilon) = \alpha$$

uniformly with respect to $(\xi_\pm,\alpha)$.

Remark 4.3. According to Theorem 4.2 we have

$$\begin{aligned} h(x_+(t_i^*(\xi_+,\alpha,\varepsilon),\xi_+,\alpha,\varepsilon),y_+(t_i^*(\xi_+,\alpha,\varepsilon),\xi_+,\alpha,\varepsilon)) = c_i, \\ h(x_-(t_{-i}^*(\xi_-,\alpha,\varepsilon),\xi_-,\alpha,\varepsilon),y_-(t_{-i}^*(\xi_-,\alpha,\varepsilon),\xi_-,\alpha,\varepsilon)) = c_i. \end{aligned} \tag{4.8}$$

Differentiating (4.8) with respect to ξ_+, ξ_-, at $\varepsilon = 0$ we obtain a formula for the derivatives

$$\frac{\partial t_i^*}{\partial \xi_+}(\xi_+,\alpha,0), \quad \frac{\partial t_{-i}^*}{\partial \xi_-}(\xi_-,\alpha,0), \quad i = 1,\ldots,N.$$

However we have to distinguish when $t \to t_i^*(\xi_+,\alpha,0)^+$ or $t \to t_i^*(\xi_+,\alpha,0)^-$ (resp. $t \to t_{-i}^*(\xi_-,\alpha,0)^+$ or $t \to t_{-i}^*(\xi_-,\alpha,0)^-$). For example if $t \to t_i^*(\xi_+,\alpha,0)^+$, $x_+(t,\xi_+,\alpha,0)$ is the solution of $\dot{x} = f_{i+1}(x,\alpha)$ and then, differentiating (4.8) with respect to ξ_+, we get, with $t_i^* = t_i^*(\xi_+,\alpha,0)$:

$$h_x(x_+(t_i^*,\xi_+,\alpha,0),\alpha)[f_{i+1}(x_+(t_i^*,\xi_+,\alpha,0),\alpha)\frac{\partial t_i^*}{\partial \xi_+}(\xi_+,\alpha,0) + x_{+,\xi_+}(t_i^{*+},\xi_+,\alpha,0)] = 0.$$

Vice versa, when $t \to t_i^*(\xi_+,\alpha,0)^-$, $x_+(t,\xi_+,\alpha,0)$ is the solution of $\dot{x} = f_i(x,\alpha)$ and then

$$h_x(x_+(t_i^*,\xi_+,\alpha,0),\alpha)[f_i(x_+(t_i^*,\xi_+,\alpha,0),\alpha)\frac{\partial t_i^*}{\partial \xi_+}(\xi_+,\alpha,0) + x_{+,\xi_+}(t_i^{*-},\xi_+,\alpha,0)] = 0.$$

Similarly we get, with $t_{-i}^* = t_{-i}^*(\xi_-,\alpha,0)$:

$$h_x(x_-(t_{-i}^*,\xi_-,\alpha,0),\alpha)[f_{i+1}(x_-(t_{-i}^*,\xi_-,\alpha,0),\alpha)\frac{\partial t_{-i}^*}{\partial \xi_-}(\xi_-,\alpha,0) + x_{-,\xi_-}(t_{-i}^{*-},\xi_-,\alpha,0)] = 0$$

and

$$h_x(x_-(t_{-i}^*,\xi_-,\alpha,0),\alpha)[f_i(x_+(t_{-i}^*,\xi_-,\alpha,0),\alpha)\frac{\partial t_{-i}^*}{\partial \xi_-}(\xi_-,\alpha,0) + x_{-,\xi_-}(t_{-i}^{*+},\xi_-,\alpha,0)] = 0.$$

We will use this remark in the next section.

5 The discontinuous variational equation

For any fixed $\alpha \in \mathbb{R}^m$ and $\ell = \pm 1, \dots, \pm N$ we define linear operators $B_\ell(\alpha) : \mathbb{R}^n \to \mathbb{R}^n$ as follows:

$$B_\ell(\alpha)x = x - \frac{h_x(u(t_\ell(\alpha), \alpha), \alpha)x}{h_x(u(t_\ell(\alpha), \alpha), \alpha)\dot{u}(t_\ell(\alpha)^-, \alpha)}[\dot{u}(t_\ell(\alpha)^-, \alpha), \alpha) - \dot{u}(t_\ell(\alpha)^+, \alpha), \alpha)]. \quad (5.1)$$

The following result has been proved in [6, Propositioon 5.1, 5.2].

Proposition 5.1. *For any $\alpha \in \mathbb{R}^m$, $x \mapsto B_\ell(\alpha)x$ are invertible linear maps. Moreover $x_{+,\xi_+}(t, 0, \alpha, 0)$ is a solution of*

$$\begin{aligned} \dot{x} = A(t,\alpha)x &:= \begin{cases} f_{i,x}(u(t,\alpha),\alpha)x & \text{if } t_{i-1}(\alpha) \le t < t_i(\alpha), \\ & \quad i = 1,\dots,N \\ f_{N+1,x}(u(t,\alpha),\alpha)x & \text{if } t \ge t_N(\alpha), \end{cases} \\ x(t_i(\alpha)^+) &= B_i(\alpha)x(t_i(\alpha)^-), \quad i = 1,\dots,N \end{aligned} \quad (5.2)$$

which is C^1 for $t \neq t_i(\alpha)$, bounded for $t \ge 0$ and can be assumed to be right-continuous at $t = t_i(\alpha)$. Similarly $x_{-,\xi_-}(t, 0, \alpha, 0)$ is a solution of

$$\begin{aligned} \dot{x} = A(t,\alpha)x &:= \begin{cases} f_{i,x}(u(t,\alpha),\alpha)x & \text{if } t_{-i}(\alpha) < t \le t_{-i+1}(\alpha), \\ & \quad i = 1,\dots,N \\ f_{N+1,x}(u(t,\alpha),\alpha)x & \text{if } t \le t_{-N}(\alpha) \end{cases} \\ x(t_{-i}(\alpha)^+) &= B_{-i}(\alpha)x(t_{-i}(\alpha)^-), \quad i = 1,\dots,N \end{aligned} \quad (5.3)$$

which is C^1 for $t \neq t_{-i}(\alpha)$,bounded for $t \le 0$ and can be assumed to be left-continuous at $t = t_{-i}(\alpha)$. Finally, for $t \ge 0$, resp. $t \le 0$, the function

$$\dot{u}(t,\alpha) = \begin{cases} \dot{u}_i^+(t,\alpha) & \text{for } t_{i-1}(\alpha) \le t < t_i(\alpha), \\ & \quad i = 1,\dots,N \\ \dot{u}_{N+1}^+(t,\alpha) & \text{for } t \ge T_N(\alpha) \end{cases}$$

resp.

$$\dot{u}(t,\alpha) = \begin{cases} \dot{u}_i^-(t,\alpha) & \text{for } t_{-i}(\alpha) < t \le t_{-i+1}(\alpha), \\ & \quad i = 1,\dots,N \\ \dot{u}_{N+1}^-(t,\alpha) & \text{for } t \le T_{-N}(\alpha) \end{cases}$$

is a solution of (5.2) (resp. (5.3)) bounded on $t \ge 0$ (resp, $t \le 0$).

6 Main result

First we recall that $P_+(y)$ is the projections of the exponential dichotomy on $t \ge 0$, of the linear system (4.1) with constant K and exponent δ. Then, from Lemma 4.1, we see that (4.4) has an exponential dichotomy on $t \ge t_N(y)$ with exponent δ and projection

$$U_{N+1}^+(t_N(y), y)U_{N+1}^+(T_+, y)^{-1}P_+(y)U_{N+1}^+(T_+, y)U_{N+1}^+(t_N(y), y)^{-1}.$$

Similarly, the linear system (4.5) has an exponential dichotomy on $t \le t_{-N}(y)$ with exponent δ and projection

$$U_{N+1}^-(t_{-N}(y), y)U_{N+1}^-(T_-, y)^{-1}P_-(y)U_{N+1}^-(T_-, y)U_{N+1}^-(t_{-N}(y), y)^{-1}.$$

From Lemma 3.3–3.4 we obtain the following

Proposition 6.1. *For any $\alpha \in \mathbb{R}^m$, the discontinuous linear system (5.2), resp. (5.3), has an exponential dichotomy on $\mathbb{R}_+$, resp. $\mathbb{R}_-$, with projections $Q_+(\alpha)$, resp. $Q_-(\alpha)$, given by*

$$\begin{aligned} Q_+(\alpha) &= X_+(t_N(\alpha)^+,\alpha)^{-1}U^+_{N+1}(t_N(\alpha),\alpha)U^+_{N+1}(T_+,\alpha)^{-1} \\ &\quad \cdot P_+(\alpha)U^+_{N+1}(T_+,\alpha)U^+_{N+1}(t_N(\alpha),\alpha)^{-1}X_+(t_N(\alpha)^+,\alpha) \\ Q_-(\alpha) &= X_-(t_{-N}(\alpha)^-,\alpha)^{-1}U^-_{N+1}(t_{-N}(\alpha),\alpha)U^-_{N+1}(T_-,\alpha)^{-1} \\ &\quad \cdot P_-(\alpha)U^-_{N+1}(T_-,\alpha)U^-_{N+1}(t_{-N}(\alpha),\alpha)^{-1}X_-(t_{-N}(\alpha)^-,\alpha) \end{aligned}$$

where

$$\begin{aligned} X_+(t_N^+(\alpha),\alpha) &= B_N(\alpha)U_N^+(t_N(\alpha))U_N^+(t_{N-1}(\alpha),\alpha)^{-1}\dots B_1(\alpha)U_1^+(t_1(\alpha),\alpha) \\ X_-(t_{-N}(\alpha)^-,\alpha) &= \ B_{-N}(\alpha)^{-1}U_N^-(t_{-N}(\alpha))U_N^-(t_{-N+1}(\alpha),\alpha)^{-1}\dots B_{-1}(\alpha)^{-1}U_1^-(t_{-1}(\alpha),\alpha). \end{aligned}$$

Moreover $\mathcal{R}Q_+(\alpha)$ (resp. $\mathcal{N}Q_-(\alpha)$) is the space of initial conditions of solutions of (5.2), resp. (5.3), right-continuous, when $t \geq 0$ (resp. left-continuous, when $t \leq 0$) and bounded on $\mathbb{R}_+$, (resp, on $\mathbb{R}_-$).

We assume the following condition holds:

A_5) For any $\alpha \in \mathbb{R}^m$, $\dim[\mathcal{R}Q_+(\alpha) \cap \mathcal{N}Q_-(\alpha)] = d \leq m$.

From Proposition 5.1 we know that $\dot{u}(0,\alpha) \in \mathcal{R}Q_+(\alpha) \cap \mathcal{N}Q_-(\alpha)$ so

$$1 \leq \dim[\mathcal{R}Q_+(\alpha) + \mathcal{N}Q_-(\alpha)]^\perp = d.$$

Next, from A_3) it follows that $\dim \mathcal{R}Q_+(\alpha) = k$ and $\dim \mathcal{N}Q_-(\alpha) = n-k$, hence $d \leq \min\{k, n-k\}$.

Let $\psi_1(\alpha), \dots, \psi_d(\alpha) \in \mathbb{R}^n$ be such that

$$[\mathcal{R}Q_+(\alpha) + \mathcal{N}Q_-(\alpha)]^\perp = \operatorname{span}\{\psi_1(\alpha), \dots, \psi_d(\alpha)\}.$$

Without loss of generality we assume that $\{\psi_1(\alpha), \dots, \psi_d(\alpha)\}$ is an orthonormal set.

The purpose of this section is to prove the following

Theorem 6.2. *Suppose that A_1)–A_5) hold. Suppose further that there exists $\alpha_0 \in \mathbb{R}^m$ such that the vector function*

$$M(\alpha) := \left(\int_{-\infty}^{\infty} \psi_j(\alpha)^T G(t,\alpha) u_y(t,\alpha) g(u(t,\alpha),\alpha,0) dt \right)_{j=1,\dots,d}$$

where

$$G(t,\alpha) = \begin{cases} Q_-(\alpha)X_-(t,\alpha)^{-1} & \text{if } t \leq 0, \\ (\mathbb{I} - Q_+(\alpha))X_+(t,\alpha)^{-1} & \text{if } t \geq 0 \end{cases}$$

satisfies $M(\alpha_0) = 0$ and $\operatorname{rank} M'(\alpha_0) = d$. Then there exists $\rho > 0$ and $\varepsilon_0 > 0$ such that for $0 \leq \varepsilon \leq \varepsilon_0$ system (1.1) has a $(m-d)$-dimensional manifold of continuous, piecewise C^r solutions $(x(t), y(t))$ such that

$$\sup_{t\in\mathbb{R}} |x(t) - u(t, y(t)) < \rho,$$

$$\sup_{t\in\mathbb{R}} |x(t) - u(t, y(t))| \to 0$$

as $\varepsilon \to 0$.

Proof. Arguing as in [6, Theorem 6.2] we know that

$$\begin{aligned} x_+(t,\xi_+,\alpha,\varepsilon) = u(t,y_+(t,\xi_+,\alpha,\varepsilon)) + X_+(t,\alpha)\tilde{\xi}_+ \\ + \int_0^t X_+(t,\alpha)Q_+(\alpha)X_+(s,\alpha)^{-1}b_+(s)ds \\ s - \int_t^\infty X_+(t,\alpha)(\mathbb{I} - Q_+(\alpha))X_+(s,\alpha)^{-1}b_+(s)ds \end{aligned} \tag{6.1}$$

where

$$\begin{aligned} b_+(t) &= b_+(t,\xi_+,\alpha,\varepsilon) \\ &:= f(x_+(t,\xi_+,\alpha,\varepsilon),y_+(t,\xi_+,\alpha,\varepsilon)) - f(u(t,y_+(t,\xi_+,\alpha,\varepsilon)),y_+(t,\xi_+,\alpha,\varepsilon)) \\ &\quad - \mathcal{A}(t,\alpha)[x_+(t,\xi_+,\alpha,\varepsilon) - u(t,y_+(t,\xi_+,\alpha,\varepsilon))] \\ &\quad - \varepsilon u_y(t,y_+(t,\xi_+,\alpha,\varepsilon))g(x_+(t,\xi_+,\alpha,\varepsilon),y_+(t,\xi_+,\alpha,\varepsilon),\varepsilon) \end{aligned}$$

and

$$\tilde{\xi}_+ = Q_+(\alpha)[x_+(0,\xi_+,\alpha,\varepsilon) - u(0,y_+(0,\xi_+,\alpha,\varepsilon))] \in \mathcal{R}Q_+(\alpha).$$

Moreover, for ε sufficiently small, the map $(\xi_+,\alpha) \mapsto (\tilde{\xi}_+, y_+(0,\xi_+,\alpha,\varepsilon))$ from $\mathcal{R}P_+(\alpha) \times \mathbb{R}^m$ into $\mathcal{R}Q_+(\alpha) \times \mathbb{R}^m$ is linearly invertible.

Similarly, for $|\alpha_- - y_0|$ sufficiently small we have

$$\begin{aligned} x_-(t,\xi_-,\alpha_-,\varepsilon) = u(t,y_-(t,\xi_-,\alpha_-,\varepsilon)) + X_-(t,\alpha_-)\tilde{\xi}_- \\ + \int_{-\infty}^t X_-(t,\alpha_-)Q_-(\alpha_-)X_-(s,\alpha_-)^{-1}b_-(s)ds \\ - \int_t^0 X_-(t,\alpha_-)(\mathbb{I} - Q_-(\alpha_-))X_-(s,\alpha_-)^{-1}b_-(s)ds \end{aligned} \tag{6.2}$$

where

$$\begin{aligned} b_-(t) &= b_-(t,\xi_-,\alpha_-,\varepsilon) \\ &:= f(x_-(t,\xi_-,\alpha_-,\varepsilon),y_-(t,\xi_-,\alpha_-,\varepsilon)) - f(u(t,y_-(t,\xi_-,\alpha_-,\varepsilon)),y_-(t,\xi_-,\alpha_-,\varepsilon)) \\ &\quad - \mathcal{A}(t,\alpha_-)[x_-(t,\xi_-,\alpha_-,\varepsilon) - u(t,y_-(t,\xi_-,\alpha_-,\varepsilon))] \\ &\quad - \varepsilon u_y(t,y_-(t,\xi_-,\alpha_-,\varepsilon))g(x_-(t,\xi_-,\alpha_-,\varepsilon),y_-(t,\xi_-,\alpha_-,\varepsilon),\varepsilon) \end{aligned}$$

and

$$\tilde{\xi}_- = [\mathbb{I} - Q_-(\alpha_-)][x_-(0,\xi_-,\alpha_-,\varepsilon) - u(0,y_-(0,\xi_+,\alpha_-,\varepsilon))] \in \mathcal{N}Q_-(\alpha_-).$$

Moreover, for ε sufficiently small, the map $(\xi_-,\alpha_-) \mapsto (\tilde{\xi}_-, y_-(0,\xi_-,\alpha_-,\varepsilon))$ from $\mathcal{N}P_-(\alpha_-) \times \mathbb{R}^m$ into $\mathcal{N}Q_-(\alpha_-) \times \mathbb{R}^m$ is linearly invertible.

From (6.1)-(6.2) we get, for $|\alpha - y_0| + |\alpha_- - y_0|$ sufficiently small

$$\begin{aligned} x_+(0,\xi_+,\alpha,\varepsilon) - x_-(0,\xi_-,\alpha_-,\varepsilon) \\ = u(0,y_+(0,\xi_+,\alpha,\varepsilon)) - u(0,y_-(0,\xi_-,\alpha_-,\varepsilon)) + \tilde{\xi}_+ - \tilde{\xi}_- \\ - \int_0^\infty (\mathbb{I} - Q_+(\alpha))X_+(s,\alpha)^{-1}b_+(s)ds - \int_{-\infty}^0 Q_-(\alpha_-)X_-(s,\alpha_-)^{-1}b_-(s)ds. \end{aligned} \tag{6.3}$$

Then the system

$$\begin{cases} x_+(0,\xi_+,\alpha,\varepsilon) = x_-(0,\xi_-,\alpha_-,\varepsilon), \\ y_+(0,\xi_+,\alpha,\varepsilon) = y_-(0,\xi_-,\alpha_-,\varepsilon) \end{cases}$$

is equivalent to

$$\begin{cases} \tilde{\xi}_+ - \tilde{\xi}_- = k(\xi_+, \xi_-, \alpha, \alpha_-, \varepsilon), \\ y_-(0, \xi_-, \alpha_-, \varepsilon) - y_+(0, \xi_+, \alpha, \varepsilon) = 0 \end{cases} \tag{6.4}$$

where

$$k(\xi_+, \xi_-, \alpha, \alpha_-, \varepsilon) = \int_0^\infty (\mathbb{I} - Q_+(\alpha))X_+(s,\alpha)^{-1} b_+(s)ds + \int_{-\infty}^0 Q_-(\alpha_-)X_-(s,\alpha_-)^{-1}b_-(s)ds.$$

Differentiating $b_+(t) = b_+(t, \xi_+, \alpha, \varepsilon)$ with respect to ξ_+ at $\xi_+ = 0$, $\varepsilon = 0$ and also using $x_+(t, 0, \alpha, 0) = u(t, \alpha)$, $y_+(t, 0, \alpha, 0) = \alpha$, we see that, for $t_{i-1}(\alpha) < t < t_i(\alpha)$, we have

$$\tfrac{\partial b_+}{\partial \xi_+}(t, 0, \alpha, 0) = [f_{i,x}(u(t,\alpha), \alpha) - A(t,\alpha)]x_{+,\xi_+}(t, 0, \alpha, 0) = 0$$

and for $t > t_N(\alpha)$:

$$\tfrac{\partial b_+}{\partial \xi_+}(t, 0, \alpha, 0) = [f_{N+1,x}(u(t,\alpha), \alpha) - A(t,\alpha)]x_{+,\xi_+}(t, 0, \alpha, 0) = 0.$$

Then

$$\frac{\partial}{\partial \xi_+}\left[\int_0^\infty (\mathbb{I} - Q_+(\alpha))X_+(s,\alpha)^{-1}b_+(s)ds\right]_{\xi_+=0,\varepsilon=0} = 0.$$

Similarly we get, for $|\alpha_- - y_0|$ sufficiently small,

$$\frac{\partial}{\partial \xi_-}\left[\int_{-\infty}^0 Q_-(\alpha_-)X_-(s,\alpha_-)^{-1}b_-(s)ds\right]_{\xi_-=0,\varepsilon=0} = 0.$$

As a consequence (6.4) reads:

$$\begin{aligned} \tilde{\xi}_+ - \tilde{\xi}_- &= R_1(\tilde{\xi}_+, \tilde{\xi}_-, \alpha, \alpha_-, \varepsilon), \\ \alpha_- - \alpha &= R_2(\tilde{\xi}_+, \tilde{\xi}_-, \alpha, \alpha_-, \varepsilon) \end{aligned} \tag{6.5}$$

where

$$\begin{aligned} R_1(\tilde{\xi}_+, \tilde{\xi}_-, \alpha, \alpha_-, \varepsilon) &= k(\xi_+, \xi_-, \alpha, \alpha_-, \varepsilon) \\ \tilde{\xi}_+ &= Q_+(\alpha)[x_+(0, \xi_+, \alpha, \varepsilon) - u(0, y_+(0, \xi_+, \alpha, \varepsilon))] \\ \tilde{\xi}_- &= [\mathbb{I} - Q_-(\alpha_-)][x_-(0, \xi_-, \alpha_-, \varepsilon) - u(0, y_-(0, \xi_-, \alpha_-, \varepsilon))]. \end{aligned}$$

Note that, being $(\xi_+, \xi_-) \mapsto (\tilde{\xi}_+, \tilde{\xi}_-)$ linearly invertible, we derive: $R_1(\tilde{\xi}_+, \tilde{\xi}_-, \alpha, \alpha_-, \varepsilon) = O(|\tilde{\xi}_+|^2 + |\tilde{\xi}_-|^2 + |\varepsilon|)$ and $R_2(\tilde{\xi}_+, \tilde{\xi}_-, \alpha, \alpha_-, \varepsilon) = O(|\varepsilon|)$, uniformly with respect to (α, α_-).

Now, as $\tilde{\xi}_- \in \mathcal{N}Q_-(\alpha_-)$, we have

$$(\mathbb{I} - Q_-(\alpha))\tilde{\xi}_- = \tilde{\xi}_- - (Q_-(\alpha) - Q_-(\alpha_-))\tilde{\xi}_-$$

and hence

$$\frac{1}{2}|\tilde{\xi}_-| \le |(\mathbb{I} - Q_-(\alpha))\tilde{\xi}_-| \le 2|\tilde{\xi}_-|$$

provided $|\alpha_- - y_0|$ and $|\alpha - y_0|$ are sufficiently small. Hence the map $\tilde{\xi}_- \mapsto (\mathbb{I} - Q_-(\alpha))\tilde{\xi}_-$ from $\mathcal{N}Q_-(\alpha_-)$ into $\mathcal{N}Q_-(\alpha)$ is linearly invertible. Then, setting

$$\bar{\xi}_+ = \tilde{\xi}_+, \quad \bar{\xi}_- = (\mathbb{I} - Q_-(\alpha))\tilde{\xi}_-, \tag{6.6}$$

(6.5) can be written as

$$\begin{aligned} \bar{\xi}_+ - \bar{\xi}_- &= \bar{R}_1(\bar{\xi}_+, \bar{\xi}_-, \alpha, \alpha_-, \varepsilon), \\ \alpha_- - \alpha &= \bar{R}_2(\bar{\xi}_+, \bar{\xi}_-, \alpha, \alpha_-, \varepsilon) \end{aligned} \tag{6.7}$$

with

$$\begin{aligned}(\bar{\xi}_+, \bar{\xi}_-) &\in \mathcal{R}Q_+(\alpha) \times \mathcal{N}Q_-(\alpha),\\ \bar{R}_1(\bar{\xi}_+, \bar{\xi}_-, \alpha, \alpha_-, \varepsilon) &= R_1(\tilde{\xi}_+, \tilde{\xi}_-, \alpha, \alpha_-, \varepsilon),\\ \bar{R}_2(\bar{\xi}_+, \bar{\xi}_-, \alpha_+, \alpha_-, \varepsilon) &= R_2(\tilde{\xi}_+, \tilde{\xi}_-, \alpha, \alpha_-, \varepsilon)\end{aligned}$$

where $(\tilde{\xi}_+, \tilde{\xi}_-)$ is the point corresponding to $(\bar{\xi}_+, \bar{\xi}_-)$ through (6.6). Note that it holds $\bar{R}_1(\bar{\xi}_+, \bar{\xi}_-, \alpha, \alpha_-, \varepsilon) = O(|\bar{\xi}_+|^2 + |\bar{\xi}_-|^2 + |\varepsilon|)$, $\bar{R}_2(\bar{\xi}_+, \bar{\xi}_-, \alpha, \alpha_-, \varepsilon) = O(|\varepsilon|)$ uniformly with respect to (α, α_-).

Let α, α_- be such that $|\alpha - y_0|$ and $|\alpha_- - y_0|$ are sufficiently small. The map $(\bar{\xi}_+, \bar{\xi}_-) \mapsto \bar{\xi}_+ - \bar{\xi}_-$ is a linear map from $\mathcal{R}Q_+(\alpha) \times \mathcal{N}Q_-(\alpha)$ into $\mathcal{R}Q_+(\alpha) + \mathcal{N}Q_-(\alpha)$ whose kernel is $\mathcal{R}Q_+(\alpha) \cap \mathcal{N}Q_-(\alpha)$ which, by assumption A_5), is d-dimensional.

Let $W(\alpha) \subset \mathcal{R}Q_+(\alpha)$ be a complement of $\mathcal{R}Q_+(\alpha) \cap \mathcal{N}Q_-(\alpha)$ in $\mathcal{R}Q_+(\alpha)$, so that

$$\mathcal{R}Q_+(\alpha) + \mathcal{N}Q_-(\alpha) = W(\alpha) \oplus \mathcal{N}Q_-(\alpha).$$

Note that $\dim W(\alpha) = k - d$ and

$$\mathbb{R}^n = [\mathcal{R}Q_+(\alpha) + \mathcal{N}Q_-(\alpha)] \oplus \operatorname{span}\{\psi_1(\alpha), \ldots, \psi_d(\alpha)\}.$$

Next, let $Q(\alpha) : \mathbb{R}^n \to \mathbb{R}^n$ be the orthogonal projection such that $\mathcal{R}Q(\alpha) = \mathcal{R}Q_+(\alpha) + \mathcal{N}Q_-(\alpha)$ and $\mathcal{N}Q(\alpha) = \operatorname{span}\{\psi_1(\alpha), \ldots, \psi_d(\alpha)\}$. Since

$$(\mathbb{I} - Q(\alpha))x \in \mathcal{N}Q(\alpha) = \operatorname{span}\{\psi_1(\alpha), \ldots, \psi_d(\alpha)\}$$

and $(\psi_1(\alpha), \ldots, \psi_d(\alpha))$ is orthonormal we get

$$\begin{aligned}(\mathbb{I} - Q(\alpha))x &= \sum_{j-1}^{d} \langle \psi_j(\alpha), (\mathbb{I} - Q(\alpha))x \rangle \psi_j(\alpha)\\ &= \sum_{j-1}^{d} \langle (\mathbb{I} - Q(\alpha))\psi_j(\alpha), x \rangle \psi_j(\alpha) = \sum_{j-1}^{d} (\psi_j(\alpha)^T x)\psi_j(\alpha).\end{aligned}$$

Hence we replace (6.7) with

$$\begin{aligned}\bar{\xi}_+ - \bar{\xi}_- &= Q(\alpha)\bar{R}_1(\bar{\xi}_+, \bar{\xi}_-, \alpha, \alpha_-, \varepsilon),\\ \alpha - \alpha_- &= \bar{R}_2(\bar{\xi}_+, \bar{\xi}_-, \alpha, \alpha_-, \varepsilon),\\ \psi_j^T(\alpha)\bar{R}_1(\bar{\xi}_+, \bar{\xi}_-, \alpha, \alpha_-, \varepsilon) &= 0.\end{aligned} \tag{6.8}$$

We solve (6.8) for $(\bar{\xi}_+, \bar{\xi}_-, \alpha, \alpha_-) \in W(\alpha) \times \mathcal{N}Q_-(\alpha) \times \mathbb{R}^m \times \mathbb{R}^m$ in terms of ε.

Since $\dim[\mathcal{R}Q_+(\alpha) + \mathcal{N}Q_-(\alpha)] = n - d$, we see that for any fixed ε

$$\begin{aligned}\bar{\xi}_+ - \bar{\xi}_- &= Q(\alpha)\bar{R}_1(\bar{\xi}_+, \bar{\xi}_-, \alpha, \alpha_-, \varepsilon)],\\ \alpha - \alpha_- &= \bar{R}_2(\bar{\xi}_+, \bar{\xi}_-, \alpha, \alpha_-, \varepsilon)\end{aligned} \tag{6.9}$$

is essentially a system of $n - d + m$ equations in the $n - d + 2m$ variables $(\bar{\xi}_+, \bar{\xi}_-, \alpha, \alpha_-)$ such that, when $\varepsilon = 0$, has the solution

$$(\bar{\xi}_+, \bar{\xi}_-) = (0, 0), \qquad \alpha_- = \alpha.$$

The Jacobian matrix at this point is

$$J = \begin{pmatrix} L & 0 & 0 \\ 0 & \mathbb{I}_{\mathbb{R}^m} & -\mathbb{I}_{\mathbb{R}^m} \end{pmatrix}$$

where $L : W \times \mathcal{N}Q_-(\alpha) \to W \oplus \mathcal{N}Q_-(\alpha)$ is the invertible linear map given by $L(\bar{\xi}_+, \bar{\xi}_-) = \bar{\xi}_+ - \bar{\xi}_-$. We have

$$\operatorname{rank} J = n - d + m$$

hence, for $\varepsilon \neq 0$ and sufficiently small (6.9) has a m-dimensional C^r-manifold of solutions

$$\bar{\xi}_+ = \bar{\xi}_+(\alpha, \varepsilon), \quad \bar{\xi}_- = \bar{\xi}_-(\alpha, \varepsilon), \quad \alpha_- = \alpha_-(\alpha, \varepsilon)$$

where

$$\begin{aligned} |\bar{\xi}_\pm(\alpha, \varepsilon)| &= O(|\varepsilon|), \\ |\alpha_-(\alpha, \varepsilon) - \alpha| &= O(|\varepsilon|) \end{aligned} \tag{6.10}$$

uniformly with respect to α. Plugging this solution in the third equation in (6.8) we obtain the system of equations

$$\psi_j^T(\alpha) \bar{R}_1(\bar{\xi}_+(\alpha, \varepsilon), \bar{\xi}_-(\alpha, \varepsilon), \alpha, \alpha_-(\alpha, \varepsilon), \varepsilon) = 0, \quad j = 1, \ldots, d.$$

As $\bar{R}_1(0, 0, \alpha, \alpha, 0) = 0$ we see that this equation is identically satisfied when $\varepsilon = 0$, so we replace it with

$$\mathcal{M}(\alpha, \varepsilon) = 0$$

where $\mathcal{M}(\alpha, \varepsilon)$ is the C^{r-1}-function:

$$\mathcal{M}(\alpha, \varepsilon) = \begin{cases} \varepsilon^{-1} \left(\psi_j^T(\alpha) [\bar{R}_1(\bar{\xi}_+(\alpha, \varepsilon), \bar{\xi}_-(\alpha, \varepsilon), \alpha, \alpha_-(\alpha, \varepsilon), \varepsilon) \right)_{j=1,\ldots,d} & \text{for } \varepsilon \neq 0, \\ \left[\left(\frac{\partial}{\partial \varepsilon} \psi_j^T(\alpha) \bar{R}_1(\bar{\xi}_+(\alpha, \varepsilon), \bar{\xi}_-(\alpha, \varepsilon), \alpha, \alpha_-(\alpha, \varepsilon), \varepsilon) \right)_{j=1,\ldots,d} \right]_{|\varepsilon=0} & \text{for } \varepsilon = 0. \end{cases}$$

We have already observed that $\bar{R}_1(\bar{\xi}_+, \bar{\xi}_-, \alpha, \alpha_-, \varepsilon) = O(|\bar{\xi}_+|^2 + |\bar{\xi}_-|^2 + |\varepsilon|)$ uniformly with respect to (α, α_-), then

$$\mathcal{M}(\alpha, 0) = \left(\psi_j^T(\alpha) \bar{R}_{1,\varepsilon}(0, 0, \alpha, \alpha, 0)] \right)_{j=1,\ldots,d}.$$

We now compute $\bar{R}_{1,\varepsilon}(0, 0, \alpha, \alpha, 0)$. Since the map $(\tilde{\xi}_+, \tilde{\xi}_-) \mapsto (\bar{\xi}_+, \bar{\xi}_-)$ where $\bar{\xi}_+ = \tilde{\xi}_+$ and $\bar{\xi}_- = (\mathbb{I} - Q(\alpha))\tilde{\xi}_-$ is a linear isomorphism we see that

$$\bar{R}_1(0, 0, \alpha, \alpha, \varepsilon) = k(0, 0, \alpha, \alpha, \varepsilon)$$

and hence

$$\begin{aligned} \bar{R}_{1\varepsilon}(0, 0, \alpha, \alpha, 0) &= k_\varepsilon(0, 0, \alpha, \alpha, 0) \\ &= \int_{-\infty}^{0} Q_-(\alpha) X_-(t, \alpha)^{-1} \frac{\partial b_-}{\partial \varepsilon}(t, 0, 0, \alpha, \alpha, 0) dt \\ &\quad + \int_{0}^{\infty} (\mathbb{I} - Q_+(\alpha)) X_+(t, \alpha)^{-1} \frac{\partial b_+}{\partial \varepsilon}(t, 0, 0, \alpha, \alpha, 0) dt \end{aligned}$$

that is

$$\mathcal{M}(\alpha,0) = \left(\int_{-\infty}^{\infty} \psi_j^T(t,\alpha) b_\varepsilon(t,0,0,\alpha,\alpha,0)dt\right)_{j=1,\dots,d}$$

where

$$\psi_j^T(t,\alpha) = \begin{cases} \psi_j^T(\alpha) Q_-(\alpha) X_-(t,\alpha)^{-1} & \text{if } t<0, \\ \psi_j^T(\alpha)(\mathbb{I} - Q_+(\alpha)) X_+(t,\alpha)^{-1} & \text{if } t \geq 0 \end{cases} \tag{6.11}$$

and

$$b_\varepsilon(t,0,0,\alpha,\alpha,0) = \begin{cases} \frac{\partial b_-}{\partial \varepsilon}(t,0,0,\alpha,\alpha,0) & \text{if } t<0, \\ \frac{\partial b_+}{\partial \varepsilon}(t,0,0,\alpha,\alpha,0) & \text{if } t \geq 0. \end{cases}$$

Now, it is easy to check that

$$\begin{cases} \frac{\partial b_-}{\partial \varepsilon}(t,0,0,\alpha,\alpha,0) & \text{if } t<0, \\ \frac{\partial b_+}{\partial \varepsilon}(t,0,0,\alpha,\alpha,0) & \text{if } t \geq 0 \end{cases} = -u_y(t,\alpha) g(u(t,\alpha),\alpha,0).$$

Hence

$$\mathcal{M}(\alpha,0) = -\left(\int_{-\infty}^{\infty} \psi_j^T(t,\alpha) u_y(t,\alpha) g(u(t,\alpha),\alpha,0)dt\right)_{j=1,\dots,d} = -M(\alpha). \tag{6.12}$$

The thesis follows now from the Implicit Function Theorem. □

Remark 6.3. i) The orthonormal basis $(\psi_1(\alpha),\dots,\psi_d(\alpha))$ of $[\mathcal{R}Q_+(\alpha) + \mathcal{N}Q_-(\alpha)]^\perp$ can be replaced by any independent set $(\tilde\psi_1(\alpha),\dots,\tilde\psi_d(\alpha))$ such that

$$\mathbb{R}^n = [\mathcal{R}Q_+(\alpha) + \mathcal{N}Q_-(\alpha)] \oplus \operatorname{span}\{\tilde\psi_1(\alpha),\dots,\tilde\psi_d(\alpha)\}.$$

Indeed, let $\langle\cdot,\cdot\rangle$ be a scalar product on $\mathbb{R}^n$ such that

$$[\mathcal{R}Q_+(\alpha) + \mathcal{N}Q_-(\alpha)]^\perp = \operatorname{span}\{\tilde\psi_1(\alpha),\dots,\tilde\psi_d(\alpha)\}$$

and let $(\psi_1(\alpha),\dots,\psi_d(\alpha))$ be an orthonormal basis of $\operatorname{span}\{\tilde\psi_1(\alpha),\dots,\tilde\psi_d(\alpha)\}$. Then a smooth, invertible $d\times d$ matrix $N(\alpha)$ exists such that

$$(\tilde\psi_1(\alpha)\dots\tilde\psi_d(\alpha)) = (\psi_1(\alpha)\dots\psi_d(\alpha))N(\alpha).$$

Set

$$\tilde M(\alpha) = \left[\int_{-\infty}^{\infty} \tilde\psi_j^T(t,\alpha) u_y(t,\alpha) g(u(t,\alpha),\alpha,0)dt\right]_{j=1,\dots,d}.$$

We have

$$\begin{aligned} &[\tilde\psi_j(\alpha)^T u_y(t,\alpha) g(u(t,\alpha),\alpha,0)]_{j=1,\dots,d} \\ &\quad = (\tilde\psi_1(\alpha)\dots\tilde\psi_d(\alpha))^T [u_y(t,\alpha) g(u(t,\alpha),\alpha,0)] \\ &\quad = N(\alpha)^T (\psi_1(\alpha)\dots\psi_d(\alpha))^T u_y(t,\alpha) g(u(t,\alpha),\alpha,0) \\ &\quad = N(\alpha)^T [\psi_j(\alpha)^T [u_y(t,\alpha) g(u(t,\alpha),\alpha,0)]_{j=1,\dots,d} \end{aligned}$$

that is

$$\tilde M(\alpha) = N(\alpha)^T M(\alpha).$$

Now, assuming that $M(\alpha_0) = 0$ and $\operatorname{rank} M'(\alpha_0) = d$, we see that $\tilde M(\alpha_0) = N(\alpha_0)^T M(\alpha_0) = 0$ and

$$\tilde M'(\alpha_0) = N(\alpha_0)^T M'(\alpha_0).$$

So $\tilde{M}(\alpha_0) = 0$ and $\operatorname{rank} \tilde{M}'(\alpha_0) = d$. The vice versa is proved in the same way using the equality

$$M(\alpha) = [N(\alpha)^T]^{-1}\tilde{M}(\alpha).$$

ii) The adjoint system to (5.2) and (5.3) is given by [1]

$$\begin{aligned} \dot{w} &= -A^T(t,\alpha)w \quad \text{if } t \geq 0, \\ w(t_i(\alpha)^+) &= (B_i^*(\alpha)^T)^{-1}w(t_i(\alpha)^-), \\ w(t_{-i}(\alpha)^+) &= (B_{*,i}(\alpha)^T)^{-1}w(t_{-i}(\alpha)^-). \end{aligned} \tag{6.13}$$

It is easy to check that, if $\psi(\alpha) \in [\mathcal{R}Q_+(\alpha) + \mathcal{N}Q_-(\alpha)]^\perp$, the function $\psi(t,\alpha)$ defined in (6.11) is a bounded solution of (6.13). We prove that if

$$\operatorname{span}\{\psi_1(\alpha), \dots, \psi_d(\alpha)\} = [\mathcal{R}Q_+(\alpha) + \mathcal{N}Q_-(\alpha)]^\perp$$

then $\{\psi_1(t,\alpha), \dots, \psi_d(t,\alpha)\}$ is a basis for the space of the bounded solutions of (6.13). Indeed, the fundamental matrix of (6.13) on $t \geq 0$ is $[X_+(t,\alpha))^T]^{-1}$, and the fundamental matrix of (6.13) on $t \leq 0$ is $[X_-(t,\alpha))^T]^{-1}$. As a consequence (6.13) has an exponential dichotomy on $\mathbb{R}_+$ and $\mathbb{R}_-$ with projections $(\mathbb{I} - Q_+^T)$ and $(\mathbb{I} - Q_-^T)$ respectively. So, the space of bounded solutions of (6.13), C^1 for $t \neq t_{\pm i}(\alpha)$, are those whose initial condition belongs to

$$\mathcal{R}(\mathbb{I} - Q_+^T(\alpha)) \cap \mathcal{N}(\mathbb{I} - Q_-^T(\alpha)) = (\mathcal{R}Q_+v)^\perp \cap (\mathcal{N}Q_-(\alpha))^\perp = (\mathcal{R}Q_+(\alpha) + \mathcal{N}Q_-(\alpha))^\perp.$$

Then the dimension of the space of solutions of (6.13), bounded on $\mathbb{R}$, is d and vectors $\{\psi_1(t,\alpha), \dots, \psi_d(t,\alpha)\}$ span this space.

As in [5,9] we see that if $x(t,\alpha)$ and $\psi(t,\alpha)$ are bounded solutions on $\mathbb{R}$ of (5.2)–(5.3) and (6.13) resp., both continuous for $t \neq t_{\pm i}(\alpha)$ then $\psi(t,\alpha)^T x(t,\alpha)$ is constant on $\mathbb{R}$.

7 An example

The simplest case of application of Theorem 6.2 is when $d = 1$ that is when

$$\mathcal{R}Q_+(\alpha) \cap \mathcal{N}Q_-(\alpha) = \operatorname{span}\{\dot{u}(0,\alpha)\}.$$

This condition is trivially satisfied when $n = 2$ since in this case $k = n - k = 1$. Moreover, when $n = 2$, we also have $\dim \mathcal{R}Q_+(\alpha) = \dim \mathcal{N}Q_-(\alpha) = 1$ and hence

$$\mathcal{R}Q_+(\alpha) = \mathcal{N}Q_-(\alpha) = \operatorname{span}\{\dot{u}(0,\alpha)\}. \tag{7.1}$$

In this section we consider examples of applications of Theorem 6.2 with $n = 2$, $m = 1$ and $d = 1$. Let

$$J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.$$

The following result that has been proved in [6]:

Proposition 7.1. *Consider the system in $\mathbb{R}^3$:*

$$\begin{aligned} \dot{x}_1 &= F_1(x_1, x_2, y), \\ \dot{x}_2 &= F_2(x_1, x_2, y), \\ \dot{y} &= \varepsilon g(x_1, x_2, y). \end{aligned} \tag{7.2}$$

and suppose that for any $\alpha \in \mathbb{R}$, the unperturbed equation

$$\begin{aligned} \dot{x}_1 &= F_1(x_1, x_2, \alpha), \\ \dot{x}_2 &= F_2(x_1, x_2, \alpha) \end{aligned} \tag{7.3}$$

has a solution $u(t,\alpha)$ satisfying assumptions $A_1) - A_5)$. Let

$$A(t,\alpha) = [a_{jk}(t,\alpha)]_{1\le j,k\le 2} := [F_{j,x_k}(u_1(t), u_2(t), \alpha)]_{1\le j,k\le 2},$$

$B_i(\alpha)$ as in (5.1) and

$$v(t,\alpha) := e^{-\int_0^t a_{11}(s,\alpha)+a_{22}(s,\alpha)ds} J\dot{u}(t,y_0) = e^{-\int_0^t a_{11}(s,\alpha)+a_{22}(s,\alpha)ds} \begin{pmatrix} -\dot{u}_2(t,\alpha) \\ \dot{u}_1(t,\alpha) \end{pmatrix}. \tag{7.4}$$

Then the space of bounded solution of the adjoint variational system are of the form

$$\psi(t,\alpha) = \begin{cases} \mu_{-N}(\alpha)v(t,\alpha) & \text{for } t \le t_{-N}(\alpha), \\ \mu_{-i}(\alpha)v(t,\alpha), & \text{for } t_{-i-1}(\alpha) < t \le t_{-i}(\alpha), \\ \mu_i(\alpha)v(t,\alpha), & \text{for } t_i(\alpha) \le t < t_{i+1}(\alpha), \\ \mu_N(\alpha)v(t,\alpha) & \text{for } t \ge t_N(\alpha) \end{cases}$$

where $\mu_{-N}(\alpha) \neq 0$ is arbitrary and, for any $i = 1, \ldots, N$,

$$\begin{aligned} \mu_{-i+1}(\alpha)v(t_{-i}(\alpha)^+,\alpha) &= \mu_{-i}(\alpha)[B_{-i}(\alpha)^T]^{-1} v(t_{-i}(\alpha)^-,\alpha), \\ \mu_i(\alpha)v(t_i(\alpha)^+,\alpha) &= \mu_{i-1}(\alpha)[B_i(\alpha)^T]^{-1} v(t_i(\alpha)^-,\alpha). \end{aligned} \tag{7.5}$$

Remark 7.2. i) From (7.5) we have

$$\begin{aligned} \mu_{-i+1}(\alpha)J\dot{u}(t_{-i}(\alpha)^+,\alpha)) &= \mu_{-i}(\alpha)[B_{-i}^T(\alpha)]^{-1} J\dot{u}(t_{-i}(\alpha)^-,\alpha)), \\ \mu_i(\alpha)J\dot{u}(t_i(\alpha)^+,\alpha)) &= \mu_{i-1}(\alpha)[B_i^T(\alpha)]^{-1} J\dot{u}(t_i(\alpha)^-,\alpha)) \end{aligned}$$

and then

$$\begin{aligned} \mu_i(\alpha)\|\dot{u}(t_i(\alpha)^+,\alpha))\|^2 &= \mu_i(\alpha)\langle J\dot{u}(t_i(\alpha)^+,\alpha)), J\dot{u}(t_i(\alpha)^+,\alpha))\rangle, \\ &= \mu_{i-1}(\alpha)\langle [B_i^T(\alpha)]^{-1} J\dot{u}(t_i(\alpha)^-,\alpha)), J\dot{u}(t_i(\alpha)^+,\alpha))\rangle \end{aligned}$$

and similarly

$$\begin{aligned} \mu_{-i+1}(\alpha)\|\dot{u}(t_{-i}(\alpha)^+,\alpha))\|^2 &= \mu_{-i}(\alpha)\langle J\dot{u}(t_{-i}(\alpha)^+,\alpha)), J\dot{u}(t_{-i}(\alpha)^+,\alpha))\rangle, \\ &= \mu_{-i}(\alpha)\langle [B_{-i}^T(\alpha)]^{-1} J\dot{u}(t_{-i}(\alpha)^-,\alpha)), J\dot{u}(t_{-i}(\alpha)^+,\alpha))\rangle. \end{aligned}$$

Hence all $\mu_i(\alpha)$'s can be computed in terms of $\dot{u}(t_i(\alpha)^\pm,\alpha))$.

ii) Since $\mu_{-N}(\alpha) \neq 0$ and all $B_i(\alpha)$, $B_{-i}(\alpha)$ are invertible, we see that $\mu_{\pm i}(\alpha) \neq 0$ for all $i = 0, \ldots, N$.

The next Proposition, proved in [6], states that in some circumstances all $\mu_i(\alpha)$'s are equal. This case is of particular interest, since then we can take $\psi(t,\alpha) = v(t,\alpha)$ and the Melnikov condition reads

$$\Delta(\alpha_0) = 0, \quad \operatorname{rank} \Delta'(\alpha_0) = d$$

where

$$\Delta(\alpha) := \int_{-\infty}^{\infty} e^{-\int_0^t a_{11}(s,\alpha)+a_{22}(s,\alpha)ds} \begin{pmatrix} -\dot{u}_2(t,\alpha) \\ \dot{u}_1(t,\alpha) \end{pmatrix}^T \begin{pmatrix} u_{1,\alpha}(t,\alpha) \\ u_{2,\alpha}(t,\alpha) \end{pmatrix} g(u(t,\alpha),\alpha,0)dt.$$

If, moreover, $a_{11}(t,\alpha) + a_{22}(t,\alpha) = 0$ we have

$$\Delta(\alpha) = \int_{-\infty}^{\infty} [\dot{u}_1(t,\alpha)u_{2,\alpha}(t,\alpha) - \dot{u}_2(t,\alpha)u_{1,\alpha}(t,\alpha)] g(u(t,\alpha),\alpha,0)dt. \tag{7.6}$$

Proposition 7.3. *Equations* (7.5) *are satisfied with* $\mu_i = 1$, $i = -N, \ldots, N$, *if and only if there exist* $\nu_i^{\pm}(\alpha)$, $i = 1, \ldots, N$, *such that*

$$J[f_{i+1}(u(t_{\pm i}(\alpha), \alpha), \alpha) - f_i(u(t_{\pm i}(\alpha), \alpha), \alpha)] = \nu_i(\alpha)^{\pm} h_x(u(t_{\pm i}(\alpha), \alpha), \alpha)^T. \tag{7.7}$$

For example, suppose

$$h(x, y) = x_k$$

where either $k = 1$ or $k = 2$. Recalling that

$$f_i(x, y) = \begin{pmatrix} F_1^i(x_1, x_2, y) \\ F_2^i(x_1, x_2, y) \end{pmatrix}$$

we get, omitting arguments (that can be either $(u(t_{-i}), y_0)$ or $(u(t_i), y_0)$) for simplicity:

$$J[f_{i+1} - f_i] = \begin{pmatrix} F_2^i - F_2^{i+1} \\ F_1^{i+1} - F_1^i \end{pmatrix}$$

and then (7.7) holds if and only if

$$F_k^i(u(t_{\pm i}(\alpha)), \alpha) = F_k^{i+1}(u(t_{\pm i}(\alpha)), \alpha) \tag{7.8}$$

for all $i = 1, \ldots, N$.

As a concrete example we consider the following two dimensional equation (see [8]):

$$\ddot{x} = \lambda p(t) \Phi(x)$$

where $\lambda \gg 1$ is a large parameter, $p(t) > 0$ is a positive, C^2, periodic function, and $\Phi(x)$ is a piecewise C^2 function such that

$$\Phi(x) = \begin{cases} \Phi_-(x) & \text{if } x < \frac{1}{2}, \\ \Phi_+(x) & \text{if } x > \frac{1}{2}. \end{cases}$$

Then $h(x_1, x_2) = x_1$ and the discontinuity manifold is $\mathcal{S} = \{x_1 = \frac{1}{2}\}$.

Taking $\lambda = \varepsilon^{-2}$ and changing the time scale $t \mapsto \varepsilon^{-1} t$, the equation reads

$$\begin{aligned} \ddot{x} &= p(y) \Phi(x), \\ \dot{y} &= \varepsilon \end{aligned} \tag{7.9}$$

or

$$\begin{aligned} \dot{x}_1 &= x_2, \\ \dot{x}_2 &= p(y) \Phi(x_1), \\ \dot{y} &= \varepsilon. \end{aligned}$$

We assume that $x = 0$, $\dot{x} = 0$ is a hyperbolic fixed point of equation $\ddot{x} = \Phi(x)$ with an associated solution $(u(t), \dot{u}(t))$, homoclinic to $(0, 0)$ and such that

$$\begin{aligned} 0 < u(t) < \frac{1}{2} &\quad \text{for } t < t_- \text{ or } t > t_+, \\ u(t) > \frac{1}{2} &\quad \text{for } t_- < t < t_+, \\ u(t_+) = u(t_-) = \frac{1}{2}, & \\ \dot{u}(t_\pm) \neq 0. & \end{aligned} \tag{7.10}$$

Then (7.9) has the family of homoclinic solutions

$$(u(t,\alpha),\dot{u}(t,\alpha)) = (u(t\sqrt{p(\alpha)}), \sqrt{p(\alpha)}\dot{u}(t\sqrt{p(\alpha)}))$$

that satisfy assumptions A_1)–A_4). Note that, according to assumption we have

$$t_\pm(\alpha) = \frac{t_\pm}{\sqrt{p(\alpha)}}$$

and

$$\left|\begin{pmatrix} u(t,\alpha) \\ \dot{u}(t,\alpha) \end{pmatrix}\right| \leq \sqrt{1+p(\alpha)}e^{-\delta t\sqrt{p(\alpha)}} \leq \sqrt{1+p_{\max}}e^{-\delta t\sqrt{p_{\min}}}$$

where $0 < p_{\min} := \min\{p(\alpha)\} < \max\{p(\alpha)\} := p_{\max}$.

As $F_1(x_1,x_2,y) = x_2$ is continuous and $h(x_1,x_2,y) = x_1$ we see that (7.8) is certainly satisfied. Then

$$\begin{aligned}\Delta(\alpha) = \int_{-\infty}^{\infty} \sqrt{p(\alpha)}\dot{u}(t\sqrt{p(\alpha)}) \left[\frac{p'(\alpha)}{2\sqrt{p(\alpha)}}\dot{u}(t\sqrt{p(\alpha)}) + \sqrt{p(\alpha)}\ddot{u}(t\sqrt{p(\alpha)})\frac{tp'(\alpha)}{2\sqrt{p(\alpha)})}\right] \\ - p(\alpha)\ddot{u}(t\sqrt{p(\alpha)}\dot{u}(t\sqrt{p(\alpha)})\frac{tp'(\alpha)}{2\sqrt{p(\alpha)})}dt = \frac{1}{2}p'(\alpha)\int_{-\infty}^{\infty} \dot{u}(t\sqrt{p(\alpha)})^2 dt \\ = \frac{p'(\alpha)}{2\sqrt{p(\alpha)}}\int_{-\infty}^{\infty} \dot{u}(t)^2 dt.\end{aligned}$$

As a consequence $\Delta(\alpha)$ has a simple zero at $\alpha = \alpha_0$ if and only if $p(\alpha)$ has a non degenerate critical point at $\alpha = \alpha_0$. From Theorem 6.2 we conclude with the following

Proposition 7.4. *Let $\Phi_\pm(x)$ be C^2-functions and suppose that*

$$\ddot{x} = \Phi(x) := \begin{cases} \Phi_-(x) & \text{if } 0 < x < \frac{1}{2}, \\ \Phi_+(x) & \text{if } x > \frac{1}{2} \end{cases}$$

has the hyperbolic fixed point $(u,\dot{u}) = (0,0)$ together with a homoclinic orbit such that (7.10) holds. Then, if $p(\alpha)$ is a periodic C^2-functions having a non-degenerate maximum (or minimum) at $\alpha = \alpha_0$ then there exists $\lambda_0 \gg 1$ and a unique, C^1, $\alpha(\lambda)$ such that $\lim_{\lambda\to\infty}\alpha(\lambda) = \alpha_0$ and for $\lambda > \lambda_0$ the perturbed equation

$$\ddot{x} = \lambda p(t)\Phi(x)$$

has a solution $(x(t,\lambda),\dot{x}(t,\lambda))$ such that

$$\sup_{t\in\mathbb{R}} |x(t,\lambda) - u(t, t\lambda^{-\frac{1}{2}} + \alpha(\lambda))| \to 0,$$
$$\sup_{t\in\mathbb{R}} |\dot{x}(t,\lambda) - \dot{u}(t, t\lambda^{-\frac{1}{2}} + \alpha(\lambda)))| \to 0$$

as $\lambda \to \infty$.

As a concrete example we take

$$\Phi_\pm(x) = \mp x, \quad p(y) = 2 + \sin y$$

so that system (7.9) reads

$$\begin{aligned} \ddot{x} &= (2+\sin(y))x, && x < \frac{1}{2}, \\ \ddot{x} &= -(2+\sin(y))x, && x > \frac{1}{2}, \\ \dot{y} &= \varepsilon. \end{aligned} \tag{7.11}$$

The homoclinic solution of the frozen system ($\varepsilon = 0$) is

$$u(t) = \begin{cases} \frac{e^{\frac{\pi}{4}}}{2} e^t & \text{if } t \le -\frac{\pi}{4}, \\ \frac{1}{\sqrt{2}} \cos t & \text{if } -\frac{\pi}{4} \le t \le \frac{\pi}{4}, \\ \frac{e^{\frac{\pi}{4}}}{2} e^{-t} & \text{if } t \ge \frac{\pi}{4}. \end{cases}$$

Solving $p'(\alpha) = \cos\alpha = 0$, we get $\alpha_1 = \frac{\pi}{2}$ and $\alpha_2 = \frac{3\pi}{2}$ with $p''(\alpha_{1,2}) = -\sin\alpha_{1,2} = \mp 1 \neq 0$. Now we add some numerical figures of solutions of (7.11) near

$$v(t) = u\left(t\sqrt{2+\sin(\alpha_1+\varepsilon t)}\right)$$

and

$$w(t) = u\left(t\sqrt{2+\sin(\alpha_2+\varepsilon t)}\right)$$

for ε small, say $\varepsilon = 0.1$ and for

$$y(0) \sim \alpha_{1,2}. \tag{7.12}$$

Note

$$v(0) = w(0) = u(0) = \frac{1}{\sqrt{2}}, \qquad \dot{v}(0) = \dot{w}(0) = \dot{u}(0) = 0.$$

Here we draw some pictures of the solutions of equation (7.11) where we take $y(0) = \frac{\pi}{2} \pm 0.05$. In all these pictures we take $\varepsilon = 0.1$. Figures 7.2–7.5 in the paper show the curves of $(t, x(t))$

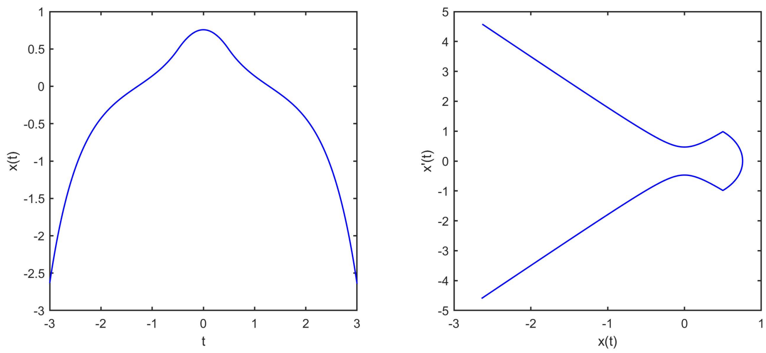

Figure 7.1: The plot of $(v(t), \dot{v}(t))$ for $t \in (-10, 10)$.

and $(x(t), x'(t))$ corresponding to $\varepsilon = 0.1$.

In the case of keeping initial conditions unchanged but taking $\varepsilon = 0.01$, we have the following Figures 7.6–7.9.

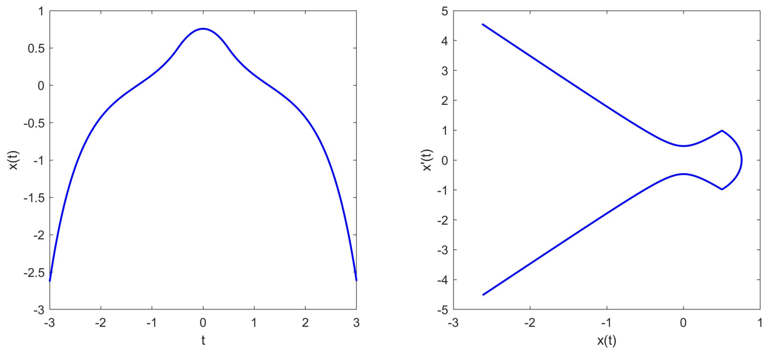

Figure 7.2: The plot of $(t, x(t))$ and $(x(t), \dot{x}(t))$ for $t = [-3, 3]$ with $y(0) = \frac{\pi}{2} + 0.05$, $x(0) = \frac{1}{\sqrt{2}} + 0.05$, $\dot{x}(0) = 0$. Note that the solution escapes very quickly from a neighbourhood of the fixed point $x = \dot{x} = 0$ as $t \to \pm\infty$.

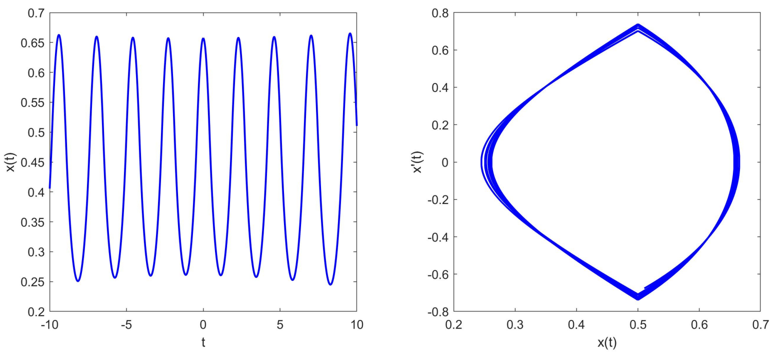

Figure 7.3: The plot of $(t, x(t))$ and $(x(t), \dot{x}(t))$ for $t = [-10, 10]$ with $y(0) = \frac{\pi}{2} + 0.05$, $x(0) = \frac{1}{\sqrt{2}} - 0.05$, $\dot{x}(0) = 0$. Here the solution looks like a periodic solution in the bounded domain $0.2 \leq x \leq 0.7$, $-0.8 \leq \dot{x} \leq 0.8$.

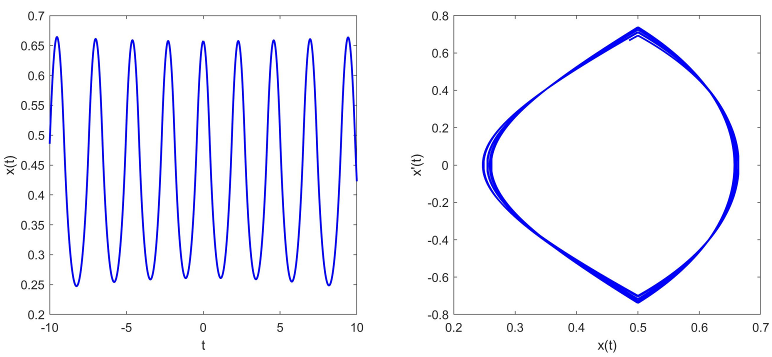

Figure 7.4: The plot of $(t, x(t))$ and $(x(t), \dot{x}(t))$ for $t = [-10, 10]$ with $y(0) = \frac{\pi}{2} - 0.05$, $x(0) = \frac{1}{\sqrt{2}} - 0.05$, $\dot{x}(0) = 0$. Also in this case the solution looks like a periodic solution in the bounded domain $0.2 \leq x \leq 0.7$, $-0.8 \leq \dot{x} \leq 0.8$.

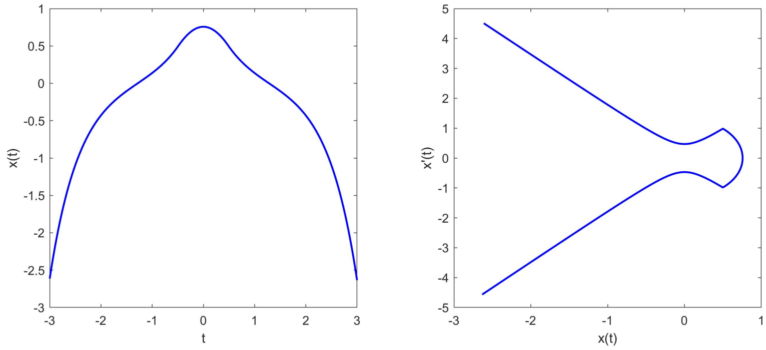

Figure 7.5: The plot of $(t, x(t))$ and $(x(t), \dot{x}(t))$ for $t = [-3, 3]$ with $y(0) = \frac{\pi}{2} - 0.05$, $x(0) = \frac{1}{\sqrt{2}} + 0.05$, $\dot{x}(0) = 0$. For these initial values the solution escapes very quickly from a neighbourhood of the fixed point $x = \dot{x} = 0$ as $t \to \pm\infty$.

