Abstract. We study the solvability of Sturm–Liouville boundary value problems for $x'' = f(t,x,x'), t \in (0,1)$. The nonlinearity can be defined on a bounded set and is required to be continuous on its subset. The results obtained are based on combinations of well-known conditions with barrier strip type conditions.

Keywords: nonlinear boundary value problem, Sturm–Liouville boundary conditions, existence, barrier strips conditions.

2020 Mathematics Subject Classification: 34B15.

1 Introduction

This paper is devoted to the solvability of boundary value problems (BVPs) for the equation

$$x'' = f(t,x,x'), \qquad t \in (0,1), \tag{1.1}$$

with Sturm–Liouville boundary conditions (BCs) either

$$-\alpha x(0) + \beta x'(0) = A, \qquad a x(1) + b x'(1) = B, \tag{1.2}$$

$$x'(0) = A, \qquad a x(1) + b x'(1) = B, \tag{1.3}$$

or

$$-\alpha x(0) + \beta x'(0) = A, \qquad x'(1) = B, \tag{1.4}$$

where $f : [0,1] \times D_x \times D_p \to \mathbb{R}$, $D_x, D_p \subseteq \mathbb{R}$, $\alpha, \beta, a, b > 0$, and $A, B \in \mathbb{R}$.

This paper is motivated by A. Granas et al. [6]. The authors prove that BVP (1.1), (1.2) has a solution in $C^2[0,1]$ assuming that the function $f(t,x,p)$ is continuous on $[0,1] \times \mathbb{R}^2$ and there is a constant $M \geq 0$ such that

$$x f(t,x,0) \geq M \quad \text{for } t \in [0,1] \text{ and } |x| > M \tag{1.5}$$

✉Corresponding author. Email: pskeleved@abv.bg

and the well-known Bernstein's growth condition holds, that is, there exist positive constants $G_i, i = 1,2$, for which

$$|f(t,x,p)| \le G_1 p^2 + G_2 \quad \text{for } (t,x) \in [0,1] \times [-M_0, M_0], \tag{1.6}$$

where $M_0 = \max\{|A/\alpha|, |B/a|, M\}$. A similar result guarantees $C^2[0,1]$-solutions to BVPs (1.1), (1.3) and (1.1), (1.4). In it, (1.5) is replaced by the assumption that $f(t,x,p)$ is differentiable with respect to x and there is a constant $K > 0$ such that

$$f_x(t,x,p) \ge K \quad \text{for } (t,x,p) \in [0,1] \times \mathbb{R} \times \{C\}, \tag{1.7}$$

where $C = A$ or $C = B$. The conditions imposed guarantee a priori bounds. Moreover, each of the conditions (1.5) and (1.7) provide a priori bound for the solutions to the considered BVP, that is, for $|x(t)|$, and (1.6) provides the bound for $|x'(t)|$. The established a priori bounds are needed for applying the Topological transversality theorem.

One of the BVPs studied in C. Tisdell [10] is (1.1), (1.2). Here, the Leray–Schauder degree theory and a priori bounds are used. The well known condition

$$f(t,-R_1,0) < 0 \quad \text{and} \quad f(t,R_2,0) > 0, \qquad t \in [0,1],$$

where R_1 and R_2 are some positive constants with $\min\{R_1,R_2\} > \max\{|A/\alpha|, |B/a|\}$, gives the bound for $|x(t)|$, and this for $|x'(t)|$ follows from the assumption that there exist non-negative constants α and K such that

$$|f(t,x,p)| \le \alpha f(t,x,p) + K \quad \text{for all } t \in [0,1], |x| \le R, p \in \mathbb{R},$$

where $R = \max\{R_1, R_2\}$.

Other results on the solvability of BVPs for various equations with Sturm–Liouville boundary conditions can be found, for example, in M. Dobkevich and F. Sadyrbaev [3], A. M. A. El-Sayed et al. [4,5], T. Xue et al. [12], Y. Liu et al. [9], F. H. Wong et al. [11] and L. Zhang et al. [13].

The purpose of this paper is to give sufficient conditions for the existence of solutions in which growth restrictions on $f(t,x,p)$ are not imposed, that is, we do not use condition (1.6). It is replaced by sign conditions of barrier strips type.

The existence discussion is based on the basic existence theorem proved in R. P. Agarwal et al. [2], which is a variant of [6, Chapter V, Theorem 1.1]. Let us prepare its wording.

Consider the BVP

$$\begin{cases} x^{(n)} + \sum_{k=0}^{n-1} s_k(t) x^{(k)} = f(t,x,x',\dots,x^{(n-1)}), \ t \in [0,1], \\ V_i(x) = A_i, \ i = \overline{1,n}, \end{cases} \tag{1.8}$$

of which the considered boundary value problems (1.1), (1.2)–(1.4) are special cases. Here $s_k(t), k = \overline{0,n-1}$, are continuous on $[0,1]$, $f : [0,1] \times D_0 \times D_1 \times \cdots \times D_{n-1} \to \mathbb{R}$,

$$V_i(x) \equiv \sum_{j=0}^{n-1} [a_{ij} x^{(j)}(0) + b_{ij} x^{(j)}(1)], \qquad i = \overline{1,n},$$

with constants a_{ij} and b_{ij} for which $\sum_{j=0}^{n-1}(a_{ij}^2 + b_{ij}^2) > 0, i = \overline{1,n}$, and $A_i \in \mathbb{R}$.

For $\lambda \in [0,1]$, consider also the family of BVPs

$$\begin{cases} x^{(n)} + \sum_{k=0}^{n-1} s_k(t) x^{(k)} = g(t,x,x',\dots,x^{(n-1)},\lambda), \ t \in [0,1], \\ V_i(x) = A_i, \ i = \overline{1,n}, \end{cases} \tag{1.9}$$

where $g : [0,1] \times D_0 \times D_1 \times \cdots \times D_{n-1} \times [0,1] \to \mathbb{R}$, and $s_k(t), k = \overline{0,n-1}, V_i, A_i, i = \overline{1,n}$, are as above.

Let, as usual, $C[0,1]$ be the Banach space of continuous functions on $[0,1]$ with the norm $\|x\|_0 = \sup_{t\in[0,1]} |x(t)|$, and $C^n[0,1]$ be the Banach space of n-times continuously differentiable functions with $\|x\|_n = \max\{\|x\|_0, \ldots, \|x^{(n)}\|_0\}$.

Let $\mathcal{B}$ denote the set of functions that satisfy the BCs $V_i(x) = A_i$, $i = \overline{1,n}$, and $\mathcal{B}_0$ be the set of functions satisfying $V_i(x) = 0, i = \overline{1,n}$. Finally, let $C^n_{\mathcal{B}}[0,1] = C^n[0,1] \cap \mathcal{B}$ and $C^n_{\mathcal{B}_0}[0,1] = C^n[0,1] \cap \mathcal{B}_0$.

We are now ready to formulate the basic existence theorem.

Theorem 1.1 ([2, Theorem 4]). *Assume that:*

(i) *For $\lambda = 0$ problem (1.9) has a unique solution in $C^n[0,1]$.*

(ii) *Problems (1.8) and (1.9) are equivalent when $\lambda = 1$.*

(iii) *The map $\Lambda_h : C^n_{\mathcal{B}_0}[0,1] \to C[0,1]$, defined by*

$$\Lambda_h x = x^{(n)} + \sum_{k=0}^{n-1} s_k(t) x^{(k)},$$

is one-to-one.

(iv) *Each solution $x \in C^n[0,1]$ to family (1.9) satisfies the bounds*

$$m_i \le x^{(i)}(t) \le M_i \quad \text{for } t \in [0,1],\ i = \overline{0,n},$$

where the constants $-\infty < m_i, M_i < \infty$, $i = \overline{0,n}$, are independent of λ and x.

(v) *There is a sufficiently small $\delta > 0$ such that*

$$[m_i - \delta, M_i + \delta] \subseteq D_i, \qquad i = \overline{0,n-1},$$

and the function $g(t, p_0, \ldots, p_{n-1}, \lambda)$ is continuous on $[0,1] \times D \times [0,1]$, where

$$D = [m_0 - \delta, M_0 + \delta] \times [m_1 - \delta, M_1 + \delta] \times \cdots \times [m_{n-1} - \delta, M_{n-1} + \delta];$$

$m_i, M_i, i = \overline{0,n-1}$, are as in (iv).

Then, BVP (1.8) has at least one solution in $C^n[0,1]$.

To apply Theorem 1.1 for studying the considered BVPs, we use families of BVPs for

$$x'' = \lambda f(t,x,x') + (1-\lambda)(x - x'), \qquad t \in (0,1), \tag{1.1}$$

and

$$x'' = \lambda f(t,x,x') + (1-\lambda)(x + x'), \qquad t \in (0,1), \tag{1.1}$$

where $\lambda \in [0,1]$. They are adapted to the application of the barrier strips type conditions used here, namely conditions **(B_1)** and **(B_2)** below.

In order to achieve the a priori bounds of condition *(iv)* of Theorem 1.1, we impose three sets of conditions. The conditions of set **A**, these are (1.5) and (1.7), guarantee the a priori bounds for each eventual $C^2[0,1]$-solution $x(t)$ to the used families, those of the set **B** give the bounds for $x'(t)$, and **C** ensures the bounds for $x''(t)$.

Following are the hypotheses used in this article.

(A$_1$) There is a constant $M \geq 0$ such that $[-M, M] \subseteq D_x$ and

$$xf(t, x, 0) \geq 0 \quad \text{for } t \in [0, 1] \text{ and } x \in D_x \setminus [-M, M].$$

In the formulation of the next hypothesis, we use the functions

$$v(t) = At + \frac{B - A(a + b)}{a} \quad \text{and} \quad w(t) = Bt + \frac{B\beta - A}{\alpha}, \qquad t \in [0, 1],$$

and more precisely the constants $m_v = \min_{[0,1]} v(t)$, $M_v = \max_{[0,1]} v(t)$, $m_w = \min_{[0,1]} w(t)$ and $M_w = \max_{[0,1]} w(t)$.

(A$_2$) $J \subseteq D_x$, here $J = [m_v, M_v]$ for (1.3) and $J = [m_w, M_w]$ for (1.4), and there is a constant $K > 0$ such that

$$f_x(t, x, C) \geq K \quad \text{for } (t, x) \in [0, 1] \times D_x,$$

where $C = A$ for (1.3) and $C = B$ for (1.4).

For some constants M_0, G_m and G_M, they will be specified later for each problem, suppose that:

(B$_1$) There are constants $F_i, L_i, i = 1, 2$, such that $[F_2, L_2] \subseteq D_p$,

$$F_2 < F_1 \leq \min\{-M_0, G_m\}, \qquad \max\{M_0, G_M\} \leq L_1 < L_2,$$

$$f(t, x, p) \leq 0 \quad \text{for } (t, x, p) \in [0, 1] \times [-M_0, M_0] \times [L_1, L_2], \tag{1.10}$$

$$f(t, x, p) \geq 0 \quad \text{for } (t, x, p) \in [0, 1] \times [-M_0, M_0] \times [F_2, F_1]. \tag{1.11}$$

(B$_2$) There are constants $F_i', L_i', i = 1, 2$, such that $[F_2', L_2'] \subseteq D_p$,

$$F_2' < F_1' \leq \min\{-M_0, G_m\}, \qquad \max\{M_0, G_M\} \leq L_1' < L_2',$$

$$f(t, x, p) \geq 0 \quad \text{for } (t, x, p) \in [0, 1] \times [-M_0, M_0] \times [L_1', L_2'], \tag{1.12}$$

$$f(t, x, p) \leq 0 \quad \text{for } (t, x, p) \in [0, 1] \times [-M_0, M_0] \times [F_2', F_1'].$$

(C) There are constants $m_i \leq M_i, i = 0, 1$, and a sufficiently small $\delta > 0$ such that

$$[m_0 - \delta, M_0 + \delta] \subseteq D_x, \qquad [m_1 - \delta, M_1 + \delta] \subseteq D_p,$$

and $f(t, x, p)$ is continuous on $[0, 1] \times [m_0 - \delta, M_0 + \delta] \times [m_1 - \delta, M_1 + \delta]$.

The paper is organized as follows. In Section 2 we establish a priori bounds for $x(t)$ and $x'(t)$ for each solution $x \in C^2[0, 1]$ to the families of BVPs for $(1.1)_\lambda^-$ with BCs (1.2) or (1.3) and for $(1.1)_\lambda^+$ with BCs (1.2) or (1.4). In Section 3 we use the obtained bounds to prove existence results for the considered BVPs. Examples illustrate the application of the obtained results in Section 4.

2 Auxiliary results

We need a well known maximum principle, see for example [6, Chapter II, Lemma 1.1], concerning equations of the form

$$x'' = h(t, x, x'), \qquad t \in [0, 1]. \tag{2.1}$$

It is based on the following assumption.

(A) There is a constant $M \geq 0$ such that $[-M, M] \subseteq D_x$ and

$$xh(t, x, 0) > 0 \quad \text{for } t \in [0, 1] \text{ and } x \in D_x \setminus [-M, M].$$

Lemma 2.1. *Let $x \in C^2[0, 1]$ be a solution to equation (2.1) such that $|x(t)|$ does not achieve its maximum at $t = 0$ or $t = 1$. Assume further that* **(A)** *holds. Then $x(t)$ satisfies the bound*

$$|x(t)| \leq M \text{ for } t \in [0, 1].$$

Proof. By the assumption of the lemma, $|x(t)|$ must achieve a positive maximum at a point $t_0 \in (0, 1)$. Clearly, the function $y(t) = (x(t))^2$ also has a maximum at t_0. Thus,

$$y''(t_0) = 2x(t_0)x''(t_0) = 2x(t_0)h(t_0, x(t_0), 0) \leq 0.$$

Next, reasoning by contradiction, assume $|x(t_0)| > M$. Then from **(A)** it follows

$$x(t_0)h(t_0, x(t_0), 0) > 0$$

and the derived contradiction proves the lemma. □

The proofs of the following two lemmas follow the idea of proof of [6, Chapter II, Lemma 1.2].

Lemma 2.2. *Let* **(A)** *hold. Then each solution $x \in C^2[0, 1]$ to (2.1), (1.3) with $A = B = 0$ satisfies the bound*

$$|x(t)| \leq M, \qquad t \in [0, 1].$$

Proof. Suppose that $|x(0)|$ is the maximum value of $|x(t)|$. We claim that $|x(0)| > M$ is impossible. To verify this, by contradiction, assume it is true. Then,

$$x(0)x''(0) = x(0)h(0, x(0), 0) > 0.$$

Now, if $x(0) < 0$, then $x''(0) < 0$. Because of the continuity of $x''(t)$ on $[0, 1]$, there is a neighborhood $N_0 \subseteq [0, 1]$ of $t = 0$ where $x''(t) < 0$. This means that $x'(t)$ is strictly decreasing on N_0 and so $x'(t) < x'(0) = 0$ for $t \in N_0$. Consequently $x(t)$ is also strictly decreasing on N_0 and so $|x(0)|$ can not be the maximum of $|x(t)|$ on $[0, 1]$, a contradiction. If $x(0) > 0$, then $x''(0) > 0$, from where conclude $x'(t) > x'(0) = 0$ for $t \in U_0$, where $U_0 \subseteq [0, 1]$ is any neighborhood of $t = 0$. Thus, $x(t) > x(0) > 0$ for $t \in U_0$, which means that $|x(t)| > |x(0)|, t \in U_0$, again a contradiction. So, $|x(0)| \leq M$.

Let $|x(1)|$ be the maximum value of $|x(t)|, t \in [0, 1]$. Then, $x(1)x'(1) \geq 0$ and

$$0 \leq x(1)bx'(1) = x(1)(-ax(1)) = -a(x(1))^2 \leq 0,$$

which is possible if $x(1) = 0$. So, we have $\max_{[0,1]} |x(t)| = 0$, which means $x(t) = 0$ for $t \in [0,1]$ and the lemma is true.

Finally, if $|x(t)|$ achieve its maximum in $(0,1)$, then

$$|x(t)| \leq M, \qquad t \in [0,1],$$

by Lemma 2.1. □

Lemma 2.3. *Let* **(A)** *hold. Then each solution* $x \in C^2[0,1]$ *to* (2.1), (1.4) *with* $A = B = 0$ *satisfies the bound*

$$|x(t)| \leq M, \qquad t \in [0,1].$$

Proof. If $|x(0)|$ is the maximum value of $|x(t)|$, we have $x(0)x'(0) \leq 0$ from where obtain

$$0 \geq x(0)\beta x'(0) = x(0)(\alpha x(0)) = \alpha(x(0))^2 \geq 0.$$

This implies $\max_{[0,1]} |x(t)| = |x(0)| = 0$ which means $x(t) = 0$ on $[0,1]$ and so the lemma is true.

If $|x(t)|$ achieves its maximum at $t = 1$, the assumption that $|x(1)| > M$ yields

$$x(1)x''(1) = x(1)h(1, x(1), 0) > 0.$$

Next, following the proof of Lemma 2.2, we derive contradictions in the cases $x(1) < 0$ and $x(1) > 0$ and conclude that $|x(1)| \leq M$.

Finally, if $|x(t)|$ achieves its maximum somewhere at the interval $(0,1)$, then the bound

$$|x(t)| \leq M, \qquad t \in [0,1],$$

follows from Lemma 2.1. □

Following the proof of [6, Chapter II, Theorem 3.3], establish the assertion.

Lemma 2.4. *Let* **(A)** *hold for* (1.1). *Then each solution* $x \in C^2[0,1]$ *to* $(1.1)^-_\lambda$, (1.2) *or to* $(1.1)^+_\lambda$, (1.2) *satisfies the bound*

$$|x(t)| \leq \max\{|A/\alpha|, |B/a|, M\}, \qquad t \in [0,1].$$

Proof. We will prove the assertion about family $(1.1)^-_\lambda$, (1.2), the proof for family $(1.1)^+_\lambda$, (1.2) is practically the same.

If $|x(0)|$ is the maximum value of $|x(t)|$ on $[0,1]$ we have $x(0)x'(0) \leq 0$, from where obtain

$$0 \geq x(0)\beta x'(0) = x(0)(A + \alpha x(0)) = \alpha(x(0))^2\Big[\frac{A}{\alpha x(0)} + 1\Big].$$

This yields consecutively

$$\frac{A}{\alpha x(0)} + 1 \leq 0, \qquad \left|\frac{A}{\alpha x(0)}\right| \geq 1 \quad \text{and} \quad |x(0)| \leq |A/\alpha|.$$

Likewise, if $|x(t)|$ achieves its maximum at $t = 1$, we obtain

$$|x(1)| \leq |B/a|.$$

Now, let $|x(t)|$ achieve its maximum in an interior point of $(0,1)$. For the right-hand side of equation $(1.1)_\lambda^-$ we have

$$\lambda x f(t,x,0) + (1-\lambda)x^2 > 0 \quad \text{for each} \quad \lambda \in [0,1], t \in [0,1] \quad \text{and} \quad x \in D_x \setminus [-M,M],$$

that is, **(A)** is satisfied for $(1.1)_\lambda^-$. Thus,

$$|x(t)| \le M, \qquad t \in [0,1],$$

by Lemma 2.1. □

Now, let

$$L_- = \max\{\max|f(t,x,A)|, \max|x-A|\},$$

where the maximums are computed for $(t,x) \in [0,1] \times [m_v, M_v]$.

Lemma 2.5. *Let* **(A_2)** *hold for* $J = [m_v, M_v]$ *and* $C = A$. *Then each solution* $x \in C^2[0,1]$ *to* $(1.1)_\lambda^-$, (1.3) *satisfies the bound*

$$|x(t)| \le \frac{L_-}{\min\{1,K\}} + \max\{|m_v|, |M_v|\}, \qquad t \in [0,1].$$

Proof. Define the function $y(t) = x(t) - v(t), t \in [0,1]$. Since $v(t)$ satisfies BC (1.3), $y(t)$ is a $C^2[0,1]$-solution to the homogeneous BVP

$$\begin{aligned} y'' &= h(t,y,y',\lambda), \qquad t \in (0,1), \\ y'(0) &= 0, \qquad ay(1) + by'(1) = 0, \end{aligned}$$

where $h(t,y,y',\lambda) = \lambda f(t,y+v,y'+v') + (1-\lambda)(y+v-y'-v'),\ \lambda[0,1]$. Besides,

$$\begin{aligned} yh(t,y,0,\lambda) &= y\Big(\lambda f(t,y+v,v') + (1-\lambda)(y+v-v')\Big) \\ &= y\Big(\lambda f(t,y+v,A) + (1-\lambda)(y+v-A) - \lambda f(t,v,A) \\ &\quad - (1-\lambda)(v-A) + \lambda f(t,v,A) + (1-\lambda)(v-A)\Big) \\ &= y\Big(\lambda f_x(t,\theta y+v,A)y + (1-\lambda)y\Big) + y\Big(\lambda f(t,v,A) + (1-\lambda)(v-A)\Big) \end{aligned}$$

for any $\theta \in (0,1)$. Let us note, $f_x(t,\theta y+v,A), t \in [0,1]$, is well defined since for $t \in [0,1]$ $\theta y(t) + v(t) \in \big[\min\{m_v, \min_{[0,1]} x(t)\}, \max\{M_v, \max_{[0,1]} x(t)\}\big] \subseteq D_x$. Then

$$yh(t,y,0,\lambda) \ge y^2(\lambda K + (1-\lambda)) - |y|L_- \ge |y|(|y|\min\{1,K\} - L_-),$$

from where it follows

$$yh(t,y,0,\lambda) > 0 \quad \text{for } t \in [0,1] \text{ and } |y| > \frac{L_-}{\min\{1,k\}}$$

and for each $\lambda \in [0,1]$. Thus,

$$|y(t)| \le \frac{L_-}{\min\{1,k\}} \quad \text{for } t \in [0,1],$$

by Lemma 2.2. Keeping in mind that $x(t) = y(t) + v(t)$, we obtain the lemma. □

Now, let

$$L_+ = \max\{\max|f(t,x,B)|, \max|x+B|\},$$

where the maximums are computed over $(t,x) \in [0,1] \times [m_w, M_w]$.

Lemma 2.6. *Let* **(A_2)** *hold for* $J = [m_w, M_w]$ *and* $C = B$. *Then each solution* $x \in C^2[0,1]$ *to* $(1.1)^+_\lambda$, (1.4) *satisfies the bound*

$$|x(t)| \le \frac{L_+}{\min\{1,K\}} + \max\{|m_w|, |M_w|\}, \qquad t \in [0,1].$$

Proof. Following the proof of Lemma 2.5, introduce the function $y(t) = x(t) - w(t), t \in [0,1]$. Since $w(t)$ satisfies BC (1.4), $y(t)$ is a $C^2[0,1]$-solution to the homogeneous BVP

$$\begin{aligned} y'' &= h(t,y,y',\lambda), \quad t \in (0,1), \\ -\alpha y(0) + \beta y'(0) &= 0, \quad y'(0) = 0, \end{aligned}$$

where $h(t,y,y',\lambda) = \lambda f(t,y+w,y'+w') + (1-\lambda)(y+w+y'+w')$. Besides,

$$\begin{aligned} yh(t,y,0,\lambda) &= y\Big(\lambda f(t,y+w,w') + (1-\lambda)(y+w+w')\Big) \\ &= y\Big(\lambda f(t,y+w,B) + (1-\lambda)(y+w+B) - \lambda f(t,w,B) \\ &\qquad - (1-\lambda)(w+B) + \lambda f(t,w,B) + (1-\lambda)(w+B)\Big) \\ &= y\Big(\lambda f_x(t,\theta y+w,B)y + (1-\lambda)y\Big) + y\Big(\lambda f(t,w,B) + (1-\lambda)(w+B)\Big) \end{aligned}$$

for any $\theta \in (0,1)$. Then

$$yh(t,y,0,\lambda) \ge y^2(\lambda K + (1-\lambda)) - |y|L_+ \ge |y|(|y|\min\{1,K\} - L_+),$$

from where it follows

$$yh(t,y,0,\lambda) > 0 \text{ for } t \in [0,1] \text{ and } |y| > \frac{L_+}{\min\{1,k\}}$$

and for each $\lambda \in [0,1]$. Thus,

$$|y(t)| \le \frac{L_+}{\min\{1,k\}} \quad \text{for } t \in [0,1],$$

by Lemma 2.3, which yields the bound for $|x(t)|$. □

The considerations used in the proofs of the following statements are standard for proofs of lemmas based on barrier strips conditions. These results provide a priori bounds for the $(n-1)$th derivative of the nth-order differential equations, see for example Lemma 2 of R. P. Agarwal and P. Kelevedjiev [1], Lemma 3.1 of P. Kelevedjiev and T. Todorov [7] and Theorem 3.1 of P. Kelevedjiev [8].

Lemma 2.7. *Let* **(B_1)** *hold for constants* M_0, $G_m = (A - \alpha M_0)\beta^{-1}$ *and* $G_M = (A + \alpha M_0)\beta^{-1}$. *Then each solution* $x \in C^2[0,1]$ *to* $(1.1)^-_\lambda$, (1.2) *with the property*

$$-M_0 \le x(t) \le M_0, \qquad t \in [0,1],$$

satisfies the bound

$$F_1 \le x'(t) \le L_1, \qquad t \in [0,1].$$

Proof. Reasoning by contradiction, assume that $x'(t) > L_1$ for some $t \in (0,1]$. Then, the continuity of $x'(t)$ on $[0,1]$ and

$$x'(0) = \frac{A + \alpha x(0)}{\beta} \leq \frac{A + \alpha M_0}{\beta} \leq L_1$$

imply that the set

$$S_- = \{t \in [0,1] : L_1 < x'(t) \leq L_2\}$$

is not empty. Also, that there is a $\gamma \in S_-$ such that

$$x''(\gamma) > 0.$$

Because $x(t)$ is a $C^2[0,1]$-solution to $(1.1)^-_\lambda$, we have in particular

$$x''(\gamma) = \lambda f(\gamma, x(\gamma), x'(\gamma)) + (1-\lambda)(x(\gamma) - x'(\gamma)).$$

Now, from $(\gamma, x(\gamma), x'(\gamma)) \in S_- \times [-M_0, M_0] \times (L_1, L_2]$ and (1.10) we get

$$\lambda f(\gamma, x(\gamma), x'(\gamma)) \leq 0,$$

and $x'(\gamma) > L_1 \geq M_0 \geq x(\gamma)$ yields $x(\gamma) - x'(\gamma) < 0$. As a result

$$x''(\gamma) \leq 0,$$

a contradiction. Thus,

$$x'(t) \leq L_1 \text{ for } t \in [0,1].$$

Similarly, assuming that $x'(t) < F_1$ for some $t \in (0,1]$ and using that

$$x'(0) = \frac{A + \alpha x(0)}{\beta} \geq \frac{A - \alpha M_0}{\beta} \geq F_1,$$

we establish that

$$S_+ = \{t \in [0,1] : F_2 \leq x'(t) < F_1\}$$

is the empty set and so

$$x'(t) \geq F_1 \quad \text{for } t \in [0,1]. \qquad \square$$

Lemma 2.8. *Let* **(B_2)** *hold for constants* M_0, $G_m = (B - aM_0)b^{-1}$ *and* $G_M = (B + aM_0)b^{-1}$. *Then each solution* $x \in C^2[0,1]$ *to* $(1.1)^+_\lambda$, (1.2) *with the property*

$$-M_0 \leq x(t) \leq M_0, \qquad t \in [0,1],$$

satisfies the bound

$$F_1' \leq x'(t) \leq L_1', \qquad t \in [0,1].$$

Proof. By contradiction, assume that $x'(t) > L_1'$ for some $t \in [0,1)$. This means that the set

$$S_+ = \{t \in [0,1] : L_1' < x'(t) \leq L_2'\}$$

is not empty because $x'(t)$ is continuous on $[0,1]$ and

$$x'(1) = \frac{B - ax(1)}{b} \leq \frac{B + aM_0}{b} \leq L_1'.$$

Also, there is a $\gamma \in S_+$ such that

$$x''(\gamma) < 0.$$

As $x(t)$ is a $C^2[0,1]$-solution to $(1.1)^+_\lambda$,

$$x''(\gamma) = \lambda f(\gamma, x(\gamma), x'(\gamma)) + (1-\lambda)(x(\gamma) + x'(\gamma)).$$

Now, $(\gamma, x(\gamma), x'(\gamma)) \in S_+ \times [-M_0, M_0] \times (L_1', L_2']$ and (1.12) imply

$$\lambda f(\gamma, x(\gamma), x'(\gamma)) \geq 0.$$

Besides, $x(\gamma) + x'(\gamma) > 0$ because $x'(\gamma) > L_1' \geq M_0 \geq x(\gamma) \geq -M_0$. Thus,

$$x''(\gamma) \geq 0,$$

a contradiction. Consequently,

$$x'(t) \leq L_1' \quad \text{for } t \in [0,1].$$

Along similar lines, assuming on the contrary that the set

$$S_- = \{t \in [0,1] : F_2' \leq x'(t) < F_1'\}$$

is not empty and using that

$$x'(1) = \frac{B - ax(0)}{b} \geq \frac{B - aM_0}{b} \geq F_1',$$

we achieve a contradiction which implies that

$$F_1' \leq x'(t) \quad \text{for } t \in [0,1]. \qquad \square$$

Lemma 2.9. *Let* **(B_1)** *hold for constants* M_0, $G_m = \min\{-M_0, A\}$ *and* $G_M = \max\{M_0, A\}$. *Then each solution* $x \in C^2[0,1]$ *to* $(1.1)^-_\lambda$, (1.3) *with the property*

$$-M_0 \leq x(t) \leq M_0, \qquad t \in [0,1],$$

satisfies the bound

$$F_1 \leq x'(t) \leq L_1, \qquad t \in [0,1].$$

Proof. Let, on the contrary, $x'(t) < F_1$ for some $t \in (0,1]$. Then, the continuity of $x'(t)$ on $[0,1]$ and $x'(0) = A \geq F_1$ imply that the set

$$S_+ = \{t \in [0,1] : F_2 \leq x'(t) < F_1\}$$

is not empty and there is a $\gamma \in S_+$ such that

$$x''(\gamma) < 0.$$

On the other hand, since $x(t)$ is a $C^2[0,1]$-solution to $(1.1)^-_\lambda$, we have in particular

$$x''(\gamma) = \lambda f(\gamma, x(\gamma), x'(\gamma)) + (1-\lambda)(x(\gamma) - x'(\gamma)).$$

But, $(\gamma, x(\gamma), x'(\gamma)) \in S_+ \times [-M_0, M_0] \times [F_2, F_1)$ and (1.11) imply

$$\lambda f(\gamma, x(\gamma), x'(\gamma)) \geq 0,$$

and $x(\gamma) - x'(\gamma) > 0$, because $x'(\gamma) < F_1 \le -M_0 \le x(\gamma)$. As a result

$$x''(\gamma) \ge 0$$

and a contradiction is achieved. Thus,

$$x'(t) \ge F_1 \quad \text{for } t \in [0,1].$$

Similar reasoning based on the use of (1.10) shows that

$$S_- = \{t \in [0,1] : L_1 < x'(t) \le L_2\}$$

is empty and so

$$x'(t) \le L_1 \quad \text{for } t \in [0,1]. \qquad \square$$

The proof of the next assertion is omitted, it follows the lines of proof of Lemmas 2.7, 2.8 and 2.9.

Lemma 2.10. *Let* **(B_2)** *hold for constants* M_0, $G_m = \min\{-M_0, B\}$ *and* $G_M = \max\{M_0, B\}$. *Then each solution* $x \in C^2[0,1]$ *to* $(1.1)^+_\lambda$, (1.4) *with the property*

$$-M_0 \le x(t) \le M_0, \qquad t \in [0,1],$$

satisfies the bound

$$F_1' \le x'(t) \le L_1', \qquad t \in [0,1].$$

3 Existence results

BVP $(1.1)^-_0$, (1.2), arising from $(1.1)^-_\lambda$, (1.2) for $\lambda = 0$, has the form

$$\begin{aligned} x'' + x' - x &= 0, \qquad t \in (0,1), \\ -\alpha x(0) + \beta x'(0) &= A, \qquad a x(1) + b x'(1) = B. \end{aligned}$$

By standard reasoning, we obtain that the solutions of the differential equation are the functions $x(t) = C_1 e^{r_1 t} + C_2 e^{r_2 t}$, and the system for C_1 and C_2 gives a unique solution to the BVP if

$$\begin{vmatrix} \beta r_1 - \alpha & \beta r_2 - \alpha \\ (a + b r_1) e^{r_1} & (a + b r_2) e^{r_2} \end{vmatrix} \ne 0, \tag{3.1}$$

where $r_1 = -\frac{1+\sqrt{5}}{2}$ and $r_2 = \frac{-1+\sqrt{5}}{2}$ are the roots of the characteristic equation.

Theorem 3.1. *Let* **(A_1)** *hold,* **(B_1)** *hold for*

$$M_0 = \max\{|A/\alpha|, |B/a|, M\}, \qquad G_m = (A - \alpha M_0)\beta^{-1} \quad \textit{and} \quad G_M = (A + \alpha M_0)\beta^{-1},$$

(C) *hold for the same constant* M_0 *and for* $m_0 = -M_0, m_1 = F_1, M_1 = L_1$ *and* (3.1) *be satisfied. Then BVP* (1.1), (1.2) *has at least one solution in* $C^2[0,1]$.

Proof. We divide the proof into two steps.

First step. We will check the hypotheses of Theorem 1.1 for the family of BVPs $(1.1)^-_\lambda$, (1.2) and BVP (1.1), (1.2) assuming firstly that the inequality in **(A$_1$)** is strong, that is,

$$xf(t,x,0) > 0 \quad \text{for } t \in [0,1] \text{ and } x \in D_x \setminus [-M,M]. \tag{3.2}$$

Condition *(i)* is fulfilled because we know from above that (3.1) guarantees a unique $C^2[0,1]$-solution to BVP $(1.1)^-_0$, (1.2). Apparently *(ii)* also holds. To check *(iii)* we establish, by standard reasoning, that for an arbitrary $y(t) \in C[0,1]$ the BVP

$$\begin{gathered} x'' = y(t) \\ -\alpha x(0) + \beta x'(0) = 0, \qquad ax(1) + bx'(1) = 0, \end{gathered}$$

has a unique solution in $C^2[0,1]$, which means that the map $\Lambda_h : C^2_{\mathcal{B}_0}[0,1] \to C[0,1]$, defined by $\Lambda_h x = x''$, is one-to-one. Besides, for each solution $x(t) \in C^2[0,1]$ to $(1.1)^-_\lambda$, (1.2) we have

$$m_0 \le x(t) \le M_0, \qquad t \in [0,1], \quad \text{by Lemma 2.4,}$$

and

$$m_1 \le x'(t) \le M_1, \qquad t \in [0,1], \quad \text{by Lemma 2.7.}$$

In view of **(C)**, the function $f(t,x,p)$ is continuous on $[0,1] \times [m_0,M_0] \times [m_1,M_1]$. Thus, there are constants m_2 and M_2 such that

$$\begin{gathered} m_2 \le \lambda f(t,x,p) + (1-\lambda)(x-p) \le M_2 \\ \text{for} \quad \lambda \in [0,1] \quad \text{and} \quad (t,x,p) \in [0,1] \times [m_0,M_0] \times [m_1,M_1]. \end{gathered}$$

Since for $t \in [0,1]$ we have $(x(t),x'(t)) \in [m_0,M_0] \times [m_1,M_1]$, the equation $(1.1)^-_\lambda$ implies

$$m_2 \le x''(t) \le M_2 \quad \text{for } t \in [0,1].$$

Hence, *(iv)* also holds. Finally, *(v)* follows again from **(C)**. Therefore, we can apply Theorem 1.1 to conclude that assertion is true when we have (3.2).

Second step. Now, assuming that **(A$_1$)** is in the form given, consider the family of BVPs

$$\begin{cases} x'' = f_n(t,x,x'),\ t \in (0,1), \\ -\alpha x(0) + \beta x'(0) = A,\ ax(1) + bx'(1) = B, \end{cases} \tag{3.3}$$

where $f_n(t,x,x') = f(t,x,x') + (x-x') : n,\ n = 1,2,3,\ldots$. Clearly,

$$xf_n(t,x,0) = xf(t,x,0) + \frac{x^2}{n} > 0 \text{ for } t \in [0,1], x \in D_x \setminus [-M,M],$$

that is, (3.2) is satisfied for each $n = 1,2,3,\ldots$. Besides,

$$\begin{aligned} &\frac{x-p}{n} \le 0 \quad \text{for } x \in [-M_0,M_0] \text{ and } p \ge L_1 \ge M_0, \\ &\frac{x-p}{n} \ge 0 \quad \text{for } x \in [-M_0,M_0] \text{ and } p \le F_1 \le -M_0, \end{aligned}$$

and **(B$_1$)** imply

$$f_n(t,x,p) \le 0 \quad \text{for } (t,x,p) \in [0,1] \times [-M_0,M_0] \times [L_1,L_2],$$

and

$$f_n(t,x,p) \geq 0 \quad \text{for } (t,x,p) \in [0,1] \times [-M_0, M_0] \times [F_2, F_1].$$

Thus, family (3.3) satisfies **(B_1)** for all $n = 1,2,3,\ldots$. Obviously, (3.3) satisfies **(C)** as well. Finally, to verify (3.1), we just have to consider that for each fixed $n = 1,2,3,\ldots$, the λ-family corresponding to (3.3) is

$$x'' = \lambda\left(f(t,x,x') + \frac{x-x'}{n}\right) + (1-\lambda)(x-x'), \qquad \lambda \in [0,1],$$
$$-\alpha x(0) + \beta x'(0) = A, \qquad ax(1) + bx'(1) = B,$$

and to see that for $\lambda = 0$ we have again BVP $(1.1)_0^-$, (1.2). So, taking into consideration the proved in *First step*, we conclude that family (3.3) has a solution $x_n \in C^2[0,1]$ for each $n = 1,2,3,\ldots$.

Further, just as in the proof of Lemma 2.4, we find that

$$|x_n(t)| \leq M_0 \quad \text{for } t \in [0,1],$$

and just as in the proof of Lemma 2.7 establish that

$$F_1 \leq x_n'(t) \leq L_1 \quad \text{for } t \in [0,1]$$

for each $n = 1,2,3,\ldots$. Finally,

$$|f_n(t,x,p)| \leq |f(t,x,p)| + \frac{|x-p|}{n} \leq |f(t,x,p)| + |x-p|$$

together with the continuity of $f(t,x,p)$ on $[0,1] \times [-M_0, M_0] \times [F_1, L_1]$ implies that there is a constant M_2 independent of n such that

$$|x_n''(t)| \leq M_2 \quad \text{for } t \in [0,1].$$

The estimates for $|x_n(t)|$, $|x_n'(t)|$ and $|x_n''(t)|$ allow us to use the Arzelà–Ascoli theorem to extract a subsequence $\{x_{n_k}\}$, $k = 1,2,3,\ldots$, of $\{x_n\}$ converging uniformly on $[0,1]$ to a function $x \in C^1[0,1]$. We will show that $x(t)$ is a $C^2[0,1]$-solution to BVP (1.1), (1.2). For this purpose introduce the sequence $\{y_{n_k}\}$, $k = 1,2,3,\ldots$, where $y_{n_k}(t) = x_{n_k}(t) - r(t)$, $t \in [0,1]$, with

$$r(t) = \frac{\alpha B + aA}{\alpha a + \alpha b + a\beta} t - \frac{Aa + Ab - \beta B}{\alpha a + \alpha b + a\beta}.$$

Clearly, $\{y_{n_k}\}$ converges uniformly on $[0,1]$ to the function $y(t) = x(t) - r(t)$ and $y \in C^1[0,1]$. Besides, since $r(t)$ satisfies BCs (1.2), $y_{n_k}(t)$ is a solution to the BVP

$$y_{n_k}'' = f_{n_k}(t, y_{n_k} + r, y_{n_k}' + r'), \qquad t \in (0,1),$$
$$-\alpha y_{n_k}(0) + \beta y_{n_k}'(0) = 0, \qquad a y_{n_k}(1) + b y_{n_k}'(1) = 0,$$

and its integral form

$$y_{n_k}(t) = \int_0^1 G(t,s) f_{n_k}(s, y_{n_k}(s) + r(s), y_{n_k}'(s) + r'(s))\,ds, \tag{3.4}$$

for $k = 1,2,3,\ldots$, where $G(t,s)$ is the Green function for the BVP

$$x'' = 0, \qquad t \in (0,1),$$

$$-\alpha x(0)+\beta x'(0)=0, \qquad ax(1)+bx'(1)=0,$$

and

$$f_{n_k}(t,y_{n_k}+r,y'_{n_k}+r')=f(t,y_{n_k}+r,y'_{n_k}+r')+\frac{y_{n_k}+r-y'_{n_k}-r'}{n_k}.$$

Since $|y_{n_k}+r-y'_{n_k}-r'|=|x_{n_k}-x'_{n_k}|\le M_0+\max\{|F_1|,L_1\}$, letting $k\to\infty$ in (3.4), we obtain

$$y(t)=\int_0^1 G(t,s)f(s,y(s)+r(s),y'(s)+r'(s))ds.$$

Thus,

$$x(t)=\int_0^1 G(t,s)f(s,x(s),x'(s))ds+r(t),$$

which means that $x(t)$ is a $C^2[0,1]$-solution to BVP (1.1), (1.2). □

Now let us look at BVP $(1.1)_0^+$, (1.2)

$$\begin{aligned} x''-x'-x&=0, \qquad t\in(0,1),\\ -\alpha x(0)+\beta x'(0)&=A, \qquad ax(1)+bx'(1)=B.\end{aligned}$$

It has a unique solution if

$$\begin{vmatrix} \beta s_1-\alpha & \beta s_2-\alpha \\ (a+bs_1)e^{s_1} & (a+bs_2)e^{s_2}\end{vmatrix}\neq 0, \tag{3.5}$$

where $s_1=\frac{1-\sqrt{5}}{2}$ and $s_2=\frac{1+\sqrt{5}}{2}$ are the roots of the characteristic equation.

Theorem 3.2. *Let* **(A_1)** *hold,* **(B_2)** *hold for*

$$M_0=\max\{|A/\alpha|,|B/a|,M\}, \qquad G_m=(B-aM_0)b^{-1} \quad \text{and} \quad G_M=(B+aM_0)b^{-1},$$

(C) *hold for the same constant M_0 and for $m_0=-M_0, m_1=F_1', M_1=L_1'$ and (3.5) be satisfied. Then BVP (1.1), (1.2) has at least one solution in $C^2[0,1]$.*

Proof. It is similar to the proof of the previous theorem. Now we will apply Theorem 1.1 on the family of BVPs $(1.1)_\lambda^+$, (1.2).

First step. Again assume firstly that the inequality in **(A_1)** is strong, that is, **(A)** holds.

The condition *(i)* follows from (3.5). The condition *(ii)* is again obvious, and the verification of *(iii)* is as in Theorem 3.1. Now, the bounds

$$m_0\le x(t)\le M_0 \quad \text{and} \quad m_1\le x'(t)\le M_1, \qquad t\in[0,1],$$

for each solution $x(t)\in C^2[0,1]$ to $(1.1)_\lambda^+$, (1.2), follow by Lemmas 2.4 and 2.8, respectively, and the bound

$$m_2\le x''(t)\le M_2 \quad \text{for } t\in[0,1]$$

follows by arguments similar to those in the proof of Theorem 3.1. Thus, *(iv)* holds. Finally, *(v)* follows again from **(C)**. So, the assertion is true by Theorem 1.1.

Second step. Now, **(A_1)** is in the form given. Consider the family of BVPs

$$\begin{cases} x''=f_n(t,x,x'),\ t\in(0,1),\\ -\alpha x(0)+\beta x'(0)=A,\ ax(1)+bx'(1)=B,\end{cases} \tag{3.6}$$

where $f_n(t,x,x') = f(t,x,x') + (x+x') : n,\ n = 1,2,3,\dots$. Clearly,

$$xf_n(t,x,0) = xf(t,x,0) + \frac{x^2}{n} > 0 \quad \text{for } t \in [0,1], x \in D_x \setminus [-M,M],$$

that is, **(A)** is satisfied for each $n = 1,2,3,\dots$. Besides,

$$\frac{x+p}{n} \geq 0 \quad \text{for } x \in [-M_0,M_0] \text{ and } p \geq L_1' \geq M_0,$$
$$\frac{x+p}{n} \leq 0 \quad \text{for } x \in [-M_0,M_0] \text{ and } p \leq F_1' \leq -M_0,$$

and **(B_2)** imply

$$f_n(t,x,p) \geq 0 \quad \text{for } (t,x,p) \in [0,1] \times [-M_0,M_0] \times [L_1', L_2'],$$

and

$$f_n(t,x,p) \leq 0 \quad \text{for } (t,x,p) \in [0,1] \times [-M_0,M_0] \times [F_2', F_1'].$$

Thus, family (3.6) satisfies **(B_2)** for all $n = 1,2,3,\dots$. Obviously, (3.6) satisfies and **(C)**. As in the proof of Theorem 3.1, we notice that (3.5) is also fulfilled. Consequently, according to what we proved in the *First step*, each boundary value problem arising from the family (3.6) for $n = 1,2,3,\dots$ has a solution $x_n \in C^2[0,1]$.

Further, just as in the proof of Lemma 2.4, we find that

$$|x_n(t)| \leq M_0 \quad \text{for } t \in [0,1],$$

and just as in the proof of Lemma 2.8 establish that

$$F_1' \leq x_n'(t) \leq L_1' \quad \text{for } t \in [0,1]$$

for each $n = 1,2,3,\dots$ Besides, the continuity of $|f(t,x,p)| + |x+p|$ on the compact set $[0,1] \times [-M_0,M_0] \times [F_1', L_1']$ implies that there is a constant M_2 independent of n such that

$$|x_n''(t)| \leq M_2 \quad \text{for } t \in [0,1].$$

By the Arzelà–Ascoli theorem the sequence $\{x_n\}$ has a subsequence $\{x_{n_k}\}$, $k = 1,2,3,\dots$, converging uniformly on $[0,1]$ to a function $x \in C^1[0,1]$. Next, arguing as in the proof of Theorem 3.1, establish that $x(t)$ is a $C^2[0,1]$-solution to BVP (1.1), (1.2). □

It is standardly found that the BVP

$$x'' + x' - x = 0, \quad t \in (0,1),$$
$$x'(0) = A, \quad ax(1) + bx'(1) = B,$$

in fact this is $(1.1)_0^-$, (1.3), has a unique solution in $C^2[0,1]$ if

$$\begin{vmatrix} r_1 & r_2 \\ (a+br_1)e^{r_1} & (a+br_2)e^{r_2} \end{vmatrix} \neq 0, \tag{3.7}$$

where r_1 and r_2 are as in (3.1).

Theorem 3.3. *Let* **(A_2)** *hold for* $J = [m_v, M_v]$ *and* $C = A$, **(B_1)** *hold for constants*

$$M_0 = \frac{L_-}{\min\{1, K\}} + \max\{|m_v|, |M_v|\}, \qquad G_m = \min\{-M_0, A\} \quad \text{and} \quad G_M = \max\{M_0, A\},$$

(C) *hold for the same constant* M_0 *and for* $m_0 = -M_0, m_1 = F_1$ *and* $M_1 = L_1$ *and* (3.7) *be satisfied. Then BVP* (1.1), (1.3) *has at least one solution in* $C^2[0,1]$.

Proof. We will apply Theorem 1.1 on family $(1.1)^-_\lambda$, (1.3). The hypothesis *(i)* follows immediately from (3.7). Besides, *(ii)* is obvious. The map $\Lambda_h : C^2_{\mathcal{B}_0}[0,1] \to C[0,1]$, defined by $\Lambda_h x = x''$ is one-to-one, because for an arbitrary $y(t) \in C[0,1]$ the BVP

$$\begin{aligned} x'' &= y(t) \\ x'(0) = 0, &\qquad ax(1) + bx'(1) = 0, \end{aligned}$$

has a unique solution in $C^2[0,1]$, *(iii)* is also fulfilled. For each solution $x(t) \in C^2[0,1]$ to $(1.1)^-_\lambda$, (1.3) we have

$$\begin{aligned} m_0 \le x(t) \le M_0, &\qquad t \in [0,1], \quad \text{by Lemma 2.5,} \\ m_1 \le x'(t) \le M_1, &\qquad t \in [0,1], \quad \text{by Lemma 2.9,} \end{aligned}$$

and the bound

$$m_2 \le x''(t) \le M_2 \quad \text{for } t \in [0,1]$$

follows as in the proof of Theorem 3.1. So, *(iv)* also holds. Finally, **(C)** ensures the validity of *(v)*. Therefore, we can apply Theorem 1.1 to conclude that the assertion is true. □

It is easily established that BVP $(1.1)^+_0$, (1.4), namely,

$$\begin{aligned} x'' - x' - x = 0, &\qquad t \in (0,1), \\ x'(0) = A, &\qquad ax(1) + bx'(1) = B, \end{aligned}$$

has a unique solution if

$$\begin{vmatrix} \beta s_1 - \alpha & \beta s_2 - \alpha \\ s_1 e^{s_1} & s_2 e^{s_2} \end{vmatrix} \neq 0, \tag{3.8}$$

where s_1 and s_2 are as in (3.5).

Theorem 3.4. *Let* **(A_2)** *hold for* $J = [m_w, M_w]$ *and* $C = B$, **(B_2)** *hold for constants*

$$M_0 = \frac{L_+}{\min\{1, K\}} + \max\{|m_w|, |M_w|\}, \qquad G_m = \min\{-M_0, B\} \quad \text{and} \quad G_M = \max\{M_0, B\},$$

(C) *hold for the same constant* M_0 *and for* $m_0 = -M_0, m_1 = F_1', M_1 = L_1'$ *and* (3.8) *be satisfied. Then BVP* (1.1), (1.4) *has at least one solution in* $C^2[0,1]$.

Proof. The proof is virtually the same as that of Theorem 3.3. Now, apply Theorem 1.1 on family $(1.1)^+_\lambda$, (1.4). *(i)* follows from (3.8), to check *(iii)* show that for an arbitrary $y(t) \in C[0,1]$ the BVP

$$\begin{aligned} x'' &= y(t) \\ -\alpha x(0) + \beta x'(0) = 0, &\qquad x'(1) = 0, \end{aligned}$$

has a unique solution in $C^2[0,1]$, and the bounds from *(iv)*,

$$\begin{aligned} m_0 \le x(t) \le M_0, &\qquad t \in [0,1], \\ m_1 \le x'(t) \le M_1, &\qquad t \in [0,1], \end{aligned}$$

for each solution $x(t) \in C^2[0,1]$ to $(1.1)^+_\lambda$, (1.4) follow from Lemmas 2.6 and 2.10, respectively. □

4 Examples

The following examples illustrate the application of the obtained results.

Example 4.1. Consider the BVPs for the equation

$$x'' = x'(x'-10) + (x-2)^2(x+2), \qquad t \in (0,1),$$
$$-3x(0) + 2x'(0) = 6, \qquad 2x(1) + x'(1) = -3.$$

We easily check that **(A_1)** holds for $M = 2$. Calculate $M_0 = 2, G_m = 0$ and $G_M = 6$. Next, keeping in mind that

$$0 \le (x-2)^2(x+2) < 1 \quad \text{for } x \in [-2,2],$$

we can choose, for example, $F_2 = -4, F_1 = -3, L_1 = 7$ and $L_2 = 8$ to see that **(B_1)** also hold. **(C)** is obvious, and (3.1) is also easily verifiable. So, we can apply Theorem 3.1 to conclude that the considered BVP has at least one solution in $C^2[0,1]$.

Example 4.2. Consider the BVP

$$x'' = x'^3 + (x-1)\sqrt{x+10}, \qquad t \in (0,1),$$
$$-x(0) + 4x'(0) = 5, \qquad 2x(1) + x'(1) = 4.$$

First observe that

$$xf(t,x,0) = x(x-1)\sqrt{x+10} \ge 0 \text{ for } x \in [-10,\infty) \setminus [-1,1],$$

which means that **(A_1)** is satisfied for $M = 1$. Then $M_0 = 5, G_m = -6, G_M = 14$. Besides,

$$-6\sqrt{5} \le (x-1)\sqrt{x+10} \le 4\sqrt{15} \quad \text{for } x \in [-5,5].$$

So, we can choose $F_2' = -8, F_1' = -7, L_1' = 15$ and $L_2' = 16$ to check **(B_2)**. In addition $f(t,x,p) = p^3 + (x-1)\sqrt{x+10}$ is continuous on the set $[0,1] \times [-5-\delta, 5+\delta] \times [-7-\delta, 15+\delta]$, where $\delta > 0$ is sufficiently small, to say $\delta = 0.1$, that is, **(C)** is satisfied. Checking (3.5) also presents no difficulty. So, we can apply Theorem 3.2 to conclude that the considered BVP has a solution in $C^2[0,1]$.

Example 4.3. Consider the BVP

$$x'' = \phi(t,x) + P_n(x'), \qquad t \in (0,1),$$
$$x'(0) = A, \qquad ax(1) + bx'(1) = B,$$

where the function $\phi\colon [0,1] \times \mathbb{R} \to \mathbb{R}$ is continuous, differentiable with respect to x and there is a constant $K > 0$ for which

$$\phi_x(t,x) \ge K > 0 \quad \text{for } (t,x) \in [0,1] \times \mathbb{R},$$

the polynomial $P_n(p) = \sum_{k=0}^{n} a_k p^k, n = 2s+1, s \in \mathbf{N}$, is such that $a_n < 0$, and a and b are such that (3.7) holds.

Clearly, **(A_2)** is satisfied. Further, if

$$f_{\max} := \max |\phi(t,x) + P_n(A)| \quad \text{for } (t,x) \in [0,1] \times [m_v, M_v],$$

where m_v and M_v are the constants used in Theorem 3.3, and

$$g_{\max} := \max|x - A| \quad \text{for } (t,x) \in [0,1] \times [m_v, M_v],$$

we determine first

$$L_- = \max\{f_{\max}, g_{\max}\}$$

and then M_0. Because the continuity of ϕ, there are constants $\phi_m, \phi_M \in \mathbb{R}$ such that

$$\phi_m \le \phi(t,x) \le \phi_M \quad \text{for } (t,x) \in [0,1] \times [-M_0, M_0].$$

Then, for sufficiently large $p > \max\{M_0, A\}$ we have

$$P_n(p) < -\max\{|\phi_m|, |\phi_M|\},$$

which implies that the constants L_1 and L_2 of **($\mathbf{B_1}$)** exist. Besides, for sufficiently small $p < \min\{-M_0, A\}$ we have

$$P_n(p) > \max\{|\phi_m|, |\phi_M|\},$$

which means that the constants F_1 and F_2 of **($\mathbf{B_1}$)** also exist. Finally, **(C)** is obvious and so the considered BVP has a solution in $C^2[0,1]$ by Theorem 3.3.

Example 4.4. Consider the BVP

$$\begin{aligned} x'' &= \phi(t,x) + P_n(x'), \qquad t \in (0,1), \\ -\alpha x'(0) + \beta x'(0) &= A, \qquad x'(1) = B, \end{aligned}$$

where the function $\phi[0,1] \times \mathbb{R} \to \mathbb{R}$ is continuous, differentiable with respect to x and there is a constant $K > 0$ for which

$$\phi_x(t,x) \ge K > 0 \quad \text{for } (t,x) \in [0,1] \times \mathbb{R},$$

the polynomial $P_n(p) = \sum_{k=0}^{n} a_k p^k, n = 2s+1, s \in \mathbf{N}$, is such that $a_n > 0$, and α and β are such that (3.8) holds.

An analysis similar to that of Example 4.3 shows that we can apply Theorem 3.4 to conclude that this BVP has a solution in $C^2[0,1]$.

Example 4.5. Consider the BVP

$$\begin{aligned} x'' &= x + 10^{-1} x' \sqrt{(x'+14)(11-x')}, \qquad t \in (0,1), \\ -x(0) + x'(0) &= 3, \qquad x'(1) = 2. \end{aligned}$$

We will check the conditions of Theorem 3.4. Here $w(t) = 2t - 1$ with $m_w = -1$ and $M_w = 1$. Then **($\mathbf{A_2}$)** is satisfied for $K = 1$, $J = [-1,1]$ and $C = 2$, because $f_x(t,x,2) = 1$ for $(t,x) \in [0,1] \times \mathbb{R}$. Form $f(t,x,2) = x + 2.4$. Then, for $(t,x) \in [0,1] \times [-1,1]$ we have $\max|f(t,x,2)| = 3.4$ and $\max|x+2| = 3$. We calculate $L_+ = 3.4, M_0 = 4.4, G_m = -4.4$ and $G_M = 4.4$. We are now ready to check that **($\mathbf{B_2}$)** is satisfied for $F_2' = -6, F_1' = -5, L_1' = 5$ and $L_2' = 6$. Keeping in mind that $f(t,x,p)$ is defined and continuous for $(t,x,p) \in [0,1] \times \mathbb{R} \times [-14,11]$, we easily conclude that **(C)** also holds for $m_0 = -4.4, M_0 = 4.4, m_1 = -5, M_1 = 5$ and, to say, $\delta = 0.01$. Finally, to check that (3.8) is satisfied, we establish that the determinant

$$\begin{vmatrix} \frac{1-\sqrt{5}}{2} - 1 & \frac{1+\sqrt{5}}{2} - 1 \\ \frac{1-\sqrt{5}}{2} e^{\frac{1-\sqrt{5}}{2}} & \frac{1+\sqrt{5}}{2} e^{\frac{1+\sqrt{5}}{2}} \end{vmatrix}$$

is different from zero. So, we can apply Theorem 3.4 to conclude that the considered BVP has a solution in $C^2[0,1]$.

5 Conclusions

Here we will comment on conditions (3.1), (3.5), (3.7) and (3.8). In fact, they are not essential. If, for example, (3.1) is not fulfilled, we can replace $(1.1)_\lambda^-$ with

$$x'' = \lambda f(t, x, x') + (1 - \lambda)(x - kx'), \qquad t \in (0, 1),$$

where $\lambda \in [0, 1]$ and $k > 0$. Now $(1.1)_0^-$ has the form

$$x'' + kx' - x = 0$$

and we can choose k such that its characteristic equation has roots r_1 and r_2 for which (3.1) is satisfied. This necessitates a slight change in **(B_1)**, namely

$$F_2 < F_1 \leq \min\{-M_0/k, G_m\}, \qquad \max\{M_0/k, G_M\} \leq L_1 < L_2,$$

Abstract. This paper is concerned with the existence and multiplicity of a ground state solution for the following class of elliptic fractional type problems given by

$$\begin{cases} (-\Delta)_p^s u + |u|^{p-2}u = \lambda h_1(x)|u|^{\theta-2}u \ln|u| + \dfrac{q}{q+r} b_1(x)|v|^r|u|^{q-2}u & \text{in } \Omega, \\ (-\Delta)_p^t v + |v|^{p-2}v = \mu h_2(x)|v|^{\theta-2}v \ln|v| + \dfrac{q}{q+r} b_2(x)|u|^r|v|^{q-2}v & \text{in } \Omega, \\ u = v = 0, & \text{in } \mathbb{R}^N \setminus \Omega, \end{cases}$$

where $\Omega \subset \mathbb{R}^N$ is a bounded domain with Lipschitz boundary, $s,t \in (0,1)$, $N > \max\{ps, pt\}$, $\lambda, \mu > 0$, $p \le \theta$, $2 < q + r < \min\left\{\frac{pN}{N-ps}, \frac{pN}{N-pt}\right\}$, and the additional weights $h_1, h_2, b_1, b_2 \in C(\overline{\Omega})$ are such that: $b_1(x), b_2(x)$ are positive functions and $h_1(x), h_2(x)$ are sign-changing functions. The operators $(-\Delta)_p^s$ and $(-\Delta)_p^t$ represents, both, fractional p-Laplacian operator, a generalization for the fractional Laplacian $(-\Delta)^s, 0 < s < 1$ $(p = 2)$, defined in a integral way as

$$(-\Delta)^s u(x) := \frac{c(n,s)}{2} \int_{\mathbb{R}^N} \frac{2u(x) - (x+y) - u(x-y)}{|y|^{n+2s}} dy, \qquad x \in \mathbb{R}^N,$$

where $c(n,s)$ is a positive normalizing constant, and another fractional operator.

Specifically, the operators $(-\Delta)_p^s$ and $(-\Delta)_p^t$ are defined, up to a normalization constant, by the formula

$$(-\Delta)_p^\ell u(x) := \lim_{\varepsilon \to 0^+} 2 \int_{\mathbb{R}^N \setminus B_\varepsilon(x)} \frac{|u(x) - u(y)|^{p-2}(u(x) - u(y))}{|x-y|^{N+sp}} dy,$$

for all $u \in C_0^\infty(\mathbb{R}^N), x \in \mathbb{R}^N$, and $\ell \in \{s, t\}$.

Keywords: fractional p-Laplacian operator, logarithmic nonlinearity, Nehari manifold, mountain pass theorem.

1 Introduction and main results

Since logarithmic nonlinearities play a significant role in depicting the mathematical and physical phenomena, they have received much attention in PDEs (see [15, 16, 19] and references therein).

In [15], the authors studied the existence and multiplicity of a class of fractional Laplacian systems with logarithmic nonlinearity in which three types of weights with certain regularity are involved.

$$\begin{cases} (-\Delta)^s u = \lambda h_1(x) u \ln(|u|) + \dfrac{p}{p+q} b(x)|v|^q |u|^{p-2}u & \text{in } \Omega, \\ (-\Delta)^t v = \mu h_2(x) v \ln(|v|) + \dfrac{r}{q+r} b(x)|u|^r |v|^{q-2}v & \text{in } \Omega, \\ u = v = 0, & \text{in } \mathbb{R}^N \setminus \Omega \end{cases} \tag{1.1}$$

where $\Omega \subset \mathbb{R}^N$ is a bounded domain with Lipschitz boundary, $s, t \in (0,1)$, $N > \max\{2s, 2t\}$, $\lambda, \mu > 0$, $2 < q + p < \min\left\{\frac{2N}{N-2s}, \frac{2N}{N-2t}\right\}$, and the additional weights $h_1, h_2, b \in C(\overline{\Omega})$ are such that: $b(x)$ are positive functions and $h_1(x), h_2(x)$ are sign-changing functions.

In [16], the authors studied a class of systems of equations where they showed the existence and multiplicity of solutions for a mixed local-nonlocal system with logarithmic nonlinearities

$$\begin{cases} (-\Delta)^s u_j + u_j = \lambda_j a_j(x) u_j \ln|u_j| + \displaystyle\sum_{i \neq j} \beta_{ij} |u_j|^{q-2} u_j & \text{in } \Omega, \\ u = v = 0, & \text{in } \mathbb{R}^N \setminus \Omega \end{cases} \tag{1.2}$$

where $\Omega \subset \mathbb{R}^N$ is a bounded domain with Lipschitz boundary, $s \in (0,1)$, $N > 4$, λ_j are parameters, $\beta_{ij} > 0$ for all $1 \leq i < j \leq k$, $\beta_{ij} = \beta_{ji}$ for all $i, j = 1, \ldots, k$, $a_j \in C(\overline{\Omega})$. When $1 < 2q < 2 < 2^* = \frac{2N}{N-2}$ and a_j they are functions that change sign, they obtained two different solutions using Nehari method. When $1 < q < 2 < 2^* = \frac{2N}{N-2}$ and a_j are positive constant functions, the existence of the ground state solution is obtained using the minimization method.

In [9], the authors studied a class of fractional Laplacian systems where they showed the existence of solutions using the Nehari method and multiplicity of solutions using the Lusternik–Schnirelmann category, with polynomial nonlinearity.

$$\begin{cases} (-\Delta)^s u = \lambda |u|^{p-2}u + \dfrac{2\alpha}{\alpha+\beta} |v|^\beta |u|^{\alpha-2}u & \text{in } \Omega, \\ (-\Delta)^s v = \mu |u|^{p-2}u + \dfrac{2\beta}{\alpha+\beta} |u|^\alpha |v|^{\beta-2}v & \text{in } \Omega, \\ u = v = 0, & \text{in } \mathbb{R}^N \setminus \Omega \end{cases} \tag{1.3}$$

where $\Omega \subset \mathbb{R}^N$ is a bounded domain, $s \in (0,1)$, $N > 4s$, $\lambda, \mu > 0$ are parameters, $\alpha + \beta = \frac{2N}{N-2s}$ is the critical Sobolev exponent.

In [6], the authors showed the existence of solutions for the fractional critical system (p, q)

Laplacian using variational method

$$\begin{cases} (-\Delta)_p^{s_1} u + (-\Delta)_q^{s_2} u = \lambda Q(x)|u|^{r-2}u + \dfrac{2\alpha}{\alpha+\beta}|v|^{\beta}|u|^{\alpha-2}u & \text{in } \Omega, \\ (-\Delta)_p^{s_1} v + (-\Delta)_q^{s_2} v = \mu Q(x)|u|^{r-2}u + \dfrac{2\beta}{\alpha+\beta}|u|^{\alpha}|v|^{\beta-2}v & \text{in } \Omega, \\ u = v = 0, & \text{in } \mathbb{R}^N \setminus \Omega \end{cases} \tag{1.4}$$

where $\Omega \subset \mathbb{R}^N$ is a bounded domain, $0 < s_2 < s_1 < 1$, $1 < q < p < r < p_{s_1}^*$, $N > ps_1$, $\lambda, \mu > 0$ are parameters and $\alpha > 1$ $\beta > 1$ satisfy $\alpha + \beta = p_{s_1}^*$ with $\frac{Np}{N-ps_1}$ is the critical Sobolev exponent, and $(-\Delta)_t^s$ is the fractional t-Laplacian operator.

In [19] was concerned with the existence and asymptotic behavior of normalized ground states solutions for the following coupled Schrödinger system with logarithmic terms:

$$\begin{cases} -\Delta u_1 + \omega_1 u_1 = \mu_1 u_1 \log u_1^2 + \dfrac{p}{p+q}|u_2|^q |u_1|^{p-2}u_1, \\ -\Delta u_2 + \omega_2 u_2 = \mu_2 u_2 \log u_2^2 + \dfrac{q}{p+q}|u_1|^p |u_2|^{q-2}u_2, \\ \displaystyle\int_\Omega |u_i|^2 dx = \rho_i, \ i = 1, 2, \end{cases} \tag{1.5}$$

where $\Omega = \mathbb{R}^N$ or $\Omega \subset \mathbb{R}^N (N \geq 3)$ is a bounded smooth domain, $\omega_i \in \mathbb{R}, \mu_i, \rho_i > 0, i = 1, 2$. Moreover, $p, q \geq 1, 2 \leq p + q \leq 2^*$ where $2^* := \frac{2N}{N-2}$.

In [17] the authors studied the existence of least energy solutions to the following fractional Kirchhoff problem with logarithmic nonlinearity

$$\begin{cases} M([u]_{s,t}^p)(-\Delta)_p^s u = h(x)|u|^{\theta p-2}u \ln|u| + \lambda|u|^{q-2}u, & x \in \Omega \\ u = 0, & x \in \mathbb{R}^N \setminus \Omega, \end{cases} \tag{1.6}$$

where $s \in (0,1)$, $1 < p < Np$, $\Omega \subset \mathbb{R}^N$ is a bounded domain with Lipschitz boundary, $M([u]_{s,p}^p) = [u]_{s,p}^{(\theta-1)p}$, with $\theta \geq 1$ and $u, h \in C(\overline{\Omega})$ may change sign, $\lambda > 0$ and $q \in (1, p_s^*)$.

On the other hand, parabolic and hyperbolic type equations with logarithmic nonlinearity have been studied extensively in recent years. Here we only refer some results involving fractional Laplacian. [2] considered the Cauchy problem of the following Schrödinger equation

$$iu_t - (-\Delta)^s u + u \log|u|^2 = 0, \quad x \in \Omega, \ t > 0. \tag{1.7}$$

The existence of global solutions was obtained by using a compactness method. Moreover, the author obtained the existence of ground states by the Nehari manifold approach. Xiang et al. [18] studied the initial boundary value problem of the following parabolic equation involving logarithmic nonlinearity

$$u_t + [u]_s^{2(\kappa-1)}(-\Delta)^s u = |u|^{q-2}u \ln|u|^2, \quad x \in \Omega, \ t > 0. \tag{1.8}$$

where $\kappa \in (1, 2_s^*/2)$ and $2\kappa < q < 2^*$. By the potential well theory, the existence of global solutions and blow-up properties of local solutions were discussed. Particularly, using the Nehari manifold approach, the existence of ground state solutions for above stationary problem was investigated.

The main tool used in this paper is the so-called fibering method introduced by Pohozaev [11], [12] and [13], and applied to a single equation of p-Laplacian type by Drábek and Pohozaev in [8]. Bozhkov and Mitidieri [4] used this method to study the existence for multiple solution for a quasilinear system. Fibering method is very used to proof existence of multiple solution for a large class of equations. For example, Brown and Wu [5] used this method to show the existence of at least two positive solutions for the semilinear elliptic boundary-value problem. For more recent applying of fibering method we indicate [1], used to show existence of multiple solution for a class of Schrödinger equations involving indefinite weight functions, and other interesting work involving the fractional operator is [7]

In this paper motivated by [9, 15, 16, 19] we deal with the existence and multiplicity of ground state solutions for the subcritical for the following class of problems

$$\begin{cases} (-\Delta)_p^s u + |u|^{p-2}u = \lambda h_1(x)|u|^{\theta-2}u\ln(|u|) + \dfrac{q}{q+r}b_1(x)|v|^r|u|^{q-2}u & \text{in } \Omega, \\ (-\Delta)_p^t v + |v|^{p-2}v = \mu h_2(x)|v|^{\theta-2}v\ln(|v|) + \dfrac{r}{q+r}b_2(x)|u|^r|v|^{q-2}v & \text{in } \Omega, \\ u = v = 0, & \text{in } \mathbb{R}^N \setminus \Omega. \end{cases} \tag{P}$$

Taking $W_0^{s,j} = \{u \in W^{s,j}(\mathbb{R}^N) : u = 0 \text{ in } \mathbb{R}^N \setminus \Omega\}$, we define the normed space W, denoted by $W := W_0^{s,p}(\Omega) \times W_0^{s,t}(\Omega)$ (see Section 3), the main results of this paper is writing as follows:

Theorem 1.1. *Problem (P) has a nontrivial ground state solution in W for $s,t \in (0,1)$, $2 < p+q < \min\{p_s^*, p_t^*\}$ and $h_1(x), h_2(x)$ positive functions in $C(\overline{\Omega})$.*

Theorem 1.2. *Problem (P) has a nontrivial ground state solution in W for $s,t \in (0,1)$, $2 < p+q < \min\{p_s^*, p_t^*\}$ and $h_1(x), h_2(x)$ two sign-changing functions in $C(\overline{\Omega})$.*

The paper is organized as follows. In Section 2 we study the variational framework. In Section 3 study Nehari manifold and fibering map analysis. In Section 4 we prove Theorem 1.1. In Section 5 we prove Theorem 1.2.

2 The variational framework

First of all, in this section we introduce the fractional Sobolev space where lies the solution for Problem (P). After defining this space, we introduce some technical results that will be used to proof the main theorems.

Let $\Omega \subset \mathbb{R}^N$ be a domain. For for $p \in [1,\infty)$ and $s \in (0,1)$, we define the fractional Sobolev space

$$W^{s,p}(\Omega) := \left\{ u \in L^p(\Omega) : \frac{|u(x)-u(y)|}{|x-y|^{\frac{N}{p}+s}} \in L^p(\Omega\times\Omega) \right\}; \tag{2.1}$$

i.e., an intermediary Banach space between $L^p(\Omega)$ and $W^{1,p}(\Omega)$, endowed with the natural norm

$$\|u\|_s = \|u\|_{W^{s,p}(\Omega)} = \left(\int_\Omega |u|^p dx + \int_\Omega\int_\Omega \frac{|u(x)-u(y)|^p}{|x-y|^{N+ps}} dxdy \right)^{1/p}$$

where

$$[u]_s = [u]_{W^{s,p}(\Omega)} := \left(\int_\Omega \int_\Omega \frac{|u(x) - u(y)|^p}{|x-y|^{N+ps}} dxdy \right)^{1/p}$$

is the so-called Gagliardo seminorm of u.

Moreover, we define the corresponding local fractional Sobolev spaces by

$$W^{s,p}_{\text{loc}}(\Omega) := \{u \in L^p_{\text{loc}}(\Omega) : \ u \in W^{s,p}(\Omega') \text{ for any } \Omega' \subset\subset \Omega\}.$$

Also, we define the space

$$W^{s,p}_0(\Omega) := \{u \in W^{s,p}(\mathbb{R}^N) : \ u = 0 \text{ in } \mathbb{R}^N \setminus \Omega\}.$$

Now we are able to define the space $W := W^{s,p}_0(\Omega) \times W^{s,t}_0(\Omega)$ where lies the solutions of the Problem (P) in the Theorems 1.1 and 1.2. One can check that $(W, |\cdot|)$ is a normed space, with norm given by

$$\|(u,v)\| := \|(u,v)\|_W = \left([u]^p_s + |u|^p_p + [v]^p_t + |v|^p_p\right)^{1/p}.$$

Motivated by [10] we show the following lemma for system.

Lemma 2.1. *W is continuously embedding on $L^{s,p}(\Omega) \times L^{s,t}(\Omega)$.*

Proof. Let $u \in W^{s,p}(\Omega)$. Since $\Omega \subset \mathbb{R}^N$ is an extension domain for $W^{s,p}$, then there exists a constant $C_1 = C_1(N,p,s,\Omega) > 0$ such that

$$\|\tilde{u}\|_{W^{s,p}(\mathbb{R}^N)} \leq C_1 \|u\|_{W^{s,p}(\Omega)} \tag{2.2}$$

with $\tilde{u}$ such that $\tilde{u}(x) = u(x)$ for x a.e. in Ω. On the other hand, by [10, Theorem 6.7], the space $W^{s,p}(\mathbb{R}^N)$ is continuously embedded in $L^r(\mathbb{R}^N)$, for any $r \in [p, p^*_s]$; i.e., there exists a constant $C_2 = C_2(N,p,s) > 0$ such that

$$\|\tilde{u}\|_{L^r(\mathbb{R}^N)} \leq C_2 \|\tilde{u}\|_{W^{s,p}(\mathbb{R}^N)}. \tag{2.3}$$

Using (2.2) and (2.3), we get

$$\|u\|_{L^r(\Omega)} = \|\tilde{u}\|_{L^r(\Omega)} \leq \|\tilde{u}\|_{L^r(\mathbb{R}^N)} \leq C_2 \|\tilde{u}\|_{W^{s,p}(\mathbb{R}^N)} \leq C_2 C_1 \|u\|_{W^{s,p}(\Omega)}. \tag{2.4}$$

Similarly we have the following inequality

$$\|v\|_{L^\eta(\Omega)} = \|\tilde{v}\|_{L^\eta(\Omega)} \leq \|\tilde{v}\|_{L^\eta(\mathbb{R}^N)} \leq C_3 \|\tilde{v}\|_{W^{t,p}(\mathbb{R}^N)} \leq C_3 C_4 \|v\|_{W^{t,p}(\Omega)}. \tag{2.5}$$

Finally using (2.4) and (2.5) we have

$$\|(u,v)\|_{L^r(\Omega)\times L^\eta(\Omega)} \leq \tilde{C} \|(u,v)\|_W \tag{2.6}$$

for some $C \in (0,\infty)$, from which follows the proposition. □

Lemma 2.2. *If $q + r < \min\{p^*_s, p^*_t\}$ then there exists a positive constant c such that*

$$\left(\int_\Omega |u|^r |v|^q dx \right)^{\frac{1}{q+r}} \leq c \|(u,v)\|.$$

Proof. The proof follows from the definition

$$S_{r,q} := \inf_{(u,v)\in W\setminus\{(0,0)\}} \left\{ \frac{\|(u,v)\|^p}{\left(\int_\Omega |u|^r|v|^q dx\right)^{\frac{p}{q+r}}} \right\}. \tag{2.7}$$

and the inequality $|u|^r|v|^q \leq \frac{r}{r+q}|u|^{r+q} + \frac{q}{r+q}|v|^{r+q} \leq |u|^{r+q} + |v|^{r+q}$. □

Lemma 2.3. *Let $\xi, \eta \in \mathbb{R}^N$. Then,*

$$|\xi-\eta|^p \leq \begin{cases} 2^p\left(|\xi|^{p-2}\xi + |\eta|^{p-2}\eta\right)(\xi-\eta), & \text{for } p \geq 2, \\ \dfrac{1}{(p-1)} \dfrac{\left[\left(|\xi|^{p-2}\xi + |\eta|^{p-2}\eta\right)(\xi-\eta)\right]^{p/2}}{\left(|\xi|^p + |\eta|^p\right)^{(p-2)/p}}, & \text{for } 1 < p < 2. \end{cases} \tag{2.8}$$

The proof of this lemma can be found in [14, Lemma 6].

Definition 2.4. We say that $(u,v) \in W$ is a (weak) solution of Problem (P) if

$$\begin{aligned} &\int_\Omega\int_\Omega \frac{|u(x)-u(y)|^{p-2}(u(x)-u(y))(\varphi(x)-\varphi(y))}{|x-y|^{N+ps}}dxdy + \int_\Omega |u|^{p-2}u\varphi dx \\ &\quad + \int_\Omega\int_\Omega \frac{|v(x)-v(y)|^{p-2}(v(x)-v(y))(\phi(x)-\phi(y))}{|x-y|^{N+pt}}dxdy + \int_\Omega |v|^{p-2}v\phi dx \\ &= \lambda\int_\Omega h_1(x)|u|^{\theta-2}u\ln|u|\varphi dx + \mu\int_\Omega h_2(x)|v|^{\theta-2}v\ln|v|\phi dx \\ &\quad + \frac{q}{q+r}\int_\Omega b_1(x)|v|^r|u|^{q-2}u\varphi dx + \frac{r}{q+r}\int_\Omega b_2(x)|u|^q|v|^{r-2}v\phi dx, \end{aligned}$$

for any $(\varphi,\phi) \in W$.

Now we consider the energy functional for Problem (P), $E : W \to \mathbb{R}$ defined by

$$\begin{aligned} E(u,v) = &\frac{1}{p}[u]^p_{s,p} + \frac{1}{p}\int_\Omega |u|^p dx + \frac{1}{p}[v]^p_{s,t} + \frac{1}{p}\int_\Omega |v|^p dx - \frac{\lambda}{\theta}\int_\Omega h_1(x)|u|^\theta \ln|u|dx \\ &+ \frac{\lambda}{\theta^2}\int_\Omega h_1(x)|u|^\theta dx - \frac{\mu}{\theta}\int_\Omega h_2(x)|v|^\theta\ln|v|dx + \frac{\mu}{\theta^2}\int_\Omega h_2(x)|v|^\theta dx \\ &- \frac{1}{q+r}\int_\Omega b_1(x)|u|^q|v|^r dx - \frac{1}{q+r}\int_\Omega b_2(x)|u|^q|v|^r dx. \end{aligned}$$

We also consider the functional

$$\begin{aligned} I(u,v) = &[u]^p_{s,p} + \int_\Omega |u|^p dx + [v]^p_{s,t} + \int_\Omega |v|^p dx - \lambda\int_\Omega h_1(x)|u|^\theta\ln|u|dx \\ &- \mu\int_\Omega h_2(x)|v|^\theta\ln|v|dx - \int_\Omega b_1(x)|u|^q|v|^r dx - \int_\Omega b_2(x)|u|^q|v|^r dx. \end{aligned}$$

As consequence of embedding on Remark 2.1 and Lemma 2.2, we obtain that the functional I

is well-defined and $E, I \in C^1(W, \mathbb{R})$. Moreover, note that, for all $(\varphi, \phi) \in W$,

$$\begin{aligned}
E'(u,v)(\varphi,\phi) = &\int_\Omega\int_\Omega \frac{|u(x)-u(y)|^{p-2}(u(x)-u(y))(\varphi(x)-\varphi(y))}{|x-y|^{N+ps}}dxdy + \int_\Omega |u|^{p-2}u\varphi dx \\
&+ \int_\Omega\int_\Omega \frac{|v(x)-v(y)|^{p-2}(v(x)-v(y))(\phi(x)-\phi(y))}{|x-y|^{N+pt}}dxdy + \int_\Omega |v|^{p-2}v\phi dx \\
&- \lambda\int_\Omega h_1(x)|u|^{\theta-2}u\ln|u|\varphi dx - \mu\int_\Omega h_2(x)|v|^{\theta-2}v\ln|v|\phi dx \\
&- \frac{q}{q+r}\int_\Omega b_1(x)|v|^r|u|^{q-2}u\varphi dx - \frac{r}{q+r}\int_\Omega b_2(x)|u|^q|v|^{r-2}v\phi dx
\end{aligned}$$

and

$$\begin{aligned}
I'(u,v)(\varphi,\phi) = &\, p\int_\Omega\int_\Omega \frac{|u(x)-u(y)|^{p-2}(u(x)-u(y))(\varphi(x)-\varphi(y))}{|x-y|^{N+ps}}dxdy + p\int_\Omega |u|^{p-2}u\varphi dx \\
&+ p\int_\Omega\int_\Omega \frac{|v(x)-v(y)|^{p-2}(v(x)-v(y))(\phi(x)-\phi(y))}{|x-y|^{N+pt}}dxdy + p\int_\Omega |v|^{p-2}v\phi dx \\
&- \lambda\theta\int_\Omega h_1(x)|u|^{\theta-2}u\varphi\ln|u|dx - \lambda\int_\Omega h_1(x)|u|^{\theta-2}u\varphi dx \\
&- \mu\theta\int_\Omega h_2(x)|v|^{\theta-2}v\phi\ln|v|dx - \mu\int_\Omega h_2(x)|v|^{\theta-2}v\phi dx \\
&- (q+r)\int_\Omega b_1(x)|v|^r|u|^{q-2}u\varphi dx - (q+r)\int_\Omega b_2(x)|u|^q|v|^{r-2}v\phi dx.
\end{aligned}$$

Some important results will be used in this paper, including those concerning Sobolev's Logarithmic Inequalities to obtain some estimates of the problem and to resolve some arisen difficult in the logarithmic term:

Lemma 2.5. *Let ρ be a positive real number. Then we have the following inequalities*

$$\ln t \le \frac{t^\rho}{e\rho} \quad \text{for all } 1 \le t \tag{2.9}$$

and

$$|t^\rho \ln t| \le \frac{1}{e\rho} \quad \text{for all } 0 < t < 1. \tag{2.10}$$

where e is Euler logarithm basis.

Proof. We consider the following function $h : [1, \infty) \to \mathbb{R}$ defined by

$$h(t) = \ln t - \frac{1}{e\rho}t^\rho \quad \text{for all } t \ge 1.$$

With respect to t, just by taking a simple derivative, we deduce

$$h'(t) = \frac{1}{t} - \frac{1}{e}t^{\rho-1} \quad \text{for all } t \ge 1.$$

Then, $t_* = e^{1/\rho}$ is the unique maximum point of function h. Thus, $h(t) \le h(t_*) = 0$ for all $t \ge 1$ and the inequality (2.9) is valid.

To prove the inequality (2.10), we consider $g : (0, 1] \to \mathbb{R}$ defined by

$$g(t) = t^\rho|\ln t| \quad \text{for all } t \in (0, 1].$$

We can verify that $t_* = e^{-1/\rho}$ is the unique minimum point of the function g. We can also check that $\lim_{t\to 0^+} g(t) = 0$. Thus,

$$g(t) \geq g(t_*) = -\frac{1}{e\rho}$$

and the proof is complete. □

Lemma 2.6. *Assume that (u_n, v_n) is bounded in W such that u_n converges to u a.e. and v_n converges to v in Ω. Then*

$$\lim_{n\to\infty} \int_\Omega h_1(x)|u_n|^\theta \ln|u_n| dx = \int_\Omega h_1(x)|u|^\theta \ln|u| dx.$$

and

$$\lim_{n\to\infty} \int_\Omega h_2(x)|v_n|^\theta \ln|v_n| dx = \int_\Omega h_2(x)|v|^\theta \ln|v| dx,$$

for $2 < \theta < q + r$.

Proof. Since that (u_n, v_n) is bounded in W, we get that $\|(u_n, v_n)\| \leq C$, for all $n \in \mathbb{N}$, we first need to discuss the two cases of $|u_n|$ as follows.

Case I. If $\frac{|u_n(x)|}{\|(u_n,v_n)\|} < 1$. By Lemma 2.5 with (2.9) with $\rho = \theta < p_s^*$, from the Sobolev Inequalities, we get

$$\begin{aligned}\left|h_1(x)|u_n|^\theta \ln\left(\frac{|u(x)|}{\|(u_n,v_n)\|}\right)\right| &\leq C_{h_1}\left||u|^\theta \ln\left(\frac{|u(x)|}{\|(u_n,v_n)\|}\right)\right| \\ &= C_{h_1}\|(u_n,v_n)\|^\theta \left|\frac{|u_n(x)|}{\|(u_n,v_n)\|}\right|^\theta \left|\ln\left(\frac{|u_n(x)|}{\|(u_n,v_n)\|}\right)\right| \\ &\leq \frac{C_{h_1}}{e\theta}\|(u_n,v_n)\|^\theta =: g_n^1. \end{aligned} \tag{2.11}$$

Since $(u_n, v_n) \rightharpoonup (0,0)$ in W, then $(u_n, v_n) \to (0,0)$ in $L^\theta(\Omega) \times L^\theta(\Omega)$ for all $\theta \in (1, \min\{p_s^*, p_t^*\})$ using the Sobolev embeddings, we have

$$\int_\Omega |g_n^1(x)| dx \leq \frac{C_{H_1}}{e\theta}\|(u_n,v_n)\|^\theta \to 0, \quad \text{as } n \to \infty. \tag{2.12}$$

Thus, $|g_n^1| \to 0$ in $L^1(\Omega)$, which means that there exists some $g_1 \in L^1(\Omega)$ such that $|g_n^1(x)| \leq g^1(x)$ a.e. in Ω for all $n \in \mathbb{N}$.

Case II. If $\frac{|u_n(x)|}{\|(u_n,v_n)\|} > 1$. Using Lemma 2.5 with (2.9) and Hölder's inequality, we get

$$\begin{aligned}\left|h_1(x)|u_n|^\theta \ln\left(\frac{|u(x)|}{\|(u_n,v_n)\|}\right)\right| &\leq C_{h_1}\left||u_n|^\theta \ln\left(\frac{|u(x)|}{\|(u_n,v_n)\|}\right)\right| \\ &= C_{h_1}\|(u_n,v_n)\|^{\theta-\rho}|u_n|^\rho \left|\frac{|u_n(x)|}{\|(u_n,v_n)\|}\right|^{\theta-\rho} \left|\ln\left(\frac{|u_n(x)|}{\|(u,v)\|}\right)\right| \\ &\leq C_{h_1}\frac{\|(u_n,v_n)\|^{\theta-\rho}}{e(\theta-\rho)}|u_n|^\rho := g_2^n. \end{aligned} \tag{2.13}$$

Since $(u_n, v_n) \rightharpoonup (0,0)$ in W, then $(u_n, v_n) \to (0,0)$ in $L^\theta(\Omega) \times L^\theta(\Omega)$ for all $\theta \in (1, \min\{p_s^*, p_t^*\})$ using the Sobolev embeddings, we have

$$\int_\Omega |g_n^2(x)| dx \leq \frac{C_{h_1}}{e(\theta-\rho)}\|(u_n,v_n)\|^\theta \to 0, \quad \text{as } n \to \infty. \tag{2.14}$$

Thus, $|g_n^2| \to 0$ in $L^1(\Omega)$, which means that there exists some $g_1 \in L^1(\Omega)$ such that $|g_n^2(x)| \leq g^1(x)$ a.e. in Ω for all $n \in \mathbb{N}$. Now, defining $f_n := |u_n(x)|^\theta|\varphi|$, we also have $f_n \to 0$ in $L^1(\Omega)$, which provides $f \in L^1(\Omega)$ such that $|f_n(x)| \leq f(x)$ a.e. in $\mathbb{N}$ for all $n \in \mathbb{N}$.
Combining (2.11) and (2.13) , we have the following estimate

$$\begin{aligned}\left|h_1(x)|u_n(x)|^\theta \ln\left(\frac{|u_n(x)|\cdot\|(u_n,v_n)\|}{\|(u_n,v_n)\|}\right)\right| &\leq C_{h_1}\left[\left||u_n(x)|^\theta \ln\left(\frac{|u(x)|}{\|(u_n,v_n)\|}\right)\right|\right.\\ &\quad\left.+\ln\|(u_n,v_n)\||u_n(x)|^\theta\right]\\ &\leq g_n^1+g_n^2+f_n, \end{aligned} \tag{2.15}$$

where $g_n^1+g_n^2+f_n \in L^1(\Omega)$, for all $n \in \mathbb{N}$. For other hand, since $\{(u_n,v_n)\}$ is bounded in W, up to a subsequence, we may assume that $(u_n(x),v_n(x)) \to (u(x),v(x))$ a.e in Ω. This implies that

$$h_1(x)|u_n(x)|^\theta \ln|u_n(x)| \to h_1(x)|u(x)|^\theta \ln|u(x)|, \quad \text{a.e. in } \Omega. \tag{2.16}$$

Therefore, using (2.15) and (2.16) the Lebesgue Dominated Convergence Theorem yields that

$$\lim_{n\to+\infty}\int_\Omega h_1(x)|u_n|^\theta \ln|u_n|dx = \int_\Omega h_1(x)|u|^\theta \ln|u|dx. \tag{2.17}$$

Using the same idea of equation (2.17), we have the following convergence

$$\lim_{n\to+\infty}\int_\Omega h_2(x)|v_n|^\theta \ln|v_n|dx = \int_\Omega h_2(x)|v|^\theta \ln|v|dx. \tag{2.18}$$

The proof is concluded. □

Lemma 2.7. *Let $\Omega \subset \mathbb{R}^N$ be a domain, $q \in [0,\infty)$ and (u_n) be a bounded sequence in $L^r(\Omega)$. If $u_n \to u$ almost everywhere on Ω as $n \to +\infty$, then for every $q \in [1,r]$.*

$$\lim_{n\to+\infty}\int_\Omega \left||u_n|^q - |u_n-u|^q - |u|^q\right|^{\frac{r}{q}}dx = 0. \tag{2.19}$$

Also recall that pointwise convergence of a bounded sequence implies weak converge (see for example [3, Proposition 4.7.12])

Lemma 2.8. *Let the sequences (u_n) and (v_n) be in $\in W_0^{s,p}(\Omega)$ such that $u_n \rightharpoonup u$, $v_n \rightharpoonup v$ in $W_0^{s,p}(\Omega)$ and $u_n(x) \to u(x)$, $v_n(x) \to v(x)$ a.e. in Ω. Then,*

$$\lim_{n\to\infty}\int_\Omega \left[|u_n|^q|v_n|^r - |u_n-u|^q|v_n-v|^r\right]dx = \int_\Omega |u|^q|v|^r dx.$$

Proof. By direct calculation we have the following equality of integrals

$$\begin{aligned}&\int_\Omega \Big(|u_n|^q|v_n|^r - |u_n-u|^q|v_n-v|^r\Big)dx\\ &\quad= \int_\Omega \Big(|u_n|^q - |u_n-u|^q)|v_n|^r + |u_n-u|^q(|v_n|^r - |v_n-v|^r\Big)dx.\end{aligned}$$

Since that $u_n \rightharpoonup u$, $v_n \rightharpoonup v$ in $W_0^{s,p}(\Omega)$ and using Lemma 2.7, we get

$$\lim_{n\to+\infty}\int_\Omega \Big(|u_n|^q - |u_n-u|^q - |u|^q\Big)^{\frac{q+r}{q}}dx = 0. \tag{2.20}$$

which means that $|u_n|^q - |u_n - u|^q \to |u|^q$ in $L^{\frac{q+r}{q}}(\Omega)$, for other hand $|v_n|^r \rightharpoonup |v|^r$ in $L^{\frac{q+r}{r}}(\Omega)$, this implies that

$$\lim_{n\to+\infty}\int_\Omega \Big(|u_n|^q - |u_n-u|^q - |u|^q\Big)|v_n|^r dx = 0.$$

Also, note that $|v_n|^r - |v_n - v|^r \to |v|^q$ in $L^{\frac{q+r}{r}}(\Omega)$. As $|u_n - u|^q \rightharpoonup 0$ in $L^{\frac{q+r}{q}}(\Omega)$, this implies that

$$\lim_{n\to+\infty}\int_\Omega |u_n-u|^q\Big(|v_n|^r - |v_n-v|^r\Big)dx = 0. \tag{2.21}$$

This concludes the proof. □

Lemma 2.9. *Let $(u,v) \in W \setminus \{(0,0)\}$. Then*

$$\begin{aligned}&\lambda\int_\Omega h_1(x)|u|^\theta \ln|u|dx + \mu\int_\Omega h_2(x)|v|^\theta\ln|v|dx\\ &\quad\le (\lambda C_{h_1} + \mu C_{h_2})L\|(u,v)\|^p + \ln\|(u,v)\|\left[\lambda\int_\Omega h_1(x)|u|^\theta dx + \mu\int_\Omega h_2(x)|v|^\theta dx\right]\end{aligned}$$

where

$$L := \frac{|\Omega|}{e\theta} + \frac{1}{e(p_s^*-\theta)}p_{p_s^*}^{p_{p_s^*}} + \frac{1}{e(p_t^*-\theta)}p_{p_t^*}^{p_{p_t^*}},\quad C_{h_1} := \max_{x\in\overline{\Omega}}|h_1(x)|,\quad C_{h_2} := \max_{x\in\overline{\Omega}}|h_2(x)|,$$

and $S_{p_s^*}^{p_{p_s^*}}, S_{p_t^*}^{p_{p_t^*}} > 0$ denote the best constants of embeddings from $W_0^{s,p}(\Omega)$, and $W_0^{t,p}(\Omega)$, respectively.

Proof. Let us consider $\Omega = \Omega_1 \cup \Omega_2$, using integration properties over Ω, where $\Omega_1 = \{x \in \Omega : |u(x)| \le \|(u,v)\|\}$ and $\Omega_2 = \{x\in\Omega : |u(x)| > \|(u,v)\|\}$. Then

$$\int_\Omega h_1(x)|u|^\theta \ln\frac{|u(x)|}{\|(u,v)\|}dx = \int_{\Omega_1} h_1(x)|u|^\theta\ln\frac{|u(x)|}{\|(u,v)\|}dx + \int_{\Omega_2} h_1(x)|u|^\theta\ln\frac{|u(x)|}{\|(u,v)\|}dx.$$

Using (2.10) by direct calculation gives that

$$\begin{aligned}\int_{\Omega_1} h_1(x)|u|^\theta\ln\frac{|u(x)|}{\|(u,v)\|}dx &\le C_{h_1}\|(u,v)\|^\theta\int_\Omega\left|\frac{u(x)}{\|(u,v)\|}\right|^\theta\left|\ln\frac{|u(x)|}{\|(u,v)\|}\right|dx\\ &\le C_{h_1}\|(u,v)\|^\theta\int_\Omega\frac{1}{e\theta}dx = C_{h_1}\|(u,v)\|^\theta|\Omega|\frac{1}{e\theta}.\end{aligned}$$

By Lemma 2.5 for $\rho = p_s^* - \theta > 0$ and direct calculation

$$\begin{aligned}\int_{\Omega_2} h_1(x)|u|^\theta\ln\frac{|u(x)|}{\|(u,v)\|}dx &\le C_{h_1}\int_\Omega |u|^\theta\ln\frac{|u(x)|}{\|(u,v)\|}dx\\ &\le \frac{C_{h_1}}{e(p_s^*-\theta)}\int_\Omega|u|^\theta\left[\frac{|u(x)|}{\|(u,v)\|}\right]^{p_s^*-\theta}dx\\ &\le \frac{C_{h_1}}{e(p_s^*-\theta)}\frac{1}{\|(u,v)\|^{p_s^*-\theta}}\int_\Omega|u|^{p_s^*}dx\\ &\le \frac{C_{h_1}}{e(p_s^*-\theta)}\frac{1}{\|(u,v)\|^{p_s^*-\theta}}S_{p_s^*}^{p_s^*}\|u\|_{p_s^*}^{p_s^*}\\ &\le \frac{C_{h_1}}{e(p_s^*-\theta)}\frac{1}{\|(u,v)\|^{p_s^*-\theta}}S_{p_s^*}^{p_s^*}\|(u,v)\|^{p_s^*}\\ &= \frac{C_{h_1}}{e(p_s^*-\theta)}S_{p_s^*}^{p_s^*}\|(u,v)\|^\theta.\end{aligned}$$

Consequently we get

$$\int_\Omega |u|^\theta \ln\left[\frac{|u(x)|}{\|(u,v)\|}\right]dx \le C_{h_1}\left[\frac{|\Omega|}{e\theta}+\frac{S_{p_s^*}^{p_s^*}}{e(p_s^*-\theta)}\right]\|(u,v)\|^\theta.$$

For other hand

$$\begin{aligned}\lambda\int_\Omega h_1(x)|u|^\theta\ln|u|dx &= \lambda\int_\Omega h_1(x)|u|^\theta\ln\left[\frac{|u(x)|}{\|(u,v)\|}\right]dx+\ln(\|(u,v)\|)\int_\Omega \lambda h_1(x)|u|^\theta dx\\ &\le \lambda C_{h_1}\left[\frac{|\Omega|}{e\theta}+\frac{S^{p_s^*}}{e(p_s^*-\theta)}\right]\|(u,v)\|^\theta + C_{h_1}\ln(\|(u,v)\|)\int_\Omega \lambda|u|^\theta dx.\end{aligned}$$

Similarly,

$$\mu\int_\Omega h_2(x)|v|^\theta\ln|v|dx \le \mu C_{h_2}\left[\frac{|\Omega|}{e\theta}+\frac{S^{p_s^*}}{e(p_t^*-\theta)}\right]\|(u,v)\|^\theta + C_{h_2}\ln(\|(u,v)\|)\int_\Omega \mu|v|^\theta dx.$$

Adding the integrals for Ω_1 and Ω_2 we have

$$\begin{aligned}&\lambda\int_\Omega h_1(x)|u|^\theta\ln|u|dx+\mu\int_\Omega h_2(x)|v|^\theta\ln|v|dx\\ &\quad\le (\lambda C_{h_1}+\mu C_{h_2})\left[\frac{|\Omega|}{e\theta}+\frac{S^{p_s^*}}{e(p_s^*-\theta)}+\frac{S^{p_s^*}}{e(p_t^*-\theta)}\right]\|(u,v)\|^\theta\\ &\qquad+\ln\|(u,v)\|\int_\Omega\left[\lambda h_1(x)|u|^\theta+\mu h_2(x)|v|^\theta\right]dx.\end{aligned}$$

□

3 Nehari manifold and fibering map analysis

The main tool used in this paper is the so-called fibering method introduced by Pohozaev [11], [12] and [13]. In this section, we assume $\lambda,\mu>0$, and the functions $h_1,h_2,b_1,b_2\in C(\overline{\Omega})$.

We define the Nehari manifolds as

$$\mathcal{N}:=\{(u,v)\in W\setminus\{(0,0)\}\mid I(u,v)=0\}.$$

For all $(u,v)\in\mathcal{N}$, we have $(u,v)\neq 0$ and

$$\|(u,v)\|^p=\lambda\int_\Omega h_1(x)|u|^\theta\ln|u|dx+\mu\int_\Omega h_2(x)|v|^\theta\ln|v|dx+\int_\Omega(b_1(x)+b_2(x))|u|^q|v|^r dx.$$

Now we define the $C^2(0,\infty)$ fibering map $\Phi_{(u,v)}:(0,\infty)\to\mathbb{R}$ as $\Phi_{(u,v)}(k):=E(k(u,v))$, for $k>0$, it is

$$\begin{aligned}\Phi_{(u,v)}(k)=&\frac{k^p}{p}\|(u,v)\|^p-\frac{\lambda k^\theta}{\theta}\ln|k|\int_\Omega h_1(x)|u|^\theta dx-\frac{\lambda k^\theta}{\theta}\int_\Omega h_1(x)|u|^\theta\ln|u|dx\\ &+\frac{\lambda k^\theta}{\theta^2}\int_\Omega h_1(x)|u|^\theta dx-\frac{\mu k^\theta}{\theta}\ln|k|\int_\Omega h_2(x)|v|^\theta dx-\frac{\mu k^\theta}{\theta}\int_\Omega h_2(x)|v|^\theta\ln|v|dx\\ &+\frac{\mu k^\theta}{\theta^2}\int_\Omega h_2(x)|v|^\theta dx-\frac{k^{q+r}}{q+r}\int_\Omega(b_1(x)+b_2(x))|u|^q|v|^r dx.\end{aligned}$$

Consequentially:

$$\begin{aligned}\Phi'_{(u,v)}(k)=&k^{p-1}\|(u,v)\|^p-\lambda k^{\theta-1}\int_\Omega h_1(x)|u|^\theta\ln|ku|dx-\mu k^{\theta-1}\int_\Omega h_2(x)|v|^\theta\ln|kv|dx\\ &-k^{q+r-1}\int_\Omega(b_1(x)+b_2(x))|u|^q|v|^r dx\end{aligned}$$

and also,

$$\begin{aligned}\Phi''_{(u,v)}(k) &= (p-1)k^{p-2}\|(u,v)\|^p - (\theta-1)k^{\theta-2}\lambda\int_\Omega h_1(x)|u|^\theta \ln|ku|dx \\ &\quad - (\theta-1)k^{\theta-2}\mu\int_\Omega h_2(x)|v|^\theta \ln|kv|dx - \lambda k^{\theta-2}\int_\Omega h_1(x)|u|^\theta dx \\ &\quad - \mu k^{\theta-2}\int_\Omega h_2(x)|v|^\theta dx - (q+r-1)k^{q+r-2}\int_\Omega (b_1(x)+b_2(x))|u|^q|v|^r dx.\end{aligned}$$

Thus, one can easily verify that for all $(u,v)\in\mathcal{N}$,

$$\Phi'_{(u,v)}(1) = 0,$$

and

$$\begin{aligned}\Phi''_{(u,v)}(1) &= (p-1)\|(u,v)\|^p - \lambda(\theta-1)\int_\Omega h_1(x)|u|^\theta \ln|u|dx - \mu(\theta-1)\int_\Omega h_2(x)|v|^\theta \ln|v|dx \\ &\quad - \lambda\int_\Omega h_1(x)|u|^\theta dx - \mu\int_\Omega h_2(x)|v|^\theta dx - (q+r-1)\int_\Omega (b_1(x)+b_2(x))|u|^q|v|^r dx,\end{aligned}$$

consequently

$$\begin{aligned}\Phi''_{(u,v)}(1) &= (p-1)\lambda\int_\Omega h_1(x)|u|^\theta \ln|u|dx + (p-1)\mu\int_\Omega h_2(x)|v|^\theta \ln|v|dx \\ &\quad + (p-1)\int_\Omega (b_1(x)+b_2(x))|u|^q|v|^r dx - \lambda(\theta-1)\int_\Omega h_1(x)|u|^\theta \ln|u|dx \\ &\quad - \mu(\theta-1)\int_\Omega h_2(x)|v|^\theta \ln|v|dx - \lambda\int_\Omega h_1(x)|u|^\theta dx - \mu\int_\Omega h_2(x)|v|^\theta dx \\ &\quad - (q+r-1)\int_\Omega (b_1(x)+b_2(x))|u|^q|v|^r dx,\end{aligned}$$

which implies that

$$\begin{aligned}\Phi''_{(u,v)}(1) &= \lambda(p-\theta)\int_\Omega h_1(x)|u|^\theta \ln|u|dx + \mu(p-\theta)\int_\Omega h_2(x)|v|^\theta \ln|v|dx \\ &\quad - \lambda\int_\Omega h_1(x)|u|^\theta dx - \mu\int_\Omega h_2(x)|v|^\theta dx - (q+r-p)\int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx.\end{aligned}$$

As a consequence of the previously calculus, it's make possible to rewrite the Nehari manifold $\mathcal{N}$ as

$$\mathcal{N} = \mathcal{N}^+ \cup \mathcal{N}^0 \cup \mathcal{N}^-,$$

where

$$\begin{aligned}\mathcal{N}^+ &= \left\{(u,v)\in\mathcal{N} \mid \Phi''_{(u,v)}(1) > 0\right\}; \\ \mathcal{N}^0 &= \left\{(u,v)\in\mathcal{N} \mid \Phi''_{(u,v)}(1) = 0\right\};\end{aligned}$$

and

$$\mathcal{N}^- = \left\{(u,v)\in\mathcal{N} \mid \Phi''_{(u,v)}(1) < 0\right\}.$$

Lemma 3.1. *Assume $(u,v)\in W\setminus\{(0,0)\}$ and $k>0$. Then $(ku,kv)\in\mathcal{N}$ if, and only if, $\Phi'_{(u,v)}(k)=0$.*

Proof. If $k(u,v) \in \mathcal{N}$, for $k > 0$ we have $I(ku, kv) = 0$. So

$$\begin{aligned} 0 = k^p \|(u,v)\|^p - \lambda k^\theta \int_\Omega h_1(x)|u|^\theta \ln|ku| dx - \mu k^\theta \int_\Omega h_2(x)|u|^\theta \ln|kv| dx \\ - k^{q+r} \int_\Omega b_1(x)|u|^q |v|^r dx - k^{q+r} \int_\Omega b_2(x)|u|^q |v|^r dx. \end{aligned}$$

Dividing the above equation for $k > 0$, we have

$$\begin{aligned} 0 &= k^{p-1} \|(u,v)\|^p - \lambda k^{\theta-1} \int_\Omega h_1(x)|u|^\theta \ln|ku| dx - \mu k^{\theta-1} \int_\Omega h_2(x)|u|^\theta \ln|kv| dx \\ &\quad - k^{q+r-1} \int_\Omega (b_1 + b_2)(x)|u|^q |v|^r dx \\ &= \Phi'(k). \end{aligned}$$

This completes the proof. □

Lemma 3.2. *If (u,v) is a local minimizer for the functional E on $\mathcal{N}$, with $(u,v) \neq \mathcal{N}^0$, then $E'(u,v) = 0$.*

Proof. By the assumption for $u \in \mathcal{N}$, applying Lagrange's multipliers, there exists $\gamma \in \mathbb{R}$ such that

$$E'(u,v)(u,v) = \gamma I'(u,v)(u,v). \tag{3.1}$$

But because of $(u,v) \in \mathcal{N}$, we get

$$\begin{aligned} E'(u,v)(u,v) &= \|(u,v)\|^p - \lambda \int_\Omega h_1(x)|u|^\theta \ln|u| dx - \mu \int_\Omega h_2(x)|v|^\theta \ln|v| dx \\ &\quad - \int_\Omega (b_1 + b_2)(x)|u|^q |v|^r dx \\ &= 0. \end{aligned}$$

Thus, $\gamma I'(u,v)(u,v) = 0$. Now since $(u,v) \in \mathcal{N}^0$, we get

$$\begin{aligned} I'(u,v)(u,v) &= \lambda(p-\theta)\int_\Omega h_1(x)|u|^\theta \ln|u| dx + \mu(p-\theta)\int_\Omega h_2(x)|v|^\theta \ln|v| dx - \lambda \int_\Omega h_1(x)|u|^\theta dx \\ &\quad - \mu \int_\Omega h_2(x)|v|^\theta dx + (p-q-r)\int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx \\ &= \Phi''_{(u,v)}(1) \neq 0. \end{aligned}$$

Thus, $\gamma \neq 0$, and $E'(u,v) = 0$. □

Lemma 3.3. *Let $0 < \lambda C_{h_1} + \mu C_{h_2} < \frac{1}{L}$ and $2 < q + r < \min\{p_s^*, p_t^*\}$. If $b_1, b_2 \in L^\infty(\Omega)$ are non-negative functions satisfying $C_B < K$, where $C_B := \max_{x \in \overline{\Omega}} |b_1(x) + b_2(x)|$ then, for any $(u,v) \in W \setminus \{(0,0)\}$, we get*

1) *If $\lambda \int_\Omega h_1(x)|u|^\theta + \mu \int_\Omega h_2(x)|v|^\theta dx \geq 0$, then there exists a unique $k_{(u,v)} > 0$ such that $\Phi'_{(u,v)}(k_{(u,v)}) = 0$ and $k_{(u,v)}(u,v) \in \mathcal{N}^-$. Moreover,*

$$E(k_{(u,v)}u, k_{(u,v)}v) = \sup_{k>0} E(ku, kv).$$

2) *If* $\lambda \int_\Omega h_1(x)|u|^\theta + \mu \int_\Omega h_2(x)|v|^\theta dx < 0$, *then there exists* $k_1, k_2 > 0$ *such that* $0 < k_1 < k_{\max} < K_2 < \infty$ *where* $\Phi'_{(u,v)}(k_1) = 0 = \Phi'_{(u,v)}(k_2)$ *witch* $(k_1u, k_1v) \in \mathcal{N}^+$ *and* $(k_2u, k_2v) \in \mathcal{N}^-$. *Moreover,*

$$E(k_1u, k_1v) = \inf_{0<k<k_{\max}} E(ku, kv) \quad \text{and} \quad E(k_2u, k_2v) = \sup_{k>0} E(ku, kv).$$

Proof. Define, for $k > 0$, a function $f : \mathbb{R} \to W$ given by

$$f(k) = k^{p-q-r}\|(u,v)\|^p - k^{p-q-r}\Big(\lambda \int_\Omega h_1(x)|u|^\theta \ln|ku| dx + \mu \int_\Omega h_2(x)|v|^\theta \ln|kv| dx\Big).$$

We can rewrite $f(k)$, for $k > 0$, as

$$\begin{aligned} f(k) = k^{p-q-r}\|(u,v)\|^p &- k^{p-q-r}\ln|k|\Big(\lambda \int_\Omega h_1(x)|u|^\theta dx\Big) - k^{p-q-r}\Big(\lambda \int_\Omega h_1(x)|u|^\theta \ln|u| dx\Big) \\ &- k^{p-q-r}\ln|k|\Big(\lambda \int_\Omega h_2(x)|v|^\theta dx\Big) - k^{p-q-r}\Big(\lambda \int_\Omega h_2(x)|v|^\theta \ln|v| dx\Big). \end{aligned}$$

A direct computation shows that

$$\begin{aligned} f'(k) = k^{p-q-r-1}\Bigg[&(p-q-r)\|(u,v)\|^p - \lambda \int_\Omega h_1(x)|u|^\theta dx - \lambda(p-q-r)\int_\Omega h_1(x)|u|^\theta \ln|u| dx \\ &- \mu \int_\Omega h_2(x)|v|^\theta dx - \mu(p-q-r)\int_\Omega h_2(x)|v|^\theta \ln|v| dx \\ &- (p-q-r)\ln|k|\Big(\lambda \int_\Omega h_1(x)|u|^\theta dx + \mu \int_\Omega h_2(x)|v|^\theta dx\Big)\Bigg]. \end{aligned}$$

Now we analyze all the possibilities:

i) If $\lambda \int_\Omega h_1(x)|u|^\theta dx + \mu \int_\Omega h_2(x)|v|^\theta dx > 0$, then $f \in C(0,\infty)$ and because $q + r > p$, we have

$$\lim_{k\to 0^+} f(k) = +\infty \quad \text{and} \quad \lim_{k\to\infty} f(k) = 0.$$

then there exists a unique minimum point $k_{\min} > 0$ such that $f'(k_{\min}) = 0$. Because $k_{\min} > 0$,

$$\begin{aligned} &(p-q-r)\ln|k_{\min}|\Big(\lambda \int_\Omega h_1(x)|u|^\theta dx + \mu \int_\Omega h_2(x)|v|^\theta dx\Big) \\ &\quad = (p-q-r)\|(u,v)\|^p - \lambda \int_\Omega h_1(x)|u|^\theta dx - \lambda(p-q-r)\int_\Omega h_1(x)|u|^\theta \ln|u| dx \\ &\qquad - \mu \int_\Omega h_2(x)|u|^\theta dx - \mu(p-q-r)\int_\Omega h_2(x)|v|^\theta \ln|v| dx. \end{aligned}$$

Thus

$$k_{\min} = \exp\left(\frac{\|(u,v)\|^p - \lambda \int_\Omega h_1(x)|u|^\theta \ln|u| dx - \mu \int_\Omega h_2(x)|v|^\theta \ln|v| dx}{\lambda \int_\Omega h_1(x)|u|^\theta dx + \mu \int_\Omega h_2(x)|v|^\theta dx} - \frac{1}{p-q-r}\right) \tag{3.2}$$

Obviously, f is decreasing on $(0, k_{\min})$ and increasing on $(k_{\min}, \infty)$. Then, because equation (3.2), the fact that $k_{\min} > 0$ and that $\lambda \int_\Omega h_1(x)|u|^\theta dx + \mu \int_\Omega h_2(x)|v|^\theta dx > 0$, we get

$$\begin{aligned} f(k_{\min}) &= k_{\min}^{p-q-r}\Bigg[\|(u,v)\|^p - \ln|k_{\min}|\Big(\lambda \int_\Omega h_1(x)|u|^\theta dx + \mu \int_\Omega h_2(x)|v|^\theta dx\Big) \\ &\qquad - \Big(\lambda \int_\Omega h_1(x)|u|^\theta \ln|u| dx + \mu \int_\Omega h_2(x)|v|^\theta \ln|v| dx\Big)\Bigg] \\ &= k_{\min}^{p-q-r}\Bigg[\frac{1}{p-q-r}\Big(\lambda \int_\Omega h_1(x)|u|^\theta dx + \mu \int_\Omega h_2(x)|v|^\theta dx\Big)\Bigg] \\ &< 0. \end{aligned}$$

Since we have

$$\int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx > 0, \quad \text{and} \quad \lambda \int_\Omega h_1(x)|u|^\theta \ln|u| dx + \mu \int_\Omega h_2(x)|v|^\theta \ln|v| dx > 0,$$

and because

$$\begin{aligned}&\Phi'_{(u,v)}(k)\\ &\quad = k^{q+r+\theta-p-1}\left[f(k) - (k^{2p-q-r-\theta} + k^{p-q-r})\|(u,v)\|^p - k^{p-\theta}\int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx\right],\end{aligned}$$

there exists a unique $k_{(u,v)}$ such that $0 < k_{(u,v)} < k_{\min}$ such that

$$f(k_{(u,v)}) = \left(k_{(u,v)}^{2p-q-r-\theta} + k_{(u,v)}^{p-q-r}\right)\|(u,v)\|^p + k_{(u,v)}^{p-\theta}\int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx,$$

and $f'(k_{(u,v)}) < 0$, we get $k_{(u,v)}(u,v) \in \mathcal{N}^-$. Moreover, it follows from $f(k) < f(k_{(u,v)})$, for all $k > k_{(u,v)}$ and $f(k) > f(k_{(u,v)})$, for all $k < k_{(u,v)}$, that

$$E(k_{(u,v)}(u,v)) = \sup_{k>0} E(ku,kv).$$

ii) If $\lambda \int_\Omega h_1(x)|u|^\theta dx + \mu \int_\Omega h_2(x)|v|^\theta dx = 0$, it follows from Lemma 2.9 there exists a unique $k_{(u,v)} > 0$ such that $k_{(u,v)}(u,v) \in \mathcal{N}^-$, and

$$E(k_{(u,v)}) = \sup_{k>0} E(ku,kv).$$

iii) If $\lambda \int_\Omega h_1(x)|u|^\theta dx + \mu \int_\Omega h_2(x)|v|^\theta dx < 0$, then $f \in C(0,\infty)$, $\lim_{k\to 0^+} f(k) = -\infty$ and $\lim_{k\to\infty} f(k) = 0$. Then f has a unique maximum point $k_{\max} > 0$ which is given by

$$k_{\max} = \exp\left(\frac{\|(u,v)\|^p - \lambda\int_\Omega h_1(x)|u|^\theta \ln|u| dx + \mu\int_\Omega h_2(x)|v|^\theta \ln|v| dx}{\lambda\int_\Omega h_1(x)|u|^\theta dx + \mu\int_\Omega h_2(x)|v|^\theta dx} - \frac{1}{p-q-r}\right).$$

Moreover, f is increasing on $(0,k_{\max})$ and decreasing on $(k_{\max},\infty)$. By Lemma (2.9), we get

$$k_{\max} \geq \exp\left(\frac{(1-(\lambda C_{h_1}+\mu C_{h_2})L)\|(u,v)\|^p}{\lambda\int_\Omega h_1(x)|u|^\theta dx + \mu\int_\Omega h_2(x)|v|^\theta dx} - \ln\|(u,v)\| - \frac{1}{p-q-r}\right).$$

So,

$$k_{\max}^{p-q-r} \geq \exp\left((p-q-r)\frac{(1-(\lambda C_{h_1}+\mu C_{h_2})L)\|(u,v)\|^p}{\lambda\int_\Omega h_1(x)|u|^\theta dx + \mu\int_\Omega h_2(x)|v|^\theta dx} - 1\right)\|(u,v)\|^{q+r}.$$

It is known that the following inequality holds:

$$\exp(k-1) \geq k, \qquad \forall\, k \geq 0.$$

Then

$$k_{\max}^{p-q-r} \geq (p-q-r)\frac{1-(\lambda C_{h_1}+\mu C_{h_2})L}{\lambda\int_\Omega h_1(x)|u|^\theta dx + \mu\int_\Omega h_2(x)|v|^\theta dx}\|(u,v)\|^{q+r}.$$

Therefore

$$f(k_{\max}) = k_{\max}^{p-q-r}\frac{\lambda\int_\Omega h_1(x)|u|^\theta dx + \mu\int_\Omega h_2(x)|v|^\theta dx}{p-q-r}$$
$$\geq (1-(\lambda C_{h_1}+\mu C_{h_2})L)\|(u,v)\|^{q+r}.$$

Because $\left(k_{(u,v)}^{2p-q-r-\theta}+k_{(u,v)}^{p-q-r}\right)\|(u,v)\|^p + k_{(u,v)}^{p-\theta}\int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx, > 0$. By Hölder's inequality,

$$\int_\Omega (b_1+b_2)(x)|u|^p|v|^r dx \leq C_B|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}}\left(\int_\Omega |u|^{2_s^*}\right)^{\frac{q}{p_s^*}}\left(\int_\Omega |v|^{2_t^*}\right)^{\frac{r}{p_t^*}}$$
$$\leq C_B|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}} S_{p_s^*}^q S_{p_t^*}^r \|(u,v)\|^{q+r},$$

for all $(u,v)\in W$, where $C_B = \max_{x\in\overline{\Omega}}|b_1(x)+b_2(x)|$ and $S_{p_s^*}^q, S_{p_t^*}^r > 0$ denote the best constants of embeddings $W_0^{s,p}\hookrightarrow L^{p_s^*}$ and $W_0^{t,p}\hookrightarrow L^{p_t^*}$, respectively.

Then

$$(1-(\lambda C_{h_1}+\mu C_{h_2})L)S_{p_s^*}^q S_{p_t^*}^r |\Omega|^{\frac{q}{p_s^*}+\frac{r}{p_t^*}-1} > C_B,$$

it implies that

$$f(k_{\max}) > \left(k_{(u,v)}^{2p-q-r-\theta}+k_{(u,v)}^{p-q-r}\right)\|(u,v)\|^p + k_{(u,v)}^{p-\theta}\int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx > 0 = \lim_{k\to\infty} f(k),$$

and it show us there exists k_1, k_2 in which,

$$0 < k_1 < k_{\max} < k_2 < \infty,$$

such that

$$f(k_1) = \left(k_{(u,v)}^{2p-q-r-\theta}+k_{(u,v)}^{p-q-r}\right)\|(u,v)\|^p + k_{(u,v)}^{p-\theta}\int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx = f(k_2).$$

It show us that $\Phi'_{(u,v)}(k_1) = 0 = \Phi'_{(u,v)}(k_2)$. Moreover, f is increasing on $(0,k_{\max})$ and decreasing on $(k_{\max},\infty)$. So

$$k_1(u,v)\in\mathcal{N}^+ \quad \text{and} \quad k_2(u,v)\in\mathcal{N}^-.$$

Moreover, we have

$$f(k) \geq \left(k^{2p-q-r-\theta}+k^{p-q-r}\right)\|(u,v)\|^p + k^{p-\theta}\int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx, \qquad \forall k\in[k_1,k_2],$$

and

$$f(k) < \left(k^{2p-q-r-\theta}+k^{p-q-r}\right)\|(u,v)\|^p + k^{p-\theta}\int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx, \qquad \forall k\in\mathbb{R}_+^*\setminus[k_1,k_2].$$

Thus

$$E(k_1(u,v)) = \inf_{0<k\leq k_{\max}} E(k(u,v)) \quad \text{and} \quad E(k_2(u,v)) = \sup_{k>0} E(k(u,v)).$$

The proof is complete. □

Remark 3.4. In what follows, we define

$$M := \frac{|\Omega|^{1-\frac{q}{p_s^*}}S_{p_s^*}^q + |\Omega|^{1-\frac{q}{p_s^*}}S_{p_t^*}^q}{q+r-p}, \quad \text{and} \quad K := \frac{1-(\lambda C_{h_1}+\mu C_{h_2})(L+M)}{|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}}S_{p_s^*}^q S_{p_t^*}^r}.$$

Lemma 3.5. *If* $0 < \lambda C_{h_1} + \mu C_{h_2} < \frac{1}{L+M}$ *and* $C_B < K$, *then* $\mathcal{N}^0 = \emptyset$.

Proof. Arguing by contradiction, let $(u,v) \in \mathcal{N}^0$. Then $I(u,v) = 0$, and

$$\|(u,v)\|^p - \lambda \int_\Omega h_1(x)|u|^\theta dx - \mu \int_\Omega h_2(x)|v|^\theta dx = \int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx \tag{3.3}$$

and

$$\begin{aligned} 0 = {} & \lambda(p-\theta)\int_\Omega h_1(x)|u|^\theta \ln|u| dx + \mu(p-\theta)\int_\Omega h_2(x)|v|^\theta \ln|v| dx \\ & - \lambda \int_\Omega h_1(x)|u|^\theta dx - \mu \int_\Omega h_2(x)|v|^\theta dx \\ & + (p-q-r)\int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx. \end{aligned} \tag{3.4}$$

From equations (3.3) and (3.4), and Lemma 2.9, we get

$$\begin{aligned} & \|(u,v)\|^p - \int_\Omega (b_1+b_2)(x)|u|^\theta dx \\ & \quad \le (\lambda C_{h_1} + \mu C_{h_2}) L \|(u,v)\|^p + \ln\|(u,v)\| \Big(\lambda \int_\Omega h_1(x)|u|^\theta dx + \mu \int_\Omega h_2(x)|v|^\theta dx \Big). \end{aligned}$$

Then, again by (3.4)

$$\begin{aligned} (1-(\lambda C_{h_1} + \mu C_{h_2})L)\|(u,v)\|^p \le {} & \ln\|(u,v)\| \Big(\lambda \int_\Omega h_1(x)|u|^\theta dx + \mu \int_\Omega h_2(x)|v|^\theta dx \Big) \\ & + \int_\Omega (b_1+b_2)(x)|v|^q|v|^r dx \\ \le {} & \ln\|(u,v)\| \Big(\lambda \int_\Omega h_1(x)|u|^\theta dx + \mu \int_\Omega h_2(x)|v|^\theta dx \Big) \\ & + \frac{1}{p-q-r}\Big[-\lambda(p-\theta)\int_\Omega h_1(x)|u|^\theta \ln|u| dx \\ & - \mu(p-\theta)\int_\Omega h_2(x)|v|^\theta \ln|v| dx \\ & + \lambda \int_\Omega h_1(x)|u|^\theta dx + \mu \int_\Omega h_2(x)|v|^\theta dx \Big]. \end{aligned}$$

That is,

$$\begin{aligned} (1-(\lambda C_{h_1} + \mu C_{h_2})L)\|(u,v)\|^p \le {} & \ln\|(u,v)\| \Big(\lambda \int_\Omega h_1(x)|u|^\theta dx + \mu \int_\Omega h_2(x)|v|^\theta dx \Big) \\ & + \frac{1}{p-q-r}\Big[-\lambda(p-\theta)\int_\Omega h_1(x)|u|^\theta \ln|u| dx \\ & - \mu(p-\theta)\int_\Omega h_2(x)|v|^\theta \ln|v| dx \Big] \\ & + \frac{\lambda C_{h_1} + \mu C_{h_2}}{q+r-p}\Big(|\Omega|^{1-\frac{q}{p_s^*}} S_{p_s^*}^q + |\Omega|^{1-\frac{q}{p_s^*}} S_{p_t^*}^q \Big)\|(u,v)\|^p, \end{aligned} \tag{3.5}$$

which means that

$$\begin{aligned} & \Big[1 - (\lambda C_{h_1} + \mu C_{h_2})L - \frac{\lambda C_{h_1} + \mu C_{h_2}}{q+r-p}\Big(|\Omega|^{1-\frac{q}{p_s^*}} S_{p_s^*}^q + |\Omega|^{1-\frac{q}{p_s^*}} S_{p_t^*}^q \Big) \Big] \|(u,v)\|^p \\ & \quad \le \ln\|(u,v)\| \Big(\lambda \int_\Omega h_1(x)|u|^\theta dx + \mu \int_\Omega h_2(x)|v|^\theta dx \Big) \\ & \qquad + \frac{1}{p-q-r}\Big(-\lambda(p-\theta)\int_\Omega h_1(x)|u|^\theta \ln|u| dx - \mu(p-\theta)\int_\Omega h_2(x)|v|^\theta \ln|v| dx \Big). \end{aligned}$$

Because $p < q + r$, equation (3.4) show us that

$$0 > -\lambda(p-\theta)\int_\Omega h_1(x)|u|^\theta \ln|u|dx - \mu(p-\theta)\int_\Omega h_2(x)|v|^\theta \ln|v|dx + \lambda\int_\Omega h_1(x)|u|^\theta dx + \mu\int_\Omega h_2(x)|v|^\theta dx.$$

Then, we have

$$0 > \ln\|(u,v)\|\Big(\lambda\int_\Omega h_1(x)|u|^\theta dx + \mu\int_\Omega h_2(x)|v|^\theta dx\Big) + \frac{1}{p-q-r}\Big(-\lambda(p-\theta)\int_\Omega h_1(x)|u|^\theta \ln|u|dx - \mu(p-\theta)\int_\Omega h_2(x)|v|^\theta \ln|v|dx\Big).$$

Thus, it follows from $\lambda C_{h_1} + \mu C_{h_2} < \frac{1}{L+M}$ that $\|(u,v)\| \leq 1$, where, here we consider M as on Remark 3.4.

Otherwise, using (3.5), and one more time (3.3) and (3.4),

$$\begin{aligned}[1-(\lambda C_{h_1}+\mu C_{h_2})L]\|(u,v)\|^p &\leq \ln\|(u,v)\|\Big(\lambda\int_\Omega h_1(x)|u|^\theta dx + \mu\int_\Omega h_2(x)|v|^\theta dx\Big) \\ &\quad + \int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx \\ &\leq (p-q-r)\ln\|(u,v)\|\int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx \\ &\quad + (\lambda C_{h_1}+\mu C_{h_2})M\|(u,v)\|^p. \end{aligned} \tag{3.6}$$

Now, we can note that

$$\int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx \leq C_B|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}} S_{p_s^*}^q S_{p_t^*}^r \|(u,v)\|^{q+r}, \tag{3.7}$$

Thus

$$[1-(\lambda C_{h_1}+\mu C_{h_2})(L+M) - C_B|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}} S_{p_s^*}^q S_{p_t^*}^r]\|(u,v)\|^p \leq 0.$$

Since $(\lambda C_{h_1}+\mu C_{h_2}) < \frac{1}{L+M}$, and

$$C_B < K := \frac{1-(\lambda C_{h_1}+\mu C_{h_2})(L+M)}{|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}} S_{p_s^*}^q S_{p_t^*}^r},$$

it follows that $\|(u,v)\| = 0$. Then $(u,v) = (0,0)$, a contradiction. Therefore $\mathcal{N}^0 = \emptyset$. □

Remark 3.6. For next result, we consider

$$\Lambda_{\lambda,\mu} := \min\left\{1, \left(\frac{1-(\lambda C_{h_1}+\mu C_{h_2})L - C_B|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}} S_{p_s^*}^q S_{p_t^*}^r}{C_B|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}} S_{p_s^*}^q S_{p_t^*}^r}\right)^{\frac{1}{q+r-p}}\right\}.$$

Lemma 3.7. *If $0 < \lambda C_{h_1} + \mu C_{h_2} < \frac{1}{L+M}$ and $C_B < K$, then $\|(U,V)\| \geq \Lambda_{\lambda,\mu}$, for all $(U,V) \in \mathcal{N}^-$ and $\|(u,v)\| \leq 1$, for all $(u,v) \in \mathcal{N}^+$.*

Proof. Let $(U,V) \in \mathcal{N}^-$. Then

$$\|(U,V)\|^p - v\lambda \int_\Omega h_1(x)|U|^\theta \ln|U|dx - \mu \int_\Omega h_2(x)|V|^\theta \ln|V|dx = \int_\Omega (b_1+b_2)(x)|U|^q|V|^r dx, \quad (3.8)$$

and

$$\begin{aligned}(p-q-r)&\int_\Omega (b_1+b_2)(x)|U|^q|V|^r dx \\ &< \lambda \int_\Omega h_1(x)|U|^\theta dx + \mu \int_\Omega h_2(x)|V|^\theta dx \\ &\quad - (p-\theta)\Big(\lambda \int_\Omega h_1(x)|U|^\theta \ln|U|dx + \mu \int_\Omega h_2(x)|V|^\theta \ln|V|dx\Big). \end{aligned} \quad (3.9)$$

Similar to equation (3.6) in Lemma 3.5, we have

$$\begin{aligned}[1-(\lambda C_{h_1}+\mu C_{h_2})L]\|(U,V)\|^p \le \ln\|(U,V)\|&\Big(\lambda \int_\Omega h_1(x)|U|^\theta dx + \mu \int_\Omega h_2(x)|V|^\theta dx\Big) \\ &+ C_B|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}} S_{p_s^*}^q S_{p_t^*}^r \|(U,V)\|^{q+r}. \end{aligned} \quad (3.10)$$

We consider two cases:

i) If $\lambda \int_\Omega h_1(x)|U|^\theta dx + \mu \int_\Omega h_2(x)|V|^\theta dx > 0$, then $\|(U,V)\| \ge 1$, because otherwise, being $\|(U,V)\| < 1$, we have

$$[1-(\lambda C_{h_1}+\mu C_{h_2})L]\|(U,V)\|^p < C_B|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}} S_{p_s^*}^q S_{p_t^*}^r \|(U,V)\|^{q+r},$$

and together with $C_B < K$, we get

$$\|(U,V)\| > \left(\frac{1-(\lambda C_{h_1}+\mu C_{h_2})L}{C_B|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}} S_{p_s^*}^q S_{p_t^*}^r}\right)^{\frac{1}{q+r-p}} > 1, \quad (3.11)$$

a contradiction. Thus $\|(U,V)\| \ge 1$.

ii) If $\lambda \int_\Omega h_1(x)|U|^\theta dx + \mu \int_\Omega h_2(x)|V|^\theta dx < 0$, we have two more cases to analyze:

2.1) If $\|(U,V)\| > 1$, similar to case i) above, we get the same equation (3.11).

2.2) If $\|(U,V)\| < 1$, we have by equations (3.8) and (3.9),

$$\begin{aligned}&[1-(\lambda C_{h_1}+\mu C_{h_2})L]\|(U,V)\|^p \\ &< C_B|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}} S_{p_s^*}^q S_{p_t^*}^r \|(U,V)\|^p \\ &\quad + (p-\theta)\Big(\lambda \int_\Omega h_1(x)|U|^\theta \ln|U|dx + \mu \int_\Omega h_2(x)|V|^\theta \ln|V|dx\Big) \\ &\quad + C_B|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}} S_{p_s^*}^q S_{p_t^*}^r \|(U,V)\|^{q+r}, \end{aligned}$$

So, because $p \le \theta$,

$$\|(U,V)\| > \left(\frac{1-(\lambda C_{h_1}+\mu C_{h_2})L - C_B|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}} S_{p_s^*}^q S_{p_t^*}^r}{C_B|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}} S_{p_s^*}^q S_{p_t^*}^r}\right)^{\frac{1}{q+r-p}} > 1.$$

Thus, $\|(U,V)\| \ge \Lambda_{\lambda,\mu}$, for all $(U,V) \in \mathcal{N}^-$.

Now, if $(u,v) \in \mathcal{N}^+$, a similar discussion show us that $\|(u,v)\| \leq 1$. □

Lemma 3.8. *If $0 < \lambda C_{h_1} + \mu C_{h_2} < \frac{1}{L+M}$ and $C_B < K$, then $\mathcal{N}^-$ is a closed subset o W.*

Proof. The proof follows directly from Lemmas 3.5 and 3.7. □

Lemma 3.9. *If $0 < \lambda C_{h_1} + \mu C_{h_2} < \frac{1}{L+M}$. Then the functional E is bounded from below on $\mathcal{N}$.*

Proof. Because of the relationship between the functionals E and I, for $(u,v) \in \mathcal{N}$, we have

$$\begin{aligned} E(u,v) = & \left(\frac{1}{p} - \frac{1}{\theta}\right)\|(u,v)\|^p + \frac{1}{\theta^2}\Big(\lambda\int_\Omega h_1(x)|u|^\theta dx + \mu\int_\Omega h_2(x)|v|^\theta dx\Big) \\ & - \left(\frac{1}{q+r} - \frac{1}{\theta}\right)\int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx. \end{aligned}$$

Because $(u,v) \in \mathcal{N}$, we have also

$$\int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx = \|(u,v)\|^p - \lambda\int_\Omega h_1(x)|u|^\theta \ln|u| dx - \mu\int_\Omega h_2(x)|v|^\theta \ln|v| dx.$$

So

$$\begin{aligned} E(u,v) = & \left(\frac{1}{p} - \frac{1}{q+r}\right)\|(u,v)\|^p + \frac{1}{\theta^2}\Big(\lambda\int_\Omega h_1(x)|u|^\theta dx + \mu\int_\Omega h_2(x)|v|^\theta dx\Big) \\ & + \left(\frac{1}{\theta} - \frac{1}{q+r}\right)\Big(\lambda\int_\Omega h_1(x)|u|^\theta \ln|u| dx + \mu\int_\Omega h_2(x)|v|^\theta \ln|v| dx\Big). \end{aligned}$$

Now, concerning to exposed above, we consider two cases:

i) If $\lambda\int_\Omega h_1(x)|u|^\theta dx + \mu\int_\Omega h_2(x)|v|^\theta dx > 0$, because $0 < p < \theta < q+r$, it follows that

$$E(u,v) > \left(\frac{1}{\theta} - \frac{1}{q+r}\right)\int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx \geq 0.$$

ii) If $\lambda\int_\Omega h_1(x)|u|^\theta dx + \mu\int_\Omega h_2(x)|v|^\theta dx \leq 0$, it follows from Lemma (2.9) that

$$\begin{aligned} E(u,v) = & \left(\frac{1}{p} - \frac{1}{q+r}\right)[1 - (\lambda C_{h_1} + \mu C_{h_2})L]\|(u,v)\|^p \\ & + \left[\frac{1}{\theta^2} - \left(\frac{1}{\theta} - \frac{1}{q+r}\right)\ln\|(u,v)\|\right]\Big(\lambda\int_\Omega h_1(x)|u|^\theta dx + \mu\int_\Omega h_2(x)|v|^\theta dx\Big). \end{aligned}$$

Now, if $\frac{1}{\theta^2} - (\frac{1}{\theta} - \frac{1}{q+r})\ln\|(u,v)\| \geq 0$, then $E(u,v) \geq 0$.
Otherwise, if $\frac{1}{\theta^2} - (\frac{1}{\theta} - \frac{1}{q+r})\ln\|(u,v)\| < 0$, there exists a constant $C > 0$ such that

$$\begin{aligned} E(u,v) \geq & \left(\frac{1}{p} - \frac{1}{q+r}\right)[1 - (\lambda C_{h_1} + \mu C_{h_2})L]\|(u,v)\|^p \\ & + \left[\frac{1}{\theta^2} - \left(\frac{1}{\theta} - \frac{1}{q+r}\right)\ln\|(u,v)\|\right]\Big(\lambda\int_\Omega h_1(x)|u|^\theta dx + \mu\int_\Omega h_2(x)|v|^\theta dx\Big) \\ \geq & \left(\frac{1}{p} - \frac{1}{q+r}\right)[1 - (\lambda C_{h_1} + \mu C_{h_2})L]\|(u,v)\|^p \\ & - C\left[\frac{1}{\theta^2} - \left(\frac{1}{\theta} - \frac{1}{q+r}\right)\ln\|(u,v)\|\right] \\ \geq & -C. \end{aligned}$$

Thus, E is bounded from below on $\mathcal{N}$. □

4 Nontrivial ground state solution for positive weight function

In this section, we establish the existence of a ground state solution for problem (P) when the weights functions $h_1, h_2 > 0$ by Mountain Pass theorem and the existence of a level $c_* \in W$, where the functional E satisfy the $(PS)_{c_*}$ condition.

Lemma 4.1. *Let $h_1, h_2 \in C(\overline{\Omega})$ and $h_1(x), h_2(x) > 0$ for all $x \in \Omega$. Then there are exist $\eta, \zeta > 0$, such that*

(i) $E(u,v) \geq \eta > 0$ for all $\|(u,v)\| = \zeta$,

(ii) There exists $(u,v) \in W$ such that $E(u,v) < 0$ if $\|(u,v)\| > \zeta$.

Proof. Because the definition of E and inequality (3.7), we have

$$\begin{aligned} E(u,v) \geq & \left[\frac{1}{p} - \frac{1}{\theta}(\lambda C_{h_1} + \mu C_{h_2})L\right] \|(u,v)\|^p \\ & - \frac{1}{\theta}\ln\|(u,v)\|\left(\lambda \int_\Omega h_1(x)|u|^\theta dx + \mu \int_\Omega h_2(x)|v|^\theta dx\right) \\ & - \frac{C_B|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}} S_{p_s^*}^q S_{p_t^*}^r}{q+r}\|(u,v)\|^{q+r}, \end{aligned}$$

what implies that, for all $(u,v) \in W$ with $0 < \|(u,v)\| \leq 1$,we have

$$E(u,v) \geq \left[\frac{1}{p} - \frac{1}{\theta}(\lambda C_{h_1} + \mu C_{h_2})L\right] \|(u,v)\|^p - \frac{C_B|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}} S_{p_s^*}^q S_{p_t^*}^r}{q+r}\|(u,v)\|^{q+r}.$$

Choosing $\zeta \in (0,1]$ small enough, such that

$$\left(\frac{1}{p} - \frac{1}{\theta}(\lambda C_{h_1} + \mu C_{h_2})L\right) - \frac{C_B|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}} S_{p_s^*}^q S_{p_t^*}^r}{q+r}\zeta^{q+r} > 0,$$

we have

$$E(u,v) \geq \left[\left(\frac{1}{p} - \frac{1}{\theta}(\lambda C_{h_1} + \mu C_{h_2})L\right) - \frac{C_B|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}} S_{p_s^*}^q S_{p_t^*}^r}{q+r}\zeta^{q+r}\right]\zeta^p > 0,$$

for all $(u,v) \in W$, with $\|(u,v)\| = \zeta$. Thus (i) holds.

Otherwise, for all $(u,v) \in W \setminus \{0,0\}$ and $k > 0$, we have

$$\begin{aligned} & E(ku,kv) \\ & = k^{q+r}\left[\frac{k^{p-q-r}}{p}\|(u,v)\|^p\right. \\ & \quad - \frac{k^{\theta-q-r}\ln|k|}{\theta}\int_\Omega h_1(x)|u|^\theta dx - \frac{k^{\theta-q-r}}{\theta}\lambda\int_\Omega h_1(x)|u|^\theta \ln|u|dx + \frac{k^{\theta-q-r}}{\theta^2}\lambda\int_\Omega h_1(x)|u|^\theta dx \\ & \quad \left. - \frac{k^{\theta-q-r}\ln|k|}{\theta}\int_\Omega h_2(x)|v|^\theta dx - \frac{k^{\theta-q-r}}{\theta}\mu\int_\Omega h_2(x)|v|^\theta \ln|v|dx + \frac{k^{\theta-q-r}}{\theta^2}\mu\int_\Omega h_2(x)|v|^\theta dx\right], \end{aligned}$$

and because $2 < p < \theta < q+r$, it implies that there exists $k_0 > 0$ large enough such that $\|(k_0u, k_0v)\| > \zeta$ and $E(k_0u, k_0v) < 0$. So, taking $(u,v) = (k_0u, k_0v)$, item (ii) holds □

Lemma 4.2. *Let (u_n, v_n) be a $(PS)_{c_*}$ sequence of the functional E. Then, a sequence (u_n, v_n) is bounded in W.*

Proof. For $c_* \in \mathbb{R}$, we assume that $\{(u_n, v_n)\}_n \subset W$ with $\|(u_n, v_n)\| > 1$ is a $(PS)_{c_*}$ sequence with, it is

$$E(u_n, v_n) \to c_* \quad \text{and} \quad E'(u_n, v_n)(u_n, v_n) \to 0,$$

as $n \to \infty$. Since (u_n, v_n) is a $(PS)_{c_*}$ sequence for functional E, we have

$$\begin{aligned} c_* + o_n(1) + C\|(u_n, v_n)\| &\geq E(u_n, v_n) - \frac{1}{p}E'(u_n, v_n)(u_n, v_n) \\ &= \frac{1}{p^2}\Big(\lambda \int_\Omega h_1(x)|u_n|^\theta dx + \mu \int_\Omega h_2(x)|v_n|^\theta dx\Big) \\ &\quad + \left(\frac{1}{p} - \frac{1}{q+r}\right)\int_\Omega (b_1 + b_2)(x)|u_n|^q|v_n|^r dx \\ &= \frac{1}{p^2}\Big(\lambda \int_\Omega h_1(x)|u_n|^\theta dx + \mu \int_\Omega h_2(x)|v_n|^\theta dx\Big). \end{aligned} \tag{4.1}$$

We have also

$$\begin{aligned} &c_* + o_n(1) + C\|(u_n, v_n)\| \\ &\quad \geq E(u_n, v_n) - \frac{1}{q+r}E'(u_n, v_n)(u_n, v_n) \\ &\quad = \left(\frac{1}{p} - \frac{1}{q+r}\right)\|(u_n, v_n)\|^p \\ &\qquad - \left(\frac{1}{p} - \frac{1}{q+r}\right)\left(\lambda \int_\Omega h_1(x)|u_n|^\theta \ln u_n dx + \mu \int_\Omega h_2(x)|v_n|^\theta \ln v_n dx\right) \\ &\qquad + \frac{1}{p^2}\left(\lambda \int_\Omega h_1(x)|u_n|^\theta dx + \mu \int_\Omega h_2(x)|v_n|^\theta dx\right) \\ &\quad \geq \left(\frac{1}{p} - \frac{1}{q+r}\right)\|(u_n, v_n)\|^p \\ &\qquad - \left(\frac{1}{p} - \frac{1}{q+r}\right)\left(\lambda \int_\Omega h_1(x)|u_n|^\theta \ln u_n dx + \mu \int_\Omega h_2(x)|v_n|^\theta \ln v_n dx\right). \end{aligned} \tag{4.2}$$

Combining equations (4.1) and (4.2), Lemma (2.5) and Lemma (2.9), we have

$$\begin{aligned} &\left[\left(\frac{1}{p} - \frac{1}{q+r}\right)[1 - (\lambda C_{h_1} + \mu C_{h_2})L]\right]\|(u, v)\| \\ &\quad \leq \left(\frac{1}{p} - \frac{1}{q+r}\right)\frac{p^2[(u_n, v_n)]^\sigma}{e\sigma}\left[c_* + C\|(u_n, v_n)\| + o(1)\right] \\ &\qquad + c_* + C\|(u_n, v_n)\| + o(1) \\ &\quad \leq C\left(1 + \|(u_n, v_n)\|^{1+\sigma}\right) + o(1), \end{aligned}$$

where $\sigma \in (0, p-1)$. Thus $\{(u_n, v_n)\}_n$ is bounded in W. □

Lemma 4.3. *Let (u_n, v_n) be a $(PS)_{c_*}$ sequence of the functional E. Then, functional E satisfies the $(PS)_{c_*}$ condition at any level c_*.*

Proof. By Lemmas 2.6 and 2.8, we get

$$\lim_{n\to\infty}\int_\Omega h_1(x)u|u_n|^{\theta-1}\ln|u|dx=\int_\Omega h_1(x)|u|^\theta\ln|u|dx, \tag{4.3}$$

$$\lim_{n\to\infty}\int_\Omega h_2(x)v|v_n|^{\theta-1}\ln|v|dx=\int_\Omega h_2(x)|v|^\theta\ln|v|dx, \tag{4.4}$$

$$\lim_{n\to\infty}\int_\Omega (b_1+b_2)(x)|u_n|^{q-2}u_n|v_n|^r(u_n-u)dx=0, \tag{4.5}$$

$$\lim_{n\to\infty}\int_\Omega (b_1+b_2)(x)|v_n|^{r-2}v_n|u_n|^q(v_n-v)dx=0. \tag{4.6}$$

Note that

$$\begin{aligned}\|(u_n-u,v_n-v)\|^p=&(E'(u_n,v_n)-E'(u,v))(u_n-u,v_n-v)\\&+\lambda\int_\Omega h_1(x)\left(|u_n|^{\theta-1}\ln|u_n|-|u|^{\theta-1}\ln|u|\right)(u_n-u)dx\\&+\mu\int_\Omega h_2(x)\left(|v_n|^{\theta-1}\ln|v_n|-|v|^{\theta-1}\ln|v|\right)(v_n-v)dx\\&+\frac{q}{q+r}\int_\Omega (b_1+b_2)(x)\left(|v_n|^r u_n^{q-2}u_n-|v|^r|u|^{q-2}u\right)(u_n-u)dx\\&+\frac{r}{q+r}\int_\Omega (b_1+b_2)(x)\left(|u_n|^q v_n^{r-2}v_n-|u|^q|v|^{r-2}v^{r-2}v\right)(v_n-v)dx.\end{aligned}$$

Since $(E'(u_n,v_n)-E'(u,v))(u_n-u,v_n-v)\to 0$ as $n\to\infty$, it follow from equations (4.3), (4.4), (4.5), (4.6) and Lemma 2.3, that $(u_n,v_n)\to(u,v)$ in W. It yields the proof. □

Now we can prove one of our main results, Theorem 1.1.

4.1 Proof of Theorem 1.1

Define $\mathfrak{N}:=\{(u,v)\in W\setminus\{0,0\}\mid E'(u,v)(u,v)=0\}$. By the previous lemmas, $\mathfrak{N}$ is nonempty. Let $(u,v)\in\mathfrak{N}$, from Lemma (2.9), we have

$$\begin{aligned}0=&\|(u,v)\|^p-\left(\lambda\int_\Omega h_1(x)|u|^\theta\ln|u|dx+\mu\int_\Omega h_2(x)|v|^\theta\ln|v|dx\right)-\int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx\\\geq&(1-(\lambda C_{h_1}+\mu C_{h_2})L)\|(u,v)\|^p-\ln\|(u,v)\|\left(\lambda\int_\Omega h_1(x)|u|^\theta\ln|u|dx+\mu\int_\Omega h_2(x)|v|^\theta\ln|v|dx\right)\\&-\int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx\end{aligned} \tag{4.7}$$

If $\|(u,v)\|\leq 1$, it follows from the above equation (4.7) that

$$[1-(\lambda C_{h_1}+\mu C_{h_2})]\|(u,v)\|^p\leq\int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx\leq C_B|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}}\|(u,v)\|^{q+r}.$$

Then,

$$\|(u,v)\|\geq\left[\frac{1-(\lambda C_{h_1}+\mu C_{h_2})L}{C_B|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}}S_{p_s^*}^q S_{p_t^*}^r}\right]^{\frac{1}{q+r-p}},$$

which implies that

$$\int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx \geq [1-(\lambda C_{h_1}+\mu C_{h_2})L]\|(u,v)\|^p \geq \left[\frac{[1-(\lambda C_{h_1}+\mu C_{h_2})L]^{q+r}}{\left(C_B|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}}S_{p_s^*}^q S_{p_t^*}^r\right)^p}\right]^{\frac{1}{q+r-p}}. \tag{4.8}$$

Define

$$\tilde{C} := \left[\frac{[1-(\lambda C_{h_1}+\mu C_{h_2})L]^{q+r}}{\left(C_B|\Omega|^{1-\frac{q}{p_s^*}-\frac{r}{p_t^*}}S_{p_s^*}^q S_{p_t^*}^r\right)^p}\right]^{\frac{1}{q+r-p}} \quad \text{and} \quad \mathfrak{C} := \inf\{E(u,v) \mid (\tilde{U}_n,\tilde{V}_n)\in\mathfrak{N}\},$$

then $\mathfrak{C}>0$, because otherwise, there exists $\{(\tilde{U}_n,\tilde{V}_n)\}_n \subset \mathfrak{N}$ such that $E'(\tilde{U}_n,\tilde{V}_n)\to 0$.

It follows from

$$\begin{aligned} E(u,v) = &\left(\frac{1}{p}-\frac{1}{\theta}\right)\|(u,v)\|^p + \frac{1}{\theta}I(u,v) \\ &+\frac{1}{\theta^2}\left(\lambda\int_\Omega h_1(x)|u|^\theta dx + \mu\int_\Omega h_2(x)|v|^\theta dx\right) \\ &-\left(\frac{1}{q+r}-\frac{1}{p}\right)\int_\Omega (b_1+b_2)(x)|u|^q|v|^r dx, \end{aligned}$$

that

$$\frac{1}{\theta^2}\left(\lambda\int_\Omega h_1(x)|\tilde{U}_n|^\theta dx + \mu\int_\Omega h_2(x)|\tilde{V}_n|^\theta dx\right) - \left(\frac{1}{q+r}-\frac{1}{p}\right)\int_\Omega (b_1+b_2)(x)|\tilde{U}_n|^q|\tilde{V}_n|^r dx \to 0,$$

when $n\to\infty$, and by Lemma 4.2. But, from equation (4.8) follows that

$$\int_\Omega (b_1+b_2)(x)|\tilde{U}_n|^q|\tilde{V}_n|^r dx \geq \tilde{C} > 0,$$

and it implies that $0\geq\tilde{C}>0$, a contradiction. Thus, $\mathfrak{C}>0$.

Finally, let $\{(u_n,v_n)\}_n \subset \mathfrak{N}$ be a minimizing sequence. Then $E'(u_n,v_n)(u_n,v_n)=0$ and $\lim_{n\to\infty} E(u_n,v_n)=\mathfrak{C}>0$. Again by Lemma 4.2, there exists $(u_0,v_0)\in W\setminus\{0,0\}$ such that

$$(u_n,v_n)\to(u_0,v_0)$$

in W. Hence $E(u_0,v_0)=\mathfrak{C}$ and $E'(u_0,v_0)=0$, and it means that (u_0,v_0) is a nontrivial ground state solution of problem (P).

5 Nontrivial solutions for sing-changing weight functions

Lemma 5.1. *E has a nontrivial and nonnegative minimizer on $\mathcal{N}^+$.*

Proof. The proof of this lemma will be shown with two steps.

Step 1. The strong convergence of minimizing sequence. By Lemma 3.9, we get

$$c^+ = \inf_{(u,v)\in\mathcal{N}^+} E(u,v).$$

We claim that $c^+ < 0$. Indeed, for each $(u,v) \in \mathcal{N}^+$, we get

$$\begin{aligned}\|(u,v)\|^p = \lambda \int_\Omega h_1(x)|u|^\theta \ln|u|dx + \mu \int_\Omega h_2(x)|v|^\theta \ln|v|dx \\ + \int_\Omega (b_1(x)+b_2(x))|u|^q|v|^r dx. \end{aligned} \tag{5.1}$$

Substituting (5.1), in the energy functional E, we have the following expression

$$\begin{aligned}E(u,v) &= \frac{1}{p}\|(u,v)\|^p - \frac{\lambda}{\theta}\int_\Omega h_1(x)|u|^\theta \ln|u|dx + \frac{\lambda}{\theta^2}\int_\Omega h_1(x)|u|^\theta dx - \frac{\mu}{\theta}\int_\Omega h_2(x)|v|^\theta \ln|v|dx \\ &\quad + \frac{\mu}{\theta^2}\int_\Omega h_2(x)|v|^\theta dx - \frac{1}{q+r}\int_\Omega (b_1(x)+b_2(x))|u|^q|v|^r dx \\ &= \frac{1}{p}\left[\lambda\int_\Omega h_1(x)|u|^\theta \ln|u|dx + \mu\int_\Omega h_2(x)|v|^\theta \ln|v|dx + \int_\Omega (b_1(x)+b_2(x))|u|^q|v|^r dx\right] \\ &\quad - \frac{\lambda}{\theta}\int_\Omega h_1(x)|u|^\theta \ln|u|dx + \frac{\lambda}{\theta^2}\int_\Omega h_1(x)|u|^\theta dx - \frac{\mu}{\theta}\int_\Omega h_2(x)|v|^\theta \ln|v|dx \\ &\quad + \frac{\mu}{\theta^2}\int_\Omega h_2(x)|v|^\theta dx - \frac{1}{q+r}\int_\Omega (b_1(x)+b_2(x))|u|^q|v|^r dx \\ &= \left(\frac{1}{p}-\frac{1}{\theta}\right)\left[\lambda\int_\Omega h_1(x)|u|^\theta \ln|u|dx + \mu\int_\Omega h_2(x)|v|^\theta \ln|v|dx\right] \\ &\quad + \frac{1}{\theta^2}\left[\lambda\int_\Omega h_1(x)|u|^\theta dx + \mu\int_\Omega h_2(x)|v|^\theta dx\right] \\ &\quad + \left(\frac{1}{p}-\frac{1}{q+r}\right)\int_\Omega (b_1(x)+b_2(x))|u|^q|v|^r dx.\end{aligned}$$

Using the logarithmic estimates for positive weight functions in addition with $p < \theta$ and $p < q+r$, we have the following inequality

$$\begin{aligned}&(p-\theta)\left[\lambda\int_\Omega h_1(x)|u_n|^\theta \ln|u|dx + \mu\int_\Omega h_2(x)|v_n|^\theta \ln|v|dx\right] \\ &\quad > (q+r-p)\int_\Omega (b_1(x)+b_2(x))|u|^q|v|^r dx + \lambda\int_\Omega h_1(x)|u|^\theta dx + \mu\int_\Omega h_2(x)|v|^\theta dx.\end{aligned}$$

From the last inequality, we have that

$$\begin{aligned}\lambda\int_\Omega h_1(x)|u_n|^\theta \ln|u|dx + \mu\int_\Omega h_2(x)|v_n|^\theta \ln|v|dx \\ < -\frac{q+r-p}{\theta-p}\int_\Omega (b_1(x)+b_2(x))|u|^q|v|^r dx \\ - \frac{1}{\theta-p}\left[\lambda\int_\Omega h_1(x)|u|^\theta dx + \mu\int_\Omega h_2(x)|v|^\theta dx\right].\end{aligned} \tag{5.2}$$

Finally, using (5.2) in the functional E, it follows that

$$\begin{aligned}E(u,v) = \left(\frac{1}{p}-\frac{1}{\theta}\right)\left[\lambda\int_\Omega h_1(x)|u|^\theta \ln|u|dx + \mu\int_\Omega h_2(x)|v|^\theta \ln|v|dx\right] \\ + \frac{1}{\theta^2}\left[\lambda\int_\Omega h_1(x)|u|^\theta dx + \mu\int_\Omega h_2(x)|v|^\theta dx\right] \\ + \left(\frac{1}{p}-\frac{1}{q+r}\right)\int_\Omega (b_1(x)+b_2(x))|u|^q|v|^r dx\end{aligned}$$

$$< (p-q-r)\left(\frac{1}{\theta-p}-\frac{1}{p(q+r)}\right)\int_\Omega (b_1(x)+b_2(x))|u|^q|v|^r dx$$
$$+\left(\frac{1}{\theta^2}-\frac{1}{\theta-p}\right)\left[\lambda\int_\Omega h_1(x)|u|^\theta dx+\mu\int_\Omega h_2(x)|v|^\theta dx\right]<0.$$

Let $\{(u_n,v_n)\}\subset\mathcal{N}^+$ be a minimizing sequence. Then, we get

$$\|(u_n,v_n)\|^p=\lambda\int_\Omega h_1(x)|u_n|^\theta\ln|u|dx+\mu\int_\Omega h_2(x)|v_n|^\theta\ln|v|dx$$
$$+\int_\Omega (b_1(x)+b_2(x))|u|^q|v|^r dx \tag{5.3}$$

and

$$\Phi''_{(u_n,v_n)}(1)=\|(u_n,v_n)\|^p-\lambda\int_\Omega h_1(x)|u_n|^\theta\ln|u_n|dx-\mu\int_\Omega h_2(x)|v|^\theta\ln|v|dx$$
$$-\int_\Omega (b_1+b_2)(x)|u_n|^q|v_n|^r dx-\lambda\int_\Omega h_1(x)|u_n|^\theta dx$$
$$-\mu\int_\Omega h_2(x)|v_n|^\theta dx+(p-q-r)\int_\Omega (b_1(x)+b_2(x))|u|^q|v|^r dx. \tag{5.4}$$

Using $\{(u_n,v_n)\}\subset\mathcal{N}^+$ and $\Phi''_{(u_n,v_n)}(1)>0$, we conclude that

$$-\lambda\int_\Omega h_1(x)|u_n|^\theta dx-\mu\int_\Omega h_2(x)|v_n|^\theta dx+(p-q-r)\int_\Omega (b_1(x)+b_2(x))|u|^q|v|^r dx>0. \tag{5.5}$$

Since $\{(u_n,v_n)\}$ is bounded by Lemma 3.8, up to subsequence we assume that

$$\begin{cases}(u_n,v_n)\rightharpoonup(u^+,v^+) & \text{in } W;\\ u_n\to u^+, v_n\to v^+ & \text{strongly in } L^t(\Omega),\ \text{for } 1\le t<\min\{p_s^*,p_t^*\};\\ u_n(x)\to u^+(x), v_n(x)\to v^+(x) & \text{a.e. in } \Omega.\end{cases} \tag{5.6}$$

Similar to Lemma 4.3, we obtain the following convergences:

$$\lim_{n\to\infty}\int_\Omega h_1(x)u_n|u_n|^\theta\ln|u_n|dx=\int_\Omega h_1(x)|u^+|^\theta\ln|u^+|dx, \tag{5.7}$$

and

$$\lim_{n\to\infty}\int_\Omega h_2(x)v_n|v_n|^\theta\ln|v_n|dx=\int_\Omega h_2(x)|v^+|^\theta\ln|v^+|dx, \tag{5.8}$$

Furthermore, the dominated convergence theorem of Lebesgue is valid for the product of functions $|u|^q$ and $|v|^r$, hence we have that

$$\lim_{n\to\infty}\int_\Omega b_1(x)|u_n|^q|v_n|^r dx=\int_\Omega b_2(x)|u^+|^q|v^+|^r dx, \tag{5.9}$$

and

$$\lim_{n\to\infty}\int_\Omega b_2(x)|u_n|^q|v_n|^r dx=\int_\Omega b_2(x)|u^+|^q|v^+|^r dx. \tag{5.10}$$

If $(u_n,v_n)\rightharpoonup(u^+,v^+)$ in W, then

$$\|(u^+,v^+)\|^2\le\liminf_{n\to+\infty}\|(u_n,v_n)\|^2.$$

This implies that

$$\begin{aligned}
&\|(u^+,v^+)\|^p - \lambda\int_\Omega h_1(x)|u^+|^\theta \ln|u^+|dx - \mu\int_\Omega h_1(x)|v^+|^\theta \ln|v^+|dx\\
&\quad - \int_\Omega b_1(x)|u^+|^q|v^+|^r dx - \int_\Omega b_2(x)|u^+|^q|v^+|^r dx\\
&< \liminf_{n\to+\infty}\Big[\|(u_n,v_n)\|^2 - \lambda\int_\Omega h_1(x)|u_n|^\theta \ln|u_n|dx - \mu\int_\Omega h_1(x)|v_n|^\theta \ln|v_n|dx\\
&\quad - \int_\Omega b_1(x)|u_n|^q|v_n|^r dx - \int_\Omega b_2(x)|u_n|^q|v_n|^r dx\Big] = 0. \qquad (5.11)
\end{aligned}$$

Now we prove that for (u^+,v^+) there exists $0 < t_{(u^+,v^+)} \neq 1$ such that

$$t_{(u^+,v^+)}(u^+,v^+) \in \mathcal{N}^+.$$

Since $c^+ < 0$, one can show that $(u^+,v^+) \neq (0,0)$. By (5.5), we deduce that

$$\lambda\int_\Omega b_1(x)|u^+|^q dx + \mu\int_\Omega b_2(x)|v^+|^r dx < 0,$$

then by Lemma 3.3 there exists $t_{(u^+,v^+)} > 0$ such that

$$t_{(u^+,v^+)}(u^+,v^+) \in \mathcal{N}^+ \quad \text{and} \quad \Psi'_{(u^+,v^+)}(t_{(u^+,v^+)}) = 0.$$

By (5.11), $\Psi'_{(u^+,v^+)}(1)) < 0$. Thus, $t_{(u^+,v^+)} \neq 1$. Note that $t_{(u^+,v^+)}(u^+,v^+)$ is minimizer of $g(t) = E(\tau(u^+,\tau v^+)$. Thus,

$$E(t_{(u^+,v^+)}u^+, t_{(u^+,v^+)}v^+) < E(u^+,v^+)) \leq \lim_{n\to+\infty} E(u_n,v_n) = \inf_{(u,v)\in\mathcal{N}^+} E(u,v),$$

and this is absurd. Therefore, we obtain $(u_n,v_n) \to (u^+,v^+)$ in W.

Step 2. Existence of nonnegative minimizers. If $(u_n,v_n) \to (u^+,v^+)$ in W and Lemma 3.9, we get

$$-\lambda\int_\Omega h_1(x)|u^+|^\theta dx - \mu\int_\Omega h_2(x)|v^+|^\theta dx + (p-q-r)\int_\Omega (b_1+b_2)(x)|u^+|^q|v^+|^r dx > 0. \quad (5.12)$$

Thus, we obtain that $(u^+,v^+) \in \mathcal{N}^+$. This gives that (u^+,v^+) is a minimizer of E on $\mathcal{N}^+$. Proof, we can prove $(|u^+|,|v^+|)$ is also a minimizer $\mathcal{N}^+$. Since

$$E(|u^+|,|v^+|) \leq E(u^+,v^+)$$

and using (5.12) hold for $(|u^+|,|v^+|)$, it suffices to show that

$$\begin{aligned}
&\|(u^+,v^+)\|^p - \lambda\int_\Omega h_1(x)|u^+|^\theta \ln|u^+|dx - \mu\int_\Omega h_1(x)|v^+|^\theta \ln|v^+|dx\\
&\quad = \int_\Omega b_1(x)|u^+|^q|v^+|^r dx + \int_\Omega b_2(x)|u^+|^q|v^+|^r dx. \qquad (5.13)
\end{aligned}$$

Using $[|u^+|]_s^p \leq [u^+]_s^p$, we obtain

$$\begin{aligned}
&\|(u^+,v^+)\|^p - \lambda\int_\Omega h_1(x)|u^+|^\theta \ln|u^+|dx - \mu\int_\Omega h_1(x)|v^+|^\theta \ln|v^+|dx\\
&\quad \leq \int_\Omega b_1(x)|u^+|^q|v^+|^r dx + \int_\Omega b_2(x)|u^+|^q|v^+|^r dx. \qquad (5.14)
\end{aligned}$$

If

$$\|(u^+,v^+)\|^p - \lambda\int_\Omega h_1(x)|u^+|^\theta \ln|u^+|dx - \mu\int_\Omega h_1(x)|v^+|^\theta\ln|v^+|dx$$
$$< \int_\Omega b_1(x)|u^+|^q|v^+|^r dx + \int_\Omega b_2(x)|u^+|^q|v^+|^r dx, \tag{5.15}$$

then $\Psi'_{(|u^+|,|v^+|)}(1)) < 0$. For $(|u^+|,|v^+|)$, by Lemma 3.3 there exist $t_{(|u^+|,|v^+|)} \in \mathcal{N}^+$ and $\Psi'_{(|u^+|,|v^+|)}t_{(|u^+|,|v^+|)} = 0$. Thus, $t_{(|u^+|,|v^+|)} \neq 1$. For other hand $t_{(|u^+|,|v^+|)}$ is a minimizer of

$$\xi(t) := E(u^+,v^+).$$

Thus,

$$E(t_{(|u^+|,|v^+|)}|u^+|, t_{(|u^+|,|v^+|)}|v^+| \leq E(|u^+|,|v^+|) \leq E(u^+,v^+) = \inf_{(u,v)\in\mathcal{N}^+} E(u,v).$$

This is absurd. Thus, $(|u^+|,|v^+|) \in \mathcal{N}^+$ and

$$E(|u^+|,|v^+|) = \inf_{(u,v)\in\mathcal{N}^+} E(u,v)$$

In conclusion, we get nonnegative minimizer E on $\mathcal{N}^+$. □

Lemma 5.2. *E has a nontrivial and nonnegative minimizer on $\mathcal{N}^-$.*

Proof. By Lemma 3.9, we know $c^- := \inf_{(u,v)\in\mathcal{N}^-} E(u,v)$ is attained. Let $\{(u_n,v_n)\}_n \subset \mathcal{N}^-$ be a minimizing sequence such that $E(u_n,v_n) \to c^-$. Then

$$\|(u_n,v_n)\|^p - \lambda\int_\Omega h_1(x)|u_n|^\theta dx - \mu\int_\Omega h_2(x)|v_n|^\theta dx = \int_\Omega (b_1+b_2)(x)|u_n|^q|v_n|^r dx, \tag{5.16}$$

and,

$$0 > \lambda(p-\theta)\int_\Omega h_1(x)|u_n|^\theta\ln|u_n|dx + \mu(p-\theta)\int_\Omega h_2(x)|v_n|^\theta\ln|v_n|dx$$
$$-\lambda(p-\theta)\int_\Omega h_1(x)|u_n|^\theta dx - \mu(p-\theta)\int_\Omega h_2(x)|v_n|^\theta dx$$
$$-(q+r-p)\int_\Omega (b_1+b_2)(x)|u_n|^q|v_n|^r dx. \tag{5.17}$$

We claim that $\{(u_n,v_n)\}_n$ is bounded in $\mathcal{N}^-$.

Without loss of generality, we assume that $\|(u_n,v_n)\| \geq 1$. Then

$$c^- + o_n(1) = E(u_n,v_n) - \frac{1}{p}E'(u_n,v_n)(u_n,v_n)$$
$$\left(\frac{1}{p}-\frac{1}{\theta}\right)\left(\lambda\int_\Omega h_1(x)|u_n|^\theta\ln|u_n|dx + \mu\int_\Omega h_2(x)|v_n|^\theta\ln|v_n|dx\right)$$
$$+\frac{1}{\theta^2}\left(\lambda\int_\Omega h_1(x)|u_n|^\theta dx + \mu\int_\Omega h_2(x)|v_n|^\theta dx\right)$$
$$+\left(\frac{1}{p}-\frac{1}{q+r}\right)\int_\Omega (b_1+b_2)(x)|u_n|^q|v_n|^r dx. \tag{5.18}$$

So

$$c^- + o_n(1) \geq \left(\frac{1}{p} - \frac{1}{\theta}\right)\left(\lambda \int_\Omega h_1(x)|u_n|^\theta \ln|u_n|dx + \mu \int_\Omega h_2(x)|v_n|^\theta \ln|v_n|dx\right) + \frac{1}{\theta^2}\left(\lambda \int_\Omega h_1(x)|u_n|^\theta dx + \mu \int_\Omega h_2(x)|v_n|^\theta dx\right). \tag{5.19}$$

If $\lambda \int_\Omega h_1(x)|u_n|^\theta dx + \mu \int_\Omega h_2(x)|v_n|^\theta dx \geq 0$, then from equations (5.18), (5.19), we have

$$\|(u,v)\| \leq \left(\frac{1}{\frac{1}{p} - \frac{1}{\theta}(\lambda C_{h_1} + \mu C_{h_2})L}\right)^{\frac{1}{p-2}}.$$

If, $\lambda \int_\Omega h_1(x)|u_n|^\theta dx + \mu \int_\Omega h_2(x)|v_n|^\theta dx < 0$, from equation (5.19), we have

$$\begin{aligned} c^- + o_n(1) &= E(u_n, v_n) \\ &\geq \left[\frac{1}{p} - \frac{1}{\theta}(\lambda C_{h_1} + \mu C_{h_2})L\right]\|(u_n,v_n)\|^p \\ &\quad + \left[\frac{1}{\theta^2} - \left(\frac{1}{\theta} - \frac{1}{q+r}\right)\ln\|(u_n,v_n)\|\right]\left(\lambda \int_\Omega h_1(x)|u_n|^\theta dx + \mu \int_\Omega h_2(x)|v_n|^\theta dx\right). \end{aligned}$$

We have two cases to analyze:

i) If $\frac{1}{\theta^2} - \left(\frac{1}{\theta} - \frac{1}{q+r}\right)\ln\|(u_n,v_n)\| \leq 0$, we have

$$c^- + o_n(1) = \left(\frac{1}{p} - \frac{1}{q+r}\right)[1 - (\lambda C_{h_1} + \mu C_{h_2})L]\|(u_n,v_n)\|^p,$$

which implies that

$$\|(u_n,v_n)\| \leq \left[\frac{p(q+r)(c^- + o_n(1))}{(q+r-p)[1-(\lambda C_{h_1} + \mu C_{h_2})L]}\right]^{\frac{1}{p}}.$$

ii) If $\frac{1}{\theta^2} - \left(\frac{1}{\theta} - \frac{1}{q+r}\right)\ln\|(u_n,v_n)\| > 0$, then $\|(u_n,v_n)\| < \exp\left(\frac{q+r-\theta}{\theta^3(q+r)}\right)$. So there exists $C > 0$ such that $\|(u_n,v_n)\| < C$.

Thus, every minimizer sequence of E on $\mathcal{N}^-$ is bounded.
Now, since $\{(u_n,v_n)\}$ is bounded in $\mathcal{N}^-$, up to a subsequence, we may assume that

$$\begin{aligned} &(u_n,v_n) \rightharpoonup (u_-,v_-) && \text{weakly in } W; \\ &(u_n,v_n) \to (u_-,v_-) && \text{strongly in } L^\nu(\Omega)\times L^\tau(\Omega); \\ &(u_n,v_n) \to (u_+,v_+) && \text{a.e in } \Omega, \end{aligned}$$

where $1 < \nu, \tau < \min\{p_s^*, p_t^*\}$. It implies that

$$\begin{aligned} \lim_{n\to\infty}\int_\Omega h_1(x)|u_n|^\theta \ln|u_n|dx &= \int_\Omega h_1(x)|u_-|^\theta \ln|u_-|dx; \\ \lim_{n\to\infty}\int_\Omega h_2(x)|v_n|^\theta \ln|v_n|dx &= \int_\Omega h_2(x)|v_-|^\theta \ln|v_-|dx; \\ \lim_{n\to\infty}\int_\Omega h_1(x)|u_n|^\theta dx &= \int_\Omega h_1(x)|u_-|^\theta dx; \\ \lim_{n\to\infty}\int_\Omega h_1(x)|v_n|^\theta dx &= \int_\Omega h_2(x)|v_-|^\theta dx. \end{aligned}$$

An easy computation, combined with equation (5.17), shows that

$$I(u_-, v_-) \leq \liminf_{n\to\infty} I(u_n, v_n) = 0.$$

It means that $(u_-, v_-) \in \mathcal{N}^-$. Now, by Lemma 3.3 (1), there exists $k_{(u,v)} > 0$ such that $I'_{(u_-,v_-)}k_{(u_-,v_-)} = 0$ and $k_{(u_-,v_-)} \neq 1$. Since $(u_n, v_n) \not\to (u_-, v_-)$, we get

$$k_{(u_-,v_-)}(u_n, v_n) \not\to k_{(u_-,v_-)}(u_-, v_-)$$

in W. Another easy computation shows that

$$E(k_{(u_-,v_-)}u_-, k_{(u_-,v_-)}v_-) \leq E(k_{(u_-,v_-)}u_n, k_{(u_-,v_-)}v_n).$$

Now, observe that the function $z(k) := E(ku_n, kv_n)$ attains its maximum at $k = k_{(u_-,v_-)}$. So

$$\begin{aligned} E(k_{(u_-,v_-)}u_-, k_{(u_-,v_-)}v_-) &< \liminf_{n\to\infty} E(k_{(u_-,v_-)}u_n, k_{(u_-,v_-)}v_n) \\ &\leq \lim_{n\to\infty} E(u_n, v_n) \\ &= \inf_{(u,v)\in\mathcal{N}^-} E(u, v), \end{aligned}$$

a contradiction. Thus $(u_n, v_n) \to (u_-, v_-)$ in W.

Because $(u_-, v_-) \in \mathcal{N}^-$, then (u_-, v_-) is a minimizer of E on $\mathcal{N}^-$. Moreover, a similar discussion as Theorem 5.1 - *step* 2- one can show that $(|u_-|, |v_-|)$ is a minimizer of E on $\mathcal{N}^-$. This yields the proof. □

Now it is possible to prove Theorem 1.2.

5.1 Proof of Theorem 1.2

From Theorems 5.1 and 5.2, E has two non-negative minimizers $(u_+, v_+) \in \mathcal{N}^+$ and $(u_-, v_-) \in \mathcal{N}^-$. Then, from Theorem 3.2, E has two non-negative critical points on W, which is non-trivial and non-negative local least energy solution of Problem (P). This two solution are distinct, because is obviously that $\mathcal{N}^- \cap \mathcal{N}^+ = \emptyset$.

We claim that (u_+, v_+) and (u_-, v_-) are not semi-trivial solution.

Supposing, otherwise, $v_t = 0$ in (u_+, v_+), we get that u_+ is a non-trivial solution of the problem

$$\begin{cases} (-\Delta)^s_p u + |u|^{p-2}u = \lambda h_1(x)|u|^{\theta-2}u \ln|u| & \text{in } \Omega, \\ (u, v) \in W_0^{s,p}(\Omega) \times W_0^{t,p}(\Omega) \end{cases} \tag{P'}$$

Then $\|(u_+, 0)\|^p = [u_+]^p_s = \lambda \int_\Omega h_1(x)|u_+|^\theta \ln|u_+|dx$, and because $(u_+, 0) \in \mathcal{N}^+$ and $\Phi''_{(u,v)}(1) > 0$, we get

$$\lambda(p-\theta)\int_\Omega h_1(x)|u_+|^\theta dx < \lambda \int_\Omega h_1(x)|u_+|^\theta dx.$$

Because $p < \theta$, we have $\int_\Omega h_1(x)|u_+|^\theta dx < 0$.

Now we choose $w \in W_0^{t,p}(\Omega) \setminus \{0\}$ such that $\int_\Omega h_1(x)|w|^\theta dx < 0$.

For (u_+, w), by Lemma 3.3, there exists a unique $k_1 > 0$ such that $k_1(u_+, w) \in \mathcal{N}^+$. Moreover, we have

$$k_{\max} = \exp\left(\frac{\|(u_+, w)\|^p - \lambda\int_\Omega h_1(x)|u_+|^\theta \ln|u_+|^\theta dx + \mu\int_\Omega h_2(x)|w|^\theta \ln|w|^\theta dx}{\lambda\int_\Omega h_1(x)^\theta dx + \mu\int_\Omega h_2(x)|w|^\theta dx} - \frac{1}{p-q-r}\right),$$

and

$$E(k_1u_+, k_1w) = \inf_{0<k<k_{\max}} E(ku_+, kw).$$

It follows that

$$c^+ \leq E(k_1u_+, k_1w) < E(u_+, w) < E(u_+, 0) = c^+,$$

a contradiction. Thus (u_+, v_+) is not a semi-trivial solution for problem (P).

Otherwise, (u_-, v_-) is not a semi-trivial solution for problem (P), by using the same above argument, but this time assuming $v_- = 0$. In this case $(u_-, 0)$ is a nontrivial solution for problem (P') and $\int_\Omega h_1(x)|u_-|^\theta dx > 0$ and $w \in W_0^{t,p}(\Omega) \setminus \{0\}$ is taking such that

$$\lambda \int_\Omega h_1(x)|u_-|^\theta dx + \mu \int_\Omega h_2(x)|w|^\theta dx < 0.$$

In this way we concluded what we wanted.

Abstract. We introduce new transversality conditions in terms of derivatives with respect to a nondecreasing function $g : \mathbb{R} \longrightarrow \mathbb{R}$, and we use them to prove the existence of solutions for discontinuous systems of Stieltjes differential equations, i.e. differential equations where usual derivatives are replaced with derivatives with respect to the derivator g. The proof of our main existence result leans on some interesting new results on g-derivatives also proven in this paper.

Keywords: discontinuous differential equations, Carathéodory solutions, Stieltjes differential equations.

2020 Mathematics Subject Classification: 34A06, 34A36.

1 Introduction

We are concerned with initial value problems for first order systems of Stieltjes differential equations of the form

$$x'_g = f(t,x), \quad t \in I = [t_0, t_0 + L), \ x(t_0) = x_0, \tag{1.1}$$

where $g : \mathbb{R} \longrightarrow \mathbb{R}$ is a nondecreasing function, $t_0, L \in \mathbb{R}$, $L > 0$, $x_0 \in \mathbb{R}^n$ ($n \in \mathbb{N}$) and $f = (f_1, f_2, \ldots, f_n) : I \times \mathbb{R}^n \longrightarrow \mathbb{R}^n$ need not be continuous.

As usual, x'_g stands for the derivative with respect to g which, roughly speaking, means

$$x'_g(t) = \lim_{s \to t} \frac{x(s) - x(t)}{g(s) - g(t)},$$

and it allows us to study difference and differential equations, with or without impulses, under the unified formulation of (1.1).

