$$f_2(tz) = t^d f_2(z) \quad \text{for all } t > 0 \text{ and } z \in \mathbb{R}.$$

Finally, put

$$K_M = \max_{t\in\mathbb{R}_0^+} k^*(t) = \sup\{k(t,y) : (t,y) \in \mathbb{R}_0^+ \times [\nu_1, \nu_2]\}$$

and suppose that

$$\frac{c_1 d_1}{K_M^d} \geq \sigma\rho \quad \text{and} \quad \gamma\frac{c_1 d_1}{K_M^d} \geq \sigma + \delta. \tag{4.3}$$

Remark 4.1. When $\delta = -1$ in (III)$_2$ we address the critical case.

Our aim is to prove that, in the present setting, all the hypotheses of Theorem 3.9 are satisfied. As a consequence, there exists a solution $u \in C^1(\mathbb{R}_0^+; \mathbb{R}) \cap W^{2,p}_{loc}(\mathbb{R}_0^+)$ of (4.1).

Remark 4.2. Before proceeding, we highlight, for future reference, a few consequences of the above assumptions (I)–(IV), that will also be employed in the sequel.

(A) For every $\nu \in (-\infty, p]$ it results

$$\int_1^\infty \frac{1}{t^\sigma k_*^\nu(t)} dt < +\infty.$$

Indeed, since $k(t,y) \geq k_*(t)$ for all for all $(t,y) \in \mathbb{R}_0^+ \times [\nu_1,\nu_2]$ and k is bounded in $\mathbb{R}_0^+ \times [\nu_1,\nu_2]$, it follows that k_* is bounded in $\mathbb{R}_0^+$. Therefore, recalling that the map $t \mapsto t^{-\sigma}/k_*^p(t)$ is integrable in $\{t \geq 1\}$ by (II)$_2$, for any $\nu \in (-\infty, p]$ we have

$$\int_1^\infty \frac{1}{t^\sigma k_*^\nu(t)} dt \leq \sup_{\mathbb{R}_0^+} k_*^{p-\nu} \int_1^\infty \frac{1}{t^\sigma k_*^p(t)} dt < +\infty.$$

(B) For all $\zeta > 0$ it is $\max_{|z|\leq\zeta} |\Phi(z)| = \Phi(\zeta)$. Indeed, if $z \in \mathbb{R}$ is such that $|z| \leq \zeta$, since Φ is odd and strictly increasing, we get $-\Phi(\zeta) = \Phi(-\zeta) \leq \Phi(z) \leq \Phi(\zeta)$.

(C) Combining (III)$_2$ with (III)$_3$ we have that

$$f_1(t,x,y) \leq -c_1 t^{-1} < 0$$

for a.a. $t \geq T_0$, all $x \in [u_0 + t\nu_1, u_0 + t\nu_2]$, all $y \in [\nu_1, \nu_2]$.

Obviously assumptions (A_1)–(A_3) are verified by virtue of (I)–(IV), with

$$f : \mathbb{R}_0^+ \times \mathbb{R}^3 \to \mathbb{R}, \quad f(t,x,y,z) = f_1(t,x,y) f_2(z).$$

Now, we are going to prove that also assumptions (H_1)–(H_3) are verified. To this aim, let T_0 be the positive number introduced in (III), and define

$$\alpha(t) = u_0 + t\nu_1 \quad \text{and} \quad \beta(t) = u_0 + t\nu_2, \quad t \in \mathbb{R}_0^+.$$

Clearly $\alpha, \beta \in C^\infty(\mathbb{R}_0^+;\mathbb{R}) \subset W^{2,p}_{loc}(\mathbb{R}_0^+)$, with $p > 1$ introduced in (II), and they are, respectively, a lower and a upper solution to (ODE), since $f_2(0) = 0$ by (IV)$_1$ and $\Phi(0) = 0$ by (I). Finally, $\alpha(0) = \beta(0) = u_0$ and $\alpha'(t) = \nu_1 < \nu_2 = \beta'(t)$ for all $t \in \mathbb{R}_0^+$, so that the pair (α, β) is ordered in $\mathbb{R}_0^+$.

Hypothesis (H_1)**.** Obviously β' is increasing in $(T_0, +\infty)$, being $\beta''(t) = 0$ for all $t \in \mathbb{R}_0^+$, and $\lim_{t\to+\infty} \beta'(t) = \nu_2$.

Hypothesis (H_2)**.** Let $H > 0$, $d_3 > 0$ and $q \in (1, +\infty]$ be as in (IV)$_3$. Combining (IV)$_1$ with (III)$_1$ and (IV)$_3$, we obtain

$$|f(t,x,y,z)| = |f_1(t,x,y)|f_2(z) \le d_3 \tilde{f}_1(t)|z|^{\frac{q-1}{q}}$$

for a.a. $t \in [0, T_0]$, all $x \in [\alpha(t), \beta(t)]$, all $y \in [\nu_1, \nu_2]$ and all $z \in \mathbb{R}$ with $|z| \ge H$. Hence assumption (H_2) is verified with

$$\psi \equiv 1, \quad \ell \equiv 0, \quad \mu(t) = d_3 \tilde{f}_1(t).$$

Observe that $\mu = d_3 \tilde{f}_1 \in L^q([0, T_0])$, being $\tilde{f}_1 \in L^\infty_{loc}(\mathbb{R}_0^+)$ by (III)$_1$.

Hypothesis (H_3)**.** Define the map $K_0 : \mathbb{R}_0^+ \to \mathbb{R}$ as follows

$$K_0(t) = \begin{cases} 0, & 0 \le t \le T_0, \\ \displaystyle\int_{T_0}^t f_0(s)ds, & t > T_0, \end{cases}$$

where

$$f_0(s) = \min\left\{|f_1(s,x,y)| : (x,y) \in [\alpha(t), \beta(t)] \times [\nu_1, \nu_2]\right\}.$$

Observe that

- f_0 is well defined in $\mathbb{R}_0^+$ since f_1 is Carathéodory by assumption (III);
- $f_0 \in L^1_{loc}(\mathbb{R}_0^+)$, being $\tilde{f}_1 \in L^\infty_{loc}(\mathbb{R}_0^+)$ by (III)$_1$ and

$$f_0(t) \le |f_1(t,x,y)| \le \tilde{f}_1(t) \quad \text{for all } t \in \mathbb{R}_0^+, \text{ all } x \in [\alpha(t), \beta(t)] \text{ and all } y \in [\nu_1, \nu_2].$$

Hence $K_0 \in AC(\mathbb{R}_0^+;\mathbb{R}) \cap W^{1,1}_{loc}(\mathbb{R}_0^+)$. Furthermore, K_0 is strictly increasing in $[T_0, +\infty)$, and

$$K_0(t) \ge c_1 \int_{T_0}^t \frac{ds}{s} = c_1 \log \frac{t}{T_0} \quad \text{for all } t \ge T_0, \tag{4.4}$$

by (III)$_2$ and (III)$_3$; see also Remark 4.2–(C).

Now, let $L > 0$ be fixed arbitrarily and put

$$m(L) = \min_{z^* \le |z| \le L} f_2(z), \quad M(L) = \max_{z^* \le |z| \le L} |\Phi(z)|, \quad c(L) = \min\left\{\frac{d_1}{K_M^d}, \frac{m(L)}{M(L)K_M^d}\right\} > 0.$$

Define the function $K_L : \mathbb{R}_0^+ \to \mathbb{R}$ as follows

$$H_L(t) = \Phi^{-1}\left(\Phi(L)e^{-c(L)K_0(t)}\right).$$

By (4.4) it follows that $K_0(t) \to +\infty$ as $t \to +\infty$, so that $H_L(t) \to 0$ as $t \to +\infty$. Therefore it is possible to find $t_L > T_0$ such that

$$H_L(t) \le z^* \quad \text{for all } t \ge t_L. \tag{4.5}$$

We then claim that the function $K_L(t) : \mathbb{R}_0^+ \to \mathbb{R}$ defined by

$$K_L(t) = \begin{cases} c(L)K_0(t), & 0 \le t \le t_L, \\ c(L)K_0(t_L) + \dfrac{d_1}{K_M^d} \displaystyle\int_{t_L}^t f_0(s)ds, & t > t_L, \end{cases}$$

satisfies all the properties in assumption (H_3). Observe that

- K_L is continuous in $\mathbb{R}_0^+$, being K_0 continuous in $\mathbb{R}_0^+$;
- $K_L \equiv K_0 \equiv 0$ in $[0, T_0]$ and K_L is strictly increasing in $[T_0, +\infty)$ since the same holds for K_0 and $t_L > T_0$; see Remark 4.2–(C).

Moreover, $K_L \in W^{1,1}_{loc}(\mathbb{R}_0^+)$, since the same is true for K_0, and for a.a. $t \in R_0^+$, all $x \in [\alpha(t), \beta(t)]$ and all $y \in [\nu_1, \nu_2]$, it is

$$K_L'(t) = \begin{cases} 0, & 0 \le t \le T_0 \\ c(L)f_0(t), & T_0 < t \le t_L \\ \dfrac{d_1}{K_M^d} f_0(t), & t > t_L \end{cases} \le \begin{cases} 0, & 0 \le t \le T_0, \\ c(L)|f_1(t,x,y)|, & T_0 < t \le t_L, \\ \dfrac{d_1}{K_M^d}|f_1(t,x,y)|, & t > t_L. \end{cases} \tag{4.6}$$

Now, we observe that $K_L(t) \ge c(L)K_0(t)$ for all $t \in \mathbb{R}_0^+$ so that

$$\mathcal{N}_L(t) = \Phi^{-1}\left(\Phi(L)e^{-K_L(t)}\right) \le H_L(t) \quad \text{for all } t \in \mathbb{R}_0^+,$$

and in turn, by (4.5), it follows that

$$\mathcal{N}_L(t) \le z^* \quad \text{for all } t \ge t_L. \tag{4.7}$$

Consequently, using $(IV)_4$ and $(IV)_2$, by (4.6), we obtain

$$\begin{aligned} |f(t,x,y,z)| &= \frac{|f_1(t,x,y)|}{k^d(t,y)} f_2(k(t,y)z) \ge \frac{d_1}{k^d(t,y)}|f_1(t,x,y)| \cdot |\Phi(k(t,y)z)| \\ &\ge \frac{d_1}{K_M^d}|f_1(t,x,y)| \cdot |\Phi(k(t,y)z)| \ge K_L'(t)|\Phi(k(t,y)z)|, \end{aligned} \tag{4.8}$$

for a.a. $t > t_L$, $x \in [\alpha(t), \beta(t)]$, $y \in [\nu_1, \nu_2]$ and $z \in \mathbb{R}$ such that $|k(t,y)z| \le \mathcal{N}_L(t)$.

On the other hand, by definition of $\mathcal{N}_L$ it is $\mathcal{N}_L(t) \le L$ for all $t \in \mathbb{R}_0^+$. Therefore, using again $(IV)_4$ and $(IV)_2$ and (4.6), it results

$$\begin{aligned} |f(t,x,y,z)| &= \frac{|f_1(t,x,y)|}{k^d(t,y)} f_2(k(t,y)z) \ge \frac{1}{K_M^d}|f_1(t,x,y)|f_2(k(t,y)z) \\ &\ge \begin{cases} \dfrac{d_1}{K_M^d}|f_1(t,x,y)| \cdot |\Phi(k(t,y)z)|, & |k(t,y)z| \le z^*, \\ \dfrac{m_L}{M_L K_M^d}|f_1(t,x,y)| \cdot |\Phi(k(t,y)z)|, & z^* \le |k(t,y)z| \le \mathcal{N}_L(t), \end{cases} \\ &\ge c(L)|f_1(t,x,y)| \cdot |\Phi(k(t,y)z)| \\ &\ge K_L'(t)|\Phi(k(t,y)z)|, \end{aligned} \tag{4.9}$$

a.a. $t \in [T_0, t_L]$, $x \in [\alpha(t), \beta(t)]$, $y \in [\nu_1, \nu_2]$ and $z \in \mathbb{R}$ such that $|k(t,y)z| \le \mathcal{N}_L(t)$.

Combining (4.8) with (4.9), it follows that

$$|f(t,x,y,z)| \geq K_L'(t)|\Phi(k(t,y)z)|$$

for a.a. $t \geq T_0$, all $x \in [\alpha(t), \beta(t)]$, all $y \in [\nu_1, \nu_2]$ and all $z \in \mathbb{R}$ such that $|z| \leq \mathcal{N}_L(t)/k(t,y)$, that is condition (H_3)–(i) is satisfied.

Now we are going to prove the validity of (3.3). To this aim, observe that, since K_L is continuous in $\mathbb{R}_0^+$ and $1/k_* \in L^p_{loc}(\mathbb{R}_0^+)$ by (II), it results

$$\int_{T_0}^{t_L} \frac{1}{k_*(t)} e^{-\frac{K_L(t)}{\rho}}\, dt < +\infty. \tag{4.10}$$

On the other hand, using the definition of K_L and (III)$_2$, we get

$$\begin{aligned}
\int_{t_L}^{\infty} \frac{1}{k_*(t)} e^{-\frac{K_L(t)}{\rho}}\, dt &= e^{-\frac{c(L)K_0(t_L)}{\rho}} \int_{t_L}^{\infty} \frac{1}{k_*(t)} e^{-\frac{d_1}{\rho K_M^d}\int_{t_L}^{t} f_0(s)ds}\, dt \\
&\leq e^{-\frac{c(L)K_0(t_L)}{\rho}} \int_{t_L}^{\infty} \frac{1}{k_*(t)} \left(\frac{t_L}{t}\right)^{\frac{c_1 d_1}{\rho K_M^d}} dt \\
&= t_L^{\frac{c_1 d_1}{\rho K_M^d}} e^{-\frac{c(L)K_0(t_L)}{\rho}} \int_{t_L}^{\infty} \frac{1}{k_*(t)} \left(\frac{1}{t}\right)^{\frac{c_1 d_1}{\rho K_M^d}} dt.
\end{aligned} \tag{4.11}$$

Now, recalling that the map $t \mapsto t^{-\sigma}/k_*(t)$ is integrable in $\{t \geq 1\}$, see Remark 4.2–(A), it follows that also the map $t \mapsto t^{-\frac{c_1 d_1}{\rho K_M^d}}/k_*(t)$ is integrable in $\{t \geq 1\}$, since

$$\int_{t_L}^{\infty} \frac{1}{k_*(t)} \left(\frac{1}{t}\right)^{\frac{c_1 d_1}{\rho K_M^d}} dt \leq \int_{t_L}^{\infty} \frac{1}{k_*(t)} \left(\frac{1}{t}\right)^{\sigma} dt < +\infty,$$

being $\sigma \leq c_1 d_1/\rho K_M^d$ by (4.3), which implies

$$\int_{t_L}^{\infty} \frac{1}{k_*(t)} \left(\frac{1}{t}\right)^{\frac{c_1 d_1}{\rho K_M^d}} dt < +\infty. \tag{4.12}$$

Combining (4.11) with (4.12) we get (3.3).

Now, we want to prove the existence of a non-negative function $\eta_L \in L^1(\mathbb{R}_0^+)$ satisfying (H_3)–(ii) (note that $\gamma_L = \hat{\gamma}_L$ in $\mathbb{R}_0^+$, being $\alpha'' \equiv \beta'' \equiv 0$ in $\mathbb{R}_0^+$). By (4.7), using also (IV)$_4$, (III)$_2$ and (IV)$_2$, see also Remark 4.2–(C), for a.a. $t \in \mathbb{R}_0^+$, all $x \in [\alpha(t), \beta(t)]$, all $y \in [\nu_1, \nu_2]$ and all $z \in \mathbb{R}$ such that $|k_*(t)z| \leq \mathcal{N}_L(t)$ we find

$$\begin{aligned}
|f(t,x,y,z)| &= \frac{|f_1(t,x,y)|}{k_*^d(t)} f_2(k_*(t)z) \\
&\leq \begin{cases} c_2 d_2 \dfrac{t^\delta}{k_*^d(t)} |\Phi(k_*(t)z)|^\gamma \leq c_2 d_2 \dfrac{t^\delta}{k_*^d(t)} \left[\Phi(\mathcal{N}_L(t))\right]^\gamma, & t > t_L, \\[2ex] \max\limits_{[0,L]} f_2 \cdot \dfrac{\tilde{f}_1(t)}{k_*^d(t)}, & 0 \leq t \leq t_L, \end{cases} \\
&=: \eta_L(t).
\end{aligned}$$

Finally, we claim that $\eta_L \in L^1(\mathbb{R}_0^+)$. First observe that, since $d \le p$, $\tilde{f}_1 \in L^\infty_{loc}(\mathbb{R}_0^+)$ and $1/k_* \in L^p_{loc}(\mathbb{R}_0^+)$, we get

$$\begin{aligned}\int_0^{t_l} \eta_L(t)dt &\le \max_{[0,L]} f_2 \cdot \|\tilde{f}_1\|_{L^\infty([0,t_L])} \int_0^{t_L} \frac{1}{k_*^d(t)} dt \\ &\le \max_{[0,L]} f_2 \cdot \|\tilde{f}_1\|_{L^\infty([0,t_L])} \sup_{\mathbb{R}_0^+} k_*^{p-d} \int_0^{t_L} \frac{1}{k_*^p(t)} dt \\ &< +\infty.\end{aligned} \tag{4.13}$$

On the other hand, by (III)$_2$, from the definition of η_L, it is

$$\begin{aligned}\int_{t_L}^\infty \eta_L(t)dt &= c_2 d_2 \int_{t_L}^\infty \frac{t^\delta}{k_*^d(t)} \left[\Phi(\mathcal{N}_L(t))\right]^\gamma dt \\ &= c_2 d_2 \Phi(L)^\gamma \int_{t_L}^\infty \frac{t^\delta}{k_*^d(t)} e^{-\gamma K_L(t)} dt \\ &= c_2 d_2 \Phi(L)^\gamma e^{-\gamma c(L) K_0(t_L)} \int_{t_L}^\infty \frac{t^\delta}{k_*^d(t)} e^{-\gamma \frac{d_1}{K_M^d} \int_{t_L}^t f_0(s)ds} dt \\ &\le c_3 \int_{t_L}^\infty \frac{1}{k_*^d(t)} \left(\frac{1}{t}\right)^{\gamma \frac{c_1 d_1}{K_M^d} - \delta} dt,\end{aligned} \tag{4.14}$$

with $c_3 > 0$ appropriate constant.

Now, observe that, if $t_L \ge 1$, recalling that $\gamma \frac{c_1 d_1}{K_M^d} - \delta \ge \sigma$ by (4.3), we get

$$\int_{t_L}^\infty \frac{1}{k_*^d(t)} \left(\frac{1}{t}\right)^{\gamma \frac{c_1 d_1}{K_M^d} - \delta} dt \le \int_1^\infty \frac{1}{k_*^d(t)} \left(\frac{1}{t}\right)^{\gamma \frac{c_1 d_1}{K_M^d} - \delta} dt \le \int_1^\infty \frac{1}{k_*^d(t) t^\sigma} dt < +\infty,$$

since $d \le p$ by assumption, see Remark 4.2–(A); on the other hand, if $t_L < 1$, then

$$\begin{aligned}\int_{t_L}^\infty \frac{1}{k_*^d(t)} \left(\frac{1}{t}\right)^{\gamma \frac{c_1 d_1}{K_M^d} - \delta} dt &= \int_{t_L}^1 \frac{1}{k_*^d(t)} \left(\frac{1}{t}\right)^{\gamma \frac{c_1 d_1}{K_M^d} - \delta} dt + \int_1^\infty \frac{1}{k_*^d(t)} \left(\frac{1}{t}\right)^{\gamma \frac{c_1 d_1}{K_M^d} - \delta} dt \\ &\le \int_{t_L}^1 \frac{1}{k_*^d(t)} \left(\frac{1}{t}\right)^{\gamma \frac{c_1 d_1}{K_M^d} - \delta} dt + \int_1^\infty \frac{1}{k_*^d(t) t^\sigma} dt \\ &< +\infty,\end{aligned}$$

since the map $t \mapsto k_*^{-d}(t) t^{\delta - \gamma \frac{c_1 d_1}{K_M^d}}$ is bounded in $[t_L, 1]$ and, as before, $\int_1^\infty \frac{1}{k_*^d(t) t^\sigma} dt < +\infty$, being $d \le p$. Therefore, from (4.14), we infer that

$$\int_{t_L}^\infty \eta_L(t) dt < +\infty. \tag{4.15}$$

Combining (4.13) with (4.15) we get the claim.

Gathering together all these facts, we are entitled to apply Theorem 3.9 to the BVP (4.1), getting at least a solution $u \in C^1(\mathbb{R}_0^+) \cap W^{2,p}_{loc}(\mathbb{R}_0^+)$ such that

$$u_0 + t\nu_1 \le u(t) \le u_0 + t\nu_2 \quad \text{and} \quad \nu_1 \le u'(t) \le \nu_2 \quad \text{for a.a. } t \in \mathbb{R}_0^+.$$

Remark 4.3. It is worth noting that, in the particular case when the homeomorphism Φ in (I) is also homogeneous of degree $r \in (0, p]$, the growth assumption (IV)$_3$ can be replaced with the following one:

(IV)$'_3$ there exists $H > 0$ and $d_3 > 0$ such that, if $z \in \mathbb{R}$ and $|z| \geq H$, then

$$f_2(z) \leq d_3 |\Phi(z)|^{\overline{\alpha}} \quad \text{for some } \overline{\alpha} \leq 1. \tag{4.16}$$

Indeed, if (4.16) holds, it follows

$$|f_1(t,x,y)| f_2(z) \leq d_3 |f_1(t,x,y)| \cdot |\Phi(z)|^{\overline{\alpha}} = d_3 \frac{|f_1(t,x,y)|}{k(t,y)^{r\overline{\alpha}}} |\Phi(k(t,y)z)|^{\overline{\alpha}}$$
$$\leq d_3 \frac{\tilde{f}_1(t)}{k_*^{r\overline{\alpha}}(t)} |\Phi(k(t,y)z)|^{\overline{\alpha}},$$

for a.a. $t \in [0, T_0]$, all $x \in [u_0 + tv_1, u_0 + tv_2]$, all $y \in [v_1, v_2]$ and all $z \in \mathbb{R}$ such that $|z| \geq H$.

As a consequence, hypothesis (H_2) in Theorem 3.9 is fulfilled with

$$\psi(s) = s^{\overline{\alpha}}, \quad \ell(t) = d_3 \frac{\tilde{f}_1(t)}{k_*^{\overline{\alpha} r}(t)}, \quad \mu(t) \equiv 0.$$

Note that, since $\overline{\alpha} \leq 1$, the function ψ satisfies (H_2)–(i); furthermore, since $\tilde{f}_1 \in L^\infty_{loc}(\mathbb{R}^+_0)$, the function $1/k_* \in L^p_{loc}(\mathbb{R}^+_0)$ and $\overline{\alpha} r \leq r \leq p$, we infer that $\ell \in L^1([0, T_0])$.

We conclude this section by presenting some concrete examples of BVPs of the form (4.1), satisfying assumptions (I)–(IV) introduced above.

Example 4.4. Let us consider the following boundary value problem

$$\begin{cases} \left(\Phi \left(e^{-u'(t)^2} \min \left\{ \sqrt{t}, \dfrac{1}{t^2} \right\} u'(t) \right) \right)' = f(t, u, u'(t), u''(t)), \quad \text{a.a. } t \in \mathbb{R}^+_0, \\ u(0) = 0, \quad u'(0) = 0, \quad u'(+\infty) = 1, \end{cases} \tag{4.17}$$

with $m > 1$ to be fixed later, $\theta \in (0, 1)$ and

$$\Phi(z) = z + \sin z, \quad f(t,x,y,z) = -m[\arctan(x^3 + y^2) + \pi] \cdot |z|^\theta \frac{t}{1+t^2}.$$

Obviously, problem (4.17) takes the form (4.1) with

- $\Phi : \mathbb{R} \to \mathbb{R}, \quad \Phi(z) = z + \sin z;$
- $k : \mathbb{R}^+_0 \times \mathbb{R} \to \mathbb{R}, \quad k(t,y) = e^{-y^2} \min\{\sqrt{t}, 1/t^2\};$
- $f_1 : \mathbb{R}^+_0 \times \mathbb{R}^2 \to \mathbb{R}, \quad f_1(t,x,y) = -[\arctan(x^3 + y^2) + \pi] \dfrac{mt}{1+t^2};$
- $f_2 : \mathbb{R} \to \mathbb{R}, \quad f_2(z) = |z|^\theta.$

We claim that the functions Φ, k, f_1 and f_2 satisfy all the assumptions (I)–(IV) introduced in this section, with suitable constants fulfilling (4.3).

Assumption (I) It is straightforward to recognize that Φ is an odd strictly increasing homeomorphism. Moreover, since

$$\lim_{z \to 0^+} \frac{\Phi(z)}{z} = \lim_{z \to 0^+} \frac{z + \sin z}{z} = 2,$$

condition (4.2) is satisfied with $\rho = 1$.

Assumption (II) Clearly k is continuous, strictly positive a.e. in $\mathbb{R}_0^+ \times \mathbb{R}$ and bounded in $\mathbb{R}_0^+ \times [0,1]$. Moreover, it is very easy to see that the map $t \mapsto 1/k(t,y) \in L^p_{loc}(\mathbb{R}_0^+)$ for all $y \in \mathbb{R}$, for every fixed $p \in (1,2)$, and the same is true for $1/k_*(t) = e/\min\{\sqrt{t}, t^2\}$. Moreover,

$$\int_1^\infty \frac{1}{t^\sigma k_*^p(t)}dt = e^p \int_1^\infty \frac{1}{t^{\sigma-2p}}dt < +\infty, \quad \text{for every } \sigma > 2p+1.$$

Assumption (III) f_1 is a Carathéodory function in $\mathbb{R}_0^+ \times \mathbb{R}^2$, being continuous in the same set, and it is also decreasing with respect to x in $\mathbb{R}_0^+ \times \mathbb{R}^2$.

Moreover, for all $t \in \mathbb{R}_0^+$, all $x \in [0,t]$ and all $y \in [0,1]$ it is

$$\begin{aligned}|f_1(t,x,y)| &= \left[\arctan(x^3+y^2)+\pi\right]\frac{mt}{1+t^2}\\ &\le \left[\arctan(1+t^3)+\pi\right]\frac{mt}{1+t^2} =: \tilde{f}_1(t) \in C(\mathbb{R}_0^+;\mathbb{R}) \subseteq L^\infty_{loc}(\mathbb{R}_0^+)\end{aligned}$$

and also

$$\frac{\pi}{2}\cdot\frac{mt^2}{1+t^2} = \left(\pi - \frac{\pi}{2}\right)\frac{mt^2}{1+t^2} \le t|f_1(t,x,y)| \le t\tilde{f}_1(t) = \left[\arctan(1+t^3)+\pi\right]\frac{mt^2}{1+t^2}. \tag{4.18}$$

Now, since

$$\lim_{t\to+\infty}\frac{\pi}{2}\cdot\frac{mt^2}{1+t^2} = m\frac{\pi}{2} \quad \text{and} \quad \lim_{t\to+\infty}\left[\arctan(1+t^3)+\pi\right]\frac{mt^2}{1+t^2} = \frac{3}{2}m\pi,$$

from (4.18) we deduce that for any $\varepsilon \in (0, m\pi/2)$ there exists $T_0 = T_0(\varepsilon) > 0$ such that

$$\left(m\frac{\pi}{2} - \varepsilon\right)\frac{1}{t} \le |f_1(t,x,y)| \le \left(\frac{3}{2}m\pi + \varepsilon\right)\frac{1}{t}$$

for all $t \ge T_0$, all $x \in [0,t]$ and all $y \in [0,1]$, so that $(\mathrm{III})_2$ holds with

$$c_1 = m\frac{\pi}{2} - \varepsilon, \quad c_2 = \frac{3}{2}m\pi + \varepsilon, \quad \delta = -1. \tag{4.19}$$

Note that $c_1 = m\frac{\pi}{2} - \varepsilon > 0$. Finally, condition $(\mathrm{III})_3$ is trivially satisfied.

Assumption (IV) Clearly f_2 is continuous in $\mathbb{R}$, being $\theta > 0$, and $(\mathrm{IV})_1$ trivially holds. Moreover,

$$\lim_{z\to 0}\frac{f_2(z)}{|\Phi(z)|^\theta} = \lim_{z\to 0}\frac{|z|^\theta}{|z+\sin z|^\theta} = \frac{1}{2^\theta},$$

so that for any $\varepsilon \in (0, 1/2^\theta)$ there exists $z^* = z^*(\varepsilon) > 0$ such that

$$\left(\frac{1}{2^\theta} - \varepsilon\right)|\Phi(z)| \le f_2(z) \le \left(\frac{1}{2^\theta} + \varepsilon\right)|\Phi(z)|^\theta \quad \text{for all } z \in \mathbb{R} : \ |z| < z^*.$$

Hence condition $(\mathrm{IV})_2$ is satisfied with

$$d_1 = \frac{1}{2^\theta} - \varepsilon, \quad d_2 = \frac{1}{2^\theta} + \varepsilon, \quad \gamma = \theta. \tag{4.20}$$

Furthermore, condition $(\mathrm{IV})_3$ holds with any constant $H > 0$, any number $d_3 \ge 1$ and $q = 1/(1-\theta) > 1$. Finally f_2 is homogeneous of degree $d = \theta < 1 < p$.

Now, we claim that, for any fixed $p \in (1,2)$, it is possible to choose

$$m > 1 \quad \text{and} \quad 0 < \varepsilon < \frac{1}{2^\theta} < m\frac{\pi}{2}$$

in such a way that (4.3) holds. To prove the claim, first note that

$$K_M = \sup_{\mathbb{R}_0^+ \times [0,1]} e^{-y^2} \min\{\sqrt{t}, 1/t^2\} = 1.$$

Now, since

$$\lim_{\varepsilon \to 0^+} (m - \varepsilon) \cdot \left(\frac{1}{2^\theta} - \varepsilon\right) = \frac{m}{2^\theta},$$

we can choose $m > 1$ and $\varepsilon \in (0, 1/2^\theta)$ satisfying

$$(m - \varepsilon) \cdot \left(\frac{1}{2^\theta} - \varepsilon\right) > \max\left\{1 + 2p, \frac{2p}{\theta}\right\}. \tag{4.21}$$

Consequently, by (4.19)–(4.20) and recalling that $\rho = 1$, one gets

$$\frac{c_1 d_1}{K_M^d} = (m - \varepsilon) \cdot \left(\frac{1}{2^\theta} - \varepsilon\right) > 1 + 2p = (1 + 2p)\rho.$$

On the other hand, using again (4.19)–(4.20) and recalling that $\delta = -1$, we see that

$$\gamma \frac{c_1 d_1}{K_M^d} = \theta(m - \varepsilon) \cdot \left(\frac{1}{2^\theta} - \varepsilon\right) > 2p = (1 + 2p) + \delta.$$

From this, since σ can be chosen arbitrarily close to $1 + 2p$, we conclude that (4.3) is satisfied.

We are then entitled to apply Theorem 3.9 which ensures the existence of a solution $u \in C^1(\mathbb{R}_0^+; \mathbb{R}) \cap W_{loc}^{2,p}(\mathbb{R}_0^+)$ of (4.17).

Remark 4.5. A further example which covers the critical case can be constructed following Example 4.4, but choosing $\nu_1 = 1 < \nu_2$ and substituting the function f_1 with the following one

$$f_1(t, x, y) = m\left[e^{-(x+y)} - 1\right] t \sin\left(\frac{1}{t^2 + 1}\right).$$

Indeed, $f_1 \in C(\mathbb{R}_0^+ \times \mathbb{R}^2)$, it is non positive whenever $x + y \geq 0$ and decreasing with respect to x in the whole of $\mathbb{R}_0^+ \times \mathbb{R}^2$.

Furthermore, for all $t \geq 1$, all $x \in [t, t\nu_2]$ and all $y \in [1, \nu_2]$ we have

$$\frac{m}{2} t \sin\left(\frac{1}{t^2 + 1}\right) \leq m\left[1 - e^{-(x+y)}\right] t \sin\left(\frac{1}{t^2 + 1}\right) = |f_1(t, x, y)| \leq mt \sin\left(\frac{1}{t^2 + 1}\right) =: \tilde{f}_1(t),$$

with $\tilde{f}_1 \in C(\mathbb{R}_0^+)$, which implies

$$\frac{m}{2} t^2 \sin\left(\frac{1}{t^2 + 1}\right) \leq t|f_1(t, x, y)| \leq mt^2 \sin\left(\frac{1}{t^2 + 1}\right).$$

Therefore, for any $\varepsilon \in (0, m/2)$ there exists $T_0 = T_0(\varepsilon)$ that can be chosen greater or equal than 1, such that, for all $t \geq T_0$, all $x \in [t, t\nu_2]$ and all $y \in [1, \nu_2]$, it is

$$\left(\frac{m}{2} - \varepsilon\right) \frac{1}{t} \leq |f_1(t, x, y)| \leq (m - \varepsilon)\frac{1}{t},$$

so that condition (III) holds with

$$T_0 = 1, \quad c_1 = \frac{m}{2} - \varepsilon, \quad c_2 = m - \varepsilon, \quad \delta = -1.$$

Finally, we conclude by choosing $m > 1$ and $\varepsilon \in \left(0, 1/2^\theta\right)$ satisfying

$$\left(\frac{m}{2} - \varepsilon\right) \cdot \left(\frac{1}{2^\theta} - \varepsilon\right) > \max\left\{1 + 2p, \frac{2p}{\theta}\right\}$$

in place of (4.21).

Example 4.6. Let $\overline{p} \in (1, +\infty)$ be fixed and let $r, \theta \in \mathbb{R}$ be such that

$$1 < r < \overline{p} + 1 \quad \text{and} \quad 0 < \theta < r - 1.$$

Let us consider the following boundary value problem

$$\begin{cases} \left(\Phi\left(\frac{|\sin t|^{1/\overline{p}} + |\sin^2 u'(t)|}{2} u''(t)\right)\right)' = f(t, u(t), u'(t), u''(t)), & \text{a.a. } t \in \mathbb{R}_0^+, \\ u(0) = 0, \ u'(0) = 1, \ u'(+\infty) = \nu_2, \end{cases} \tag{4.22}$$

with $\nu_2 > 1$, $m > 1$ to be fixed later and

$$\Phi(z) = \Phi_r(z) = |z|^{r-2}z \quad \text{and} \quad f(t, x, y, z) = -\frac{m + t|\cos t|}{1 + t}\left(x + |\cos y|\right)^3 |z|^\theta.$$

Problem (4.22) takes the form (4.1) with

- $\Phi : \mathbb{R} \to \mathbb{R}$ is the *r-Laplacian*;
- $k : \mathbb{R}_0^+ \times \mathbb{R} \to \mathbb{R}, \quad k(t, y) = \frac{|\sin t|^{1/\overline{p}} + |\sin^2 y|}{2}$;
- $f_1 : \mathbb{R}_0^+ \times \mathbb{R}^2 \to \mathbb{R}, \quad f_1(t, x, y) = -\frac{m + t|\cos t|}{1 + t}(x + |\cos y|)^3$;
- $f_2 : \mathbb{R} \to \mathbb{R}, \quad f_2(z) = |z|^\theta$.

We shall see that the functions Φ, k, f_1 and f_2 satisfy all the assumptions (I)–(IV) introduced in this section, with suitable constants fulfilling (4.3).

Assumption (I) Clearly the *r-Laplacian* is an odd strictly increasing homeomorphism, for which condition (4.2) is satisfied with $\rho = r - 1$, being $\lim_{z \to 0^+} \frac{\Phi(z)}{z^{r-1}} = 1$.

Assumption (II) The function k is continuous and bounded in $\mathbb{R}_0^+ \times \mathbb{R}$, and it is strictly positive a.e. in $\mathbb{R}_0^+ \times \mathbb{R}$.

Moreover, it is very easy to check that the map $t \mapsto 1/k(t, y) \in L^p_{loc}(\mathbb{R}_0^+)$ for all $y \in \mathbb{R}$, for every fixed $p \in (1, \overline{p})$, and the same is true for $1/k_*(t) = 2/|\sin t|^{1/\overline{p}}$, so that (II)$_1$ holds.

Now, choose $p > 1$ in such a way that

$$p \in (\max\{1, r - 1\}, \overline{p}).$$

For any $\sigma > 1$ it results

$$\begin{aligned} \int_{2\pi}^{\infty} \frac{1}{t^\sigma k_*^p(t)} dt &= 2^p \int_{2\pi}^{\infty} \frac{1}{t^\sigma |\sin t|^{p/\overline{p}}} dt = 2^p \sum_{n=1}^{\infty} \int_{2n\pi}^{2(n+1)\pi} \frac{1}{t^\sigma |\sin t|^{p/\overline{p}}} dt \\ &= 2^p \sum_{n=1}^{+\infty} \int_0^{2\pi} \frac{1}{(t + 2n\pi)^\sigma |\sin t|^{p/\overline{p}}} dt \le 2^p \sum_{n=1}^{+\infty} \int_0^{2\pi} \frac{1}{(2n\pi)^\sigma |\sin t|^{p/\overline{p}}} dt \\ &= 2^p \sum_{n=1}^{+\infty} \frac{1}{(2n\pi)^\sigma} \int_0^{2\pi} \frac{1}{|\sin t|^{p/\overline{p}}} dt < +\infty, \end{aligned}$$

and, consequently, assumption (II)$_2$ is fulfilled.

Assumption (III) f_1 is a Carathéodory function in $\mathbb{R}_0^+ \times \mathbb{R}^2$, being continuous in the same set, and it is also decreasing with respect to x in $\mathbb{R}_0^+ \times \mathbb{R}^2$.

Now, take $T_0 = 1$. For all $t \geq T_0$, all $x \in [t, t\nu_2]$ and all $y \in \mathbb{R}$ it results $f_1(t,x,y) \leq 0$ and

$$|f_1(t,x,y)| = \frac{m + t|\cos t|}{1+t}(x + |\cos y|)^3 \leq 4\frac{(m+t|\cos t|)}{1+t}(x^3 + |\cos y|^3)$$
$$\leq \frac{4(m+t)(t^3\nu_2^3 + 1)}{1+t} =: \tilde{f}_1(t),$$

with $\tilde{f}_1 \in C(\mathbb{R}_0^+;\mathbb{R}) \subseteq L^\infty_{loc}(\mathbb{R}_0^+)$. Furthermore, for all $t \geq 1$, all $x \in [t, t\nu_2]$ and all $y \in \mathbb{R}$

$$|f_1(t,x,y)| \leq \tilde{f}_1(t) \leq 4(m+1)(\nu_2^3 + 1)t^3. \tag{4.23}$$

On the other hand, for all $t \geq 1$, all $x \in [t, t\nu_2]$ and all $y \in \mathbb{R}$, it is also true that

$$|f_1(t,x,y)| \geq \frac{m + t|\cos t|}{1+t}x^3 \geq \frac{m}{1+t} \geq \frac{m}{2}\cdot\frac{1}{t}. \tag{4.24}$$

Hence, combining (4.23) with (4.24) we see that (III)$_2$ holds with

$$T_0 = 1, \quad c_1 = \frac{m}{2}, \quad c_2 = 2(m+1)(1+\nu_2^2), \quad \delta = 3. \tag{4.25}$$

Assumption (IV) Clearly $f_2 > 0$ in $\mathbb{R}^+$ and $f_2(0) = 0$. Moreover, if $z \in \mathbb{R}$ and $|z| < 1$, then

$$|\Phi(z)| = |z|^{r-1} < |z|^\theta = f_2(z) = |z|^{\gamma(r-1)} = |\Phi(z)|^\gamma,$$

provided that $\gamma = \theta/(r-1) < 1$. Therefore, condition (IV)$_2$ is satisfied with $z^* = 1$ and

$$d_1 = d_2 = 1. \tag{4.26}$$

Now, observe that, since Φ is homogeneous of degree $r - 1 < p$ and

$$f_2(z) = |z|^\theta \leq |z|^{r-1} = |\Phi(z)| \quad \text{for all } z \in \mathbb{R} \text{ with } |z| \geq 1,$$

we find that assumption (IV)$_3'$ in Remark 4.3 holds with

$$H = 1, \quad d_3 = 1 \quad \overline{\alpha} = 1.$$

Finally, f_2 is homogeneous of degree $d = \theta$.

Now, in order to prove the validity of (4.3), take $m > 1$ satisfying

$$m > 2(r-1)\max\left\{1, \frac{4}{\theta}\right\}.$$

By definition

$$K_M = \sup_{\mathbb{R}_0^+ \times [1,\nu_2]} \frac{|\sin t|^{1/\overline{p}} + \sin^2 y}{2} \leq 1,$$

so that, by (4.25)–(4.26), and recalling that $\rho = r - 1$, it is

$$\frac{c_1 d_1}{K_M^d} \geq c_1 d_1 = \frac{m}{2} > r - 1 = \rho.$$

On the other hand, using again (4.25)–(4.26), we find

$$\gamma\frac{c_1 d_1}{K_M^d} \geq \gamma c_1 d_1 = \frac{\theta}{r-1}\cdot\frac{m}{2} > 4 = 1 + \delta.$$

Choosing σ arbitrarily close to 1 we obtain (4.3).

In conclusion, by Theorem 3.9 there exists a solution $u \in C^1(\mathbb{R}_0^+;\mathbb{R}) \cap W^{2,p}_{loc}(\mathbb{R}_0^+)$ of (4.22).

Abstract. In this paper, we use variational methods to prove the existence of a positive solution for the following class of logarithmic fractional Schrödinger–Poisson system:

$$\begin{cases} \epsilon^{2s}\,(-\Delta)^s\,u + V(x)u - \phi(x)u = u\log u^2 & \text{in } \mathbb{R}^3, \\ \epsilon^{2t}\,(-\Delta)^t\,\phi = |u|^2 & \text{in } \mathbb{R}^3, \end{cases}$$

where $\epsilon > 0$, $s,t \in (0,1)$, $(-\Delta)^\alpha$ is the fractional Laplacian and V is a saddle-like potential.

Keywords: fractional Schrödinger–Poisson system, logarithmic nonlinearity, variational methods.

2020 Mathematics Subject Classification: 35A15, 35R11, 35J60.

1 Introduction and main result

In this article, we consider the following fractional Schrödinger–Poisson system:

$$\begin{cases} \epsilon^{2s}\,(-\Delta)^s\,u + V(x)u - \phi(x)u = u\log u^2 & \text{in } \mathbb{R}^3, \\ \epsilon^{2t}\,(-\Delta)^t\,\phi = |u|^2 & \text{in } \mathbb{R}^3, \end{cases} \tag{1.1}$$

where $\epsilon > 0$ is a small parameter, $s,t \in (0,1)$ and $(-\Delta)^\alpha$, with $\alpha \in \{s,t\}$, is the fractional Laplacian operator which may be defined for any $u : \mathbb{R}^3 \to \mathbb{R}$ belonging to the Schwartz class by

$$(-\Delta)^\alpha u(x) = C(3,\alpha)P.V.\int_{\mathbb{R}^3} \frac{u(x)-u(y)}{|x-y|^{3+2\alpha}}\mathrm{d}y \quad (x \in \mathbb{R}^3),$$

where P.V. stands for the Cauchy principal value and $C(3,\alpha)$ is a normalizing constant; see Di Nezza–Palatucci–Valdinoci [13]. In recent years, there has been a surge of interest in studying partial differential equations involving nonlocal fractional Laplace operators. This type of nonlocal operator comes up naturally in the real world in many different applications, such as

✉ Corresponding author. Email: linli@ctbu.edu.cn & lilin420@gmail.com

phase transitions, game theory, finance, image processing, Lévy processes, and optimization. For more details and applications, we refer the interested reader to the works of Applebaum [6], Bahrouni–Rădulescu–Winkert [7], Caffarelli–Silvestre [9], Di Nezza–Palatucci–Valdinoci [13], Molica Bisci–Rădulescu–Servadei [21], Pucci–Xiang–Zhang [23, 24] and their references.

In the fractional scenario, there are many results for the fractional Schrödinger–Poisson system. Teng [29] studied the existence of ground state solutions for the fractional Schrödinger–Poisson system with the critical Sobolev exponent. Yang–Yu–Zhao [31] were concerned with the existence and concentration behavior of ground state solutions for the fractional Schrödinger–Poisson system with critical nonlinearity. Ambrosio [5] used penalization techniques and Ljusternik–Schnirelmann theory to deal with the multiplicity and concentration of positive solutions for a fractional Schrödinger–Poisson type system with critical growth. Meng–Zhang–He [20] dealt with the existence of a positive and a sign-changing least energy solution for a class of fractional Schrödinger–Poisson system with critical growth and vanishing potentials. Finally, other interesting results in this direction can be found in the papers of Chen–Li–Peng [10], Ji [15], Murcia–Siciliano [22], Qu–He [25] and the references therein.

The case where potential V has a saddle-like geometry was considered in del Pino–Felmer–Miyagaki [12], essentially they assumed the potential V is bounded and $V \in C^2(\mathbb{R}^3)$, which verifies the following conditions:

Fix two subspaces $X, Y \subset \mathbb{R}^3$ such that $\mathbb{R}^3 = X \oplus Y$, then fix $c_0, c_1 > 0$ such that

$$c_0 = \inf_{z\in\mathbb{R}^3} V(z) > 0 \quad \text{and} \quad c_1 = \sup_{x\in X} V(x),$$

satisfying the following geometric condition

(V_1) There exists a number $\lambda \in (0,1)$, such that

$$c_0 = \inf_{R>0} \sup_{x\in\partial B_R(0)\cap X} V(x) < \inf_{y\in Y_\lambda} V(y).$$

where Y_λ is the cone about Y given by

$$Y_\lambda = \left\{ z \in \mathbb{R}^3 : |z \cdot y| > \lambda |z||y|, \text{ for some } y \in Y \right\}.$$

In addition to the above hypotheses, they imposed the conditions below:

(V_2) The functions $V, \frac{\partial V}{\partial x_i}, \frac{\partial^2 V}{\partial x_i \partial x_j}$ are bounded in $\mathbb{R}^3$, for all $i, j \in \{1,2,3\}$;

(V_3) V satisfies the Palais–Smale condition, that is, if $(x_n) \subset \mathbb{R}^3$, such that $(V(x_n))$ is limited and $\nabla V(x_n) \to 0$, then (x_n) possesses a convergent subsequence in $\mathbb{R}^3$.

Using the above conditions on V, and supposing that

$$c_1 < 2^{\frac{2(p-1)}{N+2-p(N-2)}} c_0,$$

the authors studied the existence of positive solutions for the following Schrödinger equation:

$$-\epsilon^2 \Delta u + V(z)u = |u|^{p-2}u \quad \text{in } \mathbb{R}^N,$$

where $p \in (2, 2^*)$ if $N \geq 3$ and $p \in (2, +\infty)$ if $N = 1, 2$, for $\epsilon > 0$ small enough. After, Alves [1] showed the existence of a positive solution for the following elliptic equation with exponential critical growth in $\mathbb{R}^2$:

$$-\epsilon^2 \Delta u + V(z)u = f(u) \quad \text{in } \mathbb{R}^2,$$

Alves and Miyagaki [4] considered the following nonlinear fractional elliptic equation with critical growth in $\mathbb{R}^N$:

$$\epsilon^{2s} (-\Delta)^s u + V(z)u = \lambda |u|^{q-2} u + |u|^{2_s^* - 2} u \quad \text{in } \mathbb{R}^N,$$

where $\lambda > 0$ is a positive parameter, $q \in (2, 2_s^*)$. Recently, under the same assumptions on the potential V, Alves and Ji [3] used the variational method to prove the existence of a positive solution for the following logarithmic Schrödinger equation:

$$-\epsilon^2 \Delta u + V(z)u = u \log u^2 \quad \text{in } \mathbb{R}^N.$$

Motivated by the above papers, in this work we consider the correlation result of the fractional Schrödinger–Poisson system. Now, we state the main result.

Theorem 1.1. *Suppose that V satisfies (V_1)–(V_3). If $V(0) > c_0$ and $c_1 < c_0 + 1$, then there exists $\epsilon_0 > 0$ such that for each $\epsilon \in (0, \epsilon_0)$, the system (1.1) has a positive solution.*

Remark 1.2. Noting that in this paper we consider the nonlocal term ϕ with negative coefficient. We want to point out that if we deal with the positive nonlocal term, i.e.,

$$\begin{cases} \epsilon^{2s} (-\Delta)^s u + V(x)u + \phi(x)u = u \log u^2 & \text{in } \mathbb{R}^3, \\ \epsilon^{2t} (-\Delta)^t \phi = |u|^2 & \text{in } \mathbb{R}^3, \end{cases} \tag{1.2}$$

it is not easy to obtain the boundedness of Palais–Smale sequence (u_n). In fact, by the logarithmic Sobolev inequality, the key point is to prove the boundedness of (u_n), where the negative coefficient plays an important role, see Lemma 3.7. In contrast, if we study (1.2), the inequality may not necessarily hold true, then the boundedness of (u_n) fails to obtain. However, we believe system (1.2) is an interesting problem, we shall consider it further in our future work.

The paper is organized as follows. In Section 2, we recall some lemmas which we will use in the paper. In Section 3, we show some estimates and prove a technical result. In Section 4, we apply the deformation lemma to provide the proof of Theorem 1.1.

2 Preliminaries

If $A \subset \mathbb{R}^3$, we denote by $|u|_{L^q(A)}$ the $L^q(A)$-norm of a function $u : \mathbb{R}^3 \to \mathbb{R}$, and by $|u|_q$ its $L^q(\mathbb{R}^3)$-norm. Let us define $D^{s,2}(\mathbb{R}^3)$ as the completion of $C_c^\infty(\mathbb{R}^3)$ with respect to

$$[u]^2 = \iint_{\mathbb{R}^6} \frac{|u(x) - u(y)|^2}{|x - y|^{3+2s}} \mathrm{d}x\mathrm{d}y.$$

Then, we consider the fractional Sobolev space

$$H^s(\mathbb{R}^3) = \left\{ u \in L^2 \left(\mathbb{R}^3\right) : [u] < \infty \right\},$$

endowed with the norm

$$\|u\|^2 = [u]^2 + |u|_2^2.$$

Now, we recall the following main embeddings for the fractional Sobolev spaces, see Di Nezza–Palatucci–Valdinoci [13].

Lemma 2.1. *Let $s \in (0,1)$. Then $H^s(\mathbb{R}^3)$ is continuously embedded in $L^p(\mathbb{R}^3)$ for any $p \in [2, 2_s^*]$ and compactly in $L^p_{loc}(\mathbb{R}^3)$ for any $p \in [1, 2_s^*)$ with $2_s^* = \frac{6}{3-2s}$.*

We also recall a version of the well-known concentration-compactness principle, see Felmer–Quaas–Tan [14].

Lemma 2.2. *If (u_n) is a bounded sequence in $H^s(\mathbb{R}^3)$ and if*

$$\lim_{n\to\infty} \sup_{y\in\mathbb{R}^3} \int_{B_R(y)} |u_n|^2 \,\mathrm{d}x = 0,$$

where $R > 0$, then $u_n \to 0$ in $L^r(\mathbb{R}^3)$ for all $r \in (2, 2_s^*)$.

By Lemma 2.1, we have

$$H^s(\mathbb{R}^3) \subset L^{\frac{12}{3+2t}}(\mathbb{R}^3). \tag{2.1}$$

For any fixed $u \in H^s(\mathbb{R}^3)$, $L_u : D^{t,2}(\mathbb{R}^3) \to \mathbb{R}$ be the functional given by

$$L_u(v) = \int_{\mathbb{R}^3} u^2 v \mathrm{d}x,$$

which is continuous in view of the Hölder inequality and (2.1). Indeed

$$|L_u(v)| \leq \left(\int_{\mathbb{R}^3} |u|^{\frac{12}{3+2t}} \mathrm{d}x\right)^{\frac{3+2t}{6}} \left(\int_{\mathbb{R}^3} |v|^{2_t^*} \mathrm{d}x\right)^{\frac{1}{2_t^*}} \leq C\|u\|^2 \|v\|_{D^{t,2}},$$

where

$$\|v\|^2_{D^{t,2}} = \iint_{\mathbb{R}^6} \frac{|v(x) - v(y)|^2}{|x-y|^{3+2t}} \mathrm{d}x\mathrm{d}y.$$

Then, by the Lax–Milgram Theorem there is a unique $\phi_u^t \in D^{t,2}(\mathbb{R}^3)$, such that $\langle \phi_u^t, v\rangle$ for each $v \in D^{t,2}(\mathbb{R}^3)$, where $\langle \cdot, \cdot \rangle$ is the inner product on $D^{t,2}(\mathbb{R}^3)$. Thus, we obtain the t-Riesz formula

$$\phi_u^t(x) = c_t \int_{\mathbb{R}^3} \frac{u^2(y)}{|x-y|^{3-2t}} \mathrm{d}y, \quad \text{where } c_t = \pi^{-\frac{3}{2}} 2^{-2t} \frac{\Gamma(3-2t)}{\Gamma(t)},$$

is the only weak solution of the problem

$$(-\Delta)^t \phi_u^t = u^2 \quad \text{in } \mathbb{R}^3.$$

Then, we state the following useful properties whose proofs can be found in Liu–Zhang [19] and Teng [29]:

Lemma 2.3. *For all $u \in H^s(\mathbb{R}^3)$, then the following properties hold:*

(1) $\|\phi_u^t\|_{D^{t,2}} \leq C|u|^2_{\frac{12}{3+2t}} \leq C\|u\|^2$ *and* $\int_{\mathbb{R}^3} \phi_u^t u^2 \mathrm{d}x \leq C_t |u|^4_{\frac{12}{3+2t}}$. *Moreover* $\phi_u^t : H^s(\mathbb{R}^3) \to D^{t,2}(\mathbb{R}^3)$ *is continuous and maps bounded sets into bounded sets;*

(2) $\phi_u^t \geq 0$ *in* $\mathbb{R}^3$*;*

(3) *if* $y \in \mathbb{R}^3$ *and* $\bar{u}(x) = u(x+y)$, *then* $\phi^t_{\bar{u}}(x) = \phi^t_u(x+y)$ *and* $\int_{\mathbb{R}^3} \phi^t_{\bar{u}} \bar{u}^2 \mathrm{d}x = \int_{\mathbb{R}^3} \phi^t_u u^2 \mathrm{d}x$;

(4) $\phi^t_{ru} = r^2 \phi^t_u$ *for all* $r \in \mathbb{R}$;

(5) *if* $u_n \rightharpoonup u$ *in* $H^s(\mathbb{R}^3)$, *then* $\phi^t_{u_n} \rightharpoonup \phi^t_u$ *in* $D^{t,2}(\mathbb{R}^3)$;

(6) *if* $u_n \rightharpoonup u$ *in* $H^s(\mathbb{R}^3)$, *then* $\int_{\mathbb{R}^3} \phi^t_{u_n} u^2 \mathrm{d}x = \int_{\mathbb{R}^3} \phi^t_{(u_n-u)} (u_n-u)^2 \mathrm{d}x + \int_{\mathbb{R}^3} \phi^t_u u^2 \mathrm{d}x + o_n(1)$;

(7) *if* $u_n \to u$ *in* $H^s(\mathbb{R}^3)$, *then* $\phi^t_{u_n} \to \phi^t_u$ *in* $D^{t,2}(\mathbb{R}^3)$ *and* $\int_{\mathbb{R}^3} \phi^t_{u_n} u^2 \mathrm{d}x \to \int_{\mathbb{R}^3} \phi^t_u u^2 \mathrm{d}x$.

In order to study system (1.1), we use the change of variable $x \to \epsilon x$, and the system (1.1) is equivalent to the easier handle system

$$\begin{cases} (-\Delta)^s u + V(\epsilon x)u - \phi(\epsilon x)u = u \log u^2 & \text{in } \mathbb{R}^3, \\ (-\Delta)^t \phi = |u|^2 & \text{in } \mathbb{R}^3. \end{cases} \tag{2.2}$$

Substituting $\phi^t = \phi^t_u$ into system (2.2), we can rewrite (2.2) as a single equation

$$(-\Delta)^s u + V(\epsilon x)u - \phi^t_u u = u \log u^2 \quad \text{in } \mathbb{R}^3. \tag{2.3}$$

We shall use the variational method to study the problem (2.3). Note that, a weak solution of (2.3) in $H^s(\mathbb{R}^3)$ is a critical point of the associated energy functional

$$\mathcal{I}_\epsilon(u) := \frac{1}{2}\|u\|^2_\epsilon - \frac{1}{4}\int_{\mathbb{R}^3} \phi^t_u |u|^2 \mathrm{d}x - \frac{1}{2}\int_{\mathbb{R}^3} u^2 \log u^2 \mathrm{d}x,$$

defined for all $u \in \mathcal{H}_\epsilon$ where

$$\mathcal{H}_\epsilon := \left\{ u \in H^s(\mathbb{R}^3) : \int_{\mathbb{R}^3} V(\epsilon x) u^2 \mathrm{d}x < \infty \right\}$$

is endowed with the norm

$$\|u\|^2_\epsilon := [u]^2 + \int_{\mathbb{R}^3} (V(\epsilon x) + 1)\, u^2 \mathrm{d}x.$$

Obviously, $\mathcal{H}_\epsilon$ is a Hilbert space with inner product

$$(u,v)_\epsilon = \iint_{\mathbb{R}^6} \frac{(u(x)-u(y))(v(x)-v(y))}{|x-y|^{3+2s}} \mathrm{d}x\mathrm{d}y + \int_{\mathbb{R}^3} (V(\epsilon x) + 1)\, uv \mathrm{d}x.$$

Definition 2.4. A solution of the problem (2.3) is a function $u \in H^s(\mathbb{R}^3)$ such that $u^2 \log u^2 \in L^1(\mathbb{R}^3)$ and

$$\iint_{\mathbb{R}^6} \frac{(u(x)-u(y))(v(x)-v(y))}{|x-y|^{3+2s}} \mathrm{d}x\mathrm{d}y + \int_{\mathbb{R}^3} V(\epsilon x) uv \mathrm{d}x \\ - \int_{\mathbb{R}^3} \phi^t_u uv \mathrm{d}x = \int_{\mathbb{R}^3} uv \log u^2 \mathrm{d}x, \quad \forall u, v \in C^\infty_0(\mathbb{R}^3).$$

Due to the lack of smoothness of $\mathcal{I}_\epsilon$, we shall use the approach explored in Ji–Szulkin [16] and Squassina–Szulkin [26]. Let us decompose it into a sum of a C^1 functional plus a convex lower semicontinuous functional, respectively. For $\delta > 0$, let us define the following functions:

$$F_1(\xi) = \begin{cases} 0, & \text{if } \xi = 0, \\ -\frac{1}{2}\xi^2 \log \xi^2 & \text{if } 0 < |\xi| < \delta, \\ -\frac{1}{2}\xi^2 \left(\log \delta^2 + 3\right) + 2\delta|\xi| - \frac{1}{2}\delta^2, & \text{if } |\xi| \geq \delta \end{cases}$$

and

$$F_2(\xi) = \begin{cases} 0, & \text{if } |\xi| < \delta, \\ \frac{1}{2}\xi^2 \log\left(\xi^2/\delta^2\right) + 2\delta|\xi| - \frac{3}{2}\xi^2 - \frac{1}{2}\delta^2, & \text{if } |\xi| \geq \delta. \end{cases}$$

Then,

$$F_2(\xi) - F_1(\xi) = \frac{1}{2}\xi^2 \log \xi^2, \quad \forall \xi \in \mathbb{R},$$

and the functional $\mathcal{I}_\epsilon : \mathcal{H}_\epsilon \to (-\infty, +\infty]$ may be rewritten as

$$\mathcal{I}_\epsilon(u) = \Phi_\epsilon(u) + \Psi(u), \quad u \in \mathcal{H}_\epsilon, \tag{2.4}$$

where

$$\Phi_\epsilon(u) = \frac{1}{2}\|u\|_\epsilon^2 - \frac{1}{4}\int_{\mathbb{R}^3} \phi_u^t |u|^2 \mathrm{d}x - \int_{\mathbb{R}^3} F_2(u)\mathrm{d}x,$$

and

$$\Psi(u) = \int_{\mathbb{R}^3} F_1(u)\mathrm{d}x,$$

As proven in Ji–Szulkin [16] and Squassina–Szulkin [26], $F_1, F_2 \in C^1(\mathbb{R}, \mathbb{R})$. If $\delta > 0$ is small enough, F_1 is convex, even,

$$F_1(\xi) \geq 0 \quad \text{and} \quad F_1'(\xi)\xi \geq 0, \quad \forall \xi \in \mathbb{R}.$$

For each fixed $p \in (2, 2_s^*)$, there exists $C > 0$ such that

$$|F_2'(\xi)| \leq C|\xi|^{p-1}, \quad \forall \xi \in \mathbb{R}.$$

If potential V in (2.3) is replaced by a constant $A > -1$, we have the following problem

$$(-\Delta)^s u + Au - \phi_u^t u = u \log u^2 \quad \text{in } \mathbb{R}^3. \tag{2.5}$$

And the corresponding energy functional associated to (2.5) will be denoted by $\mathcal{I}_A : \mathcal{H}_\epsilon \to (-\infty, +\infty]$ and defined as

$$\mathcal{I}_A(u) = \frac{1}{2}[u]^2 + \frac{1}{2}\int_{\mathbb{R}^3} (A+1)u^2 \mathrm{d}x - \frac{1}{4}\int_{\mathbb{R}^3} \phi_u^t |u|^2 \mathrm{d}x - \frac{1}{2}\int_{\mathbb{R}^3} u^2 \log u^2 \mathrm{d}x.$$

Moreover, let us denote by $m(A)$ the mountain pas level associated with $\mathcal{I}_A$, which possesses the following characterizations

$$m(A) = \inf_{u \in \mathcal{H}_\epsilon \setminus \{0\}} \left\{ \max_{t \geq 0} \mathcal{I}_A(tu) \right\} = \inf_{u \in \mathcal{M}_A} \mathcal{I}_A(u),$$

where $\mathcal{M}_A$ is the Nehari Manifold associated with $\mathcal{I}_A$, given by

$$\mathcal{M}_A = \left\{ u \in \mathcal{H}_\epsilon \setminus \{0\} : \mathcal{I}_A'(u)u = 0 \right\}.$$

3 Technical results

In the section, we recall some definitions that can be found in Szulkin [28].

Definition 3.1. Let E be a Banach space, E' be the dual space of E and $\langle \cdot, \cdot \rangle$ be the duality paring between E' and E. Let $J : E \to \mathbb{R}$ be a functional of the form $J(u) = \Phi(u) + \Psi(u)$, where $\Phi \in C^1(E, \mathbb{R})$ and Ψ is convex and lower semicontinuous. Let us list some definitions:

(i) The sub-differential $\partial J(u)$ of the functional J at a point $u \in E$ is the following set

$$\left\{w \in E' : \left\langle \Phi'(u), v-u \right\rangle + \Psi(v) - \Psi(u) \geq \langle w, v-u \rangle, \forall v \in E \right\}; \tag{3.1}$$

(ii) A critical point of J is a point $u \in E$ such that $J(u) < +\infty$ and $0 \in \partial J(u)$, i.e.

$$\left\langle \Phi'(u), v-u \right\rangle + \Psi(v) - \Psi(u) \geq 0, \quad \forall v \in E; \tag{3.2}$$

(iii) A Palais–Smale sequence at level d for J is a sequence $(u_n) \subset E$ such that $J(u_n) \to d$ and there exists a numerical sequence $\tau_n \to 0^+$ with

$$\left\langle \Phi'(u_n), v-u_n \right\rangle + \Psi(v) - \Psi(u_n) \geq -\tau_n \|v-u_n\|, \quad \forall v \in E;$$

(iv) The functional J satisfies the Palais–Smale condition at level d ($(\mathrm{PS})_d$ condition, for short) if all Palais–Smale sequences at level d have a convergent subsequence;

(v) The effective domain of J is the set $D(J) = \{u \in E : J(u) < +\infty\}$.

In what follows, for each $u \in D(\mathcal{I}_\epsilon)$, we set the functional $\mathcal{I}'_\epsilon(u) : \mathcal{H}_{\epsilon,c} \to \mathbb{R}$ given by

$$\left\langle \mathcal{I}'_\epsilon(u), z \right\rangle = \left\langle \Phi'_\epsilon(u), z \right\rangle - \int F'_1(u) z \mathrm{d}x, \quad \forall z \in \mathcal{H}_{\epsilon,c},$$

where

$$\mathcal{H}_{\epsilon,c} = \{u \in \mathcal{H}_\epsilon : u \text{ has compact support } \},$$

and define

$$\|\mathcal{I}'_\epsilon(u)\| = \sup\left\{\left\langle \mathcal{I}'_\epsilon(u), z \right\rangle : z \in \mathcal{H}_{\epsilon,c} \text{ and } \|z\|_\epsilon \leq 1\right\}.$$

If $\|\mathcal{I}'_\epsilon(u)\|$ is finite, then $\mathcal{I}'_\epsilon(u)$ may be extended to a bounded operator in $\mathcal{H}_\epsilon$, and so, it can be seen as an element of $\mathcal{H}'_\epsilon$.

Lemma 3.2. *Let $\mathcal{I}_\epsilon$ satisfy (2.4), then:*

(i) *If $u \in D(\mathcal{I}_\epsilon)$ is a critical point of $\mathcal{I}_\epsilon$. Then, the following hold:*

$$\left\langle \Phi'_\epsilon(u), v-u \right\rangle + \Psi(v) - \Psi(u) \geq 0, \quad \forall v \in \mathcal{H}_\epsilon;$$

(ii) *For each $u \in D(\mathcal{I}_\epsilon)$ such that $\|\mathcal{I}'_\epsilon(u)\| < +\infty$, we have $\partial \mathcal{I}_\epsilon(u) \neq \emptyset$, that is, there exists $w \in \mathcal{H}'_\epsilon$, which is denoted by $w = \mathcal{I}'_\epsilon(u)$, such that*

$$\left\langle \Phi'_\epsilon(u), v-u \right\rangle + \int_{\mathbb{R}^3} F_1(v) \mathrm{d}x - \int_{\mathbb{R}^3} F_1(u) \mathrm{d}x \geq \langle w, v-u \rangle, \quad \forall v \in \mathcal{H}_\epsilon;$$

(iii) *If a function $u \in D(\mathcal{I}_\epsilon)$ is a critical point of $\mathcal{I}_\epsilon$, then u is a solution of (2.3);*

(iv) *If $(u_n) \subset \mathcal{H}_\epsilon$ is a Palais–Smale sequence, then*

$$\left\langle \mathcal{I}'_\epsilon(u_n), z \right\rangle = o_n(1) \|z\|_\epsilon, \quad \forall z \in \mathcal{H}_{\epsilon,c};$$

(v) *If Ω is a bounded domain with regular boundary, then Ψ (and hence $\mathcal{I}_\epsilon$) is of class C^1 in $H^s(\Omega)$. More precisely, the functional*

$$\Psi(u) = \int_\Omega F_1(u) \mathrm{d}x, \quad \forall u \in H^s(\Omega)$$

belongs to $C^1(H^s(\Omega), \mathbb{R})$.

Proof. (i) follows from (3.2). (ii) can be obtained arguing as in the proof of Squassina–Szulkin [27] and recalling that $C_c^\infty(\mathbb{R}^3)$ is dense in $\mathcal{H}_\epsilon$. (iii) and (iv) follow the same lines of the proofs of Ji–Szulkin [16]. To verify (v), since $|F_1'(\tau)| \le C(1+|\tau|^{q-1})$ with $q \in (2, 2_s^*)$, it is enough to proceed as in the proof of Willem [30]. □

As a consequence of the above proprieties, we have the following result.

Lemma 3.3. *If $u \in D(\mathcal{I}_\epsilon)$ and $\|\mathcal{I}_\epsilon'(u)\| < +\infty$, then $F_1'(u)u \in L^1(\mathbb{R}^3)$.*

Proof. Let $\varpi \in C_c^\infty(\mathbb{R}^3)$ be such that $0 \le \varpi \le 1$ in $\mathbb{R}^3$, $\varpi(x) = 1$ for $|x| \le 1$ and $\varpi(x) = 0$ for $|x| \ge 2$. For $R > 0$ and $u \in D(\mathcal{I}_\epsilon)$, let $\varpi_R(x) = \varpi(\frac{x}{R})$ and $u_R(x) = \varpi_R(x)u(x)$. Let us prove that

$$\lim_{R\to\infty} \|u_R - u\|_\epsilon = 0. \tag{3.3}$$

Clearly, $u_R \to u$ in $L^2(\mathbb{R}^3)$. On the other hand,

$$\begin{aligned}[u_R - u]^2 &\le 2\left[\iint_{\mathbb{R}^6} \frac{|\varpi_R(x) - \varpi_R(y)|^2}{|x-y|^{3+2s}}|u(x)|^2 \mathrm{d}x\mathrm{d}y + \iint_{\mathbb{R}^6} \frac{|u(x) - u(y)|^2}{|x-y|^{3+2s}}|\varpi_R(x) - 1|^2 \mathrm{d}x\mathrm{d}y\right] \\ &= 2\left[\mathcal{A}_R + \mathcal{B}_R\right].\end{aligned}$$

Since

$$\begin{aligned}\mathcal{A}_R &= \iint_{\mathbb{R}^6} \frac{|\varpi_R(x) - \varpi_R(y)|^2}{|x-y|^{3+2s}}|u(x)|^2 \mathrm{d}x\mathrm{d}y \\ &= \int_{\mathbb{R}^3} |u(x)|^2 \left(\int_{|x-y|>R} \frac{|\varpi_R(x) - \varpi_R(y)|^2}{|x-y|^{3+2s}}\mathrm{d}x + \int_{|x-y|\le R} \frac{|\varpi_R(x) - \varpi_R(y)|^2}{|x-y|^{3+2s}}\mathrm{d}x\right)\mathrm{d}y \\ &\le \int_{\mathbb{R}^3} |u(x)|^2 \left(\int_{|x-y|>R} \frac{4\|\varpi\|^2_{L^\infty(\mathbb{R}^3)}}{|x-y|^{3+2s}}\mathrm{d}x + R^{-2}\int_{|x-y|\le R} \frac{\|\nabla\varpi\|^2_{L^\infty(\mathbb{R}^3)}}{|x-y|^{3+2s}}\mathrm{d}x\right)\mathrm{d}y \\ &\le C\int_{\mathbb{R}^3} |u(x)|^2 \mathrm{d}y \left(\int_R^\infty \frac{1}{r^{2s+1}}\mathrm{d}r + R^{-2}\int_0^R \frac{1}{r^{2s-1}}\mathrm{d}r\right) \\ &\le \frac{C}{R^{2s}},\end{aligned}$$

it follows that $0 \le \mathcal{A}_R \to 0$. Moreover, $\mathcal{B}_R \to 0$ by the dominated convergence theorem. Then, (3.3) holds.

From Lemma 3.2-(ii),

$$\langle \Phi_\epsilon'(u), u_R\rangle + \int_{\mathbb{R}^3} F_1'(u_R)u_R \mathrm{d}x = \langle w, u_R\rangle, \quad \forall w \in \mathcal{H}_\epsilon'. \tag{3.4}$$

Then, combining (3.3), (3.4) with Lemma 3.2-(v), we can see that $\int_{\mathbb{R}^3} F_1'(u)u_R \mathrm{d}x \le C$ for large $R > 0$. From $u_R \to u$ a.e. in $\mathbb{R}^3$ as $R \to \infty$ and Fatou's lemma, we derive that

$$\int_{\mathbb{R}^3} F_1'(u)u\mathrm{d}x \le \liminf_{R\to\infty} \int_{\mathbb{R}^3} F_1'(u)u_R \mathrm{d}x \le \liminf_{R\to\infty} \int_{\mathbb{R}^3} F_1'(u)\varpi_R \mathrm{d}x \le C$$

The proof has been completed. □

An immediate consequence of the last lemma is the following.

Corollary 3.4. *For each $u \in D(\mathcal{I}_\epsilon)\backslash\{0\}$ with $\|\mathcal{I}'_\epsilon(u)\| < +\infty$, we have that*

$$\mathcal{I}'_\epsilon(u)u = [u]^2 + \int_{\mathbb{R}^3} V(\epsilon x)u^2 \mathrm{d}x - \int_{\mathbb{R}^3} \phi_u^t u^2 \mathrm{d}x - \int_{\mathbb{R}^3} u^2 \log u^2 \mathrm{d}x,$$

and

$$\mathcal{I}_\epsilon(u) - \frac{1}{2}\mathcal{I}'_\epsilon(u)u = \frac{1}{2}\int_{\mathbb{R}^3} u^2 \mathrm{d}x + \frac{1}{4}\int_{\mathbb{R}^3} \phi_u^t u^2 \mathrm{d}x.$$

Corollary 3.5. *If $(u_n) \subset \mathcal{H}_\epsilon$ is a* (PS) *sequence for $\mathcal{I}_\epsilon$, then $\mathcal{I}'_\epsilon(u_n)u_n = o_n(1)\|u_n\|_\epsilon$. If (u_n) is bounded, we have*

$$\begin{aligned}\mathcal{I}_\epsilon(u_n) &= \mathcal{I}_\epsilon(u_n) - \frac{1}{2}\mathcal{I}'_\epsilon(u_n)u_n + o_n(1)\|u_n\|_\epsilon \\ &= \frac{1}{2}\int_{\mathbb{R}^3} u_n^2 \mathrm{d}x + \frac{1}{4}\int_{\mathbb{R}^3} \phi_{u_n}^t u_n^2 \mathrm{d}x + o_n(1)\|u_n\|_\epsilon, \forall n \in \mathbb{N}.\end{aligned}$$

Corollary 3.6. *If $u \in \mathcal{H}_\epsilon$ is a critical point of $\mathcal{I}_\epsilon$ and $v \in \mathcal{H}_\epsilon$ verifies $F_1'(u)v \in L^1(\mathbb{R}^3)$, then $\mathcal{I}'_\epsilon(u)v = 0$.*

Now, we will prove some results that will be useful in the proof of Theorem 1.1.

Lemma 3.7. *For any $\epsilon > 0$, all* (PS) *sequences of $\mathcal{I}_\epsilon$ are bounded in $\mathcal{H}_\epsilon$.*

Proof. Let (u_n) be a $(\mathrm{PS})_d$ sequence. By Corollary 3.5, one concludes

$$\begin{aligned}\int_{\mathbb{R}^3} u_n^2 \mathrm{d}x + \frac{1}{2}\int_{\mathbb{R}^3} \phi_{u_n}^t u_n^2 \mathrm{d}x &= 2\mathcal{I}_\epsilon(u_n) - \mathcal{I}'_\epsilon(u_n)u_n \\ &= 2d + o_n(1) + o_n(1)\|u_n\|_\epsilon \\ &\leq C + o_n(1)\|u_n\|_\epsilon,\end{aligned}$$

for some $C > 0$. Consequently,

$$\|u_n\|_\epsilon^2 \leq C + o_n(1)\|u_n\|_\epsilon. \tag{3.5}$$

Let us employ the following logarithmic Sobolev inequality found in Lieb–Loss [17],

$$\int_{\mathbb{R}^3} u^2 \log u^2 \mathrm{d}x \leq \frac{a^2}{\pi}|\nabla u|_2^2 + \left(\log|u|_2^2 - 3(1+\log a)\right)|u|_2^2, \tag{3.6}$$

for all $a > 0$. Fixing $\frac{a^2}{\pi} = \frac{1}{4}$ and $\xi \in (0,1)$, the inequalities (3.5) and (3.6) yield that

$$\begin{aligned}\int_{\mathbb{R}^3} u_n^2 \log u_n^2 \mathrm{d}x &\leq \frac{1}{4}|\nabla u_n|_2^2 + C\left(\log|u_n|_2^2 + 1\right)|u_n|_2^2 \\ &\leq \frac{1}{4}|\nabla u_n|_2^2 + C_1\left(1+\|u_n\|_\epsilon\right)^{1+\xi}.\end{aligned} \tag{3.7}$$

Then by (3.7), we have that

$$\begin{aligned}d + o_n(1) &= \mathcal{I}_\epsilon(u_n) - \frac{1}{4}\mathcal{I}'_\epsilon(u_n)u_n \\ &\geq \frac{1}{4}\|u_n\|_\epsilon^2 - \frac{1}{4}\int_{\mathbb{R}^3} u_n^2 \log u_n^2 \mathrm{d}x \\ &\geq C\left(\|u_n\|_\epsilon^2 - (1+\|u_n\|_\epsilon)^{1+\xi}\right),\end{aligned}$$

which shows that the sequence (u_n) is bounded. □

Lemma 3.8. *Suppose that V satisfies (V_1)–(V_3). For each $\sigma > 0$, there exists $\epsilon_0 = \epsilon_0(\sigma) > 0$ such that, if (u_n) is a $(\mathrm{PS})_c$ sequence for $\mathcal{I}_\epsilon$ with $c \in (m(c_0) + \sigma/2, 2m(c_0) - \sigma)$ and $\epsilon \in (0, \epsilon_0)$, then (u_n) has a weak limit $u_0 \neq 0$.*

Proof. We shall prove the lemma arguing by contradiction, by supposing that there exists $\sigma > 0$, a sequence $\epsilon_n \to 0$ and $(u_m^n) \subset \mathcal{H}_\epsilon$ such that

$$\lim_{m\to+\infty} \mathcal{I}_{\epsilon_n}(u_m^n) = c_n \quad \text{and} \quad \lim_{m\to+\infty} \|\mathcal{I}'_{\epsilon_n}(u_m^n)\| = 0,$$

with $u_m^n \rightharpoonup 0$, as $m \to +\infty$.

Claim I: There exists $\delta > 0$, such that

$$\liminf_{m\to+\infty} \sup_{y\in\mathbb{R}^3} \int_{B_R(y)} |u_m^n|^2 \,\mathrm{d}x \geq \delta, \quad \forall n \in \mathbb{N}.$$

Indeed, if the Claim does not hold, there is $(n_j) \subset \mathbb{N}$ satisfying

$$\liminf_{m\to+\infty} \sup_{y\in\mathbb{R}^3} \int_{B_R(y)} \left|u_m^{n_j}\right|^2 \mathrm{d}x \leq \frac{1}{j}, \quad \forall j \in \mathbb{N}.$$

Then, for each $j \in \mathbb{N}$, there is m_j large enough such that

$$\sup_{y\in\mathbb{R}^3} \int_{B_R(y)} |u_{m_j}^{n_j}|^2 \mathrm{d}x \leq \frac{2}{j}, \quad |\mathcal{I}_{\epsilon_n}(u_{n_m}^{n_j}) - c_{n_j}| \leq \frac{1}{j}, \quad \text{and} \quad \left\|\mathcal{I}'_{\epsilon_n}(u_{m_j}^{n_j})\right\| \leq \frac{1}{j}, \quad \forall j \in \mathbb{N}. \tag{3.8}$$

Setting $w_j = u_{m_j}^{n_j}$, it shows that (w_j) is a bounded sequence, and by Lions [18],

$$\limsup_{j\to+\infty} |w_j|_p = 0, \quad \forall p \in (2, 2_s^*).$$

Then, we can see

$$\limsup_{j\to+\infty} \int_{\mathbb{R}^3} F_2'(w_j)\, w_j \mathrm{d}x = 0 \quad \text{and} \quad \limsup_{j\to+\infty} \int_{\mathbb{R}^3} \phi_{w_j}^t w_j^2 \mathrm{d}x = 0.$$

On the other hand, it follows from (3.8) that

$$\begin{aligned} \|w_j\|_{\epsilon_{n_j}}^2 + \int_{\mathbb{R}^3} F_1'(w_j) w_j \mathrm{d}x &= \mathcal{I}'_{\epsilon_{n_j}}(w_j) w_j + \int_{\mathbb{R}^3} F_2'(w_j) w_j \mathrm{d}x + \int_{\mathbb{R}^3} \phi_{w_j}^t w_j^2 \mathrm{d}x \\ &\leq o_j(1) \|w_j\|_{\epsilon_{n_j}}, \end{aligned}$$

where it follows that

$$\limsup_{j\to+\infty} \|w_j\|_{\epsilon_{n_j}}^2 = 0 \quad \text{and} \quad \limsup_{j\to+\infty} \int_{\mathbb{R}^3} F_1'(w_j) w_j \mathrm{d}x = 0.$$

Combining this fact with convexity of F_1, we can see that

$$\limsup_{j\to+\infty} \int_{\mathbb{R}^3} F_1(w_j) \mathrm{d}x = 0.$$

The above analysis imply that $\mathcal{I}_{\epsilon_{n_j}}(w_j) \to 0$ as $j \to +\infty$, and so, $c_{n_j} \to 0$ as $j \to +\infty$, which is contradictory because $c_{n_j} > m(c_0) + \sigma/2$ for all $j \in \mathbb{N}$. This proves the Claim I.

For each $n \in \mathbb{N}$, there exists $(z_m^n) \subset \mathbb{R}^3$ such that

$$\int_{B_R(z_m^n)} |u_m^n|^2 \,\mathrm{d}x \geq \frac{\delta}{2}, \quad \forall n \in \mathbb{N}.$$

Since $u_m^n \rightharpoonup 0$ as $m \to +\infty$, we have that $|z_m^n| \to +\infty$ as $m \to +\infty$. From the above study, for each $n \in \mathbb{N}$, we fix $m_n \in \mathbb{N}$ large enough satisfying

$$\int_{B_R(z_m^n)} |u_m^n|^2 \mathrm{d}x \geq \frac{\delta}{2}, \quad |\epsilon_n z_{m_n}^n| \geq n, \quad \|\mathcal{I}'_{\epsilon_n}(u_{m_n}^n)\|_\epsilon \leq \frac{1}{n} \quad \text{and} \quad |\mathcal{I}_{\epsilon_n}(u_{m_n}^n) - c_n| \leq \frac{1}{n}.$$

In what follows, we denote by (z_n) and (u_n) the sequences $(z_{m_n}^n)$ and $(u_{m_n}^n)$ respectively. Then,

$$\int_{B_R(z_n)} |u_n|^2 \mathrm{d}x \geq \frac{\delta}{2}, \quad |\epsilon_n z_n| \geq n, \quad \|\mathcal{I}'_{\epsilon_n}(u_n)\|_\epsilon \leq \frac{1}{n} \quad \text{and} \quad |\mathcal{I}_{\epsilon_n}(u_n) - c_n| \leq \frac{1}{n}.$$

The boundedness of (u_n) follows by standard arguments. Then, for some subsequence, there exists $u \in \mathcal{H}_\epsilon$ such that

$$u_n \rightharpoonup u \quad \text{in } \mathcal{H}_\epsilon.$$

Considering $\omega_n = u_n(\cdot + z_n)$, we have that (ω_n) is bounded in $\mathcal{H}_\epsilon$. Thus, there exists $\omega \in \mathcal{H}_\epsilon$ such that

$$\omega_n \rightharpoonup \omega \quad \text{in } \mathcal{H}_\epsilon,$$

and

$$\int_{B_R(0)} |\omega|^2 \mathrm{d}x = \liminf_{n\to+\infty} \int_{B_R(0)} |\omega_n|^2 \,\mathrm{d}x = \liminf_{n\to+\infty} \int_{B_R(z_n)} |u_n|^2 \mathrm{d}x \geq \frac{\delta}{2},$$

which implies that $\omega \neq 0$.

Now, for each $\varphi \in C_0^\infty(\mathbb{R}^3)$, we have the equality below

$$\begin{aligned} &\iint_{\mathbb{R}^6} \frac{(\omega_n(x) - \omega_n(y))(\varphi(x) - \varphi(y))}{|x-y|^{3+2s}} \mathrm{d}x\mathrm{d}y + \int_{\mathbb{R}^3} V(\epsilon_n z_n + \epsilon_n x)\, \omega_n \varphi \mathrm{d}x \\ &\quad - \int_{\mathbb{R}^3} \phi_{\omega_n}^t \omega_n \varphi \mathrm{d}x - \int_{\mathbb{R}^3} \omega_n \varphi \log \omega_n^2 \mathrm{d}x = o_n(1)\|\varphi\|_\epsilon, \end{aligned} \tag{3.9}$$

showing that ω is a nontrivial solution of the problem

$$(-\Delta)^s u + \alpha_1 u - \phi_u^t u = u \log u^2 \quad \text{in } \mathbb{R}^3, \tag{3.10}$$

where

$$\alpha_1 = \lim_{n\to+\infty} V(\epsilon_n z_n).$$

From Cabré–Sire [8], Caffarelli–Silvestre [9] and d'Avenia–Montefusco–Squassina [11], we can see that $\omega \in C^2(\mathbb{R}^3) \cap \mathcal{H}_\epsilon$.

For each $k \in \mathbb{N}$, there is $\varphi_k \in C_0^\infty(\mathbb{R}^3)$ such that

$$\|\varphi_k - \omega\|_\epsilon \to 0 \quad \text{as } k \to +\infty,$$

that is,

$$\|\varphi_k - \omega\|_\epsilon = o_k(1).$$

Using $\frac{\partial\varphi_k}{\partial x_i}$ as a test function of (3.9), we have

$$\iint_{\mathbb{R}^6} \frac{(\omega_n(x)-\omega_n(y))(\frac{\partial\varphi_k}{\partial x_i}(x)-\frac{\partial\varphi_k}{\partial x_i}(y))}{|x-y|^{3+2s}}\mathrm{d}x\mathrm{d}y + \int_{\mathbb{R}^3} V(\epsilon_n z_n+\epsilon_n x)\,\omega_n\frac{\partial\varphi_k}{\partial x_i}\mathrm{d}x$$
$$-\int_{\mathbb{R}^3}\phi^t_{\omega_n}\omega_n\frac{\partial\varphi_k}{\partial x_i}\mathrm{d}x - \int_{\mathbb{R}^3}\omega_n\frac{\partial\varphi_k}{\partial x_i}\log\omega_n^2\mathrm{d}x = o_n(1).$$

Observing that

$$\iint_{\mathbb{R}^6} \frac{(\omega_n(x)-\omega_n(y))(\frac{\partial\varphi_k}{\partial x_i}(x)-\frac{\partial\varphi_k}{\partial x_i}(y))}{|x-y|^{3+2s}}\mathrm{d}x\mathrm{d}y$$
$$= \iint_{\mathbb{R}^6} \frac{(\omega(x)-\omega(y))(\frac{\partial\varphi_k}{\partial x_i}(x)-\frac{\partial\varphi_k}{\partial x_i}(y))}{|x-y|^{3+2s}}\mathrm{d}x\mathrm{d}y + o_n(1),$$

$$\int_{\mathbb{R}^3}\phi^t_{\omega_n}\omega_n\frac{\partial\varphi_k}{\partial x_i}\mathrm{d}x = \int_{\mathbb{R}^3}\phi^t_{\omega_n}\omega\frac{\partial\varphi_k}{\partial x_i}\mathrm{d}x + o_n(1),$$

and

$$\int_{\mathbb{R}^3}\omega_n\frac{\partial\varphi_k}{\partial x_i}\log\omega_n^2\mathrm{d}x = \int_{\mathbb{R}^3}\omega\frac{\partial\varphi_k}{\partial x_i}\log\omega^2\mathrm{d}x + o_n(1).$$

Gathering the above limit with (3.10), we derive that

$$\limsup_{n\to+\infty}\left|\int_{\mathbb{R}^3}\left(V(\epsilon_n z_n+\epsilon_n x)-V(\epsilon_n z_n)\right)\omega_n\frac{\partial\varphi_k}{\partial x_i}\mathrm{d}x\right| = 0.$$

As φ_k has compact support, the above limit gives

$$\limsup_{n\to+\infty}\left|\int_{\mathbb{R}^3}\left(V(\epsilon_n z_n+\epsilon_n x)-V(\epsilon_n z_n)\right)\omega\frac{\partial\varphi_k}{\partial x_i}\mathrm{d}x\right| = 0.$$

Recalling that $\frac{\partial\omega}{\partial x_i}\in L^2(\mathbb{R}^3)$, we have that $(\frac{\partial\varphi_k}{\partial x_i})$ is bounded in $L^2(\mathbb{R}^3)$. Then,

$$\limsup_{n\to+\infty}\left|\int_{\mathbb{R}^3}\left(V(\epsilon_n z_n+\epsilon_n x)-V(\epsilon_n z_n)\right)\varphi_k\frac{\partial\varphi_k}{\partial x_i}\mathrm{d}x\right| = o_k(1),$$

and so,

$$\limsup_{n\to+\infty}\left|\frac{1}{2}\int_{\mathbb{R}^3}\left(V(\epsilon_n z_n+\epsilon_n x)-V(\epsilon_n z_n)\right)\frac{\partial\left(\varphi_k^2\right)}{\partial x_i}\mathrm{d}x\right| = o_k(1).$$

Using Green's Theorem together with the fact that φ_k has compact support, we get the limit below

$$\limsup_{n\to+\infty}\left|\int_{\mathbb{R}^3}\frac{\partial V}{\partial x_i}(\epsilon_n z_n+\epsilon_n x)\,\varphi_k^2\mathrm{d}x\right| = o_k(1),$$

which combined with (V_2) loads to

$$\limsup_{n\to+\infty}\left|\frac{\partial V}{\partial x_i}(\epsilon_n z_n)\int_{\mathbb{R}^3}|\varphi_k|^2\mathrm{d}x\right| = o_k(1).$$

As

$$\int_{\mathbb{R}^3}|\varphi_k|^2\,\mathrm{d}x \to \int_{\mathbb{R}^3}|\omega|^2\mathrm{d}x > 0 \quad \text{as } k\to+\infty,$$

it shows that

$$\limsup_{n\to+\infty}\left|\frac{\partial V}{\partial x_i}(\epsilon_n z_n)\right| = o_k(1), \quad \forall i \in \{1,2,3\}.$$

Since k is arbitrary, we obtain

$$\nabla V(\epsilon_n z_n) \to 0 \quad \text{and} \quad V(\epsilon_n z_n) \to \alpha_1,$$

as $n \to \infty$. Therefore, $(\epsilon_n z_n)$ is a $(\mathrm{PS})_{\alpha_1}$ sequence for V, which is a contradiction, because by hypotheses V satisfies the (PS) condition and $(\epsilon_n z_n)$ does not have any convergent subsequence in $\mathbb{R}^3$. Thus, the proof is completed. □

Hereafter, we denote by $\mathcal{N}_\epsilon$ the Nehari manifold associated with $\mathcal{I}_\epsilon$, that is,

$$\mathcal{N}_\epsilon = \{u \in \mathcal{H}_\epsilon \backslash \{0\} : \mathcal{I}'_\epsilon(u)u = 0\}.$$

The next lemma will be crucial in our study to show an important estimate.

Lemma 3.9. *Let $\epsilon_n \to 0$ and $(u_n) \subset \mathcal{N}_{\epsilon_n}$ such that $\mathcal{I}_{\epsilon_n}(u_n) \to m(c_0)$. Then, there are $(z_n) \subset \mathbb{R}^3$ with $|z_n| \to +\infty$ and $u_1 \in \mathcal{H}_\epsilon \backslash \{0\}$ such that*

$$u_n(\cdot + z_n) \to u_1 \quad \text{in } \mathcal{H}_\epsilon.$$

Moreover,

$$\liminf_{n\to+\infty} |\epsilon_n z_n| > 0.$$

Proof. Since $u_n \in \mathcal{N}_{\epsilon_n}$, we can see that $\mathcal{I}'_{c_0}(u_n)\, u_n \le 0$ and $\mathcal{I}_{c_0}(u) \le \mathcal{I}_{\epsilon_n}(u)$ for all $u \in \mathcal{H}_\epsilon$ and $n \in \mathbb{N}$. Then, there exists $\tau_n \in (0,1]$ such that

$$(\tau_n u_n) \subset \mathcal{N}_{c_0} \quad \text{and} \quad \mathcal{I}_{c_0}(\tau_n u_n) \to m(c_0).$$

Since (τ_n) is bounded, by Alves–de Morais Filho [2], there exist $(z_n) \subset \mathbb{R}^3$, $u_1 \in \mathcal{H}_\epsilon \backslash \{0\}$, and a subsequence of (u_n), still denote by (u_n), verifying

$$u_n(\cdot + z_n) \to u_1 \quad \text{in } \mathcal{H}_\epsilon.$$

Claim II:

$$\liminf_{n\to+\infty} |\epsilon_n z_n| > 0.$$

Indeed, since $u_n \in \mathcal{N}_{\epsilon_n}$ for all $n \in N$, the function $u_n^1 = u_n(\cdot + z_n)$ must verify

$$\begin{aligned}[t] [u_n^1]^2 + \int_{\mathbb{R}^3} V(\epsilon_n z_n + \epsilon_n x)\left|u_n^1\right|^2 \mathrm{d}x - \int_{\mathbb{R}^3} \phi^t_{u_n^1}|u_n^1|^2 \mathrm{d}x + \int_{\mathbb{R}^3} F_1'\left(u_n^1\right) u_n^1 \mathrm{d}x \\ = \int_{\mathbb{R}^3} F_2'\left(u_n^1\right) u_n^1 \mathrm{d}x. \end{aligned} \tag{3.11}$$

Since F_1 is convex, even and $F_1(\tau) \ge F_1(0) = 0$ for all $\tau \in \mathbb{R}$, we can derive that $0 \le F_1(\tau) \le F_1'(\tau)\tau$ for all $\tau \in \mathbb{R}$. Supposing by contradiction that for some subsequence

$$\lim_{n\to+\infty} \epsilon_n z_n = 0.$$

Taking the limit of $n \to +\infty$ in (3.11), we have

$$[u_1]^2 + \int_{\mathbb{R}^3} V(0)\,|u_1|^2 \mathrm{d}x - \int_{\mathbb{R}^3} \phi^t_{u_1}|u_1|^2 \mathrm{d}x + \int_{\mathbb{R}^3} F_1'(u_1)\, u_1 \mathrm{d}x \le \int_{\mathbb{R}^3} F_2'(u_1)\, u_1 \mathrm{d}x.$$

Then, there is $\tau_1 \in (0,1]$ such that $\tau_1 u_1 \in \mathcal{M}_{V(0)}$. Thus, since $V(0) > c_0$, we derive that

$$\mathcal{I}_{V(0)}(\tau_1 u_1) \geq m(V(0)) > m(c_0) > 0. \tag{3.12}$$

On the other hand,

$$\mathcal{I}_{\epsilon_n}(u_n) \to \mathcal{I}_{V(0)}(\tau_1 u_1),$$

which leads to

$$m(c_0) \geq \mathcal{I}_{V(0)}(\tau_1 u_1). \tag{3.13}$$

From (3.12) and (3.13), we can find a contradiction, which finishes the proof. □

4 A special minimax level

To prove Theorem 1.1, we shall consider a special minimax level. To do that, we begin fixing the barycenter function by

$$\beta(u) = \frac{\int_{\mathbb{R}^3} \frac{x}{|x|} |u|^2 \mathrm{d}x}{\int_{\mathbb{R}^3} |u|^2 \mathrm{d}x}, \quad \forall u \in \mathcal{H}_\epsilon \backslash \{0\}.$$

For each $z \in \mathbb{R}^N$ and $\epsilon > 0$, let us define the function

$$\varphi_{\epsilon,z}(x) = \tau_{\epsilon,z} u_0 \left(x - \frac{z}{\epsilon}\right),$$

where $\tau_{\epsilon,z} > 0$ is such that $\varphi_{\epsilon,z} \in \mathcal{N}_\epsilon$ and u_0 is a radial positive ground state solution for $\mathcal{I}_{c_0}$, that is,

$$\mathcal{I}_{c_0}(u_0) = m(c_0) \quad \text{and} \quad \mathcal{I}'_{c_0}(u_0) = 0.$$

In what follows, we set $\Upsilon_\epsilon(z) = \varphi_{\epsilon,z}$ for all $z \in \mathbb{R}^3$.

Lemma 4.1. *The function $\Upsilon_\epsilon : \mathbb{R}^3 \to \mathcal{N}_\epsilon$ is a continuous function.*

Proof. Let $(z_n) \subset \mathbb{R}^3$ and $z \in \mathbb{R}^3$ with $z_n \to z$ in $\mathbb{R}^3$. We must prove that

$$\Upsilon_\epsilon(z_n) \to \Upsilon_\epsilon(z) \quad \text{in } \mathcal{H}_\epsilon.$$

Here, the main point is to prove that

$$\tau_{\epsilon,z_n} \to \tau_{\epsilon,z} \quad \text{in } \mathbb{R}.$$

By definition of τ_{ϵ,z_n} and $\tau_{\epsilon,z}$, they are the unique numbers that satisfy

$$\mathcal{I}_\epsilon\left(\tau_{\epsilon,z_n} u_0\left(\cdot - \frac{z_n}{\epsilon}\right)\right) = \frac{1}{2}\int_{\mathbb{R}^3} \left|\tau_{\epsilon,z_n} u_0\left(x - \frac{z_n}{\epsilon}\right)\right|^2 \mathrm{d}x,$$

and

$$\mathcal{I}_\epsilon\left(\tau_{\epsilon,z} u_0\left(\cdot - \frac{z}{\epsilon}\right)\right) = \frac{1}{2}\int_{\mathbb{R}^3} \left|\tau_{\epsilon,z} u_0\left(x - \frac{z}{\epsilon}\right)\right|^2 \mathrm{d}x,$$

that is,

$$\begin{aligned} &\frac{1}{2}[\tau_{\epsilon,z_n} u_0]^2 + \frac{1}{2}\int_{\mathbb{R}^3} (V(\epsilon x + z_n) + 1) |\tau_{\epsilon,z_n} u_0|^2 \mathrm{d}x - \frac{1}{4}\int_{\mathbb{R}^3} \phi^t_{\tau_{\epsilon,z_n} u_0} |\tau_{\epsilon,z_n} u_0|^2 \mathrm{d}x \\ &\quad + \int_{\mathbb{R}^3} F_1(\tau_{\epsilon,z_n} u_0)\,\mathrm{d}x - \int_{\mathbb{R}^3} F_2(\tau_{\epsilon,z_n} u_0)\,\mathrm{d}x = \frac{1}{2}\int_{\mathbb{R}^3} |\tau_{\epsilon,z_n} u_0|^2 \mathrm{d}x, \end{aligned} \tag{4.1}$$

and

$$\frac{1}{2}[\tau_{\epsilon,z}u_0]^2 + \frac{1}{2}\int_{\mathbb{R}^3} \left(V\left(\epsilon x + z\right) + 1\right)\left|\tau_{\epsilon,z}u_0\right|^2 \mathrm{d}x - \frac{1}{4}\int_{\mathbb{R}^3} \phi^t_{\tau_{\epsilon,z}u_0}|\tau_{\epsilon,z}u_0|^2\mathrm{d}x$$
$$+ \int_{\mathbb{R}^3} F_1\left(\tau_{\epsilon,z}u_0\right)\mathrm{d}x - \int_{\mathbb{R}^3} F_2\left(\tau_{\epsilon,z}u_0\right)\mathrm{d}x = \frac{1}{2}\int_{\mathbb{R}^3} \left|\tau_{\epsilon,z}u_0\right|^2 \mathrm{d}x.$$

A simple calculation gives that (τ_{ϵ,z_n}) is bounded, thus for some subsequence, we can assume that $\tau_{\epsilon,z_n} \to \tau_*$. Since F_1 is increasing in $[0,+\infty)$ and $F_1(\zeta u_0) \in L^1(\mathbb{R}^3)$ for all $\zeta > 0$, taking the limit of $n \to +\infty$ in (4.1) and using the Lebesgue Theorem, we have

$$\frac{1}{2}[\tau_* u_0]^2 + \frac{1}{2}\int_{\mathbb{R}^3} \left(V\left(\epsilon x + z\right) + 1\right)\left|\tau_* u_0\right|^2 \mathrm{d}x - \frac{1}{4}\int_{\mathbb{R}^3} \phi^t_{\tau_* u_0}|\tau_* u_0|^2\mathrm{d}x$$
$$+ \int_{\mathbb{R}^3} F_1\left(\tau_* u_0\right)\mathrm{d}x - \int_{\mathbb{R}^3} F_2\left(\tau_* u_0\right)\mathrm{d}x = \frac{1}{2}\int_{\mathbb{R}^3} \left|\tau_* u_0\right|^2 \mathrm{d}x,$$

By uniqueness of $\tau_{\epsilon,z}$, it shows that $\tau_{\epsilon,z} = \tau_*$, and so, $\tau_{\epsilon,z_n} \to \tau_{\epsilon,z}$. Then, since

$$u_0\left(\cdot - \frac{z_n}{\epsilon}\right) \to u_0\left(\cdot - \frac{z}{\epsilon}\right) \quad \text{in } \mathcal{H}_\epsilon,$$

the proof is completed. □

We establish several properties involving β and Υ_ϵ.

Lemma 4.2. *For each $r > 0$, we have*

$$\lim_{\epsilon\to 0}\left(\sup\left\{\left|\beta\left(\Upsilon_\epsilon(z)\right) - \frac{z}{|z|}\right| : |z| \geq r\right\}\right) = 0.$$

Proof. It is enough to show that for any $(z_n) \subset \mathbb{R}^3$ with $|z_n| \geq r$ and $\epsilon_n \to 0$, we have that

$$\left|\beta\left(\Upsilon_{\epsilon_n}(z_n)\right) - \frac{z_n}{|z_n|}\right| \to 0 \quad \text{as } n \to +\infty.$$

By change of variables,

$$\left|\beta\left(\Upsilon_{\epsilon_n}(z_n)\right) - \frac{z_n}{|z_n|}\right| = \frac{\int_{\mathbb{R}^3}\left|\frac{\epsilon_n x + z_n}{|\epsilon_n x + z_n|} - \frac{z_n}{|z_n|}\right| |u_0(x)|^2\,\mathrm{d}x}{\int_{\mathbb{R}^3}|u_0(x)|^2\,\mathrm{d}x}.$$

Since for each $x \in \mathbb{R}^3$, we have

$$\left|\frac{\epsilon_n x + z_n}{|\epsilon_n x + z_n|} - \frac{z_n}{|z_n|}\right| \to 0 \quad \text{as } n \to +\infty,$$

by the Lebesgue Dominated Convergence Theorem, we get that

$$\int_{\mathbb{R}^3}\left|\frac{\epsilon_n x + z_n}{|\epsilon_n x + z_n|} - \frac{z_n}{|z_n|}\right| |u_0(x)|^2\,\mathrm{d}x \to 0 \quad \text{as } n \to +\infty,$$

which completes the proof. □

As a by-product of the arguments explored in the proof of the last lemma, we have

Corollary 4.3. *Fixed $r > 0$, there is $\epsilon_0 > 0$ such that*

$$\left(\beta\left(\Upsilon_\epsilon(z)\right), z\right) > 0, \quad \forall |z| \geq r \text{ and } \epsilon \in (0,\epsilon_0).$$

Proof. By Lemma 4.2, for fixed $r > 0$, there is $\epsilon_0 > 0$ such that

$$\left|\beta\left(\Upsilon_\epsilon(z)\right) - \frac{z}{|z|}\right| < \frac{1}{2}, \quad \forall |z| \geq r \text{ and } \epsilon \in (0, \epsilon_0).$$

On the other hand,

$$\begin{aligned}(\beta\left(\Upsilon_\epsilon(z)\right), z) &= \left(\beta\left(\Upsilon_\epsilon(z)\right) - \frac{z}{|z|}, z\right) + \left(\frac{z}{|z|}, z\right) \\ &= \left(\beta\left(\Upsilon_\epsilon(z)\right) - \frac{z}{|z|}, z\right) + |z|, \quad \forall z \in \mathbb{R}^3 \backslash \{0\}.\end{aligned}$$

Therefore, for $|z| \geq r$, we have

$$(\beta\left(\Upsilon_\epsilon(z)\right), z) \geq |z| \left(1 - \left|\beta\left(\Upsilon_\epsilon(z)\right) - \frac{z}{|z|}\right|\right) > \frac{|z|}{2} \geq \frac{r}{2} > 0,$$

showing the corollary. □

In the sequel, we define the set

$$\mathcal{B}_\epsilon = \{u \in \mathcal{N}_\epsilon : \beta(u) \in Y\}.$$

Note that $\mathcal{B}_\epsilon \neq \emptyset$, since $\beta\left(\varphi_{\epsilon,0}\right) = 0 \in Y$, for all $\epsilon > 0$. Associated with the above set, let us consider the real number D_ϵ given by

$$D_\epsilon = \inf_{u \in \mathcal{B}_\epsilon} \mathcal{I}_\epsilon(u).$$

The next lemma establishes an important relation between the levels D_ϵ and $m(c_0)$.

Lemma 4.4. *The following conclusions are valid:*

(a) *There are ϵ_0 and $\sigma > 0$ such that*

$$D_\epsilon \geq m\left(c_0\right) + \sigma, \quad \forall \epsilon \in (0, \epsilon_0).$$

(b)

$$\limsup_{\epsilon \to 0} \left\{\sup_{x \in X} \mathcal{I}_\epsilon(\Upsilon_\epsilon(x))\right\} < 2m\left(c_0\right) - \sigma.$$

Proof. (a) By the definition of D_ϵ, we can see

$$D_\epsilon \geq m(c_0), \quad \forall \epsilon > 0.$$

Supposing by contradiction that the lemma does not hold, there is $\epsilon_n \to 0$ satisfying

$$D_{\epsilon_n} \to m(c_0).$$

Hence, there exists $u_n \in \mathcal{N}_{\epsilon_n}$ with $\beta(u_n) \in Y$ such that

$$\mathcal{I}_{\epsilon_n}(u_n) \to m(c_0).$$

Thereby, by Lemma 3.9, there are $u_1 \in \mathcal{H}_\epsilon \backslash \{0\}$ and a sequence $(z_n) \subset \mathbb{R}^3$ with

$$\liminf_{n \to +\infty} |\epsilon_n z_n| > 0$$

verifying

$$u_n(\cdot + z_n) \to u_1 \quad \text{in } \mathcal{H}_\epsilon,$$

that is

$$u_n = u_1(\cdot - z_n) + \omega_n \quad \text{with } \omega_n \to 0 \text{ in } \mathcal{H}_\epsilon.$$

From the definition of β,

$$\beta(u_1(\cdot - z_n)) = \frac{\int_{\mathbb{R}^3} \frac{\epsilon_n x + \epsilon_n z_n}{|\epsilon_n x + \epsilon_n z_n|} |u_1|^2 \, dx}{\int_{\mathbb{R}^3} |u_1|^2 \, dx}.$$

Repeating the same arguments explored in the proof of Lemma 4.2, we know that

$$\beta(u_1(\cdot - z_n)) = \frac{z_n}{|z_n|} + o_n(1),$$

and so,

$$\beta(u_n) = \beta(u_1(\cdot - z_n)) + o_n(1) = \frac{z_n}{|z_n|} + o_n(1).$$

Since $\beta(u_n) \in Y$, we conclude that $\frac{z_n}{|z_n|} \in Y_\lambda$ for n large enough. Consequently, $z_n \in Y_\lambda$ for n large enough, implying that

$$\liminf_{n\to\infty} V(\epsilon_n z_n) > c_0.$$

If $A = \liminf_{n\to\infty} V(\epsilon_n z_n)$, the last inequality and the Fatou's lemma show that

$$m(c_0) = \liminf_{n\to\infty} \mathcal{I}_{\epsilon_n}(u_n) \geq \liminf_{n\to\infty} \mathcal{I}_{\epsilon_n}(\tau u_n) \geq \mathcal{I}_A(\tau u_1) \geq m(A) > m(c_0),$$

which is a contradiction, recalling that there exists $\tau \in (0,1]$ such that $\mathcal{I}'_A(\tau u_1)\tau u_1 = 0$ and $u_1 \neq 0$.

(b) By $V(0) > c_0$, $c_1 < c_0 + 1$ and the fact that u_0 is a ground state solution associated with $\mathcal{I}_{c_0}$, we infer that

$$\begin{aligned}
\limsup_{\epsilon\to 0} \left\{ \sup_{x\in X} \mathcal{I}_\epsilon(\Upsilon_\epsilon(x)) \right\} &\leq \frac{1}{2}[u_o]^2 + \frac{1}{2}\int_{\mathbb{R}^3} (c_1+1)|u_0|^2 \, dx \\
&\quad - \frac{1}{4}\int_{\mathbb{R}^3} \phi^t_{u_0} |u_0|^2 dx - \frac{1}{2}\int_{\mathbb{R}^3} u_0^2 \log u_0^2 dx \\
&= \mathcal{I}_{c_0}(u_0) + \frac{(c_1 - c_0)}{2}\int_{\mathbb{R}^3} |u_0|^2 \, dx \\
&= \mathcal{I}_{c_0}(u_0) + (c_1 - c_0)\mathcal{I}_{c_0}(u_0) \\
&= (1 + c_1 - c_0)\, m(c_0) \\
&< 2m(c_0),
\end{aligned}$$

which completes the proof. □

Now, we are ready to show the minimax level. We fix $\epsilon \in (0, \epsilon_0)$ and the following sets

$$\mathcal{I}_\epsilon^d = \{u \in \mathcal{H}_\epsilon : \mathcal{I}_\epsilon(u) \leq d\}, \quad Q = \bar{B}_R(0) \cap X \quad \text{and} \quad \partial Q = \partial \bar{B}_R(0) \cap X.$$

By the above notations, we define the class of the functions

$$\Gamma = \{h \in C(Q, K_r) : h(x) = \Upsilon_\epsilon(x), \quad \forall x \in \partial Q\},$$

where $r > 0, K = \Upsilon_\epsilon(Q)$ and $K_r = \{u \in \mathcal{H}_\epsilon : \text{dist}(u, K) < r\}$. Note that $\Gamma \neq \emptyset$, since Lemma 4.1 ensures that $\Upsilon_\epsilon \in \Gamma$. Then, we set

$$\Omega_r = \{u \in K_r : \beta(u) \in Y\},$$

which is not empty because $\Upsilon_\epsilon(0) = \varphi_{\epsilon,0} \in K_r$ for all $r > 0$. Here we have used the fact that $\Upsilon_\epsilon(0) \in \Upsilon_\epsilon(Q)$ and $\beta(\Upsilon_\epsilon(0)) = 0 \in Y$.

Lemma 4.5. *There exists $r_0 > 0$ such that*

$$\Theta_r = \inf_{u \in \Omega_r} \mathcal{I}_\epsilon(u) > m(c_0) + \sigma/2, \quad \forall r \in (0, r_0).$$

Moreover, there is $R > 0$ such that

$$\mathcal{I}_\epsilon(\Upsilon_\epsilon(x)) \leq \frac{1}{2}\left(m(c_0) + \Theta_r\right), \quad \forall x \in \partial B_R(0) \cap X.$$

Proof. Assume by contradiction that the lemma does not hold. Then, there exist $r_n \to 0$ and $u_n \in \Omega_{r_n}$ such that $\mathcal{I}_\epsilon(u_n) \leq m(c_0) + \sigma/2$. By definition of Ω_{r_n}, there exists $v_n \in K$ such that $\|u_n - v_n\| \leq r_n$. Since K is compact, there are a subsequence of (v_n), still denoted by itself, and $v \in K$ such that $v_n \to v$ in $\mathcal{H}_\epsilon$, then $u_n \to v$ in $\mathcal{H}_\epsilon$ and $\beta(v) \in Y$, from where it follows that $v \in \mathcal{B}_\epsilon$, then by Lemma 4.4-$(a)$, $\mathcal{I}_\epsilon(v) \geq m(c_0) + \sigma$. On the other hand, since $\mathcal{I}_\epsilon$ is lower semicontinuous, we have

$$\liminf_{n \to +\infty} \mathcal{I}_\epsilon(u_n) \geq \mathcal{I}_\epsilon(v),$$

which is a contradiction.

By (V_1), given $\delta > 0$, there exist $\epsilon_0 > 0$ and $R > 0$ such that

$$\sup\{\mathcal{I}_\epsilon(\Upsilon_\epsilon(x)) : x \in \partial B_R(0) \cap X\} \leq m(c_0) + \delta, \quad \forall \epsilon \in (0, \epsilon_0).$$

Fixing $\delta = \frac{\sigma}{4}$, where σ was given in Lemma 4.4-(a), we derive

$$\sup\{\mathcal{I}_\epsilon(\Upsilon_\epsilon(x)) : x \in \partial B_R(0) \cap X\} \leq \frac{1}{2}\left(2m(c_0) + \frac{\sigma}{2}\right) < \frac{1}{2}\left(m(c_0) + \Theta_r\right), \quad \forall \epsilon \in (0, \epsilon_0),$$

which completes the proof. □

Lemma 4.6. *If $h \in \Gamma$, then $h(Q) \cap \Omega_r \neq \emptyset$ for all $r \in (0, r_0)$.*

Proof. It is enough to show that for all $h \in \Gamma$, there exists $x_* \in Q$ such that

$$\beta\left(h\left(x_*\right)\right) \in Y.$$

For each $h \in \Gamma$, we set the function $g : Q \to \mathbb{R}^3$ given by

$$g(x) = \beta(h(x)) \quad \forall x \in Q,$$

and the homotopy $\mathcal{F} : [0,1] \times Q \to X$ as

$$\mathcal{F}(\tau, x) = \tau P_X(g(x)) + (1 - \tau)x,$$

where P_X is the projection onto $X = \left\{(x, 0) : x \in \mathbb{R}^3\right\}$. By Corollary 4.3, fixed $R > 0$ and $\epsilon > 0$ small enough, one has

$$(\mathcal{F}(\tau, x), x) > 0, \quad \forall (\tau, x) \in [0,1] \times \partial Q.$$

Applying the homotopy invariance property of the topological degree, we have

$$d(g, Q, 0) = 1,$$

which implies that there is $x_* \in Q$ such that $\beta\left(h\left(x_*\right)\right) = 0$. □

Now, we define the minimax value

$$C_\epsilon = \inf_{h\in\Gamma}\sup_{x\in Q}\mathcal{I}_\epsilon(h(x)).$$

By Lemmas 4.5 and 4.6,

$$C_\epsilon \geq \Theta_r = \inf_{u\in\Omega_r}\mathcal{I}_\epsilon(u) \geq m(c_0) + \sigma/2, \tag{4.2}$$

for ϵ is small enough. On the other hand,

$$C_\epsilon \leq \sup_{x\in Q}\mathcal{I}_\epsilon(\Upsilon_\epsilon(x)).$$

Then, by Lemma 4.4-(b), if ϵ is small enough,

$$C_\epsilon \leq \sup_{x\in Q}\mathcal{I}_\epsilon(\Upsilon_\epsilon(x)) < 2m\left(c_0\right) - \sigma. \tag{4.3}$$

From (4.2) and (4.3), there is ϵ_0 such that

$$C_\epsilon \in \left(m(c_0) + \sigma/2, 2m(c_0) - \sigma\right), \quad \forall \epsilon \in (0, \epsilon_0).$$

Proof of Theorem 1.1. Before proving Theorem 1.1, we first propose the following claim.

Claim III: For a given $\tau > 0$ small enough, there exists $u_\tau \in E$ such that

$$\Phi_\epsilon'\left(u_\tau\right)\cdot\left(v-u_\tau\right)+\Psi(v)-\Psi\left(u_\tau\right) \geq -3\tau\left\|v-u_\tau\right\|_\epsilon, \quad \forall v \in E,$$

and

$$\mathcal{I}_\epsilon(u_\tau) \in \left[C_\epsilon - \tau, C_\epsilon + \tau\right].$$

In fact, to prove the claim, we follow the ideas explored in Alves–de Morais Filho [2] and Szulkin [28]. Have this in mind, by Lemma 4.5, we can fix $\tau > 0$ small enough such that

$$C_\epsilon - \tau/2 > \frac{1}{2}\left(m(c_0) + \Theta_r\right),$$

and we set

$$\Gamma_1 = \left\{h \in C(Q, K_r) : h|_{\partial Q} \approx \Upsilon_\epsilon|_{\partial Q} \text{ in } \mathcal{I}_\epsilon^{C_\epsilon - \tau/4}, \sup_{x\in\partial Q}\mathcal{I}_\epsilon(h(x)) \leq C_\epsilon - \tau/2\right\},$$

where $\approx$ denotes the homotopy relation and the number

$$C^* = \inf_{h\in\Gamma_1}\sup_{x\in Q}\mathcal{I}_\epsilon(h(x)).$$

Arguing as in Szulkin [28], we have that $C^* = C_\epsilon$, and so, it is enough to prove that Claim III holds for C^* instead C_ϵ. In order to show this, firstly let us fix $\tau > 0$ small enough and $h \in \Gamma_1$ such that

$$\Pi(h) \leq C^* + \tau \quad \text{and} \quad \Pi(g) - \Pi(h) \geq -\tau d(g, h), \quad \forall g \in \Gamma_1, \tag{4.4}$$

where

$$\Pi(g) = \sup_{x\in Q}\mathcal{I}_\epsilon(g(x)), \quad \forall g \in \Gamma_1,$$

and

$$d(g,h)=\sup_{x\in Q}\|g(x)-h(x)\|.$$

Supposing by contradiction that Claim III does not hold and arguing as in Alves–de Morais Filho [2], we can apply Proposition 2.3 of Szulkin [28] with $A=h(Q)$ to find a closed subset W containing A in it interior and a deformation $\alpha_s : W\to\mathcal{H}_\epsilon$ having the following properties:

$$\begin{cases} \|u-\alpha_s(u)\|_\epsilon\le s, & \forall u\in W \text{ and } s\approx 0^+,\\ \mathcal{I}_\epsilon(\alpha_s(u))-\mathcal{I}_\epsilon(u)\le 2s, & \forall u\in W,\\ \mathcal{I}_\epsilon(\alpha_s(u))-\mathcal{I}_\epsilon(u)\le -2\tau s, & \forall u\in W \text{ with } \mathcal{I}_\epsilon(u)\ge C^*-\tau, \end{cases} \tag{4.5}$$

and

$$\sup_{u\in A}\mathcal{I}_\epsilon(\alpha_s(u))-\sup_{u\in A}\mathcal{I}_\epsilon(u)\le -2\tau s. \tag{4.6}$$

It is easy to see that $g=\alpha_s\circ h\in\Gamma_1$, for s small enough. However, by(4.4), (4.5) and (4.6), we have

$$-\tau s\le -\tau d(g,h)\le \Pi(g)-\Pi(h)\le -2\tau s,$$

which is a contradiction. This contradiction shows that Claim III is true.

From Claim III, there exists a $(\mathrm{PS})_{C_\epsilon}$ sequence for $\mathcal{I}_\epsilon$, which will denoted by (u_n). By Lemma 3.8, we can assume that $u_n\rightharpoonup u_\epsilon$ for some $u_\epsilon\in\mathcal{H}_\epsilon\backslash\{0\}$. On the other hand, it follows from Lemma 3.2 that for each $v\in C_0^\infty(\mathbb{R}^3)$, there holds the limit $\langle\mathcal{I}_\epsilon'(u_n),v\rangle=o_n(1)\|v\|_\epsilon$, from where it shows that $\langle\mathcal{I}_\epsilon'(u_\epsilon),v\rangle=0$, or equivalently,

$$\begin{aligned}&\iint_{\mathbb{R}^6}\frac{(u_\epsilon(x)-u_\epsilon(y))(v(x)-v(y))}{|x-y|^{3+2s}}\mathrm{d}x\mathrm{d}y+\int_{\mathbb{R}^3}V(\epsilon x)u_\epsilon\cdot v\mathrm{d}x-\int_{\mathbb{R}^3}\phi_{u_\epsilon}^t u_\epsilon v\mathrm{d}x\\ &\quad=\int u_\epsilon v\log u_\epsilon^2\mathrm{d}x,\quad \forall v\in C_0^\infty(\mathbb{R}^3).\end{aligned}$$

Moreover, a similar computation also gives that

$$[u_\epsilon]^2+\int_{\mathbb{R}^3}V(\epsilon x)|u_\epsilon|^2\mathrm{d}x-\int_{\mathbb{R}^3}\phi_{u_\epsilon}^t|u_\epsilon|^2\mathrm{d}x+\int F_1'(u_\epsilon)u_\epsilon\mathrm{d}x\le\int F_2'(u_\epsilon)u_\epsilon\mathrm{d}x,$$

which implies that $u^2\log u^2\in L^1(\mathbb{R}^3)$. This proves that u_ϵ is a critical point of $\mathcal{I}_\epsilon$ with $\phi=\phi_{u_\epsilon}$ for ϵ small enough. Finally, the last inequality together with Fatou's Lemma implies that

$$\mathcal{I}_\epsilon(u_\epsilon)\le C_\epsilon<2m(c_0).$$

By Squassina–Szulkin [26], local estimates and standard bootstrap arguments show that $u_\epsilon\in C^2(\mathbb{R}^3,\mathbb{R})$. Moreover, by the Maximum Principle, we have that

$$u_\epsilon(x)>0 \text{ for } x\in\mathbb{R}.$$

For each $\epsilon>0$ small enough, let u_ϵ denote the positive solution obtained above. Setting $v_\epsilon=u_\epsilon(\frac{x}{\epsilon})$, then it shows that $(v_\epsilon,\phi_{v_\epsilon})$ gives rise to a pair of solutions of (1.1). □

Abstract. In this paper, we study a hydrodynamic system modeling the evolution of a plasma subject to a self-induced electromagnetic Lorentz force in incompressible viscous fluids. The system consists of the Navier–Stokes equations coupled with a Maxwell equation. In the three dimensional case, we show that every weak solution verifies the energy equality for the incompressible Navier–Stokes–Maxwell equations with damping. We also establish some non-explosion criteria in terms of the velocity and magnetic of local strong solution for standard Navier–Stokes–Maxwell system.

Keywords: Navier–Stokes–Maxwell system, damping term, energy conservation, non-explosion criteria.

2020 Mathematics Subject Classification: 35Q35, 76D03.

1 Introduction

In this paper, we are interested in studying the unconditional energy conservation for the weak solutions of Navier–Stokes–Maxwell (NSM for short) equations with damping (or the tamed NSM equations)

$$\begin{cases} \partial_t u + u \cdot \nabla u - \mu \Delta u + \nu |u|^{\alpha-1} u = -\nabla P + j \times B, & \operatorname{div} u = 0, \\ \frac{1}{c}\partial_t E - \nabla \times B = -j, & j = \sigma(cE + u \times B), \\ \frac{1}{c}\partial_t B + \nabla \times E + \nu |B|^{\beta-1} B = 0, & \operatorname{div} B = 0, \end{cases} \tag{1.1}$$

with initial data

$$u(0,x) = u_0, \quad E(0,x) = E_0, \quad B(0,x) = B_0 \tag{1.2}$$

for $(t,x) \in \mathbb{R}^+ \times \Omega$, where Ω is a periodic domain $\mathbb{T}^3$ or whole space $\mathbb{R}^3$. Here $c > 0$ denotes the speed of light, μ and ν denote respectively the positive viscosity and damping coefficients of the fluid, and $\sigma > 0$ is the electrical conductivity. In the above system (1.1),

✉Corresponding author. Email: wufan0319@yeah.net

$u = (u_1, u_2, u_3) = u(t,x)$ stands for the velocity field of the (incompressible) fluid, while $E = (E_1, E_2, E_3) = E(t,x)$ and $B = (B_1, B_2, B_3) = B(t,x)$ are the electric and magnetic fields, respectively. The scalar function $P = P(t,x)$ is the pressure and is also an unknown. Observe, though, that the electric current $j = j(t,x)$ is not an unknown, for it is fully determined by (u, E, B) through Ohm's law. The exponent α, β can be greater than or equal to 1.

The standard Navier–Stokes–Maxwell system (i.e., $\alpha = \beta = 1$) describes the evolution of a plasma (i.e., a charged fluid) subject to a self-induced electromagnetic Lorentz force $j \times B$.

$$\begin{cases} \partial_t u + u \cdot \nabla u = -\nabla P + j \times B, & \operatorname{div} u = 0, \\ \frac{1}{c}\partial_t E - \nabla \times B = -j, & j = \sigma(cE + u \times B), \\ \frac{1}{c}\partial_t B + \nabla \times E = 0, & \operatorname{div} B = 0. \end{cases} \tag{1.3}$$

Mathematically, NSM equations is a coupled system, constituted by the parabolic nature of the Navier–Stokes equations from fluid dynamics and the hyperbolic of the Maxwell equation from electromagnetism. Moreover, it can be derived from the Vlasov–Maxwell–Boltzmann system [3]. In the 2D case, Masmoudi [14] prove global existence of regular solutions to the Maxwell–Navier–Stokes system (1.3), and also provide an exponential growth estimate for the H^s norm of the solution when the time goes to infinity. In the 3D case, Ibrahim and Keraani [7] showed the existence of global small mild solutions of NSM system (1.3). Recently, Arsenio and Gallagher [1] have made important and new progress in this direction, they established that global existence of solutions to the 3D system (1.3) holds whenever the initial data tum (u_0, E_0, B_0) is chosen in the natural energy space L^2, while the electromagnetic field (E_0, B_0) alone lies in $\dot{H}^s$, for some given $s \in \left[\frac{1}{2}, \frac{3}{2}\right)$, and is sufficiently small when compared to some non-linear function of the initial energy

$$\mathcal{E}_0 := \frac{1}{2}\left(\|u_0\|_{L^2}^2 + \|E_0\|_{L^2}^2 + \|B_0\|_{L^2}^2\right).$$

Kang and Lee [8] showed that the maximal existence time of the local strong solution T^* is finite if and only if

$$\int_0^{T^*} \|u\|_{L^\infty}^2 + \|B\|_{L^\infty}^{\frac{8}{3}} \, \mathrm{d}t = \infty.$$

This was improved by Fan-Zhou [4] to be

$$\int_0^{T^*} \|u\|_{L^\infty}^2 + \|B\|_{L^\infty}^2 \, \mathrm{d}t = \infty.$$

Thereafter, Ma, Jiang and Zhu [12] proved the following three regularity criteria:

- $u \in L^2\left(0, T; L^\infty\left(\mathbb{R}^3\right)\right)$ and $\nabla u \in L^2\left(0, T; L^3\left(\mathbb{R}^3\right)\right)$;
- $u \in L^p\left(0, T; L^q\left(\mathbb{R}^3\right)\right)$, $\frac{2}{p} + \frac{3}{q} = 1, 3 < q \leq \infty$ and $\nabla B \in L^2\left(0, T; L^3\left(\mathbb{R}^3\right)\right)$;
- $\nabla u \in L^p\left(0, T; L^q\left(\mathbb{R}^3\right)\right)$, $\frac{2}{p} + \frac{3}{q} = 2, \frac{3}{2} < q \leqslant \infty$ and $\nabla B \in L^2\left(0, T; L^3\left(\mathbb{R}^3\right)\right)$.

More recently, this result has been improved by Zhang, Pan and iu [20], who proved that if

$$u \in L^{\frac{2}{1-r}}\left(0, T; \dot{B}^{-r}_{\infty,\infty}\left(\mathbb{R}^3\right)\right), \qquad -1 < r < 1$$

and

$$\nabla B \in L^p\left(0, T; L^q\left(\mathbb{R}^3\right)\right), \qquad \frac{2}{p} + \frac{3}{q} = 2 \quad \text{with } 2 \leq q \leq 3,$$

then the strong solution to the NSM system (1.3) can be smoothly extended beyond T. In addition, the energy balance of distributional solutions/Leray–Hopf weak solutions for the NSM system was obtained in [13,19]. In particular, for a Leray–Hopf weak solution (u, E, B) satisfies

$$u \in L^q\left(0, T; L^p(\Omega)\right), \qquad \frac{1}{q} + \frac{1}{p} \leq \frac{1}{2}, \qquad p \geq 4, \tag{1.4}$$

and

$$B \in L^r\left(0, T; L^s(\Omega)\right), \qquad \frac{1}{r} + \frac{1}{s} \leq \frac{1}{2}, \qquad s \geq 4. \tag{1.5}$$

Then it keeps energy balance.

The damping comes from the resistance to the motion of the flow. It describes various physical phenomena such as porous media flow, drag or friction effects, and some dissipative mechanisms [2]. Recently, Liu, Sun and Xin [11] considered the following 3D NSM system with damping:

$$\begin{cases} \partial_t u + u \cdot \nabla u - \mu \Delta u + |u|^{\alpha-1} u = -\nabla P + j \times B, & \operatorname{div} u = 0, \\ \partial_t E - \nabla \times B + |E| E = -j, & j = \sigma(E + u \times B), \\ \partial_t B + \nabla \times E + |B|^4 B = 0, & \operatorname{div} B = 0, \end{cases} \tag{1.6}$$

and proved the existence and uniqueness of strong solutions for system (1.6) provided that $\alpha \geq 3$.

When $E = B \equiv 0$, system (1.1) reduces to the Navier–Stokes system with damping(or the tamed Navier–Stokes equations). When viscosity and damping coefficients μ and ν equal to one, Cai and Jiu [2] first established the global existence of strong solutions provided that $\alpha \geq \frac{7}{2}$. Later, it was improved to the $\alpha \geq 3$ by Zhou [21]. Very recently, Hajduk and Robinson in [6] give a simple proof of the existence of global-in-time smooth solutions for tamed Navier–Stokes equations on a 3D periodic domain, for values of the absorption exponent α larger than 3. Furthermore, they prove that global, regular solutions exist also for the critical value of exponent $\alpha = 3$, provided that the coefficients satisfy the relation $4\mu\nu \geq 1$. Additionally, they showed that in the critical case every Leray-Hopf weak solution verifies the energy identity:

$$\|u(t)\|_{L^2}^2 + 2\mu \int_0^t \|\nabla u(s)\|_{L^2}^2 \, \mathrm{d}s + 2\nu \int_0^t \|u(s)\|_{L^4}^4 \, \mathrm{d}s = \|u(0)\|_{L^2}^2, \qquad 0 < t < T.$$

To the best of our knowledge, the validity of the energy equality is not to date verified for the NSM equations with damping (1.1) for the range of exponent values $\alpha, \beta \in [1, 3]$. For larger values of the exponent α, β with lower order damping term $|E|E$, it was already shown that the tamed NSM equations (1.6) enjoy existence of global-in-time strong solutions (see proof for whole spaces $\mathbb{R}^3$ in [11]) and hence the energy equality is satisfied. A natural question immediately arises: **does any Leray–Hopf weak solution of the tamed NSM equations** (1.1) **automatically satisfy the energy balance?** In this work, we will try to answer this question, and show the energy balance to the critical case $\alpha = \beta = 3$. In addition, for the standard NSM system (1.3) (i.e., $\alpha = \beta = 1$ in (1.1)), we will show some blow-up criteria under scaling invariant conditions on gradient of the velocity and the magnetic in some different Banach spaces, including the homogeneous Sobolev space, the weighted L^∞-space and the Morrey space, etc.

In a same fashion with [6], we first state the definition of the Leray–Hopf weak solutions to system (1.1).

Definition 1.1 (Leray–Hopf weak solution)**.** Let $(u_0, E_0, B_0) \in L^2(\Omega)$ with $\nabla \cdot u_0 = \nabla \cdot B_0 = 0$, $T > 0$. The function (u, E, B) is said to be a Leray–Hopf weak solution to tamed NSM system(1.1) if

1. $$u \in L^\infty(0,T;L^2(\Omega)) \cap L^2(0,T;\dot{H}^1((\Omega))) \cap L^{\alpha+1}(0,T;L^{\alpha+1}(\Omega))$$
$$B \in L^\infty(0,T;L^2(\Omega)) \cap L^{\beta+1}(0,T;L^{\beta+1}(\Omega))$$
$$E \in L^\infty(0,T;L^2(\Omega)),\ j \in L^2(0,T;L^2(\Omega));$$

2. for any smooth test function $\varphi \in C_c^\infty(\Omega \times [0,T))$ and $\nabla \cdot \varphi = 0$, holds that
$$-\int_0^T\int_\Omega u \cdot \partial_t \varphi \mathrm{d}x\mathrm{d}t + \mu\int_0^T\int_\Omega \nabla u : \nabla\varphi \mathrm{d}x\mathrm{d}t + \int_0^T\int_\Omega [u \cdot \nabla u - j \times B + \nu|u|^{\alpha-1}u] \cdot \varphi \mathrm{d}x\mathrm{d}t$$
$$= \int_\Omega u_0 \cdot \varphi(x,0)\mathrm{d}x,$$
$$-\frac{1}{c}\int_0^T\int_\Omega E \cdot \partial_t\varphi \mathrm{d}x\mathrm{d}t + \int_0^T\int_\Omega B\nabla \times \varphi \mathrm{d}x\mathrm{d}t + \int_0^T\int_\Omega j \cdot \varphi \mathrm{d}x\mathrm{d}t = \int_\Omega E_0 \cdot \varphi(x,0)\mathrm{d}x,$$
and
$$-\frac{1}{c}\int_0^T\int_\Omega B \cdot \partial_t\varphi \mathrm{d}x\mathrm{d}t - \int_0^T\int_\Omega E\nabla \times \varphi \mathrm{d}x\mathrm{d}t + \int_0^T\int_\Omega \nu|B|^{\beta-1}B \cdot \varphi \mathrm{d}x\mathrm{d}t = \int_\Omega B_0 \cdot \varphi(x,0)\mathrm{d}x,$$

3. for any $\Phi \in C_c^\infty(\mathbb{R}^d)$, it holds that
$$\int_\Omega u \cdot \nabla\Phi \mathrm{d}x = \int_\Omega B \cdot \nabla\Phi \mathrm{d}x = 0$$
a.e. $t \in (0,T)$;

4. (u, E, B) satisfies the energy inequality
$$\frac{1}{2}(\|u(\cdot,t)\|_{L^2}^2 + \|E(\cdot,t)\|_{L^2}^2 + \|B(\cdot,t)\|_{L^2}^2) + \int_0^T (\mu\|\nabla u\|_{L^2}^2 + \frac{1}{\sigma}\|j\|_{L^2}^2)dt$$
$$+\nu\int_0^T \|u\|_{L^{\alpha+1}}^{\alpha+1} + c\|B\|_{L^{\beta+1}}^{\beta+1}\mathrm{d}t \le \frac{1}{2}\int_\Omega(|u_0|^2 + |E_0|^2 + |B_0|^2)\mathrm{d}x,$$
for all $t \in [0,T]$.

We now make the observation that Leray–Hopf weak solutions of the tamed NSM system (1.1) with $\alpha = \beta = 3$ by Definition 1.1 satisfy the condition (1.4)–(1.5). This suggests that the energy balance holds for all weak solutions of this problem, and we will prove this in the following unconditional energy balance theorem.

Theorem 1.2. *Let $\alpha = \beta = 3$ in tamed NSM system (1.1), then every Leray–Hopf weak solution (u, E, B) with $(u_0, E_0, B_0) \in L^2(\Omega)$ satisfies the energy balance:*
$$\frac{1}{2}(\|u(\cdot,t)\|_{L^2}^2 + \|E(\cdot,t)\|_{L^2}^2 + \|B(\cdot,t)\|_{L^2}^2) + \int_0^T (\mu\|\nabla u\|_{L^2}^2 + \frac{1}{\sigma}\|j\|_{L^2}^2)dt$$
$$+\nu\int_0^T \|u\|_{L^4}^4 + c\|B\|_{L^4}^4\mathrm{d}t = \frac{1}{2}(\|u_0\|_{L^2}^2 + \|E_0\|_{L^2}^2 + \|B_0\|_{L^2}^2), \tag{1.7}$$
for all $t \in [0,T]$.

Remark 1.3. In [5], the authors approximate functions defined on smooth bounded domains by elements of the eigenspaces of the Laplacian or the Stokes operator in such a way that the approximations are bounded and converge in both Sobolev and Lebesgue spaces. As a direct application, they prove that all weak solutions of the tamed NS equations posed on a bounded domain in $\mathbb{R}^3$ satisfy the energy equality. One may establish similar result to tamed NSM equations (1.1) in smooth bounded domain by the the method developed in [4].

As mentioned in the introduction, we will give several new non-explosion criteria in terms of the velocity and magnetic for standard NSM system on the framework of different Banach spaces. (Definitions of various Banach spaces can be found in Section 3.)

Theorem 1.4. *Let $(u_0, E_0, B_0) \in H^2(\mathbb{R}^3)$ with $\nabla \cdot u_0 = \nabla \cdot B_0 = 0$. Assume that (u, E, B) be the local strong solution of the standard NSM system (1.3). If*

$$S, \nabla B \in L^2\left(0, T; \mathcal{X}\left(\mathbb{R}^3\right)\right), \tag{1.8}$$

where $\mathcal{X}$ is one of the Banach spaces:

- $\mathcal{X} = \dot{H}^{1/2}\left(\mathbb{R}^3\right)$ *(the homogeneous Sobolev space),*
- $\mathcal{X} = L^3\left(\mathbb{R}^3\right)$ *(the Lebesgue space),*
- $\mathcal{X} = \left\{f \in L^\infty_{loc}\left(\mathbb{R}^3\right) : \|f\| = \sup_{x\in\mathcal{X}} |x||f(x)| < \infty\right\}$ *(the weighted L^∞-space),*
- $\mathcal{X} = \mathcal{PM}^2\left(\mathbb{R}^3\right)$ *(the Le Jan–Sznitman space),*
- $\mathcal{X} = L^{3,\infty}\left(\mathbb{R}^3\right)$ *(the Marcinkiewicz space),*
- $\mathcal{X} = \dot{M}^3_p\left(\mathbb{R}^3\right)$ *for each $2 < p \leqslant 3$ (the Morrey space).*

Then the local strong solution can be smoothly extended beyond T. Here, $S = \nabla_{sym}(u)_{ij} = \frac{1}{2}\left(\frac{\partial u_j}{\partial x_i} + \frac{\partial u_i}{\partial x_j}\right)$.

Remark 1.5. The result in Theorem 1.4 is more weaker condition to that in [12] or [20]. On the one hand, the deformation tensor S in theorem 1.4 can be replaced ∇u or $\nabla \times u$, on the other hand, we see that the framework of several Banach spaces in theorem 1.4 is more flexible and larger than that of Lebesgue spaces.

2 Proof of Theorem 1.2

The goal of this section is to prove Theorem 1.2. The main idea is to use a Leray–Hopf weak solution as a test function. We cannot do this directly since it is not sufficiently regular in space or time. Therefore, for the sake of simplicity, we will proceed as if the solution is differentiable in time. The extra arguments needed to mollify in time are straightforward. To this end we recall here some standard facts of the theory of mollification and introduce a crucial lemma. The key lemma is as follows which was proved by Lions in [10].

Let us to define $\eta : \mathbb{R}^d \to \mathbb{R}$ be a standard mollifier, i.e. $\eta(x) = Ce^{\frac{1}{|x|^2-1}}$ for $|x| < 1$ and $\eta(x) = 0$ for $|x| \geqslant 1$, where constant $C > 0$ selected such that $\int_{\mathbb{R}^d} \eta(x)\mathrm{d}x = 1$. For any $\varepsilon > 0$, we define the rescaled mollifier $\eta_\varepsilon(x) = \varepsilon^{-d}\eta\left(\frac{x}{\varepsilon}\right)$. For any function $f \in L^1_{\mathrm{loc}}(\Omega)$, its mollified version is defined as

$$f^\varepsilon(x) = (f * \eta_\varepsilon)(x) = \int_\Omega \eta_\varepsilon(x-y)f(y)\mathrm{d}y.$$

If $f \in W^{1,p}(\Omega)$, the following local approximation is well known

$$f^\varepsilon(x) \to f \quad \text{in } W^{1,p}_{loc}(\Omega) \quad \forall p \in [1,\infty).$$

Lemma 2.1. *Let ∂ be a partial derivative in one direction. Let $f, \partial f \in L^p(\mathbb{R}^+ \times \Omega)$, $g \in L^q(\mathbb{R}^+ \times \Omega)$ with $1 \le p,q \le \infty$, and $\frac{1}{p}+\frac{1}{q} \le 1$. Then, we have*

$$\|\partial(fg) * \eta_\varepsilon - \partial\left(f(g*\eta_\varepsilon)\right)\|_{L^r(\mathbb{R}^+\times\Omega)} \le C\|\partial f\|_{L^p(\mathbb{R}^+\times\Omega)}\|g\|_{L^q(\mathbb{R}^+\times\Omega)}$$

for some constant $C>0$ independent of ε, f and g, and with $\frac{1}{r}=\frac{1}{p}+\frac{1}{q}$. In addition,

$$\partial(fg)*\eta_\varepsilon - \partial\left(f(g*\eta_\varepsilon)\right) \to 0 \quad \text{in } L^r\left(\mathbb{R}^+\times\Omega\right)$$

as $\varepsilon \to 0$, if $r<\infty$.

Proof of Theorem 1.2. First, testing system $(1.1)_{1,2,3}$ by $(u^\varepsilon)^\varepsilon$, $(E^\varepsilon)^\varepsilon$ and $(B^\varepsilon)^\varepsilon$, respectively, we infer that

$$\begin{cases} \int_\Omega u^\varepsilon\left(\partial_t u + u\cdot\nabla u - \mu\Delta u + \nu|u|^2u + \nabla P - j\times B\right)^\varepsilon \mathrm{d}x = 0, \\ \int_\Omega E^\varepsilon\left(\partial_t E - c\nabla\times B + cj\right)^\varepsilon \mathrm{d}x = 0, \\ \int_\Omega B^\varepsilon\left(\partial_t B + c\nabla\times E + c\nu|B|^2B\right)^\varepsilon \mathrm{d}x = 0. \end{cases} \tag{2.1}$$

Moreover, it yields that

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}\int_\Omega\left(|u^\varepsilon|^2+|E^\varepsilon|^2+|B^\varepsilon|^2\right)\mathrm{d}x + \mu\int_\Omega|\nabla u^\varepsilon|^2\mathrm{d}x \\ &\quad + \nu\int_\Omega\left((|u|^2u)^\varepsilon\cdot u^\varepsilon + c(|B|^2B)^\varepsilon\cdot B^\varepsilon\right)dx \\ &= -\int_\Omega \mathrm{div}(u\otimes u)^\varepsilon\cdot u^\varepsilon\mathrm{d}x + \int_\Omega (j\times B)^\varepsilon\cdot u^\varepsilon\mathrm{d}x + c\int_\Omega(\nabla\times B)^\varepsilon\cdot E^\varepsilon\mathrm{d}x \\ &\quad - c\int_\Omega j^\varepsilon\cdot E^\varepsilon\mathrm{d}x - c\int_\Omega(\nabla\times E)^\varepsilon\cdot B^\varepsilon\mathrm{d}x. \end{aligned} \tag{2.2}$$

Clearly,

$$\begin{aligned} &\int_\Omega\left(|u^\varepsilon|^2+|E^\varepsilon|^2+|B^\varepsilon|^2\right)dx - \int_\Omega\left(|u_0^\varepsilon|^2+|E_0^\varepsilon|^2+|B_0^\varepsilon|^2\right)dxdt + 2\mu\int_0^T\int_\Omega|\nabla u^\varepsilon|^2\mathrm{d}x\mathrm{d}t \\ &\quad + 2\nu\int_0^T\int_\Omega\left((|u|^2u)^\varepsilon\cdot u^\varepsilon + c(|B|^2B)^\varepsilon\cdot B^\varepsilon\right)\mathrm{d}x\mathrm{d}t \\ &= -2\int_0^T\int_\Omega \mathrm{div}(u\otimes u)^\varepsilon\cdot u^\varepsilon\mathrm{d}x\mathrm{d}t + 2\int_0^T\int_\Omega(j\times B)^\varepsilon\cdot u^\varepsilon\mathrm{d}x\mathrm{d}t \\ &\quad + 2c\int_0^T\int_\Omega(\nabla\times B)^\varepsilon\cdot E^\varepsilon\mathrm{d}x\mathrm{d}t - 2c\int_0^T\int_\Omega j^\varepsilon\cdot E^\varepsilon\mathrm{d}x\mathrm{d}t \\ &\quad - 2c\int_0^T\int_\Omega(\nabla\times E)^\varepsilon\cdot B^\varepsilon\mathrm{d}x\mathrm{d}t \\ &= I_1+I_2+I_3+I_4+I_5. \end{aligned} \tag{2.3}$$

We want to pass to the limit in (2.3) as $\varepsilon \to 0$. To this end, using Hölder's inequality, we observe the following estimates for the nonlinear terms:

$$\begin{aligned}
&\left|\int_0^T\int_\Omega (|u|^2u)^\varepsilon\cdot u^\varepsilon \mathrm{d}x\mathrm{d}t-\int_0^T\int_\Omega |u|^2u\cdot u\mathrm{d}x\mathrm{d}t\right|\\
&\quad\le\left|\int_0^T\int_\Omega \left((|u|^2u)^\varepsilon-|u|^2u\right)\cdot u^\varepsilon+|u|^2u(u^\varepsilon-u)\mathrm{d}x\mathrm{d}t\right|\\
&\quad\le\|u^\varepsilon\|_{L^4(0,T;L^4(\Omega))}\left\|\left((|u|^2u)^\varepsilon-|u|^2u\right)\right\|_{L^{\frac43}\left(0,T;L^{\frac43}(\Omega)\right)}\\
&\qquad+\|u^\varepsilon-u\|_{L^4(0,T;L^4(\Omega))}\left\||u|^2u\right\|_{L^{\frac43}\left(0,T;L^{\frac43}(\Omega)\right)}\to 0\quad\text{ as }\varepsilon\to 0.
\end{aligned}\tag{2.4}$$

Similarly,

$$\left|\int_0^T\int_\Omega (|B|^2B)^\varepsilon\cdot B^\varepsilon \mathrm{d}x\mathrm{d}t-\int_0^T\int_\Omega |B|^2B\cdot u\mathrm{d}x\mathrm{d}t\right|\to 0\quad\text{ as }\varepsilon\to 0.\tag{2.5}$$

In addition, since

$$\begin{aligned}
\operatorname{div}(u\otimes u)^\varepsilon&=[\operatorname{div}(u\otimes u)^\varepsilon-\operatorname{div}(u\otimes u^\varepsilon)]+[\operatorname{div}(u\otimes u^\varepsilon)-\operatorname{div}(u^\varepsilon\otimes u^\varepsilon)]+\operatorname{div}(u^\varepsilon\otimes u^\varepsilon)\\
&=I_{11}+I_{12}+I_{13},
\end{aligned}$$

and so

$$I_1=-2\int_0^T\int_\Omega (I_{11}+I_{12}+I_{13})\cdot u^\varepsilon\mathrm{d}x\mathrm{d}t.\tag{2.6}$$

From Lemma 2.1, one obtains

$$\|I_{11}\|_{L^{\frac43}\left(0,T;L^{\frac43}(\Omega)\right)}\le C\|u^\varepsilon\|_{L^4(0,T;L^4(\Omega))}\|\nabla u^\varepsilon\|_{L^2(0,T;L^2(\Omega))}$$

and it converges to zero in $L^{\frac43}\left(0,T;L^{\frac43}(\Omega)\right)$ as ε tends to zero. Thus, as ε goes to zero, it follows that

$$\begin{aligned}
\left|-2\int_0^T\int_\Omega I_{11}u^\varepsilon\mathrm{d}x\mathrm{d}t\right|&=\left|\int_0^T\int_\Omega [\operatorname{div}(u\otimes u)^\varepsilon-\operatorname{div}(u\otimes u^\varepsilon)]\cdot u^\varepsilon\mathrm{d}x\mathrm{d}t\right|\\
&\le\|I_{11}\|_{L^{\frac43}\left(0,T;L^{\frac43}(\Omega)\right)}\|u^\varepsilon\|_{L^4(0,T;L^4(\Omega))}\\
&\to 0.
\end{aligned}\tag{2.7}$$

Moreover, we have

$$\begin{aligned}
\left|-2\int_0^T\int_\Omega I_{12}u^\varepsilon\mathrm{d}x\mathrm{d}t\right|&=\left|\int_0^T\int_\Omega [\operatorname{div}(u\otimes u^\varepsilon)-\operatorname{div}(u^\varepsilon\otimes u^\varepsilon)]\cdot u^\varepsilon dxdt\right|\\
&=\left|\int_0^T\int_\Omega (u\otimes u^\varepsilon-u^\varepsilon\otimes u^\varepsilon)\cdot\nabla u^\varepsilon\mathrm{d}x\mathrm{d}t\right|\\
&\le\|u-u^\varepsilon\|_{L^4(0,T;L^4(\Omega))}\|u^\varepsilon\|_{L^4(0,T;L^4(\Omega))}\|\nabla u^\varepsilon\|_{L^2(0,T;L^2(\Omega))}\\
&\to 0\quad\text{ as }\varepsilon\to 0.
\end{aligned}\tag{2.8}$$

Since $\operatorname{div} u^\varepsilon=0$, one has

$$-2\int_0^T\int_\Omega I_{13}\cdot u^\varepsilon\mathrm{d}x=0.\tag{2.9}$$

Combining (2.6)–(2.9), we know that

$$I_1\to 0,\quad\text{ as }\varepsilon\to 0.\tag{2.10}$$

For the term I_2, we claim that

$$I_2 = 2\int_0^T \int_\Omega (j\times B)^\varepsilon \cdot u^\varepsilon \mathrm{d}x\mathrm{d}t \to 2\int_0^T \int_\Omega (j\times B)\cdot u \mathrm{d}x\mathrm{d}t, \quad \text{as } \varepsilon \to 0. \tag{2.11}$$

Indeed,

$$\begin{aligned}
&2\int_0^T \int_\Omega (j\times B)^\varepsilon \cdot u^\varepsilon - (j\times B)\cdot u \mathrm{d}x\mathrm{d}t \\
&\quad = 2\int_0^T \int_\Omega (j\times B)^\varepsilon \cdot u^\varepsilon - (j\times B)\cdot u^\varepsilon + (j\times B)\cdot u^\varepsilon - (j\times B)\cdot u \mathrm{d}x\mathrm{d}t \\
&\quad = 2\int_0^T \int_\Omega \left[(j\times B)^\varepsilon - (j\times B)\right]\cdot u^\varepsilon + (j\times B)\cdot (u^\varepsilon - u)\,\mathrm{d}x\mathrm{d}t \\
&\quad \le 2\left\|(j\times B)^\varepsilon - (j\times B)\right\|_{L^{\frac{4}{3}}\left(0,T;L^{\frac{4}{3}}(\Omega)\right)} \|u^\varepsilon\|_{L^4(0,T;L^4(\Omega))} \\
&\qquad + 2\left\|j\times B\right\|_{L^{\frac{4}{3}}\left(0,T;L^{\frac{4}{3}}(\Omega)\right)} \|u^\varepsilon - u\|_{L^4(0,T;L^4(\Omega))} \\
&\quad \to 0, \quad \text{as } \varepsilon \to 0,
\end{aligned} \tag{2.12}$$

where we used fact that

$$\|j\times B\|_{L^{\frac{4}{3}}\left(0,T;L^{\frac{4}{3}}(\Omega)\right)} \le \|j\|_{L^2(0,T;L^2(\Omega))}\|B\|_{L^4(0,T;L^4(\Omega))} \le C.$$

By using the same trick, we find that

$$I_4 = -2c\int_0^T \int_\Omega j^\varepsilon \cdot E^\varepsilon \mathrm{d}x\mathrm{d}t \to -2c\int_0^T \int_\Omega j\cdot E \mathrm{d}x\mathrm{d}t, \quad \text{as } \varepsilon \to 0. \tag{2.13}$$

After integration by part, the term I_3 can be dominated as

$$\begin{aligned}
I_3 &= 2c\int_0^T \int_\Omega (\nabla\times B)^\varepsilon \cdot E^\varepsilon \mathrm{d}x\mathrm{d}t \\
&= 2c\int_0^T \int_\Omega \left(\epsilon_{ijk}\partial_j B_k\right)^\varepsilon \cdot E_i^\varepsilon \mathrm{d}x\mathrm{d}t \\
&= -2c\int_0^T \int_\Omega \epsilon_{ijk} B_k^\varepsilon \cdot \partial_j E_i^\varepsilon \mathrm{d}x\mathrm{d}t \\
&= 2c\int_0^T \int_\Omega \epsilon_{kji} B_k^\varepsilon \cdot \partial_j E_i^\varepsilon \mathrm{d}x\mathrm{d}t \\
&= 2c\int_0^T \int_\Omega B^\varepsilon \cdot (\nabla\times E)^\varepsilon \mathrm{d}x\mathrm{d}t,
\end{aligned} \tag{2.14}$$

So, it follows that

$$I_3 + I_5 = 0. \tag{2.15}$$

Letting ε goes to zero in (2.3), and using the facts (2.4)–(2.5) and (2.10)–(2.15), we infer that

$$\begin{aligned}
&(\|u(\cdot,t)\|_{L^2}^2 + \|E(\cdot,t)\|_{L^2}^2 + \|B(\cdot,t)\|_{L^2}^2) + 2\int_0^T \left(\mu\|\nabla u\|_{L^2}^2 + \frac{1}{\sigma}\|j\|_{L^2}^2\right) dt \\
&\quad + 2\nu\int_0^T \|u\|_{L^4}^4 + c\|B\|_{L^4}^4 dt = (\|u_0\|_{L^2}^2 + \|E_0\|_{L^2}^2 + \|B_0\|_{L^2}^2),
\end{aligned} \tag{2.16}$$

where we have used the facts that

$$2\int_0^T\int_\Omega (j\times B)\cdot u\mathrm{d}x\mathrm{d}t-2c\int_0^T\int_\Omega j\cdot E\mathrm{d}x\mathrm{d}t=-2\int_\Omega (u\times B)\cdot j\mathrm{d}x-2c\int_\Omega E\cdot j\mathrm{d}x$$

and

$$j=\sigma(cE+u\times B).$$

The energy equality (1.7) follows easily from (2.16). □

3 Proof of Theorem 1.4

In this section, we first introduce several definitions used throughout proof of theorem 1.4 and also recall the well-known results for our analysis (see e.g. [9,16,17] and [18]). And then show the derivation details of theorem 1.4.

Definition 3.1. The weighted L^∞-space is defined by

$$\text{Weighted } L^\infty=\left\{f\in L^\infty_{loc}\left(\mathbb{R}^3\right):\|f\|_{\mathcal{X}}=\sup_{x\in\mathcal{X}}|x||f(x)|<\infty\right\}.$$

Definition 3.2. The Le Jan–Sznitman space is defined by

$$\mathcal{PM}^2=\left\{v\in\mathcal{S}'\left(\mathbb{R}^3\right):\widehat{v}\in L^1_{loc}\left(\mathbb{R}^3\right),\quad \|v\|_{\mathcal{PM}^2}=\operatorname*{ess\,sup}_{\xi\in\mathbb{R}^3}|\xi|^2|\widehat{v}(\xi)|<\infty\right\}.$$

Definition 3.3. Let $1<p\le q<\infty$, the homogeneous Morrey spaces are defined as

$$\dot{M}^q_p\left(\mathbb{R}^3\right)=\left\{f\in L^q_{loc}\left(\mathbb{R}^3\right):\|f\|_{\dot{M}^q_p}=\sup_{R>0}\sup_{x\in\mathbb{R}^3}R^{3\left(\frac{1}{p}-\frac{1}{q}\right)}\left(\int_{B_R(x)}|f(y)|^p\,\mathrm{d}y\right)^{\frac{1}{p}}<\infty\right\}.$$

Lemma 3.4 ([15])**.** *For all $-\frac{3}{2}<\alpha<\frac{3}{2}$ and for all u divergence free in the sense that $\xi\cdot\hat{u}(\xi)=0$ almost everywhere,*

$$\|S\|^2_{\dot{H}^\alpha}=\|A\|^2_{\dot{H}^\alpha}=\frac{1}{2}\|\omega\|^2_{\dot{H}^\alpha}=\frac{1}{2}\|\nabla\otimes u\|^2_{\dot{H}^\alpha},\tag{3.1}$$

where symmetric part $S=S_{ij}=\frac{1}{2}\left(\frac{\partial u_j}{\partial x_i}+\frac{\partial u_i}{\partial x_j}\right)$, which we refer to as the strain tensor, anti-symmetric part $A=A_{ij}=\frac{1}{2}\left(\frac{\partial u_j}{\partial x_i}-\frac{\partial u_i}{\partial x_j}\right)$, $\omega=\nabla\times u$.

Lemma 3.5 (Hardy-type inequalities [9])**.** *There exists a constant $K>0$ such that the following inequality holds true*

$$\left|\int_{\mathbb{R}^3}W\cdot(g\cdot\nabla)h\,\mathrm{d}x\right|\leqslant K\|W\|_{\mathcal{X}_\sigma}\|\nabla g\|_{L^2}\|\nabla h\|_{L^2},$$

for all vector fields $g,h\in\dot{H}^1\left(\mathbb{R}^3\right)$ and all $W\in\mathcal{X}_\sigma$, where $\mathcal{X}_\sigma$ (the subspace of $\mathcal{X}$ of divergence-free vector functions) is one of the Banach spaces

- *$\mathcal{X}_\sigma=\dot{H}^{1/2}_\sigma\left(\mathbb{R}^3\right)$ (the homogeneous Sobolev space),*
- *$\mathcal{X}_\sigma=L^3_\sigma\left(\mathbb{R}^3\right)$ (the Lebesgue space),*

- $\mathcal{X}_\sigma = \left\{ f \in L^\infty_{loc}\left(\mathbb{R}^3\right) : \|f\| = \sup_{x\in\mathcal{X}_\sigma} |x| |f(x)| < \infty \right\}$ *(the weighted L^∞-space),*
- $\mathcal{X}_\sigma = \mathcal{PM}^2\left(\mathbb{R}^3\right)$ *(the Le Jan–Sznitman space),*
- $\mathcal{X}_\sigma = L^{3,\infty}_\sigma\left(\mathbb{R}^3\right)$ *(the Marcinkiewicz space),*
- $\mathcal{X}_\sigma = \dot{M}^3_p\left(\mathbb{R}^3\right)$ *for each* $2 < p \leqslant 3$ *(the Morrey space).*

The following proposition is an ad hoc variant of the preceding lemma 3.5. It will be more applicable to proving theorem 1.4. This proposition is inspired by the details of the proof from lemma 3.5.

Proposition 3.6. *There exists a constant $C > 0$ such that the following inequality holds true*

$$\left| \int_{\mathbb{R}^3} Wgh \, \mathrm{d}x \right| \leqslant C \|W\|_{\mathcal{X}} \|\nabla g\|_{L^2} \|h\|_{L^2},$$

for all vector fields $g \in \dot{H}^1\left(\mathbb{R}^3\right)$, $h \in L^2\left(\mathbb{R}^3\right)$ and all $W \in \mathcal{X}$, where $\mathcal{X}$ is one of the Banach spaces

- $\mathcal{X} = \dot{H}^{1/2}\left(\mathbb{R}^3\right)$ *(the homogeneous Sobolev space),*
- $\mathcal{X} = L^3\left(\mathbb{R}^3\right)$ *(the Lebesgue space),*
- $\mathcal{X} = \{ f \in L^\infty_{loc}\left(\mathbb{R}^3\right) : \|f\| = \sup_{x\in\mathcal{X}} |x| |f(x)| < \infty \}$ *(the weighted L^∞-space),*
- $\mathcal{X} = \mathcal{PM}^2\left(\mathbb{R}^3\right)$ *(the Le Jan–Sznitman space),*
- $\mathcal{X} = L^{3,\infty}\left(\mathbb{R}^3\right)$ *(the Marcinkiewicz space),*
- $\mathcal{X} = \dot{M}^3_p\left(\mathbb{R}^3\right)$ *for each* $2 < p \leqslant 3$ *(the Morrey space).*

Proof of Theorem 1.4. We now shall prove Theorem 1.4, we only need to establish a priori estimates. Without loss of generality, we may assume $c = \sigma = 1$ in system (1.3).

Step 1: Energy estimates. Testing $(1.3)_{1,2,3}$ by u, E, B respectively, and adding up the results, we have the well-known energy equality

$$\begin{aligned}
&\frac{\mathrm{d}}{\mathrm{d}t}\|(u,E,B)\|^2_{L^2} + \|\nabla u\|^2_{L^2} \\
&\quad = \int_{\mathbb{R}^3} (j\times B)\cdot u \mathrm{d}x + \int_{\mathbb{R}^3} \operatorname{curl} B \cdot E \mathrm{d}x - \int_{\mathbb{R}^3} j\cdot E \mathrm{d}x - \int_{\mathbb{R}^3} \operatorname{curl} E\cdot B \mathrm{d}x \\
&\quad = -\int_{\mathbb{R}^3} (u\times B)\cdot j \mathrm{d}x - \int_{\mathbb{R}^3} E\cdot j \mathrm{d}x \\
&\quad = -\|j\|^2_{L^2},
\end{aligned}$$

where we have used Ohm's law: $j = (E + u\times B)$. Which gives

$$\|(u,E,B)(t)\|^2_{L^2} + 2\int_0^T \|(\nabla u, j)(t)\|^2_{L^2} \mathrm{d}t = \|(u_0,E_0,B_0)\|^2_{L^2}, \quad \forall t \geq 0.$$

Step 2: $\dot{H}^1$ estimates. First, taking $\nabla\times$ on the first equation of (1.3), we get

$$\partial_t \omega + (u\cdot\nabla)\omega - \Delta\omega - S\omega = \nabla\times(j\times B), \tag{3.2}$$

the vortex stretching term $S\omega$ is often written $(\omega \cdot \nabla)u$, that is to say $S\omega = (\omega \cdot \nabla)u$. Indeed, the symmetric part S is given by

$$S_{ij} = \nabla_{sym}(u)_{ij} = \frac{1}{2}\left(\frac{\partial u_j}{\partial x_i} + \frac{\partial u_i}{\partial x_j}\right)$$

and the anti-symmetric part A is given by

$$A_{ij} = \frac{1}{2}\left(\frac{\partial u_j}{\partial x_i} - \frac{\partial u_i}{\partial x_j}\right).$$

Naturally, $\nabla u = S + A$. In addition, we know that in three spatial dimensions the anti-symmetric matrix A can be represented as a vector. Here, we write as:

$$A = \frac{1}{2}\begin{pmatrix} 0 & \omega_3 & -\omega_2 \\ -\omega_3 & 0 & \omega_1 \\ \omega_2 & -\omega_1 & 0 \end{pmatrix}.$$

Then we have $A\omega = 0$.

Next, multiplying (3.2) by ω and integrating by parts over $\mathbb{R}^3$, one has

$$\begin{aligned} \frac{1}{2}\frac{d}{dt}\|\omega\|_{L^2}^2 + \|\nabla\omega\|_{L^2}^2 &= \int_{\mathbb{R}^3} S\omega \cdot \omega dx + \int_{\mathbb{R}^3} \mathrm{curl}\,(j \times B) \cdot \omega dx \\ &= \int_{\mathbb{R}^3} S\omega \cdot \omega dx - \int_{\mathbb{R}^3} (j \times B) \cdot \Delta u dx. \end{aligned} \tag{3.3}$$

Testing $(1.3)_{2,3}$ by $-\Delta E, -\Delta B$ in $L^2(\mathbb{R}^3)$ respectively, and putting together, we obtain

$$\begin{aligned} \frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|(\nabla E, \nabla B)\|_{L^2}^2 &= -\int_{\mathbb{R}^3} \mathrm{curl}\, B \cdot \Delta E \mathrm{d}x + \int_{\mathbb{R}^3} j \cdot \Delta E \mathrm{d}x + \int_{\mathbb{R}^3} \mathrm{curl}\, E \cdot \Delta B \mathrm{d}x \\ &= -\int_{\mathbb{R}^3} \partial_i j \cdot \partial_i E \mathrm{d}x. \end{aligned} \tag{3.4}$$

Since

$$\begin{aligned} -\sum_{i=1}^{3}\int_{\mathbb{R}^3} \partial_i j \cdot \partial_i E \mathrm{d}x &= -\sum_{i=1}^{3}\int_{\mathbb{R}^3} \partial_i j \cdot \partial_i (j - u \times B) \mathrm{d}x \\ &= -\|\nabla j\|_{L^2}^2 + \int_{\mathbb{R}^3} \partial_i (u \times B) \cdot \partial_i j \mathrm{d}x. \end{aligned} \tag{3.5}$$

From the equalities in (3.3)–(3.5), it follows that

$$\begin{aligned} &\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|(\omega, \nabla E, \nabla B)\|_{L^2}^2 + \|(\nabla\omega, \nabla j)\|_{L^2}^2 \\ &= \int_{\mathbb{R}^3} S\omega \cdot \omega \mathrm{d}x + \int_{\mathbb{R}^3} \partial_i (j \times B) \cdot \partial_i u \mathrm{d}x + \int_{\mathbb{R}^3} \partial_i (u \times B) \cdot \partial_i j \mathrm{d}x \\ &\leq \int_{\mathbb{R}^3} S\omega \cdot \omega \mathrm{d}x + \int_{\mathbb{R}^3} |j||\nabla u||\nabla B| \mathrm{d}x + \int_{\mathbb{R}^3} |u||\nabla B||\nabla j| \mathrm{d}x \\ &= I + J + K, \end{aligned} \tag{3.6}$$

where we have used the following cancellation property

$$\int_{\mathbb{R}^3} \partial_i j \times B \cdot \partial_i u \mathrm{d}x + \int_{\mathbb{R}^3} \partial_i j \cdot \partial_i u \times B \mathrm{d}x = 0.$$

Let (1.8) hold true. We use proposition 3.6 and lemma 3.4 to bound I as follows

$$\begin{aligned} I &\leq C\|S\|_{\mathcal{X}}\|\omega\|_{L^2}\|\nabla\omega\|_{L^2} \\ &\leq C\,\|S\|_{\mathcal{X}}^2\,\|\omega\|_{L^2}^2+\epsilon\|\nabla\omega\|_{L^2}^2, \end{aligned} \tag{3.7}$$

Similarly, we bound $J+K$ as follows

$$J+K \leq 2\epsilon\,\|\nabla j\|_{L^2}^2 + C\,\|\nabla B\|_{\mathcal{X}}^2\,\|\nabla u\|_{L^2}^2. \tag{3.8}$$

Where $\mathcal{X}$ is one of the Banach spaces:

- $\mathcal{X}=\dot{H}^{1/2}\left(\mathbb{R}^3\right)$ (the homogeneous Sobolev space),
- $\mathcal{X}=L^3\left(\mathbb{R}^3\right)$ (the Lebesgue space),
- $\mathcal{X}=\left\{f\in L^\infty_{loc}\left(\mathbb{R}^3\right):\|f\|=\sup_{x\in\mathcal{X}}|x\|f(x)|<\infty\right\}$ (the weighted L^∞-space),
- $\mathcal{X}=\mathcal{PM}^2\left(\mathbb{R}^3\right)$ (the Le Jan–Sznitman space),
- $\mathcal{X}=L^{3,\infty}\left(\mathbb{R}^3\right)$ (the Marcinkiewicz space),
- $\mathcal{X}=\dot{M}^3_p\left(\mathbb{R}^3\right)$ for each $2<p\leqslant 3$ (the Morrey space).

Applying the entropy identity (i.e., Lemma 3.4) and collecting (3.7) and (3.8) into (3.6), we find

$$\frac{\mathrm{d}}{\mathrm{d}t}\|(\omega,\nabla E,\nabla B)\|_{L^2}^2+\|(\nabla\omega,\nabla j)\|_{L^2}^2 \leq C\left(\|S\|_{\mathcal{X}}^2+\|\nabla B\|_{\mathcal{X}}^2\right)\|\omega\|_{L^2}^2. \tag{3.9}$$

Using the Gronwall inequality, we conclude that

$$\sup_{0\leq t\leq T}\int|\nabla u|^2+|\nabla E|^2+|\nabla B|^2\mathrm{d}x\leq C$$

and

$$\int_0^T\|\Delta u\|_{L^2}^2+\|\nabla j\|_{L^2}^2\mathrm{d}t\leq C.$$

Step 3: $\dot{H}^2$ estimates. Applying Δ to $(1.3)_{1,2,3}$ and multiplying by Δu, ΔE and ΔB, respectively, and add the result equations, one has

$$\begin{aligned} &\frac{\mathrm{d}}{\mathrm{d}t}\|\,(\Delta u,\Delta B,\Delta E)\,\|_{L^2}^2+\|\,(\nabla\Delta u,\Delta j)\,\|_{L^2}^2 \\ &\quad=\int_{\mathbb{R}^3}-\Delta(u\cdot\nabla u)\cdot\Delta u+\Delta(j\times B)\cdot\Delta u+\Delta j\cdot\Delta(u\times B)\mathrm{d}x \\ &\quad=C\left(\|\nabla u\|_{L^3}^2+1\right)\|\Delta u\|_{L^2}^2+\epsilon\|\nabla\Delta u\|_{L^2}^2 \\ &\qquad+\int_{\mathbb{R}^3}\partial_{kk}j\times B\cdot\Delta u+\partial_k j\times\partial_k B\cdot\Delta u+j\times\partial_{kk}B\cdot\Delta u\mathrm{d}x \\ &\qquad+\int_{\mathbb{R}^3}\Delta j\cdot\partial_{kk}u\times B+\Delta j\cdot\partial_k u\times\partial_k B+\Delta j\cdot u\times\partial_{kk}B\mathrm{d}x \\ &\quad=C\left(\|\nabla u\|_{L^3}^2+1\right)\|\Delta u\|_{L^2}^2+\epsilon\|\nabla\Delta u\|_{L^2}^2+\underbrace{\int_{\mathbb{R}^3}\partial_k j\times\partial_k B\cdot\Delta u+j\times\partial_{kk}B\cdot\Delta u\mathrm{d}x}_{I} \\ &\qquad+\underbrace{\int_{\mathbb{R}^3}\Delta j\cdot\partial_k u\times\partial_k B+\Delta j\cdot u\times\partial_{kk}B\mathrm{d}x}_{J}, \end{aligned} \tag{3.10}$$

where used the following cancellation property:

$$\int_{\mathbb{R}^3} \partial_{kk} j \times B \cdot \Delta u \mathrm{d}x + \int_{\mathbb{R}^3} \Delta j \cdot \partial_{kk} u \times B \mathrm{d}x = 0.$$

I can be estimated as

$$\begin{aligned} I &\leq C\|\Delta u\|_{L^2}\|\nabla B\|_{L^3}\|\nabla j\|_{L^6} + C\|j\|_{L^3}\|\Delta B\|_{L^2}\|\Delta u\|_{L^6} \\ &\leq C\|\Delta u\|_{L^2}^2\left(\|\nabla B\|_{L^2}^2 + \|\Delta B\|_{L^2}^2\right) + C\left(\|j\|_{L^2}^2 + \|\nabla j\|_{L^2}^2\right)\|\Delta B\|_{L^2}^2 + \epsilon\|\Delta j\|_{L^2} + \epsilon\|\nabla\Delta u\|_{L^2}^2 \end{aligned} \tag{3.11}$$

Similarly,

$$J \leq C\left(\|\nabla u\|_{L^2}^2 + \|\Delta u\|_{L^2}^2\right)\|\Delta B\|_{L^2}^2 + C\left(\|\nabla u\|_{L^2}^2 + \|\Delta u\|_{L^2}^2\right)\|\Delta B\|_{L^2}^2 + 2\epsilon\|\Delta j\|_{L^2}^2 \tag{3.12}$$

Putting (3.11) and (3.12) into (3.10), we obtain

$$\begin{aligned} &\frac{\mathrm{d}}{\mathrm{d}t}\|(\Delta u, \Delta B, \Delta E)\|_{L^2}^2 + \|(\nabla\Delta u, \Delta j)\|_{L^2}^2 \\ &\qquad \leq C\left(\|\nabla u\|_{L^2}^2 + \|\Delta u\|_{L^2}^2 + \|j\|_{L^2}^2 + \|\nabla j\|_{L^2}^2\right)\|(\Delta u, \Delta B, \Delta E)\|_{L^2}^2, \end{aligned} \tag{3.13}$$

and by Gronwall's lemma, we get that

$$\begin{aligned} u, B, E &\in L^\infty\left(0, T, \dot{H}^2\right); \\ \nabla u, j &\in L^2\left(0, T, \dot{H}^2\right). \end{aligned}$$

This completes the proof of Theorem 1.4. □

Communicated by Zuzana Došlá

Abstract. Oscillatory properties of perturbed half-linear differential equations are investigated. We make use of the modified Riccati technique. A certain linear differential equation associated with the modified Riccati equation plays an important part. Improved oscillation criteria for a perturbed half-linear Riemann–Weber differential equation can be obtained.

Keywords: half-linear differential equation, oscillation criteria, Riemann–Weber differential equation, principal solution.

2020 Mathematics Subject Classification: 34C10.

1 Introduction

In this paper we consider the second order half-linear ordinary differential equation

$$(p(t)\Phi_\alpha(x'))' + q(t)\Phi_\alpha(x) = 0, \quad t \geq t_0, \tag{1.1}$$

where $\Phi_\alpha(x) = |x|^\alpha \operatorname{sgn} x$ with $\alpha > 0$, $p(t)$ and $q(t)$ are real-valued continuous functions on $[t_0, \infty)$, and $p(t) > 0$ for $t \geq t_0$. If $\alpha = 1$, then (1.1) reduces to the linear equation

$$(p(t)x')' + q(t)x = 0, \quad t \geq t_0. \tag{1.2}$$

The half-linear equation (1.1) can be seen as a natural generalization of the linear equation (1.2).

For a solution $x(t)$ of (1.1), the vector function

$$(x(t), y(t)) = (x(t), p(t)\Phi_\alpha(x'(t)))$$

is a solution of the two-dimensional nonlinear system

$$x' = p(t)^{-1/\alpha}\Phi_{1/\alpha}(y), \quad y' = -q(t)\Phi_\alpha(x). \tag{1.3}$$

Conversely, for a solution $(x(t), y(t))$ of (1.3), the first component $x(t)$ is a solution of (1.1). The system of the type (1.3) was considered by Mirzov [11]. Using the result of Mirzov

✉ Email: naito.manabu078@nifty.com

[11, Lemma 2.1], we see that all local solutions of (1.1) can be continued to t_0 and ∞, and so all solutions of (1.1) exist on the entire interval $[t_0, \infty)$. Analogues of Sturm's comparison theorem and Sturm's separation theorem remain valid for (1.1) (Mirzov [11, Theorem 1.1]). Hence, if the equation (1.1) has a nonoscillatory solution, then any other nontrivial solution is also nonoscillatory. If the equation (1.1) has an oscillatory solution, then any other nontrivial solution is also oscillatory. Clearly, if $x(t)$ is a solution of (1.1), then so is $-x(t)$. Therefore we can suppose without loss of generality that a nonoscillatory solution of (1.1) is eventually positive.

In the last three decades, many results have been obtained in the theory of oscillatory and asymptotic behavior of solutions of half-linear differential equations. It is known that basic results for the second order linear equations can be generalized to the second order half-linear equations. The important works are summarized in the book of Došlý and Řehák [8]. For the recent results to half-linear equations we refer the reader to, for example, [1–7,9,10,12–16]. The present paper is strongly motivated by oscillatory and nonoscilaltory results in [2–4,6,7,9].

For the equation (1.1), it is sometimes assumed that

$$\int_{t_0}^{\infty} p(s)^{-1/\alpha} ds = \lim_{t\to\infty} \int_{t_0}^{t} p(s)^{-1/\alpha} ds = \infty \tag{1.4}$$

and

$$\begin{cases} \displaystyle\int_{t_0}^{\infty} q(s)ds = \lim_{t\to\infty} \int_{t_0}^{t} q(s)ds \quad \text{is convergent, and} \\ \displaystyle\int_{t}^{\infty} q(s)ds \geq 0, \not\equiv 0 \quad \text{on} \quad [t_0^+, \infty) \quad \text{for any} \quad t_0^+ \geq t_0. \end{cases} \tag{1.5}$$

We point out that for any nonoscillatory solution $x(t)$ of (1.1) with (1.4) and (1.5) the derivative $x'(t)$ does not vanish eventually. More precisely,

Proposition 1.1. *Consider the equation* (1.1) *under the conditions* (1.4) *and* (1.5)*. Let $x(t)$ be a nonoscillatory solution of* (1.1) *such that $x(t) > 0$ for $t \geq T$ $(\geq t_0)$. Then, $x'(t) > 0$ for $t \geq T$.*

The above fact is easily deduced from the generalized Riccati integral equation associated with (1.1). See Lemma 2.3 in the next section.

Together with the equation (1.1), we consider the equation of the same type

$$(p(t)\Phi_\alpha(x'))' + q_0(t)\Phi_\alpha(x) = 0, \quad t \geq t_0, \tag{1.6}$$

where $q_0(t)$ is a real-valued continuous function on $[t_0, \infty)$. The equation (1.1) is regarded as a perturbation of the equation (1.6). In this paper it will be assumed that (1.6) has a nonoscillatory solution $x = x_0(t)$ such that

$$x_0(t) > 0, \quad x_0'(t) > 0 \quad \text{for } t \geq T \tag{1.7}$$

and

$$\int_T^{\infty} \frac{1}{p(t)x_0(t)^2 x_0'(t)^{\alpha-1}} dt = \infty. \tag{1.8}$$

The condition (1.8) is closely related to an integral characterization of the principal solution of (1.6). For the concept of the principal solution, see Došlý and Řehák [8, Section 4.2]. The following result is known.

Theorem 1.2 (Došlý and Elbert [5] and Došlá and Došlý [1, Proposition 2]). *Suppose that $x = x_0(t)$ is a nonoscillatory solution of (1.6) satisfying (1.7).*

(i) *Let $0 < \alpha \le 1$. If (1.8) is satisfied, then $x_0(t)$ is the principal solution of (1.6).*

(ii) *Let $\alpha \ge 1$. If $x_0(t)$ is the principal solution of (1.6), then (1.8) holds.*

(iii) *Let $\alpha \ge 1$, and suppose that the conditions (1.4) and*

$$\int_{t_0}^{\infty} q_0(s)ds \quad \text{exists and} \quad \int_{t}^{\infty} q_0(s)ds \ge 0, \not\equiv 0 \quad \text{eventually} \tag{1.9}$$

are satisfied. Then, $x_0(t)$ is the principal solution of (1.6) if and only if (1.8) holds.

Note that the part (iii) of Theorem 1.2 is stated in [5, Theorem 3.3] and [8, Theorem 4.2.8] without the condition $\alpha \ge 1$. The part (iii) of Theorem 1.2 may fail to hold for $0 < \alpha < 1$ (see [1, Example 1]).

As an important oscillatory result the following theorem is known.

Theorem 1.3 (Došlý and Lomtatidze [7, Theorem 1]). *Suppose that the equation (1.6) is nonoscillatory and let $x = x_0(t)$ be the principal solution of (1.6) satisfying $x_0(t) > 0$ for $t \ge T$. If*

$$\int_{T}^{\infty} x_0(t)^{\alpha+1} \left[q(t) - q_0(t)\right] dt = \infty,$$

then the equation (1.1) is oscillatory.

Now let us consider the case where the equation (1.6) has a nonoscillatory solution $x = x_0(t)$ satisfying (1.7), (1.8) and

$$\int_{T}^{\infty} x_0(t)^{\alpha+1} \left[q(t) - q_0(t)\right] dt \quad \text{is convergent.} \tag{1.10}$$

It is not assumed that $x = x_0(t)$ is principal. Then we set

$$P(t) = p(t)x_0(t)^2 x_0'(t)^{\alpha-1} \quad \text{and} \quad Q(t) = x_0(t)^{\alpha+1}\left[q(t) - q_0(t)\right]. \tag{1.11}$$

Note that (1.7) implies $P(t) > 0$ $(t \ge T)$.

The condition

$$\liminf_{t\to\infty} p(t)x_0(t)x_0'(t)^{\alpha} > 0 \tag{1.12}$$

also plays an important part. The following nonoscillatory result has been showed by Došlý and Fišnarová.

Theorem 1.4 (Došlý and Fišnarová [6, Theorem 3]). *Suppose that the equation (1.6) has a nonoscillatory solution $x = x_0(t)$ satisfying (1.7), (1.8) and (1.12). Suppose moreover that (1.10) holds. If there exists $\varepsilon > 0$ such that the linear equation*

$$(P(t)x')' + (1+\varepsilon)\frac{\alpha+1}{2\alpha}Q(t)x = 0 \tag{1.13}$$

is nonoscillatory, then the equation (1.1) is nonoscillatory.

The following corollary is obtained by applying the classical Hille–Nehari nonoscillation criterion to the linear equation (1.13).

Corollary 1.5 (Došlý and Fišnarová [6, Corollary 1 (i)]). *Suppose that* (1.6) *has a nonoscillatory solution* $x = x_0(t)$ *satisfying* (1.7), (1.8) *and* (1.12). *Suppose moreover that* (1.10) *holds. If*

$$-\frac{3\alpha}{2(\alpha+1)} < \liminf_{t\to\infty} \left(\int_T^t \frac{1}{P(s)} ds\right) \left(\int_t^\infty Q(s) ds\right) \\ \leq \limsup_{t\to\infty} \left(\int_T^t \frac{1}{P(s)} ds\right) \left(\int_t^\infty Q(s) ds\right) < \frac{\alpha}{2(\alpha+1)},$$

then the equation (1.1) *is nonoscillatory.*

In this paper the following theorem will be proved.

Theorem 1.6. *Suppose that* $p(t)$ *and* $q(t)$ *satisfy* (1.4) *and* (1.5), *respectively. Suppose that the equation* (1.6) *has a nonoscillatory solution* $x = x_0(t)$ *satisfying* (1.7), (1.8) *and* (1.12). *Suppose moreover that* (1.10) *holds. If there exists a number* ε *with* $0 < \varepsilon < 1$ *such that the linear equation*

$$(P(t)x')' + (1-\varepsilon)\frac{\alpha+1}{2\alpha} Q(t)x = 0 \tag{1.14}$$

is oscillatory, then the equation (1.1) *is oscillatory.*

Theorem 1.6 was proved in [3, Theorem 1] under the restricted condition that

$$\lim_{t\to\infty} p(t)x_0(t)x_0'(t)^\alpha \quad \text{exists and is a positive finite value.}$$

Theorem 1.6 gives a partial extension of Theorem 4 in [6]. Applying the classical Hille–Nehari oscillation criterion to the linear equation (1.14), we have the following corollary.

Corollary 1.7. *Suppose that* $p(t)$ *and* $q(t)$ *satisfy* (1.4) *and* (1.5), *respectively. Suppose that* (1.6) *has a nonoscillatory solution* $x = x_0(t)$ *satisfying* (1.7), (1.8) *and* (1.12). *Suppose moreover that* (1.10) *holds. If*

$$\liminf_{t\to\infty} \left(\int_T^t \frac{1}{P(s)} ds\right) \left(\int_t^\infty Q(s) ds\right) > \frac{\alpha}{2(\alpha+1)}, \tag{1.15}$$

then the equation (1.1) *is oscillatory.*

Corollary 1.7 is a new result, while it is similar to Corollary 1 (ii) in [6].

Now, let

$$E(\alpha) = \frac{1}{\alpha+1}\left(\frac{\alpha}{\alpha+1}\right)^\alpha, \quad \mu(\alpha) = \frac{1}{2}\left(\frac{\alpha}{\alpha+1}\right)^\alpha, \tag{1.16}$$

and

$$\log_0 t = t, \quad \log_k t = \log(\log_{k-1} t), \quad \operatorname{Log}_k t = \prod_{j=1}^k \log_j t \quad (k = 1, 2, 3, \dots).$$

Then, consider the half-linear equation

$$(\Phi_\alpha(x'))' + \left(\frac{\alpha E(\alpha)}{t^{\alpha+1}} + \frac{\mu(\alpha)}{t^{\alpha+1}} \sum_{j=1}^n \frac{1}{(\operatorname{Log}_j t)^2} + c(t)\right) \Phi_\alpha(x) = 0, \tag{1.17}$$

where $c(t)$ is a continuous function on an interval $[t_0, \infty)$ with sufficiently large t_0. The equation (1.17) is regarded as a perturbation of the half-linear Riemann–Weber (sometimes also called Euler–Weber) differential equation

$$(\Phi_\alpha(x'))' + \left(\frac{\alpha E(\alpha)}{t^{\alpha+1}} + \frac{\mu(\alpha)}{t^{\alpha+1}} \sum_{j=1}^n \frac{1}{(\operatorname{Log}_j t)^2}\right) \Phi_\alpha(x) = 0. \tag{1.18}$$

It is known that (1.18) is nonoscillatory. Moreover, the asymptotic forms of (nonoscillatory) solutions of (1.18) are investigated by Elbert and Schneider [9, Corollary 1]. In this paper we pay attention to the fact that (1.18) has a nonoscillatory solution $x(t)$ such that

$$x(t) \sim t^{\alpha/(\alpha+1)}(\mathrm{Log}_n\, t)^{1/(\alpha+1)} \quad (t \to \infty). \tag{1.19}$$

We can prove the following theorem.

Theorem 1.8. *If*

$$\int_{t_0}^{\infty} t^{\alpha}(\mathrm{Log}_n\, t)c(t)dt = \infty, \tag{1.20}$$

then (1.17) *is oscillatory.*

The case $n = 1$ in Theorem 1.8 was obtained by Došlý [2, Corollary 1]. Theorem C in Elbert and Schneider [9] can be regarded as the case $n = 0$ in Theorem 1.8.

Next, consider the case where

$$\int_{t_0}^{\infty} t^{\alpha}(\mathrm{Log}_n\, t)c(t)dt \quad \text{is convergent.} \tag{1.21}$$

The following theorem is known.

Theorem 1.9 (Došlý [4, Theorem 3.3 (i)])**.** *Consider the equation* (1.17) *under the condition* (1.21)*. If*

$$\begin{aligned} -3\mu(\alpha) &< \liminf_{t\to\infty}\,(\log_{n+1} t) \int_t^{\infty} s^{\alpha}(\mathrm{Log}_n\, s)c(s)ds \\ &\le \limsup_{t\to\infty}\,(\log_{n+1} t) \int_t^{\infty} s^{\alpha}(\mathrm{Log}_n\, s)c(s)ds < \mu(\alpha), \end{aligned}$$

then (1.17) *is nonoscillatory.*

In the present paper the following theorem will be proved.

Theorem 1.10. *Consider the equation* (1.17) *under the condition* (1.21)*. If*

$$\liminf_{t\to\infty}\,(\log_{n+1} t) \int_t^{\infty} s^{\alpha}(\mathrm{Log}_n\, s)c(s)ds > \mu(\alpha), \tag{1.22}$$

then (1.17) *is oscillatory.*

Theorem 1.10 gives an improvement of Theorem 3.3 (ii) in [4].

Theorem 5 in [9] can be regarded as the case $n = 0$ in Theorems 1.9 and 1.10. Note that Theorem 5 in [9] is restricted to the case $n = 0$ and

$$\int_t^{\infty} s^{\alpha}c(s)ds \ge 0 \quad \text{for all large } t.$$

In the next section we state several basic (non)oscillatory results for the half-linear differential equation (1.1). The proofs are contained in the book of Došlý and Řehák [8]. For the proof of Theorem 1.6 we need some estimates for the function $F(u,v)$ which appears in the modified Riccati equation associated with (1.1). In Section 3 we state and prove the estimates for $F(u,v)$. The proof of Theorem 1.6 is given in Section 4. The proofs of Theorems 1.8 and 1.10 are presented in Section 5.

2 Basic results

For the convenience of the reader we summarize basic (non)oscillatory results for the half-linear differential equation (1.1). As usual, we use the asterisk notation

$$\xi^{\alpha *} = \Phi_\alpha(\xi) = |\xi|^\alpha \operatorname{sgn} \xi, \quad \xi \in \mathbb{R}, \quad \alpha > 0.$$

Then it is easy to see that, for $\xi, \eta \in \mathbb{R}$ and $\alpha, \alpha_1, \alpha_2 > 0$,

- $(\xi\eta)^{\alpha *} = \xi^{\alpha *}\eta^{\alpha *}, \quad (-\xi)^{\alpha *} = -\xi^{\alpha *};$
- $(\xi^{\alpha_1 *})^{\alpha_2 *} = \xi^{(\alpha_1\alpha_2)*}, \quad (\xi^{\alpha *})^{(1/\alpha)*} = \xi, \quad \left(\xi^{(1/\alpha)*}\right)^{\alpha *} = \xi;$
- $\xi^{\alpha *} \le \eta^{\alpha *}$ if and only if $\xi \le \eta$; $\xi^{\alpha *} < \eta^{\alpha *}$ if and only if $\xi < \eta$;
  $\xi^{\alpha *} = \eta^{\alpha *}$ if and only if $\xi = \eta$.

With this asterisk notation, the equation (1.1) is rewritten as

$$(p(t)(x')^{\alpha *})' + q(t)x^{\alpha *} = 0, \quad t \ge t_0.$$

Lemma 2.1. *The equation (1.1) is nonoscillatory if and only if there is a continuously differentiable function $y(t)$ which satisfies the generalized Riccati differential inequality*

$$y' + q(t) + \alpha p(t)^{-1/\alpha}|y|^{(\alpha+1)/\alpha} \le 0$$

on an interval $[T, \infty)$, $T \ge t_0$.

In what follows we consider the equation (1.1) under the condition (1.4). The next theorem is a half-linear extension of the classical Wintner oscillation criterion for (1.2).

Lemma 2.2. *Suppose that (1.4) holds. If*

$$\int_{t_0}^{\infty} q(t)dt = \infty,$$

then (1.1) is oscillatory.

As a next step we consider the case where (1.4) holds and

$$\int_{t_0}^{\infty} q(t)dt \quad \text{is convergent.} \tag{2.1}$$

Lemma 2.3. *Consider the equation (1.1) under the conditions (1.4) and (2.1). Let $x(t)$ be a nonoscillatory solution of (1.1) such that $x(t) > 0$ for $t \ge T$ $(\ge t_0)$. Then*

$$p(t)\left(\frac{x'(t)}{x(t)}\right)^{\alpha *} = \int_t^{\infty} q(s)ds + \alpha \int_t^{\infty} p(s)\left|\frac{x'(s)}{x(s)}\right|^{\alpha+1} ds, \quad t \ge T.$$

If the additional condition

$$\int_t^{\infty} q(s)ds \ge 0, \not\equiv 0 \quad \text{on} \quad [T^+, \infty) \quad \text{for any} \quad T^+ \ge T$$

is satisfied, then $x'(t) > 0$ for $t \ge T$.

The following lemma is the Hille–Nehari type (non)oscillation criteria for the equation (1.1).

Lemma 2.4. *Consider the equation* (1.1) *under the conditions* (1.4) *and* (2.1). *Let* $E(\alpha)$ *be the constant defined by the former part of* (1.16).

(i) *The equation* (1.1) *is nonoscillatory provided*

$$\begin{aligned} -(2\alpha+1)E(\alpha) &< \liminf_{t\to\infty}\left(\int_{t_0}^{t} p(s)^{-1/\alpha}ds\right)^{\alpha}\left(\int_{t}^{\infty} q(s)ds\right) \\ &\le \limsup_{t\to\infty}\left(\int_{t_0}^{t} p(s)^{-1/\alpha}ds\right)^{\alpha}\left(\int_{t}^{\infty} q(s)ds\right) < E(\alpha). \end{aligned}$$

(ii) *The equation* (1.1) *is oscillatory provided*

$$\liminf_{t\to\infty}\left(\int_{t_0}^{t} p(s)^{-1/\alpha}ds\right)^{\alpha}\left(\int_{t}^{\infty} q(s)ds\right) > E(\alpha).$$

The results mentioned here are half-linear extensions of the classical results for the linear equation (1.2). For the proofs, see [8].

3 Lemmas

It is known that the function

$$F(u,v) = |u+v|^{(\alpha+1)/\alpha} - |v|^{(\alpha+1)/\alpha} - \frac{\alpha+1}{\alpha}v^{(1/\alpha)*}u, \quad u,v\in\mathbb{R}, \tag{3.1}$$

plays a crucial role in the study of the oscillation and nonoscillation of (1.1).

Lemma 3.1 (see, e.g., Došlý and Fišnarová [6, Lemma 4])**.** *Let* $x = x(t)$ *and* $x = x_0(t)$ *be nonoscillatory solutions of* (1.1) *and* (1.6), *respectively. Suppose that* $x(t) > 0$ *and* $x_0(t) > 0$ *for* $t \ge T$ $(\ge t_0)$. *Then the function*

$$u(t) = p(t)x_0(t)^{\alpha+1}\left[\left(\frac{x'(t)}{x(t)}\right)^{\alpha*} - \left(\frac{x_0'(t)}{x_0(t)}\right)^{\alpha*}\right], \quad t \ge T, \tag{3.2}$$

is a solution of the modified Riccati differential equation

$$\begin{aligned} &u'(t) + x_0(t)^{\alpha+1}[q(t) - q_0(t)] \\ &\quad + \alpha p(t)^{-1/\alpha}x_0(t)^{-(\alpha+1)/\alpha}F(u(t), p(t)x_0(t)x_0'(t)^{\alpha*}) = 0, \quad t \ge T, \end{aligned} \tag{3.3}$$

where $F(u,v)$ *is defined by* (3.1).

Lemma 3.2. *Let* $F(u,v)$ *be the function which is defined by* (3.1).

(i) $F(u,v) \ge 0$ *for all* $u,v \in \mathbb{R}$; $F(u,v) = 0$ *if and only if* $u = 0$.

(ii) *Let* $k > 0$ *be a constant. Then there are constants* $L_1(k) > 0$ *and* $L_2(k) > 0$ *such that*

$$L_1(k)|v|^{(1/\alpha)-1}u^2 \le F(u,v) \le L_2(k)|v|^{(1/\alpha)-1}u^2 \tag{3.4}$$

for $v > 0$ *and* $-v < u \le kv$.

(iii) *Let* k_1 *and* k_2 *be constants satisfying* $0 < k_1 < k_2$. *Then there is a constant* $L(k_1, k_2) > 0$ *such that* $F(u, v)$ *can be expressed in the following form*

$$F(u,v) = \frac{\alpha+1}{2\alpha^2}|v|^{(1/\alpha)-1}u^2(1+R(u,v))$$

with

$$|R(u,v)| \le \frac{|\alpha-1|}{3\alpha}L(k_1,k_2)|u|$$

for $v > 0$ *and* $|u| \le k_1 < k_2 \le v$.

Proof. It is obvious that $F(0, v) = 0$. Differentiating the function $F(u, v)$ with respect to u, we obtain

$$\begin{aligned} F_u(u,v) &= \frac{\alpha+1}{\alpha}(u+v)^{(1/\alpha)*} - \frac{\alpha+1}{\alpha}v^{(1/\alpha)*}, \quad u,v \in \mathbb{R}, \\ F_{uu}(u,v) &= \frac{\alpha+1}{\alpha^2}|u+v|^{(1/\alpha)-1}, \quad u > -v, \\ F_{uuu}(u,v) &= \frac{(\alpha+1)(-\alpha+1)}{\alpha^3}(u+v)^{[(1/\alpha)-2]*}, \quad u > -v. \end{aligned}$$

Then, $F_u(0, v) = 0$ ($v \in \mathbb{R}$) and $F_{uu}(0, v) = [(\alpha + 1)/\alpha^2]|v|^{(1/\alpha)-1}$ ($v > 0$).

(i) Let $v \in \mathbb{R}$ be fixed. It is seen that $F_u(u, v) < 0$ for $u < 0$, $F_u(u, v) > 0$ for $u > 0$ and $F_u(0, v) = 0$. This means that $F(u, v)$ is strictly decreasing on $(-\infty, 0)$ and $F(u, v)$ is strictly increasing on $(0, \infty)$. Then, since $F(0, v) = 0$, it is clear that $F(u, v) \ge 0$ for $u \in \mathbb{R}$ and $F(u, v) = 0$ if and only if $u = 0$.

(ii) Let $v > 0$ and $-v < u \le kv$. By Taylor's theorem with integral remainder we have

$$F(u,v) = F(0,v) + F_u(0,v)u + \int_0^u (u-s)F_{uu}(s,v)ds.$$

Hence

$$\begin{aligned} F(u,v) &= \frac{\alpha+1}{\alpha^2}\int_0^u (u-s)|s+v|^{(1/\alpha)-1}ds \\ &= \frac{\alpha+1}{\alpha^2}\int_0^1 (u-u\sigma)|u\sigma+v|^{(1/\alpha)-1}ud\sigma \\ &= \frac{\alpha+1}{\alpha^2}|v|^{(1/\alpha)-1}u^2\int_0^1 (1-\sigma)\left|\frac{u}{v}\sigma+1\right|^{(1/\alpha)-1}d\sigma. \end{aligned}$$

Then, noting

$$0 \le -\sigma+1 \le \frac{u}{v}\sigma+1 \le k\sigma+1 \quad (0 \le \sigma \le 1),$$

we find that, for the case $0 < \alpha \le 1$,

$$\begin{aligned} \frac{\alpha}{\alpha+1} = \int_0^1 (1-\sigma)^{1/\alpha}d\sigma &\le \int_0^1 (1-\sigma)\left|\frac{u}{v}\sigma+1\right|^{(1/\alpha)-1}d\sigma \\ &\le \int_0^1 (1-\sigma)(k\sigma+1)^{(1/\alpha)-1}d\sigma; \end{aligned}$$

and, for the case $\alpha > 1$,

$$\begin{aligned} \int_0^1 (1-\sigma)(k\sigma+1)^{(1/\alpha)-1}d\sigma &\le \int_0^1 (1-\sigma)\left|\frac{u}{v}\sigma+1\right|^{(1/\alpha)-1}d\sigma \\ &\le \int_0^1 (1-\sigma)^{1/\alpha}d\sigma = \frac{\alpha}{\alpha+1}. \end{aligned}$$

This shows that (3.4) holds with positive constants $L_1(k)$ and $L_2(k)$ such that, for the case $0 < \alpha \le 1$,

$$L_1(k) = \frac{1}{\alpha} \quad \text{and} \quad L_2(k) = \frac{\alpha+1}{\alpha^2}\int_0^1 (1-\sigma)(k\sigma+1)^{(1/\alpha)-1}d\sigma;$$

and, for the case $\alpha > 1$,

$$L_1(k) = \frac{\alpha+1}{\alpha^2}\int_0^1 (1-\sigma)(k\sigma+1)^{(1/\alpha)-1}d\sigma \quad \text{and} \quad L_2(k) = \frac{1}{\alpha}.$$

(iii) Let $v > 0$ and $|u| \le k_1 < k_2 \le v$. By Taylor's theorem there is θ such that $0 < \theta < 1$ and

$$F(u,v) = F(0,v) + F_u(0,v)u + \frac{F_{uu}(0,v)}{2!}u^2 + \frac{F_{uuu}(\theta u,v)}{3!}u^3.$$

Hence

$$\begin{aligned} F(u,v) &= \frac{\alpha+1}{2\alpha^2}|v|^{(1/\alpha)-1}u^2 + \frac{(\alpha+1)(-\alpha+1)}{6\alpha^3}(\theta u+v)^{[(1/\alpha)-2]*}u^3 \\ &= \frac{\alpha+1}{2\alpha^2}|v|^{(1/\alpha)-1}u^2\left[1 + \frac{-\alpha+1}{3\alpha}|v|^{-(1/\alpha)+1}(\theta u+v)^{[(1/\alpha)-2]*}u\right]. \end{aligned}$$

Notice here that

$$\theta u + v \ge -|u| + v \ge -k_1 + k_2 > 0 \quad (0 < \theta < 1)$$

and

$$0 < -\frac{k_1}{k_2} + 1 \le \frac{u}{v}\theta + 1 = \frac{\theta u + v}{v} \le \frac{k_1}{k_2} + 1 \quad (0 < \theta < 1).$$

Put

$$R(u,v) = \frac{-\alpha+1}{3\alpha}|v|^{-(1/\alpha)+1}(\theta u+v)^{[(1/\alpha)-2]*}u.$$

Then it is easy to see that

$$|R(u,v)| \le \frac{|\alpha-1|}{3\alpha}\left|\frac{\theta u+v}{v}\right|^{(1/\alpha)-1}|\theta u+v|^{-1}|u| \le \frac{|\alpha-1|}{3\alpha}L(k_1,k_2)|u|,$$

where $L(k_1,k_2)$ is given by

$$L(k_1,k_2) = \begin{cases} \left(1+\dfrac{k_1}{k_2}\right)^{(1/\alpha)-1}(k_2-k_1)^{-1} & (0 < \alpha \le 1), \\ \left(1-\dfrac{k_1}{k_2}\right)^{(1/\alpha)-1}(k_2-k_1)^{-1} & (\alpha > 1). \end{cases}$$

This proves the part (iii) of Lemma 3.2. □

4 Proofs of the results

Proof of Theorem 1.6. Suppose that there is $\varepsilon \in (0,1)$ such that (1.14) is oscillatory. Assume, by contradiction, that the equation (1.1) has a nonoscillatory solution $x(t)$. We may suppose that $x(t) > 0$ for $t \ge T$. Then, we define the function $u(t)$ by (3.2). By Lemma 3.1, $u(t)$ satisfies (3.3). Integrating (3.3) from T to t, we obtain

$$\begin{aligned} &u(t) - u(T) + \int_T^t x_0(s)^{\alpha+1}[q(s)-q_0(s)]ds \\ &\quad + \alpha\int_T^t p(s)^{-1/\alpha}x_0(s)^{-(\alpha+1)/\alpha}F(u(s),p(s)x_0(s)x_0'(s)^{\alpha})ds = 0 \end{aligned} \tag{4.1}$$

for $t \geq T$. Since the integrand of the last integral in the left-hand side of (4.1) is nonnegative for $t \geq T$ (see Lemma 3.2 (i)), we have either

$$\int_T^\infty p(s)^{-1/\alpha} x_0(s)^{-(\alpha+1)/\alpha} F(u(s), p(s)x_0(s)x_0'(s)^\alpha)ds = \infty \tag{4.2}$$

or

$$\int_T^\infty p(s)^{-1/\alpha} x_0(s)^{-(\alpha+1)/\alpha} F(u(s), p(s)x_0(s)x_0'(s)^\alpha)ds < \infty. \tag{4.3}$$

Suppose first that (4.2) holds. Since (1.10) is assumed to hold, it follows from (4.1) that $u(t) \to -\infty$ as $t \to \infty$. We may suppose that $u(t) < 0$ for $t \geq T$. By Lemma 2.3 we have $x'(t) > 0$ for $t \geq T$. Hence, by (3.2), we get

$$-p(t)x_0(t)x_0'(t)^\alpha = -p(t)x_0(t)^{\alpha+1}\left(\frac{x_0'(t)}{x_0(t)}\right)^{\alpha*} < u(t) \leq p(t)x_0(t)x_0'(t)^\alpha, \quad t \geq T.$$

Applying Lemma 3.2 (ii) to the case $k = 1$, $u = u(t)$ and $v = p(t)x_0(t)x_0'(t)^\alpha$, we find that there are constants $L_1 = L_1(1) > 0$ and $L_2 = L_2(1) > 0$ such that

$$\begin{aligned} &L_1 p(t)^{-1} x_0(t)^{-2} x_0'(t)^{-\alpha+1} u(t)^2 \\ &\quad \leq p(t)^{-1/\alpha} x_0(t)^{-(\alpha+1)/\alpha} F(u(t), p(t)x_0(t)x_0'(t)^\alpha) \\ &\quad \leq L_2 p(t)^{-1} x_0(t)^{-2} x_0'(t)^{-\alpha+1} u(t)^2, \quad t \geq T. \end{aligned}$$

Therefore, (3.3) yields

$$u'(t) + x_0(t)^{\alpha+1}\left[q(t) - q_0(t)\right] + \alpha L_1 p(t)^{-1} x_0(t)^{-2} x_0'(t)^{-\alpha+1} u(t)^2 \leq 0$$

for $t \geq T$, and (4.2) gives

$$\int_T^\infty p(t)^{-1} x_0(t)^{-2} x_0'(t)^{-\alpha+1} u(t)^2 dt = \infty.$$

Thus we obtain

$$u'(t) + Q(t) + \alpha L_1 P(t)^{-1} u(t)^2 \leq 0, \quad t \geq T, \tag{4.4}$$

and

$$\int_T^\infty P(t)^{-1} u(t)^2 dt = \infty. \tag{4.5}$$

Here the functions $P(t)$ and $Q(t)$ are given by (1.11).

Put

$$\varphi(t) = \int_T^t P(s)^{-1} ds, \quad t \geq T. \tag{4.6}$$

It follows from (4.4) that

$$\begin{aligned} &\int_T^t (\varphi(t) - \varphi(s))^2 u'(s)ds + \int_T^t (\varphi(t) - \varphi(s))^2 Q(s)ds \\ &\quad + \alpha L_1 \int_T^t (\varphi(t) - \varphi(s))^2 P(s)^{-1} u(s)^2 ds \leq 0, \quad t \geq T. \end{aligned} \tag{4.7}$$

Denote by $I(t)$ the first term of the left-hand side of (4.7). Then, it is seen that

$$I(t) = -u(T)\varphi(t)^2 + 2\int_T^t (\varphi(t) - \varphi(s))P(s)^{-1} u(s)ds, \quad t \geq T,$$

and so, by the Cauchy–Schwarz inequality, we find that

$$|I(t)| \le |u(T)|\varphi(t)^2 + 2\left(\int_T^t P(s)^{-1}ds\right)^{1/2}\left(\int_T^t (\varphi(t)-\varphi(s))^2 P(s)^{-1}u(s)^2 ds\right)^{1/2}$$

for $t \ge T$. Therefore, (4.6) and (4.7) yield

$$\begin{aligned}\frac{1}{\varphi(t)^2}\int_T^t(\varphi(t)-\varphi(s))^2Q(s)ds &\le |u(T)| \\ &+ \frac{2}{\varphi(t)^{1/2}}\left(\frac{1}{\varphi(t)^2}\int_T^t(\varphi(t)-\varphi(s))^2P(s)^{-1}u(s)^2ds\right)^{1/2} \\ &- \alpha L_1\left(\frac{1}{\varphi(t)^2}\int_T^t(\varphi(t)-\varphi(s))^2P(s)^{-1}u(s)^2ds\right), \quad t > T.\end{aligned} \tag{4.8}$$

It follows from (1.8) and (4.6) that

$$\lim_{t\to\infty}\varphi(t) = \int_T^\infty P(s)^{-1}ds = \int_T^\infty p(s)^{-1}x_0(s)^{-2}x_0'(s)^{-\alpha+1}ds = \infty,$$

and, by L'Hospital's rule and (4.5), we get

$$\lim_{t\to\infty}\frac{1}{\varphi(t)^2}\int_T^t(\varphi(t)-\varphi(s))^2P(s)^{-1}u(s)^2ds = \int_T^\infty P(s)^{-1}u(s)^2ds = \infty.$$

Let β be a constant such that $0 < \beta < \alpha L_1$. Then it is easy to check that (4.8) yields

$$\frac{1}{\varphi(t)^2}\int_T^t(\varphi(t)-\varphi(s))^2Q(s)ds \le -\frac{\beta}{\varphi(t)^2}\int_T^t(\varphi(t)-\varphi(s))^2P(s)^{-1}u(s)^2ds$$

for all large t, and consequently,

$$\lim_{t\to\infty}\frac{1}{\varphi(t)^2}\int_T^t(\varphi(t)-\varphi(s))^2Q(s)ds = -\infty.$$

On the other hand, the condition (1.10), i.e., the condition

$$\lim_{t\to\infty}\int_T^t Q(s)ds = \int_T^\infty Q(s)ds \quad \text{is convergent}$$

implies

$$\lim_{t\to\infty}\frac{1}{\varphi(t)^2}\int_T^t(\varphi(t)-\varphi(s))^2Q(s)ds = \int_T^\infty Q(s)ds \in \mathbb{R}.$$

This is a contradiction. Therefore, (4.2) does not occur.

Next suppose that (4.3) holds. Using (1.10), (4.1) and (4.3), we see that $\lim_{t\to\infty}u(t)$ exists and is finite. Put $\lim_{t\to\infty}u(t) = \ell$ $(\in \mathbb{R})$. Integrating the equality (3.3) from t to τ $(T \le t \le \tau)$ and letting $\tau \to \infty$, we obtain

$$\begin{aligned}u(t) = \ell &+ \int_t^\infty x_0(s)^{\alpha+1}[q(s)-q_0(s)]ds \\ &+ \alpha\int_t^\infty p(s)^{-1/\alpha}x_0(s)^{-(\alpha+1)/\alpha}F(u(s), p(s)x_0(s)x_0'(s)^\alpha)ds\end{aligned}$$

for $t \ge T$. By Lemma 2.3 we have $x'(t) > 0$ for $t \ge T$. Hence, by (1.7), (3.2) and (1.12), there is a positive constant k such that

$$-p(t)x_0(t)x_0'(t)^\alpha < u(t) \le kp(t)x_0(t)x_0'(t)^\alpha \tag{4.9}$$

for all large t. We may suppose that (4.9) is valid for $t \geq T$. Applying Lemma 3.2 (ii) to the case $u = u(t)$ and $v = p(t)x_0(t)x_0'(t)^\alpha$, we find that there is a constant $L_1(k) > 0$ such that

$$\begin{aligned} &L_1(k)p(t)^{-1}x_0(t)^{-2}x_0'(t)^{-\alpha+1}u(t)^2 \\ &\quad \leq p(t)^{-1/\alpha}x_0(t)^{-(\alpha+1)/\alpha}F(u(t), p(t)x_0(t)x_0'(t)^\alpha), \quad t \geq T. \end{aligned}$$

Hence, (4.3) gives

$$\int_T^\infty p(t)^{-1}x_0(t)^{-2}x_0'(t)^{-\alpha+1}u(t)^2 dt < \infty.$$

If $\lim_{t\to\infty} u(t) = \ell \neq 0$, then the above fact contradicts the condition (1.8). Therefore we see that $\ell = 0$.

Since

$$\lim_{t\to\infty} u(t) = \ell = 0, \tag{4.10}$$

we find from (1.12) that there are positive constants k_1 and k_2 such that

$$|u(t)| \leq k_1 < k_2 \leq p(t)x_0(t)x_0'(t)^\alpha \tag{4.11}$$

for all large t. We may suppose that (4.11) holds for $t \geq T$. Then, applying Lemma 3.2 (iii) to the case $u = u(t)$ and $v = p(t)x_0(t)x_0'(t)^\alpha$, we deduce that $F(u(t), p(t)x_0(t)x_0'(t)^\alpha)$ is expressed as

$$F(u(t), p(t)x_0(t)x_0'(t)^\alpha) = \frac{\alpha+1}{2\alpha^2}|p(t)x_0(t)x_0'(t)^\alpha|^{(1/\alpha)-1}u(t)^2(1+R(t)) \tag{4.12}$$

with

$$|R(t)| \leq \frac{|\alpha-1|}{3\alpha}L(k_1,k_2)|u(t)| \tag{4.13}$$

for $t \geq T$. Here, $L(k_1,k_2)$ is the constant appearing in Lemma 3.2 (iii). Then, (4.12) gives

$$\begin{aligned} &p(t)^{-1/\alpha}x_0(t)^{-(\alpha+1)/\alpha}F(u(t), p(t)x_0(t)x_0'(t)^\alpha) \\ &\quad = \frac{\alpha+1}{2\alpha^2}p(t)^{-1}x_0(t)^{-2}x_0'(t)^{-\alpha+1}u(t)^2(1+R(t)), \quad t \geq T. \end{aligned} \tag{4.14}$$

By (4.10) and (4.13), we have $\lim_{t\to\infty} R(t) = 0$, and so

$$R(t) \geq -\varepsilon \quad \text{for all large } t, \tag{4.15}$$

where $\varepsilon \in (0,1)$ is the number in the statement of Theorem 1.6. Then, by (3.3), (4.14) and (4.15), we find that

$$u'(t) + Q(t) + (1-\varepsilon)\frac{\alpha+1}{2\alpha}P(t)^{-1}u(t)^2 \leq 0 \quad \text{for all large } t.$$

Therefore the function

$$y(t) = (1-\varepsilon)\frac{\alpha+1}{2\alpha}u(t) \quad \text{with } 0 < \varepsilon < 1$$

satisfies

$$y'(t) + (1-\varepsilon)\frac{\alpha+1}{2\alpha}Q(t) + P(t)^{-1}y(t)^2 \leq 0 \quad \text{for all large } t.$$

Hence, Lemma 2.1 of the case $\alpha = 1$ implies that the linear equation (1.14) is nonoscillatory. This is a contradiction to the assumption that (1.14) is oscillatory. Therefore, (4.3) also does not occur. Consequently the equation (1.1) is oscillatory. The proof of Theorem 1.6 is complete. □

Proof of Corollary 1.7. Corollary 1.7 is a simple combination of Theorem 1.6 and Lemma 2.4 (ii) with $\alpha = 1$. □

5 Proofs of the results (continued)

In this section we prove Theorem 1.8 and Theorem 1.10. It is known that the half-linear Riemann–Weber differential equation (1.18) has a nonoscillatory solution $x(t)$ satisfying (1.19) (see Elbert and Schneider [9, Corollary 1]). Put

$$x_0(t) = t^{\alpha/(\alpha+1)}(\mathrm{Log}_n\, t)^{1/(\alpha+1)}, \quad t \geq T, \tag{5.1}$$

where T is taken sufficiently large such that t and $\mathrm{Log}_j\, t$ $(j = 1, 2, \ldots, n)$ are positive for $t \geq T$. It is trivial that $x = x_0(t)$ is a positive solution of the equation

$$(\Phi_\alpha(x'))' - \frac{(\Phi_\alpha(x_0'(t)))'}{\Phi_\alpha(x_0(t))}\Phi_\alpha(x) = 0$$

on $[T, \infty)$. We define the function $c_0(t)$ by

$$c_0(t) = -\frac{(\Phi_\alpha(x_0'(t)))'}{\Phi_\alpha(x_0(t))} - \left(\frac{\alpha E(\alpha)}{t^{\alpha+1}} + \frac{\mu(\alpha)}{t^{\alpha+1}}\sum_{j=1}^{n}\frac{1}{(\mathrm{Log}_j\, t)^2}\right). \tag{5.2}$$

Then the function $x_0(t)$ is a positive solution of

$$(\Phi_\alpha(x'))' + \left(\frac{\alpha E(\alpha)}{t^{\alpha+1}} + \frac{\mu(\alpha)}{t^{\alpha+1}}\sum_{j=1}^{n}\frac{1}{(\mathrm{Log}_j\, t)^2} + c_0(t)\right)\Phi_\alpha(x) = 0. \tag{5.3}$$

In the equations (1.1) and (1.6), let $p(t) \equiv 1$ and

$$q(t) = \frac{\alpha E(\alpha)}{t^{\alpha+1}} + \frac{\mu(\alpha)}{t^{\alpha+1}}\sum_{j=1}^{n}\frac{1}{(\mathrm{Log}_j\, t)^2} + c(t) \tag{5.4}$$

and

$$q_0(t) = \frac{\alpha E(\alpha)}{t^{\alpha+1}} + \frac{\mu(\alpha)}{t^{\alpha+1}}\sum_{j=1}^{n}\frac{1}{(\mathrm{Log}_j\, t)^2} + c_0(t). \tag{5.5}$$

Then, the equations (1.1) and (1.6) become (1.17) and (5.3), respectively. The key idea of the proofs of Theorems 1.8 and 1.10 is to use the equation (5.3), not the equation (1.18).

From the calculation in [4] we see that

$$x_0'(t) = \frac{\alpha}{\alpha+1}t^{-1/(\alpha+1)}(\mathrm{Log}_n\, t)^{1/(\alpha+1)}\left(1 + \frac{1}{\alpha}\sum_{j=1}^{n}\frac{1}{\mathrm{Log}_j\, t}\right), \tag{5.6}$$

and

$$\begin{aligned}(\Phi_\alpha(x_0'(t)))' = &- t^{-(2\alpha+1)/(\alpha+1)}(\mathrm{Log}_n\, t)^{\alpha/(\alpha+1)} \\ &\times \left(\alpha E(\alpha) + \mu(\alpha)\sum_{j=1}^{n}\frac{1}{(\mathrm{Log}_j\, t)^2} + O\left(\frac{1}{(\log t)^3}\right)\right)\end{aligned}$$

as $t \to \infty$. Therefore, the function $c_0(t)$ defined by (5.2) satisfies

$$c_0(t) = O\left(\frac{1}{t^{\alpha+1}(\log t)^3}\right) \quad (t \to \infty). \tag{5.7}$$

By (5.7) it is clear that

$$\int_T^\infty c_0(s)ds \quad \text{is convergent}$$

and

$$\lim_{t\to\infty} t^\alpha \int_t^\infty c_0(s)ds = 0.$$

Therefore, in the present case, we find that

$$\int_T^\infty q_0(s)ds \quad \text{is convergent}$$

and

$$\int_t^\infty q_0(s)ds = \frac{E(\alpha)}{t^\alpha} + \mu(\alpha)\sum_{j=1}^n \int_t^\infty \frac{1}{s^{\alpha+1}(\mathrm{Log}_j\, s)^2}ds + \int_t^\infty c_0(s)ds.$$

Then it is easy to see that

$$\lim_{t\to\infty} t^\alpha \int_t^\infty q_0(s)ds = E(\alpha) > 0.$$

Consequently, the condition (1.9) is satisfied.

By (5.1) and (5.6), the condition (1.7) is satisfied. Furthermore it is easily checked that

$$x_0(t)^{-2}x_0'(t)^{-\alpha+1} \sim \left(\frac{\alpha}{\alpha+1}\right)^{-\alpha+1} \frac{1}{t\,\mathrm{Log}_n\, t} \quad (t\to\infty).$$

Note here that

$$\frac{d}{dt}\log_{n+1} t = \frac{1}{t\,\mathrm{Log}_n\, t},$$

and so

$$\int_T^t \frac{1}{s\,\mathrm{Log}_n\, s}ds = \log_{n+1} t - \log_{n+1} T.$$

This implies

$$\int_T^t x_0(s)^{-2}x_0'(s)^{-\alpha+1}ds \sim \left(\frac{\alpha}{\alpha+1}\right)^{-\alpha+1} \log_{n+1} t \quad (t\to\infty), \tag{5.8}$$

which yields (1.8) with $p(t) \equiv 1$.

We have

$$\int_T^t x_0(s)^{\alpha+1}\left[q(s)-q_0(s)\right]ds = \int_T^t s^\alpha(\mathrm{Log}_n\, s)\left[c(s)-c_0(s)\right]ds.$$

Došlý [4] showed that

$$\int_T^\infty \frac{\mathrm{Log}_n\, s}{s(\log s)^3}ds < \infty$$

and

$$\lim_{t\to\infty}(\log_{n+1} t)\int_t^\infty \frac{\mathrm{Log}_n\, s}{s(\log s)^3}ds = 0.$$

Therefore we deduce from (5.7) that

$$\int_T^\infty s^\alpha(\mathrm{Log}_n\, s)c_0(s)ds \quad \text{is convergent} \tag{5.9}$$

and

$$\lim_{t\to\infty}(\log_{n+1} t)\int_t^\infty s^\alpha(\mathrm{Log}_n\, s)c_0(s)ds = 0. \tag{5.10}$$

We are now ready to prove Theorems 1.8 and 1.10.

Proof of Theorem 1.8. We apply Theorem 1.3 with $p(t) \equiv 1$ to the equations (1.17) and (5.3). Let $q(t)$ and $q_0(t)$ be the functions defined by (5.4) and (5.5), respectively. Since (1.8) $(p(t) \equiv 1)$ and (1.9) are satisfied, the function $x_0(t)$ which is defined by (5.1) is the principal solution of (5.3). In fact, this can be derived from a direct application of Theorem 1.2 with $p(t) \equiv 1$. For the case $0 < \alpha \le 1$, use the part (i), and for the case $\alpha \ge 1$ the part (iii). If (1.20) is satisfied, then (5.9) gives

$$\int_T^\infty x_0(s)^{\alpha+1}\,[q(s) - q_0(s)]\,ds = \int_T^\infty s^\alpha (\operatorname{Log}_n s)\,[c(s) - c_0(s)]\,ds = \infty.$$

Therefore it follows from Theorem 1.3 with $p(t) \equiv 1$ that if (1.20) is satisfied, then the equation (1.17) is oscillatory. The proof of Theorem 1.8 is complete. □

Proof of Theorem 1.10. We apply Corollary 1.7 with $p(t) \equiv 1$ to the equations (1.17) and (5.3). Let $q(t)$ and $q_0(t)$ be the functions defined by (5.4) and (5.5), respectively. We first show that if (1.21) holds, then (1.5) is satisfied. To see this, note that

$$\frac{d}{dt}\operatorname{Log}_n t = \frac{\operatorname{Log}_n t}{t}\left(\sum_{j=1}^n \frac{1}{\operatorname{Log}_j t}\right)$$

and

$$\begin{aligned}\int_T^t c(s)ds &= \int_T^t \frac{1}{s^\alpha \operatorname{Log}_n s} s^\alpha (\operatorname{Log}_n s) c(s) ds \\ &= -\frac{1}{t^\alpha \operatorname{Log}_n t}\int_t^\infty r^\alpha (\operatorname{Log}_n r) c(r) dr + \frac{1}{T^\alpha \operatorname{Log}_n T}\int_T^\infty r^\alpha (\operatorname{Log}_n r) c(r) dr \\ &\quad - \int_T^t \left[\frac{\alpha}{s^{\alpha+1}\operatorname{Log}_n s} + \frac{1}{s^{\alpha+1}\operatorname{Log}_n s}\left(\sum_{j=1}^n \frac{1}{\operatorname{Log}_j s}\right)\right]\left(\int_s^\infty r^\alpha (\operatorname{Log}_n r) c(r) dr\right) ds.\end{aligned}$$

Therefore we deduce that

$$\lim_{t\to\infty}\int_T^t c(s)ds \quad \text{exists and is finite}$$

and

$$\begin{aligned}\int_t^\infty c(s)ds = \frac{1}{t^\alpha \operatorname{Log}_n t}\int_t^\infty r^\alpha (\operatorname{Log}_n r) c(r) dr \\ - \int_t^\infty \left[\frac{\alpha}{s^{\alpha+1}\operatorname{Log}_n s} + \frac{1}{s^{\alpha+1}\operatorname{Log}_n s}\left(\sum_{j=1}^n \frac{1}{\operatorname{Log}_j s}\right)\right]\left(\int_s^\infty r^\alpha (\operatorname{Log}_n r) c(r) dr\right) ds\end{aligned}$$

for $t \ge T$. Then it is easy to find that

$$\lim_{t\to\infty} t^\alpha \int_t^\infty c(s)ds = 0.$$

Since

$$\int_t^\infty q(s)ds = \frac{E(\alpha)}{t^\alpha} + \mu(\alpha)\sum_{j=1}^n \int_t^\infty \frac{1}{s^{\alpha+1}(\operatorname{Log}_j s)^2} ds + \int_t^\infty c(s)ds,$$

we obtain

$$\lim_{t\to\infty} t^\alpha \int_t^\infty q(s)ds = E(\alpha)\ (>0).$$

Thus we see that the condition (1.5) is satisfied.

As mentioned before, the conditions (1.7) and (1.8) with $p(t) \equiv 1$ are satisfied. By (5.1) and (5.6), we have

$$x_0(t)x_0'(t)^\alpha = \left(\frac{\alpha}{\alpha+1}\right)^\alpha (\mathrm{Log}_n\, t)\left(1 + \frac{1}{\alpha}\sum_{j=1}^{n}\frac{1}{\mathrm{Log}_j\, t}\right)^\alpha,$$

and so $\lim_{t\to\infty} x_0(t)x_0'(t)^\alpha = \infty$. Hence the condition (1.12) with $p(t) \equiv 1$ is also satisfied. By the definition of $P(t)$ and $Q(t)$ and the properties (5.8) and (5.10), we have

$$\begin{aligned}
&\left(\int_T^t \frac{1}{P(s)}ds\right)\left(\int_t^\infty Q(s)ds\right)\\
&= \left(\int_T^t x_0(s)^{-2}x_0'(s)^{-\alpha+1}ds\right)\left(\int_t^\infty x_0(s)^{\alpha+1}[q(s)-q_0(s)]ds\right)\\
&= \varepsilon_1(t)\left(\frac{\alpha}{\alpha+1}\right)^{-\alpha+1}(\log_{n+1} t)\left(\int_t^\infty s^\alpha(\mathrm{Log}_n\, s)[c(s)-c_0(s)]ds\right)\\
&= \varepsilon_1(t)\left(\frac{\alpha}{\alpha+1}\right)^{-\alpha+1}(\log_{n+1} t)\left(\int_t^\infty s^\alpha(\mathrm{Log}_n\, s)c(s)ds\right) + \varepsilon_2(t),
\end{aligned}$$

where $\varepsilon_1(t)$ and $\varepsilon_2(t)$ are functions such that

$$\lim_{t\to\infty}\varepsilon_1(t) = 1 \quad \text{and} \quad \lim_{t\to\infty}\varepsilon_2(t) = 0,$$

respectively. Then it is easy to see that (1.22) implies (1.15). Thus, by Corollary 1.7, we can conclude that if (1.22) holds, then the equation (1.17) is oscillatory. The proof of Theorem 1.10 is complete. □

Finally we present an equation whose oscillation follows from Theorem 1.10 and does not follow from Theorem 3.3 (ii) in [4].

Example 5.1. Consider the equation (1.17) of the case

$$c(t) = \mu(\alpha)\frac{k + \sin(2k\log_{n+2} t) - 2k\cos(2k\log_{n+2} t)}{t^{\alpha+1}(\mathrm{Log}_{n+1}\, t)^2}, \tag{5.11}$$

where k is a constant satisfying $k > 2$. In this case it can be shown without difficulty that the condition (1.21) is satisfied and

$$\int_t^\infty s^\alpha(\mathrm{Log}_n\, s)c(s)ds = \mu(\alpha)\frac{k + \sin(2k\log_{n+2} t)}{\log_{n+1} t}.$$

Therefore we have

$$\liminf_{t\to\infty}(\log_{n+1} t)\int_t^\infty s^\alpha(\mathrm{Log}_n\, s)c(s)ds = \mu(\alpha)(k-1) > \mu(\alpha).$$

Hence, by Theorem 1.10, we can conclude that, for any $\alpha > 0$, the equation (1.17) with (5.11) is oscillatory.

Theorem 3.3 (ii) in [4] requires the condition that there is a constant γ satisfying

$$t^{\alpha+1}(\log t)^3 c(t) \geq \gamma > \frac{2(\alpha+1)(\alpha-1)}{3\alpha^2}\left(\frac{\alpha}{\alpha+1}\right)^{\alpha+1}$$

for all large t. If $\alpha \geq 1$, this condition leads to $c(t) > 0$ for all large t. There exists a sequence $\{t_i\}_{i=1}^{\infty}$ such that $\lim t_i = \infty$ $(i \to \infty)$ and

$$k \log_{n+2} t_i = \pi i \quad \text{for all large } i.$$

Then, for the function $c(t)$ given by (5.11),

$$c(t_i) = \mu(\alpha) \frac{-k}{t_i^{\alpha+1} (\mathrm{Log}_{n+1} t_i)^2} < 0 \quad \text{for all large } i.$$

Therefore, if $\alpha \geq 1$, then we cannot apply Theorem 3.3 (ii) in [4] to the present case.

Abstract. This note is a reaction on a recently published sufficient condition for oscillation of all solutions of a neutral delay differential equation. It is shown by a counterexample that the result is not correct and the problem is explained in details. Several, more general, classes of neutral differential equations with time-dependent discrete, distributed as well as mixed delays are considered. New sufficient conditions for oscillation of all their solutions are proved. Applications are given for illustration.

Keywords: oscillatory solution, discrete delay, distributed delay, mixed delay.

2020 Mathematics Subject Classification: 34K11, 34K06, 34C10.

1 Introduction

Oscillation theory for first order linear neutral differential equations with delay,

$$[x(t) + P(t)\,x(t-\tau)]' + Q(t)\,x(t-\sigma) = 0, \quad t \geq t_0,$$

has attracted researchers' interest for decades (see, e.g., [1–3] and references therein).

Recently, a sufficient condition was proved in [5] for oscillation of all solutions of the neutral delay differential equation

$$[x(t) - x(\tau(t))]' + Q(t)\,x(\sigma(t)) = 0, \quad t \geq t_0 \tag{1.1}$$

for some $t_0 \in \mathbb{R}$, where $Q \in C([t_0,\infty),\mathbb{R}_+)$, $\mathbb{R}_+ = [0,\infty)$, and $\tau, \sigma \in \mathcal{T}_{t_0}$ with

$$\mathcal{T}_\xi = \left\{ f \in C([\xi,\infty),\mathbb{R}) \;\middle|\; \begin{array}{l} f \text{ is strictly increasing;} \\ f(t) < t \;\forall t \geq \xi;\ \lim_{t\to\infty} f(t) = \infty \end{array} \right\}. \tag{1.2}$$

✉Corresponding author. Email: michal.pospisil@fmph.uniba.sk

However, as we shall show in this paper, the proof is not correct and the statement does not hold. It is worth to mention that the limit property of functions from $\mathcal{T}_\xi$ was not explicitly assumed in [5], but it was applied in the proof.

In this paper, we prove a similar statement by a cautious use of a mathematical induction. We give a short remark explaining the problem of the original proof from [5]. Next, we generalize the result for the case of a convex combination of multiple discrete delays. We also consider neutral differential equations with distributed and mixed delays, and we prove analogous statements. More precisely, in addition to equation (1.1), the following equations are investigated in this paper:

$$\left[x(t) - \sum_{i=1}^{n} \lambda_i \, x(\tau_i(t))\right]' + \sum_{j=1}^{m} Q_j(t) \, x(\sigma_j(t)) = 0, \quad t \geq t_0, \tag{1.3}$$

$$\left[x(t) - \frac{\int_{\underline{\tau}(t)}^{\overline{\tau}(t)} \lambda(s)x(s)\, ds}{\int_{\underline{\tau}(t)}^{\overline{\tau}(t)} \lambda(s)\, ds}\right]' + Q(t) \int_{\underline{\sigma}(t)}^{\overline{\sigma}(t)} R(s)x(s)\, ds = 0, \quad t \geq t_0, \tag{1.4}$$

and

$$\begin{aligned}\left[x(t) - \left(\sum_{i=1}^{n_1} \lambda_i(t)x(\tau_i(t)) + \sum_{i=1}^{n_2} \int_{\underline{\tau}_i(t)}^{\overline{\tau}_i(t)} \vartheta_i(s)x(s)\, ds\right)\right]' \\ + \sum_{j=1}^{m_1} Q_j(t)x(\sigma_j(t)) + \sum_{j=1}^{m_2} S_j(t) \int_{\underline{\sigma}_j(t)}^{\overline{\sigma}_j(t)} R_j(s)x(s)\, ds = 0, \quad t \geq t_0 \end{aligned} \tag{1.5}$$

with appropriate parameters (see Theorems 3.7, 3.9, and 3.11 below).

The paper is organized as follows. In the next section, we conclude preliminary results and introduce an auxiliary function. Section 3 is devoted to the main results of this paper – sufficient conditions for oscillation of all solutions of various classes of neutral differential equations with delays. In the final section, applications to equations with particular types of delays, and concrete examples are given for illustration.

Throughout the paper, we denote by $\mathbb{N}$ ($\mathbb{N}_0$) the set of all positive (nonnegative) integers.

2 Preliminaries

In this section, we introduce some notation and prove auxiliary results.

Let us fix $\xi \in \mathbb{R}$ and consider $\tau \in \mathcal{T}_\xi$. Analogously to the iterations of function τ: $\tau^k = \tau \circ \tau^{k-1}$, $k \in \mathbb{N}$, $\tau^0 = id$, we denote $\tau^{-k} = \tau^{-1} \circ \tau^{-(k-1)}$, $k \in \mathbb{N}$ the iterations of the inverse function $\tau^{-1}\colon [\tau(\xi), \infty) \to [\xi, \infty)$. Then the following result holds.

Lemma 2.1. *Let $\xi \in \mathbb{R}$ and $\tau \in \mathcal{T}_\xi$. For any $\zeta \in [\tau(\xi), \infty)$, the sequence $\{\tau^{-k}(\zeta)\}_{k=1}^{\infty}$ is strictly increasing to ∞.*

Proof. Let $\zeta \in [\tau(\xi), \infty)$ be arbitrary and fixed. Then, $\tau(\zeta) < \zeta$ implies $\zeta < \tau^{-1}(\zeta)$, which yields $\tau^{-1}(\zeta) < \tau^{-2}(\zeta)$, etc. So, by induction, one can see that $\{\tau^{-k}(\zeta)\}_{k=1}^{\infty}$ is a strictly increasing sequence. Now, suppose by contrary that $\lim_{k\to\infty} \tau^{-k}(\zeta) = C < \infty$. Then,

$$C = \lim_{k\to\infty} \tau^{-k}(\zeta) = \lim_{k\to\infty} \tau^{-1}(\tau^{-(k-1)}(\zeta)) = \tau^{-1}\left(\lim_{k\to\infty} \tau^{-(k-1)}(\zeta)\right) = \tau^{-1}(C)$$

is a contradiction, and the proof is complete. □

For any $\zeta \in [\tau(\xi), \infty)$, we define a function $N^\tau_\zeta \colon [\zeta, \infty) \to \mathbb{N}$ such that for any $t \in [\zeta, \infty)$, $N^\tau_\zeta(t)$ satisfies

$$\tau^{-(N^\tau_\zeta(t)-1)}(\zeta) \leq t < \tau^{-N^\tau_\zeta(t)}(\zeta). \tag{2.1}$$

Due to Lemma 2.1, function N^τ_ζ is well defined. Note that

$$N^\tau_\zeta([\tau^{-k}(\zeta), \tau^{-(k+1)}(\zeta))) = k+1 \tag{2.2}$$

for each $k \in \mathbb{N}_0$. Then, it is easy to see that N^τ_ζ in nondecreasing on $[\zeta, \infty)$ and unbounded from above. Another important property of N^τ_ζ is proved in the next lemma.

Lemma 2.2. *Let $\xi \in \mathbb{R}$, $\tau \in \mathcal{T}_\xi$, $\alpha_1 \in [\xi, \infty)$, $\alpha_2 = \tau^{-k}(\alpha_1)$ for some $k \in \mathbb{N}_0$. Then*

$$N^\tau_{\alpha_1}(t) = N^\tau_{\alpha_2}(t) + k, \quad t \geq \alpha_2.$$

Proof. For any $t \geq \alpha_2$,

$$\begin{aligned} \tau^{-(N^\tau_{\alpha_2}(t)+k-1)}(\alpha_1) &= \tau^{-(N^\tau_{\alpha_2}(t)+k-1)}(\tau^k(\alpha_2)) \\ &= \tau^{-(N^\tau_{\alpha_2}(t)-1)}(\alpha_2) \leq t < \tau^{-N^\tau_{\alpha_2}(t)}(\alpha_2) \\ &= \tau^{-N^\tau_{\alpha_2}(t)}(\tau^{-k}(\alpha_1)) = \tau^{-(N^\tau_{\alpha_2}(t)+k)}(\alpha_1). \end{aligned}$$

But we know that for any $t \geq \alpha_2$ (even for any $t \geq \alpha_1$), there is a unique $\kappa \in \mathbb{N}$ satisfying $\tau^{-(\kappa-1)}(\alpha_1) \leq t < \tau^{-\kappa}(\alpha_1)$, and it is given by $\kappa = N^\tau_{\alpha_1}(t)$. Therefore, $N^\tau_{\alpha_1}(t) = N^\tau_{\alpha_2}(t) + k$. □

We will investigate solutions of equation (1.1) in the sense of the following definitions.

Definition 2.3. Let $t_0 \in \mathbb{R}$ and $Q \in C([t_0, \infty), \mathbb{R}_+)$, $\tau, \sigma \in \mathcal{T}_{t_0}$, $\varphi \in C([\min\{\tau(t_0), \sigma(t_0)\}, t_0], \mathbb{R})$ be given functions. We say that

$$x \in C([\min\{\tau(t_0), \sigma(t_0)\}, \infty), \mathbb{R})$$

is a solution of equation (1.1) along with the initial condition

$$x(t) = \varphi(t), \quad t \in [\min\{\tau(t_0), \sigma(t_0)\}, t_0] \tag{2.3}$$

if $x(t) - x(\tau(t))$ is continuously differentiable for all $t \in [t_0, \infty)$ and x satisfies (1.1), (2.3).

In the rest of the paper, we often omit initial condition (2.3). So, x is a solution of (1.1) if there exists a suitable function φ such that x solves initial value problem (1.1), (2.3).

Definition 2.4. Let $t_0 \in \mathbb{R}$ and $Q \in C([t_0, \infty), \mathbb{R}_+)$, $\tau, \sigma \in \mathcal{T}_{t_0}$ be given functions. Solution x of (1.1) is called eventually positive (eventually negative) if there is $T > t_0$ such that $x(t) > 0$ ($x(t) < 0$) for all $t \geq T$. In this case, x is called nonoscillatory. Otherwise, we say that x oscillates or that it is oscillatory.

In other neutral differential equations studied in the paper, their solutions are understood in an analogous sense.

Finally, in this section, we present an auxiliary lemma.

Lemma 2.5. *Let $A \geq B \geq 0$ and $\alpha > 1$. Then*

$$(A-B)^{\frac{1}{\alpha}} \geq A^{\frac{1}{\alpha}} - B^{\frac{1}{\alpha}}.$$

Proof. If $A = 0$, the statement is obvious. Now, let $A \neq 0$ and consider the function $f(x) = (1-x)^{\frac{1}{\alpha}} - (1 - x^{\frac{1}{\alpha}})$ for $x \in [0,1]$. Then $f(0) = 0 = f(1)$. The derivative,

$$f'(x) = \frac{1}{\alpha}\left(x^{\frac{1-\alpha}{\alpha}} - (1-x)^{\frac{1-\alpha}{\alpha}}\right)$$

vanishes if and only if $x = \frac{1}{2}$. Since

$$f\left(\frac{1}{2}\right) = \frac{2 - 2^{\frac{1}{\alpha}}}{2^{\frac{1}{\alpha}}} > 0,$$

we get that $f(x) \geq 0$ for all $x \in [0,1]$. In particular, $f(\frac{B}{A}) \geq 0$ which proves the statement. □

3 Main results

Here, we recall the result from [5] and provide a counterexample to show that it does not hold. Next, by correcting the wrong proof from [5], we prove a new sufficient condition for oscillation of all solutions of equation (1.1). Then, we give a generalization to multiple discrete delays. In Subsection 3.2, an analogous problem is studied for neutral differential equations with distributed and mixed delays.

3.1 Discrete delays

In [5], the next result was stated (we use the quotation marks to warn readers that the result is not correct):

"Theorem" 3.1. *Let $t_0 > 0$ and $Q \in C([t_0,\infty), \mathbb{R}_+)$, $\tau, \sigma \in \mathcal{T}_{t_0}$ be given functions. If*

$$\int_{t_0}^{\infty} Q(s)\, ds = \infty \tag{3.1}$$

or

$$\int_{t_0}^{\infty} s\, Q(s)\, ds = \infty, \tag{3.2}$$

then every solution of equation (1.1) oscillates.

It will be shown in the proof of Theorem 3.3 below (and it was correctly proved in [5]) that inequality (3.1) is indeed a sufficient condition for oscillation of all solutions of (1.1). In the next example, we illustrate that if (3.1) does not hold, inequality (3.2) does not guarantee the oscillation of all solutions of (1.1).

Example 3.2. Let us consider the following equation

$$\left[x(t) - x\left(\frac{t}{2}\right)\right]' + \frac{1}{t^2}\, x\left(\frac{t}{2 - t\ln(2 - e^{\frac{1}{t}})}\right) = 0, \quad t \geq t_0 \tag{3.3}$$

for some $t_0 > \frac{1}{\ln 2}$.

Since $0 < 2 - e^{\frac{1}{t_0}} \leq 2 - e^{\frac{1}{t}} < 1$, we have $\ln(2 - e^{\frac{1}{t}}) < 0$ $\forall t \geq t_0$. So,

$$\sigma(t) = \frac{t}{2 - t\ln(2 - e^{\frac{1}{t}})} < t, \quad t \geq t_0.$$

Furthermore, from

$$\sigma'(t) = \frac{4 - e^{\frac{1}{t}}}{\left(2 - e^{\frac{1}{t}}\right)\left(2 - t\ln(2 - e^{\frac{1}{t}})\right)^2},$$

one can see that $\sigma'(t) > 0$ for all $t \geq t_0$. It is easy to verify that $\sigma(t) \xrightarrow{t\to\infty} \infty$. Thus, $\sigma \in \mathcal{T}_{t_0}$. Clearly, $\tau \in \mathcal{T}_{t_0}$ for $\tau(t) = \frac{t}{2}$. Moreover,

$$\int_{t_0}^{\infty} \frac{ds}{s^2} = \frac{1}{t_0} < \infty, \qquad \int_{t_0}^{\infty} \frac{ds}{s} = \infty,$$

i.e., condition (3.1) is not satisfied, but (3.2) holds. Hence, by "Theorem" 3.1, every solution of equation (3.3) oscillates. However, a positive function $e^{-\frac{1}{t}}$ solves this equation. Indeed, for $x(t) = e^{-\frac{1}{t}}$, the left-hand side of (3.3) reads as

$$\frac{e^{-\frac{1}{t}}}{t^2} - \frac{2\,e^{-\frac{2}{t}}}{t^2} + \frac{1}{t^2}\,e^{-\frac{2 - t\ln(2 - e^{\frac{1}{t}})}{t}} = \frac{1}{t^2}\left[e^{-\frac{1}{t}} - 2\,e^{-\frac{2}{t}} + e^{-\frac{2}{t}}(2 - e^{\frac{1}{t}})\right] = 0.$$

Next, we present our result for equation (1.1).

Theorem 3.3. *Let $t_0 \in \mathbb{R}$ and $Q \in C([t_0,\infty),\mathbb{R}_+)$, $\tau,\sigma \in \mathcal{T}_{t_0}$ be given functions. If condition (3.1) is satisfied or*

$$\int_{\sigma^{-1}(t_0)}^{\infty} (N_{t_0}^{\tau}(\sigma(s)))^{\frac{1}{p}}\, Q(s)\, ds = \infty \tag{3.4$_p$}$$

for some $p > 1$, where $N_{t_0}^{\tau}(t)$ is given by (2.1), then every solution of equation (1.1) oscillates.

Note that in the label of condition $(3.4)_p$, we use the parameter $p > 1$ as the lower index.

Proof. One can easily see that condition (3.1) as well as condition $(3.4)_p$ implies that Q does not vanish for all t sufficiently large, i.e.,

$$\forall t \geq t_0\ \exists T \geq t : Q(T) > 0.$$

Without any loss of generality, we suppose in contrary that x is an eventually positive solution of (1.1). Since $\lim_{t\to\infty} \tau(t) = \lim_{t\to\infty} \sigma(t) = \infty$, there is $t_1 \geq t_0$ such that $x(t)$, $x(\tau(t))$ and $x(\sigma(t))$ are positive for all $t \geq t_1$. For $z(t) = x(t) - x(\tau(t))$, equation (1.1) gives $z'(t) \leq 0$ $\forall t \geq t_1$. Moreover, from the nonvanishing property of Q, we know that for any $t \geq t_1$ there is $T \geq t$ such that $z'(T) < 0$. Hence, $z(t)$ can not vanish for all sufficiently large t, but it is either eventually negative or eventually positive.

If z is eventually negative, then, since it is nonincreasing, there exist $t_2 \geq t_1$ and $\mu > 0$ such that $z(t) \leq -\mu$ for all $t \geq t_2$. Equivalently, we have

$$x(t) \leq x(\tau(t)) - \mu, \quad t \geq t_2.$$

In particular,

$$x(\tau^{-k}(t_2)) \leq x(\tau^{-(k-1)}(t_2)) - \mu \leq \cdots \leq x(t_2) - k\mu$$

for each $k \in \mathbb{N}$. A contradiction with the eventual positivity of x follows, since the right side tends to $-\infty$ as $k \to \infty$.

Hence, z is eventually positive, i.e., there is $t_2 \geq t_1$ such that $z(t) > 0$ $\forall t \geq t_2$. This means that

$$x(t) > x(\tau(t)) > 0, \quad t \geq t_2. \tag{3.5}$$

Therefore,

$$x(t) \geq \min_{s \in [\tau(t_2), t_2]} x(s) =: \omega > 0, \quad t \geq t_2. \tag{3.6}$$

From equation (1.1), we obtain

$$0 = z'(t) + Q(t)x(\sigma(t)) \geq z'(t) + \omega Q(t)$$

for all $t \geq t_3$ for some $t_3 \geq \sigma^{-1}(t_2)$. This gives

$$z(t) \leq z(t_3) - \omega \int_{t_3}^{t} Q(s)\, ds, \quad t \geq t_3.$$

So, if condition (3.1) is satisfied, we get $\lim_{t\to\infty} z(t) = -\infty$ which is a contradiction, and x is oscillatory.

Now, assume that

$$\int_{t_0}^{\infty} Q(s)\, ds < \infty \tag{3.7}$$

and that condition $(3.4)_p$ is satisfied for some $p > 1$. Let us take $t_4 \geq \tau^{-1}(t_2)$ such that $t_4 = \tau^{-\kappa}(t_0)$ for some $\kappa \in \mathbb{N}$.

From

$$x(t) = z(t) + x(\tau(t)), \quad t \geq t_4, \tag{3.8}$$

we get

$$x(t) = z(t) + z(\tau(t)) + \cdots + z(\tau^{(N-1)}(t)) + x(\tau^N(t))$$

for any $t \in [\tau^{-(N-1)}(t_4), \tau^{-N}(t_4))$, $N \in \mathbb{N}$. Since z is nonincreasing and $\tau \in \mathcal{T}_{t_0}$, this identity implies

$$x(t) \geq Nz(t) + x(\tau^N(t)), \quad t \in [\tau^{-(N-1)}(t_4), \tau^{-N}(t_4)),\ N \in \mathbb{N}$$

or, equivalently,

$$x(t) \geq N^{\tau}_{t_4}(t)z(t) + x(\tau^{N^{\tau}_{t_4}(t)}(t)), \quad t \geq t_4$$

(see (2.2)). Note that $\tau^{N^{\tau}_{t_4}(t)}(t) \in [\tau(t_4), t_4) \subset [t_2, \infty)$ for any $t \geq t_4$. Hence, by (3.6),

$$x(t) \geq N^{\tau}_{t_4}(t)z(t) + \omega, \quad t \geq t_4.$$

Next, using the Young inequality,

$$\frac{A^p}{p} + \frac{B^q}{q} \geq AB$$

for $A, B > 0$ and $q = \frac{p}{p-1}$, we derive

$$x(t) \geq \frac{\left(\left(pN^{\tau}_{t_4}(t)z(t)\right)^{\frac{1}{p}}\right)^p}{p} + \frac{\left((q\omega)^{\frac{1}{q}}\right)^q}{q} \geq \left(pN^{\tau}_{t_4}(t)z(t)\right)^{\frac{1}{p}} (q\omega)^{\frac{1}{q}}$$

for all $t \geq t_4$. Let us denote $\omega_1 := p^{\frac{1}{p}}(q\omega)^{\frac{1}{q}} > 0$ and take $t_5 = \sigma^{-1}(t_4)$. Then, (1.1) implies

$$\begin{aligned} z'(t) = -Q(t)x(\sigma(t)) &\leq -\omega_1 Q(t) \left(N^{\tau}_{t_4}(\sigma(t))z(\sigma(t))\right)^{\frac{1}{p}} \\ &\leq -\omega_1 Q(t) \left(N^{\tau}_{t_4}(\sigma(t))z(t)\right)^{\frac{1}{p}}, \quad t \geq t_5 \end{aligned}$$

since z is nonincreasing. Dividing by $z^{\frac{1}{p}}(t)$ and integrating over $[t_5, t]$ yields

$$\int_{t_5}^{t} \frac{z'(s)\,ds}{z^{\frac{1}{p}}(s)} = qz^{\frac{1}{q}}(t) - qz^{\frac{1}{q}}(t_5) \leq -\omega_1 \int_{t_5}^{t} \left(N_{t_4}^{\tau}(\sigma(s))\right)^{\frac{1}{p}} Q(s)\,ds$$

for all $t \geq t_5$. Now, it only remains to prove that

$$\int_{t_5}^{\infty} \left(N_{t_4}^{\tau}(\sigma(s))\right)^{\frac{1}{p}} Q(s)\,ds = \infty. \tag{3.9}$$

Consequently, we get a contradiction with the eventual positivity of z, implying that x is oscillatory.

Using Lemmas 2.2, 2.5, we derive

$$\left(N_{t_4}^{\tau}(t)\right)^{\frac{1}{p}} = \left(N_{t_0}^{\tau}(t) - \kappa\right)^{\frac{1}{p}} \geq \left(N_{t_0}^{\tau}(t)\right)^{\frac{1}{p}} - \kappa^{\frac{1}{p}}$$

for all $t \geq t_4$. Therefore, assumptions $(3.4)_p$, (3.7) imply for $t \geq t_5$,

$$\begin{aligned}\int_{t_5}^{t} \left(N_{t_4}^{\tau}(\sigma(s))\right)^{\frac{1}{p}} Q(s)\,ds &\geq \int_{t_5}^{t} \left(N_{t_0}^{\tau}(\sigma(s))\right)^{\frac{1}{p}} Q(s)\,ds - \kappa^{\frac{1}{p}} \int_{t_5}^{t} Q(s)\,ds \\ &= \int_{\sigma^{-1}(t_0)}^{t} \left(N_{t_0}^{\tau}(\sigma(s))\right)^{\frac{1}{p}} Q(s)\,ds - \kappa^{\frac{1}{p}} \int_{t_0}^{t} Q(s)\,ds + C \xrightarrow{t\to\infty} \infty\end{aligned}$$

with an appropriate constant $C \in \mathbb{R}$. □

Remark 3.4. Condition (3.1) was proved in [5], but in the proof of Theorem 3.3, we emphasize were the missing assumption was needed. Namely, to get the existence of t_1.

Remark 3.5. The original proof of "Theorem" 3.1 from [5] contains the following issues:

1. Constant $\tau = \inf_{t \geq t_3}(t - \tau(t))$ was introduced and used as positive. However, the case $\tau(t) \nearrow t$ as $t \to \infty$ was not considered.

2. For fixed t, the value $x(\tau^{N(t)}(t))$ was used, where $N(t) = \left\lfloor \frac{t-t_3}{\tau} \right\rfloor^2$, τ is defined in the previous point of this remark, and $\lfloor \cdot \rfloor$ is the greatest integer function (or the floor function). This can be a problem if $N(t)$ is so large that $\tau^{N(t)}(t) < \tau(t_2)$, because then one can not use the estimation

$$x(\tau^{N(t)-1}(t)) > x(\tau^{N(t)}(t)).$$

   Similarly, we use estimation (3.5), but, in our case, $N_{t_4}^{\tau}(t)$ is bounded for any fixed $t \geq t_4$ (as it does not depend on the infimum).

3. The proof from [5] does not work even if τ is far from zero (e.g., constant delay). The problem is in the power 2 in the definition of $N(t)$ (see the previous point). Because then one can not iterate expansion (3.8) $N(t)$-times, due to $\tau^{N(t)}(t) < \tau(t_4)$.

Remark 3.6. Since $N_{t_0}^{\tau}(t) \in \mathbb{N}$ and $Q(t) \geq 0$ for all $t \geq t_0$, inequality $k^{\frac{1}{p_1}} \leq k^{\frac{1}{p_2}}$ for each $k \in \mathbb{N}$ and all $1 \leq p_2 \leq p_1$ gives that, $(3.4)_{p_1}$ implies $(3.4)_{p_2}$ for any $1 < p_2 \leq p_1$. Similarly, (3.1) implies $(3.4)_p$ for all $p > 1$.

Now, we generalize Theorem 3.3 to the case of multiple delays.

Theorem 3.7. *Let $t_0 \in \mathbb{R}$, $n, m \in \mathbb{N}$, $\lambda_i > 0$ for $i = 1, 2, \dots, n$ be such that $\sum_{i=1}^{n} \lambda_i = 1$, and $Q_j \in C([t_0, \infty), \mathbb{R}_+)$, $\tau_i, \sigma_j \in \mathcal{T}_{t_0}$ for $i = 1, 2, \dots, n$, $j = 1, 2, \dots, m$ be given functions. If there exists $j_0 \in \{1, 2, \dots, m\}$ such that*

$$\int_{t_0}^{\infty} Q_{j_0}(s)\, ds = \infty \tag{3.10}$$

or

$$\int_{\sigma_{j_0}^{-1}(t_0)}^{\infty} (N_{t_0}^{\underline{\tau}}(\sigma_{j_0}(s)))^{\frac{1}{p}} Q_{j_0}(s)\, ds = \infty \tag*{(3.11)$_p$}$$

for some $p > 1$, where $\underline{\tau} = \min_{i=1,2,\dots,n} \tau_i$ and $N_{t_0}^{\underline{\tau}}(t)$ is given by (2.1), then every solution of equation (1.3) oscillates.

Proof. In this proof, we skip some details that are the same as in the proof of Theorem 3.3.

As in the proof of Theorem 3.3, each one of conditions (3.10), (3.11)$_p$ implies that

$$\forall t \geq t_0 \; \exists T \geq t : Q_{j_0}(T) > 0.$$

Suppose that x is an eventually positive solution of (1.3). Then, there is $t_1 \geq t_0$ such that $x(t)$, $x(\tau_i(t))$, $x(\sigma_j(t))$, $i = 1, 2, \dots, n$, $j = 1, 2, \dots, m$ are positive for all $t \geq t_1$. From equation (1.3), we get $z'(t) \leq 0$ $\forall t \geq t_1$ for $z(t) = x(t) - \sum_{i=1}^{n} \lambda_i x(\tau_i(t))$. Again, z can be only eventually negative or eventually positive.

If z is eventually negative, then there exist $t_2 \geq t_1$ and $\mu > 0$ such that $z(t) \leq -\mu$ for all $t \geq t_2$, i.e.,

$$\begin{aligned} x(t) &\leq -\mu + \sum_{i=1}^{n} \lambda_i x(\tau_i(t)) \leq -\mu + \max_{i=1,2,\dots,n} x(\tau_i(t)) \\ &\leq -\mu + \max_{s \in I(t)} x(s) \end{aligned} \tag{3.12}$$

for all $t \geq t_2$, where $I(t) = [\underline{\tau}(t), \overline{\tau}(t)]$, $\overline{\tau} = \max_{i=1,2,\dots,n} \tau_i$. Note that $\underline{\tau}, \overline{\tau} \in \mathcal{T}_{t_0}$. Denote

$$\begin{aligned} I_\ell &:= \left[\underline{\tau}^{-(\ell-1)}(t_2), \underline{\tau}^{-\ell}(t_2)\right), \quad \ell \in \mathbb{N}_0, \\ I_\ell^k &:= I_\ell \cap \left[\overline{\tau}^{-(k-1)}(\underline{\tau}^{-(\ell-1)}(t_2)), \overline{\tau}^{-k}(\underline{\tau}^{-(\ell-1)}(t_2))\right), \quad \ell \in \mathbb{N},\ k = 1, 2, \dots, K(\ell), \end{aligned} \tag{3.13}$$

where $K(\ell)$ is the largest $k \in \mathbb{N}$ for which $I_\ell^k \neq \emptyset$. Notice that by (2.2), $t \in I_\ell$ for $\ell \in \mathbb{N}_0$ if and only if $N_{t_2}^{\underline{\tau}}(t) = \ell$. Now, if $t \in I_\ell^1$ for $\ell \in \mathbb{N}$, then $\underline{\tau}(t) \in \underline{\tau}(I_\ell) = I_{\ell-1}$ and

$$\begin{aligned} \overline{\tau}(t) &\in \overline{\tau}\left(\left[\underline{\tau}^{-(\ell-1)}(t_2), \overline{\tau}^{-1}(\underline{\tau}^{-(\ell-1)}(t_2))\right)\right) \\ &= \left[\overline{\tau}(\underline{\tau}^{-(\ell-1)}(t_2)), \underline{\tau}^{-(\ell-1)}(t_2)\right) \subset I_{\ell-1}. \end{aligned}$$

Similarly, if $t \in I_\ell^k$ for $\ell \in \mathbb{N}$, $k \in \{2, 3, \dots, K(\ell)\}$, then $\underline{\tau}(t) \in \underline{\tau}(I_\ell) = I_{\ell-1}$ and

$$\begin{aligned} \overline{\tau}(t) &\in \overline{\tau}\left(\left[\overline{\tau}^{-(k-1)}(\underline{\tau}^{-(\ell-1)}(t_2)), \overline{\tau}^{-k}(\underline{\tau}^{-(\ell-1)}(t_2))\right)\right) \\ &= \left[\overline{\tau}^{-(k-2)}(\underline{\tau}^{-(\ell-1)}(t_2)), \overline{\tau}^{-(k-1)}(\underline{\tau}^{-(\ell-1)}(t_2))\right) \subset I_\ell^{k-1}. \end{aligned}$$

Using the above inclusions, we are able to work more precisely with $I(t)$ for particular values of t.

Now, we use the mathematical induction with respect to the intervals I_1^1, I_1^2, $\dots$, $I_1^{K(1)}$, $I_2^1, \dots$ to prove an estimation of $x(t)$ for all $t \geq t_2$. Let us denote $\Omega := \sup_{s \in I_0} x(s) =$

$\max_{s\in\overline{I_0}} x(s)$ and $C_\ell^k := \operatorname{conv}\{I_{\ell-1}, I_\ell^k\}$, the convex hull of the corresponding sets for $\ell \in \mathbb{N}$, $k \in \{1,2,\dots,K(\ell)\}$. For $I(I_\ell^k) = \bigcup_{t\in I_\ell^k}[\underline{\tau}(t), \overline{\tau}(t)]$, we get $I(I_\ell^1) \subset \overline{I_{\ell-1}}$ for each $\ell \in \mathbb{N}$. So, if $t \in I_1^1$, then by (3.12),

$$x(t) \le -\mu + \max_{s\in\overline{I(I_1^1)}} x(s) = -\mu + \max_{s\in\overline{I_0}} x(s) = -\mu + \Omega = -N_{t_2}^{\tau}(t)\mu + \Omega.$$

Furthermore, $I(I_\ell^k) \subset \overline{\operatorname{conv}\{I_{\ell-1}, I_\ell^{k-1}\}} = \overline{C_\ell^{k-1}}$ for $l \in \mathbb{N}$, $k \in \{2,3,\dots,K(\ell)\}$. Let us suppose that $\ell \in \mathbb{N}$, $k \in \{1,2,\dots,K(\ell)\}$ are fixed and

$$x(t) \le -N_{t_2}^{\tau}(t)\mu + \Omega$$

for all $t \in \operatorname{conv}\{I_0, I_\ell^k\}$ (due to the continuity of x, this estimation is valid for all $t \in \overline{\operatorname{conv}\{I_0, I_\ell^k\}}$). Now, if $k < K(\ell)$, for $t \in I_\ell^{k+1}$ we have $I(t) \subset I(I_\ell^{k+1}) \subset \overline{C_\ell^k}$. Hence, by (3.12),

$$\begin{aligned} x(t) &\le -\mu + \max_{s\in\overline{C_\ell^k}} x(s) \le -\mu + \max_{s\in\overline{C_\ell^k}}(-N_{t_2}^{\tau}(s)\mu + \Omega) \\ &= -\mu - (\ell-1)\mu + \Omega = -\ell\mu + \Omega = -N_{t_2}^{\tau}(t)\mu + \Omega. \end{aligned}$$

On the other side, if $k = K(\ell)$, for $t \in I_{\ell+1}^1$ we obtain

$$\begin{aligned} x(t) &\le -\mu + \max_{s\in\overline{I_\ell}} x(s) \le -\mu + \max_{s\in\overline{I_\ell}}(-N_{t_2}^{\tau}(s)\mu + \Omega) \\ &= -\mu - \ell\mu + \Omega = -(\ell+1)\mu + \Omega = -N_{t_2}^{\tau}(t)\mu + \Omega. \end{aligned}$$

So, we have proved that

$$x(t) \le -N_{t_2}^{\tau}(t)\mu + \Omega, \quad t \ge t_2.$$

Using $N_{t_2}^{\tau}(t) \xrightarrow{t\to\infty} \infty$, for $t \to \infty$ we obtain a contradiction with x being eventually positive.

Therefore, z is eventually positive, i.e., there is $t_2 \ge t_1$ such that

$$x(t) > \sum_{i=1}^{n} \lambda_i x(\tau_i(t)) \ge \min_{i=1,2,\dots,n} x(\tau_i(t)) \ge \min_{s\in I(t)} x(s) \ge \min_{s\in[\underline{\tau}(t),t]} x(s)$$

for all $t \ge t_2$. In this part of the proof, we adapt the notation from the previous part with this new value of t_2. So, we have

$$x(t) \ge \min_{s\in\overline{I_0}} x(s) =: \omega > 0, \quad t \ge t_2. \tag{3.14}$$

Consequently, from equation (1.3), we get

$$0 = z'(t) + \sum_{j=1}^{m} Q_j(t)x(\sigma_j(t)) \ge z'(t) + \omega \sum_{j=1}^{m} Q_j(t)$$

for all $t \ge t_3$ for some $t_3 \ge \underline{\sigma}^{-1}(t_2)$, $\underline{\sigma} = \min_{j=1,2,\dots,m} \sigma_j \in \mathcal{T}_{t_0}$. Integrating over $[t_3, t]$ gives

$$z(t) \le z(t_3) - \omega \sum_{j=1}^{m} \int_{t_3}^{t} Q_j(s)\, ds \le z(t_3) - \omega \int_{t_3}^{t} Q_{j_0}(s)\, ds, \quad t \ge t_3.$$

Assuming condition (3.10), this estimation results in a contradiction with eventual positivity of z for $t \to \infty$, which implies that x is oscillatory.

Now, assume that

$$\int_{t_0}^{\infty} Q_j(s)\,ds < \infty$$

for each $j = 1, 2, \ldots, m$, and that condition $(3.11)_p$ is satisfied for some $p > 1$. Then

$$x(t) = z(t) + \sum_{i=1}^{n} \lambda_i x(\tau_i(t)) \geq z(t) + \min_{i=1,2,\ldots,n} x(\tau_i(t)) \geq z(t) + \min_{s\in I(t)} x(s)$$

for all $t \geq t_4$, where $t_4 \geq \underline{\tau}^{-1}(t_2)$ is such that $t_4 = \underline{\tau}^{-\kappa}(t_0)$ for some $\kappa \in \mathbb{N}$. Let us fix arbitrary $T \geq t_4$. Then, due to $z'(t) \leq 0$ for all $t \geq t_4$,

$$x(t) \geq z(T) + \min_{s\in I(t)} x(s), \quad t \in [t_4, T].$$

Using induction as for (3.12), one can now show that

$$x(t) \geq N_{t_4}^{\underline{\tau}}(t) z(T) + \omega, \quad t \in [t_4, T].$$

In particular, this estimation is valid for $t = T$. Since $T \geq t_4$ was arbitrary, we have

$$x(t) \geq N_{t_4}^{\underline{\tau}}(t) z(t) + \omega, \quad t \geq t_4.$$

Applying Young inequality with $p > 1$ such that $(3.11)_p$ holds yields

$$x(t) \geq \left(p N_{t_4}^{\underline{\tau}}(t) z(t)\right)^{\frac{1}{p}} (q\omega)^{\frac{1}{q}}$$

for all $t \geq t_4$. Denoting $\omega_1 := p^{\frac{1}{p}} (q\omega)^{\frac{1}{q}} > 0$, we have

$$\begin{aligned} z'(t) &= -\sum_{j=1}^{m} Q_j(t) x(\sigma_j(t)) \leq -\omega_1 \sum_{j=1}^{m} Q_j(t) \left(N_{t_4}^{\underline{\tau}}(\sigma_j(t)) z(\sigma_j(t))\right)^{\frac{1}{p}} \\ &\leq -\omega_1 \sum_{j=1}^{m} Q_j(t) \left(N_{t_4}^{\underline{\tau}}(\sigma_j(t)) z(t)\right)^{\frac{1}{p}}, \quad t \geq t_5, \end{aligned}$$

where $t_5 = \underline{\sigma}^{-1}(t_4)$. Dividing by $z^{\frac{1}{p}}(t)$ and integrating over $[t_5, t]$ yields

$$q z^{\frac{1}{q}}(t) - q z^{\frac{1}{q}}(t_5) \leq -\omega_1 \int_{t_5}^{t} \left(N_{t_4}^{\underline{\tau}}(\sigma_{j_0}(s))\right)^{\frac{1}{p}} Q_{j_0}(s)\,ds, \quad t \geq t_5.$$

Now, the proof is finished as the proof of Theorem 3.3. □

Remark 3.8. Note that conditions (3.10) and $(3.11)_p$ are equivalent to

$$\sum_{j=1}^{m} \int_{t_0}^{\infty} Q_j(s)\,ds = \infty$$

and

$$\sum_{j=1}^{m} \int_{\sigma_j^{-1}(t_0)}^{\infty} \left(N_{t_0}^{\underline{\tau}}(\sigma_j(s))\right)^{\frac{1}{p}} Q_j(s)\,ds = \infty,$$

respectively.

3.2 Distributed delays

Here, we consider neutral differential equations with distributed and mixed delays.

Theorem 3.9. *Let $t_0 \in \mathbb{R}$, $\underline{\tau}, \overline{\tau}, \underline{\sigma}, \overline{\sigma} \in \mathcal{T}_{t_0}$ satisfy $\underline{\tau}(t) < \overline{\tau}(t)$ and $\underline{\sigma}(t) \leq \overline{\sigma}(t)$ for all $t \geq t_0$, $\lambda \in C([\underline{\tau}(t_0), \infty), (0, \infty))$, $Q \in C([t_0, \infty), \mathbb{R}_+)$, $R \in C([\underline{\sigma}(t_0), \infty), \mathbb{R}_+)$. If*

$$\int_{t_0}^{\infty} Q(s) \int_{\underline{\sigma}(s)}^{\overline{\sigma}(s)} R(r)\, dr\, ds = \infty \tag{3.15}$$

or

$$\int_{\underline{\sigma}^{-1}(t_0)}^{\infty} Q(s) \int_{\underline{\sigma}(s)}^{\overline{\sigma}(s)} (N_{t_0}^{\underline{\tau}}(r))^{\frac{1}{p}} R(r)\, dr\, ds = \infty \qquad (3.16)_p$$

for some $p > 1$, where $N_{t_0}^{\underline{\tau}}(t)$ is given by (2.1), then every solution of equation (1.4) oscillates.

Proof. Again, the proof is similar to the proofs of Theorems 3.3, 3.7, so we only provide some key points. For brevity, we also denote

$$\Lambda(t) = \left(\int_{\underline{\tau}(t)}^{\overline{\tau}(t)} \lambda(s)\, ds \right)^{-1}, \quad t \geq t_0.$$

As before, each one of conditions (3.15), $(3.16)_p$ implies that

$$\forall t \geq t_0 \quad \exists T \geq t: \quad Q(T) \int_{\underline{\sigma}(T)}^{\overline{\sigma}(T)} R(s)\, ds > 0.$$

We suppose that x is an eventually positive solution of (1.4). Then there exists $t_1 \geq t_0$ such that $x(t)$, $x(\underline{\tau}(t))$, $x(\underline{\sigma}(t))$ are positive for all $t \geq t_1$. Hence, by equation (1.4), $z'(t) \leq 0\ \forall t \geq t_1$ for $z(t) = x(t) - \Lambda(t) \int_{\underline{\tau}(t)}^{\overline{\tau}(t)} \lambda(s) x(s)\, ds$. We know that z is either eventually negative or eventually positive.

If z is eventually negative, there are $t_2 \geq t_1$ and $\mu > 0$ such that

$$x(t) \leq -\mu + \Lambda(t) \int_{\underline{\tau}(t)}^{\overline{\tau}(t)} \lambda(s) x(s)\, ds \leq -\mu + \max_{s \in I(t)} x(s) \tag{3.17}$$

for all $t \geq t_2$, where $I(t) = [\underline{\tau}(t), \overline{\tau}(t)]$. Analogously to inequality (3.12), one can show by induction that estimation (3.17) implies

$$x(t) \leq -N_{t_2}^{\underline{\tau}}(t)\mu + \Omega, \quad t \geq t_2,$$

where $\Omega = \max_{s \in \overline{I_0}} x(s)$ using the notation from the proof of Theorem 3.7. Using $N_{t_2}^{\underline{\tau}}(t) \xrightarrow{t \to \infty} \infty$, a contradiction is obtained for $t \to \infty$ with x being eventually positive.

Therefore, z is eventually positive. So, there is $t_2 \geq t_1$ such that

$$x(t) > \Lambda(t) \int_{\underline{\tau}(t)}^{\overline{\tau}(t)} \lambda(s) x(s)\, ds \geq \min_{s \in I(t)} x(s)$$

for all $t \geq t_2$. Adapting the notation (3.13) for I_ℓ, I_ℓ^k, estimation (3.14) follows. Next, from equation (1.4), we get

$$0 = z'(t) + Q(t) \int_{\underline{\sigma}(t)}^{\overline{\sigma}(t)} R(s) x(s)\, ds \geq z'(t) + \omega Q(t) \int_{\underline{\sigma}(t)}^{\overline{\sigma}(t)} R(s)\, ds$$

for all $t \geq t_3$ for some $t_3 \geq \underline{\sigma}^{-1}(t_2)$. Integration over $[t_3, t]$ results in

$$z(t) \leq z(t_3) - \omega \int_{t_3}^{t} Q(s) \int_{\underline{\sigma}(s)}^{\overline{\sigma}(s)} R(r)\, dr\, ds, \quad t \geq t_3.$$

Assuming condition (3.15), we get a contradiction with eventual positivity of z, since the right side of the latter inequality tends to $-\infty$ as $t \to \infty$.

Now, assume that

$$\int_{t_0}^{\infty} Q(s) \int_{\underline{\sigma}(s)}^{\overline{\sigma}(s)} R(r)\, dr\, ds < \infty \tag{3.18}$$

and that condition $(3.16)_p$ is satisfied for some $p > 1$. Then

$$x(t) = z(t) + \Lambda(t) \int_{\underline{\tau}(t)}^{\overline{\tau}(t)} \lambda(s) x(s)\, ds \geq z(t) + \min_{s \in I(t)} x(s)$$

for all $t \geq t_4$, where $t_4 \geq \underline{\tau}^{-1}(t_2)$ is such that $t_4 = \underline{\tau}^{-\kappa}(t_0)$ for some $\kappa \in \mathbb{N}$. As in the proof of Theorem 3.7, it can be shown that

$$x(t) \geq N_{t_4}^{\underline{\tau}}(t) z(t) + \omega, \quad t \geq t_4,$$

and Young inequality implies

$$x(t) \geq \left(p N_{t_4}^{\underline{\tau}}(t) z(t) \right)^{\frac{1}{p}} (q\omega)^{\frac{1}{q}}$$

for all $t \geq t_4$. Denoting $\omega_1 := p^{\frac{1}{p}} (q\omega)^{\frac{1}{q}} > 0$, from equation (1.4) we derive

$$\begin{aligned} z'(t) &= -Q(t) \int_{\underline{\sigma}(t)}^{\overline{\sigma}(t)} R(s) x(s)\, ds \leq -\omega_1 Q(t) \int_{\underline{\sigma}(t)}^{\overline{\sigma}(t)} R(s) \left(N_{t_4}^{\underline{\tau}}(s) z(s) \right)^{\frac{1}{p}} ds \\ &\leq -\omega_1 Q(t) \int_{\underline{\sigma}(t)}^{\overline{\sigma}(t)} R(s) \left(N_{t_4}^{\underline{\tau}}(s) \right)^{\frac{1}{p}} ds\, z(t)^{\frac{1}{p}}, \quad t \geq t_5, \end{aligned}$$

where $t_5 = \underline{\sigma}^{-1}(t_4)$. Dividing by $z^{\frac{1}{p}}(t)$ and integrating over $[t_5, t]$ gives

$$q z^{\frac{1}{q}}(t) - q z^{\frac{1}{q}}(t_5) \leq -\omega_1 \int_{t_5}^{t} Q(s) \int_{\underline{\sigma}(s)}^{\overline{\sigma}(s)} \left(N_{t_4}^{\underline{\tau}}(r) \right)^{\frac{1}{p}} R(r)\, dr\, ds, \quad t \geq t_5.$$

Now, it only remains to show that

$$\int_{t_5}^{\infty} Q(s) \int_{\underline{\sigma}(s)}^{\overline{\sigma}(s)} \left(N_{t_4}^{\underline{\tau}}(r) \right)^{\frac{1}{p}} R(r)\, dr\, ds = \infty$$

to obtain a contradiction with eventual positivity of z, implying that x is oscillatory. Using Lemmas 2.2, 2.5 (see the proof of Theorem 3.3), we obtain

$$\begin{aligned} &\int_{t_5}^{t} Q(s) \int_{\underline{\sigma}(s)}^{\overline{\sigma}(s)} \left(N_{t_4}^{\underline{\tau}}(r) \right)^{\frac{1}{p}} R(r)\, dr\, ds \\ &\quad \geq \int_{t_5}^{t} Q(s) \int_{\underline{\sigma}(s)}^{\overline{\sigma}(s)} \left(N_{t_0}^{\underline{\tau}}(r) \right)^{\frac{1}{p}} R(r)\, dr\, ds - \kappa^{\frac{1}{p}} \int_{t_5}^{t} Q(s) \int_{\underline{\sigma}(s)}^{\overline{\sigma}(s)} R(r)\, dr\, ds \\ &\quad = \int_{\underline{\sigma}^{-1}(t_0)}^{t} Q(s) \int_{\underline{\sigma}(s)}^{\overline{\sigma}(s)} \left(N_{t_0}^{\underline{\tau}}(r) \right)^{\frac{1}{p}} R(r)\, dr\, ds - \kappa^{\frac{1}{p}} \int_{t_0}^{t} Q(s) \int_{\underline{\sigma}(s)}^{\overline{\sigma}(s)} R(r)\, dr\, ds + C \end{aligned}$$

for an appropriate constant $C \in \mathbb{R}$. Note that, by conditions $(3.16)_p$ and (3.18), the right side tends to ∞ as $t \to \infty$. This completes the proof. □

Remark 3.10. Condition $\lambda \in C([\underline{\tau}(t_0),\infty),(0,\infty))$ in Theorem 3.9 can be weakened to $\lambda \in C([\underline{\tau}(t_0),\infty),\mathbb{R}_+)$ satisfying $\int_{\underline{\tau}(t)}^{\overline{\tau}(t)} \lambda(s)\,ds > 0$ for all $t \geq t_0$.

Finally, we present a result for neutral differential equations with mixed delays and time-dependent coefficients.

Theorem 3.11. *Let $t_0 \in \mathbb{R}$, $n_{1,2}, m_{1,2} \in \mathbb{N}_0$ be such that $n_1 + n_2 \geq 1$, $m_1 + m_2 \geq 1$. Moreover, let the following assumptions be fulfilled:*

1. *$\lambda_i \in C([t_0,\infty),\mathbb{R}_+)$ and $\tau_i \in \mathcal{T}_{t_0}$ for each $i = 1,2,\ldots,n_1$,*
2. *$\vartheta_i \in C([\underline{\tau}_i(t_0),\infty),\mathbb{R}_+)$ and $\underline{\tau}_i, \overline{\tau}_i \in \mathcal{T}_{t_0}$ are such that $\underline{\tau}_i(t) \leq \overline{\tau}_i(t)$ for all $t \geq t_0$ and for each $i = 1,2,\ldots,n_2$,*
3. *$Q_j \in C([t_0,\infty),\mathbb{R}_+)$ and $\sigma_j \in \mathcal{T}_{t_0}$ for each $j = 1,2,\ldots,m_1$,*
4. *$S_j \in C([t_0,\infty),\mathbb{R}_+)$, $R_j \in C([\underline{\sigma}_j(t_0),\infty),\mathbb{R}_+)$, and $\underline{\sigma}_j, \overline{\sigma}_j \in \mathcal{T}_{t_0}$ are such that $\underline{\sigma}_j(t) \leq \overline{\sigma}_j(t)$ for all $t \geq t_0$ and each $j = 1,2,\ldots,m_2$,*
5. *for all $t \geq t_0$,*
$$\sum_{i=1}^{n_1} \lambda_i(t) + \sum_{i=1}^{n_2} \int_{\underline{\tau}_i(t)}^{\overline{\tau}_i(t)} \vartheta_i(s)\,ds = 1.$$

If

$$\sum_{j=1}^{m_1} \int_{t_0}^{\infty} Q_j(s)\,ds + \sum_{j=1}^{m_2} \int_{t_0}^{\infty} S_j(s) \int_{\underline{\sigma}_j(s)}^{\overline{\sigma}_j(s)} R_j(r)\,dr\,ds = \infty \tag{3.19}$$

or

$$\begin{aligned}\sum_{j=1}^{m_1} &\int_{\sigma_j^{-1}(t_0)}^{\infty} (N_{t_0}^{\underline{\tau}}(\sigma_j(s)))^{\frac{1}{p}}\, Q_j(s)\,ds \\ &+ \sum_{j=1}^{m_2} \int_{\underline{\sigma}_j^{-1}(t_0)}^{\infty} S_j(s) \int_{\underline{\sigma}_j(s)}^{\overline{\sigma}_j(s)} (N_{t_0}^{\underline{\tau}}(r))^{\frac{1}{p}}\, R_j(r)\,dr\,ds = \infty\end{aligned} \tag{3.20$_p$}$$

for some $p > 1$, where $\underline{\tau} = \min\{\min_{i=1,2,\ldots,n_1} \tau_i, \min_{i=1,2,\ldots,n_2} \underline{\tau}_i\}$ and $N_{t_0}^{\underline{\tau}}(t)$ is given by (2.1), then every solution of equation (1.5) oscillates.

Proof. Each one of conditions (3.19), $(3.20)_p$ implies that

$$\begin{aligned}\forall t \geq t_0 \quad \exists T \geq t: \quad &Q_j(T) > 0 \quad \text{for some } j \in \{1,2,\ldots,m_1\} \\ \text{or} \quad S_j(T) \int_{\underline{\sigma}_j(T)}^{\overline{\sigma}_j(T)} &R_j(s)\,ds > 0 \quad \text{for some } j \in \{1,2,\ldots,m_2\}.\end{aligned} \tag{3.21}$$

Let us denote

$$\overline{\tau} := \max\left\{\max_{i=1,2,\ldots,n_1} \tau_i, \max_{i=1,2,\ldots,n_2} \overline{\tau}_i\right\}, \qquad \underline{\sigma} := \min\left\{\min_{j=1,2,\ldots,m_1} \sigma_j, \min_{j=1,2,\ldots,m_2} \underline{\sigma}_j\right\}.$$

Note that $\underline{\tau}, \overline{\tau}, \underline{\sigma} \in \mathcal{T}_{t_0}$. Let us assume without any loss of generality that x is an eventually positive solution of (1.5). Take $t_1 \geq t_0$ such that $x(t)$, $x(\underline{\tau}(t))$ and $x(\underline{\sigma}(t))$ are positive for all $t \geq t_1$. Then, by (1.5), $z'(t) \leq 0$ $\forall t \geq t_1$ for

$$z(t) = x(t) - \left(\sum_{i=1}^{n_1} \lambda_i(t) x(\tau_i(t)) + \sum_{i=1}^{n_2} \int_{\underline{\tau}_i(t)}^{\overline{\tau}_i(t)} \vartheta_i(s) x(s)\,ds\right). \tag{3.22}$$

Due to (3.21), z is either eventually negative or eventually positive.

If z is eventually negative, there are $t_2 \geq t_1$ and $\mu > 0$ such that

$$\begin{aligned} x(t) &\leq -\mu + \sum_{i=1}^{n_1} \lambda_i(t) x(\tau_i(t)) + \sum_{i=1}^{n_2} \int_{\underline{\tau}_i(t)}^{\overline{\tau}_i(t)} \vartheta_i(s) x(s)\, ds \\ &\leq -\mu + \left(\sum_{i=1}^{n_1} \lambda_i(t) + \sum_{i=1}^{n_2} \int_{\underline{\tau}_i(t)}^{\overline{\tau}_i(t)} \vartheta_i(s)\, ds \right) \max_{s \in I(t)} x(s) = -\mu + \max_{s \in I(t)} x(s) \end{aligned}$$

for all $t \geq t_2$, where $I(t) = [\underline{\tau}(t), \overline{\tau}(t)]$. As for (3.12), one can use mathematical induction to show that

$$x(t) \leq -N_{t_2}^{\underline{\tau}}(t)\mu + \Omega, \quad t \geq t_2,$$

where $\Omega = \max_{s \in \overline{I_0}} x(s)$ using the notation from the proof of Theorem 3.7. Consequently, $N_{t_2}^{\underline{\tau}}(t) \xrightarrow{t \to \infty} \infty$ yields a contradiction for $t \to \infty$ with x being eventually positive.

Hence, z is eventually positive. Take $t_2 \geq t_1$ such that

$$\begin{aligned} x(t) &> \sum_{i=1}^{n_1} \lambda_i(t) x(\tau_i(t)) + \sum_{i=1}^{n_2} \int_{\underline{\tau}_i(t)}^{\overline{\tau}_i(t)} \vartheta_i(s) x(s)\, ds \\ &\geq \left(\sum_{i=1}^{n_1} \lambda_i(t) + \sum_{i=1}^{n_2} \int_{\underline{\tau}_i(t)}^{\overline{\tau}_i(t)} \vartheta_i(s)\, ds \right) \min_{s \in I(t)} x(s) \\ &= \min_{s \in I(t)} x(s) \geq \min_{s \in [\underline{\tau}(t), t)} x(s) \geq \min_{s \in \overline{I_0}} x(s) =: \omega \end{aligned}$$

for all $t \geq t_2$, where we used the notation from the proof of Theorem 3.7, again. As a consequence, equation (1.5) implies

$$0 \geq z'(t) + \omega \left(\sum_{j=1}^{m_1} Q_j(t) + \sum_{j=1}^{m_2} S_j(t) \int_{\underline{\sigma}_j(t)}^{\overline{\sigma}_j(t)} R_j(s)\, ds \right)$$

for all $t \geq t_3$ for some $t_3 \geq \underline{\sigma}^{-1}(t_2)$. Integrating the latter inequality over $[t_3, t]$ gives

$$z(t) \leq z(t_3) - \omega \left(\sum_{j=1}^{m_1} \int_{t_3}^{t} Q_j(s)\, ds + \sum_{j=1}^{m_2} \int_{t_3}^{t} S_j(s) \int_{\underline{\sigma}_j(s)}^{\overline{\sigma}_j(s)} R_j(r)\, dr\, ds \right)$$

for all $t \geq t_3$. This results in a contradiction with the eventual positivity of z for $t \to \infty$ if (3.19) holds. So, x is oscillatory.

Now suppose that

$$\sum_{j=1}^{m_1} \int_{t_0}^{\infty} Q_j(s)\, ds + \sum_{j=1}^{m_2} \int_{t_0}^{\infty} S_j(s) \int_{\underline{\sigma}_j(s)}^{\overline{\sigma}_j(s)} R_j(r)\, dr\, ds < \infty \tag{3.23}$$

and that condition $(3.20)_p$ is fulfilled for some $p > 1$. Then, by (3.22) and assumption (5), we get

$$x(t) \geq z(t) + \min_{s \in I(t)} x(s), \quad t \geq t_4,$$

where $t_4 \geq \underline{\tau}^{-1}(t_2)$ is such that $t_4 = \underline{\tau}^{-\kappa}(t_0)$ for some $\kappa \in \mathbb{N}$. By induction as in the proof of Theorem 3.7, we derive

$$x(t) \geq N_{t_4}^{\underline{\tau}}(t) z(t) + \omega, \quad t \geq t_4.$$

Denoting $\omega_1 := p^{\frac{1}{p}}(q\omega)^{\frac{1}{q}} > 0$, Young's inequality yields

$$x(t) \geq \omega_1 \left(N^{\tau}_{t_4}(t)z(t)\right)^{\frac{1}{p}}, \quad t \geq t_4.$$

Then, equation (1.5) gives

$$\begin{aligned} z'(t) &\leq -\omega_1 \left(\sum_{j=1}^{m_1} Q_j(t) \left(N^{\tau}_{t_4}(\sigma_j(t))z(\sigma_j(t))\right)^{\frac{1}{p}} + \sum_{j=1}^{m_2} S_j(t) \int_{\underline{\sigma}_j(t)}^{\overline{\sigma}_j(t)} R_j(s) \left(N^{\tau}_{t_4}(s)z(s)\right)^{\frac{1}{p}} ds \right) \\ &\leq -\omega_1 z(t)^{\frac{1}{p}} \left(\sum_{j=1}^{m_1} Q_j(t)(N^{\tau}_{t_4}(\sigma_j(t)))^{\frac{1}{p}} + \sum_{j=1}^{m_2} S_j(t) \int_{\underline{\sigma}_j(t)}^{\overline{\sigma}_j(t)} R_j(s) \left(N^{\tau}_{t_4}(s)\right)^{\frac{1}{p}} ds \right) \end{aligned}$$

for all $t \geq t_5 = \underline{\sigma}^{-1}(t_4)$. Dividing by $z^{\frac{1}{p}}(t)$ and integrating over $[t_5, t]$ results in

$$\begin{aligned} &qz^{\frac{1}{q}}(t) - qz^{\frac{1}{q}}(t_5) \\ &\quad \leq -\omega_1 \left(\sum_{j=1}^{m_1} \int_{t_5}^{t} (N^{\tau}_{t_4}(\sigma_j(s)))^{\frac{1}{p}} Q_j(s)\, ds + \sum_{j=1}^{m_2} \int_{t_5}^{t} S_j(s) \int_{\underline{\sigma}_j(s)}^{\overline{\sigma}_j(s)} (N^{\tau}_{t_4}(r))^{\frac{1}{p}} R_j(r)\, dr\, ds \right), \quad t \geq t_5. \end{aligned}$$

If the right side tends to $-\infty$ as $t \to \infty$, we get a contradiction with the eventual positivity of z, which implies that x is oscillatory. To see this, we use Lemmas 2.2, 2.5 to estimate

$$\begin{aligned} &\sum_{j=1}^{m_1} \int_{t_5}^{t} (N^{\tau}_{t_4}(\sigma_j(s)))^{\frac{1}{p}} Q_j(s)\, ds + \sum_{j=1}^{m_2} \int_{t_5}^{t} S_j(s) \int_{\underline{\sigma}_j(s)}^{\overline{\sigma}_j(s)} (N^{\tau}_{t_4}(r))^{\frac{1}{p}} R_j(r)\, dr\, ds \\ &\geq \sum_{j=1}^{m_1} \left(\int_{t_5}^{t} (N^{\tau}_{t_0}(\sigma_j(s)))^{\frac{1}{p}} Q_j(s)\, ds - \kappa^{\frac{1}{p}} \int_{t_5}^{t} Q_j(s)\, ds \right) \\ &\quad + \sum_{j=1}^{m_2} \left(\int_{t_5}^{t} S_j(s) \int_{\underline{\sigma}_j(s)}^{\overline{\sigma}_j(s)} (N^{\tau}_{t_0}(r))^{\frac{1}{p}} R_j(r)\, dr\, ds - \kappa^{\frac{1}{p}} \int_{t_5}^{t} S_j(s) \int_{\underline{\sigma}_j(s)}^{\overline{\sigma}_j(s)} R_j(r)\, dr\, ds \right) \\ &= \sum_{j=1}^{m_1} \left(\int_{\sigma_j^{-1}(t_0)}^{t} (N^{\tau}_{t_0}(\sigma_j(s)))^{\frac{1}{p}} Q_j(s)\, ds - \kappa^{\frac{1}{p}} \int_{t_0}^{t} Q_j(s)\, ds \right) \\ &\quad + \sum_{j=1}^{m_2} \left(\int_{\underline{\sigma}_j^{-1}(t_0)}^{t} S_j(s) \int_{\underline{\sigma}_j(s)}^{\overline{\sigma}_j(s)} (N^{\tau}_{t_0}(r))^{\frac{1}{p}} R_j(r)\, dr\, ds - \kappa^{\frac{1}{p}} \int_{t_0}^{t} S_j(s) \int_{\underline{\sigma}_j(s)}^{\overline{\sigma}_j(s)} R_j(r)\, dr\, ds \right) + C \end{aligned}$$

for an appropriate constant $C \in \mathbb{R}$. Condition $(3.20)_p$ and inequality (3.23) imply that the right-hand side tends to ∞ as $t \to \infty$. This completes the proof. □

4 Applications

In this section, we apply the results of Section 3 to concrete neutral differential equations.

4.1 Discrete delays

First, let us consider the neutral differential equation with one constant and one variable delay,

$$[x(t) - x(t-\alpha)]' + Q(t)x(\sigma(t)) = 0, \quad t \geq t_0 \tag{4.1}$$

for some $t_0 \in \mathbb{R}$, $\alpha > 0$, $\sigma \in \mathcal{T}_{t_0}$, and $Q \in C([t_0, \infty), \mathbb{R}_+)$. Then $\tau^k(t) = t - k\alpha$ for $k \in \mathbb{Z}$. Now, inequality (2.1) has the form

$$\zeta + (N_\zeta^\tau(t) - 1)\alpha \le t < \zeta + N_\zeta^\tau(t)\alpha.$$

Therefrom, we derive

$$\frac{t-\zeta}{\alpha} < N_\zeta^\tau(t) \le \frac{t-\zeta}{\alpha} + 1$$

that gives

$$N_\zeta^\tau(t) = \left\lfloor \frac{t-\zeta}{\alpha} \right\rfloor + 1.$$

Since we are interested in the convergence of the integral on the left side of $(3.4)_p$ in a neighborhood of ∞, it is enough to assume that $s \ge \tilde{t}_0$, where $\tilde{t}_0 \ge \sigma^{-1}(t_0)$ is such that $\sigma(\tilde{t}_0) > 0$. Then, dividing the inequality

$$\frac{\sigma(s) - t_0}{\alpha} < N_{t_0}^\tau(\sigma(s)) \le \frac{\sigma(s) - t_0}{\alpha} + 1$$

by $\sigma(s)/\alpha$ and taking the limit $s \to \infty$, we obtain

$$\lim_{s\to\infty} \frac{\alpha}{\sigma(s)} N_{t_0}^\tau(\sigma(s)) = 1.$$

Therefore, condition $(3.4)_p$ holds if and only if

$$\int_{\tilde{t}_0}^{\infty} (\sigma(s))^{\frac{1}{p}} Q(s)\, ds = \infty. \tag{4.2$_p$}$$

Using Theorem 3.3, one can easily prove the following result.

Proposition 4.1. *Let $t_0 \in \mathbb{R}$, $\alpha > 0$, $\sigma \in \mathcal{T}_{t_0}$, $Q \in C([t_0, \infty), \mathbb{R}_+)$, and $\tilde{t}_0 \ge \sigma^{-1}(t_0)$ be such that $\sigma(\tilde{t}_0) > 0$. Every solution of equation (4.1) oscillates if condition (3.1) or $(4.2)_p$ for some $p > 1$ is satisfied.*

In a particular case of equation (4.1) when $\sigma(t) = t - \beta$, $\beta > 0$, this statement can be simplified. From the inequality

$$\frac{s - \beta - t_0}{\alpha} < N_{t_0}^\tau(\sigma(s)) \le \frac{s - \beta - t_0}{\alpha} + 1$$

for $s \ge \tilde{t}_0$, where $\tilde{t}_0 \ge t_0 + \beta$ is positive, we get

$$\lim_{s\to\infty} \frac{\alpha}{s} N_{t_0}^\tau(\sigma(s)) = 1.$$

Hence, condition $(3.4)_p$ is equivalent to

$$\int_{\tilde{t}_0}^{\infty} s^{\frac{1}{p}} Q(s)\, ds = \infty. \tag{4.3$_p$}$$

Proposition 4.2. *Let $t_0 \in \mathbb{R}$, $\alpha, \beta > 0$, $Q \in C([t_0, \infty), \mathbb{R}_+)$, and $\tilde{t}_0 \ge t_0 + \beta$ be positive. Every solution of the equation*

$$[x(t) - x(t-\alpha)]' + Q(t)x(t-\beta) = 0, \quad t \ge t_0 \tag{4.4}$$

oscillates if condition (3.1) or $(4.3)_p$ for some $p > 1$ is satisfied.

Remark 4.3. Note that condition (3.1) or $(4.3)_p$ for some $p > 1$ implies

$$\int_{t_0}^{\infty} sQ(s)\,ds = \infty$$

which, by [6], means that equation (4.4) does not have a bounded positive solution.

Remark 4.4. For $Q(t) = t^{-\alpha}$, $1 < \alpha$, equation (4.4) reads as

$$[x(t) - x(t-\alpha)]' + t^{-\alpha}x(t-\beta) = 0, \quad t \geq t_0.$$

This is known [6] to have a bounded positive solution if $\alpha > 2$, since

$$\int_{t_0}^{\infty} s^{1-\alpha}\,ds < \infty.$$

To see that for $1 < \alpha < 2$ every solution is oscillatory, one can verify that

$$\int_{t_0}^{\infty} Q(s) \exp\left\{\frac{1}{\tau}\int_{t_0}^{s} rQ(r)\,dr\right\} ds = \infty$$

with $Q(t) = t^{-\alpha}$ from [4], or take $p = \frac{1}{\alpha-1} > 1$ in $(4.3)_p$ to get

$$\int_{\tilde{t}_0}^{\infty} s^{\frac{1}{p}} Q(s)\,ds = \int_{\tilde{t}_0}^{\infty} s^{\frac{1}{p}-\alpha}\,ds = \int_{\tilde{t}_0}^{\infty} s^{-1}\,ds = \infty.$$

The case $\alpha = 2$ still remains to be unanswered, despite of the fact that in [5, Corollary] the equation is stated to be oscillatory. At least for the variable delays, we proved that the equation has a positive solution (see Example 3.2).

4.2 Distributed delays

Example 4.5. Let us consider the following equation

$$\left[x(t) - \frac{2}{\pi}\int_{t-\pi}^{t-\frac{\pi}{2}} x(s)\,ds\right]' + \frac{2}{\pi(\sin 2\sigma - \sin\sigma)}\int_{t-2\sigma}^{t-\sigma} x(s)\,ds = 0, \quad t \geq t_0 \tag{4.5}$$

for some $t_0 \in \mathbb{R}$, where $\sigma = \frac{1}{3}\left(\pi - 2\arctan\frac{2}{\pi+2}\right) \doteq 0.79988 > 0$.

This equation is of the form (1.4) with $\lambda(t) \equiv 1$, $R(t) \equiv 1$, $Q(t) \equiv \frac{2}{\pi(\sin 2\sigma - \sin\sigma)} \doteq 2.25506 > 0$, $\underline{\tau}(t) = t - \pi$, $\overline{\tau}(t) = t - \frac{\pi}{2}$, $\underline{\sigma}(t) = t - 2\sigma$, and $\overline{\sigma}(t) = t - \sigma$. It is easy to see that condition (3.15) is satisfied. Thus, by Theorem 3.9, every solution of equation (4.5) oscillates. One of such solutions is $x(t) = \sin t$. Indeed, for this function, the left-hand side of (4.5) is equal to

$$\begin{aligned}\left[\sin(t) + \frac{2}{\pi}(\cos t + \sin t)\right]' &+ \frac{2(\cos(t-2\sigma) - \cos(t-\sigma))}{\pi(\sin 2\sigma - \sin\sigma)} \\ &= \left(1 + \frac{2}{\pi}\right)\cos(t) - \frac{2}{\pi}\sin t + \frac{2\cos t}{\pi}\frac{\cos 2\sigma - \cos\sigma}{\sin 2\sigma - \sin\sigma} + \frac{2}{\pi}\sin t. \end{aligned}\tag{4.6}$$

Noting that

$$\begin{aligned}\frac{\cos 2\sigma - \cos\sigma}{\sin 2\sigma - \sin\sigma} &= -\tan\frac{3}{2}\sigma = -\tan\left(\frac{\pi}{2} - \arctan\frac{2}{\pi+2}\right) \\ &= -\cot\left(\arctan\frac{2}{\pi+2}\right) = -\frac{\pi+2}{2} = -1 - \frac{\pi}{2}\end{aligned}$$

makes the right side of (4.6) vanish.

Abstract. In this paper, a diffusive predator-prey system considering prey-taxis term with memory and maturation delays under Neumann boundary conditions is investigated. Firstly, the existence and stability of equilibria, especially the existence, uniqueness and stability of the positive equilibrium, are studied. Secondly, we prove that: (i) there is no spatially homogeneous steady state bifurcation as the eigenvalue of the negative Laplace operator is zero; (ii) as this system is only with memory delay τ_1, the the spatially nonhomogeneous Hopf bifurcation appears; (iii) when the model is only with maturation delay τ_2, the system has spatially homogeneous and nonhomogeneous periodic solutions; (iv) for the case of two delays, the system has rich dynamics, for example, stability switches, whose curves have four forms. Finally, some numerical simulations are produced to verify and support the theoretical results.

Keywords: diffusive system, fear effect, prey-taxis, memory delay, maturation delay.

2020 Mathematics Subject Classification: 92D25, 37G10.

1 Introduction

The predator-prey dynamics is of great significance for developing the mathematical ecology and has been investigated by many scholars [5, 9, 10, 15, 18, 19]. That the prey population is also affected by the fear of predators not only the direct killing has been found [18]. On the basis of the experiment of Zanette [18], Wang et al. originally introduced the fear effect into the predator-prey model. The results showed that the incorporation of fear effect into the predator-prey model with Holling-II functional response can affect the stability of equilibrium [15]. With further research, for the various biological factors, Holling-II functional response of the predator-prey model with fear effect is modified differently, such as Allee effect [5], Leslie–Gower term [9] and prey refuge [19].

It is well known that in the spatial predator-prey model, predator and prey are usually considered to move randomly and are modeled by the reaction-diffusion equation. However, species also move towards certain directions due to the attraction or repulsion of some

chemical signals, which is commonly called chemotactic movement [16]. In biology, predator population tends to move to the area where the density of the prey population is higher, which is termed prey-taxis [6,16]. This phenomenon was first noticed in a regional experiment about individual ladybugs and aphids by Karevia and Odell [7]. They derived a predator-prey model by considering prey-taxis as biased random walks, which is as follows

$$\begin{cases} \dfrac{\partial u(x,t)}{\partial t} = \Delta u - \nabla \cdot (u\rho(u,v)\nabla v) + G_1(u,v), \\ \dfrac{\partial v(x,t)}{\partial t} = D\Delta v + G_2(u,v), \end{cases} \tag{1.1}$$

where $u(x,t)$ and $v(x,t)$ represent separately the density of the prey and predator at time $t > 0$ and space location x; $-\nabla \cdot (u\rho(u,v)\nabla v)$ stands for the prey-taxis term, and $\rho(u,v)$ is a coefficient that may rely on $u(x,t)$ or $v(x,t)$ and D represents the diffusion rate; $G_1(u,v)$ and $G_2(u,v)$ describe the functional response functions.

Considering that the ability to perceive danger is also related to the memory of animals, Fagan pointed out that it is vital to incorporate spatial memory into models of animal movements [3]. Namely, combining the reaction-diffusion equation with the memory delay term, form the spatial memory model or the memory-based diffusion system, which has attracted many researchers [1, 12, 13]. For example, Aly [1] studied bifurcations of a memory-based diffusive predator-prey system. Shi et al. [12] showed the wellposedness of the memory-based diffusive system; Song [13] investigated Hopf bifurcation caused by memory delay for a memory-based diffusive system. Recently, some scholars have considered to combine memory delay with fear effect into diffusion system [2, 17]. For example, Debnath et al. [2] explored the role of memory and fear effect on prey-predator dynamics. Yang et al. [17] considered memory delay and fear effect into a predator-prey model with diffusion. They proved that the fear effect has both the stabilizing and the destabilizing effect on the coexisting equilibrium under different conditions.

After the predator gets its food, it does not immediately respond to a change in the number of population, but requires a period of digestion or pregnancy. Namely, there is a time delay to allow the predator to reach maturity. Therefore, it is necessary to introduce the maturation or digestion delay into the model. For example, Liu et al. [8] introduced the digestion delay into a predator-prey model with fear effect. They showed that the occurrence of stability switches and Hopf bifurcations as the digestion delay passes through a series of critical values. Shi et al. [11] studied a model incorporating memory-based diffusion and maturation delay. They proved that the proper association of two delay mechanisms can cause the appearance of the spatially inhomogeneous time-periodic patterns. Wang et al. [14] investigated the model collecting the spatial memory, maturation effect, prey-taxis and fear effect, which is as follows

$$\begin{cases} \dfrac{\partial u}{\partial t} = d_1\Delta u + \alpha\nabla(u\nabla v_{\tau_1}) + \dfrac{r_0 u}{1+kv_{\tau_2}} - du - au^2 - \dfrac{puv}{1+cu}, \ x \in \Omega, \ t > 0, \\ \dfrac{\partial v}{\partial t} = d_2\Delta v - mv^2 + \dfrac{quv}{1+cu}, \ x \in \Omega, \ t > 0, \\ \dfrac{\partial u}{\partial \nu} = \dfrac{\partial v}{\partial \nu} = 0, \ x \in \partial\Omega, \ t > 0, \\ u(x,t) = u_0(x) \geq 0, v(x,t) = v_0(x) \geq 0, \ x \in \Omega, \ t \in (-\max\{\tau_1,\tau_2\}, 0], \end{cases} \tag{1.2}$$

where the meanings of $u(x,t)$, $v(x,t)$ are the same to those of model (1.1); $v_{\tau_1} = v(x, t-\tau_1)$,

$v_{\tau_2} = v(x, t - \tau_2)$; τ_1 is the memory delay; τ_2 represents the maturation delay; d_1 and d_2 are self-diffusion coefficients; r_0 and d stand for separately prey's growth rate and natural death rate without considering fear cost; a and m are on behalf of the death rates for prey's and predator's intra-special competition, respectively; $\frac{1}{1+kv}$ denotes the fear factor; $\alpha\nabla(u\nabla v_{\tau_1})$ stands for the prey-taxis term; $\frac{uv}{1+cu}$ is the Holling-II functional response; Ω is a bounded domain in $\mathbb{R}^N$, $N \geq 1$, with a smooth boundary $\partial\Omega$; $\partial\nu$ is the outer flux; Δ and ∇ are Laplace and gradient operator defined in Ω. All of the parameters are positive. They showed that the model can exhibit rich dynamics, such as Turing instability, Hopf bifurcation and spatially nonhomogeneous (homogeneous) periodic distribution. They considered the spatial memory, pregnancy effect and fear effect for prey into a diffusive prey-taxis model with Holling-II functional response function. Motivated by this, we interest the system that the spatial memory and maturation effect in predator and fear effect in prey are incorporated in a diffusive prey-taxis model with the modified Leslie–Gower term and are curious about what dynamic behaviors for this complex model occur. In this paper, we aim to study the diffusive prey-taxis system considering fear effect with memory and maturation delays as follows,

$$\begin{cases} \dfrac{\partial u(x,t)}{\partial t} = d_1\Delta u + \dfrac{r_0 u}{1+av} - du - cu^2 - \dfrac{puv}{u+kv}, \ x \in \Omega, \ t > 0, \\ \dfrac{\partial v(x,t)}{\partial t} = d_2\Delta v - \chi\nabla(v\nabla u_{\tau_1}) + sv\left(1 - \dfrac{qv}{u_{\tau_2}+m}\right), \ x \in \Omega, \ t > 0, \\ \dfrac{\partial u(x,t)}{\partial \nu} = \dfrac{\partial v(x,t)}{\partial \nu} = 0, \ x \in \partial\Omega, \ t > 0, \\ u(x,t) = u_0(x) \geq 0, v(x,t) = v_0(x) \geq 0, \ x \in \Omega, \ t \in (-\max\{\tau_1,\tau_2\}, 0], \end{cases} \tag{1.3}$$

where $u_{\tau_1} = u(x, t - \tau_1)$; $u_{\tau_2} = u(x, t - \tau_2)$; $\frac{1}{1+av}$ is the fear factor; c represents the birth rate of prey; $-\chi\nabla(v\nabla u)$ stands for prey-taxis term; χ is prey-taxis coefficient; $\chi > 0$ (< 0) is called attractive (repulsive) prey-taxis; s is the intrinsic growth rate of predator; $\frac{puv}{u+kv}$ is the Holling-II functional response; $\frac{qv}{u+m}$ is the modified Leslie–Gower term. Keep the meanings and qualities of other parameters and functions be the same to system (1.2).

The remainder of this paper is structured as follows. In Sect. 2, we not only discuss the number and stability of equilibria, but also give the conditions for the existence and stability of the unique positive equilibrium. In Sect. 3, we analyze the existence of the spatially homogeneous and nonhomogeneous steady states and Hopf bifurcation, and exhibit the dynamics of the model with the cases of $\tau_1 > 0$, $\tau_2 = 0$; $\tau_1 = 0$, $\tau_2 > 0$; $\tau_1 > 0$, $\tau_2 > 0$. At the end, numerical simulations are given to substantiate the theoretical findings.

2 The existence and stability of equilibria

First, we discuss the existence and stability of the equilibria for the following ordinary differential equation of system (1.3)

$$\begin{cases} \dfrac{\mathrm{d}u}{\mathrm{d}t} = \dfrac{r_0 u}{1+av} - du - cu^2 - \dfrac{puv}{u+kv}, \\ \dfrac{\mathrm{d}v}{\mathrm{d}t} = sv\left(1 - \dfrac{qv}{u+m}\right). \end{cases} \tag{2.1}$$

Clearly, system (2.1) always has the trivial equilibrium $(0,\ 0)$ and a semi-trivial equilibrium $e_{01}(0, \frac{m}{q})$; as $r_0 > d$, the semi-trivial equilibrium $e_{10}(\frac{r_0-d}{c}, 0)$ exists; as

$$r_0 > r_0^* \triangleq (dk+p)(q+am)/kq, \tag{2.2}$$

system (2.1) has the unique positive solution $e_2(\bar{u}, \bar{v})$ with $\bar{v} = \frac{\bar{u}+m}{q}$, and $\bar{u}$ is the positive root of the equation

$$\frac{r_0 q}{a\bar{u} + am + q} - d - c\bar{u} - \frac{p(\bar{u}+m)}{(q+k)\bar{u} + km} = 0.$$

For each nonnegative equilibrium $e_2(\bar{u}, \bar{v})$, the Jacobi matrix can be expressed by

$$J_{(u,v)} := \begin{pmatrix} \dfrac{r_0}{1+av} - d - 2cu - \dfrac{pkv^2}{(u+kv)^2} & -\dfrac{ar_0 u}{(1+av)^2} - \dfrac{pu^2}{(u+kv)^2} \\ \dfrac{qsv^2}{(u+m)^2} & s - \dfrac{2qsv}{u+m} \end{pmatrix}. \tag{2.3}$$

For $(0,0)$ and $e_{10}(\frac{r_0-d}{c}, 0)$, they are always unstable because $\lambda_2 = s > 0$; for $e_{01}(0, \frac{m}{q})$, the eigenvalues of the Jacobi matrix are $\lambda_1 = \frac{r_0 q}{q+am} - d - \frac{p}{k}$, $\lambda_2 = -s < 0$, then e_{01} is locally asymptotically stable (unstable) if $r_0 < r_0^*$($r_0 > r_0^*$); the corresponding characteristic equation at the positive equilibrium $e_2\,(\bar{u}, \bar{v})$ is

$$\lambda^2 - (A_{11} - s)\,\lambda + \left(-sA_{11} - \frac{s}{q}A_{12}\right) = 0,$$

where

$$A_{11} = \frac{r_0}{1+a\bar{v}} - d - 2c\bar{u} - \frac{pk\bar{v}^2}{(\bar{u}+k\bar{v})^2},$$
$$A_{12} = -\frac{p\bar{u}}{(\bar{u}+k\bar{v})^2} - \frac{ar_0\bar{u}}{(1+a\bar{v})^2}.$$

Hence, if

$$A_{11} - s < 0, \qquad qA_{11} + A_{12} < 0, \tag{2.4}$$

then the positive equilibrium $e_2\,(\bar{u}, \bar{v})$ is locally asymptotically stable.

Summarizing the above works, we have the following theorem.

Theorem 2.1. *Model (2.1) always has an unstable trivial equilibrium $(0,0)$; if $r_0 > d$, then system (2.1) has a saddle $e_{10}(\frac{r_0-d}{c}, 0)$; the semi-trivial equilibrium $e_{01}(0, \frac{m}{q})$ is locally asymptotically stable when $r_0 < (dk+p)(q+am)/kq$ and unstable when $r_0 > (dk+p)(q+am)/kq$; suppose that condition (2.2) holds, then model (2.1) has the unique positive equilibrium $e_2\,(\bar{u}, \bar{v})$, and it is locally asymptotically stable as (2.4) are satisfied.*

Remark 2.2. Notice that (2.2) is not only the condition for the existence of positive equilibrium e_2, but also the change situation of the stability of equilibrium e_{01}. In other words, the appearance of the positive equilibrium e_2 leads to the instability of the boundary equilibrium e_{01}. Moreover, the condition for the existence of the equilibrium e_{10} is also contained in (2.2).

3 Stability analysis

In this section, we are going to analyse the stability of the positive equilibrium on one-dimension $\Omega = (0, \ell\pi)$. The linearized system of model (1.3) at $e_2(\bar{u}, \bar{v})$ is

$$\begin{cases} \dfrac{\partial u(x,t)}{\partial t} = d_1 \Delta u(x,t) + A_{11} u(x,t) + A_{12} v(x,t), & x \in \Omega, t > 0, \\ \dfrac{\partial v(x,t)}{\partial t} = d_2 \Delta v(x,t) - \chi \bar{v} \Delta u_{\tau_1} + \dfrac{s}{q} u_{\tau_2} - s v(x,t), & x \in \Omega, t > 0, \\ \dfrac{\partial u(x,t)}{\partial v} = 0, \dfrac{\partial v(x,t)}{\partial v} = 0, & x \in \partial\Omega, t > 0, \\ u(x,t) = u_0(x) \geq 0, v(x,t) = v_0(x) \geq 0, & x \in \Omega, t \in (-\max\{\tau_1, \tau_2\}, 0]. \end{cases} \tag{3.1}$$

The characteristic equation of model (3.1) at $e_2(\bar{u}, \bar{v})$ is

$$\Delta_n := \lambda^2 + A_n \lambda + B_n + C_n e^{-\lambda \tau_1} + D_n e^{-\lambda \tau_2} = 0, \qquad n \in \mathbb{N}, \tag{3.2}$$

where

$$\begin{aligned} A_n &= (d_1 + d_2) \frac{n^2}{l^2} - (A_{11} - s) > 0, & B_n &= \left(d_1 \frac{n^2}{l^2} - A_{11} \right) \left(d_2 \frac{n^2}{l^2} + s \right), \\ C_n &= -A_{12} \chi \bar{v} \frac{n^2}{l^2} > 0, & D_n &= -\frac{s}{q} A_{12} > 0. \end{aligned} \tag{3.3}$$

First, we discuss the existence of the steady states of model (1.3). Assume that $\lambda = 0$, then the characteristic equation (3.2) becomes

$$B_n + C_n + D_n = 0. \tag{3.4}$$

Note that there is no delay in equation (3.4), which is equivalent to, $\tau_1 = \tau_2 = 0$.

3.1 Steady states

If $n = 0$, one can deduce that $C_0 = 0$, then equation (3.4) can be rewritten as

$$B_0 + D_0 = -s A_{11} - \frac{s}{q} A_{12} = 0,$$

which is a contradiction with condition (2.4), therefore, there is no spatially homogeneous steady state bifurcation.

As $n \neq 0$, equation (3.4) becomes

$$d_1 d_2 \frac{n^4}{\ell^4} - (A_{11} d_2 - s d_1 + \chi A_{12} \bar{v}) \frac{n^2}{\ell^2} - \left(s A_{11} + \frac{s}{q} A_{12} \right) = 0. \tag{3.5}$$

Regard χ as a function of n^2, if

$$A_{11} d_2 - s d_1 > 0, \quad q (A_{11} d_2 + s d_1)^2 + 4 d_1 d_2 s A_{12} > 0, \tag{3.6}$$

then there is

$$\chi(n^2) = \frac{d_1 d_2 n^4 - (A_{11} d_2 - s d_1)\, l^2 n^2 - \left(s A_{11} + \frac{s}{q} A_{12}\right) l^4}{A_{12} \bar{v} l^2 n^2} > 0.$$

Taking the derivative of $\chi(n^2)$, there is

$$\chi'(n^2) = \frac{d_1 d_2 n^4 + \left(s A_{11} + \frac{s}{q} A_{12}\right) l^4}{A_{12} \bar{v} l^2 n^4}.$$

If $n < n_T$, one can deduce that $\chi'(n^2) > 0$, then $\chi(n^2)$ is increasing with n^2; if $n > n_T$, then $\chi'(n^2) < 0$, and $\chi(n^2)$ is decreasing with n^2 , where

$$n_T^2 = \ell^2 \sqrt{\frac{-(q s A_{11} + s A_{12})}{q d_1 d_2}}.$$

In order to ensure n^* is a positive integer, let

$$n^* = \begin{cases} [n_T], & \text{if } \chi([n_T]^2) > \chi\left(([n_T]+1)^2\right), \\ [n_T]+1, & \text{if } \chi([n_T]^2) < \chi\left(([n_T]+1)^2\right), \end{cases}$$

and $\chi^* = \chi(n^*)$, if $\chi > \chi^*$, then $B_n + C_n + D_n > 0$; if $\chi < \chi^*$, then there is $n \in \mathbb{N}_+$ satisfying $B_n + C_n + D_n = 0$.

To sum up, we have the following theorem.

Theorem 3.1. *Suppose that conditions (2.2), (2.4) and (3.6) hold. Let $n = 0$, then $e_2(\bar{u}, \bar{v})$ is always stable and there is no spatially homogeneous steady state bifurcation. Let $n \in \mathbb{N}_+$, if $\chi > \chi^*$, then $e_2(\bar{u}, \bar{v})$ is asymptotically stable; if $\chi < \chi^*$, then the spatially homogeneous steady state occurs.*

Remark 3.2. According to Theorem 3.1, the stability of positive equilibrium $e_2(\bar{u}, \bar{v})$ is affected by χ for the predator-prey system without delay ($\tau_1 = \tau_2 = 0$). That is to say, fast memory diffusion ($\chi > \chi^*$) remains the stability of the system, while slow memory diffusion ($\chi < \chi^*$) causes the system to be unstable. Moreover, if $A_{11} d_2 - s d_1 < 0$, $\chi(n^2) < 0$ for each $n \in \mathbb{N}_+$, then $e_2(\bar{u}, \bar{v})$ is asymptotically stable for $\chi > 0$. That is, for a sufficiently large self-diffusion d_1, there is no spatially homogeneous steady state bifurcation.

3.2 Hopf bifurcations

In this subsection, we always assume $\chi > \chi^*$ to analyze the Hopf bifurcation of model (1.3).

Let $\lambda = i\omega (\omega > 0)$, then the characteristic equation (3.2) becomes

$$-\omega^2 + B_n + C_n \cos(\omega\tau_1) + D_n \cos(\omega\tau_2) + i\big(A_n \omega - C_n \sin(\omega\tau_1) - D_n \sin(\omega\tau_2)\big) = 0. \quad (3.7)$$

As $n = 0$, equation (3.7) becomes

$$-\omega^2 + B_0 + D_0 \cos(\omega\tau_2) + i\left(A_0 \omega - D_0 \sin(\omega\tau_2)\right) = 0, \quad (3.8)$$

which only contains pregnancy delay τ_2. By equation (3.8), we have

$$\sin(\omega\tau_2) = \frac{A_0\omega}{D_0} > 0, \qquad \cos(\omega\tau_2) = \frac{\omega^2 - B_0}{D_0},$$

and

$$\omega^4 + \left(A_0^2 - 2B_0\right)\omega^2 + B_0^2 - D_0^2 = 0. \tag{3.9}$$

By condition (2.4), one can obtain $B_0 + D_0 > 0$, $A_0^2 - 2B_0 > 0$, $\left(A_0^2 - 2B_0\right)^2 - 4(B_0^2 - D_0^2) > 0$. So we consider equation (3.9) from several different cases.

1) $qA_{11} < A_{12}$, there are no positive real roots of equation (3.9), so the system is always stable;

2) $qA_{11} > A_{12}$, for this case, equation (3.9) has only one positive root satisfying

$$\omega_{2,0}^{+} = \sqrt{\frac{-q\left(A_{11}^2 + s^2\right) + \sqrt{q^2\left(A_{11}^2 - s^2\right)^2 + 4s^2A_{12}^2}}{2q}}, \tag{3.10}$$

and the transversality condition

$$\left(\frac{\mathrm{d}\Re(\lambda)}{\mathrm{d}\tau_2}\right)^{-1}\Bigg|_{\tau_2=\tau_{2,0}^{j+}} = \frac{\sqrt{q^4(1+4sA_{11})(s-A_{11})^2 + 4q^2s^2A_{12}^2}}{s^2A_{12}^2} > 0, \tag{3.11}$$

where $\tau_{2,0}^{j+}$ is a sequence as follows

$$\tau_{2,0}^{j+} = \frac{1}{\omega_{2,0}^{+}}\left(\arccos\frac{q\omega_{2,0}^{+2} + qsA_{11}}{-sA_{12}} + 2j\pi\right), \qquad j = 0, 1, 2, \ldots \tag{3.12}$$

The sequence $\{\tau_{2,0}^{j+}\}_{j=0}^{\infty}$ is an increasing sequence for j, thus $\tau_2^* = \tau_{2,0}^{0+} = \min_{j\in\mathbb{N}} \tau_{2,0}^{j+}$. If $0 < \tau_2 < \tau_2^*$, all the real parts of the roots of equation (3.2) are negative; if $\tau_2 = \tau_{2,0}^{j+}$, equation (3.2) has a pair of pure imaginary roots; if $\tau_2 > \tau_2^*$, at least, one of the roots of equation (3.2) is positive.

Theorem 3.3. *Suppose that conditions (2.2) and (2.4) hold. When $n = 0$, for $\tau_1 = 0$, we have the following statements.*

(1) If $qA_{11} < A_{12}$ or $qA_{11} > A_{12}$, $\tau_2 < \tau_2^*$, then e_2 is asymptotically stable;

(2) if $qA_{11} > A_{12}$, $\tau_2 > \tau_2^*$, then e_2 is unstable;

(3) if $qA_{11} > A_{12}$, $\tau_2 = \tau_{2,0}^{j+}$ $(j = 0, 1, 2, \ldots)$, then the spatially homogeneous Hopf bifurcation occurs.

Remark 3.4. From the above discussion, we can see that model (1.3) does not undergo the spatially homogeneous Hopf bifurcation as it only has the spatial memory delay τ_1, and for this case, memory diffusion χ has no effect on the stability of the positive equilibrium $(\bar{u}, \bar{v})$ of system (1.3).

Next, we assume $n \neq 0$, and consider the two cases (1) $\tau_1 > 0$, $\tau_2 = 0$; or $\tau_1 = 0$, $\tau_2 > 0$; (2) $\tau_1 > 0$, $\tau_2 > 0$.

Case 1. $\tau_1 = 0$, $\tau_2 > 0$ or $\tau_1 > 0$, $\tau_2 = 0$.

When $\tau_1 = 0$, $\tau_2 > 0$, equation (3.7) can be simplified as

$$-\omega^2 + B_n + C_n + D_n \cos(\omega\tau_2) + i\left(A_n\omega - D_n \sin(\omega\tau_2)\right) = 0. \tag{3.13}$$

Solving equation (3.13), we obtain

$$\sin(\omega\tau_2) = \frac{A_n\omega}{D_n} > 0, \qquad \cos(\omega\tau_2) = \frac{\omega^2 - (B_n + C_n)}{D_n},$$

and

$$\omega^4 + \left(A_n^2 - 2(B_n + C_n)\right)\omega^2 + (B_n + C_n)^2 - D_n^2 = 0, \tag{3.14}$$

where for $\forall n \in \mathbb{N}_+$, $(B_n + C_n)^2 - D_n^2 \neq 0$.

1). There exists at least a $n \in \mathbb{N}_+$ satisfying the condition

$$|B_n + C_n| < D_n, \tag{3.15}$$

or

$$|B_n + C_n| > D_n, \quad A_n^2 = 2\left((B_n + C_n) - \sqrt{(B_n + C_n)^2 - D_n^2}\right), \tag{3.16}$$

such that equation (3.14) has a unique positive root

$$\omega_{2,n}^{+} = \sqrt{\frac{-\left(A_n^2 - 2(B_n + D_n)\right) + \sqrt{A_n^4 - 4(B_n + C_n)A_n^2 + 4D_n^2}}{2}},$$

and the corresponding τ_2 is

$$\tau_{2,n}^{j+} = \frac{1}{\omega_{2,n}^{+}}\left(\arccos\frac{\omega_{2,n}^{+2} - (B_n + C_n)}{D_n} + 2j\pi\right), \qquad j = 0, 1, 2, \ldots$$

For each fixed n, $\{\tau_{2,n}^{j+}\}_{j=0}^{\infty}$ is an increasing sequence with the variable j. Denote

$$\tau_2^* := \tau_{2,n_c}^{0+} = \min_{n\in\mathbb{N}_+}\left\{\tau_{2,n}^{0+}\right\},$$

and τ_2^* is the minimum value of the sequence of $\left\{\tau_{2,n}^{j+}\right\}_{j=0}^{\infty}$, $n \in \mathbb{N}_+$. The transversality condition is

$$\left(\frac{\mathrm{d}\Re(\lambda)}{\mathrm{d}\tau_2}\right)^{-1}\Bigg|_{\tau_2=\tau_{2,0}^{j+}} = \frac{2\left(\omega_{2,0}^{+2} - B_0\right) + A_0^2}{\left(\omega_{2,0}^{+2} - B_0\right)^2 + A_0^2\omega_{2,0}^{+2}} > 0. \tag{3.17}$$

That is, if $\tau_2 < \tau_2^*$, then all the real parts of the roots of equation (3.2) are negative; if $\tau_2 = \tau_2^*$, then equation (3.2) has a pair of pure imaginary roots; if $\tau_2 > \tau_2^*$, then there is at least a root of equation (3.2) that has positive real part.

2). There exists a $n \in \mathbb{N}_+$ satisfying

$$|B_n + C_n| > D_n, \quad A_n^2 < 2\left((B_n + C_n) - \sqrt{(B_n + C_n)^2 - D_n^2}\right), \tag{3.18}$$

such that, equation (3.13) has two positive roots,

$$\omega_{2,n}^{\pm} = \sqrt{\frac{-\left(A_n^2 - 2\left(B_n + C_n\right)\right) \pm \sqrt{A_n^4 - 4\left(B_n + C_n\right) A_n^2 + 4D_n^2}}{2}},$$

and the corresponding τ_2 are

$$\tau_{2,n}^{j\pm} = \frac{1}{\omega_{2,n}^{\pm}} \left(\arccos \frac{\omega_{2,n}^{\pm 2} - (B_n + C_n)}{D_n} + 2j\pi \right), \qquad j = 0, 1, 2, \ldots$$

The transversality condition is

$$\left(\frac{\mathrm{d}\Re(\lambda)}{\mathrm{d}\tau_2} \right)^{-1} \Bigg|_{\tau_2 = \tau_{2,n}^{j+}} = \frac{\sqrt{A_n^4 - 4\left(B_n + C_n\right) A_n^2 + 4D_n^2}}{\left(\omega_{2,n}^{+2} - B_n\right)^2 + A_n^2 \omega_{2,n}^{+2}} > 0,$$

$$\left(\frac{\mathrm{d}\Re(\lambda)}{\mathrm{d}\tau_2} \right)^{-1} \Bigg|_{\tau_2 = \tau_{2,n}^{j-}} = -\frac{\sqrt{A_n^4 - 4\left(B_n + C_n\right) A_n^2 + 4D_n^2}}{\left(\omega_{2,n}^{-2} - B_n\right)^2 + A_n^2 \omega_{2,n}^{-2}} < 0.$$

For each fixed $n \in \mathbb{N}_+$, $\{\tau_{2,n}^{j+}\}_{j=0}^{\infty}$, $\{\tau_{2,n}^{j-}\}_{j=0}^{\infty}$ are increasing sequences with j, and $\tau_{2,n}^{j+} < \tau_{2,n}^{j-}$ due to $\omega_{2,n}^{j+} > \omega_{2,n}^{j-}$. Reorder $\{\tau_{2,n}^{j+}\}_{j=0}^{\infty}$, $\{\tau_{2,n}^{j-}\}_{j=0}^{\infty}$ as increasing subsequences and denote as $\{\tau_2^{S+}\}_{S=1}^{\infty}$, $\{\tau_2^{S-}\}_{S=1}^{\infty}$, respectively, and $\tau_2^* = \tau_2^{0+}$ is the minimum value. There exists a $K_2 \in \mathbb{N}$, such that all the real parts of the roots of model (3.13) are negative for

$$\tau_2 \in (0, \tau_2^{0+}) \bigcup \left(\tau_2^{0-}, \tau_2^{1+}\right) \bigcup \cdots \bigcup \left(\tau_2^{(K_2-1)-}, \tau_2^{K_2+}\right);$$

at least one root of model (3.13) has positive real part for

$$\tau_2 \in (\tau_2^{0+}, \tau_2^{0-}) \bigcup \left(\tau_2^{1+}, \tau_2^{1-}\right) \bigcup \cdots \bigcup \left(\tau_2^{K_2+}, \infty\right).$$

3). For each $n \in \mathbb{N}_+$ satisfying

$$|B_n + C_n| > D_n, \quad A_n^2 > 2\left((B_n + C_n) - \sqrt{(B_n + C_n)^2 - D_n^2} \right), \tag{3.19}$$

(3.13) has no positive root.

Theorem 3.5. *Suppose that (2.2), (2.4) and $\chi < \chi^*$ hold. When $\tau_1 = 0$, for $n \neq 0$, we have the results.*

1. The positive equilibrium $e_2(\bar{u}, \bar{v})$ is asymptotically stable if one of the following conditions is satisfied:

(1) $\exists n \in \mathbb{N}_+$, (3.15) or (3.16), $\tau_2 < \tau_2^*$;

(2) $\exists n \in \mathbb{N}_+$, (3.18), $\tau_2 \in \left(0, \tau_2^{0+}\right) \cup \cdots \cup \left(\tau_2^{(K_2-1)-}, \tau_2^{K_2+}\right)$, $K_2 \geq 0$;

(3) $\forall n \in \mathbb{N}_+$, (3.19).

2. The positive equilibrium $e_2(\bar{u}, \bar{v})$ is unstable if one of the following conditions holds:

(1) $\exists n \in \mathbb{N}_+$, (3.15) *or* (3.16) *,* $\tau_2 > \tau_2^*$*;*

(2) $\exists n \in \mathbb{N}_+$, (3.18) *holds,* $\tau_2 \in \left(\tau_2^{0+}, \tau_2^{0-}\right) \cup \cdots \cup \left(\tau_2^{K_2+}, +\infty\right)$*,* $K_2 \geq 0$.

3. *System (1.3) undergoes the spatially nonhomogeneous Hopf bifurcation if one of the following conditions is met:*

(1) $\exists n \in \mathbb{N}_+$, (3.15) *or* (3.16) *holds,* $\tau_2 = \tau_{2,n}^{j+}$ $(j = 0, 1, 2, \ldots)$*;*

(2) $\exists n \in \mathbb{N}_+$, (3.18) *holds,* $\tau_2 = \tau_2^{S\pm}$ $(S = 0, 1, 2, \ldots)$*.*

When $\tau_1 > 0$ and $\tau_2 = 0$, the discussion process is the same as above. Denote

$$\omega_{1,n}^{\pm} = \sqrt{\frac{-\left(A_n^2 - 2\left(B_n + D_n\right)\right) \pm \sqrt{A_n^4 - 4\left(B_n + D_n\right) A_n^2 + 4C_n^2}}{2}}, \tag{3.20}$$

and the corresponding delay τ_1 are

$$\tau_{1,n}^{j\pm} = \frac{1}{\omega_{1,n}^{\pm}} \left(\arccos \frac{\omega_{1,n}^{\pm 2} - \left(B_n + D_n\right)}{C_n} + 2j\pi \right), \qquad j = 0, 1, 2, \ldots \tag{3.21}$$

Let

$$\tau_1^* := \tau_1^{0+} = \min_{n \in \mathbb{N}_+} \left\{ \tau_{1,n}^{0+} \right\}. \tag{3.22}$$

We have the following statements.

Theorem 3.6. *Suppose that* (2.2), (2.4) *and* $\chi < \chi^*$ *hold. When* $\tau_2 = 0$*, for* $n \neq 0$*, the following statements hold.*

1. *The positive equilibrium* $(\bar{u}, \bar{v})$ *is asymptotically stable if the parameters satisfy one of the following conditions:*

(1) $\exists n \in \mathbb{N}_+$, $|B_n + D_n| < C_n$ *or* $|B_n + D_n| > C_n$, $A_n^2 = 2\left(\left(B_n + D_n\right) - \sqrt{\left(B_n + D_n\right)^2 - C_n^2}\right)$ *hold,* $\tau_1 < \tau_1^*$*;*

(2) $\exists n \in \mathbb{N}_+$, $|B_n + D_n| > C_n$, $A_n^2 < 2\left(\left(B_n + D_n\right) - \sqrt{\left(B_n + D_n\right)^2 - C_n^2}\right)$ *hold,* $\tau_1 \in \left(0, \tau_1^{0+}\right) \cup \cdots \cup \left(\tau_1^{(K_1-1)-}, \tau_2^{K_1+}\right)$*,* $K_1 \geq 0$*;*

(3) $\forall n \in \mathbb{N}_+$, $|B_n + D_n| > C_n$, $A_n^2 > 2\left(\left(B_n + D_n\right) - \sqrt{\left(B_n + D_n\right)^2 - C_n^2}\right)$ *hold.*

2. *The positive equilibrium* $(\bar{u}, \bar{v})$ *is unstable if the parameters meet one of the following conditions:*

(1) $\exists n \in \mathbb{N}_+$, $|B_n + D_n| < C_n$ *or* $|B_n + D_n| > C_n$, $A_n^2 = 2\left(\left(B_n + D_n\right) - \sqrt{\left(B_n + D_n\right)^2 - C_n^2}\right)$ *hold,* $\tau_1 > \tau_1^*$*;*

(2) $\exists n \in \mathbb{N}_+$, $|B_n + D_n| > C_n$, $A_n^2 < 2\left(\left(B_n + D_n\right) - \sqrt{\left(B_n + D_n\right)^2 - C_n^2}\right)$ *hold,* $\tau_1 \in \left(\tau_1^{0+}, \tau_1^{0-}\right) \cup \cdots \cup \left(\tau_1^{K_1+}, +\infty\right)$*,* $K_1 \geq 0$*;*

3. System (1.3) undergoes the spatially nonhomogeneous Hopf bifurcation if the parameters fulfill one of the following conditions:

(1) $\exists n \in \mathbb{N}_+$, $|B_n + D_n| < C_n$ *or* $|B_n + D_n| > C_n$, $A_n^2 = 2\Big((B_n + D_n) - \sqrt{(B_n + D_n)^2 - C_n^2}\Big)$ *hold,* $\tau_1 = \tau_{1,n}^{j+}$ $(j = 0, 1, 2, \dots)$;

(2) $\exists n \in \mathbb{N}_+$, $|B_n + D_n| > C_n$, $A_n^2 < 2\Big((B_n + D_n) - \sqrt{(B_n + D_n)^2 - C_n^2}\Big)$ *hold,* $\tau_1 = \tau_{1,n}^{S+}$ $(S = 0, 1, 2, \dots)$.

Case 2. $\tau_1, \tau_2 > 0$

We rewrite (3.2) with $\tau_1 > 0$ and $\tau_2 > 0$ as

$$D_n(\lambda, \tau_1, \tau_2) := P_{0,n}(\lambda) + P_{1,n}(\lambda)e^{-\lambda\tau_1} + P_{2,n}(\lambda)e^{-\lambda\tau_2} = 0, \tag{3.23}$$

where

$$P_{0,n}(\lambda) = \lambda^2 + A_n\lambda + B_n, \qquad P_{1,n}(\lambda) = C_n, \qquad P_{2,n}(\lambda) = D_n, \tag{3.24}$$

A_n, B_n, C_n and D_n are defined in (3.3). $\forall n \in \mathbb{N}_+$, $P_{S,n}(\lambda)$ $(S = 0, 1, 2)$ satisfy

(I) $\deg P_{0,n}(\lambda) \geq \max\{\deg P_{1,n}(\lambda), \deg P_{2,n}(\lambda)\}$;

(II) $P_{0,n}(0) + P_{1,n}(0) + P_{2,n}(0) = B_n + C_n + D_n \neq 0$;

(III) $P_{0,n}(\lambda)$, $P_{1,n}(\lambda)$, $P_{2,n}(\lambda)$ has no common zeros;

(IV) $\lim_{\lambda\to\infty}\left(\left|\frac{P_{1,n}(\lambda)}{P_{0,n}(\lambda)}\right| + \left|\frac{P_{2,n}(\lambda)}{P_{0,n}(\lambda)}\right|\right) < 1$.

Notice that $\lambda = 0$ is the solution of (3.23), thus we assume that the root of (3.23) is $\lambda = i\omega$ $(\omega > 0)$, and for $\forall\omega > 0$, $P_{j,n}(i\omega) \neq 0$ $(j = 0, 1, 2)$. According to [4], $\lambda = i\omega$ $(\omega > 0)$ is a solution of (3.23) if and only if Ω_n is nonempty. Ω_n is defined as,

$$\Omega_n = \left\{\omega \in \mathbb{R}_+ : |P_{1,n}(i\omega)| + |P_{2,n}(i\omega)| \geq |P_{0,n}(i\omega)|, \big||P_{1,n}(i\omega)| - |P_{2,n}(i\omega)|\big| \leq |P_{0,n}(i\omega)|\right\}. \tag{3.25}$$

If Ω_n is nonempty, then we denote the delays (τ_1, τ_2) satisfying (3.25) as

$$\begin{aligned}
\tau_{1,n,K_1}^{\pm}(\omega) &= \frac{\angle\arg\dfrac{P_{1,n}(i\omega)}{P_{0,n}(i\omega)} + (2K_1 - 1)\pi \pm \theta_{1,n}(\omega)}{\omega}, \quad K_1 = K_{1,n}^{\pm}, K_{1,n}^{\pm} + 1, K_{1,n}^{\pm} + 2, \dots, \\
\tau_{2,n,K_2}^{\pm}(\omega) &= \frac{\angle\arg\dfrac{P_{2,n}(i\omega)}{P_{0,n}(i\omega)} + (2K_2 - 1)\pi \mp \theta_{2,n}(\omega)}{\omega}, \quad K_2 = K_{2,n}^{\pm}, K_{2,n}^{\pm} + 1, K_{2,n}^{\pm} + 2, \dots,
\end{aligned} \tag{3.26}$$

where

$$\begin{aligned}
\theta_{1,n}(\omega) &= \arccos\left(\frac{|P_{0,n}(i\omega)|^2 + |P_{1,n}(i\omega)|^2 - |P_{2,n}(i\omega)|^2}{2|P_{0,n}(i\omega)||P_{1,n}(i\omega)|}\right), \\
\theta_{2,n}(\omega) &= \arccos\left(\frac{|P_{0,n}(i\omega)|^2 - |P_{1,n}(i\omega)|^2 + |P_{2,n}(i\omega)|^2}{2|P_{0,n}(i\omega)||P_{2,n}(i\omega)|}\right).
\end{aligned} \tag{3.27}$$

$K_{1,n}^{\pm}$ and $K_{2,n}^{\pm}$ is the smallest integers to ensure $\tau_{1,n,K_1}^{\pm}$, $\tau_{2,n,K_2}^{\pm}$ are positive. Furthermore, the mode-n stability switching curves (3.23) are

$$\mathcal{T}_n = \bigcup_{K=1}^{N} \left\{ \bigcup_{K_1=-\infty}^{+\infty} \bigcup_{K_2=-\infty}^{+\infty} \left(\mathcal{T}^{+K}_{n,K_1,K_2}, \mathcal{T}^{-K}_{n,K_1,K_2} \right) \bigcap \mathbb{R}^2_+ \right\},$$

where

$$\mathcal{T}^{\pm K}_{n,K_1,K_2} = \left\{ \left(\tau^{\pm}_{1,n,K_1}(\omega), \tau^{\mp}_{2,n,K_2}(\omega) \right) : \omega \in \Omega_n \right\}.$$

By [4, Proposition 4.5], we have the following conclusion about $\mathcal{T}_n$ and Ω_n.

Theorem 3.7. *The mode-n stability switching curves $\mathcal{T}_n$ and the crossing set Ω_n have the following structures with $\forall n \in \mathbb{N}_+$,*

(1) $\mathcal{T}_n$ is a series of spiral-like curves

(1a) for $\Omega_n = [\omega^r_{2,n}, \omega^r_{1,n}]$, if $|B_n| < |C_n - D_n|$;

(1b) for $\Omega_n = [\omega^l_{1,n}, \omega^l_{2,n}] \bigcup [\omega^r_{2,n}, \omega^r_{1,n}]$, if

$$C_n + D_n < |B_n|, \quad A_n^2 < 2\left(B_n - \sqrt{B_n^2 - (C_n - D_n)^2}\right);$$

(2) $\mathcal{T}_n$ contains a series of open ended curves and a series of spiral-like curves for $\Omega_n = (0, \omega^l_{2,n}] \bigcup [\omega^r_{2,n}, \omega^r_{1,n}]$, if

$$|C_n - D_n| < |B_n| < C_n + D_n, \quad A_n^2 < 2\left(B_n - \sqrt{B_n^2 - (C_n - D_n)^2}\right);$$

(3) $\mathcal{T}_n$ is a series of open ended curves for $\Omega_n = \left(0, \omega^r_{1,n}\right]$, if

$$|C_n - D_n| < |B_n| < C_n + D_n, \quad A_n^2 > 2\left(B_n - \sqrt{B_n^2 - (C_n - D_n)^2}\right);$$

(4) $\mathcal{T}_n$ is a series of closed curves for $\Omega_n = [\omega^l_{1,n}, \omega^r_{1,n}]$, if

$$C_n + D_n < |B_n|, \quad 2\left(B_n - \sqrt{B_n^2 - (C_n - D_n)^2}\right) < A_n^2 < 2\left(B_n - \sqrt{B_n^2 - (C_n + D_n)^2}\right),$$

where

$$\omega^l_{1,n} = \sqrt{\frac{-\left(A_n^2 - 2B_n\right) - \sqrt{\Delta_1}}{2}}, \qquad \omega^r_{1,n} = \sqrt{\frac{-\left(A_n^2 - 2B_n\right) + \sqrt{\Delta_1}}{2}},$$

$$\omega^l_{2,n} = \sqrt{\frac{-\left(A_n^2 - 2B_n\right) - \sqrt{\Delta_2}}{2}}, \qquad \omega^r_{2,n} = \sqrt{\frac{-\left(A_n^2 - 2B_n\right) + \sqrt{\Delta_2}}{2}},$$

and

$$\Delta_1 = A_n^4 - 4B_n A_n^2 + 4\left(C_n + D_n\right)^2,$$
$$\Delta_2 = A_n^4 - 4B_n A_n^2 + 4\left(C_n - D_n\right)^2.$$

Proof. By (3.25) and (3.24), $|P_{1,n}(i\omega)| + |P_{2,n}(i\omega)| = |P_{0,n}(i\omega)|$ can be rewritten as

$$\omega^4 + \left(A_n^2 - 2B_n\right)\omega^2 + B_n^2 - \left(C_n + D_n\right)^2 = 0. \tag{3.28}$$

We have the cases:

- when $C_n + D_n < |B_n|$, if $A_n^2 > 2\left(B_n - \sqrt{B_n^2 - (C_n + D_n)^2}\right)$, for $\forall\omega > 0$, then $|P_{1,n}(i\omega)| + |P_{2,n}(i\omega)| < |P_{0,n}(i\omega)|$, thus $\Omega_n = \emptyset$; if $A_n^2 < 2\left(B_n - \sqrt{B_n^2 - (C_n + D_n)^2}\right)$, for $\omega \in \left[\omega_{1,n}^l, \omega_{1,n}^r\right]$, then $|P_{1,n}(i\omega)| + |P_{2,n}(i\omega)| \geq |P_{0,n}(i\omega)|$;
- when $C_n + D_n > |B_n|$, $|P_{1,n}(i\omega)| + |P_{2,n}(i\omega)| \geq |P_{0,n}(i\omega)|$ for $\omega \in \left(0, \omega_{1,n}^r\right]$.

Similarly, $\left||P_{1,n}(i\omega)| - |P_{2,n}(i\omega)|\right| = |P_{0,n}(i\omega)|$ can expressed as

$$\omega^4 + \left(A_n^2 - 2B_n\right)\omega^2 + B_n^2 - \left(C_n - D_n\right)^2 = 0. \tag{3.29}$$

For the same discussion, we also have:

- when $|C_n - D_n| < |B_n|$, $\Omega_n = (0, \infty)$ for $A_n^2 < 2\left(B_n - \sqrt{B_n^2 - (C_n - D)^2}\right)$; $\Omega_n = \left(0, \omega_{2,n}^l\right] \cup \left[\omega_{2,n}^r, +\infty\right)$ for $A_n^2 > 2\left(B_n - \sqrt{B_n^2 - (C_n - D)^2}\right)$;
- when $|C_n - D_n| > |B_n|$, $\Omega_n = \left[\omega_{2,n}^r, +\infty\right)$.

Particularly, $\omega_{1,n}^l < \omega_{2,n}^l$, $\omega_{2,n}^r < \omega_{1,n}^r$ due to $\Delta_1 > \Delta_2$. □

Remark 3.8. In addition, $\Omega_n = \emptyset$ for

$$C_n + D_n < |B_n|, A_n^2 > 2\left(B_n - \sqrt{B_n^2 - (C_n - D_n)^2}\right),$$

the conditions are continue holding for $n \to \infty$.

Let $\lambda = \sigma + i\omega$, and view τ_1, τ_2 as functions $\tau_1(\sigma, \omega)$, $\tau_2(\sigma, \omega)$. Calculating from (3.23), we have

$$\begin{aligned}
\frac{P_{1,n}(i\omega)}{P_{0,n}(i\omega)}e^{-i\omega\tau_1} = & \frac{C_n}{\omega^4 + (A_n^2 - 2B_n)\omega^2 + B_n^2}\left(\left(-\omega^2 + B_n\right)\cos(\omega\tau_1) - A_n\omega\sin(\omega\tau_1)\right) \\
& + \frac{-C_n i}{\omega^4 + (A_n^2 - 2B_n)\omega^2 + B_n^2}\left(\left(-\omega^2 + B_n\right)\sin(\omega\tau_1) + A_n\omega\cos(\omega\tau_1)\right), \\
\frac{P_{2,n}(i\omega)}{P_{0,n}(i\omega)}e^{-i\omega\tau_2} = & \frac{D_n i}{\omega^4 + (A_n^2 - 2B_n)\omega^2 + B_n^2}\left(\left(-\omega^2 + B_n\right)\cos(\omega\tau_2) - A_n\omega\sin(\omega\tau_2)\right) \\
& + \frac{-D_n i}{\omega^4 + (A_n^2 - 2B_n)\omega^2 + B_n^2}\left(\left(-\omega^2 + B_n\right)\sin(\omega\tau_2) + A_n\omega\cos(\omega\tau_2)\right),
\end{aligned}$$

and

$$\begin{aligned}
R_1 &= \mathrm{Re}\left(\frac{P_{1,n}(i\omega)}{P_{0,n}(i\omega)}e^{-i\omega\tau_1}\right), \qquad I_1 = \mathrm{Im}\left(\frac{P_{1,n}(i\omega)}{P_{0,n}(i\omega)}e^{-i\omega\tau_1}\right), \\
R_2 &= \mathrm{Re}\left(\frac{P_{2,n}(i\omega)}{P_{0,n}(i\omega)}e^{-i\omega\tau_2}\right), \qquad I_2 = \mathrm{Im}\left(\frac{P_{2,n}(i\omega)}{P_{0,n}(i\omega)}e^{-i\omega\tau_2}\right).
\end{aligned}$$

Then

$$R_2 I_1 - R_1 I_2 = \frac{-C_n D_n}{\omega^4 + (A_n^2 - 2B_n)\,\omega^2 + B_n^2} \sin\left(\omega\left(\tau_1 - \tau_2\right)\right). \tag{3.30}$$

The sign of $R_2 I_1 - R_1 I_2$ is determined by $\sin\left(\omega\left(\tau_1 - \tau_2\right)\right)$ because $-C_n D_n < 0$, $\omega^4 + \left(A_n^2 - 2B_n\right)\omega^2 + B_n^2 > 0$, for $\forall \omega > 0$.

From [4, Proposition 6.1], we have the following lemma.

Lemma 3.9. *Let $\omega \in \Omega_n$, $(\tau_1, \tau_2) \in \mathcal{T}_n$ such that $i\omega$ is a simple root of (3.23). A pair of conjugate complex roots cross the imaginary axis to the right (left) for $\sin\left(\omega\left(\tau_1 - \tau_2\right)\right) < 0$ (> 0) as (τ_1, τ_2) moves from the region on the right to the left of $\mathcal{T}_n$.*

If the following conditions hold:

(1) when $n = 0$, $|B_0| > D_0$, $A_0^2 < 2\left(B_0 - \sqrt{B_0^2 - D_0^2}\right)$ or $|B_0| < D_0$;

(2) when $n \in \mathbb{N}_+$, $|B_n| > C_n + D_n$, $A_n^2 < 2\left(B_n - \sqrt{B_n^2 - (C_n + D_n)^2}\right)$ or $|B_n| < C_n + D_n$;

then there exists (τ_1^0, τ_2^0) such that (3.23) has the pure imaginary root $i\omega^0$. Moreover, when $\omega^0\left(\tau_1^0 - \tau_2^0\right) \neq k\pi$ ($k \in \mathbb{Z}$), there is a neighborhood U_1 of (τ_1^0, τ_2^0), the following results hold.

Theorem 3.10. *Denote that U_2 is the stable region enclosed by the stability curves $\mathcal{T}_n$ and $\tau_1 - \tau_2$, but not contain $\mathcal{T}_n$, then*

(1) when $(\tau_1, \tau_2) \in U_1 \cap U_2$, the positive equilibrium $(\bar{u}, \bar{v})$ is asymptotically stable;

(2) when $(\tau_1, \tau_2) \in U_1 \backslash \bar{U}_2$, the positive equilibrium $(\bar{u}, \bar{v})$ is unstable;

(3) when $(\tau_1, \tau_2) \in \mathcal{T}_n$, system (1.3) undergoes the spatially nonhomogeneous Hopf bifurcation at $(\bar{u}, \bar{v})$.

4 Numerical simulations

In this section, we give some numerical simulations to support the findings of this paper.

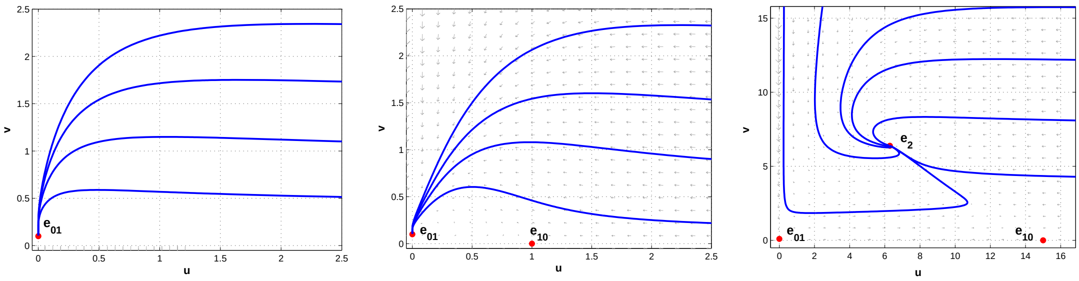
The parameters are chosen as $a = 0.1$, $c = 0.1$, $p = 0.1$, $k = 0.1$, $s = 0.1$, $m = 0.1$, $q = 1$, $d = 0.5$. Model (1.3) has only one non-negative stable solution $e_{01} = (0, 0.1)$ for $r_0 = 0.1 < d$ (see Fig. 4.1(a)); when $d < r_0 = 0.6 < (dk + p)(q + am)/kq$, model (1.3) has non-negative stable solution $e_{01} = (0, 0.1)$ and unstable solution $e_{10} = (1, 0)$ (see Fig. 4.1(b)); for $r_0 = 2 > (dk + p)(q + am)/kq$, model (1.3) has only one positive solution e_2, and non-negative solutions e_{01} and e_{10} are unstable (see Fig. 4.1(c)).

Taking the parameter values

$$r_0 = 80, \quad a = 2, \quad c = 3, \quad d = 2, \quad p = 18, \quad k = 1, \quad m = 1, \quad q = 1,$$

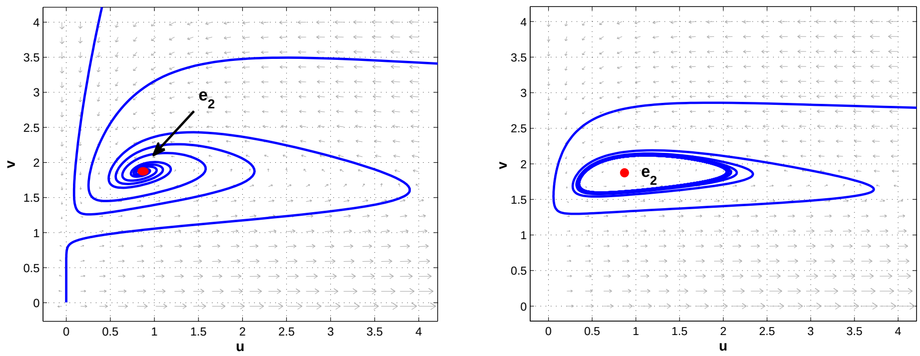
there are $(\bar{u}, \bar{v}) = (0.8678, 1.8678)$, $a_{11} = 1.292$, $a_{12} = -8.27$. According to condition (2.4), for $qa_{11} + a_{12} < 0$, the stability of $(\bar{u}, \bar{v}) = (0.8678, 1.8678)$ is determined by s. The positive equilibrium $(\bar{u}, \bar{v})$ is locally asymptotically stable when $s = 3 > 1.292$ (see Fig. 4.2(a)) and unstable when $s = 1 < 1.292$ (see Fig. 4.2(b)).

Assuming $d_1 = 0.01$, $d_2 = 10$, $\ell = 1$, $s = 1.5$, other parameters are the same as those of Fig. 4.2. Now $(\bar{u}, \bar{v}) = (0.8678, 1.8678)$, $A_{11} = 1.2952$, condition (3.6) is satisfied, $\chi^* = 0.7043$



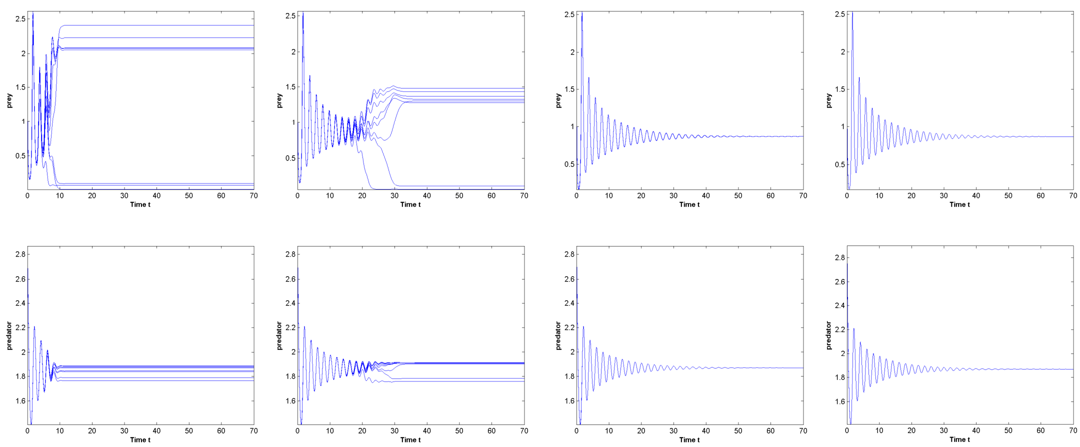
(a) $r_0 = 0.1$ (b) $r_0 = 0.6$ (c) $r_0 = 2$

Figure 4.1: The change of the number and stability of equilibrium points with the parameter r_0.



(a) $s = 3$ (b) $s = 1$

Figure 4.2: The relationship of the stability of $(\bar{u}, \bar{v})$ and s.

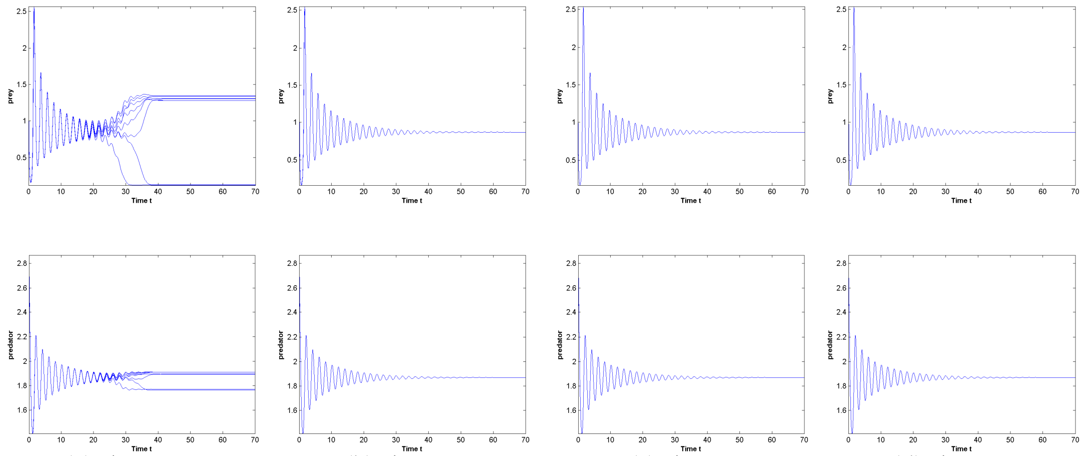


(a) $\chi = 0.01$ (b) $\chi = 0.5$ (c) $\chi = 1$ (d) $\chi = 10$

Figure 4.3: The first and second lines represent the populations of prey and predator, the stability of model (1.3) is controlled by χ, $(\bar{u}, \bar{v})$ is unstable for $\chi < \chi^*$ as (**a**) $\chi = 0.01$, (**b**) $\chi = 0.5$ and locally stable for $\chi > \chi^*$ as (**c**) $\chi = 1$, (**d**) $\chi = 10$.

for $n^* = 10$. Fig. 4.3 verifies Theorem 3.1, for $n \in \mathbb{N}_+$, $(\bar{u}, \bar{v})$ is asymptotically stable for $\chi > \chi^*$; when $\chi < \chi^*$, notice that $(\bar{u}, \bar{v})$ is unstable, Turing instability occurs (see Fig. 4.3(a)–(d)).

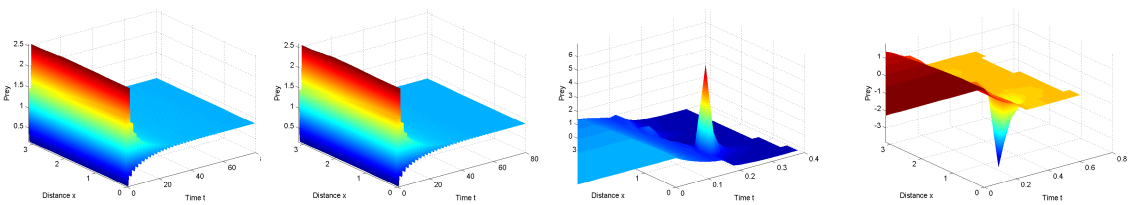
In addition, for the given χ, the stability of model (1.3) also affected by d_1. From Fig. 4.4, the spatiotemporal diagram of the prey is displayed in the figures of the first line and that of predator is showed in the figures of the second line for $\chi = 0.5$. Fig. 4.4 shows that, as the self-diffusion d_1 is big enough, there is no spatially or non-spatially homogeneous steady state bifurcation for the system.



(a) $d_1 = 0.02$ (b) $d_1 = 0.2$ (c) $d_1 = 2$ (d) $d_1 = 20$

Figure 4.4: The spatiotemporal diagram of the system. The value of d_1 is set as (**a**) $d_1 = 0.02$, (**b**) $d_1 = 0.2$, (**c**) $d_1 = 2$ and (**d**) $d_1 = 20$.

Next, we illustrate the influence of delay τ_1 and τ_2. For the delay τ_1, taking the parameter $\chi = 1 > \chi^*$, others are the same as those of Fig.4.3, then there exists $n \in \mathbb{N}_+$ satisfied $|B_n + D_n| < C_n$, and the critical values are $\omega_{1,0}^{3+} = 1.0828$ and $\tau_1^* = 0.7194$ for $n = 3$, so the positive equilibrium $(\bar{u}, \bar{v})$ is asymptotically stable for $\tau_1 < \tau_1^*$ (see Fig. 4.5(a)–(b)), and unstable for $\tau_1 > \tau_1^*$ (see Fig. 4.5(c)–(d)).

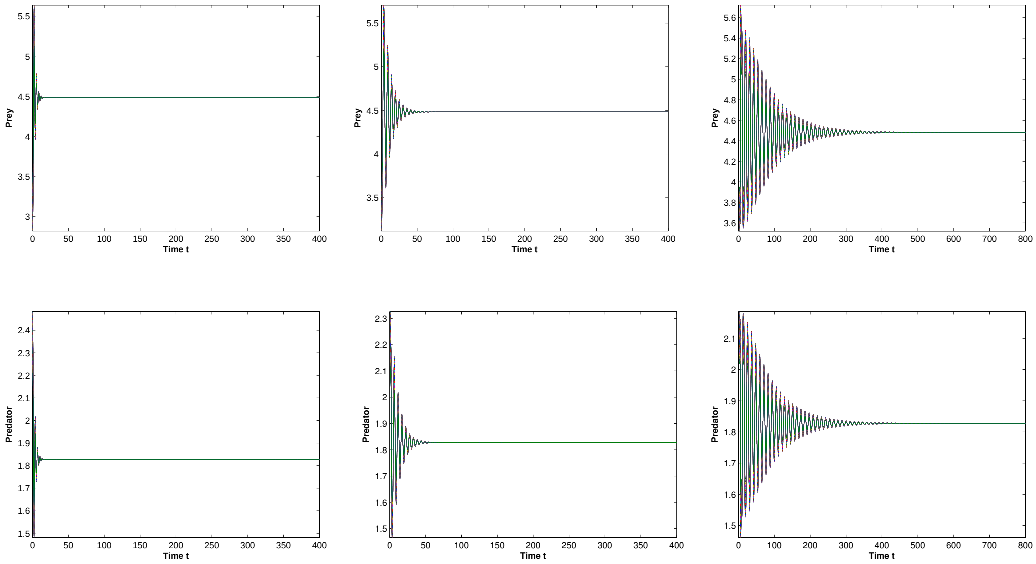


(a) $\tau_1 = 0.1$ (b) $\tau_1 = 0.2$ (c) $\tau_1 = 0.8$ (d) $\tau_1 = 1$

Figure 4.5: When $\tau_1 < \tau_1^*$, the system is always stable and unstable when $\tau_1 > \tau_1^*$, for the fixed value $\chi > \chi^*$.

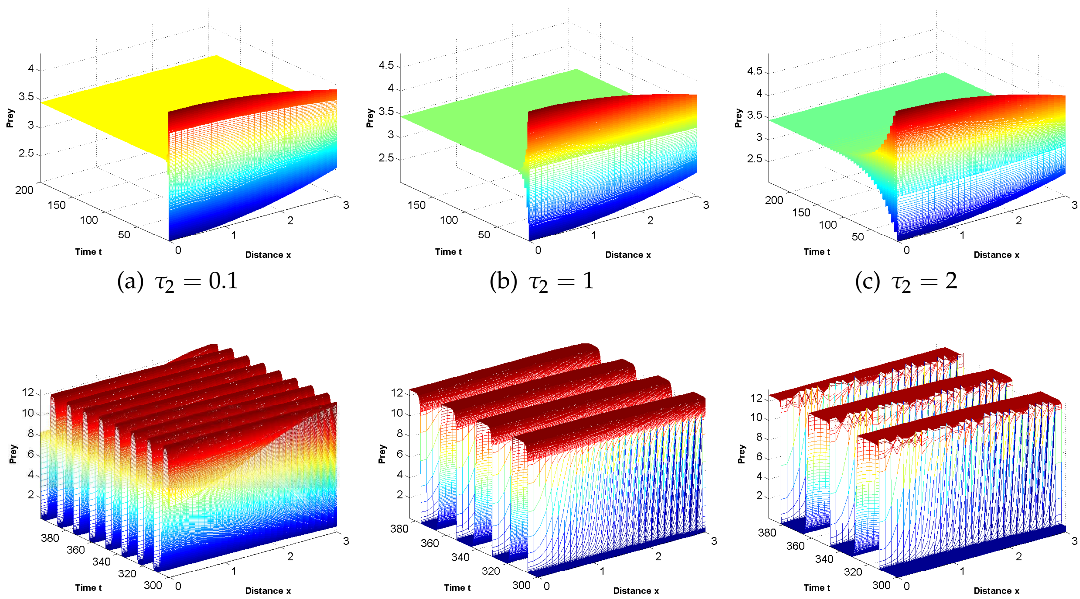
For delay τ_2 on the spatial distribution when $n = 0$, taking the parameter $q = 3$, model (1.3) has the unique positive equilibrium $(\bar{u}, \bar{v}) = (4.4826, 1.8275)$, the system is stable for $qA_{11} < A_{12}$ (see Fig. 4.6(a)–(c)).

While $q = 2$, $(\bar{u}, \bar{v}) = (3.4458, 2.2229)$, $qA_{11} > A_{12}$, we obtain the critical values $\omega_{2,0}^{0+} = 0.6008$ and $\tau_2^* = \tau_{2,0}^{0+} = 2.5366$. Taking $\tau_2 = 0.1, 1, 2 < \tau_2^*$ (see Fig. 4.7(a)–(c)), and $\tau_2 = 5, 10, 15 > \tau_2^*$ (see Fig. 4.7(d)–(f)) to verify the results of Theorem 3.3, the interval of the oscillation period becomes longer with the increasing of τ_2.



(a) $q = 3$, $\tau_2 = 1$ (b) $q = 3$, $\tau_2 = 2$ (c) $q = 3$, $\tau_2 = 5$

Figure 4.6: Spatiotemporal diagram of model (1.3). The system is always stable when $q = 3$ for any τ_2, due to $qA_{11} < A_{12}$.



(a) $\tau_2 = 0.1$ (b) $\tau_2 = 1$ (c) $\tau_2 = 2$

(d) $\tau_2 = 5$ (e) $\tau_2 = 10$ (f) $\tau_2 = 15$

Figure 4.7: Spatiotemporal diagram of prey for model (1.3). The first line shows that the system is always stable for $\tau_2 < \tau_2^*$, and the second line shows that Hopf bifurcation occurs for $\tau_2 > \tau_2^*$.

For the model with two delay ($\tau_1, \tau_2 \neq 0$), when $s = 3$, $\ell = 1$ and other parameters are the same as those of Fig. 2, the positive equilibrium is $(0.8678, 1.8678)$. For $n = 1$, the crossing set is $\Omega_1 = (0, 3.9051]$, satisfying $|C_1 - D_1| < |B_1| < C_1 + D_1$, $A_1^2 > 2\big(B_1 - \sqrt{B_1^2 - (C_1 - D_1)^2}\big)$, then the stability switching curves are a series of open ended curves, so Theorem 3.7(3) is verified (see Fig. 4.8(a)); for $n = 3$, $\Omega_1 = [2.4861, 3.0613]$, satisfying $|B_2| < |C_2 - D_2|$, the stability switching curves are a series of spiral-like curves, and Theorem 3.7(1a) is verified (see Fig. 4.8(b)). Others can be got similarly.

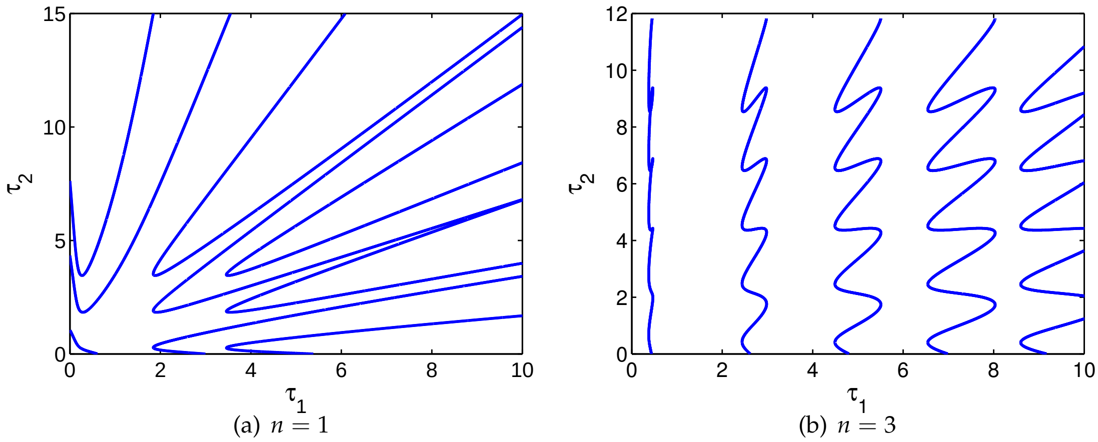


Figure 4.8: The stability switching curves for $n = 1, 2$. (a) open ended curves for $n = 1$; (b) spiral-like curves for $n = 2$.

5 Conclusion

In the paper, we propose a diffusive predator-prey system with two delays. We introduce the modified Leslie–Gower term and fear effect to the system, and consider the stability of the model with the memory delay τ_1 and maturation delay τ_2, obtaining the following results.

(1) System (1.3) always has the semi-trivial equilibrium e_{01}, which is stable for $r_0 < (dk + p)(q + am)/kq$; when $r_0 > (dk + p)(q + am)/kq$, the equilibrium e_{01} loses stable; when $r_0 > d$, there exists semi-trivial equilibrium e_{10}, which is always unstable. Meanwhile, the model has the unique positive equilibrium e_2, which is locally asymptotically stable for $a_{11} - s < 0$, $qa_{11} + a_{12} < 0$. The number and stability of model (1.3) are determined by r_0.

(2) For $n = 0$, as conditions (2.2) and (2.4) hold, there is no spatially homogeneous steady state bifurcation. When $n \neq 0$ and condition (3.6) is satisfied, for $\chi > \chi^*$, $(\bar{u}, \bar{v})$ is asymptotically stable; for $\chi < \chi^*$, the spatially homogeneous steady state bifurcation occurs at $(\bar{u}, \bar{v})$. Therefore, Turing instability appears. From the condition $A_{11}d_2 - sd_1 < 0$, one can conclude that slow prey-taxis and fast self-diffusion would cause Turing patterns to occur.

(3) System (1.3) exists the spatially nonhomogeneous Hopf bifurcation at $(\bar{u}, \bar{v})$ for fast memory delay when it only has delay τ_1; model (1.3) undergoes the spatially homogeneous and nonhomogeneous Hopf bifurcation at $(\bar{u}, \bar{v})$ for fast maturation delay when it only has delay τ_2. Specially, there is no spatially homogeneous Hopf bifurcation for any delay τ_2 ($\tau_1 = 0$) when q is big enough. For the model with two delay ($\tau_1, \tau_2 \neq 0$), the structures of mode-n stability switching curves $\mathcal{T}_n$ and the crossing set Ω_n are shown as in Theorem 3.7, and the dynamical behavior are much richer than one delay.

Abstract. The aim of this paper is to estimate an interval of the existence of positive solutions for a boundary value problem for the system of three nonlinear second-order ordinary differential equations. Krasnosel'skiĭ–Precup fixed point theorem is used to determine this interval theoretically. For Dirichlet boundary conditions theoretical result is compared with result obtained numerically.

Keywords: boundary value problem, system of second-order ODEs, interval of the existence of solutions, positive solutions, Krasnosel'skiĭ–Precup fixed point theorem.

1 Introduction

Systems of three second-order ordinary differential equations emerge naturally from the application of Newton's laws in modeling three body interaction: each equation represents the acceleration of a body in response to the forces exerted by the other two bodies. Such systems have a vital role in modeling problems of mechanics and oscillations.

In this paper, we investigate the interval of the existence of (strictly) positive solutions, i.e. we determine real positive τ for which at least one positive solution exists, for the following system of nonlinear second-order differential equations

$$x_i''(t) + f_i(t, x_1(t), x_2(t), x_3(t)) = 0, \quad t \in (0, \tau),\ i = 1, 2, 3, \tag{1.1}$$

coupled with nonlocal boundary conditions

$$x_i(0) = \varphi_i[x_i] + a_i, \quad x_i(\tau) = \psi_i[x_i] + b_i, \tag{1.2}$$

✉ Corresponding author. Email: aleksey.antonyuk1@gmail.com

where $a_i, b_i \geq 0$, $f_i : [0,\tau] \times [0,+\infty)^3 \to [0,+\infty)$ are continuous, $\varphi_i[x] = \int_0^\tau x(t)\mathrm{d}\Phi_i(t)$ and $\psi_i[x] = \int_0^\tau x(t)\mathrm{d}\Psi_i(t)$ are linear functionals defined via Riemann–Stieltjes integrals, where $\Phi_i, \Psi_i : [0,\tau] \to \mathbb{R}$ are functions of bounded variation.

We write $\varphi_i[\mathrm{Id}]$ and $\varphi_i[\tau]$ to denote φ_i applied to the identity function and constant function with value τ, respectively. The notation $|A|$ denotes the determinant of a square matrix A. Throughout the paper, we assume that

(A1) $0 \leq \varphi_i[\mathrm{Id}]$, $0 \leq \varphi_i[\tau - \mathrm{Id}] \leq \tau$ and $0 \leq \psi_i[\tau - \mathrm{Id}]$, $0 \leq \psi_i[\mathrm{Id}] \leq \tau$,

(A2) $0 < D_i = \begin{vmatrix} \tau - \varphi_i[\tau - \mathrm{Id}] & -\varphi_i[\mathrm{Id}] \\ -\psi_i[\tau - \mathrm{Id}] & \tau - \psi_i[\mathrm{Id}] \end{vmatrix}$,

are valid for every $i = 1,2,3$.

By a positive solution of problem (1.1), (1.2) we understand $(x_1, x_2, x_3) \in \left(C^2[0,\tau]\right)^3$, which satisfies system of differential equations (1.1), boundary conditions (1.2) and positive *coexistence* condition, i.e. $x_i(t) > 0$ for all $t \in (0,\tau)$ and every $i = 1,2,3$.

We do not assume $\varphi_i[x_i] \geq 0$ and $\psi_i[x_i] \geq 0$ for all $x_i \geq 0$, but we allow $\mathrm{d}\Phi_i$ and $\mathrm{d}\Psi_i$ to be signed measures. For details on signed measure and Riemann–Stieltjes integrals we refer reader, for instance, to [17–19]. But we require $\varphi_i[x_i] \geq 0$ and $\psi_i[x_i] \geq 0$ for corresponding component of the positive solution (x_1, x_2, x_3).

The term "coexistence" was introduced by Lan [11] in context of fixed points in product Banach spaces. Coexistence fixed point denotes a fixed point with all the components different from zero. The common approach to obtain solutions of operator equation is to seek the fixed points. The best-known fixed point theorems for positive solutions are Krasnosel'skiĭ's fixed point theorem in cones [10] and its generalizations, for instance, Krasnosel'skiĭ–Benjamin fixed point theorem [1], where conditions are weakened, and Guo–Krasnosel'skiĭ fixed point theorem [3], where considered region is more general. But, as it was mentioned in [12,13,15], these theorems cannot guarantee the coexistence fixed point. Motivated by this, Precup [12, 13] established (2-dimensional) vector version of Krasnosel'skiĭ's fixed point theorem, which allows to localize fixed point in the component-wise manner. Recently, Rodríguez-López [15] showed an alternative proof via fixed point index theory. As it was pointed out in [15], the result by Precup remains valid for n-dimensions. For multiplicity result of positive solutions by vector version of Krasnosel'skiĭ's fixed point theorem we refer reader to [8,14].

Generalized version of problem (1.1), (1.2) with $\tau = 1$ and $i = 1,2$, was studied by Henderson and Luca [5,6]. In [5] was considered problem (in our notations)

$$(a_i(t)x_i(t)')' - b_i(t)x_i(t) + \lambda_i p_i(t) f_i(t, x_1(t), x_2(t)) = 0, \quad t \in (0,1),\ i = 1,2, \tag{1.3}$$

$$\alpha_i x_i(0) - \beta_i a(0)x_i'(0) = \varphi_i[x_i], \quad \gamma_i x_i(1) + \delta_i a(1)x_i'(1) = \psi_i[x_i], \tag{1.4}$$

and sufficient conditions on λ_i and f_i were given such that non-negative solutions of problem (1.3), (1.4) exist. The result was based on Guo–Krasnosel'ski fixed point theorem. In [6] by applying fixed point index theory results on existence and multiplicity of positive solutions were obtained for the slightly modified problem (1.3), (1.4): the functions f_i depended on only one unknown $x_{j\neq i}$, i.e. $f_i(t, x_{j\neq i}(t))$.

In this paper, we apply two methods that allow us to obtain an interval of the existence of positive solutions for the problem (1.1), (1.2). First we find τ by solving system of inequalities, which is based on Green's functions of problem (1.1), (1.2) and behavior of functions f_i. To prove that for these τ there exist positive solutions we apply vector version of Krasnosel'skiĭ's fixed point theorem, or Krasnosel'skiĭ–Precup fixed point theorem. Let us recall this result here. A nonempty closed convex subset $K \subset X$ of normed space $(X, \|\cdot\|)$ is called a cone if $\lambda x \in K$ for every $x \in K$ and for all $\lambda \geq 0$, and $K \cap (-K) = 0$.

Theorem 1.1 (Krasnosel'skiĭ–Precup, [12,15]). *Let $(X, \|\cdot\|)$ be a normed space, $K_1, \ldots, K_n$ cones in X, $K = K_1 \times \cdots \times K_n$, $r = (r_1, \ldots, r_n)$, $R = (R_1, \ldots, R_n)$, with $0 < r_i < R_i$ for $i \in \{1, \ldots, n\}$, and*

$$\overline{K}_{r,R} = \{x = (x_1, \ldots, x_n) \in K : \forall\, i \in \{1, \ldots, n\} \quad r_i \leq \|x_i\| \leq R_i\}.$$

Assume that $T = (T_1, .., T_n) : \overline{K}_{r,R} \to K$ is a completely continuous map and for each $i \in \{1, .., n\}$ there exists $\mathrm{h}_i \in K_i \setminus \{0\}$ such that one of the following conditions is satisfied in $\overline{K}_{r,R}$:

(i) $T_i x + \mu \mathrm{h}_i \neq x_i$ *if* $\|x_i\| = r_i$ *and* $\mu > 0$, *and* $T_i x \neq \lambda x_i$ *if* $\|x_i\| = R_i$ *and* $\lambda > 1$;

(ii) $T_i x \neq \lambda x_i$ *if* $\|x_i\| = r_i$ *and* $\lambda > 1$, *and* $T_i x + \mu \mathrm{h}_i \neq x_i$ *if* $\|x_i\| = R_i$ *and* $\mu > 0$.

Then T has at least one fixed point $x \in K$ with $r_i \leq \|x_i\| \leq R_i$, $i \in \{1, \ldots, n\}$.

Conditions (i) and (ii) are called compression type and expansion type condition, respectively.

To satisfy compression and expansion type conditions various authors considered asymptotic behavior of f/x at zero and infinity. This approach is widely used in case of one differential equation or systems in which all f_i depend on only one unknown $x_{j \neq i}$ (see, for instance, [2,6,7,9,18,19]). The idea is to use limits

$$\lim_{x \to 0} \sup_t \frac{f(t,x)}{x}, \qquad \lim_{x \to \infty} \sup_t \frac{f(t,x)}{x}$$
$$\lim_{x \to 0} \inf_t \frac{f(t,x)}{x}, \qquad \lim_{x \to \infty} \inf_t \frac{f(t,x)}{x}.$$

In [9] the case where the above limits were zero or infinity was studied. In [2,7] the limits were allowed to be small or large enough, in a sense that necessary inequalities hold. In the case of systems of differential equations in which f_i depend on all unknowns many authors require additional assumptions on f_i to construct similar limits. For instance, f_i is monotone with respect to x_j, see [12,13], or bounded with respect to x_j, see [4].

If we let $\varphi_i \equiv 0$ and $\psi_i \equiv 0$, then boundary conditions (1.2) become Dirichlet boundary conditions. For such problem we compare the theoretical result with the result based on built-in functions of program *Mathematica* [20]. The numerical result is obtained by shooting method: we consider the initial value problem for system of differential equations and determine τ.

The outline of the rest of the paper is as follows. In Section 2, we rewrite boundary value problem (1.1), (1.2) as an equivalent system of integral equations by constructing the Greens functions and show the estimations of Greens functions. We prove the existence of positive solutions by applying Krasnosel'skiĭ–Precup fixed point theorem in Section 3 and formulate main result of this article in Theorem 3.7. Finally, in Section 4, we compare theoretical and numerical results for problem (1.1) with the boundary conditions $x_i(0) = a_i$, $x_i(\tau) = b_i$.

2 Construction and estimation of Green's functions

Standard approach is to rewrite problem (1.1), (1.2) as an equivalent system of integral equations via corresponding Green's functions. Results of this section are well-known and for details we refer reader to [16,18,19].

The Green's function G_0 corresponding to problem $x''(t)+h(t)=0$, $x(1)=0=x(\tau)$, is given by

$$G_0(t,s)=\frac{1}{\tau}\begin{cases} s(\tau-t), & 0\le s\le t\le\tau,\\ t(\tau-s), & 0\le t\le s\le\tau.\end{cases} \tag{2.1}$$

We denote $\mathcal{G}_{\varphi_i}(s)=\int_0^\tau G_0(t,s)\mathrm{d}\Phi_i(t)$, $\mathcal{G}_{\psi_i}(s)=\int_0^\tau G_0(t,s)\mathrm{d}\Psi_i(t)$ and in addition to (A1) and (A2) we assume

(A3) $\mathcal{G}_{\varphi_i}(s)\ge 0$ and $\mathcal{G}_{\psi_i}(s)\ge 0$ for all $s\in[0,\tau]$ and every $i=1,2,3$.

Recall that D_i is given by (A2) and $|A|$ denotes the determinant of a square matrix A.

Proposition 2.1. *A triple (x_1,x_2,x_3) is a solution of boundary value problem (1.1), (1.2) if and only if (x_1,x_2,x_3) is a solution of the system of integral equations*

$$x_i(t)=\int_0^\tau G_i(t,s)f_i(s,x_1(s),x_2(s),x_3(s))\mathrm{d}s+g_i(t),\quad t\in[0,\tau],\ i=1,2,3, \tag{2.2}$$

where

$$G_i(t,s)=\frac{1}{D_i}\begin{vmatrix}\tau-t & \tau-\varphi_i[\tau-\mathrm{Id}] & -\psi_i[\tau-\mathrm{Id}]\\ t & -\varphi_i[\mathrm{Id}] & \tau-\psi_i[\mathrm{Id}]\\ G_0(t,s) & -\mathcal{G}_{\varphi_i}(s) & -\mathcal{G}_{\psi_i}(s)\end{vmatrix} \tag{2.3}$$

and

$$g_i(t)=\frac{1}{D_i}\begin{vmatrix}\tau-t & \tau-\varphi_i[\tau-\mathrm{Id}] & -\psi_i[\tau-\mathrm{Id}]\\ t & -\varphi_i[\mathrm{Id}] & \tau-\psi_i[\mathrm{Id}]\\ 0 & -a_i & -b_i\end{vmatrix}. \tag{2.4}$$

Proof. Let (x_1,x_2,x_3) be a solution of boundary value problem (1.1), (1.2). For every $i=1,2,3$, integrating (1.1) twice from 0 to t and applying boundary conditions (1.2), we get

$$x_i(t)=\int_0^\tau G_0(t,s)f_i(s,x_1(s),x_2(s),x_3(s))\mathrm{d}s+\frac{t}{\tau}(b_i+\psi_i[x_i])+\frac{\tau-t}{\tau}(a_i+\varphi_i[x_i]). \tag{2.5}$$

Let us denote $(Fx_i)(t)=\int_0^\tau G_0(t,s)f_i(s,x_1(s),x_2(s),x_3(s))\mathrm{d}s$. Applying φ_i and ψ_i to (2.5), we get

$$\begin{aligned}\varphi_i[x_i](\tau-\varphi_i[\tau-\mathrm{Id}])-\varphi_i[\mathrm{Id}]\psi_i[x_i]&=\tau\,\varphi_i[Fx_i]+b_i\varphi_i[\mathrm{Id}]+a_i\varphi_i[\tau-\mathrm{Id}],\\ \psi_i[x_i](\tau-\psi_i[\mathrm{Id}])-\psi_i[\tau-\mathrm{Id}]\varphi_i[x_i]&=\tau\,\psi_i[Fx_i]+b_i\psi_i[\mathrm{Id}]+a_i\psi_i[\tau-\mathrm{Id}].\end{aligned} \tag{2.6}$$

We rewrite (2.6) in matrix form

$$\begin{pmatrix}\tau-\varphi_i[\tau-\mathrm{Id}] & -\varphi_i[\mathrm{Id}]\\ -\psi_i[\tau-\mathrm{Id}] & \tau-\psi_i[\mathrm{Id}]\end{pmatrix}\begin{pmatrix}\varphi_i[x_i]\\ \psi_i[x_i]\end{pmatrix}=\begin{pmatrix}\tau\,\varphi_i[Fx_i]\\ \tau\,\psi_i[Fx_i]\end{pmatrix}+\begin{pmatrix}\varphi_i[\tau-\mathrm{Id}] & \varphi_i[\mathrm{Id}]\\ \psi_i[\tau-\mathrm{Id}] & \psi_i[\mathrm{Id}]\end{pmatrix}\begin{pmatrix}a_i\\ b_i\end{pmatrix}.$$

By assumption (A2), $D_i>0$ and it follows

$$\begin{aligned}\begin{pmatrix}\varphi_i[x_i]\\ \psi_i[x_i]\end{pmatrix}&=\frac{1}{D_i}\begin{pmatrix}\tau-\psi_i[\mathrm{Id}] & \varphi_i[\mathrm{Id}]\\ \psi_i[\tau-\mathrm{Id}] & \tau-\varphi_i[\tau-\mathrm{Id}]\end{pmatrix}\begin{pmatrix}\tau\,\varphi_i[Fx_i]\\ \tau\,\psi_i[Fx_i]\end{pmatrix}\\ &+\frac{1}{D_i}\begin{pmatrix}\tau-\psi_i[\mathrm{Id}] & \varphi_i[\mathrm{Id}]\\ \psi_i[\tau-\mathrm{Id}] & \tau-\varphi_i[\tau-\mathrm{Id}]\end{pmatrix}\begin{pmatrix}\varphi_i[\tau-\mathrm{Id}] & \varphi_i[\mathrm{Id}]\\ \psi_i[\tau-\mathrm{Id}] & \psi_i[\mathrm{Id}]\end{pmatrix}\begin{pmatrix}a_i\\ b_i\end{pmatrix}.\end{aligned} \tag{2.7}$$

Substituting $\varphi_i[x_i]$ and $\psi_i[x_i]$ from (2.7) in (2.5), we get

$$\begin{aligned} x_i(t) &= (Fx_i)(t) - \frac{t}{D_i}\begin{vmatrix} \tau-\varphi_i[\tau-\mathrm{Id}] & -\psi_i[\tau-\mathrm{Id}] \\ -\varphi_i[Fx_i] & -\psi_i[Fx_i] \end{vmatrix} + \frac{\tau-t}{D_i}\begin{vmatrix} -\varphi_i[\mathrm{Id}] & \tau-\psi_i[\mathrm{Id}] \\ -\varphi_i[Fx_i] & -\psi_i[Fx_i] \end{vmatrix} \\ &\quad - \frac{t}{D_i}\begin{vmatrix} \tau-\varphi_i[\tau-\mathrm{Id}] & -\psi_i[\tau-\mathrm{Id}] \\ -a_i & -b_i \end{vmatrix} + \frac{\tau-t}{D_i}\begin{vmatrix} -\varphi_i[\mathrm{Id}] & \tau-\psi_i[\mathrm{Id}] \\ -a_i & -b_i \end{vmatrix} \\ &= \frac{1}{D_i}\begin{vmatrix} \tau-t & \tau-\varphi_i[\tau-\mathrm{Id}] & -\psi_i[\tau-\mathrm{Id}] \\ t & -\varphi_i[\mathrm{Id}] & \tau-\psi_i[\mathrm{Id}] \\ (Fx_i)(t) & -\varphi_i[Fx_i] & -\psi_i[Fx_i] \end{vmatrix} + \frac{1}{D_i}\begin{vmatrix} \tau-t & \tau-\varphi_i[\tau-\mathrm{Id}] & -\psi_i[\tau-\mathrm{Id}] \\ t & -\varphi_i[\mathrm{Id}] & \tau-\psi_i[\mathrm{Id}] \\ 0 & -a_i & -b_i \end{vmatrix} \\ &= \int_0^\tau G_i(t,s) f_i(s, x_1(s), x_2(s), x_3(s))\mathrm{d}s + g_i(t), \end{aligned}$$

where G_i is given by (2.3) and g_i is given by (2.4).

Now, let (x_1, x_2, x_3) satisfy system of integral equations (2.2). It follows that each x_i also satisfies (2.5). By differentiating (2.5) twice, it is easy to see that (x_1, x_2, x_3) satisfies (1.1), (1.2) and $(x_1, x_2, x_3) \in \left(C^2[0,\tau]\right)^3$. □

Remark 2.2. Note that $G_i \geq 0$ and $g_i \geq 0$ for every $i = 1, 2, 3$. Indeed, expansion of (2.3) and (2.4) along the first column is

$$\begin{aligned} G_i(t,s) &= \frac{\tau-t}{D_i}\begin{vmatrix} -\varphi_i[\mathrm{Id}] & \tau-\psi_i[\mathrm{Id}] \\ -\mathcal{G}_{\varphi_i}(s) & -\mathcal{G}_{\varphi_i}(s) \end{vmatrix} - \frac{t}{D_i}\begin{vmatrix} \tau-\varphi_i[\tau-\mathrm{Id}] & -\psi_i[\tau-\mathrm{Id}] \\ -\mathcal{G}_{\varphi_i}(s) & -\mathcal{G}_{\varphi_i}(s) \end{vmatrix} + G_0(t,s) \\ &= \frac{\tau-t}{D_i}\begin{vmatrix} \varphi_i[\mathrm{Id}] & \tau-\psi_i[\mathrm{Id}] \\ -\mathcal{G}_{\varphi_i}(s) & \mathcal{G}_{\varphi_i}(s) \end{vmatrix} + \frac{t}{D_i}\begin{vmatrix} \tau-\varphi_i[\tau-\mathrm{Id}] & \psi_i[\tau-\mathrm{Id}] \\ -\mathcal{G}_{\varphi_i}(s) & \mathcal{G}_{\varphi_i}(s) \end{vmatrix} + G_0(t,s) \end{aligned} \tag{2.8}$$

and

$$\begin{aligned} g_i(t) &= \frac{\tau-t}{D_i}\begin{vmatrix} -\varphi_i[\mathrm{Id}] & \tau-\psi_i[\mathrm{Id}] \\ -a_i & -b_i \end{vmatrix} - \frac{t}{D_i}\begin{vmatrix} \tau-\varphi_i[\tau-\mathrm{Id}] & -\psi_i[\tau-\mathrm{Id}] \\ -a_i & -b_i \end{vmatrix} \\ &= \frac{\tau-t}{D_i}\begin{vmatrix} \varphi_i[\mathrm{Id}] & \tau-\psi_i[\mathrm{Id}] \\ -a_i & b_i \end{vmatrix} + \frac{t}{D_i}\begin{vmatrix} \tau-\varphi_i[\tau-\mathrm{Id}] & \psi_i[\tau-\mathrm{Id}] \\ -a_i & b_i \end{vmatrix}. \end{aligned} \tag{2.9}$$

By assumptions (A1)–(A3), and $a_i, b_i \geq 0$, and fact that G_0, given by (2.1), is non-negative, determinants in last parts of (2.8) and (2.9) are non-negative for all $(t,s) \in [0,\tau] \times [0,\tau]$ and $t \in [0,\tau]$, respectively.