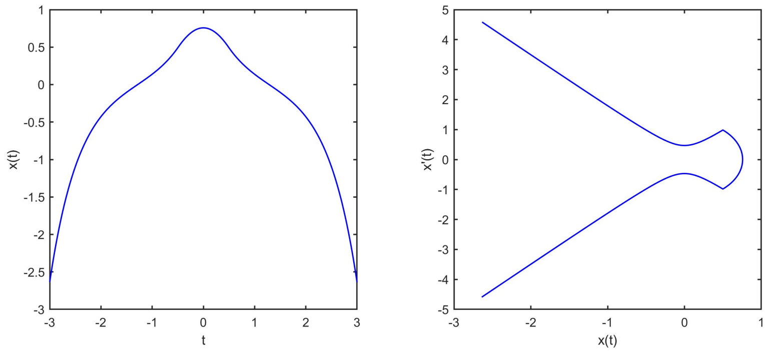

Figure 7.6: Corresponding to the case of $\varepsilon = 0.01$ in Figure 7.2.

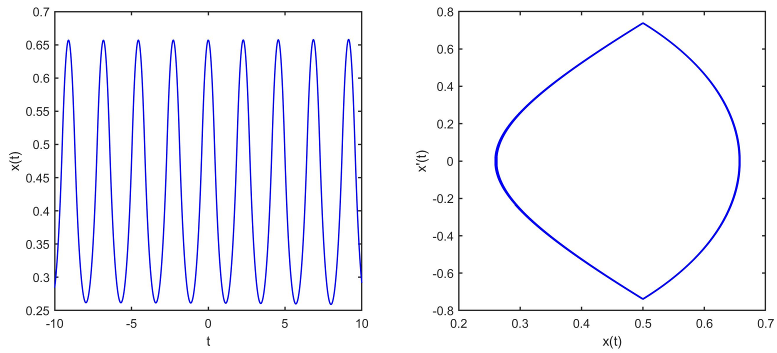

Figure 7.7: Corresponding to the case of $\varepsilon = 0.01$ in Figure 7.3.

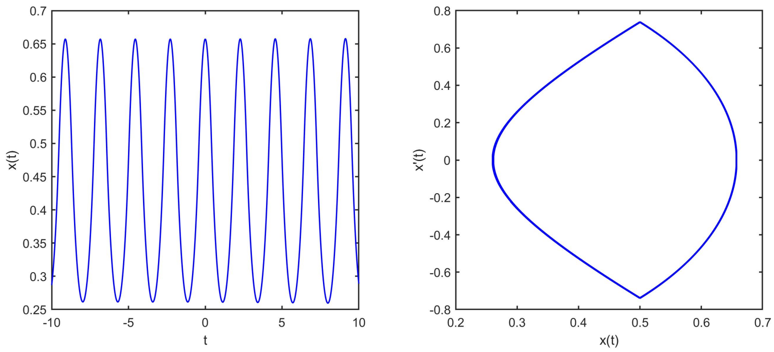

Figure 7.8: Corresponding to the case of $\varepsilon = 0.01$ in Figure 7.4.

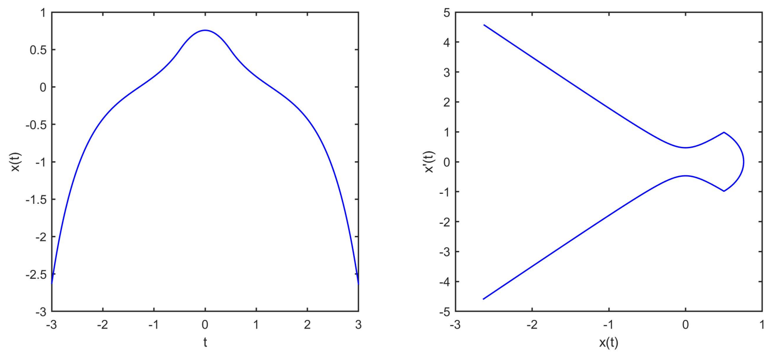

Figure 7.9: Corresponding to the case of $\varepsilon = 0.01$ in Figure 7.5.

8 Concluding remark

According to the results in [4], with the correction given in [5], the Melnikov function in the periodic case, with two discontinuity points and a family of periodic solutions $u(t,\alpha)$ of the unperturbed equation, is

$$\int_{-T(\alpha)/2}^{T(\alpha)/2} \psi_j(t,\alpha)^T f_y(u(t,\alpha),\alpha) y_\varepsilon(t,0,\alpha,0)\,dt \\ + \psi_j(t_*(\alpha)^+,\alpha)^T \frac{h_{y,*} y_{\varepsilon,*}}{h_{x,*} f_{+,*}} (f_{-,*} - f_{+,*}) + \psi_j(t^*(\alpha)^+,\alpha)^T \frac{h_y^* y_\varepsilon^*}{h_x^* f_-^*} (f_+^* - f_-^*).$$

In the following we prove that $-M(\alpha)$ extends the above expression to the heteroclinic case (i.e. with ∞ replacing $T(\alpha)$) with several discontinuity points.

Differentiating $\dot u(t,y) = f(u(t,y),y)$ with respect to y we see that, for $t \neq t_{\pm i}(\alpha)$, $i = 1,\dots,N$:

$$\dot u_y(t,\alpha) = A(t,\alpha) u_y(t,\alpha) + f_y(u(t,\alpha),\alpha)$$

and then

$$\frac{d}{dt}(u_y(t,\alpha) y_\varepsilon(t,0,\alpha,0)) = \dot u_y(t,\alpha) y_\varepsilon(t,0,\alpha,0) + u_y(t,\alpha) \dot y_\varepsilon(t,0,\alpha,0) \\ = A(t,\alpha) u_y(t,\alpha) y_\varepsilon(t,0,\alpha,0) + f_y(u(t,\alpha),\alpha) y_\varepsilon(t,0,\alpha,0) + u_y(t,\alpha) g(u(t,\alpha),\alpha).$$

So

$$\begin{aligned}
&\int_{-\infty}^{\infty} \psi_j^T(t,\alpha)u_y(t,\alpha)g(u(t,\alpha),\alpha,0)dt \\
&\quad = \int_{-\infty}^{\infty} \psi_j^T(t,\alpha)\left[\frac{d}{dt}(u_y(t,\alpha)y_\varepsilon(t,0,\alpha,0)) - A(t,\alpha)u_y(t,\alpha)y_\varepsilon(t,0,\alpha,0)\right. \\
&\qquad \left. - f_y(u(t,\alpha),\alpha)y_\varepsilon(t,0,\alpha,0)\right]dt \\
&\quad = \int_{-\infty}^{\infty} \psi_j^T(t,\alpha)\frac{d}{dt}(u_y(t,\alpha)y_\varepsilon(t,0,\alpha,0)) + \dot{\psi}_j^T(t,\alpha)u_y(t,\alpha)y_\varepsilon(t,0,\alpha,0) \\
&\qquad - \psi_j^T(t,\alpha)f_y(u(t,\alpha),\alpha)y_\varepsilon(t,0,\alpha,0)dt \\
&\quad = \int_{-\infty}^{\infty} \frac{d}{dt}[\psi_j^T(t,\alpha)u_y(t,\alpha)y_\varepsilon(t,0,\alpha,0)] - \psi_j^T(t,\alpha)f_y(u(t,\alpha),\alpha)y_\varepsilon(t,0,\alpha,0)dt.
\end{aligned}$$

Then the j-th component of $-M(\alpha)$, say $-M_j(\alpha)$, is

$$\begin{aligned}
-M_j(\alpha) = &\int_{-\infty}^{\infty} \psi_j^T(t,\alpha)f_y(u(t,\alpha),\alpha)y_\varepsilon(t,0,\alpha,0)dt \\
&- \int_{-\infty}^{\infty} \frac{d}{dt}[\psi_j^T(t,\alpha)u_y(t,\alpha)y_\varepsilon(t,0,\alpha,0)]dt.
\end{aligned}$$

Using the continuity of $y_\varepsilon(t,\xi,\alpha,\eta)$ we get:

$$\begin{aligned}
&\int_{-\infty}^{\infty} \frac{d}{dt}[\psi_j^T(t,\alpha)u_y(t,\alpha)y_\varepsilon(t,0,\alpha,0)]dt \\
&\quad = \int_{-\infty}^{t_{-N}(\alpha)} \frac{d}{dt}[\psi_j^T(t,\alpha)u_y(t,\alpha)y_\varepsilon(t,0,\alpha,0)]dt \\
&\qquad + \sum_{i=-N}^{N-1} \int_{t_i(\alpha)}^{t_{i+1}(\alpha)} \frac{d}{dt}[\psi_j^T(t,\alpha)u_y(t,\alpha)y_\varepsilon(t,0,\alpha,0)]dt \\
&\qquad + \int_{t_N(\alpha)}^{\infty} \frac{d}{dt}[\psi_j^T(t,\alpha)u_y(t,\alpha)y_\varepsilon(t,0,\alpha,0)]dt \\
&\quad = \psi_j^T(t_{-N}(\alpha)^-,\alpha)u_y(t_{-N}(\alpha)^-,\alpha)y_\varepsilon(t_{-N}(\alpha),0,\alpha,0) \\
&\qquad + \sum_{i=-N}^{N-1} \Big[\psi_j^T(t_{i+1}(\alpha)^-,\alpha)u_y(t_{i+1}(\alpha)^-,\alpha)y_\varepsilon(t_{i+1}(\alpha),0,\alpha,0) \\
&\qquad - \psi_j^T(t_i(\alpha)^+,\alpha)u_y(t_i(\alpha)^+,\alpha)y_\varepsilon(t_i(\alpha),0,\alpha,0)\Big] \\
&\qquad - \psi_j^T(t_N(\alpha)^+,\alpha)u_y(t_N(\alpha)^+,\alpha)y_\varepsilon(t_N(\alpha),0,\alpha,0) \\
&\quad = \psi_j^T(t_{-N}(\alpha)^-,\alpha)u_y(t_{-N}(\alpha)^-,\alpha)y_\varepsilon(t_{-N}(\alpha),0,\alpha,0) \\
&\qquad + \sum_{i=-N+1}^{N} \psi_j^T(t_i(\alpha)^-,\alpha)u_y(t_i(\alpha)^-,\alpha)y_\varepsilon(t_i(\alpha),0,\alpha,0) \\
&\qquad - \sum_{i=-N}^{N-1} \psi_j^T(t_i(\alpha)^+,\alpha)u_y(t_i(\alpha)^+,\alpha)y_\varepsilon(t_i(\alpha),0,\alpha,0) \\
&\qquad - \psi_j^T(t_N(\alpha)^+,\alpha)u_y(t_N(\alpha)^+,\alpha)y_\varepsilon(t_N(\alpha),0,\alpha,0)
\end{aligned}$$

$$
\begin{aligned}
&= \psi_j^T(t_{-N}(\alpha)^-,\alpha)u_y(t_{-N}(\alpha)^-,\alpha)y_\varepsilon(t_{-N}(\alpha),0,\alpha,0)\\
&\quad + \sum_{i=-N+1}^{N-1}[\psi_j^T(t_i(\alpha)^-,\alpha)u_y(t_i(\alpha)^-,\alpha) - \psi_j^T(t_i(\alpha)^+,\alpha)u_y(t_i(\alpha)^+,\alpha)]y_\varepsilon(t_i(\alpha),0,\alpha,0)\\
&\quad + \psi_j^T(t_N(\alpha)^-,\alpha)u_y(t_N(\alpha)^-,\alpha)y_\varepsilon(t_N(\alpha),0,\alpha,0)\\
&\quad - \psi_j^T(t_{-N}(\alpha)^+,\alpha)u_y(t_{-N}(\alpha)^+,\alpha)y_\varepsilon(t_{-N}(\alpha),0,\alpha,0)\\
&\quad - \psi_j^T(t_N(\alpha)^+,\alpha)u_y(t_N(\alpha)^+,\alpha)y_\varepsilon(t_N(\alpha),0,\alpha,0)\\
&= \sum_{i=-N}^{N}[\psi_j^T(t_i(\alpha)^-,\alpha)u_y(t_i(\alpha)^-,\alpha) - \psi_j^T(t_i(\alpha)^+,\alpha)u_y(t_i(\alpha)^+,\alpha)]y_\varepsilon(t_i(\alpha),0,\alpha,0)\\
&= \sum_{i=-N,i\neq 0}^{N}[\psi_j^T(t_i(\alpha)^-,\alpha)u_y(t_i(\alpha)^-,\alpha) - \psi_j^T(t_i(\alpha)^+,\alpha)u_y(t_i(\alpha)^+,\alpha)]y_\varepsilon(t_i(\alpha),0,\alpha,0).
\end{aligned}
$$

The last equality follows from the fact that $\psi_j(t,\alpha)$ and $u_y(t,\alpha)$ are continuous at $t = t_0(\alpha) = 0$.

Next, from (3.6)–(6.11) we see that, for any $\ell = \pm 1,\dots,\pm N$, we have

$$\psi_j^T(t_\ell(\alpha)^-,\alpha) = \psi_j^T(t_\ell(\alpha)^+,\alpha)B_\ell(\alpha)$$

Hence:

$$
\begin{aligned}
&\int_{-\infty}^{\infty}\frac{d}{dt}[\psi_j^T(t,\alpha)u_y(t,\alpha)y_\varepsilon(t,0,\alpha,0)]dt\\
&\qquad \sum_{\ell=-N,\ell\neq 0}^{N}\psi_j^T(t_\ell(\alpha)^+,\alpha)[B_\ell(\alpha)u_y(t_\ell(\alpha)^-,\alpha) - u_y(t_\ell(\alpha)^+,\alpha)]y_\varepsilon(t_\ell(\alpha),0,\alpha,0).
\end{aligned}
$$

From (5.1) we obtain

$$
\begin{aligned}
&B_\ell(\alpha)u_y(t_\ell(\alpha)^-,\alpha) - u_y(t_\ell(\alpha)^-,\alpha)\\
&\qquad = -\frac{h_x(u(t_\ell(\alpha),\alpha),\alpha)u_y(t_\ell(\alpha)^-,\alpha)}{h_x(u(t_\ell(\alpha),\alpha),\alpha)\dot u(t_\ell(\alpha)^-,\alpha),\alpha)}(\dot u(t_\ell(\alpha)^-,\alpha) - \dot u(t_\ell(\alpha)^+,\alpha)).
\end{aligned}
$$

Differentiating $h(u(t_\ell(\alpha),\alpha),\alpha) = c_{|\ell|}$ with respect to α we get

$$
\begin{aligned}
&h_x(u(t_\ell(\alpha),\alpha),\alpha)u_y(t_\ell(\alpha)^-,\alpha)\\
&\qquad = -h_x(u(t_\ell(\alpha),\alpha),y)\dot u(t_\ell(\alpha)^-,\alpha)t'_\ell(\alpha) - h_y(u(t_\ell(\alpha),\alpha),\alpha)
\end{aligned}
$$

and then

$$
\begin{aligned}
&B_\ell(\alpha)u_y(t_\ell(\alpha)^-,\alpha) - u_y(t_\ell(\alpha)^-,\alpha)\\
&\quad = \frac{h_x(u(t_\ell(\alpha),\alpha),\alpha)\dot u(t_\ell(\alpha)^-,y)t'_\ell(\alpha) + h_y(u(t_\ell(\alpha),\alpha),\alpha)}{h_x(u(t_\ell(\alpha),\alpha),\alpha)\dot u(t_\ell(\alpha)^-,\alpha)}(\dot u(t_\ell(\alpha)^-,\alpha) - \dot u(t_\ell(\alpha)^+,\alpha))\\
&\quad = \left[t'_\ell(\alpha) + \frac{h_y(u(t_\ell(\alpha),\alpha),\alpha)}{h_x(u(t_\ell(\alpha),\alpha),\alpha)\dot u(t_\ell(\alpha)^-,\alpha)}\right](\dot u(t_\ell(\alpha)^-,\alpha) - \dot u(t_\ell(\alpha)^+,\alpha)).
\end{aligned}
$$

So

$$
\begin{aligned}
&B_\ell(\alpha)u_y(t_\ell(\alpha)^-,\alpha) - u_y(t_\ell(\alpha)^+,\alpha)\\
&\qquad = u_y(t_\ell(\alpha)^-,\alpha) - u_y(t_\ell(\alpha)^+,\alpha) + t'_\ell(\alpha)[\dot u(t_\ell(\alpha)^-,\alpha) - \dot u(t_\ell(\alpha)^+,\alpha)]\\
&\qquad\quad + \frac{h_y(u(t_\ell(\alpha),\alpha),\alpha)}{h_x(u(t_\ell(\alpha),\alpha),\alpha)\dot u(t_\ell(\alpha)^-,\alpha)}(\dot u(t_\ell(\alpha)^-,\alpha) - \dot u(t_\ell(\alpha)^+,\alpha)).
\end{aligned}
\tag{8.1}
$$

Next, for $t_\ell(\alpha) < t < t_{\ell+1}(\alpha)$ we have:

$$u(t,\alpha) = u(t_\ell(\alpha)^-,\alpha) + \int_{t_\ell(\alpha)}^{t} \dot{u}(s,\alpha)ds.$$

Hence

$$u_y(t_\ell(\alpha)^+,\alpha) = \dot{u}(t_\ell(\alpha)^-,\alpha)t'_\ell(\alpha) + u_y(t_\ell(\alpha)^-,\alpha) - \dot{u}(t_\ell(\alpha)^+,\alpha)t'_\ell(\alpha)$$

and then

$$u_y(t_\ell(\alpha)^-,\alpha) - u_y(t_\ell(\alpha)^+,\alpha) = [\dot{u}(t_\ell(\alpha)^+,\alpha) - \dot{u}(t_\ell(\alpha)^-,\alpha)]t'_\ell(\alpha). \tag{8.2}$$

Plugging (8.2) into (8.1) we finally obtain:

$$\begin{aligned}&[B_\ell(\alpha)u_y(t_\ell(\alpha)^-,\alpha) - u_y(t_\ell(\alpha)^+,\alpha)]y_\varepsilon(t_\ell(\alpha),0,\alpha,0)\\ &\quad = \frac{h_y(u(t_\ell(\alpha),\alpha),\alpha)y_\varepsilon(t_\ell(\alpha),0,\alpha,0)}{h_x(u(t_\ell(\alpha),\alpha),\alpha)\dot{u}(t_\ell(\alpha)^-,\alpha)}(\dot{u}(t_\ell(\alpha)^-,\alpha) - \dot{u}(t_\ell(\alpha)^+,\alpha))\end{aligned}$$

Putting everything together we finally get:

$$\begin{aligned}-M_j(\alpha) = &\int_{-\infty}^{\infty} \psi_j^T(t,\alpha)f_y(u(t,\alpha),\alpha)y_\varepsilon(t,0,\alpha,0)dt\\ &+ \sum_{i=1}^{N} \psi_j^T(t_{-i}(\alpha)^+,\alpha)\frac{h_y(u(t_{-i}(\alpha),\alpha),\alpha)y_\varepsilon(t_{-i}(\alpha),0,\alpha,0)}{h_x(u(t_{-i}(\alpha),\alpha),\alpha)f_{i+1}(u(t_{-i}(\alpha),\alpha),\alpha)}\\ &\cdot (f_i(u(t_{-i}(\alpha),\alpha),\alpha) - f_{i+1}(u(t_{-i}(\alpha),\alpha),\alpha))\\ &+ \sum_{i=1}^{N} \psi_j^T(t_i(\alpha)^+,\alpha)\frac{h_y(u(t_i(\alpha),\alpha),\alpha)y_\varepsilon(t_i(\alpha),0,\alpha,0)}{h_x(u(t_i(\alpha),\alpha),\alpha)f_i(u(t_i(\alpha),\alpha),\alpha)}\\ &\cdot (f_{i+1}(u(t_i(\alpha),\alpha),\alpha) - f_i(u(t_i(\alpha),\alpha),\alpha)).\end{aligned} \tag{8.3}$$

This completes the proof that $-M(\alpha)$ extends the Melnikov function for the periodic case with two discontinuity points to the heteroclinic case with a finite number of discontinuity points.

Abstract. In this short note, we provide a self-contained proof for the criterion $\nabla u \in L^{\frac{5}{2}}(0,T;L^2(\mathbb{R}^3))$ to Navier–Stokes equations energy balance, which improves some recent results on this problem.

Keywords: Navier–Stokes equations, energy equality, distributional solutions.

2020 Mathematics Subject Classification: 35Q35, 76D03, 35B65.

1 Introduction

We are interested in the energy balance of distributional solutions to Navier–Stokes equations

$$\begin{cases} \partial_t u + u\cdot\nabla u - \Delta u + \nabla p = 0, & x\in\mathbb{R}^3, t>0 \\ \nabla\cdot u = 0, & x\in\mathbb{R}^3, t>0 \\ u|_{t=0} = u_0(x), & x\in\mathbb{R}^3. \end{cases} \tag{1.1}$$

It is well known since the work of Leray [8] and Hopf [6], that for any $u_0 \in L^2_\sigma(\mathbb{R}^3)$ one can construct a global weak solutions to (1.1), namely, a function u that, for each $T>0$, is in the class

$$u \in L^\infty(0,T;L^2_\sigma(\mathbb{R}^3)) \cap L^2(0,T;H^1(\mathbb{R}^3)) \tag{1.2}$$

and solves (1.1) in a distributional sense. Here, $L^2_\sigma(\mathbb{R}^3)$ is the subspace of $L^2(\mathbb{R}^3)$ of divergence-free vector functions. In addition, such a u satisfies the so-called energy inequality:

$$\|u(t)\|^2_{L^2} + 2\int_0^t \|\nabla u(\tau)\|^2_{L^2} d\tau \le \|u_0\|^2_{L^2}, \qquad \forall\, t\ge 0. \tag{1.3}$$

Much about the solutions of the Navier–Stokes equation is unknown, including uniqueness and regularity. The main barrier is the fact that the energy equality, which states that for any smooth solution u, it obeys the following energy balance:

$$\|u(t)\|^2_{L^2} + 2\int_0^t \|\nabla u(\tau)\|^2_{L^2} d\tau = \|u_0\|^2_{L^2}, \qquad \forall\, t\ge 0. \tag{1.4}$$

✉ Email: 2022994823@nit.edu.cn; wufan0319@yeah.net

A natural question immediately arises: does any Leray–Hopf weak (distributional) solution of the Navier–Stokes equations automatically satisfy the energy balance (1.4)? To date this question remains open, and only conditional results are available.

Energy equality is clearly a prerequisite for regularity, and can be a first step in proving conditional regularity results [2,3,11,12]. Lions [9] and Ladyzhenskaya [7] proved independently that a Leray–Hopf weak solution satisfy the (global) energy equality (1.4) under the additional assumption $u \in L^4L^4$. Shinbrot [13] generalized the Lions–Ladyzhenskaya condition to

$$u \in L^r(0,T;L^s(\mathbb{R}^d)) \quad \text{with} \quad \frac{2}{r}+\frac{2}{s} \leq 1, s \geq 4. \tag{1.5}$$

Recently, Yu [14] given a new proof to the Shinbrot energy conservation criterion. In addition, Berselli and Chiodaroli in [1] prove some new energy balance criteria in terms of the gradient of the velocity. Specially, they showed that

$$\nabla u \in L^{\frac{5}{2}}(0,T;L^2(\Omega)) \tag{1.6}$$

can ensure the energy identity.

From the PDEs point of view, it is significant to study the motion of distributional (very weak) solutions of fluid equations, see Definition 1.1. In this regard, there is not any available regularity on velocity field u, apart the solution being in $L^2_{\text{loc}}\left(\mathbb{R}^3 \times [0,T)\right)$. Recently, The famous mathematician Giovanni P. Galdi [4,5] systematically studied the relation between very weak and Leray–Hopf solutions to Navier–Stokes equations, and he first proved that if distributional solution in $L^4(0,T;L^4(\mathbb{R}^3))$, and with initial data u_0 in $L^2(\mathbb{R}^3)$, then energy equality (1.4) holds true, in particular, he emphasized that the requirement (1.2) is entirely redundant. The key observation is the use of the duality argument and the above conditions to improve the regularity of the solution (i.e., $L^\infty\left(0,T;L^2\left(\mathbb{R}^3\right)\right) \cap L^2\left(0,T;H^1\left(\mathbb{R}^3\right)\right)$).

As everyone knows, in fluid mechanics, the gradient of velocity(∇u) is an important physical quantity. Objective of this note is to prove that control the gradient of velocity, i.e., $\nabla u \in L^{\frac{5}{2}}(L^2(\mathbb{R}^3))$ along with the (necessary) condition $u_0 \in L^2_\sigma(\mathbb{R}^3)$ can ensure the energy balance. More precisely, setting

$$\mathcal{D}_T := \{\varphi \in C_0^\infty(\mathbb{R}^3 \times [0,T)) : \ \operatorname{div} \varphi = 0\}.$$

Definition 1.1 (Distributional solution)**.** Let $u_0 \in L^2(\mathbb{R}^3)$ with $\nabla \cdot u_0 = 0$, $T > 0$. The function $u \in L^2_{\text{loc}}\left(\mathbb{R}^3 \times [0,T)\right)$ is a distributional solution to the Navier–Stokes equations (1.1) if

1. for any $\Phi \in \mathcal{D}_T$, we have

$$\int_0^T \int_{\mathbb{R}^3} u \cdot (\partial_t \Phi + \Delta \Phi + u \cdot \nabla \Phi) dx dt = -\int_{\mathbb{R}^3} u(x,0) \cdot \Phi(x,0) dx;$$

2. for any $\varphi \in C_0^\infty(\mathbb{R}^3)$, it holds that

$$\int_{\mathbb{R}^3} u \cdot \nabla \varphi dx = 0,$$

for a.e. $t \in (0,T)$.

We will show the following.

Theorem 1.2. *Suppose that* $u \in L^2_{\text{loc}}\left(\mathbb{R}^3 \times [0,T)\right)$ *be a distributional solution in the sense of Definition 1.1 to the Navier–Stokes (1.1). If*

$$\nabla u \in L^{\frac{5}{2}}\left(0,T;L^2(\mathbb{R}^3)\right),$$

then

$$\int_{\mathbb{R}^3} |u(t,x)|^2 dx + 2\int_0^t \int_{\mathbb{R}^3} |\nabla u(x,\tau)|^2 dx d\tau = \int_{\mathbb{R}^3} |u_0|^2 \, dx$$

for any $t \in [0,T]$.

Remark 1.3. From a purely mathematical perspective, it seems that a new strategy for studying the energy balance of distributional solutions based on gradient of velocity, which may be applied to other incompressible fluid equations.

Remark 1.4. Note that this result is supercritical with respect to the Prodi–Serrin scaling since $\frac{3}{p} + \frac{2}{q} = \frac{3}{2} + \frac{4}{5} > 2$, showing that the energy balance holds even if one does not expect the full regularity of solutions to hold.

Remark 1.5. Berselli and Chiodaroli [1] obtained energy equality via $\nabla u \in L^{\frac{5}{2}}\left(0,T;L^2(\Omega)\right)$, however, we want to emphasize is that the finite energy ($u \in L^\infty L^2 \cap L^2 H^1$) plays a key role in their proof.

2 Proof of Theorem 1.2

This section is devoted to proof of Theorem 1.2. For the sake of simplicity, we will proceed as if the solution is differentiable in time. The extra arguments needed to mollify in time are straightforward.

Let $\eta : \mathbb{R}^3 \to \mathbb{R}$ be a standard mollifier, i.e. $\eta(x) = Ce^{\frac{1}{|x|^2-1}}$ for $|x| < 1$ and $\eta(x) = 0$ for $|x| \geqslant 1$, where constant $C > 0$ selected such that $\int_{\mathbb{R}^3} \eta(x)\mathrm{d}x = 1$. For any $\varepsilon > 0$, we define the rescaled mollifier $\eta_\varepsilon(x) = \varepsilon^{-3}\eta\left(\frac{x}{\varepsilon}\right)$. For any function $f \in L^1_{\text{loc}}(\mathbb{R}^3)$, its mollified version is defined as

$$f^\varepsilon(x) = (f * \eta_\varepsilon)(x) = \int_{\mathbb{R}^3} \eta_\varepsilon(x-y)f(y)\mathrm{d}y.$$

If $f \in W^{1,p}(\mathbb{R}^3)$, the following local approximation is well known

$$f^\varepsilon(x) \to f \quad \text{in } W^{1,p}_{\text{loc}}(\mathbb{R}^3) \quad \forall p \in [1,\infty).$$

The crucial ingredient to prove Theorem 1.2 is the following lemmas.

Lemma 2.1 ([10])**.** *Let* ∂ *be a partial derivative in one direction. Let* $f, \partial f \in L^p\left(\mathbb{R}^+ \times \mathbb{R}^3\right)$, $g \in L^q\left(\mathbb{R}^+ \times \mathbb{R}^d\right)$ *with* $1 \leq p,q \leq \infty$, *and* $\frac{1}{p} + \frac{1}{q} \leq 1$. *Then, we have*

$$\|\partial(fg) * \eta_\varepsilon - \partial\left(f(g*\eta_\varepsilon)\right)\|_{L^r(\mathbb{R}^+\times\mathbb{R}^3)} \leq C\|\partial f\|_{L^p\left(\mathbb{R}^+\times\mathbb{R}^d\right)}\|g\|_{L^q(\mathbb{R}^+\times\mathbb{R}^3)}$$

for some constant $C > 0$ *independent of* ε, f *and* g, *and with* $\frac{1}{r} = \frac{1}{p} + \frac{1}{q}$. *In addition,*

$$\partial(fg) * \eta_\varepsilon - \partial\left(f(g*\eta_\varepsilon)\right) \to 0 \quad \text{in } L^r\left(\mathbb{R}^+ \times \mathbb{R}^3\right)$$

as $\varepsilon \to 0$, *if* $r < \infty$.

Lemma 2.2. *Let $u_0 \in L^2(\mathbb{R}^3)$ with $\nabla \cdot u_0 = 0$ and let u be a distributional solution in the sense of Definition 1.1 to the Navier–Stokes equations (1.1) and satisfies*

$$\nabla u \in L^{\frac{5}{2}}\left(0, T; L^2(\mathbb{R}^3)\right),$$

then we have

$$\sup_{t\geq 0} \|u^\varepsilon(\cdot,t)\|_{L^2}^2 + \int_0^t \int_{\mathbb{R}^3} |\nabla u^\varepsilon|^2 dx d\tau \leq K, \quad \forall\, t \in [0,T],$$

where K is a constant depending only on $\|u_0\|_{L^2}$ and $\int_0^T \|\nabla u\|_{L^2}^{\frac{5}{2}} dt$.

Remark 2.3. Lemma 2.2 shows distributional solution u falls into the class of Leray–Hopf weak solutions provided that $\nabla u \in L^{\frac{5}{2}}\left(0, T; L^2(\mathbb{R}^3)\right)$.

Proof of Lemma 2.2. Multiplying $(1.1)_1$ by $(u^\varepsilon)^\varepsilon$, then integrating over $(0,T) \times \mathbb{R}^3$, we infer that

$$\frac{1}{2}\frac{d}{dt}\int_{\mathbb{R}^3} |u^\varepsilon|^2 dx + \int_{\mathbb{R}^3} |\nabla u^\varepsilon|^2 dx = -\int_{\mathbb{R}^3} \operatorname{div}(u \otimes u)^\varepsilon \cdot u^\varepsilon dx. \tag{2.1}$$

Indeed, taking advantage of the interpolation inequality, Hölder's inequality and Young's inequality, we know that

$$\begin{aligned}
\left| -\int_{\mathbb{R}^3} \operatorname{div}(u \otimes u)^\varepsilon \cdot u^\varepsilon dx \right| &\leq C\|(u\cdot\nabla u)\|_{L^{\frac{3}{2}}} \|u^\varepsilon\|_{L^3} \\
&\leq C\|u\|_{L^6}\|\nabla u\|_{L^2}\|u^\varepsilon\|_{L^3} \\
&\leq C\|\nabla u\|_{L^2}^2\|u^\varepsilon\|_{L^3} \\
&\leq C\|\nabla u\|_{L^2}^2\|u^\varepsilon\|_{L^2}^{\frac{1}{2}}\|u^\varepsilon\|_{L^6}^{\frac{1}{2}} \\
&\leq C\|\nabla u\|_{L^2}^{\frac{5}{2}}\left(\|u^\varepsilon\|_{L^2}^2 + 1\right).
\end{aligned} \tag{2.2}$$

Then substituting estimates (2.2) into (2.1), we arrive at

$$\frac{d}{dt}\int_{\mathbb{R}^3} |u^\varepsilon|^2 dx + \int_{\mathbb{R}^3} |\nabla u^\varepsilon|^2 dx \leq C\|\nabla u\|_{L^2}^{\frac{5}{2}}\left(\|u^\varepsilon\|_{L^2}^2 + 1\right). \tag{2.3}$$

Applying Gronwall's inequality to see that

$$\begin{aligned}
\sup_{t\geq 0} \|u^\varepsilon(\cdot,t)\|_{L^2}^2 + \int_0^t \int_{\mathbb{R}^3} |\nabla u^\varepsilon|^2 dx d\tau &\leq \|u_0\|_{L^2}^2 \exp C \int_0^t \|\nabla u\|_{L^2}^{\frac{5}{2}} ds \\
&\leq K,
\end{aligned} \tag{2.4}$$

for all $t \in [0,T]$, where K is a constant depending only on initial data u_0 and $\int_0^T \|\nabla u\|_{L^2}^{\frac{5}{2}} dt$. Let $\varepsilon \to 0$ in (2.4), one has

$$\sup_{t\geq 0} \|u(\cdot,t)\|_{L^2}^2 + \int_0^t \int_{\mathbb{R}^3} |\nabla u|^2 dx d\tau \leq K. \tag{2.5}$$

Then we complete the proof of Lemma 2.2. □

Proof of Theorem 1.2. With Lemma 2.1 and Lemma 2.2 in hand, we are ready to prove our main result. First, we appeal to $u \in L^\infty\left(L^2\right) \cap L^{\frac{5}{2}}(H^1)$, by interpolation inequality we show that

$$\|u\|_{L^4} \leq \|u\|_{L^2}^{\frac{1}{4}}\|u\|_{L^6}^{\frac{3}{4}},$$

By integration in $(0,T)$ one easily proves that the estimate

$$\int_0^T \|u\|_{L^4}^{\frac{10}{3}} dt \le \int_0^T \|u\|_{L^6}^{\frac{5}{2}} \|u\|_{L^2}^{\frac{5}{6}} dt \le \int_0^T \|\nabla u\|_{L^2}^{\frac{5}{2}} \|u\|_{L^2}^{\frac{5}{6}} dt \le C. \tag{2.6}$$

Next, modifying the momentum equation $(1.1)_1$ and taking the inner-product with u^ε, thus we have

$$\int_{\mathbb{R}^3} u^\varepsilon \left(\partial_t u + u \cdot \nabla u - \Delta u + \nabla p\right)^\varepsilon dx = 0. \tag{2.7}$$

This yields

$$\frac{1}{2}\frac{d}{dt}\int_{\mathbb{R}^3} |u^\varepsilon|^2 dx + \int_{\mathbb{R}^3} |\nabla u^\varepsilon|^2 dx = -\int_{\mathbb{R}^3} \operatorname{div}(u \otimes u)^\varepsilon \cdot u^\varepsilon dx. \tag{2.8}$$

Clearly,

$$\int_{\mathbb{R}^3} |u^\varepsilon|^2 dx - \int_{\mathbb{R}^3} |u_0^\varepsilon|^2 dx + 2\int_0^t \int_{\mathbb{R}^3} |\nabla u^\varepsilon|^2 dx d\tau = -2\int_0^t \int_{\mathbb{R}^3} \operatorname{div}(u \otimes u)^\varepsilon \cdot u^\varepsilon dx d\tau. \tag{2.9}$$

Notice that the incompressible condition $\operatorname{div} u = 0$ ensures

$$-2\int_0^t \int_{\mathbb{R}^3} \operatorname{div}(u \otimes u^\varepsilon) \cdot u^\varepsilon dx d\tau = 0,$$

by using Hölder's equality and Lemma 2.1, one has

$$\begin{aligned}
&-2\int_0^t \int_{\mathbb{R}^3} \operatorname{div}(u \otimes u)^\varepsilon \cdot u^\varepsilon - \operatorname{div}(u \otimes u^\varepsilon) \cdot u^\varepsilon dx d\tau \\
&= 2\int_0^t \int_{\mathbb{R}^3} [(u \otimes u)^\varepsilon - (u \otimes u^\varepsilon)] \cdot \nabla u^\varepsilon dx d\tau \\
&\le 2\int_0^t \int_{\mathbb{R}^3} \left(|(u \otimes u)^\varepsilon - u \otimes u| + |u \otimes u - u \otimes u^\varepsilon|\right) |\nabla u^\varepsilon| \, dx d\tau \\
&\le C\|\nabla u\|_{L^{\frac{5}{2}}(0,T;L^2(\mathbb{R}^3))} \Big(\|(u \otimes u)^\varepsilon - u \otimes u\|_{L^{\frac{5}{3}}(0,T;L^2(\mathbb{R}^3))} \\
&\quad + \|u\|_{L^{\frac{10}{3}}(L^4(\mathbb{R}^3))} \|u - u^\varepsilon\|_{L^{\frac{10}{3}}(0,T;L^4(\mathbb{R}^3))} \Big).
\end{aligned} \tag{2.10}$$

Thanks to (2.6) and standard properties of mollifier, we know that the right hand side of (2.10) becomes zero as $\varepsilon \to 0$, which completes the proof of this case.

Finally, letting ε go to zero in (2.9), and using the facts (2.10), what we have proved is that in the limit

$$\int_{\mathbb{R}^3} |u(t,x)|^2 dx + 2\int_0^t \int_{\mathbb{R}^3} |\nabla u(x,\tau)|^2 dx d\tau = \int_{\mathbb{R}^3} |u_0|^2 \, dx.$$

This completes the proof of Theorem 1.2. □

Abstract. This paper tightens the classical Poincaré–Bendixson theory for a positively invariant, simply-connected compact set $\mathcal{M}$ in a continuously differentiable planar vector field by further characterizing for any point $p \in \mathcal{M}$, the composition of the limit sets $\omega(p)$ and $\alpha(p)$ after counting separately the fixed points on $\mathcal{M}$'s boundary and interior. In particular, when $\mathcal{M}$ contains finitely many boundary but no interior fixed points, $\omega(p)$ contains only a single fixed point, and when $\mathcal{M}$ may have infinitely many boundary but no interior fixed points, $\omega(p)$ can, in addition, be a continuum of fixed points. When $\mathcal{M}$ contains only one interior and finitely many boundary fixed points, $\omega(p)$ or $\alpha(p)$ contains exclusively a fixed point, a closed orbit or the union of the interior fixed point and homoclinic orbits joining it to itself. When $\mathcal{M}$ contains in general a finite number of fixed points and neither $\omega(p)$ nor $\alpha(p)$ is a closed orbit or contains just a fixed point, at least one of $\omega(p)$ and $\alpha(p)$ excludes all boundary fixed points and consists only of a number of the interior fixed points and orbits connecting them.

Keywords: Poincaré–Bendixson theory, planar vector field, limit set.

2020 Mathematics Subject Classification: 34C05, 37C10, 34C60.

1 Introduction

Determining the asymptotic behavior of general continuous vector fields, even qualitatively, is still a daunting task. In the nineteenth century, Poincaré studied this problem for planar systems by focusing on the global behavior of the systems' trajectories without integrating the corresponding differential equations [7,13]. The analysis was later completed by Bendixson [2]. The related classical results are commonly referred to as the Poincaré–Bendixson theorem [2,7,9–11,14–17]. Consider the vector field

$$\dot{x} = f(x), \qquad x \in \mathbb{R}^2 \tag{1.1}$$

✉ Corresponding author. Email: pramazi@brocku.ca

where f is $\mathbf{C}^1$ on an open set $\mathcal{U}$ in $\mathbb{R}^2$. A point $x^* \in \mathbb{R}^2$ is a "fixed point" of the vector field if $f(x^*) = 0$. Denote the omega and alpha limit sets of a point p by $\omega(p)$ and $\alpha(p)$, respectively.

Theorem 1.1 (Poincaré–Bendixson theorem [23, Theorem 9.0.6], [12, Theorem 1.8])**.** *For the vector field (1.1), let $\mathcal{M} \subset \mathcal{U}$ be a positively invariant complex for the vector field containing a finite number of fixed points. For any $p \in \mathcal{M}$, one of the following holds:*

1. *$\omega(p)$ is a fixed point;*
2. *$\omega(p)$ is a closed orbit;*
3. *$\omega(p)$ consists of a finite number of fixed points $p_1, \ldots, p_n$ and orbits γ with $\alpha(\gamma) = p_i$ and $\omega(\gamma) = p_j$, where p_i and p_j are not necessarily different. Moreover, for two distinct fixed points p_i and p_j, there exists at most one orbit γ such that $\alpha(\gamma) = p_i$ and $\omega(\gamma) = p_j$.*

From this theorem, although possibilities such as strange attractors and chaotic orbits can be easily ruled out, the third case in the theorem still gives rise to sometimes a large number of possible limiting behaviors. For example, when $\mathcal{M}$ contains just four fixed points on its boundary, there can be more than 300 different compositions of $\omega(p)$ even under the simplifying assumption that there is at most one homoclinic orbit at each fixed point. Some existing results have tried to reduce the possible scenarios; in [1, Theorem 68], [18, Theorem 3] the third case has been stated more precisely by stipulating that the trajectories γ must be the continuations of one another, and in [19, Section 3.7, Theorem 3] the number of homoclinic orbits at each fixed point is limited by one when the vector field is "relatively prime analytic". However, then for the example just mentioned, $\omega(p)$ can still have more than 50 different compositions. This example shows that if one is interested in categorizing all possible asymptotic behaviors of a planar system qualitatively, a greatly needed task in fields such as mathematical biology [4], one may still encounter difficulty even with the help of the existing most tightened form of Poincaré–Bendixson theorem.

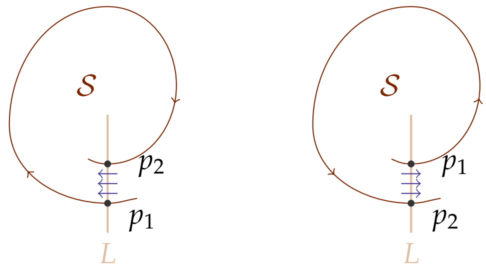
The aim of this paper is to reduce the number of possible compositions of the limit sets of a vector field when knowing the number of fixed points on the boundary and in the interior of a given positively invariant, simply-connected compact set $\mathcal{M}$.

Notations: Let $\phi(t, x)$ denote the flow generated by the vector field (1.1), which is the solution of (1.1) passing through x at time t. For a point $p \in \mathbb{R}^2$, let $\mathcal{O}(p)$ denote the *orbit* of p defined by $\mathcal{O}(p) = \{x \in \mathbb{R}^2 \mid x = \phi(t, p), t \in \mathbb{R}\}$, and $\mathcal{O}_+(p)$ denote the *positive semi-orbit* of p, defined by $\mathcal{O}_+(p) = \{x \in \mathbb{R}^2 \mid x = \phi(t, p), t \geq 0\}$ [23]. Correspondingly, for $p_1, p_2 \in \mathcal{O}_+(p)$, define the segment semi-orbit $\mathcal{O}_+(p)$ *from* p_1 *to* p_2 as $\mathcal{O}_+(p_2) - \mathcal{O}_+(p_1)$. A *homoclinic orbit* is a trajectory that joins a fixed point to itself. For a set $\mathcal{M}$, denote its *interior* by Int $\mathcal{M}$, its *boundary* by $\partial\mathcal{M}$, and its closure by $\overline{\mathcal{M}}$.

2 Main results

We first review some basic relevant results. The following lemma is applicable to higher dimensional spaces, but we restrict it here to the plane.

Lemma 2.1 ([23, Proposition 8.1.3], [3, Theorem 3-3.6])**.** *For the vector field (1.1), let $\mathcal{M} \subset \mathcal{U}$ be a positively invariant compact set. Then for any point $p \in \mathcal{M}$, it holds that $\omega(p)$ is nonempty, connected, and compact.*



(a) (b)

Figure 2.1: The two possible cases for the positive semi-orbit $\mathcal{O}_+(p)$ in the proof of Theorem 2.4.

A continuous connected arc in the plane is said to be *transverse to the vector field*, if the vector field has no fixed points on the arc and nowhere becomes tangent to the arc [11]. By a *transversal* we refer to a closed line segment $\mathcal{L}$ that is transverse to the vector field. Due to the continuity of the vector field, clearly one can construct a transversal through any non-fixed point. The following lemma illustrates how the flow through a point p approaches a transversal through a non-fixed omega limit point $q \in \omega(p)$ when it exists.

Lemma 2.2 ([8, reformulation of Lemma 1.26])**.** *For the vector field* (1.1)*, consider a point $p \in \mathcal{U}$ such that $\mathcal{O}(p) \subset \mathcal{U}$. Let $q \in \omega(p)$ be a non-fixed point of* (1.1) *and let $\mathcal{L}$ be a transversal through q. Then there exists a sequence $\{t_i\} \to \infty$, such that $\{\phi(t_i, p)\} \in \mathcal{L}$ and $\{\phi(t_i, p)\} \to q$.*

The following result guarantees the existence of a fixed point inside a closed orbit [3,6,9,23]:

Lemma 2.3 ([23, Corollary 6.0.2])**.** *Enclosed by any closed orbit of* (1.1) *in $\mathcal{U}$, there must be at least one fixed point.*

Now we are ready to present the main results of the paper.

2.1 $\mathcal{M}$ has no interior fixed point

Theorem 2.4 (No interior fixed points, positively invariant vector field)**.** *For the vector field* (1.1)*, consider a positively invariant, simply-connected compact set $\mathcal{M} \subset \mathcal{U}$ that contains a finite number of fixed points, all on $\partial\mathcal{M}$. Then for any $p \in \mathcal{M}$, $\omega(p)$ is a fixed point on $\partial\mathcal{M}$.*

Proof. From Theorem 1.1, it suffices to prove that $\omega(p)$ contains only fixed points since then only situation 1 is possible and the corresponding fixed point can only be on $\partial\mathcal{M}$ as Int $\mathcal{M}$ contains no fixed points. We prove this by contradiction, so assume on the contrary that there is a non-fixed point $q \in \omega(p)$. Then one can construct a transversal $\mathcal{L}$ through q, and from Lemma 2.2, we know that $\mathcal{O}_+(p)$ intersects $\mathcal{L}$ for infinitely many times and such intersection points are in $\mathcal{M}$ since $\mathcal{O}_+(p) \subset \mathcal{M}$. So one can pick two consecutive intersection points p_1 and p_2 such that the line segment p_1p_2 lies in $\mathcal{M}$. Should p_1 and p_2 coincide, $\omega(p)$ would be a closed orbit, lying in $\mathcal{M}$, but encircling no fixed point as all the fixed points are on $\partial\mathcal{M}$. This cannot happen in view of Lemma 2.3, and thus, p_1 and p_2 must be distinct.

As illustrated by Fig. 2.1, we construct the simply-connected compact set $\mathcal{S}$ whose boundary is formed by the segment semi-orbit $\mathcal{O}_+(p)$ from p_1 to p_2 and the line segment p_1p_2. Since

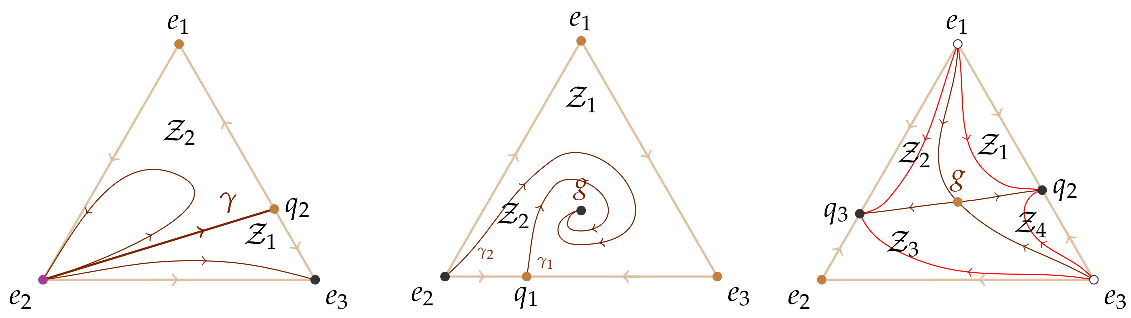


Figure 2.2: Phase portrait examples for an invariant compact set Δ. **(a)** e_1 and q_2 are hyperbolic saddle, e_3 is a hyperbolic stable and e_2 is a center fixed point. The stable invariant manifold of q_2 divides Δ into $\mathcal{Z}_1$ and $\mathcal{Z}_2$. Theorem 2.5 and the local stability results imply that for each $z \in \text{Int } \mathcal{Z}_1$, $\alpha(z) = e_2$ and $\omega(z) = e_3$, and for each $z \in \text{Int } \mathcal{Z}_2$, $\alpha(z) = \omega(z) = e_2$. **(b)** e_1, e_3 and q_1 are hyperbolic saddle, e_2 is a hyperbolic unstable, and g is a hyperbolic stable fixed point. Because of Theorem 2.7, the local stability results and the fact that no limit cycle exists, $\omega(p) = \{g\}$ for all $p \in \text{int}(\Delta)$. Hence, the unique out-going trajectory from q_1, denoted by γ_1, converges to g. The rest of the orbits in $\text{int}(\Delta)$ start from e_2 and end at g. This is because any out-going trajectory from e_2, e.g., γ_2, together with γ_1 divide the simplex into the zones $\mathcal{Z}_1$ and $\mathcal{Z}_2$, each of which satisfy the condition of $\mathcal{M}$ in Theorem 2.7. Hence, every trajectory in $\text{Int } \mathcal{Z}_i, i = 1, 2$, starts from e_2 and end at g. **(c)** e_2 and g are hyperbolic saddle, e_1 and e_3 are hyperbolic unstable and q_3 and q_2 are hyperbolic stable fixed points. The trajectories γ_1 and γ_2 lie on the unstable invariant manifold of g. Because of Theorem 2.7 and the local stability results, the unstable invariant manifold of g is confined to q_2 and q_3 and the stable invariant manifold of g is confined to e_1 and e_3. This results in the four zones $\mathcal{Z}_1, \ldots, \mathcal{Z}_4$. In view of Theorem 2.4, $\forall z \in \text{Int } \mathcal{Z}_1$, $\alpha(z) = e_1$ and $\omega(z) = q_2$, $\forall z \in \text{Int } \mathcal{Z}_2$, $\alpha(z) = e_1$ and $\omega(z) = q_3$, $\forall z \in \text{Int } \mathcal{Z}_3$, $\alpha(z) = e_3$ and $\omega(z) = q_3$, and $\forall z \in \text{Int } \mathcal{Z}_4$, $\alpha(z) = e_3$ and $\omega(z) = q_2$.

$\mathcal{O}_+(p)$ always intersects $\mathcal{L}$ from the same side to the other, the orientation of the p_1-to-p_2 semi-orbit with respect to the line segment p_1p_2 must be one of the two cases shown in Fig. 2.1. From the definition of $\mathcal{L}$, the vector field at any point on p_1p_2 intersects p_1p_2 from the same side of the line, and thus $\mathcal{S}$ is either positively invariant as shown in Fig. 2.1.(a) or negatively invariant as shown in Fig. 2.1.(b).

Since the boundary p_1-to-p_2 semi-orbit and p_1p_2 both lie in $\mathcal{M}$, we know that $\mathcal{S} \subseteq \mathcal{M}$. Hence, $\text{Int } \mathcal{S} \subseteq \text{Int } \mathcal{M}$ and contains no fixed point. Moreover, neither $\mathcal{O}_+(p)$ nor $\mathcal{L}$ contains any fixed point, so $\partial\mathcal{S}$ does not contain any fixed point. Therefore, $\mathcal{S}$ contains no fixed point. Consequently, if $\mathcal{S}$ is positively invariant, applying Theorem 1.1, we know that for any point $s \in \mathcal{S}$, $\omega(s)$ can only be a closed orbit confined in $\mathcal{S}$. But this contradicts Lemma 2.3. If on the other hand, $\mathcal{S}$ is negatively invariant, we apply the same argument after inverting the direction of the vector field and again reach the same contradiction. So the proof is complete. □

In term of the example given in the introduction, Theorem 2.4 implies that $\omega(p)$ in the example can only be one of the fixed points, so at most four possibilities. If in addition to being positively invariant, $\mathcal{M}$ is also negatively invariant, i.e., $\mathcal{M}$ is invariant, then Theorem 2.4 can get even more strengthened.

Theorem 2.5 (No interior fixed points, invariant vector field)**.** *For the vector field* (1.1)*, consider an invariant, simply-connected compact set $\mathcal{M} \subset \mathcal{U}$ that contains a finite number of fixed points, all on $\partial\mathcal{M}$. Then for any $p \in \mathcal{M}$, both $\omega(p)$ and $\alpha(p)$ are fixed points, not necessarily different, on $\partial\mathcal{M}$.*

Proof. Theorem 2.4 implies that for any $p \in \mathcal{M}$, $\omega(p)$ contains only a single fixed point on $\partial\mathcal{M}$. The same holds for $\alpha(p)$ after reversing the direction of the vector field since $\mathcal{M}$ is also negatively invariant. This completes the proof. □

Fig. 2.2 demonstrates an example from planar *replicator dynamics* [20–22], where the triangle $e_1e_2e_3$, known as a *face*, is invariant. Part (a) corresponds to Theorem 2.5. The reader may refer to [4, 5] for all 49 possible qualitatively different phase portraits of the dynamics.

2.2 $\mathcal{M}$ has no interior, but infinitely many boundary fixed points

We obtain the following theorem that is the counterpart of Theorem 2.4 when the vector field may have infinitely many fixed points on $\partial\mathcal{M}$.

Theorem 2.6. *For the vector field* (1.1)*, consider a positively invariant, simply-connected compact set $\mathcal{M} \subset \mathcal{U}$ that has no interior fixed point, but may contain an infinite number of fixed points on $\partial\mathcal{M}$. Then for any $p \in \mathcal{M}$, one of the following two holds:*

1. *$\omega(p)$ is a fixed point on $\partial\mathcal{M}$;*
2. *$\omega(p)$ is a continuum of fixed points on $\partial\mathcal{M}$.*

Proof. Following similar steps as those in the proof for Theorem 2.4, one can construct the simply-connected compact set $\mathcal{S}$ as illustrated in Fig. 2.1. Using similar arguments for $\mathcal{S}$ as those in the proof for Theorem 2.4, after applying Theorem 6.1 in [7], which is the extension of Poincaré–Bendixson theorem to the case when there are infinitely many fixed points, one knows that $\omega(p)$ does not contain any fixed point. On the other hand, $\omega(p)$ has to be connected in view of Lemma 2.1, so it can only be a connected subset of the fixed points in $\mathcal{M}$, which is either a fixed point or a continuum of fixed points on $\partial\mathcal{M}$. □

2.3 $\mathcal{M}$ has exactly one interior fixed point

Now we present the counterpart of Theorem 2.4 discussing the case when $\mathcal{M}$ contains exactly one interior and finitely many boundary fixed points.

Theorem 2.7 (One interior fixed point)**.** *For the vector field* (1.1)*, consider a positively invariant, simply-connected compact set $\mathcal{M} \subset \mathcal{U}$ that contains exactly one interior fixed point x^* and a finite number of fixed points on its boundary. Then for any $p \in \mathcal{M}$, at least one of the following holds:*

1. *$\omega(p)$ is a fixed point, a closed orbit encircling x^* or the union of $\{x^*\}$ and a (possibly union of) homoclinic orbit(s) joining x^* to itself;*
2. *$\alpha(p)$ is $\{x^*\}$, a closed orbit encircling x^* or the union of $\{x^*\}$ and a (possibly union of) homoclinic orbit(s) joining x^* to itself.*

Proof. We investigate all possibilities for $\omega(p)$ and show that each results in one of the cases of the theorem. Should $\omega(p)$ be a singleton fixed point or a closed orbit that has to encircle g according to Lemma 2.3, we arrive at Part 1. of the theorem. So consider the situation when $\omega(p)$ is neither. It then follows Theorem 1.1 that $\omega(p)$ contains non-fixed points; we pick one such point q and construct a transversal $\mathcal{L}$ through q. From Lemma 2.2, we know that $\mathcal{O}_+(p)$ intersects $\mathcal{L}$ for infinitely many times. Consider two consecutive intersections p_1 and p_2 which have to be distinctive since $\omega(p)$ is not a closed orbit. We construct the simply-connected compact set $\mathcal{S}$ whose boundary is formed by the semi-orbit $\mathcal{O}_+(p)$ from p_1 to p_2 and the line segment p_1p_2. Similar to the proof of Theorem 2.4, one can show that:

(i) $\mathcal{S}$ is in the form of one of the two cases shown in Fig. 2.1,

(ii) $\mathcal{S}$ is positively invariant in Case (a) of the figure and negatively invariant in Case (b), and

(iii) $x^* \in \operatorname{Int} \mathcal{S}$ is the only fixed point in $\mathcal{S}$.

If $\mathcal{S}$ is positively invariant, $\mathcal{O}_+(p) \cap \operatorname{Int} \mathcal{S} \neq \emptyset$, implying the existence of some $s_p \in \mathcal{O}_+(p) \cap \operatorname{Int} \mathcal{S}$. Consequently, $\omega(s_p) = \omega(p)$. Then, applying Theorem 1.1, we know that $\omega(s_p)$ consists of a number of fixed points in $\mathcal{S}$ and the orbits connecting them. However, since x^* is the only fixed point in Int $\mathcal{M}$, such orbits can only connect x^* to itself. So $\omega(s_p)$ is the union of $\{x^*\}$ and a (possibly union of) homoclinic orbit(s) joining x^* to itself, so is $\omega(p)$. So in this case Part 1 of the theorem holds.

Otherwise, if $\mathcal{S}$ is negatively invariant, then there exists a point $s_p \in \mathcal{O}_-(p) \cap \operatorname{Int} \mathcal{S}$ where $\mathcal{O}_-(p)$ is the same as $\mathcal{O}_+(p)$, but when time is reversed. Consequently, after reversing the direction of the vector field, one can check the three cases in Theorem 1.1 as $\omega(s_p)$ lead to the three cases in Part 2 of the theorem respectively. □

Theorem 2.7 is indeed restricting the third case of Theorem 1.1, for at least one of the ω or α limit sets. Note that if, in addition, x^* is hyperbolic and the vector field contains no closed orbits, then for any point $p \in \mathcal{M}$, either $\omega(p)$ is a fixed point or $\alpha(p) = \{x^*\}$. See Fig. 2.2.(b) and (c) for two examples. We highlight that the first case in Theorem 2.7 may not cover all possibilities for $\omega(p)$ (see Fig. 2.3); however, then the second case of the Theorem will be in force, determining the structure of $\alpha(p)$.

It is also worth mentioning that some cases in Part 1 and Part 2 of Theorem 2.7 never take place at the same time. For example, it is impossible to have both $\omega(p)$ and $\alpha(p)$ being the union of $\{x^*\}$ and a homoclinic orbit joining x^* to itself. We exclude such cases for general positively invariant compact regions as follows. A point is *periodic* if it is on a closed orbit.

Proposition 2.8. *Let $\mathcal{M} \subset \mathcal{U}$ be a positively invariant compact set under the vector field* (1.1)*. For any non-periodic point $p \in \mathcal{M}$, if $\omega(p) = \alpha(p)$, then the limit sets contain only fixed points.*

Either Lemma 9.0.2 in [23] or the results on the characterization of non-periodic orbits in [6] can be used for the proof, which we skip here. In case $\mathcal{M}$ contains finitely many fixed points, we can sharpen the result of Proposition 2.8 by using Proposition 8.1.3 in [23].

Corollary 2.9. *For the vector field* (1.1)*, let $\mathcal{M} \subset \mathcal{U}$ be a positively invariant compact set containing a finite number of fixed points. Then for any non-periodic point $p \in \mathcal{M}$, if $\omega(p) = \alpha(p)$, then the limit sets exclusively contain a single fixed point.*

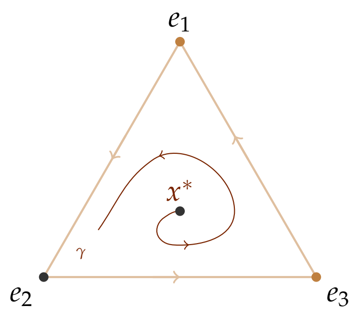

Figure 2.3: Phase portrait example for an invariant compact set $\mathcal{M}$ defined by the triangle $e_1e_2e_3$, where e_1, e_2 and e_3 are fixed points. There is exactly one interior fixed point, g. For every point p in the interior of $\mathcal{M}$, the ω-limit set of p equals $\partial\mathcal{M}$, that is the union of the fixed points e_1, e_2 and e_3 and the heteroclinic orbits connecting them to each other. This is not covered by the first case of Theorem 2.7. However, $\alpha(p) = \{x^*\}$, which is satisfied by the second case of Theorem 2.7.

2.4 $\mathcal{M}$ has finitely many interior fixed points

Following the previous subsection of having one interior fixed point in the positively invariant compact set $\mathcal{M}$, we now extend the result to the more general case of having finitely many interior fixed points in $\mathcal{M}$.

Theorem 2.10 (Finitely many interior fixed points)**.** *For the vector field* (1.1)*, consider a positively invariant, simply-connected compact set $\mathcal{M} \subset \mathcal{U}$ containing a finite number of fixed points. Then for any point $p \in \mathcal{M}$, at least one of the following holds:*

1. *$\omega(p)$ is a fixed point, a closed orbit encircling at least one interior fixed point or the union of some interior fixed points together with the orbits connecting them;*

2. *$\alpha(p)$ is an interior fixed point, a closed orbit encircling at least one interior fixed point or the union of some interior fixed points together with the orbits connecting them.*

Proof. The proof is similar to that for Theorem 2.7 and we omit it here. □

Compared to the classical form of Poincaré–Bendixson Theorem 1.1, what Theorem 2.10 has further clarified is the role of the interior fixed points of $\mathcal{M}$ play to influence the topological structure of the limit sets. For example, as an immediate result of Theorem 2.10, if the third case of Theorem 1.1 takes place for p, then $\omega(p)$ and $\alpha(p)$ cannot be free of interior fixed points at the same time; in other words, unless $\omega(p)$ is simply a fixed point or a closed orbit, some interior fixed points must be in either $\omega(p)$ or $\alpha(p)$. Another implication of Theorem 2.10 is the exclusion of the boundary fixed points from one of $\omega(p)$ and $\alpha(p)$. From Theorem 2.10, if $\omega(p)$ is not simply a fixed point, then at least one of $\omega(p)$ or $\alpha(p)$ does not contain any boundary fixed point. In a sense, this implies that the interior fixed points are more important for determining the structures of the limit sets. Finally, we note that Corollary 2.9 can also be utilized here to rule out some trivial cases when $\omega(p)$ and $\alpha(p)$ are the same.