Existence of Carathéodory type solutions for (1.1) has recently been well studied for the case when $f(t,x)$ is continuous with respect to the x variable. See [5, 6, 11–14]. In this paper,

✉ Corresponding author. Email: rodrigo.lopez@usc.es

we intend to improve on the previous references by allowing the nonlinear part $f(t,x)$ to present many discontinuities. To do so, we show that discontinuities do not matter as long as they can be covered by some subsets of $I \times \mathbb{R}^n$ satisfying a novel transversality condition with respect to the g-differential equation in (1.1).

Our new transversality condition, inspired by an idea by Bressan and Shen [2], later generalized in [10], leans on some new results on g-differentiation which are interesting in its own right. We manage to translate the ideas the authors brought in [10] from usual differential equations to Stieltjes differental equations, generalising their results even further. We achieve this by introducing some new interesting properties on the g-derivatives.

This paper is organized as follows. In Section 2 we include the basic preliminaries on g-differential equations so that this paper be self-contained; in Section 3 we prove some new results on g-differentiation, specially, on a chain rule for functions of several variables which is essential for our definition of local transversality conditions; in Section 4 we prove our main existence result for (1.1).

2 Preliminaries on Stieltjes derivatives and differential equations

In what follows, $g : \mathbb{R} \longrightarrow \mathbb{R}$ is monotone, nondecreasing and continuous from the left everywhere. Let us consider the set of points around which g is constant, namely

$$C_g = \{t \in \mathbb{R} \,:\, g \text{ is constant on } (t-\varepsilon, t+\varepsilon) \text{ for some } \varepsilon > 0\}, \tag{2.1}$$

and the set of discontinuity points of g, which is at most countable and shall be denoted by

$$D_g = \{t \in \mathbb{R} \,:\, g(t^+) - g(t) > 0\}, \tag{2.2}$$

where, as usual, $g(t^+) = \lim_{s \to t^+} g(s) \in \mathbb{R}$.

Following [11], we define the *derivative with respect to* g (or *g-derivative*) of a real-valued real function f at a point $t_0 \in \mathbb{R} \setminus C_g$ as follows, provided that the corresponding limit exists:

$$f'_g(t_0) = \lim_{t \to t_0} \frac{f(t) - f(t_0)}{g(t) - g(t_0)} \quad \text{if } t_0 \notin D_g, \text{ or} \tag{2.3}$$

$$f'_g(t_0) = \lim_{t \to t_0^+} \frac{f(t) - f(t_0)}{g(t) - g(t_0)} \quad \text{if } t_0 \in D_g, \tag{2.4}$$

where C_g and D_g are defined in (2.1) and (2.2) respectively. Notice that the g-derivative at a point $t_0 \in D_g$ exists if, and only if, $f(t_0^+)$ exists and (2.4) can be rewritten as

$$f'_g(t_0) = \frac{f(t_0^+) - f(t_0)}{g(t_0^+) - g(t_0)}. \tag{2.5}$$

We say that f is *g-differentiable at t_0* if $f'_g(t_0)$ exists, and we say that f is *g-differentiable in a set $A \subset \mathbb{R}$* when f is g-differentiable at every $t_0 \in A \setminus C_g$. There will be no need to define g-derivatives for the points in C_g because, according to [10, Proposition 2.5], we have $\mu_g(C_g) = 0$, where μ_g stands for the Lebesgue–Stieltjes measure induced by g. However, it is possible to give a reasonable definition of a g-derivative everywhere, see [13], but we shall not need it in this paper.

Roughly speaking, g-differentiable functions can be recovered by integrating their g-derivatives in the Stieltjes sense with respect to g. More precisely, we have the following Fundamental Theorem of Calculus for the Lebesgue–Stieltjes integral [10, Theorem 5.4].

Theorem 2.1 (Fundamental Theorem of Calculus for the Lebesgue–Stieltjes integral)**.** *Let $a, b \in \mathbb{R}$, $a < b$, and $F : [a, b] \longrightarrow \mathbb{R}$. The following conditions are equivalent.*

(1) The function F is absolutely continuous with respect to g *(or g-*absolutely continuous*) according to the following definition: to each $\varepsilon > 0$, there is some $\delta > 0$ such that, for any family $\{(a_n, b_n)\}_{n=1}^m$ of pairwise disjoint open subintervals of $[a, b]$, the inequality*

$$\sum_{n=1}^{m} (g(b_n) - g(a_n)) < \delta$$

implies

$$\sum_{n=1}^{m} |F(b_n) - F(a_n)| < \varepsilon.$$

(2) The function F fulfills the following properties:

(a) there exists $F'_g(t)$ for g-almost all $t \in [a, b)$ (i.e., for all t except on a set of μ_g measure zero);

(b) $F'_g \in \mathcal{L}^1_g([a, b))$, the set of Lebesgue–Stieltjes integrable functions with respect to μ_g;

(c) for each $t \in [a, b]$, we have

$$F(t) = F(a) + \int_{[a,t)} F'_g(s)\, d\mu_g. \tag{2.6}$$

We remark that $\mu_g(\{t\}) = g(t^+) - g(t) > 0$ when $t \in D_g$ (see equation (6) in [10]). In particular, if $t \in [a, b) \cap D_g$, then, (2.6) implies that

$$F(t^+) - F(t) = \int_{\{t\}} F'_g(s)\, d\mu_g = F'_g(t)(g(t^+) - g(t)),$$

which may be nonzero. Therefore, g-absolutely continuous functions need not be continuous at discontinuity points of g.

However, g-absolutely continuous functions have some nice properties.

Proposition 2.2 ([10, Proposition 5.3])**.** *If F is g-absolutely continuous on $[a, b]$, then it has bounded variation and it is continuous from the left at every $x \in [a, b)$.*

Moreover, F is continuous in $[a, b] \setminus D_g$, where D_g is the set of discontinuity points of g, and if g is constant on some $(\alpha, \beta) \subset [a, b]$, then F is constant on (α, β) as well.

We say that a vector-valued function $F : [a, b] \longrightarrow \mathbb{R}^n$ is g-absolutely continuous on $[a, b]$ if each of its components is g-absolutely continuous. We denote by $\mathcal{AC}_g([a, b])$ the set of g-absolutely continuous functions on $[a, b]$ with values in $\mathbb{R}^n$.

Definition 2.3. A (Carathéodory) *solution* of (1.1) is a g-absolutely continuous function $x : [t_0, t_0 + L] \longrightarrow \mathbb{R}^n$ such that $x(t_0) = x_0$, and

$$x'_g(t) = f(t, x(t)) \quad \text{for } g\text{-almost all } (g\text{-a.a.}) \ t \in [t_0, t_0 + L).$$

Next we introduce a useful splitting of g into its continuous and discrete parts. This is well known for bounded variation functions on bounded intervals, see, for instance, [1, Theorem 2.6.1], but we have to adjust it for functions defined on the whole real line.

Denote

$$\Delta g(t) = g(t^+) - g(t),$$

for all $t \in \mathbb{R}$ and define the function $g^B : \mathbb{R} \to \mathbb{R}$ as follows:

$$g^B(t) = \begin{cases} \sum_{s\in[0,t)} \Delta g(s), & t > 0, \\ -\sum_{s\in[t,0)} \Delta g(s), & t \leq 0. \end{cases} \tag{2.7}$$

We have that g^B is nondecreasing and left-continuous. We will say that g^B is the *discontinuous* or *jump part* of g. We say g is *totally discontinuous* when $g = g^B \neq 0$. We define the *continuous part* of g as follows:

$$g^C(t) := g(t) - g^B(t), \quad \forall t \in \mathbb{R}.$$

Thus, g^C is nondecreasing and continuous (in the usual sense).

By definition we have that $g = g^C + g^B$. In particular we have, over Borel sets, that $\mu_g = \mu_{g^C} + \mu_{g^B}$. It holds that

$$g^C(s) - g^C(t) \leq g(s) - g(t)$$
$$g^B(s) - g^B(t) \leq g(s) - g(t)$$

for all $t, s \in \mathbb{R}$, $t < s$.

Now we recall the notion of g-topology in $\mathbb{R}$, introduced for the first time in [6].

Definition 2.4. Given any $t \in \mathbb{R}$ and $\varepsilon > 0$, we define the g-ball of center t and radius ε as the set

$$B_g(t, \varepsilon) := \{s \in \mathbb{R} \mid |g(s) - g(t)| < \varepsilon\}.$$

Define the g-topology as

$$\tau_g := \{\ U \subset \mathbb{R} \ \mid\ \forall t \in U\ \ \exists \varepsilon > 0 :\ B_g(t, \varepsilon) \subset U\ \}.$$

For any $\lambda > 0$ and $B_g(t, \varepsilon)$ denote $\lambda B_g(t, \varepsilon) = B_g(t, \lambda\varepsilon)$. Denote also $B_g[t, \varepsilon]$ as the closed ball

$$B_g[t, \varepsilon] = \{s \in \mathbb{R} \mid |g(s) - g(t)| \leq \varepsilon\},$$

which need not be a closed set in the usual topology (for instance, $B_g(1, 1/2) = (0, \infty)$ if $g(t) = 0$ for $t \leq 0$ and $g(t) = 1$ for $t > 0$).

Finally, since C_g is open, we can express it as a countable union of disjoint open intervals

$$C_g = \bigcup_{n=1}^{\infty} (a_n, b_n),$$

and we denote by N_g the set of the real endpoints of all the intervals (a_n, b_n). The following technical information will be used in Section 3.

Proposition 2.5. *Let $t \in \mathbb{R}$ be such that $t \notin D_g \cup N_g \cup C_g$. Then any set N is a usual neighborhood of t iff N is a neighborhood of t in the topology τ_g.*

Proof. First, note that $\mathbb{R} - (C_g \cup N_g) = \{t \in \mathbb{R} : g(s) \neq g(t)\ \forall s \in \mathbb{R},\ s \neq t\}$. Since $t \notin D_g$, g is continuous at t. Hence,

$$\forall \epsilon > 0\ \exists \delta > 0 : (t - \delta, t + \delta) \subset B_g(t, \epsilon).$$

Fix $\epsilon > 0$ now, take $\delta = \min\{|g(t) - g(t - \epsilon)|, |g(t + \epsilon) - g(t)|\} > 0$, thus

$$B_g(t, \delta) \subset (t - \epsilon, t + \epsilon).$$

Equivalently, the function Id is g-continuous at t. In fact, g-continuity at t is equivalent to usual continuity at t. Every local basis of t (usual or on τ_g) is a local basis on both topologies. The claim is then proved. □

Remark 2.6. Let f be a function defined on a neighborhood $(t-\epsilon, t+\epsilon)$ of $t \notin D_g \cup N_g \cup C_g$. If $f'_g(t)$ exists, then f is continuous at t.

To prove it, simply observe that there exists $\delta > 0$ such that

$$|f(t) - f(s)| \leq (|f'_g(t)| + 1)|g(t) - g(s)| \quad \forall s \in (t-\delta, t+\delta),$$

which implies that f is continuous at t because so g is.

3 Covering lemmas and fine results on g-derivatives

This section is devoted to proving some technical results on g-null sets and g-derivatives which will play a fundamental role in the proof of our main existence result for (1.1).

We start with the following lemma on existence of special subcollections of arbitrary collections of sets.

Lemma 3.1. *Let X be a nonempty set and let $\mathcal{B}$ be a collection of subsets of X containing at least one nonempty set. Then, there exists a subcollection of subsets $\mathcal{C} \subset \mathcal{B}$ satisfying the following conditions:*

(1) $A \cap B = \emptyset$, for all $A, B \in \mathcal{C}$, $A \neq B$.

(2) For any $B \in \mathcal{B}$, there exists some $C \in \mathcal{C}$ such that $B \cap C \neq \emptyset$.

Proof. Let Ω be the set of all disjoint subcollections of $\mathcal{B}$ equipped with the partial order $\subset$. Clearly $\Omega \neq \emptyset$ as $\{B\} \in \Omega$ for any $B \in \mathcal{B}$. Let Λ be a nonempty chain in Ω. If it were to happen that

$$\mathcal{D} = \bigcup_{\mathcal{A} \in \Lambda} \mathcal{A} \in \Omega,$$

then $\mathcal{D}$ would be an upper bound of Λ. Let us prove the above. Clearly, $\mathcal{D} \subset \mathcal{B}$ since $\mathcal{A} \subset \mathcal{B}$ for all $\mathcal{A} \in \Lambda$. Besides, for any $A, B \in \mathcal{D}$, $A \neq B$, there exists some $\mathcal{A} \in \Lambda$ such that $A, B \in \mathcal{A}$, therefore, $A \cap B = \emptyset$. Hence, $\mathcal{D} \in \Omega$. By Zorn's lemma there exists some maximal element $\mathcal{C} \in \Omega$. $\mathcal{C}$ satisfies (1) and (2). □

As we will prove now, we can recover the Vitali Covering Theorem using the balls defined with the derivator. Our proof is basically identical to [4, Theorem 1.24], since the classical proof holds for the Stieltjes case as well.

Theorem 3.2 (The Stieltjes–Vitali Covering Theorem)**.** *Let Ω be an arbitrary collection of balls such that*

$$R = \sup\{\, \mathrm{rad}(B_g) \ : \ B_g \in \Omega \,\} < \infty$$

where $\mathrm{rad}(B_g)$ denotes the radius of B_g. Then, there exists a countable disjoint subcollection $\Lambda \subset \Omega$ of balls such that

$$\bigcup_{B_g \in \Omega} B_g \subset \bigcup_{A_g \in \Lambda} 5A_g.$$

Besides, each $B_g \in \Omega$ intersects some $A_g \in \Lambda$ such that $B_g \subset 5A_g$.

Proof. Denote

$$F_j = \left\{ B_g \in \Omega \ : \ \mathrm{rad}(B_g) \in \left(\frac{R}{2^{j+1}}, \frac{R}{2^j} \right] \right\} \quad \text{for} \quad j = 0, 1, 2, \ldots.$$

We define Λ_n as follows:

(1) Let Λ_0 be any maximal disjoint subcollection of F_0, which exists by Lemma 3.1.

(2) Suppose $\Lambda_0, \dots, \Lambda_{n-1}$ are already defined, define Λ_n to be the maximal disjoint subcollection of balls in

$$\left\{ B_g \in F_n \ : \ B_g \cap A_g = \emptyset, \ \forall A_g \in \bigcup_{k=0}^{n-1} \Lambda_k \right\}$$

given by Lemma 3.1.

Define now

$$\Lambda = \bigcup_{n=0}^{\infty} \Lambda_n.$$

By construction, Λ is a disjoint subcollection of balls in Ω, and hence, countable, since τ_g is second countable [3, Proposition 2.5]. Take any $B_g \in \Omega$, there exist some index $n \geq 0$ such that $B_g \in F_n$. There must exist then some $A_g \in \cup_{k=0}^{n} \Lambda_k$ such that $B_g \cap A_g \neq \emptyset$. Hence, $\operatorname{rad}(B_g) \leq 2 \operatorname{rad}(A_g)$. Let $x \in B_g \cap A_g$ and x_1, x_2 be the centers of B_g and A_g respectively. Then, for every, $y \in B_g$,

$$d_g(y, x_2) \leq d_g(y, x_1) + d_g(x_1, x) + d_g(x, x_2) \leq 2 \operatorname{rad}(B_g) + \operatorname{rad}(A_g) \leq 5 \operatorname{rad}(A_g).$$

Thus, $B_g \subset 5A_g$. □

Since g is nondecreasing, every ball B_g is connected and thus an interval on $\mathbb{R}$. Fix any $t \in \mathbb{R}$ and $\varepsilon > 0$ and consider the closed ball $B_g[t, \varepsilon]$. Assume $B_g[t, \varepsilon]$ to be bounded, take $a = \inf B_g[t, \varepsilon]$ and $b = \sup B_g[t, \varepsilon]$. Hence

$$(a, b) \subset B_g[t, \varepsilon]. \tag{3.1}$$

Recall that B_g must be non degenerate since g is left-continuous, so $a \neq b$. We have that,

$$g(s) \leq g(t) + \varepsilon$$

for all $s < b$, hence $b \in B_g$ by left-continuity. Now, a may or may not be on $B_g[t, \varepsilon]$ depending whether $\Delta g(a)$ equals zero or not. In any case

$$\mu_g(B_g[t, \varepsilon]) = \mu_g((a, b]) = g(b^+) - g(a^+) = \Delta g(b) + g(b) - g(a^+) \leq \Delta g(b) + 2\varepsilon.$$

Note that, since g^C is continuous, singletons have zero measure. So,

$$\mu_{g^C}(B_g[t, \varepsilon]) = \mu_{g^C}((a, b]) = \mu_{g^C}((a, b)) = g^C(b) - g^C(a^+) \leq g(b) - g(a^+) \leq 2\varepsilon. \tag{3.2}$$

Lemma 3.3. *Let $\Lambda = \{ B_g(t_k, \varepsilon_k) \ : \ k = 1, \dots, n \}$ be a finite disjoint collection of open balls. Assume there exists some $t \in \mathbb{R}$ and $\varepsilon > 0$ such that*

$$\bigcup_{B_g \in \Lambda} B_g \subset B_g(t, \varepsilon).$$

Then, $\varepsilon > \frac{1}{4} \sum_{k=1}^{n} \varepsilon_k$.

Proof. Let us look first at the case $n = 2$. Suppose then we have two balls of center t_1 and t_2 and radius ε_1 and ε_2 respectively. Since the balls are disjoint, we have that $t_2 \notin B_g(t_1, \varepsilon_1)$ and $t_1 \notin B_g(t_2, \varepsilon_2)$. Hence

$$\max\{\varepsilon_1, \varepsilon_2\} \leq |g(t_2) - g(t_1)|.$$

Go back to the general case and assume without loss of generality that the center of the balls $t_1, \ldots, t_n$ are ordered from left to right. We have that

$$\begin{aligned} g(t_n) - g(t_1) &= \sum_{k=1}^{n-1} g(t_{k+1}) - g(t_k) \geq \sum_{k=1}^{n-1} \max\{\varepsilon_{k+1}, \varepsilon_k\} \geq \sum_{k=1}^{n-1} \frac{\varepsilon_{k+1} + \varepsilon_k}{2} \\ &\geq \sum_{k=2}^{n-1} \varepsilon_k + \frac{1}{2}\varepsilon_1 + \frac{1}{2}\varepsilon_n \geq \frac{1}{2} \sum_{k=1}^{n} \varepsilon_k. \end{aligned}$$

Now $t_1, t_n \in B_g(t, \varepsilon)$, hence

$$\frac{1}{2} \sum_{k=1}^{n} \varepsilon_k \leq g(t_n) - g(t_1) < 2\varepsilon. \qquad \square$$

Remark 3.4. The bounds

$$\frac{\varepsilon_1 + \varepsilon_2}{2} \leq \max\{\varepsilon_1, \varepsilon_2\}, \quad \frac{1}{2} \sum_{k=1}^{n} \varepsilon_k \leq \sum_{k=2}^{n-1} \varepsilon_k + \frac{1}{2}\varepsilon_1 + \frac{1}{2}\varepsilon_n$$

made on Lemma 3.3 are just arbitrary and of course suboptimal. We wish for our bounds just to be comfortable to manage with series as this next result is the whole purpose of the above.

Corollary 3.5. *Let $\Lambda = \{ B_g(t_k, \varepsilon_k) \mid k \in \mathbb{N}\}$ be a countable disjoint collection of open balls. If*

$$\bigcup_{B_g \in \Lambda} B_g \subset B_g(t, \varepsilon)$$

for some $t \in \mathbb{R}$ and $\varepsilon > 0$, the series $\sum_{k=1}^{\infty} \varepsilon_k$ converges.

Theorem 3.6. *Let X be a nonempty subset of $\mathbb{R}$. Let Ω be a collection of closed balls whose union covers X and satisfies the following property:*

For all $t \in X$ and $\delta > 0$, there exists some $A_g \in \Omega$ such that $A_g \subset B_g(t, \delta)$.

Then there exists a countable disjoint subcollection $\Lambda \subset \Omega$ which covers X up to a g^C-null measure set. In other words, such that

$$\mu_{g^C}\left(X - \bigcup_{B_g \in \Lambda} B_g \right) = 0.$$

Proof. Without loss of generality assume all balls in Ω have radius less than 1. Denote as Λ the countable disjoint subcollection given by Theorem 3.2. We show now that

$$E = X - \bigcup_{B_g \in \Lambda} B_g$$

has null g^C-measure. Take $E_n = E \cap B_g(0, n)$ for $n \in \mathbb{N}$, is enough to show that $\mu_{g^C}(E_n) = 0$ for all $n \in \mathbb{N}$. Denote $\Lambda_n = \{ B_g^k \equiv B_g[t_k, \varepsilon_k] \mid k \in \mathbb{N}\}$ the subcollection of balls of Λ that meet $B_g(0, n)$. Let $t \in E_n$ and $m \in \mathbb{N}$, since $K = \bigcup_{k=0}^{m} B_g^k$ is closed in τ_g, there exists some $A_g \in \Omega$

containing t, contained in $B_g(0,n)$ and disjoint from K. By the property of Λ, A_g intersects some $B_g^i \in \Lambda_n$ for which $A_g \subset 5B_g^i$. This means, $i > m$ and therefore,

$$E_n \subset \bigcup_{k>m} 5B_g^k.$$

This gives the inequality

$$\mu_{g^C}^*(E_n) \leq \mu_{g^C}\left(\bigcup_{k>m} 5B_g^k\right) \leq \sum_{k>m} \mu_{g^C}(5B_g^k) \tag{3.3}$$

for all $m \in \mathbb{N}$. Now, the balls Λ_n are all contained in $B_g(0,n+2)$. From Corollary 3.5, $\sum_{k=1}^{\infty} \varepsilon_k < \infty$, where $\varepsilon_k = \operatorname{rad}(B_g^k)$. Hence, by equation (3.2)

$$\sum_{k=1}^{\infty} \mu_{g^C}(5B_g[t_k,\varepsilon_k]) \leq 10 \sum_{k=1}^{\infty} \varepsilon_k < \infty.$$

From (3.3), $\mu_{g^C}^*(E_n) = 0$. □

Theorem 3.7. *Let $f : [a,b] \longrightarrow \mathbb{R}$ be an arbitrary function and E the set of points of $[a,b]$ at which f has nonzero g-derivative (ie. the g-derivative exists and takes nonzero values). Then, for every null Lebesgue measure set Z, the set $f^{-1}(Z) \cap E$ has null g^C-measure.*

Proof. It suffices to prove the result for the set of points where the g-derivative is positive, which we shall denote again by E. The result for the set of points where the g-derivative is negative follows from the other one applied to the function $-f$ and the null set $-Z$.

Moreover, since $\mu_{g^C}(N_g \cup C_g \cup D_g \cup \{a,b\}) = 0$, we can redefine E to be

$$E = \{t \in (a,b) : f_g'(t) \text{ exists and is positive, } g \text{ is continuous at } t \text{ and } g(s) \neq g(t)\ \forall s \in \mathbb{R},\ s \neq t\}.$$

We can express

$$E = \bigcup_{n=1}^{\infty} \left\{ t \in E \,:\, f_g'(t) > \frac{1}{n} \right\},$$

so it suffices to prove that, for any $\delta > 0$, the set

$$E_\delta = \left\{ t \in E \,:\, f_g'(t) > \delta \right\}$$

has a g^C-null intersection with $f^{-1}(Z)$, for any Z as in the statement.

For a fixed $\delta > 0$ and $q, p \in \mathbb{Q} \cap (a,b)$, $q < p$, we define

$$A_{q,p} = \left\{ t \in E \cap (q,p) : \frac{f(t) - f(s)}{g(t) - g(s)} > \delta,\ \forall s \in (q,p),\ s \neq t \right\},$$

and we have

$$E_\delta \subset \bigcup_{\substack{q,p \in \mathbb{Q} \cap (a,b) \\ q<p}} A_{q,p}.$$

This reduces the proof to showing that for each fixed null Lebesgue measure set Z, for each fixed $\delta > 0$ and for each fixed pair $q, p \in \mathbb{Q} \cap (a,b)$, $q < p$, we have $\mu_{g^C}(f^{-1}(Z) \cap A_{q,p}) = 0$.

First, observe that for $t_1, t_2 \in A_{q,p}$, $t_1 < t_2$, we have

$$\frac{f(t_1)-f(t_2)}{g(t_1)-g(t_2)} > \delta \Rightarrow f(t_1)-f(t_2) < \delta(g(t_1)-g(t_2)) < 0 \Rightarrow f(t_1) < f(t_2),$$

so f is increasing on $A_{q,p}$.

Let $\epsilon > 0$ be fixed and let U be a usual open set of measure less than ϵ that contains Z.

The definition of $A_{q,p}$ guarantees that for any $t \in A_{q,p}$ we can use Proposition 2.5 to ensure that the g-balls $B_g[t,r]$, $r > 0$, are usual neighborhoods of t and, by Remark 2.6, that f is continuous at t. Moreover, $B_g[t,r]$ shrinks to $\{t\}$ as r tends to zero. Therefore, for each $t \in f^{-1}(Z) \cap A_{q,p}$ there exists $r(t) > 0$ such that the usual closure $\overline{B_g[t,r(t)]} \subset (q,p)$ and $f\left(\overline{B_g[t,r(t)]}\right) \subset U$.

Define Ω as the collection of all closed g-balls $B_{t,k} = B_g[t, r(t)/k]$, $t \in f^{-1}(Z) \cap A_{q,p}$, $k \in \mathbb{N}$. Plainly, $f^{-1}(Z) \cap A_{q,p} \subset \bigcup_{t,k} B_{t,k}$ and, moreover, for each $t \in f^{-1}(Z) \cap A_{q,p}$ and each $\rho > 0$ there exists $k \in \mathbb{N}$ such that $B_{t,k} \subset B_g(t,\rho)$. By Vitali's Theorem 3.6 there exists a countable and disjoint subfamily of Ω that covers $f^{-1}(Z) \cap A_{q,p}$ up to a null g^C-measure set. Denote this subcollection as $\{B_g[t_n, r_n] : n \in \mathbb{N}\}$ and put

$$[a_n, b_n] = \overline{B_g[t_n, r_n]}, \quad n \in \mathbb{N}.$$

Since $[a_n, b_n] \subset (q,p)$ and $t_n \in A_{q,p}$,

$$\begin{aligned} f(b_n)-f(a_n) &= (f(b_n)-f(t_n)) + (f(t_n)-f(a_n)) \\ &> \delta((g(b_n)-g(t_n)) + (g(t_n)-g(a_n))) = \delta(g(b_n)-g(a_n)), \end{aligned} \tag{3.4}$$

and, moreover, $[f(a_n), f(b_n)] \subset U$.

Now, take $m, k \in \mathbb{N}$ such that $m \neq k$. Since the intervals $[t_m, b_m]$ and $[t_k, b_k]$ are disjoint we can suppose that $b_m < t_k$. Therefore,

$$f(t_m) < f(b_m) < f(t_k) < f(b_k)$$

since t_m and t_k belong in $A_{q,p}$. Hence, $\{(f(t_n), f(b_n)), n \in \mathbb{N}\}$ forms a disjoint family of nondegenerate intervals such that the sum of their lengths is less than ϵ since they are all contained in U. A similar argument proves the same for the intervals $(f(a_n), f(t_n))$, $n \in \mathbb{N}$. We deduce from (3.4) that

$$\begin{aligned} \mu_{g^C}\left(\bigcup_{n=1}^{\infty} B_g[t_n, r_n]\right) &\leq \sum_{n=1}^{\infty} \mu_{g^C}([a_n, b_n]) \leq \sum_{n=1}^{\infty} g(b_n) - g(a_n) \\ &< \frac{1}{\delta}\sum_{n=1}^{\infty} f(b_n) - f(a_n) = \frac{1}{\delta}\sum_{n=1}^{\infty} f(b_n) - f(t_n) + f(t_n) - f(a_n) \\ &= \frac{1}{\delta}\sum_{n=1}^{\infty} f(b_n) - f(t_n) + \frac{1}{\delta}\sum_{n=1}^{\infty} f(t_n) - f(a_n) \leq 2\frac{\epsilon}{\delta}, \end{aligned}$$

which implies that $\mu_{g^C}\left(f^{-1}(Z) \cap A_{a,p}\right) < 2\varepsilon/\delta$ for any $\epsilon > 0$. □

4 Chain rule

Here we shall prove a new version of the chain rule in higher dimensions which is crucial in the transversality conditions to be introduced in our main existence result for (1.1).

Proposition 4.1. *Let $t, \varepsilon \in \mathbb{R}$, $\varepsilon > 0$, be fixed. Let $h : (t-\epsilon, t+\epsilon) \longrightarrow \mathbb{R}^n$, $f : U \longrightarrow \mathbb{R}$ where U is a usual open set of $\mathbb{R}^n$ such that $h(t-\varepsilon, t+\varepsilon) \subset U$.*

If $t \notin D_g \cup C_g$, h is g-differentiable at t and f is differentiable at $h(t)$, then $f \circ h$ is g-differentiable at t and

$$(f \circ h)'_g(t) = \nabla f(h(t)) \cdot h'_g(t),$$

where $\cdot$ denotes the usual inner product.

Proof. Since $t \notin C_g$ we have $g(s) < g(t)$ for all $s < t$, or $g(s) > g(t)$ for all $s > t$, or both. Since $t \notin D_g$, the existence of $h'_g(t)$ means, in any of the previous three cases, that there exists

$$h'_g(t) = \lim_{\substack{s \to t \\ g(s) \neq g(t)}} \frac{h(s) - h(t)}{g(s) - g(t)}$$

and we want to prove that

$$\lim_{\substack{s \to t \\ g(s) \neq g(t)}} \frac{f(h(s)) - f(h(t))}{g(s) - g(t)} = \nabla f(h(t)) \cdot h'_g(t).$$

Since g is continuous at t, there exists

$$\lim_{\substack{s \to t \\ g(s) \neq g(t)}} h(s) - h(t) = \lim_{\substack{s \to t \\ g(s) \neq g(t)}} \frac{h(s) - h(t)}{g(s) - g(t)} (g(s) - g(t)) = 0. \tag{4.1}$$

Observe that, as long as $g(s) \neq g(t)$, we have

$$\left| \frac{f(h(s)) - f(h(t))}{g(s) - g(t)} - \nabla f(h(t)) \cdot h'_g(t) \right| \leq \underbrace{\left| \frac{f(h(s)) - f(h(t)) - \nabla f(h(t)) \cdot (h(s) - h(t))}{g(s) - g(t)} \right|}_{=A(s)}$$
$$+ \underbrace{\|\nabla f(h(t))\| \left\| \frac{h(s) - h(t)}{g(s) - g(t)} - h'_g(t) \right\|}_{=B(s)},$$

and $B(s) \to 0$ as $s \to t$ ($g(s) \neq g(t)$) by definition of $h'_g(t)$. On the other hand, if $h(s) = h(t)$, then $A(s) = 0$, and otherwise we have

$$A(s) = \frac{|f(h(s)) - f(h(t)) - \nabla f(h(t)) \cdot (h(s) - h(t))|}{\|h(s) - h(t)\|} \left\| \frac{h(s) - h(t)}{g(s) - g(t)} \right\|,$$

which tends to zero as $s \to t$ ($g(s) \neq g(t)$) by definition of $\nabla f(h(t))$ and (4.1). □

Corollary 4.2. *Let $t, \varepsilon \in \mathbb{R}$, $\varepsilon > 0$ be fixed. Let $x : (t-\epsilon, t+\epsilon) \longrightarrow \mathbb{R}^n$, $\tau : (t-\epsilon, t+\epsilon) \times U \longrightarrow \mathbb{R}$ where U is a usual open set of $\mathbb{R}^n$ such that $x(t-\varepsilon, t+\varepsilon) \subset U$.*

If $t \notin D_g \cup C_g$, $g'(t) > 0$, x is g-differentiable at t and τ is differentiable at $(t, x(t))$, then $\tau(\cdot, x(\cdot))$ is g-differentiable at t and

$$\frac{d}{dg(t)} \tau(t, x(t)) = \nabla \tau(t, x(t)) \cdot (1/g'(t), x'_g(t)).$$

Proof. Apply Proposition 4.1 with $h(t) = (t, x(t))$ and $f(y) = \tau(y)$ for $y = (t, x) \in (t - \varepsilon, t + \varepsilon) \times \mathbb{R}^n$. The condition $g'(t) > 0$ implies that h is g-differentiable at t and $h'_g(t) = (1/g'(t), x'_g(t))$. □

5 Main result

We are already in a position to prove our new existence result of Carathéodory solutions of (1.1). Our arguments lean on the chain rule, established in Section 4, along with a transversality condition of the g-differential equation with respect to the sets where discontinuities are allowed for $f(t,x)$.

A Krasovskij solution of (1.1) is defined as a g-absolutely continuous function $x : I \longrightarrow \mathbb{R}^n$ such that $x(t_0) = x_0$ and

$$x'_g(t) \in \bigcap_{\varepsilon>0} \overline{\text{co}}\, f\,(t, B_\varepsilon(x(t))) \quad \text{for } g\text{-a.a. } t \in [t_0, t_0+L), \tag{5.1}$$

where $\overline{\text{co}}$ means closed convex hull and $B_\varepsilon(x) = \{y \in \mathbb{R}^n \,:\, \|y-x\| < \varepsilon\}$. Observe that, in the scalar case ($n=1$), we have $B_\varepsilon(x) = (x-\varepsilon, x+\varepsilon)$.

We are now in a position to prove a result on the existence of Carathéodory solutions for (1.1).

Theorem 5.1. *Assume that for all $x \in \mathbb{R}^n$ the mapping $f(\cdot,x)$ is g-measurable, for all $t \in [t_0,t_0+L) \cap D_g$ the mapping $f(t,\cdot)$ is continuous, and there exists $M \in L^1_g([t_0,t_0+L))$ such that for g-almost all $t \in [t_0,t_0+L)$ and all $x \in \mathbb{R}^n$ we have $\|f(t,x)\| \le M(t)$.*

Moreover, assume that there exist null Lebesgue measure sets $A_k \subset \mathbb{R}$, $k \in \mathcal{C} \subset \mathbb{N}$, and differentiable mappings $\tau_k : [a_k,b_k] \times \mathbb{R}^n \longrightarrow \mathbb{R}$, $[a_k,b_k] \subset I$, such that for g-a.a. $t \in [t_0,t_0+L) \setminus D_g$ the following conditions hold:

(a) $g'(t) > 0$;

(b) There exists a set $N(t) \subset \mathbb{R}^n$ such that $f(t,\cdot)$ is continuous in $\mathbb{R}^n \setminus N(t)$;

(c) For each $x \in N(t)$ there exists $k \in \mathcal{C}$ such that $t \in [a_k,b_k]$, $\tau_k(t,x) \in A_k$, and

$$\nabla \tau_k(t,x) \cdot (1/g'(t), z) \neq 0 \quad \textit{for all } z \in \bigcap_{\varepsilon>0} \overline{\text{co}}\, f\,(t, B_\varepsilon(x)). \tag{5.2}$$

Then, problem (1.1) has at least one Carathéodory solution.

Proof. The assumptions imply that the multivalued mapping

$$(t,x) \longmapsto \mathcal{F}(t,x) = \bigcap_{\varepsilon>0} \overline{\text{co}}\, f\,(t, B_\varepsilon(x))$$

is compact and convex-valued, and it is upper semicontinuous. Hence, Theorem 3.9 in [8] ensures that problem (1.1) has at least one Krasovskij solution $x : I \longrightarrow \mathbb{R}^n$. Let us prove that x is a Carathéodory solution of (1.1).

Let $E \subset I$ be a g-null measure set such that, first, conditions (a), (b) and (c) hold for all $t \in I \setminus E$, and, second,

$$x'_g(t) \in \mathcal{F}(t,x(t)) \quad \text{for all } t \in I \setminus E.$$

Observe that for each $t \in I \setminus E$ such that $t \in D_g$ or $x(t) \notin N(t)$ the assumptions ensure that $f(t,\cdot)$ is continuous at $x(t)$, and therefore

$$x'_g(t) \in \mathcal{F}(t,x(t)) = \{f(t,x(t))\}.$$

Hence, it suffices to prove that the set $J = \{t \in I \setminus E,\, t \notin D_g \,:\, x(t) \in N(t)\}$ is g-null.

We deduce from condition (c) that

$$J \subset \bigcup_{k\in\mathcal{C}} \{t \in [a_k, b_k] \setminus E,\ t \notin D_g\ :\ \tau_k(t, x(t)) \in A_k\},$$

so the proof is reduced to showing that each $J_k = \{t \in [a_k, b_k] \setminus E,\ t \notin D_g\ :\ \tau_k(t, x(t)) \in A_k\}$ is a null g-measure set. For an arbitrarily fixed $k \in \mathcal{C}$, we define $\varphi(t) = \tau_k(t, x(t))$ for all $t \in [a_k, b_k]$, so that $J_k \subset \varphi^{-1}(A_k) \setminus D_g$ and it suffices to prove that $\varphi^{-1}(A_k) \setminus D_g$ is g-null. Since $m(A_k) = 0$, Theorem 3.7 guarantees the existence of a set $B \subset \varphi^{-1}(A_k)$, with null g^c-measure, such that for every $t \in \varphi^{-1}(A_k) \setminus B$ we have $\varphi'_g(t) = 0$, i.e. $\varphi'_g(t) = 0$ for g^c-a.a. $t \in \varphi^{-1}(A_k)$ or, equivalently, for g-a.a. $t \in \varphi^{-1}(A_k) \setminus D_g$ we have

$$\frac{d}{dg(t)} \tau_k(t, x(t)) = 0. \tag{5.3}$$

Let us prove that $\varphi^{-1}(A_k) \setminus D_g \subset E$, thus showing that $\varphi^{-1}(A_k) \setminus D_g$ is g-null. Reasoning by contradiction, we assume that there is some $t \in \varphi^{-1}(A_k) \setminus D_g$ such that $t \notin E$, and then we can use the chain rule in (5.3) to deduce that

$$\nabla \tau_k(t, x(t)) \cdot (1/g'(t), x'_g(t)) = 0,$$

a contradiction with condition (5.2). □

Checking the transversality condition (5.2) might be a difficult task in practical situations. Our next corollary gives a more friendly sufficient condition for it. Basically, it tells us that (5.2) is satisfied provided that $\partial\tau_k/\partial t$ is far from zero and $g'(t)$ is small enough. This is an interesting condition from the viewpoint of Stieltjes differential equations because it leans precisely on the slopes of the derivator.

Corollary 5.2. *Assume that for all $x \in \mathbb{R}^n$ the mapping $f(\cdot, x)$ is g-measurable, for all $t \in [t_0, t_0 + L) \cap D_g$ the mapping $f(t, \cdot)$ is continuous, and there exists $M \in L^1_g([t_0, t_0 + L))$ such that for g-almost all $t \in [t_0, t_0 + L)$ and all $x \in \mathbb{R}^n$ we have $\|f(t, x)\| \leq M(t)$.*

Moreover, assume that there exist null Lebesgue measure sets $A_k \subset \mathbb{R}$, $k \in \mathcal{C} \subset \mathbb{N}$, and differentiable mappings $\tau_k : [a_k, b_k] \times \mathbb{R}^n \longrightarrow \mathbb{R}$, $[a_k, b_k] \subset I$, such that for g-a.a. $t \in [t_0, t_0 + L) \setminus D_g$ the following conditions hold:

(a) $g'(t) > 0$;

(b) There exists a set $N(t) \subset \mathbb{R}^n$ such that $f(t, \cdot)$ is continuous in $\mathbb{R}^n \setminus N(t)$;

(c) For each $x \in N(t)$ there exists $k \in \mathcal{C}$ such that $t \in [a_k, b_k]$, $\tau_k(t, x) \in A_k$, and*

$$\left|\frac{\partial \tau_k}{\partial t}(t, x)\right| > g'(t)\, M(t) \sum_{j=1}^{n} \left|\frac{\partial \tau_k}{\partial x_j}(t, x)\right|. \tag{5.4}$$

Then, problem (1.1) has at least one Carathéodory solution.

Proof. We only have to check that condition $(c*)$ implies condition (c) in Theorem 5.1. To do it, we take x as in (c^*) and we observe that $z = (z_1, z_2, \ldots, z_n) \in \bigcap_{\varepsilon>0} \overline{\text{co}}\, f(t, B_\varepsilon(x))$ implies

that $|z_j| \le M(t)$ for $j = 1, 2, \dots, n$, so we have

$$\begin{aligned}
\left|\nabla\tau_k(t,x)\cdot(1/g'(t),z)\right| &= \left|\frac{1}{g'(t)}\frac{\partial\tau_k}{\partial t}(t,x) + \sum_{j=1}^{n} z_j \frac{\partial\tau_k}{\partial x_j}(t,x)\right| \\
&= \left|\frac{1}{g'(t)}\frac{\partial\tau_k}{\partial t}(t,x) - \sum_{j=1}^{n}(-z_j)\frac{\partial\tau_k}{\partial x_j}(t,x)\right| \\
&\ge \frac{1}{g'(t)}\left|\frac{\partial\tau_k}{\partial t}(t,x)\right| - \left|\sum_{j=1}^{n}(-z_j)\frac{\partial\tau_k}{\partial x_j}(t,x)\right| \\
&\ge \frac{1}{g'(t)}\left|\frac{\partial\tau_k}{\partial t}(t,x)\right| - M(t)\sum_{j=1}^{n}\left|\frac{\partial\tau_k}{\partial x_j}(t,x)\right|
\end{aligned}$$

and the last term is positive thanks to condition (5.4). □

Observe that condition (5.4) is fulfilled when $\partial\tau_k/\partial t$ is positive and either g' is small enough or $\partial\tau_k/\partial t$ is large enough. Corollary 5.2 is new even in case $g(t) = t$, i.e. for ordinary differential equations, where condition (5.4) reduces to

$$\left|\frac{\partial\tau_k}{\partial t}(t,x)\right| > M(t)\sum_{j=1}^{n}\left|\frac{\partial\tau_k}{\partial x_j}(t,x)\right|.$$

Finally, we get an interesting consequence for the scalar case in connection with bounded variation (not necessarily continuous) nonlinear parts of the g-differential equations.

Corollary 5.3. *The scalar problem*

$$x'_g = f(t,x), \quad t \in I = [t_0, t_0 + L),\ x(t_0) = x_0, \tag{5.5}$$

has at least one Carathéodory solution provided that there exists $M > 0$ such that $|f(t,x)| \le M$ for all $(t,x) \in I \times \mathbb{R}$, $f(t,\cdot)$ is continuous whenever $t \in [t_0, t_0 + L) \cap D_g$, and for g-a.a. $t \in [t_0, t_0 + L) \setminus D_g$ we have $g'(t) > 0$ and we can express $f(t,x) = F(\tau(t,x))$ for some functions F and τ satisfying the following assumptions:

(i) $F : \mathbb{R} \longrightarrow \mathbb{R}$ *has bounded variation on any compact interval;*

(ii) $\tau : I \times \mathbb{R} \longrightarrow \mathbb{R}$ *is differentiable and*

$$\left|\frac{\partial\tau}{\partial t}(t,x)\right| > M\,g'(t)\left|\frac{\partial\tau}{\partial x}(t,x)\right|, \quad (t,x) \in ([t_0, t_0 + L) \setminus D_g) \times \mathbb{R}. \tag{5.6}$$

Proof. The result follows from Corollary 5.2. First, observe that for any $x \in \mathbb{R}$ the composition $f(\cdot,x) = F(\tau(\cdot,x))$ is Borel measurable, hence g-measurable in the Lebesgue–Stieltjes sense. On the other hand, for any $t \in I \setminus D_g$ the function $f(t,\cdot) = F(\tau(t,\cdot))$ is continuous everywhere except at those $x \in \mathbb{R}$ such that $\tau(t,x)$ is a discontinuity point of F. Let A be a countable set such that F is continuous in $\mathbb{R} \setminus A$; then $f(t,\cdot)$ is continuous in $\mathbb{R} \setminus N(t)$, where

$$N(t) = \{x \in \mathbb{R} : \tau(t,x) \in A\} = \tau(t,\cdot)^{-1}(A).$$

Obviously, for each $x \in N(t)$ we have $\tau(t,x) \in A$, and condition (5.6) implies condition (5.4). □

Remark 5.4. In the conditions of Corollary 5.3, solutions $x(t)$ of (5.5) satisfy $|x(t) - x_0| \le M\,(g(t) - g(t_0)) \le M\,(g(t_0 + L) - g(t_0))$ for all $t \in [t_0, t_0 + L)$. Hence, condition (5.6) is really needed only for all $(t,x) \in ([t_0, t_0 + L) \setminus D_g) \times \mathbb{R}$ such that $|x - x_0| \le M\,(g(t) - g(t_0))$.

5.1 An example

Let $g : \mathbb{R} \longrightarrow \mathbb{R}$ be nondecreasing, left-continuous everywhere and assume that $g'(t) > 0$ for g-a.a. $t \in [t_0, t_0 + L) \setminus D_g$.

We consider the following particular case of problem (5.5):

$$x_g' = F(\alpha\, t + \beta\, x)\chi_{I\setminus D_g}(t) + F(t)\chi_{I\cap D_g}(t), \quad t \in I = [t_0, t_0 + L),\ x(t_0) = x_0, \tag{5.7}$$

where $\alpha, \beta \in \mathbb{R}$, χ_A denotes the characteristic function of a set $A \subset \mathbb{R}$, and $F : \mathbb{R} \longrightarrow \mathbb{R}$ is given by

$$F(y) = \sum_{r_n < y} 2^{-n}, \quad y \in \mathbb{R},$$

where $r_n = r(n)$, $n \in \mathbb{N}$, and $r : \mathbb{N} \longrightarrow \mathbb{Q}$ is a bijection.

Observe that F is increasing, $0 < F(y) < 1$ for all $y \in \mathbb{R}$, and F is discontinuous at every rational number.

It is easy to check that Corollary 5.3 applies if

$$|\alpha| > g'(t)|\beta| \quad \text{for } g\text{-a.a. } t \in I \setminus D_g,$$

so in that case (5.7) has at least one solution.

Abstract. In this paper, we study the existence and multiplicity of weak solutions for a Steklov problem involving $p(x)$-Laplacian operator in a bounded domain $\Omega \subset \mathbb{R}^N$ $(N \geq 2)$ with smooth boundary $\partial\Omega$. The boundary equation is perturbed with some weight functions belonging to approriate generalized Lebesgue spaces and two real parameters. Our arguments are based on variational method, using "Mountain Pass Theorem", "Fountain Theorem" and "Dual Fountain Theorem" combined with the critical points theory, we prove several existence results.

Keywords: Steklov problem, $p(x)$-Laplacian operator, generalized Lebesgue–Sobolev spaces, variational method, Mountain Pass Theorem, Fountain Theorem, Dual Fountain Theorem.

1 Introduction

We are interested in the existence and multiplicity of weak solutions for the following quasi-linear elliptic problem with Steklov boundary condition involving variable exponents

$$\begin{aligned} \Delta_{p(x)}u &= a(x)|u|^{p(x)-2}u \quad \text{in } \Omega, \\ |\nabla u|^{p(x)-2}\frac{\partial u}{\partial \nu} &= \lambda V(x)|u|^{q(x)-2}u + \mu W(x)|u|^{r(x)-2}u \quad \text{on } \partial\Omega, \end{aligned} \tag{$S_{\lambda,\mu}$}$$

where $\Omega \subset \mathbb{R}^N$ $(N \geq 2)$ is a bounded domain with smooth boundary $\partial\Omega$, ν is the outward unit normal to $\partial\Omega$, λ, μ are real parameters, $p, q, r : \overline{\Omega} \to (1, +\infty)$ are continuous functions, $a \in L^\infty(\Omega)$ is a positive function, V, W are positive measurable weight functions belonging to some generalized Lebesgue space and $\Delta_{p(x)}u$ is the $p(x)$-Laplacian operator defined by $\Delta_{p(x)}u = \operatorname{div}(|\nabla u|^{p(x)-2}\nabla u)$ which is a natural extension of the p-Laplacian operator obtained in the constant case $p(x) \equiv p$, if $p \equiv 2$ we have the classical Laplacian operator $\Delta u = \operatorname{div}(\nabla u)$.

In recent years, nonlinear boundary value problems with variable exponents have received an increasing attention. This is partly due to their frequent appearance in a lot of models in mathematical physics such as the modeling of electrorheological fluids, elasticity problems, flow in porous medium and image processing, see [17, 42, 44, 51]. The study of variable exponent problems is more difficult than the constant one, since the $p(x)$-Laplacian operator possesses more complicated structures than the p-Laplacian operator, for example it is inhomogeneous. Recently, boundary value problems involving a such operator have been a subject of many researchers, we refer to [1, 15, 24, 29, 33, 34, 36, 39], in which the authors have extended some well known results from constant to variable exponents case.

Problems of Steklov type appear in the modeling of an elastic membrane problem whose mass is concentrated on the boundary [45]. In the past decades, many works have extended the results of [45] from Laplacian operator to p-Laplacian operator [7–10, 22, 38, 40, 47] and more general $p(x)$-Laplacian operator [2–6, 11, 12, 14, 19, 43].

In [11], problem $(S_{\lambda,\mu})$ is considered with $a(x) \equiv 1$, $V(x) \equiv 1$ and $\mu = 0$. For any $\lambda > 0$, if $q^+ < p^-$, the authors proved the existence of a sequence of nontrivial weak solutions, and if $p^+ < q^- \leq q^+ < p^\partial(x)$, the existence of nontrivial weak solution. In [14], the authors considered problem $(S_{\lambda,\mu})$ with $\mu = 0$ and $V(x)$ belonging to some generalized Lebesgue space. Under condition $1 \leq q^+ < p^-$, the authors proved the existence of at least one non trivial weak solution with negative energy for all $\lambda > 0$, and non trivial weak solution for all $\lambda \in (0, \lambda^*)$, where λ^* is a positive constant. It should be noticed that in [24, 36], problem like $(S_{\lambda,\mu})$ was considered but with Dirichlet boundary condition. Under appropriate conditions on the variable exponents, the authors proved several existence and multiplicity results by changing the role of parameters λ, μ with respect to their signs.

Inspired by the above mentioned works [11, 14, 24, 36], we study the Steklov problem $(S_{\lambda,\mu})$ with some weight functions and two parameters. The appropriate functional spaces and their basic properties used in this work are guaranteed by the paper of S. G. Deng [19], namely, the compact embedding from the generalized Sobolev space to the generalized Lebesgue space with weight. Under relaxed conditions on the variable exponents and real parameters λ, μ that the ones use in [11, 14], we obtain new criteria on existence and multiplicity results of $(S_{\lambda,\mu})$.

We make the following basic hypotheses on the data of $(S_{\lambda,\mu})$:

$$\begin{gathered} s, t : \overline{\Omega} \to (1, +\infty) \quad \text{are variable exponents such that :} \\ s(x), t(x) > \frac{N-1}{p(x)-1}, \quad \text{for a.e. } x \in \partial\Omega, \\ 1 \leq q(x) < \frac{s(x)-1}{s(x)} p^\partial(x), \qquad 1 \leq r(x) < \frac{t(x)-1}{t(x)} p^\partial(x), \quad \text{for a.e. } x \in \partial\Omega, \end{gathered} \tag{$\mathbf{H_1}$}$$

where $p^\partial(x)$ is the critical Sobolev exponent on $\partial\Omega$;

$$a \in L^\infty(\Omega), \quad \text{with } \operatorname*{ess\,inf}_{x\in\Omega} a(x) = a^- > 0; \tag{$\mathbf{H_2}$}$$

$$V \in L^{s(x)}(\partial\Omega), \qquad W \in L^{t(x)}(\partial\Omega), \quad \text{with } V(x), W(x) > 0 \quad \text{for a.e. } x \in \partial\Omega. \tag{$\mathbf{H_3}$}$$

Our main results in this paper are given by the following theorems.

Theorem 1.1. *Assume that hypotheses* ($\mathbf{H_1}$)–($\mathbf{H_2}$)–($\mathbf{H_3}$) *are fulfilled. Denote by* p^+, q^+, r^+ *(resp.* p^-, q^-, r^-*) the maximum (resp. the minimum) of functions* $p(x)$, $q(x)$, $r(x)$ *on* $\overline{\Omega}$*, respectively.*

(i) *If* $\max\{q^+, r^+\} < p^-$, *then for any* $\lambda, \mu \in \mathbb{R}$, *problem* $(S_{\lambda,\mu})$ *has a nonnegative solution.*

(ii) *If* $\min\{q^-, r^-\} > p^+$, *then for any* $\lambda, \mu \geq 0$, *problem* $(S_{\lambda,\mu})$ *has a nontrivial nonnegative solution.*

Theorem 1.2. *Assume that hypotheses* $(\mathbf{H_1})$–$(\mathbf{H_2})$–$(\mathbf{H_3})$ *are fulfilled. Denote by* Ψ *the energy fuctional associated to* $(S_{\lambda,\mu})$ *and* p^+, q^+, r^+ *(resp.* p^-, q^-, r^-*) the maximum (resp. the minimum) of functions* $p(x)$, $q(x)$, $r(x)$ *on* $\overline{\Omega}$, *respectively.*

(i) *If* $1 < p^- \leq p^+ < r^- \leq q^-$, *then for any* $\lambda, \mu \geq 0$, *problem* $(S_{\lambda,\mu})$ *has a sequence of solutions* $(\pm u_n)$ *such that* $\Psi(\pm u_n) \to \infty$ *as* $n \to \infty$.

(ii) *If* $1 < q^- \leq q^+ < p^- \leq p^+ < r^-$, *then for any* $\lambda \in \mathbb{R}$ *and* $\mu > 0$, *problem* $(S_{\lambda,\mu})$ *has a sequence of solutions* $(\pm u_n)$ *such that* $\Psi(\pm u_n) \to \infty$ *as* $n \to \infty$.

(iii) *If* $1 < q^- \leq q^+ = p^- \leq p^+ < r^-$, *then for any* $\lambda \in \mathbb{R}$ *with* $|\lambda| < \lambda_0 := \frac{\frac{1}{p^+} - \frac{1}{r^-}}{(\frac{1}{q^-} - \frac{1}{h^-})C^{q^+}}$ *and* $\mu > 0$, *problem* $(S_{\lambda,\mu})$ *has a sequence of solutions* $(\pm u_n)$ *such that* $\Psi(\pm u_n) \to \infty$ *as* $n \to \infty$.

(iv) *If* $1 < q^- \leq q^+ < p^- \leq p^+ < r^-$, *then for any* $\lambda > 0$ *and* $\mu \in \mathbb{R}$, *problem* $(S_{\lambda,\mu})$ *has a sequence of solutions* $(\pm v_n)$ *such that* $\Psi(\pm v_n) < 0$, *for all* n, *and* $\Psi(\pm v_n) \to 0$ *as* $n \to \infty$.

(v) *If* $1 < q^- \leq q^+ < \min\{p^-, r^-\}$ *and* $p^+ < r^+$, *then for any* $\lambda > 0$ *and* $\mu \leq 0$, *problem* $(S_{\lambda,\mu})$ *has a sequence of solutions* $(\pm v_n)$ *such that* $\Psi(\pm v_n) < 0$, *for all* n, *and* $\Psi(\pm v_n) \to 0$ *as* $n \to \infty$.

To prove these results, our approach is variational combined with the critical point theory. Theorem 1.1 is established by using the global minimizer method for the case (i) and Mountain Pass Theorem of Ambrosetti–Rabinowitz for the case (ii). For the proof of Theorem 1.2 we need to use the fountain theorem established by T. Bartsch in 1993 and the dual of fountain theorem established by T. Bartsch and M. Willem in 1995, which are both simple and powerful tools in searching solutions for large energy and small energy of several boundary value problems.

The remainder of this paper is organized in the following way. In Section 2, we give some preliminaries on variable exponent Lebesgue and Sobolev spaces. In particular, we give a weighted variable exponent Sobolev trace compact embedding theorem which will be useful in this work. In Section 3, we begin by the preliminary results of $(S_{\lambda,\mu})$, state some abstract abstract critical point theorems and establish the technical lemmas which allow us to use the abstract theorems in order to guarantee the existence of solutions. Section 4 is devoted to the proof of our main results : Theorem 1.1 and Theorem 1.2. Finally, in the Appendix we give some examples of variable exponents illustrating Theorem 1.1 and Theorem 1.2.

2 Preliminaries on generalized Lebesgue–Sobolev spaces

We need to recall here some basic properties of variable exponent Lebesgue and Sobolev spaces which will be used later. We refer to [19, 21, 24, 29, 30, 37] for more details on the properties of these space.

Let Ω be a bounded domain of $\mathbb{R}^N$ with a smooth boundary $\partial\Omega$. Let us denote by

$$C_+(\overline{\Omega}) = \{p \in C(\overline{\Omega}) : p(x) > 1 \text{ for any } x \in \overline{\Omega}\};$$

for $p \in C_+(\overline{\Omega})$,

$$p^- = \min_{x\in\overline{\Omega}} p(x) \quad \text{and} \quad p^+ = \max_{x\in\overline{\Omega}} p(x).$$

Let $p \in C_+(\overline{\Omega})$, the variable exponent Lebesgue spaces $L^{p(x)}(\Omega)$ is defined by

$$L^{p(x)}(\Omega) = \left\{ u \colon \Omega \to \mathbb{R} \text{ measurable function } : \int_\Omega |u(x)|^{p(x)} dx < \infty \right\},$$

endowed with the so-called Luxemburg norm given by

$$\|u\|_{L^{p(x)}(\Omega)} = \|u\|_{p(x)} = \inf \left\{ \lambda > 0 : \int_\Omega \left| \frac{u(x)}{\lambda} \right|^{p(x)} dx \le 1 \right\}.$$

Remark 2.1. The spaces $\left(L^{p(x)}(\Omega), \|\cdot\|_{p(x)}\right)$ resembles to the classical Lebesgue spaces in many case, namely, they are separable Banach spaces, the Hölder inequality holds, the inclusions between Lebesgue spaces are also valid, that is, if $0 < \text{meas}(\Omega) < \infty$ and $p(x) < q(x)$ a.e. in Ω, then there exists a continuous embedding $L^{q(x)}(\Omega) \hookrightarrow L^{p(x)}(\Omega)$.

The variable exponent Sobolev space $W^{1,p(x)}(\Omega)$ is defined by

$$W^{1,p(x)}(\Omega) = \left\{ u \in L^{p(x)}(\Omega) : |\nabla u| \in L^{p(x)}(\Omega) \right\},$$

endowed with the norm

$$\|u\|_{1,p(x)} = \inf \left\{ \lambda > 0 : \int_\Omega \left(\left| \frac{\nabla u(x)}{\lambda} \right|^{p(x)} + \left| \frac{u(x)}{\lambda} \right|^{p(x)} \right) dx \le 1 \right\},$$

that is $\|u\|_{1,p(x)} = \|\nabla u\|_{p(x)} + \|u\|_{p(x)}$.

Proposition 2.2 ([30]). *Both $L^{p(x)}(\Omega)$ and $W^{1,p(x)}(\Omega)$ are separable, reflexive and uniformly convex Banach spaces.*

Let $L^{p'(x)}(\Omega)$ be the conjugate space of $L^{p(x)}(\Omega)$, with $\frac{1}{p(x)} + \frac{1}{p'(x)} = 1$ for all $x \in \overline{\Omega}$.

Proposition 2.3 ([30]). *The Hölder inequality holds, namely*

$$\int_\Omega |u(x)||v(x)|dx \le \left(\frac{1}{p^-} + \frac{1}{p'^-} \right) \|u\|_{p(x)} \|v\|_{p'(x)} \le 2\|u\|_{p(x)} \|v\|_{p'(x)},$$

for all $u \in L^{p(x)}(\Omega)$ and $v \in L^{p'(x)}(\Omega)$.

In what follows, for brevity we write $X = W^{1,p(x)}$ and denote X^* its dual space.
Let $a \in L^\infty(\Omega)$ with $\operatorname{ess\,inf}_{x\in\Omega} a(x) > 0$. For any $u \in X$, let us define

$$\|u\|_a = \inf \left\{ \lambda > 0 : \int_\Omega \left(\left| \frac{\nabla u(x)}{\lambda} \right|^{p(x)} + a(x) \left| \frac{u(x)}{\lambda} \right|^{p(x)} \right) dx \le 1 \right\}.$$

Then, $\|\cdot\|_a$ is a norm on X equivalent to the norm $\|\cdot\|_{1,p(x)}$ (see [2, 19]). In what follows, we will use $\|\cdot\|_a$ instead of $\|\cdot\|_{1,p(x)}$ on X.

The modular is an important tool in studying problems involving generalized Lebesgue–Sobolev spaces, it is a mapping ρ_a defined on X by

$$\rho_a(u) = \int_\Omega \left(|\nabla u(x)|^{p(x)} + a(x)|u(x)|^{p(x)} \right) dx.$$

The following proposition connect $\|u\|_a$ with $\rho_a(u)$, it will be very useful in this work.

Proposition 2.4 ([20,30]). *Then, for all $u, u_n \in X$ $(n = 1, 2, \dots)$, we have*

(i) $\|u\|_a < 1 (= 1; > 1) \Leftrightarrow \rho_a(u) < 1 (= 1; > 1)$;

(ii) $\|u\|_a \leq 1 \Rightarrow \|u\|_a^{p^+} \leq \rho_a(u) \leq \|u\|_a^{p^-}$;

(iii) $\|u\|_a \geq 1 \Rightarrow \|u\|_a^{p^-} \leq \rho_a(u) \leq \|u\|_a^{p^+}$;

(iv) $\|u_n\|_a \to 0 \Leftrightarrow \rho_a(u_n) \to 0$ *(as $n \to \infty$).*

Consider the real valued fuctional defined on X by

$$\phi(u) = \int_\Omega \frac{1}{p(x)} \left(|\nabla u|^{p(x)} + a(x)|u|^{p(x)} \right) dx.$$

The following properties of ϕ are very interesting in the study of variational problems.

Proposition 2.5 ([25,26]). *Then, ϕ is convex, sequentially weakly lower semi-continuous and continuously Fréchet differentiable such that*

$$\langle \phi'(u), v \rangle = \int_\Omega \left(|\nabla u|^{p(x)-2} \nabla u \nabla v + a(x)|u|^{p(x)-2} uv \right) dx, \quad \text{for all } u, v \in X.$$

Moreover, The derivative function ϕ' satisfies

(i) $\phi' : X \to X^*$ *is continuous, bounded and strictly monotone operator;*

(ii) $\phi' : X \to X^*$ *is a mapping of type (S^+), that is, if $u_n \xrightarrow{weakly} u$ in X and $\limsup_{n\to\infty} \langle \phi'(u_n) - \phi'(u), u_n - u \rangle \leq 0$, then $u_n \xrightarrow{strongly} u$ in X;*

(iii) $\phi' : X \to X^*$ *is a homeomorphism.*

Let $b : \partial\Omega \to \mathbb{R}$ be a measurable function. The weighted variable exponent Lebesgue space is defined by

$$L_{b(x)}^{p(x)}(\partial\Omega) = \left\{ u \colon \partial\Omega \to \mathbb{R} \text{ measurable function} : \int_{\partial\Omega} |b(x)||u(x)|^{p(x)} d\sigma < \infty \right\},$$

endowed with the norm

$$\|u\|_{(p(x),b(x))} = \|u\|_{L_{b(x)}^{p(x)}(\partial\Omega)} = \inf \left\{ \tau > 0 : \int_{\partial\Omega} |b(x)| \left| \frac{u(x)}{\tau} \right|^{p(x)} d\sigma \leq 1 \right\},$$

where $d\sigma$ is the surface measure on the boundary.

Remark 2.6. The space $L_{b(x)}^{p(x)}(\partial\Omega)$ is a Banach space. In particular, when $b(x) \equiv 1$ on $\partial\Omega$ or more general $b(x) \in L^\infty(\partial\Omega)$, $L_{b(x)}^{p(x)}(\partial\Omega) = L^{p(x)}(\partial\Omega)$.

For $u \in L_{b(x)}^{p(x)}(\partial\Omega)$, consider the real valued functional

$$\rho(u) = \int_{\partial\Omega} |b(x)||u(x)|^{p(x)} d\sigma.$$

The following proposition connect $\|u\|_{(p(x),b(x))}$ with $\rho(u)$.

Proposition 2.7 ([19]). *Then, for all $u, u_n \in L^{p(x)}_{b(x)}(\partial\Omega)$ $(n = 1, 2, \dots)$, we have*

(i) $\|u\|_{(p(x),b(x))} \leq 1 \Rightarrow \|u\|^{p^+}_{(p(x),b(x))} \leq \rho(u) \leq \|u\|^{p^-}_{(p(x),b(x))}$;

(ii) $\|u\|_{(p(x),b(x))} \geq 1 \Rightarrow \|u\|^{p^-}_{(p(x),b(x))} \leq \rho(u) \leq \|u\|^{p^+}_{(p(x),b(x))}$;

(iii) $\|u_n\|_{(p(x),b(x))} \to 0 \Leftrightarrow \rho(u_n) \to 0 (as\ n \to \infty)$.

Consequently,

$$\|u\|^{p^-}_{(p(x),b(x))} - 1 \leq \rho(u) \leq \|u\|^{p^+}_{(p(x),b(x))} + 1, \quad \text{for all } u \in L^{p(x)}_{b(x)}(\partial\Omega).$$

Proposition 2.8 ([13]). *The map $u \in L^{p(x)}(\partial\Omega) \longmapsto |u|^{q(x)-2}u \in L^{p'(x)}(\partial\Omega)$ is continuous.*

For $p \in C_+(\overline{\Omega})$ and $r \in C_+(\partial\Omega)$, the Sobolev critical exponents are defined by

$$p^*(x) = \begin{cases} \frac{Np(x)}{N-p(x)} & \text{if } p(x) < N, \\ +\infty & \text{if } p(x) \geq N, \end{cases} \quad \text{and} \quad p^\partial(x) = \begin{cases} \frac{(N-1)p(x)}{N-p(x)} & \text{if } p(x) < N, \\ +\infty & \text{if } p(x) \geq N. \end{cases}$$

Let $p^\partial_{r(x)}(x)$ defined by

$$p^\partial_{r(x)}(x) = \frac{r(x)-1}{r(x)} p^\partial(x).$$

Proposition 2.9 ([19, 28]). *Assume that the boundary of Ω possesses the cone property and $p \in C_+(\overline{\Omega})$. Suppose that $b \in L^{r(x)}(\partial\Omega)$, $r \in C_+(\partial\Omega)$ with $r(x) > \frac{p^\partial(x)}{p^\partial(x)-1}$ for all $x \in \partial\Omega$. Then, we have the following properties.*

(i) If $q \in C_+(\overline{\Omega})$ and $1 \leq q(x) < p^*(x)$ for any $x \in \overline{\Omega}$. Then, the embedding from $W^{1,p(x)}(\Omega)$ into $L^{q(x)}(\Omega)$ is compact and continuous.

(ii) If $q \in C_+(\partial\Omega)$ and $1 \leq q(x) < p^\partial_{r(x)}(x)$ for any $x \in \partial\Omega$. Then, the embedding from $W^{1,p(x)}(\Omega)$ into $L^{q(x)}_{b(x)}(\partial\Omega)$ is compact and continuous. In particular, there is a compact and continuous embedding from $W^{1,p(x)}(\Omega)$ into $L^{q(x)}(\partial\Omega)$, where $1 \leq q(x) < p^\partial(x)$, for any $x \in \partial\Omega$.

3 Preliminary results, abstract theorems and technical lemmas

We investigate here the preliminary results, state some well known abstract critical point theorems and establish the technical lemmas which allow us to prove our main results. Here and henceforth, we denote by X the generalized Sobolev space $W^{1,p(x)}(\Omega)$ equipped with the norm $\|\cdot\|_a$ and X^* its dual space.

3.1 Preliminary results

Definition 3.1. We say that $u \in X$ is a weak solution of the Steklov problem $(S_{\lambda,\mu})$ if and only if for all $v \in X$

$$\int_\Omega |\nabla u|^{p(x)-2}\nabla u \nabla v dx + \int_\Omega a(x)|u|^{p(x)-2}uvdx = \lambda \int_{\partial\Omega} V(x)|u|^{q(x)-2}uvd\sigma + \mu \int_{\partial\Omega} W(x)|u|^{r(x)-2}uvd\sigma,$$

where $d\sigma$ is the surface measure on the boundary of Ω.

Denote by $\Psi : X \to \mathbb{R}$ the Euler–Lagrange functional (energy functional) associated with the problem ($S_{\lambda,\mu}$), it is defined by

$$\Psi(u) = \int_\Omega \frac{1}{p(x)}|\nabla u|^{p(x)}dx + \int_\Omega \frac{a(x)}{p(x)}|u|^{p(x)}dx - \lambda \int_{\partial\Omega} \frac{V(x)}{q(x)}|u|^{q(x)}d\sigma - \mu \int_{\partial\Omega} \frac{W(x)}{r(x)}|u|^{r(x)}d\sigma.$$

For $u \in X$, we denote by $u^+ = \max\{u, 0\}$, $u^- = \max\{-u, 0\}$ and we define the functional

$$\Psi_+(u) = \int_\Omega \frac{1}{p(x)}|\nabla u|^{p(x)}dx + \int_\Omega \frac{a(x)}{p(x)}|u|^{p(x)}dx - \lambda \int_{\partial\Omega} \frac{V(x)}{q(x)}(u^+)^{q(x)}d\sigma - \mu \int_{\partial\Omega} \frac{W(x)}{r(x)}(u^+)^{r(x)}d\sigma.$$

Introduce the functionals $\phi, \psi : X \to \mathbb{R}$ defined by

$$\phi(u) = \int_\Omega \frac{1}{p(x)}|\nabla u|^{p(x)}dx + \int_\Omega \frac{a(x)}{p(x)}|u|^{p(x)}dx$$
$$\psi(u) = \lambda \int_{\partial\Omega} \frac{V(x)}{q(x)}|u|^{q(x)}d\sigma + \mu \int_{\partial\Omega} \frac{W(x)}{r(x)}|u|^{r(x)}d\sigma.$$

From assumptions ($\mathbf{H_1}$)–($\mathbf{H_2}$)–($\mathbf{H_3}$) and Proposition 2.9, we deduce the following compact and continuous embeddings

$$X \hookrightarrow L^{q(x)}_{V(x)}(\partial\Omega) \quad \text{and} \quad X \hookrightarrow L^{r(x)}_{W(x)}(\partial\Omega),$$

that is, there exists a positive constant C such that

$$|u|_{(q(x),V(x))} \le C\|u\|_a \quad \text{and} \quad |u|_{(r(x),W(x))} \le C\|u\|_a, \quad \text{for all } u \in X. \tag{3.1}$$

Without loss of generality, we can suppose that $C > 1$.

Remark 3.2. If $u \in X$, then we have

$$V(x)^{\frac{1}{q(x)}}u \in L^{q(x)}(\partial\Omega) \quad \text{and} \quad V(x)^{\frac{1}{q'(x)}}u^{q(x)-1} \in L^{q'(x)}(\partial\Omega).$$

Moreover, $\|V(x)^{\frac{1}{q(x)}}u\|_{q(x),\partial} = \|u\|_{(q(x),V(x))}$.

Proposition 3.3. *The functionals $\Psi, \Psi_+ \in C^1(X, \mathbb{R})$ (i.e., Ψ and Ψ_+ are continuously Fréchet differentiable) and $u \in X$ is a critical point of Ψ (respectively Ψ_+) if and only if u is a solution (respectively a nonnegative solution) of the Steklov problem ($S_{\lambda,\mu}$).*

Proof. From Proposition 2.5, it is clear that the functional $\phi \in C^1(X, \mathbb{R})$. Then, it is enough to show that $\psi \in C^1(X, \mathbb{R})$. Consider the functional $J : X \to \mathbb{R}$ defined by

$$J(u) = \int_{\partial\Omega} \frac{V(x)}{q(x)}|u|^{q(x)}d\sigma.$$

We prove that J is Fréchet differentiable, i.e., at any $u \in X$ there exists $J'(u) \in X^*$ such that

$$\lim_{t\to 0} \frac{J(u+tv) - J(u)}{t} = \langle J'(u), v\rangle \quad \text{for all } v \in X \quad \text{and} \quad J' : X \to X^* \quad \text{is continuous.}$$

For $\epsilon > 0$ small enough, let $\gamma : [-\epsilon, \epsilon] \to \mathbb{R}$ defined by $\gamma(t) = J(u + tv)$, then we have

$$\begin{aligned}\frac{d\gamma(t)}{dt} &= \frac{dJ(u+tv)}{dt} = \frac{d}{dt}\int_{\partial\Omega}\frac{V(x)}{q(x)}|u+tv|^{q(x)}d\sigma \\ &= \int_{\partial\Omega}\frac{\partial}{\partial t}\left(\frac{V(x)}{q(x)}|u+tv|^{q(x)}\right)d\sigma \\ &= \int_{\partial\Omega} V(x)|u+tv|^{q(x)-2}(u+tv)vd\sigma.\end{aligned}$$

Indeed, the differentiation under the integral is allowed for t close to zero, since for $|t| < 1$ we have

$$|V(x)|u+tv|^{q(x)-2}(u+tv)v| \leq V(x)(|u|+|v|)^{q(x)-1}|v| \in L^1(\partial\Omega),$$

because of Remark 3.2. It follows that

$$\lim_{t\to 0}\frac{J(u+tv)-J(u)}{t} = \lim_{t\to 0}\frac{\gamma(t)-\gamma(0)}{t} = \frac{d\gamma(t)}{dt}|t=0 = \int_{\partial\Omega} V(x)|u|^{q(x)-2}uvd\sigma.$$

For $u \in X$, let $J'(u) : X \to \mathbb{R}$ be an operator defined by

$$\langle J'(u), v\rangle = \int_{\partial\Omega} V(x)|u|^{q(x)-2}uvd\sigma, \quad \text{for all } v \in X.$$

Obviously, $J'(u)$ is a linear operator for each given $u \in X$. Using Remark 3.2, Hölder's inequality, Proposition 2.7, and inequality (3.1), the following inequalities hold true

$$\begin{aligned}|\langle J'(u), v\rangle| &\leq \int_{\partial\Omega} V(x)|u|^{q(x)-1}|v|d\sigma \\ &= \int_{\partial\Omega} V(x)^{\frac{1}{q'(x)}}|u|^{q(x)-1}V(x)^{\frac{1}{q(x)}}|v|d\sigma \\ &\leq 2\left|V(x)^{\frac{1}{q'(x)}}|u|^{q(x)-1}\right|_{q'(x),\partial}\left|V(x)^{\frac{1}{q(x)}}|v|\right|_{q(x),\partial} \\ &\leq 2\left(1+\int_{\partial\Omega} V(x)|u|^{q(x)}d\sigma\right)^{\frac{1}{(q')^-}}|v|_{(q(x),V(x))} \\ &\leq 2\left(2+|u|^{q^+}_{(q(x),V(x))}\right)^{\frac{1}{(q')^-}}|v|_{(q(x),V(x))} \\ &\leq 2C\left(2+|u|^{q^+}_{(q(x),V(x))}\right)^{\frac{1}{(q')^-}}\|v\|_a \\ &\leq M\|v\|_a,\end{aligned}$$

where $M = 2C\left(2+|u|^{q^+}_{(q(x),V(x))}\right)^{\frac{1}{(q')^-}}$ is a positive constant. So, $J'(u)$ is a linear and bounded operator, hence continuous, i.e., $J'(u) \in X^*$. The functional J is then Gâteaux differentiable at any $u \in X$ and its Gâteaux derivative is $J'(u)$. Next, we will prove that for $(u_n)_{n\in\mathbb{N}} \subset X$ and $u \in X$, we have

$$u_n \longrightarrow u \quad \text{as } n \longrightarrow \infty \text{ in } X \quad \Longrightarrow \quad J'(u_n) \longrightarrow J'(u) \quad \text{as } n \longrightarrow \infty \text{ in } X^*.$$

Using Remark 3.2, Hölder's inequality, Proposition 2.7, and inequality (3.1), the following

inequalities hold true for all $v \in X$

$$\begin{aligned}\left|\langle J'(u_n) - J'(u), v\rangle\right| &\leq \int_{\partial\Omega} V(x)\left||u_n|^{q(x)-2}u_n - |u|^{q(x)-2}u\right||v|d\sigma \\ &\leq 2\left|V(x)^{\frac{1}{q'(x)}}|u_n|^{q(x)-2}u_n - V(x)^{\frac{1}{q'(x)}}|u|^{q(x)-2}u\right|_{q'(x),\partial}\left|V(x)^{\frac{1}{q(x)}}|v|\right|_{q(x),\partial} \\ &\leq 2C\left|V(x)^{\frac{1}{q'(x)}}|u_n|^{q(x)-2}u_n - V(x)^{\frac{1}{q'(x)}}|u|^{q(x)-2}u\right|_{q'(x),\partial}\|v\|_a.\end{aligned}$$

So, we have

$$\|J'(u_n) - J'(u)\|_{X^*} \leq 2C\left|V(x)^{\frac{1}{q'(x)}}|u_n|^{q(x)-2}u_n - V(x)^{\frac{1}{q'(x)}}|u|^{q(x)-2}u\right|_{q'(x),\partial}. \tag{3.2}$$

Since the mapping $u \mapsto |u|^{q(x)-2}u$ from $L^{q(x)}(\partial\Omega)$ into $L^{q'(x)}(\partial\Omega)$ is continuous, using the compact and continuous embedding $X \hookrightarrow L^{q(x)}_{V(x)}(\partial\Omega)$, we deduce that

$$V(x)^{\frac{1}{q(x)}}u_n \longrightarrow V(x)^{\frac{1}{q(x)}}u \quad \text{as } n \longrightarrow \infty \text{ in } L^{q(x)}(\partial\Omega),$$

and then

$$V(x)^{\frac{1}{q'(x)}}|u_n|^{q(x)-2}u_n \longrightarrow V(x)^{\frac{1}{q'(x)}}|u|^{q(x)-2}u \quad \text{as } n \longrightarrow \infty \text{ in } L^{q'(x)}(\partial\Omega). \tag{3.3}$$

From (3.2) and (3.3), we obtain

$$\|J'(u_n) - J'(u)\|_{X^*} \longrightarrow 0 \quad \text{as } n \longrightarrow \infty,$$

that is, the mapping $J' : X \to X^*$ is continuous. Then $J \in C^1(X, \mathbb{R})$, i.e., J is Fréchet differentiable. By similar computation the functional $\int_{\partial\Omega}\frac{W(x)}{r(x)}|u|^{r(x)}d\sigma$ is of class $C^1(X, \mathbb{R})$. Then $\Psi \in C^1(X, \mathbb{R})$, and for $u, v \in X$, we have

$$\begin{aligned}\langle \Psi'(u), v\rangle = &\int_\Omega \left(|\nabla u|^{p(x)-2}\nabla u\nabla v + a(x)|u|^{p(x)-2}uv\right)dx \\ &- \lambda\int_{\partial\Omega} V(x)|u|^{q(x)-2}uvd\sigma - \mu\int_{\partial\Omega} W(x)|u|^{r(x)-2}uvd\sigma.\end{aligned}$$

Similarly, one can show that $\Psi_+ \in C^1(X, \mathbb{R})$, and for $u, v \in X$, we have

$$\begin{aligned}\langle \Psi'_+(u), v\rangle = &\int_\Omega \left(|\nabla u|^{p(x)-2}\nabla u\nabla v + a(x)|u|^{p(x)-2}uv\right)dx \\ &- \lambda\int_{\partial\Omega} V(x)(u^+)^{q(x)-1}vd\sigma - \mu\int_{\partial\Omega} W(x)(u^+)^{r(x)-1}vd\sigma.\end{aligned}$$

It is easy to see that $u \in X$ is a weak solution (rep. nonnegative weak solution) of $(S_{\lambda,\mu})$ if and only if u is a critical point of Ψ (resp. Ψ_+). Indeed, let $u \in X$ be a critical point of Ψ_+, then

$$\begin{aligned}\int_\Omega \left(|\nabla u|^{p(x)-2}\nabla u\nabla u^- + a(x)|u|^{p(x)-2}uu^-\right)dx - \lambda\int_{\partial\Omega} V(x)(u^+)^{q(x)-1}u^-d\sigma \\ - \mu\int_{\partial\Omega} W(x)(u^+)^{r(x)-1}u^-d\sigma = 0,\end{aligned}$$

which gives $\int_\Omega \left(|\nabla u^-|^{p(x)} + a(x)|u^-|^{p(x)}\right)dx = 0$. From Proposition 2.4 (iv), it follows that $\|u^-\|_a = 0$ and then $u^- = 0$ in X, i.e., u is nonnegative function. Since u is nonnegative, we have $u^+ = u$, then u is also a critical point of Ψ. □

Proposition 3.4. *Ψ and Ψ_+ are sequentially weakly lower semicontinuous functionals.*

Proof. By Proposition 2.5, the functional ϕ is sequentially weakly lower semicontinuous. We have only to show that ψ is also sequentially weakly lower semicontinuous. Let $(u_n)_{n\in\mathbb{N}} \subset X$ be a sequence weakly convergent to some u in X. Let us prove that, up to a subsequence, $(\psi(u_n))_n$ converge strongly to $\psi(u)$ in $\mathbb{R}$. By virtue of the compact embedding $X \hookrightarrow L^{q(x)}_{V(x)}(\partial\Omega)$, we have

$$|u_n - u|_{(q(x),V(x))} \longrightarrow 0 \quad \text{as } n \longrightarrow \infty \quad \Longleftrightarrow \quad \int_{\partial\Omega} V(x)|u_n - u|^{q(x)} d\sigma \longrightarrow 0 \quad \text{as } n \longrightarrow \infty.$$

According to the reciprocal of Lebesque's dominated convergence theorem, there is a subsequence of $(u_n)_n$ still denoted by $(u_n)_n$ such that

$$u_n(x) \longrightarrow u(x) \quad \text{as } n \longrightarrow \infty \text{ for a.e. } x \in \partial\Omega, \qquad V(x)|u_n - u|^{q(x)} \leq g,$$

with $g \in L^1(\partial\Omega)$. Then, we deduce that

$$\frac{V(x)}{q(x)}|u_n|^{q(x)} \longrightarrow \frac{V(x)}{q(x)}|u|^{q(x)} \quad \text{as } n \longrightarrow \infty \text{ for a.e. } x \in \partial\Omega.$$

Using the inequality $(a+b)^q \leq 2^{q-1}(a^q + b^q)$, for $a, b \geq 0$ and $q \geq 1$, we have

$$\begin{aligned}
\frac{V(x)}{q(x)}|u_n|^{q(x)} &\leq V(x)|u_n|^{q(x)} \leq V(x)\left(|u| + |u_n - u|\right)^{q(x)} \\
&\leq 2^{q(x)-1}(V(x)|u|^{q(x)} + V(x)|u_n - u|^{q(x)}) \\
&\leq 2^{q^+-1}(V(x)|u|^{q(x)} + g(x)).
\end{aligned}$$

By Lebesgue's dominated convergence theorem, we obtain

$$\lim_{n\to\infty} \int_{\partial\Omega} \frac{V(x)}{q(x)}|u_n|^{q(x)} d\sigma = \int_{\partial\Omega} \frac{V(x)}{q(x)}|u|^{q(x)} d\sigma. \tag{3.4}$$

Similarly, we also have

$$\lim_{n\to\infty} \int_{\partial\Omega} \frac{W(x)}{r(x)}|u_n|^{r(x)} d\sigma = \int_{\partial\Omega} \frac{W(x)}{r(x)}|u|^{r(x)} d\sigma. \tag{3.5}$$

Then, $\lim_{n\to\infty} \psi(u_n) = \psi(u)$. Since $\liminf_{n\to\infty} \phi(u_n) \geq \phi(u)$, we have

$$\liminf_{n\to\infty} \Psi(u_n) \geq \Psi(u).$$

By similar steps one can show that the functional Ψ_+ is also sequentially weakly lower semicontinuous. □

Proposition 3.5. *The derivative functions Ψ' and Ψ'_+ are of (S^+) type operators.*

Proof. Let $(u_n)_{n\in\mathbb{N}} \subset X$ be a sequence weakly convergent to some u in X such that

$$\limsup_{n\to\infty} \langle \Psi'(u_n) - \Psi'(u), u_n - u \rangle \leq 0.$$

As in the proof of Lemma 3.3, we obtain the following inequalities

$$\begin{aligned}\left|\langle J'(u_n)-J'(u),u_n-u\rangle\right| &\leq \int_{\partial\Omega} V(x)\left||u_n(x)|^{q(x)-2}u_n(x)-|u(x)|^{q(x)-2}u(x)\right||u_n-u|d\sigma\\ &\leq 2\left|V(x)^{\frac{1}{q'(x)}}|u_n|^{q(x)-2}u_n - V^{\frac{1}{q'(x)}}|u|^{q(x)-2}u\right|_{q'(x),\partial}|u_n-u|_{(q(x),V(x))}.\end{aligned}$$

From the compact embedding $X \hookrightarrow L^{q(x)}_{V(x)}(\partial\Omega)$ and the continuity of the mapping $u \mapsto |u|^{q(x)-2}u$ from $L^{q(x)}(\partial\Omega)$ into $L^{q'(x)}(\partial\Omega)$, we obtain

$$\langle J'(u_n)-J'(u),u_n-u\rangle \longrightarrow 0 \quad \text{as } n\longrightarrow\infty.$$

Similarly for the functional $u\mapsto\int_{\partial\Omega}\frac{W(x)}{r(x)}|u|^{r(x)}d\sigma$. Then, $\lim_{n\to\infty}\langle\psi'(u_n)-\psi'(u),u_n-u\rangle=0$. We have

$$\limsup_{n\to\infty}\langle\phi'(u_n)-\phi'(u),u_n-u\rangle=\limsup_{n\to\infty}\langle\Psi'(u_n)-\Psi'(u),u_n-u\rangle\leq 0.$$

Combine the last inequality and the (S^+) property of the operator ϕ' (see Proposition 2.5, it follows that $(u_n)_n$ converge strongly to u in X. The operator Ψ' is then of (S^+) type. Similarly, one can show that the operator Ψ'_+ is also of (S^+) type. □

We need to recall some classical well known results of the theory of Banach spaces which will be useful in the sequel. Let X be a reflexive and separable Banach space, there exist $(e_n)_{n\in\mathbb{N}^*}\subseteq X$ and $(f_n)_{n\in\mathbb{N}^*}\subseteq X^*$ such that $\langle f_n,e_m\rangle=\delta_{nm}$ for all $n,m\in\mathbb{N}^*$, $X=\overline{\text{Span}\{e_n\mid n\in\mathbb{N}^*\}}$, $X^*=\overline{\text{Span}\{f_n\mid n\in\mathbb{N}^*\}}^{w^*}$ (see [49], Section 17), where X^* denote the dual space of X. For $k\in\mathbb{N}^*$, consider the subsets of X :

$$X_k=\text{Span}\{e_k\},\qquad Y_k=\bigoplus_{j=1}^{k}X_j,\qquad Z_k=\overline{\bigoplus_{k}^{\infty}X_j}.$$

Proposition 3.6 ([27]). *Assume that $\psi: X\to\mathbb{R}$ is weakly-strongly continuous and $\psi(0)=0$. Let $r>0$ be given and set*

$$\beta_k=\beta_k(r)=\sup\{|\psi(u)|\mid u\in Z_k,\|u\|_a\leq r\}.$$

Then $\beta_k\to 0$ as $k\to\infty$.

Definition 3.7. Let X be a reflexive Banach space and $\Phi: X\to\mathbb{R}$ be a functional such that $\Phi\in C^1(X,\mathbb{R})$.

(i) The C^1-functional Φ is said to satisfy the Palais–Smale condition (in short (PS) condition) if any sequence $(u_n)_{n\in\mathbb{N}}\subset X$ for which $(\Phi(u_n))_{n\in\mathbb{N}}\subset\mathbb{R}$ is bounded and $\Phi'(u_n)\to 0$ as $n\to\infty$, has a convergent subsequence.

(ii) The C^1-functional Φ is said satisfy the $(PS)_c$ condition, where $c\in\mathbb{R}$, if any sequence $(u_n)_{n\in\mathbb{N}}\subset X$ for which $\Phi(u_n)\to c$ and $\Phi'(u_n)\to 0$ as $n\to\infty$, has a convergent subsequence.

(iii) Let Y_n, $n\in\mathbb{N}^*$, as defined above. The C^1-functional Φ is said to satisfy the $(PS)^*_c$ condition, where $c\in\mathbb{R}$, if any sequence $(u_n)_{n\in\mathbb{N}^*}\subset X$ for which $u_n\in Y_n$ for any $n\in\mathbb{N}^*$, $\Phi(u_n)\to c$ and $(\Phi|_{Y_n})'(u_n)\to 0$ as $n\to\infty$, has a subsequence convergent to a critical point of Φ.

Remark 3.8. It is easy to remark that if Φ satisfies the (PS) condition, then Φ satisfies the $(PS)_c$ condition for every $c\in\mathbb{R}$.

3.2 Abstract theorems

Theorem 3.9 ([46]). *Let X be a reflexive Banach space and $\Phi : X \to \mathbb{R}$ be a functional such that*

(i) Φ is sequentially weakly lower semicontinuous, i.e., for any sequence $(u_n)_n$ and u in X

$$u_n \xrightarrow{\text{weakly}} u \quad \text{as } n \longrightarrow \infty \quad \Longrightarrow \quad \Phi(u) \leq \liminf_{n\to\infty} \Phi(u_n);$$

(ii) Φ is coercive, i.e.,

$$\Phi(u) \longrightarrow \infty \quad \text{as } \|u\|_X \longrightarrow \infty.$$

Then Φ is bounded below and its minimum is achieved at a point $u_0 \in X$.

Theorem 3.10 (Mountain Pass Theorem, [48]). *Let X be a real Banach space and $\Phi \in C^1(X, \mathbb{R})$ be a functional satisfying the Palais-Smale (PS) condition. Suppose $\Phi(0) = 0$ and*

(i) there are constants $\alpha, \rho > 0$ such that $\Phi|_{\|x\|=\alpha} \geq \rho$;

(ii) there is an element $e \in X$ such that $\Phi(e) \leq 0$.

Then Φ possesses a critical value $c \geq \rho$. Moreover, c can be characterized as

$$c = \inf_{g\in\Gamma} \max_{t\in[0,1]} \Phi(g(t)) \text{ where } \Gamma = \{g \in C([0,1], X) : g(0) = 0,\ g(1) = e\}.$$

Theorem 3.11 (Fountain Theorem, [48]). *Let X be a reflexive and separable Banach space, $\Phi \in C^1(X, \mathbb{R})$ an even functional and the subspaces X_k, Y_k, Z_k as defined above. If for each $k \in \mathbb{N}^*$ there exist $\rho_k > r_k > 0$ such that*

(F1) $\inf_{x\in Z_k,\ \|x\|=r_k} \Phi(x) \to \infty$ *as* $k \to \infty$;

(F2) $\max_{x\in Y_k,\ \|x\|=\rho_k} \Phi(x) \leq 0$;

(F3) Φ satisfies the $(PS)_c$ condition for every $c > 0$.

Then, Φ has a sequence of critical values tending to $+\infty$.

Theorem 3.12 (Dual Fountain Theorem, [48]). *Let X be a reflexive and separable Banach space, $\Phi \in C^1(X, \mathbb{R})$ an even functional and the subspaces X_k, Y_k, Z_k as defined above. Assume there is a $k_0 \in \mathbb{N}^*$ such that, for each $k \in \mathbb{N}^*$, $k \geq k_0$, there exist $\rho_k > r_k > 0$ such that*

(D1) $\inf_{x\in Z_k,\ \|x\|=\rho_k} \Phi(x) \geq 0$;

(D2) $b_k := \max_{x\in Y_k,\ \|x\|=r_k} \Phi(x) < 0$;

(D3) $d_k := \inf_{x\in Z_k,\ \|x\|\leq\rho_k} \Phi(x) \to 0$ *as* $k \to \infty$;

(D4) Φ satisfies the $(PS)^*_c$ condition for every $c \in [d_{k_0}, 0)$.

Then, Φ has a sequence of negative critical values converging to 0.

3.3 Technical lemmas

Lemma 3.13. *Assume that hypotheses* ($\mathbf{H_1}$)–($\mathbf{H_2}$)–($\mathbf{H_3}$) *are fulfilled. If* $\min\{q^-, r^-\} > p^+$ *and* $\lambda, \mu \geq 0$, *then there exists* $\varphi \in X \setminus \{0\}$ *such that* $\varphi \geq 0$ *and* $\Psi_+(t\varphi) \to -\infty$ *as* $t \to +\infty$.

Proof. Suppose that $\theta = \min\{q^-, r^-\} > p^+$ and $\lambda, \mu \geq 0$. Choose $\varphi \in C_0^\infty(\Omega)$, $\varphi \geq 0$ and $\varphi \not\equiv 0$. For any $t > 1$, we have

$$\begin{aligned}
\Psi_+(t\varphi) &= \int_\Omega \frac{t^{p(x)}}{p(x)} \left(|\nabla \varphi(x)|^{p(x)} + a(x)|\varphi(x)|^{p(x)} \right) dx \\
&\quad - \lambda \int_{\partial\Omega} \frac{t^{q(x)}}{q(x)} V(x)\varphi(x)^{q(x)} d\sigma - \mu \int_{\partial\Omega} \frac{t^{r(x)}}{r(x)} W(x)\varphi(x)^{r(x)} d\sigma \\
&\leq \frac{t^{p^+}}{p^-} \int_\Omega \left(|\nabla \varphi(x)|^{p(x)} + a(x)|\varphi(x)|^{p(x)} \right) dx \\
&\quad - \frac{\lambda t^{q^-}}{q^+} \int_{\partial\Omega} W(x)\varphi(x)^{q(x)} d\sigma - \frac{\mu t^{r^-}}{r^+} \int_{\partial\Omega} W(x)\varphi(x)^{r(x)} d\sigma \\
&\leq \frac{t^{p^+}}{p^-} \int_\Omega \left(|\nabla \varphi(x)|^{p(x)} + a(x)|\varphi(x)|^{p(x)} \right) dx \\
&\quad - t^\theta \left(\frac{\lambda}{q^+} \int_{\partial\Omega} V(x)\varphi(x)^{q(x)} d\sigma + \frac{\mu}{r^+} \int_{\partial\Omega} W(x)\varphi(x)^{r(x)} d\sigma \right).
\end{aligned}$$

Since $\theta > p^+$, it follows that $\Psi_+(t\varphi) \to -\infty$ as $t \to +\infty$. □

Lemma 3.14. *Assume that hypotheses* ($\mathbf{H_1}$)–($\mathbf{H_2}$)–($\mathbf{H_3}$) *are fulfilled.*

(i) If $\min\{q^-, r^-\} > p^+$ *and* $\lambda, \mu \geq 0$, *then there exist* $\tau, \rho > 0$ *such that* $\Psi_+(u) \geq \tau$ *if* $\|u\|_a = \rho$.

(ii) If $p^+ < r^-$, *then for each given* $\mu \in \mathbb{R}$, *there exists* $\lambda^0 = \lambda^0(\mu) > 0$ *such that, for any* $\lambda < \lambda^0$, *there exist* $\tau, \rho > 0$ *such that* $\Psi_+(u) \geq \tau$ *if* $\|u\|_a = \rho$.

(iii) If $q^+ < p^-$, *then for each given* $\lambda \in \mathbb{R}$, *there exists* $\mu^0 = \mu^0(\lambda) > 0$ *such that, for any* $\mu < \mu^0$, *there exist* $\overline{\tau}, \overline{\rho} > 0$ *such that* $\Psi_+(u) \geq \overline{\tau}$ *if* $\|u\|_a = \overline{\rho}$.

Proof. We have seen, from (3.1), that there exists a positive constant $C > 1$ such that

$$|u|_{(q(x),V(x))} \leq C\|u\|_a \text{ and } |u|_{(r(x),W(x))} \leq C\|u\|_a, \text{ for all } u \in X.$$

(i) Suppose that $\min\{q^-, r^-\} > p^+$ and $\lambda, \mu \geq 0$. Fix a positive constant ρ such that

$$\rho < \frac{1}{C} < 1 \text{ and } \rho \leq \min\left\{ \left(\frac{q^-}{4\lambda p^+ C^{q^-}} \right)^{\frac{1}{q^- - p^+}}, \left(\frac{r^-}{4\mu p^+ C^{r^-}} \right)^{\frac{1}{r^- - p^+}} \right\}.$$

Then, using Proposition 2.4, Proposition 2.7 and inequalities (3.1), for all $u \in X$ with $\|u\|_a =$

$\rho < 1$, we have

$$\begin{aligned}
\Psi_+(u) \geq & \frac{1}{p^+}\int_\Omega \left(|\nabla u(x)|^{p(x)} + a(x)|u(x)|^{p(x)}\right) dx \\
& - \frac{\lambda}{q^-}\int_{\partial\Omega} V(x)|u(x)|^{q(x)}d\sigma - \frac{\mu}{r^-}\int_{\partial\Omega} W(x)|u(x)|^{r(x)}d\sigma \\
\geq & \frac{1}{p^+}\rho_a(u) - \frac{\lambda}{q^-}|u|^{q^-}_{(q(x),V(x))} - \frac{\mu}{r^-}|u|^{r^-}_{(r(x),W(x))}\} \\
\geq & \frac{1}{p^+}\|u\|_a^{p^+} - \frac{\lambda C^{q^-}}{q^-}\|u\|_a^{q^-} - \frac{\mu C^{r^-}}{r^-}\|u\|_a^{r^-} \\
= & \frac{1}{p^+}\rho^{p^+} - \frac{\lambda C^{q^-}}{q^-}\rho^{q^-} - \frac{\mu C^{r^-}}{r^-}\rho^{r^-} \\
\geq & \frac{1}{p^+}\rho^{p^+} - \frac{1}{4p^+}\rho^{p^+} - \frac{1}{4p^+}\rho^{p^+} \\
= & \frac{1}{2p^+}\rho^{p^+}.
\end{aligned}$$

Then, there exist $\rho > 0$ and $\tau = \frac{1}{2p^+}\rho^{p^+} > 0$ such that $\Psi_+(u) \geq \tau$ for all $u \in X$ with $\|u\|_a = \rho$.

(ii) Suppose that $p^+ < h^-$. For each given $\mu \in \mathbb{R}$, fix ρ such that

$$0 < \rho < \frac{1}{C} \quad \text{and} \quad \frac{|\mu|C^{r^-}}{r^-}\rho^{r^-} \leq \frac{1}{2p^+}\rho^{p^+}.$$

Then, using Proposition 2.4, Proposition 2.7 and inequalities (3.1), for all $u \in X$ with $\|u\|_a = \rho < 1$, we have

$$\begin{aligned}
\Psi_+(u) \geq & \frac{1}{p^+}\int_\Omega \left(|\nabla u(x)|^{p(x)} + a(x)|u(x)|^{p(x)}\right) dx \\
& - \frac{\max\{\lambda,0\}}{q^-}\int_{\partial\Omega} V(x)|u(x)|^{q(x)}d\sigma - \frac{|\mu|}{r^-}\int_{\partial\Omega} W(x)|u(x)|^{r(x)}d\sigma \\
\geq & \frac{1}{p^+}\rho_a(u) - \frac{\max\{\lambda,0\}}{q^-}|u|^{q^-}_{(q(x),V(x))} - \frac{|\mu|}{r^-}|u|^{r^-}_{(r(x),W(x))} \\
\geq & \frac{1}{p^+}\|u\|_a^{p^+} - \frac{\max\{\lambda,0\}C^{q^-}}{q^-}\|u\|_a^{q^-} - \frac{|\mu|C^{r^-}}{r^-}\|u\|_a^{r^-} \\
\geq & \frac{1}{2p^+}\rho^{p^+} - \frac{\max\{\lambda,0\}C^{q^-}}{q^-}\rho^{q^-}.
\end{aligned}$$

We can choose

$$\lambda^0 = \frac{q^-\rho^{p^+-q^-}}{4p^+C^{q^-}} \quad \text{and} \quad \tau = \frac{1}{4p^+}\rho^{p^+}.$$

Then, for any $\lambda < \lambda^0$, $\Psi_+(u) \geq \tau > 0$ for all $u \in X$ with $\|u\|_a = \rho$.

(iii) From Proposition 2.7 and inequalities (3.1), for all $u \in X$, we have

$$\begin{aligned}
&\int_{\partial\Omega} V(x)|u(x)|^{q(x)}d\sigma \leq \max\{C^{q^-}\|u\|_a^{q^-}, C^{q^+}\|u\|_a^{q^+}\}, \\
&\int_{\partial\Omega} W(x)|u(x)|^{r(x)}d\sigma \leq \max\{C^{r^-}\|u\|_a^{r^-}, C^{r^+}\|u\|_a^{r^+}\}.
\end{aligned} \tag{3.6}$$

Suppose that $q^+ < p^-$. For each given $\lambda \in \mathbb{R}$, setting $\overline{\rho} \geq 1$ and $\frac{|\lambda| C^{q^+}}{q^-}\overline{\rho}^{q^+} \leq \frac{1}{2p^+}\overline{\rho}^{p^-}$. Then, using Proposition 2.4 and inequalities (3.6), for all $u \in X$ with $\|u\|_a = \overline{\rho} \geq 1$, we have

$$\begin{aligned}\Psi_+(u) &\geq \frac{1}{p^+}\int_\Omega \left(|\nabla u(x)|^{p(x)} + a(x)|u(x)|^{p(x)}\right) dx \\ &\quad - \frac{|\lambda|}{q^-}\int_{\partial\Omega} V(x)|u(x)|^{q(x)}d\sigma - \frac{\max\{\mu,0\}}{h^-}\int_{\partial\Omega} W(x)|u(x)|^{r(x)}d\sigma \\ &\geq \frac{1}{p^+}\|u\|_a^{p^-} - \frac{|\lambda|C^{q^+}}{q^-}\|u\|_a^{q^+} - \frac{\max\{\mu,0\}C^{r^+}}{r^-}\|u\|_a^{r^+} \\ &\geq \frac{1}{2p^+}\overline{\rho}^{p^-} - \frac{\max\{\mu,0\}C^{r^+}}{r^-}\overline{\rho}^{r^+}.\end{aligned} \tag{3.7}$$

We can choose

$$\mu^0 = \frac{r^-\overline{\rho}^{p^- - r^+}}{4p^+C^{r^+}} \quad \text{and} \quad \overline{\tau} = \frac{1}{4p^+}\overline{\rho}^{p^-}.$$

Then, for any $\mu < \mu^0$, $\Psi_+(u) \geq \overline{\tau} > 0$ for all $u \in X$ with $\|u\|_a = \overline{\rho}$. □

Lemma 3.15. *Assume that hypotheses* ($\mathbf{H_1}$)–($\mathbf{H_2}$)–($\mathbf{H_3}$) *are fulfilled. Then, the functional* Ψ_+ *satisfies* (PS) *condition if one of the following assertions is satisfied :*

(i) $\min\{q^-, r^-\} > p^+$ *and* $\lambda, \mu \geq 0$;

(ii) $q^+ < p^- \leq p^+ < r^-$ *and* $\lambda \in \mathbb{R}$, $\mu \geq 0$;

(iii) $q^+ = p^- \leq p^+ < r^-$ *and* $\lambda \in \mathbb{R}$ *with* $|\lambda| < \lambda_0 := \frac{\frac{1}{p^+} - \frac{1}{r^-}}{(\frac{1}{q^-} - \frac{1}{r^-})C^{q^+}}$, $\mu \geq 0$;

(iv) $p^+ < r^-$, $q^+ \leq r^-$ *and* $\lambda \leq 0$, $\mu \geq 0$.

Proof. In the first time, we show that every (PS) sequence of Ψ_+ is bounded in X under condition (i)–(iv). Let $(u_n)_{n\in\mathbb{N}}$ be a (PS) sequence of Ψ_+, that is

$$|\Psi_+(u_n)| < M, \quad \text{for all } n \in \mathbb{N}, \text{ with } M > 0 \quad \text{and} \quad \Psi'_+(u_n) \to 0 \quad \text{in } X^* \text{ as } n \to \infty.$$

Arguing by contradiction, let us suppose that

$$\|u_n\|_a \to +\infty \quad \text{as} \quad n \to \infty.$$

Case (i), assume that $\theta = \min\{q^-, r^-\} > p^+$ and $\lambda, \mu \geq 0$. If $\|u_n\|_a > 1$ for n large enough, using Proposition 2.4, we have

$$\begin{aligned}M + \|u_n\|_a &\geq \Psi_+(u_n) - \frac{1}{\theta}\langle \Psi'_+(u_n), u_n\rangle \\ &\geq \frac{1}{p^+}\int_\Omega \left(|\nabla u_n(x)|^{p(x)} + a(x)|u_n(x)|^{p(x)}\right) dx \\ &\quad - \frac{\lambda}{q^-}\int_{\partial\Omega} V(x)(u_n^+)^{q(x)}d\sigma - \frac{\mu}{r^-}\int_{\partial\Omega} W(x)(u_n^+)^{r(x)}d\sigma \\ &\quad - \frac{1}{\theta}\int_\Omega \left(|\nabla u_n(x)|^{p(x)} + a(x)|u_n(x)|^{p(x)}\right) dx \\ &\quad + \frac{\lambda}{\theta}\int_{\partial\Omega} V(x)(u_n^+)^{q(x)}d\sigma + \frac{\mu}{\theta}\int_{\partial\Omega} W(x)(u_n^+)^{r(x)}d\sigma\end{aligned}$$

$$\geq \left(\frac{1}{p^+} - \frac{1}{\theta}\right) \int_\Omega \left(|\nabla u_n(x)|^{p(x)} + a(x)|u_n(x)|^{p(x)}\right) dx$$
$$\geq \left(\frac{1}{p^+} - \frac{1}{\theta}\right) \|u_n\|_a^{p^-}.$$

From the last inequality, for $n \in \mathbb{N}$ large, we obtain a contradiction since $p^- > 1$. So, the sequence $(u_n)_{n\in\mathbb{N}}$ is bounded in X.
Cases (ii) and (iii), assume that $q^+, p^+ \leq r^-$ and $\lambda \in \mathbb{R}, \mu \geq 0$. If $\|u_n\|_a > 1$ for any $n \in \mathbb{N}$, then

$$\begin{aligned} M + \|u_n\|_a &\geq \Psi_+(u_n) - \frac{1}{r^-}\langle \Psi'_+(u_n), u_n\rangle \\ &\geq \left(\frac{1}{p^+} - \frac{1}{r^-}\right) \int_\Omega \left(|\nabla u_n(x)|^{p(x)} + a(x)|u_n(x)|^{p(x)}\right) dx \\ &\quad - \lambda \int_{\partial\Omega} \frac{1}{q(x)} V(x)(u_n^+)^{q(x)} d\sigma + \frac{\lambda}{r^-} \int_{\partial\Omega} V(x)(u_n^+)^{q(x)} d\sigma \\ &\geq \left(\frac{1}{p^+} - \frac{1}{r^-}\right) \int_\Omega \left(|\nabla u_n(x)|^{p(x)} + a(x)|u_n(x)|^{p(x)}\right) dx \\ &\quad - |\lambda| \left(\frac{1}{q^-} - \frac{1}{r^-}\right) \int_{\partial\Omega} V(x)(u_n^+)^{q(x)} d\sigma. \end{aligned} \tag{3.8}$$

Taking into account inequalities (3.6), inequality (3.8) and Proposition 2.4 imply that

$$M + \|u_n\|_a \geq \left(\frac{1}{p^+} - \frac{1}{r^-}\right) \|u_n\|_a^{p^-} - \left(\frac{1}{q^-} - \frac{1}{r^-}\right) |\lambda| C^{q^+} \|u_n\|_a^{q^+}.$$

This last inequality yields a contradiction if $n \in \mathbb{N}$ is large, since $p^- > 1$, $q^+ \leq p^-$ and $|\lambda| < \lambda_0$. So, the sequence $(u_n)_{n\in\mathbb{N}}$ is bounded in X in both cases (ii) and (iii).
Case (iv), by a similar computation as above, we have

$$M + \|u_n\|_a \geq \left(\frac{1}{p^+} - \frac{1}{r^-}\right) \|u_n\|_a^{p^-},$$

which gives a contradiction if $n \in \mathbb{N}$ is large, since $p^- > 1$.
Thus, the sequence $(u_n)_{n\in\mathbb{N}}$ is bounded in X.

Next, we show that there is a subsequence of $(u_n)_{n\in\mathbb{N}}$ strongly convergent in X. Because of the reflexiveness of X, since $(u_n)_{n\in\mathbb{N}}$ is bounded in X, we can extract a subsequence $(u_{n_k})_{k\in\mathbb{N}}$ weakly convergent to some $u \in X$. We have

$$\begin{aligned} |\langle \Psi'_+(u_{n_k}) - \Psi'_+(u), u_{n_k} - u\rangle| &\leq |\langle \Psi'_+(u_{n_k}), u_{n_k} - u\rangle| + |\langle \Psi'_+(u), u_{n_k} - u\rangle| \\ &\leq |\langle \Psi'_+(u_{n_k}), u_{n_k}\rangle| + |\langle \Psi'_+(u_{n_k}), u\rangle| \\ &\quad + |\langle \Psi'_+(u), u_{n_k}\rangle - \langle \Psi'_+(u), u\rangle| \\ &\leq \|\Psi'_+(u_{n_k})\|_{X^*} \|u_{n_k}\|_a + \|\Psi'_+(u_{n_k})\|_{X^*} \|u\|_a \\ &\quad + |\langle \Psi'_+(u), u_{n_k}\rangle - \langle \Psi'_+(u), u\rangle|. \end{aligned} \tag{3.9}$$

Since $\Psi'_+(u_{n_k}) \longrightarrow 0$ in X^* as $k \longrightarrow \infty$ and $(u_{n_k})_{k\in\mathbb{N}}$ is bounded in X, inequality (3.9) and the weak convergence $u_{n_k} \xrightarrow{\text{weakly}} u$ as $k \to \infty$ yield

$$\lim_{k\to\infty} \langle \Psi'_+(u_{n_k}) - \Psi'_+(u), u_{n_k} - u\rangle = 0. \tag{3.10}$$

Combine (3.10) and the (S^+) property of Ψ'_+, we obtain that the subsequence $(u_{n_k})_{k\in\mathbb{N}}$ converges strongly to u in X. □

Remark 3.16. All statements of Lemmas 3.13–3.15 remain valid if we replace Ψ_+ by Ψ.

4 Proof of main theorems

4.1 Proof of Theorem 1.1

(i) Assume that $\max\{q^+, r^+\} < p^-$ and $\lambda, \mu \in \mathbb{R}$. From Lemma 3.4 the C^1-functional Ψ_+ is sequentially weakly lower semicontinuous, we only have to show that Ψ_+ is coercive to apply Theorem 3.9. Let $u \in X$ be such that $\|u\|_a > 1$, from Proposition 2.4 and inequalities (3.6), we have

$$\begin{aligned}\Psi_+(u) &\geq \frac{1}{p^+}\int_\Omega \left(|\nabla u(x)|^{p(x)} + a(x)|u(x)|^{p(x)}\right) dx \\ &\quad - \frac{|\lambda|}{q^-}\int_{\partial\Omega} V(x)|u(x)|^{q(x)}d\sigma - \frac{|\mu|}{r^-}\int_{\partial\Omega} W(x)|u(x)|^{r(x)}d\sigma \\ &\geq \frac{1}{p^+}\|u\|_a^{p^-} - \frac{|\lambda|C^{q^+}}{q^-}\|u\|_a^{q^+} - \frac{|\mu|C^{r^+}}{r^-}\|u\|_a^{r^+},\end{aligned}$$

Since $\max\{q^+, r^+\} < p^-$, we have $\Psi_+(u) \to \infty$ as $\|u\|_a \to \infty$, then Ψ_+ is coercive. Applying Theorem 3.9, the functional Ψ_+ has a minimum point u_0 in X which is a nonnegative solution of $(S_{\lambda,\mu})$, as a critical point of Ψ_+.

(ii) Assume that $\min\{q^-, r^-\} > p^+$ and $\lambda, \mu \geq 0$. From Lemma 3.14 (i), there exist $\tau, \rho > 0$ such that $\Psi_+(u) \geq \tau$ if $\|u\|_a = \rho$. From Lemma 3.13, there exists $\varphi \in X \setminus \{0\}$ such that $\varphi \geq 0$ and $\Psi_+(t\varphi) \to -\infty$ as $t \to +\infty$. Therefore, for $t > 1$ large enough, there is $e = t\varphi \in X$ such that $\|e\|_a > \rho$ and $\Psi_+(e) < 0$. Moreover, from Lemma 3.15 (i), Ψ_+ satisfies the (PS) condition. Then, the functional Ψ_+ satisfies all requirements of the mountain geometry. Consequently, according to the Mountain Pass Theorem (see Theorem 3.10), Ψ_+ admits a critical value $c \geq \tau$ which is characterized by

$$c = \inf_{g\in\Gamma}\max_{t\in[0,1]} \Psi_+(g(t)), \quad \text{where } \Gamma = \{g \in C([0,1], X) : g(0) = 0,\ g(1) = e\}.$$

We deduce the existence of a critical point u of Ψ_+ associated with the critical value c satisfying $\Psi_+(u) \geq \tau$. Hence, the Steklov problem $(S_{\lambda,\mu})$ has a nontrivial nonnegative solution.

4.2 Proof of Theorem 1.2

(i) Assume $1 < p^- \leq p^+ < r^- \leq q^-$ and $\lambda, \mu \geq 0$. We will prove that the functional Ψ satisfies the conditions of Theorem 3.11. Obviously, from Lemma 3.3 and Lemma 3.15, $\Psi \in C^1(X, \mathbb{R})$ is an even functional and satisfies (PS) condition. Then, Ψ satisfies also $(PS)_c$ condition for every $c > 0$. Next, we will prove that if k is large enough, then there exist $\rho_k > r_k > 0$ such that conditions (F1) and (F2) of Theorem 3.11 hold. For $r > 0$ and $k \in \mathbb{N}^*$, let

$$\beta_k(r) = \sup\{|\psi(u)| \mid u \in Z_k, \|u\|_a \leq r\},$$

with $\psi(u) = \lambda\int_{\partial\Omega}\frac{V(x)}{q(x)}|u|^{q(x)}d\sigma + \mu\int_{\partial\Omega}\frac{W(x)}{r(x)}|u|^{r(x)}d\sigma$. The functional ψ is weakly-strongly continuous (see Lemma 3.4). Since $\beta_k(r) \to 0$ as $k \to \infty$ (see Proposition 3.6), it follows that, for each $n \in \mathbb{N}^*$, there exists $k_0(n) \in \mathbb{N}^*$ such that $\beta_k(n) \leq 1$ if $k \geq k_0(n)$. Without loss of generality, we may assume that $k_0(n) < k_0(n+1)$ for each $n \in \mathbb{N}^*$. Let us define the sequence r_k, $k \in \mathbb{N}^*$, by

$$r_k = \begin{cases} 1 & \text{if } 1 \leq k < k_0(1), \\ n & \text{if } k_0(n) \leq k < k_0(n+1). \end{cases}$$

It is easy to see that $r_k \to \infty$ as $k \to \infty$. For $k \in \mathbb{N}^*$ large enough, let $u \in Z_k$ with $\|u\|_a = r_k$, we have

$$\Psi(u) = \int_\Omega \frac{1}{p(x)} \left(|\nabla u|^{p(x)} dx + a(x)|u|^{p(x)} \right) dx - \psi(u) \geq \frac{1}{p^+} (r_k)^{p^-} - 1,$$

because $\psi(u) \leq \beta_k(n) \leq 1$. Therefore,

$$\inf_{u \in Z_k,\ \|u\|_a = r_k} \Psi(u) \to \infty \quad \text{as } k \to \infty.$$

So, the condition (F1) of Theorem 3.11 is satisfied.

Since Y_k is a finite dimensional space, the norms $\|\cdot\|_a$, $|\cdot|_{(q(x),V(x))}$ and $|\cdot|_{(r(x),W(x))}$ are equivalent. Then, there exist positive constants δ_1, δ_2 such that $|u|_{(q(x),V(x))} \geq \delta_1 \|u\|_a$ and $|u|_{(r(x),W(x))} \geq \delta_2 \|u\|_a$, for all $u \in Y_k$. For $k \in \mathbb{N}^*$, let $u \in Y_k$ with $\|u\|_a > 1$ large enough such that $|u|_{(q(x),V(x))} > 1$ and $|u|_{(r(x),W(x))} > 1$, from Proposition 2.7, we deduce that

$$\begin{aligned}
\Psi(u) &\leq \frac{1}{p^-} \|u\|_a^{p^+} - \frac{\lambda}{q^+} \int_{\partial\Omega} V(x)|u|^{q(x)} d\sigma - \frac{\mu}{r^+} \int_{\partial\Omega} W(x)|u|^{r(x)} d\sigma \\
&\leq \frac{1}{p^-} \|u\|_a^{p^+} - \frac{\lambda}{q^+} |u|^{q^-}_{(q(x),V(x))} - \frac{\mu}{r^+} |u|^{r^-}_{(r(x),W(x))} \\
&\leq \frac{1}{p^-} \|u\|_a^{p^+} - \frac{\lambda}{q^+} (|u|^{q^-}_{(q(x),V(x))} - 1) - \frac{\mu}{r^+} (|u|^{r^-}_{(r(x),W(x))} - 1 \\
&\leq \frac{1}{p^-} \|u\|_a^{p^+} - \frac{\lambda}{q^+} (\delta_1^{q^-} \|u\|_a^{q^-} - 1) - \frac{\mu}{r^+} (\delta_2^{r^-} \|u\|_a^{r^-} - 1) \\
&\leq \frac{1}{p^-} \|u\|_a^{p^+} - (\frac{\lambda \delta_1^{q^-}}{q^+} + \frac{\mu \delta_2^{r^-}}{r^+}) \|u\|_a^\theta + C(\lambda, \mu, q^+, r^+),
\end{aligned} \tag{4.1}$$

where $\theta = \min\{q^-, r^-\}$ and $C(\lambda, \mu, q^+, r^+) > 0$ a constant. From the last inequality, since $\theta > p^+$, we obtain that $\Psi(u) \to -\infty$ as $\|u\|_a \to \infty$. Thus for each $k \in \mathbb{N}^*$, there exists a sufficiently large $\rho_k > r_k$ such that $\Psi(u) < 0$ for all $u \in Y_k$ with $\|u\|_a = \rho_k$. Therefore,

$$\max_{u \in Y_k,\ \|u\|_a = \rho_k} \Psi(u) \leq 0.$$

So, the condition (F2) of Theorem 3.11 is satisfied.

According to the Fountain Theorem 3.11, the functional Ψ has a sequence of critical values $(c_n)_n$ tending to $+\infty$, which correspond to a sequence $(u_n)_n \subset X$ of critical points of Ψ such that $\Psi(u_n) \longrightarrow +\infty$ as $n \longrightarrow +\infty$.

(ii)–(iii) Assume $q^+ \leq p^- \leq p^+ < h^-$, $\lambda \in \mathbb{R}$ and $\mu > 0$. We will prove that the functional Ψ satisfies the conditions of Theorem 3.11. As above, there exists $r_k \to \infty$ as $k \to \infty$ such that for $k \in \mathbb{N}^*$ large enough, $u \in Z_k$ with $\|u\|_a = r_k$, we have

$$\Psi(u) = \int_\Omega \frac{1}{p(x)} \left(|\nabla u|^{p(x)} dx + a(x)|u|^{p(x)} \right) dx - \psi(u) \geq \frac{1}{p^+} (r_k)^{p^-} - 1.$$

Therefore,

$$\inf_{u \in Z_k,\ \|u\|_a = r_k} \Psi(u) \to \infty \quad \text{as } k \to \infty.$$

So, the condition (F1) of Theorem 3.11 is satisfied.

For $k \in \mathbb{N}^*$, let $u \in Y_k$ with $\|u\|_a > 1$, from Proposition 2.7, we deduce that

$$\begin{aligned}\Psi(u) &\leq \frac{1}{p^-}\|u\|_a^{p^+} + \frac{|\lambda|}{q^-}\left(|u|^{q^+}_{(q(x),V(x))} + 1\right) - \frac{\mu}{r^+}\left(|u|^{r^-}_{(r(x),W(x))} - 1\right) \\ &\leq \frac{1}{p^-}\|u\|_a^{p^+} + \frac{|\lambda|\delta_1^{q^+}}{q^-}\|u\|_a^{q^+} - \frac{\mu\delta_2^{r^-}}{r^+}\|u\|_a^{r^-} + C(\lambda,\mu,q^-,r^+),\end{aligned} \tag{4.2}$$

where $C(\lambda,\mu,q^-,r^+) > 0$ is a constant and δ_1, δ_2 as in the proof of (i). From the last inequality, since $q^+ \leq p^+ < r^-$, we obtain that $\Psi(u) \to -\infty$ as $\|u\|_a \to \infty$. Thus for each $k \in \mathbb{N}^*$, there exists a sufficiently large $\rho_k > r_k$ such that $\Psi(u) < 0$ for all $u \in Y_k$ with $\|u\|_a = \rho_k$. Therefore,

$$\max_{u\in Y_k,\ \|u\|_a=\rho_k} \Psi(u) \leq 0.$$

So, the condition (F2) of Theorem 3.11 is satisfied.

By Theorem 3.11, there is a sequence $(u_n)_n \subset X$ of critical points of Ψ such that $\Psi(u_n) \longrightarrow +\infty$ as $n \longrightarrow +\infty$.

(iv)–(v) Assume $q^+ < \min\{p^-, r^-\}$, $\lambda > 0$ and $\mu \in \mathbb{R}$. We will prove that the functional Ψ satisfies the conditions of Theorem 3.12. We have already seen that $\Psi \in C^1(X,\mathbb{R})$ is an even functional. For $r > 0$ and $k \in \mathbb{N}^*$, let

$$\beta_k(r) = \sup\{|\psi(u)| \mid u \in Z_k, \|u\|_a \leq r\},$$

with $\psi(u) = \lambda\int_{\partial\Omega}\frac{V(x)}{q(x)}|u|^{q(x)}d\sigma + \mu\int_{\partial\Omega}\frac{W(x)}{r(x)}|u|^{r(x)}d\sigma$. The functional ψ is weakly-strongly continuous (see Lemma 3.4). Since $\beta_k(r) \to 0$ as $k \to \infty$ (see Proposition 3.6), then there exists $k_0 \in \mathbb{N}^*$ such that $\beta_k(1) \leq \frac{1}{2p^+}$ if $k \geq k_0$. Setting $\rho_k = 1$, then for $k \geq k_0$ and $u \in Z_k$ with $\|u\|_a = \rho_k = 1$, we have

$$\Psi(u) \geq \frac{1}{p^+}\rho_a(u) - \psi(u) \geq \frac{1}{p^+} - \frac{1}{2p^+} = \frac{1}{2p^+} > 0.$$

Therefore,

$$\inf_{u\in Z_k,\ \|u\|_a=\rho_k} \Psi(u) \geq 0.$$

So, the condition (D1) of Theorem 3.12 is satisfied.

Let r be a positive small real number such that $0 < r < \frac{1}{C}$, where $C > 1$ appears in (3.1). As above, since Y_k is a finite dimensional space, there are positive constants δ_1, δ_2 such that for all $u \in Y_k$ with $\|u\|_a = r < 1$, we have

$$\Psi(u) \leq \frac{1}{p^-}\|u\|_a^{p^-} - \frac{\lambda\delta_1^{q^+}}{q^+}\|u\|_a^{q^+} + \frac{|\mu|\delta_2^{r^-}}{r^-}\|u\|_a^{r^-}.$$

Since $q^+ < \min\{p^-, r^-\}$, we can choose $r_k \in (0, \rho_k)$ small enough such that $\Psi(u) < 0$ for all $u \in Y_k$ with $\|u\|_a = r_k$. Therefore,

$$\max_{u\in Y_k,\ \|u\|_a=r_k} \Psi(u) < 0.$$

So, the condition (D2) of Theorem 3.12 is satisfied.

From the definition of Y_k and Z_k, it follows that $Y_k \cap Z_k \neq \emptyset$ for each $k \in \mathbb{N}^*$. Let $u_0 \in Y_k \cap Z_k$ with $u_0 \not\equiv 0$, and set $u_k = \frac{r_k}{\|u_0\|_a}u_0$ for each $k \geq k_0$, then $\|u_k\|_a = r_k$. For $k \geq k_0$, since $0 < r_k < \rho_k$, we have

$$d_k := \inf_{u\in Z_k,\ \|u\|_a\leq\rho_k} \Psi(u) \leq \Psi(u_k) \leq b_k := \max_{u\in Y_k,\ \|u\|_a=r_k} \Psi(u) < 0.$$

For $u \in Z_k$ with $\|u\|_a \leq \rho_k = 1$, we have

$$\Psi(u) = \phi(u) - \psi(u) \geq -\psi(u) \geq -\beta_k(1),$$

and then

$$-\beta_k(1) \leq d_k := \inf_{u \in Z_k,\ \|u\|_a \leq \rho_k} \Psi(u) < 0.$$

Since $\beta_k(1) \to 0$ as $k \to \infty$, we deduce from the last inequality that

$$d_k := \inf_{u \in Z_k,\ \|u\|_a \leq \rho_k} \Psi(u) \to 0 \text{ as } k \to \infty.$$

So, the condition (D3) of Theorem 3.12 is satisfied.

Next, we will prove that Ψ satisfy condition $(PS)_c^*$ for every $c \in \mathbb{R}$. Let $(u_n)_{n \in \mathbb{N}^*} \subset X$ and $c \in \mathbb{R}$ such that

$$u_n \in Y_n \quad \text{for each } n \in \mathbb{N}^*, \qquad \Psi(u_n) \longrightarrow c \quad \text{and} \quad (\Psi|_{Y_n})'(u_n) \longrightarrow 0 \quad \text{as } n \to \infty.$$

Let us show that the sequence (u_n) is bounded in X. Arguing by contradiction, assume $\|u_n\|_a \to \infty$ as $n \to \infty$. For $\lambda > 0, \mu \geq 0$ and $n \in \mathbb{N}^*$ large enough such that $\|u_n\|_a > 1$, we have

$$\begin{aligned} c + 1 + \|u_n\|_a \geq & \Psi(u_n) - \frac{1}{r^-} \langle (\Psi|_{Y_n})'(u_n), u_n \rangle \\ = & \Psi(u_n) - \frac{1}{r^-} \langle \Psi'(u_n), u_n \rangle \\ \geq & \left(\frac{1}{p^+} - \frac{1}{r^-} \right) \|u_n\|_a^{p^-} - \lambda \left(\frac{1}{q^-} - \frac{1}{r^-} \right) C^{q^+} \|u_n\|_a^{q^+}. \end{aligned}$$

Since $p^- > 1$, we obtain a contradiction for a large $n \in \mathbb{N}^*$. For $\lambda > 0, \mu \leq 0$ and $n \in \mathbb{N}^*$ large enough such that $\|u_n\|_a > 1$, we have

$$\begin{aligned} c + 1 + \|u_n\|_a \geq & \Psi(u_n) - \frac{1}{r^+} \langle (\Psi|_{Y_n})'(u_n), u_n \rangle \\ = & \Psi(u_n) - \frac{1}{r^+} \langle \Psi'(u_n), u_n \rangle \\ \geq & \left(\frac{1}{p^+} - \frac{1}{r^+} \right) \|u_n\|_a^{p^-} - \lambda \left(\frac{1}{q^-} - \frac{1}{r^+} \right) C^{q^+} \|u_n\|_a^{q^+}. \end{aligned}$$

Since $p^- > 1$, we obtain a contradiction for a large $n \in \mathbb{N}^*$. Then, (u_n) is bounded in X. As X is a reflexive Banach space, we can extract a subsequence $(u_{n_k})_{k \in \mathbb{N}^*}$ of $(u_n)_{n \in \mathbb{N}^*}$ weakly convergent to some $u \in X$. We can write X as

$$X = \overline{\bigcup_{n \in \mathbb{N}^*} Y_n}.$$

By choosing $(v_n)_{n \in \mathbb{N}^*}$ such that

$$v_n \in Y_n \quad \text{for each } n \in \mathbb{N}^* \quad \text{and} \quad \lim_{n \to \infty} v_n = u \quad \text{in } X,$$

we obtain

$$\begin{aligned} \lim_{k \to \infty} \langle \Psi'(u_{n_k}), u_{n_k} - u \rangle &= \lim_{k \to \infty} \langle \Psi'(u_{n_k}), u_{n_k} - v_{n_k} \rangle + \lim_{k \to \infty} \langle \Psi'(u_{n_k}), v_{n_k} - u \rangle \\ &= \lim_{k \to \infty} \langle (\Psi|_{Y_{n_k}})'(u_{n_k}), u_{n_k} - v_{n_k} \rangle = 0, \end{aligned}$$

because of $(\Psi|_{Y_{n_k}})'(u_{n_k}) \to 0$ as $k \to \infty$, $u_{n_k} - v_{n_k} \rightharpoonup 0$ in Y_{n_k} and $v_{n_k} \to u \in X$. Then, we deduce that

$$\lim_{k\to\infty} \langle \Psi'(u_{n_k}) - \Psi'(u), u_{n_k} - u \rangle = 0.$$

By the (S^+) property of the functional Ψ, we get the strong convergence of $(u_{n_k})_{k\in\mathbb{N}^*}$ to u in X. It remains to prove that u is a critical point of Ψ. Choosing an arbitrary $w_n \in Y_n$, for any $n_k \geq n$, we have

$$\begin{aligned} \langle \Psi'(u), w_n \rangle =& \langle \Psi'(u) - \Psi'(u_{n_k}), w_n \rangle + \langle \Psi'(u_{n_k}), w_n \rangle \\ =& \langle \Psi'(u) - \Psi'(u_{n_k}), w_n \rangle + \langle (\Psi|_{Y_{n_k}})'(u_{n_k}), w_n \rangle. \end{aligned} \tag{4.3}$$

Since $\Psi \in C^1(X, \mathbb{R})$ and $\lim_{k\to\infty} u_{n_k} = u$ in X, then $\lim_{k\to\infty} \Psi'(u_{n_k}) = \Psi'(u)$. In expression (4.3), letting $k \to \infty$ we deduce that $\langle \Psi'(u), w_n \rangle = 0$, for all $w_n \in Y_n$, it follows that $\Psi'(u) = 0$. Consequently, Ψ satisfies the $(PS)^*_c$ condition for every $c \in \mathbb{R}$.

According to the Dual Fountain Theorem 3.12, the functional Ψ has a sequence of negative critical values $(c_n)_n$ converging to 0, which correspond to a sequence $(u_n)_n \subset X$ of critical points of Ψ such that $\Psi(u_n) \leq 0$, for each $n \in \mathbb{N}$ and $\Psi(u_n) \longrightarrow 0$ as $n \longrightarrow +\infty$.

Appendix

Some examples of variable exponents illustrating (i)–(ii) of Theorem 1.1

Example 1 : Suppose that $N = 1$ and $\Omega = [a, b]$ the closed set of $\mathbb{R}$.

(i) Consider the continuous functions $p, q, r : \Omega = [a, b] \longrightarrow (1, +\infty)$ defined by :

$$p(x) = 4 + \frac{1}{1 + (x - c)^2}, \text{ with } c \in [a, b];\ q(x) = 1 + \sin(x);\ r(x) = 2 + \cos(x).$$

We have

$$\max\{q^+, r^+\} = \max\{2, 3\} = 3 < 4 < p^-.$$

(ii) Consider the continuous functions $p, q, r : \Omega = [a, b] \longrightarrow (1, +\infty)$ defined by :

$$p(x) = 1 + \frac{1}{1 + (x - c)^2}, \text{ with } c \in [a, b];\ q(x) = 4 + \sin(x);\ r(x) = 5 + \cos(x).$$

We have

$$\min\{q^-, r^-\} = \min\{3, 4\} = 3 > p^+ = 2.$$

Example 2 : Suppose that $N = 2$ and $\Omega = [0, 1] \times [0, 1]$ the closed set of $\mathbb{R}^2$.

(i) Consider the continuous functions $p, q, r : \Omega \longrightarrow (1, +\infty)$ defined by :

$$\begin{aligned} p(x, y) &= 5 + \frac{1}{1 + x^2 + y^2}; \\ q(x, y) &= 2 + \sin(\pi x)\cos(\pi x); \\ r(x, y) &= 3 + \cos(\pi x)\sin(\pi x). \end{aligned}$$

We have

$$\max\{q^+, r^+\} = \max\{3, 4\} = 4 < p^- = \frac{16}{3}.$$

(ii) Consider the continuous functions $p, q, r : \Omega = [a, b] \longrightarrow (1, +\infty)$ defined by :

$$\begin{aligned} p(x,y) &= 2 + \frac{1}{1+x^2+y^2}; \\ q(x,y) &= 5 + \sin(\pi x)\cos(\pi x); \\ r(x,y) &= 6 + \cos(\pi x)\sin(\pi x). \end{aligned}$$

We have

$$\min\{q^-, r^-\} = \max\{4, 5\} = 4 > p^+ = 3.$$

Some examples of variable exponents illustrating (i)–(v) of Theorem 1.2

Example 1 : Suppose that $N = 1$ and $\Omega = [a, b]$ the closed set of $\mathbb{R}$.

(i) Consider the continuous functions $p, q, r : \Omega = [a, b] \longrightarrow (1, +\infty)$ defined by :

$$p(x) = 1 + \frac{1}{1+(x-c)^2}, \quad \text{with } c \in [a, b]; \qquad q(x) = 5 + \sin(x); \qquad r(x) = 4 + \cos(x).$$

We have

$$p^+ = 2 < r^- = 3 < q^- = 4.$$

(ii) Consider the continuous functions $p, q, r : \Omega = [a, b] \longrightarrow (1, +\infty)$ defined by :

$$p(x) = 4 + \sin(x); \qquad q(x) = 1 + \frac{1}{1+(x-c)^2}, \quad \text{with } c \in [a, b]; \qquad r(x) = 7 + \cos(x).$$

We have

$$q^+ = 2 < p^- = 3 < p^+ = 5 < r^- = 6.$$

(iii) Consider the continuous functions $p, q, r : \Omega = [a, b] \longrightarrow (1, +\infty)$ defined by :

$$p(x) = 5 + \sin(x); \qquad q(x) = 3 + \frac{1}{1+(x-c)^2}, \quad \text{with } c \in [a, b]; \qquad r(x) = 6 + \cos(x).$$

We have

$$q^+ = p^- = 4 < r^- = 5.$$

(iv) The same example of (ii).

(v) Consider the continuous functions $p, q, r : \Omega = [a, b] \longrightarrow (1, +\infty)$ defined by :

$$p(x) = 4 + \sin(x); \qquad q(x) = 1 + \frac{1}{1+(x-c)^2}, \quad \text{with } c \in [a, b]; \qquad r(x) = 5 + \cos(x).$$

We have

$$q^+ = 2 < \min\{p^-, r^-\} = 3 \quad \text{and} \quad p^+ = 5 < r^+ = 6.$$

Example 2 : Suppose that $N = 2$ and $\Omega = [0, 1] \times [0, 1]$ the closed set of $\mathbb{R}^2$.

(i) Consider the continuous functions $p, q, r : \Omega = [a, b] \longrightarrow (1, +\infty)$ defined by :

$$\begin{aligned} p(x,y) &= 2 + \frac{1}{1+x^2+y^2}; \\ (x,y) &= 6 + \sin(\pi x)\cos(\pi y); \\ r(x,y) &= 5 + \cos(\pi x)\sin(\pi y). \end{aligned}$$

We have

$$p^+ = 3 < r^- = 4 < q^- = 5.$$

(ii) Consider the continuous functions $p, q, r : \Omega \longrightarrow (1, +\infty)$ defined by :

$$\begin{aligned} p(x,y) &= 5 + \sin(\pi x)\cos(\pi y); \\ q(x,y) &= 2 + \frac{1}{1+x^2+y^2}; \\ r(x,y) &= 8 + \cos(\pi x)\sin(\pi x). \end{aligned}$$

We have

$$q^+ = 3 < p^- = 4 < p^+ = 6 < r^- = 7.$$

(iii) Consider the continuous functions $p, q, r : \Omega \longrightarrow (1, +\infty)$ defined by :

$$\begin{aligned} p(x,y) &= 5 + \sin(\pi x)\cos(\pi y); \\ q(x,y) &= 3 + \frac{1}{1+x^2+y^2}; \\ r(x,y) &= 8 + \cos(\pi x)\sin(\pi x). \end{aligned}$$

We have

$$q^+ = 4 = p^- < p^+ = 6 < r^- = 7.$$

(iv) The same example of (ii).

(v) Consider the continuous functions $p, q, r : \Omega \longrightarrow (1, +\infty)$ defined by :

$$\begin{aligned} p(x,y) &= 5 + \sin(\pi x)\cos(\pi y); \\ q(x,y) &= 2 + \frac{1}{1+x^2+y^2}; \\ r(x,y) &= 6 + \cos(\pi x)\sin(\pi x). \end{aligned}$$

We have

$$q^+ = 3 < \min\{p^-, r^-\} = 4 \quad \text{and} \quad p^+ = 6 < r^+ = 7.$$

Abstract. In this note, we consider a critical elliptic equation perturbed by a logarithmic type subcritical term in $\mathbb{R}^4$, and investigate how the logarithmic term affects the existence of weak solutions to such a problem. Since the logarithmic term does not satisfy the standard monotonicity condition, essential difficulty arises when one looks for weak solutions to this problem in the variational framework. After some delicate estimates on the logarithmic term we can control the mountain pass level of the corresponding functional so that it satisfies the local compactness condition. Then a positive weak solution follows with the application of the Mountain Pass Lemma and the Brézis–Lieb Lemma. Our result implies that the logarithmic term plays a positive role for the problem to admit positive solutions.

Keywords: critical, logarithmic type perturbation, Brézis–Lieb Lemma.

2020 Mathematics Subject Classification: 35J61, 35J20.

1 Introduction and the main results

In this note, we confine ourselves to the following critical elliptic problem with a logarithmic type perturbation

$$\begin{cases} -\Delta u = \lambda |u|^{q-2} u \ln u^2 + u^3, & x \in \Omega, \\ u(x) = 0, & x \in \partial\Omega, \end{cases} \tag{1.1}$$

where $\Omega \subset \mathbb{R}^4$ is a bounded smooth domain with boundary $\partial\Omega$, $q \in (2,4)$ and $\lambda > 0$ is a parameter. Without loss of generality, we may assume that $0 \in \Omega$.

It is clear that problem (1.1) is a special form of the following elliptic boundary value problem

$$\begin{cases} (-\Delta)^m u = \mu u + f(x,u) + |u|^{p-2}u, & x \in \Omega, \\ D^\alpha u = 0, \quad for\ |\alpha| \le m-1, & x \in \partial\Omega, \end{cases} \tag{1.2}$$

where $m \in \mathbb{N}$, $\Omega \subset \mathbb{R}^N (N > 2m)$ is a bounded smooth domain, $\mu \in \mathbb{R}$, $p = \frac{2N}{N-2m}$ and $f(x,u)$ is a nonlinear term. One of the main features of the equation in (1.2) is that it involves a critical

✉Corresponding author. Email: yzhan@jlu.edu.cn

term in the sense that the embedding $H_0^m(\Omega) \hookrightarrow L^p(\Omega)$ is not compact, which brings essential difficulty in proving the existence of weak solutions to (1.2). Therefore, the study of elliptic problems with critical exponents is not only interesting, but also challenging. However, it was mainly after the pioneering work of Brézis and Nirenberg [2] that such problems were extensively investigated, and remarkable progress has been made on the existence, nonexistence and multiplicity of weak solutions to such problems.

On the other hand, partial differential equations with logarithmic nonlinearities have also been attracting more and more attention in recent years due to their wide applications in many applied sciences. Interested readers may refer to [3,5,8–11] and the references therein for the study of different kinds of equations with logarithmic nonlinearity. For example, when $m = 1$, $f(x,u) = \mu u \ln u^2$ ($\mu \neq 0$), Deng et al. [3] considered the existence and nonexistence of positive solutions to problem (1.2). With the help of some delicate estimates on the logarithmic term, they showed, among many other interesting results, that problem (1.2) admits a positive mountain pass type solution when $N \geq 4$, $\lambda \in \mathbb{R}$ and $\mu > 0$, which is also a ground state solution. Later, the main results in [3] were extended to second order elliptic system by Hajaiej et al. [4] and to critical bi-harmonic equation by Li et al. [5].

It is worth pointing out that the exponent of the logarithmic term in all the above mentioned literature is $q = 2$, and it seems that there is no result for $q > 2$. Motivated mainly by [3,5,11] we will consider problem (1.1) and investigate what role the logarithmic term plays for the problem to admit weak solutions. Since the logarithmic term does not satisfy the standard monotonicity condition, additional difficulty arises when we look for weak solutions to problem (1.1) by using variational methods. A key step in this process is to control the mountain pass level of the corresponding energy functional from above by a small constant such that it satisfies the (PS) condition locally. This is done with the help of some very delicate estimates on the logarithmic function of the truncated Talenti's functions. Then by combining the Mountain Pass Lemma with the Brézis–Lieb Lemma, we can show for $q \in (2,4)$ that problem (1.1) admits a positive mountain pass type solution for all $\lambda > 0$, which, compared with the case $\lambda = 0$ (see Remark 1.2 below), means that the logarithmic type subcritical perturbation plays a positive role for problem (1.1) to admit positive solutions.

The notations used in this paper are almost standard. We use $\|\cdot\|_p$ to denote the $L^p(\Omega)$ norm for $1 \leq p \leq \infty$, and equip the Sobolev space $H_0^1(\Omega)$ with the norm $\|u\| := \|u\|_{H_0^1(\Omega)} = \|\nabla u\|_2$. The dual space of $H_0^1(\Omega)$ is denoted by $H^{-1}(\Omega)$ and the dual pair between $H_0^1(\Omega)$ and $H^{-1}(\Omega)$ is written as $\langle\cdot,\cdot\rangle$. For each Banach space B, we use $\to$ and $\rightharpoonup$ to denote the strong and weak convergence in it, respectively. We also use C, C_1, C_2, ... to denote (possibly different) positive constants. The positive constant S denotes the best embedding constant from $H_0^1(\Omega)$ to $L^4(\Omega)$, i.e.,

$$S = \inf_{u \in H_0^1(\Omega)\setminus\{0\}} \frac{\|u\|^2}{\|u\|_4^2}. \tag{1.3}$$

Finally, $B_r(x_0)$ is a ball of radius r centered at x_0 and $B_r(0)$ is simply written as B_r when no confusion arises. The symbol $O(t)$ means $|\frac{O(t)}{t}| \leq C$ as $t \to 0$ and $o_n(1)$ is an infinitesimal as $n \to \infty$.

The energy functional associated with problem (1.1) and its Fréchet derivative are denoted respectively by $I(u)$ and $I'(u)$, i.e.,

$$I(u) = \frac{1}{2}\|u\|^2 + \frac{2\lambda}{q^2}\|u\|_q^q - \frac{\lambda}{q}\int_\Omega |u|^q \ln u^2 \mathrm{d}x - \frac{1}{4}\|u\|_4^4, \qquad u \in H_0^1(\Omega), \tag{1.4}$$

and

$$\langle I'(u),\phi\rangle = \int_\Omega \nabla u\nabla\phi \mathrm{d}x - \lambda\int_\Omega |u|^{q-2}u\phi \ln u^2 \mathrm{d}x - \int_\Omega u^3\phi \mathrm{d}x, \qquad u,\phi\in H_0^1(\Omega). \tag{1.5}$$

It is obviously that $I(u)$ is a C^1 functional on $H_0^1(\Omega)$, and each critical point of $I(u)$ is also a weak solution to problem (1.1). Since $I(u) = I(|u|)$, we may assume that $u \geq 0$ in the sequel. The main result of this paper is the following theorem.

Theorem 1.1. *Assume that $q \in (2,4)$. Then problem (1.1) admits a positive mountain pass type solution u for all $\lambda > 0$.*

Remark 1.2. In [6], Pohožaev showed that problem (1.1) with $\lambda = 0$ admits no positive solution if Ω is star-shaped. However, Theorem 1.1 shows that this situation can be reversed when the logarithmic term is introduced. This means that the logarithmic term plays a positive role for problem (1.1) to admit positive solutions.

Remark 1.3. The solution obtained in Theorem 1.1 is actually a ground state solution to problem (1.1). To see this, set

$$\mathcal{N} = \left\{u\in H_0^1(\Omega)\setminus\{0\} : \langle I'(u),u\rangle = 0\right\},$$

$c_1 = \inf_{u\in\mathcal{N}} I(u)$ and $c_2 = \inf_{u\in H_0^1(\Omega)\setminus\{0\}}\max_{t\geq 0} I(tu)$. Then it is easily to verify that $c_1 = c_2$. Let c_0 be the mountain pass level defined in Lemma 2.7. Since $q\in(2,4)$, one sees that $I(tu) < 0$ for $u\in H_0^1(\Omega)\setminus\{0\}$ and t large enough, which implies that $c_0 \leq c_2$. Noticing that the Nehari's manifold $\mathcal{N}$ separates $H_0^1(\Omega)$ into two components. The component containing the origin also contains a small ball around the origin. Moreover $I(u)\geq 0$ for all u in this component, by the assumption $q\in(2,4)$. Thus every $\gamma\in\Gamma$ has to cross $\mathcal{N}$ and $c_1 \leq c_0$. Therefore, $c_0 = c_1$ and the solution u obtained in Theorem 1.1 is a ground state solution.

Remark 1.4. When $q = 2$ and $N = 3,4$, Deng et al. [3] also considered the case that $\lambda < 0$, and obtained a positive solution by using the Mountain Pass Lemma without compactness condition. However, it seems quite difficult to derive the same conclusion for $q\in(2,4)$. This can be seen from (2.23) and (2.24). Indeed, from (2.23) and (2.24) we know that compared with $\int_\Omega |u_\varepsilon|^q \ln u_\varepsilon^2 \mathrm{d}x$, $\|u_\varepsilon\|_q^q$ is an infinitesimal of higher order as $\varepsilon\to 0$ and consequently we can not control the mountain pass level as was done in [3]. So the treatment for the case $q\in(2,4)$ must be different from those in [3] and new ideas and techniques may be needed.

2 Proof of the main result

We begin this section with some definitions, lemmas and basic inequalities, which will be used in the proof of the main result.

Definition 2.1. ($(PS)_c$ condition) Assume that B is a real Banach space, $I : B\to\mathbb{R}$ is a C^1 functional and $c\in\mathbb{R}$. We say that I satisfies the $(PS)_c$ condition if any sequence $\{u_n\}\subset B$ such that

$$I(u_n)\to c \quad\text{and}\quad I'(u_n)\to 0 \quad \text{in } B' \text{ (the dual space of } B) \quad \text{as } n\to\infty$$

has a convergent subsequence.

Lemma 2.2 (Mountain Pass Lemma [5,7]). *Assume that $(B, \|\cdot\|_B)$ is a real Banach space, $I : B \to \mathbb{R}$ is a C^1 functional and there exist $\alpha > 0$ and $\rho > 0$ such that I satisfies the following mountain pass geometry*

(i) $I(u) \geq \alpha > 0$ *if* $\|u\|_B = \rho$;

(ii) There exists a $\overline{u} \in B$ *such that* $\|\overline{u}\|_B > \rho$ *and* $I(\overline{u}) < 0$.

Then there exist a sequence $\{u_n\} \subset B$ *such that* $I(u_n) \to c_0$ *and* $I'(u_n) \to 0$ *in* B' *as* $n \to \infty$, *where*

$$c_0 := \inf_{\gamma\in\Gamma} \max_{t\in[0,1]} I(\gamma(t)) \geq \alpha, \qquad \Gamma = \{\gamma \in C([0,1], B) : \gamma(0) = 0, \gamma(1) = \overline{u}\}.$$

Furthermore, c_0 *(which is usually called the mountain level) is a critical value of* I *if* I *satisfies the* $(PS)_{c_0}$ *condition.*

Lemma 2.3 (Brézis–Lieb Lemma [1]). *Let* $p \in (1, \infty)$. *Suppose that* $\{u_n\}$ *is a bounded sequence in* $L^p(\Omega)$ *and* $u_n \to u$ *a.e. in* Ω. *Then*

$$\lim_{n\to\infty} (\|u_n\|_p^p - \|u_n - u\|_p^p) = \|u\|_p^p.$$

Lemma 2.4. *For any* $\delta > 0$, *there exists a positive constant* C_δ *such that*

$$|\ln t| \leq C_\delta(t^\delta + t^{-\delta}), \qquad \forall\, t > 0, \tag{2.1}$$

$$\ln t \leq \frac{t^\delta}{e\delta}, \qquad \forall\, t \geq 1. \tag{2.2}$$

In order to apply the Mountain Pass Lemma, we then verify the mountain pass geometry for I around 0 when $q \in (2, 4)$ and $\lambda > 0$.

Lemma 2.5. *Assume that* $q \in (2, 4)$ *and* $\lambda > 0$. *Then* $I(u)$ *satisfies the mountain pass geometry around* 0.

Proof. By recalling (2.2) with $\delta \in (0, 4 - q)$ and making use of the Sobolev embedding inequality, one has

$$\begin{aligned} I(u) &= \frac{1}{2}\|u\|^2 + \frac{2\lambda}{q^2}\|u\|_q^q - \frac{\lambda}{q}\int_\Omega |u|^q \ln u^2 \mathrm{d}x - \frac{1}{4}\|u\|_4^4 \\ &\geq \frac{1}{2}\|u\|^2 - \frac{\lambda}{q}\int_{\Omega_1} |u|^q \ln u^2 \mathrm{d}x - \frac{\lambda}{q}\int_{\Omega_2} |u|^q \ln u^2 \mathrm{d}x - \frac{1}{4}\|u\|_4^4 \\ &\geq \frac{1}{2}\|u\|^2 - C\|u\|^{q+\delta} - \frac{1}{4}S^{-2}\|u\|^4 \\ &= \|u\|^2\left(\frac{1}{2} - C\|u\|^{q+\delta-2} - \frac{1}{4}S^{-2}\|u\|^2\right), \end{aligned}$$

where $\Omega_1 = \{x \in \Omega : |u(x)| < 1\}$, $\Omega_2 = \{x \in \Omega : |u(x)| \geq 1\}$. Hence, there exist positive constants α and ρ such that

$$I(u) \geq \alpha \quad \text{for all } \|u\| = \rho.$$

On the other hand, for any $v \in H_0^1(\Omega) \setminus \{0\}$, one has $\lim_{t\to\infty} I(tv) = -\infty$ since $q < 4$, which ensures that there exists a $t(v) > 0$ such that $\|t(v)v\| > \rho$ and $I(t(v)v) < 0$. Thus, I satisfies the mountain pass geometry around 0. The proof is complete. □

Next, we shall verify that I satisfies the $(PS)_c$ condition when $c < \frac{1}{4}S^2$. This condition will play a key role in showing the existence of weak solutions to problem (1.1).

Lemma 2.6. *Assume that $q \in (2,4)$ and $\lambda > 0$. Then $I(u)$ satisfies the $(PS)_c$ condition when $c < \frac{1}{4}S^2$.*

Proof. Let $\{u_n\} \subset H_0^1(\Omega)$ be a (PS) sequence for $I(u)$ at the level c with $c < \frac{1}{4}S^2$, i.e., $I(u_n) \to c$ and $I'(u_n) \to 0$ in $H^{-1}(\Omega)$ as $n \to \infty$. First, we claim that $\{u_n\}$ is bounded. Indeed, from the definition of the (PS) sequence, one obtains, for n suitably large, that

$$\begin{aligned} c + 1 + o(1)\|u_n\| &\geq I(u_n) - \frac{1}{q}\langle I'(u_n), u_n\rangle \\ &= \left(\frac{1}{2} - \frac{1}{q}\right)\|u_n\|^2 + \frac{2\lambda}{q^2}\|u_n\|_q^q + \left(\frac{1}{q} - \frac{1}{4}\right)\|u_n\|_4^4 \\ &\geq \left(\frac{1}{2} - \frac{1}{q}\right)\|u_n\|^2, \end{aligned}$$

which implies that $\{u_n\}$ is bounded in $H_0^1(\Omega)$. Consequently, there is a subsequence of $\{u_n\}$ (still denoted by $\{u_n\}$) such that, as $n \to \infty$,

$$\begin{cases} u_n \rightharpoonup u & \text{in } H_0^1(\Omega), \\ u_n \to u & \text{in } L^r(\Omega)\ (1 \leq r < 4), \\ u_n \rightharpoonup u & \text{in } L^4(\Omega), \\ |u_n|^2 u_n \rightharpoonup |u|^2 u & \text{in } L^{\frac{4}{3}}(\Omega), \\ u_n \to u & \text{a.e. in } \Omega. \end{cases} \tag{2.3}$$

Next, we show that

$$\lim_{n\to\infty} \int_\Omega |u_n|^q \ln u_n^2 \mathrm{d}x = \int_\Omega |u|^q \ln u^2 \mathrm{d}x. \tag{2.4}$$

Indeed, since $u_n \to u$ a.e. in Ω as $n \to \infty$, we get

$$|u_n|^q \ln u_n^2 \to |u|^q \ln u^2 \quad \text{a.e. in } \Omega. \tag{2.5}$$

Moreover, by recalling (2.2) with $\delta < 4 - q$ and (2.3), one has

$$\big||u_n|^q \ln u_n^2\big| \leq C_\delta(|u_n|^{q-\delta} + |u_n|^{q+\delta}) \to C_\delta(|u|^{q-\delta} + |u|^{q+\delta}) \quad \text{in } L^1(\Omega). \tag{2.6}$$

Then (2.4) follows from (2.5), (2.6) and Lebesgue's dominated convergence theorem. Similarly,

$$\lim_{n\to\infty} \int_\Omega |u_n|^{q-2} u_n \phi \ln u_n^2 \mathrm{d}x = \int_\Omega |u|^{q-2} u\phi \ln u^2 \mathrm{d}x, \qquad \forall\ \phi \in H_0^1(\Omega). \tag{2.7}$$

To prove that $u_n \to u$ in $H_0^1(\Omega)$ as $n \to \infty$, set $w_n = u_n - u$. Then $\{w_n\}$ is also a bounded sequence in $H_0^1(\Omega)$, and therefore there exists a subsequence of $\{w_n\}$ (which we still denote by $\{w_n\}$) such that

$$\lim_{n\to\infty} \|w_n\|^2 = l \geq 0. \tag{2.8}$$

We claim that $l = 0$. Indeed, in view of the weak convergence $u_n \rightharpoonup u$ in $H_0^1(\Omega)$, we have

$$\|u_n\|^2 = \|w_n\|^2 + \|u\|^2 + o_n(1), \qquad n \to \infty. \tag{2.9}$$

Moreover, (2.3) implies that we can apply the Brézis–Lieb Lemma to obtain

$$\|u_n\|_4^4 = \|w_n\|_4^4 + \|u\|_4^4 + o_n(1), \qquad n \to \infty. \tag{2.10}$$

With (2.3), (2.4), (2.7), (2.9), (2.10) at hand and recalling the boundedness of $\{u_n\}$ and the assumption that $I'(u_n) \to 0$ in $H^{-1}(\Omega)$, we have

$$o_n(1) = \langle I'(u_n), u_n\rangle = \langle I'(u), u\rangle + \|w_n\|^2 - \|w_n\|_4^4 + o_n(1), \qquad n \to \infty, \tag{2.11}$$

and

$$o_n(1) = \langle I'(u_n), \phi\rangle = \langle I'(u), \phi\rangle + o_n(1), \qquad n \to \infty,\ \forall\ \phi \in H_0^1(\Omega). \tag{2.12}$$

It follows from (2.12) that u is a weak solution to problem (1.1).

Choosing $\phi = u$ in (2.12), one obtains

$$\langle I'(u), u\rangle = 0, \tag{2.13}$$

which, together with (2.11), implies that

$$\|w_n\|^2 - \|w_n\|_4^4 = o_n(1), \qquad n \to \infty. \tag{2.14}$$

In addition, by the Sobolev embedding one has

$$\|w_n\|_4^4 \le S^{-2}\|w_n\|^4, \qquad \forall\ n \in \mathbb{N}. \tag{2.15}$$

Letting $n \to \infty$ on both sides of (2.15) and recalling (2.8) and (2.14), one arrives at

$$l \le S^{-2} l^2. \tag{2.16}$$

If $l > 0$, then

$$l \ge S^2. \tag{2.17}$$

On one hand, by virtue of (2.13), we have

$$I(u) = I(u) - \frac{1}{q}\langle I'(u), u\rangle = \left(\frac{1}{2} - \frac{1}{q}\right)\|u\|^2 + \frac{2\lambda}{q^2}\|u\|_q^q + \left(\frac{1}{q} - \frac{1}{4}\right)\|u\|_4^4 \ge 0,$$

since $q \in (2,4)$ and $\lambda > 0$.

On the other hand, in view of (2.3), (2.4), (2.9), (2.10) and the fact that $I(u_n) = c + o_n(1)$ as $n \to \infty$, we deduce that

$$o_n(1) + c = I(u_n) = I(u) + \frac{1}{2}\|w_n\|^2 - \frac{1}{4}\|w_n\|_4^4 + o_n(1), \qquad n \to \infty,$$

which yields

$$I(u) = c - \frac{1}{2}\|w_n\|^2 + \frac{1}{4}\|w_n\|_4^4 + o_n(1), \qquad n \to \infty.$$

From this and recalling (2.8), (2.14) and (2.17) one has

$$I(u) = c - \left(\frac{1}{2} - \frac{1}{4}\right) l \le c - \frac{1}{4}S^2 < 0,$$

which is a contradiction. Therefore, we have $\lim_{n\to\infty}\|w_n\|^2 = l = 0$, i.e., $u_n \to u$ in $H_0^1(\Omega)$ as $n \to \infty$. The proof is complete. □

Lemma 2.7. *Assume that $q \in (2,4)$ and $\lambda > 0$. If there exists a $v \in H_0^1(\Omega) \setminus \{0\}$ such that*

$$\sup_{t\geq 0} I(tv) < \frac{1}{4}S^2, \tag{2.18}$$

then problem (1.1) possesses a nontrivial weak solution.

Proof. From Lemma 2.5, we know that I satisfies the mountain pass geometry around 0. Consequently, in view of Lemma 2.2, there exists a sequence $\{u_n\} \subset H_0^1(\Omega)$ such that $I(u_n) \to c_0$ and $I'(u_n) \to 0$ in $H^{-1}(\Omega)$ as $n \to \infty$, where

$$0 < \alpha \leq c_0 = \inf_{\gamma\in\Gamma}\max_{t\in[0,1]} I(\gamma(t)), \quad \Gamma = \{\gamma \in C([0,1], H_0^1(\Omega)) : \gamma(0) = 0, \gamma(1) = t(v)v\}, \tag{2.19}$$

and $t(v) > 0$ is the constant determined in the proof of Lemma 2.5. According to (2.18), we have

$$c_0 \leq \max_{t\in[0,1]} I(tt(v)v) \leq \sup_{t\geq 0} I(tv) < \frac{1}{4}S^2. \tag{2.20}$$

Then by (2.20) and Lemma 2.6, we know that there exists a convergent subsequence of $\{u_n\}$ (still denoted by $\{u_n\}$), such that $u_n \to u$ in $H_0^1(\Omega)$ as $n \to \infty$, which implies that $I(u) = c_0$ and $I'(u) = 0$, i.e., u is a nontrivial mountain pass type solution to problem (1.1). The proof is complete. □

From Lemma 2.7 it is easily seen that a nontrivial nonnegative mountain pass type solution to problem (1.1) follows once we can find a $v \in H_0^1(\Omega) \setminus \{0\}$ such that (2.18) holds. This is done with the help of some delicate estimates on the truncated Talenti's functions, inspired mainly by Brézis and Nirenberg [2], Deng et al. [3] and Li et al. [5].

For any $\varepsilon > 0$, define

$$U_\varepsilon(x) = \frac{\sqrt{8}\varepsilon}{\varepsilon^2 + |x|^2}, \qquad x \in \mathbb{R}^4. \tag{2.21}$$

It is well known that $U_\varepsilon(x)$ is a solution to the critical problem

$$-\Delta u = u^3, \qquad x \in \mathbb{R}^4,$$

which is also a minimizer for S.

Lemma 2.8. *Let $\varphi \in C_0^\infty(\Omega)$ satisfy $0 \leq \varphi(x) \leq 1$ in Ω and*

$$\varphi(x) = \begin{cases} 1, & |x| < R, \\ 0, & |x| > 2R, \end{cases}$$

where $R > 0$ is a constant such that $B_{2R}(0) \subset \Omega$. Set $u_\varepsilon(x) = \varphi(x)U_\varepsilon(x)$. Then, as $\varepsilon \to 0$,

$$\begin{aligned} \|u_\varepsilon\|^2 &= S^2 + O(\varepsilon^2), \\ \|u_\varepsilon\|_4^4 &= S^2 + O(\varepsilon^4), \end{aligned} \tag{2.22}$$

$$\|u_\varepsilon\|_q^q = O(\varepsilon^{4-q}), \qquad 2 < q < 4, \tag{2.23}$$

and

$$\int_\Omega |u_\varepsilon|^q \ln u_\varepsilon^2 dx = C\varepsilon^{4-q}\ln\left(\frac{1}{\varepsilon}\right) + O(\varepsilon^{4-q}). \tag{2.24}$$

Proof. (2.22) is well known and can be referred, for example, to [2] and [3]. We only prove (2.23) and (2.24).

By the definition of u_ε, one has

$$\begin{aligned}\|u_\varepsilon\|_q^q &= C\int_{B_{2R}} \frac{\varphi^q(x)\varepsilon^q}{(\varepsilon^2+|x|^2)^q}\mathrm{d}x\\ &= C\int_{B_R} \frac{\varepsilon^q}{(\varepsilon^2+|x|^2)^q}\mathrm{d}x + C\int_{B_{2R}\setminus B_R} \frac{\varphi^q(x)\varepsilon^q}{(\varepsilon^2+|x|^2)^q}\mathrm{d}x\\ &= I_1 + O(\varepsilon^q).\end{aligned}$$

By direct computation, we obtain

$$\begin{aligned}I_1 &= C\int_{B_{R/\varepsilon}} \frac{\varepsilon^q\cdot\varepsilon^4}{\varepsilon^{2q}(1+|y|^2)^q}\mathrm{d}y = C\varepsilon^{4-q}\int_0^{R/\varepsilon}\frac{r^3}{(1+r^2)^q}\mathrm{d}r\\ &= C\varepsilon^{4-q}\left(\int_0^\infty \frac{r^3}{(1+r^2)^q}\mathrm{d}r - \int_{R/\varepsilon}^\infty \frac{r^3}{(1+r^2)^q}\mathrm{d}r\right)\\ &= C\varepsilon^{4-q} - O(\varepsilon^q),\end{aligned}$$

where we have used the fact that

$$\left|\int_{R/\varepsilon}^\infty \frac{r^3}{(1+r^2)^q}\mathrm{d}r\right| \le \int_{R/\varepsilon}^\infty r^{3-2q}\mathrm{d}r = O(\varepsilon^{2q-4}).$$

Therefore,

$$\|u_\varepsilon\|_q^q = C\varepsilon^{4-q} + O(\varepsilon^q) = O(\varepsilon^{4-q}).$$

Next we prove (2.24). Set

$$\begin{aligned}J &= \int_\Omega |u_\varepsilon|^q \ln u_\varepsilon^2 \mathrm{d}x\\ &= \int_\Omega \varphi^q(x)U_\varepsilon^q(x)\ln\varphi^2(x)\mathrm{d}x + \int_\Omega \varphi^q(x)U_\varepsilon^q(x)\ln U_\varepsilon^2(x)\mathrm{d}x\\ &= \int_\Omega \varphi^q(x)U_\varepsilon^q(x)\ln\varphi^2(x)\mathrm{d}x + \int_{B_R} U_\varepsilon^q(x)\ln U_\varepsilon^2(x)\mathrm{d}x + \int_{B_{2R}\setminus B_R}\varphi^q(x)U_\varepsilon^q(x)\ln U_\varepsilon^2(x)\mathrm{d}x\\ &= J_1 + J_2 + J_3,\end{aligned} \tag{2.25}$$

where

$$|J_1| = \left|\int_{B_{2R}\setminus B_R}\varphi^q(x)U_\varepsilon^q(x)\ln\varphi^2(x)\mathrm{d}x\right| \le C\int_{B_{2R}\setminus B_R} U_\varepsilon^q(x)\mathrm{d}x = O(\varepsilon^q). \tag{2.26}$$

By applying (2.1) with $\delta_1 \in (0, 2q-4)$ to J_3, one has

$$|J_3| \le C_{\delta_1}\int_{B_{2R}\setminus B_R}\left(U_\varepsilon^{q-\delta_1}(x) + U_\varepsilon^{q+\delta_1}(x)\right)\mathrm{d}x = O(\varepsilon^{q-\delta_1}). \tag{2.27}$$

To estimate J_2, we rewrite it as follows:

$$\begin{aligned}
J_2 =& \int_{B_R} U_\varepsilon^q(x)\ln U_\varepsilon^2(x)\mathrm{d}x \\
=& C\int_{B_R}\frac{\varepsilon^q}{(\varepsilon^2+|x|^2)^q}\ln\left(\frac{C\varepsilon^2}{(\varepsilon^2+|x|^2)^2}\right)\mathrm{d}x \\
=& C\varepsilon^{4-q}\int_{B_{R/\varepsilon}}\frac{1}{(1+|y|^2)^q}\ln\left(\frac{C}{\varepsilon^2(1+|y|^2)^2}\right)\mathrm{d}y \\
=& C\varepsilon^{4-q}\ln\left(\frac{1}{\varepsilon}\right)\int_{B_{R/\varepsilon}}\frac{1}{(1+|y|^2)^q}\mathrm{d}y + C\varepsilon^{4-q}\int_{B_{R/\varepsilon}}\frac{1}{(1+|y|^2)^q}\ln\left(\frac{C}{1+|y|^2}\right)\mathrm{d}y \\
=& C\varepsilon^{4-q}\ln\left(\frac{1}{\varepsilon}\right)\left[\int_{\mathbb{R}^4}\frac{1}{(1+|y|^2)^q}\mathrm{d}y - \int_{B^c_{R/\varepsilon}}\frac{1}{(1+|y|^2)^q}\mathrm{d}y\right] \\
&+ C\varepsilon^{4-q}\int_{B_{R/\varepsilon}}\frac{1}{(1+|y|^2)^q}\ln\left(\frac{C}{1+|y|^2}\right)\mathrm{d}y \\
=& C\varepsilon^{4-q}\ln\left(\frac{1}{\varepsilon}\right) - C\varepsilon^{4-q}\ln\left(\frac{1}{\varepsilon}\right)\int_{B^c_{R/\varepsilon}}\frac{1}{(1+|y|^2)^q}\mathrm{d}y \\
&+ C\varepsilon^{4-q}\int_{B_{R/\varepsilon}}\frac{1}{(1+|y|^2)^q}\ln\left(\frac{C}{1+|y|^2}\right)\mathrm{d}y,
\end{aligned} \tag{2.28}$$

where

$$\left|\int_{B^c_{R/\varepsilon}}\frac{1}{(1+|y|^2)^q}\mathrm{d}y\right| \le C\int_{R/\varepsilon}^{\infty}\frac{r^3}{(1+r^2)^q}\mathrm{d}r = O(\varepsilon^{2q-4}). \tag{2.29}$$

The last term in (2.28) can be estimated as follows:

$$\begin{aligned}
&\left|\int_{B_{R/\varepsilon}}\frac{1}{(1+|y|^2)^q}\ln\left(\frac{C}{1+|y|^2}\right)\mathrm{d}y\right| \\
&= \left|\int_{\mathbb{R}^4}\frac{1}{(1+|y|^2)^q}\ln\left(\frac{C}{1+|y|^2}\right)\mathrm{d}y - \int_{B^c_{R/\varepsilon}}\frac{1}{(1+|y|^2)^q}\ln\left(\frac{C}{1+|y|^2}\right)\mathrm{d}y\right| \\
&= \left|C - \int_{B^c_{R/\varepsilon}}\frac{1}{(1+|y|^2)^q}\ln\left(\frac{C}{1+|y|^2}\right)\mathrm{d}y\right| \\
&\le C + C_{\delta_2}\int_{B^c_{R/\varepsilon}}\left(\frac{1}{(1+|y|^2)^{q-\delta_2}} + \frac{1}{(1+|y|^2)^{q+\delta_2}}\right)\mathrm{d}y \\
&= C + O(\varepsilon^{2q-4-2\delta_2}),
\end{aligned} \tag{2.30}$$

where we have used (2.1) with $\delta_2 \in (0, q-2)$. Substituting (2.26)–(2.30) into (2.25) and noticing the choice of δ_1 and δ_2 one sees that

$$\begin{aligned}
J &= O(\varepsilon^q) + C\varepsilon^{4-q}\ln\left(\frac{1}{\varepsilon}\right) + O\left(\varepsilon^q\ln\left(\frac{1}{\varepsilon}\right)\right) + O(\varepsilon^{4-q}) + O(\varepsilon^{q-2\delta_2}) + O(\varepsilon^{q-\delta_1}) \\
&= C\varepsilon^{4-q}\ln\left(\frac{1}{\varepsilon}\right) + O(\varepsilon^{4-q}).
\end{aligned}$$

Therefore, (2.24) is valid. The proof is complete. □

On the basis of the estimates in Lemma 2.8, we can find a $v \in H_0^1(\Omega)\setminus\{0\}$ such that (2.18) holds.

Lemma 2.9. *Assume that $q \in (2,4)$ and $\lambda > 0$. Then for $\varepsilon > 0$ suitably small, we have*

$$\sup_{t\geq 0} I(tu_\varepsilon) < \frac{1}{4}S^2. \tag{2.31}$$

Proof. Let u_ε be given in Lemma 2.8 and set $\psi_{u_\varepsilon}(t) = I(tu_\varepsilon)$. Then $\lim_{t\to 0}\psi_{u_\varepsilon}(t) = 0$, $\psi_{u_\varepsilon}(t) > 0$ for suitably small $t > 0$ and $\lim_{t\to+\infty}\psi_{u_\varepsilon}(t) = -\infty$ uniformly for $\varepsilon \in (0,\varepsilon_1)$, where $\varepsilon_1 > 0$ is a suitably small but fixed number. Consequently, for each $\varepsilon \in (0,\varepsilon_1)$, there exists a $t_\varepsilon \in (0,+\infty)$ such that

$$\sup_{t\geq 0} I(tu_\varepsilon) = \sup_{t\geq 0}\psi_{u_\varepsilon}(t) = \psi_{u_\varepsilon}(t_\varepsilon),$$

and

$$\psi'_{u_\varepsilon}(t_\varepsilon) = t_\varepsilon\left(\|u_\varepsilon\|^2 - \lambda t_\varepsilon^{q-2}\int_\Omega |u_\varepsilon|^q \ln(t_\varepsilon u_\varepsilon)^2 \mathrm{d}x - t_\varepsilon^2\|u_\varepsilon\|_4^4\right) = 0,$$

which implies that

$$\|u_\varepsilon\|^2 = t_\varepsilon^2\|u_\varepsilon\|_4^4 + \lambda t_\varepsilon^{q-2}\int_\Omega |u_\varepsilon|^q \ln u_\varepsilon^2 \mathrm{d}x + \lambda t_\varepsilon^{q-2}\ln t_\varepsilon^2\|u_\varepsilon\|_q^q. \tag{2.32}$$

Combining (2.22)–(2.24) with (2.32) we see that there exist $0 < T_0 < T^0$ such that, for $\varepsilon > 0$ uniformly small,

$$T_0 \leq t_\varepsilon \leq T^0. \tag{2.33}$$

By the boundedness of t_ε and (2.22)–(2.24) one gets

$$\begin{aligned}
\sup_{t\geq 0} I(tu_\varepsilon) = I(t_\varepsilon u_\varepsilon) &= \frac{1}{2}t_\varepsilon^2\|u_\varepsilon\|^2 - \frac{1}{4}t_\varepsilon^4\|u_\varepsilon\|_2^4 + \frac{2\lambda}{q^2}t_\varepsilon^q\|u_\varepsilon\|_q^q - \frac{\lambda}{q}\int_\Omega |t_\varepsilon u_\varepsilon|^q \ln(t_\varepsilon u_\varepsilon)^2 \mathrm{d}x \\
&= \frac{1}{2}t_\varepsilon^2\|u_\varepsilon\|^2 - \frac{1}{4}t_\varepsilon^4\|u_\varepsilon\|_2^4 + \frac{\lambda}{q}t_\varepsilon^q\left(\frac{2}{q} - \ln t_\varepsilon^2\right)\|u_\varepsilon\|_q^q - \frac{\lambda}{q}t_\varepsilon^q\int_\Omega |u_\varepsilon|^q \ln u_\varepsilon^2 \mathrm{d}x \\
&= \left(\frac{1}{2}t_\varepsilon^2 - \frac{1}{4}t_\varepsilon^4\right)\left(S^2 + O(\varepsilon^2)\right) + O(\varepsilon^{4-q}) - \frac{\lambda}{q}t_\varepsilon^q\left(C\varepsilon^{4-q}\ln\left(\frac{1}{\varepsilon}\right) + O(\varepsilon^{4-q})\right) \\
&\leq \frac{1}{4}S^2 + O(\varepsilon^2) + O(\varepsilon^{4-q}) - C\varepsilon^{4-q}\ln\left(\frac{1}{\varepsilon}\right).
\end{aligned} \tag{2.34}$$

Since $2 < q < 4$, we see that

$$\lim_{\varepsilon\to 0}\frac{\varepsilon^2}{\varepsilon^{4-q}\ln\left(\frac{1}{\varepsilon}\right)} = 0, \qquad \lim_{\varepsilon\to 0}\frac{\varepsilon^{4-q}}{\varepsilon^{4-q}\ln\left(\frac{1}{\varepsilon}\right)} = 0. \tag{2.35}$$

Consequently, it follows from (2.34) and (2.35) that $\sup_{t\geq 0} I(tu_\varepsilon) < \frac{1}{4}S^2$ for sufficiently small $\varepsilon > 0$. The proof is complete. □

With the above lemmas at hand, we are now in the position to prove Theorem 1.1.

Proof of Theorem 1.1. Assume that $q \in (2,4)$ and $\lambda > 0$. By virtue of Lemmas 2.5, 2.7 and 2.9 we know that problem (1.1) admits a nontrivial mountain pass type solution u. The nonnegativity of u follows from the nonnegativity of the (PS) sequence $\{u_n\}$ which we have assumed without loss of generality to be valid since the energy functional $I(u)$ satisfies $I(u) = I(|u|)$ for any $u \in H_0^1(\Omega)$. Finally, by applying the standard arguments used in the proof of Theorem 1.2 in [3] we can show that the solution is positive in Ω. The proof is complete. □

Remark 2.10. Although we only consider problem (1.1) when the space dimension $N = 4$, the same result can be obtained for general $N \geq 5$ with little modification when $q \in (2, \frac{2N}{N-2})$ and $\lambda > 0$. Interested readers may check it themselves.

Abstract. In this paper, under the condition that there exists an ordered interval composed of two internal ordered intervals which have the location similar to that of Amann's three-solution theorem, we add some simple conditions and then we obtain some results about the existence of multiple critical points inside and outside the ordered interval. The main results of this paper can be regarded as an extension of the classical Amann three-solution theorem and the mountain pass lemma on the ordered interval of Shujie Li and Zhiqiang Wang. To show our main results, we extend the method of invariant sets of descending flow that proposed by Jingxian Sun for smooth functionals to the locally Lipschitz functionals. Our main results can be applied to the study of differential inclusion problems with concave-convex nonlinearity. In this way, we partially extend some relevant results concerning the differential equation boundary value problems with a concave-convex nonlinearity that was first studied by A. Ambrosetti, H. Brezis and G. Cerami.

Keywords: locally Lipschitz functionals, critical points, differential inclusion problems.

1 Introduction

In the study of nonlinear functional, ordered intervals are often used to study the existence of critical points or fixed points. It is well known that under simpler conditions, one can get the result that there is at least one critical point or fixed point in the ordered interval. If the ordered interval has a finer internal structure, one can often get multiple fixed points or critical points. A famous result of this is Amann's three-solution theorem [1]. In the case of the ordered interval composed of two pairs of upper and lower solutions, Amann used the fixed point index method to prove that there are at least three fixed points in the ordered interval. Later, Li and Wang [20] generalize this result to smooth functionals using the method of invariant set of descending flow, and establish the mountain pass theorem in the ordered interval.

✉Corresponding author. Email: qinbaoxia@126.com

In [20], as an application of their mountain pass theorem in the ordered interval, Li and Wang studied the multiple solutions of the boundary value problem

$$\begin{cases} -\Delta u = \lambda |u|^{q-2}u + g(u) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.1$_\lambda$}$$

where $\Omega \subset \mathbb{R}^N$ is a bounded domain, $\lambda > 0$ is a parameter, $1 < q < 2$ and $g(u)$ is a superlinear term. The nonlinearity of (1.1$_\lambda$) may involve a combination of concave and convex terms. This type of nonlinearity has been studied for a long times and has been extensively studied by many authors; See [2, 10, 16, 20, 28] and the references therein. A. Ambrosetti, H. Brezis, G. Cerami in their well known paper [2] firstly considered the boundary value problem with a concave-convex terms nonlinearity

$$\begin{cases} -\Delta u = \lambda u^q + u^p & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.2$_\lambda$}$$

where $0 < q < 1 < p$ and $\lambda > 0$ be a parameter. They fund a $\Lambda > 0$ such that (1.2$_\lambda$) has two positive solutions for all $\lambda \in (0, \Lambda)$, at least one positive solution for $\lambda = \Lambda$ and has no positive for all $\lambda > \Lambda$. Li and Wang [20] fund a $\lambda^* > 0$ such that for $\lambda \in (0, \lambda^*)$, (1.1$_\lambda$) has at least two positive solutions, at least two negative solutions and at least two sign-changing solutions. Their proof method is to combine the mountain pass lemma in the ordered interval with the invariant set method of descending flow. They first established two pairs of upper and lower solutions which have the location similar to those of H. Amann's three solution theorem. Then, by using the mountain pass theorem in the ordered interval they obtained the result of at least one positive critical point, one negative critical point and one sign-changing critical point inside the ordered interval, and by using the invariant set method of descending flow obtained the result of at least one positive critical point, one negative critical point and one sign-changing critical point outside the ordered interval.