Let $m(t) = \min\{t/\tau,\ 1 - t/\tau\}$. It is known that Green's function G_0 satisfies

$$m(t)G_0(s,s) \leq G_0(t,s) \leq G_0(s,s), \quad (t,s) \in [0,\tau] \times [0,\tau].$$

Proposition 2.3. *Green's function G_i, given by (2.3), satisfies*

$$m(t)H_i(s) \leq G_i(t,s) \leq H_i(s), \quad (t,s) \in [0,\tau] \times [0,\tau],$$

where

$$H_i(s) = \frac{1}{D_i}\begin{vmatrix} \tau & \tau-\varphi_i[\tau-\mathrm{Id}] & -\psi_i[\tau-\mathrm{Id}] \\ \tau & -\varphi_i[\mathrm{Id}] & \tau-\psi_i[\mathrm{Id}] \\ G_0(s,s) & -\mathcal{G}_{\varphi_i}(s) & -\mathcal{G}_{\psi_i}(s) \end{vmatrix}.$$

Proof. Expansion of $G_i(t,s)$ along the first column is given by (2.8). We replace $\tau - t$ with τ in first determinant, t with τ in second determinant, $G_0(t,s)$ with $G_0(s,s)$ in third determinant and get $H_i(s)$. Therefore, $H_i \geq 0$ by the same argument as $G_i \geq 0$.

We get inequality $G_i(t,s) \leq H_i(s)$ by estimating $\tau - t \leq \tau$, $t \leq \tau$ and $G_0(t,s) \leq G_0(s,s)$.

It is clear that $1 - t/\tau \geq m(t)$ and $t/\tau \geq m(t)$ for all $t \in [0,\tau]$. We get inequality $G_i(t,s) \geq m(t)H_i(s)$ by estimating $\tau - t \geq m(t)\tau$, $t \geq m(t)\tau$ and $G_0(t,s) \geq m(t)G_0(s,s)$. □

Observe that if $a_i = b_i = 0$, then $g_i \equiv 0$. By (2.9), it is easy to see that $g_i(t)$ is a polynomial with degree at most one. Hence g_i is concave. Concavity of g_i implies

$$g_i(t) \geq m(t)\, g_i(t_0), \quad (t,t_0) \in [0,\tau] \times [0,\tau]. \tag{2.10}$$

For every $c \in (0,\tau/2)$ inequality $\tau c \leq m(t)$ holds for $t \in [c,\tau - c]$. As it was mentioned in [18, 19], for Green's function G_0 optimal constant is $c = \tau/4$. Optimal in a sense that $\inf\{\int_c^{\tau-c} G_0(t,s)\mathrm{d}s : t \in [c,\tau-c]\}$ is maximal.

3 Theoretical result on the existence of a positive solution

Consider Banach space $C[0,\tau]$ endowed with the norm $\|x\| = \max\{|x(t)| : t \in [0,\tau]\}$. We define cone k_i by

$$k_i = \left\{ u \in C[0,\tau] : u(t) \geq 0 \text{ for } t \in [0,\tau],\ \min_{t\in[\tau/4,3\tau/4]} u(t) \geq \frac{1}{4}\|u\|,\ \varphi_i[u] \geq 0,\ \psi_i[u] \geq 0 \right\}.$$

Let $K = k_1 \times k_2 \times k_3$, $x = (x_1,x_2,x_3)$ and $T = (T_1,T_2,T_3) : K \to (C[0,\tau])^3$ be an operator defined by

$$(T_i x)(t) = \int_0^\tau G_i(t,s) f_i(s,x_1(s),x_2(s),x_3(s))\mathrm{d}s + g_i(t), \tag{3.1}$$

where G_i is given by (2.3) and g_i is given by (2.4).

Observe that T is a completely continuous operator. Indeed, g_i is obviously completely continuous and $T_i x - g_i$ is completely continuous by application of Arzelà–Ascoli theorem. Boundary value problem (1.1), (1.2) has a non-negative solution if and only if operator T has a fixed point in K. To prove that maximal value of each x_i is positive, and hence the solution is positive, we apply Krasnosel'skiĭ–Precup fixed point theorem (Theorem 1.1). Now, we show that T maps K into itself.

Proposition 3.1. *Operator T, given by (3.1), satisfies $T(K) \subset K$.*

Proof. It is obvious that $T_i x \geq 0$ for each $i = 1,2,3$.

Let $T_i x$ achieve maximum value at point t_0, i.e. $(T_i x)(t_0) = \|T_i x\|$. By Proposition 2.3 and (2.10), for every $t \in [\tau/4, 3\tau/4]$ we have

$$\begin{aligned}
(T_i x)(t) &= \int_0^\tau G_i(t,s) f_i(s,x_1(s),x_2(s),x_3(s))\mathrm{d}s + g_i(t) \\
&\geq m(t) \int_0^\tau H_i(s) f_i(s,x_1(s),x_2(s),x_3(s))\mathrm{d}s + m(t) g_i(t_0) \\
&\geq \frac{1}{4}\Big(\int_0^\tau G_i(t_0,s) f_i(s,x_1(s),x_2(s),x_3(s))\mathrm{d}s + g_i(t_0) \Big) \\
&= \frac{1}{4}\|T_i x\|.
\end{aligned}$$

Next, consider

$$\varphi_i[Tx_i] = \int_0^\tau \left(\int_0^\tau G_i(t,s) \mathrm{d}\Phi_i(t) \right) f_i(s, x_1(s), x_2(s), x_3(s)) \mathrm{d}s + \varphi_i[g_i].$$

By (A1)–(A3), we get $\int_0^\tau G_i(t,s)\mathrm{d}\Phi_i(t) \geq 0$ and $\varphi_i[g_i] \geq 0$. Hence $\varphi_i[Tx_i] \geq 0$. Similarly $\psi_i[Tx_i] \geq 0$. Therefore, $T(K) \subset K$. □

Now, we briefly describe the main result. First, we show that if certain conditions on f_i hold, then T_i satisfies compression type condition (i) or expansion type condition (ii) of Krasnosel'skiĭ–Precup fixed point theorem (Theorem 1.1). Then we choose r and R such that each T_i satisfies either condition (i) or (ii) for all $x \in \overline{K}_{r,R}$. Finally, we conclude that at least one positive solution of problem (1.1), (1.2) exists.

Let us introduce notations

$$A_i = \inf_{t \in [\tau/4, 3\tau/4]} \int_{\tau/4}^{3\tau/4} G_i(t,s) \mathrm{d}s, \quad B_i = \sup_{t \in [0,\tau]} \int_0^\tau G_i(t,s) \mathrm{d}s.$$

To prove the following Lemma 3.2 (and Proposition 3.6) we use standard techniques. See, for instance, [2,7,9,18,19].

Lemma 3.2. *Operator T_i satisfies compression type condition (i) if there exist constants $0 < q < Q$ such that*

$$q < \min_{\substack{t \in [\tau/4, 3\tau/4] \\ x_i \in [q/4, q] \\ x_{j \neq i} \in [q/4, Q]^2}} f_i(t,x) \cdot A_i \quad \text{and} \quad \max_{\substack{t \in [0,\tau] \\ x \in [0,Q]^3}} f_i(t,x) \cdot B_i + \|g_i\| < Q, \tag{3.2}$$

and T_i satisfies expansion type condition (ii) if there exist constants $0 < q < Q$ such that

$$Q < \min_{\substack{t \in [\tau/4, 3\tau/4] \\ x_i \in [Q/4, Q] \\ x_{j \neq i} \in [q/4, Q]^2}} f_i(t,x) \cdot A_i \quad \text{and} \quad \max_{\substack{t \in [0,\tau] \\ x_i \in [0,q] \\ x_{j \neq i} \in [0,Q]^2}} f_i(t,x) \cdot B_i + \|g_i\| < q. \tag{3.3}$$

Proof. Let $\overline{K}_{q,Q} = \{x \in K : q \leq \|x_i\| \leq Q,\ i = 1,2,3\}$. We show a proof for compression type condition. Proof for expansion type condition is similar.

Let $\|x_i\| = Q$ and $\Omega = [0,\tau] \times [0,Q]^3$. We show that $\|T_i x\| \leq \|x_i\|$. It is known that this implies $T_i x \neq \lambda x_i$ for $\lambda > 1$. Consider

$$\begin{aligned}
\|T_i x\| &\leq \max_{t \in [0,\tau]} \int_0^\tau G_i(t,s) f_i(s, x_1(s), x_2(s), x_3(s)) \mathrm{d}s + \|g_i\| \\
&\leq \max_{(t,x) \in \Omega} f_i(t,x) \cdot B_i + \|g_i\| < Q = \|x_i\|.
\end{aligned}$$

Now, suppose to contrary that there exists x_i with $\|x_i\| = q$ such that $T_i x + \mu \mathrm{h} = x_i$ for $\mu > 0$ and $\mathrm{h} : t \mapsto 1$. Since $x \in \overline{K}_{q,Q}$, we have

$$x_j(t) \geq \frac{1}{4} \|x_j\| \geq \frac{1}{4} q, \quad t \in [\tau/4, 3\tau/4],\ j = 1,2,3.$$

Let $\omega = [\tau/4, 3\tau/4] \times [q/4, q] \times [q/4, Q]^2$. We get

$$\begin{aligned} x_i(t) &= \int_0^\tau G_i(t,s) f_i(s, x_1(s), x_2(s), x_3(s)) \mathrm{d}s + g_i(t) + \mu \\ &\geq \int_{\tau/4}^{3\tau/4} G_i(t,s) f_i(s, x_1(s), x_2(s), x_3(s)) \mathrm{d}s + g_i(t) + \mu \\ &\geq \min_{(t, x_i, x_{j\neq i}) \in \omega} f_i(t,x) \cdot A_i + g_i(t) + \mu \\ &> q + g_i(t) + \mu, \end{aligned}$$

which gives contradiction. □

Let us show examples of f_i, $i = 1,2,3$, that satisfy (3.2) and (3.3) for sufficiently small q and sufficiently large Q, i.e. there exist $q_i < Q_i$ such that f_i satisfies (3.2) or (3.3) for $0 < q \leq q_i$ and $Q_i \leq Q < +\infty$. The ability to choose such q and Q is used to define proper $\overline{K}_{r,R}$ in the proof of the main result.

Let us define

$$u_{ij}^w = \begin{cases} u, & i = j, \\ w, & i \neq j. \end{cases}$$

We use notation u_{ij}^w to denote that i-th element of a triple $(u_{i1}^w, u_{i2}^w, u_{i3}^w)$ is u and j-th element $(j \neq i)$ is w, e.g. $(u_{11}^w, u_{12}^w, u_{13}^w) = (u, w, w)$ and $(u_{21}^0, u_{22}^0, u_{23}^0) = (0, u, 0)$.

Example 3.3. Let f_i be non-decreasing with respect to all x_i, $i = 1,2,3$. Function f_i satisfies (3.2) for sufficiently small q and sufficiently large Q if

$$1 < \lim_{u \to 0+} \inf_{t \in [\tau/4, 3\tau/4]} \frac{f_i(t,u,u,u)}{u} \cdot \frac{A_i}{4}, \qquad \lim_{u \to +\infty} \sup_{t \in [0,\tau]} \frac{f_i(t,u,u,u)}{u} \cdot B_i < 1,$$

and satisfies (3.3) for sufficiently small q and sufficiently large Q if $a_i = b_i = 0$ and

$$\begin{aligned} \forall w \in [0, +\infty) \ \lim_{u \to 0+} \sup_{t \in [0,\tau]} \frac{f_i(t, u_{i1}^w, u_{i2}^w, u_{i3}^w)}{u} = 0, \\ 1 < \lim_{u \to +\infty} \inf_{t \in [\tau/4, 3\tau/4]} \frac{f_i(t, u_{i1}^0, u_{i2}^0, u_{i3}^0)}{u} \cdot \frac{A_i}{4}. \end{aligned} \tag{3.4}$$

For proof see Proposition 3.6.

Example 3.4. Let f_i be bounded with respect to x_i and non-decreasing with respect to every $x_{j\neq i}$, $j = 1,2,3$. Function f_i satisfies (3.2) for sufficiently small q and sufficiently large Q if

$$1 < \lim_{w \to 0+} \inf_{\substack{t \in [\tau/4, 3\tau/4] \\ u \in [0,+\infty)}} \frac{f_i(t, u_{i1}^w, u_{i2}^w, u_{i3}^w)}{w} \cdot \frac{A_i}{4}, \qquad \lim_{w \to +\infty} \sup_{\substack{t \in [0,\tau] \\ u \in [0,+\infty)}} \frac{f_i(t, u_{i1}^w, u_{i2}^w, u_{i3}^w)}{w} \cdot B_i < 1,$$

and satisfies (3.3) for sufficiently small q and sufficiently large Q if $a_i = b_i = 0$ and (3.4).

Example 3.5. Let f_i be bounded with respect to every $x_{j\neq i}$, $j = 1,2,3$. Function f_i satisfies (3.2) for sufficiently small q and sufficiently large Q if

$$1 < \lim_{x_i \to 0+} \inf_{\substack{t \in [\tau/4, 3\tau/4] \\ x_{j\neq i} \in [0,+\infty)^2}} \frac{f_i(t, x_1, x_2, x_3)}{x_i} \cdot \frac{A_i}{4}, \quad \lim_{x_i \to +\infty} \sup_{\substack{t \in [0,\tau] \\ x_{j\neq i} \in [0,+\infty)^2}} \frac{f_i(t, x_1, x_2, x_3)}{x_i} \cdot B_i < 1,$$

and satisfies (3.3) for sufficiently small q and sufficiently large Q if $a_i = b_i = 0$ and

$$\lim_{x_i \to 0+} \sup_{\substack{t\in[0,\tau] \\ x_{j\neq i}\in[0,+\infty)^2}} \frac{f_i(t,x_1,x_2,x_3)}{x_i} \cdot B_i < 1, \quad 1 < \lim_{x_i\to+\infty} \inf_{\substack{t\in[\tau/4,3\tau/4] \\ x_{j\neq i}\in[0,+\infty)^2}} \frac{f_i(t,x_1,x_2,x_3)}{x_i} \cdot \frac{A_i}{4}.$$

Proposition 3.6. *Function f_i from Example 3.3 satisfies inequalities* (3.2) *and* (3.3) *for sufficiently small q and sufficiently large Q.*

Proof. First, we show that f_i satisfies (3.2). Let us denote

$$\underline{f_0} = \lim_{u\to 0+} \inf_{t\in[\tau/4,3\tau/4]} \frac{f_i(t,u,u,u)}{u}, \quad \overline{f_\infty} = \lim_{u\to+\infty} \sup_{t\in[0,\tau]} \frac{f_i(t,u,u,u)}{u}.$$

Choose $\varepsilon > 0$ and $\delta > 0$ such that

$$1 < (\underline{f_0} - \varepsilon)A_i/4 \quad \text{and} \quad (\overline{f_\infty} + \delta)B_i < 1.$$

Then there exist positive constants r and p such that

$$\begin{aligned} f_i(t,u,u,u) &\geq (\underline{f_0} - \varepsilon)u, \quad (t,u) \in [\tau/4, 3\tau/4] \times (0,r], \\ f_i(t,u,u,u) &\leq (\overline{f_\infty} + \delta)u, \quad (t,u) \in [0,\tau] \times [p,+\infty). \end{aligned}$$

We denote $M = \max\{f_i(t,u,u,u) : t \in [0,\tau],\ u \in [0,p]\}$. Then

$$f_i(t,u,u,u) \leq M + (\overline{f_\infty} + \delta)u, \quad (t,u) \in [0,\tau] \times [0,+\infty).$$

We choose $q \in (0,r]$, define

$$Q = \frac{B_iM + \|g_i\|}{1 - B_i(\overline{f_\infty} + \delta)} + q$$

and let $\overline{K}_{q,Q} = \{x \in K : q \leq \|x_i\| \leq Q,\ i = 1,2,3\}$. Observe that

$$\begin{aligned} \max_{\substack{t\in[0,\tau] \\ x\in[0,Q]^3}} f_i(t,x) \cdot B_i + \|g_i\| &\leq \max_{t\in[0,\tau]} f_i(t,Q,Q,Q) \cdot B_i + \|g_i\| \leq B_iM + B_i(\overline{f_\infty} + \delta)Q + \|g_i\| \\ &= (B_iM + \|g_i\|) + \frac{(B_iM + \|g_i\|)B_i(\overline{f_i^\infty} + \delta)}{1 - B_i(\overline{f_\infty} + \delta)} + q\,B_i(\overline{f_\infty} + \delta) \\ &= \frac{B_iM + \|g_i\|}{1 - B_i(\overline{f_\infty} + \delta)} + q\,B_i(\overline{f_\infty} + \delta) < Q \end{aligned}$$

and

$$\min_{\substack{t\in[\tau/4,3\tau/4] \\ x_i\in[q/4,q] \\ x_{j\neq i}\in[q/4,Q]^2}} f_i(t,x) \cdot A_i \geq \min_{t\in[\tau/4,3\tau/4]} f_i(t,q/4,q/4,q/4) \cdot A_i \geq A_i(\underline{f_0} - \varepsilon)q/4 > q.$$

Now, we show that f_i satisfies (3.3). Recall that $a_i = b_i = 0$ implies $\|g_i\| = 0$. Let us denote

$$\underline{f_\infty} = \lim_{u\to+\infty} \inf_{t\in[\tau/4,3\tau/4]} \frac{f_i(t,u_{i1}^0,u_{i2}^0,u_{i3}^0)}{u}.$$

Choose $\varepsilon > 0$ such that $(\overline{f_\infty} - \varepsilon)A_i/4 > 1$. Then there exist positive constants r and p such that

$$f_i(t, u_{i1}^w, u_{i2}^w, u_{i3}^w) \leq B_i^{-1}u, \quad (t,u,w) \in [0,\tau] \times (0,r] \times [0,+\infty)^2,$$
$$f_i(t, u_{i1}^0, u_{i2}^0, u_{i3}^0) \geq (\underline{f_\infty} - \varepsilon)u, \quad (t,u) \in [\tau/4, 3\tau/4] \times [p,+\infty),$$

We choose $q \in (0,r]$, $Q \in [4p+q, +\infty)$ and let $\overline{K}_{q,Q} = \{x \in K : q \leq \|x_i\| \leq Q,\ i = 1,2,3\}$. Observe that

$$\max_{\substack{t\in[0,\tau] \\ x_i \in [0,q] \\ x_{j\neq i}\in[0,Q]^2}} f_i(t,x) \cdot B_i \leq \max_{t\in[0,\tau]} f_i(t, q_{i1}^Q, q_{i2}^Q, q_{i3}^Q) \cdot B_i < q$$

and

$$\min_{\substack{t\in[\tau/4,3\tau/4] \\ x_i\in[Q/4,Q] \\ x_{j\neq i}\in[q/4,Q]^2}} f_i(t,x) \cdot A_i \geq \min_{t\in[\tau/4,3\tau/4]} f_i\Big(t, (Q/4)_{i1}^0, (Q/4)_{i2}^0, (Q/4)_{i3}^0\Big) \cdot A_i \geq (\underline{f_\infty} - \varepsilon)A_i Q/4 > Q.$$

Finally, note that constants q and Q could be chosen as small and as large as desired, respectively. □

The main result of this paper is following.

Theorem 3.7. *If for every f_i, $i = 1,2,3$, exist $q_i < Q_i$ such that f_i satisfies (3.2) or (3.3) for $0 < q \leq q_i$ and $Q_i \leq Q < +\infty$, then boundary value problem (1.1), (1.2) has at least one positive solution.*

Proof. We denote $r = \min\{q_i : i = 1,2,3\}$, $R = \max\{Q_i : i = 1,2,3\}$ and let

$$\overline{K}_{r,R} = \{x \in K : r \leq \|x_i\| \leq R,\ i = 1,2,3\}.$$

By Lemma 3.2, each T_i satisfies compression type condition (i) or expansion type condition (ii) in $\overline{K}_{r,R}$. Therefore, by Krasnosel'skiĭ–Precup fixed point theorem, operator T has a fixed point in $\overline{K}_{r,R}$, which implies that boundary value problem (1.1), (1.2) has at least one positive solution. □

Let us show applicability of Theorem 3.7 in following example. Here and in Section 4, we round numbers to three decimal places unless we can calculate the numbers exactly.

Example 3.8. Consider system of differential equations

$$\begin{aligned} x_1'' + x_1^2(t + x_2x_3)^3 &= 0, \quad t \in (0,\tau), \\ x_2'' + \Big(x_1 t + x_3^{1/3}\Big)\frac{\exp(-x_2) + 1}{2} &= 0, \quad t \in (0,\tau), \\ x_3'' + \frac{80x_3 t}{x_3^3 + 1} + 7\sin(x_1 - x_2) + 7 &= 0, \quad t \in (0,\tau), \end{aligned} \tag{3.5}$$

with boundary conditions

$$\begin{aligned} x_1(0) &= 3x_1(1/5) - x_1(1/2), & x_1(\tau) &= \frac{1}{2}\int_0^\tau t^2 x_1(t)\mathrm{d}t, \\ x_2(0) &= a_2, & x_2(\tau) &= \int_0^\tau (\tau - t)x_2(t)\mathrm{d}t + b_2, \\ x_3(0) &= x_3(1/2) + a_3, & x_3(\tau) &= b_3, \end{aligned} \tag{3.6}$$

where a_2, b_2, a_3, $b_3 \geq 0$. Observe that $1/5$ and $1/2$ appear in the multi-point boundary conditions in first and third line of (3.6). Hence τ is greater than $1/2$.

In this example, the Green's functions (and intervals where assumptions (A1)–(A3) are valid) are as follows (recall that G_0 is given by (2.1)):

$$G_1(t,s) = \frac{1}{\tau/10 - \tau^4/60} \begin{vmatrix} \tau - t & 1/10 & -\tau^4/24 \\ t & -1/10 & \tau - \tau^4/8 \\ G_0(t,s) & G_0(1/2,s) - 3G_0(1/5,s) & -(s\tau^3 - s^4)/24 \end{vmatrix}, \tau \in (1/2, 6^{1/3}),$$

$$G_2(t,s) = \frac{1}{\tau^2(1-\tau^2/6)} \begin{vmatrix} \tau - t & \tau & -\tau^3/3 \\ t & 0 & \tau - \tau^3/6 \\ G_0(t,s) & 0 & -(s^3 - 3s^2\tau + 2s\tau^2)/6 \end{vmatrix}, \quad \tau \in (1/2, \sqrt{6}),$$

$$G_3(t,s) = \frac{2}{\tau} \begin{vmatrix} \tau - t & 1/2 & 0 \\ t & -1/2 & \tau \\ G_0(t,s) & -G_0(1/2,s) & 0 \end{vmatrix}, \quad \tau \in (1/2, +\infty).$$

Observe that $f_1(t,x) = x_1^2(t + x_2x_3)^3$ is non-decreasing with respect to all x_i, $i = 1,2,3$, and $a_1 = b_1 = 0$, and

$$\forall w \in [0,+\infty) \lim_{u\to 0+} \sup_{t\in[0,\tau]} \frac{u^2(t+w^2)^3}{u} = 0, \qquad \lim_{u\to+\infty} \inf_{t\in[\tau/4,3\tau/4]} \frac{u^2(t+0)^3}{u} = +\infty.$$

We do not need to calculate B_1 and A_1. But we need $A_1 > 0$, which is true for $\tau \in (1/2, 6^{1/3})$. Therefore (see Example 3.3), f_1 satisfies (3.3) for $\tau \in (1/2, 6^{1/3})$.

Next, $f_2(t,x) = (x_1 t + x_3^{1/3})(\exp(-x_2) + 1)/2$ is bounded with respect to x_2, non-decreasing with respect to x_1, x_3 and

$$\lim_{w\to 0+} \inf_{\substack{t\in[\tau/4,3\tau/4] \\ u\in[0,+\infty)}} \left(wt + w^{1/3}\right) \frac{\exp(-u)+1}{2w} = +\infty,$$

$$\lim_{w\to+\infty} \sup_{\substack{t\in[0,\tau] \\ u\in[0,+\infty)}} \left(wt + w^{1/3}\right) \frac{\exp(-u)+1}{2w} = \tau.$$

We expand $G_2(t,s)$ along the second column and consider

$$\begin{aligned} B_2 &= \sup_{t\in[0,\tau]} \int_0^\tau G_2(t,s)\mathrm{d}s \\ &= \sup_{t\in[0,\tau]} \frac{1}{\tau^2(1-\tau^2/6)} \int_0^\tau \left(\frac{\tau\, t(s^3 - 3s^2\tau + 2s\tau^2)}{6} + \tau\left(\tau - \frac{\tau^3}{6}\right) G_0(t,s) \right) \mathrm{d}s \\ &= \sup_{t\in[0,\tau]} \frac{\tau\, t(\tau^2 - 12) - 2t^2(\tau^2 - 6)}{4(\tau^2 - 6)} = \begin{cases} (144\tau^2 - 24\tau^4 + \tau^6)/(32(\tau^2-6)^2), & 1/2 < \tau < 2, \\ \tau^4/(4(6-\tau^2)), & 2 \leq \tau < \sqrt{6}. \end{cases} \end{aligned}$$

Calculations show that $\tau B_2 < 1$ for $\tau \in (1/2, 1.612)$. Therefore (see Example 3.4), f_2 satisfies (3.2) for $\tau \in (1/2, 1.612)$.

Next, $f_3(t,x) = 80x_3t/(x_3^3 + 1) + 7\sin(x_1 - x_2) + 7$ is bounded with respect to x_1, x_2 and

$$\lim_{x_3\to 0+} \inf_{\substack{t\in[\tau/4,3\tau/4] \\ x_1,x_2\in[0,+\infty)}} \frac{80x_3t}{(x_3^3+1)x_3} + \frac{7\sin(x_1-x_2)+7}{x_3} = 20\tau,$$

$$\lim_{x_3\to+\infty} \sup_{\substack{t\in[0,\tau]\\ x_1,x_2\in[0,+\infty)}} \frac{80x_3t}{(x_3^3+1)x_3} + \frac{7\sin(x_1-x_2)+7}{x_3} = 0.$$

We expand $G_3(t,s)$ along the third column and consider

$$\begin{aligned} A_3 &= \inf_{t\in[\tau/4,3\tau/4]} \int_{\tau/4}^{3\tau/4} G_3(t,s)\mathrm{d}s = \inf_{t\in[\tau/4,3\tau/4]} \frac{2}{\tau}\int_{\tau/4}^{3\tau/4} \Big(\tau(\tau-t)G_0(1/2,s) + \frac{\tau}{2}G_0(t,s)\Big)\,\mathrm{d}s \\ &= \inf_{t\in[\tau/4,3\tau/4]} \frac{-16t^2-\tau(8-15\tau+2\tau^2)+2t(4+\tau^2)}{32} \\ &= \begin{cases} (-12\tau+28\tau^2-3\tau^3)/64, & 1/2<\tau\le 2(2-\sqrt{3}) \text{ or } 2(2+\sqrt{3})<\tau, \\ (-4\tau+12\tau^2-\tau^3)/64, & 2(2-\sqrt{3})<\tau\le 2(2+\sqrt{3}). \end{cases} \end{aligned}$$

Calculations show that $1 < 5\tau A_3$ for $\tau \in (1.197, 8.877)$. Therefore (see Example 3.5), f_3 satisfies (3.2) for $\tau \in (1.197, 8.877)$.

Finally, we consider interval

$$(1/2, 6^{1/3}) \cap (1/2, 1.612) \cap (1.197, 8.877) = (1.197, 1.612).$$

Each f_i satisfies either (3.2) or (3.3) for sufficiently small q, sufficiently large Q and $\tau \in (1.197, 1.612)$. Therefore, by Theorem 3.7, boundary value problem (4.3), (4.4) has at least one positive solution for $\tau \in (1.197, 1.612)$.

4 Numerical result for Dirichlet boundary conditions

In this section, we consider problem (1.1) with boundary conditions

$$x_i(0) = a_i,\ x_i(\tau) = b_i, \tag{4.1}$$

and show examples where is compared theoretical estimation of τ with result obtained numerically. Note that here $G_i = G_0$, $A_i = \tau^2/16$ and $B_i = \tau^2/8$ for every $i = 1,2,3$.

For numerical result let us consider the initial conditions

$$x_i(0) = a_i, \quad x_i'(0) = c_i \in \mathbb{R}, \quad i = 1,2,3. \tag{4.2}$$

Let $c = (c_1, c_2, c_3)$ and $x^c = (x_1^c, x_2^c, x_3^c)$ be a solution of initial value problem (1.1), (4.2). We denote by $t_1(c) > 0$ the positive argument for which $x^c(t_1(c)) = (b_1, b_2, b_3)$ holds for the first time. Such $t_1(c)$ exists if and only if boundary value problem (1.1), (4.1) has a solution for $t_1(c) = \tau$. Thus set of values of the map $c \mapsto t_1(c)$ determines values of the τ. We assume that if there is no c such that $t_1(c) = \tau > 0$, then $t_1(c) = 0$.

In case of one equation this method is known as the shooting method. We do the following in our case. We fix c_1 and consider $t_1(c_1,\cdot,\cdot)$. If problem (1.1), (4.1) has a solution for $t_1(c) = \tau$, then $t_1(c_1,\cdot,\cdot)$ is everywhere zero except one point.

To obtain the result we are using "brute force", i.e. go through all possible choices. To make count of choices less, we consider meshes with step sizes θ_i for c_i, $i = 1,2,3$. To make sure to "shoot somewhere", we consider weakened conditions

$$\Big(x_2(t_1(c)) - b_2\Big)^2 + \Big(x_3(t_1(c)) - b_3\Big)^2 < \varepsilon^2.$$

Thus for every c_1 there exists a set $\Omega_\varepsilon \subset \mathbb{R}^2$ such that $t_1(c) > 0$ for $(c_2, c_3) \in \Omega_\varepsilon$. We denote $t_M(c_1) = \max\{t_1(c) : (c_2, c_3) \in \mathbb{R}^2\}$. Numerical result is a discrete plot $c_1 \mapsto t_M(c_1)$.

In the following examples we compare the results. Examples emphasize that Theorem 3.7 gives sufficient conditions.

Example 4.1. Consider system of differential equations

$$\begin{aligned} x_1'' + (x_1 t^3 + x_3)^{1/2}\, x_2^{1/3} &= 0, \quad t \in (0,\tau), \\ x_2'' + (x_1 t^3 + x_3^{1/2})\frac{\exp(-x_2) + 1}{10} &= 0, \quad t \in (0,\tau), \\ x_3'' + \frac{16^2 x_3^4 + x_3}{1 + x_3^3}\Big(2 + \sin(x_1 t + x_2)\Big) &= 0, \quad t \in (0,\tau), \end{aligned} \tag{4.3}$$

with boundary conditions

$$\begin{aligned} x_1(0) &= 0.2, & x_1(\tau) &= 0, \\ x_2(0) &= 0, & x_2(\tau) &= 0.2, \\ x_3(0) &= 0, & x_3(\tau) &= 0. \end{aligned} \tag{4.4}$$

Here $f_1(t,x) = (x_1 t^3 + x_3)^{1/2}\, x_2^{1/3}$ is non-decreasing with respect to all x_i, $i = 1,2,3$, and

$$\lim_{u \to 0+} \inf_{t \in [\tau/4, 3\tau/4]} \frac{(ut^3 + u)^{1/2}\, u^{1/3}}{u} = +\infty, \qquad \lim_{u \to +\infty} \sup_{t \in [0,\tau]} \frac{(ut^3 + u)^{1/2} u^{1/3}}{u} = 0.$$

Therefore, f_1 satisfies (3.2) for $\tau \in (0, +\infty)$.

Next, $f_2(t,x) = (x_1 t^3 + x_3^{1/2})(\exp(-x_2) + 1)/10$ is bounded with respect to x_2, non-decreasing with respect to x_1, x_3 and

$$\lim_{w \to 0+} \inf_{\substack{t \in [\tau/4, 3\tau/4] \\ u \in [0,+\infty)}} \left(wt^3 + w^{1/2}\right) \frac{\exp(-u) + 1}{10w} = +\infty,$$

$$\lim_{w \to +\infty} \sup_{\substack{t \in [0,\tau] \\ u \in [0,+\infty)}} \left(wt^3 + w^{1/2}\right) \frac{\exp(-u) + 1}{10w} = \frac{\tau^3}{5}.$$

Calculations show that $B_2 \tau^3/5 < 1$ for $\tau \in (0, 40^{1/5})$. Therefore, f_2 satisfies (3.2) for $\tau \in (0, 40^{1/5})$.

Next, $f_3(t,x) = (16^2 x_3^4 + x_3)(2 + \sin(x_1 t + x_2))/(1 + x_3^3)$ is bounded with respect to x_1, x_2, and

$$\lim_{x_3 \to 0+} \sup_{\substack{t \in [0,\tau] \\ x_1, x_2 \in [0,+\infty)}} \frac{16^2 x_3^4 + x_3}{(1 + x_3^3) x_3}\Big(2 + \sin(x_1 t + x_2)\Big) = 3,$$

$$\lim_{x_3 \to +\infty} \inf_{\substack{t \in [\tau/4, 3\tau/4] \\ x_1, x_2 \in [0,+\infty)}} \frac{16^2 x_3^4 + x_3}{(1 + x_3^3) x_3}\Big(2 + \sin(x_1 t + x_2)\Big) = 16^2.$$

Calculations show that $3B_3 < 1 < 16^2 A_3/4$ for $\tau \in (1/2,\, 2\sqrt{2/3})$. Therefore, f_3 satisfies (3.3) for $\tau \in (1/2,\, 2\sqrt{2/3})$.

Each f_i satisfies either (3.2) or (3.3) for sufficiently small q, sufficiently large Q and $\tau \in (1/2, 2\sqrt{2/3})$. Therefore, by Theorem 3.7, the theoretical result is $1/2 < \tau < 2\sqrt{2/3}$, or approximately $1/2 < \tau < 1.633$.

Since $a_2 \leq b_2$ and $a_3 \leq b_3$, we consider non-negative c_2 and c_3. For numerical result we make meshes in interval $[-1,1]$ for c_1, $[0,2]$ for c_2 and $[0.001, 2.001]$ for c_3 with step sizes $\theta_1 = \theta_2 = \theta_3 = 0.1$ and $\varepsilon = 0.1$. The result is illustrated in Figure 4.1. Numerical result shows that $0.200 \leq \tau \leq 2.579$.

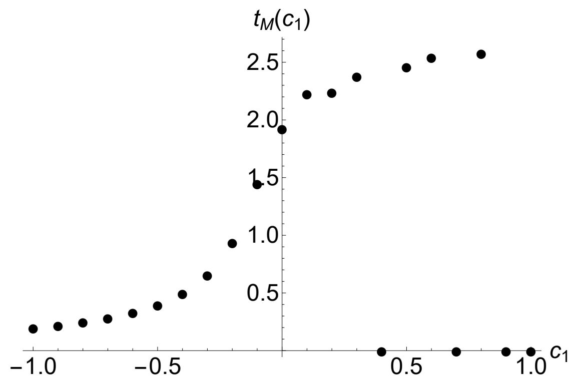

Figure 4.1: Graph of the $c_1 \mapsto t_M(c_1)$ for problem (4.3), (4.4).

Example 4.2. Consider system of differential equations

$$\begin{aligned} x_1'' + (x_1x_2x_3)^{1/4} &= 0, \quad t \in (0,\tau), \\ x_2'' + \frac{1}{1+tx_2} + \frac{1}{1+x_1x_3} &= 0, \quad t \in (0,\tau), \\ x_3'' + + \frac{(15+4t)x_3}{1+x_3^2} + \cos x_1 \sin x_2 + 1 &= 0, \quad t \in (0,\tau), \end{aligned} \tag{4.5}$$

with boundary conditions

$$\begin{aligned} x_1(0) &= 1, \quad x_1(\tau) = 0, \\ x_2(0) &= 0, \quad x_2(\tau) = 1, \\ x_3(0) &= 1, \quad x_3(\tau) = 1. \end{aligned} \tag{4.6}$$

Here $f_1(t,x) = (x_1x_2x_3)^{1/4}$ is non-decreasing with respect to all x_i, $i = 1,2,3$, and

$$\lim_{u\to 0+} \inf_{t\in[\tau/4,3\tau/4]} \frac{u^{3/4}}{u} = +\infty, \qquad \lim_{u\to+\infty} \sup_{t\in[0,\tau]} \frac{u^{3/4}}{u} = 0.$$

Therefore, f_1 satisfies (3.2) for $\tau \in (0,+\infty)$.

Next, $f_2(t,x) = (1+tx_2)^{-1} + (1+x_1x_3)^{-1}$ is bounded with respect to x_1, x_3 and

$$\lim_{x_2\to 0+} \inf_{\substack{t\in[\tau/4,3\tau/4] \\ x_1,x_3\in[0,+\infty)}} \frac{1}{(1+tx_2)x_2} + \frac{1}{(1+x_1x_3)x_2} = +\infty,$$

$$\lim_{x_2\to +\infty} \sup_{\substack{t\in[0,\tau] \\ x_1,x_3\in[0,+\infty)}} \frac{1}{(1+tx_2)x_2} + \frac{1}{(1+x_1x_3)x_2} = 0.$$

Therefore, f_2 satisfies (3.2) for $\tau \in (0,+\infty)$.

Next, $f_3(t,x) = (15+4t)x_3/(1+x_3^2) + \cos x_1 \sin x_2 + 1$ is bounded with respect to x_1, x_2, and

$$\lim_{x_3\to 0+} \inf_{\substack{t\in[\tau/4,3\tau/4] \\ x_1,x_2\in[0,+\infty)}} \frac{(15+4t)x_3}{(1+x_3^2)x_3} + \frac{\cos x_1 \sin x_2 + 1}{x_3} = 15 + \tau,$$

$$\lim_{x_3\to+\infty} \sup_{\substack{t\in[0,\tau]\\ x_1,x_2\in[0,+\infty)}} \frac{(15+4t)x_3}{(1+x_3^2)x_3} + \frac{\cos x_1 \sin x_2 + 1}{x_3} = 0.$$

Calculations show that $1 < (15+\tau)A_3/4$ for $\tau \in (1.944, +\infty)$. Therefore, f_3 satisfies (3.2) for $\tau \in (1.944, +\infty)$.

Each f_i satisfies (3.2) for sufficiently small q, sufficiently large Q and $\tau \in (1.944, +\infty)$. Therefore, by Theorem 3.7, the theoretical result is $\tau > 1.944$.

For numerical result we make meshes in interval $[-7, 0]$ for c_1, $[0, 7]$ for c_2 and c_3 with step sizes $\theta_1 = 1$, $\theta_2 = \theta_3 = 0.1$ and $\varepsilon = 0.1$. The result is illustrated in Figure 4.2. Numerical result shows that τ could be less than 1.944.

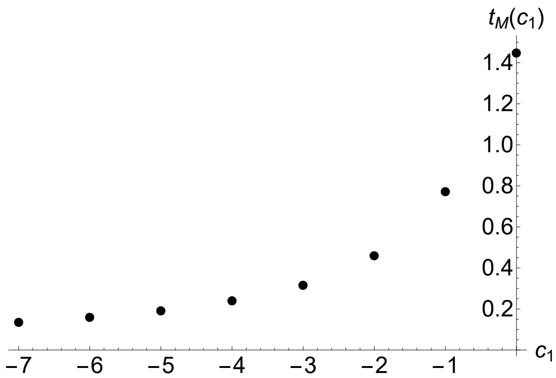

Figure 4.2: Graph of the $c_1 \mapsto t_M(c_1)$ for problem (4.5), (4.6).

Remark 4.3. There is no ground to say that this method is not suitable for nonlocal conditions, for instance, $x(0) = \varphi_i[x_i] + a_i$, $x(\tau) = b_i$. But, since we are using “brute force” (which is long itself), in case of nonlocal conditions program needs much smaller step size to get nonzero $t_M(c_1)$, and hence much more time to run, which makes the program inefficient.

Abstract. We investigate the following logarithmic Kirchhoff-type equation:

$$\left(a + b\int_{\mathbb{R}^3} |\nabla u|^2 + V(x)u^2 dx\right)[-\Delta u + V(x)u] = |u|^{p-2}u\ln|u|, \qquad x \in \mathbb{R}^3,$$

where $a, b > 0$ are constants, $4 < p < 2^* = 6$. Under some appropriate hypotheses on the potential function V, we prove the existence of a positive ground state solution, a ground state sign-changing solution and a sequence of solutions by using the constraint variational methods, topological degree theory, quantitative deformation lemma and symmetric mountain pass theorem. Our results complete those of Gao et al. [*Appl. Math. Lett.* **139**(2023), 108539] with the case of $4 < p < 6$.

Keywords: Kirchhoff-type equation, logarithmic nonlinearity, ground state sign-changing solution, variational methods, topological degree theory.

2020 Mathematics Subject Classification: 35J50, 35J61.

1 Introduction and main result

In this work, we are concerned with the existence of ground state sign-changing solutions for the following logarithmic Kirchhoff-type equation

$$\left(a + b\int_{\mathbb{R}^3} |\nabla u|^2 + V(x)u^2 dx\right)[-\Delta u + V(x)u] = |u|^{p-2}u\ln|u|, \qquad x \in \mathbb{R}^3, \tag{1.1}$$

where $a, b > 0$ are constants, $4 < p < 6$. Besides, we shall impose the following conditions on potential function V:

(V_1) $V \in C(\mathbb{R}^3, \mathbb{R})$ and $\lim_{|x|\to\infty} V(x) = +\infty$;

(V_2) There exists a constant V_0 such that $\inf_{x\in\mathbb{R}^3} V(x) \geq V_0 > 0$.

✉ Corresponding author. E-mail address: liaojiafeng@163.com

As is known to all, Kirchhoff [12] first proposed the following Kirchhoff model given by the stationary analogue of equation

$$\rho\frac{\partial^2 u}{\partial t^2}-\left(\frac{P_0}{h}+\frac{E}{2L}\int_0^L\left|\frac{\partial u}{\partial x}\right|^2dx\right)\frac{\partial^2 u}{\partial x^2}=0,$$

where ρ is the mass density, P_0 is the initial tension, h represents the area of the cross-section, E is the Young modulus of the material and L is the length of the string. The above model is an extension of the classical D'Alembert wave equation by taking into account the changes in the length of the string during the transverse vibrations. After that, Lions [13] derived the following Kirchhoff equation by using the functional analysis method

$$u_{tt}-\left(a+b\int_{\mathbb{R}^3}|\nabla u|^2dx\right)\Delta u=f(x,u). \tag{1.2}$$

This model is used to describe the chord length variation of elastic strings caused by lateral vibration, where u is displacement, f is external force, b is initial tension force and a is related to inherent properties of strings (see [1, 2, 5, 7] and the references therein). The corresponding problem associated with equation (1.2) is called as the Kirchhoff-type problem.

In the past years, logarithmic nonlinearity appears frequently in partial differential equations, which has numerous applications to quantum optics, quantum mechanics, nuclear physics, transport and diffusion phenomenon etc (see [22] and the references therein). Therefore, many scholars studied the following Kirchhoff-type problem with logarithmic nonlinearity

$$-\left(a+b\int_{\mathbb{R}^3}|\nabla u|^2dx\right)\Delta u+V(x)u=|u|^{p-2}u\log u^2,\qquad x\in\mathbb{R}^3, \tag{1.3}$$

where $4<p<6$ and $V\in C(\mathbb{R}^3,\mathbb{R})$. By using the constrained variational method, deformation lemma and topological degree theory, Hu and Gao [10] proved that equation (1.3) owns both positive solution and sign-changing solution under different types of potential (coercive potential and periodic potential). Wen, Tang and Chen [20] verified that equation (1.3) in smooth bounded domain $\Omega\subset\mathbb{R}^3$ has a ground state solution and a ground state sign-changing solution, besides, the energy of sign-changing solution is larger than twice of the ground state energy.

In particular, letting $a=1, b=0$ and $p=2$ in equation (1.3), it leads to the following logarithmic Schrödinger equation

$$-\Delta u+V(x)u=u\log u^2,\qquad x\in\mathbb{R}^N. \tag{1.4}$$

Equation (1.4) has received much attention in mathematical analysis and applications. Ji and Szulkin [11] got infinitely many solutions by adapting some arguments of the fountain theorem when the potential is coercive (i.e. $\lim_{|x|\to\infty}V(x)=+\infty$), and in the case of bounded potential (i.e. $\lim_{|x|\to\infty}V(x)=V_\infty\in(-1,+\infty)$), they obtained a ground state solution. By using the direction derivative and constrained minimization method, Shuai [16] proved the existence of positive and sign-changing solutions of equation (1.4) under different types of potential (coercive potential and periodic potential). When the potential is radially symmetric, the author constructed infinitely many radial nodal solutions. Zhang and Zhang [24] proved the existence, uniqueness, non-degeneracy and some qualitative properties of positive solutions of equation (1.4) when the potential $V\in C^2(\mathbb{R}^N,\mathbb{R})$ is radially symmetric and allowed to be singular at $x=0$ and repulsive at infinity(i.e. $\lim_{|x|\to\infty}V(x)=-\infty$). When potential

$V \in C(\mathbb{R}^N, \mathbb{R})$ satisfies $\lim_{|x|\to\infty} V(x) = V_\infty$ and $V(x) < V_\infty + \log 2$, Feng, Tang and Zhang [8] proved that equation (1.4) has a positive bound state solution.

After that, inspired by [10], Gao, Jiang and Liu et al. [9] studied the existence of solutions to equation (1.1) for the first time, and proved that equation (1.1) has only trivial solution for large $b > 0$ and two positive solutions for small $b > 0$ and $2 < p < 4$. To the best of our knowledge, there is no result for the existence of positive ground state, ground state sign-changing solutions and sequence of solutions of equation (1.1) with $4 < p < 6$. Inspired by the above literature, we are interested in the existence of positive ground state solutions, ground state sign-changing solutions and sequence of solutions for equation (1.1).

Equation (1.1) is formally associated with the energy functional $I : H \to \mathbb{R}$ defined by

$$\begin{aligned} I(u) = \frac{a}{2}\int_{\mathbb{R}^3}(|\nabla u|^2 + V(x)u^2)dx + \frac{b}{4}\left(\int_{\mathbb{R}^3}(|\nabla u|^2 + V(x)u^2)dx\right)^2 \\ - \frac{1}{p}\int_{\mathbb{R}^3}|u|^p \ln|u|dx + \frac{1}{p^2}\int_{\mathbb{R}^3}|u|^p dx, \end{aligned} \tag{1.5}$$

with $I(0) = 0$, where Sobolev space H is defined as follows:

$$H := \left\{u \in H^1(\mathbb{R}^3) : \int_{\mathbb{R}^3} V(x)u^2 dx < +\infty\right\}.$$

endowed with the inner product

$$\langle u, v\rangle := \int_{\mathbb{R}^3}(\nabla u \cdot \nabla v + V(x)uv)dx, \qquad \forall u, v \in H$$

and endowed with the norm

$$\|u\|^2 := \langle u, u\rangle = \int_{\mathbb{R}^3}(|\nabla u|^2 + V(x)u^2)dx.$$

Denote $|u|_k = \left(\int_{\mathbb{R}^3}|u|^k dx\right)^{1/k}$ the norm of $u \in L^k(\mathbb{R}^3)$ for $k \geq 1$, the $C, C_1, C_2, \ldots$ represent several different positive constants. A elementary computation, we have

$$\lim_{t\to 0}\frac{t^{p-1}\ln|t|}{t} = 0 \quad \text{and} \quad \lim_{t\to\infty}\frac{t^{p-1}\ln|t|}{t^{q-1}} = 0,$$

where $4 < p < q < 6$. Therefore, for arbitrarily $\varepsilon > 0$, there exists $C_\varepsilon > 0$ such that

$$|t^{p-1}\ln|t|| \leq \varepsilon|t| + C_\varepsilon|t|^{q-1}, \qquad \forall\, t \in \mathbb{R}\backslash\{0\}. \tag{1.6}$$

By (1.6) and [19, Lemma 3.10], we get that $I \in C^1(H, \mathbb{R})$ and the Fréchet derivative of I is given by

$$\langle I'(u), v\rangle = (a + b\|u\|^2)\int_{\mathbb{R}^3}(\nabla u\nabla v + V(x)uv)dx - \int_{\mathbb{R}^3}|u|^{p-2}uv\ln|u|dx, \tag{1.7}$$

for all $u, v \in H$. $u \in H$ is a weak solution of equation (1.1) if and only if u is a critical point of I. Additional, if $u \in H$ is a weak solution of equation (1.1) with $u^\pm \neq 0$, then u is called a sign-changing solution of equation (1.1), where

$$u^+ := \max\{u(x), 0\}, \qquad u^- := \min\{u(x), 0\}.$$

From (1.7), we know

$$\langle I'(u),u\rangle = a\|u\|^2 + b\|u\|^4 - \int_{\mathbb{R}^3} |u|^p \ln|u| dx \tag{1.8}$$

and

$$\langle I'(u),u^\pm\rangle = (a+b\|u\|^2)\|u^\pm\|^2 - \int_{\mathbb{R}^3} |u^\pm|^p \ln|u^\pm| dx. \tag{1.9}$$

By virtue of (1.8) and (1.9), it is noticed that if $u \not\equiv 0$, then

$$\begin{aligned} I(u) &= I(u^+) + I(u^-) + \frac{b}{2}\|u^+\|^2\|u^-\|^2, \\ \langle I'(u),u^+\rangle &= \langle I'(u^+),u^+\rangle + b\|u^+\|^2\|u^-\|^2, \\ \langle I'(u),u^-\rangle &= \langle I'(u^-),u^-\rangle + b\|u^+\|^2\|u^-\|^2. \end{aligned}$$

In this paper, our main purpose is to seek the ground state sign-changing solution for equation (1.1). As we all known, there are some very interesting results for the existence and multiplicity of sign-changing solutions of the following Schrödinger equation

$$-\Delta u + V(x)u = f(x,u), \qquad x \in \mathbb{R}^N. \tag{1.10}$$

However, these methods of seeking sign-changing solutions dependent on the following decomposition

$$J(u) = J(u^+) + J(u^-), \tag{1.11}$$

and

$$\langle J'(u),u^+\rangle = \langle J'(u^+),u^+\rangle, \qquad \langle J'(u),u^-\rangle = \langle J'(u^-),u^-\rangle, \tag{1.12}$$

where J is the energy functional of equation (1.10) given by

$$J(u) = \frac{1}{2}\int_{\mathbb{R}^N} (|\nabla u|^2 + V(x)u^2)dx - \int_{\mathbb{R}^N} F(x,u)dx.$$

However, it follows from (1.5) that the energy functional I does not possess the same decompositions as (1.11) and (1.12). Indeed, a direct calculation yields that

$$I(u) > I(u^+) + I(u^-),$$

and

$$\langle I'(u),u^+\rangle > \langle I'(u^+),u^+\rangle, \qquad \langle I'(u),u^-\rangle > \langle I'(u^-),u^-\rangle$$

for $u^\pm \neq 0$. Therefore, the method of getting sign-changing solutions for the local problem (1.10) does not seem applicable to equation (1.1). In order to overcome this difficulty, we follow in [4] by the following Nehari manifold and the nodal Nehari sets respectively

$$\mathcal{N} := \left\{u \in H\backslash\{0\} : \langle I'(u),u\rangle = 0\right\},$$

and

$$\mathcal{M} := \left\{u \in H, u^\pm \neq 0 : \langle I'(u),u^\pm\rangle = 0\right\}.$$

It is well known that the existence of positive ground state and sign-changing solutions to equation (1.1) can be transformed into studying the following minimization problems respectively

$$c := \inf_{u\in\mathcal{N}} I(u) \quad \text{and} \quad m := \inf_{u\in\mathcal{M}} I(u).$$

Now, we state the main results.

Theorem 1.1. *Assume that (V_1)–(V_2) hold and $4 < p < 6$, then equation (1.1) possesses a positive ground state solution $\bar{u} \in \mathcal{N}$ such that $I(\bar{u}) = c$.*

Theorem 1.2. *Assume that (V_1)–(V_2) hold and $4 < p < 6$, then equation (1.1) has a ground state sign-changing solution $u_* \in \mathcal{M}$ with precisely two nodal domains such that $I(u_*) = m$. Moreover, $m > 2c$.*

Theorem 1.3. *Assume that (V_1)–(V_2) hold and $4 < p < 6$, then equation (1.1) owns a sequence of solutions of $\{u_n\}$ with $I(u_n) \to +\infty$ as $n \to \infty$.*

Remark 1.4. To our best knowledge, our results are up to date. Compared with [9], we study the case of $4 < p < 6$. Moreover, we consider the ground state sign-changing solution and a sequence of high energy solutions for equation (1.1).

The remaining of paper is organized as follows. In Section 2, we show some necessary logarithmic inequalities and important lemmas. In Section 3, we prove Theorems 1.1–1.3 by the maximum principle, quantitative deformation lemma, topological degree theory and symmetric mountain pass theorem.

2 Some preliminary results

Firstly, because of the existence of logarithmic nonlinearity, the following lemmas will be used to obtain vital estimates for our problem.

Lemma 2.1. *The following inequalities hold*

$$(1 - x^s) + sx^s \ln x > 0, \qquad \forall x \in (0,1) \cup (1, +\infty), s > 0; \tag{2.1}$$

$$\ln x \le \frac{1}{e\sigma} x^\sigma, \qquad \forall x \in (0, +\infty), \sigma > 0. \tag{2.2}$$

Proof. Define $f(x) := (1 - x^s) + sx^s \ln x$, then $f'(x) := s^2 x^{s-1} \ln x$, it's easy to see that the function $f(x)$ is decreasing on $(0,1)$ and increasing on $(1, +\infty)$. So $f(x) > f(1) = 0$, i.e.

$$(1 - x^s) + sx^s \ln x > 0.$$

Thus, (2.1) is true. The proof of (2.2) is similar to that of (2.1), here we omit it. □

Next, we give the following lemma by the conclusions of [3].

Lemma 2.2. *Under the assumptions (V_1)–(V_2), then the embedding $H \hookrightarrow L^q(\mathbb{R}^3)$ is compact for $q \in [2, 6)$.*

By virtue of Lemma 2.2, we define the following Sobolev embedding constants

$$S_q = \inf_{u \in H \setminus \{0\}} \frac{\|u\|^q}{|u|_q^q}, \qquad q \in [2, 6]. \tag{2.3}$$

As is known to all, the logarithmic nonlinearity $|u|^{p-2} u \ln |u|$ satisfies neither the well-known Nehari type monotonicity condition in [23] nor (AR) condition in [17]. Therefore, we will establish an energy inequality related to $I(u)$, $I(su^+ + tu^-)$, $\langle I'(u), u^+ \rangle$ and $\langle I'(u), u^- \rangle$ in order to overcome the this difficulty.

Lemma 2.3. *For all $u \in H$ and $s, t \geq 0$, there holds*

$$I(u) \geq I(su^+ + tu^-) + \frac{1-s^p}{p}\langle I'(u), u^+\rangle + \frac{1-t^p}{p}\langle I'(u), u^-\rangle. \tag{2.4}$$

Proof. It follows from (1.9) that (2.4) holds for $u = 0$, then we only consider the case when $u \in H\backslash\{0\}$. Set

$$\Omega^+ = \{u \in \mathbb{R}^3 : u(x) \geq 0\}, \qquad \Omega^- = \{u \in \mathbb{R}^3 : u(x) < 0\}.$$

For all $u \in H\backslash\{0\}$ and $s, t \geq 0$, one has

$$\begin{aligned}
&\int_{\mathbb{R}^3} |su^+ + tu^-|^p \ln|su^+ + tu^-| dx \\
&= \int_{\Omega^+} |su^+ + tu^-|^p \ln|su^+ + tu^-| dx + \int_{\Omega^-} |su^+ + tu^-|^p \ln|su^+ + tu^-| dx \\
&= \int_{\Omega^+} |su^+|^p \ln|su^+| dx + \int_{\Omega^-} |tu^-|^p \ln|tu^-| dx \\
&= \int_{\mathbb{R}^3} (|su^+|^p \ln|su^+| + |tu^-|^p \ln|tu^-|) dx.
\end{aligned} \tag{2.5}$$

It follows from (1.5), (1.8), (2.1) and (2.5) that

$$\begin{aligned}
&I(u) - I(su^+ + tu^-) \\
&= \frac{a}{2}\left(\|u\|^2 - \|su^+ + tu^-\|^2\right) + \frac{b}{4}\left(\|u\|^4 - \|su^+ + tu^-\|^4\right) \\
&\quad + \frac{1}{p^2}\int_{\mathbb{R}^3} \left(|u|^p - |su^+ + tu^-|^p\right) dx \\
&\quad + \frac{1}{p}\int_{\mathbb{R}^3} \left(|u|^p \ln|u| - |su^+ + tu^-|^p \ln|su^+ + tu^-|\right) dx \\
&= \frac{a(1-s^2)}{2}\|u^+\|^2 + \frac{a(1-t^2)}{2}\|u^-\|^2 + \frac{b(1-s^4)}{4}\|u^+\|^4 + \frac{b(1-t^4)}{4}\|u^-\|^4 \\
&\quad + \frac{b(1-s^2t^2)}{2}\|u^+\|^2\|u^-\|^2 + \frac{(1-s^p)}{p^2}\int_{\mathbb{R}^3} |u^+|^p dx + \frac{(1-t^p)}{p^2}\int_{\mathbb{R}^3} |u^-|^p dx \\
&\quad - \frac{1}{p}\int_{\mathbb{R}^3} \left(|u^+|^p \ln|u^+| - |su^+|^p \ln|u^+| - |su^+|^p \ln s\right) dx \\
&\quad - \frac{1}{p}\int_{\mathbb{R}^3} \left(|u^-|^p \ln|u^-| - |tu^-|^p \ln|u^-| - |tu^-|^p \ln t\right) dx \\
&= \frac{1-s^p}{p}\langle I'(u), u^+\rangle + \frac{1-t^p}{p}\langle I'(u), u^-\rangle \\
&\quad + a\left[\left(\frac{1-s^2}{2} - \frac{1-s^p}{p}\right)\|u^+\|^2 + \left(\frac{1-t^2}{2} - \frac{1-t^p}{p}\right)\|u^-\|^2\right] \\
&\quad + b\left[\left(\frac{1-s^4}{4} - \frac{1-s^p}{p}\right)\|u^+\|^4 + \left(\frac{1-t^4}{4} - \frac{1-t^p}{p}\right)\|u^-\|^4\right] \\
&\quad + b\left(\frac{1-s^2t^2}{2} - \frac{1-s^p}{p} - \frac{1-t^p}{p}\right)\|u^+\|^2\|u^-\|^2 \\
&\quad + \frac{(1-s^p) + ps^p \ln s}{p^2}\int_{\mathbb{R}^3} |u^+|^p dx + \frac{(1-t^p) + pt^p \ln t}{p^2}\int_{\mathbb{R}^3} |u^-|^p dx.
\end{aligned}$$

Since the function $f(x) = \frac{1-a^x}{x}$ is monotonically decreasing on $(0, +\infty)$ for $a \in (0,1) \cup (1, +\infty)$. It follows from the above equation that

$$\begin{aligned}
&I(u) - I(su^+ + tu^-) \\
&\geq \frac{1-s^p}{p}\langle I'(u), u^+\rangle + \frac{1-t^p}{p}\langle I'(u), u^-\rangle + b\left(\frac{1-s^2t^2}{2} - \frac{1-s^p}{p} - \frac{1-t^p}{p}\right)\|u^+\|^2\|u^-\|^2 \\
&= \frac{1-s^p}{p}\langle I'(u), u^+\rangle + \frac{1-t^p}{p}\langle I'(u), u^-\rangle \\
&\quad + b\left[\frac{(s^2-t^2)^2}{4} + \left(\frac{1-s^4}{4} - \frac{1-s^p}{p}\right) + \left(\frac{1-t^4}{4} - \frac{1-t^p}{p}\right)\right]\|u^+\|^2\|u^-\|^2 \\
&\geq \frac{1-s^p}{p}\langle I'(u), u^+\rangle + \frac{1-t^p}{p}\langle I'(u), u^-\rangle.
\end{aligned}$$

Hence, (2.4) holds for all $u \in H$ and $s, t \geq 0$. □

Let $s = t$ in (2.4), we can obtain the following corollary.

Corollary 2.4. *For all $u \in H$ and $t \geq 0$, there holds*

$$I(u) \geq I(tu) + \frac{1-t^p}{p}\langle I'(u), u\rangle.$$

According to Lemma 2.3 and Corollary 2.4, we have the following lemmas.

Lemma 2.5. *For all $u \in \mathcal{M}$, there holds $I(u) = \max_{s,t\geq 0} I(su^+ + tu^-)$.*

Lemma 2.6. *For all $u \in \mathcal{N}$, there holds $I(u) = \max_{t\geq 0} I(tu)$.*

By Lemmas 2.3 and 2.5, we have the following lemma.

Lemma 2.7. *For all $u \in \mathcal{M}$ and $s, t \geq 0$, there holds $I(u) \geq I(su^+ + tu^-)$, and the equality sign holds if and only if $s = t = 1$.*

Lemma 2.8. *For any $u \in H$ with $u^\pm \neq 0$, there exists a unique positive numbers pair (s_0, t_0) such that $s_0u^+ + t_0u^- \in \mathcal{M}$.*

Proof. We firstly prove that there exists positive numbers pair (s_0, t_0) such that $s_0u^+ + t_0u^- \in \mathcal{M}$. For any $u \in H$ with $u^\pm \neq 0$, let

$$g(s,t) = \langle I'(su^+ + tu^-), su^+\rangle, \qquad h(s,t) = \langle I'(su^+ + tu^-), tu^-\rangle.$$

From (1.9), one gets

$$g(s,t) = (a + b\|su^+ + tu^-\|^2)\|su^+\|^2 - \int_{\mathbb{R}^3} |su^+|^p \ln|su^+| dx; \tag{2.6}$$

$$h(s,t) = (a + b\|su^+ + tu^-\|^2)\|tu^-\|^2 - \int_{\mathbb{R}^3} |tu^-|^p \ln|tu^-| dx. \tag{2.7}$$

Let $t = s$ in (2.6), then

$$\begin{aligned}
g(s,s) &= (a + b\|su\|^2)\|su^+\|^2 - \int_{\mathbb{R}^3} |su^+|^p \ln|su^+| dx \\
&= as^2\|u^+\|^2 + bs^4\|u^+\|^4 + bs^4\|u^+\|^2\|u^-\|^2 \\
&\quad - s^p \int_{\mathbb{R}^3} |u^+|^p \ln|u^+| dx - s^p \ln s \int_{\mathbb{R}^3} |u^+|^p dx.
\end{aligned}$$

Obviously $g(s,s)$ is continuous, it is easy to verify that $g(s,s) > 0$ when $0 < s < 1$ small enough and $g(s,s) < 0$ when $s > 1$ large enough. Similarly, $h(t,t) > 0$ when $0 < t < 1$ small enough and $h(t,t) < 0$ when $t > 1$ large enough. Therefore, there exists $0 < r < R$ such that

$$g(r,r) > 0, h(r,r) > 0; \qquad g(R,R) < 0, h(R,R) < 0. \tag{2.8}$$

It follows from (2.6)–(2.8) that we have

$$\begin{aligned} &g(r,t) > 0, \quad &g(R,t) < 0, \quad &\forall t \in [r,R], \\ &h(s,r) > 0, \quad &h(s,R) < 0, \quad &\forall s \in [r,R]. \end{aligned}$$

Based on Miranda's Theorem [14], there exist $r < s_0, t_0 < R$ such that $g(s_0,t_0) = h(s_0,t_0) = 0$, which implies that $s_0u^+ + t_0u^- \in \mathcal{M}$.

Next, we prove the uniqueness of (s_0,t_0). By contradiction, we suppose that there are two pairs positive numbers $(s_1,t_1),(s_2,t_2)$ with $s_1 \neq s_2, t_1 \neq t_2$ such that $g(s_1,t_1) = g(s_2,t_2) = 0, h(s_1,t_1) = h(s_2,t_2) = 0$. Let $s = \frac{s_1}{s_2}$ and $t = \frac{t_1}{t_2}$, then $s \neq 1$ and $t \neq 1$. From Lemma 2.7, we know

$$I(s_1u^+ + t_1u^-) = I(s(s_2u^+) + t(t_2u^-)) < I(s_2u^+ + t_2u^-). \tag{2.9}$$

Similarly, one has

$$I(s_2u^+ + t_2u^-) < I(s_1u^+ + t_1u^-),$$

which contradicts (2.9). Therefore, (s_0,t_0) is unique. □

Lemma 2.9. *For any $u \in H$ with $u \neq 0$, there exists a unique positive number $t_0 > 0$ such that $t_0u \in \mathcal{N}$.*

Proof. Define a function $g(t) = \langle I'(tu), tu\rangle$ on $(0,+\infty)$, then

$$\begin{aligned} g(t) &= a\|tu\|^2 + b\|tu\|^4 - \int_{\mathbb{R}^3} |tu|^p \ln|tu|dx \\ &= at^2\|u\|^2 + bt^4\|u\|^4 - t^p \int_{\mathbb{R}^3} |u|^p \ln|u|dx - t^p \ln t \int_{\mathbb{R}^3} |u|^p dx. \end{aligned} \tag{2.10}$$

Combined with (1.8), we know

$$g(t) = t^p\langle I'(u), u\rangle + a(t^2 - t^p)\|u\|^2 + b(t^4 - t^p)\|u\|^4 - t^p \ln t \int_{\mathbb{R}^3} |u|^p dx.$$

If $u \in \mathcal{N}$, then $t_0 = 1$. Therefore, we only consider the existence of t_0 when $u \notin \mathcal{N}$. Since $4 < p < 6$ and in view of (2.3), we have $\int_{\mathbb{R}^3} |u|^p dx \leq S_p^{-1}\|u\|^p < +\infty$. It follows from (2.10) that $g(t) > 0$ for $0 < t < 1$ small enough and $g(t) < 0$ for $t > 1$ large enough. Since $g(t)$ is continuous, there exists $t_0 > 0$ such that $g(t_0) = \langle I'(t_0u), t_0u\rangle = 0$, i.e. $t_0u \in \mathcal{N}$. As a similar argument of Lemma 2.8, we can obtain the uniqueness of t_0. □

Lemma 2.10. *Assume there exists $u \in H$ with $u^\pm \neq 0$ such that $\langle I'(u), u^\pm\rangle \leq 0$, then the unique positive numbers pair (s_0,t_0) obtained in Lemma 2.8 satisfies* $0 < s_0, t_0 \leq 1$.

Proof. From Lemma 2.8, there exists a unique positive numbers pair (s_0,t_0) such that $s_0u^+ + t_0u^- \in \mathcal{M}$. Without loss of generally, we may suppose that $s_0 \geq t_0 > 0$. Since $s_0u^+ + t_0u^- \in \mathcal{M}$, we have

$$\begin{aligned} I'(s_0u^+ + t_0u^-), s_0u^+\rangle &= as_0^2\|u^+\|^2 + bs_0^4\|u^+\|^4 + bs_0^2t_0^2\|u^+\|^2\|u^-\|^2 \\ &\quad - \int_{\mathbb{R}^3} |s_0u^+|^p \ln|s_0u^+|dx. \end{aligned}$$

Therefore,

$$\begin{aligned}\int_{\mathbb{R}^3} |s_0 u^+|^p \ln |s_0 u^+| dx &= a s_0^2 \|u^+\|^2 + b s_0^4 \|u^+\|^4 + b s_0^2 t_0^2 \|u^+\|^2 \|u^-\|^2 \\ &\leq a s_0^2 \|u^+\|^2 + b s_0^4 \|u^+\|^4 + b s_0^4 \|u^+\|^2 \|u^-\|^2.\end{aligned} \tag{2.11}$$

Since $\langle I'(u), u^+ \rangle \leq 0$, one has

$$a\|u^+\|^2 + b\|u^+\|^4 + b\|u^+\|^2\|u^-\|^2 \leq \int_{\mathbb{R}^3} |u^+|^p \ln |u^+| dx.$$

Multiplying the both sides of the above equation with $-s_0^p$, then

$$- s_0^p \int_{\mathbb{R}^3} |u^+|^p \ln |u^+| dx \leq -a s_0^p \|u^+\|^2 - b s_0^p \|u^+\|^4 - b s_0^p \|u^+\|^2 \|u^-\|^2. \tag{2.12}$$

It follows from (2.11) and (2.12) that

$$s_0^p \ln s_0 \int_{\mathbb{R}^3} |u^+|^p dx \leq a(s_0^2 - s_0^p)\|u^+\|^2 + b(s_0^4 - s_0^p)\|u^+\|^4 + b(s_0^4 - s_0^p)\|u^+\|^2\|u^-\|^2.$$

Clearly, if $s_0 > 1$, the left-hand side of the above inequality is positive, while the right-hand side of the above inequality is always negative. This is a contradiction. Therefore, $s_0 \leq 1$. Similarly, we can also obtain $t_0 \leq 1$. □

Lemma 2.11. *The following minimax characterization hold*

$$\inf_{u \in \mathcal{N}} I(u) = c = \inf_{u \in H \setminus \{0\}} \max_{t \geq 0} I(tu),$$

and

$$\inf_{u \in \mathcal{M}} I(u) = m = \inf_{u \in H, u^{\pm} \neq 0} \max_{s,t \geq 0} I(su^+ + tu^-).$$

Moreover,

$$c > 0 \quad \text{and} \quad m > 0 \quad \text{are achieved.}$$

Proof. Firstly, we prove the second equality since the first equality is similar. On one hand, it follows from Lemma 2.5 that

$$\inf_{u \in H, u^{\pm} \neq 0} \max_{s,t \geq 0} I(su^+ + tu^-) \leq \inf_{u \in \mathcal{M}} \max_{s,t \geq 0} I(su^+ + tu^-) = \inf_{u \in \mathcal{M}} I(u) = m. \tag{2.13}$$

On the other hand, for all $u \in H$ with $u^{\pm} \neq 0$, Lemma 2.8 implies that there exists a unique positive numbers pair (s_0, t_0) such that $s_0 u^+ + t_0 u^- \in \mathcal{M}$. Let $v := s_0 u^+ + t_0 u^- \in \mathcal{M}$, we have

$$m = \inf_{v \in \mathcal{M}} I(v) \leq I(s_0 u^+ + t_0 u^-) \leq \max_{s,t \geq 0} I(su^+ + tu^-),$$

which implies that

$$m = \inf_{v \in \mathcal{M}} I(v) \leq \inf_{u \in H, u^{\pm} \neq 0} \max_{s,t \geq 0} I(su^+ + tu^-). \tag{2.14}$$

Thus, the conclusion directly follows from (2.13) and (2.14).

Next, we prove that $m > 0$ is achieved. Let $\{u_n\} \subset \mathcal{M}$ be a minimizing sequence, i.e. $I(u_n) \to m$ as $n \to \infty$. In light of (1.5) and (1.8), one has

$$\begin{aligned} m + o(1) &= I(u_n) - \frac{1}{p}\langle I'(u_n), u_n\rangle \\ &= a\left(\frac{1}{2} - \frac{1}{p}\right)\|u_n\|^2 + b\left(\frac{1}{4} - \frac{1}{p}\right)\|u_n\|^4 + \frac{1}{p^2}\int_{\mathbb{R}^3} |u_n|^p dx \\ &\geq a\left(\frac{1}{2} - \frac{1}{p}\right)\|u_n\|^2. \end{aligned}$$

This implies that $\{u_n\}$ is bounded in H. Thus, up to a subsequence, there exists $u_* \in H$ such that

$$\begin{cases} u_n^{\pm} \rightharpoonup u_*^{\pm}, & \text{in } H, \\ u_n^{\pm} \to u_*^{\pm}, & \text{in } L^q(\mathbb{R}^3),\ 2 \leq q < 6, \\ u_n^{\pm}(x) \to u_*^{\pm}(x), & \text{a.e. in } \mathbb{R}^3. \end{cases}$$

Since $\{u_n\} \subset \mathcal{M}$, we have $\langle I'(u_n), u_n^{\pm}\rangle = 0$. In light of (1.9), (2.2) and (2.3), for all $q \in (p, 6)$ and taking $\sigma = q - p$ in (2.2), we have

$$\begin{aligned} aS_q^{2/q}\left(\int_{\mathbb{R}^3} |u_n^{\pm}|^q dx\right)^{2/q} &\leq a\|u_n^{\pm}\|^2 \leq a\|u_n^{\pm}\|^2 + b\|u_n\|^2\|u_n^{\pm}\|^2 \\ &\leq \int_{\mathbb{R}^3} (|u_n^{\pm}|^p \ln|u_n^{\pm}|)^+ dx \\ &\leq \frac{1}{e(q-p)}\int_{\mathbb{R}^3} |u_n^{\pm}|^q dx. \end{aligned} \tag{2.15}$$

Thus,

$$\int_{\mathbb{R}^3} |u_n^{\pm}|^q dx \geq C > 0.$$

By Lemma 2.2, we get

$$\int_{\mathbb{R}^3} |u_*^{\pm}|^q dx \geq C > 0, \tag{2.16}$$

which implies that $u_*^{\pm} \neq 0$.

Since $\langle I'(u_n), u_n\rangle = \langle I'(u_n), u_n^+\rangle + \langle I'(u_n), u_n^-\rangle = 0$, in view of (2.3) and (2.15), we have

$$a\|u_n\|^2 \leq a\|u_n\|^2 + b\|u_n\|^4 \leq \int_{\mathbb{R}^3} (|u_n|^p \ln|u_n|)^+ dx \leq C\int_{\mathbb{R}^3} |u_n|^q dx \leq CS_q^{-1}\|u_n\|^q, \tag{2.17}$$

which implies that

$$\|u_n\| \geq C > 0.$$

If $\|u_n\| \to 0$ as $n \to \infty$, from (2.17) we know $\int_{\mathbb{R}^3} |u_n|^q dx \to 0$. Using Lemma 2.2 we get $\int_{\mathbb{R}^3} |u_*|^q dx = 0$, which is in contradiction with (2.16). Therefore

$$m = \lim_{n\to\infty}\left[a(\frac{1}{2} - \frac{1}{p})\|u_n\|^2 + b(\frac{1}{4} - \frac{1}{p})\|u_n\|^4 + \frac{1}{p^2}\int_{\mathbb{R}^3} |u_n|^p dx\right] \geq C > 0.$$

By the Lebesgue dominated convergence theorem and the weak semi-continuity of norm, we have

$$\begin{aligned} a\|u_*^{\pm}\|^2 + b\|u_*\|^2\|u_*^{\pm}\|^2 &\leq \liminf_{n\to\infty}\left(a\|u_n^{\pm}\|^2 + b\|u_n\|^2\|u_n^{\pm}\|^2\right) \\ &= \liminf_{n\to\infty}\int_{\mathbb{R}^3} |u_n^{\pm}|^p \ln|u_n^{\pm}| dx \\ &= \int_{\mathbb{R}^3} |u_*^{\pm}|^p \ln|u_*^{\pm}| dx. \end{aligned}$$

Together with (1.9), it shows that

$$\langle I'(u_*), u_*^{\pm}\rangle \leq 0.$$

According to Lemma 2.10, there are two positive constants $0 < s_0, t_0 \leq 1$ such that $s_0u_*^+ + t_0u_*^- \in \mathcal{M}$. Define $\tilde{u} := s_0u_*^+ + t_0u_*^-$, it follows from (1.5), (1.8) and weak semi-continuity of norm that

$$\begin{aligned}
m &\leq I(\tilde{u}) - \frac{1}{p}\langle I'(\tilde{u}), \tilde{u}\rangle \\
&= a\left(\frac{1}{2} - \frac{1}{p}\right)\|s_0u_*^+ + t_0u_*^-\|^2 + b\left(\frac{1}{4} - \frac{1}{p}\right)\|s_0u_*^+ + t_0u_*^-\|^4 \\
&\quad + \frac{1}{p^2}\int_{\mathbb{R}^3}|s_0u_*^+ + t_0u_*^-|^p dx \\
&= a\left(\frac{1}{2} - \frac{1}{p}\right)(s_0^2\|u_*^+\|^2 + t_0^2\|u_*^-\|^2) \\
&\quad + b\left(\frac{1}{4} - \frac{1}{p}\right)(s_0^4\|u_*^+\|^4 + t_0^4\|u_*^-\|^4 + 2s_0^2t_0^2\|u_*^+\|^2\|u_*^-\|^2) \\
&\quad + \frac{1}{p^2}\left(s_0^p\int_{\mathbb{R}^3}|u_*^+|^p dx + t_0^p\int_{\mathbb{R}^3}|u_*^-|^p dx\right) \\
&\leq a\left(\frac{1}{2} - \frac{1}{p}\right)\|u_*\|^2 + b\left(\frac{1}{4} - \frac{1}{p}\right)\|u_*\|^4 + \frac{1}{p^2}\int_{\mathbb{R}^3}|u_*|^p dx \\
&\leq \liminf_{n\to\infty}\left[a\left(\frac{1}{2} - \frac{1}{p}\right)\|u_n\|^2 + b\left(\frac{1}{4} - \frac{1}{p}\right)\|u_n\|^4 + \frac{1}{p^2}\int_{\mathbb{R}^3}|u_n|^p dx\right] \\
&\leq \liminf_{n\to\infty}\left[I(u_n) - \frac{1}{p}\langle I'(u_n), u_n\rangle\right] \\
&= m.
\end{aligned}$$

This means that $s_0 = t_0 = 1$, i.e. $\tilde{u} = u_* \in \mathcal{M}$ and $I(u_*) = m > 0$. By a similar argument as above, we have that $c > 0$ is achieved. □

Lemma 2.12. *The minimizers of* $\inf_{u\in\mathcal{N}} I(u)$ *and* $\inf_{u\in\mathcal{M}} I(u)$ *are critical points of* I.

Proof. According to Lemma 2.11, we have $u_* = u_*^+ + u_*^- \in \mathcal{M}$ and $I(u_*) = m$, Therefore it is only necessary to prove that $I'(u_*) = 0$. Arguing by contradiction, assume that $I'(u_*) \neq 0$. Then, there exist $\delta > 0$ and $\gamma > 0$ such that

$$\|I'(u)\| \geq \gamma, \qquad \forall \|u - u_*\| \leq 3\delta \text{ and } u \in H.$$

Let $D := \left(\frac{1}{2}, \frac{3}{2}\right) \times \left(\frac{1}{2}, \frac{3}{2}\right)$, by Lemma 2.7, one has

$$\tilde{m} := \max_{(s,t)\in\partial D} I(su_*^+ + tu_*^-) < m. \tag{2.18}$$

Set $\varepsilon := \min\{(m - \tilde{m})/3, \delta\gamma/8\}$ and $S_\delta := B(u_*, \delta)$. By applying [19, Lemma 2.3], there exists a deformation $\eta \in ([0,1] \times H, H)$ such that

(i) $\eta(1, u) = u$, if $u \notin I^{-1}([m - 2\varepsilon, m + 2\varepsilon]) \cap S_{2\delta}$;

(ii) $\eta(1, I^{m+\varepsilon} \cap S_\delta) \subset I^{m-\varepsilon}$;

(iii) $I(\eta(1, u)) \leq I(u)$, $\forall u \in H$.

From (iii) and Lemma 2.7, for each $s, t > 0$ with $|s-1|^2 + |t-1|^2 \geq \delta^2/\|u_*\|^2$, one has

$$I(\eta(1, su_*^+ + tu_*^-)) \leq I(su_*^+ + tu_*^-) < I(u_*) = m. \tag{2.19}$$

By Lemma (2.3), we have $I(su_*^+ + tu_*^-) \leq I(u_*) = m$ for $s, t > 0$. According to (ii), one has

$$I(\eta(1, su_*^+ + tu_*^-)) \leq m - \varepsilon, \qquad \forall s, t > 0, |s-1|^2 + |t-1|^2 < \delta^2/\|u_*\|^2. \tag{2.20}$$

Thus, from (2.19) and (2.20), we get

$$\max_{(s,t)\in \bar{D}} I(\eta(1, su_*^+ + tu_*^-)) < m. \tag{2.21}$$

Let $h(s,t) = su_*^+ + tu_*^-$, we prove that $\eta(1, h(D)) \cap \mathcal{M} \neq \emptyset$, which contradicts the definition of m. Define

$$k(s,t) := \eta(1, h(s,t)),$$

$$\Phi(s,t) := \left(\langle I'(h(s,t)), u_*^+\rangle, \langle I'(h(s,t)), u_*^-\rangle\right) := \left(\Phi_1(s,t), \Phi_2(s,t)\right),$$

and

$$\Psi(s,t) := \left(\frac{1}{s}\langle I'(k(s,t)), (k(s,t))^+\rangle, \frac{1}{t}\langle I'(k(s,t)), (k(s,t))^-\rangle\right),$$

where

$$\begin{aligned}\Phi_1(s,t) &= \frac{1}{s}\langle I'(su_*^+ + tu_*^-), su_*^+\rangle \\ &= a(s - s^{p-1})\|u_*^+\|^2 + b(s^3 - s^{p-1})\|u_*^+\|^4 + b(st^2 - s^{p-1})\|u_*^+\|^2\|u_*^-\|^2 \\ &\quad - s^{p-1}\ln s \int_{\mathbb{R}^3} |u_*^+|^p dx,\end{aligned}$$

and

$$\begin{aligned}\Phi_2(s,t) &= \frac{1}{t}\langle I'(su_*^+ + tu_*^-), tu_*^-\rangle \\ &= a(t - t^{p-1})\|u_*^-\|^2 + b(t^3 - t^{p-1})\|u_*^-\|^4 + b(ts^2 - t^{p-1})\|u_*^+\|^2\|u_*^-\|^2 \\ &\quad - t^{p-1}\ln t \int_{\mathbb{R}^3} |u_*^-|^p dx.\end{aligned}$$

Obviously, Φ is C^1 functions. Moreover, by a direct calculation we have

$$\left.\frac{\partial \Phi_1(s,t)}{\partial s}\right|_{(1,1)} = a(2-p)\|u_*^+\|^2 + b(4-p)\|u_*^+\|^4 + b(2-p)\|u_*^+\|^2\|u_*^-\|^2 - \int_{\mathbb{R}^3} |u_*^+|^p dx,$$

and

$$\left.\frac{\partial \Phi_1(s,t)}{\partial t}\right|_{(1,1)} = 2b\|u_*^+\|^2\|u_*^-\|^2.$$

Similarly, we obtain

$$\left.\frac{\partial \Phi_2(s,t)}{\partial s}\right|_{(1,1)} = 2b\|u_*^+\|^2\|u_*^-\|^2,$$

and

$$\left.\frac{\partial \Phi_2(s,t)}{\partial t}\right|_{(1,1)} = a(2-p)\|u_*^-\|^2 + b(4-p)\|u_*^-\|^4 + b(2-p)\|u_*^+\|^2\|u_*^-\|^2 - \int_{\mathbb{R}^3} |u_*^-|^p dx.$$

Let

$$M = \begin{bmatrix} \frac{\partial \Phi_1(s,t)}{\partial s}\Big|_{(1,1)} & \frac{\partial \Phi_2(s,t)}{\partial s}\Big|_{(1,1)} \\ \frac{\partial \Phi_1(s,t)}{\partial t}\Big|_{(1,1)} & \frac{\partial \Phi_2(s,t)}{\partial t}\Big|_{(1,1)} \end{bmatrix},$$

then we have that

$$\begin{aligned} \det M &= \frac{\partial \Phi_1(s,t)}{\partial s}\Big|_{(1,1)} \times \frac{\partial \Phi_2(s,t)}{\partial t}\Big|_{(1,1)} - \frac{\partial \Phi_1(s,t)}{\partial t}\Big|_{(1,1)} \times \frac{\partial \Phi_2(s,t)}{\partial s}\Big|_{(1,1)} \\ &= \left[a(2-p)\|u_*^+\|^2 + b(4-p)\|u_*^+\|^4 + b(2-p)\|u_*^+\|^2\|u_*^-\|^2 - \int_{\mathbb{R}^3} |u_*^+|^p dx\right] \\ &\quad \times \left[a(2-p)\|u_*^-\|^2 + b(4-p)\|u_*^-\|^4 + b(2-p)\|u_*^+\|^2\|u_*^-\|^2 - \int_{\mathbb{R}^3} |u_*^-|^p dx\right] \\ &\quad - 4b^2\|u_*^+\|^4\|u_*^-\|^4 \\ &> 0. \end{aligned}$$

Hence, the solution of equation (1.1) is the unique isolated zero point of $\Phi(s,t)$. Then, the topological degree theory [6, 21] implies that $\deg(\Phi, D, 0) = 1$. Combining (2.18) with (i), we have that $h = k$ on ∂D, then we obtain

$$\deg(\Phi, D, 0) = \deg(\Psi, D, 0) = 1.$$

So, $\Psi(s_0, t_0) = 0$ for some $(s_0, t_0) \in D$, and

$$\eta(1, h(s_0, t_0)) = k(s_0, t_0) \in \mathcal{M},$$

which is a contradiction with (2.21). So we get that $I'(u_*) = 0$. Similarly, we can prove that any minimizer of $\inf_{u\in\mathcal{N}} I(u)$ are a critical point of $I(u)$. □

3 Proof of theorems

Firstly, we prove the existence of positive ground state solutions for equation (1.1).

Proof of Theorem 1.1. According to Lemma 2.11 and Lemma 2.12, there exists $\bar{u} \in \mathcal{N}$ such that

$$I(\bar{u}) = c, \qquad I'(\bar{u}) = 0.$$

Now, we only need to prove that $\bar{u}$ is a positive solution of equation (1.1). Indeed, replacing $I(u)$ with the functional

$$\begin{aligned} I(\bar{u}) = \frac{a}{2}\int_{\mathbb{R}^3}(|\nabla \bar{u}|^2 + V(x)\bar{u}^2)dx + \frac{b}{4}\left(\int_{\mathbb{R}^3}(|\nabla \bar{u}|^2 + V(x)\bar{u}^2)dx\right) \\ - \frac{1}{p}\int_{\mathbb{R}^3} |\bar{u}^+|^p \ln|\bar{u}^+| dx + \frac{1}{p^2}\int_{\mathbb{R}^3} |\bar{u}^+|^p dx. \end{aligned}$$

In this way we can get a solution $\bar{u}$ such that

$$\left(a + b\int_{\mathbb{R}^3} |\nabla \bar{u}|^2 + V(x)\bar{u}^2 dx\right)[-\Delta \bar{u} + V(x)\bar{u}] = |\bar{u}^+|^{p-2}\bar{u}^+ \ln|\bar{u}^+|, \qquad x \in \mathbb{R}^3. \tag{3.1}$$

Multiplying the both sides of (3.1) with u^-, we deduce that

$$a\|\bar{u}^-\|^2 + b\|\bar{u}^-\|^4 + b\|\bar{u}^+\|^2\|\bar{u}^-\|^2 = 0.$$

It follows that $\bar{u}^-(x) = 0$, and then $\bar{u}(x) \geq 0$ for a.e. $x \in \mathbb{R}^3$. The regularity theory of elliptic equation implies that $\bar{u} \in C^2(\mathbb{R}^3)$ is nonnegative classical solution of equation (1.1). Since $p \in (4,6)$, we know that $\lim_{\bar{u}\to 0^+} \bar{u}^{p-1}\ln \bar{u} = 0$. It makes sense to denote $\bar{u}^{p-1}\ln \bar{u} = 0$ for $\bar{u} = 0$. Let $\Omega^+ = \{\bar{u} \in \mathbb{R}^3 : \bar{u}(x) \geq 0\}$. Then $\bar{u}(x)$ is positive solution in $\mathbb{R}^3$ if $\partial\Omega^+ = \emptyset$. In the following, we prove that $\partial\Omega^+ = \emptyset$. Otherwise, let $x_0 \in \partial\Omega^+$ and $B_\rho(x_0) = \{x \in \mathbb{R}^3 : |x - x_0| < \rho\}$ with small $\rho > 0$. Define

$$\alpha = \left(a + b\int_{\mathbb{R}^3} |\nabla\bar{u}|^2 + V(x)\bar{u}^2 dx\right) > 0,$$

and

$$c(x) = \left(a + b\int_{\mathbb{R}^3} |\nabla\bar{u}|^2 + V(x)\bar{u}^2 dx\right) V(x) - \bar{u}^{p-1}\ln|\bar{u}|.$$

Then, $\bar{u}|_{B_\rho(x_0)}$ is nontrivial solution of the following boundary value problem

$$-\alpha\triangle v + c(x)v = 0, \qquad x \in B_\rho(x_0) \quad \text{and} \quad v(x) = \bar{u}(x) \quad \text{for } x \in \partial B_\rho(x_0).$$

Under the assumptions, we see that $c(x) > 0$ in $B_\rho(x_0)$ for $\rho > 0$ small enough. By the maximum principle [18], we see that $\bar{u}(x) > 0$ for all $x \in B_\rho(x_0)$, which contradicts to that $x_0 \in \partial\Omega^+$. In conclusion, $\bar{u}$ is a positive ground state solution of equation (1.1). Thus the proof of Theorem 1.1 is completed. □

Secondly, we verify that equation (1.1) has a ground state sign-changing solution with precisely two nodal domains.

Proof of Theorem 1.2. In light of Lemma 2.11 and Lemma 2.12, there exists $u_* \in \mathcal{M}$ such that

$$I(u_*) = m, \qquad I'(u_*) = 0. \tag{3.2}$$

Now, we show that u_* has exactly two nodal domains. Set $u_* = u_1 + u_2 + u_3$, where

$$u_1 \geq 0, \qquad u_2 \leq 0, \qquad \Omega_1 \cap \Omega_2 = \emptyset, \qquad u_1|_{\mathbb{R}^3\setminus\Omega_1} = u_2|_{\mathbb{R}^3\setminus\Omega_2} = u_3|_{\Omega_1\cup\Omega_2} = 0, \tag{3.3}$$

$$\Omega_1 := \{x \in \mathbb{R}^3 : u_1 > 0\}, \qquad \Omega_2 := \{x \in \mathbb{R}^3 : u_2 < 0\},$$

and Ω_1, Ω_2 are connected open subsets of $\mathbb{R}^3$. Letting $v = u_1 + u_2$, then $v^+ = u_1$ and $v^- = u_2$, i.e. $v^\pm \neq 0$. Note that $I'(u_*) = 0$, by a straightforward calculation, we can obtain

$$\langle I'(v), v^+\rangle = -b\|v^+\|^2\|u_3\|^2, \tag{3.4}$$

and

$$\langle I'(v), v^-\rangle = -b\|v^-\|^2\|u_3\|^2. \tag{3.5}$$

It follows from (1.5), (1.8), (2.4), (3.2)–(3.5) that

$$\begin{aligned} m = I(u_*) &= I(u_*) - \frac{1}{p}\langle I'(u_*), u_*\rangle \\ &= I(v) + I(u_3) + \frac{b}{2}\|v\|^2\|u_3\|^2 - \frac{1}{p}\left[\langle I'(v), v\rangle + \langle I'(u_3), u_3\rangle + 2b\|v\|^2\|u_3\|^2\right] \end{aligned}$$

$$
\begin{aligned}
&\geq \sup_{s,t\geq 0}\left[I(sv^+ + tv^-) + \frac{1-s^p}{p}\langle I'(v), v^+\rangle + \frac{1-t^p}{p}\langle I'(v), v^-\rangle\right] \\
&\quad + I(u_3) - \frac{1}{p}\langle I'(v), v\rangle - \frac{1}{p}\langle I'(u_3), u_3\rangle \\
&\geq \sup_{s,t\geq 0}\left[I(sv^+ + tv^-) + \frac{bs^p}{p}\|v^+\|^2\|u_3\|^2 + \frac{bt^p}{p}\|v^-\|^2\|u_3\|^2\right] \\
&\quad + a\left(\frac{1}{2}-\frac{1}{p}\right)\|u_3\|^2 + b\left(\frac{1}{4}-\frac{1}{p}\right)\|u_3\|^4 + \frac{1}{p^2}\int_{\mathbb{R}^3}|u_3|^p dx \\
&\geq \max_{s,t\geq 0} I(sv^+ + tv^-) + a\left(\frac{1}{2}-\frac{1}{p}\right)\|u_3\|^2 \\
&\geq m + a\left(\frac{1}{2}-\frac{1}{p}\right)\|u_3\|^2,
\end{aligned}
$$

which implies that $u_3 = 0$. Therefore, u_* has exactly two nodal domains.

Next, we show that the energy of sign-changing solution of equation (1.1) is strictly larger than twice of the energy of positive ground state solution. By Lemma 2.9, there exist $s_*, t_* > 0$ such that $s_*u_*^+, t_*u_*^- \in \mathcal{N}$. Then it follows from (3.2) and Lemma 2.7 that

$$
\begin{aligned}
m = I(u_*) &\geq I(s_*u_*^+ + t_*u_*^-) \\
&= I(s_*u_*^+) + I(t_*u_*^-) + 2bs_*^2t_*^2\|u_*^+\|^2\|u_*^-\|^2 \\
&> I(s_*u_*^+) + I(t_*u_*^-) \geq 2c > 0.
\end{aligned}
$$

To sum up, u_* is a ground state sign-changing solution of equation (1.1) with precisely two nodal domains. Besides, $m > 2c$. Then, the proof of Theorem 1.2 is completed. □

Finally, we prove that equation (1.1) has a sequence of solutions to infinity by the following symmetric mountain pass theorem:

Theorem 3.1 ([15, Theorem 9.12])**.** *Let E be an infinite dimensional Banach space, and let $I \in C^1(E, \mathbb{R})$ be even, satisfying (PS) condition and $I(0) = 0$. If $E = V \bigoplus X$, where V is finite dimensional and I satisfies*

- *(i) there are constants $\rho, \alpha > 0$ such that $I|_{\partial B_\rho \cap X} \geq \alpha$,*
- *(ii) for each finite dimensional subspace $\tilde{E} \subset E$, there exists an $R = R(\tilde{E})$ such that $I \leq 0$ on $\tilde{E}\backslash B_{R(\tilde{E})}$,*

then I possesses an unbounded sequence critical values.

Lemma 3.2. *Assume that (V_1)–(V_2) hold, then I satisfies (PS) condition.*

Proof. Let $\{u_n\} \subset H$ be a sequence with $\{I(u_n)\}$ bounded and $I'(u_n) \to 0$. We first claim that $\{u_n\}$ is bounded in H. Indeed,

$$
\begin{aligned}
C + o(1)\|u_n\| &\geq I(u_n) - \frac{1}{p}\langle I'(u_n), u_n\rangle \\
&= a\left(\frac{1}{2}-\frac{1}{p}\right)\|u_n\|^2 + b\left(\frac{1}{4}-\frac{1}{p}\right)\|u_n\|^4 + \frac{1}{p^2}\int_{\mathbb{R}^3}|u_n|^p dx \\
&\geq a\left(\frac{1}{2}-\frac{1}{p}\right)\|u_n\|^2.
\end{aligned}
$$

This implies that $\{u_n\}$ is bounded in H. Going if necessary up to subsequence, we may assume that there exists $u \in H$ such that

$$\begin{cases} u_n \rightharpoonup u, & \text{in } H, \\ u_n \to u, & \text{in } L^q(\mathbb{R}^3),\ 2 \le q < 6, \\ u_n(x) \to u(x), & \text{a.e. in } \mathbb{R}^3. \end{cases} \tag{3.6}$$

By $\lim_{n\to\infty} \|\langle I'(u_n), u_n - u\rangle\| \le \lim_{n\to\infty} \|I'(u_n)\| \|u_n - u\| = 0$ and $\|\langle I'(u), u_n - u\rangle\| \le \lim_{n\to\infty} \|I'(u_n)\| \|u_n - u\| = 0$, we deduce that

$$\langle I'(u_n) - I'(u), u_n - u\rangle = \langle I'(u_n), u_n - u\rangle - \langle I'(u), u_n - u\rangle \to 0, \quad \text{as } n \to \infty.$$

On the other hand, it follows from (3.6) and Hölder's inequality that

$$\begin{aligned} \lim_{n\to\infty} \langle u, u_n - u\rangle &= \lim_{n\to\infty} \int_{\mathbb{R}^3} \nabla u[\nabla u_n - \nabla u] + V(x)u(u_n - u)dx \\ &\le \int_{\mathbb{R}^3} \nabla u[\nabla u - \nabla u]dx + \left(\int_{\mathbb{R}^3} (V(x)u)^2 dx\right)^{1/2} |u_n - u|_2 \\ &= 0. \end{aligned}$$

Therefore, by some preliminary calculations, one has

$$\begin{aligned} &(a + b\|u_n\|^2)\|u_n - u\|^2 \\ &\quad= (a + b\|u_n\|^2) \int_{\mathbb{R}^3} [\nabla u_n \nabla(u_n - u) + V(x)u_n(u_n - u)]dx \\ &\qquad - (a + b\|u\|^2 + b\|u_n\|^2 - b\|u\|^2) \int_{\mathbb{R}^3} [\nabla u \nabla(u_n - u) + V(x)u(u_n - u)]dx \\ &\quad= \langle I'(u_n), u_n - u\rangle + b(\|u\|^2 - \|u_n\|^2) \int_{\mathbb{R}^3} [\nabla u \nabla(u_n - u) + V(x)u(u_n - u)]dx \\ &\qquad + \int_{\mathbb{R}^3} |u_n|^{p-2}u_n(u_n - u)\ln|u_n|dx - \langle I'(u), u_n - u\rangle - \int_{\mathbb{R}^3} |u|^{p-2}u(u_n - u)\ln|u|dx \\ &\quad= \langle I'(u_n) - I'(u), u_n - u\rangle + b(\|u\|^2 - \|u_n\|^2)\langle u, u_n - u\rangle \\ &\qquad + \int_{\mathbb{R}^3} (|u_n|^{p-2}u_n \ln|u_n| - |u|^{p-2}u\ln|u|)(u_n - u)dx. \end{aligned}$$

We obtain the conclusion if the last term of the above formula tend to zero as $n \to +\infty$. Indeed, in view of (1.7), (3.6) and Hölder's inequality, for any $\varepsilon > 0$ small enough we deduce that

$$\begin{aligned} &\left| \int_{\mathbb{R}^3} (|u_n|^{p-2}u_n \ln|u_n| - |u|^{p-2}u\ln|u|)(u_n - u)dx \right| \\ &\qquad \le \int_{\mathbb{R}^3} \left(||u_n|^{p-1}\ln|u_n|| + ||u|^{p-1}\ln|u||\right) |u_n - u|dx \\ &\qquad \le \int_{\mathbb{R}^3} \left[\varepsilon(|u_n| + |u|) + C_\varepsilon(|u_n|^{q-1} + |u|^{q-1})\right] |u_n - u|dx \\ &\qquad \le 4\varepsilon\left(|u_n|_2^2 + |u|_2^2\right) + C_\varepsilon\left(|u_n|_q^{q-1} + |u|_q^{q-1}\right)|u_n - u|_q \\ &\qquad \le \varepsilon C + C_\varepsilon|u_n - u|_q. \end{aligned}$$

These estimates show that $u_n \to u$ in H, so I satisfies (PS) condition. □

Proof of Theorem 1.3. In Theorem 3.1, let $E = H$ and the functional I given by (1.5). By Lemma 3.2, the functional I satisfies (PS) condition, so we just need to verify that I satisfies conditions (i) and (ii) of Theorem 3.1. Note that

$$\begin{aligned} I(u) &\geq \frac{a}{2}\|u\|^2 + \frac{b}{4}\|u\|^4 - \frac{1}{p}\int_{\mathbb{R}^3} |u|^p \ln|u| dx \\ &\geq \frac{a}{2}\|u\|^2 - \frac{1}{p}\int_{\{x:|u|\geq 1\}} |u|^p \ln|u| dx \\ &\geq \frac{a}{2}\|u\|^2 - C_1\|u\|^{p+\sigma}, \end{aligned}$$

where $0 < \sigma < 6 - p$. Thus, we can choose $\rho > 0$ and $\alpha > 0$ small enough such that $I|_{\partial B_\rho} \geq \alpha > 0$.

We suppose that $\tilde{E}$ is a finite dimensional subspace of H, and for $u \in \tilde{E}\backslash\{0\}$, define $v = u/\|u\|$, then $\|v\| = 1$. one has

$$\begin{aligned} I(u) &= \|u\|^p\left(\frac{a}{2}\|u\|^{2-p} + \frac{b}{4}\|u\|^{4-p} - \frac{1}{p}\int_{\mathbb{R}^3} |v|^p \ln|v| dx + \frac{1}{p^2}\int_{\mathbb{R}^3} |v|^p dx - \frac{1}{p}(\ln\|u\|)\int_{\mathbb{R}^3} |v|^p dx\right) \\ &\leq \|u\|^p\left(\frac{a}{2}\|u\|^{2-p} + \frac{b}{4}\|u\|^{4-p} + C_1\|v\|^2 + C_2\|v\|^q + \frac{S_p^{-1}}{p^2}\|v\|^p - \frac{1}{p}(\ln\|u\|)\int_{\mathbb{R}^3} |v|^p dx\right) \\ &= \|u\|^p\left(\frac{a}{2}\|u\|^{2-p} + \frac{b}{4}\|u\|^{4-p} + C - \frac{1}{p}(\ln\|u\|)\int_{\mathbb{R}^3} |v|^p dx\right). \end{aligned}$$

Thus, there exists an $R = R(\tilde{E})$ large enough such that $I \leq 0$ on $\tilde{E}\backslash B_{R(\tilde{E})}$.

To sum up, all conditions of Theorem 3.1 are satisfied. Therefore, equation (1.1) owns a sequence of solutions $\{u_n\}$ with $I(u_n) \to +\infty$ as $n \to \infty$. This completes the proof of Theorem 1.3. □

Abstract. We consider the class $\mathcal{X}$ of 3-dimensional piecewise smooth vector fields that admit a first integral which leaves invariant any sphere centered at the origin. In this class, we prove that a linear vector field does not admit isolated invariant cones. Moreover, we provide the existence of at least ten 1-parameter families of crossing closed trajectories for quadratic vector fields in $\mathcal{X}$.

Keywords: piecewise smooth vector fields with invariant spheres, invariant cones, 1-parameter families of closed trajectories.

2020 Mathematics Subject Classification: 34C07, 34C23, 37C27.

1 Introduction

Differential equations and dynamical systems can be used to model natural phenomena and we can obtain information about it from their solutions. An interesting tool used to understand the behavior of the solutions of a dynamical system is the existence of first integrals because, when they exist, the trajectories of the corresponding vector field remain restricted to the level surfaces of these functions. We say that a n-dimensional differential system is completely integrable when it has $n-1$ independent first integrals and the orbits of it are obtained just intersecting the level sets of the first integrals. Moreover, if it has less than $n-1$ first integrals, it is said to be partially integrable. The $2n$-dimensional Hamiltonian systems are particular cases of partially integrable systems, for which we commonly study their behavior restricted to their invariant level sets. The study of Hamiltonian systems has many applications and it is very important in mechanics, for example, as we can see in [28].

Observe that, if the system restricted to an invariant level set of the first integral has a hyperbolic closed trajectory, then the original system has a 1-parameter family of hyperbolic

periodic orbits. As we will work with 3-dimensional piecewise smooth vector fields having a first integral that keeps invariant all the spheres centered at origin, in fact we deal with 1-parameter radial families. For more details about how to consider 3-dimensional smooth vector fields (resp. 3-dimensional piecewise smooth vector fields) with invariant spheres as 1-parameter radial family see for instance Section 5 of [4] (resp. [5]). In [6] it was proved that the behavior of a homogeneous vector field restricted to an invariant sphere of radius $\rho = 1$ is topologically equivalent to the behavior of the same system restricted to any other level. So, when a homogeneous vector field restricted to an invariant sphere has a limit cycle (resp. a center), the 3-dimensional vector field has an isolated (resp. non-isolated) invariant cone fulfilled of closed trajectories. On the other hand, the behavior of non-homogeneous vector fields could be totally different in distinct levels of invariant spheres (see again [6]). In this case, each hyperbolic closed trajectory restricted to an invariant sphere of radius ρ generates a 1-parameter radial family of closed trajectories of the 3-dimensional vector field near the sphere of radius ρ. So, it has locally a topological invariant cylinder near the sphere of radius ρ fulfilled of closed trajectories. In general, it is very difficult to classify the invariant surfaces generated by these 1-parameter families, as they can have very different behavior depending on the vector field. Understanding it certainly depends on the knowledge on the behavior of the vector fields restricted to each invariant sphere.

As these invariant surfaces are generated by closed trajectories of the restricted vector field, this problem is strictly related to the Hilbert's 16th problem, presented by D. Hilbert in 1900, at the International Congress of Mathematicians, in Paris. The second part of the Hilbert's 16th problem asks for an estimation of the maximal number of limit cycles that a planar polynomial vector field can have, being one of the most important open problems in Qualitative Theory of Ordinary Differential Equations and Dynamical Systems. For more details we refer the reader to [20].

In the last years, many classes of piecewise smooth dynamical systems have also been studied and a rigorous formulation of their qualitative properties was given by Filippov, in [15]. This theory is very important in many areas of science, see for instance [12]. Note that, the Hilbert's 16th problem has been extended to piecewise polynomial vector fields in a natural way (see for example [16, 24]). In part of this paper we will analyze the existence of (crossing) invariant cones for piecewise linear and quadratic vector fields. This dynamics also appears in 3-dimensional piecewise linear systems as in [7–9].

In this work, we consider 3-dimensional piecewise differential vector fields with a separation set given by $\Sigma = \{(x, y, z) \in \mathbb{R}^3 : z = 0\}$, that is

$$Y(x, y, z) = \begin{cases} X^+(x, y, z), & z \geq 0, \\ X^-(x, y, z), & z \leq 0. \end{cases} \tag{1.1}$$

As Y can be multi-valued in Σ, we will follow the Filippov's convention on the escaping and sliding regions, see again [15].

In the piecewise smooth case, as in the smooth one, the integrability of the vector fields $X^{\pm}$ is an important tool used to understand the behavior of the trajectories of $Y = (X^+, X^-)$, in the classification of phase portraits, and also to answer questions related to the existence of crossing limit cycles (i.e. isolated crossing periodic orbits). See Section 2.2 and also [27] for more details. Furthermore, when both $X^{\pm}$ have the same first integral the dimension of the phase space where the trajectories of the piecewise smooth vector field $Y = (X^+, X^-)$ are defined is reduced by one. This property has motivated us to study 3-dimensional piecewise smooth vector fields partially integrable (that is, having both $X^{\pm}$ the same first integral $H : \mathbb{R}^3 \to \mathbb{R}$) restricted to invariant level sets of H, as we explain on the following.

Let $\mathfrak{X}$ be the class of smooth vector fields $X : \mathbb{R}^3 \to \mathbb{R}^3$ that admits $H(x, y, z) = x^2 + y^2 + z^2$ as a first integral. This class was previously studied in [6]. Note that all the spheres centered at the origin with radius ρ, $\mathbb{S}^2_\rho = \{(x, y, z) \in \mathbb{R}^3 : x^2 + y^2 + z^2 = \rho^2\}$, are invariant by the flow of $X \in \mathfrak{X}$. We denote by $\mathfrak{X}_n$ (resp. $\mathfrak{X}^H_n$) the class of polynomials (resp. homogeneous polynomials) vector fields of degree n in $\mathfrak{X}$. In this work, we consider the class of piecewise differential vector fields given by (1.1) such that $X^{\pm} \in \mathfrak{X}$. We denote this class by $\mathcal{X}$ and by $\mathcal{X}_n$ (resp. $\mathcal{X}^H_n$) when $X^{\pm} \in \mathfrak{X}_n$ (resp. $X^{\pm} \in \mathfrak{X}^H_n$). Hence, if $Y \in \mathcal{X}$, then any sphere centered at the origin is invariant by the flow of the piecewise differential system Y. Observe that we can consider invariant ellipsoids instead of invariant spheres. Although all the results can be easily generalized to this case, we have preferred not to do it here, to avoid repetitions. In the sequel, we describe the results that we have obtained for piecewise linear and quadratic (homogeneous and nonhomogeneous) differential systems in $\mathcal{X}$. We remark that, in general, the 3-dimensional homogeneous vector fields will not be when we consider them projected to a 2-dimensional space.

Before introducing our main results, we recall some properties about homogeneous vector fields $X \in \mathfrak{X}^H$ proved in [6]. $X \in \mathfrak{X}_1$ is homogeneous and it writes in the form

$$X(\mathrm{x}; a_1, a_2, a_3) = (-a_1 y - a_2 z, a_1 x - a_3 z, a_2 x + a_3 y), \tag{1.2}$$

where, $\mathrm{x} = (x, y, z)$. Moreover, (1.2) has (generically) only a line of equilibrium points passing through the origin. Further, when we consider the restriction of (1.2) to the invariant spheres $\mathbb{S}^2_\rho$, we conclude that (1.2) has only two equilibrium points on each sphere which are centers and antipodals of each other (see Lemma 3.1, for more details). It means that the 3-dimensional smooth vector field (1.2) has a continuous of invariant cones fulfilled of non-isolated closed trajectories. In Proposition 4.3 we show that a quadratic homogeneous vector field $X \in \mathfrak{X}^H_2$ can present an isolated invariant cone, fulfilled of closed trajectories, showing an important difference between linear and quadratic homogeneous vector fields in the class $\mathfrak{X}$.

Using (1.2) we can see that each 3-dimensional piecewise linear system $Y = (X^+, X^-) \in \mathcal{X}_1$ is of the form

$$Y(x, y, z) = \begin{cases} X^+(\mathrm{x}; a_1^+, a_2^+, a_3^+), & z \geq 0, \\ X^-(\mathrm{x}; a_1^-, a_2^-, a_3^-), & z \leq 0, \end{cases} \tag{1.3}$$

with

$$X^{\pm}(\mathrm{x}; a_1^{\pm}, a_2^{\pm}, a_3^{\pm}) = (-a_1^{\pm} y - a_2^{\pm} z, a_1^{\pm} x - a_3^{\pm} z, a_2^{\pm} x + a_3^{\pm} y). \tag{1.4}$$

As explained in Section 2.3, we use the stereographic projection to study the local behavior of $Y \in \mathcal{X}$ restricted to the invariant spheres. Moreover, the projection of a linear (resp. quadratic) vector field defined on an invariant sphere is a quadratic (resp. cubic) planar vector field. We observe that they lose the property of homogeneity once projected. Usually, the behavior of piecewise smooth vector fields is richer than the behavior of the smooth ones. This property made us to look for isolated invariant cones in $\mathcal{X}_1$. However, the next result proves that they do not exist.

Theorem 1.1. *No piecewise differential system $Y \in \mathcal{X}_1$, given by (1.3), admits an isolated invariant cone.*

We prove it in Section 3, where we also show the possible phase portraits of (1.3), restricted to the invariant sphere $\mathbb{S}^2_\rho$, with respect to the admissibility of its equilibria (see Figures 3.3

and 3.4). We point out that the existence of crossing invariant cones for piecewise linear vector fields which are continuous in the separation set Σ was studied in [8,9]. But the results cannot be applied to our study because the continuity condition is not satisfied.

Inspired by the homogeneity property of the linear vector fields in $\mathcal{X}$, we study some families in $\mathcal{X}_2^H$ in Section 4, where we prove that they can present isolated and non-isolated crossing invariant cones, showing an important difference between piecewise linear and quadratic homogeneous vector fields in $\mathcal{X}$. We prove it considering the restriction of a piecewise smooth vector field $Y \in \mathcal{X}_2^H$ to the sphere of radius $\rho = 1$ and showing that they can present centers for some specific values of the coefficients and crossing limit cycles for others. Another difference can be observed when we compare the piecewise quadratic homogeneous vector fields defined on $\mathbb{S}_1^2$ and on $\mathbb{R}^2$. To see it, we recall briefly the concept of reversible vector field defined in open regions of $\mathbb{R}^m$. Let $\varphi : \mathbb{R}^m \to \mathbb{R}^m$ be a $\mathcal{C}^r$-involution. It means that $\varphi \circ \varphi(\mathrm{x}) = \mathrm{x}$, where $\mathrm{x} \in \mathbb{R}^m$. Let $\mathrm{Fix}(\varphi) = \{\mathrm{x}; \varphi(\mathrm{x}) = \mathrm{x}\}$. We say that a differential vector field X, defined in $\mathbb{R}^m$, is φ-reversible if $D\varphi \circ X = -X \circ \varphi$, where $D\varphi$ denotes the Jacobian matrix of φ. We say that X is reversible with respect to a line (resp. a point) when $\mathrm{Fix}(\varphi)$ is a line (resp. a point). We refer [23], for an interesting survey about reversible differential systems. We recall that any quadratic homogeneous vector field defined in $\mathbb{R}^2$ is reversible with respect to the origin and, because of that, it does not have an equilibrium point of center type (see [2]). Thus, we cannot consider the center-focus problem for piecewise quadratic homogeneous vector fields on the plane. Note that the concept of reversibility can also be considered for piecewise smooth vector fields. For more details see Section 2.2.

Finally, we have also analyzed the local behavior of a piecewise quadratic vector field $\mathcal{X}_2$, proving the following result.

Theorem 1.2. *There exist at least ten* 1*-parameter radial families of invariant crossing closed trajectories in the quadratic family* $\mathcal{X}_2$*, near the radius* $\rho = 1$.

For proving Theorem 1.2, see Section 5, we consider the restriction of a piecewise smooth vector field $Y \in \mathcal{X}_2$ to the invariant sphere of radius $\rho = 1$ and we show that it has 10 hyperbolic crossing limit cycles on the sphere $\mathbb{S}_1^2$. Since these crossing limit cycles are hyperbolic on $\mathbb{S}_1^2$, they are normally hyperbolic with respect to the radial direction. This implies that $Y \in \mathcal{X}_2$ has at least ten 1-parameter radial families of crossing periodic orbits which cross the sphere of radius ρ in isolated closed trajectories, with $1 - \varepsilon < \rho < 1 + \varepsilon$ for ε sufficiently small. So, the 3-dimensional vector field $Y \in \mathcal{X}_2$ has invariant surfaces, foliated by crossing closed trajectories, which are locally topologically equivalent to cylinders. The global structure of each invariant surface is due to the birth or death of limit cycles. For example, this surface is topologically equivalent to a sphere when we have exactly two Hopf points in $\mathbb{S}_{\rho_*}^2$ and $\mathbb{S}_{\rho^*}^2$, being $\rho_* < 1 < \rho^*$.

This paper is structured as follows. Section 2 is devoted to recalling the tools used to prove our main results. In Section 3 we study piecewise linear vector fields with invariant spheres and we also prove Theorem 1.1. In Section 4 we give some families of centers for piecewise continuous quadratic homogeneous vector fields, in the sphere $\mathbb{S}_1^2$. Finally, in Section 5 we prove Theorem 1.2.

2 Preliminary results

This section is dedicated to recall some concepts and bifurcation techniques for piecewise smooth vector fields, that we use in the proofs of the results of this paper. Firstly, we recall the integrability concept and the Filippov's convention for piecewise smooth vector fields. After that, we consider a smooth vector field $X : \mathbb{R}^3 \to \mathbb{R}^3$ having $H(x, y, z) = x^2 + y^2 + z^2$ as a first integral and define a piecewise smooth vector field with the same property. Considering that the center-focus problem and local cyclicity will be studied projecting each 3-dimensional piecewise smooth vector field defined on the invariant sphere into a planar one, we also recall some definitions and the computation algorithm of the center conditions (or Lyapunov constants) for planar piecewise smooth vector fields.

2.1 Integrability

Let $P : \mathbb{R}^m \to \mathbb{R}^m$ such that $P(\mathrm{x}) = (P_1(\mathrm{x}), \ldots, P_m(\mathrm{x}))$, where $\mathrm{x} = (x_1, \ldots, x_m) \in \mathbb{R}^m$ and P_i, $i = 1, \ldots, m$, are polynomials in the variables x_i with real coefficients. Let n be the maximum between the degrees of P_i, $i = 1, \ldots, m$ and consider an m-dimensional differential system

$$\dot{\mathrm{x}} = P(\mathrm{x}). \tag{2.1}$$

Let $U \subset \mathbb{R}^m$ be an open subset. If there exists a non-constant analytic function $H : U \to \mathbb{R}$ such that

$$\langle P(\mathrm{x}), \nabla H(\mathrm{x}) \rangle = \sum_{i=1}^{m} P_i(\mathrm{x}) \frac{\partial H}{\partial x_i}(\mathrm{x}) = 0, \quad \text{for } \mathrm{x} \in U,$$

then (2.1) is *partially integrable* on U and H is a *first integral* of (2.1) on U. Moreover, if P has $m - 1$ independent first integrals then P is called a *completely integrable* system. In [14], it was proved that any m-dimensional linear system has $m - 1$ independent first integrals and then this is an example of a class of completely integrable systems.

It is worth to say that when a system P is completely integrable its trajectories are determined by the intersection of the level sets of its first integrals, see [13] for more details about it. Moreover, each $X \in \mathfrak{X}$ has at least one first integral and, in Section 3 we will see that the key point for the proof of Theorem 1.1 is the existence of a second first integral for $X^{\pm} \in \mathfrak{X}_1$ and to have a good knowledge of how the levels of these first integrals interact with the separation curve of piecewise system (1.3).

2.2 Filippov vector fields

In this subsection we recall the definition of a piecewise smooth vector field under the Filippov's convention (see [15] for more details). We restrict our attention to piecewise smooth vector fields defined in $\mathbb{R}^m$, the same definitions can be extended easily to m-dimensional manifolds.

Let $\mathrm{x} = (x_1, \ldots, x_m) \in \mathbb{R}^m$ and consider $f : \mathbb{R}^m \to \mathbb{R}$ a $\mathcal{C}^r$-class function such that $0 \in \mathbb{R}$ is a regular value of f. Therefore, $\Sigma = f^{-1}(0) = \{\mathrm{x} \in \mathbb{R}^m : f(\mathrm{x}) = 0\}$ is an embedded codimension one submanifold of $\mathbb{R}^m$. Consider $\Sigma^+ = f^{-1}([0, +\infty)) = \{\mathrm{x} \in \mathbb{R}^m : f(\mathrm{x}) \geq 0\}$, $\Sigma^- = f^{-1}((-\infty, 0]) = \{\mathrm{x} \in \mathbb{R}^m : f(\mathrm{x}) \leq 0\}$ and the piecewise smooth vector field with separation set Σ defined by

$$Y(\mathrm{x}) = \begin{cases} X^+(\mathrm{x}), & \mathrm{x} \in \Sigma^+, \\ X^-(\mathrm{x}), & \mathrm{x} \in \Sigma^-, \end{cases} \tag{2.2}$$

where $X^{\pm}$ are smooth vector fields defined on $\Sigma^{\pm}$. The equilibrium points of X^+ and X^- located in Σ^+ and Σ^-, respectively, are called admissible (or visible) equilibrium points or simply equilibrium points of (2.2). On the other hand, the equilibrium points of X^+ and X^-

located in Σ^- and Σ^+, respectively, are called non-admissible (or invisible) equilibrium points of (2.2).

The Lie derivative of f with respect to the vector field $X^\pm$ at the point $p \in \Sigma$ is defined by $X^\pm f(p) = X^\pm(p) \cdot \nabla f(p)$, where the dot stands for the scalar or usual product on $\mathbb{R}^m$. The successive Lie derivatives are given by $(X^\pm)^n f(p) = X^\pm(p) \cdot \nabla (X^\pm)^{n-1} f(p)$, $n \geq 2$. When $X^+ f(p) = X^- f(p)$, for all $p \in \Sigma$, we say that (2.2) is a refractive system (on Σ). For more details about refractive systems we refer the reader to [3,5].

On the following, we recall the definitions of tangency points and tangency sets of (2.2). We say that $p \in \Sigma$ is a fold point of Y if $X^+ f(p) = 0, (X^+)^2 f(p) \neq 0$ and $X^- f(p) \neq 0$ (or $X^- f(p) = 0, (X^-)^2 f(p) \neq 0$ and $X^+ f(p) \neq 0$). Hence, p is a fold-fold point when $X^+ f(p) = 0$, $X^- f(p) = 0$, $(X^+)^2 f(p) \neq 0$, and $(X^-)^2 f(p) \neq 0$. We also define the tangency set of $X^\pm$ with Σ by $S_{X^\pm} = \{p \in \Sigma : \ X^\pm f(p) = 0\}$ and the tangency set of Y by $S_Y = S_{X^+} \cup S_{X^-}$.

As usual, we consider the crossing region $\Sigma^c = \{p \in \Sigma : (X^+ f(p))(X^- f(p)) > 0\}$, the sliding region $\Sigma^s = \{p \in \Sigma : X^+ f(p) < 0, \ X^- f(p) > 0\}$ and the escaping region $\Sigma^e = \{p \in \Sigma : X^+ f(p) > 0, \ X^- f(p) < 0\}$. So Σ is the disjoint union $\Sigma^c \cup \Sigma^s \cup \Sigma^e \cup S_Y$ and following the Filippov's convention we define the Filippov vector field $F_Y(p)$ on $\Sigma^s \cup \Sigma^e$ by

$$F_Y(p) = \frac{1}{X^- f(p) - X^+ f(p)} \left(X^- f(p) X^+(p) - X^+ f(p) X^-(p) \right).$$

We also recall that a crossing trajectory is an orbit that have isolated crossing points of intersection with the separation set Σ. Moreover, a crossing limit cycle is an isolated crossing periodic orbit.

Finally, we say that (2.2) is time φ-reversible if $\mathrm{Fix}(\varphi) \subset \Sigma^c$ and $D\varphi \circ Y = -Y \circ \varphi$, where φ is an $\mathcal{C}^r$-involution defined in $\mathbb{R}^m$. As in the smooth case, each piecewise reversible vector field presents a certain symmetry. For more details, see [21].

2.3 Orthogonal change of coordinates and stereographic projection

We say that a change of coordinates is orthogonal when the matrix of it is orthogonal, in other words, if M is this matrix it must satisfy $M^t = M^{-1}$. This kind of change of coordinates keeps all the spheres invariant and using it we can assume that the equilibrium point of a smooth vector field, that always exists on each invariant sphere $\mathbb{S}^2_\rho$, can be located at any (x_0, y_0, z_0) that we choose. Note that, when we consider piecewise smooth vector fields on invariant spheres, this kind of change of coordinates (on the whole sphere) allows us to assume that some equilibrium point of the Filippov vector field or some fold point can be located at any $(x_0, y_0, 0) \in \Sigma$.

To study local behaviors, we use the stereographic projection with respect to the point $(0, -\rho, 0)$. It allows us to consider planar vector fields instead of 3-dimensional ones restricted to spheres. In the following, we define the piecewise projected vector field. Consider the stereographic projection, $\mathfrak{p} : \mathbb{S}^2_\rho \setminus \{(0, -\rho, 0)\} \to \mathbb{R}^2$, on the plane $\{(x, y, z) \in \mathbb{R}^3 : y = \rho\}$ given by $\mathfrak{p}(x, y, z) = 2\rho(x, z)/(y + \rho)$. We define the projected vector field associated to $X \in \mathfrak{X}$ by

$$\mathcal{P}_X(\mathrm{u}) = d\mathfrak{p}_{\mathfrak{p}^{-1}(\mathrm{u})} \circ X \circ \mathfrak{p}^{-1}(\mathrm{u}),$$

where $X = X_{|_{\mathbb{S}^2_\rho}}$, $\mathrm{u} = (u, v)$ and $\mathfrak{p}(\mathrm{x}) = \mathrm{u}$. Note that, this stereographic projection sends the separation set $\Sigma = \{(x, y, z) \in \mathbb{R}^3 : z = 0\}$ of a piecewise smooth vector field $Y \in \mathcal{X}$ to

$\{(u,v)\in\mathbb{R}^2 : v=0\}$. Thus, the projection $\mathcal{P}_Y:\mathbb{R}^2\to\mathbb{R}^2$ of (1.1) is written as

$$\mathcal{P}_Y(\mathrm{u})=\begin{cases}\mathcal{P}_{X^+}(\mathrm{u}),\ v\geq 0,\\ \mathcal{P}_{X^-}(\mathrm{u}),\ v\leq 0,\end{cases}\tag{2.3}$$

where $X^{\pm}=X^{\pm}_{|_{\mathbb{S}^2_\rho}}$, $\mathrm{u}=(u,v)$. Besides, $\mathfrak{p}$ preserves closed curves and contact between curves contained on its domain of definition, so $p\in\mathbb{S}^2_\rho$ is said to be a monodromic equilibrium point of (1.1) if $q=\mathfrak{p}(p)$ is a monodromic equilibrium point of (2.3).

2.4 Lyapunov constants and local cyclicity for planar piecewise systems

In this section, we will recall the stability algorithm (see [16, 17] and references therein) for planar piecewise smooth vector fields of the form

$$Y(x,y)=\begin{cases}X^+(x,y),\ y\geq 0,\\ X^-(x,y),\ y\leq 0,\end{cases}\tag{2.4}$$

having both $X^{\pm}$ an equilibrium point of nondegenerate center-focus type at the origin. That is,

$$X^{\pm}(x,y)=\left(\alpha^{\pm}x-\beta^{\pm}y+\sum_{k=2}^{n}P_k^{\pm}(x,y),\beta^{\pm}x+\alpha^{\pm}y+\sum_{k=2}^{n}Q_k^{\pm}(x,y)\right),$$

with $P_k^{\pm}$ and $Q_k^{\pm}$ homogeneous polynomials of degree k in the variables x and y. We have assumed that both linear parts are in Jordan's normal form. Furthermore, we follow the Filippov's convention to define the trajectories of Y on the separation set $\Sigma=\{(x,y)\in\mathbb{R}^2 : y=0\}$ and we assume $\beta^{\pm}\neq 0$ as the non degeneracy condition for each $X^{\pm}$. Using polar coordinates, $(x,y)=(r\cos\theta,r\sin\theta)$, we write system (2.4) as

$$\begin{cases}\dot r=R^+(r,\theta), & \theta\in[0,\pi],\\ \dot r=R^-(r,\theta), & \theta\in[\pi,2\pi],\end{cases}$$

where the dot represents the derivative with respect to θ.

Consider $r^{\pm}(\theta,r_0)$ the solution of $\dot r=R^{\pm}(r,\theta)$ with initial condition $r^{\pm}(0,r_0)=r_0$ and $r_0>0$ sufficiently small. The expansion in Taylor's series of the solution $r^{\pm}(\theta,r_0)$ can be written as

$$r^{\pm}(\theta,r_0)=r_0+\sum_{k=1}^{\infty}r_k^{\pm}(\theta)r_0^k,$$

with $r_k^{\pm}(0)=0$, for all $k\geq 1$, and with r^+ defined for $\theta\in[0,\pi]$ and r^- defined for $\theta\in[\pi,2\pi]$. The *Poincaré half-return maps* are defined by

$$\Pi^+(r_0)=r^+(\pi,r_0),$$
$$\widetilde{\Pi}^-(r_0)=r^-(-\pi,r_0),$$

where $\widetilde{\Pi}^-$ denotes the inverse of Π^- since both $r^{\pm}$ are defined with initial condition $\theta=0$ and $r_0>0$ sufficiently small. The *displacement function*, which is analytic, is given by

$$\Delta(r_0) = \widetilde{\Pi}^-(r_0) - \Pi^+(r_0) = \sum_{k=1}^{\infty} L_k r_0^k,$$

for r_0 small enough. When $\alpha^+\alpha^- \neq 0$ the origin is a hyperbolic equilibrium point. Otherwise $L_1 = 0$ and, for $k \geq 2$, we can define the k-th *Lyapunov constant* by $L_k \neq 0$, when $L_1 = \cdots = L_{k-1} = 0$. In this case, if there exists $k \geq 2$ so that $L_k \neq 0$, then the origin of system (2.4) is a weak focus of order k. Otherwise the origin is a center. For more details see for instance [16,17]. Usually, to simplify computations we take $\alpha^+ = \alpha^- = 0$. Note that on the smooth case the first non-vanishing Lyapunov constant has always odd subscript while in the piecewise class this property does not hold. Recall that, for analytical vector fields, the classical *Hopf bifurcation* occurs when one limit cycle of small amplitude bifurcates from a weak focus of first order (with the above notation it occurs when $L_1 = L_2 = 0$ and $L_3 \neq 0$), while the limit cycles arise from a higher-order weak focus in the degenerate Hopf bifurcation (see [1] for more details). Moreover, for piecewise smooth vector fields, in [11] it is shown that one more limit cycle appears moving the equilibrium points on Σ. Because a sliding or escaping segment is created adding adequately some perturbative parameters which implies that the displacement function of a piecewise-smooth vector field could be of the form

$$\Delta(r_0) = \widetilde{\Pi}^-(r_0) - \Pi^+(r_0) = L_0 + \sum_{k=1}^{\infty} L_k r_0^k,$$

with r_0 sufficiently small. So, by the derivative division algorithm, it is possible to obtain one limit cycle more when $L_0 \neq 0$. This is known as a pseudo-Hopf type bifurcation. Because in [22], this limit cycle bifurcation was called *pseudo-Hopf* near a fold-fold point and proved previously in [15]. For more details see [10,19]. We notice that a weak focus of order k, generically, unfolds exactly k limit cycles. Note that when we deal with continuous or refractive perturbations we do have not pseudo-Hopf type bifurcations because, in these cases, we never have sliding or escaping segments on Σ.

As we deal with polynomial perturbations of a piecewise center, we can use the Implicit Function Theorem to obtain hyperbolic crossing limit cycles of small amplitude in a neighborhood of the origin of (2.4). In this case, like in the analytical one, when we perturb a center under the condition $\alpha^{\pm} = 0$, the expressions of L_k are polynomials that vanish when the perturbative parameters do. Therefore, we can compute the Taylor series of $L_2, \ldots, L_l$ with respect to the perturbative parameters. We denote by $L_i^{[1]}$, $i = 2, \ldots, l$ their linear parts. Consequently, if the matrix $[L_2^{[1]}, \ldots, L_l^{[1]}]$, with respect to the perturbative parameters, has rank $l-1$, as we have previously explained, adding the traces and the sliding or escaping segments we can get l small amplitude hyperbolic crossing limit cycles in a neighborhood of the origin. For more details see [17] and references therein.

We can also study bifurcations of small amplitude limit cycles for piecewise smooth vector fields using the Melnikov's method. It is also used to study global bifurcations that occur near one-parameter families of periodic orbits. In particular, the first Melnikov Function and the first-order of the Lyapunov constants are related and we know that if, after perturbing a center, the rank of the matrix defined by the coefficients of $[L_2^{[1]}, \ldots, L_m^{[1]}]$, with respect to the parameters, is $l-1$, where $m > l$, then there exist l hyperbolic crossing limit cycles bifurcating from this center, when we also use the trace and the sliding parameters. For more details, see [18].

3 Piecewise linear vector fields on invariant spheres

In this section, we study piecewise linear vector fields defined on invariant spheres. We prove Theorem 1.1 and we provide all phase portraits of piecewise smooth vector fields $Y \in \mathcal{X}$ when we restrict on a invariant sphere. From the complete analysis of the phase portraits we can have a more complete result, Proposition 3.3, that also shows the nonexistence of other type of limit cycles on the invariant spheres, different from the crossing ones. In fact, Theorem 1.1 can be also thought as a corollary of it. Of course, the nonexistence of limit cycles on spheres, by the homogeneity, proves immediately the nonexistence of any kind of isolated invariant cones.

At first we summarize some results about smooth vector fields presented in [6] that we use in what follows.

Lemma 3.1. *Let $X \in \mathfrak{X}_1$. The following statements are true.*

(a) If $p \in \mathbb{S}^2_\rho = \{(x,y,z) \in \mathbb{R}^3 : x^2+y^2+z^2=\rho^2\}$ is an equilibrium point of system (1.2), then p is a center.

(b) Any $X \in \mathfrak{X}_1$ is completely integrable with the second first integral

$$\widetilde{H}(x,y,z) = a_3x - a_2y + a_1z. \tag{3.1}$$

(c) $X \in \mathfrak{X}_1$ has only two equilibrium points of center type on each sphere $\mathbb{S}^2_\rho$ which are antipodal of each other.

(d) The equilibrium points of (1.2) are $(0,0,\rho)$ if, and only if, $a_2 = a_3 = 0$. In this case, the second first integral of (1.2), given by (3.1), is of the form $\widetilde{H}(x,y,z) = a_1z$.

(e) Suppose that $a_3 \neq 0$. Then the equilibrium points of (1.2) are of the form

$$\{(x,y,z) \in \mathbb{R}^3 : y = -(a_2/a_3)x, z = (a_1/a_3)x\}.$$

(f) Suppose that $a_2 \neq 0$. Then the equilibrium points of (1.2) are of the form

$$\{(x,y,z) \in \mathbb{R}^3 : x = -(a_3/a_2)y, z = -(a_1/a_2)y\}.$$

(g) System (1.2) is invariant by the change of coordinates $(x,y,z,t) \mapsto (-x,-y,-z,t)$.

(h) The phase portrait of any $X \in \mathfrak{X}_1$ on $\mathbb{S}^2_\rho$, with $\rho > 0$, is topologically equivalent to the one on $\mathbb{S}^2_1$.

So, (1.2) has (generically) only a line of equilibrium points passing through the origin. As we observed in the introduction, by Lemma 3.1, we conclude that the 3-dimensional smooth vector field (1.2) has a continuous of invariant cones fulfilled of non-isolated closed trajectories. One of these cones is illustrated in Figure 3.1.

Now we consider the 3-dimensional piecewise smooth vector fields $Y = (X^+, X^-) \in \mathcal{X}_1$ given by (1.3), with separation set $\Sigma = \{(x,y,z) \in \mathbb{R}^3 : z = 0\}$. Observe that, when we restrict our study to an invariant sphere $\mathbb{S}^2_\rho$ we deal with a piecewise smooth vector field defined on $\mathbb{S}^2_\rho$ with separation set $\{(x,y,z) \in \mathbb{S}^2_\rho : z = 0\}$. Sure that there will be no doubt, to simplify the notation we will continue calling the separation set and the vector fields Y and $X^\pm$ restricted to the sphere $\mathbb{S}^2_\rho$ by Σ, Y, and $X^\pm$.

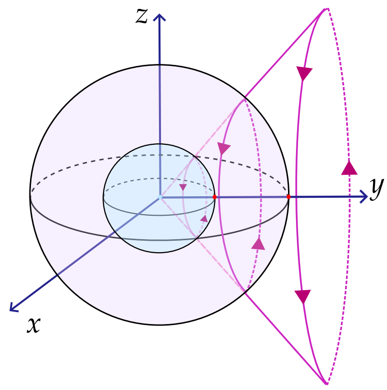

Figure 3.1: Invariant cone of the linear vector field $X(x,y,z) = (z, 0, -x) \in \mathfrak{X}_1$.

Firstly, we use Lemma 3.1 to analyze the possible positions of the equilibrium points of (1.4) with respect to the separation set Σ. By Lemma 3.1(d), the equilibria of the linear systems $X^{\pm}$, defined by (1.4), are $(0,0,\rho)$ if, and only if, $a_2^{\pm} = a_3^{\pm} = 0$. Note that the item (d) of Lemma 3.1 also implies that Σ is invariant by the flow of $X^{\pm}$ and that $(0,0,\pm\rho)$ are the unique equilibria of $X^{\pm}$ on each sphere when $a_2^{\pm} = a_3^{\pm} = 0$. So, on the following we assume that $(a_2^{\pm})^2 + (a_3^{\pm})^2 \neq 0$. We do all the calculations assuming that $a_3^{\pm} \neq 0$, the case $a_2^{\pm} \neq 0$ is analogous. Under this condition, Lemma 3.1(e) implies that the equilibria of $X^{\pm}$ are of the form $\{(x,y,z) \in \mathbb{R}^3 : y = -(a_2^{\pm}/a_3^{\pm})x, z = (a_1^{\pm}/a_3^{\pm})x\}$. Hence, the equilibria of $X^{\pm}$ are on the separation set Σ if, and only if, $a_1^{\pm} = 0$. Moreover, by Lemma 3.1(c), both $X^{\pm}$ have two equilibrium points of center type on each sphere. So, if $a_1^{\pm} \neq 0$ we conclude that the vector field $X^{\pm}$ has one admissible and one non-admissible equilibrium point.

Following [27], we use the first integrals $H(x,y,z) = x^2 + y^2 + z^2$ and $\widetilde{H}^{\pm}(x,y,z)$, given by (3.1), of the linear vector fields (1.4) to calculate a difference map, on Σ, defined below. With this map we can analyze and describe the behavior of the levels curves of (3.1) on $\mathbb{S}^2_\rho$ and how these levels interact with the separation set Σ. It allows us to know the behavior of the trajectories of (1.4) on each sphere $\mathbb{S}^2_\rho$, and, in particular, see if any system (1.3) admits crossing limit cycles on $\mathbb{S}^2_\rho$.

Lemma 3.2. *No piecewise differential system $Y \in \mathcal{X}_1$, given by (1.3), admits crossing limit cycles restricting the dynamics on each fixed sphere $\mathbb{S}^2_\rho$, with $\rho > 0$.*

Proof. As we saw before, $a_2^{\pm} = a_3^{\pm} = 0$ implies that Σ is invariant by the flow of (1.4). Therefore, in this case we cannot define a difference map using (3.1). Then, on the following, we assume that $(a_2^{\pm})^2 + (a_3^{\pm})^2 \neq 0$. We do all the calculations assuming that $a_3^{\pm} \neq 0$. The case $a_2^{\pm} \neq 0$ is analogous.

Let $p = (x_0, y_0, 0) \in \Sigma \cap \mathbb{S}^2_\rho$. Then, there exist $k^{\pm}$ such that $\widetilde{H}^{\pm}(p) = k^{\pm}$. The half-return maps $\pi^{\pm}(p) = q^{\pm} = (x_1^{\pm}, y_1^{\pm}, 0)$ satisfy

$$
\begin{aligned}
H(q^{\pm}) &= \rho^2, \\
\widetilde{H}^{+}(q^{+}) &= a_3^{+} x_1^{+} - a_2^{+} y_1^{+} = k^{+}, \\
\widetilde{H}^{-}(q^{-}) &= a_3^{-} x_1^{-} - a_2^{-} y_1^{-} = k^{-}.
\end{aligned}
$$

Solving the systems of equations

$$
\{H(q^{+}) = \rho^2, \widetilde{H}^{+}(q^{+}) = k^{+}\}, \qquad \{H(q^{-}) = \rho^2,\ \widetilde{H}^{-}(q^{-}) = k^{-}\}
$$

we obtain the solutions

$$q^{\pm}=\left(-\frac{((a_2^{\pm})^2-(a_3^{\pm})^2)x_0+2a_2^{\pm}a_3^{\pm}y_0}{(a_2^{\pm})^2+(a_3^{\pm})^2},\frac{((a_2^{\pm})^2-(a_3^{\pm})^2)y_0-2a_2^{\pm}a_3^{\pm}x_0}{(a_2^{\pm})^2+(a_3^{\pm})^2},0\right).$$

So, the difference map, $d(p)=\pi^{+}(p)-\pi^{-}(p):\Sigma\to\mathbb{R}$, is such that

$$\begin{aligned}d(p)=\big(&2(a_2^-a_3^+-a_3^-a_2^+)((a_2^-a_3^++a_2^+a_3^-)x_0-(a_2^-a_2^+-a_3^-a_3^+)y_0),\\&-2(a_2^-a_3^+-a_3^-a_2^+)((a_2^-a_2^+-a_3^-a_3^+)x_0+(a_2^-a_3^++a_2^+a_3^-)y_0),0\big).\end{aligned}$$

Consequently, it is identically zero if, and only if, $a_2^+a_3^-=a_2^-a_3^+$. Hence, either all the crossing trajectories of (1.3), on $\mathbb{S}^2_\rho$, are closed or none of them are, which concludes the proof. □

Proof of Theorem 1.1. It is a direct consequence of the fact that system (1.3) does not admit isolated crossing periodic orbits, by Lemmas 3.1(a) and 3.2. □

The remainder of this section is devoted to describing the behavior of any piecewise smooth vector field (1.3) restricted to the sphere of radius ρ, that is $\mathbb{S}^2_\rho$. We show also that no piecewise differential system $Y\in\mathcal{X}_1$, given by (1.3), admits sliding limit cycles on each fixed sphere $\mathbb{S}^2_\rho$, with $\rho>0$. Moreover, we provide the possible phase portraits of $Y\in\mathcal{X}_1$ and, consequently, we will prove the following result.

Proposition 3.3. *A piecewise differential system $Y\in\mathcal{X}_1$, given by* (1.3)*, does admit neither a crossing nor any other type of limit cycle on each fixed invariant sphere $\mathbb{S}^2_\rho$, with $\rho>0$.*

We start studying the behavior of the tangency lines of (1.4) assuming that $a_3\neq 0$, under the condition $(a_2^{\pm})^2+(a_3^{\pm})^2\neq 0$.

Lemma 3.4. *The tangency lines of* (1.4) *are given by*

$$S_{X^{\pm}}=\left\{(x,y,z)\in\mathbb{R}^3: y=-(a_2^{\pm}/a_3^{\pm})x, z=0\right\}.$$

Moreover, these tangency lines intersect the sphere $\mathbb{S}^2_\rho$ at the points

$$\left\{x=-\rho a_3^{\pm}/\sqrt{(a_2^{\pm})^2+(a_3^{\pm})^2},\ y=\ \rho a_2^{\pm}/\sqrt{(a_2^{\pm})^2+(a_3^{\pm})^2}\right\}$$

and their antipodals. Then, (1.3) *has two fold points on $\mathbb{S}^2_\rho$, for all $\rho\in\mathbb{R}$, $\rho\neq 0$. Besides, one of these tangency points is visible and the other one is invisible unless that $a_1^{\pm}=0$. Finally, when $S_{X^+}=S_{X^-}$ we have two fold-fold points of $Y=(X^+,X^-)$ on each sphere and it occurs if, and only if, $a_2^+a_3^-=a_2^-a_3^+$.*

Proof. Let $f:\mathbb{R}^3\to\mathbb{R}$ given by $f(x,y,z)=z$. So, $\Sigma=\{(x,y,z)\in\mathbb{R}^3; z=0\}=f^{-1}(0)$. Thus, $X^{\pm}f=X^{\pm}\cdot\nabla f=a_2^{\pm}x+a_3^{\pm}y$ and the first part of the result follows. With straightforward computations we prove the other statements. □

It is important to note that the symmetry of the problem guarantees that if one equilibrium point of X^+ or X^- remains on Σ, then so does the other. Moreover, if an equilibrium point of X^+ coincides with a tangency or an equilibrium point of X^- the other one also coincides. Besides, the change of coordinates $(x,y,z)\mapsto(x,y,-z)$ allows us to change the behavior of the southern and northern hemispheres and then we can fix the behavior in one of them in the next analysis.

As we saw in Section 2, we can define the projected vector field associated to (1.3), on the sphere $\mathbb{S}^2_\rho$, using (2.3). It is of the form

$$\mathcal{P}_Y(u,v) = \begin{cases} \mathcal{P}_{X^+}(u,v), \; v \geq 0, \\ \mathcal{P}_{X^-}(u,v), \; v \leq 0, \end{cases}$$

where,

$$\mathcal{P}_{X^\pm}(u,v) = \big(-4\rho^2 a_1^\pm - 4\rho a_2^\pm v - a_1^\pm u^2 + 2a_3^\pm uv + a_1^\pm v^2, \\ 4\rho^2 a_3^\pm + 4\rho a_2^\pm u - a_3^\pm u^2 - 2a_1^\pm uv + a_3^\pm v^2 \big).$$

The projected Filippov vector field is 1-dimensional and it is well defined at the points $(u,0)$ for which $(\mathcal{P}_{X^+} f)(\mathcal{P}_{X^-} f)(u) = (4\rho^2 a_3^+ + 4\rho a_2^+ u - a_3^+ u^2)(4\rho^2 a_3^- + 4\rho a_2^- u - a_3^- u^2) < 0$. In this case, we have

$$F_Y(u) = \frac{(4\rho^2 + u^2)\left((a_1^- a_3^+ - a_1^+ a_3^-)u^2 + 4(a_1^+ a_2^- - a_1^- a_2^+)u\rho + 4(a_1^+ a_3^- - a_1^- a_3^+)\rho^2\right)}{(a_3^- - a_3^+)u^2 + 4\rho(a_2^+ - a_2^-)u + 4\rho^2(a_3^+ - a_3^-)}. \tag{3.2}$$

Now, we summarize the key points of the proof of Proposition 3.3, providing after the necessary technical lemmas.

Using the two first integrals of $X^\pm$ we prove, in Lemma 3.5, that there exist only 10 possible behaviors for the levels curves of (1.3) on each sphere $\mathbb{S}^2_\rho$, concerning the admissibility of equilibrium points of $Y \in \mathcal{X}_1$, which are the ones in Figure 3.2. After that, we study the behavior of the Filippov vector field, F_Y, given by (3.2). Note that, (3.2) is not defined when Σ is a trajectory of X^+ or X^- on $\mathbb{S}^2_\rho$. In Lemma 3.7, we conclude that if the equilibrium points of both $X^\pm$ stay on Σ ($a_1^+ = a_1^- = 0$) or if there exists $\lambda \in \mathbb{R}$ such that $X^+ = \lambda X^-$, then the Filippov vector field (3.2) is identically zero. In Lemma 3.9, we prove that (3.2) has two symmetric equilibrium points r_1 and r_2 if, and only if, $a_1^+ a_3^- - a_1^- a_3^+ \neq 0$, $a_1^+ a_1^- < 0$ and $a_2^+ a_3^- - a_2^- a_3^+ \neq 0$. In this case, the equilibrium points r_1 and r_2 have the same (1-dimensional) stability and they are stable (resp. unstable) if $(a_2^+ a_3^- - a_2^- a_3^+)(a_1^+ - a_1^-) > 0$ (resp. < 0). In addition, (3.2) can have isolated equilibrium points only when the sliding and escaping segments are delimited by two tangency points of the same type otherwise both vector fields X^+ and X^- point towards the same direction on Σ. Moreover, (3.2) does not have isolated equilibrium points when $Y \in \mathcal{X}_1$ has fold-fold points or the equilibrium points of X^+ or X^- stay on Σ.

Now, changing the time orientation of the piecewise smooth vector field (1.3), if it is necessary, we can fix an orientation for the vector field X^- in $\Sigma^- = \{(x,y,z) \in \mathbb{S}^2_\rho : \; z \leq 0\}$ and choose between two different ones for X^+ in $\Sigma^+ = \{(x,y,z) \in \mathbb{S}^2_\rho : \; z \geq 0\}$. Doing this, in Figure 3.2 we draw the possible phase portraits for system (1.3) on the sphere $\mathbb{S}^2_\rho$, with respect to the admissibility of equilibrium points of $Y \in \mathcal{X}_1$, which are the ones in Figures 3.3 and 3.4. Note that, in Figures 3.3 and 3.4 we do not distinguish the cases in which it is possible to have connections (see Remark 3.6), because it will not be necessary to conclude the proof of Proposition 3.3.

Joining the information about the positions of the equilibrium points on each sphere $\mathbb{S}^2_\rho$ with the property of the difference map detailed on Lemma 3.2, we can classify the possible behavior of the invariant curves of piecewise smooth vector fields (1.3) on $\mathbb{S}^2_\rho$, with respect to the admissibility of its equilibrium points.

Lemma 3.5. *With respect to the admissibility of equilibrium points, the behavior of the level curves of (1.3) on each fixed sphere $\mathbb{S}^2_\rho$, $\rho > 0$, are shown in Figure 3.2.*

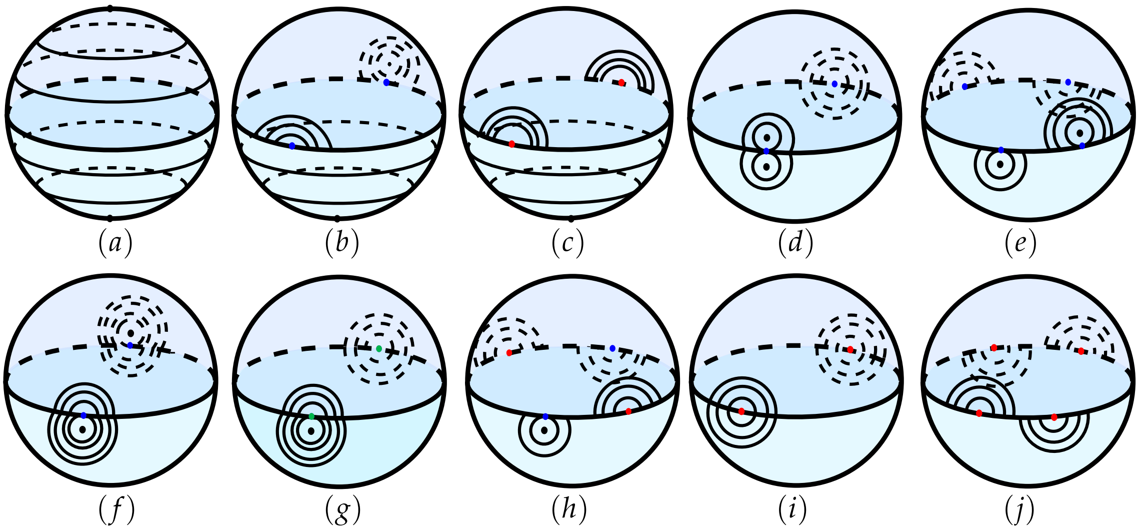

Figure 3.2: Invariant curves of $Y \in \mathcal{X}_1$. The blue, red, green and black dots indicate, respectively, tangency points; equilibrium points of $X^{\pm}$ on Σ; the coincidence of equilibrium and tangency points on Σ; the admissible center points of $X^{\pm}$.

Proof. Let $Y = (X^+, X^-) \in \mathcal{X}_1$. Denote by $p_i^{\pm}$ and $q_i^{\pm}$, with $i = 1, 2$ the equilibrium and the tangency points of $X^{\pm}$, respectively. On the following we assume that $p_1^{\pm} = (x_0, y_0, z_0)$ is such that $z_0 \geq 0$ and $p_2^{\pm} = (x_0, y_0, z_0)$ is such that $z_0 \leq 0$. We show the possible behaviors of the level curves of $Y \in \mathcal{X}_1$ on $\mathbb{S}^2_\rho$ in Figure 3.2. We divide the analysis into three cases depending on the position of the equilibrium points of X^- on $\mathbb{S}^2_\rho$.

Firstly, if $p_1^- = (0, 0, \rho)$ and $p_2^- = -p_1^-$ the trajectories of X^- on $\mathbb{S}^2_\rho$ are parallel to Σ. The same property holds when $p_1^+ = (0, 0, \rho)$ and $p_2^+ = -p_1^+$. If $p_i^+ = (x_0, y_0, z_0)$, $i = 1, 2$, are such that $z_0 \neq \pm\rho$ and $z_0 \neq 0$, then we have one admissible and one non-admissible center for X^+ on $\mathbb{S}^2_\rho$ and therefore, two tangency points, $q_i^+ \in \Sigma$, $i = 1, 2$, one visible and one invisible. Finally, if $p_i^+ = (x_0, y_0, 0)$, $i = 1, 2$, both equilibrium points of X^+ are on Σ. We draw the invariant curves of these cases in Figure 3.2 $(a) - (c)$.

Now we consider the case where $p_i^- = (x_0, y_0, z_0)$, $i = 1, 2$, with $z_0 \neq 0$ and $z_0 \neq \rho$. Then, we have one admissible and one non-admissible center for X^- on $\mathbb{S}^2_\rho$ and therefore, two tangency points, $q_i^- \in \Sigma$, $i = 1, 2$, one visible and one invisible, respectively. Here, as we have already considered the case where the trajectories of X^- are parallel to Σ, using the change of coordinates $(x, y, z) \mapsto (x, y, -z)$ explained before, we only need to consider the following two behaviors of X^+ on $\mathbb{S}^2_\rho$. If $p_i^+ = (x_0, y_0, z_0)$, $i = 1, 2$, are such that $z_0 \neq \rho$ and $z_0 \neq 0$, we have one admissible and one non-admissible center for X^+ and therefore, two tangency points $q_i^+ \in \Sigma$, $i = 1, 2$, one visible and one invisible, respectively. Hence, we have three new global behaviors depending on the relative position of $q_i^{\pm}$, $i = 1, 2$ that occur when $q_1^+ = q_1^-$ and $q_2^+ = q_2^-$, when they do not coincide and when $q_1^+ = q_2^-$ and $q_2^+ = q_1^-$. Finally, if $p_i^+ = (x_0, y_0, 0)$, $i = 1, 2$, the two equilibrium points of X^+ are on Σ and we have two new global behaviors depending on the positions of these equilibrium points, that is $p_i^+ = q_i^-$ or $p_i^+ \neq q_i^-$, $i = 1, 2$. We show the invariant curves of these cases in Figure 3.2 $(d) - (h)$.

We finish the analysis considering the case where the two centers of X^- on $\mathbb{S}^2_\rho$ are on Σ, it means that $p_i^- = (x_0, y_0, 0)$, $i = 1, 2$. Using the change of coordinates $(x, y, z) \mapsto (x, y, -z)$, we can restrict to the case in which the two equilibrium points of X^+, p_i^+ for $i = 1, 2$, are also on

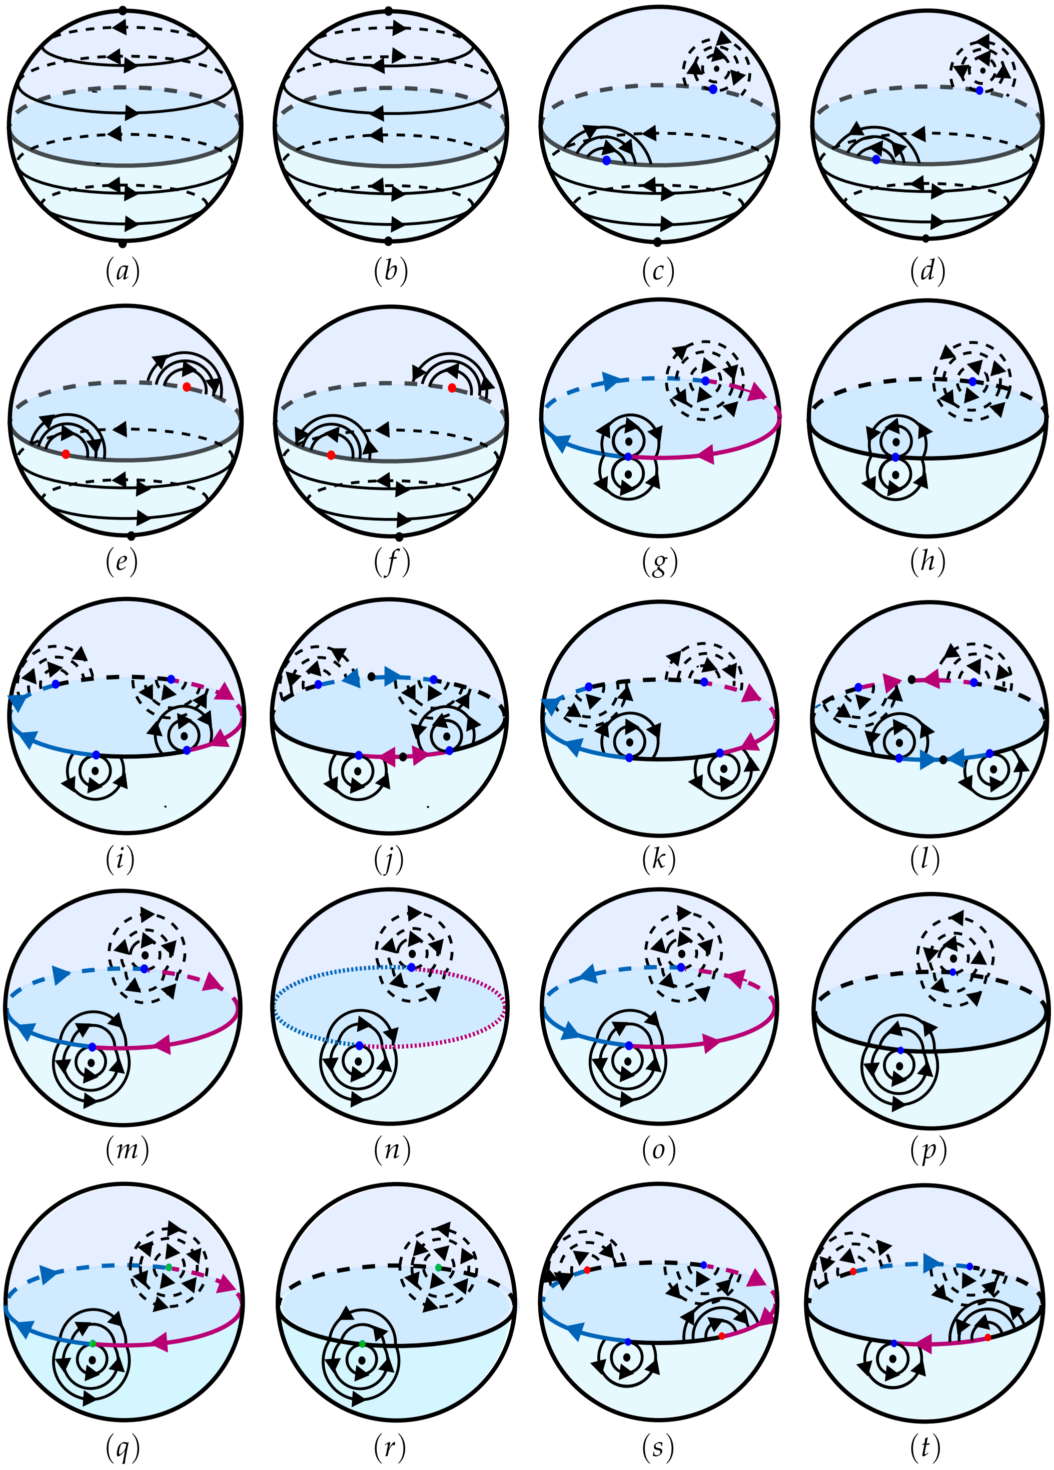

Figure 3.3: Possible phase portraits of $Y \in \mathcal{X}_1$. The gray, blue, pink and black segments indicate, respectively, that the Filippov's convention does not apply; the escaping, sliding, and the crossing regions. Moreover, the blue, red, green and black dots indicate, respectively, tangency points; equilibrium points of $X^{\pm}$ on Σ; the coincidence of equilibrium and tangency points on Σ; the admissible center points of $X^{\pm}$ or the critical points of the Fillipov vector field F_Y.

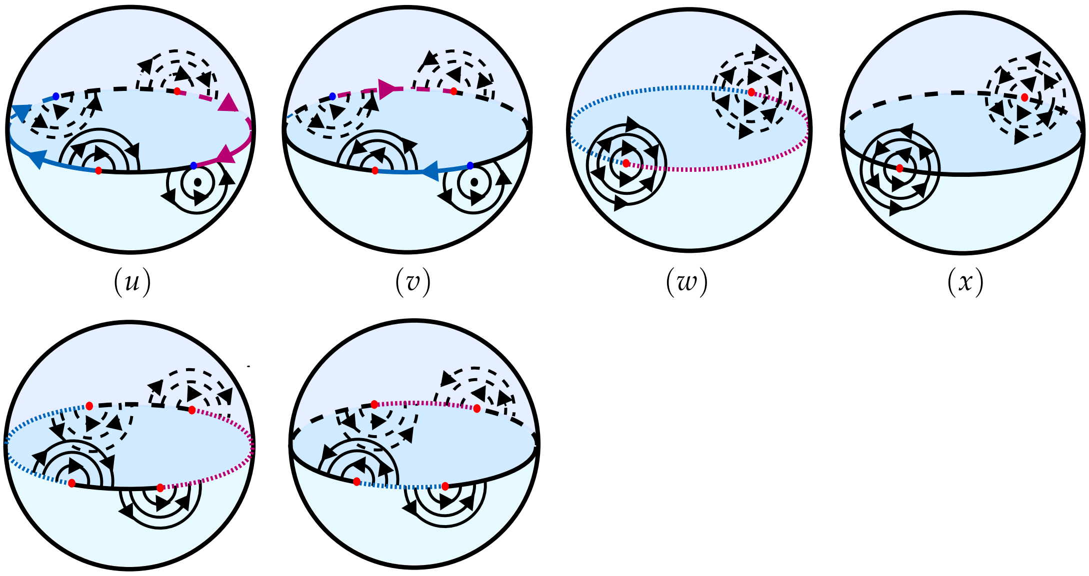

Figure 3.4: Possible phase portraits of $Y \in \mathcal{X}_1$. The blue, pink and black segments indicate, respectively, the escaping, sliding, and the crossing regions. Moreover, the blue, red and black dots indicate, respectively, tangency points; equilibrium points of $X^{\pm}$ on Σ; the admissible center points of $X^{\pm}$.

Σ. Here we have two new global behaviors depending on the positions of these equilibrium points: $p_i^+ = p_i^-$ or $p_i^+ \neq p_i^-$. We draw the invariant curves of these cases in Figure 3.2 (i)–(j). □

Remark 3.6. Note that the tangency points of $X^{\pm}$ are antipodal of each other. Therefore, the tangency lines $S_{X^{\pm}}$ of $X^{\pm}$ are contained in the plane $\{(x, y, z) \in \mathbb{R}^3 : z = 0\}$ and pass through the origin. Observe that when these tangency lines are perpendicular $Y \in \mathcal{X}_1$ admits a tangential connection. It occurs because the trajectories of $X^{\pm}$ are restricted to the level curves of (3.1), on $\mathbb{S}^2_\rho$. Thus, depending on the relative position of the tangency lines, the behavior illustrated in the cases (e), (h), and (j) of Figure 3.2 are not unique. But for our purpose we do not need to distinguish the cases in which there are or not separatrix connections.

As in the above analysis, we only have considered the level curves of $X^{\pm}$ we have not taken into account the behavior of the Filippov vector field. On the following lemmas we describe the behavior of it using the projected Filippov vector field (3.2) associated to (1.3) restricted to the sphere $\mathbb{S}^2_\rho$, because it is 1-dimensional.

Lemma 3.7. *The Filippov vector field* (3.2) *is well defined when* $(\mathcal{P}_{X^+}f)(\mathcal{P}_{X^-}f) < 0$. *In this case, it is identically zero if, and only if,* $a_1^- a_3^+ - a_1^+ a_3^- = 0$ *and* $a_1^- a_2^+ - a_1^+ a_2^- = 0$.

Proof. It follows since (3.2) is a rational function and its numerator is identically zero if, and only if, $(a_1^- a_3^+ - a_1^+ a_3^-)u^2 + 4\rho(a_1^+ a_2^- - a_1^- a_2^+)u + 4\rho^2(a_1^+ a_3^- - a_1^- a_3^+) \equiv 0$. □

Remark 3.8. The geometric implication of Lemma 3.7 is the following. Firstly, we note that $a_2^+ = a_2^- = 0$ and $a_3^+ = a_3^- = 0$ imply that $a_1^- a_3^+ - a_1^+ a_3^- = 0$ and $a_1^- a_2^+ - a_1^+ a_2^- = 0$. But, in this case, $(\mathcal{P}_{X^+}f)(\mathcal{P}_{X^-}f)$ is identically zero and then (3.2) is not defined for these values of the coefficients. In addition, $a_1^+ = a_1^- = 0$ implies that $a_1^- a_3^+ - a_1^+ a_3^- = 0$ and $a_1^- a_2^+ - a_1^+ a_2^- = 0$

and then (3.2) vanishes identically when the equilibrium points of both X^+ and X^- are on Σ. Finally, when $(a_1^+)^2 + (a_1^-)^2 \neq 0$, the conditions $a_1^- a_3^+ - a_1^+ a_3^- = 0$ and $a_1^- a_2^+ - a_1^+ a_2^- = 0$ imply that $a_2^- a_3^+ - a_3^- a_2^+ = 0$ and then X^+ and X^- are multiple of each other, which means that the equilibrium points and tangency lines of X^+ and X^- coincide. So, we have that (3.2) is identically zero if, and only if, the equilibrium points of both $X^\pm$ are on Σ or if X^+ and X^- are multiple of each other.

Note that when $a_1^+ a_3^- - a_1^- a_3^+ \neq 0$, the projected Filippov vector field (3.2) can have at most two real roots, for $i = 1, 2$, given by

$$r_i = \frac{2\rho\left((a_1^+ a_2^- - a_1^- a_2^+) - (-1)^i \sqrt{(a_1^+ a_2^- - a_1^- a_2^+)^2 + (a_1^+ a_3^- - a_1^- a_3^+)^2}\right)}{a_1^+ a_3^- - a_1^- a_3^+} \tag{3.3}$$

if $(\mathcal{P}_{X^+} f)(\mathcal{P}_{X^-} f)(r_i) < 0$. In addition, $(\mathcal{P}_{X^+} f)(\mathcal{P}_{X^-} f)(r_i) > 0$ means that X^+ and X^- are parallel at a crossing point and then (3.2) is not defined at this point. On the other hand, when $a_1^+ a_3^- - a_1^- a_3^+ = 0$ the projected Filippov vector field has a unique possible real root at the origin. The symmetry of the problem ensures that the other root is situated at infinity. We can avoid this and suppose that $(0, 0)$ is not an equilibrium point of (3.2) making the same orthogonal change of coordinates in X^+ and X^- that put $(0, \rho, 0)$ in (x_0, y_0, z_0) with $y_0 \neq \rho$, as it was done previously. So, without loss of generality, we only analyze the case $a_1^+ a_3^- - a_1^- a_3^+ \neq 0$ and study the stability of the equilibrium points of the Filippov vector field, when it is well defined.

Lemma 3.9. *The Filippov vector field (3.2) is well defined when $(\mathcal{P}_{X^+} f)(\mathcal{P}_{X^-} f) < 0$. In this case, it has two symmetric equilibrium points r_1 and r_2 defined in (3.3) if, and only if, $a_1^+ a_3^- - a_1^- a_3^+ \neq 0$, $a_1^+ a_1^- < 0$ and $a_2^+ a_3^- - a_2^- a_3^+ \neq 0$. The equilibrium points r_1 and r_2 have the same (1-dimensional) stability. Moreover, they are stable (resp. unstable) if $(a_2^+ a_3^- - a_2^- a_3^+)(a_1^+ - a_1^-) > 0$ (resp. < 0).*

Proof. As we saw before, when $a_1^+ a_3^- - a_1^- a_3^+ \neq 0$, the Filippov vector field can have at most two real roots r_1 and r_2 given in (3.3). Note that, for $i = 1, 2$, we have

$$(\mathcal{P}_{X^+} f)(\mathcal{P}_{X^-} f)(r_i) = \frac{64\rho^4 a_1^+ a_1^- (a_2^+ a_3^- - a_2^- a_3^+)^2}{(a_1^+ a_3^- - a_1^- a_3^+)^4}$$
$$\left(\sqrt{(a_1^+ a_2^- - a_1^- a_2^+)^2 + (a_1^+ a_3^- - a_1^- a_3^+)^2} - (-1)^i (a_1^+ a_2^- - a_1^- a_2^+)\right)^2.$$

As we are assuming $a_1^+ a_3^- - a_1^- a_3^+ \neq 0$, then

$$\sqrt{(a_1^+ a_2^- - a_1^- a_2^+)^2 + (a_1^+ a_3^- - a_1^- a_3^+)^2} \pm (a_1^+ a_2^- - a_1^- a_2^+)$$

are always different from zero. Consequently, the projected vector field (3.2) is defined at r_1 and r_2 if, and only if, $a_1^+ a_1^- < 0$ and $a_2^+ a_3^- - a_2^- a_3^+ \neq 0$. It means that, when the equilibrium points of both X^+ and X^- are on Σ and when the tangential points of X^+ and X^- coincide, the projected Filippov vector field does not have isolated equilibrium points.

When $a_2^+ a_3^- - a_2^- a_3^+ \neq 0$ and $a_1^+ a_1^- < 0$ we study the stability of these equilibrium points. As $4\rho^2 + u^2$ is a positive factor of (3.2), we can study the stability of the equilibrium points of $F_Y(u)/(4\rho^2 + u^2)$. In this case, the derivative with respect to u is nonvanishing for all u, because it is

$$-\frac{4\rho(4\rho^2 + u^2)(a_2^+ a_3^- - a_2^- a_3^+)(a_1^+ - a_1^-)}{((a_3^- - a_3^+)u^2 + 4\rho(a_2^+ - a_2^-)u + 4\rho^2(a_3^+ - a_3^-))^2}.$$

Thus, r_1 and r_2 have the same stability which depends on the sign of

$$(a_2^+ a_3^- - a_2^- a_3^+)(a_1^+ - a_1^-). \qquad \square$$

Remark 3.10. As we saw above, (3.2) is not defined when Σ is a trajectory of X^+ or X^-. Moreover (3.2) does not have isolated equilibrium points neither when it has fold-fold points nor when the equilibrium points of X^+ or X^- stay on Σ. Besides this, the Filippov vector field (3.2) can have equilibrium points only when the sliding and escaping segments are delimited by two tangency points of the same type, otherwise both vector fields X^+ and X^- point on the same direction.

Now, changing the time orientation of the piecewise smooth vector field (1.3), if it is necessary, we can fix a time orientation for the vector field X^- and choose two different ones for X^+ on $\mathbb{S}^2_\rho$. Hence, when we add a time orientation in Figure 3.2 we obtain the possible behaviors for system (1.3), that are depicted in Figures 3.3 and 3.4. Note that Figures 3.3 and 3.4 do not take into account connections of (1.3). These elements do not influence in the existence of limit cycles. Moreover, the nonexistence of limit cycles in $\mathbb{S}^2_\rho$ is not related to the existence of connections. This is due to the arrangement of tangency points, admissible and non-admissible equilibrium points, and, as (1.3) is completely integrable, the difference map does not have isolated zeros.

With this analysis we conclude that system (1.3) has neither limit cycles nor crossing limit cycles on the spheres $\mathbb{S}^2_\rho$, with $\rho > 0$. So, the proof of Proposition 3.3 follows.

4 Centers and limit cycles for piecewise continuous quadratic homogeneous vector fields

In this section, inspired by the homogeneity property of linear vector fields with invariant spheres, we study the center-focus problem for piecewise quadratic homogeneous vector fields in $\mathcal{X}_2^H$. Because of the difficulty of the problem, we restrict our attention to the class of continuous homogeneous vector fields and give some families of centers in Proposition 4.3. Even with this restriction, in Proposition 4.5 we exhibit a system in $\mathcal{X}_2^H$ with a weak focus of third-order at the point $(0,1,0)$ from which 2 small amplitude crossing limit cycles bifurcate on $\mathbb{S}^2_1$ with a continuous perturbation in $\mathcal{X}_2^H$. Note that with a continuous perturbation, we cannot produce a sliding segment and then it is natural that we do not reach the maximum upper bound for the number of small amplitude limit cycles that can bifurcate from a generic weak focus of third-order. Moreover, in this section we only consider the perturbation in $\mathcal{X}_2^H$ and, in the next section we deal with a general quadratic perturbation in $\mathcal{X}_2$.

On the following, we recall some assumptions given in [6], for a quadratic homogeneous vector field $X \in \mathfrak{X}_2^H$. Firstly, doing an orthogonal change of coordinates we can assume, without loss of generality, that $(0,\rho,0) \in \mathbb{S}^2_\rho$ is an equilibrium point of $X \in \mathfrak{X}_2^H$. With this assumption, we can write X in the form

$$\begin{aligned} \dot{x} &= -a_4xy - a_5xz - (a_6+a_7)yz - a_8z^2, \\ \dot{y} &= a_4x^2 + a_6xz - a_9z^2, \\ \dot{z} &= a_5x^2 + a_7xy + a_8xz + a_9yz. \end{aligned} \tag{4.1}$$

Observe that the equilibrium point $(0,\rho,0)$ of (4.1) is located at the origin after projection and let J be the Jacobian matrix associated to the projected vector field $\mathcal{P}_X$ at the origin. Therefore,

$(0,\rho,0)$ is of nondegenerate center-focus type if, and only if, the trace of J is zero and its determinant is positive. A straightforward computation shows that it occurs if, and only if, $a_4 - a_9 = 0$ and $a_6a_7 + a_7^2 - a_9^2 > 0$. We also assume $a_7 \neq 0$, otherwise $a_6a_7 + a_7^2 - a_9^2 = -a_9^2 \leq 0$. Hence, with these assumptions $(0,\rho,0)$ is a weak focus of (4.1). Doing $w^2 = a_6a_7 + a_7^2 - a_9^2$, and $\varrho = (w^2 + a_4a_9)/a_7$ the projected system $\mathcal{P}_X$ is of the form:

$$\begin{aligned} \dot{u} &= -4a_4u - 4\varrho v - 4a_5uv - 4a_8v^2 - a_4u^3 - (\varrho - 2a_7)u^2v + (a_4 + 2a_9)uv^2 + \varrho v^3, \\ \dot{v} &= 4a_7u + 4a_9v + 4a_5u^2 + 4a_8uv - a_7u^3 - (2a_4 + a_9)u^2v - (2\varrho - a_7)uv^2 + a_9v^3. \end{aligned} \tag{4.2}$$

Now, the trace and the determinant of J are $-4(a_4 - a_9)$ and $16w^2$, respectively. The next theorem was proved in [6] and gives the conditions to have a center of (4.1) at the point $(0,1,0)$, on the sphere $\mathbb{S}_1^2$.

Theorem 4.1 ([6])**.** *The equilibrium point $(0,1,0)$ of system (4.1) is a nondegenerate center if, and only if, $a_7 \neq 0$, $a_4 = a_9$, and $a_4a_5a_8a_9 + a_5a_6a_7a_8 + a_5^2a_7a_9 + a_5a_8a_9^2 - a_7a_8^2a_9 = 0$.*

Next we will show an important difference between polynomial homogeneous vector fields defined on the sphere $\mathbb{S}_1^2$ and on the plane. Also in our special case that the dynamics is restricted on a invariant sphere. Firstly, we recall that a planar quadratic homogeneous vector field does not have limit cycles. The following example shows a quadratic homogeneous vector field $X \in \mathfrak{X}_2^H$ which has at least one limit cycle on the sphere $\mathbb{S}_1^2$. It occurs because the projected vector field (4.2) is a planar cubic non-homogeneous vector field. Fore more results about quadratic homogeneous vector fields defined on invariant spheres we refer the reader to [25,26]. As in the previous section, this limit cycle forces the existence of an invariant cone fulfilled of periodic orbits for (4.1).

Proposition 4.2. *The quadratic homogeneous vector field (4.1) has at least one limit cycle bifurcating from $(0,1,0)$ on the sphere $\mathbb{S}_1^2$.*

Proof. Consider the quadratic homogeneous vector field (4.1) and its projection (4.2) with the parameters values $(a_4, a_5, a_7, a_8, a_9, w) = (1+\varepsilon, 1, 1, 0, 1, 1)$. Note that with these values, (4.2) writes as the following cubic vector field

$$\begin{aligned} \dot{u} &= (-4+\varepsilon)u - 4(2+\varepsilon)v - 4uv - (1+\varepsilon)u^3 + \varepsilon u^2v + (3+\varepsilon)uv^2 + (2+\varepsilon)v^3, \\ \dot{v} &= 4u + 4v + 4u^2 - u^3 - (3+\varepsilon)u^2v - (3+\varepsilon)uv^2 + v^3. \end{aligned} \tag{4.3}$$

As we observed before, the origin is an equilibrium point of (4.3). Let J be the Jacobian matrix associated to (4.3) at the origin. As the trace of J is ε and its determinant is $16 + 12\varepsilon$, then the origin is a weak focus for $\varepsilon = 0$. Note that we can use the algorithm explained in Section 2.4 to calculate the Lyapunov constants of analytical vector fields assuming that $\mathcal{P}_{X^+}$ and $\mathcal{P}_{X^-}$ are both defined by (4.3), because it is a generalization of the algorithm presented in Chapter IX of [1]. So, when $\varepsilon = 0$, we calculate the first Lyapunov constant of (4.3) being $L_3 = 4 \neq 0$. Thus, by the classical Hopf bifurcation, there exist values of ε for which (4.3) has one limit cycle bifurcating from the origin. □

On the following we will focus our attention on the center-focus problem that appears naturally for the piecewise smooth system

$$Y(x,y,z) = \begin{cases} X^+(x,y,z), \ z \geq 0, \\ X^-(x,y,z), \ z \leq 0, \end{cases} \tag{4.4}$$

where we obtain $X^{\pm}$ doing $a_i = a_i^{\pm}$ in (4.1) and assuming that $p = (0,1,0) \in \Sigma = \{(x,y,z) \in \mathbb{R}^3 : z = 0\}$ is of center type for both X^+ and X^- on $\mathbb{S}^2_{\rho}$. Here, as we commented above, because of the number of free parameters, we also assume that the system (4.4) is continuous but not differentiable on the separation set Σ. Note that, system (4.4), and the projected associated systems $\mathcal{P}_Y = (\mathcal{P}_{X^+}, \mathcal{P}_{X^-})$, where $\mathcal{P}_{X^{\pm}}$ are obtained doing $a_i = a_i^{\pm}$ in (4.2), are continuous on its separation set if, and only if, $a_4^- = a_4^+$, $a_5^- = a_5^+$, and $a_7^- = a_7^+$. Consequently, on the following, we are assuming these conditions.

As we are interested in exhibiting some families of centers for this family of piecewise smooth vector fields we use the method explained in Section 2.4, to calculate the Lyapunov constants for the projected system $\mathcal{P}_Y$. To do that, we need to consider $\mathcal{P}_{X^{\pm}}$ in its Jordan canonical form.

Note that the change of coordinates $\{\mathrm{u} = v, \mathrm{v} = (cu + dv)/w\}$, where $c = 4a_7$ and $d = 4a_9$ puts the linear part of (4.2) in its Jordan canonical form

$$\begin{aligned}
\dot{\mathrm{u}} &= \mathrm{v} + \frac{a_9\,(a_5a_9 - a_7a_8)}{wa_7{}^2}\mathrm{u}^2 - \frac{(2a_5a_9 - a_7a_8)}{a_7{}^2}\mathrm{uv} + \frac{a_5w}{a_7{}^2}\mathrm{v}^2 + \frac{wa_9}{2a_7{}^2}\mathrm{u}^3 \\
&\quad + \frac{(a_7{}^2 + a_9{}^2 - 2w^2)}{4a_7{}^2}\mathrm{u}^2\mathrm{v} - \frac{w^2}{4a_7{}^2}\mathrm{v}^3, \\
\dot{\mathrm{v}} &= -\mathrm{u} + \frac{(a_5a_9 - a_7a_8)(a_7{}^2 + a_9{}^2)}{a_7{}^2w^2}\mathrm{u}^2 - \frac{(a_5a_7{}^2 + 2a_5a_9{}^2 - a_7a_8a_9)}{wa_7{}^2}\mathrm{uv} \\
&\quad + \frac{a_5a_9}{a_7{}^2}\mathrm{v}^2 + \frac{(a_7{}^2 + a_9{}^2)}{4a_7{}^2}\mathrm{u}^3 + \frac{(2a_7{}^2 + 2a_9{}^2 - w^2)}{4a_7{}^2}\mathrm{uv}^2 - \frac{wa_9}{2a_7{}^2}\mathrm{v}^3.
\end{aligned} \tag{4.5}$$

Moreover, the change of coordinates $\{\mathrm{u} = v, \mathrm{v} = (cu + dv)/w^{\pm}\}$ puts $\mathcal{P}_{X^{\pm}}$ in the canonical form and the separation set $\Sigma = \{(u,v) \in \mathbb{R}^2 : v = 0\}$ becomes $\widetilde{\Sigma} = \{(\mathrm{u},\mathrm{v}); \mathrm{u} = 0, \mathrm{v} = cu/w^{\pm}\}$. Consequently, after this change of coordinates, we deal with the piecewise smooth system

$$\mathcal{P}_Y(\mathrm{u},\mathrm{v}) = \begin{cases} \mathcal{P}_{X^+}(\mathrm{u},\mathrm{v}),\ \mathrm{u} \geq 0, \\ \mathcal{P}_{X^-}(\mathrm{u},\mathrm{v}),\ \mathrm{u} \leq 0, \end{cases} \tag{4.6}$$

where $\mathcal{P}_{X^{\pm}}$ are obtained doing $a_i = a_i^{\pm}$ in (4.5) and then, in polar coordinates, it is written as

$$\begin{cases} \dot{r} = R^+(r,\theta),\ \theta \in [-\pi/2, \pi/2], \\ \dot{r} = R^-(r,\theta),\ \theta \in [-\pi/2, -3\pi/2]. \end{cases}$$

Therefore, we use the technique shown in Section 2.4 after a rotation of angle $\pi/2$, to calculate the Lyapunov constants of (4.6). Note that after the change of coordinates $\{\mathrm{u} = v, \mathrm{v} = (cu + dv)/w^{\pm}\}$ the separation set of (4.6), $\widetilde{\Sigma} = \{(\mathrm{u},\mathrm{v}); \mathrm{u} = 0, \mathrm{v} = cu/w^{\pm}\}$, is parameterized in two different ways when $w^+ \neq w^-$ and then the continuity condition must be considered before doing it and we also take it into account when we compute the Lyapunov constants.

On the following, we give some families of centers for the piecewise smooth vector field (4.4). Some of these centers appear in a family of reversible vector fields with respect to a line (see the definition in Section 2.2).

Proposition 4.3. *The piecewise continuous vector field (4.4) has a center at the equilibrium point $(0,1,0)$, on $\mathbb{S}^2_1$, if $a_7^{\pm} \neq 0$, $a_4^{\pm} = a_9^{\pm}$ and one of the following conditions is satisfied:*

(a) $a_8^- = -a_8^+$, $a_9^- = 0$, *and* $w^+ = w^-$;

(b) $a_7^- = \pm w$, $a_9^- = 0$, *and* $w^+ = w^-$;

(c) $a_8^+ = a_8^-$, $(a_5^-)^2 a_7^- a_9^- - a_5^-(a_7^-)^2 a_8^- + a_5^- a_8^-(a_9^-)^2 + a_5^- a_8^- w^2 - a_7^-(a_8^-)^2 a_9^- = 0$, *and* $w^+ = w^-$;

(d) $a_5^- = 0$ *and* $a_9^- = 0$.

Proof. In case (a), the piecewise projected continuous vector field $\mathcal{P}_Y = (\mathcal{P}_{X^+}, \mathcal{P}_{X^-})$ is reversible with respect to the separation set. The case (b) follows because in polar coordinates we have $dr/dt = 0$ for both $\mathcal{P}_{X^\pm}$, which implies that the difference map defined in Σ, in a neighborhood of the origin, is zero. In case (c), the vector field $\mathcal{P}_Y$ is smooth and it satisfies the condition given on Theorem 4.1. Finally, case (d) follows because both vector fields $\mathcal{P}_{X^\pm}$ are reversible with respect to the u-axis and then the difference map defined in Σ, in a neighborhood of the origin, is zero which concludes the proof. □

If $w^+ = w^-$ the change of coordinates that puts the system (4.2) on form (4.5) is the same for X^+ and X^- and then the parametrization of $\widetilde{\Sigma}$ coincides before this change of coordinates. In this case, the only possible center families for (4.4) are that given on items (a)-(d) of Proposition 4.3.

Proposition 4.4. *The piecewise continuous vector field* (4.4) *with* $w^+ = w^-$ *has a center at the equilibrium point* $(0,1,0)$, *on* $\mathbb{S}_1^2$, *if, and only if,* $a_7^\pm \neq 0$, $a_4^\pm = a_9^\pm$ *and one of the conditions (a), (b), (c), or (d) of Proposition 4.3 is satisfied.*

Proof. To simplify the notation of this proof, we eliminate the superscript $\pm$ when the corresponding coefficients of X^+ and X^- are equal. Hence, we consider $w^+ = w^- = w$, $a_4^+ = a_4^- = a_4$, $a_5^+ = a_5^- = a_5$, $a_7^+ = a_7^- = a_7$, and $a_9^+ = a_9^- = a_9$. According to the proof of Proposition 4.3, all the families detailed in the statement have a center at the origin. Consequently, we only need to check that these are the only ones when $w^+ = w^- = w$. To do that, we compute four Lyapunov constants using the method explained in Section 2.4 for system (4.6), with the statement assumptions, and we obtain

$$
\begin{aligned}
L_2 &= \frac{2}{3wa_7} a_9(a_8^+ - a_8^-),\\
L_3 &= \frac{\pi}{8w^3a_7^3}\big(2a_5^2a_7a_9(a_7^2 + a_9^2 + w^2) - a_5(a_7^4a_8^+ - 2a_8^+a_9^4 - 4a_8^+a_9^2w^2\\
&\qquad - (a_8^+ + a_8^-)w^4) - 2a_7a_9(a_7^2(a_8^+)^2 + (a_8^-)^2a_9^2 + (a_8^+)^2w^2)\big),\\
L_4 &= \frac{4}{45a_7^4w^5} a_5((a_8^+)^2 - (a_8^-)^2)(a_7^2 - w^2)(4a_7^4 + 3a_7^2w^2 + 2w^4),\\
L_5 &= \frac{\pi}{12w^3a_7^3}(a_5^2 + (a_8^+)^2 - w^2)\big(2a_5^2a_7a_9 - a_5a_7^2a_8^+ - a_5a_7^2a_8^-\\
&\qquad + 2a_5a_8^+a_9^2 + a_5a_8^+w^2 + a_5a_8^-w^2 - 2a_7(a_8^+)^2a_9\big).
\end{aligned}
$$

When we solve the system of equations $\mathcal{S}_L = \{L_2 = \cdots = L_5 = 0\}$ we obtain the real solutions given on statements (a)-(d) of Proposition 4.3 and four more complex solutions given by $\left\{a_5 = \pm\sqrt{-(a_8^-)^2 + w^2}, a_7 = \pm\,\mathrm{i}\sqrt{a_9^2 + w^2}, a_8^+ = a_8^-\right\}$ and $\{a_7 = \pm\,\mathrm{i}\,a_9, a_8^+ = a_8^-, w = 0\}$. As we are interested in real families with $w \neq 0$ we conclude the proof. □

Proposition 4.5. *Consider system* (4.4) *with* $a_5^- = 1, a_7^- = 1, a_8^+ = 3, a_8^- = 1, a_9^- = 0$, *and* $w^+ = w^- = 2$. *Then, the equilibrium point* $p = (0,1,0)$ *is a weak focus of third-order and there exist* 2 *small amplitude limit cycles, on* $\mathbb{S}_1^2$, *bifurcating from* p *with a continuous perturbation in* $\mathcal{X}_2^H$.

Proof. Using the expressions of L_i, $i = 2, \dots, 5$ given in the above proposition we conclude that, for these values of parameters, we have $L_2 = 0$ and $L_3 = 15\pi/16 \neq 0$. Hence, adding the trace parameter and using the derivation-division algorithm (see more details in [29]) we obtain 2 small amplitude crossing limit cycles bifurcating from the equilibrium point $(0, 1, 0)$ on $\mathbb{S}_1^2$. □

We emphasize that, when we deal with a continuous perturbation, we do not have the sliding parameter to get the maximum upper bound for the number of small amplitude crossing limit cycles bifurcating from a center or a weak focus, as we have explained in Section 2.4. Because of that, the maximum number of limit cycles that we can obtain bifurcating from the weak focus of third-order, in the last result, is 2.

5 Local cyclicity for quadratic vector fields in $\mathfrak{X}_2$ with piecewise smooth perturbation in $\mathcal{X}$

In this section, we study the local cyclicity of centers and weak focus families of quadratic smooth vector fields with piecewise quadratic perturbations in $\mathcal{X}_2$. The continuous or refractive perturbation cases are also analyzed. We show the results that we have obtained in Propositions 5.1 and 5.2. The proof of Theorem 1.2 follows directly from Proposition 5.2(c).

On the following, we summarize some assumptions and results given in [6] for a quadratic vector field $X \in \mathfrak{X}_2$ which will be useful in the sequence. Firstly, the behavior of system X can be totally different in two different levels of invariant spheres. Hence, we restrict our analysis to the unit sphere $\mathbb{S}_1^2 = \{(x, y, z) \in \mathbb{R}^3 : x^2 + y^2 + z^2 = 1\}$. In this case any $X \in \mathfrak{X}_2$ can be written in its canonical form

$$\begin{aligned} \dot{x} &= -a_1 y - a_2 z - a_4 xy - a_5 xz - a_{10} y^2 - (a_6 + a_7) yz - a_8 z^2, \\ \dot{y} &= a_1 x - a_3 z + a_4 x^2 + a_{10} xy + a_6 xz - a_{11} yz - a_9 z^2, \\ \dot{z} &= a_2 x + a_3 y + a_5 x^2 + a_7 xy + a_8 xz + a_{11} y^2 + a_9 yz. \end{aligned} \tag{5.1}$$

Note that $(0, 1, 0)$ is an equilibrium point of (5.1) if, and only if, $a_1 + a_{10} = 0$, $a_3 + a_{11} = 0$. Consequently, to have the origin as an equilibrium point of the projected vector field $\mathcal{P}_X$ associated to (5.1), we assume these conditions on the following. Next we will impose the conditions that ensure that $(0, 1, 0)$ is an equilibrium point of nondegenerate center-focus type on the sphere $\mathbb{S}_1^2$. We will do that analyzing the trace and the determinant of the Jacobian matrix J associated to the projected vector field $\mathcal{P}_X$ at the equilibrium point $(0, 0)$. Recall that $\mathcal{P}_X$ has an equilibrium point of nondegenerate center-focus type at origin if, and only if, the trace of J is zero and its determinant is positive. It occurs when $a_4 = a_9$ and $a_2 a_6 + a_6 a_7 + 2a_2 a_7 + a_2^2 + a_7^2 - a_9^2 > 0$. As explained in [6], due to the high number of free parameters, we will restrict our analysis adding two extra conditions: $a_9 = 0$ and $a_2 + a_7 = 1$. With these assumptions, the projected vector field $\mathcal{P}_X$ has a weak focus at the origin if, and only if, $a_4 = 0$ and $a_6 + 1 > 0$. Moreover, with these restrictions the projected vector field has a center-focus point at the origin with a Jacobian matrix in Jordan normal form. Doing $a_4 = 0$ and $w^2 = a_6 + 1$, with $w \neq 0$, the following system is obtained from (5.1)

$$\begin{aligned} \dot{x} &= -a_1 y - (1 - a_7) z - a_5 xz + a_1 y^2 + (1 - a_7 - w^2) yz - a_8 z^2, \\ \dot{y} &= a_1 x + a_{11} z - a_1 xy + (w^2 - 1) xz - a_{11} yz, \\ \dot{z} &= (1 - a_7) x - a_{11} y + a_5 x^2 + a_7 xy + a_8 xz + a_{11} y^2. \end{aligned} \tag{5.2}$$

After a time reparameterization and the change of coordinates $u \to wu$, the corresponding projected system obtained from (5.2) is

$$\begin{aligned}\dot{u} &= -v - \frac{a_1}{2}u^2 - \frac{a_5}{w}uv - \frac{a_1+2a_8}{2w^2}v^2 + \frac{2a_7-w^2}{4}u^2v \\ &\quad + \frac{w^2+2a_7-2}{4w^2}v^3 - \frac{a_1w^2}{8}u^4 - \frac{a_{11}w}{4}u^3v - \frac{a_{11}}{4w}uv^3 + \frac{a_1}{8w^2}v^4, \\ \dot{v} &= u + \frac{(2a_5-a_{11})w}{2}u^2 + a_8uv - \frac{a_{11}}{2w}v^2 - \frac{(2a_7-1)w^2}{4}u^3 \\ &\quad - \frac{2w^2+2a_7-3}{4}uv^2 + \frac{w^3a_{11}}{8}u^4 - \frac{w^2a_1}{4}u^3v - \frac{a_1}{4}uv^3 - \frac{a_{11}}{8w}v^4.\end{aligned} \tag{5.3}$$

In items (a) and (b) of Proposition 5.2, we show that with a continuous (resp. refractive) perturbation in $\mathcal{X}_2$ we obtain 5 (resp. 6) crossing limit cycles bifurcating from a center family of (5.2). Moreover, when we consider a piecewise quadratic general perturbation in $\mathcal{X}_2$ we obtain 10 limit cycles, as we will see in item (c) of Proposition 5.2, which proves Theorem 1.2. We also exhibit a piecewise quadratic perturbation of a weak focus in Proposition 5.1 for a fixed value of w.

In the following, we will describe the type of piecewise smooth perturbation of $X \in \mathfrak{X}_2$ that we will consider and which are the conditions that will make this perturbation continuous or refractive.

Let $X = X(\mathrm{x}, \mathrm{a}) \in \mathfrak{X}_2$ given by (5.2) where $\mathrm{x} = (x, y, z)$ and $\mathrm{a} = (a_1, a_5, a_7, a_8, a_{11}, w)$. Denoting $\mathrm{a} + \varepsilon^{\pm} = (a_1 + \varepsilon_1^{\pm}, \ldots, w + \varepsilon_6^{\pm})$ we consider the piecewise smooth perturbation of X defined by

$$Y(\mathrm{x}, \varepsilon) = \begin{cases} X(\mathrm{x}; \mathrm{a} + \varepsilon^{+}), \, z \geq 0, \\ X(\mathrm{x}; \mathrm{a} + \varepsilon^{-}), \, z \leq 0, \end{cases} \tag{5.4}$$

and the projected vector field associated, defined by (2.3), which is of the form

$$\mathcal{P}_Y(\mathrm{u}, \varepsilon) = \begin{cases} \mathcal{P}_X(\mathrm{u}; \mathrm{a} + \varepsilon^{+}), \, v \geq 0, \\ \mathcal{P}_X(\mathrm{u}; \mathrm{a} + \varepsilon^{-}), \, v \leq 0, \end{cases} \tag{5.5}$$

where $\mathrm{u} = (u, v)$ and $\mathcal{P}_X(\mathrm{u}, 0)$ is given by (5.3).

So, when $\varepsilon = 0$ we have the unperturbed analytical systems (5.2) and (5.3). Following the same idea of the last section, we will say that the perturbation of the vector field Y is continuous (resp. refractive) if (5.4) is continuous (resp. refractive) in the separation set. With a straightforward computation we see that (5.4) is continuous (resp. refractive) if, and only if, $\varepsilon_i^{+} = \varepsilon_i^{-}$, for $i = 1, 2, 3, 4$ (resp. $\varepsilon_i^{+} = \varepsilon_i^{-}$, for $i = 2, 3, 4$).

Note that the origin is on the boundary of two crossing segments of the perturbative system (5.5) as well as of the unperturbed one. This is because we assumed that the origin is an equilibrium point of the center type for the unperturbed system and the perturbative parameters do not change the linear part of it. If we assume $a_3 = -a_{11} + \varepsilon_7$ instead of $a_3 = -a_{11}$ we can create a sliding segment in a neighborhood of the origin, because in this case, the projected system is of the form

$$\left(-\frac{a_4}{w}u - v + \mathcal{O}_2(u, v), \frac{\varepsilon_7}{w} + u + \mathcal{O}_2(u, v)\right).$$

Thus, we also use the perturbative parameter ε_7 when we deal with a piecewise perturbation instead of piecewise continuous or piecewise refractive ones, to obtain one more crossing limit cycle of small amplitude creating from a sliding or escaping segment, as it was explained in Section 2.

Now we are able to prove the last results. It is important to note that we confine the dynamics to an invariant sphere of fixed radius, which remains unchanged with the considered perturbations because the notion of 2-dimensional limit cycle make no sense if the perturbations do not keep the 2-dimensional spheres invariant.

Proposition 5.1. *Consider the system*

$$\begin{aligned}\dot{x} &= 2\alpha y + \frac{9}{20}z - xz - 2\alpha y^2 - \frac{89}{20}yz - \alpha z^2,\\ \dot{y} &= -2\alpha x + 2z + 2\alpha xy + 3xz - 2yz,\\ \dot{z} &= -\frac{9}{20}x - 2y + x^2 + \frac{29}{20}xy + \alpha xz + 2y^2.\end{aligned} \tag{5.6}$$

Then, for $\alpha = \pm\sqrt{857/488}$ there exists a piecewise quadratic perturbation in $\mathcal{X}$ such that at least 9 hyperbolic crossing limit cycles of small amplitude bifurcate from the equilibrium point $(0,1,0)$ on $\mathbb{S}^2_1$.

Proof. Let $\alpha = \pm\sqrt{857/488}$. Note that system (5.6) is obtained doing $a_1 = -2\alpha, a_4 = 0, a_5 = 1, a_7 = 29/20, a_8 = \alpha, a_{11} = 2$, and $w = 2$ in (5.2). It was proved in [6] that the equilibrium point $p = (0,1,0)$ of (5.6) is a weak focus of fourth-order and that there exist 4 small amplitude limit cycles, on $\mathbb{S}^2_1$, bifurcating from p considering an analytical perturbation of (5.6) inside family (5.2). Now we consider a piecewise smooth perturbation $(a_1^\pm, a_5^\pm, a_7^\pm, a_8^\pm, a_{11}^\pm, w^\pm) = (-2\alpha + \varepsilon_1^\pm, 1 + \varepsilon_2^\pm, 29/20 + \varepsilon_3^\pm, \alpha + \varepsilon_4^\pm, 2 + \varepsilon_5^\pm, 2 + \varepsilon_6^\pm)$ in the piecewise projected system (5.3). As we saw before, we consider the separation set $\{(u,v) \in \mathbb{R}^2 : v = 0\}$ of the projected system and then we consider the perturbative parameter $\varepsilon^+ = (\varepsilon_1^+, \ldots, \varepsilon_6^+)$ for $v > 0$, $\varepsilon^- = (\varepsilon_1^-, \ldots, \varepsilon_6^-)$ for $v < 0$, and joining all $\varepsilon = (\varepsilon_1^+, \ldots, \varepsilon_6^+, \varepsilon_1^-, \ldots, \varepsilon_6^-)$. Let $L_i(\varepsilon)$ be the corresponding Lyapunov constants. Using the method explained in Section 2.4 we compute the Taylor series of these Lyapunov constants up to first-order with respect to ε, $L_i^{[1]}(\varepsilon)$, and we write $L_i(\varepsilon) = L_i^{[1]}(\varepsilon) + \mathcal{O}_2(\varepsilon)$, where

$$\begin{aligned}L_2^{[1]}(\varepsilon) =& -2\varepsilon_2^- + 2\varepsilon_5^- - \varepsilon_6^- + 2\varepsilon_2^+ - 2\varepsilon_5^+ + \varepsilon_6^+,\\ L_3^{[1]}(\varepsilon) =&\ 15616\varepsilon_2^- - 15616\varepsilon_5^- + 7808\varepsilon_6^- - 15616\varepsilon_2^+ + 15616\varepsilon_5^+ - 7808\varepsilon_6^+\\ &+ 13\pi\sqrt{104554}\left(-2\varepsilon_2^- + \varepsilon_5^- - 2\varepsilon_2^+ + \varepsilon_5^+\right) + \pi\left(427\varepsilon_1^- + 854\varepsilon_4^- + 427\varepsilon_1^+ + 854\varepsilon_4^+\right),\\ L_4^{[1]}(\varepsilon) =& -5916624\varepsilon_2^- + 1112640\varepsilon_3^- + 5433936\varepsilon_5^- - 2314584\varepsilon_6^- + 5916624\varepsilon_2^+ - 1112640\varepsilon_3^+\\ &- 5433936\varepsilon_5^+ + 2314584\varepsilon_6^+ + \sqrt{104554}\left(-80\varepsilon_1^- - 160\varepsilon_4^- + 80\varepsilon_1^+ + 160\varepsilon_4^+\right.\\ &\left.+\pi\left(9750\varepsilon_2^- - 4875\varepsilon_5^- + 9750\varepsilon_2^+ - 4875\varepsilon_5^+\right)\right) + \pi\left(-160125\varepsilon_1^- - 320250\varepsilon_4^-\right.\\ &\left.-160125\varepsilon_1^+ - 320250\varepsilon_4^+\right),\end{aligned} \tag{5.7}$$

we omit the expressions of $L_i^{[1]}(\varepsilon)$, $5 \le i \le 9$, because of their size.

We get $L_2^{[1]}(0) = \cdots = L_8^{[1]}(0) = 0$ and $L_9^{[1]}(0) \neq 0$. Hence, as the matrix formed with the coefficients of $(L_2^{[1]}, \ldots, L_8^{[1]})$ with respect to ε has rank 7, we obtain eight hyperbolic crossing limit cycles of small amplitude bifurcating from the origin adding the trace parameter and using the Implicit Function Theorem and then the derivation-division algorithm (see again [29]). Finally, adding the sliding parameter we obtain the ninth hyperbolic crossing limit cycle of small amplitude. □

Proposition 5.2. *Consider the system*

$$\begin{aligned}\dot{x} &= -\frac{4}{5}y - \frac{13}{8}z - \frac{5}{2}xz + \frac{4}{5}y^2 - \frac{59}{8}yz - z^2,\\ \dot{y} &= \frac{4}{5}x + 2z - \frac{4}{5}xy + 8xz - 2yz,\\ \dot{z} &= \frac{13}{8}x - 2y + \frac{5}{2}x^2 - \frac{5}{8}xy + xz + 2y^2.\end{aligned} \tag{5.8}$$

(a) There exists a continuous quadratic perturbation of (5.8) in $\mathcal{X}$ such that at least 5 hyperbolic crossing limit cycles of small amplitude bifurcate from the equilibrium point $(0,1,0)$ on $\mathbb{S}^2_1$.

(b) There exists a refractive quadratic perturbation of (5.8) in $\mathcal{X}$ such that at least 6 hyperbolic crossing limit cycles of small amplitude bifurcate from the equilibrium point $(0,1,0)$ on $\mathbb{S}^2_1$.

(c) There exists a piecewise quadratic perturbation of (5.8) in $\mathcal{X}$ such that at least 10 hyperbolic crossing limit cycles of small amplitude bifurcate from the equilibrium point $(0,1,0)$ on $\mathbb{S}^2_1$.

Proof. It was proved in [6] that system (5.2), with $w \neq 1$, has a center at the origin when its coefficients satisfy the conditions,

$$a_1 = \frac{w^2-1}{w^2+1}a_8, \quad a_4 = 0, \quad a_5 = \frac{w^2+1}{w^2-1}a_{11}, \quad \text{and} \quad a_7 = \frac{1}{w^2+1} - \frac{1}{(w^2+1)}a_8^2 - \frac{w^2+1}{(w^2-1)^2}a_{11}^2,$$

exhibiting an inverse integral factor for the system. Moreover, there exists an analytical perturbation inside family (5.2) such that at least 3 small amplitude limit cycles bifurcate from the equilibrium point $(0,1,0)$ on $\mathbb{S}^2_1$. Thus, as system (5.8) is obtained doing $a_1 = 4/5, a_4 = 0, a_5 = 5/2, a_7 = -5/8, a_8 = 1, a_{11} = 2$, and $w = 3$ in (5.2) it has a center at $(0,1,0)$. So, we take the parameter values $(a_1, a_5, a_7, a_8, a_{11}, w)$ satisfying it and we consider the piecewise smooth perturbation $(a_1, a_5, a_7, a_8, a_{11}, w) = (4/5 + \varepsilon_1^{\pm}, 5/2 + \varepsilon_2^{\pm}, -5/8 + \varepsilon_3^{\pm}, 1 + \varepsilon_4^{\pm}, 2 + \varepsilon_5^{\pm}, 3 + \varepsilon_6^{\pm})$ in the projected system (5.3). As we saw before, we consider the separation set $\{(u,v) \in \mathbb{R}^2 : v = 0\}$ of the projected system and then we consider the perturbative parameter $\varepsilon^+ = (\varepsilon_1^+, \dots, \varepsilon_6^+)$ for $v > 0$, $\varepsilon^- = (\varepsilon_1^-, \dots, \varepsilon_6^-)$ for $v < 0$ and $\varepsilon = (\varepsilon_1^+, \dots, \varepsilon_6^+, \varepsilon_1^-, \dots, \varepsilon_6^-)$. We denote by $L_i(\varepsilon)$, the corresponding Lyapunov constants. When $\varepsilon = 0$ the origin is a center and then $L_i(0) = 0$ for all i. Using the method explained in Section 2.4 we compute the Taylor series of these Lyapunov constants up to first-order with respect to ε, $L_i^{[1]}(\varepsilon)$, and we write $L_i(\varepsilon) = L_i^{[1]}(\varepsilon) + \mathcal{O}_2(\varepsilon)$ where

$$\begin{aligned}L_2^{[1]}(\varepsilon) =& -48\varepsilon_2^- + 33\varepsilon_5^- - 36\varepsilon_6^- + 48\varepsilon_2^+ - 33\varepsilon_5^+ + 36\varepsilon_6^+,\\ L_3^{[1]}(\varepsilon) =& -7680\varepsilon_2^- + 5280\varepsilon_5^- - 5760\varepsilon_6^- + 7680\varepsilon_2^+ - 5280\varepsilon_5^+ + 5760\varepsilon_6^+ + \pi\,(675\varepsilon_1^- - 56\varepsilon_2^-\\ & -540\varepsilon_4^- + 70\varepsilon_5^- - 102\varepsilon_6^- + 675\varepsilon_1^+ - 56\varepsilon_2^+ - 540\varepsilon_4^+ + 70\varepsilon_5^+ - 102\varepsilon_6^+),\\ L_4^{[1]}(\varepsilon) =& \,6380640\varepsilon_1^- - 263540576\varepsilon_2^- - 50641200\varepsilon_3^- - 6099840\varepsilon_4^- + 152862163\varepsilon_5^-\\ & - 159148902\varepsilon_6^- - 6380640\varepsilon_1^+ + 263540576\varepsilon_2^+ + 50641200\varepsilon_3^+ + 6099840\varepsilon_4^+\\ & - 152862163\varepsilon_5^+ + 159148902\varepsilon_6^+ + \pi\,(13668750\varepsilon_1^- - 1134000\varepsilon_2^- - 10935000\varepsilon_4^-\\ & +1417500\varepsilon_5^- - 2065500\varepsilon_6^- + 13668750\varepsilon_1^+ - 1134000\varepsilon_2^+ - 10935000\varepsilon_4^+\\ & +1417500\varepsilon_5^+ - 2065500\varepsilon_6^+).\end{aligned} \tag{5.9}$$

We omit the expressions of $L_i^{[1]}(\varepsilon)$, $5 \le i \le 12$ because of their size.

In the case (a) (resp. (b)) we consider a continuous (resp. refractive) perturbation of this center family. As we saw above, it implies that $\varepsilon_i^+ = \varepsilon_i^-$, for $i = 1,2,3,4$ (resp. $\varepsilon_i^+ = \varepsilon_i^-$, for $i = 2,3,4$). With this assumption, the matrix formed by the coefficients of $(L_2^{[1]}, \dots, L_7^{[1]})$ with respect to ε has rank 5 (resp. 6). Adding the trace parameter and using the Melnikov theory, as we have explained in the Section 2.4, we obtain 5 (resp. 6) hyperbolic crossing limit cycles of small amplitude bifurcating from the origin.

Finally, in the case (c), the proof follows because the matrix formed by the coefficients of $(L_2^{[1]}, \ldots, L_{12}^{[1]})$ with respect to ε has rank 9, so adding the trace parameter and using the Melnikov theory, as we explained in the Section 2.4, we get 9 hyperbolic crossing limit cycles of small amplitude bifurcating from the origin. Adding the sliding or escaping segments we obtain one more crossing limit cycle and the proof follows. □

Abstract. In this paper, we are devoted to establishing that the existence of positive solutions for a class of generalized quasilinear elliptic equations in $\mathbb{R}^N$ with Sobolev critical growth, which have appeared from plasma physics, as well as high-power ultrashort laser in matter. To begin, by changing the variable, quasilinear equations are transformed into semilinear equations. The positive solutions to semilinear equations are then presented using the Mountain Pass Theorem for locally Lipschitz functionals and the Concentration-Compactness Principle. Finally, an inverse translation reveals the presence of positive solutions to the original quasilinear equations.

Keywords: variational methods, Sobolev critical growth, locally Lipschitz functional.

2020 Mathematics Subject Classification: 35J20, 35J62.

1 Introduction

In this paper, we aim at studying the existence of positive solutions for the following generalized quasilinear elliptic equations

$$-\operatorname{div}(g^2(u)\nabla u) + g(u)g'(u)|\nabla u|^2 + V(x)u = h(x,u), \quad \text{in } \mathbb{R}^N, \tag{1.1}$$

where $N \geq 3$, $g \in C^1(\mathbb{R}, \mathbb{R}^+)$ is an even function and $g'(t) \geq 0$ for all $t \geq 0$ and $g(0) = 1$, the potential $V \in C(\mathbb{R}^N, \mathbb{R})$, h is a measurable function defined on $\mathbb{R}^N \times \mathbb{R}$. These equations are closely related to the existence of standing wave solutions for the following quasilinear Schrödinger equations

$$i\partial_t z = -\Delta z + E(x)z - \sigma(x, |z|^2)z - \Delta[l(|z|^2)]l'(|z|^2)z, \tag{1.2}$$

where $z : \mathbb{R}^N \times \mathbb{R} \to \mathbb{C}$, $E : \mathbb{R}^N \to \mathbb{R}$ is a potential function and $\sigma : \mathbb{R}^N \times \mathbb{R} \to \mathbb{R}$, $l : \mathbb{R} \to \mathbb{R}$ are suitable functions. Notice that equation (1.2) can be reduced to elliptic equations with the

✉ Corresponding author. Email: nianzhang411@163.com

following formal structure (see [15]) by setting $z(x,t) = \exp(-iFt)u(x)$, where $F \in \mathbb{R}$ and u is a real function,

$$-\Delta u + V(x)u - \Delta[l(u^2)]l'(u^2)u = h(x,u), \quad \text{in } \mathbb{R}^N. \tag{1.3}$$

Furthermore, we take $g^2(u) = 1 + \frac{(l'(u^2))^2}{2}$, then (1.3) turns into (1.1) (see [16,28]).

To the best of our knowledge, the quasilinear equation (1.1) have been utilized to simulate a range of physical phenomena corresponding to various types of $g(u)$ in several fields of mathematical physics. For instance, the case $g^2(u) = 1 + 2u^2$, that is, $l(u) = u$ in (1.3), we get

$$-\Delta u + V(x)u - u\Delta(u^2) = h(x,u), \quad \text{in } \mathbb{R}^N, \tag{1.4}$$

which simulates the time evolution of the condensate wave function in a superfluid film (see [20]). For equation (1.1), if we take $g^2(u) = 1 + \frac{u^2}{2(1+u^2)}$, that is, $l(u) = \sqrt{1+u}$, we get

$$-\Delta u + V(x)u - [\Delta\sqrt{1+u^2}]\frac{u}{2\sqrt{1+u^2}}u = h(x,u), \quad \text{in } \mathbb{R}^N. \tag{1.5}$$

Equation (1.5) is often used as a model of the self-channeling of a high-power ultrashort laser in matter (see [8, 12, 25]). For more physical backgrounds about equation (1.1), readers can refer to [7, 19, 23, 24] and the references within. So, the study for general quasilinear elliptic equation (1.1) is meaningful and important.

In [21], the quasilinear equation (1.4) was firstly transformed to a semilinear one by using a change of variable. Then, they chose an Orlicz space as the working space and obtained the existence of positive solutions to equation (1.4) by using the Mountain Pass theorem. Afterwards, the same change of variable was applied in [14,30,31], but the usual Sobolev space framework was used as the working space. For example, Silva and Vieira in [30] obtained the existence of positive solutions of equation (1.4) in an asymptotically periodic condition with critical growth. In [28], Shen and Wang used a new change of variable developed by (1.4) to show the existence of positive solutions of equation (1.1) when $h(x,u)$ was superlinear and subcritical. Following that, by applying the same modification in variable as in [28] and the classical Mountain Pass Theorem, Deng et al. in [16] proved the existence of a positive solution for equation (1.1) where nonlinearity was critical growth, and Shi and Chen in [29] proved the existence of positive solutions of equation (1.1) when nonlinearity was periodic or asymptotically periodic cases with critical growth. On the other hand, Candela et al. in [9] considered the more general quasilinear ellptic equation:

$$-\operatorname{div}(A(x,u)|\nabla u|^{p-2}\nabla u) + \frac{1}{p}A_u(x,u)|\nabla u|^p + V(x)|u|^{p-2}u = h(x,u), \quad \text{in } \mathbb{R}^N,$$

with $p > 1$ and $A : \mathbb{R}^N \times \mathbb{R} \to \mathbb{R}$ such that $A_u(x,u) = \frac{\partial A}{\partial u}(x,u)$. When $A(x,u) = g^2(u)$ and $p = 2$, the above equation turns to (1.1) with $N = 3$. They employed an entirely new approach to deal with (1.1) because the arguments of change of variable frequently need $g(u)$ to meet certain particular assumptions, and the features of $g(u)$ directly affect the hypotheses on the nonlinear term $h(x,u)$. By using the Mountain Pass Theorem with the weak Cerami Palais Smale condition, they established the existence of week-bounded solutions under certain appropriate hypotheses on $V(x)$ and $h(x,u)$, which are independent of $g(u)$.

It is worth pointing out that the continuity of nonlinearity is always required in these aforementioned papers. It seems that there are no results concerning equation (1.1) with discontinuous nonlinearities. Actually, many free boundary problems and obstacle problems arising from physics can be described with nonlinear partial differential equations with discontinuous nonlinearities. For more problems with discontinuous nonlinearities, readers can refer to [1,3,6,10,22,26,35] and their references. Hence, our goal is to discuss the existence of positive solutions for problem (1.1) with discontinuous nonlinearities. In this paper, we consider equation (1.1) with $h(x,t) = \kappa f(x,t) + g(t)|G(t)|^{2^*-2}G(t)$, where $\kappa > 0$, $G(t) = \int_0^t g(s)ds$, $2^* = \frac{2N}{N-2}$ and $f : \mathbb{R}^N \times \mathbb{R} \to \mathbb{R}$ is a discontinuous function. We rewrite equation (1.1) as follows:

$$-\operatorname{div}(g^2(u)\nabla u) + g(u)g'(u)|\nabla u|^2 + V(x)u = \kappa f(x,u) + g(u)|G(u)|^{2^*-2}G(u), \quad \text{in } \mathbb{R}^N. \tag{1.6}$$

The hypotheses on the function V and f are the following:

(V_1) There exist a function $V_p(x) \in C(\mathbb{R}^N, \mathbb{R})$, $\mathbb{Z}^N$-periodic with respect to variable x, satisfying

$$V_p(x) \geq V_0, \qquad \forall x \in \mathbb{R}^N,$$

and a function $W(x) \in L^{\frac{N}{2}}(\mathbb{R}^N) \cap C(\mathbb{R}^N, \mathbb{R})$ with $W(x) \geq 0$ such that

$$V(x) = V_p(x) - W(x) \geq W_0, \qquad \forall x \in \mathbb{R}^N,$$

where V_0, W_0 are positive constants and the inequality $W(x) \geq 0$ is strict on a subset of positive measure in $\mathbb{R}^N$.

(f_1) $f(x,t)$ is a measurable function defined on $\mathbb{R}^N \times \mathbb{R}$ and the functions

$$\underline{f}(x,t) := \lim_{\delta \downarrow 0} \text{ess inf}\{f(x,s); |t-s| < \delta\}$$

and

$$\overline{f}(x,t) := \lim_{\delta \downarrow 0} \text{ess sup}\{f(x,s); |t-s| < \delta\},$$

are N-mensurable (see [11]).

(f_2) $f(x,t) \equiv 0$ if $t \leq 0$ and $\limsup_{t \to 0^+} \frac{f(x,t)}{t} = 0$, uniformly in $x \in \mathbb{R}^N$.

(f_3) There are $C > 0$ and $q \in (2, 2^*)$ such that

$$|f(x,t)| \leq C(1 + g(t)|G(t)|^{q-1}), \qquad \forall (x,t) \in \mathbb{R}^N \times [0, \infty).$$

(f_4) There exists $\theta \in (2, 2^*)$ such that

$$0 \leq \theta g(t)F(x,t) \leq G(t)\min\{f(x,t), \varrho\}, \qquad \forall \varrho \in \partial_t F(x,t) \quad \text{and} \quad \forall (x,t) \in \mathbb{R}^N \times [0, \infty),$$

where $F(x,t) = \int_0^t f(x,s)ds$ and $\partial_t F(x,t) := [\underline{f}(x,t), \overline{f}(x,t)]$ denotes the generalized gradient of $F(x,t)$ with respect to variable t (see [4]).

Here, we provide a nonlinearity f that satisfies the assumptions above as following: fixed $T > 0$, let us consider the function

$$f(x,t) = \begin{cases} 0, & t \in (-\infty, 0], \\ g(t)(G(t))^{q-2}\left[G(t) - \arctan(G(t))\right], & t \in (0, T], \\ g(t)(G(t))^{q-2}\left[G(t) - \mu \arctan(G(t))\right], & t \in (T, +\infty), \end{cases}$$

where $0 < \mu < 1$.

The asymptotic periodicity of f at infinity is given by the following condition:

(f_5) There exists a function $f_p(x,t) \in C(\mathbb{R}^N \times \mathbb{R}, \mathbb{R})$, $\mathbb{Z}^N$-periodic with respect to variable x, such that $f_p(x,t) \equiv 0$ if $t \le 0$ and $\frac{f_p(x,t)}{g(t)G(t)}$ is nondecreasing for all $t > 0$.

(f_6) There exists $\nu \in (2, 2^*)$ such that

$$0 \le \nu g(t) F_p(x,t) \le G(t) f_p(x,t), \qquad \forall (x,t) \in \mathbb{R}^N \times \mathbb{R},$$

where $F_p(x,t) = \int_0^t f_p(x,s) ds$.

(f_7) $F(x,t) \ge F_p(x,t) = \int_0^t f_p(x,s) ds$, $\forall (x,t) \in \mathbb{R}^N \times [0,\infty)$ and

$$|f(x,t) - f_p(x,t)| \le \pi(x) g(t) |G(t)|^{q-1}, \qquad \forall (x,t) \in \mathbb{R}^N \times [0,\infty),$$

$$|\varrho - f_p(x,t)| \le \pi(x) g(t) |G(t)|^{q-1}, \qquad \forall (x,t) \in \mathbb{R}^N \times [0,\infty), \text{ and } \varrho \in \partial_t F(x,t),$$

where $\pi(x) > 0$ for all $x \in \mathbb{R}^N$, $\pi(x) \in L^\infty(\mathbb{R}^N)$, and $\pi(x) \to 0$ as $|x| \to \infty$.

Next, we provide a suitable example of function $f(x,t)$ that satisfies the assumptions (f_1)–(f_7). Fixed $T > 0$, let

$$f(x,t) = \begin{cases} 0, & t \in (-\infty, 0], \\ f_p(x,t), & t \in (0, T], \\ f_p(x,t) + \mu \exp(-|x|) g(t) (G(t))^{q-2} \arctan(G(t)), & t \in (T, +\infty), \end{cases}$$

where $0 < \mu < 1$ and

$$f_p(x,t) = \begin{cases} 0, & t \in (-\infty, 0], \\ g(t)(G(t))^{q-2} \left[G(t) - \arctan(G(t)) \right], & t \in (0, +\infty). \end{cases}$$

Since $f(x,t)$ is discontinuous, inspired by [11] and [27], we give the definition of solutions for (1.6). We say a function u is a solution for the multivalued problem (1.6) if it satisfies

$$-\operatorname{div}(g^2(u)\nabla u) + g(u)g'(u)|\nabla u|^2 + V(x)u - g(u)|G(u)|^{2^*-2}G(u) \in \kappa \hat{f}(x,u), \quad \text{a.e. in } \mathbb{R}^N, \tag{1.7}$$

where $\hat{f}$ is the multivalued function

$$\hat{f}(x,t) = [\underline{f}(x,t), \overline{f}(x,t)].$$

Below, we describe the main results of this paper.

Theorem 1.1 (The non periodic case)**.** *Assume that (V_1) and (f_1)–(f_7) are satisfied. Then, there exists $\kappa^* > 0$ such that the problem (1.6) possesses a positive solution for all $\kappa \ge \kappa^*$.*

When f is $\mathbb{Z}^N$ periodic and $V = V_p$ given by (V_1), problem (1.6) can turns to the following periodic problem:

$$-\operatorname{di} v(g^2(u)\nabla u) + g(u)g'(u)|\nabla u|^2 + V_p(x)u = \kappa f(x,u) + g(u)|G(u)|^{2^*-2}G(u), \quad \text{in } \mathbb{R}^N. \tag{1.8}$$

For periodic problem (1.8), we may state:

Theorem 1.2 (The periodic case)**.** *Assume that (f_1)–(f_4) are satisfied and f is $\mathbb{Z}^N$ periodic. Then, there exists $\kappa^* > 0$ such that the problem (1.8) possesses a positive solution for all $\kappa \ge \kappa^*$.*

Remark 1.3. As is known to all, the discontinuity of nonlinearity causes a lack of functional differentiability. In this paper, as f is discontinuous, the modified energy functional associated with (1.6) is only locally Lipschitz continuous. The classical variational methods cannot be directly utilized for nonsmooth functionals. For smooth functionals, it is essential that the energy functional can be studied on the Nehari manifold and that the mountain pass level is equal to the minimum of the energy functional on the Nehari manifold. However, these results are not valid for nonsmooth cases. Hence, the proof of the existence of solutions for equation (1.6) is more difficult.

Remark 1.4. Similar equations have been considered in [9]. However, our assumptions on nonliearities are critical growth and discontinuous.

Below we give a sketch of the proofs of our main results:

1) Firstly, we make a change of variable to reduce the quasilinear problem (1.6) to a semilinear problem (2.1) which can be well defined in $H^1(\mathbb{R}^N)$ and satisfies the geometric hypotheses of the Mountain Pass Theorem. Hence, we get a $(PS)_c$ sequence associated with the minimax level. And by using standard arguments, we show that the weak convergence limit of $(PS)_c$ sequence is a solution of the problem (2.1).

2) Furthermore, for adopting the similar technical scheme due to [30], we assume this solution is trivial. Thereby, we get a nontrivial critical point of the functional associated with the periodic case, and use the nontrivial critical point to construct a special path to prove that the maximum of the functional associated with (2.1) is strictly less than the one of the functional associated with the periodic case, which is a contradiction.

3) Hence, we obtain the existence of nontrivial solutions of the problem (2.1). Finally, by Lemma 2.2, Theorem 1.1 is proved.

The outline of the article is as follows: in Section 2, we introduce the variational setting associated with problem (1.6) and some basic knowledge of the critical point theory of locally Lipschitz continuous functionals. In Section 3, we prove the geometric structure of the Mountain Pass Theorem and some preliminary lemmas. In Section 4 and Section 5, we prove Theorem 1.1 and Theorem 1.2, respectively.

Throughout this paper, we make use of the following notations:

- M, C, C_ε denote positive constants, which may vary from line to line.
- $L^p(\mathbb{R}^N)$ denotes the Lebesgue space with the norm $\|\cdot\|_p = \left(\int_{\mathbb{R}^N} |u|^p dx\right)^{\frac{1}{p}}$ for $1 \leq p \leq \infty$.
- The dual space of a Banach space X will be denoted by X^*.
- The strong (respectively, weak) convergence is denoted by $\to$ (respectively, $\rightharpoonup$).
- $o_n(1)$ denotes $o_n(1) \to 0$ as $n \to \infty$.
- Denote the function space $D^{1,2}(\mathbb{R}^N) := \{v \in L^{2^*}(\mathbb{R}^N) : |\nabla v| \in L^2(\mathbb{R}^N)\}$. Here, S is the best constant that verifies
$$S\left(\int_{\mathbb{R}^N} |u|^{2^*}\right)^{\frac{2}{2^*}} \leq \int_{\mathbb{R}^N} |\nabla u|^2, \quad \text{for all } u \in D^{1,2}(\mathbb{R}^N).$$
- Denote the function space $H^1(\mathbb{R}^N) = \{v \in L^2(\mathbb{R}^N) : |\nabla v| \in L^2(\mathbb{R}^N)\}$ with the usual norm
$$\|v\|_{H^1}^2 = \int_{\mathbb{R}^N} \left(|\nabla v|^2 + |v|^2\right).$$

2 Variational setting and preliminary knowledge

From the variational point of view, we note that we may not directly apply the variational method to deal with the problem (1.6), since the functional associated with (1.6) may not be well defined in general $H^1(\mathbb{R}^N)$. The first difficulty associated with (1.6) is to find an appropriate function space where the functional responding to (1.6) is well defined. In order to overcome this difficulty, we we change the variables $u = G^{-1}(v)$, where G is defined as

$$v = G(u) = \int_0^u g(t)dt$$

by Shen and Wang in [28].

Now, we present some important properties about the functions g, G and G^{-1}, which proofs can be found in [16].

Lemma 2.1. *The functions $g(s)$ and $G(s) = \int_0^s g(t)dt$ enjoy the following properties.*

(i) *$G(s)$ and $G^{-1}(t)$ are odd and strictly increasing.*

(ii) *For all $s \geq 0$, $t \geq 0$,*

$$G(s) \leq g(s)s, \qquad G^{-1}(t) \leq \frac{t}{g(0)} = t.$$

(iii) *For all $t \geq 0$, $\frac{G^{-1}(t)}{t}$ is nonincreasing and*

$$\lim_{t\to 0} \frac{G^{-1}(t)}{t} = \frac{1}{g(0)} = 1, \qquad \lim_{t\to\infty} \frac{G^{-1}(t)}{t} = \begin{cases} \frac{1}{g(\infty)}, & \text{if } g \text{ is bounded,} \\ o(1), & \text{if } g \text{ is unbounded.} \end{cases}$$

(iv) *Denote $T(t) = \frac{G^{-1}(t)}{g(G^{-1}(t))}$, then $t^2T'(t) \leq T(t)t$, $\forall t \in \mathbb{R}$.*

After the change of variable $u = G^{-1}(v)$, the problem(1.6) can be rewritten as follows:

$$-\Delta v + V(x)\frac{G^{-1}(v)}{g(G^{-1}(v))} = \frac{f(x, G^{-1}(v))}{g(G^{-1}(v))} + |v|^{2^*-2}v, \quad \text{in } \mathbb{R}^N. \tag{2.1}$$

As a consequence of Lemma 2.1, the functional associated with (2.1) is well defined in $H^1(\mathbb{R}^N)$.

Lemma 2.2. *From Lemma 2.1, direct calculations demonstrate that $u = G^{-1}(v)$ shall be a solution of the equation (1.6) when v is a solution of the problem (2.1). That is to say, $v \in H^1(\mathbb{R}^N)$ satisfies*

$$-\Delta v + V(x)\frac{G^{-1}(v)}{g(G^{-1}(v))} - |v|^{2^*-2}v \in \frac{\hat{f}(x, G^{-1}(v))}{g(G^{-1}(v))} \quad \text{a.e. in } \mathbb{R}^N, \tag{2.2}$$

where

$$\frac{\hat{f}(x, G^{-1}(v))}{g(G^{-1}(v))} = \left[\frac{\underline{f}(x, G^{-1}(v))}{g(G^{-1}(v))}, \frac{\overline{f}(x, G^{-1}(v))}{g(G^{-1}(v))}\right].$$

From the above commentaries, in order to find solutions to equation (1.6), it suffices to study the existence of solutions to equation (2.1). The second difficulty associated with (2.1) is that the classical critical theory for smooth functionals cannot be directly applied to (2.1) since the function $f(x, G^{-1}(t))$ is discontinuous. To study nonsmooth problems like (2.1), we will apply the critical point theory of locally Lipschitz continuous functionals developed by Clarke [13]. For the convenience of the readers, here we provide some relevant knowledge of the critical point theory of locally Lipschitz continuous functionals.

Let X be a real Banach space and $I : X \to \mathbb{R}$.

Definition 2.3 ([27])**.** If given $v \in X$ there exists an open neighborhood $U := U_v \subset X$ and some constant $C_U > 0$ such that

$$|I(v_1) - I(v_2)| \leq C_U \|v_1 - v_2\|_X, \qquad v_i \in U, \ \ i = 1, 2.$$

We call that I is locally Lipschitz continuous ($I \in \mathrm{Lip}_{\mathrm{loc}}(X, \mathbb{R})$ for short).

Definition 2.4 ([27])**.** The generalized directional derivative of $I \in \mathrm{Lip}_{\mathrm{loc}}(X, \mathbb{R})$ at v in the direction of $\tilde{v} \in X$ is defined by

$$I^\circ(v; \tilde{v}) = \limsup_{u \to 0 \ t \downarrow 0} \frac{I(v + u + t\tilde{v}) - I(v + u)}{t}.$$

The definition 2.4 implies that $I^\circ(v; .)$ is continuous, convex and its subdifferential at $w \in X$ is given by

$$\partial I^\circ(v; w) = \{\mu \in X^*; I^\circ(v; u) \geq I^\circ(v; w) + \langle \mu, u - w \rangle, \quad \forall u \in X\},$$

where X^* is the dual of X and $\langle ., . \rangle$ is the duality paring between X^* and X.

Definition 2.5. ([27]) The general gradient of $I \in \mathrm{Lip}_{\mathrm{loc}}(X, \mathbb{R})$ at v is the set

$$\partial I(v) = \{\mu \in X^*; I^\circ(v; u) \geq \langle \mu, u \rangle, \quad \forall u \in X\}.$$

Since $I^\circ(v; 0) = 0$, $\partial I(v)$ is the subdifferential of $I^\circ(v; 0)$. Moreover, $\partial I(v) \subset X^*$ is convex, nonempty and weak* compact. If I is C^1 functional, $\partial I(v) = \{I'(v)\}$. We denote by $\lambda_I(u)$ the following real number

$$\lambda_I(v) := \min\{\|\mu\|_{X^*};\ \mu \in \partial I(v)\}.$$

Definition 2.6 ([27])**.** An element $v \in X$ is a critical point of I if $0 \in \partial I(v)$ or equivalently, when $\lambda_I(v) = 0$.

Lemma 2.7. *If $I_1 \in C^1(X, \mathbb{R})$ and $I_2 \in \mathrm{Lip}_{\mathrm{loc}}(X, \mathbb{R})$, then*

$$\partial(I_1 + I_2)(v) = \{I_1'(v)\} + \partial I_2(v), \qquad \forall v \in X.$$

Lemma 2.8 ([13] and [34])**.** *Let Y be a Banach space and $j : Y \to X$ be a continuously differentiable function. Then $I \circ j$ is locally Lipschitz and*

$$\partial(I \circ j)(v) \subset \partial I(j(v)) \circ j'(v), \qquad \forall v \in Y.$$

Lemma 2.9 ([13])**.** *Let $I \in \mathrm{Lip}_{\mathrm{loc}}(X, \mathbb{R})$ with $I(0) = 0$ and X be a Banach space. Suppose there are constants $\alpha,\ \rho > 0$ and function $e \in X$, such that* *(i)* $I(v) \geq \alpha$, *for all* $v \in X$ *with* $\|v\|_X = \rho$,

(ii) $I(e) < 0$ *and* $\|e\|_X > r$.

Let

$$c = \inf_{\gamma \in \Gamma_I} \max_{t \in [0,1]} I(\gamma(t)),$$

where

$$\Gamma_I = \{\gamma \in C([0,1], X) : \gamma(0) = 0, I(\gamma(1)) < 0\}.$$

Then, $c \geq \alpha$ *and there exists a sequence* $\{v_n\} \subset X$ *satisfying* $I(v_n) \to c$ *and* $\lambda_I(v_n) \to 0$. *The sequence* $\{v_n\}$ *is called a* $(PS)_c$ *sequence for* I.

3 Some preliminary lemmas

Hypotheses (f_1)–(f_3) imply that, for any $\varepsilon > 0$, there is $C_\varepsilon > 0$ such that

$$\begin{aligned} |f(x,t)| &\leq \varepsilon|t| + C_\varepsilon g(t)|G(t)|^{q-1}, \qquad \forall t \in \mathbb{R},\ \forall x \in \mathbb{R}^N, \\ |F(x,t)| &\leq \frac{\varepsilon}{2}|t|^2 + \frac{C_\varepsilon}{q}|G(t)|^q, \qquad \forall t \in \mathbb{R},\ \forall x \in \mathbb{R}^N. \end{aligned} \tag{3.1}$$

From the second inequality of (3.1) and Lemma 2.1-(ii), we can prove

$$\Psi(v) = \int_{\mathbb{R}^N} F(x, G^{-1}(v)) \leq \int_{\mathbb{R}^N} \left(\frac{\varepsilon}{2}|v|^2 + \frac{C_\varepsilon}{q}|v|^q\right) \leq C(\|v\|_2 + \|v\|_q), \tag{3.2}$$

so functional Ψ is well defined in $H^1(\mathbb{R}^N)$. However, in order to apply variational methods for locally Lipschitz functionals, it is preferable to deal with the functional Ψ in a more appropriate space, that is $\Psi : L^\Phi(\mathbb{R}^N) \to \mathbb{R}$, for $\Phi(t) = |t|^2 + |t|^q$, where $L^\Phi(\mathbb{R}^N)$ denotes the Orlicz space associated with the N-function Φ. In this paper, we are working in $\mathbb{R}^N$ and the conditions on f yield

$$|F(x, G^{-1}(t))| \leq C(|t|^2 + |t|^q), \qquad \forall t \in \mathbb{R}, \tag{3.3}$$

then Ψ is not well defined in $L^p(\mathbb{R}^N)$. The above estimate involving the function F suggests that the best space to work is the Orlicz space $L^\Phi(\mathbb{R}^N)$. In bounded domains, the Orlicz space $L^\Phi(\mathbb{R}^N)$ is not necessary. In this case, (3.2) implies that the functional Ψ is well defined in $L^p(\Omega)$. Since $2 < q < 2^*$, we obtain that the embedding $H^1(\mathbb{R}^N) \hookrightarrow L^\Phi(\mathbb{R}^N)$ is continuous and Φ satisfies Δ_2 condition which ensures that $L^\Phi(\mathbb{R}^N)$ and $L^{\tilde{\Phi}}(\mathbb{R}^N)$ are reflexive spaces ($\tilde{\Phi}$ is the conjugate function of Φ (see [17])). Hence, given $\varsigma \in (L^\Phi(\mathbb{R}^N))^*$, we get

$$\varsigma(v) = \int_{\mathbb{R}^N} u_\varsigma v, \qquad \forall v \in L^\Phi(\mathbb{R}^N),$$

for some $u_\varsigma \in L^{\tilde{\Phi}}(\mathbb{R}^N)$. Essentially, by the definition of Φ and (f_1)–(f_3) the conditions below occur:

$$\begin{aligned} |\zeta| &\leq \varepsilon|t| + C_\varepsilon|t|^{q-1} \leq C\Phi'(|t|), \qquad \forall \zeta \in \partial_t F(x, G^{-1}(t)), \\ |F(x, G^{-1}(t))| &\leq \frac{\varepsilon}{2}|t|^2 + \frac{C_\varepsilon}{q}|t|^{q-1} \leq C\Phi(t), \end{aligned} \tag{3.4}$$

for all $t \in \mathbb{R}$ and $x \in \mathbb{R}^N$. Here, $\partial_t F(x, G^{-1}(t))$ denotes the generalized gradient of $F(x, G^{-1}(t))$ with respect to variable t. The above information involving Ψ and Φ is crucial in the below.

The next two lemmas establish important properties of the functional Ψ given in (3.2).

Lemma 3.1 ([2, Theorem 4.1] and [5, Theorem 4.2]). *Assume (3.4). Then, the functional* $\Psi : L^{\Phi}(\mathbb{R}^N) \to \mathbb{R}$ *given by*

$$\Psi(v) = \int_{\mathbb{R}^N} F(x, G^{-1}(v)), \qquad v \in L^{\Phi}(\mathbb{R}^N),$$

is well defined and $\Psi \in \mathrm{Lip}_{\mathrm{loc}}(L^{\Phi}(\mathbb{R}^N), \mathbb{R})$*. Furthermore,*

$$\partial\Psi(v) \subset \partial_t F(x, G^{-1}(v)), \qquad \forall\, v \in L^{\Phi}(\mathbb{R}^N),$$

in the sense that for every $\varrho^* \in \partial\Psi(v) \subset (L^{\Phi}(\mathbb{R}^N))^* \cong L^{\tilde{\Phi}}(\mathbb{R}^N)$ *there exists* $\varrho \in L^{\tilde{\Phi}}(\mathbb{R}^N)$ *such that*

$$\varrho(x) \in \partial_t F(x, G^{-1}(v(x))) = \left[\frac{\underline{f}(x, G^{-1}(v(x)))}{g(G^{-1}(v(x)))}, \frac{\overline{f}(x, G^{-1}(v(x)))}{g(G^{-1}(v(x)))} \right] \quad \text{a.e. in } \mathbb{R}^N$$

and

$$\langle \varrho^*, v \rangle = \int_{\mathbb{R}^N} \varrho v, \qquad \forall\, v \in L^{\Phi}(\mathbb{R}^N).$$

As a similar consequence of Proposition 2.3 in [5], we obtain the following lemma and the proof will be omitted. More details can be found in [5].

Lemma 3.2. *Assume (3.4). If* $\{v_n\} \subset H^1(\mathbb{R}^N)$ *satisfies* $v_n \rightharpoonup v$ *in* $H^1(\mathbb{R}^N)$ *and* $\varrho_n \in \partial\Psi(v_n)$ *satisfies* $\varrho_n \overset{*}{\rightharpoonup} \varrho$ *in* $(H^1(\mathbb{R}^N))^*$*, then* $\varrho \in \partial\Psi(v)$*.*

We consider $H^1(\mathbb{R}^N)$ endowed with the following norm

$$\|v\|^2 = \int_{\mathbb{R}^N} \left(|\nabla v|^2 + V(x)|v|^2 \right).$$

Under the assumption (V_1), the norm $\|\cdot\|$ is equivalent to the standard norm $\|\cdot\|_{H^1}$.

In order to get the positive solutions, we consider the functional corresponding to (2.1) given by $J(v) = Q(v) - \kappa\Psi(v)$, $v \in H^1(\mathbb{R}^N)$, where

$$Q(v) = \frac{1}{2} \int_{\mathbb{R}^N} \left(|\nabla v|^2 + V(x)|G^{-1}(v)|^2 \right) - \frac{1}{2^*} \int_{\mathbb{R}^N} (v^+)^{2^*}$$

and

$$\Psi(v) = \int_{\mathbb{R}^N} F(x, G^{-1}(v)).$$

By standard arguments, we get the functional $Q \in C^1(H^1(\mathbb{R}^N), \mathbb{R})$ and

$$\langle Q'(v), \varphi \rangle = \int_{\mathbb{R}^N} \left(\nabla u \nabla \varphi + V(x) \frac{G^{-1}(v)}{g(G^{-1}(v))} \varphi \right) - \int_{\mathbb{R}^N} (v^+)^{2^*-1} \varphi,$$

for all $v, \varphi \in H^1(\mathbb{R}^N)$. Then, by Lemma 3.1, $J \in \mathrm{Lip}_{\mathrm{loc}}(H^1(\mathbb{R}^N), \mathbb{R})$ and

$$\partial J(v) = \{Q'(v)\} - \kappa \partial\Psi(v). \tag{3.5}$$

Lemma 3.3. *Assume that* (V_1) *and* (f_1)–(f_3) *are satisfied. Then there exist* $\rho, \alpha > 0$*, such that*

$$J(v) \geq \alpha, \qquad \forall v \in H^1(\mathbb{R}^N) \text{ with } \|v\| = \rho.$$

Proof. Since $\lim_{|t|\to 0} \frac{G^{-1}(t)}{t} = 1$, by (3.1), for any $\varepsilon > 0$, there is C_ε such that

$$|F(x, G^{-1}(t))| \le \varepsilon |t|^2 + C_\varepsilon |t|^q, \ \forall t \in \mathbb{R}.$$

From Lemma 2.1, we have

$$\lim_{s\to+\infty} \frac{G^{-1}(t)}{t} = \begin{cases} \dfrac{1}{g(\infty)}, & \text{if } g \text{ is bounded,} \\ o(1), & \text{if } g \text{ is unbounded.} \end{cases}$$

If g is bounded, in view of that $\frac{G^{-1}(t)}{t}$ is nonincreasing, we get

$$\begin{aligned} J(v) &= \frac{1}{2}\int_{\mathbb{R}^N} \left(|\nabla v|^2 + V(x)|G^{-1}(v)|^2\right) - \kappa \int_{\mathbb{R}^N} F(x, G^{-1}(v)) - \frac{1}{2^*}\int_{\mathbb{R}^N} (v^+)^{2^*} \\ &\ge \frac{1}{2}\int_{\mathbb{R}^N} \left(|\nabla v|^2 + W_0|G^{-1}(v)|^2\right) - \kappa \int_{\mathbb{R}^N} (\varepsilon|v|^2 + C_\varepsilon |v|^q) - \frac{1}{2^*}\int_{\mathbb{R}^N} (v^+)^{2^*} \\ &\ge \frac{1}{2}\int_{\mathbb{R}^N} |\nabla v|^2 + \left(\frac{W_0}{2g(\infty)} - \kappa\varepsilon\right)\int_{\mathbb{R}^N} |v|^2 - \kappa C_\varepsilon \int_{\mathbb{R}^N} |v|^q - \frac{1}{2^*}\int_{\mathbb{R}^N} |v|^{2^*}. \end{aligned} \tag{3.6}$$

If g is unbounded, we set $\Upsilon(t) := -\frac{1}{2}W_0|G^{-1}(t)|^2 + \kappa F(x, G^{-1}(t))$, then

$$\lim_{t\to 0} \frac{\Upsilon(t)}{t^2} = -\frac{W_0}{2} < 0, \qquad \lim_{t\to+\infty} \frac{\Upsilon(t)}{t^{2^*}} = 0.$$

Therefore,

$$\begin{aligned} J(v) &= \frac{1}{2}\int_{\mathbb{R}^N} \left(|\nabla v|^2 + V(x)|G^{-1}(v)|^2\right) - \kappa \int_{\mathbb{R}^N} F(x, G^{-1}(v)) - \frac{1}{2^*}\int_{\mathbb{R}^N} (v^+)^{2^*} \\ &\ge \frac{1}{2}\int_{\mathbb{R}^N} |\nabla v|^2 - \int_{\mathbb{R}^N} \Upsilon(v) - \frac{1}{2^*}\int_{\mathbb{R}^N} (v^+)^{2^*} \\ &\ge \frac{1}{2}\int_{\mathbb{R}^N} |\nabla v|^2 + \left(\frac{W_0}{2} - \varepsilon\right)\int_{\mathbb{R}^N} |v|^2 - C_\varepsilon \int_{\mathbb{R}^N} |v|^{2^*} - \frac{1}{2^*}\int_{\mathbb{R}^N} |v|^{2^*}. \end{aligned} \tag{3.7}$$

By (3.6), (3.7) and Sobolev's inequality, we get

$$J(v) \ge C\|v\|^2 - C\|v\|^q - C\|v\|^{2^*}.$$

Since $2 < q < 2^*$, taking $\rho > 0$ sufficiently small, we conclude that there exists $\alpha > 0$ such that

$$J(v) \ge \alpha, \qquad \forall v \in H^1(\mathbb{R}^N) \text{ with } \|v\| = \rho.$$

This proof is completed. □

Lemma 3.4. *Suppose that (V_1) and (f_4) are satisfied. Then, for all $\kappa > 0$, there exists function $e \in H^1(\mathbb{R}^N)$ such that $J(e) \le 0$ and $\|e\| > \rho$.*

Proof. Fixing $\phi \in H^1(\mathbb{R}^N)$ with $\phi \ge 0$ and $\phi \not\equiv 0$, by Lemma 2.1-(i), (ii), we get

$$\begin{aligned} J(t\phi) &= \frac{1}{2}\int_{\mathbb{R}^N} \left(|t\nabla\phi|^2 + V(x)|G^{-1}(t\phi)|^2\right) - \kappa \int_{\mathbb{R}^N} F(x, G^{-1}(t\phi)) - \frac{1}{2^*}\int_{\mathbb{R}^N} (t\phi)^{2^*} \\ &\le \frac{t^2}{2}\|\phi\|^2 - \frac{t^{2^*}}{2^*}\int_{\mathbb{R}^N} \phi^{2^*}. \end{aligned}$$

Then, we can choose some t_0 large enough such that $\|t_0\phi\| > \rho$ and $J(t_0\phi) < 0$. The lemma is completed when $e = t_0\phi$. □

Note that $J(0) = 0$ and by Lemma 3.3 and Lemma 3.4, (i) and (ii) of Lemma 2.9 are satisfied. Thereby, we may define

$$c_\kappa = \inf_{\gamma\in\Gamma_J} \max_{t\in[0,1]} J(\gamma(t)),$$

where

$$\Gamma_J = \{\gamma \in C([0,1], H^1(\mathbb{R}^N)) : \gamma(0) = 0, J(\gamma(1)) < 0\}.$$

By Lemma 2.9, there exists a sequence $\{v_n\} \subset H^1(\mathbb{R}^N)$ satisfying $J(v_n) \to c_\kappa$ and $\lambda_J(v_n) \to 0$. Namely, the sequence $\{v_n\}$ is a $(PS)_{c_\kappa}$ sequence for functional J.

Lemma 3.5. *Assume that (V_1), (f_1) and (f_4) hold. Then any $(PS)_{c_\kappa}$ sequence for J is bounded in $H^1(\mathbb{R}^N)$.*

Proof. Let $\{v_n\} \subset H^1(\mathbb{R}^N)$ be a $(PS)_{c_\kappa}$ sequence for J, that is,

$$J(v_n) \to c_\kappa \quad \text{and} \quad \lambda_J(v_n) \to 0, \quad \text{as } n \to \infty.$$

Then, there exists $w_n \in \partial J(v_n) \subset (H^1(\mathbb{R}^N))^*$ such that

$$\|w_n\|_* = \lambda_J(v_n) = o_n(1)$$

and

$$w_n = Q'(v_n) - \varrho_n,$$

where $\|w_n\|_* := \|w_n\|_{(H^1(\mathbb{R}^N))^*}$ and $\varrho_n \in \partial\Psi(v_n) \subset L^{\tilde{\Phi}}(\mathbb{R}^N)$.

Therefore, we obtain that

$$\begin{aligned} c + 1 + \|v_n\| &\geq J(v_n) - \frac{1}{\theta}\langle w_n, v_n\rangle \\ &= \left(\frac{1}{2} - \frac{1}{\theta}\right)\int_{\mathbb{R}^N} |\nabla v_n|^2 + \int_{\mathbb{R}^N} V(x)G^{-1}(v_n)\left(\frac{1}{2}G^{-1}(v_n) - \frac{1}{\theta}\frac{v_n}{g(G^{-1}(v_n))}\right) \\ &\quad - \kappa\int_{\mathbb{R}^N}\left(F(x, G^{-1}(v_n)) - \frac{1}{\theta}\varrho_n v_n\right) - \left(\frac{1}{2^*} - \frac{1}{\theta}\right)\int_{\mathbb{R}^N} |v_n^+|^{2^*}. \end{aligned}$$

From (f_4) and $\varrho_n(x) \in \left[\frac{\underline{f}(x,G^{-1}(v_n(x)))}{g(G^{-1}(v_n(x)))}, \frac{\overline{f}(x,G^{-1}(v_n(x)))}{g(G^{-1}(v_n(x)))}\right]$ a.e. in $\mathbb{R}^N$, we have

$$\frac{1}{\theta}\varrho_n v_n \geq F(x, G^{-1}(v_n)) \geq 0 \quad \text{a.e. in } \mathbb{R}^N.$$

Hence, by Lemma 2.1-(ii), we get

$$c + 1 + \|v_n\| \geq \left(\frac{1}{2} - \frac{1}{\theta}\right)\int_{\mathbb{R}^N}\left(|\nabla v_n|^2 + V(x)|G^{-1}(v_n)|^2\right). \tag{3.8}$$

For all $t \geq 1$, by (f_4), we can verify that there exists some $C > 0$ such that $CF(x,t) \geq (G(t))^\theta \geq (G(t))^2$. Then

$$\begin{aligned} \int_{\{|G^{-1}(v_n)|>1\}} V(x)v_n^2 &\leq \kappa C\int_{\{|G^{-1}(v_n)|>1\}} F(x, G^{-1}(v_n)) \\ &\leq \kappa C\int_{\mathbb{R}^N} F(x, G^{-1}(v_n)) + \frac{C}{2^*}\int_{\mathbb{R}^N} |v_n^+|^{2^*} \\ &= C\left[\frac{1}{2}\int_{\mathbb{R}^N}\left(|\nabla v_n|^2 + V(x)|G^{-1}(v_n)|^2\right) - J(v_n)\right] \\ &= C\left[\frac{1}{2}\int_{\mathbb{R}^N}\left(|\nabla v_n|^2 + V(x)|G^{-1}(v_n)|^2\right) - c_\kappa + o_n(1)\right]. \end{aligned} \tag{3.9}$$

For $\{|G^{-1}(v_n)| \le 1\}$, by Lemma 2.1-(ii) and $g'(t) \ge 0$ for all $t \ge 0$, we have

$$\begin{aligned}\frac{1}{g^2(1)} \int_{\{|G^{-1}(v_n)|\le 1\}} V(x)v_n^2 &\le \int_{\{|G^{-1}(v_n)|\le 1\}} V(x)|G^{-1}(v_n)|^2 \\ &\le \int_{\mathbb{R}^N} V(x)|G^{-1}(v_n)|^2.\end{aligned} \tag{3.10}$$

By (3.8)–(3.10), we deduce that

$$\begin{aligned}\|v_n\|^2 &= \int_{\mathbb{R}^N} \left(|\nabla v_n|^2 + V(x)|v_n|^2\right) \\ &\le C \int_{\mathbb{R}^N} \left(|\nabla v_n|^2 + V(x)|G^{-1}(v_n)|^2\right) + C \\ &\le C\|v_n\| + C,\end{aligned}$$

which implies that the sequence $\{v_n\}$ is bounded in $H^1(\mathbb{R}^N)$. □

Next, the following lemma shows the behavior of c_κ associated with the parameter κ.

Lemma 3.6. *Suppose that (V_1) and (f_4) are satisfied, then $\lim_{\kappa\to+\infty} c_\kappa = 0$.*

Proof. Since $J(v)$ is nonsmooth functional, unlike the method used to prove Lemma 3.1 in [29], we will not use the Nehari manifold. For ϕ given by Lemma 3.4, it follows that there is $t_\kappa > 0$ satisfying

$$J(t_\kappa\phi) = \max_{t\ge 0} J(t\phi) \ge \alpha > 0.$$

Then, we have

$$\frac{t_\kappa^2}{2}\int_{\mathbb{R}^N} |\nabla\phi|^2 + \frac{1}{2}\int_{\mathbb{R}^N} V(x)|G^{-1}(t_\kappa\phi)|^2 \ge \kappa\int_{\mathbb{R}^N} F(x, G^{-1}(t_\kappa\phi)) + \frac{t_\kappa^{2^*}}{2^*}\int_{\mathbb{R}^N}\phi^{2^*}.$$

By (f_4), we get

$$\frac{t_\kappa^2}{2}\left(\int_{\mathbb{R}^N} |\nabla\phi|^2 + \int_{\mathbb{R}^N} V(x)|\phi|^2\right) \ge \frac{t_\kappa^{2^*}}{2^*}\int_{\mathbb{R}^N}\phi^{2^*},$$

which implies that t_κ is bounded.

Next, we will prove that $t_\kappa \to 0$ as $\kappa \to +\infty$. Suppose, by contradiction, that there exists a sequence $\kappa_n \to +\infty$ and a constant $\bar{t} > 0$ such that $t_{\kappa_n} \to \bar{t}$ as $n \to \infty$. The boundedness of t_{κ_n} implies that there is $M > 0$ such that

$$\frac{t_{\kappa_n}^2}{2}\int_{\mathbb{R}^N} |\nabla\phi|^2 + \int_{\mathbb{R}^N} V(x)|G^{-1}(t_{\kappa_n}\phi)|^2 \le M.$$

Hence,

$$\kappa_n\int_{\mathbb{R}^N} F(x, G^{-1}(t_{\kappa_n}\phi)) + \frac{t_{\kappa_n}^{2^*}}{2^*}\int_{\mathbb{R}^N}\phi^{2^*} \le M.$$

If $\bar{t} > 0$, we have that

$$\lim_{n\to\infty}\left[\kappa_n\int_{\mathbb{R}^N} F(x, G^{-1}(t_{\kappa_n}\phi)) + \frac{t_{\kappa_n}^{2^*}}{2^*}\int_{\mathbb{R}^N}\phi^{2^*}\right] = +\infty$$

which is absurd. Thus, we have $t_\kappa \to 0$ as $\kappa \to +\infty$.

Observe that

$$J(t_\kappa\phi) \le \frac{t_\kappa^2}{2}\int_{\mathbb{R}^N} |\nabla\phi|^2 + \frac{1}{2}\int_{\mathbb{R}^N} V(x)|G^{-1}(t_\kappa\phi)|^2 \le \frac{t_\kappa^2}{2}\|\phi\|^2.$$

Due to $t_\kappa \to 0$ as $\kappa \to +\infty$, we get $c_\kappa \le J(t_\kappa\phi) \to 0$ as $\kappa \to +\infty$, which finishes the proof. □

Lemma 3.7. *Suppose that* (V_1) *and* (f_1)*–*(f_3) *are satisfied. Let* $\{v_n\} \subset H^1(\mathbb{R}^N)$ *be a* $(PS)_{c_\kappa}$ *sequence for* J *with* $v_n \rightharpoonup 0$ *in* $H^1(\mathbb{R}^N)$*. Then there is* $\kappa^* > 0$*. When* $\kappa > \kappa^*$*, there exists a sequence* $\{y_n\} \subset \mathbb{R}^N$ *and* $\delta > 0$ *such that*

$$\limsup_{n\to\infty} \int_{B_1(y_n)} |v_n|^2 \geq \delta > 0.$$

Proof. By Lemma 3.5, there exists a constant $\kappa^* > 0$ satisfying

$$c_\kappa < \frac{1}{N} S^{\frac{N}{2}},$$

for all $\kappa > \kappa^*$. Suppose, by contradiction, that $\{v_n\}$ is vanishing. Then, from Lions compactness lemma [33], we deduce that $v_n \to 0$ in $L^r(\mathbb{R}^N)$ for all $2 < r < 2^*$. From $|G^{-1}(v_n)| \leq |v_n|$, we get $G^{-1}(v_n) \to 0$ in $L^r(\mathbb{R}^N)$ for all $2 < r < 2^*$. Since $\{v_n\}$ is a $(PS)_{c_\kappa}$ sequence for J, there exists $w_n \in \partial J(v_n)$ with $\|w_n\|_* = \lambda_J(v_n) = o_n(1)$ and $w_n = Q'(v_n) - \varrho_n$, where $\varrho_n \in \partial\Psi(v_n)$. By (3.1) and Lemma 3.1, we have

$$\int_{\mathbb{R}^N} F(x, G^{-1}(v_n)) \to 0 \quad \text{and} \quad \int_{\mathbb{R}^N} \varrho_n v_n \to 0, \quad \text{as } n \to \infty. \tag{3.11}$$

Therefore, by (3.11), we have

$$\begin{aligned} c_\kappa + o_n(1) &= J(v_n) - \frac{1}{2}\langle w_n, v_n\rangle \\ &= \frac{1}{2}\int_{\mathbb{R}^N} V(x)\left[|G^{-1}(v_n)|^2 - \frac{G^{-1}(v_n)}{g(G^{-1}(v_n))} v_n\right] + \frac{1}{N}\int_{\mathbb{R}^N} |v_n^+|^{2^*}. \end{aligned} \tag{3.12}$$

We claim that

$$\lim_{n\to\infty} \int_{\mathbb{R}^N} V(x)\left[|G^{-1}(v_n)|^2 - \frac{G^{-1}(v_n)}{g(G^{-1}(v_n))} v_n\right] = 0. \tag{3.13}$$

For proving (3.13), we only verify that

$$\begin{aligned} \lim_{n\to\infty} \int_{\mathbb{R}^N} V(x)\left[|G^{-1}(v_n)|^2 - |v_n|^2\right] &= 0, \\ \lim_{n\to\infty} \int_{\mathbb{R}^N} V(x)\left[|v_n|^2 - \frac{G^{-1}(v_n)}{g(G^{-1}(v_n))} v_n\right] &= 0. \end{aligned} \tag{3.14}$$

For $\delta > 0$ to be chosen later, we have

$$\begin{aligned} &\int_{\mathbb{R}^N} V(x)\left[|G^{-1}(v_n)|^2 - |v_n|^2\right] \\ &\quad = \int_{\{|v_n|>\delta\}} V(x)\left[|G^{-1}(v_n)|^2 - |v_n|^2\right] + \int_{\{|v_n|\leq\delta\}} V(x)\left[|G^{-1}(v_n)|^2 - |v_n|^2\right]. \end{aligned}$$

By Lemma 2.1-(ii) and (V_1), we get

$$\begin{aligned} \int_{\{|v_n|>\delta\}} V(x)\left[|G^{-1}(v_n)|^2 - |v_n|^2\right] &\leq 2\|V\|_\infty \int_{\{|v_n|>\delta\}} |v_n|^2 \\ &\leq \frac{2\|V\|_\infty}{\delta^{r-2}} \int_{\mathbb{R}^N} |v_n|^r = o_n(1), \end{aligned} \tag{3.15}$$

where $2 < r < 2^*$.

On the other hand, given $\varepsilon > 0$, by Lemma 2.1-(iii), we choose $\delta > 0$ so that

$$\left|\left(\frac{G^{-1}(s)}{s}\right)^2 - 1\right| < \varepsilon, \quad \text{if } |s| \leq \delta.$$

Then, we have

$$\begin{aligned}&\limsup_{n\to\infty}\int_{\{0<|v_n|\le\delta\}} V(x)|v_n|^2\left|\left(\frac{G^{-1}(v_n)}{v_n}\right)^2-1\right|\\&\le\|V\|_\infty\limsup_{n\to\infty}\int_{\{0<|v_n|\le\delta\}}|v_n|^2\left|\left(\frac{G^{-1}(v_n)}{v_n}\right)^2-1\right|\\&\le\varepsilon\limsup_{n\to\infty}\int_{\mathbb{R}^N}|v_n|^2.\end{aligned}$$

Hence

$$\begin{aligned}&\limsup_{n\to\infty}\int_{\mathbb{R}^N}V(x)\left[|G^{-1}(v_n)|^2-|v_n|^2\right]\\&\le\limsup_{n\to\infty}\int_{\{|v_n|>\delta\}}V(x)\left[|G^{-1}(v_n)|^2-|v_n|^2\right]+\varepsilon\limsup_{n\to\infty}\int_{\mathbb{R}^N}|v_n|^2.\end{aligned}$$

As $\varepsilon>0$ is arbitrary and $\{v_n\}\subset H^1(\mathbb{R}^N)$ is bounded, using (3.15), we have the first limit in (3.14).

By Lemma 2.1-(ii), (iii) and the fact that

$$(G^{-1})'(s)=\frac{1}{g(G^{-1}(s))}\to 1\quad\text{as } s\to 0,$$

the verification of the second limit in (3.14) is similar to the first one. Therefore, our claim (3.13) is true.

Then, by (3.12) and (3.13), we obtain

$$\lim_{n\to\infty}\int_{\mathbb{R}^N}|v_n^+|^{2^*}=Nc_\kappa. \tag{3.16}$$

From the fact $\langle w_n,v_n\rangle=o_n(1)$ and the second limit in (3.11), we get

$$\int_{\mathbb{R}^N}|\nabla v_n|^2+\int_{\mathbb{R}^N}V(x)\frac{G^{-1}(v_n)}{g(G^{-1}(v_n))}v_n-\int_{\mathbb{R}^N}|v_n^+|^{2^*}=o_n(1). \tag{3.17}$$

From the definition of $G^{-1}(s)$ and (V_1), the second integral in (3.17) is nonnegative. Then, we have

$$\int_{\mathbb{R}^N}|\nabla v_n|^2\le\int_{\mathbb{R}^N}|v_n^+|^{2^*}+o_n(1). \tag{3.18}$$

By the definition of S, (3.16) and (3.18), it follows that

$$\int_{\mathbb{R}^N}|v_n^+|^{2^*}\le\int_{\mathbb{R}^N}|v_n|^{2^*}\le S^{-\frac{2^*}{2}}\left(\int_{\mathbb{R}^N}|\nabla v_n|^2\right)^{\frac{2^*}{2}}\le S^{-\frac{2^*}{2}}\left(\int_{\mathbb{R}^N}|v_n^+|^{2^*}+o_n(1)\right)^{\frac{2^*}{2}}.$$

Taking $n\to\infty$ in the above inequality, in view of (3.16), we get

$$Nc_\kappa\le S^{-\frac{2^*}{2}}(Nc_\kappa)^{\frac{2^*}{2}},$$

that is,

$$c_\kappa\ge\frac{1}{N}S^{\frac{N}{2}},$$

which is a contradiction. Hence $\{v_n\}$ is non-vanishing. This concludes the proof. □

4 Proof of Theorem 1.1

In the following, we will prove that there exists $v \in H^1(\mathbb{R}^N)$ is a positive solution of problem (1.6). With this aim in mind, we need to show that there is $v \in H^1(\mathbb{R}^N)$ and $v > 0$ such that

$$-\Delta v + V(x)\frac{G^{-1}(v)}{g(G^{-1}(v))} - v^{2^*-1} \in \left[\frac{\underline{f}(x, G^{-1}(v))}{g(G^{-1}(v))}, \frac{\overline{f}(x, G^{-1}(v))}{g(G^{-1}(v))}\right] \quad \text{a.e. in } \mathbb{R}^N.$$

By Lemma 3.3 and Lemma 3.4, the functional J satisfies all hypotheses of Lemma 2.9. Then, by Lemma 2.9 and Lemma 3.5 , there exists a bounded sequence $\{v_n\} \subset H^1(\mathbb{R}^N)$ satisfying

$$J(v_n) \to c_\kappa \geq \alpha > 0 \quad \text{and} \quad \lambda_J(v_n) \to 0, \quad \text{as } n \to \infty,$$

where

$$c_\kappa = \inf_{\gamma \in \Gamma_J} \max_{t \in [0,1]} J(\gamma(t)),$$

and

$$\Gamma_J = \{\gamma \in C([0,1], H^1(\mathbb{R}^N)) : \gamma(0) = 0, J(\gamma(1)) < 0\}.$$

Therefore, there exists $w_n \in \partial J(v_n)$ such that $\|w_n\|_* = \lambda_J(v_n)$, $w_n = Q'(v_n) - \varrho_n$ where $\varrho_n \in \partial\Psi(v_n)$. For all $\psi \in H^1(\mathbb{R}^N)$,

$$\langle w_n, \psi\rangle = \langle Q'(v_n), \psi\rangle - \langle \varrho_n, \psi\rangle, \qquad \forall n \in \mathbb{N}.$$

Since $H^1(\mathbb{R}^N)$ is reflexive, taking a subsequence if necessary, there exists $v \in H^1(\mathbb{R}^N)$ such that $v_n \rightharpoonup v$ in $H^1(\mathbb{R}^N)$. Thus, we obtain

$$\langle \varrho_n, \psi\rangle = \langle Q'(v_n), \psi\rangle - \langle w_n, \psi\rangle \to \langle Q'(v), \psi\rangle, \quad \text{as } n \to \infty,$$

that is, $\varrho_n \overset{*}{\rightharpoonup} Q'(v)$ in $(H^1(\mathbb{R}^N))^*$. By Lemma 3.2, we get $Q'(v) \in \partial\Psi(v)$. Then, there exits $\varrho \in \partial\Psi(v)$ such that $Q'(v) = \varrho$ and

$$\int_{\mathbb{R}^N}\left(\nabla v \nabla \psi + V(x)\frac{G^{-1}(v)}{g(G^{-1}(v))}\psi\right) - \int_{\mathbb{R}^N}(v^+)^{2^*-1}\psi = \int_{\mathbb{R}^N}\varrho\psi, \qquad \forall \psi \in H^1(\mathbb{R}^N),$$

where

$$\varrho(x) \in \left[\frac{\underline{f}(x, G^{-1}(v(x)))}{g(G^{-1}(v(x)))}, \frac{\overline{f}(x, G^{-1}(v(x)))}{g(G^{-1}(v(x)))}\right] \quad \text{a.e. in } \mathbb{R}^N.$$

Taking $\psi = v^- := \min\{v, 0\}$, we obtain

$$\int_{\mathbb{R}^N}\left(|\nabla v^-|^2 + V(x)\frac{G^{-1}(v^-)}{g(G^{-1}(v^-))}v^-\right) \leq 0,$$

which implies $v^- \equiv 0$. Thus, we get $v = v^+ \geq 0$ satisfying

$$\begin{cases} -\Delta v + V(x)\dfrac{G^{-1}(v)}{g(G^{-1}(v))} = \varrho + v^{2^*-1} & \text{in } \mathbb{R}^N, \\ v \in H^1(\mathbb{R}^N). \end{cases}$$

Furthermore, since $\varrho \in L^{\tilde{\Psi}}(\mathbb{R}^N) \subset L^{\frac{q}{q-1}}_{\text{loc}}(\mathbb{R}^N)$, the elliptic regularity theory gives that $v \in W^{2,\frac{2^*}{2^*-1}}_{\text{loc}}(\mathbb{R}^N)$ and v satisfies

$$-\Delta v + V(x)\frac{G^{-1}(v)}{g(G^{-1}(v))} = \varrho + v^{2^*-1} \quad \text{a.e. in } \mathbb{R}^N,$$

that is,

$$-\Delta v+V(x)\frac{G^{-1}(v)}{g(G^{-1}(v))}-v^{2^*-1}\in\left[\frac{\underline{f}(x,G^{-1}(v))}{g(G^{-1}(v))},\frac{\overline{f}(x,G^{-1}(v))}{g(G^{-1}(v))}\right]\quad\text{a.e. in } \mathbb{R}^N.$$

Finally, in order to prove Theorem 1.1, it suffices to verify that v is nontrivial. Suppose, by contradiction, that v is trivial. Then, we claim that in this case $\{v_n\}$ is also a $(PS)_{c_\kappa}$ sequence for J_p defined by

$$J_p(v)=\frac{1}{2}\int_{\mathbb{R}^N}\left(|\nabla v|^2+V_p(x)|G^{-1}(v)|^2\right)-\frac{1}{2^*}\int_{\mathbb{R}^N}(v^+)^{2^*}-\int_{\mathbb{R}^N}F_p(x,G^{-1}(v)),$$

for $v\in H^1(\mathbb{R}^N)$ and J_p possesses a nontrivial critical point. It is well known that $J_p\in C^1(H^1(\mathbb{R}^N),\mathbb{R})$, with

$$\langle J_p'(v),\varphi\rangle=\int_{\mathbb{R}^N}\left(\nabla u\nabla\varphi+V_p(x)\frac{G^{-1}(v)}{g(G^{-1}(v))}\varphi\right)-\int_{\mathbb{R}^N}(v^+)^{2^*-1}\varphi-\int_{\mathbb{R}^N}\frac{f_p(x,G^{-1}(v))}{g(G^{-1}(v))}\varphi,$$

for all $\varphi\in H^1(\mathbb{R}^N)$.

Lemma 4.1. *If $\{v_n\}$ is given by the above, then*

$$\varrho_n-\Psi_p'(v_n)\to 0\quad\textit{and}\quad\Psi(v_n)-\Psi_p(v_n)\to 0,$$

where

$$\Psi(v)=\int_{\mathbb{R}^N}F(x,G^{-1}(v))\quad\textit{and}\quad\Psi_p(v)=\int_{\mathbb{R}^N}F_p(x,G^{-1}(v)).$$

Proof. For any $\varphi\in H^1(\mathbb{R}^N)$ with $\|\varphi\|\le 1$, by (f_7), we obtain

$$\begin{aligned}\left|\langle\varrho_n-\Psi_p'(v_n),\varphi\rangle\right|&\le\int_{\mathbb{R}^N}\left|\varrho_n-\frac{f_p(x,G^{-1}(v_n))}{g(G^{-1}(v_n))}\right||\varphi|\\&\le\int_{\mathbb{R}^N}\pi(x)|v_n|^{q-1}|\varphi|\\&\le\left(\int_{\mathbb{R}^N}|\pi(x)|^{\frac{q}{q-1}}|v_n|^q\right)^{\frac{q-1}{q}}\|\varphi\|_q\\&\le C\left(\int_{\mathbb{R}^N}|\pi(x)|^{\frac{q}{q-1}}|v_n|^q\right)^{\frac{q-1}{q}}.\end{aligned}$$

Since $\{v_n\}$ is bounded in $H^1(\mathbb{R}^N)$, there is $M>0$ with $\|v_n\|_q\le M$ for all $n\in\mathbb{N}$. Using the fact that $\pi(x)\to 0$ as $|x|\to+\infty$, given $\varepsilon>0$ there is $R_\varepsilon>0$ such that $|\pi(x)|\le\varepsilon$ for $|x|>R_\varepsilon$. Since $H^1(B_{R_\varepsilon}(0))\hookrightarrow L^q(B_{R_\varepsilon}(0))$ is compact, we have $v_n\to 0$ in $L^q(B_{R_\varepsilon}(0))$. Thus, there is $n_0\in\mathbb{N}$ satisfying $\|v_n\|_{L^q(B_{R_\varepsilon}(0))}\le\varepsilon$, for all $n\ge n_0$, and so,

$$\begin{aligned}\int_{\mathbb{R}^N}|\pi(x)|^{\frac{q}{q-1}}|v_n|^q&=\int_{B_{R_\varepsilon}(0)}|\pi(x)|^{\frac{q}{q-1}}|v_n|^q+\int_{B^c_{R_\varepsilon}(0)}|\pi(x)|^{\frac{q}{q-1}}|v_n|^q\\&\le\|\pi(x)\|_\infty^{\frac{q}{q-1}}\int_{B_{R_\varepsilon}(0)}|v_n|^q+\varepsilon^{\frac{q}{q-1}}\int_{\mathbb{R}^N}|v_n|^q\\&\le\varepsilon^q\|\pi(x)\|_\infty^{\frac{q}{q-1}}+\varepsilon^{\frac{q}{q-1}}M^q.\end{aligned}$$

As ε is arbitrary,

$$\varrho_n - \Psi_p'(v_n) \to 0 \quad \text{in } (H^1(\mathbb{R}^N))^*.$$

A similar argument guarantees that

$$\Psi(v_n) - \Psi_p(v_n) \to 0 \quad \text{in } \mathbb{R}. \qquad \square$$

Since $W(x) \in L^{\frac{N}{2}}(\mathbb{R}^N)$ and $v_n \rightharpoonup 0$ in $H^1(\mathbb{R}^N)$, we can conclude

$$\int_{\mathbb{R}^N} W(x)|G^{-1}(v_n)|^2 \le \int_{\mathbb{R}^N} W(x)|v_n|^2 \to 0. \tag{4.1}$$

From Lemma 4.1 and (4.1), we deduce

$$\begin{aligned}
\left|J(v_n) - J_p(v_n)\right| &= \left|\frac{1}{2}\int_{\mathbb{R}^N} W(x)|G^{-1}(v_n)|^2 + \kappa \int_{\mathbb{R}^N} F(x, G^{-1}(v_n)) - F_p(x, G^{-1}(v_n))\right| \\
&\le \frac{1}{2}\int_{\mathbb{R}^N} W(x)|G^{-1}(v_n)|^2 + \kappa \left|\int_{\mathbb{R}^N} F(x, G^{-1}(v_n)) - F_p(x, G^{-1}(v_n)\right| \\
&\le \frac{1}{2}\int_{\mathbb{R}^N} W(x)|v_n|^2 + \kappa \left|\Psi(v_n) - \Psi_p(v_n)\right| \\
&= o_n(1),
\end{aligned} \tag{4.2}$$

which shows that $J_p(v_n) \to c_\kappa$ as $n \to \infty$.

On the other hand, note that $w_n = Q'(v_n) - \varrho_n$ and $\|w_n\|_* = \lambda_J(v_n) = o_n(1)$, where $\varrho_n \in \partial\Psi(v_n)$. From Lemma 4.1 and (4.1), for $\varphi \in H^1(\mathbb{R}^N)$ with $\|\varphi\| \le 1$, we obtain

$$\begin{aligned}
&\left|\langle w_n, \varphi\rangle - \langle J_p'(v_n), \varphi\rangle\right| \\
&\quad= \left|\int_{\mathbb{R}^N} W(x)\frac{G^{-1}(v_n)}{g(G^{-1}(v_n))}\varphi + \kappa \int_{\mathbb{R}^N}\left(\varrho_n\varphi - \frac{f_p(x, G^{-1}(v_n))}{g(G^{-1}(v_n))}\varphi\right)\right| \\
&\quad\le \int_{\mathbb{R}^N} W(x)\left|\frac{G^{-1}(v_n)}{g(G^{-1}(v_n))}\right||\varphi| + \kappa\left|\int_{\mathbb{R}^N}\left(\varrho_n\varphi - \frac{f_p(x, G^{-1}(v_n))}{g(G^{-1}(v_n))}\varphi\right)\right| \\
&\quad\le \left(\int_{\mathbb{R}^N} W(x)|v_n|^2\right)^{\frac{1}{2}} \|w\|_{\frac{N}{2}}\|\varphi\|_{2^*}^{\frac{1}{2}} + \kappa\left|\langle \varrho_n - \Psi_p'(v_n), \varphi\rangle\right| \\
&\quad= o_n(1),
\end{aligned} \tag{4.3}$$

which shows that $J_p'(v_n) \to 0$, as $n \to \infty$. Thus, by (4.2) and (4.3), $\{v_n\}$ is a $(PS)_{c_\kappa}$ sequence for J_p.

As we suppose that v is trivial, by Lemma 3.7, there exists a sequence $\{y_n\} \subset \mathbb{R}^N$ and $\delta > 0$ such that

$$\limsup_{n\to\infty} \int_{B_1(y_n)} |v_n|^2 \ge \delta > 0.$$

So, we can find a sequence $\{z_n\} \subset \mathbb{Z}^N$ such that $|z_n - y_n| < \sqrt{N}$ for all $n \in \mathbb{N}$ and

$$\limsup_{n\to\infty} \int_{B_{1+\sqrt{N}}(z_n)} |v_n|^2 \ge \limsup_{n\to\infty} \int_{B_1(y_n)} |v_n|^2 \ge \delta > 0. \tag{4.4}$$

Since $v_n \to v$ in $L^s_{\text{loc}}(\mathbb{R}^N)$ for all $s \in [1, 2^*)$ and $v = 0$, we may suppose that $|z_n| \to \infty$ up to a subsequence. Denote $\hat{v}_n(x) = v_n(x + z_n)$. Since $\{v_n\}$ is a $(PS)_{c_\kappa}$ sequence for J_p, in view of the periodicities of V_p and f_p, $\{\hat{v}_n\}$ is also a $(PS)_{c_\kappa}$ sequence for J_p. As $\{v_n\}$ is bounded in

$H^1(\mathbb{R}^N)$, it follows that $\{\hat{v}_n\}$ is also bounded in $H^1(\mathbb{R}^N)$. Without loss of generality, we may suppose that

$$\begin{cases} \hat{v}_n \rightharpoonup \hat{v} & \text{in } H^1(\mathbb{R}^N), \\ \hat{v}_n \to \hat{v} & \text{in } L^r_{\text{loc}}(\mathbb{R}^N),\ \forall\, r \in [1, 2^*), \\ \hat{v}_n \to \hat{v} & \text{a.e. in } \mathbb{R}^N, \end{cases}$$

then $J_p'(\hat{v}) = 0$. By (4.4), going to a subsequence if necessary, there exists $n_1 \in \mathbb{N}$ such that

$$\int_{B_{1+\sqrt{N}}(z_n)} |v_n|^2 \geq \frac{\delta}{2} > 0, \qquad \forall\, n \geq n_1.$$

Since $\hat{v}_n(x) = v_n(x + z_n)$ and $\hat{v}_n \to \hat{v}$ in $L^2_{\text{loc}}(\mathbb{R}^N)$, we get

$$\int_{B_{1+\sqrt{N}}(0)} |\hat{v}|^2 = \lim_{n\to\infty} \int_{B_{1+\sqrt{N}}(0)} |\hat{v}_n|^2 = \lim_{n\to\infty} \int_{B_{1+\sqrt{N}}(z_n)} |v_n|^2 \geq \frac{\delta}{2} > 0,$$

which shows $\hat{v} \not\equiv 0$. Besides,

$$0 = \langle J_p'(\hat{v}), \hat{v}^- \rangle = \int_{\mathbb{R}^N} \left(|\nabla \hat{v}^-|^2 + V(x) \frac{G^{-1}(\hat{v}^-)}{g(G^{-1}(\hat{v}^-))} \hat{v}^- \right),$$

which implies $\hat{v} = \hat{v}^+ \geq 0$. Thus, by Fatou's Lemma and (f_6), we have

$$\begin{aligned} c_\kappa &= \limsup_{n\to\infty} \left[J_p(\hat{v}_n) - \frac{1}{2} \langle J_p'(\hat{v}_n), \hat{v}_n \rangle \right] \\ &= \frac{1}{2} \limsup_{n\to\infty} \int_{\mathbb{R}^N} V_p(x) \left[|G^{-1}(\hat{v}_n)|^2 - \frac{G^{-1}(\hat{v}_n)}{g(G^{-1}(\hat{v}_n))} \hat{v}_n \right] + \frac{1}{N} \limsup_{n\to\infty} \int_{\mathbb{R}^N} |\hat{v}_n^+|^{2^*} \\ &\quad - \kappa \limsup_{n\to\infty} \int_{\mathbb{R}^N} \left[F_p(x, G^{-1}(\hat{v}_n)) - \frac{1}{2} \frac{f_p(x, G^{-1}(\hat{v}_n))}{g(G^{-1}(\hat{v}_n))} \hat{v}_n \right] \\ &\geq \frac{1}{2} \int_{\mathbb{R}^N} V_p(x) \left[|G^{-1}(\hat{v})|^2 - \frac{G^{-1}(\hat{v})}{g(G^{-1}(\hat{v}))} \hat{v} \right] + \frac{1}{N} \int_{\mathbb{R}^N} |\hat{v}^+|^{2^*} \\ &\quad - \kappa \int_{\mathbb{R}^N} \left[F_p(x, G^{-1}(\hat{v})) - \frac{1}{2} \frac{f_p(x, G^{-1}(\hat{v}))}{g(G^{-1}(\hat{v}))} \hat{v} \right] \\ &= J_p(\hat{v}) - \frac{1}{2} \langle J_p'(\hat{v}), \hat{v} \rangle = J_p(\hat{v}). \end{aligned}$$

Thus, $\hat{v}$ is a nontrivial critical point of J_p and $J_p(\hat{v}) \leq c_\kappa$.

Claim 4.2. $\hat{v} > 0$ in $\mathbb{R}^N$.

For proving the result, we adapt the same ideas used in [30]. Since $\hat{v}$ is a critical point of J_p (namely $J_p'(\hat{v}) = 0$), $\hat{v}$ is a weak solution of the following equation

$$-\Delta \hat{v} = \zeta, \quad \text{a.e. in } \mathbb{R}^N, \tag{4.5}$$

where

$$\zeta(x, \hat{v}) = \hat{v}^{2^*-1} + \kappa \frac{f_p(x, G^{-1}(\hat{v}))}{g(G^{-1}(\hat{v}))} - V_p(x) \frac{G^{-1}(\hat{v})}{g(G^{-1}(\hat{v}))}.$$

From the conditions (V), (f_7), (3.1) and the Lemma 2.1-(ii), we get

$$\begin{aligned}&\left|\hat{v}^{2^*-1}+\kappa\frac{f_p(x,G^{-1}(\hat{v}))}{g(G^{-1}(\hat{v}))}-V_p(x)\frac{G^{-1}(\hat{v})}{g(G^{-1}(\hat{v}))}\right|\\&\quad\le|\hat{v}|^{2^*-1}+\kappa\left(\varepsilon|\hat{v}|+C_\varepsilon|\hat{v}|^{q-1}+\pi(x)|\hat{v}|^{q-1}\right)+V_p(x)|\hat{v}|\\&\quad\le C\left(|\hat{v}|^{2^*-1}+|\hat{v}|^{q-1}+|\hat{v}|\right)\\&\quad\le C\left(|\hat{v}|^{2^*-1}+1\right).\end{aligned}\tag{4.6}$$

Using a result concluded by Brézis–Kato (see [32]), it yields that $\zeta(x,\hat{v})\in L^r(B_R(0))$ for every $r\in[1,+\infty)$, with $R>0$ arbitrary. By standard elliptic regularity theory, we get that $\hat{v}\in W^{2,r}(B_R(0))$. So, there exits some $\sigma\in(0,1)$ such that $\hat{v}\in C^{1,\sigma}_{\mathrm{loc}}(\mathbb{R}^N)$.

Arguing by contradiction, we assume that there exits $x_0\in\mathbb{R}^N$ such that $\hat{v}(x_0)=0$. Meanwhile, we have

$$\begin{aligned}-\Delta\hat{v}(x)+b(x)\hat{v}(x)=V_p(x)&\left(\frac{\hat{v}(x)}{g(G^{-1}(\hat{v}(x)))}-\frac{G^{-1}(\hat{v}(x))}{g(G^{-1}(\hat{v}(x)))}\right)\\&+\hat{v}^{2^*-1}(x)+\kappa\frac{f_p(x,G^{-1}(\hat{v}(x)))}{g(G^{-1}(\hat{v}(x)))},\end{aligned}\tag{4.7}$$

where $b(x):=\frac{V_p(x)}{g(G^{-1}(\hat{v}(x)))}\ge0$, for $x\in\mathbb{R}^N$. Combining Lemma 2.1-(i) and (ii), we get $\frac{\hat{v}(x)}{g(G^{-1}(\hat{v}(x)))}-\frac{G^{-1}(\hat{v}(x))}{g(G^{-1}(\hat{v}(x)))}\ge0$. By the hypotheses of $V_p(x)$, we know $-\Delta\hat{v}(x)+b(x)\hat{v}(x)\ge0$. In view of (V_1), $b(x)$ is continuous in $\mathbb{R}^N$. Thus, applying the Maximum Principle for the weak solution (see [18]) on an arbitrary ball centered in x_0, we get that $\hat{v}\equiv0$. This is a contradiction.

Claim 4.3. There exists a curve $\gamma(t):[0,1]\to H^1(\mathbb{R}^N)$ such that

$$\begin{cases}\gamma(0)=0,\ J_p(\gamma(1))<0,\ \hat{v}\in\gamma([0,1]),\\\gamma(t)(x)>0,\ \forall x\in\mathbb{R}^N,\ t\in(0,1],\\\max_{t\in[0,1]}J_p(\gamma(t))=J_p(\hat{v}).\end{cases}\tag{4.8}$$

Defining the function $\tilde{\gamma}(t)(x)=t\hat{v}(x)$ for $t\ge0$, we have

$$\begin{aligned}J_p(\tilde{\gamma}(t))=J_p(t\hat{v})&=\frac12\int_{\mathbb{R}^N}\left(|t\nabla\hat{v}|^2+V_p(x)|G^{-1}(t\hat{v})|^2\right)-\kappa\int_{\mathbb{R}^N}F_p(x,G^{-1}(t\hat{v}))-\frac{1}{2^*}\int_{\mathbb{R}^N}|t\hat{v}|^{2^*}\\&\le\frac{t^2}{2}\int_{\mathbb{R}^N}\left(|\nabla\hat{v}|^2+V_p(x)|\hat{v}|^2\right)-\frac{t^{2^*}}{2^*}\int_{\mathbb{R}^N}|\hat{v}|^{2^*}.\end{aligned}$$

Therefore, we may choose a sufficiently large constant $L>1$ such that $J_p(\tilde{\gamma}(L))<0$ with $\tilde{\gamma}(t)(x)>0$, for all $(x,t)\in\mathbb{R}^N\times(0,L]$. Furthermore, since $\hat{v}$ is a critical point of J_p, set $\varsigma(t)=J_p(t\hat{v})$ and we may write

$$\begin{aligned}\varsigma'(t)&=t\int_{\mathbb{R}^N}|\nabla\hat{v}|^2+\int_{\mathbb{R}^N}V_p(x)\frac{G^{-1}(t\hat{v})}{g(G^{-1}(t\hat{v}))}\hat{v}-\kappa\int_{\mathbb{R}^N}\frac{f_p(x,G^{-1}(t\hat{v}))}{g(G^{-1}(t\hat{v}))}\hat{v}-t^{2^*-1}\int_{\mathbb{R}^N}|\hat{v}|^{2^*}\\&=t\left\{\int_{\mathbb{R}^N}|\nabla\hat{v}|^2+\int_{\mathbb{R}^N}\left[V_p(x)\frac{G^{-1}(t\hat{v})}{g(G^{-1}(t\hat{v}))t\hat{v}}-\kappa\frac{f_p(x,G^{-1}(t\hat{v}))}{g(G^{-1}(t\hat{v}))t\hat{v}}-(t\hat{v})^{2^*-2}\right]\hat{v}^2\right\}.\end{aligned}$$

As a direct consequence of Lemma 2.1-(iv) and (f_5), fixed $x \in \mathbb{R}^N$, the function $\eta : (0, +\infty) \to \mathbb{R}$ defined by

$$\eta(t) = V_p(x)\frac{G^{-1}(t)}{g(G^{-1}(t))t} - \kappa\frac{f_p(x, G^{-1}(t))}{g(G^{-1}(t))t} - t^{2^*-2}$$

is decreasing.

Since $\hat{v}$ is a critical point of J_p, we have $\varsigma'(1) = 0$. Moreover, $\varsigma(t) > 0$ for $0 < t < 1$ and $\varsigma(t) < 0$ for $t > 1$. Hence,

$$J_p(\hat{v}) = \varsigma(1) = \max_{t\geq 0}\varsigma(t) = \max_{t\geq 0} J_p(t\hat{v}) = \max_{t\in[0,L]} J_p(t\hat{v}) = \max_{t\in[0,L]} J_p(\tilde{\gamma}(t)).$$

Let $\gamma(t) = \tilde{\gamma}(tL)$. We can check the curve $\gamma(t)$ satisfies (4.8). From $J(\phi) \leq J_p(\phi)$ for all $\phi \in H^1(\mathbb{R}^N)$, we get $\gamma \in \Gamma_J$.

Due to the fact that $\gamma \in \Gamma_J$ satisfies (4.8) and the inequality $W(x) \geq 0$ is strict on a subset of positive measure in $\mathbb{R}^N$, we deduce that

$$c_\lambda \leq \max_{t\in[0,1]} J(\gamma(t)) := J(\gamma(\bar{t})) < J_p(\gamma(\bar{t})) \leq \max_{t\in[0,1]} J_p(\gamma(t)) = J_p(\hat{v}) \leq c_\lambda,$$

which is absurd.

Thus, we conclude that v is a nontrivial solution to problem (2.1). An argument similar to Claim 4.2 shows $v > 0$ in $\mathbb{R}^N$. By Lemma 2.2, problem (1.6) possesses a positive solution $u = G^{-1}(v)$.

5 Proof of Theorem 1.2

The following section gives the proof of Theorem 1.2. First, note that the lemmas in Section 3 are not dependent on the periodicity of function f, but only on its growth, meaning all of them are also valid here. As f satisfies (f_1)–(f_4), by Lemmas 3.3, 3.4 and 3.5, there is a bounded $(PS)_{c_\kappa}$ sequence for J, denoted by $\{v_n\} \subset H^1(\mathbb{R}^N)$, that is,

$$J(v_n) \to c_\kappa \geq \alpha > 0 \ \text{ and } \ \lambda_J(v_n) \to 0, \quad \text{as } n \to \infty.$$

Consider $w_n \in \partial J(v_n)$ such that $\|w_n\|_* = \lambda_J(v_n) = o_n(1)$ and $w_n = Q'(v_n) - \varrho_n$, where $\varrho_n \in \partial\Psi(v_n)$. Without loss of generality, we may suppose that $v_n \rightharpoonup v$ in $H^1(\mathbb{R}^N)$. If v is nontrivial, then Theorem 1.2 is proved. Indeed, repeating the analogous arguments as in the initial steps of the proof of Theorem 1.1, we can instantly obtain that $v = v^+ \geq 0$ and satisfies

$$-\Delta v + V_p(x)\frac{G^{-1}(v)}{g(G^{-1}(v))} = \varrho + v^{2^*-1} \quad \text{a.e. } \mathbb{R}^N,$$

that is,

$$-\Delta v + V_p(x)\frac{G^{-1}(v)}{g(G^{-1}(v))} - v^{2^*-1} \in \left[\frac{\underline{f}(x, G^{-1}(v))}{g(G^{-1}(v))}, \frac{\overline{f}(x, G^{-1}(v))}{g(G^{-1}(v))}\right] \quad \text{a.e. in } \mathbb{R}^N.$$

By the argument similar to the one used in Claim 4.2, we can show $v > 0$. Then, $u = G^{-1}(v)$ will be a positive solution of problem (1.8).

Hence, in order to prove Theorem 1.2, it suffices to assume that $v = 0$.

In view of Lemma 3.6, it follows that there exists κ^* such that $c_\kappa < \frac{1}{N}S^{\frac{N}{2}}$ for all $\kappa > \kappa^*$. Furthermore, by Lemma (3.8), there exists a sequence $\{y_n\} \subset \mathbb{R}^N$ and $\delta > 0$ such that

$$\limsup_{n\to\infty} \int_{B_1(y_n)} |v_n|^2 \geq \delta > 0, \qquad \text{for all } n \in \mathbb{N}. \tag{5.1}$$

Since $v_n \to v$ in $L^2_{\text{loc}}(\mathbb{R}^N)$ and $v = 0$, we may suppose that $|y_n| \to \infty$ up to a subsequence. As in the proof of Theorem 1.1, without loss of generality, we can suppose that $\{y_n\} \subset \mathbb{Z}^N$. Defining $\tilde{v}_n(x) = v_n(x + y_n)$, we get $\|\tilde{v}_n\| = \|v_n\|$. Then, taking a subsequence if necessary, there exists $\tilde{v} \in H^1(\mathbb{R}^N)$ such that

$$\begin{cases} \tilde{v}_n \rightharpoonup \tilde{v} & \text{in } H^1(\mathbb{R}^N), \\ \tilde{v}_n \to \tilde{v} & \text{in } L^r_{\text{loc}}(\mathbb{R}^N),\ \forall\, r \in [1, 2^*), \\ \tilde{v}_n \to \tilde{v} & \text{a.e. in } \mathbb{R}^N. \end{cases}$$

The fact that

$$\int_{B_1(0)} |\tilde{v}|^2 = \lim_{n\to\infty} \int_{B_1(0)} |\tilde{v}_n|^2 = \lim_{n\to\infty} \int_{B_1(y_n)} |v_n|^2,$$

and (5.1) imply that $\tilde{v} \neq 0$.

Now, we claim $\tilde{v}$ is a nontrivial solution of periodic problem.

First, we note that $\varrho_n \in \partial\Psi(v_n)$. By the definition of $\partial\Psi(v_n)$,

$$\Psi^\circ(v_n, \psi) \geq \langle \varrho_n, \psi \rangle, \qquad \forall \psi \in L^\Phi(\mathbb{R}^N).$$

Since $H^1(\mathbb{R}^N) \hookrightarrow L^\Phi(\mathbb{R}^N)$ is continuous, a simple change variable implies

$$\begin{aligned} \Psi^\circ(v_n; \psi(\cdot - y_n)) &\geq \langle \varrho_n, \psi(\cdot - y_n) \rangle \\ &= \int_{\mathbb{R}^N} \varrho_n \psi(\cdot - y_n) \\ &= \int_{\mathbb{R}^N} \varrho_n(\cdot + y_n)\psi \\ &= \langle \tilde{\varrho}_n, \psi \rangle, \end{aligned} \tag{5.2}$$

where $\tilde{\varrho}_n = \varrho_n(\cdot + y_n)$. Meanwhile, we can easily verify

$$\Psi(v_n + h + t\psi(\cdot - y_n)) = \Psi(\tilde{v}_n + h(\cdot + y_n) + t\psi) \quad \text{and} \quad \Psi(v_n + h) = \Psi(\tilde{v}_n + h(\cdot + y_n)),$$

where $h \in H^1(\mathbb{R}^N)$ and $t \in \mathbb{R}$. Thus, directly calculations demonstrate

$$\Psi^\circ(v_n + \psi(\cdot - y_n)) = \Psi^\circ(\tilde{v}_n + \psi). \tag{5.3}$$

By (5.2) and (5.3), we get

$$\Psi^\circ(\tilde{v}_n + \psi) \geq \langle \tilde{\varrho}_n, \psi \rangle, \qquad \forall \psi \in H^1(\mathbb{R}^N),$$

which shows $\tilde{\varrho}_n \in \partial\Psi(\tilde{v}_n)$. Furthermore, for all $\psi \in H^1(\mathbb{R}^N)$, we have

$$\begin{aligned} \langle w_n, \psi(\cdot - y_n) \rangle &= \langle Q'(v_n), \psi(\cdot - y_n) \rangle - \langle \varrho_n, \psi(\cdot - y_n) \rangle \\ &= \langle Q'(\tilde{v}_n), \psi \rangle - \langle \tilde{\varrho}_n, \psi \rangle. \end{aligned}$$

Setting $\langle w_n, \psi(\cdot - y_n) \rangle = \langle \tilde{w}_n, \psi \rangle$, we assert

$$\tilde{w}_n = Q'(\tilde{v}_n) - \tilde{\varrho}_n. \tag{5.4}$$

Claim 5.1. $\tilde{w}_n \in \partial J(\tilde{v}_n)$.

Similarly, by change of variables, we get

$$J^\circ(v_n; \psi(\cdot - y_n)) = J^\circ(\tilde{v}_n; \psi). \tag{5.5}$$

And as $w_n \in \partial J(v_n)$, then

$$J^\circ(v_n; \psi(\cdot - y_n)) \geq \langle w_n, \psi(\cdot - y_n)\rangle = \langle \tilde{w}_n, \psi\rangle, \qquad \forall \psi \in H^1(\mathbb{R}^N). \tag{5.6}$$

Combining (5.5) and (5.6), we have

$$J^\circ(\tilde{v}_n; \psi) \geq \langle \tilde{w}_n, \psi\rangle, \qquad \forall \psi \in H^1(\mathbb{R}^N),$$

which shows $\tilde{w}_n \in \partial J(\tilde{v}_n)$.

Moreover, by definition of $\tilde{w}_n$, we get

$$\|\tilde{w}_n\|_* = \sup_{\psi \in H^1(\mathbb{R}^N)} \frac{|\langle \tilde{w}_n, \psi\rangle|}{\|\psi\|} \leq \|w_n\|_*, \qquad \forall n \in \mathbb{N}.$$

Therefore,

$$0 \leq \|\tilde{w}_n\|_* \leq \|w_n\|_* = \lambda_J(v_n) = o_n(1). \tag{5.7}$$

By (5.4), we get

$$\langle \tilde{w}_n, \psi\rangle = \langle Q'(\tilde{v}_n), \psi\rangle - \langle \tilde{\varrho}_n, \psi\rangle, \qquad \forall \psi \in H^1(\mathbb{R}^N). \tag{5.8}$$

From (5.7) and (5.8), we obtain

$$\langle \tilde{\varrho}_n, \psi\rangle = \langle Q'(\tilde{v}_n), \psi\rangle - \langle \tilde{w}_n, \psi\rangle \to \langle Q'(\tilde{v}), \psi\rangle, \quad \text{as } n \to \infty,$$

that is, $\tilde{\varrho}_n \overset{*}{\rightharpoonup} Q'(\tilde{v})$ in $(H^1(\mathbb{R}^N))^*$.

This limit together with Lemma 3.2 shows that $Q'(\tilde{v}) \in \partial\Psi(v)$. Thereby, $Q'(\tilde{v}) = \tilde{\varrho} \in \partial\Psi(\tilde{v})$, and so,

$$\int_{\mathbb{R}^N} \left(\nabla\tilde{v}\nabla\psi + V_p(x)\frac{G^{-1}(\tilde{v})}{g(G^{-1}(\tilde{v}))}\psi\right) - \int_{\mathbb{R}^N} (\tilde{v}^+)^{2^*-1}\psi = \int_{\mathbb{R}^N} \tilde{\varrho}\psi, \qquad \forall\ \psi \in H^1(\mathbb{R}^N),$$

where

$$\tilde{\varrho}(x) \in \left[\frac{\underline{f}(x, G^{-1}(\tilde{v}(x)))}{g(G^{-1}(\tilde{v}(x)))}, \frac{\overline{f}(x, G^{-1}(\tilde{v}(x)))}{g(G^{-1}(\tilde{v}(x)))}\right] \quad \text{a.e. in } \mathbb{R}^N.$$

Repeating the analogous steps of the proof of Theorem 1.1, $\tilde{v} = \tilde{v}^+ \geq 0$ and satisfies

$$-\Delta\tilde{v} + V_p(x)\frac{G^{-1}(\tilde{v})}{g(G^{-1}(\tilde{v}))} = \tilde{\varrho} + \tilde{v}^{2^*-1} \quad \text{a.e. } \mathbb{R}^N,$$

that is,

$$-\Delta\tilde{v} + V_p(x)\frac{G^{-1}(\tilde{v})}{g(G^{-1}(\tilde{v}))} - \tilde{v}^{2^*-1} \in \left[\frac{\underline{f}(x, G^{-1}(\tilde{v}))}{g(G^{-1}(\tilde{v}))}, \frac{\overline{f}(x, G^{-1}(\tilde{v}))}{g(G^{-1}(\tilde{v}))}\right] \quad \text{a.e. in } \mathbb{R}^N.$$

Similarly, we also have $\tilde{v} > 0$ in $\mathbb{R}^N$ by the analogous argument used in Claim 4.2. Since (1.8) is only the periodic case for (1.6), Lemma 2.2 is also valid. Hence, we can see that $u = G^{-1}(\tilde{v})$ will be a positive solution of problem (1.8).

Acknowledgements

We wish to thank both the editor and the reviewers for their diligent efforts and constructive criticism, which were instrumental in shaping the final version of this manuscript.

Communicated by Gennaro Infante

Abstract. We are concerned with the principal eigenvalue of

$$\begin{cases} -\Delta_p u = \lambda\theta_1\varphi_p(v), & x \in \Omega, \\ -\Delta_p v = \lambda\theta_2\varphi_p(u), & x \in \Omega, \\ u = 0 = v, & x \in \partial\Omega \end{cases} \tag{P}$$

and the global structure of positive solutions for the system

$$\begin{cases} -\Delta_p u = \lambda f(v), & x \in \Omega, \\ -\Delta_p v = \lambda g(u), & x \in \Omega, \\ u = 0 = v, & x \in \partial\Omega, \end{cases} \tag{Q}$$

where $\varphi_p(s) = |s|^{p-2}s$, $\Delta_p s = \text{div}(|\nabla s|^{p-2}\nabla s)$, $\lambda > 0$ is a parameter, $\Omega \subset \mathbb{R}^N$, $N > 2$, is a bounded domain with smooth boundary $\partial\Omega$, $f, g : \mathbb{R} \to (0, \infty)$ are continuous functions with p-superlinear growth at infinity. We obtain the principal eigenvalue of (P) by using a nonlinear Krein–Rutman theorem and the unbounded branch of positive solutions for (Q) via bifurcation technology.

Keywords: p-Laplacian, principal eigenvalue, positive solutions, bifurcation.

2020 Mathematics Subject Classification: 35B32, 35B40, 35J92.

1 Introduction

In this paper, we are concerned with the global structure of positive solutions for the system

$$\begin{cases} -\Delta_p u = \lambda f(v), & x \in \Omega, \\ -\Delta_p v = \lambda g(u), & x \in \Omega, \\ u = 0 = v, & x \in \partial\Omega, \end{cases} \tag{1.1}$$

✉Corresponding author. Email: mary@nwnu.edu.cn

where $\Delta_p s = \operatorname{div}(|\nabla s|^{p-2}\nabla s)$, $\lambda > 0$ is a parameter, $\Omega \subset \mathbb{R}^N$, $N > 2$, is a bounded domain with smooth boundary $\partial\Omega$, $f, g : \mathbb{R} \to (0, \infty)$ are continuous functions with p-superlinear growth at infinity.

The bifurcation behavior for p-Laplacian scalar equation has been investigated by many authors, see [11, 12, 22, 23, 30] for finite interval ($N = 1$) and [10, 18] for bounded domain ($N > 1$). For example, in [18], Fleckinger and Reichel established the global solution branches for the problem

$$\begin{cases} -\Delta_p u = \lambda(1 + u^q), & x \in \Omega, \\ u = 0, & x \in \partial\Omega, \end{cases} \tag{1.2}$$

where $\lambda \geqslant 0$ and $q > p - 1$. Let $p^* := Np/(N - p)$ if $N > p$ and $p^* := \infty$ if $n \leqslant p$. They obtained, in supercritical case, that is, $q > p^* - 1$, then there exists an unbounded continuum $\mathscr{C}^+ \subset [0, +\infty) \times C_0^1(\bar{\Omega})$ of solutions of (1.2). Moreover, in subcritical case, that is, $q \in (p - 1, p^* - 1)$, then $\mathscr{C}^+$ is bounded in the λ-direction and becomes unbounded near $\lambda = 0$ under some additional conditions.

In [8], Chhetri and Girg studied global structure of the semilinear system

$$\begin{cases} -\Delta u = \lambda f(v), & x \in \Omega, \\ -\Delta v = \lambda g(u), & x \in \Omega, \\ u = 0 = v, & x \in \partial\Omega, \end{cases} \tag{1.3}$$

they make the following assumptions:

(H1) $f, g \in C(\mathbb{R}, (0, \infty))$ are continuous and non-decreasing functions;

(C2) f and g satisfy

$$\lim_{s \to +\infty} \frac{f(s)}{s} = +\infty, \qquad \lim_{s \to +\infty} \frac{g(s)}{s} = +\infty.$$

Under (H1) and (C2), they obtained the global behavior of positive solutions set of (1.3) by using bifurcation technology. To be more precise, in supercritical case, they obtained a component of positive solutions for (1.3), emanating from the origin, which is bounded in positive λ-direction. If in addition, Ω is convex, and $f, g \in C^1$ satisfy certain subcriticality conditions, they showed that the component must bifurcate from infinity at $\lambda = 0$.

As for p-Laplacian system (1.1), the first result of which we are aware concerning is the one by Hai and Shivaji in [20], by means of sub- and supersolutions, it was proved that (1.1) has a large positive solution (u, v) for $\lambda > \lambda_0$ with some p-sublinear conditions for f and g. Quite recently, there are some authors concerned with the positive solutions for p-Laplacian systems, refer to [9, 15, 17, 26, 27, 29] and references therein. But all of them only obtain the positive solution and do not provide any information about the global structure of positive solutions set.

The global structure is very useful for computing the numerical solutions of differential equations as it can be used to guide numerical work. For example, it can be used to estimate the u-interval in advance in applying the finite difference method and when applying the shooting method, it can be used to restrict the range of initial values that need to be considered.

As we all know, if we want to get global structure of positive solutions for (1.1) by using bifurcation technology, it is necessary to investigate the eigenvalue of corresponding eigenvalue problem. However, to the best of our knowledge, the spectral theory of the corresponding p-Laplacian system has not yet been established. In fact, for $p = 2$, the principal eigenvalue ν_1 of linear system corresponding to (1.3) can be directly expressed as

$$\nu_1 = \hat{\eta}_1 / \sqrt{\theta_1 \theta_2},$$

see [7, Prop. B.1], where $\hat{\eta}_1$ is the principal eigenvalue of scalar equation. However, this result do not hold for $p \neq 2$ because p-Laplacian operator is neither self-adjoint linear nor symmetric. In order to overcome this, we introduce a nonlinear version of Krein–Rutman theorem established by Arapostathis [2]. Let $\varphi_p(s) = |s|^{p-2}s$. By using the nonlinear Krein–Rutman theorem, we obtain that

$$\begin{cases} -\Delta_p u = \lambda \theta_1 \varphi_p(v), & x \in \Omega, \\ -\Delta_p v = \lambda \theta_2 \varphi_p(u), & x \in \Omega, \\ u = 0 = v, & x \in \partial\Omega, \end{cases} \tag{1.4}$$

has a positive simple eigenvalue, expressed as μ_1, having the smallest absolute value, that is to say, μ_1 is the principal eigenvalue of (1.4).

The additional difficulty is the bifurcation results in dealing with semilinear boundary value problems [8] cannot be applied directly to quasilinear problems. Hence, we use the jumps of the index of the trivial solution to obtain a branch of nontrivial solutions. In addition to that, since Δ_p is asymmetric, the proof used in Theorem 1.1 of [8] do not applicable to (1.1). To this end, we adopt a new approach, with the help of sub- and supersolutions, to prove the nonexistence of solution for (1.1).

Let $X = C(\bar{\Omega}) \times C(\bar{\Omega})$, it is easy to know X is a Banach space endowed with the norm $\|(u_1, u_2)\| = \|u_1\|_C + \|u_2\|_C$, where $\|u\|_C$ is equipped with the supremum norm. By a solution of (1.1), we mean a $(\lambda, (u, v))$ that solves (1.1) in the weak sense, that is, $(u, v) \in E$, where $E := W_0^{1,p}(\Omega) \times W_0^{1,p}(\Omega)$, and satisfies

$$\int_\Omega |\nabla u|^{p-2} \nabla u \nabla \omega \mathrm{d}x = \lambda \int_\Omega f(v) \omega \mathrm{d}x,$$
$$\int_\Omega |v|^{p-2} \nabla v \nabla \varpi \mathrm{d}x = \lambda \int_\Omega g(u) \varpi \mathrm{d}x$$

for all $(\omega, \varpi) \in E$. We denote Π of the form

$$\Pi = \overline{\{(\lambda, (u, v)) \in \mathbb{R} \times E \mid (\lambda, (u, v)) \text{ solution of } (1.1)\}}.$$

If $(\lambda, (u, v)) \in \Pi$ and $u > 0$, $v > 0$, then we say that $(\lambda, (u, v))$ is a *positive solution* of (1.1). By a *continuum* of solutions of (1.1) we mean a subset $\mathscr{K} \subset \Pi$ which is closed and connected. By a *component* of solutions set Π we mean a continuum which is maximal with respect to inclusion ordering. We say that λ_∞ is a *bifurcation point* from infinity if the solution set Π contains a sequence $(\lambda_n, (u_n, v_n))$ such that $\lambda_n \to \lambda_\infty$ and $\|(u_n, v_n)\| \to +\infty$ as $n \to +\infty$. We say that a continuum $\mathscr{C}$ bifurcates from infinity at $\lambda \in \mathbb{R}$ if there exists a sequence of solutions $(\lambda_n, (u_n, v_n)) \in \mathscr{C}$ such that $\lambda_n \to \lambda_\infty$ and $\|(u_n, v_n)\| \to +\infty$ as $n \to +\infty$.

Let $\eta_1 > 0$ be the principal eigenvalue of the problem

$$\begin{cases} -\Delta_p u = \lambda \varphi_p(u), & x \in \Omega, \\ u = 0, & x \in \partial\Omega, \end{cases} \tag{1.5}$$

by [1], η_1 is simple, isolated, and the unique positive eigenvalue having a nonnegative eigenfunction χ_1.

Further we assume that:

(H2) f and g satisfy

$$\lim_{s\to+\infty}\frac{f(s)}{\varphi_p(s)}=+\infty,\qquad \lim_{s\to+\infty}\frac{g(s)}{\varphi_p(s)}=+\infty.$$

We first state a nonexistence result in Theorem 1.1, which holds under weaker assumptions than (H1)–(H2). Theorem 1.2 gives a existence result when f and g have supercritical growth at infinite. Specifically, there is an unbounded branch $\mathscr{C}$ of positive solutions for (1.1), bifurcating from infinity and going through trivial solution, which is bounded in positive λ-direction. Moreover, when Ω is convex with C^2 boundary and $p\in(1,2)$, f and g satisfy certain subcritical growth restrictions, Theorem 1.3 shows that $\lambda=0$ is the unique bifurcation point from infinity for the continuum $\mathscr{C}$ obtained in Theorem 1.2.

Theorem 1.1. *Let $m>0$, and suppose $f(s),g(s)\geqslant m\varphi_p(s)$ for all $s>0$, then (1.1) has no solution for $\lambda\geqslant\bar\lambda:=\eta_1/m$.*

Theorem 1.2 (Supercritical case)**.** *Let (H1)–(H2) hold. Then there exists an unbounded component $\mathscr{C}\subset\Pi$ satisfying the following:*

(a) *$(\lambda,(u,v))\in\mathscr{C}$ is positive whenever $\lambda\in(0,\bar\lambda)$;*

(b) *(0,(0,0)) is the only element belonging to $\mathscr{C}$ with $\lambda=0$;*

(c) $\mathrm{Proj}_{\lambda\in[0,+\infty)}\mathscr{C}\overset{def}{=}\{\lambda\in[0,+\infty)\mid\exists(u,v)\in E \text{ with } (\lambda,(u,v))\in\mathscr{C}\}\subset[0,\bar\lambda)$;

(d) *any sequence $(\lambda_n,(u_n,v_n))\in\mathscr{C}$ such that $\|(u_n,v_n)\|\to+\infty$ as $n\to+\infty$ and $\lambda_n>0$ must satisfy $\lambda_n\to0^+$ as $n\to+\infty$.*

Theorem 1.3 (Subcritical case)**.** *Assume that (H1)–(H2) hold. Let $p\in(1,2)$, $N>2$ and Ω be convex with C^2 boundary, f,g satisfy*

$$\lim_{s\to+\infty}\frac{f(s)}{s^{q_1}}=C,\qquad \lim_{s\to+\infty}\frac{g(s)}{s^{q_2}}=D, \tag{1.6}$$

for some positive constants C,D, and $q_1q_2>(p-1)^2$ satisfy

$$\max\left\{\frac{p(q_1+p-1)}{q_1q_2-(p-1)^2}-\frac{N-p}{p-1},\ \frac{p(q_2+p-1)}{q_1q_2-(p-1)^2}-\frac{N-p}{p-1}\right\}\geqslant 0.$$

Then $\mu_1=0$ is the unique bifurcation point from infinity, for the continuum $\mathscr{C}\subset\Pi$ from Theorem 1.2.

Corollary 1.4. *We may obtain the number of positive solutions of (1.1) from Theorem 1.3:*

(i) *(1.1) has no positive solution for $\lambda\geqslant\bar\lambda$;*

(ii) *there exists $\underline{\lambda}<\bar\lambda$ such that (1.1) has at least two positive solutions for each $\lambda\in(0,\underline{\lambda})$.*

Remark 1.5. It is worth remarking that Theorem 1.1 and Theorem 1.2 are direct generalizations of the results in [8]. However, Theorem 1.3 only holds for $p\in(1,2)$ because *a priori estimates* established in [4] is not available to $p=2$.

2 Preliminaries

Next we state some notations from [2].

An *ordered Banach space* is a real Banach space W with a cone K. When the interior of K, denoted as int$K$, is nonempty, we call W a *strongly ordered* Banach space. As usual, we write $x \preceq y$ if $y - x \in K$. A continuous map $T : W \to W$ is

- order-preserving or increasing if $x \preceq y \Rightarrow T(x) \preceq T(y)$;
- homogeneous of degree one, or 1-homogeneous, if $T(tx) = tT(x)$ for all $t \geqslant 0$.

Lemma 2.1 ([4, Lemma 1.1]). *Let $\Omega \subset \mathbb{R}^N$ be a bounded domain of class $C^{1,\beta}$ for some $\beta \in (0,1)$ and $g \in L^\infty(\Omega)$. Then the problem*

$$\begin{cases} \int_\Omega |\nabla u|^{p-2}\nabla u \nabla \omega dx = \lambda \int_\Omega f(u)\omega dx, & \forall \omega \in C_c^\infty(\Omega), \\ u \in W_0^{1,p}(\Omega), \quad p > 1 \end{cases} \tag{2.1}$$

has a unique solution $u \in C_0^1(\bar{\Omega})$. Moreover, if we define the operator $K : L^\infty(\Omega) \to C_0^1(\bar{\Omega}) : g \mapsto u$ where u is the unique solution of (2.1), then K is continuous, compact and order-preserving.

Now we give a definition of weak sub- and supersolutions of (1.1), which is defined by [20].

Definition 2.2. We say that (α_u, α_v) is a weak subsolution of problem (1.1) if (α_u, α_v) satisfies

$$\int_\Omega |\nabla \alpha_u|^{p-2}\nabla \alpha_u \nabla \omega \mathrm{d}x \leqslant \lambda \int_\Omega f(\alpha_v)\omega \mathrm{d}x,$$
$$\int_\Omega |\nabla \alpha_v|^{p-2}\nabla \alpha_v \nabla \omega \mathrm{d}x \leqslant \lambda \int_\Omega g(\alpha_u)\omega \mathrm{d}x$$

for all $\omega \in W_0^{1,p}(\Omega)$ with $\omega \geqslant 0$. Similarly, we say that (β_u, β_v) is a weak supersolution of problem (1.1) if (β_u, β_v) satisfies

$$\int_\Omega |\nabla \beta_u|^{p-2}\nabla \beta_u \nabla \omega \mathrm{d}x \geqslant \lambda \int_\Omega f(\beta_v)\omega \mathrm{d}x,$$
$$\int_\Omega |\nabla \beta_v|^{p-2}\nabla \beta_v \nabla \omega \mathrm{d}x \geqslant \lambda \int_\Omega f(\beta_u)\omega \mathrm{d}x$$

for all $\omega \in W_0^{1,p}(\Omega)$ with $\omega \geqslant 0$.

Proposition 2.3 ([34, Theorem 14.D]). *Let Y be a Banach space with $Y \neq \{0\}$ and let $F : Y \to Y$ be compact. Then the solution component $\mathfrak{C} \subset \mathbb{R} \times Y$ of the equation*

$$x = \lambda F(x)$$

which contains $(0,0) \in \mathbb{R} \times Y$ is unbounded as are both subsets

$$\mathfrak{C}_\pm \overset{def}{=} \mathfrak{C} \cap (\mathbb{R}_\pm \times Y),$$

where $\mathbb{R}_+ \overset{def}{=} [0,\infty)$ and $\mathbb{R}_- \overset{def}{=} (-\infty, 0]$.

Definition 2.4 ([33]). Let Z be a Banach space and $\{C_n \mid n = 1,2,\cdots\}$ be a certain infinite collection of subset of Z. Then the superior limit of $\mathcal{D}$ of $\{C_n\}$ is defined by

$$\mathcal{D} := \limsup_{n\to\infty} C_n = \{x \in Z \mid \exists \{n_i\} \subset \mathbb{N} \text{ and } x_{n_i} \in C_{n_i}, \text{ such that } x_{n_i} \to x\}.$$

Lemma 2.5 ([33]). *Let Z be a Banach space with the norm $\|\cdot\|_Z$, let $\{C_n\}$ be a family of closed subsets of Z. Assume that:*

(i) *there exist $z_n \in C_n$, $n = 1, 2, \dots,$ and $z^* \in Z$, such that $z_n \to z^*$;*

(ii) $d_n = \sup\{\|x\|_Z \mid x \in C_n\} = \infty$;

(iii) *for every $R > 0$, $(\bigcup_{n=1}^{\infty} C_n) \cap B_R$ is a relatively compact set of Z, where*

$$B_R = \{x \in Z \mid \|x\|_Z \leqslant R\},$$

then there exists an unbounded component $\mathcal{C}$ in $\mathcal{D}$ and $z^* \in \mathcal{C}$.

The following nonlinear version of the Krein–Rutman theorem is firstly established by Mahadevan [25] and corrected by Arapostathis [2].

Let

$$\sigma_+(T) := \{\lambda > 0 : T(x) = \lambda x,\ x \in K \setminus \{0\}\}.$$

Consider the following hypotheses:

(B1) If $x \in \partial K \setminus \{0\}$, then $x - \beta T(x) \notin K$ for all $\beta > 0$.

(B2) If $x - y \in \partial K \setminus \{0\}$, then $x - y - \beta(T(x) - T(y)) \notin K$ for all $\beta > 0$.

Lemma 2.6 ([2, Theorem 3]). *Let W be strongly ordered, and $T : K \to K$ be an order-preserving, 1-homogeneous map with $\sigma_+(T) \neq \emptyset$.*

(i) If (B1) holds, then $T(\operatorname{int} K) \subset \operatorname{int} K$, $\sigma_+(T)$ is a singleton, and all eigenvectors lie in $\operatorname{int} K$.

(ii) If (B2) holds, then the unique eigenvalue in $\sigma_+(T)$ is simple.

3 Eigenvalue problems

Consider the eigenvalue of problem

$$\begin{cases} -\Delta_p u = \lambda\theta_1\varphi_p(v), & x \in \Omega, \\ -\Delta_p v = \lambda\theta_2\varphi_p(u), & x \in \Omega, \\ u = 0 = v, & x \in \partial\Omega, \end{cases} \tag{3.1}$$

where $\theta_1, \theta_2 > 0$, then (3.1) is equivalent to

$$-\Delta_p \begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} 0 & \theta_1 \\ \theta_2 & 0 \end{pmatrix} \begin{pmatrix} \varphi_p(u) \\ \varphi_p(v) \end{pmatrix},$$

that is,

$$\begin{pmatrix} u \\ v \end{pmatrix} = -\Delta_p^{-1} \begin{pmatrix} 0 & \theta_1 \\ \theta_2 & 0 \end{pmatrix} \begin{pmatrix} \varphi_p(u) \\ \varphi_p(v) \end{pmatrix}.$$

It is equivalent to

$$U = -\Delta_p^{-1} A\varphi_p(U) =: HU,$$

where

$$U = \begin{pmatrix} u \\ v \end{pmatrix}, \qquad A = \begin{pmatrix} 0 & \theta_1 \\ \theta_2 & 0 \end{pmatrix}.$$

Obviously, H is 1-homogeneous by the property of φ_p and φ_p^{-1}. Lemma 2.1 shows H is a continuous, positively compact operator, and by the strictly increasing property of φ_p and $(-\Delta_p)^{-1}$ we know that H is strictly increasing.

Taking the cone to be

$$P = \left\{ w \in C_0^1(\overline{\Omega}) : w \geqslant 0 \text{ in } \Omega,\ \frac{\partial w}{\partial n} \leqslant 0 \text{ on } \partial\Omega \right\}.$$

Lemma 3.1 ([32, Lemma 2.2.1])**.** *Let $u, v \in C^1(\overline{\Omega})$ with $u|_{\partial\Omega} = 0$, $v|_{\partial\Omega} \geqslant 0$, $u > 0$ in Ω, and $\partial_{\mathbf{n}} u|_{\partial\Omega} < 0$. Then there exists a positive constant $\varepsilon > 0$ such that $u + \varepsilon v > 0$ in Ω.*

By Lemma 3.1, the interior of P can be expressed as

$$\operatorname{int} P = \left\{ w \in C_0^1(\overline{\Omega}) : w > 0 \text{ in } \Omega,\ \frac{\partial w}{\partial n} < 0 \text{ on } \partial\Omega \right\}.$$

Let

$$K = P \times P.$$

Obviously, (B1) can be obtained by letting $y = 0$ in (B2), therefore, we only show that H satisfies (B2). In fact, since K is a closed set, if we choose $V_1, V_2 \in K$ such that $V_1 - V_2 \in \partial K \setminus \{0\}$, then $V_1 - V_2 \in K$, that is to say, $V_1 \succeq V_2$. The strong maximum principle shows $H(V_1), H(V_2) \in K$. In addition, by the property that H is strictly increasing we have $H(V_1) \succeq H(V_2)$, this means $H(V_1) - H(V_2) \in K$ with $H(V_1) - H(V_2) \neq \{0\}$. On the other hand, $V_1 - V_2 \in \partial K \setminus \{0\}$, then any neighborhood of $V_1 - V_2$ contains some points that do not belong to K, this means

$$V_1 - V_2 - \beta(H(V_1) - H(V_2)) \notin K$$

for all $\beta > 0$.

Lemma 3.2. *System (3.1) has a positive and simple eigenvalue $\mu_1 > 0$ with a eigenfunction $U_1 = (\phi_1, \psi_1) > 0$.*

Proof. By Lemma 2.1, H is compact, then $\sigma_+(T) \neq \emptyset$. By (i) of Lemma 2.6, $\sigma_+(T)$ is a singleton, denoted by λ_1, and all eigenvectors lie in $\operatorname{int} K$, that is, λ_1 is unique. Moreover, (B2) shows λ_1 is simple. Therefore, H has a unique positive eigenvector (eigenfunction) $U_1 = (\phi_1, \psi_1)$, which satisfies

$$HU_1 = \lambda_1 U_1,$$

Subsequently, $\mu_1 = 1/\lambda_1$ is a simple, isolated and positive eigenvalue of (1.4). □

4 Auxiliary results

Proof of Theorem 1.1. Suppose that there is a sequence of $\{\lambda_n\}$ such that $\lambda_n \to \infty$ as $n \to \infty$, and (1.1) has a positive solution (u_n, v_n) when $\lambda = \lambda_n$. Then there is a $\lambda_{n_0} > 0$ such that $\lambda_n > \frac{\eta_1}{m}$ for all $n > n_0$. We can choose a suitable $\epsilon_0 > 0$ such that $\lambda^* = \eta_1 + \epsilon_0$ and

$$\lambda_n m > \lambda^*, \qquad n > n_0.$$

Then

$$\begin{aligned}\int_\Omega |\nabla u_n|^{p-2}\nabla u_n \nabla \omega \mathrm{d}x - \lambda^* \int_\Omega \varphi_p(v_n)\omega \mathrm{d}x \\ = \lambda_n \int_\Omega f(v_n)\omega \mathrm{d}x - \lambda^* \int_\Omega \varphi_p(v_n)\omega \mathrm{d}x \\ \geqslant \lambda_n \int_\Omega m\varphi_p(v_n)\omega \mathrm{d}x - \lambda^* \int_\Omega \varphi_p(v_n)\omega \mathrm{d}x \\ > 0.\end{aligned}$$

Similarly,

$$\begin{aligned}\int_\Omega |\nabla v_n|^{p-2}\nabla v_n \nabla \omega \mathrm{d}x - \lambda^* \int_\Omega \varphi_p(u_n)\omega \mathrm{d}x \\ = \lambda_n \int_\Omega g(u_n)\omega \mathrm{d}x - \lambda^* \int_\Omega \varphi_p(u_n)\omega \mathrm{d}x \\ \geqslant \lambda_n \int_\Omega m\varphi_p(u_n)\omega \mathrm{d}x - \lambda^* \int_\Omega \varphi_p(u_n)\omega \mathrm{d}x \\ > 0.\end{aligned}$$

That is, (u_n, v_n) is a weak supersolution of the problem

$$\begin{cases} -\Delta_p u = (\eta_1 + \epsilon_0)\varphi_p(v), & x \in \Omega, \\ -\Delta_p v = (\eta_1 + \epsilon_0)\varphi_p(u), & x \in \Omega, \\ u = 0 = v, & x \in \partial\Omega. \end{cases} \tag{4.1}$$

On the other hand $t(\chi_1, \chi_1)$, $t > 0$, is a subsolution of (4.1). Letting $t > 0$ be such that $t(\chi_1, \chi_1) \leqslant (u_n, v_n)$, then by the method of sub- and super-solutions, for every $n > n_0$, (4.1) has a positive solution (x_n, y_n). (The proof of the existence of (x_n, y_n) have been showed, see [16, 20] for details. We omit it here.) On the other hand, since $\epsilon_0 > 0$ is arbitrary, this contradicts with the fact that η_1 is isolated. □

Now, consider an asymptotically positively homogeneous system of the form

$$\begin{cases} -\Delta_p u = \lambda\theta_1\varphi_p(v^+) + \lambda\widetilde{f}(v), & x \in \Omega, \\ -\Delta_p v = \lambda\theta_2\varphi_p(u^+) + \lambda\widetilde{g}(u), & x \in \Omega, \\ u = 0 = v, & x \in \partial\Omega, \end{cases} \tag{4.2}$$

where $x^+ \overset{\text{def}}{=} \max\{0, x\}$ is the positive part of x, and θ_1, θ_2 are defined above. The nonlinear perturbations $\widetilde{f}, \widetilde{g} : \mathbb{R} \to \mathbb{R}$ satisfy the following assumptions:

(A1) $\widetilde{f}$ and $\widetilde{g}$ are continuous, non-negative, and bounded functions;

(A2) $\theta_1\varphi_p(y^+) + \widetilde{f}(y) > 0$, $\theta_2\varphi_p(x^+) + \widetilde{g}(x) > 0$ for all $x, y \in \mathbb{R}$.

Let

$$\mathscr{T} = \{(\lambda, (u, v)) \in \mathbb{R} \times E \mid (\lambda, (u, v)) \text{ solution of } (4.2)\},$$

then we prove the following bifurcation result.

Proposition 4.1. *If μ_∞ is a bifurcation point from infinity for (4.2), then $\mu_\infty = \mu_1$. Moreover, for any sequence $(\lambda_j, (u_j, v_j)) \in \mathbb{R} \times E$ with $\lambda_j \to \mu_1$ and $\|(u_j, v_j)\| \to +\infty$ as $j \to +\infty$, there exists a subsequence $(\lambda_{j_k}, (u_{j_k}, v_{j_k}))$ such that*

$$\lim_{j_k \to +\infty} \frac{(u_{j_k}, v_{j_k})}{\|(u_{j_k}, v_{j_k})\|} = \frac{(\phi_1, \psi_1)}{\|(\phi_1, \psi_1)\|},$$

where the convergence is in E.

Proof. The operator equation corresponding to the system (4.2) is

$$\begin{pmatrix} u \\ v \end{pmatrix} = \lambda(-\Delta_p^{-1}) \begin{pmatrix} \theta_1 \varphi_p(v^+) + \widetilde{f}(v) \\ \theta_2 \varphi_p(u^+) + \widetilde{g}(u) \end{pmatrix}. \tag{4.3}$$

Let $(\lambda_j, (u_j, v_j)) \in \mathbb{R} \times E$ be a solution of (4.2) such that $\|(u_j, v_j)\| \to +\infty$ and $\lambda_j \to \mu_\infty$. Then $(\hat{u}_j, \hat{v}_j) = \frac{(u_j, v_j)}{\|(u_j, v_j)\|}$ satisfies

$$\hat{u}_j = \lambda_j(-\Delta_p^{-1}) \left(\theta_1 \varphi_p(\hat{v}_j^+) + \frac{\widetilde{f}(v_j)}{\|(u_j, v_j)\|} \right), \tag{4.4}$$

$$\hat{v}_j = \lambda_j(-\Delta_p^{-1}) \left(\theta_2 \varphi_p(\hat{u}_j^+) + \frac{\widetilde{g}(u_j)}{\|(u_j, v_j)\|} \right). \tag{4.5}$$

It then follows from (A1) that the right hand side of (4.4) and (4.5) are bounded in X (independent of j). Hence $\|\hat{u}_j\|_{C^1}$ and $\|\hat{v}_j\|_{C^1}$ are bounded (independent of j), and there exists subsequence of $\hat{u}_j$ and $\hat{v}_j$ converging to $\hat{u}$ and $\hat{v}$ and satisfying

$$\begin{cases} -\Delta_p \hat{u} = \mu_\infty \theta_1 \varphi_p(\hat{v}^+), & x \in \Omega, \\ -\Delta_p \hat{v} = \mu_\infty \theta_2 \varphi_p(\hat{u}^+), & x \in \Omega, \\ \hat{u} = 0 = \hat{v}, & x \in \partial\Omega. \end{cases} \tag{4.6}$$

Suppose $\mu_\infty \leqslant 0$. Since $\hat{u}^+, \hat{v}^+ \geqslant 0$, it follows by applying the maximum principle to (4.6) that $\hat{u} \equiv 0$ and repeating the same argument we get $\hat{v} \equiv 0$ as well. This leads to a contradiction since $\|(\hat{u}, \hat{v})\| = 1$.

For $\mu_\infty > 0$, we distinguish two cases: the first case is $\hat{v}^+ \equiv 0$ and $\hat{u}^+ \equiv 0$, and the second is one of $\hat{v}^+ \not\equiv 0$ or $\hat{u}^+ \not\equiv 0$ holding. In the first case, we get $\hat{u} \equiv 0$, a contradiction as before. In the other case, we get $\hat{u} > 0$ from maximum principle and $\hat{v} > 0$ by repeating the same argument. Thus μ_∞ and $\hat{u}, \hat{v} > 0$ satisfies the eigenvalue problem (3.1).

However, we already discussed that (3.1) has precisely one eigenvalue μ_1 with componentwise positive eigenfunction (ϕ_1, ψ_1). Therefore, it must be that $\mu_\infty = \mu_1$ and

$$(\hat{u}, \hat{v}) = \frac{(\phi_1, \psi_1)}{\|(\phi_1, \psi_1)\|}.$$

This concludes the proof of Proposition 4.1. □

Lemma 4.2. *Let (A1)–(A2) hold and Λ be a compact interval with $\mu_1 \notin \Lambda$. Then there is a $M_\Lambda > 0$ such that all solutions $(\lambda, (u, v))$ of (4.2) with $\lambda \in \Lambda$ must satisfy $\|(u, v)\| < M_\Lambda$.*

Proof. Assume to the contrary that there exist sequences $\lambda_j \in \Lambda$ and $(u_j, v_j) \in E$ satisfying (4.2) with $\|(u_j, v_j)\| \to \infty$ as $j \to \infty$. Then there is a subsequence $(\lambda_{j_k}, (u_{j_k}, v_{j_k}))$ of $(\lambda_j, (u_j, v_j))$ satisfying $\lambda_{j_k} \to \tilde{\lambda}$ and $\|(u_{j_k}, v_{j_k})\| \to \infty$. Dividing (4.2) by $\|(u_{j_k}, v_{j_k})\|$, then the same argument as in the proof of Proposition 4.1, we obtain that $\tilde{\lambda} = \mu_1 \in \Lambda$, which contradicts $\mu_1 \notin \Lambda$. □

Lemma 4.3. *Let (A1)–(A2) hold, then for $\tau \in [0, 1]$, the system*

$$\begin{cases} -\Delta_p u = \lambda\theta_1\varphi_p(v^+) + \lambda\widetilde{f}(v) + \tau\|(u,v)\|^p, & x \in \Omega, \\ -\Delta_p v = \lambda\theta_2\varphi_p(u^+) + \lambda\widetilde{g}(u) + \tau\|(u,v)\|^p, & x \in \Omega, \\ u = 0 = v, & x \in \partial\Omega \end{cases} \tag{4.7}$$

has no solution for $\lambda > \nu := \mu_1 / \min\{\theta_1, \theta_2\}$.

Proof. Suppose that there is a sequence of $\{\lambda_n\}$ such that $\lambda_n \to \infty$ as $n \to \infty$, and (4.7) has a positive solution (u_n, v_n) when $\lambda = \lambda_n$. Then there is a $\lambda_{n_0} > 0$ such that $\lambda_n > \frac{\mu_1}{\min\{\theta_1, \theta_2\}}$ for all $n > n_0$. We can choose a suitable $\epsilon_0 > 0$ such that $\mu^* = \mu_1 + \epsilon_0$ and

$$\lambda_n \min\{\theta_1, \theta_2\} > \mu^*, n > n_0.$$

Since (u_n, v_n) is the positive solution of (4.7), then $u_n^+ = u_n,\ v_n^+ = v_n$, and

$$\begin{aligned} &\int_\Omega |\nabla u_n|^{p-2}\nabla u_n \nabla\omega \mathrm{d}x - \mu^* \int_\Omega \theta_1\varphi_p(v_n)\omega \mathrm{d}x \\ &\quad = \lambda_n \int_\Omega \theta_1\varphi_p(v_n^+)\omega \mathrm{d}x + \lambda_n \int_\Omega \widetilde{f}(v_n)\omega \mathrm{d}x + \int_\Omega \tau\|(u_n, v_n)\|^p\omega \mathrm{d}x - \mu^* \int_\Omega \varphi_p(v_n)\omega \mathrm{d}x \\ &\quad = \lambda_n \int_\Omega \theta_1\varphi_p(v_n)\omega \mathrm{d}x - \mu^* \int_\Omega \varphi_p(v_n)\omega \mathrm{d}x + \lambda_n \int_\Omega \widetilde{f}(v_n)\omega \mathrm{d}x + \int_\Omega \tau\|(u_n, v_n)\|^p\omega \mathrm{d}x \\ &\quad > \lambda_n \int_\Omega \widetilde{f}(v_n)\omega \mathrm{d}x + \int_\Omega \tau\|(u_n, v_n)\|^p\omega \mathrm{d}x \\ &\quad > 0. \end{aligned}$$

Similarly,

$$\begin{aligned} &\int_\Omega |\nabla v_n|^{p-2}\nabla v_n \nabla\omega \mathrm{d}x - \mu^* \int_\Omega \theta_2\varphi_p(u_n)\omega \mathrm{d}x \\ &\quad = \lambda_n \int_\Omega \theta_2\varphi_p(u_n^+)\omega \mathrm{d}x + \lambda_n \int_\Omega \widetilde{g}(u_n)\omega \mathrm{d}x + \int_\Omega \tau\|(u_n, v_n)\|^p\omega \mathrm{d}x - \mu^* \int_\Omega \theta_2\varphi_p(u_n)\omega \mathrm{d}x \\ &\quad = \lambda_n \int_\Omega \theta_2\varphi_p(u_n)\omega \mathrm{d}x - \mu^* \int_\Omega \theta_2\varphi_p(u_n)\omega \mathrm{d}x + \lambda_n \int_\Omega \widetilde{g}(u_n)\omega \mathrm{d}x + \int_\Omega \tau\|(u_n, v_n)\|^p\omega \mathrm{d}x \\ &\quad > \lambda_n \int_\Omega \widetilde{g}(v_n)\omega \mathrm{d}x + \int_\Omega \tau\|(u_n, v_n)\|^p\omega \mathrm{d}x \\ &\quad > 0. \end{aligned}$$

That is, (u_n, v_n) is a weak supersolution of the problem

$$\begin{cases} -\Delta_p u = (\mu_1 + \epsilon_0)\theta_1\varphi_p(v), & x \in \Omega, \\ -\Delta_p v = (\mu_1 + \epsilon_0)\theta_2\varphi_p(u), & x \in \Omega, \\ u = 0 = v, & x \in \partial\Omega. \end{cases} \tag{4.8}$$

On the other hand $t(\phi_1, \psi_1)$, $t > 0$, is a subsolution of (4.8). Letting $t > 0$ be such that $t(\phi_1, \psi_1) \leqslant (u_n, v_n)$, then the same argument with the proof of Theorem 1.1 we obtain a contradiction with that μ_1 is isolated. □

Define the operator $L : X \to X$ by

$$Q_1 \begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} \theta_1 \varphi_p(v^+) \\ \theta_2 \varphi_p(u^+) \end{pmatrix}$$

and

$$T_\lambda(u,v) := (-\Delta_p^{-1}) \circ \lambda Q_1(u,v).$$

It is well known that T_λ is completely continuous in X. By Lemma 3.2, μ_1 is a isolated eigenvalue of (3.1), therefore, there is no nontrivial solution of (3.1) in $\lambda \in (\mu_1 - \delta, \mu_1) \cup (\mu_1, \mu_1 + \delta)$ for some $\delta > 0$, that is, T_λ has no fixed point in $\partial B_r(0)$ for arbitrary r-ball $B_r(0)$ when $\lambda \in (\mu_1 - \delta, \mu_1) \cup (\mu_1, \mu_1 + \delta)$. Subsequently, the Leray–Schauder degree $\deg(I - T_\lambda, B_r(0), (0,0))$ is well defined arbitrary r-ball $B_r(0)$ with $\lambda \in (\mu_1 - \delta) \cup (\mu_1, \mu_1 + \delta)$.

Define the operator $Q : X \to X$ by

$$Q \begin{pmatrix} u \\ v \end{pmatrix} = Q_1 \begin{pmatrix} u \\ v \end{pmatrix} + Q_2 \begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} \theta_1 \varphi_p(v^+) \\ \theta_2 \varphi_p(u^+) \end{pmatrix} + \begin{pmatrix} \widetilde{f}(v) \\ \widetilde{g}(u) \end{pmatrix}.$$

Then it is clear that Q is continuous operator and problem (4.2) can be equivalently written as

$$(u,v) = (-\Delta_p^{-1}) \circ \lambda Q(u,v) := \mathcal{F}_\lambda(u,v).$$

Since $-\Delta_p^{-1} : X \to X$ is compact, then $\mathcal{F}_\lambda : X \to X$ is completely continuous. Let

$$\Upsilon_\lambda^p(u,v) = (u,v) - (-\Delta_p^{-1}) \circ \mathcal{F}_\lambda(\tau, u, v) = (u,v) - (-\Delta_p^{-1}) \circ \lambda(Q_1(u,v) + Q_2(u,v)).$$

By (A1), $\widetilde{f}, \widetilde{g}$ are bounded, then we have $Q_2(u,v) \to (0,0)$ for (u,v) large enough, that is, $\Upsilon_\lambda^p(u,v)$ close to $T_\lambda(u,v)$ when $(u,v) \to (+\infty, +\infty)$, and subsequently, $\Upsilon_\lambda^p(u,v)$ has no nontrivial solution when $\lambda \in (\mu_1 - \delta) \cup (\mu_1, \mu_1 + \delta)$. Let $(y,z) = (u,v)/\|(u,v)\|^p$, then $(u,v) \to (+\infty, +\infty)$ is equivalent to $(y,z) \to (0,0)$.

$$\begin{aligned} \Psi_\lambda^p(y,z) = \frac{\Upsilon_\lambda^p(u,v)}{\|(u,v)\|^p} &= (y,z) - \|(y,z)\|^p \mathcal{F}_\lambda\left(\frac{(y,z)}{\|(y,z)\|^p}\right) \\ &= (y,z) - \|(y,z)\|^p (-\Delta_p^{-1}) \circ \lambda \left[Q_1\left(\frac{(y,z)}{\|(y,z)\|^p}\right) + Q_2\left(\frac{(y,z)}{\|(y,z)\|^p}\right)\right]. \end{aligned} \tag{4.9}$$

Obviously, $\Psi_\lambda^p(y,z) = (0,0)$ has no nontrivial solution when (y,z) small enough, a similar argument with T_λ we have Leray–Schauder degree $\deg(\Psi_\lambda^p, B_r(0), (0,0))$ is well defined with r small enough for $\lambda \in (\mu_1 - \delta, \mu_1) \cup (\mu_1, \mu_1 + \delta)$.

Next we will show μ_1 is a bifurcation point, defined in Section 1, from infinity of (4.2). By Rabinowitz [28], it is equivalent to show that

$$\deg(\Psi_{r_1}^p, B_r(0), (0,0)) \neq \deg(\Psi_{r_2}^p, B_r(0), (0,0)),$$

where $r_1 \in [\mu_1 - \delta, \mu_1), r_2 \in (\mu_1, \mu_1 + \delta]$.

Lemma 4.4. *μ_1 is a bifurcation point from infinity of problem* (4.2).

Proof. By (4.9), one has that μ_1 is a bifurcation from infinity for (4.2) if and only if it is a bifurcation from the trivial solution for $\Psi^p_\lambda(u,v)=0$. Next we show

$$\deg(\Psi^p_\lambda, B_r(0),(0,0))=1, \qquad \lambda\in[\mu_1-\delta,\mu_1)$$

and

$$\deg(\Psi^p_\lambda, B_r(0),(0,0))=0, \qquad \lambda\in(\mu_1,\mu_1+\delta].$$

Suppose $(\mu_1,(0,0))$ is not a bifurcation point of (4.2), then there are $\delta,\rho_0>0$ such that for $|\lambda-\mu_1|\leqslant\delta$ and $0<\rho<\rho_0$, that is, equation

$$(y,z)-\mathscr{F}(\lambda,y,z)\neq 0$$

for $\|(y,z)\|_X=\rho$, where

$$\mathscr{F}(\lambda,y,z):=\|(y,z)\|^p\mathcal{F}_\lambda\left(\frac{(y,z)}{\|(y,z)\|^p}\right).$$

Consider the homotopy problem

$$(y,z)-\tau\mathscr{F}(\lambda,y,z)\neq 0,$$

where $\tau\in[0,1]$, then by the invariance of the degree of the compact, the same argument with [5, Corollary 3.2], we have

$$\deg(I-\mathscr{F}(\lambda,y,z),B_\rho(0),(0,0))=\deg(I,B_\rho(0),(0,0))=1 \tag{4.10}$$

for $\lambda\in[\mu_1-\delta,\mu_1)$.

Next we show, for $\lambda\in(\mu_1,\mu_1+\delta]$,

$$\deg(\Psi^p_\lambda(y,z),B_\rho(0),(0,0))=0.$$

Let $\check{\lambda}=\max\{\mu_1+\delta,\nu\}$. Define

$$\Phi(\lambda,(y,z))=\Psi^p_\lambda(y,z)$$

and consider the following one parameter family of operators

$$\Phi((1-\sigma)(\mu_1+\delta)+\sigma\check{\lambda},(y,z)), \qquad \sigma\in[0,1].$$

Obviously,

$$(1-\sigma)(\mu_1+\delta)+\sigma\check{\lambda}\in[\mu_1+\delta,\check{\lambda}].$$

By Lemma 4.2, the solutions of (4.2) satisfy

$$\|(u,v)\|<M(\varepsilon).$$

Since $(y,z)=(u,v)/\|(u,v)\|^p$, then all solutions of (4.2) satisfy

$$\|(y,z)\|=\frac{1}{\|(u,v)\|^{p-1}}>\frac{1}{[M(\varepsilon)]^{p-1}}.$$

Hence the problem (4.2) with $\lambda = (1-\sigma)(\mu_1+\delta)+\sigma\check{\lambda}$ does not have any solution on ∂B_ρ with $0<\rho<1/[M(\varepsilon)]^{p-1}$. Then by the homotopy invariance of degree with respect to $\sigma \in [0,1]$, we have

$$\deg(\Phi(\mu_1+\delta,(y,z)),B_\rho,(0,0)) = \deg(\Phi(\check{\lambda},(y,z)),B_\rho,(0,0)). \tag{4.11}$$

Obviously, we wish to show that

$$\deg(\Phi(\check{\lambda},(y,z)),B_\rho,(0,0)) = 0.$$

This would be trivial if $\Phi(\check{\lambda},(y,z)) = (0,0)$ has no solution on B_ρ. Therefore, we construct an admissible homotopy connecting $\Phi(\check{\lambda},(y,z))$ to an operator which does not have any solution on B_ρ for $0<\rho<1/[M(\varepsilon)]^{p-1}$. To this end, for $\tau \in [0,1]$, consider the operator

$$\Phi(\check{\lambda},(y,z)) - \tau\xi$$

with $(0,0) \neq \xi := (-\Delta_p)^{-1}(\chi_\Omega,\chi_\Omega)$, where χ_Ω stands for the characteristic function of Ω, that is,

$$\chi_\Omega(x) = \begin{cases} 1, & x\in\Omega, \\ 0, & x \notin \Omega. \end{cases}$$

First we show that, for all $\tau \in [0,1]$ and $0<\rho<1/[M(\varepsilon)]^{p-1}$,

$$\Phi(\check{\lambda},(y,z)) - \tau\xi = (0,0) \tag{4.12}$$

does not have any solution on ∂B_ρ. Indeed, assume to the contrary that there exists a solution (y,z) of (4.12) with $\|(y,z)\| = \rho > 0$. Then $(u,v) = (y,z)/\|(y,z)\|^p$ must satisfy (4.7), which is absurd due to Lemma 4.3. Therefore, (4.2) does not have any nontrivial solution for all $\tau \in [0,1]$. Moreover, since $(0,0)$ is not a solution of (4.2), then

$$\deg(\Phi(\check{\lambda},(y,z)) - \tau\xi, B_\rho,(0,0)) = 0 \quad \text{for all } \tau\in[0,1].$$

Then homotopy invariance of degree with respect to $\tau \in [0,1]$ yields

$$\deg(\Phi(\check{\lambda},(y,z)),B_\rho,(0,0)) = \deg(\Phi(\check{\lambda},(y,z)) - \xi, B_\rho,(0,0)) = 0.$$

Since this holds for any $0<\rho<1/[M(\varepsilon)]^{p-1}$, it follows from (4.11) that

$$\deg(\Phi(\mu_1+\delta,(y,z)),B_\rho,(0,0)) = \deg(\Phi(\check{\lambda},(y,z)),B_\rho,(0,0)) = 0.$$

This combine (4.10) we have μ_1 is a bifurcation point of (4.2) from infinity. □

Lemma 4.5. *Let (A1)–(A2) hold. Then μ_1 is the unique bifurcation point from infinity for* (4.2)*. Moreover, there exists a continuum $\mathscr{D} \subset \mathscr{T}$ bifurcating from infinity at μ_1 and satisfies the following:*

(i) *if $(\lambda,(u,v)) \in \mathscr{D}$ and $\lambda > 0$ then $u>0$ and $v>0$;*

(ii) *for $\lambda = 0$, $(u,v) = (0,0)$ is the only solution of* (4.2) *and (0,(0,0))$\in \mathscr{D}$;*

(iii) $\mathrm{Proj}_\lambda \mathscr{C} \overset{def}{=} \{\lambda \in \mathbb{R} \mid \exists\, (u,v) \in E \text{ with } (\lambda,(u,v)) \in \mathscr{D}\}$ *is bounded from above and unbounded from below.*

Proof. By Lemma 4.4 and Proposition 4.1, μ_1 is the unique bifurcation point from infinity for (4.2). It is easy to see that operator $\mathcal{F}_\lambda : X \to X$ satisfies the hypotheses of Proposition 2.3. Then there exist unbounded continua

$$\mathscr{D}_\pm \subset \widehat{\mathscr{S}} \stackrel{\text{def}}{=} \{(\lambda,(u,v)) \in \mathbb{R} \times E \mid (\lambda,(u,v)) \text{ solution of } (4.2)\}$$

containing $(0,(0,0))$. By the nonexistence result of Theorem 1.1

$$\mathscr{D}_+ \subset ([0,\lambda^*) \times E),$$

and thus $\mathscr{D}_+$ must be unbounded in the Banach space E-direction. Then $\mathscr{D} \stackrel{\text{def}}{=} \mathscr{D}_+ + \mathscr{D}_-$ is a continuum containing (0,(0,0)). By Proposition 4.1, μ_1 is the only bifurcation point from infinity for (4.2) and $\mathscr{D}_+$ is unbounded in the E-direction, hence $\mathscr{D}_+$ must bifurcate from infinity at μ_1. To conclude the proof of Lemma 4.5, it remains to verify that $\mathscr{D}$ satisfies the properties (i)–(iii).

It follows from assumption (A2) and maximum principle that $u,v > 0$ whenever $(\lambda,(u,v)) \in \mathscr{D}$ and $\lambda > 0$, this implies part (i). For $\lambda = 0, (u,v) = (0,0)$ is the only solution of (4.2) and $(0,(0,0)) \in \mathscr{D}$, hence part (ii) holds. Applying Proposition 2.3, we see that $\mathscr{D}_-$ must be unbounded in $\mathbb{R} \times E$. However, by part (ii) and the fact that ν_1 is the unique bifurcation point from infinity for (4.3), we see that $\mathscr{D}_-$ must be unbounded in the negative λ-direction, hence $(-\infty,\nu_1) \subset \mathrm{Proj}_\lambda \mathscr{D}$. This completes the proof of Lemma 4.5. □

5 Proof of Theorem 1.2

Step 1. Approximation problems

Fix $n \in \mathbb{N}$ and define $f_n(s), g_n(s) : \mathbb{R} \to (0,\infty)$ by

$$f_n(s) \stackrel{\text{def}}{=} \begin{cases} f(s); & s \leqslant n, \\ \frac{f(n)}{\varphi_p(n)}\varphi_p(s); & s > n, \end{cases}$$

$$g_n(s) \stackrel{\text{def}}{=} \begin{cases} g(s); & s \leqslant n, \\ \frac{g(n)}{\varphi_p(n)}\varphi_p(s); & s > n, \end{cases}$$

Then f_n and g_n are continuous functions. Note that, $f_n(s) = f(s)$ for $s \leqslant n$, $\lim_{s\to n^-} f_n(s) = f(n)$, hence f_n is continuous. On the other hand, by assumption (H2),

$$\lim_{s\to\infty} \frac{f_n(s)}{\varphi_p(s)} = \lim_{s\to\infty} \frac{\frac{f(n)}{\varphi_p(n)}\varphi_p(s)}{\varphi_p(s)} = \frac{f(n)}{\varphi_p(n)} \to \infty$$

as $n \to \infty$, then f_n approaches f. Similarly, g_n approaches g as $n \to \infty$.

For each n, we consider the following problem

$$\begin{cases} -\Delta_p u = \lambda f_n(v), & x \in \Omega, \\ -\Delta_p v = \lambda g_n(u), & x \in \Omega, \\ u = 0 = v, & x \in \partial\Omega, \end{cases} \tag{5.1}$$

by above argument, which approaches (1.1) as $n \to +\infty$. We will use Lemma 4.5 to treat (5.1) and thus we rewrite (5.1) in the form of system (4.2) as

$$\begin{cases} -\Delta_p u = \frac{f(n)}{\varphi_p(n)}\varphi_p(v^+) + \lambda \widetilde{f}_n(v), & x \in \Omega, \\ -\Delta_p v = \frac{g(n)}{\varphi_p(n)}\varphi_p(u^+) + \lambda \widetilde{g}_n(u), & x \in \Omega, \\ u = 0 = v, & x \in \partial\Omega, \end{cases} \tag{5.2}$$

where

$$\widetilde{f}_n(y) \stackrel{\text{def}}{=} f_n(y) - \frac{f(n)}{\varphi_p(n)}\varphi_p(y^+),$$
$$\widetilde{g}_n(y) \stackrel{\text{def}}{=} g_n(y) - \frac{g(n)}{\varphi_p(n)}\varphi_p(y^+).$$

We note that $\widetilde{f}_n(y)$ and $\widetilde{g}_n(y)$ are bounded in $\mathbb{R}$. Indeed, since $f_n(y)$ is nondecreasing and $f_n(x) = f(x) > 0$ for $s \leqslant n$, we get

$$|\widetilde{f}_n(x)| \leqslant \sup_{x\in\mathbb{R}} \left| f_n(x) - \frac{f(n)}{\varphi_p(n)}\varphi_p(x^+) \right| \leqslant \max_{x\in[0,n]} \left| f_n(x) - \frac{f(n)}{\varphi_p(n)}\varphi_p(x^+) \right| + f(0) = +\infty,$$

where the constant only depends on n. And a same argument we can get $\widetilde{g}_n$ is bounded.

Since $f_n, g_n > 0$, it is easy to see that (5.2) satisfies the hypotheses of Lemma 4.5 by taking $\theta_1 = \frac{f(n)}{\varphi_p(n)}$, $\theta_2 = \frac{g(n)}{\varphi_p(n)}$ Moreover, by Lemma 4.5, there is a $\mu_{1,n}$, such that $\nu_{1,n}$ is the unique bifurcation point from infinity for (5.2) and there exists a continuum $\mathscr{C}_n$ of positive solutions of (5.2), which bifurcates from infinity at $\mu_{1,n}$ and satisfies the properties (i)–(iii) of Lemma 4.5. In particular, $(0,(0,0)) \in \mathscr{C}_n$, $\mathscr{C}_n$ is bounded above by the hyperplane $\lambda = \bar{\lambda}$.

Step 2. Passing to the limit

Now we verify $\{\mathscr{C}_n\}$ satisfying the conditions of Lemma 2.5. By the definition of continuum, $\mathscr{C}_n$ is closed.

Since all of $\mathscr{C}_n$ contain $(0,(0,0))$, we can choose $z_n \in \mathscr{C}_n$ such that $z_n = (0,(0,0))$ for each $n = 1, 2, \dots$. Naturally, $z_n \to z^* = (0,(0,0))$, the condition (i) of Lemma 2.5 is satisfied.

Obviously, because of the unboundedness of $\{\mathscr{C}_n\}$, then

$$d_n = \sup\{|\mu| + \|(u,v)\| \mid (\mu,(u,v)) \in \mathscr{C}_n\} = +\infty,$$

(ii) of Lemma 2.5 holds.

(iii) in Lemma 2.5 can be deduced directly from the Arzelà–Ascoli theorem and the definition of f_n, g_n.

Therefore, the superior limit of $\{\mathscr{C}_n\}$ contains a component $\mathscr{C} \subset \Pi$ joining $(0,(0,0))$ with infinity, and it follows from $u, v > 0$ for $\lambda > 0$ whenever $(\lambda,(u,v)) \in \mathscr{C}$, which establishes (a). Part (b) follows from $(0,(0,0)) \in \mathscr{C}$ and $f(0), g(0) > 0$. (c) in Theorem 1.2 can be deduced directly from the Theorem 1.1.

6 Proof of Theorem 1.3

Now we only show if the conditions of Theorem 1.3 are satisfied, then the unique point from infinity must be $\lambda = 0$.

In order to do this, we use a *rescaling* technology below, which is used by Ambrosetti et al. [3] to prove the scalar case as $p = 2$ and by Drábek et al. [6] to deal with the semipositone p-Laplacian system.

Let

$$F(s) := f(s) - C|s|^{q_1}, \qquad G(s) := g(s) - D|s|^{q_2},$$

where C, D was defined in (1.6). Let

$$\lambda = \gamma^{\sigma}, \qquad w_1 = \gamma^{\kappa_1} u, \qquad w_2 = \gamma^{\kappa_2} v,$$

where $\sigma, \kappa_1, \kappa_2$ are parameters and provided by [6, Proof of Theorem 4.3]. Then (1.1) can be translated to the form

$$\begin{cases} -\Delta_p w_1 = \tilde{F}(\gamma, w_2), & x \in \Omega, \\ -\Delta_p w_2 = \tilde{G}(\gamma, w_1), & x \in \Omega, \\ w_1 = 0 = w_2, & x \in \partial\Omega \end{cases} \tag{6.1}$$

with

$$\tilde{F}(\gamma, s_2) := \gamma^{\kappa_2 q_1} F(s_2/\gamma^{\kappa_2}) + C|s_2|^{q_1},$$
$$\tilde{G}(\gamma, s_1) := \gamma^{q_2} G(s_1/\gamma) + D|s_1|^{q_2}.$$

Then, by a directly result of [4, Theorem 1.1], there is a $M > 0$ such that for all positive solutions $(w_1, w_2) \in C_0^1(\bar{\Omega}) \times C_0^1(\bar{\Omega})$ of (6.1) we have

$$\|w_1\|_{C^1} + \|w_2\|_{C^1} \leqslant M. \tag{6.2}$$

Now let $\lambda_n \in \mathbb{R}$ be a decreasing sequence with $\lambda_1 < \bar{\lambda}$ such that $\lambda_n \to 0^+$ as $n \to \infty$. Then for each n, we can get γ_n and the sequence $w_{1,n}, w_{2,n}$ of the solution for (6.1), such that

$$\|w_{1,n}\|_{C^1} + \|w_{2,n}\|_{C^1} \leqslant M_n. \tag{6.3}$$

Now let $n \to \infty$, then $\lambda_n \to 0^+$ and $\gamma_n = \lambda_n^{\sigma} \to 0^+$, then $(u_n, v_n) = (w_{1,n}/\gamma_n^{\kappa_1}, w_{2,n}/\gamma_n^{\kappa_2})$ gives the solution of (1.1) and $\|(u_n, v_n)\| \to \infty$ as $n \to \infty$.

Finally, we prove $\mathscr{C}$ must bifurcate from infinity at $\lambda \to 0^+$. Now let $(\lambda_n, (u_n, v_n)) \in \mathscr{C}$ with $\|(\mu_n, (u_n, v_n))\| \to +\infty$ as $n \to +\infty$ and $\lambda_n > 0$ for all $n \in \mathbb{N}$. Suppose to the contrary that $\lambda_n \to \lambda' > 0$ as $n \to +\infty$, then there exists a closed and bounded interval I such that $\lambda' \in I$. By above proof,

$$\|(u_n, v_n)\| \leqslant M < +\infty$$

for all λ', a contradiction to $\|(u_n, v_n)\| \to +\infty$ as $n \to +\infty$, which completes the proof of Theorem 1.3.

Abstract. This paper studies the global phase portraits of uniform isochronous quintic centers at the origin with time reversibility such that their nonlinear part is not homogeneous. By using Poincaré compactification, we obtain all possible phase portraits of this quintic polynomial differential system.

Keywords: quintic polynomial system, uniform isochronous centers, global phase portraits, time reversibility.

2020 Mathematics Subject Classification: 35C15, 35Q51.

1 Introduction

In the qualitative theory of planar differential systems, one of the classical problems is to study the global phase portraits of polynomial differential systems. The global phase portraits of polynomial differential systems have been extensively investigated, see for example [7, 9, 11, 20–27].

The isochronous center's interest started the works of Huygens [15]. The isochronicity phenomena occurred in many physical problems [10]. In the past few decades the study of isochronicity, specially in the case of polynomial differential systems, has been driven by the diffusion of more powerful methods of computerized analysis [1, 8, 13, 16, 28].

We assume that p is a center, then p is a *uniform isochronous center* if the system, in polar coordinates $x = r\cos\theta, y = r\sin\theta$, is of the form $\dot{r} = G(\theta, r), \dot{\theta} = k, k \in \mathbb{R}\backslash\{0\}$. That is, the angular velocity of the orbits of an uniform isochronous center does not depend on the radius [13].

Proposition 1.1. *Assume that a planar differential polynomial system $\dot{x} = P(x,y), \dot{y} = Q(x,y)$ of degree n has a center at the origin of coordinates. Then, this center is uniform isochronous if and only if by doing a linear change of variables and a rescaling of time it can be written into the form*

$$\dot{x} = -y + xf(x,y), \qquad \dot{y} = x + yf(x,y). \tag{1.1}$$

Where $f(x,y)$ is a polynomial in x and y of degree $n-1$, and $f(0,0) = 0$.

See for instance [18] for a proof of Proposition 1.1.

Recently, the global phase portraits of differential systems with uniform isochronous centers has attracted scholars' attention, for example [2, 8, 12, 17–19]. In 1999, Chavarriga et al. study the phase portraits of the quadratic polynomial differential system S_2 at P_{33} of [8]. Collins [12] found that differential systems with uniform isochronous cubic centers may have three global different portraits. In 2016, Itikawa and Llibre [19] study the phase portraits of uniform isochronous quartic centers. The first studies on some of these phase portraits are due to Algaba et al. [3]. The phase portraits of uniform isochronous quartic centers whose nonlinear part is homogeneous and not homogeneous were studied in [19] and [18], respectively. However, there are some mistakes in [18], which are corrected in [5]. Until now there are few results about the global phase portraits of differential system with uniform isochronous of degree 5 [2]. In this paper, we will study the global phase portraits of uniform isochronous quintic centers at the origin with time reversibility such that their nonlinear part is not homogeneous. We say that systems (1.1) reversible with respect to the y-axis if it is invariant under the transformation $(x, y, t) \mapsto (-x, y, -t)$. For this case, the differential system (1.1) of quintic reversible uniform isochronous centers can be written as

$$\begin{cases} \frac{\mathrm{d}x}{\mathrm{d}t} = -y + x(a_1x + a_2xy + a_3x^3 + a_4xy^2 + a_5xy^3 + a_6x^3y), \\ \frac{\mathrm{d}y}{\mathrm{d}t} = x + y(a_1x + a_2xy + a_3x^3 + a_4xy^2 + a_5xy^3 + a_6x^3y), \end{cases} \tag{1.2}$$

where $a_i \in \mathbb{R}$, $i = 1, 2, 3, 4, 5, 6$, with $a_1^2 + a_2^2 + a_3^2 + a_4^2 \neq 0$ and $a_5^2 + a_6^2 \neq 0$.

If $a_3 \neq 0$, by a scaling $(x, y) \to \left(a_3^{-1/3}x, a_3^{-1/3}y\right)$, we can assume $a_3 = 1$, then system (1.2) becomes

$$\begin{cases} \frac{\mathrm{d}x}{\mathrm{d}t} = -y + x(a_1x + a_2xy + x^3 + a_4xy^2 + a_5xy^3 + a_6x^3y), \\ \frac{\mathrm{d}y}{\mathrm{d}t} = x + y(a_1x + a_2xy + x^3 + a_4xy^2 + a_5xy^3 + a_6x^3y). \end{cases} \tag{1.3}$$

And if $a_3 = 0$, then system (1.2) becomes

$$\begin{cases} \frac{\mathrm{d}x}{\mathrm{d}t} = -y + x(a_1x + a_2xy + a_4xy^2 + a_5xy^3 + a_6x^3y), \\ \frac{\mathrm{d}y}{\mathrm{d}t} = x + y(a_1x + a_2xy + a_4xy^2 + a_5xy^3 + a_6x^3y). \end{cases} \tag{1.4}$$

In what follows we state our main results.

Theorem 1.2. *The phase portrait in the Poincaré disk of uniform isochronous quintic centers with time reversibility is topologically equivalent to one of the following 67 possibilities global phase portraits of Figure 1.1.*

The rest of this paper is organized as follows. In Section 2, we characterize the global phase portraits of system (1.2) in the Poincaré disc, that is we prove Theorem 1.2.

2 Proof of the results

In this section, we will prove Theorem 1.2. In order to obtain all possible phase portraits in the Poincaré disc for the uniform isochronous system of degree 5, we shall study the finite and infinite singular points of system (1.2).

By discussing the coefficient a_3 of system (1.2), we divide into the following two cases: if $a_3 \neq 0$, by parameter and time scale transformation, the system (1.2) can be given by system (1.3); if $a_3 = 0$, the system (1.2) can be given by system (1.4). Next, we will study the phase portraits of system (1.3) and system (1.4).

Figure 1.1	System (1.3)
(1)–(5)	$a_6 = 0, \ \ a_5 > 0;$
	$a_5 = 0, \ \ a_6 > 0, \ \ a_4 = 0;$
	$a_5 a_6 > 0, \ \ a_5 > 0.$
(6)	$a_6 = 0, \ \ a_5 < 0;$
	$a_5 = 0, \ \ a_6 < 0, \ \ a_4 = 0, \ \ a_6 < -{a_2}^2/4;$
	$a_5 a_6 > 0, \ \ a_6 < 0.$
(7)–(12)	$a_5 = 0, \ \ -{a_2}^2/4 \le a_6 < 0, \ \ a_4 = 0.$
(13)–(14)	$a_5 = 0, \ \ a_6 > 0, \ \ a_4 > 0.$
(15)–(18)	$a_5 = 0, \ \ a_6 > 0, \ \ a_4 < 0.$
(19)–(21)	$a_5 = 0, \ \ a_6 < 0, \ \ a_4 \neq 0.$
(25)–(30)	$a_4 a_6 - a_5 = 0, \ \ a_5 a_6 < 0, \ \ a_6 < 0, \ \ 4(a_5 - a_6) \ge {a_2}^2.$
(31)–(46)	$a_4 a_6 - a_5 = 0, \ \ a_5 a_6 < 0, \ \ a_6 < 0, \ \ a_2 \neq 0, \ \ 4(a_5 - a_6) < {a_2}^2.$
(47)–(51)	$a_4 a_6 - a_5 = 0, \ \ a_5 a_6 < 0, \ \ a_6 > 0;$
	$a_4 a_6 - a_5 \neq 0, \ \ a_5 a_6 < 0, \ \ a_6 > 0.$
(52)–(66)	$a_4 a_6 - a_5 \neq 0, \ \ a_5 a_6 < 0, \ \ a_6 < 0.$

In polar coordinates defined by $(x, y) = (r\cos\theta, r\sin\theta)$, a planar differential system (1.2) with an uniform isochronous center at the origin always can be written as $\dot{r} = p(r, \theta), \dot{\theta} = 1$. Hence such systems have no finite points except the origin.

By using Poincaré compactification in [14], in the local chart U_1, we obtain

$$\begin{cases} \dot{u} = (1+u^2)v^4, \\ \dot{v} = (uv^4 - a_1 v^3 - a_2 u v^3 - a_3 v - a_4 u^2 v - a_5 u^3 - a_6 u)v, \end{cases} \tag{2.1}$$

Table 1.2: The corresponding relationship between the global phase portraits of system (1.4) and Figure 1.1

Figure 1.1	System (1.4)
(1)–(5)	$a_5 = 0,\ \ a_6 > 0.$

(52)–(66)	$a_5a_6 < 0,\ \ a_6 < 0,\ \ a_4 \neq 0.$
(29), (67)	$a_5a_6 < 0,\ \ a_6 > 0,\ \ a_4 \neq 0;$
	$a_5a_6 < 0,\ \ a_6 > 0,\ \ a_4 = 0.$

and therefore all the points $(u, 0)$ for all $u \in \mathbb{R}$ are infinite singular points of the system (2.1) in U_1. In order to obtain the local phase portraits near the infinity, we make a transformation $\mathrm{d}s = v\mathrm{d}t$ and obtain the following system

$$\begin{cases} u' = (1+u^2)v^3, \\ v' = uv^4 - a_1v^3 - a_2uv^3 - a_3v - a_4u^2v - a_5u^3 - a_6u. \end{cases} \tag{2.2}$$

Where the prime denotes derivative with respect to s and the system (2.2) has infinite singular points in the u-axis.

In the local chart U_2, we obtain

$$\begin{cases} \dot{u} = -(1+u^2)v^4, \\ \dot{v} = (-uv^4 - a_1uv^3 - a_2uv^2 - a_3u^3v - a_4u^2v - a_5u - a_6u^3)v. \end{cases} \tag{2.3}$$

After the rescaling of time $\mathrm{d}s = v\mathrm{d}t$, we obtain

$$\begin{cases} u' = -(1+u^2)v^4, \\ v' = -uv^4 - a_1uv^3 - a_2uv^2 - a_3u^3v - a_4u^2v - a_5u - a_6u^3. \end{cases} \tag{2.4}$$

It is obvious that the system (2.4) has the only singular point $O_{u_2}(0,0)$.

2.1 Global phase portraits of system (1.3)

In this section, we discuss the global phase portraits of system (1.3). According to the number of the singular points in the u-axis, the system can be divided into the following five cases.

Case I: $a_6 = 0$, $a_5 \neq 0$.

In the chart U_1, the system (2.2) has one singular point in the u-axis, that is $O_{U_1}\ (0,0)$, the corresponding linear part of system (2.2) is

$$\begin{pmatrix} 0 & 0 \\ 0 & -1 \end{pmatrix}.$$

By the Theorem 2.19 of [14], we have the statements: if $a_5 > 0$, then O_{U_1} $(0,0)$ is a stable node; if $a_5 < 0$, then O_{U_1} $(0,0)$ is a saddle.

For chart U_2, the system (2.4) has only one singular point O_{U_2} $(0,0)$, the corresponding linear part of system (2.4) is

$$\begin{pmatrix} 0 & 0 \\ -a_5 & 0 \end{pmatrix}.$$

It is easy to find that O_{U_2} $(0,0)$ is a nilpotent singularity. By the Theorem 3.5 of [14], we have the statements: if $a_5 > 0$, then O_{U_2} $(0,0)$ is a nilpotent saddle; if $a_5 < 0$, and the system (2.4) is symmetry about v-axis, then O_{U_2} $(0,0)$ is a center. If the same situation appears again, we will not explain in detail.

By the above analysis, if $a_5 > 0$, the local phase portrait of system (1.3) is shown in Figure 2.1. Since $v' \mid_{v=0} = -a_5 u^3$: when $u > 0$, $v' < 0$; when $u < 0$, $v' > 0$, the direction of the local phase portrait through the disc is shown in the Figure 2.1.

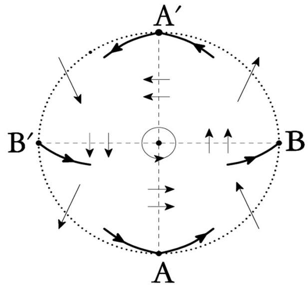

Figure 2.1: Local phase portrait of system (1.3) on the Poincaré disk of Case I for $a_5 > 0$.

In Figure 2.1, there are four singularities on the equator, i.e. A, B, A', B', and the direction between any two points is shown. Firstly, we consider the point A_1. Since the system (1.3) is symmetry about y axis, there are only four possibilities for the ω-limit set of unstable manifold: a singularity on the arc $\overset{\frown}{BA'}$, a point A, a point B, and itself (return to point A_1 after bypassing the periodic orbit around the origin, forming a homoclinic orbit). They are shown in Figure 2.2 (1)–(4).

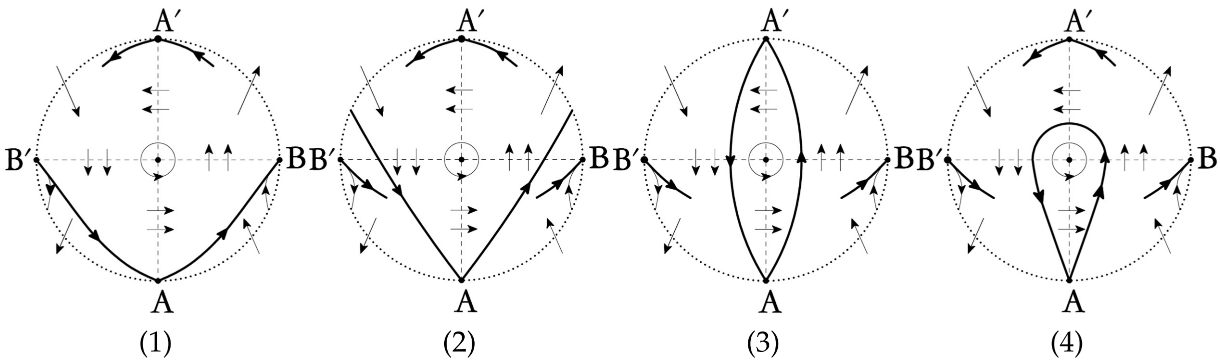

Figure 2.2: Consider the point A in Figure 2.1, four possibilities for the ω limit set of an unstable manifold.

The ω-limit set of the unstable manifold at point A' in Figure 2.2 (1) can only be itself (bypass the origin and returns to A' again, forming a homoclinic orbit). Therefore, there are two possibility global phase portraits on the Poincaré disk, as shown in Figure 1.1 (1) and (2).

The ω-limit set of the unstable manifold at point A' in Figure 2.2 (2) can only be itself (bypass the origin and returns to A' again, forming a homoclinic orbit). Next, we consider a singular point on the arc $\overset{\frown}{AB'}$, and its α-limit set can only be a point B'. Based on the symmetry of the original system, the ω-limit set of a singular point on the arc $\overset{\frown}{AB}$ can only be a point B, and its phase portrait is equivalent to the Figure 1.1 (3).

The α-limit set of a singular point on the arc $\overset{\frown}{AB'}$ in Figure 2.2 (3) can only be the point B'. Based on the symmetry of the original system, the ω-limit set of a singular point on the arc $\overset{\frown}{AB}$ can only be the point B, its phase portrait is equivalent to the Figure 1.1 (4).

The α-limit set of the stable manifold at point A' in Figure 2.2 (4) can only be a singular point on the arc $\overset{\frown}{AB}$. Based on the symmetry of the original system, the ω-limit set of a singular point on the arc $\overset{\frown}{AB'}$ can only be the point B, and its phase portrait is equivalent to the Figure 1.1 (5).

If $a_5 < 0$, the local phase portrait of the system (1.3) on the Poincaré disk is shown in Figure 2.3, which has four singularities on its equator.

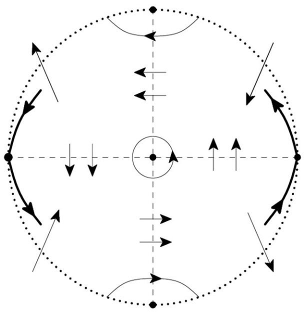

Figure 2.3: The local phase portraits of system (1.3) on the Poincaré disk of Case I for $a_5 < 0$.

By the same argument as Figure 2.1, Figure 2.3 has only one global phase portrait, as shown in the Figure 1.1 (6). This is the only one global phase portrait that can be determined. Therefore, there are 6 possible global phase portraits of system (1.3) in Case I, as shown in Figure 1.1 (1)–(6).

Case II: $a_5 = 0$**,** $a_6 \neq 0$**.**

In chart U_1, O_{U_1} $(0,0)$ is a singular point of system (2.2), and its linear part is

$$\begin{pmatrix} 0 & 0 \\ -a_6 & -1 \end{pmatrix}.$$

Applying the Theorem 2.19 of [14], we have the statements: if $a_6 > 0$, then O_{U_1} $(0,0)$ is a stable node; if $a_6 < 0$, then O_{U_1} $(0,0)$ is an unstable node.

For the chart U_2, the system (2.4) can be written as

$$\begin{cases} u' = -(1+u^2)v^3, \\ v' = -uv^4 - a_1uv^3 - a_2uv^2 - u^3v - a_4uv - a_6u^3. \end{cases} \tag{2.5}$$

The origin O_{U_2} $(0,0)$ of system (2.5) is a singular point and its linear part is identically zero, so the O_{U_2} $(0,0)$ is degenerate.

To investigate the local phase portraits of the degenerate singular points, we use the quasi-homogeneous directional blow up(or (α,β)-blow up) technique [4,6] . Since the choice of the exponents α and β depends on the coefficients a_4 of system (2.5), we need to consider whether a_4 is zero. Thus we apply a (3,2)-blow up and (1,1)-blow up to system (2.5) if $a_4 \neq 0$ and $a_4 = 0$, respectively.

Case II.1: $a_4 = 0$**.** When $a_4 = 0$, applying a $(1,1)$-blow up to system (2.5). Firstly, we apply blow-up $(u,v) \mapsto (\bar{u},\bar{u}\bar{v})$ in the positive u-direction. After division by $\bar{u}^2$, we get,

$$\begin{cases} \bar{u}' = -(1+\bar{u}^2)\bar{u}\bar{v}^3, \\ \bar{v}' = -(-\bar{v}^4 + a_1\bar{u}\bar{v}^3 + a_2\bar{v}^2 + \bar{u}\bar{v} + a_6). \end{cases} \tag{2.6}$$

Since in the line $\bar{u} = 0$, we have

$$\bar{v}^4 - a_2\bar{v}^2 - a_6 = 0.$$

Next, we only need to discuss the existence of the roots of the above equation.

(a) If $\sqrt{{a_2}^2 + 4a_6} > a_2$, i.e. $a_6 > 0$, the equilibrium of (2.6) are $P_1(0, \sqrt{(a_2 + \sqrt{{a_2}^2+4a_6})/2})$ and $P_2(0, -\sqrt{(a_2 + \sqrt{{a_2}^2+4a_6})/2})$. The corresponding linear part of system (3.11) at P_1 is

$$\begin{pmatrix} -\left(\sqrt{\left(a_2 + \sqrt{{a_2}^2+4a_6}\right)/2}\right)^3 & 0 \\ * & 2\sqrt{\left(a_2 + \sqrt{{a_2}^2+4a_6}\right)/2}\sqrt{{a_2}^2+4a_6} \end{pmatrix},$$

where "$*$" stands for the formula about parameters a_2 and a_6. Applying the Theorem 2.15 of [14], we have P_1 is a saddle. By the same argument, P_2 is a saddle.

(b) If $\sqrt{{a_2}^2 + 4a_6} < a_2$, i.e. $-{a_2}^2/4 < a_6 < 0, a_2 > 0$, the singular points of system (2.6) in the line $\bar{u} = 0$ are $P_1(0, \sqrt{(a_2 + \sqrt{{a_2}^2+4a_6})/2})$, $P_2(0, -\sqrt{(a_2 + \sqrt{{a_2}^2+4a_6})/2})$, $P_3(0, \sqrt{(a_2 - \sqrt{{a_2}^2+4a_6})/2})$ and $P_4(0,\ \sqrt{(a_2 - \sqrt{{a_2}^2+4a_6})/2})$. By the Theorem 2.15 of [14], P_1 is a saddle, P_2 is a saddle, P_3 is a stable node, and P_4 is an unstable node.

(c) If ${a_2}^2 + 4a_6 < 0$, i.e. $-{a_2}^2/4 > a_6$, then $\bar{v}^4 - a_2\bar{v}^2 - a_6 = 0$ has no roots, that is, the system (2.6) has no singular point in $\bar{v}$-axis.

(d) If ${a_2}^2 + 4a_6 = 0$, i.e. $-{a_2}^2/4 = a_6$, the singular points of system (2.6) in the line $\bar{u} = 0$ are $P_1\left(0, \sqrt{a_2/2}\right)$, $P_2\left(0, \sqrt{a_2/2}\right)$. By Theorem 3.5 of [14], P_1 is a saddle-node, and P_2 is a saddle-node.

Consider the blow-up $(u,v) \mapsto (-\bar{u},\bar{u}\bar{v})$ in the negative u-direction. After cancelling a common factor $\bar{u}^2$, we obtain

$$\begin{cases} \bar{u}' = (1+\bar{u}^2)\bar{u}\bar{v}^3, \\ \bar{v}' = -\bar{v}^4 + a_1\bar{u}\bar{v}^3 + a_2\bar{v}^2 + \bar{u}\bar{v} + a_6. \end{cases} \tag{2.7}$$

It can be verified that system (2.7) and system (2.6) have the same number and type of singularities.

In addition, we apply blow-up $(u,v) \mapsto (\bar{u}\bar{v}, \bar{v})$ in the positive v-direction as well as $(u,v) \mapsto (\bar{u}\bar{v}, -\bar{v})$ in the negative v-direction. After division by $\bar{v}^2$, we get, respectively,

$$\begin{cases} \bar{u}' = -1 + \bar{u}^2(a_1\bar{v} + a_2 + a_3\bar{u}^2\bar{v} + a_6\bar{u}^2), \\ \bar{v}' = -\bar{u}\bar{v}(\bar{v}^2 + a_1\bar{v} + a_2 + a_3\bar{u}^2\bar{v} + a_6\bar{u}^2), \end{cases} \tag{2.8}$$

and

$$\begin{cases} \bar{u}' = 1 + \bar{u}^2(-a_1\bar{v} + a_2 - a_3\bar{u}^2\bar{v} + a_6\bar{u}^2), \\ \bar{v}' = \bar{u}\bar{v}(\bar{v}^2 - a_1\bar{v} + a_2 - a_3\bar{u}^2\bar{v} + a_6\bar{u}^2). \end{cases} \tag{2.9}$$

It is obvious that the origin of system (2.8) and system (2.9) are not a singular point.

The blow up procedure and local phase portrait of the system (2.5) at the origin are shown in Figure 2.4 in Case (a). The trajectories of the circle is shown in Figure 2.4 (1). Retracting the circle to the origin and obtaining the trajectories in the uov plane near the origin, see Figure 2.4 (2). Considering the transformation d$s = v$dt, the u axis is filled with singular points, and the negative v-axis direction is reversed, as shown in Figure 2.4 (3).

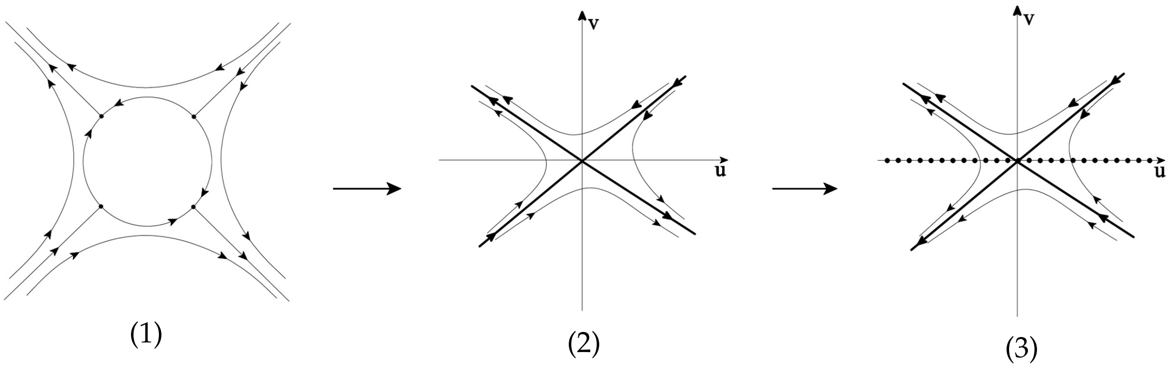

Figure 2.4: The local phase portrait of system (2.3) at the origin. The horizontal axis (3) is filled with singular points.

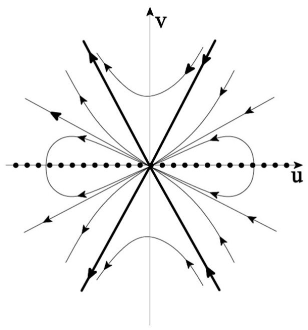
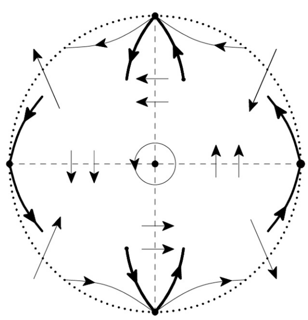
By the same argument as Case (a), we can obtain the local phase portrait of the system (2.5) of Case (b) and Case (d) at the origin and is shown in Figure 2.5(a). Then the local phase portrait of (1.3) of Case (a), Case (b) (d) and Case (c) are shown in Figure 2.1, Figure 2.5(b) and Figure 2.3, respectively.



(a) The local phase portrait of the system (2.5) of Case (b) at the origin.

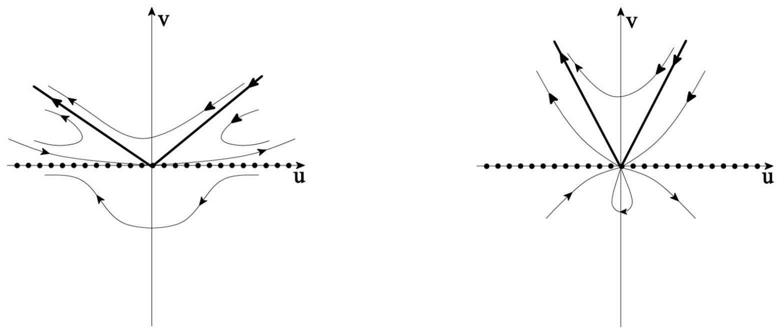


(b) Local phase portrait of system (1.3) on the Poincaré disk of Case (b).

Figure 2.5: Local phase portraits of systems (2.5) and (1.3).

For Case II.1, according to the symmetry and the direction through the Poincaré disk of system (1.3), we can obtain that, for Case (a), Figure 2.1 corresponds to the possible global phase portraits are Figure 1.1 (1)–(5); for Case (b) and Case (d), Figure 2.5(b) corresponds to the possible global phase portraits are Figure 1.1 (7)–(12); for Case (c), Figure 2.3 corresponds to the possible global phase portraits is Figure 1.1 (6). Therefore, there are 12 possible global phase portraits of system (1.2) of Case II.1, see Figure 1.1 (1)–(12).

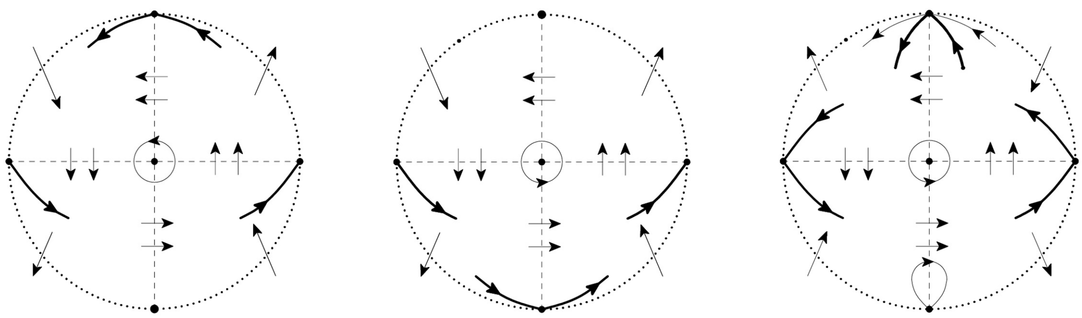
Case II.2: $a_4 \neq 0$. Since $a_4 \neq 0$, applying a $(3,2)$-blow up to system (2.5). By the same argument as Case II.1, we get the local phase portrait of system (2.5) at the origin, see Figure 2.6. Then the local phase portraits of $a_6 > 0, a_4 < 0$ and $a_6 < 0, a_4 < 0$ of the system (2.5) are topologically equivalent to (1) and (2) in Figure 2.6, respectively.



(1) $a_6 > 0, a_4 > 0$ (2) $a_6 < 0, a_4 > 0$

Figure 2.6: The local phase portrait of system (2.5) at the origin of Subcase II.2.

From the above analysis, we characterize the local phase portrait of system (1.3) on the Poincaré disk, see Figure 2.7 (1)–(3), and they are topologically equivalent to the possible global phase portraits Figure 1.1 (13)–(14), (15)–(18), (19)–(21) of Theorem 1.2, respectively. Therefore we can obtain the global phase portraits for Subcase II.2 shown in Figure 1.1 (13)–(21) of Theorem 1.2.



(1) $a_6 > 0$, $a_4 > 0$. (2) $a_6 > 0$, $a_4 < 0$. (3) $a_6 < 0$.

Figure 2.7: Local phase portrait of system (1.3) on the Poincaré disk of Subcase II.2.

Case III: $a_5 a_6 > 0$.

In the chart U_1, we consider the system (2.2). Since $a_5 a_6 > 0$, the system (2.2) has only one singular point $O_{U_1}(0,0)$, and its linear part of system (2.2) is

$$\begin{pmatrix} 0 & 0 \\ -a_6 & -1 \end{pmatrix}.$$

Its type of singular point is the same as the Case II.

In the chart U_2, the origin is the only one singular point of system (2.4). Its linear part is

$$\begin{pmatrix} 0 & 0 \\ -a_5 & 0 \end{pmatrix}.$$

Applying the Theorem 3.5 of [14], we have if $a_5 > 0$, then the origin $O_{U_2}(0,0)$ is a saddle; and if $a_5 < 0$, then $O_{U_2}(0,0)$ is a center.

According to the above analysis, we characterize the local phase portrait of system (1.3) on the Poincaré disk, see Figure 2.1 and Figure 2.3. Consequently the possible global phase portraits can referenced by Case I, that is, they are shown in Figure 1.1(1)–(6) of Theorem 1.2.

Case IV: $a_4a_6 - a_5 = 0$, $a_5a_6 < 0$.

In the chart U_1, we consider the system (2.2). It is easy to find that there are three singular points, $O_{U_1}(0,0)$, $P_1(\sqrt{-a_6/a_5}, 0)$ and $P_2(\sqrt{-a_6/a_5}, 0)$.

For the point $O_{U_1}(0,0)$, we have the same results as the Case II. For the points P_1 and P_2, their linear part is

$$\begin{pmatrix} 0 & 0 \\ 2a_6 & 0 \end{pmatrix}.$$

By the Theorem 3.5 of [14], if $a_6 > 0$, then P_1 and P_2 are saddles. If $a_6 < 0$,

- **(a)** For $a_2 \neq 0$, we have the following statements hold.
  - **(a.1)** If $4(a_5 - a_6) \geq a_2^2$, then P_1 and P_2 are centers;
  - **(a.2)** If $4(a_5 - a_6) < a_2^2$, then the phase portrait of P_1 and P_2 of the system (2.2) consists of one hyperbolic and one elliptic sector.
- **(b)** If $a_1 \neq 0$, $a_2 = 0$, and $9a_1^2a_5 < 16a_6(a_6 - a_5)$, then P_1 and P_2 are centers.
- **(c)** If $a_1 = 0$, $a_2 = 0$, and $4(a_5 - a_6) > 9$, then P_1 and P_2 are centers.

In the chart U_2, the origin $O_{U_2}(0,0)$ is the only one singular point of system (2.4). By the same argument as the Case III, we have if $a_5 > 0$, then the origin $O_{U_2}(0,0)$ is a saddle, and if $a_5 < 0$, then the origin $O_{U_2}(0,0)$ is a center.

Except Case (a.2), the local phase portraits of system (1.3) on the Poincaré disk is shown in Figure 2.8.

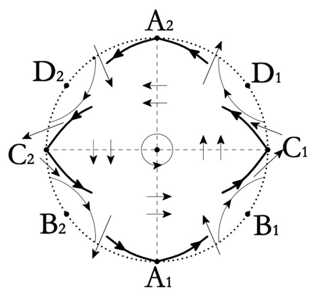


Figure 2.8: The local phase portrait of system (1.3) on the Poincaré disk except Case (a.2).