At the end of this section, we present the following version of Theorem 2.10 without requiring $\mathcal{M}$ to be simply connected.

Theorem 2.11. *For the vector field* (1.1)*, consider a positively invariant, compact set* $\mathcal{M} \subset \mathcal{U}$ *that contains a finite number of fixed points. Then for any* $p \in \mathcal{M}$*, at least one of the following holds:*

1. $\omega(p)$ *is a fixed point, a closed orbit or the union of some interior fixed points with the orbits connecting them;*

2. $\alpha(p)$ *is one of the interior fixed points, a closed orbit or the union of some interior fixed points with the orbits connecting them.*

Proof. The proof is similar to that of Theorem 2.7. The difference is that if $\omega(p)$ or $\alpha(p)$ is a closed orbit, it may encircle areas that do not belong to $\mathcal{M}$. □

Abstract. Consider a general reaction-diffusion problem, $u_t = \Delta u + f(x, u, u_x)$, on a revolution surface or in an n-dimensional ball with Dirichlet boundary conditions. In this work, we provide conditions related to the geometry of the domain and the spatial heterogeneities of the problem that ensure the existence or not of a non-constant stationary stable solution. Several applications are presented, particularly with regard to the Allen–Cahn, Fisher–KPP and sine-Gordon equations.

Keywords: patterns, Dirichlet boundary conditions, surface of revolution.

2020 Mathematics Subject Classification: 35B35, 35B36.

1 Introduction

In this work we consider the following problem

$$\begin{cases} u_t = \Delta u + f(x, u, u_x), & (t, x) \in \mathbb{R}^+ \times \Omega, \\ u(t, x) = B, & (t, x) \in \mathbb{R}^+ \times \partial\Omega \end{cases} \tag{1.1}$$

where f is a C^1 function, $B \in \mathbb{R}$ and Ω is a surface of revolution in $\mathbb{R}^3$ or is an n-dimensional ball. We say that U is a *stationary solution* of (1.1) if U is a solution of (1.1) independent of temporal variable t, that is

$$\begin{cases} \Delta U + f(x, U, U_x) = 0, & x \in \Omega, \\ U(x) = B, & x \in \partial\Omega. \end{cases} \tag{1.2}$$

A stationary solution U of (1.1) is called *stable* if for every $\eta > 0$ there exists $\delta > 0$ such that for every solution v to (1.1) satisfying $\|v(0, \cdot) - U(\cdot)\|_{L^\infty} < \delta$ it holds that $\|v(t, \cdot) - U(\cdot)\|_{L^\infty} < \eta$, for all $t > 0$. Finally, if U is a non-constant stable stationary solution of (1.1), then U is commonly referred to as the *spatial pattern* or simply *pattern*.

The study of reaction-diffusion equations has been a central focus in the field of mathematical modeling for several decades. These systems have wide-ranging applications in various scientific disciplines, including chemistry, biology, physics, and ecology. One of the intriguing phenomena that often arises in reaction-diffusion systems is the spontaneous formation of spatial patterns. These patterns, which can take on diverse shapes and structures, emerge as a consequence of the interplay between the underlying reaction kinetics and the diffusion of the interacting species [9,20].

In this work, we are interested in investigating the role of spatial heterogeneities as well as the domain geometry concerning the existence or not of patterns. The literature on this subject is extensive, mainly when Neumann boundary conditions are considered. The difficulty in obtaining results with Dirichlet boundary conditions leads to a reduced number of studies. Here, we cite [8,11,21], where the authors achieve results for one-dimensional problems, and [13] for problems in n-dimensional balls. Some results on surfaces of revolution can be found in [19].

Our proposal to study the problem on surfaces of revolution is motivated by the recent interest of the scientific community in these domains [3,4,14,16,18,19], and success is primarily attributed to the well-established symmetry properties of stable solutions in this domain (similar phenomena are observed in the case of balls in $\mathbb{R}^n$). Such symmetry leads us to one-dimensional problems, and this is crucial for obtaining the results.

The proposed ideas can be applied in various situations. In this study, we provide several examples involving the Allen–Cahn, Fisher–KPP, and sine-Gordon problems. These choices were made given the significant relevance of these models. However, as evident, the potential applications extend to many other cases, including reaction-convection-diffusion problems.

The work is divided as follows. In Section 2, we present preliminary results related to the existence and uniqueness of solutions for one-dimensional nonlinear second-order problems. In this section, we illustrate how to obtain results regarding the existence or not of patterns in one-dimensional problems, underscoring the significance of this section in its own right. In Section 3, we present the main results for the problem on surfaces of revolution, whereas Section 4 is dedicated to the sine-Gordon problem in an n-dimensional ball. Finally, in Section 5, we provide some concluding remarks.

2 Preliminaries and some general one-dimensional results

In this section, we will present three general results on the existence and uniqueness of solutions for certain elliptic problems in a interval. In this case, for the sake of simplicity, we will replace the notation u_x with u'. Results of this type are commonly understood when $f(x,u,u')$ satisfies a specific uniform Lipschitz condition, assuming the interval length for the variable u where the problem occurs is sufficiently small. However, in numerous scenarios, it is necessary to extend this result to include functions $f(x,u,u')$ that are Lipschitz not for all u but solely for u within a bounded interval. This is what is accomplished in the first theorem below, which considers Dirichlet conditions at the boundary.

Additionally, it is crucial to highlight that instead of the typical Lipschitz condition, we presume a set of one-sided conditions which, while not more restrictive, proves to be considerably more practical. Further elaboration on this matter can be found in [1,2,6].

The subsequent results in this section are related to a function $g \in C^1$ such that

$$g(s,0,0) = 0 \tag{2.1}$$

and

$$G_1(u-v, u'-v') \le g(s,u,u') - g(s,v,v') \le G_2(u-v, u'-v') \tag{2.2}$$

where

$$G_2(u,u') = \begin{cases} M_2u' + K_2u, & u \geq 0,\ u' \geq 0, \\ M_1u' + K_2u, & u \geq 0,\ u' \leq 0, \\ M_1u' + K_1u, & u \leq 0,\ u' \leq 0, \\ M_2u' + K_1u, & u \leq 0,\ u' \geq 0, \end{cases} \tag{2.3}$$

$$G_1(u,u') = \begin{cases} M_1u' + K_1u, & u \geq 0,\ u' \geq 0, \\ M_2u' + K_1u, & u \geq 0,\ u' \leq 0, \\ M_2u' + K_2u, & u \leq 0,\ u' \leq 0, \\ M_1u' + K_2u, & u \leq 0,\ u' \geq 0, \end{cases} \tag{2.4}$$

and $M_i, K_i \in \mathbb{R}$ ($i = 1,2$) are constant.

The next three theorems are crucial to all the results of this work.

Theorem 2.1 (Theorem 1 in [1]). *For $(s,u,u') \in [0,L] \times J \times \mathbb{R}$, where J is a closed interval in $\mathbb{R}$, let $g(s,u,u')$ be a continuous function satisfying (2.1) and (2.2). If the two problems ($i = 1,2$)*

$$\begin{cases} u_i''(s) + G_i(u_i(s), u_i'(s)) = 0, & s \in (a,b), \\ u_i(a) = A', \quad u_i(b) = B', \end{cases} \tag{2.5}$$

have unique solutions on every sub-interval $[a,b]$ of $[0,L]$ for arbitrary A', B', and if for $a = 0$, $b = L$, $A' = A$, $B' = B$ the ranges of u_i ($i = 1,2$) are subsets of J, then the problem

$$\begin{cases} u''(s) + g(s,u(s),u'(s)) = 0, \\ u(0) = A, \quad u(L) = B, \end{cases} \tag{2.6}$$

has a unique solution $u(s)$, which remains in J and it satisfies

$$u_1(s) \leq u(s) \leq u_2(s),$$

where u_1 and u_2 are solutions of (2.5) with G_1 and G_2, respectively, and $a = 0$, $b = L$, $A' = A$, $B' = B$.

Before stating the next theorem, we define

$$\alpha(M,K) = \begin{cases} \dfrac{2}{\sqrt{4K - M^2}} \cos^{-1}\left(\dfrac{M}{2\sqrt{K}}\right), & \text{if } 4K - M^2 > 0, \\ \dfrac{2}{\sqrt{M^2 - 4K}} \cosh^{-1}\left(\dfrac{M}{2\sqrt{K}}\right), & \text{if } 4K - M^2 < 0,\ M > 0,\ K > 0, \\ \dfrac{2}{M}, & \text{if } 4K - M^2 = 0,\ M > 0, \\ +\infty, & \text{otherwise} \end{cases} \tag{2.7}$$

and

$$\beta(M,K) = \begin{cases} \dfrac{2}{\sqrt{4K - M^2}} \cos^{-1}\left(\dfrac{-M}{2\sqrt{K}}\right), & \text{if } 4K - M^2 > 0, \\ \dfrac{2}{\sqrt{M^2 - 4K}} \cosh^{-1}\left(\dfrac{-M}{2\sqrt{K}}\right), & \text{if } 4K - M^2 < 0,\ M < 0,\ K > 0, \\ \dfrac{-2}{M}, & \text{if } 4K - M^2 = 0,\ M < 0, \\ +\infty, & \text{otherwise.} \end{cases} \tag{2.8}$$

The next theorem is fundamental for verifying the existence and uniqueness of solution to problems in (2.5) in the theorem above.

Theorem 2.2 (Theorem 1 in [2]). *Let $G(y, y')$ be a continuous real valued function satisfying $G(0, 0) = 0$ and (2.2) (assuming $g(s, y, y') = G(y, y')$) with G_1 and G_2 defined in (2.4) and (2.3). If*

$$L < \alpha(M_2, K_2) + \beta(M_1, K_2),$$

then the boundary value problem

$$\begin{cases} u''(s) + G(u(s), u'(s)) = 0, & s \in (0, L), \\ u(0) = A', \quad u(L) = B' \end{cases} \tag{2.9}$$

has a unique solution for every pair of real numbers A', B'.

Below, we present a new result regarding existence and uniqueness, specifically for mixed boundary conditions. In particular, we will use this theorem to investigate the sine-Gordon problem in an n-dimensional ball.

Theorem 2.3 (Theorem 1 in [6]). *Let $g(s, y, y')$ be a continuous real valued function satisfying (2.2) with G_1 and G_2 defined in (2.4) and (2.3). If*

$$L < \beta(M_1, K_2),$$

then the mixed boundary value problem

$$\begin{cases} u''(s) + g(s, u(s), u'(s)) = 0, & s \in (0, L), \\ u'(0) = A, \quad u(L) = B \end{cases} \tag{2.10}$$

has a unique solution for every pair of real numbers A, B.

With the aforementioned theorems, it is not difficult to derive results regarding the non-existence of patterns in one-dimensional problems and zero Dirichlet boundary conditions. Although this is not the main objective of this work, we present a simple example below.

Example 2.4. Consider the following problem

$$\begin{cases} u_t = u_{xx} + \rho(x)u(1-u), & (t, x) \in \mathbb{R}^+ \times (0, L), \\ u(0) = 0, \quad u(L) = 0, \end{cases} \tag{2.11}$$

where ρ is a continuous function with sign-changing or not. Note that this includes the important Fisher–KPP equation which will be further elucidated in the subsequent section.

In this case we consider $J = [0, 1]$ and then, $g(x, u) = \rho(x)u(1-u)$ satisfies (2.1) and (2.2) with G_1 and G_2 given by (2.4) and (2.3) if

$$M_1 = M_2 = 0, \quad K_1 = -\sup_{x \in [0,L]} |\rho(x)| \text{ and } K_2 = \sup_{x \in [0,L]} |\rho(x)|.$$

Now, in order to use Theorem 2.1 we have to analyse

$$\begin{cases} z'' + G_i(z) = 0, & (0, L), \\ z(0) = A', \quad z(L) = B' \end{cases} \tag{2.12}$$

with $i = 1,2$. We can use Theorem 2.2 to conclude that if $L < \alpha(M_2, K_2) + \beta(M_1, K_2)$, that is

$$\frac{2}{\sqrt{4K_2 - M_2^2}} \cos^{-1}\left(\frac{M_2}{2\sqrt{K_2}}\right) + \frac{2}{\sqrt{4K_2 - M_1^2}} \cos^{-1}\left(\frac{-M_1}{2\sqrt{K_2}}\right) = \frac{\pi}{2\sqrt{K_2}} + \frac{\pi}{2\sqrt{K_2}} = \frac{\pi}{\sqrt{K_2}} > L$$

or

$$K_2 < (\pi/L)^2,$$

then (2.12) has a unique solution (for $i = 1,2$) for any $A', B' \in \mathbb{R}$. In particular, it is easy to see that if $A' = B' = 0$, then $z \equiv 0 \in J = [0,1]$ is the unique solution. Finally, Theorem 2.1 yields that, in these conditions, $u \equiv 0$ is the unique stationary solution of (2.11), and thus, (2.11) does not admit patterns.

Remark 2.5. Note that the interval J ($= [0,1]$ in the above example) is associated with the range of variation of u and with the inequalities in (2.2). Evidently, its choice affects the values of M_i and K_i, and consequently the application of the results of existence and uniqueness of solution to determine whether patterns emerge or not.

Below, we present a simple example of pattern existence for a problem with mixed boundary conditions. In this case, the chosen nonlinearity is related to the sine-Gordon equation.

Example 2.6. Consider the following problem with mixed boundary conditions

$$\begin{cases} u_t = (e^{5x} u_x)_x + (x+6)\sin(u), & (t,x) \in \mathbb{R}^+ \times (0,1), \\ u_x(t,0) = 1/2, \quad u(t,1) = 1/4. \end{cases} \tag{2.13}$$

This problem can be written as

$$\begin{cases} \dfrac{u_t}{e^{5x}} = u_{xx} + 5u_x + \dfrac{(x+6)}{e^{5x}} \sin(u), & (t,x) \in \mathbb{R}^+ \times (0,1), \\ u_x(t,0) = 1/2, \quad u(t,1) = 1/4, \end{cases} \tag{2.14}$$

and the corresponding stationary problem is

$$\begin{cases} u_{xx} + 5u_x + \dfrac{(x+6)}{e^{5x}} \sin(u) = 0, & x \in (0,1), \\ u_x(0) = 1/2, \quad u(1) = 1/4. \end{cases} \tag{2.15}$$

We note that $h(x, u, u_x) = 5u_x + \frac{(x+6)}{e^{5x}} \sin(u)$ satisfies (2.2) with G_1 and G_2 defined in (2.4) and (2.3) with

$$M_1 = M_2 = 5, \quad K_1 = -6, \quad K_2 = 6.$$

A simple analysis of (2.8) shows that

$$\beta(M_1, K_2) = \infty.$$

From Theorem 2.3, it follows that (2.15) has a unique solution U. Now note that $E : \{u \in H^1(0,1); u(1) = 1/4\} \to \mathbb{R}$ defined by

$$E[u] = \int_0^1 \frac{e^{5x}}{2}(u_x)^2 - F(u,x)dx + \frac{u(0)}{2},$$

where $F(u,x) = (x+6)\int_0^u \sin(\sigma)d\sigma$ is the energy functional associated with (2.15), its critical points are solutions to (2.15). Now, we state that E serves as a strict Lyapunov functional for (2.13) i.e., except at stationary states, $E[u(t,\cdot)]$ is strictly decreasing on orbits. To verify this, we take a solution u of (2.13) and a function $v \in H^1(0,1)$ such that $v(1) = 0$. Then

$$u_t = (e^{5x}u_x)_x + (x+6)\sin(u)$$

and we can multiply this equation by v, integrate on $(0,1)$ and use integration by parts to achieve

$$\begin{aligned}\int_0^1 vu_t dx &= \int_0^1 ve^{5x}u_{xx}dx + \int_0^1 v5e^{5x}u_x dx + \int_0^1 v(x+6)\sin(u)dx \\ &= \int_0^1 v5e^{5x}u_x dx + v(1)e^5 u_x(t,1) - v(0)u_x(t,0) - \int_0^1 (ve^{5x})_x u_x dx \\ &\quad + \int_0^1 v(x+6)\sin(u)dx \\ &= \int_0^1 v5e^{5x}u_x dx - \frac{v(0)}{2} - \int_0^1 v_x e^{5x}u_x dx - \int_0^1 v5e^{5x}u_x dx \\ &\quad + \int_0^1 v(x+6)\sin(u)dx.\end{aligned}$$

We can cancel the first and fourth term of the last equality to obtain

$$\int_0^1 vu_t dx = -\frac{v(0)}{2} - \int_0^1 v_x e^{5x}u_x dx + \int_0^1 v(x+6)\sin(u)dx. \tag{2.16}$$

Now observe that if u is a solution of (2.13), then $u_t(t,\cdot) \in H^1(0,1)$, $u(t,1) = 1/4$ for all t, and thus $u_t(t,1) = 0$. If we differentiate $E[u(t,\cdot)]$ with respect to t, we obtain

$$\frac{d}{dt}E[u(t,\cdot)] = \int_0^1 e^{5x}u_x u_{tx}dx - \int_0^1 (x+6)\sin(u)u_t dx + \frac{u_t(t,0)}{2}. \tag{2.17}$$

We can compare (2.16) and (2.17) to get

$$\frac{d}{dt}E[u(t,\cdot)] = -\int_0^1 (u_t)^2 dx.$$

Therefore, we have a system with a gradient structure, and then the bounded trajectories of (2.13) approach the set of stationary solutions (for the reader's convenience, we cite [7] for topics related to the dynamics of (2.13) and [15, Chapter 2] for results related to the existence and boundedness of solutions of (2.13)). Since U is non-constant and the only stationary solution of the problem, we conclude that U is a pattern as defined above.

3 Surfaces of revolution

Considering a smooth curve C in $\mathbb{R}^3$ parameterized by $(\psi(s), 0, \chi(s))$, where $s \in [l_1, l_2]$ ($[0,1] \subset (l_1, l_2)$), with $\psi(l_1) = \psi(l_2) = 0$, we can generate a borderless surface of revolution $\mathcal{M}$. This surface can be parametrized by

$$x = (\psi(s)\cos(\theta), \psi(s)\sin(\theta), \chi(s)), \quad (s,\theta) \in [l_1, l_2] \times [0, 2\pi). \tag{3.1}$$

Let $\mathcal{M}$ be the surface of revolution parametrized by (3.1). We also assume that $\psi, \chi \in C^2$, $\psi > 0$ in (l_1, l_2), $(\psi_s)^2 + (\chi_s)^2 = 1$ and $\chi_s(s) \geq 0$ in $[l_1, l_2]$. Moreover, $\psi_s(l_1) = -\psi_s(l_2) = 1$, and as stated above, we assume $\psi(l_1) = \psi(l_2) = 0$.

By setting $x^1 = s$ and $x^2 = \theta$, we can conclude that the surface of revolution $\mathcal{M}$, with the above parametrization, is a 2-dimensional Riemannian manifold with the metric

$$g = ds^2 + \psi^2(s)d\theta^2. \tag{3.2}$$

$\mathcal{M}$ has no boundary, and we always assume that $\mathcal{M}$ and the Riemannian metric g on it are smooth (see [5], for instance). The area element on $\mathcal{M}$ is given by $d\sigma = \psi d\theta ds$, and the gradient of u with respect to the metric g is given by

$$\nabla_g u = \left(\partial_s u, \frac{1}{\psi^2}\partial_\theta u\right).$$

The Laplace–Beltrami operator Δ_g on $\mathcal{M}$ can be expressed as

$$\Delta_g u = u_{ss} + \frac{\psi_s}{\psi}u_s + \frac{1}{\psi^2}u_{\theta\theta}. \tag{3.3}$$

We consider $\mathcal{S} \subset \mathcal{M}$ as a surface of revolution with a boundary parameterized by

$$x = (\psi(s)\cos(\theta), \psi(s)\sin(\theta), \chi(s)), \quad (s, \theta) \in [0,1] \times [0, 2\pi). \tag{3.4}$$

Hence, $\partial\mathcal{S} = \mathcal{C}_0 \cup \mathcal{C}_1$, where $\mathcal{C}_0$ and $\mathcal{C}_1$ are two circles parameterized by ($\theta \in [0, 2\pi)$)

$$(\psi(0)\cos(\theta), \psi(0)\sin(\theta), \chi(0))$$

and

$$(\psi(1)\cos(\theta), \psi(1)\sin(\theta), \chi(1)),$$

respectively.

Theorem 3.1. *Consider the following problem on a surface $\mathcal{S}$ as defined above*

$$\begin{cases} u_t = \Delta_g u + h(x, u), & (t, x) \in \mathbb{R}^+ \times \mathcal{S}, \\ u(t, x) = 0, & (t, x) \in \mathbb{R}^+ \times \partial\mathcal{S} = \mathbb{R}^+ \times (\mathcal{C}_0 \cup \mathcal{C}_1), \end{cases} \tag{3.5}$$

where h is a function of class C^1 and $h(\cdot, \eta)$ is independent of angular variation. Suppose that

(a) $\tilde{h}(s, u, u_s) := \frac{\psi_s}{\psi}u_s + h(s, u)$ satisfies (2.1) and (2.2) with G_i ($i = 1, 2$) given by (2.3), (2.4) for $(s, u, u_s) \in [0, 1] \times J \times \mathbb{R}$ where $J \subset \mathbb{R}$ is a closed interval containing 0;

(b) $\alpha(M_2, K_2) + \beta(M_1, K_2) > 1$ where α and β are numbers defined in (2.7) and (2.8).

Then problem (3.5) does not admit patterns.

Proof. First, we observe that stable stationary solutions of (3.5) must be independent of angular variation. This is a well-known result that can be seen in [3, 14]. Thus, due to (3.3), we can conclude that if u is a stable stationary solution of (3.5), then u satisfies:

$$\begin{cases} u_{ss} + \dfrac{\psi_s}{\psi}u_s + h(s, u) = 0, & s \in [0, 1], \\ u(0) = u(1) = 0. \end{cases} \tag{3.6}$$

Our goal now is to prove that problem (3.6) has a unique solution $u \equiv 0$. To achieve this, we use Theorem 2.1.

According to hypothesis (a), $\tilde{h}(s,u,u_s) = \frac{\psi_s}{\psi}u_s + h(s,u)$ satisfies (2.1) and (2.2) with G_i given by (2.3) and (2.4), and it is the first part of Theorem 2.1. Note that, by hypothesis (b), we can use Theorem 2.2 twice (with $L = 1$ and $G = G_1$ and again with $G = G_2$) to conclude that the two problems ($i = 1,2$)

$$\begin{cases} u_i'' + G_i(u_i(s), u_i'(s)) = 0, \\ u_i(a) = A', \quad u_i(b) = B' \end{cases} \tag{3.7}$$

have unique solutions on every sub-interval $[a,b] \subset [0,1]$ for arbitrary A', B'.

Finally, the problems ($i = 1,2$)

$$\begin{cases} z'' + G_i(z,z') = 0, \quad s \in [0,1], \\ z(0) = z(1) = 0, \end{cases} \tag{3.8}$$

has $z = 0 \in J$ as solution, which allows us to utilize Theorem 2.1 and conclude that $u \equiv 0$ is the unique solution of (3.6). Hence, it follows that problem (3.5) does not admit the existence of patterns, and the theorem is proved. □

3.1 The Allen–Cahn problem

The aim now is to apply Theorem 3.1 to some relevant cases commonly found in the literature. In this subsection, we address the nonlinearity of Allen–Cahn. In this case, we consider problem (3.5) with $h(x,u) = u - u^3$, i.e.

$$\begin{cases} u_t = \Delta_g u + u - u^3, \quad (t,x) \in \mathbb{R}^+ \times \mathcal{S}, \\ u(t,x) = 0, \quad (t,x) \in \mathbb{R}^+ \times \partial\mathcal{S} = \mathbb{R}^+ \times (\mathcal{C}_0 \cup \mathcal{C}_1). \end{cases} \tag{3.9}$$

As we know, a stable solution of (3.9) must satisfy

$$\begin{cases} u_{ss} + \dfrac{\psi_s}{\psi}u_s + u - u^3 = 0, \quad s \in [0,1], \\ u(0) = u(1) = 0. \end{cases} \tag{3.10}$$

A simple computation shows that $\tilde{h}(s,u,u_s) = \frac{\psi_s}{\psi}u_s + u - u^3$ satisfies (2.2) if we consider, for example: $J = [0,1]$, G_1 and G_2 given by (2.4) and (2.3), respectively, with

$$M_1 = \inf_{s\in[0,1]} \left\{ \frac{\psi_s}{\psi} \right\}, \quad M_2 = \sup_{s\in[0,1]} \left\{ \frac{\psi_s}{\psi} \right\}, \quad K_1 = -2 \text{ and } K_2 = 1. \tag{3.11}$$

Hence, if we assume ψ such that

$$\alpha(M_2, K_2) + \beta(M_1, K_2) > 1,$$

we have the hypothesis (b) and we can use Lemma 2.2 to ensure that the problems ($i = 1,2$)

$$\begin{cases} z'' + G_i(z,z') = 0, \quad s \in [0,1], \\ z(0) = z(1) = 0, \end{cases} \tag{3.12}$$

have unique solutions $u_i \equiv 0 \in [0,1]$ ($i = 1,2$).

Remark 3.2. The conditions (a) and (b) of Theorem 3.1 involve the geometry of the domain (represented by the function ψ) along with the reaction term of the problem. In particular, $\frac{\psi'}{\psi}$ (see also (3.11)) represents the geodesic curvature of the parallel circles $s =$ constant on $\mathcal{S}$.

Example 3.3. Consider the problem (3.9) where $\mathcal{S}_1$ is a finite straight cylinder, that is, $\psi(s) = 1$ ($\chi(s) = s + 1$) for all $s \in [0, 1]$. In this case, $M_1 = M_2 = 0$, $K_1 = -2$ and $K_2 = 1$. Thus, it easy to see that

$$\alpha(0,1) + \beta(0,1) = \frac{\pi}{2} + \frac{\pi}{2} = \pi > 1$$

and we can conclude that there are no patterns for this case.

Similarly, if $\psi(s) = s^2/4 + 1/2$ and $\chi(s) = \frac{s}{4}\sqrt{4 - s^2} + \arcsin(s/2)$ for $s \in [0, 1]$, then $\mathcal{S}_2$ resembles a frustum of a hyperboloid (see figure below) and we have $M_1 = 0$, $M_2 = 2/3$, $K_1 = -2$ and $K_2 = 1$. It follows that

$$\alpha(2/3, 1) + \beta(0, 1) > 1$$

and again there are no patterns for the problem (3.9) in this case.

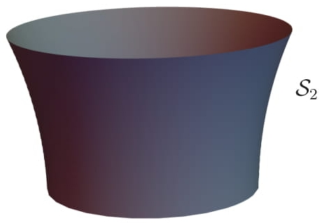

Figure 3.1: Surface of revolution $\mathcal{S}_2$

Our results can also be applied to spatially heterogeneous problems. For instance, we can consider $a \in C^1(\mathcal{S})$ as a positive diffusivity coefficient and $b \in C^1(\mathcal{S})$ as a positive reaction coefficient multiplying $u - u^3$. In this case, the problem becomes:

$$\begin{cases} u_t = \operatorname{div}_g(a(x)\nabla u) + b(x)(u - u^3), & (t, x) \in \mathbb{R}^+ \times \mathcal{S}, \\ u(t, x) = 0, & (t, x) \in \mathbb{R}^+ \times \partial\mathcal{S} = \mathbb{R}^+ \times (\mathcal{C}_0 \cup \mathcal{C}_1). \end{cases} \tag{3.13}$$

If we assume the functions a and b are independent of angular variation, then we have

$$\begin{cases} u_t = a u_{ss} + \dfrac{(a\psi)_s}{\psi} u_s + \dfrac{a}{\psi^2} u_{\theta\theta} + b(u - u^3), & (t, s, \theta) \in \mathbb{R}^+ \times [0, 1] \times [0, 2\pi), \\ u(t, 0, \theta) = u(t, 1, \theta) = 0, & (t, \theta) \in \mathbb{R}^+ \times [0, 2\pi), \end{cases} \tag{3.14}$$

and the stable solutions satisfy

$$\begin{cases} u_{ss} + \tilde{h}(s, u, u_s) = 0, & s \in [0, 1], \\ u(0) = u(1) = 0, \end{cases} \tag{3.15}$$

where $\tilde{h}(s, u, u_s) = \frac{(a(s)\psi(s))_s}{a(s)\psi(s)} u_s(s) + \frac{b(s)}{a(s)}(u(s) - u^3(s))$.

In this case, $\tilde{h}$ satisfies (2.1) and satisfies (2.2) if we consider

$$M_1 = \inf_{s\in[0,1]} \left\{ \frac{(a\psi)_s}{a\psi} \right\}, \tag{3.16}$$

$$M_2 = \sup_{s\in[0,1]} \left\{ \frac{(a\psi)_s}{a\psi} \right\}, \tag{3.17}$$

$$K_1 = \inf_{s\in[0,1]} \left\{ \frac{-2b(s)}{a(s)} \right\} \tag{3.18}$$

and

$$K_2 = \sup_{s\in[0,1]} \left\{ \frac{b(s)}{a(s)} \right\}. \tag{3.19}$$

Now, if we proceed as before, we find that if a, b, ψ are taken such that

$$\alpha(M_2, K_2) + \beta(M_1, K_2) > 1$$

occurs, we can also conclude the non-existence of patterns for this spatially heterogeneous problem.

3.2 The Fisher–KPP problem

A similar analysis can also be conducted for the Fisher–KPP problem. In this case, considering $a, b \in C^1(\mathcal{S})$, we have

$$\begin{cases} u_t = \mathrm{div}_g(a(x)\nabla u) + b(x)(u-u^2), & (t,x) \in \mathbb{R}^+ \times \mathcal{S}, \\ u(t,x) = 0, & (t,x) \in \mathbb{R}^+ \times \partial\mathcal{S} = \mathbb{R}^+ \times (\mathcal{C}_0 \cup \mathcal{C}_1). \end{cases} \tag{3.20}$$

Similar to the previous case, several instability results can be derived from the relationship between functions a and b, and the geometry of $\mathcal{S}$ represented by the function ψ. However, now, we will demonstrate with examples how we can utilize the ideas developed here to obtain results of the existence of patterns for problems with non-zero Dirichlet boundary conditions. In this case, we once again make use of the symmetry of stable solutions, and as usual (see [3,14,18]), we analyze the existence of stable solution to the problem

$$\begin{cases} u_t = au_{ss} + \dfrac{(a(s)\psi)_s}{\psi} u_s + b(s)(u-u^2), & (t,s) \in \mathbb{R}^+ \times [0,1], \\ u(t,0) = A, & t \in \mathbb{R}^+, \\ u(t,1) = B, & t \in \mathbb{R}^+. \end{cases} \tag{3.21}$$

Example 3.4. Consider $a \equiv b \equiv 1$ and $\mathcal{S}$ again a finite straight cylinder ($\psi(s) = 1$ and $\chi(s) = s+1$ for all $s \in [0,1]$). Then we consider the following Fisher–KPP problem with non-zero Dirichlet boundary conditions

$$\begin{cases} u_t = \Delta_g u + (u-u^2), & (t,x) \in \mathbb{R}^+ \times \mathcal{S}, \\ u(t,x) = 1/3, & (t,x) \in \mathbb{R}^+ \times \mathcal{C}_0, \\ u(t,x) = 1/2, & (t,x) \in \mathbb{R}^+ \times \mathcal{C}_1. \end{cases} \tag{3.22}$$

In this case, we have to analyze the following problem

$$\begin{cases} u_{ss} + (u-u^2) = 0, & s \in [0,1], \\ u(0) = 1/3, \quad u(1) = 1/2. \end{cases} \tag{3.23}$$

It is not difficult to see that $h(u) = u - u^2$ satisfies (2.1) and (2.2) with $J = [0,1]$ and

$$M_1 = M_2 = 0, \quad K_1 = -1, \quad K_2 = 1.$$

Moreover,

$$\begin{aligned}\alpha(M_2, K_2) + \beta(M_1, K_2) &= \frac{2}{\sqrt{4K_2 - M_2^2}} \cos^{-1}\left(\frac{M_2}{2\sqrt{K_2}}\right) + \frac{2}{\sqrt{4K_2 - M_1^2}} \cos^{-1}\left(\frac{-M_1}{2\sqrt{K_2}}\right) \\ &= \frac{\pi}{2} + \frac{\pi}{2} = \pi > 1.\end{aligned}$$

Hence, we can use Lemma 2.2 to ensure that

$$\begin{cases} z'' + z = 0, & s \in (0,1), \\ z(a) = A', & z(b) = B' \end{cases} \tag{3.24}$$

and

$$\begin{cases} z'' - z = 0, & s \in (0,1), \\ z(a) = A', & z(b) = B' \end{cases} \tag{3.25}$$

have unique solutions on every sub-interval $[a,b]$ of $[0,1]$ for arbitrary A', B'. Finally, in order to apply Theorem 2.1 we have to consider the problems (3.24) and (3.25) with $a = 0$, $b = 1$, $A' = 1/3$ e $B' = 1/2$. After a few calculations, it's not hard to see that

$$z_1(s) = \frac{2\cos(s) - 2\cot(1)\sin(s) + 3\csc(1)\sin(s)}{6}$$

and

$$z_2(s) = \frac{e^{-s}(-3e + 2e^2 - 2e^{2s} + 3e^{(1+2s)})}{6(e^2 - 1)}$$

are solutions of (3.24) and (3.25) respectively (with $a = 0$, $b = 1$, $A' = 1/3$ e $B' = 1/2$), and both solutions have range contained in $[0,1]$. According to Theorem 2.1, problem (3.23) has a unique solution U. Now we proceed as in the Example 2.6. The energy functional $E : \{u \in H^1(\mathcal{S}); u(x) = 1/3 \text{ for } x \in \mathcal{C}_0,\ u(x) = 1/2 \text{ for } x \in \mathcal{C}_1\} \to \mathbb{R}$ associated with the problem (3.23) is defined by

$$E[u] = \int_{\mathcal{S}} \frac{1}{2}|\nabla_g u|^2 + F(u)dx$$

where $F(u) = \int_0^u s - s^2 ds$. It is routine to verify that (3.22) is a gradient system (see Example 2.6), so we can conclude that U is a pattern.

Once again, depending on computational capacity, one can contemplate more general problems involving heterogeneities, different boundary values, and alternative surfaces.

4 Sine-Gordon equation in an n-dimensional ball

This section is dedicated to studying the sine-Gordon equation. In this equation, we have $f(u) = \sin(u)$ and since f is globally bounded, we can, in this case, analyze the problem in an n-dimensional ball $\mathcal{B}$ centered at the origin with a radius equal to 1. Hence, we consider the following problem

$$\begin{cases} u_t = \mathrm{div}(a(x)\nabla u) + b(x)\sin(u), & (t,x) \in \mathbb{R}^+ \times \mathcal{B}, \\ u(t,x) = B, & (t,x) \in \mathbb{R}^+ \times \partial\mathcal{B}, \end{cases} \tag{4.1}$$

where a and b are functions of class C^1 with radial symmetry, and $B \in \mathbb{R}$.

It is well-known that stable solutions of (4.1) are radially symmetric; thus, if u is a stable solution it satisfies (for simplicity, we consider $n = 2$)

$$\begin{cases} u_{rr} + \dfrac{(a(r)r)_r}{a(r)r} u_r + \dfrac{b(r)}{a(r)} \sin(u) = 0, & r \in (0,1), \\ u_r(0) = 0, \quad u(1) = B. \end{cases} \tag{4.2}$$

We can state the following theorem.

Theorem 4.1. *Consider* (4.1) *and suppose that*

$$h(r,u,u_r) := \frac{(a(r)r)_r}{a(r)r} u_r + \frac{b(r)}{a(r)} \sin(u)$$

satisfies (2.2) *with* G_1 *and* G_2 *defined in* (2.4) *and* (2.3)*, respectively, and* $\beta(M_1, K_2) > 1$*. Then, if* $B = 2k\pi$ *(*$k \in \mathbb{Z}$*)* (4.1) *does not admit patterns.*

Proof. A direct application of Theorem 2.3 gives us that the problem (4.2) with $B = 2k\pi$ ($k \in \mathbb{Z}$) has $u \equiv 2k\pi$ as its unique solution. Therefore, (4.1) does not admit patterns. □

Example 4.2. If a and b are taken such that $a(r) = e^{5r}/r$ and $b(r) = (r+6)e^{5r}/r$ then $h(r,u,u_r) = 5u_r + (r+6)\sin(u)$. Hence h satisfies (2.2) with

$$M_1 = M_2 = 5, \quad K_1 = -6, \quad K_2 = 6.$$

It follows that $\beta(M_1, K_2) = \infty$ e therefore (4.1) does not admit patterns if $B = 2k\pi$ ($k \in \mathbb{Z}$).

5 Concluding remarks

In this paper, we present a straightforward and efficient approach to studying pattern formation in problems with Dirichlet boundary conditions. The symmetry of the domains under consideration, along with the well-known properties of stable solutions, enabled us to leverage results on the existence, uniqueness, and stability of solutions in one-dimensional problems to achieve our objectives. Below, we provide some concluding remarks that complement the ideas discussed thus far.

(i) Evidently, the problem of sine-Gordon could be considered on revolution surfaces as before, and then results of existence or non-existence of patterns would also be generated for this case. On the other hand, the absence of a result like Theorem 2.1 for problems with mixed boundary conditions prevents us from considering the nonlinearities of Allen–Cahn and Fisher–KPP in an n-dimensional ball.

(ii) The examples presented in this work serve the purpose of illustrating how one can apply the developed theory. In this regard, the parameters (surfaces and heterogeneities) were chosen in a way to simplify the computations. Particularly, in Example 4.2, the choice of the diffusion coefficient $a(r) = e^{5r}/r$ made the problem more straightforward and allowed us to use Theorem 4.1.

(iii) Similarly, other equations can be considered beyond those highlighted in this work (namely Allen–Cahn, Fisher–KPP and sine-Gordon equations). For instance, with a nonlinearity of the form $f(u,x) = u(u-\theta(x))(1-u)$, where $0 < \theta(x) < 1$, which is related to the *Fife–Greenlee equation* [10], or the *perturbed sine-Gordon equation* where $f(u) = \sin(u) - g(u)$ [17], or even in problems with advection terms, that is, in reaction–convection–diffusion problems, see [12] and references therein.

Abstract. In this paper we study the well-posedness for the periodic Cauchy problem and the internal controllability of a one-dimensional system that describes the propagation of long water waves with small amplitude in the presence of surface tension. The well-posedness is proved by using the Fourier transform restriction method and the controllability is proved by using the moment method.

Keywords: nonlinear system, water waves, well-posedness, Bourgain spaces, spectral analysis, internal control.

2020 Mathematics Subject Classification: 25E15, 93B05, 35Q35.

1 Introduction

In the present work we consider the periodic Cauchy problem and the internal controllability of the following one-dimensional system

$$\begin{cases} \eta_t + \partial_x^2 \Phi - \partial_x^4 \Phi + \partial_x (\eta \partial_x \Phi) = 0, \\ \Phi_t + \eta - \partial_x^2 \eta + \dfrac{1}{2} (\partial_x \Phi)^2 = 0, \end{cases} \tag{1.1}$$

which is a rescaled version of the system derived in [14] from the evolution of long water waves with small amplitude in the presence of surface tension, where $\Phi = \Phi(x,t)$ represents the nondimensional velocity potential on the bottom $z = 0$ and the variable $\eta = \eta(x,t)$ corresponds the free surface elevation.

As happens in water wave models, there is a Hamiltonian type structure which is clever to characterize the space for the study of the Cauchy problem. In our particular system (1.1), the Hamiltonian functional $\mathcal{H} = \mathcal{H}(t)$ is defined as

$$\mathcal{H}\begin{pmatrix} \eta \\ \Phi \end{pmatrix} = \frac{1}{2} \int_{\mathbb{R}} \left(\eta^2 + (\partial_x \eta)^2 + (\partial_x \Phi)^2 + (\partial_x^2 \Phi)^2 + \eta (\partial_x \Phi)^2 \right) dx,$$

✉ Corresponding author. Email: rcordoba@udenar.edu.co

and the Hamiltonian type structure is given by

$$\begin{pmatrix} \eta_t \\ \Phi_t \end{pmatrix} = \mathcal{J}\mathcal{H}' \begin{pmatrix} \eta \\ \Phi \end{pmatrix}, \qquad \mathcal{J} = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

We see directly that the functional $\mathcal{H}$ is well defined when

$$\eta(\cdot,t), \Phi_x(\cdot,t) \in H^1(\mathbb{R}),$$

for t in some interval. These conditions already characterize the natural space for the study of solutions of the system (1.1). Certainly, J. Quintero and A. Montes in [16] showed for the model (1.1) the existence of solitary wave solutions which propagate with speed of wave $\theta > 0$, i.e. solutions of the form

$$\eta(x,t) = u(x-\theta t), \quad \Phi(x,t) = v(x-\theta t),$$

in the energy space $H^1(\mathbb{R}) \times \mathcal{V}^2(\mathbb{R})$, where $H^1(\mathbb{R})$ is the usual Sobolev space of order 1 and the space $\mathcal{V}^2(\mathbb{R})$ is defined with respect to the norm given by

$$\|w\|^2_{\mathcal{V}^2(\mathbb{R})} = \|w'\|^2_{H^1(\mathbb{R})} = \int_{\mathbb{R}} \left((w')^2 + (w'')^2\right) dx.$$

They also showed, using the estimates of the Kato's commutator, the local well-posedness for the Cauchy problem associated to the system (1.1) in the Sobolev type space $H^s(\mathbb{R}) \times \mathcal{V}^{s+1}(\mathbb{R})$, with $s > 3/2$, where $H^s(\mathbb{R})$ is the usual Sobolev space of order s defined as the completion of the Schwartz class with respect to the norm

$$\|w\|_{H^s(\mathbb{R})} = \| \,(1+|\xi|)^s\, \widehat{w}(\xi)\|_{L^2_\xi}$$

and $\mathcal{V}^{s+1}(\mathbb{R})$ denotes the completion of the Schwartz class with respect to the norm

$$\|w\|_{\mathcal{V}^{s+1}(\mathbb{R})} = \| \,(1+|\xi|)^s\, |\xi|\widehat{w}(\xi)\|_{L^2_\xi},$$

where $\widehat{w}$ is the Fourier transform of w in the space variable x and ξ is the variable in the frequency space related to the variable x. Using Bourgain type spaces, in work [13] the authors showed that the Cauchy problem associated to the system (1.1) is locally well-posedness in the space $H^s(\mathbb{R}) \times \mathcal{V}^{s+1}(\mathbb{R})$ for $s \geq 0$.

On the case of the periodic domain $\mathbb{T} = \mathbb{R}/(2\pi\mathbb{Z})$ (the one-dimensional torus), it was proved in [15] the local well-posedness of the Cauchy problem associated to system (1.1) in the space $H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})$, for $s > 3/2$, where the periodic Sobolev space $H^s(\mathbb{T})$ is defined by

$$H^s(\mathbb{T}) = \left\{ w = \sum_{k\in\mathbb{Z}} w_k e^{ikx} \;\; : \;\; \sum_{k\in\mathbb{Z}} (1+|k|^2)^s |w_k|^2 \, < \, +\infty \right\}$$

and the space $\mathcal{V}^{s+1}(\mathbb{T})$ is defined by the norm

$$\|w\|_{\mathcal{V}^{s+1}(\mathbb{T})} = \left[\sum_{k\in\mathbb{Z}} (1+|k|^2)^s |k|^2 |w_k|^2 \right]^{1/2},$$

where $w_k = \widehat{w}(k)$ denotes the k-Fourier coefficient with respect to the spatial variable x. In this paper, we prove that the Cauchy problem associated to system (1.1) with the initial condition

$$\eta(x,0) = \eta_0(x), \quad \Phi(x,0) = \Phi_0(x) \tag{1.2}$$

is locally well-posed in the space $H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})$ for $s \geq 0$. Hence we improve the result found in [15].

To study the Cauchy problem (1.1)–(1.2) we use its integral equivalent formulation,

$$(\eta(t), \Phi(t)) = S(t)(\eta_0, \Phi_0) - \int_0^t S(t-t')\Big(\partial_x(\eta \partial_x \Phi), \frac{1}{2}(\partial_x \Phi)^2\Big)(t')dt', \tag{1.3}$$

where $S(t)(\eta_0, \Phi_0)$ is the solution of the linear problem, that is

$$S(t)(\eta_0, \Phi_0) = (S_1(t)(\eta_0, \Phi_0), S_2(t)(\eta_0, \Phi_0))$$

with

$$S_1(t)(\eta_0, \Phi_0) = \sum_{k \in \mathbb{Z}} e^{ikx} \left[\cos(\phi(k)t)\widehat{\eta}_0(k) + |k| \sin(\phi(k)t)\widehat{\Phi}_0(k)\right],$$

$$S_2(t)(\eta_0, \Phi_0) = \sum_{k \in \mathbb{Z}} e^{ikx} \left[-\frac{\sin(\phi(k)t)\widehat{\eta}_0(k)}{|k|} + \cos(\phi(k)t)\widehat{\Phi}_0(k)\right],$$

and the function ϕ defined as

$$\phi(k) = |k|^3 + |k|$$

is the Fourier symbol associated to the spacial linear part of the system (1.1).

The method of proof will be the application of the contraction mapping principle in a suitable Banach function space $C\left([0,T] : H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})\right) \cap \mathcal{Z}^s$, where the appropriated space-time weight norm for $\mathcal{Z}^s$ is determined by the knowledge of certain estimates for the solutions of the linear part. This method, introduced by J. Bourgain in [2]-[3] and simplified by C. Kenig, G. Ponce and L. Vega in [8]-[9], not only benefits of the above mentioned space-time estimates, but also exploits structural properties of the nonlinearity.

As usual when dealing with dispersive models in Bourgain spaces, we slightly modify the terms in the right-hand of (1.3) by means of a cut off function. In the following, let $\psi \in C_0^\infty(\mathbb{R})$ with support in $(-2, 2)$, such that $0 \leq \psi \leq 1$, and $\psi \equiv 1$ in $[-1, 1]$. Thus, for $0 < T < 1$ we consider the following modified version of (1.3),

$$(\eta(t), \Phi(t)) = \psi(t)S(t)(\eta_0, \Phi_0) - \psi(t) \int_0^t S(t-t')\psi(t')\Big(\partial_x(\eta \partial_x \Phi), \frac{1}{2}\left(\partial_x \Phi\right)^2\Big)(t')dt'. \tag{1.4}$$

We will show the existence of a solution of the integral problem (1.4) using the Banach fixed point theorem and appropriate linear and nonlinear estimates.

The second part of this paper is concerned with the internal control problem for the system (1.1) on the periodic domain $\mathbb{T}$: choose an appropriate internal control function

$$F = F(x,t) = (f_1(x,t), f_2(x,t))$$

to guide the model

$$\begin{cases} \eta_t + \partial_x^2 \Phi - \partial_x^4 \Phi + \partial_x(\eta \partial_x \Phi) = f_1, & x \in \mathbb{T},\ t \geq 0, \\ \Phi_t + \eta - \partial_x^2 \eta + \frac{1}{2}\left(\partial_x \Phi\right)^2 = f_2, & x \in \mathbb{T},\ t \geq 0, \end{cases} \tag{1.5}$$

during a time interval $[0, T]$, from a given initial state to another preassigned terminal state, in an appropriate function space of system states.

During the last years, there have been many contributions to the internal controllability for different dispersive wave models. For instance, in the case of the Korteweg–de Vries equation

D. Russell and B. Zhang in [18] showed that for $T > 0$ and functions $u_0, u_T \in H^s(\mathbb{T})$, $s \geq 0$, one can always find a control f so that the Cauchy problem

$$u_t + uu_x + u_{xxx} = f, \quad u(x,0) = u_0(x),$$

has a solution $u \in C\left([0,T] : H^s(\mathbb{T})\right)$ satisfying

$$u(x,T) = u_T(x), \quad x \in \mathbb{T},$$

when the initial and terminal states are sufficiently small. A similar result was proved by B. Zhang in [20] for the Boussinesq model,

$$u_{tt} - u_{xx} + \left(u^2 + u_{xx}\right)_{xx} = f, \quad u(x,0) = u_0(x), \quad u_t(x,0) = v_0(x),$$

with the condition

$$u(x,T) = u_T(x), \quad u_t(x,T) = v_T(x),$$

in the space $H^s(\mathbb{T}) \times H^{s-2}(\mathbb{T})$ with $s \geq 2$. In the work [5], E. Cerpa and I. Rivas showed controllability for the Boussinesq equation in low regularity, this is, in the space $H^s(\mathbb{T}) \times H^{s-2}(\mathbb{T})$ with $s > -\frac{1}{4}$.

For the Benjamin–Bona–Mahony equation, L. Rosier and B. Zhang in [17] proved that

$$u_t + u_x - u_{xxt} + uu_x = a(x+ct)h(x,t),$$

with a moving distributed control is controllable in $H^s(\mathbb{T})$ for any $s \geq 1$ in (sufficiently) large time. The control time is chosen in such a way that the support of the control, which is moving at the constant velocity c, can visit all the domain $\mathbb{T}$.

C. Laurent, F. Linares and L. Rosier in [11] and F. Linares and L. Rosier in [12] considered the control problem for the Benjamin–Ono equation,

$$u_t + \mathcal{H}(u_{xx}) + uu_x = f, \quad u(x,0) = u_0(x), \quad u(x,T) = u_T(x).$$

In the latter work, authors proved a controllability result in $L^2(\mathbb{T})$ that allows to prove the global controllability in large time.

Our main result in Theorem 5.4 gives a positive answer to the internal controllability for the system (1.5) in a local sense. We will show that for $T > 0$ and initial an terminal states

$$(\eta_0, \Phi_0), \quad (\eta_T, \Phi_T) \in H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T}), \quad s \geq 0,$$

sufficiently small, there exists a control function $F = (f_1, f_2)$ such that the Cauchy problem associated to the system (1.5) with the initial condition

$$\eta(x,0) = \eta_0(x), \quad \Phi_0(x,0) = \Phi_0(x), \quad x \in \mathbb{T}, \tag{1.6}$$

has a solution $(\eta, \Phi) \in C\left([0,T] : H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})\right)$ satisfying the condition

$$\eta(x,T) = \eta_T(x), \quad \Phi(x,T) = \Phi_T(x), \quad x \in \mathbb{T}.$$

Following the same approach used in the case of the KdV equation and Boussinesq equation, we restrict our attention to a control of the form

$$F(x,t) = (f_1(x,t), f_2(x,t)) = (\rho_1 h_1(x,t), \rho_2 h_2(x,t)),$$

with ρ_i being a smooth function defined on $\mathbb{T}$. Thus

$$H(x,t) = (h_1(x,t), h_2(x,t))$$

is a new control input. Here, the function ρ_i can have a support strictly contained on the torus; thus, it can represent a localization of the control $h_i(x,t)$, which would be only able to act on a part of the domain. First, we perform a spectral analysis for the operator

$$M = \begin{pmatrix} 0 & -(I-\partial_x^2)\partial_x^2 \\ -(I-\partial_x^2) & 0 \end{pmatrix},$$

defined in the space $H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})$. Using that the k-Fourier symbol for the operator M is given by

$$M_k = \begin{pmatrix} 0 & (1+k^2)k^2 \\ -(1+k^2) & 0 \end{pmatrix},$$

we prove for M the existence of a discrete spectral decomposition since the eigenvectors form a Riesz basis of the space $H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})$. Next, using this spectral analysis and the moment method we establish that the linear system associated with (1.5),

$$\begin{cases} \eta_t + \partial_x^2\Phi - \partial_x^4\Phi = f_1, \\ \Phi_t + \eta - \partial_x^2\eta = f_2, \end{cases} \tag{1.7}$$

is exactly controllable in the space $H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})$, with the conditions

$$\eta(0) = \eta_0, \quad \eta(T) = \eta_T, \quad \Phi(0) = \Phi_0, \quad \Phi(T) = \Phi_T. \tag{1.8}$$

Finally, the nonlinear problem is treated as a perturbation by fixed point theory.

The paper is organized as follows. In Section 2, first we define the Bourgain spaces related to our problem and next we establish all the linear estimates needed to proved the result of well-posedness. In Section 3 we estimate the bilinear forms $\partial_x(\eta\partial_x\Phi)$ and $(\partial_x\Phi)(\partial_x\Phi_1)$ associated to the nonlinear part of the system. The Section 4 will be dedicated to establish the result of local well-posedness, via a standard fixed point argument. In Section 5.1, we perform the spectral analysis for the operator M defined in the space $H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})$, for $s \geq 0$. In Section 5.2, by solving a moment problem we found the characterization of the internal control $F = (f_1, f_2)$ for the linear problem (1.7)–(1.8). In Section 5.3, we prove the exact controllability result for the nonlinear problem, by imposing smallness of the initial and terminal states. The proof of this result is mainly based on the linear controllability and the Banach Fixed Point Theorem.

2 Bourgain spaces and linear estimates

We star with the definition of the Bourgain type spaces. We consider the space $\mathcal{Y}$ of functions w such that

(i) $w : \mathbb{T} \times \mathbb{R} \to \mathbb{C}$, (ii) $w(x,\cdot) \in \mathcal{S}(\mathbb{R})$ for all $x \in \mathbb{T}$,

(iii) $x \to w(x,\cdot) \in C^\infty(\mathbb{R})$, (iv) $\widehat{w}(0,t) = 0$ for all $t \in \mathbb{R}$,

Definition 2.1. For $s, \beta \in \mathbb{R}$ we define the Bourgain spaces $X^{s,\beta}$ to be the completion of the space $\mathcal{Y}$ with respect to the norm

$$\|w\|_{X^{s,\beta}} = \|\langle k\rangle^s \langle|\tau| - \phi(k)\rangle^\beta \widetilde{w}\|_{\ell^2_k L^2_\tau},$$

where $\langle a\rangle = 1 + |a|$; $\tilde{w}$ denotes the time-space Fourier transform of w,

$$\widetilde{w}(k,\tau) = \frac{1}{4\pi^2}\int_{\mathbb{R}}\int_{\mathbb{T}} e^{-ixk-it\tau} w(x,t)dxdt;$$

and the function ϕ is defined as

$$\phi(k) = |k|^3 + |k|.$$

The spaces $Y^{s+1,\beta}$ to be the completion of the Schwartz class $\mathcal{S}_{per,2\pi} = \mathcal{S}(\mathbb{T}\times\mathbb{R})$ with respect to the norm

$$\|w\|_{Y^{s+1,\beta}} = \||k|\langle|\tau| - \phi(k)\rangle^\beta \langle k\rangle^s \widetilde{w}\|_{\ell^2_k L^2_\tau}.$$

We similarly introduce the spaces Z^s, W^{s+1}, $s \in \mathbb{R}$, with the norms

$$\|w\|_{Z^s} = \|w\|_{X^{s,-1/2}} + \left\|\frac{\langle k\rangle^s \widetilde{w}(k,\tau)}{\langle|\tau| - \phi(k)\rangle}\right\|_{\ell^2_k L^1_\tau},$$

and

$$\|w\|_{W^{s+1}} = \|w\|_{Y^{s+1,-1/2}} + \left\|\frac{|k|\langle k\rangle^s \widetilde{w}(k,\tau)}{\langle|\tau| - \phi(k)\rangle}\right\|_{\ell^2_k L^1_\tau}.$$

Also, we consider the spaces $U^s, V^{s+1}, s \in \mathbb{R}$, where U^s denotes the completion of the Schwartz class $\mathcal{S}_{per,2\pi}$ with respect to the norm

$$\|w\|_{U^s} = \|w\|_{X^{s,1/2}} + \|\langle k\rangle^s \widetilde{w}(k,\tau)\|_{\ell^2_k L^1_\tau}$$

and V^{s+1} denotes the completion of the Schwartz class $\mathcal{S}_{per,2\pi}$ with respect to the norm

$$\|w\|_{V^{s+1}} = \|w\|_{Y^{s+1,1/2}} + \||k|\langle k\rangle^s \widetilde{w}(k,\tau)\|_{\ell^2_k L^1_\tau}.$$

For $T > 0$ we denote by U^s_T the space space of the restrictions to the interval $[0,T]$ of the elements $w \in U^s$ with norm defined by

$$\|\eta\|_{U^s_T} = \inf_{w\in U^s}\{\|w\|_{U^s} : \eta(t) = w(t) \quad \text{on } [0,T]\}.$$

and by V^{s+1}_T the space space of the restrictions to the interval $[0,T]$ of the elements $w \in V^{s+1}$ with norm defined by

$$\|\Phi\|_{V^{s+1}_T} = \inf_{w\in V^{s+1}}\{\|w\|_{V^{s+1}} : \Phi(t) = w(t) \quad \text{on } [0,T]\}.$$

Next we look at some basic results.

Lemma 2.2. *Let $s \in \mathbb{R}$, then there exists $C > 0$ such that*

(i) $\|\psi\eta\|_{X^{s,-1/2}} \le C\|\eta\|_{X^{s,-1/2}}$,

(ii) $\|\psi\Phi\|_{Y^{s+1,-1/2}} \le C\|\Phi\|_{Y^{s+1,-1/2}}$.

Proof. We will use the notation $\widehat{w}^{(t)}$ for the Fourier transform of w in the time variable t. Note that

$$\widetilde{\psi\eta}(k,\tau) = \frac{1}{4\pi^2}\int_{\mathbb{R}}\int_{\mathbb{T}} e^{-ixk}e^{-it\tau}\left(\int_{\mathbb{R}} e^{it\lambda}\widehat{\psi}^{(t)}(\lambda)d\lambda\right)\eta(x,t)dxdt$$
$$= \int_{\mathbb{R}} \widehat{\psi}^{(t)}(\lambda)\widetilde{\eta}(k,\tau-\lambda)d\lambda$$

and also

$$\|\psi\eta\|^2_{X^{s,-1/2}} = \sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\int_{\mathbb{R}}\langle|\tau|-\phi(k)\rangle^{-1}\left|\int_{\mathbb{R}}\widehat{\psi}^{(t)}(\lambda)\widetilde{\eta}(k,\tau-\lambda)d\lambda\right|^2 d\tau.$$

Moreover

$$\begin{aligned}
&\sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\int_{-\infty}^{0}\langle|\tau|-\phi(k)\rangle^{-1}\left|\int_{\mathbb{R}}\widehat{\psi}^{(t)}(\lambda)\widetilde{\eta}(k,\tau-\lambda)d\lambda\right|^2 d\tau\\
&\quad\le \sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\int_{\mathbb{R}}\langle\tau+\phi(k)\rangle^{-1}\left|\int_{\mathbb{R}}\widehat{\psi}^{(t)}(\lambda)\widetilde{\eta}(k,\tau-\lambda)d\lambda\right|^2 d\tau\\
&\quad= \left\|\langle\tau+\phi(k)\rangle^{-1/2}\langle k\rangle^{s}\int_{\mathbb{R}}\widehat{\psi}^{(t)}(\lambda)\widetilde{\eta}(k,\tau-\lambda)d\lambda\right\|^2_{\ell^2_kL^2_\tau}\\
&\quad\le \int_{\mathbb{R}}|\widehat{\psi}^{(t)}(\lambda)|^2\|\langle\tau+\phi(k)\rangle^{-1/2}\langle k\rangle^{s}\widetilde{\eta}(k,\tau-\lambda)\|^2_{\ell^2_kL^2_\tau}d\lambda
\end{aligned}$$

and

$$\begin{aligned}
&\sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\int_{0}^{+\infty}\langle|\tau|-\phi(k)\rangle^{-1}\left|\int_{\mathbb{R}}\widehat{\psi}^{(t)}(\lambda)\widetilde{\eta}(k,\tau-\lambda)d\lambda\right|^2 d\tau\\
&\quad\le \left\|\langle\tau-\phi(k)\rangle^{-1/2}\langle k\rangle^{s}\int_{\mathbb{R}}\widehat{\psi}^{(t)}(\lambda)\widetilde{\eta}(k,\tau-\lambda)d\lambda\right\|^2_{\ell^2_kL^2_\tau}\\
&\quad\le \int_{\mathbb{R}}|\widehat{\psi}^{(t)}(\lambda)|^2\|\langle\tau-\phi(k)\rangle^{-1/2}\langle k\rangle^{s}\widetilde{\eta}(k,\tau-\lambda)\|^2_{\ell^2_kL^2_\tau}d\lambda.
\end{aligned}$$

Next, using the inequality

$$\big||\tau|-\phi(k)\big| \le \min\{|\tau-\phi(k)|,|\tau+\phi(k)|\},$$

we have for all $\lambda\in\mathbb{R}$, $\langle|\tau|-\phi(k)\rangle \le \langle\tau\pm\phi(k)\rangle \le \langle\tau+\lambda\pm\phi(k)\rangle\langle\lambda\rangle$, and then

$$\begin{aligned}
&\int_{\mathbb{R}}|\widehat{\psi}^{(t)}(\lambda)|^2\|\langle\tau\pm\phi(k)\rangle^{-1/2}\langle k\rangle^{s}\widetilde{\eta}(k,\tau-\lambda)\|^2_{\ell^2_kL^2_\tau}d\lambda\\
&\quad= \int_{\mathbb{R}}|\widehat{\psi}^{(t)}(\lambda)|^2\Big(\sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\int_{\mathbb{R}}\langle\tau+\lambda\pm\phi(k)\rangle^{-1}|\widetilde{\eta}(k,\tau)|^2d\tau\Big)d\lambda\\
&\quad\le \int_{\mathbb{R}}|\widehat{\psi}^{(t)}(\lambda)|^2\Big(\sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\int_{\mathbb{R}}\langle\lambda\rangle\langle|\tau|-\phi(k)\rangle^{-1}|\widetilde{\eta}(k,\tau)|^2d\tau\Big)d\lambda\\
&\quad= \|\langle|\tau|-\phi(k)\rangle^{-1/2}\langle k\rangle^{s}\widetilde{\eta}\|^2_{\ell^2_kL^2_\tau}\int_{\mathbb{R}}\langle\lambda\rangle|\widehat{\psi}^{(t)}(\lambda)|^2d\lambda\\
&\quad\le C\|\eta\|^2_{X^{s,-1/2}}.
\end{aligned}$$

Thus, we conclude that

$$\|\psi\eta\|_{X^{s,-1/2}} \le C\|\eta\|_{X^{s,-1/2}}.$$

In a similar fashion we have that

$$\int_{\mathbb{R}} |\widehat{\psi}(\lambda)^{(t)}|^2 \|\langle \tau \pm \phi(k)\rangle^{-1/2}|k|\langle k\rangle^s \widetilde{\Phi}(k,\tau-\lambda)\|^2_{\ell^2_k L^2_\tau} d\lambda \\ \leq \|\langle |\tau| - \phi(k)\rangle^{-1/2}|k|\langle k\rangle^s \widetilde{\Phi}\|^2_{\ell^2_k L^2_\tau} \int_{\mathbb{R}} \langle\lambda\rangle |\widehat{\psi}^{(t)}(\lambda)|^2 d\lambda \leq C\|\Phi\|^2_{Y^{s+1,-1/2}}.$$

Therefore

$$\|\psi\Phi\|_{Y^{s+1,-1/2}} \leq C\|\Phi\|_{Y^{s+1,-1/2}}. \qquad \square$$

Similarly, we have also the following lemma.