Inspired by Li and Wang's idea of proof, in the present paper we will establish some results about multiple critical points for locally Lipschitz functionals inside and outside the ordered interval composed of two internal ordered intervals, which have the location similar to that of Amann's three-solution theorem. In the last 40 years, critical point theories and their applications for locally Lipschitz functionals have been extensively studied by many peoples; see [5–8, 12, 13, 17, 18, 23–25, 27] . Our main results in this paper can be thought as an extension of Amann's three solutions theorem and Li and Wang's mountain pass theorem in ordered intervals. By adding some simple conditions, we obtain the existence of critical points both inside and outside the ordered interval. Also, in this paper we introduce an ordering in the Banach space and give the locations of theses critical points.

To show our main results, we will employ the invariant set method of descending flow proposed by Sun [32]. For theories of invariant set of descending flow of C^1 functionals, one can also refer to [22]. According to this method, finding different critical points may be attributed to finding different invariant sets of descending flow. So far, it has been widely used to study the existence of solutions of various of elliptic equation boundary value problems. However, to our best knowledge, there are no one study the existence of critical points for locally Lipschitz functionals by using this method. There are two main difficulties to use the method of invariant sets of descending flow finding critical points of locally Lipschitz functionals. As is well known, to use the method of invariant sets of descending flow for C^1 functionals one need first construct a pseudogradient vector field over the Banach space. However, for the

Lipschitz functional case, one usually only can construct locally a pseudogradient vector field over a subset of the Banach space rather than the whole Banach space. This is the first difficulty need to overcome. In the course of the study, one need to determine whether a closed convex set is an invariant set of the descending flow generated by the pseudogradient vector field. In the cases of the functionals being of C^1, one can use the Schauder invariance condition presented in the literatures [22, 32, 33]. However, in the cases of the functionals being of locally Lipschitz, no one has yet used the Schauder invariance condition to establish invariant flows on convex closed sets. This is the second difficulty we face.

In this paper, we will analyze the energy of the possible critical points of the locally Lipschitz functionals in advance, construct locally a pseudogradient vector field on a neighborhood of the energy, and then extend this pseudogradient vector field to the entire Banach space. We can then use the method of invariant sets of descending flow that Sun have proposed to obtain the existence results for the critical points of the locally Lipschitz functionals. By this way we overcome the first difficulty. For the second difficulty, based on the conclusion in [25] about the relationship between the critical points on the whole space and the critical points on the closed convex sets under the Schauder invariance condition, and using the Von Neumann theorem to establish the descending flow on closed convex sets, we get the result that some closed convex sets are descending flow invariant sets. In this paper we get the theoretical results for the existence of at least one sign-changing, at least one nontrivial, at least two positive and at least two negative critical points of the locally Lipschitz functionals considered. The theoretical results can be applied to the study of the existence of sign-changing solutions, positive solutions and negative solutions for differential inclusion problems with a concave-convex nonlinearity terms. In this way, we extend the relevant results on concave-convex nonlinearity terms in literatures.

The critical points of this paper are in the sense of Chang [6]. The study of critical points of non-smooth functional has been greatly developed in the last thirty years. Some peoples have studied the critical point of the Motreanu–Panagiotopopoulos functionals [26, 29, 34]. This kind of functional has the form: $f := h + \psi$, with h a locally Lipschitz functional and ψ a covex,proper and l.s.c. functional. The Motreanu–Panagiotopopoulos critical point theory contain as particular cases both the the critical point theory in the sense of Chang as well as in the sense of Szulkin [34]. Obviously, how to study the critical point theory of the Motreanu–Panagiotopopoulos functionals in Banach space by using the invariant set method of descending flow is an interesting problem worthy of further study.

2 Preliminaries

In what follows we will let X and E be two real Banach spaces with the norms $\|\cdot\|$ and $\|\cdot\|_1$, respectively. Assume that X is reflexive, E is densely and continuously embedded in X. Let X^* be the topological dual of X and $\langle\cdot,\cdot\rangle$ denote the duality pairing between X^* and X. Let P be a cone of X, that is, P is closed convex set in X, $\lambda x \in P$ for all $x \in P$ and $\lambda \geqslant 0$, and $P \cap (-P) = \{0\}$. The P is said to be generating if $X = P - P$. Let $P_1 = P \cap E$. Then P_1 is a cone in E. We assume that P_1 has a nonempty interior in the E topology, and denote its interior in the E topology by $\operatorname{int} P_1$. For each $x, y \in X$, let us define the ordering $\leqslant$ in X by

$$x \leqslant y \quad \text{if and only if} \quad y - x \in P.$$

For each $x, y \in E$, if $y - x \in \operatorname{int} P_1$, we write $x \ll y$. For $x \in X$ and $A \subset X$, let $\operatorname{dist}(x, A) = \inf_{y\in A} \|x - y\|$. For any $R > 0$, let $B(0, R) = \{x \in X : \|x\| < R\}$ and $S_R = \{x \in X : \|x\| = R\}$.

Given $B \subset A \subset E$, we write $\partial_A B$ for the boundary of B in A and $\operatorname{int}_A B$ for the interior of B in A.

Let us recall some theories concerning the sub-differential theory of locally Lipschitz functionals due to Clarke [7]. A functional $\varphi : X \to \mathbb{R}$ is said to be locally Lipschitz, if for every $x \in X$, there exists a neighborhood U of x and a constant $k > 0$ depending on U such that $|\varphi(z) - \varphi(y)| \leqslant k\|z - y\|$ for all $z, y \in U$. For such a functional we define generalized directional derivative $\varphi^0(x; h)$ at $x \in X$ in the direction $h \in X$ by

$$\varphi^0(x; h) = \limsup_{x' \to x \ \lambda \downarrow 0^+} \frac{\varphi(x' + \lambda h) - \varphi(x')}{\lambda}.$$

The function $h \mapsto \varphi^0(x; h)$ is sublinear, continuous. So by the Hahn–Banach theorem we know that $\varphi^0(x; \cdot)$ is the support function of a nonempty, convex and w^*-compact set

$$\partial\varphi(x) = \{x^* \in X^* : \langle x^*, h\rangle \leqslant \varphi^0(x; h) \text{ for all } h \in X\}.$$

The set $\partial\varphi(x)$ is called the generalized or Clarke sub-differential of φ at x. A point $x \in X$ is a critical point of φ if $0 \in \partial\varphi(x)$. Let $\mathbb{K} = \{x \in X : 0 \in \partial\varphi(x)\}$.

Proposition 2.1 ([5, 12]). *1) If $\varphi, \psi : X \to \mathbb{R}$ are locally Lipschitz functionals, then $\partial(\varphi + \psi)(x) \subset \partial\varphi(x) + \partial\psi(x)$, while for any $\lambda \in \mathbb{R}$ we have $\partial(\lambda\varphi)(x) = \lambda\partial\varphi(x)$; 2) If $\varphi : X \to \mathbb{R}$ is also convex, then this sub-differential coincides with the sub-differential in the sense of convex analysis. If φ is strictly differentiable, then $\partial\varphi(x) = \{\varphi'(x)\}$; 3) If $\varphi : X \to \mathbb{R}$ is locally Lipschitz functional, $\partial\varphi(u)$ is a weakly*-compact subset of X^* which is bounded by the Lipschitz constant $k > 0$ of φ near u.*

S. T. Kyritsi and N. S. Papageorgiou [18] developed a critical point theory for non-smooth locally Lipschitz functionals defined on a closed, convex set extending this way the work of Struwe. Let $C \subset X$ be a nonempty, non-singleton, closed and convex set. For $x \in C$ we define

$$m_C(x) = \inf_{x^*} \sup_{y} \{\langle x^*, x - y\rangle : y \in C, \|x - y\| < 1, x^* \in \partial\varphi(x)\}.$$

Evidently, $m_C(x) \geqslant 0$ for all $x \in C$. This quantity can be viewed as a measure of the generalized slope of φ at $x \in C$. If φ admits an extension $\hat{\varphi} \in C^1(X)$, then $\partial\varphi(x) = \{\varphi'(x)\}$ and so we have

$$m_C(x) = \sup\{\langle \varphi'(x), x - y\rangle : y \in C, \|x - y\| < 1\},$$

which is the quantity used by Struwe [31, p. 147]. Also if $C = X$, then we have

$$m_C(x) = m(x) = \inf\{\|x^*\|_* : x^* \in \partial\varphi(x)\},$$

which is the quantity used by Chang [6].

Now let us introduce the outwardly directed condition and the Schauder invariance condition for set value mappings in a manner as in [25]. Let X be reflexive. As usual, we will identify X^{**} with X while $\mathsf{F} : X^* \mapsto 2^X$ will denote the duality map, given by

$$\mathsf{F}(x^*) := \{x \in X : \langle x^*, x\rangle = \|x^*\|_*^2 = \|x\|^2\}, \qquad \forall x^* \in X^*.$$

The set $\mathsf{F}(x^*)$ turns out to be nonempty, convex, and closed; see, e.g. [13, pp. 311–319]. Define

$$\nabla\varphi(x) := \mathsf{F}(\partial\varphi(x)), \qquad x \in X. \tag{2.1}$$

Clearly, $\nabla\varphi(x)$ depends on the choice of the duality pairing between X and X^* whenever it is compatible with the topology of X. If X is a Hilbert space, the duality paring becomes the scalar product and (2.1) gives the usual gradient. Write I for the identity operator on X.

Suppose C is a convex and closed set of X. Let $\delta_C : X \to \mathbb{R} \cup \{+\infty\}$ be the indicator function of C, namely

$$\delta_C(x) := \begin{cases} 0, & \text{if } x \in C, \\ +\infty, & \text{otherwise.} \end{cases}$$

Then we have

$$\partial\delta_C(x) = \left\{x^* \in X^* : \langle x^*, z - x\rangle \leqslant 0, \forall z \in C\right\}$$

The set $\partial\delta_C(x)$ is usually called normal cone to C at x.

Definition 2.2. Suppose X is reflexive, C is a convex and closed set of X, $\varphi : X \mapsto \mathbb{R}$ is locally Lipschitz continuous. If $(-\partial\delta_C(x)) \cap \partial\varphi(x) \subset \{0\}$ for any $x \in \partial C$ when $\operatorname{int} C \neq \emptyset$, or for any $x \in C$ when $\operatorname{int} C = \emptyset$, then we say that $\partial\varphi$ turns out to be outwardly directed on C. This clearly rewrites as

$$\forall z^* \in \partial\varphi(x)\backslash\{0\} \quad \text{there exists} \quad z \in C \quad \text{fulfilling} \quad \langle z^*, z - x\rangle < 0.$$

Definition 2.3 (Schauder invariance condition)**.** Suppose X is reflexive, C is a convex and closed set of X, $\varphi : X \mapsto \mathbb{R}$ is locally Lipschitz continuous. Then we say φ satisfies the Schauder invariance condition on C if $\big(I - \nabla\varphi\big)(\partial C) \subset C$ when $\operatorname{int} C \neq \emptyset$, if $\big(I - \nabla\varphi\big)(C) \subset C$ when $\operatorname{int} C = \emptyset$

Remark 2.4. Definition 2.2 and 2.3 essentially come from [25]. However, there are some subtle differences here and [25]. The well known Schauder invariance condition for a C^1-functional φ on a Hilbert space X reads as $(I - \varphi')(C) \subset C$; see [15, 22, 32, 33]. It has been extend to Banach spaces in [19]. The notation of Schauder invariance condition was firstly put forward by J. Sun in [33].

It follows from [25, Theorem 4.4 and 4.5] we have the following Lemma 2.5.

Lemma 2.5. *Suppose X is reflexive, C is a convex and closed set of X, $\varphi : X \mapsto \mathbb{R}$ is locally Lipschitz continuous, φ is outwardly directed on C or φ satisfies the Schauder invariance condition on C. Then $m_C(x) = 0$ if and only if $m(x) = 0$.*

Lemma 2.6 ([30], von Neumann)**.** *Let X, Y be two Hausdorff topological linear spaces, $C \subset X$, $D \subset Y$ be two convex and compact sets. Let $\psi : X \times Y \mapsto \mathbb{R}$ satisfy:*

1) $x \mapsto \psi(x, y)$ is upper semi-continuous (usc.) and concave;

2) $y \mapsto \psi(x, y)$ is lower semi-continuous (lsc.) and convex.

Then ψ has at least one saddle point $(\bar{x}, \bar{y}) \in C \times D$, that is

$$\psi(x, \bar{y}) \leqslant \psi(\bar{x}, \bar{y}) \leqslant \psi(\bar{x}, y) \quad \text{for } (x, y) \in C \times D.$$

Definition 2.7. Let D be a nonempty closed subset of X. We say that φ satisfies the non-smooth CPS-condition on D, denoted by $(CPS)_D$, if every sequence $\{x_n\} \subset D$ such that $\{\varphi(x_n)\}$ is bounded and $(1 + \|x_n\|)m_D(x_n) \to 0$ as $n \to \infty$, has a convergent subsequence. If $D = X$, denoted simply by (CPS).

The following Lemma 2.8 comes from [4, p. 63], in which X is required to be a Hilbert space. However, we can easily see that the conclusion also holds if we assume that X is a real Banach space.

Lemma 2.8 ([4]). *Let C be a convex set of X. Then for all $x \in \operatorname{int} C$ and $y \in \bar{C}$, $\alpha x + (1-\alpha)y \subset \operatorname{int} C$ for all $\alpha \in (0,1]$.*

Proposition 2.9. *Assume that X is reflexive, C is a convex and closed set of X, $x_0 \in C$, $\varphi : X \mapsto \mathbb{R}$ is locally Lipschitz. Then there exists $(x_0^*, u(x_0)) \in \partial\varphi(x_0) \times \big((x_0 - C) \cap \bar{B}(0,1)\big)$ such that $m_C(x_0) = \langle x_0^*, u(x_0)\rangle$. In particular, $m(x_0) = \langle x_0^*, u(x_0)\rangle$ for some $(x_0^*, u(x_0)) \in \partial\varphi(x_0) \times \bar{B}(x_0, 1)$ if $X = C$.*

Proof. Let X_w and X_w^* be the spaces X and X^* equipped with their weak topology respectively. Since X is reflexive, it follows from Proposition 2.1 that $\partial\varphi(x_0)$ is a compact set in X_w^*. Obviously, $\big(x_0 - C\big) \cap \bar{B}(0,1)$ is a compact set in X_w. Let $\psi : \big((x_0 - C) \cap \bar{B}(0,1)\big) \times \partial\varphi(x_0) \mapsto \mathbb{R}$ be defined by $\psi(x, y^*) = \langle y^*, x\rangle$ for any $(x, y^*) \in \big((x_0 - C) \cap \bar{B}(0,1)\big) \times \partial\varphi(x_0)$. It follows from Lemma 2.6 that ψ has at least one saddle point $(u(x_0), x_0^*) \in \big((x_0 - C) \cap \bar{B}(0,1)\big) \times \partial\varphi(x_0)$, that is

$$\langle x_0^*, x\rangle \leqslant \langle x_0^*, u(x_0)\rangle \leqslant \langle x^*, u(x_0)\rangle, \qquad \forall x^* \in \partial\varphi(x_0), x \in (x_0 - C) \cap \bar{B}(0,1).$$

Hence, $m_C(x_0) = \langle x_0^*, u(x_0)\rangle$. The proof is complete. □

Remark 2.10. By using Proposition 2.9 we can find $(u(x_0), x_0^*) \in \big((x_0 - C) \cap \bar{B}(0,1)\big) \times \partial\varphi(x_0)$ such that $m_C(x_0) = \langle x_0^*, u(x_0)\rangle$. By this way we give an unified treatment for the case $C = X$ in [6] and the case C being a proper closed and convex set in [18]. It should be pointed out that in order to prove Proposition 2.9, we only need C to be weakly sequence compact not weakly compact. A direct proof of Proposition 2.9 can be found in the Appendix.

Proposition 2.11. *Assume that X is reflexive, C is a convex and closed set of X, $\varphi : X \mapsto \mathbb{R}$ is locally Lipschitz, $(I - \nabla\varphi)(C) \subset C$. Then*

$$m_C(x) \geqslant \min\left\{\frac{1}{2}, m(x)\right\} m(x) \quad \text{for all } x \in C. \tag{2.2}$$

Proof. It follows from of Proposition 2.9 that for each $x_0 \in C$, there exists $(u(x_0), x_0^*) \in \big(\{x_0\} - C\big) \cap \bar{B}(0,1)\big) \times \partial\varphi(x_0)$ satisfying $m_C(x_0) = \langle x_0^*, u(x_0))$. Take $y_0 \in \{x_0\} - \mathsf{F}(x_0^*)$. It follows from the condition $(I - \nabla\varphi)(C) \subset C$ that $y_0 \in C$. So, if $\|x_0 - y_0\| < 1$,

$$m_C(x_0) = \langle x_0^*, u(x_0))\rangle \geqslant \langle x_0^*, x_0 - y_0\rangle = \langle x_0^*, \mathsf{F}(x_0^*)\rangle = \|x_0^*\|_*^2 \geqslant m^2(x_0);$$

if $\|x_0 - y_0\| \geqslant 1$, let $z_0 = x_0 + \frac{y_0 - x_0}{2\|x_0 - y_0\|}$, we have $z_0 \in C$ and $\|x_0 - z_0\| = \frac{1}{2}$, and so

$$\begin{aligned} m_C(x_0) = \langle x_0^*, u(x_0))\rangle &\geqslant \langle x_0^*, x_0 - z_0\rangle \\ &= \frac{1}{2\|x_0 - y_0\|}\langle x_0^*, x_0 - y_0\rangle \\ &= \frac{1}{2\|x_0\|_*}\|x_0^*\|_*^2 = \frac{1}{2}\|x_0^*\|_* \geqslant \frac{1}{2}m(x_0) \end{aligned}$$

So, (2.2) holds. The proof is complete. □

Definition 2.12. Let D be a nonempty closed subset of X. We say that φ satisfies the nonsmooth PS-condition on D, denoted by $(PS)_D$, if every sequence $\{x_n\} \subset D$ such that $\{\varphi(x_n)\}$ is bounded and $m_D(x_n) \to 0$ as $n \to \infty$, has a convergent subsequence. If $D = X$, denoted simply by (PS).

Remark 2.13. Assume that all conditions of Proposition 2.11 hold. Then, by (2.2), we see that φ satisfies the condition $(PS)_C$ if and only if φ satisfies the condition (PS) for each convex and closed set C. Moreover, $m_C(x_0) = 0$ if and only if $m(x_0) = 0$ for $x_0 \in C$. So, we can deduce Lemma 2.5 by (2.2) if φ satisfies the Schauder invariance condition.

Lemma 2.14 ([10]). *Assume U is bounded connected open set of $\mathbb{R}^2$ and $(0,0) \in U$, then there exists a connected component Γ' of the boundary of U, such that each one side ray l emitting from the origin satisfies $l \cap \Gamma' \neq \emptyset$.*

3 Main results

3.1 Critical points outside the ordered interval

Let $u_0, v_1 \in E$ be such that $u_0 \ll 0 \ll v_1$. Set $D_1 = [u_0, v_1]$ and $G_1 = D_1 \cap E$. Now let us introduce the following conditions:

(H_1) $\varphi^{-1}([a,b]) \cap \mathbb{K}$ is compact in E for each $a < b$;

(H_2) φ satisfies the conditions (CPS), $(CPS)_{\pm P}$ and $(CPS)_D$ for any ordered interval D in X;

(H_3) there exist subspace E_1 of E and $R_0 > 0$ such that $\dim E_1 = 2$,

$$E_1 \cap D_1 \subset B(0, R_0), \ E_1 \cap \operatorname{int} P_1 \neq \emptyset \tag{3.1}$$

and

$$\alpha_0 := \max_{u \in S_{R_0} \cap E_1} \varphi(u) < \beta_0 := \inf_{u \in D_1} \varphi(u). \tag{3.2}$$

We have the following result concerning the existence of multiple critical points outside the ordered interval D_1.

Theorem 3.1. *Suppose that (H_1)$\sim$(H_3) hold, φ has no nontrivial critical point on $\partial_E(\pm P_1)$ and $\partial_E G_1$. Moreover, either*

(H_4') φ is outwardly directed on $\pm P$, D_1 and $\pm P \cap D_1$, and P is generating; or

(H_5') $(I - \nabla\varphi)(\pm P) \subset \pm P$ and $(I - \nabla\varphi)(D_1) \subset D_1$.

Then φ has at least one positive critical point $\bar{u}_1$, one negative critical point $\bar{u}_2$ and one sign-changing critical point $\bar{u}_3$ outside D_1.

Remark 3.2. The condition (H_5') is stronger than (H_4'). In fact, it follows from [25, Theorem 4.5] that φ is outwardly directed on $\pm P$ if $(I - \nabla\varphi)(\pm P) \subset \pm P$.

Let $\alpha_1 = \sup_{u \in B(0,R_0) \cap E_1} \varphi(u)$, $D_0 = \varphi^{-1}([\alpha_0 - 1, \alpha_1 + 1])$, and $K = D_0 \cap \mathbb{K}$. Assume without loss of generality that $D_0 \backslash K \neq \emptyset$. Since φ has no nontrivial critical point on $\partial_E(\pm P_1)$ and $\partial_E G_1$, by using the conditions (H_1) we may take $\delta > 0$ small enough such that $D_0^\delta \neq \emptyset$, and

$$K_{3\delta} \cap \left(\partial_E P_1 \cup \partial_E(-P_1) \cup \partial_E G_1\right) = \emptyset \tag{3.3}$$

where $K_{3\delta} = \{x \in D_0 : \operatorname{dist}(x, K) < 3\delta\}$ and $D_0^\delta = D_0 \backslash K_\delta$.

In what follows of this Subsection 3.1, we assume that all conditions of Theorem 3.1 hold.

Lemma 3.3. *There exists a locally Lipschitz mapping $v : D_0^\delta \mapsto X$ such that $\|v(x)\| \leqslant 2(1+\|x\|)$ for any $x \in D_0^\delta$, $\langle x^*, v(x)\rangle \geqslant \frac{\gamma}{16}$ for some $\gamma > 0$ and all $x^* \in \partial\varphi(x)$. Moreover, $v : D_0^\delta \cap E \mapsto E$ is locally Lipschitz, and*

$$x - \frac{1}{1+\|x\|}v(x) \in \pm P_1 \quad \textit{for any} \quad x \in \pm P \cap D_0^\delta, \tag{3.4}$$

$$x - \frac{1}{1+\|x\|}v(x) \in G_1 \quad \textit{for any} \quad x \in D_1 \cap D_0^\delta, \tag{3.5}$$

$$x - \frac{1}{1+\|x\|}v(x) \in \pm P_1 \cap G_1 \quad \textit{for any} \quad x \in \pm P \cap D_1 \cap D_0^\delta. \tag{3.6}$$

Proof. Let $S = D_0^\delta \backslash \big(P \cup (-P) \cup D_1\big)$ and $\widetilde{S} = D_0^\delta \cap (D_1 \backslash (P \cup (-P)))$. First we claim that for some $\gamma > 0$,

$$(1+\|x\|)m(x) \geqslant \gamma, \qquad \forall x \in S, \tag{3.7}$$

$$(1+\|x\|)m_P(x) \geqslant \gamma, \qquad \forall x \in (D_0^\delta \cap P)\backslash D_1, \tag{3.8}$$

$$(1+\|x\|)m_{-P}(x) \geqslant \gamma, \qquad \forall x \in (D_0^\delta \cap (-P))\backslash D_1, \tag{3.9}$$

$$(1+\|x\|)m_{D_1}(x) \geqslant \gamma, \qquad \forall x \in \widetilde{S}, \tag{3.10}$$

$$(1+\|x\|)m_{P\cap D_1}(x) \geqslant \gamma, \qquad \forall x \in D_0^\delta \cap P \cap D_1, \tag{3.11}$$

$$(1+\|x\|)m_{-P\cap D_1}(x) \geqslant \gamma, \qquad \forall x \in D_0^\delta \cap (-P) \cap D_1. \tag{3.12}$$

We only show that (3.11) holds. In a similar way we can show that (3.7)$\sim$(3.10) and (3.12) hold. Arguing by contradiction, assume that (3.11) does not hold. Then there exists an sequence $\{x_n\} \subset D_0^\delta \cap D_1 \cap P$ such that $(1+\|x_n\|)m_{P\cap D_1}(x_n) \to 0$ as $n \to \infty$. Obviously, $\{\varphi(x_n) : n = 1, 2, \ldots\} \subset [\alpha_0 - 1, \alpha_1 + 1]$. It follows from (H_2) that φ satisfies the condition $(CPS)_{D_1\cap P}$. Thus, up to a subsequence if necessary, $x_n \to x_0$ as $n \to \infty$ for some $x_0 \in D_0^\delta \cap D_1 \cap P$. Since $m_{D_1\cap P} : D_1 \cap P \mapsto \mathbb{R}$ is lsc., we have $m_{D_1\cap P}(x_0) = 0$. It follows from (H_4') or (H_5') and Lemma 2.5 that $m(x_0) = 0$, which is a contradiction. Thus, (3.11) holds.

Pick $x_0 \in S$. It follows from Proposition 2.9 and (3.7) that there exist $(u_1(x_0), x_0^*) \in \bar{B}(x_0, 1) \times \partial\varphi(x_0)$ such that for any $y^* \in \partial\varphi(x_0)$,

$$\langle y^*, u_1(x_0)\rangle \geqslant \langle x_0^*, u_1(x_0)\rangle = m(x_0) > \frac{\gamma}{2(1+\|x_0\|)}.$$

Since the map $x \mapsto \partial\varphi(x)$ is usc. from X into X_w^*, we may take an open neighborhood $B_1(x_0, r_1(x_0))$ of x_0, such that

$$\langle y^*, u_1(x_0)\rangle > \frac{\gamma}{4(1+\|y\|)}, \qquad \forall y^* \in \partial\varphi(y),\ y \in U_1(x_0), \tag{3.13}$$

where $U_1(x_0) = B_1(x_0, r_1(x_0)) \cap S$. Since S is an open subset of D_0^δ, we may take $r_1(x_0) > 0$ small enough such that $U_1(x_0) \subset S$.

Pick $x_0 \in (D_0^\delta \cap P)\backslash D_1$. It follows from Proposition 2.9 and inequality (3.8) that there exist $(u_2(x_0), x_0^*) \in \big((x_0 - P) \cap \bar{B}(0,1)\big) \times \partial\varphi(x_0)$,such that for any $x^* \in \partial\varphi(x_0)$,

$$\langle x^*, u_2(x_0)\rangle \geqslant \langle x_0^*, u_2(x_0)\rangle = m_P(x_0) > \frac{\gamma}{2(1+\|x_0\|)}.$$

Again by using the fact that $x \mapsto \partial\varphi(x)$ is usc., we know that there exists an open neighborhood $B_2(x_0, r_2(x_0))$ of x_0 such that for any $y \in U_2(x_0)$, $y^* \in \partial\varphi(y)$,

$$\langle y^*, u_2(x_0)\rangle > \frac{\gamma}{4(1+\|y\|)}. \tag{3.14}$$

where $U_2(x_0) = B_2(x_0, r_2(x_0)) \cap D_0^\delta$. Since $x_0 \in (D_0^\delta \cap P)\backslash D_1$ and $D_0^\delta\backslash(D_1 \cup (-P))$ is an open set of D_0^δ, we may take $r_2(x_0) > 0$ small such that $U_2(x_0) \cap \big(D_1 \cup (-P)\big) = \emptyset$.

Similarly, by (3.9) and Proposition 2.9 we can show that for each $x_0 \in (D_0^\delta \cap (-P))\backslash D_1$, there exist $U_3(x_0) := B_3(x_0, r_3(x_0)) \cap D_0^\delta$, $u_3(x_0) \in X$ with $\|u_3(x_0)\| \leqslant 1$, such that

$$x_0 - u_3(x_0) \in -P, \qquad U_3(x_0) \cap (D_1 \cup P) = \emptyset$$

and for any $y \in U_3(x_0)$, $y^* \in \partial\varphi(y)$,

$$\langle y^*, u_3(x_0)\rangle > \frac{\gamma}{4(1+\|y\|)}. \tag{3.15}$$

By (3.10) we can show that for each $x_0 \in \widetilde{S}$, there exist $U_4(x_0) := B_4(x_0, r_4(x_0)) \cap D_0^\delta$, $u_4(x_0) \in X$ with $\|u_4(x_0)\| \leqslant 1$, such that

$$x_0 - u_4(x_0) \in D_1, \qquad U_4(x_0) \cap (P \cup (-P)) = \emptyset$$

and for any $y \in U_4(x_0)$, $y^* \in \partial\varphi(y)$,

$$\langle y^*, u_4(x_0)\rangle > \frac{\gamma}{4(1+\|y\|)}. \tag{3.16}$$

It follows from (H_4') or (H_5') that $\partial\varphi(0) = \{0\}$. Then 0 is a critical point. Pick $x_0 \in D_0^\delta \cap D_1 \cap P$. Then $x_0 \neq 0$. By using Proposition 2.9 and (3.11) we obtain that there exist $U_5(x_0) := B_5(x_0, r_5(x_0)) \cap D_0^\delta$, $u_5(x_0) \in X$ with $\|u_5(x_0)\| \leqslant 1$, such that

$$x_0 - u_5(x_0) \in D_1 \cap P, \qquad U_5(x_0) \cap (-P) = \emptyset$$

and for any $y \in U_5(x_0)$, $y^* \in \partial\varphi(y)$,

$$\langle y^*, u_5(x_0)\rangle > \frac{\gamma}{4(1+\|y\|)}. \tag{3.17}$$

Similarly, by (3.12) we can show that for each $x_0 \in D_0^\delta \cap D_1 \cap (-P)$, there exist $U_6(x_0) := B_6(x_0, r_6(x_0)) \cap D_0^\delta$, $u_6(x_0) \in X$ with $\|u_6(x_0)\| \leqslant 1$, such that

$$x_0 - u_6(x_0) \in D_1 \cap (-P), \qquad U_6(x_0) \cap P = \emptyset$$

and for any $y \in U_6(x_0)$, $y^* \in \partial\varphi(y)$,

$$\langle y^*, u_6(x_0)\rangle > \frac{\gamma}{4(1+\|y\|)}. \tag{3.18}$$

By 3) in Proposition 2.1, we may assume that $\|x^*\|_* \leqslant L_{\alpha,i}$ for some $L_{\alpha,i} > 0$ and any $x \in U_i(x_\alpha)$ with $i = 1, 2, \ldots, 6$ and $x^* \in \partial\varphi(x)$. Also, we assume that for $i = 1, 2, \ldots, 6$, $B_i(x_\alpha, r_i(x_\alpha))$ has a small radius $r_i(x_\alpha) > 0$ such that $(1 + \|x\|)(1 + \|x_\alpha\|)^{-1} \leqslant 2$ for each $x \in U_i(x_\alpha)$, and

$$0 < r_i(x_\alpha) \leqslant \min\left\{\frac{1}{2}, \frac{\gamma}{64(1+\|x_\alpha\|)L_{\alpha,i}}\right\}.$$

Let

$$\begin{aligned}
\mathscr{A}_1 &= \big\{U_1(x_0) : x_0 \in S\big\},\\
\mathscr{A}_2 &= \big\{U_2(x_0) : x_0 \in (D_0^\delta \cap P)\backslash D_1\big\},\\
\mathscr{A}_3 &= \big\{U_3(x_0) : x_0 \in (D_0^\delta \cap (-P))\backslash D_1\big\},\\
\mathscr{A}_4 &= \big\{U_4(x_0) : x_0 \in \widetilde{S}\big\},\\
\mathscr{A}_5 &= \big\{U_5(x_0) : x_0 \in D_0^\delta \cap P \cap D_1\big\},\\
\mathscr{A}_6 &= \big\{U_6(x_0) : x_0 \in D_0^\delta \cap (-P) \cap D_1\big\},
\end{aligned}$$

and $\mathscr{A} = \bigcup_{i=1,2,\ldots,6} \mathscr{A}_i$. Then $\mathscr{A}$ is an open cover of D_0^δ.

By paracompactness we can find a locally finite refinement $\mathscr{B} = \{V_\alpha : \alpha \in \Lambda\}$ and a locally Lipschitz partition of unit $\{\gamma_\alpha : \alpha \in \Lambda\}$ sub-ordinate to it, with $\operatorname{supp}\gamma_\alpha \subset V_\alpha$. For each $\alpha \in \Lambda$ we can find $x_\alpha \in D_0^\delta$ such that $V_\alpha \subset U_{i(\alpha)}(x_\alpha)$ for some $i(\alpha) \in \{1,2,\ldots,6\}$, and $U_{i(\alpha)}(x_\alpha) \in \mathscr{A}$. To this $x_\alpha \in D_0^\delta$ corresponds the element $w_\alpha^{i(\alpha)}$ such that $\|w_\alpha^{i(\alpha)}\| \leqslant 1$, and $w_\alpha^{i(\alpha)} = u_{i(\alpha)}(x_\alpha)$ if $V_\alpha \subset U_{i(\alpha)}(x_\alpha)$ for some $i(\alpha) \in \{1,2,\ldots,6\}$. Since E is densely embedded in X, and so $P_1, -P_1, G_1$ are densely embedded in $P, -P, D_1$, respectively. Thus, we may take $\bar{x}_\alpha, \bar{w}_\alpha^{i(\alpha)} \in E$ with $\|\bar{w}_\alpha^{i(\alpha)}\| \leqslant 1$ such that

$$\max\left\{\|w_\alpha^{i(\alpha)} - \bar{w}_\alpha^{i(\alpha)}\|, \|x_\alpha - \bar{x}_\alpha\|\right\} < \min\left\{\frac{1}{2}, \frac{\gamma}{64(1+\|x_\alpha\|)L_{\alpha,i(\alpha)}}\right\}. \tag{3.19}$$

and

$$\bar{x}_\alpha - \bar{w}_\alpha^{i(\alpha)} \in \begin{cases} P_1 & \text{if } x_\alpha \in P \cap D_0^\delta; \\ -P_1 & \text{if } x_\alpha \in -P \cap D_0^\delta; \\ G_1 & \text{if } x_\alpha \in \widetilde{S}; \\ G_1 \cap P_1 & \text{if } x_\alpha \in P \cap D_1 \cap D_0^\delta; \\ G_1 \cap (-P_1) & \text{if } x_\alpha \in -P \cap D_1 \cap D_0^\delta. \end{cases} \tag{3.20}$$

Now, let $v : D_0^\delta \mapsto X$ be defined by

$$v(x) = (1+\|x\|)\sum_{\alpha\in\Lambda}\gamma_\alpha(x)(\bar{w}_\alpha^{i(\alpha)} - \bar{x}_\alpha + x). \tag{3.21}$$

Then, $v : D_0^\delta \mapsto X$ is locally Lipschitz. Since $E \hookrightarrow X$, $\gamma_\alpha : D_0^\delta \cap E \mapsto \mathbb{R}$ is also locally Lipschitz. Thus, $v : D_0^\delta \cap E \mapsto E$ is locally Lipschitz.

By (3.19) and (3.21) , we have for any $x \in D_0^\delta$,

$$\|v(x)\| \leqslant (1+\|x\|)\sum_{\alpha\in\Lambda}\gamma_\alpha(x)\big(\|\bar{w}_\alpha^{i(\alpha)}\| + \|\bar{x}_\alpha - x_\alpha\| + \|x_\alpha - x\|\big) \leqslant 2(1+\|x\|).$$

Moreover, we have for any $x \in D_0^\delta$ and $x^* \in \partial\varphi(x)$,

$$\begin{aligned}
&(1+\|x\|)\Big|\sum_{\alpha\in\Lambda}\gamma_\alpha(x)\langle x^*, x - \bar{x}_\alpha\rangle\Big| \\
&\quad\leqslant \sum_{\alpha\in\Lambda}\frac{1+\|x\|}{1+\|x_\alpha\|}(1+\|x_\alpha\|)\gamma_\alpha(x)\|x^*\|_*\big(\|x - x_\alpha\| + \|x_\alpha - \bar{x}_\alpha\|\big) \\
&\quad\leqslant 2\sum_{\alpha\in\Lambda}L_{\alpha,i(\alpha)}\big(\|x - x_\alpha\| + \|x_\alpha - \bar{x}_\alpha\|\big)(1+\|x_\alpha\|) \\
&\quad< \frac{\gamma}{16}
\end{aligned}$$

and

$$\begin{aligned}
\left|\sum_{\alpha\in\Lambda}\gamma_\alpha(x)(1+\|x\|)\langle x^*, \bar{w}_\alpha^{i(\alpha)} - w_\alpha^{i(\alpha)}\rangle\right| &\leqslant \sum_{\alpha\in\Lambda}\frac{1+\|x\|}{1+\|x_\alpha\|}(1+\|x_\alpha\|)\gamma_\alpha(x)\|x^*\|_*\|\bar{w}_\alpha^{i(\alpha)} - w_\alpha^{i(\alpha)}\| \\
&\leqslant 2\sum_{\alpha\in\Lambda}(1+\|x_\alpha\|)L_{\alpha,i(\alpha)}\|\bar{w}_\alpha^{i(\alpha)} - w_\alpha^{i(\alpha)}\| < \frac{\gamma}{16}.
\end{aligned}$$

So, by (3.13)∼(3.18) we have for any $x \in D_0^\delta$ and $x^* \in \partial\varphi(x)$,

$$\begin{aligned}\sum_{\alpha\in\Lambda}\gamma_\alpha(x)(1+\|x\|)\langle x^*, \bar{w}_\alpha^{i(\alpha)}\rangle &= \sum_{\alpha\in\Lambda}\gamma_\alpha(x)(1+\|x\|)\langle x^*, \bar{w}_\alpha^{i(\alpha)} - w_\alpha^{i(\alpha)} + w_\alpha^{i(\alpha)}\rangle\\ &= \sum_{\alpha\in\Lambda}\gamma_\alpha(x)(1+\|x\|)\langle x^*, w_\alpha^{i(\alpha)}\rangle\\ &\quad + \sum_{\alpha\in\Lambda}\gamma_\alpha(x)(1+\|x\|)\langle x^*, \bar{w}_\alpha^{i(\alpha)} - w_\alpha^{i(\alpha)}\rangle\\ &\geqslant \frac{\gamma}{4} - \frac{\gamma}{16} \geqslant \frac{\gamma}{8}.\end{aligned}$$

Hence, we have for any $x \in D_0^\delta$ and $x^* \in \partial\varphi(x)$,

$$\begin{aligned}\langle x^*, v(x)\rangle = &\sum_{\alpha\in\Lambda}\gamma_\alpha(x)(1+\|x\|)\langle x^*, \bar{w}_\alpha^{i(\alpha)}\rangle\\ &+ \sum_{\alpha\in\Lambda}\gamma_\alpha(x)(1+\|x\|)\langle x^*, x-\bar{x}_\alpha\rangle \geqslant \frac{\gamma}{16}.\end{aligned}$$

For a given $x \in D_0^\delta$, we assume that $x \in U_{i(\alpha)}(x_\alpha)$ for some $U_{i(\alpha)}(x_\alpha) \in \mathscr{A}$. Recalling the construction of $\mathscr{A}$, we have

$$U_{i(\alpha)}(x_\alpha) \in \begin{cases}\mathscr{A}_2 \cup \mathscr{A}_5 & \text{if } x \in (D_0^\delta \cap P)\backslash D_1;\\ \mathscr{A}_3 \cup \mathscr{A}_6 & \text{if } x \in (D_0^\delta \cap (-P))\backslash D_1;\\ \mathscr{A}_4 \cup \mathscr{A}_5 \cup \mathscr{A}_6 & \text{if } x \in \widetilde{S};\\ \mathscr{A}_5 & \text{if } x \in D_0^\delta \cap P \cap D_1;\\ \mathscr{A}_6 & \text{if } x \in D_0^\delta \cap (-P) \cap D_1.\end{cases} \tag{3.22}$$

It follows from (3.21) and (3.22) that (3.4)∼(3.6) hold. The proof is complete. □

Let $l_1, l_2 : X \mapsto \mathbb{R}$ be defined by

$$\begin{aligned}l_1(x) &= \frac{\text{dist }(x, K_\delta)}{\text{dist }(x, K_\delta) + \text{dist }(x, X\backslash K_{2\delta})},\\ l_2(x) &= \frac{\text{dist }(x, \Gamma_1)}{\text{dist }(x, \Gamma_2) + \text{dist }(x, \Gamma_1)},\end{aligned} \tag{3.23}$$

$$v_1(x) = \begin{cases} v(x), & x \in D_0^\delta;\\ 0, & \text{otherwise,}\end{cases}$$

and $V(x) = l_1(x)l_2(x)v_1(x)$ for any $x \in X$, where

$$\Gamma_1 = \varphi^{-1}\left(\left[\alpha_1 + \frac{1}{2}, +\infty\right)\right) \cup \varphi^{-1}\left(\left(-\infty, \alpha_0 - \frac{1}{2}\right]\right), \qquad \Gamma_2 = \varphi^{-1}\left(\left[\alpha_0 - \frac{1}{4}, \alpha_1 + \frac{1}{4}\right]\right).$$

Then $l_1, l_2 : X \mapsto \mathbb{R}$ are locally Lipschitz, and so $V : X \mapsto X$ is locally Lipschitz. Since $E \hookrightarrow X$, $l_1, l_2 : E \mapsto \mathbb{R}$ are also locally Lipschitz, and so $V : E \mapsto E$ is locally Lipschitz.

Consider the following initial value problem

$$\begin{cases}\frac{du}{dt} = -V(u),\\ u(0) = v_0 \in X.\end{cases} \tag{3.24}$$

By the theories for initial value problems of ordinary equations in Banach space, we see that (3.24) has a unique solution $\sigma(t, v_0)$ in X, with its right maximal existence interval $[0, T(v_0))$, and its right maximal existence interval $[0, T_1(v_0))$ in E. Obviously, we have $T_1(v_0) \leqslant T(v_0)$. Concerning the solution $\sigma(t, v_0)$ of (3.24), we have the following Lemmas 3.4∼3.6.

Lemma 3.4. *For each $v_0 \in X$, $T(v_0) = +\infty$*

Proof. The proof is standard. For the reader's convenience we give detailed process. Arguing by contradiction, let us assume that $T(v_0) < +\infty$. By (3.24) we have

$$\|\sigma(t, v_0) - v_0\| \leqslant \int_0^t \|V(\sigma(s, v_0))\| ds \leqslant 2 \int_0^t \big(1 + \|\sigma(s, v_0)\|\big) ds.$$

So, we have

$$\begin{aligned} \frac{1}{2}\|\sigma(t, v_0) - v_0\| &\leqslant \int_0^t (1 + \|\sigma(s, v_0)\|) ds \\ &\leqslant \int_0^t \|\sigma(s, v_0) - v_0\| ds + (1 + \|v_0\|)t, \end{aligned}$$

By the well known Gronwall's inequality, we have

$$\begin{aligned} \frac{1}{2}\|\sigma(t, v_0) - v_0\| &\leqslant \int_0^t (1 + \|v_0\|)e^{t-s} ds + (1 + \|v_0\|)t \\ &\leqslant (1 + \|v_0\|)(e^t - 1) + (1 + \|v_0\|)t \\ &\leqslant (1 + \|v_0\|)(t + e^t - 1) \\ &\leqslant (1 + \|v_0\|)(T(v_0) + e^{T(v_0)}). \end{aligned}$$

So, we have

$$\|\sigma(t, v_0)\| \leqslant 2(1 + \|v_0\|)(T(v_0) + e^{T(v_0)}) + 2\|v_0\| =: M_1.$$

Take $\{t_n\} \subset [0, T(v_0))$ such that $t_n \to T^-(v_0)$ and for $n = 1, 2, \ldots$,

$$|t_n - t_{n-1}| < \frac{1}{2 \cdot 2^n (1 + M_1)}.$$

Then we have

$$\begin{aligned} \|\sigma(t_n, v_0) - \sigma(t_{n-1}, v_0)\| &\leqslant \int_{t_{n-1}}^{t_n} \|V(\sigma(s, v_0)\| ds \\ &\leqslant 2 \int_{t_{n-1}}^{t_n} \big(1 + \|\sigma(s, v_0)\|\big) ds \\ &\leqslant 2(1 + M_1)(t_n - t_{n-1}) < \frac{1}{2^n}. \end{aligned}$$

This implies that $\{\sigma(t_n, v_0)\}$ is a Cauchy sequence in X. Thus, there exists $\bar{u} \in X$ such that $\sigma(t_n, v_0) \to \bar{u}$ as $t_n \to T^-(v_0)$. Then we can show that $\sigma(t, v_0) \to \bar{u}$ as $t \to T^-(v_0)$.

Now we consider the initial value problem

$$\begin{cases} \frac{du}{dt} = -V(u), \\ u(0) = \bar{u}. \end{cases} \tag{3.25}$$

Then (3.25) has a unique solution on $[0, \bar{\delta})$ for some $\bar{\delta} > 0$, and so (3.24) has a unique solution on $[0, T(v_0) + \bar{\delta})$, which is a contradiction. Thus, we have $T(v_0) = +\infty$. The proof is complete. □

Lemma 3.5. *If* $o(v_0) := \{\sigma(t, v_0) \subset X : t \in [0, +\infty)\} \subset \Gamma_2 \backslash K_{2\delta}$, *then* $T_1(v_0) = +\infty$.

Proof. Let the operator $A : E \to X$ be defined by

$$Ax = x - \frac{1}{1 + \|x\|} V(x), \qquad \forall x \in E.$$

Then we have

$$Ax = \sum_{\alpha \in \Lambda} \gamma_\alpha(x)(\bar{x}_\alpha - \bar{w}_\alpha^{i(\alpha)}), \qquad \forall x \in \Gamma_2 \backslash K_{2\delta}. \tag{3.26}$$

Let

$$\mu(t) = \int_0^t \big(1 + \|\sigma(s, v_0)\|\big) ds \quad \text{for } t \in [0, +\infty).$$

Obviously, $\mu : [0, +\infty) \to [0, +\infty)$ is strictly increasing. And so, μ^{-1}, the inverse function of μ, exists. Then we have

$$\begin{cases} \frac{d}{dt}\big(e^{\mu(t)}\sigma(t, v_0)\big) = e^{\mu(t)}\big(1 + \|\sigma(t, v_0)\|\big) A\sigma(t, v_0), \\ \sigma(0, v_0) = v_0. \end{cases}$$

By direct computation, we have

$$\sigma(t, v_0) = e^{-\mu(t)} v_0 + e^{-\mu(t)} \int_0^t e^{\mu(s)} \big(1 + \|\sigma(s, v_0)\|\big) A\sigma(s, v_0) ds. \tag{3.27}$$

where the integral is in the sense of X topology. Now we show that $T_1(v_0) = +\infty$ when $o(v_0) \subset \Gamma_2 \backslash K_{2\delta}$. Arguing by contradiction, let us assume that $T_1(v_0) < +\infty$. Take $T > T_1(v_0)$. It follows from (3.26) that $\{A(\sigma(t, v_0)) : t \in [0, T]\}$ is contained in a finite-dimensional subspace of X. Then, there exists $M_1(T) > 0$ such that for $s \in [0, T]$,

$$\|e^{\mu(s)}\big(1 + \|\sigma(s, v_0)\|\big) A\sigma(s, v_0)\|_1 \leqslant M_1(T).$$

Let $\{t_n\} \subset [0, T_1(v_0))$ such that $t_n \to T_1^-(v_0)$ as $n \to \infty$. Note (3.27) also holds in which the integral is in the sense of E topology for any $t \in [0, T_1(v_0))$. Assume without loss of generality that $\{t_n\}$ is increasing. Then we have

$$\begin{aligned} \|\sigma(t_n, v_0) - \sigma(t_{n-1}, v_0)\|_1 &\leqslant |e^{-\mu(t_n)} - e^{-\mu(t_{n-1})}| \Big(\|v_0\|_1 \\ &\quad + \int_0^{t_n} e^{\mu(s)} \big(1 + \|\sigma(s, v_0)\|\big) \|A\sigma(s, v_0)\|_1 ds \Big) \\ &\quad + e^{-\mu(t_{n-1})} \int_{t_{n-1}}^{t_n} e^{\mu(s)} \big(1 + \|\sigma(s, v_0)\|\big) \|A\sigma(s, v_0)\|_1 ds \\ &\leqslant |e^{-\mu(t_n)} - e^{-\mu(t_{n-1})}| \big(\|v_0\|_1 + TM_1(T) \big) + M_1(T)(t_n - t_{n-1}). \end{aligned}$$

So, $\{\sigma(t_n, v_0)\}$ is a Cauchy sequence in E. Assume that that $\sigma(t_n, v_0) \to \bar{u}$ in E as $t \to T_1^-(v_0)$. Since $V : E \mapsto E$ is locally Lipschitz. Then we can easily obtain a contradiction as in the proof of $T(v_0) = +\infty$. Thus, we have $T_1(v_0) = +\infty$. The proof is complete. □

Lemma 3.6. $\varphi(\sigma(t, v_0))$ *is non-increasing in* $t \in [0, T_1(v_0))$.

Proof. Let $h(t,v_0)=\varphi(\sigma(t,v_0))$ for all $t\in[0,T_1(v_0))$. It is easy to see that $h(t,v_0)$ is locally Lipschitz in $t\in[0,T_1(v_0))$, hence differentiable almost everywhere. According to Lebourg's Mean Theorem we have

$$\begin{aligned}\frac{\partial}{\partial s}h(s,v_0)&\leqslant\max\left\{\left\langle w^*,\frac{\partial}{\partial s}\sigma(s,v_0)\right\rangle : w^*\in\partial\varphi(\sigma(s,v_0))\right\}\quad\text{a.e.}\\&=-\min\left\{\langle w^*,V(\sigma(s,v_0))\rangle : w^*\in\partial\varphi(\sigma(s,v_0))\right\}\quad\text{a.e.}\\&\leqslant\begin{cases}-\frac{\gamma}{16}, & \text{if } \sigma(s,v_0)\in\varphi^{-1}([\alpha_0-\frac14,\alpha_1+\frac14])\backslash K_{2\delta};\\ 0, & \text{otherwise.}\end{cases}\end{aligned}\tag{3.28}$$

Consequently, $\varphi(\sigma(t,v_0))$ is non-increasing in $t\in[0,T_1(v_0))$. The proof is complete. □

As in [22], we give the following Definition 3.7 and 3.8

Definition 3.7. A nonempty subset D of E is called an invariant set of descending flow of (3.24) if $o(v_0)\subset D$ for all $v_0\in D$, where $o(v_0)=\{\sigma(t,v_0):t\in[0,T_1(v_0))\}$.

Definition 3.8. Let $M\subset E$ be a connected invariant set of the descending flow of (3.24), D be an open subset of M and be an invariant set of descending flow of (3.24). Denote

$$C_M(D)=\{v_0:v_0\in D \text{ or } v_0\in M\backslash D \text{ and there exists } t'\in(0,T_1(v_0)) \text{ such that } \sigma(t',v_0)\in D\}.$$

If $D=C_M(D)$, then D is called a complete invariant set of descending flow of (3.24) in M.

Lemma 3.9. *$\pm P_1$, $\operatorname{int}(\pm P_1)$, G_1 and $\operatorname{int}G_1$ are all invariant sets of descending flow of (3.24).*

Proof. 1) P_1, $-P_1$ and G_1 are all invariant sets of descending flow of (3.24).

For $u\in\partial_E G_1$, it follows from Lemma 3.3 that for $\lambda>0$ small enough,

$$u+\lambda(-V(u))=\lambda g(u)\left(u-\frac{v_1(u)}{1+\|u\|}\right)+(1-\lambda g(u))\,u\in G_1,$$

where $g(u)=l_1(u)l_2(u)(1+\|u\|)$. It follows from the theorem due to Brezis–Martin (see [11]) that G_1 is an invariant sets of descending flow of (3.24).

In a similar way we can show that $P_1,-P_1$ are also invariant sets of descending flow of (3.24).

2) $\operatorname{int}P_1$, $\operatorname{int}(-P_1)$ and $\operatorname{int}G_1$ are all invariant sets of descending flow of (3.24)

Take $v_0\in\operatorname{int}G_1$. Note (3.27) also holds where the integral is in the sense of E topology for $t\in[0,T_1(v_0))$. Make a variable change $\tau=e^{\mu(s)}-1$ in (3.27). Then we have

$$s=\mu^{-1}(\ln(1+\tau)),\qquad ds=\frac{e^{-\mu(s)}}{\mu'(s)}d\tau$$

and

$$\begin{aligned}&e^{-\mu(t)}\int_0^{e^{\mu(t)}-1}A\sigma\left(\mu^{-1}(\ln(1+\tau)),v_0\right)d\tau\quad\text{(the integral is in the sense of } E\text{ topology)}\\&=\lim_{n\to\infty}\frac1n(1-e^{-\mu(t)})\sum_{k=0}^{n-1}A\sigma\left(\mu^{-1}\left(\ln(1+\frac{k(e^{\mu(t)}-1)}{n}\right),v_0\right).\end{aligned}$$

For any $x \in G_1$, we have

$$Ax = \begin{cases} x, & \text{if } x \in \big(E\backslash\varphi^{-1}(\alpha_0 - \frac{1}{2}, \alpha_1 + \frac{1}{2})\big) \cup K_\delta; \\ x - \frac{1}{1+\|x\|}v(x), & \text{if } x \in \varphi^{-1}([\alpha_0 - \frac{1}{4}, \alpha_1 + \frac{1}{4}])\backslash K_{2\delta}; \\ l(x)\Big(x - \frac{1}{1+\|x\|}v_1(x)\Big) + (1 - l(x))x, & \text{otherwise.} \end{cases} \in G_1, \tag{3.29}$$

where $l(x) := l_1(x)l_2(x) \in (0,1)$, that is $A(G_1) \subset G_1$. Since G_1 is an invariant set of descending flow of (3.24), by (3.29) we have

$$\bar{v} := \lim_{n\to\infty} \frac{1}{n} \sum_{k=0}^{n-1} A\sigma\left(\mu^{-1}\left(\ln(1 + \frac{k(e^{\mu(t)} - 1)}{n}\right), v_0\right) \in G_1.$$

It follows from (3.27) that

$$\sigma(t, v_0) = e^{-\mu(t)}v_0 + (1 - e^{-\mu(t)})\bar{v}. \tag{3.30}$$

Since $v_0 \in \operatorname{int} G_1$ and $e^{-\mu(t)} \in (0,1)$, it follows from Lemma 2.8 and (3.30) that $\sigma(t, v_0) \in \operatorname{int} G_1$ for $t \in [0, T_1(v_0))$. Thus, $\operatorname{int} G_1$ is an invariant set of descending flow of (3.24).

Similarly, we can show that $\operatorname{int}(\pm P_1)$ are invariant sets for the descending flow of (3.24). The proof is complete. □

Lemma 3.10. *For each $v_0 \in \varphi^{-1}\big((-\infty, \alpha_1 + \frac{1}{4}]\big) \cap E$ with $\inf_{u\in o(v_0)} \varphi(u) \geqslant \alpha_0 - \frac{1}{4}$, there exists $\tau(v_0) \geqslant 0$ such that $\sigma(\tau(v_0), v_0) \in K_{2\delta}$.*

Proof. Assume that $o(v_0) \cap K_{2\delta} = \emptyset$. It follows from (3.28) that

$$\varphi(v_0) - \varphi(\sigma(t, v_0)) = -\int_0^t \frac{\partial}{\partial s} h(s, v_0) ds \geqslant \frac{\gamma}{16} t \quad \text{for } t \in [0, T_1(v_0)).$$

It follows from Lemma 3.5 that the maximal existence interval of $\sigma(t, v_0)$ in E is $[0, +\infty)$. So, we may take $t_0 = 16\gamma^{-1}(\alpha_1 - \alpha_0 + 2)$, and have

$$\varphi(\sigma(t_0, v_0)) \leqslant \varphi(v_0) - \frac{\gamma}{16} t_0 \leqslant \alpha_1 + \frac{1}{4} - \frac{\gamma}{16} t_0 < \alpha_0 - 1,$$

which contradicts to $\inf_{u\in o(v_0)} \varphi(u) \geqslant \alpha_0 - \frac{1}{4}$. The proof is complete. □

Similar to the proof of Lemma 3.1 in [22] we have the following Lemma 3.11.

Lemma 3.11. *Let $G \subset E$ be a connected and invariant set of (3.24), and D be an open invariant subset of G. Then the following assertions hold:*

1) *$C_G(D)$ is an open subset of G;*

2) *$\partial_G C_G(D)$ is an invariant set of descending flow of (3.24);*

3) *$\inf_{u\in\partial_G C_G(D)} \varphi(u) \geqslant \inf_{u\in\partial_G D} \varphi(u)$.*

Proof of Theorem 3.1. It follows from Lemma 3.9 that $\operatorname{int}(\pm P_1)$ and $\operatorname{int} G_1$ are all invariant sets of descending flow of (3.24). So, $\operatorname{int}(P_1 \cap G_1)$ and $\operatorname{int}(-P_1 \cap G_1)$ are invariant sets of descending flow of (3.24). It follows from Lemma 3.11 that $C_E(\operatorname{int} G_1)$ is an open invariant set of

descending flow of (3.24). It follows from (3.2) that $C_E(\operatorname{int} G_1) \neq E$, and so $\partial_E C_E(\operatorname{int} G_1) \neq \emptyset$. By Lemma 3.11 we have

$$\inf_{u\in\partial_E C_E(\operatorname{int} G_1)} \varphi(u) \geqslant \inf_{u\in\partial_E G_1} \varphi(u) \geqslant \inf_{u\in D_1} \varphi(u) = \beta_0 > \alpha_0 - \frac{1}{4}. \tag{3.31}$$

Since $C_E(\operatorname{int} G_1)$ is open in E, $C_E(\operatorname{int} G_1) \cap E_1 \subset B(0, R_0)$ is an open and bounded subset of E_1 containing 0. It follows from Lemma 2.14 that there exists a connected component Γ' of the boundary of $C_E(\operatorname{int} G_1) \cap E_1$, such that each one side ray l emitting from the origin satisfies $l \cap \Gamma' \neq \emptyset$. Let Γ be the connected component of $\partial_E C_E(\operatorname{int} G_1)$ containing Γ'. It follows from Lemma 3.11 that Γ is an invariant set of descending flow of (3.24).

It follows from (3.1) that $S_{R_0} \cap E_1 \cap \operatorname{int} P_1 \neq \emptyset$. Thus, $\Gamma \cap \operatorname{int} P_1$ is an invariant set of descending flow of (3.24). Take $\widetilde{v}_1 \in S_{R_0} \cap E_1 \cap \operatorname{int} P_1$ and let $\widetilde{l}$ be the ray emitting from the origin and passing through $\widetilde{v}_1$. Then, we have $\widetilde{l} \cap (\Gamma \cap P_1) \neq \emptyset$, and so $\Gamma \cap P_1 \cap \varphi^{-1}\big((-\infty, \alpha_1 + \frac{1}{4}]\big) \neq \emptyset$. Take $v_0 \in \Gamma \cap P_1 \cap \varphi^{-1}\big((-\infty, \alpha_1 + \frac{1}{4}]\big)$. It follows from (3.31) that $\inf_{u\in o(v_0)} \varphi(u) \geqslant \alpha_0 - \frac{1}{4}$, that is $o(v_0) \subset \varphi^{-1}\big([\alpha_0 - \frac{1}{4}, \alpha_1 + \frac{1}{4}]\big)$.

Now we have the following two cases:

1) If $v_0 \in K_{2\delta}$, it follows from (3.3) that there must exists a u_1 with

$$\bar{u}_1 \in P_1 \cap \varphi^{-1}\left(\left[\alpha_0 - \frac{1}{4}, \alpha_1\right]\right) \cap (K\backslash\{0\})$$

and $\bar{u}_1 \in E\backslash(D_1)_\delta$.

2) If $v_0 \in \big(\Gamma \cap P_1 \cap \varphi^{-1}([\alpha_0 - \frac{1}{4}, \alpha_1 + \frac{1}{4}])\big)\backslash K_{2\delta}$, by Lemma 3.10 we see that $\sigma(\tau(v_0), v_0) \in K_{2\delta} \cap P_1$ for some $\tau(v_0) > 0$, also by (3.3) we see that there must exists a $\bar{u}_1$ with

$$u_1 \in P_1 \cap \varphi^{-1}\left(\left[\alpha_0 - \frac{1}{4}, \alpha_1 + \frac{1}{4}\right]\right) \cap (K\backslash\{0\}),$$

and $\bar{u}_1 \in E\backslash(D_1)_\delta$. Hence, φ has at least one positive critical point $\bar{u}_1$ outside D_1.

Similarly, we can show that φ has at least one negative critical point $\bar{u}_2$ outside D_1.

Now we show that φ has at least one sign-changing critical point $\bar{u}_3$. Obviously, $\Gamma \cap \operatorname{int} P_1$ and $\Gamma \cap \operatorname{int}(-P_1)$ are two open invariant sets of descending flow of (3.24) in Γ. It follows from Lemma 3.11 that $C_\Gamma(\Gamma \cap \operatorname{int} P_1)$ and $C_\Gamma(\Gamma \cap \operatorname{int}(-P_1))$ are two open invariant sets of descending flow of (3.24) in Γ. By the connectedness of Γ, we see that

$$O_1 := \Gamma\backslash\big(C_\Gamma(\Gamma \cap \operatorname{int} P_1) \cup C_\Gamma(\Gamma \cap \operatorname{int}(-P_1)\big) \neq \emptyset.$$

Let

$$O_2 := \Gamma'\backslash\big(C_\Gamma(\Gamma \cap \operatorname{int} P_1) \cup C_\Gamma(\Gamma \cap \operatorname{int}(-P_1)\big).$$

Obviously, $O_2 \subset O_1$. Also by the connectedness of Γ', we have $O_2 \neq \emptyset$. Take $v_0 \in O_2$. It follows from (3.31) that $\inf_{u\in o(v_0)} \varphi(u) \geqslant \alpha_0 - \frac{1}{4}$. Then we can show that φ has a sign-changing critical point $\bar{u}_3$. Indeed, if $v_0 \in K_{2\delta}$, by (3.31) there must exist a $\bar{u}_3 \in S \cap \varphi^{-1}([\alpha_0 - \frac{1}{4}, \alpha_1 + \frac{1}{4}]) \cap K$, where S is defined as in Lemma 3.3. If $v_0 \in \varphi^{-1}([\alpha_0 - \frac{1}{4}, \alpha_1 + \frac{1}{4}])\backslash K_{2\delta}$, it follows from Lemma 3.10 that $\sigma(\tau(v_0), v_0) \in K_{2\delta}$ for some $\tau(v_0) > 0$. By (3.3), we see that there must exists a $\bar{u}_3$ with

$$\bar{u}_3 \in (E\backslash(P \cup (-P))) \cap \varphi^{-1}\left(\left[\alpha_0 - \frac{1}{4}, \alpha_1 + \frac{1}{4}\right]\right) \cap (K\backslash\{0\})$$

and $u_3 \in E\backslash(D_1)_\delta$. Hence, φ has at least one sign-changing critical point $\bar{u}_3$ outside D_1. The proof is complete. □

Remark 3.12. According to Remark 2.13, if (H_5') holds, then (H_2) can be substituted with the condition that φ satisfies the condition (PS). So, we have the following Corollary 3.13.

Corollary 3.13. *it Suppose that (H_1), (H_3) and (H_5') hold. Moreover, φ satisfies the condition (PS) and has no nontrivial critical point on $\partial_E(\pm P_1)$ and $\partial_E G_1$. Then the conclusion in Theorem 3.1 holds.*

3.2 Critical points inside the ordered interval

Next in this section we will give the existence results for critical points inside the ordered interval D_1. Assume that $u_0, v_0, u_1, v_1 \in E$ such that $u_0 \ll v_0 \ll 0 \ll u_1 \ll v_1$. Set $D_2 = [u_0, v_0]$, $D_3 = [u_1, v_1]$ and $G_i = D_i \cap E$ for $i = 2, 3$.

Theorem 3.14. *Suppose that (H_1) holds, φ has no nontrivial critical point on $\partial_E G_i$ for $i = 1, 2, 3$, and φ satisfies $(CPS)_D$ for any ordered interval D in X. Moreover, either*

(H_4'') φ is outwardly directed on D_i for $i = 1, 2, 3$; or

(H_5'') $(I - \nabla\varphi)(D_i) \subset D_i$ for $i = 1, 2, 3$.

Then φ has at least one positive critical point $\bar{u}_4$, one negative critical point $\bar{u}_5$ and one critical point $\bar{u}_6$ inside D_1. Moreover, $\bar{u}_6$ is nontrivial if there exists a curve l in E_1 such that $l \cap D_2 \neq \emptyset$, $l \cap D_3 \neq \emptyset$ and $\max_{u\in l} \varphi(u) < \varphi(0)$.

Corollary 3.15. *Suppose that (H_1) holds, φ has no nontrivial critical point on $\partial_E G_i$ for $i = 1, 2, 3$, φ satisfies (PS) and $(I - \nabla\varphi)(D_i) \subset D_i$ for $i = 1, 2, 3$. Then the conclusion in Theorem 3.14 holds.*

Set

$$\begin{aligned}
\widetilde{K}_r &= \{x \in D_1 : \varphi(x) = r, m(x) = 0\} \text{ for any } r \in \mathbb{R},\\
(\widetilde{K}_r)_\delta &= \{x \in D_1 : d(x, \widetilde{K}_r) < \delta\}, (\widetilde{K}_r)^c_\delta = D_1 \backslash (\widetilde{K}_r)_\delta \text{ for any } r \in \mathbb{R}, \delta > 0,\\
D_1(r, \varepsilon, \delta) &= \{x \in D_1 : r - \varepsilon \leqslant \varphi(x) \leqslant r + \varepsilon, x \in (\widetilde{K}_r)^c_\delta\} \text{ for any } r \in \mathbb{R}, \delta > 0, \varepsilon > 0.
\end{aligned}$$

Lemma 3.16. *Assume that all conditions in Theorem 3.14 hold. Let $r \in \mathbb{R}, \delta > 0$ be given. Then there exist $\bar{\varepsilon} > 0$, $\gamma > 0$ and a locally Lipschitz mapping $\widetilde{v} : D_1(r, \bar{\varepsilon}, \delta) \mapsto D_1$ such that $\|\widetilde{v}(x)\| \leqslant 2(1 + \|x\|)$ for any $x \in D_1(r, \bar{\varepsilon}, \delta)$, $\langle x^*, \widetilde{v}(x)\rangle \geqslant \frac{\gamma}{16}$ for any $x \in D_1(r, \bar{\varepsilon}, \delta)$ and $x^* \in \partial\varphi(x)$. Moreover, $\widetilde{v} : D_1(r, \bar{\varepsilon}, \delta) \cap E \mapsto E$ is locally Lipschitz, and for $i = 1, 2, 3$,*

$$x - \frac{1}{1 + \|x\|}\widetilde{v}(x) \in G_i \quad \text{for any } x \in D_i \cap D_1(r, \bar{\varepsilon}, \delta). \tag{3.32}$$

Proof. The proof is similar to Lemma 3.3. Now we only sketch it. First we can show that for $i = 1, 2, 3$ and some $\bar{\varepsilon}, \gamma > 0$,

$$(1 + \|x\|)m_{D_i}(x) \geqslant \gamma, \qquad \forall x \in D_1(r, \bar{\varepsilon}, \delta) \cap D_i. \tag{3.33}$$

Then, by using (3.33), as the proof in Lemma 3.3, we can find a $\widetilde{u}_i(x) \in X$ for $i = 1, 2, 3$, an open neighborhood $\widetilde{U}_1(x)$ for $x \in D_1(r, \bar{\varepsilon}, \delta)\backslash(D_2 \cup D_3)$, an open neighborhood $\widetilde{U}_2(x)$ for $x \in D_2 \cap D_1(r, \bar{\varepsilon}, \delta)$, and an open neighborhood $\widetilde{U}_3(x)$ for $x \in D_3 \cap D_1(r, \bar{\varepsilon}, \delta)$ such that, $\|\widetilde{u}_i(x)\| \leqslant 1, x - \widetilde{u}_i(x) \in D_i$,

$$\widetilde{U}_1(x) \cap (D_2 \cup D_3) = \emptyset, \qquad \widetilde{U}_2(x) \cap D_3 = \emptyset, \qquad \widetilde{U}_3(x) \cap D_2 = \emptyset,$$

and

$$\langle y^*, \widetilde{u}_i(x_0)\rangle > \frac{\gamma}{4(1+\|y\|)}, \qquad \forall y^* \in \partial\varphi(y),\ y \in \widetilde{U}_i(x), \tag{3.34}$$

where $\widetilde{U}_i(x) = B(x, r_i(x)) \cap D_1(r, \bar{\varepsilon}, \delta)$ for $i = 1, 2, 3$.

Let $\mathscr{A}_1 = \{\widetilde{U}_1(x) : x \in D_1(r, \bar{\varepsilon}, \delta)\backslash(D_2 \cup D_3)\}$, $\mathscr{A}_i = \{\widetilde{U}_i(x) : x \in D_i \cap D_1(r, \bar{\varepsilon}, \delta)\}$ for $i = 2, 3$ and $\mathscr{A} = \mathscr{A}_1 \cup \mathscr{A}_2 \cup \mathscr{A}_3$. The collection $\mathscr{A}$ is an open cover of the set $D_1(r, \bar{\varepsilon}, \delta)$. So, by the paracompactness we can find a locally finite refinement $\{V_\alpha : \alpha \in \Lambda\}$ and a locally Lipschitz partition of unit $\{\gamma_\alpha : \alpha \in \Lambda\}$ sub-ordinate to it with $\operatorname{supp}\gamma_\alpha \subset V_\alpha$ for each $\alpha \in \Lambda$. For each $\alpha \in \Lambda$, we can find $x_\alpha \in D_1(r, \bar{\varepsilon}, \delta)$ such that $V_\alpha \subset \widetilde{U}_{i(\alpha)}(x_\alpha)$ for some $i(\alpha) \in \{1, 2, 3\}$, and $\widetilde{U}_{i(\alpha)}(x_\alpha) \in \mathscr{A}$. To this $x_\alpha \in D_1(r, \bar{\varepsilon}, \delta)$ corresponds the element $w_\alpha^{i(\alpha)}$ such that $\|w_\alpha^{i(\alpha)}\| \leqslant 1$, and $w_\alpha^{i(\alpha)} = \bar{u}_{i(\alpha)}(x_\alpha)$ if $V_\alpha \subset U_{i(\alpha)}(x_\alpha)$ for some $i(\alpha) \in \{1, 2, 3\}$. Since E is densely embedded in X, and so G_1, G_2, G_3 are densely embedded in D_1, D_2, D_3, respectively. Thus, we may take $\bar{x}_\alpha, \bar{w}_\alpha^{i(\alpha)} \in E$ with $\|\bar{w}_\alpha^{i(\alpha)}\| \leqslant 1$ such that

$$\max\left\{\|w_\alpha^{i(\alpha)} - \bar{w}_\alpha^{i(\alpha)}\|, \|x_\alpha - \bar{x}_\alpha\|\right\} < \min\left\{\frac{1}{2}, \frac{\gamma}{64(1+\|x_\alpha\|)L_{\alpha,i(\alpha)}}\right\}. \tag{3.35}$$

and

$$\bar{x}_\alpha - \bar{w}_\alpha^{i(\alpha)} \in G_i \quad \text{if } x_\alpha \in D_i \cap D_1(r, \bar{\varepsilon}, \delta) \text{ for } i = 1, 2, 3. \tag{3.36}$$

Now, let $\widetilde{v} : D_1(r, \bar{\varepsilon}, \delta) \mapsto X$ be defined by

$$\widetilde{v}(x) = (1 + \|x\|) \sum_{\alpha\in\Lambda} \gamma_\alpha(x)(\bar{w}_\alpha^{i(\alpha)} - \bar{x}_\alpha + x). \tag{3.37}$$

Then, by (3.34), (3.35) and (3.37) we have $\|\widetilde{v}(x)\| \leqslant 2(1 + \|x\|)$, and $\langle x^*, \widetilde{v}(x)\rangle \geqslant \frac{\gamma}{16}$ for any $x \in D_1(r, \bar{\varepsilon}, \delta)$ and $x^* \in \partial\varphi(x)$.

For a given $x \in D_1(r, \bar{\varepsilon}, \delta)$, we assume that $x \in U_{i(\alpha)}(x_\alpha)$ for some $U_{i(\alpha)}(x_\alpha) \in \mathscr{A}$. Recalling the construction of $\mathscr{A}$, we have

$$U_{i(\alpha)}(x_\alpha) \in \begin{cases} \mathscr{A}_1 \cup \mathscr{A}_2 \cup \mathscr{A}_3 & \text{if } x \in D_1(r, \bar{\varepsilon}, \delta)\backslash(D_2 \cup D_3); \\ \mathscr{A}_2 & \text{if } x \in D_2 \cap D_1(r, \bar{\varepsilon}, \delta); \\ \mathscr{A}_3 & \text{if } x \in D_3 \cap D_1(r, \bar{\varepsilon}, \delta). \end{cases} \tag{3.38}$$

It follows from (3.36), (3.37), (3.38) that (3.32) holds. The proof of is complete. □

Since φ has no nontrivial critical point on $\partial_E G_i$ for $i = 1, 2, 3$, by using the conditions (H_1) we may take $\delta > 0$ small enough such that

$$(\widetilde{K}_r)_{3\delta} \cap (\partial_{G_1} G_2 \cup \partial_{G_1} G_3) = \emptyset. \tag{3.39}$$

Let $O = G_1\backslash(G_2 \cup G_3)$ and $\widetilde{K}_r^0 = \widetilde{K}_r \cap O$.

Lemma 3.17. *Assume that all the conditions in Theorem 3.14 hold. Let $r \in \mathbb{R}, \delta > 0$ be such that (3.39) holds. Then there exists $\bar{\varepsilon}_0 > 0$ such that for any $0 < \varepsilon < \frac{1}{3}\bar{\varepsilon}_0$ and any compact set $B \subset \varphi^{r+\varepsilon} \cap G_1$, there exists $\eta \in C([0, 1] \times G_1, G_1)$ such that*

1) *$\eta(t, x) = x$ for $t = 0$; or $x \notin G_1 \cap D_1(r, \bar{\varepsilon}_0, \delta)$;*

2) *$\eta(1, B\backslash(\widetilde{K}_r^0)_{3\delta}) \subset (O \cap \varphi^{r-\varepsilon}) \cup \operatorname{int}_{G_1} G_2 \cup \operatorname{int}_{G_1} G_3$;*

3) $\eta(t,\cdot)$ *is a homeomorphism of* G_1 *for* $t \in [0,1]$;

4) $\varphi(\eta(\cdot,x))$ *is non-increasing for any* $x \in G_1$;

5) $\eta(1,G_2) \subset G_2$, $\eta(1,G_3) \subset G_3$;

6) $\eta(1,\mathrm{int}_{G_1} G_2) \subset \mathrm{int}_{G_1} G_2$, $\eta(1,\mathrm{int}_{G_1} G_3) \subset \mathrm{int}_{G_1} G_3$.

Proof. It follows from Lemma 3.16 that there exists $\widetilde{v} : D_1(r,\bar{\varepsilon},\delta) \to X$ such that such that $\|\widetilde{v}(x)\| \leqslant 2(1+\|x\|)$ for any $x \in D_1(r,\bar{\varepsilon},\delta)$, $\langle x^*, \widetilde{v}(x)\rangle \geqslant \frac{\gamma}{16}$ for some $\gamma > 0$ and all $x^* \in \partial\varphi(x)$, and (3.32) holds. Since $\widetilde{K}_r$ is compact in X, we may choose $R_0 > 0$ such that $\|x\| \leqslant R_0$ for all $x \in (\widetilde{K}_r)_{3\delta}$. Take

$$0 < \bar{\varepsilon}_0 < \min\left\{\bar{\varepsilon}, \frac{\gamma\delta}{32(1+R_0)}\right\}. \tag{3.40}$$

Take $0 < \varepsilon < \frac{1}{3}\bar{\varepsilon}_0$. Let $l_i : D_1 \to \mathbb{R}$ for $i = 1,2$ be defined by

$$l_1(x) = \frac{d\big(x, D_1\backslash\varphi_{r-\bar{\varepsilon}_0}^{r+\bar{\varepsilon}_0}\big)}{d\big(x, D_1\backslash\varphi_{r-\bar{\varepsilon}_0}^{r+\bar{\varepsilon}_0}\big) + d\big(x, D_1 \cap \varphi_{r-2\varepsilon}^{r+2\varepsilon}\big)},$$

and

$$l_2(x) = \frac{d\big(x, D_1 \cap (\widetilde{K}_r)_\delta\big)}{d\big(x, D_1 \cap (\widetilde{K}_r)_\delta\big) + d\big(x, D_1\backslash(\widetilde{K}_r)_{2\delta}\big)}.$$

Then $l_i : D_1 \to \mathbb{R}$ for $i = 1,2$ is locally Lipschitz continuous in X. It is easy to see that $l_i : G_1 \to \mathbb{R}$ for $i = 1,2$ is locally Lipschitz continuous in E. Let $V(x) = l_1(x)l_2(x)\widetilde{v}_1(x)$ for all $x \in D_1$, where

$$\widetilde{v}_1(x) = \begin{cases} \widetilde{v}(x), & x \in D_1(r,\bar{\varepsilon},\delta); \\ 0, & \text{otherwise.} \end{cases}$$

Then $V : D_1 \to X$ is locally Lipschitz, $V : G_1 \to E$ is also locally Lipschitz.

Consider the initial value problem in X

$$\begin{cases} \frac{d\sigma}{dt} = -V(\sigma(t,u)), \\ \sigma(0) = u \in G_1. \end{cases} \tag{3.41}$$

Obviously, (3.41) has a unique solution $\sigma(t,u)$ in X, with its right maximal existence interval $[0,T(u))$, where $0 < T(u) \leqslant +\infty$. Since $V : G_1 \to E$ is also locally Lipschitz, (3.41) has a unique solution $\sigma(t,u)$ in E, with its right maximal existence interval $[0,T_1(u))$, where $0 < T_1(u) \leqslant T(u) = +\infty$.

In a similar way as in the proof of Lemmas 3.4, 3.6, 3.9,we can show the following conclusions hold: 1) $T(u) = +\infty$; 2). G_1, G_2, G_3, $\mathrm{int}_{G_1} G_2$ and $\mathrm{int}_{G_1} G_3$ are invariant sets for the flow of (3.41). Moreover, the following inequality hold: for any $[t_1,t_2] \subset [0,T_1(u))$,

$$\begin{aligned} \varphi\big(\sigma(t_1,u)\big) - \varphi\big(\sigma(t_2,u)\big) &= -\int_{t_1}^{t_2} \frac{d\varphi(\sigma(s,u))}{ds} ds \\ &\geqslant \frac{\gamma}{16}(t_2 - t_1) \ \text{ if } \ \sigma(s,u) \in G_1 \cap D_1(r,2\varepsilon,2\delta) \text{ for } s \in [t_1,t_2]. \end{aligned} \tag{3.42}$$

Let $B \subset \varphi^{r+\varepsilon} \cap G_1$ be a compact set, $u_0 \in B\backslash(K_r^0)_{3\delta}$ and $o(u_0) = \{\sigma(t,u_0) : t \in [0,T_1(u_0))\}$. Then we have the following cases:

1) $o(u_0) \cap \mathrm{int}_{G_1} G_2 \neq \emptyset$. Assume that $u_1 := \sigma(t(u_0), u_0) \in \mathrm{int}_{G_1} G_2$ for some $t(u_0) \in [0, T_1(u_0))$. Take a neighborhood $U(u_1)$ of u_1 in G_1 such that $U(u_1) \subset \mathrm{int}_{G_1} G_2$. By the continuous dependence of ordinary differential equations on initial data, there exists an open neighborhood $U(u_0)$ of u_0, such that $\sigma(t(u_0), u) \in U(u_1) \subset \mathrm{int}_{G_1} G_2$ for any $u \in U(u_0)$. Since $\mathrm{int}_{G_1} G_2$ is an invariant set, $\sigma(t, u) \in \mathrm{int}_{G_1} G_2$ for all $u \in U(u_0)$ and $t \geqslant t(u_0)$.

2) $o(u_0) \cap \mathrm{int}_{G_1} G_3 \neq \emptyset$. A similar argument as above yields that, there is a neighborhood $U(u_0)$ of u_0 and $t(u_0) > 0$, such that $\sigma(t, u) \in \mathrm{int}_{G_1} G_3$ for any $u \in U(u_0)$ and $t \geqslant t(u_0)$.

3) $o(u_0) \cap \big(\mathrm{int}_{G_1} G_2 \cup \mathrm{int}_{G_1} G_3\big) = \emptyset$. In this case we have the following two subcases:

3a) $o(u_0) \cap (\widetilde{K}_r^0)_{2\delta} = \emptyset$. First we show that $o(u_0) \cap \{x \in X : \varphi(x) < r - \varepsilon\} \neq \emptyset$. Assume indirectly that this is not the case, then $o(u_0) \cap \{x \in X : \varphi(x) < r - \varepsilon\} = \emptyset$. Assume without loss of generality that $o(u_0) \subset \varphi^{-1}([r - \varepsilon, r + \varepsilon])$. Let $Ax = x - \frac{1}{1+\|x\|} V(x)$ for all $x \in D_1$. Note that

$$Ax = \sum_{\alpha \in \Lambda} \gamma_\alpha(x)(\bar{x}_\alpha - \bar{w}_\alpha), \qquad \forall x \in D_1 \cap \varphi^{-1}([r - \varepsilon, r + \varepsilon]) \backslash (\widetilde{K}_r)_{2\delta}.$$

So, in a similar way as in the proof of Lemma 3.5 we can easily show that $T_1(u_0) = +\infty$. Then, we can take $t_1 = \frac{32\varepsilon}{\gamma}$. By (3.42) we have

$$vr(\sigma(t_1, u_0)) \leqslant \varphi(u_0) - \frac{\gamma}{16} t_1 \leqslant \varphi(u_0) - \frac{\gamma}{16} t_1 < r - \varepsilon. \tag{3.43}$$

which is a contradiction. Thus, $o(u_0) \cap \{x \in X : \varphi(x) < r - \varepsilon\} \neq \emptyset$. Assume that $u_1 := \sigma(t(u_0), u_0) \in \{x \in X : \varphi(x) < r - \varepsilon\}$ for some $t(u_0) \geqslant 0$. Take a neighborhood $U(u_1)$ of u_1 such that $U(u_1) \subset \{x \in X : \varphi(x) < r - \varepsilon\}$. Then, there exists an open neighborhood $U(u_0)$ of u_0, such that $\sigma(t(u_0), u) \in U(u_1) \subset \{x \in X : \varphi(x) < r - \varepsilon\}$ for any $u \in U(u_0)$. Since $\sigma(t, u)$ is non-increasing in $t \in [0, +\infty)$, we have $\sigma(t, u) \subset \{x \in X : \varphi(x) < r - \varepsilon\}$ for any $u \in U(u_0)$ and $t \geqslant t(u_0)$.

3b) $o(u_0) \cap (\widetilde{K}_r^0)_{2\delta} \neq \emptyset$. In this case, we may take $[t_1, t_2] \subset [0, +\infty)$ such that $\sigma(t_1, u_0) \in \partial(\widetilde{K}_r)_{3\delta}$, $\sigma(t_2, u_0) \in \partial(\widetilde{K}_r)_{2\delta}$, and $\sigma(t, u_0) \in (\widetilde{K}_r^0)_{3\delta} \backslash (\widetilde{K}_r^0)_{2\delta}$ for $t \in [t_1, t_2]$. By (3.41) we have

$$\begin{aligned} \|\sigma(t_2, u_0) - \sigma(t_1, u_0)\| &\leqslant \int_{t_1}^{t_2} \|V(\sigma(s, u_0)\| ds \\ &\leqslant 2 \int_{t_1}^{t_2} \big(1 + \|\sigma(s, u_0)\|\big) ds \\ &\leqslant 2\big(1 + R_0\big)(t_2 - t_1). \end{aligned}$$

So, we have

$$t_2 - t_1 \geqslant \frac{\|\sigma(t_2, u_0) - \sigma(t_1, u_0)\|}{2\big(1 + R_0\big)} \geqslant \frac{\delta}{2\big(1 + R_0\big)}. \tag{3.44}$$

Now we show that there must exist $t(u_0) \in [t_1, t_2]$ such that $\sigma(t(u_0), u_0) \in \{x \in X : \varphi(x) < r - \varepsilon\}$. Assume indirectly that this is not the case, then

$$\{\sigma(t, u_0) : t \in [t_1, t_2]\} \cap \{x \in X : \varphi(x) < r - \varepsilon\} = \emptyset.$$

Then, by (3.42) and (3.44) we have

$$\begin{aligned} \varphi(\sigma(t_2, u_0)) &\leqslant \varphi(\sigma(t_1, u_0)) - \frac{\gamma}{16}(t_2 - t_1) \\ &\leqslant \varphi(u_0) - \frac{\gamma}{16}(t_2 - t_1) \\ &\leqslant r + \varepsilon - \frac{\gamma\delta}{32\big(1 + R_0\big)} \\ &< r + \varepsilon - \bar{\varepsilon}_0 < r - \varepsilon, \end{aligned}$$

which is a contradiction. Thus, there must exist $t(u_0) \in [t_1, t_2]$ such that $\sigma(t(u_0), u_0) \in \{x \in X : \varphi(x) < r - \varepsilon\}$. Then, as the arguments in the case 3a), we can show that there exists a open neighborhood of $U(u_0)$ of u_0 such that $\sigma(t, u) \subset \{x \in X : \varphi(x) < r - \varepsilon\}$ for any $u \in U(u_0)$ and $t \geqslant t(u_0)$.

Let $\mathscr{B} = \{U(u_0) : u_0 \in B\backslash(\widetilde{K}_r^0)_{3\delta}\}$. Then $\mathscr{B}$ is an open cover of $B\backslash(\widetilde{K}_r^0)_{3\delta}$. Since $B\backslash(\widetilde{K}_r^0)_{3\delta}$ is a compact set, then there exist finite sets of $\mathscr{B}$, say $U(u_1), U(u_2), \ldots, U(u_m)$, such that $B\backslash(\widetilde{K}_r^0)_{3\delta} \subset \bigcup_{i=1}^m U(u_i)$. Let $T = \max\{t(u_1), t(u_2), \ldots, t(u_m)\}$ and $\eta(Tt, u)$ for all $t \in [0,1]$ and $u \in B\backslash(\widetilde{K}_r^0)_{3\delta}$. Then we can easily check that all conclusions hold. The proof is complete. □

Proof of Theorem 3.14. Let

$$r = \inf_{\gamma\in\Gamma} \sup_{u\in\gamma([0,1])\cap O} \varphi(u),$$

where

$$\Gamma = \{\gamma \in C([0,1], G_1) : \gamma(0) \in \mathrm{int}_{G_1} G_2, \gamma(1) \in \mathrm{int}_{G_1} G_3\}.$$

Now we show that $\widetilde{K}_r \cap O \neq \emptyset$. Arguing by contradiction that $O \cap \widetilde{K}_r = \emptyset$. Take $\delta > 0$ small enough such that (3.39) holds. By using Lemma 3.17, there exists $\bar{\varepsilon}_0 > 0$ such that for any $0 < \varepsilon < \frac{1}{3}\bar{\varepsilon}_0$ and any compact set $B \subset \varphi^{r+\varepsilon} \cap G_1$, there exists $\eta \in C([0,1] \times G_1, G_1)$ such that the conclusions 1)∼6) in Lemma 3.17 hold.

Take $\gamma \in \Gamma$ such that $\sup_{u\in\gamma([0,1])\cap O} \varphi(u) < r + \varepsilon$. Let $\gamma_1 = \eta(1, \gamma(\cdot))$. Since

$$\eta(1, \mathrm{int}_{G_1} G_2) \subset \mathrm{int}_{G_1} G_2, \qquad \eta(1, \mathrm{int}_{G_1} G_3) \subset \mathrm{int}_{G_1} G_3,$$

$$\gamma(0) \in \mathrm{int}_{G_1} G_2, \qquad \gamma(1) \in \mathrm{int}_{G_1} G_3,$$

then we have $\gamma_1(0) \in \mathrm{int}_{G_1} G_2$ and $\gamma_1(1) \in \mathrm{int}_{G_1} G_3$. So, $\gamma_1 \in \Gamma$.

On the other hand, we have by 2) in Lemma 3.17,

$$r \leqslant \sup_{u\in\gamma_1([0,1])\cap O} \varphi(u) \leqslant \sup_{u\in(\varphi^{r-\varepsilon}\cup\mathrm{int}_{G_1} G_2\cup\mathrm{int}_{G_1} G_3)\cap O} \varphi(u) \leqslant \sup_{u\in\varphi^{r-\varepsilon}} \varphi(u) \leqslant r - \varepsilon,$$

which is a contradiction. So, $\widetilde{K}_r \cap O \neq \emptyset$.

If there exists a curve l in E_1 such that $l \cap D_2 \neq \emptyset$, $l \cap D_3 \neq \emptyset$ and $\max_{u\in l} \varphi(u) < \varphi(0)$, then we have $r < \varphi(0)$. So, $\widetilde{K}_r \cap (O\backslash\{0\}) \neq \emptyset$. The proof is complete. □

Remark 3.18. Here in Theorem 3.14 we have proved a three critical points theorem in ordered interval, which can be thought as a mountain pass theorem in ordered interval. It should be pointed out that Theorem 3.14 can also be obtained by the method showing Theorem 3.1.

3.3 Critical points inside and outside the ordered interval

By Theorem 3.1 and 3.14 we can get the following Theorem 3.19.

Theorem 3.19. *Suppose that (H_1)∼(H_3) hold, φ has no nontrivial critical point on $\partial_E(\pm P_1)$ and $\partial_E(D_i \cap E)$ for $i = 1, 2, 3$. Moreover, either*

(H_4) φ is outwardly directed on $\pm P$, D_i for $i = 1, 2, 3$ and $\pm P \cap D_1$; or

(H_5) $(I - \nabla\varphi)(\pm P) \subset \pm P$ and $(I - \nabla\varphi)(D_i) \subset D_i$ for $i = 1, 2, 3$.

Then φ has at least one positive critical point $\bar{u}_1$, one negative critical point $\bar{u}_2$ and one sign-changing critical point $\bar{u}_3$ outside D_1; 2) φ has at least one positive critical point $\bar{u}_4$, one negative critical point $\bar{u}_5$ and one critical point $\bar{u}_6$ inside D_1; moreover, $\bar{u}_6$ is nontrivial if there exists a curve l in E_1 such that $l \cap D_2 \neq \emptyset$, $l \cap D_3 \neq \emptyset$ and $\max_{u\in l} \varphi(u) < \varphi(0)$.

Remark 3.20. Obviously, by the method above we can study the existence of multiple critical points inside and outside the ordered interval which not contain the origin. Moreover, we can give results for at least one or two critical points exist outside the ordered interval, and we can also use the concept of parallel pair of upper and lower solutions to establish the results for multiple critical points. For the sake of brevity, we will only list two of such kind results and not give their proofs.

Theorem 3.21. *Let $u_0 \ll v_1$, $D_1 = [u_0, v_1]$ and $G_1 = D_1 \cap E$. Suppose that (H_1) and (H_3) hold, φ satisfies the condition (PS) and has no critical points on $\partial_E G_1$, $(I - \nabla\varphi)(D_1) \subset D_1$. Then φ has at least one critical point outside D_1, and at least one critical point inside D_1.*

Theorem 3.22. *Let $u_0 \ll u_1 \ll v_1$, $D_1 = [u_0, v_1]$, $D_2 = [u_1, v_1]$, $G_1 = D_1 \cap E$, $G_2 = D_2 \cap E$ and $O_1 = \{x \in X : x \geqslant u_1\}$. Suppose that (H_1) and (H_3) hold, φ satisfies the condition (PS) and has no critical points on $\partial_E G_1 \cup \partial_E(O_1 \cap E) \cup \partial_E G_2$, $(I - \nabla\varphi)(D_1) \subset D_1$, $(I - \nabla\varphi)(D_2) \subset D_2$, and $(I - \nabla\varphi)(O_1) \subset O_1$. Then φ has at least two critical points $\bar{u}_1, \bar{u}_2$ outside D_1 and at least one critical point $\bar{u}_3$ inside D_1 such that $\bar{u}_1 \gg u_1$, $\bar{u}_2 \not\gg u_1$, and $u_1 \ll \bar{u}_3 \ll v_1$.*

Remark 3.23. Obviously, we can also study the existence of fixed points for set value operators using the methods described above. Moreover, our main results also be applicable for φ being of C^1 class, and some of our main results are new even for the case of φ being of C^1 class.

4 Application to the differential inclusion problem with a convex-concave nonlinearity

As the application of Theorem 3.19, in this section we will show multiple solutions of a differential inclusion problem with a convex-concave nonlinearity. The main result of this section extend some relevant results concerning the differential equation boundary value problems with a concave-convex nonlinearity that was first studied by A. Ambrosetti, H. Brezis and G. Cerami [2].

Let

$$\|u\| = \left(\int_\Omega \|Du\|^p dx\right)^{\frac{1}{p}}, \qquad |u|_k = \left(\int_\Omega |u|^k dx\right)^{\frac{1}{k}}$$

be the standard norms of $W_0^{1,p}(\Omega)$, respectively $L^k(\Omega)$ for $1 < k < p^*$. Let $X = W_0^{1,p}(\Omega)$ and $E = C_0^1(\Omega)$.

Consider the following Dirichlet problem for differential inclusion problem

$$\begin{cases} -\mathrm{div}\big(\|Du(x)\|^{p-2}Du(x)\big) - \lambda|u(x)|^{q-2}u(x) \in \partial j(x,u) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{4.1}$$

where Ω is a bounded open domain in $\mathbb{R}^N$ with a smooth boundary, $1 < q < p < +\infty$, the reaction term $\partial j(x,s)$ is the generalized gradient of a non-smooth potential $s \mapsto j(x,s)$, which is subject to the following conditions.

(H_j) $j : \Omega \times \mathbb{R} \mapsto \mathbb{R}$ is a Carathéodory function and there exist constants $a_1 > 0$, $q < p < r < p^*$ such that

(i) $j(x,\cdot)$ is locally Lipschitz for almost every $x \in \Omega$, $j(x,z) \geqslant 0$ for all $z \in \mathbb{R}$ and $\partial j(x,0) = \{0\}$ a.e. on Ω;

(ii) $|\xi| \leqslant a_1(1+|s|^{r-1})$ a.e. in Ω and for all $s \in \mathbb{R}$, $\xi \in \partial j(x,s)$;

(iii) there exist constants $\mu > p$ and $M > 0$ such that

$$\inf_{x\in\Omega} j(x,M) > 0 \quad \text{and} \quad \mu j(x,z) \leqslant -j^o(x,z;-z) \quad \text{a.e. on } \Omega \text{ all } z \geqslant M;$$

(iv) there exist $M_+ > 0$, $M_- < 0$ such that

$$\max \partial j(x, M_+^{\frac{1}{p-1}} e) < \frac{M_+}{2} \quad \text{and} \quad \min \partial j(x, M_-^{\frac{1}{p-1}} e) > \frac{M_-}{2} \quad \text{a.e. in } \Omega,$$

where $e \in W_0^{1,p}(\Omega)$ such that $-\Delta_p e = 1$.

(v) both $\min \partial j(x,z) + m|z|^{p-2}z$ and $\max \partial j(x,z) + m|z|^{p-2}z$ are nondecreasing in $z \in \mathbb{R}$ for a.e. $x \in \Omega$ and some $m \geqslant 0$.

Remark 4.1. (H_j) (iii) was firstly put forward by [27]. It is a super-linear condition; see (4.14) below. So, (4.1) has a concave-convex nonlinearity. The condition (H_j) (iv) assures the existence of a pair of strict upper and lower solution of (4.1).

For $\lambda > 0$, we introduce the energy functional $\varphi_\lambda : X \mapsto \mathbb{R}$ by

$$\varphi_\lambda(u) = \frac{1}{p}\|u\|_p^p - \frac{\lambda}{q}|u|_q^q - \int_\Omega j(x,u(x))dx,$$

Let $P = \{u \in X : u(x) \geqslant 0 \text{ a.e. } x \in \Omega\}$ and $P_1 = P \cap E$. Given $\lambda > 0$, we say that $u \in X$ is a (weak) solution of (4.1_λ) if $\Delta_p u \in L^{r'}(\Omega)$, where $\frac{1}{r} + \frac{1}{r'} = 1$, and

$$-\Delta_p u(x) \in \lambda|u(x)|^{q-2}u(x) + \partial j(x,u(x)) \quad \text{for almost every } x \in \Omega.$$

Let $K_\lambda = \{x \in X : 0 \in \partial\varphi_\lambda(x)\}$ for $\lambda > 0$.

Theorem 4.2. *Assume (H_j) holds. Then there exists $\lambda^* > 0$, such that for $\lambda \in (0,\lambda^*)$, (4.1) has at least two positive solutions $\bar{u}_1, \bar{u}_2 \in \operatorname{int} P_1$, two negative solutions $\bar{u}_3, \bar{u}_4 \in \operatorname{int}(-P_1)$, one sign-changing solution $\bar{u}_5 \in C_0^1(\bar{\Omega})$ and one nontrivial solution $\bar{u}_6 \in C_0^1(\bar{\Omega})$.*

Example 4.3. Assume $\partial j(x,u) := g(u)$ satisfies:

(a) $g : \mathbb{R} \to \mathbb{R}$ is continuous;

(b) $|g(u)| \leqslant a_1(1+|u|^{r-1})$ for some $a_1 > 0$ and $q < p < r < p^*$;

(c) there exists $\mu > p$ and $M \geqslant 0$ such that $0 < \mu G(u) \leqslant ug(u)$ for all $u \geqslant M$, where $G(u) = \int_0^u g(s)ds$;

(d) $\lim_{u\to 0} \frac{g(u)}{|u|^{p-2}u} = 0$;

(e) there exists $m_0 \geqslant 0$ such that $g(u) + m_0|u|^{p-2}u$ is nondecreasing in u.

Note $e \in L^\infty(\Omega)$ if $e \in W_0^{1,p}(\Omega)$ and $-\Delta_p e = 1$. By the condition (d) we can see the condition (H_j) (iv) holds. Thus, all of the conditions in (H_j) hold if all conditions (a)$\sim$(e) hold. According to Theorem 4.2, we see that, for small enough $\lambda > 0$, the following boundary value problem

$$\begin{cases} -\operatorname{div}\big(\|Du(x)\|^{p-2}Du(x)\big) - \lambda|u(x)|^{q-2}u(x) = g(u) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

has at least two positive solutions $\bar{u}_1, \bar{u}_2 \in \operatorname{int} P_1$, two negative solutions $\bar{u}_3, \bar{u}_4 \in \operatorname{int}(-P_1)$, one sign-changing solution $\bar{u}_5 \in C_0^1(\bar{\Omega})$ and one nontrivial solution $\bar{u}_6 \in C_0^1(\bar{\Omega})$.

We should point out that in this case $\bar{u}_6$ may be taken as a sign-changing solution. The result of this kind has been obtained in [20]. Hence, Theorem 4.2 can be thought as an extension of some main results in [20].

Example 4.4. Let

$$j(s) = \begin{cases} \frac{a}{r_1}|s|^{r_1}, & \text{if } s < 1, \\ \frac{b}{r_2}|s|^{r_2} + \left(\frac{a}{r_1} - \frac{b}{r_2}\right), & \text{if } s \geqslant 1, \end{cases}$$

where $p < r_1 < r_2 < p^*$, $0 < a < b$. Let $Q = [a, b]$, then we have

$$\partial j(s) = \begin{cases} a|s|^{r_1-2}s, & \text{if } s < 1, \\ Q, & \text{if } s = 1, \\ b|s|^{r_2-2}s, & \text{if } s > 1. \end{cases}$$

It is easy to check that (H_j) holds for the above j.

To show Theorem 4.2 we will apply Theorem 3.19. To this end, we need to check that all conditions in Theorem 3.19 hold. By now, many of these proofs are standard and well known. Nevertheless, for the convenience of the reader, we will give detailed proofs of some lemmas. Some of our proofs refer to [17, 27]. In what follows we will assume that $m = 0$. It is not difficult to show the result holds in the case of $m > 0$.

Let $A : W_0^{1,p}(\Omega) \mapsto W^{-1,p'}(\Omega)$ be defined by

$$\langle A(u), v\rangle = \int_\Omega \|Du(z)\|^{p-2}(Du(z), Dv(z))_{\mathbb{R}^N} dz \quad \text{for } u, v \in W_0^{1,p}(\Omega).$$

The following Lemma 4.5 can be found in [17, p. 435].

Lemma 4.5. *The mapping $A : W^{1,p} \mapsto W^{-1,p'}(\Omega)$ is continuous and has the $(S)_+$ property, i.e., if $\{u_n\}$ is a sequence in $W^{1,p}(\Omega)$ such that $u_n \rightharpoonup u$ in $W^{1,p}(\Omega)$ and*

$$\limsup_{n\to\infty} \langle A(u_n), u_n - u\rangle \leqslant 0,$$

then $u_n \to u$ in $W^{1,p}(\Omega)$.

Recall some facts about the spectrum of the p-Laplacian with Dirichlet boundary condition. Consider the nonlinear eigenvalue problem

$$\begin{cases} -\operatorname{div}\big(\|Du(x)\|^{p-2}Du(x)\big) = \lambda|u(x)|^{p-2}u(x) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases} \tag{4.2}$$

Let λ_1 be the principal eigenvalue of $(-\Delta_p, W_0^{1,p}(\Omega))$. Then λ_1 is positive, isolated and simple. There is the following variational characterization of λ_1 using Rayleigh quotient:

$$\lambda_1 = \inf\left\{\frac{\|Du\|_p^p}{|u|_p^p} : u \in W_0^{1,p}(\Omega), u \neq 0\right\}.$$

This minimum is actually realized at normalized eigenfunction $\widetilde{u}_1$. The Ljusternik–Schnirelmann theory gives, in addition to λ_1, a whole strictly increasing sequence of positive numbers $\lambda_1 < \lambda_2 \leqslant \lambda_3 \leqslant \cdots \leqslant \lambda_k \leqslant \cdots$ for which there exist nontrivial solutions for problem (4.2). In what follows we let $\widetilde{u}_2 \in W_0^{1,p}(\Omega)$ be a nontrivial solutions for problem (4.2) corresponding to λ_2, and $E_1 = \operatorname{span}\{\widetilde{u}_1, \widetilde{u}_2\}$.

Lemma 4.6. *If $u \in K_\lambda$, then $u \in C_0^1(\bar{\Omega})$ and u solves (4.1). Moreover, if $u \in \pm P \cap K_\lambda$ and $u \neq 0$, then $u \in \operatorname{int}(\pm P_1) \cap K_\lambda$.*

Proof. The proof is similar to Proposition 3.1 and 3.2 in [17]. Obviously, $u \mapsto \frac{1}{p}\|u\|^p$ is a C^1-functional whose derivative is the operator A. Aubin–Clarke's Theorem ensures that the functional

$$u \mapsto \int_\Omega j(x,u)dx$$

is Lipschitz continuous on any bounded subset of $L^r(\Omega)$ and its gradient is included in the set

$$N(u) = \{w \in L^{r'}(\Omega) : w(x) \in \partial j(x, u(x)) \text{ for almost every } x \in \Omega\}.$$

Since X continuously embedded in $L^r(\Omega)$, the function φ_λ turns out to be locally Lipschitz on X. So, we have

$$\partial\varphi_\lambda(u) \subset A(u) - \lambda|u|^{q-2}u - N(u). \tag{4.3}$$

Now, if $u \in X$ complies with $0 \in \partial\varphi_\lambda(u)$ then

$$A(u) = \lambda|u|^{q-2}u + w \quad \text{in } X^*$$

for some $w \in N(u)$. Hence, $\Delta_p u \in L^{r'}(\Omega)$ and u solves (4.1). By the condition (H_j) (ii) and (4.3) we get the estimate

$$-u\Delta_p u \leqslant a_1(|u| + |u|^r) \quad \text{a.e. in } \Omega.$$

Hence, by [12, Theorem 1.5.5], we have $u \in L^\infty(\Omega)$. From (H_j) (ii) it follows $\Delta_p u \in L^\infty(\Omega)$. So, by [12, Theorem 1.5.6], we have $u \in C_0^1(\bar{\Omega})$.

Let $u \in P \cap K_\lambda$ and $u \neq 0$. By (H_j) (v), we can find a constant $c_0 > 0$

$$\Delta_p u = -\lambda u^{q-1} - w \leqslant c_0 u^{p-1}$$

for some $w \in \partial j(x,u)$. The Vázquez maximum principle yields $u \in \operatorname{int} P_1$.

Similarly, if $u \in -P \cap K_\lambda$ and $u \neq 0$, then $u \in \operatorname{int}(-P_1) \cap K_\lambda$. The proof is complete. □

Lemma 4.7. *If $\{x_n\} \subset W_0^{1,p}(\Omega)$ is bounded, and either $(1 + \|x_n\|)m(x_n) \to 0$, or $(1 + \|x_n\|)m_{\pm P}(x_n) \to 0$, or $(1 + \|x_n\|)m_D(x_n) \to 0$ as $n \to +\infty$, where D is an ordered interval in X, then $\{x_n\}$ has a convergent subsequence.*

Proof. We only consider the case of $(1+\|x_n\|)m(x_n)\to 0$ as $n\to+\infty$. In a similar way we can prove other cases.

Since $\{x_n\}$ is bounded, by passing to a subsequence if necessary, we may assume

$$x_n \rightharpoonup x \quad \text{in } W_0^{1,p}(\Omega), \quad x_n \to x \quad \text{in } L^k(\Omega) \quad \text{for } 1<k<p^*, \quad x_n(z)\to x(z) \quad \text{a.e. on } \Omega$$

and $|x_n(z)|\leqslant g(z)$ a.e. on Ω, for all $n\geqslant 1$, with $g\in L^r(\Omega)$. Take $x_n^*\in\partial\varphi_\lambda(x_n)$ such that $m(x_n)=\|x_n^*\|_*$ for $n\geqslant 1$. Then we have

$$x_n^* = A(x_n)-\lambda|x_n|^{q-2}x_n-u_n \tag{4.4}$$

with $u_n\in L^{r'}(\Omega)$, where $\frac{1}{r}+\frac{1}{r'}=1$, satisfying $u_n(x)\in\partial\varphi(x,x_n(x))$ a.e. on Ω.

Now, we can deduce from $(1+\|x_n\|)m(x_n)\to 0$ that $|\langle x_n^*, x_n-x\rangle|\leqslant\frac{1}{n}\|x_n-x\|$. This reads

$$\left|\langle A(x_n),x_n-x\rangle-\lambda\int_\Omega|x_n|^{q-2}x_n(x_n-x)dz-\int_\Omega u_n(x_n-x)dz\right|\leqslant\frac{1}{n}\|x_n-x\|.$$

Then, we have

$$\lambda\int_\Omega|x_n|^{q-2}x_n(x_n-x)dz\to 0 \quad\text{and}\quad \int_\Omega u_n(x_n-x)dz\to 0 \quad \text{as } n\to\infty,$$

and so,

$$\lim_{n\to\infty}\langle A(x_n),x_n-x\rangle=0.$$

It follows from Lemma 4.5 that $x_n\to x$ in $W_0^{1,p}(\Omega)$. The proof is complete. □

Lemma 4.8. *For $\lambda>0$ small enough, the functional $\varphi_\lambda: X\mapsto\mathbb{R}$ satisfies the conditions (CPS), $(CPS)_{\pm P}$ and $(CPS)_D$ for any ordered interval $D\subset X$.*

Proof. The proof is similar to claim 1 of Theorem 3.1 in [27]. We only prove that $\varphi_\lambda: X\mapsto\mathbb{R}$ satisfies the conditions $(CPS)_P$ and $(CPS)_D$ for any interval $D\subset X$.

Let $c_1>0$ is the best embedding constant of $L^p(\Omega)\hookrightarrow L^q(\Omega)$. Assume that $\widetilde{\lambda}>0$ be such that

$$\left(\frac{\mu}{p}-1\right)-\frac{\widetilde{\lambda}c_1^p}{\lambda_1^{\frac{q}{p}}}\left(\frac{\mu}{q}-1\right)>0.$$

Let $\lambda\in(0,\widetilde{\lambda})$. In what follows $c_2,\dots,c_8$ denote some positive constants. Let $\{x_n\}\subset P$ be such that $|\varphi_\lambda(x_n)|\leqslant M_1$ for some $M_1>0$, and $(1+\|x_n\|)m_P(x_n)\to 0$ as $n\to\infty$. By Proposition 2.9 that $m_P(x_n)=\langle x_n^*,u(x_n)\rangle$ for some $x_n^*\in\partial\varphi_\lambda(x_n)$ and $u(x_n)\in(x_n-P)\cap\bar{B}(0,1)$. So, we have

$$\langle x_n^*,x_n-y\rangle\leqslant\langle x_n^*,u(x_n)\rangle \quad \text{for all } y\in P, \|x_n-y\|<1. \tag{4.5}$$

Let $y_n=x_n+\frac{1}{2\|x_n\|}x_n$ for $n\geqslant 1$. Then, $y_n\in P$, $\|x_n-y_n\|<1$. And so, by (4.5) we have

$$\begin{aligned}(1+\|x_n\|)\langle x_n^*,x_n-y_n\rangle &= -\frac{(1+\|x_n\|)}{2\|x_n\|}\langle x_n^*,x_n\rangle\\ &= -\frac{(1+\|x_n\|)}{2\|x_n\|}\left(\langle A(x_n),x_n\rangle-\lambda|x_n|_q^q+\int_\Omega j^o(z,x_n(z);-x_n(z))dz\right)\\ &\leqslant (1+\|x_n\|)\langle x_n^*,u(x_n)\rangle=:\varepsilon_n \quad \text{with } \varepsilon_n\downarrow 0.\end{aligned}$$

So we obtain

$$-\left(\langle A(x_n), x_n\rangle - \lambda|x_n|_q^q + \int_\Omega j^o(z, x_n(z); -x_n(z))dz\right) \leqslant \frac{2\|x_n\|}{(1+\|x_n\|)}\varepsilon_n.$$

which leads

$$-\|Dx_n\|_p^p + \lambda|x_n|_q^q - \int_\Omega j^o(z, x_n(z); -x_n(z))dz \leqslant \frac{2\|x_n\|}{(1+\|x_n\|)}\varepsilon_n = \varepsilon_n', \varepsilon_n' \downarrow 0. \tag{4.6}$$

Assume without loss of generality that $\varepsilon_n' \leqslant 1$ for all n. Since $|\varphi_\lambda(x_n)| \leqslant M_1$ for all $n \geqslant 1$, we have

$$\frac{1}{p}\|Dx_n\|_p^p - \frac{\lambda}{q}|x_n|_q^q - \int_\Omega j(z, x_n(z))dz \leqslant M_1. \tag{4.7}$$

By (4.6) and (4.7) we obtain that if $\|x_n\| \geqslant 1$,

$$\begin{aligned}\left(\frac{\mu}{p}-1\right)\|Dx_n\|_p^p - \lambda\left(\frac{\mu}{q}-1\right)|x_n|_q^q - \int_\Omega \left(\mu j(z, x_n(z)) + j^o(z, x_n(z); -x_n(z))\right)dz \\ \leqslant \mu M_1 + \varepsilon_n'.\end{aligned} \tag{4.8}$$

By (H_j) (ii)(iii) we have for some $\beta_1 > 0$ (see [27, 2531]),

$$\int_\Omega \left(\mu j(z, x_n(z)) + j^o(z, x_n(z); -x_n(z))\right)dz \geqslant -\beta_1. \tag{4.9}$$

It follows from (4.8) and (4.9) that for $n \geqslant 1$,

$$\left[\left(\frac{\mu}{p}-1\right) - \frac{\lambda c_1^q}{\lambda_1^{\frac{q}{p}}}\left(\frac{\mu}{q}-1\right)\right]\|Dx_n\|_p^p \leqslant \mu M_1 + 1 + \beta_1.$$

Then, we infer that $\{x_n\} \subset W_0^{1,p}(\Omega)$ is bounded. So, by Lemma 4.7 we see that $\{x_n\}$ has a convergent subsequence. Thus, φ_λ satisfies the condition $(CPS)_P$.

Now we show that φ_λ satisfies the condition $(CPS)_D$ for any ordered interval $D \subset X$. Let $\{x_n\} \subset D$ be such that $|\varphi_\lambda(x_n)| \leqslant M_2$ for some $M_2 > 0$ and $(1+\|x_n\|)m_D(x_n) \to 0$ as $n \to \infty$. Obviously, we see that $\{|x_n|_\mu\}$ is bounded. Take $s > 1$ such that $r < s < \min\left\{p^*, \frac{p\max\{N,p\}+\mu)}{\min\{N,p\}}\right\}$. By (H_j) (ii) we have for a.e. $x \in \Omega$, and $z \in \mathbb{R}$,

$$j(x,z) \leqslant c_2 + c_3|z|^s, c_2, c_3 > 0.$$

Take

$$\theta = \begin{cases}\frac{p^*(s-\mu)}{s(p^*-\mu)}, & N > p,\\ 1-\frac{\mu}{s}, & N \leqslant p.\end{cases}$$

Then we have $0 < \theta < 1$, and

$$\frac{1}{s} = \frac{1-\theta}{\mu} + \frac{\theta}{p^*}.$$

Thus, by using the interpolation inequality and the Sobolev embedding theorem, we obtain

$$|x_n|_s \leqslant |x_n|_\mu^{1-\theta}|x_n|_{p^*}^\theta \leqslant c_4\|x_n\|^\theta \quad \text{for some} \quad c_4 > 0.$$

Since $|\varphi_\lambda(x_n)| \leqslant M_1$, $L^s(\Omega) \hookrightarrow L^p(\Omega)$ and $L^s(\Omega) \hookrightarrow L^q(\Omega)$, by using the well known Young's inequality we have

$$\begin{aligned}\frac{1}{p}\|Dx_n\|_p^p &\leqslant \frac{1}{q}|x_n|_q^q + c_2|\Omega| + c_3|x_n|_s^s + M_1\\ &\leqslant c_5 + c_6|x_n|_s^s \leqslant c_7 + c_8\|Dx_n\|_p^{\theta s}.\end{aligned}$$

If $N > p$, then $Ns < p(N+\mu)$, and so we have

$$\theta s = \frac{p^*(s-\mu)}{p^*-\mu} = \frac{pN}{N-p}\cdot\frac{(s-\mu)(N-p)}{pN-N\mu+p\mu} < \frac{pN}{N-p}\cdot\frac{(s-\mu)(N-p)}{Ns-N\mu} = p.$$

If $N \leqslant p$, then $s < p+\mu$. So,

$$\theta s = \Big(1-\frac{\mu}{s}\Big)s = s-\mu < p.$$

Thus, in both cases we have $\theta s < p$. Consequently, $\{\|x_n\|\}$ is bounded. So, by Lemma 4.6 we see that $\{x_n\}$ has a convergent subsequence. Thus, φ_λ satisfies the condition $(CPS)_D$. The proof is complete. □

By the condition (H_j)(iv), we may take $\rho_+ > 1$ and $\lambda_+ > 0$ such that

$$\max\partial j(x, M_+^{\frac{1}{p-1}}e) < \frac{M_+}{2\rho_+} \text{ and } \lambda_+(M_+)^{\frac{q-p}{p-1}}\|e\|_\infty^{q-1} < \frac{1}{2\rho_+}.$$

Then we have for $\lambda \in (0, \lambda_+)$,

$$\rho_+^{-1}\big(-\Delta_p(M_+^{\frac{1}{p-1}}e)\big) > \lambda|M_+^{\frac{1}{p-1}}e|^{q-2}(M_+^{\frac{1}{p-1}}e) + \max\partial j(x, M_+^{\frac{1}{p-1}}e) \quad \text{a.e. in } \Omega. \tag{4.10}$$

Similarly, there exist $\rho_- > 1, \lambda_- > 0$ such that for $\lambda \in (0, \lambda_-)$,

$$\rho_-\big(-\Delta_p(M_-^{\frac{1}{p-1}}e)\big) < \lambda|M_-^{\frac{1}{p-1}}e|^{q-2}(M_-^{\frac{1}{p-1}}e) + \min\partial j(x, M_-^{\frac{1}{p-1}}e) \quad \text{a.e. in } \Omega.$$

Let $\rho = \min\{\rho_+, \rho_-\}$ and $\lambda^* = \min\{\lambda_-, \lambda_+, \widetilde{\lambda}\}$. For each $\lambda \in (0, \lambda^*)$, let

$$\varepsilon_0(\lambda) = \left(\frac{\lambda^{\frac{1}{p-q}}}{(\rho\lambda_1)^{\frac{1}{p-q}}\|\widetilde{u}_1\|_\infty}\right)^{p-1}.$$

Then for each $\varepsilon \in (0, \varepsilon_0(\lambda))$, we have

$$\begin{aligned}\rho\big(-\Delta_p(\varepsilon^{\frac{1}{p-1}}\widetilde{u}_1)\big) &= \rho\varepsilon\lambda_1\widetilde{u}_1^{p-1} < \lambda(\varepsilon^{\frac{1}{p-1}}\widetilde{u}_1)^{q-1}\\ &\leqslant \lambda(\varepsilon^{\frac{1}{p-1}}\widetilde{u}_1)^{q-1} + \min\partial j(x, \varepsilon^{\frac{1}{p-1}}\widetilde{u}_1) \quad \text{a.e. in } \Omega,\end{aligned} \tag{4.11}$$

and

$$\begin{aligned}\rho^{-1}\big(-\Delta_p(-\varepsilon^{\frac{1}{p-1}}\widetilde{u}_1)\big) &= -\varepsilon\lambda_1|\widetilde{u}_1|^{p-2}\widetilde{u}_1\\ &> -\lambda|\varepsilon^{\frac{1}{p-1}}\widetilde{u}_1|^{q-2}\varepsilon^{\frac{1}{p-1}}\widetilde{u}_1 + \max\partial j(x, -\varepsilon^{\frac{1}{p-1}}\widetilde{u}_1) \quad \text{a.e. in } \Omega.\end{aligned}$$

Since $\widetilde{u}_1, e \in P_1$, there exists $\varepsilon_1(\lambda) \in (0, \varepsilon_0(\lambda))$ such that for each $\lambda \in (0, \lambda^*)$ and $\varepsilon \in (0, \varepsilon_1(\lambda))$,

$$M_-^{\frac{1}{p-1}}e \ll -\varepsilon^{\frac{1}{p-1}}\widetilde{u}_1 \ll 0 \ll \varepsilon^{\frac{1}{p-1}}\widetilde{u}_1 \ll M_+^{\frac{1}{p-1}}e.$$

Let

$$u_0 = M_-^{\frac{1}{p-1}}e, v_0 = -\varepsilon^{\frac{1}{p-1}}\widetilde{u}_1, u_1 = \varepsilon^{\frac{1}{p-1}}\widetilde{u}_1, v_1 = M_+^{\frac{1}{p-1}}e \tag{4.12}$$

and $D_1 = [u_0, v_1], D_2 = [u_0, v_0], D_3 = [u_1, v_1]$.

Lemma 4.9.

1) There exists $R_0 > 0$ such that for $\lambda \in (0, \lambda^*)$,

$$\sup_{u \in S_{R_0} \cap E_1} \varphi_\lambda(u) < \varphi(0). \tag{4.13}$$

2) Let $l_\varepsilon = S_\varepsilon \cap E_1$ such that $l_\varepsilon \cap G_2 \neq \emptyset$ and $l_\varepsilon \cap G_3 \neq \emptyset$. Then there exits $\bar{\varepsilon}_0 > 0$ such that $\alpha(\varepsilon) := \max_{u \in l_\varepsilon} \varphi_\lambda(u) < 0$ for $\varepsilon \in (0, \bar{\varepsilon}_0)$.

Proof. 1) The proof is similar to claim 3 of Theorem 3.1 in [27]. For almost all $x \in \Omega$ and all $z \in \mathbb{R}$, the function $s \mapsto \frac{1}{s^\mu} j(x, sz)$ is locally Lipschitz on $(0, +\infty)$. Using the mean value theorem for locally Lipschitz functions, for $s > 1$ we can find $\theta \in (1, s)$ such that

$$\begin{aligned} \frac{1}{s^\mu} j(x, sz) - j(x, z) &\in \Big(- \frac{\mu}{\theta^{\mu+1}} j(x, \theta z) + \frac{1}{\theta^\mu} \partial_z j(x, \theta z) z \Big)(s - 1) \\ &= \frac{s-1}{\theta^{\mu+1}} \big(- \mu j(x, \theta z) + \partial_z j(x, \theta z) \theta z \big). \end{aligned}$$

By (H_j) (iii), for almost all $x \in \Omega$ and all $z \geqslant M$, we have

$$\frac{1}{s^\mu} j(x, sz) - j(x, z) \geqslant \frac{s-1}{\theta^{\mu+1}} \big(- \mu j(x, \theta z) - j^o(x, \theta z; -\theta z) \big) \geqslant 0.$$

Then for almost all $x \in \Omega$ and all $z \geqslant M$, we have

$$j(x, z) = j\Big(x, \frac{z}{M} M\Big) \geqslant \Big(\frac{z}{M}\Big)^\mu j(x, M) \geqslant \Big(\frac{z}{M}\Big)^\mu \inf_{x \in \Omega} j(x, M).$$

Take $p_1 \in (p, \mu)$. So, it is seen that for a given $\eta > 0$ we can find a constant $c_\eta > 0$ such that

$$j(x, z) \geqslant \frac{\eta}{p} z^{p_1} - c_\eta \quad \text{for a.e. } x \in \Omega. \tag{4.14}$$

Let $\bar{u} \in S_1 := \{u \in W_0^{1,p}(\Omega) : \|Du\|_p = 1\}$. It follows from (4.14) that for $t \in [0, +\infty)$,

$$\begin{aligned} \varphi_\lambda(t\bar{u}) &= \frac{1}{p} \|D(t\bar{u})\|_p^p - \frac{\lambda t^q}{q} |\bar{u}|_q^q - \int_\Omega j\big(x, t\bar{u}(x)\big) dx \\ &\leqslant \frac{t^p}{p} - \frac{\lambda t^q}{q} |\bar{u}|_q^q - \frac{\eta t^{p_1}}{p} |\bar{u}|_{p_1}^{p_1} + c_\eta |\Omega|. \end{aligned} \tag{4.15}$$

This implies that

$$\lim_{t \to +\infty} \varphi_\lambda(t\bar{u}) = -\infty.$$

Since $E_1 \cap S_1$ is compact, there exists $R_0 > 0$ such that (4.13) holds.

2) For each $u \in l_\varepsilon$, let $\bar{u} = \frac{u}{\|u\|} \in S_1$. Since $j(x, z) \geqslant 0$ for a.e. $x \in \Omega$ and $z \in \mathbb{R}$, as in the proof of (4.15) we have

$$\begin{aligned} \varphi_\lambda(\varepsilon\bar{u}) &= \frac{1}{p} \|D(\varepsilon\bar{u})\|_p^p - \frac{\lambda \varepsilon^q}{q} |\bar{u}|_q^q - \int_\Omega j\big(x, \bar{u}(x)\big) dx \\ &\leqslant \frac{\varepsilon^p}{p} - \frac{\lambda \varepsilon^q}{q} |\bar{u}|_q^q \end{aligned}$$

Thus, there exists $\bar{\varepsilon}_0 > 0$ such that $\alpha(\varepsilon) < 0$ for $\varepsilon \in (0, \bar{\varepsilon}_0)$. The proof is complete. □

Lemma 4.10. *φ_λ is outwardly directed on $\pm P$, D_i and $\pm P \cap D_i$ for $i = 1,2,3$ and $\lambda \in (0,\lambda^*)$. Moreover, φ_λ has no critical point at $\partial_E(\pm P_1)$, and $\partial_E(D_i \cap E)$ for $i = 1,2,3$ and $\lambda \in (0,\lambda^*)$, where D_i be defined by (4.12).*

Proof. We only prove that φ_λ is outwardly directed on $[u_1, v_1]$ and has no critical point on $\partial_E([u_1, v_1] \cap E)$ for $\lambda \in (0,\lambda^*)$. In the same way we can show other cases.

Assume to the contrary that $\partial_E([u_1, v_1] \cap E) \cap K_\lambda \neq \emptyset$. Take $u \in \partial_E([u_1, v_1] \cap E) \cap K_\lambda$. Then we have $u = (-\Delta_p)^{-1}\big(\lambda|u|^{q-2}u + w\big)$ for some $w \in N(u)$. It follows from $u_1, v_1 \in E$ and $u_1 \leqslant u \leqslant v_1$ that $u \in L^\infty(\Omega)$. Then we have by (4.10) and (4.11),

$$\begin{aligned} -\Delta_p u &= \lambda|u|^{q-2}u + w \geqslant \lambda|u|^{q-2}u + \min \partial j(x,u) \\ &\geqslant \lambda|u_1|^{q-2}u_1 + \min \partial j(x,u_1) \geqslant \rho\big(-\Delta_p u_1\big), \end{aligned}$$

and

$$\begin{aligned} -\Delta_p u &= \lambda|u|^{q-2}u + w \leqslant \lambda|u|^{q-2}u + \max \partial j(x,u) \\ &\leqslant \lambda|v_1|^{q-2}v_1 + \max \partial j(x,v_1) \leqslant \rho^{-1}\big(-\Delta_p v_1\big). \end{aligned}$$

As a consequence of the weak comparison theorem [35] we obtain $u \geqslant \rho^{\frac{1}{p-1}} u_1 \gg u_1$ and $v_1 \geqslant \rho^{\frac{1}{p-1}} u \gg u$. This implies that $u \in \mathrm{int}([u_1, v_1] \cap E)$, which is a contradiction. Hence, φ_λ has no critical point on $\partial_E([u_1, v_1] \cap E)$.

The following elementary inequality is well known:

$$\big(|y|^{p-2}y - |h|^{p-2}h, y-h\big)_{\mathbb{R}^N} \geqslant \begin{cases} c_1(p)(|y|+|h|)^{p-2}|y-h|^2 & \text{if } 1 < p < 2, \\ c_2(p)|y-h|^p & \text{if } p \geqslant 2 \end{cases}$$

for all $y, h \in \mathbb{R}^N$, where $c_1(p), c_2(p) > 0$ are constants.

For $u^* = Au - \lambda|u|^{q-2}u - w \in \partial\varphi_\lambda(u)$, we let $v = (-\Delta_p)^{-1}\big(\lambda|u|^{q-2}u + w\big)$, where $w \in L^{r'}(\Omega)$ and $w \in \partial j(x,u)$. If $u^* \neq 0$, then $u \neq v$, and so

$$\begin{aligned} \langle u^*, u-v\rangle &= \langle Au - \lambda|u|^{q-2}u - w, u-v\rangle \\ &= \langle Au + \Delta_p v, u-v\rangle = \langle Au, u-v\rangle + \langle \Delta_p v, u-v\rangle \\ &= \int_\Omega |\nabla u|^{p-2}\nabla u \cdot \nabla(u-v) + \int_\Omega (u-v)\Delta_p v \\ &= \int_\Omega |\nabla u|^{p-2}\nabla u \cdot \nabla(u-v) - \int_\Omega |\nabla v|^{p-2}\nabla v \cdot \nabla(u-v) \\ &\geqslant \begin{cases} c_1(p)\int_\Omega (|\nabla u| + |\nabla v|)^{p-2}|\nabla(u-v)|^2 & \text{if } 1 < p < 2, \\ c_2(p)\int_\Omega |\nabla(u-v)|^p & \text{if } p \geqslant 2 \end{cases} \\ &> 0. \end{aligned}$$

This implies that φ_λ is outwardly directed on $[u_1, v_1]$. The proof is complete. □

Lemma 4.11. *For any $a, b \in \mathbb{R}$ with $a < b$, $K_\lambda \cap \varphi_\lambda^{-1}([a,b])$ is compact in E.*

Proof. We follow some ideas in Lemma 3.2 and 3.3 in [3]. For each $u \in K_\lambda \cap \varphi_\lambda^{-1}([a,b])$, it follows from the proof of Lemma 4.6 that $u = (-\Delta_p)^{-1}(\lambda|u|^{q-2}u + w)$ for some $w \in N(u)$. By a similar way as the proof of Lemma 4.8 we can prove that $K_\lambda \cap \varphi_\lambda^{-1}([a,b])$ is bounded in X. Let

$$B(\lambda) := \big\{\lambda|u|^{q-2}u + w : u \in K_\lambda \cap \varphi_\lambda^{-1}([a,b]), w \in N(u)\big\}.$$

If $p > N$ then $X \hookrightarrow L^\infty(\Omega)$. So, $K_\lambda \cap \varphi_\lambda^{-1}([a,b])$ is bounded in $L^\infty(\Omega)$ if $p > N$. It follows the condition (H_j) (ii) that the set $B(\lambda)$ is bounded in $L^\infty(\Omega)$. According to [21], there exists $0 < \alpha < 1$ and $c_1 > 0$ such that

$$\|(-\Delta_p)^{-1}u\|_{C^{1,\alpha}} \leqslant c_1\|u\|_\infty^{\frac{1}{p-1}} \quad \text{for all } u \in L^\infty(\Omega). \tag{4.16}$$

Hence, $K_\lambda \cap \varphi_\lambda^{-1}([a,b])$ is bounded in $C^{1,\alpha}(\bar{\Omega})$, and is compact in E.

If $1 < p \leqslant N$, take $p^* > \widetilde{r} > \frac{(r-1)N}{p}$. According to [14] we have

$$\|(-\Delta_p)^{-1}u\|_\infty \leqslant c_2\|u\|_{\widetilde{r}}^{\frac{1}{p-1}} \quad \text{for all } u \in L^{\widetilde{r}}(\Omega).$$

So, for each $u \in K_\lambda \cap \varphi_\lambda^{-1}([a,b])$, $u = (-\Delta_p)^{-1}\big(\lambda|u|^{q-2}u + w\big)$ for some $w \in N(u)$, we have

$$\|u\|_\infty = \|(-\Delta_p)^{-1}(\lambda|u|^{q-2}u + w)\|_\infty \leqslant c_2\|(\lambda|u|^{q-2}u + w)\|_{\widetilde{r}}^{\frac{1}{p-1}}. \tag{4.17}$$

It follows from the Sobolev embedding theorem and the condition (H_j) (ii) that the set $B(\lambda)$ is bounded in $L^{\widetilde{r}}(\Omega)$. Thus, it follows from (4.17) that $K_\lambda \cap \varphi_\lambda^{-1}([a,b])$ is bounded in $L^\infty(\Omega)$. Then, by (4.16) , we see that $K_\lambda \cap \varphi_\lambda^{-1}([a,b])$ is compact in E. The proof is complete. □

Proof of Theorem 4.2. It follows from Lemmas 4.5∼4.11 that all conditions in Theorem 3.19 hold. According to Theorem 3.19, (4.1) has at least two positive solutions $\bar{u}_1, \bar{u}_2$, two negative solutions $\bar{u}_3, \bar{u}_4$, one sign-changing solution $\bar{u}_5$ and one nontrivial solutions $\bar{u}_6$. The proof is complete. □

Remark 4.12. There have been some papers studied the existence for sign-changing solutions of differential inclusion problems; see [3,8,17,36] and the references therein. For example, by combing variational methods with truncation techniques the paper [17] obtained the existence of positive, negative and nodal solutions to differential inclusion problems with a parameter. Here, our method is different to that in [8,17].

Remark 4.13. Here, we cannot be sure that the nontrivial solution $\bar{u}_6$ is a sign-changing solution. How to get the nontrivial solution to be a sign-changing solution under the condition of $q < p$ is a problem that needs to be further discussed.

5 Appendix: Another proof of Proposition 2.9

Proof. We follow some ideas to show von Neumann–Sion Saddle-point Theorem. Set $D = \partial\varphi(x_0)$. Let X_w^* and X_w denote the spaces X^* and X furnished their weak topology, respectively. Then $\big((x_0 - C) \cap \bar{B}(0,1)\big)$ is a sequentially compact set in the space X_w. Define $h : D \to \mathbb{R}$ by $h(y^*) = \sup_{x \in \big((x_0-C)\cap\bar{B}(0,1)\big)} \langle y^*, x\rangle$ for $y^* \in D$. Then $h : D \to \mathbb{R}$ is lower weakly semi-continuous. Note that D is a compact set of X_w^*. Hence, $\alpha = \min_{y^* \in D} \max_{x \in ((x_0-C)\cap\bar{B}(0,1))} \langle y^*, x\rangle$ exists.

For each $\delta > 0$ and $x \in \big((x_0 - C) \cap \bar{B}(0,1)\big)$, let $g_x(y^*) = \langle y^*, x\rangle - \alpha + \delta$ for all $y^* \in D$. For each $x \in \big((x_0 - C) \cap \bar{B}(0,1)\big)$ and $\varepsilon > 0$, let

$$G_{x,\varepsilon} = \{y^* \in D : g_x(y^*) > \varepsilon\}.$$

Since g_x is continuous in X_w^*, $G_{x,\varepsilon}$ is an open subset in X_w^* for each $x \in \big((x_0 - C) \cap \bar{B}(0,1)\big)$ and $\varepsilon > 0$. Note that the inequalities

$$g_x(y^*) \leqslant 0, \qquad \forall x \in \big((x_0 - C) \cap \bar{B}(0,1)\big)$$

has no solution in D. Then, for each $y^* \in D$, there at least exist $x \in \big((x_0 - C) \cap \bar{B}(0,1)\big)$ such that $g_x(y^*) > 0$. Hence, $\mathscr{A} = \{G_{x,\varepsilon} : x \in \big((x_0 - C) \cap \bar{B}(0,1)\big), \varepsilon > 0\}$ is an open cover of D in X_w^*. Since D is compact in X_w^*, then there exist finite sets in $\mathscr{A}$, say $G_{x_1,\varepsilon_1}, G_{x_2,\varepsilon_2}, \ldots, G_{x_m,\varepsilon_m}$, such that $D \subset \bigcup_{i=1}^m G_{x_i,\varepsilon_i}$. Let $\varepsilon_0 = \min\{\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_m\}$. Then we have $D \subset \bigcup_{i=1}^m G_{x_i,\varepsilon_0}$.

Let $T : D \to \mathbb{R}^m$ be defined by

$$T(y^*) = \big(g_{x_1}(y^*), g_{x_2}(y^*), \ldots, g_{x_m}(y^*)\big).$$

Set $A = \{(y_1, y_2, \ldots, y_m) : y_i < \varepsilon_0, i = 1, 2, \ldots, m\}$. Then, we have $\operatorname{co}\big(T(D)\big) \cap A = \emptyset$. In fact, for any $y = (y_1, y_2, \ldots, y_m) \in \operatorname{co}\big(T(D)\big)$, there exist $z_1, z_2, \ldots, z_\gamma \in T(D)$ and $t_i \geqslant 0$ for $1 \leqslant i \leqslant \gamma$, $\sum_{i=1}^m t_i = 1$ such that $y = \sum_{i=1}^\gamma t_i z_i$. Moreover, for each $z_i \in T(D)$, $1 \leqslant i \leqslant \gamma$, there exist $y_i^* (1 \leqslant i \leqslant \gamma)$ such that

$$z_i = \big(g_{x_1}(y_i^*), g_{x_2}(y_i^*), \ldots, g_{x_m}(y_i^*)\big), \qquad i = 1, 2, \ldots, \gamma.$$

Thus, we have

$$y_j = \sum_{i=1}^{\gamma} t_i g_{x_j}(y_i^*) = g_{x_j}\left(\sum_{i=1}^{\gamma} t_i y_i^*\right), \qquad j = 1, 2, \ldots, m.$$

Since $\sum_{i=1}^\gamma t_i y_i^* \in D$, then there exists $j_0 \in \{1, 2, \ldots, m\}$ such that $y_{j_0} = g_{x_{j_0}}\big(\sum_{i=1}^\gamma t_i y_i^*\big) > \varepsilon_0$. This implies that $y \notin A$, and so $\operatorname{co}\,(T(D)) \cap A = \emptyset$.

By using the Eidelheit convex separation theorem, there exists $\lambda_1', \lambda_2', \ldots, \lambda_n'$, such that $\sum_{i+1}^m \lambda_i' y_i \leqslant 1$ for all $(y_1, y_2, \ldots, y_m) \in A$, and $\sum_{i=1}^m \lambda_i' g_{x_i}(y^*) \geqslant 1$ for each $y^* \in D$ and $T(y^*) = \big(g_{x_1}(y^*), g_{x_2}(y^*), \ldots, g_{x_m}(y^*)\big) \in T(D)$. It is easy to see that $\lambda_i' \geqslant 0$ and $(\lambda_1', \lambda_2', \ldots, \lambda_m') \neq (0, 0, \ldots, 0)$. Let $\lambda = \sum_{i=1}^m \lambda_i'$ and $\lambda_i = \frac{\lambda_i'}{\lambda}$ for $i = 1, 2, \ldots, m$. Then we have for all $y^* \in D$,

$$g(y^*) := \sum_{i=1}^{m} \lambda_i g_{x_i}(y^*) \geqslant \frac{1}{\lambda} > 0.$$

Note that

$$g(y^*) = \sum_{i=1}^{m} \lambda_i \big(\langle y^*, x_i\rangle - \alpha + \delta\big) = \left\langle y^*, \sum_{i=1}^{m} \lambda_i x_i \right\rangle - \alpha + \delta.$$

Thus, we have for all $y^* \in D$,

$$\left\langle y^*, \sum_{i=1}^{m} \lambda_i x_i \right\rangle > \alpha - \delta.$$

So, we have

$$\min_{y^* \in D} \left\langle y^*, \sum_{i=1}^{m} \lambda_i x_i \right\rangle \geqslant \alpha - \delta.$$

Since $\delta > 0$ is arbitrarily given, we have

$$\max_{x \in \big((x_0 - C) \cap \bar{B}(0,1)\big)} \min_{y^* \in D} \langle y^*, x\rangle \geqslant \alpha.$$

On the other hand, we have

$$\min_{z^*\in D}\langle z^*, x\rangle \leqslant \langle y^*, x\rangle, \qquad \forall y^* \in D, x \in \big((x_0 - C)\cap \bar{B}(0,1)\big),$$

and so

$$\max_{x\in\left((x_0-C)\cap\bar{B}(0,1)\right)} \min_{z^*\in D}\langle z^*, x\rangle \leqslant \max_{x\in\left((x_0-C)\cap\bar{B}(0,1)\right)} \langle y^*, x\rangle.$$

Hence,

$$\max_{x\in\left((x_0-C)\cap\bar{B}(0,1)\right)} \min_{z^*\in D}\langle z^*, x\rangle \leqslant \min_{y^*\in D}\max_{x\in\left((x_0-C)\cap\bar{B}(0,1)\right)} \langle y^*, x\rangle = \alpha.$$

Then we have

$$\max_{x\in\left((x_0-C)\cap\bar{B}(0,1)\right)} \min_{y^*\in D}\langle y^*, x\rangle = \min_{y^*\in D}\max_{x\in\left((x_0-C)\cap\bar{B}(0,1)\right)} \langle y^*, x\rangle = \alpha.$$

Moreover, there exists $(x_0^*, x_0) \in D \times \big((x_0 - C)\cap \bar{B}(0,1)\big)$ such that

$$\max_{x\in\left((x_0-C)\cap\bar{B}(0,1)\right)} \min_{y^*\in D}\langle y^*, x\rangle = \langle x_0^*, x_0\rangle = \min_{y^*\in D}\max_{x\in\left((x_0-C)\cap\bar{B}(0,1)\right)} \langle y^*, x\rangle.$$

This implies that for all $x \in \big((x_0 - C)\cap \bar{B}(0,1)\big)$ and $y^* \in D$,

$$\langle x_0^*, x\rangle \leqslant \langle x_0^*, x_0\rangle \leqslant \langle y^*, x_0\rangle.$$

The proof is complete. □

Abstract. In this paper, we study the multiplicity of solutions to a class of Kirchhoff-type equation with critical growth

$$-\left(a+b\int_{\mathbb{R}^3}|\nabla u|^2dx\right)\Delta u+V(x)u=\lambda h(x)f(u)+g(x)u^5 \quad \text{in } \mathbb{R}^3,$$

where a, $b>0$, λ is a positive parameter and f is a continuous nonlinearity with subcritical growth. Under suitable conditions on the potentials $V(x)$, $h(x)$ and $g(x)$, we prove the multiplicity results and investigate the relation between the number of solutions with the topology of the set where g attains its maximum value for small values of the parameter λ. The proofs are based on Nehari manifold and Lusternik–Schnirelmann theory.

Keywords: Kirchhoff-type problem, critical growth, variational method.

2020 Mathematics Subject Classification: 35B33, 35J20, 35J60.

1 Introduction

Consider the following Kirchhoff-type problem

$$-\left(a+b\int_{\mathbb{R}^3}|\nabla u|^2dx\right)\Delta u+V(x)u=\lambda h(x)f(u)+g(x)u^5 \quad \text{in } \mathbb{R}^3, \tag{1.1}$$

where a, $b>0$ are constants and $\lambda>0$ is a parameter. The Kirchhoff-type problem is primarily introduced in [10] to generalize the classical D'Alembert wave equation for free vibrations of elastic strings. More precisely, the original equation is

$$h\rho\frac{\partial^2u}{\partial t^2}-\left(P_0+\frac{Eh}{2L}\int_0^L\left|\frac{\partial u}{\partial x}\right|^2dx\right)\frac{\partial^2u}{\partial x^2}+\delta\frac{\partial u}{\partial t}+f(x,u)=0 \tag{1.2}$$

for $t\geq 0$ and $0<x<L$, where $u=u(t,x)$ is the lateral displacement at the time t and at the space coordinate x, L the length of the string, h the cross-section area, E the Young modulus

✉ Corresponding author. Email: yeyiwei2011@126.com

of the material, ρ the mass density, P_0 the initial axial tension, δ the resistance modulus and f the external force. When $\delta = f = 0$, equation (1.2) is introduced by Kirchhoff [10]. For more physical and mathematical background on Kirchhoff-type problems, we refer the readers to [2,7] and the references therein.

If we set $V = 0$ and replace $\mathbb{R}^3$ by a smooth bounded domain $\Omega \subset \mathbb{R}^N (N \geq 3)$, then problem (1.1) becomes a special case of the following Kirchhoff Dirichlet problem

$$\begin{cases} -\left(a + b\int_\Omega |\nabla u|^2 dx\right)\Delta u = \hat{f}(x,u) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases} \tag{1.3}$$

Problem (1.3) is often referred to be nonlocal because of the presence of the term $\left(\int_\Omega |\nabla u|^2 dx\right)\Delta u$ which implies that (1.3) is no longer a pointwise identity. This phenomenon causes some mathematical difficulties, which make the study of problem (1.3) particularly interesting. After Lions [12] proposed an abstract functional analysis framework, problem (1.3) had attracted much attention, see, for example, [6,17–19] and the references therein. In [19], Qin et al. considered (1.3) in the case where $\hat{f}(x,u) := Q(x)u^5 + \lambda|u|^{p-1}u$ $(3 < p < 5)$, and proved the existence of one ground state solution by using variational methods that are constrained to the Nehari manifold. The relation between the number of maxima of Q and the number of positive solutions for the problem was also investigated. In [17], Naimen generalized the result of Brézis and Nirenberg ([5]) to problem (1.3) for the case when $\hat{f}(x,u) := \lambda f(x,u) + |u|^{2^*-2}u$, a, $b \geq 0$ and $a + b > 0$. Some existence results as well as nonexistence results were obtained. In [18], the authors further studied the high dimensional case $(N \geq 5)$, and proved the multiplicity of positive solutions of problem (1.3) when $\hat{f}(x,u) := \lambda u^p + u^{2^*-1}$ with $q \in [1, 2^* - 1)$. By combining the variational method and Lusternik–Schnirelmann theory, Cai et al. [6] discussed problem (1.3), where $N = 3$ and $\hat{f}(x,u) := |u|^{4-\varepsilon}u - \lambda u$ with $\varepsilon \in (0,2)$ and $\lambda \geq 0$, and obtained the existence of multiple positive solutions.

Recently, many researchers focused on the existence, multiplicity and asymptotic behavior of solutions of the following problem

$$\begin{cases} -\left(a + b\int_{\mathbb{R}^3} |\nabla u|^2 dx\right)\Delta u + V(x)u = \hat{f}(x,u) & \text{in } \mathbb{R}^3, \\ u \in H^1(\mathbb{R}^3), \end{cases} \tag{1.4}$$

where $V : \mathbb{R}^3 \to \mathbb{R}$ is a potential function and $\hat{f} \in C(\mathbb{R}^3 \times \mathbb{R}, \mathbb{R})$, see [8,11,23–27] and the references therein. In [25], Zhang studied problem (1.4) in the case where $V = 1$ and $\hat{f}(x,u) = a(x)|u|^{p-2}u + \lambda b(x)|u|^{q-2}u + u^5$ with $p, q \in (4,6)$. Besides some other conditions, he assumed that a, $b \in C(\mathbb{R}^3, \mathbb{R})$, $\lim_{|x|\to\infty} a(x) = a_\infty$, $\lim_{|x|\to\infty} b(x) = 0$ and $a(x) \geq a_\infty - Ce^{-a_0|x|}$ for some $a_0 > 0$ and $x \in \mathbb{R}^3$, and proved the existence of one ground state solution for each $\lambda > 0$. It was also proven the existence of two nontrivial solutions for $\lambda > 0$ small. Fan [8] discussed problem (1.4) when $V = 1$ and $\hat{f}(x,u) = \lambda f(x)u^{p-2} + g(x)u^5$ with $(4 < p < 6)$. With the help of Nehari manifold and Lusternik–Schnirelmann theory, he obtained a relationship between the number of positive solutions and the topology of the global maximum set of g. Later, by using a technique introduced by Adachi and Tanaka [1], Zhang et al. [27] obtained the existence of two nontrivial solutions for problem (1.4) when $\hat{f}(x,u) := \lambda f(u) + g(x)u^5$ with f belongs to $C^1(\mathbb{R}, \mathbb{R})$, V has a positive lower bound and satisfies the condition

$$\exists r > 0 \text{ such that } \lim_{|y|\to\infty} \operatorname{meas}\left\{x \in \mathbb{R}^3 : |x - y| < r, V(x) \leq M\right\} = 0, \qquad \forall M > 0.$$

Following [27], Zhang et al. [28] studied the multiplicity of solutions for the ciritical fractional Schrödinger equation with a small superlinear term of the form $(-\Delta)^s u + V(x)u = \lambda f(x,u) + g(x)|u|^{2_s^*-2}u$ in $\mathbb{R}^N$, where $N \geq 3$, $s \in (0,1)$ and $2_s^* = \frac{2N}{N-2s}$ is the critical exponent. Li et al. [11] studied the existence and concentration of positive solutions for the following nonlinear Kirchhoff-type problem

$$-\left(\varepsilon^2 a + \varepsilon b \int_{\mathbb{R}^3} |\nabla u|^2 dx\right)\Delta u + V(x)u = P(x)f(u) + Q(x)u^5 \quad \text{in } \mathbb{R}^3,$$

where $a, b > 0$, $\varepsilon > 0$ is a parameter and f is a continuous subcritical nonlinearity. As $\varepsilon \to 0$, they explored the asymptotic behavior of the semiclassical solutions. See also [26, 30] for related results.

Motivated by the works mentioned above, in this paper, we consider the multiplicity of solutions for the critical Kirchhoff-type problem (1.1) under more general conditions. Precisely, we make the following hypotheses:

(V) $V \in C(\mathbb{R}^3, \mathbb{R})$, $\inf_{x\in\mathbb{R}^3} V(x) := V_0 > 0$ and $\lim_{|x|\to\infty} V(x) = V_\infty > 0$.

(h) $h \in C(\mathbb{R}^3, \mathbb{R})$, $\inf_{x\in\mathbb{R}^3} h(x) := h_0 > 0$ and $\lim_{|x|\to\infty} h(x) = h_\infty > 0$.

(f_1) $f \in C(\mathbb{R}, \mathbb{R})$ and $\lim_{s\to 0} \frac{f(s)}{s} = \lim_{|s|\to\infty} \frac{f(s)}{s^5} = 0$.

(f_2) $\frac{f(s)}{s^3}$ is positive for $s \neq 0$, nonincreasing on $(-\infty, 0)$ and nondecreasing on $(0, +\infty)$.

(f_3) $\lim_{s\to+\infty} \frac{F(s)}{|s|^4} = +\infty$, where $F(s) = \int_0^s f(t)dt$.

(g_1) $g \in C(\mathbb{R}^3, \mathbb{R})$, $g_0 := \inf_{x\in\mathbb{R}^3} g(x) > 0$, $g_M := \sup_{x\in\mathbb{R}^3} g(x) < +\infty$ and $g_\infty := \liminf_{|x|\to\infty} g(x) < g_M$.

(g_2) There exists $\rho_0 > 0$ such that $g(x) = g_M$ for $\rho_0 < |x| < 2\rho_0$. Moreover, $g(0) < g_M$.

For dealing with the multiplicity of solutions to problem (1.1), we recall the Lusternik–Schnirelmann category theory. Suppose that Y is a closed subset of a topological space X, we denoted by $\mathrm{cat}_X(Y)$ the Lusternik–Schnirelmann category of Y in X, that is the least number of closed and contractible sets in X which cover Y; see [4] for more details. Denote

$$\Lambda := \{y \in \mathbb{R}^3 : g(y) = g_M\} \quad \text{and} \quad \Lambda_d := \{x \in \mathbb{R}^3 : \mathrm{dist}(x, \Lambda) < d\} \quad \text{for } d > 0.$$

We assume that

(g_3) The set Λ is nonempty and bounded, there exists $\rho \geq 1$ such that $g(x) - g(y) = O(|x-y|^\rho)$ as $x \to y$ uniformly for $y \in \Lambda$.

The main results of this paper are the following.

Theorem 1.1. *Assume that (V), (h), (f_1)–(f_3) and (g_1)–(g_2) are satisfied. Then there exists $\lambda_0 > 0$ such that problem (1.1) has at least two nontrivial solutions for $\lambda \in (0, \lambda_0)$.*

Theorem 1.2. *Assume that (V), (h), (f_1)–(f_3), (g_1) and (g_3) are satisfied. Then for any $d > 0$, there exists $\lambda_d > 0$ such that, for any $\lambda \in (0, \lambda_d)$, problem (1.1) has at least $\mathrm{cat}_{\Lambda_d}(\Lambda)$ nontrivial solutions.*

Remark 1.3. By assumption (g_3), there exist $C, r > 0$ such that for any $y \in \Lambda$,

$$|g(x) - g(y)| \le C|x - y|^\rho, \qquad \forall x \in B_r(y),$$

where $B_r(y)$ denotes the ball in $\mathbb{R}^3$ with radius r and center y.

Remark 1.4. We point out that, in some special cases, Theorem 1.2 permits to find an arbitrarily large number of solutions of problem (1.1). For example, suppose that (V), (h), (f_1)–(f_3) hold, $g \in C(\mathbb{R}^3, (0, +\infty))$ satisfying $0 < g_0 \le g_\infty < g_M$, and there exist k points $x_1, x_2, \ldots, x_k$ in $\mathbb{R}^3$ such that $g(x_i)$ are strict local maxima satisfying $g(x_i) = g_M = \max_{x\in\mathbb{R}^3} g(x)$, and

$$|g(x) - g(x_i)| = O(|x - x_i|^\rho) \quad \text{as } x \to x_i$$

for each $i = 1, 2, \ldots, k$ and some $\rho \ge 1$. Then it is easy to check that there exists $d = d(k) > 0$ such that $\mathrm{cat}_{\Lambda_d}(\Lambda) \ge k$. By Theorem 1.2, problem (1.1) has at least k solutions for any $\lambda \in (0, \lambda_d)$.

The proofs of Theorem 1.1 and Theorem 1.2 are based on variational methods. Since f is only continuous, we can not use the Nehari manifold arguments developed in [9, 14, 16] in which the condition $f \in C^1$ is required and to overcome this difficulty, we apply some variants of critical point theorems due to Szulkin and Weth [20]. Moreover, there are two main difficulties to prove our result. First, the lack of compactness which caused by the unbounded domain and the critical growth terms makes the bounded (PS) sequences could not converge. Second, the appearance of the nonlocal term, it would be natural to consider how the interaction between the nonlocal term and the critical nonlinear term will effect the existence and multiplicity of solutions of problem (1.1). To overcome these difficulties, we adapt a technique introduced by Benci and Cerami [4] and use the Lusternik–Schnirelmann category.

The paper is organized as follows. In Section 2, we present some technique lemmas and make the estimations for the functionals associated to problem (1.1). In Sections 3 and 4, we show the multiplicity results and complete the proofs of Theorems 1.1 and 1.2, respectively.

Throughout the paper, we make use of the following **notations**. $H^1(\mathbb{R}^3)$ is the Hilbert space endowed with the norm $\|u\|^2 = \int_{\mathbb{R}^3}(|\nabla u|^2 + u^2)dx$. $L^s(\mathbb{R}^3)$, $1 \le s \le +\infty$, denotes the usual Lebesgue space with the norm $\|\cdot\|_s$. $\mathcal{D}^{1,2}(\mathbb{R}^3)$ is the completion of $C_0^\infty(\mathbb{R}^3)$ with respect to the norm $\|u\|^2_{\mathcal{D}^{1,2}} := \int_{\mathbb{R}^3} |\nabla u|^2 dx$. S denotes the best Sobolev constant $S := \inf_{u\in\mathcal{D}^{1,2}(\mathbb{R}^3)\setminus\{0\}} \|u\|^2_{\mathcal{D}^{1,2}} \setminus \|u\|^2_6$. Finally, $C, C_1, C_2, \ldots$ denote different positive constants whose exact value is inessential.

2 Preliminaries

Let $E = H^1(\mathbb{R}^3)$ and $\|u\| = \left(\int_{\mathbb{R}^3}(a|\nabla u|^2 + V(x)u^2)dx\right)^{1/2}$. Then, by (V), $\|\cdot\|$ is an equivalent norm on E. We defined the functional on E by

$$I_\lambda(u) = \frac{1}{2}\|u\|^2 + \frac{b}{4}\left(\int_{\mathbb{R}^3} |\nabla u|^2 dx\right)^2 - \int_{\mathbb{R}^3}\left(\lambda h(x)F(u) + \frac{1}{6}g(x)|u|^6\right)dx.$$

It follows from (f_1) that for any $\varepsilon > 0$, $p \in (2, 6)$, there exists $C_\varepsilon > 0$ such that

$$\max\{|F(u)|, |f(u)u|\} \le \varepsilon|u|^2 + C_\varepsilon|u|^6, \qquad \forall u \in \mathbb{R}, \tag{2.1}$$

$$\max\{|F(u)|, |f(u)u|\} \leq \varepsilon(|u|^2 + |u|^6) + C_\varepsilon |u|^p, \qquad \forall u \in \mathbb{R}. \tag{2.2}$$

By (f_2), we derive that

$$\frac{1}{4} f(u)u \geq F(u) \geq 0, \qquad \forall u \in \mathbb{R} \tag{2.3}$$

and

$$\frac{1}{4} f(t)t - F(t) \text{ is nondecreasing in } t > 0 \text{ and nonincreasing in } t < 0. \tag{2.4}$$

Indeed, for $0 \leq s \leq t$, we have

$$\begin{aligned}
\left(\frac{1}{4} f(t)t - F(t)\right) - \left(\frac{1}{4} f(s)s - F(s)\right) &= \frac{1}{4}\left(f(t)t - f(s)s\right) - \left(F(t) - F(s)\right) \\
&= \int_0^t \frac{f(t)}{t^3}\tau^3 d\tau - \int_0^s \frac{f(s)}{s^3}\tau^3 d\tau - \int_s^t f(\tau) d\tau \\
&= \int_0^s \left(\frac{f(t)}{t^3} - \frac{f(s)}{s^3}\right)\tau^3 d\tau + \int_s^t \left(\frac{f(t)}{t^3} - \frac{f(\tau)}{\tau^3}\right)\tau^3 d\tau \\
&\geq 0.
\end{aligned}$$

Arguing similarly for the case $t \leq s \leq 0$.

In order to find the critical points of I_λ, we consider the Nehari manifold

$$\mathcal{M}_\lambda = \left\{u \in E \setminus \{0\} : \langle I'_\lambda(u), u\rangle = 0\right\}.$$

Obviously, $\mathcal{M}_\lambda$ contains all nontrivial critical points of I_λ. Since it is not assumed that f is differentiable, $\mathcal{M}_\lambda$ may not be a C^1-manifold. To overcome the non-differentiability of $\mathcal{M}_\lambda$, we adapt a technique developed in Szulkin and Weth [20].

Lemma 2.1. *Under conditions (V), (h), (f_1)–(f_2) and (g_1), for $\lambda \in (0,1)$, we have*

(i) for each $u \in E \setminus \{0\}$, there exists a unique $t_u > 0$ such that $t_u u \in \mathcal{M}_\lambda$. Moreover, the point t_u is a maximum for $t \to I_\lambda(tu)$;

(ii) the set $\mathcal{M}_\lambda$ is bounded away from 0;

(iii) let $S_1 = \{u \in E : \|u\| = 1\}$, then there exists $\alpha > 0$ such that $t_u \geq \alpha$ for each $u \in S_1$ and, for each compact subset $K \subset S_1$, there exists a constant $C_K > 0$ such that $t_u \leq C_K$ for all $u \in K$;

(iv) the mapping m_λ is a homeomorphism between S_1 and $\mathcal{M}_\lambda$, and for every $u \in \mathcal{M}_\lambda$, $m_\lambda^{-1}(u) = \frac{u}{\|u\|} \in S_1$.

Proof. (i) For each $u \in E \setminus \{0\}$ and $t > 0$, set $g(t) = I_\lambda(tu)$. It is easy to see that $g(0) = 0$, $g(t) > 0$ for $t > 0$ small and $g(t) < 0$ for $t > 0$ large. Thus g has a positive maximum at $t = t_u > 0$ such that $g'(t_u) = 0$ and $t_u u \in \mathcal{M}_\lambda$. Noticing

$$g'(t) = t\left[\|u\|^2 + t^2\left(\int_{\mathbb{R}^3} |\nabla u|^2 dx\right)^2\right] - t^3\left[\lambda \int_{\mathbb{R}^3} h(x)\frac{f(tu)}{(tu)^3}u^4 dx + t^2 \int_{\mathbb{R}^3} g(x)|u|^6 dx\right],$$

we have that t_u is unique. Indeed, suppose $t'_u > t_u > 0$ such that $t'_u u$, $t_u u \in \mathcal{M}_\lambda$. Then we deduce

$$\frac{\|u\|^2}{t_u^2} + b\|\nabla u\|_2^4 = \lambda \int_{\mathbb{R}^3} h(x)\frac{f(t_u u)}{(t_u u)^3}u^4 dx + t_u^2 \int_{\mathbb{R}^3} g(x)|u|^6 dx,$$

$$\frac{\|u\|^2}{t_u'^2}+b\|\nabla u\|_2^4=\lambda\int_{\mathbb{R}^3}h(x)\frac{f(t_u'u)}{(t_u'u)^3}u^4dx+t_u'^2\int_{\mathbb{R}^3}g(x)|u|^6dx,$$

and hence,

$$\left(\frac{1}{t_u^2}-\frac{1}{t_u'^2}\right)\|u\|^2=\lambda\int_{\mathbb{R}^3}h(x)\left(\frac{f(t_uu)}{(t_uu)^3}-\frac{f(t_u'u)}{(t_u'u)^3}\right)u^4dx+\left(t_u^2-t_u'^2\right)\int_{\mathbb{R}^3}g(x)|u|^6dx,$$

which is impossible in view of (f_2) and $t_u'>t_u>0$.

(ii) By using (2.1), (h) and (g_1), we deduce that for any $u\in\mathcal{M}_\lambda$,

$$\begin{aligned}\|u\|^2&\le\int_{\mathbb{R}^3}\left(\lambda h(x)f(u)u+g(x)|u|^6\right)dx\\&\le C\varepsilon\int_{\mathbb{R}^3}|u|^2dx+(C_1C_\varepsilon+g_M)\int_{\mathbb{R}^3}|u|^6dx\\&\le\frac{C\varepsilon}{V_0}\|u\|^2+\frac{C_1C_\varepsilon+g_M}{(aS)^3}\|u\|^6,\end{aligned}$$

which implies that $\|u\|^2\ge C_2$ for some $C_2>0$.

(iii) For each $u\in S_1$, there exists $t_u>0$ such that $t_uu\in\mathcal{M}_\lambda$. By (ii), we have

$$t_u=\|t_uu\|\ge\alpha.$$

Now we prove that $t_u\le C_K$ for all $u\in K\subset S_1$. Arguing indirectly, assume that there exists $\{u_n\}\subset K\subset S_1$ such that $t_{u_n}\to\infty$. Since K is compact, we have $u_n\to u\in K$ and $\int_{\mathbb{R}^3}|u_n|^6dx\to\int_{\mathbb{R}^3}|u|^6dx>0$. Then,

$$I_\lambda(t_{u_n}u_n)\le\frac{t_{u_n}^2}{2}\|u_n\|^2+\frac{bt_{u_n}^4}{4}\left(\int_{\mathbb{R}^3}|\nabla u_n|^2dx\right)^2-\frac{t_{u_n}^6}{6}\int_{\mathbb{R}^3}g_0|u_n|^6dx\to-\infty$$

as $n\to\infty$, which leads to a contradiction because (2.3) implies that, for all $u\in\mathcal{M}_\lambda$,

$$\begin{aligned}I_\lambda(u)&=I_\lambda(u)-\frac{1}{4}\langle I_\lambda'(u),u\rangle,\\&=\frac{1}{4}\|u\|^2+\lambda\int_{\mathbb{R}^3}h(x)\left(\frac{1}{4}f(u)u-F(u)\right)dx+\frac{1}{12}\int_{\mathbb{R}^3}g(x)|u|^6dx\\&\ge0.\end{aligned}$$

(iv) Let us define the maps $\hat{m}_\lambda:E\setminus\{0\}\to\mathcal{M}_\lambda$ and $m_\lambda:S_1\to\mathcal{M}_\lambda$ by setting

$$\hat{m}_\lambda(u)=t_uu\quad\text{and}\quad m_\lambda=\hat{m}_\lambda|_{S_1}.\tag{2.5}$$

By virtue of (i)–(iii) and [20, Proposition 3.1], we deduce that m_λ is a homemorphism between S_1 and $\mathcal{M}_\lambda$, and the inverse of m_λ is given by $m_\lambda^{-1}(u)=\frac{u}{\|u\|}$. □

Now we define the functionals $\hat{J}_\lambda:E\setminus\{0\}\to\mathbb{R}$ and $J_\lambda:S\to\mathbb{R}$, as

$$\hat{J}_\lambda(u)=I_\lambda(\hat{m}_\lambda(u))\quad\text{and}\quad J_\lambda(u)=\hat{J}_\lambda|_{S_1},$$

where $\hat{m}_\lambda(u)=t_uu$ is given in (2.5). As in [20], we have the following conclusion.

Lemma 2.2. *Under the conditions of Lemma 2.1, for $\lambda\in(0,1)$, we have*

(i) $J_\lambda \in C^1(S_1, \mathbb{R})$ *and for each* $v \in T_u(S_1) := \{v \in E : \langle u, v\rangle = 0\}$,

$$\langle J'_\lambda(u), v\rangle = \|m_\lambda(u)\|\langle I'_\lambda(m_\lambda(u)), v\rangle;$$

(ii) $\{u_n\}$ *is a Palais–Smale sequence for* J_λ *if and only if* $\{m_\lambda(u_n)\}$ *is a Palais–Smale sequence for* I_λ. *If* $\{u_n\} \subset \mathcal{M}_\lambda$ *is a bounded Palais–Smale sequence for* I_λ, *then* $\{m_\lambda^{-1}(u_n)\}$ *is a Palais–Smale sequence for* J_λ;

(iii) $u \in S_1$ *is a critical point of* J_λ *if and only if* $m_\lambda(u)$ *is a nontrivial critical point of* I_λ. *Moreover, the corresponding values coincide and* $\inf_{S_1} J_\lambda = \inf_{\mathcal{M}_\lambda} I_\lambda$.

Taking

$$c^* := \frac{a}{3}\left(\frac{bS^3 + \sqrt{(bS^3)^2 + 4aS^3 g_M}}{2g_M}\right) + \frac{b}{12}\left(\frac{bS^3 + \sqrt{(bS^3)^2 + 4aS^3 g_M}}{2g_M}\right)^2$$

and $m_\lambda^\infty := \inf_{u\in\mathcal{M}_\lambda^\infty} I_\lambda^\infty(u)$, where

$$I_\lambda^\infty(u) = \frac{1}{2}\|u\|_{V_\infty}^2 + \frac{b}{4}\left(\int_{\mathbb{R}^3} |\nabla u|^2 dx\right)^2 - \int_{\mathbb{R}^3}\left(\lambda h_\infty F(u) + \frac{1}{6}g_\infty |u|^6\right) dx,$$

$\mathcal{M}_\lambda^\infty = \{u \in E \setminus \{0\} : \langle I_\lambda^{\infty\prime}(u), u\rangle = 0\}$ and $\|u\|_{V_\infty} = \left(\int_{\mathbb{R}^3}(a\nabla u \cdot \nabla v + V_\infty uv)dx\right)^{\frac{1}{2}}$. We have the following local compactness result for I_λ.

Lemma 2.3. *Assume that conditions* (V), (h), (f_1)–(f_2) *and* (g_1) *are satisfied. Let* $\lambda > 0$ *and* $\{u_n\} \subset E$ *be a sequence such that* $I_\lambda(u_n) \to c_\lambda \in (-\infty, \min\{c^*, m_\lambda^\infty\})$ *and* $I'_\lambda(u_n) \to 0$ *as* $n \to \infty$. *Then* (u_n) *has a strongly convergent subsequence.*

Proof. By (V) and (2.3), we have

$$c_\lambda + o(1) + o(1)\|u_n\| = I_\lambda(u_n) - \frac{1}{4}\langle I'_\lambda(u_n), u_n\rangle \geq \frac{1}{4}\|u_n\|^2,$$

which implies that $\{u_n\}_{n\in\mathbb{N}} \subset E$ is bounded. Going if necessary to a subsequence, we may assume that there is $u \in E$ such that for each bounded domain $\Omega \subset \mathbb{R}^3$,

$$\begin{aligned} u_n &\rightharpoonup u \quad \text{in } E, \qquad u_n(x) \to u(x) \ \text{ a.e. } x \in \mathbb{R}^3, \\ u_n &\to u \quad \text{in } L^s(\Omega) \ \ (2 < s < 6), \\ |u_n(x)| &\leq w(x) \quad \text{for some } w \in L^s(\Omega). \end{aligned} \tag{2.6}$$

Take $A = \lim_{n\to\infty}\int_{\mathbb{R}^3}|\nabla u_n|^2 dx$. We define the functionals G, H, Φ, Ψ on E by

$$\begin{aligned} G(u) &= \frac{1}{2}\|u\|^2 + \frac{bA}{2}\int_{\mathbb{R}^3}|\nabla u|^2 dx - \int_{\mathbb{R}^3}\left(\lambda h(x)F(u) + \frac{1}{6}g(x)u^6\right)dx, \\ H(u) &= \frac{1}{2}\|u\|_{V_\infty}^2 + \frac{bA}{2}\int_{\mathbb{R}^3}|\nabla u|^2 dx - \int_{\mathbb{R}^3}\left(\lambda h_\infty F(u) + \frac{1}{6}g(x)u^6\right)dx, \\ \Phi(u) &= \frac{1}{2}\|u\|^2 + \frac{bA}{4}\int_{\mathbb{R}^3}|\nabla u|^2 dx - \int_{\mathbb{R}^3}\left(\lambda h(x)F(u) + \frac{1}{6}g(x)u^6\right)dx, \\ \Psi(u) &= \frac{1}{2}\|u\|_{V_\infty}^2 + \frac{bA}{4}\int_{\mathbb{R}^3}|\nabla u|^2 dx - \int_{\mathbb{R}^3}\left(\lambda h_\infty F(u) + \frac{1}{6}g(x)u^6\right)dx. \end{aligned}$$

We claim that $G'(u) = 0$, i.e., $\langle G'(u), \varphi\rangle = 0$ for any $\varphi \in C_0^\infty(\mathbb{R}^3)$. Assume that $1 \le p, q, r, s < +\infty$, Ω is a bounded domain and $h \in C(\Omega \times \mathbb{R})$ satisfying $|h(x,u)| \le C(|u|^{p/r} + |u|^{q/s})$, then, according to [22, Theorem A.4], the operator

$$A : L^p(\Omega)\bigcap L^q(\Omega) \longrightarrow L^r(\Omega) + L^s(\Omega) : u \to h(x,u)$$

is continuous, where $L^p(\Omega)\bigcap L^q(\Omega)$ is the space endowed with the norm $|u|_{p\wedge q} = \|u\|_{L^p(\Omega)} + \|u\|_{L^q(\Omega)}$ and $L^r(\Omega) + L^s(\Omega)$ endowed with the norm

$$|u|_{r\vee s} = \inf\left\{\|v\|_{L^r(\Omega)} + \|w\|_{L^s(\Omega)} : u = v + w, v \in L^r(\Omega), w \in L^s(\Omega)\right\}.$$

Now set $p = r = 2$, $q \in (5,6)$, $s = q/5$ and $h(x,u) = \lambda h(x) f(u)u + g(x)u^5$. By (h), (g) and (f_1), we have

$$|h(x,u)| \le C(|u|^{\frac{2}{2}} + |u|^{\frac{q}{s}}), \qquad \forall (x,u) \in \mathbb{R}^3 \times \mathbb{R}.$$

Since $\varphi \in C_0^\infty(\mathbb{R}^3)$ has a compact support Ω_0, $u_n \rightharpoonup u$ in E implies that $u_n \to u$ in $L^2(\Omega_0)\bigcap L^q(\Omega_0)$. So, by virtue of [22, Theorem A.4],

$$h(x,u_n) \to h(x,u) \quad \text{in } L^2(\Omega_0) + L^s(\Omega_0).$$

Hence

$$\begin{aligned}\int_{\mathbb{R}^3} |(h(x,u_n) - h(x,u))\varphi| dx &= \int_{\Omega_0} |(h(x,u_n) - h(x,u))\varphi| dx \\ &\le |h(x,u_n) - h(x,u)|_{2\vee s} |\varphi|_{2\wedge s'} \xrightarrow{n} 0,\end{aligned}$$

where $1/s + 1/s' = 1$. Combining this and (2.6), we get that $o(1) = \langle I'_\lambda(u_n), \varphi\rangle = \langle G'(u), \varphi\rangle + o(1)$ for any $\varphi \in C_0^\infty(\mathbb{R}^3)$. Thus $G'(u) = 0$.

Let $v_n := u_n - u$. It follows from the Brézis–Lieb lemma, [31, Lemma 2.2] and (f_1) that

$$\begin{aligned}\|u_n\|^2 - \|v_n\|^2 - \|u\|^2 &= o(1),\\ \int_{\mathbb{R}^3} g(x)(u_n^6 - u^6 - v_n^6)dx &= o(1),\\ \int_{\mathbb{R}^3} h(x)\left(F(u_n) - F(u) - F(v_n)\right)dx &= o(1).\end{aligned} \tag{2.7}$$

Noting u is a critical point of G, arguing as in [29, Lemma 2.3], we can conclude that u is locally bounded. Hence, for each $\xi \in E$, by [22, Lemma 8.9], we get

$$\left|\int_{\mathbb{R}^3} g(x)(u_n^5 - u^5 - v_n^5)\xi dx\right| = o(1)\|\xi\|, \tag{2.8}$$

and, similar to [22, Lemma 8.1],

$$\left|\int_{\mathbb{R}^3} h(x)(f(u_n) - f(u) - f(v_n))\xi dx\right| = o(1)\|\xi\|. \tag{2.9}$$

Since $v_n \rightharpoonup 0$ in E, by (V), (h) and (2.2), we deduce that

$$\int_{\mathbb{R}^3} (V(x) - V_\infty)v_n^2 dx \to 0, \qquad \int_{\mathbb{R}^3} (h(x) - h_\infty)F(v_n)dx \to 0, \tag{2.10}$$

and

$$\int_{\mathbb{R}^3} (V(x) - V_\infty)v_n\xi dx \to 0, \qquad \int_{\mathbb{R}^3} (h(x) - h_\infty)f(v_n)\xi dx, \qquad \forall \xi \in E \tag{2.11}$$

as $n \to \infty$. Hence we have

$$\begin{aligned} c_\lambda + o(1) &= I_\lambda(u_n) \\ &= \frac{1}{2}(\|u\|^2 + \|v_n\|^2) + \frac{bA}{4}\int_{\mathbb{R}^3}(|\nabla u|^2 + |\nabla v_n|^2)dx \\ &\quad - \int_{\mathbb{R}^3}\lambda h(x)(F(u) + F(v_n))dx - \int_{\mathbb{R}^3}\frac{1}{6}g(x)(u^6 + v_n^6)dx + o(1) \\ &= \frac{1}{2}(\|u\|^2 + \|v_n\|_{V_\infty}^2) + \frac{bA}{4}\int_{\mathbb{R}^3}(|\nabla u|^2 + |\nabla v_n|^2)dx \\ &\quad - \int_{\mathbb{R}^3}\lambda(h(x)F(u) + h_\infty F(v_n))dx - \int_{\mathbb{R}^3}\frac{1}{6}g(x)(u^6 + v_n^6)dx + o(1) \\ &= \Phi(u) + \Psi(v_n) + o(1), \end{aligned}$$

by (2.10) and (2.7). Moreover, noting $G'(u) = 0$, by (h), (g_1) and (2.3) we have

$$\begin{aligned} \Phi(u) &= \Phi(u) - \frac{1}{4}\langle G'(u), u\rangle \\ &= \frac{1}{4}\|u\|^2 + \int_{\mathbb{R}^3}\left[\lambda h(x)\left(\frac{1}{4}f(u)u - F(u)\right) + \frac{1}{12}g(x)u^6\right]dx \\ &\geq 0, \end{aligned}$$

and hence

$$c_\lambda + o(1) \geq \Psi(v_n). \tag{2.12}$$

Combining (2.8), (2.9) and (2.11), we obtain that

$$\begin{aligned} o(1) &= \langle I'_\lambda(u_n), \xi\rangle - \langle G'(u), \xi\rangle \\ &= (v_n, \xi) + bA\int_{\mathbb{R}^3}\nabla v_n \nabla\xi dx - \int_{\mathbb{R}^3}(\lambda h(x)f(v_n)\xi + g(x)v_n^5\xi)dx + o(1) \\ &= \int_{\mathbb{R}^3}(a\nabla v_n\nabla\xi + V_\infty v_n\xi)dx + bA\int_{\mathbb{R}^3}\nabla v_n\nabla\xi dx - \int_{\mathbb{R}^3}(\lambda h_\infty f(v_n)\xi + g(x)v_n^5\xi)dx + o(1) \\ &= \langle H'(v_n), \xi\rangle + o(1), \qquad \forall \xi \in E, \end{aligned}$$

which implies that

$$H'(v_n) = o(1). \tag{2.13}$$

Next we prove that $v_n \to 0$ in E. According to [31, Lemma 2.1], for some subsequence of $\{v_n\}$, either "vanishing" or "nonvanishing" holds. If "nonvanishing" occurs, we can find $(y_n) \subset \mathbb{R}^3$ with $y_n \overset{n}{\to} \infty$ such that, for $w_n(x) := v_n(x + y_n)$, there is $w \in E \setminus \{0\}$ satisfying

$$\begin{aligned} w_n &\rightharpoonup w \qquad \text{in } E, \\ w_n &\to w \qquad \text{in } L^s_{loc}(\mathbb{R}^3) \ \ (2 \leq s < 6), \\ w_n(x) &\to w(x) \quad \text{a.e. } x \in \mathbb{R}^3. \end{aligned} \tag{2.14}$$

We claim that

$$L'(w) = 0, \tag{2.15}$$

where

$$L(u) = \frac{1}{2}\|u\|_{V_\infty}^2 + \frac{bA}{2}\int_{\mathbb{R}^3}|\nabla u|^2 dx - \int_{\mathbb{R}^3}\left(\lambda h_\infty F(u) + \frac{1}{6}g_\infty u^6\right)dx.$$

Indeed, for every $\xi \in E$, set $\xi_n(x) = \xi(x - y_n)$. We have $\|\xi_n\|_{H^1} = \|\xi\|_{H^1}$, and hence, by (2.13) and (2.14),

$$\begin{aligned}
&|\langle H'(v_n), \xi_n\rangle| \\
&\quad = \left| \int_{\mathbb{R}^3} \left(a\nabla v_n \cdot \nabla \xi_n + V_\infty v_n \xi_n + bA\nabla v_n \cdot \nabla \xi_n - \lambda h_\infty f(v_n)\xi_n - g(x)v_n^5 \xi_n\right) dx \right| \\
&\quad = \left| \int_{\mathbb{R}^3} \left(a\nabla w_n \cdot \nabla \xi + V_\infty w_n \xi + bA\nabla w_n \cdot \nabla \xi - \lambda h_\infty f(w_n)\xi - g(x+y_n)w_n^5 \xi\right) dx \right| \\
&\quad = \left| \int_{\mathbb{R}^3} \left(a\nabla w \cdot \nabla \xi + V_\infty w \xi + bA\nabla w \cdot \nabla \xi\right) dx - \int_{supp\xi} \left(\lambda h_\infty f(w)\xi + g_\infty w^5 \xi\right) dx \right| + o(1) \\
&\quad = |\langle L'(w), \xi\rangle| + o(1),
\end{aligned}$$

and

$$|\langle H'(v_n), \xi_n\rangle| \le \|H'(v_n)\|\|\xi_n\| \le C\|H'(v_n)\|\|\xi_n\|_{H^1} \le C\|H'(v_n)\|\|\xi\|_{H^1} \xrightarrow{n} 0.$$

So (2.15) holds. From (2.15), we see that

$$\|w\|_{V_\infty}^2 + bA\int_{\mathbb{R}^3} |\nabla w|^2 dx = \int_{\mathbb{R}^3} (\lambda h_\infty f(w)w + g_\infty |w|^6) dx. \tag{2.16}$$

Since $w \neq 0$, there exists a unique $t > 0$ such that $tw \in \mathcal{M}_\lambda^\infty$, i.e.,

$$t^2\|w\|_{V_\infty}^2 + bt^4\left(\int_{\mathbb{R}^3} |\nabla w|^2 dx\right)^2 = \int_{\mathbb{R}^3} (\lambda h_\infty f(tw)tw + t^6 g_\infty |w|^6) dx. \tag{2.17}$$

We claim that $t \le 1$. For otherwise $t > 1$, then it follows from (2.17), (2.16), (f_2) and the fact $A \ge \int_{\mathbb{R}^3} |\nabla w|^2 dx$ that

$$\begin{aligned}
t^2\|w\|_{V_\infty}^2 + bt^4\left(\int_{\mathbb{R}^3} |\nabla w|^2 dx\right)^2 &< t^4\left[\|w\|_{V_\infty}^2 + b\left(\int_{\mathbb{R}^3} |\nabla w|^2 dx\right)^2\right] \\
&\le t^4\left(\|w\|_{V_\infty}^2 + bA\int_{\mathbb{R}^3} |\nabla w|^2 dx\right) \\
&= t^4 \int_{\mathbb{R}^3} (\lambda h_\infty f(w)w + g_\infty |w|^6) dx \\
&\le \int_{\mathbb{R}^3} (\lambda h_\infty f(w)t^4 w + t^6 g_\infty |w|^6) dx \\
&\le \int_{\mathbb{R}^3} \left(\lambda h_\infty \frac{f(tw)}{(tw)^3} t^4 w^4 + t^6 g_\infty |w|^6\right) dx \\
&= \int_{\mathbb{R}^3} (\lambda h_\infty f(tw)tw + t^6 g_\infty |w|^6) dx \\
&= t^2\|w\|_{V_\infty}^2 + bt^4\left(\int_{\mathbb{R}^3} |\nabla w|^2 dx\right)^2,
\end{aligned}$$

a contradiction. Thus $t \le 1$. Combining this with (2.4), (2.12), (2.13) and Fatou's lemma, we deduce that

$$\begin{aligned}
c_\lambda + o(1) &\ge \Psi(v_n) - \frac{1}{4}\langle H'(v_n), v_n\rangle \\
&= \frac{1}{4}\|v_n\|_{V_\infty}^2 + \int_{\mathbb{R}^3} \lambda h_\infty \left(\frac{1}{4}f(v_n)v_n - F(v_n)\right) dx + \frac{1}{12}\int_{\mathbb{R}^3} g(x)|v_n|^6 dx
\end{aligned}$$

$$
\begin{aligned}
&= \frac{1}{4}\|w_n\|^2_{V_\infty} + \int_{\mathbb{R}^3} \lambda h_\infty \left(\frac{1}{4}f(w_n)w_n - F(w_n)\right) dx + \frac{1}{12}\int_{\mathbb{R}^3} g(x+y_n)|w_n|^6 dx \\
&\geq \frac{1}{4}\|w\|^2_{V_\infty} + \int_{\mathbb{R}^3} \lambda h_\infty \left(\frac{1}{4}f(w)w - F(w)\right) dx + \frac{1}{12}\int_{\mathbb{R}^3} g_\infty |w|^6 dx + o(1) \\
&\geq \frac{1}{4}\|tw\|^2_{V_\infty} + \int_{\mathbb{R}^3} \lambda h_\infty \left(\frac{1}{4}f(tw)tw - F(tw)\right) dx + \frac{1}{12}\int_{\mathbb{R}^3} g_\infty |tw|^6 dx + o(1) \\
&= I^\infty_\lambda(tw) - \frac{1}{4}\langle I^{\infty\prime}_\lambda(tw), tw\rangle + o(1) \\
&= I^\infty_\lambda(tw) + o(1) \\
&\geq m^\infty_\lambda + o(1),
\end{aligned}
$$

which contradicts $c_\lambda < m^\infty_\lambda$.