In Figure 2.8, there are eight singularities on the equator, i.e. $A_1, B_1, C_1, D_1, A_2, B_2, C_2, D_2$, and the direction between any two points is shown. Firstly, we consider the point A_1. Since the system (1.3) is symmetry about y axis, there are only five possibilities for the ω-limit set of unstable manifold: a singularity on the arc $\overset{\frown}{B_1C_1}$, a point C_1, a singular on the arc $\overset{\frown}{D_1A_2}$, a point A_2, and itself (bypass the origin and return to A_1 again, forming a homoclinic orbit). As shown in Figure 2.9 (1)–(5).

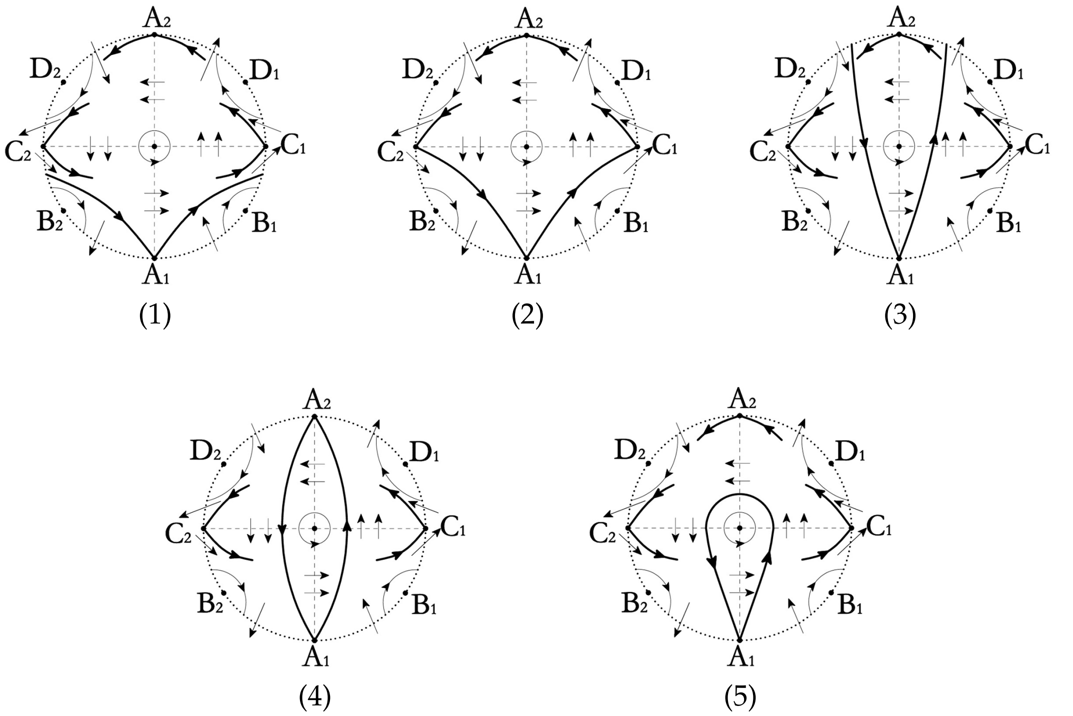

Figure 2.9: Consider the point A_1 of Figure 2.8, five possibilities for the ω-limit set of an unstable manifold at this point.

Figure 2.9 (1): Consider the point C_2, the ω-limit set of the unstable manifold at this point can only be the point C_1. Next, we consider the unstable manifold at point C_1. According to the symmetry of the original system, there are three possibilities for the ω-limit set of an unstable manifold at the point C_1, which are a point on $\overset{\frown}{D_1A_2}$, A_2 and C_2.

When the ω-limit set of an unstable manifold at point C_1 is a singular point on arc $\overset{\frown}{D_1A_2}$, ω-limit set of the unstable manifold at this point can only be a itself (bypass the origin and return to A_2 again, forming a homoclinic orbit), C_2 and a singular point on arc $\overset{\frown}{D_2C_2}$, respectively. According to the symmetry of the original system, the global phase portraits are equivalent to Figure 1.1 (25), (26) and (27), respectively.

Figure 2.9 (2): Consider the unstable manifold at point C_1, there are three possibilities for the ω-limit set on point C_1, which are a singular on the arc $\overset{\frown}{D_1A_2}$, A_2 and C_2. When the ω-limit set of an unstable manifold at C_1 is a singular point on arc $\overset{\frown}{D_1A_2}$, ω-limit set of the unstable manifold at this point can only be a itself (bypass the origin and return to A_2 again, forming a homoclinic orbits), C_2 and a singular point on arc $\overset{\frown}{D_2C_2}$, respectively. According to the symmetry of the original system, the global phase portraits are equivalent to the Figure 1.1 (29), (28) and (26), respectively.

Figure 2.9 (3): Consider the point A_2, the ω-limit set of the unstable manifold at this point can only be a itself (bypass the origin and return to A_2 again, forming a homoclinic orbit). The α-limit set of the stable manifold at point C_1 can only be a singular on the arc $\widehat{A_1B_1}$. The ω-limit set of the unstable manifold at point C_1 can only be a singular on the arc $\widehat{D_1A_2}$. According to the symmetry of the original system, the global phase portrait is equivalent to the Figure 1.1 (30).

Figure 2.9 (4): Consider the point C_1, the ω-limit set of the unstable manifold at this point can only be a singular on the arc $\widehat{D_1A_2}$. The α-limit set of the stable manifold at point C_1 can only be a singular on the arc $\widehat{A_1B_1}$. According to the symmetry of the original system, the global phase portrait is equivalent to the Figure 1.1 (27).

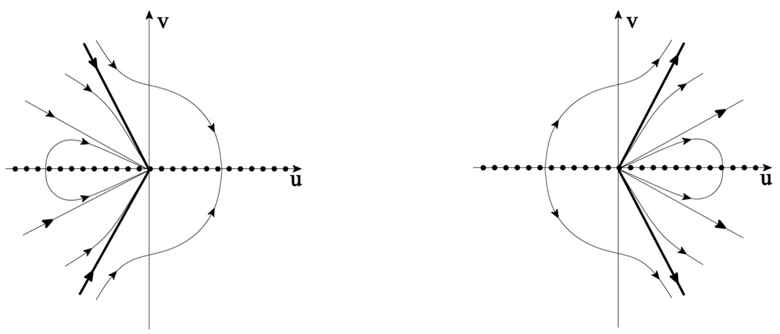
Figure 2.9 (5): Consider the point C_1, α-limit set of the unstable manifold at this point can only be a singular on the arc $\widehat{A_1B_1}$. Based on the the symmetry, ω-limit set of the unstable manifold at the point C_2 can only be a a singular on the arc $\widehat{A_1B_2}$. Fixed the unstable manifold of C_1, there are three possibilities for the ω-limit set on the C_1 , which are a singular on the arc $\widehat{D_1A_2}$, A_2 and C_2. Then the global phase portraits are equivalent to the Figure 1.1 (30) (29) (27).

Therefore, the local phase portraits Figure 2.8 have 6 possible global phase portraits as shown in Figure 1.1 (25)–(30).

For case (a.2): $a_2 \neq 0$, $4(a_5 - a_6) < a_2^2$, the local phase portrait of P_1 and P_2 of the system (2.2) consists of one hyperbolic and one elliptic sector by using blowing up. Moving P_1 to the origin through the change of coordinates $(u, v) \mapsto \left(u + \sqrt{-a_6/a_5}, v\right)$, the system (2.2) becomes

$$\begin{cases} u' = [1 + (u + 2^2)]v^3, \\ v' = uv^4 + \sqrt{-\dfrac{a_6}{a_5}}v^4 - a_1v^3 - a_2uv^2 - a_2\sqrt{-\dfrac{a_6}{a_5}}v^2 - 2a_4\sqrt{-\dfrac{a_6}{a_5}}uv \\ \qquad - a_4u^2v - a_5u^3 - 3a_5\sqrt{-\dfrac{a_6}{a_5}}u^2 + 2a_6u. \end{cases} \tag{2.10}$$

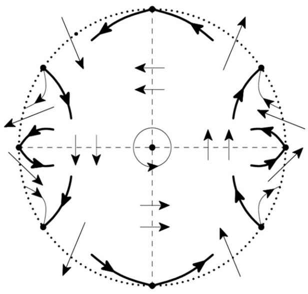
We apply a (2,1)-blow up to the system (2.1), and the local phase portrait of point P_1 in the system (2.1) is shown in Figure 2.10 (1). By the same argument, the local phase portrait of point P_2 in the system (2.1) is shown in Figure 2.10 (2). In the chart U_2, we have the same results as the Case IV.



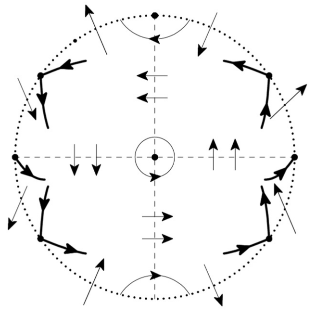
(1) P_1 (2) P_2

Figure 2.10: Local phase portrait of system (2.1) at point P_1 and point P_2 . The horizontal axis is filled with singular points.

After the analysis of case (a.2): $a_2 \neq 0$, $4(a_5 - a_6) < a_2^2$, we characterize the local phase portrait of system (1.3) on the Poincaré disk, see Figure 2.11 (1). By the symmetry of the system and the directions of the Poincaré disc, the possible global phase portraits of system (1.3) are shown in Figure 1.1 (31)–(46) of Theorem 1.2.



(1) case (a.2).



(2) $a_6 > 0$.

Figure 2.11: Local phase portrait of system (1.3) on the Poincaré disk of Case IV.

Using the similar argument as previous cases, if $a_6 > 0$, the local phase portrait of system (1.3) is Figure 2.11 (2), then the global phase portraits in the Poincaré disk are Figure 1.1 (47)–(51).

For Case IV, the possible global phase portrait of system (1.3) is shown in Figure 1.1 (25)–(51) of Theorem 1.2.

Case V: $a_4a_6 - a_5 \neq 0$, $a_5a_6 < 0$.

In the chart U_1, we consider the system (2.2). It is easy to find that there are three singular points in the u-axis: $O_{U_1}(0,0)$, $P_1(\sqrt{-a_6/a_5}, 0)$ and $P_2(\sqrt{-a_6/a_5}, 0)$. For the point $O_{U_1}(0,0)$, its singular point is the same to the system (2.2), please refer to Case II(i) and (ii) for details.

For the points P_1 and P_2, their linear part is

$$\begin{pmatrix} 0 & 0 \\ 2a_6 & \frac{a_4a_6 - a_5}{a_5} \end{pmatrix}.$$

If $a_4a_6 - a_5 \neq 0$, we have the following statements hold.

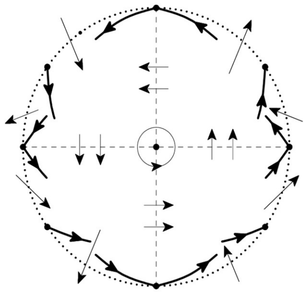
(A.1) If $a_6 < 0$ and $a_4a_6 - a_5 > 0$, then P_1 and P_2 are unstable nodes.

(A.2) If $a_6 < 0$ and $a_4a_6 - a_5 < 0$, then P_1 and P_2 are stable nodes.

(A.3) If $a_6 > 0$, then P_1 and P_2 are saddles.

In the chart U_2 the origin is the only one singular point of system (2.4). By the same argument as the Case III, if $a_6 < 0$, then the origin is a saddle, and if $a_6 > 0$, then the origin is a center.

Based on the above analysis, we characterize the local phase portrait of system (1.2) on the poincaré disk. If $a_6 > 0$, it is shown in Figure 2.11 (2); if $a_6 < 0$, Case (A.1) and Case (A.2) are equivalent to Figure 2.12.



$a_6 < 0, a_4 a_6 < a_5$

Figure 2.12: Local phase portrait of system (1.3) on the Poincaré disk of Case (A.1) and (A.2).

By the same argument as Figure 2.8, the possible global phase portraits of Figure 2.12 are Figure 1.1 (52)–(66). For Case IV, the possible global phase portraits of Figure 2.11 (2) are Figure 1.1 (47)–(51).

Therefore, the possible global phase portraits of Case V of system (1.3) are Figure 1.1(47)-(66).

2.2 Global phase portraits of system (1.4)

In this section, we discuss the global phase portraits of system (1.4). For $a_6 = 0$, $a_5 \neq 0$, the global phase portraits of system (1.4) has been studied in [2], thus we only investigate the following situations.

Case i: $a_5 = 0$**,** $a_6 \neq 0$**.**

In the chart U_1, the origin $O_{U_1}(0,0)$ of system (2.2) is a singular point and its linear part is

$$\begin{pmatrix} 0 & 0 \\ -a_6 & 0 \end{pmatrix}.$$

By the Theorem 3.5 of [14], if $a_6 < 0$, then $O_{U_1}(0,0)$ is a saddle, and if $a_6 > 0$, then $O_{U_1}(0,0)$ is a center.

In the chart U_2, the origin $O_{U_2}(0,0)$ is the only one singular point of system (2.4). Due to in the chart U_2, the coefficient a_3 does not work, the conclusion of system (1.4) is same to system (1.3), as shown Case II.1 and Case II.2 in Section 2.1.

Based on the above analysis, the corresponding local and global phase portraits of system (1.4) in Case I can be summarized as follows:

i.1 $a_4 = 0$. If $a_6 > 0$, the local phase portrait of system (1.4) on the Poincaré disk is Figure 2.3, but it needs to be rotated $\pi/2$ clockwise rotation, and all possible global phase portraits are topologically equivalent to Figure 1.1 (6) and (22). If $a_6 < 0$, the local phase portrait of system (1.4) is Figure 2.5(a) and Figure 2.3, and all possible global phase portrait is Figure 1.1 (7)–(12) and (6).

i.2 $a_4 \neq 0$. If $a_6 > 0$, the local phase portrait of system (1.4) on the Poincaré disk is Figure 2.13, all possible global phase portraits are topologically equivalent to Figure 1.1 (23) and (24). If $a_6 < 0$, the local phase portrait of system (1.4) is Figure 2.7 (3), and all possible global phase portraits are Figure 1.1 (19)–(21).

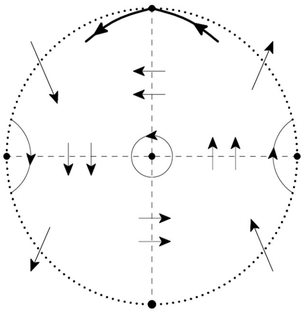


Figure 2.13: Local phase portrait of system (1.4) on the Poincaré disk of Case i.2 for $a_6 > 0$.

Therefore, the system (1.4) has 13 possible global phase portraits in Case i, as shown in Figure 1.1 (6)–(12) and (19)–(24).

Case ii: $a_5 a_6 > 0$**.**

If $a_6 > 0$, the local phase portrait of system (1.4) on the Poincaré disk is Figure 2.3, but it needs to be rotated $\pi/2$ clockwise rotation, all possible global phase portraits are topologically equivalent to Figure 1.1 (6) and (22). If $a_6 < 0$, the local phase portrait of system (1.4) is Figure 2.3, and all possible global phase portrait is Figure 1.1(6).

Therefore, the system (1.4) has 2 possible global phase portraits in Case ii, as shown in Figure 1.1 (6) and (22).

Case iii: $a_5 a_6 < 0$**,** $a_4 \neq 0$**.**

If $a_6 > 0$, the local phase portrait of system (1.4) on the Poincaré disk is Figure 2.14, all possible global phase portraits are topologically equivalent to Figure 1.1 (29) and (67). If $a_6 < 0$, the local phase portrait of system (1.4) is Figure 2.12, and all possible global phase portraits are Figure 1.1 (52)–(66).

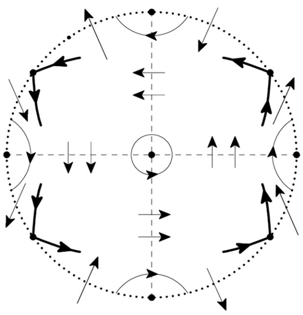

Figure 2.14: Local phase portrait of system (1.4) on the Poincaré disk of Case iii for $a_6 > 0$.

Therefore, the system (1.4) has 17 possible global phase portraits in Case iii, as shown in Figure 1.1 (29) and (52)–(67).

Case iv: $a_5 a_6 < 0$**,** $a_4 = 0$**.**

If $a_6 > 0$, the local phase portrait of system (1.4) is same to Case iii: $a_6 > 0$, as shown in Figure 2.14, its corresponding all possible global phase portraits are Figure 1.1 (29) and (67). If $a_6 < 0$, the local phase portrait of system (1.4) is same to Case IV: $a_6 < 0$, as shown in Figure

2.8 and Figure 2.11 (1), and its corresponding all possible global phase portraits are Figure 1.1 (25)–(30) and (31)–(46).

Consequently, the system (1.4) has 22 possible global phase portraits in Case iv, as shown in Figure 1.1 (25)–(46) and (67).

To sum up, the system (1.2) has 67 possible global phase portraits.

This completes the proof of Theorem 1.2.

Abstract. In this work, we aim to investigate an integro-differential model that involves localized viscoelastic effects at the boundary of the domain under the history framework. We have established that the equation is well-posed and exhibits exponential stability when a localized admissible kernel is applied, along with the δ-condition.

Keywords: wave equation, localized boundary feedback, exponential stability.

2020 Mathematics Subject Classification: 35L05, 35L20, 35B40.

1 Introduction

1.1 The model and literature overview

We consider the following problem

$$\begin{cases} u_{tt} - \Delta u + f(u) = 0 & \text{in } \Omega \times (0,\infty), \\ u = 0 & \text{on } \Gamma_0 \times (0,\infty), \\ \dfrac{\partial u}{\partial \nu} + \displaystyle\int_0^\infty g(s)a(x)u_t(x,t-s)\,ds = 0 & \text{on } \Gamma_1 \times (0,\infty), \\ u(x,-t) = u^0(x,-t), \quad u_t(x,0) = u_t^0(x) & \text{in } \Omega \times (0,\infty) \end{cases} \tag{1.1}$$

where $\Omega \subset \mathbb{R}^d$, $d \geq 2$, is an open bounded domain with a sufficiently smooth boundary $\Gamma = \partial\Omega$ such that $\Gamma = \Gamma_0 \cup \Gamma_1$ and $\overline{\Gamma}_0 \cap \overline{\Gamma}_1 = \emptyset$, $u^0 : \Omega \times [0,\infty) \to \mathbb{R}$ is the prescribed past history of u. We denote by ω, ω_0, ω_1 the intersection of Ω with a neighborhood of Γ, Γ_0, Γ_1 in $\mathbb{R}^d$, respectively. In addition, $a = a(x)$, is real valued non-negative function, responsible for the localized dissipative effect, $f : \mathbb{R}^+ \to \mathbb{R}^+$ represents a source term and $g : \mathbb{R}^+ \to \mathbb{R}^+$ is a nonnegative function having the form

$$g(s) = \int_s^\infty \mu(\tau)\,d\tau, \tag{1.2}$$

✉ Email: jcofaria@uem.br

where $\mu : \mathbb{R}^+ \to \mathbb{R}^+$ is an integrable function. Other assumptions on the functions f, g, μ and a will be precisely stated ahead.

It is worth mentioning that the study of stabilization of evolution equations subjected to boundary dissipation has been gaining more attention in the academic world over the past few years. In the absence of the viscolelastic term

$$\int_0^\infty g(s)a(x)u_t(x,t-s)ds,$$

problem (1.1) has been handled by many authors when a frictional damping term (linear or not) at the boundary is included; see for instance [7, 9, 26, 28, 40] among others. Related to viscoelastic boundary conditions, Aassila and Cavalcanti [2] studied the following problem

$$\begin{cases} u_{tt} - \Delta u = 0 & \text{in } \Omega \times (0,\infty), \\ u = 0 & \text{on } \Gamma_0 \times (0,\infty), \\ \dfrac{\partial u}{\partial \nu} + \displaystyle\int_0^t k(t-s,x)u'(s)\,ds + a(x)g(u') = 0 & \text{on } \Gamma_1 \times (0,\infty), \\ u(x,0) = u_0(x), \quad u'(x) = u_1(x) & \text{in } \Omega \times (0,\infty) \end{cases} \tag{1.3}$$

where $\Omega \subset \mathbb{R}^n$ is an open bounded domain with a sufficiently smooth boundary $\Gamma = \Gamma_0 \cup \Gamma_1$, $a : \Gamma_1 \to \mathbb{R}^+$ is such that $a(x) \geq a_0 > 0$. Under the following assumptions on functions k and g

$$k \geq 0, \qquad k' \leq 0, \qquad k'' \geq \alpha k' \quad \text{on } \Gamma_1 \times \mathbb{R}^+, \tag{1.4}$$

$$C_1|x|^p \leq |g(x)| \leq C_2|x|^{1/p},\ |x| \leq 1; \qquad C_3|x| \leq |g(x)| \leq C_4|x|,\ |x| \geq 1, \tag{1.5}$$

for some positive constants α, $C_i (1 \leq i \leq 4)$, the authors obtained the energy decays exponentially if $p = 1$ and decays polynomially if $p > 1$ when $u_0 = 0$ in Γ_1, extending the work of [23] to the case of nonlinear frictional dampings at boundary. Park and collaborators, in [35], considered a similar extension to a nonlinear boundary condition of memory type with the same assumption on k but without the above assumption on u_0. They also included a nonlinear source term $|u|^\rho u$ acting on the domain Ω, which turns the problem more subtle than those previously cited. For other problems in connection with viscoelastic and dynamic boundary conditions, the reader is referred to [10], [1, 11, 19, 20, 25] and references therein.

Nowadays a question that has been extensively investigated is the role of the kernel k in a viscoelastic term of type

$$\int_0^t k(t-s,x)w(s)ds \qquad (w = u \text{ or } w = u') \tag{1.6}$$

acting on the domain and/or the boundary to provide existence, as well stability of solutions. A reasonably large class of them has been carried out for many authors. Indeed, since the highly cited article of Dafermos [15], a flurry of work has been done with increasing kernels $k \in L^1(\mathbb{R}^+) \cap C^1(\mathbb{R}^+)$ satisfying $k(s) > 0$ and conditions like $1 - \int_0^\infty k(s)\,ds > 0$, together with the classical conditions (1.4) and improvements of them to provided existence and stability of solutions, we quote for instance [1, 10, 21, 29, 33, 36, 38] among others. A generalization of condition (1.4) was considered by Alabau-Boussouira and Cannarsa in [3] (see also [30–32]), where the main assumption is that the kernel k solves a suitable differential inequality. Other refinements of such condition are also discussed in [24, 27, 34].

Efforts are being made to achieve a less restricted assumption on the memory kernel k. Indeed, in [12], the authors introduced a general class of kernels called admissible kernels. These kernels are allowed not being strictly decreasing and can be locally flat while still fulfilling the so-called δ-condition: for some $\delta > 0$, there exists $C \geq 1$ such that

$$k(t+s) \leq Ce^{-\delta t}k(s)$$

for every $t \geq 0$ and $s > 0$. On these conditions, some authors have explored questions related to existence and stability of solutions, see for example [6,13,14].

1.2 Contribution and article structure

As mentioned earlier, previous research on viscoelastic dissipation at boundaries has mainly focused on the standard assumptions for the kernel, k. However, we have not found any studies that explore the effects of a more general memory kernel at the system's boundary, nor in a localized framework. Therefore, this paper's main contribution is its novel approach to this topic. We consider the past history framework together with a localized admissible kernel under the δ-condition to show exponential stability without the inclusion of frictional damping, unlike some of the articles mentioned earlier. However, this approach presents certain technical difficulties that must be addressed to obtain an observability inequality, which is crucial to proving the exponential stability of the problem.

Indeed, to demonstrate the exponential stability, we draw inspiration from the works of Dehman, Gérard, Lebeau [16] and Dehman, Lebeau, and Zuazua [17]. The key step in this approach involves establishing the observability inequality:

$$E(0) \leq C\left(\int_0^T \int_{\Gamma_1} \int_0^\infty -\mu'(s)a(x)|\eta^t(s)|^2\,ds\,d\Gamma\,dt\right)$$

for all $t \geq T_0$.

To prove this statement we employ a contradiction argument and seek a sequence (u_m, η_m^t) of weak solutions to the equivalent problem (2.2) such that $E_m(0) = 1$. By utilizing a boundary observability theorem by Duyckaerts, Zhang, and Zuazua [18], we aim to derive the desired contradiction by showing that $E_m(0) \to 0$ as $m \to \infty$. However, challenges arise due to the nature of μ satisfying the δ-condition, making it difficult to establish that the convergence

$$\lim_{m\to\infty} \int_0^T \int_{\Gamma_1} \int_0^\infty -\mu'(s)a(x)|\eta_m^t|^2\,ds\,d\Gamma\,dt = 0$$

implies

$$\lim_{m\to\infty} \int_0^T \int_{\Gamma_1} \int_0^\infty \mu(s)a(x)|\eta_m^t|^2\,ds\,d\Gamma\,dt = 0,$$

which is usual in this kind of problem, and is a crucial step for completing our contradiction argument.

Based on the above statements, this article is structured as follows: Section 2 discusses the well-posedness of problem (1.1) by introducing the well-known relative displacement history variable introduced by [15] to obtain an equivalent problem, as is typical in this kind of approach. In Section 3, the exponential stability of the solution is established by demonstrating an appropriate observability inequality.

2 Existence and uniqueness of solution

Through this article, we will use basic notations and results from books by [5,8,39].

In this section, we will prove the first result of this paper regarding the existence and uniqueness of solution for the system (2.2). To achieve this, we will introduce an equivalent problem that will enable us to utilize the Semigroups theory, as well the main assumptions and notations to be used throughout this paper.

As in the pioneer work of [15], and by following [22], we introduce the following new variable corresponding to the relative displacement history

$$\eta^t(x,s) = u(x,t) - u(x,t-s), \qquad x \in \Omega,\ s > 0,\ t \geq 0, \tag{2.1}$$

in order to translate (1.1) into the autonomous problem

$$\begin{cases} u_{tt} - \Delta u + f(u) = 0 & \text{in } \Omega \times (0,\infty), \\ u = 0 & \text{on } \Gamma_0 \times (0,\infty), \\ \dfrac{\partial u}{\partial \nu} + \displaystyle\int_0^\infty \mu(s) a(x) \eta^t(x,s)\, ds = 0 & \text{on } \Gamma_1 \times (0,\infty), \\ \eta^t_s + \eta^t_t = u_t & \text{in } \Omega \times (0,\infty) \times (0,\infty), \\ u(x,-t) = u^0(x,-t) & \text{in } \Omega \times (0,\infty) \\ u(x,0) = u_0(x) = u^0(x,0), \quad u_t(x,0) = u_1(x) = u^0_t(x) & \text{in } \Omega, \\ \eta^t(x,s) = 0 & \text{on } \Gamma_0 \times (0,\infty) \times (0,\infty), \\ \eta^0(x,s) = \eta_0(x,s) = u^0(x,0) - u^0(x,-s) & \text{on } \Omega \times (0,\infty) \end{cases} \tag{2.2}$$

in the two variables $u = u(t)$ and $\eta = \eta^t(s)$.

In the sequel, to state our main results on the well-posedness and asymptotic behavior of problem (1.1), let us consider the following assumptions and notations:

A.1. $a : \Gamma_1 \to \mathbb{R}^+ \in L^\infty(\Gamma_1) \cap C(\overline{\omega}_1)$ is such that

- *i.* $a(x) \geq 0$ on Γ_1;
- *ii.* $a(x) \geq a_0 > 0$ in $\omega_1 \subset\subset \Gamma_1$.

A.2. $g : \mathbb{R}^+ \to \mathbb{R}^+$ is a nonnegative function having the form

$$g(s) = \int_s^\infty \mu(\tau)\, d\tau, \tag{2.3}$$

where $\mu : \mathbb{R}^+ \to \mathbb{R}^+$ is a pointwise absolutely continuous function, nonincreasing, integrable and such that

- *i.* $l = \int_0^\infty \mu(s)\, ds \in (0,1)$;
- *ii.* there exists a strictly increasing sequence $\{s_n\}$, with $s_0 = 0$, either finite or converging to $s_\infty \in (0,\infty]$, such that μ has jumps at $s = s_n,\ n > 0$.

A.3. $f \in C^2(\mathbb{R})$ satisfies

- *i.* $f(0) = 0$;

ii. the primitive $F(s) = \int_0^s f(\tau)\, d\tau$ is such that

$$-\frac{\gamma|s|^2}{2} \le F(s) \le f(s)s + \frac{\gamma|s|^2}{2}, \tag{2.4}$$

$\gamma \in [0, \lambda_1[$, where $\lambda_1 > 0$ is the first eigenvalue corresponding to the Laplacian operator with Dirichlet boundary condition;

iii. there exists $c > 0$ such that

$$|f^{(j)}(s)| \le c(1+|s|)^{p-j}, \quad \forall s \in \mathbb{R},\ j = 1, 2, \tag{2.5}$$

where

$$p \ge 1 \text{ if } n = 2 \quad \text{and} \quad 1 \le p < \frac{n}{n-2} \text{ if } n \ge 3. \tag{2.6}$$

Remark 2.1.

1. Notice that the function μ defined in Assumption A.2 can be unbounded in a neighborhood of zero. Moreover, μ is differentiable almost everywhere, and $\mu'(s) \le 0$ for almost every s.

2. Observe that the growth condition on f implies that

$$|f(s)| \le c(p)|s| + c(p)|s|^p. \tag{2.7}$$

We still note that (2.4) implies $f'(0) + \gamma \ge 0$ as well.

Now, consider $A : D(A) \subset H^1_{\Gamma_0}(\Omega) \to H^{-1}(\Omega)$ the operator $Au = -\Delta u$, with $D(A) = \{u \in H^1_{\Gamma_0}(\Omega),\ \partial_\nu u_{|\Gamma_1} = 0\}$, $h : \mathcal{M} \to L^2(\Gamma_1)$, $h(w(s)) = \int_0^\infty \mu(s)a(x)w(s)\, ds$ and $N : L^2(\Omega) \to L^2(\Omega)$ be the Neumann map

$$\begin{cases} -\Delta u = 0 & \text{in } \Omega, \\ Ng = 0 & \text{on } \Gamma_0, \\ \dfrac{\partial(Ng)}{\partial\nu} = g & \text{on } \Gamma_1. \end{cases}$$

Therefore, we have that

$$N^* A^* v = -v_{|\Gamma_1}, \qquad \forall v \in D(A^{\frac{1}{2}}) \tag{2.8}$$

as well as the system (2.2) is equivalent to

$$\begin{cases} u_{tt} + A(u - N[h(\eta)]) + f(u) = 0 & \text{in } \Omega \times (0,\infty), \\ u = 0 & \text{on } \Gamma_0 \times (0,\infty), \\ \dfrac{\partial u}{\partial \nu} = 0 & \text{on } \Gamma_1 \times (0,\infty), \\ \eta^t_s + \eta^t_t = u_t & \text{in } \Omega \times (0,\infty) \times (0,\infty), \\ u(x,-t) = u^0(x,-t) & \text{in } \Omega \times (0,\infty) \\ u(x,0) = u_0(x) = u^0(x,0), \quad u_t(x,0) = u_1(x) = u^0_t(x) & \text{in } \Omega, \\ \eta^t(x,s) = 0 & \text{on } \Gamma_0 \times (0,\infty) \times (0,\infty), \\ \eta^0(x,s) = \eta_0(x,s) = u^0(x,0) - u^0(x,-s) & \text{on } \Omega \times (0,\infty). \end{cases} \tag{2.9}$$

Next, let a be a function satisfying Assumption A.1, and define the μ-weighted space with values in $L^2(\Gamma_1)$ as

$$\mathcal{M} = \left\{ \eta : \mathbb{R}^+ \to L^2(\Gamma_1);\ \int_0^\infty \mu(s) \|\sqrt{a}\eta(s)\|^2 < \infty \right\}, \tag{2.10}$$

which is a Hilbert space endowed with the inner-product

$$(\eta, \zeta)_{\mathcal{M}} = \int_0^\infty \mu(s) \int_{\Gamma_1} \sqrt{a}\eta(s)\sqrt{a}\zeta(s)\, d\Gamma\, ds.$$

Throughout this article, $\mathcal{H}$ represents the energy space

$$\mathcal{H} = H^1_{\Gamma_0}(\Omega) \times L^2(\Omega) \times \mathcal{M},$$

where $H^1_{\Gamma_0}(\Omega) := \{u \in H^1(\Omega) : u|_{\Gamma_0} = 0\}$, and $\mathcal{H}$ is endowed with the inner product

$$\langle (u_1, v_1, \eta_1), (u_2, v_2, \eta_2) \rangle_{\mathcal{H}} = \int_\Omega (\nabla u_1 \nabla u_2 + v_1 v_2)\, dx + \int_0^\infty \mu(s) \int_{\Gamma_1} \sqrt{a}\eta_1 \sqrt{a}\eta_2\, d\Gamma\, ds.$$

Therefore, denoting $U = (u, u_t, \eta)^T$ we can write, equivalently, the system (2.9) in the form

$$\begin{cases} \frac{d}{dt}U(t) + \mathcal{S}U(t) + \mathcal{F}(U(t)) = 0, \\ U(0) = (u_0, u_1 \eta_0), \end{cases} \tag{2.11}$$

where $\mathcal{S} : D(\mathcal{S}) \subset \mathcal{H} \to \mathcal{H}$ is given by

$$\mathcal{S} \begin{bmatrix} u \\ v \\ \eta \end{bmatrix} = \begin{bmatrix} -v \\ A(u - N[h(\eta)]) \\ v - \eta^t_s \end{bmatrix},$$

$$D(\mathcal{S}) = \left\{ (u, v, \eta) \in \mathcal{H} :\ v \in H^1_{\Gamma_0},\ u - N[h(\eta)] \in D(A),\ \eta^t_s \in \mathcal{M},\ \eta(0) = 0 \right\},$$

which is well-defined in view of the previous explanation, and $\mathcal{F} : \mathcal{H} \to \mathcal{H}$ is set by

$$\mathcal{F}(U) = (0, f(u), 0)^T,$$

being also well-defined by virtue of the growth condition on f and standard Sobolev embeddings. The Hadamard well-posedness of problem (2.11) and, consequently, of the original system (1.1), reads as follows.

Theorem 2.2. *Under the Assumptions A.1–A.3 we have:*

(i) *If $U_0 = (u_0, u_1, \eta_0) \in D(\mathcal{S})$, then there exists a unique regular solution $U = (u, u_t, \eta)$ of (2.11) such that*

$$u \in W^{2,\infty}(0, T; L^2(\Omega)) \cap W^{1,\infty}(0, T; H^1_{\Gamma_0}(\Omega)), \quad \eta \in W^{1,\infty}(0, T; \mathcal{M}),$$

with $U(t) = (u(t), u_t(t), \eta^t) \in D(\mathcal{S})$, for all $t \in [0, T]$, for a given $T > 0$.

(ii) *If $U_0 = (u_0, u_1, \eta_0) \in \mathcal{H}$, then there exists a unique mild solution $U = (u, u_t, \eta)$ of (2.11) such that*

$$u \in C^1([0, T]; L^2(\Omega)) \cap C([0, T]; H^1_{\Gamma_0}(\Omega)), \quad \eta \in C([0, T], \mathcal{M}),$$

for all $T > 0$ given.

(iii) *Moreover, these solutions are continuously dependent of the initial data, in the norm of* $C([0,T],\mathcal{H})$*, for all* $T>0$.

Proof. To establish this result, firstly we shall prove that $\mathcal{S}$ is monotone and $I-\mathcal{S}$ is surjective on the space $\mathcal{H}$. Indeed, for $\eta \in D(\mathcal{S})$, define

$$\mathbb{J}[\eta] = \sum_{n\geq 1} (\mu(s_n^-) - \mu(s_n^+))\|\eta(s_n)\|^2_{\mathcal{M}},$$

which is a nonpositive quantity in view of Assumption A.2. Following [37, Lemma 3.4], one notices that $\eta \in D(\mathcal{S})$ satisfies

$$2(\eta_s,\eta)_{\mathcal{M}} = \int_0^\infty \mu'(s)\|\eta(s)\|^2_{\mathcal{M}}\,ds + \mathbb{J}[\eta].$$

Let

$$\begin{bmatrix} u_1 \\ v_1 \\ \eta_1 \end{bmatrix}, \begin{bmatrix} u_2 \\ v_2 \\ \eta_2 \end{bmatrix} \in D(\mathcal{S}).$$

Then

$$\begin{aligned} &\left\langle \mathcal{S}\begin{bmatrix} u_1 \\ v_1 \\ \eta_1 \end{bmatrix} - \mathcal{S}\begin{bmatrix} u_2 \\ v_2 \\ \eta_2 \end{bmatrix}, \begin{bmatrix} u_1 \\ v_1 \\ \eta_1 \end{bmatrix} - \begin{bmatrix} u_2 \\ v_2 \\ \eta_2 \end{bmatrix}\right\rangle \\ &= \langle -v_1+v_2, u_1-u_2\rangle_{H^1_{\Gamma_0}} + \langle Av_1 - Av_2, v_1-v_2\rangle_{L^2(\Omega)} \\ &\quad - \langle A(N[h(\eta_1)-h(\eta_2)]), v_1-v_2\rangle_{L^2(\Omega)} + (v_1-v_2,\eta_1-\eta_2)_{L^2(\Omega)} \\ &\quad - ((\eta_1)_s - (\eta_2)_s, \eta_1-\eta_2)_{\mathcal{M}} \\ &= -\frac{1}{2}\mathbb{J}[\eta] \geq 0, \end{aligned}$$

which shows that $\mathcal{S}$ is monotone.

Next, we will prove that $I-\mathcal{S}$ is surjective. To this end, we show the equation

$$(I-\mathcal{S})\left(\begin{bmatrix} u \\ v \\ \eta \end{bmatrix}\right) = \begin{bmatrix} h_1 \\ h_2 \\ h_3 \end{bmatrix}$$

has a solution

$$\begin{bmatrix} u \\ v \\ \eta \end{bmatrix} \in \mathcal{H}, \quad \text{for any} \quad h = \begin{bmatrix} h_1 \\ h_2 \\ h_3 \end{bmatrix} \in \mathcal{H}.$$

The above equation is equivalent to write

$$\begin{cases} u+v = h_1, \\ v - A(u - N[h(\eta)]) = h_2 \\ \eta + \eta_s - v = h_3. \end{cases} \tag{2.12}$$

Combining the above identities we deduce in the weak space

$$\begin{cases} -A(-v - N[h(\eta)]) + v = h_2 + A(h_1) \\ \eta + \eta_s - v = h_3. \end{cases} \tag{2.13}$$

Denote

$$R(v,\eta) = (T_0 + T_1 + T_2)(v,\eta),$$
$$T_0(v,\eta) = (0, \eta + s), \quad T_1(v,\eta) = (Av + v, \eta), \quad T_2(v,\eta) = (A(N(h(\eta))), -v).$$

It is well-known that T_0 is maximal monotone in $H^1_{\Gamma_0} \times \mathcal{M}$. Also, T_1 is monotone and from the Lax–Milgram Theorem follows that it is surjective, therefore maximal monotone in $H^1_{\Gamma_0} \times \mathcal{M}$. Furthermore, T_2 is monotone and Lipschitz continuous in $H^1_{\Gamma_0} \times \mathcal{M}$. Then, using standard perturbation results in [4], we conclude that $R = (T_0 + T_1 + T_2)$ is maximal monotone and coercive, therefore the left hand term in (2.13) is surjective. Then, (2.13) possesses a unique solution $(v,\eta) \in H^1_{\Gamma_0}(\Omega) \times \mathcal{M}$. Since $u = v + h_1$ we obtain $u \in H^1_{\Gamma_0}(\Omega)$, which implies that $I - \mathcal{S}$ is surjective.

Next, to finish the proof we observe that from Assumption A.3, for a given $T > 0$, f generates a locally Lipschitz perturbation on the phase space $\mathcal{H}$ which after some standard calculations guarantees, by using the Kato's Theorem, the existence of a unique strong solution $U \in W^{1,\infty}([0,T], \mathcal{H})$ such that $U(t) \in D(S)$ for all $t \in [0,T]$. Moreover, this solution continuously depends on the initial data for any $T > 0$. □

3 Asymptotic stability result

In this section the goal is to establish the exponential stability result concerning problem (2.2).

Denoting $U = (u, u_t, \eta)$ the unique global solution to the problem (2.11) as stated in Theorem 2.2, then the couple (u,η) is the corresponding solution to the equivalent system (2.2). The associated energy functional is given by

$$E(t) = \frac{1}{2}\left[|u_t|^2 + |\nabla u|^2 + \|\eta\|^2_{\mathcal{M}} + 2\int_\Omega \int_0^u f(\tau)\, d\tau dx \right]. \tag{3.1}$$

A straightforward computation provides the identity

$$\frac{d}{dt}E(t) = \frac{1}{2}\int_{\Gamma_1}\int_0^\infty \mu'(s)a(x)|\eta^t(s)|^2 ds\, d\Gamma,$$

which, in view on Assumption A.2, implies that $E(t)$ is a non-increasing function for all $t > 0$ and satisfies the identity

$$E(T) - E(0) = \frac{1}{2}\int_0^T \int_{\Gamma_1}\int_0^\infty \mu'(s)a(x)|\eta^t(s)|^2 ds\, d\Gamma\, dt$$

for all $T > 0$.

In order to obtain the desired stability, we need to make some complementary assumptions on the given functions, as well to make some remarks and comments which will be necessary to prove the exponential stability.

Concerning the memory kernel $\mu : \mathbb{R}^+ \to \mathbb{R}^+$ defined in Assumption A.2 it is also assumed that

A.4. (i) there exist $\delta > 0$ and $C \geq 1$ such that

$$\mu(t+s) \leq Ce^{-\delta t}\mu(s) \tag{3.2}$$

for every $t \geq 0$ and almost every $s > 0$;

(ii) μ is not completely flat, that is, the set

$$D = \{s > 0,\ \mu'(s) < 0\}$$

has positive Lebesgue measure.

Remark 3.1.

a. A kernel μ satisfying Assumption A.4(i) is said to fulfill the δ-condition;

b. Particularly, the δ-condition implies that, for each $t \geq 0$

$$|N_t = \{s \in \mathbb{R}^+,\ Ce^{-\delta t}\mu(s) - \mu(t+s) < 0\}| = 0, \tag{3.3}$$

where $|\cdot|$ stands for the Lebesgue measure of the set.

c. If $S_\infty = \sup\{s,\ \mu(s) > 0\} < \infty$, then μ fulfills the δ-condition for every $\delta > 0$;

d. When $C = 1$, (3.2) is equivalent to the well-known condition in the literature $\mu'(s) + \delta\mu(s) \leq 0$, for almost every $s > 0$;

e. Regarding Assumption A.4(ii), it is fairly easy to show that there exists $\alpha > 0$ large enough such that the set

$$N = \{s \in \mathbb{R}^+,\ \alpha\mu'(s) + \mu(s) < 0\} \tag{3.4}$$

has positive Lebesgue measure.

In view of the aforementioned considerations, the stability result reads as follows.

Theorem 3.2. *Assume that Assumptions A.1–A.4 are in force and let $R > 0$ be a given constant. If $E(0) \leq R$, there exist $T_0 > 0$ and constants $C_0, \lambda > 0$, depending on R, verifying*

$$E(t) \leq C_0 E(0) e^{-\lambda t}, \quad \forall t > T_0. \tag{3.5}$$

As mentioned earlier, an important step to prove estimate (3.5) relies on obtaining an observability inequality through a contradiction argument. To accomplish this it is needed, among other tools, to obtain the following convergence

$$\lim_{n\to\infty} \int_0^T \int_{\Gamma_1} \int_0^\infty \mu(s)a(x)|\eta_n^t|^2 ds\, d\Gamma\, dt = 0,$$

for a sequence $\{(u_n, \eta_n^t)\}$ of solutions to the problem (2.2), which is not an easy task since μ satisfies the δ-condition $A.4(i)$. The proof of this convergence is stated in the following result:

Lemma 3.3. *Let $\{(u_n, \eta_n^t)\}$ be a sequence of solutions to the problem (2.2). By assuming Assumption A.4, if*

$$\lim_{n\to\infty} \int_0^T \int_{\Gamma_1} \int_0^\infty -\mu'(s)a(x)|\eta_n^t|^2 ds\, d\Gamma\, dt = 0,$$

then

$$\lim_{n\to\infty} \int_0^T \int_{\Gamma_1} \int_0^\infty \mu(s)a(x)|\eta_n^t|^2 ds\, d\Gamma\, dt = 0.$$

Proof. First one notices that, according to Remark 4.1(e), as

$$\lim_{n\to\infty}\int_0^T\int_{\Gamma_1}\int_0^\infty \mu(s)a(x)|\eta_n^t|^2 ds\, d\Gamma\, dt = \lim_{n\to\infty}\int_0^T\int_{\Gamma_1}\int_N \mu(s)a(x)|\eta_n^t|^2 ds\, d\Gamma\, dt + \lim_{n\to\infty}\int_0^T\int_{\Gamma_1}\int_{\mathbb{R}^+\setminus N} \mu(s)a(x)|\eta_n^t|^2 ds\, d\Gamma\, dt,$$

we have that

$$\lim_{n\to\infty}\int_0^T\int_{\Gamma_1}\int_N \mu(s)a(x)|\eta_n^t|^2 ds\, d\Gamma\, dt \le \lim_{n\to\infty}\alpha\int_0^T\int_{\Gamma_1}\int_0^\infty -\mu'(s)a(x)|\eta_n^t|^2 ds\, d\Gamma\, dt = 0. \tag{3.6}$$

Next, suppose that $\lim_{n\to\infty}\int_0^T\int_{\Gamma_1}\int_{\mathbb{R}^+\setminus N}\mu(s)a(x)|\eta_n^t|^2 ds\, d\Gamma\, dt \neq 0$. Thus, there exists n_1 large enough such that

$$\int_{\mathbb{R}^+\setminus N}\mu(s)a(x)\|\eta_{n_1}^t\|^2_{L^2(\Gamma_1)}ds > 0,$$

for all $t \ge 0$. To not overload the notation, the index n_1 shall be omitted in the next calculations.

As in [12] consider, for $\eta_0 \in \mathcal{M}$, $U(t) = \mathcal{R}(t)(0,0,\eta_0)$. Therefore, as μ satisfies (3.2), if $\tilde{C}_1 > \max\{1, \tilde{C}\}$, one gets

$$\begin{aligned}
0 < \int_{\mathbb{R}^+\setminus N}\mu(s)a(x)\|\eta_0\|^2_{L^2(\Gamma_1)}ds &\le \int_0^\infty \mu(s)a(x)\|\eta_0\|^2_{L^2(\Gamma_1)}ds \\
&\le \int_0^\infty \mu(s-t)a(x)\|\eta_0\|^2_{L^2(\Gamma_1)}ds \\
&\le 2\|a\|\left[\int_t^\infty \mu(s)(\tilde{C}\|\eta^t(s)\|^2_{L^2(\Gamma_1)} + \|u(t)\|^2)ds\right] \\
&\le 2\|a\|\left[\tilde{C}\int_0^\infty \mu(s+t)\|\eta_0(s)\|^2_{L^2(\Gamma_1)} + \int_0^\infty \mu(s)\|u(t)\|^2 ds\right] \\
&< \tilde{C}_1(C+M)e^{-\delta t}\|\eta_0\|^2_{\mathcal{M}},
\end{aligned}$$

where $M = \|\mathcal{R}(t)\|$.

Particularly, for $t > 0$ fixed and $\eta_0(s) = \chi_{N_t}\phi(s)$, where $\|\phi\|_{L^2(\Gamma_1)} = 1$, we obtain

$$\int_0^\infty [1 - \tilde{C}_1(C+M)]e^{-\delta t}\chi_{N_t}(s)ds < 0. \tag{3.7}$$

On the other hand, for any fixed $t > 0$, define

$$\mathcal{N}_t = \{s \in \mathbb{R}^+,\ \mu(t+s) - \tilde{C}_1(C+M)e^{-\delta t}\mu(s) > 0\}.$$

Thus, from Remark 4.1(b) follows that

$$0 = \int_{\mathcal{N}_t}\mu(t+s) - \tilde{C}_1(C+M)e^{-\delta t}\mu(s)\, ds \le \tilde{C}_1(C+M)e^{-\delta t}|\mathcal{N}_t|,$$

which contradicts (3.7) and shows that

$$\lim_{n\to\infty}\int_0^T\int_{\Gamma_1}\int_{\mathbb{R}^+\setminus N}\mu(s)a(x)|\eta_n^t|^2 ds\, d\Gamma\, dt = 0.$$

□

Next, to the aim of obtaining the desired observability inequality which lead us to the proof of Theorem 3.2, and in order to use an appropriate boundary observability inequality in our arguments it is considered, for each $k \in \mathbb{N}$, the following approximation of problem (2.2):

$$\begin{cases} \partial_{tt}u^k - \Delta u^k + f^k(u^k) = 0 & \text{in } \Omega \times (0,\infty), \\ u^k = 0 & \text{on } \Gamma_0 \times (0,\infty), \\ \dfrac{\partial u^k}{\partial \nu} + \displaystyle\int_0^\infty \mu(s) a(x) \eta^{t,k}(x,s) ds = 0 & \text{on } \Gamma_1 \times (0,\infty), \\ \partial_s \eta^{t,k} + \partial_t \eta^{t,k} = \partial_t u^k & \text{in } \Omega \times (0,\infty) \times (0,\infty), \\ u^k(x,-t) = u^0(x,-t) & \text{in } \Omega \times (0,\infty) \\ u^k(x,0) = u_0^k(x) = u^0(x,0), \quad \partial_t u^k(x,0) = u_1^k(x) = \partial_t u^0(x) & \text{in } \Omega, \\ \eta^{t,k}(x,s) = 0 & \text{on } \Gamma_0 \times (0,\infty) \times (0,\infty), \\ \eta^{0,k}(x,s) = \eta_0^k(x,s) = u_0^k(x,0) - u_0^k(x,-s) & \text{on } \Omega \times (0,\infty), \end{cases} \tag{3.8}$$

where the function f^k is defined by

$$f^k(s) = \begin{cases} f(s), & |s| \le k \\ f(k), & s \ge k \\ f(-k), & s \le -k. \end{cases}$$

Notice that, for each k, f^k is Lipschitz continuous on $\mathbb{R}$ and the associated energy functional is given by

$$E^k(t) = \frac{1}{2}\left[|\partial_t u^k|^2 + |\nabla u^k|^2 + \|\eta^{t,k}\|^2_{\mathcal{M}} + 2\int_\Omega \int_0^{u^k} f^k(\tau)\, d\tau dx \right]. \tag{3.9}$$

An observability inequality to the truncated problem (3.8) shall be provided by the next result.

Proposition 3.4. *Let us take Assumptions A.1-A.4 and let $R > 0$ be a given constant. The solution (u^k, η^k) of (3.8) satisfies the following inequality*

$$E^k(0) \le C \left(\int_0^T \int_{\Gamma_1} \int_0^\infty -\mu'(s) a(x) |\eta^{t,k}(s)|^2 \, ds d\Gamma dt \right), \tag{3.10}$$

for all $T \ge T_0$ and some constant C depending only on $U_0 = (u_0, u_1, \eta_0)$, provided that $E^k(0) \le R$.

Proof. To prove (3.10) we argue by contradiction. Indeed, if such inequality does not hold, there exist $T > T_0 > 0$, $R > 0$ and a sequence $\{(u_n^k, \eta_n^{t,k})\}$ of solutions to

$$\begin{cases} \partial_{tt}u_n^k - \Delta u_n^k + f^k(u_n^k) = 0 & \text{in } \Omega \times (0,\infty), \\ u_n^k = 0 & \text{on } \Gamma_0 \times (0,\infty), \\ \dfrac{\partial u_n^k}{\partial \nu} + \displaystyle\int_0^\infty \mu(s) a(x) \eta_n^{t,k}(x,s) ds = 0 & \text{on } \Gamma_1 \times (0,\infty), \\ \partial_s \eta_n^{t,k} + \partial_t \eta_n^{t,k} = \partial_t u_n^k & \text{in } \Omega \times (0,\infty) \times (0,\infty), \\ u_n^k(x,-t) = u^0(x,-t) & \text{in } \Omega \times (0,\infty) \\ u_n^k(x,0) = u_{0n}^k(x) = u_n^0(x,0), \; \partial_t u_n^k(x,0) = u_{1n}^k(x) = \partial_t u_n^0(x) & \text{in } \Omega, \\ \eta_n^{t,k}(x,s) = 0 & \text{on } \Gamma_0 \times (0,\infty) \times (0,\infty), \\ \eta_n^{0,k}(x,s) = \eta_{0n}^k(x,s) = u_{0n}^k(x,0) - u_{0n}^k(x,-s) & \text{on } \Omega \times (0,\infty), \end{cases} \tag{3.11}$$

such that $E_n^k(0) \le R$, which satisfies

$$\lim_{n\to\infty} \frac{E_n^k(0)}{\int_0^T \int_{\Gamma_1} \int_0^\infty -\mu'(s)a(x)|\eta_n^{t,k}(s)|^2 ds d\Gamma dt} = \infty. \tag{3.12}$$

Since $E_n^k(t) \le E_n^k(0) \le R$ for all $t \ge 0$, from (3.12) one gets

$$\lim_{n\to\infty} \int_0^T \int_{\Gamma_1} \int_0^\infty -\mu'(s)a(x)|\eta_n^{t,k}(s)|^2 ds d\Gamma dt = 0, \tag{3.13}$$

and also guarantees the existence of a subsequence of $\{(u_n^k, \eta_n^{t,k})\}$, still denoted by $\{(u_n^k, \eta_n^{t,k})\}$, such that

$$\begin{aligned} u_n^k &\overset{*}{\rightharpoonup} u^k \quad \text{in } L^\infty(0,T;H_0^1(\Omega)), \\ \partial_t u_n^k &\overset{*}{\rightharpoonup} \partial_t u^k \quad \text{in } L^\infty(0,T;L^2(\Omega)), \end{aligned} \tag{3.14}$$

when $n \to \infty$. By using compactness arguments we also obtain

$$u_n^k \to u^k \text{ in } L^2(0,T;L^2(\Omega)). \tag{3.15}$$

In the sequel, with respect to the limit function u^k, the proof is twofold: $u^k \neq 0$ and $u^k = 0$.

Case I: $u^k \neq 0$. Taking in mind (3.13), (3.14) and Lemma 3.3, from (3.11) one obtains, when $n \to \infty$

$$\begin{cases} \partial_{tt}u^k + \Delta u^k + f^k(u^k) = 0 & \text{in } \Omega \times (0,\infty), \\ u^k = 0 & \text{on } \Gamma_0 \times (0,\infty), \\ \dfrac{\partial u^k}{\partial \nu} = 0 & \text{on } \Gamma_1 \times (0,\infty), \\ u^k(x,-t) = u^{0,k}(x,-t) & \text{in } \Omega \times (0,\infty) \\ u^k(x,0) = u_0^k(x) = u^{0,k}(x,0), \quad \partial_t u^k(x,0) = u_1^k(x) = \partial_t u^{0,k}(x) & \text{in } \Omega, \end{cases} \tag{3.16}$$

Since f^k is globally Lipschitz, for each $k \in \mathbb{N}$ we find by the boundary observability theorem due to the Theorem 2.2 in [18] that $u^k = 0$, which presents the desired contradiction.

Case II: $u^k = 0$. Denote

$$\alpha_n = \left(E_n^k(0)\right)^{\frac{1}{2}}, \quad v_n^k = \frac{1}{\alpha_n} u_n^k, \quad \zeta_n^k = \frac{1}{\alpha_n}\eta_n^k. \tag{3.17}$$

Whereupon, $\{(v_n^k, \zeta_n^k)\}$ is solution of the normalized problem

$$\begin{cases} \partial_{tt}v_n^k - \Delta v_n^k + \dfrac{1}{\alpha_n} f^k(\alpha_n v_n^k) = 0 & \text{in } \Omega \times (0,\infty), \\ v_n^k = 0 & \text{on } \Gamma_0 \times (0,\infty), \\ \dfrac{\partial v_n^k}{\partial \nu} + \displaystyle\int_0^\infty \mu(s)a(x)\zeta_n^{t,k}(x,s)ds = 0 & \text{on } \Gamma_1 \times (0,\infty), \\ \partial_s \zeta_n^{t,k} + \partial_t \zeta_n^{t,k} = \partial_t v_n^k & \text{in } \Omega \times (0,\infty) \times (0,\infty), \\ v_n^k(x,-t) = v^0(x,-t) & \text{in } \Omega \times (0,\infty) \\ v_n^k(x,0) = v_{0n}^k(x) = v_n^0(x,0), \ \partial_t v_n^k(x,0) = v_{1n}^k(x) = \partial_t v_n^0(x) & \text{in } \Omega, \\ \zeta_n^{t,k}(x,s) = 0 & \text{on } \Gamma_0 \times (0,\infty) \times (0,\infty), \\ \zeta_n^{0,k}(x,s) = \zeta_{0n}^k(x,s) = v_{0n}^k(x,0) - v_{0n}^k(x,-s) & \text{on } \Omega \times (0,\infty), \end{cases} \tag{3.18}$$

whose energy functional is defined by

$$E^{v_n^k}(t) = \frac{1}{2}\left[|\partial_t v_n^k|^2 + |\nabla v_n^k|^2 + \|\zeta_n^{t,k}\|_{\mathcal{M}}^2 + 2\int_\Omega \int_0^{v_n^k} f^k(\tau)\, d\tau dx\right]. \tag{3.19}$$

Further, as $E^{v_n^k}(t) = \frac{1}{\alpha_n^2} E_n^k(t)$ for all $t \geq 0$ we deduce

$$E^{v_n^k}(0) = \frac{1}{\alpha_n^2} E_n^k(0) = 1 \tag{3.20}$$

for all $n > 0$, and also the existence of a subsequence $\{(v_n^k, \zeta_n^k)\}$ such that such that

$$\begin{aligned} v_n^k &\overset{*}{\rightharpoonup} v^k && \text{in } L^\infty(0,T; H_0^1(\Omega)),\\ \partial_t v_n^k &\overset{*}{\rightharpoonup} \partial_t v^k && \text{in } L^\infty(0,T; L^2(\Omega)),\\ v_n^k &\to v^k && \text{in } L^2(0,T; L^2(\Omega)), \end{aligned} \tag{3.21}$$

since $E^{v_n^k}(t) \leq E^{v_n^k}(0)$ for all $t \geq 0$. Moreover, by combining (3.13) and Lemma 3.3 we get

$$\lim_{n\to\infty} \int_0^T \int_{\Gamma_1} \int_0^\infty \mu(s) a(x) |\zeta_n^{t_k}|^2 ds\, d\Gamma\, dt = 0. \tag{3.22}$$

If we show that $E^{v_n^k}(T)$ goes to zero uniformly for each k fixed the desired contradiction is proved, since

$$E^{v_n^k}(T) = E^{v_n^k}(0) + \int_0^T \int_{\Gamma_1} \int_0^\infty \mu'(s) a(x) \zeta_n^{t,k}\, ds d\Gamma dt.$$

Indeed, for this purpose observe that, for an eventual subsequence, $\alpha_n \to \alpha$, where $\alpha \geq 0$. Therefore we separate the proof in two subcases: $\alpha > 0$ and $\alpha = 0$.

If $\alpha > 0$, since we have $\alpha_n v^n = u_n^k \to 0$ strongly in $L^2(0, T, L^2(\Omega))$, passing to the limit in (3.18) when $n \to \infty$, and taking (3.21) and (3.22) into account, we arrive at

$$\begin{cases} \partial_{tt} v^k - \Delta v^k + \frac{1}{\alpha} f^k(0) = 0 & \text{in } \Omega \times (0,\infty),\\ v^k = 0 & \text{on } \Gamma_0 \times (0,\infty),\\ \dfrac{\partial v^k}{\partial \nu} = 0 & \text{on } \Gamma_1 \times (0,\infty),\\ v^k(x,-t) = v^0(x,-t) & \text{in } \Omega \times (0,\infty)\\ v^k(x,0) = v_0^k(x) = v^0(x,0),\ \partial_t v^k(x,0) = v_1^k(x) = \partial_t v^0(x) & \text{in } \Omega \end{cases} \tag{3.23}$$

which implies, as in the Case I, that $v^k = 0$.

Now, consider $\alpha = 0$. Firstly notice that, by Taylor's formula, we have

$$\begin{aligned} \frac{1}{\alpha_n} f(\alpha_n v_n^k) &= \frac{f'(0)\alpha_n v_n^k}{\alpha_n} + \frac{R(\alpha_n v_n^k)}{\alpha_n},\\ \frac{|R(\alpha_n v_n^k)|}{\alpha_n} &\leq \frac{\alpha_n^2 |v_n^k|^2}{\alpha_n} + \frac{\alpha_n^p |v_n^k|^p}{\alpha_n}. \end{aligned} \tag{3.24}$$

Next, by defining the set $\Omega_n^t = \{x \in \Omega \text{ s.t. } |u_n^k(x,t)| > k\}$, we have, thanks to assumption $A.3$

and Sobolev's embbeding,

$$
\begin{aligned}
&\left\|\frac{1}{\alpha_n} f^k(v_n^k) - \frac{1}{\alpha_n} f(v_n^k)\right\|^2_{L^2(0,T;L^2(\Omega))} \\
&\quad = \left\|\frac{1}{\alpha_n} f^k(u_n^k) - \frac{1}{\alpha_n} f(u_n^k)\right\|^2_{L^2(0,T;L^2(\Omega))} \\
&\quad = \frac{1}{\alpha_n^2}\int_0^T \int_{\Omega_n^t} \left|f^k(u_n^k) - f(u_n^k)\right|^2 \, dxdt \\
&\quad \leq c\frac{1}{\alpha_n^2}\int_0^T \int_{\Omega_n^t} \left|f^k(u_n^k)\right|^2 \, dxdt + \frac{1}{\alpha_n^2}\int_0^T \int_{\Omega_n^t} \left|f(u_n^k)\right|^2 \, dxdt \\
&\quad \leq c\frac{1}{\alpha_n^2}\int_0^T \int_{\Omega_m^t} (|k|^2 + |k|^{2p}) \, dxdt + \frac{1}{\alpha_n^2}\int_0^T \int_{\Omega_n^t} (|u_n^k|^2 + |u_n^k|^{2p}) \, dxdt \\
&\quad \leq c\alpha_n^{2(p-1)} \left\|v_m^k\right\|^{2p}_{L^{2p}(0,T;L^{2p}(\Omega))} \longrightarrow 0.
\end{aligned}
\tag{3.25}
$$

Also, it is not difficult to see that, up to a subsequence,

$$
\frac{R(\alpha_n v_n^k)}{\alpha_n} \rightharpoonup 0 \quad \text{in } L^2(0,T;L^2(\Omega)). \tag{3.26}
$$

Therefore, from (3.24) – (3.26), and since

$$
\frac{1}{\alpha_n} f^k(\alpha_n v_n^k) - f'(0)v_n^k = \frac{1}{\alpha_n} f^k(u_n^k) - f'(0)v_k = \frac{1}{\alpha_n} f^k(u_n^k) - \frac{1}{\alpha_n} f(u_n^k) + \frac{1}{\alpha_n} f(u_n^k) - f'(0)v_k,
$$

one obtain

$$
\frac{1}{\alpha_n} f^k(\alpha_n v_n^k) - (f^k)'(0)v_k \to 0 \quad \text{in } L^2(0,T;L^2(\Omega)), \tag{3.27}
$$

By passing to the limit in (3.18) when $n \to \infty$, and taking (2.9), (3.22), (3.25) and (3.27) into account, we arrive at

$$
\begin{cases}
\partial_{tt} v^k - \Delta v^k + \frac{1}{\alpha}(f^k)'(0)v^k = 0 & \text{in } \Omega \times (0,\infty), \\
v^k = 0 & \text{on } \Gamma_0 \times (0,\infty), \\
\dfrac{\partial v^k}{\partial \nu} = 0 & \text{on } \Gamma_1 \times (0,\infty), \\
v^k(x,-t) = v^0(x,-t) & \text{in } \Omega \times (0,\infty) \\
v^k(x,0) = v_0^k(x) = v^0(x,0), \quad \partial_t v^k(x,0) = v_1^k(x) = \partial_t v^0(x) & \text{in } \Omega
\end{cases}
\tag{3.28}
$$

allowing us to conclude, as before, that $v^k = 0$. Thus, convergences (3.14) and (3.15) read as

$$
\begin{aligned}
v_n^k &\overset{*}{\rightharpoonup} 0 \quad \text{in } L^\infty(0,T : H_0^1(\Omega)), \\
\partial_t v_n^k &\overset{*}{\rightharpoonup} 0 \quad \text{in } L^\infty(0,T;L^2(\Omega)), \\
v_n^k &\to 0 \quad \text{in } L^2(0,T;L^2(\Omega)).
\end{aligned}
\tag{3.29}
$$

Besides that,

$$
\frac{1}{\alpha_n} f^k(\alpha_n v_n^k) \to 0 \quad \text{in } L^2(0,T,L^2(\Omega)). \tag{3.30}
$$

In light of these calculations, consider now $\phi_n^k(x,t) = \int_0^\infty \mu(s)\zeta_n^{t,k}(x,s)\, ds$ and $\theta \in C^\infty(0,T)$; $0 \le \theta < 1$; $\theta(t) = 1$ in $(\varepsilon, T-\varepsilon)$. Multiplying the first equation of (3.18) by $\psi_n = \theta\phi_n^k$ and integrating by parts, we infer

$$\begin{aligned}\mu_0 \int_0^T \int_\Omega |\partial_t v_n^k|^2 \theta dxdt = & -\int_0^T \int_\Omega \partial_t v_n^k \left(\int_0^\infty \mu(s)\partial_s v_n^k ds\right)\theta dxdt + \int_0^T \int_\Omega \nabla v_n^k \nabla \phi_n^k \theta dxdt \\ & -\int_0^T \int_\Omega \partial_t v_n^k \phi_n^k \theta_t dxdt + \int_0^T \int_{\Gamma_1} a(x)\left(\int_0^\infty \mu(s)\zeta_n^{t,k} ds\right)^2 \theta\, d\Gamma dt \\ & + \int_0^T \int_\Omega \frac{1}{\alpha_n} f^k(\alpha_n v_n^k)\phi_n^k \theta\, dxdt = I_1 + I_2 + I_3 + I_4 + I_5.\end{aligned} \tag{3.31}$$

From convergences (3.22), (3.29) and (3.30) it is not hard to conclude that

$$\lim_{n\to\infty} I_1 = \cdots = \lim_{n\to\infty} I_5 = 0.$$

Thus, $\lim_{n\to\infty} \int_\varepsilon^{T-\varepsilon} |\partial_t v_n^k|^2 dxdt = 0$, that is,

$$\lim_{n\to\infty} \int_0^T |\partial_t v_n^k|^2 dxdt = 0. \tag{3.32}$$

The next step is to show that the potential energy converges to zero. To this aim, we multiply the first equation of (3.18) by θv_n^k and integrate by parts to get

$$\begin{aligned}\int_0^T \int_\Omega |\nabla v_n^k|^2 \theta dxdt = & \int_0^T \int_\Omega |\partial_t v_n^k|^2 \theta dxdt + \int_0^T \int_\Omega \partial_t v_n^k v_n^k \theta_t dxdt \\ & - \int_0^T \int_{\Gamma_1} a(x) \int_0^\infty \mu(s)\zeta_n^{t,k} v_n^k \theta ds\, d\Gamma dt \\ & - \int_0^T \int_\Omega \frac{1}{\alpha_n} f^k(\alpha_n v_n^k) v_n^k \theta\, dxdt \\ = & J_1 + J_2 + J_3 + J_4,\end{aligned} \tag{3.33}$$

which, through an analysis similar to the performed previously, produces

$$\lim_{n\to\infty} \int_0^T \int_\Omega |\nabla v_n^k|^2 dxdt = 0. \tag{3.34}$$

Therefore, since $E^{v_n^k}(t)$ is non-increasing, from (3.30)–(3.34) we conclude that

$$\lim_{n\to\infty} E^{v_n^k}(T) = 0,$$

which concludes this proof. □

Proof of Theorem 3.2. Notice that since $C > 0$ in (3.10) does not depend on k, by arguing similarly to [7, Lemma 2.1 and Proposition 2.1] one can pass (3.10) to limit to obtain the observability inequality

$$E(0) \le C\left(\int_0^T \int_{\Gamma_1} \int_0^\infty -\mu'(s)a(x)|\eta^t(s)|^2\, dsd\Gamma dt\right) \tag{3.35}$$

and, consequently, the desired exponential stability. □

Abstract. This paper considers the existence of multiple normalized solutions of the following $(2, q)$-Laplacian equation:

$$\begin{cases} -\Delta u - \Delta_q u = \lambda u + h(\epsilon x) f(u), & \text{in } \mathbb{R}^N, \\ \int_{\mathbb{R}^N} |u|^2 \mathrm{d}x = a^2, \end{cases}$$

where $2 < q < N$, $\epsilon > 0, a > 0$ and $\lambda \in \mathbb{R}$ is a Lagrange multiplier which is unknown, h is a continuous positive function and f is also continuous satisfying L^2-subcritical growth. When ϵ is small enough, we show that the number of normalized solutions is at least the number of global maximum points of h by Ekeland's variational principle.

Keywords: normalized solution, multiplicity, $(2, q)$-Laplacian, variational methods.

2020 Mathematics Subject Classification: 35A15, 35B38, 35J60, 35J20.

1 Introduction

This paper is devoted to the existence of multiple normalized solutions, with $X := H^1(\mathbb{R}^N) \cap D^{1,q}(\mathbb{R}^N)$, of the following $(2, q)$-Laplacian equation:

$$-\Delta u - \Delta_q u = \lambda u + h(\epsilon x) f(u), \text{ in } \mathbb{R}^N \tag{1.1}$$

under the constraint

$$\int_{\mathbb{R}^N} |u|^2 \mathrm{d}x = a^2, \tag{1.2}$$

where $\epsilon, a > 0$, $\Delta_q u = \mathrm{div}(|\nabla u|^{q-2} \nabla u)$ is the q-Laplacian of u, $2 < q < N$ and $\lambda \in \mathbb{R}$ is a Lagrange multiplier which is unknown. The continuous function f satisfies the following conditions:

(f_1) f is odd and $\lim_{t \to 0} \frac{|f(t)|}{|t|^{p-1}} = \alpha > 0$ for some $p \in \left(2, 2 + \frac{4}{N}\right)$;

✉Corresponding author. Email: wangli.423@163.com

(f_2) There exist some constants $c_1, c_2 > 0$ and $p_1 \in (q, q + \frac{2q}{N})$ such that $|f(t)| \le c_1 + c_2|t|^{p_1-1}$, $\forall t \in \mathbb{R}$;

(f_3) the mapping $t \mapsto \frac{f(t)}{t^{q-1}}$ is a non-decreasing function when $t > 0$.

Hereafter, the continuous function h satisfies the following assumptions:

(h_1) $0 < h_0 = \inf_{x\in\mathbb{R}^N} h(x) \le \max_{x\in\mathbb{R}^N} h(x) = h_{\max}$;

(h_2) $h_\infty = \lim_{|x|\to+\infty} h(x) < h_{\max}$;

(h_3) $h^{-1}(\{h_{\max}\}) = \{e_1, e_2, \dots, e_l\}$ with $e_1 = 0$ and $e_j \ne e_k$ when $j \ne k$.

In particular, since restriction of (1.2), we are seeking normalized solutions to (1.1), which corresponds to seek critical points of the following functional

$$I_\epsilon(u) = \frac{1}{2}\int_{\mathbb{R}^N} |\nabla u|^2 dx + \frac{1}{q}\int_{\mathbb{R}^N} |\nabla u|^q dx - \int_{\mathbb{R}^N} h(\epsilon x)F(u) dx$$

on the sphere

$$S(a) := \left\{ u \in X := H^1(\mathbb{R}^N) \cap D^{1,q}(\mathbb{R}^N) : |u|_2^2 = \int_{\mathbb{R}^N} |u|^2\, dx = a^2 \right\}, \tag{1.3}$$

where $|\cdot|_\tau$ denotes the usual norm on $L^\tau(\mathbb{R}^N)$ for $\tau \in [1, +\infty)$ and $D^{1,q}(\mathbb{R}^N) := \{u \in L^{q^*}(\mathbb{R}^N) : \nabla u \in L^q(\mathbb{R}^N)\}$ with semi-norm $\|u\|_{D^{1,q}(\mathbb{R}^N)} = \|\nabla u\|_q$. Moreover, $\|u\|_X = \|u\|_{H^1(\mathbb{R}^N)} + \|u\|_{D^{1,q}(\mathbb{R}^N)}$. It is well known that $I_\epsilon \in C^1(X, \mathbb{R})$ and

$$\langle I'_\epsilon(u), \varphi\rangle = \int_{\mathbb{R}^N} \nabla u \nabla\varphi dx + \int_{\mathbb{R}^N} |\nabla u|^{q-2}\nabla u\nabla\varphi dx - \int_{\mathbb{R}^N} h(\epsilon x) f(u)\varphi dx$$

for all $u, \varphi \in X$.

The equation (1.1) is related to the general reaction-diffusion system

$$\partial_t u - \Delta_p u - \Delta_q u = f(x, u). \tag{1.4}$$

The system has wide range of applications in physics and related sciences, such as biophysics, chemical reaction and plasma physics. In such applications, the function u describes a concentration, the (p,q)-Laplacian term in (1.4) corresponds to the diffusion as $\operatorname{div}\left[\left(|\nabla u|^{p-2} + |\nabla u|^{q-2}\right)\nabla u\right] = \Delta_p u + \Delta_q u$, whereas the term $f(x,u)$ is the reaction and relates to sources and loss processes. Another model related to the (p,q)-Laplacian operator concerns the Lavrentiev gap phenomenon, which involved variational functions with non-standard (p,q) growth conditions, e.g., in [9,30].

The stationary version of equation (1.4)

$$-\Delta_p u - \Delta_q u = f(x,u), \quad x \in \mathbb{R}^N$$

has been extensively studied. Where $N \ge 3, 1 < p < q < N$, C. J. He et al. in [11] proved the existence of solution by mountain pass theorem and the concentration–compactness principle when f does not satisfy the Ambrosetti–Rabinowitz condition and they derived the regularity of weak solutions in [12]. Furthermore, when nonlinear function f is discontinuous and satisfies the Ambrosetti–Rabinowitz condition, the authors in [31] showed the existence of solution by mountain pass theorem and the concentration-compactness principle. Moreover, some researchers had studied the existence results for the nonlinear function f involving the critical Sobolev exponent in a bounded domain. G. B. Li et al. [21] studied $f = |u|^{p^*-2}u + \mu|u|^{r-2}u$ and obtained infinitely many weak solutions by genus theorem when $1 < r < q < p < N, \mu > 0$. Later on, in [28], the authors proved multiplicity of positive solutions by using the Lusternik–Schnirelman category theorem where $p < r < p^*$. [13] proved some nonexistence results where $N \geq 2, 1 < q < p < N$ and $1 < r < p^*$. Finally, we refer the interested readers works [8,29] for a development of the existence theory for various problems of the (p,q)-Laplacian.

In literature, the following equation

$$\begin{cases} -\Delta u + \lambda u = |u|^{p-2}u, \text{ in } \mathbb{R}^N, \\ \displaystyle\int_{\mathbb{R}^N} |u|^2 \mathrm{d}x = a^2 \end{cases} \tag{1.5}$$

has been widely studied by many researchers. In the L^2-subcritical problem, namely $2 < p < 2 + \frac{4}{N}$, it is well konwn that the functional

$$E(u) = \frac{1}{2}\int_{\mathbb{R}^N} |\nabla u|^2 \mathrm{d}x - \frac{1}{p}\int_{\mathbb{R}^N} |u|^p \mathrm{d}x, u \in H^1(\mathbb{R}^N)$$

is bounded from below on the set $\left\{u \in H^1(\mathbb{R}^N) : \|u\|_2^2 = \int_{\mathbb{R}^N} |u|^2 \, \mathrm{d}x = a^2\right\}$, so we can found a solution as a global minimizer on the sphere, see [24]. While in the L^2-supercritical problem, namely $2 + \frac{4}{N} < p < \frac{2N}{N-2}$, $E|_{S(a)}$ is unbounded from below. One of the main difficulties in dealing with normalized solutions is proving the Palais–Smale condition, as a compactness property. Jeanjean in [14] got one normalized solution by a mountain pass structure for an auxiliary functional. Furthermore, in [5], the authors obtained infinitely many normalized solutions by using linking geometry for a stretched functional. More results about L^2-supercritical problem can be found in [6,15]. Regarding the critical case, we cite the articles [7,23]. Furthermore, in a recent paper, Yang and Baldelli [27] considered the following equation

$$\begin{cases} -\Delta u - \Delta_q u + \lambda u = |u|^{p-2}u, \text{ in } \mathbb{R}^N, \\ \displaystyle\int_{\mathbb{R}^N} |u|^2 \mathrm{d}x = a^2 \end{cases}$$

in all the possible cases, where $2 < p < \min\{2^*, q^*\}$ and $1 < q < N$. They showed a ground state solution by using Ekeland's variational principle in L^2-subcritical case, while in L^2-critical case, they proved existence and nonexistence results, at last, they get a solution by using a natural constraint approach in L^2-supercritical case.

In addition, the multiplicity of normalized solutions has been wildly researched. For example, Jeanjean and Lu [18] studied the following problem

$$\begin{cases} -\Delta u = \lambda u + h(u), \text{ in } \mathbb{R}^N, \\ u > 0, \quad \displaystyle\int_{\mathbb{R}^N} |u|^2 \mathrm{d}x = a^2, \end{cases}$$

they obtained multiple normalized solutions by the variational methods and genus theory. More information about multiplicity of normalized solutions by using genus theory and deformation arguments, see [2,16,17]. Particularly, without use of the genus theory, the authors [19] studied the following problem

$$\begin{cases} -\Delta u + \lambda u = (I_\alpha * [h(\epsilon x)|u|^{\frac{N+\alpha}{N}}])h(\epsilon x)|u|^{\frac{N+\alpha}{N}-2}u + \mu|u|^{q-2}u, \quad x \in \mathbb{R}^N, \\ \displaystyle\int_{\mathbb{R}^N} |u|^2 \mathrm{d}x = a^2. \end{cases}$$

They showed multiple normalized solutions by Ekeland's variational principle when ϵ small enough, $\mu, a > 0$, $2 < q < 2 + \frac{4}{N}$, $\lambda \in \mathbb{R}$ and h is a continuous positive function satisfying (h_1)–(h_3).

This paper is devoted to study the problem (1.1)–(1.2), which has not been studied in our knowledge. In order to get the existence of multiple normalized solutions for (1.1), we will follow the variational methods in [19]. Moreover, since the workspace is $X = H^1(\mathbb{R}^N) \cap D^{1,q}(\mathbb{R}^N)$, it will be more complicated to obtain the strong $L^2(\mathbb{R}^N)$ convergence of the selected Palais-Smale sequence in X.

The main result of this paper is the following:

Theorem 1.1. *Assume that f satisfies (f_1)–(f_3) and h satisfies (h_1)–(h_3). Then, there exists ϵ_0 such that (1.1) has at least l couples weak solutions $(u_j, \lambda_j) \in X \times \mathbb{R}$ for $0 < \epsilon < \epsilon_0$. Moreover, $\lambda_j < 0$ and $I_\epsilon(u_j) < 0$ for $j = 1, 2, \ldots, l$.*

Now, we will give the outline about this paper. In Section 2, we prove a compactness theorem in the autonomous case. In Section 3, we use the compactness theorem to study the non-autonomous case. Finally, we give the proof of Theorem 1.1 in Section 4.

2 The autonomous case

Firstly, we consider the existence of normalized solution $(u, \lambda) \in X \times \mathbb{R}$, where $X = H^1(\mathbb{R}^N) \cap D^{1,q}(\mathbb{R}^N)$, for the problem below

$$\begin{cases} -\Delta u - \Delta_q u = \lambda u + \mu f(u), \\ \int_{\mathbb{R}^N} |u|^2 \mathrm{d}x = a^2, \end{cases} \tag{2.1}$$

where $a, \mu > 0$, $\lambda \in \mathbb{R}$ and f satisfies (f_1)–(f_3). It is well known that the critical point of the functional

$$J_\mu(u) = \frac{1}{2}\int_{\mathbb{R}^N} |\nabla u|^2 \mathrm{d}x + \frac{1}{q}\int_{\mathbb{R}^N} |\nabla u|^q \mathrm{d}x - \int_{\mathbb{R}^N} \mu F(u) \mathrm{d}x$$

is a solution to the problem (2.1), which is restricted to the sphere $S(a)$, where $F(t) = \int_0^t f(s)\mathrm{d}s$. Next, we will show that problem (2.1) has a normalized solution.

Lemma 2.1 ([20, Lemma 2.7]). *Assume that $k > 1$, Ω is an open set in $\mathbb{R}^N$, $\alpha, \beta > 0$ and $\Theta \in C(\Omega \times \mathbb{R}^N, \mathbb{R}^N)$ satisfying*

(1) $\alpha|\xi|^k \le \Theta(x, \xi)\xi$, $\forall (x, \xi) \in \Omega \times \mathbb{R}^N$,

(2) $|\Theta(x, \xi)| \le \beta|\xi|^{k-1}, \forall (x, \xi) \in \Omega \times \mathbb{R}^N$,

(3) $(\Theta(x, \xi) - \Theta(x, \eta))(\xi - \eta) > 0$, $\forall (x, \xi) \in \Omega \times \mathbb{R}^N$ with $\xi \neq \eta$,

(4) $\Theta(x, \gamma\xi) = \gamma|\gamma|^{k-2}\Theta(x, \xi)$, $\forall (x, \xi) \in \Omega \times \mathbb{R}^N$ and $\gamma \in \mathbb{R} \setminus \{0\}$.

Consider $(u_n), u \in W^{1,k}(\Omega)$, then $\nabla u_n \to \nabla u$ in $L^k(\Omega)$ if and only if

$$\lim_{n \to \infty} \int_\Omega (\Theta(x, \nabla u_n(x)) - \Theta(x, \nabla u(x)))(\nabla u_n(x) - \nabla u(x))\, \mathrm{d}x = 0.$$

Lemma 2.2. *The functional J_μ restricts to $S(a)$ is bounded from below.*

Proof. From the conditions (f_1)–(f_2), we can infer that there exist some constants $C_1, C_2 > 0$ such that

$$|F(t)| \leq C_1|t|^p + C_2|t|^{p_1}, \quad \forall t \in \mathbb{R}.$$

By the L^q-Gagliardo–Nirenberg inequality [1, Theorem 2.1], we get that

$$|u|_l \leq C|\nabla u|_q^{\nu_{l,q}}|u|_2^{(1-\nu_{l,q})}, \quad \forall u \in D^{1,q}(\mathbb{R}^N) \cap L^2(\mathbb{R}^N) \tag{2.2}$$

for some positive constant $C > 0$, where $\nu_{l,q} = \frac{Nq(l-2)}{l[Nq-2(N-q)]}$, $l \in (2, q^* = \frac{Nq}{N-q})$. Hence,

$$\begin{aligned} J_\mu(u) \geq \frac{1}{q}\int_{\mathbb{R}^N}|\nabla u|^q\mathrm{d}x - CC_1a^{(1-\nu_{p,q})p}\left(\int_{\mathbb{R}^N}|\nabla u|^q\mathrm{d}x\right)^{\frac{\nu_{p,q}p}{q}} \\ - CC_2a^{(1-\nu_{p_1,q})p_1}\left(\int_{\mathbb{R}^N}|\nabla u|^q\mathrm{d}x\right)^{\frac{\nu_{p_1,q}p_1}{q}}. \end{aligned} \tag{2.3}$$

As $p \in (2, 2+\frac{4}{N})$, $p_1 \in (q, q+\frac{2q}{N})$, clearly $\nu_{p,q}p, \nu_{p_1,q}p_1 < q$, which ensures the boundedness of J_μ from below. If J_μ is not bound from below, then there is u such that

$$\frac{1}{q}\int_{\mathbb{R}^N}|\nabla u|^q\mathrm{d}x - C\left(\int_{\mathbb{R}^N}|\nabla u|^q\mathrm{d}x\right)^{\frac{\nu_{p,q}p}{q}} - C\left(\int_{\mathbb{R}^N}|\nabla u|^q\mathrm{d}x\right)^{\frac{\nu_{p_1,q}p_1}{q}} \to -\infty,$$

which is a contradiction since $\nu_{p,q}p, \nu_{p_1,q}p_1 < q$. □

This lemma ensures that $m_\mu(a) := \inf_{u\in S(a)} J_\mu(u)$ is well defined.

Lemma 2.3. *Let $\mu, a > 0$, then $m_\mu(a) < 0$.*

Proof. By (f_1), we can deduce $\lim_{t\to 0}\frac{pF(t)}{t^p} = \alpha > 0$, which implies that, for some $\delta > 0$,

$$\frac{pF(t)}{t^p} \geq \frac{\alpha}{2} \tag{2.4}$$

for all $t \in [0, \delta]$. Let $0 < u_0 \in S(a) \cap L^\infty(\mathbb{R}^N)$, we set

$$H(u_0, r)(x) = e^{\frac{Nr}{2}}u_0(e^r x), \quad \forall x \in \mathbb{R}^N, \ \forall r \in \mathbb{R}.$$

It is well known that

$$\int_{\mathbb{R}^N}|H(u_0,r)(x)|^2\mathrm{d}x = a^2.$$

Furthermore, by a direct calculation, we have

$$\int_{\mathbb{R}^N}F(H(u_0,r)(x))\mathrm{d}x = e^{-Nr}\int_{\mathbb{R}^N}F(e^{\frac{Nr}{2}}u_0(x))\mathrm{d}x.$$

Then, for $r < 0$ and $|r|$ big enough, we have

$$0 \leq e^{\frac{Nr}{2}}u_0(x) \leq \delta, \quad \forall x \in \mathbb{R}^N.$$

Furthermore, by (2.4), we derive

$$\int_{\mathbb{R}^N}F(H(u_0,r)(x))\mathrm{d}x \geq \frac{\alpha}{2p}e^{\frac{(p-2)Nr}{2}}\int_{\mathbb{R}^N}|u_0(x)|^p\mathrm{d}x,$$

so,

$$J_\mu(H(u_0,r)) \leq \frac{e^{2r}}{2}\int_{\mathbb{R}^N}|\nabla u_0|^2\mathrm{d}x + \frac{e^{\frac{Nqr}{2}+rq-rN}}{2}\int_{\mathbb{R}^N}|\nabla u_0|^q\mathrm{d}x - \frac{\mu\alpha e^{\frac{(p-2)Nr}{2}}}{2p}\int_{\mathbb{R}^N}|u_0(x)|^p\mathrm{d}x.$$

Since $q>2, p\in\left(2,2+\frac{4}{N}\right)$, increasing $|r|$ if necessary, we get that

$$\frac{e^{2r}}{2}\int_{\mathbb{R}^N}|\nabla u_0|^2\mathrm{d}x + \frac{e^{\frac{Nqr}{2}+rq-rN}}{2}\int_{\mathbb{R}^N}|\nabla u_0|^q\mathrm{d}x - \frac{\mu\alpha e^{\frac{(p-2)Nr}{2}}}{2p}\int_{\mathbb{R}^N}|u_0(x)|^p\mathrm{d}x = A_r < 0,$$

then

$$J_\mu(H(u_0,r)) \leq A_r < 0,$$

showing that $m_\mu(a)<0$. □

Lemma 2.4. *If $\mu>0$, $a>0$, then*

(i) $a\mapsto m_\mu(a)$ is a continuous mapping;

(ii) if $a_1\in(0,a)$ and $a_2=\sqrt{a^2-a_1^2}$, we have $m_\mu(a)<m_\mu(a_1)+m_\mu(a_2)$.

Proof. (i) Let $a>0$ and $(a_n)\subset(0,+\infty)$ such that $a_n\to a$, we need to prove that $m_\mu(a_n)\to m_\mu(a)$. There exists $u_n\in S(a_n)$ such that $m_\mu(a_n)\leq J_\mu(u_n)<m_\mu(a_n)+\frac{1}{n}$ for every $n\in\mathbb{N}^+$. Firstly, we deduce from Lemma 2.3 that $m_\mu(a_n)<0$. Then by Lemma 2.2, we can get that (u_n) is bounded in X. Now considering $v_n:=\frac{a}{a_n}u_n\in S(a)$, since the boundedness of (u_n) and $a_n\to a$, we have

$$\begin{aligned}
m_\mu(a) &\leq J_\mu(v_n)\\
&= J_\mu(u_n)+\frac{1}{2}\left(\frac{a^2}{a_n^2}-1\right)\int_{\mathbb{R}^N}|\nabla u_n|^2\mathrm{d}x+\frac{1}{q}\left(\frac{a^q}{a_n^q}-1\right)\int_{\mathbb{R}^N}|\nabla u_n|^q\mathrm{d}x\\
&\quad+\int_{\mathbb{R}^N}\Big(\mu F(u_n)\mathrm{d}x-\mu F(\frac{a}{a_n}u_n)\Big)\mathrm{d}x\\
&= J_\mu(u_n)+o_n(1).
\end{aligned}$$

Let $n\to+\infty$, we can get $m_\mu(a)\leq\lim_{n\to+\infty}\inf m_\mu(a_n)$. In the same manner, let (w_n) be a bounded minimizing sequence of $m_\mu(a)$ and $z_n:=\frac{a_n}{a}w_n\in S(a_n)$, then we have

$$m_\mu(a_n)\leq J_\mu(z_n)=J_\mu(w_n)+o_n(1)\Longrightarrow \lim_{n\to+\infty}\sup m_\mu(a_n)\leq m_\mu(a),$$

so we get $m_\mu(a_n)\to m_\mu(a)$.

(ii) For any fix $a_1\in(0,a)$, we first claim that

$$m_\mu(\theta a_1)<\theta^2 m_\mu(a_1),\ \forall\theta>1. \tag{2.5}$$

Let $(u_n)\subset S(a_1)$ be a minimizing sequence for $m_\mu(a_1)$, then $u_n(\theta^{-\frac{2}{N}}x)\in S(\theta a_1)$. Since $\theta>1$ and $\frac{2(N-q)}{N}<\frac{2(N-2)}{N}<2$, we have

$$\begin{aligned}
m_\mu(\theta a_1)-\theta^2 J_\mu(u_n) &\leq J_\mu(u_n(\theta^{-\frac{2}{N}}x))-\theta^2 J_\mu(u_n)\\
&=\frac{\theta^{\frac{2(N-2)}{N}}-\theta^2}{2}|\nabla u_n|_2^2+\frac{\theta^{\frac{2(N-q)}{N}}-\theta^2}{q}|\nabla u_n|_q^q\leq 0.
\end{aligned}$$

As a consequence $m_\mu(\theta a_1) \le \theta^2 m_\mu(a_1)$. If $m_\mu(\theta a_1) = \theta^2 m_\mu(a_1)$, we will have $|\nabla u_n|_2^2 \to 0$ and $|\nabla u_n|_q^q \to 0$ as $n \to +\infty$, which can indicates that $\int_{\mathbb{R}^N} F(u_n)\mathrm{d}x \to 0$ by inequality (2.2). Then,

$$\begin{aligned}
0 &> m_\mu(a_1) \\
&= \lim_{n\to+\infty} J_\mu(u_n) = \frac{1}{2}\lim_{n\to+\infty}\int_{\mathbb{R}^N}|\nabla u_n|^2\mathrm{d}x + \frac{1}{q}\lim_{n\to+\infty}\int_{\mathbb{R}^N}|\nabla u_n|^q\mathrm{d}x - \lim_{n\to+\infty}\int_{\mathbb{R}^N}\mu F(u_n)\mathrm{d}x \\
&= 0,
\end{aligned}$$

which is a contradiction. So we get $m_\mu(\theta a_1) < \theta^2 m_\mu(a_1)$. In the same manner, we can get

$$m_\mu(\theta a_2) < \theta^2 m_\mu(a_2), \quad \forall \theta > 1. \tag{2.6}$$

Finally, apply (2.5) with $\theta = \frac{a}{a_1} > 1$ and (2.6) with $\theta = \frac{a}{a_2} > 1$ respectively, we get

$$m_\mu(a) = \frac{a_1^2}{a^2} m_\mu\left(\frac{a}{a_1}a_1\right) + \frac{a_2^2}{a^2} m_\mu\left(\frac{a}{a_2}a_2\right) < m_\mu(a_1) + m_\mu(a_2). \qquad \square$$

Next, we will show the compactness theorem on $S(a)$ which is useful for studying the autonomous and the nonautonomous case.

Proposition 2.5. *Assume that $(u_n) \subset S(a)$ is a minimizing sequence of $m_\mu(a)$. Then, for some subsequence, either*

(i) (u_n) is strongly convergent,

or

(ii) there exists a sequence $v_n(\cdot) = u(\cdot + y_n)$ with $|y_n| \to +\infty$ and $(y_n) \subset \mathbb{R}^N$, which is strongly convergent to a function $v \in S(a)$ with $J_\mu(v) = m_\mu(a)$.

Proof. It is easy to obtain the boundedness of sequence (u_n) by Lemma 2.2, then there is a subsequence $u_n \rightharpoonup u$ in X, which is still denoted as itself. For the case of $u \neq 0$ and $|u|_2 = b$, by the Brézis–Lieb lemma in [26], we can deduce that $b \in (0, a)$ and

$$\begin{aligned}
|u_n|_2^2 &= |u|_2^2 + |u_n - u|_2^2 + o_n(1), \\
|\nabla u_n|_2^2 &= |\nabla u|_2^2 + |\nabla(u_n - u)|_2^2 + o_n(1).
\end{aligned}$$

Moreover, according to the assumption of f, we can deduce

$$\int_{\mathbb{R}^N} F(u_n)\mathrm{d}x = \int_{\mathbb{R}^N} F(u)\mathrm{d}x + \int_{\mathbb{R}^N} F(u_n - u)\mathrm{d}x + o_n(1).$$

Now, we will prove $\nabla u_n \to \nabla u$ a.e. on $\mathbb{R}^N$, up to subsequences. Choose $\psi \in C_0^\infty(\mathbb{R}^N)$ satisfying $0 \le \psi \le 1$ in $\mathbb{R}^N$, $\psi(x) = 1$ for every $x \in B_1(0)$ and $\psi(x) = 0$ for every $x \in \mathbb{R}^N \setminus B_2(0)$. Take $R > 1$ and define $\psi_R(x) = \psi(x/R)$. Using the $\langle J'_\mu(u), \phi\rangle$ with $u = u_n$ and $\phi = (u_n - u)\psi_R$, we get

$$\begin{aligned}
&\int_{\mathbb{R}^N} \left[\nabla u_n - \nabla u + |\nabla u_n|^{q-2}\nabla u_n - |\nabla u|^{q-2}\nabla u\right](\nabla u_n - \nabla u)\psi_R\mathrm{d}x \\
&\quad= \langle J'_\mu(u_n), (u_n - u)\psi_R\rangle - \int_{\mathbb{R}^N}\nabla u_n u_n \nabla\psi_R\mathrm{d}x - \int_{\mathbb{R}^N}|\nabla u_n|^{q-2}\nabla u_n u_n\nabla\psi_R dx \\
&\qquad+ \int_{\mathbb{R}^N}\mu f(u_n)u_n\psi_R\mathrm{d}x + \int_{\mathbb{R}^N}\nabla u_n u\nabla\psi_R + \int_{\mathbb{R}^N}|\nabla u_n|^{q-2}\nabla u_n u\nabla\psi_R\mathrm{d}x \\
&\qquad- \int_{\mathbb{R}^N}\mu f(u_n)u\psi_R\mathrm{d}x - \int_{\mathbb{R}^N}\nabla u_n\nabla u\psi_R\mathrm{d}x - \int_{\mathbb{R}^N}|\nabla u|^{q-2}\nabla u\nabla u_n\psi_R\mathrm{d}x. \\
&\qquad+ \int_{\mathbb{R}^N}|\nabla u|^q\psi_R\mathrm{d}x + \int_{\mathbb{R}^N}|\nabla u|^2\psi_R\mathrm{d}x.
\end{aligned}$$

Since, $(u_n) \subset S(a)$ and $(J_\mu|_{S(a)})'(u_n) \to 0$, we have $\langle J'_\mu(u_n), (u_n - u)\psi_R\rangle \to 0$ as $n \to \infty$. Moreover, combining with the definition of ψ_R and $u_n \rightharpoonup u$ in X, we can get, as $n \to \infty$,

$$\int_{\mathbb{R}^N} \nabla u_n u_n \nabla \psi_R \mathrm{d}x - \int_{\mathbb{R}^N} \nabla u_n u \nabla \psi_R \mathrm{d}x \to 0,$$

$$\int_{\mathbb{R}^N} |\nabla u_n|^{q-2}\nabla u_n u_n \nabla \psi_R \mathrm{d}x - \int_{\mathbb{R}^N} |\nabla u_n|^{q-2}\nabla u_n u \nabla \psi_R \mathrm{d}x \to 0,$$

$$\int_{\mathbb{R}^N} \mu f(u_n) u_n \psi_R \mathrm{d}x - \int_{\mathbb{R}^N} \mu f(u_n) u \psi_R \mathrm{d}x \to 0,$$

$$\int_{\mathbb{R}^N} |\nabla u|^{q-2}\nabla u \nabla u_n \psi_R \mathrm{d}x \to \int_{\mathbb{R}^N} |\nabla u|^q \psi_R \mathrm{d}x,$$

$$\int_{\mathbb{R}^N} \nabla u_n \nabla u \psi_R \mathrm{d}x \to \int_{\mathbb{R}^N} |\nabla u|^2 \psi_R \mathrm{d}x.$$

So,

$$\lim_{n\to\infty} \int_{\mathbb{R}^N} \left[\nabla u_n - \nabla u + |\nabla u_n|^{q-2}\nabla u_n - |\nabla u|^{q-2}\nabla u\right] (\nabla u_n - \nabla u)\psi_R \mathrm{d}x = 0,$$

which is equivalent to

$$\lim_{n\to\infty} \int_{\mathbb{R}^N} (\nabla u_n - \nabla u)^2 \psi_R dx = 0, \ \lim_{n\to\infty} \int_{\mathbb{R}^N} (\nabla u_n - \nabla u)^q \psi_R \mathrm{d}x = 0.$$

Then, by Lemma 2.1 for $\Theta(x, \xi) = |\xi|^{k-2}\xi$ with $k = 2, k = q$, we have $\nabla u_n \to \nabla u$ in $L^2(B_2(0))$ and $L^q(B_2(0))$, which ensures that $\nabla u_n \to \nabla u$ a.e. on $\mathbb{R}^N$, up to subsequence. Now, applying Brézis–Lieb lemma in [26] again, we obtain

$$|\nabla u_n|_q^q = |\nabla u|_q^q + |\nabla(u_n - u)|_q^q + o_n(1).$$

Let $v_n = u_n - u$ and $|v_n|_2 = d_n \to d$, we can get that $a^2 = b^2 + d^2$ and $d_n \in (0, a)$ for n big enough. So,

$$m_\mu(a) + o_n(1) = J_\mu(u_n) = J_\mu(u) + J_\mu(v_n) + o_n(1) \geq m_\mu(d_n) + m_\mu(b) + o_n(1).$$

By the continuity of $a \mapsto m_\mu(a)$ (see Lemma 2.4(i)), we have

$$m_\mu(a) \geq m_\mu(d) + m_\mu(b),$$

which is contradicted to the conclusion of Lemma 2.4(ii), where $a^2 = b^2 + d^2$. This asserts that $|u|_2 = a$.

Combining with $|u_n|_2 = |u|_2 = a$, $u_n \rightharpoonup u$ in $L^2(\mathbb{R}^N)$ and $L^2(\mathbb{R}^N)$ is reflexive, we can get

$$u_n \to u \text{ in } L^2(\mathbb{R}^N). \tag{2.7}$$

Combining with the inequality (2.2) and $(f_1) - (f_2)$, we get

$$\int_{\mathbb{R}^N} F(u_n)\mathrm{d}x \to \int_{\mathbb{R}^N} F(u)\mathrm{d}x. \tag{2.8}$$

So

$$m_\mu(a) = J_\mu(u_n) + o_n(1) = J_\mu(u) + J_\mu(v_n) + o_n(1) \geq \frac{1}{2}|\nabla v_n|_2^2 + \frac{1}{q}|\nabla v_n|_q^q + m_\mu(a) + o_n(1),$$

which indicates $|\nabla v_n|_2^2, |\nabla v_n|_q^q \leq o_n(1)$. So we have $v_n \to 0$ in X, which means $u_n \to u$ in X.

Let us assume $u=0$, i.e., $u_n \rightharpoonup 0$ in X. Then, for some $\varsigma, r>0$ and $\{y_n\}\subset \mathbb{R}^N$, we have

$$\int_{B_r(y_n)} |u_n|^2 \mathrm{d}x \geq \varsigma, \ \forall y_n \in \mathbb{R}^N. \tag{2.9}$$

Otherwise we must have $u_n \to 0$ in $L^k(\mathbb{R}^N), \forall k\in(2,2^*)$, which implies $F(u_n)\to 0$ in $L^1(\mathbb{R}^N)$. But it contradicts to the fact that

$$0 > m_\mu(a) + o_n(1) = J_\mu(u_n) \geq -\int_{\mathbb{R}^N} F(u_n)\mathrm{d}x.$$

Then (2.9) holds. Since $u=0$, combining with the inequality (2.9) and the Sobolev embedding, we can infer that (y_n) is unbounded. Then we consider $v_n(x)=u(x+y_n)$, which is easy to check that (v_n) is also a minimizing sequence of $m_\mu(a)$ and $(v_n)\subset S(a)$. So, there holds $v_n \rightharpoonup v$ in X, where $v\in X\setminus\{0\}$. According to the proof of the first part, we deduce that $v_n \to v$ in X. □

Lemma 2.6. *Assume* (f_1)*–*(f_3) *hold,* $\mu>0$*. Then, problem* (2.1) *has a positive radial solution* u *and* $\lambda<0$*.*

Proof. We can assume that there is a bounded minimizing sequence $(u_n)\subset S(a)$ of $m_\mu(a)$ by Lemma 2.2. Then, applying Proposition 2.5, we can deduce $m_\mu(a)=J_\mu(u)$, where $u\in S(a)$. Thus, we can get that there exists a constant $\lambda_a\in\mathbb{R}$ such that

$$J'_\mu(u) = \lambda_a \Psi'(u) \text{ in } X', \tag{2.10}$$

where $\Psi(u) := \int_{\mathbb{R}^N} |u|^2\mathrm{d}x$. Then, according to (2.10),

$$-\Delta u - \Delta_q u = \lambda_a u + \mu f(u), \quad x\in\mathbb{R}^N,$$

and

$$\int_{\mathbb{R}^N} |\nabla u|^2\mathrm{d}x + \int_{\mathbb{R}^N} |\nabla u|^q\mathrm{d}x - \int_{\mathbb{R}^N} \lambda_a u^2\mathrm{d}x - \int_{\mathbb{R}^N} \mu f(u)u\mathrm{d}x = 0.$$

By (f_3), it is easy to obtain $qF(t)\leq f(t)t$ when $t\geq 0$, furthermore, since $m_\mu(a)=J_\mu(u)<0$, we get

$$\begin{aligned}
0 &> J_\mu(u) - \frac{1}{q}\Big(\int_{\mathbb{R}^N} |\nabla u|^2\mathrm{d}x + \int_{\mathbb{R}^N} |\nabla u|^q\mathrm{d}x - \int_{\mathbb{R}^N} \lambda_a u^2\mathrm{d}x - \int_{\mathbb{R}^N} \mu f(u)u\mathrm{d}x\Big) \\
&= (\frac{1}{2}-\frac{1}{q})\int_{\mathbb{R}^N} |\nabla u|^2\mathrm{d}x + \frac{1}{q}\int_{\mathbb{R}^N} \lambda_a u^2\mathrm{d}x + \frac{1}{q}\int_{\mathbb{R}^N} \mu f(u)u\mathrm{d}x - \int_{\mathbb{R}^N} \mu F(u)\mathrm{d}x \\
&\geq \frac{1}{q}\int_{\mathbb{R}^N} \lambda_a u^2\mathrm{d}x,
\end{aligned}$$

which implies that $\lambda_a<0$.

Next, we will show that u is positive. From the definition of $J_\mu(u)$, we have $J_\mu(|u|)=J_\mu(u)$. Moreover we can get $|u|\in S(a)$. Then, we deduce

$$m_\mu(a) = J_\mu(u) = J_\mu(|u|) \geq m_\mu(a).$$

Then we have $J_\mu(|u|)=m_\mu(a)$. Therefore, we replace u by $|u|$. If u^* is the Schwarz's Symmetrization of u [22, Section 3.3], we have

$$\int_{\mathbb{R}^N} |\nabla u|^2\mathrm{d}x \geq \int_{\mathbb{R}^N} |\nabla u^*|^2\mathrm{d}x, \quad \int_{\mathbb{R}^N} |\nabla u|^q\mathrm{d}x \geq \int_{\mathbb{R}^N} |\nabla u^*|^q\mathrm{d}x$$

and
$$\int_{\mathbb{R}^N} F(u)\mathrm{d}x = \int_{\mathbb{R}^N} F(u^*)\mathrm{d}x.$$
It is easy to check that $u^* \in S(a)$ and $J_\mu(u^*) = m_\mu(a)$. Thus, we replace u by u^*.

Next, we prove $u(x)$ is positive for all $x \in \mathbb{R}^N$. Firstly, we assume that the conclusion is false, then there is $x_0 \in \mathbb{R}^N$ satisfying $u(x_0) = 0$. Furthermore, we can assume that there is $x_1 \in \mathbb{R}^N$ satisfying $u(x_1) > 0$ by $u \neq 0$. Thus, we can find a ball with a sufficiently large radius $R > 0$ such that $x_0, x_1 \in B_R(0)$. Then, combining with the Harnack Inequality ([10, Theorem 8.20]), we can infer there is a constant $C > 0$ such that
$$\sup_{y\in B_R(0)} u(y) \leq C \inf_{y\in B_R(0)} u(y),$$
which contradicts to the fact that
$$\sup_{y\in B_R(0)} u(y) \geq u(x_1) > 0 \quad \text{and} \quad \inf_{y\in B_R(0)} u(y) = u(x_0) = 0. \qquad \square$$

The next corollary is obtained by Lemma 2.6.

Corollary 2.7. *Fix $a > 0$ and let $0 \leq \mu_1 < \mu_2$. Then, $m_{\mu_2}(a) < m_{\mu_1}(a) < 0$.*

Proof. Let $u_{\mu_1} \in S(a)$ satisfy $J_{\mu_1}(u_{\mu_1}) = m_{\mu_1}(a)$, then
$$m_{\mu_2}(a) \leq J_{\mu_2}(u_{\mu_1}) < J_{\mu_1}(u_{\mu_1}) = m_{\mu_1}(a). \qquad \square$$

3 The nonautonomous case

Next, we will show some properties of $I_\epsilon : X \to \mathbb{R}$,
$$I_\epsilon(u) = \frac{1}{2}\int_{\mathbb{R}^N} |\nabla u|^2\mathrm{d}x + \frac{1}{q}\int_{\mathbb{R}^N} |\nabla u|^q\mathrm{d}x - \int_{\mathbb{R}^N} h(\epsilon x)F(u)\mathrm{d}x,$$
which is restricted to $S(a)$.

Firstly, we define $I_{\max}, I_\infty : X \to \mathbb{R}$ as
$$I_{\max}(u) = \frac{1}{2}\int_{\mathbb{R}^N} |\nabla u|^2\mathrm{d}x + \frac{1}{q}\int_{\mathbb{R}^N} |\nabla u|^q\mathrm{d}x - \int_{\mathbb{R}^N} h_{\max}F(u)\mathrm{d}x$$
and
$$I_\infty(u) = \frac{1}{2}\int_{\mathbb{R}^N} |\nabla u|^2\mathrm{d}x + \frac{1}{q}\int_{\mathbb{R}^N} |\nabla u|^q\mathrm{d}x - \int_{\mathbb{R}^N} h_\infty F(u)\mathrm{d}x.$$
Moreover, Lemma 2.2 guarantees that
$$m_\infty(a) = \inf_{u\in S(a)} I_\infty(u),\ m_\epsilon(a) = \inf_{u\in S(a)} I_\epsilon(u),\ m_{\max}(a) = \inf_{u\in S(a)} I_{\max}(u).$$
Then, according to Corollary 2.7 and $h_\infty < h_{\max}$, we can immediately get
$$m_{\max}(a) < m_\infty(a) < 0. \tag{3.1}$$

Now, we fix $0 < \rho_1 = \frac{1}{2}(m_\infty(a) - m_{\max}(a))$.

Lemma 3.1. $\lim_{\epsilon\to 0^+} m_\epsilon(a) \leq m_{\max}(a)$. *Hence, there exists $\epsilon_0 > 0$ such that $m_\epsilon(a) < m_\infty(a)$ for all $0 < \epsilon < \epsilon_0$.*

Proof. Let $u_0 \in S(a)$ satisfying $I_{\max}(u_0) = m_{\max}(a)$. A simple calculus gives that

$$m_\epsilon(a) \leq I_\epsilon(u_0) = \frac{1}{2}\int_{\mathbb{R}^N} |\nabla u_0|^2 dx + \frac{1}{q}\int_{\mathbb{R}^N} |\nabla u_0|^q dx - \int_{\mathbb{R}^N} h(\epsilon x)F(u_0)dx.$$

Letting $\epsilon \to 0^+$ and applying (h_3) we can get

$$\limsup_{\epsilon\to 0^+} m_\epsilon(a) \leq \lim_{\epsilon\to 0^+} I_\epsilon(u_0) = I_{\max}(u_0) = m_{\max}(a).$$

According to (3.1), we obtain $m_\epsilon(a) < m_\infty(a)$ for ϵ small enough. □

The following two lemmas will be used to prove $(PS)_c$ condition for I_ϵ at some levels.

Lemma 3.2. *Assume that $(u_n) \subset S(a)$ is a minimizing sequence with $I_\epsilon(u_n) \to c$ and $c < m_{\max}(a) + \rho_1 < 0$. If $u_n \rightharpoonup u$ in X, then $u \neq 0$.*

Proof. Firstly, we assume the conclusion is false, i.e., $u \equiv 0$. Then, we have

$$c = m_\epsilon(a) = I_\epsilon(u_n) + o_n(1) = I_\infty(u_n) + \int_{\mathbb{R}^N} (h_\infty - h(\epsilon x))\, F(u_n)dx + o_n(1).$$

According to (h_2), there exist some constants $\xi, R > 0$ such that

$$h_\infty \geq h(x) - \xi, \quad |x| > R.$$

Thus, we have the following estimate

$$c = I_\epsilon(u_n) + o_n(1) \geq I_\infty(u_n) + \int_{B_{R/\epsilon}(0)} (h_\infty - h(\epsilon x))\, F(u_n)dx - \xi \int_{B^c_{R/\epsilon}(0)} F(u_n)dx + o_n(1).$$

Recalling that (u_n) is bounded in X, then for some constant $C > 0$, there holds

$$\int_{\mathbb{R}^N} F(u_n)dx \leq C_1 \left(\int_{\mathbb{R}^N} |\nabla u|^q dx\right)^{\frac{\nu_{p,q}p}{q}} + C_2 \left(\int_{\mathbb{R}^N} |\nabla u|^q dx\right)^{\frac{\nu_{p_1,q}p_1}{q}} \leq C.$$

By the fact of $u_n \to 0$ in $L^l(B_{R/\epsilon}(0))$ when $l \in [1, 2^*)$, one has

$$c = I_\epsilon(u_n) + o_n(1) \geq I_\infty(u_n) - \xi C > m_\infty(a) - \xi C + o_n(1),$$

which combines with the arbitrariness of $\xi > 0$, we can get

$$c \geq m_\infty(a),$$

which contradicts to the fact that $c < m_{\max}(a) + \rho_1 < m_\infty(a)$. So, we can get that $u \neq 0$. □

Lemma 3.3. *Assume that $(u_n) \subset S(a)$ is a $(PS)_c$ sequence of I_ϵ satisfying $u_n \rightharpoonup u_\epsilon$ in X when $c < m_{\max}(a) + \rho_1 < 0$, that is, as $n \to +\infty$,*

$$I_\epsilon(u_n) \to c \quad \text{and} \quad \|I_\epsilon|'_{S(a)}(u_n)\| \to 0.$$

Then there holds

$$\liminf_{n\to+\infty} |u_n - u_\epsilon|_2^2 \geq \beta,$$

where $u_n \nrightarrow u_\epsilon$ in X and $\beta > 0$ independent of $\epsilon \in (0, \epsilon_0)$.

Proof. Firstly, defining the functional $\Psi : X \to \mathbb{R}$ with $\Psi(u) = \frac{1}{2}\int_{\mathbb{R}^N} |u|^2 dx$, we can see $S(a) = \Psi^{-1}(\{a^2/2\})$. According to [26, Proposition 5.12], there exist $(\lambda_n) \subset \mathbb{R}$ such that

$$\|I_\epsilon'(u_n) - \lambda_n \Psi'(u_n)\|_{X'} \to 0 \quad \text{as } n \to +\infty.$$

(u_n) is bounded in X since I_ϵ is bounded from below and coercive as J_μ, which ensures that (λ_n) is bounded, then there exists λ_ϵ such that $\lambda_n \to \lambda_\epsilon$ as $n \to +\infty$. Thus, we have

$$I_\epsilon'(u_\epsilon) - \lambda_\epsilon \Psi'(u_\epsilon) = 0 \quad \text{in } X',$$

and

$$\|I_\epsilon'(v_n) - \lambda_\epsilon \Psi'(v_n)\|_{X'} \to 0 \quad \text{as } n \to +\infty,$$

where $v_n := u_n - u_\epsilon$. According to (f_3), we can get $qF(t) \le f(t)t$ when $t \ge 0$. Then we have

$$0 > \rho_1 + m_{\max}(a) > c = \liminf_{n\to+\infty} I_\epsilon(u_n) = \liminf_{n\to+\infty}\left(I_\epsilon(u_n) - \frac{1}{q}\langle I_\epsilon'(u_n), u_n\rangle + \frac{1}{q}\lambda_n a^2\right) \ge \frac{1}{q}\lambda_\epsilon a^2,$$

which implies that

$$\limsup_{\epsilon\to 0} \lambda_\epsilon \le \frac{q(\rho_1 + m_{\max}(a))}{a^2} < 0.$$

Then, there is a constant λ^* satisfying $\lambda_\epsilon < \lambda^* < 0$, which is independent of ϵ. Therefore,

$$\int_{\mathbb{R}^N} |\nabla v_n|^2 dx + \int_{\mathbb{R}^N} |\nabla v_n|^q dx - \lambda_\epsilon \int_{\mathbb{R}^N} |v_n|^2 dx = \int_{\mathbb{R}^N} h(\epsilon x) f(v_n) v_n dx + o_n(1),$$

and

$$\int_{\mathbb{R}^N} |\nabla v_n|^2 dx + \int_{\mathbb{R}^N} |\nabla v_n|^q dx - \lambda^* \int_{\mathbb{R}^N} |v_n|^2 dx \le \int_{\mathbb{R}^N} h(\epsilon x) f(v_n) v_n dx + o_n(1).$$

According to (f_1), we get $f(t) < \varepsilon t, \forall \varepsilon > 0$ if t small enough, which combines with (f_2) to give

$$\int_{\mathbb{R}^N} f(v_n) v_n dx \le C_2 \int_{\mathbb{R}^N} |v_n|^{p_1} dx + \varepsilon \int_{\mathbb{R}^N} |v_n|^2 dx \le C_2 \int_{\mathbb{R}^N} |v_n|^{p_1} dx.$$

So, we obtain

$$\begin{aligned}\int_{\mathbb{R}^N} |\nabla v_n|^2 dx + \int_{\mathbb{R}^N} |\nabla v_n|^q dx + C_0 \int_{\mathbb{R}^N} |v_n|^2 dx \\ \le h_{\max} \int_{\mathbb{R}^N} f(v_n) v_n dx \le C_2 h_{\max} \int_{\mathbb{R}^N} |v_n|^{p_1} dx + o_n(1)\end{aligned}$$

for some constant $C_0 > 0$ independent of $\epsilon \in (0, \epsilon_0)$. Since $v_n \nrightarrow 0$ in X, we can assume that $\liminf_{n\to+\infty} \|v_n\|_X > C > 0$. Thus, there holds

$$\liminf_{n\to+\infty} |v_n|_{p_1}^{p_1} \ge C_3 \tag{3.2}$$

for some constant $C_3 > 0$. By (2.2), we can deduce

$$C_3 \le \liminf_{n\to+\infty} |v_n|_{p_1}^{p_1} \le C(\liminf_{n\to+\infty} |v_n|_2)^{(1-\nu_{p_1,q})p_1} K^{\nu_{p_1,q} p_1}, \tag{3.3}$$

where $K > 0$ is independent of $\epsilon \in (0, \epsilon_0)$ with $\|v_n\| \le K$ for all $n \in \mathbb{N}$. Then, combining with (3.2), and (3.3), we achieve the proof. □

Next, we consider $0 < \rho < \min\{\frac{1}{2}, \frac{\beta}{a^2}\}(m_\infty(a) - m_{\max}(a))$.

Lemma 3.4. *Assume that $0 < \epsilon < \epsilon_0$ and $c < m_{\max}(a) + \rho$. Then, I_ϵ restricted to $S(a)$ satisfies the $(PS)_c$ condition.*

Proof. Firstly, we can get that (u_n) is bounded by Lemma 2.2, then let $(u_n) \subset S(a)$ be $(PS)_c$ sequence of I_ϵ with $u_n \rightharpoonup u_\epsilon$, where $u_\epsilon \neq 0$ by Lemma 3.2 and $c < m_{\max}(a) + \rho$. Set $v_n = u_n - u_\epsilon$. If $v_n \to 0$ in X, the proof is complete. If $v_n \nrightarrow 0$ in X and $|u_\epsilon|_2 = b$, by Lemma 3.3, we have

$$\liminf_{n\to+\infty} |v_n|_2^2 \geq \beta \tag{3.4}$$

for some $\beta > 0$ which is independent of $\epsilon \in (0, \epsilon_0)$.

Let $|v_n|_2 = d_n \to d \geq \beta^{\frac{1}{2}}$, we have $a^2 = b^2 + d^2$. From $d_n \in (0, a)$ for n large enough, we can deduce

$$c + o_n(1) = I_\epsilon(u_n) = I_\epsilon(v_n) + I_\epsilon(u_\epsilon) + o_n(1) \geq m_\infty(d_n) + m_{\max}(b) + o_n(1).$$

Applying Lemma 2.4(i) and inequality (2.5), letting $n \to +\infty$, we get

$$m_{\max}(a) + \rho > c \geq m_\infty(d) + m_{\max}(b) \geq \frac{d^2}{a^2} m_\infty(a) + \frac{b^2}{a^2} m_{\max}(a).$$

Then

$$\rho \geq \frac{d^2}{a^2}(m_\infty(a) - m_{\max}(a)) \geq \frac{\beta}{a^2}(m_\infty(a) - m_{\max}(a)),$$

which is contradicted to the fact of $\rho < \frac{\beta}{a^2}(m_\infty(a) - m_{\max}(a))$. Then, it holds $v_n \to 0$ in X, that is, $u_n \to u_\epsilon$ in X, which implies that $u_\epsilon \in S(a)$ and

$$-\Delta u_\epsilon - \Delta_q u_\epsilon = \lambda_\epsilon u_\epsilon + h(\epsilon x) f(u_\epsilon), \quad x \in \mathbb{R}^N.$$

□

4 Multiplicity result

In the following, we do some technical stuff. Let $\rho_0, r_0 > 0$, e_j be defined in (h_3), satisfying:

- $\overline{B_{\rho_0}(e_i)} \cap \overline{B_{\rho_0}(e_j)} = \emptyset$ for $i \neq j$ and $i, j \in \{1, \ldots, l\}$.
- $\bigcup_{i=1}^{l} B_{\rho_0}(e_i) \subset B_{r_0}(0)$.
- $K_{\frac{\rho_0}{2}} = \bigcup_{i=1}^{l} \overline{B_{\frac{\rho_0}{2}}(e_i)}$.

Set $\kappa : \mathbb{R}^N \to \mathbb{R}^N$ with

$$\kappa(x) := \begin{cases} x, & \text{if } |x| \leq r_0, \\ r_0 \frac{x}{|x|}, & \text{if } |x| > r_0. \end{cases}$$

Now we consider the function $G_\epsilon : X \backslash \{0\} \to \mathbb{R}^N$ with

$$G_\epsilon(u) := \frac{\int_{\mathbb{R}^N} \kappa(\epsilon x)|u|^2 \mathrm{d}x}{\int_{\mathbb{R}^N} |u|^2 \mathrm{d}x},$$

Then, we will get the existence of (PS) sequences of I_ϵ, which is restricted to $S(a)$ by the next two lemmas.

Lemma 4.1. *Decreasing ϵ_0 if necessary, there exists a positive constant $\delta_0 < \rho$ such that*

$$G_\epsilon(u) \in K_{\frac{\rho_0}{2}}, \quad \forall \epsilon \in (0, \epsilon_0),$$

where $u \in S(a)$ and $I_\epsilon(u) \leq m_{\max}(a) + \delta_0$.

Proof. We assume that the conclusion is false, so there exist $\delta_n \to 0$, $u_n \in S(a)$ and $\epsilon_n \to 0$ such that

$$I_{\epsilon_n}(u_n) \leq m_{\max}(a) + \delta_n$$

and

$$G_{\epsilon_n}(u_n) \notin K_{\frac{\rho_0}{2}}.$$

Firstly, we know

$$m_{\max}(a) \leq I_{\max}(u_n) \leq I_{\epsilon_n}(u_n) \leq m_{\max}(a) + \delta_n,$$

then,

$$I_{\max}(u_n) \to m_{\max}(a), \quad \text{as } n \to \infty.$$

We will analyze the following two cases by Proposition 2.5.

(i) $u_n \to u$ in X, where $u \in S(a)$. According to the Lebesgue dominated convergence theorem, we can deduce that

$$G_{\epsilon_n}(u_n) = \frac{\int_{\mathbb{R}^N} \kappa(\epsilon_n x)|u_n|^2 \mathrm{d}x}{\int_{\mathbb{R}^N} |u_n|^2 \mathrm{d}x} \to \frac{\int_{\mathbb{R}^N} \kappa(0)|u|^2 \mathrm{d}x}{\int_{\mathbb{R}^N} |u|^2 \mathrm{d}x} = 0 \in K_{\frac{\rho_0}{2}},$$

which contradicts to $G_{\epsilon_n}(u_n) \notin K_{\frac{\rho_0}{2}}$ for n large.

(ii) There exists a sequence $v_n(\cdot) = u(\cdot + y_n)$ with $|y_n| \to +\infty$ and $(y_n) \subset \mathbb{R}^N$, which is convergent in X for some $v \in S(a)$. Then, we can also study the following two cases:

When $|\epsilon_n y_n| \to +\infty$, we can deduce that

$$I_{\epsilon_n}(u_n) = \frac{1}{2}\int_{\mathbb{R}^N} |\nabla v_n|^2 \mathrm{d}x + \frac{1}{q}\int_{\mathbb{R}^N} |\nabla v_n|^q \mathrm{d}x - \int_{\mathbb{R}^N} h(\epsilon_n x + \epsilon_n y_n) F(v_n) \mathrm{d}x \to I_\infty(v).$$

Since $I_{\epsilon_n}(u_n) \leq m_{\max}(a) + \delta_n$, there holds

$$m_{\max}(a) \geq I_\infty(v) \geq m_\infty(a),$$

which contradicts to (3.1).

When $\epsilon_n y_n \to y$ for some $y \in \mathbb{R}^N$, we get

$$I_{\epsilon_n}(u_n) = \frac{1}{2}\int_{\mathbb{R}^N} |\nabla v_n|^2 \mathrm{d}x + \frac{1}{q}\int_{\mathbb{R}^N} |\nabla v_n|^q \mathrm{d}x - \int_{\mathbb{R}^N} h(\epsilon_n x + \epsilon_n y_n) F(v_n) \mathrm{d}x \to I_{h(y)}(v),$$

then we obtain

$$m_{h(y)}(a) \leq m_{\max}(a). \tag{4.1}$$

If $h(y) < h_{\max}$, Corollary 2.7 implies that $m_{h(y)}(a) > m_{\max}(a)$, which contradicts to (4.1). Thus, it holds $h(y) = h_{\max}$, which means $y = e_i$ for some $i = 1, \ldots, l$. Then we have

$$G_{\epsilon_n}(u_n) = \frac{\displaystyle\int_{\mathbb{R}^N} \kappa(\epsilon_n x)|u_n|^2 \mathrm{d}x}{\displaystyle\int_{\mathbb{R}^N} |u_n|^2 \mathrm{d}x} = \frac{\displaystyle\int_{\mathbb{R}^N} \kappa(\epsilon_n x + \epsilon_n y_n)|v_n|^2 \mathrm{d}x}{\displaystyle\int_{\mathbb{R}^N} |v_n|^2 \mathrm{d}x} \to \frac{\displaystyle\int_{\mathbb{R}^N} \kappa(y)|v|^2 \mathrm{d}x}{\displaystyle\int_{\mathbb{R}^N} |v|^2 \mathrm{d}x} = e_i \in K_{\frac{\rho_0}{2}},$$

which contradicts to $G_{\epsilon_n}(u_n) \notin K_{\frac{\rho_0}{2}}$ for n large. □

Next, we introduce some notations:

- $\theta_\epsilon^i := \{u \in S(a); |G_\epsilon(u) - e_i| \le \rho_0\}$,
- $\partial\theta_\epsilon^i := \{u \in S(a); |G_\epsilon(u) - e_i| = \rho_0\}$,
- $\eta_\epsilon^i := \inf_{u\in\theta_\epsilon^i} I_\epsilon(u)$,
- $\tilde{\eta}_\epsilon^i := \inf_{u\in\partial\theta_\epsilon^i} I_\epsilon(u)$.

Lemma 4.2. *Let* $0 < \delta_0 < \rho < \min\{\frac{1}{2}, \frac{\beta}{a^2}\}(m_\infty(a) - m_{\max}(a))$. *Then, there holds*

$$\eta_\epsilon^i < m_{\max}(a) + \rho \quad and \quad \eta_\epsilon^i < \tilde{\eta}_\epsilon^i, \quad \forall \epsilon \in (0, \epsilon_0).$$

Proof. By Proposition (2.5), we set that

$$m_{\max}(a) = I_{\max}(u), \ I'_{\max}(u) = 0,$$

where $u \in S(a)$. Let $u_\epsilon^i : \mathbb{R}^N \to \mathbb{R}$ be $u_\epsilon^i(x) = u(x - e_i/\epsilon)$ for $1 \le i \le l$. By direct calculation, we get

$$I_\epsilon(u_\epsilon^i(x)) = \frac{1}{2}\int_{\mathbb{R}^N} |\nabla u|^2 \mathrm{d}x + \frac{1}{q}\int_{\mathbb{R}^N} |\nabla u|^q \mathrm{d}x - \int_{\mathbb{R}^N} h(\epsilon x + e_i)F(u)\mathrm{d}x,$$

which implies that

$$\limsup_{\epsilon\to 0} I_\epsilon(u_\epsilon^i(x)) \le I_{\max}(u) = m_{\max}(a). \tag{4.2}$$

If $\epsilon \to 0^+$, there holds

$$G_\epsilon(u_\epsilon^i) = \frac{\displaystyle\int_{\mathbb{R}^N} \kappa(\epsilon x)|u_\epsilon^i|^2 \mathrm{d}x}{\displaystyle\int_{\mathbb{R}^N} |u_\epsilon^i|^2 \mathrm{d}x} = \frac{\displaystyle\int_{\mathbb{R}^N} \kappa(\epsilon x + e_i)|u|^2 \mathrm{d}x}{\displaystyle\int_{\mathbb{R}^N} |u|^2 \mathrm{d}x} \to e_i.$$

Then we can infer that $u_\epsilon^i \in \theta_\epsilon^i$ when ϵ is small enough. Moreover, by (4.2),

$$I_\epsilon(u_\epsilon^i(x)) \le m_{\max}(a) + \frac{\delta_0}{4}, \quad \forall \epsilon \in (0, \epsilon_0).$$

From this, decreasing ϵ_0 if necessary,

$$\eta_\epsilon^i \le m_{\max}(a) + \frac{\delta_0}{4}, \quad \forall \epsilon \in (0, \epsilon_0).$$

Then,

$$\eta_\epsilon^i \le m_{\max}(a) + \rho, \quad \forall \epsilon \in (0, \epsilon_0),$$

showing the first inequality.

If there holds $u \in \partial\theta_\epsilon^i$, i.e.,

$$u \in S(a) \quad \text{and} \quad |G_\epsilon(u) - e_i| = \rho_0 > \frac{\rho_0}{2},$$

which implies $G_\epsilon(u) \notin K_{\frac{\rho_0}{2}}$. Then, combining with Lemma 4.1, we have

$$I_\epsilon(u) > m_{\max}(a) + \frac{\delta_0}{2}, \quad \forall u \in \partial\theta_\epsilon^i, \quad \forall \epsilon \in (0, \epsilon_0),$$

and so,

$$\tilde{\eta}_\epsilon^i \ge m_{\max}(a) + \frac{\delta_0}{2}, \quad \forall \epsilon \in (0, \epsilon_0),$$

from which it follows that

$$\eta_\epsilon^i < \tilde{\eta}_\epsilon^i, \quad \forall \epsilon \in (0, \epsilon_0).$$

□

4.1 Proof of Theorem 1.1

By Ekeland's variational principle, we can get that there exists a sequence $(u_n^i) \subset S(a)$ such that

$$I_\epsilon(u_n^i) \to \eta_\epsilon^i$$

and

$$I_\epsilon(v) - I_\epsilon(u_n^i) \geq -\frac{1}{n}\|v - u_n^i\|, \quad \forall v \in \theta_\epsilon^i \quad \text{with} \quad v \neq u_n^i$$

for each $i \in \{1, \ldots, l\}$. Then, we get $u_n^i \in \theta_\epsilon^i \setminus \partial\theta_\epsilon^i$ for n large enough by Lemma 4.2.

Given $v \in T_{u_n^i} S(a) = \{w \in X : \int_{\mathbb{R}^N} u_n^i w \mathrm{d}x = 0\}$, we can define the path $\sigma : (-\xi, \xi) \to S(a)$ with

$$\sigma(t) = a \frac{(u_n^i + tv)}{|u_n^i + tv|_2},$$

where $\xi > 0$. It is obvious to know that $\sigma \in C^1((-\xi, \xi), S(a))$ and we have

$$\sigma(t) \in \theta_\epsilon^i \backslash \partial\theta_\epsilon^i, \ \forall t \in (-\xi, \xi), \ \sigma(0) = u_n^i \text{ and } \sigma'(0) = v.$$

Then we get

$$I_\epsilon(\sigma(t)) - I_\epsilon(u_n^i) \geq -\frac{1}{n}\|\sigma(t) - u_n^i\|$$

for $t \in (-\xi, \xi)$, which implies that

$$\begin{aligned}
\frac{I_\epsilon(\sigma(t)) - I_\epsilon(\sigma(0)))}{t} &= \frac{I_\epsilon(\sigma(t)) - I_\epsilon(u_n^i)}{t} \\
&\geq -\frac{1}{n}\left\|\frac{\sigma(t) - u_n^i}{t}\right\| \\
&= -\frac{1}{n}\left\|\frac{\sigma(t) - \sigma(0)}{t}\right\|, \quad \forall t \in (0, \xi).
\end{aligned}$$

Taking the limit of $t \to 0^+$, we have

$$\langle I_\epsilon'(u_n^i), v\rangle \geq -\frac{1}{n}\|v\|.$$

Then, we can replace v by $-v$ to deduce

$$\sup\{|\langle I_\epsilon'(u_n^i), v\rangle| : \|v\| \leq 1\} \leq \frac{1}{n},$$

which implies that

$$I_\epsilon(u_n^i) \to \eta_\epsilon^i \quad \text{and} \quad \|I_\epsilon|'_{S(a)}(u_n^i)\| \to 0 \quad \text{as } n \to +\infty,$$

which means $(u_n^i) \subset S(a)$ is a $(PS)_{\eta_\epsilon^i}$ sequence of I_ϵ. Combining with Lemma 3.4 and $\eta_\epsilon^i < m_{\max}(a) + \rho$, we can infer that there is u^i such that $u_n^i \to u^i$ in X. So, we have

$$u^i \in \theta_\epsilon^i, \ I_\epsilon(u^i) = \eta_\epsilon^i \quad \text{and} \quad I_\epsilon|'_{S(a)}(u^i) = 0.$$

According to our assumptions, we have

$$G_\epsilon(u^i) \in \overline{B_{\rho_0}(e_i)}, \quad G_\epsilon(u^j) \in \overline{B_{\rho_0}(e_j)}$$

and

$$\overline{B_{\rho_0}(e_i)} \cap \overline{B_{\rho_0}(e_j)} = \emptyset \text{ for } i \neq j,$$

which means $u^i \neq u^j$ for $i \neq j$ while $1 \leq i, j \leq l$. Thus, for any $\epsilon \in (0, \epsilon_0)$, I_ϵ has at least l nontrivial critical points, i.e.,

$$-\Delta u^i - \Delta_q u^i = \lambda_i u^i + h(\epsilon x) f(u^i), \quad \forall i \in \{1, 2, \dots, l\},$$

which ensures

$$\int_{\mathbb{R}^N} |\nabla u^i|^2 \mathrm{d}x + \int_{\mathbb{R}^N} |\nabla u^i|^q \mathrm{d}x - \int_{\mathbb{R}^N} \lambda_i |u^i|^2 \mathrm{d}x - \int_{\mathbb{R}^N} h(\epsilon x) f(u^i) u^i \mathrm{d}x = 0.$$

Combining with $I_\epsilon(u^i) < 0$, we have

$$\begin{aligned} 0 &> I_\epsilon(u^i) - \frac{1}{q}\Big(\int_{\mathbb{R}^N} |\nabla u^i|^2 \mathrm{d}x + \int_{\mathbb{R}^N} |\nabla u^i|^q \mathrm{d}x - \int_{\mathbb{R}^N} \lambda_i |u^i|^2 \mathrm{d}x - \int_{\mathbb{R}^N} h(\epsilon x) f(u^i) u^i \mathrm{d}x \Big) \\ &= \left(\frac{1}{2} - \frac{1}{q} \right) \int_{\mathbb{R}^N} |\nabla u|^2 \mathrm{d}x + \frac{1}{q} \int_{\mathbb{R}^N} \lambda_i |u^i|^2 \mathrm{d}x + \frac{1}{q} \int_{\mathbb{R}^N} h(\epsilon x) f(u^i) u^i \mathrm{d}x - \int_{\mathbb{R}^N} h(\epsilon x) F(u^i) \mathrm{d}x \\ &\geq \frac{1}{q} \int_{\mathbb{R}^N} \lambda_i |u^i|^2 \mathrm{d}x, \end{aligned}$$

which implies $\lambda_i < 0$. This proves the desired result.

Abstract. We show the theoretical solvability of the system of difference equations

$$x_{n+k} = \frac{y_{n+l}y_n - cd}{y_{n+l} + y_n - c - d}, \quad y_{n+k} = \frac{x_{n+l}x_n - cd}{x_{n+l} + x_n - c - d}, \quad n \in \mathbb{N}_0,$$

where $k \in \mathbb{N}$, $l \in \mathbb{N}_0$, $l < k$, $c, d \in \mathbb{C}$ and $x_j, y_j \in \mathbb{C}$, $j = \overline{0, k-1}$. For several special cases of the system, we give some detailed explanations on how some formulas for their general solutions can be found in closed form, that is, we show their practical solvability. To do this, among other things, we use the theory of homogeneous linear difference equations with constant coefficients and the product-type difference equations with integer exponents, which are theoretically solvable.

Keywords: symmetric system of difference equations, solvable system, solution in closed form.

2020 Mathematics Subject Classification: 39A20, 39A45.

1 Introduction

Finding general solutions to difference equations and systems of difference equations is a classical problem which can be traced back to the beginning of the 18th century, [5,8,9]. During the century many important results on the problem have been obtained [10, 16, 18–20]. A majority of the results were on linear difference equations and systems of difference equations, but some of them were also on the nonlinear ones (see also [6, 12, 17, 21, 22]). For some later presentations and applications of the equations, see [11, 13, 23, 26, 37]. Since the solvability

✉Corresponding author. Email: sscite1@gmail.com

theory for linear difference equations was essentially completed during that time, and since it is practically impossible to find some general methods for solving nonlinear equations, interest in the topic diminished during the 19th century. Although from time to time, some solvable difference equations occurred, for example, in computational mathematics [7], problem books [2, 14, 24, 25] and in some popular journals for a wide audience. Solvable difference equations are also useful in some comparison results [4, 15, 40]. One can study the invariants of the equations and systems, as it was the case, e.g., in [28–30, 32, 38, 39], but only some of their very special classes were considered therein.

During the last two decades there has been a renewed interest in the area. It seems mostly because of the use of some computer calculations. We have analysed some of the recent papers and given many comments and theoretical explanations related to them (see, for example, [47] where some of the analyses, comments and explanations are given). An interesting fact is that the solvability of almost all of the recently presented classes of solvable difference equations and systems rely on the solvability of some linear ones (see, for example, [3, 35, 47, 49] and the related references therein). However, it is of some interest to enlarge the list of solvable nonlinear difference equations and systems which are not obtained from linear ones in an obvious way.

There has been some interest in systems of difference equations which are close to symmetric ones since the mid of the nineties [27, 31, 33, 34, 38, 39], which attracted our attention. We have devoted a part of our investigation also in this direction (see, e.g., [41–47]).

Motivated by the equation

$$x_n = \frac{x_{n-s}x_{n-t} + a}{x_{n-s} + x_{n-t}}, \quad n \in \mathbb{N}_0, \tag{1.1}$$

where $s, t \in \mathbb{N}$, $a \in \mathbb{C}$ and $x_{-j} \in \mathbb{C}$, $j = \overline{0, \max\{s, t\}}$ ([36, 48]), in [49] we studied the equation

$$x_{n+s} = \frac{x_{n+t}x_n - ab}{x_{n+t} + x_n - a - b}, \quad n \in \mathbb{N}_0, \tag{1.2}$$

where $s \in \mathbb{N}$, $t \in \mathbb{N}_0$, $t < s$, $a, b \in \mathbb{C}$ and $x_j \in \mathbb{C}$, $j = \overline{0, s-1}$, and showed its theoretical solvability. Equation (1.1) is a natural generalization of its special case with $s = 1$ and $t = 2$, which can be obtained by using the secant method [7]

$$x_n = \frac{x_{n-2}f(x_{n-1}) - x_{n-1}f(x_{n-2})}{f(x_{n-1}) - f(x_{n-2})}, \quad n \in \mathbb{N}_0,$$

for $f(x) = x^2 - a$ (see, e.g., [15]).

On the other hand, motivated by our studies of the systems which stem from equation (1.1) (see the nonlinear systems of difference equations in [41–45]), in [46] we investigated a nonlinear system of difference equations which is related to equation (1.2), showed its solvability and discussed some special cases of the system in detail.

Here, we continue above mentioned investigations on solvability by studying the system

$$x_{n+k} = \frac{y_{n+l}y_n - cd}{y_{n+l} + y_n - c - d}, \quad y_{n+k} = \frac{x_{n+l}x_n - cd}{x_{n+l} + x_n - c - d}, \quad n \in \mathbb{N}_0, \tag{1.3}$$

where $k \in \mathbb{N}$, $l \in \mathbb{N}_0$, $l < k$, $c, d \in \mathbb{C}$ and $x_j, y_j \in \mathbb{C}$, $j = \overline{0, k-1}$, which is a symmetric relative to equation (1.2) and has not been considered in the literature yet.

Definition 1.1. We say that a nonlinear difference equation or system is *theoretically solvable* if by some changes of variables it can be transformed to a linear difference equation or system with constant coefficients. If the general solution to the linear difference equation or system can be found in closed form, we say that the nonlinear difference equation or system is *practically solvable*.

Remark 1.2. Not all linear difference equations with constant coefficients are practically solvable. For example, the difference equation

$$x_{n+5} - 6x_{n+1} + 3x_n = 0, \quad n \in \mathbb{N}_0,$$

is one of them, since we cannot find the roots of the associated characteristic polynomial

$$q_5(\lambda) = \lambda^5 - 6\lambda + 3$$

by radicals (see, e.g., [50]), due to the famous result by Abel and Ruffini [1].

Here we show the theoretical solvability of system (1.3), and give a detailed explanation on how in some cases can be found the general solution, that is, how to show their practical solvability.

2 Main results

Here we state and prove our main results.

Theorem 2.1. *Suppose $k \in \mathbb{N}$, $l \in \mathbb{N}_0$, $l < k$, and $c, d \in \mathbb{C}$. Then, system (1.3) is theoretically solvable.*

Proof. Suppose $c \neq d$. Note that

$$x_{n+k} - d = \frac{(y_{n+l} - d)(y_n - d)}{y_{n+l} + y_n - c - d},$$
$$x_{n+k} - c = \frac{(y_{n+l} - c)(y_n - c)}{y_{n+l} + y_n - c - d},$$
$$y_{n+k} - d = \frac{(x_{n+l} - d)(x_n - d)}{x_{n+l} + x_n - c - d},$$
$$y_{n+k} - c = \frac{(x_{n+l} - c)(x_n - c)}{x_{n+l} + x_n - c - d},$$

for $n \in \mathbb{N}_0$.

Dividing the first two relations we get

$$\frac{x_{n+k} - d}{x_{n+k} - c} = \frac{(y_{n+l} - d)(y_n - d)}{(y_{n+l} - c)(y_n - c)},$$

for $n \in \mathbb{N}_0$, whereas dividing the last two relations we get

$$\frac{y_{n+k} - d}{y_{n+k} - c} = \frac{(x_{n+l} - d)(x_n - d)}{(x_{n+l} - c)(x_n - c)},$$

for $n \in \mathbb{N}_0$.

Now we define two auxiliary sequences as follows

$$\zeta_n = \frac{x_n - d}{x_n - c}, \quad \eta_n = \frac{y_n - d}{y_n - c}, \tag{2.1}$$

for $n \in \mathbb{N}_0$.

They obviously satisfy the relations

$$\zeta_{n+k} = \eta_{n+l}\eta_n, \quad \eta_{n+k} = \zeta_{n+l}\zeta_n, \tag{2.2}$$

for $n \in \mathbb{N}_0$, which yields that ζ_n and η_n are two solutions to the equation

$$\omega_{n+2k} = \omega_{n+2l}\omega_{n+l}^2\omega_n, \quad n \in \mathbb{N}_0, \tag{2.3}$$

a product-type difference equation with integer exponents, which is theoretically solvable. Hence, such one is the system (1.3).

Note also that from (2.1) we have

$$x_n = \frac{c\zeta_n - d}{\zeta_n - 1}, \quad y_n = \frac{c\eta_n - d}{\eta_n - 1}, \tag{2.4}$$

for $n \in \mathbb{N}_0$.

Now suppose $c = d$. Note that

$$x_{n+k} - c = \frac{(y_{n+l} - c)(y_n - c)}{y_{n+l} + y_n - 2c}, \tag{2.5}$$

$$y_{n+k} - c = \frac{(x_{n+l} - c)(x_n - c)}{x_{n+l} + x_n - 2c}, \tag{2.6}$$

for $n \in \mathbb{N}_0$.

Now we define the two auxiliary sequences

$$\zeta_n = \frac{1}{x_n - c}, \quad \eta_n = \frac{1}{y_n - c}, \tag{2.7}$$

for $n \in \mathbb{N}_0$.

Combining (2.5)–(2.7), we get

$$\zeta_{n+k} = \eta_{n+l} + \eta_n, \quad \eta_{n+k} = \zeta_{n+l} + \zeta_n, \tag{2.8}$$

for $n \in \mathbb{N}_0$, which implies that ζ_n and η_n satisfy the equation

$$\omega_{n+2k} - \omega_{n+2l} - 2\omega_{n+l} - \omega_n = 0, \tag{2.9}$$

for $n \in \mathbb{N}_0$, which according to Definition 1.1 means that system (1.3) is theoretically solvable in this case. □

A natural problem is to find special cases of system (1.3) for which it is possible to find some closed-form formulas for their general solutions.

The polynomial

$$q_{2k}(\lambda) = \lambda^{2k} - \lambda^{2l} - 2\lambda^l - 1,$$

is the characteristic one associated to equation (2.9) [11,13,23,25]. Note that

$$q_{2k}(\lambda) = \lambda^{2k} - (\lambda^l + 1)^2 = (\lambda^k - \lambda^l - 1)(\lambda^k + \lambda^l + 1). \tag{2.10}$$

In some cases it is possible to find its roots (but, of course, not always [1]), for instance, if $0 \le l < k \le 4$ (there are ten cases). In all these cases, among other ones, equation (2.9) is practically solvable. Now we present the general solution to system (1.3) in some of these cases.

Theorem 2.2. *Consider the system* (1.3) *with* $k = 1$, $l = 0$ *and* $c, d \in \mathbb{C}$.

(a) If $c = d$, $x_0 \ne c \ne y_0$, *then*

$$x_{2m} = c + \frac{x_0 - c}{4^m}, \tag{2.11}$$

$$x_{2m+1} = c + \frac{y_0 - c}{2 \cdot 4^m}, \tag{2.12}$$

$$y_{2m} = c + \frac{y_0 - c}{4^m}, \tag{2.13}$$

$$y_{2m+1} = c + \frac{x_0 - c}{2 \cdot 4^m}, \tag{2.14}$$

for $m \in \mathbb{N}_0$.

(b) If $c \ne d$, *then well-defined solutions to the system are given by*

$$x_{2m} = \frac{c\left(\frac{x_0-d}{x_0-c}\right)^{4^m} - d}{\left(\frac{x_0-d}{x_0-c}\right)^{4^m} - 1}, \tag{2.15}$$

$$x_{2m+1} = \frac{c\left(\frac{y_0-d}{y_0-c}\right)^{2\cdot 4^m} - d}{\left(\frac{y_0-d}{y_0-c}\right)^{2\cdot 4^m} - 1}, \tag{2.16}$$

$$y_{2m} = \frac{c\left(\frac{y_0-d}{y_0-c}\right)^{4^m} - d}{\left(\frac{y_0-d}{y_0-c}\right)^{4^m} - 1}, \tag{2.17}$$

$$y_{2m+1} = \frac{c\left(\frac{x_0-d}{x_0-c}\right)^{2\cdot 4^m} - d}{\left(\frac{x_0-d}{x_0-c}\right)^{2\cdot 4^m} - 1}, \tag{2.18}$$

for $m \in \mathbb{N}_0$.

Proof. (a) First, note that (2.8) is

$$\zeta_{n+1} = 2\eta_n, \quad \eta_{n+1} = 2\zeta_n,$$

for $n \in \mathbb{N}_0$. Thus

$$\zeta_{n+2} = 4\zeta_n, \quad \eta_{n+2} = 4\eta_n,$$

for $n \in \mathbb{N}_0$, which yields

$$\zeta_{2m} = 4^m\zeta_0, \quad \zeta_{2m+1} = 4^m\zeta_1, \quad \eta_{2m} = 4^m\eta_0, \quad \eta_{2m+1} = 4^m\eta_1,$$

for $m \in \mathbb{N}_0$. This and (2.7) imply (2.11)–(2.14), under the assumption $c = d$.

(b) If we assume that $c \ne d$, then from (2.3) we have

$$\zeta_{n+2} = \zeta_n^4, \quad \eta_{n+2} = \eta_n^4, \quad n \in \mathbb{N}_0.$$

Therefore

$$\zeta_{2m} = \zeta_0^{4^m}, \quad \zeta_{2m+1} = \zeta_1^{4^m}, \quad \eta_{2m} = \eta_0^{4^m}, \quad \eta_{2m+1} = \eta_1^{4^m},$$

for $m \in \mathbb{N}_0$.

These four relations, the transformation in (2.1), and (2.4), imply (2.15)–(2.18), completing the proof. □

Remark 2.3. Assume that in Theorem 2.2, $c = d$, and that $x_0 = c$ or $y_0 = c$. Note that from (1.3) we have

$$x_1 = \frac{y_0^2 - c^2}{2(y_0 - c)} \tag{2.19}$$

and

$$y_1 = \frac{x_0^2 - c^2}{2(x_0 - c)}. \tag{2.20}$$

Hence, if $x_0 = c$, then from (2.20) we see that y_1 is not defined, whereas if $y_0 = c$, then from (2.19) we see that x_1 is not defined.

Corollary 2.4. *The system* (1.3) *with* $c, d \in \mathbb{C}$, $l = 0$ *and* $k \in \mathbb{N} \setminus \{1\}$ *is practically solvable.*

Proof. Under these conditions, we have

$$x_{n+k} = \frac{y_n^2 - cd}{2y_n - c - d}, \quad y_{n+k} = \frac{x_n^2 - cd}{2x_n - c - d}, \quad n \in \mathbb{N}_0,$$

which is a system with interlacing indices ([47]).

Let

$$x_m^{(j)} = x_{mk+j}, \quad y_m^{(j)} = y_{mk+j},$$

for $m \in \mathbb{N}_0$ and $j = \overline{0, k-1}$.

Then, $(x_m^{(j)}, y_m^{(j)})_{m \in \mathbb{N}_0}$, $j = \overline{0, k-1}$, are k solutions to the system

$$x_{m+1} = \frac{y_m^2 - cd}{2y_m - c - d}, \quad y_{m+1} = \frac{x_m^2 - cd}{2x_m - c - d}, \quad m \in \mathbb{N}_0.$$

Note that it is the system (1.3) with $k = 1$ and $l = 0$.

Thus, if $c = d$, $x_0^{(j)} \neq c \neq y_0^{(j)}$, $j = \overline{0, k-1}$, by Theorem 2.2 we get

$$x_{2m}^{(j)} = c + \frac{x_0^{(j)} - c}{4^m},$$

$$x_{2m+1}^{(j)} = c + \frac{y_0^{(j)} - c}{2 \cdot 4^m},$$

$$y_{2m}^{(j)} = c + \frac{y_0^{(j)} - c}{4^m},$$

$$y_{2m+1}^{(j)} = c + \frac{x_0^{(j)} - c}{2 \cdot 4^m},$$

for $m \in \mathbb{N}_0$, $j = \overline{0, k-1}$, whereas if $c \neq d$, then well-defined solutions to the system are

$$x_{2m}^{(j)} = \frac{c\left(\frac{x_0^{(j)}-d}{x_0^{(j)}-c}\right)^{4^m} - d}{\left(\frac{x_0^{(j)}-d}{x_0^{(j)}-c}\right)^{4^m} - 1},$$

$$x_{2m+1}^{(j)} = \frac{c\left(\frac{y_0^{(j)}-d}{y_0^{(j)}-c}\right)^{2\cdot 4^m} - d}{\left(\frac{y_0^{(j)}-d}{y_0^{(j)}-c}\right)^{2\cdot 4^m} - 1},$$

$$y_{2m}^{(j)} = \frac{c\left(\frac{y_0^{(j)}-d}{y_0^{(j)}-c}\right)^{4^m} - d}{\left(\frac{y_0^{(j)}-d}{y_0^{(j)}-c}\right)^{4^m} - 1},$$

$$y_{2m+1}^{(j)} = \frac{c\left(\frac{x_0^{(j)}-d}{x_0^{(j)}-c}\right)^{2\cdot 4^m} - d}{\left(\frac{x_0^{(j)}-d}{x_0^{(j)}-c}\right)^{2\cdot 4^m} - 1}$$

for $m \in \mathbb{N}$, $j = \overline{0, k-1}$.

Hence, if $c = d$ we have

$$x_{2mk+j} = c + \frac{x_j - c}{4^m},$$

$$x_{(2m+1)k+j} = c + \frac{y_j - c}{2 \cdot 4^m},$$

$$y_{2mk+j} = c + \frac{y_j - c}{4^m},$$

$$y_{(2m+1)k+j} = c + \frac{x_j - c}{2 \cdot 4^m},$$

for $m \in \mathbb{N}_0$, $j = \overline{0, k-1}$, whereas if $c \neq d$ we have

$$x_{2mk+j} = \frac{c\left(\frac{x_j-d}{x_j-c}\right)^{4^m} - d}{\left(\frac{x_j-d}{x_j-c}\right)^{4^m} - 1},$$

$$x_{(2m+1)k+j} = \frac{c\left(\frac{y_j-d}{y_j-c}\right)^{2\cdot 4^m} - d}{\left(\frac{y_j-d}{y_j-c}\right)^{2\cdot 4^m} - 1},$$

$$y_{2mk+j} = \frac{c\left(\frac{y_j-d}{y_j-c}\right)^{4^m} - d}{\left(\frac{y_j-d}{y_j-c}\right)^{4^m} - 1},$$

$$y_{(2m+1)k+j} = \frac{c\left(\frac{x_j-d}{x_j-c}\right)^{2\cdot 4^m} - d}{\left(\frac{x_j-d}{x_j-c}\right)^{2\cdot 4^m} - 1}$$

for $m \in \mathbb{N}$, $j = \overline{0, k-1}$. □

Theorem 2.5. *The system (1.3) with $c, d \in \mathbb{C}$, $l = 1$ and $k = 2$ is practically solvable.*

Proof. Suppose $c \neq d$. From (2.3) we get that $(\zeta_n)_{n\in\mathbb{N}_0}$ and $(\eta_n)_{n\in\mathbb{N}_0}$ are the solutions to

$$\omega_{n+4} = \omega_{n+2}\omega_{n+1}^2\omega_n, \quad n \in \mathbb{N}_0, \tag{2.21}$$

with the initial values

$$\zeta_0, \quad \zeta_1, \quad \zeta_2 = \eta_1\eta_0, \quad \zeta_3 = \zeta_1\zeta_0\eta_1, \tag{2.22}$$

$$\eta_0, \quad \eta_1, \quad \eta_2 = \zeta_1\zeta_0, \quad \eta_3 = \eta_1\eta_0\zeta_1, \tag{2.23}$$

respectively.

Rewrite (2.21) as follows

$$\omega_n = \omega_{n-2}^{a_1}\omega_{n-3}^{b_1}\omega_{n-4}^{c_1}\omega_{n-5}^{d_1}, \quad n \geq 5, \tag{2.24}$$

where

$$a_1 := 1, \quad b_1 := 2, \quad c_1 := 1, \quad d_1 := 0. \tag{2.25}$$

Further, we have

$$\begin{aligned}\omega_n &= (\omega_{n-4}\omega_{n-5}^2\omega_{n-6})^{a_1}\omega_{n-3}^{b_1}\omega_{n-4}^{c_1}\omega_{n-5}^{d_1} \\ &= \omega_{n-3}^{b_1}\omega_{n-4}^{a_1+c_1}\omega_{n-5}^{2a_1+d_1}\omega_{n-6}^{a_1} \\ &= \omega_{n-3}^{a_2}\omega_{n-4}^{b_2}\omega_{n-5}^{c_2}\omega_{n-6}^{d_2},\end{aligned} \tag{2.26}$$

for $n \geq 6$, where $a_2 := b_1$, $b_2 := a_1 + c_1$, $c_2 := 2a_1 + d_1$ and $d_2 := a_1$.

A simple inductive argument shows that

$$\omega_n = \omega_{n-k-1}^{a_k}\omega_{n-k-2}^{b_k}\omega_{n-k-3}^{c_k}\omega_{n-k-4}^{d_k}, \tag{2.27}$$

for $n \geq k + 4$, and

$$a_k = b_{k-1}, \quad b_k = a_{k-1} + c_{k-1}, \quad c_k = 2a_{k-1} + d_{k-1}, \quad d_k = a_{k-1} \tag{2.28}$$

for $k \geq 2$.

For $k = n - 4$ from (2.27) and (2.28), we get

$$\begin{aligned}\omega_n &= \omega_3^{a_{n-4}}\omega_2^{b_{n-4}}\omega_1^{c_{n-4}}\omega_0^{d_{n-4}} \\ &= \omega_3^{a_{n-4}}\omega_2^{a_{n-3}}\omega_1^{a_{n-2}-a_{n-4}}\omega_0^{a_{n-5}},\end{aligned} \tag{2.29}$$

for $n \geq 6$, whereas from (2.28), we get

$$a_k = a_{k-2} + 2a_{k-3} + a_{k-4}, \tag{2.30}$$

for $k \geq 5$, and

$$a_1 = 1, \quad a_2 = 2, \quad a_3 = 2, \quad a_4 = 4. \tag{2.31}$$

The polynomial

$$q_4(\lambda) = \lambda^4 - \lambda^2 - 2\lambda - 1 = (\lambda^2 - \lambda - 1)(\lambda^2 + \lambda + 1), \tag{2.32}$$

is the characteristic one associated to (2.30), with the zeros

$$\lambda_{1,2} = \frac{1 \pm \sqrt{5}}{2} \quad \text{and} \quad \lambda_{3,4} = \frac{-1 \pm i\sqrt{3}}{2}. \tag{2.33}$$

Since

$$a_{k-4} = a_k - a_{k-2} - 2a_{k-3}, \tag{2.34}$$

by using (2.31) we can find a_k for $k \le 0$, and get

$$a_{-4} = a_{-3} = a_{-2} = 0, \quad a_{-1} = 1 \quad \text{and} \quad a_0 = 0. \tag{2.35}$$

Using [41, Lemma 1] we obtain

$$a_n = \frac{\lambda_1^{n+4}}{q_4'(\lambda_1)} + \frac{\lambda_2^{n+4}}{q_4'(\lambda_2)} + \frac{\lambda_3^{n+4}}{q_4'(\lambda_3)} + \frac{\lambda_4^{n+4}}{q_4'(\lambda_4)}, \tag{2.36}$$

for $n \in \mathbb{Z}$.

Since

$$q_4'(\lambda) = 4\lambda^3 - 2\lambda - 2 = 2(2\lambda^3 - \lambda - 1) = 2(\lambda - 1)(2\lambda^2 + 2\lambda + 1),$$

we have

$$q_4'(\lambda_1) = 5 + 3\sqrt{5}, \quad q_4'(\lambda_2) = 5 - 3\sqrt{5}, \tag{2.37}$$

$$q_4'(\lambda_3) = 3 - i\sqrt{3}, \quad q_4'(\lambda_4) = 3 + i\sqrt{3}. \tag{2.38}$$

Using (2.37) and (2.38) in (2.36) imply

$$\begin{aligned} a_n &= \frac{\lambda_1^{n+4}}{5 + 3\sqrt{5}} + \frac{\lambda_2^{n+4}}{5 - 3\sqrt{5}} + \frac{\lambda_3^{n+4}}{3 - i\sqrt{3}} + \frac{\lambda_4^{n+4}}{3 + i\sqrt{3}} \\ &= \frac{\lambda_1^{n+2} - \lambda_2^{n+2}}{2\sqrt{5}} + \frac{\lambda_3^{n+2} - \lambda_4^{n+2}}{2i\sqrt{3}}, \end{aligned} \tag{2.39}$$

for $n \in \mathbb{Z}$. Employing this formula it is not difficult to check that (2.29) holds for all $n \in \mathbb{N}_0$.

Relations (2.22) and (2.29) imply

$$\begin{aligned} \zeta_n &= \zeta_3^{a_{n-4}} \zeta_2^{a_{n-3}} \zeta_1^{a_{n-2} - a_{n-4}} \zeta_0^{a_{n-5}} \\ &= (\eta_1 \zeta_0 \zeta_1)^{a_{n-4}} (\eta_1 \eta_0)^{a_{n-3}} \zeta_1^{a_{n-2} - a_{n-4}} \zeta_0^{a_{n-5}} \\ &= \zeta_0^{a_{n-4} + a_{n-5}} \zeta_1^{a_{n-2}} \eta_0^{a_{n-3}} \eta_1^{a_{n-3} + a_{n-4}}, \end{aligned} \tag{2.40}$$

for $n \in \mathbb{N}_0$, and due to the symmetry

$$\eta_n = \eta_0^{a_{n-4} + a_{n-5}} \eta_1^{a_{n-2}} \zeta_0^{a_{n-3}} \zeta_1^{a_{n-3} + a_{n-4}}, \tag{2.41}$$

for $n \in \mathbb{N}_0$.

By some simple calculation and use of the Viète formulas we get

$$\begin{aligned} a_n + a_{n-1} &= \frac{(\lambda_1 + 1)\lambda_1^{n+1} - (\lambda_2 + 1)\lambda_2^{n+1}}{2\sqrt{5}} + \frac{(\lambda_3 + 1)\lambda_3^{n+1} - (\lambda_4 + 1)\lambda_4^{n+1}}{2i\sqrt{3}} \\ &= \frac{\lambda_1^{n+3} - \lambda_2^{n+3}}{2\sqrt{5}} - \frac{\lambda_3^{n+3} - \lambda_4^{n+3}}{2i\sqrt{3}}, \end{aligned} \tag{2.42}$$

for $n \in \mathbb{Z}$.

From (2.39)–(2.42) we get

$$\zeta_n = \zeta_0^{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} - \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}} \zeta_1^{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} + \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}} \eta_0^{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} + \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}} \eta_1^{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} - \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}},$$
$$\eta_n = \eta_0^{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} - \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}} \eta_1^{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} + \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}} \zeta_0^{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} + \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}} \zeta_1^{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} - \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}},$$

for $n \in \mathbb{N}_0$, from which together with (2.1) with $n = 0, 1$, we get

$$\begin{aligned} \zeta_n = {} & \left(\frac{x_0-d}{x_0-c}\right)^{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} - \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}} \left(\frac{x_1-d}{x_1-c}\right)^{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} + \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}} \\ & \times \left(\frac{y_0-d}{y_0-c}\right)^{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} + \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}} \left(\frac{y_1-d}{y_1-c}\right)^{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} - \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}}, \end{aligned} \tag{2.43}$$

$$\begin{aligned} \eta_n = {} & \left(\frac{x_0-d}{x_0-c}\right)^{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} + \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}} \left(\frac{x_1-d}{x_1-c}\right)^{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} - \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}} \\ & \times \left(\frac{y_0-d}{y_0-c}\right)^{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} - \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}} \left(\frac{y_1-d}{y_1-c}\right)^{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} + \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}}, \end{aligned} \tag{2.44}$$

for $n \in \mathbb{N}_0$.

Combining (2.4), (2.43) and (2.44), we have

$$x_n = \frac{c\left(\frac{x_0-d}{x_0-c}\right)^{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} - \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}} \left(\frac{x_1-d}{x_1-c}\right)^{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} + \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}} \left(\frac{y_0-d}{y_0-c}\right)^{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} + \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}} \left(\frac{y_1-d}{y_1-c}\right)^{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} - \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}} - d}{\left(\frac{x_0-d}{x_0-c}\right)^{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} - \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}} \left(\frac{x_1-d}{x_1-c}\right)^{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} + \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}} \left(\frac{y_0-d}{y_0-c}\right)^{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} + \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}} \left(\frac{y_1-d}{y_1-c}\right)^{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} - \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}} - 1}$$
$$y_n = \frac{c\left(\frac{y_0-d}{y_0-c}\right)^{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} - \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}} \left(\frac{y_1-d}{y_1-c}\right)^{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} + \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}} \left(\frac{x_0-d}{x_0-c}\right)^{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} + \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}} \left(\frac{x_1-d}{x_1-c}\right)^{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} - \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}} - d}{\left(\frac{y_0-d}{y_0-c}\right)^{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} - \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}} \left(\frac{y_1-d}{y_1-c}\right)^{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} + \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}} \left(\frac{x_0-d}{x_0-c}\right)^{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} + \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}} \left(\frac{x_1-d}{x_1-c}\right)^{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} - \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}} - 1},$$

for $n \in \mathbb{N}_0$.

Now assume that $c = d$. In this case, we have

$$\zeta_{n+2} = \eta_{n+1} + \eta_n, \quad \eta_{n+2} = \zeta_{n+1} + \zeta_n, \tag{2.45}$$

for $n \in \mathbb{N}_0$, implying that $(\zeta_n)_{n\in\mathbb{N}_0}$ and $(\eta_n)_{n\in\mathbb{N}_0}$ are the two solutions to the equation

$$\omega_{n+4} - \omega_{n+2} - 2\omega_{n+1} - \omega_n = 0, \tag{2.46}$$

for $n \in \mathbb{N}_0$, with the initial values

$$\zeta_0, \quad \zeta_1, \quad \zeta_2 = \eta_1 + \eta_0, \quad \zeta_3 = \eta_1 + \zeta_1 + \zeta_0, \tag{2.47}$$

$$\eta_0, \quad \eta_1, \quad \eta_2 = \zeta_1 + \zeta_0, \quad \eta_3 = \zeta_1 + \eta_1 + \eta_0, \tag{2.48}$$

respectively (see (2.45)).

If we write equation (2.46) in the form

$$\begin{aligned} \omega_n &= \omega_{n-2} + 2\omega_{n-3} + \omega_{n-4} + 0 \cdot \omega_{n-5} \\ &= a_1\omega_{n-2} + b_1\omega_{n-3} + c_1\omega_{n-4} + d_1\omega_{n-5}, \end{aligned}$$

where a_1, b_1, c_1, d_1 are given in (2.25), then by a simple inductive argument we can prove that

$$\omega_n = a_k\omega_{n-k-1} + b_k\omega_{n-k-2} + c_k\omega_{n-k-3} + d_k\omega_{n-k-4}, \tag{2.49}$$

for $n \geq k+4$, where $(a_k)_{k\in\mathbb{N}}$, $(b_k)_{k\in\mathbb{N}}$, $(c_k)_{k\in\mathbb{N}}$ and $(d_k)_{k\in\mathbb{N}}$, satisfy (2.28). Thus (2.39) holds.

For $k = n-4$ we have

$$\omega_n = a_{n-4}\omega_3 + a_{n-3}\omega_2 + (a_{n-2} - a_{n-4})\omega_1 + a_{n-5}\omega_0, \tag{2.50}$$

for $n \geq 6$, from which along with (2.47), we get

$$\begin{aligned}\zeta_n &= a_{n-4}(\eta_1 + \zeta_1 + \zeta_0) + a_{n-3}(\eta_1 + \eta_0) + (a_{n-2} - a_{n-4})\zeta_1 + a_{n-5}\zeta_0 \\ &= (a_{n-4} + a_{n-5})\zeta_0 + a_{n-2}\zeta_1 + a_{n-3}\eta_0 + (a_{n-3} + a_{n-4})\eta_1,\end{aligned} \tag{2.51}$$

for $n \in \mathbb{N}_0$. Therefore

$$\eta_n = (a_{n-4} + a_{n-5})\eta_0 + a_{n-2}\eta_1 + a_{n-3}\zeta_0 + (a_{n-3} + a_{n-4})\zeta_1, \tag{2.52}$$

for $n \in \mathbb{N}_0$.

Combining (2.39), (2.42), (2.51) and (2.52) it follows that

$$\zeta_n = \frac{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} - \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}}{x_0 - c} + \frac{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} + \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}}{x_1 - c} + \frac{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} + \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}}{y_0 - c} + \frac{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} - \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}}{y_1 - c},$$

$$\eta_n = \frac{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} - \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}}{y_0 - c} + \frac{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} + \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}}{y_1 - c} + \frac{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} + \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}}{x_0 - c} + \frac{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} - \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}}{x_1 - c},$$

for $n \in \mathbb{N}_0$.

Thus

$$x_n = \frac{c\left(\frac{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} - \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}}{x_0 - c} + \frac{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} + \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}}{x_1 - c} + \frac{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} + \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}}{y_0 - c} + \frac{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} - \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}}{y_1 - c}\right) + 1}{\frac{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} - \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}}{x_0 - c} + \frac{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} + \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}}{x_1 - c} + \frac{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} + \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}}{y_0 - c} + \frac{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} - \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}}{y_1 - c}},$$

$$y_n = \frac{c\left(\frac{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} - \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}}{y_0 - c} + \frac{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} + \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}}{y_1 - c} + \frac{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} + \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}}{x_0 - c} + \frac{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} - \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}}{x_1 - c}\right) + 1}{\frac{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} - \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}}{y_0 - c} + \frac{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} + \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}}{y_1 - c} + \frac{\frac{\lambda_1^{n-1}-\lambda_2^{n-1}}{2\sqrt{5}} + \frac{\lambda_3^{n-1}-\lambda_4^{n-1}}{2i\sqrt{3}}}{x_0 - c} + \frac{\frac{\lambda_1^{n}-\lambda_2^{n}}{2\sqrt{5}} - \frac{\lambda_3^{n}-\lambda_4^{n}}{2i\sqrt{3}}}{x_1 - c}},$$

for $n \in \mathbb{N}_0$, where we have used the change of variables (2.7). □

Corollary 2.6. *The system* (1.3) *with $c, d \in \mathbb{C}$, $k = 2s$, $l = s$, for some $s \in \mathbb{N}$, is practically solvable.*

Proof. Under these conditions we have

$$x_{n+2s} = \frac{y_{n+s}y_n - cd}{y_{n+s} + y_n - c - d}, \quad y_{n+2s} = \frac{x_{n+s}x_n - cd}{x_{n+s} + x_n - c - d}, \quad n \in \mathbb{N}_0,$$

which is a system with interlacing indices ([47]).

Let

$$x_m^{(j)} = x_{ms+j}, \quad y_m^{(j)} = y_{ms+j},$$

for $m \in \mathbb{N}_0$ and $j = \overline{0, s-1}$. Then, $(x_m^{(j)}, y_m^{(j)})_{m\in\mathbb{N}_0}$, $j = \overline{0, s-1}$, are s solutions to the system

$$x_{m+2} = \frac{y_{m+1}y_m - cd}{y_{m+1} + y_m - c - d},$$

$$y_{m+2} = \frac{x_{m+1}x_m - cd}{x_{m+1} + x_m - c - d},$$

for $m \in \mathbb{N}_0$. Note that it is the system (1.3) with $k = 2$ and $l = 1$.

Thus, Theorem 2.5 can be applied, and if $c \neq d$, we get

$$x_m^{(j)} = \frac{c\left(\frac{x_0^{(j)}-d}{x_0^{(j)}-c}\right)^{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}-\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}\left(\frac{x_1^{(j)}-d}{x_1^{(j)}-c}\right)^{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}+\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}\left(\frac{y_0^{(j)}-d}{y_0^{(j)}-c}\right)^{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}+\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}\left(\frac{y_1^{(j)}-d}{y_1^{(j)}-c}\right)^{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}-\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}-d}{\left(\frac{x_0^{(j)}-d}{x_0^{(j)}-c}\right)^{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}-\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}\left(\frac{x_1^{(j)}-d}{x_1^{(j)}-c}\right)^{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}+\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}\left(\frac{y_0^{(j)}-d}{y_0^{(j)}-c}\right)^{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}+\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}\left(\frac{y_1^{(j)}-d}{y_1^{(j)}-c}\right)^{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}-\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}-1},$$

$$y_m^{(j)} = \frac{c\left(\frac{y_0^{(j)}-d}{y_0^{(j)}-c}\right)^{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}-\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}\left(\frac{y_1^{(j)}-d}{y_1^{(j)}-c}\right)^{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}+\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}\left(\frac{x_0^{(j)}-d}{x_0^{(j)}-c}\right)^{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}+\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}\left(\frac{x_1^{(j)}-d}{x_1^{(j)}-c}\right)^{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}-\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}-d}{\left(\frac{y_0^{(j)}-d}{y_0^{(j)}-c}\right)^{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}-\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}\left(\frac{y_1^{(j)}-d}{y_1^{(j)}-c}\right)^{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}+\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}\left(\frac{x_0^{(j)}-d}{x_0^{(j)}-c}\right)^{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}+\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}\left(\frac{x_1^{(j)}-d}{x_1^{(j)}-c}\right)^{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}-\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}-1},$$

for $m \in \mathbb{N}_0$ and $j = \overline{0, s-1}$, whereas if $c = d$, we get

$$x_m^{(j)} = \frac{c\left(\frac{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}-\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}{x_0^{(j)}-c}+\frac{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}+\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}{x_1^{(j)}-c}+\frac{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}+\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}{y_0^{(j)}-c}+\frac{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}-\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}{y_1^{(j)}-c}\right)+1}{\frac{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}-\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}{x_0^{(j)}-c}+\frac{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}+\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}{x_1^{(j)}-c}+\frac{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}+\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}{y_0^{(j)}-c}+\frac{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}-\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}{y_1^{(j)}-c}},$$

$$y_m^{(j)} = \frac{c\left(\frac{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}-\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}{y_0^{(j)}-c}+\frac{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}+\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}{y_1^{(j)}-c}+\frac{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}+\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}{x_0^{(j)}-c}+\frac{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}-\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}{x_1^{(j)}-c}\right)+1}{\frac{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}-\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}{y_0^{(j)}-c}+\frac{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}+\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}{y_1^{(j)}-c}+\frac{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}+\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}{x_0^{(j)}-c}+\frac{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}-\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}{x_1^{(j)}-c}},$$

for $m \in \mathbb{N}_0$ and $j = \overline{0, s-1}$, that is, if $c \neq d$, we have

$$x_{ms+j} = \frac{c\left(\frac{x_j-d}{x_j-c}\right)^{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}-\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}\left(\frac{x_{s+j}-d}{x_{s+j}-c}\right)^{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}+\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}\left(\frac{y_j-d}{y_j-c}\right)^{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}+\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}\left(\frac{y_{s+j}-d}{y_{s+j}-c}\right)^{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}-\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}-d}{\left(\frac{x_j-d}{x_j-c}\right)^{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}-\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}\left(\frac{x_{s+j}-d}{x_{s+j}-c}\right)^{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}+\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}\left(\frac{y_j-d}{y_j-c}\right)^{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}+\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}\left(\frac{y_{s+j}-d}{y_{s+j}-c}\right)^{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}-\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}-1},$$

$$y_{ms+j} = \frac{c\left(\frac{y_j-d}{y_j-c}\right)^{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}-\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}\left(\frac{y_{s+j}-d}{y_{s+j}-c}\right)^{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}+\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}\left(\frac{x_j-d}{x_j-c}\right)^{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}+\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}\left(\frac{x_{s+j}-d}{x_{s+j}-c}\right)^{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}-\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}-d}{\left(\frac{y_j-d}{y_j-c}\right)^{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}-\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}\left(\frac{y_{s+j}-d}{y_{s+j}-c}\right)^{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}+\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}\left(\frac{x_j-d}{x_j-c}\right)^{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}}+\frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}\left(\frac{x_{s+j}-d}{x_{s+j}-c}\right)^{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}}-\frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}-1},$$

for $m \in \mathbb{N}_0$ and $j = \overline{0, s-1}$, whereas if $c = d$, we get

$$x_{ms+j} = \frac{c\left(\frac{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}} - \frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}{x_j - c} + \frac{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}} + \frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}{x_{s+j} - c} + \frac{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}} + \frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}{y_j - c} + \frac{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}} - \frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}{y_{s+j} - c}\right) + 1}{\frac{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}} - \frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}{x_j - c} + \frac{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}} + \frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}{x_{s+j} - c} + \frac{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}} + \frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}{y_j - c} + \frac{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}} - \frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}{y_{s+j} - c}},$$

$$y_{ms+j} = \frac{c\left(\frac{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}} - \frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}{y_j - c} + \frac{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}} + \frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}{y_{s+j} - c} + \frac{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}} + \frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}{x_j - c} + \frac{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}} - \frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}{x_{s+j} - c}\right) + 1}{\frac{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}} - \frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}{y_j - c} + \frac{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}} + \frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}{y_{s+j} - c} + \frac{\frac{\lambda_1^{m-1}-\lambda_2^{m-1}}{2\sqrt{5}} + \frac{\lambda_3^{m-1}-\lambda_4^{m-1}}{2i\sqrt{3}}}{x_j - c} + \frac{\frac{\lambda_1^{m}-\lambda_2^{m}}{2\sqrt{5}} - \frac{\lambda_3^{m}-\lambda_4^{m}}{2i\sqrt{3}}}{x_{s+j} - c}},$$

for $m \in \mathbb{N}_0$ and $j = \overline{0, s-1}$. □

Remark 2.7. Theorem 2.2, Corollary 2.4, Theorem 2.5 and Corollary 2.6, show the practical solvability of system (1.3) in the following six cases: $k = 1$, $l = 0$; $k = 2$, $l = 0$; $k = 2$, $l = 1$; $k = 3$, $l = 0$; $k = 4$, $l = 0$ and $k = 4$, $l = 2$. Practical solvability of the system (1.3) in the cases: $k = 3$, $l = 1$; $k = 3$, $l = 2$; $k = 4$, $l = 1$ and $k = 4$, $l = 3$ is shown similarly, but with more technical details.

Remark 2.8. Employing the formulas for the general solutions to system (1.3), one can describe their well-defined solutions. The standard problem is left to the reader as an exercise.

Author Contributions. Stevo Stević proposed this research project. All the authors contributed to the study. All authors have read and agreed to this version of the manuscript.

Funding. This work was partially supported by the Ministry of Science, Technological Development and Innovation of the Republic of Serbia under contract number: 451-03-65/2024-03/200103. This research is also partially supported by the Science Fund of the Republic of Serbia, #GRANT No 7632, Project "Mathematical Methods in Image Processing under Uncertainty"– MaMIPU.

Abstract. We use essential limits inferior and superior of the nonlinear part of a discontinuous ODE to introduce some novel transversality conditions which imply that Filippov solutions are Carathéodory solutions. We also prove some uniqueness criteria based on different Lipschitz conditions on different parts of the domain separated from one another by boundaries which satisfy certain transversality conditions.

Keywords: discontinuous differential equations, Carathéodory solutions, Filippov solutions, differential inclusions.

2020 Mathematics Subject Classification: 34A36.

1 Introduction

Consider the initial value problem

$$x' = f(t,x), \qquad t \in I = [t_0, t_0 + L], \quad x(t_0) = x_0, \tag{1.1}$$

where $t_0, L \in \mathbb{R}$, $L > 0$, $x_0 \in \mathbb{R}^n$ ($n \in \mathbb{N}$) and $f = (f_1, f_2, \dots, f_n) : I \times \mathbb{R}^n \longrightarrow \mathbb{R}^n$ need not be continuous. In this paper, we prove new existence and uniqueness results on Carathéodory and Filippov solutions to (1.1).

Assume that for a.a. $t \in I$ the mapping $f(t, \cdot)$ is locally essentially bounded. A Filippov solution of (1.1) is defined as an absolutely continuous function $x : I \longrightarrow \mathbb{R}^n$ such that $x(t_0) = x_0$ and

$$x'(t) \in \bigcap_{\varepsilon>0} \bigcap_{m(N)=0} \overline{\text{co}}\, f\left(t, B_\varepsilon(x(t)) \setminus N\right) \quad \text{for a.a. } t \in I, \tag{1.2}$$

where m is the Lebesgue measure, $\overline{\text{co}}$ means closed convex hull and $B_\varepsilon(x) = \{y \in \mathbb{R}^n : \|y - x\| < \varepsilon\}$. Here and henceforth, we denote by $\|x\|$ the usual norm of a vector $x \in \mathbb{R}^n$. Observe that, in the scalar case ($n = 1$), we have $B_\varepsilon(x) = (x - \varepsilon, x + \varepsilon)$.

✉ Corresponding author. Email: rodrigo.lopez@usc.es

Filippov solutions satisfy

$$x'(t) \in \prod_{j=1}^{n} \left[\operatorname*{ess\,lim\,inf}_{y \to x(t)} f_j(t,y), \operatorname*{ess\,lim\,sup}_{y \to x(t)} f_j(t,y) \right] \quad \text{for a.a. } t \in I, \tag{1.3}$$

where ess lim inf and ess lim sup stand for the essential limit inferior and superior, respectively. Namely, for each $j \in \{1, 2, \dots, n\}$,

$$\operatorname*{ess\,lim\,inf}_{y \to x} f_j(t,y) = \lim_{\varepsilon \to 0^+} \operatorname*{ess\,inf}_{0<\|x-y\|<\varepsilon} f_j(t,y) = \sup_{\varepsilon>0} \operatorname*{ess\,inf}_{0<\|x-y\|<\varepsilon} f_j(t,y).$$

The essential limit superior is defined analogously.

With this information on Filippov solutions we shall deduce some sufficient conditions for the existence of Carathédory solutions in terms of essential limits.

This paper is organized as follows. In Section 2 we prove (1.3). In Section 3 we introduce novel transversality conditions on $f(t,x)$ in terms of essential limits which ensure that, first, Filippov solutions of (1.1) exist and, second, every Filippov solution is a Carathéodory solution. In Section 4, we deduce new uniqueness results for both Carathéodory and Filippov solutions of (1.1).

2 Preliminaries

This section is mainly devoted to proving that Filippov solutions of (1.1) satisfy (1.3). We thank the anonymous reviewer of a previous version of this paper for having brought to our attention reference [9], where Filippov himself uses (1.3) omiting its proof.

Proposition 2.1. *Let $f = (f_1, f_2, \dots, f_n) : I \times \mathbb{R}^n \longrightarrow \mathbb{R}^n$ be an arbitrary function.*

For all $t \in I$ and every $x \in \mathbb{R}^n$ such that $f(t, \cdot)$ is essentially bounded on a neighborhood of x, we have

$$\bigcap_{\varepsilon>0} \bigcap_{m(N)=0} \overline{\text{co}}\, f\,(t, B_\varepsilon(x) \setminus N) \subset \prod_{j=1}^{n} \left[\operatorname*{ess\,lim\,inf}_{y \to x} f_j(t,y), \operatorname*{ess\,lim\,sup}_{y \to x} f_j(t,y) \right]. \tag{2.1}$$

Moreover, in the scalar case ($n = 1$) we have

$$\bigcap_{\varepsilon>0} \bigcap_{m(N)=0} \overline{\text{co}}\, f\,(t, B_\varepsilon(x) \setminus N) = \left[\operatorname*{ess\,lim\,inf}_{y \to x} f(t,y), \operatorname*{ess\,lim\,sup}_{y \to x} f(t,y) \right]. \tag{2.2}$$

Proof. For each $j \in \{1, 2, \dots, n\}$ and each sufficiently small $\varepsilon > 0$ there exist $c_*(j)$, $c^*(j) \in \mathbb{R}$, essential lower and upper bounds of the set

$$A_\varepsilon(j) = \{f_j(t,y) \,:\, 0 < \|x-y\| < \varepsilon\},$$

i.e., there exists a null measure set N_ε such that

$$c_*(j) \le f_j(t,y) \le c^*(j) \quad \text{provided that } 0 < \|x-y\| < \varepsilon,\, y \notin N_\varepsilon.$$

We may (and we do) assume that $x \in N_\varepsilon$ and that N_ε does not depend on j. Hence

$$\overline{\text{co}}\, f\,(t, B_\varepsilon(x) \setminus N_\varepsilon) \subset \prod_{j=1}^{n} [c_*(j), c^*(j)],$$

which implies that

$$\bigcap_{m(N)=0} \overline{\text{co}}\, f\,(t, B_\varepsilon(x) \setminus N) \subset \prod_{j=1}^{n} [c_*(j), c^*(j)].$$

Since $c_*(j)$ and $c^*(j)$ were arbitrary essential lower and upper bounds of $A_\varepsilon(j)$, we deduce that

$$\bigcap_{m(N)=0} \overline{\text{co}}\, f\,(t, B_\varepsilon(x) \setminus N) \subset \prod_{j=1}^{n} \left[\operatorname*{ess\,inf}_{0<\|x-y\|<\varepsilon} f_j(t,y),\ \operatorname*{ess\,sup}_{0<\|x-y\|<\varepsilon} f_j(t,y) \right].$$

Finally, since ε was fixed arbitrarily, we conclude that

$$\bigcap_{\varepsilon>0} \bigcap_{m(N)=0} \overline{\text{co}}\, f\,(t, B_\varepsilon(x) \setminus N) \subset \prod_{j=1}^{n} \left[\text{ess} \liminf_{y \to x} f_j(t,y), \text{ess} \limsup_{y \to x} f_j(t,y) \right]. \tag{2.3}$$

Next we prove (2.2) in the scalar case. Notice that if

$$\xi \in \left[\text{ess} \liminf_{y \to x} f(t,y), \text{ess} \limsup_{y \to x} f(t,y) \right]$$

then for each $\varepsilon > 0$ and each $N \subset \mathbb{R}$, $m(N) = 0$, we have

$$\xi \geq \text{ess} \liminf_{y \to x} f(t,y) \geq \operatorname*{ess\,inf}_{B_\varepsilon(x)} f(t,y) \geq \inf_{B_\varepsilon(x) \setminus N} f(t,y),$$

and, analogously,

$$\xi \leq \sup_{B_\varepsilon(x) \setminus N} f(t,y).$$

Hence, for each $\varepsilon > 0$ and each null measure set $N \subset \mathbb{R}$, we have

$$\xi \in \left[\inf_{B_\varepsilon(x) \setminus N} f(t,y),\ \sup_{B_\varepsilon(x) \setminus N} f(t,y) \right] = \overline{\text{co}} f\,(t, B_\varepsilon(x) \setminus N)\,,$$

as desired. □

In applications we shall often have some more assumptions on $f(t,x)$, which yield a clearer version of (2.2). An interesting particular case is considered in our next lemma.

Lemma 2.2. *Assume that $f : I \times \mathbb{R}^n \longrightarrow \mathbb{R}$ satisfies that for a.a. $t \in I$ there is a null measure set $N(t)$ such that the restriction of $f(t,\cdot)$ to $\mathbb{R}^n \setminus N(t)$ is continuous.*

Then, for a.a. $t \in I$ and every $x \in \mathbb{R}^n$ such that $f(t,\cdot)$ is essentially bounded on a neighborhood of x, we have

$$\text{ess} \liminf_{y \to x} f(t,y) = \liminf_{y \to x,\, y \notin N(t)} f(t,y), \tag{2.4}$$

and

$$\text{ess} \limsup_{y \to x} f(t,y) = \limsup_{y \to x,\, y \notin N(t)} f(t,y). \tag{2.5}$$

Proof. Let us prove (2.4). The proof of (2.5) is analogous and we omit it.

Les us fix $t \in I$ such that the restriction of $f(t,\cdot)$ to $\mathbb{R}^n \setminus N(t)$ is continuous and $N(t)$ is null. Observe that (2.4) is obviously true in case $x \in \mathbb{R}^n \setminus N(t)$ because the restriction of $f(t,\cdot)$ to $\mathbb{R}^n \setminus N(t)$ is continuous at x, so we assume that $x \in N(t)$.

By definition, we have

$$\operatorname{ess}\liminf_{y\to x} f(t,y) = \lim_{\varepsilon\to 0^+} \operatorname*{ess\,inf}_{0<\|x-y\|<\varepsilon} f(t,y),$$

so it suffices to check that for all sufficiently small $\varepsilon > 0$ we have

$$\eta := \operatorname*{ess\,inf}_{0<\|x-y\|<\varepsilon} f(t,y) = \inf_{0<\|x-y\|<\varepsilon,\, y\notin N(t)} f(t,y) =: \iota. \tag{2.6}$$

Take any $\varepsilon > 0$ such that $f(t,\cdot)$ is essentially bounded on $B_\varepsilon(x)$. Clearly, ι is an essential lower bound for the set $\{f(t,y) : 0 < \|x-y\| < \varepsilon\}$, hence $\iota \le \eta$.

Now assume, reasoning by contradiction, that $\iota < \eta$. The definition of ι guarantees that we can find $y_0 \in \mathbb{R}^n \setminus N(t)$, $0 < \|x-y_0\| < \varepsilon$, such that

$$\iota \le f(t,y_0) < \eta.$$

Since the restriction of $f(t,\cdot)$ to $\mathbb{R}^n \setminus N(t)$ is continuous at y_0, there is a neighborhood of y_0 relative to $\mathbb{R}^n \setminus N(t)$ of points y satisfying $0 < \|x-y\| < \varepsilon$ for which we have $f(t,y) < \eta$, so η cannot be an essential lower bound for the set $\{f(t,y) : 0 < \|x-y\| < \varepsilon\}$, a contradiction. The proof of (2.6) is complete. □

3 Existence of Carathéodory solutions

In this section we use a deep existence result due to Filippov [10, Theorem 8, page 85] along with Proposition 2.1 and Lemma 2.2, to establish a new existence result of Carathéodory solutions for (1.1). We recall that a Carathéodory solution of (1.1) is an absolutely continuous function $x : I \longrightarrow \mathbb{R}^n$ such that $x(t_0) = x_0$ and $x'(t) = f(t,x(t))$ for a.a. $t \in I$.

For the convenience of the reader, we gather the main ingredients we need from [10, Theorem 8, page 85] in the following proposition.

Proposition 3.1. *Assume that $f : I \times \mathbb{R}^n \longrightarrow \mathbb{R}^n$ satisfies the following conditions.*

(i) The function $f(t,x)$ is measurable;

(ii) There exists $\psi \in L^1(I)$ such that for a.a. $t \in I$ and all $x \in \mathbb{R}^n$ we have

$$|f(t,x)| \le \psi(t).$$

Then, problem (1.1) has at least one Filippov solution.

We shall also employ the following result, which follows from [3, Lemma 5.8.13].

Lemma 3.2. *Let a, $b \in \mathbb{R}$, $a < b$. If $\varphi : [a,b] \longrightarrow \mathbb{R}$ is almost everywhere differentiable on $[a,b]$, then for each null measure set $A \subset \mathbb{R}$ there exists a null measure set $B \subset \varphi^{-1}(A)$ such that*

$$\varphi'(t) = 0 \quad \textit{for all } t \in \varphi^{-1}(A) \setminus B.$$

We are now in a position to prove a result on the existence of Carathéodory solutions for (1.1).

Theorem 3.3. *In the conditions of Proposition 3.1, assume also that there exist null measure sets $A_k \subset \mathbb{R}$, $k \in \mathcal{C} \subset \mathbb{N}$, and differentiable mappings $\tau_k : [a_k,b_k] \times \mathbb{R}^n \longrightarrow \mathbb{R}$, $[a_k,b_k] \subset I$, such that for a.a. $t \in I$ the following conditions hold:*

(a) *There exists a null measure set $N(t) \subset \mathbb{R}^n$ such that the restriction of $f(t,\cdot)$ to $\mathbb{R}^n \setminus N(t)$ is continuous;*

(b) *For each $x \in N(t)$ there exists $k \in \mathcal{C}$ such that $t \in [a_k, b_k]$, $\tau_k(t,x) \in A_k$, and*

$$\nabla \tau_k(t,x) \cdot (1,z) \neq 0 \quad \textit{for all } z \in \prod_{j=1}^{n} \left[\liminf_{y\to x,\, y\notin N(t)} f_j(t,y),\ \limsup_{y\to x,\, y\notin N(t)} f_j(t,y) \right]. \tag{3.1}$$

Then, problem (1.1) has at least one Carathéodory solution, which is also a Filippov solution.

Proof. By virtue of Proposition 2.1, problem (1.1) has at least one Filippov solution $x : I \longrightarrow \mathbb{R}^n$, which, according to (1.2), (2.1) and (2.4)–(2.5), satisfies

$$x'(t) \in \prod_{j=1}^{n} \left[\liminf_{y\to x(t),\, y\notin N(t)} f_j(t,y),\ \limsup_{y\to x(t),\, y\notin N(t)} f_j(t,y) \right] \quad \text{for a.a. } t \in I.$$

We shall prove that x is a Carathéodory solution of (1.1).

Let $E \subset I$ be a null measure set such that, first, conditions (a) and (b) hold for all $t \in I \setminus E$, and, second,

$$x'(t) \in \prod_{j=1}^{n} \left[\liminf_{y\to x(t),\, y\notin N(t)} f_j(t,y),\ \limsup_{y\to x(t),\, y\notin N(t)} f_j(t,y) \right] \quad \text{for all } t \in I \setminus E.$$

Observe that for each $t \in I \setminus E$ such that $x(t) \notin N(t)$ condition (a) ensures that the restriction of $f(t,\cdot)$ to $\mathbb{R}^n \setminus N(t)$ is continuous at $x(t)$ and therefore

$$x'(t) \in \prod_{j=1}^{n} \left[\liminf_{y\to x(t),\, y\notin N(t)} f_j(t,y),\ \limsup_{y\to x(t),\, y\notin N(t)} f_j(t,y) \right] = \{f(t,x(t))\}.$$

Hence, it suffices to prove that the set $J = \{t \in I \setminus E \,:\, x(t) \in N(t)\}$ is null.

We deduce from condition (b) that

$$J \subset \bigcup_{k\in\mathcal{C}} \{t \in [a_k,b_k] \setminus E \,:\, \tau_k(t,x(t)) \in A_k\},$$

so the proof is reduced to showing that each $J_k = \{t \in [a_k,b_k] \setminus E \,:\, \tau_k(t,x(t)) \in A_k\}$ is a null measure set. For an arbitrarily fixed $k \in \mathcal{C}$, we define $\varphi(t) = \tau_k(t,x(t))$ for all $t \in [a_k,b_k]$, so that $J_k \subset \varphi^{-1}(A_k)$ and it suffices to prove that $\varphi^{-1}(A_k)$ is null. Since $m(A_k) = 0$, Lemma 3.2 guarantees the existence of a set $B \subset \varphi^{-1}(A_k)$, with $m(B) = 0$, such that for every $t \in \varphi^{-1}(A_k) \setminus B$ we have $\varphi'(t) = 0$, i.e.

$$\frac{d}{dt}\tau_k(t,x(t)) = 0. \tag{3.2}$$

Let us prove that $\varphi^{-1}(A_k) \subset B \cup E$, thus showing that $\varphi^{-1}(A_k)$ is null. Reasoning by contradiction, we assume that there is some $t \in \varphi^{-1}(A_k)$ such that $t \notin B \cup E$, and then we can use the chain rule in (3.2) to deduce that

$$\nabla \tau_k(t,x(t)) \cdot (1,x'(t)) = 0,$$

a contradiction with condition (3.1). □

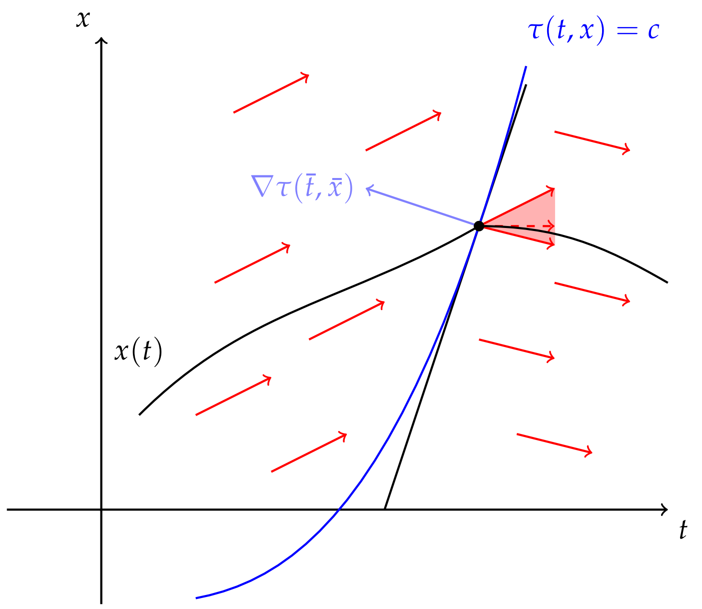

Figure 3.1: Visualization of the transversality condition (3.1) at $(\bar{t},\bar{x}) = (\bar{t}, x(\bar{t}))$.

Remark 3.4. Observe that, under the assumptions of Theorem 3.3, every Filippov solution of (1.1) is in fact a Carathéodory solution.

Note that, in general, Carathéodory solutions need not be Filippov solutions. Indeed, the constant function $x(t) \equiv 0$ is a Carathéodory solution of the initial value problem

$$x' = f(x) = \begin{cases} 1, & \text{if } x \neq 0, \\ 0, & \text{if } x = 0, \end{cases} \qquad t \in [0,1], \quad x(0) = 0, \tag{3.3}$$

but it is not a Filippov solution. Readers can find in [15] a good account on the relations between Carathéodory and Filippov solutions.

The transversality condition (3.1) is based on an original idea by Bressan and Shen [6], later improved and applied by the authors in [12, 13]. All those papers assumed that

$$f(t,x) = F(t, g_1(\tau_1(t,x),x), g_2(\tau_2(t,x),x), \dots, g_N(\tau_N(t,x),x)) \quad \text{for some } N \in \mathbb{N},$$

for functions F and g_k under suitable conditions, a technical drawback which we avoid in this paper.

Figure 3.1 can help readers to have a clearer intuition of what (3.1) means, at least in the very specific setting of one dimension and just one discontinuity curve $\tau(t,x) = c$. Note that vectors $(1,z)$ in condition (3.1) are represented as the red triangle in the figure, and condition (3.1) means that the red triangle cannot contain tangent vectors to $\tau(t,x) = c$ at $(\bar{t},\bar{x})$.

In addition, in [12, 13], we first look for Krasovskij solutions and then we use a transversality condition to prove that they are Carathéodory solutions. In this paper, we use Filippov solutions instead of Krasovskij's, thus getting a milder transversality condition in terms of essential limits. Both transversality conditions are compared in our next example.

Example 3.5. Consider the initial value problem (3.3). Theorem 3.3 ensures that (3.3) has at least one Carathéodory solution. Indeed, the function f is continuous on $\mathbb{R} \setminus \{0\}$ and so conditions (a) and (b) in Theorem 3.3 hold with $\mathcal{C} = \{1\}$, $N = A_1 = \{0\}$ and $\tau_1(t,x) = x$, since

$$\left[\liminf_{y\to 0} f(y), \limsup_{y\to 0} f(y)\right] = \{1\}.$$

The main results in [12,13] do not apply because they are based on the larger Krasovskij envelope

$$\mathcal{K}f(x) := \left[\min\left\{f(x), \liminf_{y\to x} f(y)\right\}, \max\left\{f(x), \limsup_{y\to x} f(y)\right\}\right],$$

so the transversality condition in [12,13], namely,

$$\nabla\tau_1(t,x)\cdot(1,z) = z \neq 0 \quad \text{for all } z \in \mathcal{K}f(0) = [0,1],$$

fails (at $z = 0$).

We also stress that the information provided by Proposition 2.1 and Lemma 2.2 concerning the Filippov envelope is useful in order to reduce the regularity required to the function f. Note that in the previous mentioned papers [12,13], it was basically assumed that for a.a. $t \in I$ there exists a null measure set $N(t) \subset \mathbb{R}^n$ such that $f(t,\cdot)$ is continuous on $\mathbb{R}^n \setminus N(t)$, instead of the weaker assumption (a) in Theorem 3.3. We highlight that Theorem 3.3 can be even applied to functions f which are discontinuous at every point of its domain, as shown by the following example.

Example 3.6. Any planar system of the form

$$\begin{cases} x' = f_1(t,x,y), & x(0) = 0, \\ y' = f_2(t,x,y), & y(0) = 0, \end{cases}$$

where f_1 is continuous and bounded and f_2 is measurable, bounded and its restriction to $[0,L] \times (\mathbb{R} \setminus A) \times \mathbb{R}$ is continuous with A a null measure set, has at least one absolutely continuous solution defined in the interval $[0,L]$ provided that $f_1(t,x,y) \neq 0$ for all (t,x,y) such that $x \in A$.

Indeed, it suffices to apply Theorem 3.3 with $\mathcal{C} = \{1\}$, $\tau_1(t,x,y) = x$, $A_1 = A$ and $N(t) = A \times \mathbb{R}$. Note that the transversality condition (3.1) can be written in this case as

$$z_1 \neq 0 \quad \text{for all } (z_1,z_2) \in \prod_{j=1}^{2} \left[\liminf_{(u,v)\to(x,y),\, u\notin A} f_j(t,u,v), \limsup_{(u,v)\to(x,y),\, u\notin A} f_j(t,u,v)\right],$$

for each $(x,y) \in \mathbb{R}^2$ such that $x \in A$. Since f_1 is continuous,

$$\left[\liminf_{(u,v)\to(x,y),\, u\notin A} f_1(t,u,v), \limsup_{(u,v)\to(x,y),\, u\notin A} f_1(t,u,v)\right] = \{f_1(t,x,y)\},$$

and thus the conclusion follows from the fact that f_1 does not vanish at the points (t,x,y) with $x \in A$.

For instance, we can choose $f_1(t,x,y) = \cos^2(x\,y) + e^{t-x^2-y^2}$ and $f_2(t,x,y) = \varphi(x)e^{\sin(t+y)}$, where $\varphi : \mathbb{R} \to \mathbb{R}$ is given by

$$\varphi(x) = \chi_{\mathbb{Q}}(x) - \chi_{\mathbb{R}\setminus\mathbb{Q}}(x),$$

where χ_B denotes the characteristic function of the set $B \subset \mathbb{R}$. It is worth mentioning that φ is discontinuous at every point which, to the best of the authors' knowledge, falls outside the scope of earlier existence results. Observe, however that its restriction to the set $\mathbb{R} \setminus \mathbb{Q}$ is continuous and therefore Theorem 3.3 applies.

Our existence result applies for discontinuous ODE-systems associated with two-phase flows, that is, initial value problem (1.1) with a nonlinearity f which is discontinuous over a single hypersurface $\Sigma(t)$ defined as

$$\Sigma(t) := \{x \in \mathbb{R}^n \, : \, \tau(t,x) = 0\},$$

where $\tau : I \times \mathbb{R}^n \longrightarrow \mathbb{R}$ is a differentiable mapping. More precisely, let us consider an initial value problem of type

$$x' = f(t,x) = \begin{cases} f^+(t,x) & \text{if } x \in \Sigma^+(t), \\ f^-(t,x) & \text{if } x \in \Sigma^-(t), \end{cases} \qquad t \in I, \quad x(t_0) = x_0, \tag{3.4}$$

where

$$\Sigma^+(t) = \{x \in \mathbb{R}^n \, : \, \tau(t,x) > 0\} \text{ and } \Sigma^-(t) = \{x \in \mathbb{R}^n \, : \, \tau(t,x) < 0\},$$

and $f^\pm : I \times \mathbb{R}^n \longrightarrow \mathbb{R}^n$ are L^1–bounded Carathéodory mappings. Note that the definition of f on $\Sigma(t)$ is not relevant in order to apply Theorem 3.3, so we may assume that either $f(t,x) = f^+(t,x)$ or $f(t,x) = f^-(t,x)$ on $\Sigma(t)$.

As a straightforward consequence of Theorem 3.3, we obtain the following existence result for (3.4).

Corollary 3.7. *Assume that for a.a. $t \in I$ and for each $x \in \Sigma(t)$ we have*

$$\nabla\tau(t,x) \cdot (1,z) \neq 0 \quad \textit{for all } z \in \overline{\text{co}} \left\{ f^-(t,x), f^+(t,x) \right\}. \tag{3.5}$$

Then problem (3.4) has at least one Carathéodory solution.

Note that we need less regularity on $f^\pm$ than some related results (cf. Step 1 of [4, Theorem 1], where they are required to be locally Lipschitz continuous in x instead of merely continuous in x).

Let us now focus on the scalar case of (1.1), i.e., $n = 1$. By the implicit function theorem, if τ is regular enough, the discontinuity curve $\tau(t,x) = c$ can be seen, at least locally, as the graph of a time-dependent curve $x = \gamma(t)$ provided that $\frac{\partial \tau}{\partial x}(t,x) \neq 0$. Note that the transversality condition (3.1) implies that $\nabla\tau(t,x) \neq (0,0)$ over the discontinuity points of f which satisfy $\tau(t,x) = c$, where c belongs to a suitable null measure set.

With this in mind, we have the following alternative version of Theorem 3.3.

Corollary 3.8. *In the conditions of Proposition 3.1 and in the case $n = 1$, assume also that there exist null measure sets $A_k \subset \mathbb{R}$, $k \in \mathcal{C} \subset \mathbb{N}$, and differentiable mappings $\gamma_k : [a_k, b_k] \subset I \longrightarrow \mathbb{R}$ such that for a.a. $t \in I$ the following conditions hold:*

(a) the restriction of $f(t,\cdot)$ to the set $\mathbb{R} \setminus N(t)$ is continuous, where

$$N(t) = \bigcup_{\{k \in \mathcal{C} \, : \, t \in [a_k,b_k]\}} \bigcup_{c \in A_k} \{\gamma_k(t) + c\} \, ;$$

(b) for each $k \in \mathcal{C}$ such that $t \in [a_k, b_k]$, and each $c \in A_k$, we have either

$$\gamma_k'(t) < \liminf_{y \to \gamma_k(t), \, y \notin N(t)} f(t, y + c) \tag{3.6}$$

or

$$\gamma_k'(t) > \limsup_{y \to \gamma_k(t), \, y \notin N(t)} f(t, y + c). \tag{3.7}$$

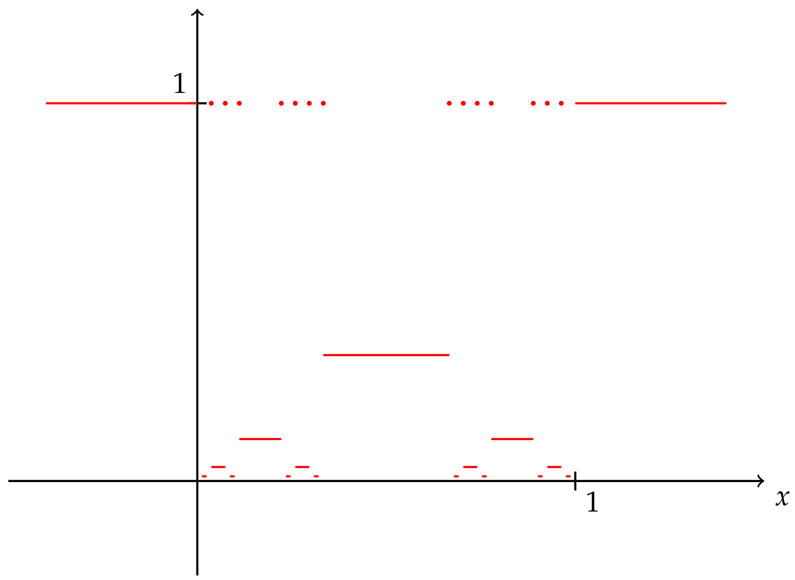

Figure 3.2: Approximate plot of $x \mapsto f(0,x)$, discontinuous at every point of Cantor's ternary set.

Then, problem (1.1) *has at least one Carathéodory solution.*

Proof. It suffices to apply Theorem 3.3 with $\tau_k(t,x) = x - \gamma_k(t)$. □

Example 3.9. Let C denote Cantor's ternary set. We have

$$[0,1] \setminus C = \bigcup_{n=1}^{\infty} (a_n, b_n),$$

where $(a_n, b_n) \cap (a_m, b_m) = \emptyset$ if $n \neq m$.

Define $f : [0,1] \times \mathbb{R} \longrightarrow \mathbb{R}$ as $f(t,x) = b_n - a_n$ provided that $x + t \in (a_n, b_n)$ for some $n \in \mathbb{N}$, and $f(t,x) = 1$ otherwise. See Figure 3.2 for a plot of $x \mapsto f(0,x)$.

Corollary 3.8 guarantees that the corresponding initial value problem (1.1) (with $t_0 = x_0 = 0$ and $L = 1$) has at least one Carathéodory solution. To prove it, just define $\mathcal{C} = \{1\}$, $A_1 = C$, and $\gamma_1(t) = -t$ for $t \in [0,1]$. In this case, $N(t) = -t + C$ for all $t \in [0,1]$ and the restriction of $f(t,\cdot)$ to $\mathbb{R} \setminus (-t + C)$ is continuous; moreover, condition (3.6) holds for all $t \in [0,1]$.

Observe that the set $-t + C$ is not countable for any t, so discontinuities of f cannot be covered by countable unions of curves, as required, for instance, in Corollary 3.7 or Corollary 3.8 in [7]. Remarkably, solutions are increasing on $[0,1]$, so they cross every line $x + t = c$, $c \in C$.

The previous result does not cover some situations in which the set of Filippov solutions is a subset of that of Carathéodory solutions for (1.1). Indeed, one may easily verify that every Filippov solution of the initial value problem

$$x' = f(t,x) = \begin{cases} 0, & \text{if } x > t, \\ 1, & \text{if } x = t, \\ 2, & \text{if } x < t, \end{cases} \qquad t \in [0,1], \quad x(0) = 0, \tag{3.8}$$

is in fact a Carathéodory solution. Nevertheless, f is discontinuous over the line $x = \gamma(t) := t$, $t \in [0,1]$, which does not satisfy neither (3.6) nor (3.7), since

$$\gamma'(t) = 1 \in [0,2] = \left[\liminf_{y\to t} f(t,y), \limsup_{y\to t} f(t,y)\right].$$

Note that γ is a solution of the initial value problem (3.8).

In the following result, we admit that f be discontinuous over the graphs of a countable family of solutions of the differential equation $x' = f(t,x)$.

Proposition 3.10. *In the conditions of Proposition 3.1 and in the case $n = 1$, assume also that there exist null measure sets $A_k \subset \mathbb{R}$, $k \in \mathcal{C} \subset \mathbb{N}$, $j \in \mathcal{D} \subset \mathbb{N}$, and differentiable mappings $\gamma_k : [a_k, b_k] \subset I \longrightarrow \mathbb{R}$ and $\psi_j : [\tilde{a}_j, \tilde{b}_j] \subset I \longrightarrow \mathbb{R}$ such that for a.a. $t \in I$ the following conditions hold:*

(a) the restriction of $f(t,\cdot)$ to the set $\mathbb{R} \setminus N(t)$ is continuous, where

$$N(t) = N_1(t) \cup N_2(t), \qquad N_1(t) = \bigcup_{k\in\mathcal{C}} \bigcup_{c_k\in A_k} \{\gamma_k(t) + c_k\} \quad \text{and} \quad N_2(t) = \bigcup_{j\in\mathcal{D}} \{\psi_j(t)\};$$

(b) for each $k \in \mathcal{C}$ and each $c_k \in A_k$, the function γ_k satisfies that for a.a. $t \in [a_k, b_k]$ either (3.6) or (3.7) holds;

(c) for each $j \in \mathcal{D}$, $\psi_j'(t) = f(t, \psi_j(t))$ for a.a. $t \in [\tilde{a}_j, \tilde{b}_j]$.

Then, problem (1.1) has at least one Carathéodory solution.

Proof. It follows from Proposition 3.1 that problem (1.1) has at least one Filippov solution x. Let us prove that x is a Carathéodory solution.

It can be shown (just as in the proof of Theorem 3.3) that the set

$$J^{\gamma} = \bigcup_{k\in\mathcal{C}} \{t \in [a_k, b_k] : x(t) - \gamma_k(t) \in A_k\}$$

has Lebesgue measure zero. Suppose that there exists $j \in \mathcal{D}$ such that $m(J_j^{\psi}) > 0$, with

$$J_j^{\psi} = \{t \in [\tilde{a}_j, \tilde{b}_j] : x(t) = \psi_j(t)\} \quad \text{and} \quad J^{\psi} = \bigcup_{j\in\mathcal{D}} J_j^{\psi}.$$

Then $x'(t) = \psi_j'(t)$ for a.a. $t \in J_j^{\psi}$. By the definition of ψ_j, we have that $\psi_j'(t) = f(t, \psi_j(t))$ for a.a. $t \in J_j^{\psi}$ and thus $x'(t) = f(t, x(t))$ for a.a. $t \in J_j^{\psi}$. Hence, $x'(t) = f(t, x(t))$ for a.a. $t \in J^{\psi}$.

Finally, since the restriction of $f(t,\cdot)$ to $\mathbb{R} \setminus N(t)$ is continuous at $x(t)$ for a.a. $t \in I \setminus (J^{\gamma} \cup J^{\psi})$, we conclude that x is a Carathéodory solution of (1.1). □

We shall say that both the functions γ_k satisfying (3.6) or (3.7) and the functions of type ψ_j are *admissible discontinuity curves*(cf. [8]).

Note that the previous result is sharp in the following sense: if there exists a differentiable function $\gamma : [t_0, t_1] \subset I \to \mathbb{R}$ which is not an admissible discontinuity curve and such that $\gamma(t_0) = x_0$ and for each $t \in [t_0, t_1]$, $f(t,\cdot)$ is discontinuous at $\gamma(t)$, then γ can be extended to a Filippov solution of (1.1) which is not a solution in the sense of Carathéodory.

4 Uniqueness of Carathéodory and Filippov solutions

In this section we show that a similar transversality condition to that employed in Theorem 3.3 can be used to deduce uniqueness of Filippov or Carathéodory solutions of (1.1). Note that recently Fjordholm [11] gave necessary and sufficient conditions for the uniqueness of Filippov solutions in the scalar autonomous case of (1.1), complementing the results for Carathéodory solutions due to Binding [2]. Our results concern non-autonomous discontinuous systems.

First, we use some transversality conditions to prove uniqueness of Filippov solutions of (1.1). Surprisingly enough, it does not guarantee uniqueness of Carathéodory solutions.

Basically, we assume that $f(t,x)$ satisfies a Lipschitz condition with respect to x in every gap delimited in $I \times \mathbb{R}^n$ by a set of hypersurfaces (not necessarily a finite set) where f may be discontinuous and where some suitable transversality conditions hold.

We need some notation for our first main result on uniqueness. Let $A \subset \mathbb{R}$ be a non-empty set. We will say that $x_0 \in A$ is a *left-isolated point*(*right-isolated point*) of A if there is $\delta > 0$ such that $(x_0 - \delta, x_0) \cap A = \emptyset$ ($(x_0, x_0 + \delta) \cap A = \emptyset$). In the sequel, we denote by $\mathcal{I}^-(A)$ the set of left-isolated points of A and by $\mathcal{I}^+(A)$ that of right-isolated points. Obviously, if $x_0 \in \mathcal{I}^-(A) \cap \mathcal{I}^+(A)$, it is an isolated point of the subset A.

Theorem 4.1. *In the conditions of Proposition 3.1, assume also that there exist continuously differentiable mappings $\tau_k : I \times \mathbb{R}^n \longrightarrow \mathbb{R}$ ($k = 1, 2, \ldots, m$, $m \in \mathbb{N}$) and countable closed sets $A_k \subset \mathbb{R}$ satisfying that $A_k = \mathcal{I}^-(A_k) \cup \mathcal{I}^+(A_k)$ such that the following conditions hold:*

(i) For each $k \in \{1, 2, \ldots, m\}$ and each $(t,x) \in \tau_k^{-1}(A_k)$, there exists $\varepsilon > 0$ such that for a.a. $s \in (t, t+\varepsilon)$ and all $\zeta \in B_\varepsilon(x)$ we have

$$\nabla \tau_k(s,\zeta) \cdot (1,z) > 0 \quad \text{for all } z \in \prod_{j=1}^{n} \left[\operatorname{ess} \liminf_{y \to \zeta} f_j(s,y), \operatorname{ess} \limsup_{y \to \zeta} f_j(s,y) \right] \tag{4.1}$$

if $\tau_k(t,x) \in \mathcal{I}^+(A_k) \setminus \mathcal{I}^-(A_k)$;

$$\nabla \tau_k(s,\zeta) \cdot (1,z) < 0 \quad \text{for all } z \in \prod_{j=1}^{n} \left[\operatorname{ess} \liminf_{y \to \zeta} f_j(s,y), \operatorname{ess} \limsup_{y \to \zeta} f_j(s,y) \right] \tag{4.2}$$

if $\tau_k(t,x) \in \mathcal{I}^-(A_k) \setminus \mathcal{I}^+(A_k)$; and either (4.1) or (4.2) if $\tau_k(t,x) \in \mathcal{I}^-(A_k) \cap \mathcal{I}^+(A_k)$.

(ii) For each connected component, $\mathcal{O}$, of the set $I \times \mathbb{R}^n \setminus \bigcup_{k=1}^m \tau_k^{-1}(A_k) = \bigcap_{k=1}^m \tau_k^{-1}(\mathbb{R} \setminus A_k)$, there exists $l \in L^1(I)$ such that for a.a. $t \in I$ and all x, y such that (t,x), $(t,y) \in \mathcal{O}$ we have

$$\|f(t,x) - f(t,y)\| \le l(t) \|x - y\|. \tag{4.3}$$

Then, problem (1.1) has exactly one Filippov solution.

Proof. We can assume, without loss of generality, that $A_k = \mathcal{I}^+(A_k)$ for every $k = 1, 2, \ldots, m$. Indeed, if for some k we have $\mathcal{I}^-(A_k) \neq \emptyset$, then we replace the set A_k by two sets, namely, $A_{k,1} = \mathcal{I}^+(A_k)$ (which satisfies (4.1) with τ_k) and $A_{k,2} = -\mathcal{I}^-(A_k)$ (which satisfies $A_{k,2} = \mathcal{I}^+(A_{k,2})$) and we define a new function $\tilde{\tau}_k = -\tau_k$. Now, condition (4.2) for $\mathcal{I}^-(A_k)$ and τ_k implies condition (4.1) for $A_{k,2}$ and $\tilde{\tau}_k$.

By virtue of Proposition 3.1, problem (1.1) has at least one Filippov solution. Let us prove uniqueness. Let $x(t)$ and $y(t)$ be Filippov solutions of (1.1); we shall prove that $x(t) = y(t)$ for all $t \in I$. Reasoning by contradiction, we assume that there exists some $t_1 \in [t_0, t_0 + L)$ and $\rho > 0$ such that $x(t_1) = y(t_1)$ and $\|x(t) - y(t)\| > 0$ for all $t \in (t_1, t_1 + \rho)$.

Let $z(t)$ be an arbitrary solution of (1.1) such that $z(t_1) = x(t_1)$. Observe that for all $t \in I$, $t \geq t_1$, we have

$$\|z(t) - x(t_1)\| \leq \int_{t_1}^{t} \|z'(r)\| \, dr \leq \int_{t_1}^{t} \psi(r) \, dr,$$

so for any $\varepsilon > 0$ there exists $\mu > 0$ (independent of the solution $z(t)$) such that $z(t) \in B_\varepsilon(x(t_1))$ for all $t \in [t_1, t_1 + \mu]$.

Let $k \in \{1, 2, \ldots, m\}$ be fixed. If $\tau_k(t_1, x(t_1)) \notin A_k$, then there exists an open interval $I_k \subset \mathbb{R} \setminus A_k$ such that $\tau_k(t_1, z(t_1)) = \tau_k(t_1, x(t_1)) \in I_k$ (observe that I_k does not depend on the specific solution $z(t)$). Since τ_k is continuous at $(t_1, x(t_1))$, there exists $r_k > 0$ (independent of the solution $z(t)$) such that $\tau_k(t, z(t)) \in I_k$ for all $t \in [t_1, t_1 + r_k)$, or, equivalently, $(t, z(t)) \in \tau_k^{-1}(I_k)$ for all $t \in [t_1, t_1 + r_k)$.

If $\tau_k(t_1, x(t_1)) =: a \in A_k = \mathcal{I}^+(A_k)$, then there is $\delta > 0$ such that $(a, a + \delta) \cap A_k = \emptyset$ and we define $I_k = (a, a + \delta)$ (which does not depend on the solution $z(t)$). Then, assumption (i) implies that there exists $\varepsilon > 0$ such that for a.a. $s \in (t_1, t_1 + \varepsilon)$ and $\zeta \in B_\varepsilon(x(t_1))$ we have

$$\nabla \tau_k(s, \zeta) \cdot (1, z) > 0 \quad \text{for all } z \in \prod_{j=1}^{n} \left[\operatorname*{ess\,lim\,inf}_{y \to \zeta} f_j(s, y), \operatorname*{ess\,lim\,sup}_{y \to \zeta} f_j(s, y) \right]. \tag{4.4}$$

Take a sufficiently small $r_k \in (0, \varepsilon)$ such that $z(t) \in B_\varepsilon(x(t_1))$ for all $t \in [t_1, t_1 + r_k)$. For a.a. $t \in [t_1, t_1 + r_k)$ we use the chain rule and (4.4) to deduce that

$$\frac{d}{dt} \tau_k(t, z(t)) = \nabla \tau_k(t, z(t)) \cdot (1, z'(t)) > 0,$$

because, as a Filippov solution, $z(t)$ satisfies (1.3). Note that the composition $\tau_k(\cdot, z(\cdot))$ is absolutely continuous, so the previous inequality implies that $\tau_k(t, z(t)) > a$ for all $t \in (t_1, t_1 + r_k)$.

Let $r = \min\{r_1, r_2, \ldots, r_m\}$; we have proven that for every $t \in (t_1, t_1 + r)$ we have

$$(t, z(t)) \in \bigcap_{k=1}^{m} \tau_k^{-1}(I_k),$$

and r does not depend on the specific solution $z(t)$ such that $z(t_1) = x(t_1)$.

We know from [10, Theorem 9] that the set of all Filippov solutions of (1.1) with initial condition $(t_1, x(t_1))$ is a connected subset of $\mathcal{C}([t_1, t_1 + r])$. Hence, for a fixed $t^* \in (t_1, t_1 + r)$ the set

$$S(t^*) = \{(t^*, z(t^*)) \, : \, z(t) \text{ solution}, \, z(t_1) = x(t_1)\}$$

is a connected subset of $I \times \mathbb{R}^n$. This implies that the set

$$S = \{(t, z(t)) \, : \, z(t) \text{ solution}, \, z(t_1) = x(t_1) \text{ and } t \in (t_1, t_1 + r)\}$$

is a connected subset of $I \times \mathbb{R}^n$ because it is the union of all the graphs $\{(t, z(t)) : t \in (t_1, t_1 + r)\}$ which are connected and each contains a point in $S(t^*)$. Therefore, S must be inside one of the connected components of $\bigcap_{k=1}^{m} \tau_k^{-1}(I_k)$, which is contained in a connected component of $I \times \mathbb{R}^n \setminus \bigcup_{k=1}^{m} \tau_k^{-1}(A_k)$. Now condition (ii) ensures the existence of some $l \in L^1(I)$ such that

$$\|x(t) - y(t)\| \leq \int_{t_1}^{t} \|f(s, x(s)) - f(s, y(s))\| \, ds \leq \int_{t_1}^{t} l(s) \|x(s) - y(s)\| \, ds, \quad t \in [t_1, t_1 + r],$$

and we deduce from Gronwall's inequality that $\|x - y\| = 0$ on $[t_1, t_1 + r]$, a contradiction. $\square$

Remark 4.2. The mappings τ_k may be defined in $[a_k, b_k] \times \mathbb{R}^n$, with $[a_k, b_k] \subset I$, instead of the whole $I \times \mathbb{R}^n$. Indeed, the set $\{a_1, b_1, a_2, b_2, \dots, a_m, b_m\}$ defines a partition of the interval $[t_0, t_0 + L]$ and it suffices to apply Theorem 4.1 in each subinterval defined by the partition in order to obtain uniqueness of Filippov solutions to (1.1).

Remark 4.3. The Lipschitz type condition (4.3) can be replaced, for instance, by one-sided Lipschitz, Osgood's or Montel–Tonelli's conditions (see [1]) in such a way that uniqueness of Filippov solutions is proven in a similar manner.

Observe that, in the hypotheses of Theorems 3.3 and 4.1, although existence of Carathéodory solutions for the initial value problem (1.1) is guaranteed, uniqueness cannot be ensured, as shown by the Cauchy problem (3.3). Hence, to obtain uniqueness of Carathéodory solutions, it is necessary to reinforce the assumptions on Theorem 4.1. Obviously, it would be sufficient to ensure that the set of Carathéodory solutions and the set of Filippov solutions coincide (as pointed out in Remark 3.4, Filippov solutions are Carathéodory solutions, so it only remains to ensure the reverse inclusion). In case of autonomous systems, some comparison between them can be found in [15]. In general, this can be directly obtained if one assumes that f is a selection of the Filippov envelope or, even less, if for a.e. t and all x,

$$\operatorname{ess}\liminf_{y \to x} f_j(t,y) \le f_j(t,x) \le \operatorname{ess}\limsup_{y \to x} f_j(t,y), \qquad j = 1, \dots, n, \tag{4.5}$$

which provides uniqueness of Carathéodory solutions as a straightforward consequence of Theorem 4.1.

Corollary 4.4. *In the conditions of Theorem 4.1, if in addition f satisfies (4.5), then problem (1.1) has exactly one Carathéodory solution.*

This simple uniqueness criterion can be useful in practice. In particular, it enables us to establish uniqueness of Carathéodory solutions for discontinuous ODE-systems associated with two-phase flows, namely, initial value problems of type (3.4).

Corollary 4.5. *Let $f^{\pm} : I \times \mathbb{R}^n \longrightarrow \mathbb{R}^n$ be L^1-bounded Carathéodory mappings. Assume that $f^{\pm}$ are Lipschitz continuous in x and that for a.a. $t \in I$ and for each $x \in \Sigma(t)$, there exists $\varepsilon > 0$ such that for all $s \in (t, t+\varepsilon)$ and all $\zeta \in B_\varepsilon(x)$ we have either*

$$\nabla\tau(s,\zeta) \cdot (1,z) > 0 \quad \textit{for all } z \in \overline{\text{co}}\left\{f^-(s,\zeta), f^+(s,\zeta)\right\}$$

or

$$\nabla\tau(s,\zeta) \cdot (1,z) < 0 \quad \textit{for all } z \in \overline{\text{co}}\left\{f^-(s,\zeta), f^+(s,\zeta)\right\}.$$

Then problem (3.4) has a unique Carathéodory solution.

Once existence is guaranteed, uniqueness of both Carathéodory and Filippov solutions can be obtained simultaneously, without assuming (4.5), provided that there exists a unique Krasovskij solution of (1.1). To do so, we shall strengthen the transversality condition (i) in Theorem 4.1.

Theorem 4.6. *In the conditions of Theorems 3.3 and 4.1, assume that hypothesis (i) is replaced by the following one:*

(i) For each $k \in \{1,2,\dots,m\}$ and each $(t,x) \in \tau_k^{-1}(A_k)$, there exists $\varepsilon > 0$ such that for a.a. $s \in (t,t+\varepsilon)$ and all $\zeta \in B_\varepsilon(x)$ we have*

$$\nabla \tau_k(s,\zeta)\cdot(1,z) > 0 \quad \text{for all } z \in \mathcal{K}f(s,\zeta) \tag{4.6}$$

if $\tau_k(t,x) \in \mathcal{I}^+(A_k) \setminus \mathcal{I}^-(A_k)$;

$$\nabla \tau_k(s,\zeta)\cdot(1,z) < 0 \quad \text{for all } z \in \mathcal{K}f(s,\zeta), \tag{4.7}$$

if $\tau_k(t,x) \in \mathcal{I}^-(A_k) \setminus \mathcal{I}^+(A_k)$; and either (4.6) or (4.7) if $\tau_k(t,x) \in \mathcal{I}^-(A_k) \cap \mathcal{I}^+(A_k)$ (where $\mathcal{K}f$ denotes the Krasovskij envelope of f).

Then problem (1.1) has exactly one Krasovskij solution, which is also the unique Carathéodory and Filippov solution of (1.1).

Proof. It follows, in an analogous way to the proof of Theorem 4.1, that the differential inclusion

$$x' \in \mathcal{K}f(t,x), \quad t \in I, \; x(t_0) = x_0, \tag{4.8}$$

has a unique solution.

To conclude, it suffices to observe that any Carathéodory, Filippov or Krasovskij solution of (1.1) is, in particular, an absolutely continuous solution of (4.8). □

Remark 4.7. Note that the Krasovskij envelope of the function f satisfies that

$$\begin{aligned}\mathcal{K}f(s,\zeta) &:= \bigcap_{\varepsilon>0} \overline{\text{co}}\, f\left(s, B_\varepsilon(\zeta)\right) \\ &\subset \prod_{j=1}^{n} \left[\min\left\{f_j(s,\zeta), \liminf_{y\to\zeta} f_j(s,y)\right\}, \max\left\{f_j(s,\zeta), \limsup_{y\to\zeta} f_j(s,y)\right\}\right].\end{aligned}$$

Example 4.8. Let $\lfloor\cdot\rfloor$ be the floor function. The system

$$\begin{cases} x' = f_1(x,y), & x(0)=0, \\ y' = f_2(x,y), & y(0)=0, \end{cases}$$

with $f = (f_1,f_2) : \mathbb{R}^2 \to \mathbb{R}^2$ defined as

$$f(x,y) = \begin{cases} \left(5x + \dfrac{1}{\lfloor 1/(1-x^2-y^2)\rfloor}, 5y + \dfrac{1}{\lfloor 1/(1-x^2-y^2)\rfloor}\right), & \text{if } x^2+y^2<1, \\ \left(5x\, e^{1-x^2-y^2}, 5y\, e^{1-x^2-y^2}\right), & \text{otherwise,} \end{cases}$$

has exactly one Carathéodory solution in any interval $[0,L]$ ($L>0$).

Observe that Theorem 4.6 can be applied with $m=1$, $\tau_1(x,y) = x^2+y^2$ and the closed countable set $A_1 = \{1-1/(k+1) : k \in \mathbb{N}\} \cup \{1\}$ (clearly, $A_1 = \mathcal{I}^+(A_1)$ and for any open interval I the set $\tau_1^{-1}(I)$ is empty or connected). Indeed, in order to check condition (i*), notice that

$$\frac{1}{\lfloor 1/(1-x^2-y^2)\rfloor} = \frac{1}{j} \quad (j \in \mathbb{N}) \quad \text{if and only if} \quad 1-\frac{1}{j} \le x^2+y^2 < 1-\frac{1}{j+1}.$$

Hence, for $j \in \mathbb{N}$, $j \geq 2$, and $x^2 + y^2 = 1 - 1/j$ fixed, we have that

$$\begin{aligned}\mathcal{K}f(x,y) &\subset \prod_{i=1}^{2}\left[\liminf_{(z_1,z_2)\to(x,y)} f_i(z_1,z_2),\ \limsup_{(z_1,z_2)\to(x,y)} f_i(z_1,z_2)\right]\\ &\subset \left[5x+\frac{1}{j}, 5x+\frac{1}{j-1}\right]\times\left[5y+\frac{1}{j}, 5y+\frac{1}{j-1}\right].\end{aligned}$$

It follows that for $(z_1,z_2) \in \mathcal{K}f(x,y)$,

$$\nabla\tau_1(x,y)\cdot(z_1,z_2) = (2x,2y)\cdot(5x+a_j, 5y+b_j) = 10(x^2+y^2) + 2(xa_j + yb_j)$$

where $a_j, b_j \in [1/j, 1/(j-1)]$. Then

$$\nabla\tau_1(x,y)\cdot(z_1,z_2) \geq 10\left(1-\frac{1}{j}\right) - 2\left(|x|+|y|\right)\frac{1}{j-1} > 10\left(1-\frac{1}{j}\right) - 4 \geq 1$$

for all $(z_1,z_2) \in \mathcal{K}f(x,y)$.

Note that f is continuous at any (x,y) such that $x^2+y^2 = 1$, so $\mathcal{K}f(x,y) = \{f(x,y)\}$ and

$$\nabla\tau_1(x,y)\cdot(f_1(x,y), f_2(x,y)) = (2x,2y)\cdot(5x,5y) = 10.$$

Finally, by continuity, we deduce that condition (i*) holds. Moreover, f is Lipschitz continuous in the sets $\mathcal{O}_- = \{(x,y) \in \mathbb{R}^2 : x^2+y^2 < 1\}$, $\mathcal{O}_+ = \{(x,y) \in \mathbb{R}^2 : x^2+y^2 > 1\}$ and

$$\mathcal{O}_j = \left\{(x,y) \in \mathbb{R}^2 : 1-\frac{1}{j} < x^2+y^2 < 1-\frac{1}{j+1}\right\} \quad (j \in \mathbb{N},\ j \geq 2).$$

Therefore, Theorem 4.6 is applicable and the conclusion follows.

As a consequence of Theorem 4.6, we can also deduce a discontinuous version of a classical uniqueness criterion due to Norris and Driver [14]. Observe that condition (c) is slightly stronger than condition (i^*) in Theorem 4.6 because we need to use Theorem 3.3.

Corollary 4.9. *Let $f : I \times \mathbb{R}^n \longrightarrow \mathbb{R}^n$ a measurable function satisfying the following hypotheses:*

(a) There exist a constant $K > 0$ and functions $g_k : \mathbb{R} \longrightarrow \mathbb{R}$ and $\tau_k : I \times \mathbb{R}^n \longrightarrow \mathbb{R}$, for $k = 1, 2, \ldots, m$, such that

$$\|f(t,x) - f(t,y)\| \leq K\|x-y\| + K\sum_{k=1}^{m}|g_k(\tau_k(t,x)) - g_k(\tau_k(t,y))|$$

for all $(t,x), (t,y) \in I \times \mathbb{R}^n$.

(b) Each function $g_k : \mathbb{R} \longrightarrow \mathbb{R}$ is bounded in $\mathbb{R}$ and Lipschitz continuous in each bounded interval contained in $\mathbb{R} \setminus A_k$, where A_k is a countable closed subset of $\mathbb{R}$ such that $A_k = \mathcal{I}^-(A_k) \cup \mathcal{I}^+(A_k)$.

(c) Each function $\tau_k : I \times \mathbb{R}^n \longrightarrow \mathbb{R}$ is continuously differentiable and for each $(t,x) \in \tau_k^{-1}(A_k)$, there exists $\varepsilon > 0$ such that for a.a. $s \in [t, t+\varepsilon)$ and all $\zeta \in B_\varepsilon(x)$ we have

$$\nabla\tau_k(s,\zeta)\cdot(1,z) > 0 \quad \textit{for all } z \in \mathcal{K}f(s,\zeta) \tag{4.9}$$

if $\tau_k(t,x) \in \mathcal{I}^+(A_k) \setminus \mathcal{I}^-(A_k)$;

$$\nabla\tau_k(s,\zeta)\cdot(1,z) < 0 \quad \textit{for all } z \in \mathcal{K}f(s,\zeta), \tag{4.10}$$

if $\tau_k(t,x) \in \mathcal{I}^-(A_k) \setminus \mathcal{I}^+(A_k)$; and either (4.9) or (4.10) if $\tau_k(t,x) \in \mathcal{I}^-(A_k) \cap \mathcal{I}^+(A_k)$ (where $\mathcal{K}f$ denotes the Krasovskij envelope of f).

Then the initial value problem

$$x' = f(t,x), \qquad x(t_0) = x_0, \tag{4.11}$$

has a unique local Carathéodory solution.

Proof. Existence follows from Theorem 3.3. Let us prove uniqueness as a consequence of Theorem 4.6.

Consider an arbitrary collection of open bounded intervals $I_k \subset \mathbb{R} \setminus A_k$, $k = 1, 2, \dots, m$, such that

$$\mathcal{O} = \bigcap_{k=1}^{m} \tau_k^{-1}(I_k) \neq \emptyset.$$

For each $k \in \{1, 2, \dots, m\}$, the function g_k is Lipschitz continuous in the interval I_k, so there is $L_k > 0$ such that

$$|g_k(z_1) - g_k(z_2)| \le L_k |z_1 - z_2| \quad \text{for all } z_1, z_2 \in I_k.$$

Hence, for all $(t,x), (t,y) \in \mathcal{O}$, we have that $\tau_k(t,x), \tau_k(t,y) \in I_k$ and thus

$$\sum_{k=1}^{m} |g_k(\tau_k(t,x)) - g_k(\tau_k(t,y))| \le \sum_{k=1}^{m} L_k |\tau_k(t,x) - \tau_k(t,y)| \le C \|x - y\|,$$

for some positive constant C, since the functions τ_k are Lipschitz continuous w.r.t. x on any compact set which contains the graphs of the solutions. Therefore, for all $(t,x), (t,y) \in \mathcal{O}$ we have

$$\|f(t,x) - f(t,y)\| \le (K + KC) \|x - y\|.$$

The conclusion follows now from Theorem 4.6 guaranteeing uniqueness of solutions for (4.11) in the interval $I = [t_0, t_0 + \delta]$. □

In view of the general assumptions on Theorem 3.3 concerning existence of Carathéodory solutions, one may wonder whether a Lipschitz continuous condition outside the set of discontinuities of f implies uniqueness of Carathéodory solutions of (1.1).

Theorem 4.10. *In the conditions of Proposition 3.1, assume also that there exist null measure sets $A_k \subset \mathbb{R}$, $k \in \mathcal{C} \subset \mathbb{N}$, and differentiable mappings $\tau_k : [a_k, b_k] \times \mathbb{R}^n \longrightarrow \mathbb{R}$, $[a_k, b_k] \subset I$, such that for a.a. $t \in I$ the following conditions hold:*

(a) There exists a null measure set $N(t) \subset \mathbb{R}^n$ such that the restriction of $f(t,\cdot)$ to $\mathbb{R}^n \setminus N(t)$ is locally Lipschitz continuous, i.e., for each compact set $K \subset \mathbb{R}^n$ there exists $l_K \in L^1(I)$ such that for a.a. $t \in I$ and all $x, y \in K \cap (\mathbb{R}^n \setminus N(t))$ we have

$$\|f(t,x) - f(t,y)\| \le l_K(t) \|x - y\|.$$

(b) For each $x \in N(t)$ there exists $k \in \mathcal{C}$ such that $t \in [a_k, b_k]$, $\tau_k(t,x) \in A_k$ and

$$\nabla \tau_k(t,x) \cdot (1, z) \neq 0 \quad \text{for all } z \in \mathcal{K}f(t,x). \tag{4.12}$$

Then, problem (1.1) has exactly one Carathéodory solution, which is also the unique Filippov solution.

Proof. Existence follows from Theorem 3.3. For uniqueness, first note that if x is a Carathéodory solution, then it is a solution in the sense of Krasovskij and so the transversality condition (4.12) implies that

$$m\left(\{t \in I : x(t) \in N(t)\}\right) = 0.$$

Let $x(t)$ and $y(t)$ be Carathéodory solutions of (1.1); we shall prove that $x(t) = y(t)$ for all $t \in I$. Reasoning by contradiction, we assume that there exists some $t_1 \in [t_0, t_0 + L)$ such that $x(t_1) = y(t_1)$ and $\|x - y\| > 0$ on $(t_1, t_1 + \rho)$ for some $\rho > 0$. Note that $x(t), y(t) \in \mathbb{R}^n \setminus N(t)$ for a.a. $t \in (t_1, t_1 + \rho)$. Hence, there exists $l \in L^1(I)$ such that for a.a. $t \in (t_1, t_1 + \rho)$ we have

$$\|f(t, x(t)) - f(t, y(t))\| \le l(t)\|x(t) - y(t)\|.$$

Then

$$\|x(t) - y(t)\| \le \int_{t_1}^{t} \|f(s, x(s)) - f(s, y(s))\|\, ds \le \int_{t_1}^{t} l(s)\|x(s) - y(s)\|\, ds, \quad t \in [t_1, t_1 + \rho),$$

and we deduce from Gronwall's inequality that $\|x - y\| = 0$ on $[t_1, t_1 + \rho)$, a contradiction. □

Remark 4.11. Note that the transversality condition (4.12) cannot be replaced by (3.1) in Theorem 4.10 in order to ensure uniqueness of Carathéodory solutions for (1.1), as shown once again by Example 3.3. Nevertheless, it is enough to ensure uniqueness of Filippov solutions for (1.1).

Example 4.12. The planar system

$$\begin{cases} x' = f_1(t, x, y), & x(0) = 0, \\ y' = f_2(t, x, y), & y(0) = 0, \end{cases}$$

where $f_1(t, x, y) = \cos^2(x\,y) + e^{t - x^2 - y^2}$ and $f_2(t, x, y) = \left(\chi_{\mathbb{Q}}(x) - \chi_{\mathbb{R}\setminus\mathbb{Q}}(x)\right) e^{\sin(t+y)}$, already considered in Example 3.6, has a unique Carathéodory solution. Indeed, the restriction of the function $f = (f_1, f_2)$ to $I \times (\mathbb{R} \setminus \mathbb{Q}) \times \mathbb{R}$ is clearly locally Lipschitz continuous with respect to (x, y) and, moreover, condition (b) in Theorem 4.10 can be verified as in Example 3.6 since f_1 is continuous.

Unlike assumption (a) in Theorem 3.3, which is a reasonable condition to obtain existence for discontinuous ODEs, condition (a) in Theorem 4.10 imposes strong restrictions on the discontinuities of f (for instance, f cannot have jump discontinuities).

Finally, let us observe that the following simple result, which leans on local directional Lipschitz conditions in the line of [5], can be useful in many situations with discontinuous nonlinearities.

Theorem 4.13. *In the conditions of Proposition 3.1, assume also that for each $t \in [t_0, t_0 + L)$ and each $\xi \in \mathbb{R}^n$ there exist $\varepsilon = \varepsilon(t, \xi) > 0$ and $l = l_{(t,\xi)} \in L^1(I)$ such that for a.a. $s \in (t, t + \varepsilon)$ we have*

$$\|f(s, x) - f(s, y)\| \le l(s)\|x - y\| \quad \text{for all } x, y \in \prod_{j=1}^{n} \left[\xi_j - \int_t^s \psi(r)\, dr, \xi_j + \int_t^s \psi(r)\, dr\right]. \tag{4.13}$$

Then problem (1.1) has at most one Carathéodory solution.

Proof. Let $x(t)$ and $y(t)$ be Carathéodory solutions of (1.1); we shall prove that $x(t) = y(t)$ for all $t \in I$. Reasoning by contradiction, we assume that there exists some $t_1 \in [t_0, t_0 + L)$ such that $x(t_1) = y(t_1)$ and $\|x - y\| > 0$ on $(t_1, t_1 + \rho)$ for some $\rho > 0$.

Take $\varepsilon \in (0, \rho)$ and $l \in L^1(I)$ in the conditions of (4.13) for the point $(t, \xi) = (t_1, x(t_1))$. We have

$$\|x(t) - y(t)\| \leq \int_{t_1}^{t} \|f(s, x(s)) - f(s, y(s))\|\, ds \leq \int_{t_1}^{t} l(s)\|x(s) - y(s)\|\, ds, \quad t \in [t_1, t_1 + \varepsilon),$$

and then Gronwall's inequality yields $\|x - y\| = 0$ on $[t_1, t_1 + \varepsilon)$, a contradiction. □

Abstract. In this paper, ground-state solutions to a Hartree–Fock type system with a critical growth are studied. Firstly, instead of establishing the local Palais–Smale (P.–S.) condition and estimating the mountain-pass critical level, a perturbation method is used to recover compactness and obtain the existence of ground-state solutions. To achieve this, an important step is to get the right continuity of the mountain-pass level on the coefficient in front of perturbing terms. Subsequently, depending on the internal parameters of coupled nonlinearities, whether the ground state is semi-trivial or vectorial is proved.

Keywords: Hartree–Fock systems, ground-state solutions, critical growth.

2020 Mathematics Subject Classification: 35J60, 35A23, 35J50.

1 Introduction

In this paper, we will study the following class of Hartree–Fock (HF) system

$$\begin{cases} -\Delta u + u + \phi_{u,v} u = |u|^{2q-2}u + \beta |v|^q |u|^{q-2} u + \mu(u^5 + \alpha |v|^3 |u| u), & x \in \mathbb{R}^3, \\ -\Delta v + v + \phi_{u,v} v = |v|^{2q-2}v + \beta |u|^q |v|^{q-2} v + \mu(v^5 + \alpha |u|^3 |v| v), & x \in \mathbb{R}^3, \end{cases} \tag{1.1}$$

where the Coulomb term $\phi_{u,v}$ has the following form

$$\phi_{u,v}(x) = \frac{1}{4\pi} \int_{\mathbb{R}^3} \frac{u^2(y) + v^2(y)}{|x-y|} \mathrm{d}y, \qquad x \in \mathbb{R}^3, \tag{1.2}$$

$\alpha, \beta, \mu \in \mathbb{R}_+ := [0, \infty)$ are parameters and $q \in (2, 3)$.

It is well known that the (HF) equation is one of the most important equations in quantum physics, condensed matter physics and quantum chemistry. For example, in the study of a molecular system composed of M atomic nucleus interacting with N electrons through Coulomb potential, the (HF) equation is used as an approximation to describe the stationary state, and one can refer to [5] for the specific process of derivation. According to [5], in the system (1.1), $-\Delta u, -\Delta v$ represent the kinetic part of the electronic system, Vu, Vv denote potentials of the action on electronic system by nucleus, $\phi_{u,v} u, \phi_{u,v} v$ represent the electron-electron

Coulomb interactions, and the power-type nonlinearity describes the effects of exchange and correlation among electrons. For more details on the physical aspects of the Hartree–Fock system, we refer readers to [1,2,8–11] and the references therein.

In mathematics, a particular case of system (1.1), when $\mu = 0$, leads to the following class of Hartree–Fock type system with a cooperative pure power and subcritical nonlinearity

$$\begin{cases} -\Delta u + u + \phi_{u,v} u = |u|^{2q-2}u + \beta |v|^q |u|^{q-2}u, & x \in \mathbb{R}^3, \\ -\Delta v + v + \phi_{u,v} v = |v|^{2q-2}v + \beta |u|^q |v|^{q-2}v, & x \in \mathbb{R}^3, \end{cases} \tag{1.3}$$

which has been studied by d'Avenia, Maia and Siciliano in [5]. In the case that $q \in (3/2, 3)$, they showed the existence of semitrivial and vectorial ground state depending on parameters involved. Furthermore, they also derived the asymptotic behavior of ground states with respect to the parameter β.

In view of conclusions obtained in [5], we considered the Sobolev critical case $q = 3$. However, combining the Pohozaev identity and Nehari manifold, it could be proved that the system (1.3) has no nontrivial solution when $q = 3$. Motivated by the above facts, we would like to consider the system (1.1), which is obtained through a Sobolev perturbation basing on the above system (1.3). It is well known that since Brezis and Nirenberg published their famous paper [3] in 1983, elliptic equations or systems with Sobolev critical growth have been researched extensively. The usual strategy to achieve the ground-state solution to these critical problems is establishing the local (P.-S.) condition and verifying that the ground-state energy belongs to the interval where the (P.-S.) condition holds. Differently, in this paper, we will achieve the existence of ground-state solutions to the system (1.1) with a perturbation method.

Before stating our main results, we introduce the variational setting used in this paper. Firstly, let $H^1_r(\mathbb{R}^3) = \{w \in H^1(\mathbb{R}^3) : w(x) = w(|x|)\}$ and $\|w\|_1^2 = \int_{\mathbb{R}^3} [|\nabla w|^2 + w^2]$ for $w \in H^1_r(\mathbb{R}^3)$. Then our working space is $H := H^1_r(\mathbb{R}^3) \times H^1_r(\mathbb{R}^3)$ endowed with the norm

$$\|(u,v)\| = \left(\|u\|_1^2 + \|v\|_1^2\right)^{1/2}, \qquad (u,v) \in H.$$

It is well known that the embedding $H^1_r(\mathbb{R}^3) \hookrightarrow L^s(\mathbb{R}^3)$ is continuous for $s \in [2,6]$ and compact for $s \in (2,6)$. Hence the same conclusions hold for the embedding $H \hookrightarrow L^s(\mathbb{R}^3) \times L^s(\mathbb{R}^3)$ for $s \in [2,6]$. Throughout this paper, denote the norm endowed in $L^s(\mathbb{R}^3)$ by $|\cdot|_s$: $|w|_s = \left[\int_{\mathbb{R}^3} |w|^s\right]^{1/s}$ for $w \in L^s(\mathbb{R}^3)$. While the norm of $L^s(\mathbb{R}^3) \times L^s(\mathbb{R}^3)$ is $|(u,v)|_s = \left(|u|_s^s + |v|_s^s\right)^{1/s}$ for $(u,v) \in L^s(\mathbb{R}^3) \times L^s(\mathbb{R}^3)$. Subsequently, we will give the energy functional corresponding to the system (1.1). According to the Hardy–Littlewood–Sobolev inequality, the nonlocal term $\int_{\mathbb{R}^3} \phi_{u,v}(u^2+v^2)$ is well defined in H. Therefore, we could define the energy functional related to the system (1.1) as

$$\begin{aligned} J_\mu(u,v) &= \frac{1}{2}\|(u,v)\|^2 + \frac{1}{4}\int_{\mathbb{R}^3} \phi_{u,v}(u^2+v^2) - \frac{1}{2q}\left[|u|_{2q}^{2q} + |v|_{2q}^{2q} + 2\beta \int_{\mathbb{R}^3} |u|^q |v|^q\right] \\ &\quad - \frac{\mu}{6}\left[|u|_6^6 + |v|_6^6 + 2\alpha \int_{\mathbb{R}^3} |u|^3 |v|^3\right] \\ &=: \frac{1}{2}A(u,v) + \frac{1}{4}B(u,v) - \frac{1}{2q}C(u,v) - \frac{\mu}{6}D(u,v), \quad (u,v) \in H. \end{aligned} \tag{1.4}$$

Via a standard proof, there also holds that $J_\mu \in C^1(H, \mathbb{R})$ with

$$\begin{aligned}\left\langle J'_\mu(u,v),(\varphi,\psi)\right\rangle = &\int_{\mathbb{R}^3}(\nabla u\cdot\nabla\varphi+\nabla v\cdot\nabla\psi+u\varphi+v\psi)+\int_{\mathbb{R}^3}\phi_{u,v}(u\varphi+v\psi)\\ &-\int_{\mathbb{R}^3}\left[|u|^{2q-2}u\varphi+|v|^{2q-2}v\psi+\beta(|v|^q|u|^{q-2}u\varphi+|u|^q|v|^{q-2}v\psi)\right]\\ &-\mu\int_{\mathbb{R}^3}\left[u^5\varphi+v^5\psi+\alpha(|v|^3|u|u\varphi+|u|^3|v|v\psi)\right], \qquad (u,v),(\varphi,\psi)\in H.\end{aligned}$$

Hence, finding solutions of the system (1.1) is equivalent to seeking critical points of the functional J_μ in H. Furthermore, to achieve the ground-state solution to the system (1.1), we may consider the ground state of the energy functional J_μ, and the Nehari manifold is used in this paper. Now, let I_μ be the related Nehari functional, that is, $I_\mu(u,v) := \langle J'_\mu(u,v),(u,v)\rangle$, $(u,v)\in H$. Then adopting notations given in (1.4) it could be rewritten as

$$I_\mu(u,v) = A(u,v)+B(u,v)-C(u,v)-\mu D(u,v), \qquad (u,v)\in H. \tag{1.5}$$

Let us denote by $\mathcal{N}_\mu$ the Nehari manifold associated to the functional J_μ, namely

$$\mathcal{N}_\mu = \{(u,v)\in H\setminus\{(0,0)\} : I_\mu(u,v)=0\},$$

and define the ground-state energy as

$$d(\mu) = \inf_{\mathcal{N}_\mu} J_\mu.$$

In this context, the ground-state solution to be found in this paper is a radial ground state whose energy is minimal among all other radial ones.

Now, we formulate our first result for the system (1.1).

Theorem 1.1. *Assume that $q\in(2,3)$. Then for any given $\alpha,\beta\in\mathbb{R}_+$, there exists $\mu_0>0$ such that the system (1.1) has a ground-state solution $(u_\mu,v_\mu)\neq(0,0)$ for all $\mu\in[0,\mu_0)$.*

An important step to prove Theorem 1.1 via perturbation methods is estimating the distance between the (P.–S.)$_{m(\mu)}$ sequence of the functional J_μ and the ground-state critical points set of the functional J_0 for μ small enough. Here $m(\mu)$ is the mountain-pass level of the functional J_μ. To achieve this, we first verify the fact that $m(\mu)=d(\mu)$ and get the right continuity of $m(\cdot)$ at $\mu=0$ by showing that $\lim_{\mu\to0^+} d(\mu)=d(0)$ subsequently, where the implicit function theorem is used.

Basing on the existence of ground-state radial solutions, motivated by [4] and [5], we also consider whether the ground state obtained above is semitrivial or vectorial and get the following conclusion. Here we say that $(u,v)\neq(0,0)$ is semitrivial if $u=0$ or $v=0$, and (u,v) is vectorial if $u\neq0$ and $v\neq0$.

Theorem 1.2. *Assume that $q\in(2,3)$ and $\mu\in[0,\mu_0)$, where μ_0 is given by Theorem 1.1. Let (u_μ,v_μ) be the ground state achieved in Theorem 1.1.*

(i) If $0\leqslant\alpha<3, 0\leqslant\beta<2^{q-1}-1$, then (u_μ,v_μ) is semitrivial.

(ii) If $\alpha>3,\beta>2^{q-1}-1$, then (u_μ,v_μ) is vectorial.

In view of Theorem 1.2, there is an open question that whether the ground state obtained in Theorem 1.1 is semitrivial or vectorial in the cases that $(\alpha,\beta) \in (0,3] \times [2^{q-1}-1,\infty)$ or $(\alpha,\beta) \in [3,\infty) \times (0,2^{q-1}-1]$. This is caused by the non-homogeneity of the nonlinearity in the system (1.1).

This paper is organized as follows. In Section 2, we give some preliminaries to get the existence of ground state via the perturbation method, subsequently, Theorems 1.1 and 1.2 are proved in Sections 3 and 4 respectively. Throughout this paper, $C_i (i = 0,1,2,\dots)$ represent some positive constants which may be different from line to line.

2 Preliminaries

In this section, we first give some inequalities about the four functionals A, B, C, and D by the following lemma.

Lemma 2.1. *There exist some constants C_0, C_1, C_2 independent of μ such that for any $(u,v) \in H$, the following inequalities hold*

$$B(u,v) \leqslant C_0[A(u,v)]^2, \tag{2.1}$$

$$C(u,v) \leqslant C_1|(u,v)|_{2q}^{2q} \leqslant C_2[A(u,v)]^q, \tag{2.2}$$

$$D(u,v) \leqslant C_1|(u,v)|_6^6 \leqslant C_2[A(u,v)]^3. \tag{2.3}$$

Proof. For (2.1), it follows from (1.2) that $\phi_{u,v} \in D^{1,2}(\mathbb{R}^3)$ is a weak solution to the equation $-\Delta\phi_{u,v} = u^2 + v^2$ for all $(u,v) \in H$. Consequently,

$$B(u,v) = \int_{\mathbb{R}^3} \phi_{u,v}(u^2+v^2) = \int_{\mathbb{R}^3} |\nabla\phi_{u,v}|^2.$$

By the Hölder inequality and the Sobolev embedding, there exists a constant $C_0 > 0$ independent of (u,v) such that

$$\int_{\mathbb{R}^3} \phi_{u,v}u^2 \leqslant |\phi_{u,v}|_6 |u|_{12/5}^2 \leqslant C_0|\nabla\phi_{u,v}|_2\|u\|_1^2.$$

Similarly, we get

$$\int_{\mathbb{R}^3} \phi_{u,v}v^2 \leqslant C_0|\nabla\phi_{u,v}|_2\|v\|_1^2.$$

Thus

$$|\nabla\phi_{u,v}|_2^2 = \int_{\mathbb{R}^3} \phi_{u,v}(u^2+v^2) \leqslant C_0|\nabla\phi_{u,v}|_2\|(u,v)\|^2 = C_0|\nabla\phi_{u,v}|_2 A(u,v),$$

which implies that (2.1) holds.

By the Hölder inequality and the embedding that $H \hookrightarrow L^s(\mathbb{R}^3) \times L^s(\mathbb{R}^3)$ for $s \in [2,6]$,

$$C(u,v) \leqslant |u|_{2q}^{2q} + |v|_{2q}^{2q} + 2\beta|u|_{2q}^q|v|_{2q}^q \leqslant \max\{\beta,1\}\left(|u|_{2q}^q + |v|_{2q}^q\right)^2 \leqslant C_1|(u,v)|_{2q}^{2q} \leqslant C_2[A(u,v)]^q.$$

Hence (2.2) holds. Similarly, (2.3) holds. □

Next, we prove that the functional J_μ has a mountain pass geometry structure for all $\mu \in \mathbb{R}_+$. Let

$$\Gamma_\mu = \{\gamma \in C([0,1],H) : \gamma(0) = 0, J_\mu(\gamma(1)) < 0\},$$

and

$$m(\mu) = \inf_{\gamma\in\Gamma_\mu} \max_{t\in[0,1]} J_\mu(\gamma(t)).$$

Then we could prove that both Γ_μ and $m(\mu)$ are well defined.

Lemma 2.2. *Assume $\mu \in \mathbb{R}_+$. Then $\Gamma_\mu \neq \emptyset$ and $m(\mu) > 0$.*

Proof. First, for any $(u,v) \in H\backslash\{(0,0)\}$, we define a fiber mapping corresponding to the functional J_μ as follows:

$$\begin{aligned} g_{u,v}(t) &= J_\mu(t(u,v)) \\ &= \frac{t^2}{2}A(u,v) + \frac{t^4}{4}B(u,v) - \frac{t^{2q}}{2q}C(u,v) - \frac{\mu}{6}t^6 D(u,v), \quad t \in \mathbb{R}. \end{aligned} \tag{2.4}$$

Since $q \in (2,3)$, there exists a sufficiently small positive number δ depending on μ such that $g_{u,v}(t) > 0, t \in (0,\delta)$. Moreover, note that $g_{u,v}(t) \to -\infty$ as $t \to \infty$. Then there exists $t_0 > 0$ such that $J_\mu(t_0(u,v)) = g_{u,v}(t_0) < 0$. Let $\gamma_0(t) = tt_0(u,v), t \in [0,1]$. Then $\gamma_0 \in \Gamma_\mu$.

For $\mu \in \mathbb{R}_+$, it follows from inequalities (2.2) and (2.3) that

$$J_\mu(u,v) \geqslant \frac{1}{2}A(u,v) - \frac{1}{2q}C_2[A(u,v)]^q - \frac{1}{6}\mu C_2[A(u,v)]^3, \quad (u,v) \in H.$$

Therefore, there exists $\rho > 0$ depending on μ such that if $0 < \|(u,v)\|^2 = A(u,v) < \rho^2$, then $J_\mu(u,v) > 0$. Moreover,

$$\alpha_\mu := \inf_{\|(u,v)\|=\rho} J_\mu(u,v) > 0.$$

Furthermore, by the standard process one can deduce that $m(\mu) \geqslant \alpha_\mu > 0$. □

Lemma 2.3. *Suppose that $(u,v) \in H\backslash\{(0,0)\}$. Then the following conclusions hold:*

(i) for any $\mu \in \mathbb{R}_+$, there exists a unique $t(\mu) > 0$ such that $t(\mu)(u,v) \in \mathcal{N}_\mu$, $I_\mu(t(u,v)) > 0, t \in (0,t(\mu))$ and $I_\mu(t(u,v)) < 0, t \in (t(\mu),\infty)$. Furthermore,

$$J_\mu(t(\mu)(u,v)) = \max_{t\in\mathbb{R}_+} J_\mu(t(u,v));$$

(ii) the function $t(\cdot)\colon \mathbb{R}_+ \to (0,\infty)$ is differentiable and

$$t'(\mu) = -\frac{t^5(\mu)D(u,v)}{2A(u,v) + 4t^2(\mu)B(u,v) + 2qt^{2q-2}(\mu)C(u,v) + 6\mu t^4(\mu)D(u,v)}. \tag{2.5}$$

Moreover, $t(\cdot)$ is decreasing in μ.

Proof. (i) Assume $\mu \in \mathbb{R}_+$. For each $(u,v) \in H\backslash\{(0,0)\}$, recall the definition of $g_{u,v}$ given in (2.4). Then

$$g'_{u,v}(t) = tA(u,v) + t^3B(u,v) - t^{2q-1}C(u,v) - \mu t^5 D(u,v), \qquad t \in \mathbb{R}_+, \tag{2.6}$$

which yields that

$$g'_{u,v}(t)/t \to A(u,v) > 0, t \to 0^+, \qquad g'_{u,v}(t) \to -\infty,\ t \to \infty. \tag{2.7}$$

Therefore, there exists $t(\mu) > 0$ satisfying $g'_{u,v}(t(\mu)) = 0$, and so $t(\mu)u \in \mathcal{N}_\mu$. Furthermore, it follows from (2.6) that

$$t^{-2}(\mu)A(u,v) - t^{2q-4}(\mu)C(u,v) - \mu t^2(\mu)D(u,v) = -B(u,v).$$

Because the function $t \mapsto t^{-2}A(u,v) - t^{2q-4}C(u,v) - \mu t^2 D(u,v)$ is decreasing in t, then $g'_{(u,v)}(t) = 0$ has a unique positive root. Hence, $t(\mu)$ is the unique positive critical point of $g_{u,v}$. Combining this with (2.7) and (1.5), we know that (i) holds.

(ii) Let $H(t,\mu) = I_\mu(t(u,v)), (t,\mu) \in (-\delta,\infty) \times (-\delta,\infty)$ for some $\delta > 0$. Then it follows from (1.5) that

$$H(t,\mu) = t^2 A(u,v) + t^4 B(u,v) - t^{2q} C(u,v) - \mu t^6 D(u,v), \qquad (t,\mu) \in (-\delta,\infty) \times (-\delta,\infty).$$

For any $(t,\mu) \in (-\delta,\infty) \times (-\delta,\infty)$ for some $\delta > 0$, we have

$$\frac{\partial H}{\partial t}(t,\mu) = 2tA(u,v) + 4t^3 B(u,v) - 2qt^{2q-1} C(u,v) - 6\mu t^5 D(u,v) \tag{2.8}$$

and

$$\frac{\partial H}{\partial \mu}(t,\mu) = -t^6 D(u,v).$$

Note that $H(t(\mu),\mu) = 0$ i.e. $I_\mu(t(\mu)(u,v)) = 0$ for $\mu \in [0,1]$. Then it could be derived from (2.8) and (1.5) that

$$\frac{\partial H}{\partial t}(t(\mu),\mu) = -2t(\mu)A(u,v) - (2q-4)t^{2q-1}(\mu)C(u,v) - 2\mu t^5(\mu)D(u,v) < 0.$$

Therefore, by the implicit function theorem, we can obtain that $t(\cdot) : \mathbb{R}_+ \to (0,\infty)$ is continuous and differentiable, and (2.5) holds. It then follows from (2.5) directly that for given $(u,v) \in H \backslash \{(0,0)\}$, $t(\cdot)$ is decreasing in μ. □

Lemma 2.4. $\inf_{\mu \in [0,1]} \operatorname{dist}(0, \mathcal{N}_\mu) > 0$.

Proof. Assume $\mu \in [0,1]$. Given $(u,v) \in \mathcal{N}_\mu$, it follows from (1.5), (2.2) and (2.3) that

$$\begin{aligned} A(u,v) &\leqslant A(u,v) + B(u,v) \\ &= C(u,v) + \mu D(u,v) \\ &\leqslant C_2 \left[[A(u,v)]^q + [A(u,v)]^3 \right]. \end{aligned}$$

Therefore there exists a $\sigma > 0$ independent of μ such that $\|(u,v)\|^2 = A(u,v) \geqslant \sigma$ for all $(u,v) \in \mathcal{N}_\mu$. The proof is complete. □

In view of Lemma 2.4, since $2q > 4$, then for any $(u,v) \in \mathcal{N}_\mu$, it holds that

$$J_\mu(u,v) = J_\mu(u,v) - \frac{1}{4} I_\mu(u,v) \geqslant \frac{1}{4}\|(u,v)\|^2, \qquad (u,v) \in \mathcal{N}_\mu, \tag{2.9}$$

from which one can also derive that $d(\mu)$ is well defined for all $\mu \in \mathbb{R}_+$. Moreover, recall the definition of $m(\mu)$. Then by Lemma 2.2 and (i) of Lemma 2.3, we can prove that following lemma via a standard process similarly to the proof of [12, Theorem 4.2, p. 73].

Lemma 2.5. *For any $\mu \in \mathbb{R}_+$, it holds that $m(\mu) = d(\mu)$.*

Note that due to definitions of J_μ, Γ_μ and $m(\mu)$ for $\mu \in \mathbb{R}_+$, it could be concluded that $m(\cdot)$ is decreasing on $\mathbb{R}_+$. Then by Lemma 2.5, $d(\cdot)$ is also decreasing on $\mathbb{R}_+$. Now, we will prove the continuity of $m(\cdot)$ at $\mu = 0$. Actually, by the above lemma, it is sufficient to illustrate the right continuity of $d(\cdot)$ at $\mu = 0$. Hence, we have the following lemma.

Lemma 2.6. *$d(\cdot)$ is right continuous at $\mu = 0$.*

Proof. Assume $\{\mu_n\} \subset [0,1]$ satisfies that $\mu_n \to 0^+$ as $n \to \infty$. Then, according to the definition of $d(\mu_n)$, for each $\varepsilon \in (0, d(0))$, there exists $(u_n, v_n) \in \mathcal{N}_{\mu_n}$ such that

$$J_{\mu_n}(u_n, v_n) \leqslant d(\mu_n) + \varepsilon/2, \qquad n \in \mathbb{N}. \tag{2.10}$$

Combining this with (2.9), one gets that

$$A(u_n, v_n) = \|(u_n, v_n)\|^2 \leqslant 4d(\mu_n) + 2\varepsilon < 6d(0). \tag{2.11}$$

Thus, there exist $(u, v) \in H$ and a subsequence of $\{(u_n, v_n)\}$ (still denoted by $\{(u_n, v_n)\}$) such that $(u_n, v_n) \rightharpoonup (u, v)$. Moreover, $(u, v) \neq (0, 0)$. Otherwise, it follows from $(u_n, v_n) \in \mathcal{N}_{\mu_n}$, (2.2), the compact embedding $H \hookrightarrow L^{2q}(\mathbb{R}^3) \times L^{2q}(\mathbb{R}^3)$, (2.3) and (2.11) that

$$A(u_n, v_n) + B(u_n, v_n) = C(u_n, v_n) + \mu_n D(u_n, v_n) \leqslant C_1 |(u_n, v_n)|_{2q}^{2q} + \mu_n C_2 [A(u_n, v_n)]^3 \to 0,$$

which contradicts to Lemma 2.4. Hence $(u, v) \neq (0, 0)$. Consequently, noting $(u_n, v_n) \to (u, v)$ in $L^{2q}(\mathbb{R}^3) \times L^{2q}(\mathbb{R}^3)$, there exists some $N_0 > 0$ such that for $n > N_0$,

$$C(u_n, v_n) \geqslant |(u_n, v_n)|_{2q}^{2q} \geqslant |(u, v)|_{2q}^{2q}/2 > 0,$$

which implies that for some positive number C_3 independent of n such that

$$C(u_n, v_n) \geqslant C_3 > 0, \qquad n \in \mathbb{N} \tag{2.12}$$

Now, for given $n > N_0$, according to (i) of Lemma 2.3, let $t_n(\mu)$ satisfy that $t_n(\mu)(u_n, v_n) \in \mathcal{N}_\mu$ for all $\mu \in [0, \mu_n]$, and define

$$h_n(\mu) = J_\mu(t_n(\mu)(u_n, v_n)), \qquad \mu \in [0, \mu_n].$$

Since $t_n(\mu)(u_n, v_n) \in \mathcal{N}_\mu$, one could derive that

$$\begin{aligned} h_n'(\mu) &= \left\langle J_\mu'(t_n(\mu)(u_n, v_n)), (u_n, v_n) \right\rangle t_n'(\mu) - \frac{1}{6} t_n^6(\mu) \left[|u_n|_6^6 + |v_n|_6^6 + 2\alpha \int_{\mathbb{R}^3} |u_n|^3 |v_n|^3 \right] \\ &= -\frac{1}{6} t_n^6(\mu) D(u_n, v_n), \quad \mu \in [0, \mu_n]. \end{aligned}$$

Hence, from $t_n(\mu_n) = 1$, (ii) of Lemma 2.3, (2.3) and (2.11), we arrive at

$$\begin{aligned} & J_0(t_n(0)(u_n, v_n)) - J_{\mu_n}(u_n, v_n) \\ &\quad = h_n(0) - h_n(\mu_n) \\ &\quad = -\int_0^{\mu_n} h_n'(s) \mathrm{d}s \\ &\quad = \frac{1}{6} \int_0^{\mu_n} t_n^6(s) D(u_n, v_n) \mathrm{d}s \\ &\quad \leqslant \frac{1}{6} t_n^6(0) \mu_n C_2 [A(u_n, v_n)]^3 \leqslant 36 t_n^6(0) \mu_n C_2 d^3(0). \end{aligned} \tag{2.13}$$

Next, we shall illustrate that $\{t_n(0)\}$ is bounded. Indeed, due to $I_0(u_n, v_n) > I_\mu(u_n, v_n) = 0$ and (i) of Lemma 2.3, it holds that $t_n(0) > 1$. Moreover, by (2.12), (2.1) and (2.11) one can deduce that

$$C_3 t_n^{2q}(0) \leqslant t_n^{2q}(0) C(u_n, v_n) = t_n^2(0) A(u_n, v_n) + t_n^4(0) B(u_n, v_n) \leqslant 6d(0) t_n^2(0) + 36 C_2 d^2(0) t_n^4(0).$$

Since $q > 2$, this implies that there exists some C_4 independent of n such that $1 < t_n(0) \leqslant C_4$ for $n \in \mathbb{N}$.

Subsequently, combining this with (2.13), it holds that

$$J_0(t_n(0)(u_n, v_n)) - J_{\mu_n}(u_n, v_n) \leqslant 36C_4^6\mu_n C_2 d^3(0).$$

Furthermore, as a consequence of Lemma 2.5, the fact that $m(0) \geqslant m(\mu)$ for $\mu \geqslant 0$ and (2.10), we also get that

$$0 \leqslant d(0) - d(\mu_n) \leqslant J_0(t_n(0)(u_n, v_n)) - J_{\mu_n}(u_n, v_n) + \varepsilon/2 \leqslant 36C_4^6\mu_n C_2 d^3(0) + \varepsilon/2.$$

Thus,

$$0 \leqslant \limsup_{n\to\infty}[d(0) - d(\mu_n)] \leqslant \varepsilon/2,$$

which yields that $d(\mu_n) \to d(0)$ as a consequence of the arbitrariness of ε. The proof is complete. □

3 Proof of Theorem 1.1

Lemma 3.1. *Assume $\mu \in (0,1]$ and $\{(u_n^\mu, v_n^\mu)\}$ is a (P.–S.)$_{m(\mu)}$ sequence for the functional J_μ. Then*

$$\lim_{\mu\to 0}\lim_{n\to\infty} \operatorname{dist}\big((u_n^\mu, v_n^\mu), K\big) = 0,$$

where

$$K = \{(u,v) \in H : J_0'(u,v) = 0, J_0(u,v) = m(0)\}.$$

Proof. This proof is motivated by [13] and [6]. Firstly, by the mountain pass theorem and the fact that J_0 satisfies the (P.–S.) condition on H, it holds that $K \neq \emptyset$.

Secondly, for any $\mu \in (0,1]$, since $\{(u_n^\mu, v_n^\mu)\}$ is a (P.–S.)$_{m(\mu)}$ sequence for the functional J_μ, we have

$$m(\mu) + 1 + \|(u_n^\mu, v_n^\mu)\| \geqslant J_\mu(u_n^\mu, v_n^\mu) - \frac{1}{4}I_\mu(u_n^\mu, v_n^\mu).$$

Thus, similarly to (2.9) we can derive that

$$m(0) + 1 + \|(u_n^\mu, v_n^\mu)\| \geqslant \frac{1}{4}\|(u_n^\mu, v_n^\mu)\|^2. \tag{3.1}$$

Therefore, there is a constant $C_5 > 0$ independent of μ and n such that $\|(u_n^\mu, v_n^\mu)\| \leqslant C_5$ for all $n \in \mathbb{N}$ and $\mu \in (0,1]$.

Now, assume that $\{\mu_i\}$ satisfies $\mu_i \to 0$ as $i \to \infty$. Denote the (P.–S.)$_{m(\mu_i)}$ sequence of the functional J_{μ_i} by $\{(u_n^{\mu_i}, v_n^{\mu_i})\}$. Furthermore, for any given i, we could find $n_i > i$ such that

$$|J_{\mu_i}(u_{n_i}^{\mu_i}, v_{n_i}^{\mu_i}) - m(\mu_i)| \leqslant \frac{1}{i}, \qquad \left\|J_{\mu_i}'(u_{n_i}^{\mu_i}, v_{n_i}^{\mu_i})\right\| \leqslant \frac{1}{i}.$$

Denote $\{(u_{n_i}^{\mu_i}, v_{n_i}^{\mu_i})\}$ by $\{(u_i, v_i)\}$. Then by (2.3), the uniform boundedness of the sequence $\{(u_n^\mu, v_n^\mu)\}$, Lemma 2.6 and $\mu_i \to 0$, we can derive that

$$\begin{aligned}|J_0(u_i, v_i) - m(0)| &\leqslant |J_{\mu_i}(u_i, v_i) - m(\mu_i)| + \frac{\mu_i}{6}\left[|u_i|_6^6 + |v_i|_6^6 + 2\alpha\int_{\mathbb{R}^3}|u_i|^3|v_i|^3\right] + m(0) - m(\mu_i)\\ &\leqslant \frac{1}{i} + \frac{\mu_i}{6}C_2C_5^6 + m(0) - m(\mu_i) \to 0, \qquad i \to \infty.\end{aligned}$$

Similarly,

$$\|J_0'(u_i, v_i)\| \leqslant \|J_0'(u_i, v_i)\| + \mu_i C_6 \|(u_i, v_i)\|^5 \to 0, \qquad i \to \infty,$$

where C_6 is some positive constant independent of i. These yield that $\{(u_i, v_i)\}$ is a (P.-S.)$_{m(0)}$ sequence of J_0. Due to the fact that J_0 satisfies the (P.–S.) condition on H, then there exists $(u_0, v_0) \in K$ and up to a subsequence still denoted by $\{(u_i, v_i)\}$ such that $(u_i, v_i) \to (u_0, v_0)$ as $i \to \infty$. Thus, one can derive that

$$\lim_{i\to\infty} \lim_{n\to\infty} \operatorname{dist}\big((u_n^{\mu_i}, v_n^{\mu_i}), K\big) \leqslant \lim_{i\to\infty} \operatorname{dist}\big((u_i, v_i), K\big) = 0.$$

In the end, by the arbitrariness for $\{\mu_i\}$, the proof is complete. □

Proof of Theorem 1.1. Assume $\mu \in [0,1]$ and $\{(u_n^\mu, v_n^\mu)\}$ is a (P.–S.)$_{m(\mu)}$ sequence of the functional J_μ. Similarly to (3.1), we can derive that $\{(u_n^\mu, v_n^\mu)\}$ is uniformly bounded for $\mu \in [0,1]$, then there exists $(u_\mu, v_\mu) \in H$ and a subsequence for $\{(u_n^\mu, v_n^\mu)\}$ still denoted by $\{(u_{n_i}^\mu, v_{n_i}^\mu)\}$ such that $(u_{n_i}^\mu, v_{n_i}^\mu) \rightharpoonup (u_\mu, v_\mu)$ as $i \to \infty$ and $J_\mu'(u_\mu, v_\mu) = 0$.

In what follows, we will prove that there exists $\mu_0 > 0$, such that $(u_\mu, v_\mu) \neq (0,0)$ for $\mu \in [0, \mu_0]$. Indeed, since $m(0) > 0$ and K is nonempty and compact, $\delta_0 := \operatorname{dist}((0,0), K) = \min_{(u,v)\in K} \|(u,v)\| > 0$. According to Lemma 3.1,

$$\lim_{\mu\to 0} \lim_{i\to\infty} \operatorname{dist}\big((u_{n_i}^\mu, v_{n_i}^\mu), K\big) = 0.$$

Hence, for any given $\delta < \delta_0/2$, there exists some $\mu_0 = \mu_0(\delta)$ satisfying: for any $\mu \in (0, \mu_0)$ there is $i_0 = i_0(\mu)$ such that

$$\operatorname{dist}\big((u_{n_i}^\mu, v_{n_i}^\mu), K\big) < \delta, \qquad i > i_0.$$

Thus, for fixed $\mu \in (0, \mu_0)$, by the compactness of K, one can obtain a sequence $\{(u_i^\mu, v_i^\mu)\} \subset K$ such that $\|(u_{n_i}^\mu, v_{n_i}^\mu) - (u_i^\mu, v_i^\mu)\| \leqslant \delta$ for $i > i_0$. Moreover, noting that there is $(u_0^\mu, v_0^\mu) \in K$ such that $(u_i^\mu, v_i^\mu) \to (u_0^\mu, v_0^\mu)$ as $i \to \infty$, it also holds that $(u_{n_i}^\mu, v_{n_i}^\mu) \in B_{2\delta}(u_0^\mu, v_0^\mu)$ for i large. Therefore, the facts that $\overline{B_{2\delta}(u_0^\mu, v_0^\mu)}$ is closed weakly and $(u_{n_i}^\mu, v_{n_i}^\mu) \rightharpoonup (u_\mu, v_\mu)$ lead to

$$(u_\mu, v_\mu) \in \overline{B_{2\delta}(u_0^\mu, v_0^\mu)}.$$

Thereby, owing to the choosing of δ,

$$\|(u_\mu, v_\mu)\| \geqslant \|(u_0^\mu, v_0^\mu)\| - 2\delta > 0, \qquad \mu \in (0, \mu_0).$$

In the end, we will prove that (u_μ, v_μ) is a ground-state solution to the system (1.1). Actually, it is sufficient to prove that $J_\mu(u_\mu, v_\mu) = d(\mu)$ since $(u_\mu, v_\mu) \neq (0,0)$ and $J_\mu'(u_\mu, v_\mu) = 0$. To achieve this, we calculate the following inequalities:

$$\begin{aligned}
d(\mu) &\leqslant J_\mu(u_\mu, v_\mu) \\
&= J_\mu(u_\mu, v_\mu) - I_\mu(u_\mu, v_\mu)/4 \\
&= A(u_\mu, v_\mu)/4 + (q-2)C(u_\mu, v_\mu)/(4q) + \mu D(u_\mu, v_\mu)/12 \\
&\leqslant \liminf_{i\to\infty} \big[A(u_{n_i}^\mu, v_{n_i}^\mu)/4 + (q-2)C(u_{n_i}^\mu, v_{n_i}^\mu)/(4q) + \mu D(u_{n_i}^\mu, v_{n_i}^\mu)/12\big] \\
&= \liminf_{i\to\infty} [J_\mu(u_{n_i}^\mu, v_{n_i}^\mu) - I_\mu(u_{n_i}^\mu, v_{n_i}^\mu)/4] = m(\mu).
\end{aligned}$$

Hence, it follows from Lemma 2.5 that $J_\mu(u_\mu, v_\mu) = d(\mu)$. Therefore, (u_μ, v_μ) is a ground-state solution to the system (1.1). □

4 Proof of Theorem 1.2

Lemma 4.1. *Let $p \in [2,\infty)$, and $\sigma \geqslant 0$. Define*

$$h_\sigma(s) = s^p + (1-s)^p + 2\sigma s^{p/2}(1-s)^{p/2}, \qquad s \in [0,1].$$

Then

(i) *if $\sigma < 2^{p-1}-1$, then $h_\sigma(s) < 1$ for all $s \in (0,1)$;*

(ii) *if $\sigma > 2^{p-1}-1$, then $h_\sigma(1/2) > 1$.*

Proof. For (i) one can refer to [4, Lemma 2.7] or [5, Lemma 2.4], while (ii) could be derived through a direct calculation. □

Lemma 4.2. *Assume that $q \in (2,3)$, $\mu > 0$, $0 \leqslant \alpha < 3, 0 \leqslant \beta < 2^{q-1}-1$. If $(u,v) \in H$ is a ground-state radial solution to the system (1.1) with $J_\mu(u,v) = d(\mu)$, then $u = 0$ or $v = 0$.*

Proof. Suppose by contradiction, $u \neq 0$ and $v \neq 0$. Then replacing (u,v) with $(|u|,|v|)$, by a regularity process and the maximum principle, one could also assume that $u > 0$ and $v > 0$. Now, let (ρ,θ) be the polar form of (u,v), that is, that is,

$$(u,v) = (\rho\cos\theta, \rho\sin\theta), \qquad \rho = \rho(x) > 0, \qquad \theta = \theta(x) \in (0,\pi/2).$$

Then on one aspect, by the convexity inequality for gradients in [7], there also holds that $\rho = \sqrt{u^2+v^2} \in H_r^1(\mathbb{R}^3)$. On the other aspect, through calculations, we could get that

$$\nabla u = (\cos\theta)\nabla\rho - \rho(\sin\theta)\nabla\theta, \qquad \nabla v = (\sin\theta)\nabla\rho + \rho(\cos\theta)\nabla\theta.$$

Hence, it follows from definitions of functionals A, B, C and D given in (1.4),

$$\begin{aligned}
A(u,v) &= \int_{\mathbb{R}^3} \left[|\nabla\rho|^2 + \rho^2|\nabla\theta|^2 + \rho^2\right] = A(\rho,0) + \int_{\mathbb{R}^3} \rho^2|\nabla\theta|^2,\\
B(u,v) &= \lambda\int_{\mathbb{R}^3} \phi_{u,v}(u^2+v^2) = \lambda\int_{\mathbb{R}^3} \phi_{\rho,0}\rho^2 = B(\rho,0),\\
C(u,v) &= \int_{\mathbb{R}^3} \rho^{2q}\left[\cos^{2q}\theta + \sin^{2q}\theta + 2\beta\cos^q\theta\sin^q\theta\right] = \int_{\mathbb{R}^3} \rho^{2q} h_\beta(\cos^2\theta),
\end{aligned}$$

and similarly there holds

$$D(u,v) = \int_{\mathbb{R}^3} \rho^6 h_\alpha(\cos^2\theta).$$

Furthermore, since $\theta \in (0,1)$, then by Lemma 4.1 it holds that

$$C(u,v) < |\rho|_{2q}^{2q} = C(\rho,0), \quad D(u,v) < D(\rho,0).$$

Note that by (i) of Lemma 2.3 there exists some $t(\mu) > 0$ such that $t(\mu)(\rho,0) \in \mathcal{N}_\mu$. Then

$$\begin{aligned}
d(\mu) &\leqslant J_\mu(t(\mu)(\rho,0))\\
&= \frac{1}{2}t^2(\mu)A(\rho,0) + \frac{1}{4}t^4(\mu)B(\rho,0) - \frac{1}{2q}t^{2q}(\mu)C(\rho,0) - \frac{1}{6}\mu t^6(\mu)D(\rho,0)\\
&< \frac{1}{2}t^2(\mu)A(u,v) + \frac{1}{4}t^4(\mu)B(u,v) - \frac{1}{2q}t^{2q}(\mu)C(u,v) - \frac{1}{6}\mu t^6(\mu)D(u,v)\\
&= J_\mu(t(\mu)(u,v)) < J_\mu(u,v) = d(\mu).
\end{aligned}$$

This is absurd. Thus, it could only hold that $u = 0$ or $v = 0$. □

Lemma 4.3. *Assume that $q \in (2,3)$, $\mu > 0$, $\alpha > 3, \beta > 2^{q-1} - 1$. If $(u,v) \in H$ is a ground-state radial solution to the system (1.1) with $J_\mu(u,v) = d(\mu)$, then $u \neq 0$ and $v \neq 0$.*

Proof. Arguing by contradiction, we suppose that $v = 0$. Define $(u_0, v_0) = (u/\sqrt{2}, v/\sqrt{2})$. Then $(u_0, v_0) \in H \backslash \{(0,0)\}$. Similarly to the proof of Lemma 4.2, one could derive that

$$A(u_0, v_0) = A(u,0), \qquad B(u_0, v_0) = B(u,0)$$

and

$$C(u_0, v_0) = h_\beta(1/2)C(u,0), \qquad D(u_0, v_0) = h_\alpha(1/2)D(u,0).$$

Moreover, by (i) of Lemma 2.3, there exists a unique $t(\mu) > 0$ such that $t(\mu)(u_0, v_0) \in \mathcal{N}_\mu$. Now, we make the following calculation

$$\begin{aligned} &J_\mu(t(\mu)(u_0, v_0)) \\ &\quad = \frac{1}{2}A(u_0, v_0)t^2(\mu) + \frac{1}{4}B(u_0, v_0)t^4(\mu) - \frac{1}{2q}C(u_0, v_0)t^{2q}(\mu) - \frac{1}{6}\mu D(u_0, v_0)t^6(\mu) \\ &\quad = \frac{1}{2}A(u,0)t^2(\mu) + \frac{1}{4}B(u,0)t^4(\mu) - \frac{1}{2q}h_\beta(1/2)C(u,0)t^{2q}(\mu) - \frac{1}{6}\mu h_\alpha(1/2)D(u,0)t^6(\mu) \\ &\quad < \frac{1}{2}A(u,0)t^2(\mu) + \frac{1}{4}B(u,0)t^4(\mu) - \frac{1}{2q}C(u,0)t^{2q}(\mu) - \frac{1}{6}\mu D(u,0)t^6(\mu) = J_\mu(t(\mu)(u,0)). \end{aligned}$$

Consequently,

$$d(\mu) \leqslant J_\mu(t(\mu)(u_0, v_0)) < J_\mu(t(\mu)(u,0)) \leqslant J_\mu(u,0) = d(\mu),$$

which is a contraction. Thus, it holds that $u \neq 0$ and $v \neq 0$. □

Proof of Theorem 1.2. According to Lemmas 4.2 and 4.3, one can get Theorem 1.2 directly. □

Abstract. In this paper, we utilize the Littlewood–Paley decomposition theory to establish two regularity criteria for the 3D magneto-micropolar equations in Vishik spaces, specifically focusing on the gradient of the velocity field.

Keywords: magneto-micropolar equations, regularity criteria, Vishik spaces.

2020 Mathematics Subject Classification: 35Q35, 35B40, 76A15.

1 Introduction

In this paper, we study the magneto-micropolar system in the whole space $\mathbb{R}^3$:

$$\begin{cases} \partial_t u - (\mu+\chi)\Delta u + (u\cdot\nabla)u - (b\cdot\nabla)b - \chi\nabla\times\omega + \nabla p = 0, \\ \partial_t \omega - \gamma\Delta\omega - \kappa\nabla\nabla\cdot\omega + 2\chi\omega + (u\cdot\nabla)\omega - \chi\nabla\times u = 0, \\ \partial_t b - \nu\Delta b + (u\cdot\nabla)b - (b\cdot\nabla)u = 0, \\ \nabla\cdot u = \nabla\cdot b = 0, \\ u(x,0) = u_0(x),\ \omega(x,0) = \omega_0(x), b(x,0) = b_0(x), \end{cases} \tag{1.1}$$

where $(x,t)\in\mathbb{R}^3\times\mathbb{R}^+$, $u(x,t) = (u_1(x,t), u_2(x,t), u_3(x,t))$, $\omega(x,t) = (\omega_1(x,t), \omega_2(x,t), \omega_3(x,t))$, $b(x,t) = (b_1(x,t), b_2(x,t), b_3(x,t))$ and p denote the fluid velocity, micro-rotational velocity, magnetic field and scalar pressure, respectively. Here, μ is the kinematic viscosity, χ is the vortex viscosity, $\frac{1}{\nu}$ is the magnetic Reynolds number, while κ and γ denote angular viscosities. This model has been used to study microelectrode fluid motion in the presence of a magnetic field. It was first proposed by Galdi and Rionero [8] to address microscopic physical phenomena, such as the motion of animal blood, liquid crystals, and dilute aqueous polymer solutions, which cannot be accurately described by the classical Navier–Stokes equations for incompressible viscous fluids. These fluids are characterized by asymmetric stress tensors, which is why they are referred to as asymmetric fluids. Due to the complex physical background and the richness of the phenomena involved, incompressible micropolar fluids have been extensively studied (see [1, 2, 4, 5, 12, 17, 19, 23, 24] and references therein).

Function spaces are essential tools for studying and solving systems of fluid mechanics equations. By means of Sobolev spaces [13], researchers can effectively characterize solutions to fluid dynamics problems and investigate their existence, uniqueness, and regularity. To further refine the analysis of local behavior and regularity, especially when dealing with nonlinear partial differential equations, Morrey-type spaces are employed (see [6,16,21,27]). These spaces better capture the local integrability and smoothness of solutions, aiding in the study of conditions for the emergence of local singularities and vortex structures, while also providing more precise integral estimates for nonlinear terms. The concept of weak solutions relies on the weak formulation within function spaces. By examining the well-posedness of fluid mechanics equations in various function spaces, researchers can not only ensure the reasonableness and solvability of these systems but also gain a deeper understanding of solution regularity, nonlinear characteristics, stability, and the feasibility of numerical computations. For more details, please refer to [9,10,14].

Rojas-Medar and Boldrini [18] used the Galerkin method to prove, for the first time, the existence of weak solutions to the 2D and 3D magnetic differential equations (1.1). Yuan [25] showed that if $\nabla u \in L^1(0,T;\dot{B}^0_{\infty,\infty}(\mathbb{R}^3))$, then the weak solution is smooth on $\mathbb{R}\times[0,T]$. Subsequently, Gala [7], Zhang et al. [28] and Xu [22] extended the regularity criterion to Morrey–Campanato spaces, Triebel–Lizorkin spaces and Besov spaces, respectively. Yuan and Li [26] further refined the results of Xu [22]. Recently, Wu [20] established the regularity of the weak solution to this system by imposing specific conditions on the partial derivatives of the velocity and magnetic field components. Additionally, Qin and Zhang [15] obtained optimal decay estimates for the higher-order derivatives of the strong solution to the system (1.1).

The aim of this paper is to study the regularity criterion for the solution of the magneto-micropolar equations (1.1). Understanding this criterion is crucial for comprehending the physical laws governing magneto-micropolar motion. Notably, $\dot{B}^0_{\infty,\infty}(\mathbb{R}^3)\subset \dot{V}^0_{\infty,\infty,\theta}(\mathbb{R}^3)$, where the Vishik spaces $\dot{V}^s_{p,r,\theta}(\mathbb{R}^3)$ are introduced as a class of Banach spaces (see Definition 2.3). Consequently, we anticipate that weak solution exhibit corresponding smoothness in such Banach spaces. In this paper, we demonstrate that to ensure the regularity of weak solution to (1.1), it is sufficient to impose certain conditions on the fluid's velocity field. This finding also indirectly suggests that, in the study of weak solution regularity, the fluid velocity u plays a more significant role than both the microscopic rotational velocity ω of the particles and the magnetic field b.

Our main result of the paper is stated as follows:

Theorem 1.1. *Let $(u_0,\omega_0,b_0)\in H^1(\mathbb{R}^3)$ and $\nabla\cdot u_0=\nabla\cdot b_0=0$. Assume that (u,ω,b) is a weak solution to the system (1.1) on the interval $[0,T]$. If the velocity gradient ∇u satisfies one of the following conditions:*

$$\nabla u \in L^1\Big((0,T;\dot{V}^{\frac{3}{p}}_{p,r,1}(\mathbb{R}^3)\Big),\qquad p\geq 1, \tag{1.2}$$

$$\nabla u \in L^{\frac{2p}{2p-3}}(0,T;\dot{V}^0_{p,r,1}(\mathbb{R}^3)),\qquad p\geq \frac{3}{2}, \tag{1.3}$$

then the weak solution (u,ω,b) is smooth on $[0,T]$.

Remark 1.2. Notice that for $\theta\in[1,\infty]$, we have $\dot{B}^0_{\infty,\infty}(\mathbb{R}^3)\subset\dot{V}^0_{\infty,\infty,\theta}(\mathbb{R}^3)$. Therefore, Theorem 1.1 can be viewed as a further improvement of [24].

The rest of this paper is organized as follows. Section 2 reviews some preliminaries. Section 3 is devoted to the proof of Theorem 1.1.

2 Preliminaries

Let us begin with a brief review of the definition of Littlewood–Paley decomposition, as detailed in [3]. Let χ be a smooth, radially non-increasing function that takes values in $[0,1]$ and is supported within the ball $|\xi| \leq \frac{4}{3}$. Define φ in terms of χ by setting $\varphi(\xi) := \chi(\frac{\xi}{2}) - \chi(\xi)$, so that φ is supported in the annulus $\{\frac{3}{4} \leq |\xi| \leq \frac{8}{3}\}$. These functions satisfy the following partition of unity:

$$\chi(\xi) + \sum_{j\geq 0} \varphi(2^{-j}\xi) = 1, \quad \forall \xi \in \mathbb{R}^3; \qquad \sum_{j\in\mathbb{Z}} \varphi(2^{-j}\xi) = 1, \quad \forall \xi \neq 0.$$

Let $h = \check{\varphi}, \tilde{h} = \check{\chi}$, where $\check{\varphi}$ and $\check{\chi}$ denote the inverse Fourier transforms of φ and χ, respectively. The dyadic blocks $\dot{\Delta}_j u$ and low-frequency cut-off $\dot{S}_j u$ can then be defined as:

$$\dot{\Delta}_j u = \varphi(2^{-j}D)u = 2^{3j}\int_{\mathbb{R}^3} h(2^j y)u(x-y)\mathrm{d}y,$$

$$\dot{S}_j u = \sum_{k\leq j-1} \Delta_j u = 2^{3j}\int_{\mathbb{R}^3} \tilde{h}(2^j y)u(x-y)\mathrm{d}y, \qquad j \in \mathbb{Z}.$$

According to the Bony decomposition, any distribution $u \in \mathcal{S}'(\mathbb{R}^3) \setminus \mathcal{P}(\mathbb{R}^3)$ can be expressed as:

$$u = \sum_{j=-\infty}^{+\infty} \dot{\Delta}_j u, \qquad u \in \mathcal{S}'(\mathbb{R}^3) \setminus \mathcal{P}(\mathbb{R}^3),$$

where $\mathcal{P}(\mathbb{R}^3)$ denotes the set of polynomials.

Recall the definition of the homogeneous Besov spaces [3], which are based on the Littlewood–Paley decomposition.

Definition 2.1. Let $p, r \in [1,\infty]$ and $s \in \mathbb{R}$. The homogeneous Besov spaces $\dot{B}^s_{p,r}(\mathbb{R}^3)$ are defined as

$$\dot{B}^s_{p,r}(\mathbb{R}^3) := \left\{ f \in \mathcal{S}'(\mathbb{R}^3) \setminus \mathcal{P}(\mathbb{R}^3) : \|f\|_{\dot{B}^s_{p,r}(\mathbb{R}^3)} < \infty \right\},$$

where

$$\|f\|_{\dot{B}^s_{p,r}(\mathbb{R}^3)} := \begin{cases} \left(\sum_{j=1}^{\infty} 2^{jrs}\|\dot{\Delta}_j f\|^r_{L^p}\right)^{\frac{1}{r}}, & r \neq \infty, \\ \sup_{j\in\mathbb{Z}} \|\dot{\Delta}_j f\|_{L^p}, & r = \infty. \end{cases}$$

We also recall the Bernstein inequality, which plays a key role in the proof of the main result, see [3].

Lemma 2.2. *Let $k \geq 0$ and $1 \leq a, b \leq \infty$. Then the following inequality holds*

$$\sum_{|\alpha|=k} \|\partial^\alpha \dot{\Delta}_j u\|_{L^b} \leq C 2^{kj+3j(\frac{1}{a}-\frac{1}{b})}\|\dot{\Delta}_j u\|_{L^a},$$

where $C > 0$ is a constant depending only on k, a, b.

Next, we introduce a class of Banach spaces, known as Vishik spaces [11], which generalize the homogeneous Besov spaces.

Definition 2.3. Let $p, r \in [1, \infty]$, $s \in \mathbb{R}$ and $\theta \in [1, r]$. The Vishik spaces $\dot{V}^s_{p,r,\theta}(\mathbb{R}^3)$ are defined as

$$\dot{V}^s_{p,r,\theta}(\mathbb{R}^3) := \left\{ f \in \mathcal{S}'(\mathbb{R}^3) \setminus \mathcal{P}(\mathbb{R}^3) : \|f\|_{\dot{V}^s_{p,r,\theta}(\mathbb{R}^3)} < \infty \right\},$$

where

$$\|f\|_{\dot{V}^s_{p,r,\theta}(\mathbb{R}^3)} := \begin{cases} \sup_{N \in \mathbb{N}^*} \frac{(\sum_{j=-N}^{N} 2^{j\theta s} \|\dot{\Delta}_j f\|^{\theta}_{L^p})^{\frac{1}{\theta}}}{N^{\frac{1}{\theta} - \frac{1}{r}}}, & \theta \neq \infty, \\ \|f\|_{B^0_{p,\infty}(\mathbb{R}^3)}, & \theta = \infty. \end{cases}$$

3 The proof of Theorem 1.1

Proof. By taking the L^2 inner product of the first equation, the second equation and the third equation of (1.1) with u, ω and b, respectively, summing the results, and then integrating with respect to t, we obtain

$$\|u\|^2_{L^2} + \|\omega\|^2_{L^2} + \|b\|^2_{L^2} + 2\int_0^T (\mu\|\nabla u\|^2_{L^2} + \gamma\|\nabla\omega\|^2_{L^2} + \nu\|\nabla b\|^2_{L^2})\mathrm{d}t \le C(u_0, \omega_0, b_0).$$

The first equation, as well as the second and third equations in (1.1), are multiplied by $-\Delta u$, $-\Delta\omega$ and $-\Delta b$, respectively, and then integrated over $\mathbb{R}^3$ with respect to x, which yields

$$\begin{aligned} &\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}(\|\nabla u\|^2_{L^2} + \|\nabla\omega\|^2_{L^2} + \|\nabla b\|^2_{L^2}) + (\mu+\chi)\|\Delta u\|^2_{L^2} + \gamma\|\Delta\omega\|^2_{L^2} + \nu\|\Delta b\|^2_{L^2} \\ &\qquad + 2\chi\|\nabla\omega\|^2_{L^2} + \kappa\|\nabla\nabla\cdot\omega\|^2_{L^2} \\ &\quad = \int_{\mathbb{R}^3}(u\cdot\nabla)u\cdot\Delta u\mathrm{d}x - \int_{\mathbb{R}^3}(b\cdot\nabla)b\cdot\Delta u\mathrm{d}x - \chi\int_{\mathbb{R}^3}\nabla\times\omega\cdot\Delta u\mathrm{d}x - \chi\int_{\mathbb{R}^3}\nabla\times u\cdot\Delta\omega\mathrm{d}x \\ &\qquad + \int_{\mathbb{R}^3}(u\cdot\nabla)\omega\cdot\Delta\omega\mathrm{d}x + \int_{\mathbb{R}^3}(u\cdot\nabla)b\cdot\Delta b\mathrm{d}x - \int_{\mathbb{R}^3}(b\cdot\nabla)u\cdot\Delta b\mathrm{d}x \\ &\quad =: I_1(t) + I_2(t) + I_3(t) + I_4(t) + I_5(t) + I_6(t) + I_7(t). \end{aligned} \tag{3.1}$$

According to the Littlewood–Paley decomposition theory, it can be obtained that

$$\nabla u = \sum_{j<-N}\dot{\Delta}_j\nabla u + \sum_{j=-N}^{N}\dot{\Delta}_j\nabla u + \sum_{j>N}\dot{\Delta}_j\nabla u, \tag{3.2}$$

where N is to be determined. Without loss of generality, we first estimate $I_5(t)$. Using integration by parts and (3.2), we have that

$$\begin{aligned} I_5(t) &= \int_{\mathbb{R}^3}(u\cdot\nabla)\omega\cdot\Delta\omega\mathrm{d}x \\ &= -\int_{\mathbb{R}^3}\partial_k u_i\partial_i\omega_j\partial_k\omega_j\mathrm{d}x - \int_{\mathbb{R}^3}u_i\partial_k\partial_i\omega_j\partial_k\omega_j\mathrm{d}x \\ &\le \int_{\mathbb{R}^3}|\nabla\omega|^2|\nabla u|\mathrm{d}x \\ &\le \sum_{j<-N}\int_{\mathbb{R}^3}|\nabla\omega|^2|\dot{\Delta}_j\nabla u|\mathrm{d}x + \sum_{j=-N}^{N}\int_{\mathbb{R}^3}|\nabla\omega|^2|\dot{\Delta}_j\nabla u|\mathrm{d}x + \sum_{j>N}\int_{\mathbb{R}^3}|\nabla\omega|^2|\dot{\Delta}_j\nabla u|\mathrm{d}x \\ &=: I_{51} + I_{52} + I_{53}. \end{aligned} \tag{3.3}$$

Below we estimate I_{51}–I_{53} separately. For I_{51}, by means of the Hölder inequality and the Bernstein inequality, it follows that

$$\begin{aligned}
I_{51}(t) &= \sum_{j<-N} \int_{\mathbb{R}^3} |\nabla\omega|^2 |\dot{\Delta}_j \nabla u| \mathrm{d}x \\
&\le \sum_{j<-N} \|\dot{\Delta}_j \nabla u\|_{L^\infty} \|\nabla\omega\|_{L^2}^2 \\
&\le C \sum_{j<-N} 2^{\frac{3j}{2}} \|\dot{\Delta}_j \nabla u\|_{L^2} \|\nabla\omega\|_{L^2}^2 \\
&\le C 2^{-\frac{3N}{2}} \|\nabla u\|_{L^2} \|\nabla\omega\|_{L^2}^2. \qquad (3.4)
\end{aligned}$$

For I_{52}. Let $p \ge 1$. By the Hölder inequality, the Bernstein inequality and the definition of Vishik spaces, we have

$$\begin{aligned}
I_{52}(t) &= \sum_{j=-N}^{N} \int_{\mathbb{R}^3} |\nabla\omega|^2 |\dot{\Delta}_j \nabla u| \mathrm{d}x \\
&\le \sum_{j=-N}^{N} \|\dot{\Delta}_j \nabla u\|_{L^\infty} \|\nabla\omega\|_{L^2}^2 \\
&\le C \sum_{j=-N}^{N} 2^{\frac{3j}{p}} \|\dot{\Delta}_j \nabla u\|_{L^p} \|\nabla\omega\|_{L^2}^2 \\
&\le C N^{1-\frac{1}{r}} \sup_{N\in\mathbb{N}^*} \frac{\sum_{j=-N}^{N} 2^{\frac{3j}{p}} \|\dot{\Delta}_j \nabla u\|_{L^p}}{N^{1-\frac{1}{r}}} \|\nabla\omega\|_{L^2}^2 \\
&\le C N^{1-\frac{1}{r}} \|\nabla u\|_{V_{p,r,1}^{\frac{3}{p}}} \|\nabla\omega\|_{L^2}^2. \qquad (3.5)
\end{aligned}$$

For I_{53}. From the Hölder inequality, the Bernstein inequality and space embedding relation, it follows that

$$\begin{aligned}
I_{53}(t) &= \sum_{j>N} \int_{\mathbb{R}^3} |\nabla\omega|^2 |\dot{\Delta}_j \nabla u| \mathrm{d}x \\
&\le C \sum_{j>N} \|\dot{\Delta}_j \nabla u\|_{L^3} \|\nabla\omega\|_{L^2} \|\nabla\omega\|_{L^6} \\
&\le C \sum_{j>N} 2^{\frac{j}{2}} \|\dot{\Delta}_j \nabla u\|_{L^2} \|\nabla\omega\|_{L^2} \|\Delta\omega\|_{L^2} \\
&\le C \Big(\sum_{j>N} 2^{-j} \Big)^{\frac{1}{2}} \Big(\sum_{j>N} 2^{2j} \|\dot{\Delta}_j \nabla u\|_{L^2}^2 \Big)^{\frac{1}{2}} \|\nabla u\|_{L^2} \|\Delta u\|_{L^2} \\
&\le C 2^{-\frac{N}{2}} \|\nabla u\|_{B^1_{2,2}} \|\nabla\omega\|_{L^2} \|\Delta\omega\|_{L^2} \\
&\le C 2^{-\frac{N}{2}} \|\Delta u\|_{L^2} \|\nabla\omega\|_{L^2} \|\Delta\omega\|_{L^2}. \qquad (3.6)
\end{aligned}$$

Combining (3.4)–(3.6), there are

$$\begin{aligned}
I_5(t) &\le C 2^{-\frac{3N}{2}} \|\nabla u\|_{L^2} \|\nabla\omega\|_{L^2}^2 + C N^{1-\frac{1}{\sigma}} \|\nabla u\|_{V_{p,r,1}^{\frac{3}{p}}} \|\nabla\omega\|_{L^2}^2 + C 2^{-\frac{N}{2}} \|\nabla\omega\|_{L^2} \|\Delta u\|_{L^2} \|\Delta\omega\|_{L^2} \\
&\le C 2^{-\frac{3N}{2}} (\|\nabla u\|_{L^2}^3 + \|\nabla\omega\|_{L^2}^3) + C N^{1-\frac{1}{r}} \|\nabla u\|_{V_{p,r,1}^{\frac{3}{p}}} \|\nabla\omega\|_{L^2}^2 \\
&\quad + C 2^{-\frac{N}{2}} \|\nabla\omega\|_{L^2} (\|\Delta u\|_{L^2}^2 + \|\Delta\omega\|_{L^2}^2). \qquad (3.7)
\end{aligned}$$

Similarly, we have

$$I_1(t) \le C2^{-\frac{3N}{2}}\|\nabla u\|_{L^2}^3 + CN^{1-\frac{1}{\sigma}}\|\nabla u\|_{V^{\frac{3}{p}}_{p,r,1}}\|\nabla u\|_{L^2}^2 + C2^{-\frac{N}{2}}\|\nabla u\|_{L^2}\|\Delta u\|_{L^2}^2. \tag{3.8}$$

Using the Hölder inequality and the Young inequality, one obtains that

$$\begin{aligned} I_3(t) + I_4(t) = & -\chi\int_{\mathbb{R}^3}\nabla\times\omega\cdot\Delta u \mathrm{d}x - \chi\int_{\mathbb{R}^3}\nabla\times u\cdot\Delta\omega \mathrm{d}x \\ & \le \chi(\|\nabla\omega\|_{L^2}\|\Delta u\|_{L^2} + \|\nabla u\|_{L^2}\|\Delta\omega\|_{L^2}) \\ & \le \frac{\mu+\chi}{4}\|\Delta u\|_{L^2}^2 + \frac{\gamma}{4}\|\Delta\omega\|_{L^2}^2 + C\|\nabla u\|_{L^2} + C\|\nabla\omega\|_{L^2}. \end{aligned} \tag{3.9}$$

Similar to I_5, we have

$$\begin{aligned} I_2(t) + I_6(t) + I_7(t) \le & \int_{\mathbb{R}^3}|\nabla b|^2|\nabla u|\mathrm{d}x \\ & \le C2^{-\frac{3N}{2}}(\|\nabla u\|_{L^2}^3 + \|\nabla b\|_{L^2}^3) + CN^{1-\frac{1}{\sigma}}\|\nabla u\|_{V^{\frac{3}{p}}_{p,r,1}}\|\nabla b\|_{L^2}^2 \\ & \quad + C2^{-\frac{N}{2}}\|\nabla b\|_{L^2}(\|\Delta u\|_{L^2}^2 + \|\Delta b\|_{L^2}^2). \end{aligned} \tag{3.10}$$

Combining (3.2) and (3.7)–(3.10), one has

$$\begin{aligned} & \frac{1}{2}\frac{\mathrm{d}t}{\mathrm{d}t}(\|\nabla u\|_{L^2}^2 + \|\nabla\omega\|_{L^2}^2 + \|\nabla b\|_{L^2}^2) + \frac{\mu+\chi}{2}\|\Delta u\|_{L^2}^2 + \frac{\gamma}{2}\|\Delta\omega\|_{L^2}^2 + \nu\|\Delta b\|_{L^2}^2 \\ & \qquad + 2\chi\|\nabla\omega\|_{L^2}^2 + \kappa\|\nabla\nabla\cdot\omega\|_{L^2}^2 \\ & \quad \le C2^{-\frac{3N}{2}}(\|\nabla u\|_{L^2}^3 + \|\nabla\omega\|_{L^2}^3 + \|\nabla b\|_{L^2}^3) + CN^{1-\frac{1}{r}}\|\nabla u\|_{V^{\frac{3}{p}}_{p,r,1}}(\|\nabla u\|_{L^2}^2 + \|\nabla\omega\|_{L^2}^2 + \|\nabla b\|_{L^2}^2) \\ & \qquad + C2^{-\frac{N}{2}}(\|\nabla u\|_{L^2} + \|\nabla\omega\|_{L^2} + \|\nabla b\|_{L^2})(\|\Delta u\|_{L^2}^2 + \|\Delta\omega\|_{L^2}^2 + \|\Delta b\|_{L^2}^2) \\ & \qquad + C(\|\nabla u\|_{L^2}^2 + \|\nabla\omega\|_{L^2}^2) \\ & \quad \le C2^{-\frac{3N}{2}}(\|\nabla u\|_{L^2} + \|\nabla\omega\|_{L^2} + \|\nabla b\|_{L^2})(\|\nabla u\|_{L^2}^2 + \|\nabla\omega\|_{L^2}^2 + \|\nabla b\|_{L^2}^2) \\ & \qquad + CN^{1-\frac{1}{r}}\|\nabla u\|_{V^{\frac{3}{p}}_{p,r,1}}(\|\nabla u\|_{L^2}^2 + \|\nabla\omega\|_{L^2}^2 + \|\nabla b\|_{L^2}^2) \\ & \qquad + C2^{-\frac{N}{2}}(\|\nabla u\|_{L^2} + \|\nabla\omega\|_{L^2} + \|\nabla b\|_{L^2})(\|\Delta u\|_{L^2}^2 + \|\Delta\omega\|_{L^2}^2 + \|\Delta b\|_{L^2}^2). \end{aligned} \tag{3.11}$$

We fix a large enough N, which obeys

$$C2^{-\frac{N}{2}}(\|\nabla u\|_{L^2} + \|\nabla\omega\|_{L^2} + \|\nabla b\|_{L^2}) \le \frac{1}{4}\min\{\mu+\chi, \gamma, 2\nu\},$$

i.e.

$$N \ge 4 + \frac{2lnC + 2ln(\|\nabla u\|_{L^2} + \|\nabla\omega\|_{L^2} + \|\nabla b\|_{L^2}) - 2\min\{\mu+\chi,\gamma,2\nu\}}{ln2}.$$

Taking

$$N = \left[4 + \frac{2lnC + 2ln(\|\nabla u\|_{L^2} + \|\nabla\omega\|_{L^2} + \|\nabla b\|_{L^2}) - 2\min\{\mu+\chi,\gamma,2\nu\}}{ln2}\right] + 1,$$

it follows from (3.11) that

$$\frac{1}{2}\frac{\mathrm{d}t}{\mathrm{d}t}(\|\nabla u\|_{L^2}^2+\|\nabla\omega\|_{L^2}^2+\|\nabla b\|_{L^2}^2)+\left(\frac{\mu+\chi}{2}-\frac{1}{4}\min\{\mu+\chi,\gamma,2\nu\}\right)\|\Delta u\|_{L^2}^2+2\chi\|\nabla\omega\|_{L^2}^2$$
$$+\left(\frac{\gamma}{2}-\frac{1}{4}\min\{\mu+\chi,\gamma,2\nu\}\right)\|\Delta\omega\|_{L^2}^2$$
$$+\left(\nu-\frac{1}{4}\min\{\mu+\chi,\gamma,2\nu\}\right)\|\Delta b\|_{L^2}^2+\kappa\|\nabla\nabla\cdot\omega\|_{L^2}^2$$
$$\leq C\left(1+\|\nabla u\|_{V^{\frac{3}{p}}_{p,r,1}}\right)(\|\nabla u\|_{L^2}^2+\|\nabla\omega\|_{L^2}^2+\|\nabla b\|_{L^2}^2). \tag{3.12}$$

Using the Gronwall inequality yields

$$\sup_{0\leq t\leq T}(\|\nabla u\|_{L^2}^2+\|\nabla\omega\|_{L^2}^2+\|\nabla b\|_{L^2}^2)+C\int_0^T(\|\Delta u\|_{L^2}^2+\|\Delta\omega\|_{L^2}^2+\|\Delta b\|_{L^2}^2)(t)\,\mathrm{d}t$$
$$\leq \exp\left(CT+C\int_0^T\|\nabla u\|_{V^{\frac{3}{p}}_{p,r,1}}\mathrm{d}t\right)(\|\nabla u_0\|_{L^2}^2+\|\nabla\omega_0\|_{L^2}^2+\|\nabla b_0\|_{L^2}^2).$$

Using the hypothetical condition (1.2), we get

$$u,\omega,b\in L^\infty(0,T;H^1(\mathbb{R}^3))\cap L^2(0,T;H^2(\mathbb{R}^3)).$$

For the regularity criterion (1.3), we focus our analysis on I_5. Similarly, by applying the theory of Littlewood–Paley decompositions, it follows that

$$I_5(t)\leq\sum_{j<-N}\int_{\mathbb{R}^3}|\nabla u|^2|\dot{\Delta}_j\nabla u|\mathrm{d}x+\sum_{j=-N}^{N}\int_{\mathbb{R}^3}|\nabla u|^2|\dot{\Delta}_j\nabla u|\mathrm{d}x+\sum_{j>N}\int_{\mathbb{R}^3}|\nabla u|^2|\dot{\Delta}_j\nabla u|\mathrm{d}x$$
$$=:J_{51}+J_{52}+J_{53}. \tag{3.13}$$

Using $I_{51}(t)$ and $I_{53}(t)$, one obtains that

$$J_{51}(t)+J_{53}(t)\leq C2^{-\frac{3N}{2}}\|\nabla u\|_{L^2}^3+C2^{-\frac{N}{2}}\|\nabla u\|_{L^2}\|\Delta u\|_{L^2}^2. \tag{3.14}$$

Let $p\geq\frac{3}{2}$. From the Hölder inequality, the definition of Vishik spaces, the Gagliardo–Nirenberg inequality and the Young inequality, we have

$$J_{52}(t)=\sum_{j=-N}^{N}\int_{\mathbb{R}^3}|\nabla u|^2|\dot{\Delta}_j\nabla u|\mathrm{d}x$$
$$\leq\sum_{j=-N}^{N}\|\dot{\Delta}_j\nabla u\|_{L^p}\|\nabla u\|^2_{L^{\frac{2p}{p-1}}}$$
$$\leq CN^{1-\frac{1}{r}}\sup_{N\in\mathbb{N}^*}\frac{\sum_{j=-N}^{N}\|\dot{\Delta}_j\nabla u\|_{L^p}}{N^{1-\frac{1}{r}}}\|\nabla u\|_{L^2}^{2-\frac{3}{p}}\|\Delta u\|_{L^2}^{\frac{3}{p}}$$
$$\leq CN^{1-\frac{1}{r}}\|\nabla u\|_{V^0_{p,r,1}}\|\nabla u\|_{L^2}^{2-\frac{3}{p}}\|\Delta u\|_{L^2}^{\frac{3}{p}}$$
$$\leq\frac{\mu+\chi}{4}\|\Delta u\|_{L^2}^2+CN^{\frac{(r-1)2p}{(2p-3)r}}\|\nabla u\|_{V^0_{p,r,1}}^{\frac{2p}{2p-3}}\|\Delta u\|_{L^2}^2. \tag{3.15}$$

Combining (3.13)–(3.15), yields

$$I_5(t) \le C2^{-\frac{3N}{2}}\|\nabla u\|_{L^2}^3 + \frac{\mu+\chi}{4}\|\Delta u\|_{L^2}^2 + CN^{\frac{(r-1)2p}{(2p-3)r}}\|\nabla u\|_{V^0_{p,r,1}}^{\frac{2p}{2p-3}}\|\Delta u\|_{L^2}^2 + C2^{-\frac{N}{2}}\|\nabla u\|_{L^2}\|\Delta u\|_{L^2}^2.$$

The analysis that follows is similar to that of the regularity criterion (1.3), except for a slight difference in the choice of N, which is omitted here. We leave the details to the interested reader.

Based on the above analysis, we complete the proof of Theorem 1.1. □

Abstract. In this paper, we study the following Schrödinger equations with potentials and general nonlinearities

$$\begin{cases} -\Delta u + V(x)u + \lambda u = |u|^{q-2}u + \beta f(u), \\ \int |u|^2 dx = \Theta, \end{cases}$$

both on $\mathbb{R}^N$ as well as on domains Ω_r where $\Omega_r \subset \mathbb{R}^N$ is an open bounded convex domain and $r > 0$ is large. The exponent satisfies $2 + \frac{4}{N} \leq q \leq 2^* = \frac{2N}{N-2}$ and $f : \mathbb{R} \to \mathbb{R}$ satisfies L^2-subcritical or L^2-critical growth. This paper generalizes the conclusion of Bartsch et al. in [4]. Moreover, we consider the Sobolev critical case and L^2-critical case of the above problem.

Keywords: Schrödinger equations, normalized solutions, variational methods, mixed nonlinearity.

1 Introduction and main results

This paper studies the existence of normalized solutions for the following Schrödinger equations with potentials and general nonlinearities

$$\begin{cases} -\Delta u + V(x)u + \lambda u = |u|^{q-2}u + \beta f(u), & x \in \Omega_r, \\ \int_{\Omega_r} |u|^2 dx = \Theta, u \in H_0^1(\Omega_r), & x \in \Omega_r, \end{cases} \tag{1.1}$$

where $\Omega_r \subset \mathbb{R}^N$ is either all of $\mathbb{R}^N$ or a bounded smooth convex domain, $N \geq 3$, $2 + \frac{4}{N} \leq q \leq 2^* = \frac{2N}{N-2}$, the mass $\Theta > 0$ and the parameter $\beta \in \mathbb{R}$ are prescribed. The frequency λ is unknown and to be determined.

Corresponding author. Email: wangj937@mail2.sysu.edu.cn

Such problems are motivated in particular by searching for solitary waves (stationary states) in nonlinear equations of the Schrödinger type. Specifically, consider the following nonlinear Schrödinger equation

$$\begin{cases} -i\dfrac{\partial}{\partial t}\Psi = \Delta\Psi - V(x)\Psi + f\left(|\Psi|^2\right)\Psi = 0, & (x,t) \in \mathbb{R}^N \times \mathbb{R}, \\ \Psi = \Psi(x,t), & (x,t) \in \mathbb{C}, \end{cases}$$

where $N \geq 1$. Researchers are interested in finding the existence of standing wave solutions to the above equations, that is, $\Psi(x,t) = e^{i\lambda t}u(x), \lambda \in \mathbb{R}$, and $u : \mathbb{R}^N \to \mathbb{R}$, so we get the equation

$$-\Delta u + (V(x) + \lambda)u = Q(u), \qquad x \in \mathbb{R}^N,$$

where $Q(u) = f(|u|^2)u$. For physical reasons, we focus on the existence of normalized solutions for the following problem

$$\begin{cases} -\Delta u + (V(x) + \lambda)u = Q(u), & x \in \mathbb{R}^N, \\ \displaystyle\int_{\mathbb{R}^N} |u|^2 dx = \Theta, & x \in \mathbb{R}^N. \end{cases} \tag{1.2}$$

For more physical background about the above equation, please refer to [9,16].

If potential $V(x)$ in (1.2) is constant, we call (1.2) is autonomous. In this case, recalling paper [21], Jeanjean developed an approach based on the Pohozaev identity which has been used successfully in recent years. The key to this method is to find a bounded Palais–Smale sequences by using the transformation $s * u(x) = e^{\frac{sN}{2}}u(e^s x)$. After that, by weakening the conditions in [21], Jeanjean [22] and Bieganowski [8] improved these results. Of course, these articles only consider the problem of a single nonlinear term. Recently, there have been many studies on mixed nonlinear terms. For example, Soave [26,27] studied normalized solution of (1.2) with mixed nonlinearity $f(|u|)u = \mu|u|^{q-2}u + |u|^{p-2}u$, $2 < p < 2 + \frac{4}{N} < q \leq 2^* = \frac{2N}{N-2}$. Specifically, Soave in [26] obtained many results of existence and non-existence. More precisely, if $2 < q < p = 2 + \frac{4}{N}$, that is, the leading nonlinearity is L^2-critical and a L^2-subcritical lower order term. (1.2) had a real-valued positive and radially symmetric solution for some $\lambda < 0$ in $\mathbb{R}^N$ provided $\mu > 0$ and $\Theta > 0$ small enough. Moreover, if $\mu < 0$, (1.2) had no solution. If $2 + \frac{4}{N} = q < p < 2^*$, that is, the leading term is L^2-critical and L^2-supercritical, (1.2) had a real-valued positive, radially symmetric solution for some $\lambda < 0$ in $\mathbb{R}^N$ provided $\mu > 0$ and μ, Θ satisfy the appropriate conditions. If $2 < q < 2 + \frac{4}{N} < p < 2^*$, that is, the leading term L^2-subcritical and L^2-supercritical, (1.2) also had a real-valued positive and radially symmetric solution for some $\lambda < 0$ in $\mathbb{R}^N$ provided $\Theta > 0, \mu < 0$ and μ, Θ satisfy the appropriate conditions. Soave in [27] considered the Sobolev critical case and obtained some similar results. In particular, the Sobolev critical case also has been considered in [1,2,24,25](see also the references therein). It is worth mentioning that many researchers are also interested in the existence of normalized multiple solutions. In [23], Jeanjean et al. obtained the existence of normalized multiple solutions for Sobolev critical case in (1.2). For more results on this aspect, please refer to [5–7,10,29] and its references.

If (1.2) is non-autonomous, Ikoma and Miyamoto in [19] considered question (1.2) with $V(x) \in C(\mathbb{R}^N), 0 \not\equiv V(x) \leq 0, V(x) \to 0(|x| \to \infty)$, they obtained some existence and non-existence results. After that, Ding and Zhong in [14] proved the existence of normalized solutions to the following Schrödinger equation

$$\begin{cases} -\Delta u(x) + V(x)u(x) + \lambda u(x) = g(u(x)), & x \in \mathbb{R}^N, \\ 0 \leq u(x) \in H^1(\mathbb{R}^N),\ N \geq 3, \end{cases}$$

where g satisfies:

$(G1)$ $g : \mathbb{R} \to \mathbb{R}$ is C^1 and odd.

$(G2)$ There exists some $(\alpha, \beta) \in \mathbb{R}^2_+$ satisfying $2 + \frac{4}{N} < \alpha \le \beta < \frac{2N}{N-2}$ such that

$$\alpha G(s) \le g(s)s \le \beta G(s) \text{ with } G(s) = \int_0^s g(t)dt.$$

$(G3)$ The functional defined by $\widetilde{G}(s) := \frac{1}{2} g(s)s - G(s)$ is of class C^1 and

$$\widetilde{G}'(s)s \ge \alpha \widetilde{G}(s), \forall s \in \mathbb{R},$$

where α is given by $(G2)$.

Note that, $(G3)$ plays a crucial role in the uniqueness of t_u(see [14] or [21, Lemma 2.9]). However, we do not need this condition, since we directly perform scaling and complex calculations on energy functionals. Recently, Bartsch et al. in [4] considered following Schrödinger equations with potentials and inhomogeneous nonlinearities on large convex domains

$$\begin{cases} -\Delta u + V(x)u + \lambda u = |u|^{q-2}u + \beta |u|^{p-2}u, \\ \int |u|^2 dx = \Theta, \end{cases}$$

they developed a robust method to study the existence of normalized solutions of nonlinear Schrödinger equations with potential. Under the stimulation of [4], our goal is to generalize its conclusion to general nonlinear terms and the Sobolev critical case.

In order to state our main results, we introduce some notations. Set $s_+ = \max\{s, 0\}$, $s_- = \min\{s, 0\}$ for $s \in \mathbb{R}$. The Aubin–Talenti constant [3] is denoted by S, that is, S is the best constant in the Sobolev embedding $\mathcal{D}^{1,2}(\mathbb{R}^N) \hookrightarrow L^{2^*}(\mathbb{R}^N)$, where $\mathcal{D}^{1,2}(\mathbb{R}^N)$ denotes the completion of $C_c^\infty(\mathbb{R}^N)$ with respect to the norm $\|u\|_{\mathcal{D}^{1,2}} := \|\nabla u\|_2$. It is well known [28] that the optimal constant is achieved by (any multiple of)

$$U_{\varepsilon,y}(x) = [N(N-2)]^{\frac{N-2}{4}} \left(\frac{\varepsilon}{\varepsilon^2 + |x-y|^2} \right)^{\frac{N-2}{2}}, \qquad \varepsilon > 0,\ y \in \mathbb{R}^N, \tag{1.3}$$

which are the only positive classical solutions to the critical Lane–Emden equation

$$-\Delta w = w^{2^*-1}, \qquad w > 0 \text{ in } \mathbb{R}^N.$$

Let $C_{N,s}$ be the best constant in the Gagliardo–Nirenberg inequality

$$\|u\|_s^s \le C_{N,s} \|u\|_2^{\frac{2s-N(s-2)}{2}} \|\nabla u\|_2^{\frac{N(s-2)}{2}}, \qquad 2 < s < 2^*.$$

For some results, we expect that V is C^1 and consider the function

$$\widetilde{V} : \mathbb{R}^N \to \mathbb{R}, \qquad \widetilde{V}(x) = \nabla V(x) \cdot x.$$

For $\Omega \subset \mathbb{R}^N$ and $r > 0$, let

$$\Omega_r = \left\{ rx \in \mathbb{R}^N : x \in \Omega \right\}$$

and

$$S_{r,\Theta} := S_\Theta \cap H_0^1(\Omega_r) = \left\{ u \in H_0^1(\Omega_r) : \|u\|^2_{L^2(\Omega_r)} = \Theta \right\}.$$

From now on we assume that $\Omega \subset \mathbb{R}^N$ is a bounded smooth convex domain with $0 \in \Omega$.

Our assumptions on V are:

(V_0) $V \in C^1(\mathbb{R}^N) \cap L^{\frac{N}{2}}(\mathbb{R}^N)$ is bounded and $\|V_-\|_{\frac{N}{2}} < S$.

$(\widetilde{V_0})$ $V \in C^1(\mathbb{R}^N) \cap L^{\frac{N}{2}}(\mathbb{R}^N)$ is bounded and $\|V_-\|_{\frac{N}{2}} < \frac{N(q-p_2)-2[N(p_2-2)-4]}{N(q-p_2)} S$.

$(\widehat{V_0})$ $V \in C^1(\mathbb{R}^N) \cap L^{\frac{N}{2}}(\mathbb{R}^N)$ is bounded and $\|V_-\|_{\frac{N}{2}} < \left(1 - \frac{NC_N\Theta^{\frac{2}{N}}}{N+2}\right) S$.

(V_1) V is of class $C^1, \lim_{|x|\to\infty} V(x) = 0$, and there exists $\rho \in (0,1)$ such that

$$\liminf_{|x|\to\infty} \inf_{y\in B(x,\rho|x|)} (x \cdot \nabla V(y))e^{\tau|x|} > 0 \quad \text{for any } \tau > 0.$$

Remark 1.1. In order to obtain the existence of normalized solutions in $\mathbb{R}^N$ by taking $\Omega = B_1$, the unit ball centered at the origin in $\mathbb{R}^N$, and analyzing the compactness of the solutions $u_{r,\Theta}$ established in Theorems 1.3, 1.4 and 1.5 as r tends to infinity, we require the condition (V_1).

Now, we make the following assumptions on the nonlinearity f:

(f_1) $f \in C^1(\mathbb{R}, \mathbb{R})$ and f is odd.

(f_2) There exists some $(p_1, p_2) \in \mathbb{R}^2_+$ satisfying $2 < p_2 \le p_1 < 2 + \frac{4}{N}$ such that

$$p_2F(\tau) \le f(\tau)\tau \le p_1F(\tau) \text{ with } F(\tau) = \int_0^\tau f(t)dt.$$

$(\widetilde{f_2})$ There exists some $(p_1, p_2) \in \mathbb{R}^2_+$ satisfying $2 < p_2 < p_1 = 2 + \frac{4}{N}$ such that

$$p_2F(\tau) \le f(\tau)\tau \le p_1F(\tau).$$

Remark 1.2. If $f(u) = \sum_{i=1}^m a_i|u|^{\sigma_i-2}u$, where $a_i > 0$ and $2 < \sigma_i < 2 + \frac{4}{N}$, then the assumption (f_1) can be weakened to $f \in C(\mathbb{R}, \mathbb{R})$ and f is odd. In order to ensure the boundedness of Palais–Smale sequence under constraint conditions in Lemma 3.3, we need to slightly strengthen the conditions for the nonlinear term f, that is, $f \in C^1(\mathbb{R}, \mathbb{R})$.

The main results of this paper are as follows. Firstly, we consider the Sobolev subcritical case, that is, $2 + \frac{4}{N} < q < 2^*$.

Theorem 1.3 (case $\beta \le 0$)**.** *Assume V satisfies (V_0), is of class C^1 and $\widetilde{V}$ is bounded, f satisfies (f_1)–(f_2). There hold:*

(i) For every $\Theta > 0$, there exists $r_\Theta > 0$ such that (1.1) on Ω_r with $r > r_\Theta$ has a mountain pass type solution $(\lambda_{r,\Theta}, u_{r,\Theta})$ with $u_{r,\Theta} > 0$ in Ω_r and positive energy $I_r(u_{r,\Theta}) > 0$. Moreover, there exists $C_\Theta > 0$ such that

$$\limsup_{r\to\infty} \max_{x\in\Omega_r} u_{r,\Theta}(x) < C_\Theta.$$

(ii) If in addition $\|\widetilde{V}_+\|_{\frac{N}{2}} < 2S$, then there exists $\widetilde{\Theta} > 0$ such that

$$\liminf_{r\to\infty} \lambda_{r,\Theta} > 0 \quad \textit{for any } 0 < \Theta < \widetilde{\Theta}.$$

Theorem 1.4 (case $\beta > 0$)**.** *Assume V satisfies (V_0), f satisfies (f_1)–(f_2) and set*

$$\Theta_V = \left[\frac{1 - \|V_-\|_{\frac{N}{2}} S^{-1}}{2N(q-p_1)}\right]^{\frac{N}{2}} \left[\frac{q(4-N(p_1-2))}{C_{N,q}}\right]^{\frac{4-N(p_1-2)}{2(q-p_1)}} \left[\frac{N(q-2)-4}{\alpha\beta C_{N,p_1}}\right]^{\frac{N(q-2)-4}{2(q-p_1)}}.$$

Then the following hold for $0 < \Theta < \Theta_V$:

(i) There exists $r_\Theta > 0$ such that (1.1) on Ω_r with $r > r_\Theta$ has a local minimum type solution $(\lambda_{r,\Theta}, u_{r,\Theta})$ with $u_{r,\Theta} > 0$ in Ω_r and negative energy $I_r(u_{r,\Theta}) < 0$.

(ii) There exists $C_\Theta > 0$ such that

$$\limsup_{r\to\infty} \max_{x\in\Omega_r} u_{r,\Theta}(x) < C_\Theta, \qquad \liminf_{r\to\infty} \lambda_{r,\Theta} > 0.$$

Theorem 1.5 (case $\beta > 0$)**.** *Assume V satisfies (V_0), is of class C^1 and $\widetilde{V}$ is bounded, f satisfies (f_1)–(f_2). Set*

$$\widetilde{\Theta}_V = \frac{1}{2}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)^{\frac{N}{2}} \left(\frac{C_{N,q}}{q} A_{p_1,q} + \frac{C_{N,q}}{q}\right)^{-\frac{N}{2}} \left(\frac{\alpha\beta q C_{N,p_1}}{C_{N,q} A_{p_1,q}}\right)^{\frac{N(q-2)-4}{2N(q-p_1)}},$$

where

$$A_{p_1,q} = \frac{(q-2)(N(q-2)-4)}{(p_1-2)(4-N(p_1-2))}.$$

Then the following hold for $0 < \Theta < \widetilde{\Theta}_V$:

(i) There exists $\widetilde{r}_\Theta > 0$ such that (1.1) in Ω_r admits for $r > r_\Theta$ a mountain pass type solution $(\lambda_{r,\Theta}, u_{r,\Theta})$ with $u_{r,\Theta} > 0$ in Ω_r and positive energy $I_r(u_{r,\Theta}) > 0$. Moreover, there exists $C_\Theta > 0$ such that

$$\limsup_{r\to\infty} \max_{x\in\Omega_r} u_{r,\Theta}(x) < C_\Theta.$$

(ii) There exists $0 < \bar{\Theta} \le \widetilde{\Theta}_V$ such that

$$\liminf_{r\to\infty} \lambda_{r,\Theta} > 0 \quad \text{for any } 0 < \Theta \le \bar{\Theta}.$$

If $\Omega = \mathbb{R}^N$, (V_1) is significant for obtaining the following results.

Theorem 1.6 (case $\beta > 0$)**.** *Assume V satisfies (V_0)–(V_1). Then problem (1.1) with $\Omega = \mathbb{R}^N$ admits for any $0 < \Theta < \Theta_V$, where Θ_V is as in Theorem 1.4, a solution $(\lambda_\Theta, u_\Theta)$ with $u_\Theta > 0, \lambda_\Theta > 0$, and $I(u_\Theta) < 0$.*

Theorem 1.7 (case $\beta > 0$)**.** *Assume V satisfies (V_0)–(V_1). Then (1.1) with $\Omega = \mathbb{R}^N$ admits for $0 < \Theta < \bar{\Theta}, \bar{\Theta} > 0$ as in Theorem 1.5 (ii), a solution $(\lambda_\Theta, u_\Theta)$ with $u_\Theta > 0, \lambda_\Theta > 0$, and $I(u_\Theta) > 0$. Moreover, $\lim_{\Theta\to 0} I(u_\Theta) = \infty$.*

Theorem 1.8 (case $\beta \le 0$)**.** *Assume V satisfies (V_0)–(V_1), and $\|\widetilde{V}_+\|_{\frac{N}{2}} < 2S$. Then problem (1.1) with $\Omega = \mathbb{R}^N$ admits for $0 < \Theta < \widetilde{\Theta}, \widetilde{\Theta} > 0$ as in Theorem 1.3, a solution $(\lambda_\Theta, u_\Theta)$ with $u_\Theta > 0, \lambda_\Theta > 0$, and $I(u_\Theta) > 0$. Moreover, $\lim_{\Theta\to 0} I(u_\Theta) = \infty$.*

For the Sobolev critical case, that is $q = 2^*$, we have the following results.

Theorem 1.9 (case $\beta > 0$). *Assume V satisfies (V_0), f satisfies (f_1)–(f_2). Set*

$$\Theta_V = \left(\frac{1}{N\alpha\beta C_{N,p_1}}\right)^{\frac{4}{2p_1-N(p_1-2)}} \left(1-\|V_-\|_{\frac{N}{2}} S^{-1}\right)^{\frac{N}{2}} S^{\frac{N}{2}\cdot\frac{4-N(p_1-2)}{2p_1-N(p_1-2)}}.$$

Then the following hold for $0 < \Theta < \Theta_V$:

(i) There exists $r_\Theta > 0$ such that (6.2) on Ω_r with $r > r_\Theta$ has a local minimum type solution $(\lambda_{r,\Theta}, u_{r,\Theta})$ with $u_{r,\Theta} > 0$ in Ω_r and negative energy $\mathcal{I}_r(u_{r,\Theta}) < 0$.

(ii) There exists $C_\Theta > 0$ such that

$$\limsup_{r\to\infty} \max_{x\in\Omega_r} u_{r,\Theta}(x) < C_\Theta, \qquad \liminf_{r\to\infty} \lambda_{r,\Theta} > 0.$$

Theorem 1.10 (case $\beta \le 0$). *Assume V satisfies (V_0), is of class C^1 and $\widetilde{V}$ is bounded, f satisfies (f_1)–(f_2). There hold:*

(i) There exists $r_\Theta > 0$ such that (7.1) on Ω_r with $r > r_\Theta$ has a mountain pass type solution $(\lambda_{r,\Theta}, u_{r,\Theta})$ with $u_{r,\Theta} \ge 0$ in Ω_r and positive energy $\mathcal{I}_r(u_{r,\Theta}) > 0$.

(ii) There exists $C_\Theta > 0$ such that

$$\limsup_{r\to\infty} \max_{x\in\Omega_r} u_{r,\Theta}(x) < C_\Theta.$$

Theorem 1.11 (case $\beta > 0$). *Assume V satisfies (V_0), is of class C^1 and $\widetilde{V}$ is bounded, f satisfies (f_1)–(f_2). Set*

$$\widetilde{\Theta}_V = \left(\frac{\alpha\beta C_{N,p_1} S^{\frac{2^*}{2}}}{A_{p_1}}\right)^{-\frac{4}{2p_1-N(p_1-2)}} \left[\frac{S^{\frac{2^*}{2}}}{2\cdot 2^*}\left(1-\|V_-\|_{\frac{N}{2}} S^{-1}\right)(2^* A_{p_1}+1)\right]^{\frac{2[2\cdot 2^*-N(p_1-2)]}{(2^*-2)[2p_1-N(p_1-2)]}}$$

where

$$A_{p_1} = \frac{4(2^*-2)}{N(p_1-2)(4-N(p_1-2))}.$$

Then the following hold for $0 < \Theta < \widetilde{\Theta}_V$:

(i) There exists $\widetilde{r}_\Theta > 0$ such that (8.1) in Ω_r admits for $r > r_\Theta$ a mountain pass type solution $(\lambda_{r,\Theta}, u_{r,\Theta})$ with $u_{r,\Theta} \ge 0$ in Ω_r and positive energy $\mathcal{I}_r(u_{r,\Theta}) > 0$.

(ii) There exists $C_\Theta > 0$ such that

$$\limsup_{r\to\infty} \max_{x\in\Omega_r} u_{r,\Theta}(x) < C_\Theta.$$

For the L^2-critical case, that is $p_1 = 2 + \frac{4}{N}$ or $q = 2 + \frac{4}{N}$, we have the following results.

Theorem 1.12 (case $\beta > 0$ and $p_1 = 2 + \frac{4}{N}$). *Assume V satisfies $(\widetilde{V_0})$, f satisfies (f_1) and $(\widetilde{f_2})$. Set*

$$\widetilde{\Theta}_V = \left[\frac{N(q-p_2)-4}{N\alpha\beta(q-p_2)C_N}\right]^{\frac{N}{2}}.$$

Then the following hold for $0 < \Theta < \widetilde{\Theta}_V$:

(i) *There exists* $\tilde{r}_\Theta > 0$ *such that* (1.1) *in* Ω_r *admits for* $r > r_\Theta$ *a mountain pass type solution* $(\lambda_{r,\Theta}, u_{r,\Theta})$ *with* $u_{r,\Theta} > 0$ *in* Ω_r *and positive energy* $I_r(u_{r,\Theta}) > 0$. *Moreover, there exists* $C_\Theta > 0$ *such that*

$$\limsup_{r\to\infty} \max_{x\in\Omega_r} u_{r,\Theta}(x) < C_\Theta.$$

(ii) *There exists* $0 < \bar{\Theta} \le \widetilde{\Theta}_V$ *such that*

$$\liminf_{r\to\infty} \lambda_{r,\Theta} > 0 \quad \textit{for any } 0 < \Theta \le \bar{\Theta}.$$

Theorem 1.13 (case $\beta \le 0$ and $p_1 = 2 + \frac{4}{N}$)**.** *Assume* V *satisfies* (V_0), *is of class* C^1 *and* $\widetilde{V}$ *is bounded,* f *satisfies* (f_1) *and* $(\widetilde{f_2})$. *Set*

$$\widehat{\Theta}_V = \left[\frac{(N-2)q - 2N}{2N\alpha\beta(q-p_2)C_N}\right]^{\frac{N}{2}}.$$

Then the following hold for $0 < \Theta < \widehat{\Theta}_V$:

(i) *There exists* $r_\Theta > 0$ *such that* (1.1) *on* Ω_r *with* $r > r_\Theta$ *has a mountain pass type solution* $(\lambda_{r,\Theta}, u_{r,\Theta})$ *with* $u_{r,\Theta} > 0$ *in* Ω_r *and positive energy* $I_r(u_{r,\Theta}) > 0$. *Moreover, there exists* $C_\Theta > 0$ *such that*

$$\limsup_{r\to\infty} \max_{x\in\Omega_r} u_{r,\Theta}(x) < C_\Theta.$$

(ii) *If in addition* $\|\widetilde{V}_+\|_{\frac{N}{2}} < 2S$, *then there exists* $\widetilde{\Theta} > 0$ *such that*

$$\liminf_{r\to\infty} \lambda_{r,\Theta} > 0 \quad \textit{for any } 0 < \Theta < \widetilde{\Theta}.$$

Theorem 1.14. *(**case** $\beta > 0$ **and** $q = 2 + \frac{4}{N}$) Assume* V *satisfies* $(\widehat{V_0})$, f *satisfies* (f_1)–(f_2) *and set*

$$\Theta_V = \left(\frac{N+2}{NC_N}\right)^{\frac{N}{2}}.$$

Then the following hold for $0 < \Theta < \Theta_V$:

(i) *There exists* $r_\Theta > 0$ *such that* (1.1) *on* Ω_r *with* $r > r_\Theta$ *has a global minimum type solution* $(\lambda_{r,\Theta}, u_{r,\Theta})$ *with* $u_{r,\Theta} > 0$ *in* Ω_r *and negative energy* $I_r(u_{r,\Theta}) < 0$.

(ii) *There exists* $C_\Theta > 0$ *such that*

$$\limsup_{r\to\infty} \max_{x\in\Omega_r} u_{r,\Theta}(x) < C_\Theta, \qquad \liminf_{r\to\infty} \lambda_{r,\Theta} > 0.$$

Remark 1.15.

(i) Theorems 1.3–1.11 are valid if $2 = p_2 < p_1 < 2 + \frac{4}{N}$ in (f_2). Moreover, the proof of Theorems 1.6–1.8 is very similar to [4], so we omit it in this paper.

(ii) Our conclusion also applies to $p_1 = p_2 = 2 + \frac{4}{N}$ if $2 + \frac{4}{N} < q < 2^*$, such as $f(u) = |u|^{\frac{4}{N}} u$. Therefore, our results cover certain conclusions in [26].

Remark 1.16. Theorems 1.4 and 1.9 (resp. Theorems 1.5 and 1.11) both require some limitations on Θ_V (resp. $\widetilde{\Theta}_V$), although their values are different, they all stem from changes in the geometric structure of the energy functional. In addition, there are still some unknown results for the Sobolev critical case, that is, $\liminf_{r\to\infty}\lambda_{r,\Theta} > 0$ may not necessarily hold when $\beta > 0$ or $\beta \leq 0$. In fact, the methods and techniques in Theorem 1.4 (or Theorem 1.5) cannot be applied to the Sobolev critical case since $\frac{(N-2)q-2N}{2Nq} = 0$, thus $\lambda_\Theta > 0$ cannot be obtained $0 < \Theta \leq \bar{\Theta}$.

Remark 1.17. In this paper, whether in subcritical or critical situations, the monotonicity trick in [20] is one of the keys to get the conclusion. Proposition 3.2 does not ensure the existence of a mountain pass solution for the original problem obtained when $s = 1$. However, it gives the existence of a sequence $s_n \to 1^-$, with a corresponding sequence of mountain pass critical points u_{r,s_n} of I_{r,s_n}, constrained on $S_{r,\Theta}$. We aim to show that u_{r,s_n} strongly converges to a constrained critical point of I_r. For this purpose, it is sufficient to prove that u_{r,s_n} is bounded in $H_0^1(\Omega_r)$, thanks to Proposition 3.1 in [15].

The structure of this paper is arranged as follows. In section 2, we provide some ideas in the proof of main theorems. In section 3, we obtain the mountain pass type positive solution in the case $\beta \leq 0$ and have completed the proof of Theorem 1.3. If $\beta > 0$, there are two situations, that is, Theorems 1.4 and 1.5. We get the two results in sections 3 and 4 by using different geometric analysis. After that, we consider the Sobolev critical case. Finally, we consider the L^2-critical case and give some comments.

2 Preliminary

Consider the problem

$$\begin{cases} -\Delta u + V(x)u + \lambda u = |u|^{q-2}u + \beta f(u), & x \in \Omega_r, \\ \int_{\Omega_r} |u|^2 dx = \Theta, u \in H_0^1(\Omega_r), & x \in \Omega_r, \end{cases} \tag{2.1}$$

where $N \geq 3$, $2 + \frac{4}{N} \leq q \leq 2^* = \frac{2N}{N-2}$, the mass $\Theta > 0$ and the parameter $\beta \in \mathbb{R}$ are prescribed. The frequency λ is unknown and to be determined. The energy functional $I_r : H_0^1(\Omega_r) \to \mathbb{R}$ is defined by

$$I_r(u) = \frac{1}{2}\int_{\Omega_r} |\nabla u|^2 dx + \frac{1}{2}\int_{\Omega_r} V(x)u^2 dx - \frac{1}{q}\int_{\Omega_r} |u|^q dx - \beta \int_{\Omega_r} F(u)dx \tag{2.2}$$

and the mass constraint manifold is defined by

$$S_{r,\Theta} = \left\{ u \in H_0^1(\Omega_r) : \|u\|_2^2 = \Theta \right\}. \tag{2.3}$$

If $\Omega = \mathbb{R}^N$, the energy functional $I : H_0^1(\Omega_r) \to \mathbb{R}$ is defined by

$$I(u) = \frac{1}{2}\int_{\mathbb{R}^N} |\nabla u|^2 dx + \frac{1}{2}\int_{\mathbb{R}^N} V(x)u^2 dx - \frac{1}{q}\int_{\mathbb{R}^N} |u|^q dx - \beta \int_{\mathbb{R}^N} F(u)dx \tag{2.4}$$

and the mass constraint manifold is defined by

$$S_\Theta = \left\{ u \in H_0^1(\mathbb{R}^N) : \|u\|_2^2 = \Theta \right\}. \tag{2.5}$$

The proof idea of Theorem 1.3 is as follows. In order to find a mountain pass type solution $(\lambda_{r,\Theta}, u_{r,\Theta})$, we first need to analyze the geometric structure of the energy functional corresponding to the equation (3.1). In Lemma 3.1, we perform precise geometric analysis on the energy functional corresponding to (3.1) and know that the energy functional $I_{r,s}$ has a global maximum. Next, we obtain the bounded Palais–Smale sequence by using [11, Theorem 1] and get a solution $(\lambda_{r,s}, u_{r,s})$ for (3.1). Finally, we consider Lagrange multiplier and establish an a priori estimate for the solutions of (1.1). Theorem 1.4 is relatively simple because the energy functional has a local minimum, which can be proved using the method of constrained minimization. The proof of Theorem 1.5 is similar to Theorem 1.3, but the geometric structures of the two cases are significantly different and require refined estimate of energy.

Note that, there are some differences between the proof of Lemma 5.3 and Lemma 3.4, and we cannot directly use the method of Lemma 3.4, even if q can be reduced to p_2 according to condition (f_2) and $p_2 < 2 + \frac{4}{N} < q < 2^*$. More precisely, it then follows from $\beta > 0$ and (f_2) that

$$\begin{aligned}
&\frac{1}{N}\int_{\Omega_r}|\nabla u|^2dx - \frac{1}{2N}\int_{\partial\Omega_r}|\nabla u|^2(x\cdot\mathbf{n})d\sigma - \frac{1}{2N}\int_{\Omega_r}(\nabla V\cdot x)u^2dx \\
&\quad= \frac{(q-2)s}{2q}\int_{\Omega_r}|u|^q dx + s\int_{\Omega_r}(\frac{\beta}{2}f(u)u - \beta F(u))dx \\
&\quad\geq \frac{p_2-2}{2}\left(\frac{1}{2}\int_{\Omega_r}|\nabla u|^2dx + \frac{1}{2}\int_{\Omega_r}Vu^2dx - m_{r,s}(\Theta)\right).
\end{aligned}$$

Consequently, we have

$$\begin{aligned}
\frac{p_2-2}{2}m_{r,s}(\Theta) &\geq \frac{p_2-2}{2}\left(\frac{1}{2}\int_{\Omega_r}|\nabla u|^2dx + \frac{1}{2}\int_{\Omega_r}Vu^2dx\right) - \frac{1}{N}\int_{\Omega_r}|\nabla u|^2dx \\
&\quad + \frac{1}{2N}\int_{\partial\Omega_r}|\nabla u|^2(x\cdot\mathbf{n})d\sigma + \frac{1}{2N}\int_{\Omega_r}(\nabla V\cdot x)u^2dx \\
&\geq \frac{N(p_2-2)-4}{4N}\int_{\Omega_r}|\nabla u|^2dx - \Theta\left(\frac{1}{2N}\|\nabla V\cdot x\|_\infty + \frac{p_2-2}{4}\|V\|_\infty\right).
\end{aligned}$$

However, this method is useless because $\frac{N(p_2-2)-4}{4N} < 0$, we cannot obtain that $\int_{\Omega_r}|\nabla u|^2dx$ is uniformly bounded in s and r.

3 Proof of Theorem 1.3

In this section, we assume $\beta \leq 0$ and the assumptions of Theorem 1.3 hold. In order to obtain a bounded Palais–Smale sequence, we will use the monotonicity trick inspired by [20]. For $\frac{1}{2} \leq s \leq 1$, we define the functional $I_{r,s}: S_{r,\Theta} \to \mathbb{R}$ by

$$I_{r,s}(u) = \frac{1}{2}\int_{\Omega_r}|\nabla u|^2dx + \frac{1}{2}\int_{\Omega_r}Vu^2dx - \frac{s}{q}\int_{\Omega_r}|u|^q dx - \beta\int_{\Omega_r}F(u)dx. \tag{3.1}$$

Note that if $u \in S_{r,\Theta}$ is a critical point of $I_{r,s}$, then there exists $\lambda \in \mathbb{R}$ such that (λ, u) is a solution of the equation

$$\begin{cases} -\Delta u + Vu + \lambda u = s|u|^{q-2}u + \beta f(u), & x \in \Omega_r, \\ \int_{\Omega_r}|u|^2dx = \Theta, u \in H_0^1(\Omega_r), & x \in \Omega_r. \end{cases} \tag{3.2}$$

Lemma 3.1. *For any $\Theta > 0$, there exist $r_\Theta > 0$ and $u^0, u^1 \in S_{r_\Theta,\Theta}$ such that*

(i) $I_{r,s}(u^1) \le 0$ *for any* $r > r_\Theta$ *and* $s \in \left[\frac{1}{2}, 1\right]$,

$$\left\|\nabla u^0\right\|_2^2 < \left[\frac{2q}{N(q-2)C_{N,q}}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)\Theta^{\frac{q(N-2)-2N}{4}}\right]^{\frac{4}{N(q-2)-4}} < \left\|\nabla u^1\right\|_2^2$$

and

$$I_{r,s}\left(u^0\right) < \frac{(N(q-2)-4)\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)}{2N(q-2)}\left[\frac{2q\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)}{N(q-2)C_{N,q}\Theta^{\frac{2q-N(q-2)}{4}}}\right]^{\frac{4}{N(q-2)-4}}.$$

(ii) If $u \in S_{r,\Theta}$ *satisfies*

$$\|\nabla u\|_2^2 = \left[\frac{2q}{N(q-2)C_{N,q}}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)\Theta^{\frac{q(N-2)-2N}{4}}\right]^{\frac{4}{N(q-2)-4}},$$

then there holds

$$I_{r,s}(u) \ge \frac{(N(q-2)-4)\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)}{2N(q-2)}\left[\frac{2q\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)}{N(q-2)C_{N,q}\Theta^{\frac{2q-N(q-2)}{4}}}\right]^{\frac{4}{N(q-2)-4}}.$$

(iii) Set

$$m_{r,s}(\Theta) = \inf_{\gamma\in\Gamma_{r,\Theta}} \sup_{t\in[0,1]} I_{r,s}(\gamma(t))$$

with

$$\Gamma_{r,\Theta} = \left\{\gamma \in C\left([0,1], S_{r,\Theta}\right) : \gamma(0) = u^0, \gamma(1) = u^1\right\}.$$

Then

$$\frac{(N(q-2)-4)\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)}{2N(q-2)}\left[\frac{2q\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)}{N(q-2)C_{N,q}\Theta^{\frac{2q-N(q-2)}{4}}}\right]^{\frac{4}{N(q-2)-4}} \le m_{r,s}(\Theta) \le h(T_\Theta),$$

where $h(T_\Theta) = \max_{t\in\mathbb{R}^+} h(t)$, *the function* $h : \mathbb{R}^+ \to \mathbb{R}$ *being defined by*

$$h(t) = \frac{1}{2}\left(1 + \|V\|_{\frac{N}{2}} S^{-1}\right)t^2\theta\Theta - \alpha\beta C_{N,p_1}\Theta^{\frac{p_1}{2}}\theta^{\frac{N(p_1-2)}{4}}t^{\frac{N(p_1-2)}{2}} - \frac{1}{2q}\Theta^{\frac{q}{2}}|\Omega|^{\frac{2-q}{2}}t^{\frac{N(q-2)}{2}}.$$

Here θ is the principal eigenvalue of $-\Delta$ with Dirichlet boundary conditions in Ω, and $|\Omega|$ is the volume of Ω.

Proof. (i) Clearly, the set $S_{r,\Theta}$ is path connected. Since $v_1 \in S_{1,\Theta}$ be the positive eigenfunction associated to θ and note that θ is the principal eigenvalue of $-\Delta$, then

$$\int_\Omega |\nabla v_1|^2\, dx = \theta\Theta. \tag{3.3}$$

By the Hölder inequality, we know that

$$\Theta = \int_\Omega |v_1(x)|^2 dx \le \left(\int_\Omega |v_1(x)|^q dx\right)^{\frac{2}{q}} \cdot |\Omega|^{\frac{q-2}{q}},$$

which implies

$$\int_{\Omega} |v_1(x)|^q dx \geq \Theta^{\frac{q}{2}} \cdot |\Omega|^{\frac{2-q}{2}}. \tag{3.4}$$

According to (f_2), there exists a constant $\alpha > 0$ such that

$$F(\tau) \leq \alpha \tau^{p_1}. \tag{3.5}$$

For $x \in \Omega_{\frac{1}{t}}$ and $t > 0$, define $v_t(x) := t^{\frac{N}{2}} v_1(tx)$. Using (3.3), (3.4), (3.5) and $\frac{1}{2} \leq s \leq 1$, it holds

$$\begin{aligned}
I_{\frac{1}{t},s}(v_t) &\leq \frac{1}{2}\int_{\Omega_r} |\nabla v_t|^2 dx + \frac{1}{2}\int_{\Omega_r} V v_t^2 dx - \frac{1}{2q}\int_{\Omega_r} |v_t|^q dx - \alpha\beta \int_{\Omega_r} |v_t|^{p_1} dx \\
&\leq \frac{1}{2}\left(1 + \|V\|_{\frac{N}{2}} S^{-1}\right) \int_{\Omega_r} |\nabla v_t|^2 dx - \alpha\beta C_{N,p_1} \Theta^{\frac{2p_1 - N(p_1-2)}{4}} \left(\int_{\Omega_r} |\nabla v_t|^2 dx\right)^{\frac{N(p_1-2)}{4}} \\
&\quad - \frac{1}{2q}\int_{\Omega_r} |v_t|^q dx \\
&\leq \frac{1}{2}\left(1 + \|V\|_{\frac{N}{2}} S^{-1}\right) t^2 \int_{\Omega} |\nabla v_1|^2 dx - \alpha\beta C_{N,p_1} \Theta^{\frac{2p_1 - N(p_1-2)}{4}} \left(t^2 \int_{\Omega} |\nabla v_1|^2 dx\right)^{\frac{N(p_1-2)}{4}} \\
&\quad - \frac{1}{2q} t^{\frac{N(q-2)}{2}} \int_{\Omega} |v_1|^q dx \\
&\leq \frac{1}{2}\left(1 + \|V\|_{\frac{N}{2}} S^{-1}\right) t^2 \theta \Theta - \alpha\beta C_{N,p_1} \Theta^{\frac{p_1}{2}} \theta^{\frac{N(p_1-2)}{4}} t^{\frac{N(p_1-2)}{2}} - \frac{1}{2q} t^{\frac{N(q-2)}{2}} \Theta^{\frac{q}{2}} \cdot |\Omega|^{\frac{2-q}{2}} \\
&=: h(t).
\end{aligned} \tag{3.6}$$

Note that since $2 < p_1 < 2 + \frac{4}{N} < q < 2^*$ and $\beta \leq 0$ there exist $0 < T_\Theta < t_0$ such that $h(t_0) = 0, h(t) < 0$ for any $t > t_0, h(t) > 0$ for any $0 < t < t_0$ and $h(T_\Theta) = \max_{t \in \mathbb{R}^+} h(t)$. As a consequence, there holds

$$I_{r,s}(v_{t_0}) = I_{\frac{1}{t_0},s}(v_{t_0}) \leq h(t_0) = 0 \tag{3.7}$$

for any $r \geq \frac{1}{t_0}$ and $s \in \left[\frac{1}{2}, 1\right]$. Moreover, there exists $0 < t_1 < T_\Theta$ such that

$$h(t) < \frac{(N(q-2)-4)\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)}{2N(q-2)} \left[\frac{2q\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)}{N(q-2) C_{N,q} \Theta^{\frac{2q-N(q-2)}{4}}}\right]^{\frac{4}{N(q-2)-4}} \tag{3.8}$$

for $t \in [0, t_1]$. On the other hand, it follows from the Gagliardo–Nirenberg inequality and the Hölder inequality that

$$\begin{aligned}
I_{r,s}(u) &\geq \frac{1}{2}\int_{\Omega_r} |\nabla u|^2 dx + \frac{1}{2}\int_{\Omega_r} V u^2 dx - \frac{1}{q}\int_{\Omega_r} |u|^q dx \\
&\geq \frac{\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)}{2} \int_{\Omega_r} |\nabla u|^2 dx - \frac{C_{N,q} \Theta^{\frac{2q-N(q-2)}{4}}}{q} \left(\int_{\Omega_r} |\nabla u|^2 dx\right)^{\frac{N(q-2)}{4}}.
\end{aligned} \tag{3.9}$$

Define

$$g(t) := \frac{1}{2}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right) t - \frac{C_{N,q} \Theta^{\frac{2q-N(q-2)}{4}}}{q} t^{\frac{N(q-2)}{4}}$$

and

$$\widetilde{t} = \left[\frac{2q}{N(q-2) C_{N,q}} \left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right) \Theta^{\frac{q(N-2)-2N}{4}}\right]^{\frac{4}{N(q-2)-4}},$$

it is easy to see that g is increasing on $(0,\widetilde{t})$ and decreasing on $(\widetilde{t},\infty)$, and

$$g(\widetilde{t}) = \frac{(N(q-2)-4)\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}\right)}{2N(q-2)}\left[\frac{2q\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}\right)}{N(q-2)C_{N,q}\Theta^{\frac{2q-N(q-2)}{4}}}\right]^{\frac{4}{N(q-2)-4}}.$$

For $r \geq \widetilde{r}_\Theta := \max\left\{\frac{1}{t_1}, \sqrt{\frac{2\theta\Theta}{\widetilde{t}}}\right\}$, we have $v_{\frac{1}{\widetilde{r}_\Theta}} \in S_{r,\Theta}$ and

$$\begin{aligned}\|\nabla v_{\frac{1}{\widetilde{r}_\Theta}}\|_2^2 &= \left(\frac{1}{\widetilde{r}_\Theta}\right)^2 \|\nabla v_1\|_2^2 \\ &< \left[\frac{2q}{N(q-2)C_{N,q}}\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}\right)\Theta^{\frac{q(N-2)-2N}{4}}\right]^{\frac{4}{N(q-2)-4}}. \end{aligned} \tag{3.10}$$

Moreover, there holds

$$I_{\widetilde{r}_\Theta,s}\left(v_{\frac{1}{\widetilde{r}_\Theta}}\right) \leq h\left(\frac{1}{\widetilde{r}_\Theta}\right) \leq h\left(t_1\right). \tag{3.11}$$

Setting $u^0 = v_{\frac{1}{\widetilde{r}_\Theta}}, u^1 = v_{t_0}$ and

$$r_\Theta = \max\left\{\frac{1}{t_0}, \widetilde{r}_\Theta\right\}. \tag{3.12}$$

Combining (3.7), (3.8), (3.10) and (3.11), (i) holds.

(ii) By (3.9) and a direct calculation, (ii) holds.

(iii) Since $I_{r,s}\left(u^1\right) \leq 0$ for any $\gamma \in \Gamma_{r,\Theta}$, we have

$$\|\nabla\gamma(0)\|_2^2 < \tilde{t} < \|\nabla\gamma(1)\|_2^2.$$

It then follows from (3.9) that

$$\begin{aligned}&\max_{t\in[0,1]} I_{r,s}(\gamma(t)) \geq g(\widetilde{t}) \\ &= \frac{(N(q-2)-4)\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}\right)}{2N(q-2)}\left[\frac{2q\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}\right)}{N(q-2)C_{N,q}\Theta^{\frac{2q-N(q-2)}{4}}}\right]^{\frac{4}{N(q-2)-4}}\end{aligned}$$

for any $\gamma \in \Gamma_{r,\Theta}$, hence the first inequality in (iii) holds. Now we define a path $\gamma \in \Gamma_{r,\Theta}$ by

$$\gamma(\tau)(x) = \left(\tau t_0 + (1-\tau)\frac{1}{\widetilde{r}_\Theta}\right)^{\frac{N}{2}} v_1\left(\left(\tau t_0 + (1-\tau)\frac{1}{\widetilde{r}_\Theta}\right)x\right)$$

for $\tau \in [0,1]$ and $x \in \Omega_r$. Then by (3.6) we have $m_{r,s}(\Theta) \leq h(T_\Theta)$, where $h(T_\Theta) = \max_{t\in\mathbb{R}^+} h(t)$. Note that T_Θ is independent of r and s. □

By using Lemma 3.1, the energy functional $I_{r,s}$ possesses the mountain pass geometry. To obtain bounded Palais–Smale sequence, we recall a proposition from [11,13].

Proposition 3.2 (see [11, Theorem 1]). *Let $(E,\langle\cdot,\cdot\rangle)$ and $(H,(\cdot,\cdot))$ be two infinite-dimensional Hilbert spaces and assume there are continuous injections*

$$E \hookrightarrow H \hookrightarrow E'.$$

Let

$$\|u\|^2 = \langle u, u\rangle, \quad |u|^2 = (u, u) \quad \text{for } u \in E,$$

and

$$S_\mu = \left\{u \in E : |u|^2 = \mu\right\}, \qquad T_u S_\mu = \{v \in E : (u, v) = 0\} \quad \text{for } \mu \in (0, +\infty).$$

Let $I \subset (0, +\infty)$ *be an interval and consider a family of* C^2 *functionals* $\Phi_\rho : E \to \mathbb{R}$ *of the form*

$$\Phi_\rho(u) = A(u) - \rho B(u), \quad \text{for } \rho \in I,$$

with $B(u) \geq 0$ *for every* $u \in E$*, and*

$$A(u) \to +\infty \quad \text{or} \quad B(u) \to +\infty \quad \text{as } u \in E \text{ and } \|u\| \to +\infty. \tag{3.13}$$

Suppose moreover that Φ'_ρ *and* Φ''_ρ *are* τ*-Hölder continuous,* $\tau \in (0, 1]$*, on bounded sets in the following sense: for every* $R > 0$ *there exists* $M = M(R) > 0$ *such that*

$$\left\|\Phi'_\rho(u) - \Phi'_\rho(v)\right\| \leq M\|u - v\|^\tau \quad \text{and} \quad \left\|\Phi''_\rho(u) - \Phi''_\rho(v)\right\| \leq M\|u - v\|^\tau \tag{3.14}$$

for every $u, v \in B(0, R)$*. Finally, suppose that there exist* $w_1, w_2 \in S_\mu$ *independent of* ρ *such that*

$$c_\rho := \inf_{\gamma \in \Gamma} \max_{t \in [0,1]} \Phi_\rho(\gamma(t)) > \max\left\{\Phi_\rho(w_1), \Phi_\rho(w_2)\right\} \quad \text{for all } \rho \in I,$$

where

$$\Gamma = \left\{\gamma \in C\left([0, 1], S_\mu\right) : \gamma(0) = w_1, \gamma(1) = w_2\right\}.$$

Then for almost every $\rho \in I$*, there exists a sequence* $\{u_n\} \subset S_\mu$ *such that*

(i) $\Phi_\rho(u_n) \to c_\rho$*,*

(ii) $\Phi'_\rho\big|_{S_\mu}(u_n) \to 0$*,*

(iii) $\{u_n\}$ *is bounded in* E*.*

Lemma 3.3. *For any* $\Theta > 0$*, let* $r > r_\Theta$*, where* r_Θ *is defined in Lemma 3.1. Then problem (3.1) has a solution* $(\lambda_{r,s}, u_{r,s})$ *for almost every* $s \in \left[\frac{1}{2}, 1\right]$*. Moreover,* $u_{r,s} \geq 0$ *and* $I_{r,s}(u_{r,s}) = m_{r,s}(\Theta)$*.*

Proof. By Proposition 3.2, it follows that

$$A(u) = \frac{1}{2}\int_{\Omega_r} |\nabla u|^2 dx + \frac{1}{2}\int_{\Omega_r} V(x)u^2 dx - \beta\int_{\Omega_r} F(u)dx \quad \text{and} \quad B(u) = \frac{1}{q}\int_{\Omega_r} |u|^q dx.$$

Note that the assumptions in Proposition 3.2 hold due to $\beta \leq 0$ and Lemma 3.1. Hence, for almost every $s \in \left[\frac{1}{2}, 1\right]$, there exists a bounded Palais–Smale sequence $\{u_n\}$ satisfying

$$I_{r,s}(u_n) \to m_{r,s}(\Theta) \quad \text{and} \quad I'_{r,s}(u_n)\big|_{T_{u_n} S_{r,\Theta}} \to 0,$$

where $T_{u_n} S_{r,\Theta}$ denotes the tangent space of $S_{r,\Theta}$ at u_n. Then

$$\lambda_n = -\frac{1}{\Theta}\left(\int_{\Omega_r} |\nabla u_n|^2 dx + \int_{\Omega_r} V(x)u_n^2 dx - \beta\int_{\Omega_r} f(u_n)u_n dx - s\int_{\Omega_r} |u_n|^q dx\right)$$

is bounded and

$$I'_{r,s}(u_n) + \lambda_n u_n \to 0 \quad \text{in } H^{-1}(\Omega_r). \tag{3.15}$$

Moreover, since $\{u_n\}$ is a bounded Palais–Smale sequence, there exist $u_0 \in H_0^1(\Omega_r)$ and $\lambda \in \mathbb{R}$ such that, up to a subsequence,

$$\begin{aligned} \lambda_n &\to \lambda && \text{in } \mathbb{R}, \\ u_n &\rightharpoonup u_0 && \text{in } H_0^1(\Omega_r), \\ u_n &\to u_0 && \text{in } L^t(\Omega_r) \text{ for all } 2 \le t < 2^*, \end{aligned}$$

where u_0 satisfies

$$\begin{cases} -\Delta u_0 + V u_0 + \lambda u_0 = s\,|u_0|^{q-2}\,u_0 + \beta f(u_0) & \text{in } \Omega_r \\ u_0 \in H_0^1(\Omega_r), \quad \int_{\Omega_r} |u_0|^2\,dx = \Theta. \end{cases}$$

Using (3.15), we have

$$I'_{r,s}(u_n)\,u_0 + \lambda_n \int_{\Omega_r} u_n u_0 dx \to 0 \quad \text{as } n \to \infty$$

and

$$I'_{r,s}(u_n)\,u_n + \lambda_n \Theta \to 0 \quad \text{as } \; n \to \infty.$$

Note that

$$\begin{aligned} \lim_{n\to\infty} \int_{\Omega_r} V(x) u_n^2 dx &= \int_{\Omega_r} V(x) u_0^2 dx, \\ \lim_{n\to\infty} \int_{\Omega_r} f(u_n) u_n dx &= \int_{\Omega_r} f(u_0) u_0 dx, \\ \lim_{n\to\infty} \int_{\Omega_r} f(u_n) u_0 dx &= \int_{\Omega_r} f(u_0) u_0 dx, \end{aligned}$$

so we get $u_n \to u_0$ in $H_0^1(\Omega_r)$, hence $I_{r,s}(u_0) = m_{r,s}(\Theta)$.

Now, we show that $u_{r,s} \ge 0$. In order to obtain it, we only need to modify the proof of Proposition 3.2. In fact, for almost every $s \in \left[\frac{1}{2}, 1\right]$, the derivative $m'_{r,s}$ with respect to s is well defined since the function $s \mapsto m_{r,s}$ is nonincreasing, where $m_{r,s}$ denotes $m_{r,s}(\Theta)$ for fixed Θ. Let s be such that $m'_{r,s}$ exists and $\{s_n\} \subset \left[\frac{1}{2}, 1\right]$ be a monotone increasing sequence converging to s. Similar to the proof of Proposition 3.2, there exist $\{\gamma_n\} \subset \Gamma_{r,\Theta}$ and $K = K\left(m'_{r,s}\right)$ such that:

(i) if $I_{r,s}(\gamma_n(t)) \ge m_{r,s} - \left(2 - m'_{r,s}\right)(s - s_n)$, then $\int_{\Omega_r} |\nabla \gamma_n(t)|^2\,dx \le K$.

(ii) $\max_{t\in[0,1]} I_{r,s}(\gamma_n(t)) \le m_{r,s} - \left(2 - m'_{r,s}\right)(s - s_n)$.

Letting $\widetilde{\gamma}_n(t) = |\gamma_n(t)|$ for any $t \in [0,1]$, it follows that $\{\widetilde{\gamma}_n\} \subset \Gamma_{r,\Theta}$. Observe that $\|\nabla |u|\|_2^2 \le \|\nabla u\|_2^2$ for any $u \in H^1(\mathbb{R}^N)$. Now we have:

(I) if $I_{r,s}(\widetilde{\gamma}_n(t)) \ge m_{r,s} - \left(2 - m'_{r,s}\right)(s - s_n)$, then $I_{r,s}(\gamma_n(t)) \ge m_{r,s} - \left(2 - m'_{r,s}\right)(s - s_n)$. By (i), there holds $\int_{\Omega_r} |\nabla \gamma_n(t)|^2\,dx \le K$, and hence $\int_{\Omega_r} |\nabla \widetilde{\gamma}_n(t)|^2\,dx \le K$. Thus (i) also holds for $\widetilde{\gamma}_n$.

(II) $\max_{t\in[0,1]} I_{r,s}(\widetilde{\gamma}_n(t)) \le \max_{t\in[0,1]} I_{r,s}(\gamma_n(t)) \le m_{r,s} - \left(2 - m'_{r,s}\right)(s - s_n)$.

By replacing γ_n with $\widetilde{\gamma}_n$ in the proof of Proposition 3.2, we obtain a nonnegative bounded Palais–Smale sequence $\{u_n\}$. Consequently, there exists a nonnegative normalized solution to (3.1) for almost every $s \in \left[\frac{1}{2}, 1\right]$ as above. □

In order to obtain a solution of (1.1), we need to prove a uniform estimate for the solutions of (3.1) established in Lemma 3.3.

Lemma 3.4. *If* $(\lambda_{r,s}, u_{r,s}) \in \mathbb{R} \times S_{r,\Theta}$ *is a solution of* (3.1) *established in Lemma* 3.3 *for some r and s, then*

$$\int_{\Omega_r} |\nabla u|^2 dx \leq \frac{4N}{N(q-2)-4}\left[\frac{q-2}{2}h(T_\Theta) + \Theta\left(\frac{1}{2N}\|\widetilde{V}\|_\infty + \frac{q-2}{4}\|V\|_\infty\right)\right],$$

where the constant $h(T_\Theta)$ *is defined in (iii) of Lemma* 3.1 *and is independent of r and s.*

Proof. For simplicity, we denote $(\lambda_{r,s}, u_{r,s})$ as (λ, u) in this lemma. Since u is a solution of (3.1), we have

$$\int_{\Omega_r} |\nabla u|^2 dx + \int_{\Omega_r} V(x)u^2 dx = s\int_{\Omega_r} |u|^q dx + \beta\int_{\Omega_r} f(u)u dx - \lambda\int_{\Omega_r} |u|^2 dx. \tag{3.16}$$

The Pohozaev identity implies

$$\begin{aligned}&\frac{N-2}{2N}\int_{\Omega_r} |\nabla u|^2 dx + \frac{1}{2N}\int_{\partial\Omega_r} |\nabla u|^2 (x\cdot\mathbf{n}) d\sigma + \frac{1}{2N}\int_{\Omega_r} \widetilde{V}(x)u^2 dx + \frac{1}{2}\int_{\Omega_r} Vu^2 dx\\ &\quad = -\frac{\lambda}{2}\int_{\Omega_r} |u|^2 dx + \frac{s}{q}\int_{\Omega_r} |u|^q dx + \beta\int_{\Omega_r} F(u)dx,\end{aligned}$$

where $\mathbf{n}$ denotes the outward unit normal vector on $\partial\Omega_r$. It then follows from $\beta \leq 0$ and (f_2) that

$$\begin{aligned}&\frac{1}{N}\int_{\Omega_r} |\nabla u|^2 dx - \frac{1}{2N}\int_{\partial\Omega_r} |\nabla u|^2 (x\cdot\mathbf{n}) d\sigma - \frac{1}{2N}\int_{\Omega_r} (\nabla V\cdot x)u^2 dx\\ &\quad = \frac{(q-2)s}{2q}\int_{\Omega_r} |u|^q dx + \int_{\Omega_r} (\frac{\beta}{2}f(u)u - \beta F(u))dx\\ &\quad \geq \frac{(q-2)s}{2q}\int_{\Omega_r} |u|^q dx + \frac{\beta(q-2)}{2}\int_{\Omega_r} F(u)dx\\ &\quad = \frac{q-2}{2}\left(\frac{1}{2}\int_{\Omega_r} |\nabla u|^2 dx + \frac{1}{2}\int_{\Omega_r} Vu^2 dx - m_{r,s}(\Theta)\right).\end{aligned}$$

Consequently, we have

$$\begin{aligned}\frac{q-2}{2}m_{r,s}(\Theta) &\geq \frac{q-2}{2}\left(\frac{1}{2}\int_{\Omega_r} |\nabla u|^2 dx + \frac{1}{2}\int_{\Omega_r} Vu^2 dx\right) - \frac{1}{N}\int_{\Omega_r} |\nabla u|^2 dx\\ &\quad + \frac{1}{2N}\int_{\partial\Omega_r} |\nabla u|^2 (x\cdot\mathbf{n}) d\sigma + \frac{1}{2N}\int_{\Omega_r} (\nabla V\cdot x)u^2 dx\\ &\geq \frac{N(q-2)-4}{4N}\int_{\Omega_r} |\nabla u|^2 dx - \Theta\left(\frac{1}{2N}\|\nabla V\cdot x\|_\infty + \frac{q-2}{4}\|V\|_\infty\right),\end{aligned}$$

where the last inequality holds since $x\cdot\mathbf{n}(x) \geq 0$ for any $x \in \partial\Omega_r$ due to the convexity of Ω_r. Using Lemma 3.1, we have

$$\frac{N(q-2)-4}{4N}\int_{\Omega_r} |\nabla u|^2 dx - \Theta\left(\frac{1}{2N}\|\nabla V\cdot x\|_\infty + \frac{q-2}{4}\|V\|_\infty\right) \leq \frac{q-2}{2}h(T_\Theta),$$

which implies

$$\int_{\Omega_r} |\nabla u|^2 dx \leq \frac{4N}{N(q-2)-4}\left[\frac{q-2}{2}h(T_\Theta) + \Theta\left(\frac{1}{2N}\|\widetilde{V}\|_\infty + \frac{q-2}{4}\|V\|_\infty\right)\right].$$

This completes the proof of lemma. □

Now, we obtain a solution of (1.1) by letting $s \to 1$.

Lemma 3.5. *For every $\Theta > 0$, problem (1.1) has a solution (λ_r, u_r) provided $r > r_\Theta$ where r_Θ is as in Lemma 3.1. Moreover, $u_r \geq 0$ in Ω_r.*

Proof. By using Lemma 3.3, there is a nonnegative solution $(\lambda_{r,s}, u_{r,s})$ to (3.1) for almost every $s \in \left[\frac{1}{2}, 1\right]$. In view of Lemma 3.4, $\{u_{r,s}\}$ is bounded. By an argument similar to that in Lemma 3.3, there exist $u_r \in S_{r,\Theta}$ and λ_r such that, going if necessary to a subsequence,

$$\lambda_{r,s} \to \lambda_r \quad \text{and} \quad u_{r,s} \to u_r \quad \text{in } H_0^1(\Omega_r) \quad \text{as } s \to 1.$$

Hence u_r is a nonnegative solution of problem (1.1). □

Next, we will consider the Lagrange multiplier. we first establish an a priori estimate for the solutions of (1.1).

Lemma 3.6. *If $\{(\lambda_r, u_r)\}$ is a family of nonnegative solutions of (1.1) such that $\|u_r\|_{H^1} \leq C$ with $C > 0$ independent of r, then $\limsup_{r\to\infty} \|u_r\|_\infty < \infty$.*

Proof. Using the regularity theory of elliptic partial differential equations, we know that $u_r \in C(\Omega_r)$. Assume to the contrary that there exist a sequence, for simplicity denoted by $\{u_r\}$, and $x_r \in \Omega_r$ such that

$$M_r := \max_{x\in\Omega_r} u_r(x) = u_r(x_r) \to \infty \quad \text{as } r \to \infty.$$

Suppose without loss of generality that, up to a subsequence, $\lim_{r\to\infty} \frac{x_r}{|x_r|} = (1, 0, \ldots, 0)$. Set

$$v_r(x) = \frac{u_r(x_r + \tau_r x)}{M_r} \quad \text{for } x \in \Sigma^r := \left\{x \in \mathbb{R}^N : x_r + \tau_r x \in \Omega_r\right\},$$

where $\tau_r = M_r^{\frac{2-q}{2}}$. Then $\tau_r \to 0$ as $r \to \infty$, $\|v_r\|_{L^\infty(\Sigma^r)} \leq 1$, and v_r satisfies

$$-\Delta v_r + \tau_r^2 V(x_r + \tau_r x) v_r + \tau_r^2 \lambda_r v_r = |v_r|^{q-2} v_r + \beta M_r^{1-q} f(M_r v_r) \quad \text{in } \Sigma^r. \tag{3.17}$$

In fact, since u_r is a nonnegative solution of (1.1), we obtain

$$\begin{aligned} &-\Delta u_r(x_r + \tau_r x) + V(x_r + \tau_r x) u_r(x_r + \tau_r x) + \lambda_r u_r(x_r + \tau_r x) \\ &\quad = |u_r(x_r + \tau_r x)|^{q-2} u_r(x_r + \tau_r x) + \beta f(u_r(x_r + \tau_r x)) \quad \text{in } \Omega_r, \end{aligned}$$

then by a direct calculation and the definition of $v_r(x)$, τ_r, we know that (3.17) holds. In view of (1.1), the Gagliardo–Nirenberg inequality and $\|u_r\|_{H^1} \leq C$ with C independent of r, we infer that the sequence $\{\lambda_r\}$ is bounded. It then follows from the regularity theory of elliptic partial differential equations and the Arzelà–Ascoli theorem that there exists v such that, up to a subsequence

$$v_r \to v \quad \text{in } H_0^1(\Sigma) \quad \text{and} \quad v_r \to v \quad \text{in } C_{loc}^\beta(\Sigma) \text{ for some } \beta \in (0,1),$$

where $\Sigma := \lim\limits_{r\to\infty} \Sigma^r$.

Similar to the proof of [4, Lemma 2.7], we have

$$\liminf_{r\to\infty} \frac{\operatorname{dist}(x_r, \partial\Omega_r)}{\tau_r} = \liminf_{r\to\infty} \frac{|y_r - x_r|}{\tau_r} \geq d > 0,$$

where $y_r \in \partial\Omega_r$ is such that $\operatorname{dist}(x_r, \partial\Omega_r) = |y_r - x_r|$ for any large r. As a result, by letting $r \to \infty$ in (3.17), we obtain that $v \in H_0^1(\Sigma)$ is a nonnegative solution of

$$-\Delta v = |v|^{q-2}v \quad \text{in } \Sigma,$$

where

$$\Sigma = \begin{cases} \mathbb{R}^N & \text{if } \liminf_{r\to\infty} \frac{\operatorname{dist}(x_r,\partial\Omega_r)}{\tau_r} = \infty, \\ \{x \in \mathbb{R}^N : x_1 > -d\} & \text{if } \liminf_{r\to\infty} \frac{\operatorname{dist}(x_r,\partial\Omega_r)}{\tau_r} > 0. \end{cases}$$

It then follows from the Liouville theorems (see [17]) that $v = 0$ in $H_0^1(\Sigma)$, which contradicts $v(0) = \lim_{r\to\infty} v_r(0) = 1$. □

Clearly, the proof of Lemma 3.6 does not depend on β.

Lemma 3.7. *Let $(\lambda_{r,\Theta}, u_{r,\Theta})$ be the solution of (1.1) from Lemma 3.5. If $\|\widetilde{V}_+\|_{\frac{N}{2}} < 2S$, then there exists $\bar{\Theta} > 0$ such that*

$$\liminf_{r\to\infty} \lambda_{r,\Theta} > 0 \quad \textit{for } 0 < \Theta < \bar{\Theta}.$$

Proof. Let $(\lambda_{r,\Theta}, u_{r,\Theta})$ be the solution of (1.1) established in Theorem 3.5. By the regularity theory of elliptic partial differential equations, we have $u_{r,\Theta} \in C(\Omega_r)$. Using Lemma 3.6, it holds

$$\limsup_{r\to\infty} \max_{\Omega_r} u_{r,\Theta} < \infty.$$

Setting

$$Q(\Theta) = \liminf_{r\to\infty} \max_{\Omega_r} u_{r,\Theta},$$

we claim that there is $\Theta_1 > 0$ such that $Q(\Theta) > 0$ for any $0 < \Theta < \Theta_1$. Assume to the contrary that there exists a sequence $\{\Theta_k\}$ tending to 0 as $k \to \infty$ such that $Q(\Theta_k) = 0$ for any k, that is,

$$\liminf_{r\to\infty} \max_{\Omega_r} u_{r,\Theta_k} = 0 \quad \text{for any } k. \tag{3.18}$$

As a consequence of (iii) in Lemma 3.1, for any $r > r_{\Theta_k}$, we have

$$I_r(u_{r,\Theta_k}) = m_{r,1}(\Theta_k) \to \infty \quad \text{as } k \to \infty. \tag{3.19}$$

For any given k, it follows from (3.18) and $u_{r,\Theta_k} \in S_{r,\Theta_k}$ that, up to a subsequence,

$$\int_{\Omega_r} |u_{r,\Theta_k}|^s\,dx = \int_{\Omega_r} |u_{r,\Theta_k}|^{s-2}\,|u_{r,\Theta_k}|^2\,dx \le \left|\max_{\Omega_r} u_{r,\Theta_k}\right|^{s-2} \Theta_k \to 0 \quad \text{as } r \to \infty \tag{3.20}$$

for any $s > 2$. Hence, for any given large k, there exists $\bar{r}_k > r_{\Theta_k}$ such that

$$\left|\frac{1}{q}\int_{\Omega_r} |u_{r,\Theta_k}|^q dx + \beta \int_{\Omega_r} f(u_{r,\Theta_k})dx\right| < \frac{m_{r,1}(\Theta_k)}{2} \text{ for any } r \ge \bar{r}_k.$$

In view of (3.19) and $I_r(u_{r,\Theta_k}) = m_{r,1}(\Theta_k)$, we further have

$$\int_{\Omega_r} |\nabla u_{r,\Theta_k}|^2\,dx + \int_{\Omega_r} V(x)u_{r,\Theta_k}^2 dx \ge \frac{m_{r,1}(\Theta_k)}{2} \text{ for any large } k \text{ and } r \ge \bar{r}_k. \tag{3.21}$$

It follows from (3.18), (3.20) and (3.21) that there exists $r_k \ge \bar{r}_k$ with $r_k \to \infty$ as $k \to \infty$ such that

$$\lim_{k\to\infty} \max_{\Omega_{r_k}} u_{r_k,\Theta_k} = 0, \tag{3.22}$$

$$\int_{\Omega_{r_k}} |u_{r_k,\Theta_k}|^s \, dx \le \left| \max_{\Omega_{r_k}} u_{r_k,\Theta_k} \right|^{s-2} \Theta_k \to 0 \quad \text{as } k \to \infty \text{ for any } s > 2 \tag{3.23}$$

and

$$\int_{\Omega_{r_k}} |\nabla u_{r_k,\Theta_k}|^2 \, dx + \int_{\Omega_r} V u_{r_k,\Theta_k}^2 dx \to \infty \quad \text{as } k \to \infty. \tag{3.24}$$

By (1.1), (3.23) and (3.24), we have

$$\lambda_{r_k,\Theta_k} \to -\infty \quad \text{as } k \to \infty. \tag{3.25}$$

Now (1.1) implies

$$-\Delta u_{r_k,\Theta_k} + V(x) u_{r_k,\Theta_k} + \lambda_{r_k,\Theta_k} u_{r_k,\Theta_k} = |u_{r_k,\Theta_k}|^{q-2} u_{r_k,\Theta_k} + \beta f(u_{r_k,\Theta_k}),$$

so

$$-\Delta u_{r_k,\Theta_k} + \left(\|V\|_\infty + \frac{\lambda_{r_k,\Theta_k}}{2} \right) u_{r_k,\Theta_k} \ge -\frac{\lambda_{r_k,\Theta_k}}{2} u_{r_k,\Theta_k} + |u_{r_k,\Theta_k}|^{q-2} u_{r_k,\Theta_k} + \beta f(u_{r_k,\Theta_k}).$$

Using (3.25) and (3.22), it follows that

$$-\Delta u_{r_k,\Theta_k} + \left(\|V\|_\infty + \frac{\lambda_{r_k,\Theta_k}}{2} \right) u_{r_k,\Theta_k} \ge 0$$

for large k. Let θ_{r_k} be the principal eigenvalue of $-\Delta$ with Dirichlet boundary condition in Ω_{r_k}, and $v_{r_k} > 0$ be the corresponding normalized eigenfunction. It follows that

$$\left(\theta_{r_k} + \|V\|_\infty + \frac{\lambda_{r_k,\Theta_k}}{2} \right) \int_{\Omega_{r_k}} u_{r_k,\Theta_k} v_{r_k} dx \ge 0.$$

Since $\int_{\Omega_{r_k}} u_{r_k,\Theta_k} v_{r_k} dx > 0$, we have

$$\theta_{r_k} + \|V\|_\infty + \frac{\lambda_{r_k,\Theta_k}}{2} \ge 0,$$

which contradicts (3.25) for large k. Hence the claim holds, that is, there exists $\Theta_1 > 0$ such that

$$Q(\Theta) = \liminf_{r \to \infty} \max_{\Omega_r} u_{r,\Theta} > 0 \tag{3.26}$$

for any $0 < \Theta < \Theta_1$.