Lemma 2.3. *Let $s \in \mathbb{R}$, then there exists $C > 0$ such that*

(i) $\left\| \frac{\langle k\rangle^s \widetilde{\psi\eta}(k,\tau)}{\langle |\tau| - \phi(k)\rangle} \right\|_{\ell^2_k L^1_\tau} \leq C \left\| \frac{\langle k\rangle^s \widetilde{\eta}(k,\tau)}{\langle |\tau| - \phi(k)\rangle} \right\|_{\ell^2_k L^1_\tau}$,

(ii) $\left\| \frac{|k|\langle k\rangle^s \widetilde{\psi\Phi}(k,\tau)}{\langle |\tau| - \phi(k)\rangle} \right\|_{\ell^2_k L^1_\tau} \leq C \left\| \frac{|k|\langle k\rangle^s \widetilde{\Phi}(k,\tau)}{\langle |\tau| - \phi(k)\rangle} \right\|_{\ell^2_k L^1_\tau}$.

In the following lemmas we establish estimations related with the semigroup $S(t)$.

Lemma 2.4. *Let $s \in \mathbb{R}$, then exists $C_1 > 0$ such that*

$$\|\psi(t)S_1(t)(\eta_0,\Phi_0)\|_{U^s} \leq C_1\|(\eta_0,\Phi_0)\|_{H^s(\mathbb{T})\times\mathcal{V}^{s+1}(\mathbb{T})},$$

$$\|\psi(t)S_2(t)(\eta_0,\Phi_0)\|_{V^{s+1}} \leq C_1\|(\eta_0,\Phi_0)\|_{H^s(\mathbb{T})\times\mathcal{V}^{s+1}(\mathbb{T})}.$$

Proof. We see that

$$\left[\psi(t)\sum_{k\in\mathbb{Z}} e^{ikx}e^{\pm i\phi(k)t}\widehat{\eta}_0(k)\right]^{\sim}(k,\tau) = \widehat{\eta}_0(k)\widehat{\psi}^{(t)}(\tau \mp \phi(k)).$$

So that

$$\left\|\psi(t)\sum_{k\in\mathbb{Z}} e^{ixk}e^{\pm i\phi(k)t}\widehat{\eta}_0(k)\right\|^2_{X^{s,1/2}} = \sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}|\widehat{\eta}_0(k)|^2\int_{\mathbb{R}}\langle |\tau| - \phi(k)\rangle|\widehat{\psi}^{(t)}(\tau\mp\phi(k))|^2 d\tau \\ \leq \sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}|\widehat{\eta}_0(k)|^2\int_{\mathbb{R}}\langle\tau\rangle|\widehat{\psi}^{(t)}(\tau)|^2 d\tau \leq C\|\eta_0\|^2_{H^s(\mathbb{T})}.$$

Also, we note that

$$\left\|\langle k\rangle^s\left[\psi(t)\sum_{k\in\mathbb{Z}} e^{ixk}e^{\pm i\phi(k)t}\widehat{\eta}_0(k)\right]^{\sim}\right\|^2_{\ell^2_k L^1_\tau} = \sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}|\widehat{\eta}_0(k)|^2\left(\int_{\mathbb{R}}|\widehat{\psi}^{(t)}(\tau\mp\phi(k))|d\tau\right)^2 \\ \leq C\|\eta_0\|^2_{H^s(\mathbb{T})}.$$

In a similar fashion,

$$\left\|\psi(t)\sum_{k\in\mathbb{Z}} e^{ixk}e^{\pm i\phi(k)t}|k|\widehat{\Phi}_0(k)\right\|^2_{X^{s,1/2}} \\ = \sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}|k|^2|\widehat{\Phi}_0(k)|^2\int_{\mathbb{R}}\langle |\tau| - \phi(k)\rangle|\widehat{\psi}^{(t)}(\tau\mp\phi(k))|^2 d\tau \leq C\|\Phi_0\|^2_{\mathcal{V}^{s+1}(\mathbb{T})}$$

and

$$\Big\| \langle k\rangle^s \Big[\psi(t) \sum_{k\in\mathbb{Z}} e^{ixk} e^{\pm i\phi(k)t} |k| \widehat{\Phi}_0(k)\Big]^{\sim} \Big\|^2_{\ell^2_k L^1_\tau} = \sum_{k\in\mathbb{Z}} \langle k\rangle^{2s} |k|^2 |\widehat{\Phi}_0(k)|^2 \left(\int_{\mathbb{R}} |\widehat{\psi}^{(t)}(\tau\mp\phi(k))| d\tau\right)^2$$
$$\leq C\|\Phi_0\|^2_{\mathcal{V}^{s+1}(\mathbb{T})}.$$

Thus, from the previous estimates we obtain that

$$\|\psi(t)S_1(t)(\eta_0,\Phi_0)\|_{U^s} \leq C_1\|(\eta_0,\Phi_0)\|_{H^s(\mathbb{T})\times\mathcal{V}^{s+1}(\mathbb{T})}.$$

Similarly we have that

$$\Big\|\psi(t) \sum_{k\in\mathbb{Z}} \frac{e^{ikx} e^{\pm i\phi(k)t}\widehat{\eta}_0(k)}{|k|}\Big\|_{Y^{s+1,1/2}} = \sum_{k\in\mathbb{Z}} \langle k\rangle^{2s} |\widehat{\eta}_0(k)|^2 \int_{\mathbb{R}} \langle |\tau| - \phi(k)\rangle |\widehat{\psi}^{(t)}(\tau\mp\phi(k))|^2 d\tau$$
$$\leq C\|\eta_0\|^2_{H^s(\mathbb{T})}$$

and

$$\Big\| |k|\langle k\rangle^s \Big[\psi(t) \sum_{k\in\mathbb{Z}} \frac{e^{ikx} e^{\pm i\phi(k)t}\widehat{\eta}_0(k)}{|k|}\Big]^{\sim} \Big\|_{\ell^2_k L^1_\tau} = \sum_{k\in\mathbb{Z}} \langle k\rangle^{2s} |\widehat{\eta}_0(k)|^2 \Big(\int_{\mathbb{R}} |\widehat{\psi}^{(t)}(\tau\mp\phi(k))| d\tau\Big)^2$$
$$\leq C\|\eta_0\|^2_{H^s(\mathbb{T})}.$$

Also, we have that

$$\Big\|\psi(t) \sum_{k\in\mathbb{Z}} e^{ikx} e^{\pm i\phi(k)t}\widehat{\Phi}_0(k)\Big\|_{Y^{s+1,1/2}} = \sum_{k\in\mathbb{Z}} \langle k\rangle^{2s} |k|^2 |\widehat{\Phi}_0(k)|^2 \int_{\mathbb{R}} \langle |\tau| - \phi(k)\rangle |\widehat{\psi}^{(t)}(\tau\mp\phi(k))|^2 d\tau$$
$$\leq C\|\Phi_0\|^2_{\mathcal{V}^{s+1}(\mathbb{T})}$$

and

$$\Big\| |k|\langle k\rangle^s \Big[\psi(t) \sum_{k\in\mathbb{Z}} e^{ikx} e^{\pm i\phi(k)t}\widehat{\Phi}_0(k)\Big]^{\sim} \Big\|_{\ell^2_k L^1_\tau} = \sum_{k\in\mathbb{Z}} \langle k\rangle^{2s} |k|^2 |\widehat{\Phi}_0(k)|^2 \Big(\int_{\mathbb{R}} |\widehat{\psi}^{(t)}(\tau\mp\phi(k))| d\tau\Big)^2$$
$$\leq C\|\Phi_0\|^2_{\mathcal{V}^{s+1}(\mathbb{T})}.$$

Then we conclude that

$$\|\psi(t)S_2(t)(\eta_0,\Phi_0)\|_{V^{s+1}} \leq C_1\|(\eta_0,\Phi_0)\|_{H^s(\mathbb{T})\times\mathcal{V}^{s+1}(\mathbb{T})}. \qquad \square$$

Lemma 2.5. *Let $s\in\mathbb{R}$, then there exists $C_2>0$ such that*

(i) $\Big\|\psi(t)\int_0^t f(t')dt'\Big\|_{H_t^{1/2}} \leq C_2\left(\|f\|_{H_t^{-1/2}} + \|\langle\tau\rangle^{-1}\widehat{f}^{(t)}\|_{L^1_\tau}\right).$

(ii) $\Big\|\psi(t)\int_0^t S_1(t-t')(\eta,\Phi)(t')\,dt'\Big\|_{U^s} \leq C_2\left(\|\eta\|_{Z^s} + \|\Phi\|_{W^{s+1}}\right),$

(iii) $\Big\|\psi(t)\int_0^t S_2(t-t')(\eta,\Phi)(t')\,dt'\Big\|_{V^{s+1}} \leq C_2\left(\|\eta\|_{Z^s} + \|\Phi\|_{W^{s+1}}\right).$

Proof. For the inequality (i) see Remark 3.13 of [4]. To prove the inequality (ii), first we note that

$$\begin{aligned}&\Big(\psi(t)\int_0^t \sum_{k\in\mathbb{Z}} e^{ixk}e^{\pm i(t-t')\phi(k)}\widehat{\eta}(k,t')dt'\Big)^{\wedge}(k,t)\\ &\quad=\psi(t)\int_0^t e^{\pm i(t-t')\phi(k)}\widehat{\eta}(k,t')dt'\\ &\quad=e^{\pm i\phi(k)t}\psi(t)\int_0^t e^{\mp i\phi(k)t'}\widehat{\eta}(k,t')dt'=e^{\pm i\phi(k)t}\widehat{w}(k,t),\end{aligned}$$

where $w(x,t)=\psi(t)\int_0^t e^{\mp i\phi(k)t'}\eta(x,t')dt'$. Then we obtain that

$$\Big[\psi(t)\int_0^t \sum_{k\in\mathbb{Z}} e^{ixk}e^{\pm i(t-t')\phi(k)}\widehat{\eta}(k,t')dt'\Big]^{\sim}(k,\tau)=\widetilde{w}(k,\tau\mp\phi(k)).$$

Using the fact that

$$\max\{\big||\tau+\phi(k)|-\phi(k)\big|,\big||\tau-\phi(k)|-\phi(k)\big|\}\le|\tau|$$

we have that

$$\begin{aligned}\Big\|\psi(t)\int_0^t \sum_{k\in\mathbb{Z}} e^{ixk}e^{\pm i(t-t')\phi(k)}\widehat{\eta}(k,t')dt'\Big\|^2_{X^{s,1/2}}&=\sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\int_{\mathbb{R}}\langle|\tau\pm\phi(k)|-\phi(k)\rangle|\widetilde{w}(k,\tau)|^2d\tau\\ &\le\sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\int_{\mathbb{R}}\langle\tau\rangle|\widetilde{w}(k,\tau)|^2d\tau=\sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\|\widehat{w}\|^2_{H_t^{1/2}}.\end{aligned}$$

By using part (i) we have that

$$\begin{aligned}\sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\|\widehat{w}\|^2_{H_t^{1/2}}&=\sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\Big\|\psi(t)\int_0^t e^{\mp i\phi(k)t'}\widehat{\eta}(k,t')dt'\Big\|^2_{H_t^{1/2}}\\ &\le C\Big(\sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\Big\|e^{\mp i\phi(k)t}\widehat{\eta}(k,t)\Big\|^2_{H_t^{-1/2}}\\ &\qquad+\sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\Big\|\langle\tau\rangle^{-1}\Big[e^{\mp i\phi(k)t}\widehat{\eta}(k,t)\Big]^{\wedge(t)}\Big\|^2_{L^1_\tau}\Big)\\ &\le C\Big[\sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\int_{\mathbb{R}}\langle|\tau|-\phi(k)\rangle^{-1}|\widetilde{\eta}(k,\tau)|^2d\tau\\ &\qquad+\sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\Big(\int_{\mathbb{R}}\langle|\tau|-\phi(k)\rangle^{-1}|\widetilde{\eta}(k,\tau)|d\tau\Big)^2\Big].\end{aligned}$$

Thus

$$\Big\|\psi(t)\int_0^t \sum_{k\in\mathbb{Z}} e^{ixk}e^{\pm i(t-t')\phi(k)}\widehat{\eta}(k,t')dt'\Big\|^2_{X^{s,1/2}}\le C\|\eta\|^2_{Z^s}.$$

Let ϱ a smooth cutoff function in the time variable, supported in $A=[-1,1]$. Then

$$\begin{aligned}\psi(t)\int_0^t \sum_{k\in\mathbb{Z}} e^{ixk}e^{\pm i(t-t')\phi(k)}\widehat{\eta}(k,t')dt'&=\psi(t)\sum_{k\in\mathbb{Z}}e^{ixk}\int_{\mathbb{R}}e^{\pm it\phi(k)}\widetilde{\eta}(k,\tau)\Big(\int_0^t e^{it'(\tau\mp\phi(k))}dt'\Big)d\tau\\ &=\psi(t)\sum_{k\in\mathbb{Z}}e^{ixk}\int_{\mathbb{R}}\frac{e^{i\tau t}-e^{\pm it\phi(k)}}{i(\tau\mp\phi(k))}\widetilde{\eta}(k,\tau)d\tau=S_1+S_2-S_3,\end{aligned}$$

where

$$S_1 = \psi(t)\sum_{k\in\mathbb{Z}} e^{ixk}\int_{\mathbb{R}} \frac{e^{i\tau t}-e^{\pm it\phi(k)}}{i(\tau\mp\phi(k))}\varrho(\tau\mp\phi(k))\widetilde{\eta}(k,\tau)d\tau,$$
$$S_2 = \psi(t)\sum_{k\in\mathbb{Z}} e^{ixk}\int_{\mathbb{R}} \frac{[1-\varrho(\tau\mp\phi(k))]}{i(\tau\mp\phi(k))}\widetilde{\eta}(k,\tau)e^{i\tau t}d\tau,$$
$$S_3 = \psi(t)\sum_{k\in\mathbb{Z}} e^{i(xk\pm t\phi(k))}\int_{\mathbb{R}} \frac{[1-\varrho(\tau\mp\phi(k))]}{i(\tau\mp\phi(k))}\widetilde{\eta}(k,\tau)d\tau.$$

Now,

$$\begin{aligned} S_1 &= \psi(t)\sum_{k\in\mathbb{Z}} e^{ixk}\int_{\mathbb{R}} \frac{e^{\pm it\phi(k)}\left(e^{it(\tau\mp\phi(k))}-1\right)}{i(\tau\mp\phi(k))}\varrho(\tau\mp\phi(k))\widetilde{\eta}(k,\tau)d\tau \\ &= \psi(t)\sum_{k\in\mathbb{Z}} e^{i(xk\pm\phi(k))}\int_{\mathbb{R}}\sum_{n\geq 1}\frac{t^n[i(\tau\mp\phi(k))]^{n-1}}{n!}\varrho(\tau\mp\phi(k))\widetilde{\eta}(k,\tau)d\tau \\ &= \psi(t)\sum_{n\geq 1}\frac{t^n i^{n-1}}{n!}\Big(\sum_{k\in\mathbb{Z}} e^{i(xk\pm t\phi(k))}\int_{\mathbb{R}}(\tau\mp\phi(k))^{n-1}\varrho(\tau\mp\phi(k))\widetilde{\eta}(k,\tau)d\tau\Big). \end{aligned}$$

Thus, using the notation

$$f_n(k) = \int_{\mathbb{R}} i^{n-1}(\tau\mp\phi(k))^{n-1}\varrho(\tau\mp\phi(k))\widetilde{\eta}(k,\tau)d\tau, \quad \omega_n(t)=\psi(t)t^n,$$

we see that

$$\begin{aligned} \widetilde{S_1}(k,\tau) &= \Big[\sum_{n\geq 1}\frac{\omega_n(t)}{n!}\Big(\sum_{k\in\mathbb{Z}} e^{i(xk\pm t\phi(k))}f_n(k)\Big)\Big]^{\sim}(k,\tau) \\ &= \sum_{n\geq 1}\frac{1}{n!}f_n(k)\widehat{\omega}_n^{(t)}(\tau\mp\phi(k)). \end{aligned}$$

Therefore

$$\begin{aligned} \|\langle k\rangle^s\widetilde{S}_1\|^2_{\ell^2_kL^1_\tau} &\leq C\sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\Big(\|\chi_A(\tau\mp\phi(k))\widetilde{\eta}(k,\tau)\|_{L^1_\tau}\sum_{n\geq 1}\frac{1}{n!}\int_{\mathbb{R}}|\widehat{\omega}_n^{(t)}(\tau\mp\phi(k))|d\tau\Big)^2 \\ &\leq C\sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\Big(\int_{\mathbb{R}}\langle\tau\mp\phi(k)\rangle^{-1}|\widetilde{\eta}(k,\tau)|d\tau\Big)^2 = C\|\langle k\rangle^s\langle|\tau|-\phi(k)\rangle^{-1}\widetilde{\eta}\|^2_{\ell^2_kL^1_\tau}. \end{aligned}$$

Now, if we use the notation

$$g(k,\tau) = [i(\tau\mp\phi(k))]^{-1}[1-\varrho(\tau\mp\phi(k))]\widetilde{\eta}(k,\tau)$$

then

$$\widetilde{S}_2(k,\tau) = \frac{1}{4\pi^2}\int_{\mathbb{R}}\int_{\mathbb{T}} e^{-ixk}e^{-it\tau}\psi(t)g^{\sim^{-1}}(x,t)dxdt = \widehat{\psi}^{(t)}(\tau)*g(k,\tau).$$

So that, from Young's inequality,

$$\begin{aligned} \|\langle k\rangle^s\widetilde{S}_2\|^2_{\ell^2_kL^1_\tau} &\leq \sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\|\widehat{\psi}^{(t)}(\tau)\|^2_{L^1_\tau}\|g(k,\tau)\|^2_{L^1_\tau} \\ &\leq C\sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\left(\int_{\mathbb{R}}\langle\tau\mp\phi(k)\rangle^{-1}|\chi_B(\tau\mp\phi(k))\widetilde{\eta}(k,\tau)|d\tau\right)^2 \\ &\leq C\|\langle k\rangle^s\langle|\tau|-\phi(k)\rangle^{-1}\widetilde{\eta}\|^2_{\ell^2_kL^1_\tau}, \end{aligned}$$

where $B = \{\tau : |\tau| \geq 1\}$. Next, let

$$\widehat{h}(k) = \int_{\mathbb{R}} [i(\tau \mp \phi(k))]^{-1}[1 - \varrho(\tau \mp \phi(k))]\widetilde{\eta}(k,\tau)d\tau.$$

Then

$$\begin{aligned}\|\langle k\rangle^s \widetilde{S}_3\|^2_{\ell^2_k L^1_\tau} &= \|\langle k\rangle^s \widehat{h}(k)\widehat{\psi}^{(t)}(\tau \mp \phi(k))\|^2_{\ell^2_k L^1_\tau} \\ &\leq C\sum_{k\in\mathbb{Z}} \langle k\rangle^{2s}\Big(\int_{\mathbb{R}} \langle \tau \mp \phi(k)\rangle^{-1}|\chi_B(\tau \mp \phi(k))\widetilde{\eta}(k,\tau)|d\tau\Big)^2 \\ &\leq C\|\langle k\rangle^s \langle |\tau| - \phi(k)\rangle^{-1}\widetilde{\eta}\|^2_{\ell^2_k L^1_\tau}.\end{aligned}$$

Hence, from the previous estimates we conclude that

$$\Big\|\langle k\rangle^s \Big[\psi(t)\int_0^t \sum_{k\in\mathbb{Z}} e^{ixk}e^{\pm i(t-t')\phi(k)}\widehat{\eta}(k,t')dt'\Big]^{\sim}\Big\|_{\ell^2_k L^1_\tau} \leq C\|\langle k\rangle^s\langle|\tau| - \phi(k)\rangle^{-1}\widetilde{\eta}\|_{\ell^2_k L^1_\tau}.$$

In what follows we will use similar arguments. First

$$\Big[\psi(t)\int_0^t \sum_{k\in\mathbb{Z}} e^{ixk}e^{\pm i(t-t')\phi(k)}|k|\widehat{\Phi}(k,t')dt'\Big]^{\sim}(k,\tau) = \widetilde{v}(k,\tau \mp \phi(k)).$$

where $v(x,t) = \psi(t)\int_0^t e^{\mp i\phi(k)t'}|k|\Phi(x,t')dt'$. Then we obtain that

$$\begin{aligned}\Big\|\psi(t)\int_0^t \sum_{k\in\mathbb{Z}} e^{ixk}e^{\pm i(t-t')\phi(k)}|k|\widehat{\Phi}(k,t')dt'\Big\|^2_{X^{s,1/2}} &\leq \sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\|\widehat{v}\|^2_{H^{1/2}_t} \\ &\leq C\Big[\sum_{k\in\mathbb{Z}} |k|^2\langle k\rangle^{2s}\int_{\mathbb{R}} \langle \tau \mp \phi(k)\rangle^{-1}|\widetilde{\Phi}(k,\tau)|^2 d\tau \\ &\quad + \sum_{k\in\mathbb{Z}} |k|^2\langle k\rangle^{2s}\Big(\int_{\mathbb{R}}\langle \tau \mp \phi(k)\rangle^{-1}|\widetilde{\Phi}(k,\tau)|d\tau\Big)^2\Big] \\ &\leq C\|\Phi\|^2_{W^{s+1}}.\end{aligned}$$

Now,

$$\psi(t)\int_0^t \sum_{k\in\mathbb{Z}} e^{ixk}e^{\pm i(t-t')\phi(k)}|k|\widehat{\Phi}(k,t')dt' = S_4 + S_5 - S_6,$$

where

$$\begin{aligned}S_4 &= \psi(t)\sum_{k\in\mathbb{Z}} e^{ixk}\int_{\mathbb{R}} \frac{e^{i\tau t} - e^{\pm it\phi(k)}}{i(\tau \mp \phi(k))}\varrho(\tau \mp \phi(k))|k|\widetilde{\Phi}(k,\tau)d\tau, \\ S_5 &= \psi(t)\sum_{k\in\mathbb{Z}} e^{ixk}\int_{\mathbb{R}} \frac{[1 - \varrho(\tau \mp \phi(k))]}{i(\tau \mp \phi(k))}|k|\widetilde{\Phi}(k,\tau)e^{i\tau t}d\tau, \\ S_6 &= \psi(t)\sum_{k\in\mathbb{Z}} e^{i(xk \pm t\phi(k))}\int_{\mathbb{R}} \frac{[1 - \varrho(\tau \mp \phi(k))]}{i(\tau \mp \phi(k))}|k|\widetilde{\Phi}(k,\tau)d\tau.\end{aligned}$$

We note that

$$S_4 = \psi(t)\sum_{n\geq 1}\frac{t^n i^{n-1}}{n!}\Big(\sum_{k\in\mathbb{Z}} e^{i(xk \pm t\phi(k))}\int_{\mathbb{R}} (\tau \mp \phi(k))^{n-1}\varrho(\tau \mp \phi(k))|k|\widetilde{\Phi}(k,\tau)d\tau\Big).$$

Thus, if we use the notation

$$\zeta_n(k) = \int_{\mathbb{R}} i^{n-1}(\tau \mp \phi(k))^{n-1}\varrho(\tau \mp \phi(k))|k|\widetilde{\Phi}(k,\tau)d\tau, \quad \omega_n(t) = \psi(t)t^n,$$

we obtain that

$$\begin{aligned}\widetilde{S}_4(k,\tau) &= \Big[\sum_{n\geq 1}\frac{\omega_n(t)}{n!}\Big(\sum_{k\in\mathbb{Z}} e^{i(xk\pm t\phi(k))}\zeta_n(k)\Big)\Big]^{\sim}(k,\tau) \\ &= \sum_{n\geq 1}\frac{1}{n!}\zeta_n(k)\widehat{\omega}_n^{(t)}(\tau \mp \phi(k)).\end{aligned}$$

Therefore

$$\begin{aligned}\|\langle k\rangle^s \widetilde{S}_4\|^2_{\ell^2_k L^1_\tau} &\leq \sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\Big(\sum_{n\geq 1}\frac{1}{n!}|\zeta_n(k)|\int_{\mathbb{R}}|\widehat{\omega}_n^{(t)}(\tau\mp\phi(k))|d\tau\Big)^2 \\ &\leq C\sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\|\chi_A(\tau\mp\phi(k))|k|\widetilde{\Phi}(k,\tau)\|^2_{L^1_\tau} \\ &= C\||k|\langle k\rangle^s\langle|\tau|-\phi(k)\rangle^{-1}\widetilde{\Phi}\|^2_{\ell^2_k L^1_\tau}.\end{aligned}$$

Using the notation $g_1(k,\tau) = [i(\tau\mp\phi(k))]^{-1}[1-\varrho(\tau\mp\phi(k))]|k|\widetilde{\Phi}(k,\tau)$ we see that

$$\widetilde{S}_5(k,\tau) = \Big[\psi(t)\sum_{k\in\mathbb{Z}} e^{ikx}\int_{\mathbb{R}} e^{it\tau}g_1(k,\tau)d\tau\Big]^{\sim}(k,\tau) = \widehat{\psi}^{(t)}(\tau) * g_1(k,\tau).$$

Hence

$$\begin{aligned}\|\langle k\rangle^s\widetilde{S}_5\|^2_{\ell^2_k L^1_\tau} &\leq \sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}\|\widehat{\psi}^{(t)}(\tau)\|^2_{L^1_\tau}\|g_1(k,\tau)\|^2_{L^1_\tau} \\ &\leq C\||k|\langle k\rangle^s\langle|\tau|-\phi(k)\rangle^{-1}\widetilde{\Phi}\|^2_{\ell^2_k L^1_\tau}.\end{aligned}$$

Now, let $\widehat{h}_1(k) = \int_{\mathbb{R}}[i(\tau\mp\phi(k))]^{-1}[1-\varrho(\tau\mp\phi(k))]|k|\widetilde{\Phi}(k,\tau)d\tau$. Then

$$\begin{aligned}\|\langle k\rangle^s\widetilde{S}_6\|^2_{\ell^2_k L^1_\tau} &= \sum_{k\in\mathbb{Z}}\langle k\rangle^{2s}|\widehat{h}_1(k)|^2\left(\int_{\mathbb{R}}|\widehat{\psi}^{(t)}(\tau\mp\phi(k))|d\tau\right)^2 \\ &\leq C\||k|\langle k\rangle^s\langle|\tau|-\phi(k)\rangle^{-1}\widetilde{\Phi}\|^2_{\ell^2_k L^1_\tau}.\end{aligned}$$

Consequently, from the previous estimates we have that

$$\Big\|\langle k\rangle^s\Big[\psi(t)\int_0^t\sum_{k\in\mathbb{Z}} e^{ixk}e^{\pm i(t-t')\phi(k)}|k|\widehat{\Phi}(k,t')dt'\Big]^{\sim}\Big\|_{\ell^2_k L^1_\tau} \leq C\||k|\langle k\rangle^s\langle|\tau|-\phi(k)\rangle^{-1}\widetilde{\Phi}\|_{\ell^2_k L^1_\tau}.$$

Therefore, we conclude that

$$\Big\|\psi(t)\int_0^t S_1(t-t')(\eta,\Phi)(t')\,dt'\Big\|_{U^s} \leq C_2\Big(\|\eta\|_{Z^s} + \|\Phi\|_{W^{s+1}}\Big).$$

Similarly we obtain the other inequality in (iii). □

In the following lemma we show the continuous embedding of the space $U^s \times V^{s+1}$ in the class $C(\mathbb{R} : H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T}))$ for $s \in \mathbb{R}$.

Lemma 2.6. *Let $s \in \mathbb{R}$, then there exists $C > 0$ such that*

$$\|(\eta, \Phi)\|_{C(\mathbb{R} : H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T}))} \leq C\|(\eta, \Phi)\|_{U^s \times V^{s+1}}.$$

Proof. First we prove that $U^s \subseteq L^\infty(\mathbb{R} : H^s(\mathbb{T}))$. Since

$$\|\eta(t)\|_{H^s(\mathbb{T})} \leq \Big(\sum_{k \in \mathbb{Z}} \langle k \rangle^{2s} \Big(\int_{\mathbb{R}} |\widetilde{\eta}(k, \tau)| d\tau \Big)^2 \Big)^{1/2} \leq \|\eta\|_{U^s},$$

we have that $\|\eta\|_{L^\infty(\mathbb{R} : H^s(\mathbb{T}))} \leq \|\eta\|_{U^s}$. Now,

$$\|\eta(t) - \eta(t')\|^2_{H^s(\mathbb{T})} \leq \sum_{k \in \mathbb{Z}} \langle k \rangle^{2s} \Big(\int_{\mathbb{R}} |e^{it\tau} - e^{it'\tau}| |\widetilde{\eta}(k, \tau)| d\tau \Big)^2.$$

Then, using the Dominated Convergence Theorem,

$$\|\eta(t) - \eta(t')\|_{H^s(\mathbb{T})} \to 0, \quad t \to t'.$$

Thus $\eta \in C(\mathbb{R} : H^s(\mathbb{T}))$ and moreover $\|\eta\|_{C(\mathbb{R} : H^s(\mathbb{T}))} \leq C\|\eta\|_{U^s}$. Finally,

$$\|\Phi(t)\|_{\mathcal{V}^{s+1}(\mathbb{T})} = \Big(\sum_{k \in \mathbb{Z}} |k|^2 \langle k \rangle^{2s} \Big| \int_{\mathbb{R}} e^{it\tau} \widetilde{\Phi}(k, \tau) d\tau \Big|^2 \Big)^{1/2} \leq \|\Phi\|_{V^{s+1}}.$$

Hence, as in the previous case, $\|\Phi\|_{C(\mathbb{R} : \mathcal{V}^{s+1}(\mathbb{T}))} \leq C\|\Phi\|_{V^{s+1}}$ and then

$$\|(\eta, \Phi)\|_{C(\mathbb{R} : H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T}))} \leq C\|(\eta, \Phi)\|_{U^s \times V^{s+1}}.$$

□

3 Bilinear estimates

Before proceed to the proof of the bilinear estimates, we state some elementary calculus inequalities that will be useful later, and whose proofs can be seen, respectively, in Lemma 5.3 of [10], Lemma 2.5 of [19], and Lemma 4.2 in [6].

Lemma 3.1. *If $\mu > 1/2$ and $\nu = \nu(k, \tau) > 0$, then*

$$\sup_{(k,\tau) \in \mathbb{Z} \times \mathbb{R}} \sum_{k_1 \in \mathbb{Z}} \frac{1}{(\nu + |k_1^2 + \alpha_1 k_1 + \alpha_2|)^\mu} < +\infty,$$

where $\alpha_1 = \alpha_1(k, \tau)$ and $\alpha_2 = \alpha_2(k, \tau)$.

Lemma 3.2. *If $\mu > 1/3$ and $\nu = \nu(k, \tau) > 0$, then*

$$\sup_{(k,\tau) \in \mathbb{Z} \times \mathbb{R}} \sum_{k_1 \in \mathbb{Z}} \frac{1}{(\nu^3 + |k_1^3 + \alpha_1 k_1^2 + \alpha_2 k_1 + \alpha_3|)^\mu} < +\infty,$$

where $\alpha_1 = \alpha_1(k, \tau), \alpha_2 = \alpha_2(k, \tau)$ and $\alpha_3 = \alpha_3(k, \tau)$.

Lemma 3.3. *For $p, q > 0$ and $r = \min\{p, q, p + q - 1\}$ with $p + q > 1$, we have that*

$$\int_{\mathbb{R}} \frac{dx}{\langle x - \lambda \rangle^p \langle x - \mu \rangle^q} \leq \frac{C}{\langle \lambda - \mu \rangle^r}. \tag{3.1}$$

The following nonlinear estimates constitute an important result for this work. We prove these estimates using a method originally due to Bourgain (see [2,3]) and considerably improved by Kenig, Ponce and Vega (see [8,9]).

Lemma 3.4. *Let $s \geq 0$, then exists $C_3 > 0$ such that*

(i) $\|\partial_x(\eta\partial_x\Phi)\|_{X^{s,-1/2}} \leq C_3\|\eta\|_{X^{s,1/2}}\|\Phi\|_{Y^{s+1,1/2}}$,

(ii) $\|(\partial_x\Phi)(\partial_x\Phi_1)\|_{Y^{s+1,-1/2}} \leq C_3\|\Phi\|_{Y^{s+1,1/2}}\|\Phi_1\|_{Y^{s+1,1/2}}$.

Proof. First we note that

$$\begin{aligned}
&\|\partial_x(\eta\partial_x\Phi)\|_{X^{s,-1/2}} \\
&\quad= \|\langle|\tau|-\phi(k)\rangle^{-1/2}k\langle k\rangle^s(\widetilde{\eta}*\widetilde{\partial_x\Phi})(k,\tau)\|_{\ell^2_kL^2_\tau} \\
&\quad= \sup_{\|h\|_{\ell^2_kL^2_\tau}=1}\left|\sum_{k,k_1\in\mathbb{Z}}\int_{\mathbb{R}^2} k\langle k\rangle^s\langle|\tau|-\phi(k)\rangle^{-1/2}\widetilde{\eta}(k-k_1,\tau-\tau_1)k_1\widetilde{\Phi}(k_1,\tau_1)h(k,\tau)\,d\tau d\tau_1\right|.
\end{aligned}$$

Thus, by letting

$$f(k,\tau) = \langle|\tau|-\phi(k)\rangle^{1/2}\langle k\rangle^s\widetilde{\eta}(k,\tau), \quad g(k,\tau) = \langle|\tau|-\phi(k)\rangle^{1/2}\langle k\rangle^s k\widetilde{\Phi}(k,\tau),$$

we have that (i) is equivalent to

$$|J(f,g,h)| \leq C\|f\|_{\ell^2_kL^2_\tau}\|g\|_{\ell^2_kL^2_\tau}\|h\|_{\ell^2_kL^2_\tau}, \tag{3.2}$$

where

$$J(f,g,h) = \sum_{k,k_1\in\mathbb{Z}}\int_{\mathbb{R}^2}\frac{k\langle k\rangle^s}{\langle k_1\rangle^s\langle k-k_1\rangle^s}\frac{f(k-k_1,\tau-\tau_1)g(k_1,\tau_1)h(k,\tau)d\tau d\tau_1}{\langle|\tau|-\phi(k)\rangle^{1/2}\langle|\tau_1|-\phi(k_1)\rangle^{1/2}\langle|\tau-\tau_1|-\phi(k-k_1)\rangle^{1/2}}.$$

For to perform the inequality (3.2), we analyse all possible cases for the sign of τ, τ_1 and $\tau-\tau_1$. To do this we split $\mathbb{Z}^2\times\mathbb{R}^2$ into the following regions

$$\begin{aligned}
\Gamma_1 &= \{(k,k_1,\tau,\tau_1)\in\mathbb{Z}^2\times\mathbb{R}^2 : \tau_1<0, \tau-\tau_1<0\},\\
\Gamma_2 &= \{(k,k_1,\tau,\tau_1)\in\mathbb{Z}^2\times\mathbb{R}^2 : \tau_1\geq 0, \tau-\tau_1<0, \tau\geq 0\},\\
\Gamma_3 &= \{(k,k_1,\tau,\tau_1)\in\mathbb{Z}^2\times\mathbb{R}^2 : \tau_1\geq 0, \tau-\tau_1<0, \tau<0\},\\
\Gamma_4 &= \{(k,k_1,\tau,\tau_1)\in\mathbb{Z}^2\times\mathbb{R}^2 : \tau_1<0, \tau-\tau_1\geq 0, \tau\geq 0\},\\
\Gamma_5 &= \{(k,k_1,\tau,\tau_1)\in\mathbb{Z}^2\times\mathbb{R}^2 : \tau_1<0, \tau-\tau_1\geq 0, \tau<0\},\\
\Gamma_6 &= \{(k,k_1,\tau,\tau_1)\in\mathbb{Z}^2\times\mathbb{R}^2 : \tau_1\geq 0, \tau-\tau_1\geq 0\}.
\end{aligned}$$

We note that $\tau_1<0$ and $\tau-\tau_1<0$ implies $\tau<0$, and $\tau_1\geq 0$ and $\tau-\tau_1\geq 0$ implies $\tau\geq 0$. Then the cases $\tau_1<0$, $\tau-\tau_1<0$, $\tau\geq 0$ and $\tau_1\geq 0$, $\tau-\tau_1\geq 0$, $\tau<0$ cannot occur. Now, since

$$1+|k| \leq (1+|k_1|)(1+|k-k_1|),$$

then for $s\geq 0$ we see that

$$\frac{\langle k\rangle^{2s}}{\langle k_1\rangle^{2s}\langle k-k_1\rangle^{2s}} \leq 1. \tag{3.3}$$

So, we will prove the inequality (3.2) with $Z(f,g,h)$ instead of $J(f,g,h)$, where

$$Z(f,g,h) = \sum_{k,k_1\in\mathbb{Z}} \int_{\mathbb{R}^2} \frac{kf(k_2,\tau_2)g(k_1,\tau_1)h(k,\tau)\,d\tau d\tau_1}{\langle\sigma\rangle^{1/2}\langle\sigma_1\rangle^{1/2}\langle\sigma_2\rangle^{1/2}}$$

with $k_2 = k - k_1, \tau_2 = \tau - \tau_1$ and $\sigma, \sigma_1, \sigma_2$ belonging to one of the following cases

$$\begin{aligned}
&(C_1)\,\sigma = \tau + |k|^3 + |k|,\ \sigma_1 = \tau_1 + |k_1|^3 + |k_1|,\ \sigma_2 = \tau_2 + |k_2|^3 + |k_2|,\\
&(C_2)\,\sigma = \tau - |k|^3 - |k|,\ \sigma_1 = \tau_1 - |k_1|^3 - |k_1|,\ \sigma_2 = \tau_2 + |k_2|^3 + |k_2|,\\
&(C_3)\,\sigma = \tau + |k|^3 + |k|,\ \sigma_1 = \tau_1 - |k_1|^3 - |k_1|,\ \sigma_2 = \tau_2 + |k_2|^3 + |k_2|,\\
&(C_4)\,\sigma = \tau - |k|^3 - |k|,\ \sigma_1 = \tau_1 + |k_1|^3 + |k_1|,\ \sigma_2 = \tau_2 - |k_2|^3 - |k_2|,\\
&(C_5)\,\sigma = \tau + |k|^3 + |k|,\ \sigma_1 = \tau_1 + |k_1|^3 + |k_1|,\ \sigma_2 = \tau_2 - |k_2|^3 - |k_2|,\\
&(C_6)\,\sigma = \tau - |k|^3 - |k|,\ \sigma_1 = \tau_1 - |k_1|^3 - |k_1|,\ \sigma_2 = \tau_2 - |k_2|^3 - |k_2|.
\end{aligned}$$

By hypotheses we have that $\widehat{\eta}(0,t) = 0$, for all $t \in \mathbb{R}$. Thus, if $k = k_1$ then $f(k_2,\tau_2) = 0$. Similarly if $k_1 = 0$ then $g(k_1,\tau_1) = 0$. Then, we will estimate $Z(f,g,h)$ when $k \neq 0$, $k_1 \neq 0$ and $k - k_1 \neq 0$.

By symmetry it is sufficient to estimate $Z(f,g,h)$ into the following set

$$R = \{(k,k_1,\tau,\tau_1) \in \mathbb{Z}^2 \times \mathbb{R}^2 \,:\, |\sigma_2| \leq |\sigma_1|\}.$$

Now, we write $Z(f,g,h)$ as the sum $S_1 + S_2$, where

$$S_j = \sum_k \sum_{k_1} \iint_{R_j} \frac{kf(k_2,\tau_2)g(k_1,\tau_1)h(k,\tau)\chi_{R_j}\,d\tau d\tau_1}{\langle\sigma\rangle^{1/2}\langle\sigma_1\rangle^{1/2}\langle\sigma_2\rangle^{1/2}}, \quad j = 1,2,$$

and the sets R_1, R_2 are defined by

$$R_1 = \{(k,k_1,\tau,\tau_1) \in R \,:\, |\sigma_1| \leq |\sigma|\}, \quad R_2 = \{(k,k_1,\tau,\tau_1) \in R \,:\, |\sigma| \leq |\sigma_1|\}.$$

We first consider $\sigma, \sigma_1, \sigma_2$ as the case (C_1). We will use the notations $\sum_k F_1(k)$, $\int F_2(x)dx$ to indicate that the sum or the integral are calculated, respectively, at some subset of $\mathbb{Z}$ or $\mathbb{R}$. Using the Cauchy–Schwarz inequality,

$$|S_1|^2 \leq \|h\|^2_{\ell^2_k L^2_\tau} \sum_k \int \left(\sum_{k_1} \int |f(k_2,\tau_2)g(k_1,\tau_1)|^2 d\tau_1 \right) \left(\sum_{k_1} \int \frac{\chi^2_{R_1}|k|^2 d\tau_1}{\langle\sigma\rangle\langle\sigma_1\rangle\langle\sigma_2\rangle} \right) d\tau.$$

We will prove that the expression

$$\sum_{k_1} \int \frac{\chi^2_{R_1}|k|^2 d\tau_1}{\langle\sigma\rangle\langle\sigma_1\rangle\langle\sigma_2\rangle} = \frac{|k|^2}{\langle\sigma\rangle} \sum_{k_1} \int \frac{\chi^2_{R_1} d\tau_1}{\langle\sigma_1\rangle\langle\sigma_2\rangle}$$

is bounded. But, by using inequality (3.1) in Lemma 3.3 we have that

$$\int_{\mathbb{R}} \frac{d\tau_1}{\langle\tau_1 + |k_1|^3 + |k_1|\rangle\langle\tau - \tau_1 + |k_2|^3 + |k_2|\rangle} \leq \frac{C}{\langle\tau + |k_1|^3 + |k_1| + |k_2|^3 + |k_2|\rangle}.$$

Then we will prove that there exists $C > 0$ such that

$$\frac{|k|^2}{\langle\tau + |k|^3 + |k|\rangle} \sum_{k_1} \frac{1}{\langle\tau + |k_1|^3 + |k_1| + |k - k_1|^3 + |k - k_1|\rangle} \leq C, \quad \text{on } R_1.$$

Since for $k \neq 0$, $k_1 \neq 0$ and $k \neq k_1$, $|k| = |k_1 + (k-k_1)| \leq |k_1| + |k-k_1| \leq 2|k_1(k-k_1)|$. Then

$$\frac{k^2}{2} \leq |kk_1(k-k_1)|. \tag{3.4}$$

Moreover, we observe the relation

$$\begin{aligned} \tau + |k|^3 + |k| - \left[\tau_1 + |k_1|^3 + |k_1| + \tau_2 + |k_2|^3 + |k_2|\right] \\ = |k|^3 + |k| - |k_1|^3 - |k_1| - |k_2|^3 - |k_2|. \end{aligned} \tag{3.5}$$

If $(k, k_1, \tau, \tau_1) \in R_1$ then

$$|\tau_2 + |k_2|^3 + |k_2|| \leq |\tau_1 + |k_1|^3 + |k_1|| \leq |\tau + |k|^3 + |k||.$$

Hence, using the triangle inequality in (3.5) we conclude that

$$\big||k|^3 + |k| - |k_1|^3 - |k_1| - |k_2|^3 - |k_2|\big| \leq 3|\tau + |k|^3 + |k||. \tag{3.6}$$

Assume $k_1 > 0$ and $k - k_1 > 0$. Then $k > k_1 > 0$ and, using Lemma 3.1, we obtain that

$$\begin{aligned} \sum_{k_1} \frac{1}{\langle \tau + |k_1|^3 + |k_1| + |k-k_1|^3 + |k-k_1| \rangle} &\leq \sum_{k_1 \in \mathbb{Z}} \frac{1}{\langle \tau + k^3 + k - 3k^2k_1 + 3kk_1^2 \rangle} \\ &\leq \sup_{(k,\tau) \in \mathbb{Z}^* \times \mathbb{R}} \sum_{k_1 \in \mathbb{Z}} \frac{1}{\left(\frac{1}{3|k|} + \left| k_1^2 - kk_1 + \frac{\tau}{3k} + \frac{k^2}{3} + \frac{1}{3} \right| \right)} \\ &\leq C, \end{aligned}$$

where $\mathbb{Z}^* := \mathbb{Z} \setminus \{0\}$. Moreover,

$$|k|^3 + |k| - |k_1|^3 - |k_1| - |k_2|^3 - |k_2| = k^3 + k - k_1^3 - k_1 - k_2^3 - k_2 = 3kk_1(k-k_1) > 0.$$

So, from (3.6) and inequality (3.4) we see that

$$|\tau + k^3 + k| \geq |kk_1(k-k_1)| \geq \frac{|k|^2}{2}.$$

Thus

$$\frac{|k|^2}{\langle \tau + |k|^3 + |k| \rangle} \leq C.$$

Assume $k_1 < 0$ and $k - k_1 < 0$. Then $k < k_1 < 0$ and, using Lemma 3.1, we see that

$$\begin{aligned} \sum_{k_1} \frac{1}{\langle \tau + |k_1|^3 + |k_1| + |k-k_1|^3 + |k-k_1| \rangle} &\leq \sum_{k_1 \in \mathbb{Z}} \frac{1}{\langle \tau - k^3 - k + 3k^2k_1 - 3kk_1^2 \rangle} \\ &\leq \sup_{(k,\tau) \in \mathbb{Z}^* \times \mathbb{R}} \sum_{k_1 \in \mathbb{Z}} \frac{1}{\left(\frac{1}{3|k|} + \left| k_1^2 - kk_1 - \frac{\tau}{3k} + \frac{k^2}{3} + \frac{1}{3} \right| \right)} \\ &\leq C. \end{aligned}$$

Moreover

$$\big||k|^3 + |k| - |k_1|^3 - |k_1| - |k_2|^3 - |k_2|\big| = \big| -k^3 - k + k_1^3 + k_1 + k_2^3 + k_2 \big| = 3|kk_1(k-k_1)|.$$

Hence from (3.6) and (3.4) we obtain that

$$|\tau - k^3 - k| \geq |kk_1(k-k_1)| \geq \frac{|k|^2}{2} \quad \text{and} \quad \frac{|k|^2}{\langle \tau - k^3 - k \rangle} \leq C.$$

Assume $k_1 > 0$ and $k - k_1 < 0$. Using Lemma 3.2,

$$\begin{aligned}
&\sum_{k_1} \frac{1}{\langle \tau + |k_1|^3 + |k_1| + |k-k_1|^3 + |k-k_1| \rangle} \\
&\quad \leq \sum_{k_1 \in \mathbb{Z}} \frac{1}{\langle \tau + 2k_1^3 + 2k_1 - k^3 - k + 3k^2k_1 - 3kk_1^2 \rangle} \\
&\quad \leq \sup_{(k,\tau)\in\mathbb{Z}\times\mathbb{R}} \sum_{k_1 \in \mathbb{Z}} \frac{1}{\left(\frac{1}{2} + \left|k_1^3 - \frac{3}{2}kk_1^2 + k_1 + \frac{3}{2}k^2k_1 + \frac{\tau}{2} - \frac{k^3}{2} - \frac{k}{2}\right|\right)} \leq C.
\end{aligned}$$

Moreover, if $k > 0$ then

$$\big||k|^3 + |k| - |k_1|^3 - |k_1| - |k_2|^3 - |k_2|\big| = 2|k-k_1| \left[\left(k_1 - \frac{k}{4}\right)^2 + \frac{15k^2}{16} + 1\right] \geq \frac{15}{8}k^2.$$

If $k < 0$,

$$\big||k|^3 + |k| - |k_1|^3 - |k_1| - |k_2|^3 - |k_2|\big| = 2|k_1| \left[\left(k_1 - \frac{3k}{4}\right)^2 + \frac{15k^2}{16} + 1\right] \geq \frac{15k^2}{8}.$$

Thus, from inequality (3.6) we have that

$$|\tau + |k|^3 + |k|| \geq \frac{5k^2}{8} \quad \text{and} \quad \frac{|k|^2}{\langle \tau + |k|^3 + |k| \rangle} \leq C.$$

Assume $k_1 < 0$ and $k - k_1 > 0$. Using Lemma 3.2,

$$\begin{aligned}
&\sum_{k_1} \frac{1}{\langle \tau + |k_1|^3 + |k_1| + |k-k_1|^3 + |k-k_1| \rangle} \\
&\quad \leq \sup_{(k,\tau)\in\mathbb{Z}\times\mathbb{R}} \sum_{k_1 \in \mathbb{Z}} \frac{1}{\left(\frac{1}{2} + \left|k_1^3 - \frac{3}{2}kk_1^2 + k_1 + \frac{3}{2}k^2k_1 - \frac{\tau}{2} - \frac{k^3}{2} - \frac{k}{2}\right|\right)} \leq C.
\end{aligned}$$

Now, if $k > 0$ then

$$\big||k|^3 + |k| - |k_1|^3 - |k_1| - |k_2|^3 - |k_2|\big| = 2|k_1| \left[\left(k_1 - \frac{3k}{4}\right)^2 + \frac{15k^2}{16} + 1\right] \geq \frac{15k^2}{8}.$$

and if $k < 0$ then

$$\big||k|^3 + |k| - |k_1|^3 - |k_1| - |k_2|^3 - |k_2|\big| = 2|k-k_1| \left[\left(k_1 - \frac{k}{4}\right)^2 + \frac{15k^2}{16} + 1\right] \geq \frac{15}{8}k^2.$$

Thus, by using (3.6),

$$|\tau + |k|^3 + |k|| \geq \frac{5k^2}{8} \quad \text{and} \quad \frac{|k|^2}{\langle \tau + |k|^3 + |k| \rangle} \leq C.$$

Consequently, from the previous estimates there exists $C > 0$ such that

$$\frac{|k|^2}{\langle\sigma\rangle}\sum_{k_1}\int\frac{d\tau_1}{\langle\sigma_1\rangle\langle\sigma_2\rangle}\leq C,\quad \text{on}\quad R_1.$$

Therefore

$$\begin{aligned}|S_1|^2 &\leq C\|h\|^2_{\ell^2_k L^2_\tau}\sum_{k_1\in\mathbb{Z}}\int_{\mathbb{R}}|g(k_1,\tau_1)|^2\Big(\sum_{k\in\mathbb{Z}}\int_{\mathbb{R}}|f(k_2,\tau_2)|^2 d\tau\Big)d\tau_1\\ &\leq C\|f\|^2_{\ell^2_k L^2_\tau}\|g\|^2_{\ell^2_k L^2_\tau}\|h\|^2_{\ell^2_k L^2_\tau}.\end{aligned}$$

In a similar fashion,

$$|S_2|^2\leq\|g\|^2_{\ell^2_k L^2_\tau}\sum_{k_1\in\mathbb{Z}}\int_{\mathbb{R}}\left(\sum_k\int|f(k_2,\tau_2)h(k,\tau)|^2 d\tau\right)\left(\sum_k\int\frac{\chi^2_{R_2}|k|^2 d\tau}{\langle\sigma\rangle\langle\sigma_1\rangle\langle\sigma_2\rangle}\right)d\tau_1.$$

We will prove that the expression

$$\sum_k\int\frac{\chi^2_{R_2}|k|^2 d\tau}{\langle\sigma\rangle\langle\sigma_1\rangle\langle\sigma_2\rangle}=\frac{1}{\langle\sigma_1\rangle}\sum_k\int\frac{\chi^2_{R_2}|k|^2 d\tau}{\langle\sigma\rangle\langle\sigma_2\rangle}$$

is bounded. Using inequality (3.1) in Lemma 3.3 we have that

$$\int_{\mathbb{R}}\frac{d\tau}{\langle\tau+|k|^3+|k|\rangle\langle\tau-\tau_1+|k_2|^3+|k_2|\rangle}\leq\frac{C}{\langle\tau_1+|k|^3+|k|-|k_2|^3-|k_2|\rangle}.$$

Thus, we will show that there exists $C > 0$ such that

$$\frac{1}{\langle\tau_1+|k_1|^3+|k_1|\rangle}\sum_k\frac{|k|^2}{\langle\tau_1+|k|^3+|k|-|k-k_1|^3-|k-k_1|\rangle}\leq C,\quad \text{on } R_2.$$

We note that if $(k,k_1,\tau,\tau_1)\in R_2$,

$$|\tau+|k|^3+|k||\leq|\tau_1+|k_1|^3+|k_1||,\qquad |\tau_2+|k_2|^3+|k_2||\leq|\tau_1+|k_1|^3+|k_1||.$$

So, using the triangle inequality in (3.5) we see that

$$\big||k|^3+|k|-|k_1|^3-|k_1|-|k_2|^3-|k_2|\big|\leq 3|\tau_1+|k_1|^3+|k_1||. \tag{3.7}$$

Assume $k > 0$ and $k - k_1 > 0$. Thus

$$\sum_k\frac{|k|^2}{\langle\tau_1+|k|^3+|k|-|k_2|^3-|k_2|\rangle}\leq\sum_{k\in\mathbb{Z}}\frac{|k|^2}{\langle\tau_1+k_1^3+k_1+3k^2k_1-3kk_1^2\rangle}=:J_1.$$

Moreover, if $k_1 > 0$ then, using inequality (3.4),

$$\big||k|^3+|k|-|k_1|^3-|k_1|-|k_2|^3-|k_2|\big|=3|kk_1(k-k_1)|\geq\frac{3k^2}{2}$$

and if $k_1 < 0$ then

$$\big||k|^3+|k|-|k_1|^3-|k_1|-|k_2|^3-|k_2|\big|=2|k_1|\left[\left(k_1-\frac{3k}{4}\right)^2+\frac{15k^2}{16}+1\right]\geq\frac{15k^2}{8}.$$

Hence, from (3.7) there exists $C>0$ such that

$$|\tau_1+|k_1|^3+|k_1||\geq Ck^2$$

and consequently, using Lemma 3.1, we obtain

$$\frac{1}{\langle\tau_1+|k_1|^3+|k_1|\rangle}J_1\leq\ C\sup_{(k_1,\tau_1)\in\mathbb{Z}^*\times\mathbb{R}}\sum_{k\in\mathbb{Z}}\frac{1}{\left(\frac{1}{3|k_1|}+\left|k^2-kk_1+\frac{\tau_1}{3k_1}+\frac{k_1^2}{3}+\frac{1}{3}\right|\right)}\leq C.$$

Assume $k<0$ and $k-k_1<0$. Thus

$$\sum_k\frac{|k|^2}{\langle\tau_1+|k|^3+|k|-|k-k_1|^3-|k-k_1|\rangle}\leq\sum_{k\in\mathbb{Z}}\frac{|k|^2}{\langle\tau_1-k_1^3-k_1-3k^2k_1+3kk_1^2\rangle}=:J_2.$$

Moreover, if $k_1>0$ then

$$\left||k|^3+|k|-|k_1|^3-|k_1|-|k_2|^3-|k_2|\right|=2|k_1|\left[\left(k_1-\frac{3k}{4}\right)^2+\frac{15k^2}{16}+1\right]\geq\frac{15k^2}{8}.$$

If $k_1<0$ then, using (3.4),

$$\left||k|^3+|k|-|k_1|^3-|k_1|-|k_2|^3-|k_2|\right|=3|kk_1(k-k_1)|\geq\frac{3k^2}{2}.$$

Thus, from (3.7) there exists $C>0$ such that

$$|\tau_1+|k_1|^3+|k_1||\geq Ck^2$$

and so

$$\frac{1}{\langle\tau_1+k_1^3+k_1\rangle}J_2\leq\ C\sup_{(k_1,\tau_1)\in\mathbb{Z}^*\times\mathbb{R}}\sum_{k\in\mathbb{Z}}\frac{1}{\langle\tau_1-k_1^3-k_1-3k^2k_1+3kk_1^2\rangle}\leq C.$$

Assume $k>0$ and $k-k_1<0$. Then $k_1>k>0$ and

$$\sum_k\frac{|k|^2}{\langle\tau_1+|k|^3+|k|-|k-k_1|^3-|k-k_1|\rangle}\leq\sum_{k\in\mathbb{Z}}\frac{|k|^2}{\langle\tau_1+2k^3+2k-3k^2k_1+3kk_1^2-k_1^3-k_1\rangle}=:J_3.$$

Moreover, we see that

$$\left||k|^3+|k|-|k_1|^3-|k_1|-|k_2|^3-|k_2|\right|\geq\frac{15k^2}{8}\quad\text{and}\quad|\tau_1+k_1^3+k_1|\geq\frac{5k^2}{8}.$$

Consequently

$$\begin{aligned}\frac{1}{\langle\tau_1+k_1^3+k_1\rangle}J_3&\leq C\sup_{(k_1,\tau_1)\in\mathbb{Z}\times\mathbb{R}}\sum_{k\in\mathbb{Z}}\frac{1}{\langle\tau_1+2k^3+2k-3k^2k_1+3kk_1^2-k_1^3-k_1\rangle}\\&\leq\sup_{(k_1,\tau_1)\in\mathbb{Z}\times\mathbb{R}}\sum_{k\in\mathbb{Z}}\frac{1}{\left(\frac{1}{2}+\left|k^3-\frac{3}{2}k^2k_1+k+\frac{3}{2}kk_1^2+\frac{\tau_1}{2}-\frac{k_1^3}{2}-\frac{k_1}{2}\right|\right)}\leq C.\end{aligned}$$

Assume $k<0$ and $k-k_1>0$. Then

$$\sum_k \frac{|k|^2}{\langle \tau_1+|k|^3+|k|-|k-k_1|^3-|k-k_1|\rangle} \leq \sum_{k\in\mathbb{Z}} \frac{|k|^2}{\langle \tau_1-2k^3-2k+k_1^3+k_1+3k^2k_1-3kk_1^2\rangle} =: J_4.$$

Also we see that

$$\big||k|^3+|k|-|k_1|^3-|k_1|-|k_2|^3-|k_2|\big| \geq \frac{15k^2}{8} \quad \text{and} \quad |\tau_1+k_1^3+k_1| \geq \frac{5k^2}{8}.$$

Thus, using (3.7),

$$|\tau_1+k_1^3+k_1| \geq \frac{5k^2}{8}.$$

So that

$$\begin{aligned}\frac{1}{\langle \tau_1+k_1^3+k_1\rangle} J_4 &\leq C \sup_{(k_1,\tau_1)\in\mathbb{Z}\times\mathbb{R}} \sum_{k\in\mathbb{Z}} \frac{1}{\langle \tau_1-2k^3-2k+3k^2k_1-3kk_1^2+k_1^3+k_1\rangle} \\ &\leq C \sup_{(k_1,\tau_1)\in\mathbb{Z}\times\mathbb{R}} \sum_{k\in\mathbb{Z}} \frac{1}{\left(\frac{1}{2}+\left|k^3-\frac{3}{2}k^2k_1+k+\frac{3}{2}kk_1^2-\frac{\tau_1}{2}-\frac{k_1^3}{2}-\frac{k_1}{2}\right|\right)} \leq C.\end{aligned}$$

Hence, from previous estimates we see that there exists $C>0$ such that

$$\frac{1}{\langle \sigma_1\rangle}\sum_k \int \frac{|k|^2 d\tau}{\langle \sigma\rangle\langle \sigma_2\rangle} \leq C, \quad \text{on } R_2.$$

Therefore

$$|S_2|^2 \leq C\|f\|^2_{\ell^2_k L^2_\tau}\|g\|^2_{\ell^2_k L^2_\tau}\|h\|^2_{\ell^2_k L^2_\tau}.$$

The proof of the others is similar to case (C_1). Finally, note that

$$\begin{aligned}&\|(\partial_x\Phi)(\partial_x\Phi_1)\|_{Y^{s+1,-1/2}} \\ &= \sup_{\|h\|_{\ell^2_k L^2_\tau}=1}\left|\sum_{k,k_1\in\mathbb{Z}}\int_{\mathbb{R}^2} k\langle k\rangle^s\langle|\tau|-\phi(k)\rangle^{-1/2}(k-k_1)\widetilde{\Phi}(k-k_1,\tau-\tau_1)k_1\widetilde{\Phi}_1(k_1,\tau_1)h(k,\tau)\,d\tau d\tau_1\right|.\end{aligned}$$

Then, by letting

$$f(k,\tau)=\langle|\tau|-\phi(k)\rangle^{1/2}\langle k\rangle^s k\widetilde{\Phi}(k,\tau), \quad f_1(k,\tau)=\langle|\tau|-\phi(k)\rangle^{1/2}\langle k\rangle^s k\widetilde{\Phi}_1(k,\tau)$$

we have that (ii) is equivalent to

$$|K(f,f_1,h)| \leq C\|f\|_{\ell^2_k L^2_\tau}\|f_1\|_{\ell^2_k L^2_\tau}\|h\|_{\ell^2_k L^2_\tau}, \tag{3.8}$$

where

$$K(f,f_1,h)=\sum_{k,k_1\in\mathbb{Z}}\int_{\mathbb{R}^2}\frac{k\langle k\rangle^s}{\langle k_1\rangle^s\langle k-k_1\rangle^s}\frac{f(k-k_1,\tau-\tau_1)f_1(k_1,\tau_1)h(k,\tau)\,d\tau d\tau_1}{\langle|\tau|-\phi(k)\rangle^{1/2}\langle|\tau_1|-\phi(k_1)\rangle^{1/2}\langle|\tau-\tau_1|-\phi(k-k_1)\rangle^{1/2}}.$$

The proof of (3.8) is analogous to the proof of (3.2). □

The proof of the following estimates is analogous to the proof of Lemma 3.4.

Lemma 3.5. *Let $s \geq 0$, then there exists $C_4 > 0$ such that*

(i) $\left\| \frac{\langle k\rangle^s [\partial_x(\eta\partial_x\Phi)]^{\sim}(k,\tau)}{\langle|\tau|-\phi(k)\rangle} \right\|_{\ell^2_k L^1_\tau} \leq C_4 \|\eta\|_{X^{s,1/2}} \|\Phi\|_{Y^{s+1,1/2}}$,

(ii) $\left\| \frac{|k|\langle k\rangle^s [(\partial_x\Phi)(\partial_x\Phi_1)]^{\sim}(k,\tau)}{\langle|\tau|-\phi(k)\rangle} \right\|_{\ell^2_k L^1_\tau} \leq C_4 \|\Phi\|_{Y^{s+1,1/2}} \|\Phi_1\|_{Y^{s+1,1/2}}$.