Thus, "nonvanishing" cannot occur, and then we have only the "vanishing" case. In this case, $v_n \to 0$ in $L^s(\mathbb{R}^3)$ $(2 < s < 6)$, and hence, by (2.2), we see that

$$
\int_{\mathbb{R}^3} h(x)F(v_n)dx \to 0 \quad \text{and} \quad \int_{\mathbb{R}^3} h(x)f(v_n)v_n dx \to 0
$$

as $n \to \infty$. Combining this and (2.12)–(2.13), we obtain

$$
c_\lambda + o(1) \geq \Psi(v_n) = \frac{1}{2}\|v_n\|^2_{V_\infty} + \frac{bA}{4}\int_{\mathbb{R}^3} |v_n|^2 dx - \frac{1}{6}\int_{\mathbb{R}^3} g(x)|v_n|^6 dx + o(1), \tag{2.18}
$$

$$
o(1) = \langle H'(v_n), v_n\rangle = \|v_n\|^2_{V_\infty} + bA\int_{\mathbb{R}^3} |\nabla v_n|^2 dx - \int_{\mathbb{R}^3} g(x)|v_n|^6 dx + o(1). \tag{2.19}
$$

Set $l = \lim_{n\to\infty}\left(\int_{\mathbb{R}^3} g(x)|v_n|^6 dx\right)^{\frac{1}{3}}$. If $l > 0$, then using (2.19) and the fact $g(x) \leq g_M$, we have

$$
\begin{aligned}
\int_{\mathbb{R}^3} g(x)|v_n|^6 dx &\geq \int_{\mathbb{R}^3} a|\nabla v_n|^2 dx + b\left(\int_{\mathbb{R}^3} |\nabla v_n|^2 dx\right)^2 + o(1) \\
&\geq aS\left(\int_{\mathbb{R}^3} |v_n|^6 dx\right)^{\frac{1}{3}} + bS^2\left(\int_{\mathbb{R}^3} |v_n|^6 dx\right)^{\frac{2}{3}} + o(1) \\
&\geq \frac{aS}{g_M^{\frac{1}{3}}}\left(\int_{\mathbb{R}^3} g(x)|v_n|^6 dx\right)^{\frac{1}{3}} + \frac{bS^2}{g_M^{\frac{2}{3}}}\left(\int_{\mathbb{R}^3} g(x)|v_n|^6 dx\right)^{\frac{2}{3}} + o(1),
\end{aligned}
$$

which implies that $l \geq \frac{bS^2 + \sqrt{(bS^2)^2 + 4aSg_M}}{2g_M^{\frac{2}{3}}}$. Combining this and (2.18), (2.19), we deduce that

$$
\begin{aligned}
c_\lambda + o(1) &\geq \Psi(v_n) - \frac{1}{6}\langle H'(v_n), v_n\rangle \\
&\geq \frac{a}{3}\int_{\mathbb{R}^3} |\nabla v_n|^2 dx + \frac{b}{12}\left(\int_{\mathbb{R}^3} |\nabla v_n|^2 dx\right)^2 \\
&\geq \frac{aS}{3g_M^{\frac{1}{3}}}\left(\int_{\mathbb{R}^3} g(x)|v_n|^6 dx\right)^{\frac{1}{3}} + \frac{bS^2}{12g_M^{\frac{2}{3}}}\left(\int_{\mathbb{R}^3} g(x)|v_n|^6 dx\right)^{\frac{2}{3}} \\
&\geq \frac{a}{3}\left(\frac{bS^3 + \sqrt{(bS^3)^2 + 4aS^3g_M}}{2g_M}\right) + \frac{b}{12}\left(\frac{bS^3 + \sqrt{(bS^3)^2 + 4aS^3g_M}}{2g_M}\right)^2 + o(1) \\
&= c^* + o(1),
\end{aligned}
$$

which is a contradiction. Thus $l = 0$, which, together with (2.19), yields that $v_n \to 0$ in E. Therefore $u_n \to u$ in E and the proof is complete. □

Lemma 2.4. *Under the conditions of Lemma 2.3, then there exists $\lambda_1 > 0$ such that $c^* < m_\lambda^\infty$ for $\lambda \in (0, \lambda_1)$.*

Proof. Suppose by contradiction that there is $\lambda_n \to 0$ such that $m_{\lambda_n}^\infty \le c^*$ for all n. In view of [13], $m_{\lambda_n}^\infty$ is attained by a positive solution $u_n \in M_{\lambda_n}^\infty$ such that $I_{\lambda_n}^\infty(u_n) = m_{\lambda_n}^\infty$. We claim that there exist C_3, $C_4 > 0$ (independent of λ) such that $C_3 \le \|u_n\|_{V_\infty} \le C_4$ for all n. Indeed, by (2.3), we have

$$c^* \ge m_{\lambda_n}^\infty = I_{\lambda_n}^\infty(u_n) - \frac{1}{4}\langle (I_{\lambda_n}^\infty)'(u_n), u_n\rangle \ge \frac{1}{4}\|u_n\|_{V_\infty}^2$$

for all n, that is, $\|u_n\|_{V_\infty}^2 \le 4c^*$ for all n. On the other hand, since $u_n \in M_{\lambda_n}^\infty$, by condition (g_1) and (2.1), we obtain for $\varepsilon \in (0, \frac{V_\infty}{2h_\infty})$,

$$\|u_n\|_{V_\infty}^2 \le \lambda_n h_\infty \varepsilon \int_{\mathbb{R}^3} |u_n|^2 dx + (\lambda_n h_\infty C_\varepsilon + g_\infty) \int_{\mathbb{R}^3} |u_n|^6 dx$$

and then,

$$\frac{1}{2}\|u_n\|_{V_\infty}^2 \le (h_\infty C_\varepsilon + g_\infty)(aS)^{-3}\|u_n\|_{V_\infty}^6$$

for large n, which implies that

$$\|u_n\|_{V_\infty}^2 \ge \frac{(aS)^{\frac{3}{2}}}{\sqrt{2(h_\infty C_\varepsilon + g_\infty)}} \tag{2.20}$$

for n large. Then, noting $\lambda_n \to 0$, we deduce that $\lambda_n \int_{\mathbb{R}^3} h(x)F(u_n)dx = o(1)$ and $\lambda_n \int_{\mathbb{R}^3} h(x)f(u_n)u_n dx = o(1)$. Hence

$$\begin{aligned} m_{\lambda_n}^\infty &= \frac{1}{2}\|u_n\|_{V_\infty}^2 + \frac{b}{4}\left(\int_{\mathbb{R}^3} |\nabla u_n|^2 dx\right)^2 - \frac{1}{6}\int_{\mathbb{R}^3} g_\infty |u_n|^6 dx + o(1), \\ 0 &= \|u_n\|_{V_\infty}^2 + b\left(\int_{\mathbb{R}^3} |\nabla u_n|^2 dx\right)^2 - \int_{\mathbb{R}^3} g_\infty |u_n|^6 dx + o(1). \end{aligned} \tag{2.21}$$

Set $\lim_{n\to\infty} \int_{\mathbb{R}^3} |\nabla u_n|^2 dx = D$. One has $D > 0$. Indeed, if $D = 0$, then $\int_{\mathbb{R}^3} |u_n|^6 dx \to 0$ as $n \to \infty$, and thus, by (2.21), $\|u_n\|_{V_\infty}^2 \to 0$. This gives a contradiction to (2.20). It follows from (2.21) and the definition of S that $D \ge \frac{bS^3 + \sqrt{(bS^3)^2 + 4aS^3 g_\infty}}{2g_\infty}$. Hence

$$\begin{aligned} m_{\lambda_n}^\infty &= I_{\lambda_n}^\infty(u_n) - \frac{1}{6}\langle (I_{\lambda_n}^\infty)'(u_n), u_n\rangle \\ &\ge \frac{a}{3}\int_{\mathbb{R}^3} |\nabla u_n|^2 dx + \frac{b}{12}\left(\int_{\mathbb{R}^3} |\nabla u_n|^2 dx\right)^2 + o(1) \\ &\ge \frac{a}{3}\left(\frac{bS^3 + \sqrt{(bS^3)^2 + 4aS^3 g_\infty}}{2g_\infty}\right) + \frac{b}{12}\left(\frac{bS^3 + \sqrt{(bS^3)^2 + 4aS^3 g_\infty}}{2g_\infty}\right)^2 + o(1), \end{aligned}$$

a contradiction with $m_{\lambda_n}^\infty \le c^*$ and $g_\infty < g_M$. □

Corollary 2.5. *Under the conditions of Lemma 2.3, for each $\lambda \in (0, \lambda_1)$, we have J_λ satisfies the Palais–Smale condition for $c_\lambda < c^*$.*

Proof. Let $\{u_n\} \subset S_1$ be a Palais–Smale sequence for J_λ. By Lemma 2.2, $\{m_\lambda(u_n)\} \subset \mathcal{M}_\lambda$ is a Palais–Smale sequence for I_λ, and then using Lemma 2.3, we deduce that $w_n := m_\lambda(u_n) \to w$ in E after passing to a subsequence. Since the mapping m_λ is a homeomorphism between S_1 and $\mathcal{M}_\lambda$, we see that m_λ^{-1} is continuous. Hence $u_n = m_\lambda^{-1}(w_n) \to m_\lambda^{-1}(w)$ in E. The proof is complete. □

For $\varepsilon > 0$ and $y \in \Lambda$, let

$$u_{\varepsilon,y}(x) = \frac{\psi(x)\varepsilon^{\frac{1}{4}}}{(\varepsilon + |x-y|^2)^{\frac{1}{2}}},$$

where $\psi \in C_0^\infty(B_{2r_0}(y))$ such that $\psi(x) = 1$ for $|x-y| \le r_0$, $0 \le \psi(x) \le 1$ and $|\nabla\psi| \le 2$. It is well known that S is attained by the function $\frac{\varepsilon^{1/4}}{(\varepsilon+|x|^2)^{1/2}}$. For $\varepsilon > 0$ small, we have (see [22]):

$$\int_{\mathbb{R}^3} |\nabla u_{\varepsilon,y}|^2 dx = K_1 + O(\varepsilon^{\frac{1}{2}}), \qquad \int_{\mathbb{R}^3} |u_{\varepsilon,y}|^6 dx = K_2 + O(\varepsilon^{\frac{3}{2}}) \tag{2.22}$$

and

$$\int_{\mathbb{R}^3} |u_{\varepsilon,y}|^s dx = \begin{cases} O(\varepsilon^{\frac{6-s}{4}}), & s \in (3,6), \\ O(\varepsilon^{\frac{3}{4}}|\ln\varepsilon|), & s = 3, \\ O(\varepsilon^{\frac{s}{4}}), & s \in [2,3), \end{cases} \tag{2.23}$$

where K_1, K_2 are positive constants and $S = K_1/K_2^{1/3}$.

Lemma 2.6. *Assume that conditions (V), (h), (f_1), (f_3) and (g_3) are satisfied. Then there exist C_0, $\varepsilon_0 > 0$ independent of $y \in \Lambda$ such that for $\varepsilon \in (0, \varepsilon_0)$, $\sup_{t\ge 0} I_\lambda(tu_{\varepsilon,y}) \le c^* - C_0\varepsilon^{\frac{1}{2}}$.*

Proof. For $y \in \Lambda$, we get

$$\int_{\mathbb{R}^3} g(x)|u_{\varepsilon,y}|^6 dx = \int_{\mathbb{R}^3} (g(x) - g(y))|u_{\varepsilon,y}|^6 dx + \int_{\mathbb{R}^3} g_M |u_{\varepsilon,y}|^6 dx. \tag{2.24}$$

By (g_3), there exist $r_1 \in (0, 2r_0)$ and $C > 0$ such that $|g(x) - g(y)| \le C|x-y|^\rho$ for $|x-y| < r_1$ and for $y \in \Lambda$. Then we have

$$\begin{aligned}
\int_{\mathbb{R}^3} |g(x) - g(y)||u_{\varepsilon,y}|^6 dx &= \int_{|x-y|\le 2r_0} |g(x) - g(y)||u_{\varepsilon,y}|^6 dx \\
&\le \int_{|x-y|<r_1} C|x-y|^\rho \frac{\varepsilon^{\frac{3}{2}}}{(\varepsilon + |x-y|^2)^3} dx \\
&\quad + \int_{r_1 \le |x-y| \le 2r_0} \frac{2g_M\varepsilon^{\frac{3}{2}}}{(\varepsilon + |x-y|^2)^3} dx \\
&\le C\int_0^{r_1} \frac{\varepsilon^{\frac{3}{2}} r^{2+\rho}}{(\varepsilon + r^2)^3} dr + C\int_{r_1}^{2r_0} \frac{\varepsilon^{\frac{3}{2}} r^2}{(\varepsilon + r^2)^3} dr \\
&\le C\varepsilon^{\frac{\rho}{2}} \int_0^{\frac{r_1}{\sqrt{\varepsilon}}} \frac{r^{2+\rho}}{(1+r^2)^3} dr + C\int_{\frac{r_1}{\sqrt{\varepsilon}}}^{\frac{2r_0}{\sqrt{\varepsilon}}} \frac{r^2}{(1+r^2)^3} dr \\
&\le C_5 h(\varepsilon),
\end{aligned} \tag{2.25}$$

where

$$h(\varepsilon) = \begin{cases} \varepsilon^{\frac{\rho}{2}}, & 1 \le \rho < 3, \\ \varepsilon^{\frac{3}{2}}|\ln\varepsilon|, & \rho = 3, \\ \varepsilon^{\frac{3}{2}}, & \rho > 3. \end{cases}$$

From (2.24) and (2.25), we obtain that

$$\int_{\mathbb{R}^3} g(x)|u_{\varepsilon,y}|^6 dx = g_M \int_{\mathbb{R}^3} |u_{\varepsilon,y}|^6 dx + O(h(\varepsilon)). \tag{2.26}$$

It follows from (2.22) and (2.23) that there exists $\varepsilon_1 > 0$ (independent of $y \in \Lambda$) such that for $\varepsilon \in (0, \varepsilon_1)$,

$$\int_{\mathbb{R}^3} |\nabla u_{\varepsilon,y}|^2 dx \le \frac{3K_1}{2}, \qquad \|u_{\varepsilon,y}\|^2 \le \frac{3aK_1}{2}, \qquad \int_{\mathbb{R}^3} g(x)|u_{\varepsilon,y}|^6 dx \ge \frac{g_0 K_2}{2}.$$

Then, using (2.3),

$$\begin{aligned} I_\lambda(tu_{\varepsilon,y}) &\le \frac{t^2}{2}\|u_{\varepsilon,y}\|^2 + \frac{bt^4}{4}\left(\int_{\mathbb{R}^3} |\nabla u_{\varepsilon,y}|^2 dx\right)^2 - \frac{t^6}{6}\int_{\mathbb{R}^3} g(x)|u_{\varepsilon,y}|^6 dx \\ &\le \frac{3aK_1}{4}t^2 + \frac{9bK_1^2}{16}t^4 - \frac{g_0 K_2}{12}t^6, \end{aligned}$$

which implies that there are $t_1 > 0$ small and $t_2 > 0$ large (independent of ε) such that

$$\sup_{t\in[0,t_1]\cup[t_2,+\infty)} I_\lambda(tu_{\varepsilon,y}) \le \frac{c^*}{2}. \tag{2.27}$$

Set $B_\varepsilon = \frac{\int_{\mathbb{R}^3} |\nabla u_{\varepsilon,y}|^2 dx}{\left(\int_{\mathbb{R}^3} g(x)|u_{\varepsilon,y}|^6 dx\right)^{1/3}}$. By (2.26) and (2.22), we have

$$B_\varepsilon = \frac{K_1 + O(\varepsilon^{\frac{1}{2}})}{(g_M K_2 + O(h(\varepsilon)))^{\frac{1}{3}}} \le \frac{S}{g_M^{\frac{1}{3}}} + O(\varepsilon^{\frac{1}{2}}). \tag{2.28}$$

Take $k(t) = \frac{a}{2}t^2\|\nabla u_{\varepsilon,y}\|_2^2 + \frac{b}{4}t^4\|\nabla u_{\varepsilon,y}\|_2^4 - \frac{t^6}{6}\int_{\mathbb{R}^3} g(x)|u_{\varepsilon,y}|^6 dx$. Then

$$k'(t) = t\left(a\|\nabla u_{\varepsilon,y}\|_2^2 + bt^2\|\nabla u_{\varepsilon,y}\|_2^4 - t^4\int_{\mathbb{R}^3} g(x)|u_{\varepsilon,y}|^6 dx\right),$$

and k attains its maximum at

$$t_0 = \left(\frac{b\|\nabla u_{\varepsilon,y}\|_2^4 + \sqrt{b^2\|\nabla u_{\varepsilon,y}\|_2^8 + 4a\|\nabla u_{\varepsilon,y}\|_2^2\int_{\mathbb{R}^3} g(x)|u_{\varepsilon,y}|^6 dx}}{2\int_{\mathbb{R}^3} g(x)|u_{\varepsilon,y}|^6 dx}\right)^{\frac{1}{2}}.$$

A direct calculation shows that

$$\begin{aligned} \max_{t\ge 0} k(t) &= k(t_0) \\ &= \frac{a\|\nabla u_{\varepsilon,y}\|_2^2\left(b\|\nabla u_{\varepsilon,y}\|_2^4 + \sqrt{b^2\|\nabla u_{\varepsilon,y}\|_2^8 + 4a\|\nabla u_{\varepsilon,y}\|_2^2\int_{\mathbb{R}^3} g(x)|u_{\varepsilon,y}|^6 dx}\right)}{6\int_{\mathbb{R}^3} g(x)|u_{\varepsilon,y}|^6 dx} \\ &\quad + \frac{b\|\nabla u_{\varepsilon,y}\|_2^4\left(b\|\nabla u_{\varepsilon,y}\|_2^4 + \sqrt{b^2\|\nabla u_{\varepsilon,y}\|_2^8 + 4a\|\nabla u_{\varepsilon,y}\|_2^2\int_{\mathbb{R}^3} g(x)|u_{\varepsilon,y}|^6 dx}\right)^2}{12\left(2\int_{\mathbb{R}^3} g(x)|u_{\varepsilon,y}|^6 dx\right)^2} \\ &= \frac{a}{3}\left(\frac{bB_\varepsilon^3 + \sqrt{b^2B_\varepsilon^6 + 4aB_\varepsilon^3}}{2}\right) + \frac{b}{12}\left(\frac{bB_\varepsilon^3 + \sqrt{b^2B_\varepsilon^6 + 4aB_\varepsilon^3}}{2}\right)^2 \\ &\le \frac{a}{3}\left(\frac{bS^3 + \sqrt{(bS^3)^2 + 4ag_M S^3}}{2g_M}\right) + \frac{b}{12}\left(\frac{bS^3 + \sqrt{(bS^3)^2 + 4ag_M S^3}}{2g_M}\right)^2 + C\varepsilon^{\frac{1}{2}} \\ &= c^* + C\varepsilon^{\frac{1}{2}} \end{aligned}$$

by (2.28). Hence, there exist $C_0 > 0$ and $\varepsilon_2 \in (0, \varepsilon_1)$ (independent of $y \in \Lambda$) such that for $\varepsilon \in (0, \varepsilon_2)$,

$$\begin{aligned}\sup_{t\in[t_1,t_2]} I_\lambda(tu_{\varepsilon,y}) &\le \sup_{t\ge 0} k(t) + \frac{t_2^2}{2}\int_{\mathbb{R}^3} V(x)|u_{\varepsilon,y}|^2dx - \inf_{t\in[t_1,t_2]} \lambda\int_{\mathbb{R}^3} h(x)F(tu_{\varepsilon,y})dx \\ &\le c^* + C_0\varepsilon^{\frac{1}{2}} - \inf_{t\in[t_1,t_2]} \lambda\int_{\mathbb{R}^3} h_0F(tu_{\varepsilon,y})dx. \end{aligned} \tag{2.29}$$

From (f_3), for any $L > 0$, there is $R_L > 0$ such that $F(u) \ge L|u|^4$ for all $u \ge R_L$. Now choosing $\varepsilon_0 \in \big(0, \min\big\{\varepsilon_2, r_0^2, \big(\frac{t_1}{\sqrt{2}R_L}\big)^4\big\}\big)$, we have for $\varepsilon \in (0, \varepsilon_0)$,

$$u_{\varepsilon,y}(x) = \frac{\varepsilon^{\frac{1}{4}}}{(\varepsilon + |x-y|^2)^{\frac{1}{2}}} \ge \frac{1}{\sqrt{2}\varepsilon^{\frac{1}{4}}}, \qquad \forall |x-y| \le \sqrt{\varepsilon},$$

and then,

$$\begin{aligned}\inf_{t\in[t_1,t_2]}\int_{\mathbb{R}^3} F(tu_{\varepsilon,y})dx &\ge \inf_{t\in[t_1,t_2]}\int_{|x-y|\le\sqrt{\varepsilon}} F(tu_{\varepsilon,y})dx \\ &\ge \frac{Lt_1^4}{4\varepsilon}\int_{|x-y|\le\sqrt{\varepsilon}} dx \\ &= \frac{1}{4}Lt_1^4\varepsilon^{\frac{1}{2}}\int_{|x|\le 1} dx,\end{aligned}$$

which, together with (2.29), shows that

$$\sup_{t\in[t_1,t_2]} I_\lambda(tu_{\varepsilon,y}) \le c^* + C_0\varepsilon^{\frac{1}{2}} - \frac{\lambda h_0}{4}Lt_1^4\varepsilon^{\frac{1}{2}}\int_{|x|\le 1} dx.$$

Choosing $L > 0$ large enough, we derive that there exists $\varepsilon_0 \in (0, \varepsilon_2)$ uniformly in y such that for $\varepsilon \in (0, \varepsilon_0)$, $\sup_{t\in[t_1,t_2]} I_\lambda(tu_{\varepsilon,y}) \le c^* - C_0\varepsilon^{\frac{1}{2}}$. Combining this and (2.27), we get the conclusion. □

3 Proof of Theorem 1.1

In this section, we suppose all the conditions of Theorem 1.1 are satisfied. Define

$$\hat{I}(u) = \frac{1}{2}\|u\|^2 + \frac{b}{4}\left(\int_{\mathbb{R}^3}|\nabla u|^2dx\right)^2 - \frac{1}{6}\int_{\mathbb{R}^3} g(x)|u|^6dx$$

for $u \in E$. The following lemma plays a key role in proving Theorem 1.1.

Lemma 3.1. *There exists $\lambda_0 \in (0, \lambda_1)$ such that if $\lambda \in (0, \lambda_0)$, then $\int_{\mathbb{R}^3} \frac{x}{|x|}|u|^6dx \ne 0$ for all $u \in S_1$ with $J_\lambda(u) < c^*$.*

Proof. We adapt an argument in [27]. Assume by contradiction that there exist $\lambda_n \downarrow 0$ and $\{u_n\} \subset S_1$ such that $J_{\lambda_n}(u_n) < c^*$ and $\int_{\mathbb{R}^3} \frac{x}{|x|}|u_n|^6dx = 0$. By Lemma 2.1, there exists $t_n > 0$ such that $v_n := t_nu_n \in \mathcal{M}_{\lambda_n}$. Then one has $I_{\lambda_n}(v_n) = J_{\lambda_n}(u_n) < c^*$ and $\int_{\mathbb{R}^3} \frac{x}{|x|}|v_n|^6dx = 0$. Since $\{v_n\} \subset \mathcal{M}_\lambda$, it follows from Lemma 2.1 (ii) that $\{v_n\}$ is bounded, and then, by $\lambda_n \to 0$,

$$\lambda_n\int_{\mathbb{R}^3} h(x)F(v_n)dx = o(1) \quad \text{and} \quad \lambda_n\int_{\mathbb{R}^3} h(x)f(v_n)v_ndx = o(1).$$

Therefore,

$$c^* \geq \hat{I}(v_n) + o(1) \quad \text{and} \quad \langle \hat{I}'(v_n), v_n \rangle = o(1). \tag{3.1}$$

Take $l = \lim_{n\to\infty} \left(\int_{\mathbb{R}^3} g(x)|v_n|^6 dx\right)^{\frac{1}{3}}$. By the proof of (ii) of Lemma 2.1, one infers that $\|v_n\|_6 \geq C$ for each $n \in \mathbb{N}$ and some constant $C > 0$. Therefore, $l > 0$, which, jointly with (3.1) and the fact $g(x) \leq g_M$ for all $x \in \mathbb{R}^3$, we deduce that $l \geq \left(bS^2 + \sqrt{(bS^2)^2 + 4aSg_M}\right)/2g_M^{\frac{2}{3}}$, and hence

$$\begin{aligned}
c^* + o(1) \geq & \hat{I}(v_n) - \frac{1}{6}\langle \hat{I}'(v_n), v_n \rangle \\
= & \frac{a}{3}\int_{\mathbb{R}^3} |\nabla v_n|^2 dx + \frac{1}{3}\int_{\mathbb{R}^3} V(x)|v_n|^2 dx + \frac{b}{12}\left(\int_{\mathbb{R}^3} |\nabla v_n|^2 dx\right)^2 \\
\geq & \frac{aS}{3}\left(\int_{\mathbb{R}^3} |v_n|^6 dx\right)^{\frac{1}{3}} + \frac{bS^2}{12}\left(\int_{\mathbb{R}^3} |v_n|^6 dx\right)^{\frac{2}{3}} \\
\geq & \frac{aS}{3g_M^{\frac{1}{3}}}\left(\int_{\mathbb{R}^3} g(x)|v_n|^6 dx\right)^{\frac{1}{3}} + \frac{bS^2}{12g_M^{\frac{2}{3}}}\left(\int_{\mathbb{R}^3} g(x)|v_n|^6 dx\right)^{\frac{2}{3}} \\
\geq & \frac{aS}{3g_M^{\frac{1}{3}}} l + \frac{bS^2}{12g_M^{\frac{2}{3}}} l^2 + o(1) \\
\geq & c^* + o(1),
\end{aligned}$$

which implies that $\int_{\mathbb{R}^3} V(x)|v_n|^2 dx \to 0$, $\int_{\mathbb{R}^3} |\nabla v_n|^2 dx \to \frac{bS^3 + \sqrt{(bS^3)^2 + 4aS^3 g_M}}{2g_M}$ and

$$\lim_{n\to\infty}\left(\int_{\mathbb{R}^3} g(x)|v_n|^6 dx\right)^{\frac{1}{3}} = \lim_{n\to\infty}\left(\int_{\mathbb{R}^3} g_M|v_n|^6\right)^{\frac{1}{3}} = \frac{bS^2 + \sqrt{(bS^2)^2 + 4aSg_M}}{2g_M^{\frac{2}{3}}}. \tag{3.2}$$

Set $w_n = v_n/|v_n|_6$. Then $\int_{\mathbb{R}^3} |\nabla w_n|^2 dx \to S$ and $\int_{\mathbb{R}^3} |w_n|^6 dx = 1$. From [22, Theorem 1.41], there exist $w \in E$, $\{z_n\} \subset \mathbb{R}^3$ and $\mu_n \in (0, +\infty)$ such that $\|\mu_n^{\frac{1}{2}} w_n(\mu_n x + z_n) - w\|_{D^{1,2}} \to 0$ up to a subsequence, i.e.,

$$\left\| w_n - \frac{1}{\mu_n^{\frac{1}{2}}} w\left(\frac{x - z_n}{\mu_n}\right)\right\|_{D^{1,2}} \xrightarrow{n} 0. \tag{3.3}$$

Hence $\int_{\mathbb{R}^3} |\nabla w|^2 dx = S$ and $\int_{\mathbb{R}^3} |w|^6 dx = 1$, i.e., S is achieved by w. From [21], the minimizers of S are of the form $\frac{c_0}{(1+h_0(x-x_0)^2)^{\frac{1}{2}}}$, where $c_0 \neq 0$, $h_0 > 0$ and $x_0 \in \mathbb{R}^3$. Thus

$$\left\| w_n - \frac{c_0 \mu_n^{\frac{1}{2}}}{\left(\mu_n^2 + h_0^2|\cdot - z_n - x_0\mu_n|^2\right)^{\frac{1}{2}}}\right\|_{D^{1,2}} \xrightarrow{n} 0. \tag{3.4}$$

Observing $g(0) < g_M$, we see that there is $\delta > 0$ such that $g(x) \leq \frac{g(0)+g_M}{2}$ for $|x| \leq \delta$. We distinguish two cases.

Case 1. $\mu_n \to \mu_0 \in (0, +\infty]$ as $n \to \infty$.

Since $\int_{\mathbb{R}^3} V(x)|v_n|^2 dx \to 0$ and $V(x) \geq V_0 (> 0)$, one has $\int_{\mathbb{R}^3} |v_n(x)|^2 dx \to 0$, and hence $\int_{\mathbb{R}^3} |w_n(x)|^2 dx \to 0$ $(n \to \infty)$. Setting $x = \mu_n y + z_n$, it follows that

$$\mu_n^2 \int_{\mathbb{R}^3} |\mu_n^{\frac{1}{2}} w_n(\mu_n y + z_n)|^2 dy \to 0.$$

This, together with the fact $\mu_n \to \mu_0 \in (0, +\infty]$ and (3.3), gives $\int_{\mathbb{R}^3} |w|^2 dx = 0$, which is a contradiction.

Case 2. $\mu_n \to 0$ as $n \to \infty$. We will further consider two cases.

(i) $|z_n| \le \delta$ for large n.

Letting $z_n \to z_0$ $(n \to \infty)$, then $|z_0| \le \delta$ and $g(z_0) \le \frac{g(0)+g_M}{2}$. It follows from (3.2) and (3.3) that

$$\begin{aligned} o(1) &= \int_{\mathbb{R}^3} (g_M - g(x))|w_n|^6 dx \\ &= \int_{\mathbb{R}^3} (g_M - g(x)) \left| \frac{1}{\mu_n^2} w\left(\frac{x - z_n}{\mu_n}\right)\right|^6 dx + o(1) \\ &= \int_{\mathbb{R}^3} (g_M - g(\mu_n x + z_n))|w|^6 dx + o(1). \end{aligned}$$

Using the Lebesgue dominated convergence theorem, we have

$$0 = \int_{\mathbb{R}^3} (g_M - g(z_0))|w|^6 dx \ge \frac{g_M - g(0)}{2} \int_{\mathbb{R}^3} |w|^6 dx = \frac{g_M - g(0)}{2} > 0,$$

a contradiction.

(ii) There is a subsequence $\{z_{n_k}\} \subset \{z_n\}$ such that $|z_{n_k}| \ge \delta$ for all k. Without loss of generality, we assume that $|z_n| \ge \delta$ for all n. Since $\int_{\mathbb{R}^3} \frac{x}{|x|} |v_n|^6 dx = 0$, one has $\int_{\mathbb{R}^3} \frac{x}{|x|} |w_n|^6 dx = 0$. Hence, by (3.4),

$$\begin{aligned} o(1) &= \int_{\mathbb{R}^3} \frac{x}{|x|} \frac{c_0^6 \mu_n^3}{\left(\mu_n^2 + h_0^2 |x - z_n - x_0\mu_n|^2\right)^3} dx \\ &= \int_{\mathbb{R}^3} \left(\frac{x}{|x|} - \frac{z_n + x_0\mu_n}{|z_n + x_0\mu_n|}\right) \frac{c_0^6 \mu_n^3}{\left(\mu_n^2 + h_0^2 |x - z_n - x_0\mu_n|^2\right)^3} dx \\ &\quad + \frac{z_n + x_0\mu_n}{|z_n + x_0\mu_n|} \int_{\mathbb{R}^3} \frac{c_0^6 \mu_n^3}{\left(\mu_n^2 + h_0^2 |x - z_n - x_0\mu_n|^2\right)^3} dx. \end{aligned} \tag{3.5}$$

Since $\mu_n \to 0$ and $|z_n| \ge \delta$ for all n, we have

$$|z_n + x_0\mu_n| \ge |z_n| - \mu_n |x_0| \ge \frac{\delta}{2}$$

for large n. Combining this and the fact

$$\left| \frac{x}{|x|} - \frac{z}{|z|} \right| \le \frac{|x(|z| - |x|) + |x|(x - z)|}{|x||z|} \le \frac{2|x - z|}{|z|}$$

for all $x, z \in \mathbb{R}^3 \setminus \{0\}$, we deduce that

$$\begin{aligned} &\int_{|x-(z_n+x_0\mu_n)| \le \mu_n} \left| \frac{x}{|x|} - \frac{z_n + x_0\mu_n}{|z_n + x_0\mu_n|} \right| \frac{c_0^6 \mu_n^3}{\left(\mu_n^2 + h_0^2 |x - z_n - x_0\mu_n|^2\right)^3} dx \\ &\le \int_{|x-(z_n+x_0\mu_n)| \le \mu_n} \frac{2|x - (z_n + x_0\mu_n)|}{|z_n + x_0\mu_n|} \frac{c_0^6 \mu_n^3}{\left(\mu_n^2 + h_0^2 |x - z_n - x_0\mu_n|^2\right)^3} dx \\ &\le \frac{4\mu_n}{\delta} \int_{\mathbb{R}^3} \frac{c_0^6}{\left(1 + h_0^2 |x|^2\right)^3} dx \\ &\le C_6 \mu_n \end{aligned} \tag{3.6}$$

and

$$\begin{aligned}
&\int_{|x-(z_n+x_0\mu_n)|\geq\mu_n}\left|\frac{x}{|x|}-\frac{z_n+x_0\mu_n}{|z_n+x_0\mu_n|}\right|\frac{c_0^6\mu_n^3}{\left(\mu_n^2+h_0^2|x-z_n-x_0\mu_n|^2\right)^3}dx\\
&\quad\leq\frac{2}{|z_n+x_0\mu_n|}\int_{|x-(z_n+x_0\mu_n)|\geq\mu_n}\frac{c_0^6\mu_n^3|x-(z_n+x_0\mu_n)|}{\left(\mu_n^2+h_0^2|x-z_n-x_0\mu_n|^2\right)^3}dx\\
&\quad\leq\frac{4\mu_n}{\delta}\int_{|x|\geq1}\frac{c_0^6|x|}{\left(1+h_0^2|x|^2\right)^3}dx\\
&\quad\leq C_7\mu_n. \qquad (3.7)
\end{aligned}$$

Hence we obtain, by (3.5)–(3.7),

$$\begin{aligned}
0&=\lim_{n\to\infty}\left|\frac{z_n+x_0\mu_n}{|z_n+x_0\mu_n|}\int_{\mathbb{R}^3}\frac{c_0^6\mu_n^3}{\left(\mu_n^2+h_0^2|x-z_n-x_0\mu_n|^2\right)^3}dx\right|\\
&=\int_{\mathbb{R}^3}\frac{c_0^6}{\left(1+h_0^2|x|^2\right)^3}dx>0,
\end{aligned}$$

which is a contradiction. □

To prove Theorem 1.1, we recall a multiplicity result for critical points involving Ljusternik–Schnirelman category, which has been widely used in dealing with semilinear elliptic equations.

Lemma 3.2 (see Proposition 2.4 in [1]). *Let M be a Hilbert manifold and $I\in C^1(M,\mathbb{R})$. If there exist $c_0\in\mathbb{R}$ and $k\in\mathbb{N}$ such that $I(u)$ satisfies the (PS) condition for $c\leq c_0$ and $\mathrm{cat}(\{u\in M: I(u)\leq c_0\})\geq k$, then $I(u)$ admits at least k critical points in $\{u\in M: I(u)\leq c_0\}$.*

Lemma 3.3 (see Theorem 2.5 in [1]). *Let X be a topological space. Assume that there exist two continuous mappings*

$$F:\mathbb{S}^2=\{y\in\mathbb{R}^3:|y|=1\}\to X,\qquad G:X\to\mathbb{S}^2$$

such that $G\circ F$ is homotopic to identity, that is, there is a continuous mapping $\zeta:[0,1]\times\mathbb{S}^2\to\mathbb{S}^2$ such that $\zeta(0,x)=(G\circ F)(x)$ for $x\in\mathbb{S}^2$ and $\zeta(1,x)=x$ for $x\in\mathbb{S}^2$. Then $cat(X)\geq2$.

Proof of Theorem 1.1. Let $\lambda\in(0,\lambda_0)$ with λ_0 given in Lemma 3.1. Take $y=\frac{3}{2}\rho_0 z$, where ρ_0 is the constant given in (g_2) and $z\in\mathbb{S}^2$. Let $r_1<\frac{1}{4}\rho_0$. By (g_2), one has $g(x)=g_M$ for $|x-\frac{3}{2}\rho_0 z|\leq 2r_1$. Noting

$$u_{\varepsilon,y}(x)=\frac{\psi(x)\varepsilon^{\frac{1}{4}}}{(\varepsilon+|x-\frac{3}{2}\rho_0 z|^2)^{\frac{1}{2}}},$$

where $\psi\in C_0^\infty(B_{2r_1}(\frac{3}{2}\rho_0 z))$ such that $\psi(x)=1$ for $|x-\frac{3}{2}\rho_0 z|\leq r_1$ and $0\leq\psi(x)\leq1$, we deduce that

$$\begin{aligned}
\int_{\mathbb{R}^3}g(x)|u_{\varepsilon,y}|^6dx&=\int_{|x-\frac{3}{2}\rho_0 z|<2r_1}g(x)|u_{\varepsilon,y}|^6dx\\
&=g_M\int_{|x-\frac{3}{2}\rho_0 z|<2r_1}|u_{\varepsilon,y}|^6dx\\
&=g_M\int_{\mathbb{R}^3}|u_{\varepsilon,y}|^6dx.
\end{aligned}$$

Arguing as in the proof of Lemma 2.6, we still conclude that $\sup_{t\geq 0} I_\lambda(tu_{\varepsilon,y}) \leq c^* - C_0\varepsilon^{\frac{1}{2}}$. Set $h(t) = I_\lambda\big(\frac{tu_{\varepsilon,y}}{\|u_{\varepsilon,y}\|}\big)$, where $t > 0$ and $\varepsilon \in (0,\varepsilon_0)$ with ε_0 given in Lemma 2.6. It follows from Lemma 2.1 that $h(t)$ attains its maximum at a unique point t_y and $t_y u_{\varepsilon,y} \in \mathcal{M}_\lambda$. By Lemma 2.6,

$$J_\lambda\left(\frac{u_{\varepsilon,y}}{\|u_{\varepsilon,y}\|}\right) = I_\lambda(t_y u_{\varepsilon,y}) = \sup_{t\geq 0} I_\lambda(tu_{\varepsilon,y}) \leq c^* - C_0\varepsilon^{\frac{1}{2}} < c^*.$$

Define $F : \mathbb{S}^2 \to S_1$ by $F(z) = \frac{u_{\varepsilon,y}}{\|u_{\varepsilon,y}\|}$. Then

$$F : \mathbb{S}^2 \to \{u \in S_1 : J_\lambda(u) < c^*\}.$$

Let $G : \{u \in S_1 : J_\lambda(u) < c^*\} \to \mathbb{S}^2$ by $G(u) = \frac{\int_{\mathbb{R}^3} \frac{x}{|x|}|u|^6 dx}{\left|\int_{\mathbb{R}^3} \frac{x}{|x|}|u|^6 dx\right|}$. Then G is well defined and continuous by virtue of Lemma 3.1. Define $\zeta(\theta,z) : [0,1]\times\mathbb{S}^2 \to \mathbb{S}^2$ such that $\zeta(\theta,z) = G\big(\frac{u_{(1-\theta)\varepsilon,y}}{\|u_{(1-\theta)\varepsilon,y}\|}\big)$ for $\theta \in [0,1)$ and $\zeta(1,z) = z$. It follows from (2.22) that

$$\begin{aligned}
&\lim_{\theta\to 1^-}\int_{\mathbb{R}^3}\frac{x}{|x|}|u_{(1-\theta)\varepsilon,y}|^6 dx \\
&= \lim_{\theta\to 1^-}\int_{\mathbb{R}^3}\left(\frac{x}{|x|} - \frac{\frac{3}{2}\rho_0 z}{|\frac{3}{2}\rho_0 z|}\right)|u_{(1-\theta)\varepsilon,y}|^6 dx + \lim_{\theta\to 1^-}\frac{\frac{3}{2}\rho_0 z}{|\frac{3}{2}\rho_0 z|}\int_{\mathbb{R}^3}|u_{(1-\theta)\varepsilon,y}|^6 dx \\
&= \lim_{\theta\to 1^-}\int_{\mathbb{R}^3}\left(\frac{x}{|x|} - \frac{\frac{3}{2}\rho_0 z}{|\frac{3}{2}\rho_0 z|}\right)|u_{(1-\theta)\varepsilon,y}|^6 dx + K_2 z. \qquad (3.8)
\end{aligned}$$

Since $|u_{(1-\theta)\varepsilon,y}|^6 \leq \frac{((1-\theta)\varepsilon)^{\frac{3}{2}}}{\left((1-\theta)\varepsilon+|x-\frac{3}{2}\rho_0 z|^2\right)^3}$ and since $\left|\frac{x}{|x|} - \frac{\frac{3}{2}\rho_0 z}{|\frac{3}{2}\rho_0 z|}\right| \leq \frac{2|x-\frac{3}{2}\rho_0 z|}{|\frac{3}{2}\rho_0 z|}$, we deduce that

$$\begin{aligned}
&\int_{|x-\frac{2}{3}\rho_0 z|\leq\sqrt{(1-\theta)\varepsilon}}\left|\frac{x}{|x|} - \frac{\frac{3}{2}\rho_0 z}{|\frac{3}{2}\rho_0 z|}\right||u_{(1-\theta)\varepsilon,y}|^6 dx \\
&\leq \int_{|x-\frac{2}{3}\rho_0 z|\leq\sqrt{(1-\theta)\varepsilon}}\frac{4\left|x-\frac{2}{3}\rho_0 z\right|}{3\rho_0}\frac{1}{((1-\theta)\varepsilon)^{\frac{3}{2}}\left(1+\left|\frac{x-\frac{2}{3}\rho_0 z}{\sqrt{(1-\theta)\varepsilon}}\right|^2\right)^3}dx \\
&\leq \frac{4\sqrt{(1-\theta)\varepsilon}}{3\rho_0}\int_{|x|\leq 1}\frac{1}{(1+|x|^2)^3}dx \\
&\leq C_8\sqrt{(1-\theta)\varepsilon} \qquad (3.9)
\end{aligned}$$

and

$$\begin{aligned}
&\int_{|x-\frac{2}{3}\rho_0 z|\geq\sqrt{(1-\theta)\varepsilon}}\left|\frac{x}{|x|} - \frac{\frac{3}{2}\rho_0 z}{|\frac{3}{2}\rho_0 z|}\right||u_{(1-\theta)\varepsilon,y}|^6 dx \\
&\leq \frac{4}{3\rho_0}\int_{|x-\frac{2}{3}\rho_0 z|\geq\sqrt{(1-\theta)\varepsilon}}\frac{\left|x-\frac{3}{2}\rho_0 z\right|}{((1-\theta)\varepsilon)^{\frac{3}{2}}\left(1+\left|\frac{x-\frac{2}{3}\rho_0 z}{\sqrt{(1-\theta)\varepsilon}}\right|^2\right)^3}dx \\
&\leq \frac{4\sqrt{(1-\theta)\varepsilon}}{3\rho_0}\int_{|x|\geq 1}\frac{|x|}{(1+|x|^2)^3}dx \\
&\leq C_9\sqrt{(1-\theta)\varepsilon}. \qquad (3.10)
\end{aligned}$$

Combining (3.8)–(3.10), we have

$$\lim_{\theta\to 1^-}\int_{\mathbb{R}^3}\frac{x}{|x|}|u_{(1-\theta)\varepsilon,y}|^6dx = K_2 z,$$

which, together with the continuous of G, gives that $\zeta \in C([0,1]\times\mathbb{S}^2,\mathbb{S}^2)$. Noting $\zeta(0,z) = G\big(\frac{u_{\varepsilon,y}}{\|u_{\varepsilon,y}\|}\big) = G\circ F(z)$ and $\zeta(1,z) = z$ for $z\in\mathbb{S}^2$, one has $G\circ F : \mathbb{S}^2\to\mathbb{S}^2$, $z\to G\circ F(z)$ is homotopic to the identity. Thus, by Lemma 3.3,

$$\operatorname{cat}\left\{u\in S_1 : J_\lambda(u)\le c^* - C_0\varepsilon^{\frac{1}{2}}\right\}\ge 2.$$

Therefore, using Corollary 2.5 and Lemma 3.2, we deduce that J_λ has at least two nontrivial critical points, and thus I_λ has at least two nontrivial critical points. This completes the proof. □

4 Proof of Theorem 1.2

In this section, we suppose that all the conditions of Theorem 1.2 are satisfied. By (g_1), there is $R_0>0$ such that $g(x)\le\frac{1}{2}(g_M+g_\infty)$ for all $|x|\ge R_0$. For any $d>0$, let $\rho=\rho(d)>R_0$ be such that $\Lambda_d\subset B_\rho(0)$. Define $\chi:\mathbb{R}^3\to\mathbb{R}^3$ as $\chi(x)=x$ for $|x|\le\rho$ and $\chi(x)=\rho x/|x|$ for $|x|>\rho$. We consider the barycenter map $\beta: E\setminus\{0\}\to\mathbb{R}^3$ given by

$$\beta(u)=\frac{\int_{\mathbb{R}^3}\chi(x)|u(x)|^6dx}{\int_{\mathbb{R}^3}|u(x)|^6dx}.$$

Since $\Lambda_d\subset B_\rho(0)$, by the definition of χ and Lebesgue's theorem, we have the following conclusion.

Lemma 4.1. *For any $d>0$, there exists $\lambda_d>0$ such that, if $\lambda\in(0,\lambda_d)$ and $u\in S_1$ with $J_\lambda(u)<c^*$, then $\beta(u)\in\Lambda_d$.*

Proof. Arguing indirectly, we assume that there exist $d_0>0$, $\lambda_n\downarrow 0$ and $(u_n)\subset S_1$ with $J_{\lambda_n}(u_n)<c^*$, but $\beta(u_n)\notin\Lambda_{d_0}$. From Lemma 2.1, there exists a unique $t_n>0$ such that $t_nu_n\in M_{\lambda_n}$. Take $v_n=t_nu_n$ and $w_n=v_n/|v_n|_6$. Following the steps contained in the proof of Lemma 3.1, we deduce

$$\int_{\mathbb{R}^3}|\nabla w_n|^2dx\to S,\qquad \int_{\mathbb{R}^3}|w_n|^6dx=1\quad\text{and}\quad\int_{\mathbb{R}^3}g(x)|w_n|^6dx\to g_M. \tag{4.1}$$

So, there exist $\{z_n\}\subset\mathbb{R}^3$, $\mu_n\in(0,+\infty)$ and $w\in D^{1,2}(\mathbb{R}^3)$ such that

$$\left\|w_n-\frac{1}{\mu_n^{\frac{1}{2}}}w\left(\frac{x-z_n}{\mu_n}\right)\right\|_{D^{1,2}}\to 0\qquad(n\to\infty). \tag{4.2}$$

Thus $\int_{\mathbb{R}^3}|\nabla w|^2dx=S$ and $\int_{\mathbb{R}^3}|w|^6dx=1$. Arguing as in Lemma 3.1 (Case 1), if $\mu_n\to\mu_0\in(0,+\infty]$ $(n\to\infty)$, one obtains a contradiction. Hence $\mu_n\to 0$ as $n\to\infty$, and we distinguish into two cases.

Case 1. $\mu_n\to 0$ as $n\to\infty$ and $|z_n|\le R_0$ for large n. Suppose that $z_n\to z_0$ as $n\to\infty$. Then $|z_0|\le R_0$ and $\chi(z_0)=z_0$. Applying (4.1), (4.2) and the Lebesgue dominated convergence

theorem, we obtain

$$\begin{aligned} g_M &= \lim_{n\to\infty} \int_{\mathbb{R}^3} g(x) \left| \frac{1}{\mu_n^{\frac{1}{2}}} w\left(\frac{x-z_n}{\mu_n}\right)\right|^6 dx \\ &= \lim_{n\to\infty} \int_{\mathbb{R}^3} g(\mu_n x + z_n)|w|^6 dx \\ &= g(z_0) \int_{\mathbb{R}^3} |w|^6 dx \\ &= g(z_0), \end{aligned}$$

which implies that $z_0 \in \Lambda$. Moreover, by (4.2) and using the fact $\chi(z_0) = z_0$, we conclude that

$$\begin{aligned} \beta(w_n) &= \int_{\mathbb{R}^3} \chi(x)|w_n|^6 dx \\ &= \int_{\mathbb{R}^3} \chi(x) \left| \frac{1}{\mu_n^{\frac{1}{2}}} w\left(\frac{x-z_n}{\mu_n}\right)\right|^6 dx + o(1) \\ &= \int_{\mathbb{R}^3} \chi(\mu_n x + z_n)|w|^6 dx + o(1) \\ &= z_0 \int_{\mathbb{R}^3} |w|^6 dx + o(1) \\ &= z_0 + o(1), \end{aligned}$$

which, together with $z_0 \in \Lambda$, yields that $\beta(w_n) \in \Lambda_{d_0}$ for large n. This contradicts the assumption that $\beta(w_n) = \beta(u_n) \notin \Lambda_{d_0}$ for all n.

Case 2. $\mu_n \to 0$ as $n \to \infty$ and there exits a subsequence of $\{z_n\}$ (still denoted by $\{z_n\}$) such that $|z_n| \geq R_0$ for all n. Applying (4.1) and (4.2), we deduce that

$$\begin{aligned} o(1) &= \int_{\mathbb{R}^3} (g_M - g(x))|w_n|^6 dx \\ &= \int_{\mathbb{R}^3} (g_M - g(x)) \left| \frac{1}{\mu_n^{\frac{1}{2}}} w\left(\frac{x-z_n}{\mu_n}\right)\right|^6 dx + o(1) \\ &= \int_{\mathbb{R}^3} (g_M - g(\mu_n x + z_n))|w|^6 dx + o(1). \end{aligned}$$

Recall that $g(x) \leq \frac{1}{2}(g_\infty + g_M)$ for $|x| \geq R_0$. It follows from the Lebesgue dominated convergence theorem that

$$0 = \lim_{n\to\infty} \int_{\mathbb{R}^3} (g_M - g(\mu_n x + z_n))|w|^6 dx \geq \frac{1}{2}(g_M - g_\infty) \int_{\mathbb{R}^3} |w|^6 dx = \frac{1}{2}(g_M - g_\infty) > 0,$$

which is a contradiction. □

Now we are in a position to show that problem (1.1) admits at least $\mathrm{cat}_{\Lambda_d}(\Lambda)$ solutions. For this aim, we compare the topology of Λ and the topology of a suitable energy sublevel, and use the maps J_λ and β as they are introduced before. Moreover, we shall utilize a multiplicity result for critical points involving Lusternik–Schnirelmann category, e.g. see [15].

Lemma 4.2 (see [15]). *Let M be a $C^{1,1}$ complete Riemannian manifold (modelled on a Hilbert space) and assume that $\Phi \in C^1(M,\mathbb{R})$ bounded from below and satisfies $-\infty < \inf_M \Phi < a < b < +\infty$. Suppose that Φ satisfies the Palais–Smale condition on the sublevel $\{u \in M : \Phi(u) \le b\}$ and that a is not a critical level for Φ. Then Φ has at least $cat_{\Phi^a}(\Phi^a)$ critical points in Φ^a, where $\Phi^a := \{u \in M : \Phi(u) \le a\}$.*

Lemma 4.3 (see [3,4]). *Let A, B, M be closed sets with $A \subset B$. Let $F : A \to M$ and $G : M \to B$ be two continuous maps such that $G \circ F$ is homotopically equivalent to the embedding $J : A \to B$. Then $cat_M(M) \ge cat_B(A)$.*

Remark 4.4. Since $\mathcal{M}_\lambda$ is not a C^1 submanifold of E, we can not apply Lemma 4.2 directly. Fortunately, from Lemma 2.1, we know that the mapping m_λ is a homeomorphism between $\mathcal{M}_\lambda$ and S_1, but S_1 is a C^1 submanifold of E. Thus we can apply Lemma 4.2 to $J_\lambda(u) = I_\lambda(\hat{m}_\lambda(u))\,|_{S_1} = I_\lambda(m_\lambda(u))$, where J_λ is given in Lemma 2.2.

Proof of Theorem 1.2. For any $d > 0$, let $\lambda \in (0, \min\{\lambda_1, \lambda_d\})$ with λ_1 is given in Lemma 2.4 and λ_d is given in Lemma 4.1. It is easy to see that S_1 is a $C^{1,1}$ complete Riemann manifold and $J_\lambda \in C^1(S_1,\mathbb{R})$ is bounded from below. Set $l(t) = I_\lambda(tu_{\varepsilon,y})$, where $t > 0$, $y \in \Lambda$ and $\varepsilon \in (0,\varepsilon_0)$ with ε_0 is given in Lemma 2.6. In view of Lemma 2.1, $l(t)$ admits its maximum at a unique point t_y and $t_y u_{\varepsilon,y} \in \mathcal{M}_\lambda$. Hence, by Lemma 2.6,

$$J_\lambda\left(\frac{u_{\varepsilon,y}}{\|u_{\varepsilon,y}\|}\right) = I_\lambda(t_y u_{\varepsilon,y}) = \sup_{t\ge 0} I_\lambda(tu_{\varepsilon,y}) \le c^* - \eta_0, \tag{4.3}$$

where $\eta_0 > 0$ is a constant independent of $y \in \Lambda$. From Corollary 2.5, we see that J_λ satisfies the (PS) condition on $\{u \in S_1 : J_\lambda(u) < c^*\}$. Therefore, by Lemma 4.2, J_λ has at least $\mathrm{cat}_{S_1(\eta_0)}(S_1(\eta_0))$ critical points, where $S_1(\eta_0) = \{u \in S_1 : J_\lambda(u) \le c^* - \eta_0\}$.

Define the mappings $F : \Lambda \to S_1$ and $G : S_1(\eta_0) \to \mathbb{R}^3$ by

$$F(y) = \frac{u_{\varepsilon,y}}{\|u_{\varepsilon,y}\|}, \qquad G(u) = \beta(u).$$

Then F and G are continuous. It follows from Lemma 4.1 and (4.3) that $F(\Lambda) \subset S_1(\eta_0)$ and $G(S_1(\eta_0)) \subset \Lambda_d$. Define $\xi : [0,1] \times \Lambda \to \Lambda_d$ by

$$\xi(\theta,y) = \begin{cases} G\left(\frac{u_{(1-\theta)\varepsilon,y}}{\|u_{(1-\theta)\varepsilon,y}\|}\right), & \theta \in [0,1), \\ y, & \theta = 1. \end{cases}$$

Noting $y \in \Lambda \subset B_\rho(0)$, we obtain $\chi(y) = y$ and

$$\begin{aligned} \lim_{\theta\to 1^-} G\left(\frac{u_{(1-\theta)\varepsilon,y}}{\|u_{(1-\theta)\varepsilon,y}\|}\right) &= \lim_{\theta\to 1^-} \frac{\int_{\mathbb{R}^3} \chi(x)|u_{(1-\theta)\varepsilon,y}|^6 dx}{\int_{\mathbb{R}^3} |u_{(1-\theta)\varepsilon,y}|^6 dx} \\ &= \lim_{\theta\to 1^-} \frac{\int_{\mathbb{R}^3} \frac{\chi\left(\sqrt{(1-\theta)\varepsilon}z+y\right)\left|\psi\left(\sqrt{(1-\theta)\varepsilon}z+y\right)\right|^6}{(1+|z|^2)^3} dz}{\int_{\mathbb{R}^3} \frac{\left|\psi\left(\sqrt{(1-\theta)\varepsilon}z+y\right)\right|^6}{(1+|z|^2)^3} dz} = y. \end{aligned}$$

Thus $\xi \in C([0,1]\times\Lambda, \Lambda_d)$. Then we see that $\xi(\theta,y)$ with $(\theta,y) \in [0,1]\times\Lambda$ is a homotopy between $G \circ F$ and the inclusion map $j : \Lambda \to \Lambda_d$. This fact and Lemma 4.3 yield $\mathrm{cat}_{S_1(\eta_0)}(S_1(\eta_0)) \ge \mathrm{cat}_{\Lambda_d}(\Lambda)$. Hence, J_λ has at least $\mathrm{cat}_{\Lambda_d}(\Lambda)$ critical points. Then, in view of Lemma 2.2 (iii), we conclude that I_λ has at least $\mathrm{cat}_{\Lambda_d}(\Lambda)$ nontrivial critical points. Thus, problem (1.1) has at least $\mathrm{cat}_{\Lambda_d}(\Lambda)$ nontrivial solutions. This completes the proof. □

Abstract. The following Fisher–KPP type equation

$$u_t = Ku_{xx} - Bu^q + Au^p, \quad (x,t) \in \mathbb{R} \times (0,\infty),$$

with $p > q > 0$ and A, B, K positive coefficients, is considered. For both $p > q > 1$ and $p > 1$, $q = 1$, we construct stationary solutions, establish their behavior as $|x| \to \infty$ and prove that they are separatrices between solutions decreasing to zero in infinite time and solutions presenting blow-up in finite time. We also establish decay rates for the solutions that decay to zero as $t \to \infty$.

Keywords: Fisher–KPP equation, stationary solutions, separatrix, decay rates, finite time blow-up.

1 Introduction

The aim of this paper is to bring into light some qualitative properties related to the dynamics of solutions to the following generalized Fisher–KPP model:

$$u_t = Ku_{xx} - Bu^q + Au^p, \tag{1.1}$$

posed for $(x,t) \in \mathbb{R} \times (0,\infty)$, in the generic range of exponents $p > q > 0$, $p > 1$ and with A, B, K positive coefficients. The main feature of Eq. (1.1) is the competition between three terms having different effects for large times: a source term with exponent $p > 1$ which, when alone, usually leads to finite time blow-up (see for example [25] for a thorough study of this phenomenon), an absorption term with exponent $q > 0$ which, when alone, implies a dissipation, that is, a loss of the L^1 norm (leading also to a finite time extinction if $q < 1$), and a diffusion term which is conservative with respect to the L^1 norm. Thus, the balance between

[1]Corresponding author. Email: razvan.iagar@urjc.es

reaction and absorption will determine the main features related to the large time behavior of the solutions. In order to simplify the model, we can perform the following scaling

$$x = a\overline{x}, \quad t = b\overline{t}, \quad u = c\overline{u}, \tag{1.2}$$

with coefficients

$$c = \left(\frac{B}{A}\right)^{1/(p-q)}, \quad a = \left(\frac{Kc^{1-p}}{A}\right)^{1/2}, \quad b = \frac{c^{1-p}}{A}, \tag{1.3}$$

in order to obtain that, in the new variables $(\overline{x}, \overline{t})$, the rescaled function $\overline{u}$ is a solution to

$$\overline{u}_{\overline{t}} = (\overline{u})_{\overline{x}\overline{x}} - \overline{u}^q + \overline{u}^p. \tag{1.4}$$

We shall thus work, without any loss of generality, with Eq. (1.4), and for simplicity we drop from the notation the overlines, that is, we relabel the solution and the variables in Eq. (1.4) as (u, x, t). Eq. (1.4) is a very well-established model when the reaction and absorption exponents satisfy the opposite order, that is, $0 < p < q$, stemming from the seminal works by Fisher [10] and Kolmogorov, Petrovsky and Piscounoff [21], dealing with the specific case $p = 1$ and $q = 2$ as a model in mathematical biology. Nowadays, the Fisher–KPP equation with $0 < p < q$ is rather well understood, new applications have been proposed and, from the mathematical point of view, it has been noticed that the dynamics of the solutions is well represented by solutions in form of traveling waves with a speed $c > 0$, that is

$$u(x,t) = f(x - ct), \quad c > 0, \tag{1.5}$$

where $f(\cdot)$ is the profile of the wave, see for example [1,7,9,14,22,26] and references therein. In particular, a very famous result (see for example the classical papers [1,27] for a deduction of c^* in different cases) is the existence of a critical speed $c^* > 0$ such that traveling waves only exist if the speed is $c \geq c^*$ and do not exist when $c < c^*$.

The opposite case of ordering between the reaction and absorption exponents, that is, $p > q > 0$, has been also proposed, more recently, in a number of models arising in applied sciences. As a general model, Eq. (1.4) appears in growth and diffusion models as established, for example, in the book [3]. More specific applications in the mathematical modeling of tumor growth have been proposed by authors such as Marusic and Bajzer and their collaborators, see for example [2,23,24] and references therein, and a similar simplified model in [31].

Despite these applications, we discovered that there are still some gaps in the mathematical study of Eq. (1.4). As it is already well-established, in the more "standard" Fisher–KPP equation, that is, with exponents ordered as $q > p$, traveling waves, although they are still not stable in the L^∞ norm, are asymptotically stable with respect to suitable norms involving exponential weights, as shown for example in [28,30]. In stark contrast to the Fisher–KPP case, in our case it appears that traveling waves (and other explicit or semi-explicit solutions, as we shall see in the present work) are unstable with respect to the dynamics of general solutions to Eq. (1.4); that is, even if an initial condition $u_0 \in C(\mathbb{R})$ is sufficiently close (with respect to the L^∞ norm) to one of several explicit solutions, it will evolve either by growing up (and then blowing up in finite time) or by decaying as $t \to \infty$. We mention here [25, Chapter 17] where solutions to Eq. (1.4) with $q = 1$ are studied and the short note [18] devoted to the range $p > 1 > q > 0$ and $m > 1$, where the transition from finite time extinction to blow-up is established. The existence of a separatrix in the form of a stationary solution has been thoroughly investigated for the supercritical semilinear heat equation in [4,15,16,32] (see also

references therein), while some more general equations related to Eq. (1.4), or particular cases of it, have been considered in [17,33].

Putting into light this instability of several stationary solutions is actually the core of this work; indeed, we construct several solutions to Eq. (1.4) (in either explicit or implicit form) and we then prove that they serve as separatrices for the dynamics of general solutions to the Cauchy problem associated to Eq. (1.4) with suitable initial conditions. More precisely, solutions with data lying *above* the specific solution (even very close to it) *blow up in finite time*, while solutions with data lying *below* the specific solution *decay as* $t \to \infty$ (and even *vanish in finite time* if $0 < q < 1$, as shown in [18]) and we give some decay estimates. To fix the notation, we consider throughout this work the following family of initial conditions:

$$u(x,0) = u_0(x), \quad x \in \mathbb{R}, \quad u_0 \in L^\infty(\mathbb{R}) \cap C(\mathbb{R}), \quad u_0 \geq 0, \quad u_0 \not\equiv 0. \tag{1.6}$$

Since we are dealing with a semilinear problem, solutions will be taken in classical sense. We say that u is a *subsolution* (respectively *supersolution*) to Eq. (1.4) if the sign of equality is replaced with $\leq$ (respectively $\geq$) in Eq. (1.4) and we say that u is a subsolution (respectively supersolution) to the Cauchy problem (1.4)–(1.6) if u is a subsolution (respectively supersolution) to Eq. (1.4) and, furthermore, $u(x,0) \leq u_0(x)$ for any $x \in \mathbb{R}$ (respectively $u(x,0) \geq u_0(x)$ for any $x \in \mathbb{R}$).

Thus, our main tool in the forthcoming proofs is the *comparison principle*, which is a well established property of Eq. (1.4) and even of much more general models of analogous type, see for example [6,8].

Another motivation for writing this paper is that, in a forthcoming work, we are able to map by some transformations a rather general family of a priori more complex partial differential equations into various cases of Eq. (1.4), and we did not find a proper reference in literature giving the precise information we need on Eq. (1.4). We thus decided to fill in this gap, at the same time the current work serving for completing the study of the ranges of q not considered in the short note [18] devoted to absorption exponents $q \in (0,1)$.

Concerning the organization of the material, the paper is divided into two sections, related to, by order of appearance, the ranges $q = 1$ and $q \in (1,p)$, followed by a short discussion at the end. The two main sections are further divided into subsections with the following scheme: a first subsection establishing some exact solutions (either explicit or implicit), and then one or two subsections establishing, on the one hand, the decay rate of solutions lying below the constant solution and, on the other hand, the character of separatrix of the stationary solution established in the first subsection in any of these cases. The *main difficulty* stems from the fact that, for data u_0 which are very close to the stationary solution, in any of the cases, a rather fine construction of subsolutions and supersolutions is required. We are now in a position to begin our analysis.

2 The exponent $q = 1$

As indicated in the title, throughout this section, we fix $q = 1$ in Eq. (1.4), that is,

$$u_t = u_{xx} - u + u^p. \tag{2.1}$$

We follow the plan mentioned at the end of the Introduction.

2.1 Some explicit solutions

We derive below some exact solutions to Eq. (2.1), all of them in explicit form.

• **constant solution:** it is obvious that $u(x,t) = 1$ is the unique non-trivial constant solution.

• **solutions depending only on time:** we look for solutions in the form $u(x,t) = h(t)$. With this ansatz, Eq. (2.1) becomes the differential equation

$$h'(t) = -h(t) + h(t)^p, \quad t > 0,$$

which can be integrated explicitly, leading to the family of explicit solutions

$$U(x,t;C) = h(t;C) = \left[1 + Ce^{(p-1)t}\right]^{-1/(p-1)}, \quad C \in (-1,\infty). \tag{2.2}$$

Let us notice here that the behavior of $U(\cdot,\cdot;C)$ as $t \to \infty$ depends on the sign of C. Indeed, it is obvious that U decreases as $t \to \infty$ if $C > 0$, while it blows up in finite time if $C \in (-1,0)$, noticing that we recover the constant solution $U \equiv 1$ for $C = 0$.

• **stationary solutions:** we look for solutions in the form $u(x,t) = g(x)$. With this ansatz, Eq. (2.1) becomes the differential equation

$$g''(x) - g(x) + g(x)^p = 0, \quad x \in \mathbb{R}. \tag{2.3}$$

By multiplying (2.3) by $g'(x)$ and integrating, we find that

$$(g')^2(x) - g^2(x) + \frac{2}{p+1} g^{p+1}(x) = K, \quad K \in \mathbb{R}. \tag{2.4}$$

Since we consider solutions such that $g \in L^\infty(\mathbb{R})$ and $g(x) \to 0$ as $x \to \pm\infty$, we also infer from (2.3) that $g'' \in L^\infty(\mathbb{R})$ and an application of Barbalat's Lemma [29] readily leads to $K = 0$ in (2.4). After some easy manipulations and an implicit integration, we obtain

$$C \pm x = -\frac{2}{p-1} \operatorname{arctanh} \sqrt{1 - \frac{2g(x)^{p-1}}{p+1}},$$

which can be written in an explicit form as follows:

$$g(x;C) = \left\{ \frac{p+1}{2} \left[1 - \tanh^2 \left(C + \frac{p-1}{2} x \right) \right] \right\}^{1/(p-1)}, \quad C \in \mathbb{R}, \tag{2.5}$$

an expression similar to the ones identified at the end of [18, Section 2]. Recalling the identity

$$1 - \tanh^2 \theta = \frac{4}{2 + e^{2\theta} + e^{-2\theta}}, \quad \theta \in \mathbb{R},$$

we deduce from (2.5) that the stationary solutions $g(\cdot;C)$ have an exponential decay as $|x| \to \infty$, more precisely

$$g(x;C) \sim K(C,p) e^{-|x|}, \quad K(C,p) := \left(\frac{p+1}{2} \right)^{1/(p-1)} e^{2C/(p-1)}, \quad C \in \mathbb{R}.$$

In particular, the stationary solution belongs to $L^1(\mathbb{R})$. In the forthcoming analysis, we will let for simplicity $C = 0$ and we will work with the even stationary solution $g(\cdot;0)$, but, apart from longer and more tedious calculations, the separatrix property of every stationary solution $g(\cdot;C)$ will follow in a completely analogous way.

2.2 Decay rate and large time behavior below the constant solution

The aim of this section is to show that solutions starting from data which are smaller than one decay as $t \to \infty$ and stabilize towards a profile linked with the heat equation.

Theorem 2.1. *Let $u_0 \in C(\mathbb{R}) \cap L^\infty(\mathbb{R})$ be such that $0 < \|u_0\|_\infty < 1$. Then there exists $C > 0$ such that the solution u to the Cauchy problem (2.1)–(1.6) satisfies*

$$\|u(t)\|_\infty \le Ce^{-t}, \quad (x,t) \in \mathbb{R} \times (0,\infty). \tag{2.6}$$

If furthermore $u_0 \in L^1(\mathbb{R})$, we have the following large time behavior for the solution u to the Cauchy problem (2.1)–(1.6)

$$\lim_{t\to\infty} t^{1/2}\|e^t u(t) - G(t)\|_\infty = 0, \tag{2.7}$$

where $G(t)$ is the heat kernel

$$G(x,t) = \frac{M}{\sqrt{4\pi t}} e^{-|x|^2/4t}, \quad M = \|u_0\|_1.$$

Proof. Assume first that $u_0 \in L^\infty(\mathbb{R}) \cap C(\mathbb{R})$ and $\|u_0\|_\infty \in (0,1)$. Pick $C_0 > 0$ such that

$$\|u_0\|_\infty < (1+C_0)^{-1/(p-1)}.$$

Recalling the solution $u(\cdot,\cdot;C_0)$ defined in (2.2), the comparison principle then entails that

$$u(x,t) \le U(x,t;C_0) = \left[1 + C_0 e^{(p-1)t}\right]^{-1/(p-1)} \le C_0^{-1/(p-1)} e^{-t}, \tag{2.8}$$

for any $(x,t) \in \mathbb{R} \times (0,\infty)$, and thus we have proved the estimate (2.6).

Set next

$$w(x,t) := e^t u(x,t), \quad (x,t) \in \mathbb{R} \times (0,\infty).$$

Notice that $w(x,0) = u(x,0) = u_0(x)$, for any $x \in \mathbb{R}$, and a straightforward calculation shows that w is a solution to the following equation

$$w_t = w_{xx} + e^{-(p-1)t} w^p, \quad (x,t) \in \mathbb{R} \times (0,\infty). \tag{2.9}$$

Assume now that, moreover, $u_0 \in L^1(\mathbb{R})$. The equation (2.9) strongly suggests that an asymptotic simplification to the heat equation as $t \to \infty$ is expected to take place. In order to prove it in a rigorous way, the simplest path is to apply the stability theorem by Galaktionov and Vázquez [12,13]. Indeed, if we let v to be the solution to the standard heat equation $v_t = v_{xx}$ with the same initial condition $v(x,0) = u_0(x)$, $x \in \mathbb{R}$, we easily observe that w is a supersolution to this problem, so that the comparison principle applied to the heat equation, together with (2.8), ensure that

$$v(x,t) \le w(x,t) \le C_0^{-1/(p-1)}, \quad (x,t) \in \mathbb{R} \times (0,\infty). \tag{2.10}$$

The estimates (2.10), together with well known properties of the heat equation, readily imply that the hypothesis required for the application of the above mentioned stability theorem are in force. The stability theorem thus gives that the ω-limit set of the orbits $w(\cdot;t)$ as $t \to \infty$ are contained in the solutions to the standard heat equation. However, since the initial condition is u_0, the uniqueness of the solution to the Cauchy problem for the heat equation implies that $w(t)$ approaches $v(t)$ as $t \to \infty$. Since $u_0 \in L^1(\mathbb{R})$, the well known asymptotic behavior as $t \to \infty$ for the integrable solutions to the heat equation leads to the convergence (2.7). □

Remark. We can observe by comparison with a suitable Gaussian function, which is a subsolution to (2.9), that, even if $u_0 \in L^\infty(\mathbb{R})$ but $u_0 \notin L^1(\mathbb{R})$, we have

$$Ct^{-1/2}e^{-t} \le \|u(t)\|_\infty, \quad t > 0.$$

2.3 The stationary solution as a separatrix

As commented in Section 2.1, we fix for simplicity $C = 0$ and denote by $g_0(x) = g(x;0)$, $x \in \mathbb{R}$, the stationary solution defined in (2.5) with $C = 0$. In this section, we prove that this solution (and, analogously or by a simple translation, any other stationary solution $g(\cdot;C)$) plays the role of a separatrix for the large time behavior of the solutions to the Cauchy problem (2.1)–(1.6): that is, an initial condition strictly above it produces a solution whose L^∞ norm increases with time (and in the end blows up in finite time), while an initial condition strictly below it produces a solution decaying in time, for which the outcome of Theorem 2.1 applies. This is made precise in the next statement.

Theorem 2.2.

(a) Let $u_0 \in L^\infty(\mathbb{R}) \cap C(\mathbb{R})$ such that

$$\inf_{x\in\mathbb{R}} \frac{u_0(x)}{g_0(x)} = \kappa_0 > 1. \tag{2.11}$$

Then the solution u to the Cauchy problem (2.1)–(1.6) with initial condition u_0 blows up in finite time.

(b) Let $u_0 \in L^\infty(\mathbb{R}) \cap C(\mathbb{R})$ such that

$$\sup_{x\in\mathbb{R}} \frac{u_0(x)}{g_0(x)} = \kappa^0 < 1. \tag{2.12}$$

Then the solution u to the Cauchy problem (2.1)–(1.6) with initial condition u_0 decays to zero as $t \to \infty$ and behaves as in Theorem 2.1.

Remark. Before going to the proof, let us observe that conditions (2.11) and (2.12) are in fact related to a separation of the tails as $|x| \to \infty$. Indeed, due to the strong maximum principle, another solution cannot touch from above or from below the stationary solution g_0 at a time $t > 0$, and for a fixed compact subset $K \subset \mathbb{R}$ one could really find $\kappa_0(K)$, respectively $\kappa^0(K)$ (depending in this case on the compact K) so that the previous conditions hold true in K. It is thus as $|x| \to \infty$ where a separation has to be required, as it does not follow from a maximum principle, and this is the sense of the two conditions (2.11) and (2.12).

Proof of Theorem 2.2. (a) Let us consider the function

$$G(x,t) = (t+T)^\delta g_0((t+T)^\gamma x),$$

where $T > 1$, $\delta > 0$ and $\gamma > 0$ are parameters to be determined later, in order for G to be a subsolution to the Cauchy problem (2.1)–(1.6). A direct calculations gives

$$G_t(x,t) = \delta(t+T)^{\delta-1} g_0(\zeta) + \gamma(t+T)^{\delta-1}\zeta g_0'(\zeta), \quad \zeta := (t+T)^\gamma x.$$

Since g_0 is an even function with a decreasing profile with respect to $x > 0$, we deduce that

$$G_t(x,t) \le \delta(t+T)^{\delta-1} g_0(\zeta). \tag{2.13}$$

Moreover, employing the equation (2.3) satisfied by g_0, we find that

$$G_{xx}(x,t) = (t+T)^{\delta+2\gamma} g_0''(\zeta) = (t+T)^{\delta+2\gamma}(g_0(\zeta) - g_0^p(\zeta)). \tag{2.14}$$

Gathering the outcome of (2.13) and (2.14), we obtain

$$G_t(x,t) - G_{xx}(x,t) + G(x,t) - G^p(x,t) \le (t+T)^{\delta-1}\left[\delta + T + t - (t+T)^{2\gamma+1}\right] g_0(\zeta) + (t+T)^{\delta+2\gamma}\left[1 - (t+T)^{\delta(p-1)-2\gamma}\right] g_0^p(\zeta).$$

We next choose the (up to now) free parameters as follows: fix first

$$0 < \delta < \kappa_0^{(p-1)/2} - 1, \quad \gamma = \frac{\delta(p-1)}{4}. \tag{2.15}$$

With the previous choices, we are in a position to also choose

$$T := \kappa_0^{1/\delta} > 1.$$

Let us first observe that the terms in brackets in the previous calculation are negative with these choices, for any $t \ge 0$. On the one hand, since $\delta(p-1) - 2\gamma > 0$, we immediately get that

$$1 - (t+T)^{\delta(p-1)-2\gamma} \le 1 - T^{\delta(p-1)-2\gamma} < 0, \quad t \ge 0.$$

On the other hand, since $\gamma > 0$, we have

$$(T+t)^{2\gamma+1} - (t+T) = (t+T)((T+t)^{2\gamma} - 1) \ge T(T^{2\gamma} - 1) > \kappa_0^{(p-1)/2} - 1 > \delta,$$

whence

$$\delta + T + t - (t+T)^{2\gamma+1} < 0, \quad t \ge 0.$$

We have thus proved that $G(\cdot,t)$ is a subsolution to Eq. (2.1) for any $t \ge 0$. Moreover, taking into account that g_0 is decreasing with respect to $|x|$ and that $T > 1$, $\gamma > 0$, we have

$$G(x,0) = T^\delta g_0(T^\gamma x) = \kappa_0 g_0(T^\gamma x) \le \kappa_0 g_0(x) \le u_0(x), \quad x \in \mathbb{R},$$

hence G is a subsolution to the Cauchy problem (2.1)–(1.6) with initial condition $u_0(x)$. The comparison principle then gives

$$u(x,t) \ge (t+T)^\delta g_0((t+T)^\gamma x), \quad (x,t) \in \mathbb{R} \times (0,\infty).$$

Defining then the following energy

$$E(u(t)) = \frac{1}{2}\int_{\mathbb{R}} (|u_x|^2(x,t) + u^2(x,t))\,dx - \frac{1}{p+1}\int_{\mathbb{R}} u^{p+1}(x,t)\,dx,$$

we observe that

$$\begin{aligned} E(G(t)) &= \frac{1}{2}\int_{\mathbb{R}} \left[(T+t)^{2(\delta+\gamma)}|g_0'(x(T+t)^\gamma)|^2\,dx + (T+t)^{2\delta} g_0(x(T+t)^\gamma)^2\right] dx \\ &\quad - \frac{(T+t)^{\delta(p+1)}}{p+1}\int_{\mathbb{R}} g_0^{p+1}(x(T+t)^\gamma)\,dx \\ &= \frac{1}{2}(T+t)^{2\delta+\gamma}\int_{\mathbb{R}} |g_0'(y)|^2\,dy + \frac{1}{2}(T+t)^{2\delta-\gamma}\int_{\mathbb{R}} g_0^2(y)\,dy \\ &\quad - \frac{1}{p+1}(T+t)^{(p+1)\delta-\gamma}\int_{\mathbb{R}} g_0^{p+1}\,dy < 0, \end{aligned}$$

provided $t > 0$ is taken sufficiently large, since the choice of δ and γ in (2.15) implies

$$(p+1)\delta - \gamma > 2\delta + \gamma > 2\delta - \gamma.$$

We then infer from [25, Theorem 17.6] that the solution to Eq. (2.1) with initial condition $G(t_0)$ for t_0 sufficiently large such that $E(G(t_0)) < 0$ blows up in finite time. It follows by comparison that also u blows up in finite time, as claimed.

(b) Working "in the mirror" with respect to part (a), let us consider the function

$$H(x,t) = (t+T)^{-\delta} g_0((t+T)^{-\gamma} x),$$

where $T > 1$, $\delta > 0$ and $\gamma > 0$ are parameters to be determined later, in order for H to be a supersolution to the Cauchy problem (2.1)–(1.6). A direct calculations gives

$$H_t(x,t) = -\delta(t+T)^{-\delta-1} g_0(\zeta) - \gamma(t+T)^{-\delta-1} \zeta g_0'(\zeta), \quad \zeta := (t+T)^{-\gamma} x.$$

Since g_0 is an even function with a decreasing profile with respect to $x > 0$, we deduce that

$$H_t(x,t) \geq -\delta(t+T)^{-\delta-1} g_0(\zeta). \tag{2.16}$$

Moreover, employing the equation (2.3) satisfied by g_0, we find that

$$H_{xx}(x,t) = (t+T)^{-\delta-2\gamma} g_0''(\zeta) = (t+T)^{-\delta-2\gamma}(g_0(\zeta) - g_0^p(\zeta)). \tag{2.17}$$

Gathering the outcome of (2.16) and (2.17), we obtain

$$\begin{aligned} H_t(x,t) - H_{xx}(x,t) + H(x,t) - H^p(x,t) \geq (t+T)^{-\delta-1} \left[-\delta + T + t - (t+T)^{1-2\gamma} \right] g_0(\zeta) \\ + (t+T)^{-\delta-2\gamma} \left[1 - (t+T)^{-\delta(p-1)+2\gamma} \right] g_0^p(\zeta). \end{aligned}$$

Proceeding as in part (a), we next choose the parameters as follows: fix first

$$0 < \delta < 1 - (\kappa^0)^{p-1}, \quad \gamma = \frac{\delta(p-1)}{2}. \tag{2.18}$$

With the previous choices, we are in a position to also choose

$$T := (\kappa^0)^{-1/\delta} > 1.$$

Notice that $T^{-\delta} = \kappa^0$, whence

$$H(x,0) = T^{-\delta} g_0(\zeta) = \kappa^0 g_0(T^{-\gamma} x) \geq \kappa^0 g_0(x) \geq u_0(x), \quad x \in \mathbb{R},$$

where we have employed once more the fact that g_0 is decreasing with respect to $|x|$. Moreover, since $2\gamma = \delta(p-1)$ by (2.18), we have

$$1 - (t+T)^{-\delta(p-1)+2\gamma} = 0,$$

for any $t \geq 0$, while the first term in brackets is also non-negative, since

$$T + t - (T+t)^{1-2\gamma} - \delta = (T+t)\left[1 - (T+t)^{-2\gamma}\right] - \delta \geq 1 - T^{-2\gamma} - \delta = 1 - (\kappa^0)^{(p-1)} - \delta > 0,$$

according to (2.18). We infer that H is a supersolution to the Cauchy problem (2.1)–(1.6) and thus, by comparison,

$$u(x,t) \leq (t+T)^{-\delta} g_0((t+T)^{-\gamma} x), \quad (x,t) \in \mathbb{R} \times (0,\infty). \tag{2.19}$$

We then find from (2.19) that there is $t_0 > 0$ sufficiently large such that

$$\|u(t_0)\|_\infty \leq (t_0+T)^{-\delta} \|g_0\|_\infty < 1,$$

and an application of Theorem 2.1 starting with $t = t_0$ as initial time completes the proof. □

3 The range $1 < q < p$

Throughout this section, we work with absorption exponents $q \in (1, p)$. This choice does no longer allow for explicit integrations of the differential equations giving rise to solutions depending only on time or on the space variable, in contrast to the calculations in Section 2.1. Because of this technical problem, the forthcoming analysis is more involved than the previous one. We follow the same program as in Section 2.

3.1 Some special solutions in implicit form

We examine below the properties of solutions either depending only on time or only on space, to Eq. (1.4). We have:

- **constant solution:** once more, $u(x,t) \equiv 1$ is a constant solution to Eq. (1.4).
- **solutions depending only on time:** we look for solutions of the form $u(x,t) = h(t)$, $t > 0$. With this ansatz, Eq. (1.4) becomes

$$h'(t) = h^p(t) - h^q(t). \tag{3.1}$$

It is easy to observe that $h(0) > 1$ implies $h'(t) > 0$ for any $t > 0$, while $0 < h(0) < 1$ implies $h'(t) < 0$ for any $t > 0$. We next give a more precise description of the properties of solutions to (3.1). Assume first that $h(0) > 1$, hence $h(t) > h(0)$ for any $t > 0$ and thus

$$h^p(t) > h'(t) = h^p(t)(1 - h^{q-p}(t)) > h^p(t)(1 - h(0)^{q-p}).$$

The second inequality already implies finite time blow-up of h, and let us denote by $T \in (0, \infty)$ its blow-up time. We have

$$1 - h(0)^{q-p} < h^{-p}(t)h'(t) < 1$$

and a straightforward argument of integration on (t, T) leads to the blow-up rate

$$(p-1)^{-1/(p-1)}(T-t)^{-1/(p-1)} < h(t) < [(p-1)(1-h(0)^{q-p})]^{-1/(p-1)}(T-t)^{-1/(p-1)}. \tag{3.2}$$

Assume now that $h(0) < 1$. Then we get from (3.1) that

$$-h^q(t) < h'(t) < (h(0)^{p-q} - 1)h^q(t) < 0,$$

or equivalently

$$(1-q)(h(0)^{p-q} - 1) < (h^{1-q})'(t) < -(1-q)$$

and by integration on $(0, t)$ and straightforward manipulations, we deduce the decay rate of the solution h as $t \to \infty$ as follows:

$$[(q-1)t + h(0)^{1-q}]^{-1/(q-1)} < h(t) < [(q-1)(1-h(0)^{p-q})t + h(0)^{1-q}]^{-1/(q-1)}, \tag{3.3}$$

which means in particular that $h(t)$ decays like $t^{-1/(q-1)}$ as $t \to \infty$.

- **stationary solutions:** we look for solutions of the form $u(x,t) = \psi(x)$, $x \in \mathbb{R}$. With this ansatz, Eq. (1.4) becomes

$$\psi''(x) - \psi^q(x) + \psi^p(x) = 0,$$

which, after a multiplication by $\psi'(x)$ and an obvious integration term by term (setting the integration constant to zero), reads

$$(\psi')^2(x) = \frac{2}{q+1}\psi^{q+1}(x) - \frac{2}{p+1}\psi^{p+1}(x). \tag{3.4}$$

Notice first that, at a maximum point (which we assume to be at $x = 0$, as we want an even solution for simplicity), we obtain from (3.4)

$$\psi(0) = \|\psi\|_\infty = \left(\frac{p+1}{q+1}\right)^{1/(p-q)} > 1. \tag{3.5}$$

The standard existence and uniqueness theorem applied to the Cauchy problem (3.4) (taking the square root with a minus sign in front) with initial condition (3.5) gives the existence of a stationary solution for $x > 0$, which can be then extended by symmetry to $x < 0$, having its maximum at $x = 0$ and a decreasing profile, as desired. From now on, we denote this stationary solution by ψ_0. Its asymptotic properties are stated in the following result.

Proposition 3.1. *The following behavior of ψ_0 as $|x| \to \infty$ holds true:*

$$\lim_{|x|\to\infty} |x|^{2/(q-1)}\psi_0(x) = \left[\frac{2}{q-1}\sqrt{\frac{q+1}{2}}\right]^{2/(q-1)}, \quad \lim_{|x|\to\infty} \frac{|x|\psi_0'(x)}{\psi_0(x)} = -\frac{2}{q-1}. \tag{3.6}$$

Proof. Taking into account the radial symmetry, we can work on the half-plane $x > 0$. We deduce on the one hand that

$$\psi_0'(x) = -\sqrt{\frac{2}{q+1}\psi_0^{q+1}(x) - \frac{2}{p+1}\psi_0^{p+1}(x)} > -\sqrt{\frac{2}{q+1}}\psi_0^{(q+1)/2}(x), \tag{3.7}$$

and on the other hand, for $x > 1$,

$$\begin{aligned}\psi_0'(x) &= -\sqrt{\frac{2}{q+1}\psi_0^{q+1}(x)\left[1 - \frac{q+1}{p+1}\psi_0^{p-q}(x)\right]} \\ &< -\sqrt{\frac{2}{q+1}\left[1 - \frac{q+1}{p+1}\psi_0(1)^{p-q}\right]}\psi_0^{(q+1)/2}(x).\end{aligned} \tag{3.8}$$

Gathering the estimates (3.7) and (3.8), we deduce that there exist $C_1 > C_2 > 0$ such that

$$-C_1\psi_0^{(q+1)/2}(x) < \psi_0'(x) < -C_2\psi_0^{(q+1)/2}(x), \quad x \in (1,\infty).$$

Multiplying the previous inequalities by $\psi_0^{-(q+1)/2}(x)$ and integrating on $(1,x)$ leads to the bounds

$$[\overline{C}_1(x-1) + \psi_0(1)^{(1-q)/2}]^{-2/(q-1)} < \psi_0(x) < [\overline{C}_2(x-1) + \psi_0(1)^{(1-q)/2}]^{-2/(q-1)}, \quad x > 1,$$

with $\overline{C}_i = (q-1)C_i/2$, $i = 1,2$, which in particular give that

$$0 < \overline{C}_1^{-2/(q-1)} < \liminf_{x\to\infty} x^{2/(q-1)}\psi_0(x) \le \limsup_{x\to\infty} x^{2/(q-1)}\psi_0(x) < \overline{C}_2^{-2/(q-1)}. \tag{3.9}$$

Set now $\phi_0(x) := x^{2/(q-1)}\psi_0(x)$. Straightforward calculations lead to the differential equation solved by ϕ_0, that is,

$$x\phi_0'(x) - \frac{2}{q-1}\phi_0(x) = -\phi_0^{(q+1)/2}(x)\sqrt{\frac{2}{q+1} - \frac{2}{p+1}x^{-2(p-q)/(q-1)}\phi_0^{p-q}(x)}. \tag{3.10}$$

We next have two possibilities:

• either there exists $\lim_{x\to\infty}\phi_0(x) = L \in (0,\infty)$, and in this case, an application of a standard calculus fact (see [20, Lemma 2.9] for a precise statement and proof) gives that there is a sequence $(x_j)_{j\geq 1}$ such that $x_j \to \infty$ and $x_j\phi_0'(x_j) \to 0$ as $j\to\infty$. Since $\phi_0(x_j)\to L$ as $j\to\infty$, we obtain by evaluating (3.10) at $x = x_j$ and letting $j\to\infty$ that

$$-\frac{2}{q-1}L = -L^{(q+1)/2}\sqrt{\frac{2}{q+1}}, \quad \text{that is,} \quad L = \left[\frac{2}{q-1}\sqrt{\frac{q+1}{2}}\right]^{2/(q-1)},$$

as claimed.

• or the limit of $\phi_0(x)$ as $x\to\infty$ does not exist. Since ϕ_0 is bounded according to (3.9), it follows that it oscillates infinitely many times between two extremal values and thus there are sequences $(x_j^m)_{j\geq 1}$ and $(x_j^M)_{j\geq 1}$ of local minima, respectively local maxima for ϕ_0, such that $x_j^m\to\infty$, $x_j^M\to\infty$ as $j\to\infty$ and that

$$\lim_{j\to\infty}\phi_0(x_j^m) = \liminf_{x\to\infty}\phi_0(x), \quad \lim_{j\to\infty}\phi_0(x_j^M) = \limsup_{x\to\infty}\phi_0(x).$$

By evaluating (3.10) at $x = x_j^m$, respectively $x = x_j^M$, and letting $j\to\infty$, we readily obtain that

$$\liminf_{x\to\infty}\phi_0(x) = \limsup_{x\to\infty}\phi_0(x) = \left[\frac{2}{q-1}\sqrt{\frac{q+1}{2}}\right]^{2/(q-1)},$$

which is a contradiction with the non-existence of the limit, showing that this case is not possible. Thus, the proof of the first limit in (3.6) is complete. For the second limit in (3.6), it is enough to replace $\psi_0'(x)$ by the right hand side in (3.7), obtaining thus an expression depending only on $\psi_0(x)$, and then employ the first limit in (3.6) to get the result. We leave the easy details to the reader. □

3.2 The stationary solution as a separatrix

Similarly as we did in Section 2.3, but technically more involved as we work with non-explicit solutions, we show next that the stationary solution constructed in the previous section plays the role of a separatrix for the qualitative properties of solutions to the Cauchy problem (1.4)–(1.6). This is made precise in the following statement.

Theorem 3.2.

(a) Let $u_0 \in L^\infty(\mathbb{R})\cap C(\mathbb{R})$ be an initial condition such that $\|u_0\|_\infty < 1$. Then the solution u to the Cauchy problem (1.4)–(1.6) decays as $t\to\infty$ and, more precisely, there exists $C>0$ such that

$$\|u(t)\|_\infty \leq Ct^{-1/(q-1)}, \quad t>0. \tag{3.11}$$

(b) Let $u_0 \in L^\infty(\mathbb{R})\cap C(\mathbb{R})$ such that

$$\inf_{x\in\mathbb{R}}\frac{u_0(x)}{\psi_0(x)} = \kappa_0 > 1. \tag{3.12}$$

Then the solution u to the Cauchy problem (1.4)–(1.6) with initial condition u_0 blows up in finite time.

(c) Let $u_0 \in L^\infty(\mathbb{R}) \cap C(\mathbb{R})$ such that

$$\sup_{x\in\mathbb{R}} \frac{u_0(x)}{\psi_0(x)} = \kappa^0 < 1. \tag{3.13}$$

Then the solution u to the Cauchy problem (1.4)–(1.6) with initial condition u_0 decays to zero as $t \to \infty$ as in (3.11).

Proof. (a) This follows directly by comparison with a solution $h(t)$ to (3.1) with $\|u_0\|_\infty < h(0) < 1$. The comparison principle and the estimate (3.3) lead to the conclusion.

(b) Following similar ideas as in the proof of Theorem 2.2, we construct a subsolution to the Cauchy problem (1.4)–(1.6) in the form

$$\Psi(x,t) = (T+t)^\delta \psi_0((T+t)^\gamma x), \quad (x,t) \in [0,\infty)\times[0,\infty),$$

with $T > 1$, $\delta > 0$ and $\gamma > 0$ to be determined. Setting $\zeta = (T+t)^\gamma x$, we obtain by direct calculations

$$\begin{aligned}
\Psi_t(x,t) - \Psi_{xx}(x,t) + \Psi^q(x,t) - \Psi^p(x,t) &= \delta(T+t)^{\delta-1}\psi_0(\zeta) \\
&+ \gamma(T+t)^{\delta-1}\zeta\psi_0'(\zeta) - (t+T)^{\delta+2\gamma}\psi_0^q(\zeta) + (t+T)^{\delta+2\gamma}\psi_0^p(\zeta) \\
&+ (t+T)^{q\delta}\Psi_0^q(\zeta) - (T+t)^{p\delta}\psi_0^p(\zeta) \\
= (T+t)^{\delta-1}&\left[\delta - \gamma\zeta\frac{\psi_0'(\zeta)}{\psi_0(\zeta)}\right]\psi_0(\zeta) \\
&+ (T+t)^{\delta+2\gamma}\left[1-(t+T)^{\delta(p-1)-2\gamma}\right]\psi_0^p(\zeta) \\
&+ (T+t)^{q\delta}\left[1-(t+T)^{2\gamma-\delta(q-1)}\right]\psi_0^q(\zeta) = T_1+T_2+T_3,
\end{aligned} \tag{3.14}$$

where in the formula for the term T_1 we have employed the equation (3.4) satisfied by $\psi_0'(\zeta)$ for $\zeta \in (0,\infty)$. Since we want that our function Ψ remains a subsolution for any $t > 0$, the expressions of the terms T_2 and T_3 in (3.14) imply that a necessary condition is to fix

$$\frac{\delta(q-1)}{2} < \gamma < \frac{\delta(p-1)}{2}. \tag{3.15}$$

We next fix T as follows:

$$T = \kappa_0^{1/\delta} > 1, \tag{3.16}$$

remaining thus to choose δ as the only (still) free parameter. We infer from (3.15) and (3.16) that, on the one hand,

$$(t+T)^{2\gamma-\delta(q-1)} \geq T^{2\gamma-\delta(q-1)} > 1, \quad t \geq 0$$

and, on the other hand,

$$(t+T)^{\delta(p-1)-2\gamma} \geq T^{\delta(p-1)-2\gamma} > 1, \quad t \geq 0,$$

whence $T_2 < 0$ and $T_3 < 0$ in (3.14), for any $t \geq 0$. We are left with estimating the term T_1 in (3.14). We derive from (3.6) that

$$\zeta\sqrt{\frac{2}{q+1}\psi_0^{q-1}(\zeta) - \frac{2}{p+1}\psi_0^{p-1}(\zeta)} = -\frac{\zeta\psi_0'(\zeta)}{\psi_0(\zeta)} \to \frac{2}{q-1},$$

as $\zeta \to \infty$. Since $\delta/\gamma < 2/(q-1)$ by (3.15), we deduce that there exists $R_0 > 0$ such that

$$\frac{\delta}{\gamma} < \zeta \sqrt{\frac{2}{q+1}\psi_0^{q-1}(\zeta) - \frac{2}{p+1}\psi_0^{p-1}(\zeta)}, \quad |\zeta| > R_0, \tag{3.17}$$

which in particular implies that $T_1 < 0$ if $|\zeta| > R_0$. Set next

$$L_0 := \inf_{\zeta \in [-R_0, R_0]} \psi_0(\zeta) > 0, \tag{3.18}$$

and notice that R_0 and L_0 depend only on p and q, if we fix, for example,

$$\frac{\delta}{\gamma} = \frac{1}{p-1} + \frac{1}{q-1}, \tag{3.19}$$

a choice that satisfies (3.15). We are left with estimating T_1 in (3.14) in the closed interval $[-R_0, R_0]$, and to this end we change a bit the strategy: instead of estimating T_1 alone, we recall that $\zeta\psi_0'(\zeta) \le 0$ for any $\zeta \in \mathbb{R}$ and we compensate T_1 with the negativity of T_2 in this interval. More precisely, discarding the already negative contribution of $\gamma(T+t)^{\delta-1}\zeta\psi_0'(\zeta)$, we want to choose $\delta > 0$ such that, for any $\zeta \in [-R_0, R_0]$ and $t \ge 0$, we have

$$\delta(T+t)^{\delta-1} - (T+t)^{\delta+2\gamma}\left[(T+t)^{\delta(p-1)-2\gamma} - 1\right]\psi_0^{p-1}(\zeta) < 0,$$

for which a sufficient condition is to pick δ such that

$$0 < \delta < \left(\kappa_0^{p-1-2\gamma/\delta} - 1\right) L_0^{p-1} = \left(\kappa_0^{(p-1)(p-q)/(p+q-2)} - 1\right) L_0^{p-1}, \tag{3.20}$$

taking into account (3.19) and that $T > 1$ and $\kappa_0 > 1$. It thus follows that Ψ is a subsolution to Eq. (1.4) and also satisfies (taking into account that ψ_0 has a decreasing profile with respect to $|x|$ and that $T > 1$, $\gamma > 0$)

$$\Psi(x,0) = \kappa_0\psi_0(T^\gamma x) \le \kappa_0\psi_0(x) \le u_0(x), \quad x \in \mathbb{R},$$

hence the comparison principle entails that

$$\Psi(x,t) = (T+t)^\delta \psi_0(\zeta) \le u(x,t), \quad (x,t) \in \mathbb{R} \times (0,\infty).$$

In order to prove the finite time blow-up, we adapt the argument at the end of the proof of Theorem 2.2 with a slightly changed energy functional in order to cope with the term u^q instead of u, that is,

$$E(u(t)) = \frac{1}{2}\int_{\mathbb{R}} |u_x|^2(x,t)\,dx + \frac{1}{q+1}\int_{\mathbb{R}} u^{q+1}(x,t)\,dx - \frac{1}{p+1}\int_{\mathbb{R}} u^{p+1}(x,t)\,dx.$$

The proof of [25, Theorem 17.6, (ii)] straightforwardly adapts to this energy to show that, if for a general solution u to Eq. (1.4) in $\mathbb{R} \times (0,\infty)$ we have $E(u(t)) < 0$ for some $t \ge 0$, then the solution u blows up in finite time. In our case, similarly as at the end of the proof of Theorem 2.2, we compute

$$\begin{aligned} E(\Psi(t)) = {} & \frac{1}{2}(T+t)^{2\delta+\gamma}\int_{\mathbb{R}} |\psi_0'(y)|^2\,dy + \frac{1}{q+1}(T+t)^{\delta(q+1)-\gamma}\int_{\mathbb{R}} \psi_0^{q+1}(y)\,dy \\ & - \frac{1}{p+1}(T+t)^{\delta(p+1)-\gamma}\int_{\mathbb{R}} \psi_0^{p+1}(y)\,dy < 0, \end{aligned}$$

provided $t > t_0 > 0$ is sufficiently large, since the fact that $p > q$ and (3.15) ensure that

$$(p+1)\delta - \gamma > (q+1)\delta - \gamma, \quad (p+1)\delta - \gamma > 2\delta + \gamma.$$

Thus, the solution to Eq. (1.4) with initial condition $\Psi(t_0)$ such that $E(\Psi(t_0)) < 0$ blows up in finite time. We conclude then from the comparison principle that u also blows up in finite time.

(c) We want to construct a supersolution to the Cauchy problem (1.4)–(1.6) decaying in time, and we work again "in the mirror" with respect to the construction performed in part (b), so that we will only give a sketch of it below. We consider

$$\Phi(x,t) = (T+t)^{-\delta}\psi_0(x(T+t)^{-\gamma}), \quad \zeta = (T+t)^{-\gamma}x,$$

and we want to choose the parameters and exponents T, δ, γ such that Φ is a supersolution. Direct calculations similar to the ones performed in part (b) lead to the following expression

$$\begin{aligned}
&\Phi_t(x,t) - \Phi_{xx}(x,t) + \Phi^q(x,t) - \Phi^p(x,t) \\
&\quad = -\gamma(T+t)^{-\delta-1}\left[\frac{\delta}{\gamma} + \frac{\zeta\psi_0'(\zeta)}{\psi_0(\zeta)}\right]\psi_0(\zeta) \\
&\qquad + (T+t)^{-\delta-2\gamma}\left[1 - (t+T)^{-\delta(p-1)+2\gamma}\right]\psi_0^p(\zeta) \\
&\qquad + (T+t)^{-q\delta}\left[1 - (t+T)^{-2\gamma+\delta(q-1)}\right]\psi_0^q(\zeta) \\
&\quad = T_1 + T_2 + T_3.
\end{aligned} \tag{3.21}$$

Since we want a supersolution for any $t \geq 0$, we are forced to choose δ, γ such that the powers of $T+t$ in the second and third line of (3.21) are negative, thus (3.19) remains in force. Moreover, with the experience gained in part (b), we fix

$$T = (\kappa^0)^{-1/\delta} > 1. \tag{3.22}$$

With the choices in (3.19) and (3.22), we observe that, on the one hand,

$$(t+T)^{-\delta(p-1)+2\gamma} \leq T^{-\delta(p-1)+2\gamma} < 1, \quad t \geq 0,$$

and on the other hand

$$(t+T)^{-2\gamma+\delta(q-1)} \leq T^{-2\gamma+\delta(q-1)} < 1, \quad t \geq 0.$$

This ensures that $T_2 > 0$ and $T_3 > 0$ for any $t \geq 0$. Moreover, since ψ_0 has a decreasing profile with respect to $|x|$ and $T > 1$, $\gamma > 0$, at $t = 0$ we have the comparison between initial conditions:

$$\Phi(x,0) = T^{-\delta}\psi_0(T^{-\gamma}x) = \kappa^0\psi_0(T^{-\gamma}x) \geq \kappa^0\psi_0(x) \geq u_0(x), \quad x \in \mathbb{R}. \tag{3.23}$$

It only remains to choose $\delta > 0$ such that $T_1 > 0$ too. Noticing that (3.19) and (3.6) imply

$$\frac{\delta}{\gamma} < \frac{2}{q-1} = -\lim_{\zeta\to\infty}\frac{\zeta\psi_0'(\zeta)}{\psi_0(\zeta)},$$

we infer that there is $R_0 > 0$ such that $T_1 > 0$ for $\zeta \in \mathbb{R}$ such that $|\zeta| > R_0$. For the compact interval $[-R_0, R_0]$, the proof follows by compensating T_1 by T_2 in order to choose δ, following

exactly the same lines as in the final part of the proof of part (b), this compensation, together with the choices in (3.19) and (3.22) leading to the condition

$$\delta < \min\left\{\frac{1}{2}\left(\frac{1}{p-1}+\frac{1}{q-1}\right), \left[1-(\kappa^0)^{(p-1)(p-q)/(p+q-2)}\right] L_0^{p-1}\right\},$$

with L_0 defined as in (3.18), noticing that the previous election also entails that $\gamma \in (0, 1/2)$. The comparison principle and (3.23) then entail that

$$\Phi(x,t) = (T+t)^{-\delta}\psi_0(x(T+t)^{-\gamma}) \geq u(x,t), \quad (x,t) \in \mathbb{R}\times(0,\infty),$$

and in particular

$$\|u(t)\|_\infty \leq (T+t)^{-\delta}\|\psi_0\|_\infty < 1,$$

provided $t \geq t_0$ sufficiently large. This fact together with part (a) lead to the conclusion. □

Discussion and extensions

The previous analysis raises a few questions related to a finer description of the dynamics of solutions to Eq. (1.4), that we comment in the next lines.

• **Blow-up rates and patterns.** Due to the fact that, for large values of u (close to a blow-up point), u^q is negligible compared to u^p, it is strongly expected that the blow-up behavior of solutions to Eq. (1.4) presenting finite time blow-up is totally similar to the one of the usual reaction-diffusion equation $u_t = u_{xx} + u^p$. In fact, if $T \in (0,\infty)$ is the blow-up time of the solution to the Cauchy problem (1.4)–(1.6) with an initial condition u_0 satisfying either Theorem 2.2(a) or Theorem 3.2(b), then it cannot lie completely below the solution given by either (2.2) (if $q = 1$) or to (3.1) (if $q \in (1, p)$) having the same blow-up time T. We then deduce the lower blow-up rate from (3.2), that is,

$$\|u(t)\|_\infty \geq C(T-t)^{-1/(p-1)}, \quad t \in (0,T),$$

for some $C > 0$. As for the upper rate and other fine properties of blow-up, the theory in [25] should apply without many changes. In particular, for $q = 1$ the previous rate follows as a particular case of the results in the recent paper [33].

• **Large time behavior for solutions with decay as $t \to \infty$.** As we have seen, for $q = 1$ we have obtained the large time behavior by an asymptotic simplification. The same must hold true for $q \in (1, p)$ since for u very small, the reaction u^p is negligible with respect to the absorption u^q, so that the asymptotic simplification is practically obvious at a formal level. We do not enter this discussion in detail, since the large time behavior of solutions to the pure absorption-diffusion equation (neglecting u^p) is not straightforward, but given by either a Gaussian, as a further asymptotic simplification, if $q > 3$, or some very singular solutions constructed in [5] if $1 < q < 3$.

• **Extinction behavior for $q \in (0,1)$.** As established in [18], for $q \in (0,1)$, initial conditions u_0 lying below the stationary solution lead to finite time extinction, that is, there exists $T_e \in (0,\infty)$ such that $u(t) \not\equiv 0$ for $t \in (0, T_e)$, but $u(T_e) \equiv 0$. Establishing the extinction rate (that is not studied in [18]) follows rather straightforwardly, since one can construct solutions depending only on time $h(t)$, solving the differential equation

$$h'(t) = h^p(t) - h^q(t), \quad h(0) < 1,$$

and, by estimates in the same style as the ones leading to (3.2), find that

$$[(1-q)(1-h(0)^{p-q})]^{1/(1-q)}(T_e-t)^{1/(1-q)} < h(t) < (1-q)^{1/(1-q)}(T_e-t)^{1/(1-q)}.$$

Moreover, a solution to Eq. (1.4) is a supersolution to the pure absorption-diffusion equation obtained by neglecting u^p, and about which it is known that the extinction rate of general solutions is

$$\|u(t)\|_\infty \sim C(T_e-t)^{1/(1-q)}, \quad \text{as } t \to T_e,$$

so that the same rate will be in force for Eq. (1.4) with $p > 1$ and $q \in (0,1)$. However, a finer analysis of the extinction phenomenon is rather complex, as it should be at least similar to (if not technically more involved than) the one for the absorption-diffusion equation

$$u_t = u_{xx} - u^q, \quad 0 < q < 1,$$

studied in detail in classical but quite complicated works such as [11, 19]. We leave this discussion here.

Communicated by Gabriele Bonanno

Abstract. This paper studies the existence and multiplicity of weak solutions to degenerate weighted quasilinear elliptic equations with nonlocal nonlinearities and variable exponents. The equation involves a degenerate nonlinear operator with variable exponents, a nonlocal term, and growth conditions on the nonlinearity. Using critical point theory, we prove the existence of at least three weak solutions under general assumptions, extending the applicability of the results to a broad class of nonlinear problems in mathematical physics.

Keywords: variational methods, Hardy inequality, degenerate $p(x)$-Laplacian operators.

2020 Mathematics Subject Classification: 35J15, 35J20, 35J25.

1 Introduction

Significant challenges in the analysis and behavior of solutions arise from the presence of singularities and degeneracies in elliptic equations. Singularities, especially those arising at the origin or the boundary, can dramatically alter the properties of the operator, causing the solutions to become more sensitive to changes in the domain. For example, when $1 < p < N$, it is known that $u/|x| \in L^p(\mathbb{R}^N)$ if $u \in W^{1,p}(\mathbb{R}^N)$, or $u/|x| \in L^p(\Omega)$ when $u \in W^{1,p}(\Omega)$, where Ω is a bounded domain. This leads to the emergence of Hardy-type inequalities that control the singular behavior of solutions near critical points, particularly when the equation includes singular potential terms (see, e.g., [11, 13, 15, 16]).

In addition to the challenges posed by singularities, the inclusion of nonlocal terms further complicates the situation. Nonlocal interactions, which typically arise from integral expressions or global coupling terms, create dependencies that affect the solution at each point in the domain, as well as its values across the entire domain. The nonlocal nature of these terms requires the use of advanced techniques that go beyond classical local methods to analyze the solution structure and its multiplicity.

✉ Corresponding author. Email: khaled_kefi@yahoo.fr

Furthermore, the operator's degeneracy, especially when coupled with a weighted function $\omega(x)$ in the p-Laplacian or $p(x)$-Laplacian operator, adds another layer of complexity. The degeneracy introduced by $\omega(x)$, whether singular or merely bounded, necessitates a shift in the choice of functional spaces. In such cases, traditional Sobolev spaces such as $W^{1,p}(\Omega)$ or $W^{1,p(x)}(\Omega)$ may no longer be suitable. Instead, we must consider alternative Sobolev spaces that accommodate the weight function, such as $W^{1,p}(\omega,\Omega)$, to handle the singularities or degeneracies (see [6] for further details).

This paper addresses these challenges by studying a class of weighted quasilinear elliptic equations with nonlocal nonlinearities and variable exponents. The goal is to establish the existence and multiplicity of weak solutions while taking into account the degeneracy of the operator, the Hardy-type singularities, and the nonlocal interactions that frequently arise in applied mathematical models.

In this paper, we investigate the existence of generalized solutions to a class of weighted quasilinear elliptic equations of the form:

$$\begin{cases} -\Delta_{p(x),a(x,u)}u + \frac{b(x)|u|^{q-2}u}{|x|^q} = \lambda f(x,u)\left(\int_\Omega F(x,u)\,dx\right)^r & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where, $1 < q < N$, $\Omega \subset \mathbb{R}^N$ (with $N \geq 3$) is a bounded open subset, $\partial\Omega$ denotes its smooth boundary and $b(x)$ is a non-negative measurable function. The unknown function u satisfies a weighted quasilinear elliptic equation involving a variable exponent $p(x)$, a nonlinear term $f(x,u)$, and a non-local term involving an integral expression with a positive exponent r.

The operator $\Delta_{p(x),a(x,u)}u$ is a nonlinear generalization of the standard Laplacian, defined as:

$$\Delta_{p(x),a(x,u)}u = \operatorname{div}\left(a(x,u)|\nabla u|^{p(x)-2}\nabla u\right),$$

where $a(x,u)$ is a Carathéodory function satisfying the inequality

$$a_1\omega(x) \leq a(x,u) \leq a_2\omega(x) \quad \text{for some constants } a_1, a_2 > 0,$$

and a positive measurable function $\omega(x)$. The function $\omega(x)$ is assumed to belong to the local Lebesgue space $L^1_{\text{loc}}(\Omega)$ and satisfy additional growth conditions, such as $\omega^{-h(x)} \in L^1(\Omega)$, where $h(x)$ belongs to a range related to the variable exponent $p(x)$, more precisely, we assume that

(ω) $\omega^{-h(x)} \in L^1(\Omega)$, for $h(x) \in C(\overline{\Omega})$ and $h(x) \in (N/p(x), +\infty) \cap [1/(p(x)-1), +\infty)$,

The nonlinearity in the equation is characterized by the function $f(x,u)$, which satisfies growth conditions of the form:

$$(f_1) \qquad M_1|u|^{\alpha(x)-1} \leq |f(x,u)| \leq M_2|u|^{\beta(x)-1},$$

with $1 < \alpha(x) \leq \beta(x) < p_h^*(x)$, where $p_h^*(x) = \frac{Np_h(x)}{N-p_h(x)}$ and $p_h(x) = \frac{h(x)p(x)}{h(x)+1}$. These conditions allow for a broad class of nonlinearities, including those that are locally integrable and exhibit power-like behavior at infinity.

The parameter $\lambda > 0$ scales the non-local term, which depends on the integral

$$\int_\Omega F(x,u)\,dx$$

of another function $F(x,u)$, which itself is assumed to satisfy certain conditions. These non-local terms introduce further complexity into the problem, as they may give rise to both local and global interactions within the domain Ω.

The main objective of this paper is to establish the existence of at least three weak solutions to the problem under very general assumptions on the weighted function $\omega(x)$ and the non-linear non-local term. To achieve this, we apply critical point theory to the associated energy functional, which is constructed by integrating the relevant terms of the equation over Ω. The application of critical point theorems allows us to prove the existence of solutions without the need for strict assumptions on the regularity or structure of the nonlinearity, making the result highly general and applicable to a wide variety of problems in mathematical physics and differential equations.

2 Preliminaries and variational structure

Set

$$C_+(\overline{\Omega}) = \{p(x) | p(x) \in C(\overline{\Omega}),\ p(x) > 1,\ \forall x \in \overline{\Omega}\},$$
$$p^+ = \max_{x\in\overline{\Omega}} p(x), \quad p^- = \min_{x\in\overline{\Omega}} p(x).$$

For $k > 0$, and $p(x) \in C_+(\overline{\Omega})$, we use the following notations

$$k^{\hat{p}} = \max\{k^{p^-},\ k^{p^+}\}, \quad k^{\check{p}} = \min\{k^{p^-},\ k^{p^+}\}.$$

It is easy to verify that (one can see [3], for further details)

(i) $k^{\frac{1}{\hat{p}}} = \max\left\{k^{\frac{1}{p^-}}, k^{\frac{1}{p^+}}\right\}$,

(ii) $k^{\frac{1}{\check{p}}} = \min\left\{k^{\frac{1}{p^-}}, k^{\frac{1}{p^+}}\right\}$,

(iii) $k^{\frac{1}{\hat{p}}} = a \Longleftrightarrow k = a^{\hat{p}}, k^{\frac{1}{\check{p}}} = a \Longleftrightarrow k = a^{\check{p}}$,

(iv) $(k\beta)^{\check{p}} \leq k^{\check{p}}\beta^{\check{p}} \leq (k\beta)^{\hat{p}} \leq k^{\hat{p}}\beta^{\hat{p}}$.

Denote

$$L^{p(x)}(\omega,\Omega) = \left\{u :\ \text{measurable in } \Omega \text{ such that } \int_\Omega \omega(x)|u(x)|^{p(x)}\,dx < \infty\right\}$$

with a Luxemburg-type norm defined by

$$\|u\|_{L^{p(x)}(\omega,\Omega)} = \inf\left\{\eta > 0 : \int_\Omega \omega(x)\left|\frac{u(x)}{\eta}\right|^{p(x)} dx \leq 1\right\}.$$

Now, we define the variable exponent Sobolev space

$$W^{1,p(x)}(\Omega) = \left\{u \in L^{p(x)}(\Omega) :\ |\nabla u| \in L^{p(x)}(\Omega)\right\},$$

with the norm

$$\|u\|_{W^{1,p(x)}(\Omega)} = \|\nabla u\|_{p(x)} + \|u\|_{p(x)},$$

where $\|\nabla u\|_{p(x)} = \||\nabla u|\|_{p(x)}, |\nabla u| = \left(\sum_{i=1}^N \left|\frac{\partial u}{\partial x_i}\right|^2\right)^{\frac{1}{2}}, \nabla u = \left(\frac{\partial u}{\partial x_1}, \frac{\partial u}{\partial x_2}, \ldots, \frac{\partial u}{\partial x_N}\right)$ is the gradient of u at $(x_1, x_2, \ldots, x_N)$.

Let

$$W^{1,p(x)}(\omega,\Omega)=\left\{u\in L^{p(x)}(\Omega):\omega^{\frac{1}{p(x)}}|\nabla u|\in L^{p(x)}(\Omega)\right\}$$

be the weighted Sobolev space, and denote by $W_0^{1,p(x)}(\omega,\Omega)$ the closure of $C_0^\infty(\Omega)$ in $W^{1,p(x)}(\omega,\Omega)$ with the norm

$$\|u\|=\inf\left\{\eta>0:\int_\Omega \omega(x)\left|\frac{\nabla u(x)}{\eta}\right|^{p(x)}dx\le 1\right\}.$$

Lemma 2.1 ([9]). *If $p_1(x),p_2(x)\in C_+(\overline{\Omega})$ such that $p_1(x)\le p_2(x)$ a.e. $x\in\Omega$, then there exists the continuous embedding $W^{1,p_2(x)}(\Omega)\hookrightarrow W^{1,p_1(x)}(\Omega)$.*

Proposition 2.2 ([10]). *For $p(x)\in C_+(\overline{\Omega}),u,u_n\in L^{p(x)}(\Omega)$, we have*

$$\min\left\{\|u\|_{p(x)}^{p^-},\|u\|_{p(x)}^{p^+}\right\}\le\int_\Omega|u(x)|^{p(x)}dx\le\max\left\{\|u\|_{p(x)}^{p^-},\|u\|_{p(x)}^{p^+}\right\}.$$

Let $0<d(x)\in S(\Omega)$ and $S(\Omega)$ be the set of all measurable real functions defined on Ω. Define

$$L_{d(x)}^{p(x)}(\Omega)=L^{p(x)}(d,\Omega)=\left\{u\in S(\Omega):\int_\Omega d(x)|u(x)|^{p(x)}\,dx<\infty\right\}$$

with a Luxemburg-type norm defined by

$$\|u\|_{L_{d(x)}^{p(x)}(\Omega)}=\|u\|_{(p(x),d(x))}:=\inf\left\{\eta>0:\int_\Omega d(x)\left|\frac{u(x)}{\eta}\right|^{p(x)}\,dx\le 1\right\}.$$

Proposition 2.3 ([7]). *If $p\in C_+(\overline{\Omega})$. Then*

$$\min\left\{\|u\|_{(p(x),d(x))}^{p^-},\|u\|_{(p(x),d(x))}^{p^+}\right\}\le\int_\Omega d(x)|u(x)|^{p(x)}dx\le\max\left\{\|u\|_{(p(x),d(x))}^{p^-},\|u\|_{(p(x),d(x))}^{p^+}\right\}$$

for any $u\in L_{d(x)}^{p(x)}(\Omega)$ and for a.e. $x\in\Omega$.

Combining Proposition 2.2 with Proposition 2.3, one has

Lemma 2.4. *Let*

$$\rho_\omega(u)=\int_\Omega\omega(x)\,|\nabla u(x)|^{p(x)}\,dx.$$

For $p\in C_+(\overline{\Omega}),u\in W^{1,p(x)}(\omega,\Omega)$, we have

$$\min\left\{\|u\|^{p^-},\|u\|^{p^+}\right\}\le\rho_\omega(u)\le\max\left\{\|u\|^{p^-},\|u\|^{p^+}\right\}.$$

From Proposition 2.4 of [13], if (ω) holds, $W^{1,p(x)}(\omega,\Omega)$ is a separable and reflexive Banach space.

From Theorem 2.11 of [14], if (ω) holds, the following embedding

$$W^{1,p(x)}(\omega,\Omega)\hookrightarrow W^{1,p_h(x)}(\Omega)\tag{2.1}$$

is continuous, where

$$p_h(x)=\frac{p(x)h(x)}{h(x)+1}<p(x).$$

Combining (2.1) with Proposition 2.7 and Proposition 2.8 in [8], we get the following embedding

$$W^{1,p(x)}(\omega,\Omega) \hookrightarrow L^{r(x)}(\Omega)$$

is continuous, where

$$1 \le r(x) \le p_h^*(x) = \frac{Np_h(x)}{N-p_h(x)} = \frac{Np(x)h(x)}{Nh(x)+N-p(x)h(x)}.$$

Furthermore, the following embedding

$$W^{1,p(x)}(\omega,\Omega) \hookrightarrow\hookrightarrow L^{t(x)}(\Omega)$$

is compact, when $1 \le t(x) < p_h^*(x)$.

Define the functional $\mathcal{I}_\lambda \colon W_0^{1,p(x)}(\omega,\Omega) \to \mathbb{R}$ by

$$\mathcal{I}_\lambda(u) := \Phi(u) - \lambda\Psi(u),$$

where

$$\Phi(u) := \int_\Omega \frac{a(x,u)}{p(x)}|\nabla u|^{p(x)}dx + \frac{1}{q}\int_\Omega \frac{b(x)|u|^q}{|x|^q}dx,$$
$$\Psi(u) := \frac{1}{r+1}\Big(\int_\Omega F(x,u(x))dx\Big)^{r+1},$$

and $F(x,u) = \int_0^u f(x,\tau)d\tau, \forall (x,u) \in \Omega\times\mathbb{R}$.

It is clear that functionals Φ and Ψ are continuously Gâteaux differentiable with

$$\Phi'(u)(v) = \int_\Omega a(x,u)|\nabla u|^{p(x)-2}\nabla u\nabla v dx + \int_\Omega \frac{b(x)|u|^{q-2}uv}{|x|^q}dx,$$

and

$$\Psi'(u)(v) = \left(\int_\Omega F(x,u)\,dx\right)^r \int_\Omega f(x,u)v dx, \quad \forall u,v \in W_0^{1,p(x)}(\omega,\Omega).$$

We say that $u \in W_0^{1,p(x)}(\omega,\Omega)$ is a generalized solution of the problem (1.1) if

$$\mathcal{I}'_\lambda(u)(v) = \Phi'(u)(v) - \lambda\Psi'(u)(v) = 0, \quad \forall v \in W_0^{1,p(x)}(\omega,\Omega).$$

Lemma 2.5. *The functional Φ' is coercive and strictly monotone in $W_0^{1,p(x)}(\omega,\Omega)$.*

Proof. For any $u \in W_0^{1,p(x)}(\omega,\Omega)\setminus\{0\}$, by Lemma 2.4 one has

$$\begin{aligned}\Phi'(u)(u) &= \int_\Omega a(x,u)|\nabla u|^{p(x)-2}\nabla u\nabla u dx + \int_\Omega \frac{b(x)|u|^{q-2}u^2}{|x|^q}dx\\ &\ge a_1\rho_\omega(u)\\ &\ge a_1\cdot\min\{\|u\|^{p^+},\|u\|^{p^-}\},\end{aligned}$$

thus

$$\lim_{\|u\|\to\infty}\frac{\Phi'(u)(u)}{\|u\|} \ge a_1\cdot\lim_{\|u\|\to\infty}\frac{\min\{\|u\|^{p^+},\|u\|^{p^-}\}}{\|u\|} = +\infty,$$

then Φ' is coercive in view of $p(x) \in C_+(\overline{\Omega})$.

According to (2.2) of [17], for all $x, y \in \mathbb{R}^N$, there is a positive constant C_p such that

$$\langle |x|^{p-2}x - |y|^{p-2}y, x-y\rangle \geq C_p|x-y|^p, \quad \text{if } p \geq 2,$$

and

$$\langle |x|^{p-2}x - |y|^{p-2}y, x-y\rangle \geq \frac{C_p|x-y|^2}{(|x|+|y|)^{2-p}}, \quad \text{if } 1 < p < 2, \quad \text{and} \quad (x,y) \neq (0,0),$$

where $\langle .,. \rangle$ is the usual inner product in $\mathbb{R}^N$. Thus, for any $u, v \in X$ satisfying $u \neq v$, by standard arguments we can obtain

$$\begin{aligned}\langle \Phi'(u) - \Phi'(v), u-v\rangle = &\int_\Omega a(x,u)(|\nabla u|^{p(x)-2}\nabla u - |\nabla v|^{p(x)-2}\nabla v)(\nabla u - \nabla v)dx \\ &+ \int_\Omega \frac{b(x)}{|x|^q}(|u|^{q-2}u - |v|^{q-2}v)(u-v))dx \\ &> 0,\end{aligned}$$

hence we have Φ' is strictly monotone in $W_0^{1,p(x)}(\omega, \Omega)$. □

Lemma 2.6. *The functional Φ' is a mapping of (S_+)-type, i.e. if $u_n \rightharpoonup u$ in $W_0^{1,p(x)}(\omega,\Omega)$, and $\overline{\lim}_{n\to\infty}\langle \Phi'(u_n) - \Phi'(u), u_n - u)\rangle \leq 0$, then $u_n \to u$ in $W_0^{1,p(x)}(\omega,\Omega)$.*

Proof. Let $u_n \rightharpoonup u$ in $W_0^{1,p(x)}(\omega,\Omega)$, and $\overline{\lim}_{n\to\infty}\langle \Phi'(u_n) - \Phi'(u), u_n - u\rangle \leq 0$.

Noting that Φ' is strictly monotone in $W_0^{1,p(x)}(\omega,\Omega)$, one has

$$\lim_{n\to\infty}\langle \Phi'(u_n) - \Phi'(u), u_n - u\rangle = 0,$$

while

$$\begin{aligned}\langle \Phi'(u_n) - \Phi'(u), u_n - u\rangle = &\int_\Omega a(x,u)(|\nabla u_n|^{p(x)-2}\nabla u_n - |\nabla u|^{p(x)-2}\nabla u)(\nabla u_n - \nabla u)dx \\ &+ \int_\Omega \Big(\frac{b(x)|u_n|^{q-2}}{|x|^q}u_n(u_n-u) - \frac{b(x)|u|^{q-2}}{|x|^q}u(u_n-u)\Big)dx,\end{aligned}$$

thus we get

$$\overline{\lim}_{n\to\infty}\int_\Omega a(x,u)(|\nabla u_n|^{p(x)-2}\nabla u_n - |\nabla u|^{p(x)-2}\nabla u)(\nabla u_n - \nabla u)dx \leq 0.$$

Further, by (1.2) one has

$$\overline{\lim}_{n\to\infty}\int_\Omega \omega(x)(|\nabla u_n|^{p(x)-2}\nabla u_n - |\nabla u|^{p(x)-2}\nabla u)(\nabla u_n - \nabla u)dx \leq 0,$$

then $u_n \to u$ in $W_0^{1,p(x)}(\omega,\Omega)$ via Lemma 3.2 in [12]. □

Lemma 2.7. *The functional Φ' is a homeomorphism.*

Proof. The strict monotonicity of Φ' implies that it is injective. Since Φ' is coercive, it is also surjective, and hence Φ' has an inverse mapping.

Next, we show that the inverse mapping $(\Phi')^{-1}$ is continuous.

Let $\tilde{f}_n, \tilde{f} \in (W_0^{1,p(x)}(\omega,\Omega))^*$ such that $\tilde{f}_n \to \tilde{f}$. We aim to prove that $(\Phi')^{-1}(\tilde{f}_n) \to (\Phi')^{-1}(\tilde{f})$.

Indeed, let $(\Phi')^{-1}(\tilde{f}_n) = u_n$ and $(\Phi')^{-1}(\tilde{f}) = u$, so that $\Phi'(u_n) = \tilde{f}_n$ and $\Phi'(u) = \tilde{f}$. By the coercivity of Φ', the sequence u_n is bounded. Without loss of generality, assume $u_n \rightharpoonup u_0$, which implies

$$\lim_{n\to\infty} \left(\Phi'(u_n) - \Phi'(u), u_n - u_0\right) = \lim_{n\to\infty} \left(\tilde{f}_n - \tilde{f}, u_n - u_0\right) = 0.$$

Thus, $u_n \to u_0$ because Φ' is of (S_+)-type, which ensures that $\Phi'(u_n) \to \Phi'(u_0)$. Combining this with $\Phi'(u_n) \to \Phi'(u)$, we deduce that $\Phi'(u) = \Phi'(u_0)$. Since Φ' is injective, it follows that $u = u_0$, and hence $u_n \to u$. Therefore, we have $(\Phi')^{-1}(\tilde{f}_n) \to (\Phi')^{-1}(\tilde{f})$, proving that $(\Phi')^{-1}$ is continuous. □

Lemma 2.8 (Hölder type inequality [1,8]). *Let $p, q, s \geq 1$ be measurable functions defined on Ω and*

$$\frac{1}{s(x)} = \frac{1}{p(x)} + \frac{1}{q(x)}, \quad \text{for a.e. } x \in \Omega.$$

If $f \in L^{p(x)}(\Omega)$ and $g \in L^{q(x)}(\Omega)$, then $fg \in L^{s(x)}(\Omega)$ and

$$\|fg\|_{s(x)} \leq 2\|f\|_{p(x)}\|g\|_{q(x)}. \tag{2.2}$$

Lemma 2.9. *The functional $\Psi' : X := W_0^{1,p(x)}(\omega,\Omega) \to (W_0^{1,p(x)}(\omega,\Omega))^*$ is compact.*

Proof. The condition (f_1) and the compact embedding $W_0^{1,p(x)}(\omega,\Omega) \hookrightarrow\hookrightarrow L^{\beta(x)}(\Omega)$, where $1 \leq \beta(x) < p_h^*(x)$, imply the compactness of $\Psi'(u)$. Specifically, let $(u_k)_k \subset X$ be a sequence such that $u_k \rightharpoonup u$. Since the embedding $W_0^{1,p(x)}(\omega,\Omega) \hookrightarrow\hookrightarrow L^{\beta(x)}(\Omega)$ is compact, there exists a subsequence, still denoted by $(u_k)_k$, such that $u_k \to u$ strongly in $L^{\beta(x)}(\Omega)$ and $u_k(x) \to u(x)$ almost everywhere. The continuity of $F(x,u)$ with respect to u ensures that

$$F(x,u_k) \to F(x,u) \quad \text{for almost every } x.$$

Moreover, there exists $C > 0$ such that

$$|F(x,u_k)| \leq C|u_k|^{\beta(x)}.$$

Applying the dominated Convergence theorem we can conclude

$$\int_\Omega F(x,u_k)\,dx \to \int_\Omega F(x,u)\,dx \quad \text{as } k \to +\infty. \tag{2.3}$$

From condition (f_1), it follows that the Nemytskii operator $N_f(u)(x) = f(x,u(x))$ is continuous, as $f : \Omega \times \mathbb{R} \to \mathbb{R}$ is a Carathéodory function that satisfies (f_1). Consequently, we conclude that $N_f(u_k) \to N_f(u)$ in $L^{\frac{\beta(x)}{\beta(x)-1}}(\Omega)$.

Using Hölder's inequality, for any $v \in W_0^{1,p(x)}(\omega,\Omega)$, we obtain

$$\begin{aligned}\left|\int_\Omega f(x,u_k)v dx - \int_\Omega f(x,u)v dx\right| &\leq \int_\Omega |(f(x,u_k) - f(x,u))v| dx \\ &\leq 2\|N_f(u_k) - N_f(u)\|_{\frac{\beta(x)}{\beta(x)-1}}\|v\|_{\beta(x)} \\ &\leq 2c_\beta\|N_f(u_k) - N_f(u)\|_{\frac{\beta(x)}{\beta(x)-1}}\|v\|,\end{aligned}$$

where c_β is the embedding constant of the embedding $W_0^{1,p(x)}(\omega,\Omega) \hookrightarrow L^{\beta(x)}(\Omega), 1 \leq \beta(x) < p_h^*(x)$. Thus, from (2.3) and the above inequality, $\Psi'(u_k) \to \Psi'(u)$ in X^*, i.e. Ψ' is completely continuous, thus Ψ' is compact. □

The following critical point theorems constitute the principal tools used to obtain our result.

Theorem 2.10 ([5, Theorem 3.6]). *Let X be a reflexive real Banach space, and let $\Phi : X \to \mathbb{R}$ be a coercive functional that is continuously Gâteaux differentiable and weakly lower semicontinuous in the sequential sense. Assume that the Gâteaux derivative of Φ has a continuous inverse on the dual space X^*. Additionally, let $\Psi : X \to \mathbb{R}$ be a continuously Gâteaux differentiable functional whose Gâteaux derivative is compact. Assume the following conditions hold:*

(a_0) $$\inf_X \Phi = \Phi(0) = \Psi(0) = 0.$$

There exist constants $d > 0$ and a point $\overline{x} \in X$ such that $d < \Phi(\overline{x})$, and the following conditions are satisfied:

(a_1) $$\frac{\sup_{\Phi(x)<d} \Psi(x)}{d} < \frac{\Psi(\overline{x})}{\Phi(\overline{x})},$$

(a_2) *For each $\lambda \in \Lambda_d := \left(\frac{\Phi(\overline{x})}{\Psi(\overline{x})}, \frac{d}{\sup_{\Phi(x)\leq d} \Psi(x)}\right)$, the functional $I_\lambda := \Phi - \lambda\Psi$ is coercive.*

Then, for every $\lambda \in \Lambda_d$, the functional $\Phi - \lambda\Psi$ has at least three distinct critical points in X.

3 Main results

In this section, a theorem about the existence of at least three weak solutions to the problem (1.1) are obtained.

Recall the Hardy inequality (see Lemma 2.1 in [11] for more details), which states that for $1 < p < N$, the following inequality holds:

$$\int_\Omega \frac{|u(x)|^p}{|x|^p}\,dx \leq \frac{1}{H}\int_\Omega |\nabla u|^p\,dx, \quad \forall u \in W_0^{1,p}(\Omega),$$

where $H = \left(\frac{N-p}{p}\right)^p$ is the optimal constant.

By combining this with Lemma 2.1 and using the fact that $1 < q < p_h(x) < N$, we get the continuous embeddings

$$W_0^{1,p(x)}(\omega,\Omega) \hookrightarrow W_0^{1,p_h(x)}(\Omega) \hookrightarrow W_0^{1,q}(\Omega),$$

which leads to the inequality

$$\int_\Omega \frac{|u(x)|^q}{|x|^q}\,dx \leq \frac{1}{H}\int_\Omega |\nabla u|^q\,dx, \quad \forall u \in W_0^{1,p(x)}(\omega,\Omega),$$

where $H = \left(\frac{N-q}{q}\right)^q$.

We are now ready to present our primary result. To this end, we define

$$D(x) := \sup\{D > 0 \mid B(x,D) \subseteq \Omega\}$$

for each $x \in \Omega$, where $B(x, D)$ denotes a ball centered at x with radius D. It is clear that there exists a point $x^0 \in \Omega$ such that $B(x^0, R) \subseteq \Omega$, where

$$R = \sup_{x \in \Omega} D(x).$$

In the remainder of the paper, the symbol m will represent the constant

$$m = \frac{\pi^{\frac{N}{2}}}{\frac{N}{2}\Gamma\left(\frac{N}{2}\right)},$$

with Γ denoting the Gamma function.

Theorem 3.1. *Assume that $p^- > \beta^+(r+1)$ and that there exist $d, \delta > 0$, such that*

$$\frac{a_1}{p^+}\left(\frac{2\delta}{R}\right)^{\check{p}} \|\omega\|_{L^1(\mathfrak{B})} \geq d,$$

and

$$A_\delta := \frac{\frac{a_2}{p^-}\left(\frac{2\delta}{R}\right)^{\hat{p}} \|\omega\|_{L^1(\mathfrak{B})} + \left(\frac{2\delta}{R}\right)^{q} \frac{\|b\|_\infty}{qH} m\left(R^N - \left(\frac{R}{2}\right)^N\right)}{\frac{M_1^{r+1}}{(r+1)(\alpha^+)^{r+1}}\left((\delta)^{\check{\alpha}} m(\frac{R}{2})^N\right)^{r+1}} < B_d := \frac{d}{\frac{(M_2)^{r+1}\left(c_\beta^{\hat{\beta}}\right)^{(r+1)}}{(r+1)(\beta^-)^{r+1}}\left(\left[\left(\frac{p^+}{a_1}d\right)^{\frac{1}{\hat{p}}}\right]^{\hat{\beta}}\right)^{r+1}},$$

then for any $\lambda \in]A_\delta, B_d[$, problem (1.1) admits at least three weak solutions.

Proof. It is worth noting that Φ and Ψ satisfy the regularity assumptions outlined in Theorem 2.10. We will now establish the fulfillment of conditions (a_1) and (a_2). To this end, let's consider

$$\frac{a_1}{p^+}\left(\frac{2\delta}{R}\right)^{\check{p}} \|\omega\|_{L^1(\mathfrak{B})} \geq d$$

and consider $v_\delta \in X$ such that

$$v_\delta(x) := \begin{cases} 0 & x \in \Omega \backslash B\left(x^0, R\right) \\ \frac{2\delta}{R}\left(R - \left|x - x^0\right|\right) & x \in \mathfrak{B} := \overline{B}\left(x^0, R\right) \backslash B\left(x^0, \frac{R}{2}\right), \\ \delta & x \in \overline{B}\left(x^0, \frac{R}{2}\right). \end{cases}$$

Then, by the definition of Φ , we have

$$\begin{aligned} \frac{a_1}{p^+}\left(\frac{2\delta}{R}\right)^{\check{p}} \|\omega\|_{L^1(\mathfrak{B})} &< \Phi(v_\delta) \\ &\leq \frac{a_2}{p^-}\left(\frac{2\delta}{R}\right)^{\hat{p}} \|\omega\|_{L^1(\mathfrak{B})} + \left(\frac{2\delta}{R}\right)^{q} \frac{\|b\|_\infty}{qH} m\left(R^N - \left(\frac{R}{2}\right)^N\right) \end{aligned}$$

Therefore, $\Phi(v_\delta) > d$. However, it is important to consider the following

$$\begin{aligned} \Psi(v_\delta) \geq \frac{1}{r+1}\left(\int_\Omega F(x, v_\delta)dx\right)^{r+1} &\geq \frac{M_1^{r+1}}{(r+1)(\alpha^+)^{r+1}}\left(\int_{B(x^0, \frac{R}{2})} |\delta|^{\alpha(x)}dx\right)^{r+1}, \\ &\geq \frac{M_1^{r+1}}{(r+1)(\alpha^+)^{r+1}}\left((\delta)^{\check{\alpha}} m\left(\frac{R}{2}\right)^N\right)^{r+1}, \end{aligned} \tag{3.1}$$

which yields to $\frac{\Phi(v_\delta)}{\Psi(v_\delta)} \leq A_\delta < \lambda$. In addition, for every $u \in \Phi^{-1}(]-\infty, d])$, one has the following

$$\frac{a_1}{p^+}\|u\|^{\check{p}} \leq d. \tag{3.2}$$

therefore,

$$\|u\| \leq \left(\frac{p^+}{a_1}\Phi(u)\right)^{\frac{1}{\check{p}}} < \left(\frac{p^+}{a_1}d\right)^{\frac{1}{\check{p}}}.$$

Furthermore, under the assumption (f_1), we can conclude the following

$$\begin{aligned}
\Psi(u) &\leq \frac{1}{r+1}\Big(\int_\Omega F(x,u(x))dx\Big)^{r+1}, \\
&\leq \frac{(M_2)^{r+1}}{(r+1)(\beta^-)^{r+1}}\Big(\int_\Omega |u|^{\beta(x)}dx\Big)^{r+1}, \\
&\leq \frac{(M_2)^{r+1}}{(r+1)(\beta^-)^{r+1}}\big(\|u\|_\beta^{\hat{\beta}}\big)^{r+1}, \\
&\leq \frac{(M_2)^{r+1}\big(c_\beta^{\hat{\beta}}\big)^{(r+1)}}{(r+1)(\beta^-)^{r+1}}\big(\|u\|^{\hat{\beta}}\big)^{r+1}.
\end{aligned} \tag{3.3}$$

This leads to the following result

$$\sup_{\Phi(u)<d}\Psi(u) \leq \frac{(M_2)^{r+1}\big(c_\beta^{\hat{\beta}}\big)^{(r+1)}}{(r+1)(\beta^-)^{r+1}}\left(\left[\left(\frac{p^+}{a_1}d\right)^{\frac{1}{\check{p}}}\right]^{\hat{\beta}}\right)^{r+1},$$

and

$$\frac{1}{d}\sup_{\Phi(u)<d}\Psi(u) < \frac{1}{\lambda}.$$

Furthermore, we can establish the coerciveness of $\mathcal{I}_\lambda$ for any positive value of λ by employing inequality (3.3) once more. This yields the following result

$$\Psi(u) \leq \frac{(M_2)^{r+1}\big(c_\beta^{\hat{\beta}}\big)^{(r+1)}}{(r+1)(\beta^-)^{r+1}}\big(\|u\|^{\hat{\beta}}\big)^{r+1}.$$

When $\|u\|$ is great enough, the following can be inferred

$$\Phi(u) - \lambda\Psi(u) \geq \frac{a_1}{p^+}\|u\|^{p^-} - \lambda\frac{(M_2)^{r+1}\big(c_\beta^{\hat{\beta}}\big)^{(r+1)}}{(r+1)(\beta^-)^{r+1}}\big(\|u\|^{\hat{\beta}}\big)^{r+1}.$$

By considering the fact that $p^- > \beta^+(r+1)$, we can reach the desired conclusion. In conclusion, considering the aforementioned fact that

$$\bar{\Lambda}_{d,\delta} := (A_\delta, B_d) \subseteq \left(\frac{\Phi(v_\delta)}{\Psi(v_\delta)}, \frac{d}{\sup_{\Phi(u)<d}\Psi(u)}\right),$$

Based on Theorem 2.10, it can be deduced that for any $\lambda \in \bar{\Lambda}_{d,\delta}$, the function $\Phi - \lambda\Psi$ possesses at least three critical points in $X := W_0^{1,p}(\omega,\Omega)$. These critical points correspond to weak solutions of problem (1.1). □

Remark 3.2. Setting $d = \frac{a_1}{p^+}$, then B_d becomes

$$B_d = \frac{\frac{a_1}{p^+}}{\frac{(M_2)^{r+1}\left(c_\beta^{\hat{\beta}}\right)^{(r+1)}}{(r+1)(\beta^-)^{r+1}}},$$

moreover, one has

$$p^+ \geq p^- > \beta^+(r+1) \geq \alpha^+(r+1) \quad \text{and} \quad q < p^+,$$

thus $\lim_{\delta\to 0^+} A_\delta = 0$, consequently, $]A_\delta, B_d[\neq \emptyset$ and Theorem 3.1, can be rewritten as follows: Assume that $p^- > \beta^+(r+1)$ and that there exist $\delta > 0$, such that

$$\delta \geq \frac{R}{2}\left(\frac{1}{\|\omega\|_{L^1(\mathfrak{B})}}\right)^{\frac{1}{\hat{p}}}$$

and

$$A_\delta := \frac{\frac{a_2}{p^-}\left(\frac{2\delta}{R}\right)^{\hat{p}}\|\omega\|_{L^1(\mathfrak{B})} + \left(\frac{2\delta}{R}\right)^{q}\frac{\|b\|_\infty}{qH}m\left(R^N - \left(\frac{R}{2}\right)^N\right)}{\frac{M_1^{r+1}}{(r+1)(\alpha^+)^{r+1}}\left((\delta)^{\check{\alpha}}m(\frac{R}{2})^N\right)^{r+1}} < B_d := \frac{\frac{a_1}{p^+}}{\frac{(M_2)^{r+1}\left(c_\beta^{\hat{\beta}}\right)^{(r+1)}}{(r+1)(\beta^-)^{r+1}}},$$

then for any $\lambda \in]A_\delta, B_d[$, problem (1.1) admits at least three weak solutions.

Abstract. The paper investigates periodicity properties of a linear autonomous difference system with two delayed terms. Assuming that the system matrices are simultaneously triangularizable, we formulate necessary and sufficient conditions guaranteeing the existence of a nonzero periodic solution (with an *a priori* given period) of the studied system. The analytical form of such conditions is shown to generalize the existing results on this topic. Moreover, it is supported by a geometric reformulation, offering a better understanding of the derived periodicity conditions. Information on the form of the searched periodic solution (including its prime period) is also provided.

Keywords: difference equation, delay, periodic solution.

2020 Mathematics Subject Classification: 39A23, 39A06.

1 Introduction and preliminaries

The study of periodic solutions in differential and difference systems belongs among frequent research topics. It is well known that the appearance of periodic solutions forms an important part of the bifurcation analysis of dynamical systems that is often accompanied by other interesting phenomena (such as the loss of asymptotic stability of the corresponding equilibria). There are various methods for detecting a periodic behavior in the studied systems, often based on fixed-point theorems. Since the procedures utilizing this approach do not usually give analytical expressions of the searched periodic solutions, other methods were found and applied to obtain the desired expressions (see, e.g., the Carvalho method, initially developed for delay differential equations but applicable also to discrete equations [6,7,14]). We refer to [2,8–12,17–19,21,22] for a survey of some results and techniques used in the existence theory of periodic solutions.

In the autonomous linear case, the problem of the existence of periodic solutions is related to the existence of a specific characteristic root. In particular, the delay differential system

$$y'(t) + \sum_{s=1}^{k} A_s y(t-s) = 0, \qquad t \in \mathbb{R}^+,$$

✉ Corresponding author. Email: cermak.j@fme.vutbr.cz

where $A_s \in \mathbb{R}^{d\times d}$, has a q-periodic solution $y : \mathbb{R}^+ \to \mathbb{R}^d$ (i.e., a solution satisfying $y(t+q) = y(t)$ for all $t \in \mathbb{R}^+$ and some $q \in \mathbb{R}^+$) if and only if the corresponding characteristic quasi-polynomial

$$F(\lambda) = \det\left(\lambda I + \sum_{s=1}^{k} \exp(-\lambda s) A_s\right)$$

(I being the identity matrix) has a pure imaginary root. Similarly, the difference system

$$x(n) + \sum_{s=1}^{k} A_s x(n-s) = 0, \qquad n \in \mathbb{Z}^+, \tag{1.1}$$

$A_s \in \mathbb{R}^{d\times d}$, admits a q-periodic solution $x : \mathbb{Z}^+ \to \mathbb{R}^d$ (i.e., a solution satisfying $x(n+q) = x(n)$ for all $n \in \mathbb{Z}^+$ and some $q \in \mathbb{Z}^+$) if and only if the family of roots of

$$P(\lambda) = \det\left(\lambda^k I + \sum_{s=1}^{k} \lambda^{k-s} A_s\right)$$

involves a q-th root of unity. That is, there exists a root $\lambda_{j,q}$ of P in the form

$$\lambda_{j,q} = \exp\left(\mathrm{i}\frac{2\pi j}{q}\right) \quad \text{for some } j = \left\lfloor -\frac{q}{2} \right\rfloor + 1, \left\lfloor -\frac{q}{2} \right\rfloor + 2, \ldots, \left\lfloor \frac{q}{2} \right\rfloor. \tag{1.2}$$

However, converting these theoretical conditions into efficient forms is usually regarded as questionable, therefore other approaches are preferred.

The aim of this paper is to pose arguments supporting a deeper analysis of the above stated polynomial properties when detecting a periodic behavior of the studied systems. To do this, we consider a particular case of the difference system (1.1) and apply a simple method converting the above polynomial condition into a more efficient form. In the sequel, we precise what is meant by this particular case.

If $k = 1$ in (1.1), then the roots of P are eigenvalues of the only system matrix, namely $-A_1$. Thus, (1.1) with $k = 1$ admits a periodic solution just when $-A_1$ (hence also A_1) has an eigenvalue with a unitary modulus and a rational argument. We can take this classical result as a pattern for our next investigations, and search for periodicity conditions in terms of eigenvalues of the system matrices.

Further, we consider (1.1) with two nonzero system matrices, i.e., the system

$$x(n) + Ax(n-m) + Bx(n-k) = 0 \tag{1.3}$$

with $A, B \in \mathbb{R}^{d\times d}$ and coprime $k, m \in \mathbb{Z}^+$, $k > m$ (note that if $\gcd(k,m) > 1$, then (1.3) can be easily converted to the case with coprime delays). Now, the characteristic polynomial P becomes

$$P^*(\lambda) = \det(\lambda^k I + \lambda^{k-m} A + B).$$

Contrary to the case $k = 1$, the formulation of efficient conditions on eigenvalues of A, B, ensuring that P^* has a root (1.2), seems to be extremely complicated (and perhaps lying beyond theoretical possibilities). Therefore, other methods have been developed to detect a periodic behavior in (1.3). In particular, the paper [10] successfully employed the method of circulant matrices and, for specific choices $A = -I$ and $m = 1$, extended some earlier results (see, e.g., [15,16]) to obtain complete periodicity conditions for the studied system. We recall Theorem 4.1 of [10] as the most relevant result to the topic of our paper.

Theorem 1.1. *The system (1.3) with $A = -I$ and $m = 1$ has a nontrivial periodic solution x if and only if at least one of the following conditions holds:*

(a) *B has a zero eigenvalue or has a real eigenvalue $\beta = b$ such that*

$$b \in \left\{ 2(-1)^{\ell} \sin\left(\frac{(2\ell+1)\pi}{2(2k-1)} \right),\ \ell = 0, 1, \dots, k-1 \right\}; \tag{1.4}$$

(b) *B has a pure imaginary eigenvalue $\beta = \mathrm{i}b$ ($b \in \mathbb{R}$) such that*

$$b \in \left\{ 2(-1)^{\ell} \sin\left(\frac{\ell\pi}{2k-1} \right),\ \ell = 1, \dots, 2k-2 \right\}; \tag{1.5}$$

(c) *B has a complex eigenvalue $\beta = b\exp(\mathrm{i}\phi)$ ($b, \phi \in \mathbb{R}$, $|\phi| < \pi/2$) such that, for some positive integers $\xi < \eta$,*

$$|\phi| = \frac{\xi\pi}{2\eta} \quad \text{and} \quad b \in \left\{ 2(-1)^{\ell} \sin\left(\frac{(\eta-\xi)\pi}{2\eta(2k-1)} + \frac{\ell\pi}{2k-1} \right),\ \ell = 0, 1, \dots, 2k-2 \right\}. \tag{1.6}$$

Following the conclusions of Theorem 1.1, we return to the characteristic polynomial approach. In particular, we show that Theorem 1.1 can be obtained from the root analysis of P^* as well, and moreover, this analysis appears to be applicable also in some more general situations. In fact, it utilizes a straightforward procedure how to simplify the form of P^* under a specific restriction imposed on A, B, namely their simultaneous triangularizability. This property assumes the existence of a regular matrix T such that both $T^{-1}AT$ and $T^{-1}BT$ are upper triangular. The existence of such a matrix T is guaranteed whenever A, B are commuting (for some less restrictive conditions on A, B, see, e.g., [3]). Notice that the matrices $A = -I$ and B considered in Theorem 1.1 obviously share this property. Further, if A, B are simultaneously triangularizable, then, after a few straightforward computational steps, one can decompose P^* into a significantly simpler form, namely

$$P^{**}(\lambda) = \prod_{i=1}^{d} (\lambda^k + \alpha_i \lambda^{k-m} + \beta_i), \tag{1.7}$$

where $(\alpha_i, \beta_i) \in \mathbb{C}^2$, $i = 1, \dots, d$, are simultaneously ordered couples of eigenvalues of A, B (i.e., couples involving mutually corresponding diagonal elements of the matrices $T^{-1}AT$ and $T^{-1}BT$, respectively). Thus, (1.3) with simultaneously triangularizable matrices A, B has a q-periodic solution x if and only if at least one of the trinomials involved in the product (1.7) has a root of the form (1.2).

To summarize the previous considerations, the mathematical core of discussions on the existence of periodic solutions of (1.3) with simultaneously triangularizable A, B consists in analyzing the following problem: *Find conditions under which a complex trinomial*

$$Q(\lambda) = \lambda^k + \alpha\lambda^{k-m} + \beta \tag{1.8}$$

admits a root (1.2).

Based on the previous notes, the paper is organized as follows. In Section 2, we consider (1.3) with simultaneously triangularizable A, B, and formulate a general result on the existence of a q-periodic solution of (1.3), including its form and prime period. Section 3 reveals a geometric background of this result, namely a relationship between the derived periodicity conditions and analytical description of some roulette curves. Two particular cases of (1.3)

are investigated in Section 4. Here, we provide a generalization of Theorem 1.1 to (1.3) with $A = -I$ and a general m, and derive fully explicit conditions for detecting its periodic solution. An application of the presented results in control theory is stated as well. The final section, involving survey remarks and possible perspectives of the research, concludes the paper.

2 Basic analytical conditions for the existence of a periodic solution of (1.3)

First, we consider the characteristic polynomial P that is associated with the general linear system (1.1). A simple but efficient method for analyzing the distribution of characteristic roots with respect to the unit circle is the D-partition method (in the discrete case, it is also referred to as the boundary locus technique). This method is standardly employed in stability analysis of (1.1) but can also be applied to reveal periodic behavior.

Indeed, assume that P has a unimodular root $\lambda = \exp(\mathrm{i}\phi)$, $-\pi < \phi \leq \pi$. A direct substitution into $P(\lambda) = 0$ yields

$$\det\left(\exp(\mathrm{i}k\phi)I + \sum_{s=1}^{k} \exp(\mathrm{i}(k-s)\phi)A_s\right) = 0. \tag{2.1}$$

In particular, if $\lambda = \lambda_{j,q}$ is given by (1.2), i.e., if we put $\phi = 2\pi j/q$, then (2.1) becomes

$$\det\left(\exp\left(\mathrm{i}\frac{2\pi jk}{q}\right)I + \sum_{s=1}^{k} \exp\left(\mathrm{i}\frac{2\pi j(k-s)}{q}\right)A_s\right) = 0,$$

hence,

$$\det\left(I + \sum_{s=1}^{k} \exp\left(-\mathrm{i}\frac{2\pi js}{q}\right)A_s\right) = 0. \tag{2.2}$$

Thus, (1.1) admits a q-periodic solution if and only if there exists an integer j (specified in (1.2)) such that (2.2) holds. Notice that the same conclusion was formulated in Theorem 3.1 of [10] by the use of tools of circulant matrices (contrary to Theorem 3.1 of [10], now we do not need to assume pairwise commutativity of the system matrices).

Of course, (2.2) is still rather a theoretical condition. The following assertion converts (2.2) into an efficient form if we consider (1.3) instead of (1.1), and assume that A, B are simultaneously triangularizable. In what follows, Arg denotes the principal argument of a complex number (i.e., $-\pi < \mathrm{Arg}(z) \leq \pi$ for $z \in \mathbb{C}$), and we introduce a function $(\cdot)_{2\pi} : \mathbb{R} \to (-\pi, \pi]$ as the 2π-periodic extension of the identity function defined on $(-\pi, \pi]$ (i.e., $(\cdot)_{2\pi}$ provides modulo 2π operation).

Lemma 2.1. *Let $A, B \in \mathbb{R}^{d\times d}$ be simultaneously triangularizable matrices, $k, m \in \mathbb{Z}^+$, $k > m$, be coprime and let $q \in \mathbb{Z}^+$. Then (1.3) has a nontrivial q-periodic solution if and only if there exists a couple of simultaneously ordered eigenvalues (α, β) of A, B satisfying, for some integer j such that $\lfloor -q/2 \rfloor + 1 \leq j \leq \lfloor q/2 \rfloor$, any of the following conditions:*

(i) $\alpha = 0, \quad |\beta| = 1, \quad \mathrm{Arg}(\beta) = \left(\pi + \dfrac{2\pi jk}{q}\right)_{2\pi}$;

(ii) $\beta = 0, \quad |\alpha| = 1, \quad \mathrm{Arg}(\alpha) = \left(\pi + \dfrac{2\pi jm}{q}\right)_{2\pi}$;

(iii) $\alpha\beta \neq 0$, $\big||\alpha| - |\beta|\big| \leq 1 \leq |\alpha| + |\beta|$, *and*

$$\begin{aligned} \cos\left(\operatorname{Arg}(\alpha) - \frac{2\pi jm}{q}\right) &= \frac{|\beta|^2 - |\alpha|^2 - 1}{2|\alpha|}, \\ \cos\left(\operatorname{Arg}(\beta) - \frac{2\pi jk}{q}\right) &= \frac{|\alpha|^2 - |\beta|^2 - 1}{2|\beta|}, \end{aligned} \tag{2.3}$$

where $(\operatorname{Arg}(\alpha) - 2\pi jm/q)_{2\pi}$, $(\operatorname{Arg}(\beta) - 2\pi jk/q)_{2\pi}$ *have opposite signs if both are nonzero.*

Proof. Because of the reduction of P into P^{**}, we need to describe the situation when the complex trinomial Q (with appropriate eigenvalues α and β of A and B, respectively) has a unimodular root (1.2). First note that Q has a unimodular root $\lambda = \exp(\mathrm{i}\phi)$, $-\pi < \phi \leq \pi$, just when

$$\exp(\mathrm{i}k\phi) + \alpha \exp(\mathrm{i}(k-m)\phi) + \beta = 0 \tag{2.4}$$

(see also (2.1)). Since λ should be a q-th root of unity, we put again $\phi = 2\pi j/q$, and (2.4) becomes

$$\exp\left(\mathrm{i}\frac{2\pi jk}{q}\right) + \alpha \exp\left(\mathrm{i}\frac{2\pi j(k-m)}{q}\right) + \beta = 0. \tag{2.5}$$

This immediately implies the lemma's conditions (i) and (ii).

Now assume $\alpha\beta \neq 0$. Then (2.5) can be rewritten as

$$1 + |\alpha| \exp\left(\mathrm{i}\left(\operatorname{Arg}(\alpha) - \frac{2\pi jm}{q}\right)\right) = -|\beta| \exp\left(\mathrm{i}\left(\operatorname{Arg}(\beta) - \frac{2\pi jk}{q}\right)\right)$$

which is (by comparing the real and imaginary parts) equivalent to the system

$$\begin{aligned} 1 + |\alpha| \cos\left(\operatorname{Arg}(\alpha) - \frac{2\pi jm}{q}\right) &= -|\beta| \cos\left(\operatorname{Arg}(\beta) - \frac{2\pi jk}{q}\right), \\ |\alpha| \sin\left(\operatorname{Arg}(\alpha) - \frac{2\pi jm}{q}\right) &= -|\beta| \sin\left(\operatorname{Arg}(\beta) - \frac{2\pi jk}{q}\right). \end{aligned} \tag{2.6}$$

Summing the squares of both the lines of (2.6) yields

$$1 + 2|\alpha| \cos\left(\operatorname{Arg}(\alpha) - \frac{2\pi jm}{q}\right) + |\alpha|^2 = |\beta|^2,$$

which implies $(2.3)_1$.

Now, substituting $(2.3)_1$ to the left-hand side of $(2.6)_1$, we obtain

$$1 + |\alpha| \frac{|\beta|^2 - |\alpha|^2 - 1}{2|\alpha|} = -|\beta| \cos\left(\operatorname{Arg}(\beta) - \frac{2\pi jk}{q}\right),$$

which, after a straightforward rearrangement, becomes $(2.3)_2$. Moreover, the couple (α, β) has to also satisfy the stated sign correspondence of the cosine arguments because $(2.6)_2$ implies that $(\operatorname{Arg}(\alpha) - 2\pi jm/q)_{2\pi}$ is in $(0, \pi)$ (that is positive) just when $(\operatorname{Arg}(\beta) - 2\pi jk/q)_{2\pi}$ is in $(-\pi, 0)$ (that is negative). □

Remark 2.2. If we fix $\alpha \neq 0$, then (2.3) allows to express β explicitly (in terms of its modulus and argument). Indeed, taking into account the sign relation between $(\mathrm{Arg}(\alpha) - 2\pi jm/q)_{2\pi}$ and $(\mathrm{Arg}(\beta) - 2\pi jk/q)_{2\pi}$, we get

$$\begin{aligned} |\beta| &= \sqrt{1 + |\alpha|^2 + 2|\alpha| \cos\left(\mathrm{Arg}(\alpha) - \frac{2\pi jm}{q}\right)}, \\ \mathrm{Arg}(\beta) &= \left(\kappa \arccos\left(\frac{|\alpha|^2 - |\beta|^2 - 1}{2|\beta|}\right) + \frac{2\pi jk}{q}\right)_{2\pi}, \end{aligned} \tag{2.7}$$

where $\kappa = -1$ if $(\mathrm{Arg}(\alpha) - 2\pi jm/q)_{2\pi}$ is in $(0, \pi]$, and $\kappa = 1$ if $(\mathrm{Arg}(\alpha) - 2\pi jm/q)_{2\pi}$ is in $(-\pi, 0]$. It means that, depending on the integer j, we have (for a given α) at most q possible positions of β in the complex plane such that a q-th root of unity belongs among the roots of Q.

Analogous explicit expressions can be obtained for α when $\beta \neq 0$ is fixed. More precisely, $(2.3)_2$, $(2.3)_1$ imply

$$\begin{aligned} |\alpha| &= \sqrt{1 + |\beta|^2 + 2|\beta| \cos\left(\mathrm{Arg}(\beta) - \frac{2\pi jk}{q}\right)}, \\ \mathrm{Arg}(\alpha) &= \left(\kappa \arccos\left(\frac{|\beta|^2 - |\alpha|^2 - 1}{2|\alpha|}\right) + \frac{2\pi jm}{q}\right)_{2\pi}, \end{aligned} \tag{2.8}$$

where $\kappa = -1$ if $(\mathrm{Arg}(\beta) - 2\pi jk/q)_{2\pi}$ belongs to $(0, \pi]$, and $\kappa = 1$ if $(\mathrm{Arg}(\beta) - 2\pi jk/q)_{2\pi}$ belongs to $(-\pi, 0]$. We add that a nice geometric interpretation of the conditions (2.7) and (2.8) will be discussed in the next section.

To complete the above basic periodic investigations of (1.3), we reveal the structure of the discussed q-periodic solution. As a first step, we state the following root property of P^{**}.

Proposition 2.3. *If $\lambda_{j,q} = \exp(\mathrm{i}2\pi j/q)$ (see (1.2)) is a root of P^{**}, then the complex conjugate number $\overline{\lambda}_{j,q} = \exp(-\mathrm{i}2\pi j/q)$ is also a root of P^{**}. Moreover, if v is a characteristic vector corresponding to $\lambda_{j,q}$, i.e., v solves the system $\big((\lambda_{j,q})^k I + (\lambda_{j,q})^{k-m} A + B\big)v = 0$, then its complex conjugate $\overline{v}$ is a characteristic vector corresponding to $\overline{\lambda}_{j,q}$, i.e., $\overline{v}$ satisfies $\big((\overline{\lambda}_{j,q})^k I + (\overline{\lambda}_{j,q})^{k-m} A + B\big)\overline{v} = 0$.*

Proof. Let $\lambda_{j,q}$ be a root of P^{**}. Since P^{**} and P^* are identically equal, and P^* is a real polynomial, we immediately get that $\overline{\lambda}_{j,q}$ is a root of P^{**} as well.

The complex conjugation of the corresponding characteristic vectors can be shown analogously as in the case of standard eigenvectors. Indeed, let v be a characteristic vector corresponding to $\lambda_{j,q}$, i.e., v satisfies

$$\big((\lambda_{j,q})^k I + (\lambda_{j,q})^{k-m} A + B\big)v = 0.$$

Then, taking the conjugates of both sides, we have

$$\overline{\big((\lambda_{j,q})^k I + (\lambda_{j,q})^{k-m} A + B\big)v} = \overline{0} \quad \Longrightarrow \quad \big((\overline{\lambda}_{j,q})^k I + (\overline{\lambda}_{j,q})^{k-m} A + B\big)\overline{v} = 0.$$

Therefore, $\overline{v}$ is a characteristic vector corresponding to $\overline{\lambda}_{j,q}$. □

Now, using Proposition 2.3, we can easily describe the family of all q-periodic solutions of (1.3) generated by $\lambda_{j,q}$, v, and their conjugates. Obviously, (1.3) has two such (linearly independent) solutions in the form

$$x_1^*(n) = v \exp\left(\mathrm{i}\frac{2\pi jn}{q}\right) \quad \text{and} \quad x_2^*(n) = \overline{v} \exp\left(-\mathrm{i}\frac{2\pi jn}{q}\right).$$

To avoid solutions with complex values, we put

$$x_1(n) = \frac{1}{2}\big(x_1^*(n) + x_2^*(n)\big) \quad \text{and} \quad x_2(n) = \frac{1}{\mathrm{i}2}\big(x_1^*(n) - x_2^*(n)\big)$$

to get a new pair of (linearly independent) real solutions

$$x_1(n) = v_1 \cos\left(\frac{2\pi jn}{q}\right) - v_2 \sin\left(\frac{2\pi jn}{q}\right), \qquad x_2(n) = v_2 \cos\left(\frac{2\pi jn}{q}\right) + v_1 \sin\left(\frac{2\pi jn}{q}\right), \tag{2.9}$$

where $v_1 = \Re(v)$, $v_2 = \Im(v)$. Then, any q-periodic solution x of (1.3) generated by $\lambda_{j,q}$, v, and their conjugates is given by a linear combination $x(n) = C_1x_1(n) + C_2x_2(n)$, $C_1, C_2 \in \mathbb{R}$. It is clear that the corresponding initial vectors

$$x^0(-k+1), x^0(-k+2), \dots, x^0(0)$$

have to match the form (2.9), i.e., we put

$$x_1^0(n) = v_1 \cos\left(\frac{2\pi jn}{q}\right) - v_2 \sin\left(\frac{2\pi jn}{q}\right), \qquad x_2^0(n) = v_2 \cos\left(\frac{2\pi jn}{q}\right) + v_1 \sin\left(\frac{2\pi jn}{q}\right) \tag{2.10}$$

for $n = -k+1, -k+2, \dots, 0$.

Moreover, we can easily decide whether the prescribed period q is also a prime period of the solutions (2.9). Obviously, x_1, x_2 are p-periodic ($p \in \mathbb{Z}^+$) whenever pj/q is an integer. Therefore, such a number p is a prime period if $p = q/\gcd(j,q)$. It means that if j and q are coprime, then q is a prime period.

3 Some geometric observations

In this section, we clarify a geometric background of the conditions (2.7) and (2.8). Doing this, we come back to the condition (2.4) characterizing the set of all complex α, β such that Q has a unimodular root $\lambda = \exp(\mathrm{i}\phi)$, $-\pi < \phi \le \pi$. As observed in [20], the geometric nature of such characterizations can be described in terms of some roulette curves. In the sequel, we elaborate on these issues in detail.

If we fix $\alpha \neq 0$ (as in Remark 2.2), the set of all β satisfying (2.4) is alternatively given by

$$\beta = |\alpha| \exp\big(\mathrm{i}(\pi + \operatorname{Arg}(\alpha) + (k-m)\phi)\big) - \exp(\mathrm{i}k\phi). \tag{3.1}$$

Set $s = \pi + \operatorname{Arg}(\alpha) + (k-m)\phi$ to obtain

$$\beta = |\alpha| \exp(\mathrm{i}s) - \exp\left(\mathrm{i}\frac{k}{k-m}\Big(s - (\pi + \operatorname{Arg}(\alpha))\Big)\right). \tag{3.2}$$

Further, the substitution $t = s - (\pi + \operatorname{Arg}(\alpha))k/m$ converts (3.2) to the form

$$\begin{aligned} \beta &= |\alpha| \exp\left(\mathrm{i}t + \mathrm{i}\frac{k}{m}\Big(\pi + \operatorname{Arg}(\alpha)\Big)\right) - \exp\left(\mathrm{i}\frac{k}{k-m}t + \mathrm{i}\frac{k}{m}\Big(\pi + \operatorname{Arg}(\alpha)\Big)\right) \\ &= \exp\left(\mathrm{i}\frac{k}{m}\Big(\pi + \operatorname{Arg}(\alpha)\Big)\right)\left(|\alpha| \exp(\mathrm{i}t) - \exp\left(\mathrm{i}\frac{k}{k-m}t\right)\right). \end{aligned} \tag{3.3}$$

Finally, we introduce the parameters $R = |\alpha|m/k$, $r = |\alpha|(k-m)/k$, $\delta = 1$ to rewrite (3.3) as

$$\beta = \exp\left(\mathrm{i}\frac{k}{m}\Big(\pi + \operatorname{Arg}(\alpha)\Big)\right)\left((R+r)\exp(\mathrm{i}t) - \delta \exp\left(\mathrm{i}\frac{R+r}{r}t\right)\right). \tag{3.4}$$

The second term in (3.4) represents the complex canonical parametrization of an epitrochoid, which is a roulette traced by a point attached to a circle of radius r, having distance δ from its center and rolling around the outside of a fixed circle of radius R. In addition, the appearance of the first term in (3.4) implies that the epitrochoid is rotated by the angle of rotation $\omega = \left(\frac{k}{m}(\pi + \operatorname{Arg}(\alpha))\right)_{2\pi}$. Thus, (3.1) is converted to the parametric equation of a rotated epitrochoid

$$\beta = \exp(\mathrm{i}\omega)\left((R+r)\exp(\mathrm{i}t) - \delta\exp\left(\mathrm{i}\frac{R+r}{r}t\right)\right), \tag{3.5}$$

where $t = s - (\pi + \operatorname{Arg}(\alpha))k/m = (k-m)\phi - \big(\pi + \operatorname{Arg}(\alpha)\big)(k-m)/m$. Note also that an epitrochoid is closed whenever r/R is a rational number. In our case, $r/R = (k-m)/m \in \mathbb{Q}$, and it is not difficult to check that the parametrization (3.5) has the prime period $2\pi(k-m)$.

To summarize, the complex number β satisfies (3.1) just when β is located on the (rotated) epitrochoid (3.5) with

$$R = |\alpha|\frac{m}{k}, \quad r = |\alpha|\frac{k-m}{k}, \quad \delta = 1, \quad \omega = \left(\frac{k}{m}\big(\pi + \operatorname{Arg}(\alpha)\big)\right)_{2\pi}. \tag{3.6}$$

In particular, Q has a unimodular root (1.2) just when the position of β on this epitrochoid is specified via

$$t = (k-m)\frac{2\pi j}{q} - \big(\pi + \operatorname{Arg}(\alpha)\big)\frac{k-m}{m} \quad \text{for some } j = \left\lfloor -\frac{q}{2}\right\rfloor + 1, \left\lfloor -\frac{q}{2}\right\rfloor + 2, \ldots, \left\lfloor \frac{q}{2}\right\rfloor. \tag{3.7}$$

Similarly, if we fix $\beta \neq 0$, then the set of all α satisfying (2.4) is given by

$$\alpha = |\beta|\exp\big(\mathrm{i}(\pi + \operatorname{Arg}(\beta) + (m-k)\phi)\big) - \exp(\mathrm{i}m\phi), \qquad -\pi < \phi \leq \pi.$$

Putting $s = \pi + \operatorname{Arg}(\beta) + (m-k)\phi$, we obtain

$$\alpha = |\beta|\exp(\mathrm{i}s) - \exp\left(\mathrm{i}\frac{m}{m-k}\Big(s - \big(\pi + \operatorname{Arg}(\beta)\big)\Big)\right). \tag{3.8}$$

Now, let

$$t = \frac{m}{m-k}\left(s - \Big(\pi + \operatorname{Arg}(\beta)\Big)\right) - \frac{m}{k}\operatorname{Arg}(\beta).$$

Then, (3.8) becomes

$$\begin{aligned}\alpha &= |\beta|\exp\left(\mathrm{i}\frac{m-k}{k}t + \mathrm{i}\Big(\pi + \frac{m}{k}\operatorname{Arg}(\beta)\Big)\right) - \exp\left(\mathrm{i}t + \mathrm{i}\frac{m}{k}\operatorname{Arg}(\beta)\right)\\ &= \exp\left(\mathrm{i}\Big(\pi + \frac{m}{k}\operatorname{Arg}(\beta)\Big)\right)\left(\exp(\mathrm{i}t) + |\beta|\exp\left(\mathrm{i}\frac{m-k}{m}t\right)\right).\end{aligned}$$

If we introduce $R = k/(k-m)$, $r = m/(k-m)$, $\delta = |\beta|$, and $\omega = (\pi + \operatorname{Arg}(\beta)m/k)_{2\pi}$, then

$$\alpha = \exp(\mathrm{i}\omega)\left((R-r)\exp(\mathrm{i}t) + \delta\exp\left(\mathrm{i}\frac{r-R}{r}t\right)\right), \tag{3.9}$$

where $t = \big(s - (\pi + \operatorname{Arg}(\beta))\big)m/(m-k) - \operatorname{Arg}(\beta)m/k = m\phi - \operatorname{Arg}(\beta)m/k$. Notice that the second term in (3.9) represents another roulette curve – hypotrochoid, which is a roulette traced by a point attached to a circle of radius r, having distance δ from its center, and rolling around the inside of a fixed circle of radius R ($R > r$). The first term in (3.9) again provides

a rotation of the curve by the angle ω. Since the ratio $r/R = m/k$ is a rational number, the parametrization (3.9) is periodic and its prime period is $2\pi m$ (i.e., (3.9) represents a closed curve).

Overall, analogously as above, one can conclude that Q has a unimodular root (1.2) just when α is located on the hypotrochoid (3.9) with

$$R = \frac{k}{k-m}, \quad r = \frac{m}{k-m}, \quad \delta = |\beta|, \quad \omega = \left(\pi + \frac{m}{k}\operatorname{Arg}(\beta)\right)_{2\pi}, \tag{3.10}$$

where

$$t = m\frac{2\pi j}{q} - \frac{m}{k}\operatorname{Arg}(\beta) \quad \text{for some } j = \left\lfloor -\frac{q}{2}\right\rfloor + 1, \left\lfloor -\frac{q}{2}\right\rfloor + 2, \ldots, \left\lfloor \frac{q}{2}\right\rfloor. \tag{3.11}$$

Thus, Lemma 2.1 and Remark 2.2, supported by the previous considerations, yield the following analytical and geometric characterization of the existence of a periodic solution of (1.3).

Theorem 3.1. *Let $A, B \in \mathbb{R}^{d\times d}$ be simultaneously triangularizable matrices, $k, m \in \mathbb{Z}^+$, $k > m$, be coprime and let $q \in \mathbb{Z}^+$. Then the following statements are equivalent.*

(i) *The system* (1.3) *has a nontrivial q-periodic solution.*

(ii) *Either* (iia) *or* (iib) *holds, where:*

- (iia) *There exists a zero eigenvalue α of A such that the corresponding eigenvalue β of B (in the sense of simultaneous ordering) is lying on a unit circle centered at the origin and the admissible values of arguments of β are specified via the conditions* (i) *of Lemma* 2.1.
- (iib) *There exists a nonzero eigenvalue α of A such that the corresponding eigenvalue β of B (in the sense of simultaneous ordering) is lying on the rotated epitrochoid* (3.5) *with R, r, δ, ω given by* (3.6)*; moreover, all the admissible values of the parameter t are specified via* (3.7)*. Alternatively, all such positions of β on this epitrochoid are described by* (2.7).