We consider $H^1(\Omega_r)$ as a subspace of $H^1(\mathbb{R}^N)$ for any $r > 0$. It follows from Lemma 3.4 that the set of solutions $\{u_{r,\Theta} : r > r_\Theta\}$ established in Lemma 3.5 is bounded in $H^1(\mathbb{R}^N)$, so there exist $u_\Theta \in H^1(\mathbb{R}^N)$ and $\lambda_\Theta \in \mathbb{R}$ such that up to a subsequence:

$$\begin{aligned} &\lambda_{r,\Theta} \to \lambda_\Theta, \\ &u_{r,\Theta} \rightharpoonup u_\Theta \quad \text{in } H^1(\mathbb{R}^N), \\ &u_{r,\Theta} \to u_\Theta \quad \text{in } L^k_{loc}(\mathbb{R}^N) \text{ for all } 2 \le k < 2^*, \\ &u_{r,\Theta} \to u_\Theta \quad \text{a.e. in } \mathbb{R}^N \end{aligned}$$

and u_Θ is a solution of the equation

$$-\Delta u + V(x) u + \lambda_\Theta u = |u|^{q-2} u + \beta f(u) \quad \text{in } \mathbb{R}^N.$$

Hence,

$$\int_{\mathbb{R}^N} |\nabla u_\Theta|^2\,dx + \int_{\mathbb{R}^N} V(x)u_\Theta^2 dx + \lambda_\Theta \int_{\mathbb{R}^N} u_\Theta^2 dx = \int_{\mathbb{R}^N} |u_\Theta|^q\,dx + \beta \int_{\mathbb{R}^N} f(u_\Theta)u_\Theta dx \tag{3.27}$$

and the Pohozaev identity gives

$$\begin{aligned}&\frac{N-2}{2N}\int_{\mathbb{R}^N} |\nabla u_\Theta|^2\,dx + \frac{1}{2N}\int_{\mathbb{R}^N} \widetilde{V} u_\Theta^2 dx + \frac{1}{2}\int_{\mathbb{R}^N} V(x)u_\Theta^2 dx + \frac{\lambda_\Theta}{2}\int_{\mathbb{R}^N} u_\Theta^2 dx\\ &= \frac{1}{q}\int_{\mathbb{R}^N} |u_\Theta|^q\,dx + \beta\int_{\mathbb{R}^N} F(u_\Theta)dx.\end{aligned} \tag{3.28}$$

It follows from (3.27), (3.28), (f_2), the Gagliardo–Nirenberg inequality and the fact $\beta \leq 0$ that

$$\begin{aligned}&\frac{1}{N}\int_{\mathbb{R}^N} |\nabla u_\Theta|^2\,dx + \frac{1}{2N}\int_{\mathbb{R}^N} \widetilde{V}(x)u_\Theta^2 dx\\ &= \left(\frac{1}{2}-\frac{1}{q}\right)\int_{\mathbb{R}^N} |u_\Theta|^q\,dx + \frac{\beta}{2}\int_{\mathbb{R}^N}(f(u_\Theta)u_\Theta - 2F(u_\Theta))dx\\ &\leq \frac{C_{N,q}(q-2)}{2q}\left(\int_{\mathbb{R}^N} u_\Theta^2 dx\right)^{\frac{2q-N(q-2)}{4}}\left(\int_{\mathbb{R}^N} |\nabla u_\Theta|^2\,dx\right)^{\frac{N(q-2)}{4}}.\end{aligned}$$

By using the Hölder inequality, we have

$$\left(\frac{1}{N} - \frac{\|\widetilde{V}_+\|_{\frac{N}{2}} S^{-1}}{2N}\right)\int_{\mathbb{R}^N} |\nabla u_\Theta|^2\,dx \leq \frac{1}{N}\int_{\mathbb{R}^N} |\nabla u_\Theta|^2\,dx + \frac{1}{2N}\int_{\mathbb{R}^N} \widetilde{V}(x)u_\Theta^2 dx.$$

Therefore,

$$\begin{aligned}&\left(\frac{1}{N} - \frac{\|\widetilde{V}_+\|_{\frac{N}{2}} S^{-1}}{2N}\right)\int_{\mathbb{R}^N} |\nabla u_\Theta|^2\,dx\\ &\leq \frac{C_{N,q}(q-2)}{2q}\left(\int_{\mathbb{R}^N} u_\Theta^2 dx\right)^{\frac{2q-N(q-2)}{4}}\left(\int_{\mathbb{R}^N} |\nabla u_\Theta|^2\,dx\right)^{\frac{N(q-2)}{4}}.\end{aligned}$$

If $u_\Theta \neq 0$, Using $\|\widetilde{V}_+\|_{\frac{N}{2}} < 2S$, we obtain that

$$\int_{\mathbb{R}^N} |\nabla u_\Theta|^2\,dx \geq \left[\frac{q\left(2-\|\widetilde{V}_+\|_{\frac{N}{2}} S^{-1}\right)}{NC_{N,q}(q-2)}\right]^{\frac{4}{N(q-2)-4}} \Theta^{\frac{q(N-2)-2N}{N(q-2)-4}}. \tag{3.29}$$

Next, it follows from (3.5), (3.27), (3.28), (3.29), (f_2) and $2+\frac{4}{N} < q < 2^*$ that

$$\begin{aligned}\left(\frac{1}{q}-\frac{1}{2}\right)\lambda_\Theta\int_{\mathbb{R}^N} u_\Theta^2 dx &= \left(\frac{N-2}{2N}-\frac{1}{q}\right)\int_{\mathbb{R}^N} |\nabla u_\Theta|^2\,dx + \frac{1}{2N}\int_{\mathbb{R}^N} \widetilde{V}(x)u_\Theta^2 dx\\ &\quad + \left(\frac{1}{2}-\frac{1}{q}\right)\int_{\mathbb{R}^N} V(x)u_\Theta^2 dx - \frac{\beta}{q}\int_{\mathbb{R}^N}(qF(u_\Theta) - f(u_\Theta)u_\Theta))\,dx\\ &\leq \frac{(N-2)q-2N}{2Nq}\int_{\mathbb{R}^N} |\nabla u_\Theta|^2\,dx + \frac{\|\widetilde{V}\|_\infty}{2N}\Theta + \frac{(q-2)\|V\|_\infty}{2q}\Theta\\ &\quad - \frac{\beta(q-p_2)\alpha}{q} C_{N,p_1}\Theta^{\frac{2p_1-N(p_1-2)}{4}}\left(\int_{\mathbb{R}^N} |\nabla u_\Theta|^2\,dx\right)^{\frac{N(p_1-2)}{4}}\\ &\to -\infty \quad \text{as } \Theta \to 0,\end{aligned}$$

since $\frac{(N-2)q-2N}{2Nq} < 0$. Therefore, if $u_\Theta \neq 0$ for $\Theta > 0$ small there exists $\Theta_0 > 0$ such that $\lambda_\Theta > 0$ for $0 < \Theta < \Theta_0$.

In order to complete the proof, we consider the case that there is a sequence $\Theta_k \to 0$ such that $u_{\Theta_k} = 0$ for any k. Assume without loss of generality that $u_\Theta = 0$ for any $\Theta \in (0, \Theta_1)$. Let $x_{r,\Theta} \in \Omega_r$ be such that $u_{r,\Theta}(x_{r,\Theta}) = \max_{\Omega_r} u_{r,\Theta}$. In view of (3.26), there holds $|x_{r,\Theta}| \to \infty$ as $r \to \infty$. Otherwise, there exists $x_0 \in \mathbb{R}$ such that, up to a subsequence, $x_{r,\Theta} \to x_0$, and hence $u_\Theta(x_0) \geq d_\Theta > 0$. This contradicts $u_\Theta = 0$. We claim that $\operatorname{dist}(x_{r,\Theta}, \partial\Omega_r) \to \infty$ as $r \to \infty$. Arguing by contradiction we assume that $\liminf_{r\to\infty} \operatorname{dist}(x_{r,\Theta}, \partial\Omega_r) = l < \infty$. It follows from (3.26) that $l > 0$. Let $w_r(x) = u_{r,\Theta}(x + x_{r,\Theta})$ for any $x \in \Sigma^r := \{x \in \mathbb{R}^N : x + x_{r,\Theta} \in \Omega_r\}$. Then w_r is bounded in $H^1(\mathbb{R}^N)$, and there is $w \in H^1(\mathbb{R}^N)$ such that $w_r \rightharpoonup w$ as $r \to \infty$. By the regularity theory of elliptic partial equations and $\liminf_{r\to\infty} u_{r,\Theta}(x_{r,\Theta}) > d_\Theta > 0$, we infer that $w(0) \geq d_\Theta > 0$. Assume without loss of the generality that, up to a subsequence,

$$\lim_{r\to\infty} \frac{x_{r,\Theta}}{|x_{r,\Theta}|} = e_1.$$

Setting

$$\Sigma = \left\{x \in \mathbb{R}^N : x \cdot e_1 < l\right\} = \left\{x \in \mathbb{R}^N : x_1 < l\right\},$$

we have $\phi(\cdot - x_{r,\Theta}) \in C_c^\infty(\Omega_r)$ for any $\phi \in C_c^\infty(\Sigma)$ and r large enough. It then follows that

$$\begin{aligned}\int_{\Omega_r} \nabla u_{r,\Theta} \nabla \phi(\cdot - x_{r,\Theta})\, dx + \int_{\Omega_r} V u_{r,\Theta} \phi(\cdot - x_{r,\Theta})\, dx + \lambda_{r,\Theta} \int_{\Omega_r} u_{r,\Theta} \phi(\cdot - x_{r,\Theta})\, dx \\ = \int_{\Omega_r} |u_{r,\Theta}|^{q-2} u_{r,\Theta} \phi(\cdot - x_{r,\Theta})\, dx + \beta \int_{\Omega_r} f(u_{r,\Theta}) \phi(\cdot - x_{r,\Theta})\, dx. \end{aligned} \tag{3.30}$$

Since $|x_{r,\Theta}| \to \infty$ as $r \to \infty$, it holds

$$\begin{aligned}\left| \int_{\Omega_r} V u_{r,\Theta} \phi(\cdot - x_{r,\Theta})\, dx \right| &\leq \int_{\text{Supp}\,\phi} |V(\cdot + x_{r,\Theta}) w_r \phi|\, dx \\ &\leq \|w_r\|_{2^*} \|\phi\|_{2^*} \left(\int_{\text{Supp}\,\phi} |V(\cdot + x_{r,\Theta})|^{\frac{N}{2}} dx \right)^{\frac{2}{N}} \\ &\leq \|w_r\|_{2^*} \|\phi\|_{2^*} \left(\int_{\mathbb{R}^N \setminus B_{\frac{|x_{r,\Theta}|}{2}}} |V|^{\frac{N}{2}} dx \right)^{\frac{2}{N}} \\ &\to 0 \quad \text{as } r \to \infty. \end{aligned} \tag{3.31}$$

Letting $r \to \infty$ in (3.30), we obtain for $\phi \in C_c^\infty(\Sigma)$:

$$\int_\Sigma \nabla w \cdot \nabla \phi dx + \lambda_\Theta \int_\Sigma w \phi dx = \int_\Sigma |w|^{q-2} w \phi dx + \beta \int_\Sigma f(w) \phi dx.$$

Thus $w \in H_0^1(\Sigma)$ is a weak solution of the equation

$$-\Delta w + \lambda_\Theta w = |w|^{q-2} w + \beta f(w) \quad \text{in } \Sigma. \tag{3.32}$$

Hence we obtain a nontrivial nonnegative solution of (3.32) on a half space which is impossible by the Liouville theorem (see [17]). This proves that $\operatorname{dist}(x_{r,\Theta}, \partial\Omega_r) \to \infty$ as $r \to \infty$. A similar argument as above shows that (3.32) holds for $\Sigma = \mathbb{R}^N$. Now we argue as in the case $u_\Theta \neq 0$ above that there exists Θ_2 such that $\lambda_\Theta > 0$ for any $0 < \Theta < \Theta_2$.

Setting $\bar{\Theta} = \min\{\Theta_0, \Theta_1, \Theta_2\}$, the proof is complete. □

Proof of Theorem 1.3. The proof is an immediate consequence of Lemmas 3.5, 3.6 and 3.7. □

4 Proof of Theorem 1.4

In this section, we assume that the assumptions of Theorem 1.4 hold. Since $\beta > 0$,

$$\begin{aligned} I_r(u) &\geq \frac{1}{2}\left(1-\|V_-\|_{\frac{N}{2}} S^{-1}\right)\int_{\Omega_r}|\nabla u|^2dx - \frac{C_{N,q}\Theta^{\frac{2q-N(q-2)}{4}}}{q}\left(\int_{\Omega_r}|\nabla u|^2dx\right)^{\frac{N(q-2)}{4}} \\ &\quad - \alpha\beta C_{N,p_1}\Theta^{\frac{2p_1-N(p_1-2)}{4}}\left(\int_{\Omega_r}|\nabla u|^2dx\right)^{\frac{N(p_1-2)}{4}} \\ &= h_1(t), \end{aligned}$$

where

$$\begin{aligned} h_1(t) &:= \frac{1}{2}\left(1-\|V_-\|_{\frac{N}{2}} S^{-1}\right)t^2 - \frac{C_{N,q}\Theta^{\frac{2q-N(q-2)}{4}}}{q}t^{\frac{N(q-2)}{2}} - \alpha\beta C_{N,p_1}\Theta^{\frac{2p_1-N(p_1-2)}{4}}t^{\frac{N(p_1-2)}{2}} \\ &= t^{\frac{N(p_1-2)}{2}}\left[\frac{1}{2}\left(1-\|V_-\|_{\frac{N}{2}} S^{-1}\right)t^{\frac{4-N(p_1-2)}{2}} - \frac{C_{N,q}\Theta^{\frac{2q-N(q-2)}{4}}}{q}t^{\frac{N(q-p_1)}{2}}\right] \\ &\quad - \alpha\beta C_{N,p_1}\Theta^{\frac{2p_1-N(p_1-2)}{4}}t^{\frac{N(p_1-2)}{2}}. \end{aligned}$$

Consider

$$\psi(t) := \frac{1}{2}\left(1-\|V_-\|_{\frac{N}{2}} S^{-1}\right)t^{\frac{4-N(p_1-2)}{2}} - \frac{C_{N,q}\Theta^{\frac{2q-N(q-2)}{4}}}{q}t^{\frac{N(q-p_1)}{2}}.$$

Note that ψ admits a unique maximum at

$$\bar{t} = \left[\frac{q(4-N(p_1-2))\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}\right)}{2N(q-p_1)C_{N,q}}\right]^{\frac{2}{N(q-2)-4}}\Theta^{\frac{N(q-2)-2q}{2(N(q-2)-4)}}.$$

By a direct calculation, we obtain

$$\psi(\bar{t}) = \left[\frac{1-\|V_-\|_{\frac{N}{2}} S^{-1}}{2N(q-p_1)}\right]^{\frac{N(q-p_1)}{N(q-2)-4}}\left[\frac{q(4-N(p_1-2))}{C_{N,q}}\right]^{\frac{4-N(p_1-2)}{N(q-2)-4}}[N(q-2)-4].$$

Hence,

$$\psi(\bar{t}) > \alpha\beta C_{N,p_1}\Theta^{\frac{2p_1-N(p_1-2)}{4}}$$

as long as

$$\Theta_V = \left[\frac{1-\|V_-\|_{\frac{N}{2}} S^{-1}}{2N(q-p_1)}\right]^{\frac{N}{2}}\left[\frac{q(4-N(p_1-2))}{C_{N,q}}\right]^{\frac{4-N(p_1-2)}{2(q-p_1)}}\left[\frac{N(q-2)-4}{\alpha\beta C_{N,p_1}}\right]^{\frac{N(q-2)-4}{2(q-p_1)}}.$$

Now, let $0 < \Theta < \Theta_V$ be fixed, we obtain

$$\psi(\bar{t}) > \alpha\beta C_{N,p_1}\Theta^{\frac{2p_1-N(p_1-2)}{4}} \tag{4.1}$$

and $h_1(\bar{t}) > 0$. In view of $2 < p_1 < 2+\frac{4}{N} < q < 2^*$ and (4.1), there exist $0 < R_1 < T_\Theta < R_2$ such that $h_1(t) < 0$ for $0 < t < R_1$ and for $t > R_2, h_1(t) > 0$ for $R_1 < t < R_2$, and $h_1(T_\Theta) = \max_{t\in\mathbb{R}^+} h_1(t) > 0$.

Define

$$\mathcal{V}_{r,\Theta} = \left\{u \in S_{r,\Theta} : \|\nabla u\|_2^2 \le T_\Theta^2\right\}.$$

Let θ be the principal eigenvalue of operator $-\Delta$ with Dirichlet boundary condition in Ω, and let $|\Omega|$ be the volume of Ω.

Lemma 4.1.

(i) If $r < \frac{\sqrt{C\Theta}}{T_\Theta}$, then $\mathcal{V}_{r,\Theta} = \emptyset$.

(ii) If

$$r > \max\left\{\frac{\sqrt{C\Theta}}{T_\Theta}, \left(\frac{\theta\left(1+\|V\|_{\frac{N}{2}}S^{-1}\right)}{2\alpha_1\beta}\Theta^{\frac{2-p_2}{2}}|\Omega|^{\frac{p_2-2}{2}}\right)^{\frac{2}{N(p_2-2)+4}}\right\},$$

then $\mathcal{V}_{r,\Theta} \neq \emptyset$ and

$$e_{r,\Theta} := \inf_{u\in\mathcal{V}_{r,\Theta}} I_r(u) < 0$$

is attained at some interior point $u_r > 0$ of $\mathcal{V}_{r,\Theta}$. As a consequence, there exists a Lagrange multiplier $\lambda_r \in \mathbb{R}$ such that (λ_r, u_r) is a solution of (2.1). Moreover $\liminf_{r\to\infty}\lambda_r > 0$ holds true.

Proof. (i) The Poincaré inequality implies there exists a positive constant C (only depending on Ω) such that

$$\int_{\Omega_r}|\nabla u|^2dx = \frac{1}{r^2}\int_\Omega|\nabla u|^2dx \ge \frac{C}{r^2}\int_\Omega|u|^2dx = \frac{C\Theta}{r^2}$$

for any $u \in S_{r,\Theta}$. Since T_Θ is independent of r, there holds $\mathcal{V}_{r,\Theta} = \emptyset$ if and only if $r < \frac{\sqrt{C\Theta}}{T_\Theta}$.

(ii) Let $v_1 \in S_{1,\Theta}$ be the positive normalized eigenfunction corresponding to θ. Setting

$$r_\Theta = \max\left\{\frac{\sqrt{C\Theta}}{T_\Theta}, \left[\frac{\theta\left(1+\|V\|_{\frac{N}{2}}S^{-1}\right)}{2\alpha_1\beta}\Theta^{\frac{2-p_2}{2}}|\Omega|^{\frac{p_2-2}{2}}\right]^{\frac{2}{N(p_2-2)+4}}\right\}. \tag{4.2}$$

Now, we construct for $r > r_\Theta$ a function $u_r \in S_{r,\Theta}$ such that $u_r \in \mathcal{V}_{r,\Theta}$ and $I_r(u_r) < 0$. Clearly,

$$\int_\Omega|\nabla v_1|^2dx = \theta\Theta,\ \Theta = \int_\Omega|v_1|^2dx \le \left(\int_\Omega|v_1|^{p_2}dx\right)^{\frac{2}{p_2}}|\Omega|^{\frac{p_2-2}{p_2}}.$$

Define $u_r \in S_{r,\Theta}$ by $u_r(x) = r^{-\frac{N}{2}}v_1\left(r^{-1}x\right)$ for $x \in \Omega_r$. Then

$$\int_{\Omega_r}|\nabla u_r|^2dx = r^{-2}\theta\Theta \quad\text{and}\quad \int_{\Omega_r}|u_r|^{p_2}dx \ge r^{\frac{N(2-p_2)}{2}}\Theta^{\frac{p_2}{2}}|\Omega|^{\frac{2-p_2}{2}}. \tag{4.3}$$

According to (f_2), there exists a constant $\alpha_1 > 0$ such that

$$F(\tau) \ge \alpha_1\tau^{p_2}. \tag{4.4}$$

By (4.2), (4.3), (4.4), $2 < p_2 < 2+\frac{4}{N}$ and a direct calculation we have $u_r \in \mathcal{V}_{r,\Theta}$ and

$$\begin{aligned} I_r(u_r) &\le \frac{1}{2}\left(1+\|V\|_{\frac{N}{2}}S^{-1}\right)r^{-2}\theta\Theta - \alpha_1\beta r^{\frac{N(2-p_2)}{2}}\Theta^{\frac{p_2}{2}}|\Omega|^{\frac{2-p_2}{2}} \\ &< 0. \end{aligned}$$

It then follows from the Gagliardo–Nirenberg inequality that

$$I_r(u_r) \geq \frac{1}{2}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right) \int_{\Omega_r} |\nabla u|^2 dx - C_{N,p_1}\beta\Theta^{\frac{2p_1-N(p_1-2)}{4}} \left(\int_{\Omega_r} |\nabla u|^2 dx\right)^{\frac{N(p_1-2)}{4}}$$
$$- \frac{C_{N,q}}{q}\Theta^{\frac{2q-N(q-2)}{4}} \left(\int_{\Omega_r} |\nabla u|^2 dx\right)^{\frac{N(q-2)}{4}}. \tag{4.5}$$

As a consequence I_r is bounded from below in $\mathcal{V}_{r,\Theta}$. By the Ekeland principle there exists a sequence $\{u_{n,r}\} \subset \mathcal{V}_{r,\Theta}$ such that

$$I_r(u_{n,r}) \to \inf_{u \in \mathcal{V}_{r,\Theta}} I_r(u), \; I_r'(u_{n,r})|_{T_{u_{n,r}} S_{r,\Theta}} \to 0 \quad \text{as } n \to \infty.$$

Consequently there exists $u_r \in H_0^1(\Omega_r)$ such that $u_{n,r} \rightharpoonup u_r$ in $H_0^1(\Omega_r)$ and

$$u_{n,r} \to u_r \quad \text{in } L^k(\Omega_r) \text{ for all } 2 \leq k < 2^*.$$

Moreover, $\|\nabla u_r\|_2^2 \leq \liminf_{n\to\infty} \|\nabla u_{n,r}\|_2^2 \leq T_\Theta^2$, that is, $u_r \in \mathcal{V}_{r,\Theta}$. Note that

$$\int_{\Omega_r} V u_{n,r}^2 dx \to \int_{\Omega_r} V u_r^2 dx \text{ as } n \to \infty,$$

hence

$$e_{r,\Theta} \leq I_r(u_r) \leq \liminf_{n\to\infty} I_r(u_{n,r}) = e_{r,\Theta}.$$

It follows that $u_{n,r} \to u_r$ in $H_0^1(\Omega_r)$, so $I_r(u_r) < 0$. Therefore u is an interior point of $\mathcal{V}_{r,\Theta}$ because $I_r(u) \geq h_1(T_\Theta) > 0$ for any $u \in \partial\mathcal{V}_{r,\Theta}$ by (4.5). The Lagrange multiplier theorem implies that there exists $\lambda_r \in \mathbb{R}$ such that (λ_r, u_r) is a solution of (2.1). Moreover,

$$\begin{aligned}\lambda_r\Theta &= \int_{\Omega_r} |u_r|^q\, dx + \beta\int_{\Omega_r} f(u_r)u_r dx - \int_{\Omega_r} |\nabla u_r|^2\, dx - \int_{\Omega_r} V u_r^2 dx \\ &= \int_{\Omega_r} |u_r|^q\, dx + \beta\int_{\Omega_r} f(u_r)u_r dx - \frac{2}{q}\int_{\Omega_r} |u_r|^q dx - 2\beta\int_{\Omega_r} F(u_r) dx - 2I_r(u_r) \\ &> -2I_r(u_r) = -2e_{r,\Theta}.\end{aligned} \tag{4.6}$$

It follows from the definition of $e_{r,\Theta}$ that $e_{r,\Theta}$ is nonincreasing with respect to r. Hence, $e_{r,\Theta} \leq e_{r_\Theta,\Theta} < 0$ for any $r > r_\Theta$ and $0 < \Theta < \Theta_V$. In view of (4.6), we have $\liminf_{r\to\infty} \lambda_r > 0$. Finally, the strong maximum principle implies $u_r > 0$. □

Proof of Theorem 1.4. The proof is a direct consequence of Lemma 4.1 and Lemma 3.6. □

5 Proof of Theorem 1.5

In this subsection we assume that the assumptions of Theorem 1.5 hold. For $s \in \left[\frac{1}{2}, 1\right]$, $\beta > 0$, we define the functional $J_{r,s} : S_{r,\Theta} \to \mathbb{R}$ by

$$J_{r,s}(u) = \frac{1}{2}\int_{\Omega_r} |\nabla u|^2 dx + \frac{1}{2}\int_{\Omega_r} V u^2 dx - s\left(\frac{1}{q}\int_{\Omega_r} |u|^q dx + \beta\int_{\Omega_r} F(u) dx\right).$$

Note that if $u \in S_{r,\Theta}$ is a critical point of $J_{r,s}$ then there exists $\lambda \in \mathbb{R}$ such that (λ, u) is a solution of the problem

$$\begin{cases} -\Delta u + Vu + \lambda u = s|u|^{q-2}u + s\beta f(u), & x \in \Omega_r, \\ \int_{\Omega_r} |u|^2 dx = \Theta, u \in H_0^1(\Omega_r), & x \in \Omega_r, \end{cases} \tag{5.1}$$

Lemma 5.1. *For $0<\Theta<\widetilde{\Theta}_V$ where $\widetilde{\Theta}_V$ is defined in Theorem 1.5, there exist $\widetilde{r}_\Theta>0$ and $u^0,u^1\in S_{r_\Theta,\Theta}$ such that*

(i) For $r>\widetilde{r}_\Theta$ and $s\in\left[\frac{1}{2},1\right]$ we have $J_{r,s}\left(u^1\right)\le 0$ and

$$J_{r,s}\left(u^0\right)<\frac{N(q-2)-4}{4}\left(\frac{2\left(1-\|V_-\|_{\frac{N}{2}}S\right)}{N(q-2)}\right)^{\frac{N(q-2)}{N(q-2)-4}}A^{\frac{4}{4-N(q-2)}}\Theta^{\frac{N(q-2)-2q}{N(q-2)-4}},$$

where

$$A=\left(\frac{C_{N,q}(q-2)(N(q-2)-4)}{q(p_1-2)(4-N(p_1-2))}+\frac{C_{N,q}}{q}\right).$$

Moreover,

$$\|\nabla u^0\|_2^2<\left[\frac{2\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}\right)}{N(q-2)A}\right]^{\frac{4}{N(q-2)-4}}\Theta^{\frac{N(q-2)-2q}{N(q-2)-4}}$$

and

$$\left\|\nabla u^1\right\|_2^2>\left[\frac{2\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}\right)}{N(q-2)A}\right]^{\frac{4}{N(q-2)-4}}\Theta^{\frac{N(q-2)-2q}{N(q-2)-4}}.$$

(ii) If $u\in S_{r,\Theta}$ satisfies

$$\|\nabla u\|_2^2=\left[\frac{2\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}\right)}{N(q-2)A}\right]^{\frac{4}{N(q-2)-4}}\Theta^{\frac{N(q-2)-2q}{N(q-2)-4}},$$

then there holds

$$J_{r,s}(u)\ge\frac{N(q-2)-4}{4}\left[\frac{2\left(1-\|V_-\|_{\frac{N}{2}}S\right)}{N(q-2)}\right]^{\frac{N(q-2)}{N(q-2)-4}}A^{\frac{4}{4-N(q-2)}}\Theta^{\frac{N(q-2)-2q}{N(q-2)-4}}.$$

(iii) Let

$$m_{r,s}(\Theta)=\inf_{\gamma\in\Gamma_{r,\Theta}}\sup_{t\in[0,1]}J_{r,s}(\gamma(t)),$$

where

$$\Gamma_{r,\Theta}=\left\{\gamma\in C\left([0,1],S_{r,\Theta}\right):\gamma(0)=u^0,\gamma(1)=u^1\right\}.$$

Then

$$m_{r,s}(\Theta)\ge\frac{N(q-2)-4}{4}\left[\frac{2\left(1-\|V_-\|_{\frac{N}{2}}S\right)}{N(q-2)}\right]^{\frac{N(q-2)}{N(q-2)-4}}A^{\frac{4}{4-N(q-2)}}\Theta^{\frac{N(q-2)-2q}{N(q-2)-4}}$$

and

$$m_{r,s}(\Theta)\le\frac{N(q-2)-4}{2}\left(\frac{\theta\left(1+\|V\|_{\frac{N}{2}}S^{-1}\right)}{N(q-2)}\right)^{\frac{N(q-2)}{N(q-2)-4}}(4q)^{\frac{4}{N(q-2)-4}}|\Omega|^{\frac{2(q-2)}{N(q-2)-4}}\Theta^{\frac{N(q-2)-2q}{N(q-2)-4}}.$$

where θ is the principal eigenvalue of $-\Delta$ with Dirichlet boundary condition in Ω.

Proof. Let $v_1 \in S_{1,\Theta}$ be the positive normalized eigenfunction of $-\Delta$ with Dirichlet boundary condition in Ω associated to θ, then we have

$$\int_{\Omega} |\nabla v_1|^2 \, dx = \theta\Theta. \tag{5.2}$$

By the Hölder inequality, we know

$$\int_{\Omega} |v_1(x)|^{p_2} dx \geq \Theta^{\frac{p_2}{2}} \cdot |\Omega|^{\frac{2-p_2}{2}}. \tag{5.3}$$

Setting $v_t(x) = t^{\frac{N}{2}} v_1(tx)$ for $x \in B_{\frac{1}{t}}$ and $t > 0$. Using (4.4), (5.2), (5.3) and $\frac{1}{2} \leq s \leq 1$, we get

$$\begin{aligned} J_{\frac{1}{t},s}(v_t) &\leq \frac{1}{2}\left(1 + \|V\|_{\frac{N}{2}} S^{-1}\right) t^2 \theta\Theta - \frac{\beta}{2}\alpha_1 t^{\frac{N(p_2-2)}{2}} \int_{\Omega} |v_1|^{p_2} dx - \frac{1}{2q} t^{\frac{N(q-2)}{2}} \Theta^{\frac{q}{2}} \cdot |\Omega|^{\frac{2-q}{2}} \\ &\leq h_2(t), \end{aligned} \tag{5.4}$$

where

$$h_2(t) = \frac{1}{2}\left(1 + \|V\|_{\frac{N}{2}} S^{-1}\right) t^2 \theta\Theta - \frac{1}{2q} t^{\frac{N(q-2)}{2}} \Theta^{\frac{q}{2}} \cdot |\Omega|^{\frac{2-q}{2}}.$$

A simple computation shows that $h_2(t_0) = 0$ for

$$t_0 := \left[\left(1 + \|V\|_{\frac{N}{2}} S^{-1}\right) q\theta\Theta^{\frac{2-q}{2}} |\Omega|^{\frac{q-2}{2}}\right]^{\frac{2}{N(q-2)-4}}$$

and $h_2(t) < 0$ for any $t > t_0, h_2(t) > 0$ for any $0 < t < t_0$. Moreover, $h_2(t)$ achieves its maximum at

$$t_\Theta = \left[\frac{4q\left(1 + \|V\|_{\frac{N}{2}} S^{-1}\right)\theta}{N(q-2)} \Theta^{\frac{2-q}{2}} |\Omega|^{\frac{q-2}{2}}\right]^{\frac{2}{N(q-2)-4}}.$$

This implies

$$J_{r,s}(v_{t_0}) = J_{\frac{1}{t_0},s}(v_{t_0}) \leq h_2(t_0) = 0 \tag{5.5}$$

for any $r \geq \frac{1}{t_0}$ and $s \in \left[\frac{1}{2}, 1\right]$. There exists $0 < t_1 < t_\Theta$ such that for any $t \in [0, t_1]$,

$$h_2(t) < \frac{N(q-2)-4}{4} \left(\frac{2\left(1 - \|V_-\|_{\frac{N}{2}} S\right)}{N(q-2)}\right)^{\frac{N(q-2)}{N(q-2)-4}} A^{\frac{4}{4-N(q-2)}} \Theta^{\frac{N(q-2)-2q}{N(q-2)-4}}. \tag{5.6}$$

On the other hand, it follows from (3.5), the Gagliardo–Nirenberg inequality and the Hölder inequality that

$$\begin{aligned} J_{r,s}(u) \geq{}& \frac{1}{2}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right) \int_{\Omega_r} |\nabla u|^2 dx - \frac{C_{N,q}\Theta^{\frac{2q-N(q-2)}{4}}}{q} \left(\int_{\Omega_r} |\nabla u|^2 dx\right)^{\frac{N(q-2)}{4}} \\ &- \alpha\beta C_{N,p_1} \Theta^{\frac{2p_1-N(p_1-2)}{4}} \left(\int_{\Omega_r} |\nabla u|^2 dx\right)^{\frac{N(p_1-2)}{4}}. \end{aligned} \tag{5.7}$$

Define

$$
\begin{aligned}
g_1(t) &:= \frac{1}{2}\left(1-\|V_-\|_{\frac{N}{2}} S^{-1}\right) t - \frac{C_{N,q}\Theta^{\frac{2q-N(q-2)}{4}}}{q} t^{\frac{N(q-2)}{4}} - \alpha\beta C_{N,p_1}\Theta^{\frac{2p_1-N(p_1-2)}{4}} t^{\frac{N(p_1-2)}{4}} \\
&= t^{\frac{N(p_1-2)}{4}}\left[\frac{1}{2}\left(1-\|V_-\|_{\frac{N}{2}} S^{-1}\right) t^{\frac{4-N(p_1-2)}{4}} - \frac{C_{N,q}\Theta^{\frac{2q-N(q-2)}{4}}}{q} t^{\frac{N(q-p_1)}{4}}\right] \\
&\quad - \alpha\beta C_{N,p_1}\Theta^{\frac{2p_1-N(p_1-2)}{4}} t^{\frac{N(p_1-2)}{4}}.
\end{aligned}
$$

In view of $2<p<2+\frac{2}{N}<q<2^*$ and the definition of $\widetilde{\Theta}_V$, there exist $0<l_1<l_M<l_2$ such that $g_1(t)<0$ for any $0<t<l_1$ and $t>l_2$, $g_1(t)>0$ for $l_1<t<l_2$ and $g_1(l_M)=\max\limits_{t\in\mathbb{R}^+} g_1(t)>0$. Let

$$
t_2=\left(\frac{\alpha\beta q C_{N,p_1}(p_1-2)(4-N(p_1-2))}{C_{N,q}(q-2)(N(q-2)-4)}\right)^{\frac{4}{N(q-p_1)}}\Theta^{\frac{N-2}{N}}.
$$

Then by a direct calculation, we have $g_1''(t)\le 0$ if and only if $t\ge t_2$. Hence

$$
\max_{t\in\mathbb{R}^+} g_1(t)=\max_{t\in[t_2,\infty)} g_1(t).
$$

Note that for any $t\ge t_2$,

$$
\begin{aligned}
g_1(t) &= \frac{1}{2}\left(1-\|V_-\|_{\frac{N}{2}} S^{-1}\right) t - \frac{C_{N,q}\Theta^{\frac{2q-N(q-2)}{4}}}{q} t^{\frac{N(q-2)}{4}} - \alpha\beta C_{N,p_1}\Theta^{\frac{2p_1-N(p_1-2)}{4}} t^{\frac{N(p_1-2)}{4}} \\
&= \frac{1}{2}\left(1-\|V_-\|_{\frac{N}{2}} S^{-1}\right) t - \alpha\beta C_{N,p_1}\Theta^{\frac{(q-p_1)(N-2)}{4}}\cdot\Theta^{\frac{2q-N(q-2)}{4}} t^{\frac{N(p_1-2)}{4}} \\
&\quad - \frac{C_{N,q}\Theta^{\frac{2q-N(q-2)}{4}}}{q} t^{\frac{N(q-2)}{4}} \\
&\ge \frac{1}{2}\left(1-\|V_-\|_{\frac{N}{2}} S^{-1}\right) t - \left(\frac{C_{N,q}(q-2)(N(q-2)-4)}{q(p_1-2)(4-N(p_1-2))}+\frac{C_{N,q}}{q}\right)\Theta^{\frac{2q-N(q-2)}{4}}\cdot t^{\frac{N(q-2)}{4}} \\
&=: g_2(t). \qquad (5.8)
\end{aligned}
$$

Now, we will determine the value of $\widetilde{\Theta}_V$. In fact, $g_1(l_M)=\max_{t\in\mathbb{R}^+} g_1(t)>0$ as long as $g_2(t_2)>0$, that is,

$$
\begin{aligned}
g_2(t_2) &= \frac{1}{2}\left(1-\|V_-\|_{\frac{N}{2}} S^{-1}\right)\left(\frac{\alpha\beta q C_{N,p_1}}{C_{N,q}A_{p_1,q}}\right)^{\frac{4}{N(q-p_1)}}\Theta^{\frac{N-2}{N}} - \left(\frac{C_{N,q}}{q}A_{p_1,q}+\frac{C_{N,q}}{q}\right)\cdot\Theta \\
&\quad \cdot\left(\frac{\alpha\beta q C_{N,p_1}}{C_{N,q}A_{p_1,q}}\right)^{\frac{q-2}{q-p_1}} \\
&> 0,
\end{aligned}
$$

where

$$
A_{p_1,q}=\frac{(q-2)(N(q-2)-4)}{(p_1-2)(4-N(p_1-2))}.
$$

Hence, we take

$$
\widetilde{\Theta}_V=\frac{1}{2}\left(1-\|V_-\|_{\frac{N}{2}} S^{-1}\right)^{\frac{N}{2}}\left(\frac{C_{N,q}}{q}A_{p_1,q}+\frac{C_{N,q}}{q}\right)^{-\frac{N}{2}}\left(\frac{\alpha\beta q C_{N,p_1}}{C_{N,q}A_{p_1,q}}\right)^{\frac{N(q-2)-4}{2N(q-p_1)}}.
$$

Let

$$A = \left(\frac{C_{N,q}(q-2)(N(q-2)-4)}{q(p_1-2)(4-N(p_1-2))} + \frac{C_{N,q}}{q} \right)$$

and

$$t_g = \left[\frac{2\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)}{N(q-2)A} \right]^{\frac{4}{N(q-2)-4}} \Theta^{\frac{N(q-2)-2q}{N(q-2)-4}},$$

so that $t_g > t_2$ by the definition of $\widetilde{\Theta}_V$, $\max_{t \in [t_2, \infty)} g_2(t) = g_2(t_g)$ and

$$\begin{aligned} \max_{t \in \mathbb{R}^+} g_1(t) &\geq \max_{t \in [t_2, \infty)} g_2(t) \\ &= \frac{(N(q-2)-4)}{4} \left[\frac{2\left(1 - \|V_-\|_{\frac{N}{2}} S\right)}{N(q-2)} \right]^{\frac{N(q-2)}{N(q-2)-4}} A^{\frac{4}{4-N(q-2)}} \Theta^{\frac{N(q-2)-2q}{N(q-2)-4}}. \end{aligned}$$

Set $\bar{r}_\Theta = \max\left\{\frac{1}{t_1}, \sqrt{\frac{2\theta\Theta}{t_g}}\right\}$, then $v_{\frac{1}{\bar{r}_\Theta}} \in S_{r,\Theta}$ for any $r > \bar{r}_\Theta$, and

$$\left\| \nabla v_{\frac{1}{\bar{r}_\Theta}} \right\|_2^2 = \left(\frac{1}{\bar{r}_\Theta} \right)^2 \|\nabla v_1\|_2^2 < t_g = \left[\frac{2\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)}{N(q-2)A} \right]^{\frac{4}{N(q-2)-4}} \Theta^{\frac{N(q-2)-2q}{N(q-2)-4}}. \tag{5.9}$$

Moreover,

$$J_{\bar{r}_\Theta,s}\left(v_{\frac{1}{\bar{r}_\Theta}}\right) \leq h_2\left(\frac{1}{\bar{r}_\Theta}\right) \leq h_2(t_1). \tag{5.10}$$

Let $u^0 = v_{\frac{1}{\bar{r}_\Theta}}, u^1 = v_{t_0}$ and

$$\widetilde{r}_\Theta = \max\left\{ \frac{1}{t_0}, \bar{r}_\Theta \right\}.$$

Then the statement (i) holds by (5.5), (5.6), (5.9), (5.10).

(ii) holds by (5.8) and a direct calculation.

(iii) In view of $J_{r,s}(u^1) \leq 0$ for any $\gamma \in \Gamma_{r,\Theta}$ and the definition of t_0, we have

$$\|\nabla\gamma(0)\|_2^2 < t_g < \|\nabla\gamma(1)\|_2^2.$$

It then follows from (5.8) that

$$\begin{aligned} \max_{t \in [0,1]} J_{r,s}(\gamma(t)) &\geq g_2(t_g) \\ &= \frac{N(q-2)-4}{4} \left[\frac{2\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)}{N(q-2)} \right]^{\frac{N(q-2)}{N(q-2)-4}} A^{\frac{4}{4-N(q-2)}} \Theta^{\frac{N(q-2)-2q}{N(q-2)-4}} \end{aligned}$$

for any $\gamma \in \Gamma_{r,\Theta}$, hence the first inequality in (iii) holds. We define a path $\gamma : [0,1] \to S_{r,\Theta}$ by

$$\gamma(t) : \Omega_r \to \mathbb{R}, \qquad x \mapsto \left(\tau t_0 + (1-\tau)\frac{1}{\widetilde{r}_\Theta} \right)^{\frac{N}{2}} v_1\left(\left(\tau t_0 + (1-\tau)\frac{1}{\widetilde{r}_\Theta} \right) x \right).$$

Then $\gamma \in \Gamma_{r,\Theta}$, and the second inequality in (iii) follows from (5.4). □

Lemma 5.2. *Assume* $0 < \Theta < \widetilde{\Theta}_V$ *where* $\widetilde{\Theta}_V$ *is given in Theorem 1.5. Let* $r > \widetilde{r}_\Theta$*, where* $\widetilde{r}_\Theta$ *is defined in Lemma 5.1. Then problem (5.1) admits a solution* $(\lambda_{r,s}, u_{r,s})$ *for almost every* $s \in \left[\frac{1}{2}, 1\right]$*. Moreover, there hold* $u_{r,s} > 0$ *and* $J_{r,s}(u_{r,s}) = m_{r,s}(\Theta)$*.*

Proof. The proof is similar to the Lemma 3.3. We omit it here. □

Lemma 5.3. *For fixed* $\Theta > 0$ *the set of solutions* $u \in S_{r,\Theta}$ *of (5.1) is bounded uniformly in* s *and* r*.*

Proof. Since u is a solution of (5.1), we have

$$\int_{\Omega_r} |\nabla u|^2 dx + \int_{\Omega_r} V u^2 dx = s \int_{\Omega_r} |u|^q dx + s\beta \int_{\Omega_r} f(u) u dx - \lambda \int_{\Omega_r} |u|^2 dx.$$

The Pohozaev identity implies

$$\begin{aligned}\frac{N-2}{2N} \int_{\Omega_r} |\nabla u|^2 dx &+ \frac{1}{2N} \int_{\partial\Omega_r} |\nabla u|^2 (x \cdot \mathbf{n}) d\sigma + \frac{1}{2N} \int_{\Omega_r} \widetilde{V}(x) u^2 + \frac{1}{2} \int_{\Omega_r} V u^2 dx \\ &= -\frac{\lambda}{2} \int_{\Omega_r} |u|^2 dx + \frac{s}{q} \int_{\Omega_r} |u|^q dx + s\beta \int_{\Omega_r} F(u) dx.\end{aligned}$$

It then follows from $\beta > 0$ and (f_2) that

$$\begin{aligned}\frac{1}{N} \int_{\Omega_r} |\nabla u|^2 dx &- \frac{1}{2N} \int_{\partial\Omega_r} |\nabla u|^2 (x \cdot \mathbf{n}) d\sigma - \frac{1}{2N} \int_{\Omega_r} (\nabla V \cdot x) u^2 dx \\ &= \frac{(q-2)s}{2q} \int_{\Omega_r} |u|^q dx + s \int_{\Omega_r} \left(\frac{\beta}{2} f(u) u - \beta F(u)\right) dx \\ &\geq \frac{q-2}{2} \left(\frac{1}{2} \int_{\Omega_r} |\nabla u|^2 dx + \frac{1}{2} \int_{\Omega_r} V u^2 dx - m_{r,s}(\Theta) \right) + s \frac{\beta(p_2 - q)}{2} \int_{\Omega_r} F(u) dx.\end{aligned}$$

Using Gagliardo–Nirenberg inequality, (3.5) and (iii) in Lemma 5.1, we have

$$\begin{aligned}\frac{q-2}{2} m_{r,s}(\Theta) \geq{}& \frac{N(p_2-2)-4}{4N} \int_{\Omega_r} |\nabla u|^2 dx - \Theta \left(\frac{1}{2N} \|\nabla V \cdot x\|_\infty + \frac{p_2 - 2}{4} \|V\|_\infty \right) \\ &+ \frac{s\alpha\beta(p_2-q)}{2} C_{N,p_1} \Theta^{\frac{2p_1 - N(p_1-2)}{4}} \left(\int_{\Omega_r} |\nabla u|^2 dx \right)^{\frac{N(p_1-2)}{4}}.\end{aligned}$$

Since $2 < p_1 < 2 + \frac{4}{N}$, we can bound $\int_{\Omega_r} |\nabla u|^2 dx$ uniformly in s and r. □

Lemma 5.4. *Assume* $0 < \Theta < \widetilde{\Theta}_V$*, where* $\widetilde{\Theta}_V$ *is given in Theorem 1.5, and let* $r > \widetilde{r}_\Theta$*, where* $\widetilde{r}_\Theta$ *is defined in Lemma 5.1. Then the following hold:*

(i) Equation (2.1) admits a solution $(\lambda_{r,\Theta}, u_{r,\Theta})$ *for every* $r > \widetilde{r}_\Theta$ *such that* $u_{r,\Theta} > 0$ *in* Ω_r*.*

(ii) There is $0 < \bar{\Theta} \leq \widetilde{\Theta}_V$ *such that*

$$\liminf_{r \to \infty} \lambda_{r,\Theta} > 0 \quad \textit{for any } 0 < \Theta < \bar{\Theta}.$$

Proof. The proof of (i) is similar to that of Lemma 3.5, we omit it. As be consider $H_0^1(\Omega_r)$ as a subspace of $H^1(\mathbb{R}^N)$ for every $r > 0$. In view of Lemma 5.3, there are λ_Θ and $u_\Theta \in H^1(\mathbb{R}^N)$ such that, up to a subsequence,

$$u_{r,\Theta} \rightharpoonup u_\Theta \quad \text{in } H^1(\mathbb{R}^N) \quad \text{and} \quad \lim_{r \to \infty} \lambda_{r,\Theta} \to \lambda_\Theta.$$

Arguing by contradiction, we assume that $\lambda_{\Theta_n} \le 0$ for some sequence $\Theta_n \to 0$. Let θ_r be the principal eigenvalue of $-\Delta$ with Dirichlet boundary condition in Ω_r and let $v_r > 0$ be the corresponding normalized eigenfunction. Testing (2.1) with v_r, it holds

$$(\theta_r + \lambda_{r,\Theta_n}) \int_{\Omega_r} u_{r,\Theta_n} v_r dx + \int_{\Omega_r} V u_{r,\Theta_n} v_r dx \ge 0.$$

In view of $\int_{\Omega_r} u_{r,\Theta_n} v_r dx > 0$ and $\theta_r = r^{-2}\theta_1$, there holds

$$\max_{x\in\mathbb{R}^N} V + \lambda_{r,\Theta_n} + r^{-2}\theta_1 \ge 0.$$

Hence there exists $C > 0$ independent of n such that $|\lambda_{\Theta_n}| \le C$ for any n.

Case 1. There is subsequence denoted still by $\{\Theta_n\}$ such that $u_{\Theta_n} = 0$. We first claim that there exists $d_n > 0$ for any n such that

$$\liminf_{r\to\infty} \sup_{z\in\mathbb{R}^N} \int_{B(z,1)} u^2_{r,\Theta_n} dx \ge d_n. \tag{5.11}$$

Otherwise, the concentration compactness principle implies for every n that

$$u_{r,\Theta_n} \to 0 \text{ in } L^t(\mathbb{R}^N) \quad \text{as } r \to \infty, \quad \text{for all } 2 < t < 2^*.$$

By the diagonal principle, (2.1) and $|\lambda_{r,\Theta_n}| \le 2C$ for large r, there exists $r_n \to \infty$ such that

$$\int_{\Omega_r} |\nabla u_{r_n,\Theta_n}|^2 dx \le C$$

for some C independent of n, contradicting (iii) in Lemma 5.1 for large n. As a consequence (5.11) holds, and there is $z_{r,\Theta_n} \in \Omega_r$ with $|z_{r,\Theta_n}| \to \infty$ such that

$$\int_{B(z_{r,\Theta_n},1)} u^2_{r,\Theta_n} dx \ge \frac{d_n}{2}.$$

Moreover, dist $(z_{r,\Theta_n}, \partial\Omega_r) \to \infty$ as $r \to \infty$ by an argument similar to that in Lemma 3.7. Now, for n fixed let $v_r(x) = u_{r,\Theta_n}(x + z_{r,\Theta_n})$ for $x \in \Sigma^r := \{x \in \mathbb{R}^N : x + z_{r,\Theta_n} \in \Omega_r\}$. It follows from Lemma 5.3 that there is $v \in H^1(\mathbb{R}^N)$ with $v \ne 0$ such that $v_r \rightharpoonup v$. Observe that for every $\phi \in C_c^\infty(\mathbb{R}^N)$ there is r large such that $\phi(\cdot - z_{r,\Theta_n}) \in C_c^\infty(\Omega_r)$ due to dist $(z_{r,\Theta_n}, \partial\Omega_r) \to \infty$ as $r \to \infty$. It follows that

$$\begin{aligned}\int_{\Omega_r} \nabla u_{r,\Theta_n} \nabla\phi(\cdot - z_{r,\Theta_n}) dx + \int_{\Omega_r} V u_{r,\Theta_n}\phi(\cdot - z_{r,\Theta_n}) dx + \lambda_{r,\Theta_n}\int_{\Omega_r} u_{r,\Theta_n}\phi(\cdot - z_{r,\Theta_n}) dx \\ = \int_{\Omega_r} |u_{r,\Theta_n}|^{q-2} u_{r,\Theta_n}\phi(\cdot - z_{r,\Theta_n}) dx + \beta\int_{\Omega_r} f(u_{r,\Theta_n})\phi(\cdot - z_{r,\Theta_n}) dx.\end{aligned} \tag{5.12}$$

Using $|z_{r,\Theta_n}| \to \infty$ as $r \to \infty$, it follows that

$$\begin{aligned}\left|\int_{\Omega_r} V u_{r,\Theta_n}\phi(\cdot - z_{r,\Theta_n}) dx\right| &\le \int_{\operatorname{Supp}\phi} |V(\cdot + z_{r,\Theta_n}) v_r\phi| dx \\ &\le \|v_r\|_{2^*}\|\phi\|_{2^*}\left(\int_{\mathbb{R}^N\setminus B_{\frac{|z_{r,\Theta_n}|}{2}}} |V|^{\frac{N}{2}} dx\right)^{\frac{2}{N}} \\ &\to 0 \quad \text{as } r \to \infty.\end{aligned}$$

Letting $r \to \infty$ in (5.12), we get for every $\phi \in C_c^\infty(\mathbb{R}^N)$:

$$\int_{\mathbb{R}^N} \nabla v \cdot \nabla \phi dx + \lambda_{\Theta_n} \int_{\mathbb{R}^N} v\phi dx = \int_{\mathbb{R}^N} |v|^{q-2} v\phi dx + \beta \int_{\mathbb{R}^N} f(v)\phi dx.$$

Therefore $v \in H^1(\mathbb{R}^N)$ is a weak solution of the equation

$$-\Delta v + \lambda_{\Theta_n} v = \beta f(v) + |v|^{q-2} v \quad \text{in } \mathbb{R}^N$$

and

$$\int_{\mathbb{R}^N} |\nabla v|^2 dx + \lambda_{\Theta_n} \int_{\mathbb{R}^N} |v|^2 dx = \beta \int_{\mathbb{R}^N} f(v) v dx + \int_{\mathbb{R}^N} |v|^q dx.$$

The Pohozaev identity implies

$$\frac{N-2}{2N} \int_{\mathbb{R}^N} |\nabla v|^2 dx + \frac{\lambda_{\Theta_n}}{2} \int_{\mathbb{R}^N} |v|^2 dx = \beta \int_{\mathbb{R}^N} F(v) dx + \frac{1}{q} \int_{\mathbb{R}^N} |v|^q dx,$$

hence

$$\begin{aligned} &\frac{\lambda_{\Theta_n}}{N} \int_{\mathbb{R}^N} |v|^2 dx \\ &\quad = \frac{\beta(N-2)}{2N} \int_{\mathbb{R}^N} \left[\frac{2N}{N-2} F(v) - f(v) v \right] dx + \frac{2N - q(N-2)}{2Nq} \int_{\mathbb{R}^N} |v|^q dx \\ &\quad \geq \frac{\beta(N-2)}{2N} \left(\frac{2N}{N-2} - p_1 \right) \int_{\mathbb{R}^N} F(v) dx + \frac{2N - q(N-2)}{2Nq} \int_{\mathbb{R}^N} |v|^q dx. \end{aligned} \tag{5.13}$$

We have $\lambda_{\Theta_n} > 0$ because of $2 < p_1 < 2 + \frac{4}{N} < q < 2^*$, which is a contradiction.

Case 2. $u_{\Theta_n} \neq 0$ for n large. Note that u_{Θ_n} satisfies

$$-\Delta u_{\Theta_n} + V u_{\Theta_n} + \lambda_{\Theta_n} u_{\Theta_n} = \beta f(u_{\Theta_n}) + |u_{\Theta_n}|^{q-2} u_{\Theta_n}. \tag{5.14}$$

If $v_{r,\Theta_n} := u_{r,\Theta_n} - u_{\Theta_n}$ satisfies

$$\limsup_{r \to \infty} \max_{z \in \mathbb{R}^N} \int_{B(z,1)} v_{r,\Theta_n}^2 dx = 0, \tag{5.15}$$

then the concentration compactness principle implies $u_{r,\Theta_n} \to u_{\Theta_n}$ in $L^t(\mathbb{R}^N)$ for any $2 < t < 2^*$. It then follows from (2.1) and (5.14) that

$$\begin{aligned} \int_{\Omega_r} |\nabla u_{r,\Theta_n}|^2 dx + \Theta_n \lambda_{r,\Theta_n} &= \beta \int_{\Omega_r} f(u_{r,\Theta_n}) u_{r,\Theta_n} dx + \int_{\Omega_r} |u_{r,\Theta_n}|^q dx - \int_{\Omega_r} V u_{r,\Theta_n}^2 dx \\ &\to \beta \int_{\mathbb{R}^N} f(u_{\Theta_n}) u_{r,\Theta_n} dx + \int_{\mathbb{R}^N} |u_{\Theta_n}|^q dx - \int_{\mathbb{R}^N} V u_{\Theta_n}^2 dx \\ &= \int_{\mathbb{R}^N} |\nabla u_{\Theta_n}|^2 dx + \lambda_{\Theta_n} \int_{\mathbb{R}^N} u_{\Theta_n}^2 dx. \end{aligned}$$

Using $\lambda_{r,\Theta_n} \to \lambda_{\Theta_n}$ as $r \to \infty$, we further have

$$\int_{\Omega_r} |\nabla u_{r,\Theta_n}|^2 dx + \Theta_n \lambda_{\Theta_n} \to \int_{\mathbb{R}^N} |\nabla u_{\Theta_n}|^2 dx + \lambda_{\Theta_n} \int_{\mathbb{R}^N} u_{\Theta_n}^2 dx \quad \text{as } r \to \infty. \tag{5.16}$$

Using (5.16), (iii) in Lemma 5.1 and $|\lambda_{\Theta_n}| \leq C$ for large n, there holds

$$\int_{\mathbb{R}^N} |\nabla u_{\Theta_n}|^2 dx \to \infty \quad \text{as } n \to \infty.$$

By (5.14) and the Pohozaev identity

$$\frac{N-2}{2N}\int_{\mathbb{R}^N}|\nabla u_{\Theta_n}|^2\,dx+\frac{1}{2N}\int_{\mathbb{R}^N}\widetilde{V}u_{\Theta_n}^2dx+\frac{1}{2}\int_{\mathbb{R}^N}V(x)u_{\Theta_n}^2dx+\frac{\lambda_\Theta}{2}\int_{\mathbb{R}^N}u_{\Theta_n}^2dx$$
$$=\frac{1}{q}\int_{\mathbb{R}^N}|u_{\Theta_n}|^q\,dx+\beta\int_{\mathbb{R}^N}F(u_{\Theta_n})dx.$$

It holds that

$$\begin{aligned}0&\le\frac{(2-q)\lambda_{\Theta_n}}{2q}\int_{\mathbb{R}^N}u_{\Theta_n}^2dx\\&\le\frac{(N-2)q-2N}{2Nq}\int_{\mathbb{R}^N}|\nabla u_{\Theta_n}|^2\,dx+\frac{\|\widetilde{V}\|_\infty}{2N}\Theta_n+\frac{(q-2)\|V\|_\infty}{2q}\Theta_n\\&\to-\infty\quad\text{as } n\to\infty.\end{aligned}$$

Therefore (5.15) cannot occur. Consequently there exist $d_n>0$ and $z_{r,\Theta_n}\in\Omega_r$ with $|z_{r,\Theta_n}|\to\infty$ as $r\to\infty$ such that

$$\int_{B(z_{r,\Theta_n},1)}v_{r,\Theta_n}^2dx>d_n.$$

Then $\widetilde{v}_{r,\Theta_n}:=v_{r,\Theta_n}(\cdot+z_{r,\Theta_n})\rightharpoonup\widetilde{v}_{\Theta_n}\neq 0$, and $\widetilde{v}_{\Theta_n}$ is a nonnegative solution of

$$-\Delta v+\lambda_{\Theta_n}v=\beta f(v)v+|v|^{q-2}v\quad\text{in }\mathbb{R}^N.$$

In fact, we have $\liminf_{r\to\infty}\operatorname{dist}(z_{r,\Theta_n},\partial\Omega_r)=\infty$ by the Liouville theorem on the half space. It follows from an argument similar to that of (5.13) that $\lambda_{\Theta_n}>0$ for large n, which is a contradiction. □

Proof of Theorem 1.5. The proof is a direct consequence of Lemma 5.4 and Lemma 3.6. □

6 Proof of Theorem 1.9

In this section we assume that the assumptions of Theorem 1.9 hold. Define the functional $\mathcal{I}_r:S_{r,\Theta}\to\mathbb{R}$ by

$$\mathcal{I}_r(u)=\frac{1}{2}\int_{\Omega_r}|\nabla u|^2dx+\frac{1}{2}\int_{\Omega_r}Vu^2dx-\frac{1}{2^*}\int_{\Omega_r}|u|^{2^*}dx-\beta\int_{\Omega_r}F(u)dx.\tag{6.1}$$

Note that if $u\in S_{r,\Theta}$ is a critical point of $\mathcal{I}_{r,s}$, then there exists $\lambda\in\mathbb{R}$ such that (λ,u) is a solution of the equation

$$\begin{cases}-\Delta u+Vu+\lambda u=|u|^{2^*-2}u+\beta f(u), & x\in\Omega_r,\\ \int_{\Omega_r}|u|^2dx=\Theta, u\in H_0^1(\Omega_r), & x\in\Omega_r.\end{cases}\tag{6.2}$$

Since $\beta>0$,

$$\begin{aligned}\mathcal{I}_r(u)\ge&\frac{1}{2}\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}\right)\int_{\Omega_r}|\nabla u|^2dx-\frac{1}{2^*\cdot S^{\frac{2^*}{2}}}\left(\int_{\Omega_r}|\nabla u|^2dx\right)^{\frac{2^*}{2}}\\&-\alpha\beta C_{N,p_1}\Theta^{\frac{2p_1-N(p_1-2)}{4}}\left(\int_{\Omega_r}|\nabla u|^2dx\right)^{\frac{N(p_1-2)}{4}}\\=&\widetilde{h}_1(t),\end{aligned}$$

where

$$\widetilde{h_1}(t) := \frac{1}{2}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right) t^2 - \frac{1}{2^* \cdot S^{\frac{2^*}{2}}} t^{2^*} - \alpha\beta C_{N,p_1} \Theta^{\frac{2p_1 - N(p_1-2)}{4}} t^{\frac{N(p_1-2)}{2}}.$$

Consider

$$\widehat{\psi}(t) := \frac{1}{2}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right) t^2 - \frac{1}{2^* \cdot S^{\frac{2^*}{2}}} t^{2^*}.$$

Note that $\widehat{\psi}$ admits a unique maximum at

$$\widehat{t} = \left[\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right) S^{\frac{2^*}{2}}\right]^{\frac{1}{2^*-2}}.$$

By a direct calculation, we obtain

$$\widehat{\psi}(\widehat{t}) = \frac{1}{N}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)^{\frac{N}{2}} S^{\frac{N}{2}}.$$

Hence,

$$\widehat{\psi}(\widehat{t}) > \alpha\beta C_{N,p_1} \Theta^{\frac{2p_1 - N(p_1-2)}{4}} \widehat{t}^{\frac{N(p_1-2)}{2}}$$

as long as

$$\Theta_V = \left(\frac{1}{N\alpha\beta C_{N,p_1}}\right)^{\frac{4}{2p_1 - N(p_1-2)}} \left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)^{\frac{N}{2}} S^{\frac{N}{2} \cdot \frac{4 - N(p_1-2)}{2p_1 - N(p_1-2)}}.$$

Now, let $0 < \Theta < \Theta_V$ be fixed, we obtain

$$\widehat{\psi}(\widehat{t}) > \alpha\beta C_{N,p_1} \Theta^{\frac{2p_1 - N(p_1-2)}{4}} \widehat{t}^{\frac{N(p_1-2)}{2}}$$

and $\widetilde{h_1}(\widehat{t}) > 0$. In view of $2 < p_1 < 2 + \frac{4}{N} < 2^*$, there exist $0 < \widetilde{R_1} < \widetilde{T_\Theta} < \widetilde{R_2}$ such that $\widetilde{h_1}(t) < 0$ for $0 < t < \widetilde{R_1}$ and for $t > \widetilde{R_2}$, $\widetilde{h_1}(t) > 0$ for $\widetilde{R_1} < t < \widetilde{R_2}$, and $\widetilde{h_1}(\widetilde{T_\Theta}) = \max_{t \in \mathbb{R}^+} \widetilde{h_1}(t) > 0$.

Define

$$\widetilde{\mathcal{V}}_{r,\Theta} = \left\{u \in S_{r,\Theta} : \|\nabla u\|_2^2 \le \widetilde{T_\Theta}^2\right\}.$$

Let θ be the principal eigenvalue of operator $-\Delta$ with Dirichlet boundary condition in Ω, and let $|\Omega|$ be the volume of Ω.

Lemma 6.1.

(i) If $r < \frac{\sqrt{C\Theta}}{\widetilde{T_\Theta}}$, then $\widetilde{\mathcal{V}}_{r,\Theta} = \emptyset$.

(ii) If

$$r > \max\left\{\frac{\sqrt{C\Theta}}{\widetilde{T_\Theta}}, \left(\frac{\theta\left(1 + \|V\|_{\frac{N}{2}} S^{-1}\right)}{2\alpha_1\beta} \Theta^{\frac{2-p_2}{2}} |\Omega|^{\frac{p_2-2}{2}}\right)^{\frac{2}{N(p_2-2)+4}}\right\}$$

then $\widetilde{\mathcal{V}}_{r,\Theta} \neq \emptyset$ and

$$\widetilde{e}_{r,\Theta} := \inf_{u \in \widetilde{\mathcal{V}}_{r,\Theta}} \mathcal{I}_r(u) < 0$$

is attained at some interior point $u_r > 0$ of $\widetilde{\mathcal{V}}_{r,\Theta}$. As a consequence, there exists a Lagrange multiplier $\lambda_r \in \mathbb{R}$ such that (λ_r, u_r) is a solution of (6.1). Moreover $\liminf_{r\to\infty} \lambda_r > 0$ holds true.

Proof. (i) The proof is similar to the Lemma 4.1. (ii) Let $v_1 \in S_{1,\Theta}$ be the positive normalized eigenfunction corresponding to θ. Setting

$$r_\Theta = \max\left\{\frac{\sqrt{C\Theta}}{\widetilde{T_\Theta}}, \left(\frac{\theta\left(1+\|V\|_{\frac{N}{2}}S^{-1}\right)}{2\alpha_1\beta}\Theta^{\frac{2-p_2}{2}}|\Omega|^{\frac{p_2-2}{2}}\right)^{\frac{2}{N(p_2-2)+4}}\right\}. \tag{6.3}$$

Now, we construct for $r > r_\Theta$ a function $u_r \in S_{r,\Theta}$ such that $u_r \in \widetilde{\mathcal{V}}_{r,\Theta}$ and $\mathcal{I}_r(u_r) < 0$. By (6.3), (4.3), (4.4), $2 < p_2 < 2 + \frac{4}{N}$ and a direct calculation, we have $u_r \in \widetilde{\mathcal{V}}_{r,\Theta}$ and

$$\begin{aligned}\mathcal{I}_r(u_r) &\leq \frac{1}{2}\int_{\Omega_r}|\nabla u_r|^2 dx + \frac{1}{2}\int_{\Omega_r} V u_r^2 dx - \frac{1}{2^*}\int_{\Omega_r}|u_r|^{2^*}dx - \alpha_1\beta\int_{\Omega_r}|u_r|^{p_2}dx\\ &\leq \frac{1}{2}\left(1+\|V\|_{\frac{N}{2}}S^{-1}\right) r^{-2}\theta\Theta - \alpha_1\beta r^{\frac{N(2-p_2)}{2}}\Theta^{\frac{p_2}{2}}|\Omega|^{\frac{2-p_2}{2}}\\ &< 0.\end{aligned}$$

It then follows from the Gagliardo–Nirenberg inequality that

$$\begin{aligned}\mathcal{I}_r(u_r) \geq{}& \frac{1}{2}\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}\right)\int_{\Omega_r}|\nabla u|^2dx - C_{N,p_1}\beta\Theta^{\frac{2p_1-N(p_1-2)}{4}}\left(\int_{\Omega_r}|\nabla u|^2dx\right)^{\frac{N(p_1-2)}{4}}\\ &- \frac{1}{2^*\cdot S^{\frac{2^*}{2}}}\left(\int_{\Omega_r}|\nabla u|^2dx\right)^{\frac{2^*}{2}}.\end{aligned} \tag{6.4}$$

As a consequence $\mathcal{I}_r$ is bounded from below in $\widetilde{\mathcal{V}}_{r,\Theta}$. By the Ekeland principle there exists a sequence $\{u_{n,r}\} \subset \widetilde{\mathcal{V}}_{r,\Theta}$ such that

$$\mathcal{I}_r(u_{n,r}) \to \inf_{u\in\widetilde{\mathcal{V}}_{r,\Theta}} \mathcal{I}_r(u),\ \mathcal{I}_r'(u_{n,r})|_{T_{u_{n,r}}S_{r,\Theta}} \to 0 \quad \text{as } n\to\infty \tag{6.5}$$

Consequently there exists $u_r \in H_0^1(\Omega_r)$ such that

$$u_{n,r} \rightharpoonup u_r \quad \text{in } H_0^1(\Omega_r)$$

and

$$u_{n,r} \to u_r \quad \text{in } L^k(\Omega_r) \text{ for all } 2 \leq k < 2^*. \tag{6.6}$$

We claim now that the weak limit u_r does not vanish identically. Suppose by contradiction that $u_r \equiv 0$. Since $\{u_{n,r}\}$ is bounded in $H^1(\Omega_r)$, up to a subsequence we have that $\|\nabla u_{n,r}\|_2^2 \to \ell \in \mathbb{R}$. Using (f_2), (6.5), (6.6), we have

$$\begin{aligned}\langle \mathcal{I}_r'(u_{n,r}), u_{n,r}\rangle &= \int_{\Omega_r}|\nabla u_{n,r}|^2dx + \int_{\Omega_r}Vu_{n,r}^2dx - \int_{\Omega_r}|u_{n,r}|^{2^*}dx - \beta\int_{\Omega_r}f(u_{n,r})u_{n,r}dx\\ &\to 0,\end{aligned}$$

hence

$$\|u_{n,r}\|_{2^*}^{2^*} = \|\nabla u_{n,r}\|_2^2 \to \ell$$

as well. Therefore, by the Sobolev inequality $\ell \geq S\ell^{\frac{2}{2^*}}$, and we deduce that either $\ell = 0$, or $\ell \geq S^{\frac{N}{2}}$. Let us suppose at first that $\ell \geq S^{N/2}$. Since $\mathcal{I}_r(u_{n,r}) \to \tilde{e}_{r,\Theta} < 0$, we have that

$$\begin{aligned}0 > \tilde{e}_{r,\Theta} + o(1) &= I_r(u_{n,r})\\ &= \frac{1}{2}\int_{\Omega_r}|\nabla u_{n,r}|^2dx + \frac{1}{2}\int_{\Omega_r}Vu_{n,r}^2dx - \frac{1}{2^*}\int_{\Omega_r}|u_{n,r}|^{2^*}dx - \beta\int_{\Omega_r}F(u_{n,r})dx\\ &= \frac{1}{N}\|\nabla u_{n,r}\|_2^2 + o(1) = \frac{\ell}{N} + o(1),\end{aligned}$$

which is not possible. If instead $\ell = 0$, we have $\|u_{n,r}\|_{2^*} \to 0$, $\|\nabla u_{n,r}\|_2 \to 0$ and $F(u_{n,r}) \to 0$. But then $\mathcal{I}_r(u_{n,r}) \to 0 \neq \widetilde{e}_{r,\Theta}$, which gives again a contradiction. Thus, u_r does not vanish identically.

Since $\{u_{n,r}\}$ is a bounded minimization sequence for $\mathcal{I}_r(u_{n,r})|_{S_{r,\Theta}}$, there exists $\{\lambda_n\} \subset \mathbb{R}$ such that for every $\varphi \in H^1(\Omega_r)$,

$$\int_{\Omega_r} \nabla u_{n,r} \cdot \nabla \varphi + \int_{\Omega_r} V u_{n,r}\varphi + \lambda_n u_{n,r}\varphi - \beta f(u_{n,r})\varphi - |u_{n,r}|^{2^*-2} u_{n,r}\varphi = o(1)\|\varphi\| \tag{6.7}$$

as $n \to \infty$, by the Lagrange multipliers rule. Choosing $\varphi = u_{n,r}$, we deduce that $\{\lambda_n\}$ is bounded as well, and hence up to a subsequence $\lambda_n \to \lambda_r \in \mathbb{R}$. Moreover, passing to the limit in (6.7) by weak convergence, we obtain

$$-\Delta u_r + V u_r + \lambda_r u_r = |u_r|^{2^*-2} u_r + \beta f(u_r), \qquad x \in \Omega_r.$$

Recalling that $v_{n,r} = u_{n,r} - u_r \rightharpoonup 0$ in $H_0^1(\Omega_r)$, we know

$$\|\nabla u_{n,r}\|_2^2 = \|\nabla u_r\|_2^2 + \|\nabla v_{n,r}\|_2^2 + o(1).$$

By the Brézis–Lieb lemma [12], we have

$$\|u_{n,r}\|_{2^*}^{2^*} = \|u_r\|_{2^*}^{2^*} + \|v_{n,r}\|_{2^*}^{2^*} + o(1).$$

Moreover,

$$\|\nabla u_r\|_2^2 \le \liminf_{n\to\infty} \|\nabla u_{n,r}\|_2^2 \le \widetilde{T_\Theta}^2,$$

that is, $u_r \in \widetilde{\mathcal{V}}_{r,\Theta}$. Note that

$$\int_{\Omega_r} V u_{n,r}^2 dx \to \int_{\Omega_r} V u_r^2 dx \quad \text{as } n \to \infty,$$

hence

$$\|v_{n,r}\|_{2^*}^{2^*} = \|\nabla v_{n,r}\|_2^2 \to \ell$$

as well. Therefore, $\ell \ge S\ell^{\frac{2}{2^*}}$, and we deduce that either $\ell = 0$, or $\ell \ge S^{\frac{N}{2}}$. Let us suppose at first that $\ell \ge S^{N/2}$. Since $\mathcal{I}_r(v_{n,r}) \to 0$, we have that

$$\begin{aligned} o(1) &= \mathcal{I}_r(v_{n,r}) \\ &= \frac{1}{2}\int_{\Omega_r} |\nabla v_{n,r}|^2 dx + \frac{1}{2}\int_{\Omega_r} V v_{n,r}^2 dx - \frac{1}{2^*}\int_{\Omega_r} |v_{n,r}|^{2^*} dx - \beta \int_{\Omega_r} F(v_{n,r}) dx \\ &= \frac{1}{2}\|\nabla v_{n,r}\|_2^2 + o(1) = \frac{\ell}{N} + o(1), \end{aligned}$$

which is not possible. If instead $\ell = 0$, we have that $u_{n,r} \to u_r$ in $H_0^1(\Omega_r)$, so $\mathcal{I}_r(u_r) < 0$. Therefore u is an interior point of $\widetilde{\mathcal{V}}_{r,\Theta}$ because $\mathcal{I}_r(u) \ge \widetilde{h}_1(\widetilde{T_\Theta}) > 0$ for any $u \in \partial\widetilde{\mathcal{V}}_{r,\Theta}$ by (6.4). The Lagrange multiplier theorem implies that there exists $\lambda_r \in \mathbb{R}$ such that (λ_r, u_r) is a solution of (6.1). Moreover,

$$\begin{aligned} \lambda_r\Theta &= \int_{\Omega_r} |u_r|^{2^*} dx + \beta\int_{\Omega_r} f(u_r)u_r dx - \frac{2}{2^*}\int_{\Omega_r} |u_r|^{2^*} dx - 2\beta\int_{\Omega_r} F(u_r)dx - 2I_r(u_r) \\ &= \frac{2^*-2}{2^*}\int_{\Omega_r} |u_r|^{2^*} dx + \beta\int_{\Omega_r} [f(u_r)u_r - 2F(u_r)]dx - 2I_r(u_r) \\ &> -2\mathcal{I}_r(u_r) = -2\widetilde{e}_{r,\Theta}. \end{aligned} \tag{6.8}$$

It follows from the definition of $\widetilde{e}_{r,\Theta}$ that $\widetilde{e}_{r,\Theta}$ is nonincreasing with respect to r. Hence, $\widetilde{e}_{r,\Theta} \le \widetilde{e}_{r_\Theta,\Theta} < 0$ for any $r > r_\Theta$ and $0 < \Theta < \Theta_V$. In view of (6.8), we have

$$\liminf_{r\to\infty} \lambda_r > 0.$$

Finally, the strong maximum principle implies $u_r > 0$. □

Proof of Theorem 1.9. The proof is a direct consequence of Lemma 6.1 and Lemma 3.6. □

7 Proof of Theorem 1.10

In this subsection, we assume $\beta \le 0$ and the assumptions of Theorem 1.10 hold. Consider the following equation

$$\begin{cases} -\Delta u + Vu + \lambda u = |u|^{2^*-2}u + \beta f(u), & x \in \Omega_r, \\ \int_{\Omega_r} |u|^2 dx = \Theta, u \in H_0^1(\Omega_r), & x \in \Omega_r. \end{cases} \tag{7.1}$$

For $\frac{1}{2} \le s \le 1$, we define the functional $\mathcal{I}_{r,s} : S_{r,\Theta} \to \mathbb{R}$ by

$$\mathcal{I}_{r,s}(u) = \frac{1}{2}\int_{\Omega_r} |\nabla u|^2 dx + \frac{1}{2}\int_{\Omega_r} Vu^2 dx - \frac{s}{2^*}\int_{\Omega_r} |u|^{2^*} dx - \beta\int_{\Omega_r} F(u)dx. \tag{7.2}$$

Note that if $u \in S_{r,\Theta}$ is a critical point of $\mathcal{I}_{r,s}$, then there exists $\lambda \in \mathbb{R}$ such that (λ, u) is a solution of the equation

$$\begin{cases} -\Delta u + Vu + \lambda u = s|u|^{2^*-2}u + \beta f(u), & x \in \Omega_r, \\ \int_{\Omega_r} |u|^2 dx = \Theta, u \in H_0^1(\Omega_r), & x \in \Omega_r. \end{cases} \tag{7.3}$$

Lemma 7.1. *For any $\Theta > 0$, there exist $r_\Theta > 0$ and $u^0, u^1 \in S_{r_\Theta,\Theta}$ such that*

(i) $\mathcal{I}_{r,s}(u^1) \le 0$ *for any $r > r_\Theta$ and $s \in \left[\frac{1}{2}, 1\right]$,*

$$\|\nabla u^0\|_2^2 < \left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)^{\frac{N-2}{2}} S^{\frac{N}{2}} < \left\|\nabla u^1\right\|_2^2$$

and

$$\mathcal{I}_{r,s}\left(u^0\right) < \frac{1}{N}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)^{\frac{N}{2}} S^{\frac{N}{2}}.$$

(ii) If $u \in S_{r,\Theta}$ satisfies

$$\|\nabla u\|_2^2 = \left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)^{\frac{N-2}{2}} S^{\frac{N}{2}},$$

then there holds

$$\mathcal{I}_{r,s}(u) \ge \frac{1}{N}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)^{\frac{N}{2}} S^{\frac{N}{2}}.$$

(iii) Set

$$\widetilde{m}_{r,s}(\Theta) = \inf_{\gamma\in\widetilde{\Gamma}_{r,\Theta}} \sup_{t\in[0,1]} \mathcal{I}_{r,s}(\gamma(t))$$

with

$$\widetilde{\Gamma}_{r,\Theta} = \left\{\gamma \in C\left([0,1], S_{r,\Theta}\right) : \gamma(0) = u^0, \gamma(1) = u^1\right\}.$$

Then

$$\frac{1}{N}\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}\right)^{\frac{N}{2}}S^{\frac{N}{2}}\leq \widetilde{m}_{r,s}(\Theta)\leq \mathbf{h}(\mathbf{h}_\Theta),$$

where $\mathbf{h}(\mathbf{h}_\Theta)=\max_{t\in\mathbb{R}^+}h(t)$, *the function* $\mathbf{h}:\mathbb{R}^+\to\mathbb{R}$ *being defined by*

$$\mathbf{h}(t)=\frac{1}{2}\left(1+\|V\|_{\frac{N}{2}}S^{-1}\right)t^2\theta\Theta-\alpha\beta C_{N,p_1}\Theta^{\frac{p_1}{2}}\theta^{\frac{N(p_1-2)}{4}}t^{\frac{N(p_1-2)}{2}}-\frac{1}{2\cdot 2^*}t^{2^*}\Theta^{\frac{2^*}{2}}\cdot|\Omega|^{\frac{2-2^*}{2}}.$$

Here θ *is the principal eigenvalue of* $-\Delta$ *with Dirichlet boundary conditions in* Ω, *and* $|\Omega|$ *is the volume of* Ω.

Proof. (i) By the Hölder inequality,

$$\int_\Omega |v_1(x)|^{2^*}dx\geq \Theta^{\frac{2^*}{2}}\cdot|\Omega|^{\frac{2-2^*}{2}}. \tag{7.4}$$

For $x\in\Omega_{\frac{1}{t}}$ and $t>0$, define $v_t(x):=t^{\frac{N}{2}}v_1(tx)$. Using (3.3), (7.4), (3.5) and $\frac{1}{2}\leq s\leq 1$, it holds

$$\begin{aligned}\mathcal{I}_{\frac{1}{t},s}(v_t)&\leq \frac{1}{2}\left(1+\|V\|_{\frac{N}{2}}S^{-1}\right)t^2\theta\Theta-\alpha\beta C_{N,p_1}\Theta^{\frac{p_1}{2}}\theta^{\frac{N(p_1-2)}{4}}t^{\frac{N(p_1-2)}{2}}\\&\quad-\frac{1}{2\cdot 2^*}t^{\frac{N(2^*-2)}{2}}\Theta^{\frac{2^*}{2}}\cdot|\Omega|^{\frac{2-2^*}{2}}\\&=:\mathbf{h}(t).\end{aligned}\tag{7.5}$$

Note that since $2<p_1<2+\frac{4}{N}<q=2^*$ and $\beta\leq 0$ there exist $0<\mathbf{h}_\Theta<t_0$ such that $\mathbf{h}(t_0)=0, \mathbf{h}(t)<0$ for any $t>t_0, \mathbf{h}(t)>0$ for any $0<t<t_0$ and $\mathbf{h}(\mathbf{h}_\Theta)=\max_{t\in\mathbb{R}^+}\mathbf{h}(t)$. As a consequence, there holds

$$\mathcal{I}_{r,s}(v_{t_0})=\mathcal{I}_{\frac{1}{t_0},s}(v_{t_0})\leq \mathbf{h}(t_0)=0 \tag{7.6}$$

for any $r\geq\frac{1}{t_0}$ and $s\in\left[\frac{1}{2},1\right]$. Moreover, there exists $0<t_1<\mathbf{h}_\Theta$ such that

$$\mathbf{h}(t)<\frac{1}{N}\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}\right)^{\frac{N}{2}}S^{\frac{N}{2}} \tag{7.7}$$

for $t\in[0,t_1]$. On the other hand, it follows from the Sobolev inequality and the Hölder inequality that

$$\mathcal{I}_{r,s}(u)\ \geq\ \frac{1}{2}\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}\right)\int_{\Omega_r}|\nabla u|^2dx-\frac{1}{2^*\cdot S^{\frac{2^*}{2}}}\left(\int_{\Omega_r}|\nabla u|^2dx\right)^{\frac{2^*}{2}}. \tag{7.8}$$

Define

$$\mathbf{g}(t):=\frac{1}{2}\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}\right)t-\frac{1}{2^*\cdot S^{\frac{2^*}{2}}}t^{\frac{2^*}{2}}$$

and

$$\widetilde{t}=\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}\right)^{\frac{N-2}{2}}S^{\frac{N}{2}},$$

it is easy to see that $\mathbf{g}$ is increasing on $(0,\widetilde{t})$ and decreasing on $(\widetilde{t},\infty)$, and

$$\mathbf{g}(\widetilde{t})=\frac{1}{N}\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}\right)^{\frac{N}{2}}S^{\frac{N}{2}}.$$

For $r \geq \widetilde{r}_\Theta := \max\left\{\frac{1}{t_1}, \sqrt{\frac{2\theta\Theta}{\widetilde{t}}}\right\}$ we have $v_{\frac{1}{\widetilde{r}_\Theta}} \in S_{r,\Theta}$ and

$$\|\nabla v_{\frac{1}{\widetilde{r}_\Theta}}\|_2^2 = \left(\frac{1}{\widetilde{r}_\Theta}\right)^2 \|\nabla v_1\|_2^2 < \left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)^{\frac{N-2}{2}} S^{\frac{N}{2}}. \tag{7.9}$$

Moreover, there holds

$$\mathcal{I}_{\widetilde{r}_\Theta,s}\left(v_{\frac{1}{\widetilde{r}_\Theta}}\right) \leq \mathbf{h}\left(\frac{1}{\widetilde{r}_\Theta}\right) \leq \mathbf{h}\left(t_1\right). \tag{7.10}$$

Setting $u^0 = v_{\frac{1}{\widetilde{r}_\Theta}}, u^1 = v_{t_0}$ and

$$r_\Theta = \max\left\{\frac{1}{t_0}, \widetilde{r}_\Theta\right\}. \tag{7.11}$$

Since (7.6), (7.7), (7.8) and (7.9), then (i) holds.

(ii) By (7.8) and a direct calculation, (ii) holds.

(iii) Since $\mathcal{I}_{r,s}\left(u^1\right) \leq 0$ for any $\gamma \in \Gamma_{r,\Theta}$, we have

$$\|\nabla\gamma(0)\|_2^2 < \widetilde{t} < \|\nabla\gamma(1)\|_2^2.$$

It then follows from (7.8) that

$$\max_{t\in[0,1]} \mathcal{I}_{r,s}(\gamma(t)) \geq \mathbf{g}(\widetilde{t}) = \frac{1}{N}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)^{\frac{N}{2}} S^{\frac{N}{2}}$$

for any $\gamma \in \widetilde{\Gamma}_{r,\Theta}$, hence the first inequality in (iii) holds. Now we define a path $\gamma \in \widetilde{\Gamma}_{r,\Theta}$ by

$$\gamma(\tau)(x) = \left(\tau t_0 + (1-\tau)\frac{1}{\widetilde{r}_\Theta}\right)^{\frac{N}{2}} v_1\left(\left(\tau t_0 + (1-\tau)\frac{1}{\widetilde{r}_\Theta}\right)x\right)$$

for $\tau \in [0,1]$ and $x \in \Omega_r$. Then by (7.5) we have $\widetilde{m}_{r,s}(\Theta) \leq \mathbf{h}(\mathbf{h}_\Theta)$, where $\mathbf{h}(\mathbf{h}_\Theta) = \max_{t\in\mathbb{R}^+} \mathbf{h}(t)$. Note that $\mathbf{h}_\Theta$ is independent of r and s. □

Using Proposition 3.2 to $\mathcal{I}_{r,s}$, it follows that

$$A(u) = \frac{1}{2}\int_{\Omega_r} |\nabla u|^2 dx + \frac{1}{2}\int_{\Omega_r} V(x)u^2 dx - \beta\int_{\Omega_r} F(u)dx \quad \text{and} \quad B(u) = \frac{1}{2^*}\int_{\Omega_r} |u|^{2^*} dx.$$

Hence, for almost every $s \in \left[\frac{1}{2}, 1\right]$, there exists a bounded Palais–Smale sequence $\{u_n\}$ satisfying

$$\mathcal{I}_{r,s}\left(u_n\right) \to \widetilde{m}_{r,s}(\Theta) \quad \text{and} \quad \mathcal{I}'_{r,s}\left(u_n\right)|_{T_{u_n}S_{r,\Theta}} \to 0.$$

Next, we are devoted to proving compactness.

Lemma 7.2. *If $\beta \leq 0$ and the assumptions of Theorem 1.10 hold, then $\widetilde{m}_{r,s}(\Theta) < \frac{\zeta}{N} S^{\frac{N}{2}}$, where $\zeta = s^{-\frac{2}{2^*-2}}$.*

Proof. Let U_ε be defined by $U_\varepsilon(x) := \left(\frac{\varepsilon}{\varepsilon^2+|x|^2}\right)^{\frac{N-2}{2}}$ (up to a scalar factor, U_ε is the bubble centered in the origin, with concentration parameter $\varepsilon > 0$, defined in (1.3)). Let also $\varphi \in C_c^\infty(\Omega_r)$ be a radial cut-off function with $\varphi \equiv 1$ in $B_1, \varphi \equiv 0$ in B_2^c, and φ radially decreasing. We define

$$u_\varepsilon(x) := \varphi(x)U_\varepsilon(x), \quad \text{and} \quad v_\varepsilon(x) := \sqrt{\Theta}\frac{u_\varepsilon(x)}{\|u_\varepsilon\|_2}.$$

Notice that $u_\varepsilon \in C_c^\infty(\Omega_r)$, and $v_\varepsilon \in S_{r,\Theta}$. Let us recall the following useful estimates (see [27, Lemma A.1]):

$$\|\nabla u_\varepsilon\|_2^2 = K_1 + O\left(\varepsilon^{N-2}\right), \tag{7.12}$$

$$\|u_\varepsilon\|_{2^*}^2 = \begin{cases} K_2 + O\left(\varepsilon^N\right), & \text{if } N \geq 4, \\ K_2 + O\left(\varepsilon^2\right), & \text{if } N = 3, \end{cases} \tag{7.13}$$

$$\|u_\varepsilon\|_2^2 = \begin{cases} \varepsilon^2 K_3 + O\left(\varepsilon^{N-2}\right), & \text{if } N \geq 5, \\ \omega\varepsilon^2|\log\varepsilon| + O\left(\varepsilon^2\right), & \text{if } N = 4, \\ \omega\left(\int_0^2 \varphi(r)dr\right)\varepsilon + O\left(\varepsilon^2\right), & \text{if } N = 3, \end{cases} \tag{7.14}$$

$$\|u_\varepsilon\|_q^q = \varepsilon^{N-\frac{N-2}{2}q}\left(K_4 + O\left(\varepsilon^{(N-2)q-N}\right)\right)$$
$$\text{if } N \geq 4 \text{ and } q \in (2, 2^*), \text{ and if } N = 3 \text{ and } q \in (3, 6). \tag{7.15}$$

as $\varepsilon \to 0$. Since U_ε is extremal for the Sobolev inequality, we have that $\frac{K_1}{K_2} = S$. Therefore, using $\frac{1}{2} \leq s \leq 1$, we have

$$\begin{aligned}\mathcal{I}_{r,s}(tv_\varepsilon) &\leq \frac{t^2}{2}\int_{\Omega_r}|\nabla v_\varepsilon|^2dx + \frac{t^2}{2}\int_{\Omega_r}Vv_\varepsilon^2dx - \frac{st^{2^*}}{2^*}\int_{\Omega_r}|v_\varepsilon|^{2^*}dx - \alpha\beta t^{p_1}\int_{\Omega_r}|v_\varepsilon|^{p_1}dx \\ &=: h_3(t).\end{aligned}$$

Clearly, $h_3(t) > 0$ for $t > 0$ small and $h_3(t) \to -\infty$ as $t \to \infty$, so $h_3(t)$ attains its maximum at some $t_\varepsilon > 0$ with $h_3'(t_\varepsilon) = 0$. Then, observing that the function

$$t \mapsto \frac{t^2}{2}\int_{\Omega_r}|\nabla v_\varepsilon|^2dx + \frac{t^2}{2}\int_{\Omega_r}Vv_\varepsilon^2dx - \frac{st^{2^*}}{2^*}\int_{\Omega_r}|v_\varepsilon|^{2^*}dx - \alpha\beta t^{p_1}\int_{\Omega_r}|v_\varepsilon|^{p_1}dx$$

is increasing on the interval of

$$\left[0, \left[\frac{-2^*\alpha\beta(p_1-2)\|v_\varepsilon\|_{p_1}^{p_1}}{s(2^*-2)\|v_\varepsilon\|_{2^*}^{2^*}}\right]^{\frac{1}{2^*-p_1}}\right].$$

This fact combined with (7.12)-(7.15) implies that there exist $\delta_1, \delta_2 > 0$, independent of $\varepsilon > 0$, such that

$$\delta_1 \leq t_\varepsilon \leq \delta_2.$$

Moreover, observing that the function

$$t \mapsto \frac{t^2}{2}\int_{\Omega_r}|\nabla v_\varepsilon|^2dx - \frac{st^{2^*}}{2^*}\int_{\Omega_r}|v_\varepsilon|^{2^*}dx$$

is increasing on the interval of

$$\left[0, \left(\frac{\|\nabla v_\varepsilon\|_2^2}{s\|v_\varepsilon\|_{2^*}^{2^*}}\right)^{\frac{1}{2^*-2}}\right].$$

Using (7.12)–(7.15) and the fact that $\frac{K_1}{K_2} = S$, if $N = 3$, the same estimate holds eventually, using $\|u_\varepsilon\|_{2^*}^2 = K_2 + O(\varepsilon^2)$ instead of $\|u_\varepsilon\|_{2^*}^2 = K_2 + O(\varepsilon^N)$. Therefore, the maximum level is

$$\begin{aligned}
h_3(t_\varepsilon) &\le \frac{t_\varepsilon^2}{2}\|\nabla v_\varepsilon\|_2^2 + \frac{t_\varepsilon^2}{2}\int_{\Omega_r} V v_\varepsilon^2 dx - \frac{s t_\varepsilon^{2^*}}{2^*}\int_{\Omega_r} |v_\varepsilon|^{2^*} dx - \alpha\beta t_\varepsilon^{p_1}\int_{\Omega_r} |v_\varepsilon|^{p_1} dx \\
&\le \frac{1}{N s^{\frac{2}{2^*-2}}}\left(\frac{\|\nabla v_\varepsilon\|_2^2}{\|v_\varepsilon\|_{2^*}^2}\right)^{\frac{2^*}{2^*-2}} + \frac{\int_{\Omega_r} V v_\varepsilon^2 dx}{2}\left(\frac{\|\nabla v_\varepsilon\|_2^2}{s\|v_\varepsilon\|_{2^*}^{2^*}}\right)^{\frac{2}{2^*-2}} - \alpha\beta\|v_\varepsilon\|_{p_1}^{p_1}\left(\frac{\|\nabla v_\varepsilon\|_2^2}{s\|v_\varepsilon\|_{2^*}^{2^*}}\right)^{\frac{p_1}{2^*-2}} \\
&= \frac{1}{N s^{\frac{2}{2^*-2}}}\left(\frac{\|\nabla u_\varepsilon\|_2^2}{\|u_\varepsilon\|_{2^*}^2}\right)^{\frac{N}{2}} + \frac{\int_{\Omega_r} V v_\varepsilon^2 dx}{2 s^{\frac{2}{2^*-2}}}\left(\Theta^{\frac{2-2^*}{2}} \cdot \frac{\|\nabla u_\varepsilon\|_2^2}{\|u_\varepsilon\|_{2^*}^{2^*}} \cdot \frac{\|u_\varepsilon\|_2^{2^*}}{\|u_\varepsilon\|_2^2}\right)^{\frac{2}{2^*-2}} \\
&\quad - \frac{\alpha\beta}{s^{\frac{p_1}{2^*-2}}}\left(\Theta^{\frac{2-2^*}{2}} \cdot \frac{\|\nabla u_\varepsilon\|_2^2}{\|u_\varepsilon\|_{2^*}^{2^*}} \cdot \frac{\|u_\varepsilon\|_2^{2^*}}{\|u_\varepsilon\|_2^2}\right)^{\frac{p_1}{2^*-2}} \cdot \Theta^{\frac{p_1}{2}}\frac{\|u_\varepsilon\|_{p_1}^{p_1}}{\|u_\varepsilon\|_2^{p_1}} \\
&\le \frac{1}{N s^{\frac{2}{2^*-2}}}\left[\frac{K_1 + O\left(\varepsilon^{N-2}\right)}{K_2 + O\left(\varepsilon^N\right)}\right]^{\frac{N}{2}} + \frac{\max_{x\in\Omega_r} V(x)}{2 s^{\frac{2}{2^*-2}}} \cdot \|u_\varepsilon\|_2^2 \cdot \frac{\|\nabla u_\varepsilon\|_2^{\frac{4}{2^*-2}}}{\|u_\varepsilon\|_{2^*}^{\frac{2\cdot 2^*}{2^*-2}}} \\
&\quad - \frac{\alpha\beta}{s^{\frac{p_1}{2^*-2}}} \cdot \|u_\varepsilon\|_{p_1}^{p_1} \cdot \frac{\|\nabla u_\varepsilon\|_2^{\frac{2p_1}{2^*-2}}}{\|u_\varepsilon\|_{2^*}^{\frac{p_1\cdot 2^*}{2^*-2}}} \\
&= \frac{1}{N s^{\frac{2}{2^*-2}}} S^{\frac{N}{2}} + O\left(\varepsilon^{N-2}\right) + C_1\|u_\varepsilon\|_2^2 + C_2\|u_\varepsilon\|_{p_1}^{p_1} \\
&= \frac{1}{N s^{\frac{2}{2^*-2}}} S^{\frac{N}{2}}
\end{aligned}$$

as $\varepsilon \to 0$, where $\zeta = s^{-\frac{2}{2^*-2}}$ and $C_1 \ge 0$, $C_2 \ge 0$ because of $\beta \le 0$. In the penultimate equal sign, we used

$$\frac{1}{N}\left[\frac{K_1 + O\left(\varepsilon^{N-2}\right)}{K_2 + O\left(\varepsilon^N\right)}\right]^{\frac{N}{2}} = \frac{1}{N}\left[\frac{K_1}{K_2} + O\left(\varepsilon^{N-2}\right)\right]^{\frac{N}{2}} = \frac{S^{\frac{N}{2}}}{N} + O\left(\varepsilon^{N-2}\right).$$

This completes the proof. □

Lemma 7.3. *For any $\Theta > 0$, let $r > r_\Theta$, where r_Θ is defined in Lemma 7.1. Then problem (7.3) has a solution $(\lambda_{r,s}, u_{r,s})$ for almost every $s \in \left[\frac{1}{2}, 1\right]$. Moreover, $u_{r,s} \ge 0$ and $\mathcal{I}_{r,s}(u_{r,s}) = \widetilde{m}_{r,s}(\Theta)$.*

Proof. Based on the previous analysis, we know that, for almost every $s \in \left[\frac{1}{2}, 1\right]$, there exists a bounded Palais–Smale sequence $\{u_n\}$ satisfying

$$\mathcal{I}_{r,s}(u_n) \to \widetilde{m}_{r,s}(\Theta) \quad \text{and} \quad \mathcal{I}'_{r,s}(u_n)\big|_{T_{u_n} S_{r,\Theta}} \to 0. \tag{7.16}$$

Then

$$\lambda_n = -\frac{1}{\Theta}\left(\int_{\Omega_r} |\nabla u_n|^2 dx + \int_{\Omega_r} V(x) u_n^2 dx - \beta\int_{\Omega_r} f(u_n) u_n dx - s\int_{\Omega_r} |u_n|^{2^*} dx\right)$$

is bounded and

$$\mathcal{I}'_{r,s}(u_n) + \lambda_n u_n \to 0 \quad \text{in } H^{-1}(\Omega_r). \tag{7.17}$$

Moreover, since $\{u_n\}$ is a bounded Palais–Smale sequence, there exist $u_0 \in H_0^1(\Omega_r)$ and $\lambda \in \mathbb{R}$ such that, up to a subsequence,

$$\begin{aligned} &\lambda_n \to \lambda \quad \text{in } \mathbb{R}, \\ &u_n \rightharpoonup u_0 \quad \text{in } H_0^1(\Omega_r), \\ &u_n \to u_0 \quad \text{in } L^t(\Omega_r) \text{ for all } 2 \le t < 2^*, \end{aligned} \tag{7.18}$$

where u_0 satisfies

$$\begin{cases} -\Delta u_0 + V u_0 + \lambda u_0 = s\,|u_0|^{2^*-2} u_0 + \beta f(u_0) & \text{in } \Omega_r, \\ u_0 \in H_0^1(\Omega_r), \quad \int_{\Omega_r} |u_0|^2\,dx = \Theta. \end{cases}$$

Using (7.17), we have

$$\mathcal{I}'_{r,s}(u_n)\,u_0 + \lambda_n \int_{\Omega_r} u_n u_0 dx \to 0 \quad \text{as } n \to \infty$$

and

$$I'_{r,s}(u_n)\,u_n + \lambda_n \Theta \to 0 \quad \text{as } \ n \to \infty.$$

Note that

$$\begin{aligned} \lim_{n\to\infty} \int_{\Omega_r} V(x) u_n^2 dx &= \int_{\Omega_r} V(x) u_0^2 dx, \\ \lim_{n\to\infty} \int_{\Omega_r} f(u_n) u_n dx &= \int_{\Omega_r} f(u_0) u_0 dx, \\ \lim_{n\to\infty} \int_{\Omega_r} f(u_n) u_0 dx &= \int_{\Omega_r} f(u_0) u_0 dx. \end{aligned}$$

Now, we show that $u_n \to u_0$ in $H_0^1(\Omega_r)$. Firstly, note that the weak limit u_0 does not vanish identically. Suppose by contradiction that $u_0 \equiv 0$. Since $\{u_n\}$ is bounded in $H^1(\Omega_r)$, up to a subsequence we have that $\|\nabla u_n\|_2^2 \to \ell \in \mathbb{R}$. Using (f_2), (7.17), (7.18), we have

$$\begin{aligned} \langle \mathcal{I}'_{r,s}(u_n), u_n \rangle &= \int_{\Omega_r} |\nabla u_n|^2 dx + \int_{\Omega_r} V u_n^2 dx - s \int_{\Omega_r} |u_n|^{2^*} dx - \beta \int_{\Omega_r} f(u_n) u_n dx \\ &\to 0, \end{aligned}$$

hence

$$s\|u_n\|_{2^*}^{2^*} = \|\nabla u_n\|_2^2 \to \ell$$

as well. Therefore, $\ell \ge s^{-\frac{2}{2^*}} S \ell^{\frac{2}{2^*}}$, and we deduce that either $\ell = 0$, or $\ell \ge s^{-\frac{2}{2^*-2}} S^{\frac{N}{2}}$. Let us suppose at first that $\ell \ge s^{-\frac{2}{2^*-2}} S^{\frac{N}{2}}$. Since $\mathcal{I}_{r,s}(u_n) \to \widetilde{m}_{r,s}(\Theta) < \frac{\zeta}{N} S^{\frac{N}{2}}$, we have that

$$\begin{aligned} \frac{\zeta}{N} S^{\frac{N}{2}} > \widetilde{m}_{r,s}(\Theta) &\leftarrow \mathcal{I}_{r,s}(u_n) + o(1) \\ &= \frac{1}{2} \int_{\Omega_r} |\nabla u_n|^2 dx + \frac{1}{2} \int_{\Omega_r} V u_n^2 dx - \frac{s}{2^*} \int_{\Omega_r} |u_n|^{2^*} dx - \beta \int_{\Omega_r} F(u_n) dx \\ &= \frac{\ell}{N} \ge s^{-\frac{2}{2^*-2}} \frac{S^{\frac{N}{2}}}{N}, \end{aligned}$$

which is not possible. If instead $\ell = 0$, we have $\|u_n\|_{2^*} \to 0$, $\|\nabla u_n\|_2 \to 0$ and $F(u_n) \to 0$. But then $I_{r,s}(u_n) \to 0 \neq \widetilde{m}_{r,s}(\Theta)$, which gives again a contradiction. Thus, u_r does not vanish identically.

Since $\{u_{n,r}\}$ is a bounded minimization sequence for $\mathcal{I}_r(u_{n,r})|_{S_{r,\Theta}}$, there exists $\{\lambda_n\} \subset \mathbb{R}$ such that for every $\varphi \in H^1(\Omega_r)$,

$$\int_{\Omega_r} \nabla u_{n,r} \cdot \nabla \varphi + \int_{\Omega_r} V u_{n,r}\varphi + \lambda_n u_{n,r}\varphi - \beta f(u_{n,r})\varphi - s\,|u_{n,r}|^{2^*-2} u_{n,r}\varphi = o(1)\|\varphi\| \qquad (7.19)$$

as $n \to \infty$, by the Lagrange multipliers rule. Choosing $\varphi = u_{n,r}$, we deduce that $\{\lambda_n\}$ is bounded as well, and hence up to a subsequence $\lambda_n \to \lambda_r \in \mathbb{R}$. Moreover, passing to the limit in (7.19) by weak convergence, we obtain

$$-\Delta u_r + V u_r + \lambda_r u_r = s|u_r|^{2^*-2}u_r + \beta f(u_r), \qquad x \in \Omega_r.$$

Recalling that $v_{n,r} = u_{n,r} - u_r \rightharpoonup 0$ in $H_0^1(\Omega_r)$, we know

$$\|\nabla u_{n,r}\|_2^2 = \|\nabla u_r\|_2^2 + \|\nabla v_{n,r}\|_2^2 + o(1).$$

By the Brézis–Lieb lemma [12], we have

$$\|u_{n,r}\|_{2^*}^{2^*} = \|u_r\|_{2^*}^{2^*} + \|v_{n,r}\|_{2^*}^{2^*} + o(1).$$

Note that

$$\int_{\Omega_r} V v_{n,r}^2 dx \to 0 \quad \text{as } n \to \infty,$$

hence

$$s\|v_{n,r}\|_{2^*}^{2^*} = \|\nabla v_{n,r}\|_2^2 \to \ell$$

as well. Therefore, by the Sobolev inequality $\ell \geq s^{-\frac{2}{2^*}} S \ell^{\frac{2}{2^*}}$, and we deduce that either $\ell = 0$, or $\ell \geq s^{-\frac{2}{2^*-2}} S^{\frac{N}{2}}$. Let us suppose at first that $\ell \geq s^{-\frac{2}{2^*-2}} S^{\frac{N}{2}}$. Since $\mathcal{I}_{r,s}(u_n) \to \widetilde{m}_{r,s}(\Theta) < \frac{\zeta}{N} S^{\frac{N}{2}}$, we have that

$$\begin{aligned}\frac{\zeta}{N} S^{\frac{N}{2}} > \widetilde{m}_{r,s}(\Theta) &\leftarrow \mathcal{I}_{r,s}(v_n) + o(1)\\ &= \frac{1}{2}\int_{\Omega_r} |\nabla v_n|^2 dx + \frac{1}{2}\int_{\Omega_r} V v_n^2 dx - \frac{s}{2^*}\int_{\Omega_r} |v_n|^{2^*} dx - \beta \int_{\Omega_r} F(v_n) dx\\ &= \frac{\ell}{N} \geq s^{-\frac{2}{2^*-2}} \frac{S^{\frac{N}{2}}}{N},\end{aligned}$$

which is not possible. If instead $\ell = 0$, we have that $u_{n,r} \to u_r$ in $H_0^1(\Omega_r)$, so $\mathcal{I}_r(u_r) > 0$.

Similar to the proof of Lemma 3.3, we also obtain that $u_{r,s} \geq 0$. □

In order to obtain a solution of (7.1), we also need to prove a uniform estimate for the solutions of (7.3) established in Lemma 7.3. Similar to the proof of Lemma 3.4 and Lemma 3.5, we obtain the following lemmas.

Lemma 7.4. *If $(\lambda, u) \in \mathbb{R} \times S_{r,\Theta}$ is a solution of (7.3) established in Lemma 7.3 for some r and s, then*

$$\int_{\Omega_r} |\nabla u|^2 dx \leq \frac{4N}{N(2^*-2)-4}\left(\frac{2^*-2}{2}\mathbf{h}(\mathbf{h}_\Theta) + \Theta\left(\frac{1}{2N}\|\widetilde{V}\|_\infty + \frac{2^*-2}{4}\|V\|_\infty\right)\right),$$

where the constant $\mathbf{h}(\mathbf{h}_\Theta)$ is defined in (iii) of Lemma 7.1 and is independent of r and s.

Lemma 7.5. *For every $\Theta > 0$, problem (7.3) has a solution (λ_r, u_r) provided $r > r_\Theta$ where r_Θ is as in Lemma 7.1. Moreover, $u_r \geq 0$ in Ω_r.*

Proof of Theorem 1.10. The proof is an immediate consequence of Lemmas 7.5 and 3.6. □

8 Proof of Theorem 1.11

In this subsection, we assume $\beta > 0$ and the assumptions of Theorem 1.10 hold. Consider the following equation

$$\begin{cases} -\Delta u + Vu + \lambda u = |u|^{2^*-2}u + \beta f(u), & x \in \Omega_r, \\ \int_{\Omega_r} |u|^2 dx = \Theta, u \in H_0^1(\Omega_r), & x \in \Omega_r. \end{cases} \tag{8.1}$$

For $\frac{1}{2} \le s \le 1$, we define the functional $\mathcal{J}_{r,s} : S_{r,\Theta} \to \mathbb{R}$ by

$$\mathcal{J}_{r,s}(u) = \frac{1}{2}\int_{\Omega_r} |\nabla u|^2 dx + \frac{1}{2}\int_{\Omega_r} Vu^2 dx - \frac{s}{2^*}\int_{\Omega_r} |u|^{2^*} dx - s\beta \int_{\Omega_r} F(u) dx. \tag{8.2}$$

Note that if $u \in S_{r,\Theta}$ is a critical point of $\mathcal{J}_{r,s}$, then there exists $\lambda \in \mathbb{R}$ such that (λ, u) is a solution of the equation

$$\begin{cases} -\Delta u + Vu + \lambda u = s|u|^{2^*-2}u + s\beta f(u), & x \in \Omega_r, \\ \int_{\Omega_r} |u|^2 dx = \Theta, u \in H_0^1(\Omega_r), & x \in \Omega_r. \end{cases} \tag{8.3}$$

Lemma 8.1. *For any $\Theta > 0$, there exist $\widehat{r}_\Theta > 0$ and $u^0, u^1 \in S_{r_\Theta,\Theta}$ such that*

(i) For $r > \widehat{r}_\Theta$ and $s \in \left[\frac{1}{2}, 1\right]$ we have $\mathcal{J}_{r,s}\left(u^1\right) \le 0$ and

$$\mathcal{J}_{r,s}\left(u^0\right) < \widehat{A}^{-\frac{2}{2^*-2}} \left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)^{\frac{2^*}{2^*-2}} \left[\frac{2^*-2}{2}\left(\frac{1}{2^*}\right)^{\frac{2^*}{2^*-2}}\right],$$

where

$$\widehat{A} = S^{-\frac{2^*}{2}} \left[\frac{4(2^*-2)}{N(p_1-2)(4-N(p_1-2))} + \frac{1}{2^*}\right].$$

Moreover,

$$\|\nabla u^0\|_2^2 < \left[\frac{\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)}{2^*\widehat{A}}\right]^{\frac{2}{2^*-2}}, \qquad \left\|\nabla u^1\right\|_2^2 > \left[\frac{\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)}{2^*\widehat{A}}\right]^{\frac{2}{2^*-2}}.$$

(ii) If $u \in S_{r,\Theta}$ satisfies

$$\|\nabla u\|_2^2 = \left[\frac{\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)}{2^*\widehat{A}}\right]^{\frac{2}{2^*-2}},$$

then there holds

$$\mathcal{J}_{r,s}(u) \ge \widehat{A}^{-\frac{2}{2^*-2}} \left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)^{\frac{2^*}{2^*-2}} \left[\frac{2^*-2}{2}\left(\frac{1}{2^*}\right)^{\frac{2^*}{2^*-2}}\right].$$

(iii) Let

$$\widehat{m}_{r,s}(\Theta) = \inf_{\gamma \in \widehat{\Gamma}_{r,\Theta}} \sup_{t \in [0,1]} \mathcal{J}_{r,s}(\gamma(t)),$$

where

$$\widehat{\Gamma}_{r,\Theta} = \left\{ \gamma \in C\left([0,1], S_{r,\Theta}\right) : \gamma(0) = u^0, \gamma(1) = u^1 \right\}.$$

Then

$$\widehat{m}_{r,s}(\Theta) \geq \widehat{A}^{-\frac{2}{2^*-2}} \left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)^{\frac{2^*}{2^*-2}} \left[\frac{2^*-2}{2} \left(\frac{1}{2^*}\right)^{\frac{2^*}{2^*-2}} \right]$$

and

$$\widehat{m}_{r,s}(\Theta) \leq \frac{N(2^*-2)-4}{2} \left(\frac{\theta\left(1 + \|V\|_{\frac{N}{2}} S^{-1}\right)}{N(2^*-2)} \right)^{\frac{N(2^*-2)}{N(2^*-2)-4}} (4 \cdot 2^*)^{\frac{4}{N(2^*-2)-4}} |\Omega|^{\frac{2(2^*-2)}{N(2^*-2)-4}} \cdot \Theta^{\frac{N(2^*-2)-2\cdot 2^*}{N(2^*-2)-4}},$$

where θ is the principal eigenvalue of $-\Delta$ with Dirichlet boundary condition in Ω.

Proof. (i) By the Hölder inequality, we know

$$\int_\Omega |v_1(x)|^{2^*} dx \geq \Theta^{\frac{2^*}{2}} \cdot |\Omega|^{\frac{2-2^*}{2}}. \tag{8.4}$$

For $x \in \Omega_{\frac{1}{t}}$ and $t > 0$, define $v_t(x) := t^{\frac{N}{2}} v_1(tx)$. Using (5.2), (8.4), (4.4) and $\frac{1}{2} \leq s \leq 1$, it holds

$$\begin{aligned} \mathcal{J}_{\frac{1}{t},s}(v_t) &\leq \frac{1}{2}\left(1 + \|V\|_{\frac{N}{2}} S^{-1}\right) t^2 \theta \Theta - \frac{\beta}{2} \alpha_1 t^{\frac{N(p_2-2)}{2}} \int_\Omega |v_1|^{p_2} dx - \frac{1}{2\cdot 2^*} t^{\frac{N(2^*-2)}{2}} \Theta^{\frac{2^*}{2}} \cdot |\Omega|^{\frac{2-2^*}{2}} \\ &\leq \widehat{h}_2(t), \end{aligned} \tag{8.5}$$

where

$$\widehat{h}_2(t) = \frac{1}{2}\left(1 + \|V\|_{\frac{N}{2}} S^{-1}\right) t^2 \theta \Theta - \frac{1}{2\cdot 2^*} t^{\frac{N(2^*-2)}{2}} \Theta^{\frac{2^*}{2}} \cdot |\Omega|^{\frac{2-2^*}{2}}.$$

A simple computation shows that $\widehat{h}_2(t_0) = 0$ for

$$t_0 := \left[\left(1 + \|V\|_{\frac{N}{2}} S^{-1}\right) 2^* \theta \Theta^{\frac{2-2^*}{2}} |\Omega|^{\frac{2^*-2}{2}} \right]^{\frac{2}{N(2^*-2)-4}}$$

and $\widehat{h}_2(t) < 0$ for any $t > t_0, \widehat{h}_2(t) > 0$ for any $0 < t < t_0$. Moreover, $\widehat{h}_2(t)$ achieves its maximum at

$$t_\Theta = \left[\frac{4\cdot 2^* \left(1 + \|V\|_{\frac{N}{2}} S^{-1}\right)\theta}{N(2^*-2)} \Theta^{\frac{2-2^*}{2}} |\Omega|^{\frac{2^*-2}{2}} \right]^{\frac{2}{N(2^*-2)-4}}.$$

This implies

$$\mathcal{J}_{r,s}(v_{t_0}) = J_{\frac{1}{t_0},s}(v_{t_0}) \leq \widehat{h}_2(t_0) = 0 \tag{8.6}$$

for any $r \geq \frac{1}{t_0}$ and $s \in \left[\frac{1}{2}, 1\right]$. There exists $0 < t_1 < t_\Theta$ such that for any $t \in [0, t_1]$,

$$\widehat{h}_2(t) < A^{-\frac{2}{2^*-2}} \left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)^{\frac{2^*}{2^*-2}} \left[\frac{2^*-2}{2} \left(\frac{1}{2^*}\right)^{\frac{2^*}{2^*-2}} \right]. \tag{8.7}$$

On the other hand, it follows from (3.5) that

$$\mathcal{J}_{r,s}(u) \geq \frac{1}{2}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)\int_{\Omega_r} |\nabla u|^2 dx - \frac{1}{2^* \cdot S^{\frac{2^*}{2}}}\left(\int_{\Omega_r} |\nabla u|^2 dx\right)^{\frac{2^*}{2}}$$
$$- \alpha\beta C_{N,p_1}\Theta^{\frac{2p_1-N(p_1-2)}{4}}\left(\int_{\Omega_r} |\nabla u|^2 dx\right)^{\frac{N(p_1-2)}{4}}.$$

Define

$$\begin{aligned}\widehat{g}_1(t) &:= \frac{1}{2}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)t - \frac{1}{2^* \cdot S^{\frac{2^*}{2}}} t^{\frac{2^*}{2}} - \alpha\beta C_{N,p_1}\Theta^{\frac{2p_1-N(p_1-2)}{4}} t^{\frac{N(p_1-2)}{4}} \\ &= t^{\frac{N(p_1-2)}{4}}\left[\frac{1}{2}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)t^{\frac{4-N(p_1-2)}{4}} - \frac{1}{2^* \cdot S^{\frac{2^*}{2}}} t^{\frac{2\cdot 2^*-N(p_1-2)}{4}}\right] \\ &\quad - \alpha\beta C_{N,p_1}\Theta^{\frac{2p_1-N(p_1-2)}{4}} t^{\frac{N(p_1-2)}{4}}.\end{aligned}$$

In view of $2 < p < 2 + \frac{2}{N} < q < 2^*$ and the definition of $\widetilde{\Theta}_V$, there exist $0 < l_1 < l_M < l_2$ such that $\widehat{g}_1(t) < 0$ for any $0 < t < l_1$ and $t > l_2, \widehat{g}_1(t) > 0$ for $l_1 < t < l_2$ and $\widehat{g}_1(l_M) = \max_{t\in\mathbb{R}^+}\widehat{g}_1(t) > 0$. Let

$$t_2 = \left(\frac{\alpha\beta C_{N,p_1} S^{\frac{2^*}{2}} N(p_1-2)(4-N(p_1-2))}{4(2^*-2)}\right)^{\frac{4}{2\cdot 2^*-N(p_1-2)}} \Theta^{\frac{2p_1-N(p_1-2)}{2\cdot 2^*-N(p_1-2)}}.$$

Then by a direct calculation, we have $g_1''(t) \leq 0$ if and only if $t \geq t_2$. Hence

$$\max_{t\in\mathbb{R}^+}\widehat{g}_1(t) = \max_{t\in[t_2,\infty)}\widehat{g}_1(t).$$

Note that for any $t \geq t_2$,

$$\begin{aligned} g_1(t) &= \frac{1}{2}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)t - \frac{1}{2^* \cdot S^{\frac{2^*}{2}}} t^{\frac{2^*}{2}} - \alpha\beta C_{N,p_1}\Theta^{\frac{2p_1-N(p_1-2)}{4}} t^{\frac{N(p_1-2)}{4}} \\ &= \frac{1}{2}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)t - \alpha\beta C_{N,p_1}\Theta^{\frac{2p_1-N(p_1-2)}{4}} \cdot t^{\frac{N(p_1-2)}{4}} - \frac{1}{2^* \cdot S^{\frac{2^*}{2}}} t^{\frac{2^*}{2}} \\ &= \frac{1}{2}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)t - \frac{4(2^*-2)}{S^{\frac{2^*}{2}} N(p_1-2)(4-N(p_1-2))} \cdot t_2^{\frac{2\cdot 2^*-N(p_1-2)}{4}} \cdot t^{\frac{N(p_1-2)}{4}} \\ &\quad - \frac{1}{2^* \cdot S^{\frac{2^*}{2}}} t^{\frac{2^*}{2}} \\ &\geq \frac{1}{2}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)t - S^{-\frac{2^*}{2}}\left[\frac{4(2^*-2)}{N(p_1-2)(4-N(p_1-2))} + \frac{1}{2^*}\right] t^{\frac{2^*}{2}} \\ &=: \widehat{g}_2(t). \end{aligned} \tag{8.8}$$

Now, we will determine the value of $\widetilde{\Theta}_V$. In fact, $\widehat{g}_1(l_M) = \max_{t\in\mathbb{R}^+}\widehat{g}_1(t) > 0$ as long as

$\widehat{g}_2(t_2) > 0$, that is,

$$\begin{aligned}\widehat{g}_2(t_2) &= \frac{1}{2}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right) t_2 - S^{-\frac{2^*}{2}}\left[\frac{4(2^*-2)}{N(p_1-2)(4-N(p_1-2))} + \frac{1}{2^*}\right] t_2^{\frac{2^*}{2}} \\ &= \frac{1}{2}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)\left(\frac{\alpha\beta C_{N,p_1} S^{\frac{2^*}{2}}}{A_{p_1}}\right)^{\frac{4}{2\cdot 2^* - N(p_1-2)}} \Theta^{\frac{2p_1 - N(p_1-2)}{2\cdot 2^* - N(p_1-2)}} \\ &\quad - S^{-\frac{2^*}{2}}\left(A_{p_1} + \frac{1}{2^*}\right)\left(\frac{\alpha\beta C_{N,p_1} S^{\frac{2^*}{2}}}{A_{p_1}}\right)^{\frac{2\cdot 2^*}{2\cdot 2^* - N(p_1-2)}} \Theta^{\frac{2^*[2p_1 - N(p_1-2)]}{2[2\cdot 2^* - N(p_1-2)]}} \\ &> 0,\end{aligned}$$

where

$$A_{p_1} = \frac{4(2^*-2)}{N(p_1-2)(4-N(p_1-2))}.$$

Hence, we take

$$\widetilde{\Theta}_V = \left(\frac{\alpha\beta C_{N,p_1} S^{\frac{2^*}{2}}}{A_{p_1}}\right)^{-\frac{4}{2p_1 - N(p_1-2)}}\left[\frac{S^{\frac{2^*}{2}}}{2\cdot 2^*}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)(2^* A_{p_1} + 1)\right]^{\frac{2[2\cdot 2^* - N(p_1-2)]}{(2^*-2)[2p_1 - N(p_1-2)]}}.$$

Let

$$\widehat{A} = S^{-\frac{2^*}{2}}\left[\frac{4(2^*-2)}{N(p_1-2)(4-N(p_1-2))} + \frac{1}{2^*}\right],\ t_g = \left[\frac{\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)}{2^*\widehat{A}}\right]^{\frac{2}{2^*-2}},$$

so that $t_g > t_2$ by the definition of $\widetilde{\Theta}_V, \max_{t\in[t_2,\infty)} \widehat{g}_2(t) = \widehat{g}_2(t_g)$ and

$$\max_{t\in\mathbb{R}^+} \widehat{g}_1(t) \geq \max_{t\in[t_2,\infty)} \widehat{g}_2(t) = \widehat{A}^{-\frac{2}{2^*-2}}\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)^{\frac{2^*}{2^*-2}}\left[\frac{2^*-2}{2}\left(\frac{1}{2^*}\right)^{\frac{2^*}{2^*-2}}\right].$$

Set $\bar{r}_\Theta = \max\left\{\frac{1}{t_1}, \sqrt{\frac{2\theta\Theta}{t_g}}\right\}$, then $v_{\frac{1}{\bar{r}_\Theta}} \in S_{r,\Theta}$ for any $r > \bar{r}_\Theta$, and

$$\left\|\nabla v_{\frac{1}{\bar{r}_\Theta}}\right\|_2^2 = \left(\frac{1}{\bar{r}_\Theta}\right)^2 \|\nabla v_1\|_2^2 < t_g = \left[\frac{\left(1 - \|V_-\|_{\frac{N}{2}} S^{-1}\right)}{2^*\widehat{A}}\right]^{\frac{2}{2^*-2}}. \tag{8.9}$$

Moreover,

$$\mathcal{J}_{\bar{r}_\Theta,s}\left(v_{\frac{1}{\bar{r}_\Theta}}\right) \leq \widehat{h}\left(\frac{1}{\bar{r}_\Theta}\right) \leq \widehat{h}(t_1). \tag{8.10}$$

Let $u^0 = v_{\frac{1}{\bar{r}_\Theta}}, u^1 = v_{t_0}$ and

$$\widetilde{r}_\Theta = \max\left\{\frac{1}{t_0}, \bar{r}_\Theta\right\}.$$

Then the statement (i) holds by (8.6), (8.7), (8.9), (8.10).

(ii) holds by (8.8) and a direct calculation.

(iii) In view of $J_{r,s}(u^1) \leq 0$ for any $\gamma \in \Gamma_{r,\Theta}$ and the definition of t_0, we have

$$\|\nabla\gamma(0)\|_2^2 < t_g < \|\nabla\gamma(1)\|_2^2.$$

It then follows from (8.8) that

$$\max_{t\in[0,1]} J_{r,s}(\gamma(t)) \geq g_2(t_g) = \widehat{A}^{-\frac{2}{2^*-2}}\left(1-\|V_-\|_{\frac{N}{2}} S^{-1}\right)^{\frac{2^*}{2^*-2}}\left[\frac{2^*-2}{2}\left(\frac{1}{2^*}\right)^{\frac{2^*}{2^*-2}}\right]$$

for any $\gamma \in \Gamma_{r,\Theta}$, hence the first inequality in (iii) holds. We define a path $\gamma : [0,1] \to S_{r,\Theta}$ by

$$\gamma(t) : \Omega_r \to \mathbb{R}, \quad x \mapsto \left(\tau t_0 + (1-\tau)\frac{1}{\widetilde{r}_\Theta}\right)^{\frac{N}{2}} v_1\left(\left(\tau t_0 + (1-\tau)\frac{1}{\widetilde{r}_\Theta}\right)x\right).$$

Then $\gamma \in \Gamma_{r,\Theta}$, and the second inequality in (iii) follows from (8.5). □

Using Proposition 3.2 to $\widetilde{J}_{r,s}$, it follows that

$$A(u) = \frac{1}{2}\int_{\Omega_r} |\nabla u|^2 dx + \frac{1}{2}\int_{\Omega_r} V(x)u^2 dx \quad \text{and} \quad B(u) = \frac{1}{2^*}\int_{\Omega_r} |u|^{2^*} dx + \beta\int_{\Omega_r} F(u)dx.$$

Hence, for almost every $s \in \left[\frac{1}{2},1\right]$, there exists a bounded Palais–Smale sequence $\{u_n\}$ satisfying

$$\mathcal{J}_{r,s}(u_n) \to \widetilde{m}_{r,s}(\Theta) \quad \text{and} \quad \mathcal{J}'_{r,s}(u_n)\big|_{T_{u_n}S_{r,\Theta}} \to 0.$$

Similar to the proof of Lemmas 7.2 and 7.3, we have the following lemmas.

Lemma 8.2. *If $\beta > 0$ and the assumptions of Theorem 1.11 hold, then $\widetilde{m}_{r,s}(\Theta) < \frac{\zeta}{N}S^{\frac{N}{2}}$, where $\zeta = s^{-\frac{2}{2^*-2}}$.*

Lemma 8.3. *Assume $0 < \Theta < \widetilde{\Theta}_V$ where $\widetilde{\Theta}_V$ is given in Theorem 1.11, let $r > r_\Theta$, where r_Θ is defined in Lemma 8.1. Then problem (8.3) has a solution $(\lambda_{r,s}, u_{r,s})$ for almost every $s \in \left[\frac{1}{2},1\right]$. Moreover, $u_{r,s} \geq 0$ and $\mathcal{J}_{r,s}(u_{r,s}) = \widetilde{m}_{r,s}(\Theta)$.*

In order to obtain a solution of (8.1), we also need to prove a uniform estimate for the solutions of (8.3) established in Lemma 8.3.

Lemma 8.4. *For fixed $\Theta > 0$ the set of solutions $u \in S_{r,\Theta}$ of (8.3) is bounded uniformly in s and r.*

Proof. Since u is a solution of (8.3), we have

$$\int_{\Omega_r} |\nabla u|^2 dx + \int_{\Omega_r} Vu^2 dx = s\int_{\Omega_r} |u|^{2^*} dx + s\beta\int_{\Omega_r} f(u)u dx - \lambda\int_{\Omega_r} |u|^2 dx.$$

The Pohozaev identity implies

$$\frac{N-2}{2N}\int_{\Omega_r} |\nabla u|^2 dx + \frac{1}{2N}\int_{\partial\Omega_r} |\nabla u|^2 (x\cdot\mathbf{n}) d\sigma + \frac{1}{2N}\int_{\Omega_r} \widetilde{V}(x)u^2 + \frac{1}{2}\int_{\Omega_r} Vu^2 dx$$
$$= -\frac{\lambda}{2}\int_{\Omega_r} |u|^2 dx + \frac{s}{2^*}\int_{\Omega_r} |u|^{2^*} dx + s\beta\int_{\Omega_r} F(u)dx$$

where $\mathbf{n}$ denotes the outward unit normal vector on $\partial\Omega_r$. It then follows from $\beta > 0$ and (f_2) that

$$\frac{1}{N}\int_{\Omega_r} |\nabla u|^2 dx - \frac{1}{2N}\int_{\partial\Omega_r} |\nabla u|^2 (x\cdot\mathbf{n}) d\sigma - \frac{1}{2N}\int_{\Omega_r} (\nabla V\cdot x)u^2 dx$$
$$\leq \frac{2^*-2}{2}\left(\frac{1}{2}\int_{\Omega_r} |\nabla u|^2 dx + \frac{1}{2}\int_{\Omega_r} Vu^2 dx - \widehat{m}_{r,s}(\Theta)\right) + s\frac{\beta(p_2-2^*)}{2}\int_{\Omega_r} F(u)dx.$$

Using Gagliardo–Nirenberg inequality, (3.5) and (iii) in Lemma 8.1, we have

$$\frac{2^*-2}{2}\widehat{m}_{r,s}(\Theta) \geq \frac{N(p_2-2)-4}{4N}\int_{\Omega_r}|\nabla u|^2dx - \Theta\left(\frac{1}{2N}\|\nabla V\cdot x\|_\infty + \frac{p_2-2}{4}\|V\|_\infty\right) + \frac{s\alpha\beta(p_2-2^*)}{2}C_{N,p_1}\Theta^{\frac{2p_1-N(p_1-2)}{4}}\left(\int_{\Omega_r}|\nabla u|^2dx\right)^{\frac{N(p_1-2)}{4}}.$$

Since $2<p_1<2+\frac{4}{N}$, we can bound $\int_{\Omega_r}|\nabla u|^2dx$ uniformly in s and r. □

Lemma 8.5. *Assume $0<\Theta<\widetilde{\Theta}_V$, where $\widetilde{\Theta}_V$ is given in Theorem 1.11, and let $r>\widetilde{r}_\Theta$, where $\widetilde{r}_\Theta$ is defined in Lemma 8.1. Then equation (8.3) admits a solution $(\lambda_{r,\Theta},u_{r,\Theta})$ for every $r>\widetilde{r}_\Theta$ such that $u_{r,\Theta}>0$ in Ω_r.*

Proof. The proof of lemma is similar to the Lemma 7.5. □

Proof of Theorem 1.11. The proof is an immediate consequence of Lemmas 8.5 and 3.6. □

9 Mass critical case

9.1 Proof of Theorem 1.12

This subsection considers the case of $p_1=2+\frac{4}{N}$, so we need to modify the proof of Theorem 1.5.

Lemma 9.1. *For $0<\Theta<\widetilde{\Theta}_V$ where $\widetilde{\Theta}_V$ is defined in Theorem 1.12, there exist $\widetilde{r}_\Theta>0$ and $u^0,u^1\in S_{r_\Theta,\Theta}$ such that*

(i) For $r>\widetilde{r}_\Theta$ and $s\in\left[\frac{1}{2},1\right]$ we have $J_{r,s}\left(u^1\right)\leq 0$ and

$$J_{r,s}\left(u^0\right) < \frac{(N(q-2)-4)\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}-2\alpha\beta C_N\Theta^{\frac{2}{N}}\right)^{\frac{N(q-2)}{N(q-2)-4}}}{2[N(q-2)]^{\frac{N(q-2)}{N(q-2)-4}}}\left[\frac{2q}{C_{N,q}\Theta^{\frac{2q-N(q-2)}{4}}}\right]^{\frac{4}{N(q-2)-4}}.$$

Moreover,

$$\|\nabla u^0\|_2^2 < \left[\frac{2q}{N(q-2)C_{N,q}}\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}-2\alpha\beta C_N\Theta^{\frac{2}{N}}\right)\Theta^{\frac{q(N-2)-2N}{4}}\right]^{\frac{4}{N(q-2)-4}}$$

and

$$\left\|\nabla u^1\right\|_2^2 > \left[\frac{2q}{N(q-2)C_{N,q}}\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}-2\alpha\beta C_N\Theta^{\frac{2}{N}}\right)\Theta^{\frac{q(N-2)-2N}{4}}\right]^{\frac{4}{N(q-2)-4}}.$$

(ii) If $u\in S_{r,\Theta}$ satisfies

$$\|\nabla u\|_2^2 = \left[\frac{2q}{N(q-2)C_{N,q}}\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}-2\alpha\beta C_N\Theta^{\frac{2}{N}}\right)\Theta^{\frac{q(N-2)-2N}{4}}\right]^{\frac{4}{N(q-2)-4}},$$

then there holds

$$J_{r,s}(u) \geq \frac{(N(q-2)-4)\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}-2\alpha\beta C_N\Theta^{\frac{2}{N}}\right)^{\frac{N(q-2)}{N(q-2)-4}}}{2[N(q-2)]^{\frac{N(q-2)}{N(q-2)-4}}}\left[\frac{2q}{C_{N,q}\Theta^{\frac{2q-N(q-2)}{4}}}\right]^{\frac{4}{N(q-2)-4}}.$$

(iii) Let

$$m_{r,s}(\Theta) = \inf_{\gamma\in\Gamma_{r,\Theta}} \sup_{t\in[0,1]} J_{r,s}(\gamma(t)),$$

where

$$\Gamma_{r,\Theta} = \left\{\gamma \in C\left([0,1], S_{r,\Theta}\right) : \gamma(0) = u^0, \gamma(1) = u^1\right\}.$$

Then

$$m_{r,s}(\Theta) \geq \frac{(N(q-2)-4)\left(1-\|V_-\|_{\frac{N}{2}} S^{-1} - 2\alpha\beta C_N \Theta^{\frac{2}{N}}\right)^{\frac{N(q-2)}{N(q-2)-4}}}{2[N(q-2)]^{\frac{N(q-2)}{N(q-2)-4}}} \left[\frac{2q}{C_{N,q}\Theta^{\frac{2q-N(q-2)}{4}}}\right]^{\frac{4}{N(q-2)-4}}$$

and

$$m_{r,s}(\Theta) \leq \frac{N(q-2)-4}{2}\left(\frac{\theta\left(1+\|V\|_{\frac{N}{2}} S^{-1}\right)}{N(q-2)}\right)^{\frac{N(q-2)}{N(q-2)-4}} (4q)^{\frac{4}{N(q-2)-4}} |\Omega|^{\frac{2(q-2)}{N(q-2)-4}} \Theta^{\frac{N(q-2)-2q}{N(q-2)-4}}.$$

where θ is the principal eigenvalue of $-\Delta$ with Dirichlet boundary condition in Ω.

Proof. We only need to modify the proof of Lemma 5.1. There exists $0 < t_1 < t_\Theta$ such that for any $t \in [0, t_1]$,

$$h_2(t) < \frac{(N(q-2)-4)\left(1-\|V_-\|_{\frac{N}{2}} S^{-1} - 2\alpha\beta C_N \Theta^{\frac{2}{N}}\right)^{\frac{N(q-2)}{N(q-2)-4}}}{2[N(q-2)]^{\frac{N(q-2)}{N(q-2)-4}}} \left[\frac{2q}{C_{N,q}\Theta^{\frac{2q-N(q-2)}{4}}}\right]^{\frac{4}{N(q-2)-4}}. \tag{9.1}$$

On the other hand, it follows from (3.5), the Gagliardo–Nirenberg inequality and the Hölder inequality that

$$J_{r,s}(u) = \left[\frac{1-\|V_-\|_{\frac{N}{2}} S^{-1}}{2} - \alpha\beta C_N \Theta^{\frac{2}{N}}\right] \|\nabla u\|_2^2 - \frac{C_{N,q}\Theta^{\frac{2q-N(q-2)}{4}}}{q} \|\nabla u\|_2^{\frac{N(q-2)}{2}}. \tag{9.2}$$

Define

$$g_1(t) := \left[\frac{1-\|V_-\|_{\frac{N}{2}} S^{-1}}{2} - \alpha\beta C_N \Theta^{\frac{2}{N}}\right] t - \frac{C_{N,q}\Theta^{\frac{2q-N(q-2)}{4}}}{q} t^{\frac{N(q-2)}{4}}$$

and

$$t_g = \left[\frac{2q}{N(q-2)C_{N,q}}\left(1-\|V_-\|_{\frac{N}{2}} S^{-1} - 2\alpha\beta C_N \Theta^{\frac{2}{N}}\right)\Theta^{\frac{q(N-2)-2N}{4}}\right]^{\frac{4}{N(q-2)-4}},$$

it is easy to see that g_1 is increasing on $(0, t_g)$ and decreasing on (t_g, ∞), and

$$g_1(t_g) = \frac{(N(q-2)-4)\left(1-\|V_-\|_{\frac{N}{2}} S^{-1} - 2\alpha\beta C_N \Theta^{\frac{2}{N}}\right)^{\frac{N(q-2)}{N(q-2)-4}}}{2[N(q-2)]^{\frac{N(q-2)}{N(q-2)-4}}} \left[\frac{2q}{C_{N,q}\Theta^{\frac{2q-N(q-2)}{4}}}\right]^{\frac{4}{N(q-2)-4}}.$$

Set $\bar{r}_\Theta = \max\left\{\frac{1}{t_1}, \sqrt{\frac{2\theta\Theta}{t_g}}\right\}$, then $v_{\frac{1}{\bar{r}_\Theta}} \in S_{r,\Theta}$ for any $r > \bar{r}_\Theta$, and

$$\begin{aligned}\left\|\nabla v_{\frac{1}{\bar{r}_\Theta}}\right\|_2^2 &= \left(\frac{1}{\bar{r}_\Theta}\right)^2 \|\nabla v_1\|_2^2 \\ &< t_g = \left[\frac{2q}{N(q-2)C_{N,q}}\left(1-\|V_-\|_{\frac{N}{2}} S^{-1} - 2\alpha\beta C_N \Theta^{\frac{2}{N}}\right)\Theta^{\frac{q(N-2)-2N}{4}}\right]^{\frac{4}{N(q-2)-4}}.\end{aligned} \tag{9.3}$$

Then the statement (i) holds by (5.5), (9.1), (5.9), (9.3).

(ii) holds by (9.2) and a direct calculation.

(iii) In view of $J_{r,s}\left(u^1\right) \le 0$ for any $\gamma \in \Gamma_{r,\Theta}$ and the definition of t_0, we have

$$\|\nabla\gamma(0)\|_2^2 < t_g < \|\nabla\gamma(1)\|_2^2.$$

It then follows from (9.2) that

$$\begin{aligned}\max_{t\in[0,1]} J_{r,s}(\gamma(t)) &\ge g_1\left(t_g\right)\\ &= \frac{(N(q-2)-4)\left(1-\|V_-\|_{\frac{N}{2}} S^{-1} - 2\alpha\beta C_N \Theta^{\frac{2}{N}}\right)^{\frac{N(q-2)}{N(q-2)-4}}}{2[N(q-2)]^{\frac{N(q-2)}{N(q-2)-4}}} \left[\frac{2q}{C_{N,q}\Theta^{\frac{2q-N(q-2)}{4}}}\right]^{\frac{4}{N(q-2)-4}}\end{aligned}$$

for any $\gamma \in \Gamma_{r,\Theta}$, hence the first inequality in (iii) holds. We define a path $\gamma : [0,1] \to S_{r,\Theta}$ by

$$\gamma(t) : \Omega_r \to \mathbb{R}, \qquad x \mapsto \left(\tau t_0 + (1-\tau)\frac{1}{\widetilde{r}_\Theta}\right)^{\frac{N}{2}} v_1\left(\left(\tau t_0 + (1-\tau)\frac{1}{\widetilde{r}_\Theta}\right)x\right).$$

Then $\gamma \in \Gamma_{r,\Theta}$, and the second inequality in (iii) follows from (5.4). □

Lemma 9.2. *For fixed $\Theta > 0$ the set of solutions $u \in S_{r,\Theta}$ of (5.1) is bounded uniformly in s and r.*

Proof. We only need to modify the proof of Lemma 5.3. Using the Gagliardo–Nirenberg inequality, (3.5) and (iii) in Lemma 5.1, we have

$$\begin{aligned}\frac{q-2}{2} m_{r,s}(\Theta) \ge & \left[\frac{N(p_2-2)-4}{4N} - \frac{s\alpha\beta(q-p_2)}{2} C_N \Theta^{\frac{2}{N}}\right] \int_{\Omega_r} |\nabla u|^2 dx\\ & - \Theta\left(\frac{1}{2N}\|\nabla V \cdot x\|_\infty + \frac{p_2-2}{4}\|V\|_\infty\right).\end{aligned}$$

Since $0 < \Theta < \widetilde{\Theta}_V$, we can bound $\int_{\Omega_r} |\nabla u|^2 dx$ uniformly in s and r. □

Proof of Theorem 1.12. The proof is an immediate consequence of Lemmas 5.4 and 3.6. □

9.2 Proof of Theorem 1.13

Firstly, we modify the proof of Lemma 3.1. Using (3.3), (3.4), (3.5) and $\frac{1}{2} \le s \le 1$, it holds

$$\begin{aligned} I_{\frac{1}{t},s}(v_t) &\le \frac{1}{2}\left(1 + \|V\|_{\frac{N}{2}} S^{-1} - 2\alpha\beta C_N \Theta^{\frac{2}{N}}\right) t^2 \theta\Theta - \frac{1}{2q} t^{\frac{N(q-2)}{2}} \Theta^{\frac{q}{2}} \cdot |\Omega|^{\frac{2-q}{2}}\\ &=: h(t).\end{aligned}$$

Note that since $2 + \frac{4}{N} < q < 2^*$ and $\beta \le 0$, there exist $0 < T_\Theta < t_0$ such that $h(t_0) = 0, h(t) < 0$ for any $t > t_0, h(t) > 0$ for any $0 < t < t_0$ and $h(T_\Theta) = \max_{t\in\mathbb{R}^+} h(t)$.

Lemma 9.3. *Let $(\lambda_{r,\Theta}, u_{r,\Theta})$ be the solution of (1.1) from Lemma 3.5. If $\|\widetilde{V}_+\|_{\frac{N}{2}} < 2S$, then there exists $\bar{\Theta} > 0$ such that*

$$\liminf_{r\to\infty} \lambda_{r,\Theta} > 0 \quad \textit{for } 0 < \Theta < \bar{\Theta}.$$

Proof. We only need to modify the proof of Lemma 3.7. It follows from (3.5), (3.27), (3.28), (3.29), (f_2) and $2+\frac{4}{N}<q<2^*$ that

$$\begin{aligned}\left(\frac{1}{q}-\frac{1}{2}\right)\lambda_\Theta\int_{\mathbb{R}^N}u_\Theta^2dx &\le \left[\frac{(N-2)q-2N}{2Nq}-\frac{\beta(q-p_2)\alpha C_N}{q}\Theta^{\frac{2}{N}}\right]\int_{\mathbb{R}^N}|\nabla u_\Theta|^2\,dx\\ &\quad+\frac{\|\widetilde{V}\|_\infty}{2N}\Theta+\frac{(q-2)\|V\|_\infty}{2q}\Theta\\ &\to -\infty \quad \text{as } \Theta\to 0,\end{aligned}$$

since $0<\Theta<\widehat{\Theta}_V$. □

Proof of Theorem 1.13. The proof is an immediate consequence of Lemmas 3.5, 3.6 and 9.3. □

9.3 Proof of Theorem 1.14

Similarly, we only need to modify the proof of Theorem 1.4. Since $\beta>0$, it follows from the Gagliardo–Nirenberg inequality and the Hölder inequality that

$$\begin{aligned}I_r(u)&=\frac{1}{2}\int_{\Omega_r}|\nabla u|^2dx+\frac{1}{2}\int_{\Omega_r}V(x)u^2dx-\frac{N}{2N+4}\int_{\Omega_r}|u|^{2+\frac{4}{N}}dx-\beta\int_{\Omega_r}F(u)dx\\ &\ge\frac{1}{2}\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}-\frac{NC_N\Theta^{\frac{2}{N}}}{N+2}\right)\int_{\Omega_r}|\nabla u|^2dx\\ &\quad-\alpha\beta C_{N,p_1}\Theta^{\frac{2p_1-N(p_1-2)}{4}}\left(\int_{\Omega_r}|\nabla u|^2dx\right)^{\frac{N(p_1-2)}{4}}\\ &=h_1(t),\end{aligned}$$

where

$$h_1(t):=\frac{1}{2}\left(1-\|V_-\|_{\frac{N}{2}}S^{-1}-\frac{NC_N\Theta^{\frac{2}{N}}}{N+2}\right)t^2-\alpha\beta C_{N,p_1}\Theta^{\frac{2p_1-N(p_1-2)}{4}}t^{\frac{N(p_1-2)}{2}}.$$

In view of $2<p_1<2+\frac{4}{N}$, there exists $T_\Theta>0$ such that $h_1(t)<0$ for $0<t<T_\Theta$ and $h_1(t)>0$ for $t>T_\Theta$.

Proof of Theorem 1.14. The proof is a direct consequence of Lemma 4.1 and Lemma 3.6. □

10 Final comments

Some similar result (Theorems 1.3, 1.4, 1.5, but there are subtle changes in the assumptions) can be proved for the following class of problem

$$\begin{cases}-\Delta u+V(x)u+\lambda u=w(u)+\beta|u|^{p-2}u, & x\in\Omega,\\ \int_\Omega|u|^2dx=\Theta, u\in H_0^1(\Omega), & x\in\Omega,\end{cases}$$

where $\Omega\subset\mathbb{R}^N$ is either all of $\mathbb{R}^N$ or a bounded smooth convex domain, $N\ge 3$, $2<p<2+\frac{4}{N}$, the mass $\Theta>0$ and the parameter $\beta\in\mathbb{R}$ are prescribed. Nonlinearity w satisfies:

(W_1) $w\in C^1(\mathbb{R},\mathbb{R})$ and w is odd.

(W_2) There exists some $(p_1,p_2)\in\mathbb{R}^2_+$ satisfying $2+\frac{4}{N}<p_2\le p_1<2^*$ such that

$$p_2W(\tau)\le w(\tau)\tau\le p_1W(\tau)\quad\text{with } W(\tau)=\int_0^\tau w(t)dt.$$

Abstract. Let $\Omega = (a,b) \subset \mathbb{R}$, $0 \leq m,n \in L^1(\Omega)$, $\lambda, \mu > 0$ be real parameters, and $\phi : \mathbb{R} \to \mathbb{R}$ be an odd increasing homeomorphism. In this paper we consider the existence of positive solutions for problems of the form

$$\begin{cases} -\phi\,(u')' = \lambda m(x) f(u) + \mu n(x) g(u) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

where $f, g : [0,\infty) \to [0,\infty)$ are continuous functions which are, roughly speaking, sublinear and superlinear with respect to ϕ, respectively. Our assumptions on ϕ, m and n are substantially weaker than the ones imposed in previous works. The approach used here combines the Guo–Krasnoselskiĭ fixed-point theorem and the sub-supersolutions method with some estimates on related nonlinear problems.

Keywords: elliptic one-dimensional problems, ϕ-Laplacian, positive solutions.

1 Introduction

Let $\Omega = (a,b) \subset \mathbb{R}$, $m,n \in L^1(\Omega)$ and $\lambda, \mu > 0$ be a real parameters. In this article we consider problems of the form

$$\begin{cases} -\phi\,(u')' = \lambda m\,(x)\, f\,(u) + \mu n(x) g(u) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where $\phi : \mathbb{R} \to \mathbb{R}$ is an odd increasing homeomorphism and $f, g : [0,\infty) \to [0,\infty)$ are continuous functions which are, roughly speaking, sublinear and superlinear with respect to ϕ, respectively. When the nonlinearities f and g are concave and convex, the problem (1.1) with

✉ Corresponding author. Email: lmilne@dm.uba.ar

$\phi(x) = x$ was first studied by Ambrosetti, Brezis and Cerami in their celebrated paper [1]. More precisely, in that article the authors studied the N-dimensional problem

$$\begin{cases} -\Delta u = \lambda u^q + u^p, & x \in \Omega, \\ u > 0, & x \in \Omega, \\ u = 0, & x \in \partial\Omega, \end{cases} \tag{1.2}$$

with $0 < q < 1 < p$ and Ω a bounded domain in $\mathbb{R}^N$. They proved the following facts: there exists $\Lambda > 0$ such that: if $\lambda \in (0, \Lambda)$ then (1.2) has at least two positive solutions, if $\lambda = \Lambda$ there is at least one positive solution, and if $\lambda > \Lambda$ then there are no positive solutions.

Several authors have studied generalizations of (1.2), see for instance [2, 11, 14] and their references, where the corresponding problem for the p-Laplacian is considered. Also, in [12] the authors have treated the N-dimensional problem for the ϕ-Laplacian operator.

Regarding the one-dimensional ϕ-Laplacian problem that we will deal with in this article, Wang in [15, Theorem 1.2] and [16, Theorem 1.2] studied the case $m = n \geq 0$, $m \not\equiv 0$ on any subinterval in Ω, $m \in C(\overline{\Omega})$ and $\lambda = \mu$. In these papers it is proved that there exist $\lambda_0, \lambda_1 > 0$ such that if $\lambda \in (0, \lambda_0)$, then (1.1) has at least two positive solutions; and if $\lambda > \lambda_1$, then there are no positive solutions. Let us note that the hypothesis on ϕ imposed in [15, 16] are much stronger than the ones that we shall require here. More precisely, Wang assumes

(Φ) There exist increasing homeomorphisms $\psi_1, \psi_2 : [0, \infty) \to [0, \infty)$ such that $\psi_1(t)\,\phi(x) \leq \phi(tx) \leq \psi_2(t)\,\phi(x)$ for all $t, x > 0$.

On other hand, (1.1) is also considered in [8] with $m = n \geq 0$, $m \not\equiv 0$ on any subinterval in Ω and $\lambda = \mu$ like in [15, 16]. However, the regularity assumptions for m allow some $m \in L^1_{loc}(\Omega)$. Regarding the hypothesis on ϕ they require that

(Φ') There exist an increasing homeomorphism $\psi_1 : [0, \infty) \to [0, \infty)$ and a function $\psi_2 : [0, \infty) \to [0, \infty)$ such that $\psi_1(t)\,\phi(x) \leq \phi(tx) \leq \psi_2(t)\,\phi(x)$ for all $t, x > 0$.

The authors prove that there exist $\lambda_1 \geq \lambda_0 > 0$ such that (1.1) has at least two positive solutions for $\lambda \in (0, \lambda_0)$, one positive solution for $\lambda \in [\lambda_0, \lambda_1]$, and no positive solution for $\lambda > \lambda_1$.

In this article, employing the method of sub and supersolutions and the Guo–Krasnoselskiĭ fixed-point theorem along with some estimates for related problems, we shall prove that there are at least two positive solutions for $\lambda \approx 0$, under much weaker assumptions on ϕ, m and n. Moreover, as a consequence of Theorem 4.4 we shall see that (Φ) and (Φ') are in fact equivalent.

To be more precise, let us introduce the following hypothesis.

(F) There exist $c_0, t_0, q > 0$ such that

$$f(t) \geq c_0 t^q \text{ for all } t \in [0, t_0] \quad \text{and} \quad \lim_{t \to 0^+} \frac{t^q}{\phi(t)} = \infty. \tag{1.3}$$

(G1) There exist $c_1, t_1, r_1 > 0$ such that

$$g(t) \leq c_1 t^{r_1} \text{ for all } t \in [0, t_1] \quad \text{and} \quad \lim_{t \to 0^+} \frac{t^{r_1}}{\phi(t)} = 0. \tag{1.4}$$

(G2) There exist $c_2, t_2, r_2 > 0$ such that

$$g(t) \geq c_2 t^{r_2} \text{ for all } t \geq t_2 \quad \text{and} \quad \lim_{t\to\infty} \frac{t^{r_2}}{\phi(t)} = \infty. \tag{1.5}$$

Note that when $\phi(t) = |t|^{p-2}\,t$, $f(u) = u^q$ and $g(u) = u^r$, the limits in (F) and (G1) are satisfied if and only if $0 < q < p-1 < r$. Let us set $\mathcal{C}_0^1(\overline{\Omega}) := \{u \in \mathcal{C}^1(\overline{\Omega}) : u = 0 \text{ on } \partial\Omega\}$ and

$$\mathcal{P}^\circ := \left\{ u \in \mathcal{C}_0^1(\overline{\Omega}) : u > 0 \text{ in } \Omega \text{ and } u'(b) < 0 < u'(a) \right\}.$$

Our main result is the following theorem:

Theorem 1.1. *Let $0 \leq m, n \in L^1(\Omega)$.*

(I) Assume that $m \not\equiv 0$ and (F) and (G1) hold. Then for all $\mu > 0$ there exists $\lambda_0(\mu) > 0$ such that (1.1) has a solution $u_\lambda \in \mathcal{P}^\circ$ for all $0 < \lambda < \lambda_0(\mu)$. Moreover, the solutions u_λ can be chosen such that

$$\lim_{\lambda\to 0^+} \|u_\lambda\|_\infty = 0. \tag{1.6}$$

(II) Assume that $n \not\equiv 0$ and (G1) and (G2) hold. Then for all $\mu > 0$ there exists $\lambda_1(\mu) > 0$ such that (1.1) has a solution $v_\lambda \in \mathcal{P}^\circ$ for all $0 < \lambda < \lambda_1(\mu)$. Furthermore, there exists $\rho > 0$ such that $\|v_\lambda\|_\infty > \rho$ for all $0 < \lambda < \lambda_1(\mu)$.

(III) Assume that $\{\lambda > 0 : (1.1)$ has a solution in $\mathcal{P}^\circ\} \neq \emptyset$ and (F) holds for all $t_0 > 0$. Let

$$\Lambda := \sup\{\lambda > 0 : (1.1) \text{ has a solution in } \mathcal{P}^\circ\}.$$

Then, for $0 < \lambda < \Lambda$ (1.1) has at least one solution in $\mathcal{P}^\circ$.

As an immediate consequence of the above theorem we have the following

Corollary 1.2. *Let $\mu > 0$ and $0 \leq m, n \in L^1(\Omega)$ with $m, n \not\equiv 0$. Assume that (F), (G1) and (G2) hold. Then (1.1) has at least two solutions in $\mathcal{P}^\circ$ for $\lambda \approx 0$.*

The rest of the paper is organized as follows. In the next section we state some necessary facts about nonlinear problems involving the ϕ-Laplacian, and in Section 3 we prove our main results. Finally, in Section 4 we introduce some concepts about Orlicz spaces indices which we use to prove Theorem 4.4 (and, in particular, the equivalence of (Φ) and (Φ')), and at the end of the section we give several examples of functions ϕ illustrating our conditions and their relations with the ones used in the previous works. Let us mention that all the ϕ's constructed in Example (e) satisfy conditions (F), (G1) and (G2) but do not fulfill condition (Φ).

2 Preliminaries

Let $\phi : \mathbb{R} \to \mathbb{R}$ be an odd increasing homeomorphism. We start considering problems of the form

$$\begin{cases} -\phi(v')' = h(x) & \text{in } \Omega, \\ v = 0 & \text{on } \partial\Omega. \end{cases} \tag{2.1}$$

It is well known that for all $h \in L^1(\Omega)$, (2.1) possesses a unique solution $v \in \mathcal{C}_0^1(\overline{\Omega})$ such that $\phi(v')$ is absolutely continuous and that the equation holds pointwise *a.e.* $x \in \Omega$. Furthermore, the solution operator $\mathcal{S}_\phi \colon L^1(\Omega) \to \mathcal{C}^1(\overline{\Omega})$ is completely continuous and nondecreasing, see [3, Lemma 2.1] and [6, Lemma 2.2].

We need now to introduce some notation. For $0 \le h \in L^1(\Omega)$ with $h \not\equiv 0$, set

$$\mathcal{A}_h := \{x \in \Omega : h(y) = 0 \text{ a.e. } y \in (a,x)\},$$
$$\mathcal{B}_h := \{x \in \Omega : h(y) = 0 \text{ a.e. } y \in (x,b)\},$$

and

$$\begin{aligned} \alpha_h &:= \begin{cases} \sup \mathcal{A}_h & \text{if } \mathcal{A}_h \neq \emptyset, \\ a & \text{if } \mathcal{A}_h = \emptyset, \end{cases} \qquad \beta_h := \begin{cases} \inf \mathcal{B}_h & \text{if } \mathcal{B}_h \neq \emptyset, \\ b & \text{if } \mathcal{B}_h = \emptyset, \end{cases} \\ \underline{\theta}_h &:= \min\left\{\frac{1}{\beta_h - a}, \frac{1}{b - \alpha_h}\right\}, \qquad \overline{\theta}_h := \frac{\alpha_h + \beta_h}{2}. \end{aligned} \tag{2.2}$$

We observe that $\underline{\theta}_h$ is well defined because $h \not\equiv 0$, and $\alpha_h < \beta_h$ (and so, $\overline{\theta}_h \in (\alpha_h, \beta_h)$). We also write

$$\delta_\Omega(x) := \operatorname{dist}(x, \partial\Omega) = \min(x - a, b - x).$$

We shall utilize the following estimates on several occasions in the sequel. For the proof, see [6, Lemma 2.3 and (2.6)] and [7, Corollary 2.2].

Lemma 2.1. *Let $0 \le h \in L^1(\Omega)$ with $h \not\equiv 0$.*

(i) In $\overline{\Omega}$ it holds that

$$\underline{\theta}_h \min\left\{\int_a^{\overline{\theta}_h} \phi^{-1}\left(\int_y^{\overline{\theta}_h} h\right) dy, \int_{\overline{\theta}_h}^b \phi^{-1}\left(\int_{\overline{\theta}_h}^y h\right) dy\right\} \delta_\Omega \le \mathcal{S}_\phi(h) \le \phi^{-1}\left(\int_a^b h\right) \delta_\Omega. \tag{2.3}$$

(ii) In $\overline{\Omega}$ it holds that

$$\mathcal{S}_\phi(h) \ge \underline{\theta}_h \left\|\mathcal{S}_\phi(h)\right\|_\infty \delta_\Omega. \tag{2.4}$$

(iii) For $M > 0$ there exists $c > 0$ not depending on M such that it holds that

$$\min\left\{\int_a^{\overline{\theta}_h} \phi^{-1}\left(\int_y^{\overline{\theta}_h} Mh\right) dy, \int_{\overline{\theta}_h}^b \phi^{-1}\left(\int_{\overline{\theta}_h}^y Mh\right) dy\right\} \ge c\phi^{-1}(cM). \tag{2.5}$$

Observe that, since $\overline{\theta}_h \in (\alpha_h, \beta_h)$, the constant that appears in the first term of the inequalities in (2.3) is strictly positive. Note also that, since $\underline{\theta}_h \|\delta_\Omega\|_\infty \ge 1/2$, using the lower bound of (2.3) and taking into account the monotonicity of the infinite norm we get

$$\frac{1}{2}\min\left\{\int_a^{\overline{\theta}_h} \phi^{-1}\left(\int_y^{\overline{\theta}_h} h\right) dy, \int_{\overline{\theta}_h}^b \phi^{-1}\left(\int_{\overline{\theta}_h}^y h\right) dy\right\} \le \left\|\mathcal{S}_\phi(h)\right\|_\infty. \tag{2.6}$$

Observe also that for h as in Lemma 2.1 $\mathcal{S}_\phi(h) \in \mathcal{P}^\circ$.

Let $h : \Omega \times \mathbb{R} \to \mathbb{R}$ be a Carathéodory function (that is, $h(x,\cdot)$ is continuous for *a.e.* $x \in \Omega$ and $h(\cdot,\xi)$ is measurable for all $\xi \in \mathbb{R}$). We now consider problems of the form

$$\begin{cases} -\phi(u')' = h(x,u) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases} \tag{2.7}$$

We shall say that $v \in C(\overline{\Omega})$ is a *subsolution* of (2.7) if there exists a finite set $\Sigma \subset \Omega$ such that $\phi(v') \in AC_{loc}(\overline{\Omega}\setminus\Sigma)$, $v'(\tau^+) := \lim_{x\to\tau^+} v'(x) \in \mathbb{R}$, $v'(\tau^-) := \lim_{x\to\tau^-} v'(x) \in \mathbb{R}$ for each $\tau \in \Sigma$, and

$$\begin{cases} -\phi\left(v'\right)' \leq h\left(x, v\left(x\right)\right) & a.e.\ x \in \Omega, \\ v \leq 0 \text{ on } \partial\Omega, & v'(\tau^-) < v'(\tau^+) \text{ for each } \tau \in \Sigma. \end{cases} \tag{2.8}$$

If the inequalities in (2.8) are inverted, we shall say that v is a *supersolution* of (2.7).

For the sake of completeness, we state an existence result in the presence of well-ordered sub and supersolutions, and a particular case of the well-known Guo–Krasnoselskiĭ fixed-point theorem (for a proof, see e.g. [13, Theorem 7.16] and [4, Theorem 2.3.4], respectively).

Lemma 2.2. *Let v and w be sub and supersolutions respectively of (2.7) such that $v \leq w$ in Ω. Suppose there exists $g \in L^1(\Omega)$ such that*

$$|h\left(x, \xi\right)| \leq g\left(x\right) \quad \textit{for a.e. } x \in \Omega \textit{ and all } \xi \in \left[v\left(x\right), w\left(x\right)\right].$$

Then there exists $u \in C_0^1(\overline{\Omega})$ solution of (2.7) with $v \leq u \leq w$ in Ω.

Lemma 2.3. *Let X be a Banach space and let K be a cone in X. Let $\Omega_1, \Omega_2 \subset X$ be two open sets with $0 \in \Omega_1$ and $\Omega_1 \subset \Omega_2$. Suppose that $T : K \cap (\Omega_2 \setminus \Omega_1) \to K$ is a completely continuous operator and*

$$\begin{aligned} \|Tv\| &\geq \|v\|, \quad \textit{for } v \in K \cap \partial\Omega_2, \\ \|Tv\| &\leq \|v\|, \quad \textit{for } v \in K \cap \partial\Omega_1. \end{aligned}$$

Then, T has a fixed point in $K \cap (\Omega_2 \setminus \Omega_1)$.

3 Proof of the main results

3.1 Proof of item (I)

We start this section with two lemmas concerning sub and supersolutions that shall be used to prove item (I) of Theorem 1.1.

Lemma 3.1. *Let $m, n \in L^1(\Omega)$ such that $0 \not\equiv m + n \geq 0$. Assume that (G1) holds. Then for all $\mu > 0$ there exists $\lambda_0(\mu) > 0$ such that for each $0 < \lambda < \lambda_0(\mu)$ there exists $w_\lambda \in \mathcal{P}^\circ$ supersolution of (1.1). Moreover,*

$$\lim_{\lambda\to 0^+} \|w_\lambda\|_\infty = 0. \tag{3.1}$$

Proof. Let c_1, t_1, r_1 be given by (G1). Let us define $c_\Omega := \max_{\overline{\Omega}} \delta_\Omega$. By the continuity of ϕ^{-1} and the fact that $\phi^{-1}(0) = 0$, there exists $K_0 > 0$ such that

$$\phi^{-1}\left(\kappa \int_a^b m(s) + n(s) ds\right) \leq \frac{t_1}{c_\Omega} \quad \text{for all } \kappa \leq K_0. \tag{3.2}$$

We observe that by the second condition on (1.4), for $\rho > 0$ fixed we have

$$\lim_{t\to 0^+} \frac{[\phi^{-1}(\rho t)]^{r_1}}{t} = 0. \tag{3.3}$$

We now define

$$\epsilon := \frac{1}{c_1 \mu c_\Omega^{r_1}}, \qquad \rho := \int_a^b m(s) + n(s) ds.$$

We can deduce from (3.3) that there exists $K_1 = K_1(\epsilon, \rho) > 0$ such that

$$[\phi^{-1}(\kappa\rho)]^{r_1} \leq \kappa\epsilon \quad \text{for all } \kappa \leq K_1. \tag{3.4}$$

Let $C = \max_{[0,t_1]} f(t)$ and choose $\lambda_0 > 0$ such that

$$\lambda_0 C \leq \min\{K_0, K_1\}. \tag{3.5}$$

Also, for each $0 < \lambda < \lambda_0$, pick κ_λ such that

$$\lambda C \leq \kappa_\lambda \leq \min\{K_0, K_1\}, \tag{3.6}$$

and for such κ_λ define $w_\lambda := \mathcal{S}_\phi(\kappa_\lambda(m+n))$. Since $\kappa_\lambda \leq K_0$, the upper bound in (2.3) and (3.2) tell us that $\|w_\lambda\|_\infty \leq t_1$. Taking into account (3.4), (3.5) and (3.6), employing (G1) and the upper bound in (2.3) we deduce that

$$\begin{aligned}\lambda m(x)f(w_\lambda) + \mu n(x)g(w_\lambda) &\leq \lambda m(x)C + c_1\mu n(x)w_\lambda^{r_1} \\ &\leq \kappa_\lambda m(x) + c_1\mu n(x)\left[\phi^{-1}(\kappa_\lambda \int_a^b m(s)+n(s)ds)\delta_\Omega\right]^{r_1} \\ &\leq \kappa_\lambda(m(x)+n(x)) = -\phi(w_\lambda')' \quad \text{in } \Omega,\end{aligned}$$

and hence w_λ is a supersolution of (1.1).

In order to prove (3.1), we choose κ_λ satisfying (3.6) and such that $\kappa_\lambda \to 0$ when $\lambda \to 0^+$. Hence, using the second inequality (2.3) we get that

$$0 \leq w_\lambda(x) = \mathcal{S}_\phi(\kappa_\lambda(m+n)) \leq \phi^{-1}\left(\int_a^b \kappa_\lambda(m+n)\right)\delta_\Omega(x) \to 0$$

uniformly in $\overline{\Omega}$ when $\lambda \to 0^+$. Thus, $\lim_{\lambda\to 0^+} \|w_\lambda\|_\infty = 0$. □

Lemma 3.2. *Let $0 \leq m, n \in L^1(\Omega)$ with $m \not\equiv 0$. Assume that (F) holds. Then for all $\lambda, \mu > 0$ (1.1) has a subsolution $v \in \mathcal{P}^\circ$.*

Proof. Let $\lambda, \mu > 0$ and let c_0, t_0, q be given by (F). Recall that $c_\Omega := \max_{\overline{\Omega}} \delta_\Omega$. Since ϕ^{-1} is continuous and $\phi^{-1}(0) = 0$, there exists $\varepsilon_0 > 0$ such that

$$\phi^{-1}\left(\varepsilon \int_a^b m(s)\delta_\Omega^q(s)ds\right) \leq \frac{t_0}{c_\Omega} \quad \text{for all } \varepsilon \leq \varepsilon_0. \tag{3.7}$$

By the second condition in (1.3), for $\rho > 0$ fixed

$$\lim_{t\to 0^+} \frac{[\phi^{-1}(\rho t)]^q}{t} = \infty. \tag{3.8}$$

Let us define

$$M := \frac{1}{\lambda c_0 c^q},$$

where c is the constant in (2.5) with $h = m\delta_\Omega^q$. It follows from (3.8) that there exists $\varepsilon_1 = \varepsilon_1(M, \rho)$ such that

$$[\phi^{-1}(\varepsilon\rho)]^q \geq M\varepsilon \quad \text{for all } \varepsilon \leq \varepsilon_1. \tag{3.9}$$

Let us choose

$$0 < \varepsilon < \min\{\varepsilon_0, \varepsilon_1\} \tag{3.10}$$

and for such ε define $v := \mathcal{S}_\phi(\varepsilon m\delta_\Omega^q)$. Since $\varepsilon \le \varepsilon_0$, the upper bound of Lemma 2.1 and (3.7) tell us that $\|v\|_\infty \le t_0$. Consequently, taking into account (3.9) and (3.10), employing (F) and (2.5) we deduce that

$$\lambda m(x)f(v) + \mu n(x)g(v) \ge \lambda c_0 m(x)v^q \ge \lambda c_0 m(x)[c\phi^{-1}(c\varepsilon)\delta_\Omega]^q \ge \varepsilon m(x)\delta_\Omega^q \quad \text{in } \Omega.$$

In other words, v is a subsolution of (1.1). □

Proof of Theorem 1.1 (I). Given $\mu > 0$, let $\lambda_0(\mu)$ be as in Lemma 3.1. For $0 < \lambda < \lambda_0(\mu)$, let $w_\lambda \in \mathcal{P}^\circ$ be a supersolution provided by the aforementioned lemma, and let $v_\lambda \in \mathcal{P}^\circ$ be a subsolution given by Lemma 3.2 with ε_λ chosen such that $\varepsilon_\lambda m(x)\delta_\Omega^q(x) \le \kappa_\lambda(m(x)+n(x))$ for $a.e. x \in \Omega$. It follows that v_λ, w_λ are a pair of well-ordered sub and supersolutions of (1.1). Hence, Lemma 2.2 gives a solution of (1.1) $u_\lambda \in \mathcal{P}^\circ$. Moreover, (1.6) follows from (3.1). □

3.2 Proof of item (II)

Proof of Theorem 1.1 (II). We shall use Lemma 2.3 with the operator

$$Tv := \mathcal{S}_\phi(\lambda m(x)f(v) + \mu n(x)g(v)),$$

the cone

$$\mathcal{K} := \{v \in C(\overline{\Omega}) : v \ge \underline{\theta}_n \|v\|_\infty \delta_\Omega\}$$

($\underline{\theta}_n$ as in (2.2)) and the open balls $B_R(0), B_\rho(0) \subset C(\overline{\Omega})$ with $0 < \rho < R$. Observe that $C_0^1(\overline{\Omega}) \cap (\mathcal{K} \setminus \{0\}) \subset \mathcal{P}^\circ$ and that any fixed point of T belongs to $C_0^1(\overline{\Omega})$.

Let c_2, t_2 and r_2 be given by (G2). We consider the function $h := c_2\mu\,(\underline{\theta}_n)^{r_2}\, n\delta_\Omega^{r_2}$. Taking into account (2.5), we can find $c = c(\mu) > 0$ such that for all $M > 0$

$$\min\left\{\int_a^{\overline{\theta}_n} \phi^{-1}(M\int_y^{\overline{\theta}_n} h)dy, \int_{\overline{\theta}_n}^b \phi^{-1}(M\int_{\overline{\theta}_n}^y h)dy\right\} \ge c\phi^{-1}(cM). \tag{3.11}$$

On other hand, the second condition in (G2) is equivalent to

$$\lim_{t\to\infty} \frac{\phi^{-1}(\rho t^{r_2})}{t} = \infty$$

for all fixed $\rho > 0$, and then there exists $\overline{t} > 0$ such that

$$\phi^{-1}(ct^{q_2}) \ge \frac{2t}{c} \quad \text{for all } t \ge \overline{t}. \tag{3.12}$$

Let us fix $R > \max\{t_2, \overline{t}\}$. Taking into account that $\mathcal{S}_\phi$ and ϕ^{-1} are nondecreasing, the inequality (2.6), (G2), (3.11) and (3.12) we obtain that for $v \in \mathcal{K} \cap \partial B_R(0)$,

$$\begin{aligned}
\|Tv\|_\infty &= \|\mathcal{S}_\phi(\lambda m(x)f(v)) + \mu n(x)g(v))\| \ge \|S_\phi(\mu n(x)g(v))\|_\infty \\
&\ge \frac{1}{2}\min\left\{\int_a^{\overline{\theta}_n} \phi^{-1}\left(\int_y^{\overline{\theta}_n} \mu n g(v)\right)dy, \int_{\overline{\theta}_n}^b \phi^{-1}\left(\int_{\overline{\theta}_n}^y \mu n g(v)\right)dy\right\} \\
&\ge \frac{1}{2}\min\left\{\int_a^{\overline{\theta}_n} \phi^{-1}\left(c_2\mu\int_y^{\overline{\theta}_n} n v^{r_2}\right)dy, \int_{\overline{\theta}_n}^b \phi^{-1}\left(c_2\mu\int_{\overline{\theta}_n}^y n v^{r_2}\right)dy\right\} \\
&\ge \frac{1}{2}\min\left\{\int_a^{\overline{\theta}_n} \phi^{-1}\left(c_2\mu\,(\underline{\theta}_n\|v\|_\infty)^{r_2}\int_y^{\overline{\theta}_n} n\delta_\Omega^{r_2}\right)dy, \int_{\overline{\theta}_n}^b \phi^{-1}\left(c_2\mu\,(\underline{\theta}_n\|v\|_\infty)^{r_2}\int_{\overline{\theta}_n}^y n\delta_\Omega^{r_2}\right)dy\right\} \\
&\ge \frac{1}{2}c\phi^{-1}(c\|v\|_\infty^{r_2}) \\
&\ge \|v\|_\infty.
\end{aligned}$$

That is, $\|Tv\|_\infty \geq \|v\|_\infty$ for such v.

On other side, let $N := c_1 \int_a^b n$. The second condition in (G1) implies that there exists $\underline{t} > 0$ such that $\phi(t/c_\Omega) > \mu N t^{r_1}$ for all $t \in (0, \underline{t})$. Set $C := \max_{[0,R]} f(t)$ and $M := \int_a^b m$. Let $0 < \rho < \min\{\underline{t}, R/2, t_1\}$ be fixed and define

$$\lambda_1 := \frac{\phi(\rho/c_\Omega) - \mu N \rho^{r_1}}{MC}. \tag{3.13}$$

Note that $\lambda_1 > 0$ by our election of $\underline{t}$.

Now, taking into account (2.3), (G1), (3.13) and the monotonicity of ϕ^{-1} we see for $0 < \lambda \leq \lambda_1$ and all $v \in \mathcal{K} \cap \partial B_\rho(0)$,

$$\begin{aligned} Tv &\leq \phi^{-1}\left(\int_a^b \lambda m(x) f(v) + \mu n(x) g(v) dx\right) \delta_\Omega \\ &\leq \phi^{-1}\left(\lambda C \int_a^b m(x)dx + c_1 \mu \int_a^b n(x) v^{r_1} dx\right) \delta_\Omega \\ &\leq \phi^{-1}\left(\lambda_1 MC + \mu N \rho^{r_1}\right) \delta_\Omega \\ &\leq \rho \text{ in } \Omega. \end{aligned}$$

This tells us that $\|Tv\|_\infty \leq \rho = \|v\|_\infty$ for all $v \in \mathcal{K} \cap \partial B_\rho(0)$.

Thus, Lemma 2.3 says that T has a fixed point in $\mathcal{K} \cap (\overline{B_R(0)} \setminus B_\rho(0))$. □

3.3 Proof of item (III)

Proof of Theorem 1.1 (III). In order to prove (III) we combine Lemma 3.2 and the inequality (2.4). Let $0 < \lambda < \Lambda$. By the definition of Λ there exists $\overline{\lambda} \in (\lambda, \Lambda]$ and $u_{\overline{\lambda}} \in \mathcal{P}^\circ$ solution of (1.1) associated to $\overline{\lambda}$. Since $\lambda < \overline{\lambda}$ it follows that $u_{\overline{\lambda}}$ is a supersolution (1.1) associated to λ. Now, thanks to Lemma 3.2 there exists $\varepsilon > 0$ such that $v = \mathcal{S}_\phi(\varepsilon m \delta_\Omega^q)$ is a subsolution of (1.1) associated to λ. Moreover, taking ε smaller if necessary, we get that $v \leq u_{\overline{\lambda}}$. Now, (III) follows from Lemma 2.2. □

4 Comments about the hypothesis

Let us introduce some concepts about Orlicz spaces indices. Given a nonbounded, increasing, continuous function $\phi : [0, \infty) \to [0, \infty)$ with $\phi(0) = 0$, we define

$$M(t, \phi) := \sup_{x>0} \frac{\phi(tx)}{\phi(x)}.$$

This function is nondecreasing and submultiplicative with $M(1, \phi) = 1$. Then, thanks to e.g. [9, Chapter 11], the following limits exist:

$$\alpha_\phi := \lim_{t \to 0^+} \frac{\ln M(t, \phi)}{\ln t}, \qquad \beta_\phi := \lim_{t \to \infty} \frac{\ln M(t, \phi)}{\ln t},$$

and moreover, $0 \leq \alpha_\phi \leq \beta_\phi \leq \infty$. These numbers are called **Orlicz space indices** or **Matuszewska–Orlicz's indices**, who introduced them in [10].

As usual, we say that ϕ satisfies the Δ_2 condition if there exists $k > 0$ such that

$$\phi(2x) \leq k\phi(x) \quad \text{for all } x \geq 0.$$

Remark 4.1.

(i) For $\varepsilon > 0$, there exists $t_1 > 0$ such that $\phi(tx) \leq t^{\alpha_\phi - \varepsilon}\phi(x)$ for all $x > 0$ and $t \in [0, t_1]$.

(ii) Suppose that $\beta_\phi < \infty$. Then, for $\varepsilon > 0$, there exists $t_2 > 0$ such that $\phi(tx) \leq t^{\beta_\phi + \varepsilon}\phi(x)$ for all $x > 0$ and $t \in [t_2, \infty)$. So, if $\beta_\phi < \infty$ then ϕ satisfies the Δ_2 condition.

(iii) If $x^{-p}\phi(x)$ is nondecreasing for all $x > 0$, then $\alpha_\phi \geq p$.

(iv) If $x^{-p}\phi(x)$ is nonincreasing for all $x > 0$, then $\beta_\phi \leq p$.

(v) The following relationships between the Orlicz space indices of ϕ and ϕ^{-1} hold:

$$\beta_\phi = \frac{1}{\alpha_{\phi^{-1}}} \quad \text{and} \quad \alpha_\phi = \frac{1}{\beta_{\phi^{-1}}}.$$

As usual, we set $1/0 = \infty$ and $1/\infty = 0$.

We shall need the next two useful lemmas to prove Theorem 4.4 below.

Lemma 4.2 ([5, page 34])**.** *If $0 < \alpha_\phi \leq \beta_\phi < \infty$ then there exist $C, p, q > 0$ such that*

$$C^{-1} \min\{t^p, t^q\}\phi(x) \leq \phi(tx) \leq C \max\{t^p, t^q\}\phi(x) \quad \textit{for all } t, x \geq 0.$$

Lemma 4.3 ([9, Theorem 11.7])**.** *The function ϕ satisfies the Δ_2 condition if and only if the constant β_ϕ is finite.*

Theorem 4.4. *The following hypothesis for ϕ are equivalent:*

(i) $0 < \alpha_\phi \leq \beta_\phi < \infty$.

(ii) (Φ).

(iii) (Φ').

Proof. It is obvious that (ii) implies (iii), and Lemma 4.2 shows that (i) implies (ii). Let us prove that (iii) implies (i).

Since $\alpha_\phi = 1/\beta_{\phi^{-1}}$, Lemma 4.3 and Remark 4.1 (v) tell us that $\alpha_\phi > 0$ if and only if ϕ^{-1} satisfies Δ_2. Let us check that the first inequality in (Φ') implies that ϕ^{-1} satisfies Δ_2. Indeed, taking into account that

$$\psi_1(t)\phi(x) \leq \phi(xt) \quad \text{for all } t, x > 0,$$

setting $y = \phi(x)$ and $s = \psi(t)$ we get that

$$sy \leq \phi(\psi_1^{-1}(s)\phi^{-1}(y)) \quad \text{for all } s, y > 0.$$

Since ϕ^{-1} is increasing its follows that

$$\phi^{-1}(sy) \leq \psi_1^{-1}(s)\phi^{-1}(y) \quad \text{for all } s, y > 0.$$

This implies that ϕ^{-1} satisfies Δ_2. Thus, $\alpha_\phi > 0$. Moreover, the second inequality in (Φ') implies that ϕ satisfies Δ_2. Then, $\beta_\phi < \infty$. □

The following two lemmas will be useful to compare the indices α_ϕ and β_ϕ with our hypotheses (F), (G1) and (G2) stated in Section 1.

Lemma 4.5. *Let $q > 0$.*

(i) If $\lim_{t\to 0^+} \dfrac{t^q}{\phi(t)} = 0$ *then* $\alpha_\phi \le q$.

(ii) If $\lim_{t\to \infty} \dfrac{t^q}{\phi(t)} = 0$ *then* $\beta_\phi \ge q$.

(iii) If $\lim_{t\to 0^+} \dfrac{t^q}{\phi(t)} = \infty$ *then* $\beta_\phi \ge q$.

(iv) If $\lim_{t\to \infty} \dfrac{t^q}{\phi(t)} = \infty$ *then* $\alpha_\phi \le q$.

Proof. We start proving (i). If $\alpha_\phi > q$, by Remark 4.1 (i) there exists $t_1 > 0$ such that

$$\phi(tx) \le t^q \phi(x) \quad \text{for all } x > 0 \text{ and } t \in (0, t_1).$$

Let us set $C = \phi(1)^{-1}$ and fix $x = 1$. Using the above inequality we have that $C \le \frac{t^q}{\phi(t)}$ for all $t \in (0, t_1)$, which contradicts that $\lim_{t\to 0^+} \frac{t^q}{\phi(t)} = 0$. Therefore, we must have $\alpha_\phi \le q$. Item (ii) follows similarly. Indeed, if $\beta_\phi < q$, by Remark 4.1 (ii) we have that there exists $t_1 > 0$ such that

$$\phi(tx) \le t^q \phi(x) \quad \text{for all } x > 0 \text{ and } t > t_1.$$

We now again define $C = \phi(1)^{-1}$ and fix $x = 1$. Employing the above inequality we have that $C \le \frac{t^q}{\phi(t)}$ for all $t > t_1$, contradicting that $\lim_{t\to\infty} \frac{t^q}{\phi(t)} = 0$. Thus, $\beta_\phi \ge q$.

We prove (iii). We notice first that

$$\lim_{t\to 0^+} \frac{t^q}{\phi(t)} = \infty \quad \text{if and only if} \quad \lim_{t\to 0^+} \frac{t^{1/q}}{\phi^{-1}(t)} = 0. \tag{4.1}$$

Indeed, the first limit is true if for every sequence $\{t_k\}$ with $0 < t_k \to 0$, it holds that $\frac{t_k^q}{\phi(t_k)} \to \infty$. Thus, taking $s_k = \phi(t_k)$ we have that $0 < s_k \to 0$ and $\frac{[\phi^{-1}(s_k)]^q}{s_k} \to \infty$. Since $h(t) = t^{1/q}$ is continuous and converges to ∞ as $t \to \infty$, it follows that $\frac{\phi^{-1}(s_k)}{s_k^{1/q}} \to \infty$, which is equivalent to $\frac{s_k^{1/q}}{\phi^{-1}(s_k)} \to 0$. Since $0 \le \frac{t^{1/q}}{\phi^{-1}(t)}$ for all $t > 0$ it follows that $\lim_{t\to 0^+} \frac{t^{1/q}}{\phi^{-1}(t)} = 0$. Now, from (4.1) and item (i) we deduce that $\alpha_{\phi^{-1}} \le 1/q$, and recalling Remark 4.1 (v) we get that $\beta_\phi \ge q$, and (iii) holds. Analogously, (iv) follows from (ii), taking into account that

$$\lim_{t\to \infty} \frac{t^q}{\phi(t)} = \infty \quad \text{if and only if} \quad \lim_{t\to \infty} \frac{t^{1/q}}{\phi^{-1}(t)} = 0,$$

and using again Remark 4.1 (v). □

Lemma 4.6. *Let $\phi : [0, \infty) \to [0, \infty)$ be a nonbounded, increasing, continuous function with $\phi(0) = 0$.*

(i) If $q < \alpha_\phi$ *then* $\lim_{t\to 0^+} \frac{t^q}{\phi(t)} = \infty$.

(ii) If $q > \beta_\phi$ *then* $\lim_{t\to \infty} \frac{t^q}{\phi(t)} = \infty$.

(iii) If $q < \alpha_\phi$ *then* $\lim_{t\to \infty} \frac{t^q}{\phi(t)} = 0$.

(iv) If $q > \beta_\phi$ then $\lim_{t\to 0^+} \frac{t^q}{\phi(t)} = 0$.

Let us note that the reciprocals of items (i) and (ii) of the above lemma *are not true*, see Example (e.1) below.

Proof. Let us begin by proving (i). Let $\varepsilon > 0$ such that $\alpha_\phi - \varepsilon > q$. By Remark 4.1 (i) there exists $t_1 > 0$ such that $\phi(tx) \le t^{\alpha_\phi - \varepsilon}\phi(x)$ for all $x > 0$ and $t < t_1$. Taking $x = 1$ we get that $\frac{1}{t^{\alpha_\phi-\varepsilon}} \le \frac{\phi(1)}{\phi(t)}$ for $t < t_1$. Multiplying by t^q on both sides and taking limit as $t \to 0^+$ it follows that

$$\lim_{t\to 0^+} \frac{t^q}{t^{\alpha_\phi-\varepsilon}} \le \lim_{t\to 0^+} \frac{\phi(1)t^q}{\phi(t)}.$$

Since $q < \alpha_\phi - \varepsilon$, the first limit is infinite, and so also the second one. Thus, (i) is proved.

Analogously, let $\varepsilon > 0$ such that $\beta_\phi + \varepsilon < q$. By Remark 4.1 (ii) there exists $t_1 > 0$ such that $\phi(tx) \le t^{\beta_\phi-\varepsilon}\phi(x)$ for all $x > 0$ and $t > t_1$. Taking $x = 1$ we have $\frac{1}{t^{\beta_\phi-\varepsilon}} \le \frac{\phi(1)}{\phi(t)}$ for $t < t_1$. Multiplying by t^q on both sides and taking limit as $t \to \infty$ we get

$$\lim_{t\to\infty} \frac{t^q}{t^{\beta_\phi+\varepsilon}} \le \lim_{t\to\infty} \frac{\phi(1)t^q}{\phi(t)}.$$

Since $q > \beta_\phi + \varepsilon$, the first limit is infinite, and thus also the second one.

On other hand, (iii) follows from (ii) noting that

$$\lim_{t\to\infty} \frac{t^q}{\phi(t)} = 0 \quad \text{if and only if} \quad \lim_{t\to\infty} \frac{t^{1/q}}{\phi^{-1}(t)} = \infty,$$

and taking into account that $\alpha_\phi > q$ if and only if $\beta_{\phi^{-1}} < 1/q$. Similarly, (iv) follows from (i) noting that

$$\lim_{t\to 0^+} \frac{t^q}{\phi(t)} = 0 \quad \text{if and only if} \quad \lim_{t\to 0^+} \frac{t^{1/q}}{\phi^{-1}(t)} = \infty,$$

and recalling that $\beta_\phi < q$ if and only if $\alpha_{\phi^{-1}} > 1/q$. □

Corollary 4.7. *Let q, r_1 and r_2 be given by (F), (G1) and (G2) respectively.*

1. *Suppose that α_ϕ is positive.*

   (a) If $q < \alpha_\phi$ then the limit in (F) holds.

2. *Suppose that β_ϕ is finite.*

   (a) If $r_1 > \beta_\phi$ then the limit in (G1) holds.
   (b) If $r_2 > \beta_\phi$ then the limit in (G2) holds.

4.1 Examples

Let us conclude the article with some examples of functions ϕ. We suppose $x \ge 0$ and we extend the function oddly.

a. Let

$$\phi(x) = x^{p_1} + x^{p_2}, \quad \text{with } p_1 \ge p_2 > 0.$$

Since $\phi(x)/x^{p_1}$ is nonincreasing and $\phi(x)/x^{p_2}$ is nondecreasing, we see that $\beta_\phi < \infty$ and $\alpha_\phi > 0$.

b. Let
$$\phi(x) = \frac{x^{p_1}}{1+x^{p_2}}, \quad \text{with } p_1 > p_2 > 0.$$
Since $\phi(x)/x^{p_1}$ is nonincreasing and $\phi(x)/x^{p_1-p_2}$ is nondecreasing, we get that $\beta_\phi < \infty$ and $\alpha_\phi > 0$.

c. Let
$$\phi(x) = x\left(|\ln x| + 1\right).$$
We have that $\phi(x)/x^2$ is nonincreasing. Then, $\beta_\phi < \infty$. Furthermore, given $p \in (0,1)$ there exists $T > 0$ such that
$$\phi(tx) \le t^p \phi(x) \quad \text{for } t \in [0,T] \text{ and all } x \ge 0.$$
This inequality implies that $\alpha_\phi \ge 1$.

d. Let
$$\phi(x) := x - \ln(x+1).$$
As in the above example, $\phi(x)/x^2$ is nonincreasing and then $\beta_\phi < \infty$. Also, there exist $C, T > 0$ such that
$$\phi(tx) \le \; Ct\phi(x) \quad \text{for } t \in [0,T] \text{ and all } x \ge 0.$$
The above inequality implies that $\alpha_\phi \ge 1$. Moreover, since
$$\lim_{t\to\infty} \frac{t^q}{\phi(t)} = \infty \quad \text{for all } q > 1,$$
thanks to Lemma 4.5 (iv) we deduce that $\alpha_\phi = 1$.

e. Let $h : (0,\infty) \to (1,\infty)$ be an increasing differentiable function such that $\lim_{t\to 0^+} h(t) = 1$,
$$\lim_{t\to\infty} \frac{qt^{q-1}h(t)}{h'(t)} = \infty \quad \text{for all } q > 0, \tag{4.2}$$
and there exists $p_1 > 0$ such that
$$\lim_{t\to 0^+} \frac{qt^{q-1}h(t)}{h'(t)} = \begin{cases} 0 & \text{if } q > p_1, \\ \infty & \text{if } q < p_1. \end{cases} \tag{4.3}$$
Define
$$\phi(x) := (\ln(h(x)))^p, \quad \text{with } p > 0.$$
By (4.2), ϕ satisfies the limit in (G2). Moreover, from Lemma 4.5 (iv) we can deduce that $\alpha_\phi = 0$. Then ϕ *does not satisfy* the hypothesis (Φ) (and (Φ')) at the introduction. And since (4.3) holds it follows that
$$\lim_{t\to 0^+} \frac{t^q}{\phi(t)} = \begin{cases} 0 & \text{if } q > pp_1. \\ \infty & \text{if } q < pp_1. \end{cases}$$
Therefore, ϕ satisfies the limits in (F) and (G1). Let us exhibit next a few particular cases.

e.1 Let
$$\phi(x) := (\ln(x+1))^p, \quad \text{with } p > 0.$$
A few computations show that $h(x) = x+1$ satisfies (4.2) and (4.3). Moreover, we can see that $\phi(x)/x^p$ is nonincreasing and thus $\beta_\phi \leq p$, and since
$$\lim_{t\to 0^+} \frac{t^q}{\ln(t+1)} = \infty \quad \text{for all } q < 1,$$
by Lemma 4.5 it follows that $\beta_\phi = p$. This shows that the reciprocals of the items (i) and (ii) in Lemma 4.6 *are not true*.

e.2 Let
$$\phi(x) := \text{arcsinh}(x) = \ln\left(\sqrt{x^2+1} + x\right).$$
One can see that $h(x) = \sqrt{x^2+1} + x$ satisfies (4.2) and (4.3).

e.3 Let
$$\phi(x) := \ln(\ln(x+1) + 1).$$
One can verify that $h(x) = \ln(x+1) + 1$ satisfies (4.2) and (4.3).

Abstract. A stochastic SEIR(S) model with random total population, overall saturation constant $K > 0$ and general, local Lipschitz continuous diffusion rates is presented. We prove the existence of unique, Markovian, continuous time solutions w.r.t. filtered, complete probability spaces on certain, bounded 4D prisms. The total population $N(t)$ is governed by kind of stochastic logistic equations, which allows to have an asymptotically stable maximum population constant $K > 0$. Under natural conditions on our SEIR(S) model, we establish asymptotic stochastic and moment stability of the disease-free and endemic equilibria. Those conditions naturally depend on the basic reproduction number $\mathcal{R}_0$, the growth parameter $\mu > 0$ and environmental noise intensity σ_5^2 coupled with the maximum threshold K^2 of total population $N(t)$. For the mathematical proofs, the technique of appropriate Lyapunov functionals $V(S(t), E(t), I(t), R(t))$ is exploited. Some numerical simulations of the expected Lyapunov functionals $\mathbb{E}[V(S, E, I, R)]$ depending on several parameters and time t support our findings.

Keywords: stochastic SEIR(S) model, stochastic differential equations, random transition functions, variable diffusion rates, Lyapunov functionals, asymptotic stability.

1 Introduction to stochastic SEIR(S) model based on SDEs

Research on epidemic modeling has gone quite far since the seminal contributions of Kermack and McKendrick [15]. The random, erratic nature of evolution of populations forces us to incorporate stochastic terms in modeling and analysis. For modeling of diseases with

✉Corresponding author. Email: hschurz@math.siu.edu

sensitive, randomly fluctuating transmissions such as COVID, here we suggest to make use of and analyze the stochastic SEIR(S) models based on Itô-interpreted SDEs

$$\begin{aligned} dS &= \Big(-\beta SI + \mu(K-S) + \alpha I + \zeta R \Big) dt - \sigma_1 SI \cdot F_1\big(S,E,I,R\big) dW_1 \\ &\quad + \sigma_4 R \cdot F_4(S,E,I,R) dW_4 + \sigma_5 S(K-N) dW_5 \\ dE &= \Big(\beta SI - (\mu+\eta)E \Big) dt + \sigma_1 SI \cdot F_1\big(S,E,I,R\big) dW_1 - \sigma_2 E \cdot F_2\big(S,E,I,R\big) dW_2 \\ &\quad + \sigma_5 E(K-N) dW_5 \\ dI &= \Big(\eta E - (\alpha+\gamma+\mu) I \Big) dt + \sigma_2 E \cdot F_2\big(S,E,I,R\big) dW_2 - \sigma_3 I \cdot F_3\big(S,E,I,R\big) dW_3 \\ &\quad + \sigma_5 I(K-N) dW_5 \\ dR &= \Big(\gamma I - (\mu+\zeta) R \Big) dt + \sigma_3 I \cdot F_3\big(S,E,I,R\big) dW_3 - \sigma_4 R \cdot F_4\big(S,E,I,R\big) dW_4 \\ &\quad + \sigma_5 R(K-N) dW_5, \end{aligned} \tag{1.1}$$

driven by independent, standard Wiener processes $W_k = (W_k(t))_{t \geq 0}$ on a complete, filtered probability space $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t\geq 0}, \mathbb{P})$ and the total initial population (note that they can be supposed to be nonrandom since start values are known from real-time data)

$$0 < N(0) := S(0) + E(0) + I(0) + R(0) < K$$

with nonrandom constant $K > 0$ of maximum possible threshold for total population. These models (1.1) are stochastic generalizations of deterministic counterparts in mathematical epidemiology (cf. [21, 22]). For an introduction to mathematical models in population biology and epidemiology, see the textbooks [2, 5, 6]. In biological modeling Itô calculus has to be used since the dynamics of offsprings can only depend on its past, parental generations. For an overview on the theory of Itô-interpreted stochastic differential equations (SDEs), see [1,3,10,11,14,23,24,33] for stochastic calculus with Wiener processes. Deterministic model variants of SEIR(S), SI, SIR, SIS, etc. are well-understood nowadays. The construction and analysis of dynamics along Lyapunov functions plays a key role in understanding those models, cf. [7, 9, 13, 17–19]. This is also the case with stochastic settings, cf. [12, 30–32, 34, 36]. Extinction, ergodicity, stability and recurrence of some random SEIR(S) models with constant or absent F_k are studied in [35, 37–39], restricted to unbounded cones $\mathbb{R}^d_+$. Our models (1.1) allow all solutions to live exclusively a.s. on bounded prisms of $\mathbb{R}^4$ or $\mathbb{R}^5$, resp., which represents a real requirement for biologically relevant application (due to finite resources in real life of organisms).

To the best of our knowledge, the class of SEIR(S) models (1.1) is fairly new to the literature. Our model focuses on the possible sensitivity of diseases to random transitions between compartments S of susceptible, E of exposed, I of infected, and R of recovering sub-populations, which are controlled by noise intensity functions $\sigma_k F_k$ in a fairly general manner. Those random transitions can be interpreted as random perturbations of the incidence terms βSI (i.e. **direct contact terms**), motivated by the CLT (=Central Limit Theorem, cf. Shiryaev [33]). Moreover, we allow a possible return of a share of the recovered sub-populations R to the susceptible ones as an expression for the possible loss of immunity w.r.t. the modelled disease-type, represented by the parameter ζ, and a possible switch of the infected sub-populations I to the susceptible ones, represented by the parameter α. The parameter γ stands for the rate of transitions from the infected to the recovering sub-populations. Our main focus in this paper is to verify several qualitative properties such as the boundedness and stability of all dynamics of (1.1) on certain positive prisms - properties which relate to biologically relevant models in order to to be able to replicate real scenarios.

We shall show that the new SEIR(S) model (1.1) is well-defined ($\mathbb{P}$-a.s.) on 4D prism

$$\mathbb{D} = \Big\{(S,E,I,R) \in \mathbb{R}^4_+ : \ 0 < S,E,I,R < K, \ S+E+I+R < K\Big\}.$$

For this purpose, first we shall analyze the total population $N(t)$ of the SEIR(S) model (1.1) at time t, which is defined by

$$N(t) = S(t) + E(t) + I(t) + R(t).$$

The understanding of their dynamics plays a crucial role in establishing qualitative properties of the solutions of SDEs (1.1). By summing up all equations of SEIR(S) model (1.1), the SDE for the total population $N = S + E + I + R$ is found to be of the form

$$dN(t) = \mu(K-N)\,dt + \sigma_5 N(K-N)\,dW_5 \tag{1.2}$$

on natural domain $\mathbb{D}_0 = \big(0,K\big)$, which can be treated in a separated fashion from the original system (1.1).

The paper is organized as follows. Section 2 studies the boundedness of the total population N and proves the existence of strong solutions of SDE (1.2) on open domain $\mathbb{D}_0 = (0,K)$ for all times $t \geq 0$. Section 3 is devoted to establish the existence of unique, Markovian, continuous time, strong solutions of the SEIR(S) model (1.1) on certain, positive 4D prisms. There we present the two types of equilibrium solutions, namely the disease-free and the endemic ones. Section 4 investigates stochastic stability of the disease-free equilibrium and the endemic equilibrium of SEIR(S) model (1.1). As usual, the associated basic reproduction number decides in which stable state the system is in (in the long-term sense). Moreover, we also discuss the moment and stochastic stability of its saturation equilibrium $n^* = K$ for the SDE (1.2) of the total populations. Finally, Section 5 is reporting on some graphical illustrations of simulation results related to the associated mean Lyapunov functionals depending on diverse parameters. Section 6 concludes the paper with a brief summary and outlook. An appendix recalls a general standard result on the existence of bounded, unique solutions of systems of Itô SDEs and the structure of associated infinitesimal generator, which plays a key role in our studies.

2 Existence of bounded, unique solution of (1.2) on $\mathbb{D}_0 = (0,K)$

The proof of existence of global, unique solutions of nonlinear SDE (1.2) is far from trivial, due to the quadratic nonlinearity in its diffusion term. For the sake of abbreviation, take $\sigma = \sigma_5$. Let $N(t_0) = N_0 \in \mathbb{D}_0$ with $\mathbb{D}_0 = (0,K)$ and $\mathbb{D}_r = \left(\frac{1}{r}, K - \frac{1}{r}\right), r > 1/K$. Now, consider the events $[N(t) = n]$. Define

$$n \in \mathbb{D}_0 \quad \mapsto \quad V(n) := c - \ln\Big(n(K-n)\Big) = c - \ln(n) - \ln(K-n).$$

Choose c sufficiently large such that $V \geq 0$ on $\mathbb{D}_0$. e.g. $c = \ln\left(\frac{K^2}{4}\right)$. The infinitesimal generator $\mathcal{L}$ of SDE (1.2) applied to the function V (see the general formula (A.2) in appendix) takes the form

$$\forall n \in \mathbb{D}_0: \quad \mathcal{L}V(n) = \mu(K-n)\left(\frac{-1}{n} + \frac{1}{K-n}\right) + \frac{1}{2}\sigma^2 n^2 (K-n)^2 \left[\frac{1}{n^2} + \frac{1}{(K-n)^2}\right]$$
$$= -\mu\left(\frac{K-n}{n}\right) + \mu + \frac{1}{2}\sigma^2(K-n)^2 + \frac{1}{2}\sigma^2 n^2.$$
$$\Longrightarrow \quad \mathcal{L}V(n) \overset{\mu>0}{\leq} \mu + \frac{1}{2}\sigma^2(K-n)^2 + \frac{1}{2}\sigma^2 n^2 = \mu + \frac{1}{2}\sigma^2\Big[(K-n)^2 + n^2\Big]$$
$$< \mu + \frac{1}{2}\sigma^2 K^2 =: c_0 \quad \text{since} \quad g(n) := (K-n)^2 + n^2 < K^2 \quad \text{on } \mathbb{D}_0.$$

Hence, by Dynkin's formula (1965) (cf. Dynkin [8]), we arrive at

$$\forall t \geq 0: \quad \mathbb{E}\Big[V\Big(N(t)\Big)\Big] = \mathbb{E}\Big[V\Big(N(0)\Big)\Big] + \mathbb{E}\Big[\int_0^t \mathcal{L}V(s)\,ds\Big] \leq \mathbb{E}\Big[V\Big(N(0)\Big)\Big] + c_0 \cdot t \; < \; +\infty$$

with constant $c_0 = \mu + \sigma^2 K^2/2$. Obviously, we have

$$\lim_{r\to+\infty} \inf_{t\geq 0, n\in\partial\mathbb{D}_r} V(n) = \lim_{r\to+\infty} \min\Big(V\Big(\frac{1}{r}\Big), V\Big(K - \frac{1}{r}\Big)\Big) = c - \lim_{r\to+\infty} \ln\Big(\frac{1}{r}\Big(K - \frac{1}{r}\Big)\Big) = +\infty.$$

By the remark below Theorem A.1, there exists exactly one strong, global, continuous time, unique Markovian solution $N = (N(t))_{t\geq 0}$ of SDE (1.2) with $N(t) \in \mathbb{D}_0 = (0, K)$ (a.s.) for all $t \geq 0$. This gives the positivity of N (a.s.) and boundedness $N(t) < K$ (a.s.). Of course, the equilibrium $n^* = K$ represents a solution itself (i.e. the trivial solution). Consequently, we verified the following theorem.

Theorem 2.1 (Solvability and boundedness of total population SDE (1.2))**.** *Assume that either* $N(0) = K$ *or* $N(0) \in (0, K)$ *(a.s.) is independent of sigma-algebra* $\sigma(W) = \sigma(W(t) : t \geq 0)$ *with*

$$\mathbb{E}\Big[\ln\Big(N(0)(K - N(0))\Big)\Big] \; < \; +\infty.$$

Then, *there is a unique, strong solution process* $N = (N(t))_{t\geq 0}$ *satisfying SDE* (1.2) *and* $\forall$ *nonrandom* $0 < T < +\infty$ $\forall 0 < N(0) < K$

$$\sup_{0\leq t\leq T} \mathbb{E}\Big[\ln\Big(N(t)(K - N(t))\Big)\Big] \leq \mathbb{E}\Big[\ln\Big(N(0)(K - N(0))\Big)\Big] + \Big(\mu + \frac{\sigma^2}{2}K^2\Big) \cdot T < +\infty.$$

3 Existence of bounded, unique solution of (1.1) on 4D prism $\mathbb{D}$

The following theorem establishes the existence of strong, unique solutions of SEIR(S) models (1.1) bounded to stay on certain positive prisms (a.s.).

Theorem 3.1 (Existence theorem of unique solutions of SEIR(S) model on prisms)**.** *Let* $\big(S(t_0), E(t_0), I(t_0), R(t_0)\big) = (S_0, E_0, I_0, R_0) \in \mathbb{D}$ *with*

$$\mathbb{D} = \Big\{(S, E, I, R) \in \mathbb{R}_+^4 : 0 < S, E, I, R < K, \; S + E + I + R < K\Big\}.$$

Consider the stochastic SEIR(S) model with random, nonconstant total populations

$$\begin{aligned} dS &= \big(-\beta SI + \mu(K-S) + \alpha I + \zeta R\big)dt - \sigma_1 SI \cdot F_1(S,E,I,R)dW_1 \\ &\quad + \sigma_4 R \cdot F_4(S,E,I,R)dW_4 + \sigma_5 S(K-N)dW_5 \\ dE &= \big(\beta SI - (\mu+\eta)E\big)dt + \sigma_1 SI \cdot F_1(S,E,I,R)dW_1 - \sigma_2 E \cdot F_2(S,E,I,R)dW_2 \\ &\quad + \sigma_5 E(K-N)dW_5 \\ dI &= \big(\eta E - (\alpha+\gamma+\mu)I\big)dt + \sigma_2 E \cdot F_2(S,E,I,R)dW_2 - \sigma_3 I \cdot F_3(S,E,I,R)dW_3 \\ &\quad + \sigma_5 I(K-N)dW_5 \\ dR &= \big(\gamma I - (\mu+\zeta)R\big)dt + \sigma_3 I \cdot F_3(S,E,I,R)dW_3 - \sigma_4 R \cdot F_4(S,E,I,R)dW_4 \\ &\quad + \sigma_5 R(K-N)dW_5 \\ dN &= \mu(K-N)\,dt + \sigma_5 N(K-N)\,dW_5. \end{aligned} \tag{3.1}$$

Assume that all constants $\alpha, \beta, \eta, \gamma, \zeta, \mu \geq 0$ *and*

(i) $(S_0,\ E_0,\ I_0,\ R_0) \in \mathbb{D}$ *is independent of* $\sigma\big(W_k : 1 \leq k \leq 5\big)$,

(ii) $\forall k = 1,\ 2,\ 3,\ 4,\ 5$: $F_k \in C^0_{locLip}(\mathbb{D})$ *(i.e. local Lipschitz continuous on interior* $\mathbb{D}$*)* $\bigcap C^0(\overline{\mathbb{D}})$,

(iii) $\mathbb{E}[V(S_0,E_0,I_0,R_0)] < +\infty$ *with*

$$V(S,E,I,R) = \begin{cases} R - \ln(R) + I - \ln(I) + E - \ln(E) + S - \ln(S), \\ +K - S - E - I - R - \ln(K-S-E-I-R), \end{cases}$$

(iv) $\sup_{(S,E,I,R)\in\mathbb{D}} \frac{S^2 I^2 F_1^2(S,E,I,R)}{E^2} + \sup_{(S,E,I,R)\in\mathbb{D}} \frac{E^2 F_2^2(S,E,I,R)}{I^2} + \sup_{(S,E,I,R)\in\mathbb{D}} \frac{I^2 F_3^2(S,E,I,R)}{R^2} +$ $+ \sup_{(S,E,I,R)\in\mathbb{D}} \frac{R^2 F_4^2(S,E,I,R)}{S^2} < +\infty$.

Then, *the stochastic SEIR model* (1.1) *with random total population size* $N(t)$ *admits*

(1) a unique, continuous time, Markovian, global strong solution $\big(S(t),\ E(t),\ I(t),\ R(t)\big)$ *on* $t \geq t_0$,

(2) an a.s. $\mathbb{D}$*-invariant solution (i.e. a.s. uniform boundedness of solutions on positive cone of* $\mathbb{R}^4$*)*,

(3) a uniform estimate of moments ($\forall T < +\infty$ *nonrandom)*

$$\sup_{0\leq t\leq T} \mathbb{E}[V(S(t),E(t),S(t),R(t))] \leq \mathbb{E}[V(S_0,E_0,S_0,R_0)] + [\beta K + 4\mu + \eta + \alpha + \gamma + \zeta + c_1] \cdot T,$$

where c_1 *is an appropriate constant (one may extract that from proof below).*

Proof. Define

$$\mathbb{D}_n := \Big\{ (S,E,I,R,N) \in \mathbb{R}^5_+ : e^{-n} < S,E,I,R < K - e^{-n},\ N = S+E+I+R < K(1-e^{-n}) \Big\}$$

for $n \in \mathbb{N}$. Then, due to its local Lipschitz continuous drift and diffusion coefficients, system (3.1) has a unique solution up to stopping time $\tau(\mathbb{D}_n)$ hitting the boundary of open sets $\mathbb{D}_n$ (see [3,11,16]). Furthermore, define

$$\begin{aligned} V(S,E,I,R,N) &= \begin{cases} R - \ln(R) + I - \ln(I) + E - \ln(E) + S - \ln(S) \\ +K - N - \ln(K-N) \end{cases} \\ &= V_1(S,E,I,R) + V_2(N) \end{aligned}$$

where $V_1(S,E,I,R) = R - \ln(R) + I - \ln(I) + E - \ln(E) + S - \ln(S)$,

$$V_2(N) = \widetilde{V}_2(S,E,I,R) = K - S - E - I - R - \ln(K-S-E-I-R) \ = \ K - N - \ln(K-N)$$

on $\widetilde{\mathbb{D}} = \big\{ (S,E,I,R,N) \in \mathbb{R}^5_+ : 0 < S,E,I,R < K, N = S+E+I+R < K \big\}$.

Suppose that $\mathbb{E}\big[V(S_0, E_0, I_0, R_0, N_0)\big] < +\infty$. Note that $V(S,E,I,R,N) \geq 5$ for $(S,E,I,R,N) \in \widetilde{\mathbb{D}}$ (this fact will be used below to estimate $\mathcal{L}V$). Now, calculate the infinitesimal generator $\mathcal{L}V$ applied to our SEIR(S) model 3.1 using the general formula (A.2) as stated in appendix). One encounters with the 2nd differential operator

$$\begin{aligned}
\mathcal{L}V(S,E,I,R,N) &= (-\beta SI + \mu(K-S) + \alpha I + \zeta R)\,\frac{\partial V}{\partial S} + (\beta SI - (\mu+\eta)E)\,\frac{\partial V}{\partial E} \\
&+ (\eta E - (\alpha+\gamma+\mu)I)\,\frac{\partial V}{\partial I} + (\gamma I - (\mu+\zeta)R)\,\frac{\partial V}{\partial R} + \mu(K-N)\frac{\partial V}{\partial N} \\
&+ \frac{\sigma_1^2}{2} S^2 I^2 [F_1(S,E,I,R)]^2 \left(\frac{\partial^2 V}{\partial S^2} - 2\frac{\partial^2 V}{\partial S \partial E} + \frac{\partial^2 V}{\partial E^2}\right) \\
&+ \frac{\sigma_2^2}{2} E^2 [F_2(S,E,I,R)]^2 \left(\frac{\partial^2 V}{\partial E^2} - 2\frac{\partial^2 V}{\partial E \partial I} + \frac{\partial^2 V}{\partial I^2}\right) \\
&+ \frac{\sigma_3^2}{2} I^2 [F_3(S,E,I,R)]^2 \left(\frac{\partial^2 V}{\partial I^2} - 2\frac{\partial^2 V}{\partial I \partial R} + \frac{\partial^2 V}{\partial R^2}\right) \\
&+ \frac{\sigma_4^2}{2} R^2 [F_4(S,E,I,R)]^2 \left(\frac{\partial^2 V}{\partial R^2} - 2\frac{\partial^2 V}{\partial R \partial S} + \frac{\partial^2 V}{\partial S^2}\right) \\
&+ \frac{\sigma_5^2}{2} [K-N]^2 \left(S^2\frac{\partial^2 V}{\partial S^2} + 2ES\frac{\partial^2 V}{\partial S \partial E} + E^2\frac{\partial^2 V}{\partial E^2}\right) \\
&+ \sigma_5^2 [K-N]^2 \left(SI\frac{\partial^2 V}{\partial S \partial I} + SR\frac{\partial^2 V}{\partial S \partial R} + SN\frac{\partial^2 V}{\partial S \partial N}\right) \\
&+ \sigma_5^2 [K-N]^2 \left(EI\frac{\partial^2 V}{\partial E \partial I} + ER\frac{\partial^2 V}{\partial E \partial R} + EN\frac{\partial^2 V}{\partial E \partial N} + IR\frac{\partial^2 V}{\partial I \partial R} + IN\frac{\partial^2 V}{\partial I \partial N} + RN\frac{\partial^2 V}{\partial R \partial N}\right) \\
&+ \frac{\sigma_5^2}{2} [K-N]^2 \left(I^2\frac{\partial^2 V}{\partial I^2} + R^2\frac{\partial^2 V}{\partial R^2} + N^2\frac{\partial^2 V}{\partial N^2}\right)
\end{aligned} \tag{3.2}$$

for any twice continuously differentiable function $V \in C^2(\widetilde{\mathbb{D}})$. Next, an application $\mathcal{L}V$ to our specific functional V yields that

$$\begin{aligned}
\mathcal{L}V(S,E,I,R,N) &= \mathcal{L}V_1(S,E,I,R) + \mathcal{L}V_2(N), \\
\mathcal{L}V_1(S,E,I,R) &= \mu(K-S-E-I-R) + \beta I - \frac{1}{S}\Big(\mu(K-S) + \alpha I + \zeta R\Big) - \frac{1}{E}\,\beta SI \\
&\quad + \mu + \eta - \frac{1}{I}\,\eta E + \alpha + \gamma + \mu - \frac{1}{R}\,\gamma I + \mu + \zeta + \frac{\sigma_1^2}{2}\, I^2\, F_1^2(S,E,I,R) \\
&\quad + \frac{\sigma_4^2}{2}\,\frac{R^2\, F_4^2(S,E,I,R)}{S^2} + \frac{\sigma_1^2}{2}\,\frac{S^2\, I^2\, F_1^2(S,E,I,R)}{E^2} + \frac{\sigma_2^2}{2}\, F_2^2(S,E,I,R) \\
&\quad + \frac{\sigma_2^2}{2}\,\frac{E^2\, F_2^2(S,E,I,R)}{I^2} + \frac{\sigma_3^2}{2}\, F_3^2(S,E,I,R) \\
&\quad + \frac{\sigma_3^2}{2}\,\frac{I^2\, F_3^2(S,E,I,R)}{R^2} + \frac{\sigma_4^2}{2}\, F_4^2(S,E,I,R) + 2\sigma_5^2(K-N)^2 \\
&\leq \mu(K-S-E-I-R) + \beta I + 3\mu + \alpha + \gamma + \eta + \zeta + 2\sigma_5^2(K-N)^2 \\
&\quad + \frac{\sigma_1^2}{2} \sup_{(S,E,I,R)\in\mathbb{D}} \frac{S^2 I^2 F_1^2(S,E,I,R)}{E^2} + \frac{\sigma_1^2}{2} \max_{(S,E,I,R)\in\mathbb{D}} I^2 F_1^2(S,E,I,R) \\
&\quad + \frac{\sigma_4^2}{2} \sup_{(S,E,I,R)\in\mathbb{D}} \frac{R^2 F_4^2(S,E,I,R)}{S^2} + \frac{\sigma_4^2}{2} \max_{(S,E,I,R)\in\mathbb{D}} F_4^2(S,E,I,R)
\end{aligned}$$

$$+\frac{\sigma_3^2}{2}\sup_{(S,E,I,R)\in\mathbb{D}}\frac{I^2F_3^2(S,E,I,R)}{R^2}+\frac{\sigma_3^2}{2}\max_{(S,E,I,R)\in\mathbb{D}}F_3^2(S,E,I,R)$$
$$+\frac{\sigma_2^2}{2}\sup_{(S,E,I,R)\in\mathbb{D}}\frac{E^2F_2^2(S,E,I,R)}{I^2}+\frac{\sigma_2^2}{2}\max_{(S,E,I,R)\in\mathbb{D}}F_2^2(S,E,I,R)<+\infty$$

since Theorem 3.1 (iv). Similarly, we find

$$\mathcal{L}V_2(N)=\mathcal{L}\widetilde{V}_2(S,\,E,\,I,\,R)=-\mu(K-N)+\mu+\frac{\sigma_5^2}{2}N^2.$$

Note that we may estimate $\sigma_5^2[4(K-N)^2+N^2]\leq 4\sigma_5^2K^2/5$ on $0<N<K$. Thus, we have

$$\mathcal{L}V(S,E,I,R,N)\;\leq\;\beta I+4\mu+\eta+\alpha+\gamma+\zeta+c_1\;\leq\;\beta K+4\mu+\eta+\alpha+\gamma+\zeta+c_1$$

on $\widetilde{\mathbb{D}}$, where

$$c_1=\begin{cases}\frac{2\sigma_5^2}{5}K^2+\frac{\sigma_1^2}{2}\left[\sup_{(S,E,I,R,N)\in\widetilde{\mathbb{D}}}\frac{S^2I^2F_1^2(S,E,I,R)}{E^2}+\max_{(S,E,I,R,N)\in\widetilde{\mathbb{D}}}I^2F_1^2(S,E,I,R)\right]\\ +\frac{\sigma_4^2}{2}\left[\sup_{(S,E,I,R,N)\in\widetilde{\mathbb{D}}}\frac{R^2F_4^2(S,E,I,R)}{S^2}+\max_{(S,E,I,R,N)\in\widetilde{\mathbb{D}}}F_4^2(S,E,I,R)\right]\\ +\frac{\sigma_3^2}{2}\left[\sup_{(S,E,I,R,N)\in\widetilde{\mathbb{D}}}\frac{I^2F_3^2(S,E,I,R)}{R^2}+\max_{(S,E,I,R,N)\in\widetilde{\mathbb{D}}}F_3^2(S,E,I,R)\right]\\ +\frac{\sigma_2^2}{2}\left[\sup_{(S,E,I,R,N)\in\widetilde{\mathbb{D}}}\frac{E^2F_2^2(S,E,I,R)}{I^2}+\max_{(S,E,I,R,N)\in\widetilde{\mathbb{D}}}F_2^2(S,E,I,R)\right].\end{cases} \tag{3.3}$$

Note that c_1 is finite due to hypotheses (ii) and (iv). Next, let $\tau_n(t):=\min(\tau(\mathbb{D}_n),t)$ where $\tau(\mathbb{D}_n)$ is the stopping time of the first exit from the domain $\mathbb{D}_n$. An application of Dynkin's formula [8] (1965) provides us the estimate

$$\begin{aligned}&\mathbb{E}[V(S(t),E(t),I(t),R(t),N(t))]\\ &\quad=\mathbb{E}[V(S_0,E_0,I_0,R_0,N_0)]+\mathbb{E}\left[\int_0^{\tau_n(t)}\mathcal{L}V(S(s),E(s),I(s),R(s),N(s))\,ds\right]\\ &\quad\leq\mathbb{E}[V(S_0,E_0,I_0,R_0,N_0)]+[\beta K+4\mu+\eta+\alpha+\gamma+\zeta+c_1]\cdot\mathbb{E}[\tau_n(t)]\\ &\quad\leq\mathbb{E}[V(S_0,E_0,I_0,R_0,N_0)]+[\beta K+4\mu+\eta+\alpha+\gamma+\zeta+c_1]\cdot t\quad\text{since } \tau_n(t)\leq t,\end{aligned}$$

for all nonrandom times $t>t_0$, as long as the solution $\big(S(s),E(s),I(s),R(s),N(s)\big)$ on $\widetilde{\mathbb{D}}$. Note that $\forall n\in\mathbb{N}:n>0$ and $n>\ln(K)/5$

$$\inf_{(S,E,I,R,N)\,\in\,\partial\,\mathbb{D}_n}V(S,E,I,R,N)>5n-\ln(K). \tag{3.4}$$

Recall that we have defined the stopping time $\tau_n(t):=\min\{t,\tau(\mathbb{D}_n)\}$ based on the stopping time $\tau(\mathbb{D}_n)$ arriving the first time at the boundary of $\mathbb{D}_n$. Now, apply the above estimate to get to

$$
\begin{aligned}
0 \;&\leq\; \mathbb{P}\Big(\Big[\tau(\widetilde{\mathbb{D}}) < t\Big]\Big) \overset{\mathbb{D}_n \subseteq \widetilde{\mathbb{D}}}{\leq} \mathbb{P}\Big(\Big[\tau(\mathbb{D}_n) < t\Big]\Big) = \mathbb{P}\Big(\Big[\tau_n(t) < t\Big]\Big) \\
&= \mathbb{E}\big[\mathbf{1}_{\tau_n(t)<t}\big] \quad \text{where } \mathbf{1} \text{ is the indicator function} \\
&\leq \mathbb{E}\left[\frac{V\Big(S(\tau(\mathbb{D}_n)), E(\tau(\mathbb{D}_n)), I(\tau(\mathbb{D}_n)), R(\tau(\mathbb{D}_n)), N(\tau(\mathbb{D}_n))\Big)}{\inf_{(S,E,I,R,N)\in\partial\mathbb{D}_n} V(S,E,I,R,N)} \cdot \mathbf{1}_{\tau_n<t}\right] \\
&\overset{(3)}{\leq} \frac{\mathbb{E}[V(S_0,E_0,I_0,R_0.N_0)] + \mathbb{E}[\tau_n(t)]\cdot[\beta K + 4\mu + \eta + \alpha + \gamma + \zeta + c_1]}{\inf_{(x,y,z,v,w)\in\partial\mathbb{D}_n} V(x,y,z,v,w)} \\
&\overset{(3.4)}{\leq} \frac{\mathbb{E}[V(S_0,E_0,I_0,R_0,N_0)] + t[\beta K + 4\mu + \eta + \alpha + \gamma + \zeta + c_1]}{5n - \ln(K)} \longrightarrow 0 \quad \text{as } n \to \infty
\end{aligned}
$$

for all $(S_0, E_0, I_0, R_0, N_0) \in \mathbb{D}_n$, and for all fixed, nonrandom $t \in [s, \infty)$. Thus

$$
\Longrightarrow \quad \mathbb{P}\Big(\Big[\tau(\widetilde{\mathbb{D}}) < t\Big]\Big) = \lim_{n\to+\infty} \mathbb{P}\Big(\Big[\tau(\mathbb{D}_n) < t\Big]\Big) = 0
$$

for all adapted $(S_0, E_0, I_0, R_0, N_0) \in \widetilde{\mathbb{D}}$ and all $t \geq t_0$. That means that

$$
\mathbb{P}\Big(\Big[\tau(\widetilde{\mathbb{D}}) = +\infty\Big]\Big) = 1.
$$

This proves the invariance property and global existence of solutions $\big(S(t), I(t), R(t), N(t)\big)$ on $\widetilde{\mathbb{D}}$ for any finite time t. Thus, the proof of Theorem (3.1) is complete. □

4 Asymptotic moment and stochastic stability, stability exponents

Let $p > 0$ be a real constant. Consider the d-dimensional, autonomous, Itô-interpreted SDEs

$$
dX(t) = a\big(X(t)\big)dt + b\big(X(t)\big)\,dW(t). \tag{4.1}
$$

Definition 4.1. SDE (4.1) has a **globally asymptotically p-th moment stable** equilibrium (solution) $X = x^*$ if and only if $a(x^*) = b(x^*) = 0$ and $\forall\, X(s) \in L^p(\Omega, \mathcal{F}_s, \mathbb{P})$, $s \geq 0$, $X(s) \neq x^*$ we have

$$
\lim_{t\to+\infty} \mathbb{E}\Big[\|X_{s,X(s)}(t) - x^*\|_d^p\Big] = 0
$$

(where d is the state-space dimension of the stochastic process X).

Definition 4.2. The equilibrium solution x^* of SDE (4.1) is **stochastically stable** (stable in probability) iff, for every $\varepsilon > 0$ and $s \geq t_0$, we have

$$
\lim_{x_0\to x^*} \mathbb{P}\left(\left[\sup_{t_0\leq s<\infty} \|X_{s,x_0}(t) - x^*\| \geq \varepsilon\right]\right) = 0 \tag{4.2}
$$

where $X_{s,x_0}(t)$ denotes the solution of SDE (4.1) satisfying $X(s) = x_0$ at time $t \geq s$.

Definition 4.3. The equilibrium solution x^* of SDE (4.1) is said to be **(locally) asymptotically stochastically stable** iff it is stochastically stable and

$$
\forall x_0 \in N(x^*) : \mathbb{P}\left(\left[\lim_{t\to\infty} X_{s,x_0}(t) = x^*\right]\right) = 1. \tag{4.3}
$$

Definition 4.4. The equilibrium solution x^* of SDE (4.1) is said to be **globally asymptotically stochastically stable** iff it is stochastically stable and, for every x_0 and every s, we have

$$\mathbb{P}\left(\left[\lim_{t\to\infty} X_{s,x_0}(t) = x^*\right]\right) = 1. \tag{4.4}$$

Theorem 4.5 (Stability theorem of Arnold [3])**.** *Assume that the SDE (4.1) has a unique solution started at every nonrandom x_0 in the nonrandom, a.s. invariant, open neighborhood $N(x^*) \subseteq \mathbb{R}^d$.* **Then**, *the equilibrium solution $x^* \in \overline{N(x^*)} \subseteq \mathbb{R}^d$ for SDE (4.1) is stochastically stable if $\exists$ positive definite*

$$V = V(t,x) \in C^{1,2}\Big([t_0,\infty) \times N(x^*), \mathbb{R}^1_+\Big)$$

on $N(x^*)$ such that $\forall\,(t,x) \in [t_0,\infty) \times N(x^*)$:

$$\mathcal{L}V(t,x) \le 0.$$

If additionally V is decrescent on $N(x^*)$ and

$$\forall\,(t,x) \in [t_0,\infty) \times N(x^*) \setminus \{x^*\} : \quad \mathcal{L}V(t,x) < 0,$$

then *x^* is (locally) asymptotically stochastically stable for SDE (4.1).*

We also call the equilibrium x^* of SDE (4.1) to be **globally asymptotically stochastically stable** iff it is asymptotically stochastically stable and $\mathcal{L}V < 0$ on the entire domain $\mathbb{D}$ where the dynamics of X live on (a.s.) (i.e., in this case, we may extend $N(x^*) = \mathbb{D}$ as the relevant neighborhood of x^* in above definition of stochastic stability). Note that the equilibria x^* do not have to be in the neighborhood $N(x^*)$, but $x^* \in \overline{N(x^*)}$. In fact, the Theorem 4.5 remains valid for the cases like neighborhoods of the form $N(K) = (0,K)$ or $N(K) = [\varepsilon, K)$ with equilibrium $x^* = K$ (or multidimensional variants of those examples) in order to cover the important cases of semi-stability too. For the SDE of the total population N of our SEIR(S) model, we can establish both stochastic and moment stability of the saturation constant $x^* = K$.

Theorem 4.6 (Stability of equilibrium $n^* = K$ for total populations)**.** *Consider the SDE for random total population*

$$dN = \mu(K-N)\,dt + \sigma_5 N(K-N)\,dW_5. \tag{4.5}$$

Then, *the equilibrium point $n^* = K$ of SDE (4.5) is*

(1) global asymptotically stochastically stable if $2\mu > K^2\sigma_5^2$,

(2) p-th moment exponentially stable if $2\mu > (2p-1)K^2\sigma_5^2$ and $p \ge \frac{1}{2}$, and

(3) almost surely asymptotically stable if $2\mu > (2p-1)K^2\sigma_5^2$ and $p \ge \frac{1}{2}$.

Proof. The proof for the equilibrium $n^* = K$ is naturally divided into the items (1)–(3).

(1) Let $n \in (0,K)$ for $n^* = K$. Define the Lyapunov function V by

$$n \in (0,K) \mapsto V(n) = (K-n)^2.$$

Then, we find that

$$\begin{aligned}\mathcal{L}V(n) &= \mu(K-n)\cdot 2(K-n)\cdot(-1)+\frac{1}{2}\sigma_5^2 n^2 (K-n)^2\cdot 2\\ &= (-2\mu+\sigma_5^2 n^2)\,V(n)\\ &\overset{\text{on }\mathbb{D}_0}{\leq} (-2\mu+\sigma_5^2 K^2)\,V(n).\end{aligned}$$

Now, note that $\mathcal{L}V(n) < 0$ for all $n \in (0,K)$ if $2\mu > K^2\sigma_5^2$. Therefore, an application of Arnold's Stability Theorem 4.5 confirms the claim of stochastic stability.

(2) Next, consider the Lyapunov function

$$n \in (0,K) \mapsto V(n) = (K-n)^{2p} = \left[(K-n)^2\right]^p.$$

Then, for $p \geq \frac{1}{2}$, we have

$$\begin{aligned}\mathcal{L}V(n) &= \mu(K-n)\cdot 2p(K-n)^{2p-1}\cdot(-1)+\frac{1}{2}\sigma_5^2 n^2(K-n)^2\cdot 2p(2p-1)(K-n)^{2p-2}\\ &= 2p\left[-\mu+\frac{1}{2}(2p-1)\sigma_5^2 n^2\right]\cdot V(n)\\ &\leq 2p\left[-\mu+\frac{1}{2}(2p-1)\sigma_5^2 K^2\right]\cdot V(n).\end{aligned}$$

An application of Dynkin's formula (cf. [8]) will give the conclusion that

$$\begin{aligned}\mathbb{E}\Big[V\Big(N(t)\Big)\Big] &= \mathbb{E}\Big[|K-N(t)|^{2p}\Big]\\ &\leq \mathbb{E}\Big[V\Big(N(s)\Big)\Big]\cdot e^{2p\left[-\mu+\frac{1}{2}(2p-1)\sigma_5^2K^2\right](t-s)} \qquad (4.6)\\ &\overset{t\to+\infty}{\longrightarrow} 0\end{aligned}$$

if $2\mu > (2p-1)K^2\sigma_5^2$ and $p \geq \frac{1}{2}$.

(3) The property of a.s. asymptotical stability of $n^* = K$ follows directly from the item (2) due to the fact that all exponentially moment stable equilibria also possess a.s. asymptotically stable pathwise solutions (for a proof of this fact, see [26]). This completes the proof of Theorem 4.6. □

As a by-product of the previous proof, we gain the following result on the asymptotic behavior of Lyapunov functionals $V(n) = |K-n|^{2p} = \|K-n\|_{\mathbb{R}^1}^{2p}$.

Theorem 4.7 (Uniform estimation of moment V-exponents)**.** *Consider Itô SDEs* (4.5) *for random total population* $N = (N(t))_{t\geq 0}$*.* **Then**

$$\forall p>0\ \forall N(0)=n_0\in(0,K):\ \lambda_{2p}(n_0) := \lim_{t\to+\infty}\frac{\ln\left(\mathbb{E}\left[|K-N(t)|^{2p}\right]\right)^{1/2p}}{t} \leq -\mu+\frac{1}{2}\max(2p-1,0)\sigma_5^2K^2,$$

which represents a uniform estimation of moment V-exponents $\lambda_{2p}(n_0)$ on $(0,K)$.

Proof. Return to the identity (4.6) with $V(n) = |K - n|^{2p}$. Taking $2p$-th root and the natural logarithm yield that

$$\ln\left(\mathbb{E}\left[|K - N(t)|^{2p}\right]\right)^{1/2p} \leq \ln\left(\mathbb{E}\left[|K - N(0)|^{2p}\right]\right)^{1/2p} + \left(-\mu + \frac{1}{2}\max(2p-1,0)\sigma_5^2 K^2\right) \cdot t.$$

Thus, dividing by $t > 0$ and taking the limit as $t \to +\infty$ confirms the conclusion on the asymptotic behavior of $\ln\left(\mathbb{E}[V(N(t))]\right)/t$ in the moment sense. □

Remark 4.8 (Moment V-exponents)**.** The moment V-exponents λ_{2p} measure the speed of exponential convergence of total populations $N(t)$ to the saturation constant K as time $t \to +\infty$ in the $2p$-th moment sense. The definition of moment V-exponents is made in a consistent manner (to incorporate the deterministic case). In passing, note that nonlinear V-exponents may depend on initial quantity $N(0) = n_0$, whereas V-exponents for linear systems do not depend on $N(0) = n_0$. Remarkably, for sufficiently small powers p or noise intensities σ_5 or very small constants $K > 0$, we find exponentially stable $2p$-moments (i.e. exponential moment convergence of $N(t)$ to equilibrium $n^* = K$) due to the birth parameter $\mu > 0$ in our model.

The following lemma states the form of all existing equilibria (trivial solutions) of SEIR(S) models (1.1). Its proof is an elementary exercise of algebra, hence it is omitted here.

Lemma 4.9 (Disease-free and endemic equilibria)**.** *For the drift coefficients of our SEIR(S) model* (1.1)*, we have two equilibrium points. One is disease-free and the other is the endemic equilibrium. The disease-free equilibrium of* (1.1) *is given by*

$$(S_1, E_1, I_1, R_1) = (K, 0, 0, 0) \in \overline{\mathbb{D}}$$

with its total sum $N_1 := S_1 + E_1 + I_1 + R_1 = K$ *and the endemic equilibrium by*

$$(S_2, E_2, I_2, R_2) \in \overline{\mathbb{D}},$$

$$\begin{aligned}
\text{where} \quad S_2 &= \frac{(\mu+\eta)(\alpha+\gamma+\mu)}{\beta\eta} \\
E_2 &= \frac{(\mu+\zeta)(\alpha+\gamma+\mu)}{\beta\eta}\left[\frac{\beta\eta K - (\mu+\eta)(\alpha+\gamma+\mu)}{(\mu+\zeta)(\alpha+\gamma+\mu)+\eta(\gamma+\mu+\zeta)}\right] \\
I_2 &= \left(\frac{\mu+\zeta}{\beta}\right)\left[\frac{\beta\eta K - (\mu+\eta)(\alpha+\gamma+\mu)}{(\mu+\zeta)(\alpha+\gamma+\mu)+\eta(\gamma+\mu+\zeta)}\right] \\
R_2 &= \frac{\gamma}{\beta}\left[\frac{\beta\eta K - (\mu+\eta)(\alpha+\gamma+\mu)}{(\mu+\zeta)(\alpha+\gamma+\mu)+\eta(\gamma+\mu+\zeta)}\right].
\end{aligned} \tag{4.7}$$

The disease-free equilibrium is also an equilibrium of the diffusion coefficients. For biologically meaningful occurrence of endemic equilibrium (i.e. $(S_2, E_2, I_2, R_2) \in \overline{\mathbb{D}}$*), we need to require that*

$$\beta\eta K > (\mu+\eta)(\alpha+\gamma+\mu) \tag{$*$}$$

– a condition, which is equivalent to $\mathcal{R}_0 > 1$*. For the classic concept of endemic equilibrium of both drift and diffusion terms at the same location, vanishing* $F_k(S_2, E_2, I_2, R_2) = 0$ *are imposed. Moreover, at the endemic equilibrium, we have total sum*

$$N_2 := S_2 + E_2 + I_2 + R_2 = K.$$

Proof. Elementary calculus exercise. □

Biologists and Ecologists usually express the qualitative state of systems in terms of **basic reproduction numbers** $\mathcal{R}_0$. For our SEIR(S) model (1.1), this quantity takes the form

$$\mathcal{R}_0 = \frac{\beta\eta K}{(\mu+\eta)(\alpha+\gamma+\mu)}.$$

Indeed, as we shall see below, this quantity decides about the long-term **stability mode** in which the stochastic SEIR(S) models is and the value $\mathcal{R}_0 = 1$ serves as a bifurcation parameter (cf. stability analysis in what follows). Moreover, the endemic equilibrium (S_2, E_2, I_2, R_2) can be expressed in terms of $\mathcal{R}_0$ by

$$(S_2, E_2, I_2, R_2) = \left(\frac{K}{\mathcal{R}_0}, (\mu+\zeta)\frac{K}{\mathcal{R}_0}\rho, \frac{(\mu+\zeta)}{\beta}\rho, \frac{\gamma}{\beta}\rho\right)$$

with

$$\rho := \frac{\mathcal{R}_0 - 1}{\frac{(\mu+\zeta)}{(\mu+\eta)} + \frac{(\gamma+\mu+\zeta)\mathcal{R}_0}{\beta K}}.$$

Clearly, the 2nd, 3rd and 4th components of (S_2, E_2, I_2, R_2) are positive iff $\rho > 0$ iff $\mathcal{R}_0 > 1$.

First, for stability investigation of SEIR(S) models (1.1), note that all equilibria $(S_k^*, E_k^*, I_k^*, R_k^*)$ of SDEs (1.1) possess the total sum

$$N_k^* = S_k^* + E_k^* + I_k^* + R_k^* = K$$

and are at the boundary of domain $\mathbb{D}$, i.e.

$$N_k^* \in \overline{\mathbb{D}}.$$

This is also the unique equilibrium of dynamics $N = (N(t))_{t\geq 0}$ of total populations governed by SDE (1.2). Consequently, it remains to prove that the asymptotic stability of the disease-free equilibrium when reproduction number $\mathcal{R}_0 < 1$ and the endemic equilibrium when reproduction number $\mathcal{R}_0 > 1$.

Asymptotic stability of general epidemic or environmental systems has already been investigated in [4, 13, 20, 31, 32, 34], but not our SEIR(S) model (1.1) to the best of our knowledge. These investigations are associated to appropriate Lyapunov functions or functionals (cf. [4,7,9,10,17–19] among others).

Theorem 4.10 (Asymptotic stochastic stability of disease-free equilibrium)**.** *The disease-free equilibrium solution $(S_1, E_1, I_1, R_1) = (K, 0, 0, 0)$ of (1.1) is (globally) asymptotically stochastically stable if*

$$\sigma^2 K^2 < 2\mu, \qquad \zeta \geq 0, \qquad \beta K \leq \alpha. \tag{4.8}$$

Proof. We shall apply Theorem 4.5. For this purpose, define the Lyapunov function

$$\begin{aligned} V_4(S, E, I, R) &= \frac{1}{2}(S - K + E + I + R)^2 + KE + KI + KR \\ &= \frac{1}{2}(K - N)^2 + KE + KI + KR = \hat{V}_4(E, I, R, N) \end{aligned}$$

on $\mathbb{D}$. The infinitesimal generator $\mathcal{L}$ (cf. (3.2) and generally presented one in Appendix A) acting on the Lyapunov function V_4 can be written as:

$$
\begin{aligned}
\mathcal{L}V_4(S,E,I,R) &= \big(-\beta SI + \mu(K-S) + \alpha I + \zeta R\big)(S-K+E+I+R) \\
&\quad + \big(\beta SI - (\mu+\eta)E\big)(S-K+E+I+R+K) \\
&\quad + \big(\eta E - (\alpha+\gamma+\mu)I\big)(S-K+E+I+R+K) \\
&\quad + \big(\gamma I - (\mu+\zeta)R\big)(S+E+I+R+K-K) + \frac{\sigma_5^2}{2}N^2(K-N)^2 \\
&= -\mu(S+E+I+R-K)^2 + K\big[\beta SI - \mu(E+I+R) - \alpha I - \zeta R\big] \\
&\quad + \frac{\sigma_5^2}{2}N^2(K-N)^2 \\
&= -\mu(N-K)^2 - \mu(KE+KI+KR) + K\big[(\beta S-\alpha)I - \zeta R\big] + \frac{\sigma_5^2}{2}N^2(K-N)^2 \\
&\overset{0<\delta<1}{=} -\mu(1-\delta)(N-K)^2 - \mu(KE+KI+KR) + K\big[(\beta K-\alpha)I - \zeta R\big] \\
&\quad - \Big[\delta\mu - \frac{\sigma_5^2}{2}N^2\Big](K-N)^2 \\
&\leq -\mu(1-\delta)V_4 + K\big[(\beta K-\alpha)I - \zeta R\big] - \big[\delta\mu - \frac{\sigma_5^2}{2}K^2\big](K-N)^2.
\end{aligned}
$$

Now, let $\delta \to 1-$. Then, from some $\delta > 0$ onwards as $\delta \uparrow 1$, we find a $\delta_0 < 1$ such that, for all $\delta \in (\delta_0, 1]$, we have $-\delta\mu + \sigma_5^2 K^2/2 \leq 0$ by hypothesis $2\mu > \sigma_5^2 K^2$.

Thus, $\mathcal{L}V_4(S,E,I,R) \leq 0$ is indeed negative-definite on $\mathbb{D}$ under the presumptions that $\beta K - \alpha \leq 0$, $\zeta \geq 0$ and $2\mu > \sigma_5^2 K^2$. It remains to apply stochastic stability Theorem 4.5 to confirm Theorem 4.10. □

Remark 4.11 (Role of basic reproduction number)**.** One of the most important quantities in epidemiology is the basic reproduction number $\mathcal{R}_0$, expected number of secondary infections produced when one infected individual entered a fully susceptible population [15]. It usually determines whether there is an epidemic or not. If $\mathcal{R}_0 < 1$ then the outbreak will disappear. On the contrary, if $\mathcal{R}_0 > 1$ then the epidemic will spread a population. Recall that the basic reproduction number of our SEIR(S) model is $\mathcal{R}_0 = \frac{\eta\beta K}{(\mu+\eta)(\alpha+\gamma+\mu)}$. Later we will see that this number $\mathcal{R}_0$, the magnitude of $\mu > 0$ and the parameter $\sigma_5^2 K^2$ involving environmental noise intensity σ_5 decide about whether the disease-free or the endemic equilibrium is (asymptotically) stochastically stable (cf. Theorems 4.10 and 4.15).

Remark 4.12 (Possible extinction of disease)**.** Theorem 4.10 concludes that, if $\alpha - \beta K \geq 0$ and the environmental noise level σ_5^2 is so small such that $2\mu \geq \sigma_5^2 K^2$, then the disease will die out. This statement does not contradict to the fact $\mathcal{R}_0 < 1$. Because the stability condition $\alpha - \beta K \geq 0$ can be written in terms of the basic reproduction number as follows

$$\beta K \leq \alpha < (\alpha+\gamma+\mu)\frac{(\mu+\eta)}{\eta} \quad \Rightarrow \quad \frac{\eta\beta K}{(\mu+\eta)(\alpha+\gamma+\mu)} = \mathcal{R}_0 < 1.$$

Corollary 4.13 (Exponential moment stability of disease-free equilibrium)**.** *Since*

$$\mathcal{L}V_4(S,E,I,R) \leq -\mu V_4(S,E,I,R)$$

under condition that $\beta K \le \alpha$, $\zeta \ge 0$ *and* $\mu \ge \sigma_5^2 K^2$, *by Dynkin's formula, the disease-free equilibrium* $(K,0,0,0)$ *is exponentially moment* V*-stable [26,27] with rate* $-\mu$, *i.e.* $\forall t \ge 0$:

$$\mathbb{E}\Big[V_4(S(t),E(t),I(t),R(t))\Big] \le \mathbb{E}\Big[V_4(S(0),E(0),I(0),R(0))\Big]\cdot \exp\Big(-\mu\cdot t\Big),$$

$$\text{hence} \quad \lim_{t\to\infty}\frac{\ln\left[\mathbb{E}[V_4(S(t),E(t),I(t),R(t))]\right]}{t} = -\mu < 0. \tag{4.9}$$

Proof. Recall the structure of associated infinitesimal generator $\mathcal{L}$ and the computations of $\mathcal{L}V_4$ in the proof of Theorem 4.10. There we have found that

$$\mathcal{L}V_4(S,E,I,R) = -\mu(N-K)^2 - \mu(KE+KI+KR) + K\big[(\beta S-\alpha)I - \zeta R\big] + \frac{\sigma_5^2}{2}N^2(K-N)^2.$$

Under $\mu \ge \sigma_5^2 K^2$, we further estimate

$$\begin{aligned}\mathcal{L}V_4(S,E,I,R) &= -\frac{\mu}{2}(N-K)^2 - \mu(KE+KI+KR) + K\big[(\beta S-\alpha)I-\zeta R\big] - \frac{\mu-\sigma_5^2N^2}{2}(K-N)^2\\ &\le -\mu V_4 + \underbrace{K\big[(\beta S-\alpha)I-\zeta R\big] - \frac{\mu-\sigma_5^2K^2}{2}(K-N)^2}_{\le\ 0 \text{ on } \mathbb{D} \text{ since } \beta K\le\alpha,\ \zeta\ge 0,\ \mu\ge\sigma_5^2K^2}\\ &\le -\mu V_4.\end{aligned}$$

Then, Dynkin's formula [8] gives

$$\begin{aligned}\mathbb{E}\big[V_4\big(S(t),E(t),I(t),R(t)\big)\big] &= \mathbb{E}\big[V_4\big(S_0,E_0,I_0,R_0\big)\big] + \mathbb{E}\Big[\int_0^t \mathcal{L}V_4\big(S(s),E(s),I(s),R(s)\big)ds\Big]\\ &\le \mathbb{E}\big[V_4\big(S_0,E_0,I_0,R_0\big)\big] - \mu\mathbb{E}\Big[\int_0^t V_4\big(S(s),E(s),I(s),R(s)\big)ds\Big].\end{aligned}$$

Now, apply the well-known Bellman–Gronwall lemma to the dynamics of

$$v(t) := \mathbb{E}\big[V_4\big(S(t),E(t),I(t),R(t)\big)\big]$$

to conclude exponentially moment V-stability with $V = V_4$ (for the general concept of moment V-stability, see [26,27]). This finishes the proof of Corollary 4.13. □

Remark 4.14 (Extension of exponential stability at reduced rates)**.** There is a verification of a small extension of the range of exponential stability of disease-free equilibrium possible for the case $\sigma_5^2K^2/2 < \mu < \sigma_5^2K^2$. However, this is verified only at reduced rate $-\mu + \sigma_5^2K^2/2$ of exponential convergence, compared to rate $-\mu < 0$ of Corollary 4.13. For this, one may establish the estimates $\mathcal{L}V_4 \le [-\mu + \sigma_5^2K^2/2]V_4$ from the above proof.

Now, let us turn to the study of asymptotic stability of the endemic equilibrium.

Theorem 4.15 (Asymptotic stochastic stability of endemic equilibrium)**.** *Assume that*

$$\beta\eta K > (\mu+\eta)(\alpha+\gamma+\mu)$$

(i.e. $\mathcal{R}_0 > 1$*) and* $2\mu \ge \sigma_5^2K^2$. **Then**, *the endemic equilibrium solution* (S_2,E_2,I_2,R_2) *of the system (1.1) is (globally) stochastically stable on*

$$\mathbb{D} = \big\{(S,E,I,R) : S>0, E>0, I>0, R>0, S+E+I+R<K\big\}.$$

If even $2\mu > \sigma_5^2K^2$, **then** *the endemic equilibrium* (S_2,E_2,I_2,R_2) *of* (1.1) *is (globally) asymptotically stochastically stable on* $\mathbb{D}$.

Proof. Introduce the function

$$V_5(S,E,I,R) = \begin{cases} S - S_2 + E - E_2 + I - I_2 + R - R_2 \\ -(S_2 + E_2 + I_2 + R_2)\ln\left(\dfrac{S+E+I+R}{S_2+E_2+I_2+R_2}\right) \end{cases} \tag{4.10}$$

on $\mathbb{D}$. Note that $V_5 \geq 0$ on $\mathbb{D}$ and $V_5 = 0 \iff S+E+I+R = K$ on $\mathbb{D}$ (by elementary calculus applied to $V_5(S,E,I,R) = \widetilde{V}_5(N)$ with $N = S+E+I+R \in (0,K]$. Actually $\widetilde{V}_5$ is strictly decreasing in $N \in [0,K)$). Thus, it is fairly easy to recognize that V_5 possesses all properties of a Lyapunov function on $\mathbb{D}$. Then, we have $\forall (S,E,I,R) \in \mathbb{D}$

$$\begin{aligned} \mathcal{L}V_5(S,E,I,R) &= \big(-\beta SI + \mu(K-S) + \alpha I + \zeta R\big)\left(1 - \frac{S_2+E_2+I_2+R_2}{S+E+I+R}\right) \\ &\quad + \big(\beta SI - (\mu+\eta)E\big)\left(1 - \frac{S_2+E_2+I_2+R_2}{S+E+I+R}\right) \\ &\quad + \big(\eta E - (\alpha+\gamma+\mu)I\big)\left(1 - \frac{S_2+E_2+I_2+R_2}{S+E+I+R}\right) \\ &\quad + \big(\gamma I - (\mu+\zeta)R\big)\left(1 - \frac{S_2+E_2+I_2+R_2}{(S+E+I+R)}\right) + \frac{\sigma_5^2}{2}N^2(K-N)^2 \cdot \frac{K}{N^2} \\ &= \left(1 - \frac{S_2+E_2+I_2+R_2}{S+E+I+R}\right)\mu(K-S-E-I-R) + \frac{\sigma_5^2}{2}K(K-N)^2. \end{aligned} \tag{4.11}$$

Note that, with $N = S+E+I+R$, we find that

$$\mu(K-N) = \mu(K-S-E-I-R) \overset{\text{LEM 4.9}}{=} -\mu(S+E+I+R-S_2-E_2-I_2-R_2).$$

Hence, we arrive at

$$\begin{aligned} \mathcal{L}V_5(S,E,I,R) &= -\mu(S+E+I+R-S_2-E_2-I_2-R_2)\left(1 - \frac{S_2+E_2+I_2+R_2}{S+E+I+R}\right) \\ &\quad + \frac{\sigma_5^2}{2}K(K-N)^2 \\ &= -\mu\frac{(S-S_2+E-E_2+I-I_2+R-R_2)^2}{S+E+I+R} + \frac{\sigma_5^2}{2}K(K-N)^2 \\ &= -\mu\frac{(K-N)^2}{N} + \frac{\sigma_5^2}{2}KN\frac{(K-N)^2}{N} \\ &\overset{\sigma_5^2 \geq 0}{\leq} -\left(\mu - \frac{\sigma_5^2}{2}K^2\right)\frac{(K-N)^2}{N} \leq 0 \end{aligned} \tag{4.12}$$

since $0 < N < K$ on $\mathbb{D}$ and by hypothesis $2\mu \geq \sigma_5^2 K^2$.

Therefore, by Theorem 4.5, the endemic equilibrium (S_2, E_2, I_2, R_2) is stochastically stable (globally on $\mathbb{D}$) if $\mathcal{R}_0 > 1$ and $2\mu \geq \sigma_5^2 K^2$. Moreover, when additionally $2\mu > \sigma_5^2 K^2$, a careful look again at estimation (4.12) yields that

$$\mathcal{L}V_5(S,E,I,R) \leq -\left(\mu - \frac{\sigma_5^2}{2}K^2\right)\frac{(K-N)^2}{N} < 0$$

on $\mathbb{D}$. Consequently, by Theorem 4.5, the endemic equilibrium (S_2, E_2, I_2, R_2) of SDEs (1.1) indeed is asymptotically stochastically stable (globally on $\mathbb{D}$) if $\mathcal{R}_0 > 1$ and $2\mu > \sigma_5^2 K^2$. This conclusion completes the proof of Theorem 4.15. □

Remark 4.16 (Nonlinear distance measure to endemic equilibrium)**.** The function V_5 of the form (4.10) measures the distance of solutions (S, E, I, R) to the endemic equilibrium (S_2, E_2, I_2, R_2) in a nonlinear fashion.

Corollary 4.17 (Exponential moment stability of endemic equilibrium)**.** *Assume that*

$$\beta\eta K > (\mu+\eta)(\alpha+\gamma+\mu)$$

(i.e. $\mathcal{R}_0 > 1$*),* $2\mu > \sigma_5^2 K^2$ *and the initial total population* $0 < N(0) := S(0)+E(0)+I(0)+R(0) < K$ *is nonrandom.*
Then, *the endemic equilibrium solution* (S_2, E_2, I_2, R_2) *of system* (1.1) *is exponentially moment* V_5*-stable with rate* $-(\mu-\sigma_5^2K^2/2)N(0)/K$*, i.e.* $\forall t \geq 0$:

$$\mathbb{E}[V_5(S(t),E(t),I(t),R(t))] \leq \mathbb{E}[V_5(S(0),E(0),I(0),R(0))] \cdot \exp\left(-\left(\mu-\frac{\sigma_5^2K^2}{2}\right)\frac{N(0)}{K}\cdot t\right),$$

hence

$$\lim_{t\to+\infty} \frac{\ln\left[\mathbb{E}[V_5(S(t),E(t),I(t),R(t))]\right]}{t} \leq -\left(\mu-\frac{\sigma_5^2K^2}{2}\right)\frac{N(0)}{K} < 0.$$

Proof. Define the total population $N(t) = S(t)+E(t)+I(t)+R(t)$ for $t \geq 0$. Suppose that $N(0)$ is nonrandom. Recall that $S_2+E_2+I_2+R_2 = K$ by Lemma 4.9. Now, return to the proof of Theorem 4.15 where we have computed

$$\begin{aligned}\mathcal{L}V_5(S,E,I,R) &= \left(1-\frac{S_2+E_2+I_2+R_2}{S+E+I+R}\right)\mu(K-S-E-I-R)\\ &= \left(1-\frac{K}{N}\right)\left(\mu-\frac{\sigma_5^2}{2}K^2\right)(K-N) = -\left(\mu-\frac{\sigma_5^2}{2}K^2\right)\cdot\frac{(N-K)^2}{N}\\ &\leq -\left(\mu-\frac{\sigma_5^2}{2}K^2\right)\frac{N(0)}{K}\cdot V_5(S,E,I,R) \quad \text{for } N \geq N(0)\end{aligned}$$

since the total population $N(t)$ is monotonically increasing for our SEIR model and Lyapunov functional $V_5(S,E,I,R) = N-K-K\cdot\ln\left[\frac{N}{K}\right] =: \widetilde{V}_5(N)$ on $\mathbb{D}$ with monotonically decreasing $\widetilde{V}_5(N)$ in N (calculate $\widetilde{V}_5'(N) = (N-K)/N < 0$ on $N \in (0,K)$ and the simple calculus fact that

$$-\frac{(N-K)^2}{N} < -\frac{N}{K}\widetilde{V}_5(N) < -\frac{N(0)}{K}\widetilde{V}_5(N)$$

for all $N \geq N(0)$. Finally, with nonrandom initial $N(0) = S(0)+E(0)+I(0)+R(0) < K$, apply Dynkin's formula to arrive at

$$\begin{aligned}\mathbb{E}\left[\widetilde{V}_5(N(t))\right] &= \mathbb{E}\left[\widetilde{V}_5(N(0))\right] + \mathbb{E}\left[\int_0^t \mathcal{L}\widetilde{V}_5(N(s))\,ds\right]\\ &\leq \mathbb{E}\left[\widetilde{V}_5(N(0))\right] - \left(\mu-\frac{\sigma_5^2}{2}K^2\right)\frac{N(0)}{K}\int_0^t \mathbb{E}\left[\widetilde{V}_5(N(s))\right]ds.\end{aligned}$$

It remains to use the well-known Bellman–Gronwall lemma to conclude that

$$v(t) := \mathbb{E}\left[\widetilde{V}_5(N(t))\right]$$

(recall that $V_5(S(t),E(t),I(t),R(t)) = \widetilde{V}_5(N(t))$) in order to verify exponential moment stability along functional V_5 with a "least" rate estimated by $-(\mu-\frac{\sigma_5^2}{2}K^2)\frac{N(0)}{K}$. □

Remark 4.18 (A.s. stability and rates of exponential stability)**.** Since exponential moment stability also implies a.s. asymptotic stability, from Corollary 4.17, we also gain the conclusion on a.s. asymptotic V_5-stability of the endemic equilibrium (S_2, E_2, I_2, R_2) on $\overline{\mathbb{D}}$ under the hypothesis that $\mathcal{R}_0 > 1$ and $2\mu > \sigma_5^2 K^2$ (by dissipative techniques from [27]). Besides, the continuous time and discrete time moment attractivity exponents of other appropriate functionals $V \geq 0$ can also be estimated by some results from [26]. But, this would sprinkle the frame of this paper. Note, it is common that the rates of stability or attractivity of nonlinear dynamical systems depend on the initial values like $N(0)$ above (in contrast to linear systems).

5 Illustrations of moment functionals and reproduction number

Here we illustrate the behavior of moment Lyapunov functionals along the solutions of SEIR(S) model (1.1) and the structure of reproduction number. First, we plot the 2D surface of reproduction number $\mathcal{R}_0$ depending on growth parameter μ and transition parameters $\alpha + \gamma$. The conceivable hyperplane $\mathcal{R}_0 = 1$ decides whether the system (1.1) has an asymptotically stable disease-free or endemic equilibrium. For examples, above the hyperplane $\mathcal{R}_0 = 1$ we locate the region where the endemic equilibrium is asymptotically stochastically stable (similar below that plane for stability of disease-free equilibrium). Figure 5.1 shows that increasing μ stabilizes the dynamics of SEIR model (1.1) toward the disease-free equilibrium. This also happens with increasing the transition parameter sum $\alpha + \gamma$, but at a much slower scale. For sufficiently small μ and small $\alpha + \gamma$, the endemic equilibrium is asymptotically stochastically stable since the reproduction number is well above the hyperplane $\mathcal{R}_0 = 1$, as clearly seen in left corner of Figure 5.1.

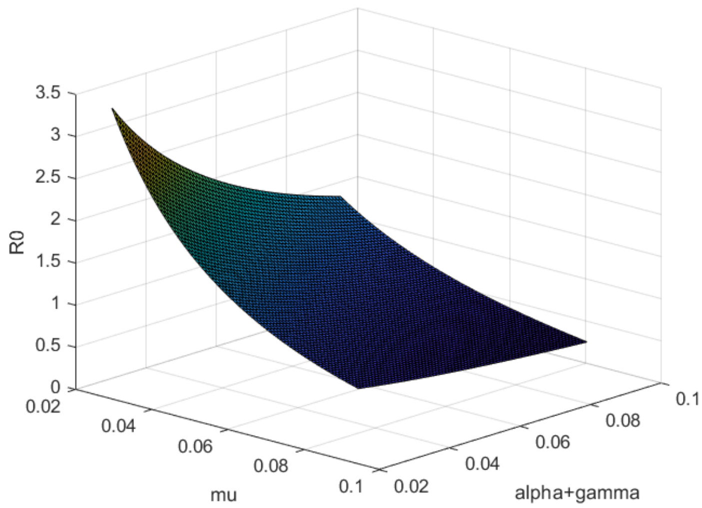

Figure 5.1: Reproduction number $\mathcal{R}_0(\mu, \alpha+\gamma)$ with $\beta = 25 \cdot 10^{-5}$, $\eta = 0.005$, $\zeta = 0.002$, $K = 1000$ depending on $\mu = mu$ and $\alpha + \gamma = r$.

Next, we illustrate the dynamics of total population process $N = (N(t))_{t \geq 0}$ in pathwise (a.s.) and mean sense. Figure 5.2 shows several paths of total population $N(t)$ generated by

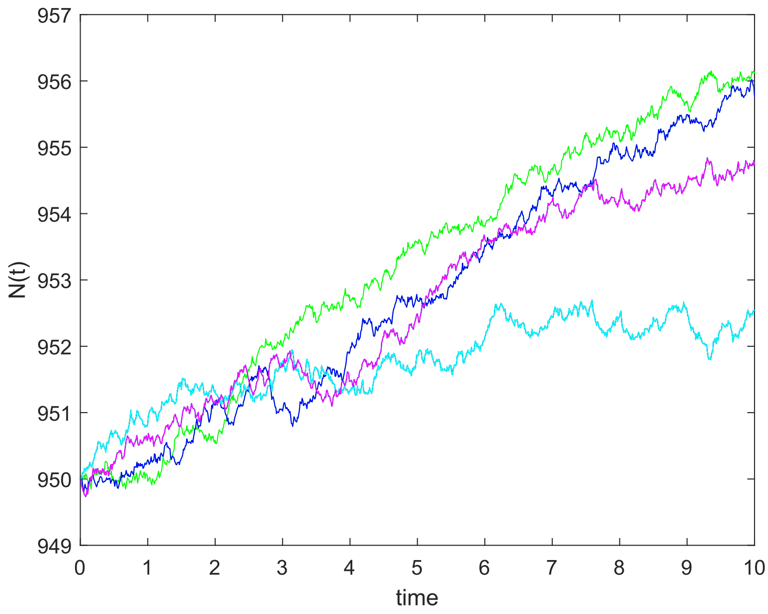

Figure 5.2: Several trajectories of total population with $\mu = 10^{-2}$, $K = 1000$, $\sigma = 10^{-5}$, $T = 10$, step size $h = 10^{-2}$, started at $N(0) = 950$.

the Euler–Maruyama method in MATLAB. This demonstrates the variety and erratic effect of noise on the solution-paths.

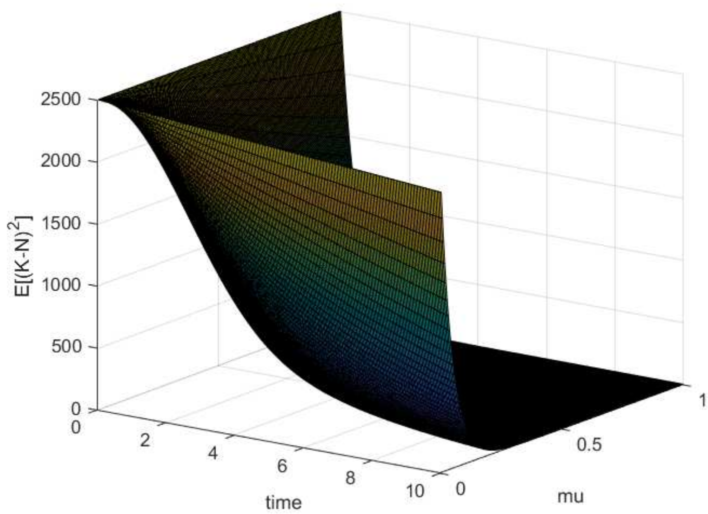

Figure 5.3: Expected Lyapunov functional $\mathbb{E}[K - N(t)]^2$ versus t and μ with $K = 1000$, $\sigma = 10^{-5}$, $T = 10$, $M = 10^6$, step size $h = 10^{-2}$, started at $N(0) = 950$.

Figure 5.3 displays the expected Lyapunov functional $\mathbb{E}[K - N(t)]^2$ versus time t and parameter μ, generated by $M = 10^6$ samples started with same total population size $N(0) = 950 < K = 10^3$ and discretized by standard Euler–Maruyama method with uniform step size $h = 10^{-2}$ in MATLAB. As seen there, the dynamics stabilize with increasing parameter μ and with advancing time t. The decline of 2D surface of $\mathbb{E}[K - N(t)]^2$ in time t and μ also confirms Theorem 4.6 that, for sufficiently large μ, we find asymptotically stable equilibrium $n^* = K$ for total population.

In Figure 5.4 the expected Lyapunov functional $\mathbb{E}[K - N(10)]^2$ versus parameters μ and σ is depicted, generated by $M = 10^6$ samples started with same total population size $N(0) = 950 < K = 10^3$ and discretized by standard Euler–Maruyama method with uniform step size $h = 10^{-2}$ in MATLAB. Clearly, we reckon that the dynamics of that functional is "destabilized" with increasing noise intensity σ and "stabilized" with increasing parameter μ. This gives us some statistical evidence for our Theorems 4.7 (i.e. decline of moments with growing $\mu > 0$) and 4.6 (i.e. the destabilizing effect of growing σ^2 on moments and stability). Of course, care is needed since growing variance with increasing σ^2 reduces our confidence in the estimation process and perhaps larger sample sizes are needed to confirm simulation results. All in all, larger noise intensities reveal a fairly nontrivial, nonlinear dependence of functionals $\mathbb{E}[K - N(10)]^2$ on model parameters (μ, σ).

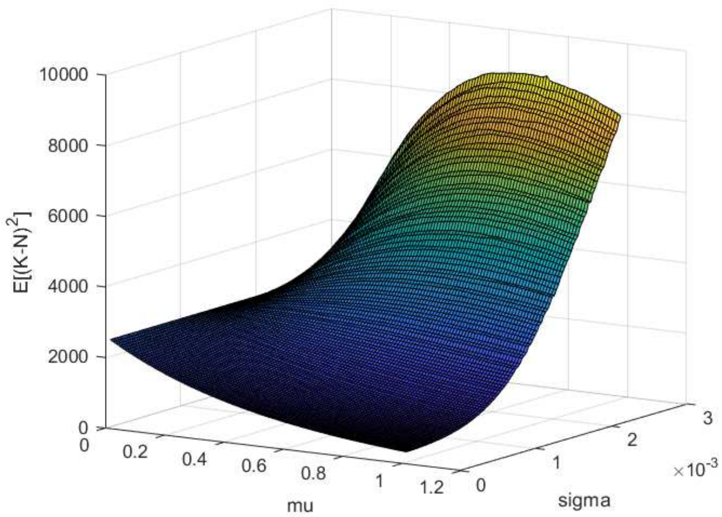

Figure 5.4: Expected Lyapunov functional $\mathbb{E}[K - N(10)]^2$ versus μ and σ with $K = 1000$, $T = 10$, $M = 10^6$, step size $h = 10^{-2}$, started at $N(0) = 950$.

Figure 5.5 plots the 2D surface of expected Lyapunov functional $\mathbb{E}[K-N(t)]^2$ versus time t and parameter σ with $\mu = 0.09$, generated by $M = 10^6$ samples started with same total population size $N(0) = 950 < K = 10^3$ and discretized by standard Euler–Maruyama method with step size $h = 10^{-2}$ in MATLAB. For small $\sigma > 0$, the surface of this functional declines at lower right corner of Figure 5.5. That is an empirical indicator that the SEIR(S) model is in the stable regime. However, for larger, increasing values of $\sigma > 0$, the 2D surface gets "destablized" as time t advances, as we especially reckon at upper right corner of Figure 5.5.

We could continue with showing more and more simulation results. Clearly, we have demonstrated the applicability of our analysis and have suggested to plot 2D surface of multi-dimensional expected Lyapunov functionals in order to get empirical evidence about which stable or unstable mode the SEIR(S) model is in. Eventually, by Figure 5.6, we display 2D surfaces of expected Lyapunov functional $m(t, p) = (\mathbb{E}[|K - N(t)|^{2p}])^{1/2p}$ depending on powers $p \geq 0.5$ and time t, while $\mu = 1.0$, $K = 1000$ and $\sigma = 10^{-5}$ are fixed. This shows the depen-

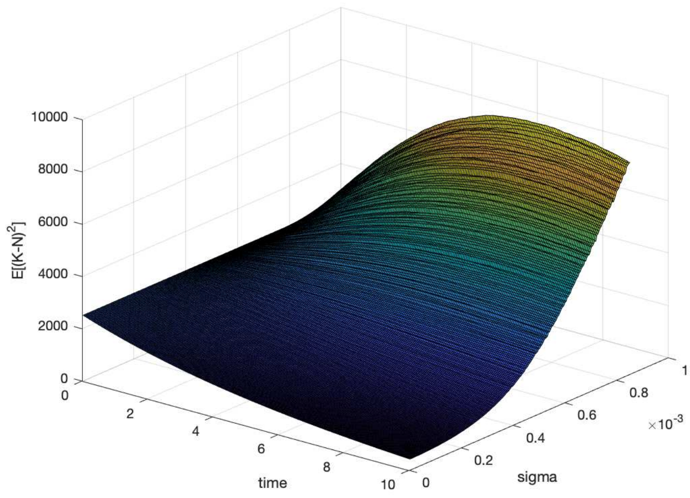

Figure 5.5: Expected Lyapunov functional $\mathbb{E}[K-N(t)]^2$ versus time t and σ with $\mu = 0.09$, $K = 1000$, $T = 10$, $M = 10^6$, step size $h = 10^{-2}$, started at $N(0) = 950$.

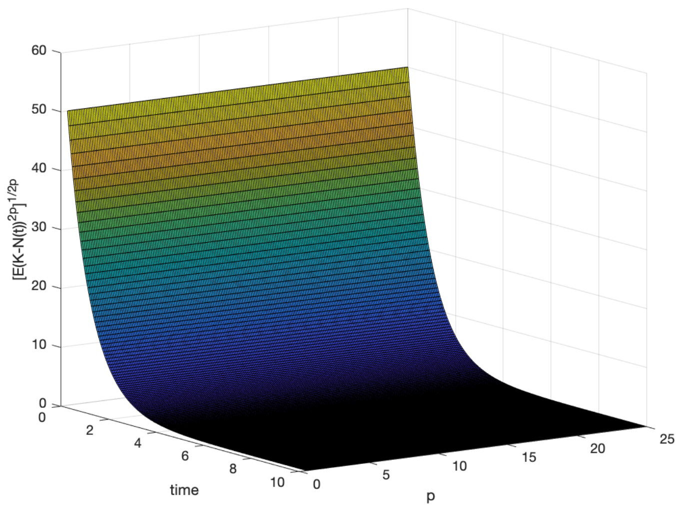

Figure 5.6: Expected Lyapunov functional $\left(\mathbb{E}[K-N(t)]^{2p}\right)^{1/2p}$ versus time t and power p with $\mu = 1.0$, $K = 1000$, $T = 10$, $M = 10^6$, step size $h = 0.05$, started at $N(0) = 950$.

dence of expected Lyapunov functionals $m(t,p)$ on powers $p \geq 0.5$ and time $t \geq 0$. As time t advances,the depicted hyperplane declines toward zero, giving some evidence of the stable mode of our SEIR(S) model since $2\mu > \sigma^2 K^2$ in our simulation. There are only small changes in p in that range. The decline of 2D-surface $m(t,p)$ in Figure 5.6 with increasing time t confirms the findings of Theorems 4.6 and 4.7 on asymptotic stability of equilibrium $n^* = N$ using Lyapunov functionals. The simulation has been conducted with the Euler–Maruyama method using step size $h = 0.05$ in MATLAB. The crude step size $h = 0.05$ is applied since the limited computational capacity of our computers, and we put our main emphasis on large sample sizes M and fine discretization of parameter space $p \in (0, 25]$ in order to get more statistical evidence (instead of higher numerical accuracy). To get some assurance of our graphical plots and stable computations, we repeated the experiments to get some confirmation by much smaller step sizes h (but at the expense of reduced sample sizes).

Similar experiments can be conducted for other functionals of biological interest like the convergence to all their equilibria. Such an endeavor is left to interested reader.

6 Summary, conclusions and outlook

This paper introduced a stochastic SEIR(S) model (1.1) based on Itô stochastic differential equations (SDEs) with a deterministic maximum saturation constant $K > 0$. The main emphasis is on the incorporation of possible random transitions from one compartment to another (sub-populations). As one of the major differences to previously introduced SEIR(S) models, our model (1.1) possesses a random total population $N = (N(t))_{t\geq 0}$, which itself is governed by a logistic Itô SDE with the equilibrium $n^* = K$. It was shown that the total population $N(t)$ is a.s. positive and bounded by the saturation constant $K > 0$ - a requirement for the practical relevance of any SEIR(S) models. Moreover, conditions have been worked out for the asymptotic stochastic and moment stability of the equilibrium K of the total population process $N = (N(t))_{t\geq 0}$. The analysis of dynamics of the total population N is essential for the understanding and qualitative control of the solutions of SEIR models (1.1).

The paper proves the existence of unique, strong solutions (S, E, I, R) of original SEIR(S) models (1.1) on bounded, positive prisms $\mathbb{D} \subset \mathbb{R}^4_+$ for all adapted, initial data residing inside $\mathbb{D}$ (with finite initial "energy"). We have also verified reasonable criteria for the asymptotic stochastic and moment stability of the disease-free and the endemic equilibria of (1.1). As commonly expected, the basic reproduction number $\mathcal{R}_0$ decides about the stable character of the equilibria ($\mathcal{R}_0 < 1$ for stability of the disease-free equilibrium and $\mathcal{R}_0 > 1$ for stability of the endemic equilibrium). Finally, we illustrated our major findings w.r.t. declining moment Lyapunov functionals, depending on several parameters. Very recently during submission of this paper, it came to our attention that there is already a generalization of SEIR(S) models with stochastic transmission by [36]. However, his model only allows back-and-forth transitions from S to E to S and there is no back coupling from R or I back to S and E, and he does not incorporate general functions F_k controlling the rates of nonlinearities (i.e. just the case of constant rates in the incidence terms). Moreover, a verification of a.s. exponential stability of equilibria is only conducted there. Our model also admits random transitions from the remaining population $K - N$ to the sub-populations S, E, I, R with $N = S + E + I + R$.

There are plenty of possible generalizations. One could try out Levy-type- or jump-processes for the random noise sources or Markovian switching or non-Markovian regimes. However, all generalizations should be done through semi-martingale theory due to the continuity requirement of the underlying integration operator in biologically relevant applications.

Itô calculus interpretations are the commonly adopted models for the sake of the fact that the offspring populations should only depend on the past, i.e. the closest parental generations. At the end, statistical matching to real data would decide on the relevance of each SEIR(S) model. We leave the practical execution of all of those ideas to the interested reader. We are convinced that our model class already offers enough flexibility and interesting phenomena, however restricted to Markovian modeling by this contribution.

A Appendix: A general existence result of solutions of SDEs

Consider d-dimensional, Itô-interpreted stochastic differential equations (SDEs) of the form

$$dX(t) = f\big(X(t),t\big)dt + g\big(X(t),t\big)dW(t) \tag{A.1}$$

with initial value $X(t_0) = X_0, t_0 \le t \le T < +\infty$, where $f : \mathbb{R}^d \times [t_0,T] \to \mathbb{R}^d$ and $g : \mathbb{R}^d \times [t_0,T] \to \mathbb{R}^{d\times m}$ are Borel measurable functions, $W = \{W(t)\}_{t\ge t_0}$ is a $\mathbb{R}^m-$valued Wiener process and X_0 is a $\mathbb{R}^d-$valued random variable. Recall that its infinitesimal generator $\mathcal{L}$ associated with the above SDE (A.1) is given by

$$\mathcal{L} \;=\; \frac{\partial}{\partial t} + \sum_{i=1}^{d} f_i(x,t)\frac{\partial}{\partial x_i} + \frac{1}{2}\sum_{j=1}^{m}\sum_{i=1}^{d}\sum_{k=1}^{d} g_i^j(x,t)g_k^j(x,t)\frac{\partial^2}{\partial x_i \partial x_k}. \tag{A.2}$$

Theorem A.1 (Improved version of a theorem from Khas'minskii (1980))**.** *Assume that*

(i) $f,g \in C^0_{locLip(L)}\big(\mathbb{D}\times[0,T]\big)$,

(ii) $(\mathbb{D}_r)_{r>0}$ *nondecreasing, bounded, connected, all* $\mathbb{D}_r \subseteq \mathbb{R}^d$ *and* $\mathbb{D} = \cup_{r>0}\mathbb{D}_r$,

(iii) $\sigma\big(X(0)\big)$ *is independent of* $\sigma\big(W(s) : s \le T\big)$ *and* $X(0) \in \mathbb{D}$,

(iv) $\exists\, V \in C^{2,1}\big(\mathbb{D}\times[0,T]\big)$ *with* $V : \mathbb{D}\times[0,T] \to \mathbb{R}^1_+$, $\exists\, a \in L^1\big([0,T]\big)$

$$\forall\, x \in \mathbb{D}\;\forall\, t \in [0,T]: \quad \mathcal{L}V(x,t) \le a \cdot V(x,t),$$

(v) $\mathbb{E}\big[V\big(X(0),0\big)\big] < +\infty$,

(vi) $\inf_{t>0,\, x\in\partial\mathbb{D}_r} V(x,t) \overset{r\to+\infty}{\longrightarrow} +\infty$.

Then, $\exists$ *strong, unique, continuous time, Markovian solution* X *of SDE* (A.1) *with* $X(0) = X_0$ *and* $X(t) \in \mathbb{D}$ *for all* $t > 0$.

Remark A.2 (Linear versus exponential moment bounds)**.** The conclusion of Theorem A.1 remains valid if one replaces the assumption (iv) by the hypothesis

(iv)' $\exists\, V \in C^{2,1}\big(\mathbb{D}\times[0,T]\big)$ with $V : \mathbb{D}\times[0,T] \to \mathbb{R}^1_+$, $\exists\, a \in L^1\big([0,T]\big)$

$$\forall\, x \in \mathbb{D}\;\forall t \in [0,T]: \quad \mathcal{L}V(x,t) \le c_0,$$

where c_0 is an appropriate constant. In this case, one is able to prove the uniform boundedness

$$\sup_{0\le t\le T} \mathbb{E}\Big[V\big(X(t),t\big)\Big] \le \mathbb{E}\Big[V\big(X(0),0\big)\Big] + [c_0]_+ \cdot T$$

of the moments along the functionals V of solutions X. In contrast to that fact, the original assumption (iv) of Theorem A.1 with any constant $a(t) = c_1$ guarantees the uniform exponential bounds

$$\sup_{0 \le t \le T} \mathbb{E}\Big[V(X(t),t)\Big] \le \mathbb{E}\Big[V(X(0),0)\Big] \cdot \exp\left([c_1]_+ \cdot T\right)$$

of the moments $\mathbb{E}[V(X(t),t)]$ as worst-case estimate. Here, $[\cdot]_+$ denotes the nonnegative part of the inscribed mathematical expression.

Remark A.3 (Comment on uniqueness of solutions)**.** Uniqueness of strong solutions X of SDEs (A.1) with local Lipschitz continuous coefficients f, g on open, connected sets $\mathbb{D} \subseteq \mathbb{R}^d$ can only be lost when the solutions explode on the boundary of $\mathbb{D}$. Common (nonrandom) equilibria x^* of both f and g are considered unique solutions $X = x^*$ of SDEs (A.1) itself, sometimes called **trivial solutions** or **equilibrium solutions** (i.e., in this case, applied to SDEs with extended drift and diffusion coefficients vanishing on entire $\mathbb{D}$). In our paper the existence of local solutions is established for SDEs with Lipschitz coefficients inside the open prism $\mathbb{D}$. The uniqueness of such local solutions inside $\mathbb{D}$ is clear from standard texts on SDEs (such as [3], [14] and [23]) since the closed prism $\overline{\mathbb{D}}$ is a compact set and we do not hit the boundary of $\mathbb{D}$ at any finite time, provided that we start inside the prism (that latter is what we presumed anyway). Recall that the equilibria of our SEIR(S) model are located on the boundary of the open prism $\mathbb{D}$. Hence, they can not be reached in any finite time from the interior of $\mathbb{D}$. Moreover, we have proved the boundedness of moments along certain Lyapunov functionals V, which implies that the solutions can not hit the boundary of the prism $\mathbb{D}$. This is obvious from the application of Khasminskij's Theorem A.1 in this appendix. We just had to construct and verify a related Lyapunov functional V and the appropriate set $\mathbb{D}$ for our SEIR(S) model.

Contribution statement

The first author suggested the work on this SEIR(S) model (1.1) and its extension (3.1). The 2nd and 3rd authors simulated all pictures (Figures 5.1–5.6) of this paper by MATLAB and checked the calculations for the related Lyapunov functionals.

Interest statement

There is not any conflict of interest and any other competitive interest of whatever nature.

Data statement

We have not used any real-world data. All our plotted data have arisen from the simulations.

Acknowledgements

We would like to thank the editors and reviewers for numerous, fruitful comments.

Abstract. The aim of this paper is to obtain an estimation of Hausdorff as well as fractal dimensions of random attractors for a stochastic reaction-diffusion equation with delay. The stochastic equation is firstly transformed into a delayed random partial differential equation by means of a random conjugation, which is then recast into an auxiliary Hilbert space. For the obtained equation, it is firstly proved that it generates a random dynamical system (RDS) in the auxiliary Hilbert space. Then it is shown that the equation possesses random attractors by a uniform estimate of the solution and the asymptotic compactness of the generated RDS. After establishing the variational equation in the auxiliary Hilbert space and the almost surely differentiable properties of the RDS, upper estimates of both Hausdorff and fractal dimensions of the random attractors are obtained.

Keywords: Hausdorff dimension, fractal dimension, random dynamical system, random attractors, delay, stochastic reaction-diffusion equations.

1 Introduction

Existence and estimation of topological dimensions of attractors play important roles in the study of the long time behavior of deterministic or random dynamical systems. For many infinite dimensional systems generated by deterministic or stochastic partial differential equations and delay differential equations, the existence of attractors can reduce the essential part of the flow to a compact set. The finite dimensionality of the attractors, which represents the

[✉]Corresponding author. Email: caraball@us.es

number of degrees of freedom presented in the long term dynamics of the system can further simplify global dynamics of complex nonlinear systems and hence it is of great significance.

The theory of attractors for deterministic infinite dimensional dynamical systems has been well established (see the monograph [26]). On the other hand, the study of random attractors for RDSs dates back to the pioneer works [15,16,24], where H. Crauel, F. Flandoli, B. Schmalfuß, amongst others, generalized the concept of global attractors of infinite dimensional dissipative systems and established the basic framework of random attractors for infinite dimensional RDSs. Since then, the existence, dimension estimation and qualitative properties of random attractors for various stochastic nonlinear evolution equations or stochastic functional differential equations have been investigated by many researchers. For example, for the stochastic reaction-diffusion equation without time delay, Caraballo et al. [7], Gao et al. [25] and Li and Guo [33] explored the existence of global attractors on bounded domains. In [2], [42] and [45], the authors obtained the existence of global attractors on unbounded domains. For the stochastic reaction diffusion equation with delay, the existence of random attractors and their structure have been studied in [5,8,12,32,41] and the references therein.

Criteria for the finite Hausdorff dimensionality of attractors for deterministic fluid dynamics models have been derived by Douady and Oesterle [20], which were later generalized by Constantin, Foiaș and Temam [13] (see also Temam [40]). Then, it was further extended to the stochastic case in [17] and [37], where the RDS is first linearized and the global Lyapunov exponents of the linearized mapping is later examined. The main difficulty of this method lies in controlling the difference between the original nonlinear RDS and its linearization, since in the stochastic case, the attractor is a random set which is not uniformly bounded. Debussche showed that the random attractors of many random dynamical systems generated by dissipative evolution equations have finite Hausdorff dimension by an ergodicity argument in [18] and further derived a precise bound on the dimension by combining the method of linearization and Lyapunov exponents in [19]. With respect to the fractal dimensionality of random sets, Langa proved the finite fractal dimensionality of the random attractor associated to a model from fluid dynamics in [30]. Langa and Robinson generalized the method in [19] to the fractal dimension by requiring differentiability of RDS in [31]. Recently, the above established framework was generalized and adopted to various stochastic and random evolution equations. For instance, Fan proved the existence of random attractor and obtained an upper bound of the Hausdorff and fractal dimension of the random attractor for a stochastic wave equations in [23] by using the method in [19]. In the recent work [46], Zhou and Zhao proved the finiteness of fractal dimension of random attractor for stochastic damped wave equation with linear multiplicative white noise.

Despite the fact that the finite Hausdorff and fractal dimensionality of attractors for abstract RDSs and applications to stochastic partial differential equations (SPDEs) have been extensively and intensively studied, to the best of our knowledge, the estimation of dimensions of SPDEs with delay, i.e., the stochastic partial functional differential equations (SPFDEs) have not been extensively studied. There are only some early results on the existence and local stability of solutions [6,27,39] and recent results on the existence and qualitative properties of random attractors [28,29,32,41,45]. Indeed, the dimension estimation of attractors for delayed partial differential equations is scarce even for the deterministic case. To this respect, the only works about dimensions of attractors for partial functional differential equations (PFDEs) we could find are [38] and the very recent work [36]. In this paper, we make an attempt to estimate topological dimensions of random attractors for a stochastic delayed reaction-diffusion equation. Specifically, we consider the following SPFDE with additive noise

$$\begin{cases} \frac{\partial u}{\partial t}(x,t) = \Delta u(x,t) - \mu u(x,t) + f\left(u(x,t-\tau)\right) + \sum_{j=1}^{m} g_j(x)\frac{\mathrm{d}w_j(t)}{\mathrm{d}t}, t > 0, x \in \mathcal{O}, \\ u_0(x,s) = \phi(x,s), -\tau \le s \le 0, x \in \mathcal{O} \\ u_0(x,t) = 0, -\tau \le t, x \in \partial\mathcal{O}, \end{cases} \tag{1.1}$$

where $\mathcal{O} \subseteq \mathbb{R}^N$ is a bounded open domain with smooth boundary $\partial\mathcal{O}$, $\{w_j\}_{j=1}^m$ are mutually independent two-sided real-valued Wiener process on an appropriate probability space to be specified below. Equation (1.2) can model many processes from chemistry or mathematical biology. For instance, it can be used to describe the evolution of mature populations for age-structured species, where Δu and μu represent the spatial diffusion and the death rate of mature individuals, τ is a positive number, representing the maturation time. The maturation time $f\left(u(x,t-\tau)\right)$ represents birth rate, $\sum_{j=1}^m g_j\frac{\mathrm{d}w_j(t)}{\mathrm{d}t}$ stands for the random perturbations or environmental effects.

Let $\mathbb{X} = L^2(\mathcal{O})$ be the space of square Lesbegue integrable functions on $\mathcal{O}$ with its usual norm $\|\cdot\|_{\mathbb{X}}$ and inner product $(\cdot,\cdot)_{\mathbb{X}}$, $\mathcal{C} = C([-\tau,0],\mathbb{X})$ be the space of continuous function from $[-\tau,0]$ to $\mathbb{X}$ with the usual supremum norm $\|\cdot\|_{\mathcal{C}}$ and $A = \Delta$. Let $u \in C([-\tau,T],\mathbb{X})$ and for each $t \in [0,T]$ define the function $u_t : [-\tau,0] \to \mathbb{X}$ by $u_t(\xi) = u(t+\xi)$ for $\xi \in [0,T]$. Then, we can rewrite the term $\tilde{f}(u(t-\tau)) = f(u_t)$ for any $u \in C([-\tau,T]$, by simply defining $f(\phi) = \tilde{f}(\phi(-\tau))$, for $\phi \in \mathcal{C}$ (notice that we are identifying the function $\tilde{f}$ in problem (1.1) with its associated Nemitskii operator: $\tilde{f}(u(x,t-\tau) \equiv \tilde{f}(u(t-\tau))(x)$ for all $x \in \mathcal{O}$ and $t \in [0,T]$). However, in order to deal with weak solutions of problem (1.1), we need to have the functional $\tilde{f}$ well defined in a bigger space than $\mathcal{C}$, namely we will extend the definition of $\tilde{f}$ to the Hilbert space $\mathcal{L} \triangleq L^2([-\tau,0],\mathbb{X})$ of all square Lebesgue integral functions from $[-\tau,0]$ to $\mathbb{X}$ equipped with the inner product $(\varphi,\psi)_{\mathcal{L}} = [\int_{-\tau}^0 (\varphi(s),\psi(s))_{\mathbb{X}}^2 ds]^{1/2}$ and norm $\|\varphi\|_{\mathcal{L}} = [\int_{-\tau}^0 \|\varphi(s)\|_{\mathbb{X}}^2 ds]^{1/2}$ for all $\varphi \in \mathcal{L}$. This can be done by imposing appropriate assumptions on the function f (or equivalently on $\tilde{f}$). This is explained in details in the next section (see also [10, 11]). From now on we will identify the notation of f and its extension to the space $\mathcal{L}$.

Then (1.1) can be written as the following abstract SPFDE in $\mathbb{X} = L^2(\mathcal{O})$

$$\frac{du(t)}{dt} = Au(t) - \mu u(t) + f\left(u_t\right) + \sum_{j=1}^{m} g_j \frac{\mathrm{d}w_j(t)}{\mathrm{d}t}. \tag{1.2}$$

The main difficulty for studying the topological dimensions of (1.2) lies in the fact that the natural phase spaces for deterministic or stochastic PFDEs are Banach spaces while all the above mentioned theories are established for dynamical systems in Hilbert spaces. Hence, in [38], the authors associated the deterministic PFDE with a nonlinear semigroup on a product space, i.e. a Hilbert space. In this paper, we extend the method established in [38] and [36] to the stochastic case. Nevertheless, the extension is not trivial since the RDSs are nonautonomous in nature and the random attractor is not uniformly bounded. In [38], the authors assumed that the deterministic PFDEs are dissipative which directly implies the existence of attractors in the auxiliary Hilbert space. In this paper, we will firstly prove the existence of a random attractor for (1.2) in the auxiliary Hilbert space and then provide explicit upper bounds of the Hausdorff and fractal dimensionality for the obtained attractor.

The rest of this paper is organized as follows. In Section 2, we introduce some notation, hypotheses and recast (1.2) into a Hilbert space. In Section 3, we prove the obtained auxiliary equation admits a global mild solution which generates a RDS and possesses a random attractor under certain conditions. In Section 4, we obtain an upper bound of the Hausdorff and fractal dimensions for the random attractor of the auxiliary equation, which directly implies the finite dimensionality of the original equation (1.2). Finally, we conclude the paper by pointing out some potential research directions.

2 Auxiliary equation

In this paper, we consider the canonical probability space $(\Omega, \mathcal{F}, P)$ with

$$\Omega = \{\omega = (\omega_1, \omega_2, \ldots, \omega_m) \in C(\mathbb{R}; \mathbb{R}^m) : \omega(0) = 0\}$$

and $\mathcal{F}$ being the Borel σ-algebra induced by the compact open topology of Ω, while P being the corresponding Wiener measure on $(\Omega, \mathcal{F})$. Then, we identify $W(t)$ with $\omega(t)$, i.e.,

$$W(t) \equiv (\omega_1(t), \omega_2(t), \ldots, \omega_m(t)) \quad \text{for } t \in \mathbb{R},$$

and the time shift by

$$\theta_t\omega(\cdot) = \omega(\cdot + t) - \omega(t), \qquad t \in \mathbb{R}.$$

We now follow the idea of [21] to transform (1.2) into a pathwise deterministic equation. The same idea has been adopted by many authors when dealing with random attractors or invariant manifolds for various stochastic evolution equations, such as [22,28,32,34]. Consider the stochastic stationary solution of the one dimensional Ornstein–Uhlenbeck equation

$$\mathrm{d}z_j + \mu z_j \mathrm{d}t = \mathrm{d}w_j(t), \qquad j = 1, \ldots, m, \tag{2.1}$$

which is given by

$$z_j(t) \triangleq z_j(\theta_t\omega_j) = -\mu \int_{-\infty}^{0} e^{\mu s} (\theta_t\omega_j)(s)\mathrm{d}s, \qquad t \in \mathbb{R}. \tag{2.2}$$

By Definition 3.4 (in Section 3), one can see that the random variable $|z_j(\omega_j)|$ is tempered and $z_j(\theta_t\omega_j)$ is P-a.e. ω continuous. Therefore, Proposition 4.3.3 in [1] implies that there exists a tempered function $0 < r(\omega) < \infty$ such that

$$\sum_{j=1}^{m} |z_j(\omega_j)|^2 \le r(\omega), \tag{2.3}$$

where $r(\omega)$ satisfies, for P-a.e. $\omega \in \Omega$,

$$r(\theta_t\omega) \le e^{\frac{\mu}{2}|t|} r(\omega), \qquad t \in \mathbb{R}. \tag{2.4}$$

Combining (3.11) with (2.4), we obtain that for P-a.e. $\omega \in \Omega$,

$$\sum_{j=1}^{m} |z_j(\theta_t\omega_j)|^2 \le e^{\frac{\mu}{2}|t|} r(\omega), \qquad t \in \mathbb{R}. \tag{2.5}$$

Moreover, we have

$$\sum_{j=1}^{m} |z_j(\theta_\xi\omega_j)|^2 \le e^{\frac{\mu\tau}{2}} r(\omega), \tag{2.6}$$

for any $\xi \in [-\tau, 0]$ and P-a.e. $\omega \in \Omega$. Putting $z(\theta_t\omega) = \sum_{j=1}^m g_j z_j(\theta_t\omega_j)$, we have

$$\mathrm{d}z + \mu z \mathrm{d}t = \sum_{j=1}^m g_j \mathrm{d}w_j.$$

Take the transformation $v(t) = u(t) - z(\theta_t\omega)$. Then, simple computation gives

$$\frac{dv(t)}{dt} = Av(t) - \mu v(t) + f(v_t + z(\theta_{t+\cdot}\omega)) + Az(\theta_t\omega), \tag{2.7}$$

where $\theta_{t+\cdot}\omega$ is defined as $\theta_{t+\xi}\omega$ for $\xi \in [-\tau, 0]$.

Throughout the remaining part of this paper, we always impose the following assumptions on A and the nonlinear term f:

Hypothesis A1 $A : D(A) \subset \mathbb{X} \to \mathbb{X}$ is a densely defined linear operator that generates a strongly continuous compact semigroup $S(t)$ on $\mathbb{X}$. Moreover, $\varrho \triangleq s(\tilde{A}) - \mu < 0$, where $s(\tilde{A})$ is defined by $s(\tilde{A}) := \sup\{\Re\lambda : \lambda \in \sigma(\tilde{A})\}$ representing the spectral bound of the linear operator $\tilde{A}$.

Hypothesis A2 $f : \mathcal{C} \to \mathbb{X}$ is Lipschitz continuous with $\mathbf{0}$ being a fixed point, that is, $f(\mathbf{0}) = \mathbf{0}$ and there exists $L_f > 0$ such that

$$\|f(\phi) - f(\varphi)\|_{\mathbb{X}} \leq L_f \|\phi - \varphi\|_{\mathcal{C}},$$

for any $\phi, \varphi \in \mathcal{C}$. Moreover, there exists $m_0 \geqslant 0$ and $C_f > 0$ such that for all $l \in [0, m_0], 0 \leqslant t, u$ and $v \in C([-\tau, t]; \mathbb{X})$, the following inequality holds

$$\int_0^t e^{ls} \|f(u_s) - f(v_s)\|_{\mathbb{X}}^2 \,\mathrm{d}s \leqslant C_f^2 \int_{-\tau}^t e^{ls} \|u(s) - v(s)\|_{\mathbb{X}}^2 \,\mathrm{d}s. \tag{2.8}$$

Remark 2.1. Notice that, thanks to Hypothesis A2, given $u \in C^0([-\tau, T]; \mathbb{X})$, the function $f_u : t \in [0, T] \to \mathbb{X}$ defined by $f_u(t) = f(u_t)\ \forall\, t \in [0, T]$, is measurable (see Bensoussan et al. [4]) and, in fact, belongs to $L^\infty(0, T; \mathbb{X})$. Then, thanks to (2.8), the mapping

$$\mathcal{F} : u \in C^0([-\tau, T]; X) \to f_u \in L^2(0, T; \mathbb{X})$$

has a unique extension to a mapping $\widetilde{\mathcal{F}}$ which is uniformly continuous from $L^2(-\tau, T; \mathbb{X})$ into $L^2(0, T; \mathbb{X})$. From now on, we will denote $f(u_t) = \widetilde{\mathcal{F}}(u)(t)$ for each $u \in L^2(-h, T; \mathbb{X})$, and thus, $\forall\, t \in [0, T]$, $\forall\, u, v \in L^2(-\tau, T; \mathbb{X})$, we will have

$$\int_0^t e^{ls} \|f(u_s) - f(v_s)\|_{\mathbb{X}}^2 \,\mathrm{d}s \leqslant C_f^2 \int_{-\tau}^t e^{ls} \|u(s) - v(s)\|_{\mathbb{X}}^2 \,\mathrm{d}s.$$

Remark 2.2. Observe that considering the abstract formulation of our original problem with a functional f satisfying Assumption A2, we not only are considering the case of constant delay $(f(u_t) = f(u(t - \tau))$ but also the distributed delay one as well, that is, when $f(u_t) = \int_\tau^0 g(s, u(t+s))ds$, for an appropriate Lipschitz function g (see Caraballo and Real [9] for more information).

Since for P-a.e. $\omega \in \Omega$, (2.7) is a path-wise deterministic equation, by similar techniques as [10, Theorem 2.3] and [43, Theorem 8], we have the following results on the existence of solutions to (2.7).

Lemma 2.3. *Assume that* ***Hypotheses A1–A2*** *hold. Then, for any initial condition* $(\phi, \phi(0)) \in \mathcal{L} \times \mathbb{X}$*, there exists a solution* $v(\cdot, \omega, \phi)$ *to problem* (2.7) *with* $v(\cdot, \omega, \phi) \in L^2(-r, T; \mathbb{X}) \cap L^\infty(0, T; \mathbb{X}) \cap C([-r, T]; \mathbb{X}), \forall T > 0$ *and P-a.e.* $\omega \in \Omega$.

In order to estimate topological dimensions of the random attractors of (1.2), unlike previous works [5, 8, 12, 32, 41], where v_t is taken as the state and $\mathcal{L}$ as state space for the above obtained pathwise deterministic delayed equation (2.7), we take $V(t) = (v_t, v(t))$ as state space and recast the equation into an auxiliary product space $H = \mathcal{L} \times \mathbb{X}$ equipped with the inner product

$$\langle (\phi, l), (\psi, k) \rangle = \int_{-\tau}^{0} (\phi(s), \psi(s))_{\mathbb{X}} ds + (h, k)_{\mathbb{X}} \quad \text{for } (\phi, l), (\psi, k) \in H$$

and norm

$$\|(\phi, l)\| = \langle (\phi, l), (\phi, l) \rangle^{1/2} \quad \text{for } (\phi, l) \in H,$$

making H a Hilbert space and hence we can overcome the lack of Hilbert space geometry in applying the abstract theory established in [18, 19, 30, 31]. Furthermore, recasting (1.2) into the Hilbert space H also facilitates us to construct an appropriate variational equation. Take $V(t) = (v_t, v(t))$,

$$\hat{f}(t, \theta_t\omega, v_t) \triangleq Az(\theta_t\omega) + f\left(v_t + z(\theta_{t+\cdot}\omega)\right) \tag{2.9}$$

and

$$F(t, \theta_t\omega, V(t)) = (0, \hat{f}(t, \theta_t\omega, v_t)). \tag{2.10}$$

We consider the following auxiliary random partial differential equation on H.

$$\begin{cases} \dfrac{dV(t)}{dt} = \tilde{A}V(t) - \tilde{L}V(t) + F(t, \theta_t\omega, V(t)), \\ V(0) = (\phi, l), \quad (\phi, l) \in H, \end{cases} \tag{2.11}$$

where operator $\tilde{A}$ is defined as

$$\tilde{A} := \begin{pmatrix} \frac{d}{dt} & 0 \\ 0 & A \end{pmatrix}, \tag{2.12}$$

with domain

$$D(\tilde{A}) = \left\{ (\phi, l) \in H : \phi \text{ is differentiable on } [-\tau, 0], \dot{\phi} \in \mathcal{L} \text{ and } h = \phi(0) \in D(A) \right\}.$$

The linear operator $\tilde{L}$ is defined by

$$\tilde{L} := \begin{pmatrix} 0 & 0 \\ 0 & \mu I \end{pmatrix}.$$

It follows from the definition of $\tilde{L}$ that

$$\|\tilde{L}\| \triangleq \sup_{\varphi \in H, \|\varphi\| = 1} \|\tilde{L}\varphi\| \leq \mu. \tag{2.13}$$

It follows from **Hypothesis A1**, Lemma 3.6, Theorem 3.25 in [3] that the operator $(\tilde{A}, D(\tilde{A}))$ is closed and densely defined on H, and generates a strongly continuous semigroup $\tilde{S}(t)$ given by

$$\tilde{S}(t) := \begin{pmatrix} S(t) & 0 \\ S_t & T_0(t) \end{pmatrix},$$

where $(T_0(t))_{t\geq 0}$ is the nilpotent left shift semigroup on $\mathcal{L}$, and $S_t : \mathbb{X} \to \mathcal{L}$ is defined by

$$(S_t x)(\xi) := \begin{cases} S(t+\xi)x & \text{if } -t < \xi \leq 0, \\ 0 & \text{if } -\tau \leq \xi \leq -t. \end{cases}$$

Moreover, by Theorem 4.11 in [3], we have

$$\|\tilde{S}(t)\| \leqslant e^{s(\tilde{A})t}, \qquad t \geqslant 0.$$

Furthermore, it follows from Pazy [35, Theorem 6.1.5] that (2.11) admits a global classical solution which can be represented by a integral equation based on the variation of constants formula.

Theorem 2.4. *Assume that* **Hypothesis A1** *holds and f is continuously differentiable. Then, for each $(\phi, l) \in H$, there exists a continuous function $V(\cdot, \omega, (\phi, l)) : [0, \infty) \to H$ such that*

$$V(t, \omega, (\phi, l)) = e^{-\tilde{L}t}\tilde{S}(t)(\phi, l) + \int_0^t e^{-\tilde{L}(t-s)}\tilde{S}(t-s)F(s, \theta_s\omega, V(s, \omega, (\phi, l)))ds, \qquad t \geqslant 0 \quad (2.14)$$

for P-a.e. $\omega \in \Omega$. Moreover, if $(\phi, l) \in D(\tilde{A})$, then $V(t, \omega, (\phi, l))$ is a strong solution of (2.11).

3 Random attractors

This section is devoted to showing the existence of random attractors for the auxiliary equation (2.11). In the sequel, we first introduce the concept of random attractor and random dynamical systems following [1] and [15, 16, 24]. Subsequently, we prove the existence of tempered pullback attractors for the auxiliary equation (2.11) by first establishing a uniform estimation for the solution and then proving that the RDS generated by (1.2) is pullback asymptotically compact. Unlike the previous works [5, 8, 12, 41], we prove the uniform a priori estimates of the solution by using the semigroup approach instead of taking inner product.

Definition 3.1. Let $\{\theta_t : \Omega \to \Omega, t \in \mathbb{R}\}$ be a family of measure preserving transformations such that $(t, \omega) \mapsto \theta_t\omega$ is measurable and $\theta_0 = \text{id}$, $\theta_{t+s} = \theta_t\theta_s$, for all $s, t \in \mathbb{R}$. The flow θ_t together with the probability space $\left(\Omega, \mathcal{F}, P, (\theta_t)_{t\in\mathbb{R}}\right)$ is called a metric dynamical system.

It follows from Definition 3.1 that $\left(\Omega, \mathcal{F}, P, (\theta_t)_{t\in\mathbb{R}}\right)$ is a metric dynamical system, where $(\Omega, \mathcal{F}, P)$ is defined in Section 2. Moreover, θ is ergodic. For a given separable Hilbert space $(H, \|\cdot\|_H)$, denote by $\mathcal{B}(H)$ the Borel σ-algebra generated by open subsets in H.

Definition 3.2. A mapping $\Phi : \mathbb{R}^+ \times \Omega \times H \to H$ is said to be a random dynamical system (RDS) on a complete separable metric space (H, d) with Borel σ-algebra $\mathcal{B}(H)$ over the metric dynamical system $\left(\Omega, \mathcal{F}, P, (\theta_t)_{t\in\mathbb{R}^+}\right)$ if

(i) $\Phi(\cdot, \cdot, \cdot) : \mathbb{R}^+ \times \Omega \times H \to H$ is $(\mathcal{B}(\mathbb{R}^+) \times \mathcal{F} \times \mathcal{B}(H), \mathcal{B}(H))$-measurable;

(ii) $\Phi(0, \omega, \cdot)$ is the identity on H for P-a.e. $\omega \in \Omega$;

(iii) $\Phi(t+s, \omega, \cdot) = \Phi(t, \theta_s\omega, \cdot) \circ \Phi(s, \omega, \cdot)$, for all $t, s \in \mathbb{R}^+$ for P-a.e. $\omega \in \Omega$.

A RDS Φ is continuous or differentiable if $\Phi(t, \omega, \cdot) : H \to H$ is continuous or differentiable for all $t \in \mathbb{R}^+$ and P-a.e. $\omega \in \Omega$.

Definition 3.3. A set-valued map $\Omega \ni \omega \mapsto D(\omega) \in 2^H$, such that $D(\omega)$ is closed, is said to be a random set in H if the mapping $\omega \mapsto d(x, D(\omega))$ is $(\mathcal{F}, \mathcal{B}(\mathbb{R}))$-measurable for any $x \in H$, where $d(x, D(\omega)) \triangleq \inf_{y \in D(\omega)} \mathrm{d}(x, y)$ is the distance in H between the element x and the set $D(\omega) \subset H$.

Definition 3.4. A random set $\{D(\omega)\}_{\omega \in \Omega}$ of H is called tempered with respect to $(\theta_t)_{t \in \mathbb{R}}$ if for P-a.e. $\omega \in \Omega$,

$$\lim_{t \to \infty} e^{-\beta t} d\left(D\left(\theta_{-t}\omega\right)\right) = 0, \quad \text{for all } \beta > 0,$$

where $d(D) = \sup_{x \in D} \|x\|_H$.

Definition 3.5. Let $\mathcal{D} = \{D(\omega) \subset H, \omega \in \Omega\}$ be a family of random sets. A random set $K(\omega) \in \mathcal{D}$ is said to be a $\mathcal{D}$-pullback absorbing set for Φ if for P-a.e. $\omega \in \Omega$ and for every $B \in \mathcal{D}$, there exists $T = T(B, \omega) > 0$ such that

$$\Phi\left(t, \theta_{-t}\omega, B\left(\theta_{-t}\omega\right)\right) \subseteq K(\omega) \quad \text{for all } t \geq T.$$

If, in addition, for all $\omega \in \Omega, K(\omega)$ is measurable in Ω with respect to $\mathcal{F}$, then we say K is a closed measurable $\mathcal{D}$-pullback absorbing set for Φ.

Definition 3.6. A RDS Φ is said to be $\mathcal{D}$-pullback asymptotically compact in H if for P-a.e. $\omega \in \Omega$, $\{\Phi\left(t_n, \theta_{-t_n}\omega, x_n\right)\}_{n \geq 1}$ has a convergent subsequence in H whenever $t_n \to \infty$ and $x_n \in D\left(\theta_{-t_n}\omega\right)$ for any given $D \in \mathcal{D}$.

Definition 3.7. A compact random set $\mathcal{A}(\omega)$ is said to be a $\mathcal{D}$-pullback random attractor associated to the RDS Φ if it satisfies the invariance property

$$\Phi(t, \omega, \mathcal{A}(\omega)) = \mathcal{A}\left(\theta_t \omega\right), \quad \text{for all } t \geq 0$$

and the pullback attracting property

$$\lim_{t \to \infty} \operatorname{dist}\left(\Phi\left(t, \theta_{-t}\omega, D\left(\theta_{-t}\omega\right)\right), \mathcal{A}(\omega)\right) = 0, \quad \text{for all } t \geq 0, D \in \mathcal{D}, P - a.e.\ \omega \in \Omega.$$

where $\operatorname{dist}(\cdot, \cdot)$ denotes the Hausdorff semidistance

$$\operatorname{dist}(A, B) = \sup_{x \in A} \inf_{y \in B} \mathrm{d}(x, y), \qquad A, B \subset H.$$

Lemma 3.8 ([15, Theorem 3.11])**.** *Let (θ, Φ) be a continuous random dynamical system. Suppose that Φ is $\mathcal{D}$-pullback asymptotically compact and has a closed pullback $\mathcal{D}$-absorbing random set $K = \{K(\omega)\}_{\omega \in \Omega} \in \mathcal{D}$. Then it possesses a random attractor $\{\mathcal{A}(\omega)\}_{\omega \in \Omega}$, where*

$$\mathcal{A}(\omega) = \cap_{\tau \geq 0} \overline{\cup_{t \geq \tau} \Phi\left(t, \theta_{-t}\omega, K\left(\theta_{-t}\omega\right)\right)}.$$

For convenience, we introduce the following Gronwall inequality in [5] that will be frequently used in our subsequent proofs.

Lemma 3.9. *Let $T > 0$ and u, α, f and g be non-negative continuous functions defined on $[0, T]$ such that*

$$u(t) \leq \alpha(t) + f(t) \int_0^t g(r) u(r) dr, \quad \textit{for } t \in [0, T].$$

Then,

$$u(t) \leq \alpha(t) + f(t) \int_0^t g(r) \alpha(r) e^{\int_r^t f(\tau) g(\tau) d\tau} dr, \quad \textit{for } t \in [0, T].$$

Apparently, under the conjugation transformation induced by (2.2), no exceptional sets appear in the equation (2.11). By the uniqueness of solution to (2.11) for each $\omega \in \Omega$, we can see the mapping $\Phi(\cdot,\cdot,\cdot) : \mathbb{R}^+ \times \Omega \times H \to H$ defined by

$$\Phi(t,\omega,(\phi,\phi(0))) = V(t,\omega,(\phi,\phi(0))) \tag{3.1}$$

generates a RDS, which is $(\mathcal{B}(\mathbb{R}^+) \times \mathcal{F} \times \mathcal{B}(H), \mathcal{B}(H))$-measurable. Let P_1 and P_2 be the projections of H onto $\mathcal{L}$ and $\mathbb{X}$ respectively. Then, by Theorem 3.1 and Proposition 3.2 in [38], we have

$$v_t(\cdot,\omega,\phi) = P_1 V(t,\omega,(\phi,\phi(0))) \tag{3.2}$$

and

$$v(t,\omega,\phi) = P_2 V(t,\omega,(\phi,\phi(0))) \tag{3.3}$$

for $t \geqslant 0$ and P-a.e. $\omega \in \Omega$, where $v(t,\omega,\phi)$ is the solution to (2.7). Therefore, the solution of (1.2) can be represented by

$$\begin{aligned} u_t(\cdot,\omega,\phi) &= v_t(\cdot,\omega,\phi) + z(\theta_{t+\cdot}\omega) = P_1[V(t,\omega,(\phi,\phi(0))) + (z(\theta_{t+\cdot}\omega), z(\theta_t\omega))] \\ &\triangleq P_1\Psi(t,\omega,(\psi,\psi(0))) \end{aligned} \tag{3.4}$$

where the mapping $\Psi : \mathbb{R}^+ \times \Omega \times H \to H$ is defined by

$$\begin{aligned} \Psi(t,\omega,(\psi,\psi(0))) &\triangleq \Phi(t,\omega,(\phi,\phi(0))) + (z(\theta_{t+\cdot}\omega), z(\theta_t\omega)) \\ &= V(t,\omega,(\phi,\phi(0))) + (z(\theta_{t+\cdot}\omega), z(\theta_t\omega)) \end{aligned} \tag{3.5}$$

and $(\psi,\psi(0)) = (\phi,\phi(0))) + (z(\theta_\cdot\omega), z(\omega))$. By the cocycle property of z and Φ, we can see that Ψ is a RDS on H. In the following, we show the existence of random attractor for Ψ.

Lemma 3.10. *Assume that **Hypotheses A1–A2** hold and $\varrho \triangleq s(\tilde{A}) - \mu < \frac{-\mu}{2}$, $\varrho + L_f < 0$, then there exists $\{K(\omega)\}_{\omega\in\Omega} \in \mathcal{D}$ satisfying that, for any $B = \{B(\omega)\}_{\omega\in\Omega} \in \mathcal{D}$ and P-a.e. $\omega \in \Omega$, there is $T_B(\omega) > 0$ such that*

$$\Psi\left(t,\theta_{-t}\omega, B\left(\theta_{-t}\omega\right)\right) \subseteq K(\omega) \quad \textit{for all } t \geqslant T_B(\omega),$$

that is, $\{K(\omega)\}_{\omega\in\Omega}$ is a random absorbing set for Ψ in $\mathcal{D}$.

Proof. We first derive uniform estimates of V by (2.14) and then obtain the existence of an absorbing set for Ψ given by $\Psi(t,\omega,(\phi,\phi(0)) = V(t,\omega,(\phi,\phi(0))) + (z(\theta_{t+\cdot}\omega), z(\theta_t\omega))$. It follows from (2.14) that, for any $t > 0$,

$$\begin{aligned} &\|V(t,\omega,(\phi,\phi(0)))\| \\ &\quad = \left\| e^{-\tilde{L}t}\tilde{S}(t)(\phi,\phi(0)) + \int_0^t e^{-\tilde{L}(t-s)}\tilde{S}(t-s)F(s,\theta_s\omega, V(s,\omega,(\phi,\phi(0))))ds \right\| \\ &\quad \le e^{\varrho t}\|(\phi,\phi(0))\| + \int_0^t e^{\varrho(t-s)}\|\tilde{f}(s,\theta_s\omega, v_s(\cdot,\omega,\phi)))\|_{\mathbb{X}} ds \\ &\quad \le e^{\varrho t}\|(\phi,\phi(0))\| + \int_0^t e^{\varrho(t-s)}(\|Az(\theta_s\omega)\|_{\mathbb{X}} + L_f\|z(\theta_{s+\cdot}\omega)\|_{\mathcal{L}})ds \\ &\qquad + L_f\int_0^t e^{\varrho(t-s)}\|v_s(\cdot,\omega,\phi)\|_{\mathcal{L}} ds \\ &\quad \le e^{\varrho t}\|(\phi,\phi(0))\| + \int_0^t e^{\varrho(t-s)}(\|Az(\theta_s\omega)\|_{\mathbb{X}} + L_f\|z(\theta_{s+\cdot}\omega)\|_{\mathcal{L}})ds \\ &\qquad + L_f\int_0^t e^{\varrho(t-s)}\|V(s,\omega,(\phi,\phi(0)))\| ds \end{aligned} \tag{3.6}$$

for P-a.e. $\omega \in \Omega$. For the sake of simplicity, we denote $\varpi(\omega) = (\phi(\cdot,\omega), \phi(0,\omega))$. By replacing ω by $\theta_{-t}\omega$, we derive from (3.6) that, for all $t \geq 0$,

$$\begin{aligned} \|V(t,\theta_{-t}\omega,\varpi(\theta_{-t}\omega))\| \leq e^{\varrho t}\|\varpi(\theta_{-t}\omega)\| + L_f \int_0^t e^{\varrho(t-s)}\|V(s,\theta_{-t}\omega,\varpi(\theta_{-t}\omega)\|ds \\ + \int_0^t e^{\varrho(t-s)}(\|Az(\theta_{-t}\theta_s\omega)\|_{\mathbb{X}} + L_f\|z(\theta_{-t}\theta_{s+\cdot}\omega)\|_{\mathcal{L}})ds. \end{aligned} \tag{3.7}$$

Since $g_j \in \mathbb{X}$, $Ag_j \in \mathbb{X}$ and $z(\omega) = \sum_{j=1}^m g_j z_j(\omega_j)$, it follows from (2.5) and (2.6) that there exists a constant c such that $p_1(\omega) \triangleq \|Az(\omega)\|_{\mathbb{X}} + L_f\|z(\theta_{\cdot}\omega)\|_{\mathcal{L}} \leq c\sum_{j=1}^m |z_j(\omega_j)|^2$. Therefore, it follows from (2.4) and (2.5) that

$$\int_0^t e^{\varrho(t-s)} p_1(\theta_{s-t}\omega)\,\mathrm{ds} \leq c\int_0^t e^{(\varrho+\frac{\mu}{2})(t-s)} r(\omega)\mathrm{ds} \leq cr(\omega), \tag{3.8}$$

where the second inequality follows from the assumption that $\rho + \frac{\mu}{2} < 0$. Incorporating (3.8) into (3.7) gives rise to

$$\|V(t,\theta_{-t}\omega,\varpi(\theta_{-t}\omega)\| \leq e^{\varrho t}\|\varpi(\theta_{-t}\omega)\| + L_f\int_0^t e^{\varrho(t-s)}\|V(s,\theta_{-t}\omega,\varpi(\theta_{-t}\omega))\|ds + cr(\omega). \tag{3.9}$$

Multiplying both sides of (3.9) by $e^{-\varrho t}$,

$$\begin{aligned} &e^{-\varrho t}\|V(t,\theta_{-t}\omega,\varpi(\theta_{-t}\omega))\| \\ &\quad \leq \|\varpi(\theta_{-t}\omega)\| + L_f\int_0^t e^{-\varrho s}\|V(s,\theta_{-t}\omega,\varpi(\theta_{-t}\omega))\|ds + ce^{-\varrho t}r(\omega). \end{aligned} \tag{3.10}$$

Hence, by the Gronwall inequality (Lemma 3.9), we have

$$\begin{aligned} e^{-\varrho t}\|V(t,\theta_{-t}\omega,\varpi(\theta_{-t}\omega))\| &\leq \|\varpi(\theta_{-t}\omega)\| + ce^{-\varrho t}r(\omega) \\ &\quad + L_f\int_0^t e^{L_f(t-s)}(\|\varpi(\theta_{-s}\omega)\| + ce^{-\varrho s}r(\omega))ds \\ &\leq \|\varpi(\theta_{-t}\omega)\| + ce^{-\varrho t}r(\omega) + L_f\|\varpi(\theta_{-t}\omega)\|\int_0^t e^{L_f(t-s)}\mathrm{ds} \\ &\quad + cL_f r(\omega)\int_0^t e^{L_f(t-s)}e^{-\varrho s}\mathrm{ds}. \end{aligned} \tag{3.11}$$

Therefore, we have

$$\begin{aligned} \|V(t,\theta_{-t}\omega,\varpi(\theta_{-t}\omega))\| \leq e^{\varrho t}\|\varpi(\theta_{-t}\omega)\| + cr(\omega) + e^{\varrho t}(e^{L_f t}-1)\|\varpi(\theta_{-t}\omega)\| \\ + \frac{cL_f}{\varrho + L_f}[e^{(L_f+\varrho)t} - 1]r(\omega). \end{aligned} \tag{3.12}$$

Note that $\Psi(t,\omega,\chi(\omega)) = V(t,\omega,\varpi(\omega)) + (z(\theta_{t+\cdot}\omega), z(\theta_t\omega))$ and $\chi(\omega) = \varpi(\omega) + (z(\theta_{\cdot}\omega), z(\omega))$. The above estimate (3.12) implies that, for all $t \geq 0$

$$\begin{aligned} \|\Psi(t,\theta_{-t}\omega,\chi(\theta_{-t}\omega))\| &\leq \|V(t,\theta_{-t}\omega,\varpi(\theta_{-t}\omega))\| + \|(z(\theta_{-t}\theta_{t+\cdot}\omega), z(\theta_{-t}\theta_t\omega))\| \\ &\leq e^{\varrho t}\|\varpi(\theta_{-t}\omega)\| + 2cr(\omega) + e^{\varrho t}(e^{L_f t}-1)\|\varpi(\theta_{-t}\omega)\| \\ &\quad + \frac{cL_f}{\varrho + L_f}[e^{(L_f+\varrho)t} - 1]r(\omega). \end{aligned} \tag{3.13}$$

Therefore, if $\chi \in \mathcal{D}(\theta_{-t}\omega)$ and $L_f + \varrho < 0$, then there exists a $T_{\mathcal{D}} > 0$ such that, for all $t \geq T_D(\omega)$,

$$e^{\varrho t}\|\varpi(\theta_{-t}\omega)\| + e^{\varrho t}(e^{L_f t} - 1)\|\varpi(\theta_{-t}\omega)\| + \frac{cL_f}{\varrho + L_f}e^{(L_f+\varrho)t}r(\omega) \leq c_1(\omega), \tag{3.14}$$

which, along with (3.13) shows that, for all $t \geq T_{\mathcal{D}}(\omega)$

$$\|\Psi(t, \theta_{-t}\omega, \chi(\theta_{-t}\omega))\| \leq 2cr(\omega) + \frac{-cL_f}{\varrho + L_f}r(\omega) + c_1(\omega). \tag{3.15}$$

Given $\omega \in \Omega$, define

$$K(\omega) = \{\varphi \in H : \|\varphi\| \leq 2cr(\omega) + \frac{-cL_f}{\varrho + L_f}r(\omega) + c_1(\omega)\}. \tag{3.16}$$

Then, $K = \{K(\omega)\}_{\omega\in\Omega} \in \mathcal{D}$. Furthermore, (3.15) implies that $K(\omega)$ is a random absorbing set for the RDS Ψ in $\mathcal{D}$. □

Lemma 3.11. *Assume that* ***Hypotheses A1–A2*** *are satisfied and $\varrho \triangleq s(\tilde{A}) - \mu < \frac{-\mu}{2}$, $\varrho + L_f < 0$. Then, the RDS Ψ is $\mathcal{D}$-pullback asymptotically compact for $t > \tau$ (the time delay), i.e., for P-a.e. $\omega \in \Omega$, the sequence $\{\Psi(t_n, \theta_{-t_n}\omega, \phi_n(\theta_{-t_n}\omega))\}$ has a convergent subsequence provided $t_n \to \infty$, $B = \{B(\omega)\}_{\omega\in\Omega} \in \mathcal{D}$ and $\phi_n(\theta_{-t_n}\omega) \in B(\theta_{-t_n}\omega)$.*

Proof. Take an arbitrary random set $\{B(\omega)\}_{\omega\in\Omega} \in \mathcal{D}$, a sequence $t_n \to +\infty$ and $\phi_n \in B(\theta_{-t_n}\omega)$. We have to prove that $\{\Psi(t_n, \theta_{-t_n}\omega, \phi_n)\}$ is precompact. Since $\{K(\omega)\}$ is a random absorbing set for Ψ, there exists $T > 0$ such that, for all $\omega \in \Omega$,

$$\Psi(t, \theta_{-t}\omega, B(\theta_{-t}\omega)) \subset K(\omega) \tag{3.17}$$

for all $t \geq T$. Because $t_n \to +\infty$, we can choose $n_1 \geq 1$ such that $t_{n_1} - 1 \geq T$. Applying (3.17) for $t = t_{n_1} - 1$ and $\omega = \theta_{-1}\omega$, we find that

$$\eta_1 \triangleq \Psi\left(t_{n_1} - 1, \theta_{-t_{n_1}}\omega, \phi_{n_1}\right) \in K(\theta_{-1}\omega) \tag{3.18}$$

Similarly, we can choose a subsequence $\{n_k\}$ of $\{n\}$ such that $n_1 < n_2 < \cdots < n_k \to +\infty$ with $t_{n_k} \geq k$ and

$$\eta_k \triangleq \Psi\left(t_{n_k} - k, \theta_{-t_{n_k}}\omega, \phi_{n_k}\right) \in K(\theta_{-k}\omega) \tag{3.19}$$

Hence, by the assumptions we conclude that the sequence

$$\{\Psi(k, \theta_{-k}\omega, \eta_k)\} \text{ is precompact.} \tag{3.20}$$

On the other hand, by (3.19) we have

$$\Psi(k, \theta_{-k}\omega, \eta_k) = \Psi(k, \theta_{-k}\omega, \Psi(t_{n_k} - k, \theta_{-t_{n_k}}\omega, \phi_{n_k})) = \Psi\left(t_{n_k}, \theta_{-t_{n_k}}\omega, \phi_{n_k}\right), \tag{3.21}$$

for all $k \geq 1$. Combining (3.20) and (3.21), we obtain that the sequence $\left\{\Psi\left(t_{n_k}, \theta_{-t_{n_k}}\omega, \phi_{n_k}\right)\right\}$ is precompact. Therefore, $\{\Psi(t_n, \theta_{t_n}\omega, \phi_n)\}$ is precompact, which completes the proof. □

Lemma 3.10 says that the continuous RDS Ψ has a random absorbing set while Lemma 3.11 tells us that (θ, Ψ) is pullback asymptotically compact in H. Thus, it follows from Lemma 3.8 that the continuous RDS (θ, Ψ) possesses a random attractor. Namely, we obtain the following result.

Theorem 3.12. *Assume that **Hypotheses A1–A2** are satisfied and* $\varrho \triangleq s(\tilde{A}) - \mu < \frac{-\mu}{2}$, $\varrho + L_f < 0$, *then the continuous RDS* Ψ *admits a* $\mathcal{D}$*-pullback attractor* $\mathcal{A}_\Psi(\omega)$ *in* H *belonging to the class* $\mathcal{D}$.

Moreover, by Theorem 3.12, the relationship between the RSDs Φ and Ψ defined by (3.5) as well as Proposition 3.2 in [38], we have the following result about the existence of random attractors for equation (1.2).

Corollary 3.13. *Assume that **Hypotheses A1–A2** are satisfied and* $\varrho \triangleq s(\tilde{A}) - \mu < \frac{-\mu}{2}$, $\varrho + L_f < 0$. *Then, the continuous RDS* $P_1\Psi$ *generated by* (1.2) *admits a pullback attractor* $P_1\mathcal{A}_\Psi(\omega)$ *in* P_1H. *Moreover,* $\mathcal{A}_\Phi(\omega) \triangleq \{\zeta | \zeta = \chi - (z(\theta_{t+\cdot}\omega), z(\theta_t\omega)), \chi \in \mathcal{A}_\Psi(\omega)\}$ *is a random attractor of* Φ.

4 Topological dimensions of random attractors

The aim of this section is to estimate the Hausdorff and fractal dimensions for the attractor of (1.2). Denote by $d_H(\mathcal{A}_\Psi(\omega))$ and $d_F(\mathcal{A}_\Psi(\omega))$ the Hausdorff and fractal dimensions of a random set $\mathcal{A}_\Psi(\omega)$ respectively. We only need to prove that there exist constants d_H and d_F such that $d_H(\mathcal{A}_\Psi(\omega)) \leq d_H$ and $d_F(\mathcal{A}_\Psi(\omega)) \leq d_F$, since by Theorem 3.1 and Proposition 3.2 in [38], the topological dimensions of attractor $P_1\mathcal{A}_\Psi(\omega)$ for (1.2) satisfy $d_H(P_1\mathcal{A}_\Psi(\omega)) \leq d_H$ and $d_F(P_1\mathcal{A}_\Psi(\omega)) \leq d_F$, i.e., the random attractors of (1.2) have finite Hausdorff and fractal dimensions less than those of (2.11). In the sequel, we investigate the Hausdorff and fractal dimensions for the random attractor $\mathcal{A}_\Psi(\omega)$ of (2.11).

We first recall the concepts of Hausdorff and fractal dimensions of the attractor $\mathcal{A}_\Psi(\omega) \subset H$. More details can be found in [19] and [31]. The Hausdorff dimension of the compact set $\mathcal{A}_\Psi(\omega) \subset H$ is

$$d_H(\mathcal{A}_\Psi(\omega)) = \inf\{d : \mu_H(\mathcal{A}_\Psi(\omega), d) = 0\}$$

where, for $d \geq 0$,

$$\mu_H(\mathcal{A}_\Psi(\omega), d) = \lim_{\varepsilon \to 0} \mu_H(\mathcal{A}_\Psi(\omega), d, \varepsilon)$$

denotes the d-dimensional Hausdorff measure of the set $\mathcal{A}_\Psi(\omega) \subset H$, where

$$\mu_H(\mathcal{A}_\Psi(\omega), d, \varepsilon) = \inf \sum_i r_i^d$$

and the infimum is taken over all coverings $\mathcal{K} = \{B_i\}_{i \in I}$ of $\mathcal{A}_\Psi(\omega)$ by balls B_i of radius $r_i \leq \varepsilon$ and the sum is over all balls of $\mathcal{K}$. It can be shown that there exists $d_H(\mathcal{A}_\Psi(\omega)) \in [0, +\infty]$ such that $\mu_H(\mathcal{A}_\Psi(\omega), d) = 0$ for $d > d_H(\mathcal{A}_\Psi(\omega))$ and $\mu_H(\mathcal{A}_\Psi(\omega), d) = \infty$ for $d < d_H(\mathcal{A}_\Psi(\omega))$. $d_H(\mathcal{A}_\Psi(\omega))$ is called the Hausdorff dimension of $\mathcal{A}_\Psi(\omega)$.

The fractal dimension (or capacity) of $\mathcal{A}_\Psi(\omega)$ is defined as

$$d_F(\mathcal{A}_\Psi(\omega)) = \inf\{d > 0 : \mu_F(\mathcal{A}_\Psi(\omega), d) = 0\},$$

where

$$\mu_F(\mathcal{A}_\Psi(\omega), d) = \limsup_{\varepsilon \to 0} \varepsilon^d n_F(\mathcal{A}_\Psi(\omega), \varepsilon)$$

and $n_F(\mathcal{A}_\Psi(\omega), \varepsilon)$ is the minimum number of balls of radius $\leqslant \varepsilon$ which is necessary to cover $\mathcal{A}_\Psi(\omega)$.

Take a covering of $\mathcal{A}_\Psi(\omega)$ by balls of radii less than ε:

$$\mathcal{A}_\Psi(\omega) \subset \bigcup_{i=1} B(u_i, r_i), \qquad r_i \leq \varepsilon, \ u_i \in H$$

where $B(u_i, r_i)$ denotes the ball in H of center u_i and radius r_i. Let $\theta = \theta_1$ and define

$$\Psi(\omega)\phi = \Psi(1, \omega, \phi) \tag{4.1}$$

for any $\phi \in H$ and P-a.e. $\omega \in \Omega$. Then, it follows from the invariance of $\mathcal{A}_\Psi(\omega)$ that

$$\mathcal{A}_\Psi(\theta\omega) \subset \bigcup_{i=1} \Psi(\omega) B(u_i, r_i).$$

In order to approximate $\Psi(\omega)$ by a linear map, we impose the following almost surely uniformly differentiable assumption of $\Psi(\omega)$ on the attractor $\mathcal{A}_\Psi(\omega)$.

Hypothesis A3 The mapping $\Psi(\omega)$ is $\mathbb{P}$ almost surely differentiable on $\mathcal{A}_\Psi(\omega)$, that is, $\mathbb{P}$ almost surely, for every u in $\mathcal{A}_\Psi(\omega)$, there exists a continuous linear operator $D\Psi(\omega, u) : H \to H$, such that if $u, u+h \in \mathcal{A}_\Psi(\omega)$, then

$$\|\Psi(\omega)(u+h) - \Psi(\omega)u - D\Psi(\omega, u) \cdot h\| \leq K(\omega)\|h\|^{1+\alpha},$$

where $K(\omega)$ is a random variable such that

$$K(\omega) \geq 1, \quad \text{for all } \omega \in \Omega,$$

$\mathbb{E}(\ln K) < \infty$ and $\alpha > 0$.

We follow [40, Chapter 5] to give following definitions. For the bounded linear operator $D\Psi(\omega, u)$ on H and $n \in \mathbb{N}$, we set

$$\alpha_n(D\Psi(\omega, u)) = \sup_{\substack{G \subset H \\ \dim \leqslant n}} \inf_{\substack{\phi \in G \\ \|\phi\|=1}} \|D\Psi(\omega, u)\phi\|$$

and

$$\omega_n(D\Psi(\omega, u)) = \alpha_1(D\Psi(\omega, u)) \ldots \alpha_n(D\Psi(\omega, u)),$$

where $\alpha_n(D\Psi(\omega, u))$ are the square roots of the eigenvalues of $D\Psi(\omega, u)^* D\Psi(\omega, u)$ corresponding to orthogonal eigenvectors e_n, which are in decreasing order. We set

$$\alpha_\infty(D\Psi(\omega, u)) = \inf_n \alpha_n(D\Psi(\omega, u))$$

and further make the following assumptions.

Hypothesis A4 For every $d \in \mathbb{N}$, there exists an integrable random variable $\bar{\omega}_d$, such that $\mathbb{P}$ almost surely,

$$\omega_d(D\Psi(\omega, u)) \leq \bar{\omega}_d(\omega)$$

for any $u \in \mathcal{A}_\Psi(\omega)$ and

$$\mathbb{E}(\ln(\bar{\omega}_d)) < 0.$$

Under the above assumptions, we have the following results concerning the dimension estimation of random attractors $\mathcal{A}_\Psi(\omega)$ for Ψ, of which the proof is given in [19, 31].

Lemma 4.1. *Assume that* ***Hypotheses A3–A4*** *are satisfied. Then,* $\mathbb{P}$*-a.s.*

$$d_{\mathrm{H}}(\mathcal{A}_\Psi(\omega)) \leqslant d$$

and

$$d_{\mathrm{F}}(\mathcal{A}_\Psi(\omega)) \leqslant \gamma$$

for any γ *such that*

$$\gamma > \frac{\mathbb{E}\left[\max_{1 \leqslant j \leqslant d}(dq_j - jq_d)\right]}{-\mathbb{E}q_d},$$

where $q_j = \log \bar{\omega}_j$.

In the following, we verify **Hypothesis A3–A4**. We first establish the following result, which is a key ingredient to prove the $\mathbb{P}$ almost surely uniform differentiability results of $\Psi(\omega)$.

Proposition 4.2. *If $f : \mathcal{L} \to H$ is twice continuously differentiable, then for each $\varpi \in \mathcal{A}_\Psi(\omega)_\Phi$ and $h \in H$, there exists a continuous function $U^{\varpi,h}(t,\omega) : [0,\infty) \times \Omega \to H$ such that*

$$U^{\varpi,h}(t,\omega) = e^{-\tilde{L}t}\tilde{S}(t)h + \int_0^t e^{-\tilde{L}(t-s)}\tilde{S}(t-s)(0, D\tilde{f}(P_1\Phi(s,\omega,\varpi))\, P_1U(s,\omega))ds, \quad t \geqslant 0. \quad (4.2)$$

Moreover, if $h \in D(\tilde{A})$, then $U(t,\omega)$ is a strong solution of the following variational equation on H.

$$\begin{cases} \dfrac{dU(t,\omega)}{dt} = \tilde{A}U(t,\omega) - \tilde{L}U(t,\omega) + (0, D\tilde{f}(P_1\Phi(s,\omega,\varpi))\, P_1U(t,\omega)), \\ U(0,\omega) = h \in H, \end{cases} \quad (4.3)$$

where operators $\tilde{A}$ and $\tilde{f}$ are defined by (2.12) and (2.9), $\Phi(t,\omega,\varpi)$ is the RDS defined by (3.5) with initial condition h.

Proof. Let

$$L_1(\omega) = \sup_{\varsigma \in P_1\mathcal{A}_\Phi(\omega)} |D\tilde{f}(\varsigma)|, \quad (4.4)$$

where

$$|D\tilde{f}(\varsigma)| = \sup_{\|\eta\|_{\mathcal{L}} \leqslant 1} \|D\tilde{f}(\varsigma)\eta\|_{\mathbb{X}}. \quad (4.5)$$

Since $\tilde{f}$ is C^1 and $P_1\mathcal{A}_\Psi(\omega)$ is compact, then $L_1(\omega) < \infty$. Given any $h \in D(\tilde{A})$, define $F_\chi : H \to H$ by

$$F_\varpi(h) = (0, D\tilde{f}(P_1\Phi(t,\omega,\varpi))\, P_1h), \qquad t \geqslant 0,\ h \in H.$$

It follows from the invariance of $\mathcal{A}_\Phi(\omega)$ under Φ and $\varpi \in \mathcal{A}_\Phi(\omega)$ that $\Phi(s,\omega,\varpi) \in \mathcal{A}_\Phi(\omega)$ and hence $P_1\Phi(t,\omega,\varpi) \in P_1\mathcal{A}_\Phi(\omega)$ and $|Df(P_1\Phi(t,\omega,\varpi))| \leqslant L_1(\omega) < \infty$, for all $t \geqslant 0$. This implies that $F_\varpi(\cdot)$ is Lipschitz continuous on H. Therefore the conclusion follows from Pazy [35, Theorem 6.1.5]. □

Now, we establish the following almost surely uniform differentiability results of $\Psi(\omega)$ on the random attractor $\mathcal{A}_\Psi(\omega)$.

Theorem 4.3. *The mapping $\Psi(\omega)$ is $\mathbb{P}$ almost surely differentiable on $\mathcal{A}_\Psi(\omega)$, that is, $\mathbb{P}$ almost surely, for every u in $\mathcal{A}_\Psi(\omega)$, there exist a continuous linear operator $D\Psi(\omega,u) : H \to H$, such that if $u, u+h \in \mathcal{A}_\Psi(\omega)$, then*

$$\|\Psi(\omega)(u+h) - \Psi(\omega)u - D\Psi(\omega,u)\cdot h\| \leq K(\omega)\|h\|^{1+\alpha}$$

where $K(\omega)$ is a random variable such that

$$K(\omega) \geq 1, \qquad w \in \Omega$$

and $\alpha > 0$ is a number.

Proof. We first claim that for any constant $t > 0$ and $\chi, \chi + h \in \mathcal{A}_\Psi(\omega)$, there exists a constant $L(t) > 0$ such that

$$\|\Psi(t,\omega,\chi) - \Psi(t,\omega,\chi+h)\|_X \leqslant L(t)\|h\|.$$

By Theorem 2.4 and the relationship $\Psi(t,\omega,\chi(\omega)) = \Phi(t,\omega,\varpi(\omega)) + (z(\theta_{t+\cdot}\omega), z(\theta_t\omega))$ with $\varpi(\omega) = \chi(\omega) - (z(\theta_\cdot\omega), z(\omega))$, we have

$$\Psi(t,\omega,\chi) = e^{-\tilde{L}t}\tilde{S}(t)\chi + \int_0^t e^{-\tilde{L}(t-s)}\tilde{S}(t-s)F(s,\theta_s\omega,\Phi(s,\omega,\varpi))ds + (z(\theta_{t+\cdot}\omega), z(\theta_t\omega)), \quad (4.6)$$

$$\begin{aligned}\Psi(t,\omega,\chi+h) = e^{-\tilde{L}t}\tilde{S}(t)(\chi+h) + \int_0^t e^{-\tilde{L}(t-s)}\tilde{S}(t-s)F(s,\theta_s\omega,\Phi(s,\omega,\varpi+h)))ds \\ + (z(\theta_{t+\cdot}\omega), z(\theta_t\omega)),\end{aligned} \quad (4.7)$$

from which it follows that

$$\begin{aligned}\Psi(t,\omega,\chi+h) - \Psi(t,\omega,\chi) = e^{-\tilde{L}t}\tilde{S}(t)h + \int_0^t e^{-\tilde{L}(t-s)}\tilde{S}(t-s)[F(s,\theta_s\omega,\Phi(s,\omega,\varpi+h)) \\ - F(s,\theta_s\omega,\Phi(s,\omega,\varpi))]ds.\end{aligned} \quad (4.8)$$

Since $\|\tilde{S}(t)\| \leqslant e^{s(\tilde{A})t}, t \geqslant 0$, we have

$$\begin{aligned}&\|\Psi(t,\omega,\chi+h) - \Psi(t,\omega,\chi)\| \\ &\leq e^{\varrho t}\|h\| + L_f \int_0^t e^{\varrho(t-s)}\|P_1[\Phi(s,\omega,\varpi+h) - \Phi(s,\omega,\varpi)]\|ds \\ &= e^{\varrho t}\|h\| + L_f \int_0^t e^{\varrho(t-s)}\|P_1[\Psi(s,\omega,\chi+h) - \Psi(s,\omega,\chi)]\|ds \\ &\leq e^{\varrho t}\|h\| + L_f \int_0^t e^{\varrho(t-s)}\|\Psi(s,\omega,\chi+h) - \Psi(s,\omega,\chi)\|ds.\end{aligned} \quad (4.9)$$

Multiplying both sides of (4.9) by $e^{-\varrho t}$ and taking into account the Gronwall inequality, we obtain

$$e^{-\varrho t}\|\Psi(t,\omega,\chi+h) - \Psi(t,\omega,\chi)\| \leq e^{L_f t}\|h\|, \quad (4.10)$$

and hence

$$\|\Psi(t,\omega,\chi+h) - \Psi(t,\omega,\chi)\| \leq e^{(L_f+\varrho)t}\|h\|. \quad (4.11)$$

Therefore, the claim holds by taking $L(t) = e^{(L_f+\varrho)t}$.

Next we prove that, for any $t > 0$, there exist $K(\omega) \geq 1$ and $\alpha > 0$ such that, if $\chi, \chi + h \in \mathcal{A}_\Psi(\omega)$, then

$$\|\Psi(t,\omega,\chi+h) - \Psi(t,\omega,\chi) - U^{\chi+h,\chi}(t,\omega)\| \leq K(\omega)\|h\|^{1+\alpha}. \quad (4.12)$$

Let

$$L_2(\omega) := \sup_{\xi \in \overline{co}\mathcal{A}_\Psi(\omega)(w)} \left|D^2 f(P_1\xi)\right|, \quad (4.13)$$

where $\overline{co}\mathcal{A}_\Psi(\omega)$ represents the closed convex hull of $\mathcal{A}_\Psi(\omega)$. Since f is C^2 and $\mathcal{A}_\Psi(\omega)$ is compact, $L_2 < \infty$. By Proposition 4.2, we have

$$U^{\chi,h}(t,\omega) = e^{-\tilde{L}t}\tilde{S}(t)h + \int_0^t e^{-\tilde{L}(t-s)}\tilde{S}(t-s)(0, D\tilde{f}\,(P_1\Phi(s,\omega,\varpi))\,P_1U(s))ds, \qquad t \geqslant 0.$$

For notation simplicity, we denote $y(t,\omega) \triangleq \Psi(t,\omega,\chi+h) - \Psi(t,\omega,\chi) = \Phi(s,\omega,\varpi+h) - \Phi(s,\omega,\varpi)$ and $w(t,\omega) \triangleq \Psi(t,\omega,\chi+h) - \Psi(t,\omega,\chi) - U^{\varpi,h}(t,\omega)$. Then, it follows from (4.6) and (4.7) that

$$
\begin{aligned}
&\|w(t,\omega)\| \\
&\quad = \Big\| \int_0^t e^{-\tilde{L}(t-s)} \tilde{S}(t-s)\{0, \tilde{f}\left(P_1\Phi(s,\omega,\varpi+h)\right) \\
&\qquad - \tilde{f}\left(P_1\Phi(s,\omega,\varpi)\right) - D\tilde{f}\left(P_1\Phi(s,\omega,\varpi)\right) P_1U(s,\omega)\}ds \| \\
&\quad \le \int_0^t e^{\varrho(t-s)} \|\tilde{f}\left(P_1\Phi(s,\omega,\varpi+h)\right) - \tilde{f}\left(P_1\Phi(s,\omega,\varpi)\right) - D\tilde{f}\left(P_1\Phi(s,\omega,\varpi)\right) P_1U(s,\omega)\|_{\mathbb{X}} ds \\
&\quad \le \int_0^t e^{\varrho(t-s)} \int_0^1 |D\tilde{f}\left(P_1(\Phi(s,\omega,\varpi)+\vartheta y(s,\omega))\right) - D\tilde{f}\left(P_1\Phi(s,\omega,\varpi)\right)| d\vartheta \|P_1 y(s,\omega)\|_{\mathcal{L}} ds \\
&\qquad + \int_0^t e^{\varrho(t-s)} \|D\tilde{f}\left(P_1\Phi(s,\omega,\varpi)\right) P_1 w(s,\omega)\|_{\mathbb{X}} ds \\
&\quad \le \int_0^t e^{\varrho(t-s)} \int_0^1 \int_0^1 |D^2\tilde{f}\left(P_1(\Phi(s,\omega,\varpi)+\lambda\vartheta y(s,\omega))\right)| \lambda\vartheta d\lambda d\vartheta \|P_1 y(s,\omega)\|_{\mathcal{L}}^2 ds \\
&\qquad + \int_0^t e^{\varrho(t-s)} \|D\tilde{f}\left(P_1\Phi(s,\omega,\varpi)\right) P_1 w(s,\omega)\|_{\mathbb{X}} ds \\
&\quad \le \int_0^t e^{\varrho(t-s)} \int_0^1 \int_0^1 |D^2\tilde{f}\left(P_1(\Phi(s,\omega,\varpi)+\lambda\vartheta y(s,\omega))\right)| d\lambda d\vartheta \|y(s,\omega)\|^2 ds \\
&\qquad + \int_0^t e^{\varrho(t-s)} |D\tilde{f}\left(P_1\Phi(s,\omega,\varpi)\right)| \|w(s,\omega)\| ds.
\end{aligned} \tag{4.14}
$$

Since $\chi, \chi+h \in \mathcal{A}_\Psi(\omega)$, it follows from the invariance Corollary 3.13 that $\varpi, \varpi+h \in \mathcal{A}_\Phi(\omega)$. Therefore, the invariance of $\mathcal{A}_\Phi(\omega)$ under Φ implies that $\Phi(t,\omega,\varpi), \Phi(t,\omega,\varpi+h) \in \mathcal{A}_\Psi(\omega)$ for all $t \geqslant 0$. Therefore, $P_1\Phi(t,\omega,\varpi) + \lambda\vartheta y(s,\omega)) \in \overline{co}\left(\mathcal{A}_\Phi(\omega)\right)$, for all $\vartheta, \lambda \in [0,1]$, where $\overline{co}\mathcal{A}_\Phi(\omega)$ represents the closed convex hull of $\mathcal{A}_\Phi(\omega)$. Thus, it follows from (4.13) and (4.10) and the fact f is C^2 that

$$
\|w(t,\omega)\| \leqslant L_2(\omega) \int_0^t e^{[2(L_f+\varrho)+\varrho](t-s)} \|h\|^2 ds + L_1(\omega) \int_0^t e^{\varrho(t-s)} \|w(s,\omega)\| ds. \tag{4.15}
$$

Multiplying both sides of (4.15) by $e^{-\varrho t}$ yields that

$$
e^{-\varrho t}\|w(t,\omega)\| \leqslant \frac{-L_2(\omega)e^{-\varrho t}}{2(L_f+\varrho)+\varrho}\|h\|^2 + L_1(\omega) \int_0^t e^{-\varrho s} \|w(s,\omega)\| ds, \tag{4.16}
$$

which implies, by the Gronwall inequality, that

$$
e^{-\varrho t}\|w(t,\omega)\| \leqslant \frac{-L_2(\omega)e^{-\varrho t}}{2(L_f+\varrho)+\varrho}\|h\|^2 + \frac{L_1(\omega)e^{L_1(\omega)t}}{-(L_f+\varrho)}(e^{-(\varrho+L_1)t} - 1)\|h\|^2. \tag{4.17}
$$

Therefore, we have

$$
\|w(t,\omega)\| \leqslant \frac{-L_2(\omega)}{2(L_f+\varrho)+\varrho}(1 + \frac{L_1(\omega)(1-e^{(L_1(\omega)+\varrho)t}}{-(L_f+\varrho)})\|h\|^2. \tag{4.18}
$$

Take $D\Psi(\omega)h \triangleq U^{\varpi,h}(1,\omega)$, then it follows from (4.2) that $D\Psi(\omega)$ is linear and continuous.

Moreover, we have

$$\begin{aligned}&\|\Psi(\omega)(\chi+h)-\Psi(\omega)\chi-D\Psi(\omega,\chi)\cdot h\|\\&=\|\Psi(1,\omega,\chi+h)-\Psi(1,\omega\chi)-U^{\chi,h}(1,\omega)\|\\&\leq\frac{-L_2(\omega)}{2(L_f+\varrho)+\varrho}\left(1+\frac{L_1(\omega)(1-e^{(L_1(\omega)+\varrho)}}{-(L_f+\varrho)}\right)\|h\|^2,\end{aligned}\tag{4.19}$$

what implies that the statement of Theorem 4.3 holds by taking $\alpha = 1$ and $K(\omega) = \frac{-L_2(\omega)}{2(L_f+\varrho)+\varrho}(1+\frac{L_1(\omega)(1-e^{(L_1(\omega)+\varrho)}}{-(L_f+\varrho)})$. □

We can now prove the main results of this paper.

Theorem 4.4. *Assume that* ***Hypotheses A1–A4*** *as well as conditions of Theorem 3.12 are satisfied, $f:\mathcal{L}\to H$ is twice continuously differentiable and there exists $L_3(\omega)$ such that for all $\phi\in\mathcal{L}$ and a.e. $\omega\in\Omega$ such that*

$$(D\tilde{f}\,(P_1\Phi(t,\omega,\phi))\,\varphi_j,\varphi_j(0))<L_3(\omega),\tag{4.20}$$

where $\varphi_j\in\mathcal{C}, j=1,2,\ldots,m$ is a sequence of unit orthogonal vectors. Then, the Hausdorff and fractal dimensions of the random attractor $\mathcal{A}_\Psi(\omega)$ of (2.11) are bounded by

$$d<[\frac{L_1(\omega)}{c}]^{\frac{1}{1+2/N}},\tag{4.21}$$

where c is a positive constant, N is dimension of the spatial domain, $L_1(\omega)$ is defined by (4.4).

Proof. The existence of random attractor $\mathcal{A}_\Psi(\omega)$ has been proved in Theorem 2.4 under **Hypotheses A1–A2**. We show in the sequel the finite dimensionality of $\mathcal{A}_\Psi(\omega)$. Let $\varpi\in\mathcal{A}_\Psi(\omega)$, $h_i=(\phi_i,\phi_i(0))\in D(\tilde{A})$ and $U_i^{\varpi,h_i}(t,\omega)$ be defined by

$$U_i^{\varpi,h_i}(t,\omega)=e^{-\tilde{L}t}\tilde{S}(t)h_i+\int_0^t e^{-\tilde{L}(t-s)}\tilde{S}(t-s)(0,D\tilde{f}\,(P_1\Phi(s,\omega,\varpi))P_1U_i^{\varpi,h_i}(s,\omega))ds,\quad t\geqslant 0.\tag{4.22}$$

It follows from Proposition 4.2 that $U_i^{\varpi,h_i}(t,\omega)$ satisfies the following variational equation on H.

$$\begin{cases}\dfrac{dU_i^{\varpi,h_i}(t,\omega)}{dt}=\tilde{A}U_i^{\varpi,h_i}(t,\omega)-\tilde{L}U_i^{\varpi,h_i}(t,\omega)+(0,D\tilde{f}\,(P_1\Phi(s,\omega,\varpi))\,P_1U_i^{\varpi,h_i}(t,\omega)),\\U_i^{\varpi,h_i}(0,\omega)=h_i\in H.\end{cases}\tag{4.23}$$

Define a family of random maps $U_i(t,\omega):H\to H, i=1,\ldots,m$ by $U_i(t,\omega)h_i=U^{\varpi,h_i}(t,\omega)$. By a similar argument to that for (2.40) in [40] Chapter V, we obtain

$$\frac{1}{2}\frac{d}{dt}\,|U_1(t,\omega)\wedge\cdots\wedge U_m(t,\omega)|^2_{\wedge^m H}=|U_1(t,\omega)\wedge\cdots\wedge U_m(t,\omega)|^2_{\wedge^m H}\,\mathrm{Tr}\,(G(t)\circ Q_m(t))\,,\tag{4.24}$$

where $|\cdot|_{\wedge^m H}$ represents the exterior product and

$$Q_m(t)=Q_m\,(t,\varpi;h_1,\ldots,h_m)\tag{4.25}$$

is the orthogonal projection of H onto the space spanned by $\{U_j(t,\omega)\}_{j=1,2,\ldots,m}$ and $G(t)=G(t,\omega):H\to H$ is defined by

$$G(t,\omega)h_i=\tilde{A}h_i-\tilde{L}h_i+(0,D\tilde{f}\,(P_1\Phi(s,\omega,\varpi))\,P_1h_i).\tag{4.26}$$

Therefore

$$\begin{aligned} &|U_1(t,\omega)\wedge\cdots\wedge U_m(t,\omega)|_{\wedge^m H} \\ &\quad = |U_1(0,\omega)\wedge\cdots\wedge U_m(0,\omega)|_{\wedge^m H}\exp\left(\int_0^t \operatorname{Tr}\left(G(s,\omega)\circ Q_m(s)\right) ds\right) \\ &\quad = |h_1\wedge\cdots\wedge h_m|_{\wedge^m H}\exp\left(\int_0^t \operatorname{Tr}\left(G(s,\omega)\circ Q_m(s)\right) ds\right). \end{aligned} \tag{4.27}$$

Let us fix an orthonormal basis $\{e_j = (\varphi_j, \varphi_j(0))\}_{j=1,2,\dots,m}$ of the span $\{U_j(t,\omega)\}_{j=1,2,\dots,m}$. Then, we have

$$\begin{aligned} \operatorname{Tr}\left(G(s,\omega)\circ Q_m(s)\right) &= \sum_{j=1}^m \left\langle G(s,\omega)e_j, e_j\right\rangle \\ &= \sum_{j=1}^m \left\langle \tilde{A}e_j - \tilde{L}e_j + (0, D\tilde{f}\left(P_1\Phi(s,\omega,\varpi)\right)P_1 e_j), e_j\right\rangle \\ &= \sum_{j=1}^m \left\langle (\dot{\varphi}_j, A\varphi_j(0) - \mu\varphi_j(0) + D\tilde{f}\left(P_1\Phi(s,\omega,\varpi)\right)\varphi_j), (\varphi_j, \varphi_j(0))\right\rangle. \end{aligned} \tag{4.28}$$

By the definition of the inner product,

$$\begin{aligned} &\left\langle (\dot{\varphi}_j - L\varphi_j, A\varphi_j(0) - \mu\varphi_j(0) + D\tilde{f}\left(P_1\Phi(s,\omega,\varpi)\right)\varphi_j), (\varphi_j, \varphi_j(0))\right\rangle \\ &\quad = \int_{-\tau}^0 \left(\frac{d}{dr}\varphi_j(s+r), \varphi_j(s+r)\right) dr + \left(A\varphi_j(0), \varphi_j(0)\right) - \mu\|\varphi_j(0)\|_{\mathbb{X}} \\ &\qquad + \left(D\tilde{f}\left(P_1\Phi(s,\omega,\varpi)\right)\varphi_j, \varphi_j(0)\right) \\ &\quad \leqslant \|\varphi_j(s)\|_{\mathbb{X}}^2 - \|\varphi_j(s-\tau)\|_{\mathbb{X}}^2 - \left(-A\varphi_j(0), \varphi_j(0)\right) + L_3(\omega). \end{aligned} \tag{4.29}$$

Incorporating (4.29) into (4.28) yields

$$\operatorname{Tr}\left(G(s,\omega)\circ Q_m(s)\right) \leqslant \sum_{j=1}^m (\|\varphi_j(s)\|_{\mathbb{X}}^2 - \|\varphi_j(s-\tau)\|_{\mathbb{X}}^2) - \sum_{j=1}^m \left(-A\varphi_j(0), \varphi_j(0)\right) + L_3(\omega). \tag{4.30}$$

In order to estimate the evolution of the volume under the random maps $U_i(t,\omega) : H \to H, i = 1,\dots,m$, i.e., the norm of $|U_1(t,\omega)\wedge\cdots\wedge U_m(t,\omega)|_{\wedge^m H}$ defined by (4.27), we introduce two quantities $q_m(t,\omega)$ and $q_m(\omega)$, which are defined by

$$q_m(t,\omega) \triangleq \sup_{\chi\in\mathcal{A}_\Psi(\omega), h_i\in D(\tilde{A}), \|h_i\|_H\leq 1} \frac{1}{t}\int_0^t \operatorname{Tr}\left(G(s,\omega)\circ Q_m(s)\right) ds$$

and

$$q_m(\omega) \triangleq \lim_{t\to\infty} q_m(t,\omega)$$

respectively. Now we keep in mind that

$$q_m(t,\omega) \leqslant \frac{1}{t}\int_0^t \left[\sum_{j=1}^m \left(\|\varphi_j(s)\|_{\mathbb{X}}^2 - \|\varphi_j(s-\tau)\|_{\mathbb{X}}^2\right) - \sum_{j=1}^m \left(-A\varphi_j(0), \varphi_j(0)\right) + L_3(\omega)\right] ds, \tag{4.31}$$

and

$$\frac{1}{t}\int_0^t \sum_{j=1}^m \left(\|\varphi_j(s)\|_{\mathbb{X}}^2 - \|\varphi_j(s-\tau)\|_{\mathbb{X}}^2\right) ds = 0. \tag{4.32}$$

Moreover, by [40] Chapter VI Section 2.1, there exists a $c > 0$ such that

$$\sum_{i=1}^{m} \left(-A\varphi_j(0), \varphi_j(0)\right) \geq cm^{1+\frac{2}{N}}.$$

Then, we have $q_m \leq -cm^{1+\frac{2}{N}} + L_3(\omega)$. Therefore, the Hausdorff and fractal dimensions of the random attractor $\mathcal{A}_\Psi(\omega)$ of (2.11) obtained in Theorem 3.12 are bounded by the first integer such m that $q_m \leq 0$, that is,

$$d < \left[\frac{L_3(\omega)}{c}\right]^{\frac{1}{1+2/N}}, \tag{4.33}$$

completing the proof. □

5 Conclusions

In this paper, we have estimated the topological dimensions of random attractor for the stochastic delayed semilinear partial differential equation (1.2). In order to overcome the difficulty caused by the lack of Hilbert geometry, we recast the equation into a Hilbert space. One naturally wonders, whether we can estimate the dimension of attractors for SPFDEs in their natural phase space, i.e. Banach spaces. This requires to establish the general framework to estimate the dimension of attractors of RDS in Banach spaces, which will be studied in the near future. Moreover, there are also SPFDEs on infinite domains which can model the spatial-temporal patterns for the mature population of age-structured species under random perturbations. The existence of random attractors for a stochastic nonlocal delayed reaction-diffusion equation on a semi-infinite interval have been studied in [29]. However, little attention has been paid to the estimation of topological dimensions of random attractor for the equation therein, which also deserves much effort in the future.

Communicated by Gabriele Bonanno

Abstract. The existence of at least one or two nontrivial solutions to a general higher-order boundary value problem is established by using variational tools. Two of the results are obtained without any asymptotic behaviour at infinity of potential F of the nonlinear term f, which is a key condition in the available literature, when applying critical point theorems. Moreover, F may change sign. The last result is stated when the nonlinearity has asymptotic behaviour at both infinity and zero.

Keywords: ODE, higher-order, semilinear, Brézis–Nirenberg's linking theorem, Mountain Pass theorem, variational method.

2020 Mathematics Subject Classification: 34A12, 34B15.

1 Introduction

In this paper, we investigate the existence of at least one or two solutions for the boundary value problem

$$\begin{cases} u^{(2n)} + A_{n-1}u^{(2n-2)} + \cdots + A_1 u'' + A_0 u + f(x,u) = 0 \text{ in } \Omega = (0, L) \\ u = u'' = \cdots = u^{(2n-2)} = 0 \text{ on } \partial\Omega, \end{cases} \tag{1.1}$$

where $A_0, A_1, \ldots, A_{n-1}$ are some given real constants, f is a continuous function on $\overline{\Omega} \times \mathbb{R}$ and $n \geq 2$.

The existence of solutions for fourth-order problems ($n = 2$), which describe the deflection of an elastic beam with supported ends, has been extensively studied in the literature (see for example [2–4, 7, 8, 11, 15, 16] and the literature cited therein).

We mention the paper [12], where (1.1) (case $n = 2$) was treated under the assumption $A_1^2 > 4A_0$ by variational tools. The authors obtained existence and multiplicity results if the potential $F(x,s) = \int_0^s f(x,t)dt$ satisfies an asymptotic behaviour at zero and for some $C > 0$ and $p > 2$

$$F(x,s) \geq C|s|^p, \qquad \forall\, x \in \Omega,\ s \in \mathbb{R}. \tag{1.2}$$

✉ Email: cristian.danet@edu.ucv.ro

The case $A_1^2 = 4A_0$ was treated in [15].

The existence of solutions to sixth-order equations ($n = 3$) was investigated in [8] by using Clark's theorem provided the coefficients A_0, A_1, A_2 satisfy some relations in the particular case when $f(x,s) = a(x)s^3$. Here $a(x)$ is a continuous positive and even function.

In [13], using two Brézis–Nirenberg's linking theorems, the existence of at least two or three solutions was obtained, where $F \geq 0$ has an asymptotic behaviour at zero and satisfies

$$\frac{F(x,s)}{s^2} \to +\infty, \quad \text{uniformly with respect to } x \text{ as } |s| \to \infty. \tag{1.3}$$

Note that condition (1.2) implies the weaker super-quadratic condition (1.3). Also in the new paper [1] infinitely many solutions to equation (1.1) (case $n = 3, \Omega = (0,1)$) are obtained in the case when the nonlinear term f has an oscillating behaviour and the following restriction holds

$$\max\{A_2k, A_2k - A_1k^2, A_2k - A_1k^2 + A_0k^3\} < 1, \tag{1.4}$$

where $k = 1/\pi^2$.

For further results on sixth-order equations we refer the reader to [5,9,14,16–18].

The existence results of this paper are obtained for a general $2n-$ order equation by variational methods and hold under different assumptions on the coefficients.

We impose here suitable conditions on the coefficients $A_0, \dots, A_{n-1}$, allowing to define several norms equivalent to the usual norm of the working space. One of the condition we impose (relation (2.5)) represents a generalization to the higher-order case of condition $A_1^2 > 4A_0$ which plays a role in the works [16] and [12].

We see that even we restrict ourselves to the case $n = 3$ our conditions imposed to the coefficients are different from the condition (1.4) or from the results obtained in the above mentioned papers.

Moreover, we note that our first two main results are stated without any asymptotic behaviour at infinity. More precisely, we prove by using the Brézis–Nirenberg's linking theorem that an existence result holds without any behaviour at infinity if $F \geq 0$ (Theorem 3.1). By using Ekeland's variational principle we show (Theorem 3.4) that a result holds if F may change sign and if no asymptotic behaviour at infinity is required. The last existence result uses the Mountain Pass theorem and is stated when F may change sign and f satisfies an asymptotic behaviour at both zero and infinity (f behavies at $\pm\infty$ as $|s|^p, p > 1$).

2 Auxiliary results and variational settings

We consider the Hilbert space

$$H(\Omega) = \{u \in H^n(\Omega) \mid u = u'' = \cdots = u^{(2n-4)} = 0 \text{ on } \partial\Omega\}$$

endowed with the standard inner product

$$(u,v)_{H^n(\Omega)} = \int_\Omega \left(uv + u'v' + u''v'' + \cdots + u^{(n)}v^{(n)}\right)dx$$

and standard norm

$$\|u\|_{H^n(\Omega)} = (u,u)^{\frac{1}{2}}_{H^n(\Omega)}.$$

For the sake of simplicity we consider $n = 4k, k = 1,2,3,\dots,$ unless otherwise stated.

We recall the meaning of a weak solution to (1.1).

Definition 2.1. A weak solution of (1.1) is a function $u \in H(\Omega)$ such that

$$\int_\Omega \Big(u^{(n)}v^{(n)} - A_{n-1}u^{(n-1)}v^{(n-1)} + \cdots - A_1 u'v' + A_0 uv + f(x,u)v \Big) dx = 0, \qquad \forall\, v \in H(\Omega).$$

A classical solution of (1.1) is a function $u \in C^{2n}(\overline{\Omega})$ that satisfies (1.1).

We note that since f is a continuous function on $\overline{\Omega} \times \mathbb{R}$, it follows that a weak solution of (1.1) belongs to $C^{2n}(\overline{\Omega})$ (to get the result imitate the proof in [17]).

We also recall that the set of functions

$$\left\{ \sin \frac{m\pi x}{L},\, m \in \mathbb{N}, m \geq 1 \right\}$$

is a complete orthogonal basis in $H(\Omega)$.

The symbol $P(\xi) = \xi^{2n} - A_{n-1}\xi^{2n-2} + \cdots + A_2\xi^4 - A_1\xi^2 + A_0$ of the differential operator $L(u) = u^{(2n)} + A_{n-1}u^{(2n-2)} + \cdots + A_2 u^{(4)} + A_1 u'' + A_0 u$ plays an important role in the sequel.

Problem (1.1) has a variational structure and weak solutions in the space $H(\Omega)$ can be found as critical points of the functional

$$J : H(\Omega) \to \mathbb{R}$$

$$J(u) = \frac{1}{2}\int_\Omega \Big((u^{(n)})^2 - A_{n-1}(u^{(n-1)})^2 + \cdots - A_1(u')^2 + A_0 u^2 \Big) dx + \int_\Omega F(x,u)dx,$$

which is Fréchet differentiable and its Fréchet derivative is given by

$$\langle J'(u), v \rangle = \int_\Omega \Big(u^{(n)}v^{(n)} - A_{n-1}u^{(n-1)}v^{(n-1)} + \cdots - A_1 u'v' + A_0 uv + f(x,u)v \Big) dx,$$

for all $v \in H(\Omega)$.

Throughout the paper C denotes a universal positive constant depending on the indicated quantities, unless otherwise specified.

The next lemmas are fundamental tools in proving our existence result.

First we point out some Poincaré-type inequalities.

Lemma 2.2 ([10]). *The following relations hold true for any $u \in H(\Omega)$.*

$$\int_\Omega (u^{(k)})^2 dx \leq \left(\frac{L}{\pi}\right)^2 \int_\Omega (u^{(k+1)})^2 dx, \qquad k = 0,1,2,\ldots,n-1. \tag{2.1}$$

$$\int_\Omega u^2 dx \leq \left(\frac{L}{\pi}\right)^{2k} \int_\Omega (u^{(k)})^2 dx, \qquad k = 1,2,\ldots,n. \tag{2.2}$$

In particular,

$$\int_\Omega u^2 dx \leq \left(\frac{L}{\pi}\right)^{2n} \int_\Omega (u^{(n)})^2 dx. \tag{2.3}$$

An immediate consequence of Lemma 2.2 is the inequality

$$C(L,n)\|u\|_{H^n(\Omega)} \leq \int_\Omega (u^{(n)})^2 dx \leq \|u\|_{H^n(\Omega)}, \tag{2.4}$$

which shows that the scalar product

$$(u,v)_{H(\Omega)} = \int_\Omega u^{(n)}v^{(n)} dx$$

induces a norm equivalent (denoted $\|\cdot\|_{H(\Omega)}$) to the norm $\|\cdot\|_{H^n(\Omega)}$ in the space $H(\Omega)$.

The next lemma is an extension of Lemma 8, [16] and is proved by different means.

Lemma 2.3. *Let $u \in H(\Omega)$.*

a). Suppose that $A_0, A_2, \dots, A_{n-4} \geq 0$, $A_1, A_3, \dots, A_{n-3} \leq 0$, $A_{n-2}, A_{n-1} > 0$ and

$$A_{n-1}^2 < 4A_{n-2}. \tag{2.5}$$

Then there exists a constant k such that

$$\int_\Omega \left[(u^{(n)})^2 - A_{n-1}(u^{(n-1)})^2 + \cdots - A_1(u')^2 + A_0 u^2 \right] dx \geq k\|u\|^2_{H^n(\Omega)}. \tag{2.6}$$

A similar estimate holds for $A_0 < 0$ but under the restriction

$$A_{n-1}^2 < 4A_{n-2}A^*, \tag{2.7}$$

where $A^* = 1 + A_0\left(\frac{L}{\pi}\right)^{2n} > 0$.

b). The same estimate (2.6) holds if for some index $j = 2, 4, \dots, n-2$

$$\frac{A_{n-j-1}^2}{A_{n-j}} < 4A_{n-j-2}, \tag{2.8}$$

where

$$A_1, A_3, \dots, A_{n-j-3}, A_{n-j+1}, \dots, A_{n-1} < 0,$$
$$A_0, A_2, \dots, A_{n-j-2}, A_{n-j+2} \dots, A_{n-2} \geq 0, \quad A_{n-j-1}, A_{n-j} > 0.$$

c). Similarly, (2.6) holds if for some index $j = 1, 3, \dots, n-1$ (2.8) is fulfilled, where

$$A_1, A_3, \dots, A_{n-j-3}, A_{n-j+1}, \dots, A_{n-1} \leq 0,$$
$$A_0, A_2, \dots, A_{n-j-2}, A_{n-j+2} \dots, A_{n-2} \geq 0, \quad A_{n-j-1} < 0, A_{n-j} > 0.$$

Remark 2.4.

1. Of course if $A_{n-1} \leq 0, A_{n-2} \geq 0, \dots, A_1 \leq 0, A_0 \geq 0$, then Lemma 2.3 is always true, i.e., there is nothing to prove.

2. We easily see that if $n = 2$ (Case a).) then we obtain exactly Lemma 8, [16] for bounded domains, i.e., our result is a direct extension to the higher-order case.

3. Note that Lemma 2.5 and Lemma 2.6 can also be seen as extensions of Lemma 8, [16] and hold for bounded domains Ω as well when $\Omega = \mathbb{R}$.

Proof. a). We see that for any real α

$$\int_\Omega \left(u^{(n)} + \alpha u^{(n-1)}\right)^2 dx = \int_\Omega \left((u^{(n)})^2 - 2\alpha(u^{(n-1)})^2 + \alpha^2(u^{(n-2)})^2\right) dx.$$

It follows that for any α the quantity

$$Q_\alpha = \int_\Omega \left((u^{(n)})^2 - 2\alpha(u^{(n-1)})^2 + \alpha^2(u^{(n-2)})^2\right) dx$$

is positive.

For arbitrary $\varepsilon > 0$ and by the assumptions

$$
\begin{aligned}
&\int_\Omega \left[(u^{(n)})^2 - A_{n-1}(u^{(n-1)})^2 + \cdots - A_1(u')^2 + A_0u^2\right] dx \\
&\quad \geq \int_\Omega \left[(u^{(n)})^2 - A_{n-1}(u^{(n-1)})^2 + A_{n-2}(u^{(n-2)})^2\right] dx \\
&\quad = \left\{\varepsilon \int_\Omega \left[(u^{(n)})^2 + (u^{(n-1)})^2 + (u^{(n-2)})^2\right] dx \right.\\
&\qquad + (1-\varepsilon)\int_\Omega \left[(u^{(n)})^2 - \frac{A_{n-1}+\varepsilon}{1-\varepsilon}(u^{(n-1)})^2 + \frac{1}{4}\left(\frac{A_{n-1}+\varepsilon}{1-\varepsilon}\right)^2 (u^{(n-1)})^2\right] dx \\
&\qquad \left. + \left[A_{n-2} - \varepsilon - \frac{1}{4}\frac{(A_{n-1}+\varepsilon)^2}{1-\varepsilon}\right] \int_\Omega (u^{(n-2)})^2 dx \right\} \\
&\quad \geq \varepsilon \int_\Omega (u^{(n)})^2 dx + (1-\varepsilon) Q_{\frac{A_{n-1}+\varepsilon}{1-\varepsilon}} + \left[A_{n-2} - \varepsilon - \frac{1}{4}\frac{(A_{n-1}+\varepsilon)^2}{1-\varepsilon}\right] \int_\Omega (u^{(n-2)})^2 dx.
\end{aligned}
$$

Choosing ε sufficiently small, using that $Q_{\frac{A_{n-1}+\varepsilon}{1-\varepsilon}} \geq 0$, (2.5) and the equivalence of norms $\|\cdot\|_{H^n(\Omega)}$ and $\|\cdot\|_{H(\Omega)}$ we get the result.

b). and c). Follows from case a). □

Lemma 2.5. *Let $u \in H(\Omega)$ and $A_0 > 1$.*

Suppose that for an index i and j,

$$
A_i^2 < -4A_j, \qquad \frac{A_i^2}{-4A_j} \leq A_0 - 1, \tag{2.9}
$$

where $i = 2, 3, \ldots, \frac{n}{2}$, $A_i \neq A_j$, $1 \leq j \leq n-1$, $A_j < 0$, $A_i < 0$ if i is even and $A_i > 0$ if i is odd.

Then there exist the constants $k_{i,j} > 0$ such that

$$
\int_\Omega \left[(u^{(n)})^2 - A_{n-1}(u^{(n-1)})^2 + \cdots - A_1(u')^2 + A_0u^2\right] dx \geq k_{i,j}\|u\|^2_{H^n(\Omega)}. \tag{2.10}
$$

Proof. a). For the sake of simplicity we consider $j = 1$ and $i = 2$, i.e.,

$$
A_1, A_2 < 0, \quad A_4, \ldots, A_{n-2} \geq 0, \quad A_3, \ldots, A_{n-1} \leq 0
$$

and

$$
\frac{A_2^2}{-4A_1} \leq A_0 - 1, \qquad A_2^2 < -4A_1.
$$

We are going to prove the required inequality for $u \in H^n(\mathbb{R})$ by using the Fourier transform.

Taking in particular $u \in H(\Omega) \cap H^n(\mathbb{R})$ we get the inequalities for bounded domains Ω.

Let $\hat{u}(\xi)$ be the Fourier transform of $u(x) \in H^n(\mathbb{R})$.

First observe that by Parseval's identity we get

$$
\begin{aligned}
&\int_\mathbb{R} \left((u^{(n)})^2 - A_{n-1}(u^{(n-1)})^2 + \cdots - A_1(u')^2 + A_0u^2\right) dx \\
&\quad = \int_\mathbb{R} \left(\xi^{2n} - A_{n-1}\xi^{2n-2} + \cdots - A_1\xi^2 + A_0\right) \|\hat{u}(\xi)\|^2 d\xi.
\end{aligned} \tag{2.11}
$$

By using elementary inequalities we get for all $\xi \in \mathbb{R}$

$$\begin{aligned} A_2\xi^4 &\le \frac{A_2^2}{-4A_1}\xi^6 + (-A_1)\xi^2 \le \frac{A_2^2}{-4A_1}\xi^{2n} + (-A_1)\xi^2 + \frac{A_2^2}{-4A_1} \\ &\le \frac{A_2^2}{-4A_1}\xi^{2n} + (-A_1)\xi^2 + A_0 - 1 \\ &\le \frac{A_2^2}{-4A_1}\xi^{2n} - A_{n-1}\xi^{2n-2} + \cdots - A_3\xi^6 + (-A_1)\xi^2 + A_0 - 1. \end{aligned}$$

Hence

$$\begin{aligned} &\xi^{2n} - A_{n-1}\xi^{2n-2} + \cdots + A_2\xi^4 - A_1\xi^2 + A_0 \\ &\quad \ge \left(1 - \frac{A_2^2}{-4A_1}\right)\xi^{2n} + 1 \ge \left(1 - \frac{A_2^2}{-4A_1}\right)\left(\xi^{2n} + 1\right). \end{aligned} \tag{2.12}$$

It can be easily checked that $\forall\, \xi \in \mathbb{R}$

$$\xi^{2n} + 1 \ge \frac{1}{n}\left(1 + \xi^2 + \cdots + \xi^{2n}\right). \tag{2.13}$$

From (2.12) and (2.13) we get

$$\xi^{2n} - A_{n-1}\xi^{2n-2} + \cdots + A_2\xi^4 - A_1\xi^2 + A_0 \ge \frac{1}{n}\left(1 - \frac{A_2^2}{-4A_1}\right)\left(1 + \xi^2 + \cdots + \xi^{2n}\right). \tag{2.14}$$

Now from (2.11) and (2.14) we obtain

$$\begin{aligned} &\int_{\mathbb{R}} \left((u^{(n)})^2 - A_{n-1}(u^{(n-1)})^2 + \cdots - A_1(u')^2 + A_0u^2\right)dx \\ &\quad \ge \frac{1}{n}\left(1 - \frac{A_2^2}{-4A_1}\right)\int_{\mathbb{R}}\left(1 + \xi^2 + \cdots + \xi^{2n}\right)\|\hat{u}(\xi)\|^2 d\xi \\ &\quad = \frac{1}{n}\left(1 - \frac{A_2^2}{-4A_1}\right)\int_{\mathbb{R}}\left(u^2 + (u')^2 + \cdots + \left(u^{(2n)}\right)^2\right)dx \\ &\quad = k_{2,1}\|u\|^2_{H^n(\mathbb{R})}, \end{aligned}$$

which is the desired result. □

Lemma 2.6. *Let $u \in H(\Omega)$ and $A_0 > 1$.*

Suppose that for an index $i = 1, 3, \ldots, (n/2) - 1$, $A_i > 0$ and for an index $j = 2, 4, \ldots, n-2$, $A_j > 0$ the following inequality be fulfilled

$$A_i^2 < 4A_j, \qquad \frac{A_i^2}{4A_j} + A_j \le A_0 - 1, \tag{2.15}$$

where the rest of coefficients

$$A_1, A_3, \ldots, A_{i-2}, A_{i+2}, \ldots, A_{n-1} \le 0$$

and

$$A_2, A_4, \ldots, A_{j-2}, A_{j+2}, \ldots, A_{n-2} \ge 0.$$

Then there exist the constants $k_{i,j} > 0$ such that

$$\int_{\Omega}\left[(u^{(n)})^2 - A_{n-1}(u^{(n-1)})^2 + \cdots - A_1(u')^2 + A_0u^2\right]dx \ge k_{i,j}\|u\|^2_{H^n(\Omega)}. \tag{2.16}$$

The proof is similar to the proof of Lemma 2.5 and hence is omitted.

Lemma 2.7. *Let $u \in H(\Omega)$.*

Suppose that $A_0, A_2, \dots, A_{n-2} \geq 0$, $A_1, A_3, \dots, A_{n-1} \geq 0$, and

$$1 - A_{n-1}\left(\frac{L}{\pi}\right)^2 - A_{n-3}\left(\frac{L}{\pi}\right)^6 - \dots - A_1\left(\frac{L}{\pi}\right)^{2n-2} > 0. \tag{2.17}$$

Then there exists a constant $k_1 > 0$ such that

$$\int_\Omega \left[(u^{(n)})^2 - A_{n-1}(u^{(n-1)})^2 + \dots - A_1(u')^2 + A_0u^2\right]dx \geq k_1\|u\|^2_{H^n(\Omega)}. \tag{2.18}$$

A similar result holds if $A_0, A_2, \dots, A_{n-2} < 0$ and $A_1, A_3, \dots, A_{n-1} \geq 0$ under the assumption

$$1 - A_{n-1}\left(\frac{L}{\pi}\right)^2 + A_{n-2}\left(\frac{L}{\pi}\right)^4 - \dots - A_1\left(\frac{L}{\pi}\right)^{2n-2} + A_0\left(\frac{L}{\pi}\right)^{2n} > 0. \tag{2.19}$$

The next four lemmas gives conditions on parameters $A_i, i = 0, 1, \dots, n-1$ when the functional J is bounded below and satisfies the Palais–Smale condition. We recall here what means that J satisfies the Palais–Smale condition.

Definition 2.8. Let X be a Banach space and $J \in C^1(X, \mathbb{R})$. We say that J satisfies a Palais–Smale condition if any sequence $\{u_m\}$ in X for which $J(u_m)$ is bounded and $J'(u_m) \to 0$ as $m \to \infty$, has a convergent subsequence.

Lemma 2.9. *Let $u \in H(\Omega)$ and let $\alpha > 0$ be a constant. Suppose that $F \geq 0$, $A_0, A_2, \dots, A_{n-4} \geq 0$, $A_1, A_3, \dots, A_{n-3} \leq 0$, $A_{n-2}, A_{n-1} > 0$ and*

$$\frac{\alpha+1}{\alpha}A^2_{n-1} < 4A_{n-2}. \tag{2.20}$$

Then J is bounded below and satisfies the Palais–Smale condition.

A similar statement holds for $A_0 < 0$ but under the restriction

$$\frac{\alpha+1}{\alpha}A^2_{n-1} < 4A_{n-2}A^*, \tag{2.21}$$

where $A^* = 1 + \frac{\alpha+1}{\alpha}A_0\left(\frac{L}{\pi}\right)^{2n} > 0$.
The same conclusion holds if we are under the hypotheses of the case b). or case c). of Lemma 2.3.

Proof. We observe that for any $\alpha > 0$ we can write $J(u)$ as a sum of

$$J(u) = \frac{1}{2}\frac{1}{\alpha+1}\int_\Omega \left(u^{(n)}\right)^2 dx + \frac{\alpha}{\alpha+1}J_1(u),$$

where

$$J_1(u) = \frac{1}{2}\int_\Omega \left[(u^{(n)})^2 - \frac{\alpha+1}{\alpha}A_{n-1}(u^{(n-1)})^2 + \dots + \frac{\alpha+1}{\alpha}A_0u^2 + 2\frac{\alpha+1}{\alpha}F\right]dx.$$

Since (2.20) holds we can use Lemma 2.3 and the positivity of F to get that $J_1(u)$ is bounded below which implies that $J(u)$ is bounded below.

We now show that $J(u)$ satisfies the Palais–Smale condition.

Suppose that $\{u_m\}$ is a Palais–Smale sequence, i.e., there exists a constant $C > 0$ such that

$$|J(u_m)| \leq C \quad \text{and} \quad J'(u_m) \to 0 \quad \text{as } m \to \infty.$$

Since $J_1(u)$ is bounded below we get that there exists a constant $C_1 > 0$ such that

$$C > \frac{1}{2}\frac{1}{\alpha+1}\int_\Omega (u_m^{(n)})^2 dx - C_1,$$

which implies that $\{u_m\}$ is a bounded sequence in $H(\Omega)$.

Since

$$J(u) = \frac{1}{2}(u,u)_{H(\Omega)} - \frac{1}{2}\int_\Omega \Big[(u^{(n)})^2 - A_{n-1}(u^{(n-1)})^2 + \cdots - A_1(u')^2 + A_0u^2\Big]dx + \int_\Omega F dx,$$

we see that

$$J'(u) = u + K(u),$$

where

$$K : H(\Omega) \to H(\Omega)$$

is defined by

$$\langle K(u), v\rangle = -\int_\Omega \Big[A_{n-1}u^{(n-1)}v^{(n-1)} + \cdots + A_1u'v' - A_0uv - f(x,u)v\Big]dx.$$

Using the fact that the Sobolev imbedding $H(\Omega) \hookrightarrow C^{n-1}(\overline{\Omega})$ is compact we get that K is a complete continuous operator. Since $J'(u_m) \to 0$ as $m \to \infty$ it follows that

$$u_m = J'(u_m) - K(u_m)$$

is a convergent sequence and hence $J(u)$ satisfies the Palais–Smale condition. □

Using the same techniques we can prove

Lemma 2.10. *Let $u \in H(\Omega)$, $A_0 > 1$ and let $\alpha > 0$ be a constant.*

Suppose that for an index i and j,

$$\frac{\alpha+1}{\alpha}A_i^2 < -4A_j, \qquad \frac{A_i^2}{-4A_j} \leq A_0 - \frac{\alpha}{\alpha+1}, \tag{2.22}$$

where $i = 2,3,\ldots,\frac{n}{2}$, $A_i \neq A_j$, $1 \leq j \leq n-1$, $A_j < 0$, $A_i < 0$ if i is even and $A_i > 0$ if i is odd. Then J is bounded below and satisfies the Palais–Smale condition.

Lemma 2.11. *Let $u \in H(\Omega)$, $A_0 > 1$ and let $\alpha > 0$ be a constant.*

Suppose that for an index $i = 1,3,\ldots,(n/2)-1$, $A_i > 0$ and for an index $j = 2,4,\ldots,n-2$, $A_j > 0$ the following inequality be fulfilled

$$\frac{\alpha+1}{\alpha}A_i^2 < 4A_j, \qquad \frac{A_i^2}{4A_j} + A_j \leq A_0 - \frac{\alpha}{\alpha+1}, \tag{2.23}$$

where the rest of coefficients

$$A_1, A_3, \ldots, A_{i-2}, A_{i+2}, \ldots, A_{n-1} \leq 0,$$

and

$$A_2, A_4, \ldots, A_{j-2}, A_{j+2}, \ldots, A_{n-2} \geq 0.$$

Then J is bounded below and satisfies the Palais–Smale condition.

Lemma 2.12. *Let $u \in H(\Omega)$ and let $\alpha > 0$ be a constant.*

Suppose that $A_0, A_2, \dots, A_{n-2} \geq 0$, $A_1, A_3, \dots, A_{n-1} \geq 0$, and

$$1 - \frac{\alpha+1}{\alpha}\left[A_{n-1}\left(\frac{L}{\pi}\right)^2 + A_{n-3}\left(\frac{L}{\pi}\right)^6 + \cdots + A_1\left(\frac{L}{\pi}\right)^{2n-2}\right] > 0. \tag{2.24}$$

Then J is bounded below and satisfies the Palais–Smale condition. A similar result holds if $A_0, A_2, \dots, A_{n-2} < 0$ and $A_1, A_3, \dots, A_{n-1} \geq 0$ under the assumption

$$1 - \frac{\alpha+1}{\alpha}\left[A_{n-1}\left(\frac{L}{\pi}\right)^2 - A_{n-2}\left(\frac{L}{\pi}\right)^4 - \cdots - A_1\left(\frac{L}{\pi}\right)^{2n-2} - A_0\left(\frac{L}{\pi}\right)^{2n}\right] > 0. \tag{2.25}$$

The main tool in our approach is the Brézis–Nirenberg's linking theorem [6].

Theorem 2.13. *Suppose that $J \in C^1(H, \mathbb{R})$ satisfies the Palais–Smale condition and has a local linking at 0. Assume that J is bounded below and $\inf_H J < 0$. Then J has at least two nontrivial critical points.*

For the sake of completeness we recall the definition of local linking.

Let the Banach space H has a direct sum decomposition $H = X \oplus Y$, where X is finite dimensional.

Definition 2.14. The functional J is said to have a local linking at 0 if for some $\rho > 0$,

$$J(x) \leq 0, \qquad \forall\, x \in X,\ \|x\| \leq \rho,$$

and

$$J(y) \geq 0, \qquad \forall\, y \in Y,\ \|y\| \leq \rho.$$

3 Main results

Our existence results read.

Theorem 3.1. *Let the function $F \geq 0$, $\forall\, x \in \Omega$, $s \in \mathbb{R}$ satisfy*

$$F(x,s) \leq K|s|^p, \qquad p > 2,\ \forall\, x \in \Omega,\ s \in \mathbb{R}, s \text{ small}, \tag{3.1}$$

where $K > 0$ is a constant. Suppose that we are under hypotheses of either Lemma 2.9, Lemma 2.10, Lemma 2.11 or Lemma 2.12. If in addition there exists a natural number $m \neq 0$ such that

$$P\left(\frac{m\pi}{L}\right) < 0, \tag{3.2}$$

then the boundary value problem (1.1) has at least two nontrivial solutions.

Proof. The proof uses the Brézis–Nirenberg's linking theorem (Theorem 2.13). Hence we have to show that J satisfies the condition imposed in Theorem 2.13.

Since we are under the hypotheses of either Lemma 2.9, Lemma 2.10, Lemma 2.11 or Lemma 2.12 it follows that J is bounded below and satisfies the Palais–Smale condition.

We now follow the proof of Lemma 8, [13] and show that $\inf_{H(\Omega)} J < 0$.

We see that $P\left(\frac{m\pi}{L}\right) \to \infty$ and since (3.2) holds we get that there exists a finite set of natural numbers $\{m_1, m_2, \dots, m_k\}$ such that $P\left(\frac{m_i\pi}{L}\right) < 0$, $i = 1, 2, \dots, k$.

Introducing the finite dimensional space

$$X = \operatorname{span}\left\{ \sin \frac{m_1 \pi x}{L}, \dots, \sin \frac{m_k \pi x}{L} \right\}$$

we see that any $\varphi \in X$ can be written

$$\varphi(x) = c_1 \sin \frac{m_1 \pi x}{L} + \cdots + c_k \sin \frac{m_k \pi x}{L}$$

and its norm in $L^2(\Omega)$ is given by

$$\|\varphi\|_X^2 = c_1^2 + \cdots + c_k^2 = \rho^2,$$

where $c_1, \dots, c_k$ are real constants.

By (3.1) and Hölder's inequality we get for sufficiently small $\rho > 0$

$$\begin{aligned} \int_\Omega F(x, \varphi(x)) dx &\le K \int_\Omega |\varphi(x)|^p dx \\ &\le K \int_\Omega \left[\left(c_1^2 + \cdots + c_k^2 \right)^{\frac{1}{2}} \left(\sin \frac{m_1 \pi x}{L} + \cdots + \sin \frac{m_k \pi x}{L} \right)^{\frac{1}{2}} \right]^p \\ &\le C(K, k, p, L) \left(c_1^2 + \cdots + c_k^2 \right)^{\frac{p}{2}} = C(K, k, p, L) \rho^p. \end{aligned}$$

Hence

$$\begin{aligned} J(\varphi) &\le \frac{L}{4} \sum_{i=1}^{k} P\left(\frac{m_i \pi}{L} \right) c_i^2 + C(K, k, p, L) \rho^p \\ &\le \frac{L}{4} \alpha \rho^2 + C(K, k, p, L) \rho^p = \rho^2 \left(\frac{L}{4} \alpha + C(K, k, p, L) \rho^{p-2} \right) < 0, \end{aligned}$$

where $\alpha = \max \left\{ P\left(\frac{m_i \pi}{L}\right), i = 1, 2, \dots, k \right\} < 0$ by hypothesis.

We now show that J has a local linking at 0.

By the above estimation, we see that for sufficiently small ρ

$$J(u) \le 0, \qquad \forall\, u \in X,\ \|u\| \le \rho.$$

Also since for any $u \in Y = X^\perp$ (bear in mind that $P\left(\frac{m_{k+1}\pi}{L}\right) \ge 0$)

$$J(u) \ge \frac{1}{2} P\left(\frac{m_{k+1} \pi}{L} \right) \|u\|_{L^2(\Omega)}^2 + \int_\Omega F(x, u) dx \ge 0,$$

we get that J has a local linking at 0 and the proof follows. □

Immediate consequences of Theorem 3.1 are the following.

Corollary 3.2. *Suppose that $P(0) > 0$ and that P takes negative values. The problem (1.1) has at least two nontrivial solutions in $\Omega = (0, L)$ provided the following relation holds true*

$$\frac{m\pi}{\xi_2} < L < \frac{m\pi}{\xi_1} \quad \textit{for some natural number } m \neq 0. \tag{3.3}$$

Here $0 < \xi_1 < \xi_2$ are the first (the smallest) two positive roots of P. Note that P may have other roots.

Corollary 3.3. *Suppose that $P(0) < 0$ and let $\xi_1 > 0$ be the smallest root of P (P may have other roots). The problem (1.1) has at least two nontrivial solutions in $\Omega = (0, L)$ provided the following relation holds true*

$$L > \frac{m\pi}{\xi_1} \quad \text{for some natural number } m \neq 0. \tag{3.4}$$

We note that the uniqueness results presented in [12, 13] as well as our Theorem 3.1 are stated under the restriction $F \geq 0$ and

$$\lim_{s\to 0} \frac{F(s)}{s^2} = 0. \tag{3.5}$$

The next result is stated when F may change sign and (3.5) is weakened.

Theorem 3.4. *Let the function F satisfy*

$$F(x,s) \geq -K_1|s|^p - K_2, \qquad \forall\, x \in \Omega,\ s \in \mathbb{R}, \tag{3.6}$$

where $0 < p < 2$, and $K_1, K_2 > 0$.

Suppose that $A_{n-1} \leq 0, A_{n-2} \geq 0, \dots, A_1 \leq 0, A_0 \geq 0$ holds or we are under hypotheses of either Lemma 2.3, Lemma 2.5, Lemma 2.6 or Lemma 2.7. If in addition one of the following relation holds

$$\lim_{s\to 0^+} \frac{f(x,s)}{s^\alpha} = q(x) \quad \text{uniformly in } \overline{\Omega}, \tag{3.7}$$

where $q(x) \leq 0$, $\|q\|_{L^\infty(\Omega)} > 0$, $0 < \alpha < 1$

$$\lim_{s\to 0} \frac{F(x,s)}{s^2} = \beta(x) \in L^1(\Omega), \quad \text{uniformly in } \overline{\Omega}, \tag{3.8}$$

where

$$\int_\Omega \beta(x) \sin^2 \frac{\pi x}{L} dx + \frac{L}{4} P\left(\frac{\pi}{L}\right) < 0, \tag{3.9}$$

then the boundary value problem (1.1) has at least one nontrivial solution.

Proof. We choose $\rho > 0$ arbitrary but fixed and denote by

$$B_\rho = \{u \in H(\Omega) \mid \|u\|_{H(\Omega)} < \rho\}.$$

We first note that one of the relations (3.7) or (3.8) assures that

$$\mu = \inf_{\overline{B}_\rho} J(u) < 0.$$

Indeed, suppose that (3.7) holds.