Proof. First, notice that

$$\begin{aligned}
&\left\| \frac{\langle k\rangle^s [\partial_x(\eta\partial_x\Phi)]^{\sim}(k,\tau)}{\langle|\tau|-\phi(k)\rangle} \right\|_{\ell^2_k L^1_\tau} \\
&\quad = \left\| \frac{k\langle k\rangle^s}{\langle|\tau|-\phi(k)\rangle} \sum_{k_1\in\mathbb{Z}} \int_{\mathbb{R}} \frac{f(k-k_1,\tau-\tau_1)g(k_1,\tau_1)d\tau_1}{\langle k_1\rangle^s\langle k-k_1\rangle^s \langle|\tau_1|-\phi(k_1)\rangle^{1/2}\langle|\tau-\tau_1|-\phi(k-k_1)\rangle^{1/2}} \right\|_{\ell^2_k L^1_\tau} \\
&\quad =: J(f,g),
\end{aligned}$$

where

$$f(k,\tau) = \langle|\tau|-\phi(k)\rangle^{1/2}\langle k\rangle^s \widetilde{\eta}(k,\tau), \quad g(k,\tau) = \langle|\tau|-\phi(k)\rangle^{1/2}\langle k\rangle^s k\widetilde{\Phi}(k,\tau).$$

In view of inequality (3.3) we will prove inequality in (i) with $Z(f,g)$ instead of $J(f,g)$ where

$$Z(f,g) = \left\| \frac{k}{\langle\sigma\rangle} \sum_{k_1\in\mathbb{Z}} \int_{\mathbb{R}} \frac{f(k_2,\tau_2)g(k_1,\tau_1)d\tau_1}{\langle\sigma_1\rangle^{1/2}\langle\sigma_2\rangle^{1/2}} \right\|_{\ell^2_k L^1_\tau}.$$

More exactly, we will study the expression

$$Z_j(f,g) = \left\| \frac{k}{\langle\sigma\rangle} \sum_{k_1} \int \frac{f(k_2,\tau_2)g(k_1,\tau_1)\chi_{R_j} d\tau_1}{\langle\sigma_1\rangle^{1/2}\langle\sigma_2\rangle^{1/2}} \right\|_{\ell^2_k L^1_\tau}, \quad j=1,2,$$

with $k_2 = k-k_1, \tau_2 = \tau-\tau_1$; σ,σ_1,σ_2 belonging to one of the cases (C_1)-(C_6); and the sets R R_1, R_2 are defined by

$$R = \{(k,k_1,\tau,\tau_1) \in \mathbb{Z}^2\times\mathbb{R}^2 : |\sigma_2| \leq |\sigma_1|\},$$

$$R_1 = \{(k,k_1,\tau,\tau_1) \in R : |\sigma_1| \leq |\sigma|\} \quad \text{and} \quad R_2 = \{(k,k_1,\tau,\tau_1) \in R : |\sigma| \leq |\sigma_1|\}.$$

Using a duality argument we see that

$$Z_1(f,g) = \sup_{\|h\|_{\ell^2_k}=1} \left| \sum_k \sum_{k_1} \int\int \frac{kf(k_2,\tau_2)g(k_1,\tau_1)h(k)\chi_{R_1} d\tau d\tau_1}{\langle\sigma\rangle\langle\sigma_1\rangle^{1/2}\langle\sigma_2\rangle^{1/2}} \right|.$$

Now, consider σ,σ_1,σ_2 as in the case (C_1) and note that

$$\begin{aligned}
&\left[\sum_k \sum_{k_1} \int\int \frac{|kf(k_2,\tau_2)g(k_1,\tau_1)h(k)|\chi_{R_1} d\tau d\tau_1}{\langle\sigma\rangle\langle\sigma_1\rangle^{1/2}\langle\sigma_2\rangle^{1/2}} \right]^2 \\
&\quad \leq \|g\|^2_{\ell^2_k L^2_\tau} \sum_{k_1} \left\| \sum_{k\in\mathbb{Z}} |h(k)|^2 \int_{\mathbb{R}} |f(k_2,\tau_2)|^2 d\tau \right\|_{L^\infty_{\tau_1}} \sum_k \int\int \frac{\chi^2_{R_1}|k|^2 d\tau d\tau_1}{\langle\sigma\rangle^2\langle\sigma_1\rangle\langle\sigma_2\rangle}.
\end{aligned}$$

Then we will prove that the expression

$$\sum_k |k|^2 \int \frac{1}{\langle\sigma\rangle^2}\Big(\int \frac{\chi^2_{R_1} d\tau_1}{\langle\sigma_1\rangle\langle\sigma_2\rangle}\Big) d\tau$$

is bounded. In fact, if $(k, k_1, \tau, \tau_1) \in R_1$,

$$|\tau_2 + |k_2|^3 + |k_2|| \leq |\tau_1 + |k_1|^3 + |k_1|| \leq |\tau + |k|^3 + |k||. \tag{3.9}$$

Hence, using inequality (3.1) in Lemma 3.3, we have for $0 < r < 1/4$ that

$$\begin{aligned}
&\frac{1}{\langle\tau + |k|^3 + |k|\rangle^2} \int \frac{d\tau_1}{\langle\tau + |k_1|^3 + |k_1|\rangle\langle\tau_2 + |k_2|^3 + |k_2|\rangle} \\
&\quad\leq \frac{1}{\langle\tau + |k|^3 + |k|\rangle^{2(1-r)}} \int_{\mathbb{R}} \frac{d\tau_1}{\langle\tau + |k_1|^3 + |k_1|\rangle^{1+r}\langle\tau_2 + |k_2|^3 + |k_2|\rangle^{1+r}} \\
&\quad\leq \frac{C}{\langle\tau + |k|^3 + |k|\rangle^{2(1-r)}\langle\tau + |k_1|^3 + |k_1| + |k_2|^3 + |k_2|\rangle^{1+r}}.
\end{aligned}$$

So, for $0 < r < 1/4$, we will prove that there exists $C > 0$ such that

$$\sum_k |k|^2 \int \frac{d\tau}{\langle\tau + |k|^3 + |k|\rangle^{2(1-r)}\langle\tau + |k_1|^3 + |k_1| + |k_2|^3 + |k_2|\rangle^{1+r}} \leq C, \quad \text{on } R_1.$$

The importance of the choice of r will be noted later. We have the relation

$$\begin{aligned}
\tau + |k|^3 + |k| - \big[\tau_1 + |k_1|^3 + |k_1| + \tau_2 + |k_2|^3 + |k_2|\big]& \\
= |k|^3 + |k| - |k_1|^3 - |k_1| - |k_2|^3 - |k_2|.&
\end{aligned} \tag{3.10}$$

Using the triangle inequality in (3.10) and inequality (3.9) we obtain that

$$\big||k|^3 + |k| - |k_1|^3 - |k_1| - |k_2|^3 - |k_2|\big| \leq 3|\tau + |k|^3 + |k||. \tag{3.11}$$

Assume $k_1 > 0$ and $k - k_1 > 0$. Then

$$|k|^3 + |k| - |k_1|^3 - |k_1| - |k_2|^3 + |k_2| = 3kk_1(k - k_1) > 0.$$

Thus, from (3.4) and (3.10) we see that

$$|\tau + k^3 + k| \geq |kk_1(k - k_1)| \geq \frac{|k|^2}{2},$$

and consequently, for $0 < r < 1/4$, we have that

$$\begin{aligned}
&\sum_k |k|^2 \int \frac{d\tau}{\langle\tau + |k|^3 + |k|\rangle^{2(1-r)}\langle\tau + |k_1|^3 + |k_1| + |k - k_1|^3 + |k - k_1|\rangle^{1+r}} \\
&\quad= \sum_k |k|^2 \int \frac{d\tau}{\langle\tau + k^3 + k\rangle^{2(1-r)}\langle\tau + k_1^3 + k_1 + (k - k_1)^3 + (k - k_1)\rangle^{1+r}} \\
&\quad\leq C \sum_{k\in\mathbb{Z}^*} \frac{1}{|k|^{2-4r}} \int_{\mathbb{R}} \frac{d\tau}{\langle\tau + k^3 + k - 3k^2k_1 + 3kk_1^2\rangle^{1+r}}.
\end{aligned}$$

Assume $k_1 < 0$ and $k - k_1 < 0$. Then

$$\big||k|^3 + |k| - |k_1|^3 - |k_1| - |k_2|^3 + |k_2|\big| = 3|kk_1(k - k_1)|.$$

So, using (3.4) and (3.11) we see that

$$|\tau - k^3 - k| \geq |kk_1(k-k_1)| \geq \frac{|k|^2}{2}.$$

Hence, for $0 < r < 1/4$,

$$\sum_k |k|^2 \int \frac{d\tau}{\langle \tau + |k|^3 + |k| \rangle^{2(1-r)} \langle \tau + |k_1|^3 + |k_1| + |k-k_1|^3 + |k-k_1| \rangle^{1+r}}$$
$$\leq C \sum_{k \in \mathbb{Z}^*} \frac{1}{|k|^{2-4r}} \int_{\mathbb{R}} \frac{d\tau}{\langle \tau - k^3 + 3k^2 k_1 - 3kk_1^2 - k \rangle^{1+r}}.$$

Assume $k_1 > 0$ and $k - k_1 < 0$. Hence, if $k > 0$ then

$$\big| |k|^3 + |k| - |k_1|^3 - |k_1| - |k_2|^3 - |k_2| \big| = 2|k-k_1| \Big[\Big(k_1 - \frac{k}{4}\Big)^2 + \frac{15k^2}{16} + 1 \Big] \geq \frac{15}{8} k^2$$

and if $k < 0$ then

$$\big| |k|^3 + |k| - |k_1|^3 - |k_1| - |k_2|^3 - |k_2| \big| = 2|k_1| \Big[\Big(k_1 - \frac{3k}{4}\Big)^2 + \frac{15k^2}{16} + 1 \Big] \geq \frac{15}{8} k^2.$$

So, from inequality (3.11) we conclude that

$$|\tau + |k|^3 + |k|| \geq \frac{5}{8} k^2,$$

and

$$\sum_k |k|^2 \int \frac{d\tau}{\langle \tau + |k|^3 + |k| \rangle^{2(1-r)} \langle \tau + |k_1|^3 + |k_1| + |k-k_1|^3 + |k-k_1| \rangle^{1+r}}$$
$$\leq C \sum_{k \in \mathbb{Z}^*} \frac{1}{|k|^{2-4r}} \int_{\mathbb{R}} \frac{d\tau}{\langle \tau + 2k_1^3 + 2k_1 - k^3 + 3k^2 k_1 - 3kk_1^2 - k \rangle^{1+r}}.$$

Assume $k_1 < 0$ and $k - k_1 > 0$. Hence, if $k > 0$ then

$$\big| |k|^3 + |k| - |k_1|^3 - |k_1| - |k_2|^3 - |k_2| \big| = 2|k_1| \Big[\Big(k_1 - \frac{3k}{4}\Big)^2 + \frac{15k^2}{16} + 1 \Big] \geq \frac{15k^2}{8}$$

and if $k < 0$ then

$$\big| |k|^3 + |k| - |k_1|^3 - |k_1| - |k_2|^3 - |k_2| \big| = 2|k-k_1| \Big[\Big(k_1 - \frac{k}{4}\Big)^2 + \frac{15k^2}{16} + 1 \Big] \geq \frac{15}{8} k^2.$$

Thus, using (3.11),

$$|\tau + |k|^3 + |k|| \geq \frac{5}{8} k^2$$

and so

$$\sum_k |k|^2 \int \frac{d\tau}{\langle \tau + |k|^3 + |k| \rangle^{2(1-r)} \langle \tau + |k_1|^3 + |k_1| + |k-k_1|^3 + |k-k_1| \rangle^{1+r}}$$
$$\leq C \sum_{k \in \mathbb{Z}^*} \frac{1}{|k|^{2-4r}} \int_{\mathbb{R}} \frac{d\tau}{\langle \tau - 2k_1^3 - 2k_1 + k^3 - 3k^2 k_1 + 3kk_1^2 + k \rangle^{1+r}}.$$

Therefore, for any $h \in \ell^2_k$ we have that

$$\begin{aligned}|Z_1|^2 &\leq C\|g\|^2_{\ell^2_k L^2_\tau}\Big(\sum_{k\in\mathbb{Z}}|h(k)|^2\sum_{k_1\in\mathbb{Z}}\int_{\mathbb{R}}|f(k_2,\tau)|^2 d\tau\Big)\\ &\leq C\|f\|^2_{\ell^2_k L^2_\tau}\|g\|^2_{\ell^2_k L^2_\tau}\|h\|^2_{\ell^2_k}.\end{aligned}$$

Next, choosing $1/2 < r < 3/4$ we see that

$$\begin{aligned}|Z_2| &\leq C\Big\|\frac{|k|}{\langle\sigma\rangle^{1-r}}\sum_{k_1}\int\frac{|f(k_2,\tau_2)g(k_1,\tau_1)|\chi_{R_2}d\tau_1}{\langle\sigma_1\rangle^{1/2}\langle\sigma_2\rangle^{1/2}}\Big\|_{\ell^2_k L^2_\tau}\\ &= C\sup_{\|h\|_{\ell^2_k L^2_\tau}=1}\Big|\sum_k\sum_{k_1}\int\int\frac{|kf(k_2,\tau_2)g(k_1,\tau_1)|h(k,\tau)\chi_{R_2}d\tau d\tau_1}{\langle\sigma\rangle^{1-r}\langle\sigma_1\rangle^{1/2}\langle\sigma_2\rangle^{1/2}}\Big|.\end{aligned}$$

As before, for $1/2 < r < 3/4$ it is possible to prove that there exists $C > 0$ such that

$$\frac{1}{\langle\tau_1+|k_1|^3+|k_1|\rangle}\sum_k\frac{|k|^2}{\langle\tau_1+|k|^3+|k|-|k-k_1|^3-|k-k_1|\rangle^{2(1-r)}} \leq C, \quad \text{on } R_2.$$

and, by using Lemma 3.3, we have that

$$\int_{\mathbb{R}}\frac{d\tau}{\langle\tau+|k|^3+|k|\rangle^{2(1-r)}\langle\tau_2+|k_2|^3+|k_2|\rangle} \leq \frac{C}{\langle\tau_1+|k|^3+|k|-|k_2|^3-|k_2|\rangle^{2(1-r)}},$$

then the expression

$$\frac{1}{\langle\sigma_1\rangle}\sum_k|k|^2\int\frac{\chi^2_{R_2}d\tau}{\langle\sigma\rangle^{2(1-r)}\langle\sigma_2\rangle}$$

is bounded. Therefore, for any $h \in \ell^2_k L^2_\tau$ we have that

$$\begin{aligned}|Z_2|^2 &\leq C\|g\|^2_{\ell^2_k L^2_\tau}\sum_{k_1}\int\Big(\sum_k\int|f(k_2,\tau_2)h(k,\tau)|^2 d\tau\Big)\Big(\sum_k\int\frac{\chi^2_{R_2}|k|^2 d\tau}{\langle\sigma\rangle^{2(1-r)}\langle\sigma_1\rangle\langle\sigma_2\rangle}\Big)d\tau_1\\ &\leq C\|f\|^2_{\ell^2_k L^2_\tau}\|g\|^2_{\ell^2_k L^2_\tau}\|h\|^2_{\ell^2_k L^2_\tau}.\end{aligned}$$

In a similar way we have the rest of the proof. □

As a direct consequence of previous lemmas we have the following corollary.

Corollary 3.6. *Let $s \geq 0$, then there exists $C_5 > 0$ such that*

(i) $\|\psi\partial_x(\eta\partial_x\Phi)\|_{Z^s} \leq C_5\|\eta\|_{X^{s,1/2}}\|\Phi\|_{Y^{s+1,1/2}}$,

(ii) $\|\psi(\partial_x\eta)(\partial_x\Phi_1)\|_{W^{s+1}} \leq C_5\|\Phi\|_{Y^{s+1,1/2}}\|\Phi_1\|_{Y^{s+1,1/2}}$.

4 Well-posedness

In this section we establish the local well-posedness for the model (1.1) in the space $U^s \times V^s$.

Theorem 4.1. *Let $s \geq 0$, then for all $(\eta_0, \Phi_0) \in H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})$ we have that there exist a time $T = T(\|(\eta_0, \Phi_0)\|_{H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})}) > 0$ and a unique solution (η, Φ) of the Cauchy problem (1.1)-(1.2) such that*

$$\eta \in C([0,T] : H^s(\mathbb{T})) \cap U^s_T \quad \text{and} \quad \Phi \in C([0,T] : \mathcal{V}^{s+1}(\mathbb{T})) \cap V^{s+1}_T.$$

Moreover, for all $0 < T' < T$ there exists a neighborhood $\mathbb{V}$ of (η_0, Φ_0) in $H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})$ such that the map data-solution is Lipschitz from $\mathbb{V}$ in the class

$$C([0,T'] : H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})) \cap (U^s_T \times V^{s+1}_T).$$

Proof. For $(\eta_0, \Phi_0) \in H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})$ we consider the operator $\Gamma = (\Gamma_1, \Gamma_2)$ where

$$\Gamma_1(\eta, \Phi)(t) = \psi(t) S_1(t)(\eta_0, \Phi_0) - \psi(t) \int_0^t S_1(t-t')\psi(t') \Big(\partial_x(\eta \partial_x \Phi), \frac{1}{2}(\partial_x \Phi)^2\Big)(t')dt'$$

and

$$\Gamma_2(\eta, \Phi)(t) = \psi(t) S_2(t)(\eta_0, \Phi_0) - \psi(t) \int_0^t S_2(t-t')\psi(t') \Big(\partial_x(\eta \partial_x \Phi), \frac{1}{2}(\partial_x \Phi)^2\Big)(t')dt'.$$

Let Z_M the closed ball of radius M centered at the origin in $U^s \times V^{s+1}$,

$$Z_M = \{(\eta, \Phi) \in U^s \times V^{s+1} : \|(\eta, \Phi)\|_{U^s \times V^{s+1}} \leq M\}.$$

We will show that the correspondence $(\eta, \Phi) \mapsto \Gamma(\eta, \Phi)$ maps Z_M into itself and defines a contraction if M is well chosen. In fact, using Lemma 2.4, Lemma 2.5, and Corollary 3.6 we have that

$$\begin{aligned}
\|\Gamma_1(\eta, \Phi)\|_{U^s} &\leq C_1 \|(\eta_0, \Phi_0)\|_{H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})} + C_2 \Big(\|\psi \partial_x(\eta \partial_x \Phi)\|_{Z^s} + \|\psi(\partial_x \Phi)^2\|_{W^{s+1}}\Big) \\
&\leq C_1 \|(\eta_0, \Phi_0)\|_{H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})} + C_2 C_5 \Big(\|\eta\|_{X^{s,1/2}} \|\Phi\|_{Y^{s+1,1/2}} + \|\Phi\|^2_{Y^{s+1,1/2}}\Big) \\
&\leq C_1 \|(\eta_0, \Phi_0)\|_{H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})} + C_2 C_5 \|(\eta, \Phi)\|^2_{U^s \times V^{s+1}}
\end{aligned}$$

and also that

$$\begin{aligned}
\|\Gamma_2(\eta, \Phi)\|_{V^{s+1}} &\leq C_1 \|(\eta_0, \Phi_0)\|_{H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})} + C_2 \Big(\|\psi \partial_x(\eta \partial_x \Phi)\|_{Z^s} + \|\psi(\partial_x \Phi)^2\|_{W^{s+1}}\Big) \\
&\leq C_1 \|(\eta_0, \Phi_0)\|_{H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})} + C_2 C_5 \|(\eta, \Phi)\|^2_{U^s \times V^{s+1}},
\end{aligned}$$

so that

$$\|\Gamma(\eta, \Phi)\|_{U^s \times V^{s+1}} \leq C_1 \|(\eta_0, \Phi_0)\|_{H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})} + C_2 C_5 \|(\eta, \Phi)\|^2_{U^s \times V^{s+1}}. \tag{4.1}$$

Choosing $M = 2C_1 \|(\eta_0, \Phi_0)\|_{H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})}$ such that

$$K_1 = 4C_1 C_2 C_5 \|(\eta_0, \Phi_0)\|_{H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})} < 1,$$

we obtain that

$$\begin{aligned}
\|\Gamma(\eta, \Phi)\|_{U^s \times V^{s+1}} &\leq C_1 \|(\eta_0, \Phi_0)\|_{H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})} (1 + 4C_1 C_2 C_5 \|(\eta_0, \Phi_0)\|_{H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})}) \\
&\leq 2C_1 \|(\eta_0, \Phi_0)\|_{H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})} = M
\end{aligned}$$

and that Γ maps Z_M to itself. Now, let us prove that Γ is a contraction. In fact, if (η,Φ), $(\eta_1,\Phi_1)\in Z_M$, using Lemma 2.5 and Corollary 3.6 we have that

$$\begin{aligned}
&\|\Gamma_1(\eta,\Phi)-\Gamma_1(\eta_1,\Phi_1)\|_{U^s}\\
&\quad\le C_2\Big(\|\psi\partial_x(\eta\partial_x\Phi-\eta_1\partial_x\Phi_1)\|_{Z^s}+\|\psi((\partial_x\Phi)^2-(\partial_x\Phi_1)^2)\|_{W^{s+1}}\Big)\\
&\quad\le C_2\Big(\|\partial_x(\eta\partial_x(\Phi-\Phi_1))\|_{Z^s}+\|\partial_x((\eta-\eta_1)\partial_x\Phi_1)\|_{Z^s}\\
&\qquad+\|\partial_x(\Phi-\Phi_1)\partial_x(\Phi+\Phi_1)\|_{W^{s+1}}\Big)\\
&\quad\le C_2C_5\Big(\|\eta\|_{X^{s,1/2}}\|\Phi-\Phi_1\|_{Y^{s+1,1/2}}+\|\eta-\eta_1\|_{X^{s,1/2}}\|\Phi_1\|_{Y^{s+1,1/2}}\\
&\qquad+\|\Phi-\Phi_1\|_{Y^{s+1,1/2}}\|\Phi+\Phi_1\|_{Y^{s+1,1/2}}\Big)\\
&\quad\le C_2C_5\|(\eta,\Phi)-(\eta_1,\Phi_1)\|_{U^s\times V^{s+1}}\left(\|(\eta,\Phi)\|_{U^s\times V^{s+1}}+\|(\eta_1,\Phi_1)\|_{U^s\times V^{s+1}}\right).
\end{aligned}$$

In a similar fashion we see that

$$\begin{aligned}
&\|\Gamma_2(\eta,\Phi)-\Gamma_2(\eta_1,\Phi_1)\|_{V^{s+1}}\\
&\quad\le C_2\Big(\|\psi\partial_x(\eta\partial_x\Phi-\eta_1\partial_x\Phi_1)\|_{Z^s}+\|\psi((\partial_x\Phi)^2-(\partial_x\Phi_1)^2)\|_{W^{s+1}}\Big)\\
&\quad\le C_2C_5\|(\eta,\Phi)-(\eta_1,\Phi_1)\|_{U^s\times V^{s+1}}\left(\|(\eta,\Phi)\|_{U^s\times V^{s+1}}+\|(\eta_1,\Phi_1)\|_{U^s\times V^{s+1}}\right).
\end{aligned}$$

Then, we conclude

$$\begin{aligned}
&\|\Gamma(\eta,\Phi)-\Gamma(\eta_1,\Phi_1)\|_{U^s\times V^{s+1}}\\
&\quad\le C_2C_5\|(\eta,\Phi)-(\eta_1,\Phi_1)\|_{U^s\times V^{s+1}}\left(\|(\eta,\Phi)\|_{U^s\times V^{s+1}}+\|(\eta_1,\Phi_1)\|_{U^s\times V^{s+1}}\right).
\end{aligned}\tag{4.2}$$

So, if (4) holds we obtain that

$$\|\Gamma(\eta,\Phi)-\Gamma(\eta_1,\Phi_1)\|_{U^s\times V^{s+1}}\le K_1\|(\eta,\Phi)-(\eta_1,\Phi_1)\|_{U^s\times V^{s+1}}$$

and then Γ is a contraction in Z_M. Thus, the contraction mapping principle guarantees the existence of a unique fixed point (η,Φ) of Γ in Z_M, which is solution of the truncated integral problem (1.4). Now, if (η_1,Φ_1) is a restriction of (η,Φ) on $[0,T]$, then using Lemma 2.6 we have that

$$\eta_1\in C([0,T]\,:\,H^s(\mathbb{T}))\cap U^s,\quad \Phi_1\in C([0,T]\,:\,\mathcal{V}^{s+1}(\mathbb{T}))\cap V^{s+1}$$

and (η_1,Φ_1) is a solution of the integral problem (1.3) on $[0,T]$.

By the fixed point argument used we have the uniqueness of the solution of the truncated integral problem (1.4) in the set Z_M. We will use an argument as in [1] to obtain the uniqueness of the integral problem (1.3) in the space $U^s_T\times V^{s+1}_T$.

Let $T>0$ and $(\eta,\Phi)\in U^s\times V^{s+1}$ be the solution of the truncated integral problem (1.4) obtained above and $(\eta_1,\Phi_1)\in U^s_T\times V^{s+1}_T$ a solution of the integral problem (1.3) with the same initial data $(\eta_0,\Phi_0)\in H^s(\mathbb{T})\times\mathcal{V}^{s+1}(\mathbb{T})$. Fix an extension $(\eta_2,\Phi_2)\in U^s\times V^{s+1}$ of (η_1,Φ_1), then, for some $T^*<T<1$ to be fixed later, we have that

$$\eta_2(t)=\psi(t)S_1(t)(\eta_0,\Phi_0)-\psi(t)\int_0^t S_1(t-t')\psi(t')\Big(\partial_x(\eta_2\partial_x\Phi_2),\frac{1}{2}(\partial_x\Phi_1)^2\Big)(t')dt'$$

and

$$\Phi_2(t)=\psi(t)S_2(t)(\eta_0,\Phi_0)-\psi(t)\int_0^t S_2(t-t')\psi(t')\Big(\partial_x(\eta_2\partial_x\Phi_2),\frac{1}{2}(\partial_x\Phi_1)^2\Big)(t')dt',$$

for all $t \in [0, T^*]$.

Now, by definition of $U^s_{T^*} \times V^{s+1}_{T^*}$ we have that for any $\epsilon > 0$, there exists $(\omega, \vartheta) \in U^s \times V^{s+1}$ such that for all $t \in [0, T^*]$,

$$\omega(t) = \eta(t) - \eta_2(t), \quad \vartheta(t) = \Phi(t) - \Phi_2(t)$$

and

$$\|\omega\|_{U^s} \leq \|\eta - \eta_2\|_{U^s_{T^*}} + \epsilon, \quad \|\vartheta\|_{V^{s+1}} \leq \|\Phi - \Phi_2\|_{V^{s+1}_{T^*}} + \epsilon. \tag{4.3}$$

We define

$$\omega_1(t) = -\psi(t) \int_0^t S_1(t-t')\psi(t')\Big(\partial_x(\eta\partial_x\vartheta) + \partial_x(\omega\partial_x\Phi_2), \frac{1}{2}\partial_x\vartheta\partial_x(\Phi+\Phi_2)\Big)(t')dt',$$

$$\vartheta_1(t) = -\psi(t) \int_0^t S_2(t-t')\psi(t')\Big(\partial_x(\eta\partial_x\vartheta) + \partial_x(\omega\partial_x\Phi_2), \frac{1}{2}\partial_x\vartheta\partial_x(\Phi+\Phi_2)\Big)(t')dt'.$$

Then we have that $\omega_1(t) = \eta(t) - \eta_2(t)$ and $\vartheta_1(t) = \Phi(t) - \Phi_2(t)$ for all $t \in [0, T^*]$. Thus, from Lemma 2.5 and Corollary 3.6 we obtain that

$$\begin{aligned}\|\eta - \eta_2\|_{U^s_{T^*}} &\leq \|\omega_1\|_{U^s} \\ &\leq C_2C_5\|(\omega,\vartheta)\|_{U^s\times V^{s+1}}\Big(\|(\eta,\Phi)\|_{U^s\times V^{s+1}} + \|(\eta_2,\Phi_2)\|_{U^s\times V^{s+1}}\Big) \\ &\leq 2C_2C_5N\|(\omega,\vartheta)\|_{U^s\times V^{s+1}}\end{aligned} \tag{4.4}$$

where we assume that

$$\max\{\|(\eta,\Phi)\|_{U^s\times V^{s+1}}, \ \|(\eta_2,\Phi_2)\|_{U^s\times V^{s+1}}\} \leq N.$$

In a similar fashion we have that

$$\begin{aligned}\|\Phi - \Phi_2\|_{V^{s+1}_{T^*}} \leq \|\vartheta_1\|_{V^{s+1,1/2}} &\leq C_2C_5\|(\omega,\vartheta)\|_{U^s\times V^{s+1}}\Big(\|(\eta,\Phi)\|_{U^s\times V^{s+1}} + \|(\eta_1,\Phi_2)\|_{U^s\times V^{s+1}}\Big) \\ &\leq 2C_2C_5N\|(\omega,\vartheta)\|_{U^s\times V^{s+1}}.\end{aligned} \tag{4.5}$$

If $4C_2C_5N \leq 1/2$, then we obtain, using (4.3), (4.4) and (4.5), that

$$\begin{aligned}\|\eta - \eta_2\|_{U^s_{T^*}} + \|\Phi - \Phi_2\|_{V^{s+1}_{T^*}} &\leq 4C_2C_5N\|(\omega,\vartheta)\|_{U^s\times V^{s+1}} \\ &\leq \frac{1}{2}\Big(\|\eta - \eta_2\|_{U^s_{T^*}} + \epsilon + \|\Phi - \Phi_2\|_{V^{s+1}_{T^*}} + \epsilon\Big).\end{aligned}$$

So, we see that

$$\|\eta - \eta_2\|_{U^s_{T^*}} + \|\Phi - \Phi_2\|_{V^{s+1}_{T^*}} \leq 2\epsilon.$$

Therefore $\eta = \eta_2$ and $\Phi = \Phi_2$ on $[0, T^*]$. Now, since the argument does not depend on the initial data, we can iterate this process a finite number of times to extend the uniqueness result in the whole existence interval $[0, T]$.

Combining an identical argument to the one used in the existence proof with Lemma 2.6, one can easily show that the map data-solution is locally Lipschitz. □

5 Internal controllability

5.1 Spectral analysis

In this section we perform the spectral analysis for the operator

$$M = \begin{pmatrix} 0 & -(I-\partial_x^2)\partial_x^2 \\ -(I-\partial_x^2) & 0 \end{pmatrix},$$

defined in the space $H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})$. The result in this analysis will be the basis to transfer the internal controllability of the associated linear system to the nonlinear system. Let us define

$$E_{1,k} = \begin{pmatrix} e^{ikx} \\ 0 \end{pmatrix}, \quad E_{2,k} = \begin{pmatrix} 0 \\ \frac{1}{k}e^{ikx} \end{pmatrix},$$

for $k \in \mathbb{Z}^* = \mathbb{Z} \setminus \{0\}$. If we set

$$M_k = \begin{pmatrix} 0 & (1+k^2)k^2 \\ -(1+k^2) & 0 \end{pmatrix}, \qquad \Sigma_k = \begin{pmatrix} 0 & (1+k^2)k \\ -(1+k^2)k & 0 \end{pmatrix}, \quad k \in \mathbb{Z}^*$$

then we see directly that

$$M_k(E_{1,k}, E_{2,k}) = (E_{1,k}, E_{2,k})\Sigma_k, \quad k \in \mathbb{Z}^*.$$

Moreover, we have that the eigenvalues for Σ_k are

$$\lambda_{1,k} = i\sqrt{(1+k^2)^2k^2}, \quad \lambda_{2,k} = -i\sqrt{(1+k^2)^2k^2}, \quad k \in \mathbb{Z}^*,$$

with corresponding eigenvectors

$$\tilde{e}_{1,k} = \begin{pmatrix} 1 \\ \frac{\lambda_{1,k}}{(1+k^2)k} \end{pmatrix}, \quad \tilde{e}_{2,k} = \begin{pmatrix} 1 \\ \frac{\lambda_{2,k}}{(1+k^2)k} \end{pmatrix}, \quad k \in \mathbb{Z}^*.$$

Thus, we have that

$$\begin{aligned} M(E_{1,k}, E_{2,k})(\tilde{e}_{1,k}, \tilde{e}_{2,k}) &= (E_{1,k}, E_{2,k})\Sigma_k(\tilde{e}_{1,k}, \tilde{e}_{2,k}) \\ &= (\lambda_{1,k}(E_{1,k}, E_{2,k})\tilde{e}_{1,k}, \lambda_{2,k}(E_{1,k}, E_{2,k})\tilde{e}_{2,k}),\ k \in \mathbb{Z}^*, \end{aligned}$$

meaning that $\lambda_{1,k}$ and $\lambda_{2,k}$ are the eigenvalues for the operator M with corresponding eigenvectors

$$\eta_{j,k} = (E_{1,k}, E_{2,k})\tilde{e}_{j,k}, \quad j = 1, 2, \ \ k \in \mathbb{Z},$$

where

$$\lambda_{1,0} = \lambda_{2,0} = 0, \quad \tilde{e}_{1,0} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad \tilde{e}_{2,0} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \quad E_{1,0} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad E_{2,0} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}.$$

On the other hand, we see that

$$\lim_{k\to\pm\infty} \frac{\lambda_{1,k}}{(1+k^2)k} = \pm i, \quad \lim_{k\to\pm\infty} \frac{\lambda_{2,k}}{(1+k^2)k} = \mp i.$$

Then

$$\lim_{k\to\infty} (\tilde{e}_{1,k}, \tilde{e}_{2,k}) = \begin{pmatrix} 1 & 1 \\ \pm i & \mp i \end{pmatrix} \quad \text{and} \quad \lim_{k\to\infty} \det(\tilde{e}_{1,k}, \tilde{e}_{2,k}) = \mp 2i \neq 0.$$

In other words, $\{\nu_{1,0}, \nu_{2,0}, \nu_{1,k}, \nu_{2,k} \ : \ k \in \mathbb{Z}^*\}$ forms a Riesz basis for $H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})$ with

$$\nu_{j,k} = \frac{\eta_{j,k}}{\|\eta_{j,k}\|_{H^s \times \mathcal{V}^{s+1}}}.$$

Moreover, we also have for $j = 1, 2$ that $\nu_{j,k} = \vec{b}_{j,k} e^{ikx}$ with

$$0 < B_1 \leq \|\vec{b}_{j,k}\| \leq B_2, \quad k \in \mathbb{Z}, \quad s \geq 0. \tag{5.1}$$

From the above discussion we have the following result.

Theorem 5.1. *Let λ_k and $\phi_{j,k}$, $j = 1, 2$ be given by*

$$\lambda_k = i \ \mathrm{sign}(k) \sqrt{(1+k^2)^2 k^2}, \quad k \in \mathbb{Z},$$

$$\phi_{1,k} = \begin{cases} \nu_{1,k}, & k = 0, 1, 2, 3, \ldots \\ \nu_{2,k}, & k = -1, -2, -3, \ldots, \end{cases} \qquad \phi_{2,k} = \begin{cases} \nu_{1,-k}, & k = 1, 2, 3, \ldots \\ \nu_{2,-k}, & k = 0, -1, -2, -3, \ldots \end{cases}$$

then we have that

- *(i) The spectrum of the operator M is $\sigma(M) = \{\lambda_k \ : \ k \in \mathbb{Z}\}$, in which each λ_k is a double eigenvalue with eigenvectors $\phi_{1,k}$ and $\phi_{2,k}$.*
- *(ii) The set $\{\phi_{1,k}, \phi_{2,k} \ : \ k \in \mathbb{Z}\}$ forms an orthonormal basis for the space $H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})$ such that any $(\eta, \Phi) \in H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})$ has the following Fourier expansion*

$$(\eta, \Phi) = \sum_{k \in \mathbb{Z}} \left(\alpha_{1,k}\phi_{1,k} + \alpha_{2,k}\phi_{2,k} \right), \quad \alpha_{j,k} = \left\langle (\eta, \Phi), \phi_{j,k} \right\rangle_Q, \quad j = 1, 2, \ k \in \mathbb{Z},$$

where $Q = L^2(\mathbb{T}) \times L^2(\mathbb{T})$.

5.2 Linear controllability

In this section we consider the internal control problem for the linear system

$$\begin{cases} \eta_t + \partial_x^2 \Phi - \partial_x^4 \Phi = f_1, \\ \qquad \Phi_t + \eta - \partial_x^2 \eta = f_2, \end{cases} \tag{5.2}$$

with the initial condition

$$\eta(x, 0) = \eta_0(x), \quad \Phi(x, 0) = \Phi_0(x). \tag{5.3}$$

Theorem 5.2. *Suppose that $\rho = (\rho_1, \rho_2)$ is a non-zero smooth function defined on $\mathbb{T}$. Let $s \geq 0$ and $T > 0$, then for any (η_0, Φ_0), $(\eta_T, \Phi_T) \in H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})$ there exists a function $H = (h_1, h_2) \in L^2\left(0, T; H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})\right)$ such that if*

$$F = (f_1(x,t), f_2(x,t)) = (\rho_1 h_1(x,t), \rho_2(x) h_2(x,t))$$

we have that the problem (5.2)–(5.3) has a unique solution

$$(\eta, \Phi) \in C\left([0, T] \ : \ H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T}) \right)$$

satisfying

$$\eta(x, T) = \eta_T(x), \quad \Phi(x, T) = \Phi_T(x).$$

Moreover, there exists $C = C(T) > 0$ such that

$$\|H\|_{L^2(0,T;H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T}))} \leq C \left(\|(\eta_0, \Phi_0)\|_{H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})} + \|(\eta_T, \Phi_T)\|_{H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})} \right).$$

Proof. For sake of simplicity in the proof we will consider $\rho_2 = \Phi_0 = \Phi_T = 0$. For any function $h = h(x,t)$, we define the control operator L by

$$(Lh)(x,t) = \rho_1(x)h(x,t).$$

If $f_1 = Lh$ and $f_2 = 0$, then we rewrite the problem (5.2)–(5.3) as the following first order linear

$$\begin{pmatrix}\eta\\ \Phi\end{pmatrix}_t = M\begin{pmatrix}\eta\\ \Phi\end{pmatrix} + Bh, \tag{5.4}$$

with the initial condition

$$\eta(x,0) = \eta_0(x), \quad \Phi(x,0) = 0 \tag{5.5}$$

where

$$Bh = \begin{pmatrix}Lh\\ 0\end{pmatrix}.$$

In this case for $h \in L^2(0,T;H^s(\mathbb{T}))$, the solution of the linear problem (5.4)–(5.5) is given by

$$(\eta(t),\Phi(t)) = S(t)\,(\eta_0,0) + \int_0^t S(t-\tau)Bh(\tau)\,d\tau.$$

Now, using the spectral analysis on the operator M we have that

$$\begin{aligned}(\eta(t),\Phi(t)) = &\sum_{n\in\mathbb{Z}} e^{\lambda_n t}(\alpha_{1,n}\phi_{1,n} + \alpha_{2,n}\phi_{2,n})\\ &+ \sum_{n\in\mathbb{Z}}\int_0^t e^{\lambda_n(t-\tau)}\,(\beta_{1,n}(\tau)\phi_{1,n} + \beta_{2,n}(\tau)\phi_{2,n})\,d\tau,\end{aligned} \tag{5.6}$$

where $\alpha_{j,n}$ and $\beta_{j,n}$, for $j = 1,2$, $n \in \mathbb{Z}$, are given by

$$\alpha_{j,n} = \left\langle(\eta_0,\Phi_0),\phi_{j,n}\right\rangle_Q, \quad \beta_{j,n}(t) = \left\langle Bh,\phi_{j,n}\right\rangle_Q. \tag{5.7}$$

We verify easily that L is a self-adjoint operator in $L^2(\mathbb{T})$ such that

$$\langle Bh,(\eta,\Phi)\rangle_Q = \langle(Lh,0),(\eta,\Phi)\rangle_Q = \langle Lh,\eta\rangle_{L^2(\mathbb{T})} = \langle h,L\eta\rangle_{L^2(\mathbb{T})},$$

then we have that

$$\alpha_{j,n} = \left\langle \eta_0,\phi_{j,n}^{(1)}\right\rangle_{L^2(\mathbb{T})}, \quad \beta_{j,n}(t) = \left\langle h(\cdot,t),L(\phi_{j,n}^{(1)})\right\rangle_{L^2(\mathbb{T})},$$

where $\phi^{(m)}$ denoting the m component of ϕ.

The internal control problem consists of finding a $h \in L^2(0,T;H^s(\mathbb{T}))$ such that

$$\eta(x,T) = \eta_T(x), \quad \Phi(x,T) = 0.$$

Then, let η_0 and η_T be having the following decompositions

$$\eta_0 = \sum_{n\in\mathbb{Z}}\left(\alpha_{1,n}\phi_{1,n}^{(1)} + \alpha_{2,n}\phi_{2,n}^{(1)}\right), \quad \eta_T = \sum_{n\in\mathbb{Z}}\left(\gamma_{1,n}\phi_{1,n}^{(1)} + \gamma_{2,n}\phi_{2,n}^{(1)}\right),$$

where $\gamma_{j,n} = \langle\eta_T,\phi_{j,n}^{(1)}\rangle_{L^2(\mathbb{T})}$. But, we know that

$$\begin{aligned}(\eta(x,T),\Phi(x,T)) = &\sum_{n\in\mathbb{Z}} e^{\lambda_n T}\,(\alpha_{1,n}\phi_{1,n} + \alpha_{2,n}\phi_{2,n})\\ &+ \sum_{n\in\mathbb{Z}}\int_0^T e^{\lambda_n(T-\tau)}\,(\beta_{1,n}(\tau)\phi_{1,n} + \beta_{2,n}(\tau)\phi_{2,n})\,d\tau.\end{aligned}$$

So, in each node, we have for $j = 1, 2$ and $n \in \mathbb{Z}$ that

$$\alpha_{j,n} + \int_0^T e^{-\lambda_n \tau} \beta_{j,n}(\tau)\, d\tau = \gamma_{j,n} e^{-\lambda_n T}.$$

Now, from [7] we have that $\mathcal{P} = \{e^{\lambda_k t} : k \in \mathbb{Z}\}$ is a Riesz basis for its closed span $\mathcal{P}_T = \overline{\text{gen}}\,\mathcal{P}$ generated in $L^2(0, T)$, with a unique dual Riesz basis given by $\mathcal{L} = \{q_k : k \in \mathbb{Z}\}$ satisfying that

$$\int_0^T q_l(t) \overline{e^{\lambda_k t}}\, dt = \delta_l^k, \quad l, k \in \mathbb{Z}.$$

We assume that f_1 has the form $f_1 = Lh$ with h given by the expansion

$$h(x, t) = \sum_{l \in \mathbb{Z}} q_l(t) \left(c_{1,l} L(\phi_{1,l}^{(1)}) + c_{2,l} L(\phi_{2,l}^{(1)}) \right), \tag{5.8}$$

where the coefficients $c_{1,l}$ and $c_{2,l}$ are to be determined so that, among other things, the series (5.8) is appropriately convergent. In this case, for $j = 1, 2$ and $n \in \mathbb{Z}$ we have that

$$\begin{aligned}
\int_0^T e^{-\lambda_n \tau} \beta_{j,n}(\tau)\, d\tau &= \int_0^T e^{-\lambda_n \tau} \left\langle h(\cdot, \tau), L(\phi_{j,n}^{(1)}) \right\rangle_{L^2(\mathbb{T})} d\tau \\
&= \sum_{k \in \mathbb{Z}} \int_0^T e^{-\lambda_n \tau} \Big(\int_{\mathbb{T}} h(y, \tau) e^{iky}\, dy \Big) \overline{\left(L(\phi_{j,n}^{(1)}) \right)_k} d\tau \\
&= \sum_{k \in \mathbb{Z}} \overline{\left(L(\phi_{j,n}^{(1)}) \right)_k} \int_{\mathbb{T}} \left(\sum_{l \in \mathbb{Z}} \int_0^T q_l(\tau) \overline{e^{\lambda_n \tau}} d\tau \left(c_{1,l} L(\phi_{1,l}^{(1)}) + c_{2,l} L(\phi_{2,l}^{(1)}) \right) \right) e^{iky}\, dy \\
&= \sum_{k \in \mathbb{Z}} \overline{\left(L(\phi_{j,n}^{(1)}) \right)_k} \int_{\mathbb{T}} \left(c_{1,n} L(\phi_{1,n}^{(1)}) + c_{2,n} L(\phi_{2,n}^{(1)}) \right) e^{iky}\, dy \\
&= c_{1,n} \left\langle L(\phi_{1,n}^{(1)}), L(\phi_{j,n}^{(1)}) \right\rangle_{L^2(\mathbb{T})} + c_{2,n} \left\langle L(\phi_{2,n}^{(1)}), L(\phi_{j,n}^{(1)}) \right\rangle_{L^2(\mathbb{T})},
\end{aligned}$$

where $\left(L(\phi_{j,n}^{(1)}) \right)_k = \left(\widehat{L(\phi_{j,n}^{(1)})} \right)(k)$. Now, using the computations above, for $n \in \mathbb{Z}$, we have that $c_{1,n}$ and $c_{2,n}$ must satisfy the linear system

$$\begin{pmatrix} a_{11} & a_{21} \\ a_{12} & a_{22} \end{pmatrix} \begin{pmatrix} c_{1,n} \\ c_{2,n} \end{pmatrix} = \begin{pmatrix} -\alpha_{1,n} + \gamma_{1,n} e^{-\lambda_n T} \\ -\alpha_{2,n} + \gamma_{2,n} e^{-\lambda_n T} \end{pmatrix},$$

where $a_{jl} = \langle L(\phi_{j,n}^{(1)}), L(\phi_{l,n}^{(1)}) \rangle_{L^2(\mathbb{T})}$. Using the fact that $L(\phi_{1,n}^{(1)})$ and $L(\phi_{2,n}^{(1)})$ are linear independent, we obtain that

$$\Delta_n = \det \begin{pmatrix} a_{11} & a_{21} \\ a_{12} & a_{22} \end{pmatrix} = \|L(\phi_{1,n}^{(1)})\|_{L^2(\mathbb{T})}^2 \|L(\phi_{2,n}^{(1)})\|_{L^2(\mathbb{T})}^2 - \left| \langle L(\phi_{1,n}^{(1)}), L(\phi_{2,n}^{(1)}) \rangle_{L^2(\mathbb{T})} \right|^2 \neq 0.$$

Moreover, using that $\nu_{j,n}^{(1)} = b_{j,n}^{(1)} e^{inx}$ and the estimate (5.1), we have that

$$\|L(\phi_{j,n}^{(1)})\|_{L^2(\mathbb{T})}^2 \sim |b_{j,n}^{(1)}|^2 \geq C > 0. \tag{5.9}$$

In addition (see the estimations by B. Zhang for the Boussinesq equation in [20]), it is not hard to prove that

$$\left\langle L(\phi_{1,n}^{(1)}), L(\phi_{2,n}^{(1)}) \right\rangle \to 0, \quad n \to \infty.$$

Hence there exists $\epsilon > 0$ such that $|\Delta_n| > \epsilon$. So, we conclude that $c_{1,n}$ and $c_{2,n}$ are uniquely determine by

$$c_{1,n} = \frac{\begin{vmatrix} -\alpha_{1,n} + \gamma_{1,n}e^{-\lambda_n T} & a_{21} \\ -\alpha_{2,n} + \gamma_{2,n}e^{-\lambda_n T} & a_{22} \end{vmatrix}}{\Delta_n}, \quad c_{2,n} = \frac{\begin{vmatrix} a_{11} & -\alpha_{1,n} + \gamma_{1,n}e^{-\lambda_n T} \\ a_{12} & -\alpha_{2,n} + \gamma_{2,n}e^{-\lambda_n T} \end{vmatrix}}{\Delta_n}. \tag{5.10}$$

It remains to show that h defined by (5.8)–(5.10) belongs to the space $L^2(0,T;H^s(\mathbb{T}))$ provided that $\eta_0, \eta_T \in H^s(\mathbb{T})$. To this end, let us write

$$L(\phi_{j,l}^{(1)}) = \sum_{k\in\mathbb{Z}} a_{j,lk}e^{ikx}, \quad a_{j,lk} = \left(L(\phi_{j,l}^{(1)})\right)_k, \quad l,k \in \mathbb{Z},\ j = 1,2.$$

Thus

$$h(x,t) = h_1(x,t) + h_2(x,t),$$

where

$$h_j(x,t) = \sum_{l\in\mathbb{Z}}\sum_{k\in\mathbb{Z}} c_{j,l}a_{j,lk}q_l(t)e^{ikx}, \quad j = 1,2.$$

From this, we conclude that

$$\begin{aligned}
&\|h_j\|^2_{L^2(0,T;H^s(\mathbb{T}))} \\
&= \int_0^T \sum_{k\in\mathbb{Z}} (1+|k|)^{2s} |\left(h_j(\cdot,t)\right)_k|^2\,dt = \int_0^T \sum_{k\in\mathbb{Z}} (1+|k|)^{2s}\Big|\sum_{l\in\mathbb{Z}} a_{j,lk}c_{j,l}q_l(t)\Big|^2 dt \\
&= \sum_{k\in\mathbb{Z}} (1+|k|)^{2s} \int_0^T \Big|\sum_{l\in\mathbb{Z}} a_{j,lk}c_{j,l}q_l(t)\Big|^2 dt \le C \sum_{k\in\mathbb{Z}} (1+|k|)^{2s} \sum_{l\in\mathbb{Z}} |c_{j,l}|^2|a_{j,lk}|^2 \\
&= C\sum_{l\in\mathbb{Z}} |c_{j,l}|^2 \sum_{k\in\mathbb{Z}} (1+|k|)^{2s}|a_{j,lk}|^2,
\end{aligned}$$

where the constant $C > 0$ comes from the Riesz basis property of $\mathcal{L}$ in $\mathcal{P}_T$. Now, using (5.1), if $\rho_1 = \sum_{m\in\mathbb{Z}} \rho_m^1 e^{imx}$ we have that there exists $C > 0$ such that

$$\begin{aligned}
|a_{j,lk}| &= \left|\left\langle L(\phi_{j,l}^{(1)}),\, e^{ikx}\right\rangle_{L^2(\mathbb{T})}\right| = \left|\left\langle \rho_1\phi_{j,l}^{(1)},\, e^{ikx}\right\rangle_{L^2(\mathbb{T})}\right| \\
&= \left|\sum_{m\in\mathbb{Z}} \rho_m^1 \left\langle \phi_{j,l}^{(1)}e^{imx},\, e^{ikx}\right\rangle_{L^2(\mathbb{T})}\right| = \left|\sum_{m\in\mathbb{Z}} \rho_m^1 \left\langle b_{j,l}^{(1)}e^{ilx}e^{imx},\, e^{ikx}\right\rangle_{L^2(\mathbb{T})}\right| \\
&\le C\Big|\int_{\mathbb{T}} e^{-ix(k-l)} \sum_{m\in\mathbb{Z}} \rho_m^1 e^{imx}\,dx\Big| \le C\left|\rho_{k-l}^1\right|.
\end{aligned}$$

Then we see that

$$\begin{aligned}
\sum_{k\in\mathbb{Z}} (1+|k|)^{2s}|a_{j,lk}|^2 &\le C\sum_{k\in\mathbb{Z}} (1+|k|)^{2s}|\rho_{k-l}^1|^2 \le C\sum_{k\in\mathbb{Z}} (1+|k+l|)^{2s}|\rho_k^1|^2 \\
&\le C(1+|l|)^{2s}\sum_{k\in\mathbb{Z}} (1+|k|)^{2s}|\rho_k^1|^2 = (1+|l|)^{2s}\,\|\rho_1\|^2_{H^s(\mathbb{T})}.
\end{aligned}$$

On the other hand, we can to see that

$$\begin{aligned}
|c_{1,l}|^2 &\le C\left(|a_{22}|^2 + |a_{21}|^2\right)\left(|\alpha_{1,l}|^2 + |\alpha_{2,l}|^2 + |\gamma_{1,l}|^2 + |\gamma_{2,l}|^2\right) \\
&= C\left(\|L(\phi_{2,l}^{(1)})\|^4_{L^2(\mathbb{T})} + \left|\left\langle L(\phi_{2,l}^{(1)}), L(\phi_{1,l}^{(1)})\right\rangle_{L^2(\mathbb{T})}\right|^2\right)\left(|\alpha_{1,l}|^2 + |\alpha_{2,l}|^2 + |\gamma_{1,l}|^2 + |\gamma_{2,l}|^2\right) \\
&\le C\left(|\alpha_{1,l}|^2 + |\alpha_{2,l}|^2 + |\gamma_{1,l}|^2 + |\gamma_{2,l}|^2\right).
\end{aligned}$$

Similarly,

$$
\begin{aligned}
|c_{2,l}|^2 &\leq C\Big(\|L(\phi_{1,l}^{(1)})\|_{L^2(\mathbb{T})}^4 + \Big|\left\langle L(\phi_{1,l}^{(1)}), L(\phi_{2,l}^{(1)})\right\rangle_{L^2(\mathbb{T})}\Big|^2\Big) \times \left(|\alpha_{1,l}|^2 + |\alpha_{2,l}|^2 + |\gamma_{1,l}|^2 + |\gamma_{2,l}|^2\right) \\
&\leq C\left(|\alpha_{1,l}|^2 + |\alpha_{2,l}|^2 + |\gamma_{1,l}|^2 + |\gamma_{2,l}|^2\right).
\end{aligned}
$$

From this, we conclude that

$$
\begin{aligned}
\|h\|_{L^2(0,T;H^s(\mathbb{T}))}^2 &\leq C\|\rho_1\|_{H^s(\mathbb{T})}^2 \left(\sum_{l\in\mathbb{Z}} (1+|l|)^{2s}\left(|\alpha_{1,l}|^2 + |\alpha_{2,l}|^2 + |\gamma_{1,l}|^2 + |\gamma_{1,l}|^2\right)\right) \\
&\leq C\|\rho_1\|_{H^s(\mathbb{T})}^2 \left(\|\eta_0\|_{H^s(\mathbb{T})}^2 + \|\eta_T\|_{H^s(\mathbb{T})}^2\right).
\end{aligned}
$$

Now we consider $\rho_1 = \eta_0 = \eta_T = 0$. Since the proof is similar to the previous case, we only present some ideas. The solution of the linear problem

$$
\begin{pmatrix}\eta\\ \Phi\end{pmatrix}_t = M\begin{pmatrix}\eta\\ \Phi\end{pmatrix} + Bh, \quad (\eta(x,0),\Phi(x,0)) = (0,\Phi_0(x))
$$

with

$$
(Bh)(x,t) = \begin{pmatrix}0\\ (Lh)(x,t)\end{pmatrix} = \begin{pmatrix}0\\ \rho_2(x)h(x,t)\end{pmatrix}
$$

is given by

$$
(\eta(t),\Phi(t)) = \sum_{n\in\mathbb{Z}} e^{\lambda_n t}\left(\alpha_{1,n}\phi_{1,n} + \alpha_{2,n}\phi_{2,n}\right) + \sum_{n\in\mathbb{Z}}\int_0^t e^{\lambda_n(t-\tau)}\left(\beta_{1,n}(\tau)\phi_{1,n} + \beta_{2,n}(\tau)\phi_{2,n}\right)d\tau,
$$

where $\alpha_{j,n}$ and $\beta_{j,n}$ for $j = 1,2$, $n \in \mathbb{Z}$ are given by

$$
\alpha_{j,n} = \left\langle \Phi_0, \phi_{j,n}^{(2)}\right\rangle_{L^2(\mathbb{T})}, \quad \beta_{j,n}(t) = \left\langle h(\cdot,t), L(\phi_{j,n}^{(2)})\right\rangle_{L^2(\mathbb{T})}.
$$

Then, using the decompositions

$$
\Phi_0 = \sum_{n\in\mathbb{Z}}\left(\alpha_{1,n}\phi_{1,n}^{(2)} + \alpha_{2,n}\phi_{2,n}^{(2)}\right), \quad \Phi_T = \sum_{n\in\mathbb{Z}}\left(\gamma_{1,n}\phi_{1,n}^{(2)} + \gamma_{2,n}\phi_{2,n}^{(2)}\right),
$$

where $\gamma_{j,n} = \langle \Phi_T, \phi_{j,n}^{(2)}\rangle_{L^2(\mathbb{T})}$, then we have for $j = 1,2$ and $n \in \mathbb{Z}$ that

$$
\alpha_{j,n} + \int_0^T e^{-\lambda_n\tau}\beta_{j,n}(\tau)\,d\tau = \gamma_{j,n}e^{-\lambda_n T}.
$$

Now, we take the control h to have the form

$$
h(x,t) = \sum_{l\in\mathbb{Z}} q_l(t)\left(c_{1,l}L(\phi_{1,l}^{(2)}) + c_{2,l}L(\phi_{2,l}^{(2)})\right)
$$

with

$$
\int_0^T q_l(t)\overline{e^{\lambda_k t}}\,dt = \delta_l^k, \quad l,k \in \mathbb{Z}.
$$

Then, for $j = 1, 2$ and $n \in \mathbb{Z}$ we have that

$$\begin{aligned}\int_0^T e^{-\lambda_n \tau}\beta_{j,n}(\tau)\, d\tau &= \sum_{k\in\mathbb{Z}} \overline{\left(L\phi_{j,n}^{(2)}\right)_k} \int_0^T e^{-\lambda_n\tau}\Big(\int_{\mathbb{T}} h(y,\tau)e^{iky}\, dy\Big)\, d\tau \\ &= \sum_{k\in\mathbb{Z}} \overline{\left(L(\phi_{j,n}^{(2)})\right)_k} \int_{\mathbb{T}} \left(c_{1,n}L(\phi_{1,n}^{(2)}) + c_{2,n}L(\phi_{2,n}^{(2)})\right) e^{iky}\, dy \\ &= c_{1,n}\left\langle L(\phi_{1,n}^{(2)}), L(\phi_{j,n}^{(2)})\right\rangle_{L^2(\mathbb{T})} + c_{2,n}\left\langle L(\phi_{2,n}^{(2)}), L(\phi_{j,n}^{(2)})\right\rangle_{L^2(\mathbb{T})}.\end{aligned}$$

Thus, the coefficients $c_{1,n}$ and $c_{2,n}$ are uniquely determine by

$$c_{1,n} = \frac{\begin{vmatrix} -\alpha_{1,n} + \gamma_{1,n}e^{-\lambda_n T} & a_{21} \\ -\alpha_{2,n} + \gamma_{2,n}e^{-\lambda_n T} & a_{22}\end{vmatrix}}{\Delta_n}, \quad c_{2,n} = \frac{\begin{vmatrix} a_{11} & -\alpha_{1,n} + \gamma_{1,n}e^{-\lambda_n T} \\ a_{12} & -\alpha_{2,n} + \gamma_{2,n}e^{-\lambda_n T}\end{vmatrix}}{\Delta_n},$$

where

$$a_{jl} = \left\langle L(\phi_{j,n}^{(2)}), L(\phi_{l,n}^{(2)})\right\rangle_{L^2(\mathbb{T})}$$

and

$$\Delta_n = \|L(\phi_{1,n}^{(2)})\|^2_{L^2(\mathbb{T})}\|L(\phi_{2,n}^{(2)})\|^2_{L^2(\mathbb{T})} - \left|\langle L(\phi_{1,n}^{(2)}), L(\phi_{2,n}^{(2)})\rangle_{L^2(\mathbb{T})}\right|^2.$$

Finally, we write

$$\rho_2 = \sum_{k\in\mathbb{Z}} \rho_k^2 e^{ikx},\ L(\phi_{j,l}^{(2)}) = \sum_{k\in\mathbb{Z}} a_{j,lk}e^{ikx},\ a_{j,lk} = \left(L(\phi_{j,l}^{(2)})\right)_k,\ l,k\in\mathbb{Z},\ j = 1,2.$$

Then

$$h(x,t) = \sum_{l\in\mathbb{Z}}\sum_{k\in\mathbb{Z}} c_{1,l}a_{1,lk}q_l(t)e^{ikx} + \sum_{l\in\mathbb{Z}}\sum_{k\in\mathbb{Z}} c_{2,l}a_{2,lk}q_l(t)e^{ikx}.$$

Hence, we see that

$$\begin{aligned}\|h\|^2_{L^2(0,T;\mathcal{V}^{s+1}(\mathbb{T}))} &= \sum_{j=1}^{2}\sum_{k\in\mathbb{Z}} |k|^2(1+|k|)^{2s}\int_0^T \Big|\sum_{l\in\mathbb{Z}} a_{j,lk}c_{j,l}q_l(t)\Big|^2 dt \\ &\leq C\sum_{j=1}^{2}\sum_{l\in\mathbb{Z}} |c_{j,l}|^2 \sum_{k\in\mathbb{Z}} |k|^2(1+|k|)^{2s}|a_{j,lk}|^2.\end{aligned}$$

The fact $\left|a_{j,lk}\right| \leq C\left|\rho^2_{k-l}\right|$ implies

$$\sum_{k\in\mathbb{Z}} |k|^2(1+|k|)^{2s}|a_{j,lk}|^2 \leq C\sum_{k\in\mathbb{Z}} |k+l|^2(1+|k+l|)^{2s}|\rho_k^2|^2 \leq C|l|^2\left(1+|l|\right)^{2s}\|\rho_2\|^2_{\mathcal{V}^{s+1}(\mathbb{T})}.$$

Then, using

$$|c_{j,l}|^2 \leq C\left(|\alpha_{1,l}|^2 + |\alpha_{2,l}|^2 + |\gamma_{1,l}|^2 + |\gamma_{2,l}|^2\right),$$

we conclude that

$$\begin{aligned}\|h\|^2_{L^2(0,T;\mathcal{V}^{s+1}(\mathbb{T}))} &\leq C\|\rho_2\|^2_{\mathcal{V}^{s+1}(\mathbb{T})}\left(\sum_{l\in\mathbb{Z}} |l|^2(1+|l|)^{2s}\left(|\alpha_{1,l}|^2 + |\alpha_{2,l}|^2 + |\gamma_{1,l}|^2 + |\gamma_{1,l}|^2\right)\right) \\ &\leq C\|\rho_2\|^2_{H^s(\mathbb{T})}\left(\|\Phi_0\|^2_{\mathcal{V}^{s+1}(\mathbb{T})} + \|\Phi_T\|^2_{\mathcal{V}^{s+1}(\mathbb{T})}\right).\end{aligned}$$

□

Remark 5.3. If $T > 0$ and $(\eta_0, \Phi_0), (\eta_T, \Phi_T) \in H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})$ with $s \geq 0$, the Theorem 5.2 implies that there is F such that

$$S(T)(\eta_0, \Phi_0) + \int_0^T S(T-\tau)F(\tau)\, d\tau = (\eta_T, \Phi_T).$$

Moreover, we have that there exists $C = C(T) > 0$ such that

$$\|F\|_{L^1(0,T;H^s \times \mathcal{V}^{s+1})} \leq C \left(\|(\eta_0, \Phi_0)\|_{H^s \times \mathcal{V}^{s+1}} + \|(\eta_T, \Phi_T)\|_{H^s \times \mathcal{V}^{s+1}} \right).$$

5.3 Nonlinear controllability

Now we turn to the nonlinear system

$$\begin{cases} \eta_t + \partial_x^2 \Phi - \partial_x^4 \Phi + \partial_x (\eta \partial_x \Phi) = f_1, \\ \Phi_t + \eta - \partial_x^2 \eta + \frac{1}{2} (\partial_x \Phi)^2 = f_2, \end{cases} \tag{5.11}$$

with the initial condition

$$\eta(x,0) = \eta_0(x), \quad \Phi(x,0) = \Phi_0(x), \tag{5.12}$$

Theorem 5.4. *Let $s \geq 0$ and $T > 0$ be given, then there exists $\delta > 0$ such that for any (η_0, Φ_0), $(\eta_T, \Phi_T) \in H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})$ satisfying*

$$\|(\eta_0, \Phi_0)\|_{H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})}, \quad \|(\eta_T, \Phi_T)\|_{H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})} < \delta,$$

there exists a control function $F = (f_1, f_2) \in L^1(0, T; H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T}))$ such that the solution $(\eta, \Phi) \in C\left([0,T] : H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})\right) \cap U_T^s \times V_T^{s+1}$ of the problem (5.11)–(5.12) satisfies

$$\eta(x,T) = \eta_T(x), \quad \Phi(x,T) = \Phi_T(x).$$

Proof. We rewrite the Cauchy problem (5.11)–(5.12) in its equivalent form:

$$\begin{aligned} (\eta(t), \Phi(t)) = S(t)(\eta_0, \Phi_0) &+ \int_0^t S(t-t')F(t')\, dt' \\ &- \int_0^t S(t-t')\Big(\partial_x(\eta\partial_x\Phi), \frac{1}{2}(\partial_x\Phi)^2\Big)(t')dt'. \end{aligned} \tag{5.13}$$

Now, for any $(\eta, \Phi) = (\eta(x,t), \Phi(x,t))$ we define

$$w((\eta, \Phi), T) = \int_0^T S(T-t')\Big(\partial_x(\eta\partial_x\Phi), \frac{1}{2}(\partial_x\Phi)^2\Big)(t')\, dt'$$

According to Theorem 5.2, for given $(\eta_0, \Phi_0), (\eta_T, \Phi_T) \in H^s(\mathbb{T}) \times \mathcal{V}^{s+1}(\mathbb{T})$, if one chooses

$$F = F_{(\eta, \Phi)}$$

such that

$$S(T)(\eta_0, \Phi_0) + \int_0^T S(T-t')F_{(\eta,\Phi)}(t')\, dt' = (\eta_T, \Phi_T) + w((\eta, \Phi), T)$$

in the equation (5.13), then

$$(\eta(t),\Phi(t)) = S(t)(\eta_0,\Phi_0) + \int_0^t S(t-t')F_{(\eta,\Phi)}(t')\,dt' - \int_0^t S(t-t')\Big(\partial_x(\eta\partial_x\Phi),\frac{1}{2}(\partial_x\Phi)^2\Big)(t')dt', \tag{5.14}$$

with $(\eta(0),\Phi(0)) = (\eta_0,\Phi_0)$ and

$$\begin{aligned}(\eta(T),\Phi(T)) &= S(T)(\eta_0,\Phi_0) + \int_0^T S(T-t')F_{(\eta,\Phi)}(t')dt' \\ &\quad - \int_0^T S(T-t')\Big(\partial_x(\eta\partial_x\Phi),\frac{1}{2}(\partial_x\Phi)^2\Big)(t')dt' \\ &= (\eta_T,\Phi_T) + w((\eta,\Phi),T) - w((\eta,\Phi),T) = (\eta_T,\Phi_T).\end{aligned}$$

This suggests that we consider the map

$$\begin{aligned}\Gamma(\eta,\Phi) &= S(t)(\eta_0,\Phi_0) + \int_0^t S(t-t')F_{(\eta,\Phi)}(t')dt' \\ &\quad - \int_0^t S(t-t')\Big(\partial_x(\eta\partial_x\Phi),\frac{1}{2}(\partial_x\Phi)^2\Big)(t')dt'.\end{aligned}$$

If the map Γ is shown to be a contraction in an appropriate space, then its fixed point (η,Φ) is a solution of (5.11)-(5.12) and satisfies $(\eta(x,T),\Phi(x,T)) = (\eta_T(x),\Phi_T(x))$. We show this is the case in the space $U^s\times V^{s+1}$.