(iii) *Either* (iiia) *or* (iiib) *holds, where:*

- (iiia) *There exists a zero eigenvalue β of B such that the corresponding eigenvalue α of A (in the sense of simultaneous ordering) is lying on a unit circle centered at the origin and the admissible values of arguments of α are specified via the conditions* (ii) *of Lemma* 2.1.
- (iiib) *There exists a nonzero eigenvalue β of B such that the corresponding eigenvalue α of A (in the sense of simultaneous ordering) is lying on the rotated hypotrochoid* (3.9) *with R, r, δ, ω given by* (3.10)*; moreover, all the admissible values of the parameter t are specified via* (3.11)*. Alternatively, all such positions of α on this hypotrochoid are described by* (2.8).

Example 3.2. Consider the (planar) system (1.3) with $k = 5, m = 3$ and A, B given by

$$A = \frac{\sqrt{3}}{3}\begin{pmatrix} 8 & 9 \\ -6 & -7 \end{pmatrix}, \qquad B = \frac{\sqrt{3}}{3}\begin{pmatrix} -1 & -3 \\ 2 & 4 \end{pmatrix}.$$

It is easy to check that A and B are commuting (therefore simultaneously triangularizable), and the pairs of their simultaneously ordered eigenvalues are

$$(\alpha_1, \beta_1) = \left(-\frac{\sqrt{3}}{3}, \frac{2\sqrt{3}}{3}\right), \qquad (\alpha_2, \beta_2) = \left(\frac{2\sqrt{3}}{3}, \frac{\sqrt{3}}{3}\right).$$

Considering the first pair (α_1, β_1), we can check that the corresponding trinomial

$$\lambda^5 - \frac{\sqrt{3}}{3}\lambda^2 + \frac{2\sqrt{3}}{3},$$

appearing in the decomposition (1.7), has a unique unimodular root. More precisely, $\beta_1 = 2\sqrt{3}/3$ is located on the epitrochoid (3.5) with $R = \sqrt{3}/5$, $r = 2\sqrt{3}/15$, $\delta = 1$ and $\omega = -2\pi/3$. Moreover, its position corresponds to $t = 4\pi j/q - 4\pi/3$, where $j = 1$ and $q = 12$, see Figure 3.1 (left). Equivalently, $\alpha_1 = -\sqrt{3}/3$ is located on the hypotrochoid (3.9) with $R = 5/2$, $r = 3/2$, $\delta = 2\sqrt{3}/3$, $\omega = \pi$, and its position corresponds to $t = 6\pi j/q$, where $j = 1$ and $q = 12$, see Figure 3.1 (right). Thus, the eigenvalues β_1, α_1 obey (2.7), (2.8) with $j = 1$ and $q = 12$.

Considering the second pair (α_2, β_2), one can see that the corresponding trinomial

$$\lambda^5 + \frac{2\sqrt{3}}{3}\lambda^2 + \frac{\sqrt{3}}{3},$$

appearing in (1.7), has no unimodular root, hence β_2, α_2 do not meet (2.7), (2.8) for any integers j and q.

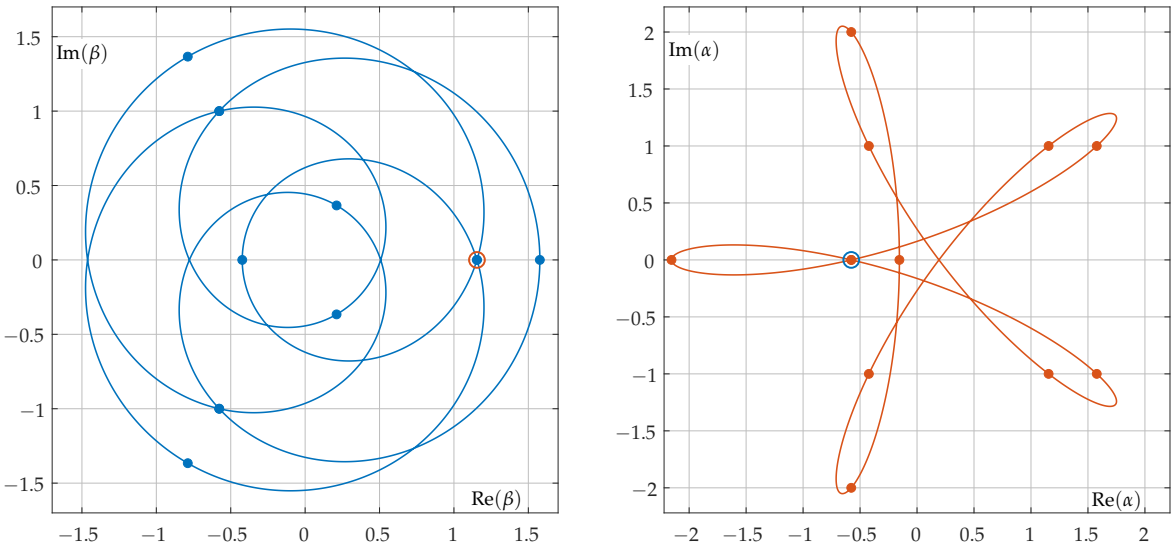

Figure 3.1: An epitrochoid (left) and a hypotrochoid (right) corresponding to the data of Example 3.2. The blue points in the left figure depict all the 12 possible positions of numbers β which can be an eigenvalue of B in a simultaneously ordered pair with α_1 of A (in fact, we have 9 positions only as one triple coincides with another one). Emphasized is the eigenvalue β_1 of B. The orange points in the right figure depict all the 12 positions of numbers α which can be an eigenvalue of A in a simultaneously ordered pair with β_1 of B (in fact, we have 11 positions only as one couple coincides). Emphasized is the eigenvalue α_1 of A.

By Theorem 3.1, the system has just a 12-periodic solution (and 12 is a prime period as $j = 1$ and $q = 12$ are coprime). Moreover, since it holds

$$(\lambda_{1,12})^k I + (\lambda_{1,12})^{k-m} A + B = \begin{pmatrix} \frac{\sqrt{3}}{2} + \mathrm{i}\frac{9}{2} & \frac{\sqrt{3}}{2} + \mathrm{i}\frac{9}{2} \\ -\frac{\sqrt{3}}{3} - \mathrm{i}3 & -\frac{\sqrt{3}}{3} - \mathrm{i}3 \end{pmatrix},$$

where $\lambda_{1,12} = \exp(\mathrm{i}2\pi/12)$, the characteristic vector corresponding to $\lambda_{1,12}$ can be taken simply as $v = (1,-1)^T$ (i.e., $v_1 = \Re(v) = (1,-1)^T$, $v_2 = \Im(v) = (0,0)^T$). Thus, using the

considerations performed at the end of Section 2, all (12-periodic) solutions of the studied system are of the form

$$x(n) = C_1 \begin{pmatrix} 1 \\ -1 \end{pmatrix} \cos\left(\frac{\pi n}{6}\right) + C_2 \begin{pmatrix} 1 \\ -1 \end{pmatrix} \sin\left(\frac{\pi n}{6}\right), \qquad C_1, C_2 \in \mathbb{R}$$

(five initial vectors $x^0(-4), x^0(-3), x^0(-2), x^0(-1), x^0(0)$ have to be prescribed accordingly). No other periodic solution can be detected in this system. Figure 3.2 depicts both components of the periodic solution x with $C_1 = 1$ and $C_2 = 2$.

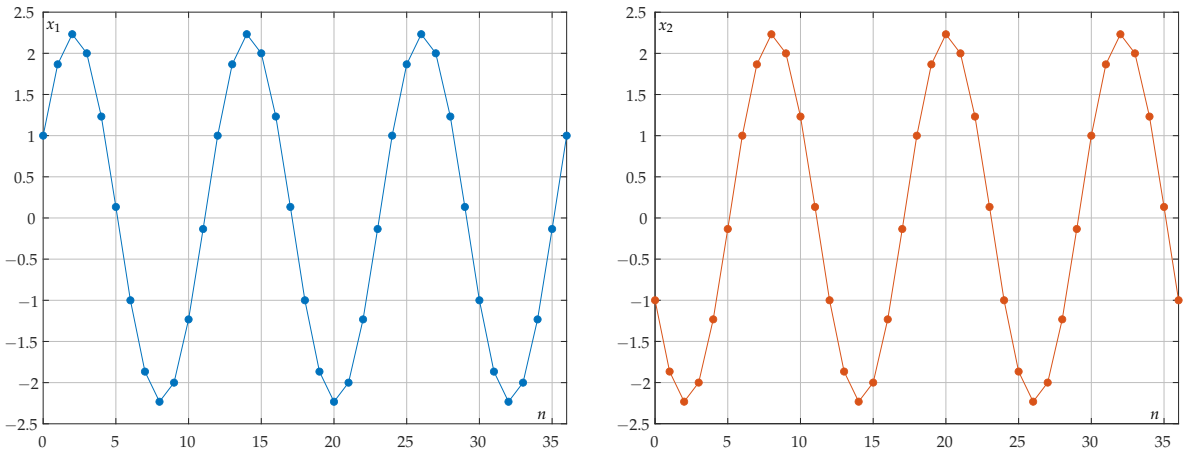

Figure 3.2: The first (left) and the second (right) component of the 12-periodic solution with respect to the data of Example 3.2.

4 Periodicity problem in two particular cases of (1.3)

In this section, we elaborate on the conclusions of Theorem 3.1 under specific choices of A (while B remains free). First, we consider the difference system

$$x(n) - x(n-m) + Bx(n-k) = 0, \tag{4.1}$$

and generalize the conditions (1.4)–(1.6) of Theorem 1.1 for arbitrary coprime integers k, m, $k > m$. Moreover, we give a new insight into a geometric structure of these conditions.

Theorem 4.1. *Let $B \in \mathbb{R}^{d\times d}$, and let $k, m \in \mathbb{Z}^+$, $k > m$, be coprime. Then the following statements are equivalent.*

(i) *The system (4.1) has a nontrivial periodic solution.*

(ii) *There exists an eigenvalue β of B lying on the epitrochoid (3.5), where $R = m/k$, $r = (k-m)/k$, $\delta = 1$, $\omega = (2\pi k/m)_{2\pi}$, and β corresponds to $t = 2\pi(k-m)(jm-q)/(qm)$ for some $q \in \mathbb{Z}^+$ and some $j = \lfloor -q/2 \rfloor + 1, \lfloor -q/2 \rfloor + 2, \ldots, \lfloor q/2 \rfloor$.*

(iii) *B has a zero eigenvalue or has an eigenvalue $\beta = b\exp(\mathrm{i}\phi)$ such that, for some $\xi \in \mathbb{Z}_0^+, \eta \in \mathbb{Z}^+$, $\xi \le \eta$, we have*

$$|\phi| = \frac{\pi\xi}{2\eta} \qquad \text{and} \qquad b = 2(-1)^{\ell} \sin\left(\frac{\pi(\eta-\xi)m}{2\eta(2k-m)} + \frac{\pi\ell m}{2k-m}\right),$$

where ℓ is any integer satisfying

$$-k+\frac{m}{2}-\frac{1}{2}\left(1-\frac{\xi}{\eta}\right)\le \ell \le k-\frac{m}{2}-\frac{1}{2}\left(1-\frac{\xi}{\eta}\right),$$
$$\ell \neq \left(\frac{2k}{m}-1\right)s-\frac{1}{2}\left(1-\frac{\xi}{\eta}\right) \qquad \text{for all integers } s \text{ such that } \quad -\left\lfloor\frac{m}{2}\right\rfloor \le s \le \left\lfloor\frac{m}{2}\right\rfloor. \tag{4.2}$$

Proof. If we put $A=-I$, then all the eigenvalues α_i of A are equal to -1 (i.e., $|\alpha_i|=1$, $\mathrm{Arg}(\alpha_i)=\pi$), and the equivalence between (i) and (ii) follows immediately from Theorem 3.1, the branches (i) and (iib). We show the equivalence between (i) and (iii).

If $\beta=0$ is an eigenvalue of B, then the corresponding trinomial (1.8) reduces to $Q(\lambda)=\lambda^k-\lambda^{k-m}$. Such a trinomial has a root $\lambda=1$ which is a q-th root of unity (for any $q\in\mathbb{Z}^+$), and the existence of a nontrivial periodic (constant) solution is straightforward.

Now, let $\beta=b\exp(\mathrm{i}\phi)$, $b\neq 0$, $|\phi|\le\pi/2$, be an eigenvalue of B. The existence of a periodic solution is guaranteed by Theorem 3.1 (branches (i) and (iib) – its alternative supplement). Hence, let us find all the possible values of b and ϕ such that the conditions (2.7) are satisfied for some $q\in\mathbb{Z}^+$ and some $j\in\mathbb{Z}$ such that $\lfloor -q/2\rfloor+1\le j\le\lfloor q/2\rfloor$. Since $\alpha_i=-1$, then, taking into account the identity $2\cos^2(t)=1+\cos(2t)$, (2.7) simplifies to

$$\begin{aligned} |\beta|=|b|&=2\left|\cos\left(\frac{\pi}{2}-\frac{\pi jm}{q}\right)\right|,\\ \mathrm{Arg}(\beta)&=\left(\kappa\arccos\left(-\frac{|b|}{2}\right)+\frac{2\pi jk}{q}\right)_{2\pi}. \end{aligned} \tag{4.3}$$

If j is such that $\cos(\pi/2-\pi jm/q)>0$, then we can write $(4.3)_1$ as

$$\frac{|b|}{2}=\cos\left(\frac{\pi}{2}-\frac{\pi jm}{q}\right) \tag{4.4}$$

and $(4.3)_2$, with help of the identity $\arccos(-t)=\pi-\arccos(t)$, becomes

$$\mathrm{Arg}(\beta)=-\pi+\arccos\left(\frac{|b|}{2}\right)+\frac{2\pi jk}{q}+2\pi p_j=-\frac{\pi}{2}+(2k-m)\frac{\pi j}{q}+2\pi p_j \tag{4.5}$$

for a suitable $p_j\in\mathbb{Z}$. On the other hand, if j is such that $\cos(\pi/2-\pi jm/q)<0$, then

$$-\frac{|b|}{2}=\cos\left(\frac{\pi}{2}-\frac{\pi jm}{q}\right) \tag{4.6}$$

and $(4.3)_2$ becomes

$$\mathrm{Arg}(\beta)=\frac{\pi}{2}+(2k-m)\frac{\pi j}{q}+2\pi p_j \tag{4.7}$$

for a suitable $p_j\in\mathbb{Z}$. Clearly, in both the cases, $\mathrm{Arg}(\beta)$ has to be a rational multiple of π, therefore, let us write $|\phi|=\frac{\pi\xi}{2\eta}$ where ξ, η are integers such that $\eta>0$ and $0\le\xi\le\eta$. We distinguish four cases according to the sign of b and ϕ.

Let $b>0$, $\phi>0$ and $\cos(\pi/2-\pi jm/q)>0$. Then $\mathrm{Arg}(\beta)=\phi=\frac{\pi\xi}{2\eta}$ and (4.5), (4.4) yield

$$\frac{j}{q}=\frac{\xi+\eta-4\eta p_j}{2\eta(2k-m)}, \tag{4.8}$$

$$b=2\cos\left(\frac{\pi}{2}-\frac{\pi jm}{q}\right)=-2\sin\left(-\frac{\pi jm}{q}\right). \tag{4.9}$$

Substituting (4.8) into (4.9), we have

$$b = 2(-1)^{\ell_j} \sin\left(\frac{\pi(\eta-\xi)m}{2\eta(2k-m)} + \frac{\pi\ell_j m}{2k-m}\right), \tag{4.10}$$

where $\ell_j = 2p_j - 1$ is an odd integer.

Similarly, if $\cos(\pi/2 - \pi jm/q) < 0$, with help of (4.7) and (4.6) we get (4.10), where $\ell_j = 2p_j$ is now an even integer.

A discussion of the remaining cases ($b > 0$ and $\phi \le 0$, $b < 0$ and $\phi > 0$, $b < 0$ and $\phi \le 0$) is quite analogous, leading to the identical description (4.10) of the values b independently of the $\cos(\pi/2 - \pi jm/q)$ sign (both odd and even integers ℓ_j are always involved).

It remains to determine the range of the integers ℓ_j, which follows easily from the fact that $-\lfloor q/2\rfloor < j \le \lfloor q/2\rfloor$. Since q can be chosen as $q = 2\eta(2k-m)$, see (4.8), we actually have $\lfloor q/2\rfloor = q/2$. Thus,

$$\left|\frac{\pi jm}{q}\right| \le \frac{\pi m}{2},$$

which implies

$$-k + \frac{m}{2} - \frac{1}{2}\left(1 - \frac{\xi}{\eta}\right) \le \ell_j \le k - \frac{m}{2} - \frac{1}{2}\left(1 - \frac{\xi}{\eta}\right).$$

Finally, the condition (4.2) excludes those integers ℓ for which the argument of sine function in (4.10) is an integer multiple of π. Therefore, the case of $b = 0$ does not occur. □

Now, we put $m = 1$ and formulate a consequence of Theorem 4.1 for the case studied in [10].

Corollary 4.2. *Let $B \in \mathbb{R}^{d\times d}$, and let $k \in \mathbb{Z}^+$. Then the following statements are equivalent.*

(i) *The system (4.1) with $m = 1$ has a nontrivial periodic solution.*

(ii) *There exists an eigenvalue β of B lying on the epitrochoid (3.5), where $R = 1/k$, $r = (k-1)/k$, $\delta = 1$, $\omega = 0$, and $t = 2\pi(k-1)(j-q)/q$ for some $q \in \mathbb{Z}^+$ and some $j = \lfloor -q/2\rfloor + 1, \lfloor -q/2\rfloor + 2, \dots, \lfloor q/2\rfloor$.*

(iii) *B has a zero eigenvalue or has an eigenvalue $\beta = b\exp(\mathrm{i}\phi)$ such that, for some $\xi \in \mathbb{Z}_0^+, \eta \in \mathbb{Z}^+$, $\xi \le \eta$, and $\ell \in \mathbb{Z}_0^+$, we have*

$$|\phi| = \frac{\pi\xi}{2\eta}, \quad b = 2(-1)^{\ell} \sin\left(\frac{\pi(\eta-\xi)}{2\eta(2k-1)} + \frac{\pi\ell}{2k-1}\right), \quad -\frac{1}{2}\left(1 - \frac{\xi}{\eta}\right) < \ell \le 2k-2. \tag{4.11}$$

Proof. The stated equivalencies follow directly from Theorem 4.1 considering $m = 1$. Indeed, while the first two statements are straightforward, the conditions (iii) of Theorem 4.1 simplify to

$$|\phi| = \frac{\pi\xi}{2\eta} \quad \text{and} \quad b = 2(-1)^{\ell} \sin\left(\frac{\pi(\eta-\xi)}{2\eta(2k-1)} + \frac{\pi\ell}{2k-1}\right),$$

where ℓ is an integer such that

$$-k + \frac{\xi}{2\eta} \le \ell < -\frac{1}{2}\left(1 - \frac{\xi}{\eta}\right) \quad \text{or} \quad -\frac{1}{2}\left(1 - \frac{\xi}{\eta}\right) < \ell \le k - 1 + \frac{\xi}{2\eta}. \tag{4.12}$$

Now, to adjust the bounds from $(4.12)_1$, we can write

$$b = 2(-1)^{\ell}\sin\left(\frac{\pi(\eta-\xi)}{2\eta(2k-1)}+\frac{\pi\ell}{2k-1}\right) = 2(-1)^{\ell+1}\sin\left(\pi+\frac{\pi(\eta-\xi)}{2\eta(2k-1)}+\frac{\pi\ell}{2k-1}\right)$$
$$= 2(-1)^{\ell'}\sin\left(\frac{\pi(\eta-\xi)}{2\eta(2k-1)}+\frac{\pi\ell'}{2k-1}\right), \quad \text{where} \quad \ell' = \ell+2k-1.$$

Thus,

$$-k+\frac{\xi}{2\eta} \le \ell < -\frac{1}{2}\left(1-\frac{\xi}{\eta}\right) \quad \text{if and only if} \quad k-1+\frac{\xi}{2\eta} \le \ell' < 2k-\frac{1}{2}\left(3-\frac{\xi}{\eta}\right).$$

Since $2 \le 3-\frac{\xi}{\eta} \le 3$, the last inequality can be written as $\ell' \le 2k-2$. □

Remark 4.3. To compare the conclusions of Corollary 4.2 and Theorem 1.1 (Theorem 4.1 of [10]), one can observe that the equivalency between (i) and (iii) of Corollary 4.2 actually agrees with the statement of Theorem 1.1. More precisely, when $\xi = 0$, we obtain $|\phi| = 0$ (i.e., $\beta = b$ is a real eigenvalue) and (4.11) reduces to

$$b = 2(-1)^{\ell}\sin\left(\frac{\pi(2\ell+1)}{2(2k-1)}\right), \qquad \ell = 0,1,\dots,2k-2.$$

It is not difficult to check that the values of b corresponding to $\ell = k, k+1, \dots, 2k-2$ are already contained in the set of all b corresponding to $\ell = 0,1,\dots,k-1$, hence we get (1.4). Further, if $\xi = \eta$, then the conditions (4.11) directly imply (1.5), and if $0 < \xi < \eta$, then the conditions (4.11) agree with (1.6).

In addition to the assertion of Theorem 1.1, the part (ii) of Corollary 4.2 reveals a geometric nature of the condition (iii).

As the second illustration of Theorem 3.1, we consider a specific control problem for the linear autonomous difference system

$$x(n) + Ax(n-1) = 0. \tag{4.13}$$

We again restrict to the planar case and assume that A has the Jordan form

$$A = \begin{pmatrix} a_1 & a_2 \\ -a_2 & a_1 \end{pmatrix}, \qquad a_1, a_2 \in \mathbb{R} \tag{4.14}$$

with the spectral norm $\|A\| = \sqrt{a_1^2+a_2^2} \ne 1$. Thus, the trivial equilibrium of this system is a focus (attractive if $\|A\| < 1$ and repelling if $\|A\| > 1$). Obviously, such a system does not admit any (nontrivial) periodic solution.

Now we extend this system by a control term $u(n) = Bx(n)$, acting with an integer delay k, to obtain a delay feedback controlled system

$$x(n) + Ax(n-1) + Bx(n-k) = 0.$$

We put $B = \rho\Phi$ with a real scalar $\rho > 0$ and a rotation matrix

$$\Phi = \begin{pmatrix} \cos\vartheta & \sin\vartheta \\ -\sin\vartheta & \cos\vartheta \end{pmatrix}, \qquad -\pi < \vartheta \le \pi.$$

Our task is to describe the set of all control parameters ρ, ϑ and k such that the controlled system

$$x(n) + \begin{pmatrix} a_1 & a_2 \\ -a_2 & a_1 \end{pmatrix} x(n-1) + \rho \begin{pmatrix} \cos\vartheta & \sin\vartheta \\ -\sin\vartheta & \cos\vartheta \end{pmatrix} x(n-k) = 0 \tag{4.15}$$

admits a (nontrivial) q-periodic solution, a positive integer q being prescribed.

From the mathematical side, we analyze the existence of a q-periodic solution of (1.3) with the above specified A, B and $m = 1$. Obviously, the matrices A, B are commuting, and the simultaneous ordering of their eigenvalues is $(a_1 + \mathrm{i}a_2, \rho\exp(\mathrm{i}\vartheta)), (a_1 - \mathrm{i}a_2, \rho\exp(-\mathrm{i}\vartheta))$. Thus, if (ρ, ϑ) is a control couple, then $(\rho, -\vartheta)$ is also a control couple, and we can restrict to one sign variant only, say $(a_1 + \mathrm{i}a_2, \rho\exp(\mathrm{i}\vartheta))$.

Now, Theorem 3.1 (see also Remark 2.2) yields that the controlled system (4.15) has a q-periodic solution if and only if the control parameters ρ, ϑ, k meet, for an integer j such that $\lfloor -q/2 \rfloor + 1 \le j \le \lfloor q/2 \rfloor$, the conditions

$$\begin{aligned} \rho^2 &= 1 + \|A\|^2 + 2\|A\| \cos\left(\mathrm{Arg}(a_1 + \mathrm{i}a_2) - \frac{2\pi j}{q} \right), \\ \vartheta &= \left(\kappa \arccos\left(\frac{\|A\|^2 - \rho^2 - 1}{2\rho} \right) + \frac{2\pi jk}{q} \right)_{2\pi} \end{aligned} \tag{4.16}$$

where

$$\kappa = -1 \quad \text{if} \quad 0 < \left(\mathrm{Arg}(a_1 + \mathrm{i}a_2) - \frac{2\pi j}{q} \right)_{2\pi} \le \pi$$

and

$$\kappa = 1 \quad \text{if} \quad -\pi < \left(\mathrm{Arg}(a_1 + \mathrm{i}a_2) - \frac{2\pi j}{q} \right)_{2\pi} \le 0.$$

In particular, if $k = q$, then we directly have

$$\vartheta = \kappa \arccos\left(\frac{\|A\|^2 - \rho^2 - 1}{2\rho} \right).$$

Alternatively, Theorem 3.1 implies that such a control couple is lying on the epitrochoid (3.5) with $R = \|A\|/k$, $r = \|A\|(k-1)/k$, $\delta = 1$, $\omega = \left(k\pi + k\,\mathrm{Arg}(a_1 + \mathrm{i}a_2)\right)_{2\pi}$ and $t = (k-1)(2\pi j/q - \pi - \mathrm{Arg}(a_1 + \mathrm{i}a_2))$ for some $j = \lfloor -q/2 \rfloor + 1, \lfloor -q/2 \rfloor + 2, \ldots, \lfloor q/2 \rfloor$.

Example 4.4. Consider the system (4.13) with A given by (4.14) and put $a_1 = -0.4$, $a_2 = -1$. The zero equilibrium of such a system is an unstable focus, therefore $\limsup_{n\to\infty} \|x(n)\| = \infty$ for any nontrivial solution x of (4.13), see Figure 4.1 (left). We wish to find control parameters ρ, ϑ, k generating a solution x of (4.15) with the period $q = 22$.

If we put $k = q = 22$ and $j = 3$, then (4.16) yields the control parameters $\rho \approx 0.353005$ and $\vartheta \approx 1.520652$. Under this choice of ρ, ϑ, k and j, the 22-nd root of unity $\lambda_{3,22} = \exp(\mathrm{i}6\pi/22)$ is also a root of the characteristic polynomial associated with the controlled system (4.15), hence, this system admits a 22-periodic solution ($q = 22$ is even a prime period since $\gcd(3, 22) = 1$). In view of the notes at the end of Section 2, any such periodic solution is a linear combination

$$x(n) = C_1 x_1(n) + C_2 x_2(n), \qquad C_1, C_2 \in \mathbb{R},$$

where x_1, x_2 are given by (2.9) with $q = 22$, $j = 3$, $v_1 = (1, 0)^T$, $v_2 = (0, 1)^T$, and the initial vectors are prescribed according to (2.10). Figure 4.1 (right) depicts a particular trajectory for $C_1 = -1$, $C_2 = 1$ (such a choice of C_1, C_2 implies $x_1(0) = -1$, $x_2(0) = 1$).

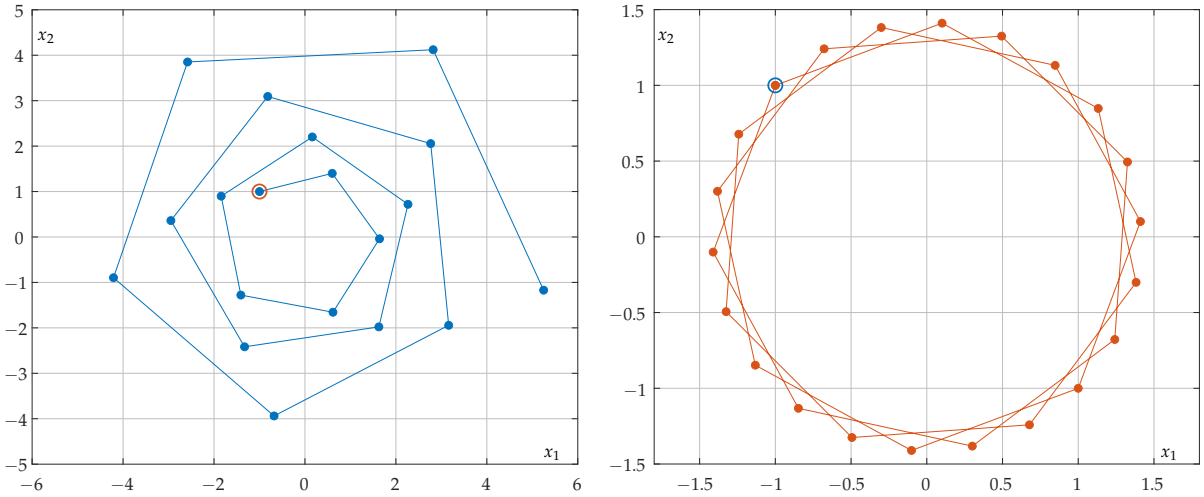

Figure 4.1: The left figure depicts a trajectory of the (uncontrolled) system (4.13) in the (x_1, x_2)-plane for the data of Example 4.4 and the initial vector $(-1, 1)^T$. The right figure then depicts a periodic trajectory (oriented clockwise) of the controlled system (4.15) (note that the prime period is $22/\gcd(3, 22) = 22$).

5 Final remarks

In this paper, we focused on detecting a periodic behavior in the linear difference system (1.3) with simultaneously triangularizable matrices A, B. Based on the analysis of the characteristic polynomial, we formulated efficient conditions for the existence of a periodic solution of (1.3). These conditions are given in terms of eigenvalues of A, B, and supported by its geometric characterization, calculating the revealed periodic solutions and their prime period.

Extending the periodicity problem from this paper to the general case of (1.3) (i.e., without the assumption on simultaneous triangularizability of A, B), or even to the system (1.1), is probably very complicated. Nice periodicity results were obtained for a scalar version of (1.3) in [11]. Similarly as in [10], the authors utilized the theory of circulant matrices in their investigations (note that those results seem to be achievable also by the D-partition technique applied in this paper). However, in a vector case, the formulation of such periodicity results in terms of eigenvalues of the system matrices is a considerably more challenging task.

The difficulty of the problem is underlined by the fact that similar problems for (1.3) and (1.1) remain open also in the related stability area. In this connection, we refer to the interesting paper [13] suggesting a method for detecting periodic solutions in some linear difference equations without knowledge of their characteristic roots. Of course, efficiency of the method for more general cases is questionable.

Taking into account recent developments on locating the trinomial roots (see, e.g., [1, 4, 5, 20]), we believe that the approach based on a suitable decomposition of the characteristic polynomial and the following analysis of the corresponding sparse polynomials has a promising potential in periodicity (as well as stability) theory of autonomous difference equations.

On the surjectivity conditions of a linear functional differential operator of the second order

Eugene Bravyi ✉

Perm National Research Polytechnic University, Perm, Russia

Received 12 December 2024, appeared 8 April 2025
Communicated by Josef Diblík

Abstract. Linear second-order functional differential equations without the Volterra condition are studied. Sufficient conditions for the everywhere solvability of the equation (surjectivity of the corresponding functional differential operator) are obtained in terms of norms of the positive and negative parts of the functional operators. These conditions are shown to be sharp in the sense that if they are not satisfied, then there exists an equation with no solution. The obtained solvability conditions are formulated directly for the equation itself, without considering specific boundary value problems.

Keywords: functional differential equations, solvability, boundary value problems, surjectivity.

2020 Mathematics Subject Classification: 34K05, 34K06, 34K10.

1 Introduction.

Functional differential equations are very important because they successfully model many phenomena in physics, engineering, biology, and economics [3, 7, 13, 20] (of course, they are also important as an independent mathematical object [3, 4, 6, 32]). Often, the most important aspect of the study is the study of solutions of boundary value problems for functional differential equations. Many works are devoted to the theory of boundary value problems for such equations [6, 16, 31]. However, given the widespread use of modeling in all fields of knowledge, a functional differential equation can be interesting even without being tied to a specific boundary value problem. In this case, first of all, the question of the existence of a solution to the equation for any right-hand side (the surjectivity of the operator) is of interest; only then can the equation be used for appropriate modeling.

So, we consider linear functional differential equations

$$(\mathcal{L}x)(t) = f(t), \quad t \in [0,1], \tag{1.1}$$

where the operator $\mathcal{L}$ acts from the space $\mathbf{AC}^1$ (real functions that are absolutely continuous together with their first derivative on the interval $[0,1]$) to the space $\mathbf{L}$ of integrable real functions and is defined by the equality

$$(\mathcal{L}x)(t) \equiv \ddot{x}(t) - (T^+x)(t) + (T^-x)(t), \quad t \in [0,1],$$

✉ Email: bravyi@perm.ru

where T^+, T^- are linear bounded positive operators acting from the space of continuous real functions $\mathbf{C}$ into the space $\mathbf{L}$. A linear operator $T : \mathbf{C} \to \mathbf{L}$ is called positive if it maps non-negative functions into almost everywhere non-negative ones. The norm of such a positive operator is defined by the equality

$$\| T\|_{\mathbf{C}\to\mathbf{L}} = \int_0^1 (T\mathbf{1})(s)\, ds,$$

where $\mathbf{1} : \mathbb{R} \to \mathbb{R}$ is the unit function. Here in the spaces $\mathbf{AC}^1$, $\mathbf{C}$, $\mathbf{L}$ the standard norms are used:

$$\| x\|_{\mathbf{AC}^1} = |x(0)| + |\dot{x}(0)| + \int_0^1 |\ddot{x}(t)|\, dt,\ \| x\|_{\mathbf{C}} = \max_{t\in[0,1]} |x(t)|,\ \| z\|_{\mathbf{L}} = \int_0^1 |z(t)|\, dt.$$

Next, we will also need the space $\mathbf{L}_\infty[0,1]$ of real functions essentially bounded on $[0,1]$ and the space $\mathbf{AC}_\infty$ of absolutely continuous real functions on $[0,1]$ with derivative $\dot{x} \in \mathbf{L}_\infty[0,1]$,

$$\| z\|_{\mathbf{L}_\infty} = \operatorname*{ess\,sup}_{s\in[0,1]} |z(t)|, \quad \| x\|_{\mathbf{AC}_\infty} = |x(0)| + \| \dot{x}\|_{\mathbf{L}_\infty}.$$

Definition 1.1. A solution of equation (1.1) is any function $x \in \mathbf{AC}^1$ that satisfies equation (1.1) for almost all $t \in [0,1]$.

Definition 1.2. We call equation (1.1) everywhere solvable if it has a solution for all $f \in \mathbf{L}$. In this case, the operator $\mathcal{L} : \mathbf{AC}^1 \to \mathbf{L}$ is surjective.

Definition 1.3. A linear boundary value problem for equation (1.1) is a system of equations consisting of equation (1.1) and two equations of the form

$$\ell_1 x = \alpha_1, \quad \ell_2 x = \alpha_2, \tag{1.2}$$

where $\ell_1, \ell_2 : \mathbf{AC}^1 \to \mathbb{R}$ are linearly independent linear bounded functionals, α_1, $\alpha_2 \in \mathbb{R}$ are given numbers.

Definition 1.4. Boundary value problem (1.1)–(1.2) is called Fredholm if the operator of this problem $[\mathcal{L}, \ell_1, \ell_2] : \mathbf{AC}^1 \to \mathbf{L} \times \mathbb{R}^2$ is a Noetherian operator of zero index [5,21].

The space $\mathbf{AC}^1$ is compactly embedded in the space $\mathbf{C}$ (see, for example, [25]). Hence, any boundary value problem (1.1)–(1.2) is Fredholm. So, a necessary and sufficient condition for the unique solvability of this problem is that the corresponding homogeneous boundary value problem

$$\mathcal{L}x = 0, \quad \ell_1 x = 0, \quad \ell_2 = 0,$$

has only the trivial solution. in the space $\mathbf{AC}^1$. Note that in [5] it was shown that even under weaker natural assumptions on the operator $\mathcal{L}$ boundary value problem (1.1)–(1.2) is Fredholm.

We are interested not in the solvability condition of boundary value problems for equation (1.1), but rather in the solvability conditions of equation (1.1) itself. Since we do not require the Volterra property [5, p. 200] of the operators T^+, T^-, the properties of our equation may not directly correspond to those of linear ordinary differential equations [5, p. 100], for which the unique solvability of the Cauchy problem guarantees solvability everywhere. It is easy to give an example of an unsolvable equation (1.1). Consider the equation

$$\ddot{x}(t) - 4\,x(0) + 8\,x(1/2) - 4\,x(1) = 1, \quad t \in [0,1]. \tag{1.3}$$

This equation has form (1.1) for

$$(T^+x)(t) = 4\,x(0) + 4\,x(1), \quad (T^-x)(t) = 8x(1/2), \quad t \in [0,1],$$

thus, $\|\,T^+\|_{\mathbf{C}\to\mathbf{L}} = 8$, $\|\,T^-\|_{\mathbf{C}\to\mathbf{L}} = 8$. Since for the solution x of equation (1.3) the function $\ddot{x}$ must be constant, then $x(t) = a_0 + a_1\,t + a_2\,t^2$, $t \in [0,1]$, for some constants a_i. It is easy to check that $\mathcal{L}x = 0$ for this x. Then $\mathcal{L}x(t) \equiv 0 \neq 1$. The contradiction shows that equation (1.3) has no solution.

Definition 1.5. Let $\mathcal{P} \geqslant 0$, $\mathcal{Q} \geqslant 0$. Denote by $\mathcal{M}_{\mathcal{P},\mathcal{Q}}$ the set of operators $\mathcal{L} : \mathbf{AC}^1 \to \mathbf{L}$ defined by the equality

$$(\mathcal{L}x)(t) \equiv \ddot{x}(t) - (T^+x)(t) + (T^-x)(t), \quad t \in [0,1], \tag{1.4}$$

such that

$$\|\,T^+\|_{\mathbf{C}\to\mathbf{L}} = \mathcal{P}, \quad \|\,T^-\|_{\mathbf{C}\to\mathbf{L}} = \mathcal{Q}. \tag{1.5}$$

Denote by $\mathcal{S}$ the set of surjective operators (1.4).

Definition 1.6. The set $\Omega \equiv \{(\mathcal{P},\mathcal{Q}) \in [0,\infty)^2 \mid \mathcal{M}_{\mathcal{P},\mathcal{Q}} \subset \mathcal{S}\}$ is called the set of everywhere solvability (or the set of surjectivity).

Remark 1.7. From the proof of Lemmas 2.3, 2.4, 2.5, and Theorem 3.1 it follows that if $(\mathcal{P},\mathcal{Q}) \in \Omega$, then $(\mathcal{P}_1,\mathcal{Q}_1) \in \Omega$ for all $\mathcal{P}_1 \in [0,\mathcal{P}]$, $\mathcal{Q}_1 \in [0,\mathcal{Q}]$.

Therefore, the equalities (1.5) in Definition 1.5 can be replaced by the inequalities

$$\|\,T^+\|_{\mathbf{C}\to\mathbf{L}} \leqslant \mathcal{P}, \quad \|\,T^-\|_{\mathbf{C}\to\mathbf{L}} \leqslant \mathcal{Q}.$$

Our goal is to find the set Ω. The following Theorem 3.1 gives a complete description of Ω.

The problem of constructing a set of everywhere solvability, apparently, has not attracted attention due to the fact that there is a simple necessary and sufficient condition for the operator $\mathcal{L}$ to be everywhere solvable.

Lemma 1.8 ([5])**.** *Equation* (1.1) *is everywhere solvable if and only if there exist linearly independent linear bounded functionals* $\ell_1, \ell_2 : \mathbf{AC}^1 \to \mathbb{R}$ *such that boundary value problem* (1.1)–(1.2) *is uniquely solvable.*

By choosing different functionals ℓ_1, ℓ_2 and finding solvability conditions for boundary value problem (1.1)–(1.2) in terms of the norms of the operators T^+ and T^-, using Lemma 1.8 we can construct only subsets of the set of everywhere solvability Ω. Finding the set of everywhere solvability is, apparently, a new problem that has not yet been solved in this formulation. Its solution can be useful in modeling various processes, including in economics, when it is required that a solution exists for each external influence from the space under consideration.

In the work [18], surjectivity was studied for a partial differential equation with constant and distributed delay. In [1], the surjectivity of functional differential operators was studied using the surjectivity module [28, p. 26] $q(\mathcal{L}) = \inf_{y\neq 0} \|\,\mathcal{L}^*y\|\,/\,\|\,y\|$, which is related to the minimal norm of the Green operator of boundary value problems for the equation $\mathcal{L}x = f$. Here it is possible to estimate the norm of the adjoint operator from below only in very special cases. For example, one effective condition for the surjectivity of a neutral functional differential operator was obtained in [2]. In the papers [29,30], conditions for surjectivity of operators in a Banach space are obtained, and the results are applied to boundary value problems. In

[14,15], perturbations of linear surjective operators are studied. Thus, surjectivity conditions for linear operators can also be useful in studying boundary value problems. Coefficient surjectivity criteria (including those for families of equations) without special requirements for functional operators have not been obtained, as far as the author knows.

A convenient criterion for surjectivity is formulated using the adjoint operator.

Lemma 1.9 ([5]). *The following statements are equivalent:*

1) *the operator $\mathcal{L}$ is surjective;*

2) $\dim\ker\mathcal{L}=2$;

3) $\ker\mathcal{L}^*=\{0\}$.

The construction of the solvability set Ω is apparently a rather difficult problem. To the author's knowledge, it has only been solved for the first-order equation [9]. The method used here is completely different from the method of [9]. It is based on the fact that if the family $\mathcal{M}_{\mathcal{P},\mathcal{Q}}$ contains a non-surjective operator, then this family contains finite-dimensional operators T^+ and T^- for which the adjoint boundary value problem has a non-trivial solution.

There are relatively many works on the conditions for the solvability of boundary value problems for functional differential equations (see, for example, [8,10–12,26,27]).

If in Lemma 1.8 we take the periodic boundary value problem $x(0)=x(1)$, $\dot{x}(0)=\dot{x}(1)$, then the solvability condition [22] of this problem gives the following conditions for the surjectivity of $\mathcal{L}$:

$$\frac{4\mathcal{P}}{4-\mathcal{P}}\leqslant\mathcal{Q}\leqslant 8+4\sqrt{4-\mathcal{P}},\ \mathcal{P}<4,\quad\text{or}\quad\frac{4\mathcal{Q}}{4-\mathcal{Q}}\leqslant\mathcal{P}\leqslant 8+4\sqrt{4-\mathcal{Q}},\ \mathcal{Q}<4. \tag{1.6}$$

Our main result, formulated in Theorem 3.1 (section 3), will significantly improve inequalities (1.6) (see Fig. 3.1, Corollaries (3.2), (3.3), (3.4)).

The general scheme of this work is as following. First we show that if $(\mathcal{P},\mathcal{Q})\notin\Omega$, there exists an operator $\mathcal{L}\in\mathcal{M}_{\mathcal{P},\mathcal{Q}}$ such that the equation $\mathcal{L}^*g=0$ has a non-trivial solution (Lemmas 2.1, 2.2). Then we prove that in this case for some $\mathcal{P}_1\leqslant\mathcal{P}$, $\mathcal{Q}_1\leqslant\mathcal{Q}$ there exists an operator $\mathcal{L}\in\mathcal{M}_{\mathcal{P}_1,\mathcal{Q}_1}$ such that the equation $\mathcal{L}^*g=0$ has a non-trivial piecewise linear solution (Lemma 2.3). In Lemmas 2.4, 2.5, is proved that it is sufficient to consider the case of a piecewise linear solution g whose graph consists of three line segments. This last case admits a simple explicit solution of the adjoint equation, which allows us to explicitly describe the set Ω (Theorem 3.1).

2 Auxiliary statements

If $\mathcal{L}\in\mathcal{M}_{\mathcal{P},\mathcal{Q}}$, then

$$\mathcal{L}x=\ddot{x}-Tx, \tag{2.1}$$

where the operator $T:T^+-T^-$ has the representation [19, p. 303–304] in the form of the Riemann–Stieltjes integral

$$(Tx)(t)=\int_0^1 x(s)\,d_sr(t,s),\quad t\in[0,1],$$

$$r(t,s)=p^+(t)k^+(t,s)-p^-(t)k^-(t,s),\quad t\in[0,1],$$

– the functions p^+, $p^- \in \mathbf{L}$ are nonnegative,

– $\| p^+ \|_{\mathbf{L}} = \mathcal{P}$, $\| p^- \|_{\mathbf{L}} = \mathcal{Q}$,

– the functions $k^+(t,\cdot)$, $k^-(t,\cdot)$ are nondecreasing for all $t \in [0,1]$,

– $k^+(t,0) = 0$, $k^-(t,0) = 0$, $k^+(t,1) = 1$, $k^-(t,1) = 1$.

The operators T^+, T^- have the representations

$$(T^{+/-}x)(t) = \int_0^1 x(s) d_s r^{+/-}(t,s), \quad t \in [0,1],$$

where $r^+(t,s) = p^+(t)k^+(t,s)$, $\quad r^-(t,s) = p^-(t)k^-(t,s)$, $\quad s,t \in [0,1]$, $\quad \int_0^1 r^+(t,1)\,dt = \mathcal{P}$, $\int_0^1 r^-(t,1)\,dt = \mathcal{Q}$.

2.1 Adjoint equation

Let $\mathcal{L}^* : (\mathbf{L})^* \to (\mathbf{AC}^1)^*$ be the adjoint operator. The $\mathbf{AC}^1$ is isomorphic to the space $\mathbf{L} \times \mathbb{R}^2$. Indeed, let $(\delta x)(t) = \ddot{x}(t)$, $t \in [0,1]$; $r_0 x = x(0)$, $r_1 x = \dot{x}(0)$. Then the operator $[\delta, r_0, r_1] : \mathbf{AC}^1 \to \mathbf{L}_1[0,1] \times \mathbb{R}^2$ defined by the equality

$$[\delta, r_0, r_1]x = \{\ddot{x}, x(0), \dot{x}(0)\},$$

is continuously invertible. Let $(\Lambda z)(t) = \int_0^t (t-s)z(s)\,ds$, $t \in [0,1]$, for every $z \in \mathbf{L}$. Then $\Lambda : \mathbf{L} \to \mathbf{AC}^1$ is a bounded operator and the Cauchy problem

$$\begin{cases} \delta x = z \\ r_0 x = c_0, \quad r_1 x = c_1, \end{cases}$$

has a unique solution

$$x(t) = c_0 + c_1 t + (\Lambda z)(t), \quad t \in [0,1]. \tag{2.2}$$

So, we have

$$\left([\delta, r_0, r_1]^{-1}\{z, c_0, c_1\}\right)(t) = c_0 + c_1\, t + (\Lambda z)(t), \quad t \in [0,1].$$

Thus, $(\mathbf{AC}^1)^* \simeq (\mathbf{L} \times \mathbb{R}^2)^* = (\mathbf{L})^* \times \mathbb{R}^2 = \mathbf{L}_\infty[0,1] \times \mathbb{R}^2$. Therefore, $\mathcal{L}^*$ acts from $(\mathbf{L})^* \simeq \mathbf{L}_\infty[0,1]$ into the space $\mathbf{L}_\infty[0,1] \times \mathbb{R}^2$.

Lemma 2.1. *Let an operator $\mathcal{L} : \mathbf{AC}^1 \to \mathbf{L}$ be defined by (2.1). Then $\mathcal{L}$ is not surjective if and only if there exists a non-trivial $g \in \mathbf{L}_\infty[0,1]$ satisfying the homogeneous adjoint equation $\mathcal{L}^* g = 0$:*

$$g(t) - \int_0^1 \left(\int_t^1 (\tau - t) d_\tau r(s,t) \right) g(s)\,ds = 0, \quad t \in [0,1], \tag{2.3}$$

$$\int_0^1 \int_0^1 d_s r(t,s) g(t)\,dt = \int_0^1 r(s,1) g(s)\,ds = 0, \tag{2.4}$$

$$\int_0^1 \int_0^1 s\, d_s r(t,s) g(t)\,dt = 0. \tag{2.5}$$

Proof. Let $\mathcal{L} \in \mathcal{M}_{\mathcal{P},\mathcal{Q}}$ from (2.1), $x \in \mathbf{AC}^1$, $g \in \mathbf{L}_\infty[0,1]$. Using the representation

$$x(t) = x(0) + t\dot{x}(0) + \int_0^1 (t-s)\ddot{x}(s)\,ds, \quad t \in [0,1],$$

we obtain

$$\begin{aligned}
&\int_0^1 g(t)(\mathcal{L}x)(t)\,dt \\
&= \int_0^1 g(t)\left[\ddot{x}(t) - \int_0^1 d_s r(t,s)\,x(0) - \int_0^1 s\,d_s r(t,s)\,\dot{x}(0) - \int_0^1 \left(\int_0^s (s-\tau)\ddot{x}(\tau)\,d\tau\right) d_s r(t,s)\right] dt \\
&= \int_0^1 \ddot{x}(t)\left[g(t) - \int_0^1 \left(\int_t^1 (s-t) d_s r(t,s)\right) g(\tau)\,d\tau\right] dt \\
&\quad - \int_0^1 \int_0^1 d_s r(t,s) g(t)\,dt\,x(0) - \int_0^1 \int_0^1 s\,d_s r(t,s) g(t)\,dt\,\dot{x}(0) = (\mathcal{L}^* g)(x), \qquad (2.6)
\end{aligned}$$

where $\mathcal{L}^* : \mathbf{L}_\infty[0,1] \to \mathbf{L}_\infty[0,1] \times \mathbb{R}^2$ is the adjoint operator of the operator $\mathcal{L}$.

If the operator $\mathcal{L}$ is not surjective, then there exists a non-trivial $g \in \mathbf{L}_\infty[0,1]$ such that $\int_0^1 g(t)(\mathcal{L}x)(t)\,dt = 0$ for all $x \in \mathbf{AC}^1$. From (2.6), it follows that $\int_0^1 g(t)(\mathcal{L}x)(t)\,dt = 0$ for all $\ddot{x} \in \mathbf{L}$, all $x(0) \in \mathbb{R}$, for all $\dot{x}(0) \in \mathbb{R}$. Therefore, in this case, there exists a non-zero solution $g \in \mathbf{L}_\infty[0,1]$ to the adjoint equation $\mathcal{L}^* g = 0$, that is g satisfies equalities (2.3), (2.4), (2.5).

If the system (2.3), (2.4), (2.5) has only the trivial solution, then there is no nontrivial g such that $\int_0^1 g(t)(\mathcal{L}x)(t)\,dt = 0$ for all $x \in \mathbf{AC}^1$. Therefore, the operator $\mathcal{L}$ is surjective. □

From equation (2.3) it follows that its solution g is differentiable and $\dot{g} \in \mathbf{L}_\infty$. Therefore, $g \in \mathbf{AC}_\infty$. Substituting $t = 1$ into equation (2.3), we obtain $g(1) = 0$. Substituting $t = 0$ into equation (2.3) and taking into account equality (2.5), we obtain $g(0) = 0$. Differentiating equality (2.3) and taking into account equality (2.4), we obtain

$$\dot{g}(t) = -\int_0^1 \left(\int_t^1 d_\tau r(s,t)\right) g(s)\,ds = -\int_0^1 (r(s,1) - r(s,t)) g(s)\,ds = \int_0^1 r(s,t) g(s)\,ds.$$

Therefore, system (2.3), (2.4), (2.5) is equivalent to the system

$$\dot{g}(t) = \int_0^1 r(s,t) g(s)\,ds, \quad t \in [0,1], \qquad (2.7)$$

$$g(0) = 0, \quad g(1) = 0 \qquad (2.8)$$

$$\int_0^1 r(s,1) g(s)\,ds = 0 \qquad (2.9)$$

where $g \in \mathbf{AC}_\infty$.

From here we obtain the following lemma.

Lemma 2.2. *Let an operator $\mathcal{L} : \mathbf{AC}^1 \to \mathbf{L}$ be defined by (2.1). Then $\mathcal{L}$ is not surjective if and only if there exists a non-trivial $g \in \mathbf{AC}_\infty$ satisfying to equalities (2.7), (2.8), (2.9) that is satisfying the homogeneous adjoint equation $\mathcal{L}^* g = 0$.*

In simplest case, when

$$(\mathcal{L}x)(t) = \ddot{x}(t) - \sum_{j=1}^n p_j(t) x(t_j), \quad t \in [0,1].$$

constructing the adjoint operator is not difficult. Let assume that $g \in (\mathbf{L})^* = \mathbf{L}_\infty[0,1]$. We use

the representation (2.2) for $x \in \mathbf{AC}^1$. We have

$$\begin{aligned} g(\mathcal{L}x) &= \int_0^1 \ddot{x}(t)g(t)\,dt - \sum_{j=1}^n p_j(t)\left(x(0) + t_j\dot{x}(0) + \int_0^{t_j}(t_j - s)\ddot{x}(s)\,ds\right) \\ &= \int_0^1 \ddot{x}(s)\left(g(s) - \sum_{j=1}^n (t_j - s)^+ \int_0^1 g(\tau)p_j(\tau)\,d\tau\right)ds \\ &\quad - x(0)\int_0^1 g(t)\sum_{j=1}^n p_j(t)\,dt - \dot{x}(0)\int_0^1 g(t)\sum_{j=1}^n t_j p_j(t)\,dt = (\mathcal{L}^*g)(x). \end{aligned}$$

Thus, $g \in \ker \mathcal{L}^*$ if and only if $g(\mathcal{L}x) = 0$ for all $x(0) \in \mathbb{R}$, all $\dot{x}(0) \in \mathbb{R}$, and for all $\ddot{x} \in \mathbf{L}$, that is

$$g(s) - \sum_{j=1}^n (t_j - s)^+ \int_0^1 g(\tau)p_j(\tau)\,d\tau = 0, \quad s \in [0,1], \tag{2.10}$$

$$\int_0^1 g(t)\sum_{j=1}^n p_j(t)\,dt = 0, \tag{2.11}$$

$$\int_0^1 g(t)\sum_{j=1}^n t_j p_j(t)\,dt = 0, \tag{2.12}$$

where

$$\alpha^+ = \begin{cases} \alpha & \text{if } \alpha > 0; \\ 0 & \text{if } \alpha \leqslant 0. \end{cases}$$

From (2.10), it follows that any solution to $\mathcal{L}^*g = 0$ is piecewise linear. Moreover, $g(1) = 0$ from (2.10) and $g(0) = 0$ from (2.10) and (2.12).

2.2 Lemmas on the existence of piecewise linear solutions of a homogeneous adjoint equation

Lemma 2.3. *Let $(\mathcal{P}, \mathcal{Q}) \notin \Omega$. Then there exists an operator $\mathcal{L} \in \mathcal{M}_{\mathcal{P},\mathcal{Q}}$ such that the equation $\mathcal{L}^*g = 0$ has a non-trivial solution g in the form*

$$g(t) = \sum_{j\in J} \varphi_j(t), \quad t \in [0,1], \tag{2.13}$$

where $J \subset \{1, 2, \ldots\}$,

$$\varphi_j(t) = \begin{cases} \frac{t-a_j}{c_j-a_j}F_j, & t \in (a_j, c_j), \\ \frac{b_j-t}{b_j-a_j}F_j, & t \in (c_j, b_j), \\ 0, & t \in [0,1]\setminus(a_j, b_j), \end{cases} \tag{2.14}$$

$c_j \in (a_j, b_j)$, $F_j \in \mathbb{R}$, $j \in J$, the intervals (a_j, b_j) are disjoint.

Proof. Since $(P, Q) \notin \Omega$, there exists an operator $\mathcal{L} \in \mathcal{M}_{\mathcal{P},\mathcal{Q}}$ such that the problem (2.7)–(2.9) has a nontrivial solution g. Denote by $\{e_j\}_{j\in J}$ the set of intervals within which g preserves its strict sign: $e_j = [a_j, b_j]$, $g(a_i) = g(b_j) = 0$, $g(t) \neq 0$ for $t \in (a_j, b_j)$, where a_j, b_j are pairs of adjacent zeros of g. There exist at most countably many such pairs. We will demonstrate how to modify the operator $\mathcal{L}$ such that the adjoint equation $\tilde{\mathcal{L}}^*\tilde{g} = 0$ of the modified operator $\tilde{\mathcal{L}}$

has a solution g satisfying the conditions of the lemma. It turns out that $|\tilde{g}(t)| \geqslant |g(t)|$ for each $t \in e_j$.

Let a, b be adjacent zeros of g, and $g(t) > 0$ for $t \in (a,b)$ (the case $g(t) < 0$, $t \in (a,b)$ is similar).

Denote $E^+ = \{\tau \in [0,1] : g(\tau) \geqslant 0\}$, $E^- = \{\tau \in [0,1] : g(\tau) < 0\}$.

We define a function $L : [a,b] \to \mathbb{R}$ by the following equalities: $L(a) = 0$; and for all $t \in (a,b]$

$$L(t) = \int_0^1 \max_{\substack{k^+(s,a) \leqslant \tilde{k}^+(s,t) \leqslant k^+(s,t) \\ k^-(s,a) \leqslant \tilde{k}^-(s,t) \leqslant k^-(s,t)}} (p^+(s)\tilde{k}^+(s,t) - p^-(s)\tilde{k}^-(s,t))g(s)\,ds$$
$$= \int_{E^+} (p^+(s)k^+(s,t) - p^-(s)k^-(s,a))g(s)ds + \int_{E^-} (p^+(s)k^+(s,a) - p^-(s)k^-(s,t))g(s)ds.$$

Since the functions $k^+(s,\cdot)$, $k^-(s,\cdot)$ are non-decreasing, the functions L and $\tilde{L}(t) \equiv \int_0^t L(s)\,ds$ are also non-decreasing, and the function $\tilde{L}$ is convex downwards. Therefore

$$\frac{\tilde{L}(c)(t-a)}{c-a} \leqslant \tilde{L}(t), \quad c \in (a,b], \quad t \in [a,c].$$

From the definition of the function L, it follows that

$$L(t) \geqslant \dot{g}(t), \quad \tilde{L}(t) \geqslant g(t), \quad t \in [a,b].$$

Similarly, we define the function R: $R(b) = 0$, when $t \in [a,b)$

$$R(t) = \int_0^1 \max_{\substack{k^+(s,t) \leqslant \tilde{k}^+(s,t) \leqslant k^+(s,b) \\ k^-(s,t) \leqslant \tilde{k}^-(s,t) \leqslant k^-(s,b)}} (p^+(s)\tilde{k}^+(s,t) - p^-(s)\tilde{k}^-(s,t))g(s)\,ds$$
$$= \int_{E^+} (p^+(s)k^+(s,t) - p^-(s)k^-(s,b))g(s)ds + \int_{E^-} (p^+(s)k^+(s,b) - p^-(s)k^-(s,t))g(s)ds.$$

It is obvious that $R(t) \leqslant \dot{g}(t)$, $t \in [a,b)$, R is non-decreasing, the function $\tilde{R}(t) \equiv -\int_t^b R(s)\,ds$ is non-increasing and convex downwards. Therefore

$$\frac{\tilde{R}(c)(b-t)}{b-c} \geqslant R(t) \geqslant g(t), \quad c \in [a,b), \quad t \in [c,b].$$

It follows from the definition of the function R that

$$R(t) \leqslant \dot{g}(t), \quad \tilde{R}(t) \geqslant g(t), \quad t \in [a,b].$$

Let $c \in (a,b)$ be a unique solution to the equation $\tilde{L}(c) = \tilde{R}(c)$.

Define a new function

$$\tilde{g}(t) \equiv \begin{cases} g(t), & t \in [0,1] \setminus [a,b], \\ \frac{\tilde{L}(c)(t-a)}{c-a}, & t \in [a,c], \\ \frac{\tilde{R}(c)(b-t)}{b-c}, & t \in [c,b]. \end{cases}$$

Define a new operator $\tilde{\mathcal{L}}$ by the equality $\tilde{\mathcal{L}}x \equiv \ddot{x} - \int_0^1 x(s)\,d_s\tilde{r}(\cdot,s)$, where

$$\tilde{r}(t,s) \equiv \tilde{p}^+(s)\tilde{k}^+(s,t) - \tilde{p}^-(s)\tilde{k}^-(s,t), \quad s,t \in [0,1],$$

and

$$\tilde p^+(t) \equiv \begin{cases} p^+(t), & t \in [0,1] \setminus (a,b), \\ \frac{p^+(t)g(t)}{\tilde g(t)}, & t \in (a,b), \end{cases} \qquad \tilde p^-(t) \equiv \begin{cases} p^-(t), & t \in [0,1] \setminus (a,b), \\ \frac{p^-(t)g(t)}{\tilde g(t)}, & t \in (a,b), \end{cases}$$

$$\tilde k^+(s,t) \equiv \begin{cases} k^+(s,a), \ s \in E^-, \ t \in [a,c], \\ k^+(s,b), \ s \in E^-, \ t \in [c,b], \\ k^+(s,t), \ \text{otherwise}, \end{cases} \qquad \tilde k^-(s,t) \equiv \begin{cases} k^-(s,a), \ s \in E^+, \ t \in [a,c], \\ k^-(s,b), \ s \in E^+, \ t \in [c,b], \\ k^-(s,t), \ \text{otherwise}. \end{cases}$$

Then $\tilde{\mathcal{L}} \in \mathcal{M}_{\mathcal{P},\mathcal{Q}}$, since $\tilde p^+(s) \leqslant p^+(s)$, $\tilde p^-(s) \leqslant p^-(s)$, $s \in [0,1]$. Moreover, the function $\tilde g$ is a solution to the equation $\tilde{\mathcal{L}}^* \tilde g = 0$.

The procedure described above can be applied to all adjacent zeros (of which there are at most countably many). After this, we obtain an operator, which we denote by $\mathcal{L} \in \mathcal{M}_{\mathcal{P},\mathcal{Q}}$, such that the equation $\mathcal{L}^* g = 0$ has a solution of the form (2.13), where ϕ_j are defined by (2.14). □

Lemma 2.4. *Let $(\mathcal{P},\mathcal{Q}) \notin \Omega$. Then there exist points $0 \leqslant a_1 < c_1 < b_1 \leqslant a_2 < c_2 < b_2 \leqslant 1$ and an operator $\mathcal{L} \in \mathcal{M}_{\mathcal{P},\mathcal{Q}}$ such that the adjoint equation $\mathcal{L}^* g = 0$ has a piecewise linear solution satisfying conditions $g(t) = 0$ for $t \in [0,1] \cup [b_1,a_2] \cup [b_2,1]$, $g(t) < 0$ for $t \in (a_1,b_1)$, $g(t) > 0$ for $t \in (a_2,b_2)$.*

Proof. By Lemma 2.3 there exists an operator $\mathcal{L} \in \mathcal{M}_{\mathcal{P},\mathcal{Q}}$ such that the adjoint equation $\mathcal{L}^* g = 0$ has a piecewise linear solution g of the form (2.13). Let $\{e_j = [a_j,b_j]\}_{j\in J}$ be the set of all intervals between adjacent zeros of the function g, $\{e_j\}_{j\in J^+}$ be the set of all intervals within which $g(t) > 0$, $J^- = J \setminus J^+$.

Assume that the solution g takes its minimum and maximum at the points $c_1 < c_2$ respectively:

$$g_{\min} \equiv \min_{t\in[0,1]} g(t) = g(c_1), \quad g_{\max} \equiv \max_{t\in[0,1]} g(t) = g(c_2).$$

Let

$$\widetilde e_1 = [a_1,c_1], \ \widetilde e_2 = [c_1,b_1], \ \widetilde e_3 = [a_2,c_2], \ \widetilde e_4 = [c_2,b_2].$$

For $t \in \widetilde e_i$, $i = 1,2,3,4$, we have

$$r(s,t) = p^+(s)k_i^+(s) - p^-(s)k_i^-(s), \quad s \in [0,1],$$

where $k_i^+(s) \leqslant k_{i+1}^+(s)$, $k_i^-(s) \leqslant k_{i+1}^-(s)$, $i = 1,2,3$.

We will write the equation for g at $t \in \widetilde e_i$:

$$\begin{aligned} \dot x(t) &= \int_0^1 r(s,t)g(s)\,ds = \int_0^1 (p^+(s)k_i^+(s) - p^-(s)k_i^-(s))\,ds \\ &= \sum_{j\in J^+} \int_{e_j} (p^+(s)k_i^+(s) - p^-(s)k_i^-(s))g(s)\,ds + \sum_{j\in J^-} \int_{e_j} (p^+(s)k_i^+(s) - p^-(s)k_i^-(s))g(s)\,ds. \end{aligned}$$

Let us stretch or compress (that is, make a suitable change of variable) all segments $[a_j,c_j]$, $[c_j,b_j]$ so that they coincide with the segments $[a_1,c_1]$, $[c_1,b_1]$, respectively, if $j \in J^-$, and coincide with the segments $[a_2,c_2]$, $[c_2,b_2]$ if $j \in J^+$. On each of these segments we multiply the functions p^+, p^- by the ratio of the corresponding segments so that the values

$$\int_{e_j} p^+(s)\,ds, \quad \int_{e_j} p^-(s)\,ds, \quad \int_{e_j} (p^+(s) - p^-(s))\,ds, \ \int_{e_j} (p^+(s)k_i^+(s) - p^-(s)k_i^-(s))\,ds,$$

do not change after the change of variable.

Therefore, for $t \in \widetilde{e}_i$ we have

$$\begin{aligned}
\dot{g}(t) = & \sum_{j\in J^-} \int\limits_{e_1} (p_j^+(s)k_{i,j}^+(s) - p_j^-(s)k_{i,j}^-(s))\, g(s) \frac{g_j}{g_{\min}} ds \\
& + \sum_{j\in J^+} \int\limits_{e_2} (p_j^+(s)k_{i,j}^+(s) - p_j^-(s)k_{i,j}^-(s))\, g(s) \frac{g_j}{g_{\max}} ds \\
= & \int_{e_1} \left(\sum_{j\in J^-} \frac{p_j^+(s)g_j}{g_{\min}} k_{i,j}^+(s) - \sum_{j\in J^-} \frac{p_j^-(s)g_j}{g_{\min}} k_{i,j}^-(s) \right) g(s) ds \\
& + \int_{e_2} \left(\sum_{j\in J^+} \frac{p_j^+(s)g_j}{g_{\max}} k_{i,j}^+(s) - \sum_{j\in J^+} \frac{p_j^-(s)g_j}{g_{\max}} k_{i,j}^-(s) \right) g(s) ds \\
= & \int_{e_1} \left(\left[\sum_{j\in J^-} \frac{p_j^+(s)g_j}{g_{\min}} \right] \widetilde{k}_i^+(s) - \left[\sum_{j\in J^-} \frac{p_j^-(s)g_j}{g_{\min}} \right] \widetilde{k}_i^-(s) \right) g(s) ds \\
& + \int_{e_2} \left(\left[\sum_{j\in J^+} \frac{p_j^+(s)g_j}{g_{\max}} \right] \widetilde{k}_i^+(s) - \left[\sum_{j\in J^+} \frac{p_j^-(s)g_j}{g_{\max}} \right] \widetilde{k}_i^-(s) \right) g(s) ds.
\end{aligned}$$

Here $p_j^{+/-}$, $k_{i,j}^{+/-}$ denote the functions $p^{+/-}$, $k_i^{+/-}$ restricted on the set e_j in the coordinates of one of the corresponding segments $\widetilde{e}_i$, $i = 1,2,3,4$; $g_j = g(c_j)$; the functions $\widetilde{k}_i^{+/-}$ are determined by the equalities

$$\sum_{j\in J^{+/-}} \frac{p_j^{+/-}(s)g_j}{g_{\max/\min}} k_{i,j}^{+/-}(s) = \left(\sum_{j\in J^{+/-}} \frac{p_j^{+/-}(s)g_j}{g_{\max/\min}} \right) \widetilde{k}_i^{+/-}(s).$$

Moreover,

$$\widetilde{k}_i^{+/-}(s) \leqslant \widetilde{k}_{i+1}^{+/-}(s), \quad s \in [0,1], \quad i = 1,2,3,$$

since

$$k_{i,j}^{+/-}(s) \leqslant k_{i+1,j}^{+/-}(s), \quad s \in [0,1], \quad i = 1,2,3, \quad j \in J.$$

We can now define

$$\widetilde{p}^+(s) \equiv \begin{cases} \sum\limits_{j\in J^-} \frac{p_j^+(s)g_j}{g_{\min}}, & s \in e_1, \\ \sum\limits_{j\in J^+} \frac{p_j^+(s)g_j}{g_{\max}}, & s \in e_2, \\ 0, & s \in [0,1] \setminus (e_1 \cup e_2), \end{cases} \qquad \widetilde{p}^-(s) \equiv \begin{cases} \sum\limits_{j\in J^-} \frac{p_j^-(s)g_j}{g_{\min}}, & s \in e_1, \\ \sum\limits_{j\in J^+} \frac{p_j^-(s)g_j}{g_{\max}}, & s \in e_2, \\ 0, & s \in [0,1] \setminus (e_1 \cup e_2). \end{cases}$$

Let $\widetilde{k}^{+/-}(s,t) = k_i(s)$ for $s \in [0,1]$, $t \in \widetilde{e}_j$. On the remaining part of the interval with respect to t, the function $\widetilde{k}^{+/-}(s,t)$ is extended in such a way that the functions $\widetilde{k}^{+/-}(s,\cdot)$ are non-decreasing for each $s \in [0,1]$.

In this case $\| \widetilde{p}^+ \|_{\mathbf{L}} \leqslant \| p^+ \|_{\mathbf{L}}$, $\| \widetilde{p}^- \|_{\mathbf{L}} \leqslant \| p^- \|_{\mathbf{L}}$, and

$$\widetilde{g}(t) = \begin{cases} g(t), & t \in e_1 \cup e_2, \\ 0, & t \in [0,1] \setminus (e_1 \cup e_2), \end{cases}$$

is a solution to the boundary value problem

$$\dot{\widetilde{g}}(t) = \int_0^1 \widetilde{r}(s,t)\widetilde{g}(s)\,ds, \quad t \in [0,1], \quad \widetilde{g}(0) = 0, \quad \widetilde{g}(1) = 0,$$
$$\int_0^1 (\widetilde{p}^+(s) - \widetilde{p}^-(s))g(s)\,ds = 0.$$

Thus, $(\mathcal{P},\mathcal{Q}) \notin \Omega$, and there exists an operator $\widetilde{\mathcal{L}} \in \mathcal{M}_{\mathcal{P},\mathcal{Q}}$ such that the equation $\widetilde{\mathcal{L}}^*\widetilde{g} = 0$ has a piecewise linear solution satisfying the conditions: $\widetilde{g}(t) = 0$ if $t \in [0,a_1] \cup [b_1,a_2] \cup [b_2,1]$, $\widetilde{g}(t) < 0$ if $t \in (a_1,b_1)$, $\widetilde{g}(t) > 0$ if $t \in (a_2,b_2)$, where $0 \leqslant a_1 < c_1 < b_1 \leqslant a_2 < c_2 < b_2 \leqslant 1$. □

Lemma 2.5. *Let $(\mathcal{P},\mathcal{Q}) \notin \Omega$. There exist points $0 = t_1 < t_2 < t_3 < t_4 = 1$, and functions $p_j \in \mathbf{L}$ such that the operator $\mathcal{L} : \mathbf{AC}^1 \to \mathbf{L}$ defined by the equality*

$$\mathcal{L}x \equiv \ddot{x}(t) - \sum_{j=1}^{4} p_j(t)x(t_j), \quad t \in [0,1],$$

belongs to the set $\mathcal{M}_{\mathcal{P},\mathcal{Q}}$ and is not surjective.

Proof. The operator $\mathcal{L}$, whose existence is asserted in the Lemma 2.4, has the form

$$(\mathcal{L}x)(t) = \ddot{x}(t) - \sum_{j\in J_1} p_j(t)x(t_j), \quad t \in [0,1],$$

where $p_j = p_j^+ - p_j^-$, p_j^+, $p_j^- \in \mathbf{L}$, $p_j^+(t) \geqslant 0$, $p_j^-(t) \geqslant 0$, $t \in [0,1]$, $\sum_{j\in J_1} \| p_j^+ \|_{\mathbf{L}} \leqslant \mathcal{P}$, $\sum_{j\in J_1} \| p_j^- \|_{\mathbf{L}} \leqslant \mathcal{Q}$. The set $\{t_j | j \in J_1\} = \{0, a_1, c_1, b_1, a_2, c_2, b_2, 1\}$ is finite.

The adjoint boundary value problem has the form (2.10), (2.11), (2.12).

By Lemma 2.4 the adjoint boundary value problem

$$g(s) - \sum_{j\in J_1} (t_j - s)^+ \int_0^1 g(\tau)p_j(\tau)\,d\tau = 0, \quad s \in [0,1], \tag{2.15}$$

$$\int_0^1 g(t) \sum_{j\in J_1} p_j(t)\,dt = 0, \tag{2.16}$$

$$\int_0^1 g(t) \sum_{j\in J_1} t_j p_j(t)\,dt = 0. \tag{2.17}$$

has a nontrivial piecewise linear solution g.

We see that problem (2.15)–(2.17) depends only on the values $A_j = \int_0^1 g(t)p_j(t)\,dt$. We know that $\min_{t\in[0,1]} g(t) = g(c_1)$, $\max_{t\in[0,1]} g(t) = g(c_2)$.

It is obvious that we can change the functions p_j so that the values A_j, $\| p_j^+ \|_L$, $\| p_j^- \|_L$ are preserved, and the support of each of the functions p_j is in any sufficiently small neighborhoods of four points, $t = 0$, $t = 1$, c_1, c_2. Let this condition be satisfied.

We will show that from the set $\{t_j | j \in J_1\}$ we can successively exclude the points a_1, b_1, a_2, b_2 by setting $p_j = 0$ for the corresponding j. Let $t_k \in (0,1)$ be one of such points, and let the supports of all functions p_k not intersect the interval (t_{k-1}, t_{k+1}). Then for some $\xi \in (0,1)$ the equality $t_k = \xi t_{k-1} + (1-\xi)t_{k+1}$ holds. Let $\widetilde{p}_k = 0$, $\widetilde{p}_{k-1} = p_{k-1} + \xi p_k$, $\widetilde{p}_{k+1} = p_{k+1} + (1-\xi)p_k$, $\widetilde{p}_i = p_i$ for $i \in J_1 \setminus \{t_{k-1}, t_k, t_{k+1}\}$. Let

$$\widetilde{g}(s) - \sum_{j\in J_1} (t_j - s)^+ \int_0^1 g(\tau)\widetilde{p}_j(\tau)\,d\tau = 0, \quad s \in [0,1].$$

It is easy to check that $\widetilde{g}$ satisfies the equation $\widetilde{\mathcal{L}}^*\widetilde{g} = 0$ for

$$(\widetilde{\mathcal{L}}x)(t) = \ddot{x}(t) - \sum_{j\in J_1} \widetilde{p}_j(t)x(t_j), \quad t \in [0,1].$$

Obviously, $\widetilde{g}$ satisfies the boundary conditions (2.16), (2.17). □

3 Main result

Let us formulate the main assertion.

Theorem 3.1. *Let non-negative $\mathcal{P}$ and $\mathcal{Q}$ be given. $(\mathcal{P},\mathcal{Q}) \in \Omega$ if and only if*

$$\mathcal{Q} \in [0,4], \quad \mathcal{P} \leqslant \min_{k\in(0,1]} \frac{(1+\sqrt{k}+\sqrt{k+1})^2(k+1) - \mathcal{Q}}{k},$$

or

$$\mathcal{Q} \in (4, 12+8\sqrt{2}], \quad \mathcal{P} \leqslant \min_{k\in[0,1]} \left((1+\sqrt{k}+\sqrt{k+1})^2(k+1) - \mathcal{Q}\,k\right).$$

Proof. By Lemma 2.5, if $(\mathcal{P},\mathcal{Q}) \notin \Omega$, then there exists a non-surjective operator $\mathcal{L} \in \mathcal{M}_{\mathcal{P},\mathcal{Q}}$ defined by

$$(\mathcal{L}x)(t) \equiv \ddot{x}(t) - \sum_{j=1}^{4} p_j(t)x(t_j), \quad t \in [0,1], \tag{3.1}$$

where $0 = t_1 < t_2 < t_3 < t_4 = 1$,

$$p_j = p_j^+ - p_j^-, \quad p_j^+, p_j^- \in \mathbf{L}, \quad p_j^+(t) \geqslant 0, \quad p_j^-(t) \geqslant 0, \quad t \in [0,1].$$

We will assume that

$$\int_0^1 p_j^+(s)\,ds = \mathcal{P}_j, \quad j = 1,\dots,4, \quad \sum_{j=1}^{4} \mathcal{P}_j = \mathcal{P},$$

$$\int_0^1 p_j^-(s)\,ds = \mathcal{Q}_j, \quad j = 1,\dots,4, \quad \sum_{j=1}^{4} \mathcal{Q}_j = \mathcal{Q}.$$

For the equation (3.1) the adjoint equation is constructed in part 2.1. Its solution satisfies the equalities (2.10), (2.11), (2.12). For convenience, we present here the adjoint boundary value problem

$$g(t) = \sum_{j=2,3,4} (t_j - t)^+ \int_0^1 g(s)p_j(s)\,ds, \quad t \in [0,1], \tag{3.2}$$

$$g(0) = 0, \quad g(1) = 0, \tag{3.3}$$

$$\sum_{j=1}^{4} \int_0^1 g(s)p_j(s)\,ds = 0, \tag{3.4}$$

$$\sum_{j=2}^{4} t_j \int_0^1 g(s)p_j(s)\,ds = 0, \tag{3.5}$$

which has a non-trivial solution g. Let us denote the maximum of this solution by $M \geqslant 0$ (taken at the point $t = t_3$) and the minimum by $-m \leqslant 0$ (taken at the point $t = t_2$). The

function g is linear on each of the intervals $[0, t_2]$, $[t_2, t_3]$, $[t_3, 1]$. At least one of the numbers M and m is positive. Let $m > 0$.

Let us find for what minimal $\mathcal{P}$, $\mathcal{Q}$ a non-zero solution to the problem (3.2)–(3.5) can exist.

Let $A_j = \int_0^1 g(s) p_j(s)\, ds$, $j = 1, 2, 3, 4$.

From (3.2) for $t \in [t_3, 1]$ it follows that

$$\dot{g}(t) = -A_4 = \frac{-M}{1 - t_3}, \tag{3.6}$$

$t \in (t_3, 1)$, therefore $A_4 \geqslant 0$.

From (3.2) for $t \in (t_2, t_3)$ it follows that $\dot{g}(t) = -A_4 - A_3 = \frac{M+m}{t_3 - t_2} > 0$. Since $A_4 \geqslant 0$, then $A_3 < 0$.

From (3.2) for $t \in (0, t_2)$ it follows that

$$\dot{g}(t) = -A_4 - A_3 - A_2 = \frac{-m}{t_2} < 0. \tag{3.7}$$

Therefore, from (3.4) it follows that $\dot{g}(t) = A_1 = \frac{-m}{t_2}$, therefore $A_1 < 0$. In addition, we have $A_3 + A_4 < 0$, $A_4 + A_3 + A_2 > 0$. Therefore, $A_2 > 0$.

So, $A_1 < 0$, $A_2 > 0$, $A_3 < 0$, $A_4 \geqslant 0$.

To satisfy these conditions with minimal $\mathcal{P}$ and $\mathcal{Q}$, the supports of the functions p_1^+, p_2^-, p_3^+, p_4^- should be concentrated in a sufficiently small neighborhood of the point $t = t_2$, which is the minimum point of the function g. Similarly, the supports of the functions p_1^-, p_2^+, p_3^-, p_4^+ should be concentrated in a sufficiently small neighborhood of the point $t = t_3$, which is the maximum point of the function g. We have

$$\inf_{\substack{\| p_i^+ \|_{\mathrm{L}} = P_i, \\ \| p_i^- \|_{\mathrm{L}} = Q_i}} A_i = -M Q_i - m P_i, \quad i = 1, 3; \qquad \sup_{\substack{\| p_i^+ \|_{\mathrm{L}} = P_i, \\ \| p_i^- \|_{\mathrm{L}} = Q_i}} A_i = M P_i + m Q_i, \quad i = 2, 4, \tag{3.8}$$

while inf and sup in (3.8) cannot be achieved for the integrable functions p_j.

Consider the limiting case

$$A_i = -M Q_i - m P_i, \quad i = 1, 3; \quad A_i = M P_i + m Q_i, \quad i = 2, 4. \tag{3.9}$$

From (3.4) and (3.9), it follows that

$$A_1 + A_2 + A_3 + A_4 = M (P_2 + P_4 - Q_1 - Q_3) - m (P_1 + P_3 - Q_2 - Q_4) = 0. \tag{3.10}$$

From (3.5) and (3.9), we obtain

$$t_2 (M P_2 + m Q_2) - t_3 (M Q_3 + m P_3) + M P_4 + m Q_4 = 0. \tag{3.11}$$

Now, for $k \equiv \frac{M}{-m} \geqslant 0$ from (3.6), (3.7), (3.10), and (3.11), it follows that

$$k = \frac{Q_4(1 - t_3)}{1 - P_4(1 - t_3)} = \frac{1 - P_1 t_2}{Q_1 t_2} = \frac{P_1 + P_3 - Q_2 - Q_4}{P_2 + P_4 - Q_1 - Q_3} = \frac{P_3 t_2 - Q_2 t_2 - Q_4}{P_2 t_2 + P_4 - Q_3 t_3}.$$

These inequalities are equivalent to the system

$$\begin{cases} P_1 + k Q_1 = \gamma_1, \\ k P_2 + Q_2 = \gamma_1 + (1 + k)\gamma_2, \\ P_3 + k Q_3 = k \gamma_3 + (1 + k)\gamma_2, \\ k P_4 + Q_4 = k \gamma_3, \end{cases} \tag{3.12}$$

where $\gamma_i \equiv \frac{1}{\Delta_i}$, $\Delta_i \equiv t_{i+1} - t_i$, $i = 1, 2, 3$.

From here and from the non-negativity of P_i, we obtain the conditions for Q_i:

$$\begin{cases} Q_1 \leqslant \frac{\gamma_1}{k}, \\ Q_2 \leqslant \gamma_1 + (1+k)\gamma_2, \\ Q_3 \leqslant \gamma_3 + \frac{(1+k)}{k}\gamma_2, \\ Q_4 \leqslant k\,\gamma_3. \end{cases} \tag{3.13}$$

From (3.12) we get

$$\mathcal{P} = \mathcal{P}_1 + \mathcal{P}_2 + \mathcal{P}_3 + \mathcal{P}_4 = \mathcal{R} - \frac{1}{k}(Q_2 + Q_4) - k(Q_1 + Q_3), \tag{3.14}$$

where

$$\mathcal{R} \equiv \gamma_1 \frac{1+k}{k} + \gamma_2 \frac{(1+k)^2}{k} + \gamma_3(1+k).$$

We need to find the minimum of $\mathcal{P}$ over $k \in (0, 1]$, over all γ_i, $i = 1, 2, 3$, $\frac{1}{\gamma_1} + \frac{1}{\gamma_2} + \frac{1}{\gamma_3} \leqslant 1$, and over all $Q_i \geqslant 0$ such that $Q_1 + Q_2 + Q_3 + Q_4 = \mathcal{Q}$ and conditions (3.13) are satisfied. Let us find the maximum value of Q for which conditions (3.13) are satisfied. We have

$$Q = Q_1 + Q_2 + Q_3 + Q_4 \leqslant \mathcal{R}.$$

Set $\Delta_2 = 1 - \Delta_1 - \Delta_3$ and find the minimum

$$\mathcal{R} = (1+k)\left(\frac{1}{\Delta_1 k} + \frac{1+k}{(1-\Delta_1-\Delta_3)k} + \frac{1}{\Delta_3}\right)$$

relative to the variables Δ_1, Δ_3, with the other arguments fixed. From the conditions $\frac{\partial \mathcal{P}}{\partial \Delta_1} = \frac{\partial \mathcal{P}}{\partial \Delta_3} = 0$, we have

$$\Delta_1 = \frac{1}{1 + \sqrt{k} + \sqrt{k+1}}, \quad \Delta_3 = \Delta_1\sqrt{k}, \quad \Delta_2 = \Delta_1\sqrt{k+1}.$$

Introduce the notations

$$G(k) \equiv (1 + \sqrt{k} + \sqrt{k+1})^2(k+1), \tag{3.15}$$

and for every Q

$$H_1(k) \equiv \frac{G(k) - Q}{k}, \tag{3.16}$$

$$H_2(k) \equiv G(k) - k\,Q. \tag{3.17}$$

Then

$$\mathcal{R} = (1+k)\frac{(1 + \sqrt{k} - \sqrt{k+1})^2}{(\sqrt{k+1} - \sqrt{k})^2(\sqrt{k+1} - 1)^2} = \frac{G(k)}{k}.$$

We can compute the derivative:

$$\frac{dR}{dk} = k^{-5/2}\frac{1 + \sqrt{k} + \sqrt{k+1}}{\sqrt{k+1}}(k^2(\sqrt{k} + \sqrt{k+1}) - \sqrt{k}(\sqrt{k+1} + 1) < 0.$$

It is easy to check that $\frac{dR}{dk} < 0$ for all $k \in (0, 1)$. Therefore, $\min_{k\in(0,1]} \mathcal{R}(k) = \mathcal{R}(1) = 2(2 + \sqrt{2})^2 = 12 + 8\sqrt{2} \equiv \mathcal{Q}^{\max}$.

Thus, if $\mathcal{Q} = \mathcal{Q}^{\max}$, then equalities (3.12) are possible only if $\mathcal{P} = 0$ and not for integrable functions p_j. If $\mathcal{Q} > \mathcal{Q}^{\max}$, then equalities (3.12) are impossible.

Let $\mathcal{Q} \in [0, \mathcal{Q}^{\max})$. Find the minimum of $\mathcal{P}$ in (3.14) for $\mathcal{Q}_i \geqslant 0$ such that $\sum_{i=1}^{4} \mathcal{Q}_i = \mathcal{Q}$ and with the other variables fixed. Increasing Q_2 and Q_4 until the constraints (3.13) are satisfied and decreasing Q_1 and Q_3 to zero, while keeping $\mathcal{Q}$ the same, we obtain one of the following two cases:

i) if $\mathcal{Q} \leqslant \gamma_1 + \gamma_2(1+k) + k\gamma_3$, then $\mathcal{Q}_1 = \mathcal{Q}_3 = 0$ and

$$\mathcal{P} = \mathcal{R} - \frac{\mathcal{Q}}{k},$$

ii) if $\mathcal{Q} \geqslant \gamma_1 + \gamma_2(1+k) + k\gamma_3$, then $\mathcal{Q}_2 = \gamma_1 + \gamma_2(1+k)$, $\mathcal{Q}_4 = k\gamma_3$ and

$$\mathcal{P} = \mathcal{R} - k(\mathcal{Q} - (\gamma_1 + \gamma_2(1+k) + k\gamma_3)) - \frac{\gamma_1 + \gamma_2(1+k) + k\gamma_3}{k} = k\mathcal{R} - k\mathcal{Q}.$$

For a fixed k, the minimum value of $\mathcal{R}$ is $\frac{G(k)}{k}$, and the following equality holds for the constraint on $\mathcal{Q}$

$$\gamma_1 + \gamma_2(1+k) + k\gamma_3 = (1 + \sqrt{k} + \sqrt{k+1})^2.$$

Thus, in case i) one should minimize $\mathcal{P} = H_1(k)$ subject to

$$\mathcal{Q} \leqslant (1 + \sqrt{k} + \sqrt{k+1})^2, \tag{3.18}$$

in the second case, one should minimize $\mathcal{P} = H_2(k)$ subject to

$$\mathcal{Q} \geqslant (1 + \sqrt{k} + \sqrt{k+1})^2. \tag{3.19}$$

It is obvious that for $\mathcal{Q} \leqslant 4$ at the minimum point of $H_1(k)$, $k \in (0,1]$, the inequality (3.18) is satisfied.

It is easy to check that at the minimum point of $H_2(k)$, $k \in (0,1]$, the inequality (3.19) is satisfied if $\mathcal{Q} \geqslant 4$.

Since the limiting case (3.9) is not achieved on integrable coefficients p_j, the obtained boundaries belong to the set of everywhere solvability Ω. □

Now we obtain a representation for the boundaries of the set Ω, which in the notation (3.15), (3.16), (3.17) in accordance with Theorem 3.1 look like this: $(\mathcal{P}, \mathcal{Q}) \in \Omega$ if and only if

$$\mathcal{Q} \in [0,4], \quad \mathcal{P} \leqslant \widetilde{\mathcal{P}_1}(\mathcal{Q}) \equiv \min_{k \in (0,1]} H_1(k).$$

or

$$\mathcal{Q} \in (4, 12 + 8\sqrt{2}], \quad \mathcal{P} \leqslant \widetilde{\mathcal{P}_2}(\mathcal{Q}) \equiv \min_{k \in [0,1]} H_2(k).$$

For all $\mathcal{Q} \in [0,4]$, the function H_1 takes its minimum at the point $k \in [0,1]$, which satisfies the equation $H_1'(k) = 0$, that is if

$$G'(k)k - G(k) + \mathcal{Q} = 0 \tag{3.20}$$

(here and below $(\cdot)' \equiv \frac{d(\cdot)}{dk}$). Therefore, the dependence $\widetilde{\mathcal{P}_1}(\mathcal{Q})$ for $\mathcal{Q} \in [0,4]$ can be defined parametrically using the equalities (3.16), (3.20) .

First, we define the number $k_0 = k_1^2 \approx 0.43$, where $k_1 \in [0,1]$ is the only root of the equation $k^4 + 6k^3 + 5k^2 - k = 0$ on the interval $[0,1]$. The number k_0 satisfies the equation (3.20) for $\mathcal{Q} = 4$. The function $\mathcal{Q}(k) = G(k) - G'(k)k$ maps $[k_0, 1]$ onto $[0,4]$.

Let us define the function $\widetilde{\mathcal{P}_1}(\mathcal{Q})$ parametrically:

$$\mathcal{Q} = G(k) - G'(k)k, \quad \widetilde{\mathcal{P}_1} \equiv G'(k), \quad k \in [k_0, 1]. \tag{3.21}$$

Denote $\mathcal{P}_4 \equiv \widetilde{\mathcal{P}_1}(4) = G'(k_0) \approx 17.7$.
We have, in particular,

$$\widetilde{\mathcal{P}_1}(0) = 12 + 8\sqrt{2} \quad (k = 1), \quad \widetilde{\mathcal{P}_1}(27/8) = 19 \quad (k = 9/16), \quad \widetilde{\mathcal{P}_1}(4) = \mathcal{P}_4.$$

For $\mathcal{Q} \in (4, \mathcal{P}_4]$, the function $H_2(k)$ takes a minimum value for $k \in [0, 1]$ at the point $k = 0$, therefore $\widetilde{\mathcal{P}_2}(\mathcal{Q}) = H_2(0) = G(0) = 4$. If $\mathcal{Q} \in (\mathcal{P}_4, 12 + 8\sqrt{2}]$, then the function $H_2(k)$ takes a minimum value at the maximum point satisfying the equality

$$H_2'(k) = G'(k) - \mathcal{Q} = 0. \tag{3.22}$$

Therefore, the dependence $\widetilde{\mathcal{P}_2}(\mathcal{Q})$ for $\mathcal{Q} \in (\mathcal{P}_4, 12 + 8\sqrt{2}]$ can also be specified parametrically using the equalities (3.17),(3.22):

$$\mathcal{Q} = G'(k), \quad \widetilde{\mathcal{P}_2} = G(k) - G'(k)k, \quad k \in [k_0, 1]. \tag{3.23}$$

From the parameterizations (3.21) and (3.23) it is clear that the dependencies $\widetilde{\mathcal{P}_1}(Q)$ and $\widetilde{\mathcal{P}_2}(\mathcal{Q})$ are mutually inverse.

If $\mathcal{Q} > 12 + 8\sqrt{2}$, the minimum value of $H_2(k)$ is negative (and is accepted for $k = 1$). Thus, operator (1.4) cannot be surjective for all linear positive operators satisfying equalities (1.5) for any P.

Fig. 3.1 shows the boundaries of the set Ω.

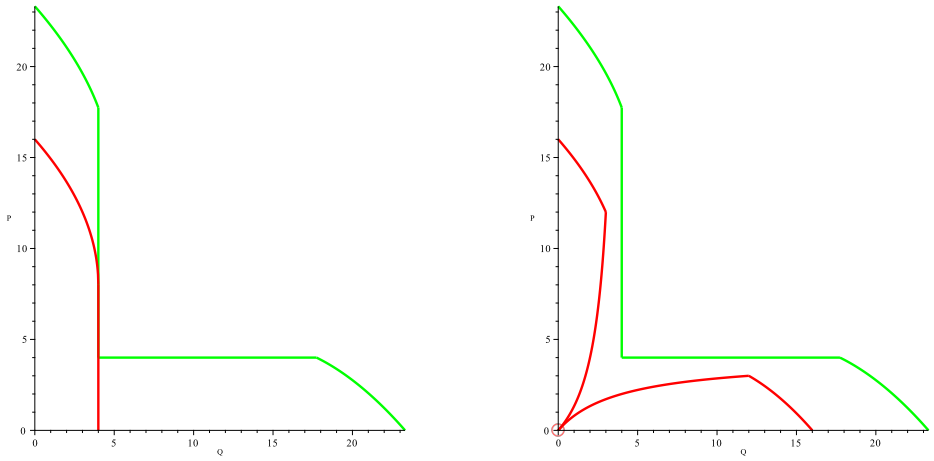

Figure 3.1: The boundaries of the set Ω are marked in green. On the left, the boundaries of the set of solvability of the two-point problem $x(0) = 0$, $x(1) = 0$ [23, 24] are marked in red. On the right, the boundaries of the set of solvability of the periodic problem (1.6) [17] are marked in red.

Let us formulate the statements just obtained as consequences of Theorem 3.1.

Corollary 3.2. *If* $(\mathcal{P},\mathcal{Q})\in\Omega$, *then* $(\mathcal{Q},\mathcal{P})\in\Omega$.

Corollary 3.3.

1. *If* $\mathcal{Q}=0$, *then* $(\mathcal{P},\mathcal{Q})\in\Omega$ *if and only if* $0\leqslant\mathcal{P}\leqslant 12+8\sqrt{2}$.
2. *If* $\mathcal{Q}\in[0,4]$, *then* $(\mathcal{P},\mathcal{Q})\in\Omega$ *if and only if* $\mathcal{P}\in[0,G'(k)]$, *where* $k\in(0,1]$ *is a unique solution to the equation* $G(k)-G'(k)k=\mathcal{Q}$.
3. *If* $\mathcal{Q}\in[4,\mathcal{P}_4]$, *then* $(\mathcal{P},\mathcal{Q})\in\Omega$ *if and only if* $\mathcal{P}\in[0,4]$.
4. *If* $\mathcal{Q}\in[\mathcal{P}_4,12+8\sqrt{2}]$, *then* $(\mathcal{P},\mathcal{Q})\in\Omega$ *if and only if* $\mathcal{P}\in[0,G(k)-G'(k)k]$, *where* $k\in(0,1]$ *is the maximum root of the equation* $G'(k)=\mathcal{Q}$.

There are also rational points on the boundary of Ω.

Corollary 3.4. *If* $\mathcal{Q}=27/8$, *then* $(\mathcal{P},\mathcal{Q})\in\Omega$ *if and only if* $\mathcal{P}\in[0,19]$.
If $\mathcal{Q}=19$, *then* $(\mathcal{P},\mathcal{Q})\in\Omega$ *if and only if* $\mathcal{P}\in[0,27/8]$.

Abstract. For autonomous C^1-smooth integral equations with infinite delay, exponential attractivity with asymptotic phase of the local center manifolds of the equilibrium 0, together with a reduction principle, is proved by means of a dynamical systems approach based on the variation-of-constants formula in the phase space established in [*Funkcial. Ekvac.* **55**(2012), 479–520]. As its application to one-parameter family of integral equations, it is also shown that saddle-node and pitchfork bifurcations occur when the equilibrium 0 (the zero solution) of the linearized equation changes its stability properties.

Keywords: integral equations with infinite delay, attractivity with asymptotic phase, center manifolds, reduction principle, bifurcation, a variation-of-constants formula.

2020 Mathematics Subject Classification: Primary 45M10; secondary 34K20.

1 Introduction

We consider in this paper the integral equation with infinite delay

$$x(t) = \int_{-\infty}^{t} K(t-s)x(s)ds + f(x_t), \tag{E}$$

where K is a measurable $m \times m$ matrix valued function with complex components that satisfies the conditions

$$\int_0^\infty \|K(t)\|e^{\rho t}dt < \infty \quad \text{and} \quad \operatorname{ess\,sup}\{\|K(t)\|e^{\rho t} : t \geq 0\} < \infty,$$

✉Corresponding author. Email: nagabuti@ous.ac.jp

and f belongs to the space $C^1(X;\mathbb{C}^m)$, the set of all continuously (Fréchet) differentiable functions mapping X into $\mathbb{C}^m$, with the property that $f(0) = 0$ and $Df(0) = 0$; here, ρ is a positive constant which is fixed throughout the paper. Let $X := L^1_\rho(\mathbb{R}^-;\mathbb{C}^m)$, $\mathbb{R}^- := (-\infty, 0]$, be a Banach space which will be introduced in the next section as the phase space for Eq. (E), and x_t denotes the element in X defined as $x_t(\theta) = x(t+\theta)$ for $\theta \in \mathbb{R}^-$. In [21] the first author et al. established a "variation-of-constants formula" for integral equations (VCF, for short) in the phase space, which allows us to study behaviors of solutions to Eq. (E) in the dynamical systems framework. Indeed, by means of VCF, the present authors have proved center manifold theorem; that is, the existence, the (local) exponential attractivity and so on of the (local) center manifolds of the equilibrium point 0 of Eq. (E). For VCF in the phase space for abstract functional differential equations with infinite delay and its applications to study of such as almost periodic solutions and invariant manifold theory, see [12–14, 25–27]. We should also refer the reader for treatments of Eq. (E) by adjoint semigroup theory to the pioneering works due to Diekmann and Gyllenberg [5], in which several important results, together with the principle of linearized stability for integral equations, are established.

One of the purposes of the paper is to improve a part of our preceding results on center manifolds for Eq. (E) [23, Theorems 4 and 5]; more precisely, to show that the local center manifolds are exponentially attractive with asymptotic phase under the assumption that the nonlinear term f is of class C^1. Thus, it turns out that the behavior of any solution of Eq. (E) in a neighborhood of the local center manifold of the (nonhyperbolic) equilibrium 0 is determined by the dynamics on this manifold which is described by a finite dimensional ordinary differential equation, which we call the *central equation* of Eq. (E). As its application we also intend to discuss one-parameter bifurcation structures for integral equations. These subjects have been extensively studied and now are popular for ordinary differential equations, functional differential equations, parabolic partial differential equations and so on (see [1, 2, 4, 6–11, 15–17, 19, 20, 24, 28, 29] and the literature cited therein). However, to the best of our knowledge, it seems that they have remained to be open problems to integral equations. Another purpose of the paper is to show that bifurcations of equilibria can occur for one-parameter family of integral equations with infinite delay. Our analysis will be thoroughly done in a dynamical systems viewpoint, based on VCF in the phase space.

The paper is organized as follows. In Section 2, we present preliminary results, e.g., VCF, the center manifold theorem for Eq. (E), and formal adjoint theory for the linear part of Eq. (E) ([21–23]), which are necessary for our later arguments. Section 3 proves the exponential attractivity with asymptotic phase of the local center manifolds of the equilibrium 0 for Eq. (E) under the assumption that the unstable subspace (of the phase space) is trivial (Theorem 3.3 (a)). In addition a reduction principle will be obtained, which is also a refinement of [23, Theorem 6]; so that, besides the asymptotic stability of the equilibrium 0 of Eq. (E), its stability also follows from that of the central equation of Eq. (E) (Theorem 3.3 (b)). We discuss in Section 4 one-parameter bifurcation problems for integral equations. For this we introduce an extended system of integral equations including the parameter as a state variable. By an application of Theorem 3.3 (a), combined with the study of the central equation of the extended system, we show that under some additional assumptions on the integral kernel, saddle-node and pitchfork bifurcations can be observed as the parameter takes the critical value (Theorem 4.4). In Section 5, we will give an example of a scalar integral equation to which our results in the previous section are applicable.

2 Notations and preliminary results

Let $\mathbb{N}$, $\mathbb{R}^-$, $\mathbb{R}^+$, $\mathbb{R}$ and $\mathbb{C}$ be the set of natural numbers, nonpositive real numbers, nonnegative real numbers, real numbers and complex numbers, respectively. For an $m \in \mathbb{N}$, we denote by $\mathbb{C}^m$ the space of all m-column vectors whose components are complex numbers, with the Euclidean norm $|\cdot|$.

Given Banach spaces $(U, \|\cdot\|_U)$ and $(V, \|\cdot\|_V)$ and positive integer n, we denote by $\mathcal{L}^n(U;V)$ the space of bounded n-linear mappings from U to W with norm

$$\|Q\|_{\mathcal{L}^n(U;V)} := \sup\{\|Q(u_1,\dots,u_n)\|_V : \|u_j\|_U \le 1,\ u_j \in U,\ j = 1,\dots,n\}$$

for $Q \in \mathcal{L}^n(U;V)$. We use the symbol $\mathcal{L}(U;V)$, the space of bounded linear operators, rather than $\mathcal{L}^1(U;V)$; and simply write $\mathcal{L}(U)$ in place of $\mathcal{L}(U;U)$. In particular, for $m \times m$-matrix M with complex components, $\|M\|$ means its operator norm $\|M\|_{\mathcal{L}(\mathbb{C}^m)}$.

For arbitrary linear operator A, the symbols $\mathcal{N}(A)$ and $\mathcal{R}(A)$ stand for the null space and the range of A, respectively.

Given an interval $J \subset \mathbb{R}$ and a Banach space U, we denote by $C(J;U)$ the space of U-valued continuous functions on J, and by $BC(J;U)$ its subspace of bounded continuous functions on J. We also use the notation $B_U(u_0;r)$ which stands for the open ball in U at the center u_0 with radius $r > 0$, that is, $B_U(u_0;r) = \{u \in U : \|u - u_0\|_U < r\}$. If $u_0 = 0$, we simply write $B_U(r)$ rather than $B_U(0;r)$. Also, $\overline{B}_U(u_0;r)$ denotes the closure of $B_U(u_0;r)$.

2.1 Phase space and initial value problems

Let ρ be a fixed positive constant, and let us introduce the function space

$$X := L^1_\rho(\mathbb{R}^-;\mathbb{C}^m) = \{\phi : \mathbb{R}^- \to \mathbb{C}^m : \phi(\theta)e^{\rho\theta} \text{ is integrable on } \mathbb{R}^-\}.$$

X is a Banach space endowed with norm

$$\|\phi\|_X := \int_{-\infty}^0 |\phi(\theta)|e^{\rho\theta}d\theta, \quad \phi \in X.$$

For any function $x : (-\infty, a) \to \mathbb{C}^m$ and $t < a$, we define a function $x_t : \mathbb{R}^- \to \mathbb{C}^m$ by $x_t(\theta) := x(t+\theta)$ for $\theta \in \mathbb{R}^-$; the function x_t is called the t-segment of $x(t)$.

Consider the integral equations

$$x(t) = \int_{-\infty}^t K(t-s)x(s)ds + p(t) \tag{2.1}$$

and

$$x(t) = \int_{-\infty}^t K(t-s)x(s)ds + f(x_t), \tag{E}$$

where we assume, throughout the paper, that the kernel K is a measurable $m \times m$-matrix valued function with complex components satisfying the condition

$$\|K\|_{1,\rho} := \int_0^\infty \|K(t)\|e^{\rho t}dt < \infty, \quad \|K\|_{\infty,\rho} := \operatorname{ess\,sup}\{\|K(t)\|e^{\rho t} : t \ge 0\} < \infty,$$

$p \in C(\mathbb{R};\mathbb{C}^m)$ and $f : X \to \mathbb{C}^m$ is of class C^1. Then Eq. (2.1) (resp. (E)) can be formulated as an abstract equation on the space X of the form

$$x(t) = F(t, x_t), \tag{2.2}$$

with $F(t,\phi) = L(\phi) + p(t)$ (resp. $L(\phi) + f(\phi)$) for $(t,\phi) \in \mathbb{R} \times X$, where

$$L(\phi) := \int_{-\infty}^{0} K(-\theta)\phi(\theta)d\theta, \quad \phi \in X.$$

Note that, in each case, $F(t,\phi)$ is well-defined because of

$$|L(\phi)| \le \int_{-\infty}^{0} \|K(-\theta)\|e^{-\rho\theta}|\phi(\theta)|e^{\rho\theta}d\theta \le \|K\|_{\infty,\rho}\|\phi\|_X.$$

Thus, X may be viewed as the phase space for Eq.'s (2.1) and (E); in what follows we will call X the phase space.

Now let $F : [b,\infty) \times X \to \mathbb{C}^m$ be any continuous function, and consider the equation (2.2) with the initial condition

$$x_\sigma = \phi, \ \text{ that is, } \ x(\sigma+\theta) = \phi(\theta) \ \text{ for } \ \theta \in \mathbb{R}^-, \tag{2.3}$$

where $(\sigma,\phi) \in [b,\infty) \times X$ is given arbitrarily. A function $x : (-\infty, a) \to \mathbb{C}^m$ is said to be a solution of the initial value problem (2.2)–(2.3) on the interval (σ, a) if x satisfies the following conditions:

(i) $x_\sigma = \phi$, that is, $x(\sigma+\theta) = \phi(\theta)$ for $\theta \in \mathbb{R}^-$;

(ii) $x \in L^1_{\mathrm{loc}}[\sigma, a)$, x is locally integrable on $[\sigma, a)$;

(iii) $x(t) = F(t, x_t)$ for $t \in (\sigma, a)$.

If $F(t,\phi)$ is locally Lipschitz continuous in ϕ, by [21, Proposition 1] the initial value problem (2.2)–(2.3) has a unique (local) solution, which is defined globally if $F(t,\phi)$ is globally Lipschitz continuous in ϕ ([21, Proposition 3]). So for any $(\sigma,\phi) \in \mathbb{R} \times X$ (2.1)–(2.3) has a unique global solution, denoted $x(t;\sigma,\phi,p)$, which is called the solution of Eq. (2.1) through (σ,ϕ). Similarly, (E)–(2.3) has a unique (local) solution, which is denoted by $x(t;\sigma,\phi,f)$. Note also that if $x(t)$ is a solution of Eq. (2.2) on (σ, a), then x_t is an X-valued continuous function on $[\sigma, a)$ (cf. [21, Lemma 1]).

When J is an interval in $\mathbb{R}$, a $\mathbb{C}^m$-valued function $\xi(t)$ is called a solution of Eq. (2.1) on J, if $\xi_t \in X$ is defined for all $t \in J$ and if it satisfies $x(t;\sigma,\xi_\sigma,p) = \xi(t)$ for all t and σ in J with $t \ge \sigma$; and, similarly, a $\mathbb{C}^m$-valued function $\xi(t)$ is called a solution of Eq. (E) on J whenever $\xi_t \in X$ for $t \in J$, and $x(t;\sigma,\xi_\sigma,f) = \xi(t)$ holds for all t and σ in J with $t \ge \sigma$.

2.2 A variation-of-constant formula and decomposition of the phase space

Now, for any $t \ge 0$ and $\phi \in X$, we define $T(t)\phi \in X$ by

$$\left[T(t)\phi\right](\theta) := x_t(\theta;,0,\phi,0) = \begin{cases} x(t+\theta;0,\phi,0), & -t < \theta \le 0, \\ \phi(t+\theta), & \theta \le -t. \end{cases}$$

Then $T(t)$ defines a bounded linear operator on X. We call $T(t)$ the solution operator of the homogeneous integral equation

$$x(t) = \int_{-\infty}^{t} K(t-s)x(s)ds. \tag{2.4}$$

$\{T(t)\}_{t\geq 0}$ is a strongly continuous semigroup of bounded linear operators on X, called a solution semigroup for Eq. (2.4).

Given a positive integer n, we introduce a continuous function $\Gamma^n : \mathbb{R}^- \to \mathbb{R}^+$ which is of compact support with $\operatorname{supp}\Gamma^n \subset [-1/n, 0]$ and satisfies $\int_{-\infty}^{0} \Gamma^n(\theta)d\theta = 1$. Obviously, $\Gamma^n x \in X$ for $x \in \mathbb{C}^m$ and the inequality $\|\Gamma^n x\|_X \leq |x|$ holds.

The following theorem plays a crucial role throughout the paper, which gives a representation formula for solutions of Eq. (2.1) in the phase space X, and is called the variation-of-constants formula (VCF, for short) in the phase space.

Theorem 2.1 ([21, Theorem 3]). *The segment $x_t(\sigma, \phi, p)$ of solution $x(\cdot; \sigma, \phi, p)$ of Eq. (2.1) satisfies the following relation in X:*

$$x_t(\sigma, \phi, p) = T(t-\sigma)\phi + \lim_{n\to\infty} \int_\sigma^t T(t-s)(\Gamma^n p(s))ds, \quad t \geq \sigma.$$

Let $\overline{X}$ be a subset of X of elements $\phi \in X$ which are continuous on $[-\varepsilon_\phi, 0]$ for some $\varepsilon_\phi > 0$, and set

$$X_0 := \{\psi \in X : \psi = \phi \text{ a.e. on } \mathbb{R}^- \text{ for some } \phi \in \overline{X}\}.$$

Then for any $\psi \in X_0$ we can define the value of ψ at $\theta = 0$ by $\psi[0] := \phi(0)$, where ϕ is an element in $\overline{X}$ satisfying $\psi = \phi$ a.e. on $\mathbb{R}^-$. $\psi[0]$ is well-defined, and X_0 is a normed linear space with norm

$$\|\psi\|_{X_0} := \|\psi\|_X + |\psi[0]|, \quad \psi \in X_0.$$

By [21, Lemma 1], we note that the solution $x(\cdot; \sigma, \phi, p)$ of Eq. (2.1) through $(\sigma, \phi) \in \mathbb{R} \times X$ satisfies $x_t(\sigma, \phi, p) \in X_0$ with $(x_t(\sigma, \phi, p))[0] = x(t; \sigma, \psi, p)$ for $t > \sigma$.

The next theorem describes an intimate relation between solutions of Eq. (2.1) and X-valued functions satisfying an integral equation which arises from the variation-of-constants formula in the phase space.

Theorem 2.2 ([21, Theorem 4]). *Let $p \in C(\mathbb{R}; \mathbb{C}^m)$.*

(i) *If $x(t)$ is a solution of Eq. (2.1) on the entire $\mathbb{R}$, then the X-valued function $\xi(t) := x_t$ satisfies the relations*

  (a) $\xi(t) = T(t-\sigma)\xi(\sigma) + \lim_{n\to\infty} \int_\sigma^t T(t-s)(\Gamma^n p(s))ds$, $\forall\, (t, \sigma) \in \mathbb{R}^2$ *with* $t \geq \sigma$, *in* X;

  (b) $\xi \in C(\mathbb{R}; X_0)$.

(ii) *Conversely, if a function $\xi : \mathbb{R} \to X$ satisfies the relation*

$$\xi(t) = T(t-\sigma)\xi(\sigma) + \lim_{n\to\infty} \int_\sigma^t T(t-s)(\Gamma^n p(s))ds, \quad \forall\, (t, \sigma) \in \mathbb{R}^2 \text{ with } t \geq \sigma,$$

then

  (c) $\xi \in C(\mathbb{R}; X_0)$;

  (d) *if we set $u(t) = (\xi(t))[0]$ for $t \in \mathbb{R}$, then $u \in C(\mathbb{R}; \mathbb{C}^m)$, $u_t = \xi(t)$ (in X) for any $t \in \mathbb{R}$ and u is a solution of Eq. (2.1) on $\mathbb{R}$.*

Based on spectral analysis of the generator A of the solution semigroup $\{T(t)\}_{t\geq 0}$, we also have established the decomposition theorem of the phase space X ([21]); let $\sigma(A)$ and $P_\sigma(A)$

be the spectrum and the point spectrum of the generator A, respectively. Then the following relation holds between the spectrum of A and the characteristic roots of Eq. (2.4)

$$\sigma(A) \cap \mathbb{C}_{-\rho} = P_\sigma(A) \cap \mathbb{C}_{-\rho} = \{\lambda \in \mathbb{C}_{-\rho} : \det \Delta(\lambda) = 0\},$$

where $\mathbb{C}_{-\rho} := \{z \in \mathbb{C} : \mathrm{Re}\, z > -\rho\}$, and $\Delta(\lambda)$ is the characteristic operator of Eq. (2.4), i.e., $\Delta(\lambda) := E_m - \int_0^\infty K(t)e^{-\lambda t}dt$, E_m being the $m \times m$-unit matrix ([21, Proposition 4]). Moreover, for ess (A), the essential spectrum of A, we have $\sup_{\lambda \in \mathrm{ess}\,(A)} \mathrm{Re}\,\lambda \leq -\rho$ ([21, Corollarly 2]). Now set $\Sigma^u := \{\lambda \in \sigma(A) : \mathrm{Re}\,\lambda > 0\}$, $\Sigma^c := \{\lambda \in \sigma(A) : \mathrm{Re}\,\lambda = 0\}$, and $\Sigma^s := \sigma(A)\backslash(\Sigma^c \cup \Sigma^u)$. The decomposition theorem of X is the following.

Theorem 2.3 ([21, Theorem 2]). *Let $\{T(t)\}_{t\geq 0}$ be the solution semigroup of Eq. (2.4). Then X is decomposed as a direct sum of closed subspaces E^u, E^c, and E^s*

$$X = E^u \oplus E^c \oplus E^s$$

with the following properties:

(i) $\dim(E^u \oplus E^c) < \infty$,

(ii) $T(t)E^u \subset E^u$, $T(t)E^c \subset E^c$, *and* $T(t)E^s \subset E^s$ *for* $t \in \mathbb{R}^+$,

(iii) $\sigma(A|_{E^u}) = \Sigma^u$, $\sigma(A|_{E^c}) = \Sigma^c$ *and* $\sigma(A|_{E^s \cap \mathcal{D}(A)}) = \Sigma^s$,

(iv) $T^u(t) := T(t)|_{E^u}$ *and* $T^c(t) := T(t)|_{E^c}$ *are extendable for* $t \in \mathbb{R}$ *as groups of bounded linear operators on* E^u *and* E^c, *respectively,*

(v) $T^s(t) := T(t)|_{E^s}$ *is a strongly continuous semigroup of bounded linear operators on* E^s, *and its generator is identical with* $A|_{E^s \cap \mathcal{D}(A)}$,

(vi) *there exist positive constants* α, ε *with* $\alpha > \varepsilon$ *and a constant* $C \geq 1$ *such that*

$$\begin{aligned} \|T^s(t)\|_{\mathcal{L}(X)} &\leq Ce^{-\alpha t}, \quad t \in \mathbb{R}^+, \\ \|T^u(t)\|_{\mathcal{L}(X)} &\leq Ce^{\alpha t}, \quad t \in \mathbb{R}^-, \\ \|T^c(t)\|_{\mathcal{L}(X)} &\leq Ce^{\varepsilon|t|}, \quad t \in \mathbb{R}. \end{aligned}$$

Note that in (vi) of the theorem above C is a constant depending only on the positive numbers α and ε, and that ε can be taken arbitrarily small. We will use the notations $E^{cu} = E^c \oplus E^u$, $E^{su} = E^s \oplus E^u$ etc, and denote by Π^s the projection from X onto E^s along E^{cu}, and likewise for Π^u, Π^{cu} etc. Also, we set

$$C_1 := \|\Pi^s\|_{\mathcal{L}(X)} + \|\Pi^c\|_{\mathcal{L}(X)} + \|\Pi^u\|_{\mathcal{L}(X)}.$$

By an *equilibrium (or equilibrium point) of the integral equation* (E) we mean that of the semi-dynamical system on the phase space X induced by Eq. (E); namely, let $U : \mathbb{R}^+ \times X \to X$ be the map defined by

$$U(t, \phi) := x_t(0, \phi, f), \quad (t, \phi) \in \mathbb{R}^+ \times X.$$

We then call $\phi \in X$ an equilibrium (or equilibrium point) of Eq. (E) if $U(t, \phi) = \phi$ holds for all $t \in \mathbb{R}^+$. If ϕ is an equilibrium, then $\phi(\theta) =$ const. a.e. $\theta \in \mathbb{R}^-$. Indeed, put $u(t) := x(t; 0, \phi, f)$, then $U(t, \phi) = \phi$ implies that $u(t + \theta) = \phi(\theta) = u(\theta)$ a.e. on $\mathbb{R}^-$ for all $t \in \mathbb{R}^+$; hence any weak derivative of $u(\theta)$ is 0 a.e., so that $\phi(\theta) = u(\theta) =$ const. a.e. on $\mathbb{R}^-$. When 0 is an equilibrium, we often call it the zero solution of the integral equation.

If $f \in C^1(X; \mathbb{C}^m)$ satisfies $f(0) = 0$ and $Df(0) = 0$, Eq. (2.4) is the linearized equation of Eq.(E) around the equilibrium 0. The equilibrium 0 (or the zero solution) of Eq. (E) is said to be *hyperbolic* provided that $\Delta(\lambda)$ is invertible on the imaginary axis; that is, $\Sigma^c = \emptyset$.

2.3 Center manifold for an integral equation with modified nonlinear term

Suppose that $f \in C^1(X;\mathbb{C}^m)$ satisfies $f(0) = 0$ and $Df(0) = 0$. Under the assumption we have established the existence of local center manifolds of the equilibrium 0 of Eq. (*E*) and proved its exponential attractivity ([23, Theorem 5]). To this end, we discussed the corresponding problems for a modified equation of (*E*)

$$x(t) = \int_{-\infty}^{t} K(t-s)x(s)ds + f_\delta(x_t), \tag{E_δ}$$

where $f_\delta : X \to \mathbb{C}^m$ ($\delta > 0$) is defined by

$$f_\delta(\phi) := \chi\big(\|\Pi^{su}\phi\|_X/\delta\big)\chi\big(\|\Pi^c\phi\|_X/\delta\big)f(\phi), \quad \phi \in X,$$

χ being a C^∞-function on $\mathbb{R}$ satisfying $\chi(t) = 1$ ($|t| \le 2$) and $\chi(t) = 0$ ($|t| \ge 3$). Note that f_δ is continuous on X, and is of class C^1 when restricted to the open set $S_\delta := \{\phi \in X : \|\Pi^{su}\phi\|_X < \delta\}$ since we may assume that $\|\Pi^c\phi\|_X$ is of class C^1 for $\phi \neq 0$ because of $\dim E^c < \infty$. Also, by the assumption $f(0) = Df(0) = 0$, there exist a $\delta_1 > 0$ and a nondecreasing continuous function $\zeta_* : (0,\delta_1] \to \mathbb{R}^+$ such that $\zeta_*(+0) = 0$,

$$\|f_\delta(\phi)\|_X \le \delta\zeta_*(\delta), \quad \text{and} \quad \|f_\delta(\phi) - f_\delta(\psi)\|_X \le \zeta_*(\delta)\|\phi - \psi\|_X$$

for $\phi, \psi \in X$ and $\delta \in (0,\delta_1]$. Indeed, we may put

$$\zeta_*(\delta) = \left(\sup_{\|\phi\|_X \le 3\delta} \|Df(\phi)\|_{\mathcal{L}(X;\mathbb{C}^m)}\right)\left(1 + 3\sup_{0\le t\le 3}|\chi'(t)|\right)$$

(cf. [4, Lemma 4.1]).

Fix a positive number η such that $\varepsilon < \eta < \alpha$, where ε and α are the constants in Theorem 2.3. For the existence of center manifold for Eq. (E_δ) and its exponential attractivity property, we have established the following:

Theorem 2.4 ([23, Theorem 4]). *There exist a positive number δ and a C^1-map $F_{*,\delta} : E^c \to E^{su}$ with $F_{*,\delta}(0) = 0$ such that the following properties hold:*

(i) $W^c_\delta := \operatorname{graph} F_{*,\delta}$ *is tangent to E^c at zero,*

(ii) W^c_δ *is invariant for Eq. (E_δ), that is, if $\xi \in W^c_\delta$, then $x_t(0,\xi,f) \in W^c_\delta$ for $t \in \mathbb{R}$.*

(iii) *Assume moreover that $\Sigma^u = \emptyset$. Then there exists a positive constant β_0 with the property that if x is a solution of Eq. (E_δ) on an interval $J = [t_0, t_1]$, then the inequality*

$$\|\Pi^s x_t - F_{*,\delta}(\Pi^c x_t)\|_X \le C\|\Pi^s x_{t_0} - F_{*,\delta}(\Pi^c x_{t_0})\|_X e^{-\beta_0(t-t_0)}, \quad t \in J$$

holds true. In particular, if x is a solution on an interval $[t_0,\infty)$, x_t tends to W^c_δ exponentially as $t \to \infty$.

It has also been proved that W^c_δ has the same smoothness as the nonlinear term $f(\phi)$ does ([23, Appendix]; see also [27] for details). Let us briefly recall the outline of the proof of the existence part. Take a $\delta_1 > 0$ sufficiently small in such a way that

$$\zeta_*(\delta_1)CC_1\left(\frac{1}{\eta-\varepsilon} + \frac{2}{\alpha+\eta} + \frac{2}{\alpha-\eta}\right) < \frac{1}{2}$$

holds. Let Y_η be the Banach space

$$Y_\eta := \{y \in C(\mathbb{R}; X) : \sup_{t\in\mathbb{R}} \|y(t)\|_X e^{-\eta|t|} < \infty\}$$

with norm

$$\|y\|_{Y_\eta} := \sup_{t\in\mathbb{R}} \|y(t)\|_X e^{-\eta|t|}, \quad y \in Y_\eta,$$

and consider the map $\mathcal{F}_\delta : E^c \times Y_\eta \to Y_\eta$ defined by

$$\begin{aligned}\mathcal{F}_\delta(\psi, y)(t) := T^c(t)\psi + \lim_{n\to\infty} \int_0^t T^c(t-s)\Pi^c\Gamma^n f_\delta(y(s))ds \\ - \lim_{n\to\infty} \int_t^\infty T^u(t-s)\Pi^u\Gamma^n f_\delta(y(s))ds + \lim_{n\to\infty} \int_{-\infty}^t T^s(t-s)\Pi^s\Gamma^n f_\delta(y(s))ds\end{aligned} \tag{2.5}$$

for $(\psi, y) \in E^c \times Y_\eta$ and $t \in \mathbb{R}$. Then, for each $\psi \in E^c$, $\mathcal{F}_\delta(\psi, \cdot)$ is a contraction map from Y_η into itself provided that $0 < \delta \le \delta_1$, and therefore has a unique fixed point, say $\Lambda_{*,\delta}(\psi) \in Y_\eta$.

Now define $F_{*,\delta} : E^c \to E^{su}$ by $F_{*,\delta}(\psi) := \Pi^{su}\big(\Lambda_{*,\delta}(\psi)(0)\big)$ for $\psi \in E^c$. One can see from (2.5) and the relation $\Lambda_{*,\delta}(\psi)(0) = \mathcal{F}_\delta(\psi, \Lambda_{*,\delta}(\psi))(0)$ that

$$\begin{aligned}F_{*,\delta}(\psi) = & - \lim_{n\to\infty} \int_0^\infty T^u(-s)\Pi^u\Gamma^n f_\delta(\Lambda_{*,\delta}(\psi)(s))ds \\ & + \lim_{n\to\infty} \int_{-\infty}^0 T^s(-s)\Pi^s\Gamma^n f_\delta(\Lambda_{*,\delta}(\psi)(s))ds.\end{aligned} \tag{2.6}$$

The map $F_{*,\delta}$ is the required one and the center manifold is given by

$$W^c_\delta := \operatorname{graph} F_{*,\delta} = \{\psi + F_{*,\delta}(\psi) : \psi \in E^c\}.$$

The definition (2.6) of $F_{*,\delta}$ shall be used in the arguments in Subsection 4.4; W^c_δ will be also denoted by $W^c_\delta(0)$ in later sections.

Let r be a positive number with $r \le \delta$, set $F_* := F_{*,\delta}|_{B_{E^c}(r)}$ and $\Omega_0 := \{\phi \in X : \|\Pi^{su}\phi\|_X < \delta,\ \|\Pi^c\phi\|_X < r\}$. Then, $f \equiv f_\delta$ on Ω_0, and therefore, Theorem 2.4 assures that $W^c_{\mathrm{loc}}(0) := \operatorname{graph} F_*$ is a local center manifold for Eq. (E) (see [23, Theorem 5]).

The following proposition is often used in the subsequent sections.

Proposition 2.5 ([23, Propositions 2 and 3]). *The maps $\Lambda_{*,\delta}$ and $F_{*,\delta}$ are (globally) Lipschitz continuous and have the following properties:*

(i) $\|F_{*,\delta}(\psi_1) - F_{*,\delta}(\psi_2)\|_X \le L(\delta)\|\psi_1 - \psi_2\|_X$ *for* $\psi_1, \psi_2 \in E^c$, *where* $L(\delta)$ *is the constant given by* $L(\delta) := 4C^2C_1\zeta_*(\delta)/(\alpha - \eta)$.

(ii) *For* $\hat\phi \in W^c_\delta$ *and* $\tau \in \mathbb{R}$,

$$\Pi^{su}x_t(\tau, \hat\phi, f_\delta) = F_{*,\delta}\big(\Pi^e x_t(\tau, \hat\phi, f_\delta)\big), \quad t \in \mathbb{R}.$$

In particular W^c_δ is invariant for (E_δ), that is, $x_t(\tau, \hat\phi, f_\delta) \in W^c_\delta$ for $t \in \mathbb{R}$, provided that $\hat\phi \in W^c_\delta$.

2.4 The projection onto the center-unstable subspace via formal adjoint theory

Let $\Sigma^{cu} = \{\lambda_1, \dots, \lambda_r\}$; then each λ_i is a normal eigenvalue of the generator A, and hence, its generalized eigenspace $\mathcal{M}_{\lambda_i}(A)$ is of the form $\mathcal{N}((A-\lambda_i I)^{p_i})$, p_i being the ascent of λ_i. The center-unstable subspace E^{cu} $(= E^c \oplus E^u)$ is then expressed as

$$E^{cu} = \bigoplus_{i=1}^{r} \mathcal{M}_{\lambda_i}(A) = \bigoplus_{i=1}^{r} \mathcal{N}((A-\lambda_i I)^{p_i}) \tag{2.7}$$

([22, Subsection 2.2]); and, in addition, each direct summand is characterized by the following proposition. Given $\lambda \in \mathbb{C}_{-\rho}$ and $k \in \mathbb{N}$, consider a function $w_k(\lambda) : \mathbb{R}^- \to \mathbb{C}$ and a $(km) \times (km)$ matrix $D_k(\lambda)$ defined by

$$w_k(\lambda)(\theta) := \frac{\theta^{k-1}}{(k-1)!} e^{\lambda\theta}, \quad \theta \le 0, \tag{2.8}$$

$$D_k(\lambda) := \begin{pmatrix} \Delta(\lambda) & \Delta'(\lambda) & \cdots & \Delta^{(k-1)}(\lambda)/(k-1)! \\ 0 & \Delta(\lambda) & \cdots & \Delta^{(k-2)}(\lambda)/(k-2)! \\ \vdots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & \Delta(\lambda) \end{pmatrix}, \tag{2.9}$$

where $\Delta^{(n)}(z) := (d^n/dz^n)\Delta(z)$ for $n \in \mathbb{N}$.

Proposition 2.6 ([22, Proposition 3.1])**.** *Let $\lambda \in \mathbb{C}_{-\rho}$ and $k \in \mathbb{N}$. Then the following statements are equivalent:*

(i) $\phi \in \mathcal{N}((A-\lambda I)^k)$,

(ii) $\phi = \sum_{j=1}^{k} w_j(\lambda)\eta_j$ *in* X, *where* $\eta_1, \dots, \eta_k$ *belong to* $\mathbb{C}^m$ *satisfying the relation*

$$D_k(\lambda)\,\mathrm{col}\,(\eta_1, \dots, \eta_k) = \mathrm{col}\,(0, \dots, 0).$$

Moreover, in [22] the formal adjoint operator $A^\sharp$ was introduced and some duality properties between A and $A^\sharp$ were observed. $A^\sharp$ is indeed defined as follows. Let $\mathbb{C}^{m*}$ be the space of all m-dimensional row vectors with complex components with the usual operator norm $|\cdot|$ as the dual space of $\mathbb{C}^m$. Let $X^\sharp$ be the Banach space defined by

$$X^\sharp := L^1_\rho(\mathbb{R}^+; \mathbb{C}^{m*}) = \left\{\alpha : \mathbb{R}^+ \to \mathbb{C}^{m*} : \alpha(s)e^{-\rho s} \text{ is integrable on } \mathbb{R}^+\right\}$$

with norm

$$\|\alpha\|_{X^\sharp} = \int_0^\infty |\alpha(s)| e^{-\rho s} ds, \quad \alpha \in X^\sharp,$$

and $\tilde{X}^\sharp$ be the subspace

$$\tilde{X}^\sharp = \Big\{\tilde{\alpha} \in X^\sharp : \tilde{\alpha} \text{ is locally absolutely continuous on } \mathbb{R}^+, \\ \frac{d}{ds}\tilde{\alpha} \in X^\sharp \text{ and } \tilde{\alpha}(0) = \int_0^\infty \tilde{\alpha}(s)K(s)ds\Big\}.$$

We define $A^\sharp : X^\sharp \supset \mathcal{D}(A^\sharp) \to X^\sharp$ by

$$A^\sharp\alpha := -\frac{d}{ds}\tilde{\alpha}, \quad \alpha \in \mathcal{D}(A^\sharp),$$

where $\mathcal{D}(A^\sharp) := \{\alpha \in X^\sharp : \alpha(s) = \tilde{\alpha}(s) \text{ a.e. } s \in \mathbb{R}^+ \text{ for some } \tilde{\alpha} \in \tilde{X}^\sharp\}$. In fact, the operator $A^\sharp$ is identical with the infinitesimal generator of the solution semigroup on $X^\sharp$ induced by an adjoint integral equation of (2.4) in some sense (see [22] for details).

A characterization of the space $\mathcal{N}((A^\sharp - \lambda I)^k)$ is obtained in a similar fashion to Proposition 2.6. For any $\lambda \in \mathbb{C}_{-\rho}$ and $k \in \mathbb{N}$, define $w_k^\sharp(\lambda) : \mathbb{R}^+ \to \mathbb{C}$ by

$$w_k^\sharp(\lambda)(s) := w_k(\lambda)(-s) = \frac{(-s)^{k-1}}{(k-1)!}e^{-\lambda s}, \quad s \geq 0. \tag{2.10}$$

Proposition 2.7 ([22, Proposition 3.4]). *Let $\lambda \in \mathbb{C}_{-\rho}$ and $k \in \mathbb{N}$. Then the following statements are equivalent:*

(i) $\alpha \in \mathcal{N}((A^\sharp - \lambda I)^k)$,

(ii) $\alpha = \sum_{j=1}^k w_j^\sharp(\lambda)\zeta_{k+1-j}$ *in* $X^\sharp$, *where* $\zeta_1, \dots, \zeta_k$ *belong to* $\mathbb{C}^{m*}$ *satisfying the relation*

$$(\zeta_1, \dots, \zeta_k)D_k(\lambda) = (0, \dots, 0).$$

Now, let us consider the bilinear form $\langle\!\langle \cdot, \cdot \rangle\!\rangle$ on $X^\sharp \times X$ given by

$$\langle\!\langle \alpha, \phi \rangle\!\rangle := \int_{-\infty}^0 \int_\theta^0 \alpha(\xi - \theta)K(-\theta)\phi(\xi)d\xi d\theta, \quad \phi \in X, \ \alpha \in X^\sharp,$$

which is well-defined and bounded. Then $\mathcal{R}((A - \lambda_i I)^{p_i})$ is characterized as the annihilator of $\mathcal{N}((A^\sharp - \lambda_i I)^{p_i})$ with respect to this pairing ([22, Proposition 3.5]). So, by virtue of the fact $X = \mathcal{N}((A - \lambda_i I)^{p_i}) \oplus \mathcal{R}((A - \lambda_i I)^{p_i})$ and the fact that $\dim \mathcal{N}((A - \lambda_i I)^{p_i}) = \dim \mathcal{N}((A^\sharp - \lambda_i I)^{p_i})$, which follows from Propositions 2.6 and 2.7, one may think of $\mathcal{N}((A^\sharp - \lambda_i I)^{p_i})$ as the dual space of $\mathcal{N}((A - \lambda_i I)^{p_i})$. Hence, $\mathcal{N}^\sharp := \bigoplus_{i=1}^r \mathcal{N}((A^\sharp - \lambda_i I)^{p_i})$ plays a role of the dual space of E^{cu} due to (2.7).

So, let $\{\phi_1, \dots, \phi_d\}$ and $\{\psi_1, \dots, \psi_d\}$ be bases for E^{cu} and $\mathcal{N}^\sharp$, respectively; set $\Phi = (\phi_1, \dots, \phi_d)$ and $\Psi = \operatorname{col}(\psi_1, \dots, \psi_d)$. We denote by $\langle\!\langle \Psi, \Phi \rangle\!\rangle$ the $d \times d$ matrix whose (i,j)-component is $\langle\!\langle \psi_i, \phi_j \rangle\!\rangle$, and by $\langle\!\langle \Psi, \phi \rangle\!\rangle$ the column vector $\operatorname{col}(\langle\!\langle \psi_1, \phi \rangle\!\rangle, \dots, \langle\!\langle \psi_d, \phi \rangle\!\rangle)$ for any $\phi \in X$. Then, we have:

Theorem 2.8 ([22, Theorem 3.1]). *Let Φ, Ψ be the ones cited above. Then the matrix $\langle\!\langle \Psi, \Phi \rangle\!\rangle$ is nonsingular, and the projection $\Pi^{cu} : X \to E^{cu}$ is given by*

$$\Pi^{cu}\phi = \Phi\langle\!\langle \Psi, \Phi \rangle\!\rangle^{-1}\langle\!\langle \Psi, \phi \rangle\!\rangle, \quad \phi \in X.$$

3 Exponential attractivity with asymptotic phase of the local center manifold and a reduction principle

In this section we prove the global exponential attractivity with asymptotic phase of the center manifold $W_\delta^c(0)$ and a reduction principle for Eq. (*E*), which are refinements of Theorem 4 (iii) and [23, Theorem 6], respectively. Thus, behaviors of the solutions of Eq. (E_δ), including stability properties, are completely described by the dynamics on $W_\delta^c(0)$. As a corollary the corresponding results are obtained for Eq. (*E*).

3.1 Main theorems and preparatory propositions

Consider the integral equation

$$x(t) = \int_{-\infty}^{t} K(t-s)x(s)ds + f_\delta(x_t). \tag{E_δ}$$

Now, assume that $\Sigma^u = \emptyset$. Let d be the dimension of E^c, and Φ, Ψ the ones in the previous subsection. Since $\{T^c(t)\}_{t\geq 0}$ is a strongly continuous semigroup on the d-dimensional space E^c, there exists a $d \times d$ matrix G_c such that $T^c(t)\Phi = \Phi e^{tG_c}$ for $t \geq 0$ and $\sigma(G_c)$, the spectrum of G_c, is identical with Σ^c. Let us consider the ordinary differential equation on $\mathbb{C}^d$

$$z'(t) = G_c z(t) + H_c f_\delta(\Phi z(t) + F_{*,\delta}(\Phi z(t))), \tag{CE_δ}$$

where H_c is the $d \times m$ matrix given by

$$H_c x := \lim_{n\to\infty} \langle\!\langle \Psi, \Gamma^n x \rangle\!\rangle, \quad x \in \mathbb{C}^m.$$

We call Eq. (CE_δ) the *central equation* of Eq. (E_δ) (cf. [23, Subsection 3.2]).

Proposition 3.1. *Let $z(t)$ be a solution of Eq. (CE_δ) with $z(t_0) = z_0$ defined on an interval J, and $x(t)$ the solution of Eq. (E_δ) with $x_{t_0} = \Phi z_0 + F_{*,\delta}(\Phi z_0)$. Then $\Phi z(t) + F_{*,\delta}(\Phi z(t))$ is the segment of $x(t)$, that is,*

$$x_t(t_0, \Phi z_0 + F_{*,\delta}(\Phi z_0), f_\delta) = \Phi z(t) + F_{*,\delta}(\Phi z(t)), \quad t \in J.$$

Proof. Put $\hat{\phi} := \Phi z_0 + F_{*,\delta}(\Phi z_0))$, and let $\hat{z}(t)$ be the function determined by $\Phi\hat{z}(t) = \Pi^c x_t(t_0, \hat{\phi}, f_\delta)$. Then, by virtue of [21, Proposition 7], $\hat{z}(t)$ is a solution of

$$z'(t) = G_c z(t) + H_c f_\delta(\Phi z(t) + \Pi^{su} x_t(t_0, \hat{\phi}, f_\delta)).$$

Moreover, it follows from Proposition 2.5 (ii) that $\Pi^{su} x_t(t_0, \hat{\phi}, f_\delta) = F_{*,\delta}(\Pi^c x_t(t_0, \hat{\phi}, f_\delta)) = F_{*,\delta}(\Phi\hat{z}(t))$. Hence, $\hat{z}(t)$ is the solution of (CE_δ) with $\Phi\hat{z}(t_0) = \Pi^c\hat{\phi} = \Phi z_0$, i.e., $\hat{z}(t_0) = z_0$, so that $z(t) = \hat{z}(t)$ $(t \in J)$ due to the uniqueness of solutions of (CE_δ). Consequently, $x_t(t_0, \hat{\phi}, f_\delta) = \Pi^c x_t(t_0, \hat{\phi}, f_\delta) + \Pi^{su} x_t(t_0, \hat{\phi}, f_\delta) = \Phi z(t) + F_{*,\delta}(\Phi z(t))$ $(t \in J)$. □

One of our main results is the following reduction principle for the modified integral equation (E_δ).

Theorem 3.2. *Assume that $f \in C^1(X; \mathbb{C}^m)$ with $f(0) = Df(0) = 0$, and furthermore that $\Sigma^u = \emptyset$. Then for small $\delta > 0$ the following statements hold.*

(a) *Let β be a positive number satisfying $\varepsilon < \beta < \alpha$. If $x(t)$ is a solution of Eq. (E_δ) defined on $J := [t_0, \infty)$, then there exists a unique solution $z(t)$ of Eq. (CE_δ) on J satisfying*

$$\begin{aligned} \|\Pi^c x_t - \Phi z(t)\|_X &\leq C_0 \|\Pi^s x_{t_0} - F_{*,\delta}(\Phi z(t_0))\|_X e^{-\beta(t-t_0)}, \\ \|\Pi^s x_t - F_{*,\delta}(\Phi z(t))\|_X &\leq C_0 \|\Pi^s x_{t_0} - F_{*,\delta}(\Phi z(t_0))\|_X e^{-\beta(t-t_0)} \end{aligned} \tag{3.1}$$

for $t \in J$, where $C_0 > C$ is a constant which can be chosen as close to C as one expects by taking δ small. In particular, we have the estimate

$$\|x_t - x_t(t_0, \hat{\phi}, f_\delta)\|_X \leq 2C_0 \|\Pi^s x_{t_0} - F_{*,\delta}(\Phi z(t_0))\|_X e^{-\beta(t-t_0)}, \quad t \in J, \tag{3.2}$$

where $\hat{\phi} = \Phi z(t_0) + F_{*,\delta}(\Phi z(t_0)) \in W^c_\delta(0)$.

(b) *If the zero solution of Eq.* (CE_δ) *is stable (resp. asymptotically stable, unstable), the zero solution of Eq.* (E_δ) *is stable (resp. asymptotically stable, unstable).*

As a corollary, we obtain the following theorem for Eq. (*E*).

Theorem 3.3. *Assume that* $f \in C^1(X;\mathbb{C}^m)$ *with* $f(0) = Df(0) = 0$, *and furthermore that* $\Sigma^u = \emptyset$. *Then the following statements hold.*

(a) *Let* β *be a positive number satisfying* $\varepsilon < \beta < \alpha$. *Then there exists an open neighborhood* Ω_0 *of* 0 *in* X *such that if* $x(t)$ *is a solution of Eq.* (*E*) *defined on* $J := [t_0, t_1]$ *satisfying* $x_t \in \Omega_0$ *for* $t \in J$, *then there exists a solution* $z(t)$ *of Eq.* (CE) *on* J *with the property*

$$\begin{aligned} \|\Pi^c x_t - \Phi z(t)\|_X &\le C_0 \|\Pi^s x_{t_0} - F_*(\Phi z(t_0))\|_X e^{-\beta(t-t_0)}, \\ \|\Pi^s x_t - F_*(\Phi z(t))\|_X &\le C_0 \|\Pi^s x_{t_0} - F_*(\Phi z(t_0))\|_X e^{-\beta(t-t_0)} \end{aligned} \tag{3.3}$$

for $t \in J$, *where* $C_0 > C$ *is a constant which can be chosen as close to* C *as one expects by taking* Ω_0 *small. In particular, we have the estimate*

$$\|x_t - x_t(t_0, \phi^0, f)\|_X \le 2C_0 \|\Pi^s x_{t_0} - F_*(\Phi z(t_0))\|_X e^{-\beta(t-t_0)}, \quad t \in J, \tag{3.4}$$

where $\phi^0 = \Phi z(t_0) + F_*(\Phi z(t_0)) \in W^c_{\mathrm{loc}}(0)$.

(b) *If the zero solution of Eq.* (CE) *is stable (resp. asymptotically stable, unstable), the zero solution of Eq.* (*E*) *is stable (resp. asymptotically stable, unstable).*

Remark 3.4. Since Eq. (E_δ) is autonomous, it follows that $x_t(t_0, \phi, f_\delta) = x_{t-t_0}(0, \phi, f_\delta)$ for $t \ge t_0$. So it is sufficient to prove part (a) of Theorem 3.2 in case that $t_0 = 0$; and likewise for that of Theorem 3.3. Also, by the same reasoning stability (resp. asymptotic stability) in statement (b) of each theorem means actually uniform stability (resp. uniform asymptotic stability).

For the proof of part (a) of Theorem 3.2 we need the following lemma, which is a modification of [23, Lemma 1].

Lemma 3.5. *The solutions of Eq.* (E_δ) *satisfying* (3.1) *with* $t_0 = 0$ *are characterized by a system of integral equations in* X; *more precisely,*

(i) *Suppose that* $x(t)$ *is a solution of Eq.* (E_δ) *defined on* $\mathbb{R}^+$ *such that there exists a solution* $z(t)$ *of Eq.* (CE_δ) *with the properties*

$$\sup_{t\in\mathbb{R}^+} \|\Pi^c x_t - \Phi z(t)\|_X e^{-\beta t} < \infty, \text{ and } \sup_{t\in\mathbb{R}^+} \|\Pi^s x_t - F_{*,\delta}(\Phi z(t))\|_X e^{-\beta t} < \infty. \tag{3.5}$$

Then the X*-valued functions* $\xi(t)$ *and* $y(t)$ *defined by*

$$\xi(t) := \Pi^c x_t - \Phi z(t) \quad \text{and} \quad y(t) := \Pi^s x_t,$$

respectively satisfy

$$y(t) = T^s(t)\phi^s + \lim_{n\to\infty} \int_0^t T^s(t-s)\Pi^s \Gamma^n f_\delta\big(\Phi z(s) + \xi(t) + y(s)\big) ds, \tag{3.6}$$

$$\xi(t) = -\lim_{n\to\infty} \int_t^\infty T^c(t-s)\Gamma^n \Pi^c g_\delta(s) ds \tag{3.7}$$

for $t \in \mathbb{R}^+$, *where* $\phi := \Phi z(0) + \Pi^s x_0$ *and* $g_\delta(t)$ *is the function defined by*

$$g_\delta(t) := f_\delta\big(\Phi z(t) + \xi(t) + y(t)\big) - f_\delta\big(\Phi z(t) + F_{*,\delta}(\Phi z(t))\big)$$

for $t \in \mathbb{R}^+$. *Moreover* ξ *and* y *belong to* $C((0,\infty); X_0)$.

(ii) *Conversely, suppose that* $z(t)$ *is a solution of Eq.* (CE_δ), *and that* ξ *and* y *are elements of* $C(\mathbb{R}^+;X)$ *with the properties*

$$\sup_{t\in\mathbb{R}^+}\|\xi(t)\|_X e^{\beta t}<\infty,\quad \textit{and}\quad \sup_{t\in\mathbb{R}^+}\|y(t)-F_{*,\delta}(\Phi z(t))\|_X e^{\beta t}<\infty \tag{3.8}$$

which satisfy (3.6) *and* (3.7), *where* $\phi:=\Phi z(0)+y(0)$. *Then* ξ *and* y *belong to* $C((0,\infty);X_0)$ *and the function* $x(t)$ *defined by*

$$x(t):=\begin{cases}\big(\Phi z(t)+\xi(t)+y(t)\big)[0], & t>0;\\ \big(\Phi z(0)+\xi(0)+y(0)\big)(t), & t\le 0\end{cases}$$

is a solution of Eq. (E_δ) *on* $\mathbb{R}^+$ *that satisfies* (3.5) *and* $x_t=\Phi z(t)+\xi(t)+y(t)$ *for* $t\in\mathbb{R}^+$.

Proof. (i) We know by VCF (Theorem 2.1)

$$x_t=T(t-\tau)x_\tau+\lim_{n\to\infty}\int_\tau^t T(t-s)\Gamma^n f_\delta(x_s)ds,\quad t\ge\tau\ge 0, \tag{3.9}$$

and hence it follows that

$$y(t)=T^s(t)y(0)+\lim_{n\to\infty}\int_0^t T^s(t-s)\Pi^s\Gamma^n f_\delta\big(\Phi z(s)+\xi(s)+y(s)\big)ds, \tag{3.10}$$

where we used the relation $x_t=\Phi z(t)+\xi(t)+y(t)$ for $t\in\mathbb{R}^+$. By the definition of ϕ one can readily see $\phi^s=y(0)$ to get (3.6). Also, (3.9) yields

$$\Pi^c x_t=T^c(t-\tau)\Pi^c x_\tau+\lim_{n\to\infty}\int_\tau^t T^c(t-s)\Pi^c\Gamma^n f_\delta(x_s)ds.$$

Since, by Proposition 3.1, $\Phi z(t)+F_{*,\delta}(\Phi z(t))$ is the segment of the solution of Eq. (E_δ) through $(0,\phi^c+F_{*,\delta}(\phi^c))$, we deduce from VCF that

$$\Phi z(t)=T^c(t-\tau)\Phi z(\tau)+\lim_{n\to\infty}\int_\tau^t T^c(t-s)\Pi^c\Gamma^n f_\delta\big(\Phi z(s)+F_{*,\delta}(\Phi z(s))\big)ds. \tag{3.11}$$

So, $\xi(t)$ satisfies

$$\xi(t)=T^c(t-\tau)\xi(\tau)+\lim_{n\to\infty}\int_\tau^t T^c(t-s)\Pi^c\Gamma^n g_\delta(s)ds. \tag{3.12}$$

The group property of $\{T^c(t)\}_{t\in\mathbb{R}}$, then implies

$$\xi(\tau)=T^c(\tau-t)\xi(t)-\lim_{n\to\infty}\int_\tau^t T^c(\tau-s)\Pi^c\Gamma^n g_\delta(s)ds,\quad t\ge\tau\ge 0. \tag{3.13}$$

On the other hand, by the assumption (3.5) there exists a constant $C_*\ge 0$ such that $\|\xi(t)\|_X\le C_*e^{-\beta t}$ and $\|y(t)-F_{*,\delta}(\Phi z(t))\|_X\le C_*e^{-\beta t}$ for $t\in\mathbb{R}^+$; it follows from Theorem 2.3 that

$$\|T^c(\tau-t)\xi(t)\|_X\le Ce^{\varepsilon|\tau-t|}C_*e^{-\beta t}=CC_*e^{-\varepsilon\tau}e^{-(\beta-\varepsilon)t},\quad t\ge\tau.$$

Letting $t\to\infty$ in (3.13), we see

$$\xi(\tau)=-\lim_{t\to\infty}\lim_{n\to\infty}\int_\tau^t T^c(\tau-s)\Pi^c\Gamma^n g_\delta(s)ds.$$

Moreover, by Proposition 2.5 we have

$$\|g_\delta(s)\|_X \le \zeta_*(\delta)\|\xi(s) + y(s) - F_{*,\delta}(\Phi z(s))\|_X \le 2\zeta_*(\delta)C_* e^{-\beta s},$$

and hence

$$\|T^c(\tau - s)\Pi^c\Gamma^n g_\delta(s)\|_X \le 2CC_1C_*\zeta_*(\delta)e^{-\varepsilon\tau-(\beta-\varepsilon)s}, \quad s \ge \tau.$$

This means that $\int_\tau^\infty T^c(\tau - s)\Pi^c\Gamma^n g_\delta(s)ds$ is convergent in X uniformly in n; and in particular that

$$\left\| \int_t^\infty T^c(\tau - s)\Pi^c\Gamma^n g_\delta(s)ds \right\|_X \le C(\delta)e^{-(\beta-\varepsilon)(t-\tau)}, \quad t \ge \tau,$$

where $C(\delta) := 2CC_1C_*\zeta_*(\delta)/(\beta - \varepsilon)$. Thus, for $n, m \in \mathbb{N}$

$$\begin{aligned}
&\left\| \int_\tau^\infty T^c(\tau - s)\Pi^c\Gamma^n g_\delta(s)ds - \int_\tau^\infty T^c(\tau - s)\Pi^c\Gamma^m g_\delta(s)ds \right\|_X \\
&\quad \le \left\| \int_t^\infty T^c(\tau - s)\Pi^c\Gamma^n g_\delta(s)ds \right\|_X + \left\| \int_t^\infty T^c(\tau - s)\Pi^c\Gamma^m g_\delta(s)ds \right\|_X \\
&\qquad + \left\| \int_\tau^t T^c(\tau - s)\Pi^c\Gamma^n g_\delta(s)ds - \int_\tau^t T^c(\tau - s)\Pi^c\Gamma^m g_\delta(s)ds \right\|_X \\
&\quad \le 2C(\delta)e^{-(\beta-\varepsilon)(t-\tau)} + \left\| T^c(\tau - t)\left(\int_\tau^t T^c(t - s)\Pi^c\Gamma^n g_\delta(s)ds - \int_\tau^t T^c(t - s)\Pi^c\Gamma^m g_\delta(s)ds \right) \right\|_X.
\end{aligned}$$

Notice that $\lim_{n\to\infty} \int_\tau^t T^c(t - s)\Pi^c\Gamma^n g_\delta(s)ds = \Pi^c x_t(\tau, 0, g_\delta)$ (Theorem 2.1), which yields

$$\limsup_{n,m\to\infty} \left\| \int_\tau^\infty T^c(\tau - s)\Pi^c\Gamma^n g_\delta(s)ds - \int_\tau^\infty T^c(\tau - s)\Pi^c\Gamma^m g_\delta(s)ds \right\|_X \le 2C(\delta)e^{-(\beta-\varepsilon)(t-\tau)}.$$

Since $t \ge \tau$ is arbitrary, $\int_\tau^\infty T^c(\tau - s)\Gamma^n g_\delta(s)ds$ turns out to converge in X as $n \to \infty$.

Consequently, the argument in the last paragraph gives

$$\begin{aligned}
\lim_{n\to\infty} \int_\tau^\infty T^c(\tau - s)\Gamma^n g_\delta(s)ds &= \lim_{n\to\infty} \lim_{t\to\infty} \int_\tau^t T^c(\tau - s)\Gamma^n g_\delta(s)ds \\
&= \lim_{t\to\infty} \lim_{n\to\infty} \int_\tau^t T^c(\tau - s)\Gamma^n g_\delta(s)ds = -\xi(\tau), \quad \tau \in \mathbb{R}^+,
\end{aligned}$$

i.e., (3.7) holds. In view of (3.10) and (3.12), combined with the fact that $\xi \in C(\mathbb{R}^+; E^c)$ and $y \in C(\mathbb{R}^+; E^s)$, the latter part of (i) immediately follows from Theorem 2.2 or [21, Theorem 4].

(ii) We observe from the assumption (3.7) that (3.12) holds for $t \ge \tau \ge 0$. So, by the same reasoning as the proof of the latter part of (i), we see that ξ and y belong to $C((0,\infty); X_0)$. Now set $u(t) := \Phi z(t) + \xi(t) + y(t)$. Adding (3.6), (3.11) and (3.12) with $\tau = 0$, and using $y(0) = \phi^s$, we have

$$\begin{aligned}
u(t) &= T(t)(\Phi z(0) + \xi(0) + y(0)) + \lim_{n\to\infty} \int_0^t T(t - s)\Gamma^n f_\delta\big(\Phi z(s) + \xi(s) + y(s)\big)ds \\
&= T(t)u(0) + \lim_{n\to\infty} \int_0^t T(t - s)\Gamma^n f_\delta(u(s))ds, \quad t \in \mathbb{R}^+.
\end{aligned}$$

Then, Theorem 2.2 implies $x(t) = \big(u(t)\big)[0] \equiv x(t; 0, u(0), f_\delta)$ and $x_t = u(t) = \Phi z(t) + \xi(t) + y(t)$ for $t \in \mathbb{R}^+$. Thus, $x(t)$ is a solution of Eq. (E_δ) defined on $\mathbb{R}^+$ with $\Pi^c x_t - \Phi z(t) = \xi(t)$ and $\Pi^s x_t = y(t)$ for $t \in \mathbb{R}^+$. Therefore, the assertion of (ii) directly follows from (3.8). □

Assume that $\delta > 0$ is small enough such that

$$K_\delta := CC_1\zeta_*(\delta) \le \min\left((\alpha-\beta)/2,\ (\beta-\varepsilon)/4\right) \tag{3.14}$$

holds as well as

$$K_\delta(1+L(\delta)) < \varepsilon. \tag{3.15}$$

We will give preparatory propositions below so as to prove Theorem 3.2. Given $\phi \in X$, denote by $z(t,\phi)$, $t \in \mathbb{R}^+$, the solution of Eq.(CE_δ) with $\Phi z(0) = \phi^c$. One can see $z(t,\phi)$ satisfies

$$\Phi z(t,\phi) = T^c(t)\phi^c + \lim_{n\to\infty}\int_0^t T^c(t-s)\Pi^c\Gamma^n f_\delta\big(\Phi z(s,\phi) + F_{*,\delta}(\Phi z(s,\phi)\big)ds \tag{3.16}$$

for $t \in \mathbb{R}^+$ (see (3.11)). Then we have:

Proposition 3.6. *Let $\phi \in X$ and $\xi \in C(\mathbb{R}^+;E^c)$ with $\sup_{t\in\mathbb{R}^+}\|\xi(t)\|_X e^{\beta t} < \infty$. Then there exists one and only one $y \in C(\mathbb{R}^+;E^s)$ that satisfies*

$$y(t) = T^s(t)\phi^s + \lim_{n\to\infty}\int_0^t T^s(t-s)\Pi^s\Gamma^n f_\delta\big(\Phi z(s,\phi) + \xi(s) + y(s)\big)ds \tag{3.17}$$

for $t \in \mathbb{R}^+$.

Proof. Let η_0 be a positive number with $\eta_0 > 2\varepsilon$, and consider the Banach space

$$Z^s_{\eta_0} := BC^{-\eta_0}(\mathbb{R}^+;E^s) = \left\{y \in C(\mathbb{R}^+;E^s) : \sup_{t\in\mathbb{R}^+}\|y(s)\|_X e^{-\eta_0 t} < \infty\right\}$$

with norm $\|y\|_{Z^s_{\eta_0}} := \sup_{t\in\mathbb{R}^+}\|y(s)\|_X e^{-\eta_0 t}$ for $y \in Z^s_{\eta_0}$. Set

$$r_0 := \max\left(\|\phi\|_X,\ \sup_{t\in\mathbb{R}^+}\|\xi(t)\|_X e^{\beta t}\right),$$

and take an $r > 0$ such that

$$r > 2r_0\left\{CC_1 + K_\delta\left(\frac{1}{\alpha-\beta} + \frac{CC_1}{\alpha+2\varepsilon}\right)\right\}.$$

Now let $A_r := \overline{B}_{Z^s_{\eta_0}}(r)$, and for each $y \in A_r$ define $\mathcal{G}_{\phi,\xi}(y) \in C(\mathbb{R}^+;E^s)$ by

$$\big(\mathcal{G}_{\phi,\xi}(y)\big)(t) := T^s(t)\phi^s + \lim_{n\to\infty}\int_0^t T^s(t-s)\Pi^s\Gamma^n f_\delta\big(\Phi z(s,\phi) + \xi(s) + y(s)\big)ds \tag{3.18}$$

for $t \in \mathbb{R}^+$. Then, $\mathcal{G}_{\phi,\xi} : y \longmapsto \mathcal{G}_{\phi,\xi}(y)$ is a contraction map from A_r to itself. Indeed, by (3.16) and Proposition 2.5 we have

$$\begin{aligned}\|\Phi z(t,\phi)\|_X &\le Ce^{\varepsilon t}\|\phi^c\|_X + \int_0^t CC_1\zeta_*(\delta)e^{\varepsilon(t-s)}\|\Phi z(s,\phi) + F_{*,\delta}(\Phi z(s,\phi)\|_X ds\\ &\le Ce^{\varepsilon t}\|\phi^c\|_X + \int_0^t K_\delta(1+L(\delta))e^{\varepsilon(t-s)}\|\Phi z(s,\phi)\|_X ds,\end{aligned}$$

or equivalently, by (3.15)

$$e^{-\varepsilon t}\|\Phi z(t,\phi)\|_X \le C\|\phi^c\|_X + \int_0^t \varepsilon e^{-\varepsilon s}\|\Phi z(s,\phi)\|_X ds,$$

so that Gronwall's inequality yields

$$\|\Phi z(t,\phi)\|_X \le C\|\phi^c\|_X e^{2\varepsilon t}, \quad t \in \mathbb{R}^+.$$

Thus, for $y \in A_r$,

$$\|(\mathcal{G}_{\phi,\xi}(y))(t)\|_X \le C\|\phi^s\|_X e^{-\alpha t} + \int_0^t K_\delta e^{-\alpha(t-s)}(C\|\phi^c\|_X e^{2\varepsilon s} + r_0 e^{-\beta s} + re^{\eta_0 s})ds,$$

and hence

$$\begin{aligned}\|(\mathcal{G}_{\phi,\xi}(y))(t)\|_X e^{-\eta_0 t} &\le CC_1 r_0 + K_\delta\Big(\frac{CC_1 r_0}{\alpha+2\varepsilon} + \frac{r_0}{\alpha-\beta} + \frac{r}{\alpha+\eta_0}\Big)\\ &\le \frac{r}{2} + \frac{K_\delta r}{\alpha+\eta_0} \le r, \quad t \in \mathbb{R}^+.\end{aligned}$$

Therefore $\mathcal{G}_{\phi,\xi}(y) \in A_r$; so, we have $\mathcal{G}_{\phi,\xi}(A_r) \subset A_r$. Next, let y_1, $y_2 \in A_r$ be given. Then

$$\begin{aligned}\|(\mathcal{G}_{\phi,\xi}(y_1))(t) - (\mathcal{G}_{\phi,\xi}(y_2))(t)\|_X &\le \int_0^t K_\delta e^{-\alpha(t-s)}\|y_1(s) - y_2(s)\|_X ds\\ &\le \int_0^t K_\delta e^{-\alpha(t-s)}\|y_1 - y_2\|_{Z^s_{\eta_0}} e^{\eta_0 s} ds \le \frac{K_\delta}{\alpha+\eta_0}\|y_1 - y_2\|_{Z^s_{\eta_0}} e^{\eta_0 t}, \quad t \in \mathbb{R}^+,\end{aligned}$$

which, combined with (3.14), implies

$$\|\mathcal{G}_{\phi,\xi}(y_1) - \mathcal{G}_{\phi,\xi}(y_2)\|_{Z^s_{\eta_0}} \le \frac{1}{2}\|y_1 - y_2\|_{Z^s_{\eta_0}}.$$

Consequently, $\mathcal{G}_{\phi,\xi}$ is a contraction map from A_r to itself; hence, it has a unique fixed point in A_r, which is a solution of Eq. (3.17) on $\mathbb{R}^+$. This proves the proposition since r can be chosen arbitrarily large. □

Let us denote by $y(\phi,\xi)(t)$ the solution of Eq. (3.17).

Proposition 3.7. *If $\phi \in X$ and $\xi \in C(\mathbb{R}^+; E^c)$ with $\sup_{t\in\mathbb{R}^+}\|\xi(t)\|_X e^{\beta t} < \infty$, then we have for $t \in \mathbb{R}^+$*

$$\|y(\phi,\xi)(t) - F_{*,\delta}(\Phi z(t,\phi))\|_X \le \Big(C\|\phi^s - F_{*,\delta}(\phi^c)\|_X + \sup_{\tau\in\mathbb{R}^+}\|\xi(\tau)\|_X e^{\beta\tau}\Big)e^{-\beta t}.$$

Proof. By the invariance of the center manifold $W^c_\delta(0)$ (Theorem 2.4) and VCF,

$$\begin{aligned}F_{*,\delta}(\Phi z(t,\phi)) &= \Pi^s x_t(0, \phi^c + F_{*,\delta}(\phi^c), f_\delta)\\ &= T^s(t)F_{*,\delta}(\phi^c) + \lim_{n\to\infty}\int_0^t T^s(t-s)\Pi^s\Gamma^n f_\delta\big(\Phi z(s,\phi) + F_{*,\delta}(\Phi z(s,\phi))\big)ds.\end{aligned}$$

Since $y(\phi,\xi) = \mathcal{G}_{\phi,\xi}(y(\phi,\xi))$, we have

$$\begin{aligned}y(\phi,\xi)(t) - F_{*,\delta}(\Phi z(t,\phi)) = T^s(t)(\phi^s - F_{*,\delta}(\phi^c)) + \lim_{n\to\infty}\int_0^t T^s(t-s)\Pi^s\Gamma^n\big\{f_\delta\big(\Phi z(s,\phi)\\ + \xi(s) + y(\phi,\xi)(s)\big) - f_\delta\big(\Phi z(s,\phi) + F_{*,\delta}(\Phi z(s,\phi))\big)\big\}ds,\end{aligned}$$

and therefore

$$\begin{aligned}
&\|y(\phi,\xi)(t) - F_{*,\delta}(\Phi z(t,\phi))\|_X \\
&\quad \le Ce^{-\alpha t}\|\phi^s - F_{*,\delta}(\phi^c)\|_X + \int_0^t K_\delta e^{-\alpha(t-s)}(\|\xi(s)\|_X + \|y(\phi,\xi)(s) - F_{*,\delta}(\Phi z(s,\phi))\|_X)ds \\
&\quad \le Ce^{-\alpha t}\|\phi^s - F_{*,\delta}(\phi^c)\|_X + \int_0^t K_\delta e^{-\alpha(t-s)}\big(\sup_{\tau\in\mathbb{R}^+}\|\xi(\tau)\|_X e^{\beta\tau}\big)e^{-\beta s}ds \\
&\qquad + \int_0^t K_\delta e^{-\alpha(t-s)}\|y(\phi,\xi)(s) - F_{*,\delta}(\Phi z(s,\phi))\|_X ds.
\end{aligned}$$

By an application of Lemma 3.8 below, combined with (3.14), we obtain

$$\begin{aligned}
&\|y(\phi,\xi)(t) - F_{*,\delta}(\Phi z(t,\phi))\|_X \\
&\quad \le C\|\phi^s - F_{*,\delta}(\phi^c)\|_X e^{-(\alpha-K_\delta)t} + \frac{K_\delta}{\alpha-\beta-K_\delta}\big(\sup_{\tau\in\mathbb{R}^+}\|\xi(\tau)\|_X e^{\beta\tau}\big)e^{-\beta t} \\
&\quad \le \big(C\|\phi^s - F_{*,\delta}(\phi^c)\|_X + \sup_{\tau\in\mathbb{R}^+}\|\xi(\tau)\|_X e^{\beta\tau}\big)e^{-\beta t}, \quad t\in\mathbb{R}^+,
\end{aligned}$$

which proves the assertion. □

The following lemma is an analogue of [23, Lemma 2] and we omit the proof.

Lemma 3.8. *Let $g, r \in C(\mathbb{R}^+;\mathbb{R})$ and $h \in C^1(\mathbb{R}^+;\mathbb{R})$ satisfy $r(t) \ge 0$ $(t\in\mathbb{R}^+)$ and*

$$g(t) \le h(t) + \int_0^t r(s)g(s)ds, \quad t\in\mathbb{R}^+.$$

Then we have

$$g(t) \le h(0)\exp\left(\int_0^t r(s)ds\right) + \int_0^t h'(s)\exp\left(\int_s^t r(u)du\right)ds, \quad t\in\mathbb{R}^+.$$

Let Z^c_β be the Banach space defined by

$$Z^c_\beta := BC^\beta(\mathbb{R}^+;E^c) = \{\xi\in C(\mathbb{R}^+;E^c) : \sup_{t\in\mathbb{R}^+}\|\xi(t)\|_X e^{\beta t} < \infty\},$$

with norm $\|\xi\|_{Z^c_\beta} := \sup_{t\in\mathbb{R}^+}\|\xi(t)\|_X e^{\beta t}$. Also, set

$$h_\delta(t,\phi,\xi) := f_\delta\big(\Phi z(t,\phi) + \xi(t) + y(\phi,\xi)(t)\big) - f_\delta\big(\Phi z(t,\phi) + F_{*,\delta}(\Phi z(t,\phi))\big)$$

for $t\in\mathbb{R}^+$, $\phi\in X$ and $\xi\in Z^c_\beta$.

Proposition 3.9. *For each $\phi\in X$ the equation*

$$\xi(t) = -\lim_{n\to\infty}\int_t^\infty T^c(t-s)\Pi^c\Gamma^n h_\delta(s,\phi,\xi)ds, \quad t\in\mathbb{R}^+ \tag{3.19}$$

has a unique solution in Z^c_β.

Proof. Let $r_0 > \|\phi\|_X$, and take a positive number r_1 satisfying

$$r_1 > \frac{1}{2}CC_1(1+L(\delta))r_0. \tag{3.20}$$

We define a map $\mathcal{H} : \overline{B}_X(r_0) \times \overline{B}_{Z^c_\beta}(r_1) \to C(\mathbb{R}^+; E^c)$ by

$$(\mathcal{H}(\phi,\xi))(t) := -\lim_{n\to\infty}\int_t^\infty T^c(t-s)\Pi^c\Gamma^n h_\delta(s,\phi,\xi)ds$$

for $t \in \mathbb{R}^+$, $\phi \in \overline{B}_X(r_0)$, and $\xi \in \overline{B}_{Z^c_\beta}(r_1)$. In view of Proposition 3.7,

$$\begin{aligned}\|h_\delta(s,\phi,\xi)\|_X &\le \zeta_*(\delta)\big(\|\xi\|_X + \|y(\phi,\xi)(s) - F_{*,\delta}(\Phi z(s,\phi))\|_X\big)\\ &\le \zeta_*(\delta)\big\{\|\xi\|_{Z^c_\beta}e^{-\beta s} + \big(C\|\phi^s - F_{*,\delta}(\phi^c)\|_X + \|\xi\|_{Z^c_\beta}\big)e^{-\beta s}\big\}\\ &= \zeta_*(\delta)\big(CC_1(1+L(\delta))\|\phi\|_X + 2\|\xi\|_{Z^c_\beta}\big)e^{-\beta s},\end{aligned} \tag{3.21}$$

and therefore

$$\begin{aligned}\|(\mathcal{H}(\phi,\xi))(t)\|_X &\le \int_t^\infty K_\delta e^{-\varepsilon(t-s)}\big(CC_1(1+L(\delta))\|\phi\|_X + 2\|\xi\|_{Z^c_\beta}\big)e^{-\beta s}ds\\ &\le \frac{K_\delta}{\beta-\varepsilon}(CC_1(1+L(\delta))r_0 + 2r_1)e^{-\beta t} \le r_1 e^{-\beta t}\end{aligned} \tag{3.22}$$

for $t \in \mathbb{R}^+$, where we used (3.14) and (3.20). So, $\mathcal{H}(\phi,\xi)$ belongs to Z^c_β with $\|\mathcal{H}(\phi,\xi)\|_{Z^c_\beta} \le r_1$; hence for each $\phi \in \overline{B}_X(r_0)$, $\mathcal{H}(\phi,\cdot)$ defines a map from $\overline{B}_{Z^c_\beta}(r_1)$ to itself. We will prove the proposition by showing that $\mathcal{H}(\phi,\cdot)$ is a contraction map. Indeed, let $\xi_1, \xi_2 \in \overline{B}_{Z^c_\beta}(r_1)$. Then

$$\begin{aligned}&\|(\mathcal{H}(\phi,\xi_1))(t) - (\mathcal{H}(\phi,\xi_2))(t)\|_X\\ &\quad\le \int_t^\infty K_\delta e^{-\varepsilon(t-s)}(\|\xi_1(s) - \xi_2(s)\|_X + \|y(\phi,\xi_1)(s) - y(\phi,\xi_2)(s)\|_X)ds.\end{aligned} \tag{3.23}$$

We know $y(\phi,\xi_i) = \mathcal{G}_{\phi,\xi_i}(y(\phi,\xi_i))$ $(i = 1,2)$, so that

$$\begin{aligned}y(\phi,\xi_1)(t) - y(\phi,\xi_2)(t) = \lim_{n\to\infty}\int_0^t T^s(t-s)\Pi^s\Gamma^n\big\{&f_\delta\big(\Phi z(s,\phi) + \xi_1(s) + y(\phi,\xi_1)(s)\big)\\ &- f_\delta\big(\Phi z(s,\phi) + \xi_2(s) + y(\phi,\xi_2(s))\big)\big\}ds.\end{aligned}$$

Hence

$$\begin{aligned}&\|y(\phi,\xi_1)(t) - y(\phi,\xi_2)(t)\|_X\\ &\quad\le \int_0^t K_\delta e^{-\alpha(t-s)}(\|\xi_1(s) - \xi_2(s)\|_X + \|y(\phi,\xi_1)(s) - y(\phi,\xi_2)(s)\|_X)ds\\ &\quad\le \int_0^t K_\delta e^{-\alpha(t-s)}\|\xi_1 - \xi_2\|_{Z^c_\beta}e^{-\beta s}ds + \int_0^t K_\delta e^{-\alpha(t-s)}\|y(\phi,\xi_1)(s) - y(\phi,\xi_2)(s)\|_X ds,\end{aligned}$$

that is,

$$\begin{aligned}&e^{\alpha t}\|y(\phi,\xi_1)(t) - y(\phi,\xi_2)(t)\|_X\\ &\quad\le \int_0^t K_\delta\|\xi_1 - \xi_2\|_{Z^c_\beta}e^{(\alpha-\beta)s}ds + \int_0^t K_\delta e^{\alpha s}\|y(\phi,\xi_1)(s) - y(\phi,\xi_2)(s)\|_X ds\end{aligned}$$

holds for $t \in \mathbb{R}^+$. It follows from Lemma 3.8 and (3.14) that

$$\|y(\phi,\xi_1)(t) - y(\phi,\xi_2)(t)\|_X \le \frac{K_\delta}{\alpha-\beta-K_\delta}\|\xi_1 - \xi_2\|_{Z^c_\beta}e^{-\beta t} \le \|\xi_1 - \xi_2\|_{Z^c_\beta}e^{-\beta t}, \quad t \in \mathbb{R}^+.$$

Consequently, we see from (3.23) that

$$\begin{aligned}\|(\mathcal{H}(\phi,\xi_1))(t)-(\mathcal{H}(\phi,\xi_2))(t)\|_X &\le \int_t^\infty K_\delta e^{-\varepsilon(t-s)}\,2\|\xi_1-\xi_2\|_{Z^c_\beta}e^{-\beta s}ds\\ &= \frac{2K_\delta}{\beta-\varepsilon}\|\xi_1-\xi_2\|_{Z^c_\beta}e^{-\beta t},\quad t\in\mathbb{R}^+,\end{aligned}$$

which, together with (3.14), implies

$$\|\mathcal{H}(\phi,\xi_1)-\mathcal{H}(\phi,\xi_2)\|_{Z^c_\beta}\le\frac{1}{2}\|\xi_1-\xi_2\|_{Z^c_\beta}.$$

Thus, $\mathcal{H}(\phi,\cdot)$ is a contraction map from $\overline{B}_{Z^c_\beta}(r_1)$ to itself; and therefore has a unique fixed point in $\overline{B}_{Z^c_\beta}(r_1)$ for $\phi\in\overline{B}_X(r_0)$. Since one can choose r_1 arbitrarily large, the proposition immediately follows. □

For $\phi\in X$ denote $\xi(\phi)(t)$ the solution of Eq. (3.19).

Proposition 3.10. *Define a map $\mathcal{K}: X\to X$ by $\mathcal{K}(\phi):=\xi(\phi)(0)$, $\phi\in X$. Then $\mathcal{K}$ is continuous.*

Proof. Since Z^c_β is a subspace of the Banach space $BC(\mathbb{R}^+;E^c)$, it is sufficient to show that $\xi:\phi\longmapsto\xi(\phi)$ is continuous as a map from X to $BC(\mathbb{R}^+;E^c)$. So letting ϕ_0 be an element of X and $\{\phi_l\}\subset X$ an arbitrary sequence converging to ϕ_0, we show $\xi(\phi_l)\to\xi(\phi_0)$ in $BC(\mathbb{R}^+;E^c)$ as $l\to\infty$. The proof will be divided into several steps.

Step 1. $\{\xi(\phi_l)\}$ is relatively compact in $BC(\mathbb{R}^+;E^c)$. To confirm the assertion, take positive numbers r_0 and r_1 in such a way that $\phi_l\in B_X(r_0)$ $(l\in\mathbb{N})$ and (3.20) are satisfied. Since $\|\xi(\phi_l)(t)\|_X\le\|\xi(\phi_l)\|_{Z^c_\beta}e^{-\beta t}\le r_1e^{-\beta t}$ $(t\in\mathbb{R}^+)$ follows from the proof of Proposition 3.9, the sequence $\{\xi(\phi_l)(t)\}$ is uniformly bounded in $\mathbb{R}^+$, and is equi-convergent (to 0) as $t\to\infty$. We next verify that $\{\xi(\phi_l)(t)\}$ is equi-continuous in $\mathbb{R}^+$. Let $t_2\ge t_1\ge 0$. In view of the relation $\xi(\phi_l)=\mathcal{H}(\phi_l,\xi(\phi_l))$ (cf. Proposition 3.9),

$$\begin{aligned}\xi(\phi_l)(t_2)-\xi(\phi_l)(t_1) &= \lim_{n\to\infty}\int_{t_1}^{t_2}T^c(t_1-s)\Pi^c\Gamma^n h_\delta(s,\phi_l,\xi(\phi_l))ds\\ &\quad+\lim_{n\to\infty}\int_{t_2}^{\infty}(T^c(t_1-s)-T^c(t_2-s))\Pi^c\Gamma^n h_\delta(s,\phi_l,\xi(\phi_l))ds\\ &= \lim_{n\to\infty}\int_{t_1}^{t_2}T^c(t_1-s)\Pi^c\Gamma^n h_\delta(s,\phi_l,\xi(\phi_l))ds\\ &\quad+\lim_{n\to\infty}\int_{t_2}^{\infty}T^c(t_1-s)(I_{E^c}-T^c(t_2-t_1))\Pi^c\Gamma^n h_\delta(s,\phi_l,\xi(\phi_l))ds,\end{aligned}$$

where I_{E^c} is the identity map of E^c. Hence it follows from (3.21) and (3.20) that

$$\begin{aligned}\|\xi(\phi_l)(t_2)-\xi(\phi_l)(t_1)\|_X &\le \int_{t_1}^{t_2}CC_1e^{\varepsilon(s-t_1)}\|h_\delta(s,\phi_l,\xi(\phi_l))\|_X ds\\ &\quad+\int_{t_2}^{\infty}CC_1e^{\varepsilon(s-t_1)}\|I_{E^c}-T^c(t_2-t_1)\|\,\|h_\delta(s,\phi_l,\xi(\phi_l))\|_X ds\\ &\le \big(C\|\phi_l^s-F_{*,\delta}(\phi_l^c)\|_X+2\|\xi(\phi_l)\|_{Z^c_\beta}\big)\\ &\quad\times\left(\int_{t_1}^{t_2}K_\delta e^{\varepsilon(s-t_1)}e^{-\beta s}ds+\int_{t_2}^{\infty}K_\delta e^{\varepsilon(s-t_1)}\|T^c(t_2-t_1)-I_{E^c}\|e^{-\beta s}ds\right)\\ &\le \frac{K_\delta}{\beta-\varepsilon}\big(CC_1(1+L(\delta))r_0+2r_1\big)\big(|t_2-t_1|+\|T^c(t_2-t_1)-I_{E^c}\|_{\mathcal{L}(E^c)}\big)\\ &\le r_1\big(|t_2-t_1|+\|T^c(t_2-t_1)-I_{E^c}\|_{\mathcal{L}(E^c)}\big),\end{aligned}$$

which shows the equi-continuity in $\mathbb{R}^+$ of $\{\xi(\phi_l)(t)\}$ since E^c is a finite-dimensional subspace.

By the properties of $\{\xi(\phi_l)(t)\}$ above and the fact that $\dim E^c < \infty$, a variant of the Arzelà–Ascoli theorem yields that $\{\xi(\phi_l)\}$ is relatively compact in $BC(\mathbb{R}^+; E^c) = Z_0^c$. So there is a subsequence of $\{\phi_l\}$, denoted $\{\phi_l\}$ again, such that $\|\xi(\phi_l) - \xi_*\|_{Z_0^c} \to 0$ $(l \to \infty)$ for some $\xi_* \in BC(\mathbb{R}^+; E^c)$.