We can choose the positive function $\varphi(x) = \sin \frac{\pi x}{L} \in H(\Omega)$ such that

$$\int_\Omega q(x) \varphi^{\alpha+1}(x) dx < 0.$$

Hence

$$\begin{aligned}
\lim_{s\to 0^+} \frac{J(s\varphi)}{s^{\alpha+1}} &= \frac{1}{2} \lim_{s\to 0^+} s^{1-\alpha} \int_\Omega \Big((\varphi^{(n)})^2 - A_{n-1}(\varphi^{(n-1)})^2 + \cdots + A_0\varphi^2 \Big) dx \\
&\quad + \lim_{s\to 0^+} \int_\Omega \frac{F(x, s\varphi)}{s^{\alpha+1}} dx \\
&= \int_\Omega \lim_{s\to 0^+} \frac{F(x,s\varphi)}{s^{\alpha+1}} dx = \int_\Omega \lim_{s\to 0^+} \frac{f(x,s\varphi)\varphi}{(\alpha+1)s^\alpha} dx \\
&= \frac{1}{\alpha+1} \int_\Omega q(x)\varphi^{\alpha+1}(x) dx < 0.
\end{aligned}$$

Similarly if (3.8) holds we see that

$$\lim_{s\to 0}\frac{J(s\varphi)}{s^2}=\frac{L}{4}P\left(\frac{\pi}{L}\right)+\int_\Omega \beta(x)\sin^2\frac{\pi x}{L}dx<0.$$

By relation (3.6), Cauchy's inequality with ε and (2.3)

$$\begin{aligned}\int_\Omega F(x,u)dx &\geq -\varepsilon\int_\Omega u^2dx-\int_\Omega\left(C(p,\varepsilon)K_1^{\frac{2}{2-p}}+K_2\right)dx \\ &\geq -\varepsilon\left(\frac{L}{\pi}\right)^{2n}\|u\|^2_{H(\Omega)}-C(p,\varepsilon,K_1,K_2,L).\end{aligned} \tag{3.10}$$

Hence if we are under hypotheses of either Lemma 2.3, Lemma 2.5, Lemma 2.6 or Lemma 2.7 we can combine (3.10) with one of relations (2.6), (2.10), (2.16) or (2.18) to get (by choosing ε sufficiently small) that $J(u)$ is bounded below on $\overline{B}_\rho$ by a negative constant.

According to the Remark, inequalities of type (2.6) are always true if $A_{n-1}\leq 0, A_{n-2}\geq 0,\dots,A_1\leq 0, A_0\geq 0$ and hence again we obtain that $J(u)$ is bounded below.

From Ekeland's variational principle it follows that there exists a minimizing sequence $\{u_m\}\subset\overline{B}_\rho$ such that

$$J(u_m)\to\mu \quad\text{and}\quad J'(u_m)\to 0,\quad \text{as } m\to\infty.$$

Since $\{u_m\}$ is bounded we can extract (by using the Sobolev imbedding) a subsequence still denoted $\{u_m\}$ such that

$$\begin{aligned} u_m &\rightharpoonup u_0 \quad \text{weakly in } H(\Omega),\\ u_m &\to u_0 \quad \text{strongly in } C^{n-1}(\overline{\Omega}).\end{aligned}$$

Arguing as in the proof Lemma 2.9 we get that $\{u_m\}$ converges strongly to u_0 in $H(\Omega)$.

As a consequence there exists $u_0\in H(\Omega)$ such that $J'(u_0)=0$, $J(u_0)<0$ i.e., problem (1.1) has at least a nontrivial solution. □

The last existence result shows that if we impose some asymptotic assumptions to f we can allow $p>2$ in (3.6). The proof uses the Mountain Pass theorem and the following two lemmas.

The first lemma shows when $J(u)$ has a mountain pass structure

Lemma 3.5. *Suppose that we are under one of the assumptions of Lemma 2.3, Lemma 2.5 or Lemma 2.6. Let F satisfy*

$$F(x,s)\leq C|s|^t,\qquad \forall\,(x,s)\in\Omega\times\mathbb{R}, \tag{3.11}$$

where $C>0, t>2$ and relation (3.7) holds.

Then

1. *there exist two positive constants ρ and η such that*

$$J(u)|_{\|u\|=\rho}\geq\eta, \tag{3.12}$$

2. *there exists $e\in H(\Omega)$ satisfying $\|u\|>\rho$ and $J(e)<0$.*

Here

$$\|u\|^2 = \int_\Omega \left[(u^{(n)})^2 - A_{n-1}(u^{(n-1)})^2 + \cdots - A_1(u')^2 + A_0 u^2 \right] dx$$

is a norm since we work under the assumptions of Lemma 2.3, Lemma 2.5 or Lemma 2.6.

We also note that $J(u)$ becomes

$$J(u) = \frac{1}{2}\|u\|^2 + \int_\Omega F(x,u)dx.$$

Proof. For a proof see [10]. □

We can now apply the Mountain Pass theorem in $H(\Omega)$ to find a Cerami type sequence, i.e.,

$$\text{there exists } \{u_m\} \subset H(\Omega) \text{ such that } J(u_m) \to \lambda \text{ and } \|J'(u_m)\|_{H^*(\Omega)} \to 0. \tag{3.13}$$

The next lemma gives the boundedness of the sequence $\{u_m\}$.

Lemma 3.6. *Suppose that we are under the hypotheses of Lemma 3.5. If in addition there exist the constants $\theta \in (0,2), K_1 \in \mathbb{R}, K_2 > 0$ such that*

$$f(x,s)s \geq K_1|s|^\theta - K_2, \qquad \forall\, x \in \Omega,\ |s| > M, \tag{3.14}$$

for some $M > 0$, then the sequence $\{u_m\}$ defined by (3.13) is bounded in $H(\Omega)$.

Proof. We argue by contradiction and suppose that $\|u_m\| \to \infty$. Let $w_m = \frac{u_m}{\|u_m\|}$. Obviously $\{w_m\}$ is a bounded sequence and we can extract a subsequence, still denoted $\{w_m\}$, such that

$$w_m \to w \quad \text{strongly in } \mathrm{C}^{\mathrm{n}-1}(\overline{\Omega}).$$

For each fixed m we define

$$\Omega_m^1 = \{x \in \Omega \mid u_m(x) \leq M\} \quad \text{and} \quad \Omega_m^2 = \{x \in \Omega \mid u_m(x) > M\}.$$

By the continuity of f there exists a constant $C_1 > 0$ such that

$$\int_{\Omega_m^1} f(x,u_m)u_m dx \geq -C_1. \tag{3.15}$$

Since

$$\langle J'(u_m), u_m \rangle = \|u_m\|^2 + \int_\Omega f(x,u_m)u_m dx,$$

we get by combining (3.14) and (3.15) that

$$\begin{aligned} \langle J'(u_m), u_m \rangle &\geq \|u_m q|^2 - C_1 - \int_{\Omega_m^2} (K_1|u_m|^\theta - K_2)dx \\ &\geq \|u_m\|^2 - C_1 - |K_1| \int_{\Omega_m^2} |u_m|^\theta dx - K_2 \operatorname{meas}(\Omega). \end{aligned} \tag{3.16}$$

Using (3.16) and the fact that $\langle J'(u_m), u_m \rangle \to 0$, as $m \to \infty$ it follows that

$$\begin{aligned} \infty = \lim_{m\to\infty} \frac{\|u_m\|^2}{\|u_m\|^\theta} &\leq \lim_{m\to\infty} \left(\frac{\langle J'(u_m), u_m \rangle}{\|u_m\|^\theta} + |K_1| \int_\Omega |w_m|^\theta dx + \frac{C_1 + K_2 \operatorname{meas}(\Omega)}{\|u_m\|^\theta} \right) \\ &= |K_1| \int_\Omega |w|^\theta dx < \infty, \end{aligned}$$

which is a contradiction.

Hence we conclude that the sequence $\{u_m\}$ is bounded. □

The last existence result reads

Theorem 3.7. *Suppose that we are under one of the assumptions of Lemma 2.3, Lemma 2.5 or Lemma 2.6 and that relation (3.7) holds. Let $p, q, r > 1$ be such that $p \geq \sigma = \max\{q, r\}$ and $L_1, L_2, L_3 \in L^\infty(\Omega)$. If in addition*

$$\lim_{|s| \to 0} \frac{f(x,s)}{|s|^p} = L_1(x) \tag{3.17}$$

and

$$\lim_{s \to \infty} \frac{f(x,s)}{s^q} = L_2(x) > 0, \qquad \lim_{s \to -\infty} \frac{f(x,s)}{|s|^r} = L_3(x) < 0, \tag{3.18}$$

uniformly in $\overline{\Omega}$, then the boundary value problem (1.1) has at least a nontrivial solution.

Proof. Combining relations (3.17) and (3.18) we get that there exists a constant $C > 0$ such that for sufficiently large M

$$-sf(x,s) \leq C|s|^{\sigma+1}, \qquad \forall\, x \in \Omega,\ |s| > M. \tag{3.19}$$

Integrating (3.19) one has

$$-F(x,s) = -\int_0^1 f(x, us) s du \leq \frac{C}{\sigma+1}|s|^{\sigma+1}, \qquad \forall\, x \in \Omega,\ |s| > M.$$

We can now apply Lemma 3.5 to get a sequence $\{u_m\}$ that satisfies (3.13).

On the other hand, in view of (3.18) we see that (3.14) is satisfied and hence $\{u_m\}$ is bounded. As a consequence $u_m \to u_0$ in $C^{n-1}(\overline{\Omega})$ and the proof follows. □

Finally, we give some examples as an application of our results.

Example 1. Let F satisfy (3.1) and suppose that (3.3) holds with $m = 1$. Then the boundary value problem

$$\begin{cases} u^{(2n)} + Au^{(4)} + Bu'' + Cu + f(x,u) = 0 \text{ in } \Omega = (0, L) \\ u = u'' = \cdots = u^{(2n-2)} = 0 \text{ on } \partial\Omega, \end{cases} \tag{3.20}$$

has at least two nontrivial solutions in $H(\Omega)$. Here $A < 0, B = 0, C > 0$, (2.25) holds and

$$\left(\frac{-2A}{n}\right)^{\frac{n(n-2)}{4}} + A\left(\frac{-2A}{n}\right)^{\frac{n-2}{2}} + C < 0. \tag{3.21}$$

In particular, the result holds if $n = 4, A = -2, 0 < C < 1, L = 2$.

The proof follows from Corollary 3.2. Since $P(\xi) = \xi^{2n} + A\xi^4 + C$ we study the function $\varphi(t) = t^{\frac{n}{2}} + At + C$. We can check that φ attains its minimum at $t_0 = (-2A/n)^{\frac{n-2}{2}}$. Imposing $\varphi(t_0) < 0$, i.e., (3.21) we see that P has (at least) two positive roots.

Consider $n = 3$. Then P becomes $P(\xi) = \xi^6 - A\xi^4 + B\xi^2 - C$. If

$$A > 0, \quad B < 0, \quad 0 > C > \gamma = \frac{1}{27}\left[9AB - 2A^3 - 2\left(A^2 - 3B\right)^{\frac{3}{2}}\right],$$

then P has precisely two positive roots $0 < \xi_1 < \xi_2$. As a consequence (3.20) has at least two nontrivial solutions in $H(\Omega)$ if (3.3) holds with $m = 1$.

The reader is referred to Appendix A, [13] where the authors give detailed conditions on parameters A, B, C and L which guarantee the existence of at least one or two positive solutions of $P(\xi) = \xi^6 - A\xi^4 + B\xi^2 - C$.

Example 2. Let F satisfy (3.1) and suppose that (3.4) holds (here ξ_1 is the unique solution of $P(\xi) = 0$). Consider the boundary value problem (3.20), where $C < 0$. Suppose that one of the following relations holds true

$$A, B \geq 0 \quad \text{and} \quad (2.25) \tag{3.22}$$

$$A > 0, \quad B < 0 \quad \text{and} \quad (2.25) \tag{3.23}$$

$$A < 0, \quad B > 0, \quad (3.4) \quad \text{and} \quad n\left(\frac{-2A}{n(n-1)}\right)^{\frac{n-1}{n-2}} + 2A\left(\frac{-2A}{n(n-1)}\right)^{\frac{1}{n-2}} + B > 0. \tag{3.24}$$

Then the boundary value problem (3.20) has at least two nontrivial solutions in Ω.

The proof follows from Corollary 3.3 by using the same techniques as in Example 1.

Example 3. In as similar way we can conclude that if F satisfies (3.1) and that (3.4) holds (here ξ_1 is the unique solution of $P(\xi) = 0$), then the problem

$$\begin{cases} u^{(2n)} + Au^{(2n-2)} + Bu^{(2n-4)} + Cu + f(x,u) = 0 \text{ in } \Omega = (0, \mathrm{L}) \\ u = u'' = \cdots = u^{(2n-2)} = 0 \text{ on } \partial\Omega, \end{cases} \tag{3.25}$$

has at least two nontrivial solutions in Ω. Here $A, B > 0, C < 0$ and we are under the assumptions of Lemma 2.9.

Example 4. Arguing as before, if $A, B > 0$, $A^2 > 4B$, F satisfies (3.1) and if (3.3) holds, it follows that the problem

$$\begin{cases} u^{(6)} + Au^{(4)} + Bu'' + f(x,u) = 0 \text{ in } \Omega = (0, \mathrm{L}) \\ u = u'' = u^{(4)} = 0 \text{ on } \partial\Omega, \end{cases} \tag{3.26}$$

has at least two nontrivial solutions in Ω.

Example 5. The functions $F_1(s) = \ln(1 + \ln(1 + \cdots + \ln(1 + |s|^p)))$, $p > 2$ and $F_2(s) = |s|(\arctan|s|^p + \ln(1 + |s|^p))$, $p > 1$ satisfy (3.1). Hence, under the requirements of Theorem 3.1 problem (1.1) (with f replaced by $f_1 = F_1'$ or $f_2 = F_2'$) has at least two nontrivial solutions in Ω.

It is easy to check that F_1, F_2 don't satisfy (1.3) and hence this existence result cannot be deduced from the corresponding results presented in [12] or [13] even if we restrict ourselves to the particular cases $n = 2$ or $n = 3$.

We can see that $F_3(s) = s^p - Cs^2$, where $p > 2$ is even and $C > 0$ changes sign and does not fulfill the restriction (3.5) imposed in [12, 13], but fulfills the requirements of Theorem 3.4 with $\beta = -C < 0$. Again we conclude that problem (1.1) (with f replaced by $f_3 = F_3'$) has at least a nontrivial solution if (3.9) is satisfied.

Example 6. Let $C > 0, q > 2, \alpha \in (0, 1)$. Then the function f_4

$$f_4(s) = \begin{cases} -s^q - C\ln(1 + s^\alpha), & s > 0 \\ |s|^q, & s \leq 0 \end{cases}$$

satisfies the requirements of Theorem 3.7. Hence the boundary value problem (1.1) with f replaced by f_4 has at least one solution.

Abstract. We consider a nonlinear Robin problem driven by the anisotropic (p,q)-Laplacian plus an indefinite potential term. In the reaction, we have the competing effects of a parametric concave (sublinear) term perturbed by a superlinear one (concave-convex problem). We prove the existence and multiplicity result for positive solutions which is global with respect to the parameter. We also show the existence of a minimal positive solution and determine its dependence on the parameter.

Keywords: nonlinear nonhomogeneous differential operator, indefinite potential, positive solutions, truncations and comparisons, nonlinear regularity, (p,q)-Laplacian, Robin boundary.

2020 Mathematics Subject Classification: 35J60, 35J66.

1 Introduction

Let $\Omega \subseteq \mathbb{R}^N$ be a bounded domain with a C^2-boundary $\partial\Omega$. In this paper, we study the following parametric anisotropic Robin boundary value problem:

$$\begin{cases} -\Delta_{p(z)}u(z) - \Delta_{q(z)}u(z) + \xi(z)(u(z))^{p(z)-1} = \lambda(u(z))^{\tau(z)-1} + f(z,u(z)) & \text{in } \Omega, \\ \frac{\partial u}{\partial n_{pq}} + \beta(z)(u(z))^{p(z)-1} = 0 \quad \text{on } \partial\Omega, \ \lambda > 0, \ u > 0, \ 1 < \tau < p. \end{cases} \tag{p_λ}$$

In this problem the variable exponents $p(\cdot)$ and $q(\cdot)$ of the two differential operators are Lipschitz continuous on $\overline{\Omega}$, that is, $p,q \in C^{0,1}(\overline{\Omega})$. Then the two operators are defined by

$$\Delta_{p(z)}u = \operatorname{div}(|Du|^{p(z)-2}Du), \quad \forall u \in W^{1,p(z)}(\Omega),$$

$$\Delta_{q(z)}u = \operatorname{div}(|Du|^{q(z)-2}Du), \quad \forall u \in W^{1,q(z)}(\Omega).$$

✉Corresponding author. Email: eozturk@hacettepe.edu.tr

There is also a potential term $\xi(z)(u(z))^{p(z)-1}$ which is in general indefinite since $\xi \in L^\infty(\Omega)$ can be sign-changing (nodal). Therefore the left hand side of (p_λ) is not coercive. In the reaction (right hand side of (p_λ)), we have the combined effects of a parametric "concave" (sublinear) term $\lambda u^{\tau(z)-1}$ with $\tau \in C(\overline{\Omega})$, $\tau_+ = \max_{\overline{\Omega}} \tau < q_- = \min_{\overline{\Omega}} q$ and of a Carathéodory perturbation $f(z,x)$ (that is, for all $x \geq 0$ $z \to f(z,x)$ is measurable and for almost a.a. $z \in \Omega$ $x \to f(z,x)$ is continuous) which is "convex" ($(p_+ - 1)$-superlinear with $p_+ = \max_{\bar{\Omega}} p$) but without satisfying the usual in such cases Ambrosetti–Rabinowitz condition.

In the boundary condition, $\frac{\partial u}{\partial n_{pq}}$ denotes the conormal derivative of u, corresponding to the anisotropic (p,q)-Laplacian. If $u \in C^1(\bar{\Omega})$ then

$$\frac{\partial u}{\partial n_{pq}} = \left(|Du|^{p(z)-2} + |Du|^{q(z)-2}\right)\frac{\partial u}{\partial n}$$

with $n(.)$ being the outward unit normal on $\partial\Omega$. The boundary coefficient $\beta \in C^{0,1}(\partial\Omega)$ with $\beta(z) \geq 0$ and either $\xi \not\equiv 0$ or $\beta \not\equiv 0$.

Therefore (p_λ) is an anisotropic version of the classical "concave-convex problem", with an indefinite potential term and Robin boundary condition. Concave-convex problems, were first studied by Ambrosetti–Brezis–Cerami [1], for semilinear Dirichlet problems driven by the Laplacian with no potential term (that is, $\xi \equiv 0$) and a reaction of the form $u \to \lambda u^{\tau-1} + u^{r-1}$ with $1 < \tau < 2 < r$. Their work was extended to p-Laplacian equations by García Azorero–Peral Alonso–Manfredi [10] and Guo–Zhang [14]. Further extensions involved more general nonlinear nonhomogeneous differential operators and more general reactions (see Marano–Marino–Papageorgiou [19], Papageorgiou–Rădulescu [29] and the references therein). For anisotropic problems, there are significantly fewer papers. We mention the works of Papageorgiou–Qin–Rădulescu [24] (Dirichlet problems driven by the anisotropic p-Laplacian) and by Deng [6], Liu–Papageorgiou [18] (Robin problems, in [6] the differential operator is the $p(z)$-Laplacian and $\xi \equiv 0$, while in [18] the equation is driven by the anisotropic (p,q)-Laplacian, with $\xi(z) > 0$ for a.a. $z \in \Omega$, the conditions on $f(z,.)$ are stronger near 0^+ and the authors employ a different superlinearity condition). Using variational tools from the critical point theory, together with truncation and comparison techniques, we prove an existence and multiplicity result for positive solutions which is global in the parameter $\lambda > 0$ (a bifurcation-type theorem). Our result here extends all the aforementioned anisotropic works. We also mention the works of [3], [12], [20], [27] and [28] on isotropic Neumann and Robin problems with indefinite potential term.

Anisotropic problems are interesting from a purely mathematical viewpoint since they exhibit challenging nonlinearities that we do not encounter in isotropic problems. The $p(z)$-Laplace differential operator is not homogeneous in contrast to the p-Laplacian. This excludes from consideration techniques which proved to be very effective in the context of isotropic problems. This makes anisotropic problems in principle more difficult to deal with. Anisotropic equations, proved to be the right mathematical tool to describe various phenomena from physics and engineering. Materials with inhomogeneities, such as electrorheological fluids (also known as "smart fluids"), can not be modelled adequately using the formalism of the classical Lebesgue and Sobolev spaces. They require the use of variable such spaces (a particular case of the so-called "Musielak–Orlicz spaces"). The book of Růžička [33] contains mathematical models of such fluids and the phenomena characterizing them (Winslow effect). Another important application of anisotropic problem is in image restoration, where we try to eliminate the effect of noise. Initially, this problem was approached by smoothing the input, which corresponds to minimizing the energy functional:

$$\varphi_1(u) = \int_\Omega (|Du|^2 + |u-i|^2)dz$$

with $i(.)$ being the input which corresponds to shades of grey in $\Omega \subset \mathbb{R}^n$. We assume that noise is additive, that is, $i = t_0 + n$ with t_0 representing the true image and n the noise which is a random variable with zero mean. It turns out that this approach destroys the small details of the image. To remedy this, it was proposed to use the "total variation smoothing", which corresponds to minimizing the energy functional:

$$\varphi_2(u) = \int_\Omega (|Du| + |u-i|^2)dz.$$

This approach does a good job of preserving the edges of the image (an edge gives rise to a large gradient of $u(\cdot)$). But unfortunately, this approach also introduces edges, where they did not exist before. For this reason Chen–Levine–Rao [4], suggested to consider the energy functional:

$$\varphi_3(u) = \int_\Omega (|Du|^{p(z)} + |u-i|^2)dz$$

with $1 \leq p(z) \leq 2$. This function is close to 1 where there are no edges and close to 2 where there are. Therefore, we have an energy functional which incorporates the positive aspects of both $\varphi_1(.)$ and $\varphi_2(.)$.

More details on the mathematical and physical applications of variable spaces can be found in the books of Cruz Uribe–Fiorenza [5], Diening–Harjulehto–Hästö–Růžička [7], Rădulescu–Repovš [31], Růžička [33].

The Robin boundary condition is a weighted combination of Dirichlet and Neumann boundary conditions and so it is more difficult to handle and for this reason it is less common in the literature. However, it is important from a physical viewpoint since it appears in electromagnetic problems (impedance boundary condition) and in heat transfer problems (convective boundary condition).

2 Mathematical background and hypotheses

In this section, we briefly review some basic facts about variable exponent spaces. A comprehensive presentation of variable exponent Lebesgue and Sobolev spaces can be found in the books of Cruz Uribe–Fiorenza [5], Diening–Harjulehto–Hästö–Růžička [7].

Let $L_1^\infty(\Omega) = \{p \in L^\infty(\Omega) : \operatorname{ess\,inf}_\Omega p \geq 1\}$. For $p \in L_1^\infty(\Omega)$, we set

$$p_- = \operatorname*{ess\,inf}_\Omega p \quad \text{and} \quad p_+ = \operatorname*{ess\,sup}_\Omega p.$$

Also, let $M(\Omega) = \{u : \Omega \to \mathbb{R} : u(\cdot) \text{ is measurable}\}$. As usual, we identify two functions which differ on a set of zero measure.

Given $p \in L_1^\infty(\Omega)$, we define the following variable exponent Lebesgue space

$$L^{p(z)}(\Omega) = \left\{ u \in M(\Omega) : \int_\Omega |u|^{p(z)}\, dz < +\infty \right\}.$$

We equip $L^{p(z)}(\Omega)$ with the following norm (known as the Luxemburg norm)

$$\|u\|_{p(z)} = \inf \left\{ \lambda > 0 : \int_\Omega \left(\frac{|u|}{\lambda} \right)^{p(z)} dz \leq 1 \right\}.$$

Also, we introduce the variable exponent Sobolev spaces as follows:

$$W^{1,p(z)}(\Omega) = \left\{ u \in L^{p(z)}(\Omega) : |Du| \in L^{p(z)}(\Omega) \right\}.$$

We equip this space with the following norm:

$$\|u\|_{1,p(z)} = \|u\|_{p(z)} + \|Du\|_{p(z)}.$$

An equivalent norm of $W^{1,p(z)}(\Omega)$ is given by:

$$\|u\|_{1,p(z)} = \inf \left\{ \lambda > 0 : \int_\Omega \left(\left(\frac{|Du|}{\lambda} \right)^{p(z)} + \left(\frac{|u|}{\lambda} \right)^{p(z)} \right) dz \le 1 \right\}.$$

We define $W_0^{1,p(z)}(\Omega)$ as the closure in the $\|\cdot\|_{1,p(z)}$ norm of all compactly supported $W^{1,p(z)}(\Omega)$-functions.

When $p \in L_1^\infty(\Omega)$ and $p_- > 1$, then the spaces $L^{p(z)}(\Omega)$, $W^{1,p(z)}(\Omega)$, and $W_0^{1,p(z)}(\Omega)$ are all separable, reflexive, and uniformly convex.

If $p, p' \in L_1^\infty(\Omega)$ and $\frac{1}{p(z)} + \frac{1}{p'(z)} = 1$, then $L^{p(z)}(\Omega)^* = L^{p'(z)}(\Omega)$, and we have the following Hölder-type inequality:

$$\int_\Omega |uv|\, dz \le \left(\frac{1}{p_-} + \frac{1}{p'_-} \right) \|u\|_{p(z)} \|v\|_{p'(z)}$$

for all $u \in L^{p(z)}(\Omega)$, $v \in L^{p'(z)}(\Omega)$.

We set

$$p^*(z) = \begin{cases} \frac{Np(z)}{N-p(z)}, & \text{if } p(z) < N, \\ +\infty, & \text{if } p(z) \ge N. \end{cases}$$

Theorem 2.1. *If $p, q \in C(\bar{\Omega})$, $p_+ < N$ and $1 \le q(z) \le p^*(z)$ (resp. $1 \le q(z) < p^*(z)$) for all $z \in \bar{\Omega}$, then $W^{1,p(z)}(\Omega)$ and $W_0^{1,p(z)}(\Omega)$ are embedded continuously (resp. compactly) into $L^{q(z)}(\Omega)$.*

We set

$$p^\partial(z) = \begin{cases} \frac{(N-1)p(z)}{N-p(z)}, & \text{if } p(z) < N, \\ +\infty, & \text{if } p(z) \ge N. \end{cases}$$

Theorem 2.2. *If $p \in C(\bar{\Omega})$, $p_- > 1$ and $q \in C(\partial\Omega)$ satisfies the condition*

$$1 \le q(z) < p^\partial(z) \quad \text{for all } z \in \partial\Omega$$

then $W^{1,p(z)}(\Omega)$ embedded compactly into $L^{q(z)}(\partial\Omega)$. In particular, $W^{1,p(z)}(\Omega)$ embedded compactly into $L^{p(z)}(\partial\Omega)$.

We introduce the following modular functions:

$$\rho(u) = \int_\Omega |u|^{p(z)}\, dz \quad \text{for all } u \in L^{p(z)}(\Omega),$$

$$\hat{\rho}(u) = \int_\Omega \left(|Du|^{p(z)} + |u|^{p(z)} \right) dz \quad \text{for all } u \in W^{1,p(z)}(\Omega).$$

We have the following properties.

Proposition 2.3.

(a) *For every* $u \in L^{p(z)}(\Omega)$, $u \neq 0$, *we have* $\|u\|_{p(z)} = \lambda \iff \rho\left(\frac{u}{\lambda}\right) = 1$;

(b) $\|u\|_{p(z)} < 1$ *(resp.* $= 1, > 1$) $\iff \rho(u) < 1$ *(resp.* $= 1, > 1$);

(c) $\|u\|_{p(z)} < 1 \Rightarrow \|u\|_{p(z)}^{p_+} \leq \rho(u) \leq \|u\|_{p(z)}^{p_-}$ *and* $\|u\|_{p(z)} > 1 \Rightarrow \|u\|_{p(z)}^{p_-} \leq \rho(u) \leq \|u\|_{p(z)}^{p_+}$;

(d) $\|u_n\|_{p(z)} \to 0 \iff \rho(u_n) \to 0$;

(e) $\|u_n\|_{p(z)} \to +\infty \iff \rho(u_n) \to +\infty$.

Similarly, we have the following implications when $p \in C^{0,1}(\overline{\Omega})$.

Proposition 2.4.

(a) *For every* $u \in W^{1,p(z)}(\Omega)$, $u \neq 0$, *we have* $\|u\|_{1,p(z)} = \lambda \iff \hat{\rho}\left(\frac{u}{\lambda}\right) = 1$;

(b) $\|u\|_{1,p(z)} < 1$ *(resp.* $= 1, > 1$) $\iff \hat{\rho}(u) < 1$ *(resp.* $= 1, > 1$);

(c) $\|u\|_{1,p(z)} < 1 \Rightarrow \|u\|_{1,p(z)}^{p_+} \leq \hat{\rho}(u) \leq \|u\|_{1,p(z)}^{p_-}$ *and* $\|u\|_{1,p(z)} > 1 \Rightarrow \|u\|_{1,p(z)}^{p_-} \leq \hat{\rho}(u) \leq \|u\|_{1,p(z)}^{p_+}$;

(d) $\|u_n\|_{1,p(z)} \to 0 \iff \hat{\rho}(u_n) \to 0$;

(e) $\|u_n\|_{1,p(z)} \to +\infty \iff \hat{\rho}(u_n) \to +\infty$.

Let $\beta \in L^\infty(\partial\Omega)$ with $\beta_- := \inf_{z\in\partial\Omega} \beta(z) > 0$, and for any $u \in W^{1,p(z)}(\Omega)$, define

$$\|u\|_\beta := \inf\left\{\tau > 0 : \int_\Omega \left(\frac{|\nabla u|}{\tau}\right)^{p(z)} dz + \int_{\partial\Omega} \beta(z) \left(\frac{|u|}{\tau}\right)^{p(z)} d\sigma \leq \tau\right\}.$$

Proposition 2.5. *Let* $\rho_\beta(u) = \int_\Omega |\nabla u|^{p(z)}\, dz + \int_{\partial\Omega} \beta(z)|u|^{p(z)}\, d\sigma$ *with* $\beta_- > 0$, *where* $d\sigma$ *is the measure on the boundary of* Ω. *For any* $u, u_k \in W^{1,p(z)}(\Omega)$ $(k = 1, 2, \dots)$, *we have that*

(a) $\|u\|_\beta \leq 1 \Rightarrow \|u\|_\beta^{p_-} \leq \rho_\beta(u) \leq \|u\|_\beta^{p_+}$;

(b) $\|u\|_\beta \geq 1 \Rightarrow \|u\|_\beta^{p_+} \leq \rho_\beta(u) \leq \|u\|_\beta^{p_-}$;

(c) $\|u_k\|_\beta \to 0 \iff \rho_\beta(u_k) \to 0$ *(as* $k \to \infty$);

(d) $\|u_k\|_\beta \to \infty \iff \rho_\beta(u_k) \to \infty$ *(as* $k \to \infty$).

Proposition 2.6. *(see [32]) If there is a vector* $l \in \mathbb{R}^n \setminus \{0\}$ *such that for any* $z \in \Omega$ *the function* $f(t) = q(z + tl)$ *is monotone for* $t \in I_z = \{t : z + tl \in \Omega\}$, *then*

$$0 < \mu^* = \inf_{u\neq 0} \frac{\int_\Omega \frac{1}{q(z)} |Du|^{q(z)} dz}{\int_\Omega \frac{1}{q(z)} |u|^{q(z)} dz}.$$

Theorem 2.7. *For any* $u \in W^{1,p(z)}(\Omega)$, *let*

$$\|u\|_\partial := \|\nabla u\|_{p(z)} + \|u\|_\beta.$$

Then $\|u\|_\partial$ *is a norm on* $W^{1,p(z)}(\Omega)$ *which is equivalent to*

$$\|u\|_{1,p(z)} = \|\nabla u\|_{p(z)} + \|u\|_{p(z)}.$$

The Banach space $C^1(\overline{\Omega})$ is an ordered with a positive (order) cone C_+ which is defined by

$$C_+ = \{u \in C^1(\overline{\Omega}) : u(z) \geq 0 \text{ for all } z \in \overline{\Omega}\}.$$

This cone has a nonempty interior given by

$$\operatorname{int} C_+ = \{u \in C_+ : u(z) > 0 \text{ for all } z \in \overline{\Omega}\}.$$

Given $u : \Omega \to \mathbb{R}$ is measurable, then we define

$$u^+(z) = \max\{u(z), 0\}, \quad u^-(z) = \max\{-u(z), 0\} \quad \text{for all } z \in \Omega.$$

These are measurable functions and $u = u^+ - u^-$, $|u| = u^+ + u^-$. Moreover, if $u \in W^{1,p(.)}(\Omega)$, then $u^\pm \in W^{1,p(.)}(\Omega)$. Suppose $u, v : \Omega \to \mathbb{R}$ are measurable functions with $u(z) \leq v(z)$ for a.a. $z \in \Omega$. We define

$$[u, v] = \{h \in W^{1,p(.)}(\Omega) : u(z) \leq h(z) \leq v(z) \text{ for a.a. } z \in \Omega\},$$

$$\operatorname{int}_{C^1(\overline{\Omega})}[u, v] = \text{the interior in } C^1(\overline{\Omega}) \text{ of } [u, v] \cap C^1(\overline{\Omega}),$$

$$[u) = \{h \in W^{1,p(.)}(\Omega) \mid u(z) \leq h(z) \text{ for a.a. } z \in \Omega\}.$$

If $u(.)$ is a measurable function, then we write $0 \prec u$ if for all $K \subseteq \Omega$ compact we have $0 < c_K \leq u(z)$ for a.a. $z \in K$.

Let X be a Banach space and $\varphi \in C^1(X)$. We say that $\varphi(.)$ satisfies the "C-condition", if it has the following property:

"Every sequence $\{u_n\}_{n \in \mathbb{N}} \subset X$ such that

- $\{\varphi(u_n)\}_{n \in \mathbb{N}} \subseteq \mathbb{R}$ is bounded,
- $(1 + \|u_n\|_X)\varphi'(u_n) \to 0$ in X^*,

admits a strongly convergent subsequence."

This is a compactness-type condition on $\varphi(\cdot)$ which compensates for the fact that the ambient space X need not be locally compact (being in general infinite-dimensional). By K_φ we denote the critical set of $\varphi(.)$, that is,

$$K_\varphi = \{u \in X : \varphi'(u) = 0\}.$$

Now we are ready to state our hypotheses on the data of problem (p_λ):

***H*₀**: $p, q \in C^{0,1}(\bar{\Omega})$, $\tau \in C(\bar{\Omega})$ and $1 < \tau(z) \leq \tau_+ < q_- \leq q_+ < p(z) < N$ for all $z \in \bar{\Omega}$. $p_+ < \frac{Np_-}{N - p_-}$, there exists $d \in \mathbb{R}^N$ such that $t \to q(z + td)$ is monotone on $I_z = \{t : \ z + td \in \Omega\}$, $\xi \in L^\infty(\Omega)$, $\beta \in C^{0,\alpha}(\partial\Omega)$ with $0 < \alpha < 1$ and $\xi \not\equiv 0$ or $\beta \not\equiv 0$.

***H*₁**: $f : \Omega \times \mathbb{R} \to \mathbb{R}$ is a Carathéodory function which satisfies the following conditions:

- (i) $0 \leq f(z, x) \leq a(z)(1 + x^{r(z)-1})$ for almost every $z \in \Omega$ and all $x \geq 0$, where $a \in L^\infty(\Omega)$, $r \in C(\bar{\Omega})$ and $p_+ < r(z) < p(z)^*$ for all $z \in \bar{\Omega}$;
- (ii) if $F(z, x) = \int_0^x f(z, s)ds$, then $\lim_{x \to +\infty} \frac{F(z,x)}{x^{p_+}} = +\infty$ uniformly for almost every $z \in \Omega$;

(iii) if for every $\lambda > 0$, we define $e(z,x) = f(z,x)x - p_+F(z,x)$ and

$$\beta_\lambda(z,x) = \lambda\left(1 - \frac{p_+}{\tau(z)}\right)x^{\tau(z)} + \xi(z)\left(\frac{p_+}{p(z)} - 1\right)x^{p(z)} + e(z,x),\ x \geq 0,$$

then there exists $\mu \in L^1(\Omega)$ such that

$$\beta_\lambda(z,x) \leq \beta_\lambda(z,y) + \mu(z)$$

for almost all $z \in \Omega$ and all $0 \leq x \leq y$;

(iv) $\lim_{x\to 0^+} \frac{f(z,x)}{x^{q(z)-1}} = 0$ uniformly for almost every $z \in \Omega$.

Remark 2.8. Since we look for positive solutions and all the above hypotheses concern the positive semiaxis, we may assume that $f(z,x) = 0$ for almost every $z \in \Omega$, all $x \leq 0$. Hypotheses $H_1(iii)$ is satisfied if there exists $M > 0$ such that for a.a. $z \in \Omega$

$$x \to \frac{\lambda x^{\tau(z)-1} + f(z,x) - \xi(z)x^{p(z)-1}}{x^{p_+-1}}$$

is nondecreasing on $x \geq M$ (see [16]).

The following function satisfies hypotheses H_1 above

$$f(z,x) = \begin{cases} (x^+)^{s(z)-1}, & \text{if } x \leq 1, \\ x^{p_+-1}\ln x + x^{\mu(z)-1}, & \text{if } 1 < x \end{cases}$$

with $s \in C(\bar{\Omega})$, $q(z) < s(z)$ for all $z \in \bar{\Omega}$, $\mu \in C(\bar{\Omega})$, $\mu(z) \leq p_+$ for all $z \in \Omega$. This function fails to satisfy the Ambrosetti–Rabinowitz condition (see [2]).

Let $p \in C^{0,1}(\overline{\Omega})$ and consider the operator $V : W^{1,p(z)}(\Omega) \to (W^{1,p(z)}(\Omega))^*$ defined by

$$\langle V(u), h\rangle = \int_\Omega \left(|\nabla u|^{p(z)-2}(Du, Dh)_{\mathbb{R}} + |\nabla u|^{q(z)-2}(Du, Dh)_{\mathbb{R}}\right)dz, \qquad \forall u, h \in W^{1,p(z)}(\Omega).$$

This operator has the following properties (see [13]).

Proposition 2.9. *The map $V : W^{1,p(z)}(\Omega) \to (W^{1,p(z)}(\Omega))^*$ defined above is bounded(that is, maps bounded sets to bounded sets), continuous, strictly monotone (hence maximal monotone, too) and for type $(S)_+$, that is*

$$u_n \rightharpoonup u \ \text{(weakly) in } W^{1,p(z)}(\Omega) \text{ and } \limsup_{n\to\infty}\langle V(u_n), (u_n - u)\rangle \leq 0 \Rightarrow u_n \to u \ \text{ in } W^{1,p(z)}(\Omega).$$

3 Positive solutions

We introduce the following two sets:

$$\mathfrak{L} := \{\lambda > 0 : \text{problem } (p_\lambda) \text{ has a positive solution}\},$$
$$S_\lambda := \text{set of positive solutions of } (p_\lambda).$$

Our first goal is to establish some basic properties of $\mathfrak{L}$. From now on $\|\cdot\| := \|\cdot\|_{1,p(z)}$.

Let $\theta > \|\xi\|_\infty$, $\lambda > 0$, and consider the functional $\hat{\varphi}_\lambda : W^{1,p(z)}(\Omega) \to \mathbb{R}$ defined by

$$\hat{\varphi}_\lambda(u) = \int_\Omega \frac{|\nabla u|^{p(z)}}{p(z)} dz + \int_\Omega \frac{|\nabla u|^{q(z)}}{q(z)} dz + \int_\Omega \frac{\xi(z)}{p(z)} |u|^{p(z)} dz + \int_\Omega \frac{\theta}{p(z)} (u^-)^{p(z)} dz + \int_{\partial\Omega} \frac{\beta(z)}{p(z)} |u|^{p(z)} d\sigma - \int_\Omega \frac{\lambda}{\tau(z)} (u^+)^{\tau(z)} dz - \int_\Omega F(z, u^+) dz$$

for all $u \in W^{1,p(z)}(\Omega)$.

Proposition 3.1. *If hypotheses H_0 and H_1 hold, and $\lambda > 0$, then $\hat{\varphi}_\lambda(\cdot)$ satisfies the C-condition.*

Proof. We consider a sequence $\{u_n\}_{n\geq 1} \subseteq W^{1,p(z)}(\Omega)$ such that

$$|\hat{\varphi}_\lambda(u_n)| \leq M_1 \quad \text{for some } M_1 > 0, \text{ all } n \in \mathbb{N}, \tag{3.1}$$

$$(1 + \|u_n\|)\hat{\varphi}'_\lambda(u_n) \to 0 \quad \text{in } W^{1,p(z)}(\Omega)^* \text{ as } n \to \infty. \tag{3.2}$$

From (3.2) we have

$$|\langle \hat{\varphi}'_\lambda(u_n), h\rangle| \leq \frac{\varepsilon_n \|h\|}{1 + \|u_n\|} \quad \text{for all } h \in W^{1,p(z)}(\Omega), \text{ all } n \in \mathbb{N}, \tag{3.3}$$

with $\varepsilon_n \to 0^+$, which implies

$$\Big| \langle V(u_n), h\rangle + \int_\Omega \xi(z)|u_n|^{p(z)-2} u_n h dz - \int_\Omega \theta (u_n^-)^{p(z)-1} h dz - \lambda \int_\Omega (u_n^+)^{\tau(z)-1} h dz + \int_{\partial\Omega} \beta(z)|u_n|^{p(z)-2} u_n h d\sigma - \int_\Omega f(z, u_n^+) h dz \Big| \leq \frac{\varepsilon_n \|h\|}{(1 + \|u_n\|)} \tag{3.4}$$

for all $h \in W^{1,p(z)}(\Omega), n \in \mathbb{N}$.

In (3.4), we choose $h = -u_n^- \in W^{1,p(z)}(\Omega)$. We have

$$\Big| \int_\Omega |Du_n^-|^{p(z)} dz + \int_\Omega |Du_n^-|^{q(z)} dz + \int_\Omega \xi(z)(u_n^-)^{p(z)} dz + \int_\Omega \theta (u_n^-)^{p(z)} dz + \int_{\partial\Omega} \beta(z)(u_n^-)^{p(z)} d\sigma \Big| \leq \varepsilon_n \tag{3.5}$$

for all $n \in \mathbb{N}$.

Then,

$$\Big| \int_\Omega |Du_n^-|^{p(z)} dz + \int_\Omega (\xi(z) + \theta)(u_n^-)^{p(z)} dz + \int_{\partial\Omega} \beta(z)(u_n^-)^{p(z)} d\sigma \Big| \leq \varepsilon_n \tag{3.6}$$

which implies

$$u_n^- \to 0 \quad \text{in } W^{1,p(z)}(\Omega) \quad (\text{recall that } \theta > \|\xi\|_\infty). \tag{3.7}$$

In (3.4), we choose $h = u_n^+ \in W^{1,p(z)}(\Omega)$. We have

$$\Big| \int_\Omega |Du_n^+|^{p(z)} dz + \int_\Omega |Du_n^+|^{q(z)} dz + \int_\Omega \xi(z)(u_n^+)^{p(z)} dz - \lambda \int_\Omega (u_n^+)^{\tau(z)} dz - \int_\Omega f(z, u_n^+) u_n^+ dz + \int_{\partial\Omega} \beta(z)(u_n^+)^{p(z)} d\sigma \Big| \leq \varepsilon_n \tag{3.8}$$

for all $n \in \mathbb{N}$.

On the other hand, from (3.1), (3.7) we have

$$\left| \int_\Omega \frac{p_+}{p(z)} |Du_n^+|^{p(z)} dz + \int_\Omega \frac{p_+}{q(z)} |Du_n^+|^{q(z)} dz + \int_\Omega \frac{p_+}{p(z)} \xi(z)(u_n^+)^{p(z)} dz \right.$$
$$\left. - \lambda \int_\Omega \frac{p_+}{\tau(z)} (u_n^+)^{\tau(z)} dz - \int_\Omega p_+ F(z, u_n^+) u_n^+ dz + \int_{\partial\Omega} \frac{p_+}{p(z)} \beta(z)(u_n^+)^{p(z)} d\sigma \right| \le M_2 \quad (3.9)$$

for some $M_2 > 0$, all $n \in \mathbb{N}$.

From (3.8) and (3.9) it follows that

$$\int_\Omega \left(\frac{p_+}{p(z)} - 1 \right) |Du_n^+|^{p(z)} dz + \int_\Omega \left(\frac{p_+}{q(z)} - 1 \right) |Du_n^+|^{q(z)} dz + \int_\Omega \xi(z) \left(\frac{p_+}{p(z)} - 1 \right) (u_n^+)^{p(z)} dz$$
$$+ \int_{\partial\Omega} \left(\frac{p_+}{p(z)} - 1 \right) \beta(z)(u_n^+)^{p(z)} d\sigma - \lambda \int_\Omega \left(\frac{p^+}{\tau(z)} - 1 \right) (u_n^+)^{\tau(z)} dz + \int_\Omega e(z, u_n^+) dz \le M_3 \quad (3.10)$$

for some $M_3 > 0$, all $n \in \mathbb{N}$.

Recall $\beta_\lambda(z,x) = \lambda(1 - \frac{p_+}{\tau(z)})x^{\tau(z)} + \xi(z)(\frac{p_+}{p(z)} - 1)x^{p(z)} + e(z,x)$ for all $x \ge 0$. Then from (3.10) we have

$$\int_\Omega \beta_\lambda(z, u_n^+) dz \le M_3 \quad \text{for all } n \in \mathbb{N}. \quad (3.11)$$

Claim. The sequence $\{u_n^+\}_{n\ge1} \subseteq W^{1,p(z)}(\Omega)$ is bounded.

Our argument proceeds through contradiction. So, suppose that the claim is not true. Then passing to a subsequence if necessary, we may assume that

$$\|u_n^+\| \to \infty \quad \text{as } n \to \infty. \quad (3.12)$$

Let $y_n = \frac{u_n^+}{\|u_n^+\|}, n \in \mathbb{N}$. Then $\|y_n\| = 1$, $y_n \ge 0$ for all $n \in \mathbb{N}$. So, we may assume that

$$y_n \rightharpoonup y \quad \text{(weakly) in } W^{1,p(z)}(\Omega) \quad \text{and} \quad y_n \to y \quad \text{in } L^{p(z)}(\Omega),\ y \ge 0. \quad (3.13)$$

Let $\Omega_+ = \{z \in \Omega : y(z) > 0\}$ and $\Omega_0 = \{z \in \Omega : y(z) = 0\}$. Then $\Omega = \Omega_+ \cup \Omega_0$.

First we assume that $|\Omega_+|_N > 0$ (by $|\cdot|_N$ we denote the Lebesgue measure on $\mathbb{R}^N$). We have $u_n^+(z) \to +\infty$ for a.a. $z \in \Omega_+$ and so on account of hypothesis $H_1(ii)$ we have

$$\int_\Omega \frac{F(z, u_n^+)}{\|u_n^+\|^{p_+}} dz \to +\infty \quad \text{as } n \to +\infty \quad \text{(see [23])}. \quad (3.14)$$

On account of (3.12), we may assume that $\|u_n^+\| \ge 1$ for all $n \in \mathbb{N}$. Then from (3.1) and (3.5), we have

$$\lambda \int_\Omega \frac{1}{\tau(z)} \frac{(u_n^+)^{\tau(z)}}{\|u_n^+\|^{p_+}} dz + \int_\Omega \frac{F(z,u_n^+)}{\|u_n^+\|^{p_+}} dz \le \varepsilon_n' + \frac{1}{p_-} \int_\Omega \frac{|Du_n^+|^{p(z)}}{\|u_n^+\|^{p_+}} dz + \frac{1}{q_-} \int_\Omega \frac{|Du_n^+|^{q(z)}}{\|u_n^+\|^{p_+}} dz$$
$$+ \frac{\|\xi\|_\infty}{p_-} \int_\Omega \frac{(u_n^+)^{p(z)}}{\|u_n^+\|^{p_+}} dz + \frac{\|\beta\|_\infty}{p_-} \int_{\partial\Omega} \frac{(u_n^+)^{p(z)}}{\|u_n^+\|^{p_+}} d\sigma$$
$$\le \varepsilon_n' + \frac{1}{p_-} \int_\Omega |Dy_n|^{p(z)} dz + \frac{1}{q_- \|u_n\|^{p_+ - q_+}} \int_\Omega |Dy_n|^{q(z)} dz + \frac{\|\xi\|_\infty}{p_-} \int_\Omega (y_n)^{p(z)} dz$$
$$+ \frac{\|\beta\|_\infty}{p_-} \int_{\partial\Omega} (y_n)^{p(z)} d\sigma \le M_4 \quad (3.15)$$

for some $M_4 > 0$ with $\varepsilon'_n \to 0$.

Comparing (3.14) and (3.15), we have a contradiction. We can assume that $y \equiv 0$, that is $|\Omega|_N = |\Omega_0|_N$. We define

$$\hat{\varphi}_\lambda(t_n u_n^+) := \max\{\hat{\varphi}_\lambda(t u_n^+) : 0 \le t \le 1\}. \tag{3.16}$$

Let $v_n = \eta^{1/p_-} y_n$ for all $n \in \mathbb{N}$, with $\eta \ge 1$. Then, we have

$$v_n \rightharpoonup 0 \quad \text{in } W^{1,p(z)}(\Omega) \quad \text{and} \quad \int_\Omega F(z, v_n)\, dz \to 0 \quad \text{as } n \to \infty \quad (\text{see [23]}). \tag{3.17}$$

Also, we have

$$\int_\Omega \frac{1}{\tau(z)} v_n^{\tau(z)}\, dz \to 0. \tag{3.18}$$

Moreover (3.12) implies that we can find $n_0 \in \mathbb{N}$ such that

$$\frac{\eta^{\frac{1}{p_-}}}{\|u_n^+\|} \in (0, 1] \quad \text{for all } n \ge n_0. \tag{3.19}$$

Hence from (3.16) and (3.19)

$$\begin{aligned}
\hat{\varphi}_\lambda(t_n u_n^+) \ge \hat{\varphi}_\lambda(v_n) &= \int_\Omega \frac{1}{p(z)} |Dv_n|^{p(z)} dz + \int_\Omega \frac{1}{q(z)} |Dv_n|^{q(z)} dz + \int_\Omega \frac{1}{p(z)} \xi(z) v_n^{p(z)}\, dz \\
&\quad - \lambda \int_\Omega \frac{1}{\tau(z)} v_n^{\tau(z)} dz + \int_{\partial\Omega} \frac{1}{p(z)} \beta(z) v_n^{p(z)}\, d\sigma - \int_\Omega F(z, v_n)\, dz \quad \text{for all } n \ge n_0 \\
&\ge \frac{1}{p_+} \left(\int_\Omega |Dv_n|^{p(z)} dz + \int_\Omega \xi(z) v_n^{p(z)}\, dz + \int_{\partial\Omega} \beta(z) v_n^{p(z)}\, d\sigma \right) - \int_\Omega F(z, v_n)\, dz \\
&\ge \frac{\eta}{2p_+} \quad (\text{see hypotheses } H_0 \text{ and (3.17)})
\end{aligned}$$

for all $n \ge n_1 \ge n_0$. Since $\eta \ge 1$ is an arbitrary number, we can infer that

$$\hat{\varphi}_\lambda(t_n u_n^+) \to +\infty \quad \text{as } n \to \infty. \tag{3.20}$$

We know that

$$\hat{\varphi}_\lambda(0) = 0 \quad \text{and} \quad \hat{\varphi}_\lambda(u_n^+) \le M_5, \quad \text{all } n \in \mathbb{N}. \tag{3.21}$$

From (3.20) and (3.21) it follows that we can find $n_2 \in \mathbb{N}$ such that

$$t_n \in (0, 1) \quad \text{for all } n \ge n_2. \tag{3.22}$$

Then from (3.16) and (3.22) we infer that

$$t_n \frac{d}{dt} \hat{\varphi}_\lambda(t u_n^+)\Big|_{t = t_n} = 0, \quad \text{then } \langle \hat{\varphi}'_\lambda(t_n u_n^+), t_n u_n^+ \rangle = 0, \quad \forall n \ge n_2,$$

$$
\begin{aligned}
\hat{\varphi}_\lambda(t_n u_n^+) &= \hat{\varphi}_\lambda(t_n u_n^+) - \frac{1}{p_+}\langle \hat{\varphi}'_\lambda(t_n u_n^+), t_n u_n^+\rangle \\
&= \int_\Omega t_n^{p(z)}\left[\frac{1}{p(z)} - \frac{1}{p_+}\right]|Du_n^+|^{p(z)}dz + \int_\Omega t_n^{q(z)}\left[\frac{1}{q(z)} - \frac{1}{p_+}\right]|Du_n^+|^{q(z)}dz \\
&\quad + \int_\Omega \left[\frac{1}{p(z)} - \frac{1}{p_+}\right]\xi(z)(t_n u_n^+)^{p(z)}dz - \int_\Omega \lambda\left[\frac{1}{\tau(z)} - \frac{1}{p_+}\right](t_n u_n^+)^{\tau(z)}dz \\
&\quad + \int_{\partial\Omega}\left[\frac{1}{p(z)} - \frac{1}{p_+}\right]\beta(z)(t_n u_n^+)^{p(z)}d\sigma + \frac{1}{p_+}\int_\Omega e(z, t_n u_n^+)dz \\
&\le \int_\Omega \left[\frac{1}{p(z)} - \frac{1}{p_+}\right]|Du_n^+|^{p(z)}dz + \int_\Omega \left[\frac{1}{q(z)} - \frac{1}{p_+}\right]|Du_n^+|^{q(z)}dz + \frac{1}{p_+}\int_\Omega \beta_\lambda(z, t_n u_n^+)dz \\
&\quad + \int_\Omega \left[\frac{1}{p(z)} - \frac{1}{p_+}\right]\xi(z)(t_n u_n^+)^{p(z)}dz + \int_{\partial\Omega}\left[\frac{1}{p(z)} - \frac{1}{p_+}\right]\beta(z)(t_n u_n^+)^{p(z)}d\sigma \\
&\le \int_\Omega \left[\frac{1}{p(z)} - \frac{1}{p_+}\right]|Du_n^+|^{p(z)}dz + \int_\Omega \left[\frac{1}{q(z)} - \frac{1}{p_+}\right]|Du_n^+|^{q(z)}dz \\
&\quad + \frac{1}{p_+}\int_\Omega \beta_\lambda(z, u_n^+)dz + \frac{1}{p_+}\|\mu\|_1 + \int_\Omega \left[\frac{1}{p(z)} - \frac{1}{p_+}\right]\xi(z)(u_n^+)^{p(z)}dz \\
&\quad + \int_{\partial\Omega}\left[\frac{1}{p(z)} - \frac{1}{p_+}\right]\beta(z)(u_n^+)^{p(z)}d\sigma \\
&= \hat{\varphi}_\lambda(u_n^+) - \frac{1}{p_+}\langle \hat{\varphi}_\lambda(u_n^+), u_n^+\rangle + \frac{1}{p_+}\|\mu\|_1.
\end{aligned}
\tag{3.23}
$$

Hence we have,

$$
\begin{aligned}
\hat{\varphi}_\lambda(t_n u_n^+) &\le \hat{\varphi}_\lambda(u_n^+) - \frac{1}{p_+}\langle \hat{\varphi}_\lambda(u_n^+), u_n^+\rangle + \frac{1}{p_+}\|\mu\|_1 \quad \text{for all } n \ge n_2 \text{ (see (3.8))} \\
&\le \hat{\varphi}_\lambda(u_n^+) + \frac{\varepsilon_n}{p_+} + \frac{1}{p_+}\|\mu\|_1
\end{aligned}
\tag{3.24}
$$

(3.20) and (3.24) give us that $\hat{\varphi}_\lambda(u_n^+) \to +\infty$, and this contradicts with (3.21).

Therefore $\{u_n^+\} \subset W^{1,p(z)}(\Omega)$ is bounded. Then from (3.7) and the claim it follows that

$$\{u_n\} \subset W^{1,p(z)}(\Omega) \quad \text{is bounded.}$$

We may assume that

$$u_n \rightharpoonup u \quad \text{in } W^{1,p(z)}(\Omega) \quad \text{and} \quad u_n \to u \quad \text{in } L^{r(z)}(\Omega) \quad \text{as } n \to \infty. \tag{3.25}$$

In (3.4), we choose $h = u_n - u \in W^{1,p(z)}(\Omega)$, pass to the limit as $n \to \infty$ and use (3.25). Then

$$\lim_{n\to\infty} \langle V(u_n), u_n - u\rangle = 0 \tag{3.26}$$

(3.26) and Proposition (2.9) give us $u_n \to u$ in $W^{1,p(z)}(\Omega)$. So $\hat{\varphi}_\lambda(\cdot)$ satisfies the C-condition. □

Proposition 3.2. *If hypotheses H_0 and H_1 hold, then $\mathfrak{L} \neq \emptyset$ and we have then $S_\lambda \subset \operatorname{int} C_+$ for every $\lambda \in \mathfrak{L}$.*

Proof. On account of hypotheses $H_1(iv)$, we see that given $\varepsilon > 0$, we can find $C_\varepsilon = C(\varepsilon) > 0$ such that

$$F(z,x) \le \frac{\varepsilon}{q(z)}x^{q(z)} + C_\varepsilon x^{r_+} \quad \text{for a.a. } z \in \Omega, \text{ all } x \ge 0.$$

For every $u \in W^{1,p(z)}(\Omega)$, we have

$$\begin{aligned}\hat{\varphi}_\lambda(u) \geq &\int_\Omega \frac{1}{p(z)}|Du|^{p(z)}\,dz + \int_\Omega \frac{1}{q(z)}|Du|^{q(z)}\,dz + \int_{\partial\Omega} \frac{\beta(z)}{p(z)}|u|^{p(z)}d\sigma + \int_\Omega \frac{\xi(z)}{p(z)}|u|^{p(z)}dz \\ &+ \int_\Omega \frac{\theta}{p(z)}(u^-)^{p(z)}dz - \int_\Omega \frac{\varepsilon}{q(z)}|u|^{q(z)}\,dz - C_\varepsilon \int_\Omega |u|^{r_+}dz - \lambda \int_\Omega \frac{1}{\tau(z)}(u^+)^{\tau(z)}dz \\ \geq &\, \tilde{C}\min\{\|u\|^{p_+}, \|u\|^{p_-}\} + \int_\Omega \frac{1}{q(z)}|Du|^{q(z)}\,dz - \int_\Omega \frac{\varepsilon}{q(z)}|u|^{q(z)}\,dz \\ &- C_\varepsilon \int_\Omega |u|^{r_+}dz - \lambda \int_\Omega \frac{1}{\tau(z)}(u^+)^{\tau(z)}dz \end{aligned} \tag{3.27}$$

for some $\tilde{C} > 0$ (recall that $\theta > \|\xi\|_\infty$).

Observe next that,

$$\int_\Omega \frac{1}{q(z)}|Du|^{q(z)}\,dz \geq \mu^* \int_\Omega \frac{1}{q(z)}|u|^{q(z)}\,dz \text{ (see Proposition 2.6).} \tag{3.28}$$

$$\int_\Omega \frac{1}{\tau(z)}(u^+)^{\tau(z)}dz \leq \frac{1}{\tau_-}\max\{\|u\|^{\tau_+}_{\tau(z)}, \|u\|^{\tau_-}_{\tau(z)}\}. \tag{3.29}$$

We return to (3.27) and use (3.28) and (3.29). Then for $u \in W^{1,p(z)}(\Omega)$ with $\|u\| \leq 1$, $\varepsilon < \mu^*$ we have

$$\begin{aligned}\hat{\varphi}_\lambda(u) &\geq \tilde{C}\|u\|^{p_+} - \lambda C_1\|u\|^{\tau_-} - C_\varepsilon\|u\|^{r_+} \\ &= (\tilde{C} - \lambda C_1\|u\|^{\tau_- - p_+} - C_\varepsilon\|u\|^{r_+ - p_+})\|u\|^{p_+},\ u \in W^{1,p(z)}(\Omega)\end{aligned} \tag{3.30}$$

for some $C_1 > 0$.

Let us set, for any $t > 0$,

$$k_\lambda(t) = \lambda C_1 t^{\tau_- - p_+} - C_\varepsilon t^{r_+ - p_+}.$$

Since $\tau_- < p_+ < r_+$ we have $\lim_{t\to\infty} k_\lambda(t) = \lim_{t\to 0^+} k_\lambda(t) = \infty$.

Then there exists $t_0 > 0$ satisfying $k'_\lambda(t_0) = 0$. One has

$$\lambda C_1(\tau_- - p_+)t_0^{\tau_- - p_+ - 1} = -C_\varepsilon(r_+ - p_+)t_0^{r_+ - p_+ - 1}$$

$$\Rightarrow t_0 = t_0(\lambda) = \left(\frac{\lambda C_1}{C_\varepsilon}\frac{p_+ - \tau_-}{r_+ - p_+}\right)^{\frac{1}{r_+ - \tau_-}}.$$

Then

$$k_\lambda(t_0) = \lambda C_1\left(\frac{\lambda C_1}{C_\varepsilon}\frac{p_+ - \tau_-}{r_+ - p_+}\right)^{\frac{\tau_- - p_+}{r_+ - \tau_-}} + C_\varepsilon\left(\frac{\lambda C_1}{C_\varepsilon}\frac{p_+ - \tau_-}{r_+ - p_+}\right)^{\frac{r_+ - p_+}{r_+ - \tau_-}}$$

and since $p_+ < \tau_+$ we have $\lim_{\lambda\to 0^+} k_\lambda(t_0) = 0$. So we can find $\lambda_0 > 0$ such that

$$k_\lambda(t_0) < \tilde{C} \quad \text{for all } \lambda \in (0, \lambda_0).$$

Then from (3.30) it follows that

$$\hat{\varphi}_\lambda(u) \geq \hat{m}_\lambda > 0 \quad \text{for all } \|u\| = t_0. \tag{3.31}$$

For $u \in \operatorname{int} C_+$, on account of the superlinearity hypothesis $H_1(ii)$, we have

$$\hat{\varphi}_\lambda(tu) \to -\infty \quad \text{as } t \to \infty. \tag{3.32}$$

Then, (3.31), (3.32) and Proposition (3.1) permit the use of mountain pass theorem. Therefore for every $\lambda \in (0, \lambda_0)$ we can find $u_\lambda \in W^{1,p(z)}(\Omega)$ such that

$$u_\lambda \in K_{\hat{\varphi}_\lambda} \quad \text{and} \quad 0 < \hat{m}_\lambda \leq \hat{\varphi}_\lambda(u_\lambda). \tag{3.33}$$

From (3.33) we have $u_\lambda \neq 0$ (recall that $\hat{\varphi}_\lambda(0) = 0$) and

$$\langle \hat{\varphi}'_\lambda(u_\lambda), h \rangle = 0 \quad \text{for all } h \in W^{1,p(z)}(\Omega). \tag{3.34}$$

Choosing $h = -u_\lambda^- \in W^{1,p(z)}(\Omega)$, we obtain

$$\int_\Omega |Du_\lambda^-|^{p(z)} dz + \int_\Omega |Du_\lambda^-|^{q(z)} dz + \int_\Omega (\theta + \xi(z))(u_\lambda^-)^{p(z)} dz + \int_{\partial\Omega} \beta(z)(u_\lambda^-)^{p(z)} d\sigma = 0$$

$$\Rightarrow \int_\Omega |Du_\lambda^-|^{p(z)} dz + \int_\Omega (\theta + \xi(z))(u_\lambda^-)^{p(z)} dz + \int_{\partial\Omega} \beta(z)(u_\lambda^-)^{p(z)} d\sigma \leq 0$$

$$\Rightarrow u_\lambda \geq 0, \; u_\lambda \neq 0.$$

Then from (3.34) it follows that u_λ is a positive solution (p_λ). From the anisotropic regularity theory (see [8] and [17] for the corresponding isotropic theory) we have

$$u_\lambda \in C_+ \setminus \{0\}.$$

For every $u \in S_\lambda$, we have $u \in C_+ \setminus \{0\}$ and

$$-\Delta_{p(z)} u(z) - \Delta_{q(z)} u(z) + \xi(z) u(z)^{p(z)-1} \geq 0 \quad \text{for a.a. } z \in \Omega,$$

$$\Rightarrow \Delta_{p(z)} u(z) + \Delta_{q(z)} u(z) \leq \|\xi\|_\infty u(z)^{p(z)-1} \quad \text{for a.a. } z \in \Omega,$$

$$\Rightarrow u \in \operatorname{int} C_+ \text{ (see [35] and [26], Proposition A2).}$$

So, we have proved that $(0, \lambda_0) \subseteq \mathfrak{L}$ and so $\mathfrak{L} \neq \emptyset$. Moreover, we have $S_\lambda \subseteq \operatorname{int} C_+$ for all $\lambda > 0$. □

Next, we show that $\mathfrak{L}$ is an interval.

Proposition 3.3. *If hypotheses H_0 and H_1 hold, $\lambda \in \mathfrak{L}$ and $0 < \mu < \lambda$ then $\mu \in \mathfrak{L}$ and given $u_\lambda \in S_\lambda$, we can find $u_\mu \in S_\mu$ such that $u_\mu \leq u_\lambda$.*

Proof. Let us introduce the Carathéodory function $g_\mu(z,x)$ defined by

$$g_\mu(z,x) = \begin{cases} \mu(x^+)^{\tau(z)-1} + f(z,x^+) + \theta(x^+)^{p(z)-1}, & \text{if } x \leq u_\lambda(z), \\ \mu u_\lambda(z)^{\tau(z)-1} + f(z,u_\lambda(z)) + \theta u_\lambda(z)^{p(z)-1}, & \text{if } u_\lambda(z) < x. \end{cases} \tag{3.35}$$

Here $\theta > \|\xi\|_\infty$.

We set $G_\mu(z,x) = \int_0^x g_\mu(z,s)\, ds$ and consider the C^1-functional $\Psi_\mu : W^{1,p(z)}(\Omega) \to \mathbb{R}$ defined by

$$\Psi_\mu(u) = \int_\Omega \frac{1}{p(z)} |Du|^{p(z)}\, dz + \int_\Omega \frac{1}{q(z)} |Du|^{q(z)}\, dz$$
$$+ \int_\Omega \frac{\theta + \xi(z)}{p(z)} |u|^{p(z)}\, dz + \int_{\partial\Omega} \frac{\beta(z)}{p(z)} |u|^{p(z)}\, d\sigma - \int_\Omega G_\mu(z,u)\, dz \tag{3.36}$$

for all $u \in W^{1,p(z)}(\Omega)$. Since $\theta > \|\xi\|_\infty$, it is clear that $\Psi_\mu(\cdot)$ is coercive. Also, using the fact that $W^{1,p(z)}(\Omega) \hookrightarrow L^{p(z)}(\Omega)$ compactly, we see that $\Psi_\mu(\cdot)$ is sequentially weakly lower semicontinuous.

So, by the Weierstrass–Tonelli theorem, there exists $u_\mu \in W^{1,p(z)}(\Omega)$ such that

$$\Psi_\mu(u_\mu) = \inf\left\{\Psi_\mu(u) : u \in W^{1,p(z)}(\Omega)\right\}. \tag{3.37}$$

Since $\tau_+ < p_-$, we see that

$$\Psi_\mu(u_\mu) < 0 = \Psi_\mu(0) \Rightarrow u_\mu \neq 0.$$

From (3.37) we have

$$\Psi'_\mu(u_\mu) = 0 \Rightarrow$$

$$\langle V(u_\mu), h\rangle + \int_\Omega [\theta + \xi(z)]|u_\mu|^{p(z)-2}u_\mu h\,dz + \int_{\partial\Omega} \beta(z)|u_\mu|^{p(z)-2}u_\mu h\,d\sigma = \int_\Omega g_\mu(z,u_\mu)h\,dz \tag{3.38}$$

for all $h \in W^{1,p(z)}(\Omega)$. In (3.38) first we choose $h = -u_\mu^- \in W^{1,p(z)}(\Omega)$. We obtain

$$\begin{aligned}&\int_\Omega |Du_\mu^-|^{p(z)}dz + \int_\Omega |Du_\mu^-|^{q(z)}dz \\ &\qquad + \int_\Omega (\theta + \xi(z))(u_\mu^-)^{p(z)}dz + \int_{\partial\Omega} \beta(z)(u_\mu^-)^{p(z)}d\sigma = \int_\Omega g_\mu(z,u_\mu)u_\mu^-\,dz \\ &\qquad \Rightarrow u_\mu \geq 0, u_\mu \neq 0 \quad (\text{see } (3.35)).\end{aligned}$$

Next, in (3.38) we choose $h = (u_\mu - u_\lambda)^+ \in W^{1,p(z)}(\Omega)$. We have

$$\begin{aligned}&\langle V(u_\mu), (u_\mu - u_\lambda)^+\rangle + \int_\Omega [\theta + \xi(z)]u_\mu^{p(z)-1}(u_\mu - u_\lambda)^+\,dz + \int_{\partial\Omega} \beta(z)|u_\mu|^{p(z)-1}u_\mu(u_\mu - u_\lambda)^+\,d\sigma \\ &= \int_\Omega [\mu u_\lambda^{\tau(z)-1} + f(z,u_\lambda) + \theta u_\lambda^{p(z)-1}](u_\mu - u_\lambda)^+\,dz \quad (\text{see } (3.35)) \\ &\leq \int_\Omega [\lambda u_\lambda^{\tau(z)-1} + f(z,u_\lambda) + \theta u_\lambda^{p(z)-1}](u_\mu - u_\lambda)^+\,dz \quad (\text{since } \mu < \lambda) \\ &= \langle V(u_\lambda), (u_\mu - u_\lambda)^+\rangle + \int_\Omega [\theta + \xi(z)]u_\lambda^{p(z)-1}(u_\mu - u_\lambda)^+\,dz \quad (\text{since } u_\lambda \in S_\lambda).\end{aligned}$$

The monotonicity of $V(\cdot)$ (see Proposition (2.9)) and the fact that $\theta > \|\xi\|_\infty$ imply that $u_\mu \leq u_\lambda, \Rightarrow u_\mu \in [0, u_\lambda], u_\mu \neq 0, \Rightarrow u_\mu \in S_\mu \subseteq \operatorname{int} C_+$ (see (3.35) and (3.38)). □

So, according to Proposition 3.3, the solution multifunction $\lambda \mapsto S_\lambda$ has a kind of weak monotonicity property. We can improve this monotonicity property by adding one more condition on the perturbation $f(z,\cdot)$.

The new hypotheses on $f(z,x)$ are the following:

***H*₂**: $f : \Omega \times \mathbb{R} \to \mathbb{R}$ is a function which is measurable in $z \in \Omega$, for a.a. $z \in \Omega$ we have $f(z,\cdot) \in C^1(\mathbb{R})$,

(i)–(iv) hypotheses $H_2(i)$–(iv) are the same as the corresponding hypotheses $H_1(i)$–(iv), and

(v) for every $\rho > 0$, there exists $\hat{\xi}_\rho > 0$ such that for a.a. $z \in \Omega$ the function $x \to f(z,x) + \hat{\xi}_\rho x^{p(z)-1}$ is nondecreasing on $[0,\rho]$.

Remark 3.4. Hypotheses $H_2(v)$ is a one-sided local Hölder condition on $f(z,\cdot)$. It is satisfied for all $z \in \Omega$, $f(z,x)$ is differentiable and for every $\rho > 0$, we can find $C_{\hat{\rho}} > 0$ such that $f'_x(z,x) \geq -C_{\hat{\rho}} x^{p(z)-1}$ for a.a. $z \in \Omega$ and all $0 \leq x \leq \rho$.

Proposition 3.5. *If hypotheses H_0, H_2 hold, $\lambda \in \mathfrak{L}$, $u_\lambda \in S_\lambda \subseteq \operatorname{int} C_+$ and $\mu \in (0,\lambda)$, then $\mu \in \mathfrak{L}$ and we can find $u_\mu \in S_\mu \subseteq \operatorname{int} C_+$ such that $u_\lambda - u_\mu \in \operatorname{int} C_+$.*

Proof. From Proposition 3.3 we know that $\mu \in \mathfrak{L}$ and there exists $u_\mu \in S_\mu \subseteq \operatorname{int} C_+$ such that

$$u_\lambda - u_\mu \in C_+ \setminus \{0\} \tag{3.39}$$

Let $\rho = \|u_\lambda\|_\infty$ and let $\hat{\xi}_\rho > 0$ be as postulated by hypothesis $H_2(v)$. We can always assume that $\hat{\xi}_\rho > \|\xi\|_\infty$. Then we have

$$\begin{aligned}
&-\Delta_{p(z)} u_\mu - \Delta_{q(z)} u_\mu + [\xi(z) + \hat{\xi}_\rho] u_\mu^{p(z)-1} \\
&\quad = \mu u_\mu^{\tau(z)-1} + f(z,u_\mu) + \hat{\xi}_\rho u_\mu^{p(z)-1} \\
&\quad \leq \mu u_\lambda^{\tau(z)-1} + f(z,u_\lambda) + \hat{\xi}_\rho u_\lambda^{p(z)-1} \quad \text{(see (3.39) and hypothesis } H_2(v)) \\
&\quad \leq \lambda u_\lambda^{\tau(z)-1} + f(z,u_\lambda) + \hat{\xi}_\rho u_\lambda^{p(z)-1} \quad (\text{since } \mu < \lambda) \\
&\quad = -\Delta_{p(z)} u_\lambda - \Delta_{q(z)} u_\lambda + [\xi(z) + \hat{\xi}_\rho] u_\lambda^{p(z)-1}.
\end{aligned} \tag{3.40}$$

Note that since $u_\lambda \in \operatorname{int} C_+$ and $\mu < \lambda$, we have

$$0 \prec (\lambda - \mu) u_\lambda^{q(z)-1}. \tag{3.41}$$

Then from (3.40), (3.41) and Proposition 2.4 in [23], we can conclude that

$$u_\lambda - u_\mu \in \operatorname{int} C_+.$$

The proof is now complete. □

Next, we show that for every $\lambda \in \mathfrak{L}$, the solution set S_λ has the smallest element (minimal positive solution). To this end, first, we consider the following auxiliary problem:

$$\begin{cases} -\Delta_{p(z)} u(z) - \Delta_{q(z)} u(z) + |\xi(z)||u(z)|^{p(z)-2} u(z) = \lambda |u(z)|^{\tau(z)-2} u(z) & \text{in } \Omega, \\ \frac{\partial u}{\partial n_{pq}} + \beta(z)|u(z)|^{p(z)-1} = 0 \text{ on } \partial\Omega, \ \lambda > 0, \ u > 0. \end{cases} \tag{3.42}$$

Proposition 3.6. *If hypotheses H_0 hold and $\lambda > 0$, then problem (3.42) admits a unique positive solution $\bar{u}_\lambda \in \operatorname{int} C_+$.*

Proof. We consider the C^1-functional $\gamma_\lambda : W^{1,p(z)}(\Omega) \to \mathbb{R}$ defined by

$$\begin{aligned}
\gamma_\lambda(u) = &\int_\Omega \frac{1}{p(z)} |Du|^{p(z)} dz + \int_\Omega \frac{1}{q(z)} |Du|^{q(z)} dz + \int_\Omega |\xi(z)||u|^{p(z)} dz \\
&- \lambda \int_\Omega \frac{1}{\tau(z)} (u^+)^{\tau(z)} dz + \int_{\partial\Omega} \frac{\beta(z)}{p(z)} |u|^{p(z)} d\sigma
\end{aligned}$$

for all $u \in W^{1,p(z)}(\Omega)$. Evidently, $\gamma_\lambda(\cdot)$ is coercive (since $\tau_+ < p_-$, $q_+ < p_-$.) and sequentially weakly lower semicontinuous. So, we can find $\bar{u}_\lambda \in W^{1,p(z)}(\Omega)$ such that

$$\gamma_\lambda(\bar{u}_\lambda) = \min\{\gamma_\lambda(u) : u \in W^{1,p(z)}(\Omega)\} < 0 = \gamma_\lambda(0) \quad (\text{since } \tau_+ < p_-),$$

which implies $\bar{u}_\lambda \neq 0$. We have

$$\gamma'_\lambda(\bar{u}_\lambda) = 0,$$

which implies

$$\langle V(\bar{u}_\lambda), h\rangle + \int_\Omega |\xi(z)||\bar{u}_\lambda|^{p(z)-2}\bar{u}_\lambda h\,dz - \lambda \int_\Omega (\bar{u}_\lambda^+)^{\tau(z)-1} h\,dz + \int_{\partial\Omega} \beta(z)|\bar{u}_\lambda|^{p(z)-2}\bar{u}_\lambda d\sigma = 0 \tag{3.43}$$

for all $h \in W^{1,p(z)}(\Omega)$.

In (3.43) we choose $h = -\bar{u}_\lambda^- \in W^{1,p(z)}(\Omega)$. Then

$$\int_\Omega |D\bar{u}_\lambda^-|^{p(z)} dz + \int_\Omega |D\bar{u}_\lambda^-|^{q(z)} dz + \int_\Omega |\xi(z)|(\bar{u}_\lambda^-)^{p(z)} dz + \int_{\partial\Omega} \beta(z)(\bar{u}_\lambda^-)^{p(z)} d\sigma = 0$$

$$\Rightarrow \int_\Omega |D\bar{u}_\lambda^-|^{p(z)} dz + \int_\Omega |\xi(z)|(\bar{u}_\lambda^-)^{p(z)} dz + \int_{\partial\Omega} \beta(z)(\bar{u}_\lambda^-)^{p(z)} d\sigma \leq 0$$

which implies $\bar{u}_\lambda \geq 0$, $\bar{u}_\lambda \neq 0$, hence $\bar{u}_\lambda$ is a positive solution of (3.42) (see (3.43)), therefore $\bar{u}_\lambda \in C_+ \setminus \{0\}$ (anisotropic regularity theory).

Therefore

$$\Delta_{p(z)}\bar{u}_\lambda(z) + \Delta_{q(z)}\bar{u}_\lambda(z) \leq \|\xi\|_\infty (\bar{u}_\lambda(z))^{p(z)-1} \quad \text{for a.a. } z \in \Omega,$$

which implies $\bar{u}_\lambda \in \operatorname{int} C_+$ (see Zhang [35]).

Next, we show that this positive solution of (3.42) is unique. Suppose that $\bar{v}_\lambda$ is another positive solution of (3.42). Again we have $\bar{v}_\lambda \in \operatorname{int} C_+$. On account of Proposition 4.1.22 of Papageorgiou, Rădulescu and Repovs [22], p. 274, we have $\frac{\bar{u}_\lambda}{\bar{v}_\lambda}, \frac{\bar{v}_\lambda}{\bar{u}_\lambda} \in L^\infty(\Omega)$. So, we can apply Theorem 2.5 of Takac and Giacomoni [34] and get

$$\begin{aligned} 0 &\leq \int_\Omega \left[\frac{-\Delta_{p(z)}\bar{u}_\lambda - \Delta_{q(z)}\bar{u}_\lambda}{(\bar{u}_\lambda)^{q_- -1}} + \frac{-\Delta_{p(z)}\bar{v}_\lambda - \Delta_{q(z)}\bar{v}_\lambda}{(\bar{v}_\lambda)^{q_- -1}} \right] ((\bar{u}_\lambda)^{q_-} - (\bar{v}_\lambda)^{q_-})\,dz \\ &= \int_\Omega \Bigg[\lambda \left(\frac{1}{(\bar{u}_\lambda)^{q_- - \tau(z)}} - \frac{1}{(\bar{v}_\lambda)^{q_- - \tau(z)}} \right) \\ &\qquad - |\xi(z)| \left((\bar{u}_\lambda)^{p(z)-q_-} - (\bar{v}_\lambda)^{p(z)-q_-} \right) \Bigg] ((\bar{u}_\lambda)^{q_-} - (\bar{v}_\lambda)^{q_-})\,dz, \end{aligned}$$

which implies $\bar{u}_\lambda = \bar{v}_\lambda$ (since $\tau_+ < p_- \leq p(z)$).

Therefore the positive solution $\bar{u}_\lambda \in \operatorname{int} C_+$ of problem (3.42) is unique. □

This solution $\bar{u}_\lambda \in \operatorname{int} C_+$ provides a lower bound for the solution set S_λ.

Proposition 3.7. *If hypotheses H_0, H_1 hold and $\lambda \in \mathfrak{L}$, then $\bar{u}_\lambda \leq u$ for all $u \in S_\lambda$.*

Proof. Let $u \in S_\lambda \subset \operatorname{int} C_+$ and consider the Carathéodory function $\beta_\lambda(z, x)$ defined by

$$\hat{\beta}_\lambda(z,x) = \begin{cases} \lambda (x^+)^{\tau(z)-1}, & \text{if } x \leq u(z), \\ \lambda u(z)^{\tau(z)-1}, & \text{if } u(z) < x. \end{cases} \tag{3.44}$$

We set $\hat{B}_\lambda(z,x) = \int_0^x \hat{\beta}_\lambda(z,s)ds$ and consider the C^1-functional $\tau_\lambda : W^{1,p(z)}(\Omega) \to \mathbb{R}$ defined by

$$\begin{aligned} \tau_\lambda(u) = &\int_\Omega \frac{1}{p(z)}|Du|^{p(z)} dz + \int_\Omega \frac{1}{q(z)}|Du|^{q(z)} dz + \int_\Omega \frac{|\xi(z)|}{p(z)}|u|^{p(z)} dz \\ &+ \int_{\partial\Omega} \frac{\beta(z)}{p(z)}|u|^{p(z)} d\sigma - \int_\Omega \hat{B}_\lambda(z,u) dz \end{aligned}$$

for all $u \in W^{1,p(z)}(\Omega)$.

From (3.44) we see that $\tau_\lambda(\cdot)$ is coercive. Also, it is sequentially weakly lower semicontinuous. So, we can find $\tilde{u}_\lambda \in W^{1,p(z)}(\Omega)$ such that

$$\tau_\lambda(\tilde{u}_\lambda) = \min\left\{\tau_\lambda(u) : u \in W^{1,p(z)}(\Omega)\right\} < 0 = \tau_\lambda(0) \quad (\text{since } \tau_+ < p_-),$$

which implies $\tilde{u}_\lambda \neq 0$.

We have

$$\tau'_\lambda(\tilde{u}_\lambda) = 0,$$

$$\langle V(\tilde{u}_\lambda), h\rangle + \int_\Omega |\xi(z)||\tilde{u}_\lambda|^{p(z)-2}\tilde{u}_\lambda h dz + \int_{\partial\Omega} \beta(z)|\tilde{u}_\lambda|^{p(z)-2}\tilde{u}_\lambda h d\sigma = \int_\Omega \hat{\beta}_\lambda(z,\tilde{u}_\lambda) h dz \tag{3.45}$$

for all $h \in W^{1,p(z)}(\Omega)$. In (3.45) we first choose $h = -\tilde{u}_\lambda^- \in W^{1,p(z)}(\Omega)$ and infer that

$$\tilde{u}_\lambda \geq 0,\ \tilde{u}_\lambda \neq 0.$$

Next, in (3.45) we choose $h = (\tilde{u}_\lambda - u)^+ \in W^{1,p(z)}(\Omega)$. We have

$$\begin{aligned}
&\langle V(\tilde{u}_\lambda), (\tilde{u}_\lambda - u)^+\rangle + \int_\Omega |\xi(z)|(\tilde{u}_\lambda)^{p(z)-1}(\tilde{u}_\lambda - u)^+ dz + \int_{\partial\Omega} \beta(z)(\tilde{u}_\lambda)^{p(z)-1}(\tilde{u}_\lambda - u)^+ d\sigma \\
&= \int_\Omega \lambda u^{\tau(z)-1}(\tilde{u}_\lambda - u)^+ dz \quad (\text{see } (3.44)) \\
&\leq \int_\Omega [\lambda u^{\tau(z)-1} + f(z,u)](\tilde{u}_\lambda - u)^+ dz \quad (\text{since } f \geq 0) \\
&\leq \langle V(u), (\tilde{u}_\lambda - u)^+\rangle + \int_\Omega |\xi(z)| u^{p(z)-1}(\tilde{u}_\lambda - u)^+ dz + \int_{\partial\Omega} \beta(z) u^{p(z)-1}(\tilde{u}_\lambda - u)^+ d\sigma
\end{aligned}$$

(since $u \in S_\lambda$)

$$\Rightarrow \tilde{u}_\lambda \leq u.$$

So, we have proved that

$$\tilde{u}_\lambda \in [0,u]\setminus\{0\}. \tag{3.46}$$

Then it follows from (3.43), (3.44), (3.46) that

$$\begin{aligned}
&\tilde{u}_\lambda \text{ is a positive solution of } (3.42), \\
&\quad \Rightarrow \tilde{u}_\lambda = \bar{u}_\lambda \in \operatorname{int} C_+ \quad (\text{see Proposition } 3.5), \\
&\quad \Rightarrow \bar{u}_\lambda \leq u \text{ for all } u \in S_\lambda.
\end{aligned}$$

The proof is now complete. □

Remark 3.8. Reasoning as in the above proof, we show that $\lambda \mapsto \bar{u}_\lambda$ is increasing, that is, if $0 < \mu < \lambda$, then $\bar{u}_\lambda - \bar{u}_\mu \in C_+ \setminus 0$.

We know that S_λ is downward directed (see Filippakis and Papageorgiou [9] and Papageorgiou, Rădulescu and Repovš [21], and recall that $V(\cdot)$ is monotone (see Proposition 2.9)).

Proposition 3.9. *If hypotheses H_0, H_1 hold and $\lambda \in \mathfrak{L}$, then there exists $u^*_\lambda \in S_\lambda \subseteq \operatorname{int} C_+$ such that*

$$u^*_\lambda \leq u \quad \textit{for all } u \in S_\lambda \textit{ (minimal positive solution of } (p_\lambda)).$$

Proof. By Lemma 3.10 of Hu and Papageorgiou [15] (p. 178), we know that we can find $\{u_n\}_{n\geq 1} \subseteq S_\lambda \subseteq \operatorname{int} C_+$ decreasing (recall that S_λ is downward directed) such that

$$\inf_{n\geq 1} u_n = \inf S_\lambda.$$

Since $u_\lambda \leq u_n \leq u_1$ for all $n \in \mathbb{N}$ (see Proposition 3.6), from hypothesis $H_1(i)$ it follows that $\{u_n\}_{n\geq 1} \subseteq W^{1,p}(\Omega)$ is bounded. So, we may assume that

$$u_n \rightharpoonup u_\lambda^* \quad \text{in } W^{1,p}(\Omega) \quad \text{and} \quad u_n \to u_\lambda^* \quad \text{in } L^{r(z)}(\Omega) \quad \text{as } n \to \infty. \tag{3.47}$$

We have

$$\begin{aligned}
&\langle V(u_n), u_n - u_\lambda^*\rangle + \int_\Omega \xi(z) u_n^{p(z)-1}(u_n - u_\lambda^*)\,dz + \int_{\partial\Omega} \beta(z) u_n^{p(z)-1}(u_n - u_\lambda^*)d\sigma \\
&= \lambda \int_\Omega u_n^{\tau(z)-1}(u_n - u_\lambda^*)\,dz + \int_\Omega f(z,u_n)(u_n - u_\lambda^*)\,dz,
\end{aligned}$$

which implies

$$\lim_{n\to\infty} \langle V(u_n), u_n - u_\lambda^*\rangle = 0,$$

and thus

$$u_n \to u_\lambda^* \quad \text{in } W^{1,p(z)}(\Omega) \quad \text{(see Proposition 2.9)}. \tag{3.48}$$

Note that $\bar{u}_\lambda \leq u_\lambda^*$ and so $u_\lambda^* \neq 0$,

$$\begin{aligned}
&\langle V(u_\lambda^*), h\rangle + \int_\Omega \xi(z)(u_\lambda^*)^{p(z)-1} h\,dz + \int_{\partial\Omega} \beta(z)(u_\lambda^*)^{p(z)-1} h d\sigma \\
&= \lambda \int_\Omega (u_\lambda^*)^{\tau(z)-1} h\,dz + \int_\Omega f(z,u_\lambda^*) h\,dz
\end{aligned}$$

for all $h \in W^{1,p(z)}(\Omega)$ (see (3.48)).

It follows that

$$u_\lambda^* \in S_\lambda \subseteq \operatorname{int} C_+ \quad \text{and} \quad u_\lambda^* = \inf S_\lambda.$$

The proof is now complete. □

We set $\lambda^* = \sup \mathfrak{L}$.

Proposition 3.10. *If hypotheses H_0, H_2 hold, then $\lambda^* < \infty$.*

Proof. On account of hypotheses $H_0, H_2(iv)$ and since $\tau^+ < p^-$, we see that we can find $\hat{\lambda} > \lambda^*$ such that

$$\lambda x^{\tau(z)-1} + f(z,x) - \xi(z) x^{p(z)-1} \geq 0 \quad \text{for a.a. } z \in \Omega, \text{ all } x \geq 0. \tag{3.49}$$

Let $\lambda > \hat{\lambda}$ and suppose that $\lambda \in \mathfrak{L}$. Then we can find $u_\lambda \in S_\lambda \subseteq \operatorname{int} C_+$. Let $\Omega_0 \subset\subset \Omega$ (that is, $\Omega_0 \subseteq \overline{\Omega}_0 \subseteq \Omega$) and assume that $\partial\Omega_0$ is a C^2-manifold. We set $m_0 = \min_{\Omega_0} u_\lambda > 0$ (recall that $u_\lambda \in \operatorname{int} C_+$). Also, let $\hat{\xi}_\rho > \|\xi\|_\infty$. Let $m_0^\delta = m_0 + \delta$ for $\delta > 0$ small enough. We have

$$\begin{aligned}
&-\Delta_{p(z)} m_0^\delta - \Delta_{q(z)} m_0^\delta + [\xi(z) + \hat{\xi}_\rho](m_0^\delta)^{p(z)-1} \\
&\leq [\xi(z) + \hat{\xi}_\rho](m_0^\delta)^{p(z)-1} + \chi(\delta) \quad \text{with } \chi(\delta) \to 0^+ \text{ as } \delta \to 0^+ \\
&\leq \hat{\lambda} m_0^{\tau(z)-1} + f(z,m_0) + \hat{\xi}_\rho m_0^{p(z)-1} + \chi(\delta) \quad \text{(see (3.49))} \\
&\leq \hat{\lambda} u_\lambda^{\tau(z)-1} + f(z,u_\lambda) + \hat{\xi}_\rho u_\lambda^{p(z)-1} + \chi(\delta) \quad \text{(see hypothesis } H_2(v)) \\
&\leq \hat{\lambda} u_\lambda^{\tau(z)-1} + f(z,u_\lambda) + \hat{\xi}_\rho u_\lambda^{p(z)-1} - [\lambda - \hat{\lambda}] m_0^{p(z)-1} + \chi(\delta) \\
&\leq -\Delta_{p(z)} u_\lambda - \Delta_{q(z)} u_\lambda + [\xi(z) + \hat{\xi}_\rho] u_\lambda^{p(z)-1} \quad \text{in } \Omega_0, \text{ for } 0 < \delta < 1 \text{ small}.
\end{aligned} \tag{3.50}$$

Note that $\delta \in (0,1)$ small enough, we will have

$$[\lambda - \hat{\lambda}] m_0^{p(z)-1} - \chi(\delta) \geq \eta > 0.$$

So, from (3.50) and Papageorgiou–Qin–Rădulescu [24], Proposition 5 (see also [25], Proposition 6) we have

$$u_\lambda(z) \geq m_{\delta_0} \quad \text{for all } z \in \Omega, \text{ all } 0 < \delta < 1 \text{ small enough}$$

which is a contradiction. Therefore $0 < \lambda^* \leq \hat{\lambda} < \infty$. □

According to this proposition, we have

$$(0, \lambda^*) \subseteq \mathfrak{L} \subseteq (0, \lambda^*]. \tag{3.51}$$

We will show that for all $\lambda \in (0, \lambda^*)$, we have at least two positive smooth solutions for problem (p_λ). To do this we need to strengthen a little the hypotheses on $f(z,\cdot)$. The new conditions on $f(z,x)$ are the following:

H$_3$: $f : \Omega \times \mathbb{R} \to \mathbb{R}$ is a Carathéodory function, hypotheses $H_3(i)$–(v) are the same as the corresponding hypotheses $H_2(i)$–(v) = $H_1(i)$–(v) and

(vi) for every $m > 0$, there exists $\eta_m > 0$ such that

$$f(z,x) \geq \eta_m > 0 \quad \text{for a.a. } z \in \Omega, \text{ all } x \geq m.$$

Proposition 3.11. *If hypotheses H_0, H_3 hold and $\lambda \in (0, \lambda^*)$, then problem (p_λ) admits at least two positive solutions $u_0, \hat{u} \in \operatorname{int} C_+$, $u_0 \neq \hat{u}$.*

Proof. Let $\eta \in (\lambda, \lambda^*)$. We have $\eta \in \mathfrak{L}$ (see (3.51)) and so we can find $u_\eta \in S_\eta \subseteq \operatorname{int} C_+$. Then according to Proposition 3.5, we can find $u_0 \in S_\lambda \subseteq \operatorname{int} C_+$ such that

$$u_\eta - u_0 \in \operatorname{int} C_+. \tag{3.52}$$

Recall that $\bar{u}_\lambda \leq u_0$ (see Proposition 3.7).

Let $\rho = \|u_0\|_\infty$ and let $\hat{\xi}_\rho > 0$ be as postulated by hypothesis $H_3(v)(H_2(v))$. We can assume that $\hat{\xi}_\rho > \|\xi\|_\infty$. Then we have

$$\begin{aligned}
&-\Delta_{p(z)}\bar{u}_\lambda - \Delta_{q(z)}\bar{u}_\lambda + [\xi(z) + \hat{\xi}_\rho]\bar{u}_\lambda^{p(z)-1} \\
&\quad \leq -\Delta_{p(z)}\bar{u}_\lambda - \Delta_{q(z)}\bar{u}_\lambda + [|\xi(z)| + \hat{\xi}_\rho]\bar{u}_\lambda^{p(z)-1} \\
&\quad = \lambda \bar{u}_\lambda^{\tau(z)-1} + \hat{\xi}_\rho \bar{u}_\lambda^{p(z)-1} \quad \text{(see Proposition 3.6)} \\
&\quad \leq \lambda u_0^{\tau(z)-1} + f(z, \bar{u}_\lambda) + \hat{\xi}_\rho u_0^{p(z)-1} \quad \text{(recall that } f \geq 0) \\
&\quad \leq \lambda u_0^{\tau(z)-1} + f(z, u_0) + \hat{\xi}_\rho u_0^{p(z)-1} \quad \text{(see Proposition 3.7 and hypothesis } H_3(v) = H_2(v)) \\
&\quad = -\Delta_{p(z)}u_0 - \Delta_{q(z)}u_0 + [\xi(z) + \hat{\xi}_\rho]u_0^{p(z)-1} \quad \text{(since } u_0 \in S_\lambda).
\end{aligned} \tag{3.53}$$

On account of hypothesis H_3(vi) and since $u_\lambda \in \operatorname{int} C_+$, we see that

$$0 \prec f(\cdot, \bar{u}_\lambda(\cdot)).$$

Then from (3.53) and Proposition 2.4 in [23] (see also [25], Proposition 7), we can conclude that

$$u_0 - \bar{u}_\lambda \in \text{int } C_+. \tag{3.54}$$

It follows from (3.52) and (3.54) that

$$u_0 \in \text{int}_{C^1(\bar{\Omega})}[\bar{u}_\lambda, u_\eta]. \tag{3.55}$$

As before, let $\theta > \|\xi\|_\infty$ and consider the Carathéodory function $k_\lambda(z,x)$ defined by

$$k_\lambda(z,x) = \begin{cases} \lambda \bar{u}_\lambda(z)^{\tau(z)-1} + f(z, \bar{u}_\lambda(z)) + \theta \bar{u}_\lambda(z)^{p(z)-1}, & \text{if } x < \bar{u}_\lambda(z) \\ \lambda x^{\tau(z)-1} + f(z,x) + \theta x^{p(z)-1}, & \text{if } \bar{u}_\lambda(z) \le x \le u_\eta(z) \\ \lambda u_\eta(z)^{\tau(z)-1} + f(z, u_\eta(z)) + \vartheta u_\eta(z)^{p(z)-1}, & \text{if } u_\eta(z) < x. \end{cases} \tag{3.56}$$

We set $K_\lambda(z,x) = \int_0^x k_\lambda(z,s)ds$ and consider the C^1-functional $\tau_\lambda : W^{1,p(z)}(\Omega) \to \mathbb{R}$ defined by

$$\begin{aligned} \tau_\lambda(u) = & \int_\Omega \frac{1}{p(z)}|Du|^{p(z)}dz + \int_\Omega \frac{1}{q(z)}|Du|^{q(z)}dz + \int_\Omega \frac{1}{p(z)}(\theta + \xi(z))|u|^{p(z)}dz \\ & - \int_\Omega K_\lambda(z,u)dz + \int_{\partial\Omega} \frac{\beta(z)}{p(z)}|u|^{p(z)}d\sigma \end{aligned}$$

for all $u \in W^{1,p(z)}(\Omega)$.

From (3.56) and since $\theta > \|\xi\|_\infty$, we infer that $\tau_\lambda(\cdot)$ is coercive. Also, it is sequentially weakly lower semicontinuous. So, we can find $\tilde{u}_0 \in W^{1,p(z)}(\Omega)$ such that

$$\begin{aligned} \tau_\lambda(\tilde{u}_0) &= \min\{\tau_\lambda(u) : u \in W^{1,p(z)}(\Omega)\}, \\ &\Rightarrow \tau'_\lambda(\tilde{u}_0) = 0, \\ &\Rightarrow \langle \tau'_\lambda(\tilde{u}_0), h \rangle = 0 \quad \text{for all } h \in W^{1,p(z)}(\Omega). \end{aligned}$$

Choosing $h = (\bar{u}_\lambda - \tilde{u}_0)^+$ and $h = (\tilde{u}_0 - u_\eta)^+$ and using (3.56), we show as before that

$$\tilde{u}_0 \in [\bar{u}_\lambda, u_\eta] \cap \text{int } C_+.$$

Therefore, we may assume that $\tilde{u}_0 = u_0$ or otherwise, we already have a second positive smooth solution and so, we are done.

Next, we consider the Carathéodory function

$$\hat{k}_\lambda(z,x) = \begin{cases} \lambda \bar{u}_\lambda(z)^{\tau(z)-1} + f(z, \bar{u}_\lambda(z)) + \theta \bar{u}_\lambda(z)^{p(z)-1}, & \text{if } x \le \bar{u}_\lambda(z) \\ \lambda x^{\tau(z)-1} + f(z,x) + \vartheta x^{p(z)-1}, & \text{if } \bar{u}_\lambda(z) < x. \end{cases} \tag{3.57}$$

We define $\hat{K}_\lambda(z,x) = \int_0^x \hat{k}_\lambda(z,s)ds$ and introduce the C^1-functional $\hat{\tau}_\lambda : W^{1,p(z)}(\Omega) \to \mathbb{R}$ defined by

$$\begin{aligned} \hat{\tau}_\lambda(u) = & \int_\Omega \frac{1}{p(z)}|Du|^{p(z)}dz + \int_\Omega \frac{1}{q(z)}|Du|^{q(z)}dz + \int_\Omega \frac{1}{p(z)}(\theta + \xi(z))|u|^{p(z)}dz \\ & - \int_\Omega \hat{K}_\lambda(z,u)dz + \int_{\partial\Omega} \frac{\beta(z)}{p(z)}|u|^{p(z)}d\sigma \end{aligned}$$

for all $u \in W^{1,p(z)}(\Omega)$.

From (3.56) and (3.57), it is clear that

$$\tau_\lambda\big|_{[\bar{u}_\lambda, u_\eta]} = \hat{\tau}_\lambda\big|_{[\bar{u}_\lambda, u_\eta]}.$$

On account of (3.55), we have that u_0 is a local $C^1(\Omega)$-minimizer of $\hat{\tau}_\lambda$,

$$\Rightarrow u_0 \text{ is a local } W^{1,p(z)}(\Omega) - \text{minimizer of } \hat{\tau}_\lambda.$$

(see Gasiński and Papageorgiou [[13], Proposition 3.3])

Using (3.57), we can easily see that

$$K_{\hat{\tau}_\lambda} \subset [\bar{u}_\lambda) \cap \operatorname{int} C_+. \tag{3.58}$$

Then from (3.57) and the above, we can infer that we may assume that $K_{\hat{\tau}_\lambda}$ is finite or otherwise, we already have an infinity of positive smooth solutions all distinct from u_0 and so, we are done. According to Theorem 5.7.6 of Papageorgiou, Rădulescu, and Repovš [[22], p. 449], we can find $\rho \in (0, 1)$ small such that

$$\hat{\tau}_\lambda(u_0) < \inf\{\hat{\tau}_\lambda(u) : \|u - u_0\| = \rho\} = \hat{m}_\rho. \tag{3.59}$$

On account of hypothesis H_3(ii) for $u \in \operatorname{int} C_+$, we have

$$\hat{\tau}_\lambda(tu) \to -\infty \quad \text{as } t \to +\infty. \tag{3.60}$$

Finally, from (3.57), it follows that

$$\phi_{\hat{\lambda}}\big|_{[\bar{u}_\lambda)} = \hat{\tau}_\lambda\big|_{[\bar{u}_\lambda)} + \hat{\eta} \quad \text{with } \hat{\eta} \in \mathbb{R},$$

$$\Rightarrow \hat{\tau}_\lambda(\cdot) \text{ satisfies the } C\text{-condition} \quad (\text{see Proposition 3.1}). \tag{3.61}$$

Then (3.59), (3.60), (3.61) permit the use of the mountain pass theorem. So, we can find $\hat{u} \in W^{1,p(z)}(\Omega)$ such that

$$\hat{u} \in K_{\hat{\tau}_\lambda} \subset [\bar{u}_\lambda) \cap \operatorname{int} C_+ \quad \text{and} \quad \hat{m}_\rho \leq \hat{\tau}_\lambda(\hat{u}). \tag{3.62}$$

From (3.62) and (3.57), we see that $\hat{u} \in S_\lambda \subseteq \operatorname{int} C_+$, while from (3.62) and (3.59), we have that $\hat{u} \neq u_0$. □

Finally, we show that the critical parameter value λ^* is admissible, that is, λ^*

Proposition 3.12. *If hypotheses H_0, H_1 hold, then $\lambda^* \in \mathfrak{L}$.*

Proof. Let $\{\lambda_n\}_{n\geq 1} \subseteq \mathfrak{L}$ such that $\lambda_n \to \lambda^*$ as $n \to \infty$. From the proof of Proposition 3.3, we know that we can find $u_n \in S_{\lambda_n} \subseteq \operatorname{int} C_+$ such that $\varphi_{\hat{\lambda}_n}(u_n) < 0$ for all $n \in \mathbb{N}$.

Also, we have $\varphi'_{\hat{\lambda}_n}(u_n) = 0$, for all $n \in \mathbb{N}$. Then as in the proof of Proposition 3.1, we show that $\{u_n\}_{n\geq 1} \subseteq W^{1,p(z)}(\Omega)$ is bounded.

We may assume that

$$u_n \rightharpoonup u^* \quad \text{in } W^{1,p(z)}(\Omega) \quad \text{and} \quad u_n \to u^* \quad \text{in } L^{r(z)}(\Omega) \quad \text{as } n \to \infty. \tag{3.63}$$

We have

$$\langle V(u_n), h\rangle + \int_\Omega \xi(z) u_n^{p(z)-1} h\, dz + \int_{\partial\Omega} \beta(z) u_n^{p(z)-1} h d\sigma = \lambda_n \int_\Omega u_n^{\tau(z)-1} h\, dz + \int_\Omega f(z, u_n) h\, dz$$

for all $h \in W^{1,p(z)}(\Omega)$, all $n \in \mathbb{N}$.

Choosing $h = u_n - u^*$, passing to the limit as $n \to \infty$ and using (3.63), we obtain

$$u_n \to u^* \quad \text{in } W^{1,p(z)}(\Omega).$$

So, in the limit as $n \to \infty$, we have

$$\begin{aligned}\langle V(u^*), h\rangle &+ \int_\Omega \xi(z)(u^*)^{p(z)-1} h\, dz + \int_{\partial\Omega} \beta(z)(u^*)^{p(z)-1} h d\sigma \\ &= \lambda^* \int_\Omega (u^*)^{q(z)-1} h\, dz + \int_\Omega f(z, u^*) h\, dz\end{aligned}$$

for all $h \in W^{1,p(z)}(\Omega)$.

We have $\bar{u}_{\lambda_1} \leq u_n$ for all $n \in \mathbb{N}$ (see the Remark 3.8),

$$\begin{aligned}&\Rightarrow \bar{u}_{\lambda_1} \leq u^*, \\ &\Rightarrow u^* \in S_{\lambda^*} \subseteq \operatorname{int} C_+ \quad \text{and so } \lambda^* \in \mathfrak{L}.\end{aligned}$$

The proof is now complete. □

Summarizing, we can state the following existence and multiplicity theorem for the problem (p_λ), which is global in the parameter $\lambda > 0$ (a bifurcation-type theorem).

Theorem 3.13. *If hypotheses H_0, H_3, hold, then there exists $\lambda^* > 0$ such that*

(a) for all $\lambda \in (0, \lambda^*)$, problem ($p_\lambda$) has at least two positive solutions

$$u_0, \hat{u} \in \operatorname{int} C_+;$$

(b) for $\lambda = \lambda^*$, problem (p_λ) has at least one positive solution

$$u^* \in \operatorname{int} C_+;$$

(c) for all $\lambda > \lambda^*$, problem (p_λ) has no positive solutions;

(d) for every $\lambda \in \mathfrak{L} = (0, \lambda^*]$, problem ($p_\lambda$) has a smallest positive solution $u_\lambda^* \in \operatorname{int} C_+$ and the map $\lambda \mapsto u_\lambda^*$ from $\mathfrak{L} = (0, \lambda^*]$ into $C_+ \setminus \{0\}$ is increasing, that is,

$$0 < \mu \leq \lambda \in \mathfrak{L} \Rightarrow u_\lambda^* - u_\mu^* \in C_+ \setminus \{0\}.$$

Abstract. This manuscript introduces a framework that focuses on the singularity of a zero-double-Hopf system with 1 : 1 resonance in general retarded differential equations (RDDs). Initially, practical algorithms are proposed to identify the zero-double-Hopf singularity and the associated generalized eigenspace that corresponds to zero and two pairs of purely imaginary eigenvalues. Subsequently, by utilizing center manifold reduction and normal form techniques, we derive a reduced form of parameterized retarded differential systems up to third-order terms.

Keywords: retarded differential equations, zero-double-Hopf with 1 : 1 resonance, center manifold, normal form.

2020 Mathematics Subject Classification: 34K17, 34K18, 34C20, 34C23.

1 Introduction

In this paper, our primary objective is to analyze the zero-double-Hopf bifurcation with 1 : 1 resonance in relation to the following equation:

$$\dot{z}(t) = A(\epsilon)z(t) + B(\epsilon)z(t-\tau) + F(z(t), z(t-\tau), \epsilon), \tag{1.1}$$

where $z \in \mathbb{R}^n$, $\epsilon \in \mathbb{R}^m$, $A(\epsilon)$, $B(\epsilon) \in C^2(\mathbb{R}^m, \mathcal{M}_{n\times n}(\mathbb{R}))$ and $F \in C^3(\mathbb{R}^{2n+m}, \mathbb{R}^n)$ satisfies

$$F(0,0,\epsilon) = \frac{\partial F}{\partial x}(0,0,\epsilon) = \frac{\partial F}{\partial y}(0,0,\epsilon) = 0.$$

The characteristic equation of (1.1) at $(z,\epsilon) = (0,0)$ is

$$\Delta(\lambda) \equiv \det(\lambda I_n - A - e^{-\lambda\tau}B) = 0, \tag{1.2}$$

Corresponding author. Email: Houssem.Achouri@uphf.fr

where I_n is the $n \times n$ identity matrix, $A = A(0)$ and $B = B(0)$.

To understand the dynamic behavior of the given differential system (1.1), it is crucial to examine the root distribution in equation (1.2). Several cases can arise, including:

- All roots of equation (1.2) have negative real parts, except for a double or triple zero root, respectively. In these scenarios, if the transversality condition is satisfied, the system (1.1) undergoes a Bogdanov–Takens bifurcation or a triple-zero bifurcation, respectively. The Bogdanov–Takens bifurcation in neutral differential systems was studied in [4], while both the Bogdanov–Takens and triple-zero bifurcations for neutral functional differential equations with multiple delays were explored in [2].

- All roots of equation (1.2) possess negative real parts, except for a pair of purely imaginary roots. In this case, if the transversality condition is met, the system (1.1) undergoes a Hopf bifurcation. This case has been discussed in [10].

- All roots of equation (1.2) exhibit negative real parts, except for a pair of purely imaginary roots and a simple zero root. If the transversality condition is satisfied, the system (1.1) experiences a zero-Hopf bifurcation. This case has been examined for delayed differential equations in [11] and for neutral differential equations in [1].

- All roots of equation (1.2) have negative real parts, except for two pairs of purely imaginary roots $\pm i w_1$ and $\pm i w_2$. In this situation, a double-Hopf bifurcation may occur. The corresponding normal form for scalar DDE has been computed in [3], while the same has been derived for systems of delay differential equations in [9] for the case where $\frac{w_1}{w_2} \notin \mathbb{Q}$.

- All roots of equation (1.2) possess negative real parts, except for two pairs of purely imaginary roots $\pm i w_1$ and $\pm i w_2$, where $w_1 = w_2$. In [14], a double-Hopf bifurcation with 1:1 resonance in a van der Pol oscillator has been studied. Where, the authors established explicit conditions for the characteristic equation to have a pair of purely imaginary roots with multiplicity 2 and they derived the corresponding normal forms up to order 2. In [12], authors presented a framework for studying the double-Hopf singularity with 1:1 resonance in general delayed differential equations. They also derived the corresponding normal form up to the third-order terms. To illustrate the application of their study, they applied these findings to a van der Pol oscillator with delayed feedback.

Explicit expressions for the eigenspace, its dual, and the coefficients of the normal form related to the zero-double-Hopf singularity in retarded differential equations have not been provided thus far. In [7], the authors presented the second-order normal form associated with the zero-Hopf singularity for one-dimensional delayed differential equations. However, it has been demonstrated in [8] that the second-order normal form is insufficient for determining and analyzing the bifurcation diagrams of the zero-Hopf singularity. Consequently, to obtain comprehensive bifurcation diagrams for this singularity, it becomes necessary to compute the third-order normal form, which poses greater challenges and complexities compared to the second-order normal form.

The remaining sections of this paper are organized as follows: Section 2 establishes specific conditions for the examined system to guarantee the existence of the zero-double-Hopf singularity. Section 3 applies the theory of normal forms to compute the normal form up to third-order terms for this singularity. The concluding remarks are presented in the final section of the manuscript.

2 Existence of the zero-double-Hopf with 1 : 1 resonance singularity

In this section, our examination focuses on the existence of the zero-double-Hopf singularity with 1 : 1 resonance in the analyzed retarded differential equation, considering the case where $\epsilon \in \mathbb{R}^3$. We make use of the concepts and notations introduced in [5,6,13] for our investigation.

The system (1.1) can be expressed in the following form:

$$\dot{z}(t) = L(\epsilon)z_t + F(z_t,\epsilon) = L(0)z_t + \hat{F}(z_t,\epsilon), \qquad z_t(\theta) = z(t+\theta), \qquad -\tau \leq \theta \leq 0, \tag{2.1}$$

with $\hat{F}(z_t,\epsilon) = (L(\epsilon)-L(0))z_t + F(z_t,\epsilon)$, $L(\epsilon)\phi = \int_{-\tau}^{0} d[\eta_\epsilon(\theta)]\phi(\theta)$, for all $\phi \in C = C([-\tau,0],\mathbb{R}^n)$, with supreme norm.

In particular, $Lz_t = L(0)z_t = Az(t) + Bz(t-\tau) = \int_{-\tau}^{0} d[\eta_0(\theta)]z_t(\theta)$.

The function η_ϵ is a bounded variation matrix-valued function defined on the interval $[-\tau,0]$ as follows:

$$\eta_\epsilon(\theta) = \begin{cases} A(\epsilon) + B(\epsilon), & \theta = 0, \\ B(\epsilon), & -\tau < \theta < 0, \\ 0, & \theta = -\tau. \end{cases}$$

Let us consider the linear system given by

$$\dot{z}(t) = L(0)z_t. \tag{2.2}$$

As stated in [13], the infinitesimal generator for the solution semigroup defined by the system (2.2) can be represented as:

$$\mathcal{A}_0\phi = \dot{\phi},$$
$$\mathbf{D}(\mathcal{A}_0) = \left\{ \phi \in C : \frac{d\phi}{d\theta} \in C, \dot{\phi}(0) = \mathrm{L}(0)\phi \right\}.$$

The adjoint innner product on $C \times C^*$ is defined by:

$$\langle \psi, \phi \rangle = \psi(0)\phi(0) - \int_{-\tau}^{0} \int_{0}^{s} \psi(\theta - s) d[\eta_0(s)]\phi(\theta) d\theta.$$

where $C^* = C([0,\tau],\mathbb{R}^{n*})$, with $\mathbb{R}^{n*}$ is the space of all row n-vector.

The adjoint $\mathcal{A}_0^*$ of $\mathcal{A}_0$ is defined as follows:

$$\mathcal{A}_0^*\psi = -\dot{\psi},$$
$$\mathbf{D}(\mathcal{A}_0^*) = \left\{ \psi \in C^*, \frac{d\phi}{d\theta} \in C^*, -\dot{\psi}(0) = \int_{-\tau}^{0} \psi(-\theta) d[\eta_0(\theta)] \right\}.$$

Now, it is necessary to impose the following hypotheses:

(**A1**): The infinitesimal generator $\mathcal{A}_0$ possesses a pair of purely imaginary eigenvalues $\lambda = \pm iw$ ($w > 0$) with an algebraic multiplicity of 2 and a geometric multiplicity of 1.

(**A2**): The infinitesimal generator $\mathcal{A}_0$ has a unique eigenvalue $\lambda = 0$.

(**A3**): All eigenvalues of the infinitesimal generator $\mathcal{A}_0$ exhibit negative real parts, except for the simple zero eigenvalue and the two pairs of purely imaginary eigenvalues.

Let P denote the eigenspace of $\mathcal{A}_0$, and let P^* represent the adjoint space of P.

The space $C = C([-\tau, 0], \mathbb{R}^n)$ can be decomposed as $C = P \oplus Q$, where $Q = \{\phi \in C : \langle \psi, \phi \rangle = 0, \forall\, \psi \in P^*\}$.

Let ϕ_1, ϕ_2, and ϕ_3 denote eigenvectors of P.

Therefore, we have $\mathcal{A}_0\phi_1 = iw\phi_1$, $(\mathcal{A}_0 - iwI_n)\phi_2 = \phi_1$, and $\mathcal{A}_0\phi_3 = 0$.
By employing the definition of $\mathcal{A}_0$, we derive the following expressions:

$$\begin{cases} \dot{\phi}_1(\theta) = iw\phi_1(\theta), & -\tau \le \theta < 0, \\ \dot{\phi}_1(0) = L_0\phi_1(\theta), & \theta = 0, \end{cases} \qquad \begin{cases} \dot{\phi}_2(\theta) = iw\phi_2(\theta) + \phi_1(\theta), & -\tau \le \theta < 0, \\ iw\phi_2(0) + \phi_1(0) = L_0\phi_2(\theta), & \theta = 0 \end{cases}$$

and

$$\begin{cases} \dot{\phi}_3(\theta) = 0, & -\tau \le \theta < 0, \\ \dot{\phi}_3(0) = L_0\phi_3(\theta), & \theta = 0. \end{cases}$$

Hence, the eigenvectors ϕ_1, ϕ_2, and ϕ_3 can be written as follows: $\phi_1(\theta) = e^{iw\theta}\phi_1^0$, $\phi_2(\theta) = e^{iw\theta}(\phi_2^0 + \theta\phi_1^0)$, and $\phi_3(\theta) = \phi_3^0$, where $\phi_1^0, \phi_2^0 \in \mathbb{C}^n \setminus \{0\}$ and $\phi_3^0 \in \mathbb{R}^n \setminus \{0\}$. These vectors satisfy the following equations:

$$iw\phi_1^0 = (A + e^{-iw\tau}B)\phi_1^0, \quad (\tau e^{-iw\tau}B + I_n)\phi_1^0 = (A + e^{-iw\tau}B - iwI_n)\phi_2^0 \quad \text{and} \quad (A + B)\phi_3^0 = 0.$$

Consequently, we have $P = \text{span}\{\phi_1, \phi_2, \bar{\phi}_1, \bar{\phi}_2, \phi_3\}$.

Now, let ψ_1, ψ_2, and ψ_3 denote the eigenvectors of $\mathcal{A}_0^*$.

Hence, we have $\mathcal{A}_0^*\psi_2 = -iw\psi_2$, $(\mathcal{A}_0^* + iwI_n)\psi_1 = \psi_2$, and $\mathcal{A}_0^*\psi_3 = 0$.
Accordingly, the eigenvectors ψ_1, ψ_2, and ψ_3 can be represented as follows:
$\psi_2(s) = e^{-iws}\psi_2^0$, $\psi_1(s) = e^{-iws}(\psi_1^0 - s\psi_2^0)$ and $\psi_3(s) = \psi_3^0$, where $\psi_1^0, \psi_2^0 \in \mathbb{C}^{n*} \setminus \{0\}$ and $\psi_3^0 \in \mathbb{R}^{n*} \setminus \{0\}$ satisfying the following equations:

$$\psi_2^0(A + e^{iw\tau}B) = -iw\psi_2^0, \quad \psi_2^0(\tau e^{iw\tau}B + I_n) = \psi_1^0(A + e^{iw\tau}B + iwI_n) \quad \text{and} \quad \psi_3^0(A + B) = 0.$$

So, $P^* = \text{span}\{\bar{\psi}_1, \bar{\psi}_2, \psi_1, \psi_2, \psi_3\}$.

It is crucial to emphasize that the eigenvectors of P and P^* must fulfill the following conditions:

$$\langle \bar{\psi}_1, \phi_1 \rangle = \langle \psi_1, \bar{\phi}_1 \rangle = \langle \bar{\psi}_2, \phi_2 \rangle = \langle \psi_2, \bar{\phi}_2 \rangle = \langle \phi_3, \psi_3 \rangle = 1 \tag{2.3}$$

and

$$\langle \psi_1, \phi_1 \rangle = \langle \psi_1, \phi_2 \rangle = \langle \psi_1, \bar{\phi}_2 \rangle = \langle \psi_1, \phi_3 \rangle = 0, \tag{2.4}$$
$$\langle \bar{\psi}_1, \bar{\phi}_1 \rangle = \langle \bar{\psi}_1, \phi_2 \rangle = \langle \bar{\psi}_1, \bar{\phi}_2 \rangle = \langle \bar{\psi}_1, \phi_3 \rangle = 0, \tag{2.5}$$
$$\langle \psi_2, \phi_1 \rangle = \langle \psi_2, \bar{\phi}_1 \rangle = \langle \psi_2, \phi_2 \rangle = \langle \psi_2, \phi_3 \rangle = 0, \tag{2.6}$$
$$\langle \bar{\psi}_2, \phi_1 \rangle = \langle \bar{\psi}_2, \bar{\phi}_1 \rangle = \langle \bar{\psi}_2, \bar{\phi}_2 \rangle = \langle \bar{\psi}_2, \phi_3 \rangle = 0, \tag{2.7}$$
$$\langle \psi_3, \phi_1 \rangle = \langle \psi_3, \bar{\phi}_1 \rangle = \langle \psi_3, \phi_2 \rangle = \langle \psi_3, \bar{\phi}_2 \rangle = 0. \tag{2.8}$$

Therefore, we can appropriately select values for ϕ_1^0, ϕ_2^0, $\bar{\phi}_1^0$, $\bar{\phi}_2^0$, ϕ_3^0, $\bar{\psi}_1^0$, $\bar{\psi}_2^0$, ψ_1^0, ψ_2^0, and ψ_3^0 to ensure the satisfaction of equations (2.3), (2.4), (2.5), (2.6), (2.7) and (2.8).

Let $\Phi = (\phi_1, \phi_2, \bar{\phi}_1, \bar{\phi}_2, \phi_3)$ and $\Psi = (\bar{\psi}_1, \bar{\psi}_2, \psi_1, \psi_2, \psi_3)^T$, then $\dot{\Phi} = \Phi J$ and $\dot{\Psi} = -J\Psi$, where

$$J = \begin{pmatrix} iw & 1 & 0 & 0 & 0 \\ 0 & iw & 0 & 0 & 0 \\ 0 & 0 & -iw & 1 & 0 \\ 0 & 0 & 0 & -iw & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}.$$

3 Calculation of the normal form

In this section, our focus is on calculating the normal form up to the third order associated with the zero-double-Hopf singularity. Our approach is based on the methodology introduced by Faria and Magalhães [5,6].

We assume that hypotheses (**A1**), (**A2**), and (**A3**) are satisfied.

Let BC the enlarged space of C, which is defined as follows:

$$BC = \{\phi : [-\tau, 0] \to \mathbb{R}^n : \ \phi \text{ uniformly continuous on } [-\tau, 0) \\ \text{and with a possible jump discontinuity at } 0\}.$$

An element $\psi \in BC$ can be expressed as: $\psi = \phi + X_0 v$, with $\phi \in C$, $v \in \mathbb{R}^n$ and

$$X_0(\theta) = \begin{cases} 0, & -\tau \leq \theta < 0, \\ I_n, & \theta = 0. \end{cases}$$

Let π be the projection defined as

$$\begin{aligned} \pi : BC &\to P \\ \phi + X_0 v &\mapsto \Phi[< \Psi, \phi > + \Psi(0)v]. \end{aligned}$$

The differential system (2.1) can be reformulated as

$$\begin{cases} \dot{x} = Jx + \sum_{j\geq 2} \frac{1}{j!} f_j^1(x, y, \epsilon) \\ \dot{y} = \mathcal{A}_{Q^1} y + \sum_{j\geq 2} \frac{1}{j!} f_j^2(x, y, \epsilon) \end{cases} \tag{3.1}$$

where $f_j^1(x, y, \epsilon) = \Psi(0)\hat{F}_j(\Phi x + y, \epsilon)$ and $f_j^2(x, y, \epsilon) = (I - \pi)\hat{F}_j(\Phi x + y, \epsilon)$, $\hat{F}(\Phi x + y, \epsilon) = \sum_{j\geq 2} \frac{1}{j!} \hat{F}_j(\Phi x + y, \epsilon)$ and $z_t = \Phi x + y$, with $x \in \mathbb{C}^5$ and $y \in Q^1 = \{\phi \in Q : \dot{\phi} \in C\}$, and $\mathcal{A}_{Q^1} \subset \ker(\pi)$, $\mathcal{A}_{Q^1}\phi = \dot{\phi} + X_0(L(0)\phi - \dot{\phi}(0))$.

The normal form associated with P of the system (3.1) can be represented as follows on its center manifold:

$$\dot{x} = Jx + \frac{1}{2} g_2^1(x, 0, \epsilon) + \frac{1}{6} g_3^1(x, 0, \epsilon) + \text{h.o.t.}, \tag{3.2}$$

where g_2^1 and g_3^1 are the second and third order terms in (x, ϵ), respectively.

Let M_j be the operator defined in $V_j^8(\mathbb{C}^5 \times \ker \pi)$ with the range in the same space by $M_j(f, g) = (M_j^1 f, M_j^2 g)$, with $V_j(Y)$ is the the space of homogeneous polynomials with degree j, for a normed space Y, where

$$M_j^1 f = M_j^1 \begin{pmatrix} f_1 \\ f_2 \\ f_3 \\ f_4 \\ f_5 \end{pmatrix} = D_x f(x, \epsilon) Jx - Jf(x, \epsilon),$$

$$M_j^2 g = M_j^2 g(x, \epsilon) = D_x g(x, \epsilon) Jx - \mathcal{A}_{Q^1} g(x, \epsilon),$$

with $f(x,\epsilon) \in V_j^8(\mathbb{C}^5)$ and $(x,\epsilon) \in V_j^8(\ker \pi)$.

By using the above notation, $g_2^1(x,0,\epsilon)$ and $g_3^1(x,0,\epsilon)$ can be written as follows:

$$g_2^1(x,0,\epsilon) = \text{Proj}_{\ker(M_2^1)} f_2^1(x,0,\epsilon) = \text{Proj}_{S^1} f_2^1(x,0,\epsilon) + \mathcal{O}(|\epsilon|^2)$$
$$g_3^1(x,0,\epsilon) = \text{Proj}_{\ker(M_3^1)} \tilde{f}_3^1(x,0,\epsilon) = \text{Proj}_{S^2} \tilde{f}_3^1(x,0,\epsilon) + \mathcal{O}(|\epsilon|^2 x),$$

where

$$\tilde{f}_3^1(x,0,\epsilon) = f_3^1(x,0,\epsilon) + \frac{3}{2}[(D_x f_2^1)(x,0,\epsilon)U_2^1(x,\epsilon) + (D_y f_2^1)(x,0,\epsilon)U_2^2(x,\epsilon)]$$

U_2^1 and U_2^2 are defined by:

$$U_2^1(x,\epsilon) = (M_2^1)^{-1}\,\text{Proj}_{Im(M_2^1)} f_2^1(x,0,\epsilon) \quad \text{and} \quad (M_2^2 U_2^2(x,\epsilon)) = f_2^2(x,0,\epsilon).$$

$\ker(M_2^1)$ is spanned by

$$\epsilon_j x_2 e_1,\ x_2 x_5 e_1,\ \epsilon_j x_4 e_3,\ x_4 x_5 e_3,\ \epsilon_1\epsilon_2 e_5,\ \epsilon_1\epsilon_3 e_5,\ \epsilon_2\epsilon_3 e_5,\ \epsilon_j^2 e_5,\ \epsilon_j x_5 e_5,\ x_2 x_4 e_5, x_5^2 e_5,$$

for $j = 1,2,3$, with $(e_1,e_2,e_3,e_4,e_5)^T$ being the canonical basis of $\mathbb{R}^5$.

$\ker(M_3^1)$ is spanned by:

$$\epsilon_j^2 x_2 e_1,\ x_2^2 x_4 e_1,\ x_5^2 x_2 e_1,\ \epsilon_j x_2 x_5 e_1,\ \epsilon_1\epsilon_2 x_2 e_1,\ \epsilon_1\epsilon_3 x_2 e_1,\ \epsilon_2\epsilon_3 x_2 e_1,$$
$$\epsilon_j^2 x_4 e_3,\ x_4^2 x_2 e_3,\ x_5^2 x_4 e_3,\ \epsilon_j x_4 x_5 e_3,\ \epsilon_1\epsilon_2 x_4 e_3,\ \epsilon_1\epsilon_3 x_4 e_3,\ \epsilon_2\epsilon_3 x_4 e_3,$$
$$\epsilon_j^3 e_5,\ \epsilon_1^2\epsilon_2 e_5,\ \epsilon_1^2\epsilon_3 e_5,\ \epsilon_2^2\epsilon_1 e_5,\ \epsilon_2^2\epsilon_3 e_5,\ \epsilon_3^2\epsilon_1 e_5,\ \epsilon_3^2\epsilon_1 e_5,\ \epsilon_j^2 x_5 e_5,\ x_5^3 e_5,$$
$$\epsilon_j x_5^2 e_5,\ \epsilon_j x_2 x_4 e_5,\ \epsilon_1\epsilon_2 x_5 e_5,\ \epsilon_1\epsilon_3 x_5 e_5,\ \epsilon_2\epsilon_3 x_5 e_5,\ x_2 x_4 x_5 e_5,$$

for $j = 1,2,3$, with $(e_1,e_2,e_3,e_4,e_5)^T$ being the canonical basis of $\mathbb{R}^5$.

Consequently, S^1 and S^2 are spanned respectively by

$$\epsilon_j x_2 e_1, x_2 x_5 e_1, \epsilon_j x_4 e_3, x_4 x_5 e_3, \epsilon_j x_5 e_5, x_2 x_4 e_5, x_5^2 e_5$$

and

$$x_2^2 x_4 e_1,\ x_5^2 x_2 e_1,\ x_4^2 x_2 e_3,\ x_5^2 x_4 e_3,\ x_5^3 e_5 x_2 x_4 x_5 e_5, \quad \text{for } j = 1,2,3.$$

Write

$$\frac{1}{2}\hat{F}_2(z_t,\epsilon) = A_1\epsilon_1 z(t) + A_2\epsilon_2 z(t) + A_3\epsilon_3 z(t) + B_1\epsilon_1 z(t-\tau) + B_2\epsilon_2 z(t-\tau) + B_3\epsilon_3 z(t-\tau)$$
$$+ \sum_{i=1}^{n} E_i z_i(t) z(t-\tau) + \sum_{i=1}^{n} F_i z_i(t) z(t) + \sum_{i=1}^{n} K_i z_i(t-\tau) z(t-\tau),$$

with $A(\epsilon) = A + \epsilon_1 A_1 + \epsilon_2 A_2 + \epsilon_3 A_3 + O(|\epsilon|^2)$ and $B(\epsilon) = B + \epsilon_1 B_1 + \epsilon_2 B_2 + \epsilon_3 B_3 + O(|\epsilon|^2)$. So

$$\frac{1}{2}\hat{F}_2(\Phi x,\epsilon) = H_1\epsilon_1 x_1 + H_2\epsilon_2 x_1 + H_3\epsilon_3 x_1 + H_4\epsilon_1 x_2 + H_5\epsilon_2 x_2 + H_6\epsilon_3 x_2 + H_7\epsilon_1 x_3 + H_8\epsilon_2 x_3$$
$$+ H_9\epsilon_3 x_3 + H_{10}\epsilon_1 x_4 + H_{11}\epsilon_2 x_4 + H_{12}\epsilon_3 x_4 + H_{13}\epsilon_1 x_5 + H_{14}\epsilon_2 x_5$$
$$+ H_{15}\epsilon_3 x_5 + H_{16} x_1^2 + H_{17} x_2^2 + H_{18} x_3^2 + H_{19} x_4^2 + H_{20} x_5^2 + H_{21} x_1 x_2 + H_{22} x_1 x_3$$
$$+ H_{23} x_1 x_4 + H_{24} x_1 x_5 + H_{25} x_2 x_3 + H_{26} x_2 x_4 + H_{27} x_2 x_5 + H_{28} x_3 x_4 + H_{29} x_3 x_5$$
$$+ H_{30} x_4 x_5 + \mathcal{O}(|\epsilon|^2 |x|),$$

and

$$\frac{1}{2}\hat{F}_2(\Phi x+y,\epsilon)=\frac{1}{2}\hat{F}_2(\Phi x,\epsilon)+\sum_{j=1}^{5}\sum_{k=1}^{n}(R_{jk}x_jy_k(0)+S_{jk}x_jy_k(-\tau))$$
$$+\sum_{j=1}^{n}(T_jy_j^2(0)+Q_jy_j^2(-\tau))+\sum_{j,k=1}^{n}(P_{jk}y_j(0)y_k(-\tau))+\mathcal{O}(|\epsilon|^2|x|), \quad (3.3)$$

with A_1, A_2, A_3, B_1, B_2, B_3, E_j, F_j, K_j, R_{jk}, S_{jk}, P_{jk}, T_j and Q_j, for $1\le j,k\le n$ are coefficient matrix. The values of H_i for $1\le i\le 30$ are provided in the appendix.

Write

$$\frac{1}{6}\hat{F}_3(z_t,0)=\sum_{i,j=1}^{n}\Omega^1_{i,j}z_i(t)z_j(t)z(t)+\sum_{i,j=1}^{n}\Omega^2_{i,j}z_i(t)z_j(t-\tau)z(t-\tau)$$
$$+\sum_{i,j=1}^{n}\Omega^3_{i,j}z_i(t-\tau)z_j(t)z(t)+\sum_{i,j=1}^{n}\Omega^4_{i,j}z_i(t-\tau)z_j(t-\tau)z(t-\tau),$$

$\Omega^1_{i,j}$, $\Omega^2_{i,j}$, $\Omega^3_{i,j}$ and $\Omega^4_{i,j}$, for $1\le i,j\le n$, are coefficient matrices. So

$$\frac{1}{6}\hat{F}_3(\Phi x,0)=G_1x_1^3+G_2x_2^3+G_3x_3^3+G_4x_4^3+G_5x_5^3+G_6x_1^2x_2+G_7x_1^2x_3+G_8x_1^2x_4+G_9x_1^2x_5$$
$$+G_{10}x_2^2x_1+G_{11}x_2^2x_3+G_{12}x_2^2x_4+G_{13}x_2^2x_5+G_{14}x_3^2x_1+G_{15}x_3^2x_2+G_{16}x_3^2x_4$$
$$+G_{17}x_3^2x_5+G_{18}x_4^2x_1+G_{19}x_4^2x_2+G_{20}x_4^2x_3+G_{21}x_4^2x_5+G_{22}x_5^2x_1+G_{23}x_5^2x_2$$
$$+G_{24}x_5^2x_3+G_{25}x_5^2x_4+G_{26}x_1x_2x_3+G_{27}x_1x_2x_4+G_{28}x_1x_2x_5+G_{29}x_1x_3x_4$$
$$+G_{30}x_1x_3x_5+G_{31}x_1x_4x_5+G_{32}x_2x_3x_4+G_{33}x_2x_3x_5+G_{34}x_2x_4x_5$$
$$+G_{35}x_3x_4x_5+\mathcal{O}(|\epsilon|^2|x|).$$

The values of G_i for $i=1,2,\ldots,35$ are provided in the appendix.

We have:

$$\frac{1}{2}g_2^1(x,0,\epsilon)=\frac{1}{2}\operatorname{Proj}_{S^1}f_2^1(x,0,\epsilon)=\frac{1}{2}\operatorname{Proj}_{S^1}\Psi(0)\hat{F}_2(\Phi x,\epsilon)=\begin{pmatrix}\alpha_1x_2+\alpha_2x_2x_5\\0\\\alpha_3x_4+\alpha_4x_4x_5\\0\\\alpha_6x_5+\alpha_7x_2x_4+\alpha_8x_5^2\end{pmatrix},$$

where $\alpha_1=\bar{\psi}_1^0(H_4\epsilon_1+H_5\epsilon_2+H_6\epsilon_3)$, $\alpha_2=\bar{\psi}_1^0H_{27}$, $\alpha_3=\psi_1^0(H_{10}\epsilon_1+H_{11}\epsilon_2+H_{12}\epsilon_3)$, $\alpha_4=\psi_1^0H_{30}$, $\alpha_5=\psi_3^0(H_{13}\epsilon_1+H_{14}\epsilon_2+H_{15}\epsilon_3)$, $\alpha_6=\psi_3^0H_{26}$ and $\alpha_7=\psi_3^0H_{20}$.

Remark 3.1. We remark that $H_4=\bar{H}_{10}$, $H_5=\bar{H}_{11}$, $H_6=\bar{H}_{12}$, $H_{27}=\bar{H}_{30}$. So, $\alpha_1=\bar{\alpha}_3$ and $\alpha_2=\bar{\alpha}_4$.

Therefore,

$$\frac{1}{2}g_2^1(x,0,\epsilon)=\begin{pmatrix}\alpha_1x_2+\alpha_2x_2x_5\\0\\\bar{\alpha}_1x_4+\bar{\alpha}_2x_4x_5\\0\\\alpha_6x_5+\alpha_7x_2x_4+\alpha_8x_5^2\end{pmatrix}.$$

Now, we will calculate the term $g_3^1(x,0,\epsilon)$.

$$\begin{aligned}\frac{1}{6}g_3^1(x,0,\epsilon) &= \frac{1}{6}\operatorname{Proj}_{\ker(M_3^1)}\tilde{f}_3^1(x,0,\epsilon)\\ &= \frac{1}{6}\operatorname{Proj}_{S^2} f_3^1(x,0,0) + \frac{1}{4}\operatorname{Proj}_{S^2}[(D_x f_2^1)(x,0,0)U_2^1(x,0)\\ &\quad + (D_y f_2^1)(x,0,0)U_2^2(x,0)] + \text{h.o.t.}\end{aligned}$$

First,

$$\frac{1}{6}\operatorname{Proj}_{S^2} f_3^1(x,0,0) = \frac{1}{6}\operatorname{Proj}_{S^2}\Psi(0)\hat{F}_3(\Phi x,0) = \begin{pmatrix}\beta_1 x_2^2 x_4 + \beta_2 x_2 x_5^2\\ 0\\ \beta_3 x_4^2 x_2 + \beta_4 x_4 x_5^2\\ 0\\ \beta_5 x_5^3 + \beta_6 x_2 x_4 x_5\end{pmatrix},$$

where $\beta_1 = \bar{\psi}_1^0 G_{12}$, $\beta_2 = \bar{\psi}_1^0 G_{23}$, $\beta_3 = \psi_1^0 G_{19}$, $\beta_4 = \psi_1^0 G_{25}$, $\beta_5 = \psi_3^0 G_5$ and $\beta_6 = \psi_3^0 G_{34}$.
Since $f_2(x,0,0) = \Psi(0)\hat{F}_2(\Phi x,0)$, then:

$$U_2^1(x,0) = U_2^1(x,\epsilon)\mid_{\epsilon=0} = (M_2^1)^{-1}\operatorname{Proj}_{Im(M_2^1)} f_2^1(x,0,0).$$

Therefore,

$$\frac{1}{4}\operatorname{Proj}_{S^2}[(D_x f_2^1)(x,0,0)U_2^1(x,0)] = \begin{pmatrix}\gamma_1 x_2^2 x_4 + \gamma_2 x_2 x_5^2\\ 0\\ \gamma_3 x_4^2 x_2 + \gamma_4 x_4 x_5^2\\ 0\\ \gamma_5 x_5^3 + \gamma_6 x_2 x_4 x_5\end{pmatrix},$$

where

$$\begin{aligned}\gamma_1 = \frac{1}{2}\bar{\psi}_1^0 H_{21}&\left[-\bar{\psi}_1^0\left(\frac{2}{(iw)^3}H_{22} + \frac{1}{(iw)^2}H_{23} + \frac{1}{(iw)^2}H_{25} + \frac{1}{iw}H_{26}\right)\right.\\ &\left.\quad +\bar{\psi}_2^0\left(\frac{5}{(iw)^4}H_{22} + \frac{2}{(iw)^3}H_{23} + \frac{1}{(iw)^3}H_{25} + \frac{1}{(iw)^2}H_{26}\right)\right]\\ &+ \frac{1}{2}\bar{\psi}_1^0 H_{23}\left[\bar{\psi}_1^0\left(\frac{2}{(iw)^3}H_{16} + \frac{1}{iw}H_{17} - \frac{1}{(iw)^2}H_{21}\right)\right.\\ &\left.\quad + \bar{\psi}_2^0\left(\frac{4}{(iw)^4}H_{16} + \frac{1}{(iw)^2}H_{17} - \frac{1}{(iw)^3}H_{21}\right)\right]\\ &- \bar{\psi}_1^0 H_{17}\bar{\psi}_2^0\left(\frac{1}{(iw)^3}H_{22} + \frac{1}{(iw)^2}H_{23} + \frac{1}{iw}H_{26}\right) + \frac{1}{2iw}\bar{\psi}_1^0 H_{26}\bar{\psi}_2^0 H_{17}\\ &+ \frac{1}{2}\bar{\psi}_1^0 H_{25}\left[\psi_1^0\left(\frac{2}{(iw)^3}H_{22} - \frac{1}{(iw)^2}H_{23} - \frac{1}{(iw)^2}H_{25} + \frac{1}{iw}H_{26}\right)\right.\\ &\left.\quad + \psi_2^0\left(\frac{4}{(iw)^4}H_{22} - \frac{2}{(iw)^3}H_{23} - \frac{1}{(iw)^3}H_{25} + \frac{1}{(iw)^2}H_{26}\right)\right]\\ &+ \frac{1}{2}\bar{\psi}_1^0 H_{28}\left[\psi_1^0\left(\frac{2}{(iw)^3}H_{16} + \frac{1}{iw}H_{17} - \frac{1}{(iw)^2}H_{21}\right)\right.\\ &\left.\quad + \psi_2^0\left(\frac{6}{(iw)^4}H_{16} + \frac{1}{(3iw)^2}H_{17} - \frac{2}{(3iw)^3}H_{21}\right)\right]\\ &+ \bar{\psi}_1^0 H_{19}\psi_2^0\left(\frac{2}{(3iw)^3}H_{16} + \frac{1}{3iw}H_{17} - \frac{2}{(3iw)^2}H_{21}\right)\end{aligned}$$

$$

&+\psi_2^0\Big(\frac{4}{(iw)^4}H_{22}-\frac{2}{(iw)^3}H_{23}-\frac{2}{(iw)^3}H_{25}+\frac{1}{(iw)^2}H_{26}\Big)\Big]\\
&+\psi_3^0 H_{19}\psi_2^0\Big(\frac{1}{2iw}H_{27}-\frac{1}{(2iw)^2}H_{24}\Big)\\
&+\frac{1}{2}\psi_3^0 H_{30}\psi_2^0\Big(\frac{1}{(iw)^3}H_{22}-\frac{1}{(iw)^2}H_{23}-\frac{1}{(iw)^2}H_{25}+\frac{1}{iw}H_{26}\Big)
\end{aligned}
$$

To compute $\mathrm{Proj}_{S^2} D_y f_2^1(x,0,\epsilon)U_2^2(x,0)$, we define $h=h(x)(\theta)=U_2^2$ and write

$$
\begin{aligned}
h(\theta)=\begin{pmatrix} h^{(1)}(\theta)\\ h^{(2)}(\theta)\\ \vdots\\ h^{(n)}(\theta)\end{pmatrix} =& h_{20000}x_1^2+h_{02000}x_2^2+h_{00200}x_3^2+h_{00020}x_4^2+h_{00002}x_5^2+h_{11000}x_1x_2\\
&+h_{10100}x_1x_3+h_{10010}x_1x_4+h_{10001}x_1x_5+h_{01100}x_2x_3+h_{01010}x_2x_4\\
&+h_{01001}x_2x_5+h_{00110}x_3x_4+h_{00101}x_3x_5+h_{00011}x_4x_5
\end{aligned}
$$

$$= \begin{pmatrix} h^{(1)}_{20000}x_1^2 + h^{(1)}_{02000}x_2^2 + h^{(1)}_{00200}x_3^2 + \cdots + h^{(1)}_{00011}x_4x_5 \\ h^{(2)}_{20000}x_1^2 + h^{(2)}_{02000}x_2^2 + h^{(2)}_{00200}x_3^2 + \cdots + h^{(2)}_{00011}x_4x_5 \\ \vdots \\ h^{(n)}_{20000}x_1^2 + h^{(n)}_{02000}x_2^2 + h^{(n)}_{00200}x_3^2 + \cdots + h^{(n)}_{00011}x_4x_5 \end{pmatrix}$$

where h_{20000},h_{02000}, h_{00200}, h_{00020}, h_{00002}, h_{11000}, h_{10100}, h_{10010}, h_{10001}, h_{01100}, h_{01010}, h_{01001}, h_{00110}, h_{00101}, $h_{00011} \in Q^1$.

The coefficients of h can be determined by solving the equation $(M_2^2 h)(x) = f_2^2(x, 0, 0)$, which can also be written as:

$$D_x hJx - \mathcal{A}_{Q^1}(h) = (I - \pi)\hat{F}_2(\Phi x, 0).$$

Next, by utilizing the definition of $\mathcal{A}_{Q^1}$ and the projection π, we derive the following system of equations:

$$\begin{cases} \dot{h} - D_x hJx = \Phi(\theta)\Psi(0)\hat{F}_2(\Phi x, 0), \\ \dot{h}(0) - Lh = \hat{F}_2(\Phi x, 0). \end{cases} \tag{3.4}$$

Here, $\dot{h}$ denotes the derivative of h with respect to θ. We have:

$$\begin{aligned} \hat{F}_2(\Phi x, 0) = 2(&H_{16}x_1^2 + H_{17}x_2^2 + H_{18}x_3^2 + H_{19}x_4^2 + H_{20}x_5^2 + H_{21}x_1x_2 \\ &+ H_{22}x_1x_3 + H_{23}x_1x_4 + H_{24}x_1x_5 + H_{25}x_2x_3 + H_{26}x_2x_4 \\ &+ H_{27}x_2x_5 + H_{28}x_3x_4 + H_{29}x_3x_5 + H_{30}x_4x_5). \end{aligned}$$

By comparing the coefficients of each monomial, we establish the following relationships: $h_{20000} = \bar{h}_{00200}$, $h_{02000} = \bar{h}_{00020}$, $h_{00110} = \bar{h}_{11000}$, $h_{00101} = \bar{h}_{10001}$, $h_{01001} = \bar{h}_{00011}$ and $h_{10010} = \bar{h}_{01100}$. By substituting (3.4) into the expressions, we find that the coefficients h_{20000}, h_{00200}, h_{10100}, h_{10010}, h_{10001}, h_{00101}, h_{00002}, h_{11000} and h_{00110} satisfy the following equations:

$$\begin{cases} \dot{h}_{20000} - 2iwh_{20000} = 2\Phi(\theta)\Psi(0)H_{16}, \\ \dot{h}_{20000}(0) - L(h_{20000}) = 2H_{16}, \end{cases} \tag{3.5}$$

$$\begin{cases} \dot{h}_{02000} - (h_{11000} + 2iwh_{02000}) = 2\Phi(\theta)\Psi(0)H_{17}, \\ \dot{h}_{02000}(0) - L(h_{02000}) = 2H_{17}, \end{cases} \tag{3.6}$$

$$\begin{cases} \dot{h}_{00002} = 2\Phi(\theta)\Psi(0)H_{20}, \\ \dot{h}_{00002}(0) - L(h_{00002}) = 2H_{20}, \end{cases} \tag{3.7}$$

$$\begin{cases} \dot{h}_{11000} - 2(h_{20000} + iwh_{11000}) = 2\Phi(\theta)\Psi(0)H_{21}, \\ \dot{h}_{11000}(0) - L(h_{11000}) = 2H_{21}, \end{cases} \tag{3.8}$$

$$\begin{cases} \dot{h}_{10100} = 2\Phi(\theta)\Psi(0)H_{22}, \\ \dot{h}_{10100}(0) - L(h_{10100}) = 2H_{22}, \end{cases} \tag{3.9}$$

$$\begin{cases} \dot{h}_{10010} - h_{10100} = 2\Phi(\theta)\Psi(0)H_{23}, \\ \dot{h}_{10010}(0) - L(h_{10010}) = 2H_{23}, \end{cases} \tag{3.10}$$

$$\begin{cases} \dot{h}_{10001} - iwh_{10001} = 2\Phi(\theta)\Psi(0)H_{24}, \\ \dot{h}_{10001}(0) - L(h_{10001}) = 2H_{24}, \end{cases} \tag{3.11}$$

$$\begin{cases} \dot{h}_{01010} - (h_{10010} + h_{01100}) = 2\Phi(\theta)\Psi(0)H_{26}, \\ \dot{h}_{00101}(0) - L(h_{00101}) = 2H_{26}, \end{cases} \tag{3.12}$$

$$\begin{cases} \dot{h}_{01001} - (h_{10001} + iwh_{01001}) = 2\Phi(\theta)\Psi(0)H_{27}, \\ \dot{h}_{00110}(0) - L(h_{00110}) = 2H_{27}. \end{cases} \tag{3.13}$$

By utilizing equations (3.3), we deduce that

$$\frac{1}{4}\,\mathrm{Proj}_{S^2}\, D_y f_2^1 \,|_{y=0,\epsilon=0}\, U_2^2 = \begin{pmatrix} \sigma_1 x_2^2 x_4 + \sigma_2 x_2 x_5^2, \\ 0 \\ \sigma_3 x_4^2 x_2 + \sigma_4 x_4 x_5^2, \\ 0 \\ \sigma_5 x_5^3 + \sigma_6 x_2 x_4 x_5 \end{pmatrix}$$

where

$$\begin{aligned}
\sigma_1 &= \frac{1}{2}\bar{\psi}_1(0)\sum_{j=1}^{n}(R_{2j}h^{(j)}_{01010}(0) + S_{2j}h^{(j)}_{01010}(-\tau) + R_{4j}h^{(j)}_{02000}(0) + S_{4j}h^{(j)}_{02000}(-\tau)),\\
\sigma_2 &= \frac{1}{2}\bar{\psi}_1(0)\sum_{j=1}^{n}(R_{2j}h^{(j)}_{00002}(0) + S_{2j}h^{(j)}_{00002}(-\tau) + R_{5j}h^{(j)}_{01001}(0) + S_{5j}h^{(j)}_{01001}(-\tau)),\\
\sigma_3 &= \frac{1}{2}\psi_1(0)\sum_{j=1}^{n}(R_{2j}h^{(j)}_{00020}(0) + S_{2j}h^{(j)}_{00020}(-\tau) + R_{4j}h^{(j)}_{01010}(0) + S_{4j}h^{(j)}_{01010}(-\tau)),\\
\sigma_4 &= \frac{1}{2}\psi_1(0)\sum_{j=1}^{n}(R_{4j}h^{(j)}_{00002}(0) + S_{4j}h^{(j)}_{00002}(-\tau) + R_{5j}h^{(j)}_{00011}(0) + S_{5j}h^{(j)}_{00011}(-\tau)),\\
\sigma_5 &= \frac{1}{2}\psi_3(0)\sum_{j=1}^{n}(R_{5j}h^{(j)}_{00002}(0) + S_{5j}h^{(j)}_{00002}(-\tau)),\\
\sigma_6 &= \frac{1}{2}\psi_3(0)\sum_{j=1}^{n}(R_{2j}h^{(j)}_{00011}(0) + S_{2j}h^{(j)}_{00011}(-\tau) + R_{5j}h^{(j)}_{01010}(0) + S_{5j}h^{(j)}_{01010}(-\tau)\\
&\quad + R_{4j}h^{(j)}_{01001}(0) + S_{4j}h^{(j)}_{01001}(-\tau)).
\end{aligned}$$

Remark 3.2. $\sigma_1 = \bar{\sigma}_3$ and $\sigma_2 = \bar{\sigma}_4$.

We can explicitly determine the expressions of h_{20000}, h_{02000}, h_{00002}, h_{11000}, h_{10100}, h_{10010}, h_{10001}, h_{01010} and h_{01001} in the same way detailed in [1,11].

By consolidating all the obtained results, we reach the following conclusion:

$$\frac{1}{6}g_3^1(x,0,\epsilon) = \begin{pmatrix} (\beta_1+\gamma_1+\sigma_1)x_2^2x_4 + (\beta_2+\gamma_2+\sigma_2)x_2x_5^2 \\ 0 \\ (\beta_3+\gamma_3+\sigma_3)x_4^2x_2 + (\beta_4+\gamma_4+\sigma_4)x_4x_5^2 \\ 0 \\ (\beta_5+\gamma_5+\sigma_5)x_5^3 + (\beta_6+\gamma_6+\sigma_6)x_2x_4x_5 \end{pmatrix}.$$

Consequently, the system described in equation (3.2) can be reformulated as:

$$\begin{cases} \dot{x}_1 = iwx_1 + x_2 + \alpha_1 x_2 + \alpha_2 x_2 x_5 + (\beta_1+\gamma_1+\sigma_1)x_2^2x_4 + (\beta_2+\gamma_2+\sigma_2)x_2x_5^2, \\ \dot{x}_2 = iwx_2, \\ \dot{x}_3 = -iwx_3 + x_4 + \alpha_3 x_4 + \alpha_4 x_4 x_5 + (\beta_3+\gamma_3+\sigma_3)x_4^2x_2 + (\beta_4+\gamma_4+\sigma_4)x_4x_5^2, \\ \dot{x}_4 = -iwx_4, \\ \dot{x}_5 = \alpha_6 x_5 + \alpha_7 x_2 x_4 + \alpha_8 x_5^2 + (\beta_5+\gamma_5+\sigma_5)x_5^3 + (\beta_6+\gamma_6+\sigma_6)x_2x_4x_5. \end{cases} \tag{3.14}$$

Given that $x_1 = \bar{x}_3$ and $x_2 = \bar{x}_4$, the system (3.14) can be expressed equivalently as:

$$\begin{cases} \dot{x}_1 = iwx_1 + x_2 + \alpha_1 x_2 + \alpha_2 x_2 x_5 + (\beta_1 + \gamma_1 + \sigma_1) x_2^2 x_4 + (\beta_2 + \gamma_2 + \sigma_2) x_2 x_5^2 \\ \dot{x}_2 = iwx_2, \\ \dot{x}_3 = -iwx_3 + x_4 + \bar{\alpha}_1 x_4 + \bar{\alpha}_2 x_4 x_5 + (\bar{\beta}_1 + \bar{\gamma}_1 + \bar{\sigma}_1) x_4^2 x_2 + (\bar{\beta}_2 + \bar{\gamma}_2 + \bar{\sigma}_2) x_4 x_5^2, \\ \dot{x}_4 = -iwx_4, \\ \dot{x}_5 = \alpha_6 x_5 + \alpha_7 x_2 x_4 + \alpha_8 x_5^2 + (\beta_5 + \gamma_5 + \sigma_5) x_5^3 + (\beta_6 + \gamma_6 + \sigma_6) x_2 x_4 x_5. \end{cases} \tag{3.15}$$

Theorem 3.3. *Assuming the validity of assumptions (**A1**), (**A2**), and (**A3**), the retarded differential system (1.1) can be equivalently represented by the reduced system (3.15).*

4 Conclusion

Despite the extensive literature on various types of singularities in retarded differential equations (RDDs), such as the Bogdanov–Takens singularity, Hopf singularity, zero-Hopf singularity, saddle-node singularity, and double-Hopf singularity, the zero-double-Hopf singularity in RDDs remains relatively unexplored. This paper addresses this research gap by providing explicit conditions for the occurrence of the zero-double-Hopf singularity with 1 : 1 resonance in general RDDs. By employing the normal form theory proposed by Faria and Magalhães, we transform the considered RDDs into a system of three ordinary differential equations. Detailed calculations and formulas are presented, facilitating their implementation in symbolic computation systems.

However, an important question arises: How can we analyze the bifurcation diagram associated with this singularity to examine and understand the dynamics of various systems modeled by delay differential equations? Answering this question will be the focus of our future research endeavors.

A Appendix

In this part, we will define the notations:

$$\begin{aligned}
H_1 &= A_1\phi_1(0) + B_1\phi_1(-\tau), H_2 = A_2\phi_1(0) + B_2\phi_1(-\tau), H_3 = A_3\phi_1(0) + B_3\phi_1(-\tau),\\
H_4 &= A_1\phi_2(0) + B_1\phi_2(-\tau), H_5 = A_2\phi_2(0) + B_2\phi_2(-\tau), H_6 = A_3\phi_2(0) + B_3\phi_2(-\tau),\\

Abstract. Optimization problems are omnipresent in the mathematical modeling of real world systems and cover a very extensive range of applications becoming apparent in all branches of Economics, Finance, Materials Science, Astronomy, Physics, Structural and Molecular Biology, Engineering, Computer Science, and Medicine. In this paper, we aim to delve deeper into the multiplicity findings concerning a specific class of quasilinear periodic boundary value problems. In fact, as an optimization problem, we look for the critical points of the energy functional related to the problem. Utilizing a corollary derived from Bonanno's local minimum theorem, we investigate the existence of a one solution under certain algebraic conditions on the nonlinear term. Additionally, we explore conditions that lead to the existence of two solutions, incorporating the classical Ambrosetti-Rabinowitz (AR) condition alongside algebraic criteria. Moreover, by employing two critical point theorems one by Averna and Bonanno, and another by Bonanno, we establish the existence of two and three solutions in a particular scenario. To illustrate our findings, we provide an example.

Keywords: multiple solutions, quasilinear periodic, critical point, variational methods.

1 Introduction

The target of global optimization is to find the best solution of decision models, in presence of the multiple local solutions. Optimization plays an ever-increasing role in mathematics,

✉Corresponding author. Emails: sh.heidarkhani@razi.ac.ir and s.heidarkhani@unirc.it

economics, engineering, health sciences, management and life sciences. Many optimization problems have existence in the real world including space planning, networking, logistic management, financial planning, and risk management. The objective of this paper is to ascertain the existence of solutions for the following quasilinear periodic boundary value problem

$$\begin{cases} -p(u')u'' + \zeta(x)u = \lambda f(x,u(x)) + \mu g(x,u(x)), & \text{a.e. } x \in [0,1], \\ u(1) - u(0) = u'(1) - u'(0) = 0 \end{cases} \tag{$P^{f,g}_{\lambda,\mu}$}$$

where $f, g : [0,1] \times \mathbb{R} \to \mathbb{R}$ are L^1-Carathéodory functions, λ is a positive parameter and $\mu \geq 0$. We need the following assumptions:

(Q_1) $p : \mathbb{R} \to (0,\infty)$ is a continuous and nondecreasing on $[0,\infty)$, there exist two positive numbers $M \geq m$ such that

$$m \leq p(x) \leq M, \qquad \forall x \in \mathbb{R} \tag{1.1}$$

(Q_2) $\zeta \in C([0,1])$ and there exist $\zeta_1 \geq \zeta_0 > 0$ such that

$$\zeta_0 \leq \zeta(x) \leq \zeta_1, \qquad \forall x \in [0,1]. \tag{1.2}$$

Exactly, as an optimization problem, we look for the critical points of the energy functional related to the problem which are the solutions of the problem.

In recent years, various fixed-point theorems, critical points, and variational methods have been effectively employed to explore the existence of solutions for quasilinear periodic boundary value problems. References such as [2,9,14,17,20,21,23,26,27] and others have extensively discussed this topic. For instance, Matzakos and Papageorgiou in [21] combined the variational method with techniques involving upper and lower solutions to establish the existence of periodic solutions for quasilinear differential equations. Similarly, Papageorgiou and Papalini in [23] utilized variational arguments, methods from the theory of nonlinear operators of monotone type, and upper and lower solution techniques to demonstrate the existence of at least two nontrivial solutions, one positive and the other negative for the following quasilinear periodic problem

$$\begin{cases} -(|u'(x)|^{p-2}u'(x))' = f(x,u(x)) = 0, & x \in [0,b], \\ u(0) = u(b),\ u'(0) = u'(b),\ 2 \leq p < \infty \end{cases}$$

where $f : T \times \mathbb{R} \to \mathbb{R}$ is a function. In [14], the existence of at least three classical solutions for a Dirichlet quasilinear elliptic system was established through the application of variational methods and critical point theory. Similarly, in [17], the utilization of a recent three critical points theorem by Bonanno and Marano led to the confirmation of at least three solutions for quasilinear second order differential equation on a compact interval $[a,b] \subset \mathbb{R}$

$$\begin{cases} -u'' = (\lambda f(x,u) + g(u))h'(u), & \text{in } (a,b), \\ u(a) - u(b) = 0 \end{cases}$$

where $f : [a,b] \times \mathbb{R} \to \mathbb{R}$ is an L^1-Carathéodory function, $g : \mathbb{R} \to \mathbb{R}$ is a Lipschitz continuous function, was discussed. Shen and Liu, in [26], utilized the symmetric mountain pass theorem and genus properties in critical point theory to explore the existence of infinitely many solutions for second-order quasilinear periodic boundary value problems with impulsive effects.

Meanwhile, Wang et al., in [27], investigated the existence of at least three periodic solutions for the problem ($P^{f,g}_{\lambda,\mu}$) by employing appropriate hypotheses and a three critical points theorem by Ricceri.

Additionally, in [15], variational methods and critical point theorems for smooth functionals defined on reflexive Banach spaces were used to discuss the existence of at least three solutions to an impulsive effects version of the problem ($P^{f,g}_{\lambda,\mu}$). Furthermore, in [19], variational methods were employed to discuss the existence of at least three weak solutions for the problem ($P^{f,g}_{\lambda,\mu}$) in the case $\mu = 0$. In [12], the investigation focused on the existence of infinitely many classical solutions for an impulsive effects version of the problem ($P^{f,g}_{\lambda,\mu}$) in the case $\mu = 0$, utilizing critical point theory. In [13], by using variational methods, the existence of non-zero solutions and the existence of multiple solutions for positive parameter values for the problem ($P^{f,g}_{\lambda,\mu}$) in the case $\mu = 0$, was discussed. Lastly, in [18], the existence of at least one weak solution and infinitely many weak solutions for the problem ($P^{f,g}_{\lambda,\mu}$) in the case $\mu = 0$ was studied based on variational methods.

Our approach employs variational methods, with the primary tools being four local minimum theorems for differentiable functionals. Specifically, we utilize a corollary of Bonanno's local minimum theorem to establish the existence of one solution under certain algebraic conditions on the nonlinear terms, and two solutions for the problem under algebraic conditions alongside the classical Ambrosetti–Rabinowitz (AR) condition on the nonlinear terms (refer to [3]). Furthermore, by leveraging two critical point theorems, one by Averna and Bonanno, and another by Bonanno, we ensure the existence of two and three solutions for the problem ($P^{f,g}_{\lambda,\mu}$) in the case $\mu = 0$.

In comparison to previous findings, we introduce novel assumptions to establish the existence of solutions for the problem ($P^{f,g}_{\lambda,\mu}$), thus extending recent related works.

Here, we present two specific cases of our main results focusing on scenarios with a single impulse.

Theorem 1.1. *Let $\psi : \mathbb{R} \to \mathbb{R}$ be a continuous function. Assume that there exist two positive constants γ and η with the property*

$$\sqrt{\frac{2h(2\eta) + 2h(-2\eta) + 8\zeta_1\eta^2}{\min\{m, \zeta_0\}}} < \gamma$$

and

- *there exist $\nu > 2$ and $R > 0$ such that*

$$0 < \nu \int_0^{\xi} \psi(s)\mathrm{d}s \le \xi\psi(\xi)$$

  for all $|\xi| \ge R$.

Then, for each

$$\lambda \in \left(0, \frac{\min\{m, \zeta_0\}\gamma^2}{8\int_0^{\gamma} \psi(s)\mathrm{d}s}\right)$$

and for every function $g : [0,1] \times \mathbb{R} \to \mathbb{R}$ satisfying the following condition:

- *there exist $\nu > 2$ and $R > 0$ such that*

$$0 < \nu \int_0^{\xi} g(x, s)\mathrm{d}s \le \xi g(x, \xi)$$

  for all $|\xi| \ge R$ and for all $x \in [0, 1]$, *there exists $\delta_\lambda > 0$, for each $\mu \in [0, \delta_\lambda[$, the problem*

$$\begin{cases} -p(u')u'' + \zeta(x)u = \lambda e^{-t}\psi(x) + \mu g(x, u(x)), & a.e.\ x \in [0,1], \\ u(1) - u(0) = u'(1) - u'(0) = 0 \end{cases} \tag{1.3}$$

admits at least two solutions u_1 and u_2 in

$$\{u : [0,1] \to \mathbb{R} : u \text{ is absolutely continuous},\ u(1) = u(0),\ u' \in L^2([0,1]\}$$

such that

$$\max_{x\in[0,1]} |u_1(x)| < \gamma.$$

Theorem 1.2. *Assume that $\psi : \mathbb{R} \to \mathbb{R}$ is a nonnegative and continuous function. Moreover, assume that*

$$\lim_{\xi\to 0^+} \frac{\psi(\xi)}{\xi} = \lim_{|\xi|\to\infty} \frac{\psi(\xi)}{|\xi|} = 0$$

and there exists a positive constant $\bar{\eta}$ such that $\int_0^{\bar{\eta}} \psi(s)ds > 0$. Then, for each $\lambda > \lambda^*$ where

$$\lambda^* = \frac{1}{4\int_{\frac{1}{4}}^{\frac{3}{4}} \theta(x)dx} \inf_{\bar{\eta}>0} \frac{h(2\bar{\eta}) + h(-2\bar{\eta}) + 4\zeta_1\bar{\eta}^2}{\int_0^{\bar{\eta}} \psi(s)ds},$$

the problem (1.3) in the case $\mu = 0$, admits at least one nonnegative and one non zero solution in

$$\{u : [0,1] \to \mathbb{R} : u \text{ is absolutely continuous},\ u(1) = u(0),\ u' \in L^2([0,1]\}.$$

The structure of the paper is outlined as follows:

Section 2 presents our fundamental theorems and revisits relevant definitions. Section 3 discusses and proves the existence of one solution for the problem $(P^{f,g}_{\lambda,\mu})$. Section 4 addresses the existence of two solutions for the problem $(P^{f,g}_{\lambda,\mu})$. Section 5 introduces a new multiplicity result aimed at obtaining at least two and three solutions for the problem $(P^{f,g}_{\lambda,\mu})$, specifically in the case $\mu = 0$.

2 Preliminaries

The main tools utilized to prove our results in Sections 3, 4, and 5 are the following theorems.

For the following notations and results, we refer the reader to [22, 24]. Let X be a real Banach space. We say that a continuously Gâteaux differentiable functional $J : X \to \mathbb{R}$ satisfies the *Palais–Smale condition* (abbreviated as (PS)-condition) if any sequence $\{u_n\}$ such that $\{J(u_n)\}$ is bounded and $\lim_{n\to\infty} \|J'(u_n)\|_{X^*} = 0$ has a convergent subsequence.

Let $\Phi, \Psi : X \to \mathbb{R}$ be two continuously Gâteaux differentiable functions. Set

$$J = \Phi - \Psi,$$

and fix $r_1, r_2 \in [-\infty, \infty]$ with $r_1 < r_2$. We say that J satisfies the *Palais–Smale condition cut off lower at r_1 and upper at r_2*(in short $^{[r_1]}(\text{PS})^{[r_2]}$-condition) if any sequence $\{u_n\}$ such that $\{J(u_n)\}$ is bounded, $\lim_{n\to\infty} \|J'(u_n)\|_{X^*} = 0$ and $r_1 < \Phi(u_n) < r_2$ for all $n \in \mathbb{N}$, has a convergent subsequence.

Clearly, if $r_1 = -\infty$ and $r_2 = \infty$ it coincides with the classical (PS)-condition. Moreover, if $r_1 = -\infty$ and $r_2 \in \mathbb{R}$ it is denoted by $(\text{PS})^{[r_2]}$, while if $r_1 \in \mathbb{R}$ and $r_2 = \infty$ it is denoted by

${}^{[r_1]}$(PS). Indeed, if Φ and Ψ be two continuously Gâteaux differentiable functionals defined on a real Banach space X and fix $r \in \mathbb{R}$. The functional $I = \Phi - \Psi$ is said to verify the Palais–Smale condition cut off upper at r (in short (PS)$^{[r]}$) if any sequence $\{u_n\}_{n\in\mathbb{N}}$ in X such that $\{I(u_n)\}$ is bounded, $\lim_{n\to\infty} \|I'(u_n)\|_{X^*} = 0$ and $\Phi(u_n) < r$ for all $n \in \mathbb{N}$, has a convergent subsequence. Furthermore, if J satisfies ${}^{[r_1]}$(PS)$^{[r_2]}$-condition, then it satisfies ${}^{[\varrho_1]}$(PS)$^{[\varrho_2]}$-condition for all $\varrho_1, \varrho_2 \in [-\infty, \infty]$ such that $r_1 \le \varrho_1 < \varrho_2 \le r_2$.

In particular, we deduce that if J satisfies the classical (PS)-condition, then it satisfies ${}^{[\varrho_1]}$(PS)$^{[\varrho_2]}$-condition for all $\varrho_1, \varrho_2 \in [-\infty, \infty]$ with $\varrho_1 < \varrho_2$.

In the proof of our main results, we will apply the following four theorems.

Theorem 2.1 ([7, Theorem 2.3]). *Let X be a real Banach space and let $\Phi, \Psi : X \to \mathbb{R}$ be two continuously Gâteaux differentiable functions such that $\inf_{u\in X} \Phi(u) = \Phi(0) = \Psi(0) = 0$. Assume that there exist $r > 0$ and $\bar{u} \in X$, with $0 < \Phi(\bar{u}) < r$, such that:*

(a_1) $\frac{\sup_{\Phi(u)\le r} \Psi(u)}{r} < \frac{\Psi(\bar{u})}{\Phi(\bar{u})}$,

(a_2) *for each $\lambda \in \left(\frac{\Phi(\bar{u})}{\Psi(\bar{u})}, \frac{r}{\sup_{\Phi(u)\le r} \Psi(u)}\right)$, the functional $I_\lambda = \Phi - \lambda\Psi$ satisfies (PS)$^{[r]}$-condition.*

Then, for each

$$\lambda \in \Lambda_r = \left(\frac{\Phi(\bar{u})}{\Psi(\bar{u})}, \frac{r}{\sup_{\Phi(u)\le r} \Psi(u)} \right),$$

there exists $u_{0,\lambda} \in \Phi^{-1}(0, r)$ such that $I_\lambda(u_{0,\lambda}) \equiv \vartheta_{X^*}$ and $I_\lambda(u_{0,\lambda}) \le I_\lambda(u)$ for all $u \in \Phi^{-1}(0, r)$.

Theorem 2.2 ([7, Theorem 3.2]). *Let X be a real Banach space, $\Phi, \Psi : X \to \mathbb{R}$ be two continuously Gâteaux differentiable functionals such that Φ is bounded from below and $\Phi(0) = \Psi(0) = 0$. Fix $r > 0$ and assume that, for each*

$$\lambda \in \left(0, \frac{r}{\sup_{u\in\Phi^{-1}(-\infty,r)} \Psi(u)} \right),$$

the functional $I_\lambda = \Phi - \lambda\Psi$ satisfies (PS)-condition and it is unbounded from below. Then, for each

$$\lambda \in \left(0, \frac{r}{\sup_{u\in\Phi^{-1}(-\infty,r)} \Psi(u)} \right),$$

the functional I_λ admits two distinct critical points.

Theorem 2.3 ([4, Theorem A]). *Let X be a reflexive real Banach space, $\Phi : X \to \mathbb{R}$ a continuously Gâteaux differentiable and sequentially weakly lower semicontinuous functional whose Gâteaux derivative admits a continuous inverse on X^*, and $\Psi : X \to \mathbb{R}$ a continuously Gâteaux differentiable functional whose Gâteaux derivative is compact. Assume that:*

(b_1) $\lim_{\|u\|\to\infty}(\Phi(u) + \lambda\Psi(u)) = \infty$ *for all $\lambda \in [0, \infty)$;*

(b_2) *there is $r \in \mathbb{R}$ such that*

$$\inf_X \Phi < r,$$

and

$$\varphi_1(r) < \varphi_2(r)$$

where

$$\varphi_1(r) = \inf_{u\in\Phi^{-1}(-\infty,r)} \frac{\Psi(u) - \inf_{\overline{\Phi^{-1}(-\infty,r)}^w} \Psi}{r - \Phi(u)},$$

$$\varphi_2(r) = \inf_{u\in\Phi^{-1}(-\infty,r)} \sup_{v\in\Phi^{-1}[r,\infty)} \frac{\Psi(u) - \Psi(v)}{\Phi(v) - \Phi(u)},$$

and $\overline{\Phi^{-1}(-\infty,r)}^w$ *is the closure of* $\Phi^{-1}(-\infty,r)$ *in the weak topology.*

Then, for each $\lambda \in \left(\frac{1}{\varphi_2(r)}, \frac{1}{\varphi_1(r)}\right)$, *the functional* $\Phi + \lambda\Psi$ *has at least three critical points in* X.

Note that $\varphi_1(r)$ in Theorem 2.3 could be 0. In this and similar cases, here and in the sequel, we agree to read $\frac{1}{0}$ as ∞.

We also use the following two critical points theorem.

Theorem 2.4 ([6, Theorem 1.1]). *Let* X *be a reflexive real Banach space, and let* $\Phi, \Psi : X \to \mathbb{R}$ *be two sequentially weakly lower semicontinuous and Gâteaux differentiable functions. Assume that* Φ *is (strongly) continuous and satisfies*

$$\lim_{\|u\|\to\infty} \Phi(u) = \infty.$$

Assume also that there exist two constants r_1 *and* r_2 *such that*

(c_1) $\inf_X \Phi < r_1 < r_2$;

(c_2) $\varphi_1(r_1) < \varphi_2^*(r_1, r_2)$;

(c_3) $\varphi_1(r_2) < \varphi_2^*(r_1, r_2)$, *where* φ_1 *is defined as in Theorem 2.3 and*

$$\varphi_2^*(r_1, r_2) = \inf_{u\in\Phi^{-1}(-\infty,r_1)} \sup_{v\in\Phi^{-1}[r_1,r_2)} \frac{\Psi(u) - \Psi(v)}{\Phi(v) - \Phi(u)}.$$

Then, for each

$$\lambda \in \left(\frac{1}{\varphi_2^*(r_1, r_2)}, \min\left\{ \frac{1}{\varphi_1(r_1)}, \frac{1}{\varphi_1(r_2)} \right\} \right),$$

the functional $\Phi + \lambda\Psi$ *admits at least two critical points which lie in* $\Phi^{-1}(-\infty, r_1]$ *and* $\Phi^{-1}[r_1, r_2)$, *respectively.*

We remind the reader that Theorem 2.3 and Theorem 2.4 rely on Ricceri's variational principle [25].

For successful application of Theorems 2.1–2.2, we recommend referring to [8] to ensure the existence of at least one and two solutions for elliptic Dirichlet problems with variable exponent. Additionally, for the utilization of Theorems 2.3–2.4, we suggest consulting [10] to guarantee the existence of at least two and three solutions for a boundary value problem on the half-line. Furthermore, for effective implementations of Theorems 2.1–2.4, we advise referring to [11, 16] to explore the existence of multiple solutions for Kirchhoff-type second-order impulsive differential equations on the half-line and to study an elastic beam equation with local nonlinearities, respectively.

In this section, we will present several fundamental definitions, notations, lemmas, and propositions utilized throughout this paper.

Let us start by defining the finite T-dimensional Banach space

$$X = \{u : [0,1] \to \mathbb{R} : u \text{ is absolutely continuous, } u(1) = u(0),\ u' \in L^2([0,1]\},\tag{2.1}$$

which is equipped with the norm

$$\|u\| = \left(\int_0^1 \left(|u'(x)|^2 + |u(x)|^2\right) \mathrm{d}x \right)^{\frac{1}{2}}.\tag{2.2}$$

Clearly, X is a Hilbert space and X^* is the dual space of X.

Setting

$$h(y) = \int_0^y \left(\int_0^\tau p(\xi)\mathrm{d}\xi \right) \mathrm{d}\tau$$

for every $y \in \mathbb{R}$, we have

$$h'(y) = \int_0^y p(\xi)\mathrm{d}\xi \quad \text{and} \quad h''(y) = p(y)$$

for every $y \in \mathbb{R}$.

We define functionals Φ, Ψ for every $u \in X$, as follows

$$\Phi(u) = \int_0^1 h(u'(x))\mathrm{d}x + \frac{1}{2}\int_0^1 \zeta(x)|u(x)|^2\mathrm{d}x\tag{2.3}$$

and

$$\Psi(u) = \int_0^1 \left(\int_0^{u(x)} f(x,\xi)\mathrm{d}\xi \right) \mathrm{d}x + \frac{\mu}{\lambda}\int_0^1 \left(\int_0^{u(x)} g(x,\xi)\mathrm{d}\xi \right) \mathrm{d}x,\tag{2.4}$$

and we put

$$I_\lambda(u) = \Phi(u) - \lambda\Psi(u)$$

for every $u \in X$. Clearly, I_λ is Gâteaux differentiable.

Definition 2.5. We mean by a (weak) solution of the BVP ($P^{f,g}_{\lambda,\mu}$), any function $u \in X$ such that

$$\int_0^1 h'(u'(x))y'(x)\mathrm{d}x + \int_0^1 \zeta(x)u(x)y(x)\mathrm{d}x - \lambda\int_0^1 f(x,u(x))y(x)\mathrm{d}x \\ -\mu\int_0^1 g(x,u(x))y(x)\mathrm{d}x = 0$$

for every $y \in X$.

Lemma 2.6. *If $u \in X$ is a critical point of I_λ in X, iff $u \in X$ is a solution of* ($P^{f,g}_{\lambda,\mu}$).

Proof. If $u \in X$ is a critical point for I_λ, we have

$$\int_0^1 h'(u'(x))y'(x)\mathrm{d}x + \int_0^1 \zeta(x)u(x)y(x)\mathrm{d}x \\ = \lambda\int_0^1 f(x,u(x))y(x)\mathrm{d}x + \mu\int_0^1 g(x,u(x))y(x)\mathrm{d}x$$

for each $y \in X$. This implies that $h' \circ u'$ has a weak derivative which equals $\zeta(x)u(x) - \lambda f(x,u(x)) - \mu g(x,u(x))$ and is thus continuous, so $h' \circ u'$ is $C^1([0,1])$. Since h' is an invertible C^1-function, it follows that u' is also in $C^1([0,1])$, hence x is in $C^2([0,1])$. Set

$$e(x) = -h'(u'(x)) + \int_0^t \zeta(\tau)u(\tau)\mathrm{d}\tau - \lambda \int_0^t f(\tau,u(\tau))\mathrm{d}\tau - \mu \int_0^t g(\tau,u(\tau))\mathrm{d}\tau - C$$

such that $\int_0^1 e(x)\mathrm{d}x = 0$. Let $y(x) = \int_0^t e(\tau)\mathrm{d}\tau$. Then $y(x) \in X$ and $\int_0^1 |e(x)|^2\mathrm{d}x = 0$, that is, $e(x) = 0$ for a.e. $x \in [0,1]$. This shows that

$$\begin{aligned} -(h' \circ u')'(x) + \zeta(x)u(x) &= -h''(u')u''(x) + \zeta(x)u(x) = -p(u'(x))u''(x) + \zeta(x)u(x) \\ &= \lambda f(x,u(x)) + \mu g(x,u(x)) \end{aligned}$$

for all $x \in [0,1]$. Hence we conclude that x is a solution of problem ($P^{f,g}_{\lambda,\mu}$) belongs to $C^2([0,1])$. □

Proposition 2.7 ([27, Proposition 2.3]). *If $p(\cdot)$ satisfies (Q_1), then h' is strongly monotone.*

Proposition 2.8 ([27, Proposition 2.4]). *If $p(\cdot)$ and $\zeta(\cdot)$ satisfy* (1.1) *and* (1.2)*, respectively, then*

(1) *Φ is well-defined in X,*

(2) *Φ is Gâteaux differentiable in X,*

(3) *Φ' is a Lipschitzian operator,*

(4) *Φ is convex in X.*

Put

$$F(x,t) = \int_0^t f(x,s)\mathrm{d}s \quad \text{and} \quad G(x,t) = \int_0^t g(x,s)\mathrm{d}s \quad \text{for all } (x,t) \in [0,1] \times \mathbb{R}.$$

3 Existence of one solution

In this section, we focus on establishing the existence of one solution for the problem ($P^{f,g}_{\lambda,\mu}$). For clarity and convenience, let us define

$$G^\theta = \int_0^1 \sup_{|\xi| \le \theta} G(x,\xi)\mathrm{d}x \quad \text{for all } \theta > 0$$

and

$$G_\eta = \inf_{[0,1]\times[0,\eta]} G(x,\xi) \quad \text{for all } \eta > 0.$$

If g is sign-changing, then clearly $G^\theta \ge 0$ and $G_\eta \le 0$.

For our goal, we fix two positive constants θ and η, put

$$\underline{\delta}_{\lambda,g} = \min\left\{ \frac{\min\{m,\zeta_0\}\theta^2 - 8\lambda \int_0^1 \sup_{|t|\le\theta} F(x,t)\mathrm{d}x}{8G^\theta}, \right.$$
$$\left. \frac{\frac{1}{4}h(2\eta) + \frac{1}{4}h(-2\eta) + \zeta_1\eta^2 - \lambda \int_{\frac{1}{4}}^{\frac{3}{4}} F(x,\eta)\mathrm{d}x}{G_\eta} \right\}$$

and

$$\overline{\delta}_{\lambda,g} = \min\left\{ \underline{\delta}_{\lambda,g}, \frac{1}{\max\left\{0, \frac{8}{\min\{m,\zeta_0\}} \limsup_{|t|\to+\infty} \frac{\sup_{x\in[0,1]} G(x,t)}{x^2}\right\}} \right\} \tag{3.1}$$

where we read $\epsilon/0 = +\infty$, so that, for instance, $\overline{\delta}_{\lambda,g} = +\infty$ when

$$\limsup_{|t|\to+\infty} \frac{\sup_{x\in[0,1]} G(x,t)}{x^2} \leq 0,$$

and $G_\eta = G^\theta = 0$.

Theorem 3.1. *Assume that there exist two positive constants γ and η with the property*

$$\sqrt{\frac{2h(2\eta)+2h(-2\eta)+8\zeta_1\eta^2}{\min\{m,\zeta_0\}}} < \gamma$$

such that

(A_1) $f(x,t) \geq 0$ *for every* $(x,t) \in [0,1] \times \left[0,\frac{1}{4}\right] \cup \left[\frac{3}{4},1\right]$,

(A_2) $\frac{\int_0^1 \sup_{|t|\leq\gamma} F(x,t)\mathrm{d}x}{\gamma^2} < \min\{m,\zeta_0\} \frac{\int_{\frac{1}{4}}^{\frac{3}{4}} F(x,\eta)\mathrm{d}x}{2h(2\eta)+2h(-2\eta)+8\zeta_1\eta^2}$,

(A_3) $\min_{x\in[0,1]} \limsup_{|\xi|\to\infty} \frac{F(x,\xi)}{|\xi|^2} \in (-\infty,0]$.

Then, for each

$$\lambda \in \Lambda = \left(\frac{h(2\eta)+h(-2\eta)+4\zeta_1\eta^2}{4\int_{\frac{1}{4}}^{\frac{3}{4}} F(x,\eta)\mathrm{d}x}, \frac{\min\{m,\zeta_0\}\gamma^2}{8\int_0^1 \sup_{|t|\leq\gamma} F(x,t)\mathrm{d}x} \right)$$

and for every function $g : [0,1] \times \mathbb{R} \to \mathbb{R}$ satisfying the condition

$$\min_{x\in[0,1]} \limsup_{|\xi|\to\infty} \frac{G(x,\xi)}{|\xi|^2} \in (-\infty,0), \tag{3.2}$$

there exists $\overline{\delta}_{\lambda,g} > 0$ given by (3.1) such that for each $\mu \in [0,\overline{\delta}_{\lambda,g})$, the problem $(P^{f,g}_{\lambda,\mu})$ admits at least one solution u_λ in X such that

$$\max_{x\in[0,1]} |u_\lambda(x)| < \gamma.$$

Proof. Our objective is to apply Theorem 2.1 to the problem $(P^{f,g}_{\lambda,\mu})$. Consider the functionals Φ and Ψ defined in (2.3) and (2.3), respectively. Our task is to demonstrate that these functionals satisfy the necessary conditions outlined in Theorem 2.1. Since $f, g : [0;1] \times \mathbb{R} \to \mathbb{R}$ are L^1-Carathéodory functions, we know that Ψ' is a well-defined and Gâteaux differentiable functional with

$$\Psi'(u)(y) = \int_0^1 f(x,u(x))y(x)\mathrm{d}x + \frac{\mu}{\lambda}\int_0^1 g(x,u(x))y(x)\mathrm{d}x$$

for every $u, y \in X$. Since the embeddings $X \hookrightarrow L^q (q \geq 1)$ and $X \hookrightarrow L^\infty$ are compact (Adams [1]), we have $\Psi' : X \to X^*$ is a continuous and compact operator, and Ψ is sequentially weakly upper semicontinuous. Moreover, Again using the Lebesgue's theorem, from the continuity of h' and the arbitrariness of $\{a_n\}$, we know that Φ is Gâteaux differentiable in X with

$$\Phi'(u)(y) = \int_0^1 h'(u'(x))y'(x)\mathrm{d}x + \int_0^1 \zeta(x)u(x)y(x)\mathrm{d}x \tag{3.3}$$

for every $u, y \in X$. Furthermore, by the definition of Φ, we observe that it is sequentially weakly lower semicontinuous and strongly continuous. Combining this observation with (1.1) and (1.2), we have

$$\int_0^1 h'(u'(x))\mathrm{d}x = \int_0^1 \left(\int_0^{u'(x)} \left(\int_0^\tau p(\xi)\mathrm{d}\xi\right)\mathrm{d}\tau\right)\mathrm{d}x$$

and

$$\begin{aligned}\frac{1}{2}\min\{m,\zeta_0\}\|u\|^2 &\le \frac{m}{2}\int_0^1 |u'(x)|^2\mathrm{d}x + \frac{\zeta_0}{2}\int_0^1 |u(x)|^2\mathrm{d}x \le \Phi(u)\\ &\le \frac{M}{2}\int_0^1 |u'(x)|^2\mathrm{d}x + \frac{\zeta_1}{2}\int_0^1 |u(x)|^2\mathrm{d}x \le \frac{1}{2}\max\{M,\zeta_1\}\|u\|^2\end{aligned} \tag{3.4}$$

for every $u \in X$, which implies that Φ is well-defined in X. By using the first inequality in (3.4), it follows

$$\lim_{\|u\|\to+\infty} \Phi(u) = +\infty,$$

namely Φ is coercive. Further, we claim that Φ admits a continuous inverse on X^*. In fact, by (1.1), (1.2), Proposition 2.7 and (3.3), we have

$$\begin{aligned}\langle \Phi'(u) - \Phi'(y), u - y\rangle &= \int_0^1 (h'(u'(x)) - h'(y'(x)), u'(x) - y'(x))\mathrm{d}x\\ &\quad + \int_0^1 \zeta(x)|u(x) - y(x)|^2\mathrm{d}x\\ &\ge \int_0^1 m|u'(x) - y'(x)|^2\mathrm{d}x + \int_0^1 \zeta_0|u(x) - y(x)|^2\mathrm{d}x\\ &\ge \min\{m,\zeta_0\}\|u(x) - y(x)\|^2\end{aligned}$$

for all $u, y \in X$, which shows that Φ' is uniformly monotone in X. Put $y = 0$, then we have

$$\min\{m,\zeta_0\}\|u\|^2 \le \langle \Phi'(u), u\rangle \le \|\Phi'(u)\|_{X^*}.\|u\|$$

$$\Rightarrow \min\{m,\zeta_0\}\|u\| \le \|\Phi'(u)\|_{X^*}$$

which shows that Φ' is coercive in X. Since Φ' is a Lipschitzian operator, it is hemicontinuous in X. According to Theorem 26.A of [28], Φ admits a continuous inverse on X^*. Additionally, the functional Ψ belongs to $C^1(X, \mathbb{R})$ and has a compact derivative. Given that the embedding $X \hookrightarrow L^q$ (where $q \ge 1$) is compact, there exists a positive constant C such that

$$|u|_{L^q([0,1])} \le C\|u\|$$

and it follows that

$$|u|_{L^2([0,1])} \le C_1\|u\|$$

where C_1 is positive constant. Moreover, for $\lambda > 0$, the functional I_λ is coercive. Indeed, since $\mu < \delta_\lambda$ we can fix κ such that

$$\min_{x\in[0,1]} \limsup_{|\xi|\to\infty} \frac{G(x,\xi)}{|\xi|^2} \in (-\infty, \kappa)$$

and $\mu\kappa < \frac{\min\{m,\zeta_0\}}{2C_1^2}$. Therefore, there exists a positive constant ϱ such that

$$G(x,\xi) \le \kappa\xi^2 + \varrho$$

for each $\xi \in \mathbb{R}$ and $x \in [0,1]$. Now, we fix $0 < \varepsilon < \frac{1}{\lambda C_1^2}\left(\frac{\min\{m,\zeta_0\}}{2} - \mu C_1^2\kappa\right)$. From the assumption (A_3) there is a positive constant ρ_ε such that

$$F(x,\xi) \le \varepsilon\xi^2 + \rho_\varepsilon$$

for every $(x,\xi) \in [0,1]\times\mathbb{R}$. It follows that, for each $u \in X$, we have

$$\begin{aligned}
\Phi(u) - \lambda\Psi(u) &\ge \frac{1}{2}\min\{m,\zeta_0\}\|u\|^2 - \lambda\int_0^1 [F(x,u(x)) + \frac{\mu}{\lambda}G(x,u(x))]\mathrm{d}x \\
&\ge \frac{1}{2}\min\{m,\zeta_0\}\|u\|^2 - \lambda\left(\varepsilon\int_0^1 |u(x)|^2\mathrm{d}x + \rho_\varepsilon\right) - \mu\left(\kappa\int_0^1 |u(x)|^2\mathrm{d}x + \varrho\right) \\
&\ge \left(\frac{1}{2}\min\{m,\zeta_0\} - \lambda C_1^2\varepsilon - \mu C_1^2\kappa\right)\|u\|^2 - \lambda\rho_\varepsilon - \mu\varrho
\end{aligned}$$

and thus

$$\lim_{\|u\|\to\infty} (\Phi(u) - \lambda\Psi(u)) = \infty,$$

which means the functional $I_\lambda = \Phi - \lambda\Psi$ is coercive. Thus, by [5, Proposition 2.1] the functional $I_\lambda = \Phi - \lambda\Psi$ verifies $(\mathrm{PS})^{[r]}$-condition for each $r > 0$ and so the condition (a_2) of Theorem 2.1 is verified. Fix $\lambda \in (0,\lambda^*)$, thus

$$\frac{\int_{\frac14}^{\frac34} F(x,\eta)\mathrm{d}x - \frac{\mu}{\lambda}G_\eta}{\frac14 h(2\eta) + \frac14 h(-2\eta) + \zeta_1\eta^2} > \frac{1}{\lambda}.$$

Put $r = \frac{\min\{m,\zeta_0\}}{8}\gamma^2$ and

$$w(x) = \begin{cases} \eta, & x \in \left[0,\frac14\right], \\ 2\eta x + \frac{\eta}{2}, & x \in \left[\frac14,\frac12\right], \\ -2\eta x + \frac{5\eta}{2}, & x \in \left[\frac12,\frac34\right], \\ \eta, & x \in \left[\frac34,1\right]. \end{cases} \tag{3.5}$$

Clearly, $w \in X$. Then, we have $\Phi(0) = \Psi(0) = 0$,

$$\begin{aligned}
\Phi(w) &= \frac14 h(2\eta) + \frac14 h(-2\eta) + \frac12\int_0^1 \zeta(x)|w(x)|^2\mathrm{d}x \\
&\le \frac14 h(2\eta) + \frac14 h(-2\eta) + \frac{\zeta_1}{2}\int_0^1 |w(x)|^2\mathrm{d}x \\
&= \frac14 h(2\eta) + \frac14 h(-2\eta) + \frac{31\zeta_1\eta^2}{2\times 24} \\
&< \frac14 h(2\eta) + \frac14 h(-2\eta) + \zeta_1\eta^2
\end{aligned} \tag{3.6}$$

and

$$\begin{aligned}\Phi(w) &\geq \frac{1}{4}h(2\eta)+\frac{1}{4}h(-2\eta)+\frac{\zeta_0}{2}\int_0^1|w(x)|^2\mathrm{d}x\\ &=\frac{1}{4}h(2\eta)+\frac{1}{4}h(-2\eta)+\frac{31\zeta_0\eta^2}{2\times 24}\\ &>\frac{1}{4}h(2\eta)+\frac{1}{4}h(-2\eta)+\frac{\zeta_0\eta^2}{8}.\end{aligned}\tag{3.7}$$

From $\min_{x\in[\frac{1}{4},\frac{3}{4}]}\{w(x)\}=\eta$, $\max_{x\in[\frac{1}{4},\frac{3}{4}]}\{w(x)\}=\frac{3\eta}{2}$ and the assumption (A_1), we have

$$\begin{aligned}\Psi(w) =&\int_0^{\frac{1}{4}}\int_0^{\eta}f(x,\xi)\mathrm{d}\xi\mathrm{d}x+\int_{\frac{1}{4}}^{\frac{3}{4}}\int_0^{w}f(x,\xi)\mathrm{d}\xi\mathrm{d}x+\int_{\frac{3}{4}}^{1}\int_0^{\eta}f(x,\xi)\mathrm{d}\xi\mathrm{d}x\\ &+\frac{\mu}{\lambda}\int_0^1\left(\int_0^{w(x)}g(x,\xi)\mathrm{d}\xi\right)\mathrm{d}x\geq\int_{\frac{1}{4}}^{\frac{3}{4}}\int_0^{\eta}f(x,\xi)\mathrm{d}\xi\mathrm{d}x+\frac{\mu}{\lambda}G_\eta\\ =&\int_{\frac{1}{4}}^{\frac{3}{4}}F(x,\eta)\mathrm{d}x+\frac{\mu}{\lambda}G_\eta.\end{aligned}$$

Thus, by the assumption

$$\sqrt{\frac{8}{\min\{m,\zeta_0\}}\left(\frac{1}{4}h(2\eta)+\frac{1}{4}h(-2\eta)+\zeta_1\eta^2\right)}<\gamma,$$

we have $0<\Phi(w)<r$. For $u\in X$, taking into account

$$|u(x)|\leq\left|\int_{t_1}^{t}u'(\tau)\mathrm{d}\tau\right|+|u(x_1)|\leq\int_0^1|u'(\tau)|\mathrm{d}\tau+|u(x_1)|$$

and

$$|u(x)|\leq\int_0^1|u'(\tau)|\mathrm{d}\tau+\int_0^1|u(x_1)|\mathrm{d}x_1\leq\left(\int_0^1|u'(\tau)|^2\mathrm{d}\tau\right)^{\frac{1}{2}}+\left(\int_0^1|u(\tau)|^2\mathrm{d}\tau\right)^{\frac{1}{2}},$$

we have

$$\max_{x\in[0,1]}|u(x)|\leq 2\|u\|.\tag{3.8}$$

From the definition of Φ and in view of (3.4) for every $r>0$, one has

$$\begin{aligned}\Phi^{-1}(-\infty,r]=&\ \{u\in X,\ \Phi(x)\leq r\}\\ &\subseteq\left\{u\in X,\ \max_{x\in[0,1]}|u(x)|\leq\sqrt{\frac{8r}{\min\{m,\zeta_0\}}}\right\}\\ &\subseteq\left\{u\in X,\ \max_{x\in[0,1]}|u(x)|\leq\gamma\right\}.\end{aligned}$$

Hence, we have

$$\sup_{\Phi(u)<r}\Psi(u)=\sup_{u\in\Phi^{-1}(-\infty,r)}\Psi(u)\leq\int_0^1\sup_{|t|\leq\gamma}F(x,t)\mathrm{d}x+\frac{\mu}{\lambda}G^{\gamma}.$$

Therefore, we have

$$\frac{\sup_{u\in\Phi^{-1}(-\infty,r]}\Psi(u)}{r}=\frac{\sup_{u\in\Phi^{-1}(-\infty,r]}\left(\int_0^1 F(x,u(x))\mathrm{d}x+\frac{\mu}{\lambda}\int_0^1 G(x,u(x))\mathrm{d}x\right)}{r}$$
$$\leq\frac{\int_0^1\sup_{|t|\leq\gamma}F(x,t)\mathrm{d}x+\frac{\mu}{\lambda}G^{\gamma}}{\frac{\min\{m,\zeta_0\}}{8}\gamma^2} \tag{3.9}$$

and

$$\frac{\Psi(w)}{\Phi(w)}\geq\frac{\int_{\frac14}^{\frac34}F(x,\eta)\mathrm{d}x+\frac{\mu}{\lambda}\int_0^1 G(x,\eta)\mathrm{d}x}{\frac14 h(2\eta)+\frac14 h(-2\eta)+\zeta_1\eta^2} \tag{3.10}$$
$$\geq\frac{\int_{\frac14}^{\frac34}F(x,\eta)\mathrm{d}x+\frac{\mu}{\lambda}G_{\eta}}{\frac14 h(2\eta)+\frac14 h(-2\eta)+\zeta_1\eta^2}.$$

Since

$$\mu<\frac{\min\{m,\zeta_0\}\gamma^2-8\lambda\int_0^1\sup_{|t|\leq\gamma}F(x,t)\mathrm{d}x}{8G^{\gamma}},$$

we have

$$8\frac{\int_0^1\sup_{|t|\leq\gamma}F(x,t)\mathrm{d}x+\frac{\mu}{\lambda}G^{\gamma}}{\min\{m,\zeta_0\}\gamma^2}<\frac{1}{\lambda}.$$

Furthermore,

$$\mu<\frac{\frac14 h(2\eta)+\frac14 h(-2\eta)+\zeta_1\eta^2-\lambda\int_{\frac14}^{\frac34}F(x,\eta)\mathrm{d}x}{G_{\eta}},$$

this means

$$\frac{\int_{\frac14}^{\frac34}F(x,\eta)\mathrm{d}x+\frac{\mu}{\lambda}G_{\eta}}{\frac14 h(2\eta)+\frac14 h(-2\eta)+\zeta_1\eta^2}>\frac{1}{\lambda}.$$

Then,

$$\frac{8}{\min\{m,\zeta_0\}}\frac{\int_0^1\sup_{|t|\leq\gamma}F(x,t)\mathrm{d}x+\frac{\mu}{\lambda}G^{\gamma}}{\gamma^2}<\frac{1}{\lambda}<\frac{\int_{\frac14}^{\frac34}F(x,\eta)\mathrm{d}x+\frac{\mu}{\lambda}G_{\eta}}{\frac14 h(2\eta)+\frac14 h(-2\eta)+\zeta_1\eta^2}. \tag{3.11}$$

Hence, from (3.9)–(3.11), the condition (a_1) of Applying Theorem 2.1 with $\bar{u}=w$ ensures the existence of a local minimum point u_λ for the functional I_λ such that $0<\Phi(u_\lambda)<r$. Thus, u_λ serves as a nontrivial solution to the problem ($P^{f,g}_{\lambda,\mu}$), satisfying

$$\max_{x\in[0,1]}|u_\lambda(x)|<\gamma.$$

□

Now, we illustrate Theorem 3.1 through the following example.

Example 3.2. We consider the following problem

$$\begin{cases}-p(u')u''+u=\lambda f(x,u(x))+\mu g(x,u(x)), & \text{a.e. } x\in[0,1],\\ u(1)-u(0)=u'(1)-u'(0)=0\end{cases} \tag{3.12}$$

where $p(t) = 3 - 2\cos(t)$ for every $t \in \mathbb{R}$, $\zeta(x) = 1$ for each $x \in [0,1]$ and

$$f(x,t) = \begin{cases} \frac{4}{10}e^{-x}t^3, & \text{for every } (x,t) \in [0,1] \times (-\infty, 1), \\ \frac{4}{10t}e^{-x}, & \text{for every } (x,t) \in [0,1] \times [1, +\infty). \end{cases}$$

By the expression of f, we have

$$F(x,t) = \begin{cases} \frac{1}{10}e^{-x}t^4, & \text{for every } (x,t) \in [0,1] \times (-\infty, 1), \\ e^{-x}\left(\frac{4}{10}\ln(t) + \frac{1}{10}\right), & \text{for every } (x,t) \in [0,1] \times [1, +\infty). \end{cases}$$

Hence, $\lim_{|\xi|\to\infty} \frac{F(x,\xi)}{|\xi|^2} = 0$, thus (A_3) holds. Choose $\gamma = 10^{-2}$, and $\eta = 1$. By simple calculations, we obtain $m = 1$, $M = 5$ and $\zeta_0 = \zeta_1 = 1$. Since

$$\frac{\int_0^1 \sup_{|t|\leq\gamma} F(x,t)\mathrm{d}x}{\gamma^2} = \frac{e-1}{10^9 e} < \frac{e^{0.75} - e^{0.25}}{(160 + 80\cos(2))e} = \frac{\min\{m, \zeta_0\} \int_{\frac{1}{4}}^{\frac{3}{4}} F(x,\eta)\mathrm{d}x}{2h(2\eta) + 2h(-2\eta) + 8\zeta_1\eta^2},$$

thus (A_2) holds true, then all conditions in Theorem 3.1 are satisfied. Therefore, it follows that for each

$$\lambda \in \left(\frac{(80 + 40\cos(2))e}{4(e^{0.75} - e^{0.25})}, \frac{10^9 e}{8(e-1)} \right)$$

and for every function $g : [0,1] \times \mathbb{R} \to \mathbb{R}$ satisfying the condition

$$\min_{x\in[0,1]} \limsup_{|\xi|\to\infty} \frac{G(x,\xi)}{|\xi|^2} \in (-\infty, 0),$$

there exists $\overline{\delta}_{\lambda,g} > 0$ such that for each $\mu \in [0, \overline{\delta}_{\lambda,g})$, the problem (3.12) admits at least one solution u_λ in X such that

$$\max_{x\in[0,1]} |u_\lambda(x)| < 10^{-2}.$$

4 Existence of two solutions

In this section, our objective is to establish the existence of two distinct solutions for the problem $(P^{f,g}_{\lambda,\mu})$. The following result is derived by applying Theorem 2.2, without the need for assumption (A_3).

Theorem 4.1. *Assume that there exist two positive constants γ and η with the property*

$$\sqrt{\frac{2h(2\eta) + 2h(-2\eta) + 8\zeta_1\eta^2}{\min\{m, \zeta_0\}}} < \gamma$$

and

(A_4) *there exist $\nu > 2$ and $R > 0$ such that*

$$0 < \nu F(x,\xi) \leq \xi f(x,\xi) \tag{4.1}$$

for all $|\xi| \geq R$ and for all $x \in [0,1]$.

Then, for each

$$\lambda \in \left(0, \frac{\min\{m, \zeta_0\}\gamma^2}{8\int_0^1 \sup_{|t|\le\gamma} F(x,t)\mathrm{d}x}\right),$$

and for every function $g : [0,1]\times\mathbb{R} \to \mathbb{R}$ *satisfying the condition* (A_4)*, there exists* $\delta_\lambda > 0$*, for each* $\mu \in [0, \delta_\lambda[$*, the problem* $(P^{f,g}_{\lambda,\mu})$ *admits at least two solutions* u_1 *and* u_2 *in* X *such that*

$$\max_{x\in[0,1]} |u_1(x)| < \gamma.$$

Proof. Our aim is to apply Theorem 2.2 to the space X with the norm is defined in (2.2) and to the functionals Φ and Ψ defined in the proof of Theorem 3.1. The functional I_λ satisfies the (PS)-condition. Indeed, assume that $\{u_n\}_{n\in\mathbb{N}} \subset X$ such that $\{I_\lambda(u_n)\}_{n\in\mathbb{N}}$ is bounded and $I'_\lambda(u_n) \to 0$ as $n \to \infty$. Then, there exists a positive constant c_0 such that

$$|I_\lambda(u_n)| \le c_0,\ |I'_\lambda(u_n)| \le c_0 \qquad \forall n \in \mathbb{N}.$$

Therefore, we deduce from the definition of I'_λ and assumption (A_3) that

$$\begin{aligned} c_0 + c_1\|u_n\| \ge \nu I_\lambda(u_n) - I'_\lambda(u_n)(u_n) &\ge \min\{m,\zeta_0\}\left(\frac{\nu}{2}-1\right)\|u_n\|^2 \\ &\quad - \lambda\int_0^1 (\nu F(x,u_n(x)) - f(x,u_n(x))(u_n(x)))\,\mathrm{d}x \\ &\quad - \mu\int_0^1 (\nu G(x,u_n(x)) - g(x,u_n(x))(u_n(x)))\,\mathrm{d}x \\ &\ge \min\{m,\zeta_0\}\left(\frac{\nu}{2}-1\right)\|u_n\|^2 \end{aligned}$$

for some $c_1 > 0$. Since $\nu > 2$, this implies that (u_n) is bounded. Consequently, since X is a reflexive Banach space we have, up to a subsequence,

$$u_n \rightharpoonup u \quad \text{in } X.$$

By $I'_\lambda(u_n) \to 0$ and $u_n \rightharpoonup u$ in X, we obtain

$$\left(I'_\lambda(u_n) - I'_\lambda(u)\right)(u_n - u) \to 0. \tag{4.2}$$

From the continuity of f and g, we have

$$\int_0^1 (f(x,u_n(x)) - f(x,u(x)))\,(u_n(x)-u(x))\mathrm{d}x \to 0, \quad \text{as } n\to\infty$$

and

$$\int_0^1 (g(x,u_n(x)) - g(x,u(x)))\,(u_n(x)-u(x))\mathrm{d}x \to 0, \quad \text{as } n\to\infty.$$

Moreover, an easy computation shows

$$\begin{aligned}\left(I'_\lambda(u_n) - I'_\lambda(u)\right)(u_n - u) = &\int_0^1 h'(u'_n(x) - u'(x))(u'_n(x) - u'(x))\mathrm{d}x \\ &+ \int_0^1 \zeta(x)(u_n(x) - u(x))(u_n(x) - u(x))\mathrm{d}x \\ &- \lambda \int_0^1 \left(f(x, u_n(x)) - f(x, u(x))\right)(u_n(x) - u(x))\mathrm{d}x \\ &- \mu \int_0^1 \left(g(x, u_n(x) - g(x, u(x))\right)(u_n(x) - u(x))\mathrm{d}x \\ \geq\; &\min\{m, \zeta_0\}\|u_n - u\|^2.\end{aligned}$$

Thus, the sequence u_n converges strongly to u in X. Therefore, I_λ satisfies the (PS)-condition. Moreover, by integrating the condition (4.1), there exist constants $a_1, a_2, a_3, a_4 > 0$ such that that

$$F(x,t) \geq a_1|t|^\nu - a_2 \quad \text{and} \quad G(x,t) \geq a_3|t|^\nu - a_4$$

for all $x \in [0,1]$ and $t \in \mathbb{R}$. Moreover, for any $u \in X$, one has

$$\frac{1}{2}\min\{m, \zeta_0\}\|u\|^2 \leq \Phi(u) \leq \frac{1}{2}\max\{M, \zeta_1\}\|u\|^2. \tag{4.3}$$

Now, choosing any $u \in X \setminus \{0\}$, for each $\tau > 0$ taking (4.3) into account one has

$$\begin{aligned}I_\lambda(\tau u) &= (\Phi + \lambda\Psi)(\tau u) \\ &\leq \frac{\max\{M, \zeta_1\}}{2}\|\tau u\|^2 - \lambda\int_0^1 F(x, \tau u(x))\mathrm{d}x - \mu\int_0^1 G(x, \tau u(x))\mathrm{d}x \\ &\leq \frac{\max\{M, \zeta_1\}\tau^2}{2}\|u\|^2 - \lambda\tau^\nu a_1\int_0^1 |u(x)|^\nu \mathrm{d}x + \mu\tau^\nu a_3\int_0^1 |u(x)|^\nu \mathrm{d}x - \lambda a_2 - \mu a_4.\end{aligned}$$

Since $\nu > 2$, this condition guarantees that I_λ is unbounded from below. Thus, all hypotheses of Theorem 2.2 are satisfied. Therefore, for each

$$\lambda \in \left(0, \frac{\min\{m, \zeta_0\}\gamma^2}{8\int_0^1 \sup_{|t| \leq \gamma} F(x,t)\mathrm{d}x}\right),$$

the functional I_λ admits two distinct critical points that are solutions of the problem $(P^{f,g}_{\lambda,\mu})$. □

Remark 4.2. Theorem 1.1 immediately follows from Theorem 4.1.

Remark 4.3. In Theorem 2.1, it is observed that if either $f(x,0) \neq 0$ for some $x \in [0,1]$ or $g(x,0) \neq 0$ for some $x \in [0,1]$, or both conditions hold true, then Theorem 4.1 guarantees the existence of two nontrivial solutions for the problem $(P^{f,g}_{\lambda,\mu})$. However, if the condition $f(x,0) \neq 0$ for some $x \in [0,1]$ and $g(x,0) \neq 0$ for some $x \in [0,1]$ does not hold, the second solution u_2 of the problem $(P^{f,g}_{\lambda,\mu})$ may be trivial, but the problem still has at least one nontrivial solution.

Remark 4.4. Using similar arguments as those provided in the proof of [7, Theorem 3.5], the non-triviality of the second solution guaranteed by Theorem 4.1 can also be achieved in the case where $f(x,0) = 0$ for all $x \in [0,1]$, provided that an extra condition at zero is imposed.

Specifically, this condition entails the existence of a non-empty open set $D \subseteq [0,1]$ and a set $B \subset D$ of positive Lebesgue measure such that

$$\limsup_{\xi \to 0^+} \frac{\operatorname{ess\,inf}_{x\in B} F(x,\xi)}{|\xi|^2} = \infty \quad \text{and} \quad \liminf_{\xi \to 0^+} \frac{\operatorname{ess\,inf}_{x\in D} F(x,\xi)}{|\xi|^2} > -\infty.$$

See [18, Theorem 3.1] for more details.

5 Another multiplicity result for the case $\mu = 0$

In this section, we focus on establishing the existence of at least two and three solutions for the problem ($P^{f,g}_{\lambda,\mu}$) in the case $\mu = 0$. To achieve this, we define

$$F^c = \int_0^1 \sup_{|t|\le c} F(x,t)\mathrm{d}x \quad \text{and} \quad F_c = \inf_{x\in[0,1]} F(x,c)$$

for every $c > 0$.

Theorem 5.1. *Assume that there exist two positive constants $\bar\gamma$ and $\bar\eta$ such that*

$$\sqrt{\frac{2h(2\bar\eta) + 2h(-2\bar\eta) + 8\zeta_1\bar\eta^2}{\min\{m,\zeta_0\}}} < \bar\gamma \tag{5.1}$$

and suppose that the assumptions (A_1) and (A_3) in Theorem 3.1 hold. Moreover, assume that

(A_5) $\frac{F^{\bar\gamma}}{\min\{m,\zeta_0\}\bar\gamma^2} < \frac{\frac{1}{2}F_{\bar\eta} - F^{\bar\gamma}}{2h(2\bar\eta)+2h(-2\bar\eta)+8\zeta_1\bar\eta^2}$.

Then, for each

$$\lambda \in \left(\frac{h(2\bar\eta) + h(-2\bar\eta) + 4\zeta_1\bar\eta^2}{2F_{\bar\eta} - 4F^{\bar\gamma}}, \frac{\min\{m,\zeta_0\}\bar\gamma^2}{8F^{\bar\gamma}} \right),$$

the problem ($P^{f,g}_{\lambda,\mu}$) in the case $\mu = 0$ admits at least three solutions in X.

Proof. Put $I_\lambda = \Phi + \lambda\Psi$, where

$$\Phi(u) = \int_0^1 h(u'(x))\mathrm{d}x + \frac{1}{2}\int_0^1 \zeta(x)|u(x)|^2\mathrm{d}x \tag{5.2}$$

and

$$\Psi(u) = -\int_0^1 F(x,u(x))\mathrm{d}x$$

for all $u \in X$. Standard arguments demonstrate that Φ and Ψ are Gâteaux differentiable functionals, and their Gâteaux derivatives at the point $u \in X$ are given by

$$\Phi'(u)(v) = \int_0^1 h'(u'(x))v'(x)\mathrm{d}x + \int_0^1 \zeta(x)u(x)v(x)\mathrm{d}x$$

and

$$\Psi'(u)(v) = -\int_0^1 f(x,u(x))v(x)\mathrm{d}x$$

for all $u, v \in X$, respectively. Hence, a critical point of the functional $\Phi + \lambda\Psi$, gives us a solution of ($P^{f,g}_{\lambda,\mu}$) in the case $\mu = 0$. Our goal is to apply Theorem 2.3 to Φ and Ψ. By sequentially weakly lower semicontinuity of the norm and continuity of h, the functional Φ is sequentially weakly lower semicontinuous. Moreover, from Section 3, Φ is continuously Gâteaux differentiable while Proposition 2.7 gives that its Gâteaux derivative admits a continuous inverse on X^*. The functional $\Psi : X \to \mathbb{R}$ is well defined and is continuously Gâteaux differentiable whose Gâteaux derivative is compact. Then, it is enough to show that Φ and Ψ satisfy (c_1) and (c_2) in Theorem 2.3. Now, we fix $0 < \epsilon < \frac{\min\{m,\zeta_0\}}{2\lambda C_1^2}$. From the assumption (A_3) there is a function $\rho_\varepsilon : [0,1] \to \mathbb{R}$ with $\rho_\epsilon(x) < \infty$ for all $x \in [0,1]$ such that

$$F(x,t) \le \varepsilon t^2 + \rho(x)$$

for every $(x,t) \in [0,1] \times \mathbb{R}$. It follows that for each $u \in X$,

$$\begin{aligned}\Phi(u) - \lambda\Psi(u) &\ge \frac{\min\{m,\zeta_0\}}{2}\|u\|^2 - \lambda\int_0^1 F(x,u(x))\mathrm{d}x \\ &\ge \frac{\min\{m,\zeta_0\}}{2}\|u\|^2 - \lambda\epsilon\int_0^1 u^2(x)\mathrm{d}x - \lambda\int_0^1 \rho(x)\mathrm{d}x \\ &\ge \left(\frac{\min\{m,\zeta_0\}}{2} - \lambda C_1^2\epsilon\right)\|u\|^2\mathrm{d}x - \lambda\int_0^1 \rho(x)\mathrm{d}x\end{aligned}$$

and thus

$$\lim_{\|u\|\to\infty}(\Phi(u) + \lambda\Psi(u)) = \infty,$$

which means the functional $I_\lambda = \Phi + \lambda\Psi$ is coercive. Now it remains to show that (c_2) of Theorem 2.3 is fulfilled. Let $\bar{r} = \frac{\min\{m,\zeta_0\}}{8}\bar{\gamma}^2$ and

$$w(x) = \begin{cases} \bar{\eta}, & x \in \left[0, \frac{1}{4}\right], \\ 2\bar{\eta}x + \frac{\bar{\eta}}{2}, & x \in \left[\frac{1}{4}, \frac{1}{2}\right], \\ -2\bar{\eta}x + \frac{5\bar{\eta}}{2}, & x \in \left[\frac{1}{2}, \frac{3}{4}\right], \\ \bar{\eta}, & x \in \left[\frac{3}{4}, 1\right]. \end{cases}$$

Clearly, $w \in X$. Then, we have $\Phi(0) = \Psi(0) = 0$,

$$\Phi(w) < \frac{1}{4}h(2\bar{\eta}) + \frac{1}{4}h(-2\bar{\eta}) + \zeta_1\bar{\eta}^2$$

and

$$\Phi(w) > \frac{1}{4}h(2\bar{\eta}) + \frac{1}{4}h(-2\bar{\eta}) + \frac{\zeta_0\bar{\eta}^2}{8}.$$

Thus by (5.1), $\Phi(w) > \bar{r}$. Moreover

$$\Psi(w) = -\int_0^1 F(x,w(x))\mathrm{d}x \le -\int_{\frac{1}{4}}^{\frac{3}{4}} F(x,\bar{\eta})\mathrm{d}x \le -\frac{1}{2}F_{\bar{\eta}}.$$

Taking (3.8) into account, for every $u \in X$ such that $\Phi(u) < \bar{r}$, we have

$$\sup_{x\in[0,1]} |u(x)| \le \bar{\gamma}.$$

Thus,

$$\sup_{\Phi(u)<\bar{r}} \Psi(u) = \sup_{u\in\Phi^{-1}(-\infty,\bar{r})} \int_0^1 F(x,u(x))\mathrm{d}x \leq \int_0^1 \sup_{|t|\leq\bar{\gamma}} F(x,t)\mathrm{d}x = F^{\bar{\gamma}}. \tag{5.3}$$

By simple calculations and from the definition of $\varphi(\bar{r})$, since $\Phi(0) = \Psi(0) = 0$ and $\overline{\Phi^{-1}(-\infty,\bar{r})}^{w} = \Phi^{-1}(-\infty,\bar{r})$, one has

$$\begin{aligned}\varphi_1(\bar{r}) &= \inf_{u\in\Phi^{-1}(]-\infty,\bar{r}[)} \frac{\Psi(u) - \inf_{\overline{\Phi^{-1}(-\infty,\bar{r})}^{w}} \Psi}{\bar{r}-\Phi(u)} \leq \frac{-\inf_{\overline{\Phi^{-1}(-\infty,\bar{r})}^{w}} \Psi}{\bar{r}} \\ &\leq \frac{8}{\min\{m,\zeta_0\}} \frac{\int_0^1 \sup_{|t|\leq\bar{\gamma}} F(x,t)\mathrm{d}x}{\bar{\gamma}^2} = \frac{8F^{\bar{\gamma}}}{\min\{m,\zeta_0\}\bar{\gamma}^2}.\end{aligned}$$

On the other hand, by (5.3), one has

$$\begin{aligned}\varphi_2(\bar{r}) &= \inf_{u\in\Phi^{-1}(-\infty,\bar{r})} \sup_{v\in\Phi^{-1}[\bar{r},\infty)} \frac{\Psi(u)-\Psi(v)}{\Phi(u)-\Phi(v)} \geq \inf_{u\in\Phi^{-1}(-\infty,\bar{r})} \frac{\Psi(u)-\Psi(w)}{\Phi(w)-\Phi(u)} \\ &\geq \frac{\inf_{u\in\Phi^{-1}(-\infty,\bar{r})} \Psi(u)-\Psi(w)}{\Phi(w)-\Phi(u)} \\ &\geq \frac{-\int_0^1 \sup_{|t|\leq\bar{\gamma}} F(x,t)\mathrm{d}x + \int_{\frac{1}{4}}^{\frac{3}{4}} F(x,\bar{\eta})\mathrm{d}x}{\Phi(w)-\Phi(u)} \\ &\geq \frac{2F_{\bar{\eta}} - 4F^{\bar{\gamma}}}{h(2\bar{\eta})+h(-2\bar{\eta})+4\zeta_1\bar{\eta}^2}.\end{aligned}$$

Hence, from (A_5), one has

$$\varphi_1(\bar{r}) < \varphi_2(\bar{r}).$$

Therefore, from Theorem 2.3, taking also into account that

$$\frac{1}{\varphi_2(\bar{r})} \leq \frac{h(2\bar{\eta})+h(-2\bar{\eta})+4\zeta_1\bar{\eta}^2}{2F_{\bar{\eta}}-4F^{\bar{\gamma}}}$$

and

$$\frac{1}{\varphi_1(\bar{r})} \geq \frac{\min\{m,\zeta_0\}\bar{\gamma}^2}{8F^{\bar{\gamma}}},$$

we obtain the desired conclusion. □

Remark 5.2. When the assumption (A_5) of Theorem 5.1 holds, simple calculations show that the condition

(A_6) $\frac{F^{\bar{\gamma}}}{\min\{m,\zeta_0\}\bar{\gamma}^2} < \frac{F_{\bar{\eta}}}{4h(2\bar{\eta})+4h(-2\bar{\eta})+16\zeta_1\bar{\eta}^2}$

implies (A_5) of Theorem 5.1. Hence, if the assumptions (5.1) and (A_6) hold, then for each

$$\lambda \in \left(\frac{h(2\bar{\eta})+h(-2\bar{\eta})+4\zeta_1\bar{\eta}^2}{2F_{\bar{\eta}}}, \frac{\min\{m,\zeta_0\}\bar{\gamma}^2}{8F^{\bar{\gamma}}} \right),$$

the problem $(P^{f,g}_{\lambda,\mu})$ in the case $\mu = 0$ admits at least three solutions.

Now, we present an application of Theorem 2.4, which will be utilized later to derive multiple solutions for the problem $(P^{f,g}_{\lambda,\mu})$ in the case $\mu = 0$, without the need for assumption (A_3).

Theorem 5.3. *Assume that there exist three positive constants $\bar{\gamma}_1$, $\bar{\eta}$ and $\bar{\gamma}_2$ with*

$$\bar{\gamma}_1 < \sqrt{\frac{8}{\min\{m,\zeta_0\}}\left(\frac{1}{4}g(2\bar{\eta}) + \frac{1}{4}g(-2\bar{\eta}) + \frac{\zeta_0\bar{\eta}^2}{8}\right)} \tag{5.4}$$

and

$$\sqrt{\frac{8}{\min\{m,\zeta_0\}}\left(\frac{1}{4}g(2\bar{\eta}) + \frac{1}{4}g(-2\bar{\eta}) + \zeta_1\bar{\eta}^2\right)} < \bar{\gamma}_2 \tag{5.5}$$

such that the assumption (A_5) in Theorem 5.1 holds and

(A_7) $\frac{1}{\min\{m,\zeta_0\}} \max\left\{\frac{F^{\bar{\gamma}_1}}{\bar{\gamma}_1^2}, \frac{F^{\bar{\gamma}_2}}{\bar{\gamma}_2^2}\right\} < \frac{F_{\bar{\eta}}}{4h(2\bar{\eta})+4h(-2\bar{\eta})+16\zeta_1\bar{\eta}^2}$.

Then, for each

$$\lambda \in \Lambda = \left(\frac{h(2\bar{\eta}) + h(-2\bar{\eta}) + 4\zeta_1\bar{\eta}^2}{2F_{\bar{\eta}}}, \min\left\{\frac{\min\{m,\zeta_0\}\bar{\gamma}_1^2}{8F^{\bar{\gamma}_1}}, \frac{\min\{m,\zeta_0\}\bar{\gamma}_2^2}{8F^{\bar{\gamma}_2}}\right\}\right),$$

the problem $(P^{f,g}_{\lambda,\mu})$ in the case $\mu = 0$ admits at least two solutions $u_{1,\lambda}$ and $u_{2,\lambda}$ such that $\max_{x\in[0,1]} |u_{1,\lambda}(x)| < \bar{\gamma}_1$ and $\max_{x\in[0,1]} |u_{2,\lambda}(x)| < \bar{\gamma}_2$.

Proof. Put

$$\overline{f}(x,t) = \begin{cases} f(x,-\bar{\gamma}_2), & \text{if } (x,t) \in [0,1]\times(-\infty,\bar{\gamma}_2), \\ f(x,t), & \text{if } (x,t) \in [0,1]\times[-\bar{\gamma}_2,\bar{\gamma}_2], \\ f(x,\bar{\gamma}_2), & \text{if } (x,t) \in [0,1]\times(\bar{\gamma}_2,\infty). \end{cases}$$

Clearly, $\overline{f} : [0,1]\times\mathbb{R} \to \mathbb{R}$ is a Carathéodory function. Now put $\overline{F}(x,\xi) = \int_0^\xi \overline{f}(x,t)\mathrm{d}x$ for all $(x,\xi) \in [0,1]\times\mathbb{R}$ and take X and Φ as (2.1) and (5.2), respectively, and

$$\Psi(u) = -\int_0^1 \overline{F}(x,u(x))\mathrm{d}x$$

for all $u \in X$. Our goal is to apply Theorem 2.4 to Φ and Ψ. It is well known that $\lim_{\|u\|\to\infty}\Phi(u) = \infty$ and Ψ is a differentiable functional whose differential at the point $u \in X$ is

$$\Psi'(u)(v) = -\int_0^1 \overline{f}(x,u(x))v(x)\mathrm{d}x$$

for any $v \in X$ as well as it is sequentially weakly lower semicontinuous. Furthermore $\Psi' : X \to X^*$ is a compact operator. Thus, it is enough to show that Φ and Ψ satisfy the conditions (c_1), (c_2) and (c_3) in Theorem 2.4. Let

$$\bar{r}_1 = \frac{\min\{m,\zeta_0\}}{8}\bar{\gamma}_1^2, \qquad \bar{r}_2 = \frac{\min\{m,\zeta_0\}}{8}\bar{\gamma}_2^2$$

and w as in the proof of Theorem 5.1. Due to the assumptions (3.4), (5.4) and (5.5) we have $\bar{r}_1 < \Phi(w) < \bar{r}_2$ and $\inf_X \Phi < \bar{r}_1 < \bar{r}_2$. Moreover, arguing as in the proof of Theorem 5.1 and taking also into account Remark 5.2 we obtain

$$\varphi_1(\bar{r}_1) \le \frac{8}{\min\{m,\zeta_0\}}\frac{\int_0^1 \sup_{|t|\le\bar{\gamma}_1} F(x,t)\mathrm{d}x}{\bar{\gamma}_1^2} = \frac{8F^{\bar{\gamma}_1}}{\min\{m,\zeta_0\}\bar{\gamma}_1^2},$$

$$\varphi_1(\bar{r}_2) \leq \frac{8}{\min\{m, \zeta_0\}} \frac{\int_0^1 \sup_{|t| \leq \bar{\gamma}_2} F(x,t) \mathrm{d}x}{\bar{\gamma}_2^2} = \frac{8F^{\bar{\gamma}_2}}{\min\{m, \zeta_0\}\bar{\gamma}_2^2}$$

and

$$\varphi_2^*(\bar{r}_1, \bar{r}_2) \geq \frac{2F_{\bar{\eta}}}{h(2\bar{\eta}) + h(-2\bar{\eta}) + 4\zeta_1 \bar{\eta}^2}.$$

Hence, from (A_7), the conditions (c_2) and (c_3) of Theorem 2.4 hold. Therefore, from Theorem 2.4 we obtain that, for each $\lambda \in \Lambda$, the problem

$$\begin{cases} -p(u')u'' + \zeta(x)u = \lambda \overline{f}(x, u(x)), & \text{a.e. } x \in [0,1], \\ u(1) - u(0) = u'(1) - u'(0) = 0 \end{cases}$$

admits at least two solutions $u_{1,\lambda}$ and $u_{2,\lambda}$ such that $\max_{x\in[0,1]} |u_{1,\lambda}(x)| < \bar{\gamma}_1$ and $\max_{x\in[0,1]} |u_{2,\lambda}(x)| < \bar{\gamma}_2$. Observing that these solutions are also solutions for the problem $(P^{f,g}_{\lambda,\mu})$ in the case $\mu = 0$, the conclusion follows. □

Now, we provide some remarks on our results in this section.

Remark 5.4. In Theorems 5.1 and 5.3, we investigated the critical points of the functional I_λ naturally associated with the problem $(P^{f,g}_{\lambda,\mu})$ in the case $\mu = 0$. It is worth noting that, in general, I_λ can be unbounded from below in X. For instance, when $f(t) = 1 + |t|^{\vartheta-2}t$ for all $t \in \mathbb{R}$ with $\vartheta > 2$, for any fixed $u \in X \backslash 0$ and $\iota \in \mathbb{R}$, we obtain

$$\begin{aligned} I_\lambda(\iota u) &\leq \frac{\max\{m, \zeta_1\}}{2} \|\iota u\|^2 - \lambda \int_0^1 F(x, \iota u(x)) \mathrm{d}x \\ &\leq \frac{\max\{M, \zeta_1\}\iota^2}{2} \|u\|^2 - \lambda \iota C_4 \|u\| - \lambda C_5 \frac{\iota^\vartheta}{\vartheta} \|u\|^\vartheta \to -\infty \end{aligned}$$

where C_4 and C_5 are positive constants, as $\iota \to \infty$. Hence, we can not use direct minimization to find critical points of the functional I_λ.

Remark 5.5. We observe that if f is non-negative, Theorem 5.3 represents a bifurcation result, indicating that the pair $(0, 0)$ belongs to the closure of the set

$$\left\{(u_\lambda, \lambda) \in X \times (0, \infty) : u_\lambda \text{ is a non-trivial solution of } (P^{f,g}_{\lambda,\mu}),\ \ \mu = 0\right\} \subset X \times \mathbb{R}.$$

Indeed, if λ goes to zero, by Theorem 5.3 we have that $\bar{\gamma}_i \to 0$, $i = 1, 2$ and since $\max_{x\in[0,1]} |u_{i,\lambda}(x)| < \bar{\gamma}_i$, $i = 1, 2$, there exist two sequences $\{u_j\}$ in X and $\{\lambda_j\}$ in $\mathbb{R}^+$ (here $u_j = u_{\lambda_j}$) such that

$$\lambda_j \to 0^+ \quad \text{and} \quad \|u_j\| \to 0,$$

as $j \to \infty$. Moreover, since f is nonnegative, $\Psi(u) < 0$ for all $u \in \mathbb{R}$ and thus

$$(0, \lambda^*) \ni \lambda \mapsto I_\lambda(u_\lambda)$$

is strictly decreasing. Hence, for every $\lambda_1, \lambda_2 \in (0, \lambda^*)$, with $\lambda_1 \neq \lambda_2$, solutions u_{λ_1} and u_{λ_2} ensured by Theorem 2.4 are different.

Remark 5.6. If f is non-negative, then the solutions guaranteed by Theorems 5.1 and 5.3 are also non-negative.

Now, we highlight some results where the function f has separated variables. Specifically, consider the following problem

$$\begin{cases} -p(u')u'' + \zeta(x)u = \lambda\theta(x)f(u(x)), & \text{a.e. } x \in [0,1], \\ u(1) - u(0) = u'(1) - u'(0) = 0 \end{cases} \qquad (P_\lambda^{f,\theta})$$

where $\theta : [0,1] \to \mathbb{R}$ is a non-negative and non-zero function such that $\theta(x) < \infty$ for all $x \in [0,1]$ and $f : \mathbb{R} \to \mathbb{R}$ is a non-negative and continuous function. Put

$$F(\xi) = \int_0^\xi f(s)ds$$

for all $\xi \in \mathbb{R}$.

The following existence results are consequences of Theorems 5.1 and 5.3, respectively, by setting $f(x,t) = \theta(x)f(x)$ for every $(x,t) \in [0,1] \times \mathbb{R}$.

Theorem 5.7. *Assume that there exist two positive constants $\bar{\gamma}$ and $\bar{\eta}$, with*

$$\sqrt{\frac{2h(2\bar{\eta}) + 2h(-2\bar{\eta}) + 8\zeta_1\bar{\eta}^2}{\min\{m,\zeta_0\}}} < \bar{\gamma}$$

such that

(A_8) $\theta(x) \geq 0$ *for every* $x \in [0,1]$ *and* $f(t) \geq 0$ *for every* $t \in [0,\frac{1}{4}] \bigcup [\frac{3}{4},1]$,

(A_9) $\frac{1}{\min\{m,\zeta_0\}} \frac{\int_0^1 \theta(x)\mathrm{d}xF(\bar{\gamma})}{\bar{\gamma}^2} < \frac{\int_{\frac{1}{4}}^{\frac{3}{4}} \theta(x)\mathrm{d}xF(\bar{\eta})}{2h(2\bar{\eta})+2h(-2\bar{\eta})+8\zeta_1\bar{\eta}^2}$,

(A_{10}) $\limsup_{|\xi|\to\infty} \frac{F(\xi)}{|\xi|^2} \in (-\infty, 0]$.

Then, for each

$$\lambda \in \left(\frac{1}{4\int_{\frac{1}{4}}^{\frac{3}{4}} \theta(x)\mathrm{d}x} \frac{h(2\bar{\eta}) + h(-2\bar{\eta}) + 4\zeta_1\bar{\eta}^2}{F(\bar{\eta})}, \frac{\min\{m,\zeta_0\}}{8\int_0^1 \theta(x)\mathrm{d}x} \frac{\bar{\gamma}^2}{F(\bar{\gamma})} \right),$$

the problem $(P_\lambda^{f,\theta})$ *admits at least three solutions in X.*

Theorem 5.8. *Assume that there exist three positive constants $\bar{\gamma}_1$, $\bar{\eta}$ and $\bar{\gamma}_2$ with*

$$\bar{\gamma}_1 < \sqrt{\frac{8}{\min\{m,\zeta_0\}} \left(\frac{1}{4}g(2\bar{\eta}) + \frac{1}{4}g(-2\bar{\eta}) + \frac{\zeta_0\bar{\eta}^2}{8} \right)}$$

and

$$\sqrt{\frac{8}{\min\{m,\zeta_0\}} \left(\frac{1}{4}g(2\bar{\eta}) + \frac{1}{4}g(-2\bar{\eta}) + \zeta_1\eta^2 \right)} < \bar{\gamma}_2$$

such that

(A_{11}) $\theta(x) \geq 0$ *for every* $x \in [0,1]$ *and* $f(t) \geq 0$ *for every* $t \in [0,\frac{1}{4}] \cup [\frac{3}{4},1]$,

(A_{12}) $\frac{\int_0^1 \theta(x)\mathrm{d}x}{\min\{m,\zeta_0\}} \max\left\{ \frac{F(\bar{\gamma}_1)}{\bar{\gamma}_1^2}, \frac{F(\bar{\gamma}_2)}{\bar{\gamma}_2^2} \right\} < \frac{\int_{\frac{1}{4}}^{\frac{3}{4}} \theta(x)\mathrm{d}xF(\bar{\eta})}{2h(2\bar{\eta})+2h(-2\bar{\eta})+8\zeta_1\bar{\eta}^2}$.

Then, for each

$$\lambda \in \Lambda = \left(\frac{1}{4\int_{\frac{1}{4}}^{\frac{3}{4}} \theta(x) \mathrm{d}x} \frac{h(2\bar{\eta}) + h(-2\bar{\eta}) + 4\zeta_1 \bar{\eta}^2}{F(\bar{\eta})}, \frac{\min\{m, \zeta_0\}}{8\int_0^1 \theta(x) \mathrm{d}x} \min\left\{ \frac{\bar{\gamma}_1^2}{F(\bar{\gamma}_1)}, \frac{\bar{\gamma}_2^2}{F(\bar{\gamma}_2)} \right\} \right),$$

the problem $(P_\lambda^{f,\theta})$ *admits at least two solutions* $u_{1,\lambda}$ *and* $u_{2,\lambda}$ *such that* $\max_{x\in[0,1]} |u_{1,\lambda}(x)| < \gamma_1$ *and* $\max_{x\in[0,1]} |u_{2,\lambda}(x)| < \gamma_2$.

Now, we point out a special case of Theorem 5.7.

Theorem 5.9. *Assume that*

$$\lim_{\xi\to 0^+} \frac{f(\xi)}{\xi} = \lim_{|\xi|\to\infty} \frac{f(\xi)}{|\xi|} = 0 \tag{5.6}$$

and there exists a positive constant $\bar{\eta}$ *such that* $F(\bar{\eta}) > 0$. *Then, for each* $\lambda > \lambda^*$, *where*

$$\lambda^* = \frac{1}{4\int_{\frac{1}{4}}^{\frac{3}{4}} \theta(x) \mathrm{d}x} \inf_{\bar{\eta}>0} \frac{h(2\bar{\eta}) + h(-2\bar{\eta}) + 4\zeta_1 \bar{\eta}^2}{F(\bar{\eta})},$$

the problem $(P_\lambda^{f,\theta})$ *admits at least one nonnegative and one non zero solution in* X.

Proof. Let $\lambda > \lambda^*$. Then, there is $\bar{\eta} > 0$ such that

$$\lambda > \frac{1}{4\int_{\frac{1}{4}}^{\frac{3}{4}} \theta(x) \mathrm{d}x} \inf_{\bar{\eta}>0} \frac{h(2\bar{\eta}) + h(-2\bar{\eta}) + 4\zeta_1 \bar{\eta}^2}{F(\bar{\eta})}.$$

From (5.6) we obtain

$$\lim_{u\to 0^+} \frac{\sup_{|\xi|\le u} f(\xi)}{u} = \lim_{u\to\infty} \frac{\sup_{|\xi|\le u} f(\xi)}{u} = 0.$$

So we can pick $\bar{\gamma}_1$ and $\bar{\gamma}_2$ such that

$$\bar{\gamma}_1 < \sqrt{\frac{8}{\min\{m, \zeta_0\}} \left(\frac{1}{4} g(2\bar{\eta}) + \frac{1}{4} g(-2\bar{\eta}) + \frac{\zeta_0 \bar{\eta}^2}{8} \right)}$$

and

$$\sqrt{\frac{8}{\min\{m, \zeta_0\}} \left(\frac{1}{4} g(2\bar{\eta}) + \frac{1}{4} g(-2\bar{\eta}) + \zeta_1 \bar{\eta}^2 \right)} < \bar{\gamma}_2,$$

$\frac{\sup_{|\xi|\le\bar{\gamma}_1} f(\xi)}{\bar{\gamma}_1} < \frac{\min\{m,\zeta_0\}}{8\int_0^1 \theta(x)\mathrm{d}x} \frac{\bar{\gamma}_1^2}{F(\bar{\gamma}_1)}$ and $\frac{\sup_{|\xi|\le\bar{\gamma}_2} f(\xi)}{\bar{\gamma}_2} < \frac{\min\{m,\zeta_0\}}{8\int_0^1 \theta(x)\mathrm{d}x} \frac{\bar{\gamma}_2^2}{F(\bar{\gamma}_2)}$. Hence, from Theorem 5.8 we obtain the conclusion. □

Remark 5.10. Theorem 1.2 immediately follows from Theorem 5.9.

Abstract. In this paper, we study the existence of multiple normalized solutions to the following Schrödinger–Poisson system with general nonlinearities:

$$\begin{cases} -\varepsilon^2\Delta u + V(x)u + \phi u = f(u) + \lambda u & \text{in } \mathbb{R}^3, \\ -\varepsilon^2\Delta\phi = u^2 & \text{in } \mathbb{R}^3, \\ \int_{\mathbb{R}^3} |u|^2 \mathrm{d}x = \varepsilon^3 a^2, \end{cases}$$

where ε, $a > 0$, $\lambda \in \mathbb{R}$ is an unknown parameter that appears as a Lagrange multiplier, $V(x) : \mathbb{R}^3 \to [0,\infty)$ is a continuous function, and f is a differentiable function satisfying L^2-subcritical growth. Through using the minimization techniques and the Lusternik–Schnirelmann category, we prove that the numbers of normalized solutions are related to the topology of the set where the potential $V(x)$ attains its minimum value.

Keywords: Schrödinger–Poisson system, normalized solutions, Lusternik–Schnirelmann category, variational methods.

2020 Mathematics Subject Classification: 35B09, 35J61.

1 Introduction

In this paper, we are concerned with the existence of multiple normalized solutions to the following Schrödinger–Poisson system with general nonlinearities:

$$\begin{cases} -\varepsilon^2\Delta u + V(x)u + \phi u = f(u) + \lambda u & \text{in } \mathbb{R}^3, \\ -\varepsilon^2\Delta\phi = u^2 & \text{in } \mathbb{R}^3, \\ \int_{\mathbb{R}^3} |u|^2 \mathrm{d}x = \varepsilon^3 a^2, \end{cases} \tag{1.1}$$

where ε, $a > 0$, $\lambda \in \mathbb{R}$ is an unknown parameter that appears as a Lagrange multiplier.

✉Corresponding author. Email: tengkaimin2013@163.com

Problem (1.1) arises in the study of the coupled Schrödinger–Poisson system:

$$\begin{cases} i\psi_t - \Delta\psi + V(x)\psi + \phi\psi = g(|\psi|^2)\psi & \text{in } \mathbb{R}^3, \\ -\Delta\phi = |\psi|^2 & \text{in } \mathbb{R}^3, \end{cases} \tag{1.2}$$

where $\psi(x,t) : \mathbb{R}^3 \times [0,T]$ is the wave function. Equation (1.2) arises from approximation of the Hartree–Fock equation which describes a quantum mechanical of many particles, see [11,12,24]. Set $\psi(x,t) = e^{i\lambda t}u(x)$ and $u : \mathbb{R}^3 \to \mathbb{R}$, one is led to the equation

$$\begin{cases} -\Delta u + V(x)u + \phi u = f(u) + \lambda u & \text{in } \mathbb{R}^3, \\ -\Delta\phi = u^2 & \text{in } \mathbb{R}^3, \end{cases}$$

where $f(u) = g(|u|^2)u$, $\lambda \in \mathbb{R}$. The system (1.1) was firstly introduced by Benci and Fortunato in [9]. System (1.1) also arises in various fields of physics, for instance, in semiconductor theory (see [10,25,26]), for more details on the physical aspects, we refer the reader to [9] and references therein.

When $\lambda \in \mathbb{R}$ is a fixed parameter, we call (1.1) the fixed frequency problem. In the last decades, the existence, concentration and multiplicity of solutions for the fixed frequency problem (1.1) has been studied by many scholars, for example [2–4, 13, 15, 27, 29] and the references therein.

Recently, the existence and multiplicity of normalized solution are attracted many people's interests. Such solutions have a prescribed L^2-norm, that is, solutions which satisfy $\|u\|_2 = a$ for a priori given $a > 0$. In this case, the parameter $\lambda \in \mathbb{R}$ cannot be fixed but instead appears as a Lagrange multiplier.

When $\varepsilon = 1$, $V(x) = 0$ and $f(u) = |u|^{p-2}u$, normalized solutions of (1.1) can be obtained by considering the critical points of the following functional

$$J(u) = \frac{1}{2}\int_{\mathbb{R}^3} |\nabla u|^2 dx + \frac{1}{4}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3} \frac{u^2(x)u^2(y)}{|x-y|} dy dx - \frac{1}{p}\int_{\mathbb{R}^3} |u|^p dx$$

on the constraint

$$S(a) = \{u \in H^1(\mathbb{R}^3) : \|u\|_2 = a\}.$$

As far as we know, the first work for normalized solutions to Schrödinger–Poisson system is due to Sánchez and Soler [28], they proved that all the minimizing sequence for σ_a are compact provided that $a \in (0, a_0)$ for a suitable $a_0 > 0$ small enough and $p = \frac{8}{3}$, where σ_a is defined by

$$\sigma_a = \inf_{u \in S(a)} J(u). \tag{1.3}$$

Bellazzini and Siciliano in [5] and [6] proved that σ_a is achieved when $a > 0$ is small and $p \in (2,3)$ and when $a > 0$ is large and $p \in (3, \frac{10}{3})$, respectively. Subsequently, Jeanjean and Luo in [22] sharpened the conclusion of [6] by showing that (1.3) has a minimizer if and only if

$$a \geq a_1 = \inf\{a > 0 : \sigma_a < 0\}.$$

Moreover, for the case of $p = 3$ or $p = \frac{10}{3}$, they proved σ_a has no minimizer for any $a > 0$.

For the L^2-supercritical case, that is, $p \in (\frac{10}{3}, 6)$, the functional $J(u)$ is no more bounded from below on $S(a)$. Bellazzini, Jeanjean and Luo in [7] found critical points of $J(u)$ on $S(a)$ by looking at the mountain-pass level for $a > 0$ sufficiently small. In 2021, Jeanjean and Le in

[21] obtained the existence of two positive solutions for (1.1) with $f(u) = |u|^{p-2}u$ which can be characterized respectively as a local minima and as a mountain pass critical point when $p \in (\frac{10}{3}, 6]$. For the general nonlinearity, Chen, Tang and Yuan in [16] studied the existence of normalized solutions for system (1.1), where $f \in C(\mathbb{R}, \mathbb{R})$ covers the case $f(u) = |u|^{p-2}u$ with $q \in (2, \frac{10}{3}) \cup (\frac{10}{3}, 6)$. When considering more general L^2-supercritical conditions without imposing the monotonicity property on f, Hu, Tang and Jin [20] obtained the existence of normalized solutions for problem (1.1) under suitable assumptions on f.

For the case combining nonlinearity, Kang, Li and Tang in [23] considered system (1.1) with $f(u) = \mu|u|^{q-2}u + |u|^{p-2}u$, where $\mu \in \mathbb{R}$, $2 < q \le \frac{10}{3} \le p < 6$ with $q \neq p$. Under some suitable assumptions on s and μ, they proved some existence, nonexistence and multiplicity of normalized solutions.

When $\varepsilon = 1$ and $V(x) \neq 0$, it is more complicated to deal with the existence of normalized solutions. Zeng and Zhang in [32] considered system (1.1) with $f(u) = |u|^p u$ $(0 < p < \frac{4}{3})$ and unbounded potential, where the potential function $V(x)$ satisfies the following conditions

$$V \in C(\mathbb{R}^N, \mathbb{R}^+), \quad \inf_{x \in \mathbb{R}^N} V(x) = 0 \quad \text{and} \quad \lim_{|x| \to +\infty} V(x) = \infty,$$

with the help of the compactness of Sobolev embedding in the working space, they obtained the existence of normalized solutions.

To our best of knowledge, there is few results for the existence of multiple normalized solutions to Schrödinger–Poisson system (1.1). Motivated by [1], the main purpose of this paper is to study the existence of multiple normalized solutions to (1.1) by using the Lusternik–Schnirelmann category when $V(x)$ satisfies the global conditions:

$$(V) \qquad V \in C(\mathbb{R}^N, \mathbb{R}) \cap L^\infty(\mathbb{R}^N), \qquad V(0) = 0, \qquad 0 = \inf_{x \in \mathbb{R}^N} V(x) < \liminf_{|x| \to +\infty} V(x) = V_\infty.$$

By change of variable $x \to \varepsilon x$, problem (1.1) reduces to the following system

$$\begin{cases} -\Delta u + V(\varepsilon x)u + \phi u = f(u) + \lambda u & \text{in } \mathbb{R}^3, \\ -\Delta \phi = u^2 & \text{in } \mathbb{R}^3, \\ \int_{\mathbb{R}^3} |u|^2 \mathrm{d}x = a^2. \end{cases} \tag{1.4}$$

We assume that $V(x)$ satisfies (V) and f satisfies the following assumptions:

(f_1) f is odd and there exist $q \in (3, \frac{10}{3})$ and $\alpha \in (0, +\infty)$ such that $\lim_{s \to 0} \frac{|f(s)|}{|s|^{q-1}} = \alpha$.

(f_2) There exist constants c_1, c_2, c_3, $c_4 > 0$ and $p \in (3, \frac{10}{3})$ such that

$$|f(s)| \le c_1 + c_2|s|^{p-1} \quad \forall s \in \mathbb{R} \quad \text{and} \quad |f'(s)| \le c_3 + c_4|s|^{p-2} \quad \forall s \in \mathbb{R}.$$

(f_3) There exists $q_1 \in (3, \frac{10}{3})$ and $q > q_1$ such that $f(s)/s^{q_1-1}$ is an increasing function of s on $(0, +\infty)$.

Remark 1.1. The conditions (f_1) and (f_3) imply that $F(t) \ge 0$ for all $t \in \mathbb{R}$. Indeed,

$$\frac{f(s)}{s^{q_1-1}} \ge \lim_{s \to 0^+} \frac{f(s)}{s^{q-1}} s^{q-q_1} = 0, \qquad s > 0,$$

that is, $f(s) \ge 0$. Hence, $F(t) \ge 0$.

An example of a function f that satisfies the above assumption is

$$f(s) = |s|^{q-2}s + |s|^{r-2}s \ln(1 + |s|) \qquad \forall s \in \mathbb{R},$$

for some $r, q \in (3, \frac{10}{3})$ and $r > q$, here (f_2) and (f_3) hold with $p \in (r, \frac{10}{3})$.

A solution u to the problem (1.4) with $\int_{\mathbb{R}^3}|u|^2 = a^2$ can be obtained by looking for critical points of the following functional

$$J_\varepsilon(u) = \frac{1}{2}\int_{\mathbb{R}^3}(|\nabla u|^2 + V(\varepsilon x)u^2)\mathrm{d}x + \frac{1}{4}\int_{\mathbb{R}^3}\phi_u u^2\mathrm{d}x - \int_{\mathbb{R}^3}F(u)\mathrm{d}x, \qquad u \in H^1(\mathbb{R}^3),$$

restricted to sphere

$$S(a) = \{u \in H^1(\mathbb{R}^3) : \|u\|_2 = a\},$$

where $\|\cdot\|_p$ denotes the usual norm in $L^p(\mathbb{R}^3)$ for $p \in [1, +\infty)$.

Moreover, it is easy to see that $J_\varepsilon \in C^1(H^1(\mathbb{R}^3), \mathbb{R})$ and

$$J'_\varepsilon(u)v = \int_{\mathbb{R}^3}(\nabla u\nabla v + V(\varepsilon x)uv)\mathrm{d}x + \int_{\mathbb{R}^3}\phi_u uv\mathrm{d}x - \int_{\mathbb{R}^3}f(u)v\mathrm{d}x, \qquad \forall v \in H^1(\mathbb{R}^3).$$

When we study the multiplicity of solutions in the nonautonomous case, we need to use the following sets:

$$M = \{x \in \mathbb{R}^3 : V(x) = 0\}$$

and

$$M_\delta = \{x \in \mathbb{R}^3 : \mathrm{dist}(x, M) \leq \delta\}, \qquad \delta > 0.$$

Now, we state our main result as follows.

Theorem 1.2. *Suppose that f satisfies the conditions (f_1)–(f_3) and that V satisfies (V). Then for each $\delta > 0$, there exist ε_0, $\mu_* > 0$ and $a_* > 0$ such that (1.1) admits at least $\mathrm{cat}_{M_\delta}(M)$ couples $(u_j, \lambda_j) \in H^1(\mathbb{R}^3) \times \mathbb{R}$ of weak solutions for $0 < \varepsilon < \varepsilon_0$, $|V|_\infty < \mu_*$ and $a > a_*$ with $\int_{\mathbb{R}^3}|u_j|^2\mathrm{d}x = a^2$ and $J_\varepsilon(u_j) < 0$.*

Remark 1.3. For $V(0) =: V_0 \neq 0$, $V_0 < V_\infty$, we can also obtain Theorem 1.2.

We recall that, if Y is a closed subset of a topological space X, the Lusternik–Schnirelmann category $cat_X(Y)$ is the least number of closed and contractible sets in X which cover Y. If $X = Y$, we use the notation $\mathrm{cat}(X)$. For more details about this subject, we cite [30].

The organization of this paper is as follows. In Section 2, we study the autonomous problem. In Section 3, we study the nonautonomous case. In this section, we also study the Palais–Smale condition on the sphere $S(a)$ for the energy functional and provide some crucial tools to establish a multiplicity result. In Section 4, we prove the multiplicity and concentration of solutions to problem (1.1).

2 The autonomous case

The following classical Gagliardo–Nirenberg inequality is so crucial in this paper, which can be found in [31]. Precisely, let $l \in [2, 6)$, then

$$|u|_l^l \leq C|u|_2^{(1-\beta_l)l}|\nabla u|_2^{\beta_l l} \quad \text{in } \mathbb{R}^3, \qquad \beta_l = \frac{3(l-2)}{2l}, \tag{2.1}$$

for some positive constant $C = C(3, l) > 0$.

In this section, we list some preliminary lemmas which used later involving the existence of normalized solution for the following Schrödinger–Poisson system

$$\begin{cases} -\Delta u + \mu u + \phi u = f(u) + \lambda u & \text{in } \mathbb{R}^3, \\ -\Delta\phi = u^2 & \text{in } \mathbb{R}^3, \\ \int_{\mathbb{R}^3}|u|^2\mathrm{d}x = a^2, \end{cases} \tag{2.2}$$

where $a > 0$, $\mu \geq 0$, and $\lambda \in \mathbb{R}$ is unknown parameter that appears as a Lagrange multiplier and f is a continuous function satisfying (f_1)–(f_3).

A solution u to the problem (2.2) corresponds to a critical point of the C^1 functional

$$I_\mu(u) = \frac{1}{2}\int_{\mathbb{R}^3}(|\nabla u|^2 + \mu u^2)\mathrm{d}x + \frac{1}{4}\int_{\mathbb{R}^3}\phi_u u^2 \mathrm{d}x - \int_{\mathbb{R}^3} F(u)\mathrm{d}x, \qquad u \in H^1(\mathbb{R}^3),$$

on the constraint $S(a)$ given by

$$S(a) = \{u \in H^1(\mathbb{R}^3) : \|u\|_2 = a\}.$$

Our main result in this section is stated as follows.

Theorem 2.1. *Suppose that f satisfies the conditions (f_1)–(f_3). Then, there exists $\mu_* > 0$ and $a_* > 0$ such that problem (2.2) has a couple (u, λ) solution when $0 \leq \mu < \mu_*$ and $a > a_*$, where u is positive.*

The proof of the theorem above will be divided into several lemmas.

Now, we recall some properties of the functions ϕ_u in the following lemma (for a proof see [27], [18] and [17]).

Lemma 2.2. *The following results hold:*

(1) $\phi_u \geq 0$;

(2) there exist some constants C_1, $C_2 > 0$ such that $\int_{\mathbb{R}^3}\phi_u u^2\mathrm{d}x \leq C_1|u|^4_{\frac{12}{5}} \leq C_2\|u\|^4$;

(3) if $u_n \to u$ in $L^t(\mathbb{R}^3)$, $\forall t \in [2,6)$, then $\int_{\mathbb{R}^3}\phi_{u_n}{u_n}^2\mathrm{d}x \to \int_{\mathbb{R}^3}\phi_u u^2\mathrm{d}x$,

where $\|\cdot\|$ denotes the usual norm in $H^1(\mathbb{R}^3)$.

Define N: $H^1(\mathbb{R}^3) \to \mathbb{R}$ by

$$N(u) = \int_{\mathbb{R}^3}\phi_u u^2\mathrm{d}x.$$

Lemma 2.3 ([33, Lemma 2.2])**.** *Let $u_n \rightharpoonup u$ in $H^1(\mathbb{R}^3)$ and $u_n \to u$ a.e. in $\mathbb{R}^3$. Then as $n \to \infty$,*

(1) $N(u_n - u) = N(u_n) - N(u) + o(1)$;

(2) $N'(u_n - u) = N'(u_n) - N'(u) + o(1)$, *in* $(H^1(\mathbb{R}^3))'$.

Lemma 2.4. *The functional I_μ is coercive and bounded from below in $S(a)$.*

Proof. According to (f_1)–(f_2), there is C_1, $C_2 > 0$ such that

$$|F(t)| \leq C_1|t|^q + C_2|t|^p \qquad \forall t \in \mathbb{R}.$$

Then it follows from (2.1) that

$$I_\mu(u) \geq \frac{1}{2}\int_{\mathbb{R}^3}|\nabla u|^2\mathrm{d}x - CC_1 a^{(1-\beta_q)q}\left(\int_{\mathbb{R}^3}|\nabla u|^2\mathrm{d}x\right)^{\frac{\beta_q q}{2}}$$
$$- CC_2 a^{(1-\beta_p)p}\left(\int_{\mathbb{R}^3}|\nabla u|^2\mathrm{d}x\right)^{\frac{\beta_p p}{2}}.$$

Since q, $p \in (2, \frac{10}{3})$, by simple calculation, we get $\beta_q q$, $\beta_p p < 2$, which ensures the coercivity and boundedness of I_μ from below. □

Lemma 2.4 guarantees that the minimization problem

$$I_{\mu,a} = \inf_{u \in S(a)} I_\mu(u)$$

is well defined. In what follows, we are going to establish some properties of I_μ related to the parameter $\mu \geq 0$.

Lemma 2.5. *There exists $\mu_* > 0$, $a_* > 0$ such that $\mathcal{I}_{\mu,a} < 0$ for $0 \leq \mu < \mu_*$ and $a > a_*$.*

Proof. By assumption (f_3), we have

$$f'(t)t - (q_1 - 1)f(t) \geq 0 \qquad \forall t > 0. \tag{2.3}$$

In order to show $t \mapsto \frac{F(t)}{t^{q_1}}$ is increasing on $(0, +\infty)$, we need to prove

$$\frac{d}{dt}\frac{F(t)}{t^{q_1}} = \frac{f(t)t^{q_1} - q_1 F(t) t^{q_1 - 1}}{t^{2q_1}} = \frac{f(t)t - q_1 F(t)}{t^{q_1+1}} \qquad \forall t > 0.$$

Define $h(t) = f(t)t - q_1 F(t)$, clearly, $h(0) = 0$ and (2.3) yields that

$$h'(t) = f'(t)t - (q_1 - 1)f(t) \geq 0 \qquad \forall t > 0,$$

which implies that

$$h(t) = f(t)t - q_1 F(t) \geq 0. \tag{2.4}$$

This leads to $\frac{\mathrm{d}}{\mathrm{dt}}\frac{F(t)}{t^{q_1}} \geq 0$, that is, the function $t \mapsto \frac{F(t)}{t^{q_1}}$ is increasing on $(0, +\infty)$, thus, we have that

$$\frac{F(ts)}{(ts)^{q_1}} \geq \frac{F(s)}{s^{q_1}} \qquad \forall s > 0 \quad \text{and} \quad t \geq 1,$$

which yields that

$$F(ts) \geq t^{q_1} F(s) \qquad \forall s > 0 \quad \text{and} \quad t \geq 1. \tag{2.5}$$

Given $u_0(x) \in S(a) \cap L^\infty(\mathbb{R}^3)$ a nonnegative function, let

$$u_0^\eta(x) = \eta^2 u_0(\eta x) \quad \text{for all } x \in \mathbb{R}^3 \text{ and all } \eta \in \mathbb{R}. \tag{2.6}$$

By simple computation, we have

$$\int_{\mathbb{R}^3} |u_0^\eta(x)|^2 \mathrm{d}x = \eta a^2,$$

that is, $u_0^\eta(x) \in S(\eta^{\frac{1}{2}} a)$. Therefore,

$$I_\mu(u_0^\eta(x)) \leq \frac{\eta^3}{2}\int_{\mathbb{R}^3} |\nabla u_0|^2 \mathrm{d}x + \frac{\mu\eta a^2}{2} + \frac{\eta^3}{4}\int_{\mathbb{R}^3} \phi_{u_0} u_0^2 \mathrm{d}x - \eta^{2q_1 - 3}\int_{\mathbb{R}^3} F(u_0(x))\mathrm{d}x.$$

When $q_1 \in (3, \frac{10}{3})$ and $\eta > 0$, $2q_1 - 3 > 3$, for $|\eta|$ large, we deduce that

$$\frac{\eta^3}{2}\int_{\mathbb{R}^3} |\nabla u_0|^2 \mathrm{d}x + \frac{\eta^3}{4}\int_{\mathbb{R}^3} \phi_{u_0} u_0^2 \mathrm{d}x - \eta^{2q_1 - 3}\int_{\mathbb{R}^3} F(u_0(x))\mathrm{d}x = A_\eta < 0,$$

thus, we obtain that

$$I_\mu(u_0^\eta(x)) \leq A_\eta + \frac{\mu a^2}{2}.$$

Hence, we fix $\mu_* > 0$ such that

$$I_\mu(u_0^\eta(x)) < 0, \qquad \forall \mu \in [0, \mu_*),$$

showing that $\mathcal{I}_{\mu, t^{\frac{1}{2}} a} < 0$. Thus, for a large enough, $\mathcal{I}_{\mu,a} < 0$. □

Lemma 2.6. *Fix $\mu \in [0, \mu_*)$ and let $a_* < a_1 < a_2$. There holds $\frac{a_1^6}{a_2^6}\mathcal{I}_{\mu,a_2} < \mathcal{I}_{\mu,a_1} < 0$.*

Proof. Let $\xi > 1$ such that $a_2 = \xi a_1$ and $\{u_n\} \subset S(a_1)$ be a nonnegative minimizing sequence with respect to the $\mathcal{I}_{\mu,a_1}$ (because $I_\mu(u) = I_\mu(|u|)$ for all $u \in H^1(\mathbb{R}^3)$), that is,

$$I_\mu(u_n) \to \mathcal{I}_{\mu,a_1} \quad \text{as } n \to +\infty.$$

Set $v_n = \xi^4 u_n(\xi^2 x)$. Obviously $v_n \in S(a_2)$ and

$$\begin{aligned}
\mathcal{I}_{\mu,a_2} &\leq I_\mu(v_n) \\
&= \frac{\xi^6}{2}\int_{\mathbb{R}^3} |\nabla u_n|^2 dx + \frac{\xi^2\mu^2}{2}\int_{\mathbb{R}^3} u_n^2 dx + \frac{\xi^6}{4}\int_{\mathbb{R}^3} \phi_{u_n} u_n^2 dx - \xi^{-6}\int_{\mathbb{R}^3} F(\xi^4 u_n(x)) dx \\
&\leq \xi^6\left[\frac{1}{2}\int_{\mathbb{R}^3} |\nabla u_n|^2 dx + \frac{\mu^2}{2}\int_{\mathbb{R}^3} u_n^2 dx + \frac{1}{4}\int_{\mathbb{R}^3} \phi_{u_n} u_n^2 dx\right] - \xi^{-6}\int_{\mathbb{R}^3} F(\xi^4 u_n(x)) dx.
\end{aligned}$$

By (2.5), we deduce that

$$\mathcal{I}_{\mu,a_2} \leq I_\mu(v_n) = \xi^6 I_\mu(u_n) + (\xi^6 - \xi^{4q_1-6})\int_{\mathbb{R}^3} F(u_n(x)) dx.$$

Claim 2.7. There exists a constant $C > 0$ and $n_0 \in \mathbb{N}$ such that

$$\int_{\mathbb{R}^3} F(u_n) dx \geq C \quad \text{for } n \geq n_0.$$

Arguing by contradiction that there exists a subsequence of $\{u_n\}$, still denoted by itself, such that

$$\int_{\mathbb{R}^3} F(u_n) dx \to 0 \text{ as } n \to +\infty.$$

Thus, we have

$$0 > \mathcal{I}_{\mu,a} + o_n(1) = I_\mu(u_n) \geq -\int_{\mathbb{R}^3} F(u_n) dx,$$

which is absurd. Thus, Claim 2.7 holds. It is easy to verify that $\xi^6 - \xi^{4q_1-6} < 0$. Hence, we have

$$\mathcal{I}_{\mu,a_2} \leq \xi^6 I_\mu(u_n) + (\xi^6 - \xi^{4q_1-6})C.$$

As $n \to +\infty$, we get

$$\mathcal{I}_{\mu,a_2} < \xi^6 \mathcal{I}_{\mu,a_1} + (\xi^6 - \xi^{4q_1-6})C < \xi^6 \mathcal{I}_{\mu,a_1},$$

that is,

$$\frac{a_1^6}{a_2^6}\mathcal{I}_{\mu,a_2} < \mathcal{I}_{\mu,a_1}.$$

□

The following theorem is a compactness theorem on $S(a)$, which is crucial to study the autonomous case and the nonautonomous case.

Theorem 2.8. *Let $\mu \in [0, \mu_*)$, $a > a_*$ and $\{u_n\} \subset S(a)$ be a minimizing sequence with respect to I_μ. Then, for some subsequence either*

(i) $\{u_n\}$ is strongly convergent in $H^1(\mathbb{R}^3)$;

or

(ii) there exists $\{y_n\} \subset \mathbb{R}^3$ with $|y_n| \to +\infty$ such that $v_n(x) = u_n(x + y_n) \to v$ in $H^1(\mathbb{R}^3)$, where $v \in S(a)$ and $I_\mu(v) = \mathcal{I}_{\mu,a}$.

Proof. Since $\mathcal{I}_\mu$ is coercive on $S(a)$, the sequence $\{u_n\}$ is bounded. Hence, up to a subsequence, still denoted by u_n, we may assume that there exists some $u \in H^1(\mathbb{R}^3)$ such that $u_n \rightharpoonup u$ in $H^1(\mathbb{R}^3)$.

If $u \neq 0$ and $|u|_2 = b \neq a$, we have that $b \in (0,a)$. It follows from Brézis–Lieb lemma (see [30]) that:

$$|u_n|_2^2 = |u_n - u|_2^2 + |u|_2^2 + o_n(1).$$

Moreover, setting $v_n = u_n - u$, $d_n = |v_n|_2$, $t \in (0,1)$, by using mean value theorem, (f_1), (f_2), and Young's inequality, we get

$$\begin{aligned}
|F(v_n+u) - F(v_n) - F(u)| &\leq |F(v_n+u) - F(v_n)| + |F(u)| \\
&\leq |f(v_n+tu)||u| + |F(u)| \\
&\leq [C_1|v_n+tu|^{q-1} + C_2|v_n+tu|^{p-1}]|u| + C_1|u|^{q-1} + C_2|u|^{p-1} \\
&\leq C(|v_n|^{q-1} + |u|^{q-1} + |v_n|^{p-1} + |u|^{p-1})|u| + C_1|u|^{q-1} + C_2|u|^{p-1} \\
&\leq C\varepsilon(|v_n|^q + |v_n|^p) + (C\varepsilon^{-(q-1)} + C_1)|u|^q + (C\varepsilon^{-(p-1)} + C_2)|u|^p.
\end{aligned}$$

Since $\lim_{n\to+\infty} |F(v_n+u) - F(v_n) - F(u)| = 0$ a.e. in $\mathbb{R}^3$, by Lebesgue dominated convergence Theorem, it is easy to get that

$$\int_{\mathbb{R}^3} F(v_n+u)\mathrm{d}x = \int_{\mathbb{R}^3} F(v_n)\mathrm{d}x + \int_{\mathbb{R}^3} F(u)\mathrm{d}x + o_n(1),$$

that is,

$$\int_{\mathbb{R}^3} F(u_n)\mathrm{d}x = \int_{\mathbb{R}^3} F(u_n-u)\mathrm{d}x + \int_{\mathbb{R}^3} F(u)\mathrm{d}x + o_n(1). \tag{2.7}$$

Suppose that $|v_n|_2 \to d$, then $a^2 = b^2 + d^2$ and $d_n \in (0,a)$ for n large enough. Thus, by Lemma 2.3 and (2.7), we have that

$$\mathcal{I}_{\mu,a} + o_n(1) = I_\mu(u_n) = I_\mu(v_n) + I_\mu(u) + o_n(1) \geq \mathcal{I}_{\mu,d_n} + \mathcal{I}_{\mu,b} + o_n(1).$$

From Lemma 2.6, it follows that

$$\mathcal{I}_{\mu,a} + o_n(1) \geq \frac{d_n^6}{a^6}\mathcal{I}_{\mu,a} + \mathcal{I}_{\mu,b} + o_n(1).$$

As $n \to +\infty$, we arrive at the inequality

$$\mathcal{I}_{\mu,a} \geq \frac{d^6}{a^6}\mathcal{I}_{\mu,a} + \mathcal{I}_{\mu,b}. \tag{2.8}$$

Since $b \in (0,a)$, by Lemma 2.6 and (2.8), we obtain

$$0 > \mathcal{I}_{\mu,a} > \frac{d^6}{a^6}\mathcal{I}_{\mu,a} + \frac{b^6}{a^6}\mathcal{I}_{\mu,a} = \frac{b^6+d^6}{a^6}\mathcal{I}_{\mu,a},$$

which yields that

$$\frac{b^6+d^6}{a^6} > 1.$$

By using $a^2 = b^2 + d^2$, we deduce that

$$b^6 + d^6 > a^6 = (b^2+d^2)^3 = b^6 + d^6 + 3b^2d^4 + 3b^4d^2,$$

which is absurd. Hence, we infer that $|u|_2 = a$, that is, $u \in S(a)$.

As $|u_n|_2 = |u|_2 = a$, $u_n \rightharpoonup u$ in $L^2(\mathbb{R}^3)$, it is easy to verify that

$$u_n \to u \quad \text{in } L^2(\mathbb{R}^3). \tag{2.9}$$

By (2.9) and interpolation theorem in the Lebesgue spaces, one infers that

$$u_n \to u \quad \text{in } L^t(\mathbb{R}^3), \qquad \forall t \in [2,6),$$

which combines with (f_1)–(f_2), we can deduce that

$$\int_{\mathbb{R}^3} F(u_n)\mathrm{d}x \to \int_{\mathbb{R}^3} F(u)\mathrm{d}x. \tag{2.10}$$

Thus, by Lemma 2.2-(3) and $\mathcal{I}_{\mu,a} = \lim_{n\to\infty} I_\mu(u_n)$, we have that $\mathcal{I}_{\mu,a} \geq I_\mu(u)$. Since $u \in S(a)$, it follows that $\mathcal{I}_{\mu,a} = I_\mu(u)$, and then $\lim_{n\to\infty} I_\mu(u_n) = \mathcal{I}_\mu(u)$, which combines with (2.9), (2.10) and Lemma 2.2-(3), we have that $u_n \to u$ in $D^{1,2}(\mathbb{R}^3)$. From (2.9), it follows that $\|u_n\|^2 \to \|u\|^2$, that is, $u_n \to u$ in $H^1(\mathbb{R}^3)$.

If $u = 0$, then $u_n \rightharpoonup 0$ in $H^1(\mathbb{R}^3)$. Similar to Claim 2.7, we prove that there exists $C > 0$ such that

$$\int_{\mathbb{R}^3} F(u_n)\mathrm{d}x \geq C \quad \text{for } n \in \mathbb{N} \text{ large}. \tag{2.11}$$

Next, we prove that there exist $R, \beta > 0$ and $y_n \in \mathbb{R}^3$ such that

$$\int_{B_R(y_n)} |u_n|^2\mathrm{d}x \geq \beta \qquad \forall n \in \mathbb{N}. \tag{2.12}$$

Suppose on the contrary, by Lions' vanishing lemma, we get that $u_n \to 0$ in $L^t(\mathbb{R}^3)$ for all $t \in (2, 2^*)$. Hence, it is easy to check that $F(u_n) \to 0$ in $L^1(\mathbb{R}^3)$, which is contradict with (2.11).

Since $u = 0$, we claim that $\{y_n\}$ is unbounded. Arguing by contradiction that $\{y_n\}$ is bounded, there exists $R_0 > 0$, such that $|y_n| < R_0$. Hence, $B_R(y_n) \subset B_{R+R_0}(0)$. Thus, we have that

$$\int_{B_R(y_n)} |u_n|^2\mathrm{d}x \leq \int_{B_{R+R_0}(0)} |u_n|^2\mathrm{d}x \to 0 \quad \text{as } n \to +\infty,$$

which is contradiction with (2.12). The claim follows.

Setting $\widetilde{u}_n(x) = u(x + y_n)$, clearly $\{\widetilde{u}_n\} \subset S(a)$ and it is also a minimizing sequence with respect to $\mathcal{I}_{\mu,a}$, up to a subsequence, we may assume that there exists $\widetilde{u} \in H^1(\mathbb{R}^3) \setminus \{0\}$ such that

$$\widetilde{u}_n \rightharpoonup \widetilde{u} \quad \text{in } H^1(\mathbb{R}^3) \quad \text{and} \quad \widetilde{u}_n(x) \to \widetilde{u}(x) \quad \text{a.e. in } \mathbb{R}^3.$$

Similarly arguing as the above proof, we can deduce that $\widetilde{u}_n \to \widetilde{u}$ in $H^1(\mathbb{R}^3)$. This completes the proof. □

2.1 Proof of Theorem 2.1

From Lemma 2.4, there exists a bounded minimizing sequence $\{u_n\} \subset S(a)$ with respect to $\mathcal{I}_{\mu,a}$, that is, $I_\mu(u_n) \to \mathcal{I}_{\mu,a}$. By Theorem 2.8, there exists $u \in S(a)$ with $I_\mu(u) = \mathcal{I}_{\mu,a}$. Hence, by the Lagrange multiplier, there exists $\lambda_a \in \mathbb{R}$ such that

$$I_\mu{}'(u) = \lambda_a \Psi'(u) \quad \text{in } (H^1(\mathbb{R}^3))', \tag{2.13}$$

where $\Psi : H^1(\mathbb{R}^3) \to \mathbb{R}$ is given by

$$\Psi(u) = \int_{\mathbb{R}^3} |u|^2 \mathrm{d}x, \qquad u \in H^1(\mathbb{R}^3).$$

By (2.13), we have

$$-\Delta u + \mu u + \phi u = \lambda_a u + f(u) \quad \text{in } \mathbb{R}^3. \tag{2.14}$$

Next, by simple calculation, it is easy to see that $I_\mu(|u|) = I_\mu(u)$. Besides, since $u \in S(a)$ implies that $|u| \in S(a)$, then the following equality holds:

$$\mathcal{I}_{\mu,a} = I_\mu(u) = I_\mu(|u|) \geq \mathcal{I}_{\mu,a},$$

thus, $I_\mu(|u|) = \mathcal{I}_{\mu,a}$. Then we can replace u by $|u|$, thus we may assume that $u \geq 0$, by standard argument, we can prove that $u(x) > 0$ in $\mathbb{R}^3$.

By Theorem 2.1, it is easy to conclude the following corollary.

Corollary 2.9. *Fix $a > a^*$ and let $0 \leq \mu_1 < \mu_2 \leq \mu_*$. There holds $\mathcal{I}_{\mu_1,a} < \mathcal{I}_{\mu_2,a} < 0$.*

Proof. Let $u_{\mu_2,a} \in S(a)$ satisfying $I_{\mu_2}(u_{\mu_2,a}) = \mathcal{I}_{\mu_2,a}$. It is easy to infer that

$$\mathcal{I}_{\mu_1,a} \leq I_{\mu_1}(u_{\mu_2,a}) < I_{\mu_2}(u_{\mu_2,a}) = \mathcal{I}_{\mu_2,a}.$$ □

3 The nonautonomous case

In this section, we will study the nonautonomous case of the Schrödinger–Poisson system (1.4). Hereafter, we will suppose that $|V|_\infty < \mu_*$ and $a > a_*$, where μ_* and a_* was given in section 2. In order to prove some properties of the functional J_ε, we give several useful definitions. We define J_0, $J_\infty : H^1(\mathbb{R}^3) \to \mathbb{R}$ by the following functionals:

$$J_0(u) = \frac{1}{2}\int_{\mathbb{R}^3} |\nabla u|^2 \mathrm{d}x + \frac{1}{4}\int_{\mathbb{R}^3} \phi_u u^2 \mathrm{d}x - \int_{\mathbb{R}^3} F(u)\mathrm{d}x$$

and

$$J_\infty(u) = \frac{1}{2}\int_{\mathbb{R}^3} (|\nabla u|^2 + V_\infty |u|^2)\mathrm{d}x + \frac{1}{4}\int_{\mathbb{R}^3} \phi_u u^2 \mathrm{d}x - \int_{\mathbb{R}^3} F(u)\mathrm{d}x.$$

Furthermore, we denote $\Upsilon_{\varepsilon,a}$, $\Upsilon_{0,a}$ and $\Upsilon_{\infty,a}$:

$$\Upsilon_{\varepsilon,a} = \inf_{u \in S(a)} J_\varepsilon(u), \qquad \Upsilon_{0,a} = \inf_{u \in S(a)} J_0(u), \qquad \Upsilon_{\infty,a} = \inf_{u \in S(a)} J_\infty(u).$$

Since $0 < V_\infty < +\infty$, we deduce from Corollary 2.9 that

$$\Upsilon_{0,a} < \Upsilon_{\infty,a} < 0. \tag{3.1}$$

In the following, we set $0 < \rho_1 = \frac{1}{2}(\Upsilon_{\infty,a} - \Upsilon_{0,a})$.

The following lemma establishes some essential relations involving the levels $\Upsilon_{\varepsilon,a}$, $\Upsilon_{0,a}$ and $\Upsilon_{\infty,a}$.

Lemma 3.1. $\limsup_{\varepsilon \to 0^+} \Upsilon_{\varepsilon,a} \leq \Upsilon_{0,a}$ *and there exists $\varepsilon_0 > 0$ such that $\Upsilon_{\varepsilon,a} < \Upsilon_{\infty,a}$ for all $\varepsilon \in (0, \varepsilon_0)$.*

Proof. Let $u_0 \in S(a)$ with $J_0(u_0) = \Upsilon_{0,a}$, we have that

$$\Upsilon_{\varepsilon,a} \leq J_\varepsilon(u_0) = \frac{1}{2}\int_{\mathbb{R}^3}(|\nabla u_0|^2 + V(\varepsilon x)|u_0|^2)\mathrm{d}x + \frac{1}{4}\int_{\mathbb{R}^3}\phi_{u_0}u_0^2\mathrm{d}x - \int_{\mathbb{R}^3}F(u_0)\mathrm{d}x.$$

As $\varepsilon \to 0^+$, we arrive at the inequality

$$\limsup_{\varepsilon\to 0^+}\Upsilon_{\varepsilon,a} \leq \lim_{\varepsilon\to 0^+} J_\varepsilon(u_0) = J_0(u_0) = \Upsilon_{0,a}.$$

By (3.1) and the above inequality, we can obtain that $\Upsilon_{\varepsilon,a} < \Upsilon_{\infty,a}$ for ε small enough. □

Lemma 3.2. *Fix $\varepsilon \in (0, \varepsilon_0)$ and let $\{u_n\} \subset S(a)$ such that $J_\varepsilon(u_n) \to c$ with $c < \Upsilon_{0,a} + \rho_1 < 0$. If $u_n \rightharpoonup u$ in $H^1(\mathbb{R}^3)$, then $u \neq 0$.*

Proof. We argue by contradiction that $u = 0$. From the definition of $J_\varepsilon(u_n)$ and $J_\infty(u_n)$, it follows that

$$\Upsilon_{0,a} + \rho_1 + o_n(1) > c + o_n(1) = J_\varepsilon(u_n) = J_\infty(u_n) + \frac{1}{2}\int_{\mathbb{R}^3}(V(\varepsilon x) - V_\infty)|u_n|^2\mathrm{d}x.$$

From (V), for any given $\zeta > 0$, there exists $R > 0$ such that

$$V(x) \geq V_\infty - \zeta, \qquad \forall\, |x| \geq R.$$

Thus, there holds

$$\Upsilon_{0,a} + \rho_1 + o_n(1) > J_\varepsilon(u_n) \geq J_\infty(u_n) + \frac{1}{2}\int_{B_{R/\varepsilon}(0)}(V(\varepsilon x) - V_\infty)|u_n|^2\mathrm{d}x - \frac{\zeta}{2}\int_{B^c_{R/\varepsilon}(0)}|u_n|^2\mathrm{d}x.$$

Since $\{u_n\}$ is bounded in $H^1(\mathbb{R}^3)$ and $u_n \to 0$ in $L^l(B_{R/\varepsilon}(0))$ for all $l \in [1, 2^*)$, we obtain

$$\Upsilon_{0,a} + \rho_1 + o_n(1) \geq J_\infty(u_n) - \zeta C \geq \Upsilon_{\infty,a} - \zeta C$$

for some $C > 0$. Because $\zeta > 0$ is arbitrary, it follows that

$$\Upsilon_{0,a} + \rho_1 \geq \Upsilon_{\infty,a},$$

which is contradict with the definition of ρ_1. The proof is completed. □

Lemma 3.3. *Let $\{u_n\} \subset S(a)$ be a $(PS)_c$ sequence for J_ε restricted to $S(a)$ with $c < \Upsilon_{0,a} + \rho_1 < 0$ and $u_n \rightharpoonup u_\varepsilon$ in $H^1(\mathbb{R}^3)$, that is,*

$$J_\varepsilon(u_n) \to c \quad \text{as } n \to +\infty \quad \text{and} \quad \|J_\varepsilon|'_{S(a)}(u_n)\| \to 0 \quad \text{as } n \to +\infty.$$

If $v_n = u_n - u_\varepsilon \nrightarrow 0$ in $H^1(\mathbb{R}^3)$, then there exists $\beta > 0$, such that

$$\liminf_{n\to+\infty}|u_n - u_\varepsilon|_2^2 \geq \beta.$$

Proof. Let the functional $\Psi : H^1(\mathbb{R}^3) \to \mathbb{R}$ be given by

$$\Psi(u) = \frac{1}{2}\int_{\mathbb{R}^3}|u|^2\mathrm{d}x,$$

we have that $S(a) = \Psi^{-1}(\{\frac{a^2}{2}\})$. Then, by Proposition 5.12 in [30], we see that

$$\|J_\varepsilon|'_{S(a)}(u_n)\| = \min_{\lambda\in\mathbb{R}}\|J_\varepsilon{}'(u_n) - \lambda\Psi'(u_n)\|_{(H^1(\mathbb{R}^3))'},$$

thus, there exists $\{\lambda_n\} \subset \mathbb{R}$ such that

$$\|J_\varepsilon{}'(u_n) - \lambda_n \Psi'(u_n)\|_{(H^1(\mathbb{R}^3))'} \to 0 \quad \text{as } n \to +\infty.$$

Since

$$\|J_\varepsilon{}'(u_n) - \lambda_n \Psi'(u_n)\|_{(H^1(\mathbb{R}^3))'} = \sup_{v \in H^1(\mathbb{R}^3)\setminus\{0\}} \frac{\langle J_\varepsilon{}'(u_n) - \lambda_n \Psi'(u_n), v\rangle}{\|v\|} \to 0 \quad \text{as } n \to +\infty.$$

In view of the boundedness of $\{u_n\}$, we can deduce that

$$\frac{\langle J_\varepsilon{}'(u_n) - \lambda_n \Psi'(u_n), u_n\rangle}{\|u_n\|} \le \|J_\varepsilon{}'(u_n) - \lambda_n \Psi'(u_n)\|_{(H^1(\mathbb{R}^3))'} \to 0 \quad \text{as } n \to +\infty,$$

which leads to

$$\lambda_n a^2 = \int_{\mathbb{R}^3} (|\nabla u_n|^2 + V(\varepsilon x) u_n^2) \mathrm{d}x + \int_{\mathbb{R}^3} \phi_{u_n} u_n^2 \mathrm{d}x - \int_{\mathbb{R}^3} f(u_n) u_n \mathrm{d}x + o_n(1). \tag{3.2}$$

From the boundedness of $\{u_n\} \in H^1(\mathbb{R}^3)$, it follows that $\{\lambda_n\}$ is also a bounded sequence, up to a subsequence, we may assume that $\lambda_n \to \lambda_\varepsilon$ as $n \to +\infty$. Hence, we have that

$$\|J_\varepsilon{}'(u_n) - \lambda_\varepsilon \Psi'(u_n)\|_{(H^1(\mathbb{R}^3))'} \le \|J_\varepsilon{}'(u_n) - \lambda_n \Psi'(u_n)\|_{(H^1(\mathbb{R}^3))'} + |\lambda_n - \lambda_\varepsilon| \|\Psi'(u_n)\|_{(H^1(\mathbb{R}^3))'},$$

which combing with $u_n \rightharpoonup u_\varepsilon$ in $H^1(\mathbb{R}^3)$, we can deduce that

$$J_\varepsilon{}'(u_\varepsilon) - \lambda_\varepsilon \Psi'(u_\varepsilon) = 0 \quad \text{in } (H^1(\mathbb{R}^3))'.$$

By using Lemma 2.3, we can prove that

$$J_\varepsilon{}'(u_n) = J_\varepsilon{}'(u_\varepsilon) + J_\varepsilon{}'(v_n) + o_n(1),$$

and

$$\Psi'(u_n) = \Psi'(u_\varepsilon) + \Psi'(v_n) + o_n(1).$$

Hence, we have

$$J_\varepsilon{}'(u_n) - \lambda_\varepsilon \Psi'(u_n) = J_\varepsilon{}'(v_n) - \lambda_\varepsilon \Psi'(v_n) + o_n(1),$$

and so

$$\|J_\varepsilon{}'(v_n) - \lambda_\varepsilon \Psi'(v_n)\|_{(H^1(\mathbb{R}^3))'} \to 0 \quad \text{as } n \to +\infty,$$

which implies that

$$\int_{\mathbb{R}^3} (|\nabla v_n|^2 + V(\varepsilon x)|v_n|^2) \mathrm{d}x + \int_{\mathbb{R}^3} \phi_{v_n} v_n{}^2 \mathrm{d}x - \lambda_\varepsilon \int_{\mathbb{R}^3} |v_n|^2 \mathrm{d}x = \int_{\mathbb{R}^3} f(v_n) v_n \mathrm{d}x + o_n(1).$$

Suppose on the contrary that $|v_n|_2 \to 0$, by interpolation inequality, one infers that

$$v_n \to 0 \quad \text{in } L^t(\mathbb{R}^3), \qquad \forall t \in [2, 6). \tag{3.3}$$

By (f_1), (f_2) and (3.3), we deduce that

$$\int_{\mathbb{R}^3} f(v_n) v_n \mathrm{d}x \le \int_{\mathbb{R}^3} C_1 |v_n|^p + C_2 |v_n|^q \mathrm{d}x \to 0 \quad \text{as } n \to +\infty,$$

and

$$\int_{\mathbb{R}^3} \phi_{v_n} v_n{}^2 \mathrm{d}x \le |v_n|^4_{\frac{12}{5}} \to 0 \quad \text{as } n \to +\infty,$$

and

$$\int_{\mathbb{R}^3} V(\varepsilon x)|v_n|^2 \mathrm{d}x \leq \int_{\mathbb{R}^3} \mu_* |v_n|^2 \mathrm{d}x \to 0 \quad \text{as } n \to +\infty.$$

Hence, we have that

$$\int_{\mathbb{R}^3} |\nabla v_n|^2 \mathrm{d}x \to 0 \quad \text{as } n \to +\infty,$$

which leads to $\|v_n\|_{H^1(\mathbb{R}^3)} \to 0$, which gives a contradiction by $v_n \nrightarrow 0$ in $H^1(\mathbb{R}^3)$. Therefore, there exists $\beta > 0$ independent of $\varepsilon \in (0, \varepsilon_0)$ such that

$$\liminf_{n \to +\infty} |u_n - u_\varepsilon|_2^2 \geq \beta. \qquad \square$$

In what follows, we set

$$0 < \rho < \min\left\{\frac{1}{2}, \frac{\beta^3}{a^6}\right\} (\Upsilon_{\infty,a} - \Upsilon_{0,a}) \leq \rho_1. \tag{3.4}$$

Lemma 3.4. *For each $\varepsilon \in (0, \varepsilon_0)$, the functional J_ε satisfies the $(PS)_c$ condition restricted to $S(a)$ for $c < \Upsilon_{0,a} + \rho$.*

Proof. Let $\{u_n\}$ be a $(PS)_c$ sequence for J_ε restricted to $S(a)$ with $u_n \rightharpoonup u_\varepsilon$ in $H^1(\mathbb{R}^3)$ and $c < \Upsilon_{0,a} + \rho$. Then, by Proposition 5.12 in [30], there exists $(\lambda_n) \subset \mathbb{R}$ such that

$$\|J_\varepsilon'(u_n) - \lambda_n \Psi'(u_n)\|_{(H^1(\mathbb{R}^3))'} \to 0 \quad \text{as } n \to +\infty.$$

By Lemma 3.3, if $v_n = u_n - u_\varepsilon \nrightarrow 0$ in $H^1(\mathbb{R}^3)$, there exists $\beta > 0$ independent of ε such that

$$\liminf_{n \to +\infty} |v_n|_2^2 \geq \beta.$$

Let $d_n = |v_n|_2$ satisfying that $|v_n|_2 \to d > 0$ and $|u_\varepsilon|_2 = b$, by Brézis-Lieb lemma, we obtain $a^2 = b^2 + d^2$. By Lemma 3.2, we have $b > 0$ and in its proof it was proved that $J_\varepsilon(v_n) \geq \Upsilon_{\infty,d_n} + o_n(1)$, we must have $d_n \in (0, a)$ for n large enough, and so

$$c + o_n(1) = J_\varepsilon(u_n) = J_\varepsilon(v_n) + J_\varepsilon(u_\varepsilon) + o_n(1) \geq \Upsilon_{\infty,d_n} + \Upsilon_{0,b} + o_n(1).$$

By Lemma 2.6, we infer that

$$\rho + \Upsilon_{0,a} > \frac{d_n^6}{a^6}\Upsilon_{\infty,a} + \frac{b^6}{a^6}\Upsilon_{0,a}.$$

As $n \to +\infty$, using $a^2 = b^2 + d^2$, we arrive at the inequality

$$\rho > \frac{d^6}{a^6}\Upsilon_{\infty,a} + \frac{b^6 - a^6}{a^6}\Upsilon_{0,a} > \frac{d^6}{a^6}(\Upsilon_{\infty,a} - \Upsilon_{0,a}) + \frac{3a^2d^4 - 3a^4d^2}{a^6}\Upsilon_{0,a} > \frac{\beta^3}{a^6}(\Upsilon_{\infty,a} - \Upsilon_{0,a}),$$

which is contradict with (3.4). Thus, $v_n \to 0$ in $H^1(\mathbb{R}^3)$, that is, $u_n \to u_\varepsilon$ in $H^1(\mathbb{R}^3)$, which implies that $|u_\varepsilon|_2 = a$ and

$$-\Delta u_\varepsilon + V(\varepsilon x)u_\varepsilon + \phi u_\varepsilon = \lambda_\varepsilon u_\varepsilon + f(u_\varepsilon) \quad \text{in } \mathbb{R}^3,$$

where λ_ε is the limit of some subsequence of $\{\lambda_n\}$. $\square$

4 Multiplicity result

Let $\delta > 0$ be fixed and w be a positive solution of the following Schrödinger–Poisson system

$$\begin{cases} -\Delta u + \phi u = f(u) + \lambda u & \text{in } \mathbb{R}^3, \\ -\Delta \phi = u^2 & \text{in } \mathbb{R}^3, \\ \int_{\mathbb{R}^3} |u|^2 \mathrm{d}x = a^2, \end{cases}$$

with $J_0(w) = \Upsilon_{0,a}$. Let η be a smooth nonincreasing cut-off function satisfying

$$\eta(s) = \begin{cases} 1, & 0 \le s \le \frac{\delta}{2}, \\ 0, & s \ge \delta. \end{cases}$$

For any $y \in M$, let us define

$$\Psi_{\varepsilon,y}(x) = \eta(|\varepsilon x - y|) w\left(\frac{\varepsilon x - y}{\varepsilon}\right), \qquad \widetilde{\Psi}_{\varepsilon,y}(x) = a\frac{\Psi_{\varepsilon,y}(x)}{|\Psi_{\varepsilon,y}|_2},$$

and denote Φ_ε: $M \to S(a)$ by $\Phi_\varepsilon(y) = \widetilde{\Psi}_{\varepsilon,y}$. Clearly, $\Phi_\varepsilon(y)$ has a compact support for any $y \in M$.

Lemma 4.1 (See [14, Chapter II, 3.2])**.** *Let I be a C^1-functional defined on C^1-Finsler manifold $\mathcal{V}$. If I is bounded from below and satisfies the (PS) condition, the I has at least $\mathrm{cat}_{\mathcal{V}}(\mathcal{V})$ distinct critical points.*

Let $\Phi : \Omega^- \to \Gamma$, $\beta : \Gamma \to \Omega^+$ be two continuous maps such that $\beta \circ \Phi$ is homotopically equivalent to the embedding $\mathrm{Id} : \Omega^- \to \Omega^+$. Then $\mathrm{cat}(\Gamma) \ge \mathrm{cat}_{\Omega^+}(\Omega^-)$.*

Lemma 4.3. *The function Φ_ε has the following property:*

$$\lim_{\varepsilon \to 0} J_\varepsilon(\Phi_\varepsilon(y)) = \Upsilon_{0,a}, \quad \textit{uniformly in } y \in M.$$

Proof. To prove this lemma, we argue by contradiction that there exist $\delta_0 > 0$, $\{y_n\} \subset M$, $\{y_n\}$ is a bounded sequence and $\varepsilon_n \to 0$ such that

$$|J_{\varepsilon_n}(\Phi_{\varepsilon_n}(y_n)) - \Upsilon_{0,a}| \ge \delta_0, \qquad \forall n \in \mathbb{N}.$$

Since

$$|\eta(\varepsilon_n z) w(z)|^2 \to |w(z)|^2 \quad \text{a.e. in } \mathbb{R}^3 \text{ as } n \to +\infty,$$

and

$$|\eta(\varepsilon_n z) w(z)|^2 \le |w(z)|^2,$$

by Lebesgue's dominated convergence theorem, we get

$$\lim_{n\to+\infty} \int_{\mathbb{R}^3} |\Psi_{\varepsilon_n, y_n}|^2 \mathrm{d}x = \lim_{n\to+\infty} \int_{\mathbb{R}^3} |\eta(\varepsilon_n z) w(z)|^2 \mathrm{d}z = \int_{\mathbb{R}^3} |w|^2 \mathrm{d}z = a^2.$$

Then, there exists $N > 0$ such that

$$|\Psi_{\varepsilon_n, y_n}|_2^2 \ge \frac{a^2}{2}, \qquad \forall n > N.$$

Setting $|\Psi_{\varepsilon_n,y_n}|_2^2 \geq C = \min\{\frac{a^2}{2}, |\Psi_{\varepsilon_1,y_1}|_2^2, |\Psi_{\varepsilon_2,y_2}|_2^2, \dots, |\Psi_{\varepsilon_N,y_N}|_2^2\}$.

Since

$$\lim_{n\to+\infty} F(\Phi_{\varepsilon_n}(y_n)) = \lim_{n\to+\infty} F\left(a\frac{\eta(\varepsilon_n z)w(z)}{|\eta(\varepsilon_n z)w(z)|_2}\right) = F(w) \quad \text{a.e. in } \mathbb{R}^3,$$

and by (f_1) and (f_2), we have that

$$|F(\Phi_{\varepsilon_n}(y_n))| = \left|F\left(a\frac{\eta(\varepsilon_n z)w(z)}{|\eta(\varepsilon_n z)w(z)|_2}\right)\right| \leq C_1|w(z)|^p + C_2|w(z)|^q,$$

thus, by Lebesgue's dominated convergence theorem, we have

$$\lim_{n\to+\infty}\int_{\mathbb{R}^3} F(\Phi_{\varepsilon_n}(y_n))\mathrm{d}x = \lim_{n\to+\infty}\int_{\mathbb{R}^3} F\left(a\frac{\eta(\varepsilon_n z)w(z)}{|\eta(\varepsilon_n z)w(z)|_2}\right)\mathrm{d}z = \int_{\mathbb{R}^3} F(w)\mathrm{d}z.$$

For almost every $z \in \mathbb{R}^3$, we deduce that

$$\begin{aligned}
&\lim_{n\to+\infty} |\nabla\Phi_{\varepsilon_n}(y_n)|^2 \\
&= \lim_{n\to+\infty} \frac{a^2}{|\Psi_{\varepsilon_n,y_n}|_2^2}|\nabla(\eta(\varepsilon_n z)w(z))|^2 \\
&= \lim_{n\to+\infty} |\nabla(\eta(\varepsilon_n z))w(z) + \eta(\varepsilon_n z)\nabla w(z)|^2 \\
&= \lim_{n\to+\infty} [\varepsilon_n^2|\nabla(\eta(\varepsilon_n z))w(z)|^2 + |\eta(\varepsilon_n z)\nabla w(z)|^2 + 2\varepsilon_n\eta(\varepsilon_n z)\nabla(\eta(\varepsilon_n z))w(z)\nabla w(z)] \\
&= \lim_{n\to+\infty} |\nabla w(z)|^2
\end{aligned}$$

and

$$\begin{aligned}
|\nabla\Phi_{\varepsilon_n}(y_n)|^2 &\leq \frac{a^2}{C}[\varepsilon_n^2|\nabla(\eta(\varepsilon_n z))w(z)|^2 + |\eta(\varepsilon_n z)\nabla w(z)|^2 + 2\varepsilon_n\eta(\varepsilon_n z)\nabla(\eta(\varepsilon_n z))w(z)\nabla w(z)] \\
&\leq \frac{a^2}{C}[C_3\varepsilon_n^2|w(z)|^2 + |\nabla w(z)|^2 + C_4\varepsilon_n^2|w(z)|^2|\nabla w(z)|^2],
\end{aligned}$$

by Lebesgue's dominated convergence theorem, we obtain

$$\lim_{n\to+\infty}\int_{\mathbb{R}^3} |\nabla\Phi_{\varepsilon_n}(y_n)|^2\mathrm{d}x = \int_{\mathbb{R}^3} |\nabla w|^2\mathrm{d}z.$$

Since

$$\lim_{n\to+\infty} V(\varepsilon_n x)|\Phi_{\varepsilon_n}(y_n)|^2 = \lim_{n\to+\infty} \frac{a^2V(\varepsilon_n z + y_n)}{|\Psi_{\varepsilon_n,y_n}|_2^2}|\eta(\varepsilon_n z)w(z)|^2 = 0 \quad \text{a.e. in } \mathbb{R}^3,$$

and

$$V(\varepsilon_n x)|\Phi_{\varepsilon_n}(y_n)|^2 = \frac{a^2V(\varepsilon_n z + y_n)}{|\Psi_{\varepsilon_n,y_n}|_2^2}|\eta(\varepsilon_n z)w(z)|^2 \leq \frac{a^2}{C}\mu_* W(z)^2,$$

by Lebesgue's dominated convergence theorem, we deduce that

$$\lim_{n\to+\infty}\int_{\mathbb{R}^3} V(\varepsilon_n x)|\Phi_{\varepsilon_n}(y_n)|^2\mathrm{d}x = 0.$$

Since

$$\begin{aligned}
&\lim_{n\to+\infty} \phi_{\Phi_{\varepsilon_n}(y_n)}\Phi_{\varepsilon_n}(y_n)^2 \\
&\quad = \lim_{n\to+\infty} \frac{\left|\frac{a}{|\Psi_{\varepsilon_n,y_n}|_2}\eta(\varepsilon_n z)w(z)\right|^2\left|\frac{a}{|\Psi_{\varepsilon_n,y_n}|_2}\eta(\varepsilon_n r)w(r)\right|^2}{|z-r|} = \phi_w w^2 \quad \text{a.e. in } \mathbb{R}^3,
\end{aligned}$$

and by Lemma 2.2-(2), we have that

$$\phi_{\Phi_{\varepsilon_n}(y_n)}\Phi_{\varepsilon_n}(y_n)^2 = \frac{\left|\frac{a}{|\Psi_{\varepsilon_n,y_n}|_2}\eta(\varepsilon_n z)w(z)\right|^2 \left|\frac{a}{|\Psi_{\varepsilon_n,y_n}|_2}\eta(\varepsilon_n r)w(r)\right|^2}{|z-r|}$$
$$\leq \frac{a^4}{C^4}\frac{|w(z)|^2|w(r)|^2}{|z-r|} \leq C_5\phi_w w^2,$$

by Lebesgue's dominated convergence theorem, there holds

$$\begin{aligned}\lim_{n\to+\infty}&\int_{\mathbb{R}^3}\phi_{\Phi_{\varepsilon_n}(y_n)}\Phi_{\varepsilon_n}(y_n)^2\mathrm{d}x\\ &= \lim_{n\to+\infty}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\frac{\left|\frac{a}{|\Psi_{\varepsilon_n,y_n}|_2}\eta(\varepsilon_n z)w(z)\right|^2 \left|\frac{a}{|\Psi_{\varepsilon_n,y_n}|_2}\eta(\varepsilon_n r)w(r)\right|^2}{|z-r|}\mathrm{d}z\mathrm{d}r\\ &= \int_{\mathbb{R}^3}\phi_w w^2\mathrm{d}z.\end{aligned}$$

Consequently,

$$\lim_{n\to+\infty} J_{\varepsilon_n}(\Phi_{\varepsilon_n}(y_n)) = J_{0,a}(w) = \Upsilon_{0,a},$$

which is absurd. Hence, we complete the proof. □

For any $\delta > 0$, let $R = R(\delta) > 0$ be such that $M_\delta \subset B_R(0)$. Let χ: $\mathbb{R}^3 \to \mathbb{R}^3$ denote by $\chi(x) = x$ for $|x| \leq R$ and $\chi(x) = \frac{Rx}{|x|}$ for $|x| \geq R$. Hereafter, we are going to consider β_ε: $S(a) \to \mathbb{R}^3$ given by

$$\beta_\varepsilon(u) = \frac{\int_{\mathbb{R}^3}\chi(\varepsilon x)|u|^2\mathrm{d}x}{a^2}.$$

Lemma 4.4. *The function Φ_ε has the following property:*

$$\lim_{\varepsilon\to 0}\beta_\varepsilon(\Phi_\varepsilon(y)) = y, \quad \textit{uniformly in } y \in M.$$

Proof. Suppose on the contrary that there exist $\delta_0 > 0$, $\{y_n\} \subset M$, and $\varepsilon_n \to 0$ such that

$$|\beta_{\varepsilon_n}(\Phi_{\varepsilon_n}(y_n)) - y_n| \geq \delta_0, \qquad \forall n \in \mathbb{N}. \tag{4.1}$$

By the definition of $\Phi_{\varepsilon_n}(y_n)$ and β_{ε_n}, we have that

$$\beta_{\varepsilon_n}(\Phi_{\varepsilon_n}(y_n)) = y_n + \frac{\int_{\mathbb{R}^3}(\chi(\varepsilon_n z + y_n) - y_n)|\eta(\varepsilon_n z)w(z)|^2\mathrm{d}z}{|\Psi_{\varepsilon_n,y_n}(\frac{\varepsilon_n+y_n}{\varepsilon_n})|_2^2}.$$

Since $(y_n) \subset M \subset B_R(0)$,

$$\frac{(\chi(\varepsilon_n z + y_n) - y_n)|\eta(\varepsilon_n z)w(z)|^2}{|\Psi_{\varepsilon_n,y_n}(\frac{\varepsilon_n+y_n}{\varepsilon_n})|_2^2} \to 0 \quad \text{a.e. in } \mathbb{R}^3,$$

and

$$\frac{(\chi(\varepsilon_n z + y_n) - y_n)|\eta(\varepsilon_n z)w(z)|^2}{|\Psi_{\varepsilon_n,y_n}(\frac{\varepsilon_n+y_n}{\varepsilon_n})|_2^2} \leq \frac{2R}{C}|w(z)|^2,$$

by Lebesgue's dominated convergence theorem, we deduce that

$$|\beta_{\varepsilon_n}(\Phi_{\varepsilon_n}(y_n)) - y_n| \to 0, \quad \text{as } n \to +\infty,$$

which attains a contradiction with (4.1). Hence, we complete the proof. □

Proposition 4.5. *Let $\varepsilon_n \to 0$ and $\{u_n\} \subset S(a)$ with $J_\varepsilon(u_n) \to \Upsilon_{0,a}$. Then, there is $\{\widetilde{y}_n\} \subset \mathbb{R}^3$ such that $v_n(x) = u_n(x + \widetilde{y}_n)$ has a strongly convergent subsequence in $H^1(\mathbb{R}^3)$. Moreover, up to a subsequence, $y_n = \varepsilon_n \widetilde{y}_n \to y$ in $\mathbb{R}^3$ for some $y \in M$.*

Proof. Firstly, we claim that there exist $R_0, \tau > 0$ and $\widetilde{y}_n \in \mathbb{R}^3$ such that

$$\int_{B_{R_0}(\widetilde{y}_n)} |u_n|^2 \mathrm{d}x \geq \tau \qquad \forall n \in \mathbb{N}.$$

Otherwise, owing to Lions' vanishing lemma, we have that $u_n \to 0$ in $L^p(\mathbb{R}^3)$ for all $p \in (2, 2^*)$, which implies that $\int_{\mathbb{R}^3} F(u_n)\mathrm{d}x \to 0$. Thus, $\lim_{n\to+\infty} J_{\varepsilon_n}(u_n) \geq 0$, which contradicts with $\lim_{n\to+\infty} J_{\varepsilon_n}(u_n) = \Upsilon_{0,a} < 0$.

Considering $v_n(x) = u_n(x + \widetilde{y}_n)$, up to a subsequence, we may assume that there exists $v \in H^1(\mathbb{R}^3) \setminus \{0\}$ satisfying $v_n \rightharpoonup v$ in $H^1(\mathbb{R}^3)$. Since $\{v_n\} \subset S(a)$ and $J_{\varepsilon_n}(u_n) \geq J_0(u_n) = J_0(v_n) \geq \Upsilon_{0,a}$, there holds that $J_0(v_n) \to \Upsilon_{0,a}$. By Theorem 2.8, $v_n \to v$ in $H^1(\mathbb{R}^3)$ and $v \in S(a)$.

In what follows, we are to prove that $\{y_n\}$ is bounded. Arguing by contradiction that for some subsequence $|y_n| \to +\infty$, the limit

$$\begin{aligned}
\Upsilon_{0,a} &= \lim_{n\to+\infty} J_{\varepsilon_n}(u_n) \\
&= \lim_{n\to+\infty} \left(\frac{1}{2} \int_{\mathbb{R}^3} (|\nabla v_n|^2 + V(\varepsilon_n x + y_n)|v_n|^2)\mathrm{d}x + \frac{1}{4} \int_{\mathbb{R}^3} \phi_{v_n} {v_n}^2 \mathrm{d}x - \int_{\mathbb{R}^3} F(v_n)\mathrm{d}x \right) \\
&\geq \frac{1}{2} \int_{\mathbb{R}^3} (|\nabla v|^2 + V_\infty |v|^2)\mathrm{d}x + \frac{1}{4} \int_{\mathbb{R}^3} \phi_v v^2 \mathrm{d}x - \int_{\mathbb{R}^3} F(v)\mathrm{d}x \\
&\geq \Upsilon_{\infty,a},
\end{aligned}$$

this gives a contradiction due to (3.1). Therefore, we can suppose that $y_n \to y$ in $\mathbb{R}^3$. Similarly discussed as above, we obtain

$$\Upsilon_{0,a} \geq \frac{1}{2} \int_{\mathbb{R}^3} (|\nabla v|^2 + V(y)|v|^2)\mathrm{d}x + \frac{1}{4} \int_{\mathbb{R}^3} \phi_v v^2 \mathrm{d}x - \int_{\mathbb{R}^3} F(v)\mathrm{d}x \geq \Upsilon_{V(y),a}.$$

By Corollary 2.9, we know that $\Upsilon_{V(y),a} > \Upsilon_{0,a}$ as $V(y) > 0$. Since $V(y) \geq 0$ for all $y \in \mathbb{R}^3$, the above inequality implies that $V(y) = 0$, that is, $y \in M$. □

Let h: $[0, +\infty) \to [0, +\infty)$ be a function such that $h(\varepsilon) \to 0$ as $\varepsilon \to 0$ and set

$$\widetilde{S}(a) = \{u \in S(a) : J_\varepsilon(u) \leq \Upsilon_{0,a} + h(\varepsilon)\}. \tag{4.2}$$

In view of Lemma 4.3, the function $h(\varepsilon) = \sup_{y\in M} |J_\varepsilon(\Phi_\varepsilon(y)) - \Upsilon_{0,a}|$ satisfies that $h(\varepsilon) \to 0$ as $\varepsilon \to 0$. Thus, $\Phi_\varepsilon(y) \in \widetilde{S}(a)$ for all $y \in M$.

Lemma 4.6. *Let $\delta > 0$ and $M_\delta = \{x \in \mathbb{R}^3 : \mathrm{dist}(x, M) \leq \delta\}$. There holds*

$$\lim_{\varepsilon\to 0} \sup_{u\in\widetilde{S}(a)} \inf_{z\in M_\delta} |\beta_\varepsilon(u) - z| = 0.$$

Proof. Let $\varepsilon_n \to 0$ and $u_n \in \widetilde{S}(a)$ such that

$$\inf_{z\in M_\delta} |\beta_{\varepsilon_n}(u_n) - z| = \sup_{u_n\in\widetilde{S}(a)} \inf_{z\in M_\delta} |\beta_{\varepsilon_n}(u_n) - z| + o_n(1).$$

According to the above equality, it is sufficient to find a sequence $\{y_n\} \subset M_\delta$ such that

$$\lim_{n\to+\infty} |\beta_{\varepsilon_n}(u_n) - y_n| = 0.$$

Since $u_n \in \widetilde{S}(a)$, we obtain

$$\Upsilon_{0,a} \leq J_0(u_n) \leq J_{\varepsilon_n}(u_n) \leq \Upsilon_{0,a} + h(\varepsilon_n) \qquad \forall n \in \mathbb{N},$$

and so,

$$u_n \in S(a) \quad \text{and} \quad J_{\varepsilon_n}(u_n) \to \Upsilon_{0,a}.$$

From Proposition 4.5, it follows that there exists $\{\widetilde{y}_n\} \subset \mathbb{R}^3$ such that $y_n = \varepsilon_n \widetilde{y}_n \to y$ for some $y \in M$ and $v_n(x) = u_n(x + \widetilde{y}_n)$ is strongly convergent to some $v \in H^1(\mathbb{R}^3)$ with $v \neq 0$. Then, $\{y_n\} \subset M_\delta$ for n large enough and

$$\beta_{\varepsilon_n}(u_n) = y_n + \frac{\int_{\mathbb{R}^3} (\chi(\varepsilon_n z + y_n) - y_n)|v_n|^2 \mathrm{d}z}{a^2},$$

which implies that

$$\beta_{\varepsilon_n}(u_n) - y_n = \frac{\int_{\mathbb{R}^3} (\chi(\varepsilon_n z + y_n) - y_n)|v_n|^2 \mathrm{d}z}{a^2} \to 0 \quad \text{as } n \to +\infty.$$

The proof is completed. □

4.1 Proof of Theorem 1.2.

In what follows, let $\varepsilon \in (0, \varepsilon_0)$. By Lemma 4.3, for any $y \in M$, we have

$$J_\varepsilon(\Phi_\varepsilon(y)) \leq \Upsilon_{0,a} + h(\varepsilon), \qquad h(\varepsilon) \to 0 \, (\varepsilon \to 0),$$

which implies that $\Phi_\varepsilon(M) \subset \widetilde{S}(a)$. By Lemma 4.6, we obtain

$$\mathrm{dist}(\beta_\varepsilon(u), M_\delta) \leq \delta, \qquad \forall u \in \widetilde{S}(a),$$

which leads to $\beta_\varepsilon(\widetilde{S}(a)) \subset M_\delta$. Hence, we have that $\beta_\varepsilon \circ \Phi_\varepsilon(M) \subset M_\delta$. We define $id : M \to M_\delta$. Hereafter, let us define $W : [0,1] \times M \to M_\delta$

$$W(t,y) = t\beta_\varepsilon \circ \Phi_\varepsilon + (1-t)\,\mathrm{id}(y) \qquad t \in [0,1],$$

satisfying $W(0,y) = \mathrm{id}(y)$, $W(1,y) = \beta_\varepsilon \circ \Phi_\varepsilon$, we can conclude that $\beta_\varepsilon \circ \Phi_\varepsilon$ is homotopic to the inclusion map $\mathrm{id} : M \to M_\delta$. By Lemma 4.2, it follows that

$$\mathrm{cat}(\widetilde{S}(a)) \geq \mathrm{cat}_{M_\delta}(M).$$

Arguing as Lemma 2.4, we also have that J_ε is bounded from below on $S(a)$. From Lemma 3.4, we have that the functional J_ε satisfies the $(PS)_c$ condition for the $c \in (\Upsilon_{0,a}, \Upsilon_{0,a} + h(\varepsilon))$. By Lemma 4.1, there exists at least $\mathrm{cat}(S(a))$ critical points of J_ε restricted to $S(a)$. Since $\widetilde{S}(a) \subset S(a)$, $\mathrm{cat}(\widetilde{S}(a)) \leq \mathrm{cat}(S(a))$. Then, by the Lusternik–Schnirelmann category theory (see [19] and Theorem 5.20 of [30]), we have that J_ε has at least $\mathrm{cat}_{M_\delta}(M)$ critical points on $S(a)$.

Abstract. We deal with limit cycles bifurcating from the period annulus of Liénard system with a hyperelliptic Hamiltonian of degree five under quartic perturbation, where Liénard system has a normal form $\dot{x} = y$, $\dot{y} = x(x-1)(x^2+ax+b)$, $a^2-4b<0$. It is proved that the perturbation of this system can produce at most six limit cycles for $a = b = 2$.

Keywords: Liénard system, Poincaré bifurcation, limit cycles.

2020 Mathematics Subject Classification: 34C05, 34C08, 34C23.

1 Introduction

In the qualitative theory of real planar differential systems, one of research focus is the number and configuration of limit cycles, which belong to the context of the second part of Hilbert's 16th Problem. Until now the problem still remains to be unsolved even though a lot of works have been done. As well known, Arnold [1] proposed a weaker version of this problem, the so-called infinitesimal Hilbert's 16th problem, that is to study the number of isolated zeros of the Abelian integrals obtained from integrating polynomial 1-forms over ovals of polynomial Hamiltonian.

Consider perturbations of the Hamiltonian system

$$\begin{cases} \dot{x} = H_y(x,y) + \varepsilon P(x,y), \\ \dot{y} = -H_x(x,y) + \varepsilon Q(x,y), \end{cases} \tag{1.1}$$

where $H(x,y)$ is a polynomial of degree $n+1$, $P(x,y)$ and $Q(x,y)$ are polynomials of degree m in x, y, and ε is a small parameter.

We assume that there is a family of ovals $\Gamma_h \subset \{(x,y) \mid H(x,y) = h\}$, continuously depending on a parameter $h \in (h_1,h_2)$, then the Abelian integral of system (1.1) is defined as

$$I(h) = \oint_{\Gamma_h} P(x,y)dy - Q(x,y)dx, \tag{1.2}$$

✉ Corresponding author. Email: mathsyishao@126.com

where Γ_h is the open punctured neighborhood foliated by periodic orbits of system (1.1) as $\varepsilon = 0$. The displacement function $d(h, \varepsilon)$ of system (1.1) is defined on a segment transversal to the flow, which is parameterized by the Hamiltonian value h, then

$$d(h, \varepsilon) = \oint_{\Gamma_h} dH = \varepsilon(I(h) + O(\varepsilon)). \tag{1.3}$$

Hence, if $I(h)$ is not identically zero, then the number of isolated zeros of the Abelian integral $I(h)$ (or be called the first order Melnikov function) gives an upper bound for the number of limit cycles of system (1.1) in any compact region of period annulus. It is well known that the limit cycles bifurcating from the period annulus is called Poincaré bifurcation.

The generalized Liénard system $\dot{x} = y, \dot{y} = f(x) + \varepsilon y g(x)$ of type (m, n) has rich dynamic behavior, where m and n are degrees of polynomials $f(x)$ and $g(x)$, respectively. If $m = 2, 3$ and $\varepsilon = 0$, then Hamiltonian functions of this system are called elliptic. Many authors studied the bifurcations of limit cycles on this system. Dumortier and Li have made a complete investigate for Liénard system of type $(3, 2)$ in a series of papers (see [3–6]), and they proved that the upper bound of number of isolated zeroes of Abelian integrals is five. In [11], the authors also investigated some Liénard systems of type $(3, 2)$ with symmetry, which exist at most two limit cycles.

If $m \geq 4$ and $\varepsilon = 0$, then Hamiltonian functions of the above Liénard system are called hyperelliptic. In [7], Gavrilov and Iliev given the topological classification of hyperelliptic Hamiltonian system of degree five, its normal form of Hamiltonian function is

$$H(x, y) = \frac{1}{2}y^2 + \frac{\lambda\mu}{2}x^2 - \frac{\lambda + \mu + \lambda\mu}{3}x^3 + \frac{1 + \lambda + \mu}{4}x^4 - \frac{1}{5}x^5, \tag{1.4}$$

where there are eleven cases having period annulus. J. Wang (see [15,16]) studied the number of limit cycles of two classes of Liénard systems of type $(4, 3)$ and $(4, 2)$, in which unperturbed systems has a saddle and degenerated polycycle, respectively. The authors of [20] obtained lower bounds of the number of limit cycles for a Liénard system of type $(4, n)$ having two elementary centers, where $20 \leq n \leq 24$.

In this paper, we choose one of eleven cases in [7], that is, we investigation Poincaré bifurcation for a Liénard system of type $(4, 3)$ with hyperelliptic Hamiltonian $H(x, y) = h$, $h \in (h_1, h_2)$ in (1.4) having a pair of conjugated complex critical points. The perturbation system is as follows

$$\begin{cases} \dot{x} = y, \\ \dot{y} = x(x-1)(x^2 + ax + b) + \varepsilon(\alpha + \beta x + \gamma x^2 + x^3)y, \quad a^2 - 4b < 0. \end{cases} \tag{1.5}$$

It is easy to know that the unperturbed system of (1.5) has a bounded period annulus surrounding the elementary center $(0, 0)$, corresponding to endpoint h_1, and a homoclinic loop (bounder of period annulus) passing through hyperbolic saddle $(1, 0)$, corresponding to endpoint h_2. By (1.2), we know that the Abelian integral of system (1.5) is

$$I(h) = \int_{\Gamma_h} (\alpha + \beta x + \gamma x^2 + x^3) y dx = \alpha I_0(h) + \beta I_1(h) + \gamma I_2(h) + I_3(h), \tag{1.6}$$

where $I_i(h) = \int_{\Gamma_h} x^i y dx, i = 0, 1, 2, 3$ and Γ_h is the compact component of $H(x, y) = h$, defined by (1.5).

There are many techniques and arguments to tackle the problem of bounding the number of zeroes of Abelian integrals, lots of them are very long and non-trivial, see [2]. Since

Hamiltonian function $H(x,y)$ has the higher degree, a purely algebraic criterion proposed in [8] and [12] are usual methods. These methods can transfer the estimation the number of zeros of Abelian integrals to that of the number of real roots of linear combinations of a tuple $(I_0(h), I_1(h), I_2(h), I_3(h))$ of associated semi-algebraic systems (SAS for short). This criterion can reduce the difficulties of qualitative analysis in limit cycle bifurcating from a center. Nonetheless, it is challenging and very difficult to obtain the cyclicity of this family of period annuli that depends on the variables a, b indeed, which need to verify the problem whether the collection of Abelian integrals is an ECT-system or a Chebyshev system with accuracy k (see [8]). We attempt several values of the variables a, b by using software *Maple*, which lead to a desktop computer to a dead end due to the huge polynomials with huge coefficients and thousands of terms.

In the present paper, we take $a = b = 2$, and use approaches of *real root isolation* and interval analysis to get the number of roots of huge polynomial, as a result, we can obtain the number of zeros of Abelian integrals of system (1.5) for $a = b = 2$. We rewrite system (1.5) as

$$\begin{cases} \dot{x} = y, \\ \dot{y} = x(x-1)(x^2+2x+2) + \varepsilon(\alpha + \beta x + \gamma x^2 + x^3)y, \end{cases} \tag{1.7}$$

where α, β, γ are arbitrary real constants and $\varepsilon > 0$ is a small parameter, and the first integral of (1.7) is

$$H(x,y) = \frac{1}{2}y^2 + x^2 - \frac{1}{4}x^4 - \frac{1}{5}x^5 = h, \qquad h \in \left(0, \frac{11}{20}\right) \tag{1.8}$$

as $\varepsilon = 0$. The projection interval of the period annulus Γ_h on the x-axis is $(x_0, 1)$, where $x_0 \approx -0.763592319985$, and it is an intersection of the homoclinic loop with the negative half axis of the x-axis. Phase portrait of the unperturbed system of (1.7) see Figure 1.1.

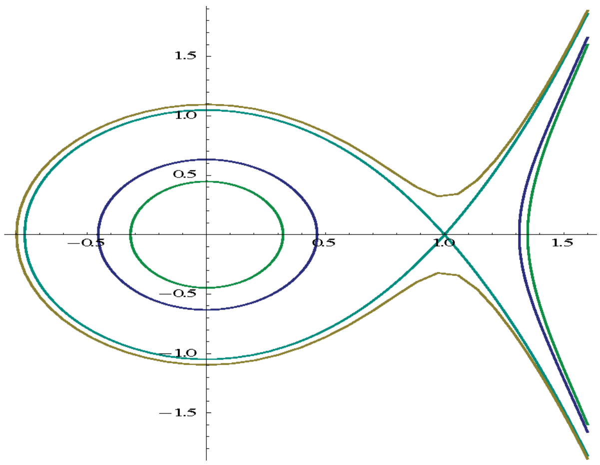

Figure 1.1: Phase portrait of system (1.5) when $\varepsilon = 0$.

The main purpose in this paper is to show that system (1.7) can undergo Poincaré bifurcation from the period annulus surrounding the origin. We can prove that the Abelian integral $I(h)$ has at most six zeros (taken into account muitiplicity), see Proposition 3.1 in Section 3. Proposition 3.1 and the equation (1.3) imply that system (1.7) can produce at most six limit cycles. The main results of this paper as follows.

Theorem 1.1. *The number of limit cycles of system* (1.7) *bifurcating from period annulus surrounding the center is at most six for arbitrary value of parameters* α, β, γ.

Note that unperturbed system of (1.7) has a period annulus surrounding the elementary center, its outer boundary is a saddle loop. According to Roussarie's theorem [14], the upper bound of number of isolated zeros of the Abelian integral $I(h)$ covers the number of limit cycles from center, from period annulus and from the homoclinic loop, therefore we have the following Theorem.

Theorem 1.2. *System (1.7) could give rise to at most six limit cycles in the finite plane surrounding the origin for sufficiently small ε and any parameters α, β, γ.*

The paper is organized as follows. In Section 2, we introduce some definitions and properties of Chebyshev systems. In Section 3, we study the number of zeros of Abelian integral $I(h)$ and obtain the maximal number of limit cycles bifurcating from period annulus by using Chebyshev criterion. Hence Proposition 3.1 is main result of this paper.

2 Preliminary properties

In order to study the number of isolated zeros of Abelian integral $I(h)$ in $h \in (0, \frac{11}{20})$, Grau et al. in [8] give a Chebyshev criterion, which check whether (I_0, I_1, I_2, I_3) in (1.6) is an extended complete Chebyshev system or Chebyshev system with accuracy k. Hence we introduce some preliminary definitions and properties, the reader can refer to [8, 12] or the recent paper [13] for more details.

Definition 2.1. Let $\varphi_0(x), \varphi_1(x), \ldots, \varphi_{n-1}(x)$ be analytic functions on an open interval L of $\mathbb{R}$.

(i) The set of functions $(\varphi_0(x), \varphi_1(x), \ldots, \varphi_{n-1}(x))$ is a Chebyshev system (T-system) with accuracy k on L if any nontrivial linear combination

$$\alpha_0\varphi_0(x) + \alpha_1\varphi_1(x) + \cdots + \alpha_{n-1}\varphi_{n-1}(x)$$

has at most $n + k - 1$ isolated zeros for $x \in L$.

(ii) The set of functions $(\varphi_0(x), \varphi_1(x), \ldots, \varphi_{n-1}(x))$ is an extended complete Chebyshev system (ECT-system) on L if for all $m = 1, 2, \ldots, n$, any nontrivial linear combination

$$\alpha_0\varphi_0(x) + \alpha_1\varphi_1(x) + \cdots + \alpha_{m-1}\varphi_{m-1}(x)$$

has at most $m - 1$ isolated zeros on L counted with multiplicities.

(iii) The continuous Wronskian of $(\varphi_0(x), \varphi_1(x), \ldots, \varphi_{m-1}(x))$ at $x \in L$ is

$$W[\varphi_0, \varphi_1, \ldots, \varphi_{m-1}](x) = \mathrm{Det}(\varphi_j^{(i)}(x))_{0\le i,j\le m-1} = \begin{vmatrix} \varphi_0(x) & \cdots & \varphi_{m-1}(x) \\ \varphi_0'(x) & \cdots & \varphi_{m-1}'(x) \\ \vdots & \ddots & \vdots \\ \varphi_0^{(m-1)}(x) & \cdots & \varphi_{m-1}^{(m-1)}(x) \end{vmatrix},$$

where $\varphi_j'(x)$ and $\varphi_j^{(i)}(x) (i \ge 2)$ represent the derivative of one order and the ith order of $\varphi_j(x)$, respectively.

Lemma 2.2 ([10] or [8]). *$(\varphi_0(x), \varphi_1(x), \ldots, \varphi_{n-1}(x))$ is an extended complete Chebyshev system on L if and only if, for each $m = 1, 2, \ldots, n$,*

$$W[\varphi_0, \varphi_1, \ldots, \varphi_{m-1}](x) \neq 0 \quad \textit{for all } x \in L.$$

Now we rewrite the first integral (1.8) as

$$H(x,y) = A(x) + B(x)y^2, \tag{2.1}$$

where

$$A(x) = x^2 - \frac{1}{4}x^4 - \frac{1}{5}x^5, \qquad B(x) = \frac{1}{2}$$

and $H(x,y)$ is an analytic function in open interval. There exists a period annulus filled by the set of ovals $\Gamma_h \in \{(x,y)|H(x,y) = h, h \in (0, \frac{11}{20})\}$ and $H(0,0) = 0$ is a local minimum. It is easy to verify that $xA'(x) = x^2(1-x)(x^2+2x+2) > 0$ for any $x \in (x_0, 1) \setminus 0$ ($x_0 \approx -0.763592319985$). Thus, there exists an analytic involution $z = \sigma(x)$ ($\sigma \circ \sigma = \text{Id}$ and $\sigma \neq \text{Id}$) with $x_0 < z < 0$ such that

$$A(x) = A(\sigma(x)) \quad \text{for all } x \in (0,1)$$

and $\sigma(0) = 0$. Using Theorem A in [12], we get the following lemma.

Lemma 2.3. *Assume that $g_i(x)$ are an analytic function on the interval $(x_0, 1)$, $i = 0, 1, 2, 3$. Denote*

$$\bar{I}_i(h) = \int_{\Gamma_h} g_i(x) y^{2s-1} dx,$$

where Γ_h is the set of periodic orbit surrounding the origin inside the level curve $\{A(x)+B(x)y^{2m} = h\}$ for each $h \in (0, \frac{11}{20})$. Let

$$\varphi_i(x) = \frac{g_i(x)}{A'(x)(B(x))^{\frac{2s-1}{2m}}} - \frac{g_i(\sigma(x))}{A'(\sigma(x))(B(\sigma(x)))^{\frac{2s-1}{2m}}}.$$

If the following statements hold:

- *(i) $W[\varphi_0, \varphi_1, \ldots, \varphi_m](x)$ is not vanish on $(0,1)$ for $m = 1, 2, \ldots, n-2$;*
- *(ii) $W[\varphi_0, \varphi_1, \ldots, \varphi_{n-1}](x)$ has k zeroes on $(0,1)$ counted with multiplicities, and*
- *(iii) $s > m(n+k-2)$,*

then $(\bar{I}_0(h), \bar{I}_1(h), \ldots, \bar{I}_{n-1}(h))$ has at most $n+k-1$ isolated zeros on $(0, \frac{11}{20})$ counted with multiplicities.

To prove Proposition 3.1 in Section 3, note that $I_i(h) = \int_{\Gamma_h} x^i y dx$, $s = 1, m = 1$ and $n = 4$, even if $k = 0$, but the condition $s > 2$ in Lemma 2.3 would not be satisfied. Hence we can not apply Lemma 2.3 directly. We need promote the power y in the integrand of $I_i(h)$ such that the conditions $s > m(n+k-2) = k+2$ hold. By using Lemma 4.1 in [8], we have

Lemma 2.4. *Let Γ_h be an oval inside the level curve $\{A(x) + B(x)y^2 = h\}$. If there exists a function $U(x)$ such that $\frac{U(x)}{A'(x)}$ is analytic at $x = 0$. Then, for any $s \in \mathbb{N}$,*

$$\int_{\Gamma_h} U(x) y^{s-2} dx = \int_{\Gamma_h} V(x) y^s dx,$$

where $V(x) = \frac{2}{s}\left(\frac{B(x)U(x)}{A'(x)}\right)' - \frac{B'(x)U(x)}{A'(x)}$.

In order to get the number of real roots of linear combinations of a tuple $(I_0(h), I_1(h), I_2(h), I_3(h))$ in (1.6), Lemma 2.3 is a main criterion in our paper. By applying this criterion, we can transfer the estimation of the number of real zeroes of Abelian integral to that of the number of real roots of a tuple, which reduce a semi-algebraic systems(SAS) and the reader is referred to see [18,19] for more details. The key to solve of SAS question is to solve polynomial equations.

We suppose that the polynomial equation $W(x,z) = 0$ has a real root (x^*, z^*) at the rectangle domain $D = \{(x,z) \mid (x,z) \in (0,1) \times (x_0, 0)\}$, where the variables x, z also satisfy the equation $q(x,z) = 0$, where $z = \sigma(x)$ is an involution and $\sigma'(x) < 0$. Solving this SAS question is to solve common root of systems of equations of two unknowns $W(x,z) = 0, q(x,z) = 0$. We divide analytic techniques into three steps.

Step 1 (Elimination variable by resultant): We can elimination variable x (or z) by the theory of resultant, that is, variables x, z satisfy the resultant equation

$$R(z) = \text{res}(W(x,z), q(x,y), x) = 0 \quad \text{or} \quad \bar{R}(x) = \text{res}(W(x,z), q(x,y), z) = 0.$$

Step 2 (Interval isolation of real root): Without loss of generality, Assume that the resultant equation $\bar{R}(x) = 0$ has a real root x^* in $[x_1, x_2] \subset [0,1]$ (corresponding z^* in $[z_1, z_2] \subset [x_0, 0]$) by using command realroot in *Maple*. We substitute $x = x_1$ and $x = x_2$ into $p(x,z) = 0$, and let maximal interval of isolation real root of equation $p(x,z) = 0$ be $[z_{11}, z_{12}] \subset [z_1, z_2]$. Thus we minimize the possible existing the rectangle domain of the common roots of $W(x,z) = 0$ and $q(x,y) = 0$.

However, it should be noted that if we solve $\bar{R}(x) = 0$ directly without using interval isolation of real root, then we can only get a approximation of x^*. But the results of these numerical calculation are sometimes unreliable due to the thousands of terms of polynomials with huge coefficients, a famous cautionary example see [17], and example of numerical calculation see Lemma 3.4 [iv] of [9].

Step 3 (Analysis of common real roots): Let the above the rectangle domain be $ABCD$, where $A(x_1, z_{12})$, $B(x_1, z_{11})$, $C(x_2, z_{11})$ and $D(x_2, z_{12})$. We can analysize whether the rectangle domain has a common root or not by positive and negative values of $W(x,z)$ and $q(x,z)$ at vertices A, B, C, D, the involution and the intermediate value theorem of continuous function. The detailed application skills see proof of Lemma 3.2.

3 Poincaré bifurcations of system (1.7)

In this Section, to prove Theorem 1.1, firstly, we will study the number of isolated zeros of Abelian integral $I(h)$ in $h \in (0, \frac{11}{20})$, that is the following Proposition 3.1.

Proposition 3.1. *For arbitrary value of parameters (α, β, γ), the Abelian integral $I(h)$ of system (1.7) has at most six zeros (counting multiplicities) in $h \in (0, \frac{11}{20})$.*

The main tools of proving Proposition 3.1 are Lemmas 2.2–2.4. Hence we need to check the Chebyshev property of the Abelian integral (1.6). Proof of Proposition 3.1 will be given at the end of this section.

Now applying Lemma 2.4, we rewrite $I_i(h)$ in (1.7) as

$$\begin{aligned} I_i(h) &= \frac{1}{h} \int_{\Gamma_h} \left(A(x) + \frac{1}{2} y^2 \right) x^i y dx = \frac{1}{h} \int_{\Gamma_h} \left[x^i A(x) y + \frac{1}{2} x^i y^3 \right] dx \\ &= \frac{1}{h} \int_{\Gamma_h} V_i(x) y^3 dx, \qquad i = 0, 1, 2, 3, \end{aligned}$$

where

$$V_i(x) = \frac{x^i \nu_i(x)}{60(x-1)^2(x^2+2x+2)^2}$$

with

$$\begin{aligned}\nu_i(x) = &(160+40i) - (130+30i)x^2 - (112+28i)x^3 \\ &+ (35+5i)x^4 + (68+9i)x^5 + (34+4i)x^6.\end{aligned}$$

To promote the power y such that the condition $s > 2$ (suppose $k = 0$) is satisfied, by using Lemma 2.4 again, we obtain that

$$\begin{aligned}I_i(h) &= \frac{1}{h^2}\int_{\Gamma_h}\left(A(x)+\frac{1}{2}y^2\right)V_i(x)y^3dx \\ &= \frac{1}{h^2}\int_{\Gamma_h}\left[V_i(x)A(x)y^3+\frac{1}{2}V_i(x)y^5\right]dx = \frac{1}{h^2}\int_{\Gamma_h} g_i(x)y^5dx,\end{aligned}$$

where

$$g_i(x) = \frac{x^i \tau_i(x)}{6000(x-1)^4(x^2+2x+2)^4} \tag{3.1}$$

with

$$\begin{aligned}\tau_i(x) = &(38400+16000i+1600i^2) - (62400+24800i+2400i^2)x^2 \\ &- (51840+21920i+2240i^2)x^3 + (44300+15200i+1300i^2)x^4 \\ &+ (81120+27600i+2400i^2)x^5 + (23992+8324i+804i^2)x^6 \\ &- (41480+11990i+820i^2)x^7 - (37939+10782i+719i^2)x^8 \\ &- (5354+1851i+134i^2)x^9 + (11096+2375i+121i^2)x^{10} \\ &+ (7344+1492i+72i^2)x^{11} + (1836+352i+16i^2)x^{12}.\end{aligned}$$

Denote

$$\bar{I}_i(h) = h^2 I_i(h) = \int_{\Gamma_h} g_i(x)y^5dx, \qquad h \in \left(0, \frac{11}{20}\right).$$

We can see that $g_i(x)$ is analytic on $(x_0, 1)$ and $(I_0(h), I_1(h), I_2(h), I_3(h))$ is an ECT-system or T-system on $(0, \frac{11}{20})$ if and only if so is $(\bar{I}_0(h), \bar{I}_1(h), \bar{I}_2(h), \bar{I}_3(h))$. Therefore, applying Lemma 2.4 to $(\bar{I}_0(h), \bar{I}_1(h), \bar{I}_2(h), \bar{I}_3(h))$ with $s = 3$, we have

$$\bar{\varphi}_i(x,z) = \bar{g}_i(x) - \bar{g}_i(z) = \left(\frac{4\sqrt{2}g_i}{A'}\right)(x) - \left(\frac{4\sqrt{2}g_i}{A'}\right)(z), \qquad i = 0,1,2,3, \tag{3.2}$$

where

$$\bar{g}_i(x) = \frac{\sqrt{2}x^{i-1}\tau_i(x)}{1500(1-x)^5(x^2+2x+2)^5},$$

$$\bar{g}_i(z) = \frac{\sqrt{2}z^{i-1}\tau_i(z)}{1500(1-z)^5(z^2+2z+2)^5}$$

and $z = \sigma(x)$ is an involution function.

On the other hand, due to

$$A(x) - A(z) = \frac{1}{20}(x-z)p(x,z) = 0,$$

where

$$p(x,z) = -20(x+z) + 5(x^3 + x^2z + xz^2 + z^3) + 4(x^4 + x^3z + x^2z^2 + xz^3 + z^4).$$

Since $\sigma(0) = 0$, It turns out that $z = \sigma(x)$ is defined by means of $p(x,z) = 0$. Moreover, we get that

$$\sigma'(x) = \frac{dz}{dx} = -\frac{p'_x(x,z)}{p'_z(x,z)}, \tag{3.3}$$

where

$$p'_x(x,z) = -20 + 15x^2 + 10xz + 5z^2 + 16x^3 + 12x^2z + 8xz^2 + 4z^3,$$
$$p'_z(x,z) = -20 + 5x^2 + 10xz + 15z^2 + 4x^3 + 8x^2z + 12xz^2 + 16z^3.$$

By Lemma 2.2, we find that the Wronskian $W[(\bar{\varphi}_0, \bar{\varphi}_1, \bar{\varphi}_2, \bar{\varphi}_3)](x)$ has two zeros on $(0,1)$ by interval analysis, which shows that $(\bar{\varphi}_0, \bar{\varphi}_1, \bar{\varphi}_2, \bar{\varphi}_3)$ is not an ECT-system on $(0,1)$. According to Lemma 2.3(iii), we need to take $s > m(n+k-2) = 4$. Hence we lift the power of y in the integrand of $I_i(h)$ to $2s-1 = 9$. But we find that the associated Wronskian $W[(\varphi_0, \varphi_1, \varphi_2, \varphi_3)](x)$ has three zeros for $x \in (0,1)$. So we further take $s = 6$ and lift the power of y of integrand of $I_i(h)$ to $2s-1 = 11$, fortunately, the associated Wronskian $W[(\tilde{\varphi}_0, \tilde{\varphi}_1, \tilde{\varphi}_2, \tilde{\varphi}_3)](x)$ has still three zeros, all of the first order Wronskians $W[(\tilde{\varphi}_i)](x) (i = 0,1,2,3)$, the second order Wronskians $W[(\tilde{\varphi}_2, \tilde{\varphi}_1)](x)$ and the third order Wronskians $W[(\tilde{\varphi}_2, \tilde{\varphi}_1, \tilde{\varphi}_0)](x)$ have all no zero for $x \in (0,1)$, which give us hope to obtain the number of zeros of linear combinations of the tuple of functions $(\tilde{\varphi}_0, \tilde{\varphi}_1, \tilde{\varphi}_2, \tilde{\varphi}_3)$ by Lemma 2.3.

Repeating the above procedures, it follows from Lemma 2.4 that

$$\tilde{I}_i(h) = h^5 I_i(h) = \int_{\Gamma_h} F_i(x) y^{11} dx, \qquad h \in \left(0, \frac{11}{20}\right). \tag{3.4}$$

where

$$F_i(x) = \frac{x^i G_i(x)}{33264000000(x-1)^{10}(x^2+2x+2)^{10}},$$

and $G_i(x)$ is a polynomial of degree 30 in x, we omit it here because the polynomial has a longer expression. Let

$$\tilde{\varphi}_i(x,z) = \left(\frac{32\sqrt{2}F_i}{A'}\right)(x) - \left(\frac{32\sqrt{2}F_i}{A'}\right)(z), \qquad i = 0,1,2,3, \tag{3.5}$$

where $z = \sigma(x)$ is an involution and $x \in (0,1)$.

According to Lemma 2.3, we need to compute the number of zeros of many Wronskians, moreover, each of Wronskians is a the huge polynomial with huge coefficients and hundreds of items. After many attempts to the ordered linear combinations of associated criterion function $(\tilde{\varphi}_0, \tilde{\varphi}_1, \tilde{\varphi}_2, \tilde{\varphi}_3)$, finally we find that the tuple of functions $(\tilde{\varphi}_2, \tilde{\varphi}_1, \tilde{\varphi}_0, \tilde{\varphi}_3)$ satisfy the statements in Lemma 2.3. Then we get the following lemma.

Lemma 3.2. $(\tilde{I}_2(h), \tilde{I}_1(h), \tilde{I}_0(h), \tilde{I}_3(h))$ *has at most six isolated zeros on* $(0, \frac{11}{20})$ *counted with multiplicities.*

Proof. It follows from Lemma 2.3 that we need to verify the statements (i) and (ii). For this purpose, we divide the proof into four cases.

Case 1: The fourth Wronskian $W[\tilde{\varphi}_2, \tilde{\varphi}_1, \tilde{\varphi}_0, \tilde{\varphi}_3](x,z)$ has three zeros for $(x,z) \in (0,1) \times (x_0, 0)$.

With the help of the computer algebraic system *Maple*, by direct computation, we get that

$$
\begin{aligned}
&W[\tilde{\varphi}_2, \tilde{\varphi}_1, \tilde{\varphi}_0, \tilde{\varphi}_3](x,z) \\
&= -\frac{(x-z)^{10}\omega_4(x,z)}{834198140917968750000000000000x^4z^4q_4(x)q_4(z)(p_z'(x,z))^6},
\end{aligned} \tag{3.6}
$$

where $\omega_4(x,z)$ is a polynomial of degree 228 in (x,z), $p_z'(x,z)$ as in (3.3),

$$
q_4(x) = (x-1)^{38}(x^2+2x+1)^{38}, \qquad q_4(z) = (z-1)^{38}(z^2+2z-1)^{38},
$$

and $z = \sigma(x)$ is an implicit function determined by the polynomial equation $p(x,z) = 0$. Meanwhile, we find that $\omega_4(x,z)$ is symmetric polynomial with respect to x, z.

We assert that $p_z'(x,z) \neq 0$ for any $(x,z) \in (0,1) \times (x_0, 0)$. In fact, by computing the resultant $R(p_z', p, z)$ with respect to z between $p_z'(x,z)$ and $p(x,z)$, we have

$$
\begin{aligned}
R(p_z', p, z) = 8000(4x^3+13x^2+22x+11)(4x^3+5x^2-20) \\
\times (16x^6 - 24x^5 - 7x^4 - 68x^3 + 256x^2 - 296x + 148).
\end{aligned}
$$

It is easy to verify that three polynomial factors in $R(p_z', p, z)$ have not zeros in $x \in (0,1)$. This implies $W[\tilde{\varphi}_2, \tilde{\varphi}_1, \tilde{\varphi}_0, \tilde{\varphi}_3](x,z)$ is well defined in $(0,1) \times (x_0, 0)$.

Next we calculate the resultant with respect to z between $\omega_4(x,z)$ and $p(x,z)$ and obtain

$$
R(\omega_4, p, z) = 396154108207169536000000000000(x-1)^{28}(x^2+20+2)^{28}\phi_4(x),
$$

where $\phi_4(x)$ is a polynomial of degree 828 in x.

Note that $\omega_4(x,z)$ and $p(x,z)$ are symmetric polynomials with respect to x, z and $z = \sigma(x)$ is an involution. Therefore the resultant $R(\omega_4, p, z)$(or $R(\omega_4, p, x)$) between $\omega_4(x,z)$ and $p(x,z)$ with respect to x (or z) suffices that the statement $R(\omega_4, q, x) = R(\omega_4, q, z)|_{z=x}$. By command realroot in *Maple*, we get that $\phi_4(x)$ has five isolate zeros $x_i^*(i = 1,2,3,4,5)$ in $(0,1)$ and three isolate zeros $z_i^*(i = 1,2,3)$ in $(x_0, 0)(x_0 \approx -0.763592319985)$. List of the isolation intervals of these zeros are as follows

$$
\begin{aligned}
x_1^* \in [\hat{x}_{11}, \hat{x}_{12}] &= \left[\frac{73134709858141}{140737488355328}, \frac{36567354929071}{70368744177664}\right], \\
x_2^* \in [\hat{x}_{21}, \hat{x}_{22}] &= \left[\frac{42527490909395}{70368744177664}, \frac{85054981818791}{140737488355328}\right], \\
x_3^* \in [\hat{x}_{31}, \hat{x}_{32}] &= \left[\frac{29671532711011}{35184372088832}, \frac{118686130844045}{140737488355328}\right], \\
x_4^* \in [\hat{x}_{41}, \hat{x}_{42}] &= \left[\frac{122355652851087}{140737488355328}, \frac{7647228303193}{8796093022208}\right], \\
x_5^* \in [\hat{x}_{51}, \hat{x}_{52}] &= \left[\frac{137735701579791}{140737488355328}, \frac{8608481348737}{8796093022208}\right]
\end{aligned}
$$

and

$$
\begin{aligned}
z_1^* \in [\hat{z}_{11}, \hat{z}_{12}] &= \left[-\frac{53678146230419}{70368744177664}, -\frac{107356292460837}{140737488355328}\right], \\
z_2^* \in [\hat{z}_{21}, \hat{z}_{22}] &= \left[-\frac{102328736960905}{140737488355328}, -\frac{12791092120113}{17592186044416}\right], \\
z_3^* \in [\hat{z}_{31}, \hat{z}_{32}] &= \left[-\frac{80910761056793}{140737488355328}, -\frac{10113845132099}{17592186044416}\right].
\end{aligned}
$$

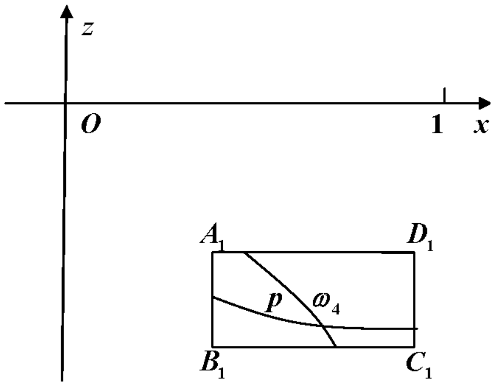

Figure 3.1: The sketch graph of $\omega_4(x,z) = 0$ and $p(x,z) = 0$ intersecting in the rectangle $A_1B_1C_1D_1$.

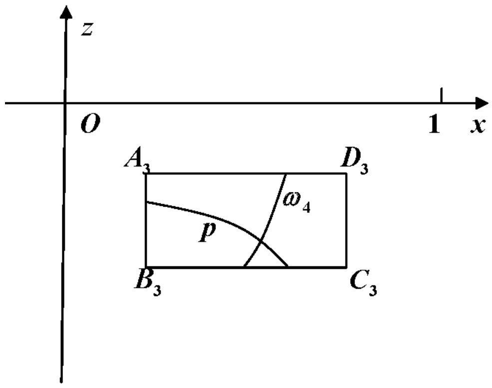

Figure 3.2: The sketch graph of $\omega_4(x,z) = 0$ and $p(x,z) = 0$ intersecting in the rectangle $A_3B_3C_3D_3$.

Since $z = \sigma(x)$ is an involution determined by $p(x,z) = 0$ and satisfy $\sigma'(x) < 0$ for $x \in (0,1)$, which imply that $\omega_4(x,z)$ and $p(x,z) = 0$ have at most three common real roots. Firstly, we substitute $z = \hat{z}_{11}$ and $z = \hat{z}_{12}$ into $p(x,z)$, then equation $p(x,z) = 0$ has one root in interval

$$[x_{11}, x_{12}] = \left[\frac{68867850789901}{70368744177664}, \frac{137735701579803}{140737488355328}\right],$$

and

$$[x_{21}, x_{22}] = \left[\frac{34433925394947}{35184372088832}, \frac{137735701579789}{140737488355328}\right],$$

respectively. It is easy to verify that interval $[x_{11}, x_{12}] \supset [\hat{x}_{51}, \hat{x}_{52}]$ and $[x_{21}, x_{22}] \supset [\hat{x}_{51}, \hat{x}_{52}]$, which shows that $\omega_4(x,z)$ and $p(x,z) = 0$ possibly have common real root.

Let the four vertices of closed rectangle containing the point (x_5^*, z_1^*) be $A_1(\hat{x}_{51}, \hat{z}_{12})$, $B_1(\hat{x}_{51}, \hat{z}_{11})$, $C_1(\hat{x}_{52}, \hat{z}_{11})$ and $D_1(\hat{x}_{52}, \hat{z}_{12})$, see Figure 3.1. Substituting coordinates of four vertices A_1, B_1, C_1, D_1 into $\omega_4(x,z)$, we get that

$$\omega_4(A_1) = -\frac{1103261\cdots6171875}{1000814\cdots7682176}, \qquad \omega_4(B_1) = -\frac{2177946\cdots3395375}{1973759\cdots7196544},$$
$$\omega_4(C_1) = \frac{3939512\cdots4495625}{2780712\cdots3723776}, \qquad \omega_4(D_1) = \frac{3353939\cdots1640625}{2365568\cdots5694464},$$

here we omit digits using dots for brevity because their numerators and denominators are all huge numbers.

Note that $\omega_4(A_1) < 0, \omega_4(B_1) < 0, \omega_4(C_1) > 0$ and $\omega_4(D_1) > 0$, by command fsolve in *Maple*, we find that $\omega_4(x,z)$ has not zero at the sides A_1B_1 and C_1D_1 of rectangle $A_1B_1C_1D_1$ as $x = \hat{x}_{51}$ and $x = \hat{x}_{52}$, respectively, which implies that $\omega_4(x,z) < 0$ at the side A_1B_1 and $\omega_4(x,z) > 0$ at the side C_1D_1. Meanwhile, the zero set of polynomial $\omega_4(x,z)$ intersecting with the sides B_1C_1 and A_1D_1 of rectangle forms a simple curve ended by points $(0.9786710221234176135, \hat{z}_{11})$ and $(0.9786710221234176104, \hat{z}_{12})$, respectively.

Using the same sequence, substituting coordinates of four vertices A_1, B_1, C_1, D_1 into $p(x,z)$, we have

$$p(A_1) = -\frac{1656260\cdots5869779}{9807971\cdots0539264}, \qquad p(B_1) = \frac{9711472\cdots0200531}{9807971\cdots0539264},$$
$$p(C_1) = \frac{5556451\cdots8475385}{6129982\cdots4408704}, \qquad p(D_1) = -\frac{2477410\cdots4753759}{9807971\cdots0539264}.$$

By direct computation, we get that $p(x,z) < 0$ at the side A_1D_1, $p(x,z) > 0$ at the side B_1C_1, a simple curve $p(x,z) = 0$ intersect the side A_1B_1 with point $(\hat{x}_{51}, -0.76281233746184644)$ and the side C_1D_1 with point $(\hat{x}_{52}, -0.76281233746184695)$. According to the Intermediate Value Theorem, curves $\omega_4(x,z) = 0$ intersect transversely with $p(x,z) = 0$ in the rectangle $A_1B_1C_1D_1$, which implies that $\omega_4(x,z) = 0$ and $p(x,z) = 0$ have and only have one common solution in the associated rectangle. Hence $W[\tilde{\varphi}_2, \tilde{\varphi}_1, \tilde{\varphi}_0, \tilde{\varphi}_3](x,z)$ has one zero in the rectangle $A_1B_1C_1D_1$.

Secondly, we substitute $z = \hat{z}_{21}$ and $z = \hat{z}_{22}$ into $p(x,z)$, we find that $p(x,z) = 0$ has one root in interval

$$[\bar{x}_{11}, \bar{x}_{12}] = \left[\frac{59343065422023}{70368744177664}, \frac{118686130844047}{140737488355328}\right],$$

and

$$[\bar{x}_{21}, \bar{x}_{22}] = \left[\frac{118686130844043}{140737488355328}, \frac{29671532711011}{35184372088832}\right],$$

respectively. Note that

$$[\min(\bar{x}_{11}, \bar{x}_{21}), \max(\bar{x}_{12}, \bar{x}_{22})] = [\bar{x}_{21}, \bar{x}_{12}] \supset [\hat{x}_{31}, \hat{x}_{32}].$$

By similar discussion and computation to the above procedure and omitting the details for the sake of brevity, we get that $W[\tilde{\varphi}_2, \tilde{\varphi}_1, \tilde{\varphi}_0, \tilde{\varphi}_3](x,z)$ has also one zero in the rectangle $A_2B_2C_2D_2$, where the vertices $A_2(\hat{x}_{31}, \hat{z}_{22})$, $B_2(\hat{x}_{31}, \hat{z}_{21}), C_2(\hat{x}_{32}, \hat{z}_{21})$ and $D_2(\hat{x}_{32}, \hat{z}_{22})$.

Finally, we substitute $z = \hat{z}_{31}$ into $p(x,z) = 0$ and get that it has one root just in interval $[\hat{x}_{21}, \hat{x}_{22}]$. Using the same sequence, let $A_3(\hat{x}_{21}, \hat{z}_{32})$, $B_3(\hat{x}_{21}, \hat{z}_{31}), C_3(\hat{x}_{22}, \hat{z}_{31})$ and $D_3(\hat{x}_{22}, \hat{z}_{32})$, see Figure 3.2. In the rectangle $A_3B_3C_3D_3$, we obtain that

$$\omega_4(A_3) < 0, \qquad \omega_4(B_3) < 0, \qquad \omega_4(C_3) > 0, \qquad \omega_4(D_3) > 0,$$

and

$$p(A_3) < 0, \qquad p(B_3) > 0, \qquad p(C_3) < 0, \qquad p(D_3) < 0,$$

here we omit the specific values of $\omega_4(x,z)$ and $p(x,z)$ at A_3, B_3, C_3, D_3 for brevity. By similar analysis, we find that one simple curve $\omega_4(x,z) = 0$ in the rectangle $A_3B_3C_3D_3$ intersect the side A_3D_3 with point $(0.604351994715489, \hat{z}_{32})$ and the side B_3C_3 with point $(0.604351994715488, \hat{z}_{31})$, the other simple curve $p(x,z) = 0$ intersect the side A_3B_3 with point $(\hat{x}_{21}, -0.574905535137251)$ and the side B_3C_3 with point $(0.604351994715491, \hat{z}_{31})$. Since $0.604351994715491 > 0.604351994715488$, it is obvious that curves $\omega_4(x,z) = 0$ and $p(x,z) = 0$ has one intersection in the rectangle $A_3B_3C_3D_3$, which shows that $W[\tilde{\varphi}_2, \tilde{\varphi}_1, \tilde{\varphi}_0, \tilde{\varphi}_3](x,z)$ has one zero in the rectangle $A_3B_3C_3D_3$.

To sum up, we prove that $W[\tilde{\varphi}_2, \tilde{\varphi}_1, \tilde{\varphi}_0, \tilde{\varphi}_3](x,z)$ has three zeros for $(x,z) \in (0,1) \times (x_0, 0)$.

Case 2: The third Wronskian $W[\tilde{\varphi}_2, \tilde{\varphi}_1, \tilde{\varphi}_0](x,z)$ has no zero for $(x,z) \in (0,1) \times (x_0, 0)$.

Applying the same method as the fourth Wronskian, we obtain the third Wronskian

$$W[\tilde{\varphi}_2, \tilde{\varphi}_1, \tilde{\varphi}_0](x,z) = \frac{\sqrt{2}(x-z)^6 \omega_3(x,z)}{57779957812500000000000 x^3 z^3 q_3(x) q_3(z) (p_z'(x,z))^3}, \tag{3.7}$$

where $\omega_3(x,z)$ is a asymmetric polynomial of degree 177 in (x,z), $p_z'(x,z)$ as in (3.3),

$$q_3(x) = (x-1)^{30}(x^2 + 2x + 2)^{30} \quad \text{and} \quad q_3(z) = (z-1)^{30}(z^2 + 2z + 2)^{30}.$$

The resultant with respect to x between $\omega_3(x,z)$ and $p(x,z)$ is

$$R(\omega_3, p, x) = 629407744000000z^2(z-1)^{24}(z^2+2z+2)^{24}\phi_3(z),$$

here $\phi_3(z)$ is a polynomial of degree 636 in z. We find three isolate zeros of $\phi_3(z)$ in $(x_0, 0)$ and one isolate zero in $(0,1)$. These real root isolation intervals are as follows

$$\tilde{z}_1 \in [\tilde{z}_{11}, \tilde{z}_{12}] = \left[-\frac{771}{2024}, -\frac{6167}{8192}\right], \qquad \tilde{z}_2 \in [\tilde{z}_{21}, \tilde{z}_{22}] = \left[-\frac{39}{64}, -\frac{4991}{8192}\right],$$
$$\tilde{z}_3 \in [\tilde{z}_{31}, \tilde{z}_{32}] = \left[-\frac{3753}{16384}, -\frac{7505}{32768}\right], \qquad \tilde{x} \in [\tilde{x}_{11}, \tilde{x}_{12}] = \left[\frac{6279}{8192}, \frac{785}{1024}\right].$$

We take interval end points $\tilde{x}_{11}$ and $\tilde{x}_{12}$ into interval polynomial equation $p(x,z)) = 0$ and get two real roots intervals in $(x_0, 0)$

$$[\bar{z}_{11}, \bar{z}_{12}] = \left[-\frac{5637}{8192}, \frac{1409}{2408}\right], \qquad [\bar{z}_{21}, \bar{z}_{22}] = \left[-\frac{2819}{4096}, \frac{5637}{8192}\right],$$

respectively. We find that each of intervals $[\bar{z}_{i,1}, \bar{z}_{i,2}] (i = 1,2)$ has not intersection with any of the intervals $[\tilde{z}_{i,1}, \tilde{z}_{i,2}]$ for $i = 1,2,3$, which implies that there does not exist value of (x,z) in plane area $D = (0,1) \times (x_0, 0)$ such that both $\omega_3(x,z) = 0$ and $p(x,z) = 0$ hold simultaneously. This shows that $W[\tilde{\varphi}_2, \tilde{\varphi}_1, \tilde{\varphi}_0](x,z) \neq 0$ for $(x,z) \in (0,1) \times (x_0, 0)$.

Case 3: The second Wronskian $W[\tilde{\varphi}_2, \tilde{\varphi}_1](x,z)$ has no zero for $(x,z) \in (0,1) \times (x_0, 0)$.

By similar calculation to Case 2, we get that

$$W[\tilde{\varphi}_2, \tilde{\varphi}_1](x,z) = \frac{(x-z)^3\omega_2(x,z)}{10005187500000000q_2(x)q_2(z)p'_z(x,z)}, \tag{3.8}$$

where $\omega_2(x,z)$ is a asymmetric polynomial of degree 120 in (x,z),

$$q_1(x) = (x-1)^{21}(x^2+2x+2)^{21} \quad \text{and} \quad q_1(z) = (z-1)^{21}(z^2+2z+2)^{21}. \tag{3.9}$$

The resultant with respect to x between $\omega_2(x,z)$ and $p(x,z)$ is

$$R(\omega_1, p, x) = 6400(z-1)^{18}(z^2+2z+2)^{18}\phi_2(z),$$

where $\phi_2(z)$ is a polynomial of degree 426 in z.

Using command realroot in *Maple*, we find that $\phi_2(z)$ has two zero in the interval $(x_0, 0)$ and one zero in $(0,1)$, which are

$$z_1 \in [z_{11}, z_{12}] = \left[-\frac{93303}{131072}, -\frac{46651}{65536}\right], \qquad z_2 \in [z_{21}, z_{22}] = \left[-\frac{85549}{262144}, -\frac{21387}{65536}\right],$$
$$x \in [x_1, x_2] = \left[\frac{39715}{65536}, \frac{79431}{131073}\right].$$

By solving polynomial equations $p([x_i, z]) = 0$ $(i = 1,2)$, we get the following the isolation intervals of real root z

$$[\bar{z}_{11}, \bar{z}_{12}] = \left[-\frac{75527}{131072}, -\frac{37763}{65536}\right] \quad \text{and} \quad [\bar{z}_{21}, \bar{z}_{22}] = \left[-\frac{9441}{16384}, -\frac{75527}{131072}\right].$$

We find that the intervals $[\bar{z}_{11}, \bar{z}_{12}]$ and $[\bar{z}_{21}, \bar{z}_{22}]$ have not intersection with intervals $[z_{11}, z_{12}]$ and $[z_{21}, z_{22}]$. This shows that $\omega_2(x,z) = 0$ and $p(x,z) = 0$ have no common root for $x_0 < z < 0 < x < 1$. Therefore, $W[\bar{\varphi}_2, \bar{\varphi}_1](x,z) \neq 0$ for all $(x,z) \in (0,1) \times (x_0, 0)$.

Case 4: The first Wronskian $W[\tilde{\varphi}_2](x,z)$ has no zero for $(x,z) \in (0,1) \times (x_0, 0)$.

We get easily that the first Wronskian

$$W[\tilde{\varphi}_2](x,z) = \tilde{\varphi}_2(x,z) = \frac{\sqrt{2}(x-z)\omega_1(x,z)}{346500000 q_1(x) q_1(z)}, \tag{3.10}$$

where $\omega_1(x,z)$ is a polynomial of degree 63 in (x,z),

$$q_1(x) = (x-1)^{11}(x^2+2x+2)^{11} \quad \text{and} \quad q_1(z) = (z-1)^{11}(z^2+2z+2)^{11}.$$

The resultant between $\omega_1(x,z)$ and $p(x,z)$ with respect to x is

$$R(\omega_1, p, x) = (z-1)^{10}(z^2+2z+2)^{10}\phi_1(z),$$

where $\phi_1(z)$ is a polynomial of degree 222 in z. It is easy to know that $\phi_1(z) \neq 0$ for $z \in (x_0, 0)$ by command realroot in *Maple* , which implies that $\omega_1(x,z) = 0$ and $p(x,z) = 0$ have no common root. Hence $W[\tilde{\varphi}_2](x,z) \neq 0$ for all $(x,z) \in (0,1) \times (x_0, 0)$.

Summarizing the above cases 1-4, we have verified that the statements (i) and (ii) in Lemma 2.3 are hold. It follows from Lemma 2.3 that Lemma 3.2 holds, thus we finish proof of Lemma 3.2. □

Proof of Proposition 3.1. Since $h^5 I_i(h) = \tilde{I}_i(h)$, $i = 0,1,2,3$, any linear combination of $(\tilde{I}_0, \tilde{I}_1, \tilde{I}_2, \tilde{I}_3)$ has the same number of zeros as that occurs with (I_0, I_1, I_2, I_3). It is easy to see that Abelian integral in (1.6) together with Hamiltonian (1.8) is the linear span of generators (I_0, I_1, I_2, I_3). By Lemma 3.2, we know that any linear combination of $(\tilde{I}_0, \tilde{I}_1, \tilde{I}_2, \tilde{I}_3)$ has at most six zeros on $(0, \frac{11}{20})$ counted with multiplicities, this implies that any linear combination of (I_0, I_1, I_2, I_3) has also at most six zeros. Therefore, the Abelian integral $I(h)$ has at most six zeros for arbitrary parameters (α, β, γ). The proof of Proposition 3.1 is completed. □

Proof of Theorem 1.1. By Proposition 3.1 and the equation (1.3), if $I(h)$ is not identically zero, then system (1.7) has at most six limit cycles bifurcating from the period annulus of unperturbed system of (1.7) by Poincaré bifurcation. Thus we complete proof of Theorem 1.1. □

Abstract. In this work, we investigate a uniform approximation of a nonautonomous delayed CNN-Hopfield-type impulsive system with an associated impulsive differential system where a partial discretization is introduced with the help of piecewise constant arguments. Sufficient conditions are formulated, which imply that the error estimate decays exponentially with time on the half-line $[0, \infty)$. A critical step for the proof of this estimate is to show that, under the assumed conditions, the solutions of the Hopfield impulsive system are exponentially bounded and exponentially stable. A bounded coefficients case is also analyzed under simplified conditions. An example is presented and simulated in order to show the applicability of our conditions.

Keywords: Hopfield neural networks, hybrid equations, impulsive differential equations, numerical approximation of solutions, piecewise constant arguments.

1 Introduction

Cellular Neural Networks (CNNs) are widely used as mathematical models of the interactions of the neurons in the human brain. For its construction, electrical and chemical properties have been considered. The synapses correspond to the connections of the neurons (excitatory and inhibitory) and are modeled by positive and negative weights. The weighted neural inputs are added up. Then, the so-called activation function defines the amplitude of the response signal of the neuron.

✉Corresponding author. Email: hartung.ferenc@mik.uni-pannon.hu

In [16], John Hopfield proposed a novel type of CNN in order to find how human memory works. They were called *Hopfield cellular neural network*, and it is represented by the following nonlinear system:

$$x_i'(t) = -a_i(t)x_i(t) + \sum_{j=1}^{m} b_{ij}g_j(x_j(t)) + c_i(t), \quad i = 1, \ldots, m, \tag{1.1}$$

This model corresponds to a mesh of linked neurons, where every neuron is connected to all other neurons without self-connection. The states of the neurons are of binary type, and it depends on whether the neuron's input exceeds a fixed value. This type of CNN has been applied in psychology and combinatorics, among others (see [22]). Since the signals travel at a finite speed between the neurons, time delays are natural to introduce in the models. Without completeness, we refer to [3, 6, 7, 18, 20, 23, 27] for investigations of different classes of delayed CNN models.

In [19], A. D. Myshkis introduced differential equations of the form

$$x'(t) = f(t, x(t), x(\tau(t))),$$

where $\tau(t)$ corresponds to a deviated argument (a discontinuous piecewise constant function). These type of equations are called *Differential Equations with Piecewise Constant Arguments* (*DEPCA*). The research in this new field started in the 80's with the works of S. Busenberg and K. L. Cooke with a model of vertically transmitted diseases (see [8, 26]). There are many fields where this type of equations have been applied (see [5, 10, 17]).

In [2], M. U. Akhmet investigated systems of the form

$$y'(t) = f(t, y(t), y(\gamma(t))), \tag{1.2}$$

where $\gamma(t)$ is a *piecewise constant argument of generalized type*. More precisely, given $(t_n)_{n\in\mathbb{Z}}$ and $(\zeta_n)_{n\in\mathbb{Z}}$ such that $t_n < t_{n+1}, \forall n \in \mathbb{Z}$ with $\lim\limits_{n\to\pm\infty} t_n = \pm\infty$ and $t_n \leq \zeta_n \leq t_{n+1}$, then

$$\gamma(t) = \zeta_n, \quad \text{if } t \in I_n = [t_n, t_{n+1}).$$

When such a function γ is introduced, it generates advanced and delayed arguments in the equation, dividing the interval I_n into two pieces $I_n = I_n^+ \cup I_n^-$, where $I_n^+ = [t_n, \zeta_n]$ corresponds to the advanced, and $I_n^- = [\zeta_n, t_{n+1}]$ to the delayed interval. These equations are known as *Differential Equations with Piecewise Constant Argument of Generalized Type* (*DEPCAG*). In this class of differential equations, the solutions are continuous functions, although γ is a discontinuous function. Integrating (1.2) from t_n to t_{n+1} we obtain a difference equation, giving the character of hybrid to this kind of equations (see also [21]).

The following example will be important for the rest of the work (when $k = 0$). Consider $\gamma(t) = \left[\frac{t+k}{h}\right]h$ with $0 \leq k < h$, where $[\cdot]$ is the greatest integer function. We have

$$\left[\frac{t+k}{h}\right]h = nh, \text{ when } t \in I_n = [nh - k, (n+1)h - k).$$

Hence, $\gamma(t) - t \geq 0 \;\Leftrightarrow\; t \leq nh$ and $\gamma(t) - t \leq 0 \;\Leftrightarrow\; t \geq nh$, that implies

$$I_n^+ = [nh - k, nh], \quad I_n^- = [nh, (n+1)h - k].$$

Now, if additionally a jump condition is applied at the endpoints of the intervals $I_n = [t_n, t_{n+1})$, it defines the class of *Impulsive differential equations with piecewise constant argument of generalized type*, (*IDEPCAG*) (see [1]),

$$\begin{aligned} y'(t) &= f(t, y(t), y(\gamma(t))), \qquad t \neq t_n \\ \Delta y(t_n) := y(t_n) - y(t_n^-) &= J_n(y(t_n^-)), \qquad t = t_n, \quad n \in \mathbb{N}. \end{aligned} \tag{1.3}$$

Definition 1.1 (IDEPCAG solution)**.** A piecewise continuous function $y(t)$ is a solution of (1.3) if:

(i) $y(t)$ is continuous on $I_n = [t_n, t_{n+1})$ with discontinuities of the first kind at t_n with $n \in \mathbb{Z}$, where $y'(t)$ exists at each $t \in \mathbb{R}$ with the possible exception of the points t_n, where the lateral derivatives exist.

(ii) On each interval I_n, the ordinary differential equation

$$y'(t) = f(t, y(t), y(\zeta_n))$$

holds, with $\gamma(t) = \zeta_n$.

(iii) For $t = t_n$, the following impulsive condition holds:

$$\Delta y(t_n) = y(t_n) - y(t_n^-) = J_n(y(t_n^-)),$$

i.e., $y(t_n) = y(t_n^-) + J_n(y(t_n^-))$, where $y(t_n^-)$ denotes the left-hand limit of the function y at t_n.

I. Győri used first DEPCAG to approximate linear delay equations with constant delays in [12]. He defined three variants of approximating DEPCAG and proved the convergence of each method on compact time intervals. See also [14] for further generalization of this approach for other classes of differential equations.

In [9], Cooke and Győri proposed an approximation of a linear delay differential equation

$$x'(t) = \sum_{i=1}^{N} q_i x(t - \tau_i), \qquad t \geq 0, \tag{1.4}$$

$$x(t) = \phi(t), \qquad t \in [-\tau, 0], \tag{1.5}$$

where $q_i \in \mathbb{R}, \tau_i > 0$, and $\phi \in C([-\tau, 0], \mathbb{R})$. Here $C([-\tau, 0], \mathbb{R})$ denotes the space of real-valued continuous functions defined on $[-\tau, 0]$. In order to approximate (1.4)–(1.5), they proposed the following DEPCAG

$$y'(t) = \sum_{i=1}^{N} q_i y([t/h - [\tau_i/h]]h), \qquad t \geq 0, \tag{1.6}$$

$$y(nh) = \phi(nh), \qquad n = k, \ldots, 0. \tag{1.7}$$

In this case, the approximation considered was uniform over the non-compact interval $[0, \infty)$. The main assumption is a condition of asymptotic stability of the trivial solution of (1.4). Note that in [13] I. Győri and F. Hartung extended this result for linear neutral differential equations.

Recently, in [15] F. Hartung investigated the numerical approximation of the following scalar delay differential equation with impulsive self-support condition

$$\begin{aligned} x'(t) &= \alpha x(t) + \beta x(t - \tau), \qquad \text{a.e } \ t \geq 0 \\ x(t) &= c + d, \qquad \text{if } x(t^-) = c \end{aligned} \tag{1.8}$$

with the initial condition

$$x(t) = \varphi(t), \qquad \text{if } t \in [-\tau, 0],$$

where $c, d > 0, \alpha + |\beta| < 0$, $\tau > 0$, $c < \varphi(t)$, for $t \in [-\tau, 0]$, and $\varphi : [-\tau, 0] \to \mathbb{R}$ a Lipschitz continuous function. The approximating equation is an associated DEPCA with a self-support condition

$$\begin{aligned} y'(t) &= \alpha y([t/h]h) + \beta y([t/h]h - [\tau/h]h), \qquad \text{a.e } t \geq 0 \\ y(kh) &= c + d, \qquad \text{if } y(kh^-) \leq c \end{aligned} \tag{1.9}$$

with the initial condition

$$y(t) = \varphi(t), \qquad \text{if } t \in [-\tau, 0].$$

The convergence of (1.9) was proved at every point except the impulsive time moments.

In [24], R. Torres et al. considered the following impulsive Hopfield-type CNN system with impulses

$$\begin{aligned} x_i'(t) &= -a_i(t)x_i(t) + \sum_{j=1}^{m} b_{ij}(t)g_j(x_j(t)) + c_i(t), && t \geq 0, \quad t \neq t_k, \\ \Delta x_i(t_k) &= -p_{i,k}x_i(t_k^-) + e_{i,k} + J_{i,k}(x_i(t_k^-)), && t = t_k, \\ x_i(t_0) &= x_i^0, \end{aligned} \tag{1.10}$$

and the following IDEPCA system

$$\begin{aligned} y_i'(t) &= -a_i(t)y_i(t) + \sum_{j=1}^{m} b_{ij}(t)g_j(y_j(\gamma(t))) + c_i(t), && t \geq 0, \quad t \neq \gamma(t_k) \\ \Delta y_i(\gamma(t_k)) &= -p_{i,k}y_i(\gamma(t_k)^-) + e_{i,k} + J_{i,k}(y_i(\gamma(t_k)^-)), && t = \gamma(t_k), \\ y_i(t_0) &= y_i^0, \end{aligned} \tag{1.11}$$

where $\gamma(t) = [t/h]h$. Assuming an ergodic stability condition over the corresponding linear homogeneous system associated with (1.10), the uniform approximation of (1.10) by the IDEPCA (1.11) was concluded over $[0, \infty)$, where the error of approximation was given by

$$|x_i(t) - y_i(t)| \leq \frac{|x_i^0 - y_i^0|}{1 - \theta_c} + \frac{o_i(h)}{1 - \theta_c},$$

with $o_i(h) \to 0$ as $h \to 0$, and $0 < \theta_c < 1$ were defined in [24].

In [11], M. Elghandouri and K. Ezzinbi, using resolvent operators theory, obtained an approximation of the mild solutions of the delayed semilinear integro-differential equation

$$\begin{aligned} x'(t) &= A(t)x(t) + \int_0^t G(t-s)x(s)ds + f(t, x(t-r)), && t \geq 0, \\ x(t) &= \varphi(t), && t \in [-r, 0], \end{aligned} \tag{1.12}$$

using an integro-differential equation with piecewise constant arguments

$$\begin{aligned} x_h'(t) &= A(t)x_h(t) + \int_0^t G(t-s)x_h(s)ds + f(t, x_h(\gamma_h(t-r))), && t \geq 0, \\ x_h(0) &= \varphi(0), \ x_h(t) = \varphi(kh), && t \in [kh, (k+1)h), \end{aligned} \tag{1.13}$$

with $k = -l, \ldots, -1$, and $\gamma_h(t) = [t/h]h$, on the Banach space $(X, \|\cdot\|)$. The approximation was done over compact and unbounded intervals. They also obtained an exponential error decay by using the stability of the resolvent operator and the Halanay's Inequality.

The interested reader in approximation of solutions of differential equations by using piecewise constant argument can see [25] for an elementary and simple introduction to the subject.

1.1 Aim of the work

In this paper, we use $\gamma(t) = [t/h]\,h$ as the piecewise constant argument function, where $[\cdot]$ is the greatest integer part function, and $h > 0$ is a fixed discretization parameter. We note that γ depends on the selection of h, but for simplicity, this dependence is not indicated explicitly in the notation, but it always should be kept in mind.

We consider a delayed CNN system with impulses

$$\begin{aligned} x_i'(t) &= -a_i(t)x_i(t) + \sum_{j=1}^{m} b_{ij}(t)g_j(x_j(t-\tau_j)) + c_i(t), && t \geq 0, \quad t \neq t_k, \\ \Delta x_i(t_k) &= -p_{i,k}x_i(t_k^-) + e_{i,k} + J_{i,k}(x_i(t_k^-)), && k \in \mathbb{N}, \\ x_i(t) &= \varphi_i(t), && t \in [-\tau, 0]. \end{aligned} \tag{1.14}$$

Similar delayed CNN systems (without impulses) were investigated, e.g., in [7, 18, 20].

For a fixed discretization parameter $h > 0$ we associate to (1.14) the IDEPCA system

$$\begin{aligned} y_i'(t) &= -a_i(t)y_i(t) + \sum_{j=1}^{m} b_{ij}(t)g_j(y_j(\gamma(t) - \gamma(\tau_j))) + c_i(t), && t \geq 0, \quad t \neq \gamma(t_k), \\ \Delta y_i(\gamma(t_k)) &= -p_{i,k}y_i(\gamma(t_k)^-) + e_{i,k} + J_{i,k}(y_i(\gamma(t_k)^-)), && k \in \mathbb{N}, \\ y_i(t) &= \psi_i(t), && t \in [-\tau, 0], \end{aligned} \tag{1.15}$$

where $i = 1, 2, \ldots, m$, $k \in \mathbb{N} = \{1, 2, 3 \ldots\}$, t_k, $p_{i,k}$, $e_{i,k}$ are real sequences, a_i, b_{ij}, c_i are real-valued locally integrable functions on $[0, \infty)$, $J_{i,k} \in C(\mathbb{R}, \mathbb{R})$ and $g_j \in C(\mathbb{R}, \mathbb{R})$ for all $i, j = 1, \ldots, m$ and $k \in \mathbb{N}$; the constant delays satisfy $\tau_i \geq 0$ and $\tau = \max\{\tau_1, \ldots, \tau_m\} > 0$, and the initial functions $\varphi_i, \psi_i : [-\tau, 0] \to \mathbb{R}$ are continuous for $i = 1, \ldots, m$.

We note that the initial time in system (1.14) is fixed to be 0. This does not affect the generality of the problem, but it simplifies the definition of the approximation in (1.15), since, in this way, the initial time is a member of the mesh points of the piecewise constant approximation, and $\gamma(t) \geq 0$, and hence $\gamma(t) - \gamma(\tau_j) \geq -\tau_j \geq -\tau$ for $t \geq 0$ and $j = 1, \ldots, m$. Also, the impulse times t_k form a strictly monotone increasing sequence of positive reals, and they are approximated by $\gamma(t_k)$ for $k \in \mathbb{N}$ for the sake of easier computation of the numerical scheme.

For simplicity of the notation we introduce $t_0 = 0$, so the sequence t_k is defined for $k \in \mathbb{N}_0 = \{0, 1, 2, \ldots\}$.

The main goal of this manuscript is to show that the solutions of (1.15) approximate that of (1.14) uniformly on $[0, \infty)$, i.e.,

$$\sup_{t \in [0,\infty)} |x_i(t) - y_i(t)| \to 0, \quad \text{as } h \to 0+, \quad i = 1, \ldots, m,$$

assuming also $\varphi_i = \psi_i$ for $i = 1, \ldots, m$, and we show that, under certain conditions, the error estimate goes to 0 as $t \to \infty$ with an exponential speed.

Remark 1.2. This paper extends the work of [24] for the case when $\tau_i > 0$ in (1.14). Moreover, in this work, we assume a different set of conditions and we use M-matrix technique to get our main results. Another improvement corresponds to the exponential error decay of the approximation, see Theorem 3.1 below. A key step to obtain the main result is to show that, under the assumed conditions, the solutions of (1.14) are exponentially bounded (see Lemma 2.2) and are exponentially stable (see Lemma 2.4, below).

1.2 Hypotheses and main assumptions

In this manuscript, we will use the following assumptions on the parameters of problem (1.14):

(H1) Let $g_j \in C(\mathbb{R},\mathbb{R})$ be such that $g_j(0)=0$, and there exist constants $L_j \geq 0$ such that

$$|g_j(u)-g_j(v)| \leq L_j\,|u-v|\,, \qquad u,v\in\mathbb{R}, \quad j=1,2,\ldots,m.$$

(H2) Let $J_{i,k} \in C(\mathbb{R},\mathbb{R})$ be such that $J_{i,k}(0)=0$, and there exist constants $l_{i,k} \geq 0$ such that

$$|J_{i,k}(u)-J_{i,k}(v)| \leq l_{i,k}\,|u-v|\,, \qquad u,v\in\mathbb{R}, \quad i=1,\ldots,m, \quad k\in\mathbb{N}.$$

(H3) There exist positive constants $p_i^*, l_i^*, e_i^*, \underline{\delta}$ and real constants $\underline{p}_i$ for $i=1,\ldots,m$ such that

(i) $\underline{p}_i \leq p_{i,k} \leq p_i^* < 1, \qquad k\in\mathbb{N}, \quad i=1,\ldots,m;$

(ii) $0 \leq l_{ik} \leq l_i^*, \qquad k\in\mathbb{N}, \quad i=1,\ldots,m;$

(iii) $|e_{i,k}| \leq e_i^*, \qquad k\in\mathbb{N}, \quad i=1,\ldots,m;$

(iv) $0 < \underline{\delta} \leq t_{k+1}-t_k, \qquad k\in\mathbb{N}_0.$

(H4) There exist positive constants $\sigma_i, \Lambda_{ij}, c_i^*$ for $i,j=1,\ldots,m$ and ε_0 such that $0<\varepsilon_0<\sigma_i$ for $i=1,\ldots,m$, and

(i) $\sigma_i(t-s) \leq \int_s^t a_i(u)\,du - \sum_{j\in J(s,t)} \ln(1-p_{i,j}), \quad 0\leq s<t, \quad i=1,\ldots,m,$ where $J(s,t)=\{j\in\mathbb{N} : s\leq t_j<t\}$;

(ii) $\int_0^t e^{-(\sigma_i-\varepsilon_0)(t-s)}|b_{ij}(s)|\,ds \leq \Lambda_{ij}, \qquad t\geq 0, \quad i,j=1,\ldots,m;$

(iii) $|c_i(t)| \leq c_i^*, \qquad t\geq 0, \quad i=1,\ldots,m.$

(H5) $\displaystyle\sum_{j=1}^m (1-\underline{p}_i^-)\Lambda_{ij}L_j + \frac{(1-\underline{p}_i^-)l_i^*}{(1-p_i^*)(1-e^{-\sigma_i\underline{\delta}})} < 1, \qquad i=1,\ldots,m,$ where $\underline{p}_i^- = \min\{0,\underline{p}_i\}$.

(H6) There exist positive constants β_1 and β_2 such that

$$|e_{i,k}| \leq e^{-\beta_1 t_k}e_i^*, \qquad k\in\mathbb{N}, \qquad \text{and} \qquad |c_i(t)| \leq e^{-\beta_2 t}c_i^*, \quad t\geq 0, \quad i=1,\ldots,m.$$

(H7) There exist positive constants a_i^* for $i=1,\ldots,m$ such that $a_i(t)\leq a_i^*$, $t\geq 0$, $i=1,\ldots,m$.

(H8) There exist positive constants b_{ij}^* for $i,j=1,\ldots,m$ and L_φ such that

$$|b_{ij}(t)| \leq b_{ij}^*, \qquad t\geq 0, \qquad \text{and} \qquad |\varphi_i(t)-\varphi_i(\bar{t})| \leq L_\varphi|t-\bar{t}|, \qquad t,\bar{t}\in[-\tau,0]$$

for $i,j=1,\ldots,m$.

Remark 1.3. We comment that (H6) and (H8) yield (H3) (iii), (H4) (iii) and (H4) (ii) with $\Lambda_{ij} = \frac{b_{ij}^*}{\sigma_i-\varepsilon_0}$, but they are not assumed in Lemmas 2.2 and 2.4.

2 Auxiliary results

Recall that t_k is a strictly monotone increasing sequence which tends to $+\infty$ as $k \to \infty$. We denote the set of time moments by $\mathcal{T} = \{t_k : k \in \mathbb{N}\}$. Throughout this manuscript, we use the notation $\ell(t)$ for the uniquely defined nonnegative integer with the property that

$$t \in [t_{\ell(t)}, t_{\ell(t)+1}), \qquad t \geq 0. \tag{2.1}$$

Note that if $t \notin \mathcal{T}$, then $t_{\ell(t)} < t$, otherwise $t_{\ell(t)} = t$.

We use the vector notation $\mathbf{x}(t) = (x_1(t), \dots, x_m(t))^T$ throughout the manuscript. For a norm of vector $\mathbf{x} = (x_1, \dots, x_m)^T \in \mathbb{R}^m$ we use the infinity norm $|\mathbf{x}|_\infty = \max\{|x_1|, \dots, |x_m|\}$. The corresponding induced matrix norm is denoted by $\|A\|_\infty$ for $A \in \mathbb{R}^{m\times m}$. For continuous functions $\psi : [-\tau, 0] \to \mathbb{R}$ and $\boldsymbol{\psi} : [-\tau, 0] \to \mathbb{R}^m$ we use the supremum norm $|\psi|_C = \max_{-\tau\leq t\leq 0} |\psi(t)|$ and $|\boldsymbol{\psi}|_C = \max_{-\tau\leq t\leq 0} |\boldsymbol{\psi}(t)|_\infty$, respectively.

The notation $\mathbf{x} \leq \mathbf{y}$ is used for $\mathbf{x} = (x_1, \dots, x_m)^T \in \mathbb{R}^m$ and $\mathbf{y} = (y_1, \dots, y_m)^T \in \mathbb{R}^m$ if the componentwise comparisons $x_i \leq y_i$ hold for all $i = 1, \dots, m$. We note that $\mathbf{0} \leq \mathbf{x} \leq \mathbf{y}$ implies $|\mathbf{x}|_\infty \leq |\mathbf{y}|_\infty$. We say that a matrix $A \in \mathbb{R}^{m\times m}$ is *monotone* if $A\mathbf{x} \leq A\mathbf{y}$ yields $\mathbf{x} \leq \mathbf{y}$ for every $\mathbf{x}, \mathbf{y} \in \mathbb{R}^m$. Let $I \in \mathbb{R}^{m\times m}$ denote the identity matrix. We say that the matrix $I - A \in \mathbb{R}^{m\times m}$ is a *nonsingular M-matrix* if $\rho(A) < 1$, where $\rho(A)$ is the spectral radius of A. We refer to [4] for 50 equivalent definitions of a nonsingular M-matrix.

The following variation of constants formula was formulated in [24] for the system (1.14) without delays. It is straightforward to extend it for (1.14).

Lemma 2.1. *The solution* $\mathbf{x}(t) = (x_1(t), \dots, x_m(t))^T$ *of* (1.14) *satisfies*

$$\begin{aligned}
x_i(t) &= e^{-\int_0^t a_i(u)du} \left(\prod_{j=1}^{\ell(t)} (1 - p_{i,j}) \right) \varphi_i(0) \\
&\quad + \sum_{r=1}^{\ell(t)} \left(\prod_{j=r}^{k(t)} (1 - p_{i,j}) \right) \int_{t_{r-1}}^{t_r} e^{-\int_s^t a_i(u)du} G_i(s, \mathbf{x}(s)) ds \\
&\quad + \sum_{r=1}^{\ell(t)} \left(\prod_{j=r+1}^{k(t)} (1 - p_{i,j}) \right) e^{-\int_{t_r}^t a_i(u)du} (J_{i,r}(x_i(t_r^-)) + e_{i,r}) \\
&\quad + \int_{t_{\ell(t)}}^t e^{-\int_s^t a_i(u)du} G_i(s, \mathbf{x}(s)) ds, \qquad i = 1, \dots, m, \quad t \geq 0,
\end{aligned} \tag{2.2}$$

where

$$G_i(t, \mathbf{x}(t)) = \sum_{j=1}^m b_{ij}(t) g_j(x_j(t - \tau_j)) + c_i(t). \tag{2.3}$$

Next we show that under conditions (H1)–(H5) the solutions of (1.14) are bounded on $[0, \infty)$. Moreover, if assumption (H6) holds, the solutions are exponentially bounded.

Lemma 2.2. *Suppose (H1)–(H5) hold. Then all solutions of* (1.14) *are bounded on* $[0, \infty)$*. Moreover, if (H6) holds too, then for every solution* $\mathbf{x}(t)$ *of* (1.14) *there exist positive constants* α_0 *and* K_0 *such that*

$$|\mathbf{x}(t)|_\infty \leq K_0 e^{-\alpha_0 t}, \qquad t \geq -\tau, \tag{2.4}$$

i.e., every solution of (1.14) *is exponentially bounded.*

Proof. 1. First, we prove the boundedness of the solutions. Let $\mathbf{x}(t) = (x_1(t), \dots, x_m(t))^T$ be the solution of (1.14) corresponding to initial condition $\boldsymbol{\varphi} = (\varphi_1, \dots, \varphi_m)^T$. Then x_i satisfies the variation of constant formula (2.2), where H_i is defined by (2.3).

Now suppose $s \in [t_{r-1}, t_r)$ for some $r \in \mathbb{N}$, $s < t$ and $t \notin \mathcal{T}$. Then we get $s < t_r < t_{\ell(t)} < t < t_{\ell(t)+1}$, $J(s,t) = \{r, r+1, \dots, \ell(t)\}$ if $t > t_r$, and $J(s,t) = \emptyset$ if $t \le t_r$, therefore (H3) (i) and (H4) (i) yield

$$e^{-\int_s^t a_i(u)\,du}\left(\prod_{j=r}^{\ell(t)}(1-p_{i,j})\right) = \exp\left(-\int_s^t a_i(u)\,du + \sum_{j\in J(s,t)} \ln(1-p_{i,j})\right) \le e^{-\sigma_i(t-s)}.$$

If $t = t_{r_0}$ for some $r_0 \in \mathbb{N}$, $s \in [t_{r-1}, t_r)$, $s < t$, then $J(s, t_{r_0}) = \{r, r+1, \dots, r_0 - 1\}$, and

$$e^{-\int_s^{t_{r_0}} a_i(u)\,du}\left(\prod_{j=r}^{\ell(t)}(1-p_{i,j})\right) = (1-p_{i,r_0})\exp\left(-\int_s^{t_{r_0}} a_i(u)\,du + \sum_{j=r}^{r_0-1} \ln(1-p_{i,j})\right) \le (1-\underline{p}_i)e^{-\sigma_i(t_{r_0}-s)}.$$

Hence

$$e^{-\int_s^t a_i(u)\,du}\left(\prod_{j=r}^{\ell(t)}(1-p_{i,j})\right) \le (1-\underline{p}_i^-)e^{-\sigma_i(t-s)}, \quad s \in [t_{r-1}, t_r), \;\; s \le t, \;\; i = 1, \dots, m, \tag{2.5}$$

where $\underline{p}_i^- = \min\{0, \underline{p}_i\}$.