As in the case of the KdV equation in [18], we modify the map $\Gamma=(\Gamma_1,\Gamma_2)$ as follow:

$$\begin{aligned}\Gamma_1(\eta,\Phi)(t) &= \psi_1(t)S_1(t)(\eta_0,\Phi_0) + \psi_1(t)\int_0^t S_1(t-t')\psi_2(t')F_{(\eta,\Phi)}(t')dt' \\ &\quad - \psi_1(t)\int_0^t S_1(t-t')\psi_2(t')\Big(\partial_x(\eta\partial_x\Phi),\frac{1}{2}(\partial_x\Phi)^2\Big)(t')dt',\end{aligned}$$

and

$$\begin{aligned}\Gamma_2(\eta,\Phi)(t) &= \psi_1(t)S_2(t)(\eta_0,\Phi_0) + \psi_1(t)\int_0^t S_2(t-t')\psi_2(t')F_{(\eta,\Phi)}(t')dt' \\ &\quad - \psi_1(t)\int_0^t S_2(t-t')\psi_2(t')\Big(\partial_x(\eta\partial_x\Phi),\frac{1}{2}(\partial_x\Phi)^2\Big)(t')dt',\end{aligned}$$

where ψ_1 is a smooth function with its support inside the interval $(T-1,T+1)$ and $\psi_1(t)=1$ for $t\in[-T,T]$, and ψ_2 is a nonnegative smooth function with $supp\,\psi_2\subset(-T-1,T+1)$ satisfying $\psi_2(t)=1$ for any t in the support of ψ_1.

As in Theorem 4.1, let Z_M be the closed ball of radius M centered at the origin in $U^s\times V^{s+1}$. Using Remark 5.3 and slight modifications of results in Lemmas 2.2–2.6 we have that

$$\begin{aligned}\|w((\eta,\Phi),T)\|_{H^s\times\mathcal{V}^{s+1}} &= \Big\|\int_0^T S(T-t')\Big(\partial_x(\eta\partial_x\Phi),\frac{1}{2}(\partial_x\Phi)^2\Big)(t')\,dt'\Big\|_{H^s\times\mathcal{V}^{s+1}} \\ &\le \sup_{t\in\mathbb{R}}\Big\|\psi_1(t)\int_0^t S(t-t')\psi_2(t')\Big(\partial_x(\eta\partial_x\Phi),\frac{1}{2}(\partial_x\Phi)^2\Big)(t')\,dt'\Big\|_{H^s\times\mathcal{V}^{s+1}} \\ &\le C\Big\|\psi_1(t)\int_0^t S(t-t')\psi_2(t')\Big(\partial_x(\eta\partial_x\Phi),\frac{1}{2}(\partial_x\Phi)^2\Big)(t')\,dt'\Big\|_{U^s\times V^{s+1}} \\ &\le C\Big(\|\partial_x(\eta\partial_x\Phi)\|_{Z^s} + \|(\partial_x\Phi)^2\|_{W^{s+1}}\Big) \\ &\le C\left(\|\eta\|_{X^{s,1/2}}\|\Phi\|_{Y^{s+1,1/2}} + \|\Phi\|^2_{Y^{s+1,1/2}}\right)\end{aligned}$$

and also that

$$\begin{aligned}\|\Gamma_1(\eta,\Phi)\|_{U^s} &\leq C(T)\left(\|(\eta_0,\Phi_0)\|_{H^s(\mathbb{T})\times\mathcal{V}^{s+1}(\mathbb{T})}+\|F_{(\eta,\Phi)}\|_{H^s(\mathbb{T})\times\mathcal{V}^{s+1}(\mathbb{T})}\right)\\ &\quad + C_2C_5\left(\|\eta\|_{X^{s,1/2}}\|\Phi\|_{Y^{s+1,1/2}}+\|\Phi\|^2_{Y^{s+1,1/2}}\right)\\ &\leq C(T)\big(\|(\eta_0,\Phi_0)\|_{H^s(\mathbb{T})\times\mathcal{V}^{s+1}(\mathbb{T})}+\|(\eta_T,\Phi_T)\|_{H^s(\mathbb{T})\times\mathcal{V}^{s+1}(\mathbb{T})}+\|(\eta,\Phi)\|^2_{U^s\times V^{s+1}}\big)\end{aligned}$$

and

$$\|\Gamma_2(\eta,\Phi)\|_{V^{s+1}} \leq C(T)\big(\|(\eta_0,\Phi_0)\|_{H^s(\mathbb{T})\times\mathcal{V}^{s+1}(\mathbb{T})}+\|(\eta_T,\Phi_T)\|_{H^s(\mathbb{T})\times\mathcal{V}^{s+1}(\mathbb{T})}+\|(\eta,\Phi)\|^2_{U^s\times V^{s+1}}\big).$$

So that

$$\|\Gamma(\eta,\Phi)\|_{U^s\times V^{s+1}} \leq C(T)\big(\|(\eta_0,\Phi_0)\|_{H^s(\mathbb{T})\times\mathcal{V}^{s+1}(\mathbb{T})}+\|(\eta_T,\Phi_T)\|_{H^s(\mathbb{T})\times\mathcal{V}^{s+1}(\mathbb{T})}+\|(\eta,\Phi)\|^2_{U^s\times V^{s+1}}\big).$$

Choosing $\delta > 0$ and

$$M = 2C(T)\left(\|(\eta_0,\Phi_0)\|_{H^s(\mathbb{T})\times\mathcal{V}^{s+1}(\mathbb{T})}+\|(\eta_T,\Phi_T)\|_{H^s(\mathbb{T})\times\mathcal{V}^{s+1}(\mathbb{T})}\right)$$

in such a way that

$$2C^2(T)M < 1, \quad 2C(T)\delta \leq M,$$

then we conclude for any $(\eta,\Phi)\in Z_M$ that

$$\begin{aligned}\|\Gamma(\eta,\Phi)\|_{U^s\times V^{s+1}} &\leq C(T)\left(\|(\eta_0,\Phi_0)\|_{H^s(\mathbb{T})\times\mathcal{V}^{s+1}(\mathbb{T})}+\|(\eta_T,\Phi_T)\|_{H^s(\mathbb{T})\times\mathcal{V}^{s+1}(\mathbb{T})}\right)(1+4C^2(T)M)\\ &\leq 2C(T)\left(\|(\eta_0,\Phi_0)\|_{H^s(\mathbb{T})\times\mathcal{V}^{s+1}(\mathbb{T})}+\|(\eta_T,\Phi_T)\|_{H^s(\mathbb{T})\times\mathcal{V}^{s+1}(\mathbb{T})}\right)\\ &\leq 2C(T)\delta \leq M\end{aligned}$$

provided that $\|(\eta_0,\Phi_0)\|_{H^s(\mathbb{T})\times\mathcal{V}^{s+1}(\mathbb{T})}+\|(\eta_T,\Phi_T)\|_{H^s(\mathbb{T})\times\mathcal{V}^{s+1}(\mathbb{T})} < \delta$. Now, using the same of computations, we have that Γ is a contraction on Z_M, and so, the Banach Fixed Point Theorem guaranties the existence fixed point (η,Φ) of Γ in Z_M. This fixed point (η,Φ) is a unique solution of the integral equation

$$\begin{aligned}(\eta(t),\Phi(t)) &= \psi_1(t)S(t)(\eta_0,\Phi_0)+\psi_1(t)\int_0^t S(t-t')\psi_2(t')F_{(\eta,\Phi)}(t')dt'\\ &\quad -\psi_1(t)\int_0^t S(t-t')\psi_2(t')\left(\partial_x(\eta\partial_x\Phi),\frac{1}{2}(\partial_x\Phi)^2\right)(t')dt'.\end{aligned}$$

In particular for $t\in[0,T]$,

$$\begin{aligned}(\eta(t),\Phi(t)) &= S(t)(\eta_0,\Phi_0)+\int_0^t S(t-t')(t')F_{(\eta,\Phi)}(t')dt'\\ &\quad -\int_0^t S(t-t')(t')\left(\partial_x(\eta\partial_x\Phi),\frac{1}{2}(\partial_x\Phi)^2\right)(t')dt'.\end{aligned}$$

That is to say, $(\eta,\Phi)\in C\left([0,T]:H^s(\mathbb{T})\times\mathcal{V}^{s+1}(\mathbb{T})\right)$ solves

$$\begin{cases}\eta_t+\partial_x^2\Phi-\partial_x^4\Phi+\partial_x(\eta\partial_x\Phi)=f_1,\\ \Phi_t+\eta-\partial_x^2\eta+\frac{1}{2}(\partial_x\Phi)^2=f_2,\end{cases}$$

with the conditions

$$\eta(x,0)=\eta_0(x),\quad \Phi(x,0)=\Phi_0(x),\quad \eta(x,T)=\eta_T(x),\quad \Phi(x,T)=\Phi_T(x) \qquad \square$$

Abstract. We show the existence of a positive solution to the (p, q)-Laplacian problem

$$\begin{cases} -\Delta_p u - a\Delta_q u = \lambda f(u) - h(x) \ \text{ in } \Omega, \\ u = 0 \ \text{ on } \partial\Omega, \end{cases}$$

for λ large, where Ω is a bounded domain in $\mathbb{R}^n$ with smooth boundary $\partial\Omega, a$ is a nonnegative constant, $h \in L^\infty(\Omega)$, $p > q > 1$, and f satisfies $f(0) = f(r) = 0$ with $f > 0$ on $(0, r)$ for some $r > 0$.

Keywords: positive solutions, (p, q) Laplacian, semipositone.

2020 Mathematics Subject Classification: 34J60, 35J62.

1 Introduction

Consider the (p, q) Laplacian problem

$$\begin{cases} -\Delta_p u - a\Delta_q u = \lambda f(u) - h(x) \text{ in } \Omega, \\ u = 0 \text{ on } \partial\Omega, \end{cases} \tag{1.1}$$

where Ω is bounded domain in $\mathbb{R}^n$ with smooth boundary $\partial\Omega$, $p > q > 1$, $\Delta_r u = \operatorname{div}(|\nabla u|^{r-2}\nabla u)$, $f : [0, \infty) \to \mathbb{R}$, $h : \Omega \to \mathbb{R}$, a is a nonnegative constant, and λ is a positive parameter.

In contrast to the p-Laplacian, the (p, q) -Laplacian is not homogenous and occurs in applied areas such as chemical reactions and quantum physics (see e.g. [2, 6]) and has been studied extensively in recent years. The existence of a positive solution to (1.1) for λ large when f is p-sublinear at ∞ was studied in [1]. We are interested here in the case when f has falling zeroes and are motivated by a result in [9, Theorem 1.1], where the existence of a positive solution to (1.1) was established for λ large when $a = 0$ (the p-Laplacian equation), $h \equiv \varepsilon$ is small, and f satisfies the following condition:

✉ Corresponding author. Email: ddh123498@yahoo.com

(H) There exists a constant $r > 0$ such that $f : [0, r] \to \mathbb{R}$ is continuous with $f(0) = f(r) = 0$ and $f > 0$ on $(0, r)$.

This result extended a previous work in [4] where $p = 2$ and $f(u) = u - u^3$. Note that under the assumption (H), the function $g(u) = \lambda f(u) - \varepsilon$ has at least two zeroes for λ large as $g(0) = g(r) < 0$ and $g(r/2) = \lambda f(r/2) - \varepsilon > 0$ for λ large. The purpose of this note is to extend the result in [9] to the general (p, q)-Laplacian. In fact, we show that for any $h \in L^\infty(\Omega)$, (1.1) has a positive solution provided that λ is large enough. This extension is nontrivial since the lack of homogeneity of the operator makes it difficult to create a positive subsolution.

Our main result is

Theorem 1.1. *Let (H) hold and $c_0 > 0$. Suppose $h \in L^\infty(\Omega)$ with $0 \le h \le c_0$ in Ω. Then there exists a constant $\lambda_0 > 0$ depending on c_0 such that (1.1) has a positive solution for $\lambda > \lambda_0$.*

We shall denote by $\|\cdot\|_p, |\cdot|_1$, and $|\cdot|_{1,\nu}$ the norms in $L^p(\Omega), C^1(\bar{\Omega})$, and $C^{1,\nu}(\bar{\Omega})$ respectively.

Lemma 1.2. *Let $f \in L^\infty(\Omega)$ with $\|f\|_\infty \le M$. Then the problem*

$$\begin{cases} -\Delta_p u - a\Delta_q u = f & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega \end{cases} \tag{1.2}$$

has a unique solution $u \in C^{1,\nu}(\bar{\Omega})$ for some $\nu \in (0, 1)$. Furthermore $|u|_{1,\nu} \le C$, where $C > 0$ is a constant depending on M (but not on a and f).

Proof. Let $E = W_0^{1,p}(\Omega)$ with norm $\|u\| = \left(\int_\Omega |\nabla u|^p\right)^{1/p}$. Define

$$\langle Au, v\rangle = \int_\Omega |\nabla u|^{p-2}\nabla u \cdot \nabla v + a\int_\Omega |\nabla u|^{q-2}\nabla u \cdot \nabla v$$

and

$$F(v) = \int_\Omega fv$$

for $u, v \in E$. Then it is easily seen that $A : E \to E^*$ is continuous with

$$\frac{\langle Au, u\rangle}{\|u\|} \ge \|u\|^{p-1} \to \infty \quad \text{as } \|u\| \to \infty$$

and

$$\langle Au - Av, u - v\rangle \ge \int_\Omega \left(|\nabla u|^{p-2}\nabla u - |\nabla v|^{p-2}\nabla v \cdot \nabla u - \nabla v\right) > 0 \quad \text{for } u \ne v.$$

Hence by the Minty–Browder Theorem (see [3]), there exists a unique $u \in E$ such that $Au = F$ in E^* i.e. u is the unique weak solution of (1.2). To show that $u \in C^{1,\nu}(\bar{\Omega})$ for some $\nu \in (0, 1)$, we need Lieberman's regularity result in [8]. By the weak comparison principle [10, Theorem 10.1], $|u| \le \tilde{u}$ in Ω, where $\tilde{u}$ satisfies

$$\begin{cases} -\Delta_p \tilde{u} - a\Delta_q \tilde{u} = M & \text{in } B(0, R), \\ \tilde{u} = 0 & \text{on } \partial B(0, R), \end{cases}$$

where $R > 0$ is such that $\Omega \subset B(0,R)$ and $B(0,R)$ denotes the open ball centered at 0 with radius R in $\mathbb{R}^n$. Note that $\tilde{u}$ is unique, radial, and

$$\tilde{u}(x) = \int_{|x|}^{R} \phi^{-1}\left(\frac{Ms}{n}\right) ds \le \int_0^R \left(\frac{Ms}{n}\right)^{\frac{1}{p-1}} ds = \left(\frac{M}{n}\right)^{\frac{1}{p-1}} R^{\frac{p}{p-1}} \equiv M_0 \qquad \forall x \in B(0,R),$$

where $\phi(t) = |t|^{p-2}t + a|t|^{q-2}t$.

Next, let $w \in C^{1,\nu}(\bar{\Omega})$ satisfy $\Delta w = f$ in $\Omega, w = 0$ on $\partial\Omega$. Then the equation in (1.2) becomes

$$\operatorname{div} A(x,u,\nabla u) = 0 \quad \text{in } \Omega,$$

where $A(x,z,\mu) = |\mu|^{p-2}\mu + a|\mu|^{q-2}\mu + \nabla w(x)$. Since $A(x,z,\mu)$ satisfies assumptions (1.10a)–(1.10d) in [8, p. 320] and $|u| \le M_0$ in Ω, it follows from the remark after Theorem 1.7 in [8] that $u \in C^{1,\nu}(\bar{\Omega})$ for some $\nu \in (0,1)$ and $|u|_{1,\nu} \le C$, where C depends on M. □

Lemma 1.3. *Let $f, g \in L^\infty(\Omega)$ and $u, v \in W_0^{1,p}(\Omega)$ satisfy*

$$\begin{cases} -\Delta_p u - a\Delta_q u = f & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \qquad \text{and} \qquad \begin{cases} -\Delta_p v - a\Delta_q v = g & \text{in } \Omega, \\ v = 0 & \text{on } \partial\Omega. \end{cases}$$

Then $|u - v|_1 \to 0$ as $\|f - g\|_1 \to 0$.

Proof. By Lemma 1.2, $u, v \in C^{1,\nu}(\bar{\Omega})$ for some $\nu \in (0,1)$ and $|u|_{1,\nu}, |v|_{1,\nu} \le C$, where C depends on an upper bound of $\|f\|_\infty, \|g\|_\infty$.

Multiplying the equation

$$-(\Delta_p u - \Delta_p v) - a(\Delta_q u - \Delta_q v) = f - g \quad \text{in } \Omega$$

by $u - v$ and integrating, we get

$$\begin{aligned} \int_\Omega |\nabla(u-v)|^p + a\int_\Omega |\nabla(u-v)|^q &= \int_\Omega (f-g)(u-v) \\ &\le 2C\|f-g\|_1 \to 0 \end{aligned}$$

as $\|f - g\|_1 \to 0$. From this and the interpolation inequality [7, Corollary 1.3],

$$|w|_1 \le c|w|_{1,\beta}^{1-\theta} \|w\|_{W^{1,p}}^{\theta} \qquad \forall w \in C^{1,\beta}(\bar{\Omega})$$

for some $c > 0$ and $\theta \in (0,1)$, we obtain $|u - v|_1 \to 0$ as $\|f - g\|_1 \to 0$, which completes the proof. □

Lemma 1.4. *Let $m > 0$ and u_m be the solution of*

$$\begin{cases} -\Delta_p u - a\Delta_q u = m & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases}$$

Then

(i) $\|u_m\|_\infty \to \infty$ *as* $m \to \infty$.

(ii) $\|u_m\|_\infty \to 0$ *as* $m \to 0$.

Proof. *(i)* A calculation shows that $u_m = m^{\frac{1}{p-1}} v_m$, where v_m satisfies

$$\begin{cases} -\Delta_p v_m - a m^{\frac{q-p}{p-1}} \Delta_q v_m = 1 & \text{in } \Omega, \\ v_m = 0 & \text{on } \partial\Omega. \end{cases} \tag{1.3}$$

Suppose $\|u_m\|_\infty \not\longrightarrow \infty$ as $m \to \infty$. Then by going to a subsequence if necessary, we can assume that $\|u_m\|_\infty \le M \ \forall m > 0$ for some $M > 0$.

This implies $|v_m| \le M m^{-\frac{1}{p-1}} \le M$ in Ω for $m > 1$. By Lemma 1.2, $|v_m|_{1,\nu} \le C$, where $C > 0$ is independent of m. Hence there exists $v_0 \in C^1(\bar{\Omega})$ and a subsequence of (v_m), which we still denote by (v_m), such that $v_m \to v_0$ in $C^1(\bar{\Omega})$. Since

$$\int_\Omega |\nabla v_m|^{p-2} \nabla v_m \cdot \nabla \psi + a m^{\frac{q-p}{p-1}} \int_\Omega |\nabla v_m|^{q-2} \nabla v_m \cdot \nabla \psi = \int_\Omega \psi \qquad \forall \psi \in W_0^{1,p}(\Omega),$$

it follows by letting $m \to \infty$ that

$$\int_\Omega |\nabla v_0|^{p-2} \nabla v_0 \cdot \nabla \psi = \int_\Omega \psi \qquad \forall \psi \in W_0^{1,p}(\Omega),$$

i.e v_0 satisfies $-\Delta_p v_0 = 1$ in Ω, $v_0 = 0$ on $\partial\Omega$. Consequently,

$$\|u_m\|_\infty = m^{\frac{1}{p-1}} \|v_m\|_\infty \to \infty \qquad \text{as } m \to \infty$$

a contradiction which proves (i).

(ii) Using Lemma 1.3 with $f = m$ and $g = 0$, we obtain the result. □

Proof of Theorem 1.1. Let u_m be defined by Lemma 1.4. By Lemma 1.3, the map $m \mapsto \|u_m\|_\infty$ is continuous. This, together with Lemma 1.4, implies the existence of an $m > 0$ such that $\|u_m\|_\infty = r$. By [10, Corollary 8.4], $u_m > 0$ in Ω and $\frac{\partial u_m}{\partial n} < 0$ on $\partial\Omega$, where n denotes the outward unit normal on $\partial\Omega$. Let $0 < \alpha < \beta < r$ and $z_{\alpha,\beta} \in C^{1,\beta}(\bar{\Omega})$ be the solution of

$$-\Delta_p z - a\Delta_q z = \begin{cases} m & \text{if } u_m \in [\alpha, \beta], \\ -c_0 & \text{otherwise} \end{cases} \equiv h_{\alpha,\beta}, \qquad z = 0 \quad \text{on } \partial\Omega.$$

Note that the existence of $z_{\alpha,\beta}$ follows from Lemma 1.2. Since $-\Delta_p u_m - a\Delta_q u_m = m$ in Ω and

$$\|h_{\alpha,\beta} - m\|_1 = (m + c_0)|B| \to 0$$

as $\alpha \to 0$ and $\beta \to r$, where $|B|$ denotes the Lebesgue measure of

$$B = \{x : u_m(x) < \alpha\} \cup \{x : \beta < u_m(x) \le r\},$$

it follows from Lemma 1.3 that $|z_{\alpha,\beta} - u_m|_1 \to 0$ as $\alpha \to 0$ and $\beta \to r$. Hence there exist α, β such that $z_{\alpha,\beta} \equiv z_0$ such that

$$\frac{u_m}{2} \le z_0 \le u_m \quad \text{in } \Omega. \tag{1.4}$$

Note that the right side inequality in (1.4) follows from the weak comparison principle in [10, Theorem 10.1]. In particular, $\frac{\alpha}{2} \le z_0 \le \beta$ when $u_m \in [\alpha, \beta]$, which implies $f(z_0) \ge \inf_{[\alpha/2,\beta]} f \equiv \gamma > 0$ and therefore

$$-\Delta_p z_0 - a\Delta_q z_0 = m \le \lambda\gamma - c_0 \le \lambda f(z_0) - h(x) \tag{1.5}$$

for $u_m \in [\alpha, \beta]$ and $\lambda > \frac{m+c_0}{\gamma}$. For such λ and $u_m \notin [\alpha, \beta]$,

$$-\Delta_p z_0 - a\Delta_q z_0 = -c_0 \le -h(x) \le \lambda f(z_0) - h(x) \tag{1.6}$$

since $f(z_0) \ge 0$ in view of (1.4). Combining (1.5) and (1.6), we see that z_0 is a subsolution of (1.1). Clearly, $z_1 \equiv r$ is a supersolution of (1.1) with $z_0 \le z_1$ in Ω. Hence (1.1) has a solution z with $z_0 \le z \le z_1$ in Ω by [5, Corollary 1], which completes the proof. □

Abstract. We consider the differential inclusion problem given by

$$-\sum_{i=1}^{N} \frac{\partial}{\partial x_i}\left(\left|\frac{\partial u}{\partial x_i}\right|^{p_i(x)-2}\frac{\partial u}{\partial x_i}\right) + V(x)|u(x)|^{p_N^o-2}u \in a(x)\partial F(x,u),$$

in $\mathbb{R}^N$. The problem deals with the anisotropic $p(x)$-Laplacian operator where p_i are Lipschitz continuous functions $2 \le p_i(x) < N$ for all $x \in \mathbb{R}^N$ and $i \in \{1,\dots,N\}$. Assume $p_N^o(x) = \max_{1\le i\le N} p_i(x)$, $a \in L^1_+(\mathbb{R}^N) \cap L^{\frac{N}{p_N^o(x)-1}}(\mathbb{R}^N)$, $F(x,t)$ is locally Lipschitz in the t-variable integrand and $\partial F(x,t)$ is the subdifferential with respect to the t-variable in the sense of Clarke. By establishing the existence of infinitely many solutions, we achieve a first result within the anisotropic framework.

Keywords: anisotropic $p(x)$-Laplacian, differential inclusion problem, locally Lipschitz function, infinitely many solutions, variational method.

1 Introduction

The Wulff shape, also known as the equilibrium crystal shape, is closely associated with a convex hypersurface in $\mathbb{R}^N$ based on a given norm. Wulff [36] introduced a variational problem concerning an anisotropic geometric functional in the context of crystal growth. He conjectured, without providing a proof, that the Wulff shape, among closed convex hypersurfaces with constant enclosed volume, minimizes the anisotropic surface energy. This seminal work by Wulff has spurred significant research in the field of phase transitions, particularly in scenarios involving anisotropic and nonhomogeneous media. Recent studies have considered the existence of solutions for anisotropic problems, (see [4, 7, 12–16, 29–34, 37] and the related literature for more details).

In 2019, Ge and Rădulescu [19] proved the existence of infinitely many solutions to the differential inclusion problem involving the $p(x)$-Laplacian

$$-\Delta_{p(x)}u + V(x)|u|^{p(x)-2}u \in a(x)\partial F(x,u), \quad \text{in } \mathbb{R}^N$$

via a combination the variational principle for locally Lipschitz functions with the properties of the generalized Lebesgue Sobolev space.

Here, with the inspiration of [19], we investigate the existence of infinitely many solutions of a differential inclusion problem involving the anisotropic $p(x)$-Laplacian

$$-\sum_{i=1}^{N} \frac{\partial}{\partial x_i}\left(\left|\frac{\partial u}{\partial x_i}\right|^{p_i(x)-2}\frac{\partial u}{\partial x_i}\right) + V(x)|u(x)|^{p_N^o(x)-2}u \in a(x)\partial F(x,u) \quad \text{in } \mathbb{R}^N, \tag{1.1}$$

where p_i are Lipschitz continuous functions such that $2 \le p_i(x) < N$ for all $x \in \mathbb{R}^N$ and $i \in \{1,\dots,N\}$, $p_N^o(x) = \max_{1\le i\le N} p_i(x)$, $a \in L^1_+(\mathbb{R}^N) \cap L^{\frac{N}{p_N^o(x)-1}}(\mathbb{R}^N)$, $F(x,t)$ is locally Lipschitz in the t-variable integrand and $\partial F(x,t)$ is the subdifferential with respect to the t-variable in the sense of Clarke [5]. Notice that $L^1_+(\mathbb{R}^N) := \{\eta \in L^1(\mathbb{R}^N) : \eta(x) > 0 \text{ for all } x \in \mathbb{R}^N\}$ and

$$C_+(\mathbb{R}^N) := \left\{h \in C(\mathbb{R}^N) : h(x) > 1 \text{ for all } x \in \mathbb{R}^N\right\}.$$

For any $h \in C_+(\mathbb{R}^N)$, we will denote

$$h^- := \inf_{x\in\mathbb{R}^N} h(x) \quad \text{and} \quad h^+ := \sup_{x\in\mathbb{R}^N} h(x).$$

Also we set the order $h_1 \ll h_2$ the fact that $\inf_{x\in\mathbb{R}^N}(h_2(x) - h_1(x)) > 0$.

For the potential function V, we make the following assumptions:

(V_1) $V \in C(\mathbb{R}^N)$, $0 < V^-$.

(V_2) There exists $r > 0$ such that for any $b > 0$,

$$\lim_{|y|\to\infty} \mu\left(\left\{x \in \mathbb{R}^N : V(x) \le b\right\} \cap B_r(y)\right) = 0,$$

where μ is the Lebesgue measure on $\mathbb{R}^N$.

For the nonlinearity F, suppose the function $F : \mathbb{R}^N \times \mathbb{R} \to \mathbb{R}$ is such that $F(x,0) = 0$ a.e. on $\mathbb{R}^N$, and

(f_0) F is a Carathéodory function, that is, for all $t \in \mathbb{R}$, the mapping $x \mapsto F(x,t)$ is measurable and, for almost all $x \in \mathbb{R}^N$, the function $t \mapsto F(x,t)$ is locally Lipschitz.

(f_1) for almost all $x \in \mathbb{R}^N$, all $t \in \mathbb{R}$ and all $w \in \partial F(x,t)$, we have

$$|w| \le c\left(1 + |t|^{p_N^o(x)-1}\right).$$

(f_2) there exist $\delta > 0$ and $\subseteq \in L^\infty_-(\mathbb{R}^N)$ such that, for almost all $x \in \mathbb{R}^N$, we have

$$\sup_{0<|t|<\delta} F(x,t) \le \subseteq(x) < 0,$$

where $L^\infty_-(\mathbb{R}^N) = \{\eta \in L^\infty(\mathbb{R}^N) : \eta(x) < 0 \text{ for all } x \in \mathbb{R}^N\}$.

(f_3) There exists $q \in C_+(\mathbb{R}^N)$ with

$$p_N^{o\,+} < q^- \le q(x) < \frac{Np_N^o(x) - p_N^o(x)(p_N^o(x)-1)}{N - p_N^o(x)} < \kappa(x) \quad \text{for all } x \in \mathbb{R}^N$$

where $\kappa(x) = p_N^{o\,*}(x) = \frac{Np_N^o(x)}{N-p_N^o(x)}$, such that for almost all $x \in \mathbb{R}^N$ we have

$$\liminf_{|t|\to\infty} \frac{F(x,t)}{|t|^{q(x)}} > 0.$$

(f_4) $F(x,-t) = F(x,t)$ for all $(x,t) \in \mathbb{R}^N \times \mathbb{R}$.

Now we state the main result of this article.

Theorem 1.1. *Suppose that* (f_0)*–*(f_4)*,* (V_1) *and* (V_2) *hold. Then problem* (1.1) *has infinitely many nontrivial solutions.*

The unique aspect of this paper lies in its capacity to extend the conclusions of Ge and Rădulescu [19] to a more generalized, anisotropic setting.

The subsequent sections of this paper are structured as follows. In Section 2, we will revisit the definitions and various properties associated with variable exponent Sobolev spaces. Moving on to Section 3, we will establish the existence of an infinite number of nontrivial solutions for the problem (1.1), with credit given to the essential ideas derived from [19].

2 Preliminaries

We recall some preliminary results on the theory of variable exponent Sobolev space. For more details see [8,10,11,17,21,23,24,26–28], where additional information and specifics can be found.

For $p(x) \in C_+(\mathbb{R}^N)$, we define the variable exponent Lebesgue space

$$L^{p(x)} := \left\{ u : u \text{ is measurable and } \int_{\mathbb{R}^N} |u(x)|^{p(x)} dx < +\infty \right\}$$

with the norm

$$|u|_{L^{p(x)}(\mathbb{R}^N)} := |u|_{p(x)} := \inf \left\{ \Lambda > 0 : \int_{\mathbb{R}^N} |\frac{u(x)}{\Lambda}|^{p(x)} dx \le 1 \right\},$$

and we define the variable exponent Sobolev space

$$W^{1,p(x)}(\mathbb{R}^N) := \left\{ u \in L^{p(x)}(\mathbb{R}^N) : |\nabla u| \in L^{p(x)}(\mathbb{R}^N) \right\},$$

with the norm $|u|_{W^{1,p(x)}(\mathbb{R}^N)} = |u|_{p(x)} + |\nabla u|_{p(x)}$. We recall that spaces $L^{p(x)}(\mathbb{R}^N)$ and $W^{1,p(x)}(\mathbb{R}^N)$ are separable and reflexive Banach spaces.

Here, we introduce a natural generalization of the variable exponent Sobolev space $W^{1,p(\cdot)}(\mathbb{R}^N)$ that will enable us to study problem (1.1) with sufficient accuracy (see [21,22]).

Let us denote by $\overrightarrow{p} : \mathbb{R}^N \to \mathbb{R}^N$ the vectorial function

$$\overrightarrow{p}(x) = (p_1(x), \dots, p_N(x)).$$

Also assume $1 < p_1(x), \ldots, p_N(x) < \infty$.

One can define $\mathcal{D}^{1,\overrightarrow{p}(\cdot)}(\mathbb{R}^N)$ by

$$\mathcal{D}^{1,\overrightarrow{p}(\cdot)}(\mathbb{R}^N) := \left\{ u \in L^{p_N^o(\cdot)}(\mathbb{R}^N) : \partial_{x_i} u \in L^{p_i(x)}(\mathbb{R}^N), i = 1, \ldots, N \right\}.$$

This is a reflexive Banach space with respect to the norm

$$\|u\|_{1,\overrightarrow{p}(\cdot)} := \sum_{i=1}^{N} \|\partial_{x_i} u\|_{L^{p_i(\cdot)}(\mathbb{R}^N)}.$$

This space continuously embedded in $L^{p_N^o(\cdot)}(\mathbb{R}^N)$, where $p_N^o = \max_{1\le i\le N} p_i(x)$. We introduce $\overrightarrow{P}_+, \overrightarrow{P}_- \in \mathbb{R}^N$ by

$$\overrightarrow{P}_+ := (p_1^+, \ldots, p_N^+), \qquad \overrightarrow{P}_- := (p_1^-, \ldots, p_N^-)$$

and $P_+^+, P_-^+, P_-^- \in \mathbb{R}^+$ by

$$P_+^+ = \max\{p_1^+, \ldots, p_N^+\}, \qquad P_-^+ = \max\{p_1^-, \ldots, p_N^-\}, \qquad P_-^- = \min\{p_1^-, \ldots, p_N^-\}. \tag{2.1}$$

Throughout this paper we assume that

$$\sum_{i=1}^{N} \frac{1}{p_i^-} > 1. \tag{2.2}$$

We define

$$p^*(x) = \frac{N}{\sum_{i=1}^{N} \frac{1}{p_i(x)} - 1}, \qquad p_\infty = \max\{P_-^+, p^{*-}\}, \tag{2.3}$$

where $p^{*-} = \inf_{x\in\mathbb{R}^N} p^*(x)$.

Define $J : \mathcal{D}^{1,\overrightarrow{p}(\cdot)}(\mathbb{R}^N) \to \mathbb{R}$ by

$$J(u) := \sum_{i=1}^{N} \int_{\mathbb{R}^N} \frac{1}{p_i(x)} |\partial_{x_i} u(x)|^{p_i(x)} dx + \int_{\mathbb{R}^N} \frac{1}{p_N^o(x)} V(x) |u(x)|^{p_N^o(x)} dx$$

for all $u \in \mathcal{D}^{1,\overrightarrow{p}(\cdot)}(\mathbb{R}^N)$. Then $J \in C^1(\mathcal{D}^{1,\overrightarrow{p}(\cdot)}(\mathbb{R}^N, \mathbb{R})$. If we denote

$$A = J' : \mathcal{D}^{1,\overrightarrow{p}(\cdot)}(\mathbb{R}^N) \to (\mathcal{D}^{1,\overrightarrow{p}(\cdot)}(\mathbb{R}^N))^*,$$

then

$$\begin{aligned}\langle A(u), v\rangle = &\sum_{i=1}^{N} \int_{\mathbb{R}^N} \frac{1}{p_i(x)} |\partial_{x_i} u(x)|^{p_i(x)-2} \partial_{x_i} u(x) \partial_{x_i} v(x) \\ &+ \int_{\mathbb{R}^N} \frac{1}{p_N^o(x)} V(x) |u(x)|^{p_N^o(x)-2} uv dx\end{aligned}$$

for all $u, v \in \mathcal{D}^{1,\overrightarrow{p}(\cdot)}(\mathbb{R}^N)$, where $\langle \cdot, \cdot \rangle$ is the duality pairing between $(\mathcal{D}^{1,\overrightarrow{p}(\cdot)}(\mathbb{R}^N))^*$ and $\mathcal{D}^{1,\overrightarrow{p}(\cdot)}(\mathbb{R}^N)$.

Definition 2.1. A mapping $f : X \to X^*$ is said to be of type $(S)_+$, if $u_n \rightharpoonup u$ in X and $\limsup_{n\to\infty} \langle f(u_n), u_n - u\rangle \le 0$ implies $u_n \to u$ in X.

Similar to [3] we have the following proposition.

Proposition 2.2. *Suppose $G := \mathcal{D}^{1,\overrightarrow{p}(\cdot)}(\mathbb{R}^N)$ and A is as above. Then $A : G \to G^*$ is*

(1) convex, bounded and strictly monotone operator;

(2) a mapping of type $(S)_+$;

(3) a homeomorphism.

Denote by $L^{q(x)}(\mathbb{R}^N)$ the conjugate space of $L^{p_N^o(x)}(\mathbb{R}^N)$ with $\frac{1}{p_N^o(x)} + \frac{1}{q(x)} = 1$. Then the Hölder type inequality

$$\int_{\mathbb{R}^N} |uv| dx \leq \left(\frac{1}{p_N^{o\,-}} + \frac{1}{q^-} \right) |u|_{L^{p_N^o(x)}(\mathbb{R}^N)} |v|_{L^{q(x)}(\mathbb{R}^N)}$$

holds for all $u \in L^{p_N^o(x)}(\mathbb{R}^N)$ and $v \in L^{q(x)}(\mathbb{R}^N)$. Furthermore, if we define the mapping $\rho : L^{p_N^o(x)}(\mathbb{R}^N) \to \mathbb{R}$ by

$$\rho(u) = \int_{\mathbb{R}^N} |u|^{p_N^o(x)} dx,$$

then the following relations hold:

$$|u|_{p_N^o(x)} = \mu \text{ for } u \neq 0 \Longleftrightarrow \rho\left(\frac{u}{\mu}\right) = 1, \tag{2.4}$$

$$|u|_{p_N^o(x)} < 1 (= 1, > 1) \Longleftrightarrow \rho(u) < 1 (= 1, > 1), \tag{2.5}$$

$$|u|_{p_N^o(x)} > 1 \Longrightarrow |u|_{p_N^o(x)}^{p_N^{o\,-}} \leq \rho(u) |u|_{p_N^o(x)}^{p_N^{o\,+}}, \tag{2.6}$$

$$|u|_{p_N^o(x)} < 1 \Longrightarrow |u|_{p_N^o(x)}^{p_N^{o\,+}} \leq \rho(u) |u|_{p_N^o(x)}^{p_N^{o\,-}}. \tag{2.7}$$

Proposition 2.3 ([9]). *Let $p_N^o(x), q(x)$ be measurable functions such that $p_N^o(x) \in L^\infty(\mathbb{R}^N)$ and $1 \leq p_N^o(x) q(x) \leq \infty$ almost everywhere in $\mathbb{R}^N$. Let $u \in L^{q(x)}(\mathbb{R}^N)$, $u \neq 0$. Then*

$$|u|_{p_N^o(x)q(x)} \geq 1 \Longrightarrow |u|_{p_N^o(x)q(x)}^{p_N^{o\,-}} \leq ||u|^{p_N^o(x)}|_{q(x)} \leq |u|_{p_N^o(x)q(x)}^{p_N^{o\,+}},$$

$$|u|_{p_N^o(x)q(x)} \leq 1 \Longrightarrow |u|_{p_N^o(x)q(x)}^{p_N^{o\,+}} \leq ||u|^{p_N^o(x)}|_{q(x)} \leq |u|_{p_N^o(x)q(x)}^{p_N^{o\,-}}.$$

In particular, if $p_N^o(x) = p_N^o$ is a constant, then $||u|^{p_N^o(x)}|_{q(x)} = |u|_{p_N^o q(x)}^{p_N^o}$.

Next we consider the case that V satisfies (V_1) and (V_2). We equip the linear subspace

$$E = \left\{ u \in \mathcal{D}^{1,\overrightarrow{p}(\cdot)}(\mathbb{R}^N) : \sum_{i=1}^N \int_{\mathbb{R}^N} |\partial_{x_i} u|^{p_i(x)} dx + \int_{\mathbb{R}^N} V(x) |u|^{p_N^o(x)} dx < +\infty \right\}$$

with the norm

$$\|u\|_E = \inf \left\{ \lambda > 0 : \sum_{i=1}^N \int_{\mathbb{R}^N} |\frac{\partial_{x_i} u}{\lambda}|^{p_i(x)} dx + \int_{\mathbb{R}^N} V(x) |\frac{u}{\lambda}|^{p_N^o(x)} dx < +\infty \right\}.$$

Then $(E, \|\cdot\|_E)$ is continuously embedded into $\mathcal{D}^{1,\overrightarrow{p}(\cdot)}(\mathbb{R}^N)$ as a closed subspace. Therefore, $(E, \|\cdot\|_E)$ is also a separable reflexive Banach space. It is easy to see that with the norm $\|\cdot\|_E$, Proposition 2.2 remains valid, that is, the following properties hold true.

Proposition 2.4. *Set* $I(u) = \sum_{i=1}^{N} \int_{\mathbb{R}^N} |\partial_{x_i} u|^{p_i(x)} dx + \int_{\mathbb{R}^N} V(x)|u|^{p_N^o(x)} dx$. *If* $u(x) \in \mathcal{D}^{1,\overrightarrow{p}(\cdot)}(\mathbb{R}^N)$, *then*

(i) *for* $u \neq 0$, $\|u\|_E = \lambda$ *if and only if* $I(\frac{u}{\lambda}) = 1$,

(ii) $\|u\|_E < 1 (= 1, > 1)$ *if and only if* $I(u) < 1 (= 1, > 1)$,

(iii) $\|u\|_E > 1$ *implies* $\|u\|_E^{{p_N^o}^-} \leq I(u) \leq \|u\|_E^{{p_N^o}^+}$,

(iv) $\|u\|_E < 1$ *implies* $\|u\|_E^{{p_N^o}^+} \leq I(u) \leq \|u\|_E^{{p_N^o}^-}$.

Here we recall the following theorem from [6, Theorem 2.4.] which implies there exits an embedding from $\mathcal{D}^{1,\overrightarrow{p}}(\mathbb{R}^N)$ into $L^{\overline{p}^\star}(\mathbb{R}^N)$, where $\overline{p}^\star := \frac{N\overline{p}}{N-\overline{p}}$. This is a particular case of the result of Troisi [35].

Theorem 2.5. *Assume* $p_i \geq 1$ *for* $i = 1, \dots, N$. *Then there exists a continuous embedding* $\mathcal{D}^{1,\overrightarrow{p}}(\mathbb{R}^N)$ *into* $L^{\overline{p}^\star}(\mathbb{R}^N)$, *i.e.* $\mathcal{D}^{1,\overrightarrow{p}}(\mathbb{R}^N) \hookrightarrow L^{\overline{p}^\star}(\mathbb{R}^N)$.

This implies that we have a continuous embedding $E \hookrightarrow L^{p_N^o(x)}(\mathbb{R}^N)$.

Now by a similar argument as [1, Theorem 3.2] which is in the Heisenberg group setting (or by combining [25, Theorem 2.1] and [2, Lemma 4.4] which are in the Euclidean setting) we have the following proposition.

Proposition 2.6. *Assume* $\kappa(x) = {p_N^o}^*(x) = \frac{Np_N^o(x)}{N-p_N^o(x)}$. *If* V *satisfies* (V_1) *and* (V_2), *then*

(i) *we have a compact embedding* $E \hookrightarrow L^{p_N^o(x)}(\mathbb{R}^N)$,

(ii) *for any measurable function* $q : \mathbb{R}^N \to \mathbb{R}$ *with* $p_N^o(x) < q(x) \ll \kappa(x)$, *we have a compact embedding* $E \hookrightarrow L^{q(x)}(\mathbb{R}^N)$.

Let $(Y, \|\cdot\|)$ be a real Banach space and Y^* its topological dual. A function $\phi : Y \to \mathbb{R}$ is called locally Lipschitz if each point $u \in Y$ possesses a neighborhood N_u such that $|f(u_1) - f(u_2)| \leq \|u_1 - u_2\|$, for all $u_1, u_2 \in N_u$, for a constant $L > 0$ depending on N_u. The generalized directional derivative of ϕ at the point $u \in Y$ in the direction $h \in Y$ is

$$\phi^o(u,h) = \liminf_{\substack{w \to u \\ t \to 0^+}} \frac{\phi(w+th) - \phi(w)}{t}.$$

The generalized gradient of ϕ at $u \in Y$ is defined by

$$\partial\phi(u) = \{u^* \in Y^* : \langle u^*, h\rangle \leq \phi^o(u,h) \text{ for all } h \in Y\},$$

which is a nonempty, convex and w^*-compact subset of Y, where $\langle\cdot,\cdot\rangle$ is the duality pairing between Y^* and Y. We say that $u \in Y$ is a critical point of ϕ if $0 \in \partial\phi(u)$, (see [3] for further details).

Definition 2.7. Let Y be a real Banach space, and $\phi : Y \to \mathbb{R}$ is a locally Lipschitz function. We say that ϕ satisfies the nonsmooth (PS_c) condition if any sequence $\{u_n\} \subset Y$ such that $\phi(u_n) \to c$ and $m(u_n) \to 0$ as $n \to \infty$ has a strongly convergent subsequence, where $m(u_n) = \inf\{\|u^*\|_{Y^*} : u^* \in \partial\phi(u_n)\}$. If this property holds at every level $c \in \mathbb{R}$, then we simply say that ϕ satisfies the nonsmooth (PS) condition.

We recall the following lemma [18, Theorem 2.1.7].

Lemma 2.8. *Assume that X is an infinite-dimensional Banach space, and let $\phi : X \to \mathbb{R}$ be a locally Lipschitz function that satisfies the nonsmooth (PS_c) condition for every $c > 0$. Assume $\phi(u) = \phi(-u)$ for all $u \in X$ and $\phi(0) = 0$. Suppose $X = X_1 \bigoplus X_2$, where X_1 is finite-dimensional, and assume the following conditions:*

(a) $\alpha > 0, \delta > 0$ such that $\|u\| = \delta$ with $u \in X_2$ implies $\phi(u) \geq \alpha$.

(b) For any finite-dimensional subspace $W \subset X_1$, there is $R = R(W)$ such that $\phi(u) \leq 0$ for $u \in W$ with $\|u\| \geq R$.

Then ϕ possesses an unbounded sequence of critical values.

Before ending this section we can define the weighted variable exponent Lebesgue space $L^{q(x)}_{a(x)}(\mathbb{R}^N)$ (see [20]) as follows:

Assume $a \in L^1_+(\mathbb{R}^N)$, then $a(x)$ is a measurable, nonnegative real-valued function for $x \in \mathbb{R}^N$. Define

$$L^{q(x)}_{a(x)}(\mathbb{R}^N) = \left\{ u \text{ is measurable and } \int_{\mathbb{R}^N} a(x)|u(x)|^{q(x)}dx < +\infty \right\}$$

with the norm

$$|u|_{L^{q(x)}_{a(x)}(\mathbb{R}^N)} = \inf\left\{ \sigma > 0 : \int_{\mathbb{R}^N} a(x)|\frac{u}{\sigma}|^{q(x)}dx \leq 1 \right\}.$$

Then $L^{q(x)}_{a(x)}(\mathbb{R}^N)$ is a Banach space.

Remark 2.9. The embedding $E \hookrightarrow W^{1,p^o_N(x)}(\mathbb{R}^N) \hookrightarrow L^{q(x)}_{a(x)}(\mathbb{R}^N)$ is continuous.

Set $h(x) = q(x)\frac{N}{N-p^o_N(x)-1}$, where $q(x)$ is mentioned in (f_3). Then ${p^o_N}^+ < h^-$ and $p^o_N(x) < h(x) < \kappa(x)$ for all $x \in \mathbb{R}^N$, where $\kappa(x) = {p^o_N}^*(x) = \frac{Np^o_N(x)}{N-p^o_N(x)}$. Hence, by Proposition 2.6, there is a continuous embedding $E \hookrightarrow L^{h(x)}(\mathbb{R}^N)$. Thus, for $u \in E$, we have $|u(x)|^{q(x)} \in L^{\frac{N}{N-p^o_N(x)+1}}(\mathbb{R}^N)$. By the Hölder inequality,

$$\int_{\mathbb{R}^N} a(x)|u|^{q(x)}dx \leq 2|a|_{L^{\frac{N}{p^o_N(x)-1}}(\mathbb{R}^N)} ||u|^{q(x)}|_{L^{\frac{N}{N-p^o_N(x)+1}}(\mathbb{R}^N)} < +\infty. \tag{2.8}$$

It follows that $u \in L^{q(x)}_{a(x)}(\mathbb{R}^N)$, and hence the embedding $E \hookrightarrow W^{1,p^o_N(x)}(\mathbb{R}^N) \hookrightarrow L^{q(x)}_{a(x)}(\mathbb{R}^N)$ is continuous.

3 Infinitely many nontrivial solutions

Here, we introduce the energy functional $\phi : E \to \mathbb{R}$ associated with problem (1.1) by

$$\phi(u) = \sum_{i=1}^{N} \int_{\mathbb{R}^N} \frac{1}{p_i(x)} |\partial_{x_i} u|^{p_i(x)}dx + \int_{\mathbb{R}^N} \frac{1}{p^o_N(x)} V(x)|u|^{p^o_N(x)}dx - \int_{\mathbb{R}^N} F(x,u)dx.$$

From the hypotheses on F, it is standard to check that ϕ is locally Lipschitz on E and $\partial\phi(u) \subset A(u) - \partial F(x,u)$ for all $u \in E$ (see [3]).

Definition 3.1. $u \in E$ is called a solution of (1.1) to which there corresponds a mapping $x \in \mathbb{R}^N \to w(x)$ with $w(x) \in \partial F(x,u)$ for almost every $x \in \mathbb{R}^N$ having the property $x \to w(x)h(x) \in L^1(\mathbb{R}^N)$ for every $h \in E$, and

$$\sum_{i=1}^{N} \int_{\mathbb{R}^N} |\partial_{x_i} u|^{p_i(x)-2} \partial_{x_i} u \partial_{x_i} h dx + \int_{\mathbb{R}^N} V(x)|u|^{p_N^o(x)-2} uh\, dx = \int_{\mathbb{R}^N} w(x)h(x)dx.$$

Notice that weak solutions of problem (1.1) are exactly the critical points of the functional ϕ.

Lemma 3.2. *Assume that all conditions of Theorem 1.1 are satisfied. Then the energy functional ϕ satisfies the nonsmooth (PS) condition in E.*

Proof. Suppose that $\{u_n\} \subset E$ is a $(\mathrm{PS_c})$ sequence for ϕ, that is $\phi(u_n) \to c$ and $m(u_n) \to 0$ as $n \to \infty$, which shows that

$$c = \phi(u_n) + o(1), \qquad m(u_n) = o(1), \tag{3.1}$$

where $o(1) \to 0$ as $n \to +\infty$.

We claim that the sequence $\{u_n\}_{n=1}^{\infty}$ is bounded. Suppose that this is not the case. By passing to a subsequence if necessary, we may assume that $\|u_n\|_E \to +\infty$ as $n \to \infty$. Without loss of generality, we assume $\|u_n\|_E \geq 1$. Let $u_n^* \partial\phi(u_n)$ be such that $m(u_n) = \|u_n^*\|_{E^*}$, $n \in N$. We have $u_n^* = A(u_n) - w_n$, $w_n(x) \in \partial F(x, u_n(x))$, $w_n \in L^{p'(x)}(\mathbb{R}^N)$, where $\frac{1}{p_N^o(x)} + \frac{1}{p'(x)} = 1$. By (3.1), there is a constant $M_1 > 0$ such that

$$|\phi(u_n)| \leq M_1, \quad \text{for all } n \geq 1, \tag{3.2}$$

and there is a constant $C > 0$ such that

$$\begin{aligned} C\|u_n\|_E &\geq \langle u_n^*, u_n \rangle \\ &= \langle A(u_n), u_n \rangle - \int_{\mathbb{R}^N} a(x) w_n u_n dx \\ &= \sum_{i=1}^{N} \int_{\mathbb{R}^N} \frac{1}{p_i(x)} |\partial_{x_i} u|^{p_i(x)} dx + \int_{\mathbb{R}^N} \frac{1}{p_N^o(x)} V(x)|u|^{p_N^o(x)} dx - \int_{\mathbb{R}^N} a(x) w_n u_n dx. \end{aligned} \tag{3.3}$$

Then by (3.2) and (3.3), we have

$$M_1 p_N^{o\,-} + C\|u_n\|_E \geq \int_{\mathbb{R}^N} a(x)(p_N^{o\,-} F(x,u_n) - w_n u_n) dx, \tag{3.4}$$

where $p_N^{o\,-}$ is given by (2.1).

Next we estimate (3.4). By virtue of (f_3), there exists $c_1 > 0$ and $M_2 > 0$ such that, for almost all $x \in \mathbb{R}^N$ and all $|t| \geq M_2$, we have $F(x,t) \geq c_1 |t|^{q(x)}$. On the other hand, from (f_1), for almost all $x \in \mathbb{R}^N$ and all $t \in \mathbb{R}$ such that $|t| < M_2$, we have $|F(x,t)| \leq C$, where $C = C(M_2) > 0$. Therefore, for almost all $x \in \mathbb{R}^N$ and all $t \in \mathbb{R}$ the above two inequalities imply

$$F(x,t) \geq c_1 |t|^{q(x)} - c_2, \quad \text{for all } x \in \mathbb{R}^N,\ t \in \mathbb{R}, \tag{3.5}$$

where $c_2 = C + \max\{M_2^{q^-}, M_2^{q^+}\} c_1$. Using (f_1) again, we deduce another estimate:

$$|wt| \leq c(|t| + |t|^{p_N^o(x)}) \leq 2c(1 + |t|^{p_N^o(x)}). \tag{3.6}$$

From (3.5) and (3.6), we have

$$p_N^{o\,-}F(x,t) - wt \geq p_N^{o\,-}c_1|t|^{q(x)} - p_N^{o\,-}c_2 - 2c(1+|t|^{p_N^o(x)}). \tag{3.7}$$

By (3.4) and (3.7), we get

$$\begin{aligned} &p_N^{o\,-}c_1\int_{\mathbb{R}^N} a(x)|u_n|^{q(x)}dx - 2c\int_{\mathbb{R}^N} a(x)|u_n|^{p_N^o(x)}dx \\ &\leq M_1 p_N^{o\,-} + C\|u_n\|_E + (p_N^{o\,-}c_2 + 2c)|a|_1. \end{aligned} \tag{3.8}$$

Note that $q^- > p_N^{o\,+}$. Then, applying Young's inequality with ϵ, we get

$$\begin{aligned} |u|^{p_N^o(x)} = 1\times|u|^{p_N^o(x)} &= \epsilon^{-\frac{p_N^o(x)}{q(x)}} \times \epsilon^{\frac{p_N^o(x)}{q(x)}}|u|^{p_N^o(x)} \\ &\leq (\epsilon^{-\frac{p_N^o(x)}{q(x)}})^{\frac{q(x)}{q(x)-p_N^o(x)}} + \epsilon||u(x)|^{p_N^o(x)}|^{\frac{q(x)}{p_N^o(x)}} \\ &= \epsilon^{-\frac{p_N^o(x)}{q(x)-p_N^o(x)}} + \epsilon|u(x)|^{q(x)} \\ &\leq \epsilon^{-\frac{p_N^{o\,+}}{q^- - p_N^{o\,+}}} + \epsilon|u(x)|^{q(x)}. \end{aligned} \tag{3.9}$$

Hence, by (3.8) and (3.9), we obtain

$$(p_N^{o\,-}c_1 - 2c\epsilon)\int_{\mathbb{R}^N} a(x)|u_n|^{q(x)}dx \leq M_1 p_N^{o\,-} + C\|u_n\|_E + (p_N^{o\,-}c_2+2c)|a|_1 + 2c\epsilon^{\frac{p_N^{o\,+}}{q^- - p_N^{o\,+}}}|a|_1.$$

Then, choosing ϵ_0 small enough such that $0 < \epsilon < \frac{p_N^{o\,-}c_1}{2c}$, we obtain

$$\begin{aligned} \int_{\mathbb{R}^N} a(x)|u_n|^{q(x)}dx \leq &\frac{M_1 p_N^{o\,-} + (p_N^{o\,-}c_2+2c)|a|_1 + 2c\epsilon^{\frac{p_N^{o\,+}}{q^- - p_N^{o\,+}}}|a|_1}{(p_N^{o\,-}c_1 - 2c\epsilon)} \\ &+ \frac{C}{(p_N^{o\,-}c_1 - 2c\epsilon)}\|u_n\|_E, \end{aligned} \tag{3.10}$$

for all $n \geq 1$.

On the other hand, using (f_1) again, we deduce another estimate:

$$|F(x,u_n)| \leq 2c(1+|u_n|^{p(x)}). \tag{3.11}$$

Hence we obtain from (3.2), (3.11) and $p_N^{o\,+} < q(x)$ that

$$\begin{aligned} \frac{1}{P_+^+}\|u_n\|_E^{p_N^{o\,-}} &\leq \sum_{i=1}^N \int_{\mathbb{R}^N} \frac{1}{p_i(x)}|\partial_{x_i}u|^{p_i(x)}dx + \int_{\mathbb{R}^N} V(x)|u_n|^{p_N^o(x)}dx \\ &= \phi(u_n) + \int_{\mathbb{R}^N} a(x)F(x,u)dx \\ &\leq M_1 + 2c|a|_1 + 2c\int_{\mathbb{R}^N} a(x)|u_n|^{p_N^o(x)}dx \\ &\leq M_1 + 2c|a|_1 + 2c\int_{\mathbb{R}^N} a(x)(1+|u_n|^{q(x)})dx \\ &= M_1 + 4c|a|_1 + 2c\int_{\mathbb{R}^N} a(x)|u_n|^{q(x)}dx. \end{aligned} \tag{3.12}$$

Therefore, combining (3.10) and (3.12), the boundedness of $\{u_n\}_{n=1}^{\infty}$ immediately follows, that is, there is constant $C > 0$ such that $\|u_n\|_E \le C$. Thus, passing to a subsequence if necessary, we assume that $u_n \rightharpoonup u_0$ in E, so it follows from (3.1) that

$$\langle A(u_n), u_n - u_0\rangle - \int_{\mathbb{R}^N} a(x) w_n (u_n - u_0) dx \le \epsilon_n, \tag{3.13}$$

with $\epsilon_n \downarrow 0$, $w_n(x)\partial F(x, u_n(x))$.