Step 2. $\{y(\phi_l, \xi(\phi_l))(t)\}$ converges to $y(\phi_0, \xi_*)(t)$ uniformly in any compact set of $\mathbb{R}^+$ as $l \to \infty$. Indeed, since $y(\phi_l, \xi(\phi_l))$ and $y(\phi_0, \xi_*)$ are the fixed points of $\mathcal{G}_{\phi_l, \xi(\phi_l)}$ and $\mathcal{G}_{\phi_0, \xi_*}$ respectively (cf. (3.18)),

$$\begin{aligned} &y(\phi_l, \xi(\phi_l))(t) - y(\phi_0, \xi_*)(t) \\ &\quad = T(t)\phi_l^s - T(t)\phi_0^s + \lim_{n\to\infty} \int_0^t T^s(t-s)\Pi^s\Gamma^n \big\{ f_\delta\big(\Phi z(s, \phi_l) + \xi(\phi_l)(s) \\ &\qquad + y(\phi_l, \xi(\phi_l)(s)\big) - f_\delta\big(\Phi z(s, \phi_0) + \xi_*(s) + y(\phi_0, \xi_*)(s)\big)\big\} ds. \end{aligned}$$

So, letting $u_l(t) := y(\phi_l, \xi(\phi_l))(t) - y(\phi_0, \xi_*)(t)$, we have

$$\begin{aligned} \|u_l(t)\|_X \le CC_1\|\phi_l - \phi_0\|_X e^{-\alpha} + \int_0^t K_\delta e^{-\alpha(t-s)} \big\{ &\|\Phi z(s, \phi_l) - \Phi z(s, \phi_0)\|_X \\ &+ \|\xi(\phi_l)(s) - \xi_*(s)\|_X + \|u_l(s)\|_X \big\} ds. \end{aligned} \tag{3.24}$$

Notice from (3.16) that

$$\|\Phi z(t, \phi_l) - \Phi z(t, \phi_0)\|_X \le Ce^{\varepsilon t}\|\phi_l^c - \phi_0^c\|_X + \int_0^t K_\delta e^{\varepsilon(t-s)}(1 + L(\delta))\|\Phi z(s, \phi_l) - \Phi z(s, \phi_0)\|_X ds;$$

then one can see from Gronwall's inequality, combined with (3.15), that

$$\|\Phi z(t, \phi_l) - \Phi z(t, \phi_0)\|_X \le C\|\phi_l^c - \phi_0^c\|_X e^{(\varepsilon + K_\delta(1+L(\delta))t} \le C\|\phi_l^c - \phi_0^c\|_X e^{2\varepsilon t}, \quad t \in \mathbb{R}^+. \tag{3.25}$$

Thus (3.24) implies

$$\begin{aligned} \|u_l(t)\|_X e^{\alpha t} \le CC_1\|\phi_l - \phi_0\|_X + \int_0^t K_\delta e^{\alpha s}(C\|\phi_l^c - \phi_0^c\|_X e^{2\varepsilon s} \\ + \|\xi(\phi_l)(s) - \xi_*(s)\|_X) ds + \int_0^t K_\delta e^{\alpha s}\|u_l(s)\|_X ds. \end{aligned}$$

By Lemma 3.8,

$$\begin{aligned} \|u_l(t)\|_X e^{\alpha t} &\le CC_1\|\phi_l - \phi_0\|_X e^{K_\delta t} + \int_0^t K_\delta e^{\alpha s}\big(C\|\phi_l^c - \phi_0^c\|_X e^{2\varepsilon s} \\ &\quad + \|\xi(\phi_l)(s) - \xi_*(s)\|_X\big) e^{K_\delta(t-s)} ds \\ &\le CC_1\|\phi_l - \phi_0\|_X e^{K_\delta t} + \frac{K_\delta C}{\alpha + 2\varepsilon - K_\delta}\|\phi_l^c - \phi_0^c\|_X e^{(\alpha+2\varepsilon)t} \\ &\quad + \frac{K_\delta}{\alpha - K_\delta}\|\xi(\phi_l) - \xi_*\|_{Z_0^c} e^{\alpha t}, \end{aligned}$$

and therefore from (3.14)

$$\|u_l(t)\|_X \le CC_1\|\phi_l - \phi_0\|_X e^{-(\alpha - K_\delta)t} + C\|\phi_l^c - \phi_0^c\|_X e^{2\varepsilon t} + \|\xi(\phi_l) - \xi_*\|_{Z_0^c}$$

holds for $t \in \mathbb{R}^+$. It follows from Step 1 that for any $\tau_* > 0$, the sequence $\{y(\phi_l, \xi(\phi_l))(t)\}$ is uniformly convergent to $y(\phi_0, \xi_*)(t)$ in $[0, \tau_*]$ as $l \to \infty$, which proves Step 2.

Step 3. ξ_* coincides with $\xi(\phi_0)$. Indeed, given positive numbers ε_* and τ, choose a τ_* in such a way that $\tau_* > \tau$ and

$$e^{-(\beta-\varepsilon)\tau_*} < \frac{\varepsilon_*}{2Cr_1} \tag{3.26}$$

hold. Observe that

$$\begin{aligned}\xi(\phi_l)(t) - \mathcal{H}(\phi_0,\xi_*)(t) = &-\lim_{n\to\infty}\int_t^{\tau_*} T^c(t-s)\Pi^c\Gamma^n(h_\delta(s,\phi_l,\xi(\phi_l)) - h_\delta(s,\phi_0,\xi_*))ds\\ &+ T^c(t-\tau_*)(\xi(\phi_l)(\tau_*) - \mathcal{H}(\phi_0,\xi_*)(\tau_*)).\end{aligned}$$

Since neither $\|\xi(\phi_l)(\tau_*)\|_X$ nor $\|\mathcal{H}(\phi_0,\xi_*)(\tau_*)\|_X$ is greater than $r_1e^{-\beta\tau_*}$ (see (3.22)), it follows from (3.26) that

$$\begin{aligned}\left\|T^c(t-\tau_*)\left(\xi(\phi_l)(\tau_*) - \mathcal{H}(\phi_0,\xi_*)(\tau_*)\right)\right\|_X &\le Ce^{\varepsilon(\tau_*-t)}(r_1e^{-\beta\tau_*} + r_1e^{-\beta\tau_*})\\ &< \varepsilon_*, \quad t\in[0,\tau_*].\end{aligned}$$

Consequently,

$$\begin{aligned}&\|\xi(\phi_l)(t) - \mathcal{H}(\phi_0,\xi_*)(t)\|_X\\ &\quad< \int_t^{\tau_*} K_\delta Ce^{\varepsilon(s-t)}\big\{(2+L(\delta))\|\Phi z(s,\phi_l) - \Phi z(s,\phi_0)\|_X\\ &\qquad+ \|\xi(\phi_l)(s) - \xi_*(s)\|_X + \|y(\phi_l,\xi(\phi_l))(s) - y(\phi_0,\xi_*)(s)\|_X\big\}ds + \varepsilon_*\\ &\quad\le \int_t^{\tau_*} K_\delta Ce^{\varepsilon(s-t)}\big\{C_1(2+L(\delta))\|\phi_l - \phi_0\|_Xe^{2\varepsilon s} + \|\xi(\phi_l) - \xi_*\|_{Z_0^c}\\ &\qquad+ \|y(\phi_l,\xi(\phi_l))(s) - y(\phi_0,\xi_*)(s)\|_X\big\}ds + \varepsilon_*\end{aligned}$$

for $0 \le t \le \tau_*$ because of (3.25). Passing to the limit as $l\to\infty$, we deduce from Steps 1 and 2 that

$$\|\xi_*(t) - \mathcal{H}(\phi_0,\xi_*)(t)\|_X = \lim_{m\to\infty}\|\xi(\phi_l)(t) - \mathcal{H}(\phi_0,\xi_*)(t)\|_X \le \varepsilon_*, \quad t\in[0,\tau].$$

Since ε_* is arbitrary, we have $\|\xi_*(t) - \mathcal{H}(\phi_0,\xi_*)(t)\|_X = 0$ for $t\in[0,\tau]$; hence ξ_* must coincide with $\mathcal{H}(\phi_0,\xi_*)$, for τ is also arbitrary. The uniqueness of fixed points of $\mathcal{H}(\phi_0,\cdot)$ then implies $\xi_* = \xi(\phi_0)$.

Step 4. The argument above shows that given a subsequence of $\{\phi_l\}$, one can choose its subsequence, say $\{\phi_{l_k}\}$, such that $\xi(\phi_{l_k})$ is convergent to $\xi(\phi_0)$ with norm $\|\cdot\|_{Z_0^c}$ as $k\to\infty$. It therefore turns out that $\{\xi(\phi_l)\}$ is itself convergent to $\xi(\phi_0)$ in $BC(\mathbb{R}^+;E^c)$. Thus, $\xi:\phi\longmapsto\xi(\phi)$ is continuous as a map from X to $BC(\mathbb{R}^+;E^c)$, which completes the proof. □

3.2 Proofs of Theorems 3.2 and 3.3

We are now able to give a proof of Theorem 3.2.

Proof of Theorem 3.2. (a) Without loss of generality, we may prove part (a) in case $t_0 = 0$ (see Remark 3.4). For each $\phi\in X$, we set $y(\phi)(t) := y(\phi,\xi(\phi))(t)$ for $t\in\mathbb{R}^+$. Then it follows from Propositions 3.6, 3.9 and 3.7 that the X-valued functions $\xi(\phi)$ and $y(\phi)$ satisfy (3.6) and (3.7) together with (3.8). Hence, by virtue of Lemma 3.5, the $\mathbb{C}^m$-valued function $x(\phi)(t)$ on $\mathbb{R}$, defined by

$$x(\phi)(t) := \begin{cases}\big(\Phi z(t,\phi) + \xi(\phi)(t) + y(\phi)(t)\big)[0], & t>0,\\ \big(\Phi z(0,\phi) + \xi(\phi)(0) + y(\phi)(0)\big)(t), & t\le 0,\end{cases}$$

is a solution of Eq. (E_δ) on $\mathbb{R}^+$, which satisfies both of

$$\|\Pi^c(x(\phi))_t - \Phi z(t,\phi)\|_X \le C_* e^{-\beta t},$$
$$\|\Pi^s(x(\phi))_t - F_{*,\delta}(\Phi z(t,\phi))\|_X \le C_* e^{-\beta t}$$

and $(x(\phi))_t = \Phi z(t,\phi) + \xi(\phi)(t) + y(\phi)(t)$ for $t \in \mathbb{R}^+$, where C_* is a nonnegative constant. So, if one can find a $\phi \in X$ with $x_0 = (x(\phi))_0$, the uniqueness of solutions for Eq. (E_δ) ensures that $x(t) \equiv x(\phi)(t)$ for $t \in \mathbb{R}^+$; so that $z(t) = z(t,\phi)$ is a solution of Eq. (CE_δ) satisfying

$$\|\Pi^c x_t - \Phi z(t)\|_X \le C_* e^{-\beta t} \quad \text{and} \quad \|\Pi^s x_t - F_{*,\delta}(\Phi z(t))\|_X \le C_* e^{-\beta t} \tag{3.27}$$

for $t \in \mathbb{R}^+$. Now consider the map $\widehat{g} : X \to X$ defined by

$$\widehat{g}(\phi) := (x(\phi))_0, \quad \phi \in X. \tag{3.28}$$

Claim 1. $\widehat{g}$ is a bijection from X to itself if $\delta > 0$ is sufficiently small.

Proof of Claim 1. We first verify the surjectivity. Note, by definition, that

$$(x(\phi))_0 = \Phi z(0,\phi) + \xi(\phi)(0) + y(\phi)(0) = \phi^c + \mathcal{K}(\phi) + \phi^s \tag{3.29}$$

for $\phi \in X$ (see also (3.16) and (3.17)), and therefore that $\widehat{g}(\phi) = \phi + \mathcal{K}(\phi)$.

Let $M(\delta) := 2CK_\delta/(\beta - \varepsilon)$ and take a δ so small that

$$C_1 M(\delta)(1 + L(\delta)) < \frac{1}{2}. \tag{3.30}$$

In the same way as (3.22), we get

$$\|\xi(\phi)\|_{Z^c_\beta} \le \frac{K_\delta}{\beta - \varepsilon}(C\|\phi^s - F_{*,\delta}(\phi^c)\|_X + 2\|\xi(\phi)\|_{Z^c_\beta})$$

and in particular by (3.14)

$$\|\mathcal{K}(\phi)\|_X \le \|\xi(\phi)\|_{Z^c_\beta} \le M(\delta)\|\phi^s - F_{*,\delta}(\phi^c)\|_X \le C_1 M(\delta)(1 + L(\delta))\|\phi\|_X. \tag{3.31}$$

Now given $\bar\phi \in \operatorname{graph} F_{*,\delta}$ and $r_0 > 0$, define $H : \overline{B}_X(\bar\phi; r_0) \times [0,1] \to X$ by

$$H(\phi,\lambda) := \phi + \lambda\mathcal{K}(\phi), \quad \phi \in \overline{B}_X(\bar\phi; r_0), \ \ \lambda \in [0,1].$$

Since $\mathcal{K}$ is continuous (Proposition 3.10), bounded on each bounded set of X, and the range of $\mathcal{K}$ is contained in E^c, which is finite-dimensional, we deduce that the map $\mathcal{K}$ is compact. In addition, observe from (3.31) and the fact $\bar\phi^s = F_{*,\delta}(\bar\phi^c)$ that

$$\begin{aligned}\|\mathcal{K}(\phi)\|_X &\le M(\delta)(\|\phi^s - \bar\phi^s\|_X + \|F_{*,\delta}(\bar\phi^c) - F_{*,\delta}(\phi^c)\|_X)\\ &\le M(\delta)(\|\phi^s - \bar\phi^s\|_X + L(\delta)\|\phi^c - \bar\phi^c\|_X)\\ &\le C_1 M(\delta)(1 + L(\delta))\|\phi - \bar\phi\|_X.\end{aligned} \tag{3.32}$$

Let $r_0 > 0$ and $\psi \in \overline{B}_X(\bar\phi; r_0/2)$, then it follows from (3.30) and (3.32) that for $\phi \in \partial B_X(\bar\phi; r_0)$ and $\lambda \in [0,1]$,

$$\begin{aligned}\|H(\phi,\lambda) - \psi\|_X &\ge \|\phi - \bar\phi\|_X - \|\psi - \bar\phi\|_X - \|\mathcal{K}(\phi)\|_X\\ &\ge \frac{r_0}{2} - C_1 M(\delta)(1 + L(\delta))r_0 > 0.\end{aligned}$$

Hence, $\deg(H(\cdot,\lambda), B_X(\bar{\phi};r_0), \psi)$, the Leray–Schauder degree ([3]) of $H(\cdot,\lambda)$, is well-defined and is independent of λ. Since H is a homotopy between $\widehat{g}$ and the identity I_X as maps from $\overline{B}_X(\bar{\phi};r_0)$ to X, it follows that

$$\deg(\widehat{g}, B_X(\bar{\phi};r_0), \psi) = \deg(I_X, B_X(\bar{\phi};r_0), \psi) = 1,$$

which shows that $\widehat{g}^{-1}(\psi) \cap B_X(\bar{\phi};r_0) \neq \emptyset$ for each $\psi \in B_X(\bar{\phi};r_0/2)$; in other words,

$$B_X(\bar{\phi};r_0/2) \subset \widehat{g}(B_X(\bar{\phi};r_0)). \tag{3.33}$$

Thus, $\widehat{g}$ is a surjection from X onto itself since $r_0 > 0$ is arbitrary.

We next prove the injectivity. Let $\delta > 0$ be so small that

$$\mu(\delta) := \frac{K_\delta(1+L(\delta))}{\beta-\varepsilon} < 1, \tag{3.34}$$

and assume that $\widehat{g}(\phi) = \widehat{g}(\tilde{\phi})$ for some ϕ and $\tilde{\phi}$ in X. Then by the definition of $\widehat{g}$ we obtain

$$\|\Pi^c x_t(0, \widehat{g}(\phi), f_\delta) - \Phi_c z(t,\phi)\|_X \le C_* e^{-\beta t}$$

and

$$\|\Pi^c x_t(0, \widehat{g}(\tilde{\phi}), f_\delta) - \Phi z(t,\tilde{\phi})\|_X \le \tilde{C}_* e^{-\beta t}$$

for $t \in \mathbb{R}^+$, where C_* and $\tilde{C}_*$ are some nonnegative constant. In particular,

$$\|\Phi z(t,\phi) - \Phi z(t,\tilde{\phi})\|_X \le C^* e^{-\beta t}, \quad t \in \mathbb{R}^+ \tag{3.35}$$

with $C^* := C_* + \tilde{C}_*$. We know by (3.16) that $\Phi z(t,\phi)$ satisfies

$$\Phi z(t,\phi) = T^c(t-\tau)\Phi z(\tau,\phi) + \lim_{n\to\infty} \int_\tau^t T^c(t-s)\Pi^c f_\delta(\Phi z(s,\phi) + F_{*,\delta}(\Phi z(s,\phi)))ds$$

for $t \ge \tau \ge 0$. So, by the group property of $\{T^c(t)\}_{t\in\mathbb{R}}$, we see

$$\Phi z(\tau,\phi) = T^c(\tau-t)\Phi z(t,\phi) - \lim_{n\to\infty} \int_\tau^t T^c(\tau-s)\Pi^c f_\delta(\Phi z(s,\phi) + F_{*,\delta}(\Phi z(s,\phi)))ds$$

and likewise for $\Phi_c z(\tau,\tilde{\phi})$. Hence it follows from (3.35) that

$$\begin{aligned}
&\|\Phi z(\tau,\phi) - \Phi z(\tau,\tilde{\phi}) - T^c(\tau-t)\big(\Phi z(t,\phi) - \Phi z(t,\tilde{\phi})\big)\|_X \\
&\quad\le \int_\tau^t K_\delta(1+L(\delta))e^{\varepsilon|\tau-s|}\|\Phi z(s,\phi) - \Phi z(s,\tilde{\phi})\|_X ds \\
&\quad\le \int_\tau^t K_\delta(1+L(\delta))e^{\varepsilon(s-\tau)}\cdot C^* e^{-\beta s} ds \le \frac{C^* K_\delta(1+L(\delta))}{\beta-\varepsilon} e^{-\beta\tau},
\end{aligned}$$

so that

$$\|\Phi z(\tau,\phi) - \Phi z(\tau,\tilde{\phi})\|_X \le CC^* e^{-\varepsilon\tau-(\beta-\varepsilon)t} + C^*\mu(\delta)e^{-\beta\tau}, \quad t \ge \tau \ge 0.$$

Passing to the limit as $t \to \infty$, we get

$$\|\Phi z(\tau,\phi) - \Phi z(\tau,\tilde{\phi})\|_X \le C^*\mu(\delta)e^{-\beta\tau}, \quad \tau \in \mathbb{R}^+. \tag{3.36}$$

Thus, (3.35) implies (3.36). Applying the same argument to (3.36) (in place of (3.35)), we have $\|\Phi z(t,\phi) - \Phi z(t,\tilde{\phi})\|_X \le C^*\mu(\delta)^2 e^{-\beta t}$ $(t \in \mathbb{R}^+)$. By the repetition of this procedure, one

reaches $\|\Phi z(t,\phi) - \Phi z(t,\tilde{\phi})\|_X \le C^* \mu(\delta)^n e^{-\beta t}$ $(t \in \mathbb{R}^+, n = 1,2,\dots)$, which yields $\|\Phi z(t,\phi) - \Phi z(t,\tilde{\phi})\|_X = 0$ $(t \in \mathbb{R}^+)$ because of (3.34). In particular, $\phi^c = \Phi z(0,\phi) = \Phi(0,\tilde{\phi}) = \tilde{\phi}^c$. Moreover, since $\Pi^s \mathcal{K}(\phi) = \Pi^s \mathcal{K}(\tilde{\phi}) = 0$, it also follows that $\phi^s = \Pi^s \widehat{g}(\phi) = \Pi^s \widehat{g}(\tilde{\phi}) = \tilde{\phi}^s$, and therefore that $\phi = \tilde{\phi}$. Consequently the claim is proved. □

In view of Claim 1, given any solution $x(t)$ of Eq. (E_δ) defined on $\mathbb{R}^+$, there exists a unique solution $z(t)$ of Eq. (CE_δ) satisfying (3.27), that is, $z(t) = z(t,\phi)$ with $\widehat{g}(\phi) = x_0$. We will estimate the constant C_* in (3.27). Since $x_0 = \widehat{g}(\phi)$ for some $\phi \in X$, $x_t = (x(\phi))_t = \Phi z(t,\phi) + \xi(\phi)(t) + y(\phi)(t)$ for $t \in \mathbb{R}^+$. Hence (3.29) yields $\phi^s = \Pi^s x_0$. It then follows from Proposition 3.7 and (3.31) that

$$\begin{aligned} \|y(\phi)(t) - F_{*,\delta}(\Phi z(t,\phi))\|_X &\le (C\|\phi^s - F_{*,\delta}(\phi^c)\|_X + \|\xi(\phi)\|_{Z^c_\beta})e^{-\beta t} \\ &\le C_0 \|\Pi^s x_0 - F_{*,\delta}(\Phi z(0,\phi))\|_X e^{-\beta t} \end{aligned} \tag{3.37}$$

for $t \in \mathbb{R}^+$, where $C_0 := C + M(\delta)$. Thus we obtain

$$\begin{aligned} \|\Pi^c x_t - \Phi z(t,\phi)\|_X = \|\xi(\phi)(t)\|_X &\le M(\delta)\|\phi^s - F_{*,\delta}(\phi^c)\|_X e^{-\beta t} \\ &\le C_0 \|\Pi^s x_0 - F_{*,\delta}(\Phi z(0,\phi))\|_X e^{-\beta t}, \end{aligned}$$

and by (3.37)

$$\|\Pi^s x_t - F_{*,\delta}(\Phi z(t,\phi))\|_X \le C_0 \|\Pi^s x_0 - F_{*,\delta}(\Phi z(0,\phi))\|_X e^{-\beta t}$$

for $t \in \mathbb{R}^+$. Obviously, C_0 can be chosen as close to C as one expects by taking $\delta > 0$ small. Moreover, we know from Proposition 3.1 that $\Phi z(t,\phi) + F_{*,\delta}(\Phi z(t,\phi)) = x_t(0,\hat{\phi},f_\delta)$ with $\hat{\phi} = \Phi z(0,\phi) + F_{*,\delta}(\Phi z(0,\phi))$, so that (3.2) readily follows. This proves part (a).

(b) Given $t_0 \in \mathbb{R}$ and $z^0 \in \mathbb{C}^d$, write the solution of Eq. (CE_δ) through (t_0,z^0) as $z(t;t_0,z^0)$; in other words, $z(t;t_0,z^0) := z(t-t_0,\Phi z^0)$, $t \in [t_0,\infty)$. Moreover we set

$$\|\Phi\|^* := \left(\sum_{j=1}^d \|\phi_j\|_X^2\right)^{1/2}, \quad \text{and} \quad \|\Phi\|_* := \inf\{\|\Phi z\|_X : |z| = 1,\ z \in \mathbb{C}^d\}.$$

Suppose that the zero solution of Eq. (CE_δ) is stable. Then for arbitrary $\hat{\varepsilon} > 0$ there exists a $\delta_0 > 0$ such that $|z(t;t_0,z^0)| < \hat{\varepsilon}/(2(1+L(\delta))\|\Phi\|^*)$ for every $t \in [t_0,\infty)$ and $z^0 \in \mathbb{C}^d$ with $|z^0| < \delta_0$. Take a $\delta_* > 0$ such that

$$\delta_* < \min\left(\frac{\|\Phi\|_*\delta_0}{2C_1}, \frac{\hat{\varepsilon}}{4C_0C_1(1+2L(\delta))}\right).$$

Now let $\psi \in B_X(\delta_*)$. Then by Claim 1 and (3.33) there exists a (unique) $\phi \in B_X(2\delta_*)$ such that $\psi = \widehat{g}(\phi)$. Let z^0 be the element of $\mathbb{C}^d$ determined by $\phi^c = \Phi z^0$. Since $\|\Phi\|_*|z^0| \le \|\phi^c\|_X \le C_1\|\phi\|_X < 2C_1\delta_*$, i.e., $|z^0| < \delta_0$, we see

$$\|\Phi z(t-t_0,\phi)\|_X \le \|\Phi\|^*|z(t;t_0,z^0)| < \frac{\hat{\varepsilon}}{2(1+L(\delta))}, \quad t \in [t_0,\infty). \tag{3.38}$$

Consider the solution $x(t) = x(t+t_0;t_0,\psi,f_\delta)$ of Eq. (E_δ). Since $x_0 = x_{t_0}(t_0,\psi,f_\delta) = \psi$ and $\Phi z(0,\phi) = \phi^c$, we have

$$\begin{aligned} \|\Pi^s x_0 - F_{*,\delta}(\Phi z(0,\phi))\|_X = \|\psi^s - F_{*,\delta}(\phi^c)\|_X &\le \|\psi^s\|_X + L(\delta)\|\phi^c\|_X \\ &\le C_1(1+2L(\delta))\delta_* < \frac{\hat{\varepsilon}}{4C_0}. \end{aligned} \tag{3.39}$$

So, by letting $\hat{\phi} := \Phi z^0 + F_{*,\delta}(\Phi z^0)$, it follows from Proposition 3.1 and (3.38) that

$$\begin{aligned}\|x_t(t_0,\hat{\phi},f_\delta)\|_X &= \|\Phi z(t-t_0,\phi) + F_{*,\delta}(\Phi z(t-t_0,\phi)\|_X \\ &\le (1+L(\delta))\|\Phi z(t-t_0,\phi)\|_X < \frac{\hat{\varepsilon}}{2},\end{aligned}$$

and hence from part (a) and (3.39) that

$$\begin{aligned}\|x_t(t_0,\psi,f_\delta)\|_X &\le \|x_t(t_0,\psi,f_\delta) - x_t(t_0,\hat{\phi},f_\delta)\|_X + \|x_t(t_0,\hat{\phi},f_\delta)\|_X \\ &< \frac{\hat{\varepsilon}}{2}e^{-\beta(t-t_0)} + \frac{\hat{\varepsilon}}{2} < \hat{\varepsilon}\end{aligned} \tag{3.40}$$

for $t \in [t_0,\infty)$. Hence the zero solution of Eq. (E_δ) is stable.

Although we had proved the asymptotic stability part in [23, Theorem 6] via construction of a Liapunov function, we will give another proof below. Let us next assume that the zero solution of Eq. (CE_δ) is asymptotically stable. Then the stability of the zero solution of Eq. (E_δ) follows from the argument above. By the attractivity of the zero solution of Eq. (CE_δ) there exists an $R_0 > 0$ with the property that given $\hat{\varepsilon} > 0$, there exists a $\tau > 0$ such that $|z(t;t_0,z^0)| < \hat{\varepsilon}/(2(1+L(\delta))\|\Phi\|^*)$ for every $t \ge t_0+\tau$ and $z^0 \in \mathbb{C}^d$ with $|z^0| \le R_0$. Now choose an $R_* > 0$ and a $\tau_* > 0$ in such a way that $R_* < \|\Phi\|_* R_0/2$ and

$$\tau_* > \max\left(\tau,\, \beta^{-1}\log\frac{4C_0C_1(1+L(\delta))R_*}{\hat{\varepsilon}}\right).$$

If $\psi \in B_X(R_*)$, then, in a similar fashion to the last paragraph, ψ can be written as $\psi = \widehat{g}(\phi)$ with some $\phi \in B_X(2R_*)$. Corresponding to (3.39), we get this time

$$\|\Pi^s x_0 - F_{*,\delta}(\Phi z(0,\phi))\|_X \le C_1(1+2L(\delta))R_* < \frac{\hat{\varepsilon}}{4C_0}e^{\beta\tau_*}.$$

and hence, in a similar way to (3.40),

$$\begin{aligned}\|x_t(t_0,\psi,f_\delta)\|_X &\le \frac{\hat{\varepsilon}}{2}e^{-\beta(t-t_0-\tau_*)} + (1+L(\delta))\|\Phi\|^*|z(t-t_0,\phi)| \\ &< \frac{\hat{\varepsilon}}{2} + \frac{\hat{\varepsilon}}{2} = \hat{\varepsilon}\end{aligned}$$

for $t \ge t_0+\tau_*$. Thus, the zero solution of Eq. (E_δ) is also asymptotically stable.

The instability part immediately follows from the invariance of $W^c_\delta(0)$. □

Proof of Theorem 3.3. (a) Let us take a $\delta > 0$ sufficiently small such that $\|F_{*,\delta}(\psi)\|_X < \delta$ for any $\psi \in B_{E^c}(\delta)$. This is possible by Proposition 2.5 and $\zeta_*(+0) = 0$ (in fact, $F_{*,\delta}(0) = 0$ and $DF_{*,\delta}(0) = 0$). Set $F_* := F_{*,\delta}|_{B_{E^c}(\delta)}$, and let Ω and Ω_0 be open neighborhoods of 0 in X defined by $\Omega := \{\phi \in X : \|\Pi^s\phi\|_X < \delta,\ \|\Pi^c\phi\|_X < \delta\}$ and $\Omega_0 := \{\phi \in X : \|\Pi^s\phi\|_X < \delta/3,\ \|\Pi^c\phi\|_X < \delta/3\}$, respectively. Observe that

$$f(\phi) = f_\delta(\phi) \quad \text{for } \phi \in \Omega. \tag{3.41}$$

Since $x(t)$ is a solution of (E) satisfying $x_t \in \Omega_0$ $(t \in J)$, by virtue of VCF, one can readily see that $x(t)$ is also a solution of (E_δ) on J. Then by Theorem 3.2 there exists a solution of (CE_δ), say $z(t)$, satisfying (3.1). So, by Claim 1 in the proof of Theorem 3.2, there exists a (unique) $\phi \in X$ such that $x_0 = \widehat{g}(\phi)$; hence $x(t) = x(\phi)(t)$, $z(t) = z(t,\phi)$, and $x_t = \Phi z(t) + \xi(\phi)(t) + y(\phi)(t)$ hold for $t \in J$. In view of (3.30) and (3.31), note that $\|\xi(\phi)\|_{Z^c_\beta} \le (1/2)\|\phi\|_X$. Also, by the

relation $B_X(r_0/2) \subset \widehat{g}(B_X(r_0))$ for $r_0 > 0$ (cf. (3.33)), one can see $\|\phi\|_X \le 2\|x_0\|_X$, which is valid even if $x_0 = 0$. Since $\Pi^c x_t = \Phi z(t) + \xi(\phi)(t)$, we have

$$\|\Phi z(t)\|_X \le \|\Pi^c x_t\|_X + \|\xi(\phi)\|_{Z^c_\beta} < \frac{\delta}{3} + \frac{1}{2}\|\phi\|_X \le \frac{\delta}{3} + \|x_0\|_X.$$

Besides, noting that

$$\|x_0\|_X \le \|\Pi^c x_0\|_X + \|\Pi^s x_0\|_X < \frac{\delta}{3} + \frac{\delta}{3} = \frac{2\delta}{3},$$

we obtain $\|\Phi z(t)\|_X < \delta$ $(t \in J)$; and therefore $\|F_{*,\delta}(\Phi z(t))\|_X < \delta$ for $t \in J$ by the choice of δ. In particular, $\Phi z(t) + F_{*,\delta}(\Phi z(t)) \in \Omega$ for $t \in J$. So, $F_{*,\delta}(\Phi z(t)) = F_*(\Phi z(t))$, and

$$f_\delta(\Phi z(t) + F_{*,\delta}(\Phi z(t))) = f(\Phi z(t) + F_*(\Phi z(t)))$$

for $t \in J$, which implies that $z(t)$ is also a solution of (CE) on J. Hence, (3.3) and (3.4) directly follow from the estimates (3.1) and (3.2). This proves part (a).

(b) Suppose that the zero solution of (CE) is stable (asymptotically stable, unstable). Then one can see from (3.41) that the zero solution of (CE_δ) is stable (asymptotically stable, unstable); so is the zero solution of (E_δ) by Theorem 3.2 (b). By (3.41) again, so is that of (E). This completes the proof. □

4 One-parameter bifurcation structures

4.1 Statement of the results

Employing Theorem 3.3, we shall in this section discuss bifurcation structures of equilibria for the parametrized integral equation of the form

$$x(t) = \lambda \int_{-\infty}^{t} P(t-s)x(s)ds + f(x_t), \quad \lambda \in \mathbb{R}, \tag{PE}$$

where P is a measurable $m \times m$-matrix valued function on $\mathbb{R}^+$ with real components that satisfies

$$\int_0^\infty \|P(t)\|e^{\rho t}dt < \infty \quad \text{and} \quad \operatorname{ess\,sup}\{\|P(t)\|e^{\rho t} : t \in \mathbb{R}^+\} < \infty, \tag{4.1}$$

and $f \in C^1(X;\mathbb{R}^m)$ satisfies $f(0) = 0$ and $Df(0) = 0$. Also, in this section we set $X := L^1_\rho(\mathbb{R}^-;\mathbb{R}^m)$, and put

$$P_0 := \int_0^\infty P(t)dt, \quad P_1 := \int_0^\infty tP(t)dt.$$

More specifically, we assume the following conditions (A_1) through (A_4) throughout this section, and show that Eq. (PE) possesses a saddle-node bifurcation structure of equilibria as well as pitchfork one when the parameter λ varies in a neighborhood of 1.

(A_1) 1 is a simple eigenvalue of P_0;

(A_2) $\mathcal{R}(E_m - P_0) \oplus P_1\big(\mathcal{N}(E_m - P_0)\big) = \mathbb{R}^m$;

(A_3) $\det \Delta(\sigma + i\omega) \neq 0$ for $(\sigma,\omega) \in \mathbb{R}^+ \times \mathbb{R}^+ \setminus \{(0,0)\}$;

(A_4) $f : X \to \mathbb{R}^m$ is given by

$$f(\phi) = Q(\phi) + g(\phi), \quad \phi \in X, \tag{4.2}$$

where $Q : X \to \mathbb{R}^m$ is defined by

$$Q(\phi) = Q_*(\phi, \phi, \dots, \phi), \quad \phi \in X \tag{4.3}$$

with Q_* a bounded n-linear map from X^n to $\mathbb{R}^m$, and $g \in C^1(X; \mathbb{R}^m)$ satisfies

$$g(\phi) = o(\|\phi\|_X^n) \quad \text{and} \quad Dg(\phi) = o(\|\phi\|_X^{n-1}) \quad \text{as } \phi \to 0 \text{ in } X \tag{4.4}$$

for some integer n greater than 1.

Remark 4.1. The assumption (A_2) is equivalent to $\mathcal{R}(E_m - P_0) + P_1\big(\mathcal{N}(E_m - P_0)\big) = \mathbb{R}^m$ because of $\dim \mathcal{N}(E_m - P_0) + \dim \mathcal{R}(E_m - P_0) = m$.

Remark 4.2. (A_3) holds for instance under the following conditions:

(a) $\int_0^\infty \|P(t)\| dt \le 1$;

(b) $\det \Delta(i\omega) \neq 0$ for $\omega > 0$.

Indeed, (a) implies

$$\|E_m - \Delta(\sigma + i\omega)\| = \Big\| \int_0^\infty P(t) e^{-(\sigma+i\omega)t} dt \Big\| \le \int_0^\infty \|P(t)\| e^{-\sigma t} dt < 1$$

for $\sigma > 0$; hence $\Delta(\sigma + i\omega)$ is invertible for $\sigma > 0$. Thus, (A_3) follows from (a) and (b).

Remark 4.3. A typical example of Q_* in (A_4) is of the form

$$Q_*(\phi_1, \phi_2, \dots, \phi_n) = \sum_{j=1}^{l} \Big(\prod_{k=1}^{n} \int_{-\infty}^{0} q_k^{(j)}(-\theta) \phi_k(\theta) d\theta \Big) v_j,$$

with $\phi_k \in X$ ($k = 1, 2, \dots, n$), where each $q_k^{(j)}$ is a measurable $\mathbb{R}^{m*}$-valued function on $\mathbb{R}^+$ that satisfies

$$\int_0^\infty |q_k^{(j)}(t)| e^{\rho t} dt < \infty \quad \text{and} \quad \operatorname{ess\,sup}\{|q_k^{(j)}(t)| e^{\rho t} : t \ge 0\} < \infty$$

($k = 1, 2, \dots, n$) and $v_j \in \mathbb{R}^m$ ($j = 1, 2, \dots, l$).

Now let η_* be an eigenvector of P_0 associated with eigenvalue 1 and ζ^* an eigenvector of P_0^*, the adjoint of P_0; and put

$$q_* := -\frac{\langle \zeta^*, P_1 \eta_* \rangle}{\langle \zeta^*, \eta_* \rangle}, \quad c_0 := \langle \zeta^*, Q(w_1(0)\eta_*) \rangle. \tag{4.5}$$

Note that $\langle \zeta^*, \eta_* \rangle \neq 0$, and q_* does not depend on the choice of η_* and ζ^* since both $\mathcal{N}(E_m - P_0)$ and $\mathcal{N}(E_m - P_0^*)$ are one-dimensional spaces due to (A_1).

Our main theorem on bifurcation structure is as follows:

Theorem 4.4. *Suppose that the assumptions (A_1) through (A_4) are satisfied. Suppose furthermore that $c_0 \neq 0$. Then, the following statements hold:*

(i) *Let n be even.*

(ia) *If $\lambda = 1$, then there exists an open neighborhood $\mathcal{W}_0$ of 0 in X such that Eq. (PE) has no equilibria in $\mathcal{W}_0$ other than 0. The equilibrium 0 is also unstable. Moreover, there exist an $\varepsilon^* > 0$ and a continuous map $\phi_* : (1-\varepsilon^*, 1+\varepsilon^*)\backslash\{1\} \to X\backslash\{0\}$ such that for each λ, ϕ_*^λ is an equilibrium of Eq. (PE), and $\phi_*^\lambda \to 0$ as $\lambda \to 1$. (Here we used the notation ϕ_*^λ rather than $\phi_*(\lambda)$ for $\lambda \in (1-\varepsilon^*, 1+\varepsilon^*)$.)*

(ib) *If $q_* < 0$, then the equilibria ϕ_*^λ and 0 are asymptotically stable (resp. unstable) in case $\lambda < 1$ (resp. $\lambda > 1$); and if $q_* > 0$, then ϕ_*^λ and 0 are unstable (resp. asymptotically stable) in case $\lambda < 1$ (resp. $\lambda > 1$).*

(ic) *There exists an open neighborhood $\mathcal{W}$ of 0 in X such that if $\phi_* \in \mathcal{W}$ is an equilibrium of Eq. (PE) with $|\lambda - 1|$ small, then $\phi_* = 0$ or $\phi_* = \phi_*^\lambda$.*

(ii) *Let n be odd and c_0 positive.*

(iia) *If $\lambda = 1$, then there exists an open neighborhood $\mathcal{W}_0$ of 0 in X such that Eq. (PE) has no equilibria in $\mathcal{W}_0$ other than 0. The equilibrium 0 is also unstable. Moreover, there exist an $\varepsilon^* > 0$ and continuous maps $\phi_\pm : (1, 1+\varepsilon^*) \to \mathcal{W}_0\backslash\{0\}$ such that for each λ, ϕ_+^λ and ϕ_-^λ are two distinct equilibria of Eq. (PE), and $\phi_\pm^\lambda \to 0$ as $\lambda \to 1+0$.*

(iib) *If $q_* < 0$, then the equilibria ϕ_+^λ and ϕ_-^λ are unstable for $\lambda > 1$, whereas 0 is asymptotically stable for $\lambda > 1$; and if $q_* > 0$, then ϕ_+^λ and ϕ_-^λ are asymptotically stable and 0 is unstable for $\lambda > 1$.*

(iic) *There exists an open neighborhood $\mathcal{W}$ of 0 in X such that if $\phi_* \in \mathcal{W}$ is an equilibrium of Eq. (PE) with $\lambda - 1 > 0$ small, then ϕ^* coincides with one of 0, ϕ_+^λ and ϕ_-^λ.*

(iii) *Let n be odd and c_0 negative.*

(iiia) *If $\lambda = 1$, then there exists an open neighborhood $\mathcal{W}_0$ of 0 in X such that Eq. (PE) has no equilibria in $\mathcal{W}_0$ other than 0. The equilibrium 0 is also asymptotically stable. Moreover, there exist an $\varepsilon^* > 0$ and continuous maps $\phi_\pm : (1-\varepsilon^*, 1) \to \mathcal{W}_0\backslash\{0\}$ such that for each λ, ϕ_+^λ and ϕ_-^λ are two distinct equilibria of Eq. (PE), and $\phi_\pm^\lambda \to 0$ as $\lambda \to 1-0$.*

(iiib) *If $q_* < 0$, then the equilibria ϕ_+^λ and ϕ_-^λ are asymptotically stable for $\lambda < 1$, whereas 0 is unstable for $\lambda < 1$; and if $q_* > 0$, then ϕ_+^λ and ϕ_-^λ are unstable and 0 is asymptotically stable for $\lambda < 1$.*

(iiic) *There exists an open neighborhood $\mathcal{W}$ of 0 in X such that if $\phi_* \in \mathcal{W}$ is an equilibrium of Eq. (PE) with $1 - \lambda > 0$ small, then ϕ^* coincides with one of 0, ϕ_+^λ and ϕ_-^λ.*

4.2 Extended system and the projection onto its center subspace

For the convenience, put $\lambda := 1 + \varepsilon$. Then, Eq. (PE) becomes

$$x(t) = \int_{-\infty}^{t} P(t-s)x(s)ds + \varepsilon \int_{-\infty}^{t} P(t-s)x(s)ds + f(x_t). \tag{4.6}$$

For the proof of Theorem 4.4, we will treat an extended system of (4.6), and apply Theorem 3.2. To do so, consider the system of integral equations

$$\begin{aligned} \varepsilon(t) &= \int_{-\infty}^{t} p_0(t-s)\varepsilon(s)ds, \\ x(t) &= \int_{-\infty}^{t} P(t-s)x(s)ds + \left(\int_{-\infty}^{t} p_0(t-s)\varepsilon(s)ds \right) \left(\int_{-\infty}^{t} P(t-s)x(s)ds \right) + f(x_t), \end{aligned} \tag{4.7}$$

where $p_0(t)$ is the function on $\mathbb{R}^+$ defined by

$$p_0(t) := \rho_0 e^{-\rho_0 t}, \quad t \in \mathbb{R}^+,$$

and ρ_0 is a positive number satisfying $\rho_0 > \rho$. Note that

$$\int_0^\infty p_0(t)dt = 1 \tag{4.8}$$

and that

$$\int_0^\infty |p_0(t)|e^{-\rho t}dt < \infty \quad \text{and} \quad \operatorname{ess\,sup}\{|p_0(t)|e^{\rho t} : t \geq 0\} < \infty.$$

Let us denote

$$\widetilde{P}(t) := \operatorname{diag}\big(p_0(t),\, P(t)\big) = \begin{pmatrix} p_0(t) & 0 \\ 0 & P(t) \end{pmatrix}, \quad t \in \mathbb{R}^+.$$

Set $\widetilde{X} := L^1_\rho(\mathbb{R}^-;\mathbb{R}^{m+1})$ and $X_1 := L^1_\rho(\mathbb{R}^-;\mathbb{R})$ (see Subsection 2.1); then $\widetilde{X}$ can be naturally identified with $X_1 \times X$. We denote by Π_1 and Π_2 the projections from $\widetilde{X}$ to X_1 and X, respectively. Moreover, define $\widetilde{G} : \widetilde{X} \to \mathbb{R}^{m+1}$ by

$$\widetilde{G}(\tilde{\phi}) := \operatorname{col}\big(0,\, G^{(2)}(\tilde{\phi})\big), \quad \tilde{\phi} \in \widetilde{X},$$

where $G^{(2)}$ is an $\mathbb{R}^m$-valued function given by

$$G^{(2)}(\tilde{\phi}) := \left(\int_{-\infty}^0 p_0(-\theta)\phi^{(1)}(\theta)d\theta\right)\left(\int_{-\infty}^0 P(-\theta)\phi^{(2)}(\theta)d\theta\right) + f(\phi^{(2)}), \tag{4.9}$$

that is, $G^{(2)}(\tilde{\phi}) = \Pi_2\widetilde{G}(\tilde{\phi})$. Here we used the notation

$$\tilde{\phi} = \operatorname{col}\,(\phi^{(1)},\, \phi^{(2)}) \quad \text{with } \phi^{(1)} \in X_1 \text{ and } \phi^{(2)} \in X. \tag{4.10}$$

By letting $\tilde{x}(t) := \operatorname{col}\,(\varepsilon(t), x(t))$, Eq. (4.7) can then be rewritten as

$$\tilde{x}(t) = \int_{-\infty}^t \widetilde{P}(t-s)\tilde{x}(s)ds + \widetilde{G}(\tilde{x}_t). \tag{$\widetilde{E}$}$$

In connection with Eq. $(\widetilde{E})$ we will also consider the integral equation

$$\tilde{x}(t) = \int_{-\infty}^t \widetilde{P}(t-s)\tilde{x}(s)ds + \widetilde{G}_\delta(\tilde{x}_t), \tag{$\widetilde{E}_\delta$}$$

where $\widetilde{G}_\delta : \widetilde{X} \to \mathbb{R}^{m+1}$ is defined by

$$\widetilde{G}_\delta(\tilde{\phi}) := \chi\big(\|\Pi^s\tilde{\phi}\|_{\widetilde{X}}/\delta\big)\chi\big(\|\Pi^c\tilde{\phi}\|_{\widetilde{X}}/\delta\big)G(\tilde{\phi}), \quad \tilde{\phi} \in \widetilde{X}$$

(see Subsection 2.3). By (4.2), (4.3) and (4.4), it is clear that $\widetilde{G}$ belongs to $C^1(\widetilde{X};\mathbb{R}^{m+1})$ with $\widetilde{G}(0) = 0$ and $D\widetilde{G}(0) = 0$. Hence Theorem 2.4 implies that there exists the (global) center manifold of the equilibrium 0 of Eq. $(\widetilde{E}_\delta)$, denoted $\widetilde{W}^c_\delta(0)$, which is given as the graph of some C^1 map $\widetilde{F}_{*,\delta} : \widetilde{E}^c \to \widetilde{E}^s$:

$$\widetilde{W}^c_\delta(0) := \big\{\psi + \widetilde{F}_{*,\delta}(\psi) : \psi \in \widetilde{E}^c\big\}. \tag{4.11}$$

Recall that $\widetilde{F}_{*,\delta}$ is defined by

$$\widetilde{F}_{*,\delta}(\psi) = \lim_{n\to\infty}\int_{-\infty}^0 \widetilde{T}^s(-s)\Pi^s\Gamma^n\widetilde{G}_\delta(\Lambda_{*,\delta}(\psi)(s))ds, \quad \psi \in \widetilde{E}^c, \tag{4.12}$$

where $\{\widetilde{T}(t)\}_{t\geq 0}$ is the solution semigroup of the integral equation

$$\widetilde{x}(t) = \int_{-\infty}^{t} \widetilde{P}(t-s)\widetilde{x}(s)ds \tag{4.13}$$

(see (2.6)). Let $\widetilde{F}_* : B_{\widetilde{E}^c}(\delta) \to \widetilde{X}$ be the restriction of $\widetilde{F}_{*,\delta}$ to $B_{\widetilde{E}^c}(\delta)$. The local center manifold $\widetilde{W}^c_{\mathrm{loc}}(0)$ of the equilibrium 0 of Eq. $(\widetilde{E})$ is then given by $\widetilde{W}^c_{\mathrm{loc}}(0) := \operatorname{graph} \widetilde{F}_* \subset \widetilde{W}^c_\delta(0)$ (see [23, Theorem 5]). Henceforth, we set

$$\widetilde{\Omega} := \{\tilde{\phi} \in \widetilde{X} : \|\Pi^c\tilde{\phi}\|_{\widetilde{X}} < \delta,\ \|\Pi^s\tilde{\phi}\|_{\widetilde{X}} < \delta\},$$

and

$$\widetilde{\Omega}_0 := \{\tilde{\phi} \in \widetilde{X} : \|\Pi^c\tilde{\phi}\|_{\widetilde{X}} < \delta/3,\ \|\Pi^s\tilde{\phi}\|_{\widetilde{X}} < \delta/3\}.$$

Proposition 4.5. *Given any $t_0 \in \mathbb{R}$ and $\tilde{\phi} \in \widetilde{X}$, let $\widetilde{x}(t; t_0, \tilde{\phi}, \widetilde{G}_\delta)$ be the solution of Eq. $(\widetilde{E}_\delta)$ with $\widetilde{x}_{t_0} = \tilde{\phi}$; and $\widetilde{x}(t; t_0, \tilde{\phi}, \widetilde{G})$ the one of Eq. $(\widetilde{E})$ with $\widetilde{x}_{t_0} = \tilde{\phi}$. Let $\varepsilon \in \mathbb{R}$ and $j_\varepsilon : X \to \widetilde{X}$ be the map defined by*

$$j_\varepsilon(\phi) := \operatorname{col}\big(w_1(0)\varepsilon, \phi\big), \quad \phi \in X \tag{4.14}$$

where $w_1(0)$ is the function defined in (2.8) (see Subsection 2.4). Then we have

(i) *Given any $\varepsilon \in \mathbb{R}$ and $\phi \in X$, $\widetilde{x}_t(t_0, j_\varepsilon(\phi), \widetilde{G}_\delta) \in j_\varepsilon(X)$ holds for $t \geq t_0$.*

(ii) *Let $x(t; t_0, \phi, f)$ be the solution on $J = [t_0, t_1]$ of Eq. (PE) satisfying $x_{t_0} = \phi \in X$. Then*

$$\widetilde{x}(t; t_0, j_\varepsilon(\phi), \widetilde{G}) = \operatorname{col}\big(\varepsilon, x(t; t_0, \phi, f)\big), \quad t \in J;$$

so that $\widetilde{x}_t(t_0, j_\varepsilon(\phi), \widetilde{G}) = j_\varepsilon(x_t(t_0, \phi, f))$ holds for every $t \in J$ and $\varepsilon \in \mathbb{R}$.

In particular, $j_\varepsilon(X)$ is positively invariant for both Eq. $(\widetilde{E}_\delta)$ and Eq. $(\widetilde{E})$.

Proof. (i) Set $\chi_0(\tilde{\phi}) := \chi\big(\|\Pi^s\tilde{\phi}\|_{\widetilde{X}}/\delta\big)\chi\big(\|\Pi^c\tilde{\phi}\|_{\widetilde{X}}/\delta\big)$ for $\tilde{\phi} \in \widetilde{X}$ and let $u(t)$ be the solution of

$$u(t) = \big(1 + \varepsilon\chi_0(j_\varepsilon(u_t))\big)\int_{-\infty}^{t} P(t-s)u(s)ds + \chi_0(j_\varepsilon(u_t))f(u_t)$$

with $u_{t_0} = \phi$. The existence and uniqueness of $u(t)$ is due to [21, Proposition 3]. Define $\widetilde{x} : \mathbb{R} \to \widetilde{X}$ by

$$\widetilde{x}(t) = \operatorname{col}\big(x^{(1)}(t), x^{(2)}(t)\big) := \operatorname{col}\big(\varepsilon, u(t)\big) \in X_1 \times X, \quad t \in \mathbb{R}.$$

Then, it readily follows from (4.8) that

$$x^{(1)}(t) = \int_{-\infty}^{t} p_0(t-s)x^{(1)}(s)ds.$$

Besides, since $\widetilde{x}_t = j_\varepsilon(u_t)$ $(t \geq t_0)$, $x^{(2)}(t)$ satisfies

$$x^{(2)}(t) = \int_{-\infty}^{t} P(t-s)x^{(2)}(s)ds + \chi_0(\widetilde{x}_t)\left(\int_{-\infty}^{t} p_0(t-s)\varepsilon ds\right)\left(\int_{-\infty}^{t} P(t-s)x^{(2)}(s)ds\right) + \chi_0(\widetilde{x}_t)f\big(x^{(2)}_t\big)$$

for $t \geq t_0$. Therefore $\widetilde{x}(t)$ is the solution of Eq. $(\widetilde{E}_\delta)$ with $\widetilde{x}_{t_0} = j_\varepsilon(u_{t_0}) = j_\varepsilon(\phi)$. Thus, we obtain $\widetilde{x}(t) = \widetilde{x}(t; t_0, j_\varepsilon(\phi), \widetilde{G}_\delta)$; hence

$$\widetilde{x}_t(t_0, j_\varepsilon(\phi), \widetilde{G}_\delta) = \widetilde{x}_t = j_\varepsilon(u_t) \in j_\varepsilon(X) \quad \text{for } t \geq t_0.$$

(ii) One can easily see that the argument above is valid with $\chi_0 = 1$, $\widetilde{G}_\delta = \widetilde{G}$ and $u(t) = x(t;t_0,\phi,f)$. Hence, it follows that $\tilde{x}(t;t_0,j_\varepsilon(\phi),\widetilde{G}) = \mathrm{col}\,(\varepsilon, x(t;t_0,\phi,f))$. So,

$$\widetilde{x}_t(t_0,j_\varepsilon(\phi),\widetilde{G}) = \mathrm{col}\,(w_1(0)\varepsilon, x_t(t_0,\phi,f)) = j_\varepsilon(x_t(t_0,\phi,f)) \in j_\varepsilon(X)$$

for $t \in J$. Thus, $j_\varepsilon(X)$ is positively invariant for Eq. ($\widetilde{E}_\delta$) and Eq. ($\widetilde{E}$). □

The bilinear form, induced in the formal adjoint theory (Subsection 2.4; see also [22]) associated with Eq. (4.13), the linear part of Eq. ($\widetilde{E}$), is given by

$$\langle\!\langle \widetilde{\psi}, \widetilde{\phi} \rangle\!\rangle := \int_{-\infty}^{0} \Big(\int_{\theta}^{0} \widetilde{\psi}(\xi-\theta)\widetilde{P}(-\theta)\widetilde{\phi}(\xi)d\xi \Big) d\theta, \quad \widetilde{\phi} \in \widetilde{X},\ \ \widetilde{\psi} \in \widetilde{X}^\sharp, \tag{4.15}$$

where $\widetilde{X}^\sharp := L^1_\rho(\mathbb{R}^+;\mathbb{R}^{m+1})$. Using the notations (4.10) and $\widetilde{\psi} = (\psi^{(1)},\ \psi^{(2)})$ with $\psi^{(1)} \in X_1^\sharp := L^1_\rho(\mathbb{R}^+;\mathbb{R})$ and $\psi^{(2)} \in X^\sharp := L^1_\rho(\mathbb{R}^+;\mathbb{R}^m)$, we have

$$\widetilde{\psi}(\xi-\theta)\widetilde{P}(-\theta)\widetilde{\phi}(\eta) = (\psi^{(1)}(\xi-\theta),\ \psi^{(2)}(\xi-\theta)) \begin{pmatrix} p_0(-\theta) & 0 \\ 0 & P(-\theta) \end{pmatrix} \begin{pmatrix} \phi^{(1)}(\theta) \\ \phi^{(2)}(\theta) \end{pmatrix};$$

hence (4.15) becomes

$$\langle\!\langle \widetilde{\psi}, \widetilde{\phi} \rangle\!\rangle = \int_{-\infty}^{0} \Big(\int_{\theta}^{0} (\psi^{(1)}(\xi-\theta)p_0(-\theta)\phi^{(1)}(\xi) + \psi^{(2)}(\xi-\theta)P(-\theta)\phi^{(2)}(\xi))d\xi \Big) d\theta. \tag{4.16}$$

The characteristic operator of Eq. (4.13) is

$$\begin{aligned} \widetilde{\Delta}(z) &= E_{m+1} - \int_0^\infty \widetilde{P}(t)e^{-zt}dt \\ &= \begin{pmatrix} 1 - \int_0^\infty p_0(t)e^{-zt}dt & 0 \\ 0 & E_m - \int_0^\infty P(t)e^{-zt}dt \end{pmatrix} = \begin{pmatrix} z/(z+\rho_0) & 0 \\ 0 & \Delta(z) \end{pmatrix}. \end{aligned}$$

So, it follows that

$$\det \widetilde{\Delta}(z) = \frac{z}{z+\rho_0} \det \Delta(z),$$

and in view of $\Delta(0) = E_m - P_0$ and (A_1), 0 is a characteristic root of Eq. (4.13) whose order as a zero of $\det \widetilde{\Delta}(z)$ is at least greater than 1 (Recall that $\det \Delta(z)$ is analytic in the domain $\mathbb{C}_{-\rho}$).

Proposition 4.6. *$\det \Delta(z)$ has 0 as a zero of order 1 (i.e., $\det \widetilde{\Delta}(z)$ has 0 as the one of order 2) if and only if (A_1) and (A_2) hold.*

Proof. Let us denote $\Delta(0) = E_m - P_0 = (a_1\ a_2\ \cdots\ a_m)$ and $P_1 = (p_1\ p_2\ \cdots\ p_m)$ with $a_j, p_j \in \mathbb{R}^m$ $(j = 1,2,\ldots,m)$. By virtue of the first inequality of (4.1), we have

$$\Delta^{(k)}(z) = -\frac{d^k}{dz^k}\int_0^\infty P(t)e^{-zt}dt = (-1)^{k-1}\int_0^\infty t^k P(t)e^{-zt}dt, \quad z \in \mathbb{C}_{-\rho},$$

$(k = 1,2,\ldots)$ and hence $\Delta(z)$ is expressed as

$$\Delta(z) = \Delta(0) + z\Delta'(0) + o(z) = E_m - P_0 + zP_1 + o(z).$$

Put $d(z) := \det \Delta(z)$. Then, $d(0) = 0$ and

$$\begin{aligned} d'(0) &= \frac{d}{dz}\Big|_{z=0} \det \Big(a_1 + zp_1 + o(z) \quad a_2 + zp_2 + o(z) \quad \cdots \quad a_m + zp_m + o(z) \Big) \\ &= \sum_{j=1}^m \det (a_1\ \cdots\ \underset{\widehat{j}}{p_j}\ \cdots\ a_m). \end{aligned}$$

Suppose that $\det \Delta(z)$ has 0 as a zero of order 1, that is, $d'(0) \neq 0$. Let $k := \dim \mathcal{R}(E_m - P_0)$ and assume that $k \leq m-2$. Without loss of generality, we may assume that $\mathcal{R}(E_m - P_0) = \operatorname{span}\{a_1, a_2, \ldots, a_k\}$. Since $\operatorname{span}\{a_1, \ldots, a_{j-1}, p_j, a_{j+1}, \ldots, a_m\} = \operatorname{span}\{a_1, \ldots, a_k, p_j\}$, we have $\dim \operatorname{span}\{a_1, \ldots, a_{j-1}, p_j, a_{j+1}, \ldots, a_m\} \leq k+1 \leq m-1$ so that

$$\det \begin{pmatrix} a_1 & \cdots & \underset{\widehat{j}}{p_j} & \cdots & a_m \end{pmatrix} = 0, \quad j = 1, 2, \ldots, m.$$

Hence, we get $d'(0) = 0$, contradicting to our assumption. Thus, we obtain $k = m-1$, and therefore (A_1) holds. Moreover, in this case, we may assume that a_m can be written as $a_m = \sum_{k=1}^{m-1} c_k a_k$ with some $c_k \in \mathbb{R}$ $(k = 1, 2, \ldots, m-1)$. Then,

$$\begin{aligned} d'(0) &= \sum_{j=1}^{m} \sum_{k=1}^{m-1} \det \begin{pmatrix} a_1 & \cdots & \underset{\widehat{j}}{p_j} & \cdots & c_k a_k \end{pmatrix} \\ &= \det \begin{pmatrix} a_1 & \cdots & a_{m-1} & p_m \end{pmatrix} + \sum_{j=1}^{m-1} \det \begin{pmatrix} a_1 & \cdots & \underset{\widehat{j}}{p_j} & \cdots & a_{m-1} & c_j a_j \end{pmatrix} \\ &= \det \begin{pmatrix} a_1 & \cdots & a_{m-1} & p_m \end{pmatrix} + \sum_{j=1}^{m-1} \det \begin{pmatrix} a_1 & \cdots & \underset{\widehat{j}}{a_j} & \cdots & a_{m-1} & -c_j p_j \end{pmatrix} \\ &= \det \begin{pmatrix} a_1 & a_2 & \cdots & a_{m-1} & p_m - \sum_{j=1}^{m-1} c_j p_j \end{pmatrix}. \end{aligned}$$

Since $\operatorname{col}(c_1, \ldots, c_{m-1}, -1) \in \mathcal{N}(E_m - P_0)$, we see $p_m - \sum_{j=1}^{m-1} c_j p_j$ belongs to $P_1\big(\mathcal{N}(E_m - P_0)\big)$. Consequently, it follows from $d'(0) \neq 0$ that (A_2) is also valid.

Conversely, suppose that (A_1) and (A_2) hold. Then $d'(0) \neq 0$ is clear from the argument above. □

Note that Eq. (4.13) has no characteristic roots with positive real parts. Indeed, (A_3) implies $\det \Delta(z) \neq 0$ for $\operatorname{Re} z > 0$ since $\Delta(z) = \overline{\Delta(\bar{z})}$. Thus, $\Sigma^u = \emptyset$, and therefore we have

$$\widetilde{X} = \widetilde{E}^c \oplus \widetilde{E}^s, \tag{4.17}$$

where $\widetilde{E}^c$ and $\widetilde{E}^s$ are the center subspace and the stable subspace of the equilibrium 0 for Eq. (4.13), respectively. Also, notice from (A_3) that $\Sigma^c = \{0\}$.

By (2.7) of Subsection 2.4, $\widetilde{E}^c$ is given by the generalized eigenspace of $\widetilde{A}$ associated with eigenvalue 0:

$$\widetilde{E}^c = \mathcal{M}_0(\widetilde{A}) = \bigcup_{k \geq 1} \mathcal{N}(\widetilde{A}^k),$$

where $\widetilde{A}$ is the generator of the solution semigroup $\{\widetilde{T}(t)\}_{t \geq 0}$ of Eq. (4.13).

Proposition 4.7. *We have* $\mathcal{M}_0(\widetilde{A}) = \mathcal{N}(\widetilde{A}) = \operatorname{span}\{w_1(0)e_1, w_1(0)\tilde{\eta}_*\}$, *where* e_1 *and* $\tilde{\eta}_*$ *are the elements of* $\mathbb{R}^{m+1}$ *given by* $e_1 := \operatorname{col}(1, 0, \ldots, 0)$, $\tilde{\eta}_* = \operatorname{col}(0, \eta_*)$, η_* *being an eigenvector of* P_0 *corresponding to eigenvalue* 1, *and* $w_1(0)$ *is the one given by* (2.8).

Proof. By virtue of Proposition 2.6 we know that $\widetilde{\phi} \in \mathcal{N}(\widetilde{A})$ if and only if $\widetilde{\phi} = w_1(0)\eta_1$ for some $\tilde{\eta}_1 \in \mathbb{R}^{m+1}$ with $\widetilde{\Delta}(0)\tilde{\eta}_1 = 0$. Since

$$D_1(0) = \widetilde{\Delta}(0) = \begin{pmatrix} 0 & 0 \\ 0 & E_m - P_0 \end{pmatrix}$$

(see ((2.9)), one can see from (A_1) that $\mathcal{N}(\widetilde{A}) = \operatorname{span}\{w_1(0)e_1,\, w_1(0)\tilde{\eta}_*\}$.

Recall the fact that

$$\mathcal{N}(\widetilde{A}^2) = \left\{ w_1(0)\tilde{\eta}_1 + w_2(0)\tilde{\eta}_2 : D_2(0)\begin{pmatrix}\tilde{\eta}_1\\ \tilde{\eta}_2\end{pmatrix} = 0,\ \tilde{\eta}_1, \tilde{\eta}_2 \in \mathbb{R}^{m+1}\right\},$$

where $D_2(0)$ is the matrix defined by

$$D_2(0) = \begin{pmatrix}\widetilde{\Delta}(0) & \widetilde{\Delta}'(0)\\ 0 & \widetilde{\Delta}(0)\end{pmatrix}$$

(see (2.9)). So, $w_1(0)\tilde{\eta}_1 + w_2(0)\tilde{\eta}_2 \in \mathcal{N}(\widetilde{A}^2)$ is equivalent to

$$\widetilde{\Delta}(0)\tilde{\eta}_1 + \widetilde{\Delta}'(0)\tilde{\eta}_2 = 0 \quad \text{and} \quad \widetilde{\Delta}(0)\tilde{\eta}_2 = 0. \tag{4.18}$$

It is also easily seen that

$$\widetilde{\Delta}'(z) = \begin{pmatrix}\rho_0/(z+\rho_0)^2 & 0\\ 0 & \int_0^\infty tP(t)e^{-zt}dt\end{pmatrix}; \quad \text{hence} \quad \widetilde{\Delta}'(0) = \begin{pmatrix}1/\rho_0 & 0\\ 0 & P_1\end{pmatrix}.$$

(4.18) implies $\widetilde{\Delta}'(0)\tilde{\eta}_2 \in \widetilde{\Delta}'(0)\big(\mathcal{N}(\widetilde{\Delta}(0))\big)$, so that $\widetilde{\Delta}(0)\tilde{\eta}_1 = 0$ and $\widetilde{\Delta}'(0)\tilde{\eta}_2 = 0$ because

$$\mathcal{R}(\widetilde{\Delta}(0)) \oplus \widetilde{\Delta}'(0)\big(\mathcal{N}(\widetilde{\Delta}(0))\big) = \mathbb{R}^{m+1} \tag{4.19}$$

follows from (A_3) immediately. In particular, $\tilde{\eta}_2 = 0$. Indeed, assume that $\tilde{\eta}_2 \neq 0$. Since $\tilde{\eta}_2$ belongs to $\mathcal{N}(\widetilde{\Delta}(0))$, which is a two-dimensional subspace spanned by e_1 and $\tilde{\eta}_*$, the fact that $\widetilde{\Delta}'(0)\tilde{\eta}_2 = 0$ means $\dim \widetilde{\Delta}'(0)\big(\mathcal{N}(\widetilde{\Delta}(0))\big) \leq 1$. On the other hand, in view of (A_1), $\dim \mathcal{R}(\widetilde{\Delta}(0)) = \dim \mathcal{R}(\Delta(0)) = m-1$, which contradicts to (4.19). Hence, we obtain $\tilde{\eta}_2 = 0$, and therefore (4.18) is equivalent to $\widetilde{\Delta}(0)\tilde{\eta}_1 = 0$ and $\tilde{\eta}_2 = 0$. Consequently, $\mathcal{N}(\widetilde{A}^2) = \{w_1(0)\tilde{\eta}_1 : \widetilde{\Delta}(0)\tilde{\eta}_1 = 0,\ \tilde{\eta}_1 \in \mathbb{R}^{m+1}\} = \mathcal{N}(\widetilde{A})$ and the proof is completed. □

Remark 4.8. By virtue of Proposition 4.6, together with [22, Cororally 3.1], one may also conclude that $\dim \mathcal{M}_0(\widetilde{A}) = 2$ under the assumptions (A_1) and (A_3).

Similarly, the generalized eigenspace of the formal adjoint operator $\widetilde{A}^\sharp$ is identical with its eigenspace.

Proposition 4.9. *We have* $\mathcal{N}((\widetilde{A}^\sharp)^k) = \mathcal{N}(\widetilde{A}^\sharp)$ $(k = 2, 3, \ldots)$ *and*

$$\mathcal{N}(\widetilde{A}^\sharp) = \operatorname{span}\{w_1^\sharp(0)e_1^*,\, w_1^\sharp(0)\tilde{\zeta}^*\},$$

where e_1^* *and* $\tilde{\zeta}^*$ *are the elements of* $\mathbb{R}^{m+1\,*}$ *given by* $e_1^* := (1, 0, \ldots, 0)$, $\tilde{\zeta}^* = (0, \zeta^*)$ *being an eigenvector of* P_0^* *associated with eigenvalue* 1, *that is,* $\zeta^* \in \mathcal{N}(\Delta(0)^*)\backslash\{0\}$, *and* $w_1^\sharp(0)$ *is the one given in* (2.10). *Here* $\Delta(0)^*$ *and* P_0^* *denote the adjoint operators of* $\Delta(0)$ *and* P_0, *respectively.*

Proof. Recall from Proposition 2.7 that $\mathcal{N}(\widetilde{A}^\sharp) = \operatorname{span}\{w_1^\sharp(0)\tilde{\zeta} : \tilde{\zeta}D_1(0) = 0,\ \tilde{\zeta} \in \mathbb{R}^{m+1\,*}\}$ and

$$\mathcal{N}((\widetilde{A}^\sharp)^2) = \{w_1^\sharp(0)\tilde{\zeta}_2 + w_2^\sharp(0)\tilde{\zeta}_1 : (\tilde{\zeta}_1, \tilde{\zeta}_2)D_2(0) = 0,\ \tilde{\zeta}_1, \tilde{\zeta}_2 \in \mathbb{R}^{m+1\,*}\}.$$

One can readily verify that $\mathcal{N}(\widetilde{A}^\sharp) = \operatorname{span}\{w_1^\sharp(0)e_1^*,\, w_1^\sharp(0)\tilde{\zeta}_*\}$. Also, $(\tilde{\zeta}_1, \tilde{\zeta}_2)D_2(0) = 0$ implies

$$\tilde{\zeta}_1\widetilde{\Delta}(0) = 0 \quad \text{and} \quad \tilde{\zeta}_1\widetilde{\Delta}'(0) + \tilde{\zeta}_2\widetilde{\Delta}(0) = 0. \tag{4.20}$$

Hence, $\tilde{\zeta}_1$ vanishes on the subspace $\mathcal{R}(\widetilde{\Delta}(0))$ of $\mathbb{R}^{m+1}$ and on $\widetilde{\Delta}'(0)(\mathcal{N}(\widetilde{\Delta}(0)))$, as well. Therefore, by (4.19), we must have $\tilde{\zeta}_1 = 0$. Thus, (4.20) is equivalent to $\tilde{\zeta}_1 = 0$ and $\tilde{\zeta}_2\widetilde{\Delta}(0) = 0$, so that $\mathcal{N}((\widetilde{A}^\sharp)^2) = \{w_1^\sharp(0)\tilde{\zeta}_2 : \tilde{\zeta}_2\widetilde{\Delta}(0) = 0,\ \tilde{\zeta}_2 \in \mathbb{R}^{m+1\,*}\} = \mathcal{N}(\widetilde{A}^\sharp)$. This completes the proof. □

By Theorem 2.8 the projection $\Pi^c : \widetilde{X} \to \widetilde{E}^c$ along the decomposition (4.17) is given as follows:

Proposition 4.10.

$$\Pi^c\widetilde{\phi} = w_1(0)\begin{pmatrix} \rho_0 \int_{-\infty}^0 p_0(-\theta)\Big(\int_\theta^0 \phi^{(1)}(\xi)d\xi\Big)d\theta \\ (1/r)\int_{-\infty}^0 \zeta^* P(-\theta)\Big(\int_\theta^0 \phi^{(2)}(\xi)d\xi\Big)d\theta\cdot\eta_* \end{pmatrix}$$

for $\widetilde{\phi} = \mathrm{col}\,(\phi^{(1)}, \phi^{(2)}) \in \widetilde{X}$, *where* r *denotes the constant* $\langle\zeta^*, P_1\eta_*\rangle$.

Proof. We first verify $r \neq 0$. Suppose by contradiction that $r = 0$; then $\zeta^*|_{\Delta'(0)(\mathcal{N}(\Delta(0)))} = 0$ because of $\mathcal{N}(\Delta(0)) = \mathrm{span}\,\{\eta_*\}$. Note that $\zeta^* \in \mathcal{N}(\Delta(0)^*) = \mathcal{R}(\Delta(0))^\perp$, where for any subspace W of $\mathbb{R}^{m+1}$, $W^\perp$ stands for the annihilator of W. By the same reasoning as the proof of Proposition 4.9, it follows from (A_3) that $\zeta^* = 0$, contradicting to the fact that ζ^* is an eigenvector of P_0^* corresponding to eigenvalue 1.

We next consider the representation of Π^c. In virtue of (4.16), it is easy to see

$$\begin{aligned}
\langle\!\langle w_1^\sharp(0)e_1^*, w_1(0)e_1\rangle\!\rangle &= \int_{-\infty}^0\Big(\int_\theta^0 p_0(-\theta)d\xi\Big)d\theta = \int_{-\infty}^0(-\theta)p_0(-\theta)d\theta = \int_0^\infty t p_0(t)dt = \frac{1}{\rho_0},\\
\langle\!\langle w_1^\sharp(0)e_1^*, w_1(0)\tilde{\eta}_*\rangle\!\rangle &= \langle\!\langle w_1^\sharp(0)\tilde{\zeta}^*, w_1(0)e_1\rangle\!\rangle = 0,\\
\langle\!\langle w_1^\sharp(0)\tilde{\zeta}^*, w_1(0)\tilde{\eta}_*\rangle\!\rangle &= \int_{-\infty}^0\Big(\int_\theta^0 \zeta^* P(-\theta)\eta_* d\xi\Big)d\theta = \zeta^*\Big(\int_{-\infty}^0(-\theta)P(-\theta)d\theta\Big)\eta_*\\
&= \zeta^*\Big(\int_0^\infty tP(t)dt\Big)\eta_* = \langle\zeta^*, P_1\eta_*\rangle = r.
\end{aligned}$$

Therefore, by letting

$$\Phi_c := (w_1(0)e_1, w_1(0)\eta_*), \quad \Psi_c := \begin{pmatrix} w_1^\sharp(0)e_1^* \\ w_1^\sharp(0)\zeta^*\end{pmatrix},$$

we have

$$\langle\!\langle\Phi_c, \Psi_c\rangle\!\rangle = \begin{pmatrix} 1/\rho_0 & 0 \\ 0 & r\end{pmatrix},$$

and so,

$$\langle\!\langle\Phi_c, \Psi_c\rangle\!\rangle^{-1}\langle\!\langle\Psi_c, \widetilde{\phi}\rangle\!\rangle = \begin{pmatrix}\rho_0 & 0\\ 0 & 1/r\end{pmatrix}\begin{pmatrix}\langle\!\langle w_1^\sharp(0)e_1^*, \widetilde{\phi}\rangle\!\rangle \\ \langle\!\langle w_1^\sharp(0)\zeta^*, \widetilde{\phi}\rangle\!\rangle\end{pmatrix} = \begin{pmatrix}\langle\!\langle w_1^\sharp(0)(\rho_0 e_1^*), \widetilde{\phi}\rangle\!\rangle \\ \langle\!\langle w_1^\sharp(0)((1/r)\zeta^*), \widetilde{\phi}\rangle\!\rangle\end{pmatrix}.$$

Hence, Theorem 2.8 yields

$$\Pi^c\widetilde{\phi} = \Phi_c\langle\!\langle\Phi_c, \Psi_c\rangle\!\rangle^{-1}\langle\!\langle\Psi_c, \widetilde{\phi}\rangle\!\rangle = w_1(0)\begin{pmatrix}\langle\!\langle w_1^\sharp(0)(\rho_0 e_1^*), \widetilde{\phi}\rangle\!\rangle \\ \langle\!\langle w_1^\sharp(0)((1/r)\zeta^*), \widetilde{\phi}\rangle\!\rangle\eta_*\end{pmatrix}.$$

Since

$$\langle\!\langle w_1^\sharp(0)(\rho_0 e_1^*), \widetilde{\phi}\rangle\!\rangle = \int_{-\infty}^0\Big(\int_\theta^0 \rho_0 p_0(-\theta)\phi^{(1)}(\xi)d\xi\Big)d\theta$$

and

$$\langle\!\langle w_1^\sharp(0)((1/r)\zeta^*), \widetilde{\phi}\rangle\!\rangle = \int_{-\infty}^0\Big(\int_\theta^0 (1/r)\zeta^* P(-\theta)\phi^{(2)}(\xi)d\xi\Big)d\theta,$$

we have

$$\Pi^c\widetilde{\phi} = w_1(0)\begin{pmatrix} \rho_0\int_{-\infty}^0 p_0(-\theta)\Big(\int_\theta^0 \phi^{(1)}(\xi)d\xi\Big)d\theta \\ (1/r)\int_{-\infty}^0 \zeta^* P(-\theta)\Big(\int_\theta^0 \phi^{(2)}(\xi)d\xi\Big)d\theta\cdot\eta_*\end{pmatrix}.$$

This completes the proof. □

4.3 Central equation for the extended system

Now we shall derive the central equation for Eq. $(\widetilde{E})$. Let $\widetilde{x}(t) = \mathrm{col}\,(\varepsilon(t), x(t))$ be a solution of Eq. $(\widetilde{E})$. Then, by Proposition 4.10,

$$\Pi^c\widetilde{x}_t = \Pi^c\begin{pmatrix}\varepsilon_t\\ x_t\end{pmatrix} = w_1(0)\begin{pmatrix} \rho_0\int_{-\infty}^0 p_0(-\theta)\Big(\int_\theta^0 \varepsilon(t+\xi)d\xi\Big)d\theta \\ (1/r)\int_{-\infty}^0 \zeta_* P(-\theta)\Big(\int_\theta^0 x(t+\xi)d\xi\Big)d\theta\cdot\eta_*\end{pmatrix}.$$

Since

$$\begin{aligned}&\int_{-\infty}^0 p_0(-\theta)\Big(\int_\theta^0 \varepsilon(t+\xi)d\xi\Big)d\theta\\ &\quad= \int_{-\infty}^0 p_0(-\theta)\Big(\int_{t+\theta}^t \varepsilon(s)ds\Big)d\theta = \int_{-\infty}^t p_0(t-\tau)\Big(\int_\tau^t \varepsilon(s)ds\Big)d\tau\\ &\quad= \int_{-\infty}^t\Big(\int_{-\infty}^s p_0(t-\tau)d\tau\Big)\varepsilon(s)ds = \int_{-\infty}^t\Big(\int_{t-s}^\infty p_0(w)dw\Big)\varepsilon(s)ds\end{aligned}$$

and similarly

$$\int_{-\infty}^0 \zeta^* P(-\theta)\Big(\int_\theta^0 x(t+\xi)d\xi\Big)d\theta = \int_{-\infty}^t\Big(\int_{t-s}^\infty \zeta^* P(w)dw\Big)x(s)ds,$$

it follows that

$$\begin{aligned}\Pi^c\widetilde{x}_t &= w_1(0)\begin{pmatrix} \rho_0\int_{-\infty}^t\Big(\int_{t-s}^\infty p_0(w)dw\Big)\varepsilon(s)ds \\ (1/r)\int_{-\infty}^t\Big(\int_{t-s}^\infty \zeta^* P(w)dw\Big)x(s)ds\cdot\eta_*\end{pmatrix}\\ &= \Phi_c\begin{pmatrix} \rho_0\int_{-\infty}^t\Big(\int_{t-s}^\infty p_0(w)dw\Big)\varepsilon(s)ds \\ (1/r)\int_{-\infty}^t\Big(\int_{t-s}^\infty \zeta^* P(w)dw\Big)x(s)ds\end{pmatrix}.\end{aligned}$$

Hence, in view of $\Pi^c\widetilde{x}_t = \Phi_c z_c(t)$, we obtain

$$z_c(t) = \begin{pmatrix} \rho_0\int_{-\infty}^t\Big(\int_{t-s}^\infty p_0(w)dw\Big)\varepsilon(s)ds \\ (1/r)\int_{-\infty}^t\Big(\int_{t-s}^\infty \zeta^* P(w)dw\Big)x(s)ds\end{pmatrix},$$

which, together with Eq. $(\widetilde{E})$ (or (4.7)), leads to

$$\begin{aligned}\frac{d}{dt}z_c(t) &= \begin{pmatrix} \rho_0\Big(\varepsilon(t) - \int_{-\infty}^t p_0(t-s)\varepsilon(s)ds\Big) \\ (1/r)\zeta^*\Big(x(t) - \int_{-\infty}^t P(t-s)x(s)ds\Big)\end{pmatrix}\\ &= \frac{1}{r}\begin{pmatrix}0\\ \zeta^* G^{(2)}(\widetilde{x}_t)\end{pmatrix} = \frac{1}{r}\begin{pmatrix}0\\ \zeta^* G^{(2)}\big(\Phi_c z_c(t) + \widetilde{F}_*(\Phi_c z_c(t))\big)\end{pmatrix}.\end{aligned}$$

Summarizing, we have:

Proposition 4.11. *The central equation of the equilibrium* 0 *of Eq.* ($\widetilde{E}$) *is described as the* 2*-dimensional ODE*

$$z' = H(z), \tag{4.21}$$

where H *is an* $\mathbb{R}^2$*-valued function defined on a neighborhood of* 0 *of* $\mathbb{R}^2$ *by*

$$H(w) := H_c\widetilde{G}\big(\Phi_c w + \widetilde{F}_*(\Phi_c w)\big) \quad \textit{for small } |w|,$$

and H_c *is the* $2 \times (m+1)$ *matrix given by* $H_c := r^{-1}\mathrm{col}\,(0, \tilde{\zeta}^*)$.

Let us denote $w = \mathrm{col}\,(\varepsilon, s) \in \mathbb{R}^2$. Then $\Phi_c w = w_1(0)(\varepsilon e_1 + s\eta_*) = \mathrm{col}\,\big(w_1(0)\varepsilon,\, w_1(0)(s\eta_*)\big)$ and hence by (4.9),

$$\begin{aligned} G^{(2)}(\Phi_c w) &= \left(\int_{-\infty}^0 p_0(-\theta)\big(w_1(0)\varepsilon\big)(\theta)d\theta\right)\left(\int_{-\infty}^0 P(-\theta)\big(w_1(0)(s\eta_*)\big)(\theta)d\theta\right) \\ &\quad + Q(w_1(0)(s\eta_*)) + g(w_1(0)(s\eta_*)) \\ &= \left(\int_{-\infty}^0 p_0(-\theta)\varepsilon d\theta\right)\left(\int_{-\infty}^0 P(-\theta)(s\eta_*)d\theta\right) + Q(w_1(0)\eta_*)s^n \\ &\quad + o(\|w_1(0)(s\eta_*)\|_X^n) \\ &= \varepsilon s\eta_* + s^n v_0 + o(|s|^n) \quad \text{as } (\varepsilon, s) \to (0,0), \end{aligned} \tag{4.22}$$

where we used the fact $P_0\eta_* = \eta_*$ and put $v_0 := Q(w_1(0)\eta_*)$.

Proposition 4.12. $\widetilde{F}_*\big(w_1(0)(\varepsilon e_1)\big) = 0$ *for sufficiently small* $|\varepsilon|$.

Proof. $\tilde{x}^\varepsilon(t) := \varepsilon e_1$ $(t \in \mathbb{R})$ is obviously a solution on $\mathbb{R}^+$ of ($\widetilde{E}$) with $\tilde{x}_t^\varepsilon = w_1(0)(\varepsilon e_1)$ $(= \Phi_c(\varepsilon e_1))$. So, if $|\varepsilon| < \rho\delta/3$, we have $\tilde{x}_t^\varepsilon \in \widetilde{\Omega}_0$ for $t \in \mathbb{R}^+$, and hence Theorem 3.3 means $\mathrm{dist}\,\big(\tilde{x}_t^\varepsilon, W_{\mathrm{loc}}^c(0)\big) \to 0$ as $t \to \infty$. Thus, $w_1(0)(\varepsilon e_1) \in W_{\mathrm{loc}}^c(0) = \mathrm{graph}\,\widetilde{F}_*$, that is,

$$w_1(0)(\varepsilon e_1) = \Pi^c(w_1(0)(\varepsilon e_1)) + \widetilde{F}_*\big(\Pi^c(w_1(0)(\varepsilon e_1))\big),$$

which proves the proposition because $\Pi^c(w_1(0)(\varepsilon e_1)) = w_1(0)(\varepsilon e_1)$. □

Proposition 4.13. $G^{(2)}(\Phi_c w + \widetilde{F}_*(\Phi_c w))$ *satisfies*

(i) $G^{(2)}(\Phi_c w + \widetilde{F}_*(\Phi_c w)) = \varepsilon s\eta_* + s^n v_0 + o(|s|^n) + o(|\varepsilon s|)$,

(ii) $(\partial/\partial s)G^{(2)}(\Phi_c w + \widetilde{F}_*(\Phi_c w)) = \varepsilon + o(|\varepsilon|) + ns^{n-1}v_0 + o(|s|^{n-1})$

as $w = \mathrm{col}\,(\varepsilon, s) \to (0,0)$.

Proof. We assume that $\|\Phi_c w\|_{\widetilde{X}} < \delta$ so that $\widetilde{F}_*(\Phi_c w)$ is well-defined. Let us denote $\widetilde{F}_*(\Phi_c w) = \mathrm{col}\,(\phi^w, \psi^w) \in \widetilde{X}$ with $\phi^w \in X_1$ and $\psi^w \in X$. By Proposition 4.12,

$$\begin{aligned} \widetilde{F}_*(\Phi_c w) &= \widetilde{F}_*(w_1(0)(\varepsilon e_1 + s\eta_*)) - \widetilde{F}_*(w_1(0)(\varepsilon e_1)) \\ &= \int_0^1 \frac{d}{d\tau}\widetilde{F}_*(w_1(0)(\varepsilon e_1 + \tau s\eta_*))d\tau \\ &= \int_0^1 D\widetilde{F}_*\big(w_1(0)(\varepsilon e_1 + \tau s\eta_*)\big)(w_1(0)(s\eta_*))d\tau, \end{aligned}$$

and hence

$$\|\widetilde{F}_*(\Phi_c w)\|_{\widetilde{X}} \le \rho^{-1}|s||\eta_*| \sup_{0\le\tau\le 1} \big\|D\widetilde{F}_*\big(w_1(0)(\varepsilon e_1 + \tau s\eta_*)\big)\big\|_{\mathcal{L}(\widetilde{E}^c;\widetilde{E}^s)}.$$

This yields $\widetilde{F}_*(\Phi_c w) = o(|s|)$ as $(\varepsilon, s) \to (0,0)$ since $\widetilde{F}_*$ is of class C^1 with $D\widetilde{F}_*(0) = 0$; so, in view of $\|\psi^w\|_X \le \|\widetilde{F}_*(\Phi_c w)\|_{\widetilde{X}}$,

$$\psi^w = o(|s|), \quad (\varepsilon, s) \to (0,0). \tag{4.23}$$

In addition, since

$$\frac{\partial}{\partial s}\widetilde{F}_*(\Phi_c w) = D\widetilde{F}_*(\Phi_c w)(w_1(0)\eta_*) = o(1) \quad \text{as } (\varepsilon, s) \to (0,0)$$

and $\|\partial\psi^w/\partial s\|_X \le \|(\partial/\partial s)\widetilde{F}_*(\Phi_c w)\|_{\widetilde{X}}$, it follows that

$$\frac{\partial}{\partial s}\psi^w = o(1), \quad (\varepsilon, s) \to (0,0). \tag{4.24}$$

(i) We first observe that $\Pi^c \widetilde{F}_*(\Phi_c w) = 0$ because of the fact $\widetilde{F}_*(\Phi_c w) \in \widetilde{E}^s$; so Proposition 4.10 yields

$$\begin{aligned} 0 &= \rho_0 \int_{-\infty}^0 p_0(-\theta)\left(\int_\theta^0 \phi^w(\xi)d\xi\right)d\theta \\ &= \int_{-\infty}^0 \left(\int_{-\infty}^\xi \rho_0 p_0(-\theta)d\theta\right)\phi^w(\xi)d\xi = \int_{-\infty}^0 p_0(-\xi)\phi^w(\xi)d\xi. \end{aligned}$$

Hence, one can see from (4.9) that

$$\begin{aligned} &G^{(2)}(\Phi_c w + \widetilde{F}_*(\Phi_c w)) - \widetilde{G}^{(2)}(\Phi_c w) \\ &= \left(\int_{-\infty}^0 p_0(-\theta)(\phi^w(\theta) + \varepsilon)d\theta\right)\left(\int_{-\infty}^0 P(-\theta)(\psi^w(\theta) + s\eta_*)d\theta\right) + f(\psi^w + w_1(0)(s\eta_*)) \\ &\quad -\left(\int_{-\infty}^0 p_0(-\theta)\varepsilon d\theta\right)\left(\int_{-\infty}^0 P(-\theta)(s\eta_*)d\theta\right) - f(w_1(0)(s\eta_*)) \\ &= \varepsilon\int_{-\infty}^0 P(-\theta)\psi^w(\theta)d\theta + f(\psi^w + w_1(0)(s\eta_*)) - f(w_1(0)(s\eta_*)). \end{aligned} \tag{4.25}$$

Notice from (4.23) that the first term is estimated by

$$\left|\varepsilon\int_{-\infty}^0 P(-\theta)\psi^w(\theta)d\theta\right| \le |\varepsilon|\|P\|_{\infty,\rho}\|\psi^w\|_X = o(|\varepsilon s|) \tag{4.26}$$

as $(\varepsilon, s) \to (0,0)$. On the other hand, we have

$$\begin{aligned} |f(\psi^w + w_1(0)(s\eta_*)) - f(w_1(0)(s\eta_*))| &\le |Q(\psi^w + w_1(0)(s\eta_*)) - Q(w_1(0)(s\eta_*))| \\ &\quad + |g(\psi^w + w_1(0)(s\eta_*)) - g(w_1(0)(s\eta_*))| =: d_1 + d_2. \end{aligned}$$

Since

$$d_2 \le \int_0^1 \|Dg(\psi^w + \tau w_1(0)(s\eta_*))\|_{\mathcal{L}(X;\mathbb{C}^m)}\|\psi^w\|_X d\tau$$

and, by (4.23) again,

$$\begin{aligned} \|\psi^w + \tau w_1(0)(s\eta_*)\|_X &\le \|\psi^w\|_X + \|w_1(0)(s\eta_*)\|_X \\ &= o(|s|) + \rho^{-1}|s||\eta_*| \le C_3|s|, \quad \tau \in [0,1] \end{aligned} \tag{4.27}$$

hold with some positive constant C_3, it follows from the assumption (4.4) that

$$d_2 = o(|s|^{n-1})\, o(|s|) = o(|s|^n) \quad \text{as} \quad (\varepsilon, s) \to (0,0).$$

Also, by the multi-linearity of Q_* and (4.27),

$$\begin{aligned}
d_1 &= |Q_*(\psi^w + w_1(0)(s\eta_*), \dots, \psi^w + w_1(0)(s\eta_*)) - Q_*(w_1(0)(s\eta_*), \dots, w_1(0)(s\eta_*))| \\
&\le \sum_{k=1}^{n} \big| Q_*(\psi^w, \dots, \psi^w, \underset{\widehat{k}}{\psi^w + w_1(0)(s\eta_*)}, \dots, \psi^w + w_1(0)s) \\
&\quad - Q_*(\psi^w, \dots, \psi^w, \underset{\widehat{k}}{w_1(0)(s\eta_*)}, \psi^w + w_1(0)(s\eta_*), \dots, \psi^w + w_1(0)(s\eta_*)) \big| \\
&= \sum_{k=1}^{n} \big| Q_*(\psi^w, \dots, \psi^w, \underset{\widehat{k}}{\psi^w}, \psi^w + w_1(0)(s\eta_*), \dots, \psi^w + w_1(0)(s\eta_*)) \big| \\
&\le \sum_{k=1}^{n} \|Q_*\|_{\mathcal{L}^n(X;\mathbb{R}^m)} \|\psi^w\|_X^k \, \|\psi^w + w_1(0)(s\eta_*)\|_X^{n-k} \\
&\le \|Q_*\|_{\mathcal{L}^n(X;\mathbb{R}^m)} \sum_{k=1}^{n} \|\psi^w\|_X^k \, (C_3|s|)^{n-k},
\end{aligned}$$

and hence (4.23) implies $d_1 = o(|s|^n)$ as $(\varepsilon, s) \to (0,0)$. By (4.25), (4.26) and the estimates of d_i $(i = 1, 2)$, we obtain

$$G^{(2)}(\Phi_c w + \widetilde{F}_*(\Phi_c w)) - G^{(2)}(\Phi_c w) = o(|\varepsilon s|) + o(|s|^m),$$

and so, by (4.22),

$$G^{(2)}(\Phi_c w + \widetilde{F}_*(\Phi_c w)) = \varepsilon s + \mu s^n v_0 + o(|s|^n) + o(\varepsilon s|) \quad \text{as} \quad (\varepsilon, s) \to (0,0).$$

(ii) We know that

$$\begin{aligned}
&G^{(2)}(\Phi_c w + \widetilde{F}_*(\Phi_c w)) \\
&\quad = \left(\int_{-\infty}^{0} p_0(\theta)(\phi^w(\theta) + \varepsilon) d\theta \right) \left(\int_{-\infty}^{0} P(\theta)(\psi^w(\theta) + s\eta_*) d\theta \right) + f(\psi^w + w_1(0)(s\eta_*)) \\
&\quad = \varepsilon s\eta_* + \varepsilon \int_{-\infty}^{0} P(\theta)\psi^w(\theta) d\theta + \mu Q(\psi^w + w_1(0)(s\eta_*)) + g(\psi^w + w_1(0)(s\eta_*)),
\end{aligned}$$

and hence

$$\begin{aligned}
\frac{\partial}{\partial s} G^{(2)}(\Phi_c w + \widetilde{F}_*(\Phi_c w)) &= \varepsilon\eta_* + \varepsilon \int_{-\infty}^{0} P(\theta) \frac{\partial}{\partial s}\psi^w(\theta) d\theta + \mu \frac{\partial}{\partial s} Q(\psi^w + w_1(0)(s\eta_*)) \\
&\quad + Dg(\psi^w + w_1(0)(s\eta_*)) \left(\frac{\partial}{\partial s}\psi^w + w_1(0)\eta_* \right).
\end{aligned} \tag{4.28}$$

In view of (4.24),

$$\left| \varepsilon \int_{-\infty}^{0} P(\theta) \frac{\partial}{\partial s}\psi^w(\theta) d\theta \right| \le |\varepsilon| \|P\|_{\infty,\rho} \left\| \frac{\partial \psi^w}{\partial s} \right\|_X = o(|\varepsilon|), \quad (\varepsilon, s) \to (0,0).$$

Moreover, observe that

$$Q(\psi^w + w_1(0)(s\eta_*)) = s^n v_0 + \sum_{(\phi_1, \dots, \phi_m) \in B} Q_*(\phi_1, \dots, \phi_m),$$

where we used the fact that $Q(w_1(0)(s\eta_*)) = s^n v_0$, and denoted by B the subset of X^n, $\{\psi^w, w_1(0)(s\eta_*)\}^n \backslash \{(w_1(0)(s\eta_*), \dots, w_1(0)(s\eta_*))\}$. Hence,

$$\frac{\partial}{\partial s} Q(\psi^w + w_1(0)(s\eta_*)) = ns^{n-1}v_0 + \sum_{(\phi_1,\dots,\phi_n)\in B} \sum_{k=1}^{n} Q_*(\phi_1, \dots, \partial\phi_k/\partial s, \dots, \phi_n).$$

One can readily deduce from (4.23) and (4.24) that for any $(\phi_1, \dots, \phi_n) \in B$,

$$Q_*(\phi_1, \dots, \partial\phi_k/\partial s, \dots, \phi_n) = o(|s|^{n-1}) \quad \text{as } (\varepsilon, s) \to (0,0),$$

so that

$$\frac{\partial}{\partial s} Q(\psi^w + w_1(0)(s\eta_*)) = ns^{n-1}v_0 + o(|s|^{n-1}).$$

Also, by (4.24) again, there exists a positive constant C_4 such that

$$\left\| \frac{\partial}{\partial s}\psi^w + w_1(0)\eta_* \right\|_X \le C_4 \quad \text{for small } |\varepsilon| \text{ and } |s|,$$

which, together with (4.27) and the assumption (4.4), means that

$$\left\| Dg(\psi^w + w_1(0)(s\eta_*)) \left(\frac{\partial}{\partial s}\psi^w + w_1(0)\eta_* \right) \right\|_X \le C_4 \|Dg(\psi^w + w_1(0)(s\eta_*)\|_X = o(|s|^{n-1}).$$

Consequently (4.28), together with the estimates above, leads to

$$\frac{\partial}{\partial s} G^{(2)}(\Phi_c w + \widetilde{F}_*(\Phi_c w)) = \varepsilon\eta_* + o(|\varepsilon|) + ns^{n-1}v_0 + o(|s|^{n-1})$$

as $(\varepsilon, s) \to (0,0)$, and this completes the proof. □

In virtue of Proposition 4.13, the central equation (4.21) turns out to be of the form

$$\begin{aligned} \varepsilon' &= 0, \\ s' &= h(\varepsilon, s), \end{aligned} \tag{$C\widetilde{E}$}$$

where $h(\varepsilon, s) = (1/r)\langle \zeta^*, G^{(2)}(\Phi_c w + \widetilde{F}_*(\Phi_c w))\rangle$ is of class C^1 and satisfies

$$\begin{aligned} h(\varepsilon, s) &= \frac{1}{r}\langle \zeta^*, \varepsilon s\eta_* + s^n v_0 + o(|s|^n) + o(\varepsilon s|)\rangle \\ &= -\frac{1}{q_*}\varepsilon s + c_0 s^n + o(|s|^n) + o(|\varepsilon s|) \end{aligned} \tag{4.29}$$

as $(\varepsilon, s) \to (0,0)$. Furthermore, its derivative with respect to s has the property

$$\frac{\partial h}{\partial s}(\varepsilon, s) = -\frac{1}{q_*}\varepsilon + nc_0 s^{n-1} + o(|s|^{n-1} + |\varepsilon|), \quad (\varepsilon, s) \to (0,0), \tag{4.30}$$

where q_* and c_0 are constants introduced in (4.5), that is,

$$q_* = -\langle \zeta^*, P_1\eta_*\rangle / \langle \zeta^*, \eta_*\rangle, \text{ and } c_0 = \langle \zeta^*, Q(w_1(0)\eta_*)\rangle.$$

4.4 Proof of Theorem 4.4

In this subsection we will prove Theorem 4.4. Under the conditions (4.29) and (4.30), the behaviors of solutions of ($C\widetilde{E}$) are determined by the following lemma, which is a slight refinement of [11, Lemma 6.3.1].

Lemma 4.14. *Let $h(\varepsilon, s)$ be a real valued function of class C^1 defined in a neighborhood U_0 of $(0,0)$ of $\mathbb{R}^2$ that satisfies*

$$h(\varepsilon, s) = -\alpha s\varepsilon + \beta s^m + o(|s|^m + |\varepsilon s|), \tag{4.31}$$

and

$$\frac{\partial h}{\partial s}(\varepsilon, s) = -\alpha\varepsilon + m\beta s^{m-1} + o(|s|^{m-1} + |\varepsilon|) \tag{4.32}$$

as $(s,\varepsilon) \to (0,0)$, where $\alpha > 0$, $\beta \neq 0$ and $m = 2, 3, \ldots$ Then we have:

(a) *If m is even, then*

(a_1) *there exists an $s^* > 0$ such that $h(0,s)$ is positive (resp. negative) definite for $0 < |s| < s^*$ in the case of $\beta > 0$ (resp. $\beta < 0$). Moreover, there exist an $\varepsilon^* > 0$ and a continuous function $s : (-\varepsilon^*, \varepsilon^*)\backslash\{0\} \to \mathbb{R}\backslash\{0\}$ such that $h(\varepsilon, s_\varepsilon) = 0$ for $0 < |\varepsilon| < \varepsilon^*$, $s_\varepsilon \to 0$ as $\varepsilon \to 0$, and*

$$\frac{\partial h}{\partial s}(\varepsilon, s_\varepsilon) \begin{cases} < 0 & (\varepsilon < 0), \\ > 0 & (\varepsilon > 0) \end{cases} \tag{4.33}$$

holds for small $|\varepsilon|$.

(a_2) *There exists an open subset U_1 of U_0 containing $(0,0)$ such that $h(\hat{\varepsilon}, \hat{s}) = 0$ with some $(\hat{\varepsilon}, \hat{s}) \in U_1$ implies $\hat{s} = 0$ or $\hat{s} = s_{\hat{\varepsilon}}$.*

(b) *If m is odd and $\beta > 0$, then*

(b_1) *there exists an $s^* > 0$ such that $sh(0,s) > 0$ for $0 < |s| < s^*$. Moreover, if $\varepsilon \leq 0$ with $|\varepsilon|$ small, $h(\varepsilon, \cdot)$ has no small zeros other than 0; on the other hand, there exist an $\varepsilon^* > 0$ and continuous functions $s^\pm : (0, \varepsilon^*) \to \mathbb{R}\backslash\{0\}$ such that $h(\varepsilon, s^+_\varepsilon) = h(\varepsilon, s^-_\varepsilon) = 0$ for $0 < \varepsilon < \varepsilon^*$, $s^\pm_\varepsilon \to 0$ as $\varepsilon \to +0$, and*

$$\frac{\partial h}{\partial s}(\varepsilon, s^\pm_\varepsilon) > 0 \quad \text{for small } \varepsilon > 0. \tag{4.34}$$

(b_2) *There exists an open subset U_1 of U_0 containing $(0,0)$ such that $h(\hat{\varepsilon}, \hat{s}) = 0$ with $(\hat{\varepsilon}, \hat{s}) \in U_1$ implies that $\hat{s}$ coincides with 0, $s^+_{\hat{\varepsilon}}$ or $s^-_{\hat{\varepsilon}}$.*

(c) *If m is odd and $\beta < 0$, then*

(c_1) *there exists an $s^* > 0$ such that $sh(0,s) < 0$ for $0 < |s| < s^*$. Moreover, if $\varepsilon \geq 0$ with $|\varepsilon|$ small, $h(\varepsilon, \cdot)$ has no small zeros other than 0; on the other hand, there exist an $\varepsilon^* > 0$ and continuous functions $s^\pm : (-\varepsilon^*, 0) \to \mathbb{R}\backslash\{0\}$ such that $h(\varepsilon, s^+_\varepsilon) = h(\varepsilon, s^-_\varepsilon) = 0$ for $-\varepsilon^* < \varepsilon < 0$, $s^\pm_\varepsilon \to 0$ as $\varepsilon \to -0$, and*

$$\frac{\partial h}{\partial s}(\varepsilon, s^\pm_\varepsilon) < 0 \quad \text{for } \varepsilon < 0 \text{ with } |\varepsilon| \text{ small.}$$

(c_2) *There exists an open subset U_1 of U_0 containing $(0,0)$ s such that $h(\hat{\varepsilon}, \hat{s}) = 0$ with $(\hat{\varepsilon}, \hat{s}) \in U_1$ implies that $\hat{s}$ coincides with 0, $s^+_{\hat{\varepsilon}}$, or $s^-_{\hat{\varepsilon}}$.*

We will first prove Theorem 4.4 and, for completeness, give a proof of Lemma 4.14 at the end of this subsection. Note that any equilibrium in $\widetilde{\Omega}_0$ of Eq. $(\widetilde{E})$ must be contained in $\widetilde{W}^c_{\mathrm{loc}}(0)$ because of the attractivity of $\widetilde{W}^c_{\mathrm{loc}}(0)$ (see [23, Theorem 5], or Theorem 3.3); so in view of Proposition 3.1, $\tilde{\phi}_* \in \widetilde{\Omega}$ is an equilibrium of Eq. $(\widetilde{E})$ if and only if there exists an equilibrium z_* of the central equation $(C\widetilde{E})$ (or (4.21)) such that

$$\tilde{\phi}_* = \Phi_c z_* + \widetilde{F}_*(\Phi_c z_*). \tag{4.35}$$

Remark 4.15. If $\tilde{\phi}_*$ is an equilibrium of Eq. $(\widetilde{E})$ (or (4.7)), then $\phi_* := \Pi_2\tilde{\phi}_*$ is an equilibrium of Eq. (PE) with $\lambda = 1+\varepsilon$, where ε is given by $w_1(0)\varepsilon = \Pi_1\tilde{\phi}_*$. Conversely, if ϕ_* is an equilibrium of Eq. (PE), then $\tilde{\phi}_* := j_{\lambda-1}(\phi_*)$ is an equilibrium of Eq. $(\widetilde{E})$ (or (4.7)), where $j_\varepsilon : X \to \widetilde{X}$ is the map defined in (4.14) (see Proposition 4.5).

Moreover, throughout this subsection, we assume that

$$L(\delta) < 1. \tag{4.36}$$

by taking $\delta > 0$ sufficiently small.

Proof of Theorem 4.4. We know by (4.29) and (4.30) that $h(\varepsilon, s)$ in Eq. $(C\widetilde{E})$ satisfies the assumptions (4.31) and (4.32).

(i) Let $\lambda = 1$, that is, $\varepsilon := \lambda - 1 = 0$, and $s^* > 0$ be the one in Lemma 4.14 (a_1). Then, $s' = h(0, s)$, the second equation of $(C\widetilde{E})$ with $\varepsilon = 0$, has no equilibria in $(-s^*, s^*)\backslash\{0\}$. By taking s^* small if necessary, we may assume that

$$s^* < \frac{\rho\delta}{3|\eta_*|}. \tag{4.37}$$

(ia) Note that $\|\Phi_c z\|_{\widetilde{X}} = \|sw_1(0)\tilde{\eta}_*\|_{\widetilde{X}} = \rho^{-1}|s||\eta_*|$ for $z = \mathrm{col}\,(0, s)$. So such a z with $s \in (-s^*, s^*)$ satisfies $\|\Phi_c z\|_{\widetilde{X}} < \delta/3$, and hence

$$\|\Phi_c z + \widetilde{F}_*(\Phi_c z)\|_{\widetilde{X}} \geq (1 - L(\delta))\|\Phi_c z\|_{\widetilde{X}} = (1 - L(\delta))\rho^{-1}|s||\eta_*.$$

Let $\rho_1 := (1 - L(\delta))\rho^{-1}s^*|\eta_*|$; then $0 < \rho_1 < \delta/3$ due to (4.36) and (4.37). Therefore, one can see from (4.35) that Eq. $(\widetilde{E})$ has no equilibria in $B_{\widetilde{X}}(\rho_1)\backslash\{0\}$. So, by Remark 4.15, Eq. (PE) has no equilibria in the set $j_0^{-1}(B_{\widetilde{X}}(\rho_1)\backslash\{0\}) = B_X(\rho_1)\backslash\{0\}$, where we used the fact that j_ε is an isometry for $\varepsilon \in \mathbb{R}$. Thus, the former part of (ia) is valid with $\mathcal{W}_0 = B_X(\rho_1)$.

Let $s : (-\varepsilon^*, \varepsilon^*)\backslash\{0\} \to \mathbb{R}\backslash\{0\}$ be the function in Lemma 4.14 (a_1) and set

$$\tilde{\phi}^\lambda_* := \Phi_c z^{\lambda-1} + \widetilde{F}_*(\Phi_c z^{\lambda-1}), \quad \lambda \in (1 - \varepsilon^*, 1 + \varepsilon^*)\backslash\{1\}, \tag{4.38}$$

where we used the notation $z^\varepsilon := \mathrm{col}\,(\varepsilon, s_\varepsilon)$ for $\varepsilon \in (-\varepsilon^*, \varepsilon^*)\backslash\{0\}$. We may assume

$$\|\Phi_c z^\varepsilon\|_{\widetilde{X}} < \delta/3 \quad \text{for } \varepsilon \in (-\varepsilon^*, \varepsilon^*)\backslash\{0\}. \tag{4.39}$$

Since z^ε is an equilibrium of Eq. $(C\widetilde{E})$, $\tilde{\phi}^\lambda_*$ is also an equilibrium of Eq. $(\widetilde{E})$ by (4.35).

Note that $\widetilde{T}(t) = \mathrm{diag}\,\big(T_0(t), T(t)\big)$, where $\{T_0(t)\}_{t\geq 0}$ is the solution semigroup of the first equation of (4.7). So, $\widetilde{T}^s(t) = \mathrm{diag}\,\big(T^s_0(t), T^s(t)\big)$ because $X_1 \times \{0\}$ and $\{0\} \times X$ are $\widetilde{T}(t)$-invariant subspaces of $\widetilde{X}$ for $t \geq 0$. Since $\Gamma^n\widetilde{G}_\delta(\Lambda_{*,\delta}(\psi)(s)) = \mathrm{col}\,\big(0, \Gamma^n G^{(2)}_\delta(\Lambda_{*,\delta}(\psi)(s))\big)$ with $G^{(2)}_\delta(\tilde{\phi}) := \Pi_2\widetilde{G}_\delta(\tilde{\phi})$, we see $\Pi_1\big(\Pi^s\Gamma^n\widetilde{G}_\delta(\Lambda_{*,\delta}(\psi)(s))\big) = 0$. Hence, (4.12) means that for $\psi \in \widetilde{E}^c$,

$$\Pi_1(\widetilde{F}_{*,\delta}(\psi)) = \lim_{n\to\infty}\int_{-\infty}^0 T^s_0(-s)\Pi_1\big(\Pi^s\Gamma^n\widetilde{G}_\delta(\Lambda_{*,\delta}(\psi)(s))\big)ds = 0. \tag{4.40}$$

It also follows from Proposition 4.10 that $\Phi_c z^{\lambda-1} = w_1(0)\big((\lambda-1)e_1 + s_{\lambda-1}\tilde{\eta}_*\big)$; so that

$$\Pi_1(\tilde{\phi}_*^\lambda) = \Pi_1(\Phi_c z^{\lambda-1}) + \Pi_1(\widetilde{F}_*(\Phi_c z^{\lambda-1})) = w_1(0)(\lambda-1)$$

because of (4.38) and the fact that $\widetilde{F}_* \equiv \widetilde{F}_{*,\delta}$ on $B_{\widetilde{E}^c}(\delta)$; in other words, $\Pi_1(\tilde{\phi}_*^\lambda)(\theta) = \lambda - 1$ for $\theta \in \mathbb{R}^-$.

Define $\phi_* : (1-\varepsilon^*, 1+\varepsilon^*)\backslash\{1\} \to X\backslash\{0\}$ by

$$\phi_*^\lambda := \Pi_2(\tilde{\phi}_*^\lambda), \quad \lambda \in (1-\varepsilon^*, 1+\varepsilon^*)\backslash\{1\}.$$

Then, ϕ_*^λ is seen to be an equilibrium of Eq. (*PE*) by Remark 4.15. In addition, ϕ_*^λ is continuous in λ and satisfies $\phi_*^\lambda \to 0$ $(\lambda \to 1)$ since $z^{\lambda-1} \to 0$ as $\lambda \to 1$.

We next show the instability of the equilibrium 0. When $\varepsilon = 0$, the second equation of $(C\widetilde{E})$ is $s' = c_0 s^n + o(|s|^n)$; so its zero solution, and hence the equilibrium 0 of $(C\widetilde{E})$, is unstable because n is even. Given $t_0 \in \mathbb{R}$ and $s_0 \in \mathbb{R}\backslash\{0\}$, let $z(t)$ be the solution of $(C\widetilde{E})$ with $z(t_0) = \mathrm{col}\,(0, s_0)$ and set $\widetilde{\psi} := \Phi_c z(t_0) + \widetilde{F}_*(\Phi_c z(t_0))$, where we assume $|s_0|$ is sufficiently small in such a way that $\|\Phi_c z(t_0)\|_X < \delta$ holds. Then it follows from (4.40) that $\Pi_1\widetilde{\psi} = 0$, so that $\widetilde{\psi} = j_0(\psi)$ with $\psi = \Pi_2\widetilde{\psi}$. So we deduce from Proposition 4.5 that

$$j_0(x_t(t_0, \psi, f)) = \widetilde{x}_t(t_0, \widetilde{\psi}, \widetilde{G}) = \Phi_c z(t) + \widetilde{F}_*(\Phi_c z(t))$$

for $t \geq t_0$ with $t - t_0$ small. Hence the instability of the equilibrium 0 of (*PE*) with $\lambda = 1$ follows from that of the equilibrium 0 of $(C\widetilde{E})$. Thus, (ia) holds.

(ib) The central equation of the equilibrium 0 of Eq. $(\widetilde{E}_\delta)$ is of the form

$$z' = H_c\widetilde{G}_\delta(\Phi_c z + \widetilde{F}_{*,\delta}(\Phi_c z)) \tag{$C\widetilde{E}_\delta$}$$

(cf. Proposition 4.11 and (4.11)). Let $h_\delta(z)$ be the second component of $H_c\widetilde{G}_\delta(\Phi_c z + \widetilde{F}_{*,\delta}(\Phi_c z))$. In view of (4.36), $\|\Phi_c z\|_{\widetilde{X}} < \delta$ implies

$$\|\widetilde{F}_{*,\delta}(\Phi_c z)\|_{\widetilde{X}} \leq L(\delta)\|\Phi_c z\|_{\widetilde{X}} < \delta,$$

and hence $\Phi_c z + \widetilde{F}_{*,\delta}(\Phi_c z) \in \widetilde{\Omega}$. So, $h(z) = h_\delta(z)$ for $\|\Phi_c z\|_{\widetilde{X}} < \delta$; in particular, by (4.39), $z^{\lambda-1}$ is also an equilibrium of Eq. $(C\widetilde{E}_\delta)$ for $\lambda \in (1-\varepsilon^*, 1+\varepsilon^*)$.

Suppose that $q_* < 0$. Notice from Lemma 4.14 (a_1) and the principle of linearized stability that $s_{\lambda-1}$ $(\lambda \neq 1)$ is the nonzero equilibrium of $s' = h(\lambda-1, s)$, hence of $s' = h_\delta(\lambda-1, s)$, which is asymptotically stable (resp. unstable) if $\lambda < 1$ (resp. $\lambda > 1$).

Now let $\lambda < 1$. Since $\{\lambda-1\} \times \mathbb{R}$ is an invariant set for Eq. $(C\widetilde{E}_\delta)$, the stability of $s_{\lambda-1}$ implies that for arbitrary $t_0 \in \mathbb{R}^+$ and $\hat{\varepsilon} > 0$, there exists a $\delta_0(\hat{\varepsilon}) > 0$ such that if $z^* \in \{\lambda-1\} \times \mathbb{R}$ satisfies $|z^* - z^{\lambda-1}| < \delta_0(\hat{\varepsilon})$, then $z(t; t_0, z^*) \in \{\lambda-1\} \times \mathbb{R}$ and $|z(t; t_0, z^*) - z^{\lambda-1}| < \hat{\varepsilon}$ hold for $t \geq t_0$, where $z(t; t_0, z^*)$ denotes the solution of Eq. $(C\widetilde{E}_\delta)$ with $z(t_0) = z^*$.

Let us denote by Π_X^c and Π_X^s the projections defined by $\Pi_X^c := \Pi_2 \circ \Pi^c \circ j_0$ and $\Pi_X^s := \Pi_2 \circ \Pi^s \circ j_0$, respectively. It is easy to see that $\Pi^c \circ j_\varepsilon = j_\varepsilon \circ \Pi_X^c$ and $\Pi^s \circ j_\varepsilon = j_0 \circ \Pi_X^s$ for $\varepsilon \in \mathbb{R}$. Set

$$\phi_*^{\lambda,c} := \Pi_X^c\phi_*^\lambda, \quad \text{and} \quad \phi_*^{\lambda,s} := \Pi_X^s\phi_*^\lambda.$$

Similarly, given $\phi \in X$ and $\tilde{\phi} \in \widetilde{X}$, we put $\phi^c := \Pi_X^c\phi$ and $\tilde{\phi}^c := \Pi^c\tilde{\phi}$; and likewise for ϕ^s and $\tilde{\phi}^s$. Given $\phi \in X$, let z^* be the point of $\mathbb{R}^2$ satisfying $\Phi_c z^* = (j_{\lambda-1}(\phi))^c = j_{\lambda-1}(\phi^c)$. Then $z(t; t_0, z^*) = z(t - t_0, j_{\lambda-1}(\phi))$ for $t \geq t_0$ (cf. (3.16)). Observe that $\Phi_c z^{\lambda-1} = \Pi^c\tilde{\phi}_*^\lambda = \Pi^c(j_{\lambda-1}(\phi_*^\lambda)) = j_{\lambda-1}(\phi_*^{\lambda,c})$ and

$$\begin{aligned}\|\Phi_c\|_*|z^* - z^{\lambda-1}| &\leq \|\Phi_c z^* - \Phi_c z^{\lambda-1}\|_{\widetilde{X}} \\ &= \|j_{\lambda-1}(\phi^c) - j_{\lambda-1}(\phi_*^{\lambda,c})\|_{\widetilde{X}} = \|\phi^c - \phi_*^{\lambda,c}\|_X,\end{aligned}$$

where the last equality is due to the fact that j_ε is an isometry. So, if $\phi \in X$ satisfies $\|\phi^c - \phi_*^{\lambda,c}\|_X < \|\Phi_c\|_* \, \delta_0(\hat{\varepsilon}/\|\Phi_c\|^*)$, then

$$\begin{aligned}\|\Phi_c z(t-t_0, j_{\lambda-1}(\phi)) - j_{\lambda-1}(\phi_*^{\lambda,c})\|_{\widetilde{X}} &= \|\Phi_c z(t;t_0,z^*) - \Phi_c z^{\lambda-1}\|_{\widetilde{X}} \\ &\le \|\Phi_c\|^* |z(t;t_0,z^*) - z^{\lambda-1}| < \hat{\varepsilon}\end{aligned} \tag{4.41}$$

for $t \ge t_0$. For $\hat{\varepsilon} > 0$, set

$$\hat{\delta}(\hat{\varepsilon}) := \min\left(\frac{\hat{\varepsilon}}{3C_0C_1(1+2L(\delta))}, \frac{\|\Phi_c\|_*}{2C_1}\delta_0\left(\frac{\hat{\varepsilon}}{3(1+L(\delta))\|\Phi_c\|^*}\right)\right). \tag{4.42}$$

Given any $\hat{\varepsilon}$ with $0 < \hat{\varepsilon} < \delta$, let $\psi \in B_X(\phi_*^\lambda; \hat{\delta}(\hat{\varepsilon}))$. Then $j_{\lambda-1}(\psi) \in B_{\widetilde{X}}(j_{\lambda-1}(\phi_*^\lambda); \hat{\delta}(\hat{\varepsilon}))$, and hence, it follows from Claim 1 (Subsection 3.2) and (3.33) that there exists a $\tilde{\phi} \in B_{\widetilde{X}}(j_{\lambda-1}(\phi_*^\lambda); 2\hat{\delta}(\hat{\varepsilon}))$ such that $\widehat{g}(\tilde{\phi}) = j_{\lambda-1}(\psi)$, where $\widehat{g}$ is the one in (3.28) applied for Eq. ($\widetilde{E}_\delta$). In particular,

$$\begin{aligned}&\|\Pi^c \widetilde{x}_t(t_0, j_{\lambda-1}(\psi), \widetilde{G}_\delta) - \Phi_c z(t-t_0, \tilde{\phi})\|_{\widetilde{X}} \\ &\quad \le C_0 \|\Pi^s \widetilde{x}_{t_0}(t_0, j_{\lambda-1}(\psi), \widetilde{G}_\delta) - \widetilde{F}_{*,\delta}(\Phi_c z(0,\tilde{\phi}))\|_{\widetilde{X}} e^{-\beta(t-t_0)}\end{aligned} \tag{4.43}$$

holds for $t \ge t_0$ because of Theorem 3.2 (a) and its proof. By Proposition 4.5 we have

$$\Pi^c \widetilde{x}_t(t_0, j_{\lambda-1}(\psi), \widetilde{G}_\delta) = \Pi^c j_{\lambda-1}(x_t(t_0,\psi,f_\delta)) = j_{\lambda-1}\big(\Pi_X^c x_t(t_0,\psi,f_\delta)\big) \in j_{\lambda-1}(X). \tag{4.44}$$

Moreover, let $\tilde{z} = \operatorname{col}(\tilde{\varepsilon}, \tilde{s})$ be the point of $\mathbb{R}^2$ determined by $\Pi^c\tilde{\phi} = \Phi_c\tilde{z}$. Then it readily follows from Eq. ($C\widetilde{E}$) that $\Phi_c z(t-t_0,\tilde{\phi}) \in j_{\tilde{\varepsilon}}(X)$. Consequently, we must have $\lambda - 1 = \tilde{\varepsilon}$ due to (4.43) and (4.44), that is, $\tilde{\phi} = j_{\lambda-1}(\phi)$ for some $\phi \in X$ with $\|\phi - \phi_*^\lambda\|_X < 2\hat{\delta}(\hat{\varepsilon})$.

Noting that $\tilde{\phi}_*^{\lambda,s} = \widetilde{F}_{*,\delta}(\tilde{\phi}_*^{\lambda,c})$ follows from $\tilde{\phi}_*^\lambda \in \widetilde{W}_\delta^c(0)$, and the fact that $\tilde{\phi}_*^\lambda = j_{\lambda-1}(\phi_*^\lambda)$, one can see $(j_{\lambda-1}(\phi_*^\lambda))^s = \widetilde{F}_{*,\delta}(j_{\lambda-1}(\phi_*^{\lambda,c}))$, so that

$$\begin{aligned}&\|\Pi^s \widetilde{x}_{t_0}(t_0, j_{\lambda-1}(\psi), \widetilde{G}_\delta) - \widetilde{F}_{*,\delta}(\Phi_c z(0, j_{\lambda-1}(\phi)))\|_{\widetilde{X}} \\ &\quad = \big\|(j_{\lambda-1}(\psi))^s - \widetilde{F}_{*,\delta}\big((j_{\lambda-1}(\phi))^c\big)\big\|_{\widetilde{X}} \\ &\quad \le \|(j_{\lambda-1}(\psi))^s - (j_{\lambda-1}(\phi_*^\lambda))^s\|_{\widetilde{X}} + \|\widetilde{F}_{*,\delta}(j_{\lambda-1}(\phi_*^{\lambda,c})) - \widetilde{F}_{*,\delta}(j_{\lambda-1}(\phi^c))\|_{\widetilde{X}} \\ &\quad \le C_1\|j_{\lambda-1}(\psi) - j_{\lambda-1}(\phi_*^\lambda)\|_{\widetilde{X}} + L(\delta)\|(j_{\lambda-1}(\phi_*^\lambda))^c - (j_{\lambda-1}(\phi))^c\|_{\widetilde{X}} \\ &\quad \le C_1(\|\psi - \phi_*^\lambda\|_X + L(\delta)\|\phi_*^\lambda - \phi\|_X) < C_1(1+2L(\delta))\hat{\delta}(\hat{\varepsilon}).\end{aligned} \tag{4.45}$$

Since

$$\|\phi^c - \phi_*^{\lambda,c}\|_X \le C_1\|\phi - \phi_*^\lambda\|_X < 2C_1\hat{\delta}(\hat{\varepsilon}) \le \|\Phi_c\|_*\delta_0\left(\frac{\hat{\varepsilon}}{3(1+L(\delta))\|\Phi_c\|^*}\right), \tag{4.46}$$

it follows from (4.41), combined with $j_{\lambda-1}(\phi_*^{\lambda,c}) = \tilde{\phi}_*^{\lambda,c}$, (4.38) and (4.39), that

$$\|\Phi_c z(t-t_0, j_{\lambda-1}(\phi))\|_{\widetilde{X}} < \|\tilde{\phi}_*^{\lambda,c}\|_{\widetilde{X}} + \frac{\hat{\varepsilon}}{3} < \frac{\delta}{3} + \frac{\delta}{3} = \frac{2\delta}{3}. \tag{4.47}$$

Hence, by (4.43) and (4.45), together with $\tilde{\phi} = j_{\lambda-1}(\phi)$,

$$\begin{aligned}\|\Pi^c \widetilde{x}_t(t_0, j_{\lambda-1}(\psi), \widetilde{G}_\delta)\|_{\widetilde{X}} &\le \|\Phi_c z(t-t_0, j_{\lambda-1}(\phi))\|_{\widetilde{X}} + C_0C_1(1+2L(\delta))\hat{\delta}(\hat{\varepsilon})e^{-\beta(t-t_0)} \\ &< \frac{2\delta}{3} + \frac{\hat{\varepsilon}}{3} < \delta, \quad t \ge t_0.\end{aligned}$$

Moreover, (3.1), (4.36), (4.45) and (4.47) yield

$$\begin{aligned}\|\Pi^s \widetilde{x}_t(t_0, j_{\lambda-1}(\psi), \widetilde{G}_\delta)\|_{\widetilde{X}} &\le \|\widetilde{F}_{*,\delta}(\Phi_c z(t-t_0, j_{\lambda-1}(\phi)))\|_{\widetilde{X}} + C_0C_1(1+2L(\delta))\hat{\delta}(\hat{\varepsilon})e^{-\beta(t-t_0)} \\ &\le \|\Phi_c z(t-t_0, j_{\lambda-1}(\phi))\|_{\widetilde{X}} + \frac{\hat{\varepsilon}}{3} < \delta, \quad t \ge t_0.\end{aligned}$$

Thus, we deduce $\widetilde{x}_t(t_0, j_{\lambda-1}(\psi), \widetilde{G}_\delta) \in \widetilde{\Omega}$ $(t \ge t_0)$. Noting that $\widetilde{G}_\delta \equiv \widetilde{G}$ on $\widetilde{\Omega}$, we have $\widetilde{x}_t(t_0, j_{\lambda-1}(\psi), \widetilde{G}_\delta) = \widetilde{x}_t(t_0, j_{\lambda-1}(\psi), \widetilde{G})$. Therefore, Proposition 4.5 ensures that the solution $x(t; t_0, \psi, f)$ is defined on $[t_0, \infty)$ and satisfies $j_{\lambda-1}\big(x_t(t_0, \psi, f)\big) = \widetilde{x}_t(t_0, j_{\lambda-1}(\psi), \widetilde{G})$ there.

We also know from (3.2) and (4.45) that

$$\begin{aligned}\|\widetilde{x}_t(t_0, j_{\lambda-1}(\psi), \widetilde{G}_\delta) - \widetilde{x}_t(t_0, j_{\lambda-1}(\phi), \widetilde{G}_\delta)\|_{\widetilde{X}} &< 2C_0C_1(1+2L(\delta))\hat{\delta}(\hat{\varepsilon})e^{-\beta(t-t_0)} \\ &\le \frac{2\hat{\varepsilon}}{3}e^{-\beta(t-t_0)}.\end{aligned} \tag{4.48}$$

So, in view of (4.48), (4.41), (4.46) and Proposition 3.1, combined with the fact that

$$j_{\lambda-1}(\phi_*^\lambda) = \tilde{\phi}_*^\lambda = \tilde{\phi}_*^{\lambda,c} + \tilde{\phi}_*^{\lambda,s} = j_{\lambda-1}(\phi_*^{\lambda,c}) + \widetilde{F}_{*,\delta}(j_{\lambda-1}(\phi_*^{\lambda,c})),$$

we conclude that if $\psi \in B_X(\phi_*^\lambda; \hat{\delta}(\hat{\varepsilon}))$, then

$$\begin{aligned}\|x_t(t_0, \psi, f) - \phi_*^\lambda\|_X &= \|j_{\lambda-1}\big(x_t(t_0, \psi, f)\big) - j_{\lambda-1}(\phi_*^\lambda)\|_{\widetilde{X}} = \|\widetilde{x}_t(t_0, j_{\lambda-1}(\psi), \widetilde{G}) - \tilde{\phi}_*^\lambda\|_{\widetilde{X}} \\ &\le \|\widetilde{x}_t(t_0, j_{\lambda-1}(\psi), \widetilde{G}_\delta) - \widetilde{x}_t(t_0, j_{\lambda-1}(\phi), \widetilde{G}_\delta)\|_{\widetilde{X}} \\ &\quad + \|\Phi_c z(t-t_0, j_{\lambda-1}(\phi)) - j_{\lambda-1}(\phi_*^{\lambda,c})\|_{\widetilde{X}} \\ &\quad + \|\widetilde{F}_{*,\delta}(\Phi_c z(t-t_0, j_{\lambda-1}(\phi))) - \widetilde{F}_{*,\delta}(j_{\lambda-1}(\phi_*^{\lambda,c}))\|_{\widetilde{X}} \\ &< \frac{2\hat{\varepsilon}}{3}e^{-\beta(t-t_0)} + (1+L(\delta))\|\Phi_c z(t-t_0, j_{\lambda-1}(\phi)) - j_{\lambda-1}(\phi_*^{\lambda,c})\|_{\widetilde{X}} < \hat{\varepsilon}\end{aligned}$$

for $t \ge t_0$. The equilibrium ϕ_*^λ is therefore stable.

We next verify the attractivity of ϕ_*^λ. By the asymptotic stability of $s_{\lambda-1}$ as an equilibrium of $s' = h_\delta(\lambda-1, s)$, together with the invariance of $\{\lambda-1\} \times \mathbb{R}$ for Eq. $(C\widetilde{E}_\delta)$, there exist an $R_0 > 0$ with the property that to any $\hat{\varepsilon} > 0$, there corresponds a $\tau(\hat{\varepsilon}) > 0$ such that $|z(t; t_0, z^*) - z^{\lambda-1}| < \hat{\varepsilon}$ for every $t \ge t_0 + \tau(\hat{\varepsilon})$ and $z^* \in \{\lambda-1\} \times \mathbb{R}$ with $|z^* - z^{\lambda-1}| \le R_0$. Let $\hat{R} := \min\big(\hat{\delta}(\delta), \|\Phi_c\|_* R_0/(2C_1)\big)$, where $\hat{\delta}(\cdot)$ is the one in (4.42). Given any $\hat{\varepsilon} \in (0, \delta)$, set

$$\hat{\tau}(\hat{\varepsilon}) := \max\left(\left(\frac{1}{\beta}\log\frac{4C_0C_1(1+2L(\delta))\hat{R}}{\hat{\varepsilon}}, \tau\left(\frac{\hat{\varepsilon}}{2(1+L(\delta))\|\Phi_c\|^*}\right)\right)\right)$$

and assume that $\psi \in B_X(\phi_*^\lambda, \hat{R})$. Then $j_{\lambda-1}(\psi) \in B_{\widetilde{X}}(j_{\lambda-1}(\phi_*^\lambda); \hat{R})$, and there exists a $\tilde{\phi} \in B_{\widetilde{X}}(j_{\lambda-1}(\phi_*^\lambda); 2\hat{R})$ with $\widehat{g}(\tilde{\phi}) = j_{\lambda-1}(\psi)$. Since $\hat{R} \le \hat{\delta}(\delta)$, we know from the former part that $\widetilde{x}_t(t_0, j_{\lambda-1}(\psi), \widetilde{G}_\delta) \in \widetilde{\Omega}$ $(t \ge t_0)$. So, in the same way as above, $\hat{\phi}$ can be written as $\hat{\phi} = j_{\lambda-1}(\phi)$ for some $\phi \in X$ with $\|\phi - \phi_*^\lambda\|_X < 2\hat{\delta}(\delta)$ and the following estimate is valid:

$$\begin{aligned}\|x_t(t_0, \psi, f) - \phi_*^\lambda\|_X &\le \|\widetilde{x}_t(t_0, j_{\lambda-1}(\psi), \widetilde{G}_\delta) - \widetilde{x}_t(t_0, j_{\lambda-1}(\phi), \widetilde{G}_\delta)\|_{\widetilde{X}} \\ &\quad + (1+L(\delta))\|\Phi_c z(t-t_0, j_{\lambda-1}(\phi)) - j_{\lambda-1}(\phi_*^{\lambda,c})\|_{\widetilde{X}} \\ &\le 2C_0C_1(1+2L(\delta))\hat{R}e^{-\beta(t-t_0)} + (1+L(\delta))\|\Phi_c\|^*|z(t; t_0, z^*) - z^{\lambda-1}| \\ &< \frac{\hat{\varepsilon}}{2} + \frac{\hat{\varepsilon}}{2} = \hat{\varepsilon} \quad \text{for } t \ge t_0 + \hat{\tau}(\hat{\varepsilon}),\end{aligned}$$

where z^* is again the point of $\mathbb{R}^2$ determined by $\Phi_c z^* = j_{\lambda-1}(\phi^c)$. Thus, ϕ^λ_* is an attractive equilibrium of Eq. (*PE*), and hence, is asymptotically stable.

Similarly, the equilibrium 0 of Eq. $s' = h(\lambda - 1, s)$ is asymptotically stable because

$$\frac{\partial h}{\partial s}(\varepsilon, 0) = -\frac{1}{q_*}\varepsilon + o(|\varepsilon|) < 0$$

for $\varepsilon < 0$ with $|\varepsilon|$ small. By the same reasoning as above, one can see the asymptotic stability of the equilibrium 0 of Eq. (*PE*).

Suppose now that $\lambda > 1$. Then $z^{\lambda-1} = \mathrm{col}\,(\lambda - 1, s_{\lambda-1})$ is a unstable equilibrium of Eq. ($C\widetilde{E}$). So, by Theorem 3.3, $\tilde{\phi}^\lambda_*$ is a unstable equilibrium of Eq. ($\widetilde{E}$). The invariance of $j_{\lambda-1}(X)$ then implies the instability of ϕ^λ_*, and likewise for the equilibrium 0.

If $q_* > 0$, then consider the function $\check{h}(\varepsilon, s) := h(\varepsilon, -s)$ $((\varepsilon, s) \in \mathbb{R}^2)$ in place of $h(\varepsilon, s)$ in Eq. ($C\widetilde{E}$). One can readily verify that $\check{h}(\varepsilon, s)$ satisfies the conditions (4.31) and (4.32) of Lemma 4.14. Applying the lemma to $\check{h}(\varepsilon, s)$ and noting that $(\partial h/\partial s)(\varepsilon, s) = -(\partial \check{h}/\partial s)(\varepsilon, -s)$, we see that the equilibrium $s_{\lambda-1}$ of the scalar equation $s' = h(\lambda - 1, s)$ is unstable (resp. asymptotically stable) if $\lambda < 1$ (resp. $\lambda > 1$). So, the argument above yields the desired stability properties of ϕ^λ_*; and similarly for the equilibrium 0.

(ic) Let U_1 be the open set of $\mathbb{R}^2$ in Lemma 4.14 (a_2). We may assume that U_1 is a rectangle $U(r) = (-r, r) \times (-r, r)$, where $r > 0$ satisfies $r < \rho\delta/3 - s^*|\eta_*|$ (see the proof of the lemma and notice (4.37)). Set

$$\mathcal{W} := \Pi_2\big(\widetilde{\Omega}_0 \cap (\Pi^c)^{-1}(\Phi_c U_1)\big);$$

then $\mathcal{W}$ is an open set of X since Φ_c is a homeomorphism as a map from $\mathbb{R}^2$ to $\widetilde{E}^c$, and Π_2 is an open map. Now assume that $\phi_* \in \mathcal{W}\backslash\{0\}$ is an equilibrium of Eq. (*PE*) with $|\lambda - 1| < r$. Since $\phi_* \in \mathcal{W}$, ϕ_* can be written as $\phi_* = \Pi_2\tilde{\phi}^\circ$, where $\tilde{\phi}^\circ \in \widetilde{\Omega}_0$ satisfies $\Pi^c\tilde{\phi}^\circ = \Phi_c z^\circ$ for some $z^\circ = \mathrm{col}\,(\lambda^\circ - 1, s^\circ) \in U_1$. Hence, $\Pi^c_X\phi_* = \Pi^c_X\Pi_2\tilde{\phi}^\circ = \Pi_2\Pi^c\tilde{\phi}^\circ = \Pi_2\Phi_c z^\circ = w_1(0)(s^\circ\eta_*)$.

On the other hand, in view of Remark 4.15, $\tilde{\phi}_* := j_{\lambda-1}(\phi_*)$ is an equilibrium of Eq. ($\widetilde{E}$). Since $\Pi^c\tilde{\phi}_* = j_{\lambda-1}(\Pi^c_X\phi_*) = w_1(0)\big((\lambda - 1)e_1 + s^\circ\eta_*\big)$ and $\Pi^s\tilde{\phi}_* = j_0(\Pi^s_X\phi_*) = j_0(\Pi_2\Pi^s\tilde{\phi}_\circ)$, we have

$$\|\Pi^c\tilde{\phi}_*\|_{\widetilde{X}} \le \rho^{-1}(|\lambda - 1| + |s^\circ||\eta_*|) < \rho^{-1}(r + s^*|\eta_*|) < \frac{\delta}{3},$$

and

$$\|\Pi^s\tilde{\phi}_*\|_{\widetilde{X}} = \|\Pi_2\Pi^s\tilde{\phi}^\circ\|_X \le \|\Pi^s\tilde{\phi}^\circ\|_{\widetilde{X}} < \frac{\delta}{3}$$

(because of $\phi^\circ \in \widetilde{\Omega}_0$). Hence $\tilde{\phi}_*$ is an equilibrium of Eq. ($\widetilde{E}$) in $\widetilde{\Omega}_0$, and therefore, by (4.35), $\tilde{\phi}_* = \Phi_c z_* + \widetilde{F}_*(\Phi_c z_*)$ for some equilibrium z_* of Eq. ($C\widetilde{E}$). Thus, we have $\Pi_1\tilde{\phi}_* = \Pi_1 j_{\lambda-1}(\phi_*) = w_1(0)(\lambda - 1)$, and $\Pi_1\tilde{\phi}_* = \Pi_1\Phi_c z_*$ as well (see (4.40)); in particular, z_* is of the form $z_* = \mathrm{col}\,(\lambda - 1, s_*) \in \mathbb{R}^2$. One can also obtain that $\Pi^c_X\phi_* = \Pi^c_X\Pi_2\tilde{\phi}_* = \Pi_2\Pi^c\tilde{\phi}_* = \Pi_2\Phi_c z_* = w_1(0)(s_*\eta_*)$, so that $s^\circ = s_*$. Consequently, $z_* = \mathrm{col}\,(\lambda - 1, s^\circ) \in U_1$. It therefore follows from Lemma 4.14 (a_2) that $z_* = z^{\lambda-1}$, and hence that $\tilde{\phi}_* = \Phi_c z^{\lambda-1} + \widetilde{F}_*(\Phi_c z^{\lambda-1}) = \tilde{\phi}^\lambda_*$, which yields $\phi_* = \phi^\lambda_*$.

(ii) (iia) Let $\lambda = 1$ and $s^* > 0$ be the one in Lemma 4.14 (b_1). In a similar manner to the proof of (ia), one can see that $\mathcal{W}_0 := B_X(\rho_1)$ is a required open set. Now let s^ε_+ and s^ε_- the functions from $(0, \varepsilon^*)$ to $\mathbb{R}\backslash\{0\}$ given in Lemma 4.14 (b_1), and set $z^\varepsilon_\pm := \mathrm{col}\,(\varepsilon, s^\varepsilon_\pm)$. Define the functions $\phi_\pm : (1, 1 + \varepsilon^*) \to X$ by

$$\phi^\lambda_\pm := \Pi_2\big(\Phi_c z^{\lambda-1}_\pm + \widetilde{F}_*(\Phi_c z^{\lambda-1}_\pm)\big), \quad \lambda \in (1, 1 + \varepsilon^*),$$

where we choose ε^* small if necessary. Then ϕ_+^λ and ϕ_-^λ are distinct equilibria of Eq. (*PE*) which tends to 0 as $\lambda \to 1+0$.

The proof of the instability of the equilibrium 0 is quite similar to that of (1a).

(iib) By the same reasoning as (iia), the stability properties of $\phi_\pm^\lambda$ and 0 directly follow from Lemma 4.14 (b_1).

(iic) Let U_1 be the open set of $\mathbb{R}^2$ in Lemma 4.14 (b_2), which may also be thought of a rectangle $U(r) = (-r, r) \times (-r, r)$ with $r > 0$ small. Then, $\mathcal{W} := \Pi_2\big(\widetilde{\Omega}_0 \cap (\Pi^c)^{-1}(\Phi_c U_1)\big)$ is a desired open set of X; the proof being similar to that of (ic).

(iii) The proof is quite the same as that of (ii), and hence we will omit it. □

Now we prove Lemma 4.14. For this, we will employ the following lemma, which is the implicit function theorem for Lipschitz continuous maps.

Lemma 4.16. *Let U and V be open sets of $\mathbb{R}^n$ and $\mathbb{R}^m$, respectively, and (u_0, v_0) a point of $U \times V$. Suppose that $G : U \times V \to \mathbb{R}^n$ is a continuous map satisfying the followings:*

(i) *For each $v \in V$, $G(\cdot, v)$ is a Lipschitz continuous map from U to $\mathbb{R}^n$; and in addition there exists an $l_* \in [0, 1)$ such that the Lipschitz constant of $E_n - G(\cdot, v)$ does not exceed l_* for $v \in V$, E_n being the $n \times n$ unit matrix.*

(ii) $G(u_0, v_0) = 0$.

Then there exist an $r > 0$ and a continuous map $\varphi : B_{\mathbb{R}^n}(u_0; r) \to V$ with the properties that $\varphi(u_0) = v_0$ and

$$G(u, \varphi(u)) = 0, \quad u \in B_{\mathbb{R}^n}(u_0; r).$$

Moreover, if $r > 0$ and $\tilde{r} > 0$ are sufficiently small, then $G(u, v) = 0$ with $(u, v) \in B_{\mathbb{R}^n}(u_0; r) \times B_{\mathbb{R}^m}(v_0; \tilde{r})$ implies $v = \varphi(u)$.

Proof of Lemma 4.14. Set $\Delta(\varepsilon, s) := h(\varepsilon, s) + \alpha s\varepsilon - \beta s^m$. By letting $s := \sigma\varepsilon^{1/(m-1)}$, $h(\varepsilon, s)$ can be written as

$$\widetilde{h}(\varepsilon, \sigma) := h(\varepsilon, \sigma\varepsilon^{1/(m-1)}) = \varepsilon^{m/(m-1)}(-\alpha\sigma + \beta\sigma^m) + \Delta(\varepsilon, \sigma\varepsilon^{1/(m-1)}).$$

So,

$$\widetilde{h}(\varepsilon, \sigma) = \varepsilon^{m/(m-1)}\big(-\alpha\sigma + \beta\sigma^m + R(\varepsilon, \sigma)\big), \quad (\varepsilon, \sigma) \in \widetilde{U}_0 := \widetilde{\tau}^{-1}(U_0), \tag{4.49}$$

where $R(\varepsilon, \sigma)$ is the function defined by

$$R(\varepsilon, \sigma) := \begin{cases} \varepsilon^{-m/(m-1)}\Delta(\varepsilon, \sigma\varepsilon^{1/(m-1)}), & \varepsilon \neq 0, \\ 0, & \varepsilon = 0, \end{cases}$$

and $\widetilde{\tau}$ is the one defined by $\widetilde{\tau}(\varepsilon, \sigma) := (\varepsilon, \sigma\varepsilon^{m/(m-1)})$. Then we have:

Claim 2. $R(\varepsilon, \sigma)$ has the following properties.

(R_1) $R(\varepsilon, \sigma)$ is of class C^1 in $\widetilde{U}_0 \backslash \{\varepsilon = 0\}$.

(R_2) $R(\varepsilon, \sigma)$ and the partial derivative $R_\sigma(\varepsilon, \sigma)$ are continuous in $\widetilde{U}_0$.

Proof of Claim 2. (R_1) is evident.

(R_2) Since m is even,

$$R(\varepsilon,\sigma)=\frac{\Delta(\varepsilon,\sigma\varepsilon^{1/(m-1)})}{|\sigma\varepsilon^{1/(m-1)}|^m+|\varepsilon\sigma\varepsilon^{1/(m-1)}|}\,(|\sigma|^m+|\sigma|),\quad \varepsilon\neq 0. \tag{4.50}$$

(4.31) therefore implies that $R(\varepsilon,\sigma)$ converges to 0 uniformly for $|\sigma|\le\sigma^*$ as $\varepsilon\to 0$, where $\sigma^*>0$ is arbitrary; and in particular $R(\varepsilon,\sigma)$ is continuous at the points in $\widetilde{U}_0\cap\{\varepsilon=0\}$, which, together with ($R_1$), yields the continuity in $\widetilde{U}_0$ of $R(\varepsilon,\sigma)$. In virtue of (4.32) and the fact that

$$R_\sigma(\varepsilon,\sigma)=\varepsilon^{-1}\frac{\partial\Delta}{\partial s}(\varepsilon,\sigma\varepsilon^{1/(m-1)})=\frac{\Delta_s(\varepsilon,\sigma\varepsilon^{1/(m-1)})}{|\sigma\varepsilon^{1/(m-1)}|^{m-1}+|\varepsilon|}\,(|\sigma|^{m-1}+1)$$

for $\varepsilon\neq 0$, $R_\sigma(\sigma,\varepsilon)$ converges to $0=R_\sigma(0,\sigma)$ uniformly for $|\sigma|\le\sigma^*$ as $\varepsilon\to 0$; hence, by the same reasoning as the former part, $R_\sigma(\varepsilon,\sigma)$ is continuous in $\widetilde{U}_0$. This proves Claim 2.

Now let

$$F(\varepsilon,\sigma):=-\alpha\sigma+\beta\sigma^m+R(\varepsilon,\sigma),\quad (\varepsilon,\sigma)\in\widetilde{U}_0.$$

(a) (a_1) The first part is obvious. Since m is even, $F(0,\sigma)$ has always two zeros, i.e., $\sigma=0$ and

$$\sigma_0:=\left(\frac{\alpha}{\beta}\right)^{1/(m-1)}. \tag{4.51}$$

Notice that $F_\sigma(0,\sigma_0)=-\alpha+m\beta\sigma_0^{m-1}=(m-1)\alpha\neq 0$, and define $G(\varepsilon,\sigma)$ by

$$G(\varepsilon,\sigma):=\frac{1}{F_\sigma(0,\sigma_0)}F(\varepsilon,\sigma),\quad (\varepsilon,\sigma)\in\widetilde{U}_0.$$

G is a continuous function with $G(0,\sigma_0)=0$ and $G(\varepsilon,\cdot)$ is locally Lipschitz continuous for each ε. In view of (R_2) and the fact that $G_\sigma(0,\sigma_0)=1$, there exist open intervals U and V containing 0 and σ_0, respectively, and an $l_0\in[0,1)$ such that $\mathrm{Lip}\,(1-G(\varepsilon,\cdot))$, the Lipschitz constant of the restriction $(1-G(\varepsilon,\cdot))\big|_V$, satisfies

$$\mathrm{Lip}\,(1-G(\varepsilon,\cdot))=\sup_{(\varepsilon,\sigma)\in U\times V}|1-G_\sigma(\varepsilon,\sigma)|\le l_0,\quad \varepsilon\in U.$$

Therefore it follows from Lemma 4.16 that there exist an $\varepsilon^*>0$ and a continuous function $\sigma:(-\varepsilon^*,\varepsilon^*)\to V$ with the properties that $\sigma(0)=\sigma_0$ and $G(\varepsilon,\sigma(\varepsilon))=0$ for $\varepsilon\in(-\varepsilon^*,\varepsilon^*)$. Hence, $\widetilde{h}(\varepsilon.\sigma(\varepsilon))=\varepsilon^{m/(m-1)}F(\varepsilon,\sigma(\varepsilon))=0$ for $\varepsilon\in(-\varepsilon^*,\varepsilon^*)\backslash\{0\}$. We may also assume that $\sigma(\varepsilon)\neq 0$ for $\varepsilon\in(-\varepsilon^*,\varepsilon^*)$ since $\sigma_0\neq 0$ and $\sigma(\varepsilon)$ is continuous. Set $s_\varepsilon:=\sigma(\varepsilon)\varepsilon^{1/(m-1)}$. Then $s:(-\varepsilon^*,\varepsilon^*)\to\mathbb{R}$ is a continuous function which maps $(-\varepsilon^*,\varepsilon^*)\backslash\{0\}$ into $\mathbb{R}\backslash\{0\}$, and satisfies

$$h(\varepsilon,s_\varepsilon)=\widetilde{h}(\varepsilon,\sigma(\varepsilon))=0,\quad \varepsilon\in(-\varepsilon^*,\varepsilon^*)\backslash\{0\}$$

together with $s_\varepsilon\to 0$ as $\varepsilon\to 0$. Moreover, it follows from (4.32) that

$$\begin{aligned}\frac{\partial h}{\partial s}(\varepsilon,s_\varepsilon)&=-\alpha\varepsilon+m\beta\sigma(\varepsilon)^{m-1}\varepsilon+o(\varepsilon)\\&=-\alpha\varepsilon+m\beta\sigma_0^{m-1}\varepsilon+m\beta(\sigma(\varepsilon)^{m-1}-\sigma(0)^{m-1})\varepsilon+o(\varepsilon)\\&=(m-1)\alpha\varepsilon+o(\varepsilon)\quad\text{as }\varepsilon\to 0,\end{aligned} \tag{4.52}$$

where we used (4.51) and the continuity of $\sigma(\varepsilon)$; so that (4.33) holds.

Also, by Lemma 4.16 $G(\varepsilon,\sigma)=0$ with $(\varepsilon,\sigma)\in(-\varepsilon^*,\varepsilon^*)\times(\sigma_0-\sigma^*,\sigma_0+\sigma^*)$ yields $\sigma=\sigma(\varepsilon)$, provided that $\varepsilon^*>0$ and $\sigma^*>0$ are small enough.

We next consider $\sigma=0$ as the other zero of $F(0,\sigma)$. Since $F_\sigma(0,0)=-\alpha\neq 0$, by applying the same argument as above to the function

$$\widetilde{G}(\varepsilon,\sigma):=\frac{1}{F_\sigma(0,0)}F(\varepsilon,\sigma),\quad (\varepsilon,\sigma)\in\widetilde{U}_0,$$

one can see that there exist an $\tilde{\varepsilon}^*>0$ and a continuous function $\tilde{\sigma}:(-\tilde{\varepsilon}^*,\tilde{\varepsilon}^*)\to V$ with the properties that $\tilde{\sigma}(0)=0$ and $\widetilde{G}(\varepsilon,\tilde{\sigma}(\varepsilon))=0$ for $\varepsilon\in(-\tilde{\varepsilon}^*,\tilde{\varepsilon}^*)$. On the other hand, it follows from (4.31) that $\Delta(\varepsilon,0)=0$, and hence $\widetilde{G}(\varepsilon,0)=0$. By the same reasoning as the last paragraph we obtain $\tilde{\sigma}(\varepsilon)=0$ for $\varepsilon\in(-\tilde{\varepsilon}^*,\tilde{\varepsilon}^*)$ with $\tilde{\varepsilon}^*>0$ small.

(a_2) Let $U(r):=(-r,r)\times(-r,r)$ and

$$d_r:=\sup\left\{|\Delta(\varepsilon,s)|/(|s|^m+|s\varepsilon|):(\varepsilon,s)\in U(r)\backslash\{s=0\}\right\}\tag{4.53}$$

for $r>0$. Then $d_r\to 0$ as $r\to 0$ by (4.31). Put

$$c_*:=\inf_{|\sigma-\sigma_0|\geq\sigma^*}|-\alpha+\beta\sigma^{m-1}|\tag{4.54}$$

and take an $r>0$ small enough so that $r<\varepsilon^*$ and

$$d_r<\min\left(\frac{|\beta|}{2},\frac{c_*}{2(|\sigma_0|^{m-1}+1)}\right).\tag{4.55}$$

Now suppose that $h(\hat{\varepsilon},\hat{s})=0$ for some $(\hat{\varepsilon},\hat{s})\in U(r)$ with $\hat{s}\neq 0$, and set $\hat{\sigma}:=\hat{s}\hat{\varepsilon}^{-1/(m-1)}$. (Notice that $\hat{\varepsilon}\neq 0$ due to (4.55).) Since $F(\hat{\varepsilon},\hat{\sigma})=0$, it follows from (4.50) that

$$|-\alpha\hat{\sigma}+\beta\hat{\sigma}^m|=|R(\hat{\varepsilon},\hat{\sigma})|\leq d_r(|\hat{\sigma}|^m+|\hat{\sigma}|).\tag{4.56}$$

Hence, in view of $\hat{\sigma}\neq 0$ and (4.55),

$$\frac{|\beta|}{2}|\hat{\sigma}|^{m-1}\leq(|\beta|-d_r)|\hat{\sigma}|^{m-1}\leq\alpha+d_r\leq\alpha+\frac{|\beta|}{2},$$

so that $|\hat{\sigma}|^{m-1}\leq 2|\sigma_0|^{m-1}+1$, and therefore (4.56) and (4.55) imply

$$|-\alpha+\beta\hat{\sigma}^{m-1}|\leq d_r(|\hat{\sigma}|^{m-1}+1)\leq 2d_r(|\sigma_0|^{m-1}+1)<c_*,$$

from which and (4.54) we deduce that $\hat{\sigma}\in(\sigma_0-\sigma^*,\sigma_0+\sigma^*)$. Thus, we arrive at $G(\hat{\varepsilon},\hat{\sigma})=0$ with $(\hat{\varepsilon},\hat{\sigma})\in(-\varepsilon^*,\varepsilon^*)\times(\sigma_0-\sigma^*,\sigma_0+\sigma^*)$. The argument in the proof of (a_1) then yields $\hat{\sigma}=\sigma(\hat{\varepsilon})$ and therefore $\hat{s}=s_{\hat{\varepsilon}}$. Consequently, ($a_2$) holds true with $U_1=U(r)$.

(b) (b_1) The first part is obvious. Let us take $r>0$ so small that $d_r<\min(\alpha,\beta)$, d_r being the one in (4.53). Then, it follows that for $(\varepsilon,s)\in U(r)$ with $s\neq 0$ and $\varepsilon\leq 0$,

$$\begin{aligned}sh(\varepsilon,s)&=s(-\alpha s\varepsilon+\beta s^m+\Delta(\varepsilon,s))\\&\geq\alpha|\varepsilon|s^2+\beta|s|^{m+1}-|s||\Delta(\varepsilon,s)|\\&\geq(\alpha-d_r)|\varepsilon|s^2+(\beta-d_r)|s|^{m+1}>0.\end{aligned}$$

Thus, $h(\varepsilon,\cdot)$ has no zeros in $(-r,r)$ other than $s=0$, provided that $-r<\varepsilon\leq 0$.

Assume now that $\varepsilon > 0$. Since m is odd, $F(0,\sigma) = 0$ has three zeros, i.e., $\sigma = 0$, $\sigma_0^+ := (\alpha/\beta)^{1/(m-1)}$ and $\sigma_0^- := -(\alpha/\beta)^{1/(m-1)}$. Define $h^+ : U_0 \to \mathbb{R}$ by

$$h^+(\varepsilon, s) := -\alpha s\varepsilon + \beta|s|^m + \Delta(\varepsilon, s), \quad (\varepsilon, s) \in U_0.$$

Then, h^+ is of class C^1 and by (4.32),

$$\frac{\partial h^+}{\partial s}(\varepsilon, s) = -\alpha\varepsilon + m\beta|s|^{m-1}\operatorname{sgn} s + o(|s|^{m-1} + |\varepsilon|),$$

where $\operatorname{sgn} s$ denotes the sign of $s \in \mathbb{R}$ with $\operatorname{sgn} 0 := 0$. Moreover, by letting $s := \sigma|\varepsilon|^{1/(m-1)}\operatorname{sgn}\varepsilon$, we have

$$\widetilde{h}^+(\varepsilon, \sigma) := h^+(\varepsilon, \sigma|\varepsilon|^{1/(m-1)}\operatorname{sgn}\varepsilon) = |\varepsilon|^{m/(m-1)}\big(-\alpha\sigma + \beta|\sigma|^m + R^+(\varepsilon, \sigma)\big),$$

according to (4.49), where

$$R^+(\varepsilon, \sigma) := \begin{cases} |\varepsilon|^{-m/(m-1)}\Delta\big(\varepsilon, \sigma|\varepsilon|^{1/(m-1)}\operatorname{sgn}\varepsilon\big), & \varepsilon \neq 0, \\ 0, & \varepsilon = 0. \end{cases}$$

Consequently, the arguments in the proof of Claim 2 (resp. (a)) are valid for R^+ (resp. h^+ with σ_0^+ in place of σ_0), and hence there exists a function $s : (-\varepsilon^*, \varepsilon^*) \to \mathbb{R}$ satisfying the properties (a_1) and (a_2). In particular, it follows from $\sigma_0^+ > 0$ that $s_\varepsilon > 0$ for $\varepsilon \in (0, \varepsilon^*)$, which, combined with the fact that $h^+(\varepsilon, s) = h(\varepsilon, s)$ for $s \geq 0$, implies that $s^+ := s|_{(0,\varepsilon^*)}$ is one of the desired functions.

For the existence of $s^- : (0, \varepsilon^*) \to \mathbb{R}$, we have only to consider the function

$$h^-(\varepsilon, s) := -\alpha s\varepsilon - \beta|s|^m + \Delta(\varepsilon, s), \quad (\varepsilon, s) \in U_0.$$

In the same way as (4.52), we also obtain

$$\begin{aligned} \frac{\partial h^\pm}{\partial s}(\varepsilon, s_\varepsilon^\pm) &= -\alpha\varepsilon + m\beta|s_\varepsilon^\pm|^{m-1} + o(\varepsilon) = -\alpha\varepsilon + m\beta|\sigma_0^\pm|^{m-1}\varepsilon + o(\varepsilon) \\ &= (m-1)\alpha\varepsilon + o(\varepsilon) \quad \text{as } \varepsilon \to +0, \end{aligned}$$

and (4.34) follows from

$$\frac{\partial h^+}{\partial s}(\varepsilon, s) = \frac{\partial h}{\partial s}(\varepsilon, s) \quad (s \geq 0), \quad \text{and} \quad \frac{\partial h^-}{\partial s}(\varepsilon, s) = \frac{\partial h}{\partial s}(\varepsilon, s) \quad (s \leq 0).$$

(b_2) Since the statement of (a_2) holds for both $h^+(\varepsilon, s)$ and $h^-(\varepsilon, s)$, the definition of s^+ and s^-, together with the argument of the first paragraph, imply the existence of a desired open set of U_0.

(c) The proof is quite similar to that of (b), and is omitted. □

5 Examples

We will show an example on one-parameter bifurcation to illustrate our Theorem 4.4.

Example 5.1. Let us consider a nonlinear scalar integral equation

$$x(t) = \lambda \int_{-\infty}^{t} p(t-s)x(s)ds + f(x_t), \tag{5.1}$$

where λ is a nonnegative parameter and p is a nonnegative continuous function on $\mathbb{R}^+$ that satisfies

$$\int_0^\infty p(t)dt = 1 \tag{5.2}$$

together with

$$\|p\|_{1,\rho} = \int_0^\infty p(t)e^{\rho t}dt < \infty \quad \text{and} \quad \|p\|_{\infty,\rho} = \operatorname{ess\,sup}\{p(t)e^{\rho t} : t \geq 0\} < \infty$$

for some positive constant ρ. Let $X := L^1_\rho(\mathbb{R}^-;\mathbb{R})$ and $f : X \to \mathbb{R}$ be of the form

$$f(\phi) = \left(\int_{-\infty}^{0} q(-\theta)\phi(\theta)d\theta \right)^3 + g(\phi),$$

where $q : \mathbb{R}^+ \to \mathbb{R}$ satisfies

$$\int_0^\infty q(t)dt > 0, \quad \int_0^\infty |q(t)|e^{\rho t}dt < \infty \quad \text{and} \quad \operatorname{ess\,sup}\{|q(t)|e^{\rho t} : t \geq 0\} < \infty$$

and $g \in C^1(X;\mathbb{R})$ with $g(\phi) = o(\|\phi\|_X^3)$ as $\|\phi\|_X \to 0$.

Since $f \in C^1(X;\mathbb{R})$ with $f(0) = 0$ and $Df(0) = 0$, so [23, Proposition 8] implies the following fact:

- If $0 \leq \lambda < 1$, then the zero solution of Eq. (5.1) is exponentially stable (in L^1_ρ);
- If $\lambda > 1$, then the zero solution of Eq. (5.1) is unstable (in L^1_ρ).

We will verify that $\lambda = 1$ is a bifurcation point and a pitchfork bifurcation occurs when λ exceeds 1. Notice that $P_0 = \int_0^\infty p(t)dt = 1$ and $P_1 = \int_0^\infty tp(t)dt > 0$. So 0 is a simple eigenvalue of P_0 and $P_1\big(\mathcal{N}(1-P_0)\big) = \mathbb{R}$; hence (A_1) and (A_2) hold together with (A_4). In addition, since the characteristic operator is $\Delta(z) = 1 - \lambda \int_0^\infty p(t)e^{-zt}dt$, we see from (5.2) that

$$\Delta(i\omega) = \int_0^\infty p(t)(1-\cos\omega t)dt + i\int_0^\infty p(t)\sin\omega t dt, \quad \omega \in \mathbb{R}.$$

So, if $\det\Delta(i\omega) = \Delta(i\omega) = 0$ for some $\omega > 0$, then

$$\int_0^\infty p(t)(1-\cos\omega t)dt = \int_0^\infty p(t)\sin\omega t dt = 0.$$

Hence, $p(t) = 0$ on $\mathbb{R}^+$ follows, for $p(t)$ is continuous and nonnegative on $\mathbb{R}^+$ and $1-\cos\omega t > 0$ ($t \in \mathbb{R}\backslash(2\pi\omega^{-1}\mathbb{Z})$); see also [22, Example 4.1]. This contradicts to (5.2), so that $\det\Delta(i\omega) \neq 0$ for $\omega > 0$; and therefore (A_3) is also valid due to Remark 4.2 and (5.2).

Since one can choose $\eta_* = 1$ and $\zeta^* = 1$, so $q_* = -P_1 < 0$ and

$$c_0 = \left(\int_{-\infty}^{0} q(-\theta)(w_1(0))(\theta)d\theta \right)^3 = \left(\int_0^\infty q(t)dt \right)^3 > 0$$

(see (4.5)). Consequently by Theorem 4.4 (iib) a pitchfork bifurcation is observed when the parameter λ exceeds 1; the equilibrium 0 becomes unstable and two more equilibria appear in a neighborhood of 0, each of which is asymptotically stable for $\lambda > 1$.

Abstract. In this paper, we investigate the existence and regularity of positive solutions for certain singular problems that involve an anisotropic (p,q)-Laplacian-type operator and a singular term with a variable exponent, under zero Dirichlet boundary conditions on $\partial\Omega$. The main equation we analyze is

$$-\sum_{i=1}^{N}\partial_i\left(|\partial_i u(x)|^{p_i-2}\partial_i u(x)\right)-\sum_{i=1}^{N}\partial_i\left(|\partial_i u(x)|^{q_i-2}\partial_i u(x)\right)=\frac{f(x)}{u(x)^{\gamma(x)}}\quad\text{in }\Omega,$$

where Ω is a bounded, regular domain in $\mathbb{R}^N$, f is a positive function belonging to a specific Lebesgue space, and $\gamma(x)$ is a positive continuous function on $\overline{\Omega}$. In our study, we do not make comparisons between p_i and q_i, and as a result, we show that the solution belongs to either $W_0^{1,\vec{p}}(\Omega)\cap W_0^{1,\vec{q}}(\Omega)$ or $W_{loc}^{1,\vec{p}}(\Omega)\cap W_{loc}^{1,\vec{q}}(\Omega)$ depending on the summability of $f(x)$ and the values of $\gamma(x)$. The results are achieved using approximation techniques that include truncation, comparison, and variational methods.

Keywords: anisotropic singular (p,q)-equations, approximation, variational methods, existence and regularity results.

2020 Mathematics Subject Classification: 35J60, 35J75, 35J30, 35B51.

1 Introduction and main results

This study investigates elliptic partial differential equations (PDEs) characterized by anisotropic (p,q)-Laplacian-type operators, focusing on their mathematical properties and physical relevance. Anisotropic (p,q)-Laplacians extend the classical Laplacian by incorporating directional dependence, making them instrumental in modeling complex phenomena in heterogeneous materials, such as heat conduction, fluid dynamics, and nonlinear elasticity. The research also highlights the importance of reaction-diffusion systems in plasma physics and

✉Corresponding author. Email: a.elamrouss@ump.ac.ma

chemical reaction design, which are driven by parabolic reaction-diffusion equations.

$$u_t - \operatorname{div}\left[|\nabla u|^{p-2}\nabla u\right] - \operatorname{div}\left[|\nabla u|^{q-2}\nabla u\right] = \mathfrak{G}(x,u).$$

These systems are fundamental for understanding pattern formation, wave propagation, and turbulence control in various scientific and engineering applications. For more technical details, we point out the following refs. [4,7,21,27,47]. By examining the theoretical framework surrounding anisotropic elliptic (PDEs) and referencing foundational works, this study underscores the critical role of these mathematical constructs in solving real-world problems in fields such as material science, image processing, and biological modeling. Can also refer to Refs. [32,34,46] and the references therein.

In this paper, we focus on the study of the following anisotropic singular problem:

$$\begin{cases} -\sum_{i=1}^{N}\partial_i\left(|\partial_i u|^{p_i-2}\partial_i u\right) - \sum_{i=1}^{N}\partial_i\left(|\partial_i u|^{q_i-2}\partial_i u\right) = \dfrac{f(x)}{u^{\gamma(x)}} & \text{in } \Omega, \\ u > 0 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where $\Omega \subset \mathbb{R}^N$ is a bounded domain with a C^2 boundary $\partial\Omega$ and $N \geq 3$. The exponent $\gamma(x)$ is a positive continuous function on $\overline{\Omega}$, and $f(x) \in L^r(\Omega)$ for some $r \geq 1$.

This study is inspired by the significant work of Giacomoni, Kumar, and Sreenadh [23], who investigate a singular quasilinear elliptic equation involving the (p,q)-Laplacian operator. In their work, the equation under consideration is

$$\begin{cases} -\operatorname{div}(|\nabla u|^{p-2}\nabla u) - \operatorname{div}(|\nabla u|^{q-2}\nabla u) = \frac{f(x)}{u^{\delta}} & \text{in } \Omega, \\ u > 0 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.2}$$

where $1 < q < p < \infty$, $\delta > 0$, and $f(x)$ is a nonnegative function that exhibits singular behavior near the boundary of Ω. Their paper proves the existence of weak solutions in appropriate Sobolev spaces and establishes the solutions' boundary behavior for different values of δ. Specifically, they derive optimal Sobolev regularity, prove uniqueness under certain conditions, and provide non-existence results in other regimes. Moreover, they obtain Hölder regularity estimates for the gradient of weak solutions, offering significant insights into equations with singular nonlinearities. For further details, the reader is referred to [12,14] and related references. Arruda and Nascimento [1] generalize the results of Giacomoni, Kumar, and Sreenadh by considering a broader class of quasilinear operators beyond the standard p-Laplacian. They study a class of nonlinear, nonhomogeneous singular elliptic equations involving the (p,q)-Laplacian operator given by

$$\begin{cases} -\operatorname{div}(a(|\nabla u|^p)|\nabla u|^{p-2}\nabla u) = \frac{h(x)}{u^{\delta}} + f(x,u) & \text{in } \Omega, \\ u > 0 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.3}$$

where Ω is a bounded domain in $\mathbb{R}^N$ (with $N \geq 3$), $2 \leq p < N$, and $\delta > 0$. By using the sub–supersolution method combined with variational techniques, they establish the existence of at least one weak solution and, under additional assumptions on f, prove the existence of two distinct solutions. Key contributions include addressing nonhomogeneous

operators without truncation techniques and accommodating general singular terms for all $\gamma > 0$. These results apply to a broad class of quasilinear operators, including the p-Laplacian (when $a(t) \equiv 1$) and the (p,q)-Laplacian (when $a(t) = 1 + t^{q-p}/p$). Interested readers are referred to [37] and [45] for additional details.

Our work extends the (p,q)-Laplacian operators studied in (1.2) and (1.3) by introducing two anisotropic operators with distinct vector exponents $\{p_i\}_{i=1}^N$ and $\{q_i\}_{i=1}^N$. This generalization allows for direction-dependent nonlinearities, unlike the isotropic (p,q)-Laplacian. Additionally, the right-hand side of our problem (1.1) features a variable exponent $\gamma(x)$ in the singular term $\frac{f(x)}{u^{\gamma(x)}}$, which introduces spatial heterogeneity in the singularity strength. Moreover, we establish L^∞-regularity for solutions to (1.1), proving that $u \in L^\infty(\Omega)$ despite the anisotropic operators and the singular term.

The singular (q,p)-Laplacian denotes a class of singular differential equations that involve both the p-Laplacian and the q-Laplacian operators. These problems frequently arise in the study of various physical and mathematical phenomena, serving as models for steady-state solutions of reaction-diffusion problems encountered in biophysics, plasma physics, and chemical reaction studies (see, for example, [5, 7]). In the context of (p,q)-Laplacian-driven reaction-diffusion equations, the (p,q)-Laplacian term represents the diffusion component of the equation, which is given by:

$$|\partial_i u|^{p-2}|\partial_i u| + |\partial_i u|^{q-2}|\partial_i u| \quad \text{in } \Omega,$$

where $\partial_i u$ denotes the partial derivative of u with respect to x_i, $2 \le q < p$. The terms $|\partial_i u|^{p-2}|\partial_i u|$ and $|\partial_i u|^{q-2}|\partial_i u|$ represent the diffusion terms associated with the (p,q)-Laplacian operator.

Researchers have explored various aspects of the (p,q)-Laplacian, including the existence and uniqueness of solutions, regularity properties, and the behavior of solutions under different conditions. Recent results in this area can be found in [2, 12, 31, 35, 36, 38]. Our research builds on these findings by focusing on the properties of solutions in anisotropic singular problems.

The study of elliptic equations with singular nonlinearities has garnered significant attention from researchers. A pioneering contribution was made in 1976 by Crandall, Rabinowitz, and Tartar [11], where the authors explored nonlinear elliptic boundary value problems characterized by singular terms. Their work established the existence of both classical and generalized solutions under various conditions for problems associated with $-\Delta$ and Dirichlet boundary conditions. Specifically, when $p_i = q_i = 2$, the problem (1.1) reduces to the well-known semilinear elliptic equation that has been extensively studied:

$$\begin{cases} -\operatorname{div}(\nabla u) = \frac{f(x)}{u^{\gamma(x)}} & \text{in } \Omega, \\ u > 0 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.4}$$

with f is a non-negative function in a suitable Lebesgue space. In 1991, Lazer and McKenna published an important paper [28], focusing on the case where f is continuous and $\gamma(x) = \gamma$. They proved existence and regularity results concerning the behavior of solutions near the boundary. Boccardo and Orsina later extended this work in [3], where they used approximation methods by truncating the singular term to prove existence, regularity, and nonexistence results for problems modeled by (1.4) with $\gamma(x) = \gamma$. These results were further generalized by Chu, Y. Gao, and W. Gao [8] as well as by Carmona and Martínez-Aparicio [6], who studied

the case where $\gamma(x)$ varies as a function of x. Their research examined how the summability of f and the values of $\gamma(x)$ affect the existence and regularity of solutions to problem (1.4).

For general p, the following p-Laplacian problem has been widely studied by numerous researchers:

$$\begin{cases} -\operatorname{div}(|\nabla u|^{p-2}\nabla u) = \frac{f(x)}{u^{\gamma(x)}} & \text{in } \Omega, \\ u > 0 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.5}$$

where f is a positive function and $p > 1$. For example, in the paper [9], Chu and Gao applied the approximation method to analyze this problem involving the p-Laplacian operator with a constant exponent $\gamma(x) = \gamma$. Subsequently, Chu, Gao, and Sun extended these results in [10], where considering cases $\gamma(x)$ varies as a function of x. Their research explored various scenarios based on the behavior of $\gamma(x)$ and f, demonstrating that solutions to problem (1.5) exist in $W_0^{1,p}(\Omega) \cap L^\infty(\Omega)$.

There has been increasing interest in singular problems involving anisotropic operators, which correspond to a specific case of our problem (1.1) when $p_i = q_i$. For instance, in [30], the following problem was studied:

$$\begin{cases} -\sum_{i=1}^{N} \partial_i \left(|\partial_i u|^{p_i-2}\partial_i u \right) = \frac{f(x)}{u^{\gamma(x)}} & \text{in } \Omega, \\ u > 0 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.6}$$

where $\gamma(x) = \gamma$ is a positive constant and f belongs to an appropriate Lebesgue space. Using perturbation techniques, Leggat and Miri demonstrated the existence of positive solutions for problem (1.6). Additionally, Miri extended this analysis in [33], considering $\gamma(x) > 0$ as a variable function and f as a positive function in $L^m(\Omega)$. They established the existence and regularity of solutions in $W_0^{1,\vec{p}}(\Omega)$ when $\gamma(x) \leq 1$ and $m = \bar{p}^{*\prime}$, and in $W_{loc}^{1,\vec{p}}(\Omega)$ when $\|\gamma\|_{L^\infty(\Omega)} \leq \gamma^*$, with $\gamma^* > 1$.

It is important to note that the results in [30] and [33] are largely based on the strong maximum principle. Additional results on singular anisotropic problems, particularly using the sub-supersolution method, can be found in works like [15] and [16].

In our previous work [25], we extended existing results on similar problems (1.6) by incorporating variable exponent singularities and critical growth within an anisotropic framework. The problem is formulated as follows:

$$\begin{cases} -\sum_{i=1}^{N} M\left(\int_\Omega |\partial_i u|^{p_i} \, dx \right) \partial_i \left(|\partial_i u|^{p_i-2}\partial_i u \right) = \frac{f_1(x)}{u^{\beta(x)}} + \lambda \, f_2(x) \, u^{\bar{p}^*-1} & \text{in } \Omega, \\ u > 0 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases}$$

Here, Ω is a bounded regular domain in $\mathbb{R}^N$ with $N > \bar{p}$. The critical Sobolev exponent $\bar{p}^*$ is given by $\bar{p}^* = \frac{N\bar{p}}{N-\bar{p}}$, where $\bar{p} = \frac{N}{\sum_{i=1}^{N} \frac{1}{p_i}}$. The parameter $\lambda > 0$ is a positive constant, while the exponent function satisfies $0 < \beta(x) < 1$. The functions f_1 and f_2 have specific properties, and M represents the Kirchhoff coefficient.

Our main result establishes the existence of at least two weak solutions with opposite energy signs. The methodology is based on the fibering method using the Nehari manifold.

While our variational framework shares similarities with previous works, this study extends the analysis by considering a double anisotropic operator, singular reaction terms and regularity analysis. To handle these challenges, we employ techniques such as truncation methods and weighted Sobolev embeddings. In addition to establishing existence, we discuss various cases of the function $\gamma(x)$ to determine the corresponding solution in each scenario. Under further assumptions on the function f, it is proven that the obtained solutions belong to $L^\infty(\Omega)$, ensuring their boundedness and physical relevance. The incorporation of a double anisotropic operator enriches the analysis, providing deeper insights into the behavior of solutions in complex settings.

The techniques developed in this work not only generalize classical results but also pave the way for future research in problems involving variable exponent spaces, nonlocal operators, and anisotropic phenomena. The rigorous approach presented here contributes to the broader understanding of non-standard growth conditions in partial differential equations.

There is a substantial amount of literature and increasing interest in anisotropic (p,q)-Laplacian problems. Noteworthy recent contributions can be found in works such as [29,39, 40,43]. For example, in [39], Razani and Figueiredo studied the following problem:

$$\begin{cases} -\sum_{i=1}^{N} \partial_i \left(|\partial_i u|^{p_i-2} \partial_i u \right) - \sum_{i=1}^{N} \partial_i \left(|\partial_i u|^{q_i-2} \partial_i u \right) = \mathfrak{H}(x,u) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.7}$$

where $\mathfrak{H}(x,u) = \lambda u^{\gamma-1}$ with $\gamma > 1$. By applying a sub-supersolution approach along with minimization techniques in convex sets, the authors proved the existence of positive solutions for problem (1.7). A similar approach was used in [43], where Tavares considered problem (1.7) with $\mathfrak{H}(x,u) = k(x)u^{\alpha-1} + f(x,u)$, where $\alpha > 1$. Under a broad set of conditions, the existence and multiplicity of solutions were demonstrated. Additionally, Leggat and Miri [29], used the variational method to prove multiplicity results for the case where $\mathfrak{H}(x,u) = \lambda f(u)$.

We now introduce the key notations and assumptions relevant to problem (1.1). Specifically, we define the following parameters

$$\vec{p} = (p_1, \dots, p_N), \quad \bar{p} := \frac{N}{\sum_{i=1}^{N} 1/p_i}, \quad \bar{p}^* := \frac{N\bar{p}}{N-\bar{p}}, \quad p_\infty := \max\{\bar{p}^*, p_N\},$$
$$\vec{q} = (q_1, \dots, q_N), \quad \bar{q} := \frac{N}{\sum_{i=1}^{N} 1/q_i}, \quad \bar{q}^* := \frac{N\bar{q}}{N-\bar{q}}, \quad q_\infty := \max\{\bar{q}^*, q_N\}.$$

Throughout this paper, we impose the following assumptions

$$2 \le p_1 \le p_2 \le \cdots \le p_N < \bar{p}^*, \quad \text{and} \quad \sum_{i=1}^{N} \frac{1}{p_i} > 1,$$
$$2 \le q_1 \le q_2 \le \cdots \le q_N < \bar{q}^*, \quad \text{and} \quad \sum_{i=1}^{N} \frac{1}{q_i} > 1,$$
$$\gamma^+ = \sup_{x\in\overline{\Omega}} \gamma(x), \quad \text{and} \quad \gamma^- = \inf_{x\in\overline{\Omega}} \gamma(x).$$

We denote by X the anisotropic Sobolev space associated with problem (1.1), defined as

$$X := W_0^{1,\vec{p}}(\Omega) \cap W_0^{1,\vec{q}}(\Omega),$$

where $\Omega \subseteq \mathbb{R}^N$ is a bounded and regular domain with $N \geq 3$. Furthermore, the space X is given by the closure

$$X = \overline{C_0^\infty(\Omega)}^{\|\cdot\|_X},$$

where the norm $\|\cdot\|_X$ is defined as

$$\|u\|_X := \|u\|_{W_0^{1,\vec{p}}(\Omega)} + \|u\|_{W_0^{1,\vec{q}}(\Omega)} = \sum_{i=1}^N \|\partial_i u\|_{L^{p_i}(\Omega)} + \sum_{i=1}^N \|\partial_i u\|_{L^{q_i}(\Omega)}.$$

Moreover, $(X, \|\cdot\|_X)$ is a uniformly convex Banach space, and consequently, it is reflexive. For further details, see [19].