For $s \in (t_{\ell(t)}, t)$ it follows $J(s,t) = \emptyset$, and

$$e^{-\int_s^t a_i(u)\,du} = \exp\left(-\int_s^t a_i(u)\,du + \sum_{j\in J(s,t)} \ln(1-p_{i,j})\right) \le e^{-\sigma_i(t-s)}. \tag{2.6}$$

For $t_r < t$, $t \notin \mathcal{T}$ we get $t_r < t_{r+1} \le t_{\ell(t)} < t$, so $J(t_r, t) = \{r, r+1, \dots, \ell(t)\}$, and therefore (H3) (i) and (H4) (i) imply

$$\begin{aligned} e^{-\int_{t_r}^t a_i(u)\,du}\left(\prod_{j=r+1}^{\ell(t)}(1-p_{i,j})\right) &= \frac{1}{1-p_{i,r}} e^{-\int_{t_r}^t a_i(u)\,du}\left(\prod_{j=r}^{\ell(t)}(1-p_{i,j})\right) \\ &\le \frac{1}{1-p_i^*}\exp\left(-\int_{t_r}^t a_i(u)\,du + \sum_{j\in J(t_r,t)} \ln(1-p_{i,j})\right) \\ &\le \frac{1}{1-p_i^*} e^{-\sigma_i(t-t_r)}. \end{aligned}$$

Finally, if $t = t_{r_0}$ for some $r_0 \in \mathbb{N}$ and $r < r_0$, then it follows $J(t_r, t_{r_0}) = \{r, r+1, \dots, r_0 - 1\}$, $\ell(t) = r_0$, and so

$$\begin{aligned} e^{-\int_{t_r}^{t_{r_0}} a_i(u)\,du}\left(\prod_{j=r+1}^{\ell(t)}(1-p_{i,j})\right) &= \frac{1-p_{i,r_0}}{1-p_{i,r}}\exp\left(-\int_{t_r}^{t_{r_0}} a_i(u)\,du + \sum_{j=r}^{r_0-1} \ln(1-p_{i,j})\right) \\ &\le \frac{1-\underline{p}_i}{1-p_i^*} e^{-\sigma_i(t_{r_0}-t_r)}. \end{aligned}$$

Combining the above two cases, we get

$$e^{-\int_{t_r}^{t} a_i(u)\,du}\left(\prod_{j=r+1}^{\ell(t)}(1-p_{i,j})\right)\le\frac{1-\underline{p}_i^-}{1-p_i^*}e^{-\sigma_i(t-t_r)},\qquad t\ge t_r,\quad r\in\mathbb{N},\quad i=1,\dots,m. \tag{2.7}$$

Then (2.2), (2.5), (2.6) and (2.7) imply for $t\ge 0$

$$\begin{aligned}|x_i(t)|&\le(1-\underline{p}_i^-)e^{-\sigma_i t}|\varphi_i(0)|+\sum_{r=1}^{\ell(t)}\int_{t_{r-1}}^{t_r}(1-\underline{p}_i^-)e^{-\sigma_i(t-s)}|G_i(s,\mathbf{x}(s))|\,ds\\&\quad+\sum_{r=1}^{\ell(t)}\frac{1-\underline{p}_i^-}{1-p_i^*}e^{-\sigma_i(t-t_r)}(|J_{i,r}(x_i(t_r^-))|+|e_{i,r}|)+\int_{t_{\ell(t)}}^{t}e^{-\sigma_i(t-s)}|G_i(s,\mathbf{x}(s))|\,ds\\&=(1-\underline{p}_i^-)e^{-\sigma_i t}|\varphi_i(0)|+\int_0^t(1-\underline{p}_i^-)e^{-\sigma_i(t-s)}|G_i(s,\mathbf{x}(s))|\,ds\\&\quad+\sum_{r=1}^{\ell(t)}\frac{1-\underline{p}_i^-}{1-p_i^*}e^{-\sigma_i(t-t_r)}(|J_{i,r}(x_i(t_r^-))|+|e_{i,r}|).\end{aligned} \tag{2.8}$$

The assumed relations (H1)–(H4), (2.8), $t\in[t_{\ell(t)},t_{\ell(t)+1})$,

$$|J_{i,r}(x_i(t_r^-))|\le l_{i,r}|x_i(t_r^-)|\le l_i^*|x_i(t_r^-)|,\qquad i=1,\dots,m,\quad r\in\mathbb{N}$$

and

$$|G_i(s,\mathbf{x}(s))|\le\sum_{j=1}^{m}|b_{ij}(s)|L_j|x_j(s-\tau_j)|+|c_i(s)|,\qquad i=1,\dots,m,\quad s\ge 0$$

yield

$$\begin{aligned}|x_i(t)|&\le(1-\underline{p}_i^-)e^{-\sigma_i t}|\varphi_i(0)|\\&\quad+\int_0^t(1-\underline{p}_i^-)e^{-\sigma_i(t-s)}\Big(\sum_{j=1}^{m}|b_{ij}(s)|L_j|x_j(s-\tau_j)|+|c_i(s)|\Big)\,ds\\&\quad+\frac{1-\underline{p}_i^-}{1-p_i^*}\sum_{r=1}^{\ell(t)}e^{-\sigma_i(t-t_r)}(l_i^*|x_i(t_r^-)|+|e_{i,r}|),\qquad i=1,\dots,m,\quad t\ge 0.\end{aligned} \tag{2.9}$$

Using relation $\underline{\delta}\le t_{r+1}-t_r$ for $r\in\mathbb{N}_0$ from (H4) and $t\in[t_{\ell(t)},t_{\ell(t)+1})$, we obtain

$$\begin{aligned}\sum_{r=1}^{\ell(t)}e^{-\sigma_i(t-t_r)}&=\sum_{r=1}^{\ell(t)}e^{-\sigma_i(t-t_{\ell(t)}+(t_{\ell(t)}-t_{\ell(t)-1})+\cdots+(t_{r+1}-t_r))}\\&\le\sum_{r=1}^{\ell(t)}e^{-\sigma_i(t-t_{\ell(t)})}e^{-\sigma_i(\ell(t)-r)\underline{\delta}}\\&\le\sum_{r=1}^{\ell(t)}\left(e^{-\sigma_i\underline{\delta}}\right)^{\ell(t)-r}\\&\le\frac{1}{1-e^{-\sigma_i\underline{\delta}}},\qquad t\ge 0.\end{aligned} \tag{2.10}$$

Combining (2.9) with assumptions (H3), (H4), relation (2.10), and the estimate

$$\int_0^t e^{-\sigma_i(t-s)}\,ds\le\frac{1}{\sigma_i},\qquad t\ge 0, \tag{2.11}$$

we get for $t \geq 0$ and $i = 1, \ldots, m$

$$\begin{aligned}
|x_i(t)| &\leq (1-\underline{p}_i^-)e^{-\sigma_i t}|\varphi_i(0)| \\
&\quad + \int_0^t (1-\underline{p}_i^-)e^{-\sigma_i(t-s)}\Big(\sum_{j=1}^m |b_{ij}(s)|L_j \sup_{-\tau\leq u\leq s}|x_j(u)| + c_i^*\Big)\,ds \\
&\quad + \frac{1-\underline{p}_i^-}{1-p_i^*}\sum_{r=1}^{\ell(t)} e^{-\sigma_i(t-t_r)}(l_i^* \sup_{0\leq u\leq t}|x_i(u)| + e_i^*) \\
&\leq (1-\underline{p}_i^-)|\varphi_i(0)| + \sum_{j=1}^m (1-\underline{p}_i^-)\Lambda_{ij}L_j \sup_{-\tau\leq u\leq t}|x_j(u)| + \frac{(1-\underline{p}_i^-)c_i^*}{\sigma_i} \\
&\quad + \frac{1-\underline{p}_i^-}{(1-p_i^*)(1-e^{-\sigma_i\underline{\delta}})}\Big(l_i^* \sup_{-\tau\leq u\leq t}|x_i(u)| + e_i^*\Big). \qquad (2.12)
\end{aligned}$$

Since the right-hand side of (2.12) is monotone increasing in t, and $|x_i(u)| \leq |\varphi_i|_C \leq (1-\underline{p}_i^-)|\varphi_i|_C$ for $u \in [-\tau, 0]$, (2.12) yields

$$\begin{aligned}
\sup_{-\tau\leq u\leq t}|x_i(u)| &\leq (1-\underline{p}_i^-)|\varphi_i|_C + \sum_{j=1}^m (1-\underline{p}_i^-)\Lambda_{ij}L_j \sup_{-\tau\leq u\leq t}|x_j(u)| + \frac{(1-\underline{p}_i^-)c_i^*}{\sigma_i} \\
&\quad + \frac{1-\underline{p}_i^-}{(1-p_i^*)(1-e^{-\sigma_i\underline{\delta}})}\Big(l_i^* \sup_{-\tau\leq u\leq t}|x_i(u)| + e_i^*\Big), \qquad (2.13)
\end{aligned}$$

for $i = 1, \ldots, m$ and $t \geq 0$. Fix a nonnegative parameter α. Then we introduce the corresponding notations

$$\begin{aligned}
\mathbf{v}^{(\alpha)}(t) &= \Big(\sup_{-\tau\leq u\leq t} e^{\alpha u}|x_1(u)|, \ldots, \sup_{-\tau\leq u\leq t} e^{\alpha u}|x_m(u)|\Big)^T \in \mathbb{R}^m, \qquad t \geq -\tau, \\
\mathbf{a}^{(\alpha)} &= (a_1^{(\alpha)}, \ldots, a_m^{(\alpha)})^T \in \mathbb{R}^m, \quad \text{where} \\
a_i^{(\alpha)} &= (1-\underline{p}_i^-)\left(|\varphi_i|_C + \frac{c_i^*}{\sigma_i-\alpha} + \frac{e_i^*}{(1-p_i^*)(1-e^{-(\sigma_i-\alpha)\underline{\delta}})}\right), \\
A^{(\alpha)} &= (a_{ij}) \in \mathbb{R}^{m\times m}, \quad a_{ij}^{(\alpha)} = \begin{cases} (1-\underline{p}_i^-)\Lambda_{ij}L_i e^{\alpha\tau_i} + \frac{(1-\underline{p}_i^-)l_i^*}{(1-p_i^*)(1-e^{-(\sigma_i-\alpha)\underline{\delta}})}, & i = j, \\ (1-\underline{p}_i^-)\Lambda_{ij}L_j e^{\alpha\tau_j}, & i \neq j. \end{cases} \qquad (2.14)
\end{aligned}$$

Hence (2.13) implies the vector inequality

$$\mathbf{v}^{(0)}(t) \leq \mathbf{a}^{(0)} + A^{(0)}\mathbf{v}^{(0)}(t), \qquad t \geq 0.$$

The definition of $\mathbf{a}^{(0)}$ yields $\mathbf{v}^{(0)}(t) \leq \mathbf{a}^{(0)}$ for $t \in [-\tau, 0]$, so

$$\mathbf{v}^{(0)}(t) \leq \mathbf{a}^{(0)} + A^{(0)}\mathbf{v}^{(0)}(t), \qquad t \geq -\tau.$$

Assumption (H5) implies $\|A^{(0)}\|_\infty < 1$, so $I - A^{(0)}$ is a nonsingular M-matrix. Therefore Theorem 6.2.3 in [4] yields that $I - A^{(0)}$ is monotone, and

$$(|x_1(t)|, \ldots, |x_m(t)|)^T \leq \mathbf{v}^{(0)}(t) \leq (I - A^{(0)})^{-1}\mathbf{a}^{(0)}, \qquad t \geq -\tau.$$

It follows

$$|\mathbf{x}(t)|_\infty \leq |(I - A^{(0)})^{-1}\mathbf{a}^{(0)}|_\infty, \qquad t \geq -\tau,$$

i.e., $\mathbf{x}(t)$ is bounded on $[-\tau, \infty)$.

2. Next, we show the exponential boundedness of the solutions under the additional assumption (H6).

We select a positive constant α_0 such that

$$\alpha_0 < \min\{\varepsilon_0, \beta_1, \beta_2\} \quad \text{and} \quad \sum_{j=1}^{m}(1-\underline{p}_i^-)\Lambda_{ij}L_j e^{\alpha_0\tau_j} + \frac{(1-\underline{p}_i^-)l_i^*}{(1-p_i^*)(1-e^{-(\sigma_i-\alpha_0)\underline{\delta}})} < 1 \tag{2.15}$$

for $i = 1, \ldots, m$. Note that such α_0 exists since (H5) holds. Multiplying both sides of (2.9) by $e^{\alpha_0 t}$ we get

$$\begin{aligned} e^{\alpha_0 t}|x_i(t)| \le{}& (1-\underline{p}_i^-)e^{-(\sigma_i-\alpha_0)t}|\varphi_i(0)| \\ &+ \int_0^t (1-\underline{p}_i^-)e^{-(\sigma_i-\alpha_0)(t-s)}\Big(\sum_{j=1}^{m}|b_{ij}(s)|L_j e^{\alpha_0\tau_j}e^{\alpha_0(s-\tau_j)}|x_j(s-\tau_j)| + e^{\alpha_0 s}|c_i(s)|\Big)ds \\ &+ \frac{1-\underline{p}_i^-}{1-p_i^*}\sum_{r=1}^{\ell(t)} e^{-(\sigma_i-\alpha_0)(t-t_r)}(l_i^* e^{\alpha_0 t_r}|x_i(t_r^-)| + e^{\alpha_0 t_r}|e_{i,r}|) \end{aligned}$$

for $i = 1, \ldots, m$ and $t \ge 0$. Then (H3), (H4), (H6), $\alpha_0 < \min\{\varepsilon_0, \beta_1, \beta_2\}$, and (2.10) and (2.11) where σ_i is replaced by $\sigma_i - \alpha_0$ imply

$$\begin{aligned} e^{\alpha_0 t}|x_i(t)| \le{}& (1-\underline{p}_i^-)|\varphi_i|_C + \sum_{j=1}^{m}(1-\underline{p}_i^-)\Lambda_{ij}L_j e^{\alpha_0\tau_j}\sup_{-\tau\le u\le t} e^{\alpha_0 u}|x_j(u)| + \frac{(1-\underline{p}_i^-)c_i^*}{\sigma_i-\alpha_0} \\ &+ \frac{(1-\underline{p}_i^-)l_i^*}{(1-p_i^*)(1-e^{-(\sigma_i-\alpha_0)\underline{\delta}})}\sup_{-\tau\le u\le t} e^{\alpha_0 u}|x_i(u)| + \frac{(1-\underline{p}_i^-)e_i^*}{(1-p_i^*)(1-e^{-(\sigma_i-\alpha_0)\underline{\delta}})} \end{aligned}$$

for $i = 1, \ldots, m$ and $t \ge 0$. Then the monotonicity of the right-hand side and $e^{\alpha_0 t}|x_i(t)| \le |\varphi_i|_C \le (1-\underline{p}_i^-)|\varphi_i|_C$ for $-\tau \le t \le 0$ imply the vector inequality

$$\mathbf{v}^{(\alpha_0)}(t) \le \mathbf{a}^{(\alpha_0)} + A^{(\alpha_0)}\mathbf{v}^{(\alpha_0)}(t), \qquad t \ge -\tau. \tag{2.16}$$

Relation (2.15) yields $\|A^{(\alpha_0)}\|_\infty < 1$, so $I - A^{(\alpha_0)}$ is a nonsingular M-matrix, hence $I - A^{(\alpha_0)}$ is monotone. Therefore

$$(e^{\alpha_0 t}|y_1(t)|, \ldots, e^{\alpha_0 t}|y_m(t)|)^T \le \mathbf{v}^{(\alpha_0)}(t) \le (I - A^{(\alpha_0)})^{-1}\mathbf{a}^{(\alpha_0)}, \qquad t \ge -\tau,$$

so (2.4) holds with

$$K_0 = |(I - A^{(\alpha_0)})^{-1}\mathbf{a}^{(\alpha_0)}|_\infty,$$

i.e., $\mathbf{x}(t)$ is exponentially bounded on $[-\tau, \infty)$. □

Remark 2.3. Let $A^{(0)}$ be defined by (2.14) with $\alpha = 0$. We remark that (H5) can be replaced by the weaker condition $\rho(A^{(0)}) < 1$, and the statement of Lemma 2.2 remains true.

Our next result shows that every solution of (1.14) is exponentially stable.

Lemma 2.4. *Suppose (H1)–(H5) hold. Then there exist positive constants α_0 and K_1 such that*

$$|\mathbf{x}(t) - \bar{\mathbf{x}}(t)|_\infty \le K_1 e^{-\alpha_0 t}|\boldsymbol{\varphi} - \bar{\boldsymbol{\varphi}}|_C, \qquad t \ge 0, \tag{2.17}$$

where $\boldsymbol{\varphi}(t) = (\varphi_1, \ldots, \varphi_m)^T$ and $\bar{\boldsymbol{\varphi}} = (\bar{\varphi}_1, \ldots, \bar{\varphi}_m)^T$ are two initial functions in (1.14), and $\mathbf{x}(t) = (x_1(t), \ldots, x_m(t))^T$ and $\bar{\mathbf{x}}(t) = (\bar{x}_1(t), \ldots, \bar{x}_m(t))^T$ are the corresponding solutions of (1.14), respectively, i.e., every solution of (1.14) is exponentially stable.

Proof. Let $(\varphi_1, \dots, \varphi_m)^T$ and $(\bar{\varphi}_1, \dots, \bar{\varphi}_m)^T$ be the vectors of two initial functions in (1.14), and $(x_1(t), \dots, x_m(t))^T$ and $(\bar{x}_1(t), \dots, \bar{x}_m(t))^T$ be the corresponding solutions of (1.14). Then the variation of constant formula (2.2) yields

$$
\begin{aligned}
x_i(t) - \bar{x}_i(t) &= e^{-\int_0^t a_i(u)\,du} \left(\prod_{j=1}^{\ell(t)} (1 - p_{i,j}) \right) (\varphi_i(0) - \bar{\varphi}_i(0)) \\
&\quad + \sum_{r=1}^{\ell(t)} \left(\prod_{j=r}^{\ell(t)} (1 - p_{i,j}) \right) \int_{t_{r-1}}^{t_r} e^{-\int_s^t a_i(u)\,du} \Big(G_i(s, \mathbf{x}(s)) - G_i(s, \bar{\mathbf{x}}(s)) \Big)\, ds \\
&\quad + \sum_{r=1}^{\ell(t)} \left(\prod_{j=r+1}^{\ell(t)} (1 - p_{i,j}) \right) e^{-\int_{t_r}^t a_i(u)\,du} \Big(J_{i,r}(x_i(t_r^-)) - J_{i,r}(\bar{x}_i(t_r^-)) \Big) \\
&\quad + \int_{t_{\ell(t)}}^t e^{-\int_s^t a_i(u)\,du} \Big(G_i(s, \mathbf{x}(s)) - G_i(s, \bar{\mathbf{x}}(s)) \Big)\, ds, \quad i = 1, \dots, m, \quad t \geq 0.
\end{aligned}
$$

We have

$$
|G_i(s, \mathbf{x}(s)) - G_i(s, \bar{\mathbf{x}}(s))| \leq \sum_{j=1}^m |b_{ij}(s)| L_j |x_j(s - \tau_j) - \bar{x}_i(s - \tau_j)|,
$$

hence, similarly to the derivation of (2.9), we get

$$
\begin{aligned}
|x_i(t) - \bar{x}_i(t)| &\leq (1 - \underline{p}_i^-) e^{-\sigma_i t} |\varphi_i(0) - \bar{\varphi}_i(0)| \\
&\quad + \sum_{j=1}^m \int_0^t (1 - \underline{p}_i^-) e^{-\sigma_i (t-s)} |b_{ij}(s)| L_j |x_j(s - \tau_j) - \bar{x}_i(s - \tau_j)|\, ds \\
&\quad + \frac{1 - \underline{p}_i^-}{1 - p_i^*} \sum_{r=1}^{\ell(t)} e^{-\sigma_i (t - t_r)} l_i^* |x_i(t_r^-) - \bar{x}_i(t_r^-)|, \qquad i = 1, \dots, m, \quad t \geq 0. \qquad (2.18)
\end{aligned}
$$

We select a positive constant α_0 such that (2.15) is satisfied. Note that such α_0 exists since (H5) holds. Multiplying both sides of (2.18) by $e^{\alpha_0 t}$ we obtain

$$
\begin{aligned}
& e^{\alpha_0 t} |x_i(t) - \bar{x}_i(t)| \\
&\quad \leq (1 - \underline{p}_i^-) e^{(\alpha_0 - \sigma_i) t} |\varphi_i(0) - \bar{\varphi}_i(0)| \\
&\qquad + \sum_{j=1}^m \int_0^t (1 - \underline{p}_i^-) e^{-(\sigma_i - \alpha_0)(t-s)} |b_{ij}(s)| L_j e^{\alpha_0 \tau_j} e^{\alpha_0 (s - \tau_j)} |x_j(s - \tau_j) - \bar{x}_i(s - \tau_j)|\, ds \\
&\qquad + \frac{1 - \underline{p}_i^-}{1 - p_i^*} \sum_{r=1}^{\ell(t)} e^{-(\sigma_i - \alpha_0)(t - t_r)} l_i^* e^{\alpha_0 t_r} |x_i(t_r^-) - \bar{x}_i(t_r^-)| \qquad (2.19)
\end{aligned}
$$

for $i = 1, \dots, m$ and $t \geq 0$. Introduce the functions

$$
v_i(t) = \sup_{-\tau \leq u \leq t} e^{\alpha_0 u} |x_i(u) - \bar{x}_i(u)|, \qquad i = 1, \dots, m, \quad t \geq -\tau.
$$

Then (2.19) combined with (2.10) where σ_i is replaced by $\sigma_i - \alpha_0$ and

$$
e^{\alpha_0 u} |x_i(u) - \bar{x}_i(u)| \leq e^{\alpha_0 u} |\mathbf{x}(u) - \bar{\mathbf{x}}(u)|_\infty \leq |\boldsymbol{\varphi} - \bar{\boldsymbol{\varphi}}|_C \leq (1 - \underline{p}_i^-) |\boldsymbol{\varphi} - \bar{\boldsymbol{\varphi}}|_C, \quad -\tau \leq u \leq 0
$$

imply

$$\begin{aligned} v_i(t) &\le (1-\underline{p}_i^-)|\boldsymbol{\varphi}-\bar{\boldsymbol{\varphi}}|_C + \sum_{j=1}^m \int_0^t (1-\underline{p}_i^-)e^{-(\sigma_i-\alpha_0)(t-s)}|b_{ij}(s)|L_j e^{\alpha_0\tau_j} v_j(s)\,ds \\ &\quad + \frac{1-\underline{p}_i^-}{1-p_i^*}\sum_{r=1}^{\ell(t)} e^{-(\sigma_i-\alpha_0)(t-t_r)} l_i^* v_i(t) \\ &\le (1-\underline{p}_i^-)|\boldsymbol{\varphi}-\bar{\boldsymbol{\varphi}}|_C + \sum_{j=1}^m (1-\underline{p}_i^-)\Lambda_{ij}L_j e^{\alpha_0\tau_j} v_j(t) \\ &\quad + \frac{(1-\underline{p}_i^-)l_i^*}{(1-p_i^*)(1-e^{-(\sigma_i-\alpha_0)\underline{\delta}})} v_i(t) \end{aligned}$$

for $i = 1,\ldots,m$ and $t \ge 0$. Therefore, the vector inequality

$$\mathbf{v}(t) \le \mathbf{b} + A^{(\alpha_0)}\mathbf{v}(t), \qquad t \ge -\tau, \tag{2.20}$$

holds, where

$$\begin{aligned} \mathbf{v}(t) &= (v_1(t),\ldots,v_m(t))^T \in \mathbb{R}^m, \qquad t \ge -\tau, \\ \mathbf{b} &= \Big((1-\underline{q}_1^-)|\boldsymbol{\varphi}-\bar{\boldsymbol{\varphi}}|_C,\ldots,(1-\underline{q}_m^-)|\boldsymbol{\varphi}-\bar{\boldsymbol{\varphi}}|_C\Big)^T \in \mathbb{R}^m, \end{aligned} \tag{2.21}$$

and $A^{(\alpha_0)}$ is defined by (2.14). Relation (2.15) yields $\|A^{(\alpha_0)}\|_\infty < 1$, hence $I - A^{(\alpha_0)}$ is a nonsingular M-matrix, so $I - A^{(\alpha_0)}$ is monotone. Therefore (2.20) gives

$$\mathbf{v}(t) \le (I - A^{(\alpha_0)})^{-1}\mathbf{b}, \qquad t \ge -\tau,$$

and hence

$$e^{\alpha_0 t}|\mathbf{x}(t) - \bar{\mathbf{x}}(t)|_\infty \le |\mathbf{v}(t)|_\infty \le \|(I - A^{(\alpha_0)})^{-1}\|_\infty |\mathbf{b}|_\infty = K_1|\boldsymbol{\varphi}-\bar{\boldsymbol{\varphi}}|_C,$$

where $K_1 = \|(I - A^{(\alpha_0)})^{-1}\|_\infty \max\{1-\underline{q}_1^-,\ldots,1-\underline{q}_m^-\}$. This completes the proof of (2.17). □

Remark 2.5. Let $A^{(\alpha)}$ be the matrix defined by (2.14). We note that $\rho(A^{(0)}) < 1$ implies $\rho(A^{(\alpha_0)}) < 1$ for sufficiently small $\alpha_0 > 0$, so assumption (H5) in Lemma 2.4 can be replaced by the weaker condition $\rho(A^{(0)}) < 1$.

Next, we prove an estimate which will be important in the proof of our main result in the next section.

Lemma 2.6. *Suppose (H1)–(H5) hold. Let $\mathbf{x} = (x_1,\ldots,x_m)^T$ be a solution of (1.14), and let $\alpha_0 > 0$ be the corresponding constant from Lemma 2.2. For $0 < \alpha < \alpha_0$ and $u > 0$ define*

$$\begin{aligned} \omega_\alpha(u) = \sup\Big\{ e^{\alpha t}|\mathbf{x}(t) - \mathbf{x}(\bar{t})|_\infty \ :\ \Big(t,\bar{t} \in [t_r,t_{r+1}),\ r \in \mathbb{N} \quad \text{or} \quad t,\bar{t} \in [-\tau,t_1)\Big), \\ \text{and} \quad |\bar{t} - t| \le u \Big\}. \end{aligned} \tag{2.22}$$

(i) Then

$$\lim_{u\to 0+} \omega_\alpha(u) = 0, \qquad 0 < \alpha < \alpha_0. \tag{2.23}$$

(ii) Assume further (H6), (H7) and (H8). Then there exist $M_0 > 0$ and $u_0 > 0$ such that

$$\omega_\alpha(u) \le M_0 u, \qquad 0 < u \le u_0, \quad 0 < \alpha < \alpha_0. \tag{2.24}$$

Proof. (i) It follows from Lemma 2.2 that $\mathbf{x}$ satisfies (2.4). Fix $0 < \alpha < \alpha_0$, $\varepsilon > 0$ and $\bar{u} > 0$. Since $t_k \to \infty$ as $k \to \infty$, there exists k_0 such that

$$K_0 e^{\alpha_0 \bar{u}} e^{(\alpha-\alpha_0)t} < \frac{\varepsilon}{2}, \qquad t \ge t_{k_0}.$$

Then, using (2.4) and the triangle inequality, we get

$$e^{\alpha t}|\mathbf{x}(t) - \mathbf{x}(\bar{t})|_\infty < e^{\alpha t}\left(K_0 e^{-\alpha_0 t} + K_0 e^{-\alpha_0 \bar{t}}\right) \le K_0 e^{(\alpha-\alpha_0)t} + K_0 e^{\alpha_0 u} e^{(\alpha-\alpha_0)t} < \varepsilon,$$

for $t, \bar{t} \ge t_{k_0}$, $|\bar{t} - t| \le u$ and $0 < u < \bar{u}$.

The function $e^{\alpha t} x_i(t)$ is uniformly continuous on the intervals $[t_k, t_{k+1})$ for $k = 1, \dots, k_0 - 1$ and $i = 1, \dots, m$, and on the interval $[-\tau, t_1)$ since it has continuous extension to the closed intervals $[t_k, t_{k+1}]$ and $[-\tau, t_1]$. Therefore, there exists $\delta > 0$ such that

$$|e^{\alpha t}\mathbf{x}(t) - e^{\alpha \bar{t}}\mathbf{x}(\bar{t})|_\infty < \frac{\varepsilon}{2} \qquad \text{and} \qquad \delta < \min\left\{\bar{u}, \frac{\varepsilon}{2(e-1)K_0\alpha}, \frac{1}{\alpha}\right\}$$

if $t, \bar{t} \in [t_r, t_{r+1})$ for some $r \in \{1, \dots, k_0 - 1\}$ or $t, \bar{t} \in [-\tau, t_1)$, and $|\bar{t} - t| \le \delta$. Then (2.4) and the estimate

$$|e^s - 1| \le (e-1)|s|, \qquad |s| \le 1 \tag{2.25}$$

imply

$$\begin{aligned}
e^{\alpha t}|\mathbf{x}(t) - \mathbf{x}(\bar{t})|_\infty &\le |e^{\alpha t}\mathbf{x}(t) - e^{\alpha \bar{t}}\mathbf{x}(\bar{t})|_\infty + |e^{\alpha t} - e^{\alpha \bar{t}}||\mathbf{x}(\bar{t})|_\infty \\
&< \frac{\varepsilon}{2} + |e^{\alpha(t-\bar{t})} - 1| e^{\alpha \bar{t}}|\mathbf{x}(\bar{t})|_\infty \\
&< \frac{\varepsilon}{2} + (e-1)\alpha\delta K_0 \\
&< \varepsilon,
\end{aligned}$$

if $t, \bar{t} \in [t_r, t_{r+1})$ for some $r \in \{1, \dots, k_0 - 1\}$ or $t, \bar{t} \in [-\tau, t_1)$, and $|\bar{t} - t| \le \delta$. Hence $\omega_\alpha(u) \le \varepsilon$ for $0 < \alpha < \alpha_0$ and $0 < u < \delta$, which completes the proof of (2.23).

(ii) Note that it follows from the proof of Lemma 2.2 that $\alpha < \alpha_0 < \beta_2$. Since $x_i(t)$ is continuously differentiable on $[t_r, t_{r+1})$, we get from (1.14) that for $t, \bar{t} \in [t_r, t_{r+1})$ for some $r \in \mathbb{N}_0$

$$e^{\alpha t}(x_i(t) - x_i(\bar{t})) = \int_{\bar{t}}^{t} e^{\alpha t}\left(-a_i(s)x_i(s) + \sum_{j=1}^{m} b_{ij}(s) g_j(x_j(s-\tau_j)) + c_i(s)\right) ds.$$

Define the constant $M = a_i^* K_0 + \sum_{j=1}^{m} b_{ij}^* L_j e^{\alpha_0 \tau_j} K_0 + c_i^*$. Then, using $e^{\alpha s}|x_i(s)| \le e^{\alpha_0 s}|x_i(s)| \le K_0$ from (2.4) and $e^{\alpha s}|c_i(s)| \le e^{\beta_2 s}|c_i(s)| \le c_i^*$ from (H6) and (2.25), we get

$$\begin{aligned}
e^{\alpha t}|x_i(t) - x_i(\bar{t})| &\le \int_{\bar{t}}^{t} e^{\alpha(t-s)}\left(a_i^* e^{\alpha s}|x_i(s)| + \sum_{j=1}^{m} b_{ij}^* L_j e^{\alpha_0 \tau_j} e^{\alpha(s-\tau_j)}|x_j(s-\tau_j)| + e^{\alpha s}|c_i(s)|\right) ds \\
&\le M \int_{\bar{t}}^{t} e^{\alpha(t-s)}\, ds \\
&= M\left(\frac{e^{\alpha(t-\bar{t})} - 1}{\alpha}\right) \\
&\le M(e-1)u, \qquad t, \bar{t} \in [t_r, t_{r+1}), \quad r \in \mathbb{N}_0,
\end{aligned}$$

for $|t - \bar{t}| \le u \le u_0 = \frac{1}{\alpha_0}$.

Assumption (H8) yields

$$e^{\alpha t}|x_i(t) - x_i(\bar{t})| \le |\varphi_i(t) - \varphi_i(\bar{t})| \le L_\varphi |t - \bar{t}|, \qquad t, \bar{t} \in [-\tau, 0].$$

Suppose $-\tau \le \bar{t} \le 0 \le t < t_1$ and $|t - \bar{t}| \le u < u_0$. Then combining the above two cases and $u_0 = \frac{1}{\alpha_0}$ we obtain

$$\begin{aligned} e^{\alpha t}|x_i(t) - x_i(\bar{t})| &\le e^{\alpha t}\Big(|x_i(t) - x_i(0)| + |x_i(0) - x_i(\bar{t})|\Big) \\ &\le M(e-1)t + e^{\alpha u_0} L_\varphi(-\bar{t}) \\ &\le M_0 u, \end{aligned}$$

where $M_0 = \max\{M(e-1), eL_\varphi\}$.

For $-\tau \le t \le 0 \le \bar{t} < t_1$ and $|t - \bar{t}| \le u < u_0$ we get

$$e^{\alpha t}|x_i(t) - x_i(\bar{t})| \le |x_i(t) - x_i(0)| + e^{\alpha \bar{t}}|x_i(0) - x_i(\bar{t})| \le L_\varphi(-t) + M(e-1)\bar{t} \le M_0 u.$$

The proof of (2.24) is completed. □

3 Main results

In this section, we prove that the solutions of (1.15) approximate that of (1.14) uniformly on $[0, \infty)$.

Theorem 3.1. *Suppose (H1)–(H7) hold. Let $\mathbf{x} = (x_1, \dots, x_m)^T$ be the solution of (1.14) corresponding to initial function $\boldsymbol{\varphi} = (\varphi_1, \dots, \varphi_m)^T$, and $\mathbf{y} = (y_1, \dots, y_m)^T$ be the solution of (1.15) corresponding to $h > 0$ and an initial function $\boldsymbol{\psi} = (\psi_1, \dots, \psi_m)^T$, and let $\alpha_0 > 0$ be the corresponding constant from Lemma 2.2.*

(i) Then for every $0 < \alpha < \alpha_0$ and $\varepsilon > 0$ there exist constants $K_2 > 0$ and $h^* > 0$, and a function $\theta(h)$ such that $\theta(h) \to 0$ as $h \to 0+$, and

$$|\mathbf{x}(t) - \mathbf{y}(t)|_\infty \le e^{-\alpha t} K_2\Big(|\boldsymbol{\varphi} - \boldsymbol{\psi}|_C + \theta(h) + \varepsilon\Big), \qquad t \in [-\tau, \infty), \quad 0 < h < h^*. \tag{3.1}$$

(ii) Assume further (H8). Then for every $0 < \alpha < \alpha_0$ there exist constants $K_2 > 0$, $M > 0$ and $\bar{h} > 0$ such that

$$|\mathbf{x}(t) - \mathbf{y}(t)|_\infty \le e^{-\alpha t} K_2\Big(|\boldsymbol{\varphi} - \boldsymbol{\psi}|_C + Mh\Big), \qquad t \in [-\tau, \infty), \quad 0 < h < \bar{h}. \tag{3.2}$$

Proof. The variation of constants formula (2.2) applied for problem (1.15) gives

$$\begin{aligned} y_i(t) &= e^{-\int_0^t a_i(u)\,du} \left(\prod_{j=1}^{\ell(t)} (1 - p_{i,j})\right) \psi_i(0) \\ &\quad + \sum_{r=1}^{\ell(t)} \left(\prod_{j=r}^{\ell(t)} (1 - p_{i,j})\right) \int_{t_{r-1}}^{t_r} e^{-\int_s^t a_i(u)\,du} G_i(s, \mathbf{y}(\gamma(s)))\,ds \\ &\quad + \sum_{r=1}^{\ell(t)} \left(\prod_{j=r+1}^{\ell(t)} (1 - p_{i,j})\right) e^{-\int_{\gamma(t_r)}^t a_i(u)\,du} (J_{i,r}(y_i(\gamma(t_r)^-)) + e_{i,r}) \\ &\quad + \int_{t_{\ell(t)}}^t e^{-\int_s^t a_i(u)\,du} G_i(s, \mathbf{y}(\gamma(s)))\,ds, \qquad i = 1, \dots, m, \quad t \ge 0, \end{aligned}$$

where

$$G_i(t,\mathbf{y}(\gamma(t))) = \sum_{j=1}^{m} b_{ij}(t) g_j(y_j(\gamma(t)-\gamma(\tau_j))) + c_i(t), \qquad i=1,\dots,m.$$

Combining it with (2.2) we get

$$\begin{aligned} x_i(t)-y_i(t) &= e^{-\int_0^t a_i(u)\,du}\left(\prod_{j=1}^{\ell(t)}(1-p_{i,j})\right)(\varphi_i(0)-\psi_i(0)) \\ &\quad + \sum_{r=1}^{\ell(t)}\left(\prod_{j=r}^{\ell(t)}(1-p_{i,j})\right)\int_{t_{r-1}}^{t_r} e^{-\int_s^t a_i(u)\,du}\Big(G_i(s,\mathbf{x}(s))-G_i(s,\mathbf{y}(\gamma(s)))\Big)\,ds \\ &\quad + \sum_{r=1}^{\ell(t)}\left(\prod_{j=r+1}^{\ell(t)}(1-p_{i,j})\right)\Big(e^{-\int_{t_r}^t a_i(u)\,du}(J_{i,r}(x_i(t_r^-))+e_{i,r}) \\ &\qquad - e^{-\int_{\gamma(t_r)}^{\mathbf{t}} a_i(u)\,du}(J_{i,r}(y_i(\gamma(t_r)^-))+e_{i,r})\Big) \\ &\quad + \int_{t_{\ell(t)}}^t e^{-\int_s^t a_i(u)\,du}\Big(G_i(s,\mathbf{x}(s))-G_i(s,\mathbf{y}(\gamma(s)))\Big)\,ds \end{aligned}$$

for $i=1,\dots,m$ and $t\geq 0$. Therefore, (2.5), (2.6) and $|\varphi_i(0)-\psi_i(0)|\leq|\boldsymbol{\varphi}-\boldsymbol{\psi}|_C$ yield

$$\begin{aligned} |x_i(t)-y_i(t)| &\leq (1-\underline{p}_i^-)e^{-\sigma_i t}|\boldsymbol{\varphi}-\boldsymbol{\psi}|_C \\ &\quad + \int_0^t (1-\underline{p}_i^-)e^{-\sigma_i(t-s)}\Big|G_i(s,\mathbf{x}(s))-G_i(s,\mathbf{y}(\gamma(s)))\Big|\,ds + A_i(t) \end{aligned} \tag{3.3}$$

for $i=1,\dots,m$ and $t\geq 0$, where

$$\begin{aligned} A_i(t) = \sum_{r=1}^{\ell(t)}\left(\prod_{j=r+1}^{\ell(t)}(1-p_{i,j})\right)\Big|&e^{-\int_{t_r}^t a_i(u)\,du}(J_{i,r}(x_i(t_r^-))+e_{i,r}) \\ &-e^{-\int_{\gamma(t_r)}^t a_i(u)\,du}(J_{i,r}(y_i(\gamma(t_r)^-))+e_{i,r})\Big|. \end{aligned}$$

Let α_0 and K_0 be the constants from (2.4). We select a positive constant α such that

$$0<\alpha<\min\{\varepsilon_0,\beta_1,\beta_2,\alpha_0\}$$

and

$$e^{\alpha\underline{\delta}}\sum_{j=1}^{m}(1-\underline{p}_i^-)\Lambda_{ij}L_j e^{\alpha\tau_j} + \frac{(1-\underline{p}_i^-)l_i^* e^{\alpha\underline{\delta}}}{(1-p_i^*)(1-e^{-(\sigma_i-\alpha)\underline{\delta}})} < 1, \qquad i=1,\dots,m. \tag{3.4}$$

Note that such α exists since (H5) holds. Multiplying (3.3) with $e^{\alpha t}$ and using (H1) we get

$$\begin{aligned}
&e^{\alpha t}|x_i(t)-y_i(t)| \\
&\quad \le (1-\underline{p}_i^-)e^{-(\sigma_i-\alpha)t}|\boldsymbol{\varphi}-\boldsymbol{\psi}|_C \\
&\qquad + \int_0^t (1-\underline{p}_i^-)e^{\alpha t-\sigma_i(t-s)}\Big|G_i(s,\mathbf{x}(s))-G_i(s,\mathbf{y}(\gamma(s)))\Big|\,ds + e^{\alpha t}A_i(t) \\
&\quad \le (1-\underline{p}_i^-)|\boldsymbol{\varphi}-\boldsymbol{\psi}|_C \\
&\qquad + \sum_{j=1}^m \int_0^t (1-\underline{p}_i^-)e^{-(\sigma_i-\alpha)(t-s)}|b_{ij}(s)|L_j e^{\alpha s}\Big|x_j(s-\tau_j)-y_j(\gamma(s)-\gamma(\tau_j))\Big|\,ds \\
&\qquad + e^{\alpha t}A_i(t) \\
&\quad \le (1-\underline{p}_i^-)|\boldsymbol{\varphi}-\boldsymbol{\psi}|_C \\
&\qquad + \sum_{j=1}^m \int_0^t (1-\underline{p}_i^-)e^{-(\sigma_i-\alpha)(t-s)}|b_{ij}(s)|L_j e^{\alpha s}\Big(\Big|x_j(s-\tau_j)-x_j(\gamma(s)-\gamma(\tau_j))\Big| \\
&\qquad\qquad + \Big|x_j(\gamma(s)-\gamma(\tau_j))-y_j(\gamma(s)-\gamma(\tau_j))\Big|\Big)ds + e^{\alpha t}A_i(t)
\end{aligned} \tag{3.5}$$

for $i=1,\ldots,m$ and $t\ge 0$. We have

$$\begin{aligned}
A_i(t) \le& \sum_{r=1}^{\ell(t)}\left(\prod_{j=r+1}^{\ell(t)}(1-p_{i,j})\right)\left|e^{-\int_{t_r}^t a_i(u)\,du}-e^{-\int_{\gamma(t_r)}^t a_i(u)\,du}\right||J_{i,r}(x_i(t_r^-))| \\
&+\sum_{r=1}^{\ell(t)}\left(\prod_{j=r+1}^{\ell(t)}(1-p_{i,j})\right)e^{-\int_{t_r}^t a_i(u)\,du}e^{-\int_{\gamma(t_r)}^{t_r} a_i(u)\,du} \\
&\quad\times\Big|J_{i,r}(x_i(t_r^-))-J_{i,r}(y_i(\gamma(t_r)^-))\Big| \\
&+\sum_{r=1}^{\ell(t)}\left(\prod_{j=r+1}^{\ell(t)}(1-p_{i,j})\right)\left|e^{-\int_{t_r}^t a_i(u)\,du}-e^{-\int_{\gamma(t_r)}^t a_i(u)\,du}\right||e_{i,r}|
\end{aligned} \tag{3.6}$$

for $i=1,\ldots,m$ and $t\ge 0$. Assumption (H7), estimates $1-e^{-t}<t$ for $t>0$, the following direct consequence of $|t-\gamma(t)|<h$:

$$t-h<\gamma(t)\le t, \qquad t\in\mathbb{R}, \tag{3.7}$$

and (2.7) imply

$$\begin{aligned}
&\left(\prod_{j=r+1}^{\ell(t)}(1-p_{i,j})\right)\left|e^{-\int_{t_r}^t a_i(u)\,du}-e^{-\int_{\gamma(t_r)}^t a_i(u)\,du}\right| \\
&\qquad = e^{-\int_{t_r}^t a_i(u)\,du}\left(\prod_{j=r+1}^{\ell(t)}(1-p_{i,j})\right)\left(1-e^{-\int_{\gamma(t_r)}^{t_r} a_i(u)\,du}\right) \\
&\qquad \le \frac{1-\underline{p}_i^-}{1-p_i^*}e^{-\sigma_i(t-t_r)}(1-e^{-a_i^* h}) \\
&\qquad \le \frac{1-\underline{p}_i^-}{1-p_i^*}e^{-\sigma_i(t-t_r)}a_i^* h, \qquad t\ge t_r.
\end{aligned} \tag{3.8}$$

Then, combining (H2), (H3) (ii), (3.6), (3.7) and (3.8), we obtain

$$\begin{aligned} e^{\alpha t}A_i(t) \le & \sum_{r=1}^{\ell(t)} e^{-(\sigma_i-\alpha)(t-t_r)} \frac{(1-\underline{p}_i^-)a_i^* h l_i^*}{1-p_i^*} e^{\alpha t_r}|x_i(t_r^-)| \\ & + \sum_{r=1}^{\ell(t)} e^{-(\sigma_i-\alpha)(t-t_r)} \frac{(1-\underline{p}_i^-)l_i^*}{1-p_i^*} e^{\alpha t_r} \\ & \times \Big(|x_i(t_r^-) - x_i(\gamma(t_r)^-)| + |x_i(\gamma(t_r)^-) - y_i(\gamma(t_r)^-)| \Big) \\ & + \sum_{r=1}^{\ell(t)} e^{-(\sigma_i-\alpha)(t-t_r)} \frac{(1-\underline{p}_i^-)a_i^* h}{1-p_i^*} e^{\alpha t_r}|e_{i,r}|, \qquad i=1,\dots,m, \quad t\ge 0. \end{aligned} \tag{3.9}$$

For $0<h<\underline{\delta}$ we have $t_{r-1}<\gamma(t_r)\le t_r$, hence (2.22) and (3.7) yield

$$e^{\alpha t_r}|x_i(t_r^-) - x_i(\gamma(t_r)^-)| = \lim_{n\to\infty} e^{\alpha\left(t_r-\frac{1}{n}\right)} \left| x_i\left(t_r - \frac{1}{n}\right) - x_i\left(\gamma(t_r) - \frac{1}{n}\right) \right| \le \omega_\alpha(h)$$

for $h<\underline{\delta}$. Therefore (3.9), (2.10) with σ_i replaced by $\sigma_i-\alpha$, $e^{\alpha t_r}|x_i(t_r^-)| \le e^{\alpha_0 t_r}|x_i(t_r^-)| \le K_0$, $e^{\alpha t_r}|e_{i,r}| \le e_i^*$ and $e^{\alpha t_r} = e^{\alpha(t_r-\gamma(t_r))}e^{\alpha\gamma(t_r)} \le e^{\alpha h}e^{\alpha\gamma(t_r)}$ imply

$$\begin{aligned} e^{\alpha t}A_i(t) \le & \sum_{r=1}^{\ell(t)} e^{-(\sigma_i-\alpha)(t-t_r)} \frac{(1-\underline{p}_i^-)a_i^* h l_i^*}{1-p_i^*} K_0 \\ & + \sum_{r=1}^{\ell(t)} e^{-(\sigma_i-\alpha)(t-t_r)} \frac{(1-\underline{p}_i^-)l_i^*}{1-p_i^*} \Big(\omega_\alpha(h) + e^{\alpha h} \sup_{0\le u\le t} e^{\alpha u}|x_i(u)-y_i(u)| \Big) \\ & + \sum_{r=1}^{\ell(t)} e^{-(\sigma_i-\alpha)(t-t_r)} \frac{(1-\underline{p}_i^-)a_i^* h e_i^*}{1-p_i^*} \\ \le & \frac{(1-\underline{p}_i^-)(a_i^* h l_i^* K_0)}{(1-p_i^*)(1-e^{-(\sigma_i-\alpha)\underline{\delta}})} + \frac{(1-\underline{p}_i^-)l_i^*\omega_\alpha(h)}{(1-p_i^*)(1-e^{-(\sigma_i-\alpha)\underline{\delta}})} \\ & + \frac{(1-\underline{p}_i^-)a_i^* h e_i^*}{(1-p_i^*)(1-e^{-(\sigma_i-\alpha)\underline{\delta}})} \\ & + \frac{(1-\underline{p}_i^-)l_i^* e^{\alpha h}}{(1-p_i^*)(1-e^{-(\sigma_i-\alpha)\underline{\delta}})} \sup_{0\le u\le t} e^{\alpha u}|x_i(u)-y_i(u)| \\ \le & d_i^* h + \bar{d}_i\omega_\alpha(h) + \hat{d}_i \sup_{0\le u\le t} e^{\alpha u}|x_i(u)-y_i(u)| \end{aligned} \tag{3.10}$$

for $t\ge 0$, $i=1,\dots,m$ and $0<h<\underline{\delta}$, where

$$d_i^* = \frac{(1-\underline{p}_i^-)(a_i^* l_i^* K_0 + a_i^* e_i^*)}{(1-p_i^*)(1-e^{-(\sigma_i-\alpha)\underline{\delta}})}, \qquad \bar{d}_i = \frac{(1-\underline{p}_i^-)l_i^*}{(1-p_i^*)(1-e^{-(\sigma_i-\alpha)\underline{\delta}})},$$

and

$$\hat{d}_i = \frac{(1-\underline{p}_i^-)l_i^* e^{\alpha\underline{\delta}}}{(1-p_i^*)(1-e^{-(\sigma_i-\alpha)\underline{\delta}})}.$$

We introduce the functions

$$\eta_i(t,h) = \sum_{j=1}^{m} \int_0^t e^{-(\sigma_i-\alpha)(t-s)} |b_{ij}(s)| L_j e^{\alpha s} \Big| x_j(s-\tau_j) - x_j(\gamma(s)-\gamma(\tau_j)) \Big| ds \tag{3.11}$$

for $t \geq 0,\ h > 0$, and

$$w_i(t) = \max_{-\tau \leq u \leq t} e^{\alpha u}|x_i(u) - y_i(u)|, \qquad t \geq -\tau, \quad h > 0$$

for $i = 1, \ldots, m$. Then estimate (3.5) together with (3.10), (3.11) and

$$e^{\alpha s} = e^{\alpha(s-\gamma(s)+\gamma(\tau_j))} e^{\alpha(\gamma(s)-\gamma(\tau_j))} \leq e^{\alpha(h+\tau_j)} e^{\alpha(\gamma(s)-\gamma(\tau_j))} \tag{3.12}$$

yields

$$\begin{aligned}
e^{\alpha t}|x_i(t) - y_i(t)| &\leq (1 - \underline{p}_i^-)|\boldsymbol{\varphi} - \boldsymbol{\psi}|_C + (1 - \underline{p}_i^-)\eta_i(t,h) + e^{\alpha t} A_i(t) \\
&\quad + \sum_{j=1}^m \int_0^t (1 - \underline{p}_i^-) e^{-(\sigma_i - \alpha)(t-s)} |b_{ij}(s)| L_j e^{\alpha s} \\
&\quad \times \Big| x_j(\gamma(s) - \gamma(\tau_j)) - y_j(\gamma(s) - \gamma(\tau_j)) \Big| ds \\
&\leq (1 - \underline{p}_i^-)|\boldsymbol{\varphi} - \boldsymbol{\psi}|_C + (1 - \underline{p}_i^-)\eta_i(t,h) + d_i^* h + \bar{d}_i \omega_\alpha(h) + \hat{d}_i w_i(t) \\
&\quad + \sum_{j=1}^m \int_0^t (1 - \underline{p}_i^-) e^{-(\sigma_i - \alpha)(t-s)} |b_{ij}(s)| L_j e^{\alpha(h+\tau_j)} w_j(s)\, ds \\
&\leq (1 - \underline{p}_i^-)|\boldsymbol{\varphi} - \boldsymbol{\psi}|_C + (1 - \underline{p}_i^-)\eta_i(t,h) + d_i^* h + \bar{d}_i \omega_\alpha(h) + \hat{d}_i w_i(t) \\
&\quad + \sum_{j=1}^m (1 - \underline{p}_i^-) \Lambda_{ij} L_j e^{\alpha(h_0+\tau_j)} w_j(t)
\end{aligned} \tag{3.13}$$

for $0 < h < \underline{\delta}$, $t \geq 0$ and $i = 1, \ldots, m$.

Define $h_1 = \underline{\delta}/2$, and next we suppose that $0 < h < h_1$, $j \in \{1, \ldots, m\}$ and $r \in \mathbb{N}$. Relation (3.7) implies

$$t_r \leq (s - h) - \tau_j \leq \gamma(s) - \gamma(\tau_j) \leq s - (\tau_j - h) < t_{r+1}, \qquad s \in [t_r + \tau_j + h, t_{r+1} + \tau_j - h).$$

Therefore

$$s - \tau_j \in [t_r, t_{r+1}) \quad \text{and} \quad \gamma(s) - \gamma(\tau_j) \in [t_r, t_{r+1}), \qquad s \in [t_r + \tau_j + h, t_{r+1} + \tau_j - h). \tag{3.14}$$

Moreover, (3.7) yields

$$|s - \tau_j - (\gamma(s) - \gamma(\tau_j))| = |s - \gamma(s) - (\tau_j - \gamma(\tau_j))| \leq h, \qquad s \in [t_r + \tau_j + h, t_{r+1} + \tau_j - h). \tag{3.15}$$

Hence it follows from (2.22), (3.14) and (3.15) that

$$\begin{aligned}
e^{\alpha s}|x_j(s - \tau_j) - x_j(\gamma(s) - \gamma(\tau_j))| &\leq e^{\alpha \tau_j} e^{\alpha(s-\tau_j)} |x_j(s - \tau_j) - x_j(\gamma(s) - \gamma(\tau_j))| \\
&\leq e^{\alpha \tau_j} \omega_\alpha(h), \qquad s \in [t_r + \tau_j + h, t_{r+1} + \tau_j - h).
\end{aligned} \tag{3.16}$$

Similarly, it is easy to check that

$$\begin{aligned}
e^{\alpha s}|x_j(s - \tau_j) - x_j(\gamma(s) - \gamma(\tau_j))| &\leq e^{\alpha \tau_j} e^{\alpha(s-\tau_j)} |x_j(s - \tau_j) - x_j(\gamma(s) - \gamma(\tau_j))| \\
&\leq e^{\alpha \tau_j} \omega_\alpha(h), \qquad s \in [0, t_1 + \tau_j - h).
\end{aligned} \tag{3.17}$$

We define the sets

$$\mathcal{A}_{j,h} = [0, t_1 + \tau_j - h] \cup \bigcup_{r=1}^{\infty} [t_r + \tau_j + h, t_{r+1} + \tau_j - h], \qquad \mathcal{B}_{j,h} = [0, \infty) \setminus \mathcal{A}_{j,h}$$

for $j = 1, \ldots, m$ and $0 < h < h_1$. We use relation (3.16) to estimate the function $\eta_i(t, h)$ defined by (3.11) for $i = 1, \ldots, m$, $t \geq 0$, $0 < h < h_1$, and for $s \in \mathcal{A}_{j,h}$:

$$\begin{aligned}\eta_i(t,h) &= \sum_{j=1}^{m}\Big(\int_{\mathcal{A}_{j,h}\cap[0,t]} e^{-(\sigma_i-\alpha)(t-s)}|b_{ij}(s)|L_j e^{\alpha s}\Big|x_j(s-\tau_j)-x_j(\gamma(s)-\gamma(\tau_j))\Big|\,ds\\ &\quad+\int_{\mathcal{B}_{j,h}\cap[0,t]} e^{-(\sigma_i-\alpha)(t-s)}|b_{ij}(s)|L_j e^{\alpha s}\Big|x_j(s-\tau_j)-x_j(\gamma(s)-\gamma(\tau_j))\Big|\,ds\Big)\\ &\le \sum_{j=1}^{m}\Big(\int_0^t e^{-(\sigma_i-\alpha)(t-s)}|b_{ij}(s)|L_j e^{\alpha\tau_j}\omega_\alpha(h)\,ds\\ &\quad+\int_{\mathcal{B}_{j,h}\cap[0,t]} e^{-(\sigma_i-\alpha)(t-s)}|b_{ij}(s)|L_j e^{\alpha s}\Big|x_j(s-\tau_j)-x_j(\gamma(s)-\gamma(\tau_j))\Big|\,ds\Big).\end{aligned} \tag{3.18}$$

For $s \in \mathcal{B}_{j,h}$ we use a different estimate. Let $0 < h < h_2 = \min\{h_1, 1/\alpha_0\}$. We have from Lemma 2.2

$$\begin{aligned}&e^{\alpha s}|x_j(s-\tau_j)-x_j(\gamma(s)-\gamma(\tau_j))|\\ &\quad\le e^{\alpha\tau_j}e^{\alpha(s-\tau_j)}|x_j(s-\tau_j)| + e^{\alpha(s-\gamma(s)+\gamma(\tau_j))}e^{\alpha(\gamma(s)-\gamma(\tau_j))}|x_j(\gamma(s)-\gamma(\tau_j))|\\ &\quad\le e^{\alpha\tau_j}K_0e^{-(\alpha_0-\alpha)(s-\tau_j)} + e^{\alpha(s-\gamma(s)+\gamma(\tau_j))}K_0e^{-(\alpha_0-\alpha)(\gamma(s)-\gamma(\tau_j))}\\ &\quad\le e^{\alpha\tau_j}K_0e^{-(\alpha_0-\alpha)(s-\tau_j)} + e^{\alpha(h+\tau_j)}K_0e^{-(\alpha_0-\alpha)(s-h-\tau_j)}\\ &\quad\le e^{\alpha\tau_j}(1+e^{\alpha_0 h})K_0e^{-(\alpha_0-\alpha)(s-\tau_j)}\\ &\quad\le e^{\alpha\tau_j}(1+e)K_0e^{-(\alpha_0-\alpha)(s-\tau)}, \qquad j=1,\ldots,m, \quad s\ge 0.\end{aligned} \tag{3.19}$$

Fix $\varepsilon > 0$. Then it follows from (3.19) that there exists $T = T(\varepsilon, \alpha)$ such that

$$e^{\alpha s}|x_j(s-\tau_j)-x_j(\gamma(s)-\gamma(\tau_j))| \le e^{\alpha\tau_j}\frac{\varepsilon}{M_2}, \qquad s\ge T, \quad j=1,\ldots,m, \tag{3.20}$$

where $M_2 = \max_{i=1,\ldots,m}\sum_{j=1}^{m}\Lambda_{ij}L_je^{\alpha\tau_j}$. Let $k_0 \in \mathbb{N}$ be the smallest index such that $t_{k_0} \geq T$. We recall that $h_2 \leq \underline{\delta}/2$. So if $1 \leq r \leq k_0$, then for $s \in [t_r + \tau_j - h, t_r + \tau_j + h]$ and $0 < h < h_2$ we have

$$s-\tau_j \le t_{k_0}+h < t_{k_0+1} \quad\text{and}\quad \gamma(s)-\gamma(\tau_j) \le s-\tau_j+h \le t_{k_0}+2h < t_{k_0+1}. \tag{3.21}$$

Similarly, for $r > k_0$, $s \in [t_r + \tau_j - h, t_r + \tau_j + h]$ and $0 < h < h_2$ we get

$$s-\tau_j \ge t_r-h > t_{r-1} \ge t_{k_0} \ge T, \quad\text{and}\quad \gamma(s)-\gamma(\tau_j) \ge s-h-\tau_j \ge t_r-2h > t_{r-1} \ge t_{k_0}. \tag{3.22}$$

Define the sets

$$\mathcal{C}_{j,h} = \bigcup_{r=1}^{k_0}[t_r+\tau_j-h, t_r+\tau_j+h] \quad\text{and}\quad \mathcal{D}_{j,h} = \bigcup_{r=k_0+1}^{\infty}[t_r+\tau_j-h, t_r+\tau_j+h].$$

Then, clearly, $\mathcal{B}_{j,h} = \mathcal{C}_{j,h} \cup \mathcal{D}_{j,h}$, $j = 1, \ldots, m$. Define the constants $\tilde{b}_{ij} = \tilde{b}_{ij}(\varepsilon)$ by

$$\tilde{b}_{ij} = \max_{0\le u\le t_{k_0+1}}|b_{ij}(u)|, \qquad i,j=1,\ldots,m.$$

Then (H3), (3.18), (3.19), (3.20), (3.21) and (3.22) yield

$$\begin{aligned}
\eta_i(t,h) &\le \sum_{j=1}^{m}\Big(\beta_{ij}^{*}L_je^{\alpha\tau_j}\omega_\alpha(h)\\
&\qquad + \int_{\mathcal{C}_{j,h}\cap[0,t]} e^{-(\sigma_i-\alpha)(t-s)}|b_{ij}(s)|L_je^{\alpha s}\Big|x_j(s-\tau_j)-x_j(\gamma(s)-\gamma(\tau_j))\Big|\,ds\\
&\qquad + \int_{\mathcal{D}_{j,h}\cap[0,t]} e^{-(\sigma_i-\alpha)(t-s)}|b_{ij}(s)|L_je^{\alpha s}\Big|x_j(s-\tau_j)-x_j(\gamma(s)-\gamma(\tau_j))\Big|\,ds\Big)\\
&\le M_2\omega_\alpha(h)+\sum_{j=1}^{m}\sum_{r=1}^{\ell(t)}\int_{t_r+\tau_j-h}^{t_r+\tau_j+h} e^{-(\sigma_i-\alpha)(t-s)}\tilde{b}_{ij}L_je^{\alpha\tau_j}(1+e)K_0\,ds\\
&\qquad +\sum_{j=1}^{m}\int_0^t e^{-(\sigma_i-\alpha)(t-s)}|b_{ij}(s)|L_je^{\alpha\tau_j}\frac{\varepsilon}{M_2}\,ds\\
&\le M_2\omega_\alpha(h)+\sum_{j=1}^{m}\sum_{r=1}^{\ell(t)}\int_{t_r+\tau_j-h}^{t_r+\tau_j+h} e^{-(\sigma_i-\alpha)(t-s)}\tilde{b}_{ij}L_je^{\alpha\tau_j}(1+e)K_0\,ds+\varepsilon
\end{aligned} \tag{3.23}$$

for $t \ge 0$ and $0 < h < h_2$. Relation (2.25) gives

$$e^t - e^{-t} = e^{-t}(e^{2t}-1) \le (e-1)2t, \qquad t\in[0,1],$$

hence, using (H7), (2.10) with σ_i is replaced by $\sigma_i-\alpha$, and (3.23), we get for $i = 1,\dots,m$

$$\begin{aligned}
\eta_i(t,h) &\le M_2\omega_\alpha(h)+\varepsilon\\
&\quad +\sum_{j=1}^{m}\tilde{b}_{ij}L_je^{\alpha\tau}(1+e)K_0\sum_{r=1}^{\ell(t)}\left(\frac{e^{-(\sigma_i-\alpha)(t-t_r-\tau_j-h)}-e^{-(\sigma_i-\alpha)(t-t_r-\tau_j+h)}}{\sigma_i-\alpha}\right)\\
&= M_2\omega_\alpha(h)+\varepsilon\\
&\quad +\sum_{j=1}^{m}\tilde{b}_{ij}L_je^{\alpha\tau}\left(\frac{(1+e)K_0}{\sigma_i-\alpha}\right)\left(e^{(\sigma_i-\alpha)(\tau_j+h)}-e^{(\sigma_i-\alpha)(\tau_j-h)}\right)\sum_{\ell=1}^{\ell(t)}e^{-(\sigma_i-\alpha)(t-t_\ell)}\\
&\le M_2\omega_\alpha(h)+\varepsilon+\sum_{j=1}^{m}\tilde{b}_{ij}L_je^{\alpha\tau}\left(\frac{(1+e)K_0}{\sigma_i-\alpha}\right)\left(\frac{e^{(\sigma_i-\alpha)h}-e^{-(\sigma_i-\alpha)h}}{1-e^{-(\sigma_i-\alpha)\underline{\delta}}}\right)\\
&\le M_2\omega_\alpha(h)+\varepsilon+\tilde{g}_ih, \qquad 0<h<h^*,
\end{aligned} \tag{3.24}$$

where $\tilde{g}_i = \tilde{g}_i(\varepsilon)$ is defined by

$$\tilde{g}_i = \sum_{j=1}^{m}\tilde{b}_{ij}L_je^{\sigma_i\tau}\frac{(1+e)K_0 2(e-1)}{1-e^{-(\sigma_i-\alpha)\underline{\delta}}} \quad \text{and} \quad h^* = \min\left\{h_2, \frac{1}{\sigma_1-\alpha},\dots,\frac{1}{\sigma_m-\alpha}\right\}.$$

Then (3.13) yields for $i = 1,\dots,m$, $t\ge 0$ and $0<h<h^*$

$$\begin{aligned}
w_i(t) &\le (1-\underline{p}_i^-)\Big(|\boldsymbol{\varphi}-\boldsymbol{\psi}|_C + M_2\omega_\alpha(h)+\tilde{g}_ih+\varepsilon\Big)+d_i^*h+\bar{d}_i\omega_\alpha(h)\\
&\quad +\sum_{j=1}^{m}(1-\underline{p}_i^-)\Lambda_{ij}L_je^{\alpha(h_0+\tau_j)}w_j(t)+\hat{d}_iw_i(t).
\end{aligned} \tag{3.25}$$

Relation (3.25) gives the vector inequality

$$\mathbf{w}(t) \le \mathbf{d}(h) + C\mathbf{w}(t), \qquad t\ge 0, \quad 0<h<h^*, \tag{3.26}$$

where

$$\begin{aligned}
\mathbf{w}(t) &= (w_1(t), \dots, w_m(t))^T, \\
\mathbf{d}(h) &= (d_1(h), \dots, d_m(h))^T, \quad \text{where} \\
d_i(h) &= (1 - \underline{p}_i^-)\Big(|\boldsymbol{\varphi} - \boldsymbol{\psi}|_C + M_2\omega_\alpha(h) + \tilde{g}_i h + \varepsilon\Big) + d_i^* h + \bar{d}_i \omega_\alpha(h), \\
C = (c_{ij}) \in \mathbb{R}^{m \times m}, &\qquad c_{ij} = \begin{cases} (1 - \underline{p}_i^-)\Lambda_{i,i} L_i e^{\alpha(h_0+\tau_i)} + \hat{d}_i, & i = j, \\ (1 - \underline{p}_i^-)\Lambda_{ij} L_j e^{\alpha(h_0+\tau_j)}, & i \neq j. \end{cases}
\end{aligned} \tag{3.27}$$

Relation (3.4) yields that $\|C\|_\infty < 1$ for $0 < h < h^*$. Then $I - C$ is an M-matrix, hence (3.26) implies

$$\mathbf{w}(t) \leq (I - C)^{-1}\mathbf{d}(h), \qquad t \geq 0, \quad 0 < h < h^*.$$

Therefore, the definitions of $\mathbf{w}(t)$, $\mathbf{d}(h)$ and

$$w_i(t) \leq \max_{-\tau \leq u \leq t} |x_i(u) - y_i(u)| \leq |\boldsymbol{\varphi} - \boldsymbol{\psi}|_C \leq d_i(h), \qquad t \in [-\tau, 0], \quad i = 1, \dots, m$$

gives

$$\mathbf{w}(t) \leq (I - C)^{-1}\mathbf{d}(h), \qquad t \geq -\tau, \quad 0 < h < h^*,$$

which yields (3.1) with

$$K_2 = \|(I - C)^{-1}\|_\infty \max_{i=1,\dots,m} (1 - \underline{p}_i^-) \quad \text{and} \quad \theta(h) = (M_2 + \max_{i=1,\dots,m} \bar{d}_i)\omega_\alpha(h) + h \max_{i=1,\dots,m} (\tilde{g}_i + d_i^*).$$

(ii) To prove (3.2) we now assume (H8) too.

Let M_0 and u_0 be the constants defined by Lemma 2.6 (ii). We consider estimate (3.18) of the proof of part (i). Now, since $b_{ij}(s)$ is bounded by b_{ij}^* for all $s \geq 0$, we estimate the last integral similarly to steps used for the set $C_{j,h}$ in the proof of part (i), but using b_{ij}^* instead of $\tilde{b}_{ij}$:

$$\eta_i(t, h) \leq M_2\omega_\alpha(h) + \sum_{j=1}^{m} \sum_{r=1}^{\ell(t)} \int_{t_r+\tau_j-h}^{t_r+\tau_j+h} e^{-(\sigma_i - \alpha)(t-s)} b_{ij}^* L_j e^{\alpha\tau_j}(1 + e)K_0 \, ds.$$

Then a calculation similar to that used in (3.24) and (2.24) gives

$$\eta_i(t, h) \leq M_2\omega_\alpha(h) + g_i^* h \leq M_2 M_0 h + g_i^* h, \qquad 0 < h < \bar{h}, \tag{3.28}$$

where

$$g_i^* = \sum_{j=1}^{m} b_{ij}^* L_j e^{\sigma_i \tau} \left(\frac{(1 + e)K_0 2(e - 1)}{1 - e^{-(\sigma_i - \alpha)\underline{\delta}}} \right) \quad \text{and} \quad \bar{h} = \min\{u_0, h^*\}.$$

Combining (2.24), (3.13) and (3.28) we get for $i = 1, \dots, m$, $t \geq 0$ and $0 < h < \bar{h}$

$$\begin{aligned}
w_i(t) \leq (1 - \underline{p}_i^-)&\Big(|\boldsymbol{\varphi} - \boldsymbol{\psi}|_C + M_2 M_0 h + g_i^* h\Big) + d_i^* h + \bar{d}_i M_0 h \\
&+ \sum_{j=1}^{m} (1 - \underline{p}_i^-)\Lambda_{ij} L_j e^{\alpha(h_0+\tau_j)} w_j(t) + \hat{d}_i w_i(t),
\end{aligned}$$

hence, the vector inequality

$$\mathbf{w}(t) \leq \hat{\mathbf{d}}(h) + C\mathbf{w}(t), \qquad t \geq 0, \quad 0 < h < \bar{h}$$

and therefore

$$\mathbf{w}(t) \le \hat{\mathbf{d}}(h) + C\mathbf{w}(t), \qquad t \ge -\tau, \quad 0 < h < \bar{h} \tag{3.29}$$

holds, where

$$\hat{\mathbf{d}}(h) = (\hat{d}_1(h), \dots, \hat{d}_m(h))^T,$$
$$\hat{d}_i(h) = (1 - \underline{p}_i^-)|\boldsymbol{\varphi} - \boldsymbol{\psi}|_C + \Big((1 - \underline{p}_i^-)(M_2 M_0 + g_i^*) + d_i^* + \bar{d}_i M_0\Big)h.$$

Then (3.29) implies

$$\mathbf{w}(t) \le (I - C)^{-1}\hat{\mathbf{d}}(h), \qquad t \ge -\tau, \quad 0 < h < \bar{h},$$

which proves (3.2) with

$$K_2 = \|(I - C)^{-1}\|_\infty \max_{i=1,\dots,m}(1 - \underline{p}_i^-) \quad \text{and} \quad M = M_2 M_0 + \max_{i=1,\dots,m}(g_i^* + d_i^* + \bar{d}_i M_0). \qquad \square$$

Remark 3.2. We note that relation (3.1) gives for $\boldsymbol{\varphi} = \boldsymbol{\psi}$ that

$$\sup_{t \in [-\tau, \infty)} |\mathbf{x}(t) - \mathbf{y}(t)|_\infty \le K_2(\theta(h) + \varepsilon),$$

which yields that the solutions of (1.15) approximate that of (1.14) uniformly on $[0, \infty)$.

Remark 3.3. Let C be the matrix defined by (3.27). Assumption (H5) in Theorem 3.1 can be replaced by the weaker condition $\rho(C) < 1$, and the statement of the theorem remains true.

Thanks to our main Theorem 3.1 and Lemma 2.2 we can give the following result concerning the *transference of the exponential estimate* of the solutions of (1.14) to the approximate solution.

Proposition 3.4. *Suppose (H1)–(H7) hold. Let* $\mathbf{x} = (x_1, \dots, x_m)^T$ *be the solution of* (1.14) *corresponding to initial function* $\boldsymbol{\varphi} = (\varphi_1, \dots, \varphi_m)^T$*, and* $\mathbf{y} = (y_1, \dots, y_m)^T$ *be the solution of* (1.15) *corresponding to* $h > 0$ *and an initial function* $\boldsymbol{\psi} = (\psi_1, \dots, \psi_m)^T$*, and let* $\alpha_0 > 0$ *be the corresponding constant from Lemma 2.2.*

(i) Then for every $0 < \alpha < \alpha_0$ *and* $\varepsilon > 0$ *there exist constants* $K_3 > 0$ *and* $h^* > 0$*, and a function* $\theta(h)$ *such that* $\theta(h) \to 0$ *as* $h \to 0+$*, and*

$$|\mathbf{y}(t)|_\infty \le e^{-\alpha t}K_3\Big(1 + |\boldsymbol{\varphi} - \boldsymbol{\psi}|_C + \theta(h) + \varepsilon\Big), \qquad t \in [-\tau, \infty), \quad 0 < h < h^*. \tag{3.30}$$

(ii) Assume further (H8). Then for every $0 < \alpha < \alpha_0$ *there exist constants* $K_3 > 0$*,* $M > 0$ *and* $\bar{h} > 0$ *such that*

$$|\mathbf{y}(t)|_\infty \le e^{-\alpha t}K_3\Big(1 + |\boldsymbol{\varphi} - \boldsymbol{\psi}|_C + Mh\Big), \qquad t \in [-\tau, \infty), \quad 0 < h < \bar{h}. \tag{3.31}$$

Proof. The proof follows immediately from $|\mathbf{z}(t)|_\infty \le |\mathbf{z}(t) - \mathbf{x}(t)|_\infty + |\mathbf{x}(t)|_\infty$, (2.4), (3.1) and (3.2) with $K_3 = \max\{K_0, K_2\}$. $\square$

4 The bounded coefficients case

In the following, we give a practical result concerning the bounded coefficients case for a CNN delayed impulsive system as a simple consequence of Theorem 3.1. In addition to our assumptions (H1)–(H3), we suppose that the coefficient functions $a_i(t)$ are bounded below too, and $b_{ij}(t)$ are bounded. This will allow to simplify conditions (H4)–(H8), as follows:

(H4′) There exist positive constants $\underline{a}_i, a_i^*, c_i^*, \sigma_i$ for $i = 1, \ldots, m$ such that

(i) $\underline{a}_i \leq a_i(t) \leq a_i^*$ for $t \geq 0$ and $i = 1, \ldots, m$;

(ii) $\underline{a}_i - \dfrac{1}{\underline{\delta}} \ln(1 - \underline{p}_i^-) \geq \sigma_i, \quad i = 1, \ldots, m$, where $\underline{p}_i^- = \min\{0, \underline{p}_i\}$;

(iii) $|b_{ij}(t)| \leq b_{ij}^*, \quad t \geq 0, \quad i = 1, \ldots, m.$

(H5′) There exists ε_0 such that $0 < \varepsilon_0 < \sigma_i$ for $i = 1, \ldots, m$, and

$$\sum_{j=1}^{m} \frac{(1 - \underline{p}_i^-) b_{ij}^*}{\sigma_i - \varepsilon_0} L_j + \frac{(1 - \underline{p}_i^-) l_i^*}{(1 - p_i^*)(1 - e^{-\sigma_i \underline{\delta}})} < 1, \qquad i = 1, \ldots, m.$$

(H6′) There exist positive constants β_1, β_2 and c_i^* $(i = 1, \ldots, m)$ such that

$$|e_{i,k}| \leq e^{-\beta_1 t_k} e_i^*, \qquad k \in \mathbb{N}, \qquad \text{and} \qquad |c_i(t)| \leq e^{-\beta_2 t} c_i^*, \qquad t \geq 0, \quad i = 1, \ldots, m.$$

(H7′) There exists a positive constant L_φ such that

$$|\varphi_i(t) - \varphi_i(\bar{t})| \leq L_\varphi |t - \bar{t}|, \qquad t, \bar{t} \in [-\tau, 0], \quad i = 1, \ldots, m.$$

Note that (H4) (i) was used in the proofs of Lemma 2.2, Lemma 2.4 and Theorem 3.1 to prove estimates (2.5), (2.6) and (2.7). Now we show that our boundedness assumptions (H4′) imply the same estimates (2.5), (2.6) and (2.7).

Suppose $\underline{p}_i < 0$, $s \in [t_{r-1}, t_r)$ for some $r \in \mathbb{N}$, and $t \geq t_r$. Then (H3) (iv), (H4′) and the estimates $(\ell(t) - r)\underline{\delta} \leq t_{\ell(t)} - t_r \leq t - s$ yield

$$\begin{aligned} e^{-\int_s^t a_i(u)\,du} \left(\prod_{j=r}^{\ell(t)} (1 - p_{i,j}) \right) &= \exp\left(-\int_s^t a_i(u)\,du + \sum_{j=r}^{\ell(t)} \ln(1 - p_{i,j}) \right) \\ &\leq \exp\left(-\underline{a}_i(t - s) + (\ell(t) - r + 1) \ln(1 - \underline{p}_i) \right) \\ &\leq (1 - \underline{p}_i) \exp\left(-\underline{a}_i(t - s) + \frac{t - s}{\underline{\delta}} \ln(1 - \underline{p}_i) \right) \\ &\leq (1 - \underline{p}_i) e^{-\sigma_i(t-s)}. \end{aligned}$$

If $s < t < t_r$, then $\ell(t) < r$, so $\prod_{j=r}^{\ell(t)} (1 - p_{i,j}) = 1$. In the case $\underline{p}_i \geq 0$ we have $\sigma_i \leq \underline{a}_i$, hence

$$e^{-\int_s^t a_i(u)\,du} \left(\prod_{j=r}^{\ell(t)} (1 - p_{i,j}) \right) \leq e^{-\int_s^t a_i(u)\,du} \leq e^{-\sigma_i(t-s)}.$$

Therefore (2.5) holds. (2.6) and (2.7) can be proved similarly under assumption (H4′).

Using Remark 1.3, we get immediately that (H5′) implies (H5). Hence Theorem 3.1 has the following corollary.

Corollary 4.1. *Assume (H1)–(H3),(H4′)–(H7′) hold. Let* $\mathbf{x} = (x_1, \dots, x_m)^T$ *be the solution of* (1.14) *corresponding to initial function* $\boldsymbol{\varphi} = (\varphi_1, \dots, \varphi_m)^T$*, and* $\mathbf{y} = (y_1, \dots, y_m)^T$ *be the solution of* (1.15) *corresponding to* $h > 0$ *and an initial function* $\boldsymbol{\psi} = (\psi_1, \dots, \psi_m)^T$*, and let* $\alpha_0 > 0$ *be the corresponding constant from Lemma* 2.2*. Then for every* $0 < \alpha < \alpha_0$ *there exist constants* $K_2 > 0$*,* $M > 0$ *and* $\bar{h} > 0$ *such that* (3.2) *holds. Hence, the solutions of* (1.14) *are approximated by that of* (1.15) *uniformly over* $[0, \infty)$.

5 An example

Now, we present an example to illustrate the applicability of our conditions.

Example 5.1. Consider the system

$$\begin{aligned} x_1'(t) &= -a_1(t)x_1(t) + \sum_{j=1}^{2} b_{1j}(t)g_j(x_j(t-\tau_j)) + c_1(t), \quad && t \neq t_n \\ x_2'(t) &= -a_2(t)x_2(t) + \sum_{j=1}^{2} b_{2j}(t)g_j(x_j(t-\tau_j)) + c_2(t), \quad && t \neq t_n \\ \Delta x_1(t_n) &= -p_{1,n}x_1(t_n^-) + e_{1,n} + J_{1,n}(x_1(t_n^-)), && n \in \mathbb{N} \\ \Delta x_2(t_n) &= -p_{2,n}x_2(t_n^-) + e_{2,n} + J_{2,n}(x_2(t_n^-)), && n \in \mathbb{N}, \end{aligned} \tag{5.1}$$

where

$$\begin{aligned} a_1(t) &= 2 + \sin(\sqrt{3}t), & a_2(t) &= 4 + \cos(t); \\ b_{11}(t) &= 0.5\sin(t), & b_{21}(t) &= 0.2\sin(t); \\ b_{12}(t) &= 0.3\cos(t), & b_{22}(t) &= 0.3\sin(t); \\ c_1(t) &= \exp(-t), & c_2(t) &= \exp(-2t); \\ p_{1,n} &= -0.15, \ n \in \mathbb{N}, & p_{2,n} &= -0.4, \ n \in \mathbb{N}; \\ e_{1,n} &= \exp(-3t_n), \ n \in \mathbb{N}, & e_{2,n} &= \exp(-4t_n), \ n \in \mathbb{N}; \\ g_1(x) &= \tanh(x), & g_2(x) &= \tanh(x); \\ J_{1,n}(x) &= \tfrac{1}{10}\tanh(x), \ n \in \mathbb{N}, & J_{2,n}(x) &= \tfrac{1}{10}\tanh(x), \ n \in \mathbb{N}. \end{aligned} \tag{5.2}$$

We suppose $\tau_1 = 1$, $\tau_2 = 2$, $\tau = \max\{\tau_1, \tau_2\} = 2$, the initial functions $\varphi_1(t), \varphi_2(t), \psi_1(t), \psi_2(t) : [-2, 0] \to \mathbb{R}$, defined as $\varphi_1(t) = \psi_1(t) = 0.5\sin(t)$ and $\varphi_2(t) = \psi_2(t) = \cos(t)$. Also, we consider $t_n = n$ for $n \in \mathbb{N}$.

System (5.1) is approximated by the following IDEPCA system

$$\begin{aligned} y_1'(t) &= -a_1(t)y_1(t) + \sum_{j=1}^{2} b_{1j}(t)g_j(y_j(\gamma(t) - \gamma(\tau_j))) + c_1(t), \quad && t \neq \gamma(t_n) \\ y_2'(t) &= -a_2(t)y_2(t) + \sum_{j=1}^{2} b_{2j}(t)g_j(y_j(\gamma(t) - \gamma(\tau_j))) + c_2(t), \quad && t \neq \gamma(t_n) \\ \Delta y_1(\gamma(t_n)) &= -p_{1,n}y_1(\gamma(t_n)^-) + e_{1,n} + I_{1,n}(y_1(\gamma(t_n)^-)), && n \in \mathbb{N} \\ \Delta y_2(\gamma(t_n)) &= -p_{2,n}y_2(\gamma(t_n)^-) + e_{2,n} + I_{2,n}(y_2(\gamma(t_n)^-)), && n \in \mathbb{N}, \end{aligned} \tag{5.3}$$

where $\gamma(t) = [t/h]h$ and all the coefficients are given in (5.2). Because $\tanh(x)$ is a Lipschitz-type function, with Lipschitz constant 1, we can conclude that $L_i = 1$ and $l_i^* = l_{i,n} = \frac{1}{10}$, $i = 1, 2,\ n \in \mathbb{N}$. We have $\underline{\delta} = 1$, $\underline{a}_1 = 1$, $\underline{a}_2 = 3$, $\underline{p}_1 = p_1^* = -0.15$ and $\underline{p}_2 = p_2^* = -0.4$, hence we get

$$\underline{a}_1 - \frac{1}{\underline{\delta}} \ln(1 - \underline{p}_1^-) \approx 0.86024, \qquad \underline{a}_2 - \frac{1}{\underline{\delta}} \ln(1 - \underline{p}_2^-) \approx 2.66353,$$

so $\sigma_1 = 0.86$ and $\sigma_2 = 2.66$ satisfy (H4′) (ii). Use $\varepsilon_0 = 0.01$, $b_{11}^* = 0.5$, $b_{12}^* = 0.3$, $b_{21}^* = 0.2$ and $b_{22}^* = 0.3$. Then

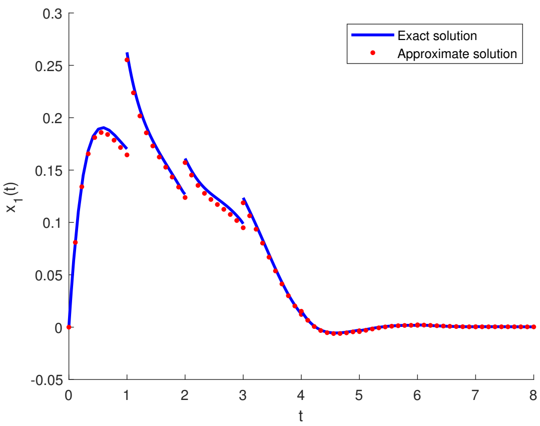
$$\frac{1 - \underline{q}_1^-}{\sigma_1 - \varepsilon_0} \sum_{j=1}^{m} b_{1j}^* L_j + \frac{(1 - \underline{q}_1^-) l_1^*}{(1 - q_1^*)(1 - e^{-\sigma_1 \underline{\delta}})} = \frac{1.15}{0.85}(0.5 + 0.3) + \frac{0.1}{1 - e^{-0.86}} \approx 0.91748,$$

and

$$\frac{1 - \underline{q}_2^-}{\sigma_2 - \varepsilon_0} \sum_{j=1}^{m} b_{2j}^* L_j + \frac{(1 - \underline{q}_2^-) l_1^*}{(1 - q_2^*)(1 - e^{-\sigma_2 \underline{\delta}})} = \frac{1.4}{0.85}(0.2 + 0.3) + \frac{0.1}{1 - e^{-2.66}} \approx 0.31884,$$

therefore (H5′) is satisfied. Therefore Corollary 4.1 yields that the solutions of (5.3) approximate that of (5.1) uniformly on $[0, \infty)$ as h goes to 0.

Figures 5.1–5.2 illustrate the solution of (5.1) and its approximation by the solution of (5.3) corresponding to the discretization parameter $h = 0.1$. Note that for this value of h and the definition of t_n, we have $\gamma(t_n) = t_n$ for all $n \in \mathbb{N}$. Both initial value problems are solved numerically using the function `ddesd` in *Matlab* on the consecutive intervals $[t_n, t_{n+1}]$. The blue curves are the graphs of $x_i(t)$, and the red dots are the values of the function $y_i(t)$ at the time values $t = 0.1n$, $n \in \mathbb{N}_0$. At the impulse time points, the left-hand limits of $y_i(t)$ are also displayed. Even though the discretization parameter is relatively large for this numerical experience, we see that the approximation error becomes smaller as time increases. This is a consequence of estimate (3.2).



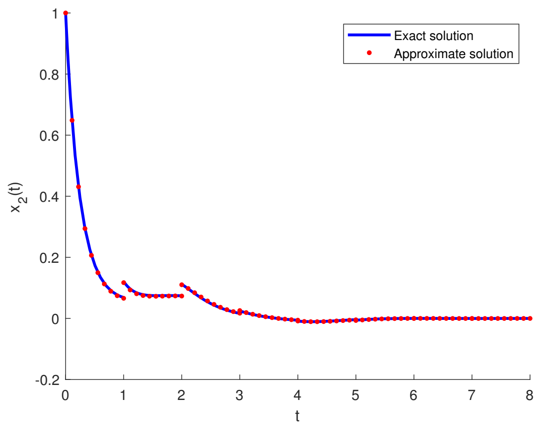


Figure 5.1: Graphs of $x_1(t), y_1(0.1n)$ (on the left) and $x_2(t), y_2(0.1n)$ (on the right) with $h = 0.1$

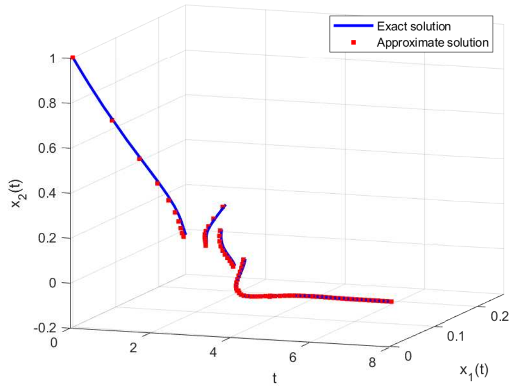

Figure 5.2: The graphs of $(t, x_1(t), x_2(t))$ and $(0.1n, z_1(0.1n), z_2(0.1n))$ with $h = 0.1$.

Abstract. This addendum presents a relevant stronger consequence of the main theorem of the paper "Higher order stroboscopic averaged functions: a general relationship with Melnikov functions", *Electron. J. Qual. Theory Differ. Equ.* **2021**, No. 77.

Keywords: averaging theory, Melnikov method, averaged functions, Melnikov functions, higher order analysis.

2020 Mathematics Subject Classification: 34C29, 34E10, 34C25.

This addendum addresses the findings presented in the paper [1] titled "Higher order stroboscopic averaged functions: a general relationship with Melnikov functions" published in *Electron. J. Qual. Theory Differ. Equ.* **2021**, No. 77.

The main result of the referred paper, [1, Theorem A], establishes a general relationship between averaged functions $\mathbf{g}_i$ and Melnikov functions $\mathbf{f}_i$. As a direct consequence of this general relationship, [1, Corollary A] states that if, for some $\ell \in \{2,\dots,k\}$, either $\mathbf{f}_1 = \cdots = \mathbf{f}_{\ell-1} = 0$ or $\mathbf{g}_1 = \cdots = \mathbf{g}_{\ell-1} = 0$, then $\mathbf{f}_i = T\,\mathbf{g}_i$ for $i \in \{1,\dots,\ell\}$. This consequence was somewhat expected based on existing results in the literature within more restricted contexts. Here, we will demonstrate that under the same conditions, the relationship $\mathbf{f}_i = T\,\mathbf{g}_i$ actually holds for every $i \in \{1,\dots,2\ell-1\}$, which represents a more unexpected outcome. The expression for $\mathbf{g}_{2\ell}(z)$ will also be provided.

Proposition 1. *Let $\ell \in \{2,\dots,k\}$. If either $\mathbf{f}_1 = \cdots = \mathbf{f}_{\ell-1} = 0$ or $\mathbf{g}_1 = \cdots = \mathbf{g}_{\ell-1} = 0$, then $\mathbf{f}_i = T\,\mathbf{g}_i$ for $i \in \{1,\dots,2\ell-1\}$ and*

$$\mathbf{g}_{2\ell}(z) = \frac{1}{T}\left(\mathbf{f}_{2\ell}(z) - \frac{1}{2}d\mathbf{f}_\ell(z)\cdot\mathbf{f}_\ell(z)\right) \text{ or, equivalently, } \mathbf{f}_{2\ell}(z) = T\mathbf{g}_{2\ell}(z) + \frac{T^2}{2}d\mathbf{g}_\ell(z)\cdot\mathbf{g}_\ell(z).$$

✉ Corresponding author. Email: ddnovaes@unicamp.br

Proof. Given $\ell \in \{2,\dots,k\}$, assume that either $\mathbf{f}_1=\cdots=\mathbf{f}_{\ell-1}=0$ or $\mathbf{g}_1=\cdots=\mathbf{g}_{\ell-1}=0$. From [1, Corollary A], we have that

$$\mathbf{g}_i=\mathbf{f}_i=0,\quad \text{for } i\in\{1,\dots,\ell-1\},\quad \text{and}\quad \mathbf{g}_\ell=\frac{1}{T}\mathbf{f}_\ell. \tag{1}$$

For any i, [1, Theorem A] provides

$$\mathbf{g}_i(z)=\frac{1}{T}\left(\mathbf{f}_i(z)-\sum_{j=1}^{i-1}\sum_{m=1}^{j}\frac{1}{j!}d^m\mathbf{g}_{i-j}(z)\int_0^T B_{j,m}(\tilde{y}_1,\dots,\tilde{y}_{j-m+1})(s,z)ds\right), \tag{2}$$

where $\tilde{y}_i(t,z)$, for $i\in\{1,\dots,k\}$, are polynomial in the variable t recursively defined as follows:

$$\begin{aligned}
&\tilde{y}_1(t,z)=t\,\mathbf{g}_1(z)\\
&\tilde{y}_i(t,z)=i!t\,\mathbf{g}_i(z)+\sum_{j=1}^{i-1}\sum_{m=1}^{j}\frac{i!}{j!}d^m\mathbf{g}_{i-j}(z)\int_0^t B_{j,m}(\tilde{y}_1,\dots,\tilde{y}_{j-m+1})(s,z)ds.
\end{aligned} \tag{3}$$

Taking (1) into account, the function $\mathbf{g}_{i-j}$ in (2) vanishes for $i-j\le \ell-1$, that is, for $j\ge i-\ell+1$. Thus,

$$\mathbf{g}_i(z)=\frac{1}{T}\left(\mathbf{f}_i(z)-\sum_{j=1}^{i-\ell}\sum_{m=1}^{j}\frac{1}{j!}d^m\mathbf{g}_{i-j}(z)\int_0^T B_{j,m}(\tilde{y}_1,\dots,\tilde{y}_{j-m+1})(s,z)ds\right). \tag{4}$$

Also, from (1) and (3), one has

$$\tilde{y}_1=\cdots\tilde{y}_{\ell-1}=0\quad\text{and}\quad \tilde{y}_\ell(t,z)=\ell!t\mathbf{g}_\ell(z)=\frac{\ell!}{T}t\mathbf{f}_\ell(z). \tag{5}$$

Now, let $i\in\{\ell+1,\dots,2\ell-1\}$. Thus, for $j\le i-\ell$ and $m\ge 1$, one has that

$$j-m+1\le i-\ell\le 2\ell-1-\ell=\ell-1,$$

which implies, from (5), that $\tilde{y}_1=\cdots=\tilde{y}_{j-m+1}=0$ in (4). Consequently, $\mathbf{f}_i(z)=T\mathbf{g}_i(z)$.

Finally, from (4),

$$\mathbf{g}_{2\ell}(z)=\frac{1}{T}\left(\mathbf{f}_{2\ell}(z)-\sum_{j=1}^{\ell}\sum_{m=1}^{j}\frac{1}{j!}d^m\mathbf{g}_{2\ell-j}(z)\int_0^T B_{j,m}(\tilde{y}_1,\dots,\tilde{y}_{j-m+1})(s,z)ds\right). \tag{6}$$

Notice that, for $1\le j\le\ell$ and $1\le m\le j$, the relationship $j-m+1\ge\ell$ implies that $m=1$ and $j=\ell$, which are the only possible values for m and j for which $\tilde{y}_{j-m+1}$ in (6) is not vanishing. In this case, from (5), $\tilde{y}_1=\cdots=\tilde{y}_{j-m}=0$ and $\tilde{y}_{j-m+1}=\tilde{y}_\ell=\ell!t\mathbf{g}_\ell(z)$. Thus,

$$\begin{aligned}
\mathbf{g}_{2\ell}(z)&=\frac{1}{T}\left(\mathbf{f}_{2\ell}(z)-\frac{1}{\ell!}d\mathbf{g}_\ell(z)\int_0^T B_{\ell,1}(0,\dots,0,\ell!t\mathbf{g}_\ell(z))\,ds\right)\\
&=\frac{1}{T}\left(\mathbf{f}_{2\ell}(z)-\frac{1}{\ell!}d\mathbf{g}_\ell(z)\int_0^T \ell!t\mathbf{g}_\ell(z)\,ds\right)\\
&=\frac{1}{T}\left(\mathbf{f}_{2\ell}(z)-\frac{T^2}{2}d\mathbf{g}_\ell(z)\cdot\mathbf{g}_\ell(z)\right)=\frac{1}{T}\left(\mathbf{f}_{2\ell}(z)-\frac{1}{2}d\mathbf{f}_\ell(z)\cdot\mathbf{f}_\ell(z)\right).
\end{aligned}$$

Equivalently,

$$\mathbf{f}_{2\ell}(z)=T\mathbf{g}_{2\ell}(z)+\frac{T^2}{2}d\mathbf{g}_\ell(z)\cdot\mathbf{g}_\ell(z).$$

Abstract. We use a functional form of the mirroring technique to fully characterize equivalence classes of unbounded stationary solutions of lattice reaction-diffusion equations with eventually negative and decreasing nonlinearities. We show that solutions which connect a stable fixed point of the nonlinearity with infinity can be characterized by a single parameter from a bounded interval. Within a two-dimensional parametric space, these solutions form a boundary to an existence region of solutions which diverge in both directions. Additionally, we reveal a natural relationship of lattice equations with an interesting functional equation which involves an unknown function and its inverse.

Keywords: Nagumo equation, lattice differential equation, patterns, unbounded solutions, equivalence class.

2020 Mathematics Subject Classification: 34A33, 39A12, 39A22, 34B22.

1 Introduction

We study a special class of unbounded stationary solutions to reaction-diffusion lattice differential equations (LDE)

$$u_i'(t) = d(u_{i-1}(t) - 2u_i(t) + u_{i+1}(t)) + g(u_i(t)), \quad i \in \mathbb{Z}, \quad t > 0, \tag{1.1}$$

in which $d > 0$ is a diffusion rate and g is a reaction function. We assume that g is a C^1-function and satisfies the following assumptions:

(g_1) $g(\ell) = 0$ for some $\ell \in \mathbb{R}$,

(g_2) $g'(u) < 0$ for all $u \in [\ell, \infty)$.

Let us immediately note that general assumptions (g_1)–(g_2) cover well-known and widely studied prototypes of monostable and bistable dynamics – the Fisher lattice equation (with logistic reaction) and the Nagumo lattice equation (with cubic reaction) as well as many others reactions, their modifications, and caricatures which have been commonly used in numerous studies on lattice equations [2,5,12,15,21]. See Section 4 for detailed examples.

The primary object of our interest is a class of unbounded stationary solutions which connect the stationary point ℓ with infinity. Therefore, we refer to them as onesided unbounded solutions.

Bounded stationary and traveling patterns

The LDE (1.1) serves as a discrete-space counterpart of the reaction-diffusion partial differential equation (PDE)

$$u_t(x,t) = du_{xx}(x,t) + g(u(x,t)), \quad x \in \mathbb{R}, \quad t > 0, \tag{1.2}$$

which occurs naturally as a model to many biological and chemical processes and has inspired many mathematical concepts and techniques – traveling wave solutions $u(x,t) = \Phi(x-ct)$, perturbation techniques, stability of waves, etc. [13].

Recent interest in the LDE (1.1) stems from its natural applications (see, e.g., [15]) and the fact that the discrete space provides new or richer dynamic phenomena in comparison with the PDE (1.2). The most notable among those is the pinning of traveling waves for sufficiently small diffusion parameters. The Nagumo lattice equation is a prototype of wave pinning [12,16,21]. In other words, for sufficiently small $d > 0$, solutions of the form $u_i(t) = \Phi(i-ct)$ of the LDE (1.1) with the bistable nonlinearity with a monotone profile Φ satisfy $c = 0$. The phenomenon is general and has been studied in various discrete-time models [11] and systems of lattice equations [4,6].

The presence of pinning regions in discrete-space models is naturally related to spatial topological chaos, the existence of large number of bounded heterogeneous stationary patterns of the LDE (1.1), [2,15]. Stationary solutions of the LDE (1.1) are double-sequences $u = (u_i)$, $i \in \mathbb{Z}$, satisfying difference equations

$$d(u_{i-1} - 2u_i + u_{i+1}) + g(u_i) = 0, \quad i \in \mathbb{Z}. \tag{1.3}$$

The structure of large number of solutions for small diffusion $0 < d \ll 1$ is still not fully understood. Partial results are related to localized pulses and their bifurcations [1] or the ordering and symmetry of exponential number of k-periodic patterns [9]. Explicit forms of specific solutions have been found for piecewise linear nonlinearities [3,5,18,20]. Connections of stable periodic patterns then lead to existence of nonmonotone waves, [8,10]. However, many fascinating open questions remain unanswered. These are related, for example, to bifurcations of pulses [1] finite-dimensional graph reaction-diffusion equations which are connected to k-periodic patterns [19] but also to the broader picture, e.g., coexistence of bounded and unbounded patterns and a related ambition to describe all types of nonnegative patterns of the LDE (1.1). The goal of this paper is to contribute by describing onesided unbounded patterns and as a by-product describe mirroring functional iterations and a relationship to a functional equation.

Unbounded stationary patterns

In [7] we fully characterized equivalence classes of generally asymmetric twosided unbounded stationary solutions of (1.1) with (g_1)–(g_2) being satisfied such that $u_i > \ell$ for every $i \in \mathbb{Z}$ and

$$\lim_{i \to \pm\infty} u_i = \infty, \tag{1.4}$$

see Figure 1.1. In contrast to twosided unbounded solutions of the PDE (1.2) we have shown that the twosided unbounded solutions (i) form a two-parametric family of equivalence classes,

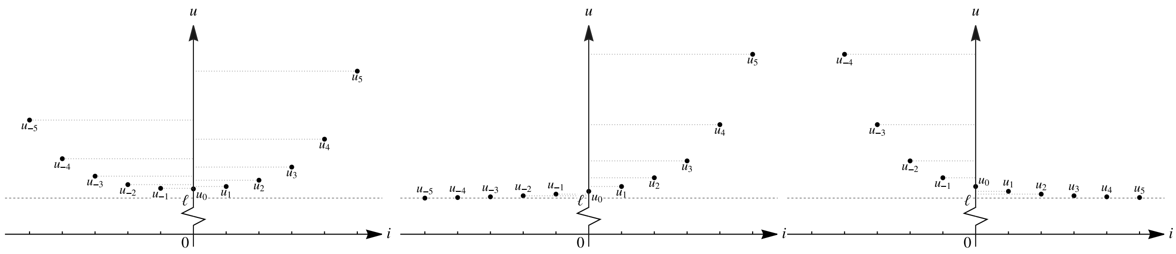

Figure 1.1: A twosided unbounded stationary solution of (1.1) satisfying (1.4) (left panel) and onesided unbounded stationary solutions satisfying either (1.5) or (1.6) (center and right panel).

(ii) are generally asymmetric, and (iii) exist on the whole unbounded integer lattice $\mathbb{Z}$ (i.e., they do not blow up at the ends of bounded spatial interval), see Theorem 3.1 below. Finally, in contrast to bounded patterns, twosided unbounded patterns of the LDE (1.1) exist for all diffusion values $d > 0$.

Onesided unbounded stationary solutions

Motivated by miscellaneous types of stationary solutions of (1.1), we primarily focus on the characterization of other type of unbounded stationary solutions, specifically, onesided unbounded stationary solutions which satisfy $u_i > \ell$ for all $i \in \mathbb{Z}$ and either (see Figure 1.1)

$$\lim_{i\to-\infty} u_i = \ell \quad \text{and} \quad \lim_{i\to\infty} u_i = \infty, \tag{1.5}$$

or

$$\lim_{i\to-\infty} u_i = \infty \quad \text{and} \quad \lim_{i\to\infty} u_i = \ell. \tag{1.6}$$

The equations (1.1) and (1.3) are autonomous in the spatial variable $i \in \mathbb{Z}$. Thus, every solution generates an equivalence class of another solutions which are only shifted in i. For this purpose, we say that stationary solutions u, u^* of (1.1) are *equivalent* (denoted $u \sim u^*$) if there exists an $s \in \mathbb{Z}$ such that $u_{i+s} = u_i^*$ for every $i \in \mathbb{Z}$. The equivalence class represented by a solution u^* is denoted by $[u^*] = \{u \in \mathbb{R}^{\mathbb{Z}} : \ u \sim u^*\}$.

The first main result of this manuscript characterizes the onesided stationary solutions of (1.1).

Theorem 1.1. *Let g be a C^1-function and satisfy (g1)–(g2). There exists a unique function $f : [\ell, \infty) \to [\ell, \infty)$ which is continuous, strictly increasing with $f(\ell) = \ell$, $\lim_{u\to\infty} f(u) = \infty$, and $f(u) > u$ for all $u > \ell$ such that for arbitrary $\xi > \ell$ every $\alpha \in [\xi, f(\xi))$ determines an equivalence class $[u^{\alpha,I}]$ of strictly increasing stationary solutions u of (1.1) satisfying $u_i > \ell$ for all $i \in \mathbb{Z}$ and (1.5); and an equivalence class $[u^{\alpha,D}]$ of strictly decreasing stationary solutions u of (1.1) satisfying $u_i > \ell$ for all $i \in \mathbb{Z}$ and (1.6). The representatives $u^{\alpha,I}$ and $u^{\alpha,D}$ satisfy*

$$u_0^{\alpha,I} = \alpha \quad \textit{and} \quad u_1^{\alpha,I} = f(\alpha); \tag{1.7}$$

and

$$u_0^{\alpha,D} = \alpha \quad \textit{and} \quad u_1^{\alpha,D} = f^{-1}(\alpha), \tag{1.8}$$

respectively. Moreover, for every $\tilde{\alpha} \in [\xi, f(\xi))$ there is $[u^{\alpha,I}] \neq [u^{\tilde{\alpha},I}]$ and $[u^{\alpha,D}] \neq [u^{\tilde{\alpha},D}]$ provided $\alpha \neq \tilde{\alpha}$.

On the contrary, every stationary solution u of (1.1) satisfying $u_i > \ell$ for every $i \in \mathbb{Z}$ and (1.5)

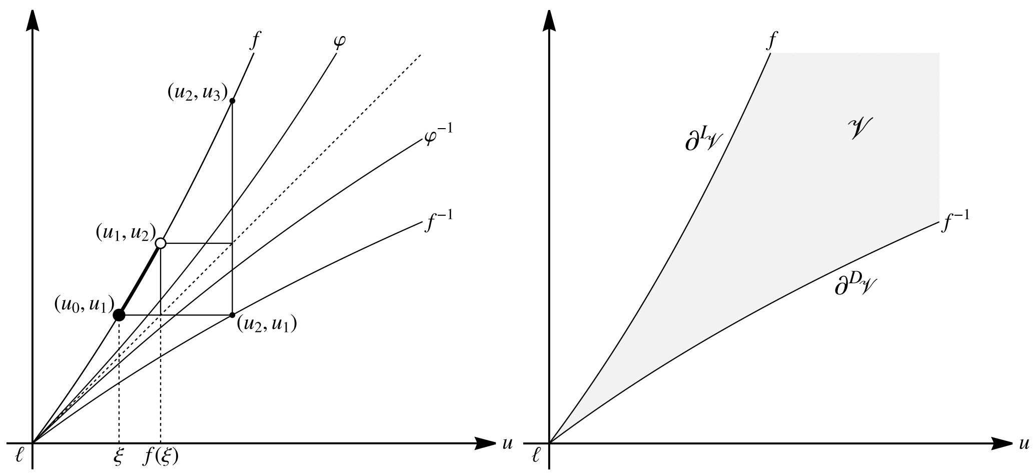

Figure 1.2: Illustration of two main results. Theorem 1.1 implies the existence of a function f and the corresponding interval $[\xi, f(\xi))$. Each value from this interval characterizes an equivalence class of increasing (1.5) or decreasing (1.6) onesided unbounded solutions. Mirroring symmetry via φ from (1.11) and cobwebbing which are used to construct the solutions are indicated (left panel). Theorem 1.2 then shows that the curves f and f^{-1} form a boundary to a set $\mathscr{V}$. All pairs $(u_i, u_{i+1}) \in \mathscr{V}$ generate twosided unbounded solutions with (1.4), whereas all pairs $(u_i, u_{i+1}) \in \partial^I\mathscr{V}$ or $(u_i, u_{i+1}) \in \partial^D\mathscr{V}$ lead to onesided unbounded solutions with (1.5) or (1.6) (right panel).

is strictly increasing and belongs into one of the above described equivalence classes $[u^{\alpha,I}]$ *for some* $\alpha \in [\xi, f(\xi))$; *and every stationary solution* u *of* (1.1) *satisfying* $u_i > \ell$ *for every* $i \in \mathbb{Z}$ *and* (1.6) *is strictly decreasing and belongs into one of the above described equivalence classes* $[u^{\alpha,D}]$ *for some* $\alpha \in [\xi, f(\xi))$.

In other words, we are able to characterize the equivalence classes by a single value $\alpha \in [\xi, f(\xi))$, see Figure 1.2. In Sections 2 and 3 we provide the proof of Theorem 1.1 which relies on an iterative construction of function f. The onesided unbounded stationary solutions can then also be iteratively constructed via mirroring or cobwebbing as indicated in Figure 1.2 as well.

Characterization of onesided and twosided unbounded stationary solutions

Combining Theorem 1.1 and results from [7] we obtain a full characterization of unbounded stationary solutions of (1.1) which satisfy $u_i > \ell$ for all $i \in \mathbb{Z}$. We define the following open set using the function f from Theorem 1.1:

$$\mathscr{V} = \left\{ (\xi, \zeta) \in \mathbb{R}^2 : \ \xi > \ell \ \text{ and } \ f^{-1}(\xi) < \zeta < f(\xi) \right\}, \tag{1.9}$$

and upper and lower parts of its boundary (see Figure 1.2)

$$\begin{aligned} \partial^I \mathscr{V} &= \left\{ (\xi, \zeta) \in \mathbb{R}^2 : \ \xi > \ell \ \text{ and } \ \zeta = f(\xi) \right\}, \\ \partial^D \mathscr{V} &= \left\{ (\xi, \zeta) \in \mathbb{R}^2 : \ \xi > \ell \ \text{ and } \ \zeta = f^{-1}(\xi) \right\}. \end{aligned} \tag{1.10}$$

Obviously, there is $\partial^I \mathscr{V} \cap \partial^D \mathscr{V} = \emptyset$ and the boundary $\partial \mathscr{V}$ of $\mathscr{V}$ satisfies

$$\partial \mathscr{V} = \partial^I \mathscr{V} \cup \partial^D \mathscr{V} \cup \{(\ell, \ell)\}.$$

Our second main result states that the sets $\mathscr{V}$, $\partial^I \mathscr{V}$, and $\partial^D \mathscr{V}$ fully describe all values of all twosided and onesided unbounded stationary solutions of (1.1) satisfying $u_i > \ell$ for all $i \in \mathbb{Z}$, respectively.

Theorem 1.2. *Let g be a C^1-function, satisfy (g_1)–(g_2), and u be a stationary solution of* (1.1) *such that $u_i > \ell$ for all $i \in \mathbb{Z}$. Then:*

(i) (1.4) *holds if and only if $(u_i, u_{i+1}) \in \mathscr{V}$ for all $i \in \mathbb{Z}$,*

(ii) (1.5) *holds if and only if $(u_i, u_{i+1}) \in \partial^I \mathscr{V}$ for all $i \in \mathbb{Z}$,*

(iii) (1.6) *holds if and only if $(u_i, u_{i+1}) \in \partial^D \mathscr{V}$ for all $i \in \mathbb{Z}$.*

Mirroring

Our main tool to study asymmetric and symmetric twosided unbounded solutions in [7] was the mirroring technique. The second order difference equation (1.3) for finding stationary solutions of (1.1) can be transformed into

$$u_{i+1} - \left(u_i - \tfrac{1}{2d} g(u_i)\right) = \left(u_i - \tfrac{1}{2d} g(u_i)\right) - u_{i-1}, \quad i \in \mathbb{Z}.$$

If we define an auxiliary function (which we call a mirroring function)

$$\varphi(u) = u - \tfrac{1}{2d} g(u), \tag{1.11}$$

we obtain a mirroring symmetry with respect to φ for all stationary solutions (1.3), since

$$u_{i+1} - \varphi(u_i) = \varphi(u_i) - u_{i-1}, \quad i \in \mathbb{Z}. \tag{1.12}$$

In this paper we go one step further and study mirroring of functions and their sequences in Section 2.

Functional equation

The mirroring (1.12) in the proof of Theorem 1.1 closely relate the problem of finding stationary solutions (1.3) of the LDE (1.1) with an interesting functional equation

$$\frac{f(u) + f^{-1}(u)}{2} = \varphi(u), \quad u \in [0, \infty), \tag{1.13}$$

in which φ is a given function and f is an unknown function to be found, see Figure 1.2. To our best knowledge, this challenging problem has not been studied itself and its analysis can have deep consequences for other stationary patterns of the LDE (1.1), most notably classes of bounded patterns. See Section 5 for more details.

Paper structure

In Section 2 we generalize the mirroring technique (1.12) to a functional iterative scheme and study the monotonicity and convergence of generated function sequences. In Section 3 we then use these results to prove Theorems 1.1 and 1.2 and show that the onesided unbounded solutions (1.5) or (1.6) are generated by a value from a single interval and form a boundary to the two-parametric domain which generate twosided unbounded solutions satisfying (1.4). We then illustrate our results by several examples with different nonlinearities g in Section 4 and discuss the functional equation (1.13) and its solvability in a special case connected to our analysis in Section 5. We conclude in Section 6 by final remarks which connect our study to the solutions of the PDE (1.2), topological chaos of the LDE (1.1), and further possible applications of mirroring schemes and the functional equation (1.13).

2 Mirroring idea and functional iterative scheme

To describe the functional generalization of the mirroring (1.12) and establish that generated iterations are well-defined, we need some functions (for now specifically φ) satisfy some desired properties. For this purpose, we say that a function $p : [\ell, \infty) \to \mathbb{R}$ satisfies *(p_1)* or *(p_2)* provided:

(p_1) $p(\ell) = \ell$,

(p_2) $p'(u) > 1$ for all $u \in [\ell, \infty)$ (which also yields that $p(u)$ is strictly increasing and thus invertible),

respectively. The next lemma states that the function φ given by (1.11) satisfies *(p_1)*–*(p_2)* provided *(g_1)*–*(g_2)* hold.

Lemma 2.1. *Let (g_1)–(g_2) be satisfied. The function φ defined by* (1.11) *is of class C^1 and satisfies (p_1)–(p_2).*

Proof. The statements follow immediately from the definition (1.11) of φ. □

Now we are able to make the following considerations. We call the relation (1.12) the mirroring scheme, since for given initial conditions $u_0 > \ell$, $u_1 > \ell$ the point (u_2, u_1) as a point in the $\mathbb{R}^2$-plane is by (1.12) the horizontal mirror image of (u_0, u_1) with respect to the graph of φ^{-1}. Then, the point (u_2, u_3) is by (1.12) the vertical mirror image of (u_2, u_1) with respect to the graph of function φ, etc. (see Figure 1.2). Therefore, the forward solution u_i of (1.3) for $i = 2, 3, \dots$ can be generated from the initial conditions u_0, u_1 by mirroring of the points with respect to φ^{-1} horizontally and with respect to φ vertically, respectively, in the switching manner.

Analogically, the backward solution u_i of (1.3) for $i = -1, -2, \dots$ can be generated from the initial conditions u_0, u_1 by mirroring of the points with respect to φ vertically and with respect to φ^{-1} horizontally, respectively.

At this stage, we generalize the mirroring scheme (1.12) to functions. Let φ satisfy *(p_1)*–*(p_2)* and consider the following functional iterative scheme:

$$f_{n+1}(u) = 2\varphi(u) - f_n^{-1}(u), \quad n \in \mathbb{N}_0, \quad u \in [\ell, \infty). \tag{2.1}$$

Generally, the iterates do not have to be well-defined because of the inverses. This fundamentally depends on the properties of the initial function f_0. We focus on two special sequences given by specific initial iterates f_0 for which we establish that all iterates given by (2.1) are well-defined.

Definition 2.2. Let φ be a C^1-function and satisfy *(p_1)*–*(p_2)*. We define functional sequences $(\underline{f}_n)$ and $(\bar{f}_n)$, $n \in \mathbb{N}_0$, as follows:

(i) $(\underline{f}_n)$ are the iterates of (2.1) initiated by $\underline{f}_0(u) = 2\varphi(u) - \varphi^{-1}(u)$,

(ii) $(\bar{f}_n)$ are the iterates of (2.1) initiated by $\bar{f}_0(u) = 2\varphi(u) - \ell$.

Let us note that the inverse φ^{-1} is well-defined thanks to *(p₂)*. Further, let us verify that the iterates $\underline{f}_n$ and $\bar{f}_n$ in Definition 2.2 are correctly defined for every $n \in \mathbb{N}_0$ as well. This (besides others) follows from the following lemma.

Lemma 2.3. *Let φ be a C^1-function and satisfy (p_1)–(p_2). If f_n is a C^1-function and satisfies (p_1)–(p_2), then f_{n+1} defined by* (2.1) *is well-defined C^1-function and satisfies (p_1)–(p_2) as well.*

In particular, $\underline{f}_n$ and $\bar{f}_n$ are well-defined C^1-functions for every $n \in \mathbb{N}_0$ and all satisfy (p_1)–(p_2).

Proof. Since $f_n'(u) > 1$ for all $u \in [\ell, \infty)$ by (p_2), the inverse f_n^{-1} is well-defined and of class C^1 by the inverse function rule

$$(f_n^{-1})'(u) = \frac{1}{f_n'(f_n^{-1}(u))}. \tag{2.2}$$

Hence, f_{n+1} defined by (2.1) is also well-defined and of class C^1. If $f_n(\ell) = \ell$ by (p_1), then $f_{n+1}(\ell) = \ell$ immediately from (2.1) and thanks to $\varphi(\ell) = \ell$ (the function φ satisfies (p_1) as well by the assumption). Moreover, if $f_n'(u) > 1$ for all $u \in [\ell, \infty)$, then $(f_n^{-1})'(u) < 1$ for all $u \in [\ell, \infty)$ again by (2.2). Since also $\varphi'(u) > 1$ for all $u \in [\ell, \infty)$ (φ satisfies (p_2)), then

$$f_{n+1}'(u) = 2\varphi'(u) - (f_n^{-1})'(u) > 2 \cdot 1 - 1 = 1 \quad \text{for all} \quad u \in [\ell, \infty)\,.$$

Finally, one can similarly show that $\underline{f}_0(u) = 2\varphi(u) - \varphi^{-1}(u)$ and $\bar{f}_0(u) = 2\varphi(u) - \ell$ satisfy (p_1)–(p_2). Then (p_1)–(p_2) hold for all $\underline{f}_n$ and $\bar{f}_n$ as well by induction. □

In the next lemma we show that the sequence $(\underline{f}_n)$ is increasing, $(\bar{f}_n)$ is decreasing, and whole sequence $(\underline{f}_n)$ lies below $(\bar{f}_n)$, see Figure 2.1.

Lemma 2.4. *Let φ be a C^1-function and satisfy (p_1)–(p_2). Then for every $m, n \in \mathbb{N}_0$ and all $u \in [\ell, \infty)$ the following hold:*

(i) $\varphi(u) \le \underline{f}_n(u) \le \underline{f}_{n+1}(u)$,

(ii) $\bar{f}_{n+1}(u) \le \bar{f}_n(u)$,

(iii) $\underline{f}_n(u) \le \bar{f}_m(u)$.

Moreover, the equalities hold if and only if $u = \ell$.

Proof. Firstly, there is $u \le \varphi(u) \le \underline{f}_0(u) \le \bar{f}_0(u)$ for all $u \in [\ell, \infty)$. Indeed, the first and last inequalities follow immediately from (p_1)–(p_2) (Lemma 2.1). The middle one is verified again by (p_1)–(p_2) and by the following:

$$\underline{f}_0(u) = 2\varphi(u) - \varphi^{-1}(u) = \varphi(u) + (\varphi(u) - \varphi^{-1}(u)) \ge \varphi(u).$$

For the inverses, the reversed inequalities $\ell \le \bar{f}_0^{-1}(u) \le \underline{f}_0^{-1}(u) \le \varphi^{-1}(u)$ hold for all $u \in [\ell, \infty)$.

Let us prove *(i)*, i.e., that $\varphi(u) \le \underline{f}_n(u) \le \underline{f}_{n+1}(u)$ for all $n \in \mathbb{N}_0$ and $u \in [\ell, \infty)$ by induction. For $n = 0$ there is $\underline{f}_0(u) = 2\varphi(u) - \varphi^{-1}(u)$, i.e., $2\varphi(u) = \underline{f}_0(u) + \varphi^{-1}(u)$, and thus

$$\underline{f}_1(u) = 2\varphi(u) - \underline{f}_0^{-1}(u) = \underline{f}_0(u) + \varphi^{-1}(u) - \underline{f}_0^{-1}(u) \ge \underline{f}_0(u) \ge \varphi(u),$$

since $\underline{f}_0(u) \ge \varphi(u) \ge \varphi^{-1}(u)$ for all $u \in [\ell, \infty)$. Assume that $\varphi(u) \le \underline{f}_{n-1}(u) \le \underline{f}_n(u)$ for some $n \in \mathbb{N}$ and all $u \in [\ell, \infty)$. Then, $\ell \le \underline{f}_n^{-1}(u) \le \underline{f}_{n-1}^{-1}(u) \le \varphi^{-1}(u)$ for all $u \in [\ell, \infty)$ by inversion. Further, for $n + 1$ there is

$$\underline{f}_{n+1}(u) = 2\varphi(u) - \underline{f}_n^{-1}(u) \ge 2\varphi(u) - \underline{f}_{n-1}^{-1}(u) = \underline{f}_n(u) \ge \varphi(u),$$

which concludes the induction step.

The inequality in *(ii)*, i.e., $\bar{f}_{n+1}(u) \le \bar{f}_n(u)$ for every $n \in \mathbb{N}_0$ and $u \in [\ell, \infty)$, and also that

$$\underline{f}_n(u) \le \bar{f}_n(u) \quad \text{for every} \quad n \in \mathbb{N}_0 \quad \text{and all} \quad u \in [\ell, \infty) \tag{2.3}$$

can be proved similarly by induction.

Hence, let us finally show *(iii)*, i.e., that $\underline{f}_n(u) \le \bar{f}_m(u)$ for all $m, n \in \mathbb{N}$ and $u \in [\ell, \infty)$. Assume by contradiction that there are some $m_c, n_c \in \mathbb{N}$, $m_c \ne n_c$, such that $\underline{f}_{n_c}(u_c) > \bar{f}_{m_c}(u_c)$ for some $u_c > \ell$ (note that for $u = \ell$ there is $\underline{f}_n(\ell) = \bar{f}_m(\ell) = \ell$ for all $m_c, n_c \in \mathbb{N}_0$). If $n_c \ge m_c$ then by *(ii)*

$$\underline{f}_{n_c}(u_c) > \bar{f}_{m_c}(u_c) \ge \bar{f}_{m_c+1}(u_c) \ge \bar{f}_{m_c+2}(u_c) \ge \dots \ge \bar{f}_{n_c}(u_c),$$

a contradiction with (2.3). If otherwise $m_c \ge n_c$ then by *(i)*

$$\bar{f}_{m_c}(u_c) < \underline{f}_{n_c}(u_c) \le \underline{f}_{n_c+1}(u_c) \le \underline{f}_{n_c+2}(u_c) \le \dots \le \underline{f}_{m_c}(u_c),$$

again a contradiction with (2.3).

One can easily check that all the verified inequalities are strict if and only if $u > \ell$. □

As a by-product, Lemma 2.4 guarantees the existence of limit functions for both $(\underline{f}_n)$ and $(\bar{f}_n)$. We show their existence in the next corollary and provide several properties of these limit functions, see Figure 2.1.

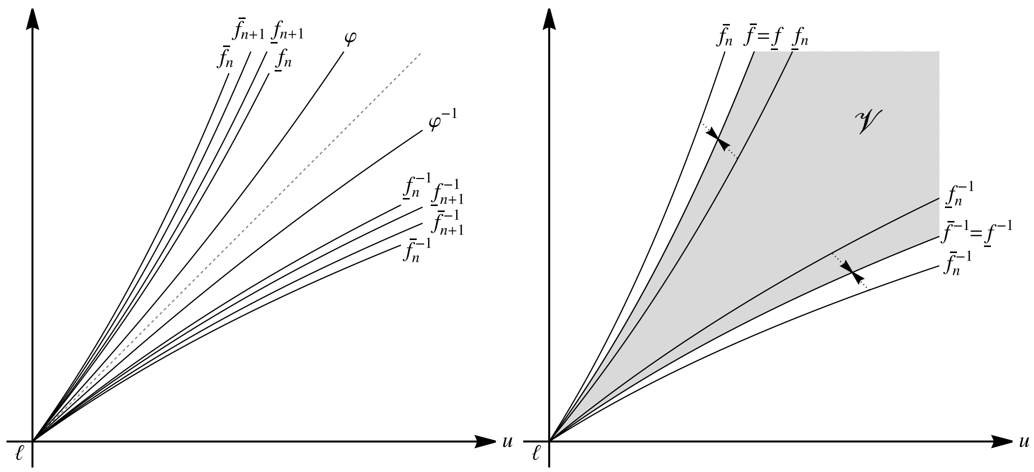

Figure 2.1: Illustration of the mirroring functional iterative scheme (2.1) and functional sequences $(\underline{f}_n)$ and $(\bar{f}_n)$ from Lemma 2.4 (left panel). Convergence of these sequences is implied by Corollaries 2.5 and 2.7 (right panel).

Corollary 2.5. *Let φ be a C^1-function and satisfy (p₁)–(p₂). There exist continuous limit functions*

$$\underline{f}(u) = \lim_{n\to\infty} \underline{f}_n(u) \quad \text{and} \quad \bar{f}(u) = \lim_{n\to\infty} \bar{f}_n(u), \qquad u \in [\ell, \infty),$$

which satisfy:

(i) $\varphi(u) \le \underline{f}_n(u) \le \underline{f}(u) \le \bar{f}(u) \le \bar{f}_n(u)$ *for all* $n \in \mathbb{N}_0$ *and* $u \in [\ell, \infty)$,

(ii) $\underline{f}$ *and* $\bar{f}$ *are strictly increasing, i.e., invertible, on* $[\ell, \infty)$ *and*

$$\underline{f}^{-1}(u) = \lim_{n\to\infty} \underline{f}_n^{-1}(u) \quad \text{and} \quad \bar{f}^{-1}(u) = \lim_{n\to\infty} \bar{f}_n^{-1}(u) \quad \text{for all} \quad u \in [\ell, \infty),$$

(iii) $\underline{f}(u) = 2\varphi(u) - \underline{f}^{-1}(u)$ *and* $\bar{f}(u) = 2\varphi(u) - \bar{f}^{-1}(u)$ *for all* $u \in [\ell, \infty)$.

Proof. The sequence $(\underline{f}_n(u))$, $n \in \mathbb{N}_0$, for given $u \in [\ell, \infty)$ is increasing and bounded from above by all $\bar{f}_n(u)$, $n \in \mathbb{N}_0$, (see Lemma 2.4) which guarantees the existence of pointwise limit $\underline{f}(u)$. The existence of $\bar{f}(u)$, $u \in [\ell, \infty)$, follows similarly.

Lemma 2.3 yields that the iterates $\underline{f}_n$ and $\bar{f}_n$ (and also their inverses $\underline{f}_n^{-1}$ and $\bar{f}_n^{-1}$), $n \in \mathbb{N}_0$, are strictly increasing C^1-functions and for all $n \in \mathbb{N}_0$ there is

$$1 < \underline{f}'_{n+1}(u) = 2\varphi'(u) - (\underline{f}_n^{-1})'(u) \le 2\varphi'(u) \quad \text{(analogically for } \bar{f}'_{n+1}(u)),$$

by (2.1). Since φ is a C^1-function, the functions $\underline{f}_n$ and $\bar{f}_n$ have uniformly bounded derivatives on every compact subinterval of $[\ell, \infty)$. This implies that they converge to their pointwise limits $\underline{f}$ and $\bar{f}$ uniformly on such intervals and thus, $\underline{f}$ and $\bar{f}$ are continuous on whole $[\ell, \infty)$.

The limits have to satisfy that $\varphi(u) \le \underline{f}_n(u) \le \underline{f}(u) \le \bar{f}(u) \le \bar{f}_n(u)$ for all $n \in \mathbb{N}_0$ and $u \in [\ell, \infty)$ by Lemma 2.4 again which proves *(i)*.

The limit functions $\underline{f}$ and $\bar{f}$ are strictly increasing and therefore invertible on $[\ell, \infty)$. Indeed, for every $u_1, u_2 \in [\ell, \infty)$ such that, e.g., $u_1 < u_2$ the mean value theorem and Lemma 2.3 implies

$$\underline{f}_n(u_2) - \underline{f}_n(u_1) = \underline{f}'_n(\xi)(u_2 - u_1) > u_2 - u_1.$$

Passing $n \to \infty$ we obtain

$$\underline{f}(u_2) - \underline{f}(u_1) \ge u_2 - u_1 > 0,$$

which implies that $\underline{f}$ (and analogously $\bar{f}$) is strictly increasing. By the reflection with respect to the axis of the first quadrant we obtain that the inverse functions $\underline{f}^{-1}$ and $\bar{f}^{-1}$ satisfy $\underline{f}^{-1}(u) = \lim_{n\to\infty} \underline{f}_n^{-1}(u)$ and $\bar{f}^{-1}(u) = \lim_{n\to\infty} \bar{f}_n^{-1}(u)$, $u \in [\ell, \infty)$, which proves *(ii)*.

Finally, both iterates $(\underline{f}_n)$ and $(\bar{f}_n)$, $n \in \mathbb{N}_0$, are consistent with the iterative scheme (2.1), specifically,

$$f_{n+1}(u) = 2\varphi(u) - f_n^{-1}(u), \quad u \in [\ell, \infty).$$

Taking $n \to \infty$ in this equality together with *(i)* and *(iii)* we obtain that both limit functions $\underline{f}$ and $\bar{f}$ satisfy

$$f(u) = 2\varphi(u) - f^{-1}(u), \quad u \in [\ell, \infty),$$

which concludes the proof of *(iii)*. □

In the rest of this section we show that $\underline{f} = \bar{f}$ on $[\ell, \infty)$, i.e., both sequences $(\underline{f}_n)$ and $(\bar{f}_n)$ converge to a common limit function (specifically, $(\underline{f}_n)$ from below and $(\bar{f}_n)$ from above). We build our argument on the following technical lemma.

Lemma 2.6. *Let φ be a C^1-function and satisfy (p_1)–(p_2). Then*

$$\bar{f}\left(\underline{f}^{-1}\left(\bar{f}(u)\right)\right) - \bar{f}(u) \ge \underline{f}^{-1}(\bar{f}(u)) - u \quad \textit{for all} \quad u \in [\ell, \infty).$$

Proof. Let $u \in [\ell, \infty)$ be arbitrary but fixed. Lemma 2.3 guarantees that $\bar{f}'_n(s) > 1$ for $s \in \left[u, \underline{f}^{-1}(\bar{f}(u))\right]$. Therefore, the mean value theorem yields that for some $\xi \in \left(u, \underline{f}^{-1}(\bar{f}(u))\right)$ there is

$$\bar{f}_n\left(\underline{f}^{-1}\left(\bar{f}(u)\right)\right) - \bar{f}_n(u) = \bar{f}'_n(\xi) \cdot (\underline{f}^{-1}(\bar{f}(u)) - u) > \underline{f}^{-1}(\bar{f}(u)) - u.$$

Taking $n \to \infty$ we obtain the statement of the lemma. □

Now we are able to show that the limit functions $\underline{f}$ and $\bar{f}$ of iterates $(\underline{f}_n)$ and $(\bar{f}_n)$ are the same, see again Figure 2.1.

Corollary 2.7. *Let φ be a C^1-function and satisfy (p₁)–(p₂). Then $\underline{f}(u) = \bar{f}(u)$ for all $u \in [\ell, \infty)$.*

Proof. Assume by contradiction that there exists $u_1 > \ell$ such that $\underline{f}(u_1) < \bar{f}(u_1)$, i.e., $\bar{f}(u_1) - \underline{f}(u_1) > 0$ (note that for $u = \ell$ there is $\underline{f}(\ell) = \bar{f}(\ell) = \ell$). Corollary 2.5 *(iii)* yields that

$$\begin{aligned}\bar{f}(u_1) - \underline{f}(u_1) &= (2\varphi(u_1) - \bar{f}^{-1}(u_1)) - (2\varphi(u_1) - \underline{f}^{-1}(u_1)) \\ &= \underline{f}^{-1}(u_1) - \bar{f}^{-1}(u_1).\end{aligned} \tag{2.4}$$

Let $u_1 = \bar{f}(\bar{u})$ for some $\bar{u} > \ell$ (recall that the limit functions are homeomorphisms of $[\ell, \infty)$, see Corollary 2.5 *(i)–(ii)*) and denote $u_2 = \underline{f}^{-1}(u_1) = \underline{f}^{-1}(\bar{f}(\bar{u}))$. Then

$$\begin{aligned}\bar{f}(u_2) - \underline{f}(u_2) &= \bar{f}(\underline{f}^{-1}(\bar{f}(\bar{u}))) - \underline{f}(\underline{f}^{-1}(\bar{f}(\bar{u}))) \\ &= \bar{f}(\underline{f}^{-1}(\bar{f}(\bar{u}))) - \bar{f}(\bar{u}) \\ &\geq \underline{f}^{-1}(\bar{f}(\bar{u})) - \bar{u} \\ &= \underline{f}^{-1}(\bar{f}(\bar{u})) - \bar{f}^{-1}(\bar{f}(\bar{u})) \\ &= \underline{f}^{-1}(u_1) - \bar{f}^{-1}(u_1) \\ &= \bar{f}(u_1) - \underline{f}(u_1),\end{aligned}$$

in which the inequality follows from Lemma 2.6 and the last equality from (2.4). Thus, there exists $u_2 = \underline{f}^{-1}(u_1) < u_1$ such that $\bar{f}(u_2) - \underline{f}(u_2) \geq \bar{f}(u_1) - \underline{f}(u_1) > 0$. By induction we construct a sequence (u_n), $n \in \mathbb{N}$, such that

$$\ell < u_{n+1} = \underline{f}^{-1}(u_n) < u_n$$

and

$$\bar{f}(u_{n+1}) - \underline{f}(u_{n+1}) \geq \bar{f}(u_n) - \underline{f}(u_n) > \bar{f}(u_1) - \underline{f}(u_1) > 0$$

for all $n \in \mathbb{N}$. Since (u_n) is decreasing, bounded, and satisfies $u_{n+1} = \underline{f}^{-1}(u_n)$, it has to converge to the unique fixed point of $\underline{f}^{-1}$, i.e., $u_n \to \ell$ for $n \to \infty$. The continuity of limit functions $\underline{f}$ and $\bar{f}$ (see Corollary 2.5) then yields

$$0 < \bar{f}(u_1) - \underline{f}(u_1) \leq \bar{f}(u_n) - \underline{f}(u_n) \to \bar{f}(\ell) - \underline{f}(\ell) = \ell - \ell = 0$$

for $n \to \infty$, a contradiction which concludes the proof. □

3 Proofs of main theorems

In this section we go back to the problem (1.3) for stationary solutions of (1.1) and prove our main result Theorem 1.1 with the help of the mirroring technique and related functional iterative scheme (2.1) for the specific mirroring function (1.11).

Firstly, let us note that using the mirroring scheme (1.12), the authors proved in [7] the following result on twosided unbounded stationary solutions of (1.1) satisfying $u_i > \ell$ for all $i \in \mathbb{Z}$ and (1.4). Specifically, we showed that these solutions are uniquely characterised and indexed by points of two-dimensional set

$$\mathscr{U} = \left\{(\alpha, \beta) \in \mathbb{R}^2 : \ \alpha > \ell \ \text{ and } \ \varphi^{-1}(\alpha) \leq \beta \leq \varphi(\alpha)\right\}, \tag{3.1}$$

in contrast to Theorem 1.1 on onesided unbounded stationary solutions in which the characterizing set is one-dimensional and even bounded. Note that while $\mathscr{U}$ consists of all unique characteristic pairs generating twosided unbounded stationary solutions, the set $\mathscr{V}$ consists of all pairs generated by initial conditions from $\mathscr{U}$, see Figure 3.1. Theorem 1.1 implies the same relationship between the curve

$$\mathscr{C} = \{(\alpha, f(\alpha)) \in \mathbb{R}^2 : \xi \le \alpha < f(\xi)\}$$

and the boundaries $\partial^I \mathscr{V}$, $\partial^D \mathscr{V}$, see the left panel of Figure 3.1.

Theorem 3.1 ([7, Theorem 5]). *Let (g₁)–(g₂) be satisfied. Then every point $(\alpha, \beta) \in \mathscr{U}$ determines an equivalence class $[u^{\alpha,\beta}]$ of stationary solutions u of (1.1) satisfying $u_i > \ell$ for all $i \in \mathbb{Z}$ and (1.4) represented by a solution $u^{\alpha,\beta}$ such that $u_0^{\alpha,\beta} = \alpha$, $u_1^{\alpha,\beta} = \beta$, and:*

(i) if $\varphi^{-1}(\alpha) < \beta < \varphi(\alpha)$, then $[u^{\alpha,\beta}] \neq [u^{\tilde{\alpha},\tilde{\beta}}]$ for every $(\tilde{\alpha}, \tilde{\beta}) \neq (\alpha, \beta)$, $(\tilde{\alpha}, \tilde{\beta}) \in \mathscr{U}$,

(ii) if either $\varphi^{-1}(\alpha) = \beta$, or $\beta = \varphi(\alpha)$, then $[u^{\alpha,\beta}] = [u^{\beta,\alpha}]$.

Moreover, every stationary solution u of (1.1) satisfying $u_i > \ell$ for all $i \in \mathbb{Z}$ and (1.4) is an element of an equivalence class $[u^{\alpha,\beta}]$ determined by a point $(\alpha, \beta) \in \mathscr{U}$.

In order to establish relationship of twosided unbounded solutions characterized by Theorem 3.1 with iterative schemes from Section 2, we focus on initial conditions outside the set $\mathscr{U}$ given by (3.1). First, let us characterize solutions which eventually also have values $u_i \notin [\ell, \infty)$.

Lemma 3.2. *Let (g_1)–(g_2) be satisfied and u be a stationary solution of (1.1). If there exists $i_0 \in \mathbb{Z}$ such that*

$$u_{i_0+1} \ge \bar{f}_{n_0}(u_{i_0}) \quad \text{or} \quad u_{i_0} \ge \bar{f}_{n_0}(u_{i_0+1}) \quad \text{for some} \quad n_0 \in \mathbb{N}_0,$$

then there has to exists $j_0 \in \mathbb{Z}$ such that $u_{j_0} \le \ell$.

Proof. Let $u_{i_0+1} \ge \bar{f}_{n_0}(u_{i_0})$ for some $i_0 \in \mathbb{Z}$ and $n_0 \in \mathbb{N}_0$ (the other case $u_{i_0} \ge \bar{f}_{n_0}(u_{i_0+1})$ is similar). Then we obtain by (2.1) that $u_{i_0+1} \ge \bar{f}_{n_0}(u_{i_0}) = 2\varphi(u_{i_0}) - \underline{f}_{n_0-1}^{-1}(u_{i_0})$ and therefore, by (1.3) that

$$u_{i_0-1} = 2u_{i_0} - u_{i_0+1} - \tfrac{1}{d} g(u_{i_0}) = 2\varphi(u_{i_0}) - u_{i_0+1} \le \underline{f}_{n_0-1}^{-1}(u_{i_0}).$$

Applying the increasing function $\underline{f}_{n_0-1}$ to this inequality (note that Lemma 2.1 verifies that φ defined by (1.11) satisfies the needed hypotheses (p_1)–(p_2) from Section 2, i.e., Lemma 2.3 *(iii)* holds), we get

$$u_{i_0} \ge \underline{f}_{n_0-1}(u_{i_0-1}).$$

Repeating this procedure n_0-times and applying Definition 2.2 we obtain that

$$u_{i_0-n_0+1} \ge \underline{f}_0(u_{i_0-n_0}) = 2\varphi(u_{i_0-n_0}) - \ell.$$

Then (1.3) yields that

$$u_{i_0-n_0-1} = 2u_{i_0-n_0} - u_{i_0-n_0+1} - \tfrac{1}{d} g(u_{i_0-n_0}) = 2\varphi(u_{i_0-n_0}) - u_{i_0-n_0+1} \le \ell,$$

i.e., we obtain the statement for $j_0 = i_0 - n_0 - 1$. □

Our next auxiliary lemma characterize initial conditions which generate $u_i > \ell$ and do not lead to onesided unbounded solutions but to twosided ones from Theorem 3.1 and are thus part of solutions characterized by a pair $(\alpha, \beta) \in \mathscr{U}$.

Lemma 3.3. *Let (g_1)–(g_2) be satisfied and u be a stationary solution of (1.1). If there exists $i_0 \in \mathbb{Z}$ such that*

$$u_{i_0} \le u_{i_0+1} \le \underline{f}_{n_0}(u_{i_0}) \quad \text{or} \quad u_{i_0+1} \le u_{i_0} \le \underline{f}_{n_0}(u_{i_0+1}) \quad \text{for some} \quad n_0 \in \mathbb{N}_0,$$

then there has to exists $j_0 \in \mathbb{Z}$ such that $(u_{j_0}, u_{j_0+1}) \in \mathscr{U}$ or $(u_{j_0+1}, u_{j_0}) \in \mathscr{U}$, respectively, and thus, (1.4) holds.

Proof. If $u_{i_0} \leq u_{i_0+1} \leq \varphi(u_{i_0})$, then $(u_{i_0}, u_{i_0+1}) \in \mathscr{U}$ by the definition (3.1) of $\mathscr{U}$. Hence, (1.4) holds by Theorem 3.1. Otherwise, if $\varphi(u_{i_0}) < u_{i_0+1} \leq \underline{f}_{n_0}(u_{i_0})$, then one can proceed analogically as in the proof of Lemma 3.2 to verify the statement.

For $u_{i_0} \leq \underline{f}_{n_0}(u_{i_0+1})$ it is again similar. □

In other words, Lemma 3.2 characterizes initial conditions outside $\overline{\mathscr{V}}$ and Lemma 3.3 inside $\mathscr{V}$. We have thus collected all tools to prove the first main result of the manuscript, Theorem 1.1.

Proof of Theorem 1.1. Let us note that the function φ defined by (1.11) is of class C^1 and satisfies *(p₁)–(p₂)*, since g satisfies *(g₁)–(g₂)* (see Lemma 2.1). Thus, all results from Section 2 hold. Let $f(u) = \underline{f}(u) = \bar{f}(u)$, $u \in [\ell, \infty)$, be the limit function of iterative scheme (2.1) and $\xi > \ell$. Let us prove the existence of equivalence class $\left[u^{\alpha,I}\right]$ of strictly increasing solutions satisfying (1.7). Firstly, put $u_0^{\alpha,I} = \alpha \in [\xi, f(\xi))$ and for $i \neq 0$ define

$$u_{i+1}^{\alpha,I} = f(u_i^{\alpha,I}), \quad \text{or equivalently,} \quad u_{i-1}^{\alpha,I} = f^{-1}(u_i^{\alpha,I}), \tag{3.2}$$

since f is invertible by Corollary 2.5 *(ii)*. Then, $(u_i^{\alpha,I})$ is defined for all $i \in \mathbb{Z}$ and is strictly increasing, because $f(u) > u$, resp. $f^{-1}(u) < u$, for all $u > \ell$. Since $u = \ell$ is the only fixed point of the mapping f (and of f^{-1} as well) on $[\ell, \infty)$ and again $f(u) > u$, resp. $\ell < f^{-1}(u) < u$, for all $u \in [\ell, \infty)$, then

$$u_i^{\alpha,I} > \ell \quad \text{for all} \quad i \in \mathbb{Z}, \quad \lim_{i\to-\infty} u_i^{\alpha,I} = \ell, \quad \text{and} \quad \lim_{i\to\infty} u_i^{\alpha,I} = \infty.$$

Let us verify that such a sequence $(u_i^{\alpha,I})$, $i \in \mathbb{Z}$, complies with (1.3) and thus forms a stationary solution of (1.1). One can compute for arbitrary $i \in \mathbb{Z}$

$$\begin{aligned} d(u_{i-1}^{\alpha,I} - 2u_i^{\alpha,I} + u_{i+1}^{\alpha,I}) + g(u_i^{\alpha,I}) &= d\left(u_{i+1}^{\alpha,I} + u_{i-1}^{\alpha,I} - 2\left(u_i^{\alpha,I} - \tfrac{1}{2d}g(u_i^{\alpha,I})\right)\right) \\ &= d\left(f(u_i^{\alpha,I}) + f^{-1}(u_i^{\alpha,I}) - 2\varphi(u_i^{\alpha,I})\right) \\ &= 0, \end{aligned}$$

which is verified by Corollary 2.5 *(iii)*.

Let $\tilde{\alpha} \in [\xi, f(\xi))$ be such that $\tilde{\alpha} < \alpha$ (for $\tilde{\alpha} > \alpha$ it is similar) and assume that $\left[u^{\alpha,I}\right] = \left[u^{\tilde{\alpha},I}\right]$, i.e., there exists $s_0 \in \mathbb{N}$ such that $u_{s_0}^{\tilde{\alpha},I} = u_0^{\alpha,I} = \alpha$. Then Corollary 2.5 *(ii)* implies

$$f(\xi) \leq f(\tilde{\alpha}) \leq f^{s_0}(\tilde{\alpha}) = u_{s_0}^{\tilde{\alpha},I} = u_0^{\alpha,I} = \alpha$$

(the symbol f^{s_0} denotes s_0-multiple composition of f), which is a contradiction.

On the contrary, let u be a stationary solution of (1.1) satisfying $u_i > \ell$ for all $i \in \mathbb{Z}$ and (1.5). This implies that (u_i), $i \in \mathbb{Z}$, is strictly increasing, since otherwise there exists $i \in \mathbb{Z}$ such that $u_{i-1} < u_i$ and $u_{i+1} \leq u_i$, i.e., $u_{i-1} - 2u_i + u_{i+1} < 0$. Therefore Eq. (1.3) implies $g(u_i) > 0$, a contradiction. Hence, there is $u_i < u_{i+1}$ for all $i \in \mathbb{Z}$. If there exists $i_0 \in \mathbb{Z}$ such that $u_{i_0+1} = f(u_{i_0})$, then the uniqueness of solution of (1.3) with given initial conditions $u_{i_0} = \alpha$ and $u_{i_0+1} = f(\alpha)$ yields that the solution lies in the equivalence class $\left[u^{\alpha,I}\right]$. If $\alpha \in [\xi, f(\xi))$, we are done. Thus, let us assume that $\alpha < \xi$ (for $\alpha \geq f(\xi)$ it is similar). Then there exists $s_0 \in \mathbb{N}$ such that $f^{s_0}(\alpha) \in [\xi, f(\xi))$ and thus, $\left[u^{\alpha,I}\right] = \left[u^{\gamma,I}\right]$ for $\gamma = f^{s_0}(\alpha)$. Indeed, since $f^s(\alpha) \to \infty$ for $s \to \infty$ there has to exist $s_0 \in \mathbb{Z}$ such that $f^{s_0-1}(\alpha) < \xi$ and $f^{s_0}(\alpha) \geq \xi$. Since f is strictly increasing on $[\ell, \infty)$ by Corollary 2.5 *(iii)*, there is

$$f^{s_0}(\alpha) = f(f^{s_0-1}(\alpha)) < f(\xi), \quad \text{i.e.,} \quad f^{s_0}(\alpha) \in [\xi, f(\xi))\,.$$

Finally, we show by Lemma 3.2 and Lemma 3.3 that other cases cannot occur. Indeed, if $u_{i+1} \neq f(u_i)$ for every $i \in \mathbb{Z}$, there is either $u_{i+1} > f(u_i)$, or $u_i < u_{i+1} < f(u_i)$ for

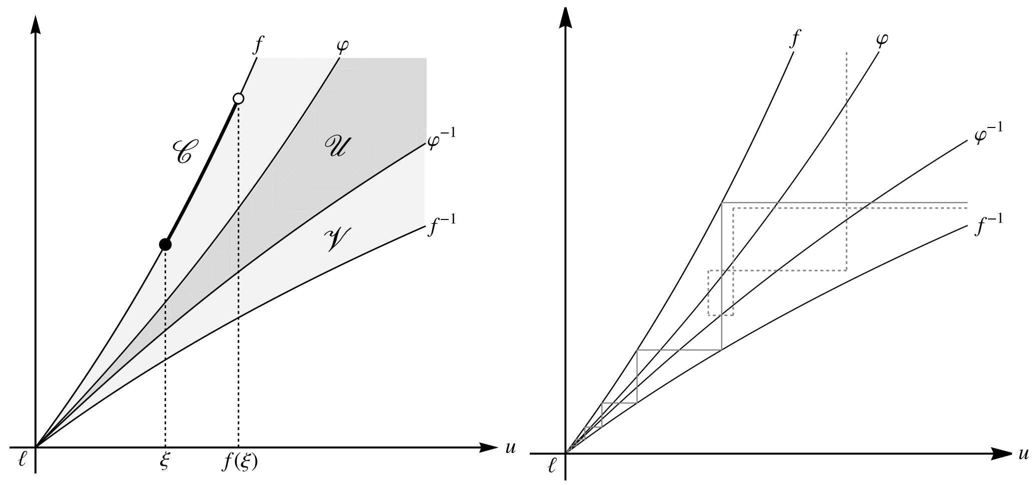

Figure 3.1: The left panel refines Figure 1.2 by including the set $\mathscr{U}$ from (3.1) which characterizes all twosided solutions (Theorem 3.1). The right panel then shows the mirroring scheme (1.12) for onesided (full line) and twosided unbounded solutions (dashed line).

some $i \in \mathbb{Z}$. If $u_{i+1} > f(u_i)$, then Corollary 2.5 *(i)* implies that there exists $n_0 \in \mathbb{N}_0$ such that $u_{i+1} > \bar{f}_{n_0}(u_i)$. Then Lemma 3.2 yields that there has to exists $j_0 \in \mathbb{Z}$ such that $u_{j_0} \leq \ell$, a contradiction. If $u_i < u_{i+1} < f(u_i)$, then Corollary 2.5 *(i)* implies that there exists $n_0 \in \mathbb{N}_0$ such that $u_i < u_{i+1} < \underline{f}_{n_0}(u_i)$. Now Lemma 3.3 implies that (1.4) holds, which is a contradiction with (1.5).

The statement of Theorem 1.1 for equivalence classes of decreasing solutions $\left[u^{\alpha,D}\right]$ can be proved similarly. □

To conclude, we prove the second main result – Theorem 1.2 which characterizes all unbounded stationary solutions of (1.1) satisfying $u_i > \ell$ for all $i \in \mathbb{Z}$.

Proof of Theorem 1.2. Let u be an unbounded stationary solution of (1.1) which satisfies $u_i > \ell$ for $i \in \mathbb{Z}$. Then $(u_i, u_{i+1}) \in \mathscr{V} \cup \partial^I\mathscr{V} \cup \partial^D\mathscr{V}$ for all $i \in \mathbb{Z}$. Indeed, assuming by contradiction that $u_{i_0+1} > f(u_{i_0})$ for some $i_0 \in \mathbb{N}_0$ (and similarly if $u_{i_0+1} < f^{-1}(u_{i_0})$) there has to exists an index $n_0 \in \mathbb{N}_0$ such that $u_{i_0+1} > \bar{f}_{n_0}(u_{i_0})$ ($\bar{f}_n \to f$). Then Lemma 3.2 yields that $u_{j_0} \leq \ell$ for some $j_0 \in \mathbb{N}_0$, a contradiction.

Let us prove *(i)* and assume that $(u_i, u_{i+1}) \in \mathscr{V}$ for all $i \in \mathbb{Z}$. Let $i_0 \in \mathbb{Z}$ be arbitrary, denote $\alpha = u_{i_0}$, and assume $u_{i_0} \leq u_{i_0+1}$ (for $u_{i_0} \geq u_{i_0+1}$ similarly). Since $(u_{i_0}, u_{i_0+1}) \in \mathscr{V}$, there is $u_{i_0} \leq u_{i_0+1} < f(u_{i_0})$ and thus $u_{i_0} \leq u_{i_0+1} \leq \underline{f}_{n_0}(u_{i_0})$ for an index $n_0 \in \mathbb{N}_0$. Consequently, Lemma 3.3 yields that (1.4) holds.

On the contrary, assuming (1.4) there has to be $(u_i, u_{i+1}) \in \mathscr{V}$ for all $i \in \mathbb{Z}$. Indeed, if $(u_{i_0}, u_{i_0+1}) \in \partial^I\mathscr{V}$ for some $i_0 \in \mathbb{N}_0$ (and similarly if $(u_{i_0}, u_{i_0+1}) \in \partial^D\mathscr{V}$), i.e., $u_{i_0+1} = f(u_{i_0})$ by definition of $\partial^I\mathscr{V}$, then Theorem 1.1 implies that $u \in \left[u^{\alpha,I}\right]$ with $\alpha = u_{i_0}$ and $\lim_{i\to-\infty} u_i = \ell$, a contradiction with (1.4).

Let us prove *(ii)* and suppose $(u_i, u_{i+1}) \in \partial^I\mathscr{V}$ for all $i \in \mathbb{Z}$. For arbitrary $i_0 \in \mathbb{Z}$ there is $u_{i_0+1} = f(u_{i_0})$ and Theorem 1.1 yields that $u \in \left[u^{\alpha,I}\right]$ with $\alpha = u_{i_0}$, i.e., (1.5) holds.

Assuming (1.5) there has to be $(u_i, u_{i+1}) \in \partial^I\mathscr{V}$ for all $i \in \mathbb{Z}$. Indeed, if $(u_{i_0}, u_{i_0+1}) \in \mathscr{V}$ for some $i_0 \in \mathbb{N}_0$ then $\lim_{i\to\pm\infty} u_i = \infty$ similarly as above which is a contradiction with (1.5).

In the same way, if $(u_{i_0}, u_{i_0+1}) \in \partial^D \mathscr{V}$, then $u_{i_0+1} = f^{-1}(u_{i_0})$ and Theorem 1.1 yields that $u \in [u^{\alpha,D}]$ and $\lim_{i\to+\infty} u_i = \ell$, again a contradiction with (1.5).

The third item *(iii)* can be proved similarly as *(ii)*. □

4 Examples of specific reaction-diffusion LDEs

In this section we illustrate Theorems 1.1 and 1.2 for specific reaction functions g in (1.1) satisfying the key assumptions *(g₁)*–*(g₂)*. Let us start with two most common reactions.

Example 4.1 (Fisher and Nagumo equation)**.** Considering the logistic (monostable) or cubic (bistable) reaction functions

$$g(u) = u(1-u) \qquad \text{or} \qquad g(u) = u(1-u)(u-a), \quad a \in (0,1), \tag{4.1}$$

the LDE (1.1) becomes the well-known Fisher or Nagumo lattice equation, respectively, [2, 15]. Both reaction functions in (4.1) satisfy (g_1)–(g_2) with $\ell = 1$. We can therefore apply Theorem 1.1 and 1.2 to characterize onesided and twosided unbounded stationary solutions u of the corresponding LDE (1.1) with $u_i > 1$ for all $i \in \mathbb{Z}$ via the function f and the set $\mathscr{V}$ (which are qualitatively the same in both cases, see Figure 3.1).

Our next example contains simple piecewise linear reaction functions for which we can analytically express boundary of $\mathscr{V}$ and explicit formulas for $u^{\alpha,I}$ and $u^{\alpha,D}$.

Example 4.2 (Sawtooth and McKean's caricatures of bistability)**.** For simplicity, let us consider the LDE (1.1) and piecewise linear caricatures of the standard cubic bistable nonlinearity

$$g(u) = \begin{cases} -u & \text{for } u \in \left[0, \frac{a}{2}\right), \\ u-a & \text{for } u \in \left[\frac{a}{2}, \frac{1+a}{2}\right], \\ 1-u & \text{for } u \in \left(\frac{1+a}{2}, \infty\right), \end{cases}$$

or

$$g(u) \begin{cases} = -u & \text{for } u \in [0,a), \\ \in [-a, 1-a] & \text{for } u = a, \\ = 1-u & \text{for } u \in (a,\infty), \end{cases} \qquad a \in (0,1),$$

(proposed by [17] and nicknamed as sawtooth and McKean's caricature, respectively, [5, 14, 20]). The functions are smooth on (a,∞) and the assumptions (g_1)–(g_2) are satisfied with $\ell = 1$ in both cases and the mirroring function φ is for $u \in [1,\infty)$ defined by

$$\varphi(u) = \tfrac{2d+1}{2d}(u-1) + 1$$

(i.e., $\varphi^{-1}(u) = \frac{2d}{2d+1}(u-1)+1$). Thus, all iterates $\underline{f}_n$ or $\bar{f}_n$, $n \in \mathbb{N}_0$, are linear functions which yields that the limit function f is linear as well, i.e., $f(u) = k(u-1)+1$ and $f^{-1}(u) = \frac{1}{k}(u-1)+1$ for some $k > 1$. Then Corollary 2.5 *(iii)* implies

$$k = k(d) = \frac{2d+1+\sqrt{4d+1}}{2d}.$$

The corresponding sets $\mathscr{U}$ and $\mathscr{V}$ are therefore cones in this case (see Figure 4.1) and

$$\lim_{d\to\infty} k(d) = 1 \qquad \text{and} \qquad \lim_{d\to 0+} k(d) = \infty.$$

Then, we obtain from (3.2) explicit formulas for the representatives $u^{\alpha,I}$ and $u^{\alpha,D}$ of equivalence

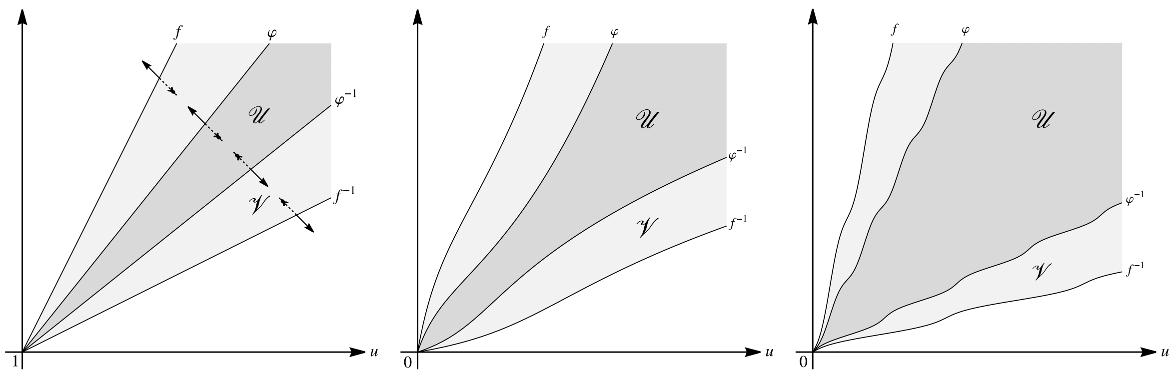

Figure 4.1: The left panel shows linear functions φ and f induced by piecewise linear bistable caricatures from Ex. 4.2. The arrows indicate widening (full arrows) and shrinking (dashed arrows) of conical sets $\mathscr{U}$ and $\mathscr{V}$ as d decreases or increases, respectively. The center and right panels then provide examples of nonconvex functions φ and f. We depict numerically obtained sets $\mathscr{U}$ and $\mathscr{V}$ for the Holling functional response of type II (4.2) with $a = 0.6$ and $b = 0.2$ from Ex. 4.3 (center panel) and the wavy reaction (4.4) with $a = 1.1$ from Ex. 4.4 (right panel).

classes $[u^{\alpha,I}]$, $[u^{\alpha,D}]$ of onesided unbounded stationary solutions, respectively, for $\alpha > 1$ as

$$u_i^{\alpha,I} = (\alpha - 1)k^i + 1 \qquad \text{and} \qquad u_i^{\alpha,D} = (\alpha - 1)k^{-i} + 1.$$

In contrast, our next example considers a reaction leading to more complicated sets $\mathscr{U}$ and $\mathscr{V}$, which we obtain only numerically. Logistic reaction with a predation term leads to sets $\mathscr{U}$ and $\mathscr{V}$ with nonconvex upper boundaries φ and f.

Example 4.3 (Holling functional response II)**.** Let us modify the Fisher equation and consider the LDE (1.1) with reaction function g consisting of the logistic term (describing the intraspecific competition) and of an external predation term determined by Holling functional response of type II (describing the interspecific competition), specifically,

$$g(u) = u(1-u) - \frac{au}{b+u}, \quad a, b > 0. \tag{4.2}$$

We discuss two distinct situations. The largest root of g is $\ell = \frac{1}{2}(1 - b + \sqrt{b^2 + 2b + 1 - 4a}) > 0$ provided

$$(a,b) \in \mathscr{P} = \left\{(a,b) \in \mathbb{R}_+^2 : \ (a \in (0,1) \wedge b > 2\sqrt{a} - 1) \ \vee \ (a \geq 1 \wedge b > a)\right\}.$$

It is possible to show that in this case

$$g''(u) < 0 \quad \text{for all} \quad u \in [\ell, \infty), \tag{4.3}$$

which implies that (g_1)–(g_2) hold for every such pair $(a,b) \in \mathscr{P}$. Thus, by application of Theorems 1.1 and 1.2 we obtain the function f and the set $\mathscr{V}$ describing onesided and twosided unbounded stationary solutions u of (1.1) with $u_i > \ell > 0$ for all $i \in \mathbb{Z}$. Moreover, (4.3) yields that $\varphi''(u) > 0$ for all $u \in [\ell, \infty)$ and hence, the function f satisfies $f''(u) > 0$ for all $u \in [\ell, \infty)$ from which we deduce that f and $\mathscr{V}$ have qualitatively same shape as in Ex. 4.1 and Figure 3.1.

For

$$(a,b) \in \mathscr{Z} = \left\{(a,b) \in \mathbb{R}_+^2 : \ (a \in (0,1) \wedge b \leq 2\sqrt{a} - 1) \ \vee \ (a \geq 1 \wedge b \leq a)\right\}$$

the largest root of g is $\ell = 0$. In this case the situation is more intricate and there are values of

$(a, b) \in \mathscr{X}$ for which (g_2) holds as well as values $(a, b) \in \mathscr{X}$ for which (g_2) is not satisfied. For example, (g_2) does not hold for $a = 0.4$ and $b = 0.2$. However, the assumption (g_2) is valid, e.g., for $a = 0.6$ and $b = 0.2$ and consequently, Theorems 1.1 and 1.2 provide the function f and the set $\mathscr{V}$ characterizing onesided and twosided unbounded stationary solutions u of (1.1) with $u_i > 0$ for all $i \in \mathbb{Z}$. Interestingly, the function φ is not convex for $u \in [\ell, \infty)$ in this case which implies that the limit function f has inflection as well, see Figure 4.1.

We conclude with an illustrative example which provides an interesting wavy shape of the corresponding function f and underlying sets $\mathscr{U}$ and $\mathscr{V}$.

Example 4.4. Considering the LDE (1.1) with

$$g(u) = \sin(u) - au, \quad a > 1, \tag{4.4}$$

the assumptions (g_1)–(g_2) are satisfied with $\ell = 0$ for all $a > 1$. The limit function f has infinitely many inflection points in this case. For the corresponding sets $\mathscr{U}$ and $\mathscr{V}$, see Figure 4.1.

5 Arithmetic mean of function with its inverse

The iterative scheme (2.1) is motivated by the mirroring form (1.12) of the equation (1.3). Focusing on Corollary 2.5 *(iii)*, we interestingly reveal a connection between stationary solutions of (1.1), iterative scheme (2.1), and the following functional equation with an unknown function f:

$$\frac{f(u) + f^{-1}(u)}{2} = \varphi(u), \quad u \in [0, \infty), \tag{5.1}$$

in which φ is a given C^1-function on $[0, \infty)$ which satisfies (p_1)–(p_2) with $\ell = 0$. In other words, the unknown function f should be such that the arithmetic mean of f and its inverse f^{-1} gives the prescribed function φ.

Remark 5.1. First of all, we point out that the functional equation (5.1) has in principle infinitely many solution pairs provided at least one exists. Indeed, let f be a solution of (5.1), $u_0 \in (0, \infty)$ be given, and (u_i), $i \in \mathbb{Z}$, be defined iteratively by

$$u_{i+1} = f(u_i) \quad \text{and} \quad u_{i-1} = f^{-1}(u_i).$$

Considering the following function:

$$g(u) = \begin{cases} f(u), & \text{if } u \neq u_i \text{ for all } i \in \mathbb{Z}, \\ f^{-1}(u), & \text{if } u = u_i \text{ for some } i \in \mathbb{Z}, \end{cases} \tag{5.2}$$

one can verify that g is also a solution of (5.1), different from f and f^{-1} (note that $f(u) \neq f^{-1}(u)$ for all $u \in (0, \infty)$ because of (p_1)–(p_2)), although it still uses only values of either f or f^{-1} (it only interchanges them at u_i, $i \in \mathbb{Z}$). This motivates the following definition.

Taking a solution f of (5.1), it has to satisfy for every $u \in [0, \infty)$ that either $f(u) > \varphi(u)$, or $f^{-1}(u) > \varphi(u)$, or $f(u) = f^{-1}(u) = \varphi(u)$. Define the mapping $P : f \mapsto P(f)$, where $P(f) : [0, \infty) \to \mathbb{R}$, as

$$P(f)(u) = \begin{cases} f(u), & \text{if } f(u) \geq \varphi(u), \\ f^{-1}(u), & \text{if } f^{-1}(u) > \varphi(u). \end{cases} \tag{5.3}$$

We immediately see that $P(f)(u) \geq \varphi(u)$ for all $u \in [0, \infty)$.

Consequently, we define an equivalence relation $f \backsim g$ between two solutions f and g of (5.1) saying that $f \backsim g$ provided $P(f) = P(g)$ (e.g., the function g defined by (5.2) is equivalent to the original solution f, also to its inverse f^{-1}, and also to its own inverse g^{-1}).

The following lemma claims that every equivalence class of solutions of (5.1) containing f and using the same values (as f and g above) has a unique representative $P(f)$ which satisfies $P(f)(u) \geq \varphi(u)$ for all $u \in [0, \infty)$.

Lemma 5.2. *Let φ be a C^1-function and satisfy (p₁)–(p₂) with $\ell = 0$. Let f be a solution of (5.1) and $P(f)$ be defined by (5.3). Then $P(f)$ is also a solution of (5.1).*

Proof. The function $P(f)$ is injective and thus invertible on $[0, \infty)$. Indeed, let us assume by contradiction that $P(f)(u_1) = P(f)(u_2)$ for some $u_1 < u_2$. If $f(u_1) \geq \varphi(u_1)$ and $f(u_2) \geq \varphi(u_2)$ (analogically for $f^{-1}(u_1) \geq \varphi(u_1)$ and $f^{-1}(u_2) \geq \varphi(u_2)$), then

$$f(u_1) = P(f)(u_1) = P(f)(u_2) = f(u_2),$$

a contradiction, since f is invertible. If $f(u_1) \geq \varphi(u_1)$ and $f^{-1}(u_2) \geq \varphi(u_2)$ (analogically for $f^{-1}(u_1) \geq \varphi(u_1)$ and $f(u_2) \geq \varphi(u_2)$), then

$$f(u_1) = P(f)(u_1) = P(f)(u_2) = f^{-1}(u_2) = w.$$

Since $w = f(u_1) = P(f)(u_1) \geq \varphi(u_1)$, $w = P(f)(u_2) = f^{-1}(u_2) \geq \varphi(u_2)$, and φ is strictly increasing and $\varphi^{-1}(u) \leq u \leq \varphi(u)$ for all $u \in [0, \infty)$ by *(p₁)–(p₂)*, then

$$f^{-1}(w) < f(w) \leq \varphi^{-1}(w) \leq \varphi(w),$$

a contradiction with (5.1). Thus, $P(f)$ is invertible, $(P(f))^{-1}(u) \leq \varphi^{-1}(u)$ for all $u \in [0, \infty)$, and by definition of $P(f)$ there has to be

$$(P(f))^{-1}(u) = \begin{cases} f^{-1}(u), & \text{if } f(u) \geq \varphi(u), \\ f(u), & \text{if } f^{-1}(u) > \varphi(u). \end{cases}$$

Therefore, $P(f)$ is also a solution of (5.1), since

$$\frac{P(f)(u) + (P(f))^{-1}(u)}{2} = \frac{f(u) + f^{-1}(u)}{2} = \varphi(u)$$

in both cases $f(u) \geq \varphi(u)$, or $f^{-1}(u) > \varphi(u)$ for a $u \in [0, \infty)$. □

Finally, as a byproduct of our previous considerations from Section 2 we obtain the following result which states that the functional equation (5.1) has a unique equivalence class of nonnegative solutions f and characterizes its representative $P(f)$.

Theorem 5.3. *Let φ be a C^1-function and satisfy (p₁)–(p₂) with $\ell = 0$. Then there exists a unique equivalence class of* nonnegative *solutions f of functional equation (5.1) (with respect to the relation $\backsim$) and its representative $P(f)$ is given by*

$$P(f)(u) = \lim_{n\to\infty} \underline{f}_n(u) = \lim_{n\to\infty} \bar{f}_n(u), \quad u \in [0, \infty),$$

in which $\underline{f}_n$ and $\bar{f}_n$ are given by the iterative scheme (2.1) with $\underline{f}_0(u) = 2\varphi(u) - \varphi^{-1}(u)$ and $\bar{f}_0(u) = 2\varphi(u)$, respectively (cf. Definition 2.2). In particular, the representative $P(f)$ is continuous.

Proof. The existence and properties of a common limit function $f(u) = \lim_{n\to\infty} \underline{f}_n(u) = \lim_{n\to\infty} \bar{f}_n(u)$, $u \in [0, \infty)$, of (2.1) follows from Corollary 2.5 *(i)–(ii)*. Moreover, f (and also f^{-1}) solves the functional equation (5.1) by Corollary 2.5 *(iii)*. Since the limit function f satisfies $f(u) \geq \varphi(u)$ for all $u \in [0, \infty)$, then $P(f)(u) = f(u)$ for all $u \in [0, \infty)$ which concludes the proof of existence and representation of the equivalence class.

Let g be another nonnegative solution of (5.1) such that $P(g) \neq P(f)$ and without loss of generality (see Lemma 5.2) assume that $P(g) = g$. Let us show that

$$\underline{f}_0(u) = 2\varphi(u) - \varphi^{-1}(u) \leq g(u) \leq 2\varphi(u) = \bar{f}_0(u) \quad \text{for all} \quad u \in [0, \infty). \tag{5.4}$$

For the former inequality, assume by contradiction that $g(u_c) < 2\varphi(u_c) - \varphi^{-1}(u_c)$ for some $u_c > 0$ (for $u = 0$ there has to be $g(0) = g^{-1}(0) = 0$, since both g and g^{-1} are assumed to be nonnegative and $\varphi(0) = 0$ by *(p_1)*). Then (5.1) yields that

$$2\varphi(u_c) - \varphi^{-1}(u_c) > g(u_c) = 2\varphi(u_c) - g^{-1}(u_c), \quad \text{i.e.,} \quad g^{-1}(u_c) > \varphi^{-1}(u_c).$$

Thus, since φ^{-1} is a strictly increasing function, there has to exist a $v_c > 0$ such that $\varphi(v_c) > g(v_c)$, which is a contradiction because $g(u) = P(g)(u) \geq \varphi(u)$ for all $u \in [0, \infty)$.

For the latter inequality in (5.4), assume again by contradiction that $g(u_c) > 2\varphi(u_c)$ for some $u_c > 0$. Then (5.1) implies that

$$2\varphi(u_c) < g(u_c) = 2\varphi(u_c) - g^{-1}(u_c), \quad \text{i.e.,} \quad g^{-1}(u_c) < 0,$$

which is a contradiction with the nonnegativeness of g^{-1}.

Finally, if two initial functions of the iterative scheme (2.1) are ordered for all $u \in [0, \infty)$, then all iterates of (2.1) are ordered in the same fashion for all $u \in [0, \infty)$, this can be proved similarly as in Lemma 2.4. Therefore, the inequalities (5.4) and the fact that g is the fixed element of (2.1) yield that

$$\underline{f}_n(u) \leq g(u) \leq \bar{f}_n(u) \quad \text{for all} \quad n \in \mathbb{N}_0 \quad \text{and} \quad u \in [0, \infty).$$

The squeeze argument then implies that

$$P(f)(u) \leftarrow \underline{f}_n(u) \leq g(u) \leq \bar{f}_n(u) \rightarrow P(f)(u) \quad \text{for all} \quad u \in [0, \infty) \quad \text{and} \quad n \to \infty,$$

i.e., $g(u) = P(g)(u) = P(f)(u)$ for all $u \in [0, \infty)$, a contradiction. This concludes the proof of the uniqueness of the equivalence class of nonnegative solutions of (5.1). □

Remark 5.4. Note that besides the existence, uniqueness, and several properties of the class of nonnegative solutions of (5.1), Theorem 5.3 presents the procedure how the continuous representative $P(f)$ can be approximated by the iterations (2.1) with $\underline{f}_0(u) = 2\varphi(u) - \varphi^{-1}(u)$ (from below) and $\bar{f}_0(u) = 2\varphi(u)$ (from above).

6 Discussion

In this paper we showed that onesided unbounded stationary solutions of the LDE (1.1) form a one-parametric family of equivalence classes, Theorem 1.1, and bound the region of unbounded twosided solutions in a two-parametric space, Theorem 1.2 and Figures 3.1 and 4.1.

Continuous counterpart

Let us emphasize the behaviour of corresponding solutions of the PDE (1.2). The simple phase plane analysis (e.g., [7, Section 4]) yields that there is only a unique equivalence class of strictly increasing solutions with (1.5) and a unique class of strictly decreasing onesided solutions satisfying (1.6). Moreover, these continuous solutions exist only on a bounded spatial interval and blow up to infinity at its ends.

Topological chaos and unbounded solutions

Let us also highlight the fact that both onesided and twosided lattice stationary solutions characterized by Theorem 1.2 exist for any diffusion parameters. This fact and a simple look at the white regions in Figure 3.1 lead to an intriguing problem. In the case of Nagumo lattice equation (1.1) with $g(u) = u(1-u)(u-a)$, $a \in (0,1)$, stationary solutions which are represented by

$$(u_i, u_{i+1}) \in \mathscr{W} = \left\{ (\xi, \zeta) \in \mathbb{R}^2 : \ \xi, \zeta > \ell \ \text{ and } \ (\xi, \zeta) \notin \overline{\mathscr{V}} \right\},$$

where $\mathscr{V}$ is defined in (1.9), can be very difficult to characterize fully because the iterations lead to the domain of topological chaos. For example, which initial conditions lead to positive stationary solutions? How does the set of such initial conditions depend on the value of $d > 0$ in the LDE (1.1)? Twosided and onesided lattice stationary solutions satisfying (1.4), (1.5), or (1.6) correspond to continuous counterparts in the PDE (1.2) and are more numerous, generally asymmetric in the twosided case (1.4) and do not blow up to infinity in finite spatial interval. Intuitively, solutions with $(u_i, u_{i+1}) \in \mathscr{W}$ may have richer behaviour and, most importantly, could generate qualitatively new types of stationary solutions.

Applications of mirroring

In this paper we generalized the mirroring technique to functional mirroring scheme and connected it to the functional equation (5.1). It is possible that this geometric approach could contribute to one of the many problems related to the topological chaos, e.g., explicit solutions for special reaction functions.

Functional equation

Our final remark is related to the functional equation (5.1). Note that φ in our case is the specific mirroring function defined by (1.11). The functional equation (5.1) represent an interesting problem itself once any function φ is considered. In principle, the solvability of functional equations is nontrivial and depend for example on the domain. Theorem 5.3 provides a specific existence and uniqueness result in the case in which φ satisfies *(p_1)*–*(p_2)*.

Abstract. This paper addresses the Lyapunov exponents of non-vanishing solutions to quasi-linear time-varying systems of differential equations. The linear part is not required to be regular but it is assumed to be integrally separated, which ensures that the associated Lyapunov exponents are distinct and stable. The nonlinear perturbations are assumed to be small in a certain sense, though less restrictive than the condition in Barreira and Valls' paper, *J. Differential Equations* **258**(2015), 339–361. The main result is a Perron-type theorem for upper and lower Lyapunov exponents, offering an alternative to Barreira and Valls' result. In addition, an analogous result holds for Bohl exponents.

Keywords: quasi-linear system, Lyapunov exponent, integral separation, nonlinear perturbation, Perron-type theorem.

1 Introduction

Asymptotic behaviour of solutions is a classical topic in the qualitative theory of differential equations. It has been discussed in well-known monographs such as [5–7]. In this paper, we study the asymptotic behavior of solutions of linear time-varying ordinary differential equations (ODEs) under nonlinear perturbations

$$x'(t) = A(t)x(t) + f(t, x(t)), \quad t \in \mathbb{I} = [t_0, \infty), \tag{1.1}$$

where the coefficient $A : \mathbb{I} \to \mathbb{C}^{n\times n}$ and the nonlinear term $f : \mathbb{I} \times \mathbb{C}^n \to \mathbb{C}^n$ are continuous. The question is that if the nonlinear term f is supposed to be sufficiently small in some sense, how certain solutions of the quasi-linear ODE (1.1) behave asymptotically comparing to those

✉Corresponding author. Email: linhvh@vnu.edu.vn

of the unperturbed linear ODE as t tends to infinity. In the case of constant matrix A, the result is known as Perron theorem, which was established long time ago, see [6, Theorem 5, p. 97].

Theorem 1.1. *Consider the equation (1.1) with a constant matrix A such that*

$$\|f(t, x(t))\| \leq \gamma(t)\|x(t)\|, \quad t \geq t_0,$$

where $\gamma(t)$ is a continuous nonnegative function satisfying

$$\int_t^{t+1} \gamma(s)ds \to 0, \quad t \to \infty. \tag{1.2}$$

If $x(t)$ is a bounded solution of (1.1) then either $x(t) = 0$ for all large t or the limit

$$\mu = \lim_{t\to\infty} \frac{1}{t} \ln \|x(t)\|$$

exists and is equal to the real part of one of the eigenvalues of A.

This is the classical version of Perron theorem. It is noted that actually Perron did prove a weaker form. This version is due to Lettenmeyer. Later Hartman and Wintner refined the proof. The number μ is called the (strict) Lyapunov exponent of the solution x [1]. Theorem 1.1 means that the Lyapunov exponent of the solution x exists and it is equal to one of the Lyapunov exponents of the linear system, i.e., no new Lyapunov exponent arises.

Recently, extensions of this result to functional differential equations [18], nonautonomous ODEs [4], and differential-algebraic equations [14] were obtained. Similar results were also obtained for difference equations [3, 17] and functional difference equations [16]. In the case of time-dependent coefficient matrix A, by using the regularity theory Barreira and Valls did prove a similar result but under a more restrictive assumption.

Theorem 1.2 ([4, Theorem 1])**.** *Consider the quasi-linear system (1.1), where $A(t)$ is supposed to be given in the block diagonal form. It is assumed further that the linear subsystems associated with each block have the same and sharp Lyapunov exponents, but the Lyapunov exponents belonging to different blocks are distinct. If $x(t)$ is a solution of (1.1) such that*

$$\|f(t, x(t))\| \leq \gamma(t)\|x(t)\|, \quad t \geq t_0,$$

where $\gamma(t)$ is a continuous nonnegative function satisfying

$$\int_t^{t+1} e^{\delta s}\gamma(s)ds \to 0, \quad t \to \infty, \tag{1.3}$$

for some $\delta > 0$ then either $x(t) = 0$ for all large t or the limit

$$\mu = \lim_{t\to\infty} \frac{1}{t} \ln \|x(t)\|$$

exists and it is equal to one of the Lyapunov exponents of the linear system.

One can see that the condition (1.3) on $\gamma(t)$ in Theorem 1.2 is much stronger than the condition (1.2) in Theorem 1.1. The variation of Lyapunov exponents under linear perturbations, i.e. $f(t, x(t)) = B(t)x(t)$ has been well investigated in the literature, see [1, Chapter 5]. The stability concept plays a key role in the preservation of Lyapunov exponents under small linear perturbations. Necessary and sufficient conditions for the stability of Lyapunov exponents have been discussed in details in [1, Chapter V]. We emphasize that neither the existence of sharp Lyapunov exponents nor the regularity does imply the stability. We note in addition that in the case of constant matrix A, the Lyapunov exponents of the linear systems are stable without any extra assumption. An analogue of the result in [4] was established for nonautonomous difference equations in [3]. Furthermore, an extension to the so-called μ-Lyapunov exponents, see [2], was obtained in [10] where more general growth rates of solutions are characterized. Some further discussions on the stability of Lyapunov exponents and computational consequences are given in [8, 9], where the numerical approximation of Lyapunov exponents is addressed.

In this paper, we present an alternative version of Perron theorem for the nonlinear system (1.1) with a time-varying coefficient A. Under an assumption that guarantees the stability of distinct (upper) Lyapunov exponents, we are able to relax the condition on the nonlinear term, i.e., the assumption on $\gamma(t)$ remains the same as in Theorem 1.1. Furthermore, we do not require the sharp Lyapunov exponents as in [4]. The proof, which differs from that in [4], relies on reducing the linear part to a diagonal system. Analogous statements are also obtained for lower Lyapunov exponents and Bohl exponents. This investigation is of particular interest because the quasi-linear system (1.1) may arise when linearizing a nonlinear system along a particular solution. As a consequence, we can obtain information about the rate at which nearby solutions converge or diverge to/from the particular solution.

The paper is organized as follows. In the next section, we provide a brief overview of the theory on Lyapunov and Bohl exponents, with a focus on the stability of Lyapunov exponents, the property of integral separation, and the relationship between them. In Section 3, we describe the asymptotic behavior of solutions under the assumption of integral separation. As the main result, Perron-type theorems that establish the exponential growth rates of solutions are then presented. In the last section, we discuss several open questions and conjectures.

2 Preliminaries

First, we recall the notion of Lyapunov exponents, which is used to characterize the asymptotic growth of functions. Then, we briefly summarize the results related to the stability of Lyapunov exponents. These results are given in details in [1].

Definition 2.1. For a non-vanishing function $f : [0,\infty) \longrightarrow \mathbb{R}^n$, the quantities $\chi^u(f) = \limsup_{t\to\infty} \frac{1}{t}\ln\|f(t)\|$, $\chi^\ell(f) = \liminf_{t\to\infty} \frac{1}{t}\ln\|f(t)\|$, are called *upper and lower Lyapunov exponents of f*, respectively. If the exact limit exists, i.e., the upper and the lower Lyapunov exponents coincide, then we say f has a sharp Lyapunov exponent.

Consider a linear system

$$x'(t) = A(t)x(t), \quad t \in \mathbb{I} = [0,\infty), \tag{2.1}$$

with a bounded and continuous matrix function A.

Definition 2.2. Given a fundamental solution matrix X of (2.1), we introduce

$$\lambda_i^u = \limsup_{t\to\infty} \frac{1}{t}\ln\|X(t)e_i\|, \qquad \lambda_i^\ell = \liminf_{t\to\infty} \frac{1}{t}\ln\|X(t)e_i\|,$$

where e_i denotes the i-th unit vector and $\|\cdot\|$ denotes the Euclidean norm. The columns of X form a *normal basis* if $\Sigma_{i=1}^n \lambda_i^u$ is minimal. The λ_i^u, $i = 1, 2, \ldots, n$ belonging to a normal basis are called *(upper) Lyapunov exponents* of (2.1).

We assume that the upper Lyapunov exponents are ordered

$$-\infty < \lambda_1^u \le \lambda_2^u \le \cdots \le \lambda_n^u < \infty.$$

The following result is known as Lyapunov's inequality.

Theorem 2.3 ([1, Theorem 2.5.1]). *Let* $\{\lambda_i^u\}_{i=1}^n$ *be the upper Lyapunov exponents of* (2.1)*. Then*

$$\sum_{i=1}^n \lambda_i^u \ge \limsup_{t\to\infty} \frac{1}{t} \int_0^t \operatorname{trace} A(s)ds. \tag{2.2}$$

Here trace A *denotes the trace of the matrix function* A.

We say that the system (2.1) is *regular* if the inequality (2.2) becomes an equality and the exact limit exists, i.e.,

$$\sum_{i}^{n} \lambda_i^u = \liminf_{t\to\infty} \frac{1}{t} \int_0^t \operatorname{trace} A(s)ds.$$

If (2.1) is regular, then for any nontrivial solution x, the sharp Lyapunov exponent exists. Hence, we have $\lambda_i^l = \lambda_i^u$ for $i = 1, \ldots, n$, i.e., the Lyapunov spectrum of (2.1) is a point spectrum. We apply the transformation $x = L(t)y$, where L is a nonsingular and continuously differentiable matrix function for $t \ge t_0$, to system (2.1), we obtain

$$y' = B(t)y, \quad B(t) = L^{-1}A(t)L(t) - L^{-1}(t)L'(t). \tag{2.3}$$

This transformation is called a kinematic similarity transformation.

Definition 2.4. The above transformation is called a Lyapunov transformation if $L(t)$, $L^{-1}(t)$ and $L'(t)$ are bounded for $t \ge t_0$.

If we apply a Lyapunov transformation to system (2.1) and obtain the new system (2.3), then we say (2.1) is reducible to (2.3). Lyapunov transformations form a group and they do not change the Lyapunov exponent.

One of the most important questions is the variation of Lyapunov exponents under small linear and nonlinear perturbations. Consider the perturbed system

$$y' = (A(t) + Q(t))y, \tag{2.4}$$

where Q is a continuous and bounded matrix function. Let the upper Lyapunov exponents of (2.4) be ordered and denoted as follows

$$-\infty < \gamma_1^u \le \gamma_2^u \le \cdots \le \gamma_n^u < \infty.$$

Definition 2.5. The upper Lyapunov exponents of system (2.1) are said to be stable if for any $\varepsilon > 0$ there exists a $\delta > 0$ such that the inequality $\sup_{t\ge t_0} \|Q(t)\| < \delta$ implies

$$|\lambda_i^u - \gamma_i^u| < \varepsilon, \quad i = 1, 2, \ldots, n.$$

It is known that regularity does not ensure the stability of exponents. In order to answer the question of stability, we need the property of integral separation.

Definition 2.6. The real, bounded and continuous functions $a_1(t)$, $a_2(t), \dots, a_n(t)$ are said to be separated on $\mathbb{R}^+$ if there exists a constant $a > 0$ such that

$$a_{k+1}(t) - a_k(t) \geq a, \quad k = 1, 2, \dots, n-1, \quad t \geq 0.$$

They are said to be integrally separated on $\mathbb{R}^+$ if there exist constants $a > 0$ and $d > 0$ such that

$$\int_s^t [a_{k+1}(\tau) - a_k(\tau)] d\tau \geq a(t-s) - d$$

for all $t \geq s \geq 0$, $k = 1, 2, \dots, n-1$.

Obviously, the condition for separateness implies integral separateness, but not vice versa.

Definition 2.7. A linear system is said to be system with integral separateness if it has solutions $x_1(t)$, $x_2(t)$, …, $x_n(t)$ such that the inequality

$$\frac{\|x_{i+1}(t)\|}{\|x_{i+1}(s)\|} : \frac{\|x_i(t)\|}{\|x_i(s)\|} \geq d e^{a(t-s)}, \quad i = 1, 2, \dots, n-1, \tag{2.5}$$

with some constants $a > 0$, $d \geq 1$, is valid for all $t \geq s$.

The definition of integral separateness implies some properties:

- integrally separated systems have different Lyapunov exponents;
- integral separateness is invariant under Lyapunov transformations;
- the solutions $x_1(t)$, $x_2(t)$, …, $x_n(t)$ in Definition 2.7 form a normal basis.

The following important property was proven by Bylov.

Theorem 2.8 ([1, Theorem 5.3.1 and Corollary 5.3.2]). *An integrally separated system is reducible to a real diagonal one by means of a Lyapunov transformation and the diagonal is integrally separated.*

Furthermore, by the use the Steklov function and the H-transformation, see [1, pp. 153-155], we have the following result.

Theorem 2.9 ([1, Theorem 5.4.1]). *A diagonal real system with an integrally separated diagonal is reducible to a diagonal system with a separated diagonal.*

By Millionshchikov's method of rotation, a necessary and sufficient condition for the stability of distinct Lyapunov exponents was obtained.

Theorem 2.10 ([1, Theorem 5.4.8]). *If system (2.1) has n distinct Lyapunov exponents $\lambda_1 < \lambda_2 < \cdots < \lambda_n$, then they are stable if and only if the system is integrally separated, i.e. there exists an integrally separated fundamental solution matrix.*

In addition to Lyapunov exponents, another characteristic of the asymptotic behavior of the solutions of system (2.1) introduced by Bohl [7], has more natural properties.

Definition 2.11. Let x be a nontrivial solution of system (2.1). The *(upper) Bohl exponent* $\kappa_B^u(x)$ of this solution is the greatest lower bound of all those numbers ρ for which there exist numbers N_ρ such that

$$\|x(t)\| \leq N_\rho e^{\rho(t-s)} \|x(s)\|, \quad t \geq s \geq 0.$$

If such numbers ρ do not exist, then one sets $\kappa_B^u(x) = +\infty$.

Similarly, the *lower Bohl exponent* $\kappa_B^\ell(x)$ is the least upper bound of all those numbers ρ' for which there exist numbers N'_ρ such that

$$\|x(t)\| \geq N'_\rho e^{\rho'(t-s)} \|x(s)\|, \quad 0 \leq s \leq t.$$

It is easy to verify the estimates

$$\kappa_B^\ell(x) \le \lambda^\ell(x) \le \lambda^u(x) \le \kappa_B^u(x)$$

as well as the formulas

$$\kappa_B^u(x) = \limsup_{s,t-s\to\infty} \frac{\ln\|x(t)\| - \ln\|x(s)\|}{t-s}, \qquad \kappa_B^\ell(x) = \liminf_{s,t-s\to\infty} \frac{\ln\|x(t)\| - \ln\|x(s)\|}{t-s}.$$

If $A(t)$ is *integrally bounded*, i.e., if

$$\sup_{t\ge 0} \int_t^{t+1} \|A(s)\|\, ds < \infty,$$

then the Bohl exponents are finite.

The relation between Lyapunov and Bohl exponents are as follows.

- Bohl exponents characterize the uniform growth rate of solutions, while Lyapunov exponents simply characterize the growth rate of solutions departing from $t = 0$.
- If the greatest bound of upper Lyapunov exponents for all solutions of (2.1) is negative, then the system is asymptotically stable. If the same holds for the greatest bound of the upper Bohl exponents then the system is uniformly exponentially stable.
- Unlike Lyapunov exponents, Bohl exponents are stable without any extra assumption, see [7, Theorem 4.6].

The following lemma will be used in the proof of the main theorem in Section 3.

Lemma 2.12 ([6, Lemma 1, p. 98])**.** *Let $\beta(v)$ be a continuous function at $v = v^*$ and let $\gamma(t)$ be a continuous nonnegative function such that (1.2) holds. If $v(t)$ is a solution of the differential inequality*

$$v' \ge \beta(v) - \gamma(t)$$

for $t \ge t_0$ and there exists a sequence $\tau_n \to \infty$ such that $v(\tau_n) \to v^*$, then $\beta(v^*) \le 0$. Moreover, the exact limit of $v(\tau)$ as $\tau \to \infty$ exists.

3 Perron-type theorems for integrally separated systems

First, we establish a generalization of the classical Perron theorem for time-varying systems (1.1).

Theorem 3.1. *Consider the quasi-linear system (1.1), where the associated linear system (2.1) is integrally separated and has finite exponents. If $x(t)$ is a solution of (1.1) such that*

$$\|f(t, x(t))\| \le \gamma(t)\|x(t)\|, \quad t \ge t_0,$$

where $\gamma(t)$ is a continuous nonnegative function satisfying condition (1.2), then either $x(t) = 0$ for all large t or

$$\limsup_{t\to\infty} \frac{1}{t} \ln\|x(t)\|$$

is equal to one of the upper Lyapunov exponents of the linear system.

The same statement holds true for the limit inferior and the lower Lyapunov exponents, respectively.

That is, here we assume the stability of distinct Lyapunov exponents instead of the regularity. The proof is quite similar to that in [6] for the case of a constant coefficient. While in the case of a constant A, the transformation to the Jordan canonical form is used, here thanks to the integral separation, the linear system can be transformed into a diagonal system with a separated diagonal.

Proof. Due to Theorem 2.8 and Theorem 2.9, without loss of generality, we assume that A is already of real diagonal form

$$A(t) = \operatorname{diag}\left(\lambda_1(t), \lambda_2(t), \dots, \lambda_n(t)\right),$$

and

$$\lambda_i(t) - \lambda_{i+1}(t) \geq a > 0, \quad \forall t \geq t_0, \; i = 1, 2, \dots, n-1.$$

Then, the i-th equation ($i = 1, 2, \dots, n$) reads

$$x_i' = \lambda_i(t) x_i + f_i(t, x),$$

which implies

$$\frac{d}{dt}|x_i|^2 = 2\lambda_i |x_i|^2 + 2\bar{x}_i f_i.$$

Here, $\bar{x}_i$ and $|x_i|$ denote the complex conjugate and the modulus of x_i, respectively. Here, the argument t of the functions is omitted for brevity. Writing $r_i = |x_i|$, we have

$$\left| \frac{d}{dt} r_i^2 - 2\lambda_i r_i^2 \right| \leq 2 r_i |f_i(t, x)|, \quad i = 1, 2, \dots, n. \tag{3.1}$$

Putting

$$\limsup_{t \to \infty} \frac{1}{t} \int_{t_0}^{t} \lambda_i(s) ds = \mu_i,$$

it clearly holds that μ_i, $i = 1, 2, \dots, n$, are the upper Lyapunov exponents of the linear system, and $\mu_i - \mu_{i+1} \geq a$. Let us denote

$$L_k = r_k^2, \qquad M_k = \sum_{i<k} r_i^2, \qquad N_k = \sum_{i \geq k} r_i^2,$$

we have so that $M_k + N_k = \sum_{i=1}^n r_i^2 = \|x\|^2$, where the Euclidean norm is used.

From (3.1), we obtain

$$\left| L_k' - 2\lambda_k L_k \right| \leq 2\gamma(t) L_k^{1/2} (M_k + N_k)^{1/2}, \tag{3.2}$$

$$M_k' \geq 2\lambda_{k-1} M_k - 2\gamma(t) M_k^{1/2} (M_k + N_k)^{1/2}, \tag{3.3}$$

$$N_k' \leq 2\lambda_k N_k + 2\gamma(t) N_k^{1/2} (M_k + N_k)^{1/2}. \tag{3.4}$$

Thus, $N_1 = \|x\|^2$ satisfies

$$2(\lambda_n(t) - \gamma(t)) N_1 \leq N_1' \leq 2(\lambda_1(t) + \gamma(t)) N_1.$$

By integration, we get for $t \geq t_1 \geq t_0$

$$e^{\int_{t_1}^t 2(\lambda_n(t) - \gamma(t)) ds} \|x(t_1)\| \leq \|x(t)\| \leq e^{\int_{t_1}^t 2(\lambda_1(t) + \gamma(t)) ds} \|x(t_1)\|.$$

This shows that if $x(t_1)$ for some $t_1 \geq t_0$, then $x(t) = 0$ for all $t \geq t_1$. Thus, we exclude this case from now on.

Consider the function

$$v(t) = v_k(t) = \frac{M_k}{M_k + N_k},$$

which is well defined for all $t \geq t_0$ and fulfills $0 \leq v \leq 1$. Furthermore, since

$$v' = \frac{M'N - MN'}{(M+N)^2} \quad \text{and} \quad v(1-v) = \frac{MN}{(M+N)^2},$$

from (3.3) and (3.4), we obtain

$$v' \geq bv(1-v) - \sqrt{2}\gamma(t), \tag{3.5}$$

where $b = b_k = 2(\lambda_{k-1} - \lambda_k) \geq 2a > 0$.

By Lemma 2.12, it follows that for each $k = 1, 2, \ldots, n$, the limit of $v_k(t)$ as $t \to \infty$ exists and equal either 0 or 1. Moreover, $v_1(t) \to 0$ as $t \to \infty$, since $M_1 \equiv 0$. Let m be the greatest value of k for which $\lim_{t\to\infty} v_k(t) = 0$. Since $M_k = L_1 + \cdots + L_{k-1}$, it follows that

$$\lim_{t\to\infty} \frac{L_k(t)}{M_k(t) + N_k(t)} = \begin{cases} 0 & \text{for } k \neq m, \\ 1 & \text{for } k = m. \end{cases} \tag{3.6}$$

Therefore, we have

$$\lim_{t\to\infty} \frac{L_k(t)}{L_m(t)} = 0 \quad \text{for } k \neq m \tag{3.7}$$

and by (3.2) with $k = m$

$$\left| \frac{d}{dt}(\ln L_m) - 2\lambda_m \right| \leq 2\gamma(t) \left(\frac{M_m + N_m}{L_m} \right)^{1/2}. \tag{3.8}$$

Note that

$$\lim_{t\to\infty} \frac{M_m(t) + N_m(t)}{L_m(t)} = 1$$

and assumption (1.2) implies $t^{-1} \int_{t_0}^t \gamma(s)ds \to 0$ as $t \to \infty$. Therefore, integrating both sides of (3.8) from t_0 to t and dividing by t, we get

$$\frac{\ln L_m(t)}{t} - \frac{2}{t} \int_{t_0}^t \lambda_m(s)ds = o(1), \quad t \to \infty.$$

This, together with the asymptotic relation

$$\frac{\ln \|x(t)\|^2}{t} = \frac{\ln L_m(t)}{t}(1 + o(1)), \quad t \to \infty,$$

implies that

$$\limsup_{t\to\infty} \frac{\ln \|x(t)\|}{t} = \limsup_{t\to\infty} \frac{\ln L_m(t)}{2t} = \limsup_{t\to\infty} \frac{1}{t} \int_{t_0}^t \lambda_m(s)ds = \mu_m,$$

which completes the proof.

If we take the limit inferior instead of the limit superior, the statement for the lower Lyapunov exponent is obtained, too. □

Remark 3.2. The condition on $f(t,x)$ in Theorem 3.1 is certainly satisfied by any solution $x(t)$ of (1.1) which tends to zero as $t \to \infty$ if

$$f(t,x) = o(\|x\|), \quad \text{for } t \to \infty,\ \|x\| \to 0.$$

In the special case of linear perturbation $f(t,x) = B(t)x$, the condition (1.2) holds in particular if $\|B(t)\| \to 0$ as $t \to \infty$ or $B(t) \in L_p[t_0,\infty)$, where $1 \le p < \infty$.

As a consequence, we obtain a theorem on the asymptotic stability of a non-stationary solution of a nonlinear system by using linearization.

Theorem 3.3. *Consider a nonlinear system*

$$y' = g(t,y), \quad t \ge t_0, \tag{3.9}$$

where g is continuous and continuously differentiable with respect to variable y. Suppose that $y^* = y^*(t)$ is a particular solution that exists on $[t_0,\infty)$. Consider the linearized system

$$x' = A(t)x, \quad A(t) = g_y(t, y^*(t)). \tag{3.10}$$

If the system (3.10) is integrally separated and all of its Lyapunov exponents are negative, then y^* is an asymptotically stable solution of (3.9).

We note the fact that all of its Lyapunov exponents are negative implies that the system (3.10) is exponentially stable, but it is not necessarily uniformly exponentially stable.

Analogously, we obtain a Perron theorem for Bohl exponents.

Theorem 3.4. *Consider the quasi-linear system (1.1), where the associated linear system (2.1) is integrally separated and has finite exponents. If $x(t)$ is a solution of (1.1) such that*

$$\|f(t,x(t))\| \le \gamma(t)\|x(t)\|, \quad t \ge t_0,$$

where $\gamma(t)$ is a continuous nonnegative function satisfying condition (1.2), then either $x(t) = 0$ for all large t or

$$\limsup_{s,t-s\to\infty} \frac{\ln\|x(t)\| - \ln\|x(s)\|}{t-s}$$

is equal to one of the upper Bohl exponents of the linear system.

The same statement holds true for the limit inferior and the lower Bohl exponents, respectively.

Proof. We proceed as in the the proof of Theorem 3.1 and integrate both sides of (3.8) from s to t and dividing by $t-s$. Then, take the limit superior/inferior as s, $t-s$ tend to ∞. □

4 Discussion

In this paper, we have derived two extended versions of the classical Perron-type theorem. Assuming integral separation, which guarantees the stability of Lyapunov exponents, we have confirmed that the Perron theorem remains valid under the same smallness condition on the nonlinear part as in the constant coefficient case. Therefore, our version of the Perron theorem differs from the one obtained in [4]. Additionally, we have established a Perron theorem for Bohl exponents as well. Extensions of these results to different growth rates and the μ-Lyapunov exponents defined in [2,10] appear to be straightforward.

Several open problems and conjectures remain. First, our results can be extended to difference equations, providing an alternative to the Perron-type theorem presented in [3]. Second, it is known that the Lyapunov exponents of linear systems may be nondistinct but still stable, as characterized in [1, Theorem 5.4.9] and [9]. In such cases, the linear system (2.1) can be reduced to block-diagonal form with upper-triangular blocks subject to additional conditions. We conjecture that Theorem 3.1 still holds, i.e., the stability of Lyapunov exponents implies their preservation under small nonlinear perturbations satisfying (1.3). This would fully generalize the classical Perron theorem to the time-varying system (1.1).

Furthermore, it is well known that Bohl exponents are stable without any additional assumptions. Therefore, we also conjecture that the result of Theorem 3.4 holds without the integral separation assumption (see the related result in [7, Chapter VII, Section 3] and [9]). However, the arguments used in the proof of Theorem 3.1 are insufficient for the last two problems, as reducibility to diagonal form no longer holds. Addressing these questions would require overcoming further technical challenges.

Lastly, recent results on the asymptotic behavior of solutions and Lyapunov exponents have been extended from ODEs to DAEs (see [11–15]). Therefore, extending the Perron-type theorem to linear time-varying DAEs under small nonlinear perturbations would also be of interest.

Abstract. We study the multiparameter p-Laplacian Dirichlet problem

$$\begin{cases} \left(\varphi_p(u'(x))\right)' + \lambda(ku^{p-1} + \sum_{i=1}^{m} a_i u^{q_i}) - \mu \sum_{j=1}^{n} b_j u^{r_j} = 0, \ \ -1 < x < 1, \\ u(-1) = u(1) = 0, \end{cases}$$

where $p > 1$, $\varphi_p(y) = |y|^{p-2}y$, $\left(\varphi_p(u')\right)'$ is the one-dimensional p-Laplacian, $\lambda > 0$ and $\mu \geq 0$ are two bifurcation parameters. We assume that $k \geq 0$, $0 < p-1 < q_1 < q_2 < \cdots < q_m < r_1 < r_2 < \cdots < r_n$, $m, n \geq 1$, $a_1 = 1$, $a_i > 0$ for $i = 1, 2, \ldots, m$ and $b_1 = 1$, $b_j > 0$ for $j = 1, 2, \ldots, n$. We mainly prove that, on the $(\lambda, \|u\|_\infty)$-plane, the bifurcation diagram consists of a strictly decreasing curve for $\mu = 0$, and always consists of a $\subset$-shaped curve for fixed $\mu > 0$. We then study the structures and evolution of the bifurcation diagrams with varying $\mu \geq 0$.

Keywords: bifurcation diagram, evolution, positive solution, p-Laplacian, $\subset$-shaped bifurcation curve, time map.

1 Introduction

In this paper we study the structures and evolution of bifurcation diagrams for the multiparameter p-Laplacian Dirichlet problem

$$\begin{cases} \left(\varphi_p(u'(x))\right)' + \lambda(ku^{p-1} + \sum_{i=1}^{m} a_i u^{q_i}) - \mu \sum_{j=1}^{n} b_j u^{r_j} = 0, \quad -1 < x < 1, \\ u(-1) = u(1) = 0, \end{cases} \tag{1.1}$$

where $p > 1$, $\varphi_p(y) = |y|^{p-2}y$, $\left(\varphi_p(u')\right)'$ is the one-dimensional p-Laplacian, and $\lambda > 0$ and $\mu \geq 0$ are two bifurcation parameters. We assume that the nonlinearity

$$f_{k,\mu,\lambda}(u) \equiv \lambda(ku^{p-1} + \sum_{i=1}^{m} a_i u^{q_i}) - \mu \sum_{j=1}^{n} b_j u^{r_j} \tag{1.2}$$

✉Corresponding author. Email: shwang@math.nthu.edu.tw

is a generalized polynomial (see [9]) satisfying

$$\begin{cases} k \geq 0,\ 0 < p-1 < q_1 < q_2 < \cdots < q_m < r_1 < r_2 < \cdots < r_n,\ m,n \geq 1, \\ a_1 = 1,\ a_i > 0 \text{ for } i = 1,2,\ldots,m \text{ and } b_1 = 1,\ b_j > 0 \text{ for } j = 1,2,\ldots,n. \end{cases} \tag{1.3}$$

This problem arises in the study of non-Newtonian fluids, nonlinear diffusion problems, and population dynamics of one species. The quantity p is a characteristic of the medium. Media with $1 < p < 2$ are called pseudoplastics fluids and those with $p > 2$ are called dilatant. If $p = 2$, they are Newtonian fluids (see, e.g., Díaz [3, 4] and their bibliographies). In population dynamics, in (1.1), the one-dimensional p-Laplacian operator $(\varphi_p(u'))'$ acts as the diffusive mechanism describing the migration of u throughout the habitat $(-1,1)$ which is assumed to be surrounded by a completely hostile boundary $\{\pm 1\}$. In (1.1), the reaction term $\lambda(ku^{p-1} + \sum_{i=1}^m a_i u^{q_i}) - \mu \sum_{j=1}^n b_j u^{r_j}$ is the growth rate of the population, which consists of a source term $\lambda(ku^{p-1} + \sum_{i=1}^m a_i u^{q_i})$ and an absorption term $\mu \sum_{j=1}^n b_j u^{r_j}$. Note that, by (1.3), if $\mu > 0$, the absorption term $\mu \sum_{j=1}^n b_j u^{r_j}$ is dominated by the source term when u near 0^+ and dominate the source term when u is large enough, and the domination of the absorption term over the source term is assumed to be strictly increasing on $(0,\infty)$. Murray [11] suggested using diffusion of the form p in the study of diffusion-kinetic enzymes problems. By a positive solution to p-Laplacian problem (1.1) with general $p > 1$, we mean a positive function $u \in C^1[-1,1]$ with $\varphi_p(u') \in C^1[-1,1]$ satisfying (1.1). Let $Z = \{x \in [-1,1] : u'(x) = 0\}$. We note that it is easy to show that, if u is a positive solution of (1.1), then $u \in C^2[-1,1]$ if $1 < p \leq 2$ and $u \in C^2([-1,1] \setminus Z)$ if $p > 2$. For the proof we refer to [1, Lemma 6].

To study bifurcation diagrams of positive solutions of (1.1), (1.3), it is important to study the shape of nonlinearity $f_{k,\mu,\lambda}(u)$ on $(0,\infty)$ in the beginning. We show that there exist three positive numbers $\beta_{\mu,\lambda} > \zeta_{\mu,\lambda} > \gamma_{\mu,\lambda}$ such that $f_{k,\mu,\lambda}(u)$ with $\lambda, \mu > 0$ satisfies (1.4), (1.9), and (1.11) stated behind. That is, positive numbers $\beta_{\mu,\lambda} > \zeta_{\mu,\lambda} > \gamma_{\mu,\lambda}$ are the unique positive zero, critical point, and p-inflection point of $f_{k,\mu,\lambda}(u)$ on $(0,\infty)$, respectively. First, we easily observe that, for $f_{k,\mu,\lambda}(u)$ with $\lambda, \mu > 0$ satisfying (1.3), the number of sign changes in the sequence of coefficients for the *generalized polynomial* $f_{k,\mu,\lambda}(u)$

$$(\lambda k, \lambda a_1, \lambda a_2, \ldots, \lambda a_m, -\mu b_1, -\mu b_2, \ldots, -\mu b_n)$$

is 1. Applying Laguerre's Theorem [10] (see also [9, Theorem 4.7]) on the number of positive zeros to the generalized polynomial $f_{k,\mu,\lambda}(u)$, we obtain that there exists a unique positive number $\beta_{\mu,\lambda}$ such that

$$\begin{cases} f_{k,\mu,\lambda}(u) > 0 \ \text{ on } (0, \beta_{\mu,\lambda}), \\ f_{k,\mu,\lambda}(0) = f_{k,\mu,\lambda}(\beta_{\mu,\lambda}) = 0, \\ f_{k,\mu,\lambda}(u) < 0 \ \text{ on } (\beta_{\mu,\lambda}, \infty). \end{cases} \tag{1.4}$$

We set $\beta_{\mu=0,\lambda} = \infty$ if $\mu = 0$. Notice that, by (1.3), it is easy to see that, for fixed $\lambda > 0$,

$$\lim_{\mu \to \infty} \beta_{\mu,\lambda} = 0. \tag{1.5}$$

In addition,

$$\text{for fixed } \mu > 0,\ \beta_{\mu,\lambda} \text{ is a continuous, strictly increasing function of } \lambda \text{ on } (0,\infty) \tag{1.6}$$

and

$$\text{for fixed } \lambda > 0,\ \beta_{\mu,\lambda} \text{ is a continuous, strictly decreasing function of } \mu \text{ on } (0,\infty). \tag{1.7}$$

Secondly, we compute that

$$f'_{k,\mu,\lambda}(u) = \lambda \left[(p-1)ku^{p-2} + \sum_{i=1}^{m} a_i q_i u^{q_i - 1} \right] - \mu \sum_{j=1}^{n} b_j r_j u^{r_j - 1}. \tag{1.8}$$

Thus again, similarly, applying (1.3) and Laguerre's Theorem [10] on the number of positive zeros to the *generalized polynomial* $f'_{k,\mu,\lambda}(u)$ in (1.8), we obtain that there exists a unique positive number $\zeta_{\mu,\lambda} < \beta_{\mu,\lambda}$ such that

$$\begin{cases} f'_{k,\mu,\lambda}(u) > 0 \ \text{ on } (0, \zeta_{\mu,\lambda}), \\ f'_{k,\mu,\lambda}(u)(\zeta_{\mu,\lambda}) = 0, \\ f'_{k,\mu,\lambda}(u) < 0 \ \text{ on } (\zeta_{\mu,\lambda}, \beta_{\mu,\lambda}). \end{cases} \tag{1.9}$$

So $f_{k,\mu,\lambda}(u)$ with $\lambda, \mu > 0$ is increasing-decreasing on $(0, \beta_{\mu,\lambda})$. Thirdly, we compute that

$$(p-2)f'_{k,\mu,\lambda}(u) - uf''_{k,\mu,\lambda}(u) = \lambda \sum_{i=1}^{m} a_i q_i (p-1-q_i) u^{q_i-1} - \mu \sum_{j=1}^{n} b_j r_j (p-1-r_j) u^{r_j-1}, \tag{1.10}$$

in which $p - 1 - q_i < 0$ for $i = 1, 2, \ldots, m$ and $p - 1 - r_j < 0$ for $j = 1, 2, \ldots, n$. Thus again, applying (1.3) and Laguerre's Theorem [10] on the number of positive zeros to the *generalized polynomial* $(p-2)f'_{k,\mu,\lambda}(u) - uf''_{k,\mu,\lambda}(u)$ in (1.10), we obtain that there exists a unique positive number $\gamma_{\mu,\lambda} < \zeta_{\mu,\lambda}$ such that

$$\begin{cases} (p-2)f'_{k,\mu,\lambda}(u) - uf''_{k,\mu,\lambda}(u) < 0 \ \text{ on } (0, \gamma_{\mu,\lambda}), \\ (p-2)f'_{k,\mu,\lambda}(\gamma_{\mu,\lambda}) - uf''_{k,\mu,\lambda}(\gamma_{\mu,\lambda}) = 0, \\ (p-2)f'_{k,\mu,\lambda}(u) - uf''_{k,\mu,\lambda}(u) > 0 \ \text{ on } (\gamma_{\mu,\lambda}, \beta_{\mu,\lambda}). \end{cases} \tag{1.11}$$

In this case $f_{k,\mu,\lambda}(u)$ with $\lambda, \mu > 0$ is said to be p-convex-concave on $(0, \beta_{\mu,\lambda})$.

Note that, in (1.1), $\lambda k u^{p-1}$ is the p-linear term for generalized polynomial nonlinearity $f_{k,\mu,\lambda}$ if bifurcation parameter $k > 0$. If $k = 0$, then $f_{k,\mu,\lambda}$ has no p-linear term. In this paper we are concerned only with positive solutions u of (1.1), (1.3) satisfying

$$0 < \|u\|_\infty < \beta_{\mu,\lambda} \begin{cases} = \infty & \text{if } \mu = 0, \\ < \infty & \text{if } \mu > 0. \end{cases} \tag{1.12}$$

Positive solutions u of (1.1), (1.3) satisfying (1.12) are called *classical* positive solutions. Note that positive solutions u of (1.1), (1.3) satisfying $\|u\|_\infty = \beta_{\mu,\lambda}$ are called *flat-core* positive solutions.

For problem (1.1), (1.3), we study evolutionary bifurcation diagrams $S_{p,k,\mu}$ on the $(\lambda, \|u\|_\infty)$-plane defined by:

$$S_{p,k,\mu} = \{(\lambda, \|u_\lambda\|_\infty) : \lambda > 0 \text{ and } u_\lambda \text{ is a (classical) positive solution of (1.1), (1.3)}\}, \ \mu \geq 0. \tag{1.13}$$

First, when $\mu = 0$ and $f_{k,\mu=0,\lambda}(u) \equiv \lambda(ku^{p-1} + \sum_{i=1}^{m} a_i u^{q_i})$, we study $S_{p,k,\mu=0}$ on the $(\lambda, \|u\|_\infty)$-plane in the next proposition. We let

$$\bar{\lambda} \equiv \left(\frac{p-1}{k}\right)\left(\frac{\pi}{p}\csc\frac{\pi}{p}\right)^p \begin{cases} < \infty & \text{if } k > 0, \\ = \infty & \text{if } k = 0. \end{cases} \tag{1.14}$$

Proposition 1.1 (See Figs. 2.1–2.2 depicted behind)**.** *Let $p > 1$. Consider p-Laplacian problem (1.1), (1.3) with $\mu = 0$ and $f_{k,\mu=0,\lambda}(u) = \lambda(ku^{p-1} + \sum_{i=1}^{m} a_i u^{q_i}) > 0$ on $(0,\infty)$. Then the bifurcation diagram $S_{p,k,\mu=0}$ satisfies the following assertions (i)–(ii):*

(i) On the $(\lambda, \|u\|_\infty)$-plane, $S_{p,k,\mu=0}$ emanates from the positive $\|u\|_\infty$-axis as $\lambda \to 0^+$, tends to the point $(\bar{\lambda}, 0) = \left(\left(\frac{p-1}{k}\right)\left(\frac{\pi}{p}\csc\frac{\pi}{p}\right)^p, 0\right)$ if $k > 0$ and tends to the positive λ-axis as $\lambda \to \infty$ if $k = 0$, and consists of a continuous, strictly decreasing curve.

(ii) Moreover, if $k = 0$, $m = 1$, $q \equiv q_1 > p - 1$ and $f_{k=0,\mu=0,\lambda}(u) \equiv \lambda u^q > 0$ on $(0,\infty)$, then

$$S_{p,k=0,\mu=0} = \left\{(\lambda, \|u_\lambda\|_\infty) = (c_{p,q}\alpha^{p-q-1}, \alpha),\ \alpha = \|u_\lambda\|_\infty > 0\right\},$$

where

$$c_{p,q} \equiv \left(\frac{p-1}{p}\right)(q+1)^{1-p}\left[\frac{\Gamma(\frac{p-1}{p})\Gamma(\frac{1}{q+1})}{\Gamma(\frac{pq+2p-q-1}{p(q+1)})}\right]^p > 0, \qquad (1.15)$$

and $\Gamma(t) \equiv \int_0^\infty x^{t-1}e^{-x}dx$ is the usual gamma function.

Proof. (I) We prove part (i). To study $S_{p,k,\mu=0}$ for p-Laplacian problem (1.1), (1.3) with $\mu = 0$, we apply the time-map method for which the time-map formula takes the form as follows:

$$\lambda^{1/p} = \left(\frac{p-1}{p}\right)^{1/p}\int_0^\alpha \frac{1}{[\bar{F}(\alpha) - \bar{F}(u)]^{1/p}}du \equiv T_{\bar{f}}(\alpha) \quad \text{for } \alpha = \|u\|_\infty > 0, \qquad (1.16)$$

where

$$\bar{f}(u) \equiv f_{k,\mu=0,\lambda=1}(u) = ku^{p-1} + \sum_{i=1}^{m} a_i u^{q_i}$$

and $\bar{F}(u) \equiv \int_0^u \bar{f}(t)dt$; see, e.g., [2, Lemmas 2.1 and 2.2] for the derivation of the time map formula $T(\alpha)$ in (1.16). We have that positive solution $u_\lambda(x)$ of p-Laplacian problem (1.1), (1.3) with $\mu = 0$ corresponds to $\|u_\lambda\|_\infty = \alpha > 0$ satisfying (1.16), e.g., [13, p. 382]. It is easy to compute that, by (1.3),

$$\lim_{u\to 0^+}\frac{\bar{f}(u)}{u^{p-1}} = \frac{ku^{p-1} + \sum_{i=1}^{m} a_i u^{q_i}}{u^{p-1}} = k \geq 0, \qquad \lim_{u\to\infty}\frac{\bar{f}(u)}{u^{p-1}} = \frac{ku^{p-1} + \sum_{i=1}^{m} a_i u^{q_i}}{u^{p-1}} = \infty,$$

and

$$(p-1)\bar{f}(u) - u\bar{f}'(u) = \sum_{i=1}^{m} a_i(p-1-q_i)u^{q_i} < 0 \quad \text{on } (0,\infty).$$

Thus, by [13, (1.7), (1.9) and (4.4)], we have that $\lim_{\alpha\to 0^+} T_{\bar{f}}(\alpha) = \left(\frac{p-1}{k}\right)^{1/p}\frac{\pi}{p}\csc\frac{\pi}{p} \in (0,\infty]$, $\lim_{\alpha\to\infty} T_{\bar{f}}(\alpha) = 0$, and $T_{\bar{f}}(\alpha)$ is a strictly decreasing function on $(0,\infty)$. So part (i) directly follows from (1.13) and (1.16).

(II) We prove part (ii). We have that $\bar{f}(u) = u^q$, $q > p-1 > 0$ and $\bar{F}(u) \equiv \int_0^u \bar{f}(t)dt = \frac{1}{q+1}u^{q+1}$. It can be computed that

$$\begin{aligned} T_{\bar{f}}(\alpha) &= \left(\frac{p-1}{p}\right)^{1/p}\int_0^\alpha \frac{1}{[\bar{F}(\alpha) - \bar{F}(u)]^{1/p}}du \\ &= \left(\frac{p-1}{p}\right)^{1/p}(q+1)^{1/p}\int_0^\alpha \frac{1}{[\alpha^{q+1} - u^{q+1}]^{1/p}}du \\ &= \left(\frac{p-1}{p}\right)^{1/p}(q+1)^{(1-p)/p}\left[\frac{\Gamma(\frac{p-1}{p})\Gamma(\frac{1}{q+1})}{\Gamma(\frac{pq+2p-q-1}{p(q+1)})}\right]\alpha^{\frac{p-q-1}{p}} \end{aligned}$$

by [6, p. 212, formula 855.42] or using symbolic manipulator *Mathematica 11.0*. Thus by (1.15) and (1.16), we obtain that

$$\begin{aligned}\lambda = \left[T_{\bar{f}}(\alpha)\right]^p &= (\frac{p-1}{p})(q+1)^{1-p}\left[\frac{\Gamma(\frac{p-1}{p})\Gamma(\frac{1}{q+1})}{\Gamma(\frac{pq+2p-q-1}{p(q+1)})}\right]^p \alpha^{p-q-1} \\ &= c_{p,q}\alpha^{p-q-1}. \end{aligned} \tag{1.17}$$

So part (ii) holds.

The proof of Proposition 1.1 is now complete. □

2 Main results

The main results in this paper are next Theorem 2.1 and Theorem 2.2 for problem (1.1), (1.3) with $1 < p \leq 2$ and $p > 2$, respectively. In Theorems 2.1–2.2 with any fixed $\mu > 0$, we prove that, on the $(\lambda, \|u\|_\infty)$-plane, the bifurcation diagram $S_{p,k,\mu}$ always consists of a continuous, ⊂-shaped curve with exactly one (right) turning point at some point $(\lambda^*, \|u_{\lambda^*}\|_\infty)$. While the upper branch of each ⊂-shaped bifurcation diagram $S_{p,k,\mu}$ is *unbounded* if $1 < p \leq 2$ and is *bounded* if $p > 2$. We then study the structures and evolution of bifurcation diagrams $S_{p,k,\mu}$ with varying $\mu \geq 0$; see Fig. 2.1 with $1 < p \leq 2$ and Fig. 2.2 with $p > 2$. Theorem 2.1 and Theorem 2.2 substantially improve [14, Corollary 2.2] and [14, Corollary 2.4], respectively. Cf. [14, Corollary 2.2] with $1 < p \leq 2$ and [14, Corollary 2.4] with $p > 2$ for details. Also see Remark 3.2 stated behind.

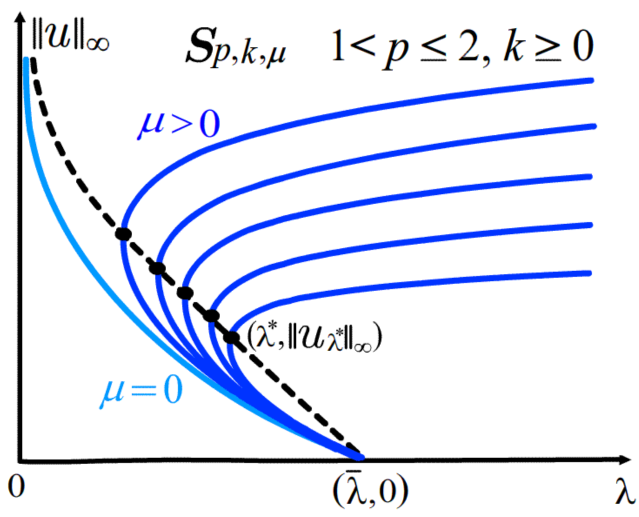

Figure 2.1: Evolutionary bifurcation diagrams $S_{p,k,\mu}$ for (1.1), (1.3) with fixed $p \in (1,2]$, $k \geq 0$ and varying $\mu \geq 0$.

Theorem 2.1 (See Fig. 2.1)**.** *Let $1 < p \leq 2$ and $k \geq 0$. Consider p-Laplacian problem* (1.1), (1.3) *with varying $\mu \geq 0$. Then the bifurcation diagram $S_{p,k,\mu}$ consists of a continuous curve on the $(\lambda, \|u\|_\infty)$-plane and the following assertions (i)–(v) hold:*

(i) For $\mu = 0$, $S_{p,k,\mu=0}$ emanates from the positive $\|u\|_\infty$-axis as $\lambda \to 0^+$, tends to the point $(\bar{\lambda}, 0) = \left(\left(\frac{p-1}{k}\right)\left(\frac{\pi}{p}\csc\frac{\pi}{p}\right)^p, 0\right)$ if $k > 0$ and tends to the positive λ-axis as $\lambda \to \infty$ if $k = 0$, and consists of a strictly decreasing curve.

(ii) *For any fixed $\mu > 0$, $S_{p,k,\mu}$ always starts at the point $(\bar{\lambda}, 0) = \left(\left(\frac{p-1}{k}\right)\left(\frac{\pi}{p}\csc\frac{\pi}{p}\right)^p, 0\right)$ if $k > 0$ and emanates from the positive λ-axis as $\lambda \to \infty$ if $k = 0$ (that is, $(\bar{\lambda}, 0) = (\infty, 0)$ if $k = 0$). $S_{p,k,\mu}$ is a $\subset$-shaped curve with exactly one turning point at some point $(\lambda^*, \|u_{\lambda^*}\|_\infty)$ satisfying*

$$0 < \lambda^* < \bar{\lambda} \text{ and } 0 < \|u_{\lambda^*}\|_\infty < \beta_{\mu,\lambda^*}.$$

In addition, the upper branch of $S_{p,k,\mu}$ tends to infinity when $\lambda \to \infty$. Thus, (1.1), (1.3) has exactly two (classical) positive solutions for $\lambda^* < \lambda < \bar{\lambda}$, exactly one (classical) positive solution for $\lambda = \lambda^*$ and $\lambda \geq \bar{\lambda}$, and no (classical) positive solution for $0 < \lambda < \lambda^*$.

(iii) *For any nonnegative $\mu_1 < \mu_2$, S_{p,k,μ_2} lies on the right hand side of S_{p,k,μ_1}. (So S_{p,k,μ_1} and S_{p,k,μ_2} do not intersect.)*

(iv) *For the turning points $(\lambda^*, \|u_{\lambda^*}\|_\infty)$ of $S_{p,k,\mu}$ with $\mu > 0$, λ^* is a continuous, strictly increasing function of $\mu > 0$, $\|u_{\lambda^*}\|_\infty$ is a continuous function of $\mu > 0$,*

$$\lim_{\mu \to 0^+}(\lambda^*, \|u_{\lambda^*}\|_\infty) = (0, \infty) \text{ and } \lim_{\mu \to \infty}(\lambda^*, \|u_{\lambda^*}\|_\infty) = (\bar{\lambda}, 0) = \left(\left(\frac{p-1}{k}\right)\left(\frac{\pi}{p}\csc\frac{\pi}{p}\right)^p, 0\right).$$

In particular, when $k = 0$, $m = 1$, $n = 1$, $q \equiv q_1 > p - 1$, $r \equiv r_1 > q$, and $f_{k=0,\mu,\lambda}(u) = \lambda u^q - \mu u^r$, then $\|u_{\lambda^*}\|_\infty$ is a strictly decreasing function of $\mu > 0$.

(v) *When $k = 0$, $m = 1$, $n = 1$, $q \equiv q_1 > p - 1$, $r \equiv r_1 > q$, and $f_{k=0,\mu,\lambda}(u) = \lambda u^q - \mu u^r$, then all points $(\lambda, \|u_\lambda\|_\infty) \in S_{p,k=0,\mu}$ satisfy*

$$0 < \left(\frac{c_{p,q}}{\lambda}\right)^{\frac{1}{q-p+1}} < \|u_\lambda\|_\infty < \beta_{\mu,\lambda} = \left(\frac{\lambda}{\mu}\right)^{\frac{1}{r-q}}, \tag{2.1}$$

where $c_{p,q}$ is defined in (1.15).

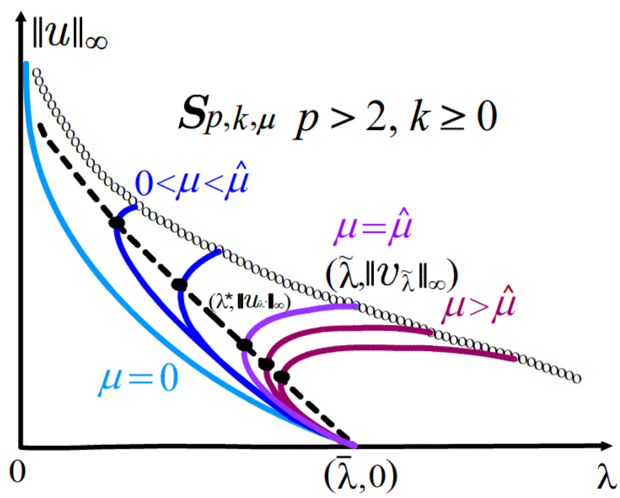

Figure 2.2: Evolutionary bifurcation diagrams $S_{p,k,\mu}$ for (1.1), (1.3) with fixed $p > 2$, $k \geq 0$ and varying $\mu \geq 0$.

Theorem 2.2 (See Fig. 2.2)**.** *Let $p > 2$ and $k \geq 0$. Consider one-dimensional p-Laplacian problem* (1.1), (1.3) *with varying $\mu \geq 0$. Then the bifurcation diagram $S_{p,k,\mu}$ consists of a continuous curve on the $(\lambda, \|u\|_\infty)$-plane and the following assertions (i)–(vi) hold:*

(i) *For* $\mu = 0$, $S_{p,k,\mu=0}$ *emanates from the positive* $\|u\|_\infty$*-axis as* $\lambda \to 0^+$, *tends to the point* $(\bar{\lambda}, 0) = \left(\left(\frac{p-1}{k}\right)\left(\frac{\pi}{p}\csc\frac{\pi}{p}\right)^p, 0\right)$ *if* $k > 0$ *and tends to the positive* λ*-axis as* $\lambda \to \infty$ *if* $k = 0$, *and consists of a strictly decreasing curve.*

(ii) *For any fixed* $\mu > 0$, $S_{p,k,\mu}$ *starts at the same point* $(\bar{\lambda}, 0) = \left(\left(\frac{p-1}{k}\right)\left(\frac{\pi}{p}\csc\frac{\pi}{p}\right)^p, 0\right)$ *if* $k > 0$ *and emanates from the positive* $\|u\|_\infty$*-axis as* $\lambda \to 0^+$ *if* $k = 0$ *(that is,* $(\bar{\lambda}, 0) = (\infty, 0)$ *if* $k = 0$*), ends at some point* $(\tilde{\lambda}, \|v_{\tilde{\lambda}}\|_\infty)$ *satisfying* $0 < \tilde{\lambda} < \infty$ *and* $0 < \|v_{\tilde{\lambda}}\|_\infty = v_{\tilde{\lambda}}(0) = \beta_{\mu,\tilde{\lambda}}$ *satisfying* $f_{k,\mu,\tilde{\lambda}}(\beta_{\mu,\tilde{\lambda}}) = 0$ *(that is,* $v_{\tilde{\lambda}}(x) \equiv \lim_{\lambda \to \tilde{\lambda}^-} v_\lambda(x)$ *is a* flat-core *positive solution of problem* (1.1), (1.3)*, see part (a) stated below for* (classical) *positive solutions* $v_\lambda(x)$ *with* $\lambda^* < \lambda < \tilde{\lambda}$*). Moreover,* $S_{p,k,\mu}$ *is a* $\subset$*-shaped curve with exactly one turning point at some point* $(\lambda^*, \|u_{\lambda^*}\|_\infty)$ *satisfying*

$$0 < \lambda^* < \min(\bar{\lambda}, \tilde{\lambda}) \quad \text{and} \quad 0 < \|u_{\lambda^*}\|_\infty < \|v_{\tilde{\lambda}}\|_\infty = \beta_{\mu,\tilde{\lambda}}.$$

Moreover, there exists a unique positive $\hat{\mu} = \hat{\mu}(p, k, q_i, r_j, a_i, b_j) < \infty$ *if* $k > 0$ *and* $\hat{\mu} = \infty$ *if* $k = 0$ *such that:*

- *(a)* *If* $0 < \mu < \hat{\mu}$, *then* $(\lambda^* <)\ \tilde{\lambda} < \bar{\lambda}$ *such that problem* (1.1), (1.3) *has exactly two (classical) positive solutions* u_λ, v_λ *with* $u_\lambda < v_\lambda$ *satisfying* $\|u_\lambda\|_\infty < \|v_\lambda\|_\infty < \beta_{\mu,\tilde{\lambda}}$ *for* $\lambda^* < \lambda < \tilde{\lambda}$, *exactly one (classical) positive solution* u_λ *satisfying* $\|u_\lambda\|_\infty < \beta_{\mu,\tilde{\lambda}}$ *for* $\lambda = \lambda^*$ *and* $\tilde{\lambda} \le \lambda < \bar{\lambda}$, *and no (classical) positive solution for* $0 < \lambda < \lambda^*$ *and* $\lambda \ge \bar{\lambda}$. *In addition,* $\lim_{\lambda \to \bar{\lambda}^-} \|u_\lambda\|_\infty = 0$ *and* $\lim_{\lambda \to \tilde{\lambda}^-} \|v_\lambda\|_\infty = \|v_{\tilde{\lambda}}\|_\infty = \beta_{\mu,\tilde{\lambda}}$.
- *(b)* *If* $\mu = \hat{\mu}$, *then* $(\lambda^* <)\ \tilde{\lambda} = \bar{\lambda}$ *such that problem* (1.1), (1.3) *has exactly two (classical) positive solutions* u_λ, v_λ *with* $u_\lambda < v_\lambda$ *satisfying* $\|u_\lambda\|_\infty < \|v_\lambda\|_\infty < \beta_{\mu,\tilde{\lambda}}$ *for* $\lambda^* < \lambda < \bar{\lambda}$, *exactly one (classical) positive solution* u_λ *satisfying* $\|u_\lambda\|_\infty < \beta_{\mu,\tilde{\lambda}}$ *for* $\lambda = \lambda^*$, *and no (classical) positive solution for* $0 < \lambda < \lambda^*$ *and* $\lambda \ge \bar{\lambda}$. *In addition,* $\lim_{\lambda \to \bar{\lambda}^-} \|u_\lambda\|_\infty = 0$ *and* $\lim_{\lambda \to \tilde{\lambda}^-} \|v_\lambda\|_\infty = \|v_{\tilde{\lambda}}\|_\infty = \beta_{\mu,\tilde{\lambda}}$.
- *(c)* *If* $\mu > \hat{\mu}$, *then* $(\lambda^* <)\ \bar{\lambda} < \tilde{\lambda}$ *such that problem* (1.1), (1.3) *has exactly two (classical) positive solutions* u_λ, v_λ *with* $u_\lambda < v_\lambda$ *satisfying* $\|u_\lambda\|_\infty < \|v_\lambda\|_\infty < \beta_{\mu,\tilde{\lambda}}$ *for* $\lambda^* < \lambda < \bar{\lambda}$, *exactly one (classical) positive solution* u_λ *satisfying* $\|u_\lambda\|_\infty < \beta_{\mu,\tilde{\lambda}}$ *for* $\lambda = \lambda^*$ *and exactly one (classical) positive solution* v_λ *satisfying* $\|v_\lambda\|_\infty < \beta_{\mu,\tilde{\lambda}}$ *for* $\bar{\lambda} \le \lambda < \tilde{\lambda}$, *and no (classical) positive solution for* $0 < \lambda < \lambda^*$ *and* $\lambda \ge \tilde{\lambda}$. *In addition,* $\lim_{\lambda \to \bar{\lambda}^-} \|u_\lambda\|_\infty = 0$ *and* $\lim_{\lambda \to \tilde{\lambda}^-} \|v_\lambda\|_\infty = \|v_{\tilde{\lambda}}\|_\infty = \beta_{\mu,\tilde{\lambda}}$.

(iii) *For any nonnegative* $\mu_1 < \mu_2$, S_{p,k,μ_2} *lies on the right hand side of* S_{p,k,μ_1}. *(So* S_{p,k,μ_1} *and* S_{p,k,μ_2} *do not intersect.)*

(iv) *For the ending points* $(\tilde{\lambda}, \|v_{\tilde{\lambda}}\|_\infty)$ *of* $S_{p,k,\mu}$ *with* $\mu > 0$, $\tilde{\lambda}$ *is a continuous, strictly increasing function of* $\mu > 0$, $\|v_{\tilde{\lambda}}\|_\infty$ *is a continuous, strictly decreasing function of* $\mu > 0$,

$$\lim_{\mu \to 0^+} (\tilde{\lambda}, \|v_{\tilde{\lambda}}\|_\infty) = (0, \infty) \ \text{ and } \ \lim_{\mu \to \infty} (\tilde{\lambda}, \|v_{\tilde{\lambda}}\|_\infty) = (\infty, 0). \tag{2.2}$$

(v) *For the turning points* $(\lambda^*, \|u_{\lambda^*}\|_\infty)$ *of* $S_{p,k,\mu}$ *with* $\mu > 0$, λ^* *is a continuous, strictly increasing function of* $\mu > 0$, $\|u_{\lambda^*}\|_\infty$ *is a continuous function of* $\mu > 0$,

$$\lim_{\mu \to 0^+} (\lambda^*, \|u_{\lambda^*}\|_\infty) = (0, \infty) \ \text{ and } \ \lim_{\mu \to \infty} (\lambda^*, \|u_{\lambda^*}\|_\infty) = (\bar{\lambda}, 0) = \left(\left(\frac{p-1}{k}\right)\left(\frac{\pi}{p}\csc\frac{\pi}{p}\right)^p, 0\right).$$

(vi) When $k = 0$, $m = 1$, $n = 1$, $q \equiv q_1 > p - 1$, $r \equiv r_1 > q$, *and* $f_{k=0,\mu,\lambda}(u) = \lambda u^q - \mu u^r$, *then all points* $(\lambda, \|u_\lambda\|_\infty) \in S_{p,k=0,\mu}$ *satisfy* (2.1).

Remark 2.3 (See Fig. 2.2)**.** By Theorem 2.2, for fixed $p \in (2, \infty)$ and $k > 0$, it is easy to see that, when $\mu \to \infty$, $S_{p,k,\mu}$ converges to the half-line $[\bar{\lambda}, \infty)$ on the positive λ-axis.

3 Lemmas

To prove Theorems 2.1–2.2 for p-Laplacian problem (1.1), (1.3), we need the following Lemmas 3.1 and 3.3–3.12. In particular, Theorems 2.1–2.2 is based on Lemma 3.1 which is due to Wang and Yeh [14]. Wang and Yeh [14] considered the p-Laplacian Dirichlet problem with one parameter λ:

$$\begin{cases} (\varphi_p(u'(x)))' + f_\lambda(u(x)) = 0, \ -1 < x < 1, \\ u(-1) = u(1) = 0. \end{cases} \tag{3.1}$$

They assumed that the nonlinearity

$$f_\lambda(u) \equiv \lambda g(u) - h(u), \tag{3.2}$$

where functions $g, h \in C[0, \infty) \cap C^2(0, \infty)$ satisfy hypotheses (H1)–(H4) if $1 < p \le 2$ and satisfy hypotheses (H1)–(H5) if $p > 2$:

(H1) $g(0) = h(0) = 0$, $g(u), h(u) > 0$ on $(0, \infty)$, and

$$0 = \lim_{u \to 0^+} \frac{h(u)}{u^{p-1}} \le m_0^g \equiv \lim_{u \to 0^+} \frac{g(u)}{u^{p-1}} < \infty.$$

(H2) The positive function $h(u)/g(u)$ is strictly increasing on $(0, \infty)$, and

$$\lim_{u \to 0^+} \frac{h(u)}{g(u)} = 0, \quad \lim_{u \to \infty} \frac{h(u)}{g(u)} = \infty.$$

(H3) $(p-2)g'(u) - ug''(u) < 0$ on $(0, \infty)$ and $(p-2)h'(u) - uh''(u) < 0$ on $(0, \infty)$.

(H4) The positive function $[(p-2)h'(u) - uh''(u)] \,/\, [(p-2)g'(u) - ug''(u)]$ is strictly increasing on $(0, \infty)$, and

$$\lim_{u \to 0^+} \frac{(p-2)h'(u) - uh''(u)}{(p-2)g'(u) - ug''(u)} = 0, \qquad \lim_{u \to \infty} \frac{(p-2)h'(u) - uh''(u)}{(p-2)g'(u) - ug''(u)} = \infty.$$

(H5) There exists a positive number $p^* > p - 1$ such that $g(u)/u^{p^*}$ is strictly decreasing on $(0, \infty)$ and $h(u)/u^{p^*}$ is strictly increasing on $(0, \infty)$. In addition, for each fixed $s \in (0, 1)$,

$$\frac{h(su)}{u^{p-1}} \left(\frac{h(u)g(su)}{g(u)h(su)} - 1 \right)$$

is a strictly increasing function of u on $(0, \infty)$, and

$$\lim_{u \to \infty} \frac{h(u)g(su)}{g(u)h(su)} \in (1, \infty].$$

Notice that, for p-Laplacian problem (3.1), hypotheses (H1)–(H2) imply that, for each fixed $\lambda > 0$, there exists a unique positive number β_λ such that

$$\begin{cases} f_\lambda(u) = \lambda g(u) - h(u) > 0 \text{ on } (0, \beta_\lambda), \\ f_\lambda(0) = \lambda g(0) - h(0) = 0 \text{ and } f_\lambda(\beta_\lambda) = \lambda g(\beta_\lambda) - h(\beta_\lambda) = 0, \\ f_\lambda(u) = \lambda g(u) - h(u) < 0 \text{ on } (\beta_\lambda, \infty). \end{cases}$$

Moreover, the number β_λ is a continuous, strictly increasing function of λ on $(0, \infty)$, $\lim_{\lambda\to 0^+} \beta_\lambda = 0$ and $\lim_{\lambda\to\infty} \beta_\lambda = \infty$. See [14, (1.4)–(1.5)]. Also, hypotheses (H1)–(H4) imply that, for each fixed $\lambda > 0$, the function $f_\lambda(u)$ with $\lambda > 0$ is p-convex-concave on $(0, \beta_\lambda)$. More precisely, there exists a unique positive number $\gamma_\lambda < \beta_\lambda$ such that

$$\begin{cases} (p-2)f'_\lambda(u) - uf''_\lambda(u) < 0 \text{ on } (0, \gamma_\lambda), \\ (p-2)f'_\lambda(\gamma_\lambda) - \gamma_\lambda f''_\lambda(\gamma_\lambda) = 0, \\ (p-2)f'_\lambda(u) - uf''_\lambda(u) > 0 \text{ on } (\gamma_\lambda, \beta_\lambda). \end{cases}$$

See [14, (1.6)]. In [14], Wang and Yeh are concerned only with positive solutions u of (3.1) satisfying $0 < \|u\|_\infty < \beta_\lambda$. Let

$$\hat{\lambda} \equiv \left(\frac{p-1}{m_0^g}\right)\left(\frac{\pi}{p}\csc\frac{\pi}{p}\right)^p \begin{cases} < \infty & \text{if } m_0^g > 0, \\ = \infty & \text{if } m_0^g = 0. \end{cases} \tag{3.3}$$

For $f_\lambda(u) = \lambda g(u) - h(u)$ in (3.2), we define $F_\lambda(u) = \int_0^u f_\lambda(t)dt$ and

$$T_\lambda(\alpha) = \left(\frac{p-1}{p}\right)^{1/p} \int_0^\alpha [F_\lambda(\alpha) - F_\lambda(u)]^{-1/p} du \quad \text{for } 0 < \alpha < \beta_\lambda.$$

Lemma 3.1. *Consider p-Laplacian problem* (3.1) *with* $p > 1$*. Then the following assertions (i)–(ii) hold:*

(i) *([14, Theorem 2.1 and Fig. 1]) Let* $1 < p \le 2$*. If* $f_\lambda(u) = \lambda g(u) - h(u)$, $g, h \in C[0,\infty) \cap C^2(0,\infty)$ *satisfy (H1)–(H4). Then the bifurcation diagram consists of a continuous, ⊂-shaped curve on the* $(\lambda, \|u\|_\infty)$*-plane. More precisely, the there exists a positive number* $\lambda^* < \hat{\lambda}$ *such that* (1.1) *has exactly two positive solutions* u_λ, v_λ *with* $u_\lambda < v_\lambda$ *for* $\lambda^* < \lambda < \hat{\lambda}$*, exactly one positive solution* v_λ *for* $\lambda = \lambda^*$ *and* $\lambda \ge \hat{\lambda}$*, and no positive solution for* $0 < \lambda < \lambda^*$*. Moreover,* $\lim_{\lambda\to\hat{\lambda}^-} \|u_\lambda\|_\infty = 0$ *and* $\lim_{\lambda\to\infty} \|v_\lambda\|_\infty = \infty$.

(ii) *([14, Theorem 2.3 and Fig. 3]) Let* $p > 2$*. If* $f_\lambda(u) = \lambda g(u) - h(u)$, $g, h \in C[0,\infty) \cap C^2(0,\infty)$ *satisfy (H1)–(H5). Then the bifurcation diagram consists of a continuous, ⊂-shaped curve on the* $(\lambda, \|u\|_\infty)$*-plane. More precisely, there exist three positive numbers* $\lambda^* < \tilde{\lambda}$ *and* $\beta_{\tilde{\lambda}}$ *satisfying* $\lambda^* < \hat{\lambda}$ $(\le \infty)$ *and* $f_{\tilde{\lambda}}(\beta_{\tilde{\lambda}}) = 0$ *and* $\lim_{\alpha\to\beta_{\tilde{\lambda}}^-} T_{\tilde{\lambda}}(\alpha) = 1$ *such that:*

  (a) *(See [14, Fig. 3(a)–(b)]) If* $\tilde{\lambda} < \hat{\lambda}$ $(\le \infty)$*, then* (1.1) *has exactly two positive solutions* u_λ, v_λ *with* $u_\lambda < v_\lambda$ *for* $\lambda^* < \lambda < \tilde{\lambda}$*, exactly one positive solution* u_λ *for* $\lambda = \lambda^*$ *and* $\tilde{\lambda} \le \lambda < \hat{\lambda}$*, and no positive solution for* $0 < \lambda < \lambda^*$ *and for* $\lambda \ge \hat{\lambda}$ *(if* $\hat{\lambda} < \infty$*).*

  (b) *(See [14, Fig.3(c)–(d)]) If* $\hat{\lambda} \le \tilde{\lambda}$*, then* (1.1) *has exactly two positive solutions* u_λ, v_λ *with* $u_\lambda < v_\lambda$ *for* $\lambda^* < \lambda < \hat{\lambda}$*, exactly one positive solution* v_λ *for* $\lambda = \lambda^*$ *and for* $\hat{\lambda} \le \lambda < \tilde{\lambda}$ *(if* $\tilde{\lambda} > \hat{\lambda}$*), and no positive solution for* $0 < \lambda < \lambda^*$ *and* $\lambda \ge \tilde{\lambda}$*. Moreover,* $\lim_{\lambda\to\hat{\lambda}^-} \|u_\lambda\|_\infty = 0$ *and* $\lim_{\lambda\to\tilde{\lambda}^-} \|v_\lambda\|_\infty = \beta_{\tilde{\lambda}}$.

Remark 3.2. To Lemma 3.1(i)–(ii), Wang and Yeh [14, Corollaries 2.2 and 2.4] gave examples of generalized polynomial nonlinearities for

$$f_\lambda(u) = \lambda g(u) - h(u) = \lambda(ku^{p-1} + u^q) - u^r$$

satisfying $r > q > p - 1 > 0$ and $k \geq 0$, which is a special case of

$$f_{k,\mu,\lambda}(u) = \lambda\left(ku^{p-1} + \sum_{i=1}^{m} a_i u^{q_i}\right) - \mu \sum_{j=1}^{n} b_j u^{r_j}$$

defined in (1.2) satisfying (1.3).

For p-Laplacian problem (1.1), (1.3) with two parameters μ and λ and $f_{k,\mu,\lambda}(u)$ defined in (1.2), we define the time map formula as follows:

$$T_{\mu,\lambda}(\alpha) = \left(\frac{p-1}{p}\right)^{1/p} \int_0^\alpha \frac{du}{\left[F_{k,\mu,\lambda}(\alpha) - F_{k,\mu,\lambda}(u)\right]^{1/p}} \quad \text{for } 0 < \alpha < \beta_{\mu,\lambda}, \tag{3.4}$$

where $\beta_{\mu,\lambda}$ is defined in (1.4) and

$$F_{k,\mu,\lambda}(u) = \int_0^u f_{k,\mu,\lambda}(t)dt. \tag{3.5}$$

We define $f_{k,\mu,\lambda}(u) = \lambda g(u) - \mu\tilde{h}(u)$ where $g(u) = ku^{p-1} + \sum_{i=1}^m a_i u^{q_i}$, $\tilde{h}(u) = \sum_{j=1}^n b_j u^{r_j}$, $G(u) = \int_0^u g(t)dt$ and $\tilde{H}(u) = \int_0^u \tilde{h}(t)dt$.

We suppose that $u_{\mu,\lambda}(x)$ is a (classical) positive solution of p-Laplacian problem (1.1), (1.3) satisfying (1.12). Then (classical) positive solution $u_{\mu,\lambda}(x)$ corresponds to $\|u_{\mu,\lambda}\|_\infty = \alpha$ and

$$T_{\mu,\lambda}(\alpha) = \left(\frac{p-1}{p}\right)^{1/p} \int_0^\alpha \frac{du}{\left[F_{k,\mu,\lambda}(\alpha) - F_{k,\mu,\lambda}(u)\right]^{1/p}} = 1 \quad \text{for } 0 < \alpha < \beta_{\mu,\lambda}. \tag{3.6}$$

See, e.g., [8, (3.9)].

Recall the number $\bar{\lambda} = \left(\frac{p-1}{k}\right)\left(\frac{\pi}{p}\csc\frac{\pi}{p}\right)^p$ defined in (1.14).

Lemma 3.3. *Consider p-Laplacian problem (1.1), (1.3) with $p > 1$, $\lambda > 0$ and $\mu > 0$. Then the following assertions (i)–(ii) hold:*

(i) $\lim_{\alpha\to 0^+} T_{\mu,\lambda}(\alpha) = (\frac{\bar{\lambda}}{\lambda})^{1/p}$ *and $T_{\mu,\lambda}(\alpha)$ has exactly an critical point at some $\alpha^*_{\mu,\lambda}$, a minimum, on $(0, \beta_{\mu,\lambda})$. Moreover,*

$$\lim_{\alpha\to\beta^-_{\mu,\lambda}} T_{\mu,\lambda}(\alpha) = \infty \quad \text{if } 1 \leq p < 2.$$

(ii) There exist two positive numbers $C < D < \beta_{\mu,\lambda}$ such that $C < \alpha^*_{\mu,\lambda} < D$ where $C = C(k, \mu, \lambda)$, $D = D(k, \mu, \lambda)$ satisfy

$$(p-1)f_{k,\mu,\lambda(\mu)}(C) - Cf'_{k,\mu,\lambda(\mu)}(C) = 0 \quad \text{and} \quad pF_{k,\mu,\lambda(\mu)}(D) - Df_{k,\mu,\lambda(\mu)}(D) = 0, \tag{3.7}$$

respectively. Cf. [14, (3.10) and (3.11)]. Then $T'_{\mu,\lambda}(\alpha) < 0$ for $\alpha \in (0, C]$ and $T'_{\mu,\lambda}(\alpha) > 0$ for $\alpha \in [D, \beta_{\mu,\lambda})$.

Proof. Parts (i) and (ii) simply follow by (1.4), (1.11), and slight modification of the proofs of [14, Lemmas 3.1 and 3.2]. We omit the detailed proofs here. □

We show comparison results for $T_{\mu,\lambda}(\alpha)$ in the next lemma; cf. [7, Lemma 3.3(i)–(ii)]. Notice that, for any fixed $\mu > 0$ and $0 < \lambda_1 < \lambda_2$, $\beta_{\mu,\lambda_1} < \beta_{\mu,\lambda_2}$ by (1.6), and for any fixed $\lambda > 0$ and $0 < \mu_1 < \mu_2$, $\beta_{\mu_2,\lambda} < \beta_{\mu_1,\lambda}$ by (1.7).

Lemma 3.4. *Consider p-Laplacian problem (1.1), (1.3) with $p > 1$. Then the following assertions (i)–(ii) hold:*

(i) For any fixed $\mu > 0$ and $0 < \lambda_1 < \lambda_2$, $T_{\mu,\lambda_1}(\alpha) > T_{\mu,\lambda_2}(\alpha)$ for $0 < \alpha < \beta_{\mu,\lambda_1}$.

(ii) For any fixed $\lambda > 0$ and $0 < \mu_1 < \mu_2$, $T_{\mu_1,\lambda}(\alpha) < T_{\mu_2,\lambda}(\alpha)$ for $0 < \alpha < \beta_{\mu_2,\lambda}$.

Proof. The proofs of parts (i)–(ii) follow by modification of those of [7, Lemma 3.3(i)–(ii)]. We omit them here. □

Lemma 3.5. *Consider p-Laplacian problem (1.1), (1.3) with $p > 1$. Then the following assertions (i)–(ii) hold:*

(i) For any fixed $\mu \geq 0$ and $0 < \lambda_1 < \lambda_2$, $T_{\mu,\lambda}(\alpha)$ is a continuous function of $\lambda \in [\lambda_1, \lambda_2]$ for $0 < \alpha < \beta_{\mu,\lambda_1}$.

(ii) For any fixed $\lambda > 0$ and $0 \leq \mu_1 < \mu_2$, $T_{\mu,\lambda}(\alpha)$ is a continuous function of $\mu \in [\mu_1, \mu_2]$ for $0 < \alpha < \beta_{\mu_2,\lambda}$.

Proof. The proofs of parts (i)–(ii) follow by modification of those of [7, Lemma 3.4(i)–(ii)]. We omit them here. □

By Lemma 3.3(i), $T_{\mu,\lambda}(\alpha)$ has exactly one critical point at some $\alpha^*_{\mu,\lambda}$, a minimum, on $(0, \beta_{\mu,\lambda})$. Let

$$m(\mu, \lambda) \equiv T_{\mu,\lambda}(\alpha^*_{\mu,\lambda}) = \min_{\alpha \in (0,\beta_{\mu,\lambda})} T_{\mu,\lambda}(\alpha).$$

Lemma 3.6. *Consider p-Laplacian problem (1.1), (1.3) with $p > 1$. Then the following assertions (i)–(ii) hold:*

(i) For any fixed $\mu \in (0, \infty)$, there exists a unique $\lambda^* > 0$ such that $m(\mu, \lambda^*) = 1$.

(ii) For any fixed $\lambda \in (0, \bar{\lambda})$, there exists a unique $\mu^* > 0$ such that $m(\mu^*, \lambda) = 1$.

Moreover, for any fixed $\lambda \geq \bar{\lambda}$ and $\mu > 0$, $m(\mu, \lambda) < 1$.

Proof. (I) We prove part (ii). We have that $\lim_{\alpha\to\infty} T_{\mu=0,\lambda}(\alpha) = 0$, which follows from Proposition 1.1(i) and since $\lim_{\mu\to 0^+} T_{\mu,\lambda}(\alpha) = T_{\mu=0,\lambda}(\alpha)$. So we can find a number $\mu_1 > 0$ such that $m(\mu_1, \lambda) = \min_{\alpha\in(0,\beta_{\mu_1,\lambda})} T_{\mu_1,\lambda}(\alpha) < 1$. In addition, we have that $\lim_{\alpha\to 0^+} T_{\mu,\lambda}(\alpha) > 1$, which follows from Lemma 3.3(i) for $0 < \lambda < \bar{\lambda}$. By (3.7), we compute and obtain that

$$\frac{\lambda}{\mu} = \frac{\sum_{j=1}^{n} b_j (r_j - p + 1) C^{r_j}}{\sum_{i=1}^{m} a_i (q_i - p + 1) C^{q_i}} = \frac{\sum_{j=1}^{n} b_j \frac{r_j - p + 1}{r_j + 1} D^{r_j}}{\sum_{i=1}^{m} a_i \frac{q_i - p + 1}{q_i + 1} D^{q_i}}.$$

So, for fixed $\lambda \in (0, \bar{\lambda})$, we have that $\lim_{\mu\to\infty} \alpha^*_{\mu,\lambda} = 0$ since $\lim_{\mu\to\infty} C = \lim_{\mu\to\infty} D = 0$ and $\alpha^*_{\mu,\lambda} \in (C, D)$ by Lemma 3.3(ii). Hence we can find a number $\mu_2 > 0$ such that $m(\mu_2, \lambda) = \min_{\alpha\in(0,\beta_{\mu_2,\lambda})} T_{\mu_2,\lambda}(\alpha) > 1$.

Next, we set positive numbers $\alpha_1 \equiv \inf_{\mu\in[\mu_1,\mu_2]} \alpha^*_{\mu,\lambda}$ and $\alpha_2 \equiv \sup_{\mu\in[\mu_1,\mu_2]} \alpha^*_{\mu,\lambda} \geq \alpha_1$. If $\alpha_1 = \alpha_2$, then $\alpha^*_{\mu,\lambda} = \alpha_1 = \alpha_2$ for all $\mu \in [\mu_1, \mu_2]$. Thus $T_{\mu_2,\lambda}(\alpha_1) = m(\mu_2, \lambda) > 1$ and $T_{\mu_1,\lambda}(\alpha_1) = m(\mu_1, \lambda) < 1$. So, by Lemma 3.5(ii) and the Intermediate Value Theorem, there exists $\mu^* \in (\mu_1, \mu_2)$ such that

$$m(\mu^*, \lambda) = T_{\mu^*,\lambda}(\alpha_1) = 1.$$

By Lemma 3.4(ii), $m(\mu, \lambda) = T_{\mu,\lambda}(\alpha_1)$ is strictly increasing in $\mu \in [\mu_1, \mu_2]$, and hence μ^* is unique.

While if $\alpha_1 < \alpha_2$, we first show that $m(\mu, \lambda)$ is a continuous function of μ on $[\mu_1, \mu_2]$ as follows. By Lemma 3.4(ii) and Lemma 3.5(ii), for each $\mu_1 < \mu_2$ and fixed $\alpha \in (0, \beta_{\mu_2,\lambda})$, $T_{\mu,\lambda}(\alpha)$ is a continuous, strictly increasing function of μ on (μ_1, μ_2). So for any fixed $\breve{\mu} \in [\mu_1, \mu_2]$, by the Dini Theorem [12, p. 195], it is easy to see that

$$\lim_{\mu\to\breve{\mu}} \left(\min_{\alpha\in[\alpha_1,\alpha_2]} T_{\mu,\lambda}(\alpha) \right) = \min_{\alpha\in[\alpha_1,\alpha_2]} T_{\breve{\mu},\lambda}(\alpha). \tag{3.8}$$

Since for any $\mu \in [\mu_1, \mu_2]$, the minimum of $T_{\mu,\lambda}(\alpha)$ occurs at $\alpha^*_{\mu,\lambda} \in [\alpha_1, \alpha_2]$. So

$$m(\mu, \lambda) = \min_{\alpha\in(0,\beta_{\mu,\lambda})} T_{\mu,\lambda}(\alpha) = \min_{\alpha\in[\alpha_1,\alpha_2]} T_{\mu,\lambda}(\alpha) \quad \text{for } \mu \in [\mu_1, \mu_2]. \tag{3.9}$$

By (3.8) and (3.9), $\lim_{\mu\to\breve{\mu}} m(\mu, \lambda) = m(\breve{\mu}, \lambda)$. Hence $m(\mu, \lambda)$ is a continuous function of μ on $[\mu_1, \mu_2]$. By the Intermediate Value Theorem, there exists $\mu^* \in (\mu_1, \mu_2)$ such that $m(\mu^*, \lambda) = 1$. Moreover, since $m(\mu, \lambda)$ is strictly increasing in $\mu \in [\mu_1, \mu_2]$, we obtain that μ^* is unique.

For any fixed $\lambda \geq \bar{\lambda}$ and $\mu > 0$. By Lemma 3.3, we have $\lim_{\alpha\to0^+} T_{\mu,\lambda}(\alpha) \leq 1$ and $m(\mu, \lambda) < 1$.

By above, part (ii) holds.

(II) The proof of part (i) is similar to that of part (ii). We omit it here.

The proof of Lemma 3.6 is now complete. □

Lemma 3.7 (See Theorems 2.1–2.2 and Figs. 2.1–2.2)**.** *Consider p-Laplacian problem* (1.1), (1.3) *with $p > 1$. Then, for the turning points $(\lambda^*, \|u_{\lambda^*}\|_\infty)$ of $S_{p,k,\mu}$ with varying $\mu > 0$, λ^* is a continuous, strictly increasing function of $\mu > 0$. Moreover, $\lim_{\mu\to0^+} \lambda^* = 0$ and $\lim_{\mu\to\infty} \lambda^* = \bar{\lambda}$.*

Proof. For fixed $\mu_2 > \mu_1 > 0$, by Lemma 3.6(i), there exists $\lambda^*_2(\mu_2) > 0$ (resp. $\lambda^*_1(\mu_1) > 0$) such that $T_{\mu_2,\lambda^*_2}(\alpha)$ (resp. $T_{\mu_1,\lambda^*_1}(\alpha)$) has exactly one minimum point $\alpha_{\mu_2,\lambda^*_2} \in (0, \beta_{\mu_2,\lambda^*_2})$ (resp. $\alpha_{\mu_1,\lambda^*_1} \in (0, \beta_{\mu_1,\lambda^*_1})$) satisfying $T_{\mu_2,\lambda^*_2}(\alpha_{\mu_2,\lambda^*_2}) = 1$ (resp. $T_{\mu_1,\lambda^*_1}(\alpha_{\mu_1,\lambda^*_1}) = 1$). Observe that $\alpha_{\mu_2,\lambda^*_2} \in (0, \beta_{\mu_2,\lambda^*_2}) \subsetneq (0, \beta_{\mu_1,\lambda^*_2})$. So we obtain that

$$\begin{aligned}
T_{\mu_1,\lambda^*_2}(\alpha_{\mu_2,\lambda^*_2}) &= \left(\frac{p-1}{p}\right)^{1/p} \int_0^{\alpha_{\mu_2,\lambda^*_2}} [\lambda^*_2(G(\alpha_{\mu_2,\lambda^*_2}) - G(u)) - \mu_1(\tilde{H}(\alpha_{\mu_2,\lambda^*_2}) - \tilde{H}(u))]^{-1/p} du \\
&< \left(\frac{p-1}{p}\right)^{1/p} \int_0^{\alpha_{\mu_2,\lambda^*_2}} [\lambda^*_2(G(\alpha_{\mu_2,\lambda^*_2}) - G(u)) - \mu_2(\tilde{H}(\alpha_{\mu_2,\lambda^*_2}) - \tilde{H}(u))]^{-1/p} du \\
&= T_{\mu_2,\lambda^*_2}(\alpha_{\mu_2,\lambda^*_2}) \\
&= 1.
\end{aligned}$$

So

$$\min_{\alpha\in(0,\beta_{\mu_1,\lambda^*_2})} T_{\mu_1,\lambda^*_2}(\alpha) \leq T_{\mu_1,\lambda^*_2}(\alpha_{\mu_2,\lambda^*_2}) < 1. \tag{3.10}$$

For any $\alpha \in (0, \beta_{\mu_1,\lambda_1^*})$, we have that

$$T_{\mu_1,\lambda_1^*}(\alpha) \geq \min_{\alpha \in (0,\beta_{\mu_1,\lambda_1^*})} T_{\mu_1,\lambda_1^*}(\alpha) = T_{\mu_1,\lambda_1^*}(\alpha_{\mu_1,\lambda_1^*}) = 1. \tag{3.11}$$

By (3.10), (3.11) and Lemma 3.4(i), we obtain $\lambda_1^*(\mu_1) < \lambda_2^*(\mu_2)$. By Lemma 3.6, we obtain $\lambda^*((0,\infty)) = (0,\bar{\lambda})$. Hence $\lambda^*(\mu) : (0,\infty) \to (0,\bar{\lambda})$ is a continuous, strictly increasing function. Moreover, $\lim_{\mu \to 0^+} \lambda^*(\mu) = 0$ and $\lim_{\mu \to \infty} \lambda^*(\mu) = \bar{\lambda}$.

The proof of Lemma 3.7 is now complete. □

Lemma 3.8 (See Theorems 2.1–2.2 and Figs. 2.1–2.2)**.** *Consider p-Laplacian problem* (1.1), (1.3) *with $p > 1$ and $k \geq 0$. Then, for the turning points $(\lambda^*, \|u_{\lambda^*}\|_\infty)$ of $S_{p,k,\mu}$ with varying $\mu > 0$, $\frac{\lambda^*(\mu)}{\mu}$ is a continuous, strictly decreasing function of $\mu > 0$. Moreover, $\lim_{\mu \to 0^+} \frac{\lambda^*(\mu)}{\mu} = \infty$ and $\lim_{\mu \to \infty} \frac{\lambda^*(\mu)}{\mu} = 0$.*

Proof. For fixed $\mu_2 > \mu_1 > 0$, we let $N_1 \equiv \frac{\lambda^*(\mu_1)}{\mu_1}$ and $N_2 \equiv \frac{\lambda^*(\mu_2)}{\mu_2}$. Then

$$\begin{aligned}
&T_{\mu_2,\lambda^*(\mu_2)}(\|u_{\lambda^*(\mu_2)}\|_\infty) = 1 = T_{\mu_1,\lambda^*(\mu_1)}(\|u_{\lambda^*(\mu_1)}\|_\infty) \\
&\quad = T_{\mu_1,N_1\mu_1}(\|u_{\lambda^*(\mu_1)}\|_\infty) \\
&\quad = \left(\frac{p-1}{p}\right)^{1/p} \int_0^{\|u_{\lambda^*(\mu_1)}\|_\infty} [N_1\mu_1(G(\|u_{\lambda^*(\mu_1)}\|_\infty) - G(u)) - \mu_1(\tilde{H}(\|u_{\lambda^*(\mu_1)}\|_\infty) - \tilde{H}(u))]^{-1/p} du \\
&\quad = \left(\frac{\mu_2}{\mu_1}\right)^{1/p} \left(\frac{p-1}{p}\right)^{1/p} \\
&\qquad \times \int_0^{\|u_{\lambda^*(\mu_1)}\|_\infty} [N_1\mu_2(G(\|u_{\lambda^*(\mu_1)}\|_\infty) - G(u)) - \mu_2(\tilde{H}(\|u_{\lambda^*(\mu_1)}\|_\infty) - \tilde{H}(u))]^{-1/p} du \\
&\quad = \left(\frac{\mu_2}{\mu_1}\right)^{1/p} T_{\mu_2,N_1\mu_2}(\|u_{\lambda^*(\mu_1)}\|_\infty) \\
&\quad > T_{\mu_2,N_1\mu_2}(\|u_{\lambda^*(\mu_1)}\|_\infty)
\end{aligned}$$

since $\mu_2 > \mu_1 > 0$. If $\lambda^*(\mu_2) \geq N_1\mu_2$, then $T_{\mu_2,N_1\mu_2}(\|u_{\lambda^*(\mu_1)}\|_\infty) \geq T_{\mu_2,\lambda^*(\mu_2)}(\|u_{\lambda^*(\mu_1)}\|_\infty) \geq T_{\mu_2,\lambda^*(\mu_2)}(\|u_{\lambda^*(\mu_2)}\|_\infty)$ by Lemma 3.4(i) and Lemma 3.3(i), which leads to a contradiction since $T_{\mu_2,\lambda^*(\mu_2)}(\|u_{\lambda^*(\mu_2)}\|_\infty) > T_{\mu_2,N_1\mu_2}(\|u_{\lambda^*(\mu_1)}\|_\infty)$. Hence we obtain $\lambda^*(\mu_2) < N_1\mu_2$. So

$$N_2 = \frac{\lambda^*(\mu_2)}{\mu_2} < N_1 = \frac{\lambda^*(\mu_1)}{\mu_1}.$$

By Lemma 3.7, we obtain that $\lambda^*(\mu)$ is a continuous function of $\mu > 0$. Hence $\frac{\lambda^*(\mu)}{\mu}$ is a continuous, strictly decreasing function of $\mu > 0$.

We prove $\lim_{\mu \to 0^+} \frac{\lambda^*(\mu)}{\mu} = \infty$ by method of contradiction. Suppose $\lim_{\mu \to 0^+} \frac{\lambda^*(\mu)}{\mu} < \infty$, then there exists a positive $N_3 > \lim_{\mu \to 0^+} \frac{\lambda^*(\mu)}{\mu}$ such that

$$\begin{aligned}
&\lim_{\mu \to 0^+} \left(\frac{1}{\mu}\right)^{1/p} T_{\mu=1,\lambda=N_3}\left(\|u_{\lambda^*(\mu)}\|_\infty\right) \\
&\quad = \lim_{\mu \to 0^+} \left(\frac{1}{\mu}\right)^{1/p} \left(\frac{p-1}{p}\right)^{1/p} \\
&\qquad \times \int_0^{\|u_{\lambda^*(\mu)}\|_\infty} [N_3(G(\|u_{\lambda^*(\mu)}\|_\infty) - G(u)) - (\tilde{H}(\|u_{\lambda^*(\mu)}\|_\infty) - \tilde{H}(u))]^{-1/p} du
\end{aligned}$$

$$
\begin{aligned}
&< \lim_{\mu\to 0^+}\left(\frac{1}{\mu}\right)^{1/p}\left(\frac{p-1}{p}\right)^{1/p} \\
&\quad \times \int_0^{\|u_{\lambda^*(\mu)}\|_\infty} [\frac{\lambda^*(\mu)}{\mu}(G(\|u_{\lambda^*(\mu)}\|_\infty)-G(u))-(\tilde{H}(\|u_{\lambda^*(\mu)}\|_\infty)-\tilde{H}(u))]^{-1/p}du \\
&= \lim_{\mu\to 0^+}\left(\frac{p-1}{p}\right)^{1/p} \\
&\quad \times \int_0^{\|u_{\lambda^*(\mu)}\|_\infty} [\lambda^*(\mu)(G(\|u_{\lambda^*(\mu)}\|_\infty)-G(u))-\mu(\tilde{H}(\|u_{\lambda^*(\mu)}\|_\infty)-\tilde{H}(u))]^{-1/p}du \\
&= \lim_{\mu\to 0^+} T_{\mu,\lambda^*(\mu)}(\|u_{\lambda^*(\mu)}\|_\infty).
\end{aligned}
$$

By Lemma 3.3(i), there exist two fixed positive numbers α_{1,N_3} and L_{1,N_3} such that $T_{\mu=1,\lambda=N_3}(\alpha_{1,N_3}) = L_{1,N_3}$ is an absolute minimum on $(0,\beta_{1,N_3})$. So

$$
1 = \lim_{\mu\to 0^+} T_{\mu,\lambda^*(\mu)}(\|u_{\lambda^*(\mu)}\|_\infty) > \lim_{\mu\to 0^+}\left(\frac{1}{\mu}\right)^{1/p} T_{\mu=1,\lambda=N_3}(\|u_{\lambda^*(\mu)}\|_\infty) \geq \lim_{\mu\to 0^+}\left(\frac{1}{\mu}\right)^{1/p} L_{1,N_3} = \infty,
$$

which leads to a contradiction. Hence $\lim_{\mu\to 0^+}\frac{\lambda^*(\mu)}{\mu} = \infty$.

Similarly, we prove $\lim_{\mu\to\infty}\frac{\lambda^*(\mu)}{\mu} = 0$ by method of contradiction. Suppose $\lim_{\mu\to\infty}\frac{\lambda^*(\mu)}{\mu} > 0$, then there exists a positive N_4 such that $N_4 < \lim_{\mu\to\infty}\frac{\lambda^*(\mu)}{\mu}$. By Lemma 3.3(i), there exist two fixed positive numbers α_{1,N_4} and L_{1,N_4} such that $T_{\mu=1,\lambda=N_4}(\alpha_{1,N_4}) = L_{1,N_4}$ is an absolute minimum on $(0,\beta_{1,N_4})$. We then need the next claim.

Claim A. $\lim_{\mu\to\infty} T_{\mu,\lambda^*(\mu)}(\alpha_{1,N_4}) \geq \lim_{\mu\to\infty} T_{\mu,\lambda^*(\mu)}(\|u_{\lambda^*(\mu)}\|_\infty)$.

Proof of Claim A. Since $N_4 < \lim_{\mu\to\infty}\frac{\lambda^*(\mu)}{\mu}$, there exists a positive number μ_0 such that, for all $\mu > \mu_0$, $N_4 < \frac{\lambda^*(\mu)}{\mu}$. By (1.4) and (1.6), for all $\mu > \mu_0$, we have $\beta_{1,N_4} < \beta_{1,\frac{\lambda^*(\mu)}{\mu}}$. For $\mu > 0$, by (1.4), we have $\beta_{1,\frac{\lambda^*(\mu)}{\mu}} = \beta_{\mu,\lambda^*(\mu)}$ since $f_{k,1,\frac{\lambda^*(\mu)}{\mu}}(\beta_{\mu,\lambda^*(\mu)}) = \frac{1}{\mu} f_{k,\mu,\lambda^*(\mu)}(\beta_{\mu,\lambda^*(\mu)}) = 0$. Hence, for all $\mu > \mu_0$, $0 < \alpha_{1,N_4} < \beta_{1,N_4} < \beta_{\mu,\lambda^*(\mu)}$. By Lemma 3.3(i), Lemma 3.6(i) and (3.6), for all $\mu > \mu_0$, we have $T_{\mu,\lambda^*(\mu)}(\alpha_{1,N_4}) \geq T_{\mu,\lambda^*(\mu)}(\|u_{\lambda^*(\mu)}\|_\infty)$. Moreover, $\lim_{\mu\to\infty} T_{\mu,\lambda^*(\mu)}(\alpha_{1,N_4}) \geq \lim_{\mu\to\infty} T_{\mu,\lambda^*(\mu)}(\|u_{\lambda^*(\mu)}\|_\infty)$. So Claim A holds.

We thus have that

$$
\begin{aligned}
&\lim_{\mu\to\infty}\left(\frac{1}{\mu}\right)^{1/p} T_{\mu=1,\lambda=N_4}(\alpha_{1,N_4}) \\
&= \lim_{\mu\to\infty}\left(\frac{1}{\mu}\right)^{1/p}\left(\frac{p-1}{p}\right)^{1/p}\int_0^{\alpha_{1,N_4}}[N_4(G(\alpha_{1,N_4})-G(u))-(\tilde{H}(\alpha_{1,N_4})-\tilde{H}(u))]^{-1/p}du \\
&> \lim_{\mu\to\infty}\left(\frac{1}{\mu}\right)^{1/p}\left(\frac{p-1}{p}\right)^{1/p}\int_0^{\alpha_{1,N_4}}\left[\frac{\lambda^*(\mu)}{\mu}(G(\alpha_{1,N_4})-G(u))-(\tilde{H}(\alpha_{1,N_4})-\tilde{H}(u))\right]^{-1/p}du \\
&= \lim_{\mu\to\infty}\left(\frac{p-1}{p}\right)^{1/p}\int_0^{\alpha_{1,N_4}}[\lambda^*(\mu)(G(\alpha_{1,N_4})-G(u))-\mu(\tilde{H}(\alpha_{1,N_4})-\tilde{H}(u))]^{-1/p}du \\
&= \lim_{\mu\to\infty} T_{\mu,\lambda^*(\mu)}(\alpha_{1,N_4}) \\
&\geq \lim_{\mu\to\infty} T_{\mu,\lambda^*(\mu)}(\|u_{\lambda^*(\mu)}\|_\infty) \quad \text{(by Claim A)} \\
&= 1,
\end{aligned}
$$

which leads to a contradiction since

$$\lim_{\mu\to\infty}\left(\frac{1}{\mu}\right)^{1/p} T_{\mu=1,\lambda=N_4}(\alpha_{1,N_4}) = \lim_{\mu\to\infty}\left(\frac{1}{\mu}\right)^{1/p} L_{1,N4} = 0.$$

Hence $\lim_{\mu\to\infty}\frac{\lambda^*(\mu)}{\mu} = 0$.

The proof of Lemma 3.8 is now complete. □

Lemma 3.9 (See Theorems 2.1–2.2 and Figs. 2.1–2.2)**.** *Consider p-Laplacian problem* (1.1), (1.3) *with $p > 1$ and $k \geq 0$. Then, for the turning points $(\lambda^*, \|u_{\lambda^*}\|_\infty)$ of $S_{p,k,\mu}$ with varying $\mu > 0$,*

$$C < \|u_{\lambda^*}\|_\infty < D, \tag{3.12}$$

where $C = C(k,\mu,\lambda^*(\mu))$, $D = D(k,\mu,\lambda^*(\mu))$ satisfy

$$(p-1)f_{k,\mu,\lambda^*(\mu)}(C) - Cf'_{k,\mu,\lambda^*(\mu)}(C) = 0 \quad \text{and} \quad pF_{k,\mu,\lambda^*(\mu)}(D) - Df_{k,\mu,\lambda^*(\mu)}(D) = 0, \tag{3.13}$$

respectively. Moreover, $\lim_{\mu\to 0^+}\|u_{\lambda^*}\|_\infty = \infty$ and $\lim_{\mu\to\infty}\|u_{\lambda^*}\|_\infty = 0$.

Proof. By Lemma 3.3(ii) and (3.6), it is easy to see that $C < \|u_{\lambda^*}\|_\infty < D$. Equations in (3.13) follow by Eqs. (3.7) directly. By (3.13), (1.2) and (3.5), we then compute and obtain that

$$\frac{\lambda^*(\mu)}{\mu} = \frac{\sum_{j=1}^n b_j(r_j-p+1)C^{r_j}}{\sum_{i=1}^m a_i(q_i-p+1)C^{q_i}} = \frac{\sum_{j=1}^n b_j\frac{r_j-p+1}{r_j+1}D^{r_j}}{\sum_{i=1}^m a_i\frac{q_i-p+1}{q_i+1}D^{q_i}},$$

in which $r_j - p + 1 > 0$ for $j = 1,2,\ldots,n$ and $q_i - p + 1 > 0$ for $i = 1,2,\ldots,m$. Thus, by applying Lemma 3.8 and (1.3), we have that $\lim_{\mu\to 0^+} C = \lim_{\mu\to 0^+} D = \infty$ and $\lim_{\mu\to\infty} C = \lim_{\mu\to\infty} D = 0$. Hence $\lim_{\mu\to 0^+}\|u_{\lambda^*}\|_\infty = \infty$ and $\lim_{\mu\to\infty}\|u_{\lambda^*}\|_\infty = 0$ by (3.12).

The proof of Lemma 3.9 is now complete. □

Lemma 3.10. *Consider p-Laplacian problem* (1.1), (1.3) *with $p > 2$ and $k \geq 0$. Then the following assertions (i)–(ii) hold:*

(i) For any fixed $\mu > 0$, $\lim_{\alpha\to\beta^-_{\mu,\lambda}} T_{\mu,\lambda}(\alpha)$ is a continuous, strictly decreasing function of λ on $(0,\infty)$. Moreover,

$$\lim_{\lambda\to 0^+}\lim_{\alpha\to\beta^-_{\mu,\lambda}} T_{\mu,\lambda}(\alpha) = \infty \quad \text{and} \quad \lim_{\lambda\to\infty}\lim_{\alpha\to\beta^-_{\mu,\lambda}} T_{\mu,\lambda}(\alpha) = 0.$$

(ii) For any fixed $\lambda > 0$, $\lim_{\alpha\to\beta^-_{\mu,\lambda}} T_{\mu,\lambda}(\alpha)$ is a continuous, strictly increasing function of μ on $(0,\infty)$. Moreover,

$$\lim_{\mu\to 0^+}\lim_{\alpha\to\beta^-_{\mu,\lambda}} T_{\mu,\lambda}(\alpha) = 0 \quad \text{and} \quad \lim_{\mu\to\infty}\lim_{\alpha\to\beta^-_{\mu,\lambda}} T_{\mu,\lambda}(\alpha) = \infty.$$

Proof. (I) We prove part (i) where

$$g(u) = ku^{p-1} + \sum_{i=1}^m a_i u^{q_i} \quad \text{and} \quad h(u) = \mu\sum_{j=1}^n b_j u^{r_j} \quad (\text{with } m,n \geq 1 \text{ and } \mu > 0)$$

satisfy (1.3). We take $p^* = \frac{q_m + r_1}{2} > p - 1$. Then it is easy to see that $\frac{g(u)}{u^{p^*}}$ is strictly decreasing on $(0, \infty)$ and $\frac{h(u)}{u^{p^*}}$ is strictly increasing on $(0, \infty)$. For each fixed $s \in (0, 1)$,

$$\frac{h(su)}{u^{p-1}}\left[\frac{h(u)g(su)}{g(u)h(su)} - 1\right] = \frac{h(u)g(su) - h(su)g(u)}{u^{p-1}g(u)}$$
$$= \frac{\mu \sum_{i=1}^{m}\sum_{j=1}^{n} a_i b_j (s^{q_i} - s^{r_j}) u^{q_i + r_j} + \mu k u^{p-1} \sum_{j=1}^{n} b_j (s^{p-1} - s^{r_j}) u^{r_j}}{u^{p-1}(k u^{p-1} + \sum_{i=1}^{m} a_i u^{q_i})}$$

is a strictly increasing function of u on $(0, \infty)$ and $\lim_{u\to\infty} \frac{h(u)g(su)}{g(u)h(su)} = s^{q_m - r_n} \in (1, \infty)$ since $s \in (0, 1)$ and $q_m < r_n$. So g, h satisfy (H5). For $\lambda \in (0, \infty)$, by (3.4), we obtain that

$$\lim_{\alpha \to \beta_{\mu,\lambda}^-} T_{\mu,\lambda}(\alpha)$$
$$= \lim_{\alpha \to \beta_{\mu,\lambda}^-} \left(\frac{p-1}{p}\right)^{1/p} \int_0^\alpha \left[\int_u^\alpha f_{k,\mu,\lambda}(t)dt\right]^{-1/p} du$$
$$= \lim_{\alpha \to \beta_{\mu,\lambda}^-} \left(\frac{p-1}{p}\right)^{1/p} \int_0^\alpha \left[\int_u^\alpha \frac{h(\beta_{\mu,\lambda})}{g(\beta_{\mu,\lambda})} g(t) - h(t)dt\right]^{-1/p} du$$

(since $f_{k,\mu,\lambda}(u) = \lambda g(u) - h(u)$ and by (1.4))

$$= \lim_{\alpha \to \beta_{\mu,\lambda}^-} \left(\frac{p-1}{p}\right)^{1/p} \alpha^{(p-1)/p} \int_0^1 \left[\int_v^1 \frac{h(\beta_{\mu,\lambda})}{g(\beta_{\mu,\lambda})} g(s\alpha) - h(s\alpha)ds\right]^{-1/p} dv$$

(let $u = \alpha v$ and $t = \alpha s$)

$$= \left(\frac{p-1}{p}\right)^{1/p} \beta_{\mu,\lambda}^{(p-1-p^*)/p} \lim_{\alpha \to \beta_{\mu,\lambda}^-} \int_0^1 \left[\int_v^1 s^{p^*} \left(\frac{h(\beta_{\mu,\lambda})g(s\alpha)}{g(\beta_{\mu,\lambda})\,(s\alpha)^{p^*}} - \frac{h(s\alpha)}{(s\alpha)^{p^*}}\right) ds\right]^{-1/p} dv$$
$$= \left(\frac{p-1}{p}\right)^{1/p} \beta_{\mu,\lambda}^{(p-1-p^*)/p} \int_0^1 \left[\int_v^1 \lim_{\alpha \to \beta_{\mu,\lambda}^-} s^{p^*} \left(\frac{h(\beta_{\mu,\lambda})g(s\alpha)}{g(\beta_{\mu,\lambda})\,(s\alpha)^{p^*}} - \frac{h(s\alpha)}{(s\alpha)^{p^*}}\right) ds\right]^{-1/p} dv$$

(by (H5) and the Monotone Convergence Theorem)

$$= \left(\frac{p-1}{p}\right)^{1/p} \int_0^1 \left[\int_v^1 \frac{h(s\beta_{\mu,\lambda})}{\beta_{\mu,\lambda}^{p-1}} \left(\frac{h(\beta_{\mu,\lambda})g(s\beta_{\mu,\lambda})}{g(\beta_{\mu,\lambda})h(s\beta_{\mu,\lambda})} - 1\right) ds\right]^{-1/p} dv. \tag{3.14}$$

By (H5) and since $\beta_{\mu,\lambda}$ is strictly increasing in $\lambda \in (0, \infty)$, we obtain that $\lim_{\alpha \to \beta_{\mu,\lambda}^-} T_{\mu,\lambda}(\alpha)$ is a strictly decreasing function of λ on $(0, \infty)$.

For any number $\lambda_0 \in (0,\infty)$, by (3.14), we obtain that

$$\begin{aligned}
\lim_{\lambda\to\lambda_0}\lim_{\alpha\to\beta_{\mu,\lambda}^-} T_{\mu,\lambda}(\alpha) &= \lim_{\lambda\to\lambda_0}\left(\frac{p-1}{p}\right)^{1/p}\int_0^1\left[\int_v^1 \frac{h(s\beta_{\mu,\lambda})}{\beta_{\mu,\lambda}^{p-1}}\left(\frac{h(\beta_{\mu,\lambda})g(s\beta_{\mu,\lambda})}{g(\beta_{\mu,\lambda})h(s\beta_{\mu,\lambda})}-1\right)ds\right]^{-1/p} dv\\
&= \left(\frac{p-1}{p}\right)^{1/p}\int_0^1\left[\int_v^1 \lim_{\lambda\to\lambda_0}\frac{h(s\beta_{\mu,\lambda})}{\beta_{\mu,\lambda}^{p-1}}\left(\frac{h(\beta_{\mu,\lambda})g(s\beta_{\mu,\lambda})}{g(\beta_{\mu,\lambda})h(s\beta_{\mu,\lambda})}-1\right)ds\right]^{-1/p} dv\\
&\qquad \text{(by (H5) and the Monotone Convergence Theorem)}\\
&= \left(\frac{p-1}{p}\right)^{1/p}\int_0^1\left[\int_v^1 \frac{h(s\beta_{\mu,\lambda_0})}{\beta_{\mu,\lambda_0}^{p-1}}\left(\frac{h(\beta_{\mu,\lambda_0})g(s\beta_{\mu,\lambda_0})}{g(\beta_{\mu,\lambda_0})h(s\beta_{\mu,\lambda_0})}-1\right)ds\right]^{-1/p} dv\\
&= \lim_{\alpha\to\beta_{\mu,\lambda_0}^-} T_{\mu,\lambda_0}(\alpha).
\end{aligned}$$

So we obtain that $\lim_{\alpha\to\beta_{\mu,\lambda}^-} T_{\mu,\lambda}(\alpha)$ is a continuous function of λ on $(0,\infty)$.

Finally, we prove $\lim_{\lambda\to 0^+}\lim_{\alpha\to\beta_{\mu,\lambda}^-} T_{\mu,\lambda}(\alpha) = \infty$ and $\lim_{\lambda\to\infty}\lim_{\alpha\to\beta_{\mu,\lambda}^-} T_{\mu,\lambda}(\alpha) = 0$. By (3.14), we obtain that

$$\begin{aligned}
\lim_{\lambda\to 0^+}\lim_{\alpha\to\beta_{\mu,\lambda}^-} T_{\mu,\lambda}(\alpha) &= \lim_{\lambda\to 0^+}\left(\frac{p-1}{p}\right)^{1/p}\int_0^1\left[\int_v^1 \frac{h(s\beta_{\mu,\lambda})}{\beta_{\mu,\lambda}^{p-1}}\left(\frac{h(\beta_{\mu,\lambda})g(s\beta_{\mu,\lambda})}{g(\beta_{\mu,\lambda})h(s\beta_{\mu,\lambda})}-1\right)ds\right]^{-1/p} dv\\
&= \left(\frac{p-1}{p}\right)^{1/p}\int_0^1\left[\int_v^1 \lim_{\lambda\to 0^+}\frac{h(s\beta_{\mu,\lambda})}{\beta_{\mu,\lambda}^{p-1}}\left(\frac{h(\beta_{\mu,\lambda})g(s\beta_{\mu,\lambda})}{g(\beta_{\mu,\lambda})h(s\beta_{\mu,\lambda})}-1\right)ds\right]^{-1/p} dv
\end{aligned}$$

and

$$\begin{aligned}
\lim_{\lambda\to \infty}\lim_{\alpha\to\beta_{\mu,\lambda}^-} T_{\mu,\lambda}(\alpha) &= \lim_{\lambda\to \infty}\left(\frac{p-1}{p}\right)^{1/p}\int_0^1\left[\int_v^1 \frac{h(s\beta_{\mu,\lambda})}{\beta_{\mu,\lambda}^{p-1}}\left(\frac{h(\beta_{\mu,\lambda})g(s\beta_{\mu,\lambda})}{g(\beta_{\mu,\lambda})h(s\beta_{\mu,\lambda})}-1\right)ds\right]^{-1/p} dv\\
&= \left(\frac{p-1}{p}\right)^{1/p}\int_0^1\left[\int_v^1 \lim_{\lambda\to \infty}\frac{h(s\beta_{\mu,\lambda})}{\beta_{\mu,\lambda}^{p-1}}\left(\frac{h(\beta_{\mu,\lambda})g(s\beta_{\mu,\lambda})}{g(\beta_{\mu,\lambda})h(s\beta_{\mu,\lambda})}-1\right)ds\right]^{-1/p} dv
\end{aligned}$$

by (H5) and the Monotone Convergence Theorem. For each fixed $s \in (0,1)$, we have that, by (H5),

$$\lim_{\lambda\to 0^+}\frac{h(s\beta_{\mu,\lambda})}{\beta_{\mu,\lambda}^{p-1}}\left(\frac{h(\beta_{\mu,\lambda})g(s\beta_{\mu,\lambda})}{g(\beta_{\mu,\lambda})h(s\beta_{\mu,\lambda})}-1\right) = \lim_{\beta_{\mu,\lambda}\to 0^+}\frac{h(s\beta_{\mu,\lambda})}{\beta_{\mu,\lambda}^{p-1}}\left(\frac{h(\beta_{\mu,\lambda})g(s\beta_{\mu,\lambda})}{g(\beta_{\mu,\lambda})h(s\beta_{\mu,\lambda})}-1\right) = 0$$

and

$$\lim_{\lambda\to \infty}\frac{h(s\beta_{\mu,\lambda})}{\beta_{\mu,\lambda}^{p-1}}\left(\frac{h(\beta_{\mu,\lambda})g(s\beta_{\mu,\lambda})}{g(\beta_{\mu,\lambda})h(s\beta_{\mu,\lambda})}-1\right) = \lim_{\beta_{\mu,\lambda}\to \infty}\frac{h(s\beta_{\mu,\lambda})}{\beta_{\mu,\lambda}^{p-1}}\left(\frac{h(\beta_{\mu,\lambda})g(s\beta_{\mu,\lambda})}{g(\beta_{\mu,\lambda})h(s\beta_{\mu,\lambda})}-1\right) = \infty.$$

So $\lim_{\lambda\to 0^+}\lim_{\alpha\to\beta_{\mu,\lambda}^-} T_{\mu,\lambda}(\alpha) = \infty$ and $\lim_{\lambda\to\infty}\lim_{\alpha\to\beta_{\mu,\lambda}^-} T_{\mu,\lambda}(\alpha) = 0$.

(II) The proof of part (ii) is similar to that of part (i). We omit it here.

The proof of Lemma 3.10 is now complete. □

Lemma 3.11. *Consider p-Laplacian problem* (1.1), (1.3) *with* $p > 2$ *and* $k \geq 0$. *Then the following assertions (i)–(ii) hold:*

(i) For any fixed $\mu \in (0,\infty)$, *there exists a unique* $\tilde{\lambda} > 0$ *such that* $\lim_{\alpha\to\beta^-_{\mu,\tilde{\lambda}}} T_{\mu,\tilde{\lambda}}(\alpha) = 1$.

(ii) For any fixed $\lambda \in (0,\infty)$, *there exists a unique* $\tilde{\mu} > 0$ *such that* $\lim_{\alpha\to\beta^-_{\tilde{\mu},\lambda}} T_{\tilde{\mu},\lambda}(\alpha) = 1$.

Proof. (I) We prove part (i). For any fixed $\mu > 0$, by Lemma 3.10(i) and the Intermediate Value Theorem, there exists a unique $\tilde{\lambda} > 0$ such that $\lim_{\alpha\to\beta^-_{\mu,\tilde{\lambda}}} T_{\mu,\tilde{\lambda}}(\alpha) = 1$.

(II) We prove part (ii). For any fixed $\lambda > 0$, by Lemma 3.10(ii) and the Intermediate Value Theorem, there exists a unique $\tilde{\mu} > 0$ such that $\lim_{\alpha\to\beta^-_{\tilde{\mu},\lambda}} T_{\tilde{\mu},\lambda}(\alpha) = 1$.

The proof of Lemma 3.11 is now complete. □

Lemma 3.12 (See Theorem 2.2 and Fig. 2.2)**.** *Consider p-Laplacian problem* (1.1), (1.3) *with* $p > 2$ *and* $k \geq 0$. *Then, for the ending points* $(\tilde{\lambda}, \|v_{\tilde{\lambda}}\|_\infty)$ *of* $S_{p,k,\mu}$ *with varying* $\mu > 0$, $\tilde{\lambda}$ *is a continuous, strictly increasing function of* $\mu > 0$. *Moreover,* $\lim_{\mu\to 0^+} \tilde{\lambda} = 0$ *and* $\lim_{\mu\to\infty} \tilde{\lambda} = \infty$.

Proof. For fixed $\mu_2 > \mu_1 > 0$, by Lemma 3.10(ii), $\lim_{\alpha\to\beta^-_{\mu_2\tilde{\lambda}_1}} T_{\mu_2,\tilde{\lambda}_1}(\alpha) > \lim_{\alpha\to\beta^-_{\mu_1,\tilde{\lambda}_1}} T_{\mu_1,\tilde{\lambda}_1}(\alpha) = 1$. If $\tilde{\lambda}_1 \geq \tilde{\lambda}_2$, then by Lemma 3.10(i), $\lim_{\alpha\to\beta^-_{\mu_2,\tilde{\lambda}_1}} T_{\mu_2,\tilde{\lambda}_1}(\alpha) \leq \lim_{\alpha\to\beta^-_{\mu_2,\tilde{\lambda}_2}} T_{\mu_2,\tilde{\lambda}_2}(\alpha) = 1$, which leads to a contradiction. So we obtain $\tilde{\lambda}_1 < \tilde{\lambda}_2$. By Lemma 3.11, we obtain $\tilde{\lambda}((0,\infty)) = (0,\infty)$. Hence $\tilde{\lambda}(\mu) : (0,\infty) \to (0,\infty)$ is a continuous, strictly increasing function of $\mu > 0$. Moreover, $\lim_{\mu\to 0^+} \tilde{\lambda} = 0$ and $\lim_{\mu\to\infty} \tilde{\lambda} = \infty$.

The proof of Lemma 3.12 is now complete. □

4 Proofs of main results

Proof of Theorem 2.1. Let $1 < p \leq 2$ and $k \geq 0$.

(I)(a) We prove that, for any fixed $\mu > 0$, the bifurcation diagram $S_{p,k,\mu}$ consists of a continuous curve on the $(\lambda, \|u\|_\infty)$-plane. For any fixed $\mu > 0$ and $\lambda > 0$, it is easy to see that $T_{\mu,\lambda}(\alpha)$ defined in (3.4) is a continuous function of $\alpha \in (0, \beta_{\mu,\lambda})$. By Lemma 3.4(i) and Lemma 3.6(i), we have that, for any fixed $\mu > 0$, the set $\{\alpha \in (0,\beta_{\mu,\lambda}) : T_{\mu,\lambda}(\alpha) = 1 \text{ for all } \lambda > 0\}$ is connected. Thus, by Lemma 3.5(i), for any fixed $\mu > 0$, $S_{p,k,\mu}$ consists of a continuous curve on the $(\lambda, \|u\|_\infty)$-plane.

(I)(b) Part (i) follows from Proposition 1.1(i).

(II) We prove part (ii) where nonlinearities

$$g(u) = ku^{p-1} + \sum_{i=1}^{m} a_i u^{q_i} \quad \text{and} \quad h(u) = \mu \sum_{j=1}^{n} b_j u^{r_j} \quad (\text{with } \mu > 0)$$

satisfy (1.3). We prove that g, h satisfy (H1)–(H4). It is first easy to see that $g, h \in C[0,\infty) \cap C^2(0,\infty)$ satisfy (H1) with $m_0^g \equiv \lim_{u\to 0^+} \frac{g(u)}{u^{p-1}} = k \geq 0$. Hence, by (3.3), $\hat{\lambda} = \left(\frac{p-1}{k}\right)\left(\frac{\pi}{p} \csc \frac{\pi}{p}\right)^p = \bar{\lambda}$. By (1.3), it is easy to see that the function

$$\frac{h(u)}{g(u)} = \frac{\mu \sum_{j=1}^{n} b_j u^{r_j}}{ku^{p-1} + \sum_{i=1}^{m} a_i u^{q_i}} \quad (\mu > 0)$$

is positive and strictly increasing on $(0,\infty)$ and satisfies that

$$\lim_{u\to 0^+} \frac{h(u)}{g(u)} = 0 \quad \text{and} \quad \lim_{u\to\infty} \frac{h(u)}{g(u)} = \infty.$$

Thus g, h satisfy (H2). It is clear that, by (1.3),

$$(p-2)g'(u) - ug''(u) = \sum_{i=1}^{m} a_i q_i (p-1-q_i) u^{q_i-1} < 0 \quad \text{on } (0,\infty),$$

$$(p-2)h'(u) - uh''(u) = \mu \sum_{j=1}^{n} b_j r_j (p-1-r_j) u^{r_j-1} < 0 \quad \text{on } (0,\infty).$$

Thus g, h satisfy (H3). Finally, by (1.3), we compute that

$$\begin{aligned}\frac{(p-2)h'(u) - uh''(u)}{(p-2)g'(u) - ug''(u)} &= \frac{\mu \sum_{j=1}^{n} b_j r_j (p-1-r_j) u^{r_j-1}}{\sum_{i=1}^{m} a_i q_i (p-1-q_i) u^{q_i-1}} \quad (\mu > 0) \\ &= \frac{\mu \sum_{j=1}^{n} b_j r_j (p-1-r_j) u^{r_j}}{\sum_{i=1}^{m} a_i q_i (p-1-q_i) u^{q_i}}\end{aligned}$$

which is positive and strictly increasing on $(0,\infty)$ and satisfies that

$$\lim_{u\to 0^+} \frac{(p-2)h'(u) - uh''(u)}{(p-2)g'(u) - ug''(u)} = 0 \quad \text{and} \quad \lim_{u\to \infty} \frac{(p-2)h'(u) - uh''(u)}{(p-2)g'(u) - ug''(u)} = \infty.$$

So g, h satisfy (H4). By above, we conclude that g, h satisfy (H1)–(H4). So part (ii) follows from Lemma 3.1(i).

(III) We prove part (iii). Consider any nonnegative $\mu_1 < \mu_2$. If, on the $(\lambda, \|u\|_\infty)$-plane, bifurcation diagrams S_{p,k,μ_1} and S_{p,k,μ_2} attain a fixed number $\|u\|_\infty = \bar{\alpha}$ for any feasible $\bar{\alpha} > 0$ at $\lambda = \lambda_1 > 0$ and $\lambda = \lambda_2 > 0$, respectively. Then by (3.6), we have the following equalities:

$$T_{\mu_1,\lambda_1}(\bar{\alpha}) = \left(\frac{p-1}{p}\right)^{1/p} \int_0^{\bar{\alpha}} [\lambda_1(G(\bar{\alpha}) - G(u)) - \mu_1(\tilde{H}(\bar{\alpha}) - \tilde{H}(u))]^{-1/p} du = 1, \tag{4.1}$$

$$T_{\mu_2,\lambda_2}(\bar{\alpha}) = \left(\frac{p-1}{p}\right)^{1/p} \int_0^{\bar{\alpha}} [\lambda_2(G(\bar{\alpha}) - G(u)) - \mu_2(\tilde{H}(\bar{\alpha}) - \tilde{H}(u))]^{-1/p} du = 1. \tag{4.2}$$

Suppose that $\lambda_1 \geq \lambda_2$, since $0 < \mu_1 < \mu_2$ and $\lambda_1 \geq \lambda_2$, we have that

$$\lambda_1(G(\bar{\alpha}) - G(u)) - \mu_1(\tilde{H}(\bar{\alpha}) - \tilde{H}(u)) > \lambda_2(G(\bar{\alpha}) - G(u)) - \mu_2(\tilde{H}(\bar{\alpha}) - \tilde{H}(u)).$$

Thus $T_{\mu_1,\lambda_1}(\bar{\alpha}) < T_{\mu_2,\lambda_2}(\bar{\alpha})$, which leads to a contradiction since the above equality (4.1) for $T_{\mu_1,\lambda_1}(\bar{\alpha})$ and equality (4.2) for $T_{\mu_2,\lambda_2}(\bar{\alpha})$ are both equal to 1. So $\lambda_1 < \lambda_2$. Hence, for any nonnegative $\mu_1 < \mu_2$, on the $(\lambda, \|u\|_\infty)$-plane, S_{p,k,μ_2} lies on the right hand side of S_{p,k,μ_1}.

(IV) We prove part (iv). By Lemma 3.7, $\lambda^*(\mu) : (0,\infty) \to (0,\bar{\lambda})$ is a continuous, strictly increasing function. Moreover, $\lim_{\mu\to 0^+} \lambda^*(\mu) = 0$ and $\lim_{\mu\to\infty} \lambda^*(\mu) = \bar{\lambda}$. It is easy to show that $\|u_{\lambda^*}\|_\infty$ $(= \|u_{\mu,\lambda^*}\|_\infty)$ is a continuous function of $\mu > 0$. By Lemma 3.9, we have that $\lim_{\mu\to 0^+} \|u_{\lambda^*}\|_\infty = \infty$ and $\lim_{\mu\to\infty} \|u_{\lambda^*}\|_\infty = 0$.

In particular, when $k = 0$, $m = 1$, $n = 1$, $q \equiv q_1 > p-1$, $r \equiv r_1 > q$, and $f_{k=0,\mu,\lambda}(u) = \lambda u^q - \mu u^r$, we let $u = u_{\mu,\lambda}$ be a (classical) positive solution of (1.1), (1.3). Then the change of variables

$$u_{\mu,\lambda}(x) = \left(\frac{\lambda}{\mu}\right)^{1/(r-q)} v(\mu^{\frac{p-q-1}{p(r-q)}} \lambda^{\frac{r-p+1}{p(r-q)}} x)$$

transforms $u_{\mu,\lambda}$ into a solution v of

$$\begin{cases} (\varphi_p(v'(x)))' + v^q - v^r = 0, & -L < x < L, \\ v(-L) = v(L) = 0, \end{cases} \tag{4.3}$$

with

$$L \equiv \mu^{\frac{p-q-1}{p(r-q)}} \lambda^{\frac{r-p+1}{p(r-q)}}. \tag{4.4}$$

Cf. [5, p. 463]. For p-Laplacian problem (4.3) with $1 < p \leq 2$ and $0 < p-1 < q < r$, we define the time map formula as follows:

$$\tilde{T}(\alpha) = \left(\frac{p-1}{p}\right)^{1/p} \int_0^\alpha \frac{dv}{\left[\tilde{F}(\alpha) - \tilde{F}(v)\right]^{1/p}} \quad \text{for } 0 < \alpha < 1, \tag{4.5}$$

where $\tilde{F}(v) \equiv \int_0^v \tilde{f}(t)dt$ and $\tilde{f}(v) \equiv v^q - v^r$. By [14, Lemma 3.1], there exist two fixed positive numbers $\|v^*\|_\infty$ and L^* such that $\tilde{T}(\alpha)$ has exactly one critical point, an absolute minimum $\tilde{T}(\|v^*\|_\infty) = L^*$, on $(0,1)$. Thus, by (4.4),

$$L^* = \mu^{\frac{p-q-1}{p(r-q)}} (\lambda^*)^{\frac{r-p+1}{p(r-q)}},$$

and hence

$$\left(\frac{\lambda^*}{\mu}\right)^{1/(r-q)} = (L^*)^{\frac{p}{r-p+1}} \mu^{\frac{1}{p-1-r}}.$$

So we get that

$$\|u_{\lambda^*}\|_\infty = \left(\frac{\lambda^*}{\mu}\right)^{1/(r-q)} \|v^*\|_\infty = (L^*)^{\frac{p}{r-p+1}} \mu^{\frac{1}{p-1-r}} \|v^*\|_\infty.$$

Since $r > p-1$, $\|u_{\lambda^*}\|_\infty$ is a continuous, strictly decreasing function of $\mu > 0$.

(V) We prove part (v). We consider $0 < \alpha < \beta_{\mu,\lambda}$ and have that

$$\begin{aligned} T_{\mu=0,\lambda}(\alpha) &= \left(\frac{p-1}{p}\right)^{1/p} \int_0^\alpha [\lambda(G(\alpha) - G(u))]^{-1/p} du \\ &< \left(\frac{p-1}{p}\right)^{1/p} \int_0^\alpha [\lambda(G(\alpha) - G(u)) - \mu(\tilde{H}(\alpha) - \tilde{H}(u))]^{-1/p} du = T_{\mu,\lambda}(\alpha). \end{aligned}$$

By (3.4), (1.16) and (1.17), we obtain that

$$\lambda^{1/p} T_{\mu=0,\lambda}(\alpha) = T_{\bar{f}}(\alpha) = (c_{p,q}\alpha^{p-1-q})^{1/p}.$$

If $T_{\mu=0,\lambda}(\alpha) = 1$, then $\alpha = \left(\frac{c_{p,q}}{\lambda}\right)^{\frac{1}{q-p+1}}$. Then by (3.6) and Proposition 1.1(ii), we obtain that

$$0 < \left(\frac{c_{p,q}}{\lambda}\right)^{\frac{1}{q-p+1}} < \|u_\lambda\|_\infty < \beta_{\mu,\lambda}$$

since $T_{\bar{f}}(\alpha)$ is a strictly decreasing function on $(0,\infty)$ and $T_{\mu=0,\lambda}\left(\left(\frac{c_{p,q}}{\lambda}\right)^{\frac{1}{q-p+1}}\right) = 1$. So (2.1) holds.

The proof of Theorem 2.1 is now complete. □

Proof of Theorem 2.2. Let $p > 2$ and $k \geq 0$.

(I)(a) We have that, for any fixed $\mu > 0$, the bifurcation diagram $S_{p,k,\mu}$ consists of a continuous curve on the $(\lambda, \|u\|_\infty)$-plane. The proof is exactly the same as that given in part (I)(a) of the proof of Theorem 2.1 with $1 < p \leq 2$. So we omit it here.

(I)(b) Part (i) follows from Proposition 1.1(i).

(II)(a) We prove part (ii) where

$$g(u) = ku^{p-1} + \sum_{i=1}^{m} a_i u^{q_i} \quad \text{and} \quad h(u) = \mu \sum_{j=1}^{n} b_j u^{r_j} \quad (\text{with } \mu > 0)$$

satisfy (1.3). We prove that g, h satisfy (H1)–(H5). We first notice that the proofs of g, h satisfying (H1)–(H4) when $p > 2$ are exactly the same as those of g, h satisfying (H1)–(H4) when $1 < p \le 2$, given in part (II) of the proof of Theorem 2.1. So we omit them here. We then show that g, h satisfy (H5). We take the number $p^* = \frac{q_m + r_1}{2} > p - 1$ by (1.3). It is easy to see that

$$\frac{g(u)}{u^{p^*}} = ku^{p-1-p^*} + \sum_{i=1}^{m} a_i u^{q_i - p^*} \quad \text{is strictly decreasing on } (0, \infty)$$

and

$$\frac{h(u)}{u^{p^*}} = \mu \sum_{j=1}^{n} b_j u^{r_j - p^*} \quad \text{is strictly increasing on } (0, \infty).$$

For each fixed $s \in (0, 1)$, we compute that

$$\begin{aligned} \frac{h(su)}{u^{p-1}} \left[\frac{h(u)g(su)}{g(u)h(su)} - 1 \right] &= \frac{h(u)g(su) - h(su)g(u)}{u^{p-1} g(u)} \\ &= \frac{\mu \sum_{i=1}^{m} \sum_{j=1}^{n} a_i b_j (s^{q_i} - s^{r_j}) u^{q_i + r_j} + \mu k u^{p-1} \sum_{j=1}^{n} b_j (s^{p-1} - s^{r_j}) u^{r_j}}{u^{p-1}(ku^{p-1} + \sum_{i=1}^{m} a_i u^{q_i})} \end{aligned}$$

which is a strictly increasing function of u on $(0, \infty)$ and satisfies that

$$\lim_{u \to \infty} \frac{h(u)g(su)}{g(u)h(su)} = s^{q_m - r_n} \in (1, \infty)$$

since $s \in (0, 1)$ and $q_m < r_n$. So g, h satisfy (H5). By above, we conclude that g, h satisfy (H1)–(H5). So part (ii) follows from Lemma 3.1(ii).

(II)(b) By Lemma 3.10(ii), we have that

$$\lim_{\mu \to 0^+} \lim_{\alpha \to \beta^-_{\mu,\bar{\lambda}}} T_{\mu,\bar{\lambda}}(\alpha) = 0, \qquad \lim_{\mu \to \infty} \lim_{\alpha \to \beta^-_{\mu,\bar{\lambda}}} T_{\mu,\bar{\lambda}}(\alpha) = \infty$$

and $\lim_{\alpha \to \beta^-_{\mu,\bar{\lambda}}} T_{\mu,\bar{\lambda}}(\alpha)$ is a continuous, strictly increasing function of μ on $(0, \infty)$. So by the Intermediate Value Theorem, there exists a positive number $\hat{\mu}$ such that $\lim_{\alpha \to \beta^-_{\mu,\bar{\lambda}}} T_{\mu,\bar{\lambda}}(\alpha) < 1$ if $0 < \mu < \hat{\mu}$, $\lim_{\alpha \to \beta^-_{\mu,\bar{\lambda}}} T_{\mu,\bar{\lambda}}(\alpha) = 1$ if $\mu = \hat{\mu}$, and $\lim_{\alpha \to \beta^-_{\mu,\bar{\lambda}}} T_{\mu,\bar{\lambda}}(\alpha) > 1$ if $\mu > \hat{\mu}$.

For each fixed $k > 0$ and $\mu > 0$, $\lim_{\alpha \to \beta^-_{\mu,\tilde{\lambda}}} T_{\mu,\tilde{\lambda}}(\alpha) = 1$ by Lemma 3.1(ii) and $\lim_{\alpha \to \beta^-_{\mu,\lambda}} T_{\mu,\lambda}(\alpha)$ is a continuous, strictly decreasing function of λ on $(0, \infty)$ by Lemma 3.10(i). Hence we obtain that $\tilde{\lambda} < \bar{\lambda}$ if $0 < \mu < \hat{\mu}$, $\tilde{\lambda} = \bar{\lambda}$ if $\mu = \hat{\mu}$, and $\bar{\lambda} < \tilde{\lambda}$ if $\mu > \hat{\mu}$.

For each $\mu > 0$ and $k = 0$, we have $\bar{\lambda} = \infty$. By Lemma 3.10(i), $\lim_{\lambda \to \infty} \lim_{\alpha \to \beta^-_{\mu,\lambda}} T_{\mu,\lambda}(\alpha) = 0$. Hence $\lim_{\alpha \to \beta^-_{\mu,\bar{\lambda}}} T_{\mu,\bar{\lambda}}(\alpha) = 0$. Since $\lim_{\alpha \to \beta^-_{\mu,\tilde{\lambda}}} T_{\mu,\tilde{\lambda}}(\alpha) = 1$ by Lemma 3.1(ii) and $\lim_{\alpha \to \beta^-_{\mu,\lambda}} T_{\mu,\lambda}(\alpha)$ is a continuous, strictly decreasing function of λ on $(0, \infty)$ by Lemma 3.10(i), we obtain that $\tilde{\lambda} < \bar{\lambda}$ and $\hat{\mu} = \infty$.

(III) The proof of part (iii) of Theorem 2.2 is exactly the same as that of part (iii) of Theorem 2.1. So we omit it here.

(IV) We prove part (iv). By Lemma 3.12, $\tilde{\lambda}(\mu) : (0, \infty) \to (0, \infty)$ is a continuous, strictly increasing function. Moreover, $\lim_{\mu \to 0^+} \tilde{\lambda} = 0$ and $\lim_{\mu \to \infty} \tilde{\lambda} = \infty$. We let $u = u_{\mu,\lambda}$ be a (classical) positive solution of (1.1), (1.3). Then the change of variables

$$u_{\mu,\lambda}(x) = v(\mu^{\frac{1}{p}} x)$$

transforms $u_{\mu,\lambda}$ into a solution v of

$$\begin{cases} \left(\varphi_p(v'(x))\right)' + \frac{\lambda}{\mu}(kv^{p-1} + \sum_{i=1}^m a_i v^{q_i}) - \sum_{j=1}^n b_j v^{r_j}, & -L < x < L, \\ v(-L) = v(L) = 0, \end{cases} \tag{4.6}$$

with

$$L \equiv \mu^{\frac{1}{p}}.$$

Cf. [5, p. 463]. By Lemma 3.11(i), for any fixed $\mu \in (0, \infty)$, there exists a unique $\tilde{\lambda}(\mu) > 0$ such that $\lim_{\alpha \to \beta^-_{\mu,\tilde{\lambda}(\mu)}} T_{\mu,\tilde{\lambda}(\mu)}(\alpha) = 1$. Then there exists a unique $\eta = \frac{\tilde{\lambda}(\mu)}{\mu} > 0$ such that $\lim_{\alpha \to \beta^-_{\mu,\tilde{\lambda}(\mu)}} T_{1,\eta}(\alpha) = \mu^{\frac{1}{p}}$ and $\beta_{\mu,\tilde{\lambda}(\mu)} = \beta_{1,\eta}$. For $0 < \mu_1 < \mu_2$,

$$\lim_{\alpha \to \beta^-_{\mu_1,\tilde{\lambda}(\mu_1)}} T_{1,\eta_1}(\alpha) = \mu_1^{\frac{1}{p}} < \mu_2^{\frac{1}{p}} = \lim_{\alpha \to \beta^-_{\mu_2,\tilde{\lambda}(\mu_2)}} T_{1,\eta_2}(\alpha).$$

Hence $\eta_1 > \eta_2$ by Lemma 3.10(i). Similarly, for any fixed $\eta \in (0, \infty)$, there exists a unique $\mu > 0$ such that $\lim_{\alpha \to \beta^-_{1,\eta}} T_{1,\eta}(\alpha) = \mu^{\frac{1}{p}}$ and $\beta_{\mu,\tilde{\lambda}(\mu)} = \beta_{1,\eta}$. It is clear that $\beta_{1,\eta}$ is a continuous, strictly increasing function of η on $(0, \infty)$. Hence

$$\|v_{\tilde{\lambda}(\mu_1)}\|_\infty = \beta_{\mu_1,\tilde{\lambda}(\mu_1)} = \beta_{1,\eta_1} > \beta_{1,\eta_2} = \beta_{\mu_2,\tilde{\lambda}(\mu_2)} = \|v_{\tilde{\lambda}(\mu_2)}\|_\infty.$$

So $\|v_{\tilde{\lambda}}\|_\infty$ is a continuous, strictly decreasing function of $\mu > 0$. By Lemma 3.10(i), $\lim_{\mu \to 0^+} \eta(\mu) = \infty$ and $\lim_{\mu \to \infty} \eta(\mu) = 0$ since $\lim_{\alpha \to \beta^-_{1,\eta}} T_{1,\eta}(\alpha) = \mu^{\frac{1}{p}}$. Hence

$$\lim_{\mu \to 0^+} \|v_{\tilde{\lambda}(\mu)}\|_\infty = \lim_{\mu \to 0^+} \beta_{\mu,\tilde{\lambda}(\mu)} = \lim_{\eta \to \infty} \beta_{1,\eta} = \infty$$

and

$$\lim_{\mu \to \infty} \|v_{\tilde{\lambda}(\mu)}\|_\infty = \lim_{\mu \to \infty} \beta_{\mu,\tilde{\lambda}(\mu)} = \lim_{\eta \to 0^+} \beta_{1,\eta} = 0.$$

(V) The proof of part (v) of Theorem 2.2 is exactly the same as that of part (iv) of Theorem 2.1. So we omit it here.

(VI) The proof of part (vi) of Theorem 2.2 is exactly the same as that of part (v) of Theorem 2.1. So we omit it here.

The proof of Theorem 2.2 is now complete. □

5 A final remark

For evolutionary bifurcation diagram $S_{p,k,\mu}$ on the $(\lambda, \|u\|_\infty)$-plane studied in Theorems 2.1–2.2, analogically, we also study evolutionary bifurcation diagrams $\Sigma_{p,k,\lambda}$ on the $(\mu, \|u\|_\infty)$-plane defined by:

$$\Sigma_{p,k,\lambda} = \left\{ (\mu, \|u_\mu\|_\infty) : \mu > 0 \text{ and } u_\mu \text{ is a (classical) positive solution of (1.1), (1.3)} \right\}, \ \lambda > 0.$$

Applying Theorems 2.1–2.2 and by modified analytic techniques used in the proof of [7, Theorem 2.2], we obtain the following Theorem 5.1 and Fig. 5.1 with $1 < p \leq 2$ and Theorem 5.2 and Fig. 5.2 with $p > 2$ for evolutionary bifurcation diagrams $\Sigma_{p,k,\lambda}$ on the $(\mu, \|u\|_\infty)$-plane. We omit the proofs here.

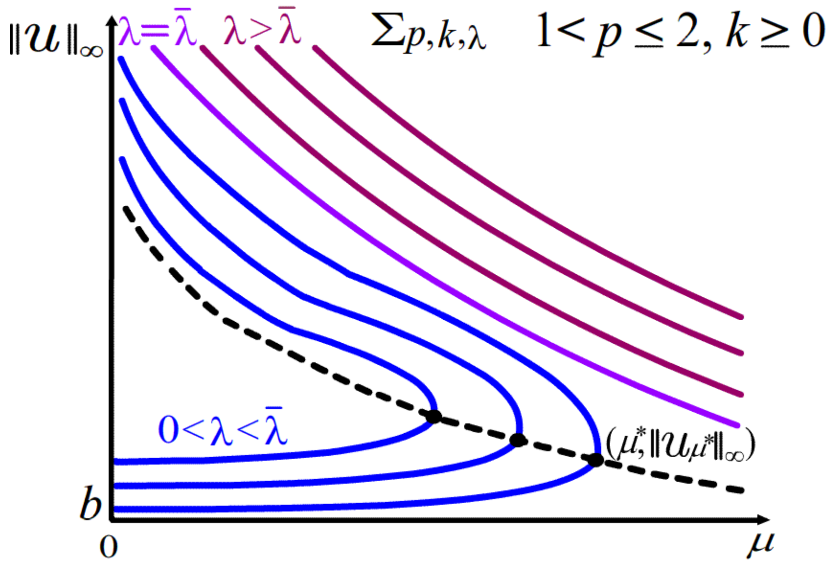

Figure 5.1: Evolutionary bifurcation diagrams $\Sigma_{p,k,\lambda}$ for (1.1), (1.3) with fixed $p \in (1, 2]$, $k \geq 0$ and varying $\lambda > 0$.

Theorem 5.1 (See Fig. 5.1)**.** *Let $1 < p \leq 2$ and $k \geq 0$. Consider p-Laplacian problem (1.1), (1.3) with varying $\lambda > 0$. Then the bifurcation diagram $\Sigma_{p,k,\lambda}$ consists of a continuous curve on the $(\mu, \|u\|_\infty)$-plane and the following assertions (i)–(iii) hold:*

(i) If

$$0 < \lambda < \bar{\lambda} = \left(\frac{p-1}{k}\right)\left(\frac{\pi}{p}\csc\frac{\pi}{p}\right)^p \begin{cases} < \infty & \text{if } k > 0, \\ = \infty & \text{if } k = 0, \end{cases}$$

then:

(a) $\Sigma_{p,k,\lambda}$ starts at some point $(0, b)$ where $b > 0$, tends to the positive $\|u\|_\infty$-axis as $\mu \to 0^+$, and is a reversed $\subset$-shaped curve with exactly one turning point at some point $(\mu^*, \|u_{\mu^*}\|_\infty)$ satisfying $\mu^* > 0$ and $\|u_{\mu^*}\|_\infty > b$. More precisely, problem (1.1), (1.3) has exactly two (classical) positive solutions u_μ, v_μ with $u_\mu < v_\mu$ for $0 < \mu < \mu^*$, exactly one (classical) positive solution u_{μ^*} for $\mu = \mu^*$, and no (classical) positive solution for $\mu > \mu^*$. In addition, $\lim_{\mu\to 0^+} \|u_\mu\|_\infty = b$ and $\lim_{\mu\to 0^+} \|v_\mu\|_\infty = \infty$.

(b) For the starting points $(0, b)$ of $\Sigma_{p,k,\lambda}$ with $0 < \lambda < \bar{\lambda}$, $b = b(\lambda)$ is a continuous, strictly decreasing function of $\lambda \in (0, \bar{\lambda})$, $\lim_{\lambda\to 0^+}(0, b) = (0, \infty)$ and $\lim_{\lambda\to\bar{\lambda}^-}(0, b) = (0, 0)$.

(c) For the turning points $(\mu^*, \|u_{\mu^*}\|_\infty)$ of $\Sigma_{p,k,\lambda}$ with $0 < \lambda < \bar{\lambda}$, μ^* is a continuous, strictly increasing function of $\lambda \in (0, \bar{\lambda})$, $\|u_{\mu^*}\|_\infty$ is a continuous function of $\lambda \in (0, \bar{\lambda})$,

$$\lim_{\lambda\to 0^+}(\mu^*, \|u_{\mu^*}\|_\infty) = (0, \infty) \quad \text{and} \quad \lim_{\lambda\to\bar{\lambda}^-}(\mu^*, \|u_{\mu^*}\|_\infty) = (\infty, 0).$$

In particular, when $k = 0$, $m = 1$, $n = 1$, $q \equiv q_1 > p - 1$, $r \equiv r_1 > q$, and $f_{k=0,\mu,\lambda}(u) = \lambda u^q - \mu u^r$, then $\|u_{\mu^*}\|_\infty$ is a strictly decreasing function of $\lambda \in (0, \bar{\lambda})$.

(ii) *If $\lambda \geq \bar{\lambda}$, then $\Sigma_{p,k,\lambda}$ emanates from the positive $\|u\|_\infty$-axis as $\mu \to 0^+$, tends to the positive μ-axis as $\mu \to \infty$, and is a strictly monotone curve. More precisely, problem* (1.1), (1.3) *has exactly one (classical) positive solution for $\mu > 0$.*

(iii) *For any positive $\lambda_2 > \lambda_1$, Σ_{p,k,λ_2} lies on the right hand side of Σ_{p,k,λ_1}. (So Σ_{p,k,λ_1} and Σ_{p,k,λ_2} do not intersect.)*

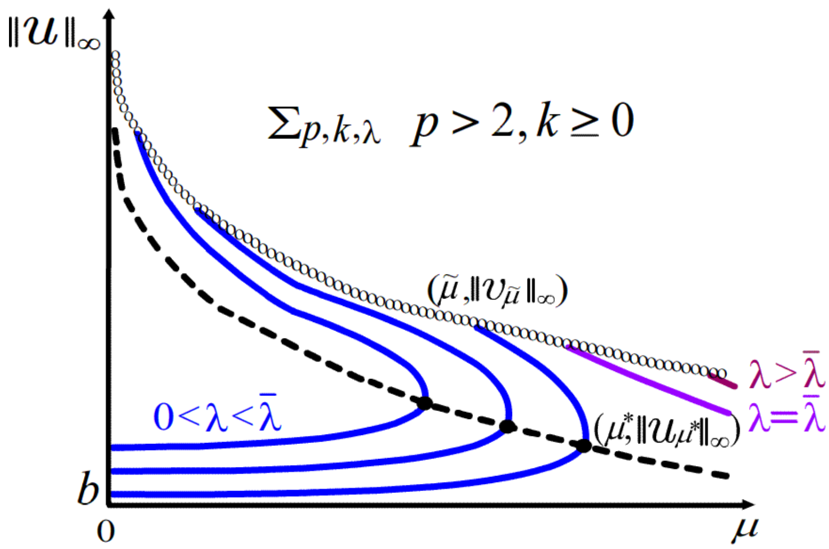

Figure 5.2: Evolutionary bifurcation diagrams $\Sigma_{p,k,\lambda}$ for (1.1), (1.3) with fixed $p > 2$, $k \geq 0$ and varying $\mu \geq 0$.

Theorem 5.2 (See Fig. 5.2)**.** *Let $p > 2$ and $k \geq 0$. Consider p-Laplacian problem (1.1), (1.3) with varying $\lambda > 0$. Then the bifurcation diagram $\Sigma_{p,k,\lambda}$ consists of a continuous curve on the $(\mu, \|u\|_\infty)$-plane and the following assertions (i)–(iv) hold:*

(i) *If*

$$0 < \lambda < \bar{\lambda} = \left(\frac{p-1}{k}\right)\left(\frac{\pi}{p}\csc\frac{\pi}{p}\right)^p \begin{cases} < \infty & \text{if } k > 0, \\ = \infty & \text{if } k = 0, \end{cases}$$

then:

(a) *$\Sigma_{p,k,\lambda}$ starts at some point $(0, b)$ where $b > 0$, ends at some point $(\tilde{\mu}, \|v_{\tilde{\mu}}\|_\infty)$ satisfying $0 < \tilde{\mu} < \infty$ and $0 < \|v_{\tilde{\mu}}\|_\infty = v_{\tilde{\mu}}(0) = \beta_{\tilde{\mu},\lambda}$ satisfying $f_{k,\tilde{\mu},\lambda}(\beta_{\tilde{\mu},\lambda}) = 0$ (that is, $v_{\tilde{\mu}}(x) \equiv \lim_{\lambda \to \tilde{\lambda}^-} v_\lambda(x)$ is a* flat-core *positive solution of* (1.1), (1.3)*, see below for* (classical) *positive solutions $v_\lambda(x)$ with $\tilde{\mu} < \mu < \mu^*$). Moreover, $\Sigma_{p,k,\lambda}$ is a reverse $\subset$-shaped curve with exactly one turning point at some point $(\mu^*, \|u_{\mu^*}\|_\infty)$ satisfying*

$$0 < \tilde{\mu} < \mu^* \quad \text{and} \quad 0 < \|u_{\mu^*}\|_\infty < \|v_{\tilde{\mu}}\|_\infty = \beta_{\tilde{\mu},\lambda}.$$

More precisely, problem (1.1), (1.3) *has exactly two (classical) positive solutions u_μ, v_μ with $u_\mu < v_\mu$ for $\tilde{\mu} < \mu < \mu^*$, exactly one (classical) positive solution u_{μ^*} for $\mu = \mu^*$ and $0 < \mu \leq \tilde{\mu}$, and no (classical) positive solution for $\mu > \mu^*$. In addition,* $\lim_{\mu \to 0^+} \|u_\mu\|_\infty = b$ *and* $\lim_{\mu \to \tilde{\mu}^-} \|v_\mu\|_\infty = \|v_{\tilde{\mu}}\|_\infty = \beta_{\tilde{\mu},\lambda}$.

(b) *For the starting points* $(0, b)$ *of* $\Sigma_{p,k,\lambda}$ *with* $0 < \lambda < \bar{\lambda}$, $b = b(\lambda)$ *is a continuous, strictly decreasing function of* $\lambda \in (0, \bar{\lambda})$, $\lim_{\lambda \to 0^+}(0, b) = (0, \infty)$ *and* $\lim_{\lambda \to \bar{\lambda}^-}(0, b) = (0, 0)$.

(c) *For the turning points* $(\mu^*, \|u_{\mu^*}\|_\infty)$ *of* $\Sigma_{p,k,\lambda}$ *with* $0 < \lambda < \bar{\lambda}$, μ^* *is a continuous, strictly increasing function of* $\lambda \in (0, \bar{\lambda})$, $\|u_{\mu^*}\|_\infty$ *is a continuous function of* $\lambda \in (0, \bar{\lambda})$,

$$\lim_{\lambda \to 0^+} (\mu^*, \|u_{\mu^*}\|_\infty) = (0, \infty) \quad \textit{and} \quad \lim_{\lambda \to \bar{\lambda}^-} (\mu^*, \|u_{\mu^*}\|_\infty) = (\infty, 0).$$

In particular, when $k = 0$, $m = 1$, $n = 1$, $q \equiv q_1 > p - 1$, $r \equiv r_1 > q$, *and* $f_{k=0,\mu,\lambda}(u) = \lambda u^q - \mu u^r$, *then* $\|u_{\mu^*}\|_\infty$ *is a strictly decreasing function of* $\lambda \in (0, \bar{\lambda})$.

(ii) *If* $\lambda \geq \bar{\lambda}$, *then* $\Sigma_{p,k,\lambda}$ *emanates from the positive* μ*-axis as* $\mu \to \infty$, *and ends at some point* $(\tilde{\mu}, \|v_{\tilde{\mu}}\|_\infty)$ *in which* $v_{\tilde{\mu}}$ *is a* flat-core *positive solution. Moreover,* $\Sigma_{p,k,\lambda}$ *is a strictly monotone curve. More precisely, problem* (1.1), (1.3) *has exactly one (classical) positive solution for* $\mu > \tilde{\mu}$.

(iii) *For any positive* $\lambda_2 > \lambda_1$, Σ_{p,k,λ_2} *lies on the right hand side of* Σ_{p,k,λ_1}. *(So* Σ_{p,k,λ_1} *and* Σ_{p,k,λ_2} *do not intersect.)*

(iv) *For the ending points* $(\tilde{\mu}, \|v_{\tilde{\mu}}\|_\infty)$ *of* $\Sigma_{p,k,\lambda}$ *with* $\lambda > 0$, $\tilde{\mu}$ *is a continuous, strictly increasing function of* $\lambda > 0$, $\|v_{\tilde{\mu}}\|_\infty$ *is a continuous, strictly decreasing function of* $\lambda > 0$,

$$\lim_{\lambda \to 0^+} (\tilde{\mu}, \|v_{\tilde{\mu}}\|_\infty) = (0, \infty) \quad \textit{and} \quad \lim_{\lambda \to \infty} (\tilde{\mu}, \|v_{\tilde{\mu}}\|_\infty) = (\infty, 0).$$

Abstract. We are concerned with the radial solutions of the Dirichlet problem $-\Delta u = K(|x|)f(u)$ on the exterior of the ball of radius $R > 0$ centered at the origin in $\mathbb{R}^N$ with $N \geq 3$ where f is superlinear at ∞ and has a singularity at 0 with $f(u) \sim \frac{1}{|u|^{q-1}u}$ and $0 < q < 1$ for small u. We prove that if $K(|x|) \sim |x|^{-\alpha}$ with $\alpha > 2(N-1)$ then there exist two infinite families of sign-changing radial solutions.

Keywords: exterior domains, singular, superlinear, radial solution.

2020 Mathematics Subject Classification: 34B40, 35B05.

1 Introduction

In this paper we study the radial solutions of

$$-\Delta u = K(|x|)f(u) \text{ on } \mathbb{R}^N \backslash B_R(0) \tag{1.1}$$

$$u(x) = 0 \text{ on } \partial B_R(0), \quad \lim_{|x|\to\infty} u(x) = 0 \tag{1.2}$$

where $\Delta : C^k(\mathbb{R}^N) \to C^{k-2}(\mathbb{R}^N)$ denotes the N-dimensional Laplacian, $B_R(0)$ denotes the unit ball centered at the origin, $|x|$ denotes the Euclidean distance of x, and $u : \mathbb{R}^N \to \mathbb{R}$ with $N \geq 3$.

Numerous papers have proved the existence of *positive* solutions of these equations with $K(|x|) = 1$. See for example [4, 5, 10]. In [10], Miyamoto and Naito studied the problem in the domain $B_R(0) \setminus \{0\}$. Some other papers have dealt with the *positive* solutions of these equations with various nonlinearities $f(u)$ and $K(|x|) \sim |x|^{-\alpha}$ with $\alpha > 0$. (See [1, 9, 11]).

We prove the existence of sign-changing solutions of (1.1)–(1.2) and analyze their properties. The papers [2, 3, 7, 8] examined the case where the non-linear function $f(u)$ in (1.1) has a unique positive zero. We choose a superlinear function $f(u)$ that has no positive zeros.

Our study of the solutions of (1.1)–(1.2) is based on the following assumptions:

✉ Corresponding author. Email: narayanaryal@my.unt.edu

(H1) $f : \mathbb{R}\backslash\{0\} \to \mathbb{R}$ is odd, locally Lipschitz, and $f > 0$ on $(0, \infty)$. (So, by the symmetry of f about the origin, $f < 0$ on $(-\infty, 0)$),

(H2) $f(u) = |u|^{p-1}u + g(u)$ with $p > 1$ for large u and $\lim_{u\to\infty} \frac{|g(u)|}{|u|^p} = 0$,

(H3) there exists a locally Lipschitz function $g_1 : \mathbb{R} \to \mathbb{R}$ such that $f(u) = \frac{1}{|u|^{q-1}u} + g_1(u)$ with $0 < q < 1$ and $g_1(0) = 0$,

(H4) $K(r)$, $K'(r)$ are continuous on $[R, \infty)$ with $K(r) > 0$ such that $2(N-1) + \frac{rK'}{K} < 0$ on $[R, \infty)$,

(H5) there exist a constant $k_0 > 0$ and $\alpha > 2(N-1)$ such that $\frac{k_0}{r^\alpha} \le K(r)$ on $[R, \infty)$.

Let $F(u) = \int_0^u f(t)\, dt$. From *(H3)* it follows that f is integrable at 0 and therefore F is continuous with $F(0) = 0$. Also, since f is odd and $f > 0$ on $(0, \infty)$, it follows that F is even and $F(u) > 0$ for $u \neq 0$.

Since we are studying the radial solutions of (1.1)–(1.2), we let $u(x) = u(|x|) = u(r)$ where $r = |x| = \sqrt{x_1^2 + x_2^2 + \cdots + x_N^2}$. Denoting $\frac{\partial u}{\partial r}$ by u' and $\frac{\partial^2 u}{\partial r^2}$ by u'' then (1.1)–(1.2) becomes:

$$u''(r) + \frac{N-1}{r}u'(r) + K(r)f(u) = 0 \quad \text{for } R < r < \infty, \tag{1.3}$$

$$u(R) = 0, \quad \lim_{r\to\infty} u(r) = 0. \tag{1.4}$$

In this paper we prove the following:

Theorem 1.1. *Assume (H1)–(H5) hold and $N \ge 3$. There exist two infinite families of non-trivial radial solutions of (1.3)–(1.4). In addition, $\exists n_0 \ge 0$ such that for every $n \ge n_0$ then there are at least two solutions of (1.3)–(1.4) with exactly n zeros on (R, ∞).*

2 Preliminaries and behavior for large a

We prove the existence of a solution of (1.3)–(1.4) with

$$u(R) = 0, \quad u'(R) = a > 0 \tag{2.1}$$

on $[R, R+\epsilon)$ for some $\epsilon > 0$. We denote $u(r)$ by $u_a(r)$ to emphasize the dependence of u on the initial parameter a. We begin first by making the following change of variables

$$u_a(r) = v_a(r^{2-N}).$$

Let $r^{2-N} = t$ and denote R^{2-N} by R^*. We observe then that solving (1.3), (2.1) is equivalent to solving the following initial value problem

$$v_a'' + h(t)f(v_a) = 0 \quad \text{on } (0, R^*) \tag{2.2}$$

$$v_a(R^*) = 0, \quad v_a'(R^*) = -\frac{aR^{N-1}}{N-2} < 0 \tag{2.3}$$

where $h(t) = \frac{t^{\frac{2(N-1)}{2-N}} K(t^{\frac{1}{2-N}})}{(N-2)^2}$. We will then try to find values of a such that $v_a(0) = 0$. From $(H4)$, $(H5)$, and the definition of $h(t)$ it follows that

$$\begin{gathered} h(t) > 0,\ h'(t) > 0 \quad \text{on } (0, R^*] \\ \text{and } \exists h_1 > 0 \text{ such that } h_1 t^{\tilde{\alpha}} \leq h(t) \text{ on } (0, R^*] \text{ where } \tilde{\alpha} = \frac{\alpha - 2(N-1)}{N-2} > 0. \end{gathered} \tag{2.4}$$

We first prove the existence of a solution for (2.2)–(2.3) on $[R^* - \epsilon, R^*]$ for some $\epsilon > 0$. To do this, we transform this equation into an integral equation and use the contraction mapping principle to solve it. Let $t > 0$ and let v_a be a solution of (2.2)–(2.3). By integrating (2.2) over (t, R^*) and using (2.3) we obtain

$$v_a'(t) = -\frac{aR^{N-1}}{N-2} + \int_t^{R^*} h(x) f\left(v_a(x)\right) dx. \tag{2.5}$$

Now integrate (2.5) over (t, R^*) and use (2.3). This gives

$$v_a(t) = \frac{aR^{N-1}}{N-2}(R^* - t) - \int_t^{R^*} \left(\int_s^{R^*} h(x) f(v_a(x))\, dx \right) ds. \tag{2.6}$$

Letting $v_a(t) = (R^* - t)y(t)$ and $y(R^*) \equiv \lim_{t \to R^{*-}} \frac{v_a(t)}{R^* - t} = -v_a'(R^*) = \frac{aR^{N-1}}{N-2}$, we can rewrite the equation (2.6) in terms of $y(t)$ as

$$y(t) = \frac{aR^{N-1}}{N-2} - \frac{1}{R^* - t} \int_t^{R^*} \left(\int_s^{R^*} h(x) f\left((R^* - x)y(x)\right)\, dx \right) ds. \tag{2.7}$$

We now solve (2.7) by defining an operator on an appropriate space and showing that it has a fixed point. For this, let $a > 0$ and consider the Banach space

$$X = \left\{ y \in C[R^* - \epsilon, R^*] : y(R^*) = \frac{aR^{N-1}}{N-2}, \left| y(t) - \frac{aR^{N-1}}{N-2} \right| \leq \frac{aR^{N-1}}{2(N-2)} \text{ on } [R^* - \epsilon, R^*] \right\}$$

equipped with the supremum norm defined by

$$\|y\| = \sup_{x \in [R^* - \epsilon, R^*]} |y(x)|.$$

We define a map $T : X \to C[R^* - \epsilon, R^*]$ by

$$(Ty)(t) = \frac{aR^{N-1}}{N-2} - \frac{1}{R^* - t} \int_t^{R^*} \left(\int_s^{R^*} h(x) f\left((R^* - x)y(x)\right) dx \right) ds \quad \text{for } R^* - \epsilon \leq t < R^* \tag{2.8}$$

and $T(R^*) = \frac{aR^{N-1}}{N-2}$. Since $f = \frac{1}{|u|^{q-1}u} + g_1(u)$ by $(H3)$, we have from (2.8) that

$$(Ty)(t) = \frac{aR^{N-1}}{N-2} - \frac{1}{R^* - t} \int_t^{R^*} \left(\int_s^{R^*} h(x) \left(\frac{1}{(R^* - x)^q y^q(x)} + g_1\left((R^* - x)y(x)\right) \right) dx \right) ds. \tag{2.9}$$

Since $0 < q < 1$ by $(H3)$, it follows that $\frac{1}{(R^* - x)^q}$ is integrable on $[0, R^*]$. Using this fact together with that g_1 is locally Lipschitz, it can be shown that T is a contraction mapping from X into itself for sufficiently small ϵ (the details are carried out in [3]). Thus by the contraction mapping principle [6], there exists a unique element $y \in X$ such that $Ty = y$ on

$[R^* - \epsilon, R^*]$. Hence, we obtain a solution $v_a(t) = (R^* - t)y(t)$ of (2.2)–(2.3) on $[R^* - \epsilon, R^*]$ if $a > 0$ and $\epsilon > 0$ is sufficiently small.

Next let $(R_1, R^*]$ be the maximal half-open interval of existence of the solution to (2.2)–(2.3). Now we define the energy of the solution

$$E_a = \frac{1}{2}\frac{v_a'^2}{h(t)} + F(v_a) \quad \text{for } R_1 < t \le R^*. \tag{2.10}$$

Then it follows from (2.2) and (2.4) that

$$E_a' = -\frac{v_a'^2 h'}{2h^2} \le 0 \quad \text{on } (R_1, R^*]. \tag{2.11}$$

Thus, E_a is non-increasing on $(R_1, R^*]$ and hence for $R_1 < t \le R^*$ we have

$$0 < \frac{1}{2}\frac{a^2 R^{2(N-1)}}{(N-2)^2 h(R^*)} = \frac{1}{2}\frac{v_a'^2(R^*)}{h(R^*)} = E_a(R^*) \le E_a = \frac{1}{2}\frac{v_a'^2}{h(t)} + F(v_a) \quad \text{on } (R_1, R^*]. \tag{2.12}$$

So $E_a > 0$ on $(R_1, R^*]$.

We next claim that the solution of (2.2)–(2.3) exists on $[0, R^*]$ and analyze the properties of the solution in several lemmas.

Lemma 2.1. *Assume (H1)–(H5) hold, $N \ge 3$ and $a > 0$. Let v_a be the solution of (2.2)–(2.3). Then v_a can be extended to the maximal interval $[0, R^*]$.*

Proof. Let v_a be the unique solution of (2.2)–(2.3) on the maximal half-open interval of existence $(R_1, R^*]$. We show that $R_1 = 0$. Suppose on the contrary that $R_1 > 0$. Using (2.2), (2.4) and that $F(v_a) \ge 0$ we obtain

$$\left(\frac{1}{2}v_a'^2 + h(t)F(v_a)\right)' = h'(t)F(v_a) \ge 0 \quad \text{on } (R_1, R^*]. \tag{2.13}$$

Let $0 < t < R_1$. Now by integrating (2.13) over (t, R^*), using (2.3) and that $h(t) > 0$, $F(v_a) \ge 0$ we obtain

$$\frac{1}{2}v_a'^2 \le \frac{1}{2}v_a'^2 + h(t)F(v_a) \le \frac{1}{2}\frac{a^2 R^{2(N-1)}}{(N-2)^2} \quad \text{on } (R_1, R^*]. \tag{2.14}$$

Therefore,

$$|v_a'| \le \frac{aR^{N-1}}{N-2} \quad \text{on } (R_1, R^*]. \tag{2.15}$$

Also, we have

$$|v_a| = \left|\int_t^{R^*} v_a' \, ds\right| \le \int_t^{R^*} |v_a'| \, ds \le \frac{aR^{N-1}}{N-2}(R^* - t) \le \frac{aR^{N-1}}{N-2}R^* = \frac{aR}{N-2} \quad \text{on } (R_1, R^*]. \tag{2.16}$$

Now let $(t_n) \subset (R_1, R^*]$ such that $t_n \to R_1^+$. Then by the mean value theorem and (2.15) we obtain

$$|v_a(t_n) - v_a(t_m)| = |v_a'(c_{n,m})||t_n - t_m| \le \frac{aR^{N-1}}{N-2}|t_n - t_m| \to 0 \quad \text{as } m, n \to \infty.$$

This shows that $(v_a(t_n))$ is a Cauchy sequence on $(R_1, R^*]$ and so $\exists L \in \mathbb{R}$ such that $\lim_{t\to R_1^+} v_a(t) = L$. Also since $h(t)F(v_a)$ and $h'(t)F(v_a)$ are continuous on $(R_1, R^*]$, integrating (2.13) on (t, R^*) we see that $\lim_{t\to R_1^+} v_a'(t) = L_1$ exists. From (2.12) we see $0 < E_a \le \frac{1}{2}\frac{L_1^2}{h(R^*)} + F(L)$ on $(R_1, R^*]$ which shows that L and L_1 cannot both be zero. Now if $L = 0$ then $L_1 \neq 0$ and we can use the contraction mapping principle as we did earlier to extend our solution to $(R_1 - \delta, R^*]$ for some $\delta > 0$. On the other hand, if $L \neq 0$, then we can use the standard existence theorem for ordinary differential equations to obtain a solution on $(R_1 - \delta, R^*]$ for some $\delta > 0$. Therefore in both cases the solution of (2.2)-(2.3) can be extended to $(R_1 - \delta, R^*]$ for some $\delta > 0$, contradicting the maximality of $(R_1, R^*]$. Hence $R_1 = 0$. It then follows from (2.15) and (2.16) that v_a and v_a' are bounded on $(0, R^*]$ and so in a similar way to earlier we see that the limits $\lim_{t\to 0^+} v_a(t)$ and $\lim_{t\to 0^+} v_a'(t)$ exist. Thus v_a and v_a' are defined and continuous $[0, R^*]$. □

Remark 2.2. If v_a solves (2.2)–(2.3) and $z \in (0, R^*)$ is such that $v_a(z) = 0$ then by (2.12), $0 < E_a(z_a) = \frac{1}{2}\frac{v_a'^2(z)}{h(z)}$ and hence $v_a'(z) \neq 0$. Thus the zeros of v_a on $(0, R^*)$ are simple. Also, since $\lim_{u\to 0}|f(u)| = \infty$, by (H3) it follows that the solution to (2.2)–(2.3) is twice differentiable except at points where $v_a(t_0) = 0$. Therefore, by a solution v_a of (2.2)–(2.3) we mean a continuously differentiable function v_a on $[0, R^*]$ that satisfies the equation (2.6) with (2.3).

Lemma 2.3. *Assume (H1)–(H5) hold, $N \ge 3$ and $a > 0$. Let v_a solve (2.2)–(2.3) on $[0, R^*]$. Then v_a depends continuously on the initial parameter a on $[0, R^*]$.*

Proof. Let $0 < a_1 < a < a_2$. Then from (2.15) we have

$$|v_a'| \le \frac{aR^{N-1}}{N-2} \le a_2 c_1 \quad \text{for all } a \text{ such that } 0 < a_1 \le a \le a_2 \tag{2.17}$$

where $c_1 = \frac{R^{N-1}}{N-2}$. And from (2.16) we have

$$|v_a| = \frac{aR}{N-2} \le a_2 c_2 \quad \text{for all } a \text{ such that } 0 < a_1 \le a \le a_2 \tag{2.18}$$

where $c_2 = \frac{R}{N-2}$. Thus, (2.17) and (2.18) show that the upper bounds for $|v_a|, |v_a'|$ can be chosen to be independent of a on $[0, R^*]$ for all a such that $0 < a_1 \le a \le a_2$.

Now let $\tilde{a} > 0$ and suppose $a \to \tilde{a}$. Then, we want to show that $v_a \to v_{\tilde{a}}$ uniformly on $[0, R^*]$. Suppose on the contrary, that there is a subsequence $(a_j) \subset \mathbb{R}$ such that $a_j \to \tilde{a}$ as $j \to \infty$ and $\epsilon_0 > 0$ such that

$$|v_{a_j}(t_j) - v_{\tilde{a}}(t_j)| \ge \epsilon_0 \quad \text{for some sequence } t_j \in [0, R^*]. \tag{2.19}$$

Since $a_j \to \tilde{a}$, there exists $N_0 \in \mathbb{N}$ such that for all $j \ge N_0$ $|a_j| \le \tilde{a} + 1$. From (2.15) and (2.16) we know that v_a and v_a' are uniformly bounded on the compact domain $[0, R^*]$. Hence, by the Arzelà–Ascoli theorem, there exists a subsequence $(v_{a_{j_k}}) \subset (v_{a_j})$ such that $v_{a_{j_k}} \to v_{\tilde{a}}$ uniformly on $[0, R^*]$ as $k \to \infty$. Therefore, as $k \to \infty$ from (2.19) we obtain

$$0 \leftarrow |v_{a_{j_k}}(t_{j_k}) - v_{\tilde{a}}(t_{j_k})| \ge \epsilon_0$$

which is a contradiction. Thus, $v_a \to v_{\tilde{a}}$ uniformly on $[0, R^*]$ and this completes the proof of the lemma. □

Lemma 2.4. *Assume (H1)–(H5) hold and $N \geq 3$. If $a > 0$ and v_a is a solution of (2.2)–(2.3), then v_a has at most finitely many zeros on $(0, R^*)$.*

Proof. Suppose on the contrary that $\exists$ a sequence $(z_{k,a}) \subset (0, R^*)$ with $0 < \cdots < z_{2,a} < z_{1,a}$ such that $v_a(z_{k,a}) = 0$. Then $z_{k,a}$ converges to some z_a^* on $[0, R^*]$. Since v_a has infinitely many zeros, $z_{k,a}$, and $v_a'(z_{k,a}) \neq 0$ by the Remark 2.2, it follows that v_a has infinitely many local extrema, $\{M_{k,a}\}_{k=1}^{\infty}$, with $z_{k+1,a} < M_{k,a} < z_{k,a}$ and so $\lim_{k\to\infty} M_{k,a} = z_a^*$. Since $E_a(t) > 0$ on $(0, R^*]$ and E is non-increasing by (2.12) we have $F(v_a(M_{k,a})) = E_a(M_{k,a}) \geq \frac{1}{2}\frac{a^2R^{2(N-1)}}{(N-2)^2h(R^*)} > 0$. So $\exists\beta_a > 0$ such that $|v_a(M_{k,a})| \geq \beta_a$ for all k. Now by the mean value theorem and (2.15) $\exists t_{k,a} \in (M_{k,a}, z_{k,a})$ such that

$$0 < \beta_a \leq |v_a(M_{k,a})| = |v_a(M_{k,a}) - v_a(z_{k,a})| = |v_a'(t_{k,a})||M_{k,a} - z_{k,a}| \leq \frac{aR^{N-1}}{(N-2)}|M_{k,a} - z_{k,a}|. \quad (2.20)$$

Since $M_{k,a} \to z_a^*$ and $z_{k,a} \to z_a^*$ as $k \to \infty$, the right-hand side of (2.20) goes to 0 as $k \to \infty$ which gives a contradiction. Therefore v_a has at most finitely many zeros on $(0, R^*)$ for $a > 0$. □

Lemma 2.5. *Assume (H1)–(H5) hold, $N \geq 3$ and let v_a solve (2.5). Then for $a > 0$ sufficiently large v_a has a local maximum, M_a. In addition, $v_a(M_a) \to \infty$ and $M_a \to R^*$ as $a \to \infty$.*

Proof. First we show for any $0 \leq t_0 < R^*$ that $\max_{[t_0,R^*)} |v_a(t)| \to \infty$ as $a \to \infty$.

If v_a has a local maximum $M_a \in [t_0, R^*)$, then $v_a'(M_a) = 0$. So, by letting $t = M_a$ in (2.12) we obtain

$$F(v_a(M_a)) \geq \frac{1}{2}\frac{a^2R^{2(N-1)}}{h(R^*)(N-2)^2}. \quad (2.21)$$

Since $h(R^*) > 0$, it follows that the right-hand side of (2.21) approaches infinity as $a \to \infty$ and hence from the definition of F we see that

$$v_a(M_a) \to \infty \quad \text{as } a \to \infty. \quad (2.22)$$

On the other hand, if v_a has no local maximum on (t_0, R^*) then v_a is decreasing on (t_0, R^*). We want to show that $\max_{[t_0,R^*)} |v_a(t)| \to \infty$ as $a \to \infty$. Suppose on the contrary that this is false. Then there exists a constant $c_3 > 0$ independent of a such that $|v_a(t)| \leq c_3$ on $[t_0, R^*]$. Then by the continuity of F there exists $c_4 > 0$ such that $F(v_a(t)) \leq c_4$. Using this and (2.3), it follows from (2.12) that

$$\frac{1}{2}\frac{v_a'^2(t)}{h(t)} + c_4 \geq \frac{1}{2}\frac{v_a'^2(t)}{h(t)} + F(v_a(t)) \geq \frac{1}{2}\frac{v_a'^2(R^*)}{h(R^*)} = \frac{1}{2}a^2c_5^2 \quad \text{on } [t_0, R^*] \quad (2.23)$$

where $c_5 = \frac{R^{N-1}}{(N-2)\sqrt{h(R^*)}}$. Rewriting (2.23) we obtain

$$|v_a'(t)| \geq \sqrt{a^2c_5^2 - 2c_4}\,\sqrt{h(t)}. \quad (2.24)$$

By (2.4) there exists $h_1 > 0$ such that $h(t) \geq h_1 t^{\tilde{\alpha}}$ on $[t_0, R^*]$. By using this and choosing a sufficiently large we can ensure that

$$|v_a'(t)| \geq \frac{ac_5}{2}\sqrt{h(t)} \geq \frac{ac_5}{2}\sqrt{h_1}t^{\frac{\tilde{\alpha}}{2}}. \quad (2.25)$$

Since v_a is decreasing, then by (2.25) we have $v_a' < 0$ on $[t_0, R^*]$. Now integrating (2.25) over (t_0, R^*) yields

$$c_3 \geq v_a(t_0) = \int_{t_0}^{R^*} -v_a'(t)\, dt \geq \frac{ac_5}{2}\sqrt{h_1}\int_{t_0}^{R^*} t^{\frac{\tilde{\alpha}}{2}}\, dt = \frac{ac_5}{2}\sqrt{h_1}\left(\frac{(R^*)^{\frac{\tilde{\alpha}}{2}+1} - t_0^{\frac{\tilde{\alpha}}{2}+1}}{\tilde{\alpha}+2}\right). \tag{2.26}$$

The left hand side of (2.26) is a constant while the right-hand side approaches ∞ as $a \to \infty$ which is a contradiction. Thus we conclude that for any $t_0 \in [0, R^*)$

$$\max_{[t_0,R^*)} |v_a(t)| \to \infty \quad \text{as } a \to \infty. \tag{2.27}$$

We claim next that v_a has a local max, M_a, and $\frac{1}{2}R^* < M_a < R^*$ if a is sufficiently large. Suppose on the contrary that v_a is decreasing on $[\frac{1}{2}R^*, R^*]$. Let

$$C_a = \frac{1}{2}\min_{[\frac{1}{2}R^*,\frac{3}{4}R^*]} \frac{h(t)f(v_a)}{v_a}. \tag{2.28}$$

By letting $t_0 = \frac{3}{4}R^*$ in (2.27), we obtain $v_a(\frac{3}{4}R^*) \to \infty$ as $a \to \infty$. Since v_a is decreasing on the interval $[\frac{1}{2}R^*, \frac{3}{4}R^*]$ we see that $v_a \to \infty$ uniformly as $a \to \infty$ on the interval $[\frac{1}{2}R^*, \frac{3}{4}R^*]$. By (2.4) $h_1 t^{\tilde{\alpha}} \leq h(t)$ on $(0, R^*]$ for some constant $h_1 > 0$ from which it follows that $h(t)$ is bounded from below on $[\frac{1}{2}R^*, \frac{3}{4}R^*]$. Also we have $f(v_a) = |v_a|^{p-1}v_a + g(v_a)$ by $(H2)$ and so it follows that if v_a is large then $f(v_a) \geq \frac{1}{2}v_a^p$. It then follows from this that $\frac{f(v_a)}{v_a} \geq \frac{1}{2}v_a^{p-1}(t) \geq \frac{1}{2}v_a^{p-1}\left(\frac{3}{4}R^*\right)$ on $[\frac{1}{2}R^*, \frac{3}{4}R^*]$. Since $p-1 > 0$ and $v_a(\frac{3}{4}R^*) \to \infty$ as $a \to \infty$, then we see $\frac{f(v_a)}{v_a} \to \infty$ on $[\frac{1}{2}R^*, \frac{3}{4}R^*]$ as $a \to \infty$. And since h is bounded from below on $[\frac{1}{2}R^*, \frac{3}{4}R^*]$, it follows from this and (2.28) that

$$C_a \to \infty \quad \text{as } a \to \infty.$$

Now we consider the differential equation

$$w_a'' + C_a w_a = 0 \tag{2.29}$$

with

$$\begin{aligned} w_a\left(\frac{3}{4}R^*\right) &= v_a\left(\frac{3}{4}R^*\right) > 0, \\ w_a'\left(\frac{3}{4}R^*\right) &= v_a'\left(\frac{3}{4}R^*\right) < 0. \end{aligned} \tag{2.30}$$

Clearly, $\{\cos\sqrt{C_a}(t - \frac{3}{4}R^*), \sin\sqrt{C_a}(t - \frac{3}{4}R^*)\}$ is a fundamental set of solutions of (2.29). So, $w_a = \alpha_1 \cos\sqrt{C_a}(t - \frac{3}{4}R^*) + \alpha_2 \sin\sqrt{C_a}(t - \frac{3}{4}R^*)$ for some constants α_1 and α_2. We also know that the distance between two consecutive zeros of w_a is $\frac{\pi}{\sqrt{C_a}} \to 0$ as $a \to \infty$. So, for $a > 0$ sufficiently large we have $\frac{1}{2}R^* < \frac{3}{4}R^* - \frac{\pi}{\sqrt{C_a}}$. Therefore, for $a > 0$ sufficiently large w_a has a zero on $[\frac{1}{2}R^*, \frac{3}{4}R^*]$ and hence has a local maximum $\tilde{M}$ on this interval with $w_a' < 0$ on $(\tilde{M}, \frac{3}{4}R^*]$.

Next, we rewrite equation (2.2) and consider

$$v_a'' + \left(\frac{h(t)f(v_a)}{v_a}\right)v_a = 0. \tag{2.31}$$

Multiplying (2.29) by v_a, (2.31) by w_a, and subtracting we obtain

$$(w_a' v_a - w_a v_a')' + \left(C_a - \frac{h(t)f(v_a)}{v_a} \right) w_a v_a = 0.$$

Integrating this on $(\tilde{M}, \frac{3}{4}R^*)$ and using (2.30) gives

$$w_a(\tilde{M}) v_a'(\tilde{M}) = \int_{\tilde{M}}^{\frac{3}{4}R^*} \left(\frac{h(t)f(v_a)}{v_a} - C_a \right) w_a v_a \, dt. \tag{2.32}$$

Since $w_a(\tilde{M}) > 0$, $C_a < \frac{h(t)f(v_a)}{v_a}$ on $[0, \frac{3}{4}R^*]$, and w_a, v_a stay positive on $[\tilde{M}, \frac{3}{4}R^*]$ it follows from (2.32) that $v_a'(\tilde{M}) > 0$, contradicting our assumption that v_a is decreasing on $[\frac{1}{2}R^*, R^*]$. Thus v_a has a local maximum, M_a, and $\frac{1}{2}R^* < M_a < R^*$ with v_a decreasing on $[M_a, R^*]$ for $a > 0$ sufficiently large. It also follows immediately from (2.22) that $v_a(M_a) \to \infty$ as $a \to \infty$.

Next we show that $M_a \to R^*$ as $a \to \infty$. Since v_a is decreasing on $[M_a, R^*)$ and $v_a(R^*) = 0$ so we see $v_a > 0$ on $[M_a, R^*)$. But then from (2.2) we know $v_a'' = -h(t)f(v_a) < 0$ on $[M_a, R^*)$ and so v_a is concave down on $[M_a, R^*)$. This implies

$$v_a \left(\lambda M_a + (1-\lambda) R^* \right) \geq \lambda v_a(M_a) + (1-\lambda) v_a(R^*) \quad \text{for } 0 \leq \lambda \leq 1.$$

So by letting $\lambda = \frac{1}{2}$ we obtain

$$v_a \left(\frac{M_a + R^*}{2} \right) \geq \frac{v_a(M_a) + v_a(R^*)}{2} = \frac{v_a(M_a)}{2} \to \infty \quad \text{as } a \to \infty. \tag{2.33}$$

By the superlinearity of f it follows that $f(v_a(t)) \geq \frac{1}{2} v_a^p(t)$ on $[M_a, \frac{M_a+R^*}{2}]$ if a is sufficiently large. By using this in (2.2) we obtain

$$v_a'' = -h(t)f(v_a(t)) \leq -\frac{1}{2} v_a^p(t).$$

Now integrating this on $[M_a, t]$ where $M_a \leq t \leq \frac{M_a+R^*}{2}$ and recalling that M_a is a local maximum of v_a with v_a decreasing on $[M_a, R^*]$ yields

$$v_a'(t) \leq -\frac{1}{2} \int_{M_a}^{t} v_a^p(x) \, dx \leq -\frac{1}{2} v_a^p(t) \int_{M_a}^{t} h(x) \, dx.$$

Rewriting the above gives

$$\frac{-v_a'}{v_a^p} \geq \frac{1}{2} \int_{M_a}^{t} h(x) \, dx.$$

Integrating again on (M_a, t) gives,

$$\frac{1}{(p-1)v_a^{p-1}(t)} \geq \frac{1}{p-1} [v_a^{1-p}(t) - v_a^{1-p}(M_a)] \geq \frac{1}{2} \int_{M_a}^{t} \int_{M_a}^{s} h(x) \, dx \, ds.$$

Evaluating at $t = \frac{M_a+R^*}{2}$ we obtain

$$\frac{1}{(p-1)v_a^{p-1}(\frac{M_a+R^*}{2})} \geq \frac{1}{2} \int_{M_a}^{\frac{M_a+R^*}{2}} \int_{M_a}^{s} h(x) \, dx \, ds. \tag{2.34}$$

Since $p - 1 > 0$, it follows from (2.33) that the left-hand side of (2.34) goes to zero as $a \to \infty$. Thus, since $h(x) > 0$ and h is continuous on $[M_a, R^*]$, it follows from (2.34) that $M_a \to R^*$ as $a \to \infty$. This completes the lemma. □

Lemma 2.6. *Assume (H1)–(H5) hold, $N \geq 3$ and let v_a solve (2.5). Then for $a > 0$ sufficiently large v_a has a zero, z_a, with $0 < z_a < M_a < R^*$ where $z_a \to R^*$ and $|v_a'(z_a)| \to \infty$ as $a \to \infty$. In addition, if a is sufficiently large and $n \geq 1$, then v_a has n zeros on $(0, R^*)$.*

Proof. First we show that $\exists z_a \in (0, M_a)$ such that $v_a(z_a) = 0$. Suppose on the contrary that v_a stays positive on $(0, M_a)$. We note that v_a cannot have a positive critical point on $(0, M_a)$. If it has a positive critical point c_a with $v_a' > 0$ on (c_a, M_a), then $v_a(c_a) > 0$ and $v_a''(c_a) \geq 0$. So by (2.2) $f(v_a(c_a)) \leq 0$ but then $v_a(c_a) \leq 0$ contradicting that $v_a > 0$ on $(0, M_a)$. Thus v_a is increasing on $(0, R^*)$. Next recall from (2.11) that $E_a' \leq 0$ on $(0, R^*]$. So we have

$$\frac{1}{2}\frac{v_a'^2}{h(t)} + F(v_a) \geq F(v_a(M_a)) \quad \text{on } (0, M_a]. \tag{2.35}$$

Rewriting (2.35) and integrating on $(0, M_a)$ by making the change of variable $s = v_a(t)$ gives

$$\begin{aligned} \int_0^{M_a} \sqrt{2h(t)}\, dt \leq \int_0^{M_a} \frac{v_a'(t)\, dt}{\sqrt{F(V_a(M_a) - F(v_a(t))}} &= \int_{v_a(0)}^{v_a(M_a)} \frac{ds}{\sqrt{F(v_a(M_a)) - F(s)}} \\ &\leq \int_0^{v_a(M_a)} \frac{ds}{\sqrt{F(v_a(M_a)) - F(s)}}. \end{aligned} \tag{2.36}$$

We now estimate the integral on the right-hand side of (2.36). Letting $s = v_a(M_a)x$, we obtain

$$\int_0^{v_a(M_a)} \frac{ds}{\sqrt{F(v_a(M_a)) - F(s)}} = \frac{v_a(M_a)}{\sqrt{F(v_a(M_a))}} \int_0^1 \frac{dx}{\sqrt{1 - \frac{F(v_a(M_a)x)}{F(v_a(M_a))}}}. \tag{2.37}$$

Let $G(u) = \int_0^u g(s)\, ds$. Then by $(H2)$ it follows that

$$\begin{aligned} \frac{F(v_a(M_a)x)}{F(v_a(M_a))} &= \frac{v_a^{p+1}(M_a)x^{p+1} + G(v_a(M_a)x)}{v_a^{p+1}(M_a) + G(v_a(M_a))} \\ &= \frac{x^{p+1} + \frac{G(v_a(M_a)x)}{v_a^{p+1}(M_a)}}{1 + \frac{G(v_a(M_a))}{v_a^{p+1}(M_a)}}. \end{aligned} \tag{2.38}$$

By $(H2)$ and L'Hôpital's rule it follows that $\frac{|G(u)|}{|u^{p+1}|} \to 0$ as $u \to \infty$. This implies that given $\epsilon > 0$ there exists U such that $|G(u)| \leq \epsilon |u|^{p+1}$ for $|u| \geq U$. Also the continuity of G implies that there exists $c_6 > 0$ such that $|G(u)| \leq c_6$ for $|u| \leq U$. Therefore

$$|G(u)| \leq c_6 + \epsilon |u|^{p+1} \quad \text{for all } u.$$

Letting $u = v_a(M_a)x$ in the above inequality and using (2.22) we obtain

$$\begin{aligned} \frac{|G(v_a(M_a)x)|}{v_a^{p+1}(M_a)} &\leq \frac{c_6}{v_a^{p+1}(M_a)} + \epsilon x^{p+1} \\ &\leq \frac{c_6}{v_a^{p+1}(M_a)} + \epsilon (R^*)^{p+1} \\ &\leq 2(R^*)^{p+1}\epsilon \quad \text{for } a \text{ sufficiently large.} \end{aligned}$$

Therefore $\lim_{a\to\infty} \frac{G(v_a(M_a)x)}{v_a^{p+1}(M_a)} = 0$ uniformly on $[0, 1]$. In particular it follows that $\lim_{a\to\infty} \frac{G(v_a(M_a))}{v_a^{p+1}(M_a)} = 0$. Thus it follows from (2.38) that $\frac{F(v_a(M_a)x)}{F(v_a(M_a))} \to x^{p+1}$ uniformly as $a \to \infty$.

Also we know that $\int_0^1 \frac{dx}{\sqrt{1-x^{p+1}}} < \infty$ since $p > 1$. So it follows from this and the fact that f is superlinear that $\frac{v_a(M_a)}{\sqrt{F(v_a(M_a)}} \to 0$ as $a \to \infty$. Therefore it follows from (2.37) that

$$\lim_{a\to\infty} \int_0^{v_a(M_a)} \frac{ds}{\sqrt{F(v_a(M_a)) - F(s)}} = 0.$$

Hence, the right-hand side of (2.36) goes to 0 as $a \to \infty$. However, we know $h(t) > 0$ on $(0, R^*)$ and $M_a \to R^*$ as $a \to \infty$ (by Lemma 2.4), so the integral on the left-hand side of (2.36) goes to $\int_0^{R^*} \sqrt{2h(t)}\, dt > 0$ which gives a contradiction. Therefore v_a has a zero, z_a, with $0 < z_a < M_a < R^*$. Now we show that $z_a \to R^*$ as $a \to \infty$. Rewriting (2.35) and integrating on (z_a, M_a) by letting $x = v_a(t)$ we obtain

$$\int_0^{v_a(M_a)} \frac{dx}{\sqrt{F(v_a(M_a)) - F(x)}} \geq \int_{z_a}^{M_a} \sqrt{2h(t)}\, dt. \tag{2.39}$$

As we have just proved above that the left-hand side of (2.39) goes to 0 as $a \to \infty$. Thus since $h > 0$ is continuous we must have $(M_a - z_a) \to 0$ as $a \to \infty$. Since we know from Lemma 2.4 that $M_a \to R^*$ as $a \to \infty$, it follows that $z_a \to R^*$ as $a \to \infty$.

Next we show that $|v_a'(z_a)| \to \infty$ as $a \to \infty$. Since $0 < z_a < M_a$ and E_a is non-increasing we have

$$\frac{1}{2}\frac{v_a'^2(z_a)}{h(z_a)} = E_a(z_a) \geq E_a(M_a) = F(v_a(M_a)).$$

So by rewriting this we obtain

$$2h(z_a)F(v_a(M_a)) \leq v_a'^2(z_a). \tag{2.40}$$

Since $z_a \to R^*$ as $a \to \infty$ and h is continuous then $h(z_a) \to h(R^*) > 0$ as $a \to \infty$. Also, in Lemma 2.4 we saw that $v_a(M_a) \to \infty$ as $a \to \infty$ and thus since F is continuous, it follows that $F(v_a(M_a)) \to \infty$ as $a \to \infty$. Thus, from (2.40) we see that $v_a'^2(z_a) \to \infty$ as $a \to \infty$ which then implies $|v_a'(z_a)| \to \infty$ as $a \to \infty$.

Finally, we denote the largest zero of v_a on $(0, R^*)$ as $z_{1,a}$. Using a similar argument as in Lemma 2.5, it can be shown that v_a has a local minimum, $m_a \in (0, z_{1,a})$ if a is sufficiently large. And by following a similar argument as above we can show that there exists a second zero, $z_{2,a} \in (0, m_a)$ of v_a, $z_{2,a} \to R^*$ as $a \to \infty$, and $|v_a'(z_{2,a})| \to \infty$ as $a \to \infty$. Continuing in this way if a is sufficiently large and n is a given non-negative integer, then v_a has n zeros on $(0, R^*)$ if a is sufficiently large. □

3 Behavior for small $a > 0$

Lemma 3.1. *Assume (H1)–(H5) hold and let v_a solve (2.2)–(2.3). Suppose a is sufficiently small. Then v_a has a zero, z_a, and a local maximum, M_a, with $0 < z_a < M_a < R^*$. In addition, $z_a \to R^*$, $M_a \to R^*$, $|v_a'(z_a)| \to 0$, and $v_a(M_a) \to 0$ as $a \to 0^+$. Furthermore, given $n \geq 1$, if a is sufficiently small then v_a has n zeros on $(0, R^*)$.*

Proof. First we want to show that v_a has a zero on $(0, R^*)$ if a is sufficiently small. Suppose on the contrary that $v_a > 0$ on $(0, R^*)$ for all $a > 0$. By (2.6) we have

$$v_a(t) = \frac{aR^{N-1}}{N-2}(R^* - t) - \int_t^{R^*} \left(\int_s^{R^*} h(x) f(v_a(x))\, dx \right) ds. \tag{3.1}$$

Since $v_a > 0$ near R^* it follows from (2.2) that $v_a'' < 0$ near R^* so by integrating this inequality twice we obtain

$$0 < v_a < \frac{aR^{N-1}}{N-2}(R^* - t). \tag{3.2}$$

From $(H1)$ and $(H3)$ there exists $f_1 > 0$ such that $f(v_a) \geq f_1 v_a^{-q}$. Substituting this into (3.1) gives

$$v_a(t) \leq ac_7(R^* - t) - f_1 \int_t^{R^*} \left(\int_s^{R^*} h(x) v_a^{-q}(x)\, dx \right) ds \tag{3.3}$$

where $c_7 = \frac{R^{N-1}}{N-2}$. Since h is increasing on $[0, R^*]$ then from (3.2) and (3.3) we obtain

$$v_a(t) \leq ac_7(R^* - t) - f_1 h(t) \int_t^{R^*} \left(\int_s^{R^*} v_a^{-q}(x)\, dx \right) ds = ac_7(R^* - t) - \frac{f_1 h(t)(R^* - t)^{2-q}}{a^q c_7^q (1-q)(2-q)}. \tag{3.4}$$

Therefore if $v_a > 0$ on $[\frac{R^*}{2}, R^*]$, then from (3.4) we obtain

$$\frac{f_1 h(t)(R^* - t)^{1-q}}{c_7^{q+1}(1-q)(2-q)} \leq a^{q+1}. \tag{3.5}$$

Letting $t = \frac{R^*}{2}$ in (3.5) we obtain

$$\frac{f_1 h(\frac{R^*}{2})(R^*)^{1-q}}{c_7^{q+1} 2^{1-q}(1-q)(2-q)} \leq a^{q+1}. \tag{3.6}$$

The left-hand side of (3.6) is a positive constant but the right-hand side goes to 0 as $a \to 0^+$. Thus we obtain a contradiction if a is sufficiently small. Hence v_a has a zero, z_a, on $[\frac{R^*}{2}, R^*]$ if $a > 0$ is sufficiently small and $v_a > 0$ on (z_a, R^*). Since $v_a(z_a) = 0 = v_a(R^*)$ and $v_a'(R^*) < 0$, it follows that v_a has a local maximum, M_a, with $0 < z_a < M_a < R^*$.

Next by letting $t = z_a$ in (3.5) we obtain

$$\frac{f_1 h(z_a)(R^* - z_a)^{1-q}}{c_7^{q+1}(1-q)(2-q)} \leq a^{q+1}. \tag{3.7}$$

Since the right-hand side of (3.7) goes to 0 as $a \to 0^+$ it follows that $z_a \to R^*$ as $a \to 0^+$. Since $z_a < M_a < R^*$ it then follows that $M_a \to R^*$ as $a \to 0^+$.

Next we know that $\frac{1}{2}v_a'^2 + h(t)F(v_a)$ is increasing by (2.13). So it follows that

$$\frac{1}{2}v_a'^2(z_a) = \frac{1}{2}v_a'^2(z_a) + h(z_a)F(v_a(z_a)) \leq \frac{1}{2}v_a'^2(R^*) + h(R^*)F(v_a(R^*)) = \frac{1}{2}\frac{a^2 R^{2(N-1)}}{(N-2)^2}. \tag{3.8}$$

The right-hand side of (3.8) goes to 0 as $a \to 0^+$ which implies that $|v_a'(z_a)| \to 0$ as $a \to 0^+$.

Now we show that $v_a(M_a) \to 0$ as $a \to 0^+$. From (2.16) we have $|v_a| \leq \frac{aR}{N-2}$ on $(0, R^*)$. Since $v_a(M_a) \geq 0$ it then follows that

$$0 \leq v_a(M_a) \leq \frac{aR}{N-2} \to 0 \quad \text{as } a \to 0^+.$$

Now if we denote the largest zero of v_a on $(0, R^*)$ as $z_{1,a}$ then by using a similar argument as above we can show that v_a has a local minimum, m_a, on $(0, z_{1,a})$ if a is sufficiently small. Also, it can be shown that there exists a zero, $z_{2,a} \in (0, m_a)$ of v_a and $z_{2,a} \to R^*$ as $a \to 0^+$. Continuing in this way, given $n \geq 1$ then v_a has n zeros on $(0, R^*)$ if a is sufficiently small . □

4 Proof of Theorem 1.1

Let $n \geq 0$ and consider the set

$$S_n = \{a > 0 \mid v_a \text{ solves (2.2)–(2.3) and } v_a \text{ has exactly } n \text{ zeros on } (0, R^*)\}.$$

By Lemma 2.4 we observe that if $a > 0$ then $S_n \neq \emptyset$ for some n. Let $n_0 \geq 0$ be the least integer n such that $S_n \neq \emptyset$ (i.e, $S_{n_0} \neq \emptyset$ and $S_n = \emptyset$ for all $0 \leq n < n_0$). Also it follows from Lemma 2.6 that S_{n_0} is bounded from above. So let

$$a_{n_0}^+ = \sup S_{n_0}.$$

Lemma 4.1. *$v_{a_n^+}$ has exactly n zeros, $v_{a_n^+}(0) = 0$, and $v'_{a_n^+}(0) \neq 0$ for all $n \geq n_0$.*

Proof. It follows from the definition of S_{n_0} that $v_{a_{n_0}^+}$ has at least n_0 zeros on $(0, R^*)$. Suppose that $v_{a_{n_0}^+}$ has an $(n_0 + 1)$st zero. Then by the continuous dependence of v_a on a it follows that v_a has an $(n_0 + 1)$st zero if a is sufficiently close to a_{n_0}. But if we choose $a \in S_{n_0}$ such that $a < a_{n_0}$ and a is sufficiently close to a_{n_0}, then v_a has only n_0 zeros on $(0, R^*)$ which gives a contradiction. Thus $v_{a_{n_0}^+}$ has exactly n_0 zeros on $(0, R^*)$. Now we want to show that $v_{a_{n_0}^+}(0) = 0$. Assume without the loss of generality that $v_{a_{n_0}^+} > 0$ on $(0, z_{a_{n_0}})$. Then by the continuity of $v_{a_{n_0}^+}$ we have $v_{a_{n_0}^+}(0) \geq 0$. Suppose $v_{a_{n_0}^+}(0) > 0$. Since the zeros of v_a are simple and $v_a(0) > 0$ it follows that v_a has exactly n_0 zeros on $(0, R^*)$ if a is close to a_{n_0}. But if $a > a_{n_0}$ then v_a has at least $n_0 + 1$ zeros on $(0, R^*)$ which is a contradiction. Therefore, we must have $v_{a_{n_0}^+}(0) = 0$.

Next we want to show that $v'_{a_{n_0}^+}(0) \neq 0$. Assume without loss of generality that $v_{a_{n_0}^+} > 0$ on $(0, z_{n_0})$ where z_{n_0} is the n_0^{th} zero of $a_{n_0}^+$ on $(0, R^*)$. Since $v_{a_{n_0}^+}$ solves (2.2) we have

$$v''_{a_{n_0}^+} + h(t) f(v_{a_{n_0}^+}) = 0.$$

From the above equation it follows that

$$(t v'_{a_{n_0}^+} - v_{a_{n_0}^+})' = t v''_{a_{n_0}^+} = -t h(t) f(v_{a_{n_0}^+}) < 0.$$

Thus, $t v'_{a_{n_0}^+} - v_{a_{n_0}^+}$ is decreasing. Also, since $\lim_{t \to 0^+}(t v'_{a_{n_0}^+} - v_{a_{n_0}^+})$=0 we have that $(t v'_{a_{n_0}^+} - v_{a_{n_0}^+}) \leq 0$ on $(0, z_{n_0})$. It then follows that

$$\left(\frac{v_{a_{n_0}^+}}{t}\right)' \leq 0. \tag{4.1}$$

Since $v_{a_{n_0}^+} > 0$ on $(0, z_{a_{n_0}})$, we see from (4.1) that $\lim_{t \to 0^+} \frac{v_{a_{n_0}^+}}{t}$ exists. Integrating (4.1) on (t, t_0) we obtain

$$0 < \frac{v_{a_{n_0}^+}(t_0)}{t_0} \leq \lim_{t \to 0^+} \frac{v_{a_{n_0}^+}(t)}{t} = v'_{a_{n_0}^+}(0).$$

Therefore, $v'_{a_{n_0}^+}(0) > 0$. □

Next let

$$S_{n_0+1} = \{a > 0 \mid v_a \text{ solves (2.2)–(2.3) and } v_a \text{ has exactly } (n_0 + 1) \text{ zeros on } (0, R^*)\}.$$

If a is sufficiently close to $a_{n_0}^+$ with $a > a_{n_0}^+$, then by the definition of $a_{n_0}^+$ it follows that v_a has an (n_0+1)st zero, $z_{a_{n_0}+1} \in (0, R^*)$. By integrating (2.13) on (t, R^*) we obtain

$$\frac{1}{2}v_a'^2 = \frac{1}{2}\frac{a^2 R^{2(N-1)}}{(N-2)^2} - \int_t^{R^*} h' F(v_a). \tag{4.2}$$

Similarly, we have

$$\frac{1}{2}v_{a_{n_0}^+}'^2 = \frac{1}{2}\frac{{a_{n_0}^+}^2 R^{2(N-1)}}{(N-2)^2} - \int_t^{R^*} h' F(v_{a_{n_0}^+}). \tag{4.3}$$

Since $v_a \to v_{a_{n_0}^+}$ uniformly as $a \to a_{n_0}^+$ it follows from (4.2) and (4.3) that

$$\lim_{a \to a_{n_0}^+} v_a'^2 = v_{a_{n_0}^+}'^2 \text{ uniformly on } [0, t_0] \text{ for } t_0 > 0. \tag{4.4}$$

Since $v_{a_{n_0}^+}'^2(0) > 0$ it follows from (4.4) that $v_a'(t) \neq 0$ if $a > a_{n_0}^+$ and a close to $a_{n_0}^+$ and t is close to 0. Hence, v_a has at most (n_0+1) zeros and therefore v_a has exactly (n_0+1) zeros if a is sufficiently close to $a_{n_0}^+$ and $a > a_{n_0}^+$. Thus, $S_{n_0+1} \neq \emptyset$. Also it follows from Lemma 2.6 that S_{n_0+1} is bounded above.

Now let

$$a_{n_0+1}^+ = \sup S_{n_0+1}.$$

Then by using a similar argument as above we can show that $v_{a_{n_0}^+ + 1}$ has exactly (n_0+1) zeros on $(0, R^*)$ and that $v_{a_{n_0}^+ + 1}(0) = 0$. Continuation of this process will generate an infinite family of solutions $\{v_{a_n^+}\}_{n \geq n_0}$ of (2.2)–(2.3) where $v_{a_n^+}$ has exactly n zeros on $(0, R^*)$ and $v_{a_{n_0}^+}(0) = 0$.

To complete the proof we again consider the set S_{n_0} as above which is non-empty. By Lemma 3.1 it follows that S_{n_0} is bounded from below by a positive real number. So we define

$$a_{n_0}^- = \inf S_{n_0}.$$

Then by using the continuous dependence of the solution v_a on a as above we can show that $v_{a_{n_0}^-}$ has exactly n_0 zeros and $v_{a_{n_0}^-}(0) = 0$ and $v'_{a_{n_0}^-}(0) \neq 0$. Now it may be possible that S_{n_0} is a singleton set. Then we have $a_{n_0}^- = a_{n_0}^+$. In this case there is only one solution with n_0 zeros. But we know that if $a > a_{n_0}^+$ then $S_{n_0+1} \neq \emptyset$. Also if $a < a_{n_0}^- = a_{n_0}^+$ and a is close to $a_{n_0}^-$, then v_a has exactly (n_0+1) zeros. Thus S_{n_0+1} has at least two points. Next let

$$a_{n_0+1}^- = \inf S_{n_0+1}.$$

Then $a_{n_0+1}^- < a_{n_0+1}^+$ and we can also show that $v_{a_{n_0}^- + 1}$ has exactly (n_0+1) solutions and $v_{a_{n_0}^- + 1}(0) = 0$. Thus, $v_{a_{n_0}^+ + 1}$ and $v_{a_{n_0}^- + 1}$ are two solutions with exactly (n_0+1) zeros on $(0, R^*)$. Continuation of this process will generate a second infinite family of solutions $\{v_{a_n^-}\}_{n \geq n_0}$ of (2.2)–(2.3) where $v_{a_n^-}$ has exactly n zeros on $(0, R^*)$ and $v_{a_{n_0}^-}(0) = 0$.

Finally, by letting $u_n^+(t) = v_{a_n}^+(t^{\frac{1}{2-N}})$ and $u_n^-(t) = v_{a_n}^-(t^{\frac{1}{2-N}})$ we obtain two infinite families of solutions of (1.3)–(1.4) with prescribed number of zeros. This ends the proof of Theorem 1.1. □

Abstract. In this paper, we consider the equation for a class of nonlinear operators containing $p(\cdot)$-Laplacian and mean curvature operator with mixed boundary conditions in a bounded domain Ω of $\mathbb{R}^N$, under the hypothesis $p(x) > 1$ in $\overline{\Omega}$. More precisely, we are concerned with the problem under the Dirichlet condition on a part of the boundary and the Steklov boundary condition on an another part of the boundary. We show the existence of one, two and infinitely many nontrivial weak solutions of the equation according to the conditions on given functions.

Keywords: $p(\cdot)$-Laplacian type operator, mean curvature operator, mixed boundary value problem, variable exponent Sobolev space.

2020 Mathematics Subject Classification: 35D30, 35A01, 35J62, 35J57.

1 Introduction

In this paper, we consider the following equation

$$\begin{cases} -\mathrm{div}\,[\boldsymbol{a}(x, \nabla u(x))] = f(x, u(x)) & \text{in } \Omega, \\ u(x) = 0 & \text{on } \Gamma_1, \\ \boldsymbol{n}(x) \cdot \boldsymbol{a}(x, \nabla u(x)) = g(x, u(x)) & \text{on } \Gamma_2. \end{cases} \tag{1.1}$$

Here Ω is a bounded domain of $\mathbb{R}^N$ $(N \geq 2)$ with a Lipschitz-continuous ($C^{0,1}$ for short) boundary $\partial\Omega = \Gamma$ satisfying that

$$\Gamma_1 \text{ and } \Gamma_2 \text{ are disjoint open subsets of } \Gamma \text{ such that } \overline{\Gamma_1} \cup \overline{\Gamma_2} = \Gamma \text{ and } \Gamma_1 \neq \emptyset, \tag{1.2}$$

✉ Corresponding author. Email: aramaki@hctv.ne.jp

and the vector field $\boldsymbol{n}$ denotes the unit, outer, normal vector to Γ. The function $\boldsymbol{a}(x,\boldsymbol{\xi}) = \nabla_{\xi}A(x,\boldsymbol{\xi})$ is a Carathéodory function on $\Omega \times \mathbb{R}^N$ satisfying some structure conditions associated with an anisotropic exponent function $p \in C(\overline{\Omega})$ with $1 < p(x)$ for $x \in \overline{\Omega}$. Then the operator div $[\boldsymbol{a}(x, \nabla u(x))]$ is more general than the $p(\cdot)$-Laplacian

$$\Delta_{p(x)}u(x) = \mathrm{div}\,[|\nabla u(x)|^{p(x)-2}\nabla u(x)]$$

and the mean curvature operator

$$\mathrm{div}\,[(1 + |\nabla u(x)|^2)^{(p(x)-2)/2}\nabla u(x)].$$

These generalities bring about difficulties and requires some conditions.

We impose the mixed boundary conditions, that is, the Dirichlet condition on Γ_1 and the Steklov condition on Γ_2. The given data $f : \Omega \times \mathbb{R} \to \mathbb{R}$ and $g : \Gamma_2 \times \mathbb{R} \to \mathbb{R}$ are Carathéodory functions satisfying some conditions.

The study of differential equations with $p(\cdot)$-growth conditions is a very interesting topic recently. Studying such problem stimulated its application in mathematical physics, in particular, in elastic mechanics (Zhikov [31]), in electrorheological fluids (Diening [10], Halsey [19], Mihăilescu and Rădulescu [22], Růžička [24]).

Since we can only find a few of papers associate with the problem with the mixed boundary condition in variable exponent Sobolev space as in (1.1). See Aramaki [2, 5]. We are convinced of the reason for existence of this paper.

Fan [13] considered the problem (1.1) when $A(x,\boldsymbol{\xi}) = \frac{1}{p(x)}|\boldsymbol{\xi}|^{p(x)}$ and $\Gamma_2 = \emptyset$, and derived the existence of a nontrivial weak solution to (1.1). Yücedağ [29] and Mashiyev et al. [21] and many authors extended the result to the case where $A(x,\boldsymbol{\xi})$ satisfies the $p(\cdot)$-uniform convexity. In Aramaki [3] and Dai and Hao [8], the authors treated the Kirchhoff-type operator in the case where $A(x,\boldsymbol{\xi})$ satisfies the $p(\cdot)$-uniform convexity. Here the $p(\cdot)$-uniform convexity of $A(x,\boldsymbol{\xi})$ means that

$$A\left(x, \frac{\boldsymbol{\xi}+\boldsymbol{\eta}}{2}\right) + c|\boldsymbol{\xi}-\boldsymbol{\eta}|^{p(x)} \leq \frac{1}{2}A(x,\boldsymbol{\xi}) + \frac{1}{2}A(x,\boldsymbol{\eta}) \tag{1.3}$$

for a.e. $x \in \Omega$ and all $\boldsymbol{\xi},\boldsymbol{\eta} \in \mathbb{R}^N$ with some constant $c > 0$. However, even in the case where $A(x,\boldsymbol{\xi}) = \frac{1}{p(x)}|\boldsymbol{\xi}|^{p(x)}$, in general, if $1 < p(x) < 2$ in a non-empty subset of Ω, then this $p(\cdot)$-uniform convexity does not hold. Of course, if $p(x) \geq 2$ in Ω, then (1.3) holds.

In this paper, we give up this condition, but we assume that $\boldsymbol{a}(x,\boldsymbol{\xi})$ is uniformly monotone (see (A.2) below in Section 3), because we think that this hypothesis is more natural for the $p(\cdot)$-Laplacian and the mean curvature operator, and allow not only the case $2 \leq p(x)$ in $\overline{\Omega}$, but also the case $1 < p(x)$ in $\overline{\Omega}$. To overcome this, if we apply a version of the idea of Glowinski and A. Marroco [18] who treated the case $p(x) = p =$ const., then we get Proposition 3.7 below. So our results are new, because the results contain the case $1 < p(x)$ in $\overline{\Omega}$.

We derive that there exist one, two and infinitely many nontrivial weak solutions. We use the standard Mountain-Pass Theorem, Ekeland variational principle and the Symmetric Mountain-Pass Theorem, respectively (cf. Aramaki [4, 6], [21]).

This paper is also an extension of the articles [13] to the case of mixed boundary value problem and of a class of operators containing the $p(\cdot)$-Laplacian and the mean curvature operator with the case where $p(x) > 1$ in $\overline{\Omega}$.

The paper is organized as follows. In Section 2, we recall some well-known results on variable exponent Lebesgue-Sobolev spaces. In Section 3, we give the assumptions to the main theorems. In Section 4, we state the main theorems (Theorem 4.3, 4.5 and 4.6) on the existence of at least one, two and infinitely many nontrivial weak solutions according to the hypotheses on given functions f and g. The proofs of these main theorems are given in Section 5.

2 Preliminaries

Throughout this paper, let Ω be a bounded domain in $\mathbb{R}^N$ $(N \geq 2)$ with a $C^{0,1}$-boundary Γ and Ω is locally on the same side of Γ. Moreover, we assume that Γ satisfies (1.2).

In the present paper, we only consider vector spaces of real valued functions over $\mathbb{R}$. For any space B, we denote B^N by the boldface character $\boldsymbol{B}$. Hereafter, we use this character to denote vectors and vector-valued functions, and we denote the standard inner product of vectors $\boldsymbol{a} = (a_1, \ldots, a_N)$ and $\boldsymbol{b} = (b_1, \ldots, b_N)$ in $\mathbb{R}^N$ by $\boldsymbol{a} \cdot \boldsymbol{b} = \sum_{i=1}^N a_i b_i$ and $|\boldsymbol{a}| = (\boldsymbol{a} \cdot \boldsymbol{a})^{1/2}$. Furthermore, we denote the dual space of B by B^* and the duality bracket by $\langle \cdot, \cdot \rangle_{B^*,B}$.

We recall some well-known results on variable exponent Lebesgue and Sobolev spaces. See Fan and Zhang [15], Kováčik and Rácosník [20] and references therein for more detail. Furthermore, we consider some new properties on variable exponent Lebesgue space. Define $C(\overline{\Omega}) = \{p; p \text{ is a continuous function on } \overline{\Omega}\}$, and for any $p \in C(\overline{\Omega})$, put

$$p^+ = p^+(\Omega) = \sup_{x \in \Omega} p(x) \text{ and } p^- = p^-(\Omega) = \inf_{x \in \Omega} p(x).$$

For any $p \in C(\overline{\Omega})$ with $p^- \geq 1$ and for any measurable function u on Ω, a modular $\rho_{p(\cdot)} = \rho_{p(\cdot),\Omega}$ is defined by

$$\rho_{p(\cdot)}(u) = \int_\Omega |u(x)|^{p(x)} dx.$$

The variable exponent Lebesgue space is defined by

$$L^{p(\cdot)}(\Omega) = \{u; u : \Omega \to \mathbb{R} \text{ is a measurable function satisfying } \rho_{p(\cdot)}(u) < \infty\}$$

equipped with the (Luxemburg) norm

$$\|u\|_{L^{p(\cdot)}(\Omega)} = \inf\left\{\lambda > 0; \rho_{p(\cdot)}\left(\frac{u}{\lambda}\right) \leq 1\right\}.$$

Then $L^{p(\cdot)}(\Omega)$ is a Banach space. We also define

$$W^{1,p(\cdot)}(\Omega) = \{u \in L^{p(\cdot)}(\Omega); |\nabla u| \in L^{p(\cdot)}(\Omega)\},$$

where ∇u is the gradient of u, that is, $\nabla u = (\partial_1 u, \ldots, \partial_N u)$, $\partial_i = \partial/\partial x_i$, endowed with the norm

$$\|u\|_{W^{1,p(\cdot)}(\Omega)} = \|u\|_{L^{p(\cdot)}(\Omega)} + \||\nabla u|\|_{L^{p(\cdot)}(\Omega)}.$$

The following three propositions are well known (see Fan et al. [16], Fan and Zhao [17], Zhao et al. [30]).

Proposition 2.1. *Let $p \in C(\overline{\Omega})$ with $p^- \geq 1$, and let $u, u_n \in L^{p(\cdot)}(\Omega)$ $(n = 1, 2, \ldots)$. Then we have the following properties.*

(i) $\|u\|_{L^{p(\cdot)}(\Omega)} < 1(= 1, > 1) \Longleftrightarrow \rho_{p(\cdot)}(u) < 1(= 1, > 1)$.

(ii) $\|u\|_{L^{p(\cdot)}(\Omega)} > 1 \Longrightarrow \|u\|^{p^-}_{L^{p(\cdot)}(\Omega)} \le \rho_{p(\cdot)}(u) \le \|u\|^{p^+}_{L^{p(\cdot)}(\Omega)}$.