Next we prove that $\int_{\mathbb{R}^N} a(x) w_n(u_n - u_0)dx$ as $n \to +\infty$. Clearly, by hypothesis (f_1), we have

$$\int_{\mathbb{R}^N} a(x)|w_n|\;|u_n - u_0|dx \le c\int_{\mathbb{R}^N} a(x)|u_n - u_0|dx + \int_{\mathbb{R}^N} a(x)|u_n|^{p_N^o(x)-1}|u_n - u_0|dx. \tag{3.14}$$

On the other hand, using Hölder's inequality, we have

$$\begin{aligned}
&\int_{\mathbb{R}^N} a(x)|u_n|^{p_N^o(x)-1}|u_n - u_0|dx \\
&\le 3|a|_{L^{\frac{N}{p_N^o(x)-1}}(\mathbb{R}^N)} \left||u_n|^{p_N^o(x)-1}\right|_{L^{\frac{\kappa(x)}{p_N^o(x)-1}}(\mathbb{R}^N)} |u_n - u_0|_{L^{p_N^o(x)}(\mathbb{R}^N)} \\
&\le 3|a|_{L^{\frac{p_N^o(x)}{p_N^o(x)-r(x)}}(\mathbb{R}^N)} |u_n - u_0|_{L^{\frac{\kappa(x)}{p_N^o(x)}}(\mathbb{R}^N)} \left||u_n|^{p_N^o(x)-1}\right|_{L^{\frac{\kappa(x)}{p_N^o(x)-1}}(\mathbb{R}^N)}.
\end{aligned} \tag{3.15}$$

where $\kappa(x) = {p_N^o}^*(x)$. We claim that

$$\left||u_n|^{p_N^o(x)-1}\right|_{L^{\frac{\kappa(x)}{p_N^o(x)-1}}(\mathbb{R}^N)} \le |u_n|_{\kappa(x)}^{{p_N^o}^+-1} + 2. \tag{3.16}$$

Indeed, we have that

$$\text{if } |u_n|_{\kappa(x)} \ge 1, \text{ then } \left||u_n|^{p_N^o(x)-1}\right|_{L^{\frac{\kappa(x)}{p_N^o(x)-1}}(\mathbb{R}^N)} \le |u_n|_{\kappa(x)}^{{p_N^o}^+-1}. \tag{I}$$

This is seen as follows: According to (2.4), to prove (I), this is equivalent to proving that $|u_n|_{\kappa(x)} \ge 1$ implies

$$\int_{\mathbb{R}^N} \frac{|u_n(x)|^{(p_N^o(x)-1)\frac{\kappa(x)}{p_N^o(x)-1}}}{|u_n(x)|_{\kappa(x)}^{({p_N^o}^+-1)\frac{\kappa(x)}{p_N^o(x)-1}}} dx = \int_{\mathbb{R}^N} \frac{|u_n(x)|^{\kappa(x)}}{|u_n(x)|_{\kappa(x)}^{({p_N^o}^+-1)\frac{\kappa(x)}{p_N^o(x)-1}}} dx \le 1.$$

This inequality is justified as follows: since $|u_n|_{p_N^o(x)} \ge 1$ and

$$\begin{aligned}
({p_N^o}^+ - 1)\frac{\kappa(x)}{p_N^o(x)-1} - \kappa(x) &= {p_N^o}^+\frac{\kappa(x)}{p_N^o(x)-1} - \left(\kappa(x) + \frac{\kappa(x)}{p_N^o(x)-1}\right) \\
&= {p_N^o}^+\frac{\kappa(x)}{p_N^o(x)-1} - p_N^o(x)\frac{\kappa(x)}{p_N^o(x)-1} \\
&= \frac{\kappa(x)}{p_N^o(x)-1}({p_N^o}^+ - p_N^o(x)) \\
&\ge 0,
\end{aligned}$$

we infer that

$$\frac{|u_n(x)|^{\kappa(x)}}{|u_n|_{\kappa(x)}^{({p_N^o}^+-1)\frac{\kappa(x)}{p_N^o(x)-1}}} = \frac{|u_n(x)|^{\kappa(x)}}{|u_n|_{\kappa(x)}^{\kappa(x)}} \frac{1}{|u_n|_{\kappa(x)}^{({p_N^o}^+-1)\frac{\kappa(x)}{p_N^o(x)-1}-\kappa(x)}} \le \frac{|u_n(x)|^{\kappa(x)}}{|u_n|_{\kappa(x)}^{\kappa(x)}},$$

which implies

$$\int_{\mathbb{R}^N} \frac{|u_n(x)|^{(p_N^o(x)-1)p'(x)}}{|u_n|_{p_N^o(x)}^{(p_N^{o\,+}-1)p'(x)}} dx \le \int_{\mathbb{R}^N} \frac{|u_n(x)|^{\kappa(x)}}{|u_n|_{\kappa(x)}^{\kappa(x)}} dx = 1,$$

and the proof of (I) is complete.

$$\text{If } |u_n|_{\kappa(x)} < 1, \text{ then } ||u_n|^{p_N^o(x)-1}|_{\frac{\kappa(x)}{p_N^o(x)-1}} < 2. \tag{II}$$

Indeed, by $|u_n|_{\kappa(x)} < \int_{\mathbb{R}^N} |u_n|^{\kappa(x)} dx + 1$ and (2.7), we obtain

$$\begin{aligned} ||u_n|^{p_N^o(x)-1}|_{\frac{\kappa(x)}{p_N^o(x)-1}} &< \int_{\mathbb{R}^N} |u_n|^{(p_N^o(x)-1)\frac{\kappa(x)}{p_N^o(x)-1}} dx + 1 \\ &= \int_{\mathbb{R}^N} |u_n|^{\kappa(x)} dx + 1 < 1 + 1 = 2. \end{aligned}$$

Clearly, (3.6) is a consequence of (I) and (II).

Notice that the inclusion $E \hookrightarrow L^{\kappa(x)}(\mathbb{R}^N)$ is continuous, and hence there exists $C_1 > 0$ such that

$$|u_n|_{\kappa(x)} \le C_1 \|u_n\|_E \le CC_1. \tag{3.17}$$

By Proposition 2.6, the embedding $E \hookrightarrow L^{p_N^o(x)}(\mathbb{R}^N)$ is compact, and $u_n \rightharpoonup u$ in E implies $u_n \to u$ in $L^{p_N^o(x)}(\mathbb{R}^N)$. Hence using (3.15), (3.16) and (3.17), we have

$$\int_{\mathbb{R}^N} a(x)|u_n|_{p_N^o(x)-1}|u_n - u_0| dx \to 0 \quad \text{as } n \to +\infty. \tag{3.18}$$

Choose $\theta(x) = \frac{p_N^o(x)}{p_N^o(x)-1}$. Then $\theta \in C_+(\mathbb{R}^N), 1 < \theta(x) < \frac{N}{p_N^o(x)-1}$ for all $x \in \mathbb{R}^N$, and there exists $\lambda : \mathbb{R}^N \to (0,1)$ such that

$$\frac{1}{\theta(x)} = \frac{\lambda(x)}{1} + \frac{1-\lambda(x)}{\frac{N}{p_N^o(x)-1}} \quad \text{a.e. } x \in \mathbb{R}^N.$$

Then, for $x \in \mathbb{R}^N$, we have

$$s(x) = \frac{1}{\theta(x)\lambda(x)} > 1, \qquad t(x) = \frac{N}{\theta(x)(p(x)-1)(1-\lambda(x))} > 1.$$

Using $a \in L^1_+(\mathbb{R}^N) \cap L^{\frac{N}{p_N^o(x)-1}}(\mathbb{R}^N)$, we deduce

$$\begin{aligned} \int_{\mathbb{R}^N} |a|^{\theta(x)} dx &= \int_{\mathbb{R}^N} |a|^{\frac{1}{s(x)}} |a|^{\frac{\frac{N}{p_N^o(x)-1}}{t(x)}} dx \\ &\le 2\left[\left(\int_{\mathbb{R}^N} |a| dx\right)^{\frac{1}{s^+}} + \left(\int_{\mathbb{R}^N} |a| dx\right)^{\frac{1}{s^-}}\right] \\ &\quad \times \left[\left(\int_{\mathbb{R}^N} |a|^{\frac{N}{p(x)-1}} dx\right)^{\frac{1}{t^+}} + \left(\int_{\mathbb{R}^N} |a|^{\frac{N}{p(x)-1}} dx\right)^{\frac{1}{t^-}}\right]. \end{aligned} \tag{3.19}$$

This implies $a \in L^{\frac{p_N^o(x)}{p_N^o(x)-1}}(\mathbb{R}^N)$. Hence

$$\int_{\mathbb{R}^N} a(x)|u_n - u_0| dx \le 2|a|_{\frac{p(x)}{p(x)-1}} |u_n - u_0|_{p(x)} \to 0 \quad \text{as } n \to +\infty.$$

Combining (3.13), (3.14), (3.18) and (3.19), we get $\lim_{n\to+\infty}\langle A(u_n), u_n - u\rangle = 0$. By Proposition 2.2 (2), we get $u_n \to u_0$ in E. This proves that $\phi(u)$ satisfies the nonsmooth (PS) condition on E. □

Lemma 3.3. *Assume that all conditions of Theorem 1.1 are satisfied. Then there exist $\alpha > 0$ and $\nu > 0$ such that, for any $u \in E$ with $\|u\|_E = \nu$, we have $\phi(u) \geq \alpha$.*

Proof. Firstly, choose $q \in C_+(\mathbb{R}^N)$ (q is mentioned in (f_3)). Then

$$1 < \frac{\kappa(x)}{\kappa(x)-q(x)} = \frac{Np_N^o(x)}{Np_N^o(x) - q(x)(N-p_N^o(x))} < \frac{N}{p_N^o(x)-1}, \qquad x \in \mathbb{R}^N. \tag{3.20}$$

By Proposition 2.6, the embedding $E \hookrightarrow L^{\kappa(x)}(\mathbb{R}^N)$ is continuous, and there is constant $c_5 > 0$ such that

$$|u|_{\kappa(x)} \leq c_5\|u\|_E \quad \text{for all } u \in E. \tag{3.21}$$

Now choose $\gamma > 0$ such that $\gamma < \min\{1, \frac{1}{c_5}\}$. Then, for such a fixed γ, we have

$$|u|_{\kappa(x)} \leq 1 \quad \text{for all } u \in E \text{ with } \|u\|_E = \gamma. \tag{3.22}$$

Moreover, by virtue of hypothesis (f_2), we obtain

$$F(x,t) \leq \vartheta(x), \tag{3.23}$$

for any $x \in \mathbb{R}^N$ and $0 < |t| < \delta$.

On the other hand, for all $x \in \mathbb{R}^N$ and all $|t| \geq \delta$, (f_1) implies

$$|F(x,t)| \leq c_6|t|^{p(x)}, \tag{3.24}$$

where $c_6 = (1+\frac{1}{\tau})c$ and $\tau = \min\{|\delta|^{p_N^{o\,+}}, |\delta|^{p_N^{o\,-}}\}$.

From (3.23) and (3.24), for all $x \in \mathbb{R}^N$ and all $t \in \mathbb{R}$, we have $F(x,t) \leq \vartheta(x) + c_7|t|^{p(x)}$, where $c_7 = c_6 + \frac{|\vartheta|_\infty}{\tau}$.
Thus, for all $u \in E$ with $\|u\|_E = \gamma$, we have

$$\begin{aligned}
\phi(u) &= \sum_{i=1}^N \int_{\mathbb{R}^N} \frac{1}{p_i(x)}|\partial_{x_i}u|^{p_i(x)}dx + \int_{\mathbb{R}^N} \frac{1}{p_N^o(x)}V(x)|u|^{p_N^o(x)}dx - \int_{\mathbb{R}^N} a(x)F(x,u)dx \\
&\geq \frac{1}{p_N^{o\,+}}\|u\|_E^{p_N^{o\,+}} - c_7\int_{\mathbb{R}^N} a(x)|u|^{p_N^o(x)}dx - \int_{\mathbb{R}^N} a(x)\vartheta(x)dx \\
&\geq \frac{1}{p_N^{o\,+}}\|u\|_E^{p_N^{o\,+}} - c_7\int_{\mathbb{R}^N} a(x)|u|^{p_N^o(x)}dx + \int_{\mathbb{R}^N} a(x)\vartheta(x)dx.
\end{aligned} \tag{3.25}$$

Applying Young's inequality with ε, we get

$$\begin{aligned}
|u|^{p_N^o(x)} &= 1 \times |u|^{p_N^o(x)} \\
&\leq \varepsilon \times 1^{\frac{q(x)}{q(x)-p_N^o(x)}} + \varepsilon^{-\frac{q(x)-p_N^o(x)}{p_N^o(x)}} \left||u|^{p_N^o(x)}\right|^{\frac{q(x)}{p_N^o(x)}} \\
&= \varepsilon + \varepsilon^{-\frac{q(x)-p_N^o(x)}{p_N^o(x)}}|u|^{q(x)} \\
&\leq \varepsilon + \varepsilon^{-\frac{q^+-p_N^{o\,-}}{p_N^{o\,-}}}|u|^{q(x)}.
\end{aligned} \tag{3.26}$$

So, returning to (3.25) and using (3.26), for all $u \in E$ with $\|u\|_E = \gamma$, we obtain

$$\begin{aligned}\phi(u) \geq & \frac{1}{p_N^{o\,+}}\|u\|^{p_N^{o\,+}} - \varepsilon^{-\frac{q^+ - p_N^{o\,-}}{p_N^{o\,-}}} c_7 \int_{\mathbb{R}^N} a(x)|u(x)|^{q(x)}dx \\ & - c_7\varepsilon \int_{\mathbb{R}^N} a(x)dx - \int_{\mathbb{R}^N} a(x)\nu(x)dx.\end{aligned} \tag{3.27}$$

Since $\nu \in L^\infty(\mathbb{R}^N)$, there exists some $c_8 > 0$ such that $-\nu(x) > c_8$. We can choose and ε_0 small enough such that $c_8|a|_1 - \varepsilon_0 c_7 |a|_1 > 0$, and then (3.27) immediately implies

$$\phi(u) \geq \frac{1}{p_N^{o\,+}}\|u\|_E^{p_N^{o\,+}} - \varepsilon^{-\frac{q^+ - p_N^{o\,-}}{p_N^{o\,-}}} c_7 \int_{\mathbb{R}^N} a(x)|u(x)|^{q(x)}dx. \tag{3.28}$$

Similarly to the proof of (3.19), and combining inequality (3.20), we have $a(x) \in L^{\frac{\kappa(x)}{\kappa(x)-q(x)}}(\mathbb{R}^N)$. Using Proposition 2.3, (3.21) and (3.22), for all $u \in E$ with $\|u\|_E = \gamma$, we obtain

$$\begin{aligned}\int_{\mathbb{R}^N} a(x)|u|^{q(x)}dx \leq & |a|_{L^{\frac{\kappa(x)}{\kappa(x)-q(x)}}(\mathbb{R}^N)} \, ||u|^{q(x)}|_{L^{\frac{\kappa(x)}{q(x)}}(\mathbb{R}^N)} \\ \leq & |a|_{L^{\frac{\kappa(x)}{\kappa(x)-q(x)}}(\mathbb{R}^N)} \, |u|^{q^-}_{\kappa(x)} \\ \leq & |a|_{L^{\frac{\kappa(x)}{\kappa(x)-q(x)}}(\mathbb{R}^N)} \, c_5^{q^-} \|u\|_E^{q^-}.\end{aligned} \tag{3.29}$$

Using (3.29) in (3.28), we see that, for any $u \in E$ with $\|u\|_E = \gamma$, we have

$$\phi(u) \geq \frac{1}{p_N^{o\,+}}\|u\|_E^{p_N^{o\,+}} - \varepsilon_0^{-\frac{q^+ - p_N^{o\,-}}{p_N^{o\,-}}} c_5^{q^-} |a|_{L^{\frac{\kappa(x)}{\kappa(x)-q(x)}}(\mathbb{R}^N)} \|u\|_E^{q^-}.$$

which implies that there exist $\alpha > 0$ and $\nu > 0$ such that $\phi(u) \geq \alpha$ for any $u \in E$ with $\|u\|_E = \nu$. □

Lemma 3.4. *Assume that all conditions of Theorem 1.1 are satisfied. Then $\phi(u) \to -\infty$ as $\|u\|_E \to +\infty$ for all $u \in \mathcal{F}$, where $\mathcal{F}$ is an arbitrary finite-dimensional subspace of E.*

Proof. By virtue of hypothesis (f_3), we can find $M_4 > 0$ such that

$$F(x,t) \geq c_9|t|^{q(x)} \quad \text{for all } x \in \mathbb{R}^N,\ |t| \geq M_4. \tag{3.30}$$

In addition, from hypothesis (f_1), for almost all $x \in \mathbb{R}^N$ and $|t| < M_4$, we have

$$|F(x,t)| \geq c_3, \tag{3.31}$$

where $c_3 = (1 + M_4^{p_N^{o\,+}} + M_4^{p_N^{o\,-}})c$. Thus, using 3.30 and 3.31, we obtain

$$F(x,t) \geq c_9|t|^{q(x)} \quad \text{for all } x \in \mathbb{R}^N,\ t \in \mathbb{R}, \tag{3.32}$$

where $c_4 = c_3 + c_9 \max\{M_4^{p_N^{o\,+}}, M_4^{p_N^{o\,-}}\}$. Moreover, similar to (2.6) and (2.7), we get

$$\begin{aligned}|u|_{L^{q(x)}_{a(x)}(\mathbb{R}^N)} > 1 \Longrightarrow |u|^{q^-}_{L^{q(x)}_{a(x)}(\mathbb{R}^N)} \leq \int_{\mathbb{R}^N} a(x)|u|^{q(x)}dx \leq |u|^{q^+}_{L^{q(x)}_{a(x)}(\mathbb{R}^N)} \\ |u|_{L^{q(x)}_{a(x)}(\mathbb{R}^N)} < 1 \Longrightarrow |u|^{q^+}_{L^{q(x)}_{a(x)}(\mathbb{R}^N)} \leq \int_{\mathbb{R}^N} a(x)|u|^{q(x)}dx \leq |u|^{q^-}_{L^{q(x)}_{a(x)}(\mathbb{R}^N)}.\end{aligned} \tag{3.33}$$

Because W is a finite-dimensional subspace of E, all norms are equivalent, so we can find $0 < C = C(\mathcal{F}) < 1$ such that

$$C\|u\|_E \le |u|_{L^{q(x)}_{a(x)}(\mathbb{R}^N)} \le \frac{1}{C}\|u\|_E \quad \text{for all } u \in \mathcal{F}. \tag{3.34}$$

Taking into account (3.32), (3.33) and (3.34), for every $u \in \mathcal{F}$ with $\|u\|_E > 1$ and $|u|_{L^{q(x)}_{a(x)}(\mathbb{R}^N)} > 1$, we have

$$\begin{aligned}
\phi(u) &= \sum_{i=1}^{N} \int_{\mathbb{R}^N} \frac{1}{p_i(x)} |\partial_{x_i} u|^{p_i(x)} dx + \int_{\mathbb{R}^N} \frac{1}{p_N^o(x)} V(x)|u|^{p_N^o(x)} dx - \int_{\mathbb{R}^N} a(x)F(x,u)dx \\
&\le \frac{1}{p_N^{o\,-}} \|u\|^{p_N^{o\,+}} - c_9 \int_{\mathbb{R}^N} a(x)|u|^{q(x)} dx + c_4 \int_{\mathbb{R}^N} a(x)dx \\
&\le \begin{cases} \frac{1}{p_N^{o\,-}} \|u\|^{p_N^{o\,+}} + c_4|a|_1 - c_9 C^{q^-} \|u\|_E^{q^-} & \text{if } |u|_{L^{q(x)}_{a(x)}(\mathbb{R}^N)} > 1, \\ \frac{1}{p_N^{o\,-}} \|u\|^{p_N^{o\,+}} + c_4|a|_1 - c_9 C^{q^+} \|u\|_E^{q^+} & \text{if } |u|_{L^{q(x)}_{a(x)}(\mathbb{R}^N)} < 1, \end{cases}
\end{aligned} \tag{3.35}$$

Because of $q^+ \ge q^- > p_N^{o\,+}$, we see that $\phi(u) \to -\infty$ as $\|u\|_E \to +\infty$. □

Here is the proof of Theorem 1.1.

Proof. It is obvious that ϕ is even and $\phi(0) = 0$. Besides, Lemmas 3.2, 3.3 and 3.4 permit the application of Lemma 2.8 with $X = E, X_1 = \mathcal{F}$ (see Lemma 3.4) and $X_2 = E \oplus \mathcal{F}$ (see Lemma 3.3). Therefore, we obtain that the functional ϕ has an unbounded sequence of critical values, so problem (1.1) possesses infinitely many nontrivial solutions. □

Communicated by Gabriele Bonanno

Abstract. In the present paper, we study the nonexistence of nontrivial weak solutions to a class of fractional p-Laplacian equation in two cases which are $sp > N$ and $sp < N$. In each of these cases, by using fractional Laplacian theory and inequality techniques, we obtain concrete range of parameter for which nontrivial weak solution of the problem does not exist. Our work complements the known nonexistence results in this direction.

Keywords: fractional p-Laplacian equation, nonexistence, weak solution.

2020 Mathematics Subject Classification: 35A01, 35J60, 35R11, 46E35.

1 Introduction

In this paper, we investigate the following fractional p-Laplacian equation of the type

$$\begin{cases} (-\Delta)_p^s u + \lambda V(x)|u|^{q-2}u = m(x)|u|^{r-2}u, & \text{in } \Omega, \\ u = 0, \quad \text{in } \mathbb{R}^N \setminus \Omega, \end{cases} \tag{1.1}$$

where $\Omega \subset \mathbb{R}^N$ is a bounded domain with smooth boundary, $s \in (0,1)$, p, q, r are positive numbers satisfying $1 < p < r < q < \infty$ or $1 < q < r < p < \infty$, $m, V \in L^1(\Omega)$ are positive functions and λ is a positive parameter.

The fractional p-Laplacian operator is defined as

$$(-\Delta)_p^s u(x) = 2 \lim_{\epsilon \searrow 0} \int_{\mathbb{R}^N \setminus B_\epsilon(x)} \frac{|u(x) - u(y)|^{p-2}(u(x) - u(y))}{|x - y|^{N+sp}} \, dy, \quad x \in \mathbb{R}^N,$$

where $B_\epsilon(x) = \{y \in \mathbb{R}^N : |x - y| < \epsilon\}$.

In recent years, many papers have been devoted to the study of the fractional p-Laplacian equations due to their interesting applications, such as game theory, image processing, optimization and so on (see [3–5]). In particular, the existence, nonexistence, multiplicity and

✉Corresponding author. Email: tomlhd983@163.com

some other properties of solutions to the following type of fractional p-Laplacian equation where $sp < N$

$$\begin{cases}(-\Delta)_p^s u + V(x)|u|^{p-2}u = f(x,u), & \text{in } \Omega,\\ u = 0, & \text{in } \mathbb{R}^N \setminus \Omega,\end{cases} \tag{1.2}$$

have been widely studied by many scholars (see [1,2,6,8,9,12–16] and the references therein). For instance, Goyal and Sreenadh [6] obtained some results on the existence and nonexistence of solutions for the following equation with respect to the parameter λ

$$\begin{cases}(-\Delta)_p^s u - \lambda V(x)|u|^{p-2}u = m(x)|u|^{r-2}u, & \text{in } \Omega,\\ u = 0, & \text{in } \mathbb{R}^N \setminus \Omega,\end{cases} \tag{1.3}$$

where $sp < N$ and $1 < r < p$ or $p < r < p_s^* = \frac{Np}{N-sp}$.

Wu and Chen [15] studied the following equation

$$(-\Delta)_p^s u + V(x)|u|^{p-2}u = |u|^{r-2}u + \lambda |u|^{q-2}u, \quad \text{in } \mathbb{R}^N, \tag{1.4}$$

for the case $sp < N$ and $1 < q < p < r$. They deduced some existence results of nontrivial solution for some range of λ.

However, as far as we know, in the case $sp > N$, there have been rarely any existence or nonexistence results for problem (1.2). Inspired by the above mentioned papers, our purpose is to establish some results on the nonexistence of nontrivial weak solution for the problem (1.1) in both cases $sp > N$ and $sp < N$ under the assumptions $1 < p < r < q < \infty$ or $1 < q < r < p < \infty$. More precisely, we aim to obtain concrete range of parameter for which nontrivial weak solution of the problem does not exist in the case $sp > N$ and the case $sp < N$, respectively.

The rest of our paper is organized as follows. In Section 2, we will introduce some necessary lemmas and properties, which will be used in the sequel. In Section 3, we derive somewhat sharp nonexistence conditions of nontrivial solutions for (1.1) in both cases: $sp > N$ and $sp < N$.

2 Preliminaries

To state our results, we introduce some notations. Let $s \in (0,1)$ and $1 < p < \infty$ be real numbers. The fractional Sobolev space $W^{s,p}(\mathbb{R}^N)$ is defined as follows:

$$W^{s,p}(\mathbb{R}^N) := \{u \in L^p(\mathbb{R}^N) : \ [u]_{s,p} < \infty\}$$

equipped with the norm

$$\|u\|_{s,p} := \left(\|u\|^p_{L^p(\mathbb{R}^N)} + [u]^p_{s,p}\right)^{1/p},$$

where

$$[u]_{s,p} = \left(\int_{\mathbb{R}^{2N}} \frac{|u(x)-u(y)|^p}{|x-y|^{N+ps}} dxdy\right)^{1/p}$$

is the Gagliardo seminorm of a measurable function $u : \mathbb{R}^N \to \mathbb{R}$.

Let Ω be a bounded domain in $\mathbb{R}^N$ with smooth boundary $\partial\Omega$. We shall work on the space

$$W_0^{s,p}(\Omega) := \left\{u \in W^{s,p}(\mathbb{R}^N) : u = 0 \text{ a.e. in } \mathbb{R}^N \setminus \Omega\right\},$$

which can be equivalently renormed by $[u]_{s,p}$.

Lemma 2.1 ([10])**.** *Let $\Omega \subset \mathbb{R}^N$ be bounded and open, $sp > N$ and $s \in (0,1)$. Then there is a constant $C_M > 0$ such that for all $u \in W_0^{s,p}(\Omega)$,*

$$|u(x) - u(y)| \leq C_M |x-y|^{\beta} [u]_{s,p}, \qquad x, y \in \mathbb{R}^N,$$

where $\beta = \frac{sp-N}{p}$.

Lemma 2.2 ([4])**.** *Let $\Omega \subset \mathbb{R}^N$ be bounded and open, $s \in (0,1)$, $1 < p < \infty$ with $sp < N$. Then, there exists a constant $C_H > 0$ such that*

$$\|u\|^p_{L^{p_s^*}(\mathbb{R}^N)} \leq C_H [u]^p_{s,p}, \qquad u \in W_0^{s,p}(\Omega),$$

where $p_s^* = \frac{Np}{N-sp}$.

Lemma 2.3 ([4])**.** *Let $\Omega \subset \mathbb{R}^N$ be an extension domain for $W^{s,p}$ with no external cusps and let $p \in [1, +\infty)$, $s \in (0,1)$ be such that $sp > N$. Then, there exists $C > 0$, depending on N, s, p and Ω, such that*

$$\|u\|_{C^{0,\alpha}(\Omega)} \leq C \Big(\|u\|^p_{L^p(\Omega)} + \int_\Omega \int_\Omega \frac{|u(x)-u(y)|^p}{|x-y|^{N+ps}} dxdy \Big)^{\frac{1}{p}},$$

for any $u \in L^p(\Omega)$, with $\alpha = (sp - N)/p$.

Lemma 2.4 ([7])**.** *Let $s \in (0,1)$ and $1 < p < \infty$ be such that $sp < N$. Assume that $\Omega \subset \mathbb{R}^N$ is a (bounded) uniform domain with a (locally) (s,p)-uniformly fat boundary. Then Ω admits an (s,p)-Hardy inequality, that is, there is a constant $C_K > 0$ such that*

$$\int_\Omega \frac{|u(x)|^p}{d(x, \partial\Omega)^{sp}} dx \leq C_K [u]^p_{s,p}, \qquad u \in W_0^{s,p}(\Omega),$$

where $d(x, \partial\Omega) = \inf\{|x-y| : y \in \partial\Omega\}$.

Lemma 2.5 ([11])**.** *Let $M > 0, L > 0, p > 0$, $q > 0$ and $r > 0$ be given. If*

(i) $1 < p < r < q$;

or

(ii) $1 < q < r < p$,

then for each $x \geq 0$,

$$Mx^r - Lx^q \leq \frac{M(q-r)}{q-p} \left(\frac{(r-p)M}{(q-p)L} \right)^{\frac{r-p}{q-r}} x^p$$

holds.

Definition 2.6. We say that $u \in W_0^{s,p}(\Omega)$ is a weak solution of (1.1) if

$$\int_{\mathbb{R}^{2N}} \frac{|u(x)-u(y)|^{p-2}(u(x)-u(y))(v(x)-v(y))}{|x-y|^{N+ps}} dxdy + \lambda \int_\Omega V(x)|u(x)|^{q-2}u(x)v(x)dx = \int_\Omega m(x)|u(x)|^{r-2}u(x)v(x)dx, \quad (2.1)$$

for all $v \in W_0^{s,p}(\Omega)$.

3 Main results

In this section, we suppose that $\Omega \subset \mathbb{R}^N$ is a bounded domain satisfying the regularities required by the fractional Sobolev inequalities given by Lemmas 2.1–2.4.

3.1 The case $sp > N$

Theorem 3.1. *Suppose that $sp > N$ and $m\left(\frac{m}{V}\right)^{\frac{r-p}{q-r}} \in L^1(\Omega)$. If*

$$\lambda > \frac{r-p}{q-p}\left(C_M^p R_\Omega^{sp-N}\frac{q-r}{q-p}\right)^{\frac{q-r}{r-p}}\left[\int_\Omega m(x)\left(\frac{m(x)}{V(x)}\right)^{\frac{r-p}{q-r}}dx\right]^{\frac{q-r}{r-p}}, \tag{3.1}$$

then problem (1.1) has no nontrivial weak solution $u \in W_0^{s,p}(\Omega)$, where C_M is given in Lemma 2.1 and $R_\Omega = \max\{d(x,\partial\Omega) : x \in \Omega\}$.

Proof. Suppose on the contrary that problem (1.1) has a nontrivial weak solution $u \in W_0^{s,p}(\Omega)$. Taking $v = u$ in (2.1) and from Lemma 2.5, we have

$$\begin{aligned}
&\int_{\mathbb{R}^{2N}}\frac{|u(x)-u(y)|^p}{|x-y|^{N+ps}}dxdy \\
&\quad= \int_\Omega\left[m(x)|u(x)|^{r-2}u(x) - \lambda V(x)|u(x)|^{q-2}u(x)\right]u(x)dx \\
&\quad\le \int_\Omega\left[m(x)|u(x)|^r - \lambda V(x)|u(x)|^q\right]dx \\
&\quad\le \int_\Omega \frac{q-r}{q-p}\left(\frac{r-p}{q-p}\right)^{\frac{r-p}{q-r}} m(x)\left(\frac{m(x)}{\lambda V(x)}\right)^{\frac{r-p}{q-r}}|u(x)|^p dx,
\end{aligned}$$

i.e.,

$$[u]_{s,p}^p \le \int_\Omega \frac{q-r}{q-p}\left(\frac{r-p}{q-p}\right)^{\frac{r-p}{q-r}} m(x)\left(\frac{m(x)}{\lambda V(x)}\right)^{\frac{r-p}{q-r}}|u(x)|^p dx. \tag{3.2}$$

By $sp > N$ and Lemma 2.3, we get u is continuous in $\mathbb{R}^N$, in particular in $\overline{\Omega}$. Then there is some $\xi \in \Omega$ such that

$$|u(\xi)| = \max\left\{|u(x)| : x \in \mathbb{R}^N\right\} > 0.$$

From Lemma 2.1, there is a constant C_M such that

$$|u(x)-u(y)| \le C_M|x-y|^{\frac{sp-N}{p}}[u]_{s,p}, \qquad x,y \in \mathbb{R}^N.$$

Taking $x = \xi$ in the above inequality, we obtain

$$|u(\xi)| \le C_M|\xi-y|^{\frac{sp-N}{p}}[u]_{s,p}, \qquad y \in \partial\Omega,$$

i.e.,

$$|u(\xi)| \le C_M R_\Omega^{\frac{sp-N}{p}}[u]_{s,p}. \tag{3.3}$$

Combining (3.2) with (3.3), we obtain

$$\begin{aligned}
|u(\xi)| &\le C_M R_\Omega^{\frac{sp-N}{p}}\left(\int_\Omega \frac{q-r}{q-p}\left(\frac{r-p}{q-p}\right)^{\frac{r-p}{q-r}} m(x)\left(\frac{m(x)}{\lambda V(x)}\right)^{\frac{r-p}{q-r}}|u(x)|^p dx\right)^{\frac{1}{p}} \\
&\le C_M R_\Omega^{\frac{sp-N}{p}}\left(\int_\Omega \frac{q-r}{q-p}\left(\frac{r-p}{q-p}\right)^{\frac{r-p}{q-r}} m(x)\left(\frac{m(x)}{\lambda V(x)}\right)^{\frac{r-p}{q-r}}dx\right)^{\frac{1}{p}}|u(\xi)|,
\end{aligned}$$

which yields

$$1 \leq C_M R_\Omega^{\frac{sp-N}{p}} \left(\int_\Omega \frac{q-r}{q-p} \left(\frac{r-p}{q-p} \right)^{\frac{r-p}{q-r}} m(x) \left(\frac{m(x)}{\lambda V(x)} \right)^{\frac{r-p}{q-r}} dx \right)^{\frac{1}{p}}.$$

Thus

$$\lambda^{\frac{p-r}{q-r}} \frac{q-r}{q-p} \left(\frac{r-p}{q-p} \right)^{\frac{r-p}{q-r}} \int_\Omega m(x) \left(\frac{m(x)}{V(x)} \right)^{\frac{r-p}{q-r}} dx \geq \frac{1}{C_M^p R_\Omega^{sp-N}},$$

which implies that

$$\lambda^{\frac{p-r}{q-r}} \geq \frac{1}{C_M^p R_\Omega^{sp-N} \frac{q-r}{q-p} \left(\frac{r-p}{q-p} \right)^{\frac{r-p}{q-r}} \int_\Omega m(x) \left(\frac{m(x)}{V(x)} \right)^{\frac{r-p}{q-r}} dx}.$$

Hence, from $\frac{p-r}{q-r} < 0$ we obtain

$$\lambda \leq \frac{r-p}{q-p} \Big(C_M^p R_\Omega^{sp-N} \frac{q-r}{q-p} \Big)^{\frac{q-r}{r-p}} \Big[\int_\Omega m(x) \Big(\frac{m(x)}{V(x)} \Big)^{\frac{r-p}{q-r}} dx \Big]^{\frac{q-r}{r-p}}, \tag{3.4}$$

which contradicts to (3.1). This completes the proof. □

3.2 The case $sp < N$

Theorem 3.2. *Suppose that* $sp < N$, $m\left(\frac{m}{V}\right)^{\frac{r-p}{q-r}} \in L^\mu(\Omega)$ *and* $\frac{N}{sp} < \mu < \infty$. *Assume that*

$$\lambda > \frac{r-p}{q-p} \left(C_K^{1-\frac{N}{\mu sp}} C_H^{\frac{N}{\mu sp}} R_\Omega^{sp-\frac{N}{\mu}} \frac{q-r}{q-p} \right)^{\frac{q-r}{r-p}} \left[\int_\Omega m(x) \left(\frac{m(x)}{V(x)} \right)^{\frac{r-p}{q-r}} dx \right]^{\frac{q-r}{r-p}}, \tag{3.5}$$

then problem (1.1) *has no nontrivial weak solution* $u \in W_0^{s,p}(\Omega)$, *where* C_H *and* C_K *are given in Lemmas* 2.2 *and* 2.4, *and* $R_\Omega = \max\{d(x, \partial\Omega) : x \in \Omega\}$.

Proof. Suppose on the contrary that problem (1.1) has a nontrivial weak solution $u \in W_0^{s,p}(\Omega)$. From the proof of Theorem 3.1, we have (3.2) holds. Let $\eta = \frac{1}{\mu-1}(\mu - \frac{N}{sp})$, $\theta = \eta p + (1-\eta)p_s^*$ where $p_s^* = \frac{Np}{N-sp}$. By a straightforward computation, we have $0 < \eta < 1$, $\theta = p\nu$, where $\frac{1}{\mu} + \frac{1}{\nu} = 1$. On the other hand, we get

$$\frac{1}{R_\Omega^{\eta sp}} \int_\Omega |u(x)|^\theta dx \leq \int_\Omega \frac{|u(x)|^\theta}{d(x, \partial\Omega)^{\eta sp}} dx, \tag{3.6}$$

and by Hölder's inequality, Lemma 2.2, Lemma 2.4 and (3.2), we obtain

$$
\begin{aligned}
&\int_\Omega \frac{|u(x)|^\theta}{d(x,\partial\Omega)^{\eta sp}}dx \\
&= \int_\Omega \frac{|u(x)|^{\eta p}|u(x)|^{(1-\eta)p_s^*}}{d(x,\partial\Omega)^{\eta sp}}dx \\
&\leq \left[\int_\Omega \frac{|u(x)|^p}{d(x,\partial\Omega)^{sp}}dx\right]^\eta \left[\int_\Omega |u(x)|^{p_s^*}dx\right]^{1-\eta} \\
&\leq C_K^\eta [u]_{s,p}^{p\eta} C_H^{\frac{(1-\eta)p_s^*}{p}} [u]_{s,p}^{(1-\eta)p_s^*} \\
&= C[u]_{s,p}^{p\eta+(1-\eta)p_s^*} \\
&= C[u]_{s,p}^{p\frac{p\eta+(1-\eta)p_s^*}{p}} \\
&= C[u]_{s,p}^{p\frac{\theta}{p}} \\
&\leq C\left(\int_\Omega \frac{q-r}{q-p}\left(\frac{r-p}{q-p}\right)^{\frac{r-p}{q-r}} m(x)\left(\frac{m(x)}{\lambda V(x)}\right)^{\frac{r-p}{q-r}} |u(x)|^p dx\right)^{\frac{\theta}{p}} \\
&= C\left(\int_\Omega \frac{q-r}{q-p}\left(\frac{r-p}{q-p}\right)^{\frac{r-p}{q-r}} m(x)\left(\frac{m(x)}{\lambda V(x)}\right)^{\frac{r-p}{q-r}} |u(x)|^p dx\right)^{\nu} \\
&\leq C\left(\int_\Omega \left[\frac{q-r}{q-p}\left(\frac{r-p}{q-p}\right)^{\frac{r-p}{q-r}} m(x)\left(\frac{m(x)}{\lambda V(x)}\right)^{\frac{r-p}{q-r}}\right]^\mu dx\right)^{\frac{\nu}{\mu}} \int_\Omega |u(x)|^\theta dx, \qquad (3.7)
\end{aligned}
$$

where $C = C_K^\eta C_H^{\frac{(1-\eta)p_s^*}{p}}$. Thus, by (11) and (12), we have

$$
\frac{1}{R_\Omega^{\eta sp}} \leq C\left(\int_\Omega \left[\frac{q-r}{q-p}\left(\frac{r-p}{q-p}\right)^{\frac{r-p}{q-r}} m(x)\left(\frac{m(x)}{\lambda V(x)}\right)^{\frac{r-p}{q-r}}\right]^\mu dx\right)^{\frac{\nu}{\mu}}.
$$

Accordingly,

$$
\int_\Omega \left[\frac{q-r}{q-p}\left(\frac{r-p}{q-p}\right)^{\frac{r-p}{q-r}} m(x)\left(\frac{m(x)}{\lambda V(x)}\right)^{\frac{r-p}{q-r}}\right]^\mu dx \geq \frac{1}{C^{\frac{\mu}{\nu}} R_\Omega^{\mu sp-N}}. \qquad (3.8)
$$

Therefore,

$$
\lambda^{\mu\frac{p-r}{q-r}} \left[\frac{q-r}{q-p}\left(\frac{r-p}{q-p}\right)^{\frac{r-p}{q-r}}\right]^\mu \left[\int_\Omega m(x)\left(\frac{m(x)}{V(x)}\right)^{\frac{r-p}{q-r}}\right]^\mu \geq \frac{1}{C^{\frac{\mu}{\nu}} R_\Omega^{\mu sp-N}}. \qquad (3.9)
$$

Hence, from $\frac{p-r}{q-r} < 0$ we obtain

$$
\lambda \leq \frac{r-p}{q-p}\left(C^{\frac{1}{\nu}} R_\Omega^{sp-\frac{N}{\mu}} \frac{q-r}{q-p}\right)^{\frac{q-r}{r-p}} \left[\int_\Omega m(x)\left(\frac{m(x)}{V(x)}\right)^{\frac{r-p}{q-r}} dx\right]^{\frac{q-r}{r-p}}. \qquad (3.10)
$$

Combining the definition of C and the inequality (3.10), we have

$$
\lambda \leq \frac{r-p}{q-p}\left(C_K^{1-\frac{N}{\mu sp}} C_H^{\frac{N}{\mu sp}} R_\Omega^{sp-\frac{N}{\mu}} \frac{q-r}{q-p}\right)^{\frac{q-r}{r-p}} \left[\int_\Omega m(x)\left(\frac{m(x)}{V(x)}\right)^{\frac{r-p}{q-r}} dx\right]^{\frac{q-r}{r-p}},
$$

which contradicts to (3.5). This completes the proof. □

Abstract. We study the existence of solutions for a class of boundary value problems on the half line, associated to a third order ordinary differential equation of the type

$$\left(\Phi(k(t,u'(t))u''(t))\right)'(t) = f\left(t,u(t),u'(t),u''(t)\right), \quad \text{a.a. } t \in \mathbb{R}_0^+.$$

The prototype for the operator Φ is the Φ-*Laplacian*; the function k is assumed to be continuous and it may vanish in a subset of zero Lebesgue measure, so that the problem can be *singular*; finally, f is a Carathéodory function satisfying a weak growth condition of *Winter–Nagumo* type. The approach we follow is based on fixed point techniques combined with the upper and lower solutions method.

Keywords: boundary value problems on unbounded domains, heteroclinic solutions, Φ-Laplacian operator, singular equations, Wintner–Nagumo condition, third order ODEs.

2020 Mathematics Subject Classification: Primary: 34B15, 34B40. Secondary: 34B60, 34C37.

1 Introduction

In this paper we are concerned with the existence of solutions to boundary value problems (BVPs) on the half line, associated to strongly nonlinear third order ordinary differential equations, of the type

$$\begin{cases} \left(\Phi\left(k(\cdot,u'(\cdot))u''(\cdot)\right)\right)'(t) = f\left(t,u(t),u'(t),u''(t)\right), & \text{a.a. } t \in \mathbb{R}_0^+, \\ u(0) = u_0, \;\; u'(0) = \nu_1, \;\; u'(+\infty) = \nu_2. \end{cases} \tag{$\mathcal{P}$}$$

Here, the operator $\Phi : \mathbb{R} \to \mathbb{R}$ is the so-called Φ-*Laplacian* and $f : \mathbb{R}_0^+ \times \mathbb{R}^3 \to \mathbb{R}$ is a Carathéodory function satisfying a weak growth condition of *Winter–Nagumo* type. Moreover, the function $k : \mathbb{R}_0^+ \times \mathbb{R} \to \mathbb{R}_0^+$ is continuous and it may vanish in a subset of zero Lebesgue measure, so that problem ($\mathcal{P}$) is possibly *singular*. Finally, $u_0, \nu_1, \nu_2 \in \mathbb{R}$ are fixed real numbers.

✉Corresponding author. Email: f.anceschi@staff.univpm.it

According to the existing literature, Φ-Laplacian type equations involve a strictly increasing homeomorphism

$$\Phi : (-a, a) \to (-b, b), \quad \text{with } 0 < a, b \le +\infty,$$

such that $\Phi(0) = 0$. When $a = b = +\infty$ the main prototype for the Φ-Laplacian is the classical *r-Laplacian* $\Phi(s) = |s|^{r-2}s$, with $r > 1$. When $a = +\infty$ and $b < +\infty$, the map Φ is usually called *non-surjective* or *bounded* Φ-Laplacian and its main prototype is the mean curvature operator

$$\Phi(s) = \frac{s}{\sqrt{1+s^2}}, \quad s \in \mathbb{R},$$

cf. [4, 21]. When $a < +\infty$, the Φ-Laplacian is said to be *singular* and in this case the main prototype is the relativistic operator

$$\Phi(s) = \frac{s}{\sqrt{1-s^2}}, \quad s \in (-1, 1),$$

see [5–7, 15, 28]. Further details on *Φ-Laplacians* BVPs can be found also in [18, 22].

One of the main reasons to study problem ($\mathcal{P}$) is the great amount of applications of the Φ-Laplace operator in different fields of physics and applied mathematics, such as non-Newtonian fluid theory, diffusion of flows in porous media, nonlinear elasticity, theory of capillary surfaces, see e.g. [20, 25], and, more recently, the modeling of glaciology, see for instance [12, 23, 29]. Moreover, problems like ($\mathcal{P}$) find many applications in fluid dynamics as generalizations of the Blasius problem modeling the flat plate problem in boundary layer theory for viscous fluids, cf. [16].

Due to the wide class of their applications, as well as for a more theoretical interest, several papers have been devoted to Φ-Laplacian type equations. Many contributions concern BVPs associated to a second order counterpart of ($\mathcal{P}$) involving equations of the type

$$\left(\Phi(k(\cdot, u(\cdot))u'(\cdot))\right)'(t) = f\left(t, u(t), u'(t)\right), \tag{1.1}$$

both in bounded and unbounded domains, under various assumptions for Φ and f, alongside with different types of boundary conditions, see [8,14,27]. We also mention [30] for third-order BVPs and [26] for higher-order BVPs in the half-line.

Recently, the multiplicity of solutions to differential equations with Φ-Laplacian has been largely investigated under periodic, Dirichlet or Neumann boundary conditions. In [17, 19] second order differential equations posed in bounded domains are considered by means of the fixed point index theory, while in [3] the authors find positive unbounded solutions for singular second-order BVPs set on the half-line.

We prove the solvability of ($\mathcal{P}$) assuming that f may have *critical* rate of decay -1 at infinity, that is $f(t, \cdot, \cdot, \cdot) \sim 1/t$ as $t \to +\infty$, cf. assumption (H_3) and Remark 3.7. Together with this assumption, we require a suitable form of the so-called *Nagumo–Wintner* condition on f, cf. (3.2) in assumption (H_2). The *Nagumo–Wintner* condition allows us to obtain a priori estimates on the derivatives of any solution u to ($\mathcal{P}$) on compact intervals of $\mathbb{R}$, see Lemma 3.11. We stress the fact that the version of the *Nagumo–Wintner* condition most frequently used in the literature for second order BVPs (see e.g. [10, 15]) is not useful in our case since it would not provide the desired estimates on the *higher* order derivative of the solution. Hence, a suitable adaptation of this condition turns out to be necessary in this context.

Our main result is Theorem 3.9 in which we prove the existence of a weak solution for problem ($\mathcal{P}$), in a sense that will be specified later. The proof is based on a fixed point technique, combined with the method of lower and upper solutions, named, respectively α and β; see assumption (H_1). More precisely, we start by proving the existence of a solution u_n to the auxiliary boundary value problem

$$\begin{cases} (\Phi(k(\cdot,u'(\cdot))u''(\cdot)))'(t) = f(t,u(t),u'(t),u''(t)), & \text{a.a. } t \in I_n, \\ u(0) = u_0,\ u'(0) = \alpha'(0),\ u'(n) = \beta'(n), \end{cases} \tag{$\mathcal{P}_n$}$$

where $I_n = [0,n]$, with $n \in \mathbb{N}$ sufficiently large. Then, by means of the a priori estimates provided by the *Nagumo–Wintner* condition, we show that a suitable sequence $(x_n)_n$, constructed by extending the functions u_n to the entire half-line, somehow converges to a solution of $(\mathcal{P})$.

Despite assumptions (H_1)–(H_3) seem rather technical, they are fulfilled by a wide class of functions, as we shall prove in Section 4. In particular, they hold for BVPs of the following type

$$\begin{cases} \left(\Phi\left(k(\cdot,u'(\cdot))u''(\cdot)\right)\right)'(t) = f_1\left(t,u(t),u'(t)\right) f_2(u''(t)), & \text{a.a. } t \in \mathbb{R}_0^+, \\ u(0) = u_0,\ \ u'(0) = \nu_1,\ \ u'(+\infty) = \nu_2, \end{cases}$$

where f_1 and f_2 satisfies suitable growth conditions and *either*

$$k(t,y) = k_1(t)k_2(y), \qquad \text{with } k_1 \geq 0,\ k_2 > 0 \text{ in } [\nu_1,\nu_2], \quad \textit{or}$$
$$k(t,y) = k_1(t) + k_2(y), \qquad \text{with } k_1,k_2 \geq 0.$$

The *critical* rate for f, as well as the possibility of dealing with *singular* equations, have been yet considered in [11], where the authors prove the existence of heteroclinic solutions for BVPs associated to (1.1). A similar framework, with $k = k(t)$, can be found in the recent work [2], where BVPs associated to third order differential equations are studied in a compact domain, and in [1], where the author proves existence results for integro-differential BVPs in a non-critical regime and in the half-line. In this context, Theorem 3.9 throws a further light on the subject treating third order equations and it extends Theorem 3.3 of [2] since the function k is more general and solutions are obtained in the half-line. In particular, in [2] only solutions on compact domains are considered and the function k only depends on t. Concerning unbounded domains, a first contribution for the existence is contained in [1], where the sub-critical regime for the asymptotic behavior of the right-hand side f is investigated together with some non-existence results. The present work aims at providing a careful study of the critical regime for the asymptotic behavior of f at the same time generalizing the choice of the function k, which can also depend on the function v and not only on t.

By performing the change of variable $v(t) = u'(t)$, our results apply to integro-differential BVPs of the type

$$\begin{cases} \left(\Phi(k(\cdot,v(\cdot))v'(\cdot))\right)'(t) = f\left(t, \int_0^t v(s)\,ds, v(t), v'(t)\right), & \text{a.a. } t \in \mathbb{R}_0^+, \\ v(0) = \nu_1,\ \ v(+\infty) = \nu_2. \end{cases}$$

Hence, when $\nu_1 \neq \nu_2$, our analysis leads to the existence of heteroclinic solutions for such BVPs. These solutions are relevant in the study of biological, physical and chemical models since they represent a phase transition process in which the system evolves from an unstable equilibrium to a stable one; see [24,27,31] and the references therein.

Finally, we highlight that a straightforward adaptation of Theorem 3.9 to problem $(\mathcal{P})$ with $k = k(t,u(t),u'(t))$ directly follows in $\mathbb{R}_0^+$ considering an additional monotonicity assumption on the second variable for $k = k(t,x,y)$ and it will be object of a forthcoming paper.

The paper is organized as follows. In Section 2 we present some preliminary facts; in particular, Theorem 2.2 is a very general result on the solvability of Φ-Laplacian BVPs in compact intervals. Section 3 is devoted to our main result Theorem 3.9. Finally, in Section 4 we present a class of examples of functions Φ, k and f satisfying the assumptions used throughout the paper.

2 Preliminary results

In this section, we present an existence result for very general BVPs in compact real intervals, that is Theorem 2.2. The proof of Theorem 2.2 is based on the forthcoming lemma. Even if the proof of Lemma 2.1 somehow follows the proof of analogous results, cf. [2, Lemma 2.1] and [10, Lemma 2.6], for the sake of clarity we prefer to show it completely.

Lemma 2.1. *Let $T > 0$ be a fixed real number and denote by $I = [0, T] \subseteq \mathbb{R}$ and let $p > 1$ be fixed. Let $F : W^{2,p}(I) \to L^1(I)$, $v \mapsto F_v \in L^1(I)$, be a continuous operator for which there exists $\Theta \in L^1(I)$ such that*

$$|F_v(t)| \leq \Theta(t) \quad \text{for all } v \in W^{2,p}(I) \text{ and a.a. } t \in I. \tag{2.1}$$

Let $K : W^{2,p}(I) \subseteq C(I; \mathbb{R}) \to C(I; \mathbb{R})$, $v \mapsto K_v \in C(I; \mathbb{R})$, be continuous with respect to the uniform topology of $C(I; \mathbb{R})$ and suppose that there exist $k_1, k_2 \in C(I; \mathbb{R})$ satisfying

$$k_1, k_2 > 0 \quad \text{a.e. in } I \quad \text{and} \quad \frac{1}{k_1}, \frac{1}{k_2} \in L^p(I), \tag{2.2}$$

such that

$$k_1(t) \leq K_v(t) \leq k_2(t) \quad \text{for all } v \in W^{2,p}(I) \text{ and a.a. } t \in I. \tag{2.3}$$

Finally, let $\Psi : \mathbb{R} \to \mathbb{R}$ be a strictly increasing homeomorphism. Then for all $v \in W^{2,p}(I)$ and for all $\delta_1, \delta_2 \in \mathbb{R}$ there exists a unique $\xi_v \in \mathbb{R}$ such that

$$\int_a^b \frac{1}{K_v(t)} \Psi^{-1} (\xi_v + \mathscr{F}_v(t))\, dt = \delta_2 - \delta_1, \tag{2.4}$$

where

$$\mathscr{F} : W^{2,p}(I) \to C(I; \mathbb{R}), \quad v \mapsto \mathscr{F}_v(t) = \int_a^t F_v(s) ds, \quad t \in I.$$

Furthermore, there exists $c_0 > 0$, independent on v, such that:

$$|\xi_v| \leq c_0 \quad \text{for all } v \in W^{2,p}(I). \tag{2.5}$$

Proof. First, we observe that the operator $\mathscr{F}$ is well defined being $\mathscr{F}_v$ continuous in I for all $v \in W^{2,p}(I)$ by (2.1). Moreover, $\mathscr{F}$ is continuous from $W^{2,p}(I)$ in $C(I, \mathbb{R})$. Indeed, F is continuous from $W^{2,p}(I)$ in $L^1(I)$ by assumption and

$$\sup_{t \in I} |\mathscr{F}_u(t) - \mathscr{F}_v(t)| \leq \|F_u - F_v\|_{L^1(I)} \quad \text{for all } u, v \in W^{2,p}(I). \tag{2.6}$$

Furthermore

$$\sup_{t \in I} |\mathscr{F}_v(t)| \leq \|\Theta\|_{L^1(I)} \quad \text{for all } v \in W^{2,p}(I). \tag{2.7}$$

Now, we fix $v \in W^{2,p}(I)$ and define

$$\mathfrak{F}_v : \mathbb{R} \to \mathbb{R}, \quad \xi \mapsto \mathfrak{F}_v(\xi) = \int_a^b \frac{1}{K_v(t)} \Psi^{-1} (\xi + \mathscr{F}_v(t))\, dt.$$

Note that also $\mathfrak{F}_v$ is continuous in I. Indeed, $\mathscr{F}_v$ is continuous on I as noted above, the function Ψ^{-1} is continuous by assumption and so, by Lebesgue's Dominated Convergence Theorem, we can infer that $\mathfrak{F}_v \in C(\mathbb{R};\mathbb{R})$.

Moreover $\mathfrak{F}_v$ is strictly increasing in $\mathbb{R}$ since $K_v \geq 0$ and Ψ^{-1} is strictly increasing by assumption. Finally

$$\Psi^{-1}\left(\xi - \|\Theta\|_{L^1(I)}\right)\int_a^b \frac{1}{K_v(t)}dt \leq \mathfrak{F}_v(\xi) \leq \Psi^{-1}\left(\xi + \|\Theta\|_{L^1(I)}\right)\int_a^b \frac{1}{K_v(t)}dt$$

which implies that $\lim_{\xi\to\pm\infty}\mathfrak{F}_v(\xi) = \pm\infty$. Then, by Bolzano's Theorem, there exists a unique $\xi_v \in \mathbb{R}$ such that $\mathfrak{F}_v(\xi_v) = \delta_2 - \delta_1$ for any choice of $\delta_1, \delta_2 \in \mathbb{R}$.

In order to prove (2.5), note that, by the Mean Value Theorem, there exists $t_v \in I$ such that

$$\mathfrak{F}_v(\xi_v) = \int_a^b \frac{1}{K_v(t)}\Psi^{-1}\left(\xi_v + \mathscr{F}_v(t)\right)dt = \delta_2 - \delta_1 = \Psi^{-1}\left(\xi_v + \mathscr{F}_v(t_v)\right)\int_a^b \frac{1}{K_v(t)}dt$$

and so

$$\xi_v + \mathscr{F}_v(t_v) = \Psi\left((\delta_2 - \delta_1)\left(\int_a^b \frac{1}{K_v(t)}dt\right)^{-1}\right). \tag{2.8}$$

Now observe that, by (2.3)

$$(\delta_2 - \delta_1)\left(\int_a^b \frac{1}{K_v(t)}dt\right)^{-1} \leq |\delta_2 - \delta_1|\left(\int_a^b \frac{1}{k_2(t)}dt\right)^{-1} =: C. \tag{2.9}$$

Hence, denoted by $\hat{\Psi} = \max_{[-C,C]}|\Psi|$ and recalling that Ψ is strictly increasing, relations (2.8)–(2.9) give

$$\begin{aligned}|\xi_v| &\leq |\xi_v + \mathscr{F}_v(t_v)| + |\mathscr{F}_v(t_v)| = \left|\Psi\left((\delta_2 - \delta_1)\left(\int_a^b \frac{1}{K_v(t)}dt\right)^{-1}\right)\right| + |\mathscr{F}_v(t_v)| \\ &\leq |\Psi(C)| + |\mathscr{F}_v(t_v)| \leq \hat{\Psi} + \|\Theta\|_{L^1(I)}.\end{aligned}$$

Choosing $c_0 = \hat{\Psi} + \|\Theta\|_{L^1(I)}$ the proof is complete. □

Theorem 2.2. *Let $T > 0$, $p > 1$ and the operators F, K and Ψ be as in in Lemma 2.1.*

Then, for all $v_0, \omega_1, \omega_2 \in \mathbb{R}$ there exists a solution v of the problem

$$\begin{cases}\left(\Psi \circ K_v v''\right)'(t) = F_v(t), \quad \text{a.a. } t \in I, \\ v(0) = v_0,\ v'(0) = \omega_1,\ v'(T) = \omega_2,\end{cases} \tag{$\mathcal{PA}$}$$

that is a function $v \in W^{2,p}(I)$ such that

- $t \mapsto (\Psi \circ K_v v'')(t) \in W^{1,p}(I)$;
- $\left(\Psi \circ K_v v''\right)'(t) = F_v(t), \quad$ *a.a.* $t \in I$;
- $v(0) = v_0,\ v'(0) = \omega_1,\ v'(T) = \omega_2.$

Proof. The proof is an adaptation of [2, Theorem 2.2] and [11, Theorem 3.1]. First, we observe that, since the operators F, K and Ψ satisfy all the assumptions of Lemma 2.1, for all $v \in$

$W^{2,p}(I)$ and all $\delta_1, \delta_2 \in \mathbb{R}$, there exists a unique $\xi_v \in \mathbb{R}$ such that (2.4) and (2.5) still hold when $\delta_1 = w_1$ and $\delta_2 = w_2$. Set

$$\mathcal{W}_0 = \left\{v \in W^{2,p}(I) : v(0) = v_0\right\}$$

and define the operator $G : \mathcal{W}_0 \to \mathcal{W}_0$, with $v \mapsto G_v$, as follows

$$G_v(t) = v_0 + \omega_1 t + \int_0^t \int_0^s g_v(\tau) d\tau ds,$$

where

$$g_v(t) = \frac{1}{K_v(t)} \Psi^{-1}\left(\xi_v + \mathscr{F}_v(t)\right), \quad t \in I.$$

It is easy to see that G is well defined and that the solutions to ($\mathcal{PA}$) correspond to the fixed points of G. Finally, following [2] and [11], it is possible to show that G is bounded, continuous and compact, so that, by Schauder's Fixed Point Theorem, we get the existence of a function v which is a fixed point of G in I, that is a solution to the problem ($\mathcal{PA}$). □

3 Functional setting and main result

Throughout the paper we assume the following structural assumptions on Φ, k and f.

(A_1) $\Phi : \mathbb{R} \to \mathbb{R}$ *is a strictly increasing homeomorphism such that* $\Phi(0) = 0$ *with*

$$\liminf_{s \to 0^+} \frac{\Phi(s)}{s^\rho} > 0 \quad \text{for some } \rho > 0.$$

(A_2) $k : \mathbb{R}_0^+ \times \mathbb{R} \to \mathbb{R}$ *is a continuous function such that*

- $k(t,y) > 0$ *for a.a.* $(t,y) \in \mathbb{R}_0^+ \times \mathbb{R}$;
- $t \mapsto 1/k(t,y) \in L^p_{loc}(\mathbb{R}_0^+)$ *for all* $y \in \mathbb{R}$, *for some* $p > 1$.

(A_3) $f : \mathbb{R}_0^+ \times \mathbb{R}^3 \to \mathbb{R}$ is a *Carathéodory function, that is*

- $t \mapsto f(t,x,y,z)$ *is measurable for all* $(x,y,z) \in \mathbb{R}^3$;
- $(x,y,z) \mapsto f(t,x,y,z)$ *is continuous for a.a.* $t \in \mathbb{R}_0^+$,

which is also decreasing with respect to the second variable, that is

$$f(t,x_1,y,z) \geq f(t,x_2,y,z) \quad \text{for a.a. } t \in \mathbb{R}_0^+,$$

for every $x_1, x_2, y, z \in \mathbb{R}$ *such that* $x_1 \leq x_2$.

Moreover, we shall refer to the equation in ($\mathcal{P}$) as (ODE), that is

$$\left(\Phi \circ \mathcal{K}_u\right)'(t) = f(t,u(t),u'(t),u''(t)), \quad \text{for a.a. } t \in \mathbb{R}_0^+, \tag{ODE}$$

where, for simplicity, we denote

$$\mathcal{K}_u(t) = k(t,u'(t))u''(t) \quad \text{with } u \in W^{2,p}_{loc}(\mathbb{R}_0^+) \text{ and } t \in \mathbb{R}_0^+.$$

Definition 3.1. A function $u \in C^1(\mathbb{R}_0^+;\mathbb{R})$ is said to be a (weak) solution of $(\mathcal{P})$ if

- $u \in W^{2,p}_{loc}(\mathbb{R}_0^+)$ and $t \mapsto (\Phi \circ \mathcal{K}_u)(t) \in W^{1,1}_{loc}(\mathbb{R}_0^+)$;
- $(\Phi \circ \mathcal{K}_u)'(t) = f(t, u(t), u'(t), u''(t))$ for a.a. $t \in \mathbb{R}_0^+$;
- $u(0) = u_0,\ u'(0) = \nu_1,\ u'(+\infty) = \nu_2$.

Remark 3.2. Since we allow the function k to vanish in a set having null measure, equation (ODE) can become singular. In this context, we search for solutions no more belonging to $C^2(\mathbb{R}_0^+)$, but to $W^{2,p}_{loc}(\mathbb{R}_0^+) \cap C^1(\mathbb{R}_0^+)$. The choice of this solution space is fairly natural if we consider that the map $t \mapsto 1/k(t,y)$ is assumed to be in $L^p_{loc}(\mathbb{R}_0^+)$ for all $y \in \mathbb{R}$.

Remark 3.3. Since $u \in W^{2,p}_{loc}(\mathbb{R}_0^+)$ is a solution of $(\mathcal{P})$, and, in particular, the map $t \mapsto (\Phi \circ \mathcal{K}_u)(t)$ is in $W^{1,1}_{loc}(\mathbb{R}_0^+)$, and Φ is a homeomorphism, then $\mathcal{K}_u$ can be considered continuous in $\mathbb{R}_0^+$ (see [9, Remark 2.1]).

Definition 3.4. A function $\alpha \in C^1(\mathbb{R}_0^+;\mathbb{R})$ is said to be a (weak) lower solution of (ODE) if

- $\alpha \in W^{2,p}_{loc}(\mathbb{R}_0^+)$ and $t \mapsto (\Phi \circ \mathcal{K}_\alpha)(t) \in W^{1,1}_{loc}(\mathbb{R}_0^+)$;
- $(\Phi \circ \mathcal{K}_\alpha)'(t) \geq f(t, \alpha(t), \alpha'(t), \alpha''(t))$ for a.a. $t \in \mathbb{R}_0^+$.