Additionally, we assume that f is a nontrivial measurable function satisfying the condition

$$(H_f) \qquad \operatorname*{ess\,inf}_{\Omega} f(x) > 0.$$

The primary objective of this article is to investigate the existence and regularity of positive weak solutions for the singular problem (1.1) in the space X by considering various cases of the function $\gamma(x)$. Our strategy is to establish the existence of critical points for the energy functional

$$\Psi(u) = \sum_{i=1}^N \frac{1}{p_i} \int_\Omega |\partial_i u|^{p_i}\, dx + \sum_{i=1}^N \frac{1}{q_i} \int_\Omega |\partial_i u|^{q_i}\, dx - \int_\Omega f|u|^{1-\gamma(x)}\, dx.$$

The singular term $u^{-\gamma(x)}$ introduces significant challenges by causing a loss of Gateaux differentiability, despite Ψ being weakly lower semi-continuous (in fact, continuous). With this framework in place, we are now ready to rigorously define the notion of a solution for the singular problem.

Definition 1.1. A function $u \in X$ is called a weak solution of (1.1) if it satisfies the following conditions:

- **(i)** $u > 0$ a.e. in Ω, $fu^{-\gamma(x)} \in L^1_{loc}(\Omega)$, and
- **(ii)** $\sum_{i=1}^N \int_\Omega |\partial_i u|^{p_i-2} \partial_i u \partial_i \phi dx + \sum_{i=1}^N \int_\Omega |\partial_i u|^{q_i-2} \partial_i u \partial_i \phi dx = \int_\Omega \frac{f\phi}{u^{\gamma(x)}} dx,$

  for all $\phi \in C_0^1(\Omega)$.

The principal theorems established in this work are as follows:

Theorem 1.2. *Suppose that f is a positive function in $L^1(\Omega)$, and (H_f) holds, with $0 < \gamma^- \leq \gamma(x) \leq \gamma^+ < 1$. Then, the problem (1.1) has a solution in X.*

Theorem 1.3. *Let f be a positive function in $L^1(\Omega)$ and assume that condition (H_f) holds, with $0 < \gamma^- < 1 < \gamma^+$. Then problem (1.1) admits a solution in the space $X_{loc} := W^{1,\vec{p}}_{loc}(\Omega) \cap W^{1,\vec{q}}_{loc}(\Omega)$. Moreover, the solution u belongs to $L^r(\Omega)$, where $r = \frac{N(\gamma^+ - 1 + \overline{m})}{(N - \overline{m})}$, with $\overline{m} = \overline{p}, \overline{q}$.*

Theorem 1.4. *Assume that f is a positive function in $L^1(\Omega)$ and condition (H_f) is satisfied, with $1 < \gamma^- \leq \gamma(x) \leq \gamma^+$. Then, problem (1.1) admits a solution in the space X_{loc}.*

Theorem 1.5. *Assume that (H_f) holds and $f \in L^r(\Omega)$ with $r \geq \frac{\min\{\bar{p}^*, \bar{q}^*\}}{\min\{\bar{p}^*, \bar{q}^*\} - \max\{\bar{p}, \bar{q}\}}$, and let $\gamma(x) > 0$. Then, the solution u of problem (1.1), as established by Theorems 1.2, 1.3, and 1.4, belongs to $L^\infty(\Omega)$.*

This paper is organized as follows. In Section 2 establishes several technical results that are essential for proving our main theorem. We begin by presenting a regularity result for the solution of the anisotropic (p,q)-Laplacian problem. Next, we introduce a comparison principle, and finally, we demonstrate that the solution remains strictly greater than a positive term. Section 3 applies the variational method and leverages the auxiliary results from Section 2 to prove that the approximate problem admits a solution in $X \cap L^{\infty}(\Omega)$. Section 4 is dedicated to the proof of the main results, while Section 5 explores possible generalizations of our existence result and discusses future research perspectives.

2 Preliminaries and technical results

This section is dedicated to establishing fundamental results essential for proving our main theorems. We begin by addressing the uniqueness and L^{∞}-regularity of solutions to the anisotropic (p,q)-Laplacian problem under consideration. Next, we introduce a comparison principle and conclude with a boundary behavior lemma, which ensures that a solution u remains bounded below by a positive quantity proportional to the distance to the boundary. Together, these results provide crucial insights into how the anisotropic structure influences the solution's regularity and its interaction with the domain's geometry. We start by examining the following anisotropic (p,q)-Laplacian problem

$$\begin{cases} -\sum_{i=1}^{N} \partial_i \left(|\partial_i u|^{p_i-2} \partial_i u \right) - \sum_{i=1}^{N} \partial_i \left(|\partial_i u|^{q_i-2} \partial_i u \right) = h(x) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases} \tag{2.1}$$

Lemma 2.1 ([43]). *Let $h \in X'$. Then, the problem (2.1) has a unique solution in X.*

The proof follows from Minty–Browder's Theorem, as stated in Lemma 3.3 of [43].

Lemma 2.2. *Let $h \in L^r(\Omega)$ with $r > \frac{\max\{\bar{p}^*,\bar{q}^*\}}{\max\{\bar{p}^*,\bar{q}^*\}-\max\{p_N,q_N\}}$. The solution u to the problem (2.1) belongs to $L^{\infty}(\Omega)$.*

Proof. Let $\Omega_k := \{x \in \Omega : |u(x)| > k\}$ for $k > 0$. Define the truncated test function

$$\xi_k := \operatorname{sign}(u) \cdot (|u| - k)^+,$$

where $(\cdot)^+$ denotes the positive part. Let $\beta := \max\{\overline{p}^*, \overline{q}^*\}$, where $\overline{p}^*$ and $\overline{q}^*$ are the critical Sobolev exponents associated with the anisotropic exponents $\{p_i\}$ and $\{q_i\}$, respectively. Observe that $\xi_k \in X$ and $\partial_i \xi_k = \partial_i u$ in Ω_k, while $\partial_i \xi_k = 0$ outside Ω_k. Let $|\Omega_k|$ denote the Lebesgue measure of Ω_k.

Using ξ_k as a test function in the weak formulation of problem (2.1) and applying Hölder's inequality, we can derive the following results

$$\begin{aligned} \sum_{i=1}^{N} \int_{\Omega_k} |\partial_i \xi_k|^{p_i} \, dx + \sum_{i=1}^{N} \int_{\Omega_k} |\partial_i \xi_k|^{q_i} \, dx &= \int_{\Omega} h \xi_k dx \\ &\leq \left(\int_{\Omega} |\xi_k|^{\beta} \, dx \right)^{\frac{1}{\beta}} \left(\int_{\Omega} |h|^r dx \right)^{\frac{1}{r}} |\Omega_k|^{1-\frac{1}{\beta}-\frac{1}{r}}. \end{aligned} \tag{2.2}$$

Define the energy minimization problem

$$\mathfrak{B} := \inf_{\substack{u\in D^{1,\vec{p}}(\mathbb{R}^N)\cap D^{1,\vec{q}}(\mathbb{R}^N)\\ \|u\|_{L^\beta(\mathbb{R}^N)}=1}} \sum_{i=1}^{N}\frac{1}{p_i}\|\partial_i u\|^{p_i}_{L^{p_i}(\mathbb{R}^N)} + \sum_{i=1}^{N}\frac{1}{q_i}\|\partial_i u\|^{q_i}_{L^{q_i}(\mathbb{R}^N)}, \tag{2.3}$$

where

$$\mathcal{D}^{1,\vec{p}}\left(\mathbb{R}^N\right) := \left\{u \in L^{\bar{p}^*}\left(\mathbb{R}^N\right) : |\partial_i u| \in L^{p_i}\left(\mathbb{R}^N\right)\right\}.$$

Form Lemma 3 in [18], if $\beta = \bar{p}^*$, we have

$$\mathfrak{B} \geq \inf_{\substack{u\in D^{1,\vec{p}}(\mathbb{R}^N)\\ \|u\|_{L^{\bar{p}^*}(\mathbb{R}^N)}=1}} \sum_{i=1}^{N}\frac{1}{p_i}\|\partial_i u\|^{p_i}_{L^{p_i}(\mathbb{R}^N)} > 0.$$

Similarly, if $\beta = \bar{q}^*$, the same argument yields $\mathfrak{B} > 0$.

By direct computation, we deduce that for every $u \in X$

$$\begin{aligned}
&\sum_{i=1}^{N}\int_\Omega |\partial_i u|^{p_i}\,dx + \sum_{i=1}^{N}\int_\Omega |\partial_i u|^{q_i}\,dx \\
&\quad\geq \|u\|^\theta_{L^\beta(\Omega)}\sum_{i=1}^{N}\int_\Omega \left|\partial_i\left(\frac{u}{\|u\|_{L^\beta(\Omega)}}\right)\right|^{p_i}dx + \|u\|^\theta_{L^\beta(\Omega)}\sum_{i=1}^{N}\int_\Omega \left|\partial_i\left(\frac{u}{\|u\|_{L^\beta(\Omega)}}\right)\right|^{q_i}dx \\
&\quad\geq \|u\|^\theta_{L^\beta(\Omega)}\left[\sum_{i=1}^{N}\frac{1}{p_i}\int_\Omega \left|\partial_i\left(\frac{u}{\|u\|_{L^\beta(\Omega)}}\right)\right|^{p_i}dx + \sum_{i=1}^{N}\frac{1}{q_i}\int_\Omega \left|\partial_i\left(\frac{u}{\|u\|_{L^\beta(\Omega)}}\right)\right|^{q_i}dx\right],
\end{aligned}$$

where

$$\theta = \begin{cases} \min\{p_1, q_1\} & \text{if } \|u\|_{L^\beta(\Omega)} > 1, \\ \max\{p_N, q_N\} & \text{if } \|u\|_{L^\beta(\Omega)} \leq 1. \end{cases}$$

Furthermore, from (2.3), we derive

$$\sum_{i=1}^{N}\int_\Omega |\partial_i u|^{p_i}\,dx + \sum_{i=1}^{N}\int_\Omega |\partial_i u|^{q_i}\,dx \geq \mathfrak{B}\times\|u\|^\theta_{L^\beta(\Omega)}. \tag{2.4}$$

Combining (2.2) and (2.4), we obtain

$$\mathfrak{B}\left(\int_{\Omega_k}|\xi_k|^\beta\,dx\right)^{\frac{\theta-1}{\beta}} \leq \|h\|_{L^r(\Omega)}|\Omega_k|^{1-\frac{1}{\beta}-\frac{1}{r}}. \tag{2.5}$$

Additionally, if $0 < k < \ell$, we have $\Omega_\ell \subset \Omega_k$, and

$$|\Omega_\ell|^{\frac{1}{\beta}}(\ell-k) = \left(\int_{\Omega_\ell}(\ell-k)^\beta dx\right)^{\frac{1}{\beta}} \leq \left(\int_{\Omega_k}|\xi_k|^\beta\,dx\right)^{\frac{1}{\beta}}.$$

Given that $\theta \geq 2$, we conclude

$$\mathfrak{B}|\Omega_\ell|^{\frac{\theta-1}{\beta}}(\ell-k)^{\theta-1} \leq \mathfrak{B}\left(\int_{\Omega_k}|\xi_k|^\beta\,dx\right)^{\frac{\theta-1}{\beta}}, \tag{2.6}$$

and by combining (2.5) and (2.6), we infer

$$|\Omega_\ell| \leq \frac{1}{(\ell-k)^\beta \mathfrak{B}^{\frac{\beta}{\theta-1}}} \|h\|_{L^r(\Omega)}^{\frac{\beta}{\theta-1}} |\Omega_k|^{\frac{\beta}{\theta-1}\left(1-\frac{1}{\beta}-\frac{1}{r}\right)}.$$

Since $r > \frac{\max\{\bar{p}^*,\bar{q}^*\}}{\max\{\bar{p}^*,\bar{q}^*\}-\max\{p_N,q_N\}} \geq \frac{\beta}{\beta-\theta}$, we deduce that $\frac{\beta}{\theta-1}\left(1-\frac{1}{\beta}-\frac{1}{r}\right) > 1$. Thus, defining

$$\begin{cases} \psi(h) = |\Omega_\ell|, \\ \sigma = \frac{\beta}{\theta-1}\left(1-\frac{1}{\beta}-\frac{1}{r}\right), \\ k_0 = 0, \end{cases}$$

we see that ψ is a positive, non-increasing function. Moreover,

$$\psi(\ell) \leq \frac{C}{(\ell-k)^\beta}\psi(k)^\beta, \qquad \text{for all } \ell > k > 0.$$

Using ((i), Lemma 4.1, in [42]), we conclude that $\psi(d) = 0$ with $d^\beta = \frac{C\|h\|_{L^r(\Omega)}^{\frac{\beta}{\theta-1}} |\Omega|^{\sigma-1}}{\mathfrak{B}^{\frac{\beta}{\theta-1}}}$. Thus, we obtain

$$\|u\|_{L^\infty(\Omega)} \leq \frac{C\|h\|_{L^r(\Omega)}^{\frac{1}{\theta-1}} |\Omega|^{\frac{\sigma-1}{\beta}}}{\mathfrak{B}^{\frac{1}{\theta-1}}}.$$

Therefore, we have established that $u \in L^\infty(\Omega)$. □

Lemma 2.3 ([43]). *Consider $u, v \in X$ satisfying the following in the weak sense*

$$\begin{cases} -\sum_{i=1}^N \partial_i\left(|\partial_i u|^{p_i-2}\partial_i u\right) - \sum_{i=1}^N \partial_i\left(|\partial_i u|^{q_i-2}\partial_i u\right) \\ \qquad \leq -\sum_{i=1}^N \partial_i\left(|\partial_i v|^{p_i-2}\partial_i v\right) - \sum_{i=1}^N \partial_i\left(|\partial_i v|^{q_i-2}\partial_i v\right) \quad \text{in } \Omega, \\ (u-v)^+ \in X. \end{cases}$$

Then, it follows that $u \leq v$ almost everywhere in Ω.

Regarding the proof, we refer the reader to Lemma 3.5 in [43].

Lemma 2.4. *Let μ be a positive constant and $u \in X$ be the unique solution to the following problem*

$$\begin{cases} -\sum_{i=1}^N \partial_i\left(|\partial_i u|^{p_i-2}\partial_i u\right) - \sum_{i=1}^N \partial_i\left(|\partial_i u|^{q_i-2}\partial_i u\right) = \mu & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases} \tag{2.7}$$

Then, there exist constants $\eta \in (0,1]$ and M, which are independent of μ and u, such that

$$u(x) \geq M \min\left\{\mu^{\max\left\{\frac{1}{p_1-1},\frac{1}{q_1-1}\right\}}, \mu^{\min\left\{\frac{1}{p_N-1},\frac{1}{q_N-1}\right\}}\right\} \min\{\eta, d(x)\},$$

with $d(x) := \operatorname{dist}(x,\partial\Omega), x \in \Omega$.

Proof. Let $\rho > 0$ define the set

$$A_\rho := \{x \in \Omega \mid d(x) < \rho\},$$

where $d(x) = \operatorname{dist}(x, \partial\Omega)$ denotes the distance from x to the boundary $\partial\Omega$. Since the boundary $\partial\Omega$ is of class C^2, there exists a sufficiently small constant $\eta \in (0, 1]$ such that

$$d \in C^2\left(\overline{A_{3\eta}}\right) \quad \text{and} \quad |\nabla d(x)| \equiv 1,$$

as stated in Lemma 14.16 of Gilbarg and Trudinger [24].

For

$$\beta > \frac{1}{\min\{p_1, q_1\} - 1},$$

we define the function

$$\varsigma(x) = \begin{cases} \kappa d(x), & \text{if } d(x) < \eta, \\ \kappa\eta + \displaystyle\int_\eta^{d(x)} \kappa \left(\frac{2\eta - t}{\eta}\right)^\beta dt, & \text{if } \eta \le d(x) < 2\eta, \\ \kappa\eta + \displaystyle\int_\eta^{2\eta} \kappa \left(\frac{2\eta - t}{\eta}\right)^\beta dt, & \text{if } d(x) \ge 2\eta, \end{cases}$$

where $\kappa > 0$ is a constant to be determined later. It is evident that $\varsigma \in C_0^1(\overline{\Omega})$.

According to direct calculations, if $x \in \Omega$ satisfies $d(x) < \eta$ and $\partial_i d(x) \neq 0$, then we have

$$\begin{aligned} &-\sum_{i=1}^N \left[\partial_i \left(|\partial_i(\kappa d)|^{p_i - 2}\, \partial_i(\kappa d)\right) + \partial_i \left(|\partial_i(\kappa d)|^{q_i - 2}\, \partial_i(\kappa d)\right)\right] \\ &\quad = -\sum_{i=1}^N \left[\left(\operatorname{sgn}\left(\partial_i d\right)\right) \kappa^{p_i - 1} \partial_i \left(\operatorname{sgn}\left(\partial_i d\right)^{p_i - 1} \left(\partial_i d\right)^{p_i - 1}\right)\right] \\ &\qquad -\sum_{i=1}^N \left[\left(\operatorname{sgn}\left(\partial_i d\right)\right) \kappa^{q_i - 1} \partial_i \left(\operatorname{sgn}\left(\partial_i d\right)^{q_i - 1} \left(\partial_i d\right)^{q_i - 1}\right)\right] \\ &\quad = -\sum_{i=1}^N \left[\kappa^{p_i - 1} \left(p_i - 1\right) \left(\left(\operatorname{sgn}\left(\partial_i d\right)\right) \partial_i d\right)^{p_i - 2} \partial_i^2 d\right] \\ &\qquad -\sum_{i=1}^N \left[\kappa^{q_i - 1} \left(q_i - 1\right) \left(\left(\operatorname{sgn}\left(\partial_i d\right)\right) \partial_i d\right)^{q_i - 2} \partial_i^2 d\right] \\ &\quad =: \Upsilon_1(x), \end{aligned}$$

where $\operatorname{sgn}(x) = 1$ if $x \ge 0$ and $\operatorname{sgn}(x) = -1$ if $x < 0$. In the case where $\eta < d(x) < 2\eta$ and

$\partial_i d(x) \neq 0$, we find that

$$
\begin{aligned}
&-\sum_{i=1}^{N}\partial_i\left(\left|\partial_i\left(\kappa\eta+\int_{\eta}^{d(x)}\kappa\left(\frac{2\eta-t}{\eta}\right)^{\beta}dt\right)\right|^{p_i-2}\partial_i\left(\kappa\eta+\int_{\eta}^{d(x)}\kappa\left(\frac{2\eta-t}{\eta}\right)^{\beta}dt\right)\right)\\
&\quad-\sum_{i=1}^{N}\partial_i\left(\left|\partial_i\left(\kappa\eta+\int_{\eta}^{d(x)}\kappa\left(\frac{2\eta-t}{\eta}\right)^{\beta}dt\right)\right|^{q_i-2}\partial_i\left(\kappa\eta+\int_{\eta}^{d(x)}\kappa\left(\frac{2\eta-t}{\eta}\right)^{\beta}dt\right)\right)\\
&=-\sum_{i=1}^{N}\partial_i\left(\left|\partial_i(d(x))\kappa\left(\frac{2\eta-d(x)}{\eta}\right)^{\beta}\right|^{p_i-2}\partial_i(d(x))\kappa\left(\frac{2\eta-d(x)}{\eta}\right)^{\beta}\right)\\
&\quad-\sum_{i=1}^{N}\partial_i\left(\left|\partial_i(d(x))\kappa\left(\frac{2\eta-d(x)}{\eta}\right)^{\beta}\right|^{q_i-2}\partial_i(d(x))\kappa\left(\frac{2\eta-d(x)}{\eta}\right)^{\beta}\right)\\
&=-\sum_{i=1}^{N}\kappa^{p_i-1}\beta\left(p_i-1\right)\left(\frac{2\eta-d(x)}{\eta}\right)^{\beta(p_i-1)-1}\left(\frac{-1}{\eta}\right)\left(\left(\operatorname{sgn}\left(\partial_i d\right)\right)\partial_i d\right)^{p_i-2}\left(\partial_i d\right)^2\\
&\quad-\sum_{i=1}^{N}\kappa^{p_i-1}\left(\frac{2\eta-d(x)}{\eta}\right)^{\beta(p_i-1)}\left(p_i-1\right)\left|\partial_i d\right|^{p_i-2}\partial_i^2(d(x))\\
&\quad-\sum_{i=1}^{N}\kappa^{q_i-1}\beta\left(q_i-1\right)\left(\frac{2\eta-d(x)}{\eta}\right)^{\beta(q_i-1)-1}\left(\frac{-1}{\eta}\right)\left(\left(\operatorname{sgn}\left(\partial_i d\right)\right)\partial_i d\right)^{q_i-2}\left(\partial_i d\right)^2\\
&\quad-\sum_{i=1}^{N}\kappa^{q_i-1}\left(\frac{2\eta-d(x)}{\eta}\right)^{\beta(q_i-1)}\left(q_i-1\right)\left|\partial_i d\right|^{q_i-2}\partial_i^2(d(x))\\
&=:\mathrm{Y}_2(x).
\end{aligned}
$$

According to the previous cases, we have

$$
\sum_{i=1}^{N}\int_{\Omega}\left|\partial_i(\varsigma)\right|^{p_i-2}\partial_i(\varsigma)\partial_i\phi dx+\sum_{i=1}^{N}\int_{\Omega}\left|\partial_i(\varsigma)\right|^{q_i-2}\partial_i(\varsigma)\partial_i\phi dx=\int_{\Omega}\mathrm{Y}\phi dx\quad\forall\phi\in X,
$$

where

$$
\mathrm{Y}(x)=\begin{cases}\mathrm{Y}_1(x) & \text{if } d(x)<\eta,\ \partial_i d(x)\neq 0,\\ \mathrm{Y}_2(x) & \text{if } \eta<d(x)<2\eta,\ \partial_i d(x)\neq 0,\\ 0 & \text{if } d(x)>2\eta \text{ or } \partial_i d(x)=0.\end{cases}
$$

Given that $\beta>1/(\min\{p_1,q_1\}-1)$ and $p_i,q_i\geq 2$ for all $i=1,\ldots,N$, we conclude that

$$
\begin{aligned}
&\sum_{i=1}^{N}\int_{\Omega}\left|\partial_i(\varsigma)\right|^{p_i-2}\partial_i(\varsigma)\partial_i\phi dx+\sum_{i=1}^{N}\int_{\Omega}\left|\partial_i(\varsigma)\right|^{q_i-2}\partial_i(\varsigma)\partial_i\phi dx\\
&\qquad\leq M_0\max\left\{\kappa^{p_1-1},\ldots,\kappa^{p_N-1}\right\}+M_1\max\left\{\kappa^{q_1-1},\ldots,\kappa^{q_N-1}\right\}\\
&\qquad\leq M\max\left\{\kappa^{p_1-1},\ldots,\kappa^{p_N-1},\kappa^{q_1-1},\ldots,\kappa^{q_N-1}\right\},
\end{aligned}
$$

in the weak sense, where M_0 and M_1 are the constants from Lemma 2.4 and $M=2\max\{M_0,M_1\}$.

Let u be the solution to problem (2.7) and $\mu>0$. Now we distinguish two cases:
In the first case, if $\frac{\mu}{M}<1$, we choose $\kappa\in(0,1)$ such that

$$
\max\left\{\kappa^{p_1-1},\ldots,\kappa^{p_N-1},\kappa^{q_1-1},\ldots,\kappa^{q_N-1}\right\}=\kappa^{\min\{p_1-1,q_1-1\}}=\frac{\mu}{M}.
$$

Applying Lemma 2.3 yields

$$u(x) \geq \varsigma(x) \geq \kappa \min\{\eta, d(x)\} = \left(\frac{\mu}{M}\right)^{\max\{\frac{1}{p_1^{-1}}, \frac{1}{q_1^{-1}}\}} \min\{\eta, d(x)\}.$$

In the second case, when $\frac{\mu}{M} \geq 1$ we can employ the same reasoning as in the first case to obtain

$$u(x) \geq \varsigma(x) \geq \kappa \min\{\eta, d(x)\} = \left(\frac{\mu}{M}\right)^{\min\{\frac{1}{p_N^{-1}}, \frac{1}{q_N^{-1}}\}} \min\{\eta, d(x)\}.$$

Consequently, we arrive at

$$u(x) \geq \min\left\{\left(\frac{\mu}{M}\right)^{\max\{\frac{1}{p_1^{-1}}, \frac{1}{q_1^{-1}}\}}, \left(\frac{\mu}{M}\right)^{\min\{\frac{1}{p_N^{-1}}, \frac{1}{q_N^{-1}}\}}\right\} \min\{\eta, d(x)\}.$$

Thus, the statement is proven. □

3 Approximation problems

To formulate a minimization problem, the energy functional Ψ must be bounded from below in X, which, unfortunately, is not the case here. Additionally, the presence of a singular term introduces non-differentiability in the energy functional, creating an additional challenge in defining the natural constrained set. As a result, we cannot directly apply the standard critical point theory to Ψ to solve problem (1.1). To overcome this difficulty and obtain our result, we study an associated approximating problem. Specifically, for any $n \in \mathbb{N}^*$, we consider the following perturbed problem

$$\begin{cases} -\sum_{i=1}^{N} \partial_i \left(|\partial_i u_n|^{p_i - 2} \partial_i u_n\right) - \sum_{i=1}^{N} \partial_i \left(|\partial_i u_n|^{q_i - 2} \partial_i u_n\right) = \dfrac{f_n}{\left(u_n + \frac{1}{n}\right)^{\gamma(x)}} & \text{in } \Omega, \\ u_n = 0 & \text{on } \partial\Omega, \end{cases} \tag{$\mathcal{P}_n$}$$

where $f_n(x) = \min\{f(x)\ ,\ n\}$.

Lemma 3.1. *Suppose that $\gamma \in C^1(\overline{\Omega})$. Then the problem ($\mathcal{P}_n$) has a non-negative solution $u_n \in X \cap L^\infty(\Omega)$.*

Proof. While many studies rely on Schauder's fixed point theorem to establish the existence of solutions, this paper adopts a variational approach. We define the functions
$f : \Omega \times (0, \infty) \longrightarrow \mathbb{R}$ and $f_n : \Omega \times [0, \infty) \longrightarrow \mathbb{R}$ by

$$f(x,t) = \frac{f(x)}{t^{\gamma(x)}}, \quad \text{and} \quad f_n(x,t) = \frac{f_n(x)}{(t + 1/n)^{\gamma(x)}}, \qquad \text{for all } n > 0.$$

It is important to note that f_n is a Carathéodory function, and its primitive is given by the function F_n, where

$$F_n(x,t) = \int_0^t f_n(x,s)ds.$$

Remark 3.2. For $t \geq 0$, the following inequalities hold

$$0 < f_n(x,t) \leq f_n(x) n^{\|\gamma\|_{L^\infty(\Omega)}}, \quad \text{and} \quad F_n(x,t) \leq f_n(x) n^{\|\gamma\|_{L^\infty(\Omega)}} t.$$

We now define the functional $\Psi_n : X \longrightarrow \mathbb{R}$ associated with the problem $(\mathcal{P}_n)$ as follows

$$\Psi_n(u) = \sum_{i=1}^{N} \frac{1}{p_i} \int_\Omega |\partial_i u|^{p_i} dx + \sum_{i=1}^{N} \frac{1}{q_i} \int_\Omega |\partial_i u|^{q_i} dx - \int_\Omega F_n(x,u) dx.$$

Since it holds that

$$W_0^{1,\vec{p}}(\Omega) \overset{\text{compact}}{\hookrightarrow} L^r(\Omega) \quad \text{for all} \quad r \in [1, p_\infty),$$

and

$$W_0^{1,\vec{q}}(\Omega) \overset{\text{compact}}{\hookrightarrow} L^r(\Omega) \quad \text{for all} \quad r \in [1, q_\infty).$$

as established in [20]. This implies that the functional Ψ_n is sequentially weakly lower semi-continuous and coercive. Indeed, we have

$$\begin{aligned}
\Psi_n(u) &= \sum_{i=1}^{N} \frac{1}{p_i} \int_\Omega |\partial_i u|^{p_i} dx + \sum_{i=1}^{N} \frac{1}{q_i} \int_\Omega |\partial_i u|^{q_i} dx - \int_\Omega F_n(x,u) dx \\
&\geq \frac{1}{p_N N^{p_N - 1}} \left(\sum_{i=1}^{N} |\partial_i u|_{L^{p_i}(\Omega)} \right)^{p_0} + \frac{1}{q_N N^{q_N - 1}} \left(\sum_{i=1}^{N} |\partial_i u|_{L^{q_i}(\Omega)} \right)^{q_0} \\
&\quad - n^{\|\gamma\|_{L^\infty(\Omega)}} \int_\Omega f_n(x) u dx - 2N \\
&\geq \frac{1}{q_N p_N N^{p_N - 1} N^{q_N - 1}} \left(\|u\|^{p_0}_{W_0^{1,\vec{p}}(\Omega)} + \|u\|^{q_0}_{W_0^{1,\vec{q}}(\Omega)} \right) - n^{\|\gamma\|_{L^\infty(\Omega)}} \int_\Omega f_n(x) u dx - 2N.
\end{aligned}$$

Here,

$$\begin{aligned}
&p_0 = p_1 \quad \text{if } \|u\|_{W_0^{1,\vec{p}}(\Omega)} > 1 \qquad \text{and} \qquad p_0 = p_N \quad \text{if } \|u\|_{W_0^{1,\vec{p}}(\Omega)} \leq 1, \\
&q_0 = q_1 \quad \text{if } \|u\|_{W_0^{1,\vec{q}}(\Omega)} > 1 \qquad \text{and} \qquad q_0 = q_N \quad \text{if } \|u\|_{W_0^{1,\vec{q}}(\Omega)} \leq 1.
\end{aligned}$$

Observe that $W_0^{1,\vec{p}}(\Omega) \overset{\text{continuous}}{\hookrightarrow} L^{p_1}(\Omega)$, implying that there exists a constant C such that, $\|u\|_{L^{p_1}(\Omega)} \leq C \|u\|_{W_0^{1,\vec{p}}(\Omega)}$. This leads to the following inequality

$$\Psi_n(u) \geq \frac{1}{q_N p_N N^{p_N - 1} N^{q_N - 1}} \left(\|u\|^{p_0}_{W_0^{1,\vec{p}}(\Omega)} + \|u\|^{q_0}_{W_0^{1,\vec{q}}(\Omega)} \right) - C n^{\|\gamma\|_{L^\infty(\Omega)}} \|f\|_{L^{p_1'}(\Omega)} \|u\|_{W_0^{1,\vec{p}}(\Omega)} - 2N.$$

Since $p_0, q_0 \geq 2$, we have

$$\Psi_n(u) \longrightarrow +\infty \quad \text{as } \|u\|_X \longrightarrow +\infty.$$

Consequently, Ψ_n has a global minimum, denoted u_n. Moreover, $\Psi_n \in C^1(X)$ with derivative at u given by

$$\langle \Psi_n'(u), \phi \rangle \sum_{i=1}^{N} \int_\Omega |\partial_i(u)|^{p_i - 2} \partial_i(u) \partial_i \phi dx + \sum_{i=1}^{N} \int_\Omega |\partial_i(u)|^{q_i - 2} \partial_i(u) \partial_i \phi dx - \int_\Omega f_n(x,u) \phi dx.$$

Hence, this global minimum is a critical point and thus constitutes a weak solution to the problem $(\mathcal{P}_n)$. Next, we consider the following problem

$$\begin{cases}
-\sum_{i=1}^{N} \partial_i \left(|\partial_i w_n|^{p_i - 2} \partial_i w_n \right) - \sum_{i=1}^{N} \partial_i \left(|\partial_i w_n|^{q_i - 2} \partial_i w_n \right) = n^{\|\gamma\|_{L^\infty(\Omega)}} f_n & \text{in } \Omega, \\
w_n = 0 & \text{on } \partial\Omega.
\end{cases}$$

According to Lemmas 2.1 and 2.2 the aforementioned problem has a solution $w_n \in L^\infty(\Omega)$, whenever the right-hand side belongs to $L^s(\Omega)$ with $s > \max\{\bar{p}^*, \bar{q}^*\}'$. Here, $\max\{\bar{p}^*, \bar{q}^*\}'$ denotes the Hölder conjugate exponent, defined by the relation $\frac{1}{\max\{\bar{p}^*, \bar{q}^*\}} + \frac{1}{\max\{\bar{p}^*, \bar{q}^*\}'} = 1$.

Since $\frac{f_n}{(u_n+\frac{1}{n})^{\gamma(x)}} \geq 0$ a.e. in Ω, by applying Lemma 2.3, we show that $u_n \geq 0$ a.e. in Ω.

Furthermore, using Lemma 2.3 again, along with the inequality $f_n(x,u) \leq n^{\|\gamma\|_{L^\infty(\Omega)}} f_n(x)$ a.e. in Ω for all $n \in \mathbb{N}^*$, we conclude that $u_n \leq w_n$ a.e. in Ω, for all $n \in \mathbb{N}^*$. This leads us to deduce that $u_n \in L^\infty(\Omega)$. □

Remark 3.3. If u_n and v_n are two solutions of problem ($\mathcal{P}_n$), then by a straightforward calculation using Lemma 2.3, we can demonstrate that $u_n \leq v_n$. Due to symmetry, this implies that the solution to problem ($\mathcal{P}_n$) is unique.

Lemma 3.4. *The sequence $\{u_n\}$ is increasing with respect to $n, u_n \geq 0$ a.e in Ω, and there exists $K > 0$ (independent of n) such that*

$$u_n(x) \geq Kd(x) > 0 \quad a.e.\ x \in \Omega, \tag{3.1}$$

for every $n \in \mathbb{N}$, where $d(x) := \operatorname{dist}(x, \partial\Omega)$.

Proof. The function $f_n(x) = \min\{f(x)\ ,\ n\}$ provides a pointwise truncation of $f(x)$. Additionally, $\gamma(x) > 0$ in Ω, observing that

$$-\sum_{i=1}^{N} \partial_i \left(|\partial_i u_n|^{p_i-2}\partial_i u_n\right) - \sum_{i=1}^{N} \partial_i \left(|\partial_i u_n|^{q_i-2}\partial_i u_n\right) = \frac{f_n}{\left(u_n + \frac{1}{n}\right)^{\gamma(x)}} \leq \frac{f_{n+1}}{\left(u_n + \frac{1}{n+1}\right)^{\gamma(x)}}$$

and

$$-\sum_{i=1}^{N} \partial_i \left(|\partial_i u_{n+1}|^{p_i-2}\partial_i u_{n+1}\right) - \sum_{i=1}^{N} \partial_i \left(|\partial_i u_{n+1}|^{q_i-2}\partial_i u_{n+1}\right) = \frac{f_{n+1}}{\left(u_{n+1} + \frac{1}{n+1}\right)^{\gamma(x)}},$$

which implies

$$\begin{aligned}
&-\sum_{i=1}^{N} \partial_i \left(|\partial_i u_n|^{p_i-2}\partial_i u_n\right) - \sum_{i=1}^{N} \partial_i \left(|\partial_i u_n|^{q_i-2}\partial_i u_n\right) \\
&\qquad + \sum_{i=1}^{N} \partial_i \left(|\partial_i u_{n+1}|^{p_i-2}\partial_i u_{n+1}\right) + \sum_{i=1}^{N} \partial_i \left(|\partial_i u_{n+1}|^{q_i-2}\partial_i u_{n+1}\right) \\
&\leq \frac{f_{n+1}}{\left(u_n + \frac{1}{n+1}\right)^{\gamma(x)}} - \frac{f_{n+1}}{\left(u_{n+1} + \frac{1}{n+1}\right)^{\gamma(x)}} \\
&\leq \left(\frac{\left(u_{n+1} + \frac{1}{n+1}\right)^{\gamma(x)} - \left(u_n + \frac{1}{n+1}\right)^{\gamma(x)}}{\left(u_n + \frac{1}{n+1}\right)^{\gamma(x)} \left(u_{n+1} + \frac{1}{n+1}\right)^{\gamma(x)}} \right) f_{n+1}.
\end{aligned} \tag{3.2}$$

In the last inequality, applying $(u_n - u_{n+1})^+$ as a test function, the right-hand side shows

$$\left(\frac{\left(u_{n+1} + \frac{1}{n+1}\right)^{\gamma(x)} - \left(u_n + \frac{1}{n+1}\right)^{\gamma(x)}}{\left(u_n + \frac{1}{n+1}\right)^{\gamma(x)} \left(u_{n+1} + \frac{1}{n+1}\right)^{\gamma(x)}} \right) (u_n - u_{n+1})^+ f_{n+1} \leq 0 \quad \text{a.e. in } \Omega. \tag{3.3}$$

Combining (3.3) and (3.2) yields

$$\sum_{i=1}^{N}\int_{\Omega}\left(|\partial_i u_n|^{p_i-2}\partial_i u_n-|\partial_i u_{n+1}|^{p_i-2}\partial_i u_{n+1}\right)\partial_i\left(u_n-u_{n+1}\right)^{+}$$
$$+\sum_{i=1}^{N}\int_{\Omega}\left(|\partial_i u_n|^{q_i-2}\partial_i u_n-|\partial_i u_{n+1}|^{q_i-2}\partial_i u_{n+1}\right)\partial_i\left(u_n-u_{n+1}\right)^{+}\leq 0.$$

We recall the following algebraic inequality (see [41], page 210)

$$\left[|\xi_1|^{m-2}\xi_1-|\xi_2|^{m-2}\xi_2\right]\cdot(\xi_1-\xi_2)\geq C\,|\xi_1-\xi_2|^{m},$$

where $\xi_1,\xi_2\in\mathbb{R}^N$, $m\geq 2$, and C is a positive constant.

Since $p_i\geq 2$ for all $i=1,\dots,N$, we apply the above inequality with $\xi_1=\partial_i u_n$ and $\xi_2=\partial_i u_{n+1}$, which yields

$$0\leq\sum_{i=1}^{N}\int_{\Omega}|\partial_i\left(u_n-u_{n+1}\right)^{+}|^{p_i}dx+\sum_{i=1}^{N}\int_{\Omega}|\partial_i\left(u_n-u_{n+1}\right)^{+}|^{q_i}dx\leq 0.$$

Consequently, we find that $\left(u_n-u_{n+1}\right)^{+}=0$ a.e. in Ω, which implies $u_n\leq u_{n+1}$ for all $n\in\mathbb{N}$.

Given that the sequence u_n is increasing with respect to n, it suffices to prove that inequality (3.1) holds for u_1. We know that u_1 is a solution of the problem $(\mathcal{P}_n)$ when $n=1$, which implies, in the weak sense

$$-\sum_{i=1}^{N}\partial_i\left(|\partial_i u_1|^{p_i-2}\partial_i u_1\right)-\sum_{i=1}^{N}\partial_i\left(|\partial_i u_1|^{q_i-2}\partial_i u_1\right)=\frac{f_1}{\left(u_1+1\right)^{\gamma(x)}}.$$

According to Lemma 3.1 and hypothesis (H_f), we have

$$\frac{f_1}{\left(u_1+1\right)^{\gamma(x)}}\geq\frac{\operatorname{ess\,inf}_{\Omega}f_1}{\left(\|u_1\|_{L^{\infty}(\Omega)}+1\right)^{\gamma^{-}}}>0.$$

Let $\lambda>0$ be such that

$$\frac{\operatorname{ess\,inf}_{\Omega}f_1}{\left(\|u_1\|_{L^{\infty}(\Omega)}+1\right)^{\gamma^{-}}}\geq\lambda. \tag{3.4}$$

By applying Lemma 2.4, there exists a unique solution $\underline{u}\in X$, to the following problem

$$\begin{cases}-\sum_{i=1}^{N}\partial_i\left(|\partial_i\underline{u}|^{p_i-2}\partial_i\underline{u}\right)-\sum_{i=1}^{N}\partial_i\left(|\partial_i\underline{u}|^{q_i-2}\partial_i\underline{u}\right)=\lambda & \text{in }\Omega,\\ \underline{u}=0 & \text{on }\partial\Omega,\end{cases}$$

such that

$$\underline{u}(x)\geq Kd(x), \tag{3.5}$$

where $d(x):=\operatorname{dist}(x,\partial\Omega)$ for $x\in\Omega$, and K is a positive constant independent of $\underline{u}$.

From (3.4), we obtain

$$-\sum_{i=1}^{N}\partial_i\left(|\partial_i u_1|^{p_i-2}\partial_i u_1\right)-\sum_{i=1}^{N}\partial_i\left(|\partial_i u_1|^{q_i-2}\partial_i u_1\right)\geq-\sum_{i=1}^{N}\partial_i\left(|\partial_i\underline{u}|^{p_i-2}\partial_i\underline{u}\right)-\sum_{i=1}^{N}\partial_i\left(|\partial_i\underline{u}|^{q_i-2}\partial_i\underline{u}\right).$$

Using Lemma 2.3 together with inequality (3.5), we conclude

$$u_1 \geq \underline{u} \geq Kd(x), \quad \text{a.e. in } \Omega. \tag{3.6}$$

Due to the monotonicity of the sequence $\{u_n\}_n$ and the result in (3.6), it follows that for all $n \in \mathbb{N}^*$

$$u_n \geq Kd(x), \quad \text{a.e. in } \Omega. \qquad \square$$

4 Proof of the main results

In this section, contingent on the behavior of the function $\gamma(x)$, we establish the main results of our work by analyzing the convergence of solutions to the regularized problems $(\mathcal{P}_n)$ and investigating the regularity properties of these solutions.

Proof of Theorem 1.2.

When $0 < \gamma(x) < 1$, the existence of solutions in X for problem (1.1) is established by showing that the sequence of solutions to the approximate problem $(\mathcal{P}_n)$ remains bounded in X. Leveraging the reflexivity of X and applying Lemma 3.4, we then conclude the existence of a solution.

Lemma 4.1. *Suppose that (H_f) holds, $f \in L^1(\Omega)$, and let u_n be the solution of $(\mathcal{P}_n)$ with $0 < \gamma^- \leq \gamma(x) \leq \gamma^+ < 1$. Then the sequence $\{u_n\}_n$ is bounded in X.*

Proof. Begin by using u_n as a test function in $(\mathcal{P}_n)$. We have

$$\begin{aligned}
\sum_{i=1}^{N} \int_\Omega |\partial_i u_n|^{p_i} dx + \sum_{i=1}^{N} \int_\Omega |\partial_i u_n|^{q_i} dx &= \int_\Omega \frac{f_n u_n}{\left(u_n + \frac{1}{n}\right)^{\gamma(x)}} dx \\
&\leq \int_\Omega f u_n^{1-\gamma(x)} dx \\
&\leq \int_{\Omega \cap \{u_n \leq 1\}} f dx + \int_{\Omega \cap \{u_n \geq 1\}} f u_n dx \\
&\leq \|f\|_{L^1(\Omega)} + \|f\|_{L^1(\Omega)} \|u_n\|_{L^\infty(\Omega)}.
\end{aligned} \tag{4.1}$$

Now, referencing the proof of Lemma 3.1, we can derive the following inequality:

$$\sum_{i=1}^{N} \int_\Omega |\partial_i u_n|^{p_i} dx + \sum_{i=1}^{N} \int_\Omega |\partial_i u_n|^{q_i} dx \geq \frac{\|u_n\|^{p_0}_{W_0^{1,\vec{p}}(\Omega)}}{N^{p_N - 1}} + \frac{\|u_n\|^{q_0}_{W_0^{1,\vec{q}}(\Omega)}}{N^{q_N - 1}} - 2N, \tag{4.2}$$

where p_0 and q_0 are identical in the proof of Lemma 3.1. Based on the previous inequalities and (4.1), we obtain

$$\begin{aligned}
\|u_n\|^{p_0}_{W_0^{1,\vec{p}}(\Omega)} + \|u_n\|^{q_0}_{W_0^{1,\vec{q}}(\Omega)} &\leq \max\left\{N^{p_N - 1}, N^{q_N - 1}\right\} \left(\|f\|_{L^1(\Omega)} + \|f\|_{L^1(\Omega)} \|u_n\|_{L^\infty(\Omega)} + 2N\right) \\
&\leq \mathfrak{C}_1(f, \varphi).
\end{aligned}$$

The fact that $u_n \in L^\infty(\Omega)$ implies that $\{u_n\}$ is bounded in X. $\square$

Since the embidding $X \hookrightarrow L^s(\Omega)$ is compact for all $s \in [1, \min\{\bar{p}^*, \bar{q}^*\})$, and given that $\{u_n\}$ is bounded in X by Lemma 4.1, we can conclude that, up to a subsequence, $u_n \rightharpoonup u$

weakly in X, where $u \in X$. Moreover, $u_n \to u$ strongly in $L^s(\Omega)$ for $1 \leq s < \min\{\bar{p}^*, \bar{q}^*\}$, and $u_n(x) \to u(x)$ almost everywhere in Ω. Thus, for every $\phi \in C_0^1(\Omega)$, we have

$$\lim_{n\longrightarrow\infty} \sum_{i=1}^{N} \int_\Omega |\partial_i u_n|^{p_i-2}\partial_i u_n \partial_i \phi dx + \sum_{i=1}^{N} \int_\Omega |\partial_i u_n|^{q_i-2}\partial_i u_n \partial_i \phi dx$$
$$= \sum_{i=1}^{N} \int_\Omega |\partial_i u|^{p_i-2}\partial_i u \partial_i \phi dx + \sum_{i=1}^{N} \int_\Omega |\partial_i u|^{q_i-2}\partial_i u \partial_i \phi dx. \quad (4.3)$$

According to Lemma 3.4, we have $u_n \geq kd(x)$ a.e. in Ω, which implies that

$$0 \leq \left| \frac{f_n \phi}{\left(u_n + \frac{1}{n}\right)^{\gamma(x)}} \right| \leq \left(\| \phi \left(kd(\cdot)\right)^{-\gamma^+} \|_{L^\infty(\Omega)} + \| \phi \left(kd(\cdot)\right)^{-\gamma^-} \|_{L^\infty(\Omega)} \right) f,$$

for all $\phi \in C_0^1(\Omega)$. By using the Dominated Lebesgue's theorem, we have

$$\lim_{n\longrightarrow\infty} \int_\Omega \frac{f_n \phi}{\left(u_n + \frac{1}{n}\right)^{\gamma(x)}} dx = \int_\Omega \frac{f\phi}{(u)^{\gamma(x)}} dx. \quad (4.4)$$

The fact that u_n is the solution of $(\mathcal{P}_n)$ allows us to conclude, using (4.3) and (4.4), that

$$\sum_{i=1}^{N} \int_\Omega |\partial_i u|^{p_i-2}\partial_i u \partial_i \phi dx + \sum_{i=1}^{N} \int_\Omega |\partial_i u|^{q_i-2}\partial_i u \partial_i \phi dx = \int_\Omega \frac{f\phi}{u^{\gamma(x)}} dx, \quad (4.5)$$

for all $\phi \in C_0^1(\Omega)$. This proves that (1.1) has a solution u in X. □

Proof of Theorem 1.3.
In the case $\gamma^- < 1 < \gamma^+$, we choose a test function $u_n^{\gamma^+}$ to demonstrate that u_n is bounded in X_{loc}, and also bounded in $L^r(\Omega)$ for some appropriate value of r. By utilizing the same arguments as in the case $0 < \gamma(x) < 1$ (Theorem 1.2), we can establish the existence and regularity of the solutions.

Lemma 4.2. *Assume that (H_f) is satisfied and that f is a nonnegative function in $L^1(\Omega)$. Let u_n denote the solution to $(\mathcal{P}_n)$ for the parameters $0 < \gamma^- < 1 < \gamma^+$. Then, the sequence $\{u_n\}_n$ is bounded in both X_{loc} and $L^r(\Omega)$, where*

$$r = \frac{N\left(\gamma^+ - 1 + \overline{m}\right)}{(N - \overline{m})},$$

with $\overline{m}$ being either $\overline{p}$ or $\overline{q}$.

Proof. Taking $u_n^{\gamma^+}$ as a test function, we obtain the following by using $(\mathcal{P}_n)$ and Lemma 3.4. Given that $u_n \in L^\infty(\Omega)$ and $\gamma^+ - \gamma^- > 0$, we obtain

$$\sum_{i=1}^{N} \gamma^+ \int_\Omega |\partial_i u_n|^{p_i} u_n^{\gamma^+-1} dx + \sum_{i=1}^{N} \gamma^+ \int_\Omega |\partial_i u_n|^{q_i} u_n^{\gamma^+-1} dx = \int_\Omega \frac{f_n u_n^{\gamma^+}}{\left(u_n + \frac{1}{n}\right)^{\gamma(x)}} dx$$
$$\leq \int_\Omega f u_n^{\gamma^+-\gamma^-} dx + \int_\Omega f dx$$
$$\leq \|f\|_{L^1(\Omega)} \left(1 + \|u_n^{\gamma^+-\gamma^-}\|_{L^\infty(\Omega)}\right)$$
$$\leq \mathfrak{C}_2(f, \gamma, \Omega). \quad (4.6)$$

Furthermore, applying Lemma 3.4 for any compact set $K \subset \Omega$ and since $\gamma^+ - 1 > 0$, we conclude

$$\sum_{i=1}^{N} \int_{\Omega} |\partial_i u_n|^{p_i} u_n^{\gamma^+ - 1} dx + \sum_{i=1}^{N} \int_{\Omega} |\partial_i u_n|^{q_i} u_n^{\gamma^+ - 1} dx$$
$$\geq \min_K (kd(x))^{\gamma^+ - 1} \left[\sum_{i=1}^{N} \int_K |\partial_i u_n|^{p_i} dx + \sum_{i=1}^{N} \int_K |\partial_i u_n|^{q_i} dx \right].$$

By the last inequalities and (4.6), we obtain

$$\sum_{i=1}^{N} \int_K |\partial_i u_n|^{p_i} dx + \sum_{i=1}^{N} \int_K |\partial_i u_n|^{q_i} dx \leq \frac{1}{\min_K (kd(x))^{\gamma^+ - 1}} \mathfrak{C}_2(f, \gamma, \Omega), \tag{4.7}$$

for any compact set $K \subset \Omega$. We conclude that u_n is bounded in X_{loc}.

Now from (4.6), we get for every $i = 1, \ldots, N$

$$\int_{\Omega} |\partial_i u_n|^{m_i} u_n^{\gamma^+ - 1} dx \leq \mathfrak{C}_2(f, \gamma, \Omega),$$

where m_i being either p_i or q_i, which implies

$$\left[\int_{\Omega} |\partial_i u_n|^{m_i} u_n^{\gamma^+ - 1} dx \right]^{\frac{1}{m_i}} \leq \mathfrak{C}_2(f, \gamma, \Omega)^{\frac{1}{m_i}}.$$

Hence,

$$\prod_{i=1}^{N} \left[\int_{\Omega} |\partial_i u_n|^{m_i} u_n^{\gamma^+ - 1} dx \right]^{\frac{1}{m_i}} \leq \mathfrak{C}_2(f, \gamma, \Omega)^{\frac{N}{\overline{m}}},$$

where $\frac{N}{\overline{m}} = \sum_{i=1}^{N} \frac{1}{m_i}$.

Now, we need to use the Sobolev inequality provided in [33, Theorem 1.2], with the following choice of exponents:

$$t_i m_i = \gamma^+ - 1, \quad r = \frac{N(\gamma^+ - 1 + \overline{m})}{(N - \overline{m})} \quad \text{and} \quad \frac{1}{r} = \frac{\gamma_i (N-1) - 1 + \frac{1}{m_i}}{t_i + 1},$$

where γ_i and t_i are defined as in [33, Theorem 1.2] . We deduce that

$$\left[\int_{\Omega} u_n^r dx \right]^{\frac{N}{\overline{m}} - 1} \leq \mathfrak{C}_2(f, \gamma, \Omega)^{\frac{N}{\overline{m}}}.$$

The fact that $N > \overline{m}$ allows us to conclude that u_n is bounded in $L^r(\Omega)$ with $r = \frac{N(\gamma^+ - 1 + \overline{m})}{(N - \overline{m})}$. □

Given that u_n is bounded in X_{loc}, we can prove the existence of a solution u in X_{loc} by following the proof of Theorem 1.2. Moreover, since u_n is bounded in $L^r(\Omega)$ with $r = \frac{N(\gamma^+ - 1 + \overline{m})}{(N - \overline{m})}$, it follows that u is also in $L^r(\Omega)$.

Proof of Theorem 1.4.

Finally, when $\gamma(x) > 1$, we select a test function $u_n(\varphi^2 + \epsilon^{\gamma^+})$ to show that u_n is bounded in X_{loc}. By adapting the arguments from the case $0 < \gamma(x) < 1$, we can conclude the existence of solutions in X_{loc}.

Lemma 4.3. *Assume that (H_f) is satisfied and that $f \in L^1(\Omega)$ is a nonnegative function. Let u_n represent the solution to $(\mathcal{P}_n)$ under the condition $1 < \gamma^- \leq \gamma(x) \leq \gamma^+$. Then, the sequence $\{u_n\}_n$ is bounded in X_{loc}.*

Proof. By using the test function $u_n(\varphi^2 + \epsilon^{\gamma^+})$ with $\varphi \in C^1(\overline{\Omega})$ and $\operatorname{supp}\varphi \subset \Omega$, and under the condition $0 < \epsilon < \frac{1}{n}$ for a fixed n, we can apply the properties from $(\mathcal{P}_n)$ and Lemma 3.4. We obtain

$$\begin{aligned}
&\sum_{i=1}^{N}\left[\int_\Omega \left(|\partial_i u_n|^{p_i} + |\partial_i u_n|^{q_i}\right)(\varphi^2+\epsilon^{\gamma^+})dx + 2\int_\Omega u_n\varphi\left(|\partial_i u_n|^{p_i-2} + |\partial_i u_n|^{q_i-2}\right)\partial_i u_n\partial_i\varphi dx\right] \\
&\quad = \int_\Omega \frac{f_n u_n(\varphi^2+\epsilon^{\gamma^+})}{\left(u_n+\frac{1}{n}\right)^{\gamma(x)}}dx \\
&\quad \leq \int_\Omega \frac{f_n u_n\varphi^2}{(kd(x))^{\gamma(x)}}dx + \int_\Omega \frac{f_n u_n\epsilon^{\gamma^+}}{\left(\frac{1}{n}\right)^{\gamma^+}}dx \\
&\quad \leq \int_{\operatorname{supp}\varphi} \frac{f u_n\varphi^2}{\left(k\min\limits_{\operatorname{supp}\varphi} d(x)\right)^{\gamma(x)}}dx + \int_\Omega f_n u_n dx,
\end{aligned}$$

where $k > 0$ is a constant. Using Hölder's inequality,

$$\begin{aligned}
&\sum_{i=1}^{N}\left[\int_\Omega \left(|\partial_i u_n|^{p_i} + |\partial_i u_n|^{q_i}\right)(\varphi^2+\epsilon^{\gamma^+})dx + 2\int_\Omega u_n\varphi\left(|\partial_i u_n|^{p_i-2} + |\partial_i u_n|^{q_i-2}\right)\partial_i u_n\partial_i\varphi dx\right] \\
&\quad \leq \left[\|\varphi^2\|_{L^\infty(\Omega)}\min\left\{\left(k\min_{\operatorname{supp}\varphi} d(x)\right)^{-\gamma^-}, \left(k\min_{\operatorname{supp}\varphi} d(x)\right)^{-\gamma^+}\right\} + 1\right]\|f\|_{L^1(\Omega)}\|u_n\|_{L^\infty(\Omega)}.
\end{aligned} \tag{4.8}$$

Let $0 < \lambda < \frac{\epsilon^{\gamma^+}}{\left(\|\varphi\|_{L^\infty(\Omega)}+1\right)^{\frac{\max\{q_N,p_N\}}{\min\{q_1,p_1\}}-1}}$. By applying Young's inequality, we get

$$\begin{aligned}
&\sum_{i=1}^{N} 2\int_{\operatorname{supp}\varphi} |\partial_i u_n|^{m_i-1}|\partial_i\varphi||u_n\varphi|dx \\
&\quad \leq \sum_{i=1}^{N}\left\{\frac{m_i-1}{m_i}\int_{\operatorname{supp}\varphi}\lambda|\partial_i u_n|^{m_i}|\varphi|^{\frac{m_i}{m_i-1}}dx + \frac{2^{m_i}}{m_i}\int_{\operatorname{supp}\varphi}\frac{1}{\lambda^{m_i-1}}|\partial_i\varphi|^{m_i}|u_n|^{m_i}dx\right\},
\end{aligned}$$

which implies

$$\begin{aligned}
&\sum_{i=1}^{N} 2\int_\Omega u_n\varphi|\partial_i u_n|^{m_i-2}\partial_i u_n\partial_i\varphi dx \\
&\quad \geq -\sum_{i=1}^{N} 2\int_{\operatorname{supp}\varphi}|\partial_i u_n|^{m_i-1}|\partial_i\varphi||u_n\varphi|dx \\
&\quad \geq -\sum_{i=1}^{N}\left\{\int_{\operatorname{supp}\varphi}\lambda|\partial_i u_n|^{m_i}|\varphi|^{\frac{m_i}{m_i-1}}dx + \frac{2^{m_i}}{m_i\lambda^{m_i-1}}\int_{\operatorname{supp}\varphi}|\partial_i\varphi|^{m_i}|u_n|^{m_i}dx\right\},
\end{aligned}$$

where $m_i = p_i$ or $m_i = q_i$. By combining the last inequalities and (4.8) yields

$$\begin{aligned}
&\sum_{i=1}^{N}\int_{\operatorname{supp}\varphi}|\partial_i u_n|^{p_i}\left(\varphi^2+\epsilon^{\gamma^+}-\lambda|\varphi|^{\frac{p_i}{p_i-1}}\right)dx+\sum_{i=1}^{N}\int_{\operatorname{supp}\varphi}|\partial_i u_n|^{q_i}\left(\varphi^2+\epsilon^{\gamma^+}-\lambda|\varphi|^{\frac{q_i}{q_i-1}}\right)dx\\
&\quad\leq\left[\|\varphi^2\|_{L^\infty(\Omega)}\min\left\{\left(k\min_{\operatorname{supp}\varphi}d(x)\right)^{-\gamma^-},\left(k\min_{\operatorname{supp}\varphi}d(x)\right)^{-\gamma^+}\right\}+1\right]\|f\|_{L^1(\Omega)}\|u_n\|_{L^\infty(\Omega)}\\
&\qquad+\sum_{i=1}^{N}\frac{2^{p_i}}{p_i\lambda^{p_i-1}}\|\partial_i\varphi\|^{p_i}_{L^\infty(\Omega)}\|u_n\|^{p_i}_{L^{p_i}(\Omega)}+\sum_{i=1}^{N}\frac{2^{q_i}}{q_i\lambda^{q_i-1}}\|\partial_i\varphi\|^{q_i}_{L^\infty(\Omega)}\|u_n\|^{q_i}_{L^{q_i}(\Omega)}\\
&\quad\leq\mathfrak{C}_3(f,\varphi),
\end{aligned}\tag{4.9}$$

where the boundedness of the sequences $\|u_n\|_{L^\infty(\Omega)}$, $\|u_n\|_{L^{p_i}(\Omega)}$, and $\|u_n\|_{L^{q_i}(\Omega)}$ for each $i=1,\dots,N$ ensures the validity of the inequality.

At this point, noting that

$$0<\lambda<\frac{\epsilon^{\gamma^+}}{\left(\|\varphi\|_{L^\infty(\Omega)}+1\right)^{\frac{\max\{q_N,p_N\}}{\min\{q_1,p_1\}-1}}},$$

we can deduce that

$$\begin{aligned}
&\sum_{i=1}^{N}\int_{\operatorname{supp}\varphi}|\partial_i u_n|^{p_i}\left(\varphi^2+\epsilon^{\gamma^+}-\lambda|\varphi|^{\frac{p_i}{p_i-1}}\right)dx+\sum_{i=1}^{N}\int_{\operatorname{supp}\varphi}|\partial_i u_n|^{q_i}\left(\varphi^2+\epsilon^{\gamma^+}-\lambda|\varphi|^{\frac{q_i}{q_i-1}}\right)dx\\
&\quad\geq\sum_{i=1}^{N}\int_{\operatorname{supp}\varphi}|\partial_i u_n|^{p_i}\left(\varphi^2+\epsilon^{\gamma^+}-\epsilon^{\gamma^+}\frac{|\varphi|^{\frac{p_i}{p_i-1}}}{\left(\|\varphi\|_{L^\infty(\Omega)}+1\right)^{\frac{\max\{q_N,p_N\}}{\min\{q_1,p_1\}-1}}}\right)dx\\
&\qquad+\sum_{i=1}^{N}\int_{\operatorname{supp}\varphi}|\partial_i u_n|^{q_i}\left(\varphi^2+\epsilon^{\gamma^+}-\epsilon^{\gamma^+}\frac{|\varphi|^{\frac{q_i}{q_i-1}}}{\left(\|\varphi\|_{L^\infty(\Omega)}+1\right)^{\frac{\max\{q_N,p_N\}}{\min\{q_1,p_1\}-1}}}\right)dx\\
&\quad\geq\sum_{i=1}^{N}\int_{\operatorname{supp}\varphi}|\partial_i u_n|^{p_i}\varphi^2dx+\sum_{i=1}^{N}\int_{\operatorname{supp}\varphi}|\partial_i u_n|^{q_i}\varphi^2dx,
\end{aligned}\tag{4.10}$$

since the inequality

$$\frac{|\varphi|^{\frac{m_i}{m_i-1}}}{\left(\|\varphi\|_{L^\infty(\Omega)}+1\right)^{\frac{\max\{q_N,p_N\}}{\min\{q_1,p_1\}-1}}}<1$$

holds for $m_i=q_i$ or $m_i=p_i$ for every $i=1,\dots,N$, it follows that, in view of (4.9) and (4.10), we obtain

$$\sum_{i=1}^{N}\int_{\Omega}|\partial_i u_n|^{p_i}\varphi^2dx+\sum_{i=1}^{N}\int_{\Omega}|\partial_i u_n|^{q_i}\varphi^2dx\leq\mathfrak{C}_3(f,\varphi).$$

Thus, the sequence $\{u_n\}_n$ is bounded in X_{loc} as desired. □

Minor adjustments in the proof of Theorem 1.2 allow us to prove the existence of u in X_{loc}.

Proof of Theorem 1.5.

By using $(u-\delta)^+$ as a test function in problem (1.1), we demonstrate that for all $\gamma(x) > 0$ and $f \in L^r(\Omega)$ for some suitable r, the solution to problem (1.1) belongs to $L^\infty(\Omega)$.

Let u be the solution for problem (1.1). Taking $(u-\delta)^+$ as a test function in (1.1) with $\delta > 0$, we obtain

$$\sum_{i=1}^{N}\int_\Omega |\partial_i u|^{p_i-2}\partial_i u\partial_i(u-\delta)^+dx + \sum_{i=1}^{N}\int_\Omega |\partial_i u|^{q_i-2}\partial_i u\partial_i(u-\delta)^+dx = \int_\Omega \frac{f(u-\delta)^+}{(u)^{\gamma(x)}}dx,$$

from which it follows that

$$\sum_{i=1}^{N}\int_\Omega |\partial_i(u-\delta)^+|^{p_i}dx + \sum_{i=1}^{N}\int_\Omega |\partial_i(u-\delta)^+|^{q_i}dx \le \int_\Omega f(u-\delta)^+\left(kd(x)\right)^{-\gamma(x)}dx,$$

thus, we obtain

$$\sum_{i=1}^{N}\int_\Omega |\partial_i(u-\delta)^+|^{p_i}dx \le \int_\Omega f(u-\delta)^+\left(kd(x)\right)^{-\gamma(x)}dx,$$

which leads to the following inequality

$$\left(\int_\Omega |\partial_i(u-\delta)^+|^{p_i}dx\right)^{\frac{1}{p_i}} \le \left(\int_\Omega f(u-\delta)^+\left(kd(x)\right)^{-\gamma(x)}dx\right)^{\frac{1}{p_i}}. \tag{4.11}$$

Additionally, we employ the following Sobolev-type inequality, as shown in [13], there exists a constant $C > 0$, dependent only on the domain Ω, such that for any $s \in [1, \bar{p}^*]$:

$$\|\xi\|_{L^s(\Omega)} \le C\prod_{i=1}^{N}\|\partial_i\xi\|^{\frac{1}{N}}_{L^{p_i}(\Omega)}, \tag{4.12}$$

where $\xi \in W_0^{1,\vec{p}}(\Omega)$, and $p_i \ge 2$ for each $i = 1,2,\dots,N$. From (4.11)–(4.12) and noting that $\min\{\bar{p}^*,\bar{q}^*\} \le \bar{p}^*$, we obtain

$$\begin{aligned}\|(u-\delta)^+\|_{L^{\min\{\bar{p}^*,\bar{q}^*\}}(\Omega)} &\le C_0\prod_{i=1}^{N}\left(\int_\Omega f(u-\delta)^+\left(kd(x)\right)^{-\gamma(x)}dx\right)^{\frac{1}{Np_i}},\\ &\le C_0\left(\int_\Omega f(u-\delta)^+\left(kd(x)\right)^{-\gamma(x)}dx\right)^{\frac{1}{\bar{p}}}.\end{aligned}$$

Applying Hölder's inequality, we have

$$\begin{aligned}&\|(u-\delta)^+\|_{L^{\min\{\bar{p}^*,\bar{q}^*\}}(\Omega)}\\ &\le C_0\left(\left[\int_{\Lambda_\delta}|f|^{\min\{\bar{p}^*,\bar{q}^*\}'}\left(kd(x)\right)^{-\gamma(x)}dx\right]^{\frac{1}{\min\{\bar{p}^*,\bar{q}^*\}'}}\|(u-\delta)^+\|_{L^{\min\{\bar{p}^*,\bar{q}^*\}}(\Omega)}\right)^{\frac{1}{\bar{p}}}\\ &\le C_0\left(\left[\int_{\Lambda_\delta}|f|^{\min\{\bar{p}^*,\bar{q}^*\}'}dx\right]^{\frac{1}{\min\{\bar{p}^*,\bar{q}^*\}'}}\|\left(kd(\cdot)\right)^{-\gamma(\cdot)}\|^{\frac{1}{\min\{\bar{p}^*,\bar{q}^*\}'}}_{L^\infty(\Lambda_\delta)}\|(u-\delta)^+\|_{L^{\min\{\bar{p}^*,\bar{q}^*\}}(\Omega)}\right)^{\frac{1}{\bar{p}}},\end{aligned}$$

with $\Lambda_\delta = \{x \in \Omega : \ u(x) > \delta\}$.

Now, applying Young's inequality to the right-hand side of the last inequality, let $\epsilon > 0$, we have

$$\begin{aligned}
&\|(u-\delta)^+\|_{L^{\min\{\bar{p}^*,\bar{q}^*\}}(\Omega)} \\
&\quad \leq C_\epsilon \| \left(kd(\cdot)\right)^{-\gamma(\cdot)} \|_{L^\infty(\Lambda_\delta)}^{\frac{\bar{p}'}{\bar{p}\min\{\bar{p}^*,\bar{q}^*\}'}} \left[\int_{\Lambda_\delta} |f|^{\min\{\bar{p}^*,\bar{q}^*\}'} dx\right]^{\frac{1}{\min\{\bar{p}^*,\bar{q}^*\}'}\times\frac{\bar{p}'}{\bar{p}}} + \frac{\epsilon}{\bar{p}}\|(u-\delta)^+\|_{L^{\min\{\bar{p}^*,\bar{q}^*\}}(\Omega)},
\end{aligned}$$

which implies

$$\left(1-\frac{\epsilon}{\bar{p}}\right)\|(u-\delta)^+\|_{L^{\min\{\bar{p}^*,\bar{q}^*\}}(\Omega)} \leq C_1 \| \left(kd(\cdot)\right)^{-\gamma(\cdot)} \|_{L^\infty(\Lambda_\delta)}^{\frac{\bar{p}'}{\bar{p}\min\{\bar{p}^*,\bar{q}^*\}'}} \left[\int_{\Lambda_\delta} |f|^{\min\{\bar{p}^*,\bar{q}^*\}'} dx\right]^{\frac{1}{\min\{\bar{p}^*,\bar{q}^*\}'}\times\frac{\bar{p}'}{\bar{p}}}.$$

By choosing ϵ such that $1-\frac{\epsilon}{\bar{p}} > 0$, we can infer that

$$\|(u-\delta)^+\|_{L^{\min\{\bar{p}^*,\bar{q}^*\}}(\Omega)} \leq C_2 \| \left(kd(\cdot)\right)^{-\gamma(\cdot)} \|_{L^\infty(\Lambda_\delta)}^{\frac{\bar{p}'}{\bar{p}\min\{\bar{p}^*,\bar{q}^*\}'}} \left[\int_{\Lambda_\delta} |f|^{\min\{\bar{p}^*,\bar{q}^*\}'} dx\right]^{\frac{1}{\min\{\bar{p}^*,\bar{q}^*\}'}\times\frac{1}{\bar{p}-1}}.$$

Applying Hölder's inequality with exponents $\frac{r}{\min\{\bar{p}^*,\bar{q}^*\}'}$ and $\left(\frac{r}{\min\{\bar{p}^*,\bar{q}^*\}'}\right)'$ yields

$$\begin{aligned}
&\|(u-\delta)^+\|_{L^{\min\{\bar{p}^*,\bar{q}^*\}}(\Omega)} \\
&\quad \leq C_3 \| \left(kd(\cdot)\right)^{-\gamma(\cdot)} \|_{L^\infty(\Lambda_\delta)}^{\frac{\bar{p}'}{\bar{p}\min\{\bar{p}^*,\bar{q}^*\}'}} \left[\|f\|_{L^r(\Omega)}^{\frac{\min\{\bar{p}^*,\bar{q}^*\}'}{r}} \operatorname{meas}(\Lambda_\delta)^{1-\frac{\min\{\bar{p}^*,\bar{q}^*\}'}{r}}\right]^{\frac{1}{\min\{\bar{p}^*,\bar{q}^*\}'}\times\frac{1}{\bar{p}-1}}.
\end{aligned}$$

Utilizing the fact that $f \in L^r(\Omega)$, where $r \geq \frac{\min\{\bar{p}^*,\bar{q}^*\}}{\min\{\bar{p}^*,\bar{q}^*\}-\max\{\bar{p},\bar{q}\}}$, we have

$$\|(u-\delta)^+\|_{L^{\min\{\bar{p}^*,\bar{q}^*\}}(\Omega)} \leq C_4 \| \left(kd(\cdot)\right)^{-\gamma(\cdot)} \|_{L^\infty(\Lambda_\delta)}^{\frac{\bar{p}'}{\bar{p}\min\{\bar{p}^*,\bar{q}^*\}'}} \operatorname{meas}(\Lambda_\delta)^{\left[1-\frac{\min\{\bar{p}^*,\bar{q}^*\}'}{r}\right]\frac{1}{\min\{\bar{p}^*,\bar{q}^*\}'}\times\frac{1}{\bar{p}-1}}. \quad (4.13)$$

Again, by Hölder's inequality, the following inequality holds

$$\int_\Omega (u-\delta)^+ dx \leq \|(u-\delta)^+\|_{L^{\min\{\bar{p}^*,\bar{q}^*\}}(\Omega)} \operatorname{meas}(\Lambda_\delta)^{1-\frac{1}{\min\{\bar{p}^*,\bar{q}^*\}}}. \quad (4.14)$$

Thus, from (4.13) and (4.14), we get

$$\begin{aligned}
&\int_\Omega (u-\delta)^+ dx \\
&\quad \leq C_5 \| \left(kd(\cdot)\right)^{-\gamma(\cdot)} \|_{L^\infty(\Lambda_\delta)}^{\frac{\bar{p}'}{\bar{p}\min\{\bar{p}^*,\bar{q}^*\}'}} \operatorname{meas}(\Lambda_\delta)^{\left[1-\frac{\min\{\bar{p}^*,\bar{q}^*\}'}{r}\right]\frac{1}{\min\{\bar{p}^*,\bar{q}^*\}'}\times\frac{1}{\bar{p}-1}} \operatorname{meas}(\Lambda_\delta)^{1-\frac{1}{\min\{\bar{p}^*,\bar{q}^*\}}}, \\
&\quad \leq C_5 \| \left(kd(\cdot)\right)^{-\gamma(\cdot)} \|_{L^\infty(\Lambda_\delta)}^{\frac{\bar{p}'}{\bar{p}\min\{\bar{p}^*,\bar{q}^*\}'}} \operatorname{meas}(\Lambda_\delta)^{1-\frac{1}{\min\{\bar{p}^*,\bar{q}^*\}}+\left[1-\frac{\min\{\bar{p}^*,\bar{q}^*\}'}{r}\right]\frac{1}{\min\{\bar{p}^*,\bar{q}^*\}'}\times\frac{1}{\bar{p}-1}}. \quad (4.15)
\end{aligned}$$

Defining $\tau(\delta) = \int_\Omega (u-\delta)^+ dx$, it follows straightforwardly that $\tau'(\delta) = -\operatorname{meas}(\Lambda_\delta)$, where $\Lambda_\delta = \{x \in \Omega : \ u(x) > \delta\}$ (see [26]). Thus, the previous inequality becomes

$$\tau(\delta)^{\frac{1}{1-\frac{1}{\min\{\bar{p}^*,\bar{q}^*\}}+\left[1-\frac{\min\{\bar{p}^*,\bar{q}^*\}'}{r}\right]\frac{1}{\min\{\bar{p}^*,\bar{q}^*\}'}\times\frac{1}{\bar{p}-1}}} \leq -C_6\tau'(\delta). \quad (4.16)$$

Let us define the parameter α as follows

$$\alpha = \frac{1}{1-\frac{1}{\min\{\bar{p}^*,\bar{q}^*\}} + \left[1-\frac{\min\{\bar{p}^*,\bar{q}^*\}'}{r}\right]\frac{1}{\min\{\bar{p}^*,\bar{q}^*\}'}\times\frac{1}{\bar{p}-1}}.$$

Using this expression in combination with equation (4.16), we can further deduce

$$1 \leq -C_6\tau'(\delta)\tau(\delta)^{-\alpha} = \frac{-C_6}{1-\alpha}\left(\tau(\delta)^{1-\alpha}\right)'.$$

Observe that assumption $r \geq \frac{\min\{\bar{p}^*,\bar{q}^*\}}{\min\{\bar{p}^*,\bar{q}^*\}-\max\{\bar{p},\bar{q}\}}$ implies $1-\alpha > 0$. Integrating the last inequality from 0 to δ, we obtain

$$\delta \leq -C_6\left(\tau(\delta)^{1-\alpha} - \tau(0)^{1-\alpha}\right),$$

which leads to

$$C_6\tau(\delta)^{1-\alpha} \leq -\delta + C_6\|u\|_{L^1(\Omega)}^{1-\alpha}.$$

From this inequality and the fact that $\tau(\delta)$ is a non-negative and decreasing, there exists a δ_0 such that $\tau(\delta_0) = 0$. Therefore, $\|u\|_{L^\infty(\Omega)} \leq C_{\delta_0}$, which implies $u \in L^\infty(\Omega)$. □

5 Concluding remarks and future directions

As kindly suggested by one of the referees of this paper, we intend to further develop and extend the analysis presented here to singular double anisotropic variable exponent problems of the form:

$$\begin{cases} -\sum_{i=1}^{N}\partial_i\left(|\partial_i u|^{p_i(x)-2}\partial_i u\right) - \sum_{i=1}^{N}\partial_i\left(|\partial_i u|^{q_i(x)-2}\partial_i u\right) = \dfrac{f(x)}{u^{\gamma(x)}} & \text{in } \Omega, \\ u > 0 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{5.1}$$

where $\Omega \subset \mathbb{R}^N$ is a rectangular domain with dimension $N \geq 3$, $\gamma(x)$ is a positive function in $C(\overline{\Omega})$, and $f(x)$ belongs to $L^r(\Omega)$ for some $r \geq 1$.

The vector functions $\vec{p}, \vec{q} : \bar{\Omega} \to \mathbb{R}^N$ are defined as

$$\vec{p}(x) = (p_1(x), \ldots, p_N(x)), \qquad \vec{q}(x) = (q_1(x), \ldots, q_N(x)),$$

where p_i and q_i belong to $C_+(\overline{\Omega})$ and satisfy certain conditions.

The energy functional associated with this model contains the unbalanced variational integral

$$u \longmapsto \sum_{i=1}^{N}\int_\Omega \frac{1}{p_i(x)}|\partial_i u|^{p_i(x)}\,dx + \sum_{i=1}^{N}\int_\Omega \frac{1}{q_i(x)}|\partial_i u|^{q_i(x)}\,dx. \tag{5.2}$$

This functional provides a sharper version of the classical energy

$$u \longmapsto \sum_{i=1}^{N}\frac{1}{p_i}\int_\Omega |\partial_i u|^{p_i}\,dx + \sum_{i=1}^{N}\frac{1}{q_i}\int_\Omega |\partial_i u|^{q_i}\,dx.$$

These problems allow for a more precise description of heterogeneous and anisotropic physical phenomena in fields such as nonlinear elasticity, material science, and homogenization. They are particularly useful for modeling composite materials with spatially varying properties, where the material behavior depends on both location and direction.

In nonlinear elasticity and material science, composite materials with locally varying hardening exponents $\vec{p}(x)$ and $\vec{q}(x)$ can be effectively characterized using the energy functional in (5.2). Furthermore, such problems have important applications in elasticity, homogenization, the modeling of strongly anisotropic materials, the Lavrentiev phenomenon, and other related areas.

Inspired by the seminal work of Chems Eddine and Repovš [17], we observe that the main results in this study can be extended to more general anisotropic problems involving variable exponents as in (5.1). Specifically, we extend the regularity of solutions to anisotropic Hölder continuous function spaces $C^{0,\overrightarrow{\beta}(\cdot)}(\overline{\Omega})$ over rectangular domains. In their work, Chems Eddine and Repovš introduced a novel framework for embedding anisotropic variable exponent Sobolev spaces into anisotropic variable exponent Hölder continuous function spaces in rectangular domains. Their results generalize classical Sobolev embedding theorems by incorporating anisotropic settings with variable exponents, providing deeper insights into function regularity in different spatial directions. Under log-Hölder continuity conditions on the variable exponents $\overrightarrow{p}(\cdot)$.

A promising new research direction focuses on anisotropic operators with variable exponents and singular reactions. Within this framework, we aim to extend the qualitative analysis conducted in this paper to singular nonlinear boundary value problems with variable exponents, modeled by the following system:

$$\begin{cases} -\sum_{i=1}^{N} \partial_i \left(|\partial_i u|^{p_i(x)-2} \partial_i u \right) = \dfrac{f(x)}{u^{\gamma(x)}} + \mathfrak{F}_u(x,u,v) & \text{in } \Omega, \\ -\sum_{i=1}^{N} \partial_i \left(|\partial_i v|^{q_i(x)-2} \partial_i v \right) = \dfrac{g(x)}{v^{\beta(x)}} + \mathfrak{F}_v(x,u,v) & \text{in } \Omega, \\ u, v > 0 & \text{in } \Omega, \\ u = v = 0 & \text{on } \partial\Omega, \end{cases} \tag{5.3}$$

This anisotropic system, which features unbalanced growth, was introduced by Figueiredo and Silva [22], where the vectors $\vec{p}$ and $\vec{q}$ are independent of x.

We conclude by noting that a key characteristic of nonlinear problems with variable exponents is the possibility of a subcritical-critical-supercritical multiple regime. A particularly intriguing open problem involves analyzing the singular case of the anisotropic system described in problem (5.3) within this multiple regime. A closely related and highly intriguing research direction involves anisotropic systems with variable exponent operators and singular reactions. These systems exhibit complex behaviors, particularly in the presence of unbalanced growth conditions and multiple regime transitions. Exploring their qualitative properties, existence results, and regularity aspects presents significant mathematical challenges and potential applications in nonlinear elasticity, material science, and phase transition models.

Acknowledgements

The authors would like to thank the reviewers for their insightful comments and suggestions, which greatly improved the paper, as well as for providing valuable references.

Abstract. In this paper we investigate the behaviour of the solutions of the following close-to-cyclic system of two difference equations with maximum:

$$x_{n+1} = \max\left\{A, \frac{y_n^p}{x_{n-1}^q}\right\},$$
$$y_{n+1} = \max\left\{B, \frac{x_n^p}{y_{n-1}^q}\right\}$$

where $n = 0, 1, \ldots$, the coefficients A, B, are positive real numbers, the exponents p, q are positive real numbers such that $p > q + 1$, and the initial values x_{-1}, x_0, y_{-1}, y_0, are positive real numbers.

Keywords: difference equations with maximum, close-to-cyclic system, equilibrium, solution eventually equal to equilibrium, periodic solutions.

2020 Mathematics Subject Classification: 39A10.

1 Introduction

Difference equations and systems of difference equations have gained much attention during the last decades due to their wide applications. These equations can be used as mathematical models to describe the biological, population and generally physical as well as economic phenomena (several models can be found, for example, in [11] and [29]). Despite that difference equations have, usually, simple forms, it is extremely difficult to fully describe precisely the global behavior of their solutions (see, for instance, [1]–[15], [17]–[21], [23]–[60] and the related references therein). For some differential equations with maximum see, for example, [16, 22].

✉Corresponding author. Email: gpapas@env.duth.gr

In addition, max operators are used in the study of problems concerning automatic control (see [16], [22] and the references cited therein). Therefore, there exist many papers concerning max difference equations, that is, max-type difference equations or difference equations with maximum (see, e.g., [1,4–7,9,10,12–15,17,18,21,23–27,35–45,47–51,56,58–60] and the related references therein).

At the beginning, difference equations with maximum containing linear terms were studied and are special cases of the difference equation

$$x_{n+1} = \max\left\{\frac{A_n^{(0)}}{x_n}, \frac{A_n^{(1)}}{x_{n-1}}, \ldots, \frac{A_n^{(k)}}{x_{n-k}}\right\}, \qquad n = 0, 1, \ldots,$$

see for example [4,5,7,10,14,15,21,23,57–60].

In 2003 S. Stević started a systematic study of the difference equations containing powers of the terms; see [32] where the difference equation

$$x_{n+1} = \alpha + \frac{x_{n-1}^p}{x_n^p}, \qquad n = 0, 1, \ldots,$$

was studied (for some later results see [3]). The equation with $p = 1$ or $p = -1$, and related ones had been considerably investigated before it (see, for example, [11,28,30,31] and the references therein). For some later generalizations of the equation in these cases see [2].

The investigation in [32] have been continued by him in a series of papers. In [34] beside the equation

$$x_{n+1} = A + \frac{x_n^p}{x_{n-1}^r}, \qquad n = 0, 1, \ldots,$$

(for some generalizations of the equation see, for instance, [20,33,36]), it was also studied its max-type counterpart

$$x_{n+1} = \max\left\{A, \frac{x_n^p}{x_{n-1}^r}\right\}, \qquad n = 0, 1, \ldots,$$

where the parameters A, p, q and the initial values x_{-1} and x_0 are positive numbers. This is one of the first papers where a difference equation with maximum containing powers of the terms was studied. The case $p = r$, was also studied in [35], where, among other results, it was proved that if $A, p \in (0, 1)$ all positive solutions converge to one. This result was later generalized in [9]. For some other results on convergence of solutions to related difference equations with maximum see also [12,13,37,38].

A complete picture regarding the boundedness character of positive solutions to the following difference equation

$$x_n = \max\left\{A, \frac{x_{n-1}^p}{x_{n-k}^p}\right\}, \qquad n = 0, 1, \ldots,$$

where $k \geq 2$, and the parameters A, p and the initial values are positive numbers, was given in [36]. The results on the boundedness therein were later generalized in [41]. For a quite general result in this direction see [49].

A study of a general difference equation with maximum, which includes above mentioned ones, was suggested in [40] (see difference equation (1) therein). Periodicity of quite general classes of difference equation with maximum was studied in [40,42,43,48,50]. Some results

are devoted to solvability of max type equations such as [44] (for some recent results on the topic see, for instance, [46,52,54,55] and the references therein).

In [8], studying cyclic systems of difference equations was initiated. The study was continued, for instance, in [19,46,47,49,52,55–57]. Paper [8] essentially suggested investigating all cyclic systems of difference equations, so also those corresponding to above-mentioned difference equations.

In [45] investigated the following max-type system

$$x_{n+1} = \max\left\{\alpha, \frac{y_n^p}{x_{n-1}^p}\right\}, \quad y_{n+1} = \max\left\{\alpha, \frac{x_n^p}{y_{n-1}^p}\right\}, \qquad n = 0, 1, \ldots,$$

where the parameters α, p and the initial values are positive numbers, whereas its generalization

$$x_{n+1} = \max\left\{\alpha, \frac{y_n^p}{x_{n-1}^q}\right\}, \quad y_{n+1} = \max\left\{\alpha, \frac{x_n^p}{y_{n-1}^q}\right\}, \qquad n = 0, 1, \ldots,$$

was studied in [51]. The corresponding cyclic system was studied in [56].

In [6] the authors studied the periodic character of the solutions of the system of difference equations with maximum

$$x_{n+1} = \max\left\{A, \frac{y_n}{x_{n-1}}\right\},$$

$$y_{n+1} = \max\left\{B, \frac{x_n}{y_{n-1}}\right\}$$

where A, B are positive constants and the initial values x_{-1}, x_0, y_{-1}, y_0, are positive real numbers.

Motivated by above mentioned studies, in this paper we continue the investigation of close-to-cyclic systems of difference equations by studying the behaviour of the solutions of the following close-to-cyclic system of difference equations with maximum:

$$\begin{aligned} x_{n+1} &= \max\left\{A, \frac{y_n^p}{x_{n-1}^q}\right\}, \\ y_{n+1} &= \max\left\{B, \frac{x_n^p}{y_{n-1}^q}\right\} \end{aligned} \tag{1.1}$$

where $n = 0, 1, \ldots$, the coefficients A, B, are positive real numbers, the exponents p, q are positive real numbers such that $p > q + 1$, and the initial values x_{-1}, x_0, y_{-1}, y_0, are positive real numbers.

2 Main results

In the first lemma we study the existence of the positive equilibriums of (1.1).

Lemma 2.1. *Consider the system of difference equations (1.1), where the coefficients A, B, the exponents p, q, and the initial values x_{-1}, x_0, y_{-1}, y_0, are positive real numbers. Assume that*

$$p > 1 + q, \ q > 0, \tag{2.1}$$

then, the following statements are true:

(i) *If*

$$0 < A^{\frac{p}{q+1}} < B < A^{\frac{q+1}{p}} < 1, \tag{2.2}$$

then, system (1.1) *has two equilibria*

$$(\bar{x},\ \bar{y}) = (A, B), \quad (\bar{x},\ \bar{y}) = (1, 1).$$

(ii) *If*

$$0 < B \leq A^{\frac{p}{q+1}} \leq 1, \tag{2.3}$$

then, system (1.1) *has*

(iia) *two equilibria*

$$(\bar{x},\ \bar{y}) = (1, 1), \quad (\bar{x}, \bar{y}) = (A,\ A^{\frac{p}{q+1}}),$$

if $A \neq 1$, *and*

(iib) *a unique equilibrium*

$$(\bar{x},\ \bar{y}) = (1, 1),$$

if $A = 1$.

(iii) *If*

$$0 < A^{\frac{q+1}{p}} \leq B \leq 1, \tag{2.4}$$

then, system (1.1) *has*

(iiia) *two equilibria*

$$(\bar{x},\ \bar{y}) = (1, 1), \quad (\bar{x}, \bar{y}) = (B^{\frac{p}{q+1}}, B),$$

if $B \neq 1$, *and*

(iiib) *a unique equilibrium*

$$(\bar{x},\ \bar{y}) = (1, 1),$$

if $B = 1$.

(iv) *If*

$$A > 1,\ B > 0 \quad or \quad B > 1,\ A > 0 \tag{2.5}$$

then, system (1.1) *has no equilibria.*

Proof. We consider the system of algebraic equations

$$x = \max\Big\{A, \frac{y^p}{x^q}\Big\}, \quad y = \max\Big\{B, \frac{x^p}{y^q}\Big\}. \tag{2.6}$$

Then, one of the following relations is satisfied

$$(i)\ x = A,\ y = B, \quad (ii)\ x = A,\ y = \frac{x^p}{y^q}, \quad (iii)\ x = \frac{y^p}{x^q},\ y = B,$$
$$(iv)\ x = \frac{y^p}{x^q},\ y = \frac{x^p}{y^q},$$

and these relations are equivalent to

$$(i)\ x = A,\ y = B, \quad (ii)\ x = A,\ y = A^{\frac{p}{q+1}}, \quad (iii)\ x = B^{\frac{p}{q+1}},\ y = B,$$

and, since $x, y, p, q > 0$ and $p \neq q+1$,

$$(iv)\ x = 1,\ y = 1.$$

(i). From (2.1) and (2.2), it is obvious that, $0 < A < 1$.

Let $x = A,\ y = B$. From (2.1), (2.2), and since $0 < A \leq 1$, we get

$$\frac{y^p}{x^q} = \frac{B^p}{A^q} < A,$$

and

$$\frac{x^p}{y^q} = \frac{A^p}{B^q} < B.$$

Hence, $(\bar{x}, \bar{y}) = (A, B)$, is an equilibrium of (1.1).

Now, suppose that $x = A,\ y = A^{\frac{p}{q+1}}$, then from (2.6) we get

$$y = A^{\frac{p}{q+1}} \geq B,$$

which contradicts with (2.2). Hence, $(\bar{x}, \bar{y}) = (A, A^{\frac{p}{q+1}})$, is not an equilibrium of (1.1).

To continue, we assume that, $x = B^{\frac{p}{q+1}},\ y = B$, then from (2.6) we have

$$x = B^{\frac{p}{q+1}} \geq A,$$

which contradicts with (2.2), since $p,\ q > 0$. So, $(B^{\frac{p}{q+1}},\ B)$, is not an equilibrium of (1.1).

Finally, since $0 < A, B < 1$, from (2.6), we have that, $(\bar{x}, \bar{y}) = (1, 1)$ is an equilibrium of system (1.1).

(ii). From (2.1) and (2.3), it is obvious that, $0 < A \leq 1$.

Let $x = A,\ y = B$. Then, from (2.6), we get $B \geq \frac{A^p}{B^q}$, and so, $B \geq A^{\frac{p}{q+1}}$, which contradicts with (2.3), except if $B = A^{\frac{p}{q+1}}$, and then, $x = A,\ y = A^{\frac{p}{q+1}}$, case that considered below. Hence, (A, B), $B \neq A^{\frac{p}{q+1}}$, is not an equilibrium of (1.1).

Now, suppose that $x = A,\ y = A^{\frac{p}{q+1}}$. From (2.1), (2.3), and since $0 < A \leq 1$, we get

$$\frac{y^p}{x^q} = \frac{A^{\frac{p^2}{q+1}}}{A^q} \leq A,$$

and

$$\frac{x^p}{y^q} = \frac{A^p}{A^{\frac{qp}{q+1}}} = A^{\frac{p}{q+1}} \geq B.$$

Hence, $(\bar{x}, \bar{y}) = (A, A^{\frac{p}{q+1}})$, is an equilibrium of (1.1). Obviously, if $A = 1$, the equilibrium of (1.1) is $(\bar{x}, \bar{y}) = (1, 1)$.

To continue, we assume that, $x = B^{\frac{p}{q+1}},\ y = B$. Then, from (2.1), (2.3) and (2.6), we have

$$B^{\frac{p}{q+1}} \geq A \geq B^{\frac{q+1}{p}}. \tag{2.7}$$

If $0 < B < 1$, relation (2.7) can not be true, since $p > q+1 > 0$. So, $(B^{\frac{p}{q+1}},\ B)$, is not an equilibrium of (1.1), if $0 < B < 1$. On the other hand, relation (2.7) is true, if $A = B = 1$, and then, $(\bar{x}, \bar{y}) = (1, 1)$ is an equilibrium of (1.1).

Finally, since $0 < A, B \leq 1$, from (2.6), we have that, $(\bar{x}, \bar{y}) = (1,1)$ is an equilibrium of system (1.1).

From all the above, it is obvious that if $A = 1$ and $0 < B \leq 1$, then, $(\bar{x}, \bar{y}) = (1,1)$ is the unique equilibrium of (1.1). This completes the proof of (ii).

(iii). Using (2.4) and (2.6), and arguing as in (ii), we can easily prove (iii).

(iv). From (2.1) and (2.6), we get

$$x \geq y^{\frac{p}{q+1}}, \quad y \geq x^{\frac{p}{q+1}},$$

and so,

$$x \geq x^{\left(\frac{p}{q+1}\right)^2}. \tag{2.8}$$

If $x > 1$, then, from (2.8), $q + 1 \geq p$, which contradicts with (2.1). Hence, $0 < x \leq 1$, and similarly, $0 < y \leq 1$. Therefore, in order to have solutions for (2.6), it is necessary $0 < A, B \leq 1$, since (2.1) holds. So, system (1.1) has no equilibria, if (2.1) and (2.5) holds. This completes the proof of the lemma. □

In the following proposition we study the asymptotic behavior of the positive solutions of (1.1). We need the following lemma on a product-type difference equation, for which related results and methods can be found in the literature (see, for instance, [32, Remark 1], [41, Theorem 1], [54] and [55]).

Lemma 2.2. *Consider the difference equation of the form*

$$z_{n+1} = \frac{z_n^a}{z_{n-1}^b}, \qquad n \geq 0, \tag{2.9}$$

where z_{-1}, z_0 are positive real numbers, and a, b are real numbers, such that

$$a > 1 + b, \ b > 0. \tag{2.10}$$

Then, the following statements are true:

(i) *If*

$$\frac{z_0^{\lambda_1}}{z_{-1}^b} > 1, \tag{2.11}$$

where

$$\lambda_1 = \frac{a + \sqrt{a^2 - 4b}}{2},$$

then

$$\lim_{n\to\infty} z_n = \infty. \tag{2.12}$$

(ii) *If*

$$\frac{z_0^{\lambda_1}}{z_{-1}^b} = 1, \tag{2.13}$$

then

$$\lim_{n\to\infty} z_n = 1. \tag{2.14}$$

(iii) *If*

$$\frac{z_0^{\lambda_1}}{z_{-1}^{b}} < 1, \tag{2.15}$$

then

$$\lim_{n\to\infty} z_n = 0. \tag{2.16}$$

Proof. We prove that the solution z_n of (2.9) is given by

$$z_n = \frac{z_0^{f_n}}{z_{-1}^{g_n}}, \qquad n \geq 1, \tag{2.17}$$

where f_n satisfies the initial value problem

$$f_{n+1} = af_n - bf_{n-1}, \quad n = 2,3,\ldots, \quad f_1 = a, \quad f_2 = a^2 - b, \tag{2.18}$$

and g_n satisfies the initial value problem

$$g_{n+1} = ag_n - bg_{n-1}, \quad n = 2,3,\ldots, \quad g_1 = b, \quad g_2 = ab. \tag{2.19}$$

From (2.9), (2.18) and (2.19), we have

$$z_1 = \frac{z_0^{a}}{z_{-1}^{b}} = \frac{z_0^{f_1}}{z_{-1}^{g_1}}, \tag{2.20}$$

and

$$z_2 = \frac{z_1^{a}}{z_0^{b}} = \frac{z_0^{af_1-b}}{z_{-1}^{ag_1}} = \frac{z_0^{a^2-b}}{z_{-1}^{ab}} = \frac{z_0^{f_2}}{z_{-1}^{g_2}}. \tag{2.21}$$

In addition, from (2.9), (2.18), (2.19), (2.20) and (2.21), we get

$$z_3 = \frac{z_2^{a}}{z_1^{b}} = \frac{z_0^{af_2}}{z_{-1}^{ag_2}} \frac{z_0^{-bf_1}}{z_{-1}^{-bg_1}} = \frac{z_0^{f_3}}{z_{-1}^{g_3}}. \tag{2.22}$$

From (2.9), (2.18), (2.19), (2.21) and (2.22), and working inductively, we can easily prove (2.17).

From relations (2.10), (2.18) and (2.19), we get

$$f_n = c_1\lambda_1^n + c_2\lambda_2^n, \qquad n = 1,2,\ldots, \tag{2.23}$$

where

$$\begin{aligned} \lambda_1 &= \frac{a+\sqrt{a^2-4b}}{2}, & \lambda_2 &= \frac{a-\sqrt{a^2-4b}}{2}, \\ c_1 &= \frac{\lambda_1}{\sqrt{a^2-4b}}, & c_2 &= \frac{-\lambda_2}{\sqrt{a^2-4b}}, \end{aligned} \tag{2.24}$$

and

$$g_n = d_1\lambda_1^n + d_2\lambda_2^n, \qquad n = 1,2,\ldots, \tag{2.25}$$

where

$$d_1 = \frac{b}{\sqrt{a^2-4b}}, \qquad d_2 = -\frac{b}{\sqrt{a^2-4b}}. \tag{2.26}$$

From (2.23) and (2.24), we get

$$f_n = \frac{1}{\sqrt{a^2-4b}}\lambda_1^{n+1} - \frac{1}{\sqrt{a^2-4b}}\lambda_2^{n+1}. \tag{2.27}$$

So, from relations (2.17), (2.25), (2.26) and (2.27), we have

$$\begin{aligned} z_n = \frac{z_0^{f_n}}{z_{-1}^{g_n}} &= \frac{z_0^{\frac{1}{\sqrt{a^2-4b}}\lambda_1^{n+1} - \frac{1}{\sqrt{a^2-4b}}\lambda_2^{n+1}}}{z_{-1}^{\frac{b}{\sqrt{a^2-4b}}\lambda_1^{n} - \frac{b}{\sqrt{a^2-4b}}\lambda_2^{n}}} \\ &= \left(\frac{z_0^{\lambda_1}}{z_{-1}^{b}}\right)^{\frac{1}{\sqrt{a^2-4b}}\lambda_1^n} \left(\frac{z_0^{\lambda_2}}{z_{-1}^{b}}\right)^{-\frac{1}{\sqrt{a^2-4b}}\lambda_2^n}. \end{aligned} \tag{2.28}$$

(i). First, suppose that (2.11) is satisfied. Since, from (2.10),

$$\lambda_1 > 1, \qquad 0 < \lambda_2 < 1, \tag{2.29}$$

then, from (2.28), we get (2.12).

(ii). Now, suppose that (2.13) hold. Then, from (2.28), we get

$$z_n = \left(\frac{z_0^{\lambda_2}}{z_{-1}^{b}}\right)^{-\frac{1}{\sqrt{a^2-4b}}\lambda_2^n},$$

and since $0 < \lambda_2 < 1$, we get (2.14).

(iii). Finally, suppose that (2.15) is satisfied. Then, from (2.28) and (2.29), we get (2.16). This completes the proof of the lemma. □

Lemma 2.3. *Consider the system of difference equations (1.1), where relations (2.1) and (2.2) hold, and the initial values x_{-1}, x_0, y_{-1}, y_0, are positive real numbers. Then, the following statements are true:*

I. *If there exists a positive integer $m \geq 2$, such that*

$$x_m \leq B^{\frac{q+1}{p}}, \tag{2.30}$$

then

$$x_{m+2k} = A, \quad y_{m+2k-1} = B, \quad k \geq 1. \tag{2.31}$$

II. *Suppose that*

$$x_{2n} > B^{\frac{q+1}{p}}, \quad \text{for any } n \geq 1. \tag{2.32}$$

(a). *If*

$$\frac{x_2^{\lambda}}{x_0^{q^2}} > 1, \qquad \lambda = \frac{p^2 - 2q + \sqrt{(p^2-2q)^2 - 4q^2}}{2}, \tag{2.33}$$

then

$$\lim_{n\to\infty} x_{2n} = \infty, \qquad \lim_{n\to\infty} y_{2n+1} = \infty. \tag{2.34}$$

(b). *If*

$$\frac{x_2^{\lambda}}{x_0^{q^2}} = 1, \tag{2.35}$$

then

$$\lim_{n\to\infty} x_{2n} = 1, \qquad \lim_{n\to\infty} y_{2n+1} = 1. \tag{2.36}$$

III. *Suppose that*

$$x_{2n+1} > B^{\frac{q+1}{p}}, \quad \text{for any } n \geq 1. \tag{2.37}$$

(a). *If*

$$\frac{x_3^{\lambda}}{x_1^{q^2}} > 1, \tag{2.38}$$

then

$$\lim_{n\to\infty} x_{2n+1} = \infty, \qquad \lim_{n\to\infty} y_{2n} = \infty. \tag{2.39}$$

(b). *If*

$$\frac{x_3^{\lambda}}{x_1^{q^2}} = 1, \tag{2.40}$$

then

$$\lim_{n\to\infty} x_{2n+1} = 1, \qquad \lim_{n\to\infty} y_{2n} = 1. \tag{2.41}$$

Proof. From (2.2) we have

$$\text{(i) } 0 < A < 1, \quad 0 < B < 1, \quad \text{(ii) } A > B^{\frac{p}{q+1}}, \quad \text{(iii) } B > A^{\frac{p}{q+1}}, \tag{2.42}$$

I. From (1.1) and (2.30), we get

$$\frac{x_m^p}{y_{m-1}^q} \leq \frac{B^{q+1}}{B^q} = B,$$

and so, from (1.1),

$$y_{m+1} = B. \tag{2.43}$$

Then, from (1.1), (i) and (ii) of (2.42) and (2.43), we get

$$\frac{y_{m+1}^p}{x_m^q} \leq \frac{B^p}{A^q} < A,$$

and so, from (1.1),

$$x_{m+2} = A. \tag{2.44}$$

In addition, from (iii) of (2.42) and (2.44), it follows that

$$x_{m+2} < B^{\frac{q+1}{p}}. \tag{2.45}$$

Using (2.45) and working as above we have

$$y_{m+3} = B, \qquad x_{m+4} = A,$$

and so, working inductively, we get (2.31).

II. From (1.1), (iii) of (2.42) and (2.32), we have

$$x_{2n} = \frac{y_{2n-1}^p}{x_{2n-2}^q}, \qquad n \geq 1. \tag{2.46}$$

From (2.1), (i) of (2.42), (2.32) and (2.46), we have, for $n \geq 2$,

$$y_{2n-1} = x_{2n}^{1/p} x_{2n-2}^{q/p} > B^{\frac{q+1}{p}\frac{1}{p}} B^{\frac{q+1}{p}\frac{q}{p}} = B^{(\frac{q+1}{p})^2} > B,$$

and so, from (1.1),

$$y_{2n-1} = \frac{x_{2n-2}^p}{y_{2n-3}^q}, \qquad n \geq 2. \tag{2.47}$$

Relations (2.46) and (2.47) imply that

$$x_{2n} = \frac{x_{2n-2}^{p^2-q}}{y_{2n-3}^{pq}}, \qquad n \geq 2,$$

and then, since from (2.46),

$$y_{2n-3}^p = x_{2n-2} x_{2n-4}^q, \qquad n \geq 2,$$

we get the following product-type difference equation (see, e.g., [54, 55])

$$x_{2n} = \frac{x_{2n-2}^a}{x_{2n-4}^b}, \quad n \geq 2, \quad a = p^2 - 2q, \quad b = q^2, \tag{2.48}$$

with interlacing indices (see [53])

Since (2.1) holds, we can easily prove that (2.10) is true. In (2.48), we set

$$x_{2n-4} = z_{n-1}, \tag{2.49}$$

(see [53]), and we get the equation

$$z_{n+1} = \frac{z_n^a}{z_{n-1}^b}, \qquad n \geq 2. \tag{2.50}$$

We consider the difference equation

$$w_{n+1} = \frac{w_n^a}{w_{n-1}^b}, \qquad n \geq 0. \tag{2.51}$$

Let w_n be the solution of (2.51), such that

$$w_{-1} = z_1, \qquad w_0 = z_2, \tag{2.52}$$

II(a). Using (2.33), (2.49) and (2.52) we have

$$\frac{w_0^\lambda}{w_{-1}^{q^2}} = \frac{z_2^\lambda}{z_1^{q^2}} = \frac{x_2^\lambda}{x_0^{q^2}} > 1. \tag{2.53}$$

Since for equation (2.51), relations (2.10) and (2.53) hold, from (i) of Lemma 2.2, we get

$$\lim_{n\to\infty} w_n = \infty,$$

and using (2.50), (2.51) and (2.52), we have

$$\lim_{n\to\infty} z_n = \infty,$$

and so, from (2.49),

$$\lim_{n\to\infty} x_{2n} = \infty.$$

Then, from (2.46), we get

$$\lim_{n\to\infty} y_{2n+1} = \infty.$$

Hence, (2.34) is true.

II(b). Since (2.35), (2.49) and (2.52) hold, we have

$$\frac{w_0^{\lambda}}{w_{-1}^{q^2}} = \frac{z_2^{\lambda}}{z_1^{q^2}} = \frac{x_2^{\lambda}}{x_0^{q^2}} = 1. \tag{2.54}$$

Since for equation (2.51), relations (2.10) and (2.54) hold, from (ii) of Lemma 2.2, we get

$$\lim_{n\to\infty} w_n = 1,$$

and using (2.50), (2.51) and (2.52), we have

$$\lim_{n\to\infty} z_n = 1,$$

and so, from (2.49) ,

$$\lim_{n\to\infty} x_{2n} = 1.$$

From (2.46), we get

$$\lim_{n\to\infty} y_{2n+1} = 1.$$

Hence, (2.36) is true.

We mention that, difference equation (2.48) is with interlacing indices, and it was expected that its behavior is similar to (2.9) (for more details see, for example, [53]).

Arguing as in cases **II(a)** and **II(b)**, we can easily prove **III(a)** and **III(b)**. □

Remark 2.4. In statement **II** of Lemma 2.3, it is impossible to have

$$\frac{x_2^{\lambda}}{x_0^{q^2}} < 1. \tag{2.55}$$

Indeed, if, on the contrary, we assume that (2.55) holds, then, arguing as in **II(a)** of Lemma 2.3, for the solution w_n of (2.51) we get

$$\frac{w_0^{\lambda}}{w_{-1}^{q^2}} < 1,$$

and so, from statement **(iii)** of Lemma 2.2,

$$\lim_{n\to\infty} w_n = 0,$$

which means that

$$\lim_{n\to\infty} x_{2n} = 0,$$

which contradicts with the fact that $x_n \geq A$, for any $n \geq 1$. So, (2.55) cannot be satisfied.

Similarly, it is impossible to have

$$\frac{x_3^{\lambda}}{x_1^{q^2}} < 1,$$

in statement **III** of Lemma 2.3.

Proposition 2.5. *Consider the system of difference equations (1.1), where relations (2.1) and (2.2) hold, and the initial values x_{-1}, x_0, y_{-1}, y_0, are positive real numbers. Let (x_n, y_n) be a solution of (1.1). Then, the following statements are true:*

I. *Suppose that there exist integers $l, r \geq 1$, such that*

$$x_{2l+1} \leq B^{\frac{q+1}{p}}, \qquad x_{2r} \leq B^{\frac{q+1}{p}}. \tag{2.56}$$

Then, (x_n, y_n) is eventually equal to the positive equilibrium (A, B) of (1.1).

II. *Suppose that there exists an integer $l \geq 1$, such that the first inequality of (2.56) and relations (2.32), (2.33) hold. Then, relation (2.34) and*

$$x_{2n+1} = A, \quad y_{2n} = B, \quad n \geq l+1, \tag{2.57}$$

are satisfied.

III. *Suppose that there exists an integer $l \geq 1$, such that the first inequality of (2.56) and relations (2.32), (2.35) hold. Then, relations (2.36) and (2.57) are satisfied.*

IV. *Suppose that there exists an integer $r \geq 1$, such that the second inequality of (2.56) and relations (2.37), (2.38) hold. Then, relation (2.39) and*

$$x_{2n} = A, \quad y_{2n+1} = B, \quad n \geq r+1, \tag{2.58}$$

are satisfied.

V. *Suppose that there exists an integer $r \geq 1$, such that the second inequality of (2.56) and relations (2.37), (2.40) hold. Then, relations (2.41) and (2.58) are satisfied.*

VI. *If relations (2.32), (2.33), (2.37) and (2.38) hold, then,*

$$\lim_{n\to\infty} x_n = \infty, \qquad \lim_{n\to\infty} y_n = \infty. \tag{2.59}$$

VII. *If relations (2.32), (2.33), (2.37) and (2.40) hold, then, relations (2.34) and (2.41) are satisfied.*

VIII. *If relations (2.32), (2.35), (2.37) and (2.38) hold, then, relations (2.36) and (2.39) are satisfied.*

IX. *If relations (2.32), (2.35), (2.37) and (2.40) hold, then,*

$$\lim_{n\to\infty} x_n = 1, \qquad \lim_{n\to\infty} y_n = 1. \tag{2.60}$$

Proof. **I.** From (2.56) and statement I of Lemma 2.3, we have

$$x_{2l+1+2k} = A, \quad y_{2l+2k} = B, \quad x_{2r+2k} = A, \quad y_{2r+2k-1} = B, \quad k = 1, 2, \ldots.$$

So, for $n \geq \max\{2l+3, 2r+2\}$, we get $x_n = A$, $y_n = B$. This implies that, (x_n, y_n) is eventually equal to (A, B).

II. From the first inequality of (2.56) and statement **I** of Lemma 2.3, we have

$$x_{2l+1+2k} = A, \qquad y_{2l+2k} = B, \qquad k = 1, 2, \ldots,$$

and so, (2.57) is true. Moreover, from (2.32), (2.33) and statement **II(a)** of Lemma 2.3, we have (2.34).

Arguing as above, using the corresponding relations and the appropriate statements of Lemma 2.3, we can easily prove statements **III–IX** of the proposition. This completes the proof of the proposition. □

Lemma 2.6. *Consider the system of difference equations* (1.1)*, where* (2.1) *and* (2.3) *hold, and the initial values* x_{-1}, x_0, y_{-1}, y_0*, are positive real numbers. Then, the following statements are true:*

I. *Suppose that there exists an integer* $m \geq 2$*, such that*

$$y_m = A^{\frac{p}{q+1}}, \tag{2.61}$$

then

$$x_{m+2k+1} = A, \quad y_{m+2k} = A^{\frac{p}{q+1}}, \quad k \geq 0. \tag{2.62}$$

II. *Suppose that*

$$y_{2n} > A^{\frac{p}{q+1}}, \quad \text{for any } n \geq 1. \tag{2.63}$$

(a). *If*

$$\frac{y_2^{\lambda}}{y_0^{q^2}} > 1, \tag{2.64}$$

where λ *was defined in* (2.33)*, then* (2.39) *holds.*

(b). *If*

$$\frac{y_2^{\lambda}}{y_0^{q^2}} = 1, \tag{2.65}$$

then (2.41) *holds.*

III. *Suppose that*

$$y_{2n+1} > A^{\frac{p}{q+1}}, \quad \text{for any } n \geq 1. \tag{2.66}$$

(a). *If*

$$\frac{y_3^{\lambda}}{y_1^{q^2}} > 1, \tag{2.67}$$

then (2.34) *holds.*

(b). *If*

$$\frac{y_3^{\lambda}}{y_1^{q^2}} = 1, \tag{2.68}$$

then (2.36) *holds.*

IV. *Suppose that there exists an integer $s \geq 2$, such that*

$$y_s < A^{\frac{p}{q+1}}. \tag{2.69}$$

Assume that

$$A^{\frac{p^2-q-1}{pq}} \leq B, \tag{2.70}$$

then

$$x_{s+2k-1} = A, \quad k \geq 1, \tag{2.71}$$

and, in addition,

(a). *If*

$$q < 1, \tag{2.72}$$

then

$$\lim_{k\to\infty} y_{s+2k} = A^{\frac{p}{q+1}}. \tag{2.73}$$

(b). *If*

$$q = 1, \tag{2.74}$$

then

$$y_{s+4k-2} = \frac{A^p}{y_s}, \quad y_{s+4k} = y_s, \quad k \geq 1. \tag{2.75}$$

(c). *If*

$$q > 1, \tag{2.76}$$

then there exists a positive integer k_0, such that

$$y_{s+4k-2} = \frac{A^p}{B^q}, \quad y_{s+4k-4} = B, \quad k \geq k_0 + 1. \tag{2.77}$$

Proof. From relations (2.1) and (2.3) we have $0 < A \leq 1$.

I. Since, from (2.1) and (2.3),

$$A^{\frac{p}{q+1}} \leq A^{\frac{q+1}{p}}, \tag{2.78}$$

from (1.1) and (2.61), we get

$$\frac{y_m^p}{x_{m-1}^q} \leq \frac{A^{q+1}}{A^q} = A,$$

and so, from (1.1),

$$x_{m+1} = A. \tag{2.79}$$

Then, from (2.3), (2.61) and (2.79), we get

$$\frac{x_{m+1}^p}{y_m^q} = \frac{A^p}{\left(A^{\frac{p}{q+1}}\right)^q} = A^{\frac{p}{q+1}} \geq B,$$

and so, from (1.1),

$$y_{m+2} = A^{\frac{p}{q+1}},$$

and working inductively, we get (2.62).

Arguing as in statements **II** and **III** of Lemma 2.3, we can easily prove **II** and **III** of this Lemma.

IV. From (1.1), (2.69) and (2.78), we get

$$\frac{y_s^p}{x_{s-1}^q} \leq \frac{A^{q+1}}{A^q} = A,$$

and so, from (1.1),

$$x_{s+1} = A. \tag{2.80}$$

Then, from (2.3), (2.69) and (2.80), we get

$$\frac{x_{s+1}^p}{y_s^q} > \frac{A^p}{\left(A^{\frac{p}{q+1}}\right)^q} = A^{\frac{p}{q+1}} \geq B,$$

and so, from (1.1),

$$y_{s+2} = \frac{A^p}{y_s^q} > A^{\frac{p}{q+1}}. \tag{2.81}$$

From (1.1), (2.70), (2.80) and (2.81), we get

$$\frac{y_{s+2}^p}{x_{s+1}^q} = \frac{A^{p^2-q}}{y_s^{pq}} \leq \frac{A^{p^2-q}}{B^{pq}} \leq \frac{A^{p^2-q}}{A^{p^2-q-1}} = A,$$

and so, from (1.1),

$$x_{s+3} = A. \tag{2.82}$$

From (2.81) and (2.82), we have

$$\frac{x_{s+3}^p}{y_{s+2}^q} = A^{p-pq} y_s^{q^2},$$

and so, from (1.1),

$$y_{s+4} = \max\left\{B,\ A^{p-pq} y_s^{q^2}\right\}. \tag{2.83}$$

In addition, from (2.81) and (2.82), we have

$$\frac{x_{s+3}^p}{y_{s+2}^q} < \frac{A^p}{\left(A^{\frac{p}{q+1}}\right)^q} = A^{\frac{p}{q+1}},$$

and so, from (1.1) and (2.3), we get

$$y_{s+4} < A^{\frac{p}{q+1}}. \tag{2.84}$$

From (2.69), (2.80), (2.81), (2.82), (2.83), (2.84), and working inductively, we get (2.71), and

$$y_{s+4k-2} = \frac{A^p}{y_{s+4k-4}^q} > A^{\frac{p}{q+1}}, \qquad k \geq 1, \tag{2.85}$$

and

$$y_{s+4k} = \max\{B,\ A^{p-pq} y_{s+4k-4}^{q^2}\} < A^{\frac{p}{q+1}}, \qquad k \geq 1. \tag{2.86}$$

IV(a). First, suppose that (2.72) holds, then, from (1.1) and (2.3), we get

$$A^{p-pq} y_{s+4k-4}^{q^2} \geq A^{p-pq} B^{q^2} \geq B,$$

and so, from (2.86), we have

$$y_{s+4k} = A^{p-pq} y_{s+4k-4}^{q^2}, \qquad k \geq 1. \tag{2.87}$$

From (2.87), and by induction, (see also [55] and note that the equation is with interlacing indices [53]), it is easy to prove that

$$y_{s+4k} = A^{p\frac{1-(q^2)^k}{q+1}} y_s^{(q^2)^k}, \qquad k \geq 1. \tag{2.88}$$

From (2.88) and (2.72), we have

$$\lim_{k\to\infty} y_{s+4k} = A^{\frac{p}{q+1}}. \tag{2.89}$$

Using (2.85) and (2.89), we have

$$\lim_{k\to\infty} y_{s+4k-2} = A^{\frac{p}{q+1}}. \tag{2.90}$$

From (2.89) and (2.90), it is obvious that (2.73) is true.

IV(b). Now, suppose that (2.74) holds, then from (1.1) and (2.86), we have

$$y_{s+4k} = \max\{B,\ y_{s+4k-4}\} = y_{s+4k-4}, \qquad k \geq 1,$$

and so, the second relation of (2.75) is true. From the second relation of (2.75) and (2.85), we have that the first relation of (2.75) is also true.

IV(c). Finally, suppose that (2.76) holds. We prove that, there exists a positive integer k_0, such that,

$$y_{s+4k_0} = B. \tag{2.91}$$

On the contrary, we assume that

$$y_{s+4k} > B, \qquad k \geq 0,$$

then, from (2.86), we get (2.87), and so, (2.88) is true. Then, from (2.88), we get

$$y_{s+4k} = A^{\frac{p}{q+1}} \left(\frac{y_s}{A^{\frac{p}{q+1}}} \right)^{(q^2)^k},$$

and so, from (2.69) and (2.76),

$$\lim_{k\to\infty} y_{s+4k} = 0,$$

which is a contradiction, since from (1.1),

$$y_{s+4k} \geq B > 0, \qquad k \geq 0.$$

So, there exists a positive integer k_0, such that (2.91) holds.
From (2.1), (2.3), (2.76), (2.85), (2.86) and (2.91), we have

$$y_{s+4k_0+2} = \frac{A^p}{B^q}, \qquad y_{s+4k_0+4} = \max\{B, A^{p-pq} B^{q^2}\} = B,$$

and working inductively, we get (2.77). This completes the proof of the lemma. □

Using Lemma 2.6 and arguing as in Proposition 2.5, we can easily prove the following proposition.

Proposition 2.7. *Consider the system of difference equations* (1.1)*, where relations* (2.1) *and* (2.3) *hold, and the initial values* x_{-1}, x_0, y_{-1}, y_0*, are positive real numbers. Let* (x_n, y_n) *be a solution of* (1.1)*. Then, the following statements are true:*

I. *Suppose that there exist integers* $l, r \geq 1$*, such that*

$$y_{2l+1} = A^{\frac{p}{q+1}}, \qquad y_{2r} = A^{\frac{p}{q+1}}. \tag{2.92}$$

Then, (x_n, y_n) *is eventually equal to the positive equilibrium* $(A, A^{\frac{p}{q+1}})$ *of* (1.1)*.*

II. *Suppose that there exists an integer* $l \geq 1$*, such that the first equality of* (2.92) *and relations* (2.63), (2.64) *hold. Then, relation* (2.39) *and*

$$x_{2n} = A, \quad y_{2n-1} = A^{\frac{p}{q+1}}, \quad n \geq l+1, \tag{2.93}$$

are satisfied.

III. *Suppose that there exists an integer* $l \geq 1$*, such that the first equality of* (2.92) *and relations* (2.63), (2.65) *hold. Then, relations* (2.41) *and* (2.93) *are satisfied.*

IV. *Suppose that there exists an integer* $r \geq 1$*, such that the second equality of* (2.92) *and relations* (2.66), (2.67) *hold. Then, relation* (2.34) *and*

$$x_{2n+1} = A, \quad y_{2n} = A^{\frac{p}{q+1}}, \quad n \geq r, \tag{2.94}$$

are satisfied.

V. *Suppose that there exists an integer* $r \geq 1$*, such that the second equality of* (2.92) *and relations* (2.66), (2.68) *hold. Then, relations* (2.36) *and* (2.94) *are satisfied.*

VI. *If relations* (2.63), (2.64), (2.66) *and* (2.67) *hold, then* (2.59) *is satisfied.*

VII. *If relations* (2.63), (2.64), (2.66) *and* (2.68) *hold, then, relations* (2.36) *and* (2.39) *are satisfied.*

VIII. *If relations* (2.63), (2.65), (2.66) *and* (2.67) *hold, then, relations* (2.34) *and* (2.41) *are satisfied.*

IX. *If relations* (2.63), (2.65), (2.66) *and* (2.68) *hold, then* (2.60) *is satisfied.*

If, in addition, relation (2.70) *holds, then the following statements are true:*

X. *Suppose that there exists an integer* $l \geq 1$*, such that the first equality of* (2.92) *holds and an integer* $t \geq 1$*, such that*

$$y_{2t} < A^{\frac{p}{q+1}}. \tag{2.95}$$

Then

(a). *if* $q < 1$*, then,*

$$x_n = A, \quad n \geq \max\{2l+2, 2t+1\},$$
$$y_{2n+1} = A^{\frac{p}{q+1}}, \quad n \geq l, \quad \lim_{n\to\infty} y_{2n} = A^{\frac{p}{q+1}},$$

(b). *if* $q = 1$*, then,*

$$x_n = A, \quad n \geq \max\{2l+2, 2t+1\}, \quad y_{2n+1} = A^{\frac{p}{q+1}}, \quad n \geq l,$$
$$y_{2t+4n-2} = \frac{A^p}{y_{2t}}, \quad y_{2t+4n} = y_{2t}, \quad n \geq 1,$$

(c). *if $q > 1$, then, there exists a positive integer n_0, such that*

$$x_n = A, \quad n \geq \max\{2l+2, 2t+1\}, \quad y_{2n+1} = A^{\frac{p}{q+1}}, \quad n \geq l,$$
$$y_{2t+4n-2} = \frac{A^p}{B^q}, \quad y_{2t+4n-4} = B, \quad n \geq n_0 + 1,$$

XI. *Suppose that there exists an integer $r \geq 1$, such that the second equality of (2.92) holds and an integer $v \geq 1$, such that*

$$y_{2v+1} < A^{\frac{p}{q+1}}. \tag{2.96}$$

Then

(a). *if $q < 1$, then,*

$$x_n = A, \quad n \geq \max\{2r+1, 2v+2\},$$
$$y_{2n} = A^{\frac{p}{q+1}}, \quad n \geq r, \quad \lim_{n\to\infty} y_{2n+1} = A^{\frac{p}{q+1}},$$

(b). *if $q = 1$, then,*

$$x_n = A, \quad n \geq \max\{2r+1, 2v+2\}, \quad y_{2n} = A^{\frac{p}{q+1}}, \quad n \geq r,$$
$$y_{2v+4n-1} = \frac{A^p}{y_{2v+1}}, \quad y_{2v+4n+1} = y_{2v+1}, \quad n \geq 1,$$

(c). *if $q > 1$, then, there exists a positive integer n_1, such that*

$$x_n = A, \quad n \geq \max\{2r+1, 2v+2\}, \quad y_{2n} = A^{\frac{p}{q+1}}, \quad n \geq r,$$
$$y_{2v+4n-1} = \frac{A^p}{B^q}, \quad y_{2v+4n-3} = B, \quad n \geq n_1 + 1.$$

XII. *If relations (2.63), (2.64) and (2.96) hold, then*

(a). *if $q < 1$, then,*

$$x_{2n} = A, \quad n \geq v+1, \quad \lim_{n\to\infty} x_{2n+1} = \infty,$$
$$\lim_{n\to\infty} y_{2n} = \infty, \quad \lim_{n\to\infty} y_{2n+1} = A^{\frac{p}{q+1}},$$

(b). *if $q = 1$, then,*

$$x_{2n} = A, \quad n \geq v+1, \quad \lim_{n\to\infty} x_{2n+1} = \infty,$$
$$\lim_{n\to\infty} y_{2n} = \infty, \quad y_{2v+4n-1} = \frac{A^p}{y_{2v+1}}, \quad y_{2v+4n+1} = y_{2v+1}, \quad n \geq 1,$$

(c). *if $q > 1$, then, there exists a positive integer n_1, such that*

$$x_{2n} = A, \quad n \geq v+1, \quad \lim_{n\to\infty} x_{2n+1} = \infty,$$
$$\lim_{n\to\infty} y_{2n} = \infty, \quad y_{2v+4n-1} = \frac{A^p}{B^q}, \quad y_{2v+4n-3} = B, \quad n \geq n_1 + 1.$$

XIII. *If relations (2.63), (2.65) and (2.96) hold, then*

(a). *if* $q < 1$, *then,*

$$x_{2n} = A, \quad n \geq v+1, \quad \lim_{n\to\infty} x_{2n+1} = 1,$$
$$\lim_{n\to\infty} y_{2n} = 1, \quad \lim_{n\to\infty} y_{2n+1} = A^{\frac{p}{q+1}},$$

(b). *if* $q = 1$, *then,*

$$x_{2n} = A, \quad n \geq v+1, \quad \lim_{n\to\infty} x_{2n+1} = 1,$$
$$\lim_{n\to\infty} y_{2n} = 1, \quad y_{2v+4n-1} = \frac{A^p}{y_{2v+1}}, \quad y_{2v+4n+1} = y_{2v+1}, \quad n \geq 1,$$

(c). *if* $q > 1$, *then, there exists a positive integer* n_1, *such that*

$$x_{2n} = A, \quad n \geq v+1, \quad \lim_{n\to\infty} x_{2n+1} = 1,$$
$$\lim_{n\to\infty} y_{2n} = 1, \quad y_{2v+4n-1} = \frac{A^p}{B^q}, \quad y_{2v+4n-3} = B, \quad n \geq n_1 + 1.$$

XIV. *If relations* (2.66), (2.67) *and* (2.95) *hold, then*

(a). *if* $q < 1$, *then,*

$$x_{2n+1} = A, \quad n \geq t, \quad \lim_{n\to\infty} x_{2n} = \infty,$$
$$\lim_{n\to\infty} y_{2n+1} = \infty, \quad \lim_{n\to\infty} y_{2n} = A^{\frac{p}{q+1}},$$

(b). *if* $q = 1$, *then,*

$$x_{2n+1} = A, \quad n \geq t, \quad \lim_{n\to\infty} x_{2n} = \infty,$$
$$\lim_{n\to\infty} y_{2n+1} = \infty, \quad y_{2t+4n-2} = \frac{A^p}{y_{2t}}, \quad y_{2t+4n} = y_{2t}, \quad n \geq 1,$$

(c). *if* $q > 1$, *then, there exists a positive integer* n_0, *such that*

$$x_{2n+1} = A, \quad n \geq t, \quad \lim_{n\to\infty} x_{2n} = \infty,$$
$$\lim_{n\to\infty} y_{2n+1} = \infty, \quad y_{2t+4n-2} = \frac{A^p}{B^q}, \quad y_{2t+4n-4} = B, \quad n \geq n_0 + 1.$$

XV. *If relations* (2.66), (2.68) *and* (2.95) *hold, then*

(a). *if* $q < 1$, *then,*

$$x_{2n+1} = A, \quad n \geq t, \quad \lim_{n\to\infty} x_{2n} = 1,$$
$$\lim_{n\to\infty} y_{2n+1} = 1, \quad \lim_{n\to\infty} y_{2n} = A^{\frac{p}{q+1}},$$

(b). *if* $q = 1$, *then,*

$$x_{2n+1} = A, \quad n \geq t, \quad \lim_{n\to\infty} x_{2n} = 1,$$
$$\lim_{n\to\infty} y_{2n+1} = 1, \quad y_{2t+4n-2} = \frac{A^p}{y_{2t}}, \quad y_{2t+4n} = y_{2t}, \quad n \geq 1,$$

(c). *if $q > 1$, then, there exists a positive integer n_0, such that*

$$x_{2n+1} = A, \quad n \geq t, \quad \lim_{n\to\infty} x_{2n} = 1,$$
$$\lim_{n\to\infty} y_{2n+1} = 1, \quad y_{2t+4n-2} = \frac{A^p}{B^q}, \quad y_{2t+4n-4} = B, \quad n \geq n_0 + 1.$$

XVI. *Suppose that there exist integers $t, v \geq 1$, such that (2.95) and (2.96) hold, then*

(a). *if $q < 1$, then,*

$$x_n = A, \quad n \geq \max\{2t+1, 2v+2\}, \quad \lim_{n\to\infty} y_n = A^{\frac{p}{q+1}},$$

(b). *if $q = 1$, then,*

$$x_n = A, \quad n \geq \max\{2t+1, 2v+2\},$$
$$y_{2t+4n-2} = \frac{A^p}{y_{2t}}, \quad y_{2t+4n} = y_{2t}, \quad n \geq 1,$$
$$y_{2v+4n-1} = \frac{A^p}{y_{2v+1}}, \quad y_{2v+4n+1} = y_{2v+1}, \quad n \geq 1,$$

(c). *if $q > 1$, then, there exist positive integers n_0, n_1, such that*

$$x_n = A, \ n \geq \max\{2t+1, 2v+2\},$$
$$y_{2t+4n-2} = \frac{A^p}{B^q}, \quad y_{2t+4n-4} = B, \quad n \geq n_0 + 1,$$
$$y_{2v+4n-1} = \frac{A^p}{B^q}, \quad y_{2v+4n-3} = B, \quad n \geq n_1 + 1.$$

Remark 2.8. If for the system of difference equations (1.1) relations (2.1), (2.3) and (2.70) hold and the initial values x_{-1}, x_0, y_{-1}, y_0, are positive real numbers, then it is impossible to exist integers $l, v \geq 1$, such that the first equality of (2.92) and (2.96) to be valid simultaneously.

Indeed, if the first equality of (2.92) holds then, from statement I of Lemma 2.6, we have

$$y_{2n+1} = A^{\frac{p}{q+1}}, \quad n \geq l,$$

and so, (2.96) can not be true for $v \geq l$.

Now, suppose that $v < l$. From statement IV of Lemma 2.6 and relations (2.69), (2.85), (2.86) and (2.96), we get

$$y_{2v+4k-1} > A^{\frac{p}{q+1}}, \quad k \geq 1,$$

and

$$y_{2v+4k+1} < A^{\frac{p}{q+1}}, \quad k \geq 1,$$

which contradicts with the first equality of (2.92), since we assume that $v < l$.

Similarly, it is impossible to exist integers $r, t \geq 1$, such that the second equality of (2.92) and (2.95) to be valid simultaneously.

Remark 2.9. If for the system of difference equations (1.1) relations (2.1) and (2.4) hold and the initial values x_{-1}, x_0, y_{-1}, y_0, are positive real numbers, then the behavior of its solutions is similar to the behavior we have in Proposition 2.7. For this reason, we omit the reference.

Proposition 2.10. *Consider the system of difference equations* (1.1)*, where relations* (2.1) *and* (2.5) *hold, and the initial values* x_{-1}, x_0, y_{-1}, y_0*, are positive real numbers. Then, all the solutions of* (1.1) *are unbounded from above.*

Proof. Suppose that $A > 1$ and (x_n, y_n) is a solution of (1.1). We prove that x_n is unbounded from above. On the contrary, we assume that there exists a positive real number M, such that

$$x_n \leq M, \quad \text{for any } n \geq 1. \tag{2.97}$$

From (1.1) and (2.97), we get

$$\frac{y_n^p}{x_{n-1}^q} \leq M, \quad \text{for any } n \geq 0,$$

and so, from (2.97), and since $q > 0$, we have

$$y_n^p \leq M x_{n-1}^q \leq M M^q = M^{q+1}, \quad \text{for any } n \geq 2,$$

which means that

$$y_n \leq M^{\frac{q+1}{p}}, \quad \text{for any } n \geq 2. \tag{2.98}$$

From (1.1) and (2.98), we get

$$\frac{x_n^p}{y_{n-1}^q} \leq M^{\frac{q+1}{p}}, \quad \text{for any } n \geq 2,$$

and so, from (2.1) and (2.98),

$$x_n^p \leq M^{\frac{q+1}{p}} y_{n-1}^q \leq M^{\frac{q+1}{p}} M^{q\frac{q+1}{p}} = M^{\frac{(q+1)^2}{p}}, \quad \text{for any } n \geq 3,$$

which means that

$$x_n \leq M^{(\frac{q+1}{p})^2}, \quad \text{for any } n \geq 3.$$

Working inductively, we get

$$\begin{aligned} x_n &\leq M^{(\frac{q+1}{p})^{2k}}, \quad \text{for any} \quad n \geq 2k+1, \quad k = 1, 2, \ldots, \\ y_n &\leq M^{(\frac{q+1}{p})^{2k-1}}, \quad \text{for any} \quad n \geq 2k, \quad k = 1, 2, \ldots \end{aligned} \tag{2.99}$$

From (2.1), it is obvious that

$$\lim_{k\to\infty} M^{(\frac{q+1}{p})^{2k}} = 1, \qquad \lim_{k\to\infty} M^{(\frac{q+1}{p})^{2k-1}} = 1. \tag{2.100}$$

Since $A > 1$, from (1.1) we have

$$x_n \geq A > 1, \quad \text{for any } n \geq 1,$$

and so, there exists a positive real number ϵ, such that

$$x_n \geq A > 1 + \epsilon, \quad \text{for any } n \geq 1. \tag{2.101}$$

From the first inequality of (2.99) and the first limit of (2.100), we get that there exists a positive integer n_0 such that

$$x_n < 1 + \epsilon, \quad \text{for any } n \geq n_0,$$

which contradicts with (2.101). So, x_n is unbounded from above, if $A > 1$.

Similarly, we can prove that y_n is unbounded from above, if $B > 1$.

We mention that, under some initial values, we can find solutions such that

$$\lim_{n\to\infty} x_n = \infty \quad \text{or} \quad \lim_{n\to\infty} y_n = \infty.$$

Indeed, we consider the difference equation (2.9) of Lemma 2.2, where $a = p$ and $b = q$. Since, from statement (i) of Lemma 2.2, if

$$\frac{z_0^{\lambda_1}}{z_{-1}^q} > 1, \qquad \lambda_1 = \frac{p + \sqrt{p^2 - 4q}}{2},$$

then

$$\lim_{n\to\infty} z_n = \infty, \tag{2.102}$$

there exists a positive integer n_1, such that

$$z_{n+1} > \max\{A, B\}, \quad \text{for any } n \geq n_1. \tag{2.103}$$

If we set

$$x_{-1} = z_{n_1+j-1}, \qquad y_0 = z_{n_1+j}, \tag{2.104}$$

$$y_{-1} = z_{n_1+w-1}, \qquad x_0 = z_{n_1+w}, \tag{2.105}$$

where j, w are arbitrary integers in $\{0, 1, 2, \dots\}$, then, from (1.1), (2.103) and (2.104),

$$x_1 = \max\left\{A, \frac{z_{n_1+j}^p}{z_{n_1+j-1}^q}\right\} = \max\{A, z_{n_1+j+1}\} = z_{n_1+j+1},$$

$$y_2 = \max\left\{B, \frac{z_{n_1+j+1}^p}{z_{n_1+j}^q}\right\} = \max\{B, z_{n_1+j+2}\} = z_{n_1+j+2},$$

and from (1.1), (2.103) and (2.105),

$$y_1 = \max\left\{B, \frac{z_{n_1+w}^p}{z_{n_1+w-1}^q}\right\} = \max\{B, z_{n_1+w+1}\} = z_{n_1+w+1},$$

$$x_2 = \max\left\{A, \frac{z_{n_1+w+1}^p}{z_{n_1+w}^q}\right\} = \max\{A, z_{n_1+w+2}\} = z_{n_1+w+2},$$

and working inductively,

$$x_{2n+1} = z_{n_1+j+2n+1}, \quad y_{2n+2} = z_{n_1+j+2n+2}, \quad \text{for any } n \geq 0, \tag{2.106}$$

and

$$y_{2n+1} = z_{n_1+w+2n+1}, \quad x_{2n+2} = z_{n_1+w+2n+2}, \quad \text{for any } n \geq 0. \tag{2.107}$$

So, if (2.104) holds, from (2.102) and (2.106) we get

$$\lim_{n\to\infty} x_{2n+1} = \infty, \qquad \lim_{n\to\infty} y_{2n} = \infty,$$

and if (2.105) holds, from (2.102) and (2.107) we get

$$\lim_{n\to\infty} x_{2n} = \infty, \qquad \lim_{n\to\infty} y_{2n+1} = \infty.$$

This completes the proof of the proposition. □

Open Problem 2.1. *Consider the system of difference equations* (1.1)*, where* (2.1) *and* (2.3) *hold, and the initial values* x_{-1}, x_0, y_{-1}, y_0*, are positive real numbers. Suppose that there exists an integer* $l \geq 2$*, such that*

$$y_l < A^{\frac{p}{q+1}}.$$

Assume that

$$A^{\frac{p^2-q-1}{pq}} > B.$$

Study the behavior of the solution (x_n, y_n) *of this system.*

Abstract. Investigation of the long-term behaviour of solutions to the nonlinear difference equation

$$x_{n+1} = A + \frac{x_{n-m}^p}{x_{n-k}^r}, \quad n \in \mathbb{N}_0,$$

where $A, p, q \in \mathbb{R}$, $k, m \in \mathbb{N}_0$, $k \neq m$, was proposed by S. Stević about twenty years ago. A very special case of the equation ($p = 1$, $r = 2$, $m = 0$) has been recently considered in [*J. Appl. Math. Comput.* **67**(2021), 423–437]. We show that the main results therein are known or have some inaccuracies. Among other things, we show that the boundedness result therein is a consequence of some known results and using one of our previous methods we give a better upper bound for positive solutions to the equation, show that the proof of the global convergence result therein is not correct and provide a complete proof of a generalization, and also show that the results on semi-cycles of positive solutions are not correct and present some correct ones. Several comments are also given and some analyses are conducted.

Keywords: difference equation, positive solutions, boundedness, convergence, semi-cycles.

2020 Mathematics Subject Classification: 39A20.

1 Introduction

There has been a considerable recent interest in investigating concrete nonlinear difference equations and systems of difference equations (see, for instance, [1,3–19,29–61] and the related references therein).

✉Corresponding author. Email: sscite1@gmail.com

1.1 Notation

The set of positive natural numbers is denoted by $\mathbb{N}$, the set of whole numbers is denoted by $\mathbb{Z}$, the set of positive numbers $(0,+\infty)$ is denoted by $\mathbb{R}_+$, whereas the set of real numbers is denoted by $\mathbb{R}$. If $l \in \mathbb{Z}$ is fixed, then for the set $\{j \in \mathbb{Z} : j \geq l\}$ we use the notation $\mathbb{N}_l$. If $k, l \in \mathbb{Z}$ and $k \leq l$, then we use the notation $j = \overline{k,l}$ instead of writing the following expression: $k \leq j \leq l$, $j \in \mathbb{Z}$. By C_j^n where $n \in \mathbb{N}_0$, $0 \leq j \leq n$, we denote the binomial coefficients, that is, $C_j^n = \frac{n!}{j!(n-j)!}$, where $n \in \mathbb{N}_0$, $0 \leq j \leq n$, and where, as usual, we regard that $0! = 1$. For some basic facts on the binomial coefficients consult, for instance, [2, 20, 21, 25, 26]. Let us mention that in a part of the literature, such as [2, 21], is used the notation C_n^j for the binomial coefficients. Another standard notation, that is, $\binom{n}{j}$ is also frequently used (see, e.g., [20, 25, 26]), but it is more robust, so, as usual, we use here the above notation.

1.2 Two important classes of difference equations with powers

Investigation of the long-term behaviour of positive solutions to the nonlinear difference equation

$$x_{n+1} = A + \frac{x_{n-m}^p}{x_{n-k}^r}, \quad n \in \mathbb{N}_0, \tag{1.1}$$

where $A > 0$, $\min\{p, q\} \geq 0$, $k, m \in \mathbb{N}_0$, $k \neq m$, as well as of its max-type counterpart

$$x_{n+1} = \max\left\{A, \frac{x_{n-m}^p}{x_{n-k}^r}\right\}, \quad n \in \mathbb{N}_0, \tag{1.2}$$

was suggested by S. Stević in January 2004, soon after acceptance of [42] where the boundedness, global attractivity, oscillations, and asymptotic periodicity of positive solutions to the equation (1.1) in the case $A \geq 0$, $p = r$, $m = 1$, $k = 0$ was investigated. This was probably the first paper with some new and non-trivial results on an equation of the form in (1.1) which is not rational (the case had been previously considered in [12], but the results therein were essentially known or incorrect). It should be mentioned that [42] also contains a result on convergence of solutions to equation (1.1) for the case of an arbitrary $m \in \mathbb{N}$.

Equations (1.1) and (1.2) are good prototypes for developing the theory of nonlinear difference equations, because of which S. Stević proposed their investigation. Since the time of his proposal for the investigation, the two classes of difference equations, as well as their various generalizations, including some systems of difference equations, have been studied a lot.

Remark 1.1. If $A = 0$ then equations (1.1) and (1.2) are reduced to the following product-type difference equation

$$x_{n+1} = \frac{x_{n-m}^p}{x_{n-k}^r}, \quad n \in \mathbb{N}_0. \tag{1.3}$$

If only positive solutions of equation (1.3) are considered, then employing the change of variables

$$y_n = \ln x_n$$

for $n \geq -\max\{k, m\}$, which can be found in old literature [22] (see, for instance, also [2, 42]), the difference equation is transformed to the linear one with constant coefficients

$$z_{n+1} - pz_{n-m} + rz_{n-k} = 0, \quad n \in \mathbb{N}_0,$$

which is (theoretically) solvable in closed form ([22–24, 26–28]). Bearing in mind this fact and many known results on the linear difference equations with constant coefficients, the equations (1.1) and (1.2) with $A = 0$ are usually not of a special interest. Hence, although we have considered some special cases of the equation (1.3) with $A = 0$, as it was the case in [42], we frequently skipped considering the case in our papers.

Remark 1.2. It should be also mentioned that solvability of product-type systems of difference equations on the domain of complex numbers, as well as the difference equations and systems which are transformed to them by some changes of variables, has attracted some recent attention. See, for example, [59, 60] and the related references therein.

Remark 1.3. Note that equations (1.1) and (1.2) are some kind of perturbations of equation (1.3), which is one of the reasons why they are good prototypes for some detailed investigations. Although, they have similar forms, the long-term behavior of their positive solutions can be quite different.

1.3 A bit on the history of investigations of equations (1.1) and (1.2)

In what follows we briefly mention some of the previous investigations of equations (1.1) and (1.2), and some of their generalizations. As we have already mentioned, in [42] was considered equation (1.1) in the case $A \geq 0$, $p = r > 0$, $m = 1$, $k = 0$. The case was also studied later in [5]. The boundedness, global attractivity, and periodicity of positive solutions to equations (1.1) and (1.2) in the case $A > 0$, $p = r > 0$, $m = 0$, $k = 1$ were investigated in [46] and [49], respectively. Equations (1.1) and (1.2) in the case $\min\{A, p, q\} > 0$, $m = 0$, $k = 1$ were considered in [47] (this was probably the first paper which also considered the case $p \neq r$). The boundedness character of positive solutions to equations (1.1) and (1.2) in the case $\min\{A, p, q\} > 0$, $m = 0$, $k = 2$ was studied in [52], where S. Stević used several new ideas and methods, among others, a new method that we called "oachkatzlschwoif/squirrel-tail" method. Equation (1.2) in the case $A > 0$, $p = r > 0$, $m = 0$, $k = 3$ was considered first in [51] and later in [16].

The boundedness character of positive solutions to the following extensions of the equations in [47]

$$x_{n+1} = A + \frac{x_n^p}{x_{n-1}^q x_{n-2}^r}, \quad n \in \mathbb{N}_0,$$

$$x_{n+1} = \max\left\{A, \frac{x_n^p}{x_{n-1}^q x_{n-2}^r}\right\}, \quad n \in \mathbb{N}_0,$$

was considered in [17] and [54], respectively.

The following generalization of equation (1.1) in the case $p = r$

$$x_n = A + \left(\frac{\sum_{i=1}^k \alpha_i x_{n-2p_i}}{\sum_{j=1}^m \beta_j x_{n-q_j}}\right)^p, \quad n \in \mathbb{N}_0,$$

where $\min\{p, A\} > 0$, $k, m \in \mathbb{N}$, $p_i \in \mathbb{N}$, $i = \overline{1,k}$, q_j, $j = \overline{1,m}$, are odd natural numbers such that $p_1 < p_2 < \cdots < p_k$, $q_1 < q_2 < \cdots < q_m$, $\min_{1\leq i\leq k, 1\leq j\leq m}\{\alpha_i, \beta_j\} > 0$ such that $\sum_{i=1}^k \alpha_i = \sum_{j=1}^m \beta_j$, was considered in [53].

The boundedness character of the equations (1.1) and (1.2) in the case $A > 0$, $p = r > 0$, $m = 0$, $k \in \mathbb{N}$ was completely characterized in [50]. Equation (1.2) in the case $p \neq q$ was

considered in [55], whereas the corresponding results for equation (1.1) in the case were presented in [15]. The case $\min\{p,q\} > 0$, $m = 1$, $k = 0$ was considered in [35], whereas the case where the constant A is replaced by a sequence A_n was considered in [36]. For some special cases of equations (1.1) and (1.2) in rational form see [1,3,4,40] and the references therein, and with a variable coefficient A_n, see [31,32,41] and the related references therein. A cyclic system of difference equations corresponding to the equation (1.1) in the case $A > 0$, $m = 0$, $k = 1$, was considered in [57], whereas the corresponding cyclic system to the equation (1.2) in the case $A > 0$, $m = 0$, $k = 1$, was studied in [61]. A quite general boundedness result for a generalization of equation (1.1) was given in [58]. For some related difference equations and systems of difference equations, some of which also contain powers of dependent variables, see also [18,29,37,38,56].

1.4 A recent investigation

Recently, in [62], E. Tasdemir considered the following difference equation

$$x_{n+1} = A + B\frac{x_n}{x_{n-m}^2}, \quad n \in \mathbb{N}_0, \tag{1.4}$$

where $m \in \mathbb{N}$ and $\min\{A,B\} > 0$.

Note that by using the change of variables

$$x_n = \sqrt{B}\, y_n, \quad n \in \mathbb{N}_0, \tag{1.5}$$

equation (1.4) is transformed to the equation

$$y_{n+1} = \frac{A}{\sqrt{B}} + \frac{y_n}{y_{n-m}^2}, \quad n \in \mathbb{N}_0, \tag{1.6}$$

which is a very special case of equation (1.1). This immediately implies that equation (1.4) is equivalent with a special case of equation (1.1), and consequently it is not a new equation at all.

Instead of using the change of variables in (1.5) the author of [62] used the change of variables

$$y_n = \frac{x_n}{A}, \quad n \in \mathbb{N}_0, \tag{1.7}$$

and obtained the equation

$$y_{n+1} = 1 + p\frac{y_n}{y_{n-m}^2}, \quad n \in \mathbb{N}_0, \tag{1.8}$$

where $p = B/A^2$, which is, of course, equivalent with the special case of equation (1.1) mentioned above.

The equilibria of equation (1.8) satisfy the algebraic equation

$$\bar{y} = 1 + \frac{p}{\bar{y}}$$

and are equal to

$$\frac{1+\sqrt{1+4p}}{2} \quad \text{and} \quad \frac{1-\sqrt{1+4p}}{2}.$$

From this and since $p > 0$, we see that

$$\bar{y} = \frac{1+\sqrt{1+4p}}{2} \tag{1.9}$$

is a unique positive equilibrium of equation (1.8).

A simple calculation shows that the linearized equation associated with (1.8) about the positive equilibrium $\bar{y}$ is given by

$$z_{n+1} - \frac{p}{\bar{y}^2} z_n + \frac{2p}{\bar{y}^2} z_{n-m} = 0, \quad n \in \mathbb{N}_0. \tag{1.10}$$

It is well-known that

$$\sum_{j=0}^{m} |a_j| < 1 \tag{1.11}$$

is a sufficient condition for the asymptotic stability of the difference equation

$$z_{n+1} + a_0 z_n + a_1 z_{n-1} + \cdots + a_m z_{n-m} = 0, \tag{1.12}$$

from which it follows immediately that if $\frac{3p}{\bar{y}^2} < 1$ and $p > 0$, equation (1.10) is asymptotically stable. A simple calculation shows that this is satisfied for $p \in (0, 3/4)$. This implies that the equilibrium point $\bar{y}$ of equation (1.8) is locally asymptotically stable for $p \in (0, 3/4)$, which was noted in [62].

Remark 1.4. Condition (1.11) is a practical condition which guarantees asymptotic stability of equation (1.12), but his disadvantage is that it is not necessary. Moreover, there are better sufficient conditions guaranteeing asymptotic stability of the equation. Unfortunately, many authors use only this one and obtain pretty narrow sets of parameters which guarantee the stability.

The following claims should be the main results in [62].

Theorem 1.5. *Every solution $(y_n)_{n \in \mathbb{N}_{-m}}$ of equation (1.8) is bounded and persist and satisfies the following estimates*

$$1 < y_n < 1 + p(1+p)^m, \tag{1.13}$$

for $n \geq 2m + 2$.

Theorem 1.6. *Let $0 < p < 3/4$. Then, the positive equilibrium point $\bar{y}$ of equation (1.8) is globally asymptotically stable.*

Theorem 1.7. *Every solution of equation (1.8) satisfies the following statements:*

(a) Every solution of equation (1.8) has semi-cycles of length at most $2m + 1$.

(b) If every solution of equation (1.8) has a semi-cycle of length at least k, then, the following semi-cycle has at least $k + 1$ terms.

Beside these three claims, and the observation related to the local asymptotic stability of the equilibrium $\bar{y}$, [62] also gives a few other simple results, which are easily proved by well known methods and simple calculations such as the nonexistence of two periodic solutions and a growth rate result for solutions converging to the equilibrium $\bar{y}$.

Remark 1.8. At the end of [62] is proposed studying two special cases of equation (1.1) as 'Open Problems' despite the fact that these, as well as some general difference equations have been studied considerably so far, as we have mentioned in the previous subsection. The author of [62] might have not seen any of the papers: [3, 15–17, 31, 32, 35, 36, 42, 46, 47, 49–55, 57, 58, 61], which have been published in several popular journals.

1.5 Our aim

Here we show that Theorem 1.5 directly follows form some of our previous results, and that employing one of known methods can be obtained a better upper estimate than the one given in (1.13). Further, we show that the proof of Theorem 1.6 is not correct and provide a complete proof of a generalization. We also show that the proof of Theorem 1.7 is not correct, and present some correct ones related to it. We also conduct some analyses and present some additional comments.

2 Main results, counterexamples and comments

In this section we give several comments concerning the claims and results in [62], conduct some analyses, correct some of the proofs therein, and extend some of the claims and results therein.

2.1 On Theorem 1.5 and relating results

As far as concerning Theorem 1.5, the fact that all positive solutions to equation (1.8) are bounded follows from several results in the literature. For example, by using one of the methods presented in [50], which essentially originates from [47], in [15] was proved the following generalization of the boundedness results in [47] and [52]:

Theorem 2.1. *Assume $p, r > 0$ and $k \in \mathbb{N}_2$. Then every positive solution of the equation*

$$x_n = A + \frac{x_{n-1}^p}{x_{n-k}^r}, \quad n \in \mathbb{N}_0, \tag{2.1}$$

is bounded if

$$0 < p < \left(\frac{rk^k}{(k-1)^{k-1}} \right)^{1/k}. \tag{2.2}$$

Now note that in equation (1.4) or in the equivalent equation (1.8), we have $p = 1$ and $r = 2$ for which the condition in (2.2) is satisfied for any $k \in \mathbb{N}_2$, from which the boundedness part of Theorem 1.5 immediately follows.

Regarding the upper bound for positive solutions to equation (1.8) given in (1.13), we must say that there is a procedure, which nowadays can be regarded as standard one, for getting upper bounds for positive solutions of related difference equations. The procedure was essentially used, e.g., in [40] and it was a starting point for getting the squirrel-tail method. Namely, by iterating the numerators of the fractions in equation (1.8) m-times, and employing a simple inductive argument we have

$$\begin{aligned} y_{n+1} &= 1 + p\frac{y_n}{y_{n-m}^2} = 1 + \frac{p}{y_{n-m}^2}\left(1 + p\frac{y_{n-1}}{y_{n-m-1}^2}\right) \\ &= 1 + \frac{p}{y_{n-m}^2} + p^2\frac{y_{n-1}}{y_{n-m}^2 y_{n-m-1}^2} = 1 + \frac{p}{y_{n-m}^2} + \frac{p^2}{y_{n-m}^2 y_{n-m-1}^2}\left(1 + p\frac{y_{n-2}}{y_{n-m-2}^2}\right) \\ &= 1 + \frac{p}{y_{n-m}^2} + \frac{p^2}{y_{n-m}^2 y_{n-m-1}^2} + \frac{p^3 y_{n-2}}{y_{n-m}^2 y_{n-m-1}^2 y_{n-m-2}^2} \end{aligned}$$

$$\vdots$$

$$\begin{aligned}
&= 1 + \frac{p}{y_{n-m}^2} + \frac{p^2}{y_{n-m}^2 y_{n-m-1}^2} + \cdots + \frac{p^m y_{n-(m-1)}}{y_{n-m}^2 y_{n-m-1}^2 \cdots y_{n-2m+1}^2} \\
&= 1 + \frac{p}{y_{n-m}^2} + \frac{p^2}{y_{n-m}^2 y_{n-m-1}^2} + \cdots + \frac{p^m}{y_{n-m}^2 y_{n-m-1}^2 \cdots y_{n-2m+1}^2} \left(1 + p\frac{y_{n-m}}{y_{n-2m}^2}\right) \\
&= 1 + \frac{p}{y_{n-m}^2} + \cdots + \frac{p^m}{y_{n-m}^2 y_{n-m-1}^2 \cdots y_{n-2m+1}^2} + \frac{p^{m+1} y_{n-m}}{y_{n-m}^2 y_{n-m-1}^2 \cdots y_{n-2m}^2} \\
&= 1 + \frac{p}{y_{n-m}^2} + \cdots + \frac{p^m}{y_{n-m}^2 y_{n-m-1}^2 \cdots y_{n-2m+1}^2} + \frac{p^{m+1}}{y_{n-m} y_{n-m-1}^2 \cdots y_{n-2m}^2}. \qquad (2.3)
\end{aligned}$$

From (2.3) and since

$$y_n > 1, \quad n \in \mathbb{N},$$

we have

$$y_{n+1} < 1 + p + \cdots + p^m + p^{m+1} = \frac{1 - p^{m+2}}{1 - p}, \qquad (2.4)$$

for $n \geq 2m + 1$, when $p \neq 1$ and

$$y_{n+1} < m + 2, \qquad (2.5)$$

for $n \geq 2m + 1$, when $p = 1$.

Let

$$S_m(p) := \sum_{j=0}^{m-1} p^j, \quad m \in \mathbb{N}.$$

Since

$$S_{m+2}(p) = 1 + p\sum_{j=0}^{m} p^j < 1 + p\sum_{j=0}^{m} C_j^m p^j = 1 + p(1+p)^m$$

we have that the upper bound given in (2.4) is better than the corresponding one in (1.13). Hence, the following result holds.

Theorem 2.2. *Let $p > 0$ and $m \in \mathbb{N}$. Then, every positive solution $(y_n)_{n \in \mathbb{N}_{-m}}$ to equation (1.8) is bounded and persistent and satisfies the following estimates*

$$1 < y_n < S_{m+2}(p),$$

for $n \geq 2m + 2$.

Remark 2.3. Some other methods which can be used in showing the boundedness of positive solutions to nonlinear difference equations, including applications of invariants, can be found, for instance, in [6,15–17,30,33,34,39,46,47,49–51,53–55,57,58], as well as in the related references therein.

2.2 On Theorem 1.6 and some related results

The proof of Theorem 1.6 in [62] is not correct. Namely, to prove it, beside some nonessential conventional inaccuracies, the author of [62] only claims that from

$$m = 1 + p\frac{m}{M^2}, \quad M = 1 + p\frac{M}{m^2} \qquad (2.6)$$

follows $m = M$ and apply a known result (i.e, [13, Theorem 1.15]) from which Theorem 1.6 immediately follows, but only if it is also employed Theorem 1.5 (this was not mentioned in [62], what can be regarded as an oversight). However, the above claim was not proved therein. It should be pointed out that its proof is neither obvious nor quite simple, although it uses only elementary mathematics (see the proof of Theorem 2.4 below). Moreover, it is possible to prove a better convergence result than Theorem 1.6. Namely, the following result holds.

Theorem 2.4. *Let $m \in \mathbb{N}$ and $p \in (0, 3/4] \cup [1, \infty)$. Then, the unique positive equilibrium point $\bar{y}$ of equation (1.8) is global attractor of all positive solutions.*

Proof. Since

$$I_p := [1, S_{m+2}(p)]$$

is an invariant interval for positive solutions to equation (1.8), as mentioned above, to apply [13, Theorem 1.15], it is enough to prove that the algebraic system (2.6) has only the solution $M = m = \bar{y}$ on the set I_p^2.

Assume that there is a solution to system (2.6) such that

$$M \neq m, \tag{2.7}$$

where $m, M \in I_p$.

From (2.6) we have

$$m - M = p\left(\frac{m}{M^2} - \frac{M}{m^2}\right) = \frac{p(m^3 - M^3)}{(mM)^2}$$

from which along with (2.7) it follows that

$$(Mm)^2 = p(m^2 + mM + M^2). \tag{2.8}$$

Further, from (2.6) we have

$$Mm = M + p\frac{m}{M} = m + p\frac{M}{m}$$

from which along with (2.7) it follows that

$$Mm = p(M + m). \tag{2.9}$$

From (2.6) we also have

$$M^2 m = M^2 + pm, \quad Mm^2 = m^2 + pM$$

from which along with (2.7) it follows that

$$Mm = M + m - p. \tag{2.10}$$

From (2.8) and (2.9) we have

$$p(M + m)^2 = m^2 + mM + M^2 = (M + m)^2 - Mm$$

and consequently

$$Mm = (1 - p)(M + m)^2. \tag{2.11}$$

If it were $p = 1$, then from (2.11) we would have $Mm = 0$, which contradicts to the assumption $m, M \in I_p$.

Now assume that $p \neq 1$. From (2.10) and (2.11) we have

$$(1-p)(M+m)^2 - (M+m) + p = (M+m-1)(M+m-p(M+m+1)) = 0. \tag{2.12}$$

Since $m, M \in I_p$ it is not possible to be $M + m = 1$. Hence, it must be $M + m = p(M + m + 1)$, that is

$$M + m = \frac{p}{1-p}. \tag{2.13}$$

From (2.13) and since $M + m > 0$ it follows that it must be $p \in (0, 1)$.

Using this fact, (2.10) and (2.13) we have

$$Mm = \frac{p}{1-p} - p = \frac{p^2}{1-p}. \tag{2.14}$$

From (2.13) and (2.14) we see that M and m are the two positive distinct roots of the quadratic polynomial

$$\widehat{P}_2(t) := t^2 - \frac{p}{1-p}t + \frac{p^2}{1-p}. \tag{2.15}$$

By direct calculation we see that the roots of polynomial (2.15) are

$$t_1 = \frac{p(1+\sqrt{4p-3})}{2(1-p)} \quad \text{and} \quad t_2 = \frac{p(1-\sqrt{4p-3})}{2(1-p)}. \tag{2.16}$$

From (2.16) we see that it is not possible to be $p \in (0, 3/4]$, since then $t_{1,2}$ will be complex numbers if $p \in (0, 3/4)$, or equal if $p = 3/4$.

Hence, the assumption $m \neq M$ is not possible, from which it follows that $M = m$, completing the proof of the theorem. □

Remark 2.5. From Theorem 2.4 and since the equilibrium $\bar{y}$ is locally asymptotically stable for $p \in (0, 3/4)$, the claim in Theorem 1.6 follows.

Remark 2.6. It is interesting to note that if $p \in (3/4, 1)$, then $t_2 > 1$. Indeed, we have

$$t_2 = \frac{2p}{1+\sqrt{4p-3}}$$

and consequently

$$t_2 - 1 = \frac{2p - 1 - \sqrt{4p-3}}{1+\sqrt{4p-3}}.$$

From this and since $2p - 1 - \sqrt{4p-3} > 0$ for $p \in (3/4, 1)$ is equivalent to $4(p-1)^2 > 0$, the claim follows.

To prove that Theorem 2.4 holds also for $p \in (3/4, 1)$ it will be enough to prove that

$$t_1 > \frac{1-p^{m+2}}{1-p}, \tag{2.17}$$

which is equivalent to

$$p(1+\sqrt{4p-3}) + 2p^{m+2} > 2.$$

Note that the function

$$f_m(t) := 2t^{m+2} + t(\sqrt{4t-3}+1) \tag{2.18}$$

is increasing for $t \geq 3/4$, and consequently on the interval $(3/4, 1)$.

On the other hand, we have

$$f_m\left(\frac{3}{4}\right) = 2\left(\frac{3}{4}\right)^{m+2} + \frac{3}{4} \leq \frac{51}{32} < 2$$

for any $m \in \mathbb{N}$, and

$$f_m(1) = 4 > 2.$$

Hence, for each $m \in \mathbb{N}$, there is a unique $\widehat{t}_m \in (3/4, 1)$, so that

$$f_m(\widehat{t}_m) = 2.$$

This with the monotonicity of the function f_m implies that inequality (2.17) holds when $p > \widehat{t}_m$.

This analysis shows that the following extension of Theorem 2.4 holds.

Theorem 2.7. *Let $m \in \mathbb{N}$, f_m be the function defined in (2.18), and $p \in (0, 3/4] \cup (\widehat{t}_m, +\infty)$, where $\widehat{t}_m$ is the unique solution to the equation $f_m(t) = 2$ on the interval $(3/4, 1)$. Then, the unique positive equilibrium point $\bar{y}$ of equation (1.8) is global attractor of all positive solutions.*

Remark 2.8. For each $m \in \mathbb{N}$ the value of $\widehat{t}_m$ can be approximated by a numeric calculation, but it seems cannot be expressed in closed form.

2.3 On Theorem 1.7 and relating results

The proof of the claim *(a)* in Theorem 1.7 is not correct. Before we present the arguments for the claim, let us mention that the constant/equilibrium solution

$$y_n = \bar{y}, \quad n \in \mathbb{N}_{-m},$$

should have been excluded from the consideration therein, since for the solution the claim is obviously not true. Namely, the solution has only one semi-cycle, which can be regarded as positive, but also it can be regarded as negative, depending on a definition of semi-cycles.

To prove the claim (for the nonconstant solutions), the author of [62] unsuccessfully copied a known method, which can be found, for example, in [1]. Namely, he chooses a positive solution $(y_n)_{n \geq \mathbb{N}_{-m}}$ to equation (1.8) and considers one of its negative semi-cycles (it is claimed that a similar argument proves the claim also for positive semi-cycles), say

$$y_N, y_{N+1}, \ldots, y_{N+2m} < \bar{y}$$

where y_N is the first term in the negative semi-cycle.

It is claimed that

$$\begin{aligned} y_{N+m+i} &= 1 + p\frac{y_{N+m+i-1}}{y_{N+i-1}^2} > 1 + p\frac{y_{N+m+i-1}}{\bar{y}^2} \\ &> \left(1 + \frac{p}{\bar{y}^2}\right) y_{N+m+i-1} > y_{N+m+i-1} \end{aligned} \tag{2.19}$$

for $i = \overline{0, m-1}$, from which it is concluded that

$$y_{N+m} < y_{N+m+1} < \cdots < y_{N+2m-1} < y_{N+2m},$$

and consequently

$$y_{N+2m+1} = 1 + p\frac{y_{N+2m}}{y_{N+m}^2} > \bar{y}.$$

However, the second inequality in (2.19) is not correct, since if it was true, then it would be $y_{N+m+i-1} < 1$, which is not possible for any N satisfying the condition $N + m + i - 1 \geq 1$.

The above proof can be applied to positive solutions to the difference equation

$$y_{n+1} = 1 + p\frac{y_n}{y_{n-m}}, \tag{2.20}$$

however, as we have just noticed, it does not hold for the case of equation (1.8).

One of the interesting problems is the existence of solutions of difference equations which do not oscillate around an equilibrium. The characteristic polynomials associated to their linearizations can be of some help in the study. Namely, if a characteristic polynomial has a zero in the interval $(0, 1)$, then it suggests the existence of solutions of the original difference equation which do not oscillate around an equilibrium. Some methods for showing the existence of such solutions, which use the idea, have been developed in the last few decades (see, e.g., [6–11, 14, 43–45, 48] and the related references therein; for another method see [19]).

These facts suggest to consider the problem of the existence of zeros of the associated characteristic polynomial

$$P_{m+1}(t) = t^{m+1} - \frac{p}{\bar{y}^2}t^m + \frac{2p}{\bar{y}^2} = 0, \quad m \in \mathbb{N}_0. \tag{2.21}$$

to equation (1.10), in the interval $(0, 1)$.

First note that

$$P_{m+1}(0) = \frac{2p}{\bar{y}^2} = \frac{4p}{1 + 2p + \sqrt{1 + 4p}} \in (0, 2) \tag{2.22}$$

and

$$P_{m+1}(1) = 1 + \frac{p}{\bar{y}^2} = 1 + \frac{2p}{1 + 2p + \sqrt{1 + 4p}} \in (1, 2) \tag{2.23}$$

when $p > 0$.

We have

$$P'_{m+1}(t) = (m + 1)t^{m-1}\left(t - \frac{2mp}{(m + 1)(1 + 2p + \sqrt{1 + 4p})}\right), \quad m \in \mathbb{N}_0. \tag{2.24}$$

Hence, the polynomial $P'_{m+1}(t)$ has two zeros $\widetilde{t}_1 = 0$ and

$$\widetilde{t}_2 = \frac{2mp}{(m + 1)(1 + 2p + \sqrt{1 + 4p})} \in (0, 1).$$

From (2.24) we have that the polynomial $P_{m+1}(t)$ has a local minimum at $\widetilde{t}_2$, which is equal to

$$P_{m+1}(\widetilde{t}_2) = \frac{p}{\bar{y}^2}\left(2 - \frac{m^m}{(m + 1)^{m+1}}\left(\frac{2p}{1 + 2p + \sqrt{1 + 4p}}\right)^m\right). \tag{2.25}$$

From (2.25) it is easy to see that

$$P_{m+1}(\widetilde{t}_2) > \frac{p}{\bar{y}^2} > 0.$$

Thus, for any $m \in \mathbb{N}$, the polynomial $P_{m+1}(t)$ does not have a zero on the interval $[0,1]$.

If m is odd, i.e., $m = 2l-1$ for some $l \in \mathbb{N}$, than t_2 is a unique local and global extremum (minimum).

If m is even, i.e., $m = 2l$ for some $l \in \mathbb{N}$, then $P_{2l+1}(t)$ has a local maximum at $\widetilde{t}_1$, and increases on the interval $(-\infty, 0]$. Hence, it has a unique negative zero. From this, (2.22) and since

$$P_{2l+1}(-1) = -1 + \frac{p}{\bar{y}^2} = -\frac{1+\sqrt{1+4p}}{1+2p+\sqrt{1+4p}} < 0 \tag{2.26}$$

when $p > 0$, we have that the polynomial $P_{2l+1}(t)$ has a unique zero t_0 in the interval $(-1,0)$. This fact suggests the existence of oscillatory solutions to equation (1.8) in this case, which is not so surprising. It also suggests that the asymptotics of some oscillatory solutions can be find by using some of the methods presented in [6–11, 14, 43–45, 48]. We will not pursue the investigation in the direction here, since the above conducted analysis also suggests that all non-equilibrium solutions are oscillatory. Indeed, the following result on the oscillatory character of positive solutions to equation (1.8) holds.

Theorem 2.9. *Let $m \in \mathbb{N}$ and $p > 0$. Then, equation (1.8) does not have positive non-equilibrium solutions which are eventually bigger or smaller than the positive equilibrium $\bar{y}$.*

Proof. Assume that $(y_n)_{n \geq \mathbb{N}_{-m}}$ is a positive non-equilibrium solution to equation (1.8) such that

$$y_n \geq \bar{y}, \tag{2.27}$$

for $n \geq n_0$, for some $n_0 \in \mathbb{N}_{-m}$. Since equation (1.8) is autonomous we may assume that $n_0 = -m$.

From (1.8) and (2.27) we have

$$y_{n+1} - \bar{y} = p\frac{y_n}{y_{n-m}^2} - \frac{p}{\bar{y}} = p\frac{y_n\bar{y} - y_{n-m}^2}{y_{n-m}^2\bar{y}} \geq 0,$$

for $n \in \mathbb{N}_0$, from which along with (2.27) it follows that

$$y_n \geq \frac{y_{n-m}^2}{\bar{y}} \geq y_{n-m}, \tag{2.28}$$

for $n \in \mathbb{N}_0$.

From (2.28) we see that the subsequences y_{mk+i}, $k \in \mathbb{N}_{-1}$, $i = \overline{0, m-1}$, are nondecreasing. From this and Theorem 1.5 it follows that there are finite limits

$$\lim_{k \to +\infty} y_{mk+i} = \bar{y}_i, \quad i = \overline{0, m-1}. \tag{2.29}$$

Note also that it must be

$$\bar{y}_i \geq \bar{y}, \quad i = \overline{0, m-1}. \tag{2.30}$$

Letting $k \to +\infty$ in the relations

$$y_{mk+i+1} = 1 + p\frac{y_{mk+i}}{y_{m(k-1)+i}^2}, \quad i = \overline{0, m-1}$$

we get that $(\bar{y}_1, \bar{y}_2, \ldots, \bar{y}_m)$ is a solution to the algebraic system

$$\bar{y}_{i+1} = 1 + \frac{p}{\bar{y}_i}, \quad i = \overline{0, m-1}, \tag{2.31}$$

where we use the standard convention $\bar{y}_i = \bar{y}_j$ when $i \equiv j \,(\bmod m)$.

If $\bar{y}_{i_0+1} = \bar{y}_{i_0}$, for some $i_0 \in \{0, 1, \ldots, m-1\}$, then from (2.31) we see that it must be $\bar{y}_{i_0+1} = \bar{y}_{i_0} = \bar{y}$, from which together with (2.31) we easily get $\bar{y}_i = \bar{y}$, for $i = \overline{0, m-1}$, which contradicts to (2.30), the monotonicity of the subsequences $(y_{mk+i})_{k\in\mathbb{N}_{-1}}$, $i = \overline{0, m-1}$, and the assumption that the solution is non-equilibrium.

Now we assume that

$$\bar{y}_i \neq \bar{y}_{i+1}, \quad i = \overline{0, m-1}. \tag{2.32}$$

From (2.31) we have

$$\bar{y}_{i+1} - \bar{y}_i = \frac{p}{\bar{y}_i} - \frac{p}{\bar{y}_{i-1}} = \frac{p(\bar{y}_{i-1} - \bar{y}_i)}{\bar{y}_{i-1}\bar{y}_i}, \quad i = \overline{0, m-1}, \tag{2.33}$$

and

$$\bar{y}_i\bar{y}_{i+1} = \bar{y}_i + p, \quad i = \overline{0, m-1}. \tag{2.34}$$

From (2.33) it follows that

$$\prod_{i=0}^{m-1}(\bar{y}_{i+1} - \bar{y}_i)\left(\prod_{i=0}^{m-1}\bar{y}_i\right)^2 = (-1)^m p^m \prod_{i=0}^{m-1}(\bar{y}_{i+1} - \bar{y}_i), \tag{2.35}$$

from which along with (2.32) we immediately get a contradiction when m is an odd number. If m is an even number we get

$$\left(\prod_{i=0}^{m-1}\bar{y}_i\right)^2 = p^m. \tag{2.36}$$

On the other hand, from (2.34) we have

$$\left(\prod_{i=0}^{m-1}\bar{y}_i\right)^2 = \prod_{i=0}^{m-1}(\bar{y}_i + p). \tag{2.37}$$

From (2.36) and (2.37) and since

$$\prod_{i=0}^{m-1}(\bar{y}_i + p) \geq \prod_{i=0}^{m-1}(\bar{y} + p) > p^m \tag{2.38}$$

we get a contradiction.

If we assume that the inequality

$$y_n \leq \bar{y},$$

holds eventually, then as above is obtained that the subsequences y_{mk+i}, $k \in \mathbb{N}_{-1}$, $i = \overline{0, m-1}$, are nonincreasing and convergent, whereas the proof that the algebraic system (2.31) in this case, does not have a nontrivial solution follows by using the same argument and the inequalities

$$\prod_{i=0}^{m-1}(\bar{y}_i + p) \geq \prod_{i=0}^{m-1}(p+1) > p^m$$

first of which follows from the first inequality in (1.13). □

Concerning the proof of the claim *(b)* in Theorem 1.7, it is quite confusing. Namely, the number k is not specified at all. It does not have any connection with the claim of the theorem and the proof given therein is incorrect.

Here we formulate a claim which should generalize what should have been the claim of Theorem 1.7 *(b)* and give a detailed and complete proof.

Before it, we quote the following convention: a positive semicycle of a solution $(y_n)_{n\in\mathbb{N}_{-m}}$ to a difference equation is a finite or infinite subsequence/string $y_l, y_{l+1}, \dots, y_{N-1}$ satisfying the condition

$$y_j \geq \bar{y}, \quad j = \overline{l, N-1},$$

with $l \geq -m$ and $N \leq +\infty$, such that either $l = -m$, or $l > -m$ and $y_{l-1} < \bar{y}$, and either $N = +\infty$, or $N < +\infty$ and $y_N < \bar{y}$; a negative semicycle of a solution $(y_n)_{n\in\mathbb{N}_{-m}}$ to the difference equation is a finite or infinite subsequence/string $y_l, y_{l+1}, \dots, y_{N-1}$ satisfying the condition

$$y_j < \bar{y}, \quad j = \overline{l, N-1},$$

with $l \geq -m$ and $N \leq +\infty$, such that either $l = -m$, or $l > -m$ and $y_{l-1} \geq \bar{y}$, and either $N = +\infty$, or $N < +\infty$ and $y_N \geq \bar{y}$.

Theorem 2.10. *Let $A > 0$, $m \in \mathbb{N}$ and $g : \mathbb{R}_+ \to \mathbb{R}_+$ be a nondecreasing continuous function. Consider the difference equation*

$$y_{n+1} = A + \frac{y_n}{y_{n-m} g(y_{n-m})}, \quad n \in \mathbb{N}_0. \tag{2.39}$$

If a solution to equation (2.39) has a semi-cycle of length at least m, then every semi-cycle after that has at least $m+1$ terms.

Proof. First note that equation (2.39) has a unique positive equilibrium $\bar{y}$ which satisfies the relation

$$\bar{y} = A + \frac{1}{g(\bar{y})}. \tag{2.40}$$

Indeed the function

$$f(t) := A + \frac{1}{g(t)}$$

is a positive nonincreasing continuous function, from which the claim follows.

Let $y_{N-m}, y_{N-m+1}, \dots, y_{N-1}$ be a semi-cycle of length at least m. We may assume that it is a negative one and that $y_N \geq \bar{y}$. So, we have

$$\max\{y_{N-m}, y_{N-m+1}, \dots, y_{N-1}\} < \bar{y} \leq y_N. \tag{2.41}$$

We may also assume that $N - m \geq 1$.

From (2.40), (2.41), the monotonicity of the function g, and since

$$y_n > A, \quad n \in \mathbb{N},$$

we have

$$y_{N+1} = A + \frac{y_N}{y_{N-m} g(y_{N-m})} \geq A + \frac{y_N}{y_{N-m} g(\bar{y})} > A + \frac{1}{g(\bar{y})} = \bar{y}. \tag{2.42}$$

If we have proved that

$$y_{N+i} \geq \bar{y}$$

for some $0 \leq i < m$, then similar to (2.42) we have

$$y_{N+i+1} = A + \frac{y_{N+i}}{y_{N+i-m}g(y_{N+i-m})} \geq A + \frac{y_{N+i}}{y_{N+i-m}g(\bar{y})} > A + \frac{1}{g(\bar{y})} = \bar{y}. \tag{2.43}$$

From the relations in (2.42) and (2.43), and employing the method of mathematical induction, we obtain that

$$y_{N+i} \geq \bar{y},$$

for $i = \overline{0, m}$, proving the claim for the case of the first semi-cycle after the chosen one.

If $y_{N-m}, y_{N-m+1}, \ldots, y_{N-1}$ is a positive semi-cycle of length at least m and $y_N < \bar{y}$, that is

$$\min\{y_{N-m}, y_{N-m+1}, \ldots, y_{N-1}\} \geq \bar{y} > y_N,$$

the proof is similar/dual, so is omitted.

Repeating the same procedure/arguments for the each next semi-cycle the theorem follows. □

A historical remark. A slightly different version of this paper was submitted to the Journal of Applied Mathematics and Computing on February 19, 2023. However, the paper has not been accepted for publication in the journal, and we have not received a real scientific explanation for the unexpected (at least for us) decision.

Author contributions. S. Stević initiated the investigation, proposed many ideas and methods, and conducted detailed investigations. B. Iričanin and W. Kosmala analyzed the proposed ideas, made some calculations, and gave some comments. All authors read and approved the final manuscript.

Funding. This research was supported by Project F-29 'Nonlinear Difference Equations, their Solvability and Asymptotic Behavior of their Solutions' of the Serbian Academy of Sciences and Arts. This work was partially supported by the Ministry of Science, Technological Development and Innovation of the Republic of Serbia under contract number: 451-03-137/2025-03/200103. Abstract. We prove the existence of at least one positive periodic solution for a second-order damped nonlinear differential equation with an indefinite singularity by assuming the corresponding linear equation have a positive Green's function. Our results are applicable to a weak singularity as well as a strong singularity. The proof is based on the Leray–Schauder alternative principle.

Keywords: Leray–Schauder alternative principle, Green's function, indefinite singularity, positive periodic solution.

2020 Mathematics Subject Classification: 34B16, 34B18, 34C25.

1 Introduction

The main purpose of this paper is to investigate the existence of a positive periodic solution for the following damped indefinite singular equation

$$x'' + p(t)x' + q(t)x = \frac{b(t)}{x^\rho} + e(t), \tag{1.1}$$

where ρ is a real constant and $\rho > 0$, q and $e \in C(\mathbb{R}/\omega\mathbb{Z})$ are positive, $p \in C(\mathbb{R}/\omega\mathbb{R})$, $b \in C^1(\mathbb{R}/\omega\mathbb{Z})$, the weight term b may have zero, even it may change sign. Moreover, note that when $p(t) \equiv 0$, equation (1.1) reduces to

$$x'' + q(t)x = \frac{b(t)}{x^\rho} + e(t). \tag{1.2}$$

According to the relevant literature [21], the singular term $\frac{b(t)}{x^\rho}$ represents a singularity of repulsive type in the case that $b(t) > 0$ for all $t \in [0, \omega]$, and a singularity of attractive type in the case that $b(t) < 0$ for all $t \in [0, \omega]$. Additionally, equation (1.1) is said to satisfy the strong force condition if $\rho \geq 1$ and the weak force condition if $0 < \rho < 1$.