(iii) $\|u\|_{L^{p(\cdot)}(\Omega)} < 1 \Longrightarrow \|u\|^{p^+}_{L^{p(\cdot)}(\Omega)} \le \rho_{p(\cdot)}(u) \le \|u\|^{p^-}_{L^{p(\cdot)}(\Omega)}$.

(iv) $\lim_{n\to\infty} \|u_n - u\|_{L^{p(\cdot)}(\Omega)} = 0 \Longleftrightarrow \lim_{n\to\infty} \rho_{p(\cdot)}(u_n - u) = 0$.

(v) $\|u_n\|_{L^{p(\cdot)}(\Omega)} \to \infty$ *as* $n \to \infty \Longleftrightarrow \rho_{p(\cdot)}(u_n) \to \infty$ *as* $n \to \infty$.

The following proposition is a generalized Hölder inequality.

Proposition 2.2. *Let* $p \in C_+(\overline{\Omega})$, *where*

$$C_+(\overline{\Omega}) := \{p \in C(\overline{\Omega}); p^- > 1\}.$$

For any $u \in L^{p(\cdot)}(\Omega)$ *and* $v \in L^{p'(\cdot)}(\Omega)$, *we have*

$$\int_\Omega |u(x)v(x)|dx \le \left(\frac{1}{p^-} + \frac{1}{(p')^-}\right) \|u\|_{L^{p(\cdot)}(\Omega)}\|v\|_{L^{p'(\cdot)}(\Omega)} \le 2\|u\|_{L^{p(\cdot)}(\Omega)}\|v\|_{L^{p'(\cdot)}(\Omega)}.$$

Here and from now on, for any $p \in C_+(\overline{\Omega})$, $p'(\cdot)$ *denote the conjugate exponent of* $p(\cdot)$, *that is,* $p'(x) = p(x)/(p(x) - 1)$.

For $p \in C_+(\overline{\Omega})$, define for $x \in \overline{\Omega}$,

$$p^*(x) = \begin{cases} \frac{Np(x)}{N-p(x)} & \text{if } p(x) < N, \\ \infty & \text{if } p(x) \ge N. \end{cases}$$

Proposition 2.3. *Let* Ω *be a bounded domain of* $\mathbb{R}^N$ *with* $C^{0,1}$*-boundary and let* $p \in C_+(\overline{\Omega})$. *Then we have the following properties.*

(i) *The spaces* $L^{p(\cdot)}(\Omega)$ *and* $W^{1,p(\cdot)}(\Omega)$ *are separable, reflexive and uniformly convex Banach spaces.*

(ii) *If* $q(x) \in C(\overline{\Omega})$ *with* $q^- \ge 1$ *satisfies that* $q(x) \le p^*(x)$ *for all* $x \in \Omega$, *then the embedding* $W^{1,p(\cdot)}(\Omega) \hookrightarrow L^{q(\cdot)}(\Omega)$, *where* $\hookrightarrow$ *means that the embedding is continuous.*

(iii) *If* $q(x) \in C(\overline{\Omega})$ *with* $q^- \ge 1$ *satisfies that* $q(x) < p^*(x)$ *for all* $x \in \Omega$, *then the embedding* $W^{1,p(\cdot)}(\Omega) \hookrightarrow L^{q(\cdot)}(\Omega)$ *is compact.*

Next we consider the trace (cf. Fan [14]). Let Ω be a bounded domain of $\mathbb{R}^N$ with a $C^{0,1}$-boundary Γ and $p \in C(\overline{\Omega})$ with $p^- \ge 1$. Since $W^{1,p(\cdot)}(\Omega) \subset W^{1,1}(\Omega)$, the trace $\gamma(u) = u\big|_\Gamma$ to Γ of any function u in $W^{1,p(\cdot)}(\Omega)$ is well defined as a function in $L^1(\Gamma)$. We define

$$(\mathrm{Tr}\, W^{1,p(\cdot)})(\Gamma) = \{f; f \text{ is the trace to } \Gamma \text{ of a function } F \in W^{1,p(\cdot)}(\Omega)\}$$

equipped with the norm

$$\|f\|_{(\mathrm{Tr}\, W^{1,p(\cdot)})(\Gamma)} = \inf\{\|F\|_{W^{1,p(\cdot)}(\Omega)}; F \in W^{1,p(\cdot)}(\Omega) \text{ satisfying } F\big|_\Gamma = f\}$$

for $f \in (\mathrm{Tr}\, W^{1,p(\cdot)})(\Gamma)$, where the infimum can be achieved. Then we can see that $(\mathrm{Tr}\, W^{1,p(\cdot)})(\Gamma)$ is a Banach space. In the later we also write $F\big|_\Gamma = g$ by $F = g$ on Γ. Moreover, for $i = 1, 2$, we denote

$$(\mathrm{Tr}\, W^{1,p(\cdot)})(\Gamma_i) = \{f\big|_{\Gamma_i}; f \in (\mathrm{Tr}\, W^{1,p(\cdot)})(\Gamma)\}$$

equipped with the norm

$$\|g\|_{(\operatorname{Tr} W^{1,p(\cdot)})(\Gamma_i)} = \inf\{\|f\|_{(\operatorname{Tr} W^{1,p(\cdot)})(\Gamma)}; f \in (\operatorname{Tr} W^{1,p(\cdot)})(\Gamma) \text{ satisfying } f|_{\Gamma_i} = g\},$$

where the infimum can also be achieved, so for any $g \in (\operatorname{Tr} W^{1,p(\cdot)})(\Gamma_i)$, there exists $F \in W^{1,p(\cdot)}(\Omega)$ such that $F|_{\Gamma_i} = g$ and $\|F\|_{W^{1,p(\cdot)}(\Omega)} = \|g\|_{(\operatorname{Tr} W^{1,p(\cdot)})(\Gamma_i)}$.

Let $q \in C_+(\Gamma) := \{q \in C(\Gamma); q^- > 1\}$ and denote the surface measure on Γ induced from the Lebesgue measure dx on Ω by $d\sigma_x$. We define

$$L^{q(\cdot)}(\Gamma) = \Big\{u; u : \Gamma \to \mathbb{R} \text{ is a measurable function with respect to } d\sigma_x \text{ satisfying } \int_\Gamma |u(x)|^{q(x)} d\sigma_x < \infty\Big\}$$

and the norm is defined by

$$\|u\|_{L^{q(\cdot)}(\Gamma)} = \inf\left\{\lambda > 0; \int_\Gamma \left|\frac{u(x)}{\lambda}\right|^{q(x)} d\sigma_x \le 1\right\},$$

and we also define a modular on $L^{q(\cdot)}(\Gamma)$ by

$$\rho_{q(\cdot),\Gamma}(u) = \int_\Gamma |u(x)|^{q(x)} d\sigma_x.$$

Similarly as Proposition 2.1, we have the following proposition.

Proposition 2.4. *Let $q \in C(\Gamma)$ with $q^- \ge 1$, and let $u, u_n \in L^{q(\cdot)}(\Gamma)$. Then we have the following properties.*

(i) $\|u\|_{L^{q(\cdot)}(\Gamma)} < 1(= 1, > 1) \iff \rho_{q(\cdot),\Gamma}(u) < 1(= 1, > 1)$.

(ii) $\|u\|_{L^{q(\cdot)}(\Gamma)} > 1 \implies \|u\|^{q^-}_{L^{q(\cdot)}(\Gamma)} \le \rho_{q(\cdot),\Gamma}(u) \le \|u\|^{q^+}_{L^{q(\cdot)}(\Gamma)}$.

(iii) $\|u\|_{L^{q(\cdot)}(\Gamma)} < 1 \implies \|u\|^{q^+}_{L^{q(\cdot)}(\Gamma)} \le \rho_{q(\cdot),\Gamma}(u) \le \|u\|^{q^-}_{L^{q(\cdot)}(\Gamma)}$.

(iv) $\|u_n\|_{L^{q(\cdot)}(\Gamma)} \to 0 \iff \rho_{q(\cdot),\Gamma}(u_n) \to 0$.

(v) $\|u_n\|_{L^{q(\cdot)}(\Gamma)} \to \infty \iff \rho_{q(\cdot),\Gamma}(u_n) \to \infty$.

The Hölder inequality also holds for functions on Γ.

Proposition 2.5. *Let $q \in C(\Gamma)$ with $q^- > 1$. Then the following inequality holds.*

$$\int_\Gamma |f(x)g(x)| d\sigma_x \le 2\|f\|_{L^{q(\cdot)}(\Gamma)} \|g\|_{L^{q'(\cdot)}(\Gamma)} \quad \textit{for all } f \in L^{q(\cdot)}(\Gamma), g \in L^{q'(\cdot)}(\Gamma).$$

Proposition 2.6. *Let Ω be a bounded domain of $\mathbb{R}^N$ with a $C^{0,1}$-boundary Γ and let $p \in C_+(\overline{\Omega})$. If $f \in (\operatorname{Tr} W^{1,p(\cdot)})(\Gamma)$, then $f \in L^{p(\cdot)}(\Gamma)$ and there exists a constant $C > 0$ such that*

$$\|f\|_{L^{p(\cdot)}(\Gamma)} \le C\|f\|_{(\operatorname{Tr} W^{1,p(\cdot)})(\Gamma)}.$$

In particular, If $f \in (\operatorname{Tr} W^{1,p(\cdot)})(\Gamma)$, then $f \in L^{p(\cdot)}(\Gamma_i)$ and $\|f\|_{L^{p(\cdot)}(\Gamma_i)} \le C\|f\|_{(\operatorname{Tr} W^{1,p(\cdot)})(\Gamma)}$ for $i = 1, 2$.

For $p \in C_+(\overline{\Omega})$, define for $x \in \overline{\Omega}$,

$$p^\partial(x) = \begin{cases} \frac{(N-1)p(x)}{N-p(x)} & \text{if } p(x) < N, \\ \infty & \text{if } p(x) \geq N. \end{cases}$$

The following proposition follows from Yao [28, Proposition 2.6].

Proposition 2.7. *Let $p \in C_+(\overline{\Omega})$. Then if $q \in C_+(\Gamma)$ satisfies $q(x) \leq p^\partial(x)$ for all $x \in \Gamma$, then the trace mapping $W^{1,p(\cdot)}(\Omega) \to L^{q(\cdot)}(\Gamma)$ is well-defined, continuous and*

$$\|u\|_{L^{q(\cdot)}(\Gamma)} \leq C\|u\|_{W^{1,p(\cdot)}(\Omega)} \text{ for } u \in W^{1,p(\cdot)}(\Omega)$$

for some constant $C > 0$.

In particular, if $q(x) < p^\partial(x)$ for all $x \in \Gamma_2$, then the trace mapping $W^{1,p(\cdot)}(\Omega) \to L^{q(\cdot)}(\Gamma)$ is compact.

Now we consider the weighted variable exponent Lebesgue space. Let $p \in C(\overline{\Omega})$ with $p^- \geq 1$ and let $a(x)$ be a measurable function on Ω with $a(x) > 0$ a.e. $x \in \Omega$. We define a modular

$$\rho_{(p(\cdot),a(\cdot))}(u) = \int_\Omega a(x)|u(x)|^{p(x)}dx \text{ for any measurable function } u \text{ in } \Omega.$$

Then the weighted Lebesgue space is defined by

$$L^{p(\cdot)}_{a(\cdot)}(\Omega) = \left\{u; u \text{ is a measurable function on } \Omega \text{ satisfying } \rho_{(p(\cdot),a(\cdot))}(u) < \infty\right\}$$

equipped with the norm

$$\|u\|_{L^{p(\cdot)}_{a(\cdot)}(\Omega)} = \inf\left\{\lambda > 0; \int_\Omega a(x)\left|\frac{u(x)}{\lambda}\right|^{p(x)} dx \leq 1\right\}.$$

Then $L^{p(\cdot)}_{a(\cdot)}(\Omega)$ is a Banach space.

We have the following proposition (cf. [13, Proposition 2.5]).

Proposition 2.8. *Let $p \in C(\overline{\Omega})$ with $p^- \geq 1$. For $u, u_n \in L^{p(\cdot)}_{a(\cdot)}(\Omega)$, we have the following.*

(i) *For $u \neq 0$, $\|u\|_{L^{p(\cdot)}_{a(\cdot)}(\Omega)} = \lambda \Longleftrightarrow \rho_{(p(\cdot),a(\cdot))}\left(\frac{u}{\lambda}\right) = 1$.*

(ii) $\|u\|_{L^{p(\cdot)}_{a(\cdot)}(\Omega)} < 1\ (= 1, > 1) \Longleftrightarrow \rho_{(p(\cdot),a(\cdot))}(u) < 1\ (= 1, > 1)$.

(iii) $\|u\|_{L^{p(\cdot)}_{a(\cdot)}(\Omega)} > 1 \Longrightarrow \|u\|^{p^-}_{L^{p(\cdot)}_{a(\cdot)}(\Omega)} \leq \rho_{(p(\cdot),a(\cdot))}(u) \leq \|u\|^{p^+}_{L^{p(\cdot)}_{a(\cdot)}(\Omega)}$.

(iv) $\|u\|_{L^{p(\cdot)}_{a(\cdot)}(\Omega)} < 1 \Longrightarrow \|u\|^{p^+}_{L^{p(\cdot)}_{a(\cdot)}(\Omega)} \leq \rho_{(p(\cdot),a(\cdot))}(u) \leq \|u\|^{p^-}_{L^{p(\cdot)}_{a(\cdot)}(\Omega)}$.

(v) $\lim_{n\to\infty} \|u_n - u\|_{L^{p(\cdot)}_{a(\cdot)}(\Omega)} = 0 \Longleftrightarrow \lim_{n\to\infty} \rho_{(p(\cdot),a(\cdot))}(u_n - u) = 0$.

(vi) $\|u_n\|_{L^{p(\cdot)}_{a(\cdot)}(\Omega)} \to \infty$ *as* $n \to \infty \Longleftrightarrow \rho_{(p(\cdot),a(\cdot))}(u_n) \to \infty$ *as* $n \to \infty$.

The author of [13] also derived the following proposition (cf. [13, Theorem 2.1]).

Proposition 2.9. *Let Ω be a bounded domain of $\mathbb{R}^N$ with a $C^{0,1}$-boundary and $p \in C_+(\overline{\Omega})$. Moreover, let $a \in L^{\alpha(\cdot)}(\Omega)$ satisfy $a(x) > 0$ a.e. $x \in \Omega$ and $\alpha \in C_+(\overline{\Omega})$. If $q \in C(\overline{\Omega})$ satisfies*

$$1 \leq q(x) < \frac{\alpha(x) - 1}{\alpha(x)} p^*(x) \quad \text{for all } x \in \overline{\Omega},$$

then the embedding $W^{1,p(\cdot)}(\Omega) \hookrightarrow L^{q(\cdot)}_{a(\cdot)}(\Omega)$ is compact.

Similarly, let $q \in C(\Gamma)$ with $q^- \geq 1$ and let $b(x)$ be a measurable function with respect to σ on Γ with $b(x) > 0$ σ-a.e. $x \in \Gamma$. We define a modular

$$\rho_{(q(\cdot),b(\cdot)),\Gamma}(u) = \int_\Gamma b(x)|u(x)|^{q(x)} d\sigma_x.$$

Then the weighted Lebesgue space on Γ is defined by

$$L^{q(\cdot)}_{b(\cdot)}(\Gamma) = \{u; u \text{ is a } \sigma\text{-measurable function on } \Gamma \text{ satisfying } \rho_{(q(\cdot),b(\cdot)),\Gamma}(u) < \infty\}$$

equipped with the norm

$$\|u\|_{L^{q(\cdot)}_{b(\cdot)}(\Gamma)} = \inf\left\{\lambda > 0; \int_\Gamma b(x)\left|\frac{u(x)}{\lambda}\right|^{q(x)} d\sigma_x \leq 1\right\}.$$

Then $L^{q(\cdot)}_{b(\cdot)}(\Gamma)$ is a Banach space.

Then we have the following proposition.

Proposition 2.10. *Let $q \in C(\Gamma)$ with $q^- \geq 1$. For $u, u_n \in L^{q(\cdot)}_{b(\cdot)}(\Gamma)$, we have the following.*

(i) $\|u\|_{L^{q(\cdot)}_{b(\cdot)}(\Gamma)} < 1\ (= 1, > 1) \Longleftrightarrow \rho_{(q(\cdot),b(\cdot)),\Gamma}(u) < 1\ (= 1, > 1)$.

(ii) $\|u\|_{L^{q(\cdot)}_{b(\cdot)}(\Gamma)} > 1 \Longrightarrow \|u\|^{q^-}_{L^{q(\cdot)}_{b(\cdot)}(\Gamma)} \leq \rho_{(q(\cdot),b(\cdot)),\Gamma}(u) \leq \|u\|^{q^+}_{L^{q(\cdot)}_{b(\cdot)}(\Omega)}$.

(iii) $\|u\|_{L^{q(\cdot)}_{b(\cdot)}(\Gamma)} < 1 \Longrightarrow \|u\|^{q^+}_{L^{q(\cdot)}_{b(\cdot)}(\Gamma)} \leq \rho_{(q(\cdot),b(\cdot)),\Gamma}(u) \leq \|u\|^{q^-}_{L^{q(\cdot)}_{b(\cdot)}(\Gamma)}$.

(iv) $\lim_{n\to\infty} \|u_n - u\|_{L^{q(\cdot)}_{b(\cdot)}(\Gamma)} = 0 \Longleftrightarrow \lim_{n\to\infty} \rho_{(q(\cdot),b(\cdot)),\Gamma}(u_n - u) = 0$.

(v) $\|u_n\|_{L^{q(\cdot)}_{b(\cdot)}(\Gamma)} \to \infty$ *as* $n \to \infty \Longleftrightarrow \rho_{(q(\cdot),b(\cdot)),\Gamma}(u_n) \to \infty$ *as* $n \to \infty$.

The following proposition plays an important role in the present paper.

Proposition 2.11. *Let Ω be a bounded domain of $\mathbb{R}^N$ with a $C^{0,1}$-boundary Γ and let $p \in C_+(\overline{\Omega})$. Assume that $0 < b \in L^{\beta(\cdot)}(\Gamma)$, $\beta \in C_+(\Gamma)$. If $r \in C(\Gamma)$ satisfies*

$$1 \leq r(x) < \frac{\beta(x) - 1}{\beta(x)} p^\partial(x) \quad \text{for all } x \in \Gamma,$$

then the embedding $W^{1,p(\cdot)}(\Omega) \hookrightarrow L^{r(\cdot)}_{b(\cdot)}(\Gamma)$ is compact.

The following proposition is due to Edmunds and Rákosník [11, Lemma 2.1].

Proposition 2.12. *Let $q \in L^\infty(\Omega)$ and p be a measurable function on Ω such that $1 \le p(x) \le \infty$ and $1 \le q(x)p(x) \le \infty$. Assume that $f \in L^{p(\cdot)}(\Omega)$ with $f \neq 0$. Then we have the following.*

$$\|f\|_{L^{q(\cdot)p(\cdot)}(\Omega)} \le 1 \Longrightarrow \|f\|^{q^+}_{L^{q(\cdot)p(\cdot)}(\Omega)} \le \||f|^{q(\cdot)}\|_{L^{p(\cdot)}(\Omega)} \le \|f\|^{q^-}_{L^{q(\cdot)p(\cdot)}(\Omega)}.$$
$$\|f\|_{L^{q(\cdot)p(\cdot)}(\Omega)} \ge 1 \Longrightarrow \|f\|^{q^-}_{L^{q(\cdot)p(\cdot)}(\Omega)} \le \||f|^{q(\cdot)}\|_{L^{p(\cdot)}(\Omega)} \le \|f\|^{q^+}_{L^{q(\cdot)p(\cdot)}(\Omega)}.$$

In particular, if $q(x) = q = \text{const.}$, then $\||f|^q\|_{L^{p(\cdot)}(\Omega)} = \|f\|^q_{L^{qp(\cdot)}(\Omega)}$.

Define a space by

$$X = \{v \in W^{1,p(\cdot)}(\Omega); v = 0 \text{ on } \Gamma_1\}. \tag{2.1}$$

Then it is clear to see that X is a closed subspace of $W^{1,p(\cdot)}(\Omega)$, so X is a reflexive and separable Banach space. We get the following Poincaré-type inequality (cf. Ciarlet and Dinca [7]).

Proposition 2.13. *Let Ω be a bounded domain of $\mathbb{R}^N$ with a $C^{0,1}$-boundary and let $p \in C_+(\overline{\Omega})$. Then there exists a constant $C = C(\Omega, N, p) > 0$ such that*

$$\|u\|_{L^{p(\cdot)}(\Omega)} \le C\|\nabla u\|_{L^{p(\cdot)}(\Omega)} \quad \textit{for all } u \in X.$$

In particular, $\|\nabla u\|_{L^{p(\cdot)}(\Omega)}$ is equivalent to $\|u\|_{W^{1,p(\cdot)}(\Omega)}$ for $u \in X$.

For the direct proof, see Aramaki [1, Lemma 2.5].

Thus we can define the norm on X so that

$$\|v\|_X = \|\nabla v\|_{L^{p(\cdot)}(\Omega)} \quad \text{for } v \in X, \tag{2.2}$$

which is equivalent to $\|v\|_{W^{1,p(\cdot)}(\Omega)}$ from Proposition 2.13.

3 Assumptions to the main theorems

In this section, we state the assumptions to the main theorems. Let $p \in C_+(\overline{\Omega})$ be fixed.

Throughout this paper, we assume the following.

(A.0) Let $A : \Omega \times \mathbb{R}^N \to [0, \infty)$ be a function satisfying that for a.e. $x \in \Omega$ the function $A(x, \cdot) : \mathbb{R}^N \ni \boldsymbol{\xi} \mapsto A(x, \boldsymbol{\xi})$ is of C^1-class, and for all $\boldsymbol{\xi} \in \mathbb{R}^N$ the function $A(\cdot, \boldsymbol{\xi}) : \Omega \ni x \mapsto A(x, \boldsymbol{\xi})$ is measurable. Moreover, suppose that $A(x, \mathbf{0}) = 0$ and put $\boldsymbol{a}(x, \boldsymbol{\xi}) = \nabla_{\boldsymbol{\xi}} A(x, \boldsymbol{\xi})$. Then $\boldsymbol{a}(x, \boldsymbol{\xi})$ is a Carathéodory function on $\Omega \times \mathbb{R}^N$.

Moreover, we assume the following structure conditions. There exist constants $C_0, k_0 > 0$, nonnegative functions $h_0 \in L^{p'(\cdot)}(\Omega)$ and $h_1 \in L^1(\Omega)$ with $h_1(x) \ge 1$ for a.e. $x \in \Omega$ such that the following conditions hold.

(A.1) $|\boldsymbol{a}(x, \boldsymbol{\xi})| \le C_0(h_0(x) + h_1(x)|\boldsymbol{\xi}|^{p(x)-1})$ for all $\boldsymbol{\xi} \in \mathbb{R}^N$ and a.e. $x \in \Omega$.

(A.2) $\boldsymbol{a}(x, \mathbf{0}) = \mathbf{0}$ for a.e. $x \in \Omega$ and

$$(\boldsymbol{a}(x, \boldsymbol{\xi}) - \boldsymbol{a}(x, \boldsymbol{\eta})) \cdot (\boldsymbol{\xi} - \boldsymbol{\eta}) \ge \begin{cases} k_0 h_1(x)|\boldsymbol{\xi} - \boldsymbol{\eta}|^{p(x)} & \text{if } p(x) \ge 2, \\ k_0 h_1(x)(1 + |\boldsymbol{\xi}| + |\boldsymbol{\eta}|)^{p(x)-2}|\boldsymbol{\xi} - \boldsymbol{\eta}|^2 & \text{if } p(x) < 2 \end{cases}$$

for a.e. $x \in \Omega$ and all $\boldsymbol{\xi}, \boldsymbol{\eta} \in \mathbb{R}^N$.

(A.3) A is $p(\cdot)$-subhomogeneous in the sense of

$$\boldsymbol{a}(x,\boldsymbol{\xi})\cdot\boldsymbol{\xi} \le p(x)A(x,\boldsymbol{\xi}) + h_1(x) \text{ for all } \boldsymbol{\xi}\in\mathbb{R}^N \text{ and a.e. } x\in\Omega.$$

Lemma 3.1. *Under (A.0) and (A.2), there exists a constant $c > 0$ such that*

$$\frac{1}{2}A(x,\boldsymbol{\xi}) + \frac{1}{2}A(x,\boldsymbol{\eta}) - A\left(x,\frac{\boldsymbol{\xi}+\boldsymbol{\eta}}{2}\right) \ge \begin{cases} c\,h_1(x)|\boldsymbol{\xi}-\boldsymbol{\eta}|^{p(x)} & \text{if } p(x)\ge 2,\\ c\,h_1(x)(1+|\boldsymbol{\xi}|+|\boldsymbol{\eta}|)^{p(x)-2}|\boldsymbol{\xi}-\boldsymbol{\eta}|^2 & \text{if } p(x) < 2\end{cases}$$

for a.e. $x\in\Omega$ and all $\boldsymbol{\xi},\boldsymbol{\eta}\in\mathbb{R}^N$.

In particular, $A(x,\boldsymbol{\xi})$ is convex with respect to $\boldsymbol{\xi}$.

Proof. Since

$$A(x,\boldsymbol{\eta}) - A\left(x,\frac{\boldsymbol{\xi}+\boldsymbol{\eta}}{2}\right) = \int_0^1 \boldsymbol{a}\left(x,\frac{\boldsymbol{\xi}+\boldsymbol{\eta}}{2} + s\left(\frac{\boldsymbol{\eta}-\boldsymbol{\xi}}{2}\right)\right)\cdot\frac{\boldsymbol{\eta}-\boldsymbol{\xi}}{2}ds,$$

and

$$A\left(x,\frac{\boldsymbol{\xi}+\boldsymbol{\eta}}{2}\right) - A(x,\boldsymbol{\xi}) = \int_0^1 \boldsymbol{a}\left(x,\boldsymbol{\xi} + s\left(\frac{\boldsymbol{\eta}-\boldsymbol{\xi}}{2}\right)\right)\cdot\frac{\boldsymbol{\eta}-\boldsymbol{\xi}}{2}ds,$$

it follows from (A.0) and (A.2) that

$$\begin{aligned}
&\frac{1}{2}A(x,\boldsymbol{\xi}) + \frac{1}{2}A(x,\boldsymbol{\eta}) - A\left(x,\frac{\boldsymbol{\xi}+\boldsymbol{\eta}}{2}\right)\\
&\quad= \frac{1}{2}\int_0^1\left(\boldsymbol{a}\left(x,\frac{\boldsymbol{\xi}+\boldsymbol{\eta}}{2}+s\frac{\boldsymbol{\eta}-\boldsymbol{\xi}}{2}\right) - \boldsymbol{a}\left(x,\boldsymbol{\xi}+s\frac{\boldsymbol{\eta}-\boldsymbol{\xi}}{2}\right)\right)\cdot\frac{\boldsymbol{\eta}-\boldsymbol{\xi}}{2}ds\\
&\quad\ge \begin{cases}\frac{1}{2}k_0h_1(x)\left|\frac{\boldsymbol{\eta}-\boldsymbol{\xi}}{2}\right|^{p(x)} & \text{if } p(x)\ge 2,\\ \frac{1}{2}k_0h_1(x)\int_0^1\left(1+\left|\frac{\boldsymbol{\xi}+\boldsymbol{\eta}}{2}+s\frac{\boldsymbol{\eta}-\boldsymbol{\xi}}{2}\right| + \left|\boldsymbol{\xi}+s\frac{\boldsymbol{\eta}-\boldsymbol{\xi}}{2}\right|\right)^{p(x)-2}\left|\frac{\boldsymbol{\eta}-\boldsymbol{\xi}}{2}\right|^2 ds & \text{if } p(x)<2\end{cases}\\
&\quad\ge \begin{cases}\left(\frac{1}{2}\right)^{p^++1}k_0h_1(x)|\boldsymbol{\xi}-\boldsymbol{\eta}|^{p(x)} & \text{if } p(x)\ge 2,\\ \frac{1}{4}k_0h_1(x)(1+|\boldsymbol{\xi}|+|\boldsymbol{\eta}|)^{p(x)-2}|\boldsymbol{\xi}-\boldsymbol{\eta}|^2 & \text{if } p(x)<2.\end{cases}
\end{aligned}$$

In particular, since $A(x,\frac{\boldsymbol{\xi}+\boldsymbol{\eta}}{2}) \le \frac{1}{2}A(x,\boldsymbol{\xi}) + \frac{1}{2}A(x,\boldsymbol{\eta})$ and $A(x,\boldsymbol{\xi})$ is continuous with respect to $\boldsymbol{\xi}$, it is well known that $A(x,\boldsymbol{\xi})$ is convex. □

Example 3.2.

(i) $A(x,\boldsymbol{\xi}) = \frac{h(x)}{p(x)}|\boldsymbol{\xi}|^{p(x)}$ with $h\in L^1(\Omega)$ satisfying $h(x)\ge 1$ for a.e. $x\in\Omega$.

(ii) $A(x,\boldsymbol{\xi}) = \frac{h(x)}{p(x)}((1+|\boldsymbol{\xi}|^2)^{p(x)/2}-1)$ with $h\in L^{p'(\cdot)}(\Omega)$ satisfying $h(x)\ge 1$ for a.e. $x\in\Omega$.

Then $A(x,\boldsymbol{\xi})$ and $\boldsymbol{a}(x,\boldsymbol{\xi}) = \boldsymbol{\nabla}_{\boldsymbol{\xi}}A(x,\boldsymbol{\xi})$ satisfy the above assumptions (A.0)–(A.3).

Proof. In the case (i), $A(x,\boldsymbol{\xi})$ is clearly differentiable with respect to $\boldsymbol{\xi}$ for $\boldsymbol{\xi}\ne\mathbf{0}$ and $\boldsymbol{a}(x,\boldsymbol{\xi}) = h(x)|\boldsymbol{\xi}|^{p(x)-2}\boldsymbol{\xi}$ for $\boldsymbol{\xi}\ne\mathbf{0}$. Since $p(x)>1$, if we define $\boldsymbol{a}(x,\mathbf{0}) = \mathbf{0}$, then we see that $A(x,\boldsymbol{\xi})$ is of C^1-class with respect to $\boldsymbol{\xi}$, so (A.0) holds. (A.1) easily holds. If we use the well-known inequality (cf. Thelin [25]): there exists a constant $k_0 > 0$ such that

$$(|\boldsymbol{\xi}|^{p(x)-2}\boldsymbol{\xi} - |\boldsymbol{\eta}|^{p(x)-2}\boldsymbol{\eta})\cdot(\boldsymbol{\xi}-\boldsymbol{\eta}) \ge \begin{cases}k_0|\boldsymbol{\xi}-\boldsymbol{\eta}|^{p(x)} & \text{if } p(x)\ge 2,\\ k_0(1+|\boldsymbol{\xi}|+|\boldsymbol{\eta}|)^{p(x)-2}|\boldsymbol{\xi}-\boldsymbol{\eta}|^2 & \text{if } p(x)<2,\end{cases}$$

for all $\boldsymbol{\xi}, \boldsymbol{\eta} \in \mathbb{R}^N$, then we see that (A.2) holds. We can easily see that (A.3) holds.

In the case (ii), clearly $A(x, \boldsymbol{\xi})$ is of C^1-class with respect to $\boldsymbol{\xi}$ and $\boldsymbol{a}(x, \boldsymbol{\xi}) = h(x)(1 + |\boldsymbol{\xi}|^2)^{(p(x)-2)/2}\boldsymbol{\xi}$.

If $p(x) \geq 2$, since $|\boldsymbol{\xi}| \leq 1 + |\boldsymbol{\xi}|^{p(x)-1}$, we have

$$|\boldsymbol{a}(x, \boldsymbol{\xi})| \leq h(x)2^{(p^+-2)/2}(1 + |\boldsymbol{\xi}|^{p(x)-2})|\boldsymbol{\xi}| \leq 2^{p^+/2}(h(x) + h(x)|\boldsymbol{\xi}|^{p(x)-1}).$$

If $p(x) < 2$,

$$|\boldsymbol{a}(x, \boldsymbol{\xi})| \leq h(x)|\boldsymbol{\xi}|^{p(x)-2}|\boldsymbol{\xi}| = h(x)|\boldsymbol{\xi}|^{p(x)-1}.$$

Thus (A.1) with $h_0 = h_1 = h$ holds. We show that (A.2) holds. We have

$$\begin{aligned}
&(\boldsymbol{a}(x, \boldsymbol{\xi}) - \boldsymbol{a}(x, \boldsymbol{\eta})) \cdot (\boldsymbol{\xi} - \boldsymbol{\eta}) \\
&\quad = h(x) \int_0^1 \frac{d}{ds} \Big[(1 + |s\boldsymbol{\xi} + (1-s)\boldsymbol{\eta}|^2)^{(p(x)-2)/2}(s\boldsymbol{\xi} + (1-s)\boldsymbol{\eta})\Big]\, ds \cdot (\boldsymbol{\xi} - \boldsymbol{\eta}) \\
&\quad = h(x) \int_0^1 (1 + |s\boldsymbol{\xi} + (1-s)\boldsymbol{\eta}|^2)^{(p(x)-2)/2} ds |\boldsymbol{\xi} - \boldsymbol{\eta}|^2 \\
&\qquad + h(x)(p(x) - 2) \int_0^1 (1 + |s\boldsymbol{\xi} + (1-s)\boldsymbol{\eta}|^2)^{(p(x)-4)/2} |(s\boldsymbol{\xi} + (1-s)\boldsymbol{\eta}) \cdot (\boldsymbol{\xi} - \boldsymbol{\eta})|^2 ds.
\end{aligned}$$

If $p(x) \geq 2$, it follows from DiBenedetto [9, p. 14] that

$$(\boldsymbol{a}(x, \boldsymbol{\xi}) - \boldsymbol{a}(x, \boldsymbol{\eta})) \cdot (\boldsymbol{\xi} - \boldsymbol{\eta}) \geq h(x) \int_0^1 |s\boldsymbol{\xi} + (1-s)\boldsymbol{\eta}|^{p(x)-2} ds |\boldsymbol{\xi} - \boldsymbol{\eta}|^2 \geq k_0 h(x) |\boldsymbol{\xi} - \boldsymbol{\eta}|^{p(x)}.$$

If $p(x) < 2$, we have

$$\begin{aligned}
&(\boldsymbol{a}(x, \boldsymbol{\xi}) - \boldsymbol{a}(x, \boldsymbol{\eta})) \cdot (\boldsymbol{\xi} - \boldsymbol{\eta}) \\
&\quad \geq h(x) \int_0^1 (1 + |s\boldsymbol{\xi} + (1-s)\boldsymbol{\eta}|^2)^{(p(x)-2)/2} ds |\boldsymbol{\xi} - \boldsymbol{\eta}|^2 \\
&\qquad + h(x)(p(x) - 2) \int_0^1 (1 + |s\boldsymbol{\xi} + (1-s)\boldsymbol{\eta}|^2)^{(p(x)-4)/2} |s\boldsymbol{\xi} + (1-s)\boldsymbol{\eta}|^2 |\boldsymbol{\xi} - \boldsymbol{\eta}|^2 ds \\
&\quad \geq h(x)(p(x) - 1) \int_0^1 (1 + |s\boldsymbol{\xi} + (1-s)\boldsymbol{\eta}|^2)^{(p(x)-2)/2} ds |\boldsymbol{\xi} - \boldsymbol{\eta}|^2 \\
&\quad \geq (p^- - 1) h(x) (1 + |\boldsymbol{\xi}| + |\boldsymbol{\eta}|)^{p(x)-2} |\boldsymbol{\xi} - \boldsymbol{\eta}|^2.
\end{aligned}$$

Thus (A.2) holds. We show that (A.3) holds.

$$\begin{aligned}
\boldsymbol{a}(x, \boldsymbol{\xi}) \cdot \boldsymbol{\xi} &= h(x)(1 + |\boldsymbol{\xi}|^2)^{(p(x)-2)/2} |\boldsymbol{\xi}|^2 \\
&= h(x)(1 + |\boldsymbol{\xi}|^2)^{(p(x)-2)/2}(1 + |\boldsymbol{\xi}|^2 - 1) \\
&= h(x)(1 + |\boldsymbol{\xi}|^2)^{p(x)/2} - h(x)(1 + |\boldsymbol{\xi}|^2)^{(p(x)-2)/2} \\
&= p(x)A(x, \boldsymbol{\xi}) + h(x)(1 - (1 + |\boldsymbol{\xi}|^2)^{(p(x)-2)/2}) \\
&\leq p(x)A(x, \boldsymbol{\xi}) + h(x).
\end{aligned}$$

If $p(x) \geq 2$, then we can delete the last term $h(x)$, however if $p(x) < 2$, then we can not delete the last term $h(x)$ since $\{(1 + |\boldsymbol{\xi}|^2)^{(p(x)-2)/2}; \boldsymbol{\xi} \in \mathbb{R}^N\} = [0, 1]$. □

Remark 3.3.

(i) When $h(x) \equiv 1$, (i) corresponds to the $p(\cdot)$-Laplacian and (ii) corresponds to the prescribed mean curvature operator for nonparametric surface.

(ii) In many papers (for example, [29], [21], [6], [4]), the authors assume that $\boldsymbol{a}(x,\boldsymbol{\xi})\cdot\boldsymbol{\xi} \le p(x)A(x,\boldsymbol{\xi})$ instead of (A.3). However, in the above Example 3.2 we saw that if the example (ii) satisfies $1 < p(x) < 2$ in a subset of Ω with positive measure, then we have to assume (A.3).

Lemma 3.4. *Under (A.0)–(A.2), we have the following.*

(i) $|A(x,\boldsymbol{\xi})| \le C_0(h_0(x)|\boldsymbol{\xi}| + h_1(x)|\boldsymbol{\xi}|^{p(x)})$ *for a.e.* $x\in\Omega$ *and all* $\boldsymbol{\xi}\in\mathbb{R}^N$.

(ii) *There exist constants* $c>0$ *and* $C\ge 0$ *such that*

$$\boldsymbol{a}(x,\boldsymbol{\xi})\cdot\boldsymbol{\xi} \ge ch_1(x)|\boldsymbol{\xi}|^{p(x)} - Ch_1(x) \text{ for a.e. } x\in\Omega \text{ and all } \boldsymbol{\xi}\in\mathbb{R}^N.$$

In particular, if $p^- \ge 2$, *then we can take* $C=0$.

Proof. (i) From (A.0) and (A.1), we have

$$|A(x,\boldsymbol{\xi})| = |A(x,\boldsymbol{\xi}) - A(x,\mathbf{0})| = \left|\int_0^1 \frac{d}{dt}A(x,t\boldsymbol{\xi})dt\right| = \left|\int_0^1 \boldsymbol{a}(x,t\boldsymbol{\xi})\cdot\boldsymbol{\xi}dt\right| \\ \le C_0(h_0(x)|\boldsymbol{\xi}| + h_1(x)|\boldsymbol{\xi}|^{p(x)}).$$

(ii) Since it follows from (A.2) with $\boldsymbol{\eta}=\mathbf{0}$ that

$$\boldsymbol{a}(x,\boldsymbol{\xi})\cdot\boldsymbol{\xi} \ge \begin{cases} k_0h_1(x)|\boldsymbol{\xi}|^{p(x)} & \text{if } p(x)\ge 2,\\ k_0h_1(x)(1+|\boldsymbol{\xi}|)^{p(x)-2})|\boldsymbol{\xi}|^2 & \text{if } p(x)<2,\end{cases}$$

it suffices to show that when $p(x)<2$, we have $(1+|\boldsymbol{\xi}|)^{p(x)-2}|\boldsymbol{\xi}|^2 \ge c'|\boldsymbol{\xi}|^{p(x)} - C'$ for some constant $c',C'>0$. Using an elementary inequality $(a+b)^q \le 2^q(a^q+b^q)$ for real numbers $a,b\ge 0$ and $q>0$, we have

$$(1+|\boldsymbol{\xi}|)^{2-p(x)} \le 2^{2-p(x)}(|\boldsymbol{\xi}|^{2-p(x)}+1) \le 2^{2-p^-}|\boldsymbol{\xi}|^{2-p(x)} + 2^{2-p^-}.$$

Thereby, $|\boldsymbol{\xi}|^{2-p(x)} \ge 2^{p^--2}(1+|\boldsymbol{\xi}|)^{2-p(x)} - 1$. When $|\boldsymbol{\xi}|\le 1$, since $p(x)-1>0$, we have

$$\begin{aligned}(1+|\boldsymbol{\xi}|)^{p(x)-2}|\boldsymbol{\xi}|^2 &= (1+|\boldsymbol{\xi}|)^{p(x)-2}|\boldsymbol{\xi}|^{2-p(x)}|\boldsymbol{\xi}|^{p(x)}\\ &\ge (1+|\boldsymbol{\xi}|)^{p(x)-2}(2^{p^--2}(1+|\boldsymbol{\xi}|)^{2-p(x)}-1)|\boldsymbol{\xi}|^{p(x)}\\ &= 2^{p^--2}|\boldsymbol{\xi}|^{p(x)} - (1+|\boldsymbol{\xi}|)^{p(x)-2}|\boldsymbol{\xi}|^{p(x)}\\ &\ge 2^{p^--2}|\boldsymbol{\xi}|^{p(x)} - (2|\boldsymbol{\xi}|)^{p(x)-2}|\boldsymbol{\xi}|^{p(x)}\\ &\ge 2^{p^--2}|\boldsymbol{\xi}|^{p(x)} - 2^{p^+-2}|\boldsymbol{\xi}|^{2(p(x)-1)}\\ &\ge 2^{p^--2}|\boldsymbol{\xi}|^{p(x)} - 2^{p^+-2}.\end{aligned}$$

When $|\boldsymbol{\xi}|\ge 1$, we have $(1+|\boldsymbol{\xi}|)^{p(x)-2}|\boldsymbol{\xi}|^2 \ge (2|\boldsymbol{\xi}|)^{p(x)-2}|\boldsymbol{\xi}|^2 \ge 2^{p^--2}|\boldsymbol{\xi}|^{p(x)}$. Therefore, we have $(1+|\boldsymbol{\xi}|)^{p(x)-2}|\boldsymbol{\xi}|^2 \ge 2^{p^--2}|\boldsymbol{\xi}|^{p(x)} - 2^{p^+-2}$ for all $\boldsymbol{\xi}\in\mathbb{R}^N$. □

For the function $h_1\in L^1(\Omega)$ with $h_1(x)\ge 1$ for a.e. $x\in\Omega$, we define a modular

$$\rho_{p(\cdot),h_1(\cdot)}(v) = \rho_{p(\cdot),h_1(\cdot),\Omega}(v) = \int_\Omega h_1(x)|\nabla v(x)|^{p(x)}dx \quad \text{for } v\in Y,$$

where Y is our basic space defined by

$$Y = Y(\Omega) = \{v \in X; \rho_{p(\cdot),h_1(\cdot)}(v) < \infty\}, \tag{3.1}$$

the space X is defined by (2.1), equipped with the norm

$$\|v\|_Y = \inf\left\{\lambda > 0; \rho_{p(\cdot),h_1(\cdot)}\left(\frac{v}{\lambda}\right) \le 1\right\}.$$

Then Y is a Banach space (see Proposition 3.5 below). We note that $C_0^\infty(\Omega) \subset Y$. Since

$$\rho_{p(\cdot),h_1(\cdot)}(v) = \rho_{p(\cdot)}(h_1^{1/p(\cdot)}\nabla v),$$

we have

$$\|v\|_Y = \|h_1^{1/p(\cdot)}\nabla v\|_{L^{p(\cdot)}(\Omega)}. \tag{3.2}$$

We have the following propositions.

Proposition 3.5. *The space $(Y, \|\cdot\|_Y)$ is a separable and reflexive Banach space.*

For the proof, see [4, Lemma 2.12].

Proposition 3.6. *Let Y be the above Banach space defined by (3.1) and X be the space defined by (2.1). Then we have the following properties.*

(i) *$Y \hookrightarrow X$ and $\|v\|_X \le \|v\|_Y$ for all $v \in Y$.*

(ii) *Let $v \in Y$. Then $\|v\|_Y > 1 (= 1, < 1) \Longleftrightarrow \rho_{p(\cdot),h_1(\cdot)}(v) > 1 (= 1, < 1)$.*

(iii) *Let $v \in Y$. Then $\|v\|_Y > 1 \Longrightarrow \|v\|_Y^{p^-} \le \rho_{p(\cdot),h_1(\cdot)}(v) \le \|v\|_Y^{p^+}$.*

(iv) *Let $v \in Y$. Then $\|v\|_Y < 1 \Longrightarrow \|v\|_Y^{p^+} \le \rho_{p(\cdot),h_1(\cdot)}(v) \le \|v\|_Y^{p^-}$.*

(v) *Let $u_n, u \in Y$. Then $\lim_{n\to\infty}\|u_n - u\|_Y = 0 \Longleftrightarrow \lim_{n\to\infty}\rho_{p(\cdot),h_1(\cdot)}(u_n - u) = 0$.*

(vi) *Let $u_n \in Y$. Then $\|u_n\|_Y \to \infty$ as $n \to \infty \Longleftrightarrow \rho_{p(\cdot),h_1(\cdot)}(u_n) \to \infty$ as $n \to \infty$.*

The following proposition fulfills an important role in this paper. In the following, we denote positive constants by c, c', C, C' which may vary from line to line, and put $\Omega_1 = \{x \in \Omega; p(x) \ge 2\}$, $\Omega_2 = \{x \in \Omega; p(x) < 2\}$.

Proposition 3.7. *Under (A.0)–(A.2), there exist positive constants c and C such that*

$$\begin{aligned}
\int_\Omega (\boldsymbol{a}(x, \nabla u(x)) - \boldsymbol{a}(x, \nabla v(x))) \cdot (\nabla u(x) - \nabla v(x))dx \ge c\rho_{h_1(\cdot),p(\cdot),\Omega_1}(u - v) \\
+ \left\{c(C + \|u\|_Y + \|v\|_Y)^{(p^-(\Omega_2)-2)p^-(\Omega_2)/2}\rho_{h_1(\cdot),p(\cdot),\Omega_2}(u - v)\right\}^{2/p^+(\Omega_2)} \\
\wedge \left\{c(C + \|u\|_Y + \|v\|_Y)^{(p^-(\Omega_2)-2)p^-(\Omega_2)/2}\rho_{h_1(\cdot),p(\cdot),\Omega_2}(u - v)\right\}^{2/p^-(\Omega_2)}
\end{aligned}$$

for $u, v \in Y$. Here and from now on, we denote $a \vee b = \max\{a, b\}$ and $a \wedge b = \min\{a, b\}$ for real numbers a and b.

In particular, if $v = 0$ and $\|u\|_Y < 1$, then we have

$$\int_\Omega \boldsymbol{a}(x, \nabla u(x)) \cdot \nabla u(x)dx \ge c_1(\rho_{h_1(\cdot),p(\cdot),\Omega_1}(u) + \rho_{h_1(\cdot),p(\cdot),\Omega_2}(u)^{2/p^-})$$

for some constant $c_1 > 0$. We also get the following estimate.

$$\int_\Omega \boldsymbol{a}(x, \nabla u(x)) \cdot \nabla u(x)dx \ge c\|u\|_Y^{p^+} \wedge \|u\|_Y^{p^-} - C\|h_1\|_{L^1(\Omega)} \quad \text{for all } u \in Y. \tag{3.3}$$

Proof. For brevity of notation, for $u, v \in Y$, we put

$$J(u(x); v(x)) = (\boldsymbol{a}(x, \nabla u(x)) - \boldsymbol{a}(x, \nabla v(x))) \cdot (\nabla u(x) - \nabla v(x)).$$

We decompose the integral of $J(u(x); v(x))$ over Ω as follows.

$$\int_\Omega J(u(x); v(x))dx = \int_{\Omega_1} J(u(x); v(x))dx + \int_{\Omega_2} J(u(x); v(x))dx.$$

We can easily see that when $|\Omega_1| > 0$, it follows from (A.2) that

$$\int_{\Omega_1} J(u(x); v(x))dx \geq k_0 \int_{\Omega_1} h_1(x)|\nabla u(x) - \nabla v(x)|^{p(x)}dx.$$

When $|\Omega_2| > 0$, it follows from (A.2) that

$$(h_1(x)^{1/p(x)} + h_1(x)^{1/p(x)}|\nabla u(x)| + h_1(x)^{1/p(x)}|\nabla v(x)|)^{2-p(x)} J(u(x); v(x)) \\ \geq k_0|h_1(x)^{1/p(x)}\nabla u(x) - h_1(x)^{1/p(x)}\nabla v(x)|^2.$$

By integrating $p(x)/2$-powers of the above inequality over Ω_2, we have

$$\int_{\Omega_2} k_0^{p(x)/2}|h_1(x)^{1/p(x)}\nabla u(x) - h_1(x)^{1/p(x)}\nabla v(x)|^{p(x)}dx \\ \leq \int_{\Omega_2} (h_1(x)^{1/p(x)} + h_1(x)^{1/p(x)}|\nabla u(x)| + h_1(x)^{1/p(x)}|\nabla v(x)|)^{(2-p(x))p(x)/2} \\ \times J(u(x); v(x))^{p(x)/2}dx.$$

We note that

$$(h_1(\cdot)^{1/p(\cdot)} + h_1(\cdot)^{1/p(\cdot)}|\nabla u(\cdot)| + h_1(\cdot)^{1/p(\cdot)}|\nabla v(\cdot)|)^{(2-p(\cdot))p(\cdot)/2} \in L^{2/(2-p(\cdot))}(\Omega_2),$$

and $(J(u(\cdot); v(\cdot))^{p(\cdot)/2} \in L^{2/p(\cdot)}(\Omega_2)$, and $(2 - p(x))/2 + p(x)/2 = 1$. By the Hölder inequality (Proposition 2.2), we have

$$k_1 \int_{\Omega_2} h_1(x)^{1/p(x)}|\nabla u(x) - h_1(x)^{1/p(x)}\nabla v(x)|^{p(x)}dx \\ \leq 2\|(h_1(\cdot)^{1/p(\cdot)} + h_1(\cdot)^{1/p(\cdot)}|\nabla u(\cdot)| + h_1(\cdot)^{1/p(\cdot)}|\nabla v(\cdot)|)^{(2-p(\cdot))p(\cdot)/2}\|_{L^{2/(2-p(\cdot))}(\Omega_2)} \\ \times \|J(u(\cdot); v(\cdot))^{p(\cdot)/2}\|_{L^{2/p(\cdot)}(\Omega_2)},$$

where $k_1 = k_0^{p^+(\Omega_2)/2} \wedge k_0^{p^-(\Omega_2)/2}$. We choose $C > 1$ so that $C\|h_1(\cdot)^{1/p(\cdot)}\|_{L^{p(\cdot)}(\Omega_2)} \geq 1$. Then $\|Ch_1(\cdot)^{1/p(\cdot)} + h_1(\cdot)^{1/p(\cdot)}|\nabla u(\cdot)| + h_1(\cdot)^{1/p(\cdot)}|\nabla v(\cdot)|\|_{L^{p(\cdot)}(\Omega_2)} \geq 1$ by the definition of $L^{p(\cdot)}$-norm. By Proposition 2.12,

$$\|(Ch_1(\cdot)^{1/p(\cdot)} + h_1(\cdot)^{1/p(\cdot)}|\nabla u(\cdot)| + h_1(\cdot)^{1/p(\cdot)}|\nabla v(\cdot)|)^{(2-p(\cdot))p(\cdot)/2}\|_{L^{2/(2-p(\cdot))}(\Omega_2)} \\ \leq \|Ch_1(\cdot)^{1/p(\cdot)} + h_1(\cdot)^{1/p(\cdot)}|\nabla u(\cdot)| + h_1(\cdot)^{1/p(\cdot)}|\nabla v(\cdot)|\|_{L^{p(\cdot)}(\Omega_2)}^{((2-p(\cdot))p(\cdot)/2)^+(\Omega_2)}.$$

Here since $(2 - p(x))p(x)/2 = -\frac{1}{2}(p(x) - 1)^2 + \frac{1}{2}$, we see that $(2 - p(x))p(x)/2)^+(\Omega_2) = (2 - p^-(\Omega_2))p^-(\Omega_2)/2$. Since it follows from Proposition 2.12 that

$$\|Ch_1(\cdot)^{1/p(\cdot)}\|_{L^{p(\cdot)}(\Omega_2)} \leq C\|h_1\|_{L^1(\Omega)}^{1/p^+(\Omega_2)} \vee \|h_1\|_{L^1(\Omega)}^{1/p^-(\Omega_2)} =: C_1,$$

and $\|h_1(\cdot)^{1/p(\cdot)}|\nabla u(\cdot)|\|_{L^{p(\cdot)}(\Omega_2)} \le \|u\|_Y$ and $\|h_1(\cdot)^{1/p(\cdot)}|\nabla v(\cdot)|\|_{L^{p(\cdot)}(\Omega_2)} \le \|v\|_Y$, we have

$$\|(Ch_1(\cdot)^{1/p(\cdot)} + h_1(\cdot)^{1/p(\cdot)}|\nabla u(\cdot)| + h_1(\cdot)^{1/p(\cdot)}|\nabla v(\cdot)|)^{(2-p(\cdot))p(\cdot)/2}\|_{L^{2/(2-p(\cdot))}(\Omega_2)} \le (C_1 + \|u\|_Y + \|v\|_Y)^{(2-p^-(\Omega_2))p^-(\Omega_2)/2}.$$

Using Proposition 2.12,

$$\|J(u(\cdot);v(\cdot))^{p(\cdot)/2}\|_{L^{2/p(\cdot)}(\Omega_2)} \le \|J(u(\cdot);v(\cdot))\|_{L^1(\Omega_2)}^{p^+(\Omega_2)/2} \vee \|J(u(\cdot);v(\cdot))\|_{L^1(\Omega_2)}^{p^-(\Omega_2)/2}.$$

Hence we have

$$\begin{aligned}\int_{\Omega_2} J(u(x);v(x))dx &= \|J(u(\cdot);v(\cdot))\|_{L^1(\Omega_2)} \\ &\ge \left\{(C_1 + \|u\|_Y + \|v\|_Y)^{(p^-(\Omega_2)-2)p^-(\Omega_2)/2} k_1 \int_{\Omega_2} h_1(x)|\nabla u(x) - \nabla v(x)|^{p(x)}dx\right\}^{2/p^+(\Omega_2)} \\ &\quad \wedge \left\{(C_1 + \|u\|_Y + \|v\|_Y)^{(p^-(\Omega_2)-2)p^-(\Omega_2)/2} k_1 \int_{\Omega_2} h_1(x)|\nabla u(x) - \nabla v(x)|^{p(x)}dx\right\}^{2/p^-(\Omega_2)}.\end{aligned}$$

In particular case where $v = 0$ and $\|u\|_Y < 1$,

$$\begin{aligned}\int_\Omega \boldsymbol{a}(x, \nabla u(x)) \cdot \nabla u(x)dx &\ge k_0 \int_{\Omega_1} h_1(x)|\nabla u(x)|^{p(x)}dx \\ &\quad + (C_1+1)^{p^-(\Omega_2)-2} k_1^{2/p^+(\Omega_2)} \wedge k_1^{2/p^-(\Omega_2)} \left\{\int_{\Omega_2} h_1(x)|\nabla u(x)|^{p(x)}dx\right\}^{2/p^-(\Omega_2)}.\end{aligned}$$

For the estimate (3.3), it suffices to use Lemma 3.4 (ii). This completes the proof. □

Here we state the assumptions on functions f and g in (1.1).

(f.1) $f = f(x,t)$ is a real Carathéodory function on $\Omega \times \mathbb{R}$ and there exist $1 \le a \in L^{\alpha(\cdot)}(\Omega)$ with $\alpha \in C_+(\overline{\Omega})$, and $q \in C_+(\overline{\Omega})$ with

$$q(x) < \frac{\alpha(x)-1}{\alpha(x)} p^*(x) \quad \text{for all } x \in \overline{\Omega}$$

such that

$$|f(x,t)| \le C_1(1 + a(x)|t|^{q(x)-1}) \quad \text{for all } t \in \mathbb{R} \text{ and a.e. } x \in \Omega,$$

where C_1 is a positive constant and $p^+ < q^-$.

(f.2) There exist $\theta > p^+$ and $t_0 > 0$ such that

$$0 < \theta F(x,t) \le f(x,t)t \quad \text{for all } t \in \mathbb{R} \setminus (-t_0, t_0) \text{ and a.e. } x \in \Omega,$$

where

$$F(x,t) = \int_0^t f(x,s)ds. \tag{3.4}$$

(f.3) $f(x,t) = o(|t|^{p^+-1})$ uniformly as $t \to 0$.

(g.1) $g = g(x,t)$ is a real Carathéodory function on $\Gamma_2 \times \mathbb{R}$ and there exist $1 \le b \in L^{\beta\cdot)}(\Gamma_2)$ with $\beta \in C_+(\overline{\Gamma_2})$, and $r \in C_+(\overline{\Gamma_2})$ with

$$r(x) < \frac{\beta(x)-1}{\beta(x)} p^{\partial}(x) \quad \text{for all } x \in \overline{\Gamma_2}$$

such that

$$|g(x,t)| \le C_2(1 + b(x)|t|^{r(x)-1}) \quad \text{for all } t \in \mathbb{R} \text{ and } \sigma\text{-a.e. } x \in \Gamma_2,$$

where C_2 is a positive constant and $p^+ < r^-$.

(g.2) Let θ and t_0 be as in (f.2). That is, there exist $\theta > p^+(\Omega_1) \vee 2p^+(\Omega_2)/p^-(\Omega_2)$ and $t_0 > 0$ such that

$$0 < \theta G(x,t) \le g(x,t)t \quad \text{for all } t \in \mathbb{R} \setminus (-t_0, t_0) \text{ and a.e. } x \in \Gamma_2,$$

where

$$G(x,t) = \int_0^t g(x,s)ds. \tag{3.5}$$

(g.3) $g(x,t) = o(|t|^{p^+-1})$ uniformly as $t \to 0$.

Lemma 3.8. *Under (f.1)–(f.3) and (g.1)–(g.3), we have the following.*

(i) *For any $\lambda > 0$, there exists a constant $C_1' > 0$ such that*

$$|F(x,t)| \le \frac{\lambda}{p^+}|t|^{p^+} + C_1' a(x)|t|^{q(x)} - \frac{1}{|\Omega|}\|h_1/p\|_{L^1(\Omega)} \quad \textit{for a.e. } x \in \Omega, t \in \mathbb{R}.$$

(ii) *For any $\lambda > 0$, there exists a constant $C_2' > 0$ such that*

$$|G(x,t)| \le \frac{\lambda}{p^+}|t|^{p^+} + C_2' b(x)|t|^{r(x)} \quad \textit{for } \sigma\textit{-a.e. } x \in \Gamma_2, t \in \mathbb{R}.$$

Proof. From (f.3), for any $\lambda > 0$, there exists $\delta \in (0,1)$ such that

$$|f(x,t)| \le \lambda |t|^{p^+-1} \quad \text{for a.e. } x \in \Omega, t \in (-\delta, \delta).$$

Hence we have

$$|F(x,t)| \le \frac{\lambda}{p^+}|t|^{p^+} \quad \text{for a.e. } x \in \Omega, t \in (-\delta, \delta).$$

On the other hand, from (f.1), we have

$$|F(x,t)| \le C_1(|t| + \frac{a(x)}{q(x)}|t|^{q(x)}) \le C_2' a(x)|t|^{q(x)} \text{ for a.e. } x \in \Omega, |t| \ge \delta.$$

If we choose $C_2'' > 0$ so that $C_2'' \delta^{q^+} \ge \frac{1}{|\Omega|}\|h_1/p\|_{L^1(\Omega)}$, then

$$C_2'' a(x)|t|^{q(x)} - \frac{1}{|\Omega|}\|h_1/p\|_{L^1(\Omega)} \ge C_2''\delta^{q^+} - \frac{1}{|\Omega|}\|h_1/p\|_{L^1(\Omega)} \ge 0$$

for a.e. $x \in \Omega$ and $|t| \ge \delta$. Hence $|F(x,t)| \le (C_2' + C_2'')a(x)|t|^{q(x)} - \frac{1}{|\Omega|}\|h_1/p\|_{L^1(\Omega)}$ for a.e. $x \in \Omega$ and $|t| \ge \delta$. It suffices to put $C_1' = C_2' + C_2''$.

Similarly (ii) holds. □

Define a functional on Y by

$$I(u) = \Phi(u) - J(u) - K(u) \quad \text{for } u \in Y, \tag{3.6}$$

where

$$\Phi(u) = \int_\Omega A(x, \nabla u(x))dx, \tag{3.7}$$

$$J(u) = \int_\Omega F(x, u(x))dx, \; F(x,t) \quad \text{is defined by (3.4)}, \tag{3.8}$$

$$K(u) = \int_{\Gamma_2} G(x, u(x))d\sigma_x, \; G(x,t) \quad \text{is defined by (3.5)}. \tag{3.9}$$

Proposition 3.9. *Assume that (A.0)–(A.3), (f.1)–(f.3) and (g.1)–(g.3) hold. Then the functionals* $\Phi, J, K \in C^1(Y, \mathbb{R})$ *and the Fréchet derivatives* Φ', J' *and* K' *satisfy the following equalities.*

$$\langle \Phi'(u), v \rangle = \int_\Omega \boldsymbol{a}(x, \nabla u(x)) \cdot \nabla v(x)dx, \tag{3.10}$$

$$\langle J'(u), v \rangle = \int_\Omega f(x, u(x))v(x)dx, \tag{3.11}$$

$$\langle K'(u), v \rangle = \int_{\Gamma_2} g(x, u(x))v(x)d\sigma_x \tag{3.12}$$

for all $u, v \in Y$. *Here and hereafter, we write the duality* $\langle \cdot, \cdot \rangle_{Y^*,Y}$ *by simply* $\langle \cdot, \cdot \rangle$.

For the proof, see [4, Proposition 4.2].

Proposition 3.10. *Assume that (A.0)–(A.3), (f.1)–(f.3) and (g.1)–(g.3) hold. Then we have the following.*

(i) *The functionals* J *and* K *are weakly continuous in* Y, *that is, if* $u_n \to u$ *weakly in* Y *as* $n \to \infty$, *then* $J(u_n) \to J(u)$ *and* $K(u_n) \to K(u)$ *as* $n \to \infty$.

(ii) *The functional* Φ *is sequentially weakly lower semi-continuous in* Y, *that is, if* $u_n \to u$ *weakly in* Y *as* $n \to \infty$, *then* $\Phi(u) \le \liminf_{n\to\infty} \Phi(u_n)$.

(iii) $\Phi(u) - \Phi(v) \ge \langle \Phi'(v), u - v \rangle$ *for all* $u, v \in Y$.

For the proof, see [4, Proposition 4.4].

Lemma 3.11. *Under (f.1)–(f.3) and (g.1)–(g.3), there exist constants* c_1, c_2, C_3 *and* C_4 *such that for* $u \in Y$ *with* $\|u\|_Y < 1$, *the following inequalities hold.*

(i) *We have*

$$J(u) \le \frac{\lambda}{p^+} c_1 \|u\|_Y^{p^+} + C_3 \|u\|_Y^{q^-} - \|h_1/p\|_{L^1(\Omega)}.$$

(ii) *We have*

$$K(u) \le \frac{\lambda}{p^+} c_2 \|u\|_Y^{p^+} + C_4 \|u\|_Y^{r^-}.$$

Proof. From Lemma 3.8,

$$J(u) \leq \frac{\lambda}{p^+} \int_\Omega |u(x)|^{p^+} dx + C_3 \int_\Omega a(x)|u(x)|^{q(x)} dx - \|h_1/p\|_{L^1(\Omega)}.$$

Here it suffices to note that

$$\int_\Omega |u(x)|^{p^+} dx \leq C\|u\|_Y^{p^+}$$

with some constant $C > 0$, and

$$\int_\Omega a(x)|u(x)|^{q(x)} dx \leq C'\|u\|_Y^{q^-}.$$

(ii) follows from the similar arguments as (i). □

Proposition 3.12. *Assume that (A.0)–(A.3), (f.1)–(f.3) and (g.1)–(g.3) hold. Then there exist constants $c, c_1, c_2 > 0$ and $C_1', C_2' > 0$ such that for $u \in Y$ with $\|u\|_Y < 1$,*

$$I(u) \geq (c - \lambda c_1 - \lambda c_2)\, \|u\|_Y^{p^+} - C_1'\|u\|_Y^{q^-} - C_2'\|u\|_Y^{r^-}.$$

In particular, there exists $\rho \in (0, 1)$ such that

$$\inf_{\|u\|_Y = \rho} I(u) > 0. \tag{3.13}$$

Proof. Let $\|u\|_Y < 1$. It follows from (A.3) and Proposition 3.7 that

$$\begin{aligned}\Phi(u) = \int_\Omega A(x, \nabla u(x))dx &\geq \int_\Omega \frac{1}{p(x)} \boldsymbol{a}(x, \nabla u(x)) \cdot \nabla u(x)dx - \|h_1/p\|_{L^1(\Omega)} \\ &\geq c\|u\|_Y^{p^+} - \|h_1/p\|_{L^1(\Omega)}.\end{aligned}$$

From Lemma 3.11,

$$I(u) = \Phi(u) - J(u) - K(u) \geq (c - \lambda c_1 - \lambda c_2)\|u\|_Y^{p^+} - C_1'\|u\|_Y^{q^-} - C_2'\|u\|_Y^{r^-}.$$

If we choose $\lambda > 0$ small enough so that $c'' := c - \lambda c_1 - \lambda c_2 > 0$, then we have

$$I(u) \geq \|u\|_Y^{p^+} (c'' - C_1'\|u\|_Y^{q^- - p^+} - C_2'\|u\|_Y^{r^- - p^+}).$$

Since $q^- > p^+$ and $r^- > p^+$, if $\|u\|_Y = \rho > 0$ is small, then we have $\inf_{\|u\|_Y = \rho} I(u) > 0$. □

Proposition 3.13. *Assume that (A.0)–(A.3), (f.1)–(f.3) and (g.1)–(g.3) hold. Then there exists a constant $C_4 > 0$ such that*

$$I(u) \geq \left(\frac{1}{p^+} - \frac{1}{\theta}\right) c\|u\|_Y^{p^+} \wedge \|u\|_Y^{p^-} + \frac{1}{\theta}\langle I'(u), u\rangle - C_4 \quad \textit{for all } u \in Y.$$

Proof. From (A.3) and Lemma 3.4 (ii), for $u \in Y$, we have

$$\begin{aligned}\Phi(u) - \frac{1}{\theta}\langle \Phi'(u), u\rangle &= \int_\Omega A(x, \nabla u(x))dx - \frac{1}{\theta}\int_\Omega \boldsymbol{a}(x, \nabla u(x)) \cdot \nabla u(x)dx \\ &\geq \int_\Omega \left(\frac{1}{p(x)} - \frac{1}{\theta}\right) \boldsymbol{a}(x, \nabla u(x)) \cdot \nabla u(x)dx - \|h_1/p\|_{L^1(\Omega)} \\ &\geq \left(\frac{1}{p^+} - \frac{1}{\theta}\right)\left(c\int_\Omega h_1(x)|\nabla u(x)|^{p(x)}dx - C\int_\Omega h_1(x)dx\right) - \|h_1/p\|_{L^1(\Omega)} \\ &\geq \left(\frac{1}{p^+} - \frac{1}{\theta}\right) c\|u\|_Y^{p^+} \wedge \|u\|_Y^{p^-} - C_1\|h_1\|_{L^1(\Omega)}\end{aligned}$$

for some constant $C_1 > 0$.

On the other hand, it follows from (f.2) that

$$0 < \theta F(x,t) \le f(x,t)t \text{ for a.e. } x \in \Omega, t \in \mathbb{R} \setminus (-t_0, t_0).$$

Put $\Omega_u = \{x \in \Omega; |u(x)| > t_0\}$. Then $\frac{1}{\theta} f(x,u(x))u(x) - F(x,u(x)) \ge 0$ for a.e. $x \in \Omega_u$. For $x \in \Omega \setminus \Omega_u$, we have

$$\left|\frac{1}{\theta} f(x,u(x))u(x) - F(x,u(x))\right| \le C_2(t_0 + a(x)t_0^{q^+} \vee t_0^{q^-}).$$

Hence we have

$$\begin{aligned}\frac{1}{\theta}\langle J'(u),u\rangle - J(u) &= \int_{\Omega_u} \left(\frac{1}{\theta} f(x,u(x))u(x) - F(x,u(x))\right) dx \\ &\quad + \int_{\Omega\setminus\Omega_u} \left(\frac{1}{\theta} f(x,u(x))u(x) - F(x,u(x))\right) dx \\ &\ge -C_2 \int_{\Omega\setminus\Omega_u} (t_0 + a(x)t_0^{q^+} \vee t_0^{q^-}) dx \\ &\ge -C_2 t_0 |\Omega| - C_2 t_0^{q^+} \vee t_0^{q^-} \|a\|_{L^1(\Omega)}.\end{aligned}$$

Similarly we have

$$\frac{1}{\theta}\langle K'(u),u\rangle - K(u) \ge -C_3 t_0 |\Gamma_2| - C_3 t_0^{r^+} \vee t_0^{r^-} \|b\|_{L^1(\Gamma_2)}.$$

Thus we have

$$\begin{aligned}I(u) - \frac{1}{\theta}\langle I'(u),u\rangle &= \Phi(u) - \frac{1}{\theta}\langle \Phi'(u),u\rangle - \left(J(u) - \frac{1}{\theta}\langle J'(u),u\rangle\right) \\ &\quad - \left(K(u) - \frac{1}{\theta}\langle K'(u),u\rangle\right) \ge \left(\frac{1}{p^+} - \frac{1}{\theta}\right) c\|u\|_Y^{p^+} \wedge \|u\|_Y^{p^-} - C_4\end{aligned}$$

for some constant C_4. □

Proposition 3.14. *Assume that (A.0)–(A.3), (f.1)–(f.3) and (g.1)–(g.3) hold. Then the functional I satisfies the Palais–Smale condition, that is, if a sequence $\{u_n\} \subset Y$ satisfies that $\lim_{n\to\infty} I(u_n) = \gamma \in \mathbb{R}$ exists and $\lim_{n\to\infty} \|I'(u_n)\|_{Y^*} = 0$, then $\{u_n\}$ has a convergent subsequence.*

Proof. Let $\{u_n\} \subset Y$ satisfy that $\lim_{n\to\infty} I(u_n) = \gamma \in \mathbb{R}$ exists and $\lim_{n\to\infty} \|I'(u_n)\|_{Y^*} = 0$.

Step 1. $\{u_n\}$ is bounded in Y. Indeed, if it is false, then passing to a subsequence, we can assume that $\lim_{n\to\infty} \|u_n\|_Y = \infty$. By proposition 3.13, we have

$$I(u_n) \ge \left(\frac{1}{p^+} - \frac{1}{\theta}\right) k_0 \|u_n\|_Y^{p^-} - \frac{1}{\theta}\|I'(u_n)\|_{Y^*}\|u_n\|_Y - C_4$$

for large n. Since $\frac{1}{p^+} - \frac{1}{\theta} > 0$ and $p^- > 1$ and $\lim_{n\to\infty} \|I'(u_n)\|_{Y^*} = 0$, we have $I(u_n) \to \infty$ as $n \to \infty$. This is a contradiction.

Step 2. Since Y is a reflexive Banach space from Proposition 3.5, there exist a subsequence $\{u_{n'}\}$ of $\{u_n\}$ and $u \in Y$ such that $u_{n'} \to u$ weakly in Y as $n' \to \infty$. Since $\{u_{n'} - u\}$ is bounded in Y and $\lim_{n'\to\infty} \|I'(u_{n'})\|_{Y^*} = 0$, we see that

$$\langle I'(u_{n'}), u_{n'} - u\rangle \to 0 \text{ as } n' \to \infty.$$

By Proposition 2.9, $u_{n'} \to u$ strongly in $L^{q(\cdot)}_{a(\cdot)}(\Omega)$ and $L^{r(\cdot)}_{b(\cdot)}(\Gamma_2)$ as $n' \to \infty$. From (f.1), using the Hölder inequality,

$$\begin{aligned}
&\left| \int_\Omega f(x, u_{n'}(x))(u_{n'}(x) - u(x))dx \right| \\
&\quad \le \int_\Omega C_1(1 + a(x)|u_{n'}(x)|^{q(x)-1})|u_{n'}(x) - u(x)|dx \\
&\quad \le C_1 \int_\Omega (a(x)^{1/q(x)}|u_{n'}(x) - u(x)| + a(x)^{1/q'(x)}|u_{n'}(x)|^{q(x)-1}a(x)^{1/q(x)}|u_{n'}(x) - u(x)|)dx \\
&\quad \le 2C_1\|1\|_{L^{q'(\cdot)}(\Omega)}\|a^{1/q(\cdot)}|u_{n'} - u|\|_{L^{q(\cdot)}(\Omega)} \\
&\qquad + 2C_1\|a^{1/q'(\cdot)}|u_{n'}(\cdot)|^{q(\cdot)-1}\|_{L^{q'(\cdot)}(\Omega)}\|a^{1/q(\cdot)}|u_{n'} - u|\|_{L^{q(\cdot)}(\Omega)}.
\end{aligned}$$

Since

$$\rho_{q'(\cdot)}(a^{1/q'(\cdot)}|u_{n'}|^{q(\cdot)-1}) = \int_\Omega a(x)|u_{n'}(x)|^{q(x)}dx$$

is bounded, we see that $\|a^{1/q'(\cdot)}|u_{n'}|^{q(\cdot)-1}\|_{L^{q'(\cdot)}(\Omega)}$ is bounded. Since $\|u_{n'} - u\|_{L^{q(\cdot)}_{a(\cdot)}(\Omega)} \to 0$ as $n' \to \infty$, we see that

$$\lim_{n'\to\infty} \langle J'(u_{n'}), u_{n'} - u\rangle = \lim_{n'\to\infty} \int_\Omega f(x, u_{n'}(x))(u_{n'}(x) - u(x))dx = 0.$$

Similarly, we have

$$\lim_{n'\to\infty} \langle K'(u_{n'}), u_{n'} - u\rangle = \lim_{n'\to\infty} \int_{\Gamma_2} g(x, u_{n'}(x))(u_{n'}(x) - u(x))d\sigma_x = 0.$$

Thus we have

$$\lim_{n'\to\infty} \langle \Phi'(u_{n'}), u_{n'} - u\rangle = \lim_{n'\to\infty} (\langle J'(u_{n'}), u_{n'} - u\rangle + \langle K'(u_{n'}), u_{n'} - u\rangle + \langle I'(u_{n'}), u_{n'} - u\rangle) = 0.$$

Since $u_{n'} \to u$ weakly in Y, we have $\lim_{n'\to\infty}\langle \Phi'(u), u_{n'} - u\rangle = 0$, so

$$\lim_{n'\to\infty} \langle \Phi'(u_{n'}) - \Phi'(u), u_{n'} - u\rangle = 0.$$

Since $\{u_{n'}\}$ is bounded in Y, it follows from Proposition 3.7 that

$$\int_\Omega h_1(x)|\nabla u_{n'}(x) - \nabla u(x)|^{p(x)}dx \to 0 \quad \text{as } n' \to \infty,$$

so $u_{n'} \to u$ strongly in Y. □

4 Main theorems

In this section, we state the main theorems (Theorem 4.3, 4.5 and 4.6).

Definition 4.1. We say $u \in Y$ is a weak solution of (1.1) if u satisfies that

$$\int_\Omega \boldsymbol{a}(x, \nabla u(x)) \cdot \nabla v(x)dx = \int_\Omega f(x, u(x))v(x)dx + \int_{\Gamma_2} g(x, u(x))v(x)d\sigma_x \tag{4.1}$$

for all $v \in Y$.

Remark 4.2. Since $C_0^\infty(\Omega) \subset Y$, if $u \in Y$ satisfies (4.1), then the equation (1.1) holds in the distribution sense.

Now we obtain the following three theorems.

Theorem 4.3. *Let Ω be a bounded domain of $\mathbb{R}^N$ $(N \geq 2)$ with a $C^{0,1}$-boundary Γ satisfying* (1.2). *Under the hypotheses (A.0)–(A.3), (f.1)–(f.3) and (g.1)–(g.3), the problem* (1.1) *has a nontrivial weak solution.*

Remark 4.4. This theorem extends the result of [8] in which the authors considered the case where $A(x,\xi) = \frac{1}{p(x)}|\xi|^{p(x)}$, $\Gamma_2 = \emptyset$ and $p^- \geq 2$. This theorem is new and also an extension to the case $p^- > 1$.

We impose one more assumption.

(f.4) For any $\delta' \in (0,1)$, the function $f(x,t)$ satisfies the following inequality.

$$f(x,t) \geq \begin{cases} ct^{m-1} & \text{for } t \in [\delta', 1], \\ 0 & \text{for } t \in [0,\infty) \setminus [\delta', 1], \end{cases}$$

where $c > 0$ and $0 < m < 1$.

For example, A function $f(x,t) = \chi_{\delta'}(t)|t|^{m-2}t + a(x)|t|^{q(x)-2}t$, where $\chi_{\delta'} \in C_0(\mathbb{R})$ satisfying that $0 \leq \chi_{\delta'} \leq 1$,

$$\chi_{\delta'}(t) = \begin{cases} 0 & \text{for } |t| \leq \delta'/2 \\ 1 & \text{for } \delta' \leq |t| \leq 1 \end{cases}$$

and that a function a is as in (f.1) verifies (f.1)–(f.4).

Theorem 4.5. *In addition to the hypotheses of Theorem 4.3, assume that (f.4) also holds. Then the problem* (1.1) *has at least two nontrivial weak solutions.*

Finally, in addition to the hypotheses of Theorem 4.3, we assume the following hypotheses.

(A.4) $A(x,\xi)$ is even with respect to ξ, that is, $A(x,-\xi) = A(x,\xi)$ for a.e. $x \in \Omega$ and all $\xi \in \mathbb{R}^N$.

(f.5) $f(x,t)$ is odd with respect to t, that is, $f(x,-t) = -f(x,t)$ for a.e. $x \in \Omega$ and all $t \in \mathbb{R}$.

(g.4) $g(x,t)$ is odd with respect to t, that is, $g(x,-t) = -g(x,t)$ for σ-a.e. $x \in \Gamma_2$ and all $t \in \mathbb{R}$.

Then we can derive that there exist infinitely many weak solutions of (1.1).

Theorem 4.6. *In addition to the hypotheses of Theorem 4.3, assume that (A.4), (f.5) and (g.4) also hold. Then the problem* (1.1) *has infinitely many nontrivial weak solutions.*

5 Proofs of Theorem 4.3, 4.5 and 4.6

In this section, we give proofs of Theorem 4.3, 4.5 and 4.6. Assume that (A.0)–(A.3), (f.1)–(f.3) and (g.1)–(g.3) hold.

The proofs of Theorem 4.3, 4.5 and 4.6 consist of some lemma and propositions.

Lemma 5.1. *Under the hypotheses of Theorem 4.3, we have the following.*

(i) $|F(x,t)| \le C_1'(1 + a(x)|t|^{q(x)})$ *for a.e.* $x \in \Omega$ *and all* $t \in \mathbb{R}$ *with some constant* $C_1' > 0$.

(ii) *There exists* $\gamma \in L^{\alpha(\cdot)}(\Omega)$ *such that* $\gamma(x) > 0$ *a.e.* $x \in \Omega$ *and* $F(x,t) \ge \gamma(x)t^\theta$ *for all* $t \in [t_0, \infty)$ *and a.e.* $x \in \Omega$, *where* $\alpha(\cdot)$ *and* t_0 *are as in (f.1) and (f.2), respectively.*

(iii) $|G(x,t)| \le C_2'(1 + b(x)|t|^{r(x)})$ *for* σ*-a.e.* $x \in \Gamma_2$ *and all* $t \in \mathbb{R}$ *with some constant* $C_2' > 0$.

(iv) *There exists* $\delta \in L^{\beta(\cdot)}(\Gamma_2)$ *such that* $\delta(x) > 0$ σ*-a.e.* $x \in \Gamma_2$ *and* $G(x,t) \ge \delta(x)t^\theta$ *for all* $t \in [t_0, \infty)$ *and* σ*-a.e.* $x \in \Gamma_2$, *where* $\beta(\cdot)$ *and* t_0 *are as in (g.1) and (g.2), respectively.*

Proof. (i) easily follows from (f.1).

(ii) From (f.2), for $t \ge t_0$,

$$0 < \theta F(x,t) \le f(x,t)t. \tag{5.1}$$

Put $\gamma(x) = F(x,t_0)t_0^{-\theta}$. Then $\gamma(x) > 0$ for a.e. $x \in \Omega$ and it follows from (ii) that

$$\gamma(x) \le C_1'(1 + a(x)t_0^{q(x)})t_0^{-\theta} \le C_1'(1 + a(x)t_0^{q^+} \vee t_0^{q^-})t_0^{-\theta}.$$

So $\gamma \in L^{\alpha(\cdot)}(\Omega)$. From (5.1),

$$\frac{\theta}{\tau} \le \frac{f(x,\tau)}{F(x,\tau)} = \frac{\frac{\partial F}{\partial \tau}(x,\tau)}{F(x,\tau)}.$$

Integrating this inequality over (t_0, t), we have

$$\theta \log \frac{t}{t_0} \le \log \frac{F(x,t)}{F(x,t_0)} \quad \text{for all } t \ge t_0.$$

This implies that $F(x,t) \ge \gamma(x)t^\theta$ for all $t \ge t_0$.

(iii) and (iv) follow from the similar argument as (i) and (ii) using (g.1) and (g.2), respectively. □

5.1 Proof of Theorem 4.3

For a proof of Theorem 4.3, we apply the following standard Mountain-Pass Theorem (cf. Willem [26]).

Proposition 5.2. *Let* $(V, \|\cdot\|_V)$ *be a Banach space and* $I \in C^1(V, \mathbb{R})$ *be a functional satisfying the Palais–Smale condition. Assume that* $I(0) = 0$, *and there exist* $\rho > 0$ *and* $z_0 \in V$ *such that* $\|z_0\|_V > \rho$, $I(z_0) \le I(0) = 0$ *and*

$$\alpha := \inf\{I(u); u \in V \text{ with } \|u\|_V = \rho\} > 0.$$

Let $G := \{\varphi \in C([0,1], V); \varphi(0) = 0, \varphi(1) = z_0\} \ne \emptyset$ *and* $\beta = \inf\{\max I(\varphi([0,1])); \varphi \in G\}$. *Then* $\beta \ge \alpha$ *and* β *is a critical value of* I.

We apply Proposition 5.2 with $(V, \|\cdot\|_V) = (Y, \|\cdot\|_Y)$. By Proposition 3.9 and Proposition 3.14, the functional I satisfies that $I \in C^1(Y, \mathbb{R})$ and the Palais–Smale condition holds. Since $\Phi(0) = J(0) = K(0) = 0$, we have $I(0) = 0$. According to (3.13),

$$\alpha = \inf_{\|v\|_Y = \rho} I(v) > 0. \tag{5.2}$$

We show that there exists $u_0 \in Y$ such that $\|u_0\|_Y > \rho$ and $I(u_0) \le 0$. Choose $v_0 \in C_0^\infty(\Omega)$ such that $v_0 \ge 0$ and $W = \{x \in \Omega; v_0(x) \ge t_0\}$ has a positive measure, where t_0 is as in (f.2). We see that $F(x, v_0(x)) > 0$ for a.e. $x \in W$ from (f.2). Let $t > 1$ and define $W_t = \{x \in \Omega; tv_0(x) \ge t_0\}$, then $W \subset W_t$. By Lemma 5.1 (ii), there exists $\gamma \in L^{\alpha(\cdot)}(\Omega)(\subset L^1(\Omega))$ such that $\gamma(x) > 0$ a.e. $x \in \Omega$ and $F(x,t) \ge \gamma(x)t^\theta$ for $t \in [t_0, \infty)$. Thereby,

$$\int_{W_t} F(x, tv_0(x))dx \ge \int_{W_t} \gamma(x)t^\theta v_0(x)^\theta dx \ge t^\theta L(v_0),$$

where $L(v_0) = \int_W \gamma(x)v_0(x)^\theta dx > 0$. For $t \in [0, t_0]$, it follows from Lemma 5.1 (i) that

$$|F(x,t)| \le C_1'(1 + a(x)t^{q(x)}) \le C_1'(1 + a(x)t_0^{q^+} \vee t_0^{q^-}).$$

By (f.2), $F(x, st) \ge F(x,t)s^\theta$ for $t \in \mathbb{R} \setminus (-t_0, t_0)$ and $s > 1$. Indeed, if we define $h(s) = F(x, st)$, then

$$h'(s) = f(x, st)t = \frac{1}{s}f(x, st)st \ge \frac{\theta}{s}F(x, st) = \frac{\theta}{s}h(s).$$

Thus $h'(s)/h(s) \ge \theta/s$, so $\log h(s)/h(1) \ge \theta \log s$ for $s > 1$. This implies $h(s) \ge h(1)s^\theta$.

(A.3) implies that

$$A(x, s\boldsymbol{\xi}) + \frac{h_1(x)}{p(x)} \le s^{p(x)}\left(A(x, \boldsymbol{\xi}) + \frac{h_1(x)}{p(x)}\right) \quad \text{for } s > 1.$$

Indeed, if we define $k(s) = A(x, s\boldsymbol{\xi}) + h_1(x)/p(x)$, then we see that $k'(s) \le \frac{1}{s}p(x)k(s)$. Hence we obtain the inequality. Thus we see that, for $t > 1$, $\Phi(su) + \|h_1/p\|_{L^1(\Omega)} \le s^{p(x)}(\Phi(u) + \|h_1/p\|_{L^1(\Omega)}$ for $u \in Y$ and $s > 1$. Thereby we see that, for $t > 1$,

$$\begin{aligned}
I(tv_0) &= \Phi(tv_0) - J(tv_0) \\
&\le \Phi(tv_0) - \int_{W_t} F(x, tv_0(x))dx - \int_{\Omega\setminus W_t} F(x, tv_0(x))dx \\
&\le t^{p^+}\Phi(v_0) + t^{p^+}\|h_1/p\|_{L^1(\Omega)} - \|h_1/p\|_{L^1(\Omega)} - t^\theta L(v_0) + C_1'|\Omega| + t_0^{q^+} \vee t_0^{q^-}\|a\|_{L^1(\Omega)}.
\end{aligned}$$

Since $\theta > p^+$ and $L(v_0) > 0$, we can see that $I(tv_0) \to -\infty$ as $t \to \infty$. Hence there exists $t_1 > 1$ such that $\|t_1v_0\|_Y > \rho$ and $I(t_1v_0) \le 0$. Put $u_0 = t_1v_0$.

If we define $\varphi(t) = tu_0$, then $\varphi \in G$, so $G \ne \emptyset$. Hence all the hypotheses of Proposition 5.2 hold. Therefore, $\beta = \inf\{\max I(\varphi([0,1]); \varphi \in G\}$ satisfies that $\beta \ge \alpha > 0$ and β is a critical value of I, that is, there exists $u_1 \in Y$ such that $I(u_1) = \beta$ and $I'(u_1) = 0$. Thus u_1 is a weak solution of (1.1). Since $I(u_1) = \beta \ge \alpha > 0 = I(0)$, u_1 is nontrivial weak solution of (1.1). This completes the proof of Theorem 4.3.

5.2 Proof of Theorem 4.5.

It follows from (f.4) that for $0 \le t \le 1$,

$$F(x,t) \ge \begin{cases} \int_{\delta'}^t f(x,s)ds & \text{if } t \ge \delta', \\ 0 & \text{if } t < \delta' \end{cases} \ge \begin{cases} \frac{c}{m}(t^m - (\delta')^m) & \text{if } t \ge \delta', \\ 0 & \text{if } t < \delta'. \end{cases}$$

Fix $t_1 \in (0,1)$ small enough and choose $\delta' \in (0,1)$ such that $(\delta')^m \le t_1$. If $(\delta')^m \le t$, then $F(x,t) \ge \frac{c}{m}(t^m - t)$ since $(\delta')^m \ge \delta'$. Choose $\varphi \in C_0^\infty(\Omega)$ so that $0 \le \varphi \le 1$ and $\varphi \not\equiv 0$. Put

$\Omega_{\delta'} = \{x \in \Omega; (\delta')^m \le t_1\varphi(x)\}$. Then we note that $|\Omega \setminus \Omega_{\delta'}| \to 0$ as $\delta' \to 0$, where $|A|$ denotes the measure of a measurable set A. Thus we have

$$\begin{aligned} J(t_1\varphi) &= \int_\Omega F(x, t_1\varphi(x))dx \\ &\ge \int_{\Omega_{\delta'}} F(x, t_1\varphi(x))dx \\ &\ge \frac{c}{m}\int_{\Omega_{\delta'}} ((t_1\varphi(x))^m - t_1\varphi(x))dx \\ &\ge \frac{c}{m}t_1^m\left(\int_\Omega \varphi(x)^m dx - \int_{\Omega\setminus\Omega_{\delta'}} \varphi(x)^m dx\right) - \frac{c}{m}t_1\int_{\Omega_{\delta'}}\varphi(x)dx \\ &\ge \frac{c}{m}t_1^m\left(\int_\Omega \varphi(x))^m dx - |\Omega\setminus\Omega_{\delta'}|\right) - \frac{c}{m}t_1|\Omega|. \end{aligned}$$

If we replace δ' with smaller one, if necessary, we may assume that $\int_\Omega \varphi(x)^m dx - |\Omega \setminus \Omega_{\delta'}| > 0$.

On the other hand, since $A(x, \boldsymbol{\xi})$ is convex with respect to $\boldsymbol{\xi}$ and $A(x, \mathbf{0}) = 0$, we have $A(x, t_1\boldsymbol{\xi}) = A(x, t_1\boldsymbol{\xi} + (1 - t_1)\mathbf{0}) \le t_1 A(x, \boldsymbol{\xi})$. Thus

$$\Phi(t_1\varphi) = \int_\Omega A(x, t_1\nabla\varphi(x))dx \le t_1\Phi(\varphi).$$

Therefore, we have

$$I(t_1\varphi) = \Phi(t_1\varphi) - J(t_1\varphi) \le t_1\left(\Phi(\varphi) + \frac{c}{m}|\Omega|\right) - \frac{c}{m}t_1^m\left(\int_\Omega \varphi(x)^m dx - |\Omega\setminus\Omega_{\delta'}|\right).$$

Since $0 < m < 1$, if $t_1 > 0$ is small enough, then we see that $I(t_1\varphi) < 0$. By Proposition 3.12, I is bounded from below on $\overline{B_\rho(0)}$, where $B_\rho(0) = \{v \in Y; \|v\|_Y < \rho\}$, ρ is as in (3.13). Hence

$$-\infty < \underline{c} := \inf_{v\in\overline{B_\rho(0)}} I(v) < 0.$$

Let $0 < \varepsilon < \inf_{v\in\partial B_\rho(0)} I(v) - \inf_{v\in\overline{B_\rho(0)}} I(v)$. Here we note that $\inf_{v\in\partial B_\rho(0)} I(v) > 0$. Then there exists $u \in \overline{B_\rho(0)}$ such that

$$\inf_{v\in\overline{B_\rho(0)}} I(v) \le I(u) \le \inf_{v\in\overline{B_\rho(0)}} I(v) + \varepsilon^2.$$

Since $\inf_{v\in\overline{B_\rho(0)}} I(v) < 0$, we can choose $u \in \overline{B_\rho(0)}$ so that $I(u) < 0$. By applying the Ekeland variational principle (cf. Ekeland [12, Theorem 1.1]) in the complete metric space $\overline{B_\rho(0)}$, there exists $u_\varepsilon \in \overline{B_\rho(0)}$ such that

$$I(u_\varepsilon) \le I(u), \tag{5.3}$$

$$I(u_\varepsilon) \le I(v) + \varepsilon\|v - u_\varepsilon\|_Y \text{ for all } v \in \overline{B_\rho(0)}, \tag{5.4}$$

$$\|u - u_\varepsilon\|_Y \le \varepsilon. \tag{5.5}$$

Define a functional $\widehat{I} : \overline{B_\rho(0)} \to \mathbb{R}$ by $\widehat{I}(v) = I(v) + \varepsilon\|v - u_\varepsilon\|_Y$ for $v \in \overline{B_\rho(0)}$. Since $I(u_\varepsilon) \le I(u) < 0$ from (5.3) and $I(v) > 0$ for all $v \in \partial B_\rho(0)$, we have $u_\varepsilon \in B_\rho(0)$. Choose $\rho' > 0$ small enough so that $u_\varepsilon + w \in \overline{B_\rho(0)}$ for $w \in \overline{B_{\rho'}(0)}$. From (5.4), since $\widehat{I}(u_\varepsilon) \le \widehat{I}(u_\varepsilon + w)$ for all $w \in \overline{B_{\rho'}(0)}$, we have

$$\begin{aligned} &\frac{\langle I'(u_\varepsilon), w\rangle + \varepsilon\|w\|_Y}{\|w\|_Y} \\ &\quad = \frac{\langle I'(u_\varepsilon), tw\rangle + \varepsilon t\|w\|_Y - (\widehat{I}(u_\varepsilon + tw) - \widehat{I}(u_\varepsilon))}{t\|w\|_Y} + \frac{\widehat{I}(u_\varepsilon + tw) - \widehat{I}(u_\varepsilon)}{t\|w\|_Y}. \end{aligned}$$

Here we note that from (5.4),

$$\widehat{I}(u_\varepsilon + tw) - \widehat{I}(u_\varepsilon) = I(u_\varepsilon + tw) + \varepsilon\|tw\|_Y - I(u_\varepsilon) \geq 0$$

for $t \in (0,1)$. Hence

$$\frac{\langle I'(u_\varepsilon), w\rangle + \varepsilon\|w\|_Y}{\|w\|_Y} \geq \frac{\langle I'(u_\varepsilon), tw\rangle - (I(u_\varepsilon + tw) - I(u_\varepsilon))}{t\|w\|_Y} \to 0 \quad \text{as } t \to +0.$$

So $\langle I'(u_\varepsilon), w\rangle + \varepsilon\|w\|_Y \geq 0$ for all $w \in \overline{B_{\rho'}(0)}$, so $\langle I'(u_\varepsilon), w\rangle \geq -\varepsilon\|w\|_Y$. Replacing w with $-w$, we have $|\langle I'(u_\varepsilon), w\rangle| \leq \varepsilon\|w\|_Y$ for all $w \in \overline{B_{\rho'}(0)}$. Thus $\|I'(u_\varepsilon)\|_{Y^*} \leq \varepsilon$. Letting $\varepsilon \to 0$, we see that $I(u_\varepsilon) \to \underline{c}$ and $I'(u_\varepsilon) \to 0$ in Y^*. Since I satisfies the Palais–Smale condition in Y, there exist a subsequence $\{u_n\}$ of $\{u_\varepsilon\}$ and $u_2 \in \overline{B_\rho(0)}$ such that $u_n \to u_2$ in Y and $I'(u_2) = 0$. Therefore, u_2 is a weak solution of (1.1). Since $I(u_2) = \underline{c} < 0 = I(0)$, u_2 is a nontrivial weak solution of (1.1). Since $I(u_2) = \underline{c} < 0 < I(u_1)$, we have $u_1 \neq u_2$. This completes the proof of Theorem 4.5.

5.3 Proof of Theorem 4.6

We apply the following Symmetric Mountain-Pass Theorem due to the Rabinowitz [23, Theorem 9.12] (cf. Xie and Xiao [27, Proposition 2.1]).

Proposition 5.3. *Let V be an infinite-dimensional real Banach space. A functional $I : V \to \mathbb{R}$ is of C^1-class and satisfies the Palais–Smale condition. Furthermore, assume that*

(I.1) *$I(0) = 0$ and I is an even functional, that is, $I(-u) = I(u)$ for all $u \in V$.*

(I.2) *There exist positive constants α and ρ such that*

$$\inf_{u\in\partial B_\rho(0)} I(u) \geq \alpha.$$

(I.3) *For each finite-dimensional linear subspace $V_1 \subset V$, the set $\{u \in V_1; I(u) \geq 0\}$ is bounded.*

Then I has an unbounded sequence of critical values.

We apply Proposition 5.3 with $V = Y$. Note that the functional I defined by (3.6) is of class C^1 (Proposition 3.9) and satisfies the Palais–Smale condition (Proposition 3.14). From (A.4), (f.5) and (g.4), (I.1) is trivial. (I.2) follows from (3.13). Thus it suffices to derive (I.3).

Let $u \in Y$ with $\|u\|_Y > 1$. Since $\Phi(u) \leq c_1\|h_0\|_{L^{p'(\cdot)}(\Omega)}\|u\|_Y + C_1\|u\|_Y^{p^+}$ from Lemma 3.4 and $p^+ > 1$, we have

$$\Phi(u) \leq C_5\|u\|_Y^{p^+} \quad \text{for some constant } C_5 > 0. \tag{5.6}$$

Since $F(x,t)$ is an even function with respect to t, it follows from Lemma 5.1 (ii) that $F(x,t) \geq \gamma(x)|t|^\theta$ for $|t| \geq t_0$. Define $\Omega_{t_0} = \{x \in \Omega; |u(x)| \geq t_0\}$. Then

$$J(u) = \int_\Omega F(x,u(x))dx = \int_{\Omega_{t_0}} F(x,u(x))dx + \int_{\Omega\setminus\Omega_{t_0}} F(x,u(x))dx.$$

From (f.1),

$$\int_{\Omega\setminus\Omega_{t_0}} |F(x,u(x))|dx \leq C_1'|\Omega| + t_0^{q^+} \vee t_0^{q^-} \|a\|_{L^1(\Omega)}.$$

Hence we have

$$\begin{aligned} J(u) &\ge \int_{\Omega_{t_0}} \gamma(x)|u(x)|^\theta dx - C_6 \\ &= \int_\Omega \gamma(x)|u(x)|^\theta dx - \int_{\Omega\setminus\Omega_{t_0}} \gamma(x)|u(x)|^\theta dx - C_6 \\ &\ge \int_\Omega \gamma(x)|u(x)|^\theta dx - C_7, \end{aligned} \tag{5.7}$$

where C_7 is a constant. Similarly we have

$$K(u) \ge \int_{\Gamma_2} \delta(x)|u(x)|^\theta d\sigma_x - C_8, \tag{5.8}$$

where C_8 is a constant.

We note that

$$\left(\int_\Omega \gamma(x)|u(x)|^\theta dx + \int_{\Gamma_2} \delta(x)|u(x)|^\theta d\sigma\right)^{1/\theta}$$

is a norm in Y.

Let Y_1 be any finite-dimensional linear subspace of Y. Since Y_1 is of finite-dimensional, the above norm is equivalent to the norm $\|u\|_Y$ in Y_1, so there exists $C_9 > 0$ such that

$$C_9\|u\|_Y^\theta \le \int_\Omega \gamma(x)|u(x)|^\theta dx + \int_{\Gamma_2} \delta(x)|u(x)|^\theta d\sigma_x.$$

Therefore, for $u \in Y_1$ with $\|u\|_Y > 1$, it follows from (5.6), (5.7) and (5.8) that

$$I(u) \le C_5\|u\|_Y^{p^+} - C_9\|u\|_Y^\theta + C_7 + C_8.$$

If $u \in Y_1$ with $\|u\|_Y > 1$ satisfies $I(u) \ge 0$, then we have $C_9\|u\|_Y^\theta \le C_5\|u\|_Y^{p^+} + C_7 + C_8$. Since $\theta > p^+$, the set $\{u \in Y_1; \|u\|_Y > 1, I(u) \ge 0\}$ is bounded, so $\{u \in Y_1; I(u) \ge 0\}$ is bounded. Since all the assumptions of Proposition 5.3 hold, I has an unbounded sequence of critical values, so problem (1.1) has infinitely many weak solutions. This completes the proof of Theorem 4.6.

Abstract. The authors consider the general third order functional differential equation

$$\left(a_2(\nu)\left[\left(a_1(\nu)\left(x'(\nu)\right)^{\alpha_1}\right)'\right]^{\alpha_2}\right)' + q(\nu)x^{\beta}(\tau(\nu)) = 0, \qquad \nu \geq \nu_0,$$

and obtain sufficient conditions for the oscillation of all solutions. It is important to note that α_i for $i = 1, 2$, and β are somewhat independent of each other. The results obtained are illustrated with examples.

Keywords: oscillation, nonoscillation, delay differential equation, comparison method.

2020 Mathematics Subject Classification: 34K11, 34N05.

1 Introduction

The primary objective of this work is to study the oscillatory behavior of solutions of the nonlinear third order differential equation

$$\left(a_2(\nu)\left[\left(a_1(\nu)\left(x'(\nu)\right)^{\alpha_1}\right)'\right]^{\alpha_2}\right)' + q(\nu)x^{\beta}(\tau(\nu)) = 0, \qquad \nu \geq \nu_0, \tag{1.1}$$

where α_i, $i = 1, 2$, and β are quotients of odd positive integers. A *solution* x of (1.1) is a continuous function on $[T_x, \infty)$, $T_x \geq \nu_0$ that satisfies (1.1) on $[T_x, \infty)$. We consider only those solutions $x(\nu)$ of (1.1) that are continuable, i.e., they satisfy $\sup\{|x(\nu)| : \nu \geq T\} > 0$ for all $T > T_x \geq \nu_0$. Such a solution is said to be *oscillatory* if it is neither eventually positive nor eventually negative, and to be *nonoscillatory* otherwise.

Throughout, we always assume that

[1]Corresponding author. Email: John-Graef@utc.edu

($\mathcal{A}_1$) $a_i(\nu), q(\nu) \in C([\nu_0,\infty),\mathbb{R}_+)$ for $i = 1,2$, with $q(\nu) \not\equiv 0$ and

$$\int_{\nu_0}^{\infty} a_1^{-\frac{1}{\alpha_1}}(s)ds = \infty = \int_{\nu_0}^{\infty} a_2^{-\frac{1}{\alpha_2}}(s)ds; \tag{1.2}$$

($\mathcal{A}_2$) $\tau \in C^1([\nu_0,\infty),\mathbb{R})$ with $\tau(\nu) \le \nu$, $\tau'(\nu) \ge 0$, and $\lim_{\nu\to\infty} \tau(\nu) = \infty$.

As equation (1.1) is regarded as a useful instrument for simulating processes in various fields of applied mathematics, physics, and chemistry (see the monographs [6,22,24]), it is important to analyze the qualitative properties of equation (1.1). For several years now, there has been a growing interest in the asymptotic behavior of solutions of various forms of linear and nonlinear third order differential equations and their applications; see, e.g., [1–5,7–16,18,21] and the references therein.

In particular, Baculíková and Džurina [4] considered the third-order nonlinear delay differential equation of the form

$$\left(a_1(\nu)\left[x''(\nu)\right]^{\alpha_1}\right)' + q(\nu)x^{\beta}(\tau(\nu)) = 0. \tag{1.3}$$

They used a comparison theorem with appropriate lower-order equations to derive sufficient condition for the asymptotic and oscillatory behaviour of Eq. (1.3). This work allows us to note the following:

(1) Eq. (1.3) is a particular case of Eq. (1.1);

(2) There is no general rule to choose the function $\xi(\nu)$ that plays a very important role in deriving the oscillation of Eq. (1.1).

Chatzarakis et al. [9] considered the third-order linear differential equation of the form

$$\left(a_2(\nu)\left[\left(a_1(\nu)\left(x'(\nu)\right)\right)'\right]\right)' + q(\nu)x(\tau(\nu)) = 0, \tag{1.4}$$

and using the integral technique, comparison method, and Gronwall inequality, they improved the results reported in [4] by relaxing the above mentioned second observation. Inspired by the papers referenced here, we wish to the study of the general equation (1.1) and derive some easily verifiable sufficient conditions for the oscillation of all it solutions.

2 Basic lemmas

In view of (1.2), we introduce the following notation:

$$A(\nu,\nu_0) = \int_{\nu_0}^{\nu} a_2^{-\frac{1}{\alpha_2}}(s)ds \quad \text{and} \quad A^*(\nu,\nu_0) = \int_{\nu_0}^{\nu} \left(\frac{A(s,\nu_0)}{a_1(s)}\right)^{\frac{1}{\alpha_1}} ds.$$

Setting $G_1(x(\nu)) = (x'(\nu))^{\alpha_1}$ and $G_2(x(\nu)) = \left[(a_1(\nu)G_1(x(\nu)))'\right]^{\alpha_2}$, we can write equation (1.1) as the equivalent equation

$$(a_2(\nu)G_2(x(\nu)))' + q(\nu)x^{\beta}(\tau(\nu)) = 0 \quad \text{for } \nu \ge \nu_0. \tag{2.1}$$

To obtain our main results, we will utilize the following lemmas, the first of which is well known.

Lemma 2.1. *Let* $(\mathcal{A}_1)$ *and* $(\mathcal{A}_2)$ *hold. If* x *is an eventually positive solution of* (1.1) *for* $\nu \geq \nu_0$*, then there exists* $\nu_1 > \nu_0$ *such that either*

$$\text{(I)} \quad G_1(x(\nu)) \geq 0 \text{ and } G_2(x(\nu)) \geq 0, \quad \text{or} \quad \text{(II)} \quad G_1(x(\nu)) \leq 0 \text{ and } G_2(x(\nu)) \geq 0$$

for $\nu \geq \nu_1$.

Lemma 2.2. *Let* $(\mathcal{A}_1)$ *and* $(\mathcal{A}_2)$ *hold. If* x *is a positive solution of* (1.1) *such that Case I of Lemma 2.1 holds for* $\nu \geq \nu_1$*, then*

$$x(\nu) \geq A^*(\nu, \nu_1)\left((a_2(\nu)G_2(x(\nu)))^{\frac{1}{\alpha_1\alpha_2}}\right) \tag{2.2}$$

for $\nu \geq \nu_2 > \nu_1$.

Proof. Let x be a nonoscillatory solution of Eq. (1.1) such that $x(\nu) > 0$, $x(\tau(\nu)) > 0$, and which satisfies Case I of Lemma 2.1 for $\nu \geq \nu_1$ for some $\nu_1 > \nu_0$. Then,

$$a_1(\nu)G_1(x(\nu)) \geq \int_{\nu_1}^{\nu} (a_1(s)G_1(x(s)))'\, ds = \int_{\nu_1}^{\nu} \frac{a_2^{\frac{1}{\alpha_2}}(s)G_2^{\frac{1}{\alpha_2}}(x(s))}{a_2^{\frac{1}{\alpha_2}}(s)} ds,$$

that is,

$$a_1(\nu)(x'(\nu))^{\alpha_1} \geq A(\nu, \nu_1)a_2^{\frac{1}{\alpha_2}}(\nu)G_2^{\frac{1}{\alpha_2}}(x(\nu)),$$

so

$$x'(\nu) \geq \left(\frac{A(\nu,\nu_1)}{a_1(\nu)}\right)^{\frac{1}{\alpha_1}} (a_2(\nu)G_2(x(\nu)))^{\frac{1}{\alpha_1\alpha_2}}. \tag{2.3}$$

Integrating from ν_1 to ν gives

$$x(\nu) \geq (a_2(\nu)G_2(x(\nu)))^{\frac{1}{\alpha_1\alpha_2}} \int_{\nu_1}^{\nu} \left(\frac{A(s,\nu_1)}{a_1(s)}\right)^{\frac{1}{\alpha_1}} ds = A^*(\nu,\nu_1)\left((a_2(\nu)G_2(x(\nu)))^{\frac{1}{\alpha_1\alpha_2}}\right),$$

which completes the proof. □

For convenience, we let

$$B(\nu, s) = \left(\frac{A(\nu,s)}{a_1(s)}\right)^{\frac{1}{\alpha_1}}$$

and

$$\widehat{A}^*(\nu, \tau(\nu)) = \int_{\tau(\nu)}^{\nu} B(\nu,s)ds.$$

Lemma 2.3. *Let* $(\mathcal{A}_1)$ *and* $(\mathcal{A}_2)$ *hold. If* x *is a positive solution of* (1.1) *such that Case II of Lemma 2.1 holds for* $\nu \geq \nu_1$*, then*

$$x(\tau(\nu)) \geq \widehat{A}^*(\nu, \tau(\nu))\Big(a_2(\nu)G_2(x(\nu))\Big)^{\frac{1}{\alpha_1\alpha_2}} \tag{2.4}$$

for $\nu \geq \nu_2 > \nu_1$.

Proof. Let x be a nonoscillatory solution of Eq. (1.1) such that $x(\nu) > 0$, $x(\tau(\nu)) > 0$, and Case II of Lemma 2.1 is satisfied for $\nu \geq \nu_1$ for some $\nu_1 > \nu_0$. For $\nu \geq s > \nu_1$, we have

$$a_1(\nu)G_1(x(\nu)) - a_1(s)G_1(x(s)) = \int_s^{\nu} (a_1(u)G_1(x(u)))'\, du = \int_s^{\nu} \frac{a_2^{\frac{1}{\alpha_2}}(u)G_2^{\frac{1}{\alpha_2}}(x(u))}{a_2^{\frac{1}{\alpha_2}}(s)} du.$$

That is,

$$-a_1(s)(x'(s))^{\alpha_1} \geq A(\nu,s)a_2^{\frac{1}{\alpha_2}}(\nu)G_2^{\frac{1}{\alpha_2}}(x(\nu)),$$

so

$$-x'(s) \geq \left(\frac{A(\nu,s)}{a_1(\nu)}\right)^{\frac{1}{\alpha_1}} (a_2(\nu)G_2(x(\nu)))^{\frac{1}{\alpha_1\alpha_2}} \geq B(\nu,s)\,(a_2(\nu)G_2(x(\nu)))^{\frac{1}{\alpha_1\alpha_2}}. \tag{2.5}$$

Integrating from $\tau(\nu)$ to ν, we obtain

$$-x(\nu)+x(\tau(\nu)) \geq \Big(a_2(\nu)G_2(x(\nu))\Big)^{\frac{1}{\alpha_1\alpha_2}} \int_{\tau(\nu)}^{\nu} B(\nu,s)ds,$$

or

$$x(\tau(\nu)) \geq \widehat{A}^*(\nu,\tau(\nu))\Big(a_2(\nu)G_2(x(\nu))\Big)^{\frac{1}{\alpha_1\alpha_2}}.$$

This proves the lemma. □

Remark 2.4. In view of Lemma 2.3, from (1.1) and (2.4), we see that

$$-\left(a_2(\nu)G_2(x(\nu))\right)' = q(\nu)x^{\beta}(\tau(\nu)) \geq q(\nu)\left(\widehat{A}^*(\nu,\tau(\nu))\right)^{\beta}\left(a_2(\nu)G_2(x(\nu))\right)^{\frac{\beta}{\alpha_1\alpha_2}}.$$

Integrating this inequality from $\tau(\nu)$ to ν, we have

$$\limsup_{\nu\to\infty}\int_{\tau(\nu)}^{\nu} q(u)\left(\widehat{A}^*(u,\tau(u))\right)^{\beta} du > 1$$

in the case where $\frac{\beta}{\alpha_1\alpha_2}=1$.

We also have the following lemma.

Lemma 2.5. *In addition to the hypotheses of Lemma 2.3, assume that there exists a constant $\gamma > 1$ such that $\gamma\tau(\nu) \leq \nu$ for $\nu \geq \nu_2 > \nu_1$. Then*

$$x(\tau(\nu)) \geq \widehat{A}^*(\gamma\tau(\nu),\tau(\nu))\Big(a_2(\gamma\tau(\nu))G_2(x(\gamma\tau(\nu)))\Big)^{\frac{1}{\alpha_1\alpha_2}} \tag{2.6}$$

for $\nu \geq \nu_2 > \nu_1$.

Proof. If we integrate (2.5) from $\tau(\nu)$ to $\gamma\tau(\nu)$, we can obtain (2.6). □

3 Oscillation results

Our first oscillation result is as follows.

Theorem 3.1. *Let $(\mathcal{A}_1)$ and $(\mathcal{A}_2)$ hold and assume that there exists a constant $\gamma > 1$ such that $\gamma\tau(\nu) \leq \nu$ for $\nu \geq \nu_2 > \nu_1$. If the first-order delay equations*

$$Y'(\nu) + q(\nu)\left(A^*(\tau(\nu),\nu_1)\right)^{\beta}\left(Y(\tau(\nu))\right)^{\frac{\beta}{\alpha_1\alpha_2}} = 0 \tag{3.1}$$

and

$$Z'(\nu) + q(\nu)\left(\widehat{A}^*(\gamma\tau(\nu),\tau(\nu))\right)^{\beta}\left(Z(\gamma\tau(\nu))\right)^{\frac{\beta}{\alpha_1\alpha_2}} = 0 \tag{3.2}$$

are oscillatory, then Eq. (1.1) is oscillatory.

Proof. Let x be a nonoscillatory solution of (1.1) such that $x(\nu) > 0$ and $x(\tau(\nu)) > 0$ for $\nu \geq \nu_1 > \nu_0$. According to Lemma 2.1, we distinguish the following two cases.

Case I. Using (2.2) in (2.1), we obtain

$$\begin{aligned} -(a_2(\nu)G_2(x(\nu)))' &= q(\nu)x^\beta(\tau(\nu)) \\ &\geq q(\nu)\left(A^*(\tau(\nu),\nu_1)\right)^\beta \left(\left(a_2(\tau(\nu))G_2(x(\tau(\nu)))\right)^{\frac{1}{\alpha_1\alpha_2}}\right)^\beta. \end{aligned}$$

Setting $Y(\nu) = a_2(\nu)G_2(x(\nu))$, this becomes

$$Y'(\nu) + q(\nu)\left(A^*(\tau(\nu),\nu_1)\right)^\beta (Y(\tau(\nu)))^{\frac{\beta}{\alpha_1\alpha_2}} \leq 0.$$

By [3, Lemma 2.1(I)], the related differential equation (3.1) also has a positive solution, which is a contradiction.

Case II. Using (2.6) in Eq. (2.1), we obtain

$$\begin{aligned} -(a_2(\nu)G_2(x(\nu)))' &= q(\nu)x^\beta(\tau(\nu)) \\ &\geq q(\nu)\left(\widehat{A}^*(\gamma\tau(\nu),\tau(\nu))\left((a_2(\gamma\tau(\nu))G_2(x(\gamma\tau(\nu))))^{\frac{1}{\alpha_1\alpha_2}}\right)\right)^\beta. \end{aligned}$$

Setting $Z(\nu) = a_2(\nu)G_2(x(\nu))$, this becomes

$$Z'(\nu) + q(\nu)\left(\widehat{A}^*(\gamma\tau(\nu),\tau(\nu))\right)^\beta (Z(\gamma\tau(\nu)))^{\frac{\beta}{\alpha_1\alpha_2}} \leq 0.$$

Again by [3, Lemma 2.1(I)], the corresponding differential equation (3.2) must have a positive solution. This contradiction proves the theorem. □

Example 3.2. Consider the third-order delay equation

$$\left(\nu\left[\left(\frac{1}{\nu^2}\left(x'(\nu)\right)\right)'\right]^3\right)' + \frac{c}{\nu^2}x^{\frac{1}{3}}\left(\frac{\nu}{3}\right) = 0, \qquad \nu \geq 1, \tag{3.3}$$

where $c > 0$ is a constant, $\alpha_1 = 1$, $\alpha_2 = 3$, $a_1(\nu) = \frac{1}{\nu^2}$, $a_2(\nu) = \nu$, $q(\nu) = \frac{c}{\nu^2}$, $\beta = \frac{1}{3}$, and $\tau(\nu) = \frac{\nu}{3}$. Clearly, $(\mathcal{A}_1)$, $(\mathcal{A}_2)$ and (1.2) hold. Using

$$A(\nu,1) = \int_1^\nu a_2^{-\frac{1}{\alpha_2}}(s)ds = \int_1^\nu s^{-\frac{1}{3}}ds = \frac{3\nu^{\frac{2}{3}} - 3}{2}$$

and

$$A^*(\tau(\nu),1) = \int_1^{\tau(\nu)} \left(\frac{A(s,1)}{a_1(s)}\right)^{\frac{1}{\alpha_1}} ds = \int_1^{\frac{\nu}{3}} \left(\frac{s^2\left(3s^{\frac{2}{3}} - 3\right)}{2}\right) ds = \frac{1}{2}\left(\frac{\nu^{\frac{11}{3}}}{33 \cdot 3^{\frac{2}{3}}} - \frac{\nu^3}{27} + \frac{2}{11}\right),$$

it is not difficult to see that equation (3.1) becomes

$$Y'(\nu) + \frac{c}{2\nu^2}\left(\frac{\nu^{\frac{11}{3}}}{33 \cdot 3^{\frac{2}{3}}} - \frac{\nu^3}{27} + \frac{2}{11}\right)^{\frac{1}{3}} Y^{\frac{1}{9}}\left(\frac{\nu}{3}\right) = 0. \tag{3.4}$$

Also, using $\gamma = 2$ and

$$B(\nu,s) = \left(\frac{A(\nu,s)}{a_1(s)}\right)^{\frac{1}{\alpha_1}} = \frac{\int_s^\nu u^{-\frac{1}{3}}du}{\frac{1}{\nu^2}} = \frac{3\nu^2(\nu^{\frac{2}{3}} - s^{\frac{2}{3}})}{2},$$

we see that

$$\widehat{A}^*(\gamma\tau(\nu),\tau(\nu)) = \int_{\tau(\nu)}^{\gamma\tau(\nu)} B(\nu,s)ds = \int_{\frac{\nu}{3}}^{\frac{2\nu}{3}} \frac{3\nu^2(\nu^{\frac{2}{3}} - s^{\frac{2}{3}})}{2}ds = \frac{\nu^{\frac{11}{3}}}{2} - \frac{2^{\frac{5}{3}}\nu^{\frac{11}{3}} - \nu^{\frac{11}{3}}}{3^{\frac{5}{3}}},$$

and so equation (3.2) becomes

$$Z'(\nu) + \frac{c}{2\nu^2}\left(\frac{\nu^{\frac{11}{3}}}{2} - \frac{2^{\frac{5}{3}}\nu^{\frac{11}{3}} - \nu^{\frac{11}{3}}}{3^{\frac{5}{3}}}\right)^{\frac{1}{3}} Z^{\frac{1}{9}}\left(\frac{2\nu}{3}\right) = 0. \tag{3.5}$$

Clearly, [19, Theorem 5] guarantee that all solutions of Eqs. (3.4) and (3.5) are oscillatory. Thus, every solution of Eq. (3.3) oscillates.

Theorem 3.3. *Let $(\mathcal{A}_1)$ and $(\mathcal{A}_2)$ hold. If the first-order delay equation (3.1) is oscillatory and*

$$\limsup_{\nu\to\infty} \int_{\tau(\nu)}^{\nu} q(u)\left(A^*(\tau(\nu),\tau(s))\right)^\beta ds > 1 \tag{3.6}$$

for $\beta = \alpha_1\alpha_2$, then Eq. (1.1) is oscillatory.

Proof. Let x be a nonoscillatory solution of Eq. (1.1) such that $x(\nu) > 0$ and $x(\tau(\nu)) > 0$ for $\nu \ge \nu_1 > \nu_0$. We again consider the two cases in Lemma 2.1.

Case I. Proceeding as in the proof of Theorem 3.1, we again obtain a contradiction.

Case II. Clearly, for $v \ge u > \nu_1$,

$$a_1(v)G_1(x(v)) - a_1(u)G_1(x(u)) = \int_u^v (a_1(s)G_1(x(s)))'ds = \int_u^v \frac{a_2^{\frac{1}{\alpha_2}}(s)G_2^{\frac{1}{\alpha_2}}(x(s))}{a_2^{\frac{1}{\alpha_2}}(s)}ds,$$

that is,

$$-a_1(u)G_1(x(u)) \ge a_2^{\frac{1}{\alpha_2}}(v)G_2^{\frac{1}{\alpha_2}}(x(v))\int_u^v \frac{1}{a_2^{\frac{1}{\alpha_2}}(s)}ds,$$

and so

$$-a_1(u)(x'(u))^{\alpha_1} \ge a_2^{\frac{1}{\alpha_2}}(v)G_2^{\frac{1}{\alpha_2}}(x(v))\int_u^v \frac{1}{a_2^{\frac{1}{\alpha_2}}(s)}ds,$$

Hence,

$$-x'(u) \ge (a_2(v)G_2(x(v)))^{\frac{1}{\alpha_1\alpha_2}}\left(\frac{1}{a_1(u)}\int_u^v \frac{1}{a_2^{\frac{1}{\alpha_2}}(s)}ds\right)^{\frac{1}{\alpha_1}},$$

and integrating from u to v gives

$$x(u) - x(v) \ge (a_2(v)G_2(x(v)))^{\frac{1}{\alpha_1\alpha_2}}\int_u^v \left(\frac{1}{a_1(y)}\int_y^v \frac{1}{a_2^{\frac{1}{\alpha_2}}(s)}ds\right)^{\frac{1}{\alpha_1}} dy,$$

or

$$x(u) \geq (a_2(v)G_2(x(v)))^{\frac{1}{\alpha_1\alpha_2}} A^*(v,u).$$

Now, for any $\nu \geq s > \nu_2$, for some $\nu_2 > \nu_1$, if we set $u = \tau(s)$ and $v = \tau(\nu)$ in the preceding inequality, gives

$$x(\tau(s)) \geq \Big(a_2(\tau(\nu))G_2(x(\tau(\nu)))\Big)^{\frac{1}{\alpha_1\alpha_2}} A^*(\tau(\nu),\tau(s)). \tag{3.7}$$

Integrating Eq. (1.1) from $\tau(\nu)$ to ν and then applying (3.7),

$$\begin{aligned} a_2(\tau(\nu))G_2(x(\tau(\nu))) &\geq \int_{\tau(\nu)}^{\nu} q(s)x^{\beta}(\tau(s))ds \\ &\geq \Big(a_2(\tau(\nu))G_2(x(\tau(\nu)))\Big)^{\frac{\beta}{\alpha_1\alpha_2}} \int_{\tau(\nu)}^{\nu} q(s)(A^*(\tau(\nu),\tau(s)))^{\beta} ds, \end{aligned}$$

which implies

$$\int_{\tau(\nu)}^{\nu} q(s)\,(A^*(\tau(\nu),\tau(s)))^{\beta}\, ds \leq 1,$$

and contradicts (3.6). □

Example 3.4. Consider the equation

$$\left(\frac{1}{\nu^2}\left[\left(\frac{1}{9\nu^2}\,(x'(\nu))\right)'\right]^3\right)' + \frac{\delta}{\nu^7}x^3\left(\frac{\nu}{2}\right) = 0, \qquad \nu \geq 1, \tag{3.8}$$

where we have $\alpha_1 = 1$, $\alpha_2 = 3$, $a_1(\nu) = \frac{1}{9\nu^2}$, $a_2(\nu) = \frac{1}{\nu^2}$, $q(\nu) = \frac{\delta}{\nu^7}$ for $\delta > 0$, $\beta = 3$ and $\tau(\nu) = \frac{\nu}{2}$. Clearly, $(\mathcal{A}_1)$, $(\mathcal{A}_2)$ and (1.2) hold. Using

$$A(\nu,1) = \int_1^{\nu} a_2^{-\frac{1}{\alpha_2}}(s)ds = \int_1^{\nu}\left(\frac{1}{s^2}\right)^{-\frac{1}{3}} ds = \frac{\left(3\nu^{\frac{5}{3}} - 3\right)}{5}$$

and

$$\begin{aligned} A^*(\tau(\nu),1) = \int_1^{\tau(\nu)}\left(\frac{A(s,1)}{a_1(s)}\right)^{\frac{1}{\alpha_1}} ds &= \int_1^{\frac{\nu}{2}} \frac{s^2\left(3s^{\frac{5}{3}} - 3\right)}{5}ds \\ &= \frac{1}{5}\left(\frac{9\nu^{\frac{14}{3}}}{224\cdot 2^{\frac{2}{3}}} - \frac{\nu^3}{8} - \frac{5}{14}\right), \end{aligned}$$

it is not difficult to see that (3.1) becomes

$$Y'(\nu) + \frac{42}{125\cdot\nu^7}\left(\frac{9\nu^{\frac{14}{3}}}{7\cdot 2^{\frac{17}{3}}} - \frac{\nu^3}{8} - \frac{5}{14}\right)^3 Y\left(\frac{\nu}{2}\right) = 0. \tag{3.9}$$

Indeed, following [20, Theorem 2.1.1], Eq. (3.9) is oscillatory if

$$\lim_{\nu\to\infty}\int_{\frac{\nu}{2}}^{\nu} \frac{\delta}{125\cdot s^7}\left(\frac{9s^{\frac{14}{3}}}{7\cdot 2^{\frac{17}{3}}} - \frac{s^3}{8} - \frac{5}{14}\right)^3 ds > \frac{1}{e}.$$

And using

$$A(\nu,u)=\int_u^\nu a_2^{-\frac{1}{\alpha_2}}(s)ds=\int_u^\nu\left(\frac{1}{s^2}\right)^{\frac{-1}{3}}ds=\frac{3\nu^{\frac{5}{3}}-3u^{\frac{5}{3}}}{5}.$$

$$\begin{aligned}A^*(\tau(\nu),\tau(s))=\int_{\tau(s)}^{\tau(\nu)}\left(\frac{A(\nu,y)}{a_1(y)}\right)^{\frac{1}{\alpha_1}}dy&=\int_{\frac{s}{2}}^{\frac{\nu}{2}}\frac{27y^2\left(\nu^{\frac{5}{3}}-y^{\frac{5}{3}}\right)}{5}dy\\&=\frac{27}{25}\left(\frac{\nu^{\frac{5}{3}}\left(\nu^3-s^3\right)}{8}-\frac{3\nu^{\frac{14}{3}}-3s^{\frac{14}{3}}}{7\cdot 2^{\frac{17}{3}}}\right).\end{aligned}$$

Eq. (3.6) becomes

$$\begin{aligned}\int_{\tau(\nu)}^{\nu}q(s)\left(A^*(\tau(\nu),\tau(s))\right)^{\beta}ds&=\int_{\frac{\nu}{2}}^{\nu}\frac{\delta}{s^7}\left(\frac{27}{25}\left(\frac{\nu^{\frac{5}{3}}\left(\nu^3-s^3\right)}{8}-\frac{3\nu^{\frac{14}{3}}-3s^{\frac{14}{3}}}{7\cdot 2^{\frac{17}{3}}}\right)\right)^3ds\\&>1.\end{aligned}$$

By Theorem 3.3, every solution of (3.8) oscillates.

Theorem 3.5. *Let* $(\mathcal{A}_1)$ *and* $(\mathcal{A}_2)$ *hold. If* $\beta=\alpha_1\alpha_2$ *and there is a nondecreasing function* $\phi\in C^1([\nu_0,\infty),(0,\infty)$ *such that* (3.6) *and*

$$\limsup_{\nu\to\infty}\int_{\nu_1}^{\nu}\left[\phi(s)q(s)-\frac{(\phi'(s))^2(\phi(s))^{\frac{1}{\alpha_1\alpha_2}-2}}{4\beta\tau'(s)}\left(\frac{A(\tau(s),\nu_1)}{a_1(s)}\right)^{\frac{-1}{\alpha_1}}\right]ds=\infty \tag{3.10}$$

hold, then equation (1.1) *is oscillatory.*

Proof. Let x be a nonoscillatory solution of Eq. (1.1) such that $x(\nu)>0$ and $x(\tau(\nu))>0$ for $\nu\geq\nu_1>\nu_0$. We again consider cases.

Case I. Define

$$\mathcal{W}(\nu)=\phi(\nu)\frac{a_2(\nu)G_2(x(\nu))}{x^{\beta}(\tau(\nu))}.$$

Then $\mathcal{W}(\nu)>0$, and using Lemma 2.2, the decreasing nature of $a_2(\nu)G_2(x(\nu))$, and (2.3)

$$\begin{aligned}\mathcal{W}'(\nu)&=\frac{\phi(\nu)(a_2(\nu)G_2(x(\nu)))'}{x^{\beta}(\tau(\nu))}+\frac{a_2(\nu)G_2(x(\nu))\phi'(\nu)}{x^{\beta}(\tau(\nu))}-\beta\frac{\phi(\nu)(a_2(\nu)G_2(x(\nu)))x'(\tau(\nu))\tau'(\nu)}{x^{\beta+1}(\tau(\nu))}\\&\leq-\phi(\nu)q(\nu)+\frac{\phi'(\nu)}{\phi(\nu)}\mathcal{W}(\nu)-\beta\tau'(\nu)\left(\frac{A(\tau(\nu),\nu_1)}{a_1(\nu)}\right)^{\frac{1}{\alpha_1}}\frac{\phi(\nu)(a_2(\nu)G_2(x(\nu)))^{1+\frac{1}{\alpha_1\alpha_2}}}{x^{\beta+1}(\tau(\nu))}\\&\leq-\phi(\nu)q(\nu)+\frac{\phi'(\nu)}{\phi(\nu)}\mathcal{W}(\nu)-\frac{\beta\tau'(\nu)}{\phi^{\frac{1}{\alpha_1\alpha_2}}(\nu)}\left(\frac{A(\tau(\nu),\nu_1)}{a_1(\nu)}\right)^{\frac{1}{\alpha_1}}\mathcal{W}^2(\nu).\end{aligned}$$

If we complete the square on the right hand side, we find that

$$\mathcal{W}'(\nu)\leq-\phi(\nu)q(\nu)+\frac{(\phi'(\nu))^2}{4\beta\tau'(\nu)}(\phi(\nu))^{\frac{1}{\alpha_1\alpha_2}-2}\left(\frac{A(\tau(\nu),\nu_1)}{a_1(\nu)}\right)^{\frac{-1}{\alpha_1}}.$$

Integrating the preceding inequality from ν_1 to ν, we see that (3.10) gives a contradiction to the fact that $W(\nu)\geq 0$.

Case II. Proceeding as in the proof of Theorem 3.3, leads to a contradiction in this case. □

Example 3.6. Consider the equation

$$\left(\frac{1}{\nu}\left[\left(\frac{1}{\nu}\left(x'(\nu)\right)^{\frac{1}{3}}\right)'\right]^3\right)' + \frac{\delta}{\nu^3}\, x\left(\frac{\nu}{3}\right) = 0, \qquad \nu \geq 1, \tag{3.11}$$

where we have $\alpha_1 = \frac{1}{3}$, $\alpha_2 = 3$, $a_1(\nu) = \frac{1}{\nu}$, $a_2(\nu) = \frac{1}{\nu}$, $q(\nu) = \frac{\delta}{\nu^3}$ for $\delta > 0$, $\beta = 1$ and $\tau(\nu) = \frac{\nu}{3}$. Clearly, $(\mathcal{A}_1)$, $(\mathcal{A}_2)$ and (1.2) hold. Using $\phi(\nu) = \nu^4$ and $A(\tau(\nu), \nu_1) = \frac{3}{4}\left[\left(\frac{\nu}{3}\right)^{\frac{4}{3}} - 1\right]$ in Eq. (3.10), we have

$$\limsup_{\nu\to\infty} \int_1^{\nu} \left[\phi(s)q(s) - \frac{(\phi'(s))^2(\phi(s))^{\frac{1}{\alpha_1\alpha_2}-2}}{4\beta\tau'(s)} \left(\frac{A(\tau(s),1)}{a_1(s)}\right)^{\frac{-1}{\alpha_1}}\right] ds$$
$$= \limsup_{\nu\to\infty} \int_1^{\nu} \left[\delta s - \frac{3s^6}{s^4}\left(\frac{3s}{4}(s^{\frac{4}{3}} - 1)\right)^{-3}\right] ds = \infty.$$

It is not difficult to see that (3.6) holds, so by Theorem 3.5, every solution of (3.11) oscillates.

4 Concluding remark

Employing the methods of comparison, Riccati substitution, and the integral method, we introduced three novel conditions for the oscillation of a general third-order nonlinear delay differential equation. Interestingly, our results are applicable to linear, sublinear, and superlinear equations. Some illustrative examples are given to show the applicability of our results.

Abstract. In this paper, we show the existence of solution for a relatively general system of semilinear parabolic equations with nonlinear reaction rate terms and inflow-outflow boundary conditions. Generally, to show the existence of global solution, it has been seen in the literature that either mass conservation or some growth condition on the source term is needed. Also, in several recent works only the nonlinearity up to certain order or of certain structure is allowed. However, our work considerably weakens the ones previously made by several authors on the coefficients of the elliptic operator, on the source (reaction rate) terms as well as on the boundary conditions. Our proof is also rather small and uses an argument based on implicit function theorem.

Keywords: semilinear parabolic equations, system of PDEs, equilibrium reaction rates, non-identical diffusion coefficients, global solution, mass action kinetics.

2020 Mathematics Subject Classification: 35K57, 35K55, 76S05, 47J35.

1 Introduction

Even a very simple semilinear parabolic equation (e.g., diffusion-reaction equation) can have merely local solutions, i.e. solutions in some perhaps small neighbourhood of the initial time t_0. The same applies to coupled systems of more than one variable. Therefore, it takes some special structure of the nonlinearities to guarantee the existence of the *global* solutions, i.e. solutions on any given time interval $[0, T)$, $T < \infty$. In this regard, nonlinearities which are obtained by modelling *equilibrium (reversible)* reactions amongst chemical species via mass-action kinetics bear some potential for producing global solutions since positive productions are accompanied by negative ones. Kräutle [11] and Mahato et al. [12] showed that the production rates of a large class of J number of equilibrium (reversible) reactions of I number of chemical species can be reduced to the following setting: let $\Omega \subset \mathbb{R}^N$ be a bounded domain with C^2-boundary $\partial\Omega$, $S := [0, T)$ be the time interval for some $T < \infty$ and we denote by

✉Corresponding author. Email: hsmahato@maths.iitkgp.ac.in

$\mathcal{S}$ the stoichiometric matrix such that $\mathcal{S} = (s_{ij}) \in M_{I\times J}$, the set of all $I \times J$ matrices, with $\text{rank}(\mathcal{S}) = J$ and $|s_{ij}| \in \{0\} \cup [1, \infty)$. The entries $s_{ij} = \nu_{ij} - \tau_{ij}$ for $1 \le i \le I$ and $1 \le j \le J$, where $-\tau_{ij} \in \mathbb{Z}_0^-$ and $\nu_{ij} \in \mathbb{Z}_0^+$ are the stoichiometric coefficients for reversible reactions given by

$$\tau_{1j}X_1 + \tau_{2j}X_2 + \cdots + \tau_{Ij}X_I \rightleftharpoons \nu_{1j}X_1 + \nu_{2j}X_2 + \cdots + \nu_{Ij}X_I, \tag{1.1}$$

where X_i, $1 \le i \le I$, denotes the chemical species involved in J reactions. Let $u = (u_1, \ldots, u_I)$ be the unknown concentration vector of I chemical species. For $k_j^f, k_j^b > 0$ and $j = 1, 2, \ldots, J$, we set

$$R_j^f(u) = k_j^f \prod_{\substack{m=1\\ s_{mj}<0}}^{I} u_m^{-s_{mj}}, R_j^b(u) = k_j^b \prod_{\substack{m=1\\ s_{mj}>0}}^{I} u_m^{s_{mj}} \tag{1.2a}$$

$$R_j(u) = \left(R_j^f(u) - R_j^b(u)\right), \quad R = (R_1, \ldots, R_J)^T, \quad \hat{f}(u) = \mathcal{S}R(u), \tag{1.2b}$$

where s_{mj}^- and s_{mj}^+ denote the negative and positive parts of s_{mj}, respectively, such that $s_{mj} = s_{mj}^+ - s_{mj}^-$. For the $i-th$ species,

$$(\mathcal{S}R(u))_i = \sum_{j=1}^{J} s_{ij} R_j(u). \tag{1.3}$$

Furthermore, let $\mathbb{D} = (D_{0_1}, \ldots, D_{0_I})$, where D_{0_i} denotes the symmetric $N \times N$ diffusive matrix of the i-th chemical species such that $D_{0_i} \in L^\infty(\Omega; \text{Sym}(N))$. Let $\boldsymbol{q} : S \times \Omega \to \mathbb{R}^N$ denote the velocity vector such that $\nabla \cdot \boldsymbol{q} = 0$. For $i = 1, 2, \ldots, I$, we now define the following operators:

$$A := \text{diag}(A_1, \ldots, A_I), \quad B := \text{diag}(B_1, \ldots, B_I), \quad A_i(\mathbb{D}, u) := A_i := \text{div}(\boldsymbol{j}_i) \tag{1.4a}$$

$$\boldsymbol{j}_i := -a_i D_{0_i} \nabla u_i + \mathbf{q} u_i \quad (= \text{diffusive + advective flux}) \tag{1.4b}$$

$$B_i(\mathbb{D}, u) := B_i := -(a_i D_{0i} \nabla u_i - \mathbf{q} u_i) \cdot \vec{n}, \tag{1.4c}$$

where $\vec{n} = \vec{n}(x)$ is the unit outward normal on $\partial\Omega$. The coefficients $a_i = a_i(x) \in \{0, 1\}$ and $\theta \in (0, 1]$ are explained below. The semilinear problem is: let g and h be given, then find a $u : \overline{S} \times \overline{\Omega} \to \mathbb{R}^I$ such that

$$\theta \frac{\partial u}{\partial t} + A(\mathbb{D}, u) = \hat{f}(u) \text{ in } S \times \Omega, \quad u(0, \cdot) = g \quad \text{in } \Omega \text{ and} \tag{1.5}$$

$$B(\mathbb{D}, u) = h \quad \text{on } S \times \partial\Omega. \tag{1.6}$$

For identical diffusion coefficients and $p > N + 1$, in [11] Kräutle's showed that the solution $u(t, \cdot)$ belongs in $H^{2,p}(\Omega)^I$ for a.a. t. Since he deals with diffusion and reaction in porous media, in his setting the porosity θ might be different from one whereas, Mahato et. al. in [12] considers a free flow and thus in his setting $\theta = 1$. Kräutle in [11] splits $\partial\Omega$ in two disjoint parts Γ_{in} and Γ_{out}, the inflow and outflow boundary parts, respectively, and specifies (1.5) as

$$-\mathbf{q}\cdot\vec{n} = 0 \quad \text{on } S \times \Gamma_{\text{in}}, \qquad -\mathbf{q}\cdot\vec{n} \le 0 \quad \text{on } S \times \Gamma_{\text{out}} \quad \text{and} \tag{1.7}$$

$$-D_{0i}\frac{\partial u_i}{\partial \vec{n}} = 0 \quad \text{on } S \times \Gamma_{\text{out}}, \qquad h \le 0 \quad \text{on } S \times \Gamma_{\text{in}} \quad \text{and} \quad h \ge 0 \quad \text{on } S \times \Gamma_{\text{out}}, \tag{1.8}$$

i.e. the outflow is entirely advective (cf. [11]). Let us denote the problem (1.5)–(1.6) by (P). In order to model the conditions in (1.6) and (1.7), we choose $a_i(x) := 1$ on (1.5)–(1.7) and $a_i(x) := 0$ on Γ_{out} whereas in Ω, $a_i(x) = 1$. The existence of solution of (1.5)–(1.7) in [11] is based on L^∞-estimates obtained via a Lyapunov functional, a fixed-point argument and classical $H^{2,p}$-theory for linear parabolic systems. An essential drawback of their approaches is that the diffusion coefficients need to be the same for all species. For a diffusion setting in a porous medium this can be justified by the observation that, usually, the advective flux dominates the diffusive one by order of magnitudes. In this note we address the issue of non-identical diffusion coefficients and show that the unique existence of weak solutions can still be guaranteed under certain assumptions which are given in next section.

1.1 Literature survey

In regards to the global in time solution, the authors in [18] showed that only mass control and positivity of the solutions are not sufficient to prevent the blowup in the solution and therefore we need a growth control condition. In the survey paper [16], the author has summarized the conditions (and limitations) under which the global solution can be guaranteed. The existence of weak solutions for (P) is shown in [17] under the assumption that the nonlinearities belong to $L^1(S \times \Omega)$. For quadratic nonlinearities, the existence of weak solutions is shown in [4] via a duality method. The authors in [8,20] showed the existence of a global renormalized solution if nonlinearities satisfy the entropy condition: $\sum_{i=1}^{I} \hat{f}_i(u)(\log u_i + \alpha_i) \leq 0$ for all $u \in (0,\infty)^I$ for some $\alpha_1, \alpha_2, \ldots, \alpha_I \in \mathbb{R}$. In [9], the global classical solutions for (P) with homogeneous Neumann boundary condition is shown under the assumption of mass conservation and entropy condition. In [9], the authors have assumed that $\hat{f}_i(u)$ has the cubic growth for $n = 1$ and $\hat{f}_i(u)$ has the quadratic growth for $n = 2$. The result later improved in [24] by utilizing a modified Gagliardo–Nirenbarg inequality. For higher-order nonlinearities in any space dimension if the diffusion coefficients are close to each other, i.e. if they are quasi-uniform, then the global existence of classical solutions is proved in [3, 5]. In [1], the authors have shown that under the polynomial growth condition, the L^∞-norm of the classical solution can be obtained, however, later on this growth condition is removed in [3]. The authors in [19] proved the global existence and uniform boundedness for quadratic growth and dimension $n = 2$ by relaxing the mass conservation to mass dissipation. This result is improved in [15] by replacing the mass dissipation assumption with a weaker intermediate sum condition. In higher dimensions, the existence of global classical solutions for nonlinearities with quadratic growth has been proved in [2,6,23] and for the case of $\Omega = \mathbb{R}^n$ is deduced in [10]. The work in [2] is based on mass conservation assumption together with the entropy condition, whereas in [23] the mass conservation condition is replaced by the mass dissipation assumption. A more general work is done in [6] under the mass control assumption. The uniform in time bound for the solutions is shown in [7]. Thus, in the previous works the global classical solutions in any space dimensions and for the higher order nonlinearities is shown under the restriction that the diffusion coefficients are close to each other and on some particular structure of the nonlinearities. Our work shows the existence of weak solution in a $H^{1,p}$ setting and far less assumptions on the nonlinearities. Our argument to prove the existence of global solution is rather small and involves less calculations. We have also incorporated inflow-outflow boundary conditions which in turn do not disturb the global existence of the solution.

2 Mathematical preliminaries

2.1 Function spaces

Let $p,q \in [1,\infty]$, $\frac{1}{p}+\frac{1}{q}=1$, $\lambda \in [0,1]$, $\Omega \subset \mathbb{R}^N$ be a bounded Lipschitz domain. $\mathrm{Sym}(N)$ is the set of all real symmetric matrices $A=(A_{ij})$ normed by $|A|_{\mathrm{Sym}(N)} := \max_{i,j=1,\dots,N} |A_{ij}|$. $(\cdot,\cdot)_{p,\lambda}$ and $[\cdot,\cdot]_\lambda$ stand for the real- and complex-interpolation functor, respectively (cf. [25]). Likewise $L^p(\Omega)$, $H^{\alpha,p}(\Omega), \alpha \in \mathbb{N}$ and $C^\lambda(\overline{\Omega})$ denote the Lebesgue, Sobolev and Hölder spaces, respectively, with their usual norms (cf. [25]). " $\hookrightarrow$ " denotes a continuous imbedding. For a normed space Y, $L^p(S;Y)$ and $H^{1,p}(S;Y)$ are the (standard) Bochner and Sobolev–Bochner spaces (cf. [25]). Y^* stands for the dual of Y. $\langle\cdot,\cdot\rangle_I$ denotes the inner product on $\mathbb{R}^I$ and $|\cdot|_I$ be the corresponding norm. If X and Y are normed spaces, then $\mathfrak{L}(X,Y)$ represents the set of all bounded linear operators from X to Y and $\mathrm{Iso}(X;Y)$ stands for the set of all linear isomorphisms of $\mathfrak{L}(X;Y)$. From here on we assume $p>N+2$ is fixed. The imbedding $L^p(\Omega)^I \hookrightarrow (H^{1,q}(\Omega)^*)^I$ is given by $L^p(\Omega)^I \ni h_0 \mapsto L_h : \langle L_h, w\rangle := \sum_{i=1}^I \int_\Omega h_{0i}(x) w_i(x)dx,\ w \in (H^{1,q}(\Omega))^I$. We set $F_p := F_p(S,\Omega) := L^p(S;H^{1,p}(\Omega)) \cap H^{1,p}(S;H^{1,q}(\Omega)^*)$ normed by

$$\|\psi\|_{F_p} := \|\psi\|_{L^p(S;H^{1,p}(\Omega))} + \|\psi'\|_{L^p(S;H^{1,q}(\Omega)^*)}, \tag{2.1}$$

where u' is the distributional derivative of u. The solution space of the system under consideration is $F_p^I = \underbrace{F_p \times F_p \times \cdots \times F_p}_{I\text{-times}}$ and its norm is defined by $\|u\|_{F_p^I} := \left[\sum_{i=1}^I \|u_i\|_{F_p}^p\right]^{\frac{1}{p}}$. Note that for $p>N+2$, $F_p \subset C(\overline{S};(H^{1,q}(\Omega)^*, H^{1,p}(\Omega))_{1-\frac{1}{p},p})$ and $F_p \subset C(\overline{S};C(\overline{\Omega}))$ (cf. [12]). For abbreviation, we set

$$V := H^{1,p}(\Omega)^I,\ W := H^{1,q}(\Omega)^I,\ W^* := [H^{1,q}(\Omega)^*]^I,\ V_0 := (H^{1,q}(\Omega)^*, H^{1,p}(\Omega))^I_{1-\frac{1}{p},p}, \tag{2.2a}$$

$$V_{\partial\Omega} := L^p(\partial\Omega)^I,\ P_0 = L^p(S;V_0),\ P_1 = F_p^I,\ P_2 := L^p(S;H^{1,q}(\Omega)^*)^I,\ P := P_2 \times V_0, \tag{2.2b}$$

$$Q_1 := C(S;C(\overline{\Omega}))^I,\ Q_2 := L^p(S;C(\overline{\Omega}))^I,\ E := Q_0 \times P_1 \text{ and } Q_0 := L^\infty(\Omega;\mathrm{Sym}(N))^I. \tag{2.2c}$$

Then, for $p>N+2$, a simple embedding result from [12] yields

$$L^p(S;V) \cap H^{1,p}(S;W^*) \hookrightarrow C(\overline{S};V_0) \hookrightarrow C(\bar{S};C(\bar{\Omega}))^I \hookrightarrow C(\bar{S};L^\infty(\Omega))^I. \tag{2.3}$$

Remark 2.1. If $\mathbb{D} = (D_{0_1}, D_{0_2}, \dots, D_{0_I}) \in L^\infty(\Omega;\mathrm{Sym}(N))^I$, i.e. $\forall i\ D_{0_i} \in L^\infty(\Omega;\mathrm{Sym}(N))$, then $|||\mathbb{D}|||_{L^\infty(\Omega;\mathrm{Sym}(N))^I} := \max_{i,j,k} \|D_{0_{ikj}}\|_{L^\infty(\Omega)} = \max_{i,j,k} \operatorname{ess\,sup}_{x\in\Omega} |D_{0_{ikj}}(x)|_{L^\infty(\Omega)}$. However, in our case, we only have $D_{0_{ikj}}(x) = D_0 = $ constant $\forall i,j,k$ and $x \in \Omega$, then $|||\mathbb{D}|||_{L^\infty(\Omega;Sym(N))^I} := \max_{i,j,k} \|D_{0_{ikj}}\|_{L^\infty(\Omega)} = \max_{i,j,k} \operatorname{ess\,sup}_{x\in\Omega} |D_{0_{ikj}}(x)| = D_0$.

To state the main theorem of the paper, we would require the following assumptions:

A1. let D_0 be a positive constant. For each $i=1,2,\dots,I$, $D_{0_i} := \mathrm{diag}(D_0,\dots,D_0) \in \mathrm{Sym}(N) \subset \mathbb{R}^{N\times N}$ be a diagonal matrix such that $\mathbb{D} := (D_{0_1},\dots,D_{0_I}) \in \mathrm{Sym}(N)^I$, where $I \in \mathbb{N}$.

A2. let $h \in L^p(\partial\Omega)^I$ and let $g \in V_0$ such that $g_i \geq 0$ for each i.

A3. let (1.6) and (1.7) hold true and $\vec{q} \in L^\infty(S\times\Omega)$ be such that $Q := \|\vec{q}\|_{L^\infty(S\times\Omega)} < \infty$ and $\vec{q}\cdot\vec{n} \in L^\infty(S\times\Gamma_{\mathrm{out}})$.

Definition 2.2 (Weak formulation). Let the assumptions A1–A3 hold true. Then, a vector $u \in F_p^I$ is said to be a weak solution of the problem (P) if $u(0) = g$ and

$$\int_S \langle \partial_t u_i, \phi_i \rangle_{W^* \times W} \, dt + \int_S \int_\Omega (D_{0_i} \nabla u_i - \vec{q} u_i) \nabla \phi_i \, dx \, dt - \int_{S \times \Gamma_i n} h\phi_i \, ds \, dt$$
$$+ \int_{S \times \Gamma_o ut} \vec{q} \cdot \vec{n} \phi_i \, ds \, dt = \int_S \langle \hat{f}_i, \phi_i \rangle_{W^* \times W} \, dt, \quad \forall \phi \in L^q(S; W). \quad (2.4)$$

Next, we state the existence theorem from [13] which addresses the question of same diffusion coefficients in the system.

Theorem 2.3. *Let the assumptions A1–A3 hold true. Then, there exists a unique global positive weak solution (in the sense of Definition 2.2) $u \in F_p^I$ of the problem (P).*

For Theorem 2.3, the global existence of solution follows from the construction of a particular type of Lyapunov function and exploiting the dissipative property of the reaction rate term and an application of Schaefer's fixed point theorem. The uniqueness and positivity follow from Gronwall's inequality.

Now, we shall state the main theorem of this paper which is existence of solution for different diffusion coefficients.

Theorem 2.4. *Let the assumptions A1–A3 hold true. Then, there is a neighborhood $U = U(D_0)$ in $L^\infty(\Omega; \mathrm{Sym}(N))^I$ such that (1.5)–(1.7) is solvable for all $\mathbb{D} \in U$. Moreover, the components of the solutions are non-negative.*

Remark 2.5. The proof of the implicit function theorem provides estimates for the size of $U(D_0)$. Here we do not yet go into detail, however, in [5,6] it has been shown that the if the diffusion co-efficients are very close to one and another, then there exists a classical solution.

Remark 2.6. In this note we do not directly employ the particular structure (1.5) of the reaction rates incorpoated into $\hat{f}(u)$, rather we use $\hat{f}$ is locally Lipschitz, then by Rademacher's theorem, we have $\hat{f} \in C^1(\mathbb{R}^I)^I$ in Theorem 2.4.

2.2 Operators

Let U, V be two Banach spaces and $x \in U$, then a continuous linear operator $\Psi : U \to V$ is called the Fréchet derivative of the operator $T : U \to V$ at x if $T(x+\theta) - T(x) = \Psi(\theta) + \phi(x,\theta)$ and $\lim_{\|\theta\|_U \to 0} \frac{\|\phi(x,\theta)\|_V}{\|\theta\|_U} = 0$ or, equivalently $\lim_{\|\theta\|_U \to 0} \frac{\|T(x+\theta) - T(x) - \Psi(\theta)\|_V}{\|\theta\|_U} = 0$. For a function $v = v(t,x)$, $t \in \overline{S}, x \in \overline{\Omega}$, we set $v(t) := v(t,\cdot)$. Let $H : U \to V$ and $G : \prod_{i=1}^n U_i \to V$, where U, U_i and V are Banach spaces. For functions $\xi \in U, \xi_i \in U_i \; \forall i$, $\mathcal{D}_{\xi^*} H(\xi)$ is the Fréchet derivative of $H = H(\xi)$ at ξ^* and $\partial_i G := \partial_{\xi_i} G := \frac{\partial G}{\partial \xi_i}$ is the partial Fréchet derivative of $G = G(\xi_1, \ldots, \xi_n)$.

We will now define the following operators:

By Remark 2.6, $\widehat{f} \in C^1(\mathbb{R}^I, \mathbb{R}^I)$ (production-rate vector). Clearly, $\widehat{f} : L^p(S;V) \to L^p(S;W^*)$ and we define $\left\langle \widehat{f}(u), v \right\rangle := \int_\Omega \widehat{f}(u(x))^T v(x) dx$ (the V-realisation of $\widehat{f}$). We then introduce the operator $F : F_p^I \to L^p(S;W^*)$ via

$$\langle \mathcal{F}(u)(t), v \rangle := \int_\Omega \langle \widehat{f}(u(t,x)), v(x) \rangle_I dx \quad a.e. \; t \in S, v \in W. \quad (2.5)$$

We further define $A(\mathbb{D},u) := A_1(\mathbb{D},u) + A_2(\mathbb{D},u)$, where $A_1(\mathbb{D},u) := -(\text{div}(D_{0_1}\nabla u_1),\ldots,\text{div}(D_{0_I}\nabla u_I))^T$, $A_2(\mathbb{D},u) := (\text{div}\, u_1\mathbf{q},\ldots,\text{div}\, u_I\mathbf{q})^T$, where

$$A(\mathbb{D},u) := A_1(\mathbb{D},u) + A_2(\mathbb{D},u),$$
$$\langle A_1(\mathbb{D},u),v\rangle := \textstyle\sum_{i=1}^{I} \int_\Omega D_{0_i}\nabla u_i \cdot \nabla v_k\, dx, \quad u \in V, v \in W,$$
$$\langle A_2(\mathbb{D},u),v\rangle := \textstyle\sum_{i=1}^{I} \int_\Omega u_i\mathbf{q} \cdot \nabla v_i\, dx, \quad u \in V, v \in W \quad \text{and}$$
$$\langle B(h),v\rangle := \textstyle\sum_{i=1}^{I} \int_{\partial\Omega} h_i v_i\, d\sigma, v \in V.$$

We note that $A : E \to P_2$. The corresponding extensions for time dependent $u = u(t)$ is, with the same notation, given by $A(\mathbb{D},u)(t) := A(\mathbb{D},u(t))$. Similarly, we proceed with A_1, A_2 and B and obtain

$$A, A_1, A_2 : E \to P_2, \quad B : L^p(S;V_{\partial\Omega}) \to P_2.$$

Also, note that $h \neq 0$ corresponds to non-homogeneous flux boundary conditions. Finally, we set

$$G_1(\mathbb{D},u) := u' + A(\mathbb{D},u) + B(h) - \mathcal{F}(u), \tag{2.6}$$
$$G_2(\mathbb{D},u) := u(0) - g, \tag{2.7}$$
$$G(\mathbb{D},u) := (G_1(\mathbb{D},u), G_2(\mathbb{D},u))^T. \tag{2.8}$$

Therefore, the problem (1.5)–(1.7) has now been formulated into an abstract evolution equation (2.6)–(2.8) and its weak formulation can be given by

Definition 2.7. Let the assumptions **A1–A3** be true. A function $u \in F_p^I$ is called a weak solution of problem (2.6)–(2.8), if $u(0) = g$ and $u'(t) + A(\mathbb{D},u(t)) + B(h(t)) = \mathcal{F}(u(t))$ in P_2. Alternatively, a function $u \in F_p^I$ is a weak solution of (2.6)–(2.8) if $G(\mathbb{D}),u) = 0$ in P.

In order to prove Theorem 2.4, we will first look in to following lemmas:

Lemma 2.8. *Let $p > N+2$. For $k = 1,2$, let P_k and Q_k be the normed spaces, defined as in (2.2a)–(2.2c), such that $P_1 \hookrightarrow Q_1$, $Q_2 \hookrightarrow P_2$. Assume further that $M : Q_1 \to Q_2$ be a Fréchet differentiable operator and set $\overline{M} := M|_{P_1}$ = restriction of M on P_1. Then,*

$$\mathfrak{L}(Q_1;Q_2) \hookrightarrow \mathfrak{L}(P_1;P_2), \quad \mathcal{D}_u\overline{M} = \mathcal{D}_u M|_{P_1} \in \mathfrak{L}(P_1;P_2). \tag{2.9}$$

Proof. Let $v \in Q_2$, then $\|v\|_{Q_2} \leq C\|v\|_{Q_1}$. Since $P_1 \hookrightarrow Q_1$ and $Q_2 \hookrightarrow P_2$, $\|v\|_{P_2} \leq C\|v\|_{Q_2} \leq C\|v\|_{Q_1} \leq C\|v\|_{P_1}$. This concludes (2.9). Now, we shall prove (2.9). We note that $M : Q_1 \to Q_2$ is a Fréchet differentiable operator, i.e. $Q_1 \ni l \mapsto \mathcal{D}_l M(l) \in Q_2$ is a bounded linear operator from Q_1 to Q_2. Then, by the definition of Fréchet derivative, we have for $\varepsilon > 0$

$$\|M(u+l) - M(u) - \mathcal{D}_l M(l)\|_{Q_2} < \varepsilon\|l\|_{Q_1}.$$

Then, by $P_1 \hookrightarrow Q_1$, $Q_2 \hookrightarrow P_2$, we obtain

$$\|M(u+l) - M(u) - \mathcal{D}_l M(l)\|_{P_2} < \varepsilon\|l\|_{P_1}. \tag{2.10}$$

(2.10) implies that $\mathcal{D}_l M : P_1 \to P_2$ is a bounded linear operator, i.e. $M : P_1 \to P_2$ is a Fréchet differentiable operator. Now, for $u,l \in P_1$, $\overline{M}(u+l) = M(u+l)$, $\overline{M}(u) = M(u)$, therefore from (2.10), we have $\|\overline{M}(u+l) - \overline{M}(u) - \mathcal{D}_l\overline{M}(l)\|_{P_2} = \|M(u+l) - M(u) - \mathcal{D}_l M(l)\|_{P_2} < \varepsilon\|l\|_{P_1}$ which implies $\mathcal{D}_l\overline{M}|_{P_1} \in \mathfrak{L}(P_1;P_2)$. □

Lemma 2.9 (Implicit Function Theorem, cf. [22]). *Suppose that X, Y, Z are Banach spaces, C is an open subset of $X \times Y$ and $T : C \to Z$ is continuous operator. Suppose further that for some $(x_0, y_0) \in C$,*

(i) $T(x_0, y_0) = 0$,

(ii) The Fréchet derivative of $T(\cdot, \cdot)$, when x is fixed is denoted by $T_y(x, y)$, is called the partial Fréchet derivative w.r.t. y which exists at each point (x, y) in a neighbourhood of the point (x_0, y_0) and is continuous at (x, y).

(iii) $[T_y(x_0, y_0)]^{-1} \in \mathfrak{L}(Z, Y)$.

Then there is an open subset U of X containing x_0 and a unique continuous mapping $y : U \to Y$ such that $T(x, y(x)) = 0$ and $y(x_0) = y_0$.

3 Proof of Theorem 2.4

Before we prove Theorem 2.4, we recall Theorem 2.4 since it deals with the system of semilinear parabolic PDEs with identical diffusion coefficients. It states that under the assumptions A1–A3, there exists a unique positive global weak solution $u \in P_1$ of the problem (1.5)–(1.7).

In other words, for a fixed $\mathbb{D} \in Q_0$ there exists a unique $u^* \in P_1$ such that we have

$$G(\mathbb{D}, u^*) = 0. \tag{3.1}$$

Now, in the spirit of Lemma 2.9, we denote $T = G, X = Q_0, Y = P_1$ and $Z = P$. Next, we will show that the following equations holds true:

$$\langle \mathcal{D}_{u^*} \mathcal{F}(u), v \rangle = \int_\Omega \langle \mathcal{D}_{u^*} \hat{f}(u(t,x)), v(x) \rangle_I dx \text{ for a.a. } t \in S,\ u \in P_1,\ v \in W, \tag{3.2}$$

$$\langle \mathcal{D}_{u^*} G_1(\mathbb{D}, u), v \rangle = \langle \partial_t u^* + A(\mathbb{D}, u^*) - \mathcal{D}_{u^*} F(u), v \rangle \text{ for } u \in P_1, \text{ and } v \in W, \tag{3.3}$$

$$\langle \mathcal{D}_{u^*} G_2(\mathbb{D}, u), v \rangle = \langle u^*(0) - g, v \rangle, \tag{3.4}$$

$$G_1 \in P_2 \text{ is Fréchet differentiable on } Q_0 \times P_1, \tag{3.5}$$

For fixed $(\mathbb{D}, u^*)$,

$$L := \mathcal{D}_{u^*} G(\mathbb{D}, u) \in \mathfrak{L}(P, P_1), \text{ i.e. } L = (\mathcal{D}_{u^*} G_1(\mathbb{D}, u), \mathcal{D}_{u^*} G_2(\mathbb{D}, u)) \in \text{Iso}(P_1, P). \tag{3.6}$$

We shall prove (3.2)–(3.6) in several steps.

Step 1: At first, we show that $G : Q_0 \times P_1 \to P_2 \times P_0$ is a continuous operator. We note that $G_1(\mathbb{D}, u) := u' + A_0(\mathbb{D}, u) + B(h) - F(u), G_2(\mathbb{D}, u) = u(0) - g$, Then, for a $\phi \in \mathfrak{D} := C_0^\infty(S \times \Omega)^I$, we have

$$\begin{aligned}\langle G_1(\mathbb{D}, u), \phi \rangle &= \langle u' + A(\mathbb{D}, u) + B(h) - \mathcal{F}(u), \phi \rangle \\ &= -\langle u, \partial_t \phi \rangle + \int_{S\times\Omega} \langle \mathbb{D} \nabla u, \nabla v \rangle_I + \int_{S\times\Omega} \langle u\mathbf{q}, \nabla \phi \rangle_I + \int_{S\times\partial\Omega} \langle h, v \rangle_I - \int_{S\times\Omega} \langle \hat{f}, \phi \rangle_I.\end{aligned}$$

By Hölder's inequality and $\mathfrak{D} \hookrightarrow P_1 \hookrightarrow P_0 \hookrightarrow P_2$, it follows that $\|G_1(\mathbb{D}, u)\|_{P_2} < \infty$. We also note that $\|G_2(\mathbb{D}, u)\|_{P_0} < \infty$. Altogether these two estimates imply that $\|G(\mathbb{D}, u)\|_{P_2 \times P_0} < \infty$, i.e. $G : Q_0 \times P_1 \to P_2 \times P_0$ is a continuous operator. Since $\hat{f} \in C^1(\mathbb{R}^I)^I$, then by definition of $\mathcal{F}(u)$ and Fréchet derivative, we obtain

$$\begin{aligned}\langle \mathcal{D}_{u^*}F(u), v\rangle &= \int_\Omega \Big\langle \Big[\hat{f}(u^*(t,x)+\theta(t,x)) - \hat{f}(u^*(t,x)) - \Psi(u^*(t,x),\theta(t,x))\Big], v(x)\Big\rangle_I \, dx \\ &= \int_\Omega \langle \mathcal{D}_{u^*}\hat{f}(u(t,x)), v(x)\rangle_I \, dx, \end{aligned} \tag{3.7}$$

for a.e. $t \in S$, $u, \theta \in V$ and $v \in W$. By (3.7), it follows that $\mathcal{D}_u F \in \mathfrak{L}(V;W)$ exists as $C(S) \hookrightarrow L^p(S)$. Now, since $H^{1,p}(\Omega) \hookrightarrow C(\overline{\Omega}) \hookrightarrow H^{1,q}(\Omega)^*$, the restriction $F|_{P_1}$ is Fréchet differentiable with $\mathcal{D}_u F|_{P_1} \in \mathfrak{L}(P_1; P_2)$ for all $u \in P_1$. Therefore, $\langle \mathcal{D}_u F, v\rangle$ exists in (3.2).

Step 2: We note from definition 2.1.1 that the Fréchet derivative of a linear operator T is T itself. Since, $\partial_t, A : F_p^I \to P_2$ are linear and B can be treated as a constant w.r.t. $u \in F_p^I$, therefore the Fréchet derivative of G_1 will yield

$$\mathcal{D}_{u^*}G_1(\mathbb{D}, u) = \partial_t u^* + A(\mathbb{D}, u^*) - \mathcal{D}_{u^*}\mathcal{F}(u) \in P_2.$$

This concludes (3.3). Likewise, (3.4) follows with similar arguments. Furthermore, by step 1, we know $\mathcal{D}_u F|_{P_1} \in \mathfrak{L}(P_1; P_2)$. This implies $\mathcal{D}_u G_1 \in \mathfrak{L}(Q_0 \times P_1; P_2)$, i.e. $\mathcal{D}_u G_1 : Q_0 \times P_1 \to P_2$ exists, i.e. $G_1(\mathbb{D}, u^*) \in P_2$ is Fréchet differentiable on $Q_0 \times P_1$.

Step 3.: We have obtained the continuity of one of the partial derivative $(\mathcal{D}_u G_1(\mathbb{D}, .))$ of a total of two and the existence of $\mathcal{D}_u G_2(\mathbb{D}, u^*)$, we obtain the existence of $\mathcal{D}G(\cdot,\cdot)$. Now the estimate

$$\|\mathcal{D}_u G_2(\mathbb{D}, u^*)\|_{P_2} = \|u_0^*\|_{P_2} \le C\|u_0^*\|_{L^p(S;V_0)} \le C\|u_0^*\|_{P_1} < \infty,$$

by the definition of function spaces and a straightforward imbedding of $P_1 \hookrightarrow P_0 \hookrightarrow P_2$. This implies the continuity of $\mathcal{D}_u G_2$. Hence, the continuity of both $\mathcal{D}_u G_1$ and $\mathcal{D}_u G_2$ imply the continuity of $\mathcal{D}G$.

Step 4: Let $(f, g) \in P_2 \times V_0$. In order to verify (3.6) it remains to show that the problem:

$$\text{Find } (\mathbb{D}, u^*) \in Q_0 \times P_1 \text{ with} \tag{3.8}$$

$$\partial_t u^* + A(\mathbb{D}, u^*) = \mathcal{D}_{u^*}\mathcal{F}(u), \quad u^*(0) = g, \tag{3.9}$$

has a unique solution. The operator $A(\mathbb{D}, u^*)$ possesses the maximal parabolic regularity property on P_1 in the L^p-sense (cf. [21]). From [21], it follows that (3.8)–(3.9) is uniquely solvable. Upon combining the steps 1 to 4, all the three conditions of implicit function theorem (Lemma 2.9) satisfied. Therefore, there exists an open neighbourhood of $\mathbb{D}$, $U(\mathbb{D}) \subset Q_0$ such that $G(D, u) = 0$ for all $D \in U(\mathbb{D})$. Moreover, the size of the neighbourhood $U(\mathbb{D})$ can be estimated, however this will be addressed somewhere else. Now, for the positivity, we multiply the PDE (1.5) with $-u_i^-$ ($-1\times$ negative part of u_i) and integrate over Ω_i^- (support of u_i^-) for all $i = 1, 2, \ldots, I$ and for a.e. $t \in S$. We use the fact that $u(0) \ge 0$ which eventually yields the positivity of the solutions via Gronwall's inequality.

Remark 3.1. Although we did not show the size of this neighbourhood in which the diffusion coefficient must lie, in [6] an idea regarding that is mentioned and recently in [14] has been shown that this can be further refined and a rather general neighbourhood can be chosen.

Acknowledgments

We would like to thank the anonymous referees for their fruitful comments and suggestions which helped us to improve the manuscript. The second author would like to thank SERB DST for their support under the project grant CRG/2020/006453.

Abstract. This work aims to obtain a positive, smooth, even, and homoclinic to zero (i.e. zero at infinity) solution to a non-autonomous, second-order, nonlinear differential equation involving quadratic growth on the derivative. We apply Galerkin's method combined with Strauss' approximation on the term involving the first derivative to obtain weak solutions. We also study the regularity of the solutions and the dependence on their existence with a parameter.

Keywords: Galerkin method, homoclinic solution, quadratic growth on the derivative, differential equation.

1 Introduction

The existence of homoclinic solutions for autonomous and non-autonomous differential equations and Hamiltonian systems is a crucial subject in qualitative theory (see [19]).

In this work, the second-order equation in the real line considered is

$$\begin{cases} -(A(u)u')'(t) + u(t) = \lambda a_1(t)|u(t)|^{q-1} + |u(t)|^{p-1} + g(|u'(t)|), & \text{in } \mathbb{R} \\ u(t) > 0, & \text{in } \mathbb{R} \\ \lim_{t\to\pm\infty} u(t) = 0, \end{cases} \tag{1.1}$$

with

(H_1) $1 < q < 2 < p < +\infty$ and $a_1 \in L^{\mathfrak{s}}(\mathbb{R}) \cap C(\mathbb{R})$, $\mathfrak{s} = \frac{2}{2-q}$, a positive even function;

✉Corresponding author. Email: p.correa@usp.br

(H_2) $A : \mathbb{R} \to \mathbb{R}$ a Lipschitz, smooth (at least $C^1(\mathbb{R})$), non-decreasing function satisfying:

$$\exists\, \gamma \in (0,1) \quad \text{such that} \quad 0 < \gamma \leq A(t) \quad \forall t \in \mathbb{R};$$

(H_3) $g : \mathbb{R} \to \mathbb{R}$ a continuous function satisfying:

$$0 \leq sg(s) \leq |s|^{\theta} \quad \text{for all } s \in \mathbb{R}, \text{ where } 2 < \theta \leq 3. \tag{1.2}$$

The equation in (1.1) arises in several real phenomena, for instance, as the study of traveling wavefronts for parabolic reaction-diffusion equations with a local reaction term, chemical models, and others, as mentioned in [13, 14], and generalizes several classical equations such as Duffing-type equations [3, 10, 16] or Liénard-like systems [18].

Now, we state our main result.

Theorem 1.1. *There exists $\lambda^* > 0$ such that, for all $\lambda \in (0, \lambda^*]$, problem (1.1) has an even, positive and $C^2(\mathbb{R})$ homoclinic solution to the origin. Moreover, as $\lambda \to 0$, this solution goes to 0 in $C^0(\mathbb{R})$.*

We also find an additional result with respect to appropriate ranges of λ in order to guarantee the existence of solutions.

Proposition 1.2. *Assume the hypotheses of Theorem 1.1. If $\lambda > 0$ is sufficiently large, then equation (1.1) has no (positive) solution in $H^1(\mathbb{R})$.*

The idea to consider problem (1.1) came from article [3], where the authors considered a similar equation but with a different set of hypotheses; namely, their formulation was focused on the study of the equation

$$\begin{cases} -(A(u)u')' + u(t) = h(t, u(t)) + g(t, u'(t)) \text{ in } \mathbb{R} \\ u(\pm\infty) = u'(\pm\infty) = 0, \end{cases}$$

with

$(\widetilde{H}_1)$ $h, g : \mathbb{R}^2 \to \mathbb{R}$ locally Hölder continuous, even in the first variable and $h(t, 0) = g(t, 0) = 0$;

$(\widetilde{H}_2)$ there exist constants $0 < r_1, r_2 < 1$ and smooth functions $b \in L^1(\mathbb{R}) \cap L^\infty(\mathbb{R})$ with $b(t) > 0$ for all $t \in \mathbb{R}$, $a_1 \in L^2(\mathbb{R})$ and $a_2 \in L^{\frac{2}{1-r_2}}(\mathbb{R})$, satisfying

$$b(t)|\mu|^{r_1} \leq h(t, \mu) \leq a_1(t) + a_2(t)|\mu|^{r_2}, \quad \forall (t, \mu) \in \mathbb{R}^2;$$

$(\widetilde{H}_3)$ there exist a constant $0 < r_3 < 1$ and smooth functions $a_3 \in L^{\frac{2}{1-r_3}}(\mathbb{R})$ and $a_4 \in L^2(\mathbb{R})$ satisfying

$$0 \leq g(t, \eta) \leq a_4(t) + a_3(t)|\eta|^{r_3} \quad \forall (t, \eta) \in \mathbb{R}^2;$$

$(\widetilde{H}_4)$ the function A is smooth, nondecreasing and there exists $\gamma \in (0,1)$ satisfying

$$0 < \gamma \leq A(t) \quad \forall t \in \mathbb{R}.$$

By comparison with our work, we considered sup-linear growth on u and u', terms involving this type of growth are not covered in [3]. Another aspect that we would like to emphasize is the weakening of the hypothesis over g: comparing with [3], we asked only for continuity over g, instead of Hölder continuity. Although the formulation presented here is not an immediate consequence of [3], some techniques therein proved to be quite solid and very useful in the study of this type of problem, transcending the circumstances framed by the authors.

Our formulation presented some interesting challenges, for instance, the problem is not variational. Among the non-variational techniques, we chose the Galerkin method as a tool to gather information about the existence of weak solutions. Although proving itself beneficial, the Galerkin method presented us with other types of challenges to circumvent. For example, the nonlinear term $g(|u'(t)|)$ with $0 \leq sg(s) \leq |s|^\theta$ and $2 < \theta \leq 3$ enables us to take $g(s) \equiv \operatorname{sign}(s)|s|^2$. Thus estimations involving $\int_\Omega |u'|^2$ become essential to the calculations but, at the same time, we cannot say much about it *a priori*: this is due to the lack of information about u', since the embedding theorems of $H_0^1(\Omega)$ do not provide substation information about u' as they do for u.

We consider the case $\theta = 3$ as the *critical* one and treat it separately in our estimations. For $\theta > 3$ we would get expressions involving $\int |u'|^{\theta-1}$ that we could not control, because $\theta - 1 > 2$ and we only know that $u' \in L^2$; for this reason we limited $\theta \leq 3$, and $\theta > 2$ was required because we wanted to focus on the sup-linear case.

There is some literature about equations on domains in $\mathbb{R}^n$ involving the term $|\nabla u|^2$ in the nonlinearity (see [1, 2, 9, 15]), some authors call this type of growth: "*critical growth on the gradient*". Simple changes on how this term appears in the equation can have dramatic effects on the outcome. For instance, a simple change in the sign of $|\nabla u|^2$ can lead to a total failure to obtain a solution (even in the weak sense), see the article [2] for more information. We also would like to emphasize article [9] for its results and broader discussion about PDE with quadratic growth on the gradient: the model problem studied by the authors is

$$-\operatorname{div}(A(x)\nabla u) = c_0(x)u + \mu(x)|\nabla u|^2 + f(x),$$

with suitable hypothesis. In this context, our problem (1.1) presents a similar structure that was not covered before, thus we believe it contributes to the discussion previously mentioned.

The methods applied in our work require certain symmetry, which is due mainly to a lack of a comparison principle (known to the authors) to guarantee that some limit-functions are not zero almost everywhere (a.e.), (see Proposition 2.24). To overcome this obstacle, we founded this work focusing on the set $\mathbb{E}_0^1(I) = \{u \in H_0^1(I); u(t) = u(-t) \text{ a.e.}\}$, $I \subset \mathbb{R}$ a symmetric interval, which is the subset of $H_0^1(I)$ consisting of even (or radial symmetric) functions.

In order to develop our study, in Section 2, we started by analyzing our equation on a bounded interval:

$$\begin{cases} -(A(u)u')'(t) + u(t) = \lambda a_1(t)|u(t)|^{q-1} + |u(t)|^{p-1} + g(|u'(t)|), \text{ in } (-n, n) \\ u(n) = u(-n) = 0. \end{cases} \tag{P_n}$$

This restriction was essential to realize our estimations and to obtain upper bound constants that were crucial to construct the solution in $\mathbb{R}$ to the problem (1.1). The process developed in Section 2 consisted mainly of two steps:

First Approximate g by a sequence of Lipschitz functions (f_k) using the *Strauss Approximation*; this sequence received this name after its first appearance in the article [17].

This approximation was useful because it helped us to work with the necessary estimations without extra hypotheses over g. We followed [5] in the definition and presentation of the properties of the sequence (f_k). In this article, the authors used this approximation to avoid the usage of the Ambrosetti–Rabinowitz condition and were able to obtain a positive solution to the equation

$$\begin{cases} -\Delta u = \lambda u^{q(r)-1} + f(r,u) & \text{in } B(0,1) \\ u > 0 & \text{in } B(0,1) \\ u = 0 & \text{on } \partial B, \end{cases}$$

see [5] for more information.

We would like to emphasize that, in [5], the authors used this approximation in a term involving u; namely they used it to approximate $f(r,u)$. In our work, we used it in u'.

Second We used the sequence (f_k) to define an approximate problem in $(-n,n)$ and used the Galerkin method to obtain a weak solution. Then, using the work done by Gary M. Liberman [12], we obtained the *a priori estimation* summarized in Proposition 2.21. Thus we obtained a strong solution to this problem. Afterward, we were able to construct a strong solution to the problem (P_n).

In Section 4 we used the pieces of information gathered in Section 2 to construct a solution to the problem (1.1), thus proving Theorem 1.1. We also prove Proposition 1.2 in Section 4. We would like to point out the role of Section 3: there we study the asymptotic behavior, in respect to λ, of the solution to the problem (P_n) – the arguments presented were inspired by the article [8]. This was useful to tackle the last assertion of Theorem 1.1.

2 Solution in a bounded interval

First, we will obtain a solution to a problem related to (1.1); namely, we will study

$$\begin{cases} -(A(u)u')'(t) + u(t) = \lambda a_1(t)|u(t)|^{q-1} + |u(t)|^{p-1} + g(|u'(t)|), \text{ in } (-n,n) \\ u(n) = u(-n) = 0, \end{cases} \tag{P_n}$$

with the same set of hypothesis $(H_1), (H_2)$ and (H_3). The motivation for this approach is to construct a solution to the problem (1.1) using the solutions of (P_n). Although the analysis of (P_n) is easier since it is defined over $(-n,n)$, rather than $\mathbb{R}$, the lack of hypothesis over g creates a difficult situation for our estimations. To overcome this matter, we will utilize the *Strauss Approximation* on g at the same time that we approximate the problem (P_n). Let us define the sequence of functions that will approximate g.

Define $G(s) = \int_0^s g(t)dt$ so that G is differentiable and $G'(s) = g(s)$. By means of G we shall construct a sequence of approximations of g by Lipschitz functions $f_k : \mathbb{R} \longrightarrow \mathbb{R}$. Let

$$f_k(s) = \begin{cases} -k[G(-k-\frac{1}{k}) - G(-k)], & \text{if } s \le -k \\ -k[G(s-\frac{1}{k}) - G(s)], & \text{if } -k \le s \le \frac{-1}{k} \\ k^2 s[G(\frac{-2}{k}) - G(\frac{-1}{k})], & \text{if } \frac{-1}{k} \le s \le 0 \\ k^2 s[G(\frac{2}{k}) - G(\frac{1}{k})], & \text{if } 0 \le s \le \frac{1}{k} \\ k[G(s+\frac{1}{k}) - G(s)], & \text{if } \frac{1}{k} \le s \le k \\ k[G(k+\frac{1}{k}) - G(k)], & \text{if } s \ge k. \end{cases} \tag{2.1}$$

Remark 2.1. The construction of the sequence (f_k) is due to [17].

The advantage of this sequence lies in the properties that one can obtain from it:

Theorem 2.2 ([5, Lemma 1])**.** *The sequence f_k as defined above satisfies:*

1. $sf_k(s) \geq 0$ *for all* $s \in \mathbb{R}$*;*
2. *for all* $k \in \mathbb{N}$ *there is a constant* $c(k)$ *such that* $|f_k(\xi) - f_k(\eta)| \leq c(k)|\xi - \eta|$*, for all* $\xi, \eta \in \mathbb{R}$*;*
3. f_k *converges uniformly to* g *in bounded sets.*

Remark 2.3. From the definition of the sequence f_k, and the fact that $\text{sign}(g(s)) = \text{sign}(s)$ for all $s \in \mathbb{R}$, it follows without difficulties that *1* is true. In [5, p. 6, Prop. 5] one can find a detailed proof of *2*, so we will only prove *3* by an alternative argumentation.

Proof. Given a bounded set $J \subset \mathbb{R}$, there exists $m_0 \in \mathbb{N}$ such that $J \subset (-m_0, m_0)$; so to prove *3* we only need to prove that it holds in intervals such as $(-m, m)$, $m \in \mathbb{N}$. We may also assume that $k > m$. Given $\epsilon > 0$, for $s \in (-m, m)$ there are four possible cases:

Case I. $-m < s \leq \frac{-1}{k}$ Here we have that

$$|f_k(s) - g(s)| = \left| -k \left[G\left(s - \frac{1}{k}\right) - G(s) \right] - g(s) \right| = \left| \frac{[G(s - \frac{1}{k}) - G(s)]}{\frac{-1}{k}} - g(s) \right|.$$

Then, since $G'(s) = g(s)$, there exists $\delta(s) > 0$ such that $0 < |h| < \delta(s)$ implies

$$\left| \frac{[G(s+h) - G(s)]}{h} - g(s) \right| < \epsilon$$

From the family of open sets $\{(s - \delta(s), s + \delta(s)); s \in [-m, 0]\}$ we extract a finite subcover $\{(s_i - \delta(s_i), s_i + \delta(s_i)); i = 1 \dots l\}$ of the compact set $[-m, 0]$ and take $\delta = \min\{\delta(s_i); i = 1, \dots l\}$. Thus, for $k > \frac{1}{\delta}$ we get $|f_k(s) - g(s)| < \epsilon$.

Case II. $\frac{-1}{k} \leq s \leq 0$

Since $g(0) = 0$ and g is continuous, for the given $\epsilon > 0$ there exists $\delta > 0$ such that $|t| < \delta$ implies $|g(t)| < \epsilon/2$. Let $k_0 \in \mathbb{N}$ be such that $k_0 > m$ and $k_0 > 2/\delta$. Then, for $k > k_0$

$$\begin{aligned} |f_k(s) - g(s)| &= \left| k^2 s \left[G\left(\frac{-2}{k}\right) - G\left(\frac{-1}{k}\right) \right] - g(s) \right| \\ &\leq k^2|s| \left| \int_{-1/k}^{-2/k} |g(t)| dt \right| + |g(s)| \\ &\leq k^2 (\frac{1}{k^2}) \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon \quad \forall s \in [\frac{-1}{k}, 0]. \end{aligned}$$

The cases $0 \leq s \leq \frac{1}{k}$ and $\frac{1}{k} \leq s < m$ can be analyzed in a similar fashion. Thus we see that, for $\epsilon > 0$, we can take $k \in \mathbb{N}$ big enough such that $|f_k(s) - g(s)| < \epsilon$ *independently* of $s \in (-m, m)$. □

Lemma 2.4 ([5, Lemma 2])**.** *Let* $g : \mathbb{R} \to \mathbb{R}$ *be a continuous function satisfying* (1.2)*. Then the sequence* f_k *of Theorem* 2.2 *satisfies*

1. *For all* $k \in \mathbb{N}$, $0 \leq sf_k(s) \leq C_1|s|^\theta$ *for every* $|s| \geq \frac{1}{k}$*;*

2. *for all $k \in \mathbb{N}$, $0 \le s f_k(s) \le C_1|s|^2$ for every $|s| \le \frac{1}{k}$;*

where C_1 is a constant independent of k.

Proof. See [5, Page 8, Lemma 2]. □

Now we are in condition – using (f_k) – to define a problem that approximates problem (P_n). Let $\psi \in L^2(-n,n) \cap C(-n,n)$ be a positive, even function. We define our *approximate problem* by:

$$\begin{cases} -(A(u)u')'(t) + u(t) = \lambda a_1(t)|u(t)|^{q-1} + |u(t)|^{p-1} + f_k(|u'(t)|) + \frac{\psi}{k}, \text{ in } (-n,n) \\ u(n) = u(-n) = 0. \end{cases} \tag{P_n^k}$$

In the next subsection we will utilize the *Galerkin method* to obtain a solution to (P_n^k); afterward, we will let k vary and thus, as $k \to \infty$, obtain a solution to (P_n). Before jumping into the next subsection, let us define what we understand as *weak solution* to problem (P_n):

Definition 2.5. We will call $w \in H_0^1(-n,n)$ a *weak solution* of (P_n) if

$$\int_{-n}^{n} A(w)w'v' + \int_{-n}^{n} wv = \int_{-n}^{n} \lambda a_1|w|^{q-1}v + \int_{-n}^{n} |w|^{p-1}v + \int_{-n}^{n} g(|w'|)v$$

for all $v \in H_0^1(-n,n)$.

Remark 2.6. We will use, for the sake of clarity, the notation $\|\cdot\|_{W^{1,2}}$ for the usual norm of H_0^1 and for $(\|u\|_{L^2} + \|u'\|_{L^2})$ or $(\|u\|_{L^2}^2 + \|u'\|_{L^2}^2)^{1/2}$. Since these norms are equivalent the results will not change but the constants may. In most of the cases $\|u\|_{W^{1,2}} = \|u\|_{L^2} + \|u'\|_{L^2}$. We also emphasize that, when the context is clear, we will omit the domain in norms such as those from the spaces $L^p(-n,n)$.

Remark 2.7. The integrals in the definition above are well defined, see for instance the estimations of Proposition 2.16. The same is true for the definitions given in the next subsection.

2.1 Solution to the approximate problem

Our main goal in this subsection is to prove the following theorem:

Theorem 2.8. *There exist $\lambda^* > 0$, $\beta \in (0,1)$ and $k^* \in \mathbb{N}$ for which the problem (P_n^k) admits a nontrivial, even, non-negative $C^{1,\beta}[-n,n] \cap C^2(-n,n)$ solution for every $\lambda \in (0,\lambda^*)$ and $k \ge k^*$.*

As mentioned, we will utilize the *Galerkin method*; thus we will start by presenting the foundations that this method requires. The next lemma is a well-known result, but it plays a central role in all arguments involving the Galerkin method.

Lemma 2.9. *Let $\mathfrak{F} : \mathbb{R}^N \to \mathbb{R}^N$ be a continuous function such that $\langle \mathfrak{F}(x), x\rangle \ge 0$ for all $x \in \mathbb{R}^N$ with $\|x\|_{\mathbb{R}^N} = r$. Then there exists x_0 in the closed ball $B[0,r]$ such that $\mathfrak{F}(x_0) = 0$.*

Proof. See [11, Chap. 5, Theorem 5.2.5]. □

Now we will define an entity called *E-weak solution*. It is well known that the main focus of the Galerkin method is to obtain a weak solution, but we will utilize it to obtain an E-weak solution first.

Definition 2.10. A function $w \in H_0^1(-n,n)$ is called an *E-weak solution* of (P_n^k) if w is an *even function* satisfying

$$\int_{-n}^{n} A(w)w'\varphi' + \int_{-n}^{n} w\varphi = \int_{-n}^{n} \lambda a_1|w|^{q-1}\varphi + \int_{-n}^{n} |w|^{p-1}\varphi + \int_{-n}^{n} f_k(|w'|)\varphi + \int_{-n}^{n} \frac{\psi}{k}\varphi$$

for all $\varphi \in \mathbb{E}_0^1(-n,n) = \{u \in H_0^1(-n,n); u(t) = u(-t) \text{ a.e.}\}$.

The use of the E-weak solution will be central in our argumentation to obtain an *even* solution to the problem (P_n^k). This symmetry – being even – will also be beneficial in the use of our comparison principle, which is stated as follows:

Theorem 2.11 ([3, Theorem 3.1])**.** *Let $\sigma : (0,+\infty) \to \mathbb{R}$ be a continuous function such that the mapping $(0,+\infty) \ni s \mapsto \frac{\sigma(s)}{s}$ is strictly decreasing and $\rho > 0$. Suppose that there exist* even functions $v, w \in C^2(-\rho,\rho) \cap C[-\rho,\rho]$ *such that:*

1. $(A(w)w')' - w + \sigma(w) \le 0 \le (A(v)v') - v + \sigma(v)$ *in* $(-\rho,\rho)$*;*
2. $v, w \ge 0$ *in* $(-\rho,\rho)$ *and* $v(\rho) \le w(\rho)$*;*
3. $\{x \in (-\rho,\rho); v(x) = 0\}$ *and* $\{x \in (-\rho,\rho); w(x) = 0\}$ *have null measure in* $\mathbb{R}$*;*
4. $v' \cdot w' \ge 0$ *in* $(-\rho,\rho)$*;*
5. $v', w' \in L^\infty(-\rho,\rho)$.

Then $v \le w$ *in* $(-\rho,\rho)$.

Proof. The same as [3, p. 2419, Thm 3.1]. □

Turns out that, obtaining an E-weak solution enables us to recuperate a weak solution in the usual sense:

Definition 2.12. We will call $w \in H_0^1(-n,n)$ a *weak solution* of (P_n^k) if

$$\int_{-n}^{n} A(w)w'v' + \int_{-n}^{n} wv = \int_{-n}^{n} \lambda a_1|w|^{q-1}v + \int_{-n}^{n} |w|^{p-1}v + \int_{-n}^{n} f_k(|w'|)v + \int_{-n}^{n} \frac{\psi}{k}v$$

for all $v \in H_0^1(-n,n)$.

This is achieved by

Lemma 2.13 ([3, Lemma 4.1])**.** *Let $w \in H_0^1(-n,n)$ be an E-weak solution of (P_n^k). Then w is a weak solution of (P_n^k).*

Proof. See [3, p. 2421, Lemma 4.1]. □

The subset $\mathbb{E}_0^1(-n,n) \subset H_0^1(-n,n)$ can be understood as the set of radial symmetric functions in $\mathbb{R}$. One can prove without difficulties the following properties of $\mathbb{E}_0^1(-n,n)$:

i) it is a Hilbert space;

ii) it is separable;

iii) it has an orthonormal basis.

Let $\mathbb{E}_0^1(-n,n) = \{u \in H_0^1(-n,n); u(t) = u(-t) \text{ a.e.}\}$ and $(e_l)_{l=1}^{\infty}$ be an orthonormal basis of $\mathbb{E}_0^1(-n,n)$.

Define $V_M = \operatorname{span}\{e_1,\dots,e_M\}$; then for every $u \in V_M$ there exist $\xi_1,\dots,\xi_M$ in $\mathbb{R}$ such that $u = \sum_{i=1}^M \xi_i e_i$. By means of $T : V_M \to \mathbb{R}^M$, $T(u) = T(\sum_{i=1}^M \xi_i e_i) = (\xi_1,\dots,\xi_M)$, which is a linear isomorphism and preserve norm, we may define $\mathfrak{F} : \mathbb{R}^M \to \mathbb{R}^M$ such that

$$\mathfrak{F}(\xi) = (\mathfrak{F}_1(\xi),\dots,\mathfrak{F}_M(\xi)) \tag{2.2}$$

and

$$\mathfrak{F}_j(\xi) = \int_{-n}^{n} A(u)u'e_j' + \int_{-n}^{n} ue_j - \int_{-n}^{n} \lambda a_1|u|^{q-1}e_j - \int_{-n}^{n} |u|^{p-1}e_j - \int_{-n}^{n} f_k(|u'|)e_j - \int_{-n}^{n} \frac{\psi}{k}e_j,$$

where $j \in \{1,\dots,M\}$ and $u = T^{-1}(\xi)$, for all $\xi \in \mathbb{R}^M$.

Lemma 2.14. *The function $\mathfrak{F}$ is continuous.*

Remark 2.15. Our proof will use the fact that, if (x_n) is a sequence that converges to x and, for all subsequence (x_{n_l}) of (x_n), there exist a subsequence $(x_{n_{l_k}})$ of (x_{n_l}) such that $\mathfrak{F}(x_{n_{l_k}})$ converges to $\mathfrak{F}(x)$, then $\mathfrak{F}(x_n)$ converges to $\mathfrak{F}(x)$.

Proof. Given $\xi = (\xi_1,\dots,\xi_M) \in \mathbb{R}^M$, let $(\xi_l)_{l=1}^{\infty}$ be a sequence in $\mathbb{R}^M$ such that $\|\xi_l - \xi\|_{\mathbb{R}^M} \to 0$. By means of T we can identify $T^{-1}(\xi) = u = \sum_{i=1}^M e_i\xi_i$ and $T^{-1}(\xi_l) = u_l = \sum_{i=1}^M e_i\xi_i^l$. Since T is isometry we have that $\|u_l - u\|_{W^{1,2}} \to 0$. That is, $\|u_l - u\|_{L^2} \to 0$ and $\|u_l' - u'\|_{L^2} \to 0$. Taking a subsequence, if necessary, we may assume that

$$u_l(x) \to u(x) \quad \text{a.e. on } (-n,n),$$
$$u_l'(x) \to u'(x) \quad \text{a.e. on } (-n,n),$$

and $|u_l(x)| \le h_1(x)$, $|u_l'(x)| \le h_2(x)$ a.e. on $(-n,n)$, with $h_1,h_2 \in L^2(-n,n)$. Let $j \in \{1,2,\dots,M\}$, we will prove that $\mathfrak{F}_j(\xi_l) \to \mathfrak{F}_j(\xi)$.

$$\left|\int_{-n}^{n} A(u_l)u_l'e_j' - \int_{-n}^{n} A(u)u'e_j'\right| \le \int_{-n}^{n} \left(|u_l'||A(u_l) - A(u)| + |A(u)||u_l' - u'|\right)|e_j'|, \tag{2.3}$$

since $|u_l'(x)||A(u_l(x)) - A(u(x))||e_j'(x)| \to 0$ a.e. and $|A(u(x))||u_l'(x) - u'(x)||e_j'(x)| \to 0$ a.e., by the Dominated Convergence Theorem (D.C.T) the left side of (2.3) tends to zero as $l \to +\infty$.

$$\left|\int_{-n}^{n} u_le_j - \int_{-n}^{n} ue_j\right| \le \int_{-n}^{n} |u_l - u||e_j| \to 0 \quad \text{by (D.C.T).} \tag{2.4}$$

$$\begin{aligned}
&\left|\int_{-n}^{n} [\lambda a_1(|u_l|^{q-1} - |u|^{q-1}) + (|u_l|^{p-1} - |u|^{p-1}) + (f_k(u_l') - f_k(u'))]e_j\right| \\
&\quad\le \int_{-n}^{n} \lambda|a_1|\left||u_l|^{q-1} - |u|^{q-1}\right||e_j| + \int_{-n}^{n} \left||u_l|^{p-1} - |u|^{p-1}\right||e_j| \\
&\qquad + \int_{-n}^{n} \left|f_k(|u_l'|) - f_k(|u'|)\right||e_j|,
\end{aligned} \tag{2.5}$$

since that $|u_l|^{q-1} \to |u|^{q-1}$ a.e. and $|u_l|^{p-1} \to |u|^{p-1}$ a.e., (D.C.T) implies that the first two integrals above converge to zero. Using the second item of Theorem 2.2, we have

$$\int_{-n}^{n} \left|f_k(|u_l'|) - f_k(|u'|)\right||e_j| \le \int_{-n}^{n} c(k)|u_l' - u'||e_j|. \tag{2.6}$$

Then, by (D.C.T), (2.6) converges to 0 as $l \to +\infty$.

These estimations show us that for every subsequence (ξ_{l_k}) of (ξ_l), there exists a subsequence $(\xi_{l_{k_n}})$ of (ξ_{l_k}) that $\mathfrak{F}_j(\xi_{l_{k_n}}) \to \mathfrak{F}_j(\xi)$. Therefore $\mathfrak{F}_j(\xi_l) \to \mathfrak{F}_j(\xi)$. □

Proposition 2.16. *There exist $\lambda^* > 0$ and $k^* \in \mathbb{N}$ for which the problem (P_n^k) admits a nontrivial weak solution for every $\lambda \in (0, \lambda^*)$ and $k \geq k^*$.*

Remark 2.17. We will, in fact, search for an E-weak solution; but as seen in Lemma 2.13 this will also be a weak solution.

Proof. Our aim is to use Lemma 2.9, with the function $\mathfrak{F}$ defined in (2.2). Given $\xi \in \mathbb{R}^M$, we have that

$$\langle \mathfrak{F}(\xi), \xi \rangle = \int_{-n}^{n} A(u)|u'|^2 + \int_{-n}^{n} |u|^2 - \int_{-n}^{n} \lambda a_1 |u|^{q-1} u - \int_{-n}^{n} |u|^{p-1} u - \int_{-n}^{n} f_k(|u'|) u - \int_{-n}^{n} \frac{\psi}{k} u. \quad (2.7)$$

In the following, we will estimate the above integrals. We have that

$$\int_{-n}^{n} \lambda a_1 |u|^{q-1} u \leq \lambda \|a_1\|_{L^s(\mathbb{R})} \|u\|_{L^2}^q \leq \lambda C_2 \|u\|_{W^{1,2}}^q, \quad (2.8)$$

$$\int_{-n}^{n} \frac{\psi}{k} u \leq \frac{\|\psi\|_{L^2(-n,n)} \|u\|_{W^{1,2}}}{k}. \quad (2.9)$$

Now let $\tilde{u} : \mathbb{R} \to \mathbb{R}$ be the extension by zero of u, then

$$\int_{-n}^{n} |u|^{p-1} u \leq \int_{-n}^{n} |u|^p = \int_{-n}^{n} |u|^2 |u|^{p-2} \quad (2.10)$$

$$\leq \|\tilde{u}\|_{L^\infty(\mathbb{R})}^{p-2} \int_{-n}^{n} |u|^2 \quad (2.11)$$

$$= \|\tilde{u}\|_{L^\infty(\mathbb{R})}^{p-2} \|u\|_{L^2}^2 \quad (2.12)$$

$$\leq C^{p-2} \|u\|_{W^{1,2}}^{p-2} \|u\|_{W^{1,2}}^2 = C^{p-2} \|u\|_{W^{1,2}}^p. \quad (2.13)$$

Where C is the constant for the embedding $W^{1,2}(\mathbb{R}) \hookrightarrow L^\infty(\mathbb{R})$.

Define

$$\Omega_{\geq} = \left\{ s \in (-n, n) : |u'(s)| \geq \frac{1}{k} \right\} \quad \text{and} \quad \Omega_{\leq} = \left\{ s \in (-n, n) : 0 < |u'(s)| \leq \frac{1}{k} \right\}.$$

Then

$$\int_{-n}^{n} f_k(|u'|) u = \int_{\Omega_{\geq}} f_k(|u'|) u + \int_{\Omega_{\leq}} f_k(|u'|) u.$$

Notice that by Lemma 2.4,

$$\int_{\Omega_{\leq}} f_k(|u'|) u \leq \int_{\Omega_{\leq}} C_1 |u'||u| \leq \int_{\Omega_{\leq}} \frac{C_1}{k} |u|$$
$$\leq \frac{C_1}{k} \int_{-n}^{n} |u| \leq \frac{C_1 (2n)^{1/2}}{k} \|u\|_{L^2}$$
$$\leq \frac{C_1 (2n)^{1/2}}{k} \|u\|_{W^{1,2}}.$$

To estimate the integral over $\Omega_{\geq}$, consider the following cases :

Case 1. $2 < \theta < 3$.

Using Lemma 2.4, we have

$$\begin{aligned}\int_{\Omega_\geq} f_k(|u'|)u &\leq \int_{\Omega_\geq} C_1|u'|^{\theta-1}|u| \leq \int_{-n}^{n} C_1|u'|^{\theta-1}|u|\\ &\leq C_1\left(\int_{-n}^{n}|u|^w\right)^{\frac{1}{w}}\left(\int_{-n}^{n}|u'|^2\right)^{\frac{\theta-1}{2}}\\ &\leq C_1\left(\int_{\mathbb{R}}|\tilde{u}|^2|\tilde{u}|^{w-2}\right)^{\frac{1}{w}}\|u'\|_{L^2}^{\theta-1}\\ &\leq C_1\|\tilde{u}\|_{L^\infty(\mathbb{R})}^{\frac{w-2}{w}}\|u\|_{L^2}^{\frac{2}{w}}\|u'\|_{L^2}^{\theta-1}\\ &\leq C_1 C^{\frac{w-2}{w}}\|u\|_{W^{1,2}}^{\frac{w-2}{w}}\|u\|_{W^{1,2}}^{\frac{2}{w}}\|u\|_{W^{1,2}}^{\theta-1} = C_1 C^{\frac{w-2}{w}}\|u\|_{W^{1,2}}^{\theta}.\end{aligned}$$

Where $w = \left(\frac{2}{\theta-1}\right)' = \frac{2}{3-\theta} > 2$.

Case 2. $\theta = 3$.

$$\begin{aligned}\int_{\Omega_\geq} f_k(|u'|)u &\leq \int_{\Omega_\geq} C_1|u'|^{2}|u| \leq \int_{-n}^{n} C_1|u'|^{2}|u|\\ &\leq C_1\|\tilde{u}\|_{L^\infty(\mathbb{R})}\|u'\|_{L^2}^2 \leq C_1 C\|u\|_{W^{1,2}}\|u\|_{W^{1,2}}^2\\ &= C_1 C\|u\|_{W^{1,2}}^3.\end{aligned}$$

Now we are able to estimate (2.7). Notice that $\frac{w-2}{w} = \theta - 2$.

$$\begin{aligned}\langle\mathfrak{F}(\xi),\xi\rangle \geq{}& \gamma\|u\|_{W^{1,2}}^2 - \lambda C_2\|u\|_{W^{1,2}}^q - C^{p-2}\|u\|_{W^{1,2}}^p\\ &- C_1\max\{C^{\theta-2},C\}\|u\|_{W^{1,2}}^\theta - \left(\frac{C_1(2n)^{1/2}}{k} + \frac{\|\psi\|_{L^2(-n,n)}}{k}\right)\|u\|_{W^{1,2}}.\end{aligned}$$

Define $Z_k : \mathbb{R}^+ \to \mathbb{R}$ by

$$Z_k(x) = \gamma x^2 - \lambda C_2 x^q - C^{p-2}x^p - C_1\max\{C^{\theta-2},C\}x^\theta - \left(\frac{C_1(2n)^{1/2}}{k} + \frac{\|\psi\|_{L^2(-n,n)}}{k}\right)x.$$

We would like to find $r > 0$ such that

$$\gamma r^2 - C^{p-2}r^p - C_1\max\{C^{\theta-2},C\}r^\theta > \frac{r^2}{2}\gamma \tag{2.14}$$

or equivalently,

$$\frac{\gamma}{2} > C^{p-2}r^{p-2} + C_1\max\{C^{\theta-2},C\}r^{\theta-2}.$$

For this, if we take

$$\delta_1 = \min\left\{\left(\frac{\gamma}{4C^{p-2}}\right)^{1/(p-2)}, \left(\frac{\gamma}{4C_1\max\{C^{\theta-2},C\}}\right)^{1/(\theta-2)}\right\},$$

then for $0 < r < \delta_1$ (2.14) is true. Consequently,

$$Z_k(r) \geq \frac{r^2}{2}\gamma - \lambda C_2\delta_1^q - \left(\frac{C_1(2n)^{1/2}}{k} + \frac{\|\psi\|_{L^2(-n,n)}}{k}\right)\delta_1.$$

Define $\rho_1 = \frac{r^2}{2}\gamma - \lambda C_2 \delta_1^q$. We will adjust $\lambda > 0$ so that $\rho_1 > 0$; for this if $\rho_1 > 0$ it would imply that

$$\frac{r^2}{2}\gamma - \lambda C_2 \delta_1^q > 0 \Leftrightarrow \frac{r^2\gamma}{2C_2\delta_1^q} > \lambda.$$

Take $\lambda^* = \frac{r^2\gamma}{2C_2\delta_1^q}$ and $0 < \lambda < \lambda^*$. Thus, $\rho_1 > 0$ and we can find $k^* \in \mathbb{N}$ such that for $k > k^*$, $\rho_1 > \left(\frac{C_1(2n)^{1/2}}{k} + \frac{\|\psi\|_{L^2(-n,n)}}{k}\right)\delta_1 > 0$. Therefore, for $0 < r < \delta_1$, $0 < \lambda < \lambda^*$ and $k > k^*$

$$Z_k(r) > 0,$$

and so, with $\|u\|_{W^{1,2}} = r$,

$$\langle \mathfrak{F}(\xi), \xi \rangle > 0. \tag{2.15}$$

By Lemma 2.9, there exists $y_M \in B[0,r]$ such that $\mathfrak{F}(y_M) = 0$ that is, identifying $v_M = T^{-1}(y_M)$, for all $j \in \{1, \ldots, M\}$

$$\begin{aligned}\int_{-n}^{n} A(v_M)v_M' e_j' + \int_{-n}^{n} v_M e_j \\ = \int_{-n}^{n} \lambda a_1 |v_M|^{q-1} e_j + \int_{-n}^{n} |v_M|^{p-1} e_j + \int_{-n}^{n} f_k(|v_M'|) e_j + \int_{-n}^{n} \frac{\psi}{k} e_j.\end{aligned} \tag{2.16}$$

Therefore (2.16) holds for all $\varphi \in V_M$, because $\{e_1, \ldots, e_M\}$ is a basis of V_M. Notice that

$$\|v_M\|_{W^{1,2}} \le r \quad \text{for all } M \in \mathbb{N}. \tag{2.17}$$

Remark 2.18. Our choice of r does not depend on M,n, λ or k. This free determination of r will be useful further down in the argumentation, because using the embedding $W^{1,2}(\mathbb{R}) \hookrightarrow L^\infty(\mathbb{R})$ we will be able to obtain a uniform upper bound, in the norm of $L^\infty(\mathbb{R})$, for the sequence of solutions of the problem (P_n^k). Then this upper bound will naturally be transferred to also bound the sequence of solution of (P_n).

Since $\|v_M\|_{W^{1,2}} \le r$ there is $v_0 \in \mathbb{E}_0^1(-n,n)$ such that $v_M \rightharpoonup v_0$ in $H_0^1(-n,n)$. By the compact embedding $W^{1,2}(-n,n) \hookrightarrow L^2(-n,n)$ we conclude $v_M \to v_0$ in $L^2(-n,n)$. Our goal is to show that v_0 is a weak solution of (P_n^k). Let $\Gamma_M : V_M \to V_M^*$ and $B_M : V_M \to V_M^*$ be defined by

$$\langle \Gamma_M(v), \varphi \rangle = \int_{-n}^{n} A(v)v'\varphi' \tag{2.18}$$

and

$$\langle B_M(v), \varphi \rangle = \int_{-n}^{n} \left(-v + \lambda a_1 |v|^{q-1} + |v|^{p-1} + f_k(|v'|) + \frac{\psi}{k} \right) \varphi. \tag{2.19}$$

Hence, $\langle \Gamma_M(v_M) - B_M(v_M), \varphi \rangle = 0$ for all $\varphi \in V_M$.

Denoting $P_M : \mathbb{E}_0^1(-n,n) \to V_M$ the projection of $\mathbb{E}_0^1(-n,n)$ onto V_M, (that is, if $u = \sum_{i=1}^{\infty} \alpha_i e_i$ then $P_M(u) = \sum_{i=1}^{M} \alpha_i e_i$) we have

$$\langle \Gamma_M(v_M) - B_M(v_M), v_M - P_M v_0 \rangle = 0,$$

so

$$\begin{aligned}\langle \Gamma_M(v_M), v_M - P_M v_0 \rangle &= \langle B_M(v_M), v_M - P_M v_0 \rangle \\ &= \int_{-n}^{n} \left(-v_M + \lambda a_1 |v_M|^{q-1} + |v_M|^{p-1} + f_k(|v_M'|) + \frac{\psi}{k} \right) (v_M - P_M v_0).\end{aligned} \tag{2.20}$$

Letting $M \to \infty$ one can see without difficulties that $\langle \Gamma_M(v_M), v_M - P_M v_0 \rangle \to 0$. This convergence allows us to prove the following

Lemma 2.19. *$v_M \to v_0$ strongly, i.e. in the norm of $H^1_0(-n,n)$.*

Remark 2.20. The idea to consider the operators Γ_M and B_M was an inspiration from the arguments presented in [7].

Proof. The limit $\|v_M - v_0\|_{L^2(-n,n)} \to 0$ has been established before, thus we will focus our efforts demonstrating the same for $\|v'_M - v'_0\|_{L^2(-n,n)}$. Let $\Phi_M, \Phi, \Psi_M, \zeta_M \in (\mathbb{E}^1_0(-n,n))^*$ be given by

$$\Phi_M(w) = \int_{-n}^{n} A(v_M) v'_0 w' \tag{2.21}$$

$$\Phi(w) = \int_{-n}^{n} A(v_0) v'_0 w' \tag{2.22}$$

$$\Psi_M(w) = \int_{-n}^{n} A(v_M) P_M v'_0 w' \tag{2.23}$$

$$\zeta_M(w) = \int_{-n}^{n} A(v_0) P_M v'_0 w'. \tag{2.24}$$

Then, by a straightforward calculation, $|\Phi_M - \Phi| \to 0$,$|\Psi_M - \Phi_M| \to 0$ and $|\zeta_M - \Phi| \to 0$ in $(\mathbb{E}^1_0(-n,n))^*$. Thus, $|\Psi_M - \zeta_M| \to 0$ in $(\mathbb{E}^1_0(-n,n))^*$, since $|\Psi_M - \zeta_M| \le |\Psi_M - \Phi_M| + |\Phi_M - \Phi| + |\Phi - \zeta_M|$. Writing $\Psi_M = (\Psi_M - \zeta_M) + \zeta_M$ yields that $\Psi_M \to \Phi$ in $(\mathbb{E}^1_0(-n,n))^*$. Remembering the weak convergence $v_M \rightharpoonup v_0$ one can conclude $(v_M - P_M v_0) \rightharpoonup 0$ in $\mathbb{E}^1_0(-n,n)$ because for all $f \in (\mathbb{E}^1_0(-n,n))^*$

$$|f(v_M) - f(P_M v_0)| \le |f(v_M) - f(v_0)| + \|f\| \|v_0 - P_M v_0\|_{W^{1,2}}.$$

Consequently, letting $M \to \infty$, $\Psi_M(v_M - P_M v_0) \to \Phi(0) = 0$. This means that

$$\int_{-n}^{n} A(v_M) P_M v'_0 (v'_M - P_M v'_0) \to 0. \tag{2.25}$$

Also, rewriting (2.20)

$$\int_{-n}^{n} A(v_M) v'_M (v'_M - P_M v'_0) \to 0 \quad \text{as } M \to \infty. \tag{2.26}$$

Therefore, from (2.26)–(2.25)

$$\int_{-n}^{n} A(v_M) (v'_M - P_M v'_0)^2 \to 0 \quad \text{as } M \to \infty. \tag{2.27}$$

Since $A(x) \ge \gamma > 0$ for all $x \in \mathbb{R}$ we conclude $\|v'_M - P_M v'_0\|_{L^2(-n,n)} \to 0$ as $M \to \infty$. Then $\|v'_M - v'_0\|_{L^2(-n,n)} \to 0$ as result of $\|v'_M - v'_0\|_{L^2(-n,n)} \le \|v'_M - P_M v'_0\|_{L^2(-n,n)} + \|v'_0 - P_M v'_0\|_{L^2(-n,n)}$, proving the lemma. □

We know that for every $\varphi \in V_M$

$$\int_{-n}^{n} A(v_M) v'_M \varphi' + \int_{-n}^{n} v_M \varphi = \int_{-n}^{n} \lambda a_1 |v_M|^{q-1} \varphi + \int_{-n}^{n} |v_M|^{p-1} \varphi + \int_{-n}^{n} f_k(|v'_M|) \varphi + \int_{-n}^{n} \frac{\psi}{k} \varphi. \tag{2.28}$$

By the previous lemma, taking a subsequence if necessary, we may assume that $v_M'(x)$ converges a.e. to $v_0'(x)$ and there exists $h \in L^2(-n,n)$ such that $|v_M'(x)| \le h(x)$ a.e. Then notice that

$$\left| \int_{-n}^{n} \left(A(v_M)v_M' - A(v_0)v_0'\right) \varphi' \right| \le \left(\int_{-n}^{n} |A(v_M)v_M' - A(v_0)v_0'|^2 \right)^{1/2} \|\varphi'\|_{L^2} \tag{2.29}$$

and exists $Q > 0$ such that $\|v_M\|_\infty < Q$ for all $M \in \mathbb{N}$, because v_M converges to v_0 in $C^0[-n,n]$ due to the embedding $W^{1,2}(-n,n) \hookrightarrow C^0[-n,n]$. We can suppose Q big enough so that $Q > 2\,(r + A(0))$ and we take $\tilde{A} = \sup_{x\in[-Q,Q]} A(x)$. Since

$$|A(v_M(x))v_M'(x) - A(v_0(x))v_0'(x)| \to 0 \quad \text{a.e.} \tag{2.30}$$

and

$$\begin{aligned} |A(v_M(x))v_M'(x) - A(v_0(x))v_0'(x)|^2 &\le \left(|A(v_M(x))v_M'(x)| + |A(v_0(x))v_0'(x)|\right)^2 \\ &= |A(v_M(x))|^2 |v_M'(x)|^2 \\ &\quad + 2|A(v_M(x))||A(v_0(x))||v_M'(x)||v_0'(x)| \\ &\quad + |A(v_0(x))|^2 |v_0'(x)|^2 \\ &\le \tilde{A}^2 Q^2 h^2(x) + 2\tilde{A}^2 Q^2 |v_0'(x)| h(x) \\ &\quad + \tilde{A}^2 Q^2 |v_0'(x)|^2 \end{aligned}$$

almost everywhere, we conclude by (D.C.T) that

$$\int_{-n}^{n} A(v_M)v_M'\varphi' \to \int_{-n}^{n} A(v_0)v_0'\varphi' \quad \text{as } M \to \infty. \tag{2.31}$$

Also, by direct calculation, the following convergences are true

$$\int_{-n}^{n} v_M\varphi \to \int_{-n}^{n} v_0\varphi \tag{2.32}$$

$$\int_{-n}^{n} \lambda a_1 |v_M|^{q-1}\varphi \to \int_{-n}^{n} \lambda a_1 |v_0|^{q-1}\varphi \tag{2.33}$$

$$\int_{-n}^{n} |v_M|^{p-1}\varphi \to \int_{-n}^{n} |v_0|^{p-1}\varphi \tag{2.34}$$

$$\int_{-n}^{n} f_k(|v_M'|)\varphi \to \int_{-n}^{n} f_k(|v_0'|)\varphi \tag{2.35}$$

as $M \to \infty$. Thus, for every $\varphi \in V_M$

$$\int_{-n}^{n} A(v_0)v_0'\varphi' + \int_{-n}^{n} v_0\varphi = \int_{-n}^{n} \lambda a_1 |v_0|^{q-1}\varphi + \int_{-n}^{n} |v_0|^{p-1}\varphi + \int_{-n}^{n} f_k(|v_0'|)\varphi + \int_{-n}^{n} \frac{\psi}{k}\varphi. \tag{2.36}$$

Furthermore, for every $u \in \mathbb{E}_0^1(-n,n)$, it follows that

$$\int_{-n}^{n} A(v_0)v_0' P_M u' \to \int_{-n}^{n} A(v_0)v_0' u' \tag{2.37}$$

$$\int_{-n}^{n} v_0 P_M u \to \int_{-n}^{n} v_0 u \tag{2.38}$$

$$\int_{-n}^{n} \lambda a_1 |v_0|^{q-1} P_M u \to \int_{-n}^{n} \lambda a_1 |v_0|^{q-1} u \tag{2.39}$$

$$\int_{-n}^{n} |v_0|^{p-1} P_M u \to \int_{-n}^{n} |v_0|^{p-1} u \tag{2.40}$$

$$\int_{-n}^{n} f_k(|v_0'|) P_M u \to \int_{-n}^{n} f_k(|v_0'|) u \tag{2.41}$$

as $M \to \infty$. Thus, for every $u \in \mathbb{E}_0^1(-n,n)$

$$\int_{-n}^{n} A(v_0)v_0'u' + \int_{-n}^{n} v_0 u = \int_{-n}^{n} \lambda a_1 |v_0|^{q-1} u + \int_{-n}^{n} |v_0|^{p-1} u + \int_{-n}^{n} f_k(|v_0'|) u + \int_{-n}^{n} \frac{\psi}{k} u. \quad (2.42)$$

So v_0 is an *E-weak solution* of (P_n^k); by Lemma 2.13 v_0 is also a weak solution. Notice that

$$\|v_0\|_{W^{1,2}} \le r,$$

and our choice of r does not depend on n, λ or k. This finishes the proof of Proposition 2.16. □

In what follows we will make $k \to \infty$ thus we can consider $\psi \equiv 1$, because the term $\frac{\psi}{k}$ will converge to 0 as $k \to \infty$.

Proposition 2.21. *The above weak solution v_0 satisfies:*

1. *there exist $\beta(L/\gamma)$ and $\hat{C}(L/\gamma, n)$, such that $v_0 \in C^{1,\beta}[-n,n] \cap C^2(-n,n)$ and*

$$|v_0|_{1+\beta} \le \hat{C},$$

where

$$L > 2\max\{Cr + \lambda a_1(n)|Cr|^{q-1} + |Cr|^{p-1} + 1, 2C_1, A(Cr), \tilde{A}\};$$

2. $v_0(t) \ge 0$.

Proof. To prove *1*, we will use [12, Theorem 1]. Let $F : [-n,n] \times [-Cr, Cr] \times \mathbb{R} \to \mathbb{R}$ be defined by $F(x,z,p) = A(z)p$, where C is the embedding constant for $W^{1,2}(\mathbb{R}) \hookrightarrow L^\infty(\mathbb{R})$, and $B(x,z,p) = z - (\lambda a_1(x)|z|^{q-1} + |z|^{p-1} + f_k(|p|) + \frac{1}{k})$ be defined in the same domain. Then, problem (P_n^k) may be rewritten as

$$\operatorname{div}_x F(x, u(x), u'(x)) + B(x, u(x), u'(x)) = 0.$$

In order to use [12, Theorem 1] we must verify the existence of nonnegative constants l, L, M_0, m, κ with $l \le L$ such that

$$\frac{\partial F}{\partial p}(x,z,p)\xi^2 \ge l(\kappa + |p|)^m \xi^2, \quad (2.43)$$

$$\left|\frac{\partial F}{\partial p}(x,z,p)\right| \le L(\kappa + |p|)^m, \quad (2.44)$$

$$|F(x,z,p) - F(y,w,p)| \le L(1+|p|)^{m+1} \cdot |z-w|, \quad (2.45)$$

$$|B(x,z,p)| \le L(1+|p|)^{m+2}, \quad (2.46)$$

for all $(x,z,p) \in \{-n,n\} \times [-M_0, M_0] \times \mathbb{R}$, $w \in [-M_0, M_0]$ and $\xi \in \mathbb{R}$. Since $\frac{\partial F}{\partial p}(x,z,p) = A(z)$, inequality (2.43) follows from $A(z)\xi^2 \ge \gamma\xi^2$, that is, $l = \gamma$.

To prove the remaining inequalities take $M_0 = Cr$,

$$T > \max\{Cr + \lambda a_1(n)|Cr|^{q-1} + |Cr|^{p-1} + 1, 2C_1, A(Cr), \tilde{A}\},$$

$L = 2T, \kappa = 0$ and $m = 0$, where $\tilde{A}$ is the Lipchitz constant of A. Then:

(2.44)

$$\left|\frac{\partial F}{\partial p}(x,z,p)\right| = A(z) \leq A(Cr) < L;$$

(2.45)

$$|F(x,z,p) - F(y,w,p)| = |A(z)p - A(w)p| \leq \tilde{A}|p||z-w| \leq L(1+|p|)|z-w|;$$

(2.46)

$$\begin{aligned} |B(x,z,p)| &= \left| z - \left(\lambda a_1(x)|z|^{q-1} + |z|^{p-1} + f_k(|p|) + \frac{1}{k} \right) \right| \\ &\leq Cr + \lambda a_1(n)|Cr|^{q-1} \\ &\quad + |Cr|^{p-1} + 1/k + C_1(1+|p|^{\theta-1}) \\ &\leq T + C_1(1+(1+|p|)^{\theta-1}) \\ &\leq T + 2C_1(1+|p|)^2 \\ &\leq T(1+(1+|p|)^2) \\ &\leq 2T(1+|p|)^2 = L(1+|p|)^2. \end{aligned} \tag{2.47}$$

Therefore, by [12, Theorem 1] there exists $\beta \in (0,1)$ and a constant $\hat{C}$, independent of k, such that $v_0 \in C^{1,\beta}([-n,n])$ and

$$|v_0|_{1+\beta} \leq \hat{C}. \tag{2.48}$$

It follows from [6, p. 317, Chap. 6, Theorem 4] that $v_0 \in W^{2,2}(-n,n)$ and since v_0 is a weak solution of (P_n^k) we have

$$v_0'' = \frac{v_0 - \lambda a_1|v_0|^{q-1} - |v_0|^{p-1} - f_k(|v_0'|) - 1/k - A'(v_0)|v_0'|^2}{A(v_0)} \tag{2.49}$$

showing that v_0'' is continuous, thus $v_0 \in C^2(-n,n)$.

To prove that $v_0(t) \geq 0$ for all $t \in (-n,n)$ we first notice that $v_0^-(t) = \max\{0, -v_0(t)\} \in H_0^1(-n,n)$. Using $v_0^-(t)$ as a test function in the definition of weak solution provides

$$-\int_{-n}^{n} A(v_0)|v_0^-|^2 - \int_{-n}^{n} |v_0^-|^2 = \int_{-n}^{n} \lambda a_1|v_0|^{q-1}v_0^- + \int_{-n}^{n} |v_0|^{p-1}v_0^- + \int_{-n}^{n} f_k(|v_0'|)v_0^- + \int_{-n}^{n} \frac{1}{k}v_0^-. \tag{2.50}$$

Then $-\gamma\|v_0^-\|_{W^{1,2}}^2 \geq 0$, thus $\|v_0^-\|_{W^{1,2}} = 0$ implying $v_0^- \equiv 0$ a.e. Since v_0 is continuous, $v_0(t) \geq 0$ for all $t \in (-n,n)$. This finishes the proof of Proposition 2.21. □

Thus, by Proposition 2.16 and Proposition 2.21 we obtain the proof of Theorem 2.8.

2.2 Constructing a solution to problem (P_n)

Let v_k be the (strong) solution of problem (P_n^k), obtained just above, with k varying. By the previous constructions, we have that $\|v_k\|_{W^{1,2}(-n,n)} \leq r$ independent of k, as noticed in Remark 2.18. Then there exists $u_n \in H_0^1(-n,n)$, $\|u_n\|_{W^{1,2}(-n,n)} \leq r$, so that v_k has a subsequence converging weakly in $H_0^1(-n,n)$ to u_n. From now on v_k will denote this subsequence. Since the function

$$H_0^1(-n,n) \ni w \mapsto \int_{-n}^{n} A(u_n)u_n' w'$$

belongs to $(H_0^1(-n,n))^*$, we have, by the weak convergence, that

$$\int_{-n}^{n} A(u_n)u_n'(v_k-u_n)' \to 0 \quad \text{as } k\to\infty.$$

This convergence will be useful in our next task: to prove that $v_k \to u_n$ strongly in $H_0^1(-n,n)$.

Lemma 2.22. *The following convergence is true*

$$\int_{-n}^{n} A(u_n)v_k'(v_k-u_n)' \to 0 \quad \text{as } k\to\infty.$$

Proof. We might write

$$\begin{aligned}\int_{-n}^{n} A(u_n)v_k'(v_k-u_n)' &= \int_{-n}^{n}[A(u_n)-A(v_k)+A(v_k)]v_k'(v_k'-u_n')\\ &= \underbrace{\int_{-n}^{n}[A(u_n)-A(v_k)]v_k'(v_k'-u_n')}_{I_1} + \underbrace{\int_{-n}^{n} A(v_k)v_k'(v_k'-u_n')}_{I_2}\end{aligned}$$

and analyze I_1 and I_2 separately.

Analysis of I_2 By the weak formulation of (P_n^k)

$$\begin{aligned}&\int_{-n}^{n} A(v_k)v_k'(v_k'-u_n')\\ &\quad=\underbrace{\int_{-n}^{n} -v_k(v_k-u_n)+\lambda a_1|v_k|^{q-1}(v_k-u_n)+|v_k|^{p-1}(v_k-u_n)+\frac{(v_k-u_n)}{k}}_{E_1}\\ &\quad\underbrace{+\int_{-n}^{n} f_k(|v_k'|)(v_k-u_n)}_{E_2}.\end{aligned}$$

Since we have compact injection of $H_0^1(-n,n)$ onto $L^2(-n,n)$, the weak convergence of v_k to u_n in $H_0^1(-n,n)$ implies $\|v_k-u_n\|_{L^2}\to 0$. Thus, it is straightforward to see that (E_1) converges to 0 as $k\to\infty$. Remains to verify what happens with (E_2) in the limit. We have that

$$\int_{-n}^{n} f_k(|v_k'|)(v_k-u_n) \le \int_{-n}^{n} C_1(|v_k'|^{\theta-1}+|v_k'|)|v_k-u_n|$$

by Lemma 2.4. Using Proposition 2.21, item *1*, that is, the estimation $|v_k|_{1,\beta}\le \hat{C}$ which is independent of k, we have that

$$|v_k'|^{\theta-1}+|v_k'| \le (\hat{C})^{\theta-1}+\hat{C}.$$

Then,

$$\begin{aligned}\int_{-n}^{n} f_k(|v_k'|)(v_k-u_n) &\le C_1[(\hat{C})^{\theta-1}+\hat{C}]\int_{-n}^{n}|v_k-u_n|\\ &\le \underbrace{(2n)^{1/2}C_1[(\hat{C})^{\theta-1}+\hat{C}]\|v_k-u_n\|_{L^2}}_{\to 0 \text{ as } k\to\infty}.\end{aligned}$$

Thus, $\lim_{k\to\infty} I_2(k)=0$.

Analysis of I_1 We also have that $\lim_{k\to\infty} I_1(k) = 0$, as one can see through

$$\begin{aligned}\left|\int_{-n}^{n}[A(u_n)-A(v_k)]v_k'(v_k'-u_n')\right| &\le \int_{-n}^{n}|A(u_n)-A(v_k)||v_k'||v_k'-u_n'| \\ &\le \hat{C}\int_{-n}^{n}|A(u_n)-A(v_k)||v_k'-u_n'| \\ &\le \hat{C}\tilde{A}\int_{-n}^{n}|u_n-v_k||v_k'-u_n'| \\ &\le \hat{C}\tilde{A}\|u_n-v_k\|_{L^2}\|v_k'-u_n'\|_{L^2} \\ &\le \hat{C}\tilde{A}2r\|u_n-v_k\|_{L^2}.\end{aligned}$$

Thus,

$$\int_{-n}^{n} A(u_n)u_n'(v_k-u_n)' \to 0 \quad \text{as } k\to\infty \tag{2.51}$$

$$\int_{-n}^{n} A(u_n)v_k'(v_k-u_n)' \to 0 \quad \text{as } k\to\infty. \tag{2.52}$$

Subtracting (2.52) from (2.51) we have

$$\int_{-n}^{n} A(u_n)(v_k'-u_n')^2 \to 0 \quad \text{as } k\to\infty \tag{2.53}$$

implying that $v_k' \to u_n'$ in $L^2(-n,n)$, since γ is a uniform lower-bound for A. Hence $v_k \to u_n$ in $H_0^1(-n,n)$. □

Remark 2.23. Since $v_k \to u_n$ in $H_0^1(-n,n)$ we conclude that u_n is also an even function; due to the embedding $W^{1,2}(-n,n) \hookrightarrow C[-n,n]$.

Proposition 2.24. *The function u_n satisfies:*

1. *u_n is strictly positive in $(-n,n)$;*
2. *u_n is a solution to (P_n).*

Proof.

Item 1. Let $\tilde{a} := \inf_{x\in[-n,n]} a_1(x)$. We will divide our argument into two cases:

Remark 2.25. This division of cases is a geometric argument that we borrowed from [3].

Case 1. There exists a subsequence $(v_{k_i})_{i\in\mathbb{N}}$ of (v_k) such that $v_{k_i}' \ge 0$ in $(-n,0)$ for all i. Consider the problem

$$\begin{cases} -(A(u)u')' + u = \lambda\tilde{a}|u|^{q-1} & \text{in } (-n,n) \\ u > 0 & \text{in } (-n,n) \\ u(-n) = u(n) = 0. \end{cases} \tag{2.54}$$

Since $v_{k_i}' \ge 0$ in $(-n,0)$ we get that $v_{k_i} > 0$ in $(-n,0)$, because, due to Proposition 2.21, v_{k_i} is an even solution of (P_n^k), thus *it can not be identically zero in an interval* and $v_{k_i} \ge 0$; i.e., supposing the existence of $x_i \in (-n,0)$ such that $v_{k_i}(x_i) = 0$ implies the existence of $y_i \in (-n,0)$ such that $v'_{k_i}(y_i) < 0$, which would be a contradiction. Thus, we see that v_{k_i} is a sup-solution for equation (2.54). Let ϕ_1 be an even and positive eigenfunction for the eigenvalue problem

$$\begin{cases} -u'' = \lambda_1 u & \text{in } (-n,n) \\ u(-n) = u(n) = 0 \end{cases} \tag{2.55}$$

where $\lambda_1 = \frac{\pi^2}{(2n)^2}$. Thus, choosing τ such that

$$\frac{\tau^{2-q}(1+\gamma\lambda_1)}{\lambda\tilde{a}} \leq \phi_1^{q-2}$$

we have that $\tau\phi_1$ is as sub-solution of (2.54). By Theorem 2.11

$$v_{k_i}(t) \geq \tau\phi_1(t) \qquad \forall t \in (-n,n),$$

therefore, in the limit,

$$u_n(t) \geq \tau\phi_1(t) > 0 \qquad \forall t \in (-n,n).$$

Case 2. There exists a subsequence $(v_{k_i})_{i\in\mathbb{N}}$ of (v_k) and there exists a sequence $(z_i)_{i\in\mathbb{N}} \subset (-n,0)$ such that $v'_{k_i}(z_i) < 0$.

Remark 2.26. Although the geometric argument is an inspiration from [3], we still need to adjust it to our necessity. Lemma 2.27 is one such adjustment.

Lemma 2.27. *Let $x \in (-n,n)$ such that $v''_{k_i}(x) \geq 0$, then $v_{k_i}(x) > (\lambda\tilde{a})^{\frac{1}{2-q}}$.*

Proof. Since v_{k_i} is a solution for the problem (P_n^k), with $k = k_i$, for all t

$$\begin{aligned} &- A'(v_{k_i}(t))|v'_{k_i}(t)|^2 - A(v_{k_i}(t))v''_{k_i}(t) + v_{k_i}(t) \\ &\quad = \lambda a_1(t)|v_{k_i}(t)|^{q-1} + |v_{k_i}(t)|^{p-1} + f_{k_i}(|v'_{k_i}(t)|) + \frac{1}{k_i} \\ &\quad \geq \lambda a_1(t)|v_{k_i}(t)|^{q-1} + |v_{k_i}(t)|^{p-1} + \frac{1}{k_i}. \end{aligned}$$

Here we used that $\operatorname{sign}(f_{k_i}(s)) = \operatorname{sign}(s)$, thus $f_{k_i}(|v'_{k_i}|) \geq 0$. Using that $|v_{k_i}|^{p-1} \geq 0$ and $a_1(t) \geq \tilde{a} > 0$ we obtain:

$$-A'(v_{k_i}(t))|v'_{k_i}(t)|^2 - A(v_{k_i}(t))v''_{k_i}(t) + v_{k_i}(t) \geq \lambda\tilde{a}|v_{k_i}(t)|^{q-1} + \frac{1}{k_i}. \tag{2.56}$$

Then, with $t = x$,

$$\begin{aligned} -A(v_{k_i}(x))v''_{k_i}(x) &\geq \lambda\tilde{a}|v_{k_i}(x)|^{q-1} - v_{k_i}(x) + A'(v_{k_i}(x))|v'_{k_i}(x)|^2 + \frac{1}{k_i} \\ &> \lambda\tilde{a}|v_{k_i}(x)|^{q-1} - v_{k_i}(x). \end{aligned}$$

Where, in the last inequality, we used that A is non-decreasing, $|v'_{k_i}| \geq 0$ and $1/k_i > 0$. Notice that the resulting estimation is strict because $1/k_i > 0$. By hypotheses $v''_{k_i}(x) \geq 0$, then $-A(v_{k_i}(x))v''_{k_i}(x) \leq 0$. Using the previous inequality,

$$v_{k_i}(x) > \lambda\tilde{a}|v_{k_i}(x)|^{q-1},$$

thus $v_{k_i}(x) \neq 0$ and $v_{k_i}(x) > (\lambda\tilde{a})^{\frac{1}{2-q}}$. □

Now, in order to use this lemma, we ought to find a $x_i \in (-n,n)$ such that $v''_{k_i}(x_i) \geq 0$. Using the fact that v_{k_i} is even and $v'_{k_i}(z_i) < 0$ we have that $v'_{k_i}(-z_i) > 0$. Let $x_i = \min_{x\in[z_i,-z_i]} v_{k_i}(x)$ and notice that $x_i \neq z_i$ and $x_i \neq -z_i$; indeed, there exist $\delta > 0$ such that, if $x \in (z_i, z_i+\delta) \cup (-z_i-\delta, -z_i)$, then $v_{k_i}(x) < v_{k_i}(z_i) = v_{k_i}(-z_i)$. Hence $x_i \in (z_i, -z_i)$ and $v'_{k_i}(x_i) = 0$; therefore $v''_{k_i}(x_i)$ must be *greater or equal than 0*, because if $v''_{k_i}(x_i) < 0$ there would be $\xi > 0$ such that, for $x \in (x_i, x_i+\xi) \subset (z_i, -z_i)$, $v'_{k_i}(x) < 0$; and for this neighborhood $v_{k_i}(x) < v_{k_i}(x_i)$ – a contradiction with the minimality of x_i. Thus, $v''_{k_i}(x_i) \geq 0$. By Lemma 2.27, we obtain for all i

$$v_{k_i}(x_i) > (\lambda\tilde{a})^{\frac{1}{2-q}}.$$

From the compactness of $[-n,n]$, there exist $x_0 \in [-n,n]$ such that $x_i \to x_0$ when $i \to \infty$; taking a subsequence if necessary. Then

$$u_n(x_0) = \lim_{i\to\infty} v_{k_i}(x_i) \geq (\lambda\tilde{a})^{\frac{1}{2-q}} > 0.$$

Finally, we will conclude *item 1* showing that, also in this case, u_n is strictly positive in $(-n,n)$.

Suppose by contradiction that there exists $y \in (-n,n)$ such that $u_n(y) = 0$. Let $(d,s) \subset (-n,n)$ be the biggest interval containing y satisfying the property: if $x \in (d,s)$ then $u_n(x) < \frac{(\lambda\tilde{a})^{\frac{1}{2-q}}}{2}$. Since $u_n(x_0) = u_n(-x_0) > \frac{(\lambda\tilde{a})^{\frac{1}{2-q}}}{2}$ we have that $d \neq -n$ or $s \neq n$. Thus we can suppose without loss of generality that $d > -n$, because on the contrary, we would apply our following arguments using the interval (d', s'), where $d' = -s$ and $s' = -d$, and the point $y' = -y$.

By the maximality of (d,s) and the continuity of u_n we have that $u_n(d) = \frac{(\lambda\tilde{a})^{\frac{1}{2-q}}}{2}$. Since $u_n(x) < \frac{(\lambda\tilde{a})^{\frac{1}{2-q}}}{2}$ for all $x \in (d,s)$ and v_{k_i} converges uniformly to u_n, there exists $i_1 \in \mathbb{N}$ such that, for $i > i_1$ and $x \in (d,s)$,

$$v_{k_i}(x) < (\lambda\tilde{a})^{\frac{1}{2-q}}.$$

Then, by Lemma 2.27 $v''_{k_i}(x) < 0$. Using that $u_n(d) = \frac{(\lambda\tilde{a})^{\frac{1}{2-q}}}{2}$, there exist $i_2 \in \mathbb{N}$ such that $i > i_2$ implies

$$v_{k_i}(d) > \frac{(\lambda\tilde{a})^{\frac{1}{2-q}}}{4}.$$

Let $i_0 > \max\{i_1, i_2\}$ and define $f : (d,s) \to \mathbb{R}$ by

$$f(x) = \frac{(\lambda\tilde{a})^{\frac{1}{2-q}}}{4} \cdot \frac{x-s}{d-s}.$$

We have that $f(d) = \frac{(\lambda\tilde{a})^{\frac{1}{2-q}}}{4}$ and $f(s) = 0$. Let $U_i(x) = v_{k_i}(x) - f(x)$ for $i \geq i_0$, then

$$\begin{cases} U''_i(x) < 0, & \text{for } x \in (d,s) \\ U_i(d) > 0, U_i(s) = v_{k_i}(s) \geq 0. \end{cases} \tag{2.57}$$

By the maximum principle, the minimum of U_i is reached on the border of the interval (d,s), implying that $U_i(x) > 0$ for all $x \in (d,s)$, that is, $v_{k_i}(x) > f(x)$ for all $x \in (d,s)$ and $i \geq i_0$. Thus, taking $x = y$ and making $i \to \infty$, we obtain

$$u_n(y) \geq f(y) > 0,$$

which is a contradiction.

Item 2. Since the estimation from Proposition 2.21 item *1* holds, that is,

$$|v_k|_{1+\beta} \leq \hat{C}$$

for all $k \in \mathbb{N}$; and, for all $1 < \alpha < \beta$, we have compact embedding $C^{1,\beta}[-n,n] \hookrightarrow C^{1,\alpha}[-n,n]$, we may assume, taking a subsequence, if necessary, that there exist $\widetilde{u_n} \in C^{1,\alpha}[-n,n]$ such that $v_k \to \widetilde{u_n}$ in $C^{1,\alpha}[-n,n]$ as $k \to \infty$. Thus,

$$\begin{aligned} v_k &\to u_n \quad \text{in } C^0[-n,n] \text{ as } k \to \infty \\ v_k &\to \widetilde{u_n} \quad \text{in } C^{1,\alpha}[-n,n] \text{ as } k \to \infty. \end{aligned}$$

Then for all $x \in [-n,n]$ we have

$$u_n(x) = \lim_{k\to\infty} v_k(x) = \widetilde{u_n}(x),$$

i.e., $u_n = \widetilde{u_n} \in C^{1,\alpha}[-n,n]$.

Considering the definition of weak solution, for all $\varphi \in H_0^1(-n,n)$

$$\int_{-n}^{n} A(v_k)v_k'\varphi' + \int_{-n}^{n} v_k\varphi = \int_{-n}^{n} (\lambda a_1|v_k|^{q-1} + |v_k|^{p-1})\varphi + \int_{-n}^{n} f_k(|v_k'|)\varphi + \int_{-n}^{n} \frac{\varphi}{k}.$$

By (D.C.T), it is straightforward to see that the following convergences are true:

$$\begin{aligned} \int_{-n}^{n} A(v_k)v_k'\varphi' &\to \int_{-n}^{n} A(u_n)u_n'\varphi', \\ \int_{-n}^{n} v_k\varphi &\to \int_{-n}^{n} u_n\varphi, \\ \int_{-n}^{n} (\lambda a_1|v_k|^{q-1} + |v_k|^{p-1})\varphi &\to \int_{-n}^{n} (\lambda a_1|u_n|^{q-1} + |u_n|^{p-1})\varphi, \\ \int_{-n}^{n} \frac{\varphi}{k} &\to 0, \end{aligned}$$

as $k \to \infty$. Let us examine the remaining integral. First notice that $f_k(|v_k'|)$ converges uniformly to $g(|u_n'|)$; indeed, g is uniformly continuous in compacts, then for the compact $[-\hat{C},\hat{C}]$ given $\epsilon > 0$ there exists $\delta > 0$ such that if $|x-y| < \delta$, then

$$|g(x) - g(y)| < \frac{\epsilon}{2}. \tag{2.58}$$

Also there exists $k_0 \in \mathbb{N}$ such that $k > k_0$ implies

$$||v_k'(x)| - |u_n'(x)|| < \delta \qquad \forall x \in [-n,n]. \tag{2.59}$$

thus for $k > k_0$

$$|g(|v_k'(x)|) - g(|u_n'(x)|)| < \frac{\epsilon}{2} \qquad \forall x \in [-n,n]. \tag{2.60}$$

In the perspective of Theorem 2.2, f_k converges to g uniformly in bounded sets; since $\|u_n'\|_\infty \leq \hat{C}$, for $x \in [-\hat{C},\hat{C}]$ there exist $k_1 \in \mathbb{N}$ such that $k > k_1$ implies

$$|f_k(x) - g(x)| < \frac{\epsilon}{2} \qquad \forall x \in [-\hat{C},\hat{C}] \tag{2.61}$$

and with all these ingredients we obtain the uniform convergence, because for $k > \max\{k_0,k_1\}$

$$\begin{aligned} |f_k(|v_k'(x)|) - g(|u_n'(x)|)| &\leq |f_k(|v_k'(x)|) - g(|v_k'(x)|)| + |g(|v_k'(x)|) - g(|u_n'(x)|)| \\ &< \epsilon \qquad \forall x \in [-n,n]. \end{aligned}$$

Thus, by (D.C.T)

$$\int_{-n}^{n} f_k(|v_k'|)\varphi \to \int_{-n}^{n} g(|u_n'|)\varphi$$

as $k \to \infty$. All these convergences together show that u_n is a weak solution for the problem (P_n).

From [6, Pag. 317, Chap. 6, Theorem 4] we conclude that $u_n \in W^{2,2}(-n,n)$; and similarly, to the argument showed in equation (2.49) we obtain that $u_n'' \in C^0(-n,n)$. Thus, u_n is a strong solution to the problem (P_n). □

3 Asymptotic solution to problem (P_n)

In this section we will briefly study the solution's behavior of problem (P_n) when $\lambda \to 0$ or $\lambda \to \lambda^*$. Our main result is the following:

Theorem 3.1. *Denoting by u_λ the solution of (P_n):*

1. *as $\lambda \to 0$, we get that $\|u_\lambda\|_{W^{1,2}} \to 0$;*
2. *one can take $\lambda = \lambda^*$ and still obtain a solution to problem (P_n).*

Proof. Let v_k be the strong solution of problem (P_n^k), with $\psi \equiv 1$. In the previous section, we proved, among other things, that $v_k \to u_\lambda$ as $k \to \infty$, (taking a subsequence, if necessary). Using v_k as test function in the Definition 2.12, we get:

$$\int_{-n}^{n} A(v_k)|v_k'|^2 + \int_{-n}^{n} |v_k|^2 = \int_{-n}^{n} \lambda a_1 |v_k|^{q-1} v_k + \int_{-n}^{n} |v_k|^{p-1} v_k + \int_{-n}^{n} f_k(|v_k'|) v_k + \int_{-n}^{n} \frac{v_k}{k}.$$

Thus, following the estimations done in Proposition 2.16, we can estimate these integrals to obtain

$$\begin{aligned}\gamma \|v_k\|_{W^{1,2}}^2 \le \lambda C_2 \|v_k\|_{W^{1,2}}^q + C^{p-2}\|v_k\|_{W^{1,2}}^p + C_1 \max\{C^{\theta-2}, C\}\|v_k\|_{W^{1,2}}^\theta \\ + \left(\frac{C_1(2n)^{1/2}}{k} + \frac{(2n)^{1/2}}{k}\right)\|v_k\|_{W^{1,2}}.\end{aligned}$$

Rearranging we obtain

$$\begin{aligned}\|v_k\|_{W^{1,2}}^2 \left(\gamma - C^{p-2}\|v_k\|_{W^{1,2}}^{p-2} - C_1 \max\{C^{\theta-2}, C\}\|v_k\|_{W^{1,2}}^{\theta-2}\right) \\ \le \lambda C_2 \|v_k\|_{W^{1,2}}^q + \left(\frac{C_1(2n)^{1/2}}{k} + \frac{(2n)^{1/2}}{k}\right)\|v_k\|_{W^{1,2}}. \quad (3.1)\end{aligned}$$

Notice that $\|v_k\|_{W^{1,2}} \le r$ independent of k and

$$r < \min\left\{\left(\frac{\gamma}{4C^{p-2}}\right)^{1/(p-2)}, \left(\frac{\gamma}{4C_1 \max\{C^{\theta-2}, C\}}\right)^{1/(\theta-2)}\right\}.$$

Thus,

$$\|v_k\|_{W^{1,2}}^2 \le \frac{2}{\gamma}\left(\lambda C_2 r^q + \left(\frac{C_1(2n)^{1/2}}{k} + \frac{(2n)^{1/2}}{k}\right) r\right). \quad (3.2)$$

Making $k \to \infty$ we end up with

$$\|u_\lambda\|^2_{W^{1,2}} \leq \lambda \cdot \left(\frac{2C_2 r^q}{\gamma}\right). \tag{3.3}$$

Then, as $\lambda \to 0$ we see that $\|u_\lambda\|^2_{W^{1,2}} \to 0$. This proves item *1*.

To prove item *2*, one can take a sequence (λ_n) in $(0, \lambda^*)$ such that $\lambda_n \to \lambda^*$. Noticing that $\|u_{\lambda_n}\|_{W^{1,2}} \leq r$ independent of λ_n, one can obtain a candidate $u_{\lambda^*} \in H^1_0(-n,n)$ such that u_{λ_n} converges weakly to u_{λ^*} in $H^1_0(-n,n)$. Then, following similar argumentation as exposed in Section 2, one can prove that u_{λ^*} is an even, positive solution to (P_n) with $\lambda = \lambda^*$. □

Remark 3.2. Let

$$\tilde{r} = \min\left\{r, \lambda^{1/2}\left(\frac{2C_2 r^q}{\gamma}\right)^{1/2}\right\}.$$

Then, by inequality (3.3) and the estimations from Proposition 2.16, we get that $\|u_\lambda\|_{W^{1,2}} \leq \tilde{r}$. Notice that $\tilde{r} \to 0$ as $\lambda \to 0$.

Remark 3.3. For now, on we will resume the previous notation, that is, we will call the strong solution of problem (P_n) by u_n. This will be useful in the next section.

4 Solution in $\mathbb{R}$

To obtain the homoclinic solution, we can proceed similarly as in [3]. However, we present a slightly different approach.

To obtain a solution defined in $\mathbb{R}$ we will utilize a subsequence construction wrapping it up with the arguments presented in Section 2. The reader should notice that the notation "u_n" used for the solution of (P_n), previously obtained, in $(-n,n)$ is not accidental: extending u_n by zero out of $[-n,n]$ we obtain a sequence (u_n) in $H^1(\mathbb{R})$. Throughout this section, we will use u_n to denote the solution "u_n" and its extension. Also, one can see that $\|u_n\|_{H^1(\mathbb{R})} = \|u_n\|_{W^{1,2}(-n,n)} \leq \tilde{r}$ for all n.

Let $K_1 = [-1,1]$; then for all $n \geq 1$ we have that $u^1_n := u_n|_{K_1}$ is well defined and $u^1_n \in H^1(-1,1)$. By the limitation $\|u^1_n\|_{W^{1,2}(-1,1)} \leq \tilde{r}$ there exists a subsequence $u_{n,1}$ and $s_1 \in H^1(-1,1)$ such that $u_{n,1} \rightharpoonup s_1$ in $H^1(-1,1)$. Notice that the compact injection $H^1(-1,1) \hookrightarrow C^0[-1,1]$ implies that, passing to a subsequence, $u_{n,1} \to s_1$ in $C^0[-1,1]$.

Let $K_2 = [-2,2]$. Taking n in the set of indices of the subsequence $u_{n,1}$, for $n \geq 2$ we have that $u^2_n := u_n|_{K_2}$ is well defined and $\|u^2_n\|_{W^{1,2}(-2,2)} \leq \tilde{r}$. Thus, there exists a subsequence $u_{n,2}$ of u^2_n and $s_2 \in H^1(-2,2)$ such that $u_{n,2} \rightharpoonup s_2$ in $H^1(-2,2)$.

Repeating the same argument, by induction we get that for all $j \in \mathbb{N}$ there exists a subsequence $u_{n,j}$ of $u_{n,j-1}$ and $s_j \in H^1(-j,j)$ such that $u_{n,j} \rightharpoonup s_j$ in $H^1(-j,j)$. Notice that $\|s_j\|_{H^1(-j,j)} \leq \tilde{r}$ for all $j \in \mathbb{N}$.

Remark 4.1. $u_{n,j}$ is the subsequence of u_n that converges weakly in $H^1(-j,j)$ to s_j. As mentioned, this weak convergence implies convergence in $C^0[-j,j]$ which gives us, in particular, that s_j is an even function, since $u_{n,j}$ is even for all $n \in \mathbb{N}$.

Lemma 4.2. $s_j|_{[1-j,j-1]} = s_{j-1}$

Proof. Given $x \in [1-j, j-1]$ we have that

$$s_{j-1}(x) = \lim_{n\to\infty} u_{n,j}(x) = s_j(x),$$

because $u_{n,j}$ is a subsequence of $u_{n,j-1}$. □

Fix $j \in \mathbb{N}$; from here and forward we will focus our attention on proving that, in fact, s_j *is smooth and positive.*

Define $W : [-n,n] \times [-Cr, Cr] \times \mathbb{R} \longrightarrow \mathbb{R}$ by

$$W(x,z,p) = z - (\lambda a_1(x)|z|^{q-1} + |z|^{p-1} + g(|p|))$$

one can see that the estimation (2.47) also holds, with W taking part as B (remember that C is the constant for the embedding $W^{1,2}(\mathbb{R}) \hookrightarrow L^\infty(\mathbb{R})$). Then, for any $n \geq j$, by Theorem 1 from [12] there exist $\hat{C}(j) > 0$ and $0 < \beta \leq 1$ such that

$$|u_n|_{1+\beta} \leq \hat{C}(j) \quad \text{in } C^{1,\beta}[-j,j].$$

Taking $0 < \alpha < \beta \leq 1$ we get (see the argumentation on *item 2* Proposition 2.24)

$$u_{n,j} \to s_j \quad \text{in } C^{1,\alpha}[-j,j].$$

Let $\widetilde{a}_j := \inf_{x\in[-j,j]} a_1(x)$. We will use the arguments presented on *Item 1* from Proposition 2.24 to prove that s_j *is strictly positive on the interval* $[-j,j]$.

Case 1. There exists a subsequence $(u_{n_i,j})_{i\in\mathbb{N}}$ of $(u_{n,j})$ such that $u'_{n_i,j} \geq 0$ in $(-j,0)$ for all i.

The analysis of this case follows exactly the same parameters of **Case 1** from *Item 1*, Proposition 2.24. The main difference is the change of $\tilde{a}$ to $\widetilde{a}_j$.

Case 2. For all subsequence of $(u_{n,j})$ there exists a sub-subsequence $(u_{n_i,j})_{i\in\mathbb{N}}$ and exists a sequence $(z_i)_{i\in\mathbb{N}} \subset (-j,0)$ such that $u'_{n_i,j}(z_i) < 0$.

For this case we can reformulate Lemma 2.27 as follows: If $x \in (-j,j)$ and $u''_{n_i,j}(x) \geq 0$, then $u_{n_i,j}(x) > (\lambda\widetilde{a}_j)^{\frac{1}{2-q}}$. This is true because we already know that $u_{n_i,j}$ is strictly positive in $(-j,j)$, then the estimation

$$-A'(u_{n_i,j}(t))|u'_{n_i,j}(t)|^2 - A(u_{n_i,j}(t))u''_{n_i,j}(t) + u_{n_i,j}(t) > \lambda\widetilde{a}_j|u_{n_i,j}(t)|^{q-1} \tag{4.1}$$

is immediately established. The remaining argumentation is similar.

Thus, we conclude that $s_j > 0$, as in Proposition 2.24. At last, let $\varphi \in C_0^\infty(-j,j)$. Then

$$\int_{-j}^{j} A(u_{n,j})u'_{n,j}\varphi' + \int_{-j}^{j} u_{n,j}\varphi = \int_{-j}^{j} (\lambda a_1|u_{n,j}|^{q-1} + |u_{n,j}|^{p-1})\varphi + \int_{-j}^{j} g(|u'_{n,j}|)\varphi.$$

When $n \to \infty$ we get

$$\int_{-j}^{j} A(s_j)s'_j\varphi' + \int_{-j}^{j} s_j\varphi = \int_{-j}^{j} (\lambda a_1|s_j|^{q-1} + |v|^{p-1})\varphi + \int_{-j}^{j} g(|s'_j|)\varphi.$$

Since $\varphi \in C_0^\infty(-j,j)$ is arbitrary, we conclude that s_j is a weak solution for the problem

$$-(A(u)u')'(t) + u(t) = \lambda a_1(t)|u(t)|^{q-1} + |u(t)|^{p-1} + g(|u'(t)|) \tag{4.2}$$

in $(-j, j)$; by [6, sect. 6.3, Theorem 1] we have that $s_j \in H^2_{\text{loc}}(-j, j)$, thus, using the same arguments as in (2.49), $s_j \in C^2(-j, j)$.

Now we will construct our candidate solution of problem (1.1). Define $w_n = u_{n,n}$, that is, w_n is the diagonal sequence. Notice that, for $n \geq j$, w_n is a subsequence of $u_{n,j}$; thus $w_n|_{[-j,j]} \to s_j$ in $C^{1,\alpha}[-j, j]$ for all $j \in \mathbb{N}$. Let $v(x)$ be defined by

$$v(x) = \lim_{n\to\infty} w_n(x).$$

Then, $v(x) = s_j(x)$ for $x \in [-j, j]$. Since $\mathbb{R} = \bigcup_{j\in\mathbb{N}}[-j, j]$, by Lemma 4.2, v is well defined in $\mathbb{R}$. Using the properties of s_j obtained just above, and the fact that $v|_{[-j,j]} = s_j$ for all $j \in \mathbb{N}$, we conclude that $v \in C^2(\mathbb{R})$, $\|v\|_{H^1(\mathbb{R})} \leq \tilde{r}$ and v is a positive, even solution of problem (1.1). From [4, p. 214, Corol. 8.9] we get the homoclinic condition.

4.1 Asymptotic solution

Throughout our previous argumentation, we fixed $\lambda \in (0, \lambda^*]$. Denote by v_λ the strong solution – obtained above – to the problem (1.1). We will analyze the behavior of v_λ as $\lambda \to 0$.

Proposition 4.3. *As $\lambda \to 0$, $v_\lambda \to 0$ in $C^0(\mathbb{R})$.*

Proof. By [4, Theorem 8.8.], we obtain

$$\|v_\lambda\|_{L^\infty(\mathbb{R})} \leq C\|v_\lambda\|_{H^1(\mathbb{R})} \leq C\tilde{r}. \tag{4.3}$$

But remember that

$$\tilde{r} = \min\left\{r, \lambda^{1/2}\left(\frac{2C_2 r^q}{\gamma}\right)^{1/2}\right\}.$$

Then, as $\lambda \to 0$, we obtain that $\|v_\lambda\|_{L^\infty(\mathbb{R})} \to 0$, completing the proof of Theorem 1.1 . □

4.2 Proof of Proposition 1.2

We proceed to prove Proposition 1.2 that says that there is no solution of (1.1) for λ large.

Proof. Suppose on the contrary that $\lambda^* = \infty$. In this way there is a sequence $\lambda_n \to \infty$ and corresponding solutions $v_{\lambda_n} > 0$ in $\mathbb{R}$ given by Theorem 1.1.

Fix $R > 0$ and define $\mathcal{P}(t, s) = \lambda a_1(t)s^{q-1} + s^{p-1}$ and $\tilde{a}_R = \inf_{(-R,R)} a_1(t)$. Define also

$$\Lambda = \lambda\, \tilde{a}_R.$$

We claim that there is a constant $C_\Lambda > 0$ such that

$$\mathcal{P}(t, s) \geq \Lambda s^{q-1} + s^{p-1} \geq C_\Lambda s \quad \text{for } s > 0, \ \ t \in (-R, R).$$

Consider the function $\mathcal{Q}(s) = (\Lambda s^{q-1} + s^{p-1})s^{-1}$. Then $\mathcal{Q}(s) \to \infty$ as $s \to 0^+$ and as $s \to \infty$. The minimum value of $\mathcal{Q}$ is achieved at the unique point

$$m = \left(\Lambda\, \frac{2-q}{p-2}\right)^{\frac{1}{p-q}}.$$

Thus $C_\Lambda = \mathcal{Q}(m)$.

Let $\sigma_1 > 0$ and $\varphi_1 > 0$, respectively, the first eigenvalue and the first eigenfunction satisfying

$$\begin{cases} -\varphi_1'' = \sigma_1 \varphi_1 & \text{in } (-R, R) \\ \varphi_1(-R) = \varphi_1(R) = 0. \end{cases}$$

Since C_Λ increases as λ_n increases, there is λ_0 such that the corresponding constant satisfies $C_{\Lambda_0} \geq A(C\tilde{r})\sigma_1 + A(C\tilde{r})\delta + 1$, for all $\delta \in (0,1)$. Hence, by (H_2)–(H_3) and (4.3), the solution $v_{\lambda_0} > 0$ in $\mathbb{R}$ of (1.1) associated to λ_0 satisfies

$$\begin{cases} -v_{\lambda_0}'' \geq \frac{(C_{\Lambda_0}-1)}{A(v_{\lambda_0})} v_{\lambda_0} \geq \frac{(C_{\Lambda_0}-1)}{A(C\tilde{r})} v_{\lambda_0} \geq (\sigma_1 + \delta) v_{\lambda_0} & \text{in } (-R, R) \\ v_{\lambda_0}(-R), v_{\lambda_0}(R) \geq 0. \end{cases}$$

Otherwise, taking $\varepsilon > 0$ small enough we obtain $\varepsilon\varphi_1 < v_0$ in $(-R, R)$ and

$$\begin{cases} -(\varepsilon\varphi_1)'' = (\varepsilon\sigma_1)\varphi_1 \leq (\sigma_1 + \delta)\varphi_1 & \text{in } (-R, R) \\ \varphi_1(-R) = \varphi_1(R) = 0. \end{cases}$$

By the method of subsolution and supersolution, there is a solution $\varepsilon\varphi_1 < \omega < v_0$ in $B_R(0)$ of

$$\begin{cases} -\omega'' = (\sigma_1 + \delta)\omega & \text{in } (-R, R) \\ \omega(-R) = \omega(R) = 0. \end{cases}$$

Hence there is a contradiction to the fact that σ_1 is isolated. Therefore, $\lambda^* < \infty$, indeed. □

Abstract. In this paper, we study the quasilinear Schrödinger equations

$$-\Delta u + V(x)u + \Delta(u^2)u = f(x,u), \qquad \forall x \in \mathbb{R}^N,$$

where $V \in C(\mathbb{R}^N;\mathbb{R})$ may change sign and f is only locally defined for $|u|$ small. Under some new assumptions on V and f, we show that the above equation has a sequence of solutions converging to zero. Some recent results in the literature are generalized and significantly improved and some examples are also given to illustrate our main theoretical results.

Keywords: variational methods, critical points, quasilinear Schrödinger equations.

2020 Mathematics Subject Classification: 49J35, 35Q40, 81V10.

1 Introduction

The aim of this paper is to establish the existence of multiple small solutions for the following quasilinear Schrödinger equations

$$-\Delta u + V(x)u + \Delta(u^2)u = f(x,u), \quad \forall x \in \mathbb{R}^N, \tag{QSE}$$

where $V \in C(\mathbb{R}^N;\mathbb{R})$ may change sign and f is only locally defined near the origin with respect to u and satisfies some weak and general sublinear assumptions.

Quasilinear Schrödinger equations (QSE) are widely used in non-Newtonian fluids, reaction-diffusion problems and other physical phenomena. More information on the physical background of these equations can be found in [6].

In recent years, with the aid of variational methods, the existence, nonexistence and multiplicity results of various solutions for (QSE) have been extensively investigated in the literature see [1, 5, 8, 10, 13] and the references therein. Here we emphasize that in all these papers V is a positive constant or possesses some kind of periodicity or radially symmetric, and the

✉ Corresponding author. Email: bridaasafa83@gmail.com

nonlinear term $f(x,u)$ is always required to satisfied various growth conditions at infinity with respect to u.

Recently, Chong et al. in [8] studied the equation (QSE) and proved the existence of multiple small solutions under the following conditions:

(C_1) There exist $\delta > 0$ and $C > 0$ such that $f \in C(\mathbb{R}^N \times [-\delta, \delta], \mathbb{R}^N)$, f is odd in x and

$$|f(x,u)| \leq C|u|, \quad \text{uniformly in } x \in \mathbb{R}^N;$$

(C_2) There exist $x_0 \in \mathbb{R}^N$ and $r_0 > 0$ such that

$$\liminf_{u\to 0}\left(\inf_{x\in B_{r_0}(x_0)} \frac{F(x,u)}{|u|^2}\right) > -\infty$$

and

$$\limsup_{u\to 0}\left(\inf_{x\in B_{r_0}(x_0)} \frac{F(x,u)}{|t|^2}\right) = +\infty,$$

where

$$F(x,u) = \int_0^u f(x,s)ds.$$

(V) For all $x \in \mathbb{R}^N$, $0 < V(x)$.

Motivated by the work of Chong et al. [8] and the [17, Lemma 2.3], in [5] the authors replaced the Condition (C_2) by a weak condition and proved the existence of multiple small solutions. Precisely, they supposed the following assumption:

(C_2') There exist $x_0 \in \mathbb{R}^{\mathbb{N}}$, two sequences (δ_n), (M_n) and constants α, $r_0 > 0$ such that δ_n, $M_n > 0$ and

$$\lim_{n\to\infty} \delta_n = 0, \quad \lim_{n\to\infty} M_n = +\infty,$$

$$\frac{F(x,u)}{{\delta_n}^2} \geq M_n \quad \text{for } |x - x_0| \leq r_0 \text{ and } |u| = \delta_n,$$

$$F(x,u) \geq -\alpha u^2 \quad \text{for } |x - x_0| \leq r_0 \text{ and } |u| \leq \delta.$$

In the present paper, different from the references mentioned above, we are going to study the existence of infinitely many solutions for (QSE) without any growth condition assumed on $f(x,u)$ at infinity with respect to u and the potential $V \in C(\mathbb{R}^N;\mathbb{R})$ may change sign. In fact, we will only require that $f(x,u)$ is locally defined for u small and satisfies some general and weak sufficient sublinear condition in u and V is neither of constant sign nor periodic. More precisely, we make the following assumptions:

(V_0) There exists a constant $a_0 > 0$ such that

$$V(x) + a_0 \geq 1, \quad \forall x \in \mathbb{R}^N,$$

$$\int_{\mathbb{R}^N} (V(x) + a_0)^{-1} dx < \infty,$$

and $\{x \in \mathbb{R}^N / V(x) \equiv 0\} \supset B(0,1)$, where $B(0,1)$ is the unit ball in $\mathbb{R}^N$.

(F_1) $F \in C^1(\mathbb{R}^N \times (-\delta, \delta))$ is even, and there exists a constant $a_1 > 0$ such that

$$|f(x,u)| \leq a_1, \quad \forall (x,u) \in \mathbb{R}^N \times (-\delta, \delta),$$

where $\delta > 0$.

For $\rho > 0$, $x \in B(0,1)$ satisfying $B(x,\rho) \subset B(0,1)$ and for $u \in (0,\delta)$, we define

$$\overline{F}(x,u,\rho) := \inf \left\{ \frac{F(y,u)}{u^2}\rho^2 : y \in B(x,\rho) \right\}, \tag{1.1}$$

$$\underline{F}(x,u,\rho) := \inf \left\{ \frac{F(y,mu)}{u^2}\rho^2 : y \in B(x,\rho), 0 \leq m \leq 1 \right\}. \tag{1.2}$$

Substituting $m = 0$ into $\frac{F(y,mu)}{u^2}\rho^2$, we see that $\underline{F}(x,u,\rho) \leq 0$. We assume:

(F_2) There exists a positive integer k_0 satisfying the following condition:
For each $k \geq k_0$, there exist $\mu_k \in (-\frac{\delta}{2}, 0) \cup (0, \frac{\delta}{2})$, $x_{k,i} \in B(0,1)$, with $1 \leq i \leq 2k$ and $\rho_k > 0$ such that $B(x_{k,i}, \rho_k) \subset B(0,1)$, $B(x_{k,i}, \rho_k) \cap B(x_{k,j}, \rho_k) = \emptyset$ for $i \neq j$ and

$$\min_{1 \leq i \leq 2k} \overline{F}(x_{k,i}, \mu_k, \rho_k) + (2^{N+1} - 1) \min_{1 \leq i \leq 2k} \underline{F}(x_{k,i}, \mu_k, \rho_k) > 2^{N+2}. \tag{1.3}$$

In (1.3), N is the dimension of the domain $\mathbb{R}^N$.

Our main results reads as follows.

Theorem 1.1. *Suppose that (V_0) and (F_1), (F_2) are satisfied. Then, equation (QSE) possesses a sequence of solutions $\{u_k\}$ such that $u_k(x) \to 0$ in L^∞ as $k \to \infty$.*

Remark 1.2.

- We insist on the fact that in the hypotheses (F_1)–(F_2), the conditions on the nonlinearity $F(x,u)$ are supposed only near $u = 0$ and there are no conditions for large $|u|$. This is essential and important. Indeed, this assumptions allows us to study equations having singularity or supercritical terms as $|u| \to \infty$.
- Under (F_1)–(F_2), $F(x,u)$ can be subquadratic, superquadratic or asymptotically quadratic at infinity. Our Theorem 1.1 is in some sense an improvement for some related results in the existing literature.
- To the best of our knowledge, there is no result concerning the existence and multiplicity of solutions for the equation (QSE) with the conditions.

Corollary 1.3. *Suppose that (V_0) and (F_1) are satisfied and $\delta > 0$ be as in (F_1). We assume that there exist sequences $M_n \to \infty$ as $n \to \infty$, $u_n \in (-\frac{\delta}{2}, 0) \cup (0, \frac{\delta}{2})$ and $\rho_n > 0$, $v_n \in B(0,1)$ such that $B(v_n, \rho_n) \subset B(0,1)$ and a constant $c \geq 0$, satisfy*

$$F(x,u_n)\rho_n^2 \geq M_n u_n^2, \; F(x, l u_n)\rho_n^2 \geq -c u_n^2 \quad \text{for } x \in B(v_n, \rho_n), \; 0 \leq l \leq 1. \tag{1.4}$$

Then, equation (QSE) possesses a sequence of solutions $\{u_k\}$ such that $u_k(x) \to 0$ in L^∞ as $k \to \infty$.

Corollary 1.4. *Suppose that (V_0) and (F_1) are satisfied and $\delta > 0$ be as in (F_1). We assume that there exist sequences $u_n \in (0, \frac{\delta}{2})$, $\rho_n > 0$ and $v_n \in B(0,1)$ such that $B(v_n, \rho_n) \subset B(0,1)$, and they satisfy*

$$\lim_{n \to \infty} \overline{F}(v_n, u_n, \rho_n) = \infty, \tag{1.5}$$

$$\liminf_{n \to \infty} \underline{F}(v_n, u_n, \rho_n) > -\infty. \tag{1.6}$$

Then, equation (QSE) possesses a sequence of solutions $\{u_k\}$ such that $u_k(x) \to 0$ in L^∞ as $k \to \infty$.

Corollary 1.5. *Suppose that* (V_0), (F) *and* (F_1) *are satisfied. Then, equation* (*QSE*) *possesses a sequence of solutions* $\{u_k\}$ *such that* $u_k(x) \to 0$ *in* L^∞ *as* $k \to \infty$.

Corollary 1.6. *Suppose that* $(V_0), (F_1)$ *and*

$$\inf_{x \in B(x_0, r_0)} u^{-2} F(x,u) \to \infty \quad \text{as } u \to 0, \tag{1.7}$$

are satisfied. Then, equation (*QSE*) *possesses a sequence of solutions* $\{u_k\}$ *such that* $u_k(x) \to 0$ *in* L^∞ *as* $k \to \infty$.

2 Preliminary results and variational setting

We employ an argument inspired by the work of Costa, Wang [11], the quasilinear problem was can be established:

$$-\operatorname{div}(h^2(u)\nabla u) + h(u)h'(u)|\nabla u|^2 + V(x)u = f(x,u), \qquad x \in \mathbb{R}^N, \tag{2.1}$$

where $h : [0, +\infty) \to \mathbb{R}$ satisfying

$$h(t) = \begin{cases} \sqrt{1-2t^2} & \text{if } 0 \le t < \frac{1}{\sqrt{6}}, \\ \frac{1}{6t} + \frac{1}{\sqrt{6}} & \text{if } t \ge \frac{1}{\sqrt{6}}, \end{cases}$$

and $h(t) = h(-t)$ for $t < 0$. It deduces that $h \in C^1(\mathbb{R}, (\left(\frac{1}{\sqrt{6}}\right), 1))$ and is increasing in $(-\infty, 0)$ and decreasing in $[0, +\infty)$. Then, we define

$$H(t) := \int_0^t h(s)ds.$$

It is well known that $H(t)$ is an odd function and inverse function $H^{-1}(t)$ exists. We now summarize some properties of $H^{-1}(t)$ as follow.

Lemma 2.1 ([1])**.** *We have:*

1. $|t| \le |H^{-1}(t)| \le \sqrt{6}|t|$ *for all* $t \in \mathbb{R}$;
2. $|H(t)| \le |t|$ *for all* $t \in \mathbb{R}$;
3. $-\frac{1}{2} \le \frac{t}{h(t)} h'(t) \le 0$ *for all* $t \ge 0$.

As in [11], in the present paper we are concerned to provide that the problem (2.1) has a sequence of weak solution $\{u_n\}$ satisfying $\|u_n\|_{L^\infty} < \min\{\delta/2, \frac{1}{\sqrt{6}}\}$, in this situation

$$h(u_n) = \left(1 - 2|u_n|^2\right)^{1/2}.$$

In order to prove our main result via the critical point theory, we need to establish the variational setting for (*QSE*). Before this, we have the following remark:

Remark 2.2. Let $V_0(x) = V(x) + a_0$, $F_0(x, H^{-1}(v)) = F(x, H^{-1}(v)) + \frac{a_0}{2}(H^{-1}(v))^2$ and $F_0(x,u) := \int_0^u f_0(x,s)ds$. Consider the following equation

$$-\Delta v + V_0(x)\frac{H^{-1}(v)}{h(H^{-1}(v))} = \frac{f_0(x, H^{-1}(v))}{h(H^{-1}(v))}, \qquad \forall x \in \mathbb{R}^N. \tag{2.2}$$

Then, equation (2.2) is equivalent to equation (QSE). It is easy to check that the hypotheses (V_0) and (F_1), (F_2) still hold for V_0 and F_0 provided that those hold for V and F. Hence, in what follows, we always assume without loss of generality that $V(x) \geq 1$ for all $x \in \mathbb{R}^N$ and $\int_{\mathbb{R}^N}(V(x))^{-1}dx < \infty$.

In view of Remark 2.2, we consider the space $E := \{u \in H^1(\mathbb{R}^N) \mid \int_{\mathbb{R}^N} V(x)u^2dx < \infty\}$ equipped with the following inner product

$$(u,v) := \int_{\mathbb{R}^N}(\nabla u \cdot \nabla v + V(x)uv)dx.$$

Then E is a Hilbert space and we denote by $\|\cdot\|$ the associated norm. In what follows, E becomes our working space. Moreover, we write E^* for the topological dual of E, and $\langle\cdot,\cdot\rangle$: $E^* \times E \to \mathbb{R}$ for the dual pairing. Evidently, E is continuously embedded into $H^1(\mathbb{R}^N)$. Using the Sobolev embedding theorem, we immediately get the following lemma.

Lemma 2.3. *If V satisfies (V_0), then E is continuously embedded in L^1.*

Proof. By (V_0) and Hölder inequality, we have for all $u \in E$

$$\begin{aligned}\int_{\mathbb{R}^N} |u|\,dx &= \int_{\mathbb{R}^N} \left|(V(x))^{\frac{-1}{2}}(V(x))^{\frac{1}{2}}u\right| dx \\ &\leq \int_{\mathbb{R}^N} (V(x))^{\frac{-1}{2}} \left|(V(x))^{\frac{1}{2}}u\right| dx \\ &\leq \left(\int_{\mathbb{R}^N}(V(x))^{-1}dx\right)^{\frac{1}{2}}\left(\int_{\mathbb{R}^N}V(x)u^2dx\right)^{\frac{1}{2}} \\ &\leq \left(\int_{\mathbb{R}^N}(V(x))^{-1}dx\right)^{\frac{1}{2}}\|u\|.\end{aligned} \tag{2.3}$$

□

Lemma 2.4. *If V satisfies (V_0) then E is compactly embedded into L^1.*

Proof. Let $(u_n) \subset E$ be a bounded sequence such that $u_n \rightharpoonup u$ in E. We will show that $u_n \to u$ in L^1. By Hölder's inequality, we have

$$\begin{aligned}&\int_{\mathbb{R}^N}|u_n - u|\,dx \\ &= \int_{|x|\leq R}|u_n-u|\,dx + \int_{|x|>R}|u_n-u|\,dx \\ &\leq \omega R^N\left(\int_{|x|\leq R}|u_n-u|^2dx\right)^{\frac{1}{2}} + \int_{|x|>R}\left|(V(x))^{\frac{-1}{2}}(V(x))^{\frac{1}{2}}(u_n-u)\right|dx \\ &\leq \omega R^N\left(\int_{|x|\leq R}|u_n-u|^2dx\right)^{\frac{1}{2}} + \int_{|x|>R}(V(x))^{-\frac{1}{2}}\left|(V(x))^{\frac{1}{2}}(u_n-u)\right|dx \\ &\leq \omega R^N\left(\int_{|x|\leq R}|u_n-u|^2dx\right)^{\frac{1}{2}} + \left(\int_{|x|>R}(V(x))^{-1}dx\right)^{\frac{1}{2}}\left(\int_{|x|>R}V(x)(u_n-u)^2dx\right)^{\frac{1}{2}} \\ &\leq \omega R^N\left(\int_{|x|\leq R}|u_n-u|^2dx\right)^{\frac{1}{2}} + \left(\int_{|x|>R}(V(x))^{-1}dx\right)^{\frac{1}{2}}\|u_n-u\|,\end{aligned} \tag{2.4}$$

where $R>0$, ω the volume of the unit ball in $\mathbb{R}^N$. Then by (V_0) and the Sobolev embedding Theorem, for any $\varepsilon>0$ there exits $R_0>0$ such that for $R>R_0$, we have

$$\int_{\mathbb{R}^N} |u_n-u|\,dx \le \varepsilon. \qquad \square$$

Lemma 2.5 ([2]). *E is continuously embedded into $L^p(\mathbb{R}^N)$ for all $p\in[2,6]$, and hence there exists $\tau_p>0$ such that*

$$\|v\|_{L^p(\mathbb{R}^N)} \le \tau_p\|u\|, \qquad \forall u\in E \text{ and } p\in[2,6]. \tag{2.5}$$

3 Proofs of main results

In order to define the corresponding variational functional on our working space E, we need modify $f(x,u)$ for u outside a neighborhood of the origin to get a globally defined $\widetilde{f}(x,u)$ as follows: Choose a constant $b\in(0,\frac{\delta}{2})$ and define a cut-off function $\chi\in C(\mathbb{R},\mathbb{R})$ satisfying

$$\chi(t) := \begin{cases} 1 \ \text{ if } -b\le t\le b \\ 0 \ \text{ if } t\ge 2b \end{cases} \quad \text{and,} \quad -\frac{2}{b}\le \chi'(t)<0 \quad \text{for } b<|t|<2b. \tag{3.1}$$

Let $\widetilde{f}(x,u):=\chi(u)f(t,u)$, for all $(x,u)\in\mathbb{R}^N\times\mathbb{R}$, and $\widetilde{F}(x,u):=\int_0^u\widetilde{f}(x,s)ds$, for all $(x,u)\in\mathbb{R}^N\times\mathbb{R}$. By (3.1) and assumption (F_1) we have, for all $(x,u)\in\mathbb{R}^N\times\mathbb{R}$,

$$\left|\widetilde{F}(x,u)\right| \le a_1\,|u| \quad \text{and} \quad \left|\widetilde{f}(x,u)\right| \le a_2, \tag{3.2}$$

where a_1 is the constant given in assumption (F_1) and a_2 is a positive constant.

Remark 3.1. As we have mentioned above, it is easy to verify that the equation (3.2) becomes

$$\left|\widetilde{F}(x,H^{-1}(v))\right| \le a_1\left|H^{-1}(v)\right| \quad \text{and} \quad \left|\widetilde{f}(x,H^{-1}(v))\right| \le a_2\left|h(H^{-1}(v))\right|. \tag{3.3}$$

Now, we consider the following modified equation

$$-\Delta v+V(x)\frac{H^{-1}(v)}{h(H^{-1}(v))} = \frac{\widetilde{f}(x,H^{-1}(v))}{h(H^{-1}(v))}, \qquad \forall x\in\mathbb{R}^N. \tag{$\widetilde{QSE}$}$$

To find the weak solutions of ($\widetilde{QSE}$) with desired properties, we focus on a Lagrangian functional defined by

$$\Phi(v) := \frac{1}{2}\int_{\mathbb{R}^N}\left(|\nabla v|^2+V(x)|H^{-1}(v)|^2\right)dx-\Psi(H^{-1}(v)), \tag{3.4}$$

with the change of variable $v=H(u)$ and $\Psi(v)=\int_{\mathbb{R}^N}\widetilde{F}(x,H^{-1}(v))dx$.

Lemma 3.2. *Suppose that conditions (V_0) and (F_1) are satisfied. If $v\in E$ is a critical point of Φ, then $u=H^{-1}(v)\in E$ and this u is a weak solution for ($\widetilde{QSE}$).*

Proof. Since $v\in E$ and by Lemma 2.1, we can conclude that $u=H^{-1}(v)\in E$. Furthermore, v is a critical point for Φ, it follows that

$$\int_{\mathbb{R}^N}\nabla v\nabla\varphi dx+\int_{\mathbb{R}^N}V(x)\frac{H^{-1}(v)}{h(H^{-1}(v))}\varphi dx = \int_{\mathbb{R}^N}\frac{\widetilde{f}(x,H^{-1}(v))}{h(H^{-1}(v))}\varphi dx, \quad \text{for all } \varphi\in E.$$

If we take the function $\varphi = h(u)\psi$, where $u = H^{-1}(v)$ and $\psi \in C_0^\infty(\mathbb{R}^N)$, then we can obtain

$$\int_{\mathbb{R}^N} \nabla v \nabla u h'(u)\psi dx + \int_{\mathbb{R}^N} \nabla v \nabla \psi h(u) dx + \int_{\mathbb{R}^N} V(x) u\psi dx - \int_{\mathbb{R}^N} \widetilde{f}(x,u)\psi dx = 0.$$

Then, we get

$$\int_{\mathbb{R}^N} \Big(-\operatorname{div}(h^2(u)\nabla u) + h(u)h'(u)|\nabla u|^2 + V(x)u - \widetilde{f}(x,u) \Big)\psi dx = 0. \qquad \square$$

According to [8], we know that in order to find solutions of ($\widetilde{QSE}$) it suffices to obtain the critical points of Φ. For this purpose we recall the following definitions and results (see [14, 15]).

Definition 3.3 ([15])**.** Let E be a real Banach space and $\phi \in C^1(E, \mathbb{R})$.

- ϕ is said to satisfy (PS) condition if any sequence $(u_k) \subset E$ for which $(\phi(u_k))$ is bounded and $\phi'(u_k) \to 0$ as $k \to +\infty$, possesses a convergent subsequence in E. Here $\phi'(u)$ denotes the Fréchet derivative of $\phi(u)$.
- Set $\Gamma := \{A \subset E \backslash \{0\} : A \text{ is closed and symmetric with respect to the origin}\}$. For $A \in \Gamma$, we say genus of A is n (denoted by $\sigma(A) = n$), if there is an odd mapping $\varphi \in C(A, \mathbb{R}^n \backslash \{0\})$, and n is the smallest integer with this property.

Theorem 3.4 ([14, Theorem 1])**.** *Let ϕ be an even C^1 functional on E with $\phi(0) = 0$. Suppose that ϕ satisfies the (PS) condition and*

(1) ϕ is bounded from below.

(2) For each $k \in \mathbb{N}$, there exists an $A_k \in \Gamma$ such that $sup_{u \in A_k}\phi(u) < 0$, where $\Gamma_k = \{A \in \Gamma : \sigma(A) \geq k\}$.

Then either (i) or (ii) below holds.

(i) There exists a critical point sequence (u_k) such that $\phi(u_k) < 0$ and $\lim_{k\to\infty} u_k = 0$.

(ii) There exist two critical point sequences (u_k) and (v_k) such that $\phi(u_k) = 0, u_k \neq 0, \lim_{k\to\infty} u_k = 0, \phi(v_k) < 0, \lim_{k\to\infty} \phi(v_k) = 0$, and (v_k) converges to a non-zero limit.

Lemma 3.5. *Let (V_0) and (F_1) be satisfied. Then $\Psi \in C^1(E, \mathbb{R})$, and hence $\Phi \in C^1(E, \mathbb{R})$. Moreover,*

$$\langle \Psi'(v), \varphi \rangle = \int_{\mathbb{R}^N} \frac{\widetilde{f}(x, H^{-1}(v))}{h(H^{-1}(v))} \varphi \, dx, \tag{3.5}$$

and

$$\begin{aligned} \langle \Phi'(v), \varphi \rangle &= \int_{\mathbb{R}^N} \Big(\nabla v \nabla \varphi + V(x) \frac{H^{-1}(v)}{h(H^{-1}(v))} \varphi \Big) dx - \langle \Psi'(v), \varphi \rangle, \\ &= \int_{\mathbb{R}^N} \Big(\nabla v \nabla \varphi + V(x) \frac{H^{-1}(v)}{h(H^{-1}(v))} \varphi \Big) dx - \int_{\mathbb{R}^N} \frac{\widetilde{f}(x, H^{-1}(v))}{h(H^{-1}(v))} \varphi \, dx, \end{aligned} \tag{3.6}$$

for all $v, \varphi \in E$, and nontrivial critical points of Φ on E are solutions of equation ($\widetilde{QSE}$).

Proof. First, we show that Φ and Ψ are both well defined. For any $v \in E$, by (2.3) and (3.2), we have

$$\begin{aligned}\int_{\mathbb{R}^N} |\widetilde{F}(x, H^{-1}(v))|dx &\le a_1 \int_{\mathbb{R}^N} |H^{-1}(v)|\ dx \\ &\le a_1 \int_{\mathbb{R}^N} |v|\ dx \\ &\le a_1 \left(\int_{\mathbb{R}^N} (V(x))^{-1} dx\right)^{\frac{1}{2}} \|v\|.\end{aligned}$$

This implies that Φ and Ψ are both well defined.

Next, we prove $\Psi \in C^1(E, \mathbb{R})$. For any given $v \in E$, define an associated linear operator $J(v) : E \to \mathbb{R}$ by

$$\langle J(v), \varphi\rangle = \int_{\mathbb{R}^N} \frac{\widetilde{f}(x, H^{-1}(v))}{h(H^{-1}(v))} \varphi\ dx, \quad \forall \varphi \in E.$$

By (2.3) and (3.2), there holds

$$\begin{aligned}|\langle J(v), \varphi\rangle| &= \int_{\mathbb{R}^N} \left|\frac{\widetilde{f}(x, H^{-1}(v))}{h(H^{-1}(v))}\right| |\varphi|\ dx \\ &\le a_2 \int_{\mathbb{R}^N} |\varphi|\ dx \\ &\le a_2 \left(\int_{\mathbb{R}^N} (V(x))^{-1}\ dx\right)^{\frac{1}{2}} \|\varphi\|.\end{aligned}$$

This implies that $J(v)$ is well defined and bounded. Observing (2.3) and (3.2), for any $v, \varphi \in E$, by the Mean Value Theorem and Lebesgue's Dominated Convergence Theorem, we have

$$\begin{aligned}\lim_{s\to 0} \frac{\Psi(H^{-1}(v) + s\varphi) - \Psi(H^{-1}(v))}{s} &= \lim_{s\to 0} \int_{\mathbb{R}^N} \frac{\widetilde{f}(x, H^{-1}(v) + \theta(x)s\varphi)}{h(H^{-1}(v) + \theta(x)s\varphi)} \varphi\ dx \\ &= \int_{\mathbb{R}^N} \frac{\widetilde{f}(x, H^{-1}(v))}{h(H^{-1}(v))} \varphi\ dx \\ &= \langle J(v), \varphi\rangle,\end{aligned} \tag{3.7}$$

where $\theta(x) \in [0, 1]$ depends on v, φ, s. This implies that Ψ is Gâteaux differentiable on E and the Gâteaux derivative of Ψ at $v \in E$ is $J(v)$. Now for any $\epsilon > 0$, by (V_0), there exists $R_\epsilon > 0$ such that

$$\left(\int_{|x|>R_\epsilon} (V(x))^{-1} dx\right)^{\frac{1}{2}} < \frac{\epsilon}{4a_2}. \tag{3.8}$$

For this end, we claim that if $H^{-1}(v_n) \rightharpoonup H^{-1}(v)$ in E, then for any $R > 0$, $\frac{\widetilde{f}(x,H^{-1}(v_n))}{h(H^{-1}(v_n))} \to \frac{\widetilde{f}(x,H^{-1}(v))}{h(H^{-1}(v))}$ in $L^2(B_R)$, where B_R denotes the ball in $\mathbb{R}^N$ centered at 0 with radius R. Arguing indirectly, by Lemma 2.5, we assume that there exist constants $R_\epsilon, \epsilon > 0$ and a subsequence $\{H^{-1}(v_{n_k})\}_{k\in\mathbb{N}}$ such that

$$H^{-1}(v_{n_k}) \to H^{-1}(v) \quad \text{in } L^2(B_{R_\epsilon}) \quad \text{and} \quad H^{-1}(v_{n_k}) \to H^{-1}(v) \quad \text{a.e. in } B_{R_\epsilon} \quad \text{as } k \to \infty, \tag{3.9}$$

but using (F_1), we have

$$\int_{|x|\le R_\epsilon} \left|\frac{\widetilde{f}(x, H^{-1}(v_{n_k}))}{h(H^{-1}(v_{n_k}))} - \frac{\widetilde{f}(x, H^{-1}(v))}{h(H^{-1}(v))}\right|^2 dx \ge \epsilon, \quad \forall k \in \mathbb{N}. \tag{3.10}$$

By (3.9), passing to a subsequence if necessary, we can assume that

$$\sum_{k=1}^{\infty} \|H^{-1}(v_{n_k}) - H^{-1}(v)\|_{L^2(B_{R_\epsilon})} < +\infty.$$

By virtue of (3.3), we get

$$\int_{|x|\le R_\epsilon} \left| \frac{\widetilde{f}(x, H^{-1}(v_{n_k}))}{h(H^{-1}(v_{n_k}))} - \frac{\widetilde{f}(x, H^{-1}(v))}{h(H^{-1}(v))} \right|^2 dx < +\infty. \tag{3.11}$$

For the R_ϵ given above, combining (3.9), (3.11) and Lebesgue's Dominated Convergence Theorem, we have

$$\lim_{k\to\infty} \int_{|x|\le R_\epsilon} \left| \frac{\widetilde{f}(x, H^{-1}(v_{n_k}))}{h(H^{-1}(v_{n_k}))} - \frac{\widetilde{f}(x, H^{-1}(v))}{h(H^{-1}(v))} \right|^2 dx = 0,$$

which contradicts (3.10). Thus the claim is true. Consequently, there exists $N_\epsilon \in \mathbb{N}$ such that

$$\int_{|x|\le R_\epsilon} \left| \frac{\widetilde{f}(x, H^{-1}(v_{n_k}))}{h(H^{-1}(v_{n_k}))} - \frac{\widetilde{f}(x, H^{-1}(v))}{h(H^{-1}(v))} \right|^2 dx < \frac{\epsilon}{2}, \ \ \forall n \ge N_\epsilon. \tag{3.12}$$

Combining (3.3), (3.8), (3.12) and the Hölder inequality, for each $n \ge N_\epsilon$, we have

$$\begin{aligned}
\|J(v_n) - J(v)\|_{E^*} &= \sup_{\|H^{-1}(v)\|=1} |\langle J(v_n) - J(v), \varphi\rangle| \\
&\le \sup_{\|H^{-1}(v)\|=1} \left| \int_{\mathbb{R}^N} \left[\frac{\widetilde{f}(x, H^{-1}(v_n))}{h(H^{-1}(v_n))} - \frac{\widetilde{f}(x, H^{-1}(v))}{h(H^{-1}(v))} \right] \varphi dx \right| \\
&\le \sup_{\|H^{-1}(v)\|=1} \left| \int_{|x|\le R_\epsilon} \left[\frac{\widetilde{f}(x, H^{-1}(v_n))}{h(H^{-1}(v_n))} - \frac{\widetilde{f}(x, H^{-1}(v))}{h(H^{-1}(v))} \right] \varphi dx \right| \\
&\quad + \sup_{\|H^{-1}(v)\|=1} \left| \int_{|x|> R_\epsilon} \left[\frac{\widetilde{f}(x, H^{-1}(v_n))}{h(H^{-1}(v_n))} - \frac{\widetilde{f}(x, H^{-1}(v))}{h(H^{-1}(v))} \right] \varphi dx \right| \\
&\le \sup_{\|H^{-1}(v)\|=1} \left(\int_{|x|\le R_\epsilon} \left| \frac{\widetilde{f}(x, H^{-1}(v_n))}{h(H^{-1}(v_n))} - \frac{\widetilde{f}(x, H^{-1}(v))}{h(H^{-1}(v))} dx \right|^2 \right)^{\frac{1}{2}} \left(\int_{|x|\le R_\epsilon} |\varphi|^2 dx \right)^{\frac{1}{2}} \\
&\quad + 2a_2 \sup_{\|H^{-1}(v)\|=1} \left(\int_{|x|>R_\epsilon} (V(x))^{-1} dx \right)^{\frac{1}{2}} \left(\int_{|x|>R_\epsilon} V(x)\varphi^2 dx \right)^{\frac{1}{2}} \\
&\le \frac{\epsilon}{2} + \frac{2a_2\epsilon}{4a_2} = \epsilon.
\end{aligned}$$

This, means that J is continuous in u. Thus, $\Psi \in C^1(E, \mathbb{R})$ and (3.5) holds. Due to the form of ϕ, we know that $\Phi \in C^1(E, \mathbb{R})$ and (3.6) also holds.

Finally, a standard argument shows that nontrivial critical points of Φ on E are solutions of ($\widetilde{QSE}$) (see, e.g., [8]). The proof is completed. □

Lemma 3.6. *Let (V_0) and (F_1) be satisfied. Then Φ is bounded from below and satisfies (PS) condition.*

Proof. We first prove that Φ is bounded from below. Combining $(F1)$, (2.3), (3.2) and the Hölder inequality, we have

$$\begin{aligned}\Phi(v) &\geq \frac{1}{2}\|v\|^2 - a_1 \int_{\mathbb{R}^N} |H^{-1}(v)|dx \\ &\geq \frac{1}{2}\|v\|^2 - a_1 \left(\int_{\mathbb{R}^N} (V(x))^{-1}dx\right)^{\frac{1}{2}} \|v\|, \quad \forall v \in E,\end{aligned} \tag{3.13}$$

where a_2 is the constant given in (3.2). Then it follows that Φ is bounded from below.

Next, we show that Φ satisfies (PS)-condition.

Let $\{v_n\} \subset E$ be a (PS)-sequence, i.e.,

$$|\Phi(v_n)| \leq D_2 \quad \text{and} \quad \Phi'(v_n) \to 0 \quad \text{as } n \to \infty \tag{3.14}$$

for some $D_2 > 0$. By (3.13) and (3.14), we have

$$D_2 \geq \frac{1}{2}\|v_n\|^2 - a_2\left(\int_{\mathbb{R}^N} (V(x))^{-1}dx\right)^{\frac{1}{2}} \|v_n\|, \quad \forall n \in \mathbb{N}.$$

This implies that $\{v_n\}$ is bounded in E. Thus, there exists a subsequence $\{H^{-1}(v)_{n_k}\}$ such that

$$H^{-1}(v_{n_k}) \rightharpoonup H^{-1}(v_0) \quad \text{as } k \to \infty \tag{3.15}$$

for some $v_0 \in E$. By Lemma 2.4, it holds that

$$H^{-1}(v_{n_k}) \to H^{-1}(v_0) \quad \text{in } L^1 \text{ as } k \to \infty. \tag{3.16}$$

This together with (3.3) yields

$$\begin{aligned}&\left|\int_{\mathbb{R}^N} \left[\frac{\widetilde{f}(x, H^{-1}(v_{n_k}))}{h(H^{-1}(v_{n_k}))} - \frac{\widetilde{f}(x, H^{-1}(v_0))}{h(H^{-1}(v_0))}\right] (H^{-1}(v_{n_k}) - H^{-1}(v_0))dx\right| \\ &\qquad \leq 2a_2 \int_{\mathbb{R}^N} |H^{-1}(v_{n_k}) - H^{-1}(v_0)|dx \to 0 \quad \text{as } k \to \infty.\end{aligned} \tag{3.17}$$

Noting that $\{\xi_n\}$ is bounded in E, we infer from (3.14) and (3.15) that

$$\langle \Phi'(\xi_{n_k}) - \Phi'(\xi_0), H^{-1}(\xi_{n_k}) - H^{-1}(\xi_0)\rangle \to 0 \quad \text{as } k \to \infty. \tag{3.18}$$

Combining (3.6), (3.17) and (3.18), we have

$$\begin{aligned}&\|H^{-1}(\xi_{n_k}) - H^{-1}(\xi_0)\|^2 \\ &\quad = \langle \Phi'(\xi_{n_k}) - \Phi'(\xi_0), H^{-1}(\xi_{n_k}) - H^{-1}(\xi_0)\rangle \\ &\qquad + \int_{\mathbb{R}N} \left(\frac{\widetilde{f}(x, \xi_{n_k})}{h(H^{-1}(\xi_{n_k}))} - \frac{\widetilde{f}(x, \xi_0)}{h(H^{-1}(\xi_0))}\right) (H^{-1}(\xi_{n_k}) - H^{-1}(\xi_0))dx \to 0 \quad \text{as } k \to \infty.\end{aligned} \tag{3.19}$$

This means that $H^{-1}(\xi_{n_k}) \to H^{-1}(\xi_0)$ in E as $k \to \infty$. Thus Φ satisfies (PS)-condition. □

We introduce a closed symmetric set V_k as below:

$$V_k \equiv \{(l_1, l_2, \ldots, l_{2k}) \in \mathbb{R}^{2k}; |l_i| \leq 1 \text{ for all } i, \text{ card}\{i : |l_i| = 1\} \geq k\}. \tag{3.20}$$

Lemma 3.7 ([15, Lemma 4.5]). *V_k has the genus of $k+1$.*

Lemma 3.8. *Let (V_0), (F_1) and (F_2) be satisfied. Then for each $k \in \mathbb{N}$, there exists an $A_k \subseteq E$ with genus $\sigma(A_k) = k+1$ such that $\sup_{u \in A_k} \Phi(v) < 0$.*

Proof. Let $\mu_k, x_{k,i}$ and ρ_k with $k \geq k_0$ be given in assumption (F_2). Since $\Gamma_k \subset \Gamma_{k-1}$ by definition, it is enough to construct an $A_k \in \Gamma_k$ for $k \geq k_0$ such that $\sup_{u \in A_k} \Phi(u) < 0$. Fix $k \geq k_0$. Instead of $\mu_k, x_{k,i}$ and ρ_k we write μ, x_i and ρ for simplicity. Using $\overline{F}$ and $\underline{F}$ given by (1.1) and (1.2) respectively, we define

$$\overline{F}_i := \overline{F}(x_i, \mu, \rho), \qquad \underline{F}_i := \underline{F}(x_i, \mu, \rho),\ 1 \leq i \leq 2k.$$

It follows from (1.1) and (1.2) and for $x \in B(x_i, \rho)$, that

$$F(x,\mu) \geq \frac{1}{\rho^2}\overline{F}_i (H^{-1}(\mu))^2 \geq \frac{1}{\rho^2}\overline{F}_i \mu^2, \tag{3.21}$$

$$F(x, l(\mu)) \geq \frac{1}{\rho^2}\underline{F}_i (H^{-1}(\mu))^2 \geq \frac{1}{\rho^2}\underline{F}_i \mu^2, \qquad |l| \leq 1. \tag{3.22}$$

We define a function $\varphi(t)$ on $\mathbb{R}$ by $\varphi(t) = 1$ for $|t| \leq 1/2$, $\varphi(t) = 2(1-|t|)$ for $1/2 \leq |t| \leq 1$, $\varphi(t) = 0$ for $|t| \geq 1$. Put $\varphi_i(x) = \varphi(|x - x_i|/\rho)$ for $x \in \mathbb{R}^N$. Then $\varphi_i \in W^{1,\infty}(\mathbb{R}^N)$. Define $B_i := B(x_i, \rho)$ and $D_i := B(x_i, \rho/2)$. Then $0 \leq \varphi_i(x) \leq 1$ in $\mathbb{R}^N$, $\varphi_i(x) = 0$ for $x \in \mathbb{R}^N \backslash B_i$ and

$$\varphi_i(x) = 1 \quad \text{for } x \in D_i, \quad |\nabla \varphi_i(x)| \leq \frac{2}{\rho} \quad \text{for } x \in \mathbb{R}^N. \tag{3.23}$$

Let V_k be given by (3.20). We define

$$A_k := \left\{ \mu \sum_{i=1}^{2k} l_i \varphi_i(x) :\ (l_1, \dots, l_{2k}) \in V_k \right\}.$$

Since all the supports of φ_i $(1 \leq i \leq 2k)$ are disjoint, they are linearly independent. Define $g(l_1, \dots, l_{2k}) := \mu \sum_{i=1}^{2k} l_i \varphi_i(x)$. Then g is a mapping from V_k onto A_k and it is an odd homeomorphism. By Lemma 3.7, the genus of V_k is $k+1$ and so is A_k. Thus $A_k \in \Gamma_k$.

We shall show that $\sup_{A_k} \Phi(v) < 0$. Fix $(l_1, \dots, l_{2k}) \in V_k$ arbitrary. Let $v := \mu \sum_{i=1}^{2k} l_i \varphi_i(x) \in A_k$ and $\mu \in (0, \frac{1}{2\sqrt{6}}\delta)$ be arbitrary. Since the support of φ_i is $\overline{B_i}$ and $B_i \cap B_j = \emptyset$ for $i \neq j$, we have

$$\begin{aligned}
\Phi(v) &= \frac{1}{2}\int_{\mathbb{R}^N} (|\nabla v|^2 + V_0(x)(H^{-1}(v))^2)dx - \int_{\mathbb{R}^N} \widetilde{F}_0(x, H^{-1}(v))dx \\
&= \frac{1}{2}\int_{\mathbb{R}^N} (|\nabla v|^2 + V(x)(H^{-1}(v))^2)dx - \int_{\mathbb{R}^N} \widetilde{F}(x, H^{-1}(v))dx \\
&= \sum_{i=1}^{2k} \int_{B_i} \frac{1}{2}\mu^2 |l_i|^2 |\nabla \varphi_i|^2 dx - \sum_{i=1}^{2k} \int_{B_i} F(x, H^{-1}(\mu l_i \varphi_i))dx.
\end{aligned}$$

By the assumption (V_0) and (3.23), we have

$$\Phi(v) \leq 4k\omega\mu^2\rho^{N-2} - \sum_{i=1}^{2k} \int_{B_i} F(x, H^{-1}(\mu l_i \varphi_i))dx. \tag{3.24}$$

To estimate the second term, we define

$$\Lambda_1 := \{i \in \{1, \dots, 2k\} : |l_i| = 1\},$$
$$\Lambda_2 := \{i \in \{1, \dots, 2k\} : |l_i| < 1\}.$$

By the definition of V_k, the cardinal number of Λ_1 greater than or equal to k. We compute the integral of F on B_i for $i \in \Lambda_1$, and for $i \in \Lambda_2$, separately. Recall that $F(x, v)$ is even with respect to v and $\varphi_i(x) = 1$ on D_i. Clearly, the volume of D_i is $2^{-N}\omega\rho^N$. By (3.21) and (3.22), we obtain, for $i \in \Lambda_1$,

$$\begin{aligned}\int_{B_i} F(x, H^{-1}(\mu l_i\varphi_i))dx &= \int_{D_i} F(x, H^{-1}(\mu))dx + \int_{B_i\setminus D_i} F(x, H^{-1}(\mu l_i\varphi_i))dx \\ &\geq 2^{-N}\omega\mu^2\rho^{N-2}\overline{F}_i + (1 - 2^{-N})\omega\mu^2\rho^{N-2}\underline{F}_i.\end{aligned} \tag{3.25}$$

We define

$$\alpha := \min_{1\leq i\leq 2k} \overline{F}_i, \quad \beta := \min_{1\leq i\leq 2k} \underline{F}_i.$$

As stated after (1.2), it holds that $\underline{F}_i \leq 0$, and hence $\beta \leq 0$. We rewrite (1.3) as

$$\alpha + (2^{N+1} - 1)\beta > 2^{N+2}. \tag{3.26}$$

We reduce (3.25) to

$$\int_{B_i} F(x, \mu l_i\varphi_i)dx \geq \left[2^{-N}\alpha + (1 - 2^{-N})\beta\right]\omega\mu^2\rho^{N-2}.$$

The right hand side is positive because of (3.26) with $\beta \leq 0$. Recall that the cardinal number of Λ_1 is greather than ou equal to k. Summing up both sides of the inequality above over $i \in \Lambda_1$, we obtain

$$\sum_{i\in\Lambda_1} \int_{B_i} F(x, \mu l_i\varphi_i)dx \geq \left[2^{-N}\alpha + (1 - 2^{-N})\beta\right]k\omega\mu^2\rho^{N-2}. \tag{3.27}$$

Next, by (3.22), for $i \in \Lambda_2$, we have

$$\int_{B_i} F(x, \mu l_i\varphi_i)dx \geq \omega\mu^2\rho^{N-2}\underline{F}_i \geq \beta\omega\mu^2\rho^{N-2}. \tag{3.28}$$

Recall that the cardinal number of Λ_2 is less than or equal to k. Summing up both sides over $i \in \Lambda_2$ and using $\beta \leq 0$, we find

$$\sum_{i\in\Lambda_2} \int_{B_i} F(x, \mu l_i\varphi_i)dx \geq k\beta\omega\mu^2\rho^{N-2}. \tag{3.29}$$

The set Λ_2 may be empty. In this case, we consider the left hand side to be zero. Then the inequality above is still valid because $\beta \leq 0$. Substituting (3.27) and (3.29) into (3.24) and using (3.26), we obtain

$$\Phi(v) \leq -\left[\alpha(2^{N+1} - 1) + \beta - 2^{N+2}\right]k\omega\mu^2\rho^{N-2} < 0,$$

which implies that $\sup_{v\in A_k} \Phi(v) < 0$. □

In order to prove our main results, we further need the following lemma.

Lemma 3.9. *If $\{v_k\}$ is a critical point sequence of Φ satisfying $v_k \to 0$ in E as $k \to \infty$, then $v_k \to 0$ in $L^\infty(\mathbb{R}^N)$ as $k \to \infty$.*

Proof. Let $v \in E$ be a weak solution of ($\widetilde{QSE}$), i.e.,

$$\int_{\mathbb{R}^N} \nabla v \nabla \varphi dx + \int_{\mathbb{R}^N} V(x) \frac{H^{-1}(v)}{h(H^{-1}(v))} \varphi dx - \int_{\mathbb{R}^N} \frac{\widetilde{f}(x, H^{-1}(v))}{h(H^{-1}(v))} \varphi dx \quad \text{for all } \varphi \in C_0^\infty(\mathbb{R}^N). \tag{3.30}$$

Set $T > 0$, and denote

$$v_T := \begin{cases} -T, & \text{if } v \le T, \\ v, & \text{if } -T < v < T, \\ T, & \text{if } v \ge T. \end{cases} \tag{3.31}$$

Taking $\varphi = |v_T|^{2(\eta-1)} v_T$ as the text function, where $\eta > 1$ to be determined later, we obtain

$$\begin{aligned} &\int_{\mathbb{R}^N} |v_T|^{2(\eta-1)} \nabla v \nabla v_T dx + 2(\eta - 1) \int_{\mathbb{R}^N} |v_T|^{2(\eta-1)-1} \nabla v \nabla v_T dx \\ &\quad + \int_{\mathbb{R}^N} V(x) \frac{H^{-1}(v)}{h(H^{-1}(v))} |v_T|^{2(\eta-1)} v_T dx \\ &= \int_{\mathbb{R}^N} \frac{\widetilde{f}(x, H^{-1}(v))}{h(H^{-1}(v))} |v_T|^{2(\eta-1)} v_T dx. \end{aligned} \tag{3.32}$$

By using the facts

$$(\eta - 1) \int_{\mathbb{R}^N} |v_T|^{2(\eta-1)-1} \nabla v \nabla v_T dx \ge 0,$$
$$\int_{\mathbb{R}^N} V(x) \frac{H^{-1}(v)}{h(H^{-1}(v))} |v_T|^{2(\eta-1)} v_T dx \ge 0$$

and Lemma 2.1, we have

$$\frac{1}{\eta^2} \int_{\mathbb{R}^N} |\nabla |v_T|^\eta|^2 dx \le \int_{\mathbb{R}^N} \frac{\widetilde{f}(x, H^{-1}(v))}{h(H^{-1}(v))} |v_T|^{2\eta-1} dx \le a_2 \int_{\mathbb{R}^N} |v|^{2\eta-1} dx. \tag{3.33}$$

On the other hand, it follows from the Sobolev inequality that

$$\frac{S}{\eta^2} \|v_T\|_{2^*\eta}^{2\eta} \le \frac{1}{\eta^2} \int_{\mathbb{R}^N} |\nabla |v_T|^\eta|^2 dx, \tag{3.34}$$

where $S = \inf\{\int_{\mathbb{R}^N} |\nabla v|^2 dx \setminus \int_{\mathbb{R}^N} |v|^{2^*} dx = 1\}$ and $2^* = 2N/(N-2)$. In what follows, by (3.33) and (3.34), we get

$$\frac{1}{\eta^2} \|v_T\|_{2^*\eta}^{2\eta} \le a_2 \int_{\mathbb{R}^N} |v|^{2\eta-1} dx. \tag{3.35}$$

From Fatou's lemma, sending $T \to \infty$ in (3.35), it follows that

$$\|v\|_{2^*\eta} \le (c\eta)^{1/\eta} \|v\|_{2\eta-1}^{(2\eta-1)/2\eta}. \tag{3.36}$$

Let us define $\eta_k := \frac{2^*\eta_k - 1}{2}$, where $k = 1, 2, \ldots.$ and $\eta_0 = \frac{2^*-1}{2}$. Next, we present the first step of Moser's iteration, which is shown below:

$$\|v\|_{\eta_1 2^*} \le (C\eta_1)^{1/\eta_1} \|v\|_{2\eta_1-1}^{(2\eta_1-1)/2\eta_1} \tag{3.37}$$
$$\le (C\eta_1)^{1/\eta_1} (C\eta_0)^{1/\eta_0(2\eta_1-1)/2\eta_1} \|v\|_{2\eta_0-1}^{(2\eta_0-1)/2\eta_0(2\eta_1-1)/2\eta_1}. \tag{3.38}$$

We can assume, without loss of generality, that $C > 1$. Moreover, for any $i < j$, we we have the inequality given by equation

$$(C\eta_i)^{(2\eta_j-1)/2\eta_j} \le C\eta_j. \tag{3.39}$$

Using equations (3.37) and (3.39), we obtain the inequality

$$\|v\|_{\eta_1 2^*} \le (C\eta_1)^{1/\eta_1}(C\eta_0)^{1/\eta_0}\|v\|_{2\eta_1-1}^{(2\eta_0-1)/p\eta_0(2\eta_1-1)/2\eta_1}.$$

Applying Moser's iteration method, we can now derive the following result.

$$\|v\|_{2\eta_{k+1}-1} \le \exp\left(\sum_{i=0}^{k}\frac{\ln(C\eta_i)}{\eta_i}\right)\|v\|_{2^*}^{\mu_k},$$

where $\mu_k = \Pi_{i=0}^{k}\frac{2\eta_i-1}{2\eta_i}$. Taking the limit as $k\to\infty$, we obtain the following result.

$$\|v\|_\infty \le \exp\left(\sum_{i=0}^{k}\frac{\ln(C\eta_i)}{\eta_i}\right)\|v\|_{2^*}^{\mu},$$

where $\mu = \Pi_{i=0}^{k}\frac{2\eta_i-1}{2\eta_i}$ $(0<\mu<1)$ and $\exp\left(\sum_{i=0}^{k}\frac{\ln(C\eta_i)}{\eta_i}\right)$ is a positive constant. This, together with the Sobolev embedding theorem, we can conclude that if v_k is a sequence of critical points of Φ such that $v_k \to 0$ strongly in E as $k\to\infty$, then v_k converges strongly to zero in $L^\infty(\mathbb{R}^N)$. □

Now we are in the position to give the proofs of our main results.

4 Proofs of Theorem 1.1 and Corollaries 1.3–1.6

The aim of this section is to establish the proofs of Theorem 1.1 and Corollaries 1.3–1.6.

4.1 Proof of Theorem 1.1

Lemmas 3.6, 3.7 and 3.8 shows that the functional Φ satisfies conditions (1) and (2) in Theorem 3.4. Therefore, there exist a sequence of nontrivial critical points (u_k) of Φ such that $\Phi(u_k) \le 0$ for all $k\in\mathbb{N}$ and $u_k \to 0$ in E as $k\to\infty$. By virtue of Lemma 3.5, $\{u_k\}$ is a sequence of solutions of $(\widetilde{QSE})$ with $u_k\to 0$ in E as $k\to\infty$. Hence, there exists $k_0\in\mathbb{N}$ such that u_k is a solution of (QSE) for each $k \ge k_0$.

4.2 Proof of Corollary 1.3 and 1.4

It is enough to show that (1.5) and (1.6) $\Rightarrow$ (1.4) $\Rightarrow$ (1.3). Impose (1.5) and (1.6). Then we shall construct $\mu_k, x_{k,i}$ and ρ_k satisfying (1.3). Fix k arbitrarily. Let C_n be the inscribed cube in $B(v_n,\rho_n)$. Then its edge has the length of $2\rho_n/\sqrt{N}$. Let q be the smallest positive integer satisfying $q^N \ge 2k$. We divide the cube $\mathcal{C}_n$ equally into q^N small cubes by planes parallel to each face of $\mathcal{C}_n$ and denote them by $\mathcal{C}_{n,i}$ with $1\le i\le q^N$. More precisely, denote C_n by

$$C_n := [0,a]\times\cdots\times[0,a] \quad \text{with } a := 2\rho_n/\sqrt{N}.$$

Put $I_j := [a(j-1)/q, aj/q]$ with $1\le j\le q$ and define

$$I(j_1,\ldots,j_N) := I_{j_1}\times\cdots\times I_{j_N} \quad \text{with } 1\le j_1,\ldots,j_N\le q.$$

This, is a cube in $\mathbb{R}^N$ and C_n is the union of all these cubes. We rename all $I(j_1, \ldots, j_N)$ to $C_{n,i}$ with $1 \le i \le q^N$. Then the edge of each $C_{n,i}$ has the length of $2\rho_n/q\sqrt{N}$. Denote the inscribed ball in $C_{n,i}$ by $B(x_{n,i}, r_n)$. Then $r_n = \rho/q\sqrt{N}$. Since $q^N \ge 2k$, $x_{n,i}$ is defined for all $1 \le i \le 2k$.

We shall show that assumption (F_2) is fulfilled with μ_k, $x_{k,i}$ and ρ_k replaced by $u_n, x_{n,i}$ and r_n, respectively, if n is large enough. It is clear that $B(x_{n,i}, r_n) \subset B(0,1)$ and $B(x_{n,i}, r_n) \cap B(x_{n,j}, r_n) = \emptyset$ when $i \ne j$. Define $M_n := \overline{F}(v_n, u_n, \rho_n)$, which implies that

$$\frac{F(x,u_n)}{u_n^2}\rho_n^2 \ge M_n \quad \text{for } x \in B(v_n, \rho_n).$$

By (1.6), there exists a $c \ge 0$ such that

$$\frac{F(x,lu_n)}{u_n^2}\rho_n^2 \ge -c \quad \text{for } x \in B(v_n, \rho_n),\ 0 \le l \le 1.$$

Then we obtain (1.4). On the other hand, substituting $\rho_n = q\sqrt{N}\,r_n$ in the two inequalities above, we have

$$\frac{NF(x,u_n)}{u_n^2}q^2r_n^2 \ge M_n, \qquad \frac{NF(x,lu_n)}{u_n^2}q^2r_n^2 \ge -c,$$

for $x \in B(v_n, \rho_n)$ and $0 \le l \le 1$. Since $B(x_{n,i}, r_n) \subset B(v_n, \rho_n)$, the inequalities above are valid for $x \in B(x_{n,i}, r_n)$ also. Taking the infimum on $B(x_{n,i}, r_n)$, we have

$$\overline{F}(x_{n,i}, u_n, r_n) \ge \frac{M_n}{Nq^2}, \qquad \underline{F}(x_{n,i}, u_n, r_n) \ge -\frac{c}{Nq^2}.$$

Then we get

$$\min_{1\le i\le 2k} \overline{F}(x_{n,i}, u_n, r_n) + (2^{N+1}-1) \min_{1\le i\le 2k} \underline{F}(x_{n,i}, u_n, r_n) \ge \frac{1}{Nq^2}\left(M_n - (2^{N+1}-1)c\right).$$

Since $\lim_{n\to\infty} M_n = \infty$ by (1.5), the right hand side is larger than 2^{N+2} for n large enough.

4.3 Proof of Corollary 1.5

To prove this corollary, it is enough to show that the assumption (F) implies (1.5) and (1.6). By (F) there exists a sequence u_n converging to zero such that

$$\inf_{x\in B(x_0,r_0)} u_n^{-2}F(x,u_n) \to \infty \quad \text{as } n \to \infty.$$

Put $B(x_n, r_n) := B(x_0, r_0)$ for all n. Then the above inequality shows (1.5). Also, by (F), there exists a constant $c \ge 0$ such that

$$\inf_{x\in B(x_0,r_0)} u^{-2}F(x,u) \ge -c \quad \text{for } 0 < |u| \le 1.$$

Putting $u := lu_n$, we find

$$\inf_{x\in B(x_0,r_0)} (lu_n)^{-2}F(x,lu_n) \ge -c \quad \text{for all large } n \text{ and } 0 < l \le 1,$$

which leads to

$$\inf_{x\in B(x_0,r_0)} u_n^{-2}F(x,lu_n) \ge -cl^2 \ge -c.$$

Therefore (1.6) holds.

4.4 Proof of Corollary 1.6

We observe that (1.7) implies (F). Therefore, Corollary 1.5 yields Corollary 1.6.

5 Example

For the reader's convenience, we present one example to illustrate our main results.

Let

$$V(x) = \begin{cases} 0 \text{ if } |x| \leq p, \\ (p^2+1)^2(|x|-p), \text{ if } p \leq |x| < p + \frac{1}{p^2+1}, \\ p^2+1, \text{ if } p + \frac{1}{p^2+1} \leq |x| < p + \frac{p^2}{p^2+1}, \\ (p^2+1)^2(p+1-|x|), \text{ if } p + \frac{p^2}{p^2+1} \leq |x| < p+1, \end{cases}$$

and

$$F(x,u) = \frac{a}{s}|u|^s - \frac{d(x)}{r}|u|^r, \tag{5.1}$$

where $p \in \mathbb{N}^*$, and s, r, a are constants satisfying $1 < r < 2,\ 1 < s < \frac{2}{3}(r+1),\ a > 0$ and

$$d(x) := \inf\{|x-y| : y \in \partial B(0,1)\}.$$

Then V is neither of constant sign nor periodic. Moreover, we have

$$\inf_{x \in B(x_0,r_0)} \frac{F(x,u)}{u^2} = \frac{a}{s}|u|^{-(2-s)} - \frac{D}{r}|u|^{-(2-r)} \to -\infty \quad \text{as } u \to 0,$$

for any $B(x_0,r_0) \subset B(0,1)$, where $D := \max_{|x-x_0| \leq r_0} d(x) > 0$. Which implies that the assumption (C_2) and (C_2') are not satisfied. Now, we show that V and F match Theorem 1.1. Indeed, it is clear that $V(x)$ and $F(x,u)$ satisfy (V_0) and (F_1) respectively. It remains to check that $F(x,u)$ satisfies (F_2). For this purpose we assume that there exists a $\delta > 0$ such that for each $k \in \mathbb{N}$, there exist points $\xi_i \in \partial B(0,1)$ with $1 \leq i \leq 2k$ which satisfy $|\xi_i - \xi_j| \geq 4\delta/k$ for $i \neq j$, and δ is independent of k. Indeed, for example, choose a smooth curve on $\partial B(0,1)$ such that $g : [0,1] \to \partial B(0,1)$ is a C^1-diffeomorphism from $[0,1]$ onto $g([0,1])$. Since g^{-1} is Lipschitz continuous, there exists a $c_0 > 0$ such that $|g(t) - g(s)| \geq c_0|t-s|$ for $t, s \in [0,1]$. Put $\xi_i := g(i/2k)$ with $1 \leq i \leq 2k$. Then we have for $i \neq j$,

$$|\xi_i - \xi_j| = |g(i/2k) - g(j/2k)| \geq c_0|(i-j)/2k| \geq c_0/2k.$$

Define $\delta := c_0/8$. Then $|\xi_i - \xi_j| \geq 4\delta/k$ for $i \neq j$ and δ is independent of k.

Put $\rho_k := \delta/k$. For each $1 \leq i \leq 2k$, there exists a unique point $x_i \in B(0,1)$ such that $B(x_i,\rho_k) \subset B(0,1)$ and $\partial B(x_i,\rho_k) \cap \partial B(0,1) = \{\xi_i\}$, after replacing δ by a small constant if necessary. Since $|\xi_i - \xi_j| \geq 4\delta/k$ for $i \neq j$, $B(x_i,\rho_k) \cap B(x_j,\rho_k) = \emptyset$ for $i \neq j$. Since $d(x) \leq 2\rho_k$ in $B(x_i,\rho_k)$, we have

$$F(x,u) \geq \frac{a}{s}|u|^s - \frac{2}{r}|u|^r\rho_k \quad \text{for } x \in B(x_i,\rho_k). \tag{5.2}$$

Define θ as follows

$$\frac{2}{2-s} < \theta < \frac{s}{2(s-r)} + 1 \quad \text{when } s > r, \tag{5.3}$$

$$\frac{2}{2-s} < \theta \quad \text{when } s \le r. \tag{5.4}$$

It follows from (5.3) and (5.4) and $1 < s < 2(r+1)/3$ that

$$-(2-s)\theta + 2 < 0, \qquad -(2-s)\theta + 2 < -(2-r)\theta + 3. \tag{5.5}$$

We define $\mu_k := \rho_k^\theta$. Let us compute $\overline{F}$ defined by (1.1). Using (5.2), we have

$$\overline{F}(x_i, \mu_k, \rho_k) \ge \frac{a}{s}\rho_k^{-(2-s)\theta+2} - \frac{2}{r}\rho_k^{-(2-r)\theta+3} \to \infty, \tag{5.6}$$

as $k \to \infty$ by (5.5). Using (5.2) and $\mu_k := \rho_k^\theta$, we compute

$$\frac{F(x, m\mu_k)}{\mu_k^2}\rho_k^2 \ge \frac{am^s}{s}\rho_k^{-(2-s)\theta+2} - \frac{2m^r}{r}\rho^{-(2-r)\theta+3}, \tag{5.7}$$

for $x \in B(x_i, \rho_k)$ and $0 \le m \le 1$. We put

$$\alpha_k := a\rho_k^{-(2-s)\theta+2}, \qquad \beta_k := 2\rho_k^{-(2-r)\theta+3}$$

and denote the right hand side of (5.7) by

$$g_k(m) := \frac{\alpha_k}{s}m^s - \frac{\beta_k}{r}m^r \quad \text{for } m \in [0,1].$$

We shall show that $g_k(m)$ is bounded from below by a constant independent of k and $m \in [0,1]$. By (5.6), $g_k(1) > 0$ for $k \ge k_0$ with a large k_0. We divide the proof into two cases.

- $s > r$. Then $g_k(m)$ achieves a negative minimum in $[0,1]$, which is computed as

  $$\min_{0\le m\le 1} g_k(m) = -\frac{s-r}{sr}\alpha_k^{-\frac{r}{s-r}}\beta_k^{\frac{s}{s-r}} = -\frac{s-r}{sr}2^{\frac{s}{s-r}}a^{-\frac{r}{s-r}}\rho_k^\nu,$$

  where
  $$\nu = \frac{1}{s-r}\Big(-2(s-r)\theta + 3s - 2r\Big).$$
  Then $\nu > 0$ because of (5.3). Thus, the minimum of g_k converges to zero as $k \to \infty$.

- $s \le r$. Since $m^s \ge m^r$, we have $g_k(m) \ge \Big((\alpha_k/s) - (\beta_k/r)\Big)m^s \ge 0$ for $k \ge k_0$ and $m \in [0,1]$.

By Cases 1 and 2, we have the inequality $g_k(m) \ge -c$ with some $c \ge 0$ independent of k and $m \in [0,1]$, which shows that $\underline{F}(x_i, \mu_k, \rho_k) \ge -c$ for all $1 \le i \le 2k$ and $k \in \mathbb{N}$. This estimate with (5.6) shows (1.3) for all large k.

Acknowledgements

We would like to express our gratitude to the editor and the anonymous reviewers for their valuable comments and suggestions, which have greatly improved the quality of this paper.

Abstract. In this paper, we investigate the existence of ground state solution to a class of Schrödinger equation involving logarithmic nonlinearity. To overcome the lack of smoothness, the corresponding functional J is first decomposed into the sum of a C^1 functional and a convex lower semicontinuous functional by adapting to the approach of Squassina–Szulkin in [*Calc. Var. Partial Differential Equations* **54**(2015), 585–597]. Secondly, the existence of a ground state solution to the studied equation is proved by using the Mountain Pass Theorem under the weakened Ambrosetti–Rabinowitz conditions.

Keywords: Schrödinger equations, ground state solution, logarithmic nonlinearity, Mountain Pass Theorem.

Mathematics Subject Classification 35J35, 35J62, 35J75, 35D30.

1 Introduction

In this paper, we consider the following Schrödinger equation involving logarithmic nonlinearity

$$\begin{cases} -\Delta u + V(x)u = Q(x)u\log u^2 + f(x,u), & \text{in } \mathbb{R}^N, \\ u \in H^1(\mathbb{R}^N), \end{cases} \tag{1.1}$$

where $N \geq 1$, the external potential $V(x)$, the term $Q(x)$ and $f(x,u)$ are continuous functions and satisfy certain properties given later.

The Schrödinger equation was first proposed by the Austrian physicist E. Schrödinger. As a more complex nonlinear Schrödinger equation, it is derived from the following classical model

$$i\partial_t\Psi + \Delta\Psi - (V(x) + w)\Psi + f(|\Psi|) = 0. \tag{1.2}$$

The solution Ψ is called the standing wave solution of (1.2). Standing wave phenomenon refers to the phenomenon that electromagnetic waves can stay in a fixed position in some media without propagating and forming a resident electromagnetic field. Its application is widely reflected in our daily lives, such as magnetic resonance imaging to scan and image the

internal structure of the human body. Applied to optical filters that allow specific wavelengths of light to pass through for spectral analysis and filtering. It is used in the field of acoustic standing wave cancellers to reduce noise and quantum mechanics theory. The interference function f in (1.2) is a nonlinear term, it can also be used to describe a variety of nonlinear waves in quantum physics, such as laser beam propagation in the medium with refractive index and wave amplitude, ionic sound wave in plasma, etc, see [4, 23] and the references therein. At present, many scholars have studied the existence and multiplicity of solutions to Schrödinger equation, see [2, 5, 6, 8–11, 14, 18, 19, 21, 22, 25, 26, 28–31] and the references therein for an overview on the related topic.

The logarithmic Schrödinger equation

$$i\partial_t \Psi + \Delta\Psi + \Psi \log |\Psi|^2 = 0, \quad \Psi : [0, +\infty) \times \mathbb{R}^N \to \mathbb{C}, \quad N \geq 3, \tag{1.3}$$

possesses wide applications to quantum mechanics, nuclear physics, open quantum systems, effective quantum gravity, transport and diffusion phenomena, theory of superfluidity and Bose–Einstein condensation, see [32] and the references therein. We refer to [7, 12] for a study of the existence and uniqueness of the solutions of the associated Cauchy problem in some suitable condition as well as the global existence and blow-up of the solutions. On the other hand, many researchers are interested in the existence, multiplicity and qualitative properties of the standing waves solution of problem (1.3). Consider the following Schrödinger equation with logarithmic nonlinear terms

$$-\Delta u + V(x)u = Q(x)u \log u^2, \qquad x \in \mathbb{R}^N. \tag{1.4}$$

When $V(x) = Q(x) = 1$, Avenia–Montefusco–Squassina [13] proved that there are infinitely many solutions to equation (1.4) by introducing weak slope and using non-smooth critical point theory. Ji–Szulkin [16] proved the existence of infinitely many solutions to equation (1.4) by Fountain theorem in the case which $Q(x) = 1$ and potential function $V(x)$ satisfies the mandatory condition, that is $\lim_{|x|\to+\infty} V(x) = +\infty$. In addition, Shuai [20] used the constraint minimization method to obtain the existence of positive solutions and node solutions of equation (1.4) under different assumptions of potential function $V(x)$. When $V(x)$ and $Q(x)$ are 1-period, Squassina–Szulkin [22] investigated the existence of infinitely many different solutions to problem (1.4) by applying non-smooth critical point theory and $\mathbb{Z}_2$ index theory, and the existence of ground state solutions of problem (1.4) was proved .

Through the analysis of the above mentioned results, as far as we know, there is few corresponding result if $V(x) \neq 1$, $Q(x) \neq 1$ and $V(x)$, $Q(x)$ are not 1-period in equation (1.4). Therefore, **a natural question is whether the equation (1.4) plus the disturbance term $f(x, u)$ can also obtain the ground state solution through the Mountain Pass Theorem with the weakened Ambrosetti–Rabinowitz conditions?** There are two key difficulties in the proof process, one is that the energy functional is not well defined and not C^1 smooth, the other is to prove the existence of the ground state solution when the Ambrosetti–Rabinowitz condition (for short AR-condition) is not satisfied.

For convenience, in this paper, it is assumed that the potential function V and the disturbance term f satisfy the following conditions:

(V1) The potential function $V(x) \in \mathcal{C}(\mathbb{R}^N, [0, +\infty))$, and there exists a constant $a_0 > 0$ such that $|\{x \in \mathbb{R}^N : V(x) \leq a_0\}| < +\infty$;

(V2) $\mathrm{int}V^{-1}(0) \neq \emptyset, Q(x) \in \mathcal{C}'(\mathbb{R}^N, [0, +\infty)), \min(V(x) + Q(x)) \geq 1.$

(f1) The function $f(x,t) \in \mathcal{C}(\mathbb{R}^N \times \mathbb{R}, \mathbb{R})$, and for any $\varepsilon > 0$ there exist constants $C(\varepsilon) > 0$ and $p \in (2, 2^*)$ such that $|f(x,t)| \leq \varepsilon|t| + C(\varepsilon)|t|^{p-1}$, where $2^* := 2N/(N-2)$ if $N \geq 3$, $2^* := \infty$ if $N = 1$ or 2;

(f2) $\lim_{|t|\to+\infty} \frac{F(x,t)}{t^2} = +\infty$, where $F(x,t) = \int_0^t f(x,\tau)d\tau$;

(f3) There exist constants $\alpha > 2$ and θ with $0 < \theta < \frac{S(\alpha-2)}{4}$ (S be given in (2.9) below), such that
$$\lim_{|t|\to\infty} \inf \frac{f(x,t)t - \alpha F(x,t)}{|t|^2} > -\theta, \quad \text{uniformly for a.e. } x \in \mathbb{R}^N.$$

Our main result states as follows.

Theorem 1.1. *Assume that (V1)–(V2) and (f1)–(f3) hold. Then problem (1.1) admits a ground state solution.*

Remark 1.2. *By (f3), there exist constants $M > 0, \alpha > 2$ such that $uf(x,u) \geq \alpha F(x,u)$ for $|u| \geq M, (x,u) \in \mathbb{R}^N \times \mathbb{R}$. Thus,*
$$uf\,(x,u) - aF\,(x,u) \geq 0 \geq -\theta|u|^2.$$
Obviously, we can show that the AR-condition implies (f3), while the inverse implication fails.

Remark 1.3. *There exists extensively the disturbance term $f(x,u)$ which satisfies conditions (f1)–(f3) of Theorem 1.1. Such as, taking $N = 3$, $2^* = 6$, then $p \in (2,6)$, if $p = 4$ for all $x \in \mathbb{R}^3$ and*
$$f(x,t) = \frac{S}{3}|\sin x|\left(|t|t + \frac{1}{2}t\sin 2t\right),$$
where S be given by formula (2.9) below, then
$$F(x,t) = \frac{S}{3}|\sin x|\left(\frac{1}{3}|t|^3 - \frac{1}{4}t\cos 2t + \frac{1}{8}\sin 2t\right).$$
Set $\alpha = 3$, $\theta = \frac{S}{5}$, then
$$\begin{aligned} f(x,t)t - \alpha F(x,t) &= \frac{S}{3}|\sin x|\left(|t|^3 + \frac{1}{2}t^2\sin 2t - \frac{\alpha}{3}|t|^3 + \frac{\alpha}{4}t\cos 2t - \frac{\alpha}{8}\sin 2t\right) \\ &\geq \frac{S}{3}|\sin x|\left((1-\frac{\alpha}{3})|t|^3 - \frac{1}{2}|t|^2 - \frac{\alpha}{4}t - \frac{\alpha}{8}\right) \\ &= -\frac{S}{3}|\sin x|\left(\frac{1}{2}|t|^2 + \frac{3}{4}t + \frac{3}{8}\right) \\ &\geq -\frac{S}{3}\left(\frac{1}{2}|t|^2 + \frac{3}{4}t + \frac{3}{8}\right), \end{aligned}$$
which implies
$$\lim_{|t|\to\infty} \inf \frac{f(x,t)t - 3F(x,t)}{|t|^2} = \lim_{|t|\to\infty} \frac{-\frac{S}{3}\left(\frac{1}{2}|t|^2 + \frac{3}{4}t + \frac{3}{8}\right)}{|t|^2} = -\frac{S}{6} > -\theta.$$
Obviously $f(x,t)$ satisfies all the conditions of Theorem 1.1.

This paper is organized as follows. In Section 2, we present some preliminary results that will be used later. Section 3 is devoted to proving the existence of ground state solutions to problem (1.1).

Notation. From now on, otherwise mentioned, we use the following notations:

- C, C_1, C_2, C_3, etc. will denote positive constants, whose exact values are not relevant.
- $\|\cdot\|_k$ denotes the usual norm of the Lebesgue space $L^k(\mathbb{R}^N)$, for $k \in [1, +\infty]$.
- $o_n(1)$ denotes a real sequence with $o_n(1) \to 0$ as $n \to +\infty$.

2 Preliminaries

To prove Theorem 1.1, we need to present some notation and auxiliary lemmas, which will be crucial in dealing with ground state solutions of problem (1.1).

Towards problem (1.1), we define the space E as follows:

$$E := \left\{ u \in H^1(\mathbb{R}^N) : \int_{\mathbb{R}^N} (V(x) + Q(x))u^2 dx < +\infty \right\},$$

endowed with the following norm:

$$\|u\|_E := \left(\int_{\mathbb{R}^N} |\nabla u|^2 + (V(x) + Q(x))u^2 dx \right)^{\frac{1}{2}}, \qquad u \in E,$$

and the space E is a Hilbert space. Problem (1.1) has a variational structure and is properly associated with the energy functional $J : E \to \mathbb{R} \cup \{+\infty\}$ defined by

$$J(u) = \frac{1}{2}\|u\|_E^2 - \int_{\mathbb{R}^N} F(x,u)dx - \frac{1}{2}\int_{\mathbb{R}^N} Q(x)u^2 \log u^2 dx, \qquad u \in E. \tag{2.1}$$

One premise, the critical point of the energy functional J is the weak solution of the corresponding equation, is that the energy functional J can be well defined and smooth. But, in general, the logarithmic term may cause that the energy functional J fails to be finite and $\mathcal{C}^1$ smooth in $H^1(\mathbb{R}^N)$. Concretely, from [17], we have the following simple modification of the standard logarithmic Sobolev inequality:

$$\int_{\mathbb{R}^N} u^2 \log u^2 dx \le \frac{a^2}{\pi}\|\nabla u\|_2^2 + (\log \|u\|_2^2 - N(1 + \log a))\|u\|_2^2, \tag{2.2}$$

for any $u \in H^1(\mathbb{R}^N)$ and $a > 0$. It follows from (2.2) that $J(u) > -\infty$ for all $u \in H^1(\mathbb{R}^N)$, but there exists $u_* \in H^1(\mathbb{R}^N)$ with $\int_{\mathbb{R}^N} u_*^2 \log u_*^2 dx = -\infty$.

Recently, many scholars have tried to find some different techniques and methods to overcome the above given difficulty. For instance, in [7], Cazenave's main idea was to find a suitable Banach space endowed with a Luxemburg type norm. On account of the definition of Luxemburg type norm and some special properties, the functional $J(u)$ is finally well defined and $\mathcal{C}^1$ smooth. Another way to overcome it comes from [15], the authors penalize the nonlinearity term around the origin and obtain a priori estimates to get a nontrivial solution at the limit.

In what follows, by *a solution* to problem (1.1) we shall usually indicate a function $u \in H^1(\mathbb{R}^N)$ such that $u^2 \log u^2 \in L^1(\mathbb{R}^N)$ and

$$\int_{\mathbb{R}^N} (\nabla u \cdot \nabla v + V(x)uv)dx = \int_{\mathbb{R}^N} Q(x)uv \log u^2 dx + \int_{\mathbb{R}^N} f(x,u)v dx, \quad \text{for any } v \in \mathcal{C}_0^\infty(\mathbb{R}^N).$$

In this paper, we take the approach from [22], although $J(u)$ is not smooth, we split the functional $J(u)$ into the sum of a $\mathcal{C}^1$ functional and a convex lower semicontinuous functional. In order to split $J(u)$, we define the following two functions for $\delta > 0$:

$$F_1(s) = \begin{cases} 0, & s = 0, \\ -\frac{1}{2}s^2 \log s^2, & 0 < |s| \le \delta, \\ -\frac{1}{2}s^2(\log \delta^2 + 3) + 2\delta|s| - \frac{1}{2}\delta^2, & |s| > \delta, \end{cases}$$

and

$$F_2(s) = \begin{cases} 0, & |s| \le \delta, \\ -\frac{1}{2}s^2 \log(s^2/\delta^2) + 2\delta|s| - \frac{3}{2}s^2 - \frac{1}{2}\delta^2, & |s| > \delta. \end{cases}$$

Then $F_2(s) - F_1(s) = \frac{1}{2}s^2 \log s^2$ for all $s \in \mathbb{R}$. Thus, the functional $J : E \to (-\infty, +\infty]$ can be rewritten as

$$J(u) = \tilde{\Phi}(u) + \Psi(u), u \in E$$

where

$$\tilde{\Phi}(u) = \frac{1}{2}\|u\|_E^2 - \int_{\mathbb{R}^N} Q(x)F_2(u)dx - \int_{\mathbb{R}^N} F(x,u)dx \tag{2.3}$$

and

$$\Psi(u) = \int_{\mathbb{R}^N} Q(x)F_1(u)dx. \tag{2.4}$$

In the sequel, we list some properties about $F_1(s), F_2(s)$ that shall be useful for our proofs later, which were proved in [16,22].

Proposition 2.1. *If $\delta > 0$ is sufficiently small, then the following results are true:*

(i) $F_1(s), F_2(s) \in \mathcal{C}^1(\mathbb{R}, \mathbb{R})$.

(ii) The function $F_1(s)$ is convex, even, and

$$F_1(s) \ge 0, F_1'(s)s \ge 0, \qquad \forall s \in \mathbb{R}. \tag{2.5}$$

(iii) For each fixed $q \in (2, 2^*)$, there is a constant $C > 0$ such that

$$|F_2'(s)| \le C|s|^{q-1}, \qquad \forall s \in \mathbb{R}. \tag{2.6}$$

Hereafter, $\delta > 0$ is fixed and sufficiently small such that the above properties of F_1, F_2 hold.

Corollary 2.1. *Assume that (V1)–(V2) and (f1) hold, then $\tilde{\Phi} \in \mathcal{C}^1(E, \mathbb{R})$.*

Proof. Let $\Phi(u) = \frac{1}{2}\|u\|_E^2 - \int_{\mathbb{R}^N} Q(x)F_2(u)dx$, according to Lemma 3.10 in [27] and (2.5), it is easy to show that $\Phi \in \mathcal{C}^1(E, \mathbb{R})$. Since

$$\tilde{\Phi}(u) = \Phi(u) - \int_{\mathbb{R}^N} F(x,u)dx,$$

we just need to prove $\int_{\mathbb{R}^N} F(x,u)dx \in \mathcal{C}^1(E, \mathbb{R})$. By condition (f1), there holds

$$|F(x,t)| \le \frac{1}{2}\varepsilon|t|^2 + \frac{1}{p}C(\varepsilon)|t|^p, \tag{2.7}$$

which implies $\int_{\mathbb{R}^N} F(x,u)dx \in \mathcal{C}^1(E, \mathbb{R})$. Thus $\tilde{\Phi} \in \mathcal{C}^1(E, \mathbb{R})$. □

Corollary 2.2. *The functional Ψ admits the following properties:*

(i) The functional $\Psi(u)$ is convex, $\Psi \geq 0$ for all $u \in E$, and $\Psi(u) = +\infty$ for certain $u \in E$. Furthermore, Ψ (and hence J) is lower semicontinuous.

(ii) If $\Omega \subset \mathbb{R}^N$ is a bounded domain, then the functional Ψ (and therefore J) is of class $\mathcal{C}^1$ in $H^1(\Omega)$.

Proof. (i) By the definition of the function $F_1(s)$, we get $\Psi \geq 0$. Since $Q(x) > 0$ and $F_1(s)$ is convex, then for all $\lambda \in [0,1]$ and u_1, $u_2 \in E$, there holds

$$\begin{aligned}\Psi(\lambda u_1 + (1-\lambda)u_2) &= \int_{\mathbb{R}^N} Q(x)F_1(\lambda u_1 + (1-\lambda)u_2)dx \\ &\leq \lambda \int_{\mathbb{R}^N} Q(x)F_1(u_1)dx + (1-\lambda)\int_{\mathbb{R}^N} Q(x)F_1(u_2)dx \\ &= \lambda\Psi(u_1) + (1-\lambda)\Psi(u_2).\end{aligned}$$

This implies that Ψ is convex, and $\Psi(u) = +\infty$ for certain $u \in E$. Moreover, there exists $s_0 \in E$, for all sequence $\{s_n\}$ with $s_n \to s_0$ as $n \to +\infty$. It follows naturally from the Fatou's lemma that

$$\begin{aligned}\lim_{n\to+\infty} \inf \Psi(s_n) &= \lim_{n\to+\infty} \inf \left(\int_{\mathbb{R}^N} Q(x)F_1(s_n)\mathrm{d}x\right) \\ &\geq \int_{\mathbb{R}^N} \lim_{n\to+\infty} \inf Q(x)F_1(s_n)dx = \Psi(s_0).\end{aligned}$$

Thus Ψ is lower semicontinuous, and the functional J is also lower semicontinuous.

(ii) By the definition of the function $F_1(s)$, we have $|F_1'(s)| \leq C(1+|s|^{p-1})$ for $p \in (2, 2^*)$. Then it follows from Lemma 2.16 of [27] that the conclusion is true in $H_0^1(\Omega)$ but the argument remains valid in $H^1(\Omega)$. □

According to some arguments in [24] and by Corollary 2.1 and Corollary 2.2, we also give the following definition:

Definition 2.3. *Let E be a Banach space, E' be the dual space of E, and $\langle\cdot,\cdot\rangle$ be the duality pairing between E' and E. Let $J : E \to \mathbb{R}$ be a functional of the form $J(u) = \tilde{\Phi}(u) + \Psi(u)$, where $\tilde{\Phi} \in \mathcal{C}^1(E, \mathbb{R})$ and $\Psi(u)$ is convex and lower semicontinuous. Let us list some definitions:*

(1) The sub-differential $\partial J(u)$ of the functional J at a point $u \in E$ is the following set

$$\{w \in E' : \langle\tilde{\Phi}'(u), v-u\rangle + \Psi(v) - \Psi(u) \geq \langle w, v-u\rangle,\ \forall v \in E\}.$$

(2) A critical point of J is a point $u \in E$ such that $J(u) < +\infty$ and $0 \in \partial J(u)$, i.e.

$$\langle\tilde{\Phi}'(u), v-u\rangle + \Psi(v) - \Psi(u) \geq 0, \qquad \forall v \in E.$$

(3) A Palais–Smale sequence at level c for J is a sequence $\{u_n\} \subset E$ such that $J(u_n) \to c$ and there is a numerical sequence $\tau_n \to 0^+$ with

$$\langle\tilde{\Phi}'(u_n), v-u_n\rangle + \Psi(v) - \Psi(u_n) \geq -\tau_n\|v-u_n\|_E, \qquad \forall v \in E.$$

(4) The functional J satisfies the Palais–Smale condition at level c ($(PS)_c$ condition, for short) if all Palais–Smale sequences at level c have a convergent subsequence.

(5) The effective domain of J is the set $D(J) = \{u \in E : J(u) < +\infty\}$.

In the sequel, for each $u \in D(J)$, we set the following functional $J'(u) : H_c^1(\mathbb{R}^N) \to \mathbb{R}$ given by

$$\langle J'(u), z\rangle = \langle \tilde{\Phi}'(u), z\rangle + \int_{\mathbb{R}^N} Q(x)F_1'(u)zdx \quad \text{for any } z \in H_c^1(\mathbb{R}^N),$$

where $H_c^1(\mathbb{R}^N) := \{u \in H^1(\mathbb{R}^N) : \ u \text{ has compact support}\}$, and define

$$\|J'(u)\| = \sup\{\langle J'(u), z\rangle : z \in H_c^1(\mathbb{R}^N) \text{ and } \|z\|_E \leq 1\}.$$

Hence, $J'(u)$ can be extended to a bounded operator in E when $\|J'(u)\|$ is finite, and it may be seen as an element of E'.

In order to prove Theorem 1.1, we will use the following Lemma 2.4, whose proof can be found in Lemma 2.4 of [22] .

Lemma 2.4. *If $u \in D(J)$, then $\partial J(u) \neq \emptyset$, i.e. there exists $w \in E'$ such that*

$$\langle \Phi'(u), v-u\rangle + \Psi(v) - \Psi(u) \geq \langle w, v-u\rangle, \quad \textit{for all } v \in E.$$

Moreover, this w is unique and satisfies

$$\langle \Phi'(u), z\rangle + \int_{\mathbb{R}^N} Q(x)F_1'(u)zdx = \langle w, z\rangle, \quad \textit{for all } z \in E \textit{ such that } F_1'(u)z \in L^1(\mathbb{R}^N).$$

As an immediate consequence, we know that the unique element $w \in E'$ introduced in Lemma 2.4 will be denoted by $J'(u)$. Moreover, there holds

$$\langle J'(u), u\rangle = \int_{\mathbb{R}^N} (|\nabla u|^2 + V(x)|u|^2)dx - \int_{\mathbb{R}^N} Q(x)u^2 \log u^2 dx - \int_{\mathbb{R}^N} f(x,u)udx, \tag{2.8}$$

for each $u \in D(J)$ with $\|J'(u)\| < +\infty$. Thus solution of problem (1.1) is equivalent to a nontrivial critical point of the functional J.

Theorem 2.5 ([27, Theorem 1.8], Sobolev imbedding theorem)**.** *The following imbeddings are continuous:*

$$\begin{aligned} H^1(\mathbb{R}^N) &\hookrightarrow L^p(\mathbb{R}^N), \qquad 2 \leq p < \infty, N = 1,2,\\ H^1(\mathbb{R}^N) &\hookrightarrow L^p(\mathbb{R}^N), \qquad 2 \leq p \leq 2^*, N \geq 3,\\ D^{1,2}(\mathbb{R}^N) &\hookrightarrow L^{2^*}(\mathbb{R}^N), \qquad N \geq 3. \end{aligned}$$

According to the norm in the space E and $L^2(\mathbb{R}^N)$ respectively, we have $\|u\|_2^2 \leq \|u\|_E^2$. In particular, the best constant for the Sobolev embedding $E \hookrightarrow L^2(\mathbb{R}^N)$ is given by

$$S := \inf_{u \in E\setminus\{0\}} \frac{\|u\|_E^2}{\|u\|_2^2}. \tag{2.9}$$

3 Proof of Theorem 1.1

In what follows, we will show that the functional J satisfies the Mountain pass geometry. The following two conclusions can be found in Theorem 3.1 and Corollary 3.1 of [1], which are crucial in our approach.

Theorem 3.1 (Mountain Pass Theorem without (PS) condition)**.** *Let X be a real Banach space and $J : X \to \mathbb{R}$ be a functional such that:*

(i) $J(u) = \tilde{\Phi}(u) + \Psi_(u), u \in X$ *with* $\tilde{\Phi}(u) \in \mathcal{C}^1(X, \mathbb{R})$*, and* $\Psi : X \to \mathbb{R}$ *is convex,* $\Psi \not\equiv +\infty$ *and is lower semicontinuous (l.s.c);*

(ii) $J(0) = 0$ *and* $J|_{\partial B_\rho} \geq \alpha_0$*, for real constants* $\rho, \alpha_0 > 0$*;*

(iii) $J(e) \leq 0$*, for some* $e \notin \overline{B_\rho}(0)$*.*

If

$$c := \inf_{\gamma \in \Gamma} \sup_{t \in [0,1]} J(\gamma(t)) \geq \alpha_0 > 0, \qquad \Gamma = \{\gamma \in \mathcal{C}([0,1], X) : \gamma(0) = 0, J(\gamma(1)) < 0\}.$$

Then, for a given $\epsilon > 0$*, there is* $u_\epsilon \in X$ *such that*

$$\langle \tilde{\Phi}'(u_\epsilon), v - u_\epsilon \rangle + \Psi(v) - \Psi(u_\epsilon) \geq -3\epsilon \|v - u_\epsilon\|, \qquad \forall v \in X, \tag{3.1}$$

and $J(u_\epsilon) \in [c - \epsilon, c + \epsilon]$*.*

Corollary 3.2. *Under the conditions of Theorem 3.1, there is a* $(PS)_c$ *sequence* $\{u_n\}$ *of the functional* $J(u)$*, that is,* $J(u_n) \to c$ *and*

$$\langle \tilde{\Phi}'(u_n), v - u_n \rangle + \Psi(v) - \Psi(u_n) \geq -\tau_n \|v - u_n\|, \qquad \forall v \in X,$$

with $\tau_n \to 0^+$*.*

Lemma 3.3. *Assume that (V1)–(V2) and (f1)–(f2) hold. Then the functional* $J(u)$*, defined with* $\tilde{\Phi}(u)$ *and* $\Psi(u)$ *in* (2.3) *and* (2.4)*, has the Mountain pass geometry.*

Proof. Now we will show that the functional J satisfies (i), (ii) and (iii) of the Theorem 3.1.

(i) For each $u \in D(J)$, the functional $J(u)$ defined with $\tilde{\Phi}(u)$ and $\Psi(u)$ in (2.3)–(2.4), respectively. According to Corollary 2.1–2.2, then $\tilde{\Phi}(u) \in \mathcal{C}^1$, $\Psi(u)$ is a convex lower semicontinuous function and $\Psi \not\equiv +\infty$.

(ii) Obviously, $J(0) = 0$. It follows from (2.5)–(2.7), and embedding theorem that there holds

$$\begin{aligned}
J(u) &= \frac{1}{2}\|u\|_E^2 - \int_{\mathbb{R}^N} F(x,u)dx - \int_{\mathbb{R}^N} Q(x)F_2(u)dx + \int_{\mathbb{R}^N} Q(x)F_1(u)dx \\
&\geq \frac{1}{2}\|u\|_E^2 - \int_{\mathbb{R}^N} F(x,u)dx - \int_{\mathbb{R}^N} Q(x)F_2(u)dx \\
&\geq \frac{1}{2}\|u\|_E^2 - \frac{1}{2}\varepsilon \int_{R^N} |u|^2 dx - \frac{1}{p}C(\varepsilon) \int_{R^N} |u|^p dx - \int_{R^N} Q(x)F_2(u)dx. \\
&\geq \frac{1}{2}\|u\|_E^2 - \frac{1}{2}\varepsilon\|u\|_2^2 - \frac{1}{p}C(\varepsilon)\|u\|_p^p - CQ_\infty\|u\|_q^q \\
&\geq \frac{1}{2}\|u\|_E^2 - \frac{\varepsilon}{2S}\|u\|_E^2 - \frac{C(\varepsilon)}{pS^{\frac{p}{2}}}\|u\|_E^p - C_1Q_\infty\|u\|_E^q \\
&= \left(\frac{1}{2} - \frac{\varepsilon}{2S} - \frac{C(\varepsilon)}{pS^{\frac{p}{2}}}\|u\|_E^{p-2} - C_1Q_\infty\|u\|_E^{q-2}\right)\|u\|_E^2,
\end{aligned}$$

where $Q_\infty := |Q(x)|_\infty$ and C_1 is a positive constant. We may choose $\varepsilon = \frac{S}{2}$ and ρ sufficiently small (i.e. ρ is such that $\frac{1}{4} - \frac{C(\varepsilon)}{pS^{\frac{p}{2}}}\rho^{p-2} - C_1Q_\infty\rho^{q-2} > 0$), thus

$$J(u) \geq \left(\frac{1}{4} - \frac{C(\varepsilon)}{pS^{\frac{p}{2}}}\rho^{p-2} - C_1Q_\infty\rho^{q-2}\right)\rho^2 : = \alpha_0 > 0, \quad \text{for any } u \in \partial B_\rho.$$

(iii) We may choose $u_* \in D(J)$ with $u_* \geq 0$ and $\text{supp}(\phi) \subset B_R(0)$ for some $R > 0$. By the condition (f2) we know that there exist constants $C_2, C_3 > 0$, such that $|F(x,u)| \geq C_2|u|^2 - C_3$ for any $u \in \mathbb{R}^+$. Then let $e := tu_*$ for any $t > 0$, there holds

$$\begin{aligned} J(e) = J(tu_*) &= \frac{1}{2}\|tu_*\|_E^2 - \frac{1}{2}\int_{\mathbb{R}^N} Q(x)t^2u_*^2 \log(tu_*)^2 dx - \int_{\mathbb{R}^N} F(x,tu_*)dx \\ &\leq t^2\left(I(u_*) - \frac{1}{2}\int_{\mathbb{R}^N} Q(x)u_*^2 \log t^2 dx\right) - C_2t^2\left(\int_{B_R(0)} u_*^2 dx + \int_{\mathbb{R}^N\setminus B_R(0)} u_*^2 dx\right) + C_4 \\ &\leq t^2\left(I(u_*) - \log t\int_{\mathbb{R}^N} Q(x)u_*^2 dx - C_2\int_{B_R(0)} u_*^2 dx\right) + C_4 \\ &\to -\infty \quad \text{as } t \to +\infty, \end{aligned}$$

where $I(u_*) = \frac{1}{2}\|u_*\|_E^2 - \frac{1}{2}\int_{\mathbb{R}^N} Q(x)u_*^2 \log u_*^2 dx$ is the energy functional of (1.4). Therefore there exists enough large $t_0 > 0$ with $\|e\|_E = \|t_0u_*\|_E > \rho$, i.e. $e \notin \bar{B}_\rho(0)$ such that

$$J(e) = J(t_0u_*) \leq 0.$$

So the proof of Lemma 3.3 is now completed. □

By Theorem 3.1 and Lemma 3.3, $J(u)$ admits a $(PS)_c$ sequence, where c is the Mountain level of $J(u)$.

Lemma 3.4. *Assume that (V1)–(V2), and (f1)–(f3) hold, then all $(PS)_c$ sequence $\{u_n\}$ are bounded in E.*

Proof. If $\{u_n\}$ is unbounded in E, then we can take, passing to a subsequence if necessary, that $\|u_n\|_E > 1$. Since $\{u_n\} \subset E$ is a $(PS)_c$ sequence, then $\{J(u_n)\}$ is bounded above and $\langle J'(u_n), u_n\rangle \to 0$ as $n \to +\infty$. Thus

$$\langle J'(u_n), z\rangle = o_n(1)\|z\|_E, \qquad \forall z \in E.$$

Since $Q(x) > 0$, then take $\sqrt{Q(x)}u$ instead of u in (2.2), there yields

$$\begin{aligned} &\int_{\mathbb{R}^N} Q(x)u^2 \log(Q(x)u^2)dx \\ &\qquad \leq \frac{a^2}{\pi}\|\nabla(\sqrt{Q(x)}u)\|_2^2 + \left(\log\|\sqrt{Q(x)}u\|_2^2 - N(1+\log a)\right)\|\sqrt{Q(x)}u\|_2^2. \end{aligned} \tag{3.2}$$

From Lemma 2.2 of [3], there exists a positive constant C_5 such that

$$N(1+\log a)\|u\|_2^2 \leq (\log\|u\|_2^2)\|u\|_2^2 + C_5\|u\|_2^2. \tag{3.3}$$

Then taking $a > 0$ enough small, there exists a positive constant C_6 such that

$$\int_{\mathbb{R}^N} Q(x)u^2 \log u^2 dx \leq \frac{1}{2}\|\nabla u\|_2^2 + C_6(\log\|u\|_2^2 + 1)\|u\|_2^2. \tag{3.4}$$

We have exploited the fact that the function $t \to \log t$ $(t > 0)$ is increasing. Then for $r \in (0,1)$, there is a constant $C_7 > 0$ satisfying

$$|t\log t| \leq C_7(1 + |t|^{1+r}), \quad \text{for any } t > 0.$$

Therefore there exists a positive constant C_8 such that

$$\|u_n\|_2^2 \log(\|u_n\|_2^2) \le C_7(1 + (\|u_n\|_2^2)^{1+r}) \le C_8(1 + \|u_n\|_E)^{1+r}. \tag{3.5}$$

From (3.3)–(3.5) and Theorem 2.5, there holds

$$\int_{\mathbb{R}^N} Q(x)u^2 \log u^2 dx \le \frac{1}{2}\|\nabla u\|_2^2 + C_9(1 + \|u_n\|_E)^{1+r}, \tag{3.6}$$

where C_9 is a positive constant. By the condition (f3), there exists a constant $M_0 > 0$ with $|u| > M_0$ such that $f(x,t)t - \alpha F(x,t) \ge -\theta|t|^2$ for all $|t| > M_0$, $x \in \mathbb{R}^N$. Let $\Omega_n = \{x \in \mathbb{R}^N : |u| > M_0\}$. It follows from (2.1), (2.8), (3.2) and (3.6) that

$$\begin{aligned}
c + \|u_n\|_E &\ge J(u_n) - \frac{1}{\alpha}\langle J'(u_n), u_n\rangle \\
&= \frac{1}{2}\int_{\mathbb{R}^N} \left(|\nabla u_n|^2 + (V(x) + Q(x))u_n^2\right) dx - \frac{1}{\alpha}\int_{\mathbb{R}^N} \left(|\nabla u_n|^2 dx + V(x)u_n^2\right) dx \\
&\quad + \left(\frac{1}{\alpha} - \frac{1}{2}\right)\int_{\mathbb{R}^N} Q(x)u_n^2 \log u_n^2 dx + \frac{1}{\alpha}\int_{\mathbb{R}^N} \left(f(x,u_n)u_n - \alpha F(x,u_n)\right) dx \\
&\ge \left(\frac{1}{2} - \frac{1}{\alpha}\right)||u_n||_E^2 + \left(\frac{1}{\alpha} - \frac{1}{2}\right)\left(\frac{1}{2}\|\nabla u_n\|_2^2 + C_9(1 + \|u_n\|_E)^{1+r}\right) \\
&\quad - \frac{\theta}{\alpha}\left(\int_{\Omega_n} + \int_{\mathbb{R}^N\setminus\Omega_n}\right)|u_n|^2 dx \\
&\ge \left(\frac{1}{2} - \frac{1}{\alpha}\right)\|u_n\|_E^2 + \left(\frac{1}{\alpha} - \frac{1}{2}\right)\left(\frac{1}{2}\|u_n\|_E^2 + C_9\left(1 + \|u_n\|_E\right)^{1+r}\right) - \frac{\theta}{\alpha}\int_{\Omega_n} |u_n|^2 dx - C_{10} \\
&\ge \left(\frac{1}{4} - \frac{1}{2\alpha} - \frac{\theta}{S\alpha}\right)\|u_n\|_E^2 + \left(\frac{1}{\alpha} - \frac{1}{2}\right) C_9\left(1 + \|u_n\|_E\right)^{1+r} - C_{10},
\end{aligned}$$

where C_{10} is a positive constant. Divide both sides of this inequality by the norm $\|u_n\|_E^2$, then this leads to the following contradiction:

$$0 > \frac{S(\alpha - 2) - 4\theta}{4S\alpha} > 0,$$

and the proof of Lemma 3.4 is completed. □

Since the sequence $\{u_n\}$ is bounded in E, it has a weakly convergent subsequence in E. Without loss of generality we can assume that there exist $u \in E$ and a subsequence of $\{u_n\}$, still denoted by itself, such that

$$\begin{cases} u_n \rightharpoonup u & \text{in } E, \\ u_n \to u & \text{in } L^p_{\text{loc}}(\mathbb{R}^N),\ p \in (2, 2^*), \\ u_n \to u & \text{a.e. } x \in \mathbb{R}^N, \end{cases}$$

as $n \to \infty$.

Lemma 3.5. *Assume that (f1) satisfies, then there hold*

$$\lim_{n\to+\infty}\int_{\mathbb{R}^N} F_2'(u_n)u_n dx = \int_{\mathbb{R}^N} F_2'(u)u dx,$$
$$\lim_{n\to+\infty}\int_{\mathbb{R}^N} f(x,u_n)u_n dx = \int_{\mathbb{R}^N} f(x,u)u dx.$$

Proof. It follows from (2.6) that we know $|F_2'(s)| \leq C|s|^{q-1}$, then

$$\left| \int_{\mathbb{R}^N} F_2'(u_n)u_n dx - \int_{\mathbb{R}^N} F_2'(u)udx \right| \leq \int_{\mathbb{R}^N} C \left||u_n|^q - |u|^q\right| dx \to 0, \quad as\ n \to +\infty.$$

By the condition (f1), there holds

$$\begin{aligned} \left| \int_{\mathbb{R}^N} (f(x,u_n)u_n - f(x,u)u) \, dx \right| &\leq \left| \int_{\mathbb{R}^N} \left(\varepsilon|u_n|^2 + C(\varepsilon)|u_n|^p - \varepsilon|u|^2 - C(\varepsilon)|u|^p\right) dx \right| \\ &\leq \varepsilon \int_{\mathbb{R}^N} \left||u_n|^2 - |u|^2\right| dx + C(\varepsilon) \int_{\mathbb{R}^N} \left||u_n|^p - |u|^p\right| dx \to 0, \end{aligned}$$

as $n \to +\infty$. The proof of Lemma 3.5 is completed. □

Lemma 3.6. *Let $\{u_n\}$ be a $(PS)_c$ sequence of J in E, then $u_n \to u$ in E.*

Proof. By Lemma 3.4, the sequence $\{u_n\}$ is bounded in E. Then without loss of generality we can assume that $u_n \rightharpoonup u$ in E, recalling that $\langle J'(u_n), u_n \rangle = o_n(1)\|u_n\|_E$ yields

$$\begin{aligned} &\int_{\mathbb{R}^N} \left[|\nabla u_n|^2 + (V(x) + Q(x))u_n^2\right] dx + \int_{\mathbb{R}^N} Q(x)F_1'(u_n)u_n dx \\ &\quad = \int_{\mathbb{R}^N} f(x,u_n)u_n dx + \int_{\mathbb{R}^N} Q(x)F_2'(u_n)u_n dx + o_n(1). \end{aligned} \tag{3.7}$$

Moreover, $\lim_{n\to\infty} \langle J'(u_n), u_n \rangle = 0$, i.e.

$$\begin{aligned} &\int_{\mathbb{R}^N} \left[|\nabla u|^2 + (V(x) + Q(x))u^2\right] dx + \int_{\mathbb{R}^N} Q(x)F_1'(u)udx \\ &\quad = \int_{\mathbb{R}^N} f(x,u)udx + \int_{\mathbb{R}^N} Q(x)F_2'(u)udx. \end{aligned} \tag{3.8}$$

By the Lemma 3.5, the right-hand side of (3.7) and (3.8) are equal. Therefore, there holds

$$\|u_n\|_E^2 + \int_{\mathbb{R}^N} Q(x)F_1'(u_n)u_n dx + o_n(1) = \|u\|_E^2 + \int_{\mathbb{R}^N} Q(x)F_1'(u)udx.$$

Without loss of generality we have $\int_{\mathbb{R}^N} F_1'(u_n)u_n dx \to \int_{\mathbb{R}^N} F_1'(u)udx$, and

$$\|u_n\|_E^2 \to \|u\|_E^2,$$

as $n \to +\infty$. Thus we can conclude that $u_n \to u$ in E. □

Because $\{u_n\} \subset E$ is the $(PS)_c$ sequence of the functional $J(u)$, and by (3) of Definition 2.3, then there exists a function $v \in C_0^\infty(\mathbb{R}^N)$, for $\tau_n \to 0^+$ such that

$$\begin{aligned} -\tau_n\|v - u_n\|_E \leq &\int_{\mathbb{R}^N} \left[\nabla u_n \nabla(v - u_n) + (V(x) + Q(x))u_n(v - u_n)\right] dx - \int_{\mathbb{R}^N} f(x,u_n)(v - u_n)dx \\ &- \int_{\mathbb{R}^N} Q(x)F_2'(u_n)(v - u_n)dx + \int_{\mathbb{R}^N} Q(x)F_1(v)dx - \int_{\mathbb{R}^N} Q(x)F_1(u_n)dx. \end{aligned}$$

Since Ψ is lower semicontinuous, then

$$\Psi(u_n) \geq \liminf_{n\to\infty} \Psi(u_n) \geq \Psi(u).$$

It follows from Lemmas 3.5–3.6 that there holds

$$\lim_{n\to\infty}(-\tau_n\|v-u\|_E) \le \int_{\mathbb{R}^N}[\nabla u\nabla(v-u)+(V(x)+Q(x))u(v-u)]\,dx - \int_{\mathbb{R}^N} f(x,u)(v-u)dx - \int_{\mathbb{R}^N} Q(x)F_2'(u)(v-u)dx + \int_{\mathbb{R}^N} Q(x)F_1(v)dx - \int_{\mathbb{R}^N} Q(x)F_1(u)dx. \tag{3.9}$$

The above formula (3.9) is equivalent to

$$\langle \Phi'(u), v-u\rangle + \Psi(v) - \Psi(u) \ge 0.$$

It can be seen that it satisfies (2) of Definition 2.3. This implies that u is the critical point of the functional $J(u)$. Therefore, u is the solution of problem (1.1).

In what follows, we mainly prove that the solution u is nontrivial and reachable.

Lemma 3.7. *Assume that (V1)–(V2) and (f1)–(f3) hold, then the functional $J(u)$ satisfies $(PS)_c$ condition, and u is a critical point of J. Furthermore, u is nontrivial solution of equation* (1.1).

Proof. If $u = 0$, then $u_n \rightharpoonup 0$ in E. One of the following two cases is always true.

(i) $u_n \to 0$, as $n \to +\infty$.

(ii) $\liminf_{n\to+\infty}\sup_{y\in\mathbb{R}^N\setminus\{0\}}\int_{B_r(y)}|u_n|^2dx > 0$.

Now we next will prove that neither (i) nor (ii) is true:

If (i) is true, then $J(u) \to 0$, but $J(u) \to c$ $(c > 0)$, which leads to a contradiction. Therefore (ii) is true. Let $\beta := \liminf_{n\to+\infty}\sup_{y\in\mathbb{R}^N\setminus\{0\}}\int_{B_r(y)}|u_n|^2dx > 0$. Choose $A_r := \{x \in \mathbb{R}^N \setminus B_r(0) : V(x) < a_0\}$, as $r \to +\infty$. It follows from (V1) that $\mathrm{meas}(A_r) \to 0$. There exists a constant r^* such that if $r > r^*$ and $q^* \in (2, 2^*)$, and according to the Hölder inequality and Sobolev imbedding inequality, we have

$$\int_{A_r}|u_n|^2dx \le \left(\int_{A_r}|u_n|^{q^*}dx\right)^{\frac{2}{q^*}}\left(\int_{A_r}1dx\right)^{\frac{q^*-2}{q^*}} \le C\|u_n\|_E^2\,(\mathrm{meas}(A_r))^{\frac{q^*-2}{q^*}} \le \frac{\beta}{4}. \tag{3.10}$$

Take $D_r := \{x \in \mathbb{R}^N \setminus B_r(0) : V(x) \ge a_0\}$, as a_0 is enough large. Then there holds

$$\int_{D_r}|u_n|^2dx \le \frac{1}{1+a_0}\int_{\mathbb{R}^N}(1+V(x))|u_n|^2dx \le \frac{C}{1+a_0} \le \frac{\beta}{4}. \tag{3.11}$$

It follows from (3.10) and (3.11) that

$$\begin{aligned}\beta &= \liminf_{n\to+\infty}\sup_{y\in\mathbb{R}^N\setminus\{0\}}\int_{B_r(y)}|u_n|^2dx \\ &\le \liminf_{n\to+\infty}\int_{\mathbb{R}^N\setminus B_r(0)}|u_n|^2dx \\ &= \liminf_{n\to+\infty}\left(\int_{D_r}|u_n|^2dx + \int_{A_r}|u_n|^2dx\right) \le \frac{\beta}{2},\end{aligned}$$

which leads to a contradiction. Thus we have $u \ne 0$. The proof of Lemma 3.7 is completed. □

Proof of Theorem 1.1. By the statement in Section 3, we admit that the sequence $\{u_n\} \subset E$ is the $(PS)_c$ sequence of the functional $J(u)$. From Lemma 3.7, the weak limit of $(PS)_c$ sequence is nontrivial, we easily infer that the weak limit is the desired ground state. On the one hand, since $u_n \to u$ $(n \to \infty)$, the norm $\|u\|_E$ and $\Psi(u)$ are lower semicontinuous, it follows from (2.1), (2.3), (2.4) that

$$\begin{aligned}
J(u) &= \tilde{\Phi}(u) + \Psi(u) \\
&= \frac{1}{2}\|u\|_E^2 - \int_{\mathbb{R}^N} F(x,u)dx - \int_{\mathbb{R}^N} Q(x)F_2(u)dx + \int_{\mathbb{R}^N} Q(x)F_1(u)dx \\
&\leq \frac{1}{2}\|u\|_E^2 - \inf\int_{\mathbb{R}^N} F(x,u)dx - \inf\int_{\mathbb{R}^N} Q(x)F_2(u)dx + \int_{\mathbb{R}^N} Q(x)F_1(u)dx \\
&\leq \liminf_{n\to+\infty}\frac{1}{2}\|u_n\|_E^2 - \liminf_{n\to+\infty}\int_{\mathbb{R}^N} F(x,u_n)dx - \liminf_{n\to+\infty}\int_{\mathbb{R}^N} Q(x)F_2(u_n)dx \\
&\quad + \liminf_{n\to+\infty}\int_{\mathbb{R}^N} Q(x)F_1(u_n)dx \\
&= \liminf_{n\to+\infty} J(u_n) = c.
\end{aligned}$$

Then we can get $J(u) \leq c$. On the other hand, by the definition of c, we have $J(u) \geq c$. Hence $J(u) = c$. In a word, we deduce that c is attained and the corresponding minimizer is a ground state solution of problem (1.1). The proof of Theorem 1.1 is completed. □

Abstract. In this paper, we consider the existence of normalized solutions for the following Kirchhoff-type problem:

$$-\left(a+b\int_{\mathbb{R}^N}|\nabla u|^2dx\right)\Delta u=\lambda u+|u|^{p-2}u+\mu|u|^{q-2}u \quad \text{in } \mathbb{R}^N,$$

with prescribed L^2-norm:

$$\int_{\mathbb{R}^N}|u|^2dx=c^2,$$

where $N=2,3$, $a\geq 0$, $b>0$ and $c>0$ are constants, $\lambda\in\mathbb{R}$, $2<q<p=2+\frac{8}{N}$ and $\mu>0$. The number $2+\frac{8}{N}$ behaves as the L^2 -critical exponent for the above problem. We prove the multiplicity of normalized solutions for the above Kirchhoff-type problem with L^2-critical nonlinearity (that is, $p=2+\frac{8}{N}$) in the two cases: $2<q<2+\frac{4}{N}$ and $2+\frac{4}{N}<q<2+\frac{8}{N}$.

Keywords: Kirchhoff equation, constrained minimization, variational method, Pohozaev manifold.

1 Introduction and main results

In this paper, we investigate the multiplicity of normalized solutions for the following Kirchhoff-type problem

$$-\left(a+b\int_{\mathbb{R}^N}|\nabla u|^2dx\right)\Delta u=\lambda u+|u|^{p-2}u+\mu|u|^{q-2}u \quad \text{in } \mathbb{R}^N, \tag{1.1}$$

with prescribed mass

$$\int_{\mathbb{R}^N}|u|^2dx=c^2,$$

✉ Corresponding author. Email: ouzengq707@sina.com

where $N = 2,3$, $a \geq 0$, $b,c > 0$, $\lambda \in \mathbb{R}$ appears as a Lagrange multiplier, $2 < q < p = 2 + \frac{8}{N}$ and $\mu > 0$. Let $L^s(\mathbb{R}^N)(1 \leq s < +\infty)$ be the Lebesgue space with norm $|u|_s = (\int_{\mathbb{R}^N} |u|^s dx)^{1/s}$, $H^1(\mathbb{R}^N)$ be the Hilbert space with the norm $\|u\| = \big(\int_{\mathbb{R}^N} (|\nabla u|^2 + |u|^2) dx\big)^{\frac{1}{2}}$.

Problem (1.1) is a special form of the following Kirchhoff problem

$$-\left(a + b\int_{\mathbb{R}^N} |\nabla u|^2 dx\right)\Delta u = f(x,u) \quad \text{in } \mathbb{R}^N,$$

which is also a variant of Dirichlet problem

$$\begin{cases} -\left(a + b\int_{\Omega} |\nabla u|^2 dx\right)\Delta u = f(x,u) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.2}$$

where $\Omega \subset \mathbb{R}^N$ is a bounded domain with smooth boundary. It is well-known that problem (1.2) appears naturally in the context of physics. Problem (1.2) is the stationary case of a nonlinear wave equation

$$u_{tt} - \left(a + b\int_{\Omega} |\nabla u|^2 dx\right)\Delta u = f(x,u), \tag{1.3}$$

first proposed by Kirchhoff [9] in 1883. Problem (1.3) is a generalization of the classical D'Alembert's wave equation which describes free vibrations of elastic strings. The parameters in problem (1.3) have specific physical meaning: f is the external force, a is related to the intrinsic properties of the string, and u means the displacement while b denotes the initial tension. Since then, problem (1.3) has received much attention, see [1, 11, 12, 14, 15] and the references therein. Since Lions in [11] proposed an abstract functional analysis framework, Kirchhoff type problem has been intensively studied during the last decades. From a mathematical perspective, problem (1.2) is not a pointwise identity as the appearance of the nonlocal term $\int_\Omega |\nabla u|^2 dx$. The nonlocal term causes some mathematical difficulties and the investigation of problem (1.2) is more interesting and challenging. Such a nonlocal model also appears in other fields as biological systems describing a process depending on the average of itself, for example one species' population density.

A way to study problem (1.1) is to search for solutions with L^2-norm constraint, and such solutions are known as normalized solutions and $\lambda \in \mathbb{R}$ appears as a Lagrange multiplier. In addition, the study of L^2-norm constraint problem can give a better insight of the dynamical properties, like orbital stability or instability, and can describe attractive Bose-Einstein condensate. Normalized solutions of problem (1.1) can be obtained by looking for critical points of the energy functional $E_{a,\mu}(u)$ constrained on S_c, where

$$E_{a,\mu}(u) := \frac{a}{2}\int_{\mathbb{R}^N} |\nabla u|^2 dx + \frac{b}{4}\left(\int_{\mathbb{R}^N} |\nabla u|^2 dx\right)^2 - \frac{1}{p}\int_{\mathbb{R}^N} |u|^p dx - \frac{\mu}{q}\int_{\mathbb{R}^N} |u|^q dx,$$

and

$$S_c := \left\{u \in H^1(\mathbb{R}^N) : \int_{\mathbb{R}^N} |u|^2 dx = c^2\right\}.$$

Many interesting results on the normalized solutions of Kirchhoff problem are also obtained not long ago, see [2,3,5,6,8,13,17,23]. Especially, many experts considered the existence of normalized solutions for problem (1.1) with combined nonlinearities. For the case $\mu > 0$, under different ranges of p and q, Li and Lou in [10] proved a multiplicity result for problem (1.1). In detail, if $2 < q < \frac{10}{3}$, $\frac{14}{3} < p < 6$ and $\mu < \min\{\mu', \mu''\}$, two solutions for problem (1.1) were obtained. If $\frac{14}{3} < q < p < 6$, problem (1.1) has a mountain pass type solution. Hu and Mao in [6] considered the following minimization problem

$$m_{a,c} = \inf_{u \in S_c} E_{a,\mu}(u), \tag{1.4}$$

and they proved that if $2 < q < \frac{10}{3}$ and $2 < q < p \leq \frac{14}{3}$, problem (1.4) has a minimizer for every $c \in (0, c_p^*)$. At the same time, when c satisfies the suitable conditions, the nonexistence of minimizers for problem (1.4) was considered in the following four cases: (i) $q = \frac{10}{3}$ and $p = \frac{14}{3}$; (ii) $\frac{10}{3} = q < p < \frac{14}{3}$; (iii) $2 < q < p = \frac{14}{3}$; (iv) $2 < q < p, \frac{14}{3} < p < 6$. Moreover, if $\frac{14}{3} < q < p < 6$, they also obtained the existence of normalized solutions for problem (1.1) by using constraint minimization on a suitable submanifold of S_c. For the Sobolev critical case (that is, $p = 6$), Feng, Liu and Zhang in [3] proved the existence and multiplicity of normalized solutions for problem (1.1) under suitable assumptions on μ and c for the following four cases: $2 < q < \frac{10}{3}$, $q = \frac{10}{3}$, $\frac{10}{3} < q < \frac{14}{3}$, $\frac{14}{3} \leq q < p = 6$. Some similar results were also obtained in [10,23]. For the case $\mu = 0$, the existence, multiplicity and uniqueness of normalized solutions for problem (1.1) have been considered in [13,19–22]. For the case $\mu < 0$, we refer to [2,6], and for the nonlinear Kirchhoff-type equations in high dimensions see [8].

As far as we known, there are few papers to consider the existence and multiplicity of normalized solutions for problem (1.1) with L^2-critical nonlinearity (that is $p = 2 + \frac{8}{N}$) in the two cases: $2 < q < 2 + \frac{4}{N}$ and $2 + \frac{4}{N} < q < 2 + \frac{8}{N}$. The object of this paper is to prove the existence and multiplicity of normalized solutions for problem (1.1) in those cases under suitable assumptions on μ and a.

Before stating the main results of this paper, let us recall the Gagliardo–Nirenberg inequality (see [18]): for any $s \in [2, \frac{2N}{N-2})$ if $N \geq 3$ and $s \geq 2$ if $N = 1, 2$, we have

$$\frac{1}{s}|u|_s^s \leq \frac{1}{2|Q_s|_2^{s-2}} |\nabla u|_2^{s\gamma_s} |u|_2^{s - s\gamma_s}, \tag{1.5}$$

where $\gamma_s := \frac{N(s-2)}{2s}$ and with equality only for $u = Q_s$, and up to translations, Q_s is the unique positive solution of

$$-\frac{N(s-2)}{4}\Delta u + \left(1 + \frac{s-2}{4}(2-N)\right) u = |u|^{s-2}u \quad \text{in } \mathbb{R}^N,$$

and satisfies

$$|\nabla Q_s|_2^2 = |Q_s|_2^2 = \frac{2}{s}|Q_s|_s^s.$$

Especially, let $p = 2 + \frac{8}{N}$, define

$$c^* := \left(\frac{b|Q_p|_2^{\frac{8}{N}}}{2}\right)^{\frac{N}{8-2N}}.$$

For $s = p = 2 + \frac{8}{N}$ and for any $u \in S_c$, we have

$$\frac{1}{p}|u|_p^p \leq \frac{1}{4}\frac{2}{c^2}\left(\frac{c}{|Q_p|_2}\right)^{\frac{8}{N}} |\nabla u|_2^4 = \frac{b}{4}\left(\frac{c}{c^*}\right)^{\frac{8-2N}{N}} |\nabla u|_2^4. \tag{1.6}$$

Set

$$\mu_* := \frac{2a|Q_q|_2^{q-2}}{(4-q\gamma_q)c^{q-q\gamma_q}} \left(\frac{2a(2-q\gamma_q)}{b(4-q\gamma_q))\left((\frac{c}{c^*})^{\frac{8-2N}{N}}-1\right)} \right)^{\frac{2-q\gamma_q}{2}}. \tag{1.7}$$

Now, our main results are following.

Theorem 1.1. *Let $2 < q < 2 + \frac{4}{N}$, $p = 2 + \frac{8}{N}$, $c > c^*$ and $0 < \mu < \mu_*$. Then problem (1.1) has two radial solutions, denoted by $\tilde{u}_{c,\mu}$ and $\hat{u}_{c,\mu}$. Moreover, $\tilde{u}_{c,\mu}$ is a local minimizer of the functional $E_{a,\mu}$ on the set*

$$\mathcal{A}_{R_0} := \{u \in S_{c,r} : |\nabla u|_2^2 < R_0\}$$

for a suitable $R_0 = R_0(c,\mu) > 0$ with $E_{a,\mu}(\tilde{u}_{c,\mu}) < 0$ and $\tilde{u}_{c,\mu}$ solves problem (1.1) for some $\tilde{\lambda}_{c,\mu} < 0$, and $\hat{u}_{c,\mu}$ is a critical point of mountain pass type for $E_{a,\mu}$ with $E_{a,\mu}(\hat{u}_{c,\mu}) > 0$ and $\hat{u}_{c,\mu}$ solves problem (1.1) for some $\hat{\lambda}_{c,\mu} < 0$.

Theorem 1.2. *If $2 + \frac{4}{N} < q < p = 2 + \frac{8}{N}$, $\mu > 0$ and $c < c^*$, we have the following results:*

(i) if $a = 0$, $m_{0,c} := \inf_{u \in S_c} E_{0,\mu}(u)$ has a radial minimizer $\tilde{u}$, and $\tilde{u}$ solves problem (1.1) for some $\tilde{\lambda} < 0$.

(ii) let $\bar{a} = \frac{b}{2}\left(1 - (\frac{c}{c^*})^{\frac{8-2N}{N}}\right)\left(\frac{2}{N(q-2)} - \frac{1}{4}\right)|\nabla \tilde{u}|_2^2 > 0$, for any $a \in (0, \bar{a})$, problem (1.1) has two radial solutions, the one is a global minimizer $\tilde{u}_{c,a}$ with $\tilde{\lambda}_{c,a} < 0$, and the other is the mountain pass type solution $u_{c,a}$ with $\lambda_{c,a} < 0$.

Remark 1.3. Theorem 1.1 complements [6, Theorem 1.2], where Hu and Mao considered the case $c \in (0, c^*)$ and obtained a minimizer of the functional $E_{a,\mu}$ on S_c. However, we deal with the case $c > c^*$ and obtain two solutions for problem (1.1) under suitable assumptions on the constant $\mu > 0$. In the proof of Theorem 1.1, since the functional $E_{a,\mu}$ is not bounded from below on S_c for $c > c^*$, we will restrict the functional $E_{a,\mu}$ on the Pohozaev set $\mathcal{P}_{c,\mu}$. We can get a local minimizer for $E_{a,\mu}|_{\mathcal{P}_{c,\mu}}$ and use mountain pass theorem to get the second critical point. We emphasis that (1.7) has been used to ensure that $\mathcal{P}_{c,\mu}$ is a smooth manifold and the existence of mountain pass type solution.

To the best of our knowledge, Hu and Mao in [6] proved that if $N = 3$, $\frac{10}{3} < q < \frac{14}{3}$, $p = \frac{14}{3}$, $c < c^*$ and $\mu > 0$ satisfy appropriate condition, problem (1.1) with has no minimizer. However, we try to prove the existence of normalized solution for problem (1.1) with $2 + \frac{4}{N} < q < p = 2 + \frac{8}{N}$ for the suitable constant $a > 0$. Furthermore, there are few results about the existence of normalized solutions to degenerate Kirchhoff equations, that is, $a = 0$, so we first establish the existence of minimizer $m_{0,c} = \inf_{u \in S_c} E_{0,\mu}(u) < 0$, which is a normalized solution of the degenerate Kirchhoff equation. And then, we establish $m_{a,c} := \inf_{u \in S_{c,r}} E_{a,\mu}(u) < 0$ with the help of the minimizer of $m_{0,c}$. At last, we will prove the existence of the second solution with the mountain pass type for problem (1.1).

To overcome the lack of compactness, we work in $H_r^1(\mathbb{R}^N)$. Although the energy functional $E_{a,\mu}$ has a bounded Palais–Smale sequence on the mass constraint set $S_{c,r}$, unfortunately, we can not deduce whether $E_{a,\mu}$ satisfies the Palais–Smale condition. To overcome this difficulty, in the proof of Theorem 1.1, we will constrain the energy functional $E_{a,\mu}$ on a submanifold of $S_{c,r}$ corresponding to the Pohozaev identity. In the proof of (2) of Theorem 1.2, we use Jeanjean's method in [7] and construct an auxiliary map $I_{a,\mu}(u,\tau) := E_{a,\mu}(\tau \star u)$, which has the same type of geometric structure on $S_{c,r} \times \mathbb{R}$ as $E_{a,\mu}$ on $S_{c,r}$.

2 Preliminaries

In this section, we will introduce some notations, then we recall a version of linking theorem. Finally, we give the compactness analysis of Palais–Smale sequences for $E_{a,\mu}|_{S_{c,r}}$. Let

$$H_r^1(\mathbb{R}^N) = \{u \in H^1(\mathbb{R}^N) : u(|x|) = u(x)\},$$
$$S_{c,r} := S_c \cap H_r^1(\mathbb{R}^N) = \{u \in S_c : u(x) = u(|x|)\}.$$

For $u \in S_c$, and $\tau \in \mathbb{R}$, define the fiber map preserving the L^2-norm

$$(\tau \star u)(x) := e^{\frac{N}{2}\tau} u(e^\tau x) \quad \text{for any } x \in \mathbb{R}^N.$$

We introduce the auxiliary functional $I_{a,\mu} : H^1(\mathbb{R}^N) \times \mathbb{R}^+ \to \mathbb{R}$ by

$$I_{a,\mu}(u,\tau) := E_{a,\mu}(\tau \star u) = \frac{e^{2\tau}a}{2}|\nabla u|_2^2 + \frac{e^{4\tau}b}{4}|\nabla u|_2^4 - \frac{e^{4\tau}}{p}|u|_p^p - \mu\frac{e^{\gamma_q q\tau}}{q}|u|_q^q, \tag{2.1}$$

then we easily see that the functional $I_{a,\mu}$ is of class C^1. In addition, we define the Pohozaev set by

$$\mathcal{P}_{c,\mu} = \{u \in S_{c,r} : P_\mu(u) = 0\}$$

with

$$P_\mu(u) = a|\nabla u|_2^2 + b|\nabla u|_2^4 - \frac{4}{p}|u|_p^p - \mu\gamma_q|u|_q^q.$$

Lemma 2.1 ([4, Theorem 2.7]). *Let φ be a C^1-functional on a complete connected C^1-Finsler manifold X and consider a homotopy-stable family $\mathcal{F}$ with extended boundary B. Set*

$$c = c(\varphi, \mathcal{F}) = \inf_{A\in\mathcal{F}} \max_{x\in A} \varphi(x)$$

and let F be a closed subset of X satisfying

$$A \cap F \backslash B \neq \emptyset \quad \text{for every } A \in \mathcal{F} \tag{2.2}$$

and

$$\sup_{x\in B} \varphi(x) \le c \le \inf_{x\in F} \varphi(x). \tag{2.3}$$

Then, for any sequence of sets $(A_n)_n \in \mathcal{F}$ such that $\lim_{n\to\infty}\sup_{A_n}\varphi = c$, there exists a sequence $(x_n)_n$ in $X\backslash B$ such that

$$\lim_{n\to\infty} \varphi(x_n) = c, \quad \lim_{n\to\infty} \|d\varphi(x_n)\| = 0, \quad \lim_{n\to\infty} \operatorname{dist}(x_n, F) = 0, \quad \lim_{n\to\infty} \operatorname{dist}(x_n, A_n) = 0.$$

Lemma 2.2. *Let $a > 0$, $b > 0$, $c > 0$, $\mu > 0$, $2 < q < p = 2 + \frac{8}{N}$. Let $\{u_n\} \subset S_{c,r}$ be a bounded Palais–Smale sequence for $E_{a,\mu}|_{S_{c,r}}$ at energy level $m \neq 0$ with $P_\mu(u_n) \to 0$ as $n \to \infty$. Then up to a subsequence $u_n \to u$ strongly in $H^1(\mathbb{R}^N)$. Moreover, $u \in S_{c,r}$ and u is a radial solution for problem (1.1) for some $\lambda < 0$.*

Proof. The proof is divided into three steps.

Step 1: Lagrange multipliers $\lambda_n \to \lambda$ in $\mathbb{R}$. Since $H_r^1(\mathbb{R}^N) \hookrightarrow L^s(\mathbb{R}^N)$ is compact for $s \in (2, \frac{2N}{N-2})$, from the boundedness of Palais–Smale sequence $\{u_n\}$, there exists a subsequence of $\{u_n\}$, still denoted by $\{u_n\}$, and $u \in H_r^1(\mathbb{R}^N)$ such that

$$u_n \rightharpoonup u \quad \text{in } H_r^1(\mathbb{R}^N), \qquad u_n \to u \quad \text{in } L^s(\mathbb{R}^N), \qquad u_n \to u \quad \text{a.e. on } \mathbb{R}^N.$$

Because $\{u_n\}$ is a Palais–Smale sequence of $E_{a,\mu}|_{S_{c,r}}$, by the Lagrange multipliers rule, there exists $\lambda_n \in \mathbb{R}$ such that

$$(a+b|\nabla u_n|_2^2)\int_{\mathbb{R}^N}\nabla u_n\nabla\varphi dx-\mu\int_{\mathbb{R}^N}|u_n|^{q-2}u_n\varphi dx \\ -\int_{\mathbb{R}^N}|u_n|^{p-2}u_n\varphi dx-\lambda_n\int_{\mathbb{R}^N}u_n\varphi dx=o_n(1) \quad (2.4)$$

for every $\varphi \in H^1(\mathbb{R}^N)$, where $o_n(1)\to 0$ as $n\to\infty$. In particular, taking $\varphi=u_n$ in (2.4), we have

$$\lambda_n c^2=a|\nabla u_n|_2^2+b|\nabla u_n|_2^4-\mu|u_n|_q^q-|u_n|_p^p+o_n(1).$$

The boundedness of $\{u_n\}$ in $H_r^1(\mathbb{R}^N)\cap L^q(\mathbb{R}^N)\cap L^p(\mathbb{R}^N)$ implies that $\{\lambda_n\}$ is bounded as well. Hence, up to a subsequence, we have $\lambda_n\to\lambda\in\mathbb{R}$.

Step 2: $\lambda<0$ and $u\not\equiv 0$. Recalling that $P_\mu(u_n)\to 0$, we have

$$\lambda_n c^2=\mu(\gamma_q-1)|u_n|_q^q+(\gamma_p-1)|u_n|_p^p+o_n(1),$$

hence, let $n\to\infty$, we have

$$\lambda c^2=\mu(\gamma_q-1)|u|_q^q+(\gamma_p-1)|u|_p^p.$$

Since $\mu>0$ and $0<\gamma_q,\gamma_p<1$, we deduce that $\lambda\le 0$, with "=" if and only if $u\equiv 0$. If $\lambda_n\to 0$, we have $\lim_{n\to\infty}|u_n|_p^p=0=\lim_{n\to\infty}|u_n|_q^q$. Using again $P_\mu(u_n)\to 0$, we have $E_{a,\mu}(u_n)\to 0$, which is a contradiction with $E_{a,\mu}(u_n)\to m\neq 0$ and thus $\lambda_n\to\lambda<0$ and $u\not\equiv 0$.