Definition 3.5. A function $\beta \in C^1(\mathbb{R}_0^+;\mathbb{R})$ is said to be a (weak) upper solution of (ODE) if

- $\beta \in W^{2,p}_{loc}(\mathbb{R}_0^+)$ and $t \mapsto (\Phi \circ \mathcal{K}_\beta)(t) \in W^{1,1}_{loc}(\mathbb{R}_0^+)$;
- $(\Phi \circ \mathcal{K}_\beta)'(t) \leq f(t, \beta(t), \beta'(t), \beta''(t))$ for a.a. $t \in \mathbb{R}_0^+$.

Finally, we say that *a pair (α, β) of lower and upper solutions of* (ODE) *is ordered if*

$$\alpha'(t) \leq \beta'(t) \quad \text{for all } t \in \mathbb{R}_0^+.$$

Besides the structural assumptions (A_1)–(A_3) introduced before, we also consider some further natural requirements, including a suitable form of the so-called *Nagumo–Wintner* growth condition on f, see (3.2) below, which allows us to obtain a priori estimates on the derivatives of the solutions of $(\mathcal{P})$ on any compact interval of $\mathbb{R}_0^+$.

From now on, let $T_0 > 0$ be a fixed positive number and denote by $J = [0, T_0]$. Finally, assume the following conditions.

There exists an ordered pair (α, β) of lower and upper solutions to (ODE) *such that $\alpha(0) = \beta(0) = u_0$, $\alpha'(0) = \nu_1$, β' is increasing in $(T_0, +\infty)$ and $\lim_{t\to+\infty} \beta'(t) = \nu_2$, satisfying the following assumptions.*

(H_1) *Denoting by*

$$k_*(t) = \min\{k(t,y) : y \in [\alpha'(t), \beta'(t)]\}, \quad k^*(t) = \max\{k(t,y) : y \in [\alpha'(t), \beta'(t)]\},$$

assume that $1/k_* \in L^p_{loc}(\mathbb{R}_0^+)$.

(H_2) *There exist a constant $H > 0$, a non-negative function $\ell \in L^1(J)$, a non-negative function $\mu \in L^q(J)$, for some $1 < q \leq +\infty$, and a measurable function $\psi : \mathbb{R}^+ \to \mathbb{R}^+$ satisfying*

$$\frac{1}{\psi} \in L^1_{loc}(\mathbb{R}^+) \quad \textit{and} \quad \int^\infty \frac{1}{\psi(t)} dt = +\infty, \tag{3.1}$$

such that

$$|f(t,x,y,z)| \leq \psi(|\Phi(k(t,y)z)|)\left(\ell(t)+\mu(t)|z|^{\frac{q-1}{q}}\right) \qquad (3.2)$$

for a.a. $t \in J$ and all $x,y,z \in \mathbb{R}$ such that $x \in [\alpha(t),\beta(t)]$, $y \in [\alpha'(t),\beta'(t)]$ and $|z| \geq H$.

(H_3) *For any $L > 0$ there exist a non-negative function $\eta_L \in L^1(\mathbb{R}_0^+)$ and a continuous function $K_L \in W^{1,1}_{loc}(\mathbb{R}_0^+)$, with K_L null in $[0,T_0]$ and strictly increasing in $[T_0,+\infty)$, satisfying*

$$\int_{T_0}^{\infty} \frac{1}{k_*(t)} e^{-\frac{K_L(t)}{\rho}} dt < +\infty, \qquad (3.3)$$

such that

- (i) *$|f(t,x,y,z)| \geq K_L'(t)|\Phi(k(t,y)z)|$ for a.a. $t \in [T_0,+\infty)$, all $x \in [\alpha(t),\beta(t)]$, all $y \in [\alpha'(t),\beta'(t)]$ and all $z \in \mathbb{R}$ with $|z| \leq \mathcal{N}_L(t)/k(t,y)$;*
- (ii) *$|f(t,x,y,z)| \leq \eta_L(t)$ for a.a. $t \in \mathbb{R}_0^+$, all $x \in [\alpha(t),\beta(t)]$, all $y \in [\alpha'(t),\beta'(t)]$ and all $z \in \mathbb{R}$ with $|z| \leq \hat{\gamma}_L(t)$;*
- (iii) *$f(t,x,y,z) \leq 0$ for a.a. $t \in [T_0,+\infty)$, all $x \in [\alpha(t),\beta(t)]$, all $y \in [\alpha'(t),\beta'(t)]$ and all $z \in \mathbb{R}$ with $|z| \leq \hat{\gamma}_L(t)$;*

where

$$\gamma_L(t) = \frac{\mathcal{N}_L(t)}{k_*(t)} \quad \text{and} \quad \hat{\gamma}_L(t) = \gamma_L(t) + |\alpha''(t)| + |\beta''(t)| \quad \text{a.a. } t \in \mathbb{R}_0^+,$$
$$\mathcal{N}_L(t) = \Phi^{-1}\left\{\Phi(L)e^{-K_L(t)}\right\} \quad t \in \mathbb{R}_0^+.$$

Remark 3.6. Note that, since $1/k_* \in L^p_{loc}(\mathbb{R}_0^+)$ by (H_1), also $1/k^* \in L^p_{loc}(\mathbb{R}_0^+)$.

Moreover, by definition of k_*, we have

$$\frac{\mathcal{N}_L(t)}{k(t,y)} \leq \frac{\mathcal{N}_L(t)}{k_*(t)} = \gamma_L(t) \leq \hat{\gamma}_L(t) \quad \text{for a.a. } t \in \mathbb{R}_0^+ \text{ and all } y \in [\alpha'(t),\beta'(t)],$$

so that, on account of (H_3)–(iii), we can rewrite (H_3)–(i) as follows

$$f(t,x,y,z) \leq -K_L'(t)|\Phi(k(t,y)z)|$$

for a.a. $t \in [T_0,+\infty)$, all $x \in [\alpha(t),\beta(t)]$, all $y \in [\alpha'(t),\beta'(t)]$ and all $z \in \mathbb{R}$ such that $|z| \leq \mathcal{N}_L(t)/k(t,y)$.

Remark 3.7. Despite their technicality, assumptions (H_1)–(H_3) are fulfilled in several remarkable cases, as it we be clear from the examples presented in Section 4.

In particular, the request (3.3) in (H_3) is compatible with the *critical* nature of the problem connected with the growth of f at infinity; see Section 4 and [11] for further details.

Remark 3.8. It is worth noting that $\mathcal{N}_L$ is continuous so that $\gamma_L = \mathcal{N}_L/k_* \in L^p_{loc}(\mathbb{R}_0^+)$, since $1/k_*$ in $L^p_{loc}(\mathbb{R}_0^+)$ by (A_2). Moreover, $\mathcal{N}_L$ is strictly positive by definition, being $\Phi(L) > 0$. Furthermore, recalling the monotonicity of K_L and the fact that Φ is a strictly increasing homeomorphism, we infer that $\mathcal{N}_L$ is strictly decreasing in $[T_0,+\infty)$. In particular, gathering the definition of $\mathcal{N}_L$ and the monotonicity of Φ, we deduce that $\mathcal{N}_L < L$ in $(T_0,+\infty)$ and $\mathcal{N}_L(t) = L$ for all $t \in J$.

Moreover, using the liminf condition in (A_1) we deduce that

$$\limsup_{\xi \to 0^+} \frac{\Phi^{-1}(\xi)}{\xi^{1/\rho}} < +\infty.$$

Consequently, combining the above considerations with (3.3) and the fact that $1/k_* \in L^p_{loc}(\mathbb{R}^+_0)$, we obtain that $\gamma_L = \mathcal{N}_L/k_* \in L^1(\mathbb{R}^+_0)$. Finally, since $\alpha, \beta \in W^{2,p}_{loc}(\mathbb{R}^+_0)$, we also have that $\hat{\gamma}_L = \gamma_L + |\alpha''| + |\beta''| \in L^1_{loc}(\mathbb{R}^+_0)$; see [9, Remark 3.7] and [11, Remark 1].

We are now ready to state our main result.

Theorem 3.9. *Assume (A_1)–(A_3) and (H_1)–(H_3). Then, problem $(\mathcal{P})$ admits at least a weak solution $u \in W^{2,p}_{loc}(\mathbb{R}^+_0)$ satisfying*

$$\alpha \leq u \leq \beta \quad \text{and} \quad \alpha' \leq u' \leq \beta' \ \text{ a.e. in } \mathbb{R}^+_0.$$

The proof of Theorem 3.9 is divided into two steps.

Step 1. Solvability on compact sets. Let $n \in \mathbb{N}$ be such that $n > T_0$ and consider problem $(\mathcal{P}_n)$. By solution to $(\mathcal{P}_n)$ we mean a function $u_n \in W^{2,p}(I_n)$ such that

- $t \mapsto \big(\Phi \circ \mathcal{K}_{u_n}\big)(t) \in W^{1,1}(I_n)$;
- $\big(\Phi \circ \mathcal{K}_{u_n}\big)'(t) = f(t, u_n(t), u_n'(t), u_n''(t))$ for a.a. $t \in I_n$;
- $u_n(0) = u_0,\ u_n'(0) = \alpha'(0),\ u_n'(n) = \beta(n)$.

Step 2. A limit argument. Once the existence on compact sets I_n is established, we construct a new sequence of functions $(x_n)_n$ by extending the functions u_n to $\mathbb{R}^+_0$ and we prove that the limit function of $(x_n)_n$ is a solution of $(\mathcal{P})$.

3.1 Solvability on compact sets

In order to prove the existence of solutions for $(\mathcal{P}_n)$ we first consider and intermediate *truncated problem*. Following [8], see also [2], for any pair of functions $\xi, \zeta \in L^1(I_n)$, satisfying the relation $\xi \leq \zeta$ a.e. in I_n, we define the truncation operator

$$\mathcal{T}^{\xi,\zeta} : L^1(I_n) \to L^1(I_n), \quad \eta \mapsto \mathcal{T}^{\xi,\zeta}_\eta,$$
$$\mathcal{T}^{\xi,\zeta}_\eta(t) = \max\{\xi(t), \min\{\eta(t), \zeta(t)\}\}, \quad t \in I_n.$$

Observe that, by definition,

$$T^{\xi,\zeta}_\eta(t) \in [\xi(t), \zeta(t)] \quad \text{for all } \eta \in L^1(I_n) \text{ and for all } t \in I_n. \tag{3.4}$$

Moreover, by [8, Lemma A.1] we know that

$(\mathcal{T}_1)$ $|\mathcal{T}^{\xi,\zeta}_{\eta_1}(t) - \mathcal{T}^{\xi,\zeta}_{\eta_2}(t)| \leq |\eta_1(t) - \eta_2(t)|$ *for all $\eta_1, \eta_2 \in L^1(I_n)$ and all $t \in I_n$;*

$(\mathcal{T}_2)$ *if $\xi, \zeta \in W^{1,1}(I_n)$, then $\mathcal{T}^{\xi,\zeta}(W^{1,1}(I_n)) \subseteq W^{1,1}(I_n)$;*

$(\mathcal{T}_3)$ *if $\xi, \zeta \in W^{1,1}(I_n)$, then $\mathcal{T}^{\xi,\zeta}$ is continuous from $W^{1,1}(I_n)$ into itself.*

Now, for all $u \in W^{2,p}(I_n)$ and for all $t \in I_n$ we denote

$$\mathcal{D}_{u'}(t) = \mathcal{T}^{-\hat{\gamma}_L,\hat{\gamma}_L}_{\left(\mathcal{T}^{\alpha',\beta'}_{u'}\right)'}(t),$$

where $\hat{\gamma}_L$ derives from assumption (H_3), and observe that this definition is well posed whenever $u \in W^{2,p}_{loc}(\mathbb{R}^+_0)$ by $(\mathcal{T}_2)$. Moreover, by property (3.4) it results that

$$|\mathcal{D}_{u'}(t)| \leq \hat{\gamma}_L(t) \quad \text{for all } t \in I_n. \tag{3.5}$$

Finally, we set

$$W_0 = \left\{u \in W^{2,p}(I_n) : \ u(0) = u_0\right\}$$

and consider the operator

$$\mathcal{F} : W_0 \to L^1(I_n), \quad u \mapsto \mathcal{F}_u,$$

defined as

$$\mathcal{F}_u(t) = f\left(t, \mathcal{T}^{\alpha,\beta}_u(t), \mathcal{T}^{\alpha',\beta'}_{u'}(t), \mathcal{D}_{u'}(t)\right) + \arctan\left(u'(t) - \mathcal{T}^{\alpha',\beta'}_{u'}(t)\right), \quad t \in I_n. \tag{3.6}$$

Then, we are in a position to introduce the truncated problem

$$\begin{cases} \left(\Phi \circ \mathcal{K}^{\mathcal{T}}_u u''\right)'(t) = \mathcal{F}_u(t), & \text{a.a. } t \in I_n, \\ u(0) = u_0, \ u'(0) = \alpha'(0), \ u'(n) = \beta'(n), \end{cases} \tag{$\mathcal{PT}_n$}$$

where

$$\mathcal{K}^{\mathcal{T}} : W^{2,p}(I_n) \to C(I_n; \mathbb{R}), \quad u \mapsto \mathcal{K}^{\mathcal{T}}_u(t) = k\left(t, \mathcal{T}^{\alpha',\beta'}_{u'}(t)\right). \tag{3.7}$$

We are going to prove that $(\mathcal{PT}_n)$ admits at least a weak solution, that is a function $u_n \in W_0$ such that

- $t \mapsto \left(\Phi \circ \mathcal{K}^{\mathcal{T}}_{u_n} u''_n\right)(t) \in W^{1,1}(I_n)$;
- $\left(\Phi \circ \mathcal{K}^{\mathcal{T}}_{u_n} u''_n\right)'(t) = \mathcal{F}_{u_n}(t)$ for a.a. $t \in I_n$;
- $u_n(0) = u_0, \ u'_n(0) = \alpha'(0), \ u'_n(n) = \beta(n)$.

To this aim, in the next result we show that $(\mathcal{PT}_n)$ can be framed into the functional setting of Theorem 2.2 and therefore it admits at least one solution. This is an intermediate step between the solvability of $(\mathcal{P}_n)$ and the solvability of $(\mathcal{P})$.

Theorem 3.10. ***Existence for*** $(\mathcal{PT}_n)$. *Assume* (A_1)–(A_3) *and* (H_1)–(H_3). *Then, problem* $(\mathcal{PT}_n)$ *admits at least a weak solution.*

Proof. We want to show that the operators $\mathcal{F}$ and $\mathcal{K}^{\mathcal{T}}$ defined in (3.6) and (3.7), respectively, satisfy the assumptions of Theorem 2.2.

First note that, since $\alpha'(t) \leq \beta'(t)$ for all $t \in \mathbb{R}^+_0$ and $\alpha(0) = \beta(0) = u_0$, we also have $\alpha(t) \leq \beta(t)$ for all $t \in \mathbb{R}^+_0$. Now, by (3.4), for all $t \in I_n$ and all $u \in W_0$ we have

$$\mathcal{T}^{\alpha,\beta}_u(t) \in [\alpha(t), \beta(t)] \quad \text{and} \quad \mathcal{T}^{\alpha',\beta'}_{u'}(t) \in [\alpha'(t), \beta'(t)],$$

so that, by assumption (H_3)–(ii) and (3.5), we get

$$\begin{aligned}|\mathcal{F}_u(t)| &= \left| f\left(t, \mathcal{T}_u^{\alpha,\beta}(t), \mathcal{T}_{u'}^{\alpha',\beta'}(t), \mathcal{D}_{u'}(t)\right) + \arctan\left(u'(t) - \mathcal{T}_{u'}^{\alpha',\beta'}(t)\right)\right| \\ &\le \left| f\left(t, \mathcal{T}_u^{\alpha,\beta}(t), \mathcal{T}_{u'}^{\alpha',\beta'}(t), \mathcal{D}_{u'}(t)\right)\right| + \frac{\pi}{2} \\ &\le \eta_L(t) + \frac{\pi}{2},\end{aligned}$$

for all $u \in W_0$ and all $t \in I_n$. Hence $\mathcal{F}$ satisfies assumption (2.1) of Lemma 2.1 with $\Theta = \eta_L + \pi/2$.

Now we shall prove that $\mathcal{F}_u$ is continuous from $W_0 \subseteq W^{2,p}(I_n)$ into $L^1(I_n)$. To this aim, let $(u_i)_i \subseteq W_0$ be a sequence in W_0 such that $u_i \to u$ in W_0. Fix a subsequence of $(\mathcal{F}u_i)_i$, still denoted by $(\mathcal{F}u_i)_i$ for simplicity. Since $u_i \to u$ in W_0 we also have

$$u_i \longrightarrow u \text{ in } W^{2,p}(I_n), \qquad u_i' \longrightarrow u' \text{ in } W^{1,p}(I_n), \qquad u_i'' \longrightarrow u'' \text{ in } L^p(I_n),$$

so that, by property $(\mathcal{T}_3)$, it follows that

$$\mathcal{T}_{u_i}^{\alpha,\beta} \longrightarrow \mathcal{T}_u^{\alpha,\beta} \quad \text{and} \quad \mathcal{T}_{u_i'}^{\alpha',\beta'} \longrightarrow \mathcal{T}_{u'}^{\alpha',\beta'} \quad \text{in } W^{1,1}(I_n),$$

and in turn

$$\left(\mathcal{T}_{u_i'}^{\alpha',\beta'}\right)' \longrightarrow \left(\mathcal{T}_{u'}^{\alpha',\beta'}\right)' \quad \text{in } L^1(I_n).$$

Hence, by Theorem 4.9 of [13], for a.a. $t \in I_n$ we have

$$\mathcal{T}_{u_i}^{\alpha,\beta}(t) \to \mathcal{T}_u^{\alpha,\beta}(t) \quad \text{and} \quad \left(\mathcal{T}_{u_i'}^{\alpha',\beta'}\right)'(t) \longrightarrow \left(\mathcal{T}_{u'}^{\alpha',\beta'}\right)'(t), \tag{3.8}$$

possibly up to a further subsequence. Moreover, using $(\mathcal{T}_1)$, for a.a. $t \in I_n$ we find

$$|\mathcal{D}_{u_i'}(t) - \mathcal{D}_{u'}(t)| = \left| \mathcal{T}^{-\hat{\gamma}_L,\hat{\gamma}_L}_{\left(\mathcal{T}_{u_i'}^{\alpha',\beta'}\right)'}(t) - \mathcal{T}^{-\hat{\gamma}_L,\hat{\gamma}_L}_{\left(\mathcal{T}_{u'}^{\alpha',\beta'}\right)'}(t)\right| \le \left|\mathcal{T}_{u_i'}^{\alpha',\beta'}(t) - \mathcal{T}_{u'}^{\alpha',\beta'}(t)\right| \longrightarrow 0,$$

that is

$$\mathcal{D}_{u_i'}(t) \longrightarrow \mathcal{D}_{u'}(t) \quad \text{for a.a. } t \in I_n. \tag{3.9}$$

Combining (3.8)–(3.9), with the fact that f is a Carathéodory function, we get

$$\begin{aligned}\mathcal{F}_{u_i}(t) &= f\left(t, \mathcal{T}_{u_i}^{\alpha,\beta}(t), \mathcal{T}_{u_i'}^{\alpha',\beta'}(t), \mathcal{D}_{u_i'}(t)\right) + \arctan\left(u_i'(t) - \mathcal{T}_{u_i'}^{\alpha',\beta'}(t)\right) \\ &\longrightarrow f\left(t, \mathcal{T}_u^{\alpha,\beta}(t), \mathcal{T}_{u'}^{\alpha',\beta'}(t), \mathcal{D}_{u'}(t)\right) + \arctan\left(u'(t) - \mathcal{T}_{u'}^{\alpha',\beta'}(t)\right) \\ &= \mathcal{F}_u(t) \quad \text{for a.a. } t \in I_n.\end{aligned}$$

Therefore we get the continuity of $\mathcal{F}$ by the Lebesgue Dominated Convergence Theorem. Now, putting

$$\alpha_n = \min_{t \in I_n} \alpha(t), \quad \alpha_n' = \min_{t \in I_n} \alpha'(t), \quad \beta_n = \min_{t \in I_n} \beta(t), \quad \beta_n' = \min_{t \in I_n} \beta'(t),$$

it follows that for all $t \in I_n$

$$\alpha_n \le \alpha(t) \le \mathcal{T}_u^{\alpha,\beta}(t) \le \beta(t) \le \beta_n \quad \text{and} \quad \alpha_n' \le \alpha'(t) \le \mathcal{T}_{u'}^{\alpha',\beta'}(t) \le \beta'(t) \le \beta_n'.$$

Since $\mathcal{T}$ is a continuous operator in $C(I_n;\mathbb{R})$, the uniform continuity of k in $I_n \times [\alpha'_n, \beta'_n]$ implies that $\mathcal{K}^{\mathcal{T}}$ is continuous with respect to the uniform topology of $C(I_n;\mathbb{R})$. Moreover, if $u \in W^{2,p}(I_n)$, then for all $t \in I_n$

$$\mathcal{T}_u^{\alpha,\beta}(t) \in [\alpha(t), \beta(t)] \subseteq [\alpha_n, \beta_n] \quad \text{and} \quad \mathcal{T}_{u'}^{\alpha',\beta'}(t) \in [\alpha'(t), \beta'(t)] \subseteq [\alpha'_n, \beta'_n]$$

so that

$$0 < k_*(t) \le \mathcal{K}_u^{\mathcal{T}}(t) = k\left(t, \mathcal{T}_{u'}^{\alpha',\beta'}(t)\right) \le k^*(t),$$

where the functions k_* and k^* have been introduced in (H_1). Thus we have that $\mathcal{K}^{\mathcal{T}}$ satisfies the assumptions of Lemma 2.1 with $k_1 = k_*$ and $k_2 = k^*$.

Finally, taking $\omega_1 = \alpha'(0)$, $\omega_2 = \beta'(n)$, problem ($\mathcal{PT}_n$) becomes ($\mathcal{PA}$). Therefore ($\mathcal{PT}_n$) admits a solution by Theorem 2.2. □

Now, in order to prove the existence of a solution for $(\mathcal{P}_n)$, we consider some useful properties characterizing every solution of $(\mathcal{PT}_n)$ that will be proved in the next lemma. To this aim, we define

$$M = \max_{t\in J} \beta'(t) - \min_{t\in J} \alpha'(t). \tag{3.10}$$

Note that the constant M is well defined, being α, $\beta \in C^1(\mathbb{R}_0^+;\mathbb{R})$. Moreover, since Φ is a continuous and strictly increasing function with $\Phi(0) = 0$, there exists $N \in \mathbb{R}^+$ such that

$$\Phi(N) > 0, \quad \Phi(-N) < 0 \quad \text{and} \quad N > \max\left\{H, \frac{M}{2T_0}\right\} \|k^*\|_{L^\infty(J)}, \tag{3.11}$$

where H is the positive constant introduced in assumption (H_2).

Finally, take $L > N$ such that

$$\min\left\{\int_{\Phi(N)}^{\Phi(L)} \frac{1}{\psi(t)}dt, \int_{-\Phi(-N)}^{-\Phi-(L)} \frac{1}{\psi(t)}dt\right\} > \|\ell\|_{L^1(J)} + \|\mu\|_{L^q(J)} \cdot M^{\frac{q-1}{q}}, \tag{3.12}$$

which is possible by virtue of (3.1).

Lemma 3.11. *Assume (A_1)–(A_3) and (H_1)–(H_3). Let $u_n \in W^{2,p}(I_n)$ be a solution of $(\mathcal{PT}_n)$. Then the following properties hold:*

(i) $\alpha(t) \le u_n(t) \le \beta(t)$ *and* $\alpha'(t) \le u'_n(t) \le \beta'(t)$ *for all* $t \in I_n$;

(ii) $\min_{t\in J} |\mathcal{K}_{u_n}(t)| \le N$;

(iii) $|\mathcal{K}_{u_n}(t)| < L$ *for all* $t \in J$;

(iv) $\mathcal{K}_{u_n}$ *is decreasing in* $[T_0, n]$;

(v) $\mathcal{K}_{u_n} \ge 0$ *in* $[T_0, n]$;

(vi) *if there exists* $t_1 \in [T_0, n]$ *such that* $\mathcal{K}_{u_n}(t_1) = 0$, *then* $\mathcal{K}_{u_n}(t) = 0$ *for all* $t \in [t_1, n]$;

(vii) $|\mathcal{K}_{u_n}(t)| \le \mathcal{N}_L(t)$ *for all* $t \in I_n$;

(viii) $\mathcal{D}_{u'_n}(t) = u''_n(t) \le \gamma_L(t) \le \hat{\gamma}_L(t)$ *for all* $t \in I_n$.

Proof. The proof is similar to other results already known for second order BVPs, so that we present it here for the sake of clarity and completeness.

Let $u_n \in W^{2,p}(I_n)$ be a solution of $(\mathcal{PT}_n)$.

Claim (i). First we show that

$$\alpha'(t) \leq u_n'(t) \leq \beta'(t) \quad \text{for all } t \in I_n. \tag{3.13}$$

Let us start with the first inequality in (3.13). Assume by contradiction that there exists $\bar{t} \in I_n$ such that $u_n'(\bar{t}) < \alpha'(\bar{t})$ and let us define

$$z(t) = u_n'(t) - \alpha'(t), \qquad t \in I_n.$$

Since u_n solves $(\mathcal{PT}_n)$ we find that

$$z(0) = u_n'(0) - \alpha'(0) = 0, \qquad z(n) = u_n'(n) - \alpha'(n) = \beta'(n) - \alpha'(n) \geq 0 \quad \text{and} \quad z(\bar{t}) < 0.$$

Thus, by the continuity of z and the compactness of I_n, there exists $\hat{t} \in I_n$ such that

$$z(\hat{t}) = \min_{t \in I_n} z(t) < 0.$$

Therefore we can find $t_1 \in [0, \hat{t})$ and $t_2 \in (\hat{t}, n]$ such that

$$z(t_1) = z(t_2) = 0 \quad \text{and} \quad z(t) < 0 \quad \text{for all } t \in (t_1, t_2). \tag{3.14}$$

Thus, by the definition of the truncating operator $\mathcal{T}$ and the fact that $u_n'(t) < \alpha'(t)$ for all $t \in (t_1, t_2)$, it follows

$$\mathcal{T}_{u_n'}^{\alpha', \beta'}(t) = \alpha'(t) \quad \text{for all } t \in (t_1, t_2), \tag{3.15}$$

and consequently

$$\mathcal{D}_{u_n'}(t) = \mathcal{T}^{-\hat{\gamma}_L, \hat{\gamma}_L}_{\left(\mathcal{T}_{u_n'}^{\alpha', \beta'}\right)'}(t) = \mathcal{T}_{\alpha''}^{-\hat{\gamma}_L, \hat{\gamma}_L}(t) = \alpha''(t) \quad \text{for all } t \in (t_1, t_2), \tag{3.16}$$

the last equality in (3.16) being true since $|\alpha''(t)| \leq \hat{\gamma}_L(t)$ for all $t \in (t_1, t_2)$ by the definition of $\hat{\gamma}_L$. Now, recalling that u_n is a weak solution of $(\mathcal{PT}_n)$ and α is a lower solution of (ODE), by (3.6) and (3.14)–(3.16), we infer

$$\begin{aligned}(\Phi \circ \mathcal{K}_{u_n}^{\mathcal{T}})'(t) = \mathcal{F}_{u_n}(t) &= f\left(t, \mathcal{T}_{u_n}^{\alpha,\beta}(t), \mathcal{T}_{u_n'}^{\alpha',\beta'}(t), \mathcal{D}_{u_n'}(t)\right) + \arctan\left(u_n'(t) - \mathcal{T}_{u_n'}^{\alpha',\beta'}(t)\right) \\ &= f\left(t, \mathcal{T}_{u_n}^{\alpha,\beta}(t), \alpha'(t), \alpha''(t)\right) + \arctan\left(u_n'(t) - \alpha'(t)\right) \\ &< f(t, \mathcal{T}_{u_n}^{\alpha,\beta}(t), \alpha'(t), \alpha''(t)) \leq f(t, \alpha(t), \alpha'(t), \alpha''(t)) \leq (\Phi \circ \mathcal{K}_\alpha)'(t),\end{aligned}$$

for all $t \in (t_1, t_2)$, that is

$$(\Phi \circ \mathcal{K}_{u_n}^{\mathcal{T}})'(t) < (\Phi \circ \mathcal{K}_\alpha)'(t) \quad \text{for all } t \in (t_1, t_2). \tag{3.17}$$

Now, we set

$$Z_1 = \{t \in (t_1, \hat{t}) : z'(t) < 0\} \quad \text{and} \quad Z_2 = \{t \in (t_1, \hat{t}) : z'(t) > 0\}.$$

Note that both Z_1 and Z_2 have positive Lebesgue measure so that, recalling that k is positive a.e. in $\mathbb{R}_0^+ \times \mathbb{R}$, we can find $t_1^* \in Z_1$ and $t_2^* \in Z_2$ such that

$$k\left(t_1^*, \mathcal{T}_{u_n'}^{\alpha',\beta'}(t_1^*)\right) > 0 \quad \text{and} \quad z'(t_1^*) < 0 \tag{3.18}$$

and
$$k\left(t_2^*, \mathcal{T}_{u_n'}^{\alpha',\beta'}(t_2^*)\right) > 0 \quad \text{and} \quad z'(t_2^*) > 0. \tag{3.19}$$
Integrating (3.17) in $[t_1^*, \hat{t}]$ we get
$$\int_{t_1^*}^{\hat{t}} \left(\Phi \circ \mathcal{K}_{u_n}^{\mathcal{T}}\right)'(t)dt \le \int_{t_1^*}^{\hat{t}} \left(\Phi \circ \mathcal{K}_\alpha\right)'(t)dt$$
which is equivalent to
$$(\Phi \circ \mathcal{K}_{u_n}^{\mathcal{T}})(\hat{t}) - (\Phi \circ \mathcal{K}_\alpha)(\hat{t}) \le (\Phi \circ \mathcal{K}_{u_n}^{\mathcal{T}})(t_1^*) - (\Phi \circ \mathcal{K}_\alpha)(t_1^*). \tag{3.20}$$
Now observe that
$$(\Phi \circ \mathcal{K}_{u_n}^{\mathcal{T}})(t_1^*) - (\Phi \circ \mathcal{K}_\alpha)(t_1^*) < 0. \tag{3.21}$$
Indeed,
$$\begin{aligned}(\Phi \circ \mathcal{K}_{u_n}^{\mathcal{T}})(t_1^*) - (\Phi \circ \mathcal{K}_\alpha)(t_1^*) &= \Phi\left(k\left(t_1^*, \mathcal{T}_{u_n'}^{\alpha',\beta'}(t_1^*)\right) u_n''(t_1^*)\right) - \Phi\left(k\left(t_1^*, \alpha'(t_1^*)\right)\alpha''(t_1^*)\right)\\ &= \Phi\left(k\left(t_1^*, \alpha'(t_1^*)\right) u_n''(t_1^*)\right) - \Phi\left(k\left(t_1^*, \alpha'(t_1^*)\right)\alpha''(t_1^*)\right) < 0,\end{aligned}$$
since $\mathcal{T}_{u_n}^{\alpha,\beta}(t_1^*) = \alpha(t_1^*)$, $u_n''(t_1^*) < \alpha''(t_1^*)$ by (3.18) and Φ is strictly increasing.

Thus, combining (3.20) and (3.21), we find
$$(\Phi \circ \mathcal{K}_{u_n}^{\mathcal{T}})(\hat{t}) - (\Phi \circ \mathcal{K}_\alpha)(\hat{t}) < 0. \tag{3.22}$$
Similarly, integrating (3.17) in $[\hat{t}, t_2^*]$, we get
$$(\Phi \circ \mathcal{K}_{u_n}^{\mathcal{T}})(\hat{t}) - (\Phi \circ \mathcal{K}_\alpha)(\hat{t}) \ge (\Phi \circ \mathcal{K}_{u_n}^{\mathcal{T}})(t_2^*) - (\Phi \circ \mathcal{K}_\alpha)(t_2^*).$$
Additionally,
$$(\Phi \circ \mathcal{K}_{u_n}^{\mathcal{T}})(t_2^*) - (\Phi \circ \mathcal{K}_\alpha)(t_2^*) > 0,$$
since $T_{u_n}^{\alpha,\beta}(t_2^*) = \alpha(t_2^*)$, $u_n''(t_2^*) > \alpha''(t_2^*)$ by (3.19) and Φ is strictly increasing. Therefore
$$(\Phi \circ \mathcal{K}_{u_n}^{\mathcal{T}})(\hat{t}) - (\Phi \circ \mathcal{K}_\alpha)(\hat{t}) > 0. \tag{3.23}$$
Now, (3.22) and (3.23) provide a contradiction. Therefore $\alpha'(t) \le u_n'(t)$ for a.a. $t \in I_n$.

By adapting the previous argument, one is also able to prove $u_n'(t) \le \beta'(t)$ for a.a. $t \in I_n$ finally obtaining $\alpha'(t) \le u_n'(t) \le \beta'(t)$ for a.a. $t \in I_n$.

Eventually, we get the thesis just by integrating (3.13) and recalling that $u_n(0) = \alpha(0) = \beta(0)$ by assumption.

Claim (ii). Suppose, by contradiction, that $\mathcal{K}_{u_n}(t) > N$ for a.a. $t \in J$. Note that
$$u_n''(t) = \frac{\mathcal{K}_{u_n}(t)}{k(t, u_n'(t))} > \frac{N}{k(t, u_n'(t))} > 0$$
for a.a. $t \in J$. Thus, applying (i) we find
$$\begin{aligned} NT_0 = \int_0^{T_0} N dt < \int_0^{T_0} \mathcal{K}_{u_n}(t)dt &= \int_0^{T_0} k\left(t, u_n'(t)\right) u_n''(t)dt\\ &\le \|k^*\|_{L^\infty(J)} \int_0^{T_0} u_n''(t)dt = \|k^*\|_{L^\infty(J)} \left[u_n'(T_0) - u_n'(0)\right]\\ &\le \|k^*\|_{L^\infty(J)} \left[\beta'(T_0) - \alpha'(0)\right] \le M\|k^*\|_{L^\infty(J)} < NT_0,\end{aligned}$$

by the choice of N in (3.11), which is a contradiction.

Similarly, we would get a contradiction assuming that $\mathcal{K}_{u_n}(t) < -N$ for a.a. $t \in J$.

Claim (iii). Suppose, by contradiction, that there exists $\bar{t} \in J$ such that $|\mathcal{K}_{u_n}(\bar{t})| \geq L$. It follows that either $\mathcal{K}_{u_n}(\bar{t}) \geq L$ or $\mathcal{K}_{u_n}(\bar{t}) \leq -L$.

Let us assume that $\mathcal{K}_{u_n}(\bar{t}) \geq L$. By (ii) we know that

$$\min_{t\in J} \mathcal{K}_{u_n}(t) \leq \min_{t\in J} |\mathcal{K}_{u_n}(t)| \leq N < L$$

and so there exists $\hat{t} \in J$ such that $\mathcal{K}_{u_n}(\hat{t}) = \min_{t\in J} \mathcal{K}_{u_n}(t) \leq N$. By the continuity of $\mathcal{K}_{u_n}$ we can find $t_1, t_2 \in J$, with $t_1 \leq t_2$, such that $\mathcal{K}_{u_n}(t_1) = N$, $\mathcal{K}_{u_n}(t_2) = L$ and

$$N < \mathcal{K}_{u_n}(t) < L \quad \text{for all } t \in (t_1, t_2). \tag{3.24}$$

Consequently, recalling the definition of $\mathcal{K}_{u_n}$ and the fact that $k > 0$ a.e. in J, we find

$$\frac{N}{k(t, u_n'(t))} < u_n''(t) < \frac{L}{k(t, u_n'(t))} \quad \text{for all } t \in (t_1, t_2).$$

Hence, taking into account Remark 3.8, for a.a. $t \in (t_1, t_2)$

$$0 < H < \frac{N}{\|k^*\|_{L^\infty(J)}} \leq \frac{N}{k(t, u_n'(t))} < u_n''(t) < \frac{L}{k(t, u_n'(t))} \leq \frac{L}{k_*(t)} = \frac{\mathcal{N}_L(t)}{k_*(t)} = \gamma_L(t) \leq \hat{\gamma}_L(t),$$

which implies, in particular, that

$$\mathcal{D}_{u_n'(t)} = u_n''(t) \quad \text{for a.a. } t \in (t_1, t_2).$$

Therefore, recalling that u_n solves ($\mathcal{PT}_n$), using (H_2) and the fact that $\Phi \circ \mathcal{K}_{u_n}(t) > 0$ by (3.24), the monotonicity of Φ and the choice of N, for a.a. $t \in (t_1, t_2)$ it results

$$\begin{aligned}
\left|\left(\Phi \circ \mathcal{K}_{u_n}^{\mathcal{T}}\right)'(t)\right| &= \left|\left(\Phi\left(k\left(t, \mathcal{T}_{u_n'}^{\alpha',\beta'}(t)\right) u_n''(t)\right)\right)'(t)\right| \\
&= \left|f\left(t, \mathcal{T}_{u_n}^{\alpha,\beta}(t), \mathcal{T}_{u_n'}^{\alpha',\beta'}(t), \mathcal{D}_{u_n'}(t)\right) + \arctan\left(u_n'(t) - \mathcal{T}_{u_n'}^{\alpha',\beta'}(t)\right)\right| \\
&= \left|f\left(t, u_n(t), u_n'(t), u_n''(t)\right)\right| \\
&\leq \psi(|\Phi \circ \mathcal{K}_{u_n}(t)|)\left(\ell(t) + \mu(t)|u_n''(t)|^{\frac{q-1}{q}}\right) \\
&= \psi(\Phi \circ \mathcal{K}_{u_n}(t))\left(\ell(t) + \mu(t)|u_n''(t)|^{\frac{q-1}{q}}\right).
\end{aligned}$$

Hence, by Hölder's inequality, we get

$$\begin{aligned}
\int_{\Phi(N)}^{\Phi(L)} \frac{1}{\psi(\tau)} d\tau = \int_{\Phi(\mathcal{K}_{u_n}(t_1))}^{\Phi(\mathcal{K}_{u_n}(t_2))} \frac{1}{\psi(\tau)} d\tau &= \int_{t_1}^{t_2} \frac{(\Phi \circ \mathcal{K}_{u_n})'(t)}{\psi(\Phi \circ \mathcal{K}_{u_n}(t))} dt \\
&\leq \int_{t_1}^{t_2} \left[\ell(t) + \mu(t)(u_n''(t))^{\frac{q-1}{q}}\right] dt \\
&\leq \|\ell\|_{L^1(J)} + \|\mu\|_{L^q(J)} \left(\int_{t_1}^{t_2} u_n''(t) dt\right)^{\frac{q-1}{q}} \\
&\leq \|\ell\|_{L^1(J)} + \|\mu\|_{L^q(J)} \left[\beta'(t_2) - \alpha'(t_1)\right]^{\frac{q-1}{q}} \\
&\leq \|\ell\|_{L^1(J)} + \|\mu\|_{L^q(J)} M^{\frac{q-1}{q}}.
\end{aligned}$$

This relation contradicts the choice of L in (3.12). Similarly, if we suppose $\mathcal{K}_{u_n}(\bar{t}) \leq -L$ we reach a contradiction again.

Claim (iv). Since u_n is a solution to ($\mathcal{PT}_n$), using (i), we find that

$$(\Phi \circ \mathcal{K}_{u_n})'(t) = f\left(t, u_n(t), u_n'(t), \mathcal{D}_{u_n'}(t)\right) \quad \text{for a.a. } t \in I_n.$$

On the other hand, by (i) and (H_3)–(iii), we get

$$f\left(t, u_n(t), u_n'(t), \mathcal{D}_{u_n'}(t)\right) \leq 0 \quad \text{for a.a. } t \in [T_0, n],$$

being $|D_{u_n'}(t)| \leq \hat{\gamma}_L(t)$ by (3.5). Hence

$$(\Phi \circ \mathcal{K}_{u_n})'(t) \leq 0 \quad \text{for a.a. } t \in [T_0, n]$$

and the claim follows since Φ is a strictly increasing homeomorphism.

Claim (v). By contradiction, suppose that there exists $t_1 \in [T_0, n]$ such that $\mathcal{K}_{u_n}(t_1) < 0$. Then, from (iv) we have that

$$\mathcal{K}_{u_n}(t) \leq \mathcal{K}_{u_n}(t_1) < 0 \quad \text{for all } t \in [t_1, n].$$

Hence, considering the definition of $\mathcal{K}_{u_n}$ we deduce

$$u_n''(t) = \frac{\mathcal{K}_{u_n}(t)}{k(t, u_n'(t))} < 0 \quad \text{for a.a. } t \in [t_1, n].$$

Now, we recall that u_n solves ($\mathcal{PT}_n$), and so, using (i) and assumption (H_1), we get

$$\beta'(n) = u_n'(n) = u_n'(t_1) + \int_{t_1}^{n} u_n''(\tau)d\tau < u_n'(t_1) \leq \beta'(t_1) \leq \beta'(n),$$

since β' is increasing in $(T_0, +\infty)$, which is a contradiction.

Claim (vi). The statement directly follows from (iv) and (v).

Claim (vii). Recalling that $\mathcal{N}_L = L$ in J, by virtue of (iii) and (v), it is sufficient to prove that

$$0 \leq \mathcal{K}_{u_n}(t) \leq \mathcal{N}_L(t) \qquad \forall t \in I_n \setminus J.$$

Put

$$t^* = \sup\left\{t \geq T_0 : \; \mathcal{K}_{u_n}(s) < \mathcal{N}_L(s) \qquad \forall\, s \in [T_0, t)\right\}.$$

Note that t^* is well defined, since $\mathcal{K}_{u_n}(T_0) < L = \mathcal{N}_L(T_0)$, and $t^* > T_0$.

We want to prove that $t^* > n$. Proceed by contradiction and suppose that $t^* \leq n$. This implies that

$$\mathcal{K}_{u_n}(t) > 0 \quad \text{for all } t \in [T_0, t^*].$$

Indeed, if there exists $\bar{t} \in [T_0, t^*]$ such that $\mathcal{K}_{u_n}(\bar{t}) = 0$, we would get $\mathcal{K}_{u_n}(t) = 0 < \mathcal{N}_L(t)$ for all $t \in [\bar{t}, n]$ by (vi). On the other hand, by definition of t^*, it results $\mathcal{K}_{u_n}(t) < \mathcal{N}_L(t)$ for all $t \in [T_0, t^*)$. Consequently, since $\bar{t} \leq t^*$, we would find $\mathcal{K}_{u_n}(t) < \mathcal{N}_L(t)$ for all $t \in [T_0, n]$ and this relation contradicts the maximality of t^*. Hence

$$0 < \mathcal{K}_{u_n}(t) = k(t, u_n'(t))u_n''(t) < \mathcal{N}_L(t) \quad \text{for a.a. } t \in [T_0, t^*),$$

and so

$$0 < u_n''(t) < \frac{\mathcal{N}_L(t)}{k(t, u_n'(t))} \leq \frac{\mathcal{N}_L(t)}{k_*(t)} = \gamma_L(t) \leq \hat{\gamma}_L(t) \quad \text{for a.a. } t \in [T_0, t^*).$$

Now, recalling that u_n'' is a solution to ($\mathcal{PT}_n$), assumptions (H_3)–(i) and (H_3)–(iii) give

$$(\Phi \circ \mathcal{K}_{u_n})'(t) = f\left(t, u_n(t), u_n'(t), u_n''(t)\right) \le -K_L'(t)\Phi \circ \mathcal{K}_{u_n}(t) \quad \text{for a.a. } t \in [T_0, t^*).$$

Recalling that $\mathcal{K}_{u_n} > 0$ a.e. in $[T_0, t^*)$ and that Φ is strictly increasing with $\Phi(0) = 0$, we infer

$$\frac{(\Phi \circ \mathcal{K}_{u_n})'(t)}{\Phi \circ \mathcal{K}_{u_n}(t)} \le -K_L'(t) \quad \text{for a.a. } t \in [T_0, t^*).$$

Integrating both sides of the previous estimate in $[T_0, t^*)$, we get

$$\log(\Phi \circ \mathcal{K}_{u_n})(t^*) - \log(\Phi \circ \mathcal{K}_{u_n})(T_0) \le -K_L(t^*),$$

since $K_L(T_0) = 0$. Now, by (iii) we know that $\mathcal{K}_{u_n}(T_0) < L$; therefore,

$$\log \frac{\Phi \circ \mathcal{K}_{u_n}(t^*)}{\Phi(L)} < -K_L(t^*),$$

being Φ strictly increasing, and in turn

$$\mathcal{K}_{u_n}(t^*) < \Phi^{-1}\left(\Phi(L)e^{-K_L(t^*)}\right) = \mathcal{N}_L(t^*).$$

This contradicts the maximality of t^*. Hence we conclude that $t^* > n$. This fact assures that $0 \le \mathcal{K}_{u_n}(t) < \mathcal{N}_L(t)$ for all $t \in [T_0, n]$.

Claim $(viii)$. Using (i) and (vii) we find

$$|u_n''(t)| = \frac{|k(t, u_n'(t))u_n''(t)|}{k(t, u_n'(t))} = \frac{|\mathcal{K}_{u_n}(t)|}{k(t, u_n'(t))} \le \frac{\mathcal{N}_L(t)}{k_*(t)} = \gamma_L(t) \le \hat{\gamma}_L(t) \quad \text{for a.a. } t \in I_n,$$

so that, by the definition of $\mathcal{D}$, we get the claim. □

Theorem 3.12. *Assume* (A_1)–(A_3) *and* (H_1)–(H_3). *Then, if* $u_n \in W^{2,p}(I_n)$ *is a solution of the truncated problem* ($\mathcal{PT}_n$)*, then it is also a solution to* ($\mathcal{P}_n$).

Proof. Let $u_n \in W^{2,p}_{loc}(\mathbb{R}_0^+)$ be a solution of ($\mathcal{PT}_n$). Then, by Lemma 3.11–(i) and $(viii)$, we find that for a.a. $t \in I_n$

$$\begin{aligned}(\Phi \circ \mathcal{K}_{u_n})'(t) &= \left(\Phi\left(k(t, u_n'(t))u_n''(t)\right)\right)'(t) = \left(\Phi\left(k\left(t, \mathcal{T}_{u_n'}^{\alpha',\beta'}\right)u_n''(t)\right)\right)'(t) \\ &= \left(\Phi \circ \mathcal{K}_{u_n}^{\mathcal{T}}\right)'(t) = \mathcal{F}_{u_n}(t) \\ &= f\left(t, \mathcal{T}_{u_n}^{\alpha,\beta}(t), \mathcal{T}_{u_n'}^{\alpha',\beta'}(t), \mathcal{D}_{u_n'}(t)\right) + \arctan\left(u_n'(t) - \mathcal{T}_{u_n'}^{\alpha',\beta'}(t)\right) \\ &= f(t, u_n(t), u_n'(t), u_n''(t)),\end{aligned}$$

that is u_n solves the equation in ($\mathcal{P}_n$). Moreover $u_n(0) = u_0$, $u_n'(0) = \alpha'(0)$ and $u_n'(n) = \beta'(n)$. Hence u_n is a weak solution to ($\mathcal{P}_n$). □

3.2 A limit argument

In order to complete the proof of Theorem 3.9 we consider a sequence $(u_n)_n$ of solutions to ($\mathcal{PT}_n$). By Theorem 3.12, every u_n is also a solution to ($\mathcal{P}_n$). We shall find a solution to ($\mathcal{P}$) via a limit argument.

To this aim, for any $n > T_0$ define

$$x_n : \mathbb{R}_0^+ \to \mathbb{R}, \qquad x_n(t) = \begin{cases} u_n(t), & t \in I_n, \\ u_n(n) + \beta'(n)(t-n), & t > n, \end{cases}$$

so that

$$x_n'(t) = \begin{cases} u_n'(t), & t \in I_n, \\ \beta'(n), & t > n. \end{cases}$$

Moreover, for all $t \in \mathbb{R}_0^+$ put

$$z_n(t) = x_n''(t) = \begin{cases} u_n''(t), & t \in I_n, \\ 0, & t > n; \end{cases} \qquad \Phi_n(t) = \begin{cases} (\Phi \circ \mathcal{K}_{u_n})'(t), & t \in I_n, \\ 0, & t > n. \end{cases}$$

By Lemma 3.11–($viii$) we have

$$|z_n(t)| = |x_n''(t)| = \begin{cases} |u_n''(t)|, & \text{a.a. } t \in I_n, \\ 0, & t > n, \end{cases} \leq \gamma_L(t) \quad \text{for a.a. } t \in \mathbb{R}_0^+. \tag{3.25}$$

Now, since u_n is a solution to ($\mathcal{P}_n$), by Lemma 3.11–(i) and ($viii$), together with (H_3)–(ii), we also find

$$|\Phi_n(t)| = \begin{cases} |f(t, u_n(t), u_n'(t), u_n''(t))|, & \text{a.a. } t \in I_n, \\ 0, & t > n, \end{cases} \leq \eta_L(t) \quad \text{for a.a. } t \in \mathbb{R}_0^+. \tag{3.26}$$

Moreover, since $\eta_L \in L^1(\mathbb{R}_0^+)$ by assumption and also $\gamma_L \in L^1(\mathbb{R}_0^+)$, see Remark 3.8, both $(z_n)_n$ and $(\Phi_n)_n$ are equi-integrable in $\mathbb{R}_0^+$ so that, by the Dunford–Pettis Theorem, there exist $z, \hat{\Phi} \in L^1(\mathbb{R}_0^+)$ such that

$$z_n \rightharpoonup z \quad \text{and} \quad \Phi_n \rightharpoonup \hat{\Phi} \quad \text{in } L^1(\mathbb{R}_0^+) \quad \text{as } n \to +\infty, \tag{3.27}$$

up to subsequences. Consequently, for all $s \in \mathbb{R}_0^+$

$$\int_0^s z_n(\tau)d\tau \longrightarrow \int_0^s z(\tau)d\tau \quad \text{and} \quad \int_0^s \Phi_n(\tau)d\tau \longrightarrow \int_0^s \hat{\Phi}(\tau)d\tau \quad \text{as } n \to +\infty. \tag{3.28}$$

On the other hand, by Lemma 3.11–(i) and (iii), the sequences $(u_n'(0))_n$ and $(\mathcal{K}_{u_n}(0))_n$ are bounded in $\mathbb{R}$ and so there exists $\mathcal{K}_0 \in \mathbb{R}$ such that

$$u_n'(0) = x_n'(0) \longrightarrow \alpha'(0) = \nu_1 \quad \text{and} \quad \mathcal{K}_{u_n}(0) \longrightarrow \mathcal{K}_0 \quad \text{as } n \to +\infty, \tag{3.29}$$

up to subsequences. Now, let us define

$$x(t) = u_0 + \nu_1 t + \int_0^t \int_0^s z(\tau)d\tau ds, \qquad t \in \mathbb{R}_0^+.$$

We want to show that x is a solution to ($\mathcal{P}$). Clearly, $x(0) = u_0$. Moreover, for all $t \in \mathbb{R}_0^+$

$$x'(t) = \nu_1 + \int_0^t z(s)ds, \quad \text{with} \quad x'(0) = \alpha'(0) = \nu_1, \quad \text{and} \quad x''(t) = z(t).$$

By (3.28)–(3.29) we have

$$x_n'(t) = x_n'(0) + \int_0^t z_n(s)ds \longrightarrow x'(t) \quad \text{for all } t \in \mathbb{R}_0^+. \tag{3.30}$$

Furthermore, for all $s \in \mathbb{R}_0^+$

$$\left| \int_0^s z_n(\tau)d\tau \right| \leq \int_0^s |z_n(\tau)|d\tau \leq \|\gamma_L\|_{L^1(\mathbb{R}_0^+)},$$

so that, by (3.28)

$$\int_0^t \int_0^s z_n(\tau)d\tau ds \longrightarrow \int_0^t \int_0^s z(\tau)d\tau ds \quad \text{for all } t \in \mathbb{R}_0^+,$$

and in turn, using also (3.29), it results

$$x_n(t) = u_0 + u_n'(0)t + \int_0^t \int_0^s z_n(\tau)d\tau ds \longrightarrow x(t) \quad \text{for all } t \in \mathbb{R}_0^+. \tag{3.31}$$

Moreover, recalling that $u_n'(t) = x_n'(t)$ and $u_n''(t) = x_n''(t)$ for a.a. $t \in I_n$, we find

$$\Phi(k(t, x_n'(t))x_n''(t)) = \Phi \circ \mathcal{K}_{u_n}(t) = \Phi \circ \mathcal{K}_{u_n}(0) + \int_0^t \Phi_n(s)ds,$$

that is

$$x_n''(t) = \frac{1}{k(t, x_n'(t))} \Phi^{-1} \left(\Phi \circ \mathcal{K}_{u_n}(0) + \int_0^t \Phi_n(s)ds \right) \quad \text{for a.a. } t \in I_n.$$

Hence, recalling that k and Φ^{-1} are continuous, and using (3.28)–(3.30), we get

$$z_n(t) = x_n''(t) \longrightarrow \frac{1}{k(t, x'(t))} \mathcal{U}(t) \quad \text{for a.a. } t \in \mathbb{R}_0^+, \tag{3.32}$$

where

$$\mathcal{U}(t) = \begin{cases} \Phi^{-1} \left(\Phi(\mathcal{K}_0) + \int_0^t \hat{\Phi}(s)ds \right), & t \in I_n, \\ 0, & t > n. \end{cases}$$

Observe that $\mathcal{U} \in C(\mathbb{R}_0^+; \mathbb{R})$, $\Phi \circ \mathcal{U} \in AC(\mathbb{R}_0^+; \mathbb{R})$ and $(\Phi \circ \mathcal{U})' = \hat{\Phi} \in L^1(\mathbb{R}_0^+)$. Now, by (3.25) and (3.32) we obtain

$$z_n = x_n'' \longrightarrow \frac{\mathcal{U}(\cdot)}{k(\cdot, x')} \quad \text{in } L^1(\mathbb{R}),$$

so that, by (3.27), we get

$$z(t) = \frac{\mathcal{U}(t)}{k(t, x'(t))} \quad \text{for a.a. } t \in \mathbb{R}_0^+, \tag{3.33}$$

which implies

$$x_n''(t) = z_n(t) \longrightarrow z(t) = x''(t) \quad \text{for a.a. } t \in \mathbb{R}_0^+. \tag{3.34}$$

Combining (3.30), (3.31) and (3.34) with the fact that f is Carathéodory, we infer

$$f(t, x_n(t), x_n'(t), x_n''(t)) \longrightarrow f(t, x(t), x'(t), x''(t)) \quad \text{for a.a. } t \in \mathbb{R}_0^+. \tag{3.35}$$

Now, fix $t \in \mathbb{R}_0^+$; clearly there exists $\bar{n} > T_0$ such that $t \in I_n$ for all $n \geq \bar{n}$. Hence, recalling that for all $n > T_0$ the function u_n solves ($\mathcal{P}_n$), for any fixed $t \in \mathbb{R}_0^+$ we have

$$\Phi_n(t) = (\Phi \circ \mathcal{K}_{u_n})'(t) = f(t, u_n(t), u_n'(t), u_n''(t)) = f(t, x_n(t), x_n'(t), x_n''(t)) \quad \text{for all } n \geq \bar{n}.$$

Consequently, from (3.35) we obtain

$$\Phi_n(t) \longrightarrow f(t, x(t), x'(t), x''(t)) \quad \text{for a.a. } t \in \mathbb{R}_0^+,$$

and, by (3.26)

$$\Phi_n \longrightarrow f(\cdot, x, x', x'') \quad \text{in } L^1(\mathbb{R}_0^+).$$

Hence, by (3.33) we deduce that

$$(\Phi \circ \mathcal{K}_x)'(t) = (\Phi \circ \mathcal{U})'(t) = \hat{\Phi}(t) = f(t, x(t), x'(t), x''(t)) \quad \text{for a.a. } t \in \mathbb{R}_0^+,$$

that is x is a solution to (ODE).

Now, by Lemma 3.11–(i), we have

$$\alpha(t) \leq x_n(t) \leq \beta(t) \quad \text{and} \quad \alpha'(t) \leq x_n'(t) \leq \beta'(t) \quad \text{for a.a. } t \in I_n \text{ and all } n > T_0,$$

so that, by (3.30)–(3.31)

$$\alpha(t) \leq x(t) \leq \beta(t) \quad \text{and} \quad \alpha'(t) \leq x'(t) \leq \beta'(t) \quad \text{for a.a. } t \in \mathbb{R}_0^+. \tag{3.36}$$

Finally, by (3.25) and (3.34) we infer that $x_n'' \longrightarrow x''$ in $L^1(\mathbb{R}_0^+)$ and, recalling (3.29), we find

$$\sup_{t \in \mathbb{R}_0^+} |x_n'(t) - x'(t)| \leq |x_n'(0) - \nu_1| + \|x_n'' - x''\|_{L^1(\mathbb{R}_0^+)} \to 0,$$

so that $x_n' \to x'$ uniformly in $\mathbb{R}_0^+$. In particular,

$$\lim_{t \to +\infty} x'(t) = \lim_{n \to +\infty} \left(\lim_{t \to +\infty} x_n'(t) \right) = \lim_{n \to +\infty} \beta'(n) = \nu_2.$$

Concerning the regularity of x, we first observe that $x \in C^1(\mathbb{R}_0^+; \mathbb{R})$, being $x_n \in C^1(\mathbb{R}_0^+; \mathbb{R})$, and so $x \in L^p_{loc}(\mathbb{R}_0^+)$. Moreover, $\mathcal{U}$ is locally bounded in $\mathbb{R}_0^+$, since it is continuous, and $1/k(\cdot, x') \in L^p_{loc}(\mathbb{R}_0^+)$ by virtue of (3.36), being $1/k_* \in L^p_{loc}(\mathbb{R}_0^+)$ by assumption. Therefore $x'' = \mathcal{U}/k(\cdot, x') \in L^p_{loc}(\mathbb{R}_0^+)$. Furthermore also $x' \in L^p_{loc}(\mathbb{R}_0^+)$, being

$$\int_a^b |x'(t)|^p dt \leq 2^{p-1}|b-a| \left(|\nu_1|^p + \|x''\|_{L^1([a,b])} \right) < +\infty \quad \text{for all } a, b \in \mathbb{R}_0^+.$$

Hence $x \in W^{2,p}_{loc}(\mathbb{R}_0^+)$.

Finally, $\Phi \circ \mathcal{K}_x = \Phi \circ \mathcal{U} \in AC(\mathbb{R}_0^+; \mathbb{R})$ so that $\Phi \circ \mathcal{K}_x \in L^1_{loc}(\mathbb{R}_0^+)$ and $(\Phi \circ \mathcal{K}_x)' = \hat{\Phi} \in L^1(\mathbb{R}_0^+)$. Therefore $\Phi \circ \mathcal{K}_x \in W^{1,1}_{loc}(\mathbb{R}_0^+)$.

In conclusion, $x \in W^{2,p}_{loc}(\mathbb{R}_0^+)$ is a solution to ($\mathcal{P}$) and the proof is complete.

4 Examples

In this section we present a class of examples of functions Φ, k and f satisfying conditions (A_1)–(A_3) and (H_1)–(H_3).

Let $u_0, \nu_1, \nu_2 \in \mathbb{R}$ be such that $\nu_1 < \nu_2$, and let's consider the following BVP

$$\begin{cases} \left(\Phi\left(k(t,u'(\cdot))u''(\cdot)\right)\right)'(t) = f_1\left(t,u(t),u'(t)\right) f_2(u''(t)), & \text{a.a. } t \in \mathbb{R}_0^+, \\ u(0) = u_0, \;\; u'(0) = \nu_1, \;\; u'(+\infty) = \nu_2, \end{cases} \tag{4.1}$$

where the functions Φ, k, f_1 and f_2 fulfill the assumptions listed below.

(I) $\Phi : \mathbb{R} \to \mathbb{R}$ is an *odd* strictly increasing homeomorphism, with $\Phi(0) = 0$, and there exists $\rho > 0$ such that

$$\liminf_{s\to 0^+} \frac{\Phi(s)}{s^\rho} > 0. \tag{4.2}$$

(II) $k : \mathbb{R}_0^+ \times \mathbb{R} \to \mathbb{R}$ is continuous, strictly positive a.e. in $\mathbb{R}_0^+ \times \mathbb{R}$ and bounded in $\mathbb{R}_0^+ \times [\nu_1, \nu_2]$.

Moreover, if we denote by

$$k_* = \min_{y\in[\nu_1,\nu_2]} k(t,y) \quad \text{and} \quad k^* = \max_{y\in[\nu_1,\nu_2]} k(t,y),$$

we suppose that there exist $p > 1$ and $\sigma > 0$ such that

(II)$_1$ $t \mapsto 1/k(t,y) \in L^p_{loc}(\mathbb{R}_0^+)$ for all $y \in \mathbb{R}$ and $1/k_* \in L^p_{loc}(\mathbb{R}_0^+)$;

(II)$_2$ $\displaystyle\int_1^\infty \frac{1}{t^\sigma k_*^p(t)} dt < +\infty.$

(III) $f_1 : \mathbb{R}_0^+ \times \mathbb{R}^2 \to \mathbb{R}$ is a Carathéodory function, decreasing with respect to the x variable, and there exists $T_0 > 0$ for which the following properties hold:

(III)$_1$ there exists $\tilde{f}_1 \in L^\infty_{loc}(\mathbb{R}_0^+)$ such that

$$|f_1(t,x,y)| \le \tilde{f}_1(t)$$

for a.a. $t \in [0, T_0]$, all $x \in [u_0 + t\nu_1, u_0 + t\nu_2]$ and all $y \in [\nu_1, \nu_2]$;

(III)$_2$ there exist c_1, $c_2 > 0$ and $\delta \ge -1$ such that

$$c_1 t^{-1} \le |f_1(t,x,y)| \le c_2 t^\delta$$

for a.a. $t \ge T_0$, all $x \in [u_0 + t\nu_1, u_0 + t\nu_2]$ and all $y \in [\nu_1, \nu_2]$;

(III)$_3$ $f_1(t,x,y) \le 0$ for all $t \ge T_0$, all $x \in [u_0 + t\nu_1, u_0 + t\nu_2]$ and all $y \in [\nu_1, \nu_2]$.

(IV) $f_2 \in C(\mathbb{R};\mathbb{R})$ and it verifies:

(IV)$_1$ $f_2(z) > 0$ for $z > 0$ and $f_2(0) = 0$;

(IV)$_2$ there exist $z^* > 0$, two real constants d_1, $d_2 > 0$ and a number $\gamma \le 1$ such that

$$d_1|\Phi(z)| \le f_2(z) \le d_2|\Phi(z)|^\gamma \quad \text{for all } z \in \mathbb{R} \text{ with } |z| < z^*;$$

(IV)$_3$ there exist $H > 0$ and $d_3 > 0$ such that if $z \in R$ and $|z| \geq H$ then

$$f_2(z) \leq d_3|z|^{\frac{q-1}{q}} \quad \text{for some } 1 < q \leq +\infty;$$

(IV)$_4$ f_2 is homogeneous of degree $d > 0$ in $\mathbb{R}$, with $d \leq p$, that is