Step 3: $u_n\to u$ in $H^1(\mathbb{R}^N)$. Since $u_n\rightharpoonup u\not\equiv 0$ in $H^1(\mathbb{R}^N)$, we get $B:=\lim_{n\to\infty}|\nabla u_n|_2^2\ge|\nabla u|_2^2>0$. Then, (2.4) implies that

$$(a+bB)\int_{\mathbb{R}^N}\nabla u\nabla\varphi dx-\mu\int_{\mathbb{R}^N}|u|^{q-2}u\varphi dx-\int_{\mathbb{R}^N}|u|^{p-2}u\varphi dx-\lambda\int_{\mathbb{R}^N}u\varphi dx=0 \quad (2.5)$$

for any $\varphi\in H^1(\mathbb{R}^N)$. Combining (2.4) with (2.5) and taking $\varphi=u_n-u$, we obtain

$$(a+bB)|\nabla(u_n-u)|_2^2-\lambda|u_n-u|_2^2\to 0 \quad \text{as } n\to\infty.$$

Since $\lambda<0$, we conclude that $\{u_n\}$ converges strongly in $H^1(\mathbb{R}^N)$. □

3 Proof of Theorem 1.1

In this section, we deal with the case $2<q<2+\frac{4}{N}$, $p=2+\frac{8}{N}$, $c>c^*$, $\mu>0$ and prove Theorem 1.1. First of all, it is well known that any critical point of the functional $E_{a,\mu}$ belongs to $\mathcal{P}_{c,\mu}$. Conversely, if $u\in\mathcal{P}_{c,\mu}$, we get $\partial_\tau I_{a,\mu}(u,0)=0$. Now, we consider the decomposition of $\mathcal{P}_{c,\mu}$ into the disjoint union $\mathcal{P}_{c,\mu}=\mathcal{P}_{c,\mu}^+\cup\mathcal{P}_{c,\mu}^0\cup\mathcal{P}_{c,\mu}^-$, where

$$\mathcal{P}_{c,\mu}^+:=\{u\in\mathcal{P}_{c,\mu}:2a|\nabla u|_2^2+4b|\nabla u|_2^4>\mu q\gamma_q^2|u|_q^q+p\gamma_p^2|u|_p^p\}=\{u\in\mathcal{P}_{c,\mu}:\partial_{\tau\tau}I_{a,\mu}(u,0)>0\},$$

$$\mathcal{P}_{c,\mu}^0:=\{u\in\mathcal{P}_{c,\mu}:2a|\nabla u|_2^2+4b|\nabla u|_2^4=\mu q\gamma_q^2|u|_q^q+p\gamma_p^2|u|_p^p\}=\{u\in\mathcal{P}_{c,\mu}:\partial_{\tau\tau}I_{a,\mu}(u,0)=0\},$$

$$\mathcal{P}_{c,\mu}^-:=\{u\in\mathcal{P}_{c,\mu}:2a|\nabla u|_2^2+4b|\nabla u|_2^4<\mu q\gamma_q^2|u|_q^q+p\gamma_p^2|u|_p^p\}=\{u\in\mathcal{P}_{c,\mu}:\partial_{\tau\tau}I_{a,\mu}(u,0)<0\}.$$

By (1.5) and (1.6), we have

$$E_{a,\mu}(u) \geq \frac{a}{2}|\nabla u|_2^2 + \frac{b}{4}\left(1-\left(\frac{c}{c^*}\right)^{\frac{8-2N}{N}}\right)|\nabla u|_2^4 - \mu\frac{c^{q-\gamma_q q}}{2|Q_q|_2^{q-2}}|\nabla u|_2^{\gamma_q q} \tag{3.1}$$

for every $u \in S_{c,r}$. Therefore, to understand the geometry of the functional $E_{a,\mu}|_{S_{c,r}}$, it is useful to consider the function $h : \mathbb{R}^+ \to \mathbb{R}$:

$$h(t) := \frac{a}{2}t + \frac{b}{4}\left(1-\left(\frac{c}{c^*}\right)^{\frac{8-2N}{N}}\right)t^2 - \mu\frac{c^{q-\gamma_q}}{2|Q_q|_2^{q-2}}t^{\frac{\gamma_q q}{2}}.$$

Now, we study the properties of $h(t)$.

Lemma 3.1. *Let $c > c^*$, $2 < q < 2+\frac{4}{N}$, $p = 2+\frac{8}{N}$, $0 < \mu < \mu_*$, where μ_* is defined in (1.7), the function h has a local strict minimum at negative level and a global strict maximum at positive level. Moreover, there exist $0 < R_0 < R_1$, both depending on c and μ, such that $h(R_0) = 0 = h(R_1)$ and $h(t) > 0$ for any $t \in (R_0, R_1)$.*

Proof. Since

$$h(t) = t^{\frac{\gamma_q q}{2}}\left(\frac{a}{2}t^{1-\frac{\gamma_q q}{2}} + \frac{b}{4}\left(1-\left(\frac{c}{c^*}\right)^{\frac{8-2N}{N}}\right)t^{2-\frac{\gamma_q q}{2}} - \mu\frac{c^{q-q\gamma_q}}{2|Q_q|_2^{q-2}}\right)$$

for $t > 0$, we have $h(t) > 0$ if and only if

$$\varphi(t) > \mu\frac{c^{q-q\gamma_q}}{2|Q_q|_2^{q-2}}, \quad \text{with } \varphi(t) := \frac{a}{2}t^{1-\frac{\gamma_q q}{2}} + \frac{b}{4}\left(1-\left(\frac{c}{c^*}\right)^{\frac{8-2N}{N}}\right)t^{2-\frac{\gamma_q q}{2}}.$$

It is not difficult to check that φ has a unique critical point $\bar{t}$ on $(0,\infty)$, which is a global maximum point at positive level:

$$\bar{t} := \frac{2a(2-q\gamma_q)}{b(4-q\gamma_q)\left((\frac{c}{c^*})^{\frac{8-2N}{N}}-1\right)},$$

and the maximum level is

$$\varphi(\bar{t}) = \frac{a}{(4-q\gamma_q)}\left(\frac{2a(2-q\gamma_q)}{b(4-q\gamma_q)\left((\frac{c}{c^*})^{\frac{8-2N}{N}}-1\right)}\right)^{1-\frac{q\gamma_q}{2}} > 0.$$

From $0 < \frac{\gamma_q q}{2} < 1$, $\mu > 0$ and $c > c^*$, it is obvious that $\lim_{t\to 0^+} h(t) = 0^-$ and $\lim_{t\to+\infty} h(t) = -\infty$. Therefore, h is positive on an open interval (R_0, R_1) if $\varphi(\bar{t}) > \mu\frac{c^{q-q\gamma_q}}{2|Q_q|_2^{q-2}}$, which is ensured by

$$0 < \mu < \mu_* := \frac{2a|Q_q|_2^{q-2}}{(4-q\gamma_q)c^{q-q\gamma_q}}\left(\frac{2a(2-q\gamma_q)}{b(4-q\gamma_q)\left((\frac{c}{c^*})^{\frac{8-2N}{N}}-1\right)}\right)^{1-\frac{q\gamma_q}{2}}.$$

It follows immediately that h has a global maximum at positive level in (R_0, R_1). Moreover, since $\lim_{t\to 0^+} h(t) = 0^-$, there exists a local minimum point at negative level in $(0, R_0)$. The fact that h has no other critical points can be verified observing that $h'(t) = 0$ if and only if

$$\psi(t) = \mu\frac{\gamma_q q c^{q-q\gamma_q}}{2|Q_q|_2^{q-2}} \quad \text{with } \psi(t) := at^{\frac{2-q\gamma_q}{2}} + b\left(1-\left(\frac{c}{c^*}\right)^{\frac{8-2N}{N}}\right)t^{\frac{4-q\gamma_q}{2}}.$$

Clearly ψ has only one critical point, which is a strict maximum, and hence the above equation has at most two solutions, which necessarily are the local minimum and the global maximum of h previously found. □

We now study the structure of the Pohozaev manifold $\mathcal{P}_{c,\mu}$. Recalling the decomposition of $\mathcal{P}_{c,\mu} = \mathcal{P}^+_{c,\mu} \cup \mathcal{P}^0_{c,\mu} \cup \mathcal{P}^-_{c,\mu}$.

Lemma 3.2. *If $2 < q < 2 + \frac{4}{N}$, $p = 2 + \frac{8}{N}$ and $0 < \mu < \mu_*$, then $\mathcal{P}^0_{c,\mu} = \emptyset$ and $\mathcal{P}_{c,\mu}$ is a smooth manifold of codimension 2 in $H^1(\mathbb{R}^N)$.*

Proof. Otherwise, let $u \in \mathcal{P}^0_{c,\mu}$, from $P_{c,\mu}(u) = 0$ and $\partial_{\tau\tau} I_{a,\mu}(u,0) = 0$, we have

$$a|\nabla u|_2^2 + b|\nabla u|_2^4 - \mu\gamma_q |u|_q^q - \frac{4}{p}|u|_p^p = 0,$$

$$2a|\nabla u|_2^2 + 4b|\nabla u|_2^4 - \mu q\gamma_q^2 |u|_q^q - p\gamma_p^2 |u|_p^p = 0.$$

By (1.5), we obtain

$$(2-q\gamma_q)a|\nabla u|_2^2 + (4-q\gamma_q)b|\nabla u|_2^4 = \gamma_p(p\gamma_p - q\gamma_q)|u|_p^p \leq (4-q\gamma_q)b\left(\frac{c}{c^*}\right)^{\frac{8-2N}{N}}|\nabla u|_2^4,$$

$$2a|\nabla u|_2^2 = \mu\gamma_q(4-q\gamma_q)|u|_q^q \leq \mu q\gamma_q(4-q\gamma_q)\frac{c^{q-q\gamma_q}}{2|Q_q|_2^{q-2}}|\nabla u|_2^{q\gamma_q}.$$

Then, the lower and upper bounds of $|\nabla u|_2$ are given by

$$\left(\frac{a(2-q\gamma_q)}{b(4-q\gamma_q)\left((\frac{c}{c_*})^{\frac{8-2N}{N}}-1\right)}\right)^{\frac{1}{2}} \leq |\nabla u|_2 \leq \left(\frac{\mu q\gamma_q(4-q\gamma_q)c^{q-q\gamma_q}}{4a|Q_q|_2^{q-2}}\right)^{\frac{1}{2-q\gamma_q}},$$

which leads to

$$\mu > \frac{4a|Q_q|_2^{q-2}}{q\gamma_q(4-q\gamma_q)c^{q-q\gamma_q}}\left(\frac{a(2-q\gamma_q)}{b(4-q\gamma_q)\left((\frac{c}{c_*})^{\frac{8-2N}{N}}-1\right)}\right)^{\frac{2-q\gamma_q}{2}} > \mu_*,$$

which contradicts to $0 < \mu < \mu_*$, hence, $\mathcal{P}^0_{c,\mu} = \emptyset$. $\mathcal{P}_{c,\mu}$ is a smooth manifold of codimension 2 in $H^1(\mathbb{R}^N)$, see proof of [16, Lemma 5.2]. □

Lemma 3.3. *Let $a > 0, b > 0, 2 < q < 2 + \frac{4}{N}$, $p = 2 + \frac{8}{N}$, $0 < \mu < \mu^*$, if $u \in P_{c,\mu}$ is a critical point for $E_{a,\mu}|_{P_{c,\mu}}$, then u is a critical point for $E_{a,\mu}|_{S_{c,r}}$, where μ^* is defined in (1.7).*

Proof. From Lemma 3.2, we deduce that $\mathcal{P}_{c,\mu}$ is a smooth manifold of codimension 2 in $H^1(\mathbb{R}^N)$ and $\mathcal{P}^0_{c,\mu} = \emptyset$. If $u \in \mathcal{P}_{c,\mu}$ is a critical point for $E_{a,\mu}|_{\mathcal{P}_{c,\mu}}$, then by the Lagrange multipliers rule, there exists $\lambda, \xi \in \mathbb{R}$ such that

$$\left\langle E'_{a,\mu}(u), \varphi\right\rangle - \lambda\int_{\mathbb{R}^N} u\varphi dx - \xi\left\langle P'_\mu(u), \varphi\right\rangle = 0, \quad \forall \varphi \in H^1\left(\mathbb{R}^N\right).$$

So u solves

$$-((1-2\xi)a + (1-4\xi)b|\nabla u|_2^2)\Delta u - \lambda u + \mu(\xi q\delta_q - 1)|u|^{q-2}u + (p\xi\gamma_p - 1)|u|^{p-2}u = 0.$$

Combining with the Pohozaev identity, we have

$$(1-2\xi)a|\nabla u|_2^2 + (1-4\xi)b|\nabla u|_2^4 + \mu\gamma_q(\xi q\gamma_q - 1)|u|_q^q + \gamma_p(p\xi\gamma_p - 1)|u|_p^p = 0.$$

Since $u \in \mathcal{P}_{c,\mu}$ and $u \notin \mathcal{P}^0_{c,\mu}$, we deduce from $\xi(2a|\nabla u|_2^2 + 4b|\nabla u|_2^4 - \mu q\gamma_q^2|u|_q^q - \gamma_p^2 p|u|_p^p) = 0$ that $\xi = 0$. □

The manifold $\mathcal{P}_{c,\mu}$ is then divided into two components $\mathcal{P}^+_{c,\mu}$ and $\mathcal{P}^-_{c,\mu}$, having disjoint closure.

Lemma 3.4. *For every $u \in S_{c,r}$, we have*

(i) if $\frac{b}{4}|\nabla u|_2^4 \geq \frac{1}{p}|u|_p^p$, the function $I_{a,\mu}(u,\cdot)$ has a critical point $s_u \in \mathbb{R}$ and a zero $c_u \in \mathbb{R}$, with $s_u < c_u$;

(ii) if $\frac{b}{4}|\nabla u|_2^4 < \frac{1}{p}|u|_p^p$, the function $I_{a,\mu}(u,\cdot)$ has exactly two critical points $s_u < t_u \in \mathbb{R}$ and two zeros $c_u < d_u \in \mathbb{R}$, with $s_u < c_u < t_u < d_u$;

(iii) $\int_{\mathbb{R}^N} |\nabla(\tau \star u)|^2 \leq R_0$ for every $\tau \leq c_u$, and

$$E_{a,\mu}(s_u \star u) = \min\left\{E_{a,\mu}(\tau\star u) : \tau \in \mathbb{R} \text{ and } \int_{\mathbb{R}^N} |\nabla(\tau\star u)|^2 dx < R_0\right\} < 0; \tag{3.2}$$

(iv) For any $u \in S_{c,r}$ with $\frac{b}{4}|\nabla u|_2^4 < \frac{1}{p}|u|_p^p$, we have

$$E_{a,\mu}(t_u \star u) = \max\{E_{a,\mu}(\tau\star u) : \tau \in \mathbb{R}\} > 0, \tag{3.3}$$

and $I_{a,\mu}$ is strictly decreasing and concave on $\tau \in (t_u, +\infty)$;

(v) The maps $u \in S_{c,r} \mapsto s_u \in \mathbb{R}$ and $u \in S_{c,r} \mapsto t_u \in \mathbb{R}$ are of class C^1.

Proof. We recall that by (3.1)

$$I_{a,\mu}(u,\tau) = E_{a,\mu}(\tau\star u) \geq h\left(\int_{\mathbb{R}^N} |\nabla(\tau\star u)|^2 dx\right) = h\left(e^{2\tau}\int_{\mathbb{R}^N} |\nabla u|^2 dx\right).$$

Thus, the function $I_{a,\mu}(u,\cdot)$ is positive on $(C(R_0), C(R_1))$ with

$$(C(R_0), C(R_1)) := \left(\frac{1}{2}\ln\left(R_0/\int_{\mathbb{R}^N}|\nabla u|^2 dx\right), \frac{1}{2}\ln\left(R_1/\int_{\mathbb{R}^N}|\nabla u|^2 dx\right)\right).$$

If $\frac{b}{4}|\nabla u|_2^4 \geq \frac{1}{p}|u|_p^p$, from (2.1), $I_{a,\mu}(u,\tau) \to +\infty$ as $\tau \to +\infty$, and $I_{a,\mu}(u,\tau) \to 0^-$ as $\tau \to -\infty$. Hence, it follows that $I_{a,\mu}$ has at least a critical point s_u, with s_u local minimum point on $(-\infty, C(R_0))$ at negative level, and $I_{a,\mu}$ has at least a zero point c_u with $s_u < c_u < C(R_0)$. Note that $\partial_\tau I_{a,\mu}(u,\tau) = 0$ reads

$$\phi(\tau) = \mu\gamma_q|u|_q^q \quad \text{with } \phi(\tau) := ae^{\frac{4-N(q-2)}{2}\tau}|\nabla u|_2^2 + be^{\frac{8-N(q-2)}{2}\tau}|\nabla u|_2^4 - \frac{4}{p}e^{\frac{8-N(q-2)}{2}\tau}|u|_p^p. \tag{3.4}$$

But $\phi(\tau)$ is increasing on $(-\infty, +\infty)$, hence, $I_{a,\mu}$ has exactly a critical point s_u and a zero point c_u.

If $\frac{b}{4}|\nabla u|_2^4 < \frac{1}{p}|u|_p^p$, $I_{a,\mu}(u,\tau) \to -\infty$ as $\tau \to +\infty$ and ϕ has a unique maximum point, and $I_{a,\mu}(u,\tau) \to 0^-$ as $\tau \to -\infty$. Therefore, we conclude that $I_{a,\mu}$ has exactly two critical points:

s_u, local minimum on $(-\infty, C(R_0))$ at negative level, and t_u, global maximum at positive level, which also gives (3.3).

From $s_u < C(R_0)$, then it holds that

$$\int_{\mathbb{R}^N} |\nabla(s_u \star u)|^2 dx = e^{2s_u} \int_{\mathbb{R}^N} |\nabla u|^2 dx < R_0.$$

In addition, we have $s_u \star u \in \mathcal{P}_{c,\mu}$, $t_u \star u \in \mathcal{P}_{c,\mu}$, and $\tau \star u \in \mathcal{P}_{c,\mu}$ implies $\tau \in \{s_u, t_u\}$. By minimality and $\mathcal{P}^0_{c,\mu} = \emptyset$, we have $\partial_{\tau\tau} I_{a,\mu}(u, s_u) > 0$, that is, $s_u \star u \in \mathcal{P}^+_{c,\mu}$. In the same way, $t_u \star u \in \mathcal{P}^-_{c,\mu}$. In particular, $I_{a,\mu}(u, \cdot)$ is concave on $[t_u, +\infty)$.

Finally, we show that $u \mapsto s_u$ and $u \mapsto t_u$ are of class C^1. To this end, we apply the implicit function theorem on the C^1 function $\Phi(u, \tau) := \partial_\tau I_{a,\mu}(u, \tau)$. We see $\Phi(u, s_u) = 0$ and $\partial_\tau \Phi(u, s_u) = \partial_{\tau\tau} I_{a,\mu}(u, s_u) > 0$, and the fact that it is not possible to pass with continuity from $\mathcal{P}^+_{c,\mu}$ to $\mathcal{P}^-_{c,\mu}$ (since $\mathcal{P}^0_{c,\mu} = \emptyset$). By the same argument, we have that $u \mapsto t_u$ is of C^1. □

From the proof of Lemma 3.4, we see that $s_u < C(R_0) < t_u$ and

$$\int_{\mathbb{R}^N} |\nabla(s_u \star u)|^2 dx < R_0 < \int_{\mathbb{R}^N} |\nabla(t_u \star u)|^2 dx,$$

which implies

$$\mathcal{P}^+_{c,\mu} \subseteq \{u \in S_{c,r} : |\nabla u|_2^2 < R_0\}$$

and

$$\mathcal{P}^-_{c,\mu} \subseteq \{u \in S_{c,r} : |\nabla u|_2^2 > R_0\}.$$

For $k > 0$, let us set

$$\mathcal{A}_k := \{u \in S_{a,r} : |\nabla u|_2^2 < k\},$$

and

$$M_{c,\mu} := \inf_{u \in \mathcal{A}_{R_0}} E_{a,\mu}(u).$$

As an immediate lemma, we have:

Lemma 3.5. $\sup_{\mathcal{P}^+_{c,\mu}} E_{a,\mu} \le 0 \le \inf_{\mathcal{P}^-_{c,\mu}} E_{a,\mu}$.

Lemma 3.6. *It results that $M_{c,\mu} \in (-\infty, 0)$, that*

$$M_{c,\mu} = \inf_{\mathcal{P}_{c,\mu}} E_{a,\mu} = \inf_{\mathcal{P}^+_{c,\mu}} E_{a,\mu}, \quad \textit{and that} \quad M_{c,\mu} < \inf_{\mathcal{A}_{R_0} \setminus \mathcal{A}_{R_0 - \rho}} E_{a,\mu}$$

for $\rho > 0$ small enough.

Proof. For any $u \in \mathcal{A}_{R_0}$, we have

$$E_{a,\mu}(u) \ge h(|\nabla u|_2^2) \ge \min_{t \in [0, R_0]} h(t) > -\infty,$$

and hence $M_{c,\mu} > -\infty$. Moreover, for any $u \in S_{c,r}$, we have $|\nabla(\tau \star u)|_2^2 < R_0$ and $E_{a,\mu}(\tau \star u) < 0$ for $\tau \ll -1$, and hence $M_{c,\mu} < 0$.

Now, $M_{c,\mu} \le \inf_{\mathcal{P}^+_{c,\mu}} E_{a,\mu}$ from $\mathcal{P}^+_{c,\mu} \subset \mathcal{A}_{R_0}$. On the other hand, if $u \in \mathcal{A}_{R_0}$, then $s_u \star u \in \mathcal{P}^+_{c,\mu} \subset \mathcal{A}_{R_0}$, and

$$E_{a,\mu}(s_u \star u) = \min \left\{ E_{a,\mu}(\tau \star u) : \tau \in \mathbb{R} \text{ and } \int_{\mathbb{R}^N} |\nabla(\tau \star u)|^2 dx < R_0 \right\} \le E_{a,\mu}(u),$$

which implies that $\inf_{\mathcal{P}^+_{c,\mu}} E_{a,\mu} \le M_{c,\mu}$. To prove that $\inf_{\mathcal{P}^+_{c,\mu}} E_{a,\mu} = \inf_{\mathcal{P}_{c,\mu}} E_{a,\mu}$, it is sufficient to recall that $E_{a,\mu}(u) > 0$ on $\mathcal{P}^-_{c,\mu}$.

Finally, by the continuity of h, there exists $\rho > 0$ such that $h(t) \ge \frac{M_{c,\mu}}{2}$ for any $t \in [R_0 - \rho, R_0]$. Therefore, we have

$$E_{a,\mu}(u) \ge h(|\nabla u|_2^2) \ge \frac{M_{c,\mu}}{2} > M_{c,\mu}$$

for every $u \in S_{c,r}$ with $R_0 - \rho \le |\nabla u|_2^2 \le R_0$. □

Lemma 3.7. *$M_{c,\mu}$ can be achieved by some $\tilde{u}_{c,\mu} \in S_{c,r}$. Moreover, $\tilde{u}_{c,\mu}$ is an interior local minimizer for $E_{a,\mu}|_{\mathcal{A}_{R_0}}$, and $\tilde{u}_{c,\mu}$ solves problem (1.1) for some $\tilde{\lambda}_{c,\mu} < 0$. Moreover, $\tilde{u}_{c,\mu}$ is a ground state of $E_{a,\mu}|_{S_{c,r}}$, any ground state of $E_{a,\mu}|_{S_{c,r}}$ is a local minimizer of $E_{a,\mu}$ on A_{R_0}.*

Proof. Let us consider a minimizing sequence $\{v_n\}$ for $E_{a,\mu}|_{\mathcal{A}_{R_0}}$. By Lemma 3.4, there exists a sequence $\{s_{v_n}\}$ such that $s_{v_n} \star v_n \in \mathcal{P}^+_{c,\mu}$ and

$$E_{a,\mu}(s_{v_n} \star v_n) = \min\left\{E_{a,\mu}(\tau \star s_{v_n}) : \tau \in \mathbb{R} \text{ and } \int_{\mathbb{R}^N} |\nabla(\tau \star s_{v_n})|^2 dx < R_0\right\} < E_{a,\mu}(v_n),$$

where the last inequality follows from $v_n \in \mathcal{A}_{R_0}$. Besides, we also see that

$$\int_{\mathbb{R}^N} |\nabla(s_{v_n} \star v_n)|^2 dx < R_0,$$

furthermore, by Lemma 3.6, we have

$$\int_{\mathbb{R}^N} |\nabla(s_{v_n} \star v_n)|^2 dx < R_0 - \rho.$$

Once again by Lemma 3.6, it holds that

$$M_{c,\mu} = \inf_{\mathcal{P}_{c,\mu}} E_{a,\mu} = \inf_{\mathcal{P}^+_{a,\mu}} E_{a,\mu}.$$

Setting $u_n = s_{v_n} \star v_n$ and using the Ekeland's variational principle, we may assume that $\{u_n\}$ is a Palais–Smale sequence for $E_{a,\mu}$ on $S_{c,r}$ and $P_\mu(u_n) = 0$. Hence, we have

$$E_{a,\mu}(u_n) = \frac{a}{4}|\nabla u_n|_2^2 - \frac{\mu}{q}\left(1 - \frac{N(q-2)}{8}\right)|u_n|_q^q = M_{c,\mu} + o_n(1).$$

It results to

$$\frac{a}{4}|\nabla u_n|_2^2 \le (M_{c,\mu} + 1) + \frac{\mu}{q}\left(1 - \frac{N(q-2)}{8}\right)\frac{c^{q-\frac{N(q-2)}{2}}}{2|Q_q|_2^{q-2}}|\nabla u_n|_2^{\frac{N(q-2)}{2}}, \tag{3.5}$$

which gives $\{|\nabla u_n|_2\}$ is bounded, hence, $\{u_n\}$ is bounded in $H^1(\mathbb{R}^N)$. From Lemma 2.2, up to a subsequence, $u_n \to \tilde{u}_{c,\mu}$ strongly in $H^1(\mathbb{R}^N)$, and $\tilde{u}_{c,\mu}$ solves problem (1.1) for some $\tilde{\lambda}_{c,\mu} < 0$. Moreover, we have $\int_{\mathbb{R}^N} |\nabla\tilde{u}_{c,\mu}|^2 dx < R_0 - \rho$ and $\tilde{u}_{c,\mu}$ is an interior local minimizer for $M_{c,\mu}$.

Since any critical point of $E_{a,\mu}|_{S_{c,r}}$ lies in $\mathcal{P}_{c,\mu}$ and $M_{c,\mu} = \inf_{\mathcal{P}_{c,\mu}} E_{a,\mu}$, we see that $\tilde{u}_{c,\mu}$ is a ground state for $E_{a,\mu}|_{S_{c,r}}$. It only remains to prove that any ground state of $E_{a,\mu}|_{S_{c,r}}$ is a local minimizer of $E_{a,\mu}$ in A_{R_0}. Let u be a critical point of $E_{a,\mu}|_{S_{c,r}}$ with $E_{a,\mu}(u) = M_{c,\mu} = \inf_{\mathcal{P}_{c,\mu}} E_{a,\mu}$. Since $E_{a,\mu}(u) < 0 < \inf_{\mathcal{P}^-_{c,\mu}} E_{a,\mu}$, necessarily $u \in \mathcal{P}^+_{c,\mu}$. Then Lemma 3.6 implies that $\mathcal{P}^+_{c,\mu} \subset A_{R_0}$. This leads to $|\nabla u|_2 < R_0$, and as a consequence u is a local minimizer for $E_{a,\mu}|_{A_{R_0}}$. Lemma 3.4 implies that $E_{a,\mu}(u) \le 0$ for any $u \in \mathcal{P}^+_{c,\mu}$, and $|\nabla u|_2^2 < R_0$. Hence, u is a local minimizer for $E_{a,\mu}|_{A_{R_0}}$. □

In the following, we focus on the existence of a second critical point for $E_{a,\mu}|_{S_{c,r}}$. Let

$$\widetilde{Q}_p(x) := c\frac{Q_p(x)}{|Q_p|_2}, \qquad Q_p^\tau(x) := c\frac{e^{\frac{N}{2}\tau}Q_p(e^\tau x)}{|Q_p|_2} \quad \text{for any } \tau > 0,$$

we have $\widetilde{Q}_p(x), Q_p^\tau(x) \in S_{c,r}$.

Lemma 3.8. *If $2 < q < 2 + \frac{4}{N}$, $p = 2 + \frac{8}{N}$, and $c > c^*$, we have $\int_{\mathbb{R}^N} |\nabla Q_p^\tau|^2 dx \to +\infty$ and $I_{a,\mu}(\widetilde{Q}_p, \tau) \to -\infty$ as $\tau \to +\infty$.*

Proof. A straightforward calculation shows that

$$\int_{\mathbb{R}^N} |\nabla Q_p^\tau|^2 dx = e^{2\tau} \int_{\mathbb{R}^N} |\nabla \widetilde{Q}_p|^2 dx.$$

From (1.5) with $s = p$ and (2.1), we have

$$\begin{aligned}
&I_{a,\mu}(\widetilde{Q}_p, \tau) \\
&= \frac{ae^{2\tau}}{2}\int_{\mathbb{R}^N} |\nabla \widetilde{Q}_p|^2 dx + \frac{be^{4\tau}}{4}\left(\int_{\mathbb{R}^N} |\nabla \widetilde{Q}_p|^2 dx\right)^2 - \frac{e^{4\tau}}{p}\int_{\mathbb{R}^N} |\widetilde{Q}_p|^p dx - \mu\frac{e^{\gamma_q q\tau}}{q}\int_{\mathbb{R}^N} |\widetilde{Q}_p|^q dx \\
&= \frac{ae^{2\tau}}{2}\frac{c^2|\nabla Q_p|_2^2}{|Q_p|_2^2} - \mu\frac{e^{\gamma_q q\tau}}{q}\frac{c^q}{|Q_p|_2^q}|Q_p|_q^q + c^4 e^{4\tau}\left(\frac{b}{4}\frac{|\nabla Q_p|_2^4}{|Q_p|_2^4} - \frac{1}{4}\frac{2}{c^2}\left(\frac{c}{|Q_p|_2}\right)^{\frac{8}{N}}\frac{2|Q_p|_p^p}{q|Q_p|_2^2}\right) \\
&= \frac{ac^2e^{2\tau}}{2} - \mu\frac{e^{\gamma_q q\tau}}{q}\frac{c^q}{|Q_p|_2^q}|Q_p|_q^q + \frac{bc^4e^{4\tau}}{4}\left(1 - \left(\frac{c}{c^*}\right)^{\frac{8-2N}{N}}\right),
\end{aligned}$$

from $c > c^*$, we have $I_{a,\mu}(\widetilde{Q}_p, \tau) \to -\infty$ as $\tau \to +\infty$. □

Lemma 3.9. *Suppose that $E_{a,\mu}(u) < M_{c,\mu}$. Then the value t_u defined by Lemma 3.4 is negative.*

Lemma 3.10. *It results that*

$$\tilde{\sigma}_{c,\mu} = \inf_{u \in \mathcal{P}_{c,\mu}^-} E_{a,\mu}(u) > 0.$$

We introduce the minimax class

$$\Gamma := \left\{\gamma \in C([0,1], S_{c,r}) : \gamma(0) \in \mathcal{P}_{c,\mu}^+ \text{ with } \frac{b}{4}|\nabla\gamma(0)|_2^4 < \frac{1}{p}|\gamma(0)|_p^p,\ E_{a,\mu}(\gamma(1)) \le 2M_{c,\mu}\right\},$$

then $\Gamma \neq \emptyset$. In fact, we have $s_{\widetilde{Q}_p} \star \widetilde{Q}_p \in \mathcal{P}_{c,\mu}^+$ by Lemma 3.4 and $E_{a,\mu}(\tau \star \widetilde{Q}_p) \to -\infty$ as $\tau \to +\infty$ by Lemma 3.8, and $\tau \mapsto \tau \star \widetilde{Q}_p$ is continuous. Thus, we can define the minimax value

$$\sigma_{c,\mu} := \inf_{\gamma \in \Gamma} \max_{t \in [0,1]} E_{a,\mu}(\gamma(t)).$$

Lemma 3.11. *$\sigma_{c,\mu} > 0$ can be achieved by some $\hat{u}_{c,\mu} \in S_{c,r}$, and $\hat{u}_{c,\mu}$ solves problem (1.1) for some $\hat{\lambda}_{c,\mu} < 0$.*

Proof. Since we want to use Lemma 2.1, next we verify the conditions of Lemma 2.1 one by one. Let us set

$$\mathcal{F} := \Gamma, \quad A := \gamma([0,1]), \quad F := \mathcal{P}_{c,\mu}^- \quad \text{and} \quad B := \mathcal{P}_{c,\mu}^+ \cup E_{a,\mu}^{2M_{c,\mu}},$$

where $E_{a,\mu}^c := \{u \in S_{c,r} : E_{a,\mu}(u) \le c\}$.

We first show that $\mathcal{F}$ is homotopy-stable family with extended boundary B: for any $\gamma \in \Gamma$ and any $\eta \in C([0,1] \times S_{c,r}; S_{c,r})$ satisfying $\eta(t,u) = u, (t,u) \in (0 \times S_{c,r}) \cup ([0,1] \times B)$, we want to get $\eta(1,\gamma(t)) \in \Gamma$. In fact, let $\tilde{\gamma}(t) = \eta(1,\gamma(t))$, then $\tilde{\gamma}(0) = \eta(1,\gamma(0)) = \gamma(0) \in \mathcal{P}^+_{c,\mu}$. Besides, $\tilde{\gamma}(1) = \eta(1,\gamma(1)) = \gamma(1) \in E^{2M_{c,\mu}}_{a,\mu}$. Therefore, we have $\eta(1,\gamma(t)) \in \Gamma$.

Next we verify the condition (2.2): by Lemma 3.5 and Lemma 3.9, we know $F \cap B = \emptyset$ and hence $F \backslash B = F$. We claim that

$$A \cap (F \backslash B) = A \cap F = \gamma([0,1]) \cap \mathcal{P}^-_{c,\mu} \neq \emptyset, \quad \forall \gamma \in \Gamma. \tag{3.6}$$

Indeed, since $\gamma(0) \in \mathcal{P}^+_{c,\mu}$ with $\frac{b}{4}|\nabla \gamma(0)|_2^4 < \frac{1}{p}|\gamma(0)|_p^p$, we know $s_{\gamma(0)} = 0$ (see the definition of s_u in Lemma 3.4) and hence $t_{\gamma(0)} > s_{\gamma(0)} = 0$. On the other hand, since $E_{a,\mu}(\gamma(1)) \leq 2M_{c,\mu} < M_{c,\mu}$ (see Lemma 3.6), we by Lemma 3.8 have $t_{\gamma(1)} < 0$. By Lemma 3.4, we know $t_{\gamma(\tau)}$ is continuous in τ. It follows that for every $\gamma \in \Gamma$ there exists $\tau_\gamma \in (0,1)$ such that $t_{\gamma(\tau_\gamma)} = 0$, that is, $\gamma(\tau_\gamma) \in \mathcal{P}^-_{c,\mu}$, and hence $A \cap (F \backslash B) \neq \emptyset$.

Finally, we verify the condition (2.3), that is, we need to show

$$\inf_{\mathcal{P}^-_{c,\mu}} E_{a,\mu} \geq \sigma_{c,\mu} \geq \sup_{\mathcal{P}^+_{c,\mu} \cup E^{2M_{c,\mu}}_{a,\mu}} E_{a,\mu}.$$

By (3.6), for every $\gamma \in \Gamma$, we have

$$\max_{t \in [0,1]} E_{a,\mu}(\gamma(t)) \geq \inf_{\mathcal{P}^-_{c,\mu}} E_{a,\mu},$$

so that $\sigma_{c,\mu} \geq \tilde{\sigma}_{c,\mu}$. On the other hand, if $u \in \mathcal{P}^-_{c,\mu}$ with $\frac{b}{4}|\nabla u|_2^4 < \frac{1}{p}|u|_p^p$, then for $s_1 \gg 1$ large enough

$$\gamma_u : \tau \in [0,1] \mapsto ((1-\tau)s_u + \tau s_1) \star u \in S_{c,r}$$

is a path in Γ. Since $u \in \mathcal{P}^-_{c,\mu}$, we know $t_u = 0$ is a global maximum point for $I_{a,\mu}$, and deduce that

$$E_{a,\mu}(u) \geq \max_{t \in [0,1]} E_{a,\mu}\left(\gamma_u(t)\right) \geq \sigma_{c,\mu},$$

which implies that $\tilde{\sigma}_{c,\mu} \geq \sigma_{c,\mu}$. Thus, we get $\sigma_{c,\mu} = \tilde{\sigma}_{c,\mu} > 0$. By Lemma 3.5, we know $E_{a,\mu}(u) \leq 0$ for any $u \in \mathcal{P}^+_{c,\mu} \cup E^{2M_{c,\mu}}_{a,\mu}$, hence we get (2.3). From Lemma 2.1, we obtain a Palais–Smale sequence $\{u_n\}$ for the functional $E_{a,\mu}$ on $S_{c,r}$ and $P_\mu\left(u_n\right) \to 0$. Similar to (3.5), $\{u_n\}$ is bounded. Hence, from Lemma 2.2, up to a subsequence, $u_n \to \hat{u}_{c,\mu}$ strongly in $H^1(\mathbb{R}^N)$, and $\hat{u}_{c,\mu}$ solves problem (1.1) for some $\hat{\lambda}_{c,\mu} < 0$. □

Proof of Theorem 1.1. Theorem 1.1 comes from Lemma 3.7 and Lemma 3.11. □

4 Proof of Theorem 1.2

In this section, we deal with the case $2 + \frac{4}{N} < q < p = 2 + \frac{8}{N}$, $\mu > 0$, $a \geq 0$ and prove Theorem 1.2. We first consider the existence of normalized ground state solution for the degenerate Kirchhoff-type equations, that is, $a = 0$, by the following minimization problem:

$$m_{0,c} = \inf_{u \in S_c} E_{a,\mu}(u).$$

And then, we discuss the the existence of normalized solutions for the nondegenerate Kirchhoff-type equations, that is, $a > 0$.

Lemma 4.1. *If $a \geq 0$, $2+\frac{4}{N} < q < p = 2+\frac{8}{N}$ and $c < c^*$, the functional $E_{a,\mu}$ is coercive on S_c. Moreover, $m_{0,c} < 0$.*

Proof. Utilizing (1.5) and (1.6), we see that for any $u \in S_c$,

$$E_{a,\mu}(u) \geq \frac{b}{4}\left(1-\left(\frac{c}{c^*}\right)^{\frac{8-2N}{N}}\right)|\nabla u|_2^4 - \mu\frac{c^{q-q\gamma_q}}{2|Q_q|_2^{q-2}}|\nabla u|_2^{q\gamma_q},$$

hence, from $2 < \gamma_q q < 4$ and $c < c^*$, we obtain that the functional $E_{a,\mu}$ is coercive on S_c.

For any $u \in S_c$, set $u^t(x) = t^{\frac{N}{2}}u(tx)$ for any $t > 0$, then $u^t \in S_c$ and

$$m_{0,c} \leq E_{0,\mu}(u^t) = \frac{b}{4}|\nabla u|_2^4 t^4 - \frac{1}{p}|u|_p^p t^4 - \frac{\mu}{q}|u|_q^q t^{\gamma_q q} \to 0^- \quad \text{as } t \to 0^+,$$

hence, from $\mu > 0$ and $2 < \gamma_q q < 4$, we obtain $m_{0,c} < 0$. □

In order to prove that the minimizer of $m_{a,c}$ can be obtained, we now give two lemmas.

Lemma 4.2. *If $m_{a,c} < 0$, we have $m_{a,c} < m_{a,\gamma} + m_{a,c-\gamma}$ for any $0 < \gamma < c$.*

Proof. The proof is similar to [19, Lemma 2.5], so we omit it. □

Corollary 4.3. *$m_{a,c}$ is strictly decreasing in $c \in (0, +\infty)$.*

Lemma 4.4. *Let $c < c^*$, $m_{0,c} := \inf u \in S_c E_{0,\mu}(u)$ has a radial minimizer $\tilde{u}$, and $\tilde{u}$ solves problem (1.1) for some $\tilde{\lambda} < 0$.*

Proof. Let $\{u_n\} \subset S_c$ be a minimizing sequence of $m_{0,c} < 0$, it can easily see that $\{u_n\}$ is bounded in $H^1(\mathbb{R}^N)$ by Lemma 4.1. Since $E_{0,\mu}$ is even, we can suppose that $u_n \geq 0$. Moreover, let u_n^* be the symmetric radial decreasing rearrangement of u_n, up to subsequence, we may assume that there exists $\tilde{u} \in H_r^1(\mathbb{R}^N)$ such that

$$u_n^* \rightharpoonup \tilde{u} \text{ in } H^1(\mathbb{R}^N), \quad u_n^* \to \tilde{u} \text{ in } L^s(\mathbb{R}^N), \quad s \in (2, 2^*), \quad u_n^*(x) \to \tilde{u}(x) \text{ a.e. in } \mathbb{R}^N. \tag{4.1}$$

Hence, we have

$$E_{0,\mu}(\tilde{u}) \leq \liminf_{n\to\infty} E_{0,\mu}(u_n^*) \leq \liminf_{n\to\infty} E_{0,\mu}(u_n) = m_{0,c}, \qquad |\tilde{u}|_2^2 \leq c^2.$$

From $E_{0,\mu}(\tilde{u}) \leq m_{0,c} < 0$, it follows that $\tilde{u} \not\equiv 0$. By Corollary 4.3, it must hold that

$$E_{0,\mu}(\tilde{u}) = m_{0,c}, \qquad |\tilde{u}|_2^2 = c^2.$$

By the Lagrange multiplier rule, there is $\tilde{\lambda} \in \mathbb{R}$ such that

$$-b|\nabla\tilde{u}|_2^2\Delta\tilde{u} = \tilde{\lambda}\tilde{u} + |\tilde{u}|^{p-2}\tilde{u} + \mu|\tilde{u}|^{q-2}\tilde{u},$$

and then, combining with the Pohozaev identity, we have

$$\tilde{\lambda}|\tilde{u}|_2^2 = \frac{4-p}{p}|\tilde{u}|_p^p + \frac{\mu}{2q}(N(q-2)-2q)|\tilde{u}|_q^q,$$

which implies $\tilde{\lambda} < 0$ from $2+\frac{4}{N} < q < p = 2+\frac{8}{N}$. □

Lemma 4.5. *Let $2 + \frac{4}{N} < q < p = 2 + \frac{8}{N}$, there is a constant $\bar{a} = \bar{a}(b, c, q) > 0$ such that for any $a \in (0, \bar{a})$, we have*

$$m_{a,c} := \inf_{u \in S_c} E_{a,\mu}(u) < 0.$$

Proof. From [21, Lemma 2.1], $\tilde{u}$ satisfies the following Pohozeav identity:

$$b|\nabla \tilde{u}|_2^4 - \frac{4}{p}|\tilde{u}|_p^p - \mu \frac{N(q-2)}{2q}|\tilde{u}|_q^q = 0,$$

and it follows that

$$\begin{aligned} m_{0,c} &= E_{0,\mu}(\tilde{u}) \\ &= \frac{b}{4}|\nabla \tilde{u}|_2^4 - \frac{1}{p}|\tilde{u}|_p^p - \mu \frac{1}{q}|\tilde{u}|_q^q \\ &= \left(\frac{1}{4} - \frac{2}{N(q-2)}\right) b|\nabla \tilde{u}|_2^4 + \left(\frac{8}{N(q-2)} - 1\right) \frac{1}{p}|\tilde{u}|_p^p \\ &< 0. \end{aligned}$$

Hence, we obtain

$$\begin{aligned} E_{a,\mu}(\tilde{u}) &= \frac{a}{2}|\nabla \tilde{u}|_2^2 + E_{0,\mu}(\tilde{u}) \\ &= \frac{a}{2}|\nabla \tilde{u}|_2^2 + \left(\frac{1}{4} - \frac{2}{N(q-2)}\right) b|\nabla \tilde{u}|_2^4 + \left(\frac{8}{N(q-2)} - 1\right) \frac{1}{p}|\tilde{u}|_p^p \\ &\leq \frac{a}{2}|\nabla \tilde{u}|_2^2 + \frac{b}{4}\left(1 - \left(\frac{c}{c^*}\right)^{\frac{8-2N}{N}}\right)\left(\frac{1}{4} - \frac{2}{N(q-2)}\right)|\nabla \tilde{u}|_2^4. \end{aligned}$$

Let

$$\bar{a} = \frac{b}{2}\left(1 - \left(\frac{c}{c^*}\right)^{\frac{8-2N}{N}}\right)\left(\frac{2}{N(q-2)} - \frac{1}{4}\right)|\nabla \tilde{u}|_2^2,$$

for any $a \in (0, \bar{a})$, we have $E_{a,\mu}(\tilde{u}) < 0$, and hence $m_{a,c} \leqslant E_{a,\mu}(\tilde{u}) < 0$. □

Lemma 4.6. *Let $0 < a < \bar{a}$ and $c < c^*$, $m_{a,c} := \inf_{u \in S_c} E_{a,\mu}(u)$ has a radial minimizer $\tilde{u}_{c,a}$, and $\tilde{u}_{c,a}$ solves problem (1.1) for some $\tilde{\lambda}_{c,a} < 0$.*

Proof. The proof is similar with that of Lemma 4.4, and we omit it. □

Lemma 4.7. *Let $0 < a < \bar{a}$, $2 + \frac{4}{N} < q < p = 2 + \frac{8}{N}$ and $c < c^*$, there exists $0 < K_{c,a} < \frac{|\nabla \tilde{u}_{c,a}|_2^2}{2}$ small enough such that*

$$0 < \sup_{u \in \mathcal{A}} E_{a,\mu}(u) < \inf_{u \in \mathcal{B}} E_{a,\mu}(u),$$

where $\mathcal{A} = \{u \in S_{c,r} : |\nabla u|_2^2 < K_{c,a}\}$, $\mathcal{B} = \{u \in S_{c,r} : |\nabla u|_2^2 = 2K_{c,a}\}$.

Proof. Let $K > 0$ be arbitrary but fixed and suppose that $u, v \in S_{c,r}$ satisfies

$$|\nabla u|_2^2 < K \quad \text{and} \quad |\nabla v|_2^2 = 2K.$$

From (1.5), we have

$$\begin{aligned} E_{a,\mu}(v) - E_{a,\mu}(u) &\geq E_{a,\mu}(v) - \frac{a}{2}|\nabla u|_2^2 - \frac{b}{4}|\nabla u|_2^4 \\ &\geq \frac{aK}{2} + \frac{3bK^2}{4} - b\left(\frac{c}{c^*}\right)^{\frac{8-2N}{N}} K^2 - \mu \frac{c^{q-q\gamma_q}}{|Q_q|_2^{q-2}}(2K)^{\frac{N(q-2)-4}{4}} \\ &= K\left(\frac{a}{2} + \left(\frac{3}{4} - \left(\frac{c}{c^*}\right)^{\frac{8-2N}{N}}\right) bK - \mu \frac{c^{q-q\gamma_q}}{|Q_q|_2^{q-2}}(2K)^{\frac{N(q-2)-4}{4}}\right), \end{aligned}$$

and
$$E_{a,\mu}(u) \geq \frac{a}{2}|\nabla u|_2^2 + \frac{b}{4}\left(1-\left(\frac{c}{c^*}\right)^{\frac{8-2N}{N}}\right)|\nabla u|_2^4 - \mu\frac{c^{q-q\gamma_q}}{2|Q_q|_2^{q-2}}|\nabla u|_2^{q\gamma_q}.$$

In summary, we can choose sufficiently small constant $0 < K_{c,a} < \frac{|\nabla \tilde{u}_{c,a}|_2^2}{2}$ such that
$$0 < \sup_{u\in\mathcal{A}} E_{a,\mu}(u) < \inf_{u\in\mathcal{B}} E_{a,\mu}(u)$$

where $\mathcal{A} = \{u \in S_{c,r} : |\nabla u|_2^2 < K_{c,a}\}$, $\mathcal{B} = \{u \in S_{c,r} : |\nabla u|_2^2 = 2K_{c,a}\}$. □

Let $u \in S_{c,r}$ be arbitrary and fixed, it is easy to see that $|\nabla(\tau \star u)|_2^2 \to 0$ and $I_{a,\mu}(u,\tau) \to 0^+$ as $\tau \to 0^+$. Hence, there exists $\hat{u}_{c,a} \in S_{c,r}$ such that $|\nabla \hat{u}_{c,a}|_2^2 < K_{c,a}$ and $E_{a,\mu}(\hat{u}_{c,a}) > 0$. Combining with Lemma 4.7, we can construct the minimax value for the functionals $E_{a,\mu}$ and $I_{a,\mu}$:
$$\widetilde{\gamma}_c = \inf_{\widetilde{h}\in\widetilde{\Gamma}_c}\max_{t\in[0,1]} I_{a,\mu}(\widetilde{h}(t))$$

with $\widetilde{\Gamma}_c = \{\widetilde{h} \in C([0,1], S_{c,r}\times\mathbb{R}) : \widetilde{h}(0) = (\hat{u}_{c,a},0),\ \widetilde{h}(1) = (\tilde{u}_{c,a},0)\}$, and
$$\gamma_c = \inf_{h\in\Gamma_c}\max_{t\in[0,1]} E_{a,\mu}(h(t))$$

with $\Gamma_c = \{h \in C([0,1], S_{c,r}) : h(0) = \hat{u}_{c,a},\ h(1) = \tilde{u}_{c,a}\}$, where $\tilde{u}_{c,a}$ is obtained in Lemma 4.6. We have the following lemma.

Lemma 4.8. *If $0 < a < \bar{a}$, $2 + \frac{4}{N} < q < p = 2 + \frac{8}{N}$ and $c < c^*$, we have*
$$\widetilde{\gamma}_c = \gamma_c \geq \max\{E_{a,\mu}(\hat{u}_{c,a}),\ E_{a,\mu}(\tilde{u}_{c,a})\} := \delta_c > 0.$$

Proof. For any $\widetilde{h} \in \widetilde{\Gamma}_c$, we can write it into
$$\widetilde{h}(t) = (\widetilde{h}_1(t), \widetilde{h}_2(t)) \in S_{c,r}\times\mathbb{R}.$$

Setting $h(t) = \widetilde{h}_2(t) \star \widetilde{h}_1(t)$, we have $h(t) \in \Gamma_c$ and
$$\max_{t\in[0,1]} I_{a,\mu}(\widetilde{h}(t)) = \max_{t\in[0,1]} E_{a,\mu}(\widetilde{h}_2(t)\star\widetilde{h}_1(t)) = \max_{t\in[0,1]} E_{a,\mu}(h(t)),$$

which implies $\widetilde{\gamma}_c \geq \gamma_c$. On the other hand, for any $h \in \Gamma_c$, set $\widetilde{h}(t) = (h(t),0)$, we get $\widetilde{h} \in \widetilde{\Gamma}_c$ and
$$\max_{t\in[0,1]} I_{a,\mu}(\widetilde{h}(t)) = \max_{t\in[0,1]} E_{a,\mu}(h(t)),$$

which provides that $\gamma_c \geq \widetilde{\gamma}_c$. Thus, we have $\widetilde{\gamma}_c = \gamma_c$. Finally, $\gamma_c \geq \max\{E_{a,\mu}(\hat{u}_{c,a}), E_{a,\mu}(\tilde{u}_{c,a})\} > 0$ follows from the definition of γ_c. □

In what follows, we give the relationship between the Palais–Smale sequence for the functional $I_{a,\mu}$ and that of the functional $E_{a,\mu}$.

Lemma 4.9. *There exists a sequence $\{(v_n, \tau_n)\} \subset S_{c,r}\times\mathbb{R}^+$ such that for $n \to \infty$, we have*

(1) $I_{a,\mu}(v_n,\tau_n) \to \widetilde{\gamma}_c$,

(2) $I'_{a,\mu}|_{S_{c,r}\times\mathbb{R}}(v_n,\tau_n)\to 0$, *i.e., it holds that*

$$\partial_\tau I_{a,\mu}(v_n,\tau_n)\to 0 \quad \textit{and} \quad \langle \partial_u I_{a,\mu}(v_n,\tau_n),\widetilde{\varphi}\rangle \to 0$$

for any

$$\widetilde{\varphi}\in T_{v_n}=\left\{\widetilde{\varphi}\in H^1(\mathbb{R}^N):\int_{\mathbb{R}^N} v_n\widetilde{\varphi}dx=0\right\}.$$

In addition, setting $u_n(x)=\tau_n\star v_n(x)$, *then for* $n\to\infty$ *we get*

(i) $E_{a,\mu}(u_n)\to\gamma_c$,

(ii) $P_\mu(u_n)\to 0$,

(iii) $E'_{a,\mu}|_{S_{c,r}}(u_n)\to 0$, *i.e., it holds that* $\langle E'_{a,\mu}(u_n),\varphi\rangle\to 0$ *for any*

$$\varphi\in T_{u_n}=\left\{\varphi\in H^1(\mathbb{R}^N):\int_{\mathbb{R}^N} u_n\varphi dx=0\right\}.$$

Proof. According to the construction of $\widetilde{\gamma}_c$, we know that the conclusions (1) and (2) follow directly from Ekeland's Variational Principle. Next we mainly prove (i)–(iii).

For (i), it is obvious from

$$E_{a,\mu}(u_n)=E_{a,\mu}(\tau_n\star v_n)=I_{a,\mu}(v_n,\tau_n)$$

and $\widetilde{\gamma}_c=\gamma_c$.

For (ii), we first have

$$\begin{aligned}
\partial_\tau I_{a,\mu}(v_n,\tau_n)&=e^{2\tau_n}a|\nabla v_n|_2^2+e^{4\tau_n}b|\nabla v_n|_2^4-\mu e^{\gamma_q q\tau_n}\gamma_q|v_n|_q^q-e^{4\tau_n}\frac{4}{p}|v_n|_p^p\\
&=a|\nabla(\tau_n\star v_n)|_2^2+b|\nabla(\tau_n\star v_n)|_2^4-\mu\gamma_q|\tau_n\star v_n|_q^q-\frac{4}{p}|\tau_n\star v_n|_p^p\\
&=a|\nabla u_n|_2^2+b|\nabla u_n|_2^4-\mu\gamma_q|u_n|_q^q-\frac{4}{p}|u_n|_p^p\\
&=P_\mu(u_n).
\end{aligned}$$

Thus, (ii) is a consequence of $\partial_\tau I_{a,\mu}(v_n,\tau_n)\to 0$ as $n\to\infty$.

For (iii), by the definition of the functional $I_{a,\mu}$, we have

$$\begin{aligned}
\langle \partial_u I_{a,\mu}(v_n,\tau_n),\widetilde{\varphi}\rangle&=e^{2\tau_n}a\int_{\mathbb{R}^N}\nabla v_n\nabla\widetilde{\varphi}dx+e^{4\tau_n}b|\nabla v_n|_2^2\int_{\mathbb{R}^N}\nabla v_n\nabla\widetilde{\varphi}dx\\
&\quad-\mu e^{\gamma_q q\tau_n}\int_{\mathbb{R}^N}|v_n|^{q-2}v_n\widetilde{\varphi}dx-e^{4\tau_n}\int_{\mathbb{R}^N}|v_n|^{p-2}v_n\widetilde{\varphi}dx,
\end{aligned}$$

where

$$\widetilde{\varphi}\in T_{v_n}=\left\{\widetilde{\varphi}\in H^1(\mathbb{R}^N):\int_{\mathbb{R}^N} v_n\widetilde{\varphi}dx=0\right\}.$$

On the other hand, for any

$$\varphi\in T_{u_n}=\left\{\varphi\in H^1(\mathbb{R}^N):\int_{\mathbb{R}^N} u_n\varphi dx=0\right\},$$

from $u_n(x) = \tau_n \star v_n(x)$, we have

$$\begin{aligned}
&\langle E'_{a,\mu}(u_n), \varphi\rangle \\
&\quad = a\int_{\mathbb{R}^N} \nabla u_n \nabla \varphi dx + b|\nabla u_n|_2^2 \int_{\mathbb{R}^N} \nabla u_n \nabla \widetilde{\varphi} dx - \mu \int_{\mathbb{R}^N} |u_n|^{q-2} u_n \varphi dx - \int_{\mathbb{R}^N} |u_n|^{p-2} u_n \varphi dx \\
&\quad = e^{2\tau_n} a \int_{\mathbb{R}^N} \nabla v_n e^{-\frac{N\tau_n}{2}} \nabla \varphi(e^{-\tau_n} x) dx + e^{4\tau_n} b |\nabla v_n|_2^2 \int_{\mathbb{R}^N} \nabla v_n e^{-\frac{N\tau_n}{2}} \nabla \varphi(e^{-\tau_n} x) dx \\
&\qquad - \mu e^{\gamma_q q \tau_n} \int_{\mathbb{R}^N} |v_n(x)|^{q-2} v_n(x) e^{-\frac{N\tau_n}{2}} \varphi(e^{-\tau_n} x) dx \\
&\qquad - e^{4\tau_n} \int_{\mathbb{R}^N} |v_n(x)|^{p-2} v_n(x) e^{-\frac{N\tau_n}{2}} \varphi(e^{-\tau_n} x) dx.
\end{aligned}$$

Setting

$$\widetilde{\varphi}(x) = e^{-\frac{N\tau_n}{2}} \varphi(e^{-\tau_n} x),$$

we get (iii) if we could show $\widetilde{\varphi} \in T_{v_n}$. In fact, $\widetilde{\varphi} \in T_{v_n}$ comes from the following equalities:

$$0 = \int_{\mathbb{R}^N} u_n \varphi dx = \int_{\mathbb{R}^N} e^{\frac{N\tau_n}{2}} v_n(e^{\tau_n} x) \varphi(x) dx = \int_{\mathbb{R}^N} v_n(x) e^{-\frac{N\tau_n}{2}} \varphi(e^{-\tau_n} x) dx = \int_{\mathbb{R}^N} v_n \widetilde{\varphi} dx. \qquad \square$$

Lemma 4.10. *$\gamma_c > 0$ can be achieved by some $u_{c,a} \in S_{c,r}$, and $u_{c,a}$ is a radial solution of problem (1.1) for some $\lambda_c < 0$.*

Proof. By Lemma 4.1 and Lemma 4.9, we obtain a bounded Palais–Smale sequence $\{u_n\} \subset S_{c,r}$ for $E_{a,\mu}|_{S_{c,r}}$ at level $\gamma_c > 0$ such that $P_\mu(u_n) \to 0$ as $n \to \infty$. By Lemma 2.2, we have $u_n \to u_{c,a}$ in $H^1_r(\mathbb{R}^N)$, and $u_{c,a} \in S_{c,r}$ is a radial solution of problem (1.1) for some $\lambda_c < 0$. □

Proof of Theorem 1.2. Theorem 1.2 comes from Lemma 4.4, Lemma 4.6 and Lemma 4.10. □

Abstract. We are interested in the existence of multiple solutions for a class of $p(x)$-curl systems arising in electromagnetism. We work on variable exponent Sobolev spaces and by using critical point theory and the variational method, we investigate the existence of at least one, two, and three solutions to the problem.

Keywords: $p(x)$-curl systems, electromagnetic problems, variational methods, variable exponent Sobolev spaces.

2020 Mathematics Subject Classification: 35J50, 47J20, 78A30, 78M30.

1 Introduction

The study of partial differential equations or systems with variable exponents is a recent research topic that developed quickly. It started when it was understood that variable exponents give better descriptions of the behavior of certain materials or phenomena.

Let $\Omega \subset \mathbb{R}^3$, is a bounded simply connected domain with a $C^{1,1}$ boundary denoted by $\partial\Omega$. In what follows, vector functions and spaces of vector functions will be denoted by boldface symbols. We will use n to denote the outward unitary normal vector to $\partial\Omega$ and ∂_x to denote the partial derivative of a function with respect to the variable x.

The divergence of a vector function $\mathbf{v} = (v_1, v_2, v_3)$ is denoted by

$$\nabla.\mathbf{v} = \partial_{x_1} v_1 + \partial_{x_2} v_2 + \partial_{x_3} v_3$$

and the curl of $\mathbf{v}$ by

$$\nabla \times \mathbf{v} = (\partial_{x_2} v_3 - \partial_{x_3} v_2, \partial_{x_3} v_1 - \partial_{x_1} v_3, \partial_{x_1} v_2 - \partial_{x_2} v_1).$$

We recall the identity

$$-\Delta \mathbf{v} = \nabla \times (\nabla \times \mathbf{v}) - \nabla.(\nabla.\mathbf{v}),$$

where $\Delta \mathbf{v} = (\Delta v_1, \Delta v_2, \Delta v_3)$ and $\Delta v_i = \nabla.(\nabla v_i), i = 1, 2, 3.$

In this article, We are interested in the existence of multiple solutions for the following intriguing system

$$\begin{cases} \nabla \times (|\nabla \times u|^{p(x)-2}\nabla \times u) + a(x)|u|^{p(x)-2}u = \lambda f(x,u), \ \nabla . u = 0 & \text{in } \Omega, \\ |\nabla \times u|^{p(x)-2}\nabla \times u \times n = 0, \ u.n = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where $\lambda \in (0,+\infty)$, $\Omega \subset \mathbb{R}^3$, is a bounded simply connected domain with a $C^{1,1}$ boundary denoted by $\partial\Omega$. We will use n to denote the outward unitary normal vector to $\partial\Omega$. a is a functional in L^∞ and there exist $a_0, a_1 > 0$ such that

$$a_0 < a(x) < a_1, \qquad \forall x \in \Omega.$$

$p \in C(\bar{\Omega})$, with

$$3 < p^- = \min_{x\in\Omega} p(x) \le p^+ = \max_{x\in\Omega} p(x) < \infty,$$

and $p(x)$ satisfies logarithmic continuity: there exists a function $\omega : \mathbb{R}_0^+ \to \mathbb{R}_0^+$ such that

$$\forall x, y \in \bar{\Omega}, |x-y| < 1, \quad |p(x) - p(y)| \le \omega(|x-y|), \quad \text{and} \quad \lim_{\tau\to 0^+} \omega(\tau)\log\frac{1}{\tau} = C < \infty. \tag{1.2}$$

The interest in transposing the problems into new problems with variable exponents is linked to a large scale of applications that are involving some nonhomogeneous materials. It was established that for appropriate treatment of these materials, we can not rely on the classical Sobolev space and that we have to allow the exponent to vary instead. Working with variable exponents, hence working in the framework of variable exponent spaces, opens the door for multiple applications. The variable exponent problems arise in many different applications, such as nonlinear elastic [26], electrorheological fluids [22], image processing [13] and other physics phenomena [2, 27]. The literature on variable exponent Sobolev spaces and their applications is quite large, here we just quote a few, see [5,6,12,13,19,20,23] and the references therein. For the basic properties of variable exponent Sobolev spaces and their applications to partial differential equations, we refer the readers to [14,21].

In [4], Antontsev, Miranda, and Santos studied the qualitative properties of solutions for the following $p(x,t)$-curl systems:

$$\begin{cases} \partial_t u + \nabla \times (|\nabla \times u|^{p(x,t)-2}\nabla \times u) = \lambda f(u), \ \nabla . u = 0 & \text{in } \Omega \times (0,T), \\ |\nabla \times u|^{p(x,t)-2}\nabla \times u \times n = 0, \ u.n = 0 & \text{on } \partial\Omega \times (0,T), \\ u(x,0) = u_0(x) & \text{in } \Omega, \end{cases} \tag{1.3}$$

where $\nabla \times (|\nabla \times u|^{p(x,t)-2}\nabla \times u)$ is the $p(x,t)$-curl operator, $f(u) = \lambda u(\int_\Omega |u|^2 dx)^{\frac{\rho-2}{2}}$ with $\lambda \in \{-1,0,1\}$ and $\rho > 0$ is constant. The authors introduced a suitable variable exponent Sobolev space and obtained the existence of local or global weak solutions for system (1.3) by using Galerkin's method. The authors also studied the blow-up and finite-time extinction properties of solutions. When $p(x,t) \equiv p$, then problem (1.3) turns into a model from the generalized Maxwell's equations in the electromagnetic field theory. More precisely, u denotes the magnetic field, $\nabla \times u$ denotes the total current density, f denotes an internalmagnetic current, and $\nabla \times (|\nabla \times u|^{p-2}\nabla \times u)$ denotes the electric field.

Motivated by the above works, we study the existence and multiplicity of solutions for systems (1.1) with general nonlinearities. To the best of our knowledge, this is the first time to deal with the existence of steady-state solutions for systems (1.1) involving the $p(x)$-curl operator by applying variational methods different from that used in [24].

Xianga, Wanga, and Zhangc [24] investigated the existence and multiplicity of solutions to problem (1.1) in the case $\lambda = 1$. They studied the existence of ground state solutions and infinitely many solutions for (1.1) in the case $\lambda = 1$ with the nonlinearity f satisfying superlinear growth conditions is obtained by combining the mountain pass theorem with the Nehari manifold method, and a variant of the mountain pass theorem.

In this paper, we obtain three different results about the existence of weak solutions to the problem (1.1) by using critical point theorems established in [8, 9, 11]. The first aim of this paper is to provide an estimate of the positive interval for the parameter λ in which the problem (1.1) possesses at least one nontrivial weak solution. We also wish to consider the existence of two solutions to our problem by using a result of Bonanno [9, Theorem 3.2]. In a recent paper, Bonanno and Chinnì [10] studied the existence of at least two distinct weak solutions to a problem involving a p(x)-Laplacian by applying critical point theory. Our first main result will require the $(P.S.)^{[r]}$ condition, while in our second one, we will ask that the (AR)-condition holds and use it to ensure that the (usual) (PS)-condition is satisfied. We refer the reader to the papers [7, 10, 17, 18] where this approach was applied successfully. Finally, our third goal is to obtain the existence of three solutions to (1.1); this problem is less studied by researchers. In this case, we consider problem (1.1) where the nonlinearity f has subcritical growth, and we apply variational methods and critical point theory. The main tool used is the critical point theorem of Bonanno and Marano [11, Theorem 3.6].

The remainder of this paper is organized as follows. First, in Section 2, we recall briefly some basic results for fractional Sobolev spaces. In Section 3, we obtain the existence of at least one, two, or three nontrivial weak solutions to the problem (1.1) provided the parameter λ belongs to a positive interval to be determined.

2 Preliminaries

In this section, we introduce some definitions and results of Sobolev spaces with variable exponents.

Let $\Omega \subset \mathbb{R}^3$ be a bounded simply connected domain with a $C^{1,1}$ boundary denoted by $\partial\Omega$. Let $p \in C(\bar{\Omega})$. Set

$$p^- = \min_{x\in\bar{\Omega}} p(x), \quad \text{and} \quad p^+ = \max_{x\in\bar{\Omega}} p(x), \quad \text{with } 1 < p^- \le p^+ < \infty.$$

We define the variable exponent Lebesgue space $L^{p(\cdot)}(\Omega)$ as the set of all measurable functions $u : \Omega \to \mathbb{R}$ for which the convex modular

$$\rho_{p(x)}(u) = \int_\Omega |u|^{p(x)} dx,$$

is finite. We define a norm, the so-called Luxemburg norm, on this space by the formula

$$\|u\|_{p(\cdot)} = \inf\left\{\gamma > 0 : \rho_{p(\cdot)}\left(\frac{u}{\gamma}\right) \le 1\right\}.$$

The space $(L^{p(\cdot)}(\Omega), \|.\|_{L^{p(\cdot)}(\Omega)})$ is a separable and reflexive Banach space. Moreover, the space $L^{p(\cdot)}(\Omega)$ is uniformly convex, hence reflexive, and its dual space is isomorphic to $L^{p'(\cdot)}(\Omega)$, where $\frac{1}{p(\cdot)} + \frac{1}{p'(\cdot)} = 1$.

Finally, we have the Hölder type inequality:

$$\left|\int_{\Omega} uvdx\right| \leq \left(\frac{1}{p^-} + \frac{1}{(p')^-}\right) \|u\|_{L^{p(\cdot)}(\Omega)} \|v\|_{L^{p'(\cdot)}(\Omega)}$$

for all $u \in L^{p(\cdot)}(\Omega)$ and $v \in L^{p'(\cdot)}(\Omega)$. An important role in manipulating the generalized Lebesgue spaces is played by the $\rho_{p(\cdot)}$-modular of the space $L^{p(\cdot)}(\Omega)$, we have the following result.

Proposition 2.1 (See [16]). *If $u \in L^{p(\cdot)}(\Omega)$, $u_n \in L^{p(\cdot)}(\Omega)$ and $p^+ < \infty$, then*

(i) if $\|u\|_{L^{p(\cdot)}(\Omega)} > 1$, then $\|u\|^{p^-}_{L^{p(\cdot)}(\Omega)} \leq \rho_{p(\cdot)}(u) \leq \|u\|^{p^+}_{L^{p(\cdot)}(\Omega)}$;

(ii) if $\|u\|_{L^{p(\cdot)}(\Omega)} < 1$, then $\|u\|^{p^+}_{L^{p(\cdot)}(\Omega)} \leq \rho_{p(\cdot)}(u) \leq \|u\|^{p^-}_{L^{p(\cdot)}(\Omega)}$;

(iii) $\lim_{n\to\infty} \|u_n - u\|_{p(\cdot)} = 0 \Leftrightarrow \lim_{n\to\infty} \rho_{p(\cdot)}(u_n - u) = 0.$

Define the variable exponent Sobolev space $W^{1,p(\cdot)}(\Omega)$ by

$$W^{1,p(\cdot)}(\Omega) = \left\{u \in L^{p(\cdot)}(\Omega) : |\nabla u| \in L^{p(\cdot)}(\Omega)\right\}$$

equipped with the norm

$$\|u\|_{W^{1,p(\cdot)}(\Omega)} = \|u\|_{L^{p(\cdot)}(\Omega)} + \|\nabla u\|_{L^{p(\cdot)}(\Omega)}.$$

The space $(W^{1,p(\cdot)}(\Omega), \|.\|_{W^{1,p(\cdot)}(\Omega)})$ is a separable and reflexive Banach space. We consider also

$$W_0^{1,p(\cdot)}(\Omega) = \left\{u \in W^{1,p(\cdot)}(\Omega) : u \mid_{\partial\Omega)} = 0\right\},$$

with the norm

$$\|u\|_{W_0^{1,p(\cdot)}(\Omega)} = \|\nabla u\|_{L^{p(\cdot)}(\Omega)}.$$

Remark 2.2. Assuming (1.2), we have $C_0^\infty(\Omega)$ is dense in $W_0^{1,p(\cdot)}(\Omega)$ and this last space can be defined as the completion of $C_0^\infty(\Omega)$ with respect to the norm $\|.\|_{W^{1,p(\cdot)}(\Omega)}$. The density of smooth functions in the space $W_0^{1,p(\cdot)}(\Omega)$ is crucial for the understanding of these spaces. The condition of log-continuity of $p(\cdot)$ is the best known and the most frequently used sufficient condition for the density of $C_0^\infty(\Omega)$ in $W_0^{1,p(\cdot)}(\Omega)$ (see [3, 14]). Although this condition is not necessary and can be substituted by other conditions (see [14, Chapter 9] for a discussion of this question) we keep it throughout the paper for the sake of simplicity of presentation.

Also, we observe that $W_0^{1,p(\cdot)}(\Omega) \subseteq W_0^{1,p^-}(\Omega)$, the Sobolev inequality

$$\|u\|_{L^{q(\cdot)}(\Omega)} \leq C\|u\|_{W^{1,p(\cdot)}(\Omega)},$$

holds, with $1 \leq q(x) < \frac{3p(x)}{3-p(x)}$ if $p^- < 3$, any q if $p^- = 3$, and $q = \infty$ if $p^- > 3$ Here $C = C(p^-, \Omega)$ is a positive constant.

Now, we define the space $\mathbf{w}^{p(x)}(\Omega)$

Let $\mathbf{L}^{p(x)}(\Omega) = L^{p(x)}(\Omega) \times L^{p(x)}(\Omega) \times L^{p(x)}\Omega$ and define

$$\mathbf{W}^{p(x)}(\Omega) = \{\mathbf{v} \in \mathbf{L}^{p(x)}(\Omega) : \nabla \times \mathbf{v} \in \mathbf{L}^{p(x)}(\Omega), \nabla.\mathbf{v}, \mathbf{v}.\mathbf{n}|_{\partial\Omega} = 0\}$$

where $\mathbf{n}$ denotes the outward unitary normal vector to $\partial\Omega$. Equip $\mathbf{W}^{p(x)}(\Omega)$ with the norm

$$\|\mathbf{v}\|_{\mathbf{W}^{p(x)}(\Omega)} = \|\mathbf{v}\|_{\mathbf{L}^{p(x)}(\Omega)} + \|\nabla \times \mathbf{v}\|_{\mathbf{L}^{p(x)}(\Omega)}.$$

If $p^- > 1$, by [4, Theorem 2.1], $\mathbf{W}^{p(x)}(\Omega)$ is a closed subspace of $\mathbf{W}_n^{1,p(x)}(\Omega)$, where

$$\mathbf{W}_n^{1,p(x)}(\Omega) = \{\mathbf{v} \in \mathbf{W}^{p(x)}(\Omega) : \mathbf{v}.\mathbf{n}|_{\partial\Omega} = 0\}$$

and

$$\mathbf{W}^{1,p(x)}(\Omega) = W^{1,p(x)}(\Omega) \times W^{1,p(x)}(\Omega) \times W^{1,p(x)}\Omega.$$

Thus, we have the following theorem.

Theorem 2.3 (see [4, Theorem 2.1])**.** *Assume that $1 < p^- \leq p^+ < \infty$ and p satisfies (1.2). Then $\mathbf{W}^{p(x)}(\Omega)$ is a closed subspace of $\mathbf{W}_n^{1,p(x)}(\Omega)$. Moreover, if $p^- > \frac{6}{5}$, then $\|\nabla \times .\|_{\mathbf{L}^{p(x)}(\Omega)}$ is a norm in $\mathbf{W}^{p(x)}(\Omega)$ and there exists $C = C(N, p^-, p^+) > 0$ such that*

$$\|\mathbf{v}\|_{\mathbf{W}^{p(x)}(\Omega)} \leq C\|\nabla \times \mathbf{v}\|_{\mathbf{L}^{p(x)}(\Omega)}.$$

Remark 2.4. By Remark 2.2 and Theorem 2.3, we know the embedding $\mathbf{W}^{p(x)}(\Omega) \hookrightarrow C_0^\infty(\Omega)$ is compact, with $3 < p^- \leq p^+ < \infty$, for all $x \in \bar{\Omega}$. Moreover, $(\mathbf{W}^{p(x)}(\Omega), \|.\|_{\mathbf{W}^{p(x)}(\Omega)})$ is a reflexive Banach space. We set

$$c_0 = \sup_{u \in \mathbf{W}^{p(x)}(\Omega)} \frac{\|u\|_\infty}{\|u\|_{\mathbf{W}^{p(x)}(\Omega)}}.$$

Definition 2.5 ([8, p. 2993], [9, p. 210])**.** Let Φ and Ψ be two continuously Gâteaux differentiable functionals defined on a real Banach space X and fix $r \in \mathbb{R}$. The functional $I = \Phi - \Psi$ is said to verify the Palais-Smale condition cut off upper at r, denoted by $(P.S.)^{[r]}$ if any sequence $\{u_n\}_{n \in \mathbb{N}}$ in X such that

(1) $\{I(u_n)\}$ is bounded;

(2) $\lim_{n\to\infty} \|I'(u_n)\|_{X^*} = 0$;

(3) $\Phi(u_n) < r$ for each $n \in \mathbb{N}$

has a convergent subsequence.

If only conditions (1) and (2) hold, then $I = \Phi - \Psi$ is said to satisfy the (usual) Palais–Smale $(P.S.)$ condition.

We next wish to define what is meant by a weak solution to our problem.

Definition 2.6. We say that a function $u \in \mathbf{W}^{p(x)}(\Omega)$ is a weak solution of the problem (1.1) if

$$\int_\Omega |\nabla \times u|^{p(x)-2} \nabla \times u . \nabla \times v dx + \int_\Omega a(x)|u|^{p(x)-2} u.v dx = \int_\Omega f(x, u).v dx,$$

holds for all $v \in \mathbf{W}^{p(x)}(\Omega)$.

Remark 2.7. Let u be a classical solution of (1.1). Let $e = |\nabla \times u|^{p(x)-2}\nabla \times u$ and v be a smooth function in Ω, then we obtain

$$\nabla(e \times v) = v.\nabla \times e - e.\nabla \times v. \tag{2.1}$$

Multiplying the first equation of (1.1) by v and integrating over Ω, we get

$$\int_\Omega \nabla \times e.vdx + \int_\Omega a(x)|u|^{p(x)-2}u.vdx = \int_\Omega f(x,u).vdx.$$

Using (2.1) and the boundary conditions in (1.1) and integrating by parts, we have

$$\int_\Omega e.\nabla \times vdx + \int_\Omega a(x)|u|^{p(x)-2}u.vdx = \int_\Omega f(x,u).vdx,$$

which means that Definition 2.6 is correct.

Assume that $f : \Omega \times \mathbb{R}^3 \to \mathbb{R}^3$ is a Carathédory function. We set

$$F(x,t) = \int_0^t f(x,\xi)d\xi \quad \text{for all } (x,t) \in \Omega \times \mathbb{R}^3.$$

The variational structure of this problem leads us to introduce We define the functionals $\Phi, \Psi : \mathbf{W}^{p(x)}(\Omega) \to \mathbb{R}$ defined by

$$\Phi(u) := \int_\Omega \frac{|\nabla \times u|^{p(x)} + a(x)|u|^{p(x)}}{p(x)}dx \tag{2.2}$$

and

$$\Psi(u) := \int_\Omega F(x,u)dx. \tag{2.3}$$

Lemma 2.8 ([24, Lemmas 3.1. and 3.2.]). *The functional Φ is of class C^1 and*

$$\langle \Phi'(u), v\rangle = \int_\Omega |\nabla \times u|^{p(x)-2}\nabla \times u.\nabla \times vdx + \int_\Omega a(x)|u|^{p(x)-2}u.vdx$$

for every $u, v \in \mathbf{W}^{p(x)}(\Omega)$. For each $u \in \mathbf{W}^{p(x)}(\Omega)$, $\Phi'(u) \in (\mathbf{W}^{p(x)}(\Omega))^*$, where $(\mathbf{W}^{p(x)}(\Omega))^*$ is the dual space of $\mathbf{W}^{p(x)}(\Omega)$. Moreover, Φ is a convex functional in $\mathbf{W}^{p(x)}(\Omega)$.

The functional Ψ is of class C^1 and

$$\langle \Psi'(u), v\rangle = \int_\Omega f(x,u).vdx$$

for every $u, v \in \mathbf{W}^{p(x)}(\Omega)$.

By Lemma 2.8, we know that $I_\lambda = \Phi - \lambda\Psi$ is of class C^1 and

$$\langle I_\lambda'(u), v\rangle = \int_\Omega |\nabla \times u|^{p(x)-2}\nabla \times u.\nabla \times vdx + \int_\Omega a(x)|u|^{p(x)-2}u.vdx - \lambda \int_\Omega f(x,u).vdx,$$

for all $u, v \in \mathbf{W}^{p(x)}(\Omega)$. Hence a critical point of I_λ is a (weak) solution of (1.1).

3 Main results

We begin by presenting a result that guarantees the existence of at least one solution to problem (1.1).

Theorem 3.1. *Let $f : \Omega \times \mathbb{R}^3 \to \mathbb{R}^3$ be a Carathédory function and assume that there exist two positive constants τ and δ, such that:*

(H_1) $\quad p^+ c_0^{p^-} a_1 \operatorname{meas}(\Omega) \max\{\delta^{p^-}, \delta^{p^+}\} < p^- \min\{1, a_0\} \tau^{p^-};$

(H_2) $\quad \frac{\int_\Omega \sup_{|t|\le\tau} F(x,t)dx}{\tau^{\underline{p}}} < \frac{p^- \min\{1,a_0\} \int_\Omega F(x,\delta)dx}{p^+ c_0^{p^-} a_1 \operatorname{meas}(\Omega) \max\{\delta^{p^-},\delta^{p^+}\}};$

(H_3) $\quad \inf_{x\in\Omega, t\in\mathbb{R}^3, |t|=1} F(x,t) > 0.$

Then, for each

$$\lambda \in \Lambda_w := \left] \frac{a_1 \operatorname{meas}(\Omega) \max\{\delta^{p^-}, \delta^{p^+}\}}{p^- \int_\Omega F(x,\delta)dx}, \frac{\min\{1, a_0\}\tau^{p^-}}{p^+ c_0^{p^-} \int_\Omega \sup_{|t|\le\tau} F(x,t)dx} \right[, \tag{3.1}$$

problem (1.1) *admits at least one nontrivial solution $u_\lambda \in \mathbf{W}^{p(x)}(\Omega)$ such that $\|u_\lambda\|_\infty \le \tau$.*

Proof. Our goal is to apply [9, Theorem 2.3] to problem (1.1). To this end, take the real Banach space $\mathbf{W}^{p(x)}(\Omega)$ with the norm as defined in Section 2, Φ, Ψ be the functionals defined in (2.2) and (2.3). We can see Φ, Ψ are of C^1 in Lemma 2.8. For each $u \in \mathbf{W}^{p(x)}(\Omega)$ we have

$$\frac{\min\{1, a_0\}}{p^+} \|u\|^{p(x)}_{\mathbf{W}^{p(x)}(\Omega)} \le \Phi(u) \le \frac{\max\{1, a_1\}}{p^-} \|u\|^{p(x)}_{\mathbf{W}^{p(x)}(\Omega)}. \tag{3.2}$$

From the first inequality in (3.2), it follows that Φ is coercive. To show that Φ' admits a continuous inverse, in view of [25, Theorem 26.A(d)], it suffices to show that Φ' is coercive, hemicontinuous, and uniformly monotone. For any $u \in \mathbf{W}^{p(x)}(\Omega)$ we have

$$\frac{\langle \Phi'(u), u\rangle}{\|u\|_{\mathbf{W}^{p(x)}(\Omega)}} = \frac{\int_\Omega |\nabla \times u|^{p(x)}dx + \int_\Omega a(x)|u|^{p(x)}dx}{\|u\|_{\mathbf{W}^{p(x)}(\Omega)}} \ge \frac{\min\{1, a_0\}\|u\|^{p(x)}_{\mathbf{W}^{p(x)}(\Omega)}}{\|u\|_{\mathbf{W}^{p(x)}(\Omega)}}.$$

By Proposition 2.1 for any $u \in \mathbf{W}^{p(x)}(\Omega)$

$$\lim_{\|u\|_{\mathbf{W}^{p(x)}(\Omega)}\to\infty} \frac{\langle \Phi'(u), u\rangle}{\|u\|_{\mathbf{W}^{p(x)}(\Omega)}} \ge \lim_{\|u\|_{\mathbf{W}^{p(x)}(\Omega)}\to\infty} (\min\{1, a_0\}\|u\|^{p^- -1}_{\mathbf{W}^{p(x)}(\Omega)}) = \infty,$$

i.e. Φ' is coercive. The fact that Φ' is hemicontinuous can be verified using standard arguments. (see, for example, [18]).

Finally, we show that Φ' is uniformly monotone. First, recall the inequality that for any $\xi, \psi \in \mathbb{R}$,

$$(|\xi|^{r-2}\xi - |\psi|^{r-2}\psi)(\xi - \psi) \ge 2^{-r}|\xi - \psi|^r, \quad \text{for all } r > 2. \tag{3.3}$$

Thus, for every $u, v \in X$, we deduce that

$$
\begin{aligned}
&\langle \Phi'(u) - \Phi'(v), u - v\rangle \\
&= \int_\Omega (|\nabla \times u|^{p(x)-2}\nabla \times u - |\nabla \times v|^{p(x)-2}\nabla \times v)(\nabla \times u - \nabla \times v)dx \\
&\quad + \int_\Omega a(x)(|u|^{p(x)-2}u - |v|^{p(x)-2}v)(u-v)dx \\
&\geq 2^{-p^+}(\int_\Omega |\nabla \times u - \nabla \times v|^{p(x)}dx + \int_\Omega a(x)|u-v|^{p(x)}dx) \\
&\geq \min\{2^{-p^+}, a_0 2^{-p^+}\}(\int_\Omega |\nabla \times u - \nabla \times v|^{p(x)}dx + \int_\Omega |u-v|^{p(x)}dx) \\
&\geq \begin{cases} c_1\|u-v\|^{p^-}_{\mathbf{W}^{p(x)}(\Omega)} & \text{if } \|u-v\|_{\mathbf{L}^{p(x)}(\Omega)}, \|\nabla \times (u-v)\|_{\mathbf{L}^{p(x)}(\Omega)} > 1, \\ c_2\|u-v\|^{p^+}_{\mathbf{W}^{p(x)}(\Omega)} & \text{if } \|u-v\|_{\mathbf{L}^{p(x)}(\Omega)}, \|\nabla \times (u-v)\|_{\mathbf{L}^{p(x)}(\Omega)} < 1, \end{cases}
\end{aligned}
$$

the last inequality is obtained from Proposition 2.1. It is easy to check that Φ' is uniformly monotone. Moreover, Ψ' is a compact operator. Indeed, it is enough to show that Ψ' is strongly continuous on $\mathbf{W}^{p(x)}(\Omega)$. For this end, for fixed $u \in \mathbf{W}^{p(x)}(\Omega)$, let $u_n \to u$ weakly in $\mathbf{W}^{p(x)}(\Omega)$ as $n \to \infty$, then $u_n(x)$ converges uniformly to $u(x)$ on Ω as $n \to \infty$; see [25]. Since f is continuous in $\mathbb{R}^3$ for every $x \in \Omega$, so

$$f(x, u_n) \to f(x, u),$$

as $n \to \infty$. Thus $\Psi'(u_n) \to \Psi'(u)$ as $n \to \infty$. Hence we proved that Ψ' is a compact operator by [25, Proposition 26.2]. This ensures that the functional $I_\lambda = \Phi - \lambda\Psi$ verifies $(P.S.)^{[r]}$ condition for each $r > 0$ (see [8, Proposition 2.1]). To apply [9, Theorem 2.3] to the functional I_λ, first note that $\inf_X \Phi = \Phi(0) = \Psi(0) = 0$. We need to show that there is an $r > 0$ and $w \in X$ with $0 < \Phi(w) < r$ such that $\frac{\sup_{\Phi(u)\leq r}\Psi(u)}{r} < \frac{\Psi(w)}{\Phi(w)}$. To this end, set

$$r := \frac{\min\{1, a_0\}}{p^+}\left(\frac{\tau}{c_0}\right)^{p^-},$$

and define $w \in \mathbf{W}^{p(x)}(\Omega)$ by

$$w(x) = \begin{cases} \delta, & \text{if } x \in \Omega, \\ 0, & \text{otherwise.} \end{cases} \tag{3.4}$$

One has

$$\Phi(w) = \int_\Omega \frac{a(x)}{p(x)}|w(x)|^{p(x)}dx \leq \frac{\text{meas}(\Omega)a_1}{p^-}\max\{\delta^{p^+}, \delta^{p^-}\}. \tag{3.5}$$

Hence, it follows from (H_1) that $0 < \Phi(w) < r$. If $u \in \Phi^{-1}([0, r])$, by Proposition 2.1 (*i*) and (3.2), for any $u \in \mathbf{W}^{p(x)}(\Omega)$ with $\|u\|_{\mathbf{W}^{p(x)}(\Omega)} > 1$, we obtain

$$\frac{\min\{1, a_0\}}{p^+}\|u\|^{p^-}_{\mathbf{W}^{p(x)}(\Omega)} \leq \Phi(u) \leq \frac{\min\{1, a_0\}}{p^+}\left(\frac{\tau}{c_0}\right)^{p^-}.$$

Similarly, by Proposition 2.1 (*ii*) and (3.2), for any $u \in \mathbf{W}^{p(x)}(\Omega)$ with $\|u\|_{\mathbf{W}^{p(x)}(\Omega)} < 1$, we obtain

$$\frac{\min\{1, a_0\}}{p^+}\|u\|^{p^+}_{\mathbf{W}^{p(x)}(\Omega)} \leq \Phi(u) \leq \frac{\min\{1, a_0\}}{p^+}\left(\frac{\tau}{c_0}\right)^{p^-}.$$

Then

$$\|u\|_{\mathbf{W}^{p(x)}(\Omega)} \le \frac{\tau}{c_0}.$$

Hence, we obtain

$$|u(x)| \le \|u\|_{L^\infty(\Omega)} \le c_0 \|u\|_{\mathbf{W}^{p(x)}(\Omega)} \le \tau \qquad \forall x \in \Omega.$$

Hence, for each $u \in \Phi^{-1}((-\infty, r])$

$$\frac{\sup_{\Phi(u)\le r} \Psi(u)}{r} = \frac{\sup_{u\in\Phi^{-1}(-\infty,r]} \int_\Omega F(x,u)dx}{\frac{\min\{1,a_0\}}{p^+}\left(\frac{\tau}{c_0}\right)^{p^-}} \le \frac{c_0^{p^-}\, p^+ \int_\Omega \sup_{|t|\le\tau} F(x,t)dx}{\min\{1,a_0\}\tau^{p^-}}. \tag{3.6}$$

Moreover, thanks to (H_2) and (3.5), one has

$$\begin{aligned} \frac{\Psi(w)}{\Phi(w)} &\ge \frac{p^- \int_\Omega F(x,\delta)dx}{a_1 \operatorname{meas}(\Omega) \max\{\delta^{p^-}, \delta^{p^+}\}} \\ &\ge \frac{c_0^{p^-}\, p^+ \int_\Omega \sup_{|t|\le\tau} F(x,t)dx}{\min\{1,a_0\}\tau^{p^-}} \\ &\ge \frac{\sup_{\Phi(u)\le r} \Psi(u)}{r}, \end{aligned}$$

which means that $\frac{\Phi(\bar v)}{\Psi(\bar v)} \ge \frac{r}{\sup_{\Phi(x)\le r} \Psi(u)}$ holds for some $\bar v \in \mathbf{W}^{p(x)}(\Omega)$. Hence, for each $\lambda \in \left]\frac{\Phi(w)}{\Psi(w)}, \frac{r}{\sup_{\Phi(x)\le r} \Psi(u)}\right[$, the functional I_λ admits at least one critical point u_λ with

$$0 < \Phi(u_\lambda) < r$$

which in turn is a nontrivial solution of problem (1.1) such that $\|u_\lambda\|_\infty < \tau$. □

Our second aim in this paper is to obtain a result on the existence of two distinct solutions to problem (1.1). The following theorem is obtained by applying [9, Theorem 3.2].

Theorem 3.2. *Let $f : \Omega \times \mathbb{R}^3 \to \mathbb{R}^3$ be a Carathédory function, and assume that*

(H_4) *(Ambrosetti–Rabinowitz Condition) there exist $\mu > p^+$ and $R > 0$ such that*

$$0 < \mu F(x,t) \le t f(x,t) \qquad \forall x \in \Omega \text{ and } t \in \mathbb{R}^3 \backslash \{0\}, \text{ with } |t| \ge R.$$

Then, for each

$$\lambda \in \Lambda_r := \left]0, \frac{\min\{1,a_0\}\tau^{p^-}}{p^+ c_0^{p^-} \int_\Omega \sup_{|t|\le\tau} F(x,t)dx}\right[,$$

the problem (1.1) admits at least two nontrivial solutions.

Proof. Let Φ, Ψ be the functionals defined in Theorem (2.2) and (2.3). Notice that they satisfy all regularity assumptions required in [9, Theorem 3.2]). Arguing as in the proof of Theorem 3.1, choosing

$$r = \frac{\min\{1,a_0\}}{p^+}\left(\frac{\tau}{c_0}\right)^{p^-},$$

for each $\lambda \in \Lambda_r$ we obtain

$$\frac{\sup_{\Phi(u)\le r}\Psi(u)}{r} \le \frac{c_0^{p^-}\, p^+ \int_\Omega \sup_{|t|\le\tau} F(x,t)dx}{\min\{1,a_0\}\tau^{p^-}} < \frac{1}{\lambda}$$

(see (3.6)). Now, from condition (H$_4$), a straight forward calculation shows that there are positive constants m and C such that

$$F(x,t) \ge m|t|^\mu - C \quad \text{for all } x\in\Omega, t\in\mathbb{R}^3.$$

Hence, for every $\lambda \in \Lambda_r$, $u \in \mathbf{W}^{p(x)}(\Omega)\setminus\{0\}$ and $t > 1$, we obtain

$$\begin{aligned} I_\lambda(tu) &= \Phi(tu) - \lambda\int_\Omega F(x,tu)dx \\ &\le \frac{t^{p^+}}{p^-}\int_\Omega (|\nabla\times u|^{p(x)} + a(x)|u|^{p(x)})dx \\ &\quad - m\lambda t^\mu \int_\Omega |u|^\mu dx + C\lambda\,\mathrm{meas}(\Omega). \end{aligned}$$

Since $\mu > p^+$, this condition guarantees that I_λ is unbounded from below. To show that I_λ satisfies the (PS)-condition, let $\{u_n\}_{n\in\mathbb{N}} \subset \mathbf{W}^{p(x)}(\Omega)$ such that $\{I_\lambda(u_n)\}_{n\in\mathbb{N}}$ is bounded and $I'_{\lambda,\mu}(u_n) \to 0$ in $(\mathbf{W}^{p(x)}(\Omega))^*$ as $n\to+\infty$. Then, there exists a positive constant s_0 such that

$$|I_\lambda(u_n)| \le s_0, \qquad \|I'_\lambda(u_n)\| \le s_0 \qquad \forall n\in\mathbb{N}.$$

Using also the condition (H$_4$), and the definition of I'_λ, we see that, for all $n\in\mathbb{N}$, there exists $D > 0$ such that

$$\begin{aligned} \mu s_0 + s_0\|u_n\|_{\mathbf{W}^{p(x)}(\Omega)} &\ge \mu I_\lambda(u_n) - I'_\lambda(u_n)u_n \\ &\ge \left(\frac{\mu}{p^+}-1\right)\int_\Omega |\nabla\times u|^{p(x)} + a_0\left(\frac{\mu}{p^+}-1\right)\int_\Omega |u|^{p(x)}dx \\ &\quad + \lambda\int_\Omega (f(x,u_n)u_n - \mu F(x,u_n))\,dx \\ &\ge \left(\frac{\mu}{p^+}-1\right)\min\{1,a_0\}\|u_n\|^{p(x)}_{\mathbf{W}^{p(x)}(\Omega)} - D. \end{aligned}$$

Since $\mu > p^+$ it follows $\{u_n\}_{n\in\mathbb{N}}$ is bounded. Consequently, since $\mathbf{W}^{p(x)}(\Omega)$ is a reflexive Banach space we have, up to taking a subsequence if necessary,

$$u_n \rightharpoonup u \quad \text{in } \mathbf{W}^{p(x)}(\Omega).$$

By the fact that $I'_\lambda(u_n) \to 0$ and $u_n \rightharpoonup u$ in $\mathbf{W}^{p(x)}(\Omega)$, we obtain

$$(I'_\lambda(u_n) - I'_\lambda(u))(u_n - u) \to 0.$$

Furthermore,

$$\int_\Omega (f(x,u_n) - f(x,u))(u_n-u)dx \to 0, \quad \text{as } n\to+\infty.$$

An easy computation shows that

$$\begin{aligned}
&\langle I'_\lambda(u_n) - I'_\lambda(u), u_n - u\rangle \\
&= \int_\Omega (|\nabla \times u_n|^{p(x)-2}\nabla \times u_n - |\nabla \times u|^{p(x)-2}\nabla \times u)(\nabla \times u_n - \nabla \times u)dx \\
&\quad + \int_\Omega a(x)(|u_n|^{p(x)-2}u_n - |u|^{p(x)-2}u)(u_n - u)dx \\
&\quad - \lambda \int_\Omega (f(x,u_n) - f(x,u))(u_n - u)dx \\
&\geq 2^{-p^+}\|\nabla \times (u_n - u)\|^{p(x)}_{\mathbf{L}^{p(x)}(\Omega)} + a_0 2^{-p^+}\|u_n - u\|^{p(x)}_{\mathbf{L}^{p(x)}(\Omega)} \\
&\quad - \lambda \int_\Omega (f(x,u_n) - f(x,u))(u_n - u)dx \\
&\geq \min\{2^{-p^+}, a_0 2^{-p^+}\}\|u_n - u\|^{p(x)}_{\mathbf{W}^{p(x)}(\Omega)} - \lambda \int_\Omega (f(x,u_n) - f(x,u))(u_n - u)dx.
\end{aligned}$$

The last of the above inequality is obtained by using (3.3). Combining the last relation with Proposition 2.1 (iii), we find that the sequence $\{u_n\}_{n\in\mathbb{N}}$ converges strongly to u in $\mathbf{W}^{p(x)}(\Omega)$. Therefore, $I_{\lambda,\mu}$ satisfies the (PS)-condition and so all hypotheses of [9, Theorem 3.2], are verified. Hence, for each $\lambda \in \Lambda_r$ the function I_λ admits at least two distinct critical points that are solutions of the problem (1.1). □

In our final result, we discuss the existence of at least three solutions to the problem (1.1).

Theorem 3.3. *Let $f : \Omega \times \mathbb{R}^3 \to \mathbb{R}^3$ be a Carathédory function, and let (H_2), (H_3) in Theorem 3.1 hold. Moreover, assume that there exist two positive constants τ and δ, such that*

(H_5) $a_0 c_0^{p^-} \operatorname{meas}(\Omega)\min\{\delta^{p^-}, \delta^{p^+}\} > \tau^{p^-}\min\{1, a_0\}$,

(H_6) *there exist constants $c > 0$, $q \in C(\bar{\Omega})$ and $1 < q(x) \leq q^+ < p^-$ in $\bar{\Omega}$ such that*

$$|F(x,t)| \leq c(1 + |t|^{q(x)}) \quad \forall (x,t) \in \Omega \times \mathbb{R}^3.$$

Then for every $\lambda \in \Lambda_w$ as in (3.1), the problem (1.1) admits at least three distinct solutions.

Proof. Our aim is to apply [11, Theorem 3.6]. We consider the functionals Φ and Ψ, defined in (2.2) and (2.3). Once again, they satisfy the regularity assumptions needed in [11, Theorem 3.6]. Now, we argue as in the proof of Theorem 3.1 with $w(x)$ defined in (3.4), and

$$r = \frac{\min\{1, a_0\}}{p^+}\left(\frac{\tau}{c_0}\right)^{p^-}.$$

In view of (H_5) we have $\Phi(w) > r > 0$. Therefore, from (H_2), inequality (3.6) holds, and so

$$\frac{\sup_{\Phi(u)\leq r}\Psi(u)}{r} < \frac{\Psi(\overline{v})}{\Phi(\overline{v})}$$

holds for some $\bar{v} \in \mathbf{W}^{p(x)}(\Omega)$.

Now, we prove that, for each $\lambda \in \Lambda_w$ the functional I_λ is coercive. By using inequality (3.2), conditions (H_6), and Sobolev embedding theorem, we easily obtain for all $u \in \mathbf{W}^{p(x)}(\Omega)$:

$$\begin{aligned}
I_\lambda(u) &\geq \frac{\min\{1, a_0\}}{p^+}\|u\|^{p^-}_{\mathbf{W}^{p(x)}(\Omega)} - \lambda \int_\Omega F(x,u)dx \\
&\geq \frac{\min\{1, a_0\}}{p^+}\|u\|^{p^-}_{\mathbf{W}^{p(x)}(\Omega)} - \lambda c\|u\|^{q^+}_{\mathbf{W}^{p(x)}(\Omega)} - \lambda c \operatorname{meas}(\Omega).
\end{aligned}$$

Since $p^- > q^+$ we see that $I_\lambda \to +\infty$ as $\|u\|_{\mathbf{W}^{p(x)}(\Omega)} \to +\infty$, so the functional I_λ is coercive. Thus, for each $\lambda \in \Lambda_w$, [11, Theorem 3.6] implies that the functional I_λ admits at least three critical points in $\mathbf{W}^{p(x)}(\Omega)$ that are solutions of the problem (1.1). □

Communicated by Dimitri Mugnai

Abstract. We consider the existence of normalized solutions for a fractional coupled Hartree system, with the upper critical exponent in the sense of the Hardy–Littelwood–Sobolev inequality. Particularly, in an L^2-subcritical regime or an L^2-supercritical regime, we establish the existence of positive normalized solutions for the two cases, respectively. Furthermore, we prove the nonexistence of positive normalized solutions, under the nonlinearities satisfying the Sobolev critical growth.

Keywords: fractional Hartree system, normalized solutions, Hardy–Littlewood–Sobolev critical exponent.

2020 Mathematics Subject Classification: 35J50, 35B33, 35R11, 58E05.

1 Introduction

This paper is concerned with the existence of solutions $(\lambda_1, \lambda_2, u, v) \in \mathbb{R}^2 \times H^s(\mathbb{R}^N, \mathbb{R}^2)$ to the following fractional critical Hartree system:

$$\begin{cases} (-\Delta)^s u = \lambda_1 u + \mu_1 |u|^{p-2} u + \beta r_1 |u|^{r_1-2} u |v|^{r_2} + (I_\alpha * |v|^{2^*_{\alpha,s}}) |u|^{2^*_{\alpha,s}-2} u, & \text{in } \mathbb{R}^N, \\ (-\Delta)^s v = \lambda_2 v + \mu_2 |v|^{p-2} v + \beta r_2 |v|^{r_2-2} v |u|^{r_1} + (I_\alpha * |u|^{2^*_{\alpha,s}}) |v|^{2^*_{\alpha,s}-2} v, & \text{in } \mathbb{R}^N, \end{cases} \tag{1.1}$$

satisfying the additional conditions

$$\int_{\mathbb{R}^N} u^2 dx = a^2, \quad \text{and} \quad \int_{\mathbb{R}^N} v^2 dx = b^2. \tag{1.2}$$

The masses $a, b > 0$ are prescribed and the parameters $\mu_1, \mu_2, \beta > 0$. Here $(-\Delta)^s$ is the fractional Laplacian, $s \in (0,1)$, $2s < N \leq 4s$, $\alpha \in (0, N)$, $2^*_{\alpha,s} = \frac{2N-\alpha}{N-2s}$ is the upper critical exponent due to the Hardy–Littlewood–Sobolev inequality, $2^*_s = \frac{2N}{N-2s}$ is the fractional Sobolev critical exponent, $r_1, r_2 > 1$, $p, r_1 + r_2 \in (2, 2^*_s]$ with $p < r_1 + r_2$ and $*$ stands for the convolution on $\mathbb{R}^N$ with $I_\alpha : \mathbb{R}^N \setminus \{0\} \to \mathbb{R}$ is the Riesz potential,

$$I_\alpha(x) = \frac{A_{N,\alpha}}{|x|^\alpha}, \quad \text{with } A_{N,\alpha} = \frac{\Gamma(\frac{\alpha}{2})}{2^{N-\alpha} \pi^{\frac{N}{2}} \Gamma(\frac{N-\alpha}{2})}.$$

The fractional Laplacian operator $(-\Delta)^s$ is defined for any $u : \mathbb{R}^N \to \mathbb{R}$ sufficiently smooth by

$$(-\Delta)^s u(x) = C(N,s)P.V. \int_{\mathbb{R}^N} \frac{u(x)-u(y)}{|x-y|^{N+2s}} dy,$$

where $P.V.$ stands for the Cauchy principal value and $C(N,s)$ is a positive constant depending only on N and s. Recently, a great attention has been devoted to study the nonlinear problems involving fractional elliptic operators, both for the pure mathematical research and applications. We refer to [3,11,16,37] for a simple introduction to basic properties of the fractional Laplacian operator and concrete applications based on variational methods. Moreover, fractional Choquard type equation with critical growth has been studied by many researchers, see [1,22,23,35,36] and references therein.

The problem under investigation comes from the research of solitary waves for the following physical model:

$$\begin{cases} (-\Delta)^s\phi_1 = -i\frac{\partial\phi_1}{\partial t} + \mu_1|\phi_1|^{p-2}\phi_1 + \beta r_1|\phi_1|^{r_1-2}\phi_1|\phi_2|^{r_2} + (I_\alpha * |\phi_2|^{2^*_{\alpha,s}})|\phi_1|^{2^*_{\alpha,s}-2}\phi_1, \\ (-\Delta)^s\phi_2 = -i\frac{\partial\phi_2}{\partial t} + \mu_2|\phi_2|^{p-2}\phi_2 + \beta r_2|\phi_2|^{r_2-2}\phi_2|\phi_1|^{r_1} + (I_\alpha * |\phi_1|^{2^*_{\alpha,s}})|\phi_2|^{2^*_{\alpha,s}-2}\phi_2, \end{cases} \tag{1.3}$$

where $i^2 = -1$ and $\phi_j (j = 1,2)$ is the wave function of the j_{th} component, and μ_j, β denote the intra-species and intra-species scattering lengths. In particular, the interaction of states is attractive if $\beta > 0$, while the interaction of states is repulsive when $\beta < 0$. Solitary wave solutions of system (1.3) are solutions having the form

$$\phi_1(x,t) = e^{i\lambda_1 t}u(x), \qquad \phi_2(x,t) = e^{i\lambda_1 t}v(x),$$

where $\lambda_1, \lambda_2 \in \mathbb{R}$ are the chemical potentials and (u,v) solves (1.1). Since $\phi_1(x,t), \phi_2(x,t)$ retain their masses over time, we consider this problem from two aspects: one can either regard the frequencies λ_1, λ_2 as fixed, or include them in the unknown and prescribe the masses.

Fixing the parameters λ_1, λ_2 in (1.1), we call it the fixed frequency problem. The two-component system with Hartree-type nonlinearities describes the boson stars in mean-field theory [18, 27], which appears naturally in optical systems [30] and is known to influence the propagation of electromagnetic waves in plasmas [7]. Moreover, the non-locality of the critical term also plays an important role in the theory of Bose-Einstein condensation, where it accounts for the finite-range many-body interaction [15]. The Hartree type systems, mainly on λ_1, λ_2 are prescribed, have been widely studied. We refer to [20] and references therein. However, much less is known when the masses are prior prescribed. In this case, $\lambda_1, \lambda_2 \in \mathbb{R}$ are unknown quantities arising as Lagrange multipliers. In recent years, since physicists are interested in normalized solutions (which L^2-norms of solutions are prescribed), mathematical researchers began to investigate the solutions of various classes of Schrödinger equations or systems having a prescribed L^2-norm, that is a solution which satisfies $\int_{\mathbb{R}^N} |u|^2 dx = c$ for a priori given c.

When $s = 1$, i.e. the fractional Laplace operator $(-\Delta)^s$ reduces to the local differential operator $-\Delta$, the literature for the normalized solutions of Schrödinger equations or systems is abundant. Starting from the seminal paper by Jeanjean in [25], he firstly studied L^2-supercritical case, and dealt with the existence of normalized solutions when the energy functional is unbounded from below, by using the mountain pass lemma and a skillful compactness argument. Furthermore, for the particular case of a combined nonlinearity of power type, in [38], Soave considered the existence of normalized solutions and orbitally stable for the following problem:

$$\begin{cases} -\Delta u = \lambda u + \mu |u|^{q-2}u + |u|^{p-2}u, & \text{in } \mathbb{R}^N, \\ \int_{\mathbb{R}^N} |u|^2 dx = c, & \text{in } \mathbb{R}^N, \end{cases} \tag{1.4}$$

where $N \geq 1$, $q, p \in (2, 2^*)$ and $q < p$. Moreover, when $p = 2^*$ in (1.4), in [39], the Sobolev critical case was studied by Soave, where he considered the energy level less than a certain number to get the compactness, and obtained the existence and nonexistence of normalized solutions. For the system case, Bartsch, Jeanjean and Soave investigated the following elliptic system

$$\begin{cases} -\Delta u = \lambda_1 u + \mu_1 u^3 + \beta u v^2, & \text{in } \mathbb{R}^3, \\ -\Delta v = \lambda_2 v + \mu_2 u^3 + \beta v u^2, & \text{in } \mathbb{R}^3, \\ \int_{\mathbb{R}^3} |u|^2 dx = a, \int_{\mathbb{R}^3} |v|^2 dx = b, \end{cases} \tag{1.5}$$

where $\mu_1, \mu_2, a, b > 0$. In [4], Bartsch, Jeanjean and Soave obtained the existence results for different ranges of $\beta > 0$ and stability properties of (1.5). Furthermore, in [6], Bartsch and Soave considered the case $\beta < 0$ of (1.5) and showed phase separation occurs for the solutions as $\beta \to -\infty$. In particular, Bartsch, Li and Zou [5] studied the normalized solutions for a Schrödinger systems with Sobolev critical nonlinearities. Specifically, in [5], they proved the existence and nonexistence results and obtained the asymptotic behavior as $\beta \to 0^+$ or $\beta \to +\infty$. When $3 \leq N \leq 4$, in [29], Li and Zou obtained the existence of positive normalized ground state for (1.5). For more researches of the normalized solutions of the Laplacian systems, we refer to [31, 34] and references therein.

The situation is different when $s \in (0, 1)$, and few results are available. We note that the L^2-critical exponent for fractional case is $\bar{p} := 2 + \frac{4s}{N}$. In [32], Luo and Zhang studied the existence and nonexistence of normalized solutions for the following fractional problem

$$\begin{cases} (-\Delta)^s u = \lambda u + \mu |u|^{q-2}u + |u|^{p-2}u, & \text{in } \mathbb{R}^N, \\ \int_{\mathbb{R}^N} |u|^2 dx = c, & \text{in } \mathbb{R}^N, \end{cases} \tag{1.6}$$

where $q, p \in (2, 2_s^*)$, $q < p$ and $\mu \in \mathbb{R}$. Moreover, when $p = 2_s^*$ in (1.6), Zhen and Zhang [44] proved the existence and nonexistence results of the normalized solutions by using the Jeanjean's skill in [25], and they also considered the behavior of the ground state obtained as $\mu \to 0^+$. Furthermore, in [24], He, Rădulescu and Zou showed the existence and nonexistence of solutions for a fractional equation with the upper critical exponent, among 3 cases: L^2-subcritical, L^2-critical and L^2-supercritical. In the case of fractional systems, Zuo and Rădulescu studied the following problem

$$\begin{cases} (-\Delta)^s u = \lambda_1 u + \mu_1 |u|^{p-2}u + |u|^{2_s^*-2}u + \gamma\alpha |u|^{\alpha-2}u|v|^{\beta}, & \text{in } \mathbb{R}^N, \\ (-\Delta)^s v = \lambda_2 v + \mu_2 |v|^{q-2}v + |v|^{2_s^*-2}v + \gamma\beta |v|^{\alpha-2}v|u|^{\beta}, & \text{in } \mathbb{R}^N. \\ \int_{\mathbb{R}^N} |u|^2 dx = a, \int_{\mathbb{R}^N} |v|^2 dx = b, & \text{in } \mathbb{R}^N, \end{cases} \tag{1.7}$$

where $s \in (0, 1)$, $p, q, \alpha + \beta \in (\bar{p}, 2_s^*)$. In [45], Zuo and Rădulescu showed the existence of positive normalized solutions when γ is big enough, and obtained the nonexistence of positive normalized solutions if $p = q = \alpha + \beta = 2_s^*$. Li [28] studied the existence of positive radial solutions for a fractional Hartree–Fock type system in L^2-subcritical case, L^2-critical case and L^2-supercritical case, but without the upper critical exponent in the sense of the Hardy–Littlewood–Sobolev inequality (see Lemma 2.1).

Inspired by the above mentioned works, in the present paper, our goal is two-fold. On one hand, we show the existence of normalized ground states for $p \in (2, 2_s^*)$, and $r_1 + r_2 \in (p, 2_s^*)$; on the other hand, we obtain the nonexistence result for $p = r_1 + r_2 = 2_s^*$. Compared to the Laplace operator, the fractional Laplacian problems are nonlocal and more challenging. Moreover, since the compactness of system is closely related to (see Proposition 4.9) the following problem

$$\begin{cases} (-\Delta)^s u = \lambda u + \mu |u|^{p-2} u, & \text{in } \mathbb{R}^N, \\ \int_{\mathbb{R}^N} u^2 dx = c^2, \end{cases} \tag{1.8}$$

we may be more careful to the energy level and solutions of (1.8). However, for $p = \bar{p}$ and $c > 0$, the Pohožaev manifold related to (1.8) is indefinite (see Lemma 5.2), which makes it difficult to construct the geometry for the related energy functional.

Before we state our main results, we introduce some notations for the fractional Sobolev space $H^s(\mathbb{R}^N)$. Let $s \in (0,1)$. We denote by $D^s(\mathbb{R}^N)$ the completion of $C_c^\infty(\mathbb{R}^N)$ with

$$[u]^2 = \iint_{\mathbb{R}^{2N}} \frac{|u(x) - u(y)|^2}{|x-y|^{N+2s}} dxdy.$$

The fractional Sobolev space is defined by

$$H^s(\mathbb{R}^N) := \{u \in L^2(\mathbb{R}^N) : \ [u] < \infty\},$$

with the standard norm and inner product

$$\|u\|^2 = [u]^2 + \int_{\mathbb{R}^N} |u|^2 dx, \quad \text{and} \quad \langle u, \varphi \rangle = \int_{\mathbb{R}^N} \Big((-\Delta)^{\frac{s}{2}} u (-\Delta)^{\frac{s}{2}} \varphi + u\varphi \Big) dx.$$

It is well known (see [2]) that the embedding $H^s(\mathbb{R}^N) \hookrightarrow L^q(\mathbb{R}^N)$ is continuous for all $q \in [2, 2_s^*]$, locally compact for all $q \in [1, 2_s^*)$ and $D^s(\mathbb{R}^N) \hookrightarrow L^{2_s^*}(\mathbb{R}^N)$ is continuous. Then we define the working space H as

$$H := \{(u,v) : u \in H^s(\mathbb{R}^N), v \in H^s(\mathbb{R}^N)\},$$

endowed with the norm

$$\|(u,v)\|_H^2 := \|u\|^2 + \|v\|^2,$$

and related inner product is, for any $(\varphi, \psi) \in H$:

$$\langle (u,v), (\varphi, \psi) \rangle_H := \langle u, \varphi \rangle + \langle v, \psi \rangle.$$

By using the variational methods, a classical way for studying the normalized solutions of system (1.1) is to look for critical points of the following C^1-functional

$$J(u,v) = \frac{1}{2}([u]^2 + [v]^2) - \frac{1}{p}(\mu_1 |u|_p^p + \mu_2 |v|_p^p) - \beta \int_{\mathbb{R}^N} |u|^{r_1} |v|^{r_2} dx - \frac{1}{2_{\alpha,s}^*} \int_{\mathbb{R}^N} (I_\alpha * |u|^{2_{\alpha,s}^*}) |v|^{2_{\alpha,s}^*} dx,$$

constrained on the set

$$S := \{(u,v) \in H : (u,v) \in S_a \times S_b\},$$

where $|u|_r = \big(\int_{\mathbb{R}^N} |u|^r dx \big)^{\frac{1}{r}}$ and $S_a := \{u \in H^s(\mathbb{R}^N) : \int_{\mathbb{R}^N} |u|^2 dx = a^2\}$. The main results of this paper can be stated as follows:

Theorem 1.1. *When $2s < N \leq 4s$, $p \in (2, \bar{p})$ and $r_1 + r_2 \in (p, 2_s^*)$, there exists $\beta^* > 0$ such that for $0 < \beta < \beta^*$, there exist $\mu_1^* = \mu_1^*(\beta), \mu_2^* = \mu_2^*(\beta)$, such that for any $\mu_1 \in (0, \mu_1^*), \mu_2 \in (0, \mu_2^*)$, (1.1)–(1.2) has a normalized ground state (u, v), which is a positive and radially symmetric function, for some $\lambda_1, \lambda_2 < 0$. Moreover, (u, v) is an interior local minimizer on the set*

$$B_r(a, b) := \{(u, v) \in S : ([u]^2 + [v]^2)^{\frac{1}{2}} < r\},$$

for a suitable $r > 0$ small enough; and any other ground state solution of $J(u, v)|_S$ is a local minimizer of $J(u, v)$ on $B_r(a, b)$.

Theorem 1.2. *When $2s < N \leq 4s$, $p \in (\bar{p}, 2_s^*)$ and $r_1 + r_2 \in (p, 2_s^*)$, there exists $\beta_0 > 0$, such that for any $\beta > \beta_0$, (1.1)–(1.2) has a normalized ground state (u, v), which is a positive and radially symmetric function, for some $\lambda_1, \lambda_2 < 0$, and (u, v) is a Mountain Pass type solution.*

Theorem 1.3. *When $2s < N \leq 4s$, suppose $p = r_1 + r_2 = 2_s^*$, then the system (1.1)–(1.2) has no positive normalized solutions.*

Remark 1.4.

(I) In Theorem 1.1, we consider 3 cases: $r_1 + r_2 \in (2, \bar{p})$, $r_1 + r_2 = \bar{p}$ and $r_1 + r_2 \in (\bar{p}, 2_s^*)$. These different situations are mainly reflected in Lemmas 4.3 and 5.3.

(II) From the processes in our proof, one difference between Theorems 1.1 and 1.2 lies in their respective geometric structures. In fact, when p changes from L^2-subcritical to L^2-supercritical, it changes the geometry of $J(u, v)|_S$ and prevents the existence of a local minimizer in Theorem 1.2.

(III) Compared with the result in [24], we need an elementary inequality (see Proposition 4.9), which combined the single case (1.8) with the coupling case (1.1), to ensure compactness result. Theorems 1.1, 1.2, 1.3 seem to be the first results of normalized solutions for a fractional coupling systems with the upper critical exponent in the sense of the Hardy–Littlewood–Sobolev inequality.

The paper is organized as follows. In Section 2, we give some preliminaries for the functional space. In Section 3, we will briefly introduce the properties of a single case (1.8), which plays an important role to the proof of Palais–Smale condition in our problem. In Section 4, we prove Theorem 1.1. In Section 5, we obtain Theorem 1.2. At last, we show the nonexistence for Theorem 1.3 in Section 6.

2 Preliminaries

Following, for the convenience of the reader, we recall some basic properties, which we shall need in the sequel. Let us first recall the well-known Hardy–Littlewood–Sobolev inequality.

Lemma 2.1 ([30])**.** *Let $t, r > 1$, $0 < \alpha < N$, with $\frac{1}{t} + \frac{\alpha}{N} + \frac{1}{r} = 2$, $f \in L^t(\mathbb{R}^N)$ and $h \in L^r(\mathbb{R}^N)$. There exists a sharp constant $C(N, t, \alpha, r)$ independent of f and h, such that*

$$\int_{\mathbb{R}^N} \int_{\mathbb{R}^N} \frac{f(x)h(y)}{|x - y|^\alpha} \leq C(N, t, \alpha, r)|f|_t |h|_r, \tag{2.1}$$

where $|\cdot|_q$ *stands for the* $L^q(\mathbb{R}^N)$*-norm for* $q \in [1, +\infty)$. *If* $t = r = \frac{2N}{2N-\alpha}$, *then*

$$C(N, t, \alpha, r) = C(N, \alpha) = \pi^{\frac{\alpha}{2}} \frac{\Gamma(\frac{N}{2} - \frac{\alpha}{2})}{\Gamma(N - \frac{\alpha}{2})}.$$

Besides, there is a equality in (2.1) *if and only if* $f \equiv (constant.)h$ *and*

$$h(x) = C(\gamma^2 + |x - a|^2)^{-\frac{2N-\alpha}{2}},$$

for some $C \in \mathbb{C}$, $\gamma \neq 0$ *and* $a \in \mathbb{R}^N$.

According to Lemma 2.1, the functional

$$\int_{\mathbb{R}^N} \int_{\mathbb{R}^N} \frac{u^p(x) u^p(y)}{|x - y|^\alpha} dy dx,$$

is well defined in $H^s(\mathbb{R}^N) \times H^s(\mathbb{R}^N)$ if $\frac{2N-\alpha}{N} \leq p \leq \frac{2N-\alpha}{N-2s}$. We often call $\frac{2N-\alpha}{N}$ is the lower Hardy–Littlewood–Sobolev critical exponent and $\frac{2N-\alpha}{N-2s}$ is the upper Hardy–Littlewood–Sobolev critical exponent. From Lemma 2.1, we define the best constant

$$S_{h,l} = \inf_{D^s(\mathbb{R}^N \setminus \{0\})} \frac{[u]^2}{\left(\int_{\mathbb{R}^N} (I_\alpha * |u|^{2^*_{\alpha,s}}) |u|^{2^*_{\alpha,s}} dx\right)^{\frac{1}{2^*_{\alpha,s}}}},$$

and from [23], we know $S_{h,l}$ is attained by the function

$$\tilde{u}_{\varepsilon,y} = \tilde{C}_{N,\alpha,s} u_{\varepsilon,y}, \quad x, y \in \mathbb{R}^N, \quad \text{and } \varepsilon > 0,$$

such that

$$[\tilde{u}_{\varepsilon,y}]^2 = S_{h,l}^{\frac{2N-\alpha}{N-\alpha+2s}},$$

with $\tilde{u}_{\varepsilon,y}$ satisfying this equation

$$(-\Delta)^s u = (I_\alpha * |u|^{2^*_{\alpha,s}}) |u|^{2^*_{\alpha,s}-2} u, \quad x \in \mathbb{R}^N.$$

The function $u_{\varepsilon,y} = \kappa(\varepsilon^2 + |x - y|^2)^{-\frac{N-2s}{2}}$ solves

$$(-\Delta)^s u = |u|^{2^*_s - 2} u, \quad \text{in } \mathbb{R}^N,$$

and achieves the infimum of

$$S := \inf_{D^s(\mathbb{R}^N \setminus \{0\})} \frac{[u]^2}{|u|^2_{2^*_s}},$$

with

$$S_{h,l} = S C_{N,\alpha,s}^{-\frac{1}{2^*_{\alpha,s}}} \quad \text{and} \quad \kappa = \left(\frac{S^{\frac{N}{2s}} \Gamma(N)}{\pi^{\frac{N}{2}} \Gamma(\frac{N}{2})} \right)^{\frac{N-2s}{2N}}.$$

In order to prove our problem, we shall make use of the following infimum

$$S^* := \inf_{(u,v) \in D^s(\mathbb{R}^N) \times D^s(\mathbb{R}^N)} \frac{[u]^2 + [v]^2}{\left(\int_{\mathbb{R}^N} (I_\alpha * |u|^{2^*_{\alpha,s}}) |v|^{2^*_{\alpha,s}} dx \right)^{\frac{1}{2^*_{\alpha,s}}}}, \tag{2.2}$$

and from [43, Lemma 2.2], we know

Lemma 2.2. *We have*

$$S^* = 2S_{h,l},$$

and S^* is achieved if and only if, for $C > 0$,

$$u = v = Cu_{\varepsilon,y}.$$

Then we recall the fractional Gagliardo–Nirenberg–Sobolev inequality, which can be seen in [19].

Lemma 2.3. *Let $N > 2s$ and $p \in (2, 2_s^*)$, then there exists a constant $C(N,p,s) > 0$, such that for all $u \in H^s(\mathbb{R}^N)$,*

$$|u|_p^p \le C(N,p,s)|(-\Delta)^{\frac{s}{2}}u|_2^{\frac{N(p-2)}{2s}}|u|_2^{p-\frac{N(p-2)}{2s}}. \tag{2.3}$$

Defining $\gamma_p := \frac{N(p-2)}{2ps}$, it is easy to see

$$p\gamma_p \begin{cases} < 2, & \text{if } 2 < p < \bar{p}, \\ = 2, & \text{if } p = \bar{p}, \text{ and } \gamma_{2_s^*} = 1, \\ > 2, & \text{if } \bar{p} < p < 2_s^*. \end{cases}$$

and

$$|u|_p^p \le C(N,p,s)|(-\Delta)^{\frac{s}{2}}u|_2^{p\gamma_p}|u|_2^{p(1-\gamma_p)}. \tag{2.4}$$

Following, we obtain the corresponding Pohožaev type identity for system (1.1). Before the statement of this result, we introduce the s-harmonic extension (see [11]) techniques. Denote $\mathbb{R}^{N+1} = \{(x,y) : x \in \mathbb{R}^N, y \in \mathbb{R}\}$ and define $X = X^s(\mathbb{R}_+^{N+1}) \times X^s(\mathbb{R}_+^{N+1})$ under the norms

$$\|(U,V)\|_X = \left(\kappa_s \int_{\mathbb{R}_+^{N+1}} y^{1-2s}|\nabla U|^2 dxdy + \kappa_s \int_{\mathbb{R}_+^{N+1}} y^{1-2s}|\nabla V|^2 dxdy\right)^{\frac{1}{2}},$$

where $X^s(\mathbb{R}_+^{N+1})$ is the completion of $C_0^\infty(\mathbb{R}_+^{N+1})$ with the norm

$$\|U\|_{X^s(\mathbb{R}_+^{N+1})} = \left(\kappa_s \int_{\mathbb{R}_+^{N+1}} y^{1-2s}|\nabla U|^2 dxdy\right)^{\frac{1}{2}}.$$

Let $(u,v) \in H$ be a solution of (1.1) and define $(U,V) \in X$ be its s-harmonic extension to the upper half space $\mathbb{R}_+^{N+1}$, then $u = U(x,0)$, $v = V(x,0)$ and (U,V) is a solution to the following problem

$$\begin{cases} -\mathrm{div}(y^{1-2s}\nabla U) = 0; -\mathrm{div}(y^{1-2s}\nabla V) = 0, & \text{in } \mathbb{R}_+^{N+1}, \\ -\frac{\partial U}{\partial y^{1-2s}} = \lambda_1 u + \mu_1|u|^{p-2}u + \beta r_1|u|^{r_1-2}u|v|^{r_2} + (I_\alpha * |v|^{2_{\alpha,s}^*})|u|^{2_{\alpha,s}^*-2}u, & \text{on } \mathbb{R}^N, \\ -\frac{\partial V}{\partial y^{1-2s}} = \lambda_2 v + \mu_2|v|^{p-2}v + \beta r_2|v|^{r_2-2}v|u|^{r_1} + (I_\alpha * |u|^{2_{\alpha,s}^*})|v|^{2_{\alpha,s}^*-2}v, & \text{on } \mathbb{R}^N. \end{cases} \tag{2.5}$$

From [8, Proposition A.1] and [42, Lemma 4.1], we have the following result.

Proposition 2.4. *Let $(u,v) \in H$ be a weak solution of (1.1), that is (u,v) satisfies:*

$$\begin{aligned} 0 = \langle u, \varphi\rangle + \langle v, \psi\rangle - \int_{\mathbb{R}^N}(\lambda_1 u\varphi + \lambda_2 v\psi)dx \\ - \int_{\mathbb{R}^N}(\mu_1|u|^{p-2}u\varphi + \mu_2|v|^{p-2}v\varphi)dx - \beta\int_{\mathbb{R}^N}(r_1|u|^{r_1-2}u|v|^{r_2}\varphi + r_2|u|^{r_1}|v|^{r_2-2}v\psi)dx \\ - \int_{\mathbb{R}^N}[(I_\alpha * |v|^{2_{\alpha,s}^*})|u|^{2_{\alpha,s}^*-2}u\varphi + (I_\alpha * |u|^{2_{\alpha,s}^*})|v|^{2_{\alpha,s}^*-2}v\psi]dx, \quad \forall(\varphi,\psi) \in H, \end{aligned}$$

then we have (u,v) *satisfies*

$$\begin{aligned}&\frac{N-2s}{2}\int_{\mathbb{R}^N}(|(-\Delta)^{\frac{s}{2}}u|^2+|(-\Delta)^{\frac{s}{2}}v|^2)dx\\&=\frac{N}{2}\int_{\mathbb{R}^N}(\lambda_1|u|^2+\lambda_2|v|^2)dx+\frac{N}{p}\int_{\mathbb{R}^N}(\mu_1|u|^p+\mu_2|v|^p)dx\\&\quad+\beta N\int_{\mathbb{R}^N}|u|^{r_1}|v|^{r_2}dx+\frac{2N-\alpha}{2^*_{\alpha,s}}\int_{\mathbb{R}^N}(I_\alpha*|u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}}dx.\end{aligned}$$

Proof. If $(u,v)\in H$ is a weak solution of (1.1), from [2, Proposition 3.2.14], we have $(u,v)\in L^\infty(\mathbb{R}^N)\times L^\infty(\mathbb{R}^N)$. Using the same arguments as in [13, Proposition 4.1], we get $(u,v)\in C^{2,\tau}(\mathbb{R}^N)\times C^{2,\tau}(\mathbb{R}^N)$ with τ depending on s. Let (U,V) be its s-harmonic extension and satisfy (2.5), then $(U,V)\in C^2(\mathbb{R}^{N+1}_+)\times C^2(\mathbb{R}^{N+1}_+)$.

Set $D_m:=\{(x,y)\in\mathbb{R}^{N+1}:|(x,y)|\le m\}$ and $Q_r=D_r^+\cup(D_r\cap(\mathbb{R}^N\times\{0\}))$, where $D_r^+=D_r\cap\mathbb{R}^{N+1}_+$. Let $\varphi\in C_0^\infty(\mathbb{R}^{N+1})$ with $0\le\varphi\le1$, $\varphi=1$ in D_1, $\varphi=0$ outside D_2 and $|\nabla\varphi|\le2$. For $R>0$, define

$$\psi_R(x,y)=\psi\left(\frac{(x,y)}{R}\right),\quad \text{where } \psi=\varphi|_{\overline{\mathbb{R}^{N+1}_+}}.$$

Multiplying (2.5) by $((x,y)\cdot\nabla U)\psi_R$ and $((x,y)\cdot\nabla V)\psi_R$ respectively, we obtain from [8, Proposition A.1],

$$\begin{aligned}\lim_{R\to\infty}\int_{D_{2R}\cap(\mathbb{R}\times\{0\})}|u|^{p-2}u\cdot(x,y)\cdot\nabla U\psi_R dx&=-\frac{N}{p}\int_{\mathbb{R}^N}|u|^pdx.\\\lim_{R\to\infty}\int_{D_{2R}\cap(\mathbb{R}\times\{0\})}u\cdot(x,y)\cdot\nabla U\psi_R dx&=-\frac{N}{2}\int_{\mathbb{R}^N}|u|^2dx.\end{aligned}$$

and

$$\begin{aligned}\lim_{R\to\infty}\int_{D_{2R}\cap(\mathbb{R}^N\times\{0\})}|v|^{p-2}v\cdot(x,y)\cdot\nabla V\psi_R dx&=-\frac{N}{p}\int_{\mathbb{R}^N}|v|^pdx.\\\lim_{R\to\infty}\int_{D_{2R}\cap(\mathbb{R}^N\times\{0\})}v\cdot(x,y)\cdot\nabla V\psi_R dx&=-\frac{N}{2}\int_{\mathbb{R}^N}|v|^2dx.\end{aligned}$$

Moreover,

$$\begin{aligned}&\lim_{R\to\infty}\int_{D_{2R}\cap(\mathbb{R}^N\times\{0\})}\left(r_1|v|^{r_2}|u|^{r_1-2}u\cdot(x,y)\cdot\nabla U\psi_R+r_2|u|^{r_1}|v|^{r_2-2}v\cdot(x,y)\cdot\nabla V\psi_R\right)dx\\&=-N\int_{\mathbb{R}^N}|u|^{r_1}|v|^{r_2}dx.\end{aligned}$$

and

$$\begin{aligned}\lim_{R\to\infty}\int_{Q_{2R}}y^{1-2s}\nabla U\nabla[((x,y)\cdot\nabla U)\psi_R]dxdy&=-\frac{N-2s}{2}\int_{\mathbb{R}^{N+1}_+}y^{1-2s}|\nabla U|^2dxdy,\\\lim_{R\to\infty}\int_{Q_{2R}}y^{1-2s}\nabla V\nabla[((x,y)\cdot\nabla V)\psi_R]dxdy&=-\frac{N-2s}{2}\int_{\mathbb{R}^{N+1}_+}y^{1-2s}|\nabla V|^2dxdy.\end{aligned}$$

Furthermore, combining with [42, Lemma 4.1], we have

$$\begin{aligned}&\lim_{R\to\infty}\int_{D_{2R}\cap(\mathbb{R}^N\times\{0\})}\big((I_\alpha*|v|^{2^*_{\alpha,s}})|u|^{2^*_{\alpha,s}-2}\cdot(x,y)\cdot\nabla U\psi_R\\&\qquad+(I_\alpha*|u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}-2}\cdot(x,y)\cdot\nabla V\psi_R\big)dx\\&=\frac{\alpha-2N}{2^*_{\alpha,s}}\int_{\mathbb{R}^N}(I_\alpha*|u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}}dx.\end{aligned}$$

Multiplying (2.5) by $U\psi_R$ and $V\psi_R$ respectively, and using the same techniques of [8, Proposition A.1], we firstly obtain

$$\int_{\mathbb{R}^{N+1}_+} y^{1-2s}|\nabla U|^2 dxdy = \int_{\mathbb{R}^N} |(-\Delta)^{\frac{s}{2}} u|^2 dx,$$
$$\int_{\mathbb{R}^{N+1}_+} y^{1-2s}|\nabla V|^2 dxdy = \int_{\mathbb{R}^N} |(-\Delta)^{\frac{s}{2}} v|^2 dx,$$

and then we finish this proof. □

Lemma 2.5. *Let $(u,v) \in H$ be a weak solution of (1.1), then we have Pohožaev manifold*

$$\mathcal{P}_{\mu_1,\mu_2} = \{(u,v) \in S : P_{\mu_1,\mu_2}(u,v) = 0\},$$

where

$$\begin{aligned} P_{\mu_1,\mu_2}(u,v) = s([u]^2 + [v]^2) - s\gamma_p(\mu_1|u|_p^p + \mu_2|v|_p^p) - s\beta(r_1+r_2)\gamma_{(r_1+r_2)} \int_{\mathbb{R}^N} |u|^{r_1}|v|^{r_2} dx \\ - 2s\int_{\mathbb{R}^N} (I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}} dx. \end{aligned} \tag{2.6}$$

Proof. Since Proposition 2.4, we have (u,v) satisfies

$$\begin{aligned} &\frac{N-2s}{2}\int_{\mathbb{R}^N} (|(-\Delta)^{\frac{s}{2}} u|^2 + |(-\Delta)^{\frac{s}{2}} v|^2) dx \\ &\quad = \frac{N}{2}\int_{\mathbb{R}^N} (\lambda_1|u|^2 + \lambda_2|v|^2) dx + \frac{N}{p}\int_{\mathbb{R}^N} (\mu_1|u|^p + \mu_2|v|^p) dx \\ &\quad\quad + \beta N \int_{\mathbb{R}^N} |u|^{r_1}|v|^{r_2} dx + \frac{2N-\alpha}{2^*_{\alpha,s}} \int_{\mathbb{R}^N} (I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}} dx, \end{aligned}$$

and

$$\begin{aligned} \int_{\mathbb{R}^N} (|(-\Delta)^{\frac{s}{2}} u|^2 + |(-\Delta)^{\frac{s}{2}} v|^2) dx = &\int_{\mathbb{R}^N} (\lambda_1|u|^2 + \lambda_2|v|^2) dx + \int_{\mathbb{R}^N} (\mu_1|u|^p + \mu_2|v|^p) dx \\ &+ \beta(r_1+r_2)\int_{\mathbb{R}^N} |u|^{r_1}|v|^{r_2} dx + 2\int_{\mathbb{R}^N} (I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}} dx. \end{aligned}$$

Thus,

$$\begin{aligned} &s\int_{\mathbb{R}^N} (|(-\Delta)^{\frac{s}{2}} u|^2 + |(-\Delta)^{\frac{s}{2}} v|^2) dx \\ &\quad = s\gamma_p \int_{\mathbb{R}^N} (\mu_1|u|^p + \mu_2|v|^p) dx + \beta s(r_1+r_2)\gamma_{(r_1+r_2)} \int_{\mathbb{R}^N} |u|^{r_1}|v|^{r_2} dx \\ &\quad\quad + 2s\int_{\mathbb{R}^N} (I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}} dx, \end{aligned}$$

and the conclusions follows. □

Under the L^2-invariant scaling introduced by Jeanjean in [25],

$$t * u := e^{\frac{Nt}{2}} u(e^t x), \quad \text{and} \quad t * (u,v) := (t * u, t * v),$$

it is natural to study the fiber maps

$$\begin{aligned} \Psi_{\mu_1,\mu_2}(t) := J(t*(u,v)) = &\frac{e^{2st}}{2}([u]^2 + [v]^2) - \frac{e^{sp\gamma_p t}}{p}(\mu_1|u|_p^p + \mu_2|v|_p^p) \\ &- \beta e^{s(r_1+r_2)\gamma_{(r_1+r_2)} t}\int_{\mathbb{R}^N} |u|^{r_1}|v|^{r_2} dx \\ &- \frac{e^{22^*_{\alpha,s} st}}{2^*_{\alpha,s}} \int_{\mathbb{R}^N} (I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}} dx, \end{aligned} \tag{2.7}$$

satisfying $\Psi'_{\mu_1,\mu_2}(t) = P_{\mu_1,\mu_2}(t * u, t * v)$, that is

$$\mathcal{P}_{\mu_1,\mu_2} = \{(u,v) \in S : \Psi'_{\mu_1,\mu_2}(0) = 0\}.$$

We decompose $\mathcal{P}_{\mu_1,\mu_2}$ into 3 disjoint unions $\mathcal{P}_{\mu_1,\mu_2} = \mathcal{P}^+_{\mu_1,\mu_2} \cup \mathcal{P}^0_{\mu_1,\mu_2} \cup \mathcal{P}^-_{\mu_1,\mu_2}$, defined by

$$\begin{aligned}\mathcal{P}^+_{\mu_1,\mu_2} &:= \{u \in \mathcal{P}_{\mu_1,\mu_2} : \Psi''_{\mu_1,\mu_2}(0) > 0\};\\ \mathcal{P}^0_{\mu_1,\mu_2} &:= \{u \in \mathcal{P}_{\mu_1,\mu_2} : \Psi''_{\mu_1,\mu_2}(0) = 0\};\\ \mathcal{P}^-_{\mu_1,\mu_2} &:= \{u \in \mathcal{P}_{\mu_1,\mu_2} : \Psi''_{\mu_1,\mu_2}(0) < 0\}.\end{aligned}$$

Set $m(a,b) = \inf_{\mathcal{P}_{\mu_1,\mu_2}} J(u,v)$ and $m^{\pm}(a,b) = \inf_{(u,v)\in\mathcal{P}^{\pm}_{\mu_1,\mu_2}} J(u,v)$, respectively. The main idea of this paper is to show whether $m(a,b)$ is achieved.

3 The relevant results

Before solving problem (1.1) and (1.2), we study the following problem:

$$\begin{cases}(-\Delta)^s u = \lambda u + \mu|u|^{p-2}u, & \text{in } \mathbb{R}^N,\\ \int_{\mathbb{R}^N} u^2 dx = c^2, & u \in H^s(\mathbb{R}^N),\end{cases} \tag{3.1}$$

where $\mu, c > 0$, $p \in (2, 2^*_s) \setminus \{\bar{p}\}$. The standard method obtaining the normalized solutions of (3.1) is to search for the critical points of

$$I_{\mu,c}(u) = \frac{1}{2}[u]^2 - \frac{\mu}{p}\int_{\mathbb{R}^N} |u|^p dx,$$

constrained on $S_c := \{u \in H^s(\mathbb{R}^N) : |u|_2^2 = c^2\}$. By the same arguments as in Section 2, the Pohožaev identity related to (3.1) is

$$P_{\mu,c}(u) = s[u]^2 - \mu\gamma_p s|u|_p^p,$$

and the corresponding Pohožaev manifold is

$$\mathcal{P}_{\mu,c} := \{u \in S_c : [u]^2 = \mu\gamma_p|u|_p^p\}.$$

Moreover, we have

$$\Psi_{\mu,c}(t) := I_{\mu,c}(t * u) = \frac{e^{2st}}{2}[u]^2 - \frac{\mu e^{p\gamma_p st}}{p}\int_{\mathbb{R}^N} |u|^p dx,$$

and $\mathcal{P}_{\mu,c}$ can also be divided into 3 disjoint unions $\mathcal{P}_{\mu,c} = \mathcal{P}^+_{\mu,c} \cup \mathcal{P}^0_{\mu,c} \cup \mathcal{P}^-_{\mu,c}$, where

$$\begin{aligned}\mathcal{P}^+_{\mu,c} &:= \{u \in \mathcal{P}_{\mu,c} : \Psi''_{\mu,c}(0) > 0\};\\ \mathcal{P}^0_{\mu,c} &:= \{u \in \mathcal{P}_{\mu,c} : \Psi''_{\mu,c}(0) = 0\};\\ \mathcal{P}^-_{\mu,c} &:= \{u \in \mathcal{P}_{\mu,c} : \Psi''_{\mu,c}(0) < 0\}.\end{aligned}$$

Define $m_\mu(c) = \inf_{u\in\mathcal{P}_{\mu,c}} I_{\mu,c}(u)$ and let $m(a,0) = m_{\mu_1}(a)$, $m(0,b) = m_{\mu_2}(b)$. From Lemma 2.3, for any $u \in S_a$, there is $C_1 := C_1(N,p,a,s) > 0$, such that

$$\int_{\mathbb{R}^N} |u|^p dx \le C(N,p,s)|u|_2^{p(1-\gamma_p)}[u]^{p\gamma_p} = C_1[u]^{p\gamma_p} \le C_1([u]^2 + [v]^2)^{\frac{p\gamma_p}{2}}. \tag{3.2}$$

In particular, when $p < \bar{p}$, from (3.2) we get

$$I_{\mu_1,a}(u) = \frac{1}{2}[u]^2 - \frac{\mu_1}{p}\int_{\mathbb{R}^N} |u|^p dx \geq \frac{1}{2}[u]^2 - \frac{C_1\mu_1}{p}[u]^{p\gamma_p} =: h([u]),$$

where

$$h(\rho) := \frac{1}{2}\rho^2 - \frac{C_1\mu_1}{p}\rho^{p\gamma_p}. \tag{3.3}$$

Setting

$$\rho_* := (C_1\mu_1\gamma_p)^{\frac{1}{2-p\gamma_p}},$$

we have that $h(\rho_*) < 0$, $h(\rho)$ is strictly decreasing in $(0, \rho_*)$, and is strictly increasing in (ρ_*, ∞). If we denote $R_0 = (\frac{2C_1\mu_1}{p})^{\frac{1}{2-p\gamma_p}}$, then $h(R_0) = 0$ and $h(\rho) < 0$ iff $\rho \in (0, R_0)$.

From [44], we have the following already known results. For the mass subcritical case:

Theorem 3.1 ([44, Theorem 1.1]). *When $2s < N \leq 4s$, $p \in (2, \bar{p})$ and $\mu, c > 0$ in (3.1), there is $\hat{\mu} > 0$, for any $\mu \in (0, \hat{\mu})$, then $I_{\mu,c}|_{S_c}$ has a ground state solution u_μ for some $\lambda < 0$. Moreover,*

$$m_\mu(c) = \inf_{u\in S_c} I_{\mu,c}(u) = I_{\mu,c}(u_\mu) < 0,$$

and u_μ is an interior local minimizer of $I_{\mu,c}$ on the set

$$\hat{B}_{R_0} := \{u \in S_c : [u] < R_0\}.$$

Besides, any other normalized ground state solution is a minimizer of $I_{\mu,c}$ on B_{R_0}.

Remark 3.2. We set $\hat{\mu}_1, \hat{\mu}_2$ to obtain Theorem 3.1, under $\mu = \mu_1, c = a$ and $\mu = \mu_2, c = b$ in (3.1), respectively.

For the mass supercritical case:

Theorem 3.3 ([44, Theorem 1.3]). *When $2s < N \leq 4s$, $p \in (\bar{p}, 2_s^*)$ and $\mu, c > 0$ in (3.1), then $I_{\mu,c}|_{S_c}$ has a ground state solution u_μ for some $\lambda < 0$. Moreover u_μ is a critical point of Mountain Pass type and*

$$m_\mu(c) = \inf_{u\in S_c}\max_{t\in\mathbb{R}} I_{\mu,c}(t * u) = \max_{t\in\mathbb{R}} I_{\mu,c}(t * u_\mu) = I_{\mu,c}(u_\mu) > 0.$$

In order to proceed our proof, we also need the following monotonicity result which is essential for Lemmas 4.6 and 5.7.

Lemma 3.4. *$m_{\mu_1}(a)$ is non-increasing with respect to a, that is*

$$m_{\mu_1}(a) \leq m_{\mu_1}(a_1), \quad \textit{for any } 0 < a_1 \leq a.$$

Proof. We will prove for any $0 < a_1 \leq a$ and an arbitrary $\varepsilon > 0$,

$$m_{\mu_1}(a) \leq m_{\mu_1}(a_1) + \varepsilon.$$

We divide this proof into two cases.

Case 1: $2 < p < \bar{p}$. For this case, from the definition of R_0 in (3.3), we see R_0 is increasing as a is increasing. Hence, by Theorem 3.1 and $a_1 \leq a$, there exists a $\hat{R}_0$ with $\hat{R}_0 < R_0$, such that

$$m_{\mu_1}(a_1) = \inf_{u\in\hat{B}_{\hat{R}_0}} I_{\mu_1}(u).$$

Let $u \in \hat{B}_{\hat{R}_0} \subset \hat{B}_{R_0}$ be such that $I_{\mu_1}(u) \leq m_{\mu_1}(a_1) + \frac{\varepsilon}{2}$. Setting $\phi \in C_0^\infty(\mathbb{R}^N)$ be a cut-off function satisfies $0 \leq \phi \leq 1$ and

$$\phi(x) = \begin{cases} 0, & \text{if } |x| \geq 2, \\ 1, & \text{if } |x| \leq 1. \end{cases}$$

For $\delta > 0$, defined $u_\delta(x) = u(x)\phi(\delta x)$, we get $u_\delta \to u$ in $H^s(\mathbb{R}^N)$ as $\delta \to 0$. Thus, for $\eta = \frac{\varepsilon}{6} > 0$, there exists $\delta > 0$ such that

$$I_{\mu_1}(u_\delta) \leq I_{\mu_1}(u) + \frac{\varepsilon}{6}, \quad \text{and} \quad [u_\delta] < R_0 - \frac{\eta}{R_0}. \tag{3.4}$$

Taking $\varphi \in C_0^\infty(\mathbb{R}^N)$ satisfies $\operatorname{supp}(\varphi) \subset O_{1+\frac{3}{\delta}}(0) \setminus O_{\frac{3}{\delta}}(0)$, where $O_m(n)$ means a ball in $\mathbb{R}^N$ with radius m and centered at n. Let

$$w(x) = \frac{(a^2 - |u_\delta|_2^2)^{\frac{1}{2}}}{|\varphi|_2}\varphi,$$

then for $t < 0$,

$$\operatorname{supp}(u_\delta) \cap \operatorname{supp}(t * w) = \emptyset.$$

Therefore, we get $u_\delta + t * w \in S_a$. Moreover, as $t \to -\infty$, we have

$$I_{\mu_1}(t * w) \leq \frac{\varepsilon}{6}, \quad \text{and} \quad [t * w] \leq \frac{\eta}{R_0}. \tag{3.5}$$

By the Hölder inequality, we obtain

$$\begin{aligned}
[u_\delta + t * w]^2 &= \iint_{\mathbb{R}^{2N}} \frac{|(u_\delta + t * w)(x) - (u_\delta + t * w)(y)|^2}{|x-y|^{N+2s}} dxdy \\
&= \iint_{\mathbb{R}^{2N}} \frac{|u_\delta(x) - u_\delta(y)|^2}{|x-y|^{N+2s}} dxdy + \iint_{\mathbb{R}^{2N}} \frac{|(t * w)(x) - (t * w)(y)|^2}{|x-y|^{N+2s}} dxdy \\
&\quad + 2\iint_{\mathbb{R}^{2N}} \frac{(u_\delta(x) - u_\delta(y))((t * w)(x) - (t * w)(y))}{|x-y|^{N+2s}} dxdy \\
&\leq [u_\delta]^2 + [t * w]^2 + 2[u_\delta][t * w] \\
&= ([u_\delta] + [t * w])^2,
\end{aligned}$$

then $[u_\delta + t * w] < R_0$. Now from Theorem 3.1, $m_{\mu_1}(a) = \inf_{u \in \hat{B}_{R_0}} I_{\mu_1}(u)$, by (3.4)–(3.5), we obtain

$$\begin{aligned}
m_{\mu_1}(a) &\leq I_{\mu_1}(u_\delta + t * w) \leq I_{\mu_1}(u_\delta) + I_{\mu_1}(t * w) + [u_\delta][t * w] \\
&\leq m_{\mu_1}(a_1) + \frac{\varepsilon}{2} + \frac{\varepsilon}{6} + \frac{\varepsilon}{6} + \frac{\varepsilon}{6} \leq m_{\mu_1}(a_1) + \varepsilon.
\end{aligned}$$

Case 2: $\bar{p} < p < 2_s^*$. In this case, $p\gamma_p > 2$, and by the definition of $m_{\mu_1}(a_1)$, there exists $u \in \mathcal{P}_{\mu_1, a_1}$, such that

$$I_{\mu_1}(u) \leq m_{\mu_1}(a_1) + \frac{\varepsilon}{2}.$$

From Theorem 3.3, we have u is bounded in $H^s(\mathbb{R}^N)$ and

$$[u]^2 = \mu_1 \gamma_p |u|_p^p.$$

Since (3.2) and $a_1 \leq a$, we get

$$[u] \geq \left(\frac{1}{\mu_1 \gamma_p C(N,p,s) a_1^{p(1-\gamma_p)}} \right)^{\frac{1}{p\gamma_p - 2}} \geq \left(\frac{1}{\mu_1 \gamma_p C(N,p,s) a^{p(1-\gamma_p)}} \right)^{\frac{1}{p\gamma_p - 2}}.$$

Hence there are $\hat{C}, \tilde{C} > 0$, which are independent with a_1, such that $[u] \geq \hat{C}$, and $|u|_p^p \geq \tilde{C}$. Later we may assume $\varepsilon < \tilde{C}$. Same definitions as in Case 1, we have $u_\delta \to u$ in $H^s(\mathbb{R}^N)$ as $\delta \to 0$ and from Theorem 3.3, $t_{u_\delta} * u_\delta \to t_u * u$ in $H^s(\mathbb{R}^N)$ as $\delta \to 0$, where t_u means strict maximum point of $\Psi_{\mu_1,a_1}(t)$ and the map $u \to t_u$ is of C^1 class. Then, for fixed $\delta > 0$, there exists $C > 0$ such that

$$I_{\mu_1}(t_{u_\delta} * u_\delta) \leq I_{\mu_1}(u) + \frac{\varepsilon}{6}, \quad [u_\delta] \leq C, \quad \text{and} \quad |u_\delta|_p^p \geq \tilde{C} - \frac{\varepsilon}{2}. \tag{3.6}$$

Choose $\psi \in C_0^\infty(\mathbb{R}^N)$ with $\text{supp}(\psi) \subset O_{1+\frac{3}{\delta}}(0) \setminus O_{\frac{3}{\delta}}(0)$, where $O_m(n)$ means a ball as defined on the previous page. Set

$$\kappa = \frac{(a^2 - |u_\delta|_2^2)^{\frac{1}{2}}}{|\psi|_2}\psi.$$

Then for $\tau < 0$, we have

$$\text{supp}(u_\delta) \cap \text{supp}(\tau * \kappa) = \emptyset.$$

Let $u_\tau := u_\delta + \tau * \kappa \in S_a$, and as $\tau \to -\infty$,

$$\begin{aligned}\int_{\mathbb{R}^N} |u_\tau|^p dx &= \int_{\mathbb{R}^N} |u_\delta|^p dx + \int_{\mathbb{R}^N} |\tau * \kappa|^p dx \\ &= \int_{\mathbb{R}^N} |u_\delta|^p dx + e^{p\gamma_p s\tau} \int_{\mathbb{R}^N} |\kappa|_p^p dx \to |u_\delta|_p^p.\end{aligned}$$

Similarly, we obtain

$$\begin{aligned}[u_\tau]^2 &\leq [u_\delta]^2 + [\tau * \kappa]^2 + 2[u_\delta][\tau * \kappa] \\ &= [u_\delta]^2 + e^{2s\tau}[\kappa]^2 + 2e^{s\tau}[u_\delta][\kappa] \to [u_\delta]^2.\end{aligned}$$

From Theorem 3.3, there exists t_τ such that $P_{\mu_1,a}(t_\tau * u_\tau) = 0$, i.e.

$$\frac{1}{e^{(p\gamma_p - 2)st_\tau}}[u_\tau]^2 = \gamma_p \mu_1 |u_\tau|_p^p.$$

Then as $\tau \to -\infty$,

$$e^{(p\gamma_p-2)st_\tau} = \frac{[u_\tau]^2}{\gamma_p \mu_1 |u_\tau|_p^p} \leq \frac{[u_\delta]^2}{\gamma_p \mu_1 |u_\delta|_p^p}.$$

Combining with (3.6), we get t_τ is bounded from above as $\tau \to -\infty$. Hence, for $\tau < -1$ sufficiently small, there exists $C^* > 0$ such that

$$[t_\tau * u_\delta] \leq C^*, \quad I_{\mu_1}((t_\tau + \tau) * \kappa) \leq \frac{\varepsilon}{6}, \quad \text{and} \quad [(t_\tau + \tau) * \kappa] < \frac{\varepsilon}{6C^*}. \tag{3.7}$$

Thus from (3.6) and (3.7), we obtain

$$\begin{aligned}m_{\mu_1}(a) &\leq I_{\mu_1}(t_\tau * u_\tau) \leq I_{\mu_1}(t_\tau * u_\delta) + I_{\mu_1}((t_\tau + \tau) * \kappa) + [t_\tau * u_\delta][(t_\tau + \tau) * \kappa] \\ &\leq I_{\mu_1}(t_{u_\delta} * u_\delta) + \frac{\varepsilon}{6} + \frac{\varepsilon}{6} \\ &\leq I_{\mu_1}(u) + \frac{\varepsilon}{6} + \frac{\varepsilon}{6} + \frac{\varepsilon}{6} \leq m_{\mu_1}(a_1) + \varepsilon.\end{aligned}$$

Then, we complete this proof. □

4 The case: $2 < p < \bar{p}$, $p < (r_1 + r_2) < 2_s^*$

In this section, we consider the mixed exponent case. For any $(u, v) \in S$, from (2.2), the Hölder inequality and (2.4), there are $C_2 = C_2(N, p, b, s) > 0$, $C_3 = C_3(N, (r_1 + r_2), s, a, b)$ and $C_4 = (S^*)^{-2^*_{\alpha,s}}$, such that

$$\int_{\mathbb{R}^N} |v|^p dx \leq C(N, p, s)|v|_2^{p(1-\gamma_p)}[v]^{p\gamma_p} = C_2[v]^{p\gamma_p} \leq C_2([v]^2 + [u]^2)^{\frac{p\gamma_p}{2}}, \tag{4.1}$$

$$\begin{aligned}\int_{\mathbb{R}^N} |u|^{r_1}|v|^{r_2}dx &\leq |u|^{r_1}_{(r_1+r_2)}|v|^{r_2}_{(r_1+r_2)} \\ &\leq C(N, (r_1 + r_2), s)|u|_2^{r_1(1-\gamma_{(r_1+r_2)})}[u]^{r_1\gamma_{(r_1+r_2)}}|v|_2^{r_2(1-\gamma_{(r_1+r_2)})}[v]^{r_2\gamma_{(r_1+r_2)}} \\ &\leq C_3([u]^2 + [v]^2)^{\frac{(r_1+r_2)\gamma_{(r_1+r_2)}}{2}},\end{aligned} \tag{4.2}$$

and

$$\int_{\mathbb{R}^N} (I_\alpha * |v|^{2^*_{\alpha,s}})|u|^{2^*_{\alpha,s}}dx \leq (S^*)^{-2^*_{\alpha,s}}([u]^2 + [v]^2)^{2^*_{\alpha,s}} = C_4([u]^2 + [v]^2)^{2^*_{\alpha,s}}. \tag{4.3}$$

Hence, substituting (3.2), (4.1)–(4.3) into $J(u, v)$, we obtain

$$\begin{aligned}J(u, v) \geq &\frac{1}{2}([u]^2 + [v]^2) - \frac{\mu_1 C_1 + \mu_2 C_2}{p}([u]^2 + [v]^2)^{\frac{p\gamma_p}{2}} - \beta C_3([u]^2 + [v]^2)^{\frac{(r_1+r_2)\gamma_{(r_1+r_2)}}{2}} \\ &- \frac{C_4}{2^*_{\alpha,s}}([u]^2 + [v]^2)^{2^*_{\alpha,s}}.\end{aligned} \tag{4.4}$$

Then we introduce the function $k : \mathbb{R}^+ \to \mathbb{R}$ by

$$k(t) := \frac{1}{2}t^2 - \frac{\mu_1 C_1 + \mu_2 C_2}{p}t^{p\gamma_p} - \beta C_3 t^{(r_1+r_2)\gamma_{(r_1+r_2)}} - \frac{C_4}{2^*_{\alpha,s}}t^{22^*_{\alpha,s}}, \tag{4.5}$$

and $k(0^+) = 0^-$, and $k(+\infty) = -\infty$.

Lemma 4.1. *There exists $\beta_* > 0$, such that for any $\beta \in (0, \beta_*)$, there exist $\mu_{1,*} = \mu_{1,*}(\beta) > 0$ and $\mu_{2,*} = \mu_{2,*}(\beta) > 0$, for any $\mu_1 \in (0, \mu_{1,*})$, $\mu_2 \in (0, \mu_{2,*})$, the function $k(t)$ has exactly two critical points, one is a local strict minimum at a negative level, and the other one is a global maximum at a positive level. Further, there exist $0 < R_2 < R_3$ such that $k(R_2) = k(R_3) = 0$, $k(t) > 0$ if and only if $t \in (R_2, R_3)$.*

Proof. Since the monotonicity of $k(t)$ will be strongly affected by the comparison of p and $r_1 + r_2$, we may divide this proof into 3 different situations.

Case 1: $2 < p < (r_1 + r_2) < \bar{p}$. In this case, we have $p\gamma_p < (r_1 + r_2)\gamma_{(r_1+r_2)} < 2$ and

$$k'(t) = t^{p\gamma_p-1}[t^{2-p\gamma_p} - C_3\beta(r_1 + r_2)\gamma_{(r_1+r_2)}t^{(r_1+r_2)\gamma_{(r_1+r_2)}-p\gamma_p} - 2C_4 t^{22^*_{\alpha,s}-p\gamma_p} - \gamma_p(\mu_1 C_1 + \mu_2 C_2)].$$

Denote

$$\tilde{k}(t) := t^{2-p\gamma_p} - C_3\beta(r_1 + r_2)\gamma_{(r_1+r_2)}t^{(r_1+r_2)\gamma_{(r_1+r_2)}-p\gamma_p} - 2C_4 t^{22^*_{\alpha,s}-p\gamma_p},$$

then

$$\begin{aligned}\tilde{k}'(t) = &t^{(r_1+r_2)\gamma_{(r_1+r_2)}-p\gamma_p-1}[(2 - p\gamma_p)t^{2-(r_1+r_2)\gamma_{(r_1+r_2)}} - 2C_4(22^*_{\alpha,s} - p\gamma_p)t^{22^*_{\alpha,s}-(r_1+r_2)\gamma_{(r_1+r_2)}} \\ &- C_3\beta(r_1 + r_2)\gamma_{(r_1+r_2)}((r_1 + r_2)\gamma_{(r_1+r_2)} - p\gamma_p)].\end{aligned}$$

Let

$$\hat{k}(t) := (2-p\gamma_p)t^{2-(r_1+r_2)\gamma_{(r_1+r_2)}} - 2C_4(22^*_{\alpha,s} - p\gamma_p)t^{22^*_{\alpha,s}-(r_1+r_2)\gamma_{(r_1+r_2)}}, \tag{4.6}$$

then

$$\begin{aligned}\hat{k}'(t) = t^{1-(r_1+r_2)\gamma_{(r_1+r_2)}}[&(2-p\gamma_p)(2-(r_1+r_2)\gamma_{(r_1+r_2)}) \\ &- 2C_4(22^*_{\alpha,s} - p\gamma_p)(22^*_{\alpha,s} - (r_1+r_2)\gamma_{(r_1+r_2)})t^{22^*_{\alpha,s}-2}].\end{aligned}$$

We see from the definition of $\hat{k}'(t)$ that $\hat{k}(t)$ has a unique critical point t_0 in $(0,+\infty)$ satisfying

$$t_0^{22^*_{\alpha,s}-2} = \frac{(2-p\gamma_p)(2-(r_1+r_2)\gamma_{(r_1+r_2)})}{2C_4(22^*_{\alpha,s} - p\gamma_p)(22^*_{\alpha,s} - (r_1+r_2)\gamma_{(r_1+r_2)})}.$$

Moreover, since $p\gamma_p < (r_1+r_2)\gamma_{(r_1+r_2)} < 2$, we have $\tilde{k}(+\infty) = -\infty$, $\tilde{k}(0^+) = 0^-$. If

$$\begin{aligned}&\hat{k}(t_0) > C_3\beta(r_1+r_2)\gamma_{(r_1+r_2)}[(r_1+r_2)\gamma_{(r_1+r_2)} - p\gamma_p]; \\ &\tilde{k}(t_0) > \gamma_p(\mu_1 C_1 + \mu_2 C_2), \quad \text{and} \quad k(t_0) > 0,\end{aligned} \tag{4.7}$$

i.e.

$$\begin{cases} \left[\dfrac{(2-p\gamma_p)(2-(r_1+r_2)\gamma_{(r_1+r_2)})}{2C_4(22^*_{\alpha,s} - p\gamma_p)(22^*_{\alpha,s} - (r_1+r_2)\gamma_{(r_1+r_2)})}\right]^{\frac{2-(r_1+r_2)\gamma_{(r_1+r_2)}}{22^*_{\alpha,s}-2}} \dfrac{(2-p\gamma_p)(22^*_{\alpha,s}-2)}{22^*_{\alpha,s} - (r_1+r_2)\gamma_{(r_1+r_2)}} \\ \quad > C_3\beta(r_1+r_2)\gamma_{(r_1+r_2)}((r_1+r_2)\gamma_{(r_1+r_2)} - p\gamma_p); \\ \left[\dfrac{(2-p\gamma_p)(2-(r_1+r_2)\gamma_{(r_1+r_2)})}{2C_4(22^*_{\alpha,s} - p\gamma_p)(22^*_{\alpha,s} - (r_1+r_2)\gamma_{(r_1+r_2)})}\right]^{\frac{p\gamma_p}{22^*_{\alpha,s}-2}} \left[1 - \dfrac{(2-p\gamma_p)(2-(r_1+r_2)\gamma_{(r_1+r_2)})}{(22^*_{\alpha,s} - p\gamma_p)(22^*_{\alpha,s} - (r_1+r_2)\gamma_{(r_1+r_2)})}\right] \\ \quad > \gamma_p(\mu_1 C_1 + \mu_2 C_2) + C_3\beta(r_1+r_2)\gamma_{(r_1+r_2)} \\ \qquad \times \left[\dfrac{(2-p\gamma_p)(2-(r_1+r_2)\gamma_{(r_1+r_2)})}{2C_4(22^*_{\alpha,s} - p\gamma_p)(22^*_{\alpha,s} - (r_1+r_2)\gamma_{(r_1+r_2)})}\right]^{\frac{(r_1+r_2)\gamma_{(r_1+r_2)}-p\gamma_p}{22^*_{\alpha,s}-2}}; \\ \left[\dfrac{(2-p\gamma_p)(2-(r_1+r_2)\gamma_{(r_1+r_2)})}{2C_4(22^*_{\alpha,s} - p\gamma_p)(22^*_{\alpha,s} - (r_1+r_2)\gamma_{(r_1+r_2)})}\right]^{\frac{22^*_{\alpha,s}}{22^*_{\alpha,s}-2}} C_4\left[\dfrac{(22^*_{\alpha,s} - p\gamma_p)(22^*_{\alpha,s} - (r_1+r_2)\gamma_p)}{(2-p\gamma_p)(2-(r_1+r_2)\gamma_{(r_1+r_2)})} - \dfrac{1}{2^*_{\alpha,s}}\right] \\ \quad > \dfrac{\mu_1 C_1 + \mu_2 C_2}{p} \times \left[\dfrac{(2-p\gamma_p)(2-(r_1+r_2)\gamma_{(r_1+r_2)})}{2C_4(22^*_{\alpha,s} - p\gamma_p)(22^*_{\alpha,s} - (r_1+r_2)\gamma_{(r_1+r_2)})}\right]^{\frac{p\gamma_p}{22^*_{\alpha,s}-2}} \\ \qquad + \beta C_3 \left[\dfrac{(2-p\gamma_p)(2-(r_1+r_2)\gamma_{(r_1+r_2)})}{2C_4(22^*_{\alpha,s} - p\gamma_p)(22^*_{\alpha,s} - (r_1+r_2)\gamma_{(r_1+r_2)})}\right]^{\frac{(r_1+r_2)\gamma_{(r_1+r_2)}}{22^*_{\alpha,s}-2}}, \end{cases} \tag{4.8}$$

then the function $k(t)$ has exactly two critical points, one is a local minimum at a negative level, the other one is a global maximum at a positive level. Therefore, there exist R_2, R_3 with $0 < R_2 < R_3$ such that $k(R_2) = k(R_3) = 0$, $k(t) > 0$ if and only if $t \in (R_2, R_3)$.

Case 2: $2 < p < r_1 + r_2 = \bar{p}$. This implies $p\gamma_p < (r_1+r_2)\gamma_{(r_1+r_2)} = 2$. We choose β such that $C_3\beta < \frac{1}{2}$ and $k(t)$ turns to be

$$k(t) = \left(\frac{1}{2} - C_3\beta\right)t^2 - \frac{\mu_1 C_1 + \mu_2 C_2}{p}t^{p\gamma_p} - \frac{C_4}{2^*_{\alpha,s}}t^{22^*_{\alpha,s}}.$$

Taking a similar argument as in *Case 1*, first we have

$$k'(t) = t^{p\gamma_p-1}[(1-2C_3\beta)t^{2-p\gamma_p} - 2C_4 t^{22^*_{\alpha,s}-p\gamma_p} - \gamma_p(\mu_1 C_1 + \mu_2 C_2)].$$

Denote

$$\tilde{k}(t) = (1-2C_3\beta)t^{2-p\gamma_p} - 2C_4 t^{22^*_{\alpha,s}-p\gamma_p},$$

and

$$\tilde{k}'(t) = t^{1-p\gamma_p}[(1-2C_3\beta)(2-p\gamma_p) - 2C_4(22^*_{\alpha,s}-p\gamma_p)t^{22^*_{\alpha,s}-2}].$$

Thus there exists $t_1 \in (0,+\infty)$ satisfying

$$t_1^{22^*_{\alpha,s}-2} = \frac{(1-2C_3\beta)(2-p\gamma_p)}{2C_4(22^*_{\alpha,s}-p\gamma_p)},$$

and if

$$\tilde{k}(t_1) > \gamma_p(\mu_1 C_1 + \mu_2 C_2), \quad \text{and} \quad k(t_1) > 0, \tag{4.9}$$

that is

$$\begin{cases} \left(\dfrac{2-p\gamma_p}{2C_4}\right)^{\frac{(2-p\gamma_p)}{22^*_{\alpha,s}-2}} (22^*_{\alpha,s}-2)(22^*_{\alpha,s}-p\gamma_p)^{\frac{p\gamma_p-22^*_{\alpha,s}}{22^*_{\alpha,s}-2}} > \gamma_p(\mu_1C_1+\mu_2C_2)(1-2C_3\beta)^{\frac{p\gamma_p-22^*_{\alpha,s}}{22^*_{\alpha,s}-2}}; \\ \left(\dfrac{22^*_{\alpha,s}-p\gamma_p}{2-p\gamma_p} - \dfrac{1}{2^*_{\alpha,s}}\right)C_4 > \dfrac{\mu_1C_1+\mu_2C_2}{p}\left[\dfrac{(1-2C_3\beta)(2-p\gamma_p)}{2C_4(22^*_{\alpha,s}-p\gamma_p)}\right]^{\frac{p\gamma_p-22^*_{\alpha,s}}{22^*_{\alpha,s}-2}}, \end{cases} \tag{4.10}$$

then we get the same conclusions as *Case 1*.

Case 3: $2 < p < \bar{p} < r_1 + r_2 < 2^*_s$. In this case, $p\gamma_p < 2 < (r_1+r_2)\gamma_{(r_1+r_2)}$. Similarily, we have

$$\tilde{k}(t) := t^{2-p\gamma_p} - C_3\beta(r_1+r_2)\gamma_{(r_1+r_2)} t^{(r_1+r_2)\gamma_{(r_1+r_2)}-p\gamma_p} - 2C_4 t^{22^*_{\alpha,s}-p\gamma_p},$$

and

$$\begin{aligned} \tilde{k}'(t) = t^{1-p\gamma_p}[&(2-p\gamma_p) - C_3\beta(r_1+r_2)\gamma_{(r_1+r_2)}((r_1+r_2)\gamma_{(r_1+r_2)} - p\gamma_p)t^{(r_1+r_2)\gamma_{(r_1+r_2)}-2} \\ &- 2C_4(22^*_{\alpha,s}-p\gamma_p)t^{22^*_{\alpha,s}-2}]. \end{aligned}$$

Therefore, $\tilde{k}(t)$ has a unique critical point $t_2 \in (0,+\infty)$. If

$$\tilde{k}(t_2) > \gamma_p(\mu_1 C_1 + \mu_2 C_2), \quad \text{and} \quad k(t_2) > 0, \tag{4.11}$$

we obtain the same conclusions as *Case 1*. Following, we get an estimate at t_2. Let

$$t_* = \left[\frac{(\mu_1C_1+\mu_2C_2)d((r_1+r_2)\gamma_{(r_1+r_2)} - p\gamma_p)}{2-p\gamma_p}\right]^{\frac{1}{2-p\gamma_p}},$$

where d will be fixed later. If $t_2 > t_*$ and $d > \frac{\gamma_p(2-p\gamma_p)}{(r_1+r_2)\gamma_{(r_1+r_2)}-2}$, we get

$$\begin{aligned} &(\mu_1C_1+\mu_2C_2)\gamma_p t_2^{p\gamma_p} + C_3\beta(r_1+r_2)\gamma_{(r_1+r_2)} t_2^{(r_1+r_2)\gamma_{(r_1+r_2)}} + 2C_4 t_2^{22^*_{\alpha,s}} \\ &\quad \le (\mu_1C_1+\mu_2C_2)\gamma_p t_*^{p\gamma_p-2} t_2^2 + \frac{2-p\gamma_p}{(r_1+r_2)\gamma_{(r_1+r_2)} - p\gamma_p} t_2^2 < t_2^2, \end{aligned}$$

and if $d > \frac{2(r_1+r_2)\gamma_{(r_1+r_2)}}{p[(r_1+r_2)\gamma_{(r_1+r_2)}-2]}$,

$$\begin{aligned} &\frac{\mu_1C_1+\mu_2C_2}{p} t_2^{p\gamma_p} + C_3\beta t_2^{(r_1+r_2)\gamma_{(r_1+r_2)}} + \frac{C_4}{2^*_{\alpha,s}} t_2^{22^*_{\alpha,s}} \\ &\quad \le \frac{2-p\gamma_p}{(r_1+r_2)\gamma_{(r_1+r_2)}[(r_1+r_2)\gamma_{(r_1+r_2)} - p\gamma_p]} t_2^2 + \frac{\mu_1C_1+\mu_2C_2}{p} t_*^{p\gamma_p-2} t_2^2 < \frac{1}{2} t_2^2. \end{aligned}$$

Therefore, if we choose $d > \frac{2(r_1+r_2)\gamma_{(r_1+r_2)}}{p((r_1+r_2)\gamma_{(r_1+r_2)}-2)}$, we get (4.11). Hence we only need $t_2 > t_*$. By the definition of t_2, we need

$$
\begin{aligned}
(2-p\gamma_p) > C_3\beta(r_1+r_2)\gamma_{(r_1+r_2)}((r_1+r_2)\gamma_{(r_1+r_2)}-p\gamma_p)t_*^{(r_1+r_2)\gamma_{(r_1+r_2)}-2} \\
+2C_4(22^*_{\alpha,s}-p\gamma_p)t_*^{22^*_{\alpha,s}-2},
\end{aligned}
$$

that is,

$$
\begin{aligned}
(2-p\gamma_p) > & \left[\frac{(\mu_1C_1+\mu_2C_2)d((r_1+r_2)\gamma_{(r_1+r_2)}-p\gamma_p)}{2-p\gamma_p}\right]^{\frac{(r_1+r_2)\gamma_{(r_1+r_2)}-2}{2-p\gamma_p}} \\
& \times \Bigg[C_3\beta(r_1+r_2)\gamma_{(r_1+r_2)}((r_1+r_2)\gamma_{(r_1+r_2)}-p\gamma_p) \\
& +2C_4(22^*_{\alpha,s}-p\gamma_p)\left(\frac{(\mu_1C_1+\mu_2C_2)d((r_1+r_2)\gamma_{(r_1+r_2)}-p\gamma_p)}{2-p\gamma_p}\right)^{\frac{22^*_{\alpha,s}-2}{2-p\gamma_p}}\Bigg].
\end{aligned} \tag{4.12}
$$

To sum up, there exists $\beta_* > 0$, such that for any $\beta \in (0,\beta_*)$, there exist $\mu_{1,*} = \mu_{1,*}(\beta) > 0$ and $\mu_{2,*} = \mu_{2,*}(\beta) > 0$, for any $\mu_1 \in (0,\mu_{1,*})$, $\mu_2 \in (0,\mu_{2,*})$, then (4.8), (4.10) and (4.12) are satisfied. We complete this lemma. □

We now study the structure of Pohožaev manifold. Recalling the decomposition of $\mathcal{P}_{\mu_1,\mu_2} = \mathcal{P}^+_{\mu_1,\mu_2} \cup \mathcal{P}^0_{\mu_1,\mu_2} \cup \mathcal{P}^-_{\mu_1,\mu_2}$, we have:

Lemma 4.2. *There exists $\tilde{\beta}_* > 0$, such that for any $\beta \in (0,\tilde{\beta}_*)$, there exist $\tilde{\mu}_{1,*} = \tilde{\mu}_{1,*}(\beta) > 0$ and $\tilde{\mu}_{2,*} = \tilde{\mu}_{2,*}(\beta) > 0$, for every $\mu_1 \in (0,\tilde{\mu}_{1,*})$, $\mu_2 \in (0,\tilde{\mu}_{2,*})$, then $\mathcal{P}^0_{\mu_1,\mu_2} = \emptyset$ and $\mathcal{P}_{\mu_1,\mu_2}$ is a C^1-submanifold in H with codimension 3.*

Proof. Firstly, assume by contradiction that there exists a $(u,v) \in \mathcal{P}^0_{\mu_1,\mu_2}$ satisfying

$$
\begin{aligned}
([u]^2+[v]^2) = \gamma_p(\mu_1|u|_p^p+\mu_2|v|_p^p) + \beta(r_1+r_2)\gamma_{(r_1+r_2)}\int_{\mathbb{R}^N}|u|^{r_1}|v|^{r_2}dx \\
+2\int_{\mathbb{R}^N}(I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}}dx,
\end{aligned} \tag{4.13}
$$

and

$$
\begin{aligned}
2([u]^2+[v]^2) = p\gamma_p^2(\mu_1|u|_p^p+\mu_2|v|_p^p) + \beta(r_1+r_2)^2\gamma^2_{(r_1+r_2)}\int_{\mathbb{R}^N}|u|^{r_1}|v|^{r_2}dx \\
+42^*_{\alpha,s}\int_{\mathbb{R}^N}(I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}}dx.
\end{aligned} \tag{4.14}
$$

Following we define

$$
\begin{aligned}
\hbar(\rho) :=\ & \rho\Psi'_{\mu_1,\mu_2}(0) - \Psi''_{\mu_1,\mu_2}(0) \\
=\ & (\rho-2)([u]^2+[v]^2) - \gamma_p(\rho-p\gamma_p)(\mu_1|u|_p^p+\mu_2|v|_p^p) \\
& -2(\rho-22^*_{\alpha,s})\int_{\mathbb{R}^N}(I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}}dx \\
& -\beta(r_1+r_2)\gamma_{(r_1+r_2)}(\rho-(r_1+r_2)\gamma_{(r_1+r_2)})\int_{\mathbb{R}^N}|u|^{r_1}|v|^{r_2}dx = 0,
\end{aligned} \tag{4.15}
$$

and let

$$\eta := ([u]^2 + [v]^2)^{\frac{1}{2}}.$$

Case 1: When $p < r_1 + r_2 < \bar{p}$, we have $p\gamma_p < (r_1 + r_2)\gamma_{(r_1+r_2)} < 2$. From (4.15) and (4.3), we have $\hbar((r_1 + r_2)\gamma_{(r_1+r_2)}) = 0$ and

$$\begin{aligned} \left[2 - (r_1 + r_2)\gamma_{(r_1+r_2)}\right]\eta^2 &\leq 2\left[22^*_{\alpha,s} - (r_1 + r_2)\gamma_{(r_1+r_2)}\right] \int_{\mathbb{R}^N} (I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}} dx \\ &\leq 2C_4\left[22^*_{\alpha,s} - (r_1 + r_2)\gamma_{(r_1+r_2)}\right]\eta^{22^*_{\alpha,s}}. \end{aligned} \tag{4.16}$$

It follows $\eta \geq \left[\frac{2-(r_1+r_2)\gamma_{(r_1+r_2)}}{2C_4(22^*_{\alpha,s}-(r_1+r_2)\gamma_{(r_1+r_2)})}\right]^{\frac{1}{22^*_{\alpha,s}-2}}$. Moreover, by $\hbar(22^*_{\alpha,s}) = 0$, from (3.2), (4.1) and (4.2),we obtain

$$\begin{aligned} (22^*_{\alpha,s} - 2)\eta^2 &= \gamma_p(22^*_{\alpha,s} - p\gamma_p)(\mu_1|u|_p^p + \mu_2|v|_p^p) \\ &\quad + \beta(r_1 + r_2)\gamma_{(r_1+r_2)}\left[22^*_{\alpha,s} - (r_1 + r_2)\gamma_{(r_1+r_2)}\right] \int_{\mathbb{R}^N} |u|^{r_1}|v|^{r_2} dx \\ &\leq \gamma_p(22^*_{\alpha,s} - p\gamma_p)(\mu_1 C_1 + \mu_2 C_2)t^{p\gamma_p} \\ &\quad + C_3\beta(r_1 + r_2)\gamma_{(r_1+r_2)}\left[22^*_{\alpha,s} - (r_1 + r_2)\gamma_{(r_1+r_2)}\right]t^{(r_1+r_2)\gamma_{(r_1+r_2)}}, \end{aligned}$$

that is

$$\begin{aligned} 22^*_{\alpha,s} - 2 \leq{}& \gamma_p(22^*_{\alpha,s} - p\gamma_p)(\mu_1 C_1 + \mu_2 C_2)\left[\frac{2 - (r_1 + r_2)\gamma_{(r_1+r_2)}}{2C_4(22^*_{\alpha,s} - (r_1 + r_2)\gamma_{(r_1+r_2)})}\right]^{\frac{p\gamma_p - 2}{22^*_{\alpha,s}-2}} \\ &+ C_3\beta(r_1 + r_2)\gamma_{(r_1+r_2)}\left[\frac{2 - (r_1 + r_2)\gamma_{(r_1+r_2)}}{2C_4(22^*_{\alpha,s} - (r_1 + r_2)\gamma_{(r_1+r_2)})}\right]^{\frac{(r_1+r_2)\gamma_{(r_1+r_2)}-2}{22^*_{\alpha,s}-2}}. \end{aligned} \tag{4.17}$$

Hence, we can choose $\tilde{\beta}_* > 0$, such that for any $\beta \in (0, \tilde{\beta}_*)$, there exist $\tilde{\mu}_{1,*} = \tilde{\mu}_{1,*}(\beta) > 0$ and $\tilde{\mu}_{2,*} = \tilde{\mu}_{2,*}(\beta) > 0$, for every $\mu_1 \in (0, \tilde{\mu}_{1,*})$, $\mu_2 \in (0, \tilde{\mu}_{2,*})$, such that (4.17) can not happen. Therefore, $\mathcal{P}^0_{\mu_1,\mu_2} = \emptyset$.

Case 2: As in $p < r_1 + r_2 = \bar{p}$, we get $p\gamma_p < (r_1 + r_2)\gamma_{(r_1+r_2)} = 2$. Similarly as in *Case 1*, from (4.1)–(4.3) and (4.15), we have $\hbar(p\gamma_p) = 0$, i.e.

$$\begin{aligned} (2 - p\gamma_p)t^2 &= \beta(r_1 + r_2)\gamma_{(r_1+r_2)}\left[(r_1 + r_2)\gamma_{(r_1+r_2)} - p\gamma_p\right] \int_{\mathbb{R}^N} |u|^{r_1}|v|^{r_2} dx \\ &\quad + 2(22^*_{\alpha,s} - p\gamma_p) \int_{\mathbb{R}^N} (I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}} dx \\ &\leq 2C_3\beta(2 - p\gamma_p)\eta^2 + 2C_4(22^*_{\alpha,s} - p\gamma_p)\eta^{22^*_{\alpha,s}}. \end{aligned} \tag{4.18}$$

From $\hbar(22^*_{\alpha,s}) = 0$ we get

$$(22^*_{\alpha,s} - 2)\eta^2 \leq \gamma_p(\mu_1 C_1 + \mu_2 C_2)(22^*_{\alpha,s} - p\gamma_p)\eta^{p\gamma_p} + 2C_3\beta(22^*_{\alpha,s} - 2)\eta^2. \tag{4.19}$$

Combining with (4.18), we first suppose $1 - 2C_3\beta > 0$ and then

$$\left[\frac{(1 - 2C_3\beta)(2 - p\gamma_p)}{2C_4(22^*_{\alpha,s} - p\gamma_p)}\right]^{\frac{1}{22^*_{\alpha,s}-2}} \leq \left[\frac{\gamma_p(\mu_1 C_1 + \mu_2 C_2)(22^*_{\alpha,s} - p\gamma_p)}{(22^*_{\alpha,s} - 2)(1 - 2C_3\beta)}\right]^{\frac{1}{2-p\gamma_p}},$$

that is

$$\left(\frac{2-p\gamma_p}{2C_4}\right)^{2-p\gamma_p}\left(\frac{22^*_{\alpha,s}-2}{\gamma_p}\right)^{22^*_{\alpha,s}-2}\left(\frac{1}{22^*_{\alpha,s}-p\gamma_p}\right)^{22^*_{\alpha,s}-p\gamma_p}$$
$$\le(\mu_1C_1+\mu_2C_2)^{22^*_{\alpha,s}-2}\left(\frac{1}{1-2C_3\beta}\right)^{22^*_{\alpha,s}-p\gamma_p}.$$

Similar argument as in Case 1, choose appropriate $\tilde{\beta}_*, \tilde{\mu}_{1,*}=\tilde{\mu}_{1,*}(\beta), \tilde{\mu}_{2,*}=\tilde{\mu}_{2,*}(\beta)$, such that the last inequality may not happen. Therefore $\mathcal{P}^0_{\mu_1,\mu_2}=\emptyset$.

Case 3: If $p<\bar{p}<r_1+r_2$, then $p\gamma_p<2<(r_1+r_2)\gamma_{(r_1+r_2)}$. Also by (3.2), (4.1)–(4.3) and (4.15), since $\hbar(p\gamma_p)=0$ we have

$$(2-p\gamma_p)\eta^2\le C_3\beta(r_1+r_2)\gamma_{(r_1+r_2)}\left[(r_1+r_2)\gamma_{(r_1+r_2)}-p\gamma_p\right]\eta^{(r_1+r_2)\gamma_{(r_1+r_2)}}$$
$$+2C_4(22^*_{\alpha,s}-p\gamma_p)\eta^{22^*_{\alpha,s}}. \tag{4.20}$$

By the definition of t_2 and t_* in Lemma 4.1, we need

$$\eta\ge t_2>t_*:=\left[\frac{(\mu_1C_1+\mu_2C_2)d((r_1+r_2)\gamma_{(r_1+r_2)}-p\gamma_p)}{2-p\gamma_p}\right]^{\frac{1}{2-p\gamma_p}}.$$

Besides, from $\hbar((r_1+r_2)\gamma_{(r_1+r_2)})=0$ we have

$$((r_1+r_2)\gamma_{(r_1+r_2)}-2)\eta^2\le\gamma_p(\mu_1C_1+\mu_2C_2)\left[(r_1+r_2)\gamma_{(r_1+r_2)}-p\gamma_p\right]\eta^{p\gamma_p}. \tag{4.21}$$

i.e.

$$\eta\le\left[\frac{\gamma_p(\mu_1C_1+\mu_2C_2)((r_1+r_2)\gamma_{(r_1+r_2)}-p\gamma_p)}{((r_1+r_2)\gamma_{(r_1+r_2)}-2)}\right]^{\frac{1}{2-p\gamma_p}}.$$

This is a contradiction with $d>\frac{2(r_1+r_2)\gamma_{(r_1+r_2)}}{p((r_1+r_2)\gamma_{(r_1+r_2)}-2)}$ in Lemma 4.1. Hence, we can fix $\tilde{\beta}_*=\beta_*$, $\tilde{\mu}_{1,*}:=\tilde{\mu}_{1,*}(\beta)=\mu_{1,*}$ and $\tilde{\mu}_{2,*}:=\tilde{\mu}_{2,*}(\beta)=\mu_{2,*}$, to make sure $t_2>t_*$ and $\mathcal{P}^0_{\mu_1,\mu_2}=\emptyset$, where $\beta_*, \mu_{1,*}$ and $\mu_{2,*}$ are from Lemma 4.1.

Following, we prove $\mathcal{P}_{\mu_1,\mu_2}$ is a C^1-submanifold in H with codimension 3. For any $(u,v)\in\mathcal{P}_{\mu_1,\mu_2}$, we have $P_{\mu_1,\mu_2}(u,v)=0$, $G(u)=0$ and $F(v)=0$, where

$$G(u):=\int_{\mathbb{R}^N}u^2-a^2dx,\quad\text{and}\quad F(v):=\int_{\mathbb{R}^N}v^2-b^2dx.$$

Then we need to prove

$$d(P_{\mu_1,\mu_2}(u,v),G(u),F(v)):H\mapsto\mathbb{R}^3\quad\text{is surjective.}$$

If not, there exist $\nu_1,\nu_2\in\mathbb{R}$, for every $(\varphi,0)$ and $(0,\psi)$ in H such that

$$2s\int_{\mathbb{R}^N}(-\Delta)^{\frac{s}{2}}u(-\Delta)^{\frac{s}{2}}\varphi dx=sp\gamma_p\int_{\mathbb{R}^N}\mu_1|u|^{p-2}u\varphi dx+s\beta(r_1+r_2)\gamma_{(r_1+r_2)}r_1\int_{\mathbb{R}^N}|u|^{r_1-2}u\varphi dx$$
$$+2s2^*_{\alpha,s}\int_{\mathbb{R}^N}(I_\alpha*|v|^{2^*_{\alpha,s}})|u|^{2^*_{\alpha,s}-2}u\varphi dx+2\nu_1\int_{\mathbb{R}^N}u\varphi dx;$$

and

$$2s\int_{\mathbb{R}^N}(-\Delta)^{\frac{s}{2}}v(-\Delta)^{\frac{s}{2}}\psi dx=sp\gamma_p\int_{\mathbb{R}^N}\mu_2|v|^{p-2}v\psi dx+s\beta(r_1+r_2)\gamma_{(r_1+r_2)}r_2\int_{\mathbb{R}^N}|v|^{r_2-2}v\psi dx$$
$$+2s2^*_{\alpha,s}\int_{\mathbb{R}^N}(I_\alpha*|u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}-2}v\psi dx+2\nu_2\int_{\mathbb{R}^N}v\psi dx.$$

From which (u,v) is a weak solution of the system in $\mathbb{R}^N$

$$\begin{cases} 2s(-\Delta)^s u = 2\nu_1 u + sp\gamma_p\mu_1|u|^{p-2}u + s\beta(r_1+r_2)\gamma_{(r_1+r_2)}r_1|u|^{r_1-2}u|v|^{r_2} \\ \qquad\qquad + 2s2^*_{\alpha,s}(I_\alpha * |v|^{2^*_{\alpha,s}})|u|^{2^*_{\alpha,s}-2}u, \\ 2s(-\Delta)^s v = 2\nu_2 v + sp\gamma_p\mu_2|v|^{p-2}v + s\beta(r_1+r_2)\gamma_{(r_1+r_2)}r_2|v|^{r_2-2}|u|^{r_1} \\ \qquad\qquad + 2s2^*_{\alpha,s}(I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}-2}v, \\ \int_{\mathbb{R}^N}|u|^2dx = a^2, \quad \int_{\mathbb{R}^N}|v|^2dx = b^2. \end{cases}$$

The related Pohožaev identity of the above system is

$$2([u]^2+[v]^2) = p\gamma_p^2(\mu_1|u|_p^p + \mu_2|v|_p^p) + \beta(r_1+r_2)^2\gamma^2_{(r_1+r_2)}\int_{\mathbb{R}^N}|u|^{r_1}|v|^{r_2}dx$$
$$+ 42^*_{\alpha,s}\int_{\mathbb{R}^N}(I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}}dx,$$

thus $P^0_{\mu_1,\mu_2}(u,v)=0$, which contradicts with $\mathcal{P}^0_{\mu_1,\mu_2}=\emptyset$. We complete this lemma. □

From Lemmas 4.1 and 4.2, we can have the geometry of Ψ_{μ_1,μ_2}.

Lemma 4.3. *For every $(u,v)\in S$, the function $\Psi_{\mu_1,\mu_2}(t)$ has exactly two critical points $s_{u,v} < t_{u,v} \in \mathbb{R}$ and two zeros $c_{u,v} < d_{u,v} \in \mathbb{R}$ with $s_{u,v} < c_{u,v} < t_{u,v} < d_{u,v}$. Moreover,*

(i) $s_{u,v} * (u,v) \in \mathcal{P}^+_{\mu_1,\mu_2}$ and $t_{u,v} * (u,v) \in \mathcal{P}^-_{\mu_1,\mu_2}$, and if $t*(u,v)\in\mathcal{P}_{\mu_1,\mu_2}$, then either $t = s_{u,v}$ or $t = t_{u,v}$.

(ii) $([t*u]^2+[t*v]^2)^{\frac12} \le R_2$ (R_2 is from Lemma 4.1) for every $t \le c_{u,v}$ and

$$J(s_{u,v}*(u,v)) = \min\{J(t*(u,v)) : t\in\mathbb{R} \quad \text{and} \quad ([t*u]^2+[t*v]^2)^{\frac12} \le R_2\}.$$

(iii) We get $J(t_{u,v}*(u,v)) = \max\{J(t*(u,v)) : t\in\mathbb{R}\} > 0$ and $\Psi_{\mu_1,\mu_2}(t)$ is strictly decreasing and concave on $(t_{u,v},\infty)$. In particular, if $t_{u,v}<0$, then $P_{\mu_1,\mu_2}(u,v)<0$.

(iv) The maps $(u,v)\mapsto s_{u,v}$, and $(u,v)\mapsto t_{u,v}$ for any $(u,v)\in S$ are of class C^1.

Proof. Let $(u,v)\in S$, then $t*(u,v)\in\mathcal{P}_{\mu_1,\mu_2}$ if and only if $\Psi'_{\mu_1,\mu_2}(t)=0$. By (4.4)-(4.5),

$$\Psi_{\mu_1,\mu_2}(t) = J(t*(u,v)) \ge k(e^{st}([u]^2+[v]^2)^{\frac12}),$$

thus from Lemma 4.1, $\Psi_{\mu_1,\mu_2}(t)$ is positive on

$$\left(s^{-1}\ln\frac{R_2}{([u]^2+[v]^2)^{\frac12}}, s^{-1}\ln\frac{R_3}{([u]^2+[v]^2)^{\frac12}}\right).$$

Since $p\gamma_p < 2$, we see $\Psi_{\mu_1,\mu_2}(-\infty)=0^-$ and $\Psi_{\mu_1,\mu_2}(+\infty)=-\infty$. Then $\Psi_{\mu_1,\mu_2}(t)$ has at least two critical points. Therefore, $\Psi_{\mu_1,\mu_2}(t)$ has a local minimum point $s_{u,v}$ at a negative level in $\big(-\infty, s^{-1}\ln\frac{R_2}{([u]^2+[v]^2)^{\frac12}}\big)$, and has a global maximum point $t_{u,v}$ at a positive level in $\big(s^{-1}\ln\frac{R_2}{([u]^2+[v]^2)^{\frac12}}, s^{-1}\ln\frac{R_3}{([u]^2+[v]^2)^{\frac12}}\big)$. We claim $\Psi_{\mu_1,\mu_2}(t)$ has exactly two critical points. Let $\Psi'_{\mu_1,\mu_2}(t)=0$, namely

$$\Psi'_{\mu_1,\mu_2}(t) = se^{2st}([u]^2+[v]^2) - s\gamma_p e^{sp\gamma_p t}(\mu_1|u|_p^p+\mu_2|v|_p^p) - 2se^{22^*_{\alpha,s}st}\int_{\mathbb{R}^N}(I_\alpha*|u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}}dx$$
$$- s\beta(r_1+r_2)\gamma_{(r_1+r_2)}e^{s(r_1+r_2)\gamma_{(r_1+r_2)}t}\int_{\mathbb{R}^N}|u|^{r_1}|v|^{r_2}dx. \tag{4.22}$$

Case 1: $2 < p < r_1 + r_2 < \bar{p}$. From (4.22) we have

$$\Psi'_{\mu_1,\mu_2}(t) = e^{sp\gamma_p t}\big[se^{(2-p\gamma_p)st}([u]^2+[v]^2) - s\beta(r_1+r_2)\gamma_{(r_1+r_2)}e^{s[(r_1+r_2)\gamma_{(r_1+r_2)}-p\gamma_p]t}\int_{\mathbb{R}^N}|u|^{r_1}|v|^{r_2}dx$$
$$-2se^{(22^*_{\alpha,s}-p\gamma_p)st}\int_{\mathbb{R}^N}(I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}}dx - s\gamma_p(\mu_1|u|_p^p+\mu_2|v|_p^p)\big].$$

Denote

$$g_1(t) := se^{(2-p\gamma_p)st}([u]^2+[v]^2) - 2se^{(22^*_{\alpha,s}-p\gamma_p)st}\int_{\mathbb{R}^N}(I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}}dx$$
$$- s\beta(r_1+r_2)\gamma_{(r_1+r_2)}e^{s[(r_1+r_2)\gamma_{(r_1+r_2)}-p\gamma_p]t}\int_{\mathbb{R}^N}|u|^{r_1}|v|^{r_2}dx,$$

then

$$g_1'(t) = e^{[(r_1+r_2)\gamma_{(r_1+r_2)}-p\gamma_p]st}\Bigg[(2-p\gamma_p)s^2e^{(2-(r_1+r_2)\gamma_{(r_1+r_2)})st}([u]^2+[v]^2)$$
$$-2(22^*_{\alpha,s}-p\gamma_p)s^2e^{(22^*_{\alpha,s}-(r_1+r_2)\gamma_{(r_1+r_2)})st}\int_{\mathbb{R}^N}(I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}}dx$$
$$-[(r_1+r_2)\gamma_{(r_1+r_2)}-p\gamma_p]s^2(r_1+r_2)\gamma_{(r_1+r_2)}\beta\int_{\mathbb{R}^N}|u|^{r_1}|v|^{r_2}dx\Bigg].$$

Now define

$$f_1(t) := (2-p\gamma_p)s^2e^{[2-(r_1+r_2)\gamma_{(r_1+r_2)}]st}([u]^2+[v]^2)$$
$$-2(22^*_{\alpha,s}-p\gamma_p)s^2e^{(22^*_{\alpha,s}-(r_1+r_2)\gamma_{(r_1+r_2)})st}\int_{\mathbb{R}^N}(I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}}dx,$$

thus

$$f_1'(t) = e^{(2-(r_1+r_2)\gamma_{(r_1+r_2)})st}\Bigg[(2-p\gamma_p)(2-(r_1+r_2)\gamma_{(r_1+r_2)})s^3([u]^2+[v]^2)$$
$$-2(22^*_{\alpha,s}-p\gamma_p)(22^*_{\alpha,s}-(r_1+r_2)\gamma_{(r_1+r_2)})s^3e^{(22^*_{\alpha,s}-2)st}\int_{\mathbb{R}^N}(I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}}dx\Bigg].$$

We see $f_1(t)$ has only one critical point $\bar{t}$, which is also a maximum point. Therefore if

$$f_1(\bar{t}) \le [(r_1+r_2)\gamma_{(r_1+r_2)}-p\gamma_p]s^2(r_1+r_2)\gamma_{(r_1+r_2)}\beta\int_{\mathbb{R}^N}|u|^{r_1}|v|^{r_2}dx,$$

we have $g_1'(t) < 0$ and $g_1(t)$ is strictly decreasing in $\mathbb{R}\setminus\{\bar{t}\}$. Since $g_1(-\infty) = 0^-$ and $g_1(+\infty) = -\infty$, we get

$$g_1(t) < 0 < s\gamma_p(\mu_1|u|_p^p+\mu_2|v|_p^p),$$

and hence $\Psi'_{\mu_1,\mu_2}(t) < 0$, which means $\Psi_{\mu_1,\mu_2}(t)$ has no critical points. On the other hand, if

$$f_1(\bar{t}) > [(r_1+r_2)\gamma_{(r_1+r_2)}-p\gamma_p]s^2(r_1+r_2)\gamma_{(r_1+r_2)}\beta\int_{\mathbb{R}^N}|u|^{r_1}|v|^{r_2}dx,$$

then by $f_1(-\infty) = 0^+$, $f_1(+\infty) = -\infty$, there exist two constants $\bar{t}_1 < \bar{t} < \bar{t}_2$, such that

$$f_1(\bar{t}_1) = f_1(\bar{t}_2) = [(r_1+r_2)\gamma_{(r_1+r_2)}-p\gamma_p]s^2(r_1+r_2)\gamma_{(r_1+r_2)}\beta\int_{\mathbb{R}^N}|u|^{r_1}|v|^{r_2}dx.$$

Therefore, we find from the definitions of $g_1(t)$ and $\Psi_{\mu_1,\mu_2}(t)$ that

$$g_1(t) = s\gamma_p(\mu_1|u|_p^p+\mu_2|v|_p^p),$$

has at most two critical points, which implies $\Psi_{\mu_1,\mu_2}(t)$ has at most two critical points.

Case 2: $2 < p < (r_1 + r_2) = \bar{p}$. In this case, (4.22) becomes

$$\begin{aligned}\Psi'_{\mu_1,\mu_2}(t) = s\Big([u]^2 + [v]^2 - 2\beta \int_{\mathbb{R}^N} |u|^{r_1}|v|^{r_2}dx\Big)e^{2st} - s\gamma_p e^{sp\gamma_p t}(\mu_1|u|_p^p + \mu_2|v|_p^p)\\ - 2se^{22^*_{\alpha,s}st}\int_{\mathbb{R}^N}(I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}}dx.\end{aligned} \tag{4.23}$$

If

$$[u]^2 + [v]^2 - 2\beta \int_{\mathbb{R}^N} |u|^{r_1}|v|^{r_2}dx \le 0,$$

we see $\Psi'_{\mu_1,\mu_2}(t) < 0$ and $\Psi_{\mu_1,\mu_2}(t)$ has no critical points. Now we suppose

$$[u]^2 + [v]^2 - 2\beta \int_{\mathbb{R}^N} |u|^{r_1}|v|^{r_2}dx > 0.$$

Then similarly as in *Case 1*, we conclude $\Psi_{\mu_1,\mu_2}(t)$ has at most two critical points.

Case 3: $2 < p < \bar{p} < r_1 + r_2$. From the definition of $g_1(t)$, we have

$$\begin{aligned}g_1'(t) &= e^{(2-p\gamma_p)st}\Big[(2-p\gamma_p)s^2([u]^2+[v]^2) - 2s^2(22^*_{\alpha,s} - p\gamma_p)e^{(22^*_{\alpha,s}-2)st}\int_{\mathbb{R}^N}(I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}}dx\\ &\quad - s^2\beta(r_1+r_2)\gamma_{(r_1+r_2)}[(r_1+r_2)\gamma_{(r_1+r_2)} - p\gamma_p]e^{((r_1+r_2)\gamma_{(r_1+r_2)}-2)st}\int_{\mathbb{R}^N}|u|^{r_1}|v|^{r_2}dx\Big]\\ &=: e^{(2-p\gamma_p)st}[(2-p\gamma_p)s^2([u]^2+[v]^2) - Q(t)],\end{aligned}$$

where

$$\begin{aligned}Q(t) &= 2s^2(22^*_{\alpha,s} - p\gamma_p)e^{(22^*_{\alpha,s}-2)st}\int_{\mathbb{R}^N}(I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}}dx\\ &\quad + s^2\beta(r_1+r_2)\gamma_{(r_1+r_2)}[(r_1+r_2)\gamma_{(r_1+r_2)} - p\gamma_p]e^{((r_1+r_2)\gamma_{(r_1+r_2)}-2)st}\int_{\mathbb{R}^N}|u|^{r_1}|v|^{r_2}dx.\end{aligned}$$

Moreover by

$$p\gamma_p < 2 < \min\{(r_1+r_2)\gamma_{(r_1+r_2)}, 22^*_{\alpha,s}\},$$

we see $Q(t)$ is strictly increasing in $\mathbb{R}$. Therefore $g_1(t)$ has a unique critical point $\hat{t}$, which is also a maximum point and $g_1(t)$ is strictly increasing in $(-\infty, \hat{t})$, strictly decreasing in $(\hat{t}, +\infty)$. On one hand, if

$$g_1(\hat{t}) \le s\gamma_p(\mu_1|u|_p^p + \mu_2|v|_p^p),$$

we have $\Psi_{\mu_1,\mu_2}(t)$ has no critical points. Besides, if

$$g_1(\hat{t}) > s\gamma_p(\mu_1|u|_p^p + \mu_2|v|_p^p),$$

then $\Psi'_{\mu_1,\mu_2}(t) = 0$ has at most two solutions, that is $\Psi_{\mu_1,\mu_2}(t)$ has at most two critical points. Hence, $\Psi_{\mu_1,\mu_2}(t)$ has exactly two critical points $s_{u,v} < t_{u,v}$.

By the definitions of $P_{\mu_1,\mu_2}(u,v)$ in (2.6) and $\Psi_{\mu_1,\mu_2}(t)$ in (2.7), we find $\Psi'_{\mu_1,\mu_2}(t) = P_{\mu_1,\mu_2}(t * u, t * v)$. Therefore we know $P_{\mu_1,\mu_2}(t * u, t * v) = 0$ if and only if t is a critical point of $\Psi_{\mu_1,\mu_2}(t)$. From above we find $\Psi_{\mu_1,\mu_2}(t)$ has exactly two critical points $s_{u,v}, t_{u,v}$, then we have $P_{\mu_1,\mu_2}(t * u, t * v) = 0$ if and only if $t = s_{u,v}$ or $t = t_{u,v}$. Moreover from Lemma 2.5 the definition of $\mathcal{P}_{\mu_1,\mu_2}$ here, by $(t * u, t * v) \in S$ we see that $(t * u, t * v) \in \mathcal{P}_{\mu_1,\mu_2}$ if and only if $t = s_{u,v}$ or $t = t_{u,v}$. Noticing $\Psi''_{\mu_1,\mu_2}(s_{u,v}) \ge 0$, $\Psi''_{\mu_1,\mu_2}(t_{u,v}) \le 0$ and $\mathcal{P}^0_{\mu_1,\mu_2} = \emptyset$, we obtain $s_{u,v} * (u,v) \in$

$\mathcal{P}^+_{\mu_1,\mu_2}$ and $t_{u,v} * (u,v) \in \mathcal{P}^-_{\mu_1,\mu_2}$. By the monotonicity and the behavior of $\Psi_{\mu_1,\mu_2}(t)$, we see $\Psi_{\mu_1,\mu_2}(t)$ has exactly two zeros $c_{u,v} < d_{u,v} \in \mathbb{R}$ with $s_{u,v} < c_{u,v} < t_{u,v} < d_{u,v}$, and $\Psi_{\mu_1,\mu_2}(t)$ has exactly two inflection points. Moreover, $\Psi_{\mu_1,\mu_2}(t)$ is concave on $[t_{u,v}, \infty)$, and if $t_{u,v} < 0$, then $P_{\mu_1,\mu_2}(u,v) = \Psi'_{\mu_1,\mu_2}(0) < 0$. Finally, we apply implicit function theorem on the C^1 function $\Phi(t,u,v) = \Psi'_{\mu_1,\mu_2}(t)$, then $\Phi(s_{u,v},u,v) = \Psi'_{\mu_1,\mu_2}(s_{u,v}) = 0$, $\partial_t\Phi(s_{u,v},u,v) = \Psi''_{\mu_1,\mu_2}(s_{u,v}) > 0$. Therefore we know $(u,v) \to s_{u,v}$ is of class C^1. Similarly, $(u,v) \to t_{u,v}$ is also of class C^1. □

For $r > 0$, define

$$B_r(a,b) := \{(u,v) \in S : ([u]^2 + [v]^2)^{\frac{1}{2}} < r\}, \quad \text{and} \quad \hat{m}(a,b) := \inf_{(u,v)\in B_{R_2}(a,b)} J(u,v).$$

From Lemma 4.3, we can deduce the following conclusion directly.

Corollary 4.4. *The set* $\mathcal{P}^+_{\mu_1,\mu_2} \subset B_{R_2}(a,b)$, *and*

$$\sup_{(u,v)\in\mathcal{P}^+_{\mu_1,\mu_2}} J(u,v) \le 0 \le \inf_{(u,v)\in\mathcal{P}^-_{\mu_1,\mu_2}} J(u,v).$$

Lemma 4.5. *We have* $\hat{m}(a,b) \in (-\infty, 0)$, *moreover*

$$\hat{m}(a,b) = m(a,b) = m^+(a,b) \quad \text{and} \quad \hat{m}(a,b) < \inf_{\overline{B_{R_2}(a,b)\setminus B_{R_2-\delta}(a,b)}} J(u,v),$$

for $\delta > 0$ *small enough.*

Proof. For any $(u,v) \in B_{R_2}(a,b)$, by (4.4) and (4.5), we get

$$J(u,v) \ge k(([u]^2 + [v]^2)^{\frac{1}{2}}) \ge \min_{t\in[0,R_2]} k(t) > -\infty.$$

Hence $\hat{m}(a,b) > -\infty$. Moreover, for any $(u,v) \in S$, when $t \ll -1$, we have $([t*u]^2 + [t*v]^2)^{\frac{1}{2}} < R_2$ and $J(t*(u,v)) < 0$. Hence $\hat{m}(a,b) < 0$. From Corollary 4.4, $\mathcal{P}^+_{\mu_1,\mu_2} \subset B_{R_2}(a,b)$, then $\hat{m}(a,b) \le m^+(a,b)$. On the other hand, for any $(u,v) \in B_{R_2}(a,b)$, from Lemma 4.3 we get

$$m^+(a,b) \le J(s_{u,v} * (u,v)) \le J(u,v).$$

Thus $m^+(a,b) = \hat{m}(a,b)$. Since $J(u,v) > 0$ on $\mathcal{P}^-_{\mu_1,\mu_2}$, we know $m(a,b) = m^+(a,b)$. Finally, by the continuity of $k(t)$ and $k(R_2) = 0$, we see from $-\infty < \hat{m}(a,b) < 0$ that there is $\delta > 0$ satisfying $k(t) \ge \frac{\hat{m}(a,b)}{2}$ if $t \in [R_2 - \delta, R_2]$. Thus

$$J(u,v) \ge k(([u]^2 + [v]^2)^{\frac{1}{2}}) \ge \frac{\hat{m}(a,b)}{2} \ge \hat{m}(a,b),$$

for any $(u,v) \in S$ with $R_2 - \delta \le ([u]^2 + [v]^2)^{\frac{1}{2}} \le R_2$. This completes the proof. □

Similarly from *Case 1* in Lemma 3.4, we obtain the monotonicity for this problem (1.1)–(1.2).

Lemma 4.6. *There exists* $\hat{\beta}_* > 0$, *for* $\beta \in (0, \hat{\beta}_*)$, *there are* $\hat{\mu}_{1,*} := \hat{\mu}_{1,*}(\beta), \hat{\mu}_{2,*} := \hat{\mu}_{2,*}(\beta) > 0$, *for any* $\mu_1 \in (0, \hat{\mu}_{1,*})$ *and* $\mu_2 \in (0, \hat{\mu}_{2,*})$, *the level satisfies* $m(a,b) \le m(a_1,b_1)$ *for any* $0 < a_1 \le a$, $0 < b_1 \le b$.

Proof. We also divide this proof into 3 cases.

Case 1: $2 < p < r_1 + r_2 < \bar{p}$. From Lemmas 4.1 and 4.3, we have $m(a,b) = \inf_{B_{t_0}(a,b)} J(u,v)$ and

$$t_0 = \left[\frac{(2 - p\gamma_p)(2 - (r_1 + r_2)\gamma_{(r_1+r_2)})}{2C_4(22^*_{\alpha,s} - p\gamma_p)(22^*_{\alpha,s} - (r_1 + r_2)\gamma_{(r_1+r_2)})} \right]^{\frac{1}{22^*_{\alpha,s}-2}},$$

which is independent with a, b. Besides, from (3.2), (4.1) and (4.2), we get C_1, C_2 and C_3 are increasing when a, b are increasing. Hence, we can choose $\hat{\beta}_* = \min\{\beta_*, \tilde{\beta}_*\}$, $\hat{\mu}_{1,*} = \min\{\mu_{1,*}, \tilde{\mu}_{1,*}\}$ and $\hat{\mu}_{2,*} = \min\{\mu_{1,*}, \tilde{\mu}_{1,*}\}$, such that there is $(u,v) \in B_{t_0}(a_1, b_1)$ with $J(u,v) \le m(a_1, b_1) + \frac{\varepsilon}{2}$, for ε is arbitrarily small. Using the same argument as Case 1 in Lemma 3.4, we get this result.

Case 2: $2 < p < r_1 + r_2 = \bar{p}$. Similarly, we have $m(a,b) = \inf_{B_{t_1}(a,b)} J(u,v)$ with

$$t_1 = \left[\frac{(1 - 2C_3\beta)(2 - p\gamma_p)}{2C_4(22^*_{\alpha,s} - p\gamma_p)} \right]^{\frac{1}{22^*_{\alpha,s}-2}} \le \left[\frac{(2 - p\gamma_p)}{2C_4(22^*_{\alpha,s} - p\gamma_p)} \right]^{\frac{1}{22^*_{\alpha,s}-2}} := t_{1,*},$$

which is independent with a, b. If there exists $\breve{\beta}_* > 0$. Then for any $\beta \in (0, \breve{\beta}_*)$, there are $\breve{\mu}_{1,*} = \breve{\mu}_{1,*}(\beta), \breve{\mu}_{2,*} = \breve{\mu}_{2,*}(\beta) > 0$, for any $\mu_1 \in (0, \breve{\mu}_{1,*})$ and $\mu_2 \in (0, \breve{\mu}_{2,*})$, such that $k(t_{1,*}) \ge 0$, that is

$$\frac{1}{2} - \frac{2 - p\gamma_p}{22^*_{\alpha,s}(22^*_{\alpha,s} - p\gamma_p)} \ge C_3\beta + \frac{\mu_1 C_1 + \mu_2 C_2}{p} \left[\frac{(2 - p\gamma_p)}{2C_4(22^*_{\alpha,s} - p\gamma_p)} \right]^{\frac{p\gamma_p - 2}{22^*_{\alpha,s}-2}}. \tag{4.24}$$

Then from Lemmas 4.1 and 4.3, we can have $m(a,b) = \inf_{B_{t_{1,*}}(a,b)} J(u,v)$. Hence, there exists $\hat{\beta}_* = \min\{\beta_*, \tilde{\beta}_*, \breve{\beta}_*\}$, for $\beta \in (0, \hat{\beta}_*)$, there are $\hat{\mu}_{1,*}(\beta) = \min\{\mu_{1,*}, \tilde{\mu}_{1,*}, \breve{\mu}_{1,*}\}, \hat{\mu}_{2,*}(\beta) = \min\{\mu_{2,*}, \tilde{\mu}_{2,*}, \breve{\mu}_{2,*}\}$, for any $\mu_1 \in (0, \hat{\mu}_{1,*})$ and $\mu_2 \in (0, \hat{\mu}_{2,*})$, there is $(u,v) \in B_{t_{1,*}}(a_1, b_1)$ with $J(u,v) \le m(a_1, b_1) + \frac{\varepsilon}{2}$. The remainder of the proof is similar to Lemma 3.4, and so we omit the details here.

Case 3: $2 < p < \bar{p} < (r_1 + r_2) < 2^*_s$. First we have $m(a,b) = \inf_{B_{t_2}(a,b)} J(u,v)$ and

$$2 - p\gamma_p = C_3\beta(r_1 + r_2)\gamma_{(r_1+r_2)}[(r_1 + r_2)\gamma_{(r_1+r_2)} - p\gamma_p] t_2^{(r_1+r_2)\gamma_{(r_1+r_2)}-2} + 2C_4(22^*_{\alpha,s} - p\gamma_p) t_2^{22^*_{\alpha,s}-2}.$$

If we choose

$$t_{2,*} = \left[\frac{2 - p\gamma_p}{2C_4(22^*_{\alpha,s} - p\gamma_p)} \right]^{\frac{1}{22^*_{\alpha,s}-2}},$$

which is independent with a, b and satisfies

$$2 - p\gamma_p < C_3\beta(r_1 + r_2)\gamma_{(r_1+r_2)}[(r_1 + r_2)\gamma_{(r_1+r_2)} - p\gamma_p] t_{2,*}^{(r_1+r_2)\gamma_{(r_1+r_2)}-2} + 2C_4(22^*_{\alpha,s} - p\gamma_p) t_{2,*}^{22^*_{\alpha,s}-2},$$

then $t_2 \le t_{2,*}$. Furthermore, if $k(t_{2,*}) \ge 0$, that is

$$\frac{1}{2} - \frac{2 - p\gamma_p}{22^*_{\alpha,s}(22^*_{\alpha,s} - p\gamma_p)} \ge \frac{\mu_1 C_1 + \mu_2 C_2}{p} \left[\frac{(2 - p\gamma_p)}{2C_4(22^*_{\alpha,s} - p\gamma_p)} \right]^{\frac{p\gamma_p - 2}{22^*_{\alpha,s}-2}} + C_3\beta \left[\frac{(2 - p\gamma_p)}{2C_4(22^*_{\alpha,s} - p\gamma_p)} \right]^{\frac{p\gamma_p - 2}{(r_1+r_2)\gamma_{(r_1+r_2)}-2}}.$$

Hence $m(a,b) = \inf_{B_{t_{2,*}}(a,b)} J(u,v)$. Like the same argument as before, choosing appropriate $\hat{\beta}_*, \hat{\mu}_{1,*}, \hat{\mu}_{2,*}$, using the same techniques in Lemma 3.4, we finish this problem. □

Lemma 4.7. *We have*

$$m(a,b) < \min\{m(a,0), m(0,b)\}.$$

Proof. From Theorem 3.1, we get $m(a,0)$ can be achieved by $\hat{u} \in S_a$. We choose a proper test function $\hat{v} \in S_b$ such that $(\hat{u}, t * \hat{v}) \in S$. By (3.3) and (4.5), we obtain $h(t) > k(t)$ for $t \in (0, +\infty)$. Hence, from Lemma 4.1, we have $R_0 < R_2$. By Theorem 3.1, we get

$$m(a,0) = \inf_{\mathcal{P}_{\mu_1,a}} I_{\mu_1,a}(u) = \inf_{B_{R_0}} I_{\mu_1,a}(u).$$

Therefore $[\hat{u}] \leq R_0 < R_2$. Thus, for $t \ll -1$, we have $(\hat{u}, t * \hat{v}) \in B_{R_2}(a,b)$ and

$$\begin{aligned} m(a,b) = & \inf_{(u,v)\in B_{R_2}(a,b)} J(u,v) \leq J(\hat{u}, t*\hat{v}) \\ = & \frac{1}{2}[\hat{u}]^2 - \frac{\mu_1}{p}\int_{\mathbb{R}^N} |\hat{u}|^p dx + \left(\frac{e^{2st}}{2}[\hat{v}]^2 - \frac{\mu_2 e^{p\gamma_p st}}{p}\int_{\mathbb{R}^N} |\hat{v}|^p dx \right. \\ & \left. - \beta \int_{\mathbb{R}^N} |\hat{u}|^{r_1} |t*\hat{v}|^{r_2} dx - \frac{1}{2^*_{\alpha,s}} \int_{\mathbb{R}^N} (I_\alpha * |\hat{u}|^{2^*_{\alpha,s}}) |t*\hat{v}|^{2^*_{\alpha,s}} dx \right) \\ < & \frac{1}{2}[\hat{u}]^2 - \frac{\mu_1}{p}\int_{\mathbb{R}^N} |\hat{u}|^p dx = m(a,0). \end{aligned}$$

Analogously, we have $m(a,b) < m(0,b)$. Hence, the proof is completed. □

To obtain the compact result, we prove the boundedness first.

Lemma 4.8. *Let $2 < p < \bar{p}$, $p < r_1 + r_2 < 2^*_s$ and $\mu_1, \mu_2, a, b > 0$. Let $\{(u_n, v_n)\} \subset S_r$ be a Palais–Smale sequence, such that*

$$J(u_n, v_n) \to c; \quad J'(u_n, v_n)|_S \to 0 \quad \textit{and} \quad P_{\mu_1,\mu_2}(u_n, v_n) \to 0,$$

where $S_r = S \cap H_r$ and H_r is the space of radially symmetric functions in H. Then $\{(u_n, v_n)\}$ is bounded in H.

Proof. We divide this proof into two cases. *Case 1*: $2 < p < r_1 + r_2 < \bar{p}$. This implies $p\gamma_p < (r_1 + r_2)\gamma_{(r_1+r_2)} < 2$. Since (3.2), (4.1)–(4.3),

$$\begin{aligned} c + o_n(1) = & J(u_n, v_n) - \frac{1}{22^*_{\alpha,s}} P_{\mu_1,\mu_2}(u_n, v_n) \\ = & \frac{N+2s-\alpha}{2(2N-\alpha)}([u_n]^2 + [v_n]^2) - \left(\frac{1}{p} - \frac{\gamma_p}{22^*_{\alpha,s}}\right)(\mu_1 |u_n|_p^p + \mu_2 |v_n|_p^p) \\ & - \beta \left[1 - \frac{(r_1+r_2)\gamma_{(r_1+r_2)}}{22^*_{\alpha,s}}\right] \int_{\mathbb{R}^N} |u_n|^{r_1} |v_n|^{r_2} dx \\ \geq & \frac{N+2s-\alpha}{2(2N-\alpha)}([u_n]^2 + [v_n]^2) - \left(\frac{1}{p} - \frac{\gamma_p}{22^*_{\alpha,s}}\right)(\mu_1 C_1 + \mu_2 C_2)([u_n]^2 + [v_n]^2)^{\frac{p\gamma_p}{2}} \\ & - \beta \left[1 - \frac{(r_1+r_2)\gamma_{(r_1+r_2)}}{22^*_{\alpha,s}}\right] C_3([u_n]^2 + [v_n]^2)^{\frac{(r_1+r_2)\gamma_{(r_1+r_2)}}{2}}. \end{aligned}$$

Then, $\{(u_n, v_n)\}$ is bounded in H.

Case 2: $2 < p < \bar{p} \le r_1 + r_2 < 2_s^*$. From (3.2), (4.1)–(4.3) and $\alpha < N$, we can obtain

$$\begin{aligned}
c + o_n(1) &= J(u_n, v_n) - \frac{1}{(r_1+r_2)\gamma_{(r_1+r_2)}} P_{\mu_1,\mu_2}(u_n, v_n) \\
&= \left[\frac{1}{2} - \frac{1}{(r_1+r_2)\gamma_{(r_1+r_2)}}\right]([u_n]^2 + [v_n]^2) - \left[\frac{1}{p} - \frac{\gamma_p}{(r_1+r_2)\gamma_{(r_1+r_2)}}\right](\mu_1|u_n|_p^p + \mu_2|v_n|_p^p) \\
&\quad - \left[\frac{1}{2_{\alpha,s}^*} - \frac{2}{(r_1+r_2)\gamma_{(r_1+r_2)}}\right]\int_{\mathbb{R}^N}(I_\alpha * |u_n|^{2_{\alpha,s}^*})|v_n|^{2_{\alpha,s}^*}dx \\
&\ge \left[\frac{1}{2} - \frac{1}{(r_1+r_2)\gamma_{(r_1+r_2)}}\right]([u_n]^2 + [v_n]^2) \\
&\quad - \left[\frac{1}{p} - \frac{\gamma_p}{(r_1+r_2)\gamma_{(r_1+r_2)}}\right](\mu_1 C_1 + \mu_2 C_2)([u_n]^2 + [v_n]^2)^{\frac{p\gamma_p}{2}}.
\end{aligned}$$

From this, we have $\{(u_n, v_n)\}$ is bounded in H. □

In what follows, we discuss the convergence of a special Palais–Smale sequence, satisfying suitable additional conditions.

Proposition 4.9. *Let $\{(u_n, v_n)\} \subset S_r$ such that as $n \to \infty$,*

$$\begin{aligned}
J'(u_n, v_n) - \lambda_{1,n}u_n - \lambda_{2,n}v_n \to 0, &\quad \text{for some } \lambda_{1,n}, \lambda_{2,n} \in \mathbb{R}; \\
J(u_n, v_n) \to m(a,b), &\quad P_{\mu_1,\mu_2}(u_n, v_n) \to 0; \\
u_n^-, v_n^- \to 0, &\quad \text{a.e. in } \mathbb{R}^N,
\end{aligned} \tag{4.25}$$

with

$$m(a,b) \neq 0, \quad \text{and} \quad m(a,b) < \frac{N+2s-\alpha}{2N-\alpha}\left(\frac{S^*}{2}\right)^{\frac{2N-\alpha}{N+2s-\alpha}}.$$

Then there exist $(u,v) \in H_r$ with $u, v > 0$ and $\lambda_1, \lambda_2 < 0$, such that up to a subsequence, $(u_n, v_n) \to (u,v)$ in H and $(\lambda_{1,n}, \lambda_{2,n}) \to (\lambda_1, \lambda_2)$ in $\mathbb{R}^2$.

Proof. From Lemma 4.8, we get $\{(u_n, v_n)\}$ is bounded in H_r. Moreover, by (4.25) we get

$$\lambda_{1,n} = \frac{1}{a^2}J'(u_n, v_n)(u_n, 0) + o_n(1), \quad \text{and} \quad \lambda_{2,n} = \frac{1}{b^2}J'(u_n, v_n)(0, v_n) + o_n(1),$$

thus $\{\lambda_{1,n}\}$ and $\{\lambda_{2,n}\}$ are bounded in $\mathbb{R}$. Therefore, there exist $(u,v) \in H_r$ and $\lambda_1, \lambda_2 \in \mathbb{R}$ such that up to a subsequence,

$$\begin{aligned}
(u_n, v_n) &\rightharpoonup (u,v), && \text{in } H_r, \\
(u_n, v_n) &\to (u,v), && \text{in } L^q(\mathbb{R}^N) \times L^q(\mathbb{R}^N), \quad \text{for } 2 < q < 2_s^*, \\
(u_n, v_n) &\to (u,v), && \text{a.e. in } \mathbb{R}^N, \\
(\lambda_{1,n}, \lambda_{2,n}) &\to (\lambda_1, \lambda_2), && \text{in } \mathbb{R}^2.
\end{aligned}$$

Since

$$|v_n|^{2_{\alpha,s}^*} \rightharpoonup |v|^{2_{\alpha,s}^*}, \quad \text{in } L^{\frac{2N}{2N-\alpha}}(\mathbb{R}^N),$$

and the map $T : L^{\frac{2N}{2N-\alpha}}(\mathbb{R}^N) \mapsto L^{\frac{2N}{\alpha}}(\mathbb{R}^N)$ defined by $T(w) = I_\alpha * w$ is well defined , linear and continuous, we have

$$I_\alpha * |v_n|^{2_{\alpha,s}^*} \rightharpoonup I_\alpha * |v|^{2_{\alpha,s}^*}, \quad \text{in } L^{\frac{2N}{\alpha}}(\mathbb{R}^N).$$

Besides, by

$$|u_n|^{2^*_{\alpha,s}-2}u_n \rightharpoonup |u|^{2^*_{\alpha,s}-2}u, \quad \text{in } L^{\frac{2N}{N+2s-\alpha}}(\mathbb{R}^N),$$

we get

$$(I_\alpha * |v_n|^{2^*_{\alpha,s}})|u_n|^{2^*_{\alpha,s}-2}u_n \rightharpoonup (I_\alpha * |v|^{2^*_{\alpha,s}})|u|^{2^*_{\alpha,s}-2}u, \quad \text{in } L^{\frac{2N}{N+2s}}(\mathbb{R}^N).$$

Hence for any $\phi, \psi \in C_0^\infty(\mathbb{R}^N)$, we get

$$\int_{\mathbb{R}^N}(I_\alpha * |v_n|^{2^*_{\alpha,s}})|u_n|^{2^*_{\alpha,s}-2}u_n\phi dx \to \int_{\mathbb{R}^N}(I_\alpha * |v|^{2^*_{\alpha,s}})|u|^{2^*_{\alpha,s}-2}u\phi dx,$$

and

$$\int_{\mathbb{R}^N}(I_\alpha * |u_n|^{2^*_{\alpha,s}})|v_n|^{2^*_{\alpha,s}-2}v_n\psi dx \to \int_{\mathbb{R}^N}(I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}-2}v\psi dx.$$

Therefore from (4.25), (u, v) satisfies

$$\begin{cases} (-\Delta)^s u = \lambda_1 u + \mu_1|u|^{p-2}u + \beta r_1|u|^{r_1-2}u|v|^{r_2} + (I_\alpha * |v|^{2^*_{\alpha,s}})|u|^{2^*_{\alpha,s}-2}u, & \text{in } \mathbb{R}^N, \\ (-\Delta)^s v = \lambda_2 v + \mu_2|v|^{p-2}v + \beta r_2|u|^{r_1}|v|^{r_2-2}v + (I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}-2}v, & \text{in } \mathbb{R}^N, \\ u \geq 0, \ v \geq 0, \end{cases} \tag{4.26}$$

and $P_{\mu_1,\mu_2}(u, v) = 0$.

Next, we will show $u \not\equiv 0$ and $v \not\equiv 0$. If not, we assume $u \equiv 0$. We claim $v \not\equiv 0$. Otherwise, from $P_{\mu_1,\mu_2}(u_n, v_n) \to 0$ and $u_n, v_n \to 0$ in $L^q(\mathbb{R}^N)$ for any $q \in (2, 2^*_s)$, we get

$$[u_n]^2 + [v_n]^2 = 2\int_{\mathbb{R}^N}(I_\alpha * |u_n|^{2^*_{\alpha,s}})|v_n|^{2^*_{\alpha,s}}dx + o_n(1).$$

Since $\{(u_n, v_n)\}$ is bounded in H, we may assume $[u_n]^2 + [v_n]^2 \to l \in \mathbb{R}$. Then from (2.2), we have

$$l = 0 \quad \text{or } l \geq 2\left(\frac{S^*}{2}\right)^{\frac{2N-\alpha}{N+2s-\alpha}}.$$

On one hand, if $l = 0$, we have $(u_n, v_n) \to (0, 0)$ in $D^s(\mathbb{R}^N) \times D^s(\mathbb{R}^N)$. Consequently $J(u_n, v_n) \to 0$ which gives a contradiction with $m(a, b) \neq 0$. On the other hand, if $l \geq 2(\frac{S^*}{2})^{\frac{2N-\alpha}{N+2s-\alpha}}$, from $P_{\mu_1,\mu_2}(u_n, v_n) \to 0$, we obtain

$$m(a, b) = J(u_n, v_n) + o_n(1) = J(u_n, v_n) - \frac{1}{2}P_{\mu_1,\mu_2}(u_n, v_n) + o_n(1) \geq \frac{N+2s-\alpha}{2N-\alpha}\left(\frac{S^*}{2}\right)^{\frac{2N-\alpha}{N+2s-\alpha}},$$

which can not happen since $m(a, b) < \frac{N+2s-\alpha}{2N-\alpha}(\frac{S^*}{2})^{\frac{2N-\alpha}{N+2s-\alpha}}$. Therefore $v \not\equiv 0$. From (4.26) and $u \equiv 0$, we have v satisfies

$$\begin{cases} (-\Delta)^s v = \lambda_2 v + \mu_2|v|^{p-2}v, & \text{in } \mathbb{R}^N, \\ v \geq 0. \end{cases}$$

Then we obtain from $|v|_2 \leq b$ and Lemma 3.4,

$$\begin{aligned} m(a, b) &= J(u_n, v_n) - \frac{1}{2}P_{\mu_1,\mu_2}(u_n, v_n) + o_n(1) \\ &= \left(\frac{\gamma_p}{2} - \frac{1}{p}\right)\mu_2|v|_p^p + \left(1 - \frac{1}{2^*_{\alpha,s}}\right)\int_{\mathbb{R}^N}(I_\alpha * |u_n|^{2^*_{\alpha,s}})|v_n|^{2^*_{\alpha,s}}dx + o_n(1) \\ &\geq \left(\frac{\gamma_p}{2} - \frac{1}{p}\right)\mu_2|v|_p^p \geq m(0, |v|_2) \geq m(0, b). \end{aligned}$$

From Lemma 4.7, which contradicts with $m(a,b) < m(0,b)$. Similar to [45, Lemma 3.7] and [32, Section 3], by the strong maximum principle [37, Proposition 2.17], we have $u > 0$. Analogously $v > 0$.

We claim $(u_n, v_n) \to (u, v)$ in $D^s(\mathbb{R}^N) \times D^s(\mathbb{R}^N)$. Indeed, if we let $(\hat{u}_n, \hat{v}_n) := (u_n - u, v_n - v)$, by [12, Lemma 2.2],

$$\int_{\mathbb{R}^N} (I_\alpha * |u_n|^{2^*_{\alpha,s}})|v_n|^{2^*_{\alpha,s}} dx - \int_{\mathbb{R}^N} (I_\alpha * |\hat{u}_n|^{2^*_{\alpha,s}})|\hat{v}_n|^{2^*_{\alpha,s}} dx + o_n(1) = \int_{\mathbb{R}^N} (I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}} dx,$$

and [45, Lemma 2.4],

$$\int_{\mathbb{R}^N} |u_n|^{r_1}|v_n|^{r_2} - |\hat{u}_n|^{r_1}|\hat{v}_n|^{r_2} - |u|^{r_1}|v|^{r_2} dx = o_n(1).$$

Therefore by the Brézis–Lieb Lemma [9], we have

$$P_{\mu_1,\mu_2}(\hat{u}_n, \hat{v}_n) = P_{\mu_1,\mu_2}(u_n, v_n) - P_{\mu_1,\mu_2}(u, v) + o_n(1) = o_n(1).$$

We deduce by the strong embedding in $L^q(\mathbb{R}^N)$ for $q \in (2, 2^*_s)$ that,

$$\lim_{n\to\infty} ([\hat{u}_n]^2 + [\hat{v}_n]^2) = \lim_{n\to\infty} 2 \int_{\mathbb{R}^N} (I_\mu * |\hat{u}_n|^{2^*_{\alpha,s}})|\hat{v}_n|^{2^*_{\alpha,s}}.$$

Same argument as before, from (2.2) we can have

$$([\hat{u}_n]^2 + [\hat{v}_n]^2) \to 0,$$

or

$$([\hat{u}_n]^2 + [\hat{v}_n]^2) \geq 2 \left(\frac{S^*}{2}\right)^{\frac{2N-\alpha}{N+2s-\alpha}}.$$

If the latter happens, we obtain from $|u|_2 \leq a$, $|v|_2 \leq b$ and Lemma 4.6,

$$\begin{aligned} m(a,b) + o_n(1) = J(u,v) + J(\hat{u}_n, \hat{v}_n) &= J(u,v) + J(\hat{u}_n, \hat{v}_n) - \frac{1}{22^*_{\alpha,s}} P_{\mu_1,\mu_2}(\hat{u}_n, \hat{v}_n) \\ &\geq m(|u|_2, |v|_2) + \frac{N+2s-\alpha}{2N-\alpha} \left(\frac{S^*}{2}\right)^{\frac{2N-\alpha}{N+2s-\alpha}} \\ &\geq m(a,b) + \frac{N+2s-\alpha}{2N-\alpha} \left(\frac{S^*}{2}\right)^{\frac{2N-\alpha}{N+2s-\alpha}}, \end{aligned}$$

this can not happen. Therefore we have $([\hat{u}_n]^2 + [\hat{v}_n]^2) \to 0$, and we finish this claim.

Following, we claim $\lambda_1, \lambda_2 < 0$. If not, we may assume $\lambda_1 \geq 0$. From $u \geq 0$ we have

$$(-\Delta)^s u = \lambda_1 u + \mu_1 |u|^{p-2} u + \beta r_1 |u|^{r_1-2} u |v|^{r_2} + (I_\alpha * |v|^{2^*_{\alpha,s}})|u|^{2^*_{\alpha,s}-2} u \geq 0.$$

From [29, Lemma 2.3] and $2s < N \leq 4s$, we have $u \equiv 0$, which is a contradiction. Hence, we obtain $\lambda_1 < 0$, and analogously $\lambda_2 < 0$. Then we deduce from taking $(u_n - u, v_n - v)$ into

(4.26) and the first formula of (4.25),

$$
\begin{aligned}
&[u_n - u]^2 + [v_n - v]^2 + o_n(1) \\
&= \int_{\mathbb{R}^N} (\lambda_{1,n} u_n - \lambda_1 u)(u_n - u) + (\lambda_{2,n} v_n - \lambda_2 v)(v_n - v) dx \\
&\quad + \mu_1 \int_{\mathbb{R}^N} (|u_n|^{p-2} u_n - |u|^{p-2} u)(u_n - u) dx \\
&\quad + \mu_2 \int_{\mathbb{R}^N} (|v_n|^{p-2} v_n - |v|^{p-2} v)(v_n - v) dx \\
&\quad + \beta r_1 \int_{\mathbb{R}^N} (|u_n|^{r_1-2} u_n |v_n|^{r_2} - |u|^{r_1-2} u |v|^{r_2})(u_n - u) dx \\
&\quad + \beta r_2 \int_{\mathbb{R}^N} (|u_n|^{r_1} |v_n|^{r_2-2} v_n - |u|^{r_1} |v|^{r_2-2} v)(v_n - v) dx \\
&\quad + \int_{\mathbb{R}^N} [(I_\alpha * |v_n|^{2^*_{\alpha,s}}) |u_n|^{2^*_{\alpha,s}-2} u_n - (I_\alpha * |v|^{2^*_{\alpha,s}}) |u|^{2^*_{\alpha,s}-2} u](u_n - u) dx \\
&\quad + \int_{\mathbb{R}^N} [(I_\alpha * |u_n|^{2^*_{\alpha,s}}) |v_n|^{2^*_{\alpha,s}-2} v_n - (I_\alpha * |u|^{2^*_{\alpha,s}}) |v|^{2^*_{\alpha,s}-2} v](v_n - v) dx.
\end{aligned}
$$

Since $(u_n, v_n) \to (u, v)$ in $D^s(\mathbb{R}^N) \times D^s(\mathbb{R}^N)$ and the embedding $D^s(\mathbb{R}^N) \hookrightarrow L^{2^*_s}(\mathbb{R}^N)$ is continuous, we have

$$
\begin{aligned}
0 &= \lim_{n\to\infty} \int_{\mathbb{R}^N} (\lambda_{1,n} u_n - \lambda_1 u)(u_n - u) + (\lambda_{2,n} v_n - \lambda_2 v)(v_n - v) dx \\
&= \lim_{n\to\infty} \int_{\mathbb{R}^N} \lambda_1 (u_n - u)^2 + \lambda_2 (v_n - v)^2 dx,
\end{aligned}
$$

by $\lambda_1, \lambda_2 < 0$, then $(u_n, v_n) \to (u, v)$ in H and we complete this proof. □

Proof of Theorem 1.1. Taking $\beta^* = \hat{\beta}_*$, there exist $\mu_1^*(\beta) = \min\{\hat{\mu}_{1,*}, \hat{\mu}_1\}$ and $\mu_2^*(\beta) = \min\{\hat{\mu}_{2,*}, \hat{\mu}_2\}$, for any $\mu_1 \in (0, \mu_1^*)$ and $\mu_2 \in (0, \mu_2^*)$, such that Lemmas 4.1, 4.2 and 4.7 are satisfied. Then, from Proposition 4.9, to finish this proof, it is sufficient to prove the existence of a sequence which satisfies Proposition 4.9. Let $\{(u_n, v_n)\}$ be a minimizing sequence for $m(a, b) = \inf_{B_{R_2}(a,b)} J(u, v)$, and assume that $\{(u_n, v_n)\} \subset S_r$ is radially decreasing, symmetry and non-negative for every $n \in \mathbb{N}$ (Firstly, due to $|(-\Delta)^{\frac{s}{2}} |u|| \le |(-\Delta)^{\frac{s}{2}} u|$, we can have (u_n, v_n) is non-negative. Secondly, we replace $|u_n|$ with $|u_n|^*$ and $|v_n|$ with $|v_n|^*$, where $|\cdot|^*$ is the Schwarz symmetrization rearrangement, then we can obtain another function in $B_{R_2}(a, b)$ with $J(|u_n|^*, |v_n|^*) \le J(u_n, v_n)$). Moreover by Lemma 4.3, $s_{u_n,v_n} * (u_n, v_n) \in \mathcal{P}^+_{\mu_1,\mu_2}$ such that

$$
([u_n]^2 + [v_n]^2)^{\frac{1}{2}} < R_2,
$$

and

$$
\begin{aligned}
J(s_{u_n,v_n} * (u_n, v_n)) &= \min\{J(t * (u_n, v_n)) : t \in \mathbb{R} \text{ and } ([t * u_n]^2 + [t * v_n]^2)^{\frac{1}{2}} < R_2\} \\
&\le J(u_n, v_n).
\end{aligned}
$$

Thus, we get another minimizing sequence $\{\tilde{u}_n := s_{u_n,v_n} * u_n, \tilde{v}_n := s_{u_n,v_n} * v_n\}$ with $\{(\tilde{u}_n, \tilde{v}_n)\} \subset S_r$. By Lemma 4.5, we have $([\tilde{u}_n]^2 + [\tilde{v}_n]^2)^{\frac{1}{2}} \le R_2 - \delta$. Then, from Ekeland's Variational Principle [17], we know there exists a radially Palais–Smale sequence $\{(w_n, z_n)\}$ for $J|_S$ satisfying $\|(w_n, z_n) - (\tilde{u}_n, \tilde{v}_n)\|_H \to 0$ as $n \to \infty$. Following, we claim $P_{\mu_1,\mu_2}(w_n, z_n) = P(\tilde{u}_n, \tilde{v}_n) + o_n(1) = o_n(1)$. Firstly, by the Brézis–Lieb Lemma and Sobolev's embedding Theorem, we have

$$
[w_n]^2 = [w_n - \tilde{u}_n]^2 + [\tilde{u}_n]^2 + o_n(1) = [\tilde{u}_n]^2 + o_n(1),
$$

and

$$\int_{\mathbb{R}^N} |w_n|^p dx = \int_{\mathbb{R}^N} |w_n - \tilde{u}_n|^p dx + \int_{\mathbb{R}^N} |\tilde{u}_n|^p dx + o_n(1) = \int_{\mathbb{R}^N} |\tilde{u}_n|^p dx + o_n(1).$$

Moreover, by the Hölder inequality and Lemma 2.1, we get

$$\int_{\mathbb{R}^N} |w_n|^{r_1} |z_n|^{r_2} dx = \int_{\mathbb{R}^N} |\tilde{u}_n|^{r_1} |\tilde{v}_n|^{r_2} dx + o_n(1),$$

and

$$\int_{\mathbb{R}^N} (I_\alpha * |w_n|^{2^*_{\alpha,s}}) |z_n|^{2^*_{\alpha,s}} dx = \int_{\mathbb{R}^N} (I_\alpha * |\tilde{u}_n|^{2^*_{\alpha,s}}) |\tilde{v}_n|^{2^*_{\alpha,s}} dx + o_n(1).$$

The same relationship happen to z_n and $\tilde{v}_n$. Therefore, we obtain

$$P_{\mu_1,\mu_2}(w_n, z_n) = P_{\mu_1,\mu_2}(\tilde{u}_n, \tilde{v}_n) + o_n(1) = o_n(1), \quad \text{and} \quad w_n^-, z_n^- \to 0, \quad \text{a.e. in } \mathbb{R}^N.$$

Thus from Proposition 4.9, we obtain there is $(u, v) \in H_r$ and $(\lambda_1, \lambda_2) \in \mathbb{R}^2$ with $\lambda_1, \lambda_2 < 0$, such that $(w_n, z_n) \to (u, v)$ in H and $(\lambda_{1,n}, \lambda_{2,n}) \to (\lambda_1, \lambda_2)$ in $\mathbb{R}^2$. Hence, $(u, v) \in \mathcal{P}_{\mu_1,\mu_2}$ is a solution for (1.1)–(1.2), which is a normalized ground state with $J(u, v) = m(a, b)$. Moreover, for any ground state solution (u, v), from $m(a, b) < 0$ and Lemma 4.2, we have

$$J(u, v) = m(a, b) = \inf_{B_{R_2}(a,b)} J(u, v), \quad \text{and} \quad ([u]^2 + [v]^2)^{\frac{1}{2}} < R_2,$$

i.e. (u, v) is a local minimizer for $J(u, v)$ on $B_{R_2}(a, b)$. □

5 The case: $\bar{p} < p < r_1 + r_2 < 2^*_s$

Firstly, we show the boundedness result for this case.

Lemma 5.1. *Let $\bar{p} < p < r_1 + r_2 < 2^*_s$ and $\mu_1, \mu_2, a, b > 0$. Let $\{(u_n, v_n)\} \subset S_r$ be a Palais–Smale sequence such that*

$$J(u_n, v_n) \to c; \quad J'(u_n, v_n)|_S \to 0, \quad \text{and} \quad P_{\mu_1,\mu_2}(u_n, v_n) \to 0.$$

Then $\{(u_n, v_n)\}$ is bounded in H.

Proof. In this case, we have $2 < p\gamma_p < (r_1 + r_2)\gamma_{(r_1+r_2)}$. Then

$$\begin{aligned} c + o_n(1) &= J_{\mu_1,\mu_2}(u_n, v_n) - \frac{1}{2} P_{\mu_1,\mu_2}(u_n, v_n) \\ &= \left(\frac{\gamma_p}{2} - \frac{1}{p}\right)(\mu_1 |u_n|_p^p + \mu_2 |v_n|_p^p) + \beta \left[\frac{(r_1 + r_2)\gamma_{(r_1+r_2)}}{2} - 1\right] \int_{\mathbb{R}^N} |u_n|^{r_1} |v_n|^{r_2} dx \\ &\quad + \left(1 - \frac{1}{2^*_{\alpha,s}}\right) \int_{\mathbb{R}^N} (I_\alpha * |u_n|^{2^*_{\alpha,s}}) |v_n|^{2^*_{\alpha,s}} dx, \end{aligned}$$

by each coefficient is positive, we get $\{(u_n, v_n)\}$ is bounded in H. The proof is completed. □

Recalling the decomposition of $\mathcal{P}_{\mu_1,\mu_2} = \mathcal{P}^+_{\mu_1,\mu_2} \cup \mathcal{P}^0_{\mu_1,\mu_2} \cup \mathcal{P}^-_{\mu_1,\mu_2}$, we have

Lemma 5.2. *$\mathcal{P}^0_{\mu_1,\mu_2} = \emptyset$ and $\mathcal{P}_{\mu_1,\mu_2}$ is a C^1-submanifold in H with codimension 3.*

Proof. If there is $(u,v) \in \mathcal{P}^0_{\mu_1,\mu_2}$, then

$$[u]^2+[v]^2 = \gamma_p(\mu_1|u|_p^p+\mu_2|v|_p^p)+\beta(r_1+r_2)\gamma_{(r_1+r_2)}\int_{\mathbb{R}^N}|u|^{r_1}|v|^{r_2}dx+2\int_{\mathbb{R}^N}(I_\alpha*|u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}}dx,$$

and

$$2([u]^2+[v]^2) = p\gamma_p^2(\mu_1|u|_p^p+\mu_2|v|_p^p)+\beta(r_1+r_2)^2\gamma^2_{(r_1+r_2)}\int_{\mathbb{R}^N}|u|^{r_1}|v|^{r_2}dx + 4\cdot 2^*_{\alpha,s}\int_{\mathbb{R}^N}(I_\alpha*|u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}}dx.$$

From above, we obtain

$$(2-p\gamma_p)([u]^2+[v]^2) = \beta(r_1+r_2)\gamma_{(r_1+r_2)}[(r_1+r_2)\gamma_{(r_1+r_2)}-p\gamma_p]\int_{\mathbb{R}^N}|u|^{r_1}|v|^{r_2}dx + 2(22^*_{\alpha,s}-p\gamma_p)\int_{\mathbb{R}^N}(I_\alpha*|u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}}dx.$$

Since $2-p\gamma_p<0$, $(r_1+r_2)\gamma_{(r_1+r_2)}-p\gamma_p>0$ and $22^*_{\alpha,s}-p\gamma_p>0$, we have $(u,v)=(0,0)$, which contradicts with $(u,v)\in S$. The remainder parts of this proof is similar with Lemma 4.2, and we omit the details here. □

Following, we show the geometry for this mass supercritical case.

Lemma 5.3. *For every $(u,v)\in S$, the function $\Psi_{\mu_1,\mu_2}(t)$ has exactly one critical point $t_{u,v}\in\mathbb{R}$ such that $t_{u,v}*(u,v)\in\mathcal{P}_{\mu_1,\mu_2}$. Moreover:*

(i) $\mathcal{P}_{\mu_1,\mu_2}=\mathcal{P}^-_{\mu_1,\mu_2}$;

(ii) $\Psi_{\mu_1,\mu_2}(t)$ is strictly decreasing and concave on $(t_{u,v},+\infty)$, and $\Psi_{\mu_1,\mu_2}(t_{u,v})=\max_{t\in\mathbb{R}}\Psi_{\mu_1,\mu_2}(t)>0$;

(iii) The map $(u,v)\mapsto t_{u,v}$ is of class C^1;

(iv) If $\mathcal{P}_{\mu_1,\mu_2}(u,v)<0$, then $t_{u,v}<0$.

Proof. From the definition of $\Psi_{\mu_1,\mu_2}(t)$, we have

$$\begin{aligned}\Psi'_{\mu_1,\mu_2}(t) &= e^{2st}\Big[s([u]^2+[v]^2)-s\gamma_p e^{(p\gamma_p-2)st}(\mu_1|u|_p^p+\mu_2|v|_p^p)-2se^{(22^*_{\alpha,s}-2)st}\int_{\mathbb{R}^N}(I_\alpha*|u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}}dx \\ &\quad - s\beta(r_1+r_2)\gamma_{(r_1+r_2)}e^{[(r_1+r_2)\gamma_{(r_1+r_2)}-2]st}\int_{\mathbb{R}^N}|u|^{r_1}|v|^{r_2}dx\Big],\end{aligned}$$

which implies $\Psi_{\mu_1,\mu_2}(t)$ has exactly one critical point $t_{u,v}$. Since

$$\Psi_{\mu_1,\mu_2}(-\infty)=0^+, \quad \text{and} \quad \Psi_{\mu_1,\mu_2}(+\infty)=-\infty,$$

we get $t_{u,v}$ is a strict maximum point at a positive level and $t_{u,v}*(u,v)\in\mathcal{P}_{\mu_1,\mu_2}$. From $\Psi''_{\mu_1,\mu_2}(t_{u,v})\le 0$ and $\mathcal{P}^0_{\mu_1,\mu_2}=\emptyset$, we have $\Psi''_{\mu_1,\mu_2}(t_{u,v})<0$, this implies $t_{u,v}*(u,v)\in\mathcal{P}^-_{\mu_1,\mu_2}$ and $\mathcal{P}_{\mu_1,\mu_2}=\mathcal{P}^-_{\mu_1,\mu_2}$. To see (iii), we use the implicit function theorem as in Lemma 4.3. Finally, since $\Psi'_{\mu_1,\mu_2}(t)<0$ if and only if $t>t_{u,v}$, we get $P_{\mu_1,\mu_2}(u,v)=\Psi'_{\mu_1,\mu_2}(0)<0$ if and only if $t_{u,v}<0$. □

Remark 5.4. From Lemma 5.3, we see $m(a,b)=m^-(a,b)$.

Lemma 5.5. $m(a,b) = \inf_{\mathcal{P}_{\mu_1,\mu_2}} J(u,v) > 0.$

Proof. For $(u,v) \in \mathcal{P}_{\mu_1,\mu_2}$, then from (3.2), (4.1)-(4.3), we get

$$([u]^2+[v]^2) \le \gamma_p(C_1\mu_1 + C_2\mu_2)([u]^2+[v]^2)^{\frac{p\gamma_p}{2}} + 2C_4([u]^2+[v]^2)^{2^*_{\alpha,s}}$$
$$+ C_3\beta(r_1+r_2)\gamma_{(r_1+r_2)}([u]^2+[v]^2)^{\frac{(r_1+r_2)\gamma_{(r_1+r_2)}}{2}}.$$

Since $p\gamma_p > 2$, we obtain $\inf_{\mathcal{P}_{\mu_1,\mu_2}}([u]^2+[v]^2) > 0$ and so

$$\begin{aligned}\inf_{\mathcal{P}_{\mu_1,\mu_2}} J(u,v) &= \inf_{\mathcal{P}_{\mu_1,\mu_2}}\left[J(u,v) - \frac{1}{2}P_{\mu_1,\mu_2}(u,v)\right]\\ &= \inf_{\mathcal{P}_{\mu_1,\mu_2}}\left[\left(\frac{\gamma_p}{2}-\frac{1}{p}\right)(\mu_1|u|_p^p + \mu_2|v|_p^p) + \beta\left(\frac{(r_1+r_2)\gamma_{(r_1+r_2)}}{2}-1\right)\int_{\mathbb{R}^N}|u|^{r_1}|v|^{r_2}dx\right.\\ &\quad\left. + \left(1-\frac{1}{2^*_{\alpha,s}}\right)\int_{\mathbb{R}^N}(I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}}dx\right] > 0.\end{aligned}$$

Therefore we have $m(a,b) > 0$. □

Lemma 5.6. *For any $\delta > 0$ sufficiently small, we have $0 < \sup_{\overline{B_\delta}} J(u,v) < m(a,b)$ and*

$$u \in \overline{B_\delta} \Rightarrow J(u,v),\ P_{\mu_1,\mu_2}(u,v) > 0,$$

where $B_\delta := \{(u,v) \in S : ([u]^2+[v]^2)^{\frac{1}{2}} < \delta\}$.

Proof. Since (3.2), (4.1)–(4.3), we get

$$J(u,v) \ge \frac{1}{2}([u]^2+[v]^2) - \frac{(\mu_1C_1+\mu_2C_2)}{p}([u]^2+[v]^2)^{\frac{p\gamma_p}{2}} - \beta C_3([u]^2+[v]^2)^{\frac{(r_1+r_2)\gamma_{(r_1+r_2)}}{2}}$$
$$- \frac{C_4}{2^*_{\alpha,s}}([u]^2+[v]^2)^{2^*_{\alpha,s}},$$

and

$$P_{\mu_1,\mu_2}(u,v) \ge s([u]^2+[v]^2) - s\gamma_p(\mu_1C_1+\mu_2C_2)([u]^2+[v]^2)^{\frac{p\gamma_p}{2}} - 2sC_4([u]^2+[v]^2)^{2^*_{\alpha,s}}$$
$$- s\beta(r_1+r_2)\gamma_{(r_1+r_2)}C_3([u]^2+[v]^2)^{\frac{(r_1+r_2)\gamma_{(r_1+r_2)}}{2}}.$$

Thus for $\delta > 0$ small enough, we have $J(u,v) > 0$ and $P_{\mu_1,\mu_2}(u,v) > 0$. Moreover, by Lemma 5.5, we can choose δ with smaller quantity, such that

$$J(u,v) \le ([u]^2+[v]^2) < m(a,b).$$ □

To use the Proposition 4.9, we need some properties about $m(a,b)$. Firstly, we get the monotonicity of $m(a,b)$. The proof is similar with *Case 2* in Lemma 3.4 and we omit this process here.

Lemma 5.7. $m(a,b) \le m(a_1,b_1)$ *for any* $0 < a_1 \le a$, $0 < b_1 \le b$.

Lemma 5.8. *For $a,b > 0$ fixed, we have* $\lim_{\beta\to+\infty} m(a,b) = 0^+$.

Proof. This lemma is equivalent to prove, for any $\varepsilon > 0$, there exists $\bar{\beta} > 0$ such that

$$m(a,b) < \varepsilon \quad \text{for any } \beta \geq \bar{\beta}.$$

Firstly, from Lemma 5.6, for any $\beta > 0$, we have $m(a,b) > 0$. If we choose $\varphi \in C_0^\infty(\mathbb{R}^N)$ with $|\varphi|_2 \leq \min\{a,b\}$, by Lemmas 5.3 and 5.7 we obtain,

$$m(a,b) \leq m(|\varphi|_2, |\varphi|_2) \leq \max_{t\in\mathbb{R}} J(t*(\varphi,\varphi)) = \max_{t\in\mathbb{R}} \left[E(t) - \beta e^{s(r_1+r_2)\gamma_{(r_1+r_2)}t} \int_{\mathbb{R}^N} |\varphi|^{(r_1+r_2)} dx\right],$$

where

$$E(t) := e^{2ts}[\varphi]^2 - \frac{e^{p\gamma_p st}}{p}(\mu_1+\mu_2)|\varphi|_p^p - \frac{e^{22^*_{\alpha,s}st}}{2^*_{\alpha,s}} \int_{\mathbb{R}^N} (I_\alpha * |\varphi|^{2^*_{\alpha,s}})|\varphi|^{2^*_{\alpha,s}} dx.$$

From $p\gamma_p - 2 > 0$ and $22^*_{\alpha,s} - 2 > 0$ we see

$$\begin{aligned} E(t) &= e^{2ts}\left([\varphi]^2 - \frac{e^{(p\gamma_p-2)st}}{p}(\mu_1+\mu_2)|\varphi|_p^p - \frac{e^{(22^*_{\alpha,s}-2)st}}{2^*_{\alpha,s}} \int_{\mathbb{R}^N} (I_\alpha * |\varphi|^{2^*_{\alpha,s}})|\varphi|^{2^*_{\alpha,s}} dx\right) \\ &= e^{2ts}([\varphi]^2 + o(1)) \to 0^+, \quad \text{as } t \to -\infty. \end{aligned}$$

And there exists $\tilde{t} > 0$ such that $E(t) < \frac{\varepsilon}{4}$ for $t < -\tilde{t}$. Moreover, there exists $\bar{\beta} > 0$, such that for any $\beta \geq \bar{\beta}$,

$$\begin{aligned} &\max_{t\geq -\tilde{t}} \left[E(t) - \beta e^{s(r_1+r_2)\gamma_{(r_1+r_2)}t} |\varphi|_{r_1+r_2}^{r_1+r_2}\right] \\ &\leq \max_{t\geq -\tilde{t}} \left[e^{2ts}[\varphi]^2 - \beta e^{s(r_1+r_2)\gamma_{(r_1+r_2)}t} |\varphi|_{(r_1+r_2)}^{(r_1+r_2)} - \frac{e^{22^*_{\alpha,s}st}}{2^*_{\alpha,s}} \int_{\mathbb{R}^N} (I_\alpha * |\varphi|^{2^*_{\alpha,s}})|\varphi|^{2^*_{\alpha,s}} dx\right] \\ &\leq \max_{t\in\mathbb{R}} \left[e^{2ts}[\varphi]^2 - \frac{e^{22^*_{\alpha,s}st}}{2^*_{\alpha,s}} \int_{\mathbb{R}^N} (I_\alpha * |\varphi|^{2^*_{\alpha,s}})|\varphi|^{2^*_{\alpha,s}} dx\right] - \beta e^{-s(r_1+r_2)\gamma_{(r_1+r_2)}\tilde{t}} |\varphi|_{r_1+r_2}^{r_1+r_2} \\ &\leq \left(1 - \frac{1}{2^*_{\alpha,s}}\right)[\varphi]^{\frac{22^*_{\alpha,s}}{2^*_{\alpha,s}-1}} \left(\int_{\mathbb{R}^N} (I_\alpha * |\varphi|^{2^*_{\alpha,s}})|\varphi|^{2^*_{\alpha,s}} dx\right)^{\frac{-1}{2^*_{\alpha,s}-1}} - \beta e^{-s(r_1+r_2)\gamma_{(r_1+r_2)}\tilde{t}} |\varphi|_{r_1+r_2}^{r_1+r_2}. \end{aligned}$$

Hence, we have $\max_{t\in\mathbb{R}} \left[E(t) - \beta e^{s(r_1+r_2)\gamma_{(r_1+r_2)}t} |\varphi|_{r_1+r_2}^{r_1+r_2}\right] < \varepsilon$ for $\beta \geq \bar{\beta}$, and $m(a,b) < \varepsilon$. □

Thus by the above lemma, we have the following conclusion:

Lemma 5.9. *There exists $\hat{\beta}_1 > 0$, we get $m(a,b) < \frac{N+2s-\alpha}{2N-\alpha}\left(\frac{S^*}{2}\right)^{\frac{2N-\alpha}{N+2s-\alpha}}$ for any $\beta > \hat{\beta}_1$.*

Lemma 5.10. *There exists $\hat{\beta}_2 > 0$ such that for any $\beta > \hat{\beta}_2$, the level satisfies*

$$m(a,b) < \min\{m(a,0), m(0,b)\}.$$

Proof. From Theorem 3.3, $m(a,0) > 0$ can be achieved by $u^* \in S_a$. Similarly, $m(0,b) > 0$ can be achieved by $v^* \in S_b$. Since

$$I_{\mu_1,a}(t*u^*) \to 0, \quad \text{and} \quad I_{\mu_2,b}(t*v^*) \to 0, \quad \text{as } t \to -\infty,$$

there is $t^* \ll -1$ which is independent of β, such that

$$\max_{t<t^*} J(u^*,v^*) < \max_{t<t^*} I_{\mu_1,a}(t*u^*) + \max_{t<t^*} I_{\mu_2,b}(t*v^*) < \min\{m(a,0), m(0,b)\}.$$

On the other hand, for $t > t^*$, firstly we have

$$\int_{\mathbb{R}^N} |t * u^*|^{r_1} |t * v^*|^{r_2} dx = e^{st(r_1+r_2)\gamma_{(r_1+r_2)}} \int_{\mathbb{R}^N} |u^*|^{r_1} |v^*|^{r_2} dx \geq C e^{st^*(r_1+r_2)\gamma_{(r_1+r_2)}},$$

for some $C > 0$. Then by Theorem 3.3, we get

$$\begin{aligned}\max_{t\geq t^*} J(t*(u^*,v^*)) &\leq \max_{t\geq t^*} I_{\mu_1,a}(t*u^*) + \max_{t\geq t^*} I_{\mu_2,b}(t*v^*) - C\beta e^{st^*(r_1+r_2)\gamma_{(r_1+r_2)}} \\ &\leq m(a,0) + m(0,b) - C\beta e^{st^*(r_1+r_2)\gamma_{(r_1+r_2)}}.\end{aligned}$$

Hence, there is $\hat{\beta}_2 > 0$, for any $\beta > \hat{\beta}_2$ such that $m(a,b) < \min\{m(a,0), m(0,b)\}$. □

To prove Theorem 1.2, we give the following minimax theorem to establish the existence of Palais–Smale sequence. At first, we show some definitions.

Definition 5.11 ([21, Definition 3.1])**.** Let Θ be a closed subset of a metric space $X \subset H$. We say that a class $\mathcal{F}$ of compact subsets of X is a homotopy-stable family with closed boundary Θ provided

(i) every set in $\mathcal{F}$ contains Θ;

(ii) for any set $Y \in \mathcal{F}$ and any $\eta \in C([0,1]\times X, X)$ satisfying $\eta(t,x) = x$ for all $(t,x) \in (\{0\}\times X) \cup ([0,1]\times\Theta)$, we have that $\eta(\{1\}\times Y) \in \mathcal{F}$.

Definition 5.12. [33] Let M be a C^∞ m-dimensional manifold and $\widetilde{TM} = TM \setminus \{0\}$, where TM is a tangent bundle. A function $F : TM \to [0,\infty)$ is called a Finsler structure on M if F has the following properties:

(i) $F(tY) = tF(Y)$, $\forall t \in \mathbb{R}^+$;

(ii) F is C^∞ on $\widetilde{TM}$;

(iii) for every non-zero $Y \in T_xM$, the induced quadratic form g_Y is an inner product in T_xM, where

$$g_Y(U,V) := \frac{1}{2}\frac{\partial^2}{\partial_s\partial_t}(F^2(Y+sU+tV))|_{s=t=0},$$

and T_xM is the tangent space at the point x. A Finsler manifold is a C^∞-manifold M with its Finsler structure F.

Remark 5.13. From [14], we know Riemannian manifolds are special cases of Finsler manifolds. Denote $X := \mathbb{R} \times S_r$. Since $\mathbb{R}$ is a Banach space and $S_r \subset H^s(\mathbb{R}^N, R) \times H^s(\mathbb{R}^N, R)$ is a Banach manifold, similar to [24] (see (7.2) there), [26, Lemma 4.8] and [32, Theorem 6.12], we know X is a para-compact space with satisfying the requirement of locally limited refinement for each open coverage. Moreover, by [41, Section 3], we can assign X a Finsler structure and we know X is a Finsler manifold.

Proposition 5.14 ([21, Theorem 3.2])**.** *Let φ be a C^1-functional on a complete connected C^1-Finsler manifold X (without boundary) and consider a homotopy stable family $\mathcal{F}$ of compact subsets of X with a closed boundary B.*

$$c = c(\varphi, \mathcal{F}) = \inf_{Y\in\mathcal{F}} \max_{u\in Y} \varphi(u),$$

and suppose that $\sup \varphi(\Theta) < c$. *Then for any sequence of sets* $\{Y_n\}$ *in* $\mathcal{F}$ *such that* $\lim_{n\to\infty} \sup_{Y_n} \varphi = c$, *there exists a sequence* $\{u_n\}$ *in* X *such that*

$$\lim_{n\to\infty} \varphi(u_n) = c; \quad \lim_{n\to\infty} \|d\varphi(u_n)\| = 0; \quad \textit{and} \quad \lim_{n\to\infty} \operatorname{dist}(u_n, Y_n) = 0.$$

Furthermore, if $d\varphi$ *is uniformly continuous, then* u_n *can be chosen to be in* Y_n *for each* n.

Proof of Theorem 1.2. Using the strategy from [25], for $\delta > 0$ be defined by Lemma 5.6, let the function $\tilde{J} : \mathbb{R} \times H \mapsto \mathbb{R}$ as

$$\begin{aligned}\tilde{J}(t,(u,v)) := J(t*(u,v)) = \frac{e^{2st}}{2}([u]^2+[v]^2) - \frac{e^{sp\gamma_p t}}{p}(\mu_1|u|_p^p + \mu_2|v|_p^p) \\ - \beta e^{s(r_1+r_2)\gamma_{(r_1+r_2)}t}\int_{\mathbb{R}^N}|u|^{r_1}|v|^{r_2}dx \\ - \frac{e^{22^*_{\alpha,s}st}}{2^*_{\alpha,s}}\int_{\mathbb{R}^N}(I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}}dx,\end{aligned}$$

then $\tilde{J} \in C^1$ and a Palais–Smale sequence for $\tilde{J}|_{\mathbb{R}\times S_r}$ is a Palais–Smale sequence for $\tilde{J}|_{\mathbb{R}\times S}$. Setting $J^c := \{(u,v) \in S, J(u,v) \le c\}$, we introduce the minimax class

$$\Gamma := \{\gamma = (\alpha,\beta) \in C([0,1], \mathbb{R}\times S_r) : \gamma(0) \in (0,\overline{B}_\delta), \gamma(1) \in (0,J^0)\},$$

with the minimax level

$$\sigma(a,b) := \inf_{\gamma\in\Gamma} \max_{(t,(u,v))\in\gamma([0,1])} \tilde{J}(t,(u,v)).$$

Let $(u,v) \in S_r$. From $[t*u]^2 + [t*v]^2 \to 0^+$ as $t \to -\infty$ and $J(t*(u,v)) \to -\infty$ as $t \to +\infty$, there is $t_0 \ll -1$ and $t_1 \gg 1$ such that

$$\gamma_{(u,v)} : \tau \in [0,1] \mapsto (0, ((1-\tau)t_0 + \tau t_1) * (u,v)) \in \mathbb{R}\times S_r, \tag{5.1}$$

which is a path in Γ and $\sigma(a,b)$ is a real number. For any $\gamma = (\alpha,\beta) \in \Gamma$, we study the function

$$\Pi_\gamma : \tau \in [0,1] \mapsto P_{\mu_1,\mu_2}(\alpha(\tau) * \beta(\tau)) \in \mathbb{R}.$$

From Lemma 5.6, we find $\Pi_\gamma(0) = P_{\mu_1,\mu_2}(\beta(0)) > 0$. Besides, from Lemma 5.3, $\Psi_{\mu_1,\mu_2}(t) > 0$ for any $t \in (-\infty, t_{u,v})$. If $(u,v) = \beta(1)$, we have $\Psi_{\mu_1,\mu_2}(0) = J(\beta(1)) \le 0$. Hence, we obtain $t_{\beta(1)} < 0$ and $\Pi_\gamma(1) = P_{\mu_1,\mu_2}(0 * \beta(1)) < 0$. Since the map $\tau \mapsto \alpha(\tau) * \beta(\tau)$ is continuous from $[0,1]$ to H, there exists $\tau_\gamma \in (0,1)$ such that $\Pi_\gamma(\tau_\gamma) = 0$, which implies $\alpha(\tau_\gamma) * \beta(\tau_\gamma) \in \mathcal{P}_{\mu_1,\mu_2} \cap S_r$ and

$$\max_{\gamma([0,1])} \tilde{J} \ge \tilde{J}(\gamma(\tau_\gamma)) = J(\alpha(\tau_\gamma) * \beta(\tau_\gamma)) \ge \inf_{\mathcal{P}_{\mu_1,\mu_2}\cap S_r} J(u,v) = m_r(a,b).$$

Therefore, $\sigma(a,b) \ge m_r(a,b)$. On the other hand, for any $(u,v) \in \mathcal{P}_{\mu_1,\mu_2} \cap S_r$, from (5.1), $\gamma_{(u,v)}$ is a path in Γ and by Lemma 5.3,

$$J(u,v) = \max_{\gamma_{(u,v)}([0,1])} \tilde{J} \ge \sigma(a,b),$$

then $m_r(a,b) \ge \sigma(a,b)$. Combining this with (5.6), we get

$$\sigma(a,b) = m_r(a,b) > \sup_{(\overline{B}_\delta\cup J^0)\cap S_r} J(u,v) = \sup_{((0,\overline{B}_\delta)\cup(0,J^0))\cap(\mathbb{R}\times S_r)} \tilde{J}.$$

From Definition 5.11, the set $\{\gamma([0,1]) : \gamma \in \Gamma\}$ is a homotopy stable family of compact subsets of $\mathbb{R} \times S_r$ with closed boundary $(0, \overline{B}_\delta) \cup (0, J^0)$. By Proposition 5.14, similar to [24,32], taking any minimizing sequence $\{\gamma_n = (\alpha_n, \beta_n)\} \subset \Gamma_n$ for $\sigma(a,b)$ with $\alpha_n \equiv 0$, and $\beta_n(\tau) \geq 0$ a.e. in $\mathbb{R}$, for every $\tau \in [0,1]$, there exists a Palais–Smale sequence $\{t_n, w_n\} \subset \mathbb{R} \times S_r$ for $\tilde{J}|_{\mathbb{R}\times S_r}$ at the level $\sigma(a,b)$, where $w_n = (u_n, v_n)$, such that,

$$\partial t \tilde{J}(t_n, w_n) \to 0, \quad \|\partial w \tilde{J}(t_n, w_n)\|_{(T_{w_n} S_r)*} \to 0, \quad \text{as } n \to \infty, \tag{5.2}$$

with an additional property

$$|t_n| + \text{dist}_H(w_n, \beta_n([0,1])) \to 0, \quad \text{as } n \to \infty. \tag{5.3}$$

From (5.3), we have t_n is bounded in both side. Besides, from the first formula of (5.2), we have $P_{\mu_1,\mu_2}(t_n * (u_n, v_n)) \to 0$, and from the second formula of (5.2) with the boundedness of t_n, for any $\varphi \in T_{w_n} S_r$,

$$dJ(t_n * w_n)[t_n * \varphi] = o_n(1)\|\varphi\| = o_n(1)\|t_n * \varphi\|, \quad \text{as } n \to \infty.$$

Following, we define $\hat{w}_n := t_n * w_n$ with $\hat{w}_n = (\hat{u}_n, \hat{v}_n)$. Therefore, $\{(\hat{u}_n, \hat{v}_n)\}$ is a Palais–Smale sequence for $J(u,v)|_{S_r}$ at the level $\sigma(a,b)$ with an additional condition $P_{\mu_1,\mu_2}(\hat{u}_n, \hat{v}_n) \to 0$. From Lemma 5.8, there exists $\hat{\beta}_1 > 0$, $m_r(a,b) \in \left(0, \frac{N+2s-\alpha}{2N-\alpha}\left(\frac{S^*}{2}\right)^{\frac{2N-\alpha}{N+2s-\alpha}}\right)$ for any $\beta > \hat{\beta}_1$. Besides, from Lemma 5.10, there exists $\hat{\beta}_2 > 0$ such that $m_r(a,b) < \min\{m(a,0), m(0,b)\}$. Following, we may require $\beta_0 = \max\{\hat{\beta}_1, \hat{\beta}_2\}$. Then for $\beta \in (\beta_0, +\infty)$, by Proposition 4.9, we know there is $(u,v) \in H$ with $u, v > 0$ a.e. in $\mathbb{R}$, such that $(\hat{u}_n, \hat{v}_n) \to (u,v)$ in H and $J(u,v) = m_r(a,b)$. Hence, we need to show

$$\inf_{\mathcal{P}_{\mu_1,\mu_2} \cap S_r} J(u,v) = \inf_{\mathcal{P}_{\mu_1,\mu_2}} J(u,v) = m(a,b).$$

If this does not happen, there is $(\bar{u}, \bar{v}) \in \mathcal{P}_{\mu_1,\mu_2} \setminus S_r$ such that $J(\bar{u}, \bar{v}) < m_r(a,b)$. Denote $(\tilde{u}, \tilde{v}) := (|\bar{u}|^*, |\bar{v}|^*)$ as the symmetric decreasing rearrangement of $(\bar{u}, \bar{v})$ such that

$$[\tilde{u}]^2 + [\tilde{v}]^2 \leq [\hat{u}]^2 + [\hat{v}]^2, \quad J(\tilde{u}, \tilde{v}) \leq J(\bar{u}, \bar{v}), \quad \text{and} \quad P_{\mu_1,\mu_2}(\tilde{u}, \tilde{v}) \leq P_{\mu_1,\mu_2}(\bar{u}, \bar{v}) = 0.$$

If $P_{\mu_1,\mu_2}(\tilde{u}, \tilde{v}) = 0$, which $(\tilde{u}, \tilde{v}) \in \mathcal{P}_{\mu_1,\mu_2} \cap S_r$, there is a contradiction. On the other hand, if $P_{\mu_1,\mu_2}(\tilde{u}, \tilde{v}) < 0$, from Lemma 5.3, we get $t_{\tilde{u},\tilde{v}} < 0$. Therefore, by $t_{\tilde{u},\tilde{v}} * (\tilde{u}, \tilde{v}) \in \mathcal{P}_{\mu_1,\mu_2}$, we have

$$\begin{aligned}
J(\bar{u}, \bar{v}) &\leq J(t_{\tilde{u},\tilde{v}} * (\tilde{u}, \tilde{v})) - \frac{1}{2} P_{\mu_1,\mu_2}(t_{\tilde{u},\tilde{v}} * (\tilde{u}, \tilde{v})) \\
&= \left(\frac{\gamma_p}{2} - \frac{1}{p}\right) e^{p\gamma_p s t_{\tilde{u},\tilde{v}}} (\mu_1 |\tilde{u}|_p^p + \mu_2 |\tilde{v}|_p^p) \\
&\quad + \beta \left[\frac{(r_1+r_2)\gamma_{(r_1+r_2)}}{2} - 1\right] e^{(r_1+r_2)\gamma_{(r_1+r_2)} s t_{\tilde{u},\tilde{v}}} \int_{\mathbb{R}^N} |\tilde{u}|^{r_1} |\tilde{v}|^{r_2} dx \\
&\quad + \left(1 - \frac{1}{2^*_{\alpha,s}}\right) e^{22^*_{\alpha,s} s t_{\tilde{u},\tilde{v}}} \int_{\mathbb{R}^N} (I_\alpha * |\tilde{u}|^{2^*_{\alpha,s}}) |\tilde{v}|^{2^*_{\alpha,s}} dx \\
&< J(\bar{u}, \bar{v}),
\end{aligned}$$

which is a contradiction. Thus, we have $m_r(a,b) = m(a,b)$ and (u,v) is a ground state solution.

□

6 The case: $p = r_1 + r_2 = 2_s^*$

Lemma 6.1. *Assume $s \in (0,1)$, $2s < N \le 4s$, $p = r_1 + r_2 = 2_s^*$ and $a, b, \mu_1, \mu_2, \beta > 0$. Then the following system*

$$\begin{cases} (-\Delta)^s u = \lambda_1 u + \mu_1 |u|^{p-2}u + \beta r_1 |u|^{r_1-2}u|v|^{r_2} + (I_\alpha * |v|^{2^*_{\alpha,s}})|u|^{2^*_{\alpha,s}-2}u, \\ (-\Delta)^s v = \lambda_2 v + \mu_2 |v|^{p-2}v + \beta r_2 |v|^{r_2-2}v|u|^{r_1} + (I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}-2}v, \\ \int_{\mathbb{R}^N} u^2 dx = a^2, \quad \int_{\mathbb{R}^N} v^2 dx = b^2, \quad u, v \in H^s(\mathbb{R}^N), \end{cases} \tag{6.1}$$

has no positive solution.

Proof. Assume by contradiction that there is a positive solution (u, v) of (6.1) for some $\lambda_1, \lambda_2 \in \mathbb{R}$. On one hand, from Proposition 4.9 and [29, Lemma 2.3], we see that $\lambda_1, \lambda_2 < 0$ for $2s < N \le 4s$. On the other hand, by Proposition 2.4 we know (u, v) satisfies the Pohožaev identity such that

$$[u]^2 + [v]^2 = (\mu_1 |u|_{2_s^*}^{2_s^*} + \mu_2 |v|_{2_s^*}^{2_s^*}) + \beta 2_s^* \int_{\mathbb{R}^N} |u|^{r_1}|v|^{r_2} dx + 2\int_{\mathbb{R}^N} (I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}} dx. \tag{6.2}$$

Moreover since (u, v) is a weak solution to (1.1)-(1.2), it satisfies

$$\begin{aligned} [u]^2 + [v]^2 = &\int_{\mathbb{R}^N} (\lambda_1 |u|^2 + \lambda_2 |v|^2) dx + (\mu_1 |u|_{2_s^*}^{2_s^*} + \mu_2 |v|_{2_s^*}^{2_s^*}) + \beta 2_s^* \int_{\mathbb{R}^N} |u|^{r_1}|v|^{r_2} dx \\ &+ 2\int_{\mathbb{R}^N} (I_\alpha * |u|^{2^*_{\alpha,s}})|v|^{2^*_{\alpha,s}} dx. \end{aligned} \tag{6.3}$$

Combining (6.2)–(6.3), we show

$$\int_{\mathbb{R}^N} \lambda_1 |u|^2 + \lambda_2 |v|^2 dx = \lambda_1 a^2 + \lambda_2 b^2 = 0.$$

From which we obtain $\lambda_1 = \lambda_2 = 0$. This is clearly a contradiction with $\lambda_1, \lambda_2 < 0$. The proof is complete. □

Proof of Theorem 1.3. Theorem 1.3 follows from Lemma 6.1, then we finish the proof. □

Abstract. In this paper, we consider small perturbations of linear random dynamical systems evolving on a Banach space and admitting a general form of trichotomy. We prove the existence of invariant center manifolds in both continuous and discrete-time. Furthermore, we provide several illustrative examples.

Keywords: invariant manifolds, random dynamical systems, trichotomies.

2020 Mathematics Subject Classification: 37L55, 37D10, 37H99.

1 Introduction

The theory of center manifolds plays a crucial role in stability and bifurcation theory, as it often enables the reduction of the dimension of the state space (see [19,29,31–33]). The origins of this theory date back to the 1960s, with the works of Pliss [49] and Kelley [34,35]. Subsequently, various results on this subject were developed by several authors. In the context of autonomous differential equations, we recommend the surveys by Vanderbauwhede [54] (see also Vanderbauwhede and Gils [56]) for the finite-dimensional case and by Vanderbauwhede and Iooss [55] in the infinite-dimensional case. For the nonautonomous case we recommend the survey by Aulbach and Wanner [3]. We also recommend [23,24] and [22,25,26,44,53] for, respectively, finite and infinite dimension.

The concept of trichotomy is an essential tool for obtaining center manifolds. The (uniform) exponential trichotomies were introduced, independently, by Sacker and Sell [51], Aulbach [2] and Elaydi and Hájek [28]. This notion was motivated by the idea of (uniform) exponential dichotomy that started in the thirties with Perron [47,48].

Several generalizations of exponential trichotomies have since emerged. Fenner and Pinto [42] introduced the (h,k)-trichotomies that use non exponential growth rates and Barreira and Valls [4,5] introduced nonuniform exponential trichotomies that take into account the initial time. Later, Barreira and Valls [6,7] introduced the ρ-nonuniform exponential trichotomies that are nonuniform and non exponential, but do not include the (h,k)-trichotomies.

✉ Corresponding author. Email: helder@ubi.pt

In [12, 15], a general type of trichotomies was introduced, for linear differential equations and linear difference equations, respectively. This new framework contains as special cases the notions of trichotomies mentioned above and also contains additional new cases (the case of dichotomies was done in [13, 14]).

Invariant manifold theory has also been extended to dynamical systems with randomness. In this work, we focus on random dynamical systems (RDS), which can be generated, for instance, by random or stochastic differential equations. In this context, various studies have addressed center, stable, unstable, and inertial invariant manifolds, both locally and globally, across a range of spaces that goes from finite to infinite dimension, including Hilbert spaces and separable Banach spaces. Arnold's monograph [1] provides a detailed exposition on the Multiplicative Ergodic Theorem and invariant manifold theory for finite-dimensional RDS. Smooth systems are discussed in [41]. For results on infinite-dimensional RDS, we refer to [8–11, 18, 27, 37, 40, 43, 45, 46, 50, 52] and the references therein.

Center manifolds for RDS have also garnered attention, either in finite or infinite dimensions. In the finite-dimensional context, Wanner [57] discusses invariant manifolds, including center manifolds, in terms of linearization in $\mathbb{R}^n$. Boxler [17] proved the existence of center manifolds for discrete random maps (random diffeomorphisms). Existence, smooth conjugacy theorems, and Takens-type theorems based on Lyapunov exponents were established by Li and Lu in [38] and by Guo and Shen in [30], in the presence of zero Lyapunov exponents. On the other hand, infinite-dimensional RDS hold significant interest not only due to their inherent mathematical richness but also for their applications in understanding stochastic and partial differential equations. Under the assumption of an exponential trichotomy, Chen, Roberts, and Duan [20] established the existence and smoothness of center manifolds for a class of stochastic evolution equations with linear multiplicative noise. In [21], Chen, Roberts and Duan established the existence of center manifolds for both discrete and continuous-time infinite-dimensional RDS, assuming an exponential trichotomy, by employing the Lyapunov–Perron method. Moreover, they provided examples illustrating the application of these results to stochastic evolution equations through their conversion into infinite-dimensional RDS. In a similar vein, Kuehn and Neamţu [36] addressed the issue of center manifolds for rough partial differential equations, which also translates into center manifolds within the RDS framework. Li, Zeng and Huan [39] established the existence and smoothness of center-unstable invariant manifolds and center-stable foliations for a class of stochastic PDE with non-dense domain, by converting them into infinite-dimensional RDS.

Exponential trichotomies have played an important role in invariant manifold theory for infinite-dimensional dynamical systems and non-autonomous systems, whether in deterministic or random scenarios, as discussed. In this work, we extend the results on the existence of center manifolds for infinite-dimensional RDS by assuming a generalized trichotomy. This type of general assumption was considered in [16] for dichotomies, and in this work, it is extended to include a central direction. This generalization allows various types of non exponential behaviours along the three subspaces of the invariant splitting. In our context, each subspace is governed by a very general type of rate for controlling the growth of the evolution operator, described in terms of a cocycle. In specific cases, these subspaces correspond to the traditional central, stable, and unstable subspaces. However, our assumptions are sufficiently general to accommodate behaviours beyond exponential-type, such as those observed in (non)uniformly (pseudo-)hyperbolic settings.

This paper is organized as follows. Section 2 introduces the setup and provides preliminaries on RDS and generalized random trichotomies, as well as a description of auxiliary spaces of functions which are essential for handling nonlinear RDS components and deriving the center manifold as the graph of a suitable regular function. Section 3 presents the main result for continuous-time RDS (Theorem 3.1), while Section 4 focuses on the discrete-time counterpart (Theorem 4.1). In Section 5, continuous-time examples are discussed, including tempered exponential trichotomies and a general framework called ψ-trichotomies, which extend beyond exponential bounds. Corresponding discrete-time examples are provided in Section 6.

2 Generalized trichotomies for RDS

2.1 Random Dynamical Systems

Consider *time* $\mathbb{T} = \mathbb{Z}$ or $\mathbb{T} = \mathbb{R}$, and set $\mathbb{T}^- = \mathbb{T} \cap]-\infty, 0]$ and $\mathbb{T}^+ = \mathbb{T} \cap [0, +\infty[$. A *measure-preserving dynamical system* is a quadruplet $\Sigma \equiv (\Omega, \mathcal{F}, \mathbb{P}, \theta)$, where $(\Omega, \mathcal{F}, \mathbb{P})$ is a measure space and

$\theta\colon \mathbb{T} \times \Omega \to \Omega$ is measurable;

$\theta^t(\cdot) = \theta(t, \cdot)\colon \Omega \to \Omega$ preserves $\mathbb{P}$ for all $t \in \mathbb{T}$;

$\theta^0 = \mathrm{Id}_\Omega$;

$\theta^{t+s} = \theta^t \circ \theta^s$ for all $t, s \in \mathbb{T}$.

A (Bochner) measurable *random dynamical system*, henceforth abbreviated as RDS, on a Banach space X over a measure-preserving dynamical system Σ with time $\mathbb{T}$ is a map

$$\Phi : \mathbb{T} \times \Omega \times X \to X$$

such that

i) $\Phi(\cdot, \cdot, x)$ is (Bochner) measurable for all $x \in X$;

ii) $\Phi^t_\omega(\cdot) = \Phi(t, \omega, \cdot)\colon X \to X$ satisfies

a) $\Phi^0_\omega = \mathrm{Id}_X$ for all $\omega \in \Omega$;

b) $\Phi^{t+s}_\omega = \Phi^t_{\theta^s\omega} \circ \Phi^s_\omega$, for all $\omega \in \Omega$ and all $s, t \in \mathbb{T}$.

When Φ^t_ω is a bounded linear operator for all $(t, \omega) \in \mathbb{T} \times \Omega$, the RDS Φ is called *linear*.

We may restrict the *driving system* Σ to a θ^t-invariant subset $\Omega' \subset \Omega$ with $\mathbb{P}$-full measure, obtaining a (Bochner) measurable RDS $\Phi|_{\mathbb{T}\times\Omega'\times X}$ over $\Sigma' \equiv (\Omega', \mathcal{F}', \mathbb{P}|_{\mathcal{F}'}, \theta|_{\Omega'})$, where $\mathcal{F}' = \{B \cap \Omega'\colon B \in \mathcal{F}\}$. In view of this, without any loss of generality, throughout this work, requiring a property to hold for all $\omega \in \Omega'$, for a θ^t-invariant subset $\Omega' \subset \Omega$ with $\mathbb{P}$-full measure, can be replaced by simply requiring it for all $\omega \in \Omega$ by restricting, if necessary, the RDS Φ to $\Phi|_{\mathbb{T}\times\Omega'\times X}$ over Σ'.

2.2 Generalized trichotomies

For every $i \in \{c, s, u\}$, consider a map $P^i\colon \Omega \times X \to X$, and set $P^i_\omega(\cdot) = P(\omega, \cdot)\colon X \to X$. Let $\mathcal{P} = (P^c, P^s, P^u)$. A (Bochner) measurable linear RDS Φ over Σ admits a (Bochner) measurable *$\mathcal{P}$-invariant splitting* if *i*) $P^i(\cdot, x)$ is (Bochner) measurable, for all $x \in X$ and every $i \in \{c, s, u\}$;

ii) P^i_ω is a bounded linear projection, for all $\omega \in \Omega$ and every $i \in \{c, s, u\}$;

iii) $P^c_\omega + P^s_\omega + P^u_\omega = \mathrm{Id}$, for all $\omega \in \Omega$;

iv) $P^c_\omega P^s_\omega = 0$, for all $\omega \in \Omega$;

v) $P^i_{\theta^t\omega}\Phi^t_\omega = \Phi^t_\omega P^i_\omega$, for all $(t, \omega) \in \mathbb{T} \times \Omega$ and every $i \in \{c, s, u\}$;

Notice that for all $\omega \in \Omega$ and $i, j \in \{c, s, u\}$, with $i \neq j$, we have $P^i_\omega P^j_\omega = 0$. To shorten the writing during future computations, for $t \in \mathbb{T}$, $\omega \in \Omega$, and $i \in \{c, s, u\}$ we will adopt the notation

$$\Phi^{i,t}_\omega = \Phi^t_\omega P^i_\omega.$$

We define the linear subspaces $E^i_\omega = P^i_\omega(X)$ for each $i \in \{c, s, u\}$. As usual, we identify $E^c_\omega \times E^s_\omega \times E^u_\omega$ and $E^c_\omega \oplus E^s_\omega \oplus E^u_\omega$. Given the maps

$$\begin{aligned} \alpha^c &: \mathbb{T} \times \Omega \to (0, +\infty), \\ \alpha^s &: \mathbb{T}^+ \times \Omega \to (0, +\infty), \\ \alpha^u &: \mathbb{T}^- \times \Omega \to (0, +\infty), \end{aligned}$$

we define $\alpha = (\alpha^c, \alpha^s, \alpha^u)$. Denote $\alpha^i(t, \omega)$ by $\alpha^i_{t,\omega}$. We say that a (Bochner) measurable linear RDS Φ over Σ exhibits a *generalized trichotomy with bounds* α (or simply an α*-trichotomy*) if it admits a (Bochner) measurable $\mathcal{P}$-invariant splitting satisfying

(T1) $\|\Phi^{c,t}_\omega\| \leqslant \alpha^c_{t,\omega}$ for all $(t, \omega) \in \mathbb{T} \times \Omega$,

(T2) $\|\Phi^{s,t}_\omega\| \leqslant \alpha^s_{t,\omega}$ for all $(t, \omega) \in \mathbb{T}^+ \times \Omega$,

(T3) $\|\Phi^{u,t}_\omega\| \leqslant \alpha^u_{t,\omega}$ for all $(t, \omega) \in \mathbb{T}^- \times \Omega$,

where the operators in (T1)-(T3) are considered as operators from X into X. In what follows, we always consider the operators defined in the whole Banach space X.

In Section 5 and Section 6, we present several examples of generalized trichotomies with both exponential and non-exponential bounds α.

In the remainder of this article, Φ will always denote a measurable (when $\mathbb{T} = \mathbb{Z}$) or Bochner measurable (when $\mathbb{T} = \mathbb{R}$) linear RDS on a Banach space X over a measure-preserving dynamical system $\Sigma \equiv (\Omega, \mathcal{F}, \mathbb{P}, \theta)$ exhibiting a trichotomy with bounds $\alpha = (\alpha^c, \alpha^s, \alpha^u)$.

2.3 Auxiliary spaces

Let $\mathscr{F}$ denote the space of maps $f\colon \Omega \times X \to X$ such that $f(\cdot, x)$ is measurable for every $x \in X$, and for which, setting $f_\omega(\cdot) = f(\omega, \cdot)$, for every $\omega \in \Omega$ we have

$$f_\omega(0) = 0 \tag{2.1}$$

and

$$\mathrm{Lip}(f_\omega) = \sup\left\{ \frac{\|f_\omega(x) - f_\omega(y)\|}{\|x - y\|} : x, y \in X,\ x \neq y \right\} < +\infty. \tag{2.2}$$

Conditions (2.2) and (2.1) ensure that for all $\omega \in \Omega$ and $x, y \in X$

$$\|f_\omega(x) - f_\omega(y)\| \leqslant \mathrm{Lip}(f_\omega)\|x - y\|, \tag{2.3}$$

and

$$\|f_\omega(x)\| \leqslant \mathrm{Lip}(f_\omega)\|x\|. \tag{2.4}$$

Let $\mathscr{F}^{(B)}$ represent the collection of functions $f \in \mathscr{F}$ for which $f(\cdot, x)$ is Bochner measurable for each $x \in X$. Additionally, define $\mathscr{F}_\alpha^{(B)}$ as the subset of $\mathscr{F}^{(B)}$ consisting of functions f such that, for every $\omega \in \Omega$, the maps

$$[a,b] \ni r \mapsto \alpha^c_{t-r,\theta^r\omega} \,\mathrm{Lip}(f_{\theta^r\omega})\alpha^c_{r,\omega},$$
$$[c,0] \ni r \mapsto \alpha^s_{-r,\theta^r\omega} \,\mathrm{Lip}(f_{\theta^r\omega})\alpha^c_{r,\omega},$$
$$[0,d] \ni r \mapsto \alpha^u_{-r,\theta^r\omega} \,\mathrm{Lip}(f_{\theta^r\omega})\alpha^c_{r,\omega}$$

are measurable for every $a < b$, $c < 0$, $d > 0$ and $t \in \mathbb{R}$.

We define the set

$$\mathcal{C} = \{(t, \omega, \xi) \in \mathbb{T} \times \Omega \times X \colon \xi \in E^c_\omega\}.$$

For a given $M > 0$, let $\mathfrak{C}_M$ (resp. $\mathfrak{C}_M^{(B)}$) denote the space of all functions $h\colon \mathcal{C} \to X$ such that, for each $(t, \omega) \in \mathbb{T} \times \Omega$, the map $h_{t,\omega}(\cdot) = h(t, \omega, \cdot)$ satisfies

$$h(\cdot, \cdot, P^c_\omega x) \text{ is measurable (resp. Bochner measurable) for all } x \in X; \tag{2.5}$$
$$h_{t,\omega}(0) = 0 \text{ for all } (t, \omega) \in \mathbb{T} \times \Omega; \tag{2.6}$$
$$h_{0,\omega} = \mathrm{Id}_{E^c_\omega} \text{ for all } \omega \in \Omega; \tag{2.7}$$
$$h_{t,\omega}(E^c_\omega) \subseteq E^c_{\theta^t\omega} \text{ for all } (t, \omega) \in \mathbb{T} \times \Omega; \tag{2.8}$$
$$\|h_{t,\omega}(\xi) - h_{t,\omega}(\xi')\| \leqslant M\alpha^c_{t,\omega}\|\xi - \xi'\| \text{ for all } (t, \omega, \xi), (t, \omega, \xi') \in \mathcal{C}. \tag{2.9}$$

From (2.9) and (2.6), it follows that

$$\|h_{t,\omega}(\xi)\| \leqslant M\alpha^c_{t,\omega}\|\xi\| \text{ for all } (t, \omega, \xi) \in \mathcal{C}. \tag{2.10}$$

Defining

$$d_1(h, g) = \sup\left\{\frac{\|h_{t,\omega}(\xi) - g_{t,\omega}(\xi)\|}{\alpha^c_{t,\omega}\|\xi\|} : (t, \omega, \xi) \in \mathcal{C},\ \xi \neq 0\right\} \tag{2.11}$$

we have that $(\mathfrak{C}_M, d_1)$ and $(\mathfrak{C}_M^{(B)}, d_1)$ are complete metric spaces.

We now consider the set

$$\mathcal{D} = \{(\omega, \xi) \in \Omega \times X \colon \xi \in E^c_\omega\}.$$

For a given $N > 0$, let $\mathfrak{D}_N$ (resp. $\mathfrak{D}_N^{(B)}$) denote the space of all functions $\varphi\colon \mathcal{D} \to X$ such that, for each $\omega \in \Omega$, the map $\varphi_\omega(\cdot) = \varphi(\omega, \cdot)$ satisfies

$$\varphi(\cdot, P^c_\omega x) \text{ is measurable (resp. Bochner measurable) for all } x \in X; \tag{2.12}$$
$$\varphi_\omega(0) = 0 \text{ for all } \omega \in \Omega; \tag{2.13}$$
$$\varphi_\omega(E^c_\omega) \subseteq E^s_\omega \oplus E^u_\omega \text{ for all } \omega \in \Omega; \tag{2.14}$$
$$\|\varphi_\omega(\xi) - \varphi_\omega(\xi')\| \leqslant N\|\xi - \xi'\| \text{ for all } (\omega, \xi), (\omega, \xi') \in \mathcal{D}. \tag{2.15}$$

By (2.15) and (2.13), taking $\xi' = 0$, we get

$$\|\varphi_\omega(\xi)\| \leqslant N\|\xi\| \text{ for all } (\omega, \xi) \in \mathcal{D}. \tag{2.16}$$

For future use, we set the notation $\varphi^s_\omega = P^s_\omega \varphi_\omega$ and $\varphi^u_\omega = P^u_\omega \varphi_\omega$. Given $\varphi \in \mathfrak{D}_N$ and $\omega \in \Omega$, we denote the *graph* of φ_ω by

$$\Gamma_{\varphi,\omega} = \{(\xi, \varphi_\omega(\xi)) : \xi \in E^c_\omega\} \subseteq X.$$

Defining now

$$d_2(\varphi, \psi) = \sup \left\{ \frac{\|\varphi_\omega(\xi) - \psi_\omega(\xi)\|}{\|\xi\|} : (\omega, \xi) \in \mathcal{D}, \xi \neq 0 \right\} \tag{2.17}$$

it follows that $(\mathfrak{D}_N, d_2)$ and $(\mathfrak{D}^{(B)}_N, d_2)$ are complete metric spaces.

To conclude this section, let $\mathfrak{U}_{M,N} = \mathfrak{C}_M \times \mathfrak{D}_N$ and $\mathfrak{U}^{(B)}_{M,N} = \mathfrak{C}^{(B)}_M \times \mathfrak{D}^{(B)}_N$. Setting

$$d((h, \varphi), (g, \psi)) = d_1(h, g) + d_2(\varphi, \psi),$$

we also have that $(\mathfrak{U}_{M,N}, d)$ and $(\mathfrak{U}^{(B)}_{M,N}, d)$ are complete metric spaces.

3 Invariant manifolds in continuous-time RDS

Throughout this section, we focus on the continuous-time case by considering $\mathbb{T} = \mathbb{R}$. Given a Bochner measurable linear RDS Φ and a map $f \in \mathscr{F}^{(B)}_\alpha$, we define

$$\sigma = \sup_{(t,\omega)\in\mathbb{R}\times\Omega} \frac{1}{\alpha^c_{t,\omega}} \left| \int_0^t \alpha^c_{t-r,\theta^r\omega} \operatorname{Lip}(f_{\theta^r\omega}) \alpha^c_{r,\omega} \, dr \right| \tag{3.1}$$

and

$$\tau = \sup_{\omega\in\Omega} \int_{-\infty}^0 \alpha^s_{-r,\theta^r\omega} \operatorname{Lip}(f_{\theta^r\omega}) \alpha^c_{r,\omega} \, dr + \int_0^{+\infty} \alpha^u_{-r,\theta^r\omega} \operatorname{Lip}(f_{\theta^r\omega}) \alpha^c_{r,\omega} \, dr. \tag{3.2}$$

If for every $(\omega, x) \in \Omega \times X$ there is a unique solution $\Psi(\cdot, \omega, x)$ of the equation

$$u(t) = \Phi^t_\omega x + \int_0^t \Phi^{t-r}_{\theta^r\omega} f_{\theta^r\omega}(u(r)) \, dr \tag{3.3}$$

then $\Psi \colon \mathbb{R} \times \Omega \times X \to X$ is a Bochner measurable RDS on X over Σ. In particular, $\Psi(\cdot, \cdot, x)$ is Bochner measurable for all $x \in X$, and

$$\Psi^t_\omega x = \Phi^t_\omega x + \int_0^t \Phi^{t-r}_{\theta^r\omega} f_{\theta^r\omega}(\Psi^r_\omega x) \, dr. \tag{3.4}$$

Theorem 3.1. *Let Φ be a Bochner measurable linear RDS exhibiting an α-trichotomy, and let $f \in \mathscr{F}^{(B)}_\alpha$. Suppose that Ψ is a Bochner measurable RDS such that $\Psi(\cdot, \omega, x)$ is the unique solution of (3.3) for all $(\omega, x) \in \Omega \times X$. If*

$$\lim_{t\to-\infty} \alpha^s_{-t,\theta^t\omega} \alpha^c_{t,\omega} = \lim_{t\to+\infty} \alpha^u_{-t,\theta^t\omega} \alpha^c_{t,\omega} = 0 \tag{3.5}$$

for all $\omega \in \Omega$, and

$$\sigma + \tau < 1/2, \tag{3.6}$$

then there are $N \in]0,1[$ *and a unique* $\varphi \in \mathfrak{D}_N^{(B)}$ *such that*

$$\Psi_\omega^t(\Gamma_{\varphi,\omega}) \subseteq \Gamma_{\varphi,\theta^t\omega} \tag{3.7}$$

for all $(t,\omega) \in \mathbb{R} \times \Omega$. *Moreover, for all* $(t,\omega,\xi), (t,\omega,\xi') \in \mathcal{C}$ *we have*

$$\|\Psi_\omega^t(\xi, \varphi_\omega(\xi)) - \Psi_\omega^t(\xi', \varphi_\omega(\xi'))\| \leqslant (N/\tau)\alpha_{t,\omega}^c \|\xi - \xi'\|. \tag{3.8}$$

The remaining part of this section is devoted to proving Theorem 3.1.

From [15, Lemma 5.1], we may find constants $M \in]1,2[$ and $N \in]0,1[$ such that

$$\sigma = \frac{M-1}{M(1+N)} \quad \text{and} \quad \tau = \frac{N}{M(1+N)}. \tag{3.9}$$

Lemma 3.2. *Consider* $(h,\varphi) \in \mathfrak{U}_{M,N}^{(B)}$.

a) For every $x \in X$ *the maps*

$$\begin{aligned}
&(t,r,\omega) \mapsto \Phi_{\theta^r\omega}^{c,t-r} f_{\theta^r\omega}(h_{r,\omega}(P_\omega^c x), \varphi_{\theta^r\omega}(h_{r,\omega}(P_\omega^c x))),\\
&(r,\omega) \mapsto \Phi_{\theta^r\omega}^{s,-r} f_{\theta^r\omega}(h_{r,\omega}(P_\omega^c x), \varphi_{\theta^r\omega}(h_{r,\omega}(P_\omega^c x))),\\
&(r,\omega) \mapsto \Phi_{\theta^r\omega}^{u,-r} f_{\theta^r\omega}(h_{r,\omega}(P_\omega^c x), \varphi_{\theta^r\omega}(h_{r,\omega}(P_\omega^c x)))
\end{aligned}$$

are Bochner measurable on $\mathbb{R} \times \mathbb{R} \times \Omega$, $\mathbb{R}^- \times \Omega$ *and* $\mathbb{R}^+ \times \Omega$, *respectively.*

b) For every $(t,\omega,x) \in \mathbb{R} \times \Omega \times X$ *the map*

$$r \mapsto \Phi_{\theta^r\omega}^{c,t-r} f_{\theta^r\omega}(h_{r,\omega}(P_\omega^c x), \varphi_{\theta^r\omega}(h_{r,\omega}(P_\omega^c x)))$$

is Bochner integrable in every closed interval with bounds 0 *and* t.

c) For every $(\omega,x) \in \Omega \times X$ *and* $t > 0$, *the maps*

$$\begin{aligned}
&r \mapsto \Phi_{\theta^r\omega}^{s,-r} f_{\theta^r\omega}(h_{r,\omega}(P_\omega^c x), \varphi_{\theta^r\omega}(h_{r,\omega}(P_\omega^c x))),\\
&r \mapsto \Phi_{\theta^r\omega}^{u,-r} f_{\theta^r\omega}(h_{r,\omega}(P_\omega^c x), \varphi_{\theta^r\omega}(h_{r,\omega}(P_\omega^c x)))
\end{aligned}$$

are Bochner integrable in $[-t,0]$ *and* $[0,t]$, *respectively.*

The proof follows similarly as [16, Lemma 3.6]. Given $\omega \in \Omega$ and $x_\omega = (x_\omega^c, x_\omega^s, x_\omega^u) \in E_\omega^c \times E_\omega^s \times E_\omega^u$, it follows from (3.4) that the trajectory $x_{\theta^t\omega} = \Psi_\omega^t x_\omega = \left(x_{\theta^t\omega}^c, x_{\theta^t\omega}^s, x_{\theta^t\omega}^u\right)$ satisfies, for all $i \in \{c,s,u\}$ and all $t \in \mathbb{R}$,

$$x_{\theta^t\omega}^i = \Phi_\omega^{i,t} x_\omega + \int_0^t \Phi_{\theta^s\omega}^{i,t-s} f_{\theta^s\omega}(x_{\theta^s\omega}^c, x_{\theta^s\omega}^s, x_{\theta^s\omega}^u)\, ds. \tag{3.10}$$

Taking into account the invariance required in (3.7), for any given $x_\omega \in \Gamma_{\varphi,\omega}$ and $t \in \mathbb{R}$ we must have $x_{\theta^t\omega} \in \Gamma_{\varphi,\theta^t\omega}$. Thus, in this situation, the equations given by (3.10) can be written as

$$\begin{aligned}
x_{\theta^t\omega}^c &= \Phi_\omega^{c,t} x_\omega + \int_0^t \Phi_{\theta^s\omega}^{c,t-s} f_{\theta^s\omega}(x_{\theta^s\omega}^c, \varphi_{\theta^s\omega}(x_{\theta^s\omega}^c))\, ds,\\
\varphi_{\theta^t\omega}^s(x_{\theta^t\omega}) &= \Phi_\omega^t \varphi_\omega^s(x_\omega^c) + \int_0^t \Phi_{\theta^s\omega}^{s,t-s} f_{\theta^s\omega}(x_{\theta^s\omega}^c, \varphi_{\theta^s\omega}(x_{\theta^s\omega}^c))\, ds,\\
\varphi_{\theta^t\omega}^u(x_{\theta^t\omega}) &= \Phi_\omega^t \varphi_\omega^u(x_\omega^c) + \int_0^t \Phi_{\theta^s\omega}^{u,t-s} f_{\theta^s\omega}(x_{\theta^s\omega}^c, \varphi_{\theta^s\omega}(x_{\theta^s\omega}^c))\, ds.
\end{aligned}$$

Lemma 3.3. *Consider* $(h,\varphi) \in \mathfrak{U}^{(B)}_{M,N}$ *such that, for all* $(t,\omega,\xi) \in \mathcal{C}$,

$$h_{t,\omega}(x) = \Phi^t_\omega \xi + \int_0^t \Phi^{c,t-r}_{\theta^r\omega} f_{\theta^r\omega}(h_{r,\omega}(\xi)\,,\varphi_{\theta^r\omega}(h_{r,\omega}(\xi)))\;dr. \tag{3.11}$$

The following properties a) and b) are equivalent:

a) For each $j \in \{s,u\}$ *and all* $(t,\omega,\xi) \in \mathcal{C}$,

$$\varphi^j_{\theta^t\omega}(h_{t,\omega}(\xi)) = \Phi^t_\omega \varphi^j_\omega(\xi) + \int_0^t \Phi^{j,t-r}_{\theta^r\omega} f_{\theta^r\omega}(h_{r,\omega}(\xi)\,,\varphi_{\theta^r\omega}(h_{r,\omega}(\xi)))\;dr \tag{3.12}$$

b) For all $(\omega,\xi) \in \mathcal{D}$

$$\varphi^s_\omega(\xi) = \int_{-\infty}^0 \Phi^{s,-r}_{\theta^r\omega} f_{\theta^r\omega}(h_{r,\omega}(\xi)\,,\varphi_{\theta^r\omega}(h_{r,\omega}(\xi)))\;dr \tag{3.13}$$

and

$$\varphi^u_\omega(\xi) = -\int_0^{+\infty} \Phi^{u,-r}_{\theta^r\omega} f_{\theta^r\omega}(h_{r,\omega}(\xi)\,,\varphi_{\theta^r\omega}(h_{r,\omega}(\xi)))\;dr. \tag{3.14}$$

Proof. From (2.4), (2.16) and (2.10) we have

$$\begin{aligned}\|f_{\theta^r\omega}(h_{r,\omega}(\xi),\varphi_{\theta^r\omega}(h_{r,\omega}(\xi)))\| &\leqslant \operatorname{Lip}(f_{\theta^r\omega})(\|h_{r,\omega}(\xi)\| + \|\varphi_{\theta^r\omega}(h_{r,\omega}(\xi))\|)\\ &\leqslant M(1+N)\operatorname{Lip}(f_{\theta^r\omega})\alpha^c_{r,\omega}\|\xi\|\end{aligned}$$

for every $(\omega,\xi) \in \mathcal{D}$. Thus, by (T2),

$$\int_{-\infty}^0 \left\|\Phi^{s,-r}_{\theta^r\omega} f_{\theta^r\omega}(h_{r,\omega}(\xi)\,,\varphi_{\theta^r\omega}(h_{r,\omega}(\xi)))\right\|\;dr \leqslant M(1+N)\tau\|\xi\|,$$

and by (T3) we obtain

$$\int_0^{+\infty} \left\|\Phi^{u,-r}_{\theta^r\omega} f_{\theta^r\omega}(h_{r,\omega}(\xi)\,,\varphi_{\theta^r\omega}(h_{r,\omega}(\xi)))\right\|\;dr \leqslant M(1+N)\tau\|\xi\|.$$

Hence the integrals are convergent.

Suppose that (3.12) holds for $j = s$ and all $(t,\omega,\xi) \in \mathcal{C}$. By applying $\Phi^{-t}_{\theta^t\omega}$ to both sides, it is equivalent to

$$\varphi^s_\omega(\xi) = \Phi^{s,-t}_{\theta^t\omega}\varphi^s_{\theta^t\omega}(h_{t,\omega}(\xi)) - \int_0^t \Phi^{s,-r}_{\theta^r\omega} f_{\theta^r\omega}(h_{r,\omega}(\xi)\,,\varphi_{\theta^r\omega}(h_{r,\omega}(\xi)))\;dr. \tag{3.15}$$

Using (T2), (2.16) and (2.10), for $t \leqslant 0$ we have

$$\left\|\Phi^{s,-t}_{\theta^t\omega}\varphi^s_{\theta^t\omega}(h_{t,\omega}(\xi))\right\| \leqslant MN\alpha^s_{-t,\theta^t\omega}\,\alpha^c_{t,\omega}\|\xi\|,$$

which converges to zero as $t \to -\infty$ by (3.5). Thus, by taking $t \to -\infty$ in equation (3.15) we obtain (3.13). Similarly, equation (3.12) with $j = u$ can be written as

$$\varphi^u_\omega(\xi) = \Phi^{u,-t}_{\theta^t\omega}\varphi_{\theta^t\omega}(h_{t,\omega}(\xi)) - \int_0^t \Phi^{u,-r}_{\theta^r\omega} f_{\theta^r\omega}(h_{r,\omega}(\xi)\,,\varphi_{\theta^r\omega}(h_{r,\omega}(\xi)))\;dr. \tag{3.16}$$

Using (T3), (2.16) and (2.10), for $t \geqslant 0$ we have

$$\left\|\Phi^{u,-t}_{\theta^t\omega}\varphi_{\theta^t\omega}(h_{t,\omega}(\xi))\right\| \leqslant MN\alpha^u_{-t,\theta^t\omega}\alpha^c_{t,\omega}\,\|\xi\|\,,$$

which, by (3.5), converges to zero as $t \to +\infty$. Thus, we obtain (3.14) by taking $t \to +\infty$ in equation (3.16).

For the converse, assume now that (3.13) and (3.14) hold for all $(\omega, \xi) \in \mathcal{D}$. For all $t \in \mathbb{R}$, we have

$$\begin{aligned}\Phi^t_\omega \varphi^s_\omega(\xi) = &\int_t^0 \Phi^{s,t-r}_{\theta^r\omega} f_{\theta^r\omega}(h_{r,\omega}(\xi), \varphi_{\theta^r\omega}(h_{r,\omega}(\xi)))\, dr \\ &+ \int_{-\infty}^0 \Phi^{s,-r}_{\theta^{t+r}\omega} f_{\theta^{t+r}\omega}(h_{t+r,\omega}(\xi), \varphi_{\theta^{t+r}\omega}(h_{t+r,\omega}(\xi)))\, dr\end{aligned}$$

and

$$\begin{aligned}\Phi^t_\omega \varphi^u_\omega(\xi) = &-\int_0^t \Phi^{u,t-r}_{\theta^r\omega} f_{\theta^r\omega}(h_{r,\omega}(\xi), \varphi_{\theta^r\omega}(h_{r,\omega}(\xi)))\, dr \\ &- \int_{-\infty}^0 \Phi^{u,-r}_{\theta^{t+r}\omega} f_{\theta^{t+r}\omega}(h_{t+r,\omega}(\xi), \varphi_{\theta^{t+r}\omega}(h_{t+r,\omega}(\xi)))\, dr.\end{aligned}$$

Since $h_{t+s,\omega}(\xi) = h_{s,\theta^t\omega}(h_{t,\omega}(\xi))$ due to the uniqueness of the solution of (3.3), we get the identity (3.12) for $j = s$ and $j = u$. □

Consider the operator C, which assigns each pair $(h, \varphi) \in \mathfrak{U}^{(B)}_{M,N}$ to the map $C(h, \varphi) \colon \mathcal{C} \to X$ given by

$$[C(h,\varphi)]\,(t,\omega,\xi) = \Phi^t_\omega \xi + \int_0^t \Phi^{c,t-r}_{\theta^r\omega} \varphi(r,\omega)\, dr.$$

Lemma 3.4. $C(\mathfrak{U}^{(B)}_{M,N}) \subseteq \mathfrak{C}^{(B)}_M$.

Proof. Fix a pair $(h, \varphi) \in \mathfrak{U}^{(B)}_{M,N}$. It is straightforward to check that $C(h, \varphi)$ satisfies conditions (2.5) to (2.8). Define

$$\gamma_{\theta^r\omega}(\xi, \xi') = \|f_{\theta^r\omega}(h_{r,\omega}(\xi), \varphi_{\theta^r\omega}(h_{r,\omega}(\xi))) - f_{\theta^r\omega}(h_{r,\omega}(\xi'), \varphi_{\theta^r\omega}(h_{r,\omega}(\xi')))\|.$$

From (2.3), (2.15) and (2.9) we have

$$\gamma_{\theta^r\omega}(\xi, \xi') \leqslant \mathrm{Lip}(f_{\theta^r\omega}) M(1+N) \|\xi - \xi'\| \alpha^c_{r,\omega}. \tag{3.17}$$

Following the previous notation, $C(h, \varphi)_{t,\omega}(\xi)$ stands for $[C(h, \varphi)](t, \omega, \xi)$. By (T1), (3.1), (3.17) and (3.9), we have

$$\begin{aligned}\|C(h,\varphi)_{t,\omega}(\xi) - C(h,\varphi)_{t,\omega}(\xi')\| &\leqslant \|\Phi^{c,t}_\omega\| \|\xi - \xi'\| + \int_0^t \|\Phi^{c,t-r}_{\theta^r\omega}\| \gamma_{\theta^r\omega}(\xi,\xi')\, dr \\ &\leqslant (1 + \sigma M(1+N))\, \alpha^c_{t,\omega} \|\xi - \xi'\| \\ &= M \alpha^c_{t,\omega} \|\xi - \xi'\|.\end{aligned}$$

Hence $C(h, \varphi)$ also satisfies (2.9). □

Consider now the operator D, which assigns each pair $(h, \varphi) \in \mathfrak{U}^{(B)}_{M,N}$ the map

$$D(h, \varphi) \colon \mathcal{D} \to X$$

given by

$$[D(h,\varphi)]\,(\omega,\xi) = [D^s(h,\varphi)]\,(\omega,\xi) + [D^u(h,\varphi)]\,(\omega,\xi)$$

where

$$[D^s(h,\varphi)](\omega,\xi) = \int_{-\infty}^{0} \Phi^{s,-r}_{\theta^r\omega} f_{\theta^r\omega}(h_{r,\omega}(\xi), \varphi_{\theta^r\omega}(h_{r,\omega}(\xi)))\, dr$$

and

$$[D^u(h,\varphi)](\omega,\xi) = -\int_{0}^{+\infty} \Phi^{u,-r}_{\theta^r\omega} f_{\theta^r\omega}(h_{r,\omega}(\xi), \varphi_{\theta^r\omega}(h_{r,\omega}(\xi)))\, dr.$$

Lemma 3.5. $D(\mathfrak{U}^{(B)}_{M,N}) \subseteq \mathfrak{D}^{(B)}_N$.

Proof. Fix $(h,\varphi) \in \mathfrak{U}^{(B)}_{M,N}$. It is immediate to check that $[D(h,\varphi)](\omega,\xi)$ satisfies conditions (2.12) to (2.14). Again, $D(h,\varphi)_\omega(\xi)$ stands for $[D(h,\varphi)](\omega,\xi)$. From (T2), (T3), (3.17), (3.2) and (3.9) we have

$$\begin{aligned}\|D(h,\varphi)_\omega(\xi) - D(h,\varphi)_\omega(\xi')\| &\leqslant \int_{-\infty}^{0} \|\Phi^{s,-r}_{\theta^r\omega}\|\, \gamma_{\theta^r\omega}(\xi,\xi')\, dr + \int_{0}^{+\infty} \|\Phi^{u,-r}_{\theta^r\omega}\|\, \gamma_{\theta^r\omega}(\xi,\xi')\, dr \\ &\leqslant \tau M(1+N)\,\|\xi-\xi'\| \\ &= N\,\|\xi-\xi'\|.\end{aligned}$$

Hence (2.15) also holds for $D(h,\varphi)$. □

Consider now $U\colon \mathfrak{U}^{(B)}_{M,N} \to \mathfrak{U}^{(B)}_{M,N}$ given by

$$U(h,\varphi) = (C(h,\varphi), D(h,\varphi)).$$

Lemma 3.6. *The operator U is a contraction in $(\mathfrak{U}^{(B)}_{M,N}, d)$.*

Proof. Consider $(h,\varphi), (g,\psi) \in \mathfrak{U}^{(B)}_{M,N}$. Define

$$\hat{\gamma}_{\theta^r\omega}(\xi) = \|f_{\theta^r\omega}(h_{r,\omega}(\xi), \varphi_{\theta^r\omega}(h_{r,\omega}(\xi))) - f_{\theta^r\omega}(g_{r,\omega}(\xi), \psi_{\theta^r\omega}(g_{r,\omega}(\xi)))\|.$$

By (2.3), (2.15), (2.11), (2.17) and (2.10), for all $(r,\omega) \in \mathbb{R}^+_0 \times \Omega$ and all $\xi \in E_\omega$,

$$\hat{\gamma}_{\theta^r\omega}(\xi) \leqslant \mathrm{Lip}(f_{\theta^r\omega})\alpha^c_{r,\omega}((1+N)d_1(h,g) + Md_2(\varphi,\psi))\,\|\xi\|. \tag{3.18}$$

Hence, in one hand, from (T1), (3.18) and (3.1), we have

$$\begin{aligned}\|C(h,\varphi)_{t,\omega}(\xi) - C(g,\psi)_{t,\omega}(\xi)\| &\leqslant \int_0^t \left\|\Phi^{c,t-r}_{\theta^r\omega}\right\| \hat{\gamma}_{\theta^r\omega}(\xi)\, dr \\ &\leqslant \sigma\alpha^c_{t,\omega}((1+N)d_1(h,g) + Md_2(\varphi,\psi))\,\|\xi\|,\end{aligned}$$

which implies

$$d_1(C(h,\varphi), C(g,\psi)) \leqslant \sigma((1+N)d_1(h,g) + Md_2(\varphi,\psi)).$$

On the other hand, from (T2), (T3), (3.18) and (3.2) we get

$$\begin{aligned}\|D(h,\varphi)_\omega(\xi) - D(g,\psi)_\omega(\xi)\| &\leqslant \int_{-\infty}^{0} \|\Phi^{s,-r}_{\theta^r\omega}\|\, \hat{\gamma}_{\theta^r\omega}(\xi)\, dr + \int_0^{+\infty} \|\Phi^{u,-r}_{\theta^r\omega}\|\, \hat{\gamma}_{\theta^r\omega}(\xi)\, dr \\ &\leqslant \tau((1+N)d_1(h,g) + Md_2(\varphi,\psi))\,\|\xi\|,\end{aligned}$$

which implies

$$d_2(D(h,\varphi), D(g,\psi)) \leqslant \tau((1+N)d_1(h,g) + Md_2(\varphi,\psi)).$$

In overall we get

$$\begin{aligned} d(U(h,\varphi),U(g,\psi)) &\leqslant (\sigma+\tau)((1+N)d_1(h,g)+Md_2(\varphi,\psi)) \\ &\leqslant \frac{1}{2}\max\{1+N,M\}\, d((h,\varphi),(g,\psi)) \end{aligned}$$

and because $N<1$ and $M<2$, U is a contraction. □

Proof of Theorem 3.1. Since U is a contraction, by the Banach Fixed Point Theorem, U has a unique fixed point (h,φ), that satisfies (3.11), (3.13) and (3.14). By Lemma 3.3, the pair (h,φ) also satisfies conditions (3.12). Therefore, for given initial condition $x_\omega = (\xi, \varphi^s_\omega(\xi), \varphi^u_\omega(\xi)) \in E^c_\omega \times E^s_\omega \times E^u_\omega$, the trajectory $x_{\theta^t\omega} = (h_{t,\omega}(\xi), \varphi_{\theta^t\omega}(h_{t,\omega}(\xi)))$ is the solution of (3.3). The graphs $\Gamma_{\varphi,\omega}$ are the required invariant manifolds of Ψ. To obtain (3.8), it follows from (2.15), (2.9) and (3.9) that, for each $(t,\omega,\xi),(t,\omega,\xi') \in \mathcal{C}$

$$\begin{aligned} &\|\Psi^t_\omega(\xi,\varphi^s_\omega(\xi),\varphi^u_\omega(\xi)) - \Psi^t_\omega(\xi',\varphi^s_\omega(\xi'),\varphi^u_\omega(\xi'))\| \\ &\quad = \|(h_{t,\omega}(\xi),\varphi_{\theta^t\omega}(h_{t,\omega}(\xi))) - (h_{t,\omega}(\xi'),\varphi_{\theta^t\omega}(h_{t,\omega}(\xi')))\| \\ &\quad \leqslant M(1+N)\alpha^c_{t,\omega}\|\xi-\bar{\xi}\| \\ &\quad \leqslant \frac{N}{\tau}\alpha^c_{t,\omega}\|\xi-\bar{\xi}\|. \end{aligned}$$

□

4 Invariant manifolds in discrete-time RDS

Throughout this section we consider $\mathbb{T}=\mathbb{Z}$. Given a measurable linear RDS Φ and a map $f\in\mathscr{F}$, we define

$$\begin{aligned} \sigma^-_\omega &= \sup_{n\in\mathbb{N}} \frac{1}{\alpha^c_{-n,\omega}} \sum_{k=-n}^{-1} \alpha^c_{-n-k-1,\theta^{k+1}\omega}\operatorname{Lip}(f_{\theta^k\omega})\alpha^c_{k,\omega}, \\ \sigma^+_\omega &= \sup_{n\in\mathbb{N}} \frac{1}{\alpha^c_{n,\omega}} \sum_{k=0}^{n-1} \alpha^c_{n-k-1,\theta^{k+1}\omega}\operatorname{Lip}(f_{\theta^k\omega})\alpha^c_{k,\omega} \end{aligned}$$

and

$$\sigma = \sup_{\omega\in\Omega}\max\{\sigma^-_\omega,\sigma^+_\omega\}.$$

Moreover, writing

$$\begin{aligned} \tau^-_\omega &= \sum_{k=-\infty}^{-1} \alpha^s_{-k-1,\theta^{k+1}\omega}\operatorname{Lip}(f_{\theta^k\omega})\alpha^c_{k,\omega}, \\ \tau^+_\omega &= \sum_{k=0}^{+\infty} \alpha^u_{-k-1,\theta^{k+1}\omega}\operatorname{Lip}(f_{\theta^k\omega})\alpha^c_{k,\omega}, \end{aligned}$$

we also define

$$\tau = \sup_{\omega\in\Omega}(\tau^-_\omega+\tau^+_\omega).$$

Consider the measurable RDS $\Psi\colon \mathbb{Z}\times\Omega\times X\to X$ given by

$$\Psi^n_\omega(x) = \begin{cases} \Phi^n_\omega x + \sum_{k=0}^{n-1} \Phi^{n-k-1}_{\theta^{k+1}\omega} f_{\theta^k\omega}(\Psi^k_\omega(x)) & \text{if } n\geqslant 1, \\ x & \text{if } n=0, \\ \Phi^n_\omega x - \sum_{k=n}^{-1} \Phi^{n-k-1}_{\theta^{k+1}\omega} f_{\theta^k\omega}(\Psi^k_\omega(x)) & \text{if } n\leqslant -1 \end{cases} \tag{4.1}$$

which encapsulates the solutions of the random nonlinear difference equation

$$x_{n+1} = \Phi^1_{\theta^n\omega} x_n + f_{\theta^n\omega}(x_n).$$

Theorem 4.1. *Let Φ be a measurable linear RDS exhibiting an α-trichotomy and let $f \in \mathscr{F}$. If*

$$\lim_{n\to-\infty} \alpha^s_{-n,\theta^n\omega}\alpha^c_{n,\omega} = \lim_{n\to+\infty} \alpha^u_{-n,\theta^n\omega}\alpha^c_{n,\omega} = 0$$

for all $\omega \in \Omega$, and

$$\sigma + \tau < 1/2,$$

then there are $N \in]0,1[$ and a unique $\varphi \in \mathfrak{D}_N$ such that for the RDS Ψ given by (4.1) we have

$$\Psi^n_\omega(\Gamma_{\varphi,\omega}) \subseteq \Gamma_{\varphi,\theta^n\omega} \tag{4.2}$$

for all $(n,\omega) \in \mathbb{Z} \times \Omega$. Moreover, for every $(n,\omega,\xi), (n,\omega,\xi') \in \mathcal{C}$ we have

$$\|\Psi^n_\omega(\xi, \varphi_\omega(\xi)) - \Psi^n_\omega(\xi', \varphi_\omega(\xi'))\| \leqslant (N/\tau)\alpha^c_{n,\omega} \|\xi - \xi'\|.$$

The proof of Theorem 4.1 is analogous to the proof of Theorem 3.1. Therefore, in the remainder of this section, we provide a guide to the necessary adaptations. Fix M and N as in (3.9). Given $\omega \in \Omega$ and

$$x_\omega = (x^c_\omega, x^s_\omega, x^u_\omega) \in E^c_\omega \times E^s_\omega \times E^u_\omega,$$

the trajectory

$$x_{\theta^n\omega} = \Psi^n_\omega x_\omega = (x^c_{\theta^n\omega}, x^s_{\theta^n\omega}, x^u_{\theta^n\omega}) \in E^c_\omega \times E^s_\omega \times E^u_\omega$$

satisfies the following equations for each $i \in \{c, s, u\}$:

$$x^i_{\theta^n\omega} = \begin{cases} \Phi^{i,n}_\omega x^i_\omega + \sum_{k=0}^{n-1} \Phi^{i,n-k-1}_{\theta^{k+1}\omega} f_{\theta^k\omega}(x^c_{\theta^k\omega}, x^s_{\theta^k\omega}, x^u_{\theta^k\omega}) & \text{if } n \geqslant 1, \\ \Phi^{i,n}_\omega x^i_\omega - \sum_{k=n}^{-1} \Phi^{i,n-k-1}_{\theta^{k+1}\omega} f_{\theta^k\omega}(x^c_{\theta^k\omega}, x^s_{\theta^k\omega}, x^u_{\theta^k\omega}) & \text{if } n \leqslant -1. \end{cases} \tag{4.3}$$

In view of the invariance required in (4.2), if $x_\omega \in \Gamma_{\varphi,\omega}$ then $x_{\theta^n\omega}$ must be in $\Gamma_{\varphi,\theta^n\omega}$ for every $n \in \mathbb{Z}$, and thus, in this situation, the equations from (4.3) can be written as

$$x^c_{\theta^n\omega} = \begin{cases} \Phi^{c,n}_\omega x^c_\omega + \sum_{k=0}^{n-1} \Phi^{c,n-k-1}_{\theta^{k+1}\omega} f_{\theta^k\omega}(x^c_{\theta^k\omega}, \varphi_{\theta^k\omega}(x^c_{\theta^k\omega})) & \text{if } n \geqslant 1, \\ \Phi^{c,n}_\omega x^c_\omega - \sum_{k=n}^{-1} \Phi^{c,n-k-1}_{\theta^{k+1}\omega} f_{\theta^k\omega}(x^c_{\theta^k\omega}, \varphi_{\theta^k\omega}(x^c_{\theta^k\omega})) & \text{if } n \leqslant -1 \end{cases} \tag{4.4}$$

and, for $j \in \{s, u\}$,

$$\varphi^j_{\theta^n\omega}(x_{\theta^n\omega}) = \begin{cases} \Phi^{j,n}_\omega \varphi_\omega(x_\omega) + \sum_{k=0}^{n-1} \Phi^{j,n-k-1}_{\theta^{k+1}\omega} f_{\theta^k\omega}(x^c_{\theta^k\omega}, \varphi_{\theta^k\omega}(x^c_{\theta^k\omega})) & \text{if } n \geqslant 1, \\ \Phi^{j,n}_\omega \varphi_\omega(x_\omega) - \sum_{k=n}^{-1} \Phi^{j,n-k-1}_{\theta^{k+1}\omega} f_{\theta^k\omega}(x^c_{\theta^k\omega}, \varphi_{\theta^k\omega}(x^c_{\theta^k\omega})) & \text{if } n \leqslant -1. \end{cases} \tag{4.5}$$

Let us prove prove that equations (4.4) and (4.5) have solutions. First, we rewrite them, by a discrete version of Lemma 3.3.

Lemma 4.2. *Consider* $(h,\varphi) \in \mathfrak{U}_{M,N}$ *such that, for all* $(n,\omega) \in \mathbb{Z} \times \Omega$ *and all* $\xi \in E^c_\omega$

$$h_{n,\omega}(\xi) = \begin{cases} \Phi^{c,n}_\omega \xi + \sum_{k=0}^{n-1} \Phi^{c,n-k-1}_{\theta^{k+1}\omega} f_{\theta^k\omega}(h_{k,\omega}(\xi), \varphi_{\theta^k\omega}(h_{k,\omega}(\xi))) & \text{if } n \geqslant 1, \\ \Phi^{c,n}_\omega \xi - \sum_{k=n}^{-1} \Phi^{c,n-k-1}_{\theta^{k+1}\omega} f_{\theta^k\omega}(h_{k,\omega}(\xi), \varphi_{\theta^k\omega}(h_{k,\omega}(\xi))) & \text{if } n \leqslant -1. \end{cases} \tag{4.6}$$

Then the following conditions a) and b) are equivalent:

a) For each $j \in \{u,s\}$ *and all* $(n,\omega,\xi) \in \mathcal{C}$

$$\varphi^j_{\theta^n\omega}(h_{n,\omega}(\xi)) = \begin{cases} \Phi^{j,n}_\omega \varphi_\omega(\xi) + \sum_{k=0}^{n-1} \Phi^{j,n-k-1}_{\theta^{k+1}\omega} f_{\theta^k\omega}(h_{k,\omega}(\xi), \varphi_{\theta^k\omega}(h_{k,\omega}(\xi))) & \text{if } n \geqslant 1, \\ \Phi^{j,n}_\omega \varphi_\omega(\xi) - \sum_{k=n}^{-1} \Phi^{j,n-k-1}_{\theta^{k+1}\omega} f_{\theta^k\omega}(h_{k,\omega}(\xi), \varphi_{\theta^k\omega}(h_{k,\omega}(\xi))) & \text{if } n \leqslant -1. \end{cases} \tag{4.7}$$

b) For all $(\omega,\xi) \in \mathcal{D}$

$$\varphi^s_\omega(\xi) = \sum_{k=-\infty}^{-1} \Phi^{s,-(k+1)}_{\theta^{k+1}\omega} f_{\theta^k\omega}(h_{k,\omega}(\xi), \varphi_{\theta^k\omega}(h_{k,\omega}(\xi))) \tag{4.8}$$

and

$$\varphi^u_\omega(\xi) = -\sum_{k=0}^{+\infty} \Phi^{u,-(k+1)}_{\theta^{k+1}\omega} f_{\theta^k\omega}(h_{k,\omega}(\xi), \varphi_{\theta^k\omega}(h_{k,\omega}(\xi))). \tag{4.9}$$

Consider here the operator C, which assigns each pair $(h,\varphi) \in \mathfrak{U}^{(B)}_{M,N}$ to the map

$$C(h,\varphi) \colon \mathcal{C} \to X$$

given by

$$[C(h,\varphi)]\,(n,\omega,\xi) = \begin{cases} \Phi^{c,n}_\omega \xi + \sum_{k=0}^{n-1} \Phi^{c,n-k-1}_{\theta^{k+1}\omega} f_{\theta^k\omega}(h_{k,\omega}(\xi), \varphi_{\theta^k\omega}(h_{k,\omega}(\xi))) & \text{if } n \geqslant 1, \\ \Phi^{c,n}_\omega \xi - \sum_{k=n}^{-1} \Phi^{c,n-k-1}_{\theta^{k+1}\omega} f_{\theta^k\omega}(h_{k,\omega}(\xi), \varphi_{\theta^k\omega}(h_{k,\omega}(\xi))) & \text{if } n \leqslant -1, \end{cases}$$

and D be the operator that assigns to each pair $(h,\varphi) \in \mathfrak{U}_{M,N}$ the map $D(h,\varphi) \colon \mathcal{D} \to X$ defined by

$$[D(h,\varphi)]\,(\omega,\xi) = [D^s(h,\varphi)]\,(\omega,\xi) + [D^u(h,\varphi)]\,(\omega,\xi),$$

where

$$[D^s(h,\varphi)]\,(\omega,\xi) = \sum_{k=-\infty}^{-1} \Phi^{s,-(k+1)}_{\theta^{k+1}\omega} f_{\theta^k\omega}(h_{k,\omega}(\xi), \varphi_{\theta^k\omega}(h_{k,\omega}(\xi)))$$

and

$$[D^u(h,\varphi)]\,(\omega,\xi) = -\sum_{k=0}^{+\infty} \Phi^{u,-(k+1)}_{\theta^{k+1}\omega} f_{\theta^k\omega}(h_{k,\omega}(\xi), \varphi_{\theta^k\omega}(h_{k,\omega}(\xi))).$$

To finalize, define $U\colon \mathfrak{U}_{M,N} \to \mathfrak{U}_{M,N}$ by

$$U(h,\varphi) = (C(h,\varphi), D(h,\varphi)) .$$

The operator U is a contraction in $(\mathfrak{U}_{M,N}, d)$. By the Banach Fixed Point Theorem, U as a unique fixed point (h,φ), which satisfies conditions (4.6), (4.8) and (4.9). By Lemma 4.2 the pair (h,φ) also satisfy the conditions in (4.7). Hence, by (4.4) and (4.5), we get that $(h_{n,\omega}(\xi), \varphi_{\theta^n\omega}(h_{n,\omega}(\xi)))$ is the orbit by Ψ of the initial condition

$$(\xi, \varphi^s_\omega(\xi), \varphi^u_\omega(\xi)) \in E^c_\omega \times E^s_\omega \times E^u_\omega.$$

The graphs $\Gamma_{\varphi,\omega}$ are the required invariant manifolds of Ψ. Furthermore, for all $\omega \in \Omega$, all $n \in \mathbb{Z}$ and all $\xi, \xi' \in E^c_\omega$ it follows from (2.15), (2.9) and (3.9) that

$$\|\Psi^n_\omega(\xi, \varphi_\omega(\xi)) - \Psi^n_\omega(\xi', \varphi_\omega(\xi'))\| \leqslant \frac{N}{\tau} \alpha^c_{n,\omega} \|\xi - \bar{\xi}\|,$$

which finishes the proof of Theorem 4.1.

5 Continuous-time examples

For this section assume $\mathbb{T} = \mathbb{R}$. Throughout this entire section we consider a constant $\delta \in]0, 1/6[$ and a random variable $G\colon \Omega \to]0, +\infty[$ satisfying

$$\int_{-\infty}^{+\infty} G(\theta^r\omega)\, dr \leqslant 1 \quad \text{for all } \omega \in \Omega.$$

In all the following examples we may consider different growth rates along the *central directions* E^c_ω, depending if we are looking to the *future* ($t \to +\infty$) or to the *past* ($t \to -\infty$).

5.1 Tempered exponential trichotomies

Let

$$\lambda^{\bar{c}}, \lambda^{\underline{c}}, \lambda^s, \lambda^u \colon \Omega \to \mathbb{R}$$

be θ-invariant random variables, i.e. satisfying $\lambda^\ell(\theta^t\omega) = \lambda^\ell(\omega)$ for all $\omega \in \Omega$, $t \in \mathbb{R}$ and $\ell \in \{\bar{c}, \underline{c}, s, u\}$. A Bochner measurable linear RDS Φ exhibits an *exponential trichotomy* if it exhibits a generalized trichotomy with bounds

$$\alpha^c_{t,\omega} = \begin{cases} K(\omega)\, \mathrm{e}^{\lambda^{\bar{c}}(\omega)t}, & t \geqslant 0, \\ K(\omega)\, \mathrm{e}^{\lambda^{\underline{c}}(\omega)t}, & t \leqslant 0, \end{cases}$$
$$\alpha^s_{t,\omega} = K(\omega)\, \mathrm{e}^{\lambda^s(\omega)t}, \quad t \geqslant 0,$$
$$\alpha^u_{t,\omega} = K(\omega)\, \mathrm{e}^{\lambda^u(\omega)t}, \quad t \leqslant 0$$

for some random variable $K : \Omega \to [1, +\infty[$. If the random variable K is *tempered*, *i.e.*, if

$$\Lambda_{K,\gamma,\omega} := \sup_{t \in \mathbb{T}} \left[\mathrm{e}^{-\gamma|t|} K(\theta^t w) \right] < +\infty \tag{5.1}$$

for all $\gamma > 0$ and all $\omega \in \Omega$, we say that Φ exhibits an *tempered exponential trichotomy*.

Corollary 5.1. *Let Φ be a Bochner measurable linear RDS exhibiting a tempered exponential trichotomy such that*

$$\lambda^{\underline{c}}(\omega) > \lambda^{s}(\omega) \quad \text{and} \quad \lambda^{\overline{c}}(\omega) < \lambda^{u}(\omega)$$

for all $\omega \in \Omega$, and let $f \in \mathscr{F}_{\alpha}^{(B)}$. Assume that Ψ is a Bochner measurable RDS such that (3.3) has unique solution $\Psi(\cdot,\omega,x)$ for every $(\omega,x) \in \Omega \times X$. Consider a θ-invariant random variable $\gamma(\omega) > 0$ satisfying

$$a(\omega) := \lambda^{\underline{c}}(\omega) - \lambda^{s}(\omega) - \gamma(\omega) > 0 \quad \text{and} \quad b(\omega) := \lambda^{u}(\omega) - \lambda^{\overline{c}}(\omega) - \gamma(\omega) > 0$$

for all $\omega \in \Omega$. If

$$\operatorname{Lip}(f_\omega) \leqslant \frac{\delta}{K(\omega)} \min\left\{G(\omega), \frac{a(\omega)}{\Lambda_{K,\gamma(\omega),\omega}}, \frac{b(\omega)}{\Lambda_{K,\gamma(\omega),\omega}}\right\}$$

for all $\omega \in \Omega$, then the same conclusions of Theorem 3.1 hold.

Proof. Since K is a tempered random variable, we have

$$\lim_{t\to-\infty} \alpha^{s}_{-t,\theta^t\omega}\alpha^{c}_{t,\omega} = \lim_{t\to-\infty} K(\omega)K(\theta^t\omega)\, \mathrm{e}^{(\lambda^{\underline{c}}(\omega)-\lambda^{s}(\omega))t} \leqslant \lim_{t\to-\infty} K(\omega)\Lambda_{K,a(\omega),\omega}\, \mathrm{e}^{\gamma(\omega)t} = 0$$

and

$$\lim_{t\to+\infty} \alpha^{u}_{-t,\theta^t\omega}\alpha^{c}_{t,\omega} = \lim_{t\to+\infty} K(\omega)K(\theta^t\omega)\, \mathrm{e}^{(\lambda^{\overline{c}}(\omega)-\lambda^{u}(\omega))t} \leqslant \lim_{t\to+\infty} K(\omega)\Lambda_{K,b(\omega),\omega}\, \mathrm{e}^{\gamma(\omega)t} = 0$$

for all $\omega \in \Omega$. Therefore condition (3.5) holds. Let us check (3.6). Indeed, for every $t \geqslant 0$ and every $\omega \in \Omega$ we have

$$\begin{aligned}\frac{1}{\alpha^{c}_{t,\omega}} \int_0^t \alpha^{c}_{t-r,\theta^r\omega} \operatorname{Lip}(f_{\theta^r\omega})\alpha^{c}_{r,\omega}\, dr &= \int_0^t K(\theta^r\omega) \operatorname{Lip}(f_{\theta^r\omega})\, dr \\ &\leqslant \delta \int_{-\infty}^{+\infty} G(\theta^r\omega)\, dr \\ &\leqslant \delta,\end{aligned}$$

and, similarly, for every $t \leqslant 0$ and every $\omega \in \Omega$ we have

$$\frac{1}{\alpha^{c}_{t,\omega}} \int_t^0 \alpha^{c}_{t-r,\theta^r\omega} \operatorname{Lip}(f_{\theta^r\omega})\alpha^{c}_{r,\omega}\, dr \leqslant \delta.$$

Thus, $\sigma \leqslant \delta$. Moreover, since $K(\omega) \leqslant \mathrm{e}^{\gamma(\omega)|r|}\, \Lambda_{K,\gamma(\omega),\theta^r\omega}$ for every $\omega \in \Omega$ and $r \in \mathbb{R}$, we have

$$\begin{aligned}\int_{-\infty}^0 \alpha^{s}_{-r,\theta^r\omega} \operatorname{Lip}(f_{\theta^r\omega})\alpha^{c}_{r,\omega}\, dr &= \int_{-\infty}^0 K(\omega)K(\theta^r\omega)\, \mathrm{e}^{(\lambda^{\underline{c}}(\omega)-\lambda^{s}(\omega))r} \operatorname{Lip}(f_{\theta^r\omega})\, dr \\ &\leqslant \delta \int_{-\infty}^0 a(\omega)\, \mathrm{e}^{a(\omega)r}\, dr \\ &\leqslant \delta.\end{aligned}$$

and

$$\begin{aligned}\int_0^{+\infty} \alpha^{u}_{-r,\theta^r\omega} \operatorname{Lip}(f_{\theta^r\omega})\alpha^{c}_{r,\omega}\, dr &= \int_0^{+\infty} K(\omega)K(\theta^r\omega)\, \mathrm{e}^{(\lambda^{\overline{c}}(\omega)-\lambda^{u}(\omega))r} \operatorname{Lip}(f_{\theta^r\omega})\, dr \\ &\leqslant \delta \int_0^{+\infty} b(\omega)\, \mathrm{e}^{-b(\omega)r}\, dr \\ &\leqslant \delta.\end{aligned}$$

Henceforth, $\sigma + \tau \leqslant 3\delta < 1/2$. □

5.2 ψ-trichotomies

Consider measurable functions

$$\psi^{\bar{c}}, \psi^{\underline{c}}, \psi^{s}, \psi^{u} \colon \mathbb{R} \times \Omega \to]0, +\infty[$$

such that for $\ell \in \{\bar{c}, \underline{c}, s, u\}$ we have

$$\psi^{\ell}(t+s, \omega) = \psi^{\ell}(t, \theta^{s}\omega)\psi^{\ell}(s, \omega) \tag{5.2}$$

for all $t, s \in \mathbb{R}$ and all $\omega \in \Omega$. A *ψ-trichotomy* is a generalized trichotomy with bounds

$$\begin{aligned} \alpha^{c}_{t,\omega} &= \begin{cases} K(\omega)\psi^{\bar{c}}(t,\omega), & t \geqslant 0, \\ K(\omega)\psi^{\underline{c}}(t,\omega), & t \leqslant 0, \end{cases} \\ \alpha^{s}_{t,\omega} &= K(\omega)\psi^{s}(t,\omega), \quad t \geqslant 0, \\ \alpha^{u}_{t,\omega} &= K(\omega)\psi^{u}(t,\omega), \quad t \leqslant 0 \end{aligned}$$

for a random variable $K \colon \Omega \to [1, +\infty[$.

For all $\ell \in \{\underline{c}, \bar{c}, u, s\}$ set

$$d_{\psi^{\ell}}(\omega) = \lim_{h \to 0} \frac{\psi^{\ell}(h, \omega) - 1}{h}. \tag{5.3}$$

Since $\psi^{\ell}(0, \omega) = 1$, from (5.2) we have

$$\frac{d}{dt}\psi^{\ell}(t, \omega) = d_{\psi^{\ell}}(\theta^{t}\omega)\psi^{\ell}(t, \omega)$$

whenever limits (5.3) exist. Moreover, in this situation we also have

$$\frac{d}{dt}\psi^{\ell}(-t, \theta^{t}\omega) = \frac{d}{dt}\frac{1}{\psi^{\ell}(t, \omega)} = -d_{\psi^{\ell}}(\theta^{t}\omega)\psi^{\ell}(-t, \theta^{t}\omega).$$

From now on we also assume that for all $\omega \in \Omega$ the following limit exists:

$$d_{K}(\omega) = \lim_{h \to 0} \frac{K(\theta^{h}\omega) - K(\omega)}{h}. \tag{5.4}$$

We notice that for all $t \in \mathbb{R}$, $\frac{d}{dt}K(\theta^{t}\omega) = d_{K}(\theta^{t}\omega)$.

Corollary 5.2. *Let Φ be a Bochner measurable linear RDS exhibiting a ψ-trichotomy such that the limits in* (5.3) *and* (5.4) *exist and satisfy*

$$d_{\psi^{\bar{c}}}(\omega) - d_{\psi^{u}}(\omega) < \frac{d_{K}(\omega)}{K(\omega)} < d_{\psi^{\underline{c}}}(\omega) - d_{\psi^{s}}(\omega)$$

for all $\omega \in \Omega$. Let $f \in \mathscr{F}^{(B)}_{\alpha}$ be such that

$$\operatorname{Lip}(f_{\omega}) \leqslant \frac{\delta}{K(\omega)} \min\left\{G(\omega), \frac{a(\omega)}{K(\omega)}, \frac{b(\omega)}{K(\omega)}\right\}$$

for all $\omega \in \Omega$, where

$$a(\omega) = \frac{d_{K}(\omega)}{K(\omega)} - d_{\psi^{\bar{c}}}(\omega) + d_{\psi^{u}}(\omega) \quad \text{and} \quad b(\omega) = -\frac{d_{K}(\omega)}{K(\omega)} + d_{\psi^{\underline{c}}}(\omega) - d_{\psi^{s}}(\omega).$$

Assume that Ψ is a Bochner measurable RDS such that (3.3) *has unique solution $\Psi(\cdot,\omega,x)$ for every $\omega \in \Omega$ and every $x \in X$. If, for all $\omega \in \Omega$,*

$$\lim_{t\to-\infty} K(\theta^t\omega)\psi^s(-t,\theta^t\omega)\psi^{\underline{c}}(t,\omega) = \lim_{t\to+\infty} K(\theta^t\omega)\psi^u(-t,\theta^t\omega)\psi^{\overline{c}}(t,\omega) = 0 \tag{5.5}$$

then the same conclusions of Theorem 3.1 hold.

Proof. Conditions in (5.5) are equivalent to those in (3.5), and, as in the proof of Corollary 5.1 we have $\sigma \leqslant \delta$. Moreover, since

$$\begin{aligned}\frac{d}{dt}\left(\frac{\psi^u(-t,\theta^t\omega)\psi^{\overline{c}}(t,\omega)}{K(\theta^t\omega)}\right) &= \frac{\left(-d_{\psi^u}(\theta^t\omega)+d_{\psi^{\overline{c}}}(t,\omega)\right)K(\theta^t\omega)-d_K(\theta^t\omega)}{[K(\theta^t\omega)]^2}\,\psi^u(-t,\theta^t\omega)\,\psi^{\overline{c}}(t,\omega)\\ &= -\frac{a(\theta^t\omega)}{K(\theta^t\omega)}\,\psi^u(-t,\theta^t\omega)\,\psi^{\overline{c}}(t,\omega),\end{aligned}$$

we have

$$\begin{aligned}\int_0^{+\infty}\alpha^u_{-r,\theta^r\omega}\operatorname{Lip}(f_{\theta^r\omega})\alpha^{\overline{c}}_{r,\omega}\,dr &= K(\omega)\int_0^{+\infty}K(\theta^r\omega)\psi^u(-r,\theta^r\omega)\operatorname{Lip}(f_{\theta^r\omega})\psi^{\overline{c}}(r,\omega)\,dr\\ &\leqslant \delta K(\omega)\int_0^{+\infty}\frac{a(\theta^r\omega)}{K(\theta^r\omega)}\,\psi^u(-r,\theta^r\omega)\,\psi^{\overline{c}}(r,\omega)\,dr\\ &= \delta-\delta K(\omega)\lim_{r\to+\infty}\frac{\psi^u(-r,\theta^r\omega)\psi^{\overline{c}}(r,\omega)}{K(\theta^r\omega)}\\ &= \delta.\end{aligned}$$

Similarly, since

$$\begin{aligned}\frac{d}{dt}\left(\frac{\psi^s(-t,\theta^t\omega)\psi^{\underline{c}}(t,\omega)}{K(\theta^t\omega)}\right) &= \frac{\left(-d_{\psi^s}(\theta^t\omega)+d_{\psi^{\underline{c}}}(t,\omega)\right)K(\theta^t\omega)-d_K(\theta^t\omega)}{[K(\theta^t\omega)]^2}\,\psi^s(-t,\theta^t\omega)\,\psi^{\underline{c}}(t,\omega)\\ &= \frac{b(\theta^t\omega)}{K(\theta^t\omega)}\,\psi^s(-t,\theta^t\omega)\,\psi^{\underline{c}}(t,\omega),\end{aligned}$$

we have

$$\begin{aligned}\int_{-\infty}^{0}\alpha^s_{-r,\theta^r\omega}\operatorname{Lip}(f_{\theta^r\omega})\alpha^{\underline{c}}_{r,\omega}\,dr &= K(\omega)\int_{-\infty}^{0}K(\theta^r\omega)\psi^s(-r,\theta^r\omega)\operatorname{Lip}(f_{\theta^r\omega})\psi^{\underline{c}}(r,\omega)\,dr\\ &\leqslant \delta K(\omega)\int_{-\infty}^{0}\frac{b(\theta^r\omega)}{K(\theta^r\omega)}\,\psi^s(-r,\theta^r\omega)\,\psi^{\underline{c}}(r,\omega)\,dr\\ &= \delta-\delta K(\omega)\lim_{r\to-\infty}\frac{\psi^s(-r,\theta^r\omega)\psi^{\underline{c}}(r,\omega)}{K(\theta^r\omega)}\\ &= \delta.\end{aligned}$$

Thus $\sigma+\tau\leqslant 3\delta<1/2$. □

In the following we provide a particular example of a ψ-trichotomy in $\mathbb{R}^4$.

Example 5.3. Let $\psi^{\overline{c}},\psi^{\underline{c}},\psi^s,\psi^u\colon \mathbb{R}\times\Omega\to]0,+\infty[$ be measurable functions satisfying (5.2) and let $K\colon\Omega\to[1,+\infty[$ be a random variable. In $X=\mathbb{R}^4$, equipped with the maximum norm, consider the projections

$$\begin{aligned}P^{\overline{c}}_\omega(x_1,x_2,x_3,x_4) &= (0,0,x_3+(K(\omega)-1)x_4,0)\\ P^{\underline{c}}_\omega(x_1,x_2,x_3,x_4) &= ((1-K(\omega))x_2,x_2,0,0)\\ P^{s}_\omega(x_1,x_2,x_3,x_4) &= (x_1+(K(\omega)-1)x_2,0,0,0)\\ P^{u}_\omega(x_1,x_2,x_3,x_4) &= (0,0,(1-K(\omega))x_4,x_4)\end{aligned}$$

For all $\omega', \omega \in \Omega$,

$$\begin{aligned} P^{\bar{c}}_{\omega'} P^u_\omega &= (0, 0, (K(\omega') - K(\omega))x_4, 0), \\ P^s_{\omega'} P^{\underline{c}}_\omega &= ((K(\omega') - K(\omega))x_2, 0, 0, 0) \end{aligned}$$

and for all the remaining $i, j \in \{\bar{c}, \underline{c}, s, u\}$, with $i \neq j$,

$$P^i_{\omega'} P^j_\omega = 0.$$

Notice that for all $\omega, \omega' \in \Omega$

$$P^s_{\omega'} P^s_\omega = P^s_\omega, \quad P^u_{\omega'} P^u_\omega = P^u_{\omega'}, \quad P^{\bar{c}}_{\omega'} P^{\bar{c}}_\omega = P^{\bar{c}}_\omega \quad \text{and} \quad P^{\underline{c}}_{\omega'} P^{\underline{c}}_\omega = P^{\underline{c}}_{\omega'}.$$

Moreover,

$$\|P^{\bar{c}}_\omega\| = \|P^s_\omega\| = K(\omega)$$

and

$$\|P^{\underline{c}}_\omega\| = \|P^u_\omega\| = \max\{K(\omega) - 1, 1\} \leqslant K(\omega).$$

We define $\Phi \colon \mathbb{R} \times \Omega \times \mathbb{R}^4 \to \mathbb{R}^4$ by

$$\Phi^t_\omega = \psi^{\bar{c}}(t, \omega)\, P^{\bar{c}}_\omega + \frac{K(\omega)}{K(\theta^t \omega)} \psi^{\underline{c}}(t, \omega)\, P^{\underline{c}}_{\theta^t \omega} + \psi^s(t, \omega) P^s_\omega + \frac{K(\omega)}{K(\theta^t \omega)} \psi^u(t, \omega)\, P^u_{\theta^t \omega}.$$

Let $P^c = P^{\bar{c}} + P^{\underline{c}}$ and $\mathcal{P} = (P^c, P^s, P^u)$. We have that Φ is a measurable linear RDS over Σ that admits a measurable $\mathcal{P}$-invariant splitting, and

$$\begin{aligned} \|\Phi^{c,t}_\omega\| &= \max\left\{\psi^{\bar{c}}(t, \omega)\|P^{\bar{c}}_\omega\|, \frac{1}{K(\theta^t \omega)} \psi^{\underline{c}}(t, \omega)\|P^{\underline{c}}_{\theta^t \omega}\|\right\} \leqslant K(\omega) \max\left\{\psi^{\bar{c}}(t, \omega), \psi^{\underline{c}}(t, \omega)\right\}, \\ \|\Phi^{s,t}_\omega\| &= \psi^s(t, \omega)\|P^s_\omega\| = K(\omega)\psi^s(t, \omega), \\ \|\Phi^{u,t}_\omega\| &= \frac{K(\omega)}{K(\theta^t \omega)} \psi^u(t, \omega)\|P^u_{\theta^t \omega}\| \leqslant K(\omega)\psi^u(t, \omega). \end{aligned}$$

Hence the linear RDS Φ exhibits a generalized trichotomy with bounds

$$\begin{aligned} \alpha^c_{t,\omega} &= K(\omega) \max\left\{\psi^{\bar{c}}(t, \omega), \psi^{\underline{c}}(t, \omega)\right\}, \\ \alpha^s_{t,\omega} &= K(\omega)\psi^s(t, \omega), \\ \alpha^u_{t,\omega} &= K(\omega)\psi^u(t, \omega). \end{aligned}$$

If we assume $\psi^{\bar{c}}(t, \omega) \geqslant \psi^{\underline{c}}(t, \omega)$ for all $t \geqslant 0$ then

$$\alpha^c_{t,\omega} = \begin{cases} K(\omega)\psi^{\bar{c}}(t, \omega) & \text{if } t \geqslant 0, \\ K(\omega)\psi^{\underline{c}}(t, \omega) & \text{if } t \leqslant 0, \end{cases}$$

and Φ exhibits a ψ-trichotomy.

Next, based on the previous example, we provide an example of a ψ-trichotomy on an infinite dimensional Banach space.

Example 5.4. Let $K_n \colon \Omega \to [1, +\infty[$ be a sequence of random variables such that

$$K(\omega) := \sup_{n \in \mathbb{N}} K_n(\omega) < +\infty \text{ for all } \omega \in \Omega.$$

In ℓ_∞, the space of bounded sequences equipped with the supremum norm, consider, for all $n \in \mathbb{N}$ and for all $\omega \in \Omega$, the projections

$$P^{\bar{c}}_{n,\omega}, P^{\underline{c}}_{n,\omega}, P^{s}_{n,\omega}, P^{u}_{n,\omega} \colon \ell_\infty \to \ell_\infty$$

defined by

$$\begin{aligned}
P^{\bar{c}}_{n,\omega}(x_1, x_2, x_3, x_4, x_5, \ldots) &= (\underbrace{0, \ldots, 0}_{4n-4 \text{ zeros}}, 0, 0, x_{4n-1} + L_n(\omega) x_{4n}, 0, 0, 0, \ldots),\\
P^{\underline{c}}_{n,\omega}(x_1, x_2, x_3, x_4, x_5, \ldots) &= (\underbrace{0, \ldots, 0}_{4n-4 \text{ zeros}}, -L_n(\omega) x_{4n-2}, x_{4n-2}, 0, 0, 0, \ldots),\\
P^{s}_{n,\omega}(x_1, x_2, x_3, x_4, x_5, \ldots) &= (\underbrace{0, \ldots, 0}_{4n-4 \text{ zeros}}, x_{4n-3} + L_n(\omega) x_{4n-2}, 0, 0, 0, \ldots),\\
P^{u}_{n,\omega}(x_1, x_2, x_3, x_4, x_5, \ldots) &= (\underbrace{0, \ldots, 0}_{4n-4 \text{ zeros}}, 0, 0, -L_n(\omega) x_{4n}, x_{4n}, 0, 0, 0, \ldots),
\end{aligned}$$

where $L_n(\omega) = K_n(\omega) - 1$. It follows that for all $\omega', \omega \in \Omega$, for all $i, j \in \{\bar{c}, \underline{c}, s, u\}$ and for all $n, m \in \mathbb{N}$, we have

$$\begin{aligned}
P^{i}_{n,\omega} P^{j}_{m,\omega'} &= 0 \quad \text{with} \quad n \neq m,\\
P^{i}_{n,\omega'} P^{j}_{n,\omega} &= 0 \quad \text{with} \quad i \neq j, \ (i,j) \neq (\bar{c}, u) \quad \text{and} \quad (i,j) \neq (s, \underline{c}),\\
P^{\bar{c}}_{n,\omega'} P^{u}_{n,\omega} &= (\underbrace{0, \ldots, 0}_{4n-4 \text{ zeros}}, 0, 0, (K_n(\omega') - K_n(\omega)) x_{4n}, 0, 0, 0, \ldots),\\
P^{s}_{n,\omega'} P^{\underline{c}}_{n,\omega} &= (\underbrace{0, \ldots, 0}_{4n-4 \text{ zeros}}, (K_n(\omega') - K_n(\omega)) x_{4n-2}, 0, 0, 0, \ldots).
\end{aligned}$$

Moreover, for all $\omega, \omega' \in \Omega$ and for all $n \in \mathbb{N}$,

$$P^{i}_{n,\omega'} P^{i}_{n,\omega} = P^{i}_{n,\omega} \quad \text{and} \quad P^{j}_{n,\omega'} P^{j}_{n,\omega} = P^{j}_{n,\omega'} \text{ with } i \in \{\bar{c}, s\} \text{ and } j \in \{\underline{c}, u\}.$$

Let $\psi^{\bar{c}}_n, \psi^{\underline{c}}_n, \psi^{s}_n, \psi^{u}_n \colon \mathbb{R} \times \Omega \to]0, +\infty[$ be sequences of measurable functions satisfying (5.2) and such that

$$\psi^i(t, \omega) := \sup_{n \in \mathbb{N}} \psi^i_n(t, \omega) < +\infty$$

for all $\omega \in \Omega$, for all $t \in \mathbb{R}$ and for all $i \in \{\bar{c}, \underline{c}, s, u\}$. If $\Phi \colon \mathbb{R} \times \Omega \times \ell_\infty \to \ell_\infty$ is given by

$$\Phi^t_\omega = \sum_{n=1}^{+\infty} \left[\psi^{\bar{c}}_n(t, \omega)\, P^{\bar{c}}_{n,\omega} + \frac{K_n(\omega)}{K_n(\theta^t \omega)} \psi^{\underline{c}}_n(t, \omega)\, P^{\underline{c}}_{n,\theta^t \omega} + \psi^{s}_n(t, \omega) P^{s}_{n,\omega} + \frac{K_n(\omega)}{K_n(\theta^t \omega)} \psi^{u}_n(t, \omega)\, P^{u}_{n,\theta^t \omega} \right],$$

then Φ is a measurable linear RDS over Σ that admits a measurable (P^c, P^s, P^u)-invariant splitting, where, for all $\omega \in \Omega$,

$$P^i_\omega = \sum_{n=1}^{+\infty} P^i_{n,\omega}, \quad i \in \{\bar{c}, \underline{c}, s, u\}, \quad \text{and} \quad P^c_\omega = P^{\bar{c}}_\omega + P^{\underline{c}}_\omega.$$

Moreover, since

$$\|P^{\bar{c}}_{n,\omega}\| = \|P^{s}_{n,\omega}\| = K_n(\omega)$$

and

$$\|P^{\underline{c}}_{n,\omega}\| = \|P^{u}_{n,\omega}\| = \max\{K_n(\omega)-1,1\},$$

it follows that

$$\left\|P^{\bar{c}}_{\omega}\right\| = \sup_{n\in\mathbb{N}} \left\|P^{s}_{n,\omega}\right\| = \sup_{n\in\mathbb{N}} K_n(\omega) = K(\omega)$$

and

$$\left\|P^{\underline{c}}_{\omega}\right\| = \left\|P^{u}_{n,\omega}\right\| = \sup_{n\in\mathbb{N}} (\max\{K_n(\omega)-1,1\}) = \max\{K(\omega)-1,1\} \leqslant K(\omega).$$

Hence

$$\begin{aligned}
\|\Phi^{c,t}_{\omega}\| &= \sup_{n\in\mathbb{N}} \left[\max\left\{\psi^{\bar{c}}_n(t,\omega)\|P^{\bar{c}}_{n,\omega}\|, \frac{1}{K_n(\theta^t\omega)}\psi^{\underline{c}}_n(t,\omega)\|P^{\underline{c}}_{n,\theta^t\omega}\|\right\}\right]\\
&\leqslant \sup_{n\in\mathbb{N}} \left[K_n(\omega)\max\left\{\psi^{\bar{c}}_n(t,\omega),\psi^{\underline{c}}_n(t,\omega)\right\}\right]\\
&\leqslant K(\omega)\max\left\{\psi^{\bar{c}}(t,\omega),\psi^{\underline{c}}(t,\omega)\right\},\\
\|\Phi^{s,t}_{\omega}\| &= \sup_{n\in\mathbb{N}} \left[\psi^{s}_n(t,\omega)\|P^{s}_{n,\omega}\|\right] = \sup_{n\in\mathbb{N}} \left[\psi^{s}_n(t,\omega)K_n(\omega)\right] \leqslant K(\omega)\psi^{s}(t,\omega),\\
\|\Phi^{u,t}_{\omega}\| &= \sup_{n\in\mathbb{N}} \left[\frac{K_n(\omega)}{K_n(\theta^t\omega)}\psi^{u}_n(t,\omega)\|P^{u}_{n,\theta^t\omega}\|\right] \leqslant K(\omega)\psi^{u}(t,\omega).
\end{aligned}$$

This implies that the linear RDS Φ admits a generalized trichotomy with bounds

$$\begin{aligned}
\alpha^{c}_{t,\omega} &= K(\omega)\max\left\{\psi^{\bar{c}}(t,\omega),\psi^{\underline{c}}(t,\omega)\right\},\\
\alpha^{s}_{t,\omega} &= K(\omega)\psi^{s}(t,\omega),\\
\alpha^{u}_{t,\omega} &= K(\omega)\psi^{u}(t,\omega).
\end{aligned}$$

If, in addition, $\psi^{\bar{c}}, \psi^{\underline{c}}, \psi^{s}, \psi^{u}$ satisfy (5.2) and $\psi^{\bar{c}}(t,\omega) \geqslant \psi^{\underline{c}}(t,\omega)$, for all $t \geqslant 0$ and for all $\omega \in \Omega$, then

$$\alpha^{c}_{t,\omega} = \begin{cases} K(\omega)\psi^{\bar{c}}(t,\omega) & \text{if } t \geqslant 0,\\ K(\omega)\psi^{\underline{c}}(t,\omega) & \text{if } t \leqslant 0,\end{cases}$$

and Φ exhibits a ψ-trichotomy.

In the next sections we consider particular ψ-trichotomies.

5.2.1 Integral exponential trichotomy

Let

$$\lambda^{\bar{c}}, \lambda^{\underline{c}}, \lambda^{s}, \lambda^{u} \colon \Omega \to \mathbb{R}$$

be random variables such that for all $\omega \in \Omega$ and $\ell \in \{\bar{c}, \underline{c}, s, u\}$, the map $r \mapsto \lambda^{\ell}(\theta^r\omega)$ is integrable in every interval $[0,t]$ An *integral exponential trichotomy* is a ψ-trichotomy with

$$\psi^{\ell}(t,\omega) = e^{\int_0^t \lambda^{\ell}(\theta^r\omega)dr}$$

for all $\ell \in \{\bar{c}, \underline{c}, s, u\}$, i.e., is a generalized trichotomy with bounds

$$\alpha^c_{t,\omega} = \begin{cases} K(\omega)\, e^{\int_0^t \lambda^{\bar{c}}(\theta^r\omega)dr}, & t \geqslant 0, \\ K(\omega)\, e^{\int_0^t \lambda^{\underline{c}}(\theta^r\omega)dr}, & t \leqslant 0, \end{cases}$$
$$\alpha^s_{t,\omega} = K(\omega)\, e^{\int_0^t \lambda^{s}(\theta^r\omega)dr}, \quad t \geqslant 0,$$
$$\alpha^u_{t,\omega} = K(\omega)\, e^{\int_0^t \lambda^{u}(\theta^r\omega)dr}, \quad t \leqslant 0.$$

Notice that if

$$\lim_{h\to 0} \frac{1}{h} \int_0^h \lambda^\ell(\theta^r\omega)\, dr = \lambda^\ell(\omega) \tag{5.6}$$

then $d_{\psi^\ell}(\omega) = \lambda^\ell(\omega)$ for all $\ell \in \{\bar{c}, \underline{c}, s, u\}$. From Corollary 5.2 we get the following.

Corollary 5.5. *Let Φ be a Bochner measurable linear RDS exhibiting an integral exponential trichotomy such that (5.6) holds and the limit (5.4) exists and satisfyies*

$$\lambda^{\bar{c}}(\omega) - \lambda^u(\omega) < \frac{d_K(\omega)}{K(\omega)} < \lambda^{\underline{c}}(\omega) - \lambda^s(\omega)$$

for all $\omega \in \Omega$. Let $f \in \mathscr{F}_\alpha^{(B)}$ be such that

$$\mathrm{Lip}(f_\omega) \leqslant \frac{\delta}{K(\omega)} \min\left\{ G(\omega), \frac{a(\omega)}{K(\omega)}, \frac{b(\omega)}{K(\omega)} \right\}$$

for all $\omega \in \Omega$, where

$$a(\omega) = \frac{d_K(\omega)}{K(\omega)} - \lambda^{\bar{c}}(\omega) + \lambda^u(\omega) \quad \text{and} \quad b(\omega) = -\frac{d_K(\omega)}{K(\omega)} + \lambda^{\underline{c}}(\omega) - \lambda^s(\omega).$$

Assume that Ψ is a Bochner measurable RDS such that (3.3) has a unique solution $\Psi(\cdot, \omega, x)$ for every $\omega \in \Omega$ and every $x \in X$. If for all $\omega \in \Omega$,

$$\lim_{t\to+\infty} K(\theta^t\omega)\, e^{\int_0^t \lambda^{\bar{c}}(\theta^r\omega) - \lambda^u(\theta^r\omega)\, dr} = \lim_{t\to-\infty} K(\theta^t\omega)\, e^{\int_0^t \lambda^{\underline{c}}(\theta^r\omega) - \lambda^s(\theta^r\omega)\, dr} = 0,$$

then the same conclusions of Theorem 3.1 hold.

5.2.2 Non exponential trichotomies

We provide now a particular type of ψ-trichotomies that can be easily handled to construct trichotomies beyhond the exponential bounds. Let

$$\lambda^{\bar{c}}, \lambda^{\underline{c}}, \lambda^s, \lambda^u \colon \Omega \to \mathbb{R}$$

be random variables such that for all $\ell \in \{\bar{c}, \underline{c}, s, u\}$ the following limit exists for all ω:

$$d_{\lambda^\ell}(\omega) := \lim_{h\to 0} \frac{\lambda^\ell(\theta^h\omega) - \lambda^\ell(\omega)}{h}. \tag{5.7}$$

Consider a ψ-trichotomy with

$$\psi^\ell(t,\omega) = \frac{\lambda^\ell(\omega)}{\lambda^\ell(\theta^t\omega)}$$

for all $\ell \in \{\bar{c}, \underline{c}, s, u\}$, i.e., is a generalized trichotomy with bounds

$$\begin{aligned} \alpha^c_{t,\omega} &= \begin{cases} K(\omega)\dfrac{\lambda^{\bar{c}}(\omega)}{\lambda^{\bar{c}}(\theta^t\omega)}, & t \geqslant 0, \\ K(\omega)\dfrac{\lambda^{\underline{c}}(\omega)}{\lambda^{\underline{c}}(\theta^t\omega)}, & t \leqslant 0, \end{cases} \\ \alpha^s_{t,\omega} &= K(\omega)\frac{\lambda^s(\omega)}{\lambda^s(\theta^t\omega)}, \quad t \geqslant 0 \\ \alpha^u_{t,\omega} &= K(\omega)\frac{\lambda^u(\omega)}{\lambda^u(\theta^t\omega)}, \quad t \leqslant 0. \end{aligned} \tag{5.8}$$

Notice that

$$d_{\psi^\ell}(\omega) = -\frac{d_{\lambda^\ell}(\omega)}{\lambda^\ell(\omega)}.$$

for all $\ell \in \{\bar{c}, \underline{c}, s, u\}$. From Corollary 5.2 we get the following.

Corollary 5.6. *Let Φ be a Bochner measurable linear RDS exhibiting an α-trichotomy, with bounds* (5.8) *and such that* (5.7) *and* (5.4) *exist and satisfy*

$$\frac{d_{\lambda^u}(\omega)}{\lambda^u(\omega)} - \frac{d_{\lambda^{\bar{c}}}(\omega)}{\lambda^{\bar{c}}(\omega)} < \frac{d_K(\omega)}{K(\omega)} < \frac{d_{\lambda^s}(\omega)}{\lambda^s(\omega)} - \frac{d_{\lambda^{\underline{c}}}(\omega)}{\lambda^{\underline{c}}(\omega)}.$$

Let $f \in \mathscr{F}^{(B)}_\alpha$ be such that for all $\omega \in \Omega$ we have

$$\operatorname{Lip}(f_\omega) \leqslant \frac{\delta}{K(\omega)} \min\left\{G(\omega), \frac{a(\omega)}{K(\omega)}, \frac{b(\omega)}{K(\omega)}\right\},$$

where

$$a(\omega) = \frac{d_K(\omega)}{K(\omega)} + \frac{d_{\lambda^{\bar{c}}}(\omega)}{\lambda^{\bar{c}}(\omega)} - \frac{d_{\lambda^u}(\omega)}{\lambda^u(\omega)} \quad \text{and} \quad b(\omega) = -\frac{d_K(\omega)}{K(\omega)} - \frac{d_{\lambda^{\underline{c}}}(\omega)}{\lambda^{\underline{c}}(\omega)} + \frac{d_{\lambda^s}(\omega)}{\lambda^s(\omega)}.$$

Assume that Ψ is a Bochner measurable RDS such that (3.3) *has a unique solution $\Psi(\cdot, \omega, x)$ for every $\omega \in \Omega$ and every $x \in X$. If for all $\omega \in \Omega$,*

$$\lim_{t\to+\infty} K(\theta^t\omega)\frac{\lambda^s(\theta^t\omega)}{\lambda^{\underline{c}}(\theta^t\omega)} = \lim_{t\to+\infty} K(\theta^t\omega)\frac{\lambda^u(\theta^t\omega)}{\lambda^{\bar{c}}(\theta^t\omega)} = 0$$

then the same conclusions of Theorem 3.1 hold.

Example 5.7 (Non exponential trichotomy)**.** Consider for the driving system the horizontal flow in $\mathbb{R}^2$ given by $\theta^t(x,y) = (x+t, y)$, which preserves the Lebesgue measure. Let $C, \xi^{\bar{c}}, \xi^{\underline{c}}, \xi^s, \xi^u$ and ε be some real constants with $C \geqslant 1$ and $\varepsilon \geqslant 0$, and set:

$$\begin{aligned} \lambda^\ell(x,y) &= (1+x^2)^{-(1+y^2)\xi_\ell}, \quad \ell \in \{\bar{c}, \underline{c}, s, u\}, \\ K(x,y) &= C(1+x^2)^{(1+y^2)\varepsilon}. \end{aligned}$$

In this case we obtain a polynomial type trichotomy. Let us assume $\lambda_{\overline{c}} \geqslant \lambda_{\underline{c}}$. Thus we have a trichotomy with

$$\alpha^c_{t,(x,y)} = \begin{cases} C\left(\dfrac{1+(x+t)^2}{1+x^2}\right)^{(1+y^2)\xi^{\overline{c}}} (1+x^2)^{(1+y^2)\varepsilon}, & t \geqslant 0, \\ C\left(\dfrac{1+(x+t)^2}{1+x^2}\right)^{(1+y^2)\xi^{\underline{c}}} (1+x^2)^{(1+y^2)\varepsilon}, & t \leqslant 0, \end{cases}$$

$$\alpha^s_{t,(x,y)} = C\left(\frac{1+(x+t)^2}{1+x^2}\right)^{(1+y^2)\xi^s} (1+x^2)^{(1+y^2)\varepsilon}, \quad t \geqslant 0,$$

$$\alpha^u_{t,(x,y)} = C\left(\frac{1+(x+t)^2}{1+x^2}\right)^{(1+y^2)\xi^u} (1+x^2)^{(1+y^2)\varepsilon}, \quad t \leqslant 0.$$

Notice that $d_{\lambda^\ell}(x,y) = \frac{\partial}{\partial x}\lambda^\ell(x,y)$.

6 Discrete-time examples

In this section we assume $\mathbb{T} = \mathbb{Z}$ and provide some corollaries to Theorem 4.1. Let X be a Banach space and let $\Sigma \equiv (\Omega, \mathcal{F}, \mathbb{P}, \theta)$ be a measure-preserving dynamical system. Throughout this subsection we consider a real number $\delta \in]0, 1/6[$ and a random variable $G \colon \Omega \to]0, +\infty[$ such that for all $\omega \in \Omega$ we have

$$\sum_{k=-\infty}^{+\infty} G(\theta^k \omega) \leqslant 1.$$

6.1 Tempered exponential trichotomies

Consider θ-invariant random variables

$$\lambda^{\overline{c}}, \lambda^{\underline{c}}, \lambda^s, \lambda^u \colon \Omega \to \mathbb{R}.$$

We say that a measurable linear RDS Φ on X over Σ exhibits an *exponential trichotomy* if it admits a generalized trichotomy with bounds

$$\alpha^c_{n,\omega} = \begin{cases} K(\omega)\, \mathrm{e}^{\lambda^{\overline{c}}(\omega) n}, & n \geqslant 0, \\ K(\omega)\, \mathrm{e}^{\lambda^{\underline{c}}(\omega) n}, & n \leqslant 0, \end{cases}$$

$$\alpha^s_{n,\omega} = K(\omega)\, \mathrm{e}^{\lambda^s(\omega) n}, \quad n \geqslant 0,$$

$$\alpha^u_{n,\omega} = K(\omega)\, \mathrm{e}^{\lambda^u(\omega) n}, \quad n \leqslant 0$$

for some random variable $K : \Omega \to [1, +\infty[$. If the random variable K is *tempered* we say that Φ exhibits an *tempered exponential trichotomy*. Notice that in the discrete-time case the condition (5.1) is equivalent to

$$\lim_{n \to \pm\infty} \frac{1}{|n|} \log K(\theta^n \omega) = 0 \quad \text{for all } \omega \in \Omega.$$

Corollary 6.1. *Let Φ be a measurable linear RDS exhibiting a tempered exponential trichotomy such that, for all $\omega \in \Omega$, satisfies*

$$\lambda^{\underline{c}}(\omega) > \lambda^s(\omega) \quad \textit{and} \quad \lambda^{\overline{c}}(\omega) < \lambda^u(\omega)$$

and let $f \in \mathscr{F}$. Consider a θ-invariant random variable $\gamma(\omega) > 0$ satisfying for all $\omega \in \Omega$

$$a(\omega) := \lambda^{\underline{c}}(\omega) - \lambda^{s}(\omega) - \gamma(\omega) > 0 \quad \text{and} \quad b(\omega) := \lambda^{u}(\omega) - \lambda^{\overline{c}}(\omega) - \gamma(\omega) > 0.$$

If

$$\operatorname{Lip}(f_\omega) \leqslant \frac{\delta}{K(\theta\omega)} \min\left\{ \mathrm{e}^{\min\{\lambda^{\underline{c}}(\omega),\lambda^{\overline{c}}(\omega)\}}\, G(\omega), \mathrm{e}^{\lambda^{u}(\omega)}\, \frac{\mathrm{e}^{a(\omega)} - 1}{\Lambda_{K,\gamma(\omega),\omega}}, \mathrm{e}^{\lambda^{s}(\omega)}\, \frac{1 - \mathrm{e}^{-b(\omega)}}{\Lambda_{K,\gamma(\omega),\omega}} \right\}$$

for all $\omega \in \Omega$ then the same conclusions of Theorem 3.1 hold.

6.2 ψ-trichotomies

Consider measurable functions

$$\psi^{\overline{c}}, \psi^{\underline{c}}, \psi^{s}, \psi^{u} \colon \mathbb{Z} \times \Omega \to]0, +\infty[$$

such that for $\ell \in \{\overline{c}, \underline{c}, s, u\}$ we have

$$\psi^{\ell}(t+s,\omega) = \psi^{\ell}(t,\theta^{s}\omega)\psi^{\ell}(s,\omega)$$

for all $t, s \in \mathbb{Z}$ and all $\omega \in \Omega$. A *ψ-trichotomy* is a generalized trichotomy with bounds

$$\begin{aligned} \alpha^{c}_{n,\omega} &= \begin{cases} K(\omega)\psi^{\overline{c}}(n,\omega), & t \geqslant 0, \\ K(\omega)\psi^{\underline{c}}(n,\omega), & t \leqslant 0, \end{cases} \\ \alpha^{s}_{t,\omega} &= K(\omega)\psi^{s}(n,\omega), \quad t \geqslant 0, \\ \alpha^{u}_{t,\omega} &= K(\omega)\psi^{u}(n,\omega), \quad t \leqslant 0 \end{aligned}$$

where $K \colon \Omega \to [1, +\infty[$ is a random variable. We notice that, as in the continuous-time case, we may consider different growth rates along the central directions E^{c}_{ω}, depending if we are looking to the *future* ($n \to +\infty$) or to the *past* ($n \to -\infty$).

Corollary 6.2. *Let Φ be a measurable linear RDS exhibiting a ψ-trichotomy such that*

$$\frac{\psi^{\overline{c}}(1,\omega)}{\psi^{u}(1,\omega)} < \frac{K(\theta\omega)}{K(\omega)} < \frac{\psi^{\underline{c}}(1,\omega)}{\psi^{s}(1,\omega)}. \tag{6.1}$$

Let $f \in \mathscr{F}$ be such that

$$\operatorname{Lip}(f_\omega) \leqslant \frac{\delta}{K(\theta\omega)} \min\left\{ \psi^{\overline{c}}(1,\omega)G(\omega), \psi^{\underline{c}}(1,\omega)G(\omega), a(\omega), b(\omega) \right\},$$

where

$$a(\omega) = \frac{\psi^{u}(1,\omega)}{K(\omega)} - \frac{\psi^{\overline{c}}(1,\omega)}{K(\theta\omega)} \quad \text{and} \quad b(\omega) = \frac{\psi^{\underline{c}}(1,\omega)}{K(\theta\omega)} - \frac{\psi^{s}(1,\omega)}{K(\omega)}.$$

If

$$\lim_{n\to-\infty} K(\theta^{n}\omega)\psi^{s}(-n,\theta^{n}\omega)\psi^{\underline{c}}(n,\omega) = \lim_{n\to+\infty} K(\theta^{n}\omega)\psi^{u}(-n,\theta^{n}\omega)\psi^{\overline{c}}(n,\omega) = 0$$

for all $\omega \in \Omega$, then the same conclusion of Theorem 4.1 holds.

Proof. We will check that we are in conditions to apply Theorem 4.1. Notice that from (6.1) we conclude $a(\omega), b(\omega) > 0$. We have

$$\begin{aligned}
\sigma_\omega^- &= \sup_{n\in\mathbb{N}} \frac{1}{\psi^{\underline{c}}(-n,\omega)} \sum_{k=-n}^{-1} K(\theta^{k+1}\omega)\psi^{\underline{c}}(-n-k-1,\theta^{k+1}\omega)\operatorname{Lip}(f_{\theta^k\omega})\psi^{\overline{c}}(k,\omega) \\
&\leqslant \delta \sum_{k=-\infty}^{+\infty} G(\theta^k\omega) \leqslant \delta,
\end{aligned}$$

and, similarly, $\sigma_\omega^+ \leqslant \delta$. Thus $\sigma \leqslant \delta$. Moreover,

$$\begin{aligned}
\tau_\omega^+ &= \sum_{k=0}^{+\infty} K(\theta^{k+1}\omega)\psi^u(-k-1,\theta^{k+1}\omega)\operatorname{Lip}(f_{\theta^k\omega})K(\omega)\psi^{\overline{c}}(k,\omega) \\
&\leqslant \delta K(\omega) \sum_{k=0}^{+\infty} \left[\frac{\psi^u(-k,\theta^k\omega)\psi^{\overline{c}}(k,\omega))}{K(\theta^k\omega)} - \frac{\psi^u(-(k+1),\theta^{k+1}\omega)\psi^{\overline{c}}(k+1,\omega))}{K(\theta^{k+1}\omega)} \right] \\
&\leqslant \delta K(\omega) \left(\frac{1}{K(\omega)} - \lim_{k\to+\infty} \frac{\psi^u(-k,\theta^k\omega)\psi^{\overline{c}}(k,\omega))}{K(\theta^k\omega)} \right) \\
&= \delta.
\end{aligned}$$

Similarly we get $\tau_\omega^- \leqslant \delta$. Therefore $\sigma + \tau \leqslant 3\delta < 1/2$. □

In the following we consider particular ψ-trichotomies.

6.2.1 Summable exponential trichotomies

We start by considering the integral (or summable) exponential trichotomies, which are a generalization of the exponential trichotomies and can be seen as the discrete counterpart of those in Section 5.2.1. Let

$$\lambda^{\overline{c}}, \lambda^{\underline{c}}, \lambda^s, \lambda^u \colon \Omega \to \mathbb{R}$$

be random variables and set For all $\ell \in \{\overline{c}, \underline{c}, s, u\}$ we set

$$S^\ell(n,\omega) = \begin{cases} \lambda^\ell(\omega) + \cdots + \lambda^\ell(\theta^{n-1}\omega), & n \geqslant 1, \\ 0, & n = 0, \\ -\lambda^\ell(\theta^n\omega) - \cdots - \lambda^\ell(\theta^{-1}\omega), & n \leqslant -1. \end{cases}$$

A *summable exponential trichotomy* is a ψ-trichotomy with

$$\psi^\ell(t,\omega) = \mathrm{e}^{S^\ell(n,\omega)}$$

for all $\ell \in \{\overline{c}, \underline{c}, s, u\}$, i.e., is a generalized trichotomy with bounds

$$\begin{aligned}
\alpha_{n,\omega}^c &= \begin{cases} K(\omega)\,\mathrm{e}^{S^{\overline{c}}(n,\omega)}, & n \geqslant 0, \\ K(\omega)\,\mathrm{e}^{S^{\underline{c}}(n,\omega)}, & n \leqslant 0, \end{cases} \\
\alpha_{n,\omega}^s &= K(\omega)\,\mathrm{e}^{S^s(n,\omega)}, \quad n \geqslant 0, \\
\alpha_{n,\omega}^u &= K(\omega)\,\mathrm{e}^{S^u(n,\omega)}, \quad n \leqslant 0
\end{aligned}$$

for some tempered random variable $K : \Omega \to [1, +\infty[$.

Corollary 6.3. *Let Φ be a measurable linear RDS exhibiting a summable exponential trichotomy such that*

$$\frac{e^{\lambda^{\bar{c}}(\omega)}}{e^{\lambda^{u}(\omega)}} < \frac{K(\theta\omega)}{K(\omega)} < \frac{e^{\lambda^{\underline{c}}(\omega)}}{e^{\lambda^{s}(\omega)}}.$$

Let $f \in \mathscr{F}$ be such that

$$\operatorname{Lip}(f_\omega) \leqslant \frac{\delta}{K(\theta\omega)} \min\left\{ e^{\lambda^{\bar{c}}(\omega)} G(\omega), e^{\lambda^{\underline{c}}(\omega)} G(\omega), a(\omega), b(\omega) \right\},$$

where

$$a(\omega) = \frac{e^{\lambda^{u}(\omega)}}{K(\omega)} - \frac{e^{\lambda^{\bar{c}}(\omega)}}{K(\theta\omega)} \quad \text{and} \quad b(\omega) = \frac{e^{\lambda^{\underline{c}}(\omega)}}{K(\theta\omega)} - \frac{e^{\lambda^{s}(\omega)}}{K(\omega)}.$$

If

$$\lim_{n\to-\infty} K(\theta^n\omega)\, e^{S^s(-n,\theta^n\omega)+S^{\underline{c}}(n,\omega)} = \lim_{n\to+\infty} K(\theta^n\omega)\, e^{S^u(-n,\theta^n\omega)+S^{\bar{c}}(n,\omega)} = 0$$

for all $\omega \in \Omega$, then the same conclusion of Theorem 4.1 holds.

6.2.2 Non exponential trichotomies

We provide a particular type of ψ-trichotomies that can be easily handled to construct trichotomies beyhond the exponential bounds in the discrete-time scenario. Consider a ψ-trichotomy with

$$\psi^\ell(n,\omega) = \frac{\lambda^\ell(\omega)}{\lambda^\ell(\theta^n\omega)}$$

for all $\ell \in \{\bar{c}, \underline{c}, s, u\}$, *i.e.*, is a generalized trichotomy with bounds

$$\begin{aligned} \alpha^c_{n,\omega} &= \begin{cases} K(\omega)\dfrac{\lambda^{\bar{c}}(\omega)}{\lambda^{\bar{c}}(\theta^n\omega)}, & n \geqslant 0, \\ K(\omega)\dfrac{\lambda^{\underline{c}}(\omega)}{\lambda^{\underline{c}}(\theta^n\omega)}, & n \leqslant 0, \end{cases} \\ \alpha^s_{n,\omega} &= K(\omega)\frac{\lambda^s(\omega)}{\lambda^s(\theta^n\omega)}, \quad n \geqslant 0, \\ \alpha^u_{n,\omega} &= K(\omega)\frac{\lambda^u(\omega)}{\lambda^u(\theta^n\omega)}, \quad n \leqslant 0. \end{aligned} \tag{6.2}$$

For future use let us define

$$a(\omega) = \frac{\lambda^u(\omega)}{\lambda^u(\theta\omega)K(\omega)} - \frac{\lambda^{\bar{c}}(\omega)}{\lambda^{\bar{c}}(\theta\omega)K(\theta\omega)} \quad \text{and} \quad b(\omega) = \frac{\lambda^{\underline{c}}(\omega)}{\lambda^{\underline{c}}(\theta\omega)K(\theta\omega)} - \frac{\lambda^s(\omega)}{\lambda^s(\theta\omega)K(\omega)}.$$

Corollary 6.4. *Let Φ be a measurable linear RDS exhibiting an α-trichotomy with bounds (6.2) and such that*

$$\frac{\lambda^{\bar{c}}(\omega)\lambda^u(\theta\omega)}{\lambda^{\bar{c}}(\theta\omega)\lambda^u(\omega)} < \frac{K(\theta\omega)}{K(\omega)} < \frac{\lambda^{\underline{c}}(\omega)\lambda^s(\theta\omega)}{\lambda^{\underline{c}}(\theta\omega)\lambda^s(\omega)}.$$

Let $f \in \mathscr{F}$ be such that

$$\operatorname{Lip}(f_\omega) \leqslant \frac{\delta}{K(\theta\omega)} \min\left\{ \frac{\lambda^{\bar{c}}(\omega)}{\lambda^{\bar{c}}(\theta\omega)} G(\omega), \frac{\lambda^{\underline{c}}(\omega)}{\lambda^{\underline{c}}(\theta\omega)} G(\omega), a(\omega), b(\omega) \right\}.$$

If

$$\lim_{n\to-\infty} \frac{K(\theta^n\omega)\lambda^s(\theta^n\omega)}{\lambda^{\underline{c}}(\theta^n\omega)} = \lim_{n\to+\infty} \frac{K(\theta^n\omega)\lambda^u(\theta^n\omega)}{\lambda^{\bar{c}}(\theta^n\omega)} = 0$$

for all $\omega \in \Omega$, then the same conclusion of Theorem 4.1 holds.

We may consider Example 5.7 with $\mathbb{T} = \mathbb{Z}$ to get an apllication of this result in a non exponential trichotomy situation.