In recent years, Schauder's fixed point theorem [10,23,26], the method of lower and upper solutions [15,17,27,28], the Leray–Schauder alternative principle [9,20,22], Krasnoselskii's fixed point theorem in cones [29,30], and coincidence degree theory [5,7,32] have been employed to investigate the existence of positive periodic solutions for equations (1.1) and (1.2) with the weight term $b(t) > 0$ or $b(t) < 0$ for all $t \in [0,\omega]$(i.e. singularity of repulsive or attractive type).

Recently, several intriguing results have been obtained on differential equations with an indefinite singularity [1,8,13,18,24], which are significant both in theory and in practice. In this paper, we aim to establish the existence of a positive periodic solution for equation (1.1) by applying the Leray–Schauder alternative principle.

Depending on the sign of the weight term b, equation (1.1) may exhibit both attractive and repulsive singularities depending on the variable t, even the singularity can vanish in certain subintervals where the weight term b equals zero. Since the weight term b of the above papers [7–10,20,22,23,26,27,29,30,32] does not change sign, the methods employed in these works are no longer applicable to proving the existence of a positive periodic solution for equation (1.1) with an indefinite singularity. Thus, an alternative approach is required to overcome these difficulties. To address the issue of an indefinite singularity (i.e., the singular term that may change sign), we introduce the change of variable $x = u^\alpha$ with $\alpha = \frac{1}{\rho+1}$ and $\alpha < 1$. This transformation simplifies equation (1.1) into a more easily treatable singular equation

$$u'' + p(t)u' + \frac{1}{\alpha}q(t)u = \frac{e(t)}{\alpha}u^{1-\alpha} + (1-\alpha)\frac{u'^2}{u} + \frac{b(t)}{\alpha}. \tag{1.3}$$

It is readily seen that the existence of a positive periodic solution to equation (1.1) reduces to proving the existence of a positive periodic solution for equation (1.3). A similar transformation method has also appeared in the literature [12].

Our purpose is to show that the Leray–Schauder alternative principle can be applied to indefinite singular equation (1.1). The rest of this paper is organized as follows. In section 2, Green's function is provided, and its positivity is obtained. In section 3, in order to facilitate the study of equation (1.3), we first study the following damped singular differential equation

$$u'' + p(t)u' + \ell(t)u = f(t,u,u') + m(t), \tag{1.4}$$

where $\ell(t) := \frac{1}{\alpha}q(t)$, $m(t) := \frac{b(t)}{\alpha}$, $f \in C(\mathbb{R}\times(0,+\infty)\times\mathbb{R},\mathbb{R})$ is ω-periodic with respect to t and exhibits a singularity of repulsive type at $u = 0$. By applying the Leray–Schauder alternative principle, we prove that equation (1.4) has at least one positive periodic solution. Afterwards, we obtain the existence of a positive periodic solution for equation (1.1), and the results are applicable to both strong and weak singularities.

2 Positivity of Green's function

We consider the following nonhomogeneous linear differential equation

$$\begin{cases} u'' + p(t)u' + \ell(t)u = h(t), \\ u(0) = u(\omega),\ u'(0) = u'(\omega), \end{cases} \tag{2.1}$$

where $h \in C(\mathbb{R}/\omega\mathbb{Z})$. Equation (2.1) has a unique ω-periodic solution which can be written as

$$u(t) = \int_0^\omega G(t,s)h(s)ds,$$

where $G(t,s)$ is the Green's function of equation (2.1). Throughout this paper, we assume that

(A) The Green's function $G(t,s)$ of equation (2.1) is positive for all $(t,s) \in [0,\omega] \times [0,\omega]$.

The rest part of this section is to make a brief on some known sufficient conditions to guarantee condition (A) is satisfied. We will discuss the following three cases.

Case I. The general case $p \in C(\mathbb{R}/\omega\mathbb{R})$.

Define functions

$$\varsigma(p)(t) = \exp\left(\int_0^t p(s)ds\right)$$

and

$$\varsigma_1(p)(t) = \varsigma(p)(\omega)\int_0^t \varsigma(p)(s)ds + \int_t^\omega \varsigma(p)(s)ds.$$

Lemma 2.1 (see [16]). *Assume that $\ell(t) \geq 0$ and $\ell \not\equiv 0$ and the following two inequalities are satisfied*

$$\int_0^\omega \ell(s)\varsigma(p)(s)\varsigma_1(-p)(s)ds \geq 0 \tag{2.2}$$

and

$$\sup_{0\leq t\leq\omega}\left\{\int_t^{t+\omega}\varsigma(-p)(s)ds, \int_t^{t+\omega}\ell(s)\varsigma(p)(s)ds\right\} \leq 4. \tag{2.3}$$

Then condition (A) holds.

Case II. Special case $\bar{p} := \frac{1}{\omega}\int_0^\omega p(t)dt > 0$.

In 2005, Wang et al. [31, Lemma 2.4] discussed the positivity of Green's function $G(t,s)$ for all $(t,s) \in [0,\omega] \times [0,\omega]$ if the following conditions are satisfied:

(A_1) There are continuous ω-periodic functions $a_1(t)$ and $a_2(t)$ such that $\int_0^\omega a_1(t)dt > 0$, $\int_0^\omega a_2(t)dt > 0$ and

$$a_1(t) + a_2(t) = p(t), \qquad a_1'(t) + a_1(t)a_2(t) = \ell(t), \quad \text{for } t \in [0,\omega].$$

(A_2) $\bar{p}^2 \geq 4\omega^2 \exp\left(\frac{1}{\omega}\int_0^\omega \ln \ell(s)ds\right)$.

Obviously, condition (A_2) is hard restrictive for the positivity of the Green's function. After that, Cheng and Ren [7] in 2018 discussed the positivity of the Green's function for all $(t,s) \in [0,\omega] \times [0,\omega]$ if only condition (A_1) is satisfied.

Case III. Special case $\bar{p} = 0$.

Define

$$D(\iota) = \begin{cases} \left(\frac{2\pi}{\iota}\right)^{1/2}\left(\frac{2}{2+\iota}\right)^{1/2-1/\iota}\frac{\Gamma(1/\iota)}{\Gamma(1/2+1/\iota)}, & \text{if } 1 \leq \iota < \infty, \\ 2, & \text{if } \iota = \infty, \end{cases}$$

where Γ is the Gamma function with $\Gamma(t) = \int_0^{+\infty} x^{t-1}e^{-x}dx$.

Lemma 2.2 (see [3, Theorem 5.1]). *Assume that $\bar{p} = 0$ and $\int_0^\omega \varsigma(p)(t)\ell(t)dt > 0$. Suppose further that there exists $1 \leq \xi \leq \infty$ such that*

$$(\Upsilon_1(\omega))^{1+1/\iota}\|\Upsilon_2\|_\xi < D^2(2\iota), \tag{2.4}$$

where $\Upsilon_1(\omega) = \int_0^\omega \varsigma(-p)(t)dt$, $\Upsilon_2(t) = \ell_+(t)(\varsigma(p)(t))^{2-1/\xi}$, $\|\Upsilon_2\|_\xi = \left(\int_0^\omega |\Upsilon_2(t)|^\xi dt\right)^{\frac{1}{\xi}}$.
Then condition (A) holds.

In follows what, we consider the case that $p(t) \equiv 0$.

Remark 2.3 (see [25, Corollary 2.3]). In the case $p(t) \equiv 0$, define

$$\widetilde{D}(\tilde{\iota}) = \begin{cases} \frac{2\pi}{\tilde{\iota}\omega^{1+2/\tilde{\iota}}} \left(\frac{2}{2+\tilde{\iota}}\right)^{1-2/\tilde{\iota}} \left(\frac{\Gamma(1/\tilde{\iota})}{\Gamma(1/2+1/\tilde{\iota})}\right)^2, & \text{if } 1 \le \tilde{\iota} < \infty, \\ \frac{4}{\omega}, & \text{if } \tilde{\iota} = \infty, \end{cases}$$

Assume that $\ell \in L^{\zeta}(0,\omega)$ for $1 \le \zeta \le \infty$ and $\ell(t) \ge 0$ for almost every $t \in [0,\omega]$. If

$$\|\ell\|_{\zeta} := \left(\int_0^{\omega} |\ell(t)|^{\zeta} dt\right)^{\frac{1}{\zeta}} < \widetilde{D}(2\zeta^*),$$

where $\zeta^* = \frac{\zeta}{\zeta-1}$ if $1 \le \zeta < \infty$ and $\zeta^* = 1$ if $\zeta = +\infty$, then the Green's function $G(t,s)$ is positive for all $(t,s) \in [0,\omega] \times [0,\omega]$.

Remark 2.4 (see [19, Lemma 2.5]). In the case $p(t) \equiv 0$ and $\ell(t) = \delta^2$ with $\delta > 0$ and $\delta \ne \frac{2k\pi}{\omega}$ for any natural k, the Green's function has the form

$$G_1(t,s) = \begin{cases} \dfrac{\cos\delta(t-s-\frac{\omega}{2})}{2\delta \sin\frac{\delta\omega}{2}}, & 0 \le s \le t \le \omega, \\ \dfrac{\cos\delta(t-s+\frac{\omega}{2})}{2\delta \sin\frac{\delta\omega}{2}}, & 0 \le t < s \le \omega. \end{cases}$$

If $\delta < \frac{\pi}{\omega}$, then Green's function $G_3(t,s)$ is positive for all $(t,s) \in [0,\omega] \times [0,\omega]$.

In this context, the general mechanism for the construction of Green functions in this context is described in [2,4].

3 Main results

In this section, we prove the existence of a positive periodic solution for equation (1.1). First, defined $X := \{u \in C^1 : u(t+\omega) \equiv u(t), \text{ for all } t \in (R)\}$ with the norm $\|u\| := \max_{t\in\mathbb{R}} |u(t)|$, X is a normed linear space (not complete). Our proof is based on the following Leray–Schauder alternative principle, which can be found in [14, p. 120-130].

Lemma 3.1. *Assume that Ω is an open subset of a convex set K in a normed linear space X and $\beta \in \Omega$. Let $T : \bar{\Omega} \to K$ be a compact map. Then one of the following two conclusions holds:*

(I) T has at least one fixed point in $\bar{\Omega}$.

(II) There exist $u \in \partial\Omega$ and $0 < \lambda < 1$ such that $u = \lambda Tu + (1-\lambda)\beta$.

From condition (A), we denote

$$\mathcal{A} := \min_{0\le s,t\le\omega} G(t,s), \qquad \mathcal{B} := \max_{0\le s,t\le\omega} G(t,s), \qquad \sigma := \frac{\mathcal{A}}{\mathcal{B}}, \qquad \iota := \frac{\max_{0\le s,t\le\omega} \left|\frac{\partial G(t,s)}{\partial t}\right|}{\mathcal{A}}. \tag{3.1}$$

It is clear that $0 < \mathcal{A} \le \mathcal{B}$ and $0 < \sigma \le 1$.

Define the function $\gamma : \mathbb{R} \to \mathbb{R}$ by

$$\gamma(t) := \int_0^{\omega} G(t,s)m(s)ds,$$

which is the unique ω-periodic solution of the following equation

$$u''(t) + p(t)u'(t) + \ell(t)u(t) = m(t).$$

Denote

$$\gamma_* := \min_{t\in\mathbb{R}} \gamma(t) \quad \text{and} \quad \gamma^* := \max_{t\in\mathbb{R}} \gamma(t).$$

3.1 The case $\gamma_* \geq 0$

Theorem 3.2. *Assume that condition (A) and $0 \leq \bar{p}\omega < 1$ hold. Furthermore, assume that the following conditions are satisfied:*

(H_1) *For each constant $L > 0$, there exists a continuous function $\phi_L \succ 0$ such that $f(t,u,y) \geq \phi_L(t)$ for all $(t,u,y) \in [0,\omega] \times (0,L] \times \mathbb{R}$, where $\phi_L(t) \succ 0$ represents $\phi_L(t) \geq 0$ for almost every $t \in [0,\omega]$.*

(H_2) *There exist continuous non-negative functions k, φ, ϱ and continuous positive function g such that*

$$0 \leq f(t,u,y) \leq g(u)\varrho(|y|) + k(t)\varphi(u) \quad \text{for all } (t,u,y) \in [0,\omega] \times (0,\infty) \times \mathbb{R},$$

and $g(u)$ is non-increasing, $\varphi(u)/g(u)$ is non-decreasing and $\varrho(\cdot)$ is non-decreasing in $(0,+\infty)$.

(H_3) *There exists a positive real constant r such that*

$$\frac{r}{g(\sigma r + \gamma_*)\left(\varrho\left(\left|\frac{r\bar{\ell}\omega}{1-\bar{p}\omega} + \gamma'^*\right|\right) + \frac{\|k\|\varphi(r+\gamma^*)}{g(r+\gamma^*)}\right)} > \Lambda^*,$$

where $\Lambda(t) := \int_0^\omega G(t,s)ds$ and $\|k\| = \max_{t\in[0,\omega]} k(t)$.

If $\gamma_* \geq 0$, then equation (1.4) has at least one positive ω-periodic solution u with $u(t) > \gamma(t)$ for all $t \in [0,\omega]$ and $0 < \|u - \gamma\| < r$.

Proof. Consider equation

$$u''(t) + p(t)u'(t) + \ell(t)u(t) = f(t, u(t) + \gamma(t), u'(t) + \gamma'(t)). \tag{3.2}$$

It is easy to see that if equation (3.2) has a positive ω-periodic solution u satisfying $u(t) + \gamma(t) > 0$ for $t \in [0,\omega]$ and $0 < \|u\| < r$, then $v(t) := u(t) + \gamma(t)$ is a positive ω-periodic solution of equation (1.4) with $0 < \|v - \gamma\| < r$. So we just need to consider equation (3.2).

Since condition (H_3) holds, we choose $n_0 \in \{1,2,\ldots\}$ such that $\frac{1}{n_0} < \sigma r + \gamma_*$ and

$$\Lambda^* g(\sigma r + \gamma_*)\left(\varrho\left(\left|\frac{r\bar{\ell}\omega}{1-\bar{p}\omega} + \gamma'^*\right|\right) + \frac{\|k\|\varphi(r+\gamma^*)}{g(r+\gamma^*)}\right) + \frac{1}{n_0} < r.$$

Let $N_0 = \{n_0, n_0+1, \ldots\}$. Consider the family of equations

$$u'' + p(t)u' + \ell(t)u = \lambda f_n(t, u(t) + \gamma(t), u'(t) + \gamma'(t)) + \frac{\ell(t)}{n}, \tag{3.3}$$

where $\lambda \in [0,1]$, and

$$f_n(t,u,y) = \begin{cases} f(t,u,y) & \text{if } u \geq \frac{1}{n}, \\ f(t,\frac{1}{n},y) & \text{if } u < \frac{1}{n}. \end{cases}$$

An ω-periodic solution of equation (3.3) is just a fixed point of operator equation

$$u = \lambda T_n u + (1-\lambda)\beta, \tag{3.4}$$

where $\beta := \frac{1}{n}$ and T_n is a continuous operator defined by

$$(T_n u)(t) := \int_0^\omega G(t,s) f_n(s, u(s)+\gamma(s), u'(s)+\gamma'(s))ds + \frac{1}{n}, \tag{3.5}$$

where we used the fact $\int_0^\omega G(t,s)\ell(s)ds \equiv 1$ from [25, Corollary 2.3] and $G(t,s) > 0$ for all $(t,s) \in [0,\omega]\times[0,\omega]$ from condition (A).

Define

$$K := \{u \in X : u(t) > 0 \text{ for all } t \in \mathbb{R}\},$$

and

$$B_r := \{u \in K : \|u\| < r\},$$

where X and r are defined in Section 3 and Theorem 3.2, respectively. Obviously, B_r is an open subset in K. Further, for any $u \in \overline{B_r}$, it follows from (A) and (H_1) that

$$(T_n u)(t) = \int_0^\omega G(t,s) f_n(s, u(s)+\gamma(s), u'(s)+\gamma'(s))ds + \frac{1}{n} \geq \frac{1}{n} > 0,$$

which implies $T_n(\overline{B_r}) \subset K$. Besides, by using the Arzelà–Ascoli Theorem, it is easy to verify that $T_n : \overline{B_r} \to K$ is completely continuous.

Next, we claim that any fixed point u of equation (3.4) for any $\lambda \in (0,1)$ must satisfy $\|u\| \neq r$. Otherwise, assume that u is a fixed point of equation (3.4) for $\lambda \in (0,1)$ such that $\|u\| = r$. Then, we give

$$\begin{aligned}
u(t) - \frac{1}{n} &= \lambda \int_0^\omega G(t,s) f_n(s, u(s)+\gamma(s), u'(s)+\gamma'(s))ds \\
&\geq \lambda\mathcal{A} \int_0^\omega f_n(s, u(s)+\gamma(s), u'(s)+\gamma'(s))ds \\
&= \lambda\sigma\mathcal{B} \int_0^\omega f_n(s, u(s)+\gamma(s), u'(s)+\gamma'(s))ds \\
&\geq \sigma \max_{t\in\mathbb{R}} \left\{ \lambda \int_0^\omega G(t,s) f_n(s, u(s)+\gamma(s), u'(s)+\gamma'(s))ds \right\} \\
&= \sigma \left\| u - \frac{1}{n} \right\|.
\end{aligned}$$

Therefore, we obtain

$$u(t) \geq \sigma\|u - \frac{1}{n}\| + \frac{1}{n} \geq \sigma\left(\|u\| - \frac{1}{n}\right) + \frac{1}{n} \geq \sigma r,$$

and then

$$u(t) + \gamma(t) \geq \sigma r + \gamma_* > \frac{1}{n},$$

since $\frac{1}{n} \leq \frac{1}{n_0} < \sigma r + \gamma_*$.

Further, we claim that

$$\|u'\| \leq \frac{r\bar{\ell}\omega}{1 - \bar{p}\omega} \tag{3.6}$$

for any ω-periodic solution $u(t)$ of equation (3.3). Integrating equation (3.3) over the interval $[0,\omega]$, we see that

$$\int_0^\omega p(t)u'(t)dt + \int_0^\omega \ell(t)u(t)dt = \lambda \int_0^\omega f_n(t,u(t)+\gamma(t),u'(t)+\gamma'(t))dt + \int_0^\omega \frac{\ell(t)}{n}dt. \quad (3.7)$$

Since $u(0) = u(\omega)$, we know that there exists a point $t_1 \in (0,\omega)$ such that $u'(t_1) = 0$. Therefore, we get

$$\begin{aligned}
\|u'\| &= \max_{t\in\mathbb{R}} \left|\frac{1}{2}(u'(t)+u'(t-\omega))\right| \\
&= \max_{t\in\mathbb{R}} \frac{1}{2}\left|\int_{t_1}^{t} u''(s)ds - \int_{t-\omega}^{t_1} u''(s)ds\right| \\
&\le \frac{1}{2}\int_0^\omega |u''(s)|ds \qquad (3.8)\\
&= \frac{1}{2}\left(\int_0^\omega \left|\lambda f_n(t,u(t)+\gamma(t),u'(t)+\gamma'(t)) + \frac{\ell(t)}{n} - \ell(t)u(t) - p(t)u'(t)\right| dt\right) \\
&\le \frac{1}{2}\int_0^\omega \left(\lambda f_n(t,u(t)+\gamma(t),u'(t)+\gamma'(t)) + \frac{\ell(t)}{n} + \ell(t)u(t)\right) dt + \frac{1}{2}\|u'\|\bar{p}\omega
\end{aligned}$$

since $f(t,u,u') > 0$, $\ell(t) > 0$ and $\bar{p} \ge 0$. Applying (3.7) to (3.8), we obtain

$$\begin{aligned}
\|u'\| \le& \int_0^\omega \ell(t)u(t)dt + \frac{1}{2}\int_0^\omega p(t)u'(t)dt + \frac{1}{2}\|u'\|\int_0^\omega p(t)dt \\
=& r\bar{\ell}\omega + \|u'\|\bar{p}\omega.
\end{aligned}$$

Since $1-\bar{p}\omega > 0$, then we deduce

$$\|u'\| \le \frac{r\bar{\ell}\omega}{1-\bar{p}\omega},$$

which proves that (3.6) holds.

On the other hand, it follows from conditions (H_2) and (H_3) that

$$\begin{aligned}
u(t) &= \lambda\int_0^\omega G(t,s)f_n(s,u(s)+\gamma(s),u'(s)+\gamma'(s))ds + \frac{1}{n} \\
&= \lambda\int_0^\omega G(t,s)f(s,u(s)+\gamma(s),u'(s)+\gamma'(s))ds + \frac{1}{n} \\
&\le \int_0^\omega G(t,s)(g(u(s)+\gamma(s))\varrho(|u'(s)+\gamma'(s)|) + k(s)\varphi(u(s)+\gamma(s)))ds + \frac{1}{n} \\
&= \int_0^\omega G(t,s)g(u(s)+\gamma(s))\left(\varrho(|u'(s)+\gamma'(s)|) + \frac{k(s)\varphi(u(s)+\gamma(s))}{g(u(s)+\gamma(s))}\right)ds + \frac{1}{n} \\
&\le g(\sigma r+\gamma_*)\left(\varrho\left(\left|\frac{r\bar{\ell}\omega}{1-\bar{p}\omega}+\gamma'^*\right|\right) + \frac{\|k\|\varphi(r+\gamma^*)}{g(r+\gamma^*)}\right)\Lambda^* + \frac{1}{n_0},
\end{aligned}$$

which implies

$$r = \|u\| \le g(\sigma r+\gamma_*)\left(\varrho\left(\left|\frac{r\bar{\ell}\omega}{1-\bar{p}\omega}+\gamma'^*\right|\right) + \frac{\|k\|\varphi(r+\gamma^*)}{g(r+\gamma^*)}\right)\Lambda^* + \frac{1}{n_0}.$$

This is a contradiction with the choice of n_0 and the claim is proved.

From this claim, Lemma 3.1 guarantees that

$$u = T_n u$$

has a fixed point, denoted by u_n in B_r. Then, we get

$$u'' + p(t)u' + \ell(t)u = f_n(t, u(t) + \gamma(t), u'(t) + \gamma'(t)) + \frac{\ell(t)}{n} \tag{3.9}$$

has an ω-periodic solution u_n with $\|u_n\| \le r$. Since $u_n(t) + \gamma(t) \ge \frac{1}{n} > 0$ for all $n > n_0$, $t \in \mathbb{R}$, u_n is actually a positive ω-periodic solution of equation (3.9).

From condition (H_1), there exists a continuous function $\phi_r(t) \ge 0$ such that $f(t,u,y) \ge \phi_r(t)$ for all $(t,u,y) \in [0,\omega] \times (0,r] \times \mathbb{R}$. Since $u_n(t) + \gamma(t) \ge \frac{1}{n} > 0$ for all $n > n_0$, $t \in \mathbb{R}$ and $\gamma_* \ge 0$, we have

$$\begin{aligned} u_n(t) + \gamma(t) &= \int_0^\omega G(t,s) f_n(s, u_n(s) + \gamma(s), u_n'(s) + \gamma'(s)) ds + \gamma(t) + \frac{1}{n} \\ &= \int_0^\omega G(t,s) f(s, u_n(s) + \gamma(s), u_n'(s) + \gamma'(s)) ds + \gamma(t) + \frac{1}{n} \\ &\ge \int_0^\omega G(t,s) \phi_{r+\gamma^*} ds + \gamma(t) \\ &\ge \Phi_* + \gamma_* =: \vartheta, \end{aligned} \tag{3.10}$$

where $\Phi(t) = \int_0^\omega G(t,s)\phi_{r+\gamma^*}(s)ds$. Since $G(t,s)$ is regular and $\phi_{r+\gamma^*}(s) > 0$, it follows that $\Phi_* > 0$. So we have $u_n(t) + \gamma(t) \ge \vartheta$.

Similar to the proof of equation (3.6), we get

$$\|u_n'\| \le \frac{r\bar{\ell}\omega}{1 - \bar{p}\omega}, \quad \text{for all } n \ge n_0. \tag{3.11}$$

Further, it follows from (3.9) and (3.11) that

$$\begin{aligned} \|u_n''\| &\le \left| p(t)u_n'(t) + \ell(t)u_n(t) + \lambda f_n(t, u_n(t) + \gamma(t), u_n'(t) + \gamma'(t)) + \frac{\ell(t)}{n} \right| \\ &\le \frac{r\|p\|\bar{\ell}\omega}{1 - \bar{p}\omega} + \|\ell\| r + \|f\| + \frac{\|\ell\|}{n_0} := M_1, \end{aligned}$$

where $\|f\| := \max_{\vartheta \le u_n + \gamma \le r + \gamma^*, \|u_n'\| \le \frac{r\bar{\ell}\omega}{1-\bar{p}\omega}} |f(t, u_n(t) + \gamma(t), u_n'(t) + \gamma'(t))|$.

In consequence, $\{u_n\}_{n\in N_0}$ and $\{u_n'\}_{n\in N_0}$ are bounded and equi-continuous family in C_ω^1. Now the Arzelà–Ascoli theorem guarantees that $\{u_n\}_{n\in N_0}$ has a subsequence $\{u_{n_j}\}_{j\in N_0}$, converging uniformly on $\mathbb{R}$ to a function $u \in C_\omega^1$. From the fact $\|u_n\| \le r$ and $\vartheta \le u_n + \gamma$, u satisfies $\vartheta \le u(t) + \gamma(t) \le r + \gamma^*$ for all t. Moreover, u_{n_j} satisfies the integral equation

$$u_{n_j}(t) = \int_0^\omega G(t,s) f(s, u_{n_j}(s) + \gamma(s), u_{n_j}'(s) + \gamma'(s)) ds + \frac{1}{n_j}.$$

Letting $j \to \infty$, we get

$$u(t) = \int_0^\omega G(t,s) f(s, u(s) + \gamma(s), u'(s) + \gamma'(s)) ds.$$

Therefore, u is a positive periodic solution of equation (3.2) and satisfies $0 < \|u\| \le r$. Besides, it is not difficult to show that $\|u\| < r$, by noting that if $\|u\| = r$, the argument similar to the proof of the first claim will lead to a contradiction. □

By Theorem 3.2, we get the following conclusion.

Corollary 3.3. *Assume that condition* (A), $0 \le \bar{p}\omega < 1$ *and* $\gamma_* \ge 0$ *hold. Furthermore, assume that the nonlinear term* f *satisfies the following condition:*

(F_1) *There exist positive constants* κ, ν, μ, η, ϵ *with* $\epsilon \le \nu + 1$ *such that*

$$f(t,u,y) = \kappa \frac{(|y|^\epsilon + 1)}{u^\nu} + \mu e(t) u^\eta, \quad \text{for all } (t,u,y) \in [0,\omega] \times (0,+\infty) \times \mathbb{R},$$

where $e(t) \in C(\mathbb{R}/\omega\mathbb{Z})$ *is positive.*

(i) If $\eta < 1$, *then equation* (1.4) *has at least one positive* ω*-periodic solution for each* $\mu > 0$.

(ii) If $\eta \ge 1$, *then equation* (1.4) *has at least one positive* ω*-periodic solution for each* $0 < \mu < \mu_1$, *where* μ_1 *is a positive constant.*

Proof. We apply Theorem 3.2. Take

$$\phi_L(t) = \frac{\kappa}{L^\nu}, \quad g(u) = \frac{1}{u^\nu}, \quad \varphi(u) = u^\eta, \quad k(t) = \mu e(t), \quad \varrho(|y|) = \kappa(|y|^\epsilon + 1).$$

Then conditions (H_1) and (H_2) are satisfied and the existence condition (H_3) becomes

$$\mu < \frac{r(\sigma r + \gamma_*)^\nu - \Lambda^* \kappa \left(\left| \frac{r\bar{\ell}\omega}{1-\bar{p}\omega} + \gamma'^* \right|^\epsilon + 1 \right)}{\Lambda^* \|e\| (r + \gamma^*)^{\eta+\nu}}$$

for $r > 0$. Therefore, equation (1.4) has at least one positive periodic solution for

$$0 < \mu < \mu_1 := \sup_{r>0} \frac{r(\sigma r + \gamma_*)^\nu - \Lambda^* \kappa \left(\left| \frac{r\bar{\ell}\omega}{1-\bar{p}\omega} + \gamma'^* \right|^\epsilon + 1 \right)}{\Lambda^* \|e\| (r + \gamma^*)^{\eta+\nu}}.$$

Note that $\mu_1 = \infty$ if $\eta < 1$ and $\mu_1 < \infty$ if $\eta \ge 1$, we have (i) and (ii). □

Theorem 3.4. *Assume that* $\bar{p} = 0$, $\int_0^\omega \varsigma(p)(t)\ell(t)dt > 0$, *inequality* (2.4) *and conditions* (H_1), (H_2) *hold. Furthermore, assume that the following condition is satisfied:*

(H_4) *There exists a positive real constant* r *such that*

$$\frac{r}{g(\sigma r + \gamma_*) \left(\varrho(|Qr + \gamma'^*|) + \frac{\|k\| \varphi(r+\gamma^*)}{g(r+\gamma^*)} \right)} > \Lambda^*,$$

where $Q := \frac{\int_0^\omega \varsigma(p)(t)\ell(t)dt}{\min_{t\in\mathbb{R}} \varsigma(p)(t)}$.

If $\gamma_* \ge 0$, *then equation* (1.4) *has at least one positive* ω*-periodic solution* u *with* $u(t) > \gamma(t)$ *for all* $t \in [0,\omega]$ *and* $0 < \|u - \gamma\| < r$.

Proof. We follow the same strategy and notations as in the proof of Theorem 3.2. Next, we claim

$$\|u'\| \le Qr \tag{3.12}$$

for any ω-periodic solution u of equation (3.3). Multiplying both sides of equation (3.3) by $\varsigma(p)(t)$, we get

$$(\varsigma(p)(t)u'(t))' + \varsigma(p)(t)\ell(t)u(t) = \varsigma(p)(t) \left(\lambda f_n(t, u(t) + \gamma(t), u'(t) + \gamma'(t)) + \frac{\ell(t)}{n} \right). \tag{3.13}$$

Integrating equation (3.13) over the interval $[0,\omega]$, we obtain

$$\int_0^\omega \varsigma(p)(t)\ell(t)u(t)dt = \int_0^\omega \varsigma(p)(t)\left(\lambda f_n(t,u(t)+\gamma(t),u'(t)+\gamma'(t))+\frac{\ell(t)}{n}\right)dt$$

since $\bar{p}=0$. Because $u(0)=u(\omega)$, we know that there exists a point $t_2\in(0,\omega)$ such that $u'(t_2)=0$. Therefore, it is clear that

$$\begin{aligned}
&|\varsigma(p)(t)u'(t)|\\
&\quad=\max_{t\in\mathbb{R}}\left|\frac{1}{2}(\varsigma(p)(t)u'(t)+\varsigma(p)(t)u'(t-\omega))\right|\\
&\quad=\max_{t\in\mathbb{R}}\frac{1}{2}\left|\int_{t_2}^{t}(\varsigma(p)(s)u'(s))'ds-\int_{t-\omega}^{t_2}(\varsigma(p)(s)u'(s))'ds\right|\\
&\quad\le\frac{1}{2}\int_0^\omega|(\varsigma(p)(t)u'(t))'|dt\\
&\quad\le\frac{1}{2}\left(\int_0^\omega\left|\varsigma(p)(t)\left(\lambda f_n(t,u(t)+\gamma(t),u'(t)+\gamma'(t))+\frac{\ell(t)}{n}\right)-\varsigma(p)(t)\ell(t)u(t)\right|dt\right)\\
&\quad=\frac{1}{2}\int_0^\omega\varsigma(p)(t)\left(\lambda f(t,u(t)+\gamma(t),u'(t)+\gamma'(t))+\frac{\ell(t)}{n}+\ell(t)u(t)\right)dt\\
&\quad=\int_0^\omega\varsigma(p)(t)\ell(t)u(t)dt\\
&\quad=r\int_0^\omega\varsigma(p)(t)\ell(t)dt,
\end{aligned}$$

where we used the assumption

$$\int_0^\omega\varsigma(p)(t)\ell(t)dt>0.$$

Therefore, we obtain

$$\min_{t\in\mathbb{R}}\varsigma(p)(t)u'(t)\le r\int_0^\omega\varsigma(p)(t)\ell(t)dt,$$

which implies (3.12) holds.

The remaining part of the proof the same as in Theorem 3.2. □

By Theorem 3.2 and Corollary 3.3, we obtain the following conclusion.

Corollary 3.5. *Assume that* $\bar{p}=0$, $\int_0^\omega\varsigma(p)(t)\ell(t)dt>0$, *inequality* (2.4), *condition* (F_1) *and* $\gamma_*\ge 0$ *hold.*

(i) If $\eta<1$, *then equation* (1.4) *has at least one positive* ω*-periodic solution for each* $\mu>0$.

(ii) If $\eta\ge 1$, *then equation* (1.4) *has at least one positive* ω*-periodic solution for each* $0<\mu<\mu_1$, *where* μ_1 *is a positive constant.*

Remark 3.6. If the nonlinear term in equation (1.3) is

$$f(t,u,y)=(1-\alpha)\frac{y^2}{u}+\frac{e(t)}{\alpha}u^{1-\alpha}.$$

From Corollary 3.3, it is easy to verify that there is no continuous function $\phi_L(t)$ such that $f(t,u,y)\ge\phi_L(t)$, for all $(t,u,y)\in[0,\omega]\times\mathbb{R}^+\times\mathbb{R}$. Hence, condition (H_1) is not satisfied. In order to get around condition (H_1), we have to study the case $\gamma_*>0$ by applications of Theorem 3.2.

Remark 3.7. It is worth mentioning that, Cheng and Ren [6] investigated the following damped equation:

$$x'' + p(t)x' + q(t)x = f(t,x) + e(t), \tag{3.14}$$

where f has a repulsive singularity at the origin. In this paper, the singular term of equation (1.1) is sign-changing, which exhibits an indefinite singularity. This makes its study more complex compared to equation (3.14). Therefore, the results of this paper can be regarded as a generalization and refinement of those in [6].

3.2 The case $\gamma_* > 0$

Theorem 3.8. *Assume that conditions* (A), (H_2), (H_3) *and* $0 \le \bar{p}\omega < 1$ *hold. If* $\gamma_* > 0$, *then equation* (1.4) *has at least one positive* ω*-periodic solution* u *with* $u(t) > \gamma(t)$ *for all* $t \in [0,\omega]$ *and* $0 < \|u - \gamma\| < r$.

Proof. We follow the same strategy and notations as in the proof of Theorem 3.2. Next, we consider that $u_n(t) + \gamma(t)$ have a uniform positive lower bound, i.e., there exists a constant $\vartheta_1 > 0$, independent of $n \in N_0$, such that

$$\min_{t\in[0,\omega]} \{u_n(t) + \gamma(t)\} \ge \vartheta_1,$$

for all $n \in N_0$.

Because $u_n(t) + \gamma(t) \ge \frac{1}{n} > 0$ for all $n > n_0$, $t \in \mathbb{R}$, it follows from (H_2) and (3.10) that

$$\begin{aligned} u_n(t) + \gamma(t) &= \int_0^\omega G(t,s) f_n(s, u_n(s) + \gamma(s), u_n'(s) + \gamma'(s))ds + \gamma(t) + \frac{1}{n} \\ &\ge \int_0^\omega G(t,s) f(s, u_n(s) + \gamma(s), u_n'(s) + \gamma'(s))ds + \gamma(t) \\ &\ge \gamma_* := \vartheta_1, \end{aligned}$$

since $\gamma_* > 0$. So we have $u_n(t) + \gamma(t) \ge \vartheta_1$. The proof left is the same as Theorem 3.2. □

By Theorem 3.8, we get the following conclusion.

Corollary 3.9. *Assume that condition* (A), $0 \le \bar{p}\omega < 1$ *and* $\gamma_* > 0$ *hold. Furthermore, assume that the nonlinear term* f *satisfies the following condition:*

(F_2) *There exist positive constants* κ, ν, μ', η, ϵ *with* $\epsilon \le \nu + 1$ *such that*

$$f(t,u,y) = \kappa \frac{|y|^\epsilon}{u^\nu} + \mu' e(t) u^\eta, \quad \text{for all } (t,u,y) \in [0,\omega] \times (0,+\infty) \times \mathbb{R}.$$

(i) If $\eta < 1$, *then equation* (1.4) *has at least one positive* ω*-periodic solution for each* $\mu' > 0$.

(ii) If $\eta \ge 1$, *then equation* (1.4) *has at least one positive* ω*-periodic solution for each* $0 < \mu' < \mu_1'$, *where* μ_1' *is a positive constant.*

Proof. We apply Theorem 3.8, and follow the same strategy and notations as in the proof of Corollary 3.3. Take

$$g(u) = \frac{1}{u^\nu}, \quad \varphi(u) = u^\eta, \quad k(t) = \mu' e(t), \quad \varrho(|y|) = \kappa |y|^\epsilon.$$

Then condition (H_2) is satisfied and the existence condition (H_3) becomes

$$\mu' < \frac{r(\sigma r+\gamma_*)^\nu - \Lambda^*\kappa\left|\frac{r\bar{\ell}\omega}{1-\bar{p}\omega}+\gamma'^*\right|^\epsilon}{\Lambda^*\|e\|(r+\gamma^*)^{\eta+\nu}}$$

for $r>0$. Therefore, equation (1.4) has at least one positive ω-periodic solution for

$$0<\mu'<\mu_1' := \sup_{r>0}\frac{r(\sigma r+\gamma_*)^\nu - \Lambda^*\kappa\left|\frac{r\bar{\ell}\omega}{1-\bar{p}\omega}+\gamma'^*\right|^\epsilon}{\Lambda^*\|e\|(r+\gamma^*)^{\eta+\nu}}.$$ □

Similar to the proof of Theorem 3.8, we get the following conclusions.

Theorem 3.10. *Assume that $\bar{p}=0$, $\int_0^\omega \varsigma(p)(t)\ell(t)dt>0$, inequality (2.4), conditions (H_2), (H_4) hold. If $\gamma_*>0$, then equation (1.4) has at least one positive ω-periodic solution u with $u(t)>\gamma(t)$ for all $t\in[0,\omega]$ and $0<\|u-\gamma\|<r$.*

By Corollary 3.9 and Theorem 3.10, we obtain the following conclusion.

Corollary 3.11. *Assume that $\bar{p}=0$, $\int_0^\omega \varsigma(p)(t)\ell(t)dt>0$, inequality (2.4), condition (F_2) and $\gamma_*>0$ hold.*

(i) If $\eta<1$, then equation (1.4) has at least one positive ω-periodic solution for each $\mu'>0$.

(ii) If $\eta\geq 1$, then equation (1.4) has at least one positive ω-periodic solution for each $0<\mu'<\mu_1'$, where μ_1' is a positive constant.

Corollary 3.12. *Let the nonlinear term in equation (1.3) be*

$$f(t,u,y)=(1-\alpha)\frac{y^2}{u}+\frac{e(t)}{\alpha}u^{1-\alpha}.$$

Assume that condition (A), $0\leq\bar{p}\omega<1$ and $\gamma_*>0$ hold. Then equation (1.1) has at least one positive ω-periodic solution.

Proof. We apply Corollary 3.9. Take

$$\kappa=1-\alpha,\quad \epsilon=2,\quad \nu=1,\quad \mu'=\frac{1}{\alpha},\quad \eta=1-\alpha.$$

Then condition (F_2) is satisfied. Since $\eta=1-\alpha<1$, equation (1.1) has at least one positive ω-periodic solution. □

Corollary 3.13. *Let the nonlinear term in equation (1.3) be*

$$f(t,u,y)=(1-\alpha)\frac{y^2}{u}+\frac{e(t)}{\alpha}u^{1-\alpha}.$$

Assume that $\bar{p}=0$, $\int_0^\omega \varsigma(p)(t)\ell(t)dt>0$, inequality (2.4) and $\gamma_*>0$ hold. Then equation (1.1) has at least one positive ω-periodic solution.

3.3 The case $p(t) \equiv 0$

Next, we prove the existence of a positive periodic solution for equation (1.2). We write equation (1.2) as

$$u'' + \ell(t)u = f(t, u, u') + m(t). \tag{3.15}$$

By Theorem 3.2, we obtain the following conclusion.

Theorem 3.14. *Assume that inequality (2.4), conditions (H_1), (H_2) and $\gamma_* \geq 0$ hold. Furthermore, assume that the following condition is satisfied:*

(H_5) *there exists a positive number $r > 0$ such that*

$$\frac{r}{g(\sigma r + \gamma_*)\left(\varrho\left(|r\bar{\ell}\omega + \gamma'^*|\right) + \frac{\|k\|\varphi(r+\gamma^*)}{g(r+\gamma^*)}\right)} > \Lambda^*.$$

Then equation (3.15) has at least one positive ω-periodic solution u with $u(t) > \gamma(t)$ for all $t \in [0, \omega]$ and $0 < \|u - \gamma\| < r$.

Proof. Consider the following equation

$$u''(t) + \ell(t)u(t) = f(t, u(t) + \gamma(t), u'(t) + \gamma'(t)). \tag{3.16}$$

We follow the same strategy and notations as the proof of Theorems 3.2 and 3.4. Now, we claim

$$\|u'\| \leq r\bar{\ell}\omega. \tag{3.17}$$

It follows from (3.8) and (3.16) that

$$\begin{aligned}
\|u'\| &\leq \frac{1}{2}\int_0^\omega |u''(t)|dt \\
&\leq \frac{1}{2}\int_0^\omega \left(\lambda f(t, u(t) + \gamma(t), u'(t) + \gamma'(t)) + \frac{\ell(t)}{n} + \ell(t)u(t)\right) dt \\
&\leq \int_0^\omega \ell(t)u(t)dt \\
&\leq r\bar{\ell}\omega,
\end{aligned}$$

since $f(t, u, u') > 0$ and $\ell(t) > 0$.

The proof left is the same as Theorem 3.2. □

By Theorems 3.8–3.14, Corollaries 3.3–3.13, we get the following conclusions.

Corollary 3.15. *Assume that inequality (2.4), condition (F_1) and $\gamma_* \geq 0$ hold.*

(i) If $\eta < 1$, then equation (3.15) has at least one positive ω-periodic solution for each $\mu > 0$.

(ii) If $\eta \geq 1$, then equation (3.15) has at least one positive ω-periodic solution for each

$$0 < \mu < \sup_{r>0} \frac{r(\sigma r + \gamma_*)^\nu - \Lambda^*\kappa(|r\bar{\ell}\omega + \gamma'^*|^\epsilon + 1)}{\Lambda^*\|e\|(r + \gamma^*)^{\eta+\nu}}.$$

Theorem 3.16. *Assume that inequality (2.4), conditions (H_2) and (H_5) hold. If $\gamma_* > 0$, then equation (3.15) has at least one positive ω-periodic solution u with $u(t) > \gamma(t)$ for all $t \in [0, \omega]$ and $0 < \|u - \gamma\| < r$.*

Corollary 3.17. *Assume that inequality* (2.4), *condition* (F_2) *and* $\gamma_* > 0$ *hold.*

(i) If $\eta < 1$, *then equation* (3.15) *has at least one positive* ω*-periodic solution for each* $\mu' > 0$.

(ii) If $\eta \geq 1$, *then equation* (3.15) *has at least one positive* ω*-periodic solution for each*

$$0 < \mu' < \sup_{r>0} \frac{r(\sigma r + \gamma_*)^\nu - \Lambda^* \kappa |r\bar{\ell}\omega + \gamma'^*|^\epsilon}{\Lambda^* \|e\| (r + \gamma^*)^{\eta+\nu}}.$$

Corollary 3.18. *Let the nonlinear term in equation* (3.15) *be*

$$f(t, u, y) = (1 - \alpha)\frac{y^2}{u} + \frac{e(t)}{\alpha} u^{1-\alpha}.$$

Assume that inequality (2.4) *and* $\gamma_* > 0$ *hold. Then equation* (1.2) *has at least one positive* ω*-periodic solution.*

Remark 3.19. It is worth mentioning that when $p(t) \equiv 0$, Chu et al. [11] studied the following equation:

$$x'' + p(t)x' = f(t, x) + e(t),$$

where f has a repulsive singularity at the origin. When $p(t) \equiv 0$, equation (1.1) exhibits an indefinite singularity, and it is evident that our results encompass those of Reference [11].

Abstract. This paper is concerned with the existence of solutions for parameters dependent Schrödinger–Kirchhoff system driven by nonlocal integro-differential operators with singular Trudinger–Moser nonlinearity in the whole Euclidean space $\mathbb{R}^N$. These parameters have a major impact on the produced analysis. It is noted that, we also study the asymptotic behaviour of solutions depending upon these parameters. The proofs of the existence results to the aforementioned system rely on the mountain pass theorem, the Ekeland variational principle, the classical deformation lemma, and the Krasnoselskii genus theory. The salient feature and novelty of this paper is that it also covers the so-called degenerate case of the Kirchhoff function, that is, it could vanish at zero.

Keywords: nonlocal integro-differential operator, mountain pass theorem, variational principle, genus theory.

2020 Mathematics Subject Classification: 35A15, 35A23, 35D30, 35R11, 35J60.

1 Introduction and main results

In this paper, we study the following nonlocal Schrödinger–Kirchhoff type system:

$$\begin{cases} M(\|(u,v)\|^p)(\mathcal{L}_p^s(u) + V(x)|u|^{p-2}u) = \dfrac{F_u(x,u,v)}{|x|^\gamma} + \lambda h(x)|u|^{q-2}u & \text{in } \mathbb{R}^N, \\ M(\|(u,v)\|^p)(\mathcal{L}_p^s(v) + V(x)|v|^{p-2}v) = \dfrac{F_v(x,u,v)}{|x|^\gamma} + \mu h(x)|v|^{q-2}v & \text{in } \mathbb{R}^N, \end{cases} \tag{$\mathcal{S}_{\lambda,\mu}$}$$

✉Corresponding author. Emails: mahanta.1@iitj.ac.in (D. K. Mahanta), tuhina@iitj.ac.in (T. Mukherjee), thinmath@gmail.com and thinnv@tnue.edu.vn (N. V. Thin)

where $N \geq 1$, $0 < s < 1$, $sp = N$, $1 < q < \infty$, $\gamma \in [0, N)$, λ and μ are two positive parameters, and the norm

$$\|(u,v)\| = \left(\|u\|^p_{W^{s,p}_{K,V}} + \|v\|^p_{W^{s,p}_{K,V}} \right)^{\frac{1}{p}},$$

where for the singular kernel $K : \mathbb{R}^N \setminus \{0\} \to \mathbb{R}^+$ with $\mathbb{R}^+ = (0, \infty)$ and $w \in \{u, v\}$, we define

$$\|w\|_{W^{s,p}_{K,V}} = \left(\int_{\mathbb{R}^N} \int_{\mathbb{R}^N} |w(x) - w(y)|^p K(x-y) \, \mathrm{d}x\mathrm{d}y + \int_{\mathbb{R}^N} V(x)|w|^p \, \mathrm{d}x \right)^{\frac{1}{p}}.$$

Consequently, $M : \mathbb{R}^+_0 \to \mathbb{R}^+_0$ with $\mathbb{R}^+_0 = [0, \infty)$ is a Kirchhoff function, $V : \mathbb{R}^N \to \mathbb{R}$ is a scalar potential, $h : \mathbb{R}^N \to \mathbb{R}^+$ is a measurable function, the functions F_u and F_v are partial derivatives of a Carathéodory function F, of exponential type and $\mathcal{L}^s_p$ is the nonlocal fractional operator which, up to a normalization constant, is defined by

$$\mathcal{L}^s_p \phi(x) = 2 \lim_{\epsilon \to 0^+} \int_{\mathbb{R}^N \setminus B_\epsilon(x)} |\phi(x) - \phi(y)|^{p-2} (\phi(x) - \phi(y)) K(x-y) \, \mathrm{d}y, \qquad \forall \, x \in \mathbb{R}^N,$$

along any $\phi \in C^\infty_0(\mathbb{R}^N)$, where $B_\epsilon(x) = \{y \in \mathbb{R}^N : |x - y| < \epsilon\}$. The singular kernel $K : \mathbb{R}^N \setminus \{0\} \to \mathbb{R}^+$ is a measurable function satisfying the following properties for $sp = N$ and $0 < s < 1$:

(a) $\eta K \in L^1(\mathbb{R}^N)$, where $\eta(x) = \min\{|x|^p, 1\}$.

(b) there exists $K_0 > 0$ such that $K(x) \geq K_0 |x|^{-(N+sp)}$ for any $x \in \mathbb{R}^N \setminus \{0\}$.

In addition, we make a note that from here onwards, $\cdot$ stands for the natural inner product in any Euclidean space $\mathbb{R}^d$ for any dimension $d \geq 1$ and $|\cdot|$ denotes the corresponding Euclidean norm.

Throughout the paper, without further mentioning, we have the following assumptions on the scalar potential V, and the Kirchhoff function M.

(V) The function $V : \mathbb{R}^N \to \mathbb{R}$ is assumed to be continuous and to satisfy:

- (V_1) There exists a constant $V_0 > 0$ such that $\inf_{\mathbb{R}^N} V \geq V_0$.
- (V_2) There exists $h > 0$ such that $\lim_{|y| \to \infty} \text{ meas} \left(\{x \in B_h(y) : V(x) \leq c\} \right) = 0$, $\forall \, c > 0$, where we denote the Lebesgue measure of any set $E \subset \mathbb{R}^N$ by meas(E).

(M) The function $M : \mathbb{R}^+_0 \to \mathbb{R}^+_0$ is assumed to be continuous and to satisfy:

- (M_1) For any $\tau > 0$, there exists $\kappa = \kappa(\tau) > 0$ such that

$$M(t) \geq \kappa, \qquad \forall \, t \geq \tau.$$

- (M_2) There exists $\theta \geq 1$ such that

$$tM(t) \leq \theta \widehat{M}(t), \qquad \forall \, t \in \mathbb{R}^+_0,$$

where

$$\widehat{M}(t) = \int_0^t M(\xi) \, \mathrm{d}\xi.$$

Remark 1.1. The condition (V_2) is weaker than the coercivity assumption, that is, $V(x) \to \infty$ as $|x| \to \infty$.

On concerns about the nonlinearity term F, we have the following assumptions.

(F) The function $F : \mathbb{R}^N \times \mathbb{R}^2 \to \mathbb{R}$ is a Carathéodory function and to satisfy:

(F_1) $F(x,\cdot,\cdot) \in C^1(\mathbb{R}^2)$ for a.e. $x \in \mathbb{R}^N$, $F(x,\cdot,\cdot) \geq 0$ in $\mathbb{R}^2$, $F(x,0,0) = 0$ for a.e. $x \in \mathbb{R}^N$, $F_u(x,u,v) = 0$ for all $u \leq 0$ and $v \in \mathbb{R}$, $F_v(x,u,v) = 0$ for all $u \in \mathbb{R}$ and $v \leq 0$, $F_u(x,u,0) = 0$ for all $u \in \mathbb{R}$ and $F_v(x,0,v) = 0$ for all $v \in \mathbb{R}$. Moreover, for all $(u,v) \in \mathbb{R}^+ \times \mathbb{R}^+$, the function $F(\cdot,u,v)$ is strictly positive for a.e. $x \in \mathbb{R}^N$.

(F_2) There exists $\alpha_0 > 0$ with the property that for all $\varepsilon > 0$, there exists $\kappa_\varepsilon > 0$ such that for a.e. $x \in \mathbb{R}^N$ and all $z = (u,v) \in \mathbb{R}^2$ with $|z| = \sqrt{u^2+v^2}$, $\nabla F = (F_u, F_v)$ and $j_p = \min\{j \in N : \ j \geq p\}$, we have

$$|\nabla F(x,u,v)| \leq \varepsilon |z|^{\theta p - 1} + \kappa_\varepsilon \Phi(\alpha_0 |z|^{p'}),$$

where

$$\Phi(t) = \exp(t) - \sum_{j=0}^{j_p - 2} \frac{t^j}{j!} \quad \text{and} \quad p' = \frac{N}{N-s}.$$

(F_3) There holds

$$\nabla F(x,u,v) = o(|z|^{\theta p - 1}) \quad \text{as } |z| \to 0^+ \text{ uniformly for } x \in \mathbb{R}^N.$$

(F_4) There exists $\sigma > \theta p$ such that

$$0 \leq \sigma F(x,u,v) \leq \nabla F(x,u,v).(u,v), \qquad \forall\ (x,u,v) \in \mathbb{R}^N \times \mathbb{R}^2.$$

In recent years, studying elliptic partial differential equations involving fractional Laplacian or more general nonlocal integro-differential operators has become a very interesting area of nonlinear analysis. Such types of operators occur naturally in several real-world applications, such as finance, optimization, game theory, image processing, multiple scattering, phase transition phenomena, population dynamics, continuum mechanics, ultra-relativistic limits of quantum mechanics, soft thin films, minimal surfaces, and the stochastic stability of Lévy processes. In this regard, we refer the readers to study [6, 12–14, 29, 31] and related references. Indeed, the literature on nonlocal fractional operators and their applications is somewhat vast, as shown by the new monographs [2, 34], the comprehensive work [19] and the references included therein.

In the context of fractional order Sobolev space, the Sobolev embedding states that for $sp < N$ with $s \in (0,1)$, the continuous embedding $W^{s,p}(\mathbb{R}^N) \hookrightarrow L^r(\mathbb{R}^N)$ holds for any $r \in [p, p_s^*]$, where $p_s^* = \frac{Np}{N-sp}$ is called the critical Sobolev exponent. In conclusion, to study the variational problems with subcritical and critical growth, the nonlinearity cannot exceed the polynomial of degree p_s^*. Despite this, in the Sobolev limiting case (commonly known as the Trudinger–Moser case), that is, $sp = N$, the continuous embedding $W^{s,p}(\mathbb{R}^N) \hookrightarrow L^q(\mathbb{R}^N)$ holds for any $q \in [p, \infty)$ but we cannot assume $q = \infty$ for such an embedding. Further, in this case, every polynomial growth is allowed. In this scenario, to deal with variational problems, many authors proved separately that the maximal growth of the nonlinearity is of exponential type, for a detailed study, we refer to [28, 36, 45]. The Trudinger–Moser inequalities have many applications, including extremal problems for determinants and zeta functions under conformal deformation of metric. For instance, on the four-dimensional sphere, the determinant of the conformal Laplacian is extremized under conformal deformation with fixed area by the

standard metric. The most important aspect of the Moser–Trudinger inequality has been its connection to the Polyakov–Onofri log determinant variation formula, as well as its later development in conformal geometry and geometric analysis of conformally invariant operators on higher-dimensional manifolds. In this regard, we refer to see [8, 16]. It is worth noting that there has been significant progress in the Trudinger–Moser inequalities to analyse the existence, nonexistence, and multiplicity of solutions to nonlinear PDEs in the context of the factional Sobolev space in $\mathbb{R}^N$. For a detailed study, one may go through [10,46,47,50–52] and references therein.

During the last few decades, there has been a tremendous amount of attention focused by many authors towards the study of Kirchhoff-type problems driven by nonlocal fractional Laplacian operators due to their applicability in various models of physical and biological systems. A typical model of Kirchhoff function M can be considered by $M(t) = a + b\theta t^{\theta-1}$ for all $t \geq 0$, where $a, b \geq 0$, $a + b > 0$ and $\theta > 1$. We say that M is of degenerate type if $a = 0$, while it is called non-degenerate type if $a > 0$. Obviously, one can easily notice that assumptions (M_1)–(M_2) in this paper also cover the degenerate case that corresponds to $M(0) = 0$. In addition, we make a note that in the study of Kirchhoff-type problems, many authors often used M as a nondecreasing function on $\mathbb{R}_0^+$, for instance, see [24, 37]. But however, in view of the assumption (M_1), one can consider that M is not monotone in nature as M can be chosen $M(t) = (1+t)^k + (1+t)^{-1}$ for $t \geq 0$ with $0 < k < 1$. Moreover, it is worth mentioning that the degenerate case in Kirchhoff's theory is more interesting and significant than the non-degenerate case. From a physical point of view, M measures the change of the tension on the string generated by the change of its length during the vibration, while $M(0) = 0$ indicates that the base tension of the string is zero. The presence of the nonlinear coefficient M is crucial to be considered when the changes in tension during the motion cannot be neglected. The existence of solutions for non-degenerate fractional Kirchhoff stationary problems are discussed in [3–5, 24, 26, 30], whereas degenerate problems are addressed in [22, 40, 48] and the relevant references. To the best of our knowledge, most of the works on Kirchhoff-type problems are driven by nonlocal fractional Laplacian or more general integro-differential operators involve the nonlinear terms satisfying some polynomial growth, but there are only a few papers dealing with nonlinear terms satisfying exponential type of growth, this is one of the key motivation towards the study of this paper. In this context, we recommend the readers to study [9, 32, 33, 43, 49].

Nowadays, the study of elliptic systems involving fractional Laplacian or more general nonlocal integro-differential operators has gained much attention due to a wide range of applications in applied sciences. Indeed, if $w = (u, v)^T$ denotes a vector of concentration variable, $H = (f(x, u, v), g(x, u, v))^T$ describes a local reaction term related to source and loss process, then for $M \equiv 1$, $K(x) = |x|^{-(N+sp)}$ and $s = 1$, the system $(\mathcal{S}_{\lambda,\mu})$ derive from the following p-Laplacian reaction-diffusion elliptic system

$$z_t = \operatorname{div}(|\nabla z|^{p-2}\nabla z) + H(x, z)$$

with

$$\operatorname{div}(|\nabla z|^{p-2}\nabla z) = \begin{pmatrix} \operatorname{div}(|\nabla u|^{p-2}\nabla u) \\ \\ \operatorname{div}(|\nabla v|^{p-2}\nabla v) \end{pmatrix}.$$

Such equations can be frequently seen in physics, plasma physics, biophysics, chemical reaction design, etc. In many situations, $H = (f(x, u, v), g(x, u, v))^T$ has both components of polynomial type with variable coefficients, but for the Liouville–Bratu–Gelfand and the

Frank–Kamenetsky models H has exponential growth at infinity. We refer to [15,17] for other physical examples of such problems. On concerning nonlocal elliptic systems with critical and subcritical growth one can see to [23,30,38] and references therein. However, concerning about nonlocal elliptic systems with exponential growth the literature is very limited (see [18,20,35]). This is another key motivation towards the study of this paper.

Motivated by the above-cited works, especially by [35,45,49], we study for the first time in the literature to solve a coupled Schrödinger–Kirchhoff elliptic system with singular exponential growth driven by the nonlocal integro-differential operator in $\mathbb{R}^N$.

To establish our main results, we first define the weak solution of the system $(\mathcal{S}_{\lambda,\mu})$.

Definition 1.2. We say that $(u,v) \in \mathbf{X}$ (see (2.1) for its definition) is a (weak) solution for the system $(\mathcal{S}_{\lambda,\mu})$, if for all $(\varphi,\psi) \in \mathbf{X}$, we have

$$M(\|(u,v)\|^p)\Big(\langle u,\varphi\rangle_{K_p,V} + \langle v,\psi\rangle_{K_p,V}\Big) = \int_{\mathbb{R}^N} \frac{\nabla F(x,u,v).(\varphi,\psi)}{|x|^\gamma}\,\mathrm{d}x + \lambda\int_{\mathbb{R}^N} h(x)|u|^{q-2}u\varphi\,\mathrm{d}x + \mu\int_{\mathbb{R}^N} h(x)|v|^{q-2}v\psi\,\mathrm{d}x,$$

where for any w_1 and w_2, we define

$$\langle w_1,w_2\rangle_{K_p,V} = \int_{\mathbb{R}^N}\int_{\mathbb{R}^N} |w_1(x)-w_1(y)|^{p-2}(w_1(x)-w_1(y))(w_2(x)-w_2(y))K(x-y)\,\mathrm{d}x\mathrm{d}y + \int_{\mathbb{R}^N} V(x)|w_1|^{p-2}w_1w_2\,\mathrm{d}x.$$

Our main results for this paper are listed below.

Theorem 1.3. *Suppose V satisfies $(V_1)-(V_2)$, M satisfies $(M_1)-(M_2)$ and (F) fulfills $(F_1)-(F_4)$. If $1<q<p$ and $h\in L^\eta(\mathbb{R}^N)$ with $\eta=\frac{N}{N-sq}$, then there exists $\widetilde{\lambda}>0$ such that for all $(\lambda,\mu)\in(0,\widetilde{\lambda})\times(0,\widetilde{\lambda})$, the system $(\mathcal{S}_{\lambda,\mu})$ admits at least one nontrivial nonnegative solution $(u_{\lambda,\mu},v_{\lambda,\mu})$ in $\mathbf{X}$. In addition, there holds*

$$\lim_{(\lambda,\mu)\to(0^+,0^+)} \|(u_{\lambda,\mu},v_{\lambda,\mu})\| = 0.$$

Theorem 1.4. *Suppose V satisfies (V_1)–(V_2), M satisfies (M_1)–(M_2) and (F) fulfills (F_1)–(F_4). If $q>\theta p$ and $h\in L^\infty(\mathbb{R}^N)$, then there exists $\widehat{\lambda}>0$ such that for all $(\lambda,\mu)\in(\widehat{\lambda},\infty)\times(\widehat{\lambda},\infty)$, the system $(\mathcal{S}_{\lambda,\mu})$ admits at least one nontrivial nonnegative solution $(u_{\lambda,\mu},v_{\lambda,\mu})$ in $\mathbf{X}$. Further, there holds*

$$\lim_{(\lambda,\mu)\to(\infty,\infty)} \|(u_{\lambda,\mu},v_{\lambda,\mu})\| = 0.$$

Theorem 1.5. *Suppose V satisfies (V_1)–(V_2) and (F) fulfills (F_2)–(F_4). In addition, we assume that F and M satisfy the following conditions:*

- (F_1') *$F(x,\cdot,\cdot)\in C^1(\mathbb{R}^2)$ for a.e. $x\in\mathbb{R}^N$, $F(x,\cdot,\cdot)\geq 0$ in $\mathbb{R}^2$ and $F(x,0,0)=0$ for a.e. $x\in\mathbb{R}^N$. Consequently, we assume that $F(x,u,v)=F(x,-u,-v)$ for all $(x,u,v)\in\mathbb{R}^N\times\mathbb{R}^2$.*
- (M') *the Kirchhoff function is of type $M(t)=a+b\theta t^{\theta-1}$ for all $t\geq 0$, where $a,b\geq 0$, $a+b>0$ and $\theta>1$.*

Then for $1<q<p$ and $h\in L^\eta(\mathbb{R}^N)$ with $\eta=\frac{N}{N-sq}$, there exists $\bar{\lambda}>0$ such that for all $(\lambda,\mu)\in(0,\bar{\lambda})\times(0,\bar{\lambda})$, the system $(\mathcal{S}_{\lambda,\mu})$ has infinitely many solutions in $\mathbf{X}$.

The rest of the paper is organized as follows: In Section 2, we discuss some preliminary results useful for the next main sections and the variational structure of the system ($\mathcal{S}_{\lambda,\mu}$). Section 3 is devoted to proving Theorem 1.3 via the Ekeland variational principle and using the standard topological tools. In Section 4, we prove Theorem 1.4 with the help of the mountain pass theorem. Finally, in Section 5, by introducing a truncated functional and using the deformation lemma along with the Krasnoselskii genus theory, we prove Theorems 1.5.

Notations. From now on in this paper, we have the following notations:

- For any Banach space $(X, \|\cdot\|_X)$, we denote its continuous dual by $(X^*, \|\cdot\|_{X^*})$.
- $o_n(1)$ denotes the real sequence such that $o_n(1) \to 0$ as $n \to \infty$.
- $\rightharpoonup$ means weak convergence and $\to$ means strong convergence.
- $u^+ = \max\{u, 0\}$ and $u^- = \max\{-u, 0\}$.

2 Preliminary results

In this section, we shall discuss about some basic properties of fractional Sobolev spaces and related lemmas, which are used in the sequel of this paper. Note that throughout this paper, we use $N \geq 1$, $s \in (0,1)$ and $sp = N$.

Let $r \in (1,\infty)$ and $L^r(\mathbb{R}^N)$ denotes the standard Lebesgue space with the norm $\|\cdot\|_r$. Moreover, for nonnegative measurable function $V : \mathbb{R}^N \to \mathbb{R}$, the space $L^r_V(\mathbb{R}^N)$, consisting of all real-valued measurable functions, with $V(x)|u|^r \in L^1(\mathbb{R}^N)$, equipped with the seminorm

$$\|u\|_{r,V} = \left(\int_{\mathbb{R}^N} V(x)|u|^r \, \mathrm{d}x \right)^{\frac{1}{r}},$$

which is a norm, thanks to (V_1). The space $\left(L^r_V(\mathbb{R}^N), \|\cdot\|_{r,V}\right)$ is a uniform convex Banach space (see [39]), thanks to $(V1)$. Consequently, under the assumption of (V_1), the embedding $L^r_V(\mathbb{R}^N) \hookrightarrow L^r(\mathbb{R}^N)$ is continuous.

For $\gamma \in [0, N)$, we define the space $L^r(\mathbb{R}^N, |x|^{-\gamma}\mathrm{d}x)$, consisting of all real-valued measurable functions, with $|u|^r|x|^{-\gamma} \in L^1(\mathbb{R}^N)$, equipped with the norm

$$\|u\|_{r,\gamma} = \left(\int_{\mathbb{R}^N} |u|^r|x|^{-\gamma} \, \mathrm{d}x \right)^{\frac{1}{r}}.$$

Define the fractional Sobolev space $W^{s,p}(\mathbb{R}^N)$ by

$$W^{s,p}(\mathbb{R}^N) = \{u \in L^p(\mathbb{R}^N) : [u]_{s,p} < \infty\},$$

where $[u]_{s,p}$ denotes the Gagliardo seminorm, defined by

$$[u]_{s,p} = \left(\int_{\mathbb{R}^N} \int_{\mathbb{R}^N} \frac{|u(x) - u(y)|^p}{|x-y|^{N+sp}} \, \mathrm{d}x\mathrm{d}y \right)^{\frac{1}{p}}.$$

Under the following norm

$$\|u\|_{W^{s,p}} = (\|u\|_p^p + [u]_{s,p}^p)^{\frac{1}{p}},$$

the space $\left(W^{s,p}(\mathbb{R}^N), \|\cdot\|_{W^{s,p}}\right)$ is a uniformly convex Banach space and hence a reflexive Banach space (see [39]).

Due to (V_1), the weighted fractional Sobolev space $W^{s,p}_V(\mathbb{R}^N)$ makes sense and defined by

$$W^{s,p}_V(\mathbb{R}^N) = \{u \in W^{s,p}(\mathbb{R}^N) : u \in L^p_V(\mathbb{R}^N)\},$$

endowed with the norm

$$\|u\|_{W^{s,p}_V} = \left(\|u\|^p_{p,V} + [u]^p_{s,p}\right)^{\frac{1}{p}}.$$

It is well-known that the space $\left(W^{s,p}_V(\mathbb{R}^N), \|\cdot\|_{W^{s,p}_V}\right)$ is a uniformly convex Banach space and $C^\infty_0(\mathbb{R}^N)$ is dense in $W^{s,p}_V(\mathbb{R}^N)$. Consequently, in virtue of (V_1), the embedding $W^{s,p}_V(\mathbb{R}^N) \hookrightarrow W^{s,p}(\mathbb{R}^N)$ is continuous and there holds $\min\{1, V_0\}\|u\|^p_{W^{s,p}} \leq \|u\|^p_{W^{s,p}_V}$ for all $u \in W^{s,p}_V(\mathbb{R}^N)$ (see [39]).

Let $K : \mathbb{R}^N \setminus \{0\} \to \mathbb{R}^+$ be the singular kernel, which is stated in the introductory part of this paper. Now we define the generalized fractional Sobolev space $W^{s,p}_K(\mathbb{R}^N)$ by

$$W^{s,p}_K(\mathbb{R}^N) = \{u \in L^p(\mathbb{R}^N) : [u]_{s,K_p} < \infty\},$$

equipped with the following norm

$$\|u\|_{W^{s,p}_K} = \left(\|u\|^p_p + [u]^p_{s,K_p}\right)^{\frac{1}{p}},$$

where

$$[u]_{s,K_p} = \left(\int_{\mathbb{R}^N}\int_{\mathbb{R}^N} |u(x) - u(y)|^p K(x-y)\, \mathrm{d}x\mathrm{d}y\right)^{\frac{1}{p}}.$$

The space $\left(W^{s,p}_K(\mathbb{R}^N), \|\cdot\|_{W^{s,p}}\right)$ is a uniformly convex Banach space and hence a reflexive Banach space (see [45]).

Under the assumption (V_1), the weighted fractional generalized Sobolev space $W^{s,p}_{V,K}(\mathbb{R}^N)$ makes sense and defined by

$$W^{s,p}_{K,V}(\mathbb{R}^N) = \{u \in W^{s,p}_K(\mathbb{R}^N) : u \in L^p_V(\mathbb{R}^N)\},$$

endowed with the norm

$$\|u\|_{W^{s,p}_{K,V}} = \left(\|u\|^p_{p,V} + [u]^p_{s,K_p}\right)^{\frac{1}{p}}.$$

It is easy to see that the space $\left(W^{s,p}_{K,V}(\mathbb{R}^N), \|\cdot\|_{W^{s,p}_{K,V}}\right)$ is a uniformly convex Banach space and hence reflexive (see [45]).

The natural function space to study the system $(\mathcal{S}_{\lambda,\mu})$ is the generalized vectorial fractional Sobolev space $\mathbf{X}$, defined by

$$\mathbf{X} = W^{s,p}_{V,K}(\mathbb{R}^N) \times W^{s,p}_{V,K}(\mathbb{R}^N), \tag{2.1}$$

endowed with the norm

$$\|(u,v)\| = \left([(u,v)]^p_{s,K_p} + \|(u,v)\|^p_{p,V}\right)^{\frac{1}{p}},$$

where

$$[(u,v)]_{s,K_p} = \left([u]^p_{s,K_p} + [v]^p_{s,K_p}\right)^{\frac{1}{p}} \quad \text{and} \quad \|(u,v)\|_{p,V} = \left(\|u\|^p_{p,V} + \|v\|^p_{p,V}\right)^{\frac{1}{p}}.$$

Consequently, we note that the space $\left(\mathbf{X}, \|(\cdot,\cdot)\|\right)$ is a uniform convex Banach space, and thus it is reflexive. Similarly, we can define the norm of the Banach space $W^{s,p}(\mathbb{R}^N) \times W^{s,p}(\mathbb{R}^N)$. Now we list some technical lemmas that will be used later in this paper. The following first three lemmas are direct consequences of [45, Lemma 2, 4 and 6].

Lemma 2.1. *Under the assumption of (V_1), the following chain of embeddings*

$$\mathbf{X} \hookrightarrow W^{s,p}(\mathbb{R}^N) \times W^{s,p}(\mathbb{R}^N) \hookrightarrow L^\nu(\mathbb{R}^N) \times L^\nu(\mathbb{R}^N)$$

are continuous for all $\nu \in [p, \infty)$ and there holds $\min\{V_0, K_0\}\|(u,v)\|^p_{W^{s,p}\times W^{s,p}} \leq \|(u,v)\|^p$ for all $(u,v) \in \mathbf{X}$. Moreover, if $\nu \in [1,\infty)$, then the embeddings $\mathbf{X} \hookrightarrow L^\nu(B_R) \times L^\nu(B_R)$ is compact for any $R > 0$.

Lemma 2.2. *Suppose (V_1) and (V_2) holds. Then the embedding $\mathbf{X} \hookrightarrow L^\nu(\mathbb{R}^N) \times L^\nu(\mathbb{R}^N)$ is compact for all $\nu \in [p,\infty)$. Consequently, there holds $\|(u,v)\|_{L^\nu(\mathbb{R}^N)\times L^\nu(\mathbb{R}^N)} \leq \mathcal{A}_\nu^{-1}\|(u,v)\|$ for all $(u,v) \in \mathbf{X}$, where $\mathcal{A}_\nu$ is the best constant in the embedding $\mathbf{X} \hookrightarrow L^\nu(\mathbb{R}^N) \times L^\nu(\mathbb{R}^N)$ and defined by*

$$\mathcal{A}_\nu = \inf_{(u,v)\in\mathbf{X}\setminus\{(0,0)\}} \frac{\|(u,v)\|}{\|(u,v)\|_{L^\nu(\mathbb{R}^N)\times L^\nu(\mathbb{R}^N)}} \text{ with } \|(u,v)\|_{L^\nu(\mathbb{R}^N)\times L^\nu(\mathbb{R}^N)} = \left(\|u\|_\nu^\nu + \|v\|_\nu^\nu\right)^{\frac{1}{\nu}}.$$

Lemma 2.3. *For any $\nu \in [p,\infty)$ and $\gamma \in [0,N)$, the embedding $\mathbf{X} \hookrightarrow L^\nu(\mathbb{R}^N, |x|^{-\gamma}\,\mathrm{d}x) \times L^\nu(\mathbb{R}^N, |x|^{-\gamma}\,\mathrm{d}x)$ is compact. In addition, there holds*

$$\|(u,v)\|_{L^\nu(\mathbb{R}^N,|x|^{-\gamma}\,\mathrm{d}x)\times L^\nu(\mathbb{R}^N,|x|^{-\gamma}\,\mathrm{d}x)} \leq \mathcal{B}_{\nu,\gamma}^{-1}\|(u,v)\|, \qquad \forall\ (u,v) \in \mathbf{X},$$

where $\mathcal{B}_{\nu,\gamma}$ is the best constant in the embedding $\mathbf{X} \hookrightarrow L^\nu(\mathbb{R}^N, |x|^{-\gamma}\,\mathrm{d}x) \times L^\nu(\mathbb{R}^N, |x|^{-\gamma}\,\mathrm{d}x)$, which is defined by

$$\mathcal{B}_{\nu,\gamma} = \inf_{(u,v)\in\mathbf{X}\setminus\{(0,0)\}} \frac{\|(u,v)\|}{\|(u,v)\|_{L^\nu(\mathbb{R}^N,|x|^{-\gamma}\,\mathrm{d}x)\times L^\nu(\mathbb{R}^N,|x|^{-\gamma}\,\mathrm{d}x)}}$$

with

$$\|(u,v)\|_{L^\nu(\mathbb{R}^N,|x|^{-\gamma}\,\mathrm{d}x)\times L^\nu(\mathbb{R}^N,|x|^{-\gamma}\,\mathrm{d}x)} = \left(\|u\|_{\nu,\gamma}^\nu + \|v\|_{\nu,\gamma}^\nu\right)^{\frac{1}{\nu}}.$$

Lemma 2.4. *Let $1 < q < p$ and $h \in L^\eta(\mathbb{R}^N)$ with $\eta = \frac{N}{N-sq}$, then the embedding $L^p(\mathbb{R}^N) \hookrightarrow L_h^q(\mathbb{R}^N)$ is continuous and there holds*

$$\|u\|_{q,h} \leq \|h\|_\eta^{\frac{1}{q}}\|u\|_p, \quad \forall\ u \in L^p(\mathbb{R}^N) \quad \text{with} \quad \|u\|_{q,h}^q = \int_{\mathbb{R}^N} h(x)|u|^q\,\mathrm{d}x.$$

Further, the embedding $W^{s,p}(\mathbb{R}^N) \hookrightarrow L_h^q(\mathbb{R}^N)$ is compact. In addition, due to [45, Lemma 4], the embedding $W_{K,V}^{s,p}(\mathbb{R}^N) \hookrightarrow L_h^q(\mathbb{R}^N)$ is compact.

Proof. Let $q \in (1,p)$ and $h \in L^\eta(\mathbb{R}^N)$ with $\eta = \frac{N}{N-sq}$. Observe that $\frac{1}{\eta} + \frac{q}{p} = 1$. Consequently, by the Hölder's inequality, we have

$$\|u\|_{q,h} \leq \|h\|_\eta^{\frac{1}{q}}\|u\|_p, \qquad \forall\ u \in L^p(\mathbb{R}^N).$$

It follows that the embedding $L^p(\mathbb{R}^N) \hookrightarrow L_h^q(\mathbb{R}^N)$ is continuous. To complete the proof, we only have to show that if $u_n \rightharpoonup u$ in $W^{s,p}(\mathbb{R}^N)$ as $n \to \infty$, then $u_n \to u$ in $L_h^q(\mathbb{R}^N)$ as $n \to \infty$. For this, first we assume that $u_n \rightharpoonup u$ in $W^{s,p}(\mathbb{R}^N)$ as $n \to \infty$. Due to [45, Lemma 4], the sequence $\{u_n - u\}_n$ is bounded in $L^p(\mathbb{R}^N)$ and thus there exists $m > 0$ such that $\|u_n - u\|_p \leq m$ for all $n \in \mathbb{N}$. Further, since $h \in L^\eta(\mathbb{R}^N)$ and using the fact that every integrable function is tight, we can assume that for every $\epsilon > 0$, there exists $R_\epsilon > 0$ large enough such that

$$\int_{\mathbb{R}^N\setminus B_{R_\epsilon}} |h(x)|^\eta\,\mathrm{d}x < \left(\frac{\epsilon}{2m^q}\right)^\eta.$$

This together with the Hölder's inequality implies at once that

$$\int_{\mathbb{R}^N\setminus B_{R_\epsilon}} h(x)|u_n-u|^q\,\mathrm{d}x \le \left(\int_{\mathbb{R}^N\setminus B_{R_\epsilon}} |h(x)|^\eta\,\mathrm{d}x\right)^{\frac{1}{\eta}} \|u_n-u\|_p^q < \frac{\epsilon}{2}.$$

In virtue of [45, Lemma 4], we also have $u_n \to u$ in $L^p(B_{R_\epsilon})$. Therefore, using the the Hölder's inequality, we get

$$\int_{B_{R_\epsilon}} h(x)|u_n-u|^q\,\mathrm{d}x \le \|h\|_\eta \left(\int_{B_{R_\epsilon}} |u_n-u|^p\,\mathrm{d}x\right)^{\frac{1}{p}} = o_n(1) \quad \text{as } n\to\infty.$$

In conclusion, there exists $n_0\in\mathbb{N}$ and $\epsilon>0$ such that $\int_{B_{R_\epsilon}} h(x)|u_n-u|^q\,\mathrm{d}x < \frac{\epsilon}{2}$ for all $n\ge n_0$. Now gathering all the above information, we obtain for all $n\ge n_0$ that

$$\|u_n-u\|_{q,h}^q = \int_{\mathbb{R}^N\setminus B_{R_\epsilon}} h(x)|u_n-u|^q\,\mathrm{d}x + \int_{B_{R_\epsilon}} h(x)|u_n-u|^q\,\mathrm{d}x < \epsilon,$$

and thus we conclude the proof. □

An immediate byproduct of the above lemma, we have the following result.

Lemma 2.5. *Let $1<q<p$ and $h\in L^\eta(\mathbb{R}^N)$ with $\eta=\frac{N}{N-sq}$, then the embedding*

$$L^p(\mathbb{R}^N)\times L^p(\mathbb{R}^N) \hookrightarrow L_h^q(\mathbb{R}^N)\times L_h^q(\mathbb{R}^N)$$

is continuous. In addition, the embedding $W^{s,p}(\mathbb{R}^N)\times W^{s,p}(\mathbb{R}^N)\hookrightarrow L_h^q(\mathbb{R}^N)\times L_h^q(\mathbb{R}^N)$ is compact. Further, due to Lemma 2.1, the embedding $\mathbf{X}\hookrightarrow L_h^q(\mathbb{R}^N)\times L_h^q(\mathbb{R}^N)$ is compact and there holds $\|(u,v)\|_{L_h^q(\mathbb{R}^N)\times L_h^q(\mathbb{R}^N)} \le \mathcal{S}_{q,h}^{-1}\|(u,v)\|$ for all $(u,v)\in\mathbf{X}$, where $\mathcal{S}_{q,h}$ is the best constant in the embedding $\mathbf{X}\hookrightarrow L_h^q(\mathbb{R}^N)\times L_h^q(\mathbb{R}^N)$, which is defined by

$$\mathcal{S}_{q,h} = \inf_{(u,v)\in\mathbf{X}\setminus\{(0,0)\}} \frac{\|(u,v)\|}{\|(u,v)\|_{L_h^q(\mathbb{R}^N)\times L_h^q(\mathbb{R}^N)}} \quad \text{with} \quad \|(u,v)\|_{L_h^q(\mathbb{R}^N)\times L_h^q(\mathbb{R}^N)} = \left(\|u\|_{q,h}^q+\|v\|_{q,h}^q\right)^{\frac{1}{q}}.$$

Lemma 2.6 (cf. [11,35])**.** *The function $\Phi(t)=\exp(t)-\sum_{j=0}^{j_p-2}\frac{t^j}{j!}$ is increasing and convex in $[0,\infty)$. Moreover, for any $\alpha>0$ and $r>1$, there exists a constant $C=C(r)$ such that for $j_p=\min\{j\in N:\ j\ge p\}$, we have*

$$\left(\exp(\alpha|s|^{p'})-\sum_{j=0}^{j_p-2}\frac{\alpha^j|s|^{jp'}}{j!}\right)^r \le C\left(\exp(\alpha r|s|^{p'})-\sum_{j=0}^{j_p-2}\frac{\alpha^j r^j|s|^{jp'}}{j!}\right), \qquad \forall\, s\in\mathbb{R}.$$

The following theorem was proved by Nguyen in [45], which is called singular Trudinger–Moser inequality in the fractional Sobolev space $W^{s,p}(\mathbb{R}^N)$. It can be read as follows:

Theorem 2.7 (Singular Trudinger–Moser inequality in $\mathbb{R}^N$)**.** *For any $\alpha>0$, $\gamma\in[0,N)$ and $u\in W^{s,p}(\mathbb{R}^N)$ with $s\in(0,1)$ and $sp=N$, there holds*

$$\frac{\Phi(\alpha|u|^{p'})}{|x|^\gamma}\in L^1(\mathbb{R}^N),$$

where Φ is defined as in (F_2). Moreover, there exists $\beta_*>0$ such that for any $0\le\alpha\le\beta_*<\alpha_*$ with $\alpha_*\le\alpha_{s,N}^*$, the following inequality holds true:

$$\sup_{u\in W^{s,p}(\mathbb{R}^N),\|u\|_{W^{s,p}}\le 1}\int_{\mathbb{R}^N}\frac{\Phi(\alpha|u|^{p'})}{|x|^\gamma}\,\mathrm{d}x<+\infty,$$

where

$$\alpha^*_{s,N} = N\left(\frac{2(N\omega_N)^2\Gamma(p+1)}{N!}\sum_{k=0}^{+\infty}\frac{(N+k-1)!}{k!}\frac{1}{(N+2k)^p}\right)^{\frac{s}{N-s}} \quad \text{with } \omega_N = \frac{\pi^{\frac{N}{2}}}{\Gamma\left(\frac{N+2}{2}\right)}.$$

In addition, the above inequality is sharp for $\alpha > \alpha^*_{s,N}$, that is, the supremum is infinity.

Since we are interested in studying the nonnegative solutions of the system $(\mathcal{S}_{\lambda,\mu})$, we define the associated Euler–Lagrange variational functional $J_{\lambda,\mu} : \mathbf{X} \to \mathbb{R}$ by

$$J_{\lambda,\mu}(u,v) = \frac{1}{p}\widehat{M}(\|(u,v)\|^p) - \int_{\mathbb{R}^N}\frac{F(x,u,v)}{|x|^\gamma}\,\mathrm{d}x - \frac{1}{q}(\lambda\|u^+\|^q_{q,h} + \mu\|v^+\|^q_{q,h}), \quad \forall\ (u,v)\in\mathbf{X}. \tag{2.2}$$

In virtue of the assumption (F_2) and Theorem 2.7, one can easily verify that $J_{\lambda,\mu}$ is well-defined, of class $C^1(\mathbf{X},\mathbb{R})$ and its Gâteaux derivative is given by

$$\begin{aligned}\langle J'_{\lambda,\mu}(u,v),(\varphi,\psi)\rangle &= M(\|(u,v)\|^p)\left(\langle u,\varphi\rangle_{K_p,V} + \langle v,\psi\rangle_{K_p,V}\right) - \int_{\mathbb{R}^N}\frac{\nabla F(x,u,v).(\varphi,\psi)}{|x|^\gamma}\,\mathrm{d}x\\ &\quad - \int_{\mathbb{R}^N} h(x)\{\lambda(u^+)^{q-1}\varphi + \mu(v^+)^{q-1}\psi\}\,\mathrm{d}x, \qquad \forall\ (\varphi,\psi)\in\mathbf{X},\end{aligned} \tag{2.3}$$

where $\langle\cdot,\cdot\rangle$ denotes the duality pairing between $\mathbf{X}^*$ and $\mathbf{X}$. It follows that the critical points of $J_{\lambda,\mu}$ are exactly the weak solutions of the system $(\mathcal{S}_{\lambda,\mu})$.

3 Proof of Theorem 1.3

In this section, for the sake of simplicity, we assume without further mentioning that the structural assumptions required in Theorem 1.3 hold.

The following lemma shows that every nontrivial (weak) solution of the system $(\mathcal{S}_{\lambda,\mu})$ is nonnegative.

Lemma 3.1. *For all $\lambda > 0$ and $\mu > 0$, any nontrivial solution of the system $(\mathcal{S}_{\lambda,\mu})$ is nonnegative in $\mathbb{R}^N$.*

Proof. Suppose $\lambda > 0$ and $\mu > 0$ are fixed and $(u,v)\in\mathbf{X}\setminus\{(0,0)\}$ is a solution of the system $(\mathcal{S}_{\lambda,\mu})$. Notice that $u = u^+ - u^-$ and $v = v^+ - v^-$ and thus testing (2.3) by $(-u^-,-v^-)$, we have

$$\langle J'_{\lambda,\mu}(u,v),(-u^-,-v^-)\rangle = 0.$$

Due to (F_1), we obtain the following estimates

$$\int_{\mathbb{R}^N}\frac{\nabla F(x,u,v).(u^-,v^-)}{|x|^\gamma}\,\mathrm{d}x = 0$$

and

$$\int_{\mathbb{R}^N} h(x)\{\lambda(u^+)^{q-1}u^- + \mu(v^+)^{q-1}v^-\}\,\mathrm{d}x = 0.$$

On the other hand, we also have

$$\int_{\mathbb{R}^N} V(x)\left(|u|^{p-2}u(-u^-) + |v|^{p-2}v(-v^-)\right)\mathrm{d}x = \int_{\mathbb{R}^N} V(x)\left(|u^-|^p + |v^-|^p\right)\mathrm{d}x.$$

Invoking [32, Lemma 2.1], for a.e. $x, y \in \mathbb{R}^N$ and $w \in \{u, v\}$, we infer that

$$|w^-(x) - w^-(y)|^p \le |w(x) - w(y)|^{p-2}(w(x) - w(y))(-w^-(x) + w^-(y)).$$

Gathering all the above information, we obtain from $\langle J'_{\lambda,\mu}(u,v), (-u^-, -v^-)\rangle = 0$ that

$$M(\|(u,v)\|^p)(\|(u^-, v^-)\|^p) \le 0.$$

Hence by using the fact that $\|(u,v)\| > 0$ and (M_1), we get $u^- = v^- = 0$ a.e. in $\mathbb{R}^N$. This shows that $u = u^+$ and $v = v^+$ a.e. in $\mathbb{R}^N$, and we finish the proof. □

To apply the minimization argument, we first prove the following geometrical structures of the functional $J_{\lambda,\mu}$.

Lemma 3.2. *There exists $\rho \in (0,1]$ and two positive numbers λ_* and j, depending upon ρ, such that $J_{\lambda,\mu}(u,v) \ge j$ for all $(u,v) \in \mathbf{X}$ with $\|(u,v)\| = \rho$ and for all $\lambda > 0$ and $\mu > 0$ such that $\max\{\lambda, \mu\} \le \lambda_*$.*

Proof. It follows from (M_2) that

$$\widehat{M}(t) \ge \widehat{M}(1)t^\theta, \qquad \forall\, t \in [0,1].$$

By using (F_3), it follows that for any $\varepsilon > 0$, there exists $\delta = \delta(\varepsilon) > 0$ such that

$$|\nabla F(x,u,v)| \le \varepsilon |z|^{\theta p - 1}, \qquad \forall\, x \in \mathbb{R}^N \text{ and } |z| \le \delta. \tag{3.1}$$

Further, by using (F_2) and Lemma 2.6, we get for any $\vartheta > \theta p$ that

$$|\nabla F(x,u,v)| \le \tilde{\kappa}_\varepsilon |z|^{\vartheta - 1}\Phi(\alpha_0 |z|^{p'}), \qquad \forall\, x \in \mathbb{R}^N \text{ and } |z| \ge \delta, \tag{3.2}$$

where there exists $r > 0$ such that $\vartheta = \theta p + r$ and $\tilde{\kappa}_\varepsilon = \frac{\varepsilon}{\delta^r \Phi(\alpha_0 \delta^{p'})} + \frac{\kappa_\varepsilon}{\delta^{\vartheta - 1}}$. Combining (3.1) and (3.2), we obtain

$$|\nabla F(x,u,v)| \le \varepsilon |z|^{\theta p - 1} + \tilde{\kappa}_\varepsilon |z|^{\vartheta - 1}\Phi(\alpha_0 |z|^{p'}), \qquad \forall\, (x,z) \in \mathbb{R}^N \times \mathbb{R}^2 \text{ and } \vartheta > \theta p. \tag{3.3}$$

Now we obtain from (3.3) and Lemma 2.6 that

$$\begin{aligned} |F(x,u,v)| &= \left| \int_0^1 \frac{d}{dt} F(x,tu,tv)\, \mathrm{d}t \right| = \left| \int_0^1 \nabla F(x,tu,tv).(u,v)\, \mathrm{d}t \right| \\ &\le \varepsilon |z|^{\theta p} \int_0^1 t^{\theta p - 1}\, \mathrm{d}t + \tilde{\kappa}_\varepsilon |z|^\vartheta \int_0^1 t^{\vartheta - 1}\Phi(\alpha_0 t^{p'} |z|^{p'})\, \mathrm{d}t \\ &\le \varepsilon |z|^{\theta p} + \tilde{\kappa}_\varepsilon |z|^\vartheta \Phi(\alpha_0 |z|^{p'}). \end{aligned}$$

This yields at once that

$$|F(x,u,v)| \le \varepsilon |z|^{\theta p} + \tilde{\kappa}_\varepsilon |z|^\vartheta \Phi(\alpha_0 |z|^{p'}), \qquad \forall\, (x,z) \in \mathbb{R}^N \times \mathbb{R}^2 \text{ and } \vartheta > \theta p. \tag{3.4}$$

Suppose $\bar{\delta} \in (0,1]$ is sufficiently small enough and there holds $0 < \|(u,v)\| \le \bar{\delta}$. It is easy to see that $|z| = \sqrt{u^2 + v^2} \le \psi := |u| + |v|$ and thus by using Lemma 2.1, we get

$$\begin{aligned} \|\psi\|_{W^{s,p}} &\le \|u\|_{W^{s,p}} + \|v\|_{W^{s,p}} \le 2\big(\|u\|^p_{W^{s,p}} + \|v\|^p_{W^{s,p}}\big)^{\frac{1}{p}} \\ &= 2\|(u,v)\|_{W^{s,p}\times W^{s,p}} \le 2(\min\{V_0, K_0\})^{-\frac{1}{p}}\|(u,v)\|. \end{aligned} \tag{3.5}$$

Choose $t, t' > 1$ satisfying $\frac{1}{t} + \frac{1}{t'} = 1$ and $\widetilde{\psi} = \psi/\|\psi\|_{W^{s,p}}$. Due to (3.5) and the fact that $\bar{\delta} \in (0,1]$ is small enough such that $0 < \|(u,v)\| \leq \bar{\delta}$, we can assume that $\alpha_0 t' \|\psi\|^{p'}_{W^{s,p}} \leq (2\bar{\delta})^{p'}(\min\{V_0, K_0\})^{-\frac{1}{p-1}}\alpha_0 t' \leq \beta_* < \alpha_*$ with $\alpha_* \leq \alpha^*_{s,N}$. Therefore, by applying the Hölder's inequality, Lemma 2.3 and Lemma 2.6, we obtain from (3.4) that

$$\begin{aligned}
&\int_{\mathbb{R}^N} \frac{|F(x,u,v)|}{|x|^\gamma}\,\mathrm{d}x \\
&\quad\leq \varepsilon \int_{\mathbb{R}^N} \frac{|z|^{\theta p}}{|x|^\gamma}\,\mathrm{d}x + \tilde{\kappa}_\varepsilon \int_{\mathbb{R}^N} \frac{|z|^\vartheta \Phi(\alpha_0|z|^{p'})}{|x|^\gamma}\,\mathrm{d}x \\
&\quad\leq 2^{\theta p}\mathcal{B}^{-\theta p}_{\theta p,\gamma}\varepsilon\|(u,v)\|^{\theta p} + \tilde{\kappa}_\varepsilon\left(\int_{\mathbb{R}^N} \frac{|z|^{\vartheta t}}{|x|^\gamma}\,\mathrm{d}x\right)^{\frac{1}{t}}\left(\int_{\mathbb{R}^N} \frac{C\,\Phi(\alpha_0 t'|z|^{p'})}{|x|^\gamma}\,\mathrm{d}x\right)^{\frac{1}{t'}} \\
&\quad\leq 2^{\theta p}\mathcal{B}^{-\theta p}_{\theta p,\gamma}\varepsilon\|(u,v)\|^{\theta p} + 2^\vartheta C^{\frac{1}{t'}}\mathcal{B}^{-\vartheta}_{\vartheta t,\gamma}\tilde{\kappa}_\varepsilon\|(u,v)\|^\vartheta\left(\int_{\mathbb{R}^N} \frac{\Phi(\alpha_0 t'\|\psi\|^{p'}_{W^{s,p}}|\widetilde{\psi}|^{p'})}{|x|^\gamma}\,\mathrm{d}x\right)^{\frac{1}{t'}} \\
&\quad\leq 2^{\theta p}\mathcal{B}^{-\theta p}_{\theta p,\gamma}\varepsilon\|(u,v)\|^{\theta p} + 2^\vartheta D C^{\frac{1}{t'}}\mathcal{B}^{-\vartheta}_{\vartheta t,\gamma}\tilde{\kappa}_\varepsilon\|(u,v)\|^\vartheta,
\end{aligned}$$

where $D > 0$ is a constant, thanks to Theorem 2.7. Gathering all the above information and using Lemma 2.5, we obtain for $0 < \|(u,v)\| \leq \bar{\delta}$ that

$$J_{\lambda,\mu}(u,v) \geq \left(\frac{\widehat{M}(1)}{p} - 2^{\theta p}\mathcal{B}^{-\theta p}_{\theta p,\gamma}\varepsilon\right)\|(u,v)\|^{\theta p} - \widetilde{C}\|(u,v)\|^\vartheta - \frac{1}{q}\max\{\lambda,\mu\}\mathcal{S}^{-q}_{q,h}\|(u,v)\|^q, \quad (3.6)$$

where $\widetilde{C} = 2^\vartheta D C^{\frac{1}{t'}}\mathcal{B}^{-\vartheta}_{\vartheta t,\gamma}\tilde{\kappa}_\varepsilon$. Take $\varepsilon = \widehat{M}(1)/2^{\theta p+1}p\mathcal{B}^{-\theta p}_{\theta p,\gamma}$, and consider the function $g : [0,\bar{\delta}] \to \mathbb{R}$ as follows:

$$g(\ell) = \frac{\widehat{M}(1)}{2(p+1)^2}\ell^{\theta p} - \widetilde{C}\ell^\vartheta, \qquad \forall\ \ell \in [0,\bar{\delta}].$$

Notice that g admits a positive maximum j in $[0,\bar{\delta}]$ at a point $\rho \in (0,\bar{\delta}]$. This shows that for all $(u,v) \in \mathbf{X}$ with $\|(u,v)\| = \rho$, one has

$$J_{\lambda,\mu}(u,v) \geq \frac{\widehat{M}(1)}{2p}\rho^{\theta p} - \widetilde{C}\rho^\vartheta - \frac{1}{q}\max\{\lambda,\mu\}\mathcal{S}^{-q}_{q,h}\rho^q \geq g(\rho) = j > 0,$$

for all $\lambda > 0$ and $\mu > 0$ with $\max\{\lambda,\mu\} \leq \lambda_*$, where λ_* is given as follows

$$\lambda_* = \frac{q\widehat{M}(1)}{2(p+1)\mathcal{S}^{-q}_{q,h}}\rho^{\theta p - q}.$$

This finishes the proof. □

Lemma 3.3. *For all $\lambda > 0$ and $\mu > 0$ with $\max\{\lambda,\mu\} \leq \lambda_*$, there holds*

$$m_{\lambda,\mu} = \inf\{J_{\lambda,\mu}(u,v) : (u,v) \in \overline{B}_\rho\} < 0.$$

where

$$B_\rho = \{(u,v) \in \mathbf{X} : \|(u,v)\| < \rho\}.$$

Finally, there exists a nonnegative sequence $\{(u_n,v_n)\}_n$ and some nonnegative function $(u_{\lambda,\mu}, v_{\lambda,\mu})$ in $\overline{B}_\rho$ such that for all $n \in \mathbb{N}$, we have

$$\begin{aligned}
&\|(u_n,v_n)\| < \rho,\ m_{\lambda,\mu} \leq J_{\lambda,\mu}(u_n,v_n) \leq m_{\lambda,\mu} + \frac{1}{n},\ (u_n,v_n) \rightharpoonup (u_{\lambda,\mu}, v_{\lambda,\mu}) \quad \text{in } \mathbf{X}, \\
&(u_n,v_n) \to (u_{\lambda,\mu}, v_{\lambda,\mu}) \quad \text{a.e. in} \quad \mathbb{R}^N \quad \text{and} \quad J'_{\lambda,\mu}(u_n,v_n) \to 0 \quad \text{in } \mathbf{X}^* \quad \text{as } n \to \infty.
\end{aligned} \quad (3.7)$$

Proof. Fix $\lambda > 0$ and $\mu > 0$ with $\max\{\lambda, \mu\} \leq \lambda_*$ and a pair $(u, v) \in \mathbf{X}$ such that $\|(u, v)\| \leq \rho$. Let $\tau \in [0, 1]$, then by using (F_1), we have

$$\begin{aligned} J_{\lambda,\mu}(\tau u, \tau v) &\leq \frac{1}{p}\widehat{M}(\|\tau(u, v)\|^p) - \frac{\tau^q}{q}\big(\lambda\|u^+\|_{q,h}^q + \mu\|v^+\|_{q,h}^q\big) \\ &\leq \tau^p\left(\frac{\rho^p}{p}\max_{s\in[0,\rho^p]} M(s)\right) - \frac{\tau^q}{q}\big(\lambda\|u^+\|_{q,h}^q + \mu\|v^+\|_{q,h}^q\big). \end{aligned}$$

Since $1 < q < p$, it follows that $J_{\lambda,\mu}(\tau u, \tau v) < 0$ for $\tau \in (0, 1]$ sufficiently small enough. This together with (3.6) implies that

$$-\infty < m_{\lambda,\mu} = \inf\{J_{\lambda,\mu}(u, v) : (u, v) \in \overline{B}_\rho\} < 0. \tag{3.8}$$

This shows that the functional $J_{\lambda,\mu}$ is bounded from below and of class C^1 on $\overline{B}_\rho$. In addition, we also know that $\overline{B}_\rho$ is a complete metric space with the metric defined by the norm of $\mathbf{X}$. Due to Lemma 3.2, we obtain that

$$\inf_{\partial B_\rho} J_{\lambda,\mu}(u, v) \geq j > 0. \tag{3.9}$$

In virtue of (3.8) and (3.9), for n large enough, we can assume that

$$\frac{1}{n} \in \left(0, \inf_{\partial B_\rho} J_{\lambda,\mu}(u, v) - \inf_{\overline{B}_\rho} J_{\lambda,\mu}(u, v)\right). \tag{3.10}$$

Now applying Ekeland variational principle [21] to the functional $J_{\lambda,\mu} : \overline{B}_\rho \to \mathbb{R}$, we can find a sequence $\{(u_n, v_n)\}_n$ in $\overline{B}_\rho$ such that

$$m_{\lambda,\mu} \leq J_{\lambda,\mu}(u_n, v_n) \leq m_{\lambda,\mu} + \frac{1}{n} \quad \text{and} \quad J_{\lambda,\mu}(u_n, v_n) \leq J_{\lambda,\mu}(u, v) + \frac{1}{n}\|(u_n, v_n) - (u, v)\| \tag{3.11}$$

for all $(u, v) \in \overline{B}_\rho$ satisfying $(u, v) \neq (u_n, v_n)$ for each $n \in \mathbb{N}$. Consequently, we obtain from (3.10) and (3.11) that

$$J_{\lambda,\mu}(u_n, v_n) \leq m_{\lambda,\mu} + \frac{1}{n} = \inf_{\overline{B}_\rho} J_{\lambda,\mu}(u, v) + \frac{1}{n} < \inf_{\partial B_\rho} J_{\lambda,\mu}(u, v).$$

It follows that $\{(u_n, v_n)\}_n \subset B_\rho$, that is, $\|(u_n, v_n)\| < \rho$ for all $n \in \mathbb{N}$. Suppose $(\varphi, \psi) \in S$, where $S = \{(\varphi, \psi) \in \mathbf{X} : \|(\varphi, \psi)\| = 1\}$, and $t > 0$ sufficiently small such that $(u_n + t\varphi, v_n + t\psi) \in \overline{B}_\rho$ for all $n \in \mathbb{N}$. By using (3.11), we can notice that

$$\langle J'_{\lambda,\mu}(u_n, v_n), (\varphi, \psi)\rangle = \lim_{t\to 0^+} \frac{J_{\lambda,\mu}(u_n + t\varphi, v_n + t\psi) - J_{\lambda,\mu}(u_n, v_n)}{t} \geq -\frac{1}{n}, \qquad \forall\ (\varphi, \psi) \in S.$$

The arbitrariness of $(\varphi, \psi) \in S$ infers that

$$|\langle J'_{\lambda,\mu}(u_n, v_n), (\varphi, \psi)\rangle| \leq \frac{1}{n}, \qquad \forall\ (\varphi, \psi) \in S.$$

This together with (3.11) implies at once that

$$J_{\lambda,\mu}(u_n, v_n) \to m_{\lambda,\mu} \quad \text{and} \quad J'_{\lambda,\mu}(u_n, v_n) \to 0 \quad \text{in } \mathbf{X}^* \quad \text{as } n \to \infty. \tag{3.12}$$

On the other hand, it is easy to see that the sequence $\{(u_n, v_n)\}_n$ is bounded, and thus up to a subsequence still denoted itself and $(u_{\lambda,\mu}, v_{\lambda,\mu}) \in \overline{B}_\rho$ such that $(u_n, v_n) \rightharpoonup (u_{\lambda,\mu}, v_{\lambda,\mu})$ in $\mathbf{X}$ as

$n \to \infty$. In view of Lemma 2.2, we have $(u_n, v_n) \to (u_{\lambda,\mu}, v_{\lambda,\mu})$ in $L^\nu(\mathbb{R}^N) \times L^\nu(\mathbb{R}^N)$ as $n \to \infty$ for all $\nu \in [p, \infty)$. Further, since the maps $u \mapsto u^\pm$ are continuous from $L^\nu(\mathbb{R}^N)$ into itself, therefore we conclude that $u_n \to u_{\lambda,\mu}, u_n^\pm \to u_{\lambda,\mu}^\pm, v_n \to v_{\lambda,\mu}$, and $v_n^\pm \to v_{\lambda,\mu}^\pm$ a.e. in $\mathbb{R}^N$ as $n \to \infty$. In addition, from (3.12), we infer that

$$\langle J'_{\lambda,\mu}(u_n, v_n), (-u_n^-, -v_n^-)\rangle \to 0 \quad \text{as } n \to \infty.$$

Now using a similar strategy developed in Lemma 3.1, we obtain

$$M(\|(u_n, v_n)\|^p)(\|(u_n^-, v_n^-)\|^p) = o_n(1) \quad \text{as } n \to \infty. \tag{3.13}$$

Hence we have two possibilities, that is, either $\inf_{n\in\mathbb{N}}\|(u_n, v_n)\| = d > 0$ or $\inf_{n\in\mathbb{N}}\|(u_n, v_n)\| = 0$.

Case 1. Let $\inf_{n\in\mathbb{N}} \|(u_n, v_n)\| = d > 0$. Denote $\kappa = \kappa(\tau)$ as the number corresponding to $\tau = d^p$ in (M_1) such that

$$M(\|(u_n, v_n)\|^p) \geq \kappa, \qquad \forall\, n \in \mathbb{N}. \tag{3.14}$$

In virtue of (3.13) and (3.14), we conclude that $(u_n^-, v_n^-) \to (0,0)$ in $\mathbf{X}$. It follows that $u_{\lambda,\mu}^- = v_{\lambda,\mu}^- = 0$ a.e. in $\mathbb{R}^N$ and thus the pair $(u_{\lambda,\mu}, v_{\lambda,\mu})$ is nonnegative in $\mathbb{R}^N$. Consequently, without loss of generality, we can assume that $(u_n, v_n) = (u_n^+, v_n^+)$, thanks to $(u_n^-, v_n^-) \to (0,0)$ in $\mathbf{X}$. This shows that the sequence $\{(u_n, v_n)\}_n$ is nonnegative.

Case 2. Let $\inf_{n\in\mathbb{N}} \|(u_n, v_n)\| = 0$, then either $(0,0)$ is an accumulation point of the sequence $\{(u_n, v_n)\}_n$ or $(0,0)$ is an isolated point of the sequence $\{(u_n, v_n)\}_n$. If $(0,0)$ is an accumulation point of $\{(u_n, v_n)\}_n$, then up to a subsequence still denoted by itself such that it strongly converges to $(u_{\lambda,\mu}, v_{\lambda,\mu}) = (0,0)$. This situation is impossible. Indeed, if not, then $0 = J_{\lambda,\mu}(0,0) = m_{\lambda,\mu} < 0$, which is a contradiction. On the other hand, if $(0,0)$ is an isolated point of $\{(u_n, v_n)\}_n$, then there exists a subsequence still denoted by itself such that $\inf_{n\in\mathbb{N}} \|(u_n, v_n)\| > 0$. In this situation, we can proceed as in Case 1 to conclude the proof.

From the above discussions, we infer that the sequence $\{(u_n, v_n)\}_n$ and $(u_{\lambda,\mu}, u_{\lambda,\mu})$ are nonnegative. This finishes the proof. □

Proof of Theorem 1.3. Due to Lemma 3.3, there exists a nonnegative sequence $\{(u_n, v_n)\}_n$ in $\overline{B}_\rho$ such that (3.7) holds, that is, we have

$$J_{\lambda,\mu}(u_n, v_n) \to m_{\lambda,\mu}\ (< 0) \quad \text{and} \quad J'_{\lambda,\mu}(u_n, v_n) \to 0 \quad \text{in } \mathbf{X}^* \quad \text{as } n \to \infty.$$

Evidently, we have two situations according to the behaviour of the Kirchhoff function M: either $\inf_{n\in\mathbb{N}} \|(u_n, v_n)\| = d > 0$ or $\inf_{n\in\mathbb{N}} \|(u_n, v_n)\| = 0$. Hence we divide the proof into two parts.

Case 1. Let $\inf_{n\in\mathbb{N}} \|(u_n, v_n)\| = d > 0$. Denote $\kappa = \kappa(\tau)$ as the number corresponding to $\tau = d^p$ in (M_1) such that

$$M(\|(u_n, v_n)\|^p) \geq \kappa, \qquad \forall\, n \in \mathbb{N}. \tag{3.15}$$

Let $\lambda > 0$ and $\mu > 0$ be such that $\max\{\lambda, \mu\} < \widetilde{\lambda}$ with $\widetilde{\lambda} = \min\{\lambda_*, \lambda_0\}$, where λ_* as in Lemma 3.2, while λ_0 is defined by

$$\lambda_0 = \frac{q\kappa(\sigma - \theta p)\big(\min\{V_0, K_0\}\big)^{\frac{p-q}{p}}}{2^{p-q}(\sigma - q)\theta p \mathcal{S}_{q,h}^{-q}} \left(\frac{\beta_*}{2\alpha_0}\right)^{\frac{p-q}{p'}} > 0. \tag{3.16}$$

By using (3.7) and Lemma 2.2, Lemma 2.3 and Lemma 2.5, one has

$$\begin{cases} (u_n, v_n) \rightharpoonup (u_{\lambda,\mu}, v_{\lambda,\mu}) & \text{in } \mathbf{X}; \\ (u_n, v_n) \to (u_{\lambda,\mu}, v_{\lambda,\mu}) & \text{in } L^{\nu}(\mathbb{R}^N) \times L^{\nu}(\mathbb{R}^N),\ \forall\ \nu \in [p, \infty); \\ (u_n, v_n) \to (u_{\lambda,\mu}, v_{\lambda,\mu}) & \text{in } L^{\xi}(\mathbb{R}^N, |x|^{-\gamma}\,\mathrm{d}x) \times L^{\xi}(\mathbb{R}^N, |x|^{-\gamma}\,\mathrm{d}x),\ \forall\ \xi \in [p, \infty); \\ (u_n, v_n) \to (u_{\lambda,\mu}, v_{\lambda,\mu}) & \text{in } L_h^q(\mathbb{R}^N) \times L_h^q(\mathbb{R}^N); \\ (u_n, v_n) \to (u_{\lambda,\mu}, v_{\lambda,\mu}) & \text{a.e. in } \mathbb{R}^N \quad \text{as} \quad n \to \infty. \end{cases} \tag{3.17}$$

For each $(u, v) \in \mathbf{X}$, we define the functional $L(u, v) : \mathbf{X} \to \mathbb{R}$ by

$$\big\langle L(u, v), (\varphi, \psi) \big\rangle = \big\langle u, \varphi \big\rangle_{K_p, V} + \big\langle v, \psi \big\rangle_{K_p, V}, \qquad \forall\ (\varphi, \psi) \in \mathbf{X}.$$

Recalling the elementary inequality as follows

$$a^{\alpha} c^{1-\alpha} + b^{\alpha} d^{1-\alpha} \le (a + b)^{\alpha} (c + d)^{1-\alpha}, \qquad \forall\ a, b, c, d \ge 0 \quad \text{and} \quad \alpha \in (0, 1). \tag{3.18}$$

By applying the Hölder's inequality and (3.18), it is not difficult to show that

$$\big|\big\langle L(u, v), (\varphi, \psi) \big\rangle\big| \le \|(u, v)\|^{p-1} \|(\varphi, \psi)\|, \qquad \forall\ (\varphi, \psi) \in \mathbf{X}.$$

Thus, the definition of L implies that for each $(u, v) \in \mathbf{X}$, $L(u, v)$ is a continuous linear functional on $\mathbf{X}$. Consequently, the weak convergence of $\{(u_n, v_n)\}_n$ in $\mathbf{X}$ gives that

$$\big\langle L(u_{\lambda,\mu}, v_{\lambda,\mu}), (u_n - u_{\lambda,\mu}, v_n - v_{\lambda,\mu}) \big\rangle = o_n(1) \quad \text{as } n \to \infty. \tag{3.19}$$

Furthermore, due to (3.17), there exists $l_p \ge 0$ such that up to a subsequence still denoted by same symbol, we have $\|(u_n, v_n)\| \to l_p$ as $n \to \infty$. In virtue of (3.7), we can also deduce that

$$\big\langle J'_{\lambda,\mu}(u_n, v_n), (u_n - u_{\lambda,\mu}, v_n - v_{\lambda,\mu}) \big\rangle = o_n(1) \quad \text{as } n \to \infty.$$

On simplifying the above convergence, we have

$$\begin{aligned} & M(\|(u_n, v_n)\|^p) \langle L(u_n, v_n), (u_n - u_{\lambda,\mu}, v_n - v_{\lambda,\mu}) \rangle \\ & \quad - \int_{\mathbb{R}^N} \frac{\nabla F(x, u_n, v_n).(u_n - u_{\lambda,\mu}, v_n - v_{\lambda,\mu})}{|x|^{\gamma}}\,\mathrm{d}x - \lambda \int_{\mathbb{R}^N} h(x) u_n^{q-1} (u_n - u_{\lambda,\mu})\,\mathrm{d}x \\ & \quad - \mu \int_{\mathbb{R}^N} h(x) v_n^{q-1} (v_n - v_{\lambda,\mu})\,\mathrm{d}x = o_n(1) \quad \text{as } n \to \infty. \end{aligned} \tag{3.20}$$

Using the notation of Lemma 2.5, (F_4), (M_2) and (3.15), we obtain from (3.7) that as $n \to \infty$

$$\begin{aligned} 0 > m_{\lambda,\mu} &= J_{\lambda,\mu}(u_n, v_n) - \frac{1}{\sigma} \langle J'_{\lambda,\mu}(u_n, v_n), (u_n, v_n) \rangle + o_n(1) \\ &\ge \frac{1}{p} \widehat{M}(\|(u_n, v_n)\|^p) - \frac{1}{\sigma} M(\|(u_n, v_n)\|^p) \|(u_n, v_n)\|^p \\ &\quad - \max\{\lambda, \mu\} \left(\frac{1}{q} - \frac{1}{\sigma}\right) \mathcal{S}_{q,h}^{-q} \|(u_n, v_n)\|^q + o_n(1) \\ &\ge \left(\frac{1}{\theta p} - \frac{1}{\sigma}\right) \kappa \|(u_n, v_n)\|^p - \max\{\lambda, \mu\} \left(\frac{1}{q} - \frac{1}{\sigma}\right) \mathcal{S}_{q,h}^{-q} \|(u_n, v_n)\|^q + o_n(1). \end{aligned}$$

Define $z_n = (u_n, v_n)$ and $z = (u_{\lambda,\mu}, v_{\lambda,\mu})$. Then it is easy to see that $|z_n| = \sqrt{u_n^2 + v_n^2} \le \psi_n := |u_n| + |v_n|$. By direct calculation, one has

$$\|\psi_n\|_{W^{s,p}} \le 2(\min\{V_0, K_0\})^{-\frac{1}{p}} \|(u_n, v_n)\|.$$

Hence from the above two inequalities and (3.16), we can easily deduce that

$$\limsup_{n\to\infty} \|\psi_n\|^{p'}_{W^{s,p}} \leq \left(\frac{2^{p-q}(\sigma-q)\theta p \mathcal{S}_{q,h}^{-q} \max\{\lambda,\mu\}}{q\kappa(\sigma-\theta p)\big(\min\{V_0,K_0\}\big)^{\frac{p-q}{p}}} \right)^{\frac{p'}{p-q}} < \frac{\beta_*}{2\alpha_0}. \tag{3.21}$$

By using the Hölder's inequality, (3.17) and (3.18), we have

$$\begin{aligned}
&\left| \int_{\mathbb{R}^N} h(x)\{\lambda u_n^{q-1}(u_n - u_{\lambda,\mu}) + \mu v_n^{q-1}(v_n - v_{\lambda,\mu})\}\, \mathrm{d}x \right| \\
&\quad \leq \max\{\lambda,\mu\}\left[\|u_n\|_{q,h}^{q-1} \|u_n - u_{\lambda,\mu}\|_{q,h} + \|v_n\|_{q,h}^{q-1} \|v_n - v_{\lambda,\mu}\|_{q,h} \right] \\
&\quad \leq \max\{\lambda,\mu\} \|(u_n,v_n)\|^{q-1}_{L_h^q(\mathbb{R}^N)\times L_h^q(\mathbb{R}^N)} \|(u_n - u_{\lambda,\mu}, v_n - v_{\lambda,\mu})\|_{L_h^q(\mathbb{R}^N)\times L_h^q(\mathbb{R}^N)} \\
&\quad \leq \max\{\lambda,\mu\} \mathcal{S}_{q,h}^{-(q-1)} \sup_{n\in\mathbb{N}} \|(u_n,v_n)\|^{q-1} \|(u_n - u_{\lambda,\mu}, v_n - v_{\lambda,\mu})\|_{L_h^q(\mathbb{R}^N)\times L_h^q(\mathbb{R}^N)} \\
&\quad \to 0 \quad \text{as } n \to \infty,
\end{aligned}$$

thanks to the boundedness of the sequence $\{(u_n, v_n)\}_n$ in $\mathbf{X}$. It follows at once that

$$\lim_{n\to\infty} \int_{\mathbb{R}^N} h(x)\{\lambda u_n^{q-1}(u_n - u_{\lambda,\mu}) + \mu v_n^{q-1}(v_n - v_{\lambda,\mu})\}\, \mathrm{d}x = 0. \tag{3.22}$$

Set

$$I_1 = \varepsilon \int_{\mathbb{R}^N} \frac{|z_n|^{\theta p-1}|z_n - z|}{|x|^\gamma}\, \mathrm{d}x \quad \text{and} \quad I_2 = \kappa_\varepsilon \int_{\mathbb{R}^N} \frac{\Phi(\alpha_0|z_n|^{p'})|z_n - z|}{|x|^\gamma}\, \mathrm{d}x.$$

Invoking the Hölder's inequality, we obtain by using (3.17) and the boundedness of $\{(u_n, v_n)\}_n$ in $\mathbf{X}$ that

$$\begin{aligned}
I_1 &\leq \varepsilon \left(\int_{\mathbb{R}^N} \frac{|z_n|^{\theta p}}{|x|^\gamma}\, \mathrm{d}x \right)^{\frac{\theta p-1}{\theta p}} \left(\int_{\mathbb{R}^N} \frac{|z_n - z|^{\theta p}}{|x|^\gamma}\, \mathrm{d}x \right)^{\frac{1}{\theta p}} \\
&\leq 2^{\theta p} \varepsilon \|(u_n,v_n)\|^{\theta p-1}_{L^{\theta p}(\mathbb{R}^N, |x|^{-\gamma}\,\mathrm{d}x)\times L^{\theta p}(\mathbb{R}^N, |x|^{-\gamma}\,\mathrm{d}x)} \\
&\qquad \times \|(u_n - u_{\lambda,\mu}, v_n - v_{\lambda,\mu})\|_{L^{\theta p}(\mathbb{R}^N, |x|^{-\gamma}\,\mathrm{d}x)\times L^{\theta p}(\mathbb{R}^N, |x|^{-\gamma}\,\mathrm{d}x)} \\
&\leq 2^{\theta p} \varepsilon \mathcal{B}_{\theta p,\gamma}^{-(\theta p-1)} \sup_{n\in\mathbb{N}} \|(u_n,v_n)\|^{\theta p-1} \\
&\qquad \times \|(u_n - u_{\lambda,\mu}, v_n - v_{\lambda,\mu})\|_{L^{\theta p}(\mathbb{R}^N, |x|^{-\gamma}\,\mathrm{d}x)\times L^{\theta p}(\mathbb{R}^N, |x|^{-\gamma}\,\mathrm{d}x)} \\
&\to 0 \quad \text{as } n \to \infty.
\end{aligned}$$

Define $\tilde{\psi}_n = \psi_n / \|\psi_n\|_{W^{s,p}}$. Suppose $t \geq p$ and $t' = \frac{t}{t-1} > 1$ such that $\frac{1}{t} + \frac{1}{t'} = 1$. Due to (3.21), there exist $m > 0$ and $n_0 \in \mathbb{N}$ such that $\|\psi_n\|^{p'}_{W^{s,p}} < m < \beta_*/2\alpha_0$ for all $n \geq n_0$. Now choose $t' > 1$ close to 1 in such a way that there holds $\alpha_0 t' \|\psi_n\|^{p'}_{W^{s,p}} < t'\beta_*/2 < \alpha_*$ for all $n \geq n_0$ with

$\alpha_* \leq \alpha^*_{s,N}$. Using the Hölder's inequality, Lemma 2.6 and (3.17), we get

$$\begin{aligned}
I_2 &\leq \kappa_\varepsilon \left\| \frac{\Phi\big(\alpha_0 |z_n|^{p'}\big)}{|x|^{\frac{\gamma}{t'}}} \right\|_{t'} \left(\int_{\mathbb{R}^N} \frac{|z_n - z|^t}{|x|^\gamma}\, \mathrm{d}x \right)^{\frac{1}{t}} \\
&\leq C^{\frac{1}{t'}} \kappa_\varepsilon \left(\int_{\mathbb{R}^N} \frac{\Phi\big(\alpha_0 t' |\psi_n|^{p'}\big)}{|x|^\gamma}\, \mathrm{d}x \right)^{\frac{1}{t'}} \left(\int_{\mathbb{R}^N} \frac{|z_n - z|^t}{|x|^\gamma}\, \mathrm{d}x \right)^{\frac{1}{t}} \\
&\leq 2C^{\frac{1}{t'}} \kappa_\varepsilon \left(\int_{\mathbb{R}^N} \frac{\Phi\big(\alpha_0 t' \|\psi_n\|^{p'}_{W^{s,p}} |\tilde{\psi}_n|^{p'}\big)}{|x|^\gamma}\, \mathrm{d}x \right)^{\frac{1}{t'}} \\
&\quad \times \|(u_n - u_{\lambda,\mu}, v_n - v_{\lambda,\mu})\|_{L^t(\mathbb{R}^N, |x|^{-\gamma}\, \mathrm{d}x) \times L^t(\mathbb{R}^N, |x|^{-\gamma}\, \mathrm{d}x)} \\
&\leq \hat{C} \|(u_n - u_{\lambda,\mu}, v_n - v_{\lambda,\mu})\|_{L^t(\mathbb{R}^N, |x|^{-\gamma}\, \mathrm{d}x) \times L^t(\mathbb{R}^N, |x|^{-\gamma}\, \mathrm{d}x)} \to 0 \quad \text{as } n \to \infty,
\end{aligned}$$

where

$$\hat{C} = 2C^{\frac{1}{t'}} \kappa_\varepsilon \left(\sup_{n \geq n_0} \int_{\mathbb{R}^N} \frac{\Phi\big(\alpha_0 t' \|\psi_n\|^{p'}_{W^{s,p}} |\tilde{\psi}_n|^{p'}\big)}{|x|^\gamma}\, \mathrm{d}x \right)^{\frac{1}{t'}} < +\infty,$$

thanks to Theorem 2.7. Consequently, we obtain from (F_2) that

$$\left| \int_{\mathbb{R}^N} \frac{\nabla F(x, u_n, v_n).(u_n - u_{\lambda,\mu}, v_n - v_{\lambda,\mu})}{|x|^\gamma}\, \mathrm{d}x \right| \leq I_1 + I_2 \to 0 \quad \text{as } n \to \infty.$$

It follows that

$$\lim_{n \to \infty} \int_{\mathbb{R}^N} \frac{\nabla F(x, u_n, v_n).(u_n - u_{\lambda,\mu}, v_n - v_{\lambda,\mu})}{|x|^\gamma}\, \mathrm{d}x = 0. \tag{3.23}$$

Passing limit $n \to \infty$ in (3.20) and using (3.22) as well as (3.23), we get

$$M(\|(u_n, v_n)\|^p) \langle L(u_n, v_n), (u_n - u_{\lambda,\mu}, v_n - v_{\lambda,\mu}) \rangle = o_n(1) \quad \text{as } n \to \infty.$$

It follows from $\inf_{n \in \mathbb{N}} \|(u_n, v_n)\| = d > 0$ that $l_p > 0$. This shows that $M(\|(u_n, v_n)\|^p) \to M(l_p^p) > 0$ as $n \to \infty$, thanks to the continuity of M. In conclusion, from the above convergence, we deduce that

$$\big\langle L(u_n, v_n), (u_n - u_{\lambda,\mu}, v_n - v_{\lambda,\mu}) \big\rangle = o_n(1) \quad \text{as} \quad n \to \infty. \tag{3.24}$$

On combining (3.19) and (3.23), we obtain

$$\big\langle L(u_n, v_n) - L(u_{\lambda,\mu}, v_{\lambda,\mu}), (u_n - u_{\lambda,\mu}, v_n - v_{\lambda,\mu}) \big\rangle = o_n(1) \quad \text{as } n \to \infty. \tag{3.25}$$

Recall the well-known Simon inequality [42] as follows:

$$|\xi - \eta|^p \leq \begin{cases} C_p (|\xi|^{p-2}\xi - |\eta|^{p-2}\eta).(\xi - \eta) & \text{for } p \geq 2, \\ \widetilde{C}_p [(|\xi|^{p-2}\xi - |\eta|^{p-2}\eta).(\xi - \eta)]^{\frac{p}{2}} (|\xi|^p + |\eta|^p)^{\frac{2-p}{2}} & \text{for } 1 < p < 2, \end{cases} \tag{3.26}$$

where $\xi, \eta \in \mathbb{R}^N$ and C_p as well as $\widetilde{C}_p$ are positive constants depending only upon p. In virtue of the Simon inequality, we distinguish the following two situations :

Situation 1. Let $p \geq 2$, then we obtain from (3.25) and (3.26) that

$$\begin{aligned}
\|(u_n, v_n) - (u_{\lambda,\mu}, v_{\lambda,\mu})\|^p &\leq C_p \big\langle L(u_n, v_n) - L(u_{\lambda,\mu}, v_{\lambda,\mu}), (u_n - u_{\lambda,\mu}, v_n - v_{\lambda,\mu}) \big\rangle \\
&\to 0 \quad \text{as } n \to \infty.
\end{aligned}$$

It follows that $(u_n, v_n) \to (u_{\lambda,\mu}, v_{\lambda,\mu})$ in $\mathbf{X}$ as $n \to \infty$ for any $p \geq 2$.

Situation 2. Let $1 < p < 2$. First, recall the following elementary inequality:

$$(a+b)^{\frac{2-p}{2}} \leq a^{\frac{2-p}{2}} + b^{\frac{2-p}{2}}, \qquad \forall\, a, b \geq 0 \quad \text{and} \quad 1 < p < 2. \tag{3.27}$$

Using the Hölder's inequality, (3.25), (3.26) and (3.27), we obtain

$$\begin{aligned}
&\|(u_n, v_n) - (u_{\lambda,\mu}, v_{\lambda,\mu})\|^p \\
&\quad \leq \widetilde{C}_p[\langle L(u_n, v_n) - L(u_{\lambda,\mu}, v_{\lambda,\mu}), (u_n - u_{\lambda,\mu}, v_n - v_{\lambda,\mu})\rangle]^{\frac{p}{2}} \\
&\qquad \times \left(\|(u_n, v_n)\|^p + \|(u_{\lambda,\mu}, v_{\lambda,\mu})\|^p\right)^{\frac{2-p}{2}} \\
&\quad \leq \widetilde{C}_p[\langle L(u_n, v_n) - L(u_{\lambda,\mu}, v_{\lambda,\mu}), (u_n - u_{\lambda,\mu}, v_n - v_{\lambda,\mu})\rangle]^{\frac{p}{2}} \\
&\qquad \times \left(\|(u_n, v_n)\|^{\frac{(2-p)p}{2}} + \|(u_{\lambda,\mu}, v_{\lambda,\mu})\|^{\frac{(2-p)p}{2}}\right) \\
&\quad \leq C[\langle L(u_n, v_n) - L(u_{\lambda,\mu}, v_{\lambda,\mu}), (u_n - u_{\lambda,\mu}, v_n - v_{\lambda,\mu})\rangle]^{\frac{p}{2}} \to 0 \quad \text{as } n \to \infty,
\end{aligned}$$

where

$$C = \widetilde{C}_p \left(\sup_{n\in\mathbb{N}} \|(u_n, v_n)\|^{\frac{(2-p)p}{2}} + \|(u_{\lambda,\mu}, v_{\lambda,\mu})\|^{\frac{(2-p)p}{2}} \right) < +\infty,$$

thanks to the uniform boundedness of the sequence

$$\left\{ \|(u_n, v_n)\|^{\frac{(2-p)p}{2}} + \|(u_{\lambda,\mu}, v_{\lambda,\mu})\|^{\frac{(2-p)p}{2}} \right\}_n \quad \text{in } \mathbb{R}.$$

This shows at once that $(u_n, v_n) \to (u_{\lambda,\mu}, v_{\lambda,\mu})$ in $\mathbf{X}$ as $n \to \infty$ for any $1 < p < 2$.

From the above discussions, we conclude that $(u_n, v_n) \to (u_{\lambda,\mu}, v_{\lambda,\mu})$ in $\mathbf{X}$ as $n \to \infty$. Now we shall discuss about the situation when $\inf_{n\in\mathbb{N}} \|(u_n, v_n)\| = 0$.

Case 2. Let $\inf_{n\in\mathbb{N}} \|(u_n, v_n)\| = 0$. If $(0,0)$ is an isolated point of the sequence $\{(u_n, v_n)\}_n$, then there exists a subsequence still denoted by the same symbol such that

$$\inf_{n\in\mathbb{N}} \|(u_n, v_n)\| = d > 0.$$

In this scenario, we can proceed as before. On the other hand, if $(0,0)$ is an accumulation point of $\{(u_n, v_n)\}_n$, then up to a subsequence still denoted by itself such that it strongly converges to $(u_{\lambda,\mu}, v_{\lambda,\mu}) = (0,0)$. This situation is impossible. Indeed, if not, then $0 = J_{\lambda,\mu}(0,0) = m_{\lambda,\mu} < 0$, which is a contradiction.

By using $(u_n, v_n) \to (u_{\lambda,\mu}, v_{\lambda,\mu})$ in $\mathbf{X}$ as $n \to \infty$, we deduce that $J_{\lambda,\mu}(u_{\lambda,\mu}, v_{\lambda,\mu}) = m_{\lambda,\mu}$ and $J'_{\lambda,\mu}(u_{\lambda,\mu}, v_{\lambda,\mu}) = 0$, thanks to $J_{\lambda,\mu} \in C^1(\mathbf{X}, \mathbb{R})$. This shows that $(u_{\lambda,\mu}, v_{\lambda,\mu}) \in \overline{B}_\rho$ and thus the solution $(u_{\lambda,\mu}, v_{\lambda,\mu})$ of the system $(\mathcal{S}_{\lambda,\mu})$ is also a minimizer of the functional $J_{\lambda,\mu}$ in $\overline{B}_\rho$. Consequently, we deduce that

$$J_{\lambda,\mu}(u_{\lambda,\mu}, v_{\lambda,\mu}) = m_{\lambda,\mu} < 0 < j \leq J_{\lambda,\mu}(u, v), \qquad \forall\, (u, v) \in \partial B_\rho,$$

thanks to Lemma 3.2. It follows that $(u_{\lambda,\mu}, v_{\lambda,\mu}) \in B_\rho$ and hence $(u_{\lambda,\mu}, v_{\lambda,\mu})$ is a nontrivial nonnegative solution of the system $(\mathcal{S}_{\lambda,\mu})$ for all $\lambda > 0$ and $\mu > 0$ such that $\max\{\lambda, \mu\} < \widetilde{\lambda}$.

On the other hand, one can see that $\{(u_{\lambda,\mu}, v_{\lambda,\mu})\}_{(\lambda,\mu)\in(0,\widetilde{\lambda})\times(0,\widetilde{\lambda})}$ is uniformly bounded in $\mathbf{X}$, thanks to the fact that $\rho > 0$, which is independent of $\lambda > 0$ and $\mu > 0$, as specified in

Lemma 3.2. In virtue of (F_4), (M_2), (3.15) and using $(u_n, v_n) \to (u_{\lambda,\mu}, v_{\lambda,\mu})$ in $\mathbf{X}$ as $n \to \infty$, one has

$$\begin{aligned} 0 > m_{\lambda,\mu} &= \lim_{n\to\infty} \left[J_{\lambda,\mu}(u_n, v_n) - \frac{1}{\sigma} \langle J'_{\lambda,\mu}(u_n, v_n), (u_n, v_n) \rangle \right] \\ &\geq \frac{1}{p} \widehat{M}(\|(u_{\lambda,\mu}, v_{\lambda,\mu})\|^p) - \frac{1}{\sigma} M(\|(u_{\lambda,\mu}, v_{\lambda,\mu})\|^p) \|(u_{\lambda,\mu}, v_{\lambda,\mu})\|^p \\ &\quad - \max\{\lambda, \mu\} \left(\frac{1}{q} - \frac{1}{\sigma} \right) \mathcal{S}_{q,h}^{-q} \|(u_{\lambda,\mu}, v_{\lambda,\mu})\|^q \\ &\geq \left(\frac{1}{\theta p} - \frac{1}{\sigma} \right) \kappa \|(u_{\lambda,\mu}, v_{\lambda,\mu})\|^p - \max\{\lambda, \mu\} \mathcal{D}_{q,h}, \end{aligned}$$

where

$$\mathcal{D}_{q,h} = \left(\frac{1}{q} - \frac{1}{\sigma} \right) \mathcal{S}_{q,h}^{-q} \sup_{(\lambda,\mu)\in(0,\widetilde{\lambda})\times(0,\widetilde{\lambda})} \|(u_{\lambda,\mu}, v_{\lambda,\mu})\|^q < +\infty.$$

This yields at once that

$$0 \geq \limsup_{(\lambda,\mu)\to(0^+,0^+)} m_{\lambda,\mu} \geq \limsup_{(\lambda,\mu)\to(0^+,0^+)} \left(\frac{1}{\theta p} - \frac{1}{\sigma} \right) \kappa \|(u_{\lambda,\mu}, v_{\lambda,\mu})\|^p \geq 0.$$

This implies that

$$\lim_{(\lambda,\mu)\to(0^+,0^+)} \|(u_{\lambda,\mu}, v_{\lambda,\mu})\| = 0,$$

and thus we conclude the proof. □

4 Proof of Theorem 1.4

Throughout this section, we assume without further mentioning that the structural assumptions required in Theorem 1.4 hold. To prove Theorem 1.4, we need the mountain pass theorem and some basic definitions, as stated below.

Definition 4.1 (Palais–Smale compactness condition)**.** Let X be a Banach space and $\mathcal{I} : X \to \mathbb{R}$ be a functional of class $C^1(X, \mathbb{R})$. We say that $\mathcal{I}$ satisfies the Palais–Smale compactness condition at a suitable level $c \in \mathbb{R}$, if for any sequence $\{u_n\}_n \subset X$ such that

$$\mathcal{I}(u_n) \to c \quad \text{and} \quad \sup_{\|\varphi\|_X=1} |\langle \mathcal{I}'(u_n), \varphi \rangle| \to 0 \quad \text{as } n \to \infty \tag{4.1}$$

has a strongly convergent subsequence in X. Note that if this strongly convergent subsequence exists only for some values of c, we say that $\mathcal{I}$ satisfies a local Palais–Smale condition. We also remark that the sequence $\{u_n\}_n \subset X$ satisfying (4.1) is known as a Palais–Smale sequence at level $c \in \mathbb{R}$ [$(PS)_c$ sequence in short].

Theorem 4.2 (The mountain pass theorem, cf. [41, 44])**.** *Let X be a real Banach space and $I \in C^1(X, \mathbb{R})$. Suppose $I(0) = 0$ and*

(a) there exist two constants $\alpha, \rho > 0$ such that $I(u) \geq \alpha$ for all $u \in X$ with $\|u\| = \rho$;

(b) there exists $e \in X$ satisfying $\|e\| > \rho$ such that $I(e) < 0$.

Define

$$\Gamma = \{\gamma_* \in C^1([0,1], X) : \ \gamma_*(0) = 1, \ \gamma_*(1) = e\}.$$

Then

$$c = \inf_{\gamma_* \in \Gamma} \max_{t \in [0,1]} I(\gamma_*(t)) \geq \alpha$$

and there exists a $(PS)_c$ sequence $\{u_n\}_n$ for I in X. Consequently, if I satisfies the Palais–Smale condition, then I possesses a critical value $c \geq \alpha$.

Now we shall verify the validity of the mountain pass geometrical structure of the functional $J_{\lambda,\mu}$.

Lemma 4.3 (Mountain Pass Geometry-I)**.** *For all $\lambda > 0$ and $\mu > 0$, there exist numbers $j_0 > 0$ and $\rho_0 \in (0,1]$ very small enough such that $J_{\lambda,\mu}(u,v) \geq j_0$ for all $(u,v) \in \mathbf{X}$ with $\|(u,v)\| = \rho_0$.*

Proof. The assumption (M_2) gives that

$$\widehat{M}(t) \geq \widehat{M}(1)t^\theta, \qquad \forall\ t \in [0,1].$$

Suppose $\bar{\delta} \in (0,1]$ small enough and there holds $0 < \|(u,v)\| \leq \bar{\delta}$. Then by using the notation of Lemma 3.2, we can easily deduce that

$$\int_{\mathbb{R}^N} \frac{|F(x,u,v)|}{|x|^\gamma}\, \mathrm{d}x \leq 2^{\theta p}\mathcal{B}_{\theta p,\gamma}^{-\theta p}\varepsilon\|(u,v)\|^{\theta p} + 2^{\vartheta} DC^{\frac{1}{t'}}\mathcal{B}_{\vartheta t,\gamma}^{-\vartheta}\tilde{\kappa}_\varepsilon\|(u,v)\|^{\vartheta}$$

for any $0 < \|(u,v)\| \leq \bar{\delta}$. Consequently, from the above information, we obtain for any $0 < \|(u,v)\| \leq \bar{\delta}$ that

$$J_{\lambda,\mu}(u,v) \geq A\|(u,v)\|^{\theta p} - B\|(u,v)\|^{\vartheta} - C\|(u,v)\|^{q}, \tag{4.2}$$

where

$$A = \frac{\widehat{M}(1)}{p} - 2^{\theta p}\mathcal{B}_{\theta p,\gamma}^{-\theta p}\varepsilon, \quad B = 2^{\vartheta} DC^{\frac{1}{t'}}\mathcal{B}_{\vartheta t,\gamma}^{-\vartheta}\tilde{\kappa}_\varepsilon \quad \text{and} \quad C = \frac{1}{q}\max\{\lambda,\mu\}\mathcal{A}_q^{-q}\|h\|_\infty.$$

Choose $\varepsilon > 0$ sufficiently small such that $A > 0$. Suppose $\xi = \min\{\vartheta, q\}$, then using the fact that $0 < \|(u,v)\| \leq \bar{\delta} \leq 1$, we obtain from (4.2) that

$$J_{\lambda,\mu}(u,v) \geq A\|(u,v)\|^{\theta p} - (B+C)\|(u,v)\|^{\xi}, \quad \forall\ (u,v) \in \mathbf{X} \text{ with } 0 < \|(u,v)\| \leq \bar{\delta}. \tag{4.3}$$

Define the function

$$f(\ell) = A\ell^{\theta p} - (B+C)\ell^{\xi}, \qquad \forall\ \ell \in [0,\bar{\delta}].$$

Observe that f admits a positive maximum j_0 in $[0,\bar{\delta}]$ at a point $\rho_0 \in (0,\bar{\delta}]$. This shows that for all $(u,v) \in \mathbf{X}$ with $\|(u,v)\| = \rho_0$, we obtain from (4.3) that

$$J_{\lambda,\mu}(u,v) \geq A\rho_0^{\theta p} - (B+C)\rho_0^{\xi} = f(\rho_0) = j_0 > 0.$$

This completes the proof. □

Lemma 4.4 (Mountain Pass Geometry-II)**.** *For all $\lambda > 0$ and $\mu > 0$, there exist a nonnegative nontrivial couple $(e_1, e_2) \in C_0^\infty(\mathbb{R}^N) \times C_0^\infty(\mathbb{R}^N)$ with both components nontrivial, and also independent of λ and μ such that $J_{\lambda,\mu}(e_1,e_2) < 0$ for all $\|(e_1,e_2)\| > \rho_0$, where ρ_0 is stated as in Lemma 4.3.*

Proof. Due to the assumption (M_2), we obtain

$$\widehat{M}(t) \leq \widehat{M}(1)t^{\theta}, \qquad \forall\, t \in [1,\infty).$$

Let $(u,v) \in C_0^\infty(\mathbb{R}^N) \times C_0^\infty(\mathbb{R}^N)$ be a nonnegative nontrivial couple with both components nontrivial such that $\|(u,v)\| = 1$ and there holds $\int_{\mathbb{R}^N} \frac{F(x,u,v)}{|x|^\gamma}\,\mathrm{d}x > 0$, thanks to (F_1).

Define the map

$$\zeta : [1,\infty) \to \mathbb{R}$$

by

$$\zeta(t) = t^{-\sigma}F(x,tu,tv) - F(x,u,v),\ \forall\, t \geq 1 \quad \text{and} \quad u,v \in \mathbb{R}^+.$$

By direct computation, we have

$$\begin{aligned}\zeta'(t) &= t^{-\sigma}F_u(x,tu,tv)u + t^{-\sigma}F_v(x,tu,tv)v - \sigma t^{-\sigma-1}F(x,tu,tv)\\ &= t^{-\sigma-1}[F_u(x,tu,tv)tu + F_v(x,tu,tv)tv - \sigma F(x,tu,tv)]\\ &= t^{-\sigma-1}[\nabla F(x,tu,tv).(tu,tv) - \sigma F(x,tu,tv)].\end{aligned}$$

This together with (F_4) implies at once that $\zeta'(t) \geq 0$ for all $t \geq 1$ and $u,v \in \mathbb{R}^+$. It follows that the map $[1,\infty) \ni t \mapsto \zeta(t)$ is monotonically increasing. In conclusion, we have

$$F(x,tu,tv) \geq t^{\sigma}F(x,u,v), \quad \forall\, t \geq 1 \quad \text{and} \quad u,v \in \mathbb{R}^+.$$

Choosing $t > \rho_0$ sufficiently large enough, we get by using the above information that

$$\begin{aligned}J_{\lambda,\mu}(tu,tv) &\leq \frac{\widehat{M}(1)}{p}t^{\theta p}\|(u,v)\|^{\theta p} - \int_{\mathbb{R}^N}\frac{F(x,tu,tv)}{|x|^\gamma}\,\mathrm{d}x\\ &\leq \frac{\widehat{M}(1)}{p}t^{\theta p} - t^{\sigma}\int_{\mathbb{R}^N}\frac{F(x,u,v)}{|x|^\gamma}\,\mathrm{d}x \to -\infty \quad \text{as } t \to \infty,\end{aligned}$$

thanks to $\sigma > \theta p$. Hence by taking $(e_1,e_2) = (tu,tv)$ with $t > \rho_0$ sufficiently large enough, we get $J_{\lambda,\mu}(e_1,e_2) < 0$ for all $\|(e_1,e_2)\| > \rho_0$ and we conclude the proof. □

In view of Lemma 4.3 and Lemma 4.4, we notice that the functional $J_{\lambda,\mu}$ satisfies the geometrical assumptions required in Theorem 4.2. Hence we infer that there exists a $(PS)_{c_{\lambda,\mu}}$ sequence $\{(u_n,v_n)\}_n \subset \mathbf{X}$ such that

$$J_{\lambda,\mu}(u_n,v_n) \to c_{\lambda,\mu} \quad \text{and} \quad J'_{\lambda,\mu}(u_n,v_n) \to 0 \quad \text{in } \mathbf{X}^* \quad \text{as } n \to \infty,$$

where

$$c_{\lambda,\mu} = \inf_{\gamma_* \in \Gamma}\max_{t\in[0,1]} I(\gamma_*(t)) \geq j_0$$

with

$$\Gamma = \{\gamma_* \in C^1([0,1],\mathbf{X}) :\ \gamma_*(0) = (0,0),\ \gamma_*(1) = (e_1,e_2)\}.$$

It is obvious that $c_{\lambda,\mu} > 0$, thanks to Lemma 4.3. Now we will discuss about the asymptotic behaviour of the mountain pass level $c_{\lambda,\mu}$.

Lemma 4.5. *There holds*

$$\lim_{(\lambda,\mu)\to(\infty,\infty)} c_{\lambda,\mu} = 0.$$

Proof. Let (e_1, e_2) be a couple as in Lemma 4.4 and thus $J_{\lambda,\mu}(te_1, te_2) \to -\infty$ as $t \to \infty$. So, there exists $t_{\lambda,\mu} > 0$ such that

$$J_{\lambda,\mu}(t_{\lambda,\mu}e_1, t_{\lambda,\mu}e_2) = \max_{t\geq 0} J_{\lambda,\mu}(te_1, te_2).$$

Consequently, we have

$$\left\langle J'_{\lambda,\mu}(t_{\lambda,\mu}e_1, t_{\lambda,\mu}e_2), (e_1, e_2)\right\rangle = 0.$$

On simplifying, we deduce by using (F_4) that

$$\begin{aligned} M(\|t_{\lambda,\mu}(e_1,e_2)\|^p)\|t_{\lambda,\mu}(e_1,e_2)\|^p &= \int_{\mathbb{R}^N} \frac{\nabla F(x, t_{\lambda,\mu}e_1, t_{\lambda,\mu}e_2).(t_{\lambda,\mu}e_1, t_{\lambda,\mu}e_2)}{|x|^\gamma}\,\mathrm{d}x \\ &\quad + t^q_{\lambda,\mu}\int_{\mathbb{R}^N} h(x)\{\lambda e_1^q + \mu e_2^q\}\,\mathrm{d}x \\ &\geq \sigma \int_{\mathbb{R}^N} \frac{F(x, t_{\lambda,\mu}e_1, t_{\lambda,\mu}e_2)}{|x|^\gamma}\,\mathrm{d}x. \end{aligned} \tag{4.4}$$

From this we conclude that $\{t_{\lambda,\mu}\}_{(\lambda,\mu)}$ is a bounded sequence of real numbers. Indeed, if not, let there exists a subsequence of $\{t_{\lambda,\mu}\}_{(\lambda,\mu)}$ still denoted by itself such that $t_{\lambda,\mu} \to \infty$ as $(\lambda,\mu) \to (\infty,\infty)$. Hence without loss of generality, we can assume $t_{\lambda,\mu} \geq 1$ for sufficiently large values of λ and μ. In addition, due to (M_2) and using similarly approach as in Lemma 4.4, we can deduce that

$$\widehat{M}(t) \leq \widehat{M}(1)t^\theta,\ \forall\ t \geq 1 \quad \text{and} \quad F(x, t_{\lambda,\mu}e_1, t_{\lambda,\mu}e_2) \geq t^\sigma_{\lambda,\mu}F(x, e_1, e_2). \tag{4.5}$$

In virtue of (M_2) and using (4.4) as well as (4.5), we get

$$\begin{aligned} \theta\widehat{M}(1)t^\theta_{\lambda,\mu}\|(e_1,e_2)\|^p &\geq \theta\widehat{M}(\|t_{\lambda,\mu}(e_1,e_2)\|^p) \geq M(\|t_{\lambda,\mu}(e_1,e_2)\|^p)\|t_{\lambda,\mu}(e_1,e_2)\|^p \\ &\geq \sigma t^\sigma_{\lambda,\mu}\int_{\mathbb{R}^N} \frac{F(x,e_1,e_2)}{|x|^\gamma}\,\mathrm{d}x. \end{aligned}$$

This yields at once that

$$\frac{1}{\sigma}\theta\widehat{M}(1)t^{\theta p-\sigma}_{\lambda,\mu}\|(e_1,e_2)\|^p \geq \int_{\mathbb{R}^N} \frac{F(x,e_1,e_2)}{|x|^\gamma}\,\mathrm{d}x.$$

Letting $(\lambda,\mu) \to (\infty,\infty)$ in the above inequality and using the fact that

$$\sigma > \theta p \quad \text{and} \quad \int_{\mathbb{R}^N} \frac{F(x,e_1,e_2)}{|x|^\gamma}\,\mathrm{d}x > 0,$$

we arrive at a contradiction, thanks to (F_1). This shows that $\{t_{\lambda,\mu}\}_{(\lambda,\mu)}$ is a bounded sequence of real numbers. Now, we fix a sequence $\{(\lambda_n,\mu_n)\}_n \subset \mathbb{R}^+ \times \mathbb{R}^+$ such that $(\lambda_n,\mu_n) \to (\infty,\infty)$ as $n \to \infty$. From the above arguments, we know that $\{t_{\lambda_n,\mu_n}\}_n$ is a bounded sequence of real numbers. This shows that there exists $t_0 \geq 0$ and a subsequence of $\{(\lambda_n,\mu_n)\}_n$ still denoted by itself such that $t_{\lambda_n,\mu_n} \to t_0$ as $n \to \infty$. In conclusion, due to the continuity of M, we infer that $\{M(\|t_{\lambda_n,\mu_n}(e_1,e_2)\|^p)\|t_{\lambda_n,\mu_n}(e_1,e_2)\|^p\}_n$ is bounded. So, there exists a constant $C > 0$ such that

$$M(\|t_{\lambda_n,\mu_n}(e_1,e_2)\|^p)\|t_{\lambda_n,\mu_n}(e_1,e_2)\|^p \leq C, \qquad \forall\ n \in \mathbb{N}.$$

We claim that $t_0 = 0$. Indeed, if not, let $t_0 > 0$. Consequently, we obtain from the above inequality and (4.4) that for all $n \in \mathbb{N}$, the following estimate holds

$$\int_{\mathbb{R}^N} \frac{\nabla F(x, t_{\lambda_n,\mu_n} e_1, t_{\lambda_n,\mu_n} e_2).(t_{\lambda_n,\mu_n} e_1, t_{\lambda_n,\mu_n} e_2)}{|x|^\gamma}\, \mathrm{d}x + t^q_{\lambda_n,\mu_n}\big(\lambda_n \|e_1\|^q_{q,h} + \mu_n \|e_2\|^q_{q,h}\big) \le C. \tag{4.6}$$

Due to (3.3) and Theorem 2.7, we obtain from the Lebesgue dominated convergence theorem that

$$\lim_{n\to\infty} \int_{\mathbb{R}^N} \frac{\nabla F(x, t_{\lambda_n,\mu_n} e_1, t_{\lambda_n,\mu_n} e_2).(t_{\lambda_n,\mu_n} e_1, t_{\lambda_n,\mu_n} e_2)}{|x|^\gamma}\, \mathrm{d}x = \int_{\mathbb{R}^N} \frac{\nabla F(x, t_0 e_1, t_0 e_2).(t_0 e_1, t_0 e_2)}{|x|^\gamma}\, \mathrm{d}x.$$

The above convergence together with $\|e_i\|^q_{q,h} > 0$ for $i = 1, 2$ implies that

$$\lim_{n\to\infty} \left[\int_{\mathbb{R}^N} \frac{\nabla F(x, t_{\lambda_n,\mu_n} e_1, t_{\lambda_n,\mu_n} e_2).(t_{\lambda_n,\mu_n} e_1, t_{\lambda_n,\mu_n} e_2)}{|x|^\gamma}\, \mathrm{d}x + t^q_{\lambda_n,\mu_n}\big(\lambda_n \|e_1\|^q_{q,h} + \mu_n \|e_2\|^q_{q,h}\big) \right] = \infty.$$

In virtue of (4.6), we arrive at a contradiction. It follows that $t_0 = 0$ and $t_{\lambda,\mu} \to 0$ as $(\lambda, \mu) \to (\infty, \infty)$, thanks to the arbitrariness of $\{(\lambda_n, \mu_n)\}_n$. Now consider the path $\xi(t) = t(e_1, e_2)$ with $t \in [0, 1]$, belongs to Γ. Using the continuity of $\widehat{M}$, we get

$$\begin{aligned} 0 < c_{\lambda,\mu} &\le \max_{t\ge 0} J_{\lambda,\mu}(\xi(t)) = J_{\lambda,\mu}(t_{\lambda,\mu} e_1, t_{\lambda,\mu} e_2) \\ &\le \frac{1}{p} \widehat{M}(\|t_{\lambda,\mu}(e_1, e_2)\|^p) \to 0 \quad \text{as } (\lambda, \mu) \to (\infty, \infty), \end{aligned}$$

thanks to the couple (e_1, e_2), which does not depend on λ and μ. This completes the proof. □

Lemma 4.6. *There exists $\widehat{\lambda} > 0$ such that for all $(\lambda, \mu) \in (\widehat{\lambda}, \infty) \times (\widehat{\lambda}, \infty)$, the functional $J_{\lambda,\mu}$ satisfies the $(PS)_{c_{\lambda,\mu}}$ condition on $\mathbf{X}$.*

Proof. Let $\{(u_n, v_n)\}_n \subset \mathbf{X}$ be a $(PS)_{c_{\lambda,\mu}}$ for $J_{\lambda,\mu}$. It follows at once that

$$\left\langle J'_{\lambda,\mu}(u_n, v_n), \frac{(u_n, v_n)}{\|(u_n, v_n)\|} \right\rangle = o_n(1) \quad \text{and} \quad J_{\lambda,\mu}(u_n, v_n) = c_{\lambda,\mu} + o_n(1) \quad \text{as } n \to \infty. \tag{4.7}$$

Possibly, we have two situations based on the nature of the Kirchhoff function M: either $\inf_{n\in\mathbb{N}} \|(u_n, v_n)\| = d > 0$ or $\inf_{n\in\mathbb{N}} \|(u_n, v_n)\| = 0$. Hence we have to discuss these situations separately.

Case 1. Let $\inf_{n\in\mathbb{N}} \|(u_n, v_n)\| = d > 0$. Denote $\kappa = \kappa(\tau)$ as the number corresponding to $\tau = d^p$ in (M_1) such that

$$M(\|(u_n, v_n)\|^p) \ge \kappa, \qquad \forall\ n \in \mathbb{N}. \tag{4.8}$$

Now we claim to prove $\{(u_n, v_n)\}_n$ is bounded in $\mathbf{X}$. For this, we first consider the case when $\theta p < \sigma \le q$. In this case, we obtain from (4.7), (4.8), (F_4) and (M_2) that as $n \to \infty$

$$\begin{aligned} c_{\lambda,\mu} + o_n(1) + o_n(1)\|(u_n, v_n)\| &= J_{\lambda,\mu}(u_n, v_n) - \frac{1}{\sigma}\langle J'_{\lambda,\mu}(u_n, v_n), (u_n, v_n)\rangle \\ &\ge \frac{1}{p}\widehat{M}(\|(u_n, v_n)\|^p) - \frac{1}{\sigma} M(\|(u_n, v_n)\|^p)\|(u_n, v_n)\|^p \\ &\ge \left(\frac{1}{\theta p} - \frac{1}{\sigma}\right)\kappa \|(u_n, v_n)\|^p. \end{aligned}$$

Since $p > 1$, we conclude from the above inequality that $\{(u_n, v_n)\}_n$ is bounded in $\mathbf{X}$ and thus we have

$$\|(u_n, v_n)\|^{p'} \leq \left(\frac{\sigma\theta p \; c_{\lambda,\mu}}{(\sigma - \theta p)\kappa} + o_n(1) \right)^{p'}. \tag{4.9}$$

Define $z_n = (u_n, v_n)$ and $z = (u_{\lambda,\mu}, v_{\lambda,\mu})$. Then it is easy to see that $|z_n| = \sqrt{u_n^2 + v_n^2} \leq \psi_n := |u_n| + |v_n|$. By direct calculation, we can deduce that

$$\|\psi_n\|_{W^{s,p}} \leq 2(\min\{V_0, K_0\})^{-\frac{1}{p}} \|(u_n, v_n)\|. \tag{4.10}$$

In virtue of (4.9) and (4.10), we infer that

$$\limsup_{n\to\infty} \|\psi_n\|^{p'}_{W^{s,p}} \leq \frac{2^{p'}}{(\min\{V_0, K_0\})^{\frac{1}{p-1}}} \left[\frac{\sigma\theta p \; c_{\lambda,\mu}}{(\sigma - \theta p)\kappa} \right]^{p'}. \tag{4.11}$$

Similarly, when $\sigma > q > \theta p$, we obtain from (4.7), (4.8), (F_4) and (M_2) that as $n \to \infty$

$$\begin{aligned} c_{\lambda,\mu} + o_n(1) + o_n(1)\|(u_n, v_n)\| &= J_{\lambda,\mu}(u_n, v_n) - \frac{1}{q}\langle J'_{\lambda,\mu}(u_n, v_n), (u_n, v_n)\rangle \\ &\geq \frac{1}{p}\widehat{M}(\|(u_n, v_n)\|^p) - \frac{1}{q}M(\|(u_n, v_n)\|^p)\|(u_n, v_n)\|^p \\ &\geq \left(\frac{1}{\theta p} - \frac{1}{q}\right)\kappa\|(u_n, v_n)\|^p. \end{aligned}$$

This shows that $\{(u_n, v_n)\}_n$ is bounded in $\mathbf{X}$. Using a similar procedure as discussed above, we have

$$\limsup_{n\to\infty} \|\psi_n\|^{p'}_{W^{s,p}} \leq \frac{2^{p'}}{(\min\{V_0, K_0\})^{\frac{1}{p-1}}} \left[\frac{q\theta p \; c_{\lambda,\mu}}{(q - \theta p)\kappa} \right]^{p'}. \tag{4.12}$$

On combining (4.11) and (4.12), we get

$$\limsup_{n\to\infty} \|\psi_n\|^{p'}_{W^{s,p}} \leq \frac{(2c_{\lambda,\mu})^{p'}}{(\min\{V_0, K_0\})^{\frac{1}{p-1}}} \left(\left[\frac{\sigma\theta p}{(\sigma - \theta p)\kappa} \right]^{p'} + \left[\frac{q\theta p}{(q - \theta p)\kappa} \right]^{p'} \right). \tag{4.13}$$

By using Lemma 4.5, there exists $\widehat{\lambda} > 0$ such that for all $(\lambda, \mu) \in (\widehat{\lambda}, \infty) \times (\widehat{\lambda}, \infty)$, we can assume

$$0 < c_{\lambda,\mu} < \left[\frac{\beta_*(\min\{V_0, K_0\})^{\frac{1}{p-1}}}{2^{p'+1}\alpha_0} \right]^{\frac{1}{p'}} \left(\left[\frac{\sigma\theta p}{(\sigma - \theta p)\kappa} \right]^{p'} + \left[\frac{q\theta p}{(q - \theta p)\kappa} \right]^{p'} \right)^{-\frac{1}{p'}}.$$

From the above inequality and (4.13), we obtain

$$\limsup_{n\to\infty} \|\psi_n\|^{p'}_{W^{s,p}} < \frac{\beta_*}{2\alpha_0}, \qquad \forall\ (\lambda, \mu) \in (\widehat{\lambda}, \infty) \times (\widehat{\lambda}, \infty).$$

Due to the boundedness of $\{(u_n, v_n)\}_n$ in $\mathbf{X}$, there exists $(u_{\lambda,\mu}, v_{\lambda,\mu}) \in \mathbf{X}$ such that up to a subsequence still denoted by itself, we can assume that $(u_n, v_n) \rightharpoonup (u_{\lambda,\mu}, v_{\lambda,\mu})$ in $\mathbf{X}$ as $n \to \infty$. In addition, by using the notations used in the proof of Theorem 1.3, it is easy to see that (3.17) holds, there exists $l_{\lambda,\mu} \geq 0$ such that up to a subsequence, we have $\|(u_n, v_n)\| \to l_{\lambda,\mu}$ as $n \to \infty$ and also we can easily obtain from (4.7) that

$$\left\langle J'_{\lambda,\mu}(u_n, v_n), (u_n - u_{\lambda,\mu}, v_n - v_{\lambda,\mu}) \right\rangle = o_n(1) \quad \text{as } n \to \infty,$$

thanks to the boundedness of $\{(u_n, v_n)\}_n$ in $\mathbf{X}$. Moreover, by using the Hölder's inequality, (3.17) and (3.18), one has

$$\begin{aligned}
&\left| \int_{\mathbb{R}^N} h(x)\{\lambda(u_n^+)^{q-1}(u_n - u_{\lambda,\mu}) + \mu(v_n^+)^{q-1}(v_n - v_{\lambda,\mu})\}\, \mathrm{d}x \right| \\
&\quad \le \max\{\lambda,\mu\}\|h\|_\infty \left[\|u_n\|_q^{q-1}\|u_n - u_{\lambda,\mu}\|_q + \|v_n\|_q^{q-1}\|v_n - v_{\lambda,\mu}\|_q \right] \\
&\quad \le \max\{\lambda,\mu\}\|h\|_\infty \|(u_n, v_n)\|^{q-1}_{L^q(\mathbb{R}^N)\times L^q(\mathbb{R}^N)} \|(u_n - u_{\lambda,\mu}, v_n - v_{\lambda,\mu})\|_{L^q(\mathbb{R}^N)\times L^q(\mathbb{R}^N)} \\
&\quad \le \max\{\lambda,\mu\}\|h\|_\infty \mathcal{A}_{q,h}^{-(q-1)} \sup_{n\in\mathbb{N}} \|(u_n, v_n)\|^{q-1} \|(u_n - u_{\lambda,\mu}, v_n - v_{\lambda,\mu})\|_{L^q(\mathbb{R}^N)\times L^q(\mathbb{R}^N)} \\
&\quad \to 0 \quad \text{as } n \to \infty.
\end{aligned}$$

It follows at once that

$$\lim_{n\to\infty} \int_{\mathbb{R}^N} h(x)\{\lambda(u_n^+)^{q-1}(u_n - u_{\lambda,\mu}) + \mu(v_n^+)^{q-1}(v_n - v_{\lambda,\mu})\}\, \mathrm{d}x = 0. \tag{4.14}$$

Using all the above information and proceeding likewise as in the proof of Theorem 1.3, we can prove that $(u_n, v_n) \to (u_{\lambda,\mu}, v_{\lambda,\mu})$ in $\mathbf{X}$ as $n \to \infty$. This together with $\inf_{n\in\mathbb{N}} \|(u_n, v_n)\| = d > 0$ implies that $l_{\lambda,\mu} = \|(u_{\lambda,\mu}, v_{\lambda,\mu})\| > 0$. This shows that $M(\|(u_n, v_n)\|^p) \to M(l^p_{\lambda,\mu}) > 0$ as $n \to \infty$, thanks to the continuity of M. Next, we claim that

$$\lim_{(\lambda,\mu)\to(\infty,\infty)} \|(u_{\lambda,\mu}, v_{\lambda,\mu})\| = 0.$$

Indeed, if not, let there exists a sequence $\{(\lambda_k, \mu_k)\}_k$ with $(\lambda_k, \mu_k) \to (\infty, \infty)$ as $k \to \infty$ such that $l_{\lambda_k,\mu_k} \to l_0 > 0$ as $k \to \infty$. It is easy to see that for $\varrho \in \{\sigma, q\}$ (according to the situations: either $\theta p < \sigma \le q$ or $\theta p < q < \sigma$), one has

$$c_{\lambda_k,\mu_k} = \lim_{n\to\infty} \left[J_{\lambda,\mu}(u_n, v_n) - \frac{1}{\varrho}\langle J'_{\lambda,\mu}(u_n, v_n), (u_n, v_n)\rangle \right] \ge \left(\frac{1}{\theta p} - \frac{1}{\varrho}\right) M(l^p_{\lambda_k,\mu_k}) l^p_{\lambda_k,\mu_k}.$$

Letting $k \to \infty$ in the above inequality and using Lemma 4.5, we get

$$0 \ge \left(\frac{1}{\theta p} - \frac{1}{\varrho}\right) M(l_0^p) l_0^p > 0,$$

which is not possible. It follows that

$$\lim_{(\lambda,\mu)\to(\infty,\infty)} \|(u_{\lambda,\mu}, v_{\lambda,\mu})\| = \lim_{(\lambda,\mu)\to(\infty,\infty)} l_{\lambda,\mu} = 0.$$

Now we shall discuss about the situation when $\inf_{n\in\mathbb{N}} \|(u_n, v_n)\| = 0$.

Case 2. Let $\inf_{n\in\mathbb{N}} \|(u_n, v_n)\| = 0$. If $(0,0)$ is an isolated point of the sequence $\{(u_n, v_n)\}_n$, then there exists a subsequence still denoted by the same symbol such that

$$\inf_{n\in\mathbb{N}} \|(u_n, v_n)\| = d > 0.$$

In this situation, we can proceed as in Case 1. Moreover, if $(0,0)$ is an accumulation point of $\{(u_n, v_n)\}_n$, then up to a subsequence still denoted by itself such that it strongly converges to $(u_{\lambda,\mu}, v_{\lambda,\mu}) = (0,0)$. This situation is impossible. Indeed, if not, then $0 = J_{\lambda,\mu}(0,0) = c_{\lambda,\mu} > 0$, which is a contradiction.

By using $(u_n, v_n) \to (u_{\lambda,\mu}, v_{\lambda,\mu})$ in $\mathbf{X}$ as $n \to \infty$ and the fact that $J_{\lambda,\mu} \in C^1(\mathbf{X}, \mathbb{R})$, we get $J_{\lambda,\mu}(u_{\lambda,\mu}, v_{\lambda,\mu}) = c_{\lambda,\mu} > 0$ and $J'_{\lambda,\mu}(u_{\lambda,\mu}, v_{\lambda,\mu}) = 0$. It follows from Lemma 3.1 that $(u_{\lambda,\mu}, v_{\lambda,\mu})$ is a nontrivial nonnegative solution of the system $(\mathcal{S}_{\lambda,\mu})$. This completes the proof. □

Proof of Theorem 1.4. Due to Lemma 4.3–4.6, we infer that $J_{\lambda,\mu}$ enjoys all the assumptions of Theorem 4.2. In addition, by Lemma 4.6, there exists $\widehat{\lambda} > 0$ such that for all $(\lambda,\mu) \in (\widehat{\lambda},\infty)\times(\widehat{\lambda},\infty)$, the functional $J_{\lambda,\mu}$ admits a nontrivial nonnegative critical point $(u_{\lambda,\mu}, v_{\lambda,\mu}) \in \mathbf{X}$, which is a mountain pass solution of the system $(\mathcal{S}_{\lambda,\mu})$. Consequently, there also holds $\|(u_{\lambda,\mu}, v_{\lambda,\mu})\| \to 0$ as $(\lambda,\mu) \to (\infty,\infty)$. This finishes the proof. □

5 Proof of Theorem 1.5

In this section, we shall prove Theorem 1.5 using the Krasnoselskii genus theory. For the sake of simplicity, we assume that the structural assumptions required in Theorem 1.5 hold. For the convenience of the readers, we first summarize some basic properties and definition of the genus.

Let X be a Banach space and A be a subset of X. A is said to be symmetric w.r.t. the origin if $u \in A$ implies $-u \in A$. Define

$$\mathbf{\Sigma} = \{A \subset X \setminus \{0\} : \ A \text{ closed and symmetric w.r.t. the origin}\}.$$

For $A \in \mathbf{\Sigma}$, we denote the genus of A by $\gamma(A)$, which is defined by

$$\gamma(A) = \min\{k \in \mathbb{N} : \ \exists\ \varphi \in C(A, \mathbb{R}^k \setminus \{0\}),\ \varphi(x) = -\varphi(-x)\}.$$

Moreover, we define $\gamma(\emptyset) = 0$. In addition, if such k does not exist, we set $\gamma(A) = \infty$. The following properties of the genus can be found in [7,25,27,41,49].

Proposition 5.1. *Let $A, B \in \mathbf{\Sigma}$. Then the following results hold:*

(a) If there exists an odd map $f \in C(A,B)$, then $\gamma(A) = \gamma(B)$;

(b) If $A \subset B$, then $\gamma(A) \le \gamma(B)$;

(c) If there exists an odd homeomorphism from A onto B, then $\gamma(A) = \gamma(B)$;

(d) If $\gamma(A) \ge 2$, then A has infinitely many points;

(e) If $\mathbb{S}$ is a sphere centered at the origin in $\mathbb{R}^k$, then $\gamma(\mathbb{S}) = k$;

(f) $\gamma(A \cup B) \le \gamma(A) + \gamma(B)$;

(g) If $\gamma(B) < \infty$, then $\gamma(\overline{A \setminus B} \ge \gamma(A) - \gamma(B)$;

(h) If A is compact, then $\gamma(A) < \infty$, and $\exists\ \delta > 0$ such that $N_\delta(A) \in \mathbf{\Sigma}$ and $\gamma(A) = \gamma(N_\delta(A))$, where

$$N_\delta(A) = \{x \in X : \ d(x,A) \le \delta\} \quad \text{and} \quad d(x,A) = \inf\{\|x-u\| : \ u \in A\};$$

(i) If X_0 is a subspace of X with codimension k, and $\gamma(A) > k$, then $A \cap X_0 \neq \emptyset$.

Next, we recall the classical deformation lemma, established by A. Ambrosetti and P. H. Rabinowitz in [1]. It can be read as follows:

Proposition 5.2. *Let X be a Banach space and $I \in C^1(X, \mathbb{R})$ satisfying the (PS) condition. If $c \in \mathbb{R}$ and N is any neighbourhood of*

$$K_c = \{u \in X : \ I(u) = c, \ I'(u) = 0\},$$

then there exist $\eta(t,u) = \eta_t(u) \in C([0,1] \times X, X)$ and constants $\bar{\epsilon} > \epsilon > 0$ such that

(a) $\eta_0(u) = u$ for all $u \in X$;

(b) $\eta_t(u) = u$ for all $u \notin I^{-1}[c - \bar{\epsilon}, c + \bar{\epsilon}]$ and all $t \in [0,1]$;

(c) η_t is a homeomorphism of X onto X for all $t \in [0,1]$;

(d) $I(\eta_t(u)) \leq I(u)$ for all $u \in X$ and all $t \in [0,1]$;

(e) $\eta_1(I^{c+\epsilon} \backslash N) \subset I^{c-\epsilon}$, where $I^c = \{u \in X : \ I(u) \leq c\}$ for all $c \in \mathbb{R}$;

(f) If $K_c = \emptyset$, then there holds $\eta_1(I^{c+\epsilon}) \subset I^{c-\epsilon}$;

(g) If I is even, then η_t is odd in u.

Remark 5.3. We note that Proposition 5.2 is also valid if I satisfies the $(PS)_c$ condition for $c < c_0$ for some $c_0 \in \mathbb{R}$.

To study the infinitely many solutions of the system $(\mathcal{S}_{\lambda,\mu})$, we define the functional $J : \mathbf{X} \to \mathbb{R}$ by

$$J(u,v) = \frac{1}{p}\widehat{M}(\|(u,v)\|^p) - \int_{\mathbb{R}^N} \frac{F(x,u,v)}{|x|^\gamma}\, \mathrm{d}x - \frac{1}{q}(\lambda\|u\|_{q,h}^q + \mu\|v\|_{q,h}^q), \qquad \forall\ (u,v) \in \mathbf{X}. \quad (5.1)$$

By using (F_2) and Theorem 2.7, it follows that J is well-defined, of class $C^1(\mathbf{X}, \mathbb{R})$ and the critical points are weak solutions of the system $(\mathcal{S}_{\lambda,\mu})$.

Note that by arguing similar arguments as in Lemma 4.4, we can prove that J is not bounded from below. Hence we have some mathematical difficulty in studying the multiplicity of critical points of the functional J. To avoid this difficulty, we use the technique used in [25]. For this, we shall construct the truncated functional I corresponding to the functional J and study the behaviour of solutions to the system $(\mathcal{S}_{\lambda,\mu})$.

Suppose that $\|(u,v)\| \leq 1$. Observe that for $\ell \in [0,1]$, we obtain from the definition of $\widehat{M}$ that

$$\widehat{M}(\ell) \geq \widehat{M}(1)\ell^\theta = (a+b)\ell^\theta.$$

Using the notations as stated in Lemma 3.2, for $\|(u,v)\| \leq \bar{\delta}$ with $\bar{\delta} \in (0,1]$, we have

$$J(u,v) \geq \left(\frac{a+b}{p} - 2^{\theta p}\mathcal{B}_{\theta p,\gamma}^{-\theta p}\varepsilon\right)\|(u,v)\|^{\theta p} - \widetilde{C}\|(u,v)\|^\vartheta - \frac{1}{q}\max\{\lambda,\mu\}\mathcal{S}_{q,h}^{-q}\|(u,v)\|^q,$$

where $\widetilde{C} = 2^\vartheta D C^{\frac{1}{\vartheta'}} \mathcal{B}_{\vartheta t,\gamma}^{-\vartheta}\tilde{\kappa}_\varepsilon$. Choosing $\varepsilon = a + b/2^{\theta p+1} p\mathcal{B}_{\theta p,\gamma}^{-\theta p}$, we obtain from the above inequality that

$$J(u,v) \geq \left(\frac{a+b}{2p}\right)\|(u,v)\|^{\theta p} - \widetilde{C}\|(u,v)\|^\vartheta - \frac{1}{q}\max\{\lambda,\mu\}\mathcal{S}_{q,h}^{-q}\|(u,v)\|^q \quad (5.2)$$

for all $(u,v) \in \mathbf{X}$ with $\|(u,v)\| \leq 1$. Define the map $H_{\lambda,\mu} : [0,\infty) \to \mathbb{R}$ as follows

$$H_{\lambda,\mu}(\ell) = \left(\frac{a+b}{2p}\right)\ell^{\theta p} - \widetilde{C}\ell^\vartheta - \frac{1}{q}\max\{\lambda,\mu\}\mathcal{S}_{q,h}^{-q}\ell^q, \qquad \forall\ \ell \in [0,\infty)$$

and write

$$H_{\lambda,\mu}(\ell) = \ell^q \widetilde{H}_{\lambda,\mu}(\ell),$$

where

$$\widetilde{H}_{\lambda,\mu}(\ell) = \left(\frac{a+b}{2p}\right)\ell^{\theta p-q} - \widetilde{C}\ell^{\vartheta-q} - \frac{1}{q}\max\{\lambda,\mu\}\mathcal{S}_{q,h}^{-q}.$$

Hence one can easily notice that $J(u,v) \geq H_{\lambda,\mu}(\|(u,v)\|)$ for all $(u,v) \in \mathbf{X}$ with $\|(u,v)\| \leq 1$. In addition, we have

$$\widetilde{H}_{\lambda,\mu}(0) < 0 \quad \text{and} \quad \widetilde{H}_{\lambda,\mu}(\ell) \to -\infty \quad \text{as } \ell \to \infty. \tag{5.3}$$

By direct calculation, one has

$$\widetilde{H}'_{\lambda,\mu}(\ell) = 0 \implies \ell = \left[\frac{(a+b)(\theta p-q)}{2p\widetilde{C}(\vartheta-q)}\right]^{\frac{1}{\vartheta-\theta p}} =: T.$$

Further, it is easy to see that $\widetilde{H}'_{\lambda,\mu}(\ell) > 0$ for all $\ell \in (0,T)$ and $\widetilde{H}'_{\lambda,\mu}(\ell) < 0$ for all $\ell \in (T,\infty)$. This shows that the map $\ell \mapsto \widetilde{H}_{\lambda,\mu}(\ell)$ is strictly increasing on $(0,T)$ and strictly decreasing on (T,∞). In virtue of (5.3), we deduce that, if if $\widetilde{H}_{\lambda,\mu}(T) > 0$, then

$$\widetilde{H}_{\lambda,\mu}(0)\widetilde{H}_{\lambda,\mu}(T) < 0 \quad \text{and} \quad \widetilde{H}_{\lambda,\mu}(T)\widetilde{H}_{\lambda,\mu}(\ell) < 0 \quad \text{for } \ell \text{ large enough.}$$

Consequently, by the intermediate value theorem, there exists at least one root of $\widetilde{H}_{\lambda,\mu}$ in between 0 and T. Since the map $\ell \mapsto \widetilde{H}_{\lambda,\mu}(\ell)$ is strictly increasing on $(0,T)$, we infer that there exists a unique root $T_0(\lambda,\mu)$ in between 0 and T for $\widetilde{H}_{\lambda,\mu}$. Similarly, we can prove that there exists a unique root $T_1(\lambda,\mu)$ in between T and ∞ for $\widetilde{H}_{\lambda,\mu}$. In conclusion, we can say, if $\widetilde{H}_{\lambda,\mu}(T) > 0$, then there exist two unique real numbers $T_0(\lambda,\mu)$ and $T_1(\lambda,\mu)$ with

$$0 < T_0(\lambda,\mu) < T < T_1(\lambda,\mu) < \infty \quad \text{such that} \quad \widetilde{H}_{\lambda,\mu}(T_0(\lambda,\mu)) = \widetilde{H}_{\lambda,\mu}(T_1(\lambda,\mu)) = 0.$$

Define

$$\boldsymbol{\lambda}^1 = \frac{q(\vartheta-\theta p)}{\mathcal{S}_{q,h}^{-q}}\left(\frac{a+b}{2p(\vartheta-q)}\right)^{\frac{\vartheta-q}{\vartheta-\theta p}}\left(\frac{\theta p-q}{\widetilde{C}}\right)^{\frac{\theta p-q}{\vartheta-\theta p}},$$

then if $\max\{\lambda,\mu\} < \boldsymbol{\lambda}^1$, there holds

$$\widetilde{H}_{\lambda,\mu}(T) = (\vartheta-\theta p)\left(\frac{a+b}{2p(\vartheta-q)}\right)^{\frac{\vartheta-q}{\vartheta-\theta p}}\left(\frac{\theta p-q}{\widetilde{C}}\right)^{\frac{\theta p-q}{\vartheta-\theta p}} - \frac{1}{q}\max\{\lambda,\mu\}\mathcal{S}_{q,h}^{-q} > 0,$$

so that, since we have $H_{\lambda,\mu}(T_0(\lambda,\mu)) = H_{\lambda,\mu}(T_1(\lambda,\mu)) = 0$, thanks to $H_{\lambda,\mu}(\ell) = \ell^q\widetilde{H}_{\lambda,\mu}(\ell)$. In addition, there holds

$$\begin{aligned} &H_{\lambda,\mu}(\ell) > 0, \ \forall\ \ell \in \big(T_0(\lambda,\mu), T_1(\lambda,\mu)\big) \quad \text{and} \\ &H_{\lambda,\mu}(\ell) \leq 0, \ \forall\ \ell \in \big[0, T_0(\lambda,\mu)\big] \cup \big[T_1(\lambda,\mu), \infty\big). \end{aligned} \tag{5.4}$$

Corollary 5.4. *The following holds*

$$\lim_{(\lambda,\mu)\to(0^+,0^+)} T_0(\lambda,\mu) = 0.$$

Proof. It follows from $H_{\lambda,\mu}(T_0(\lambda,\mu)) = 0$ and $H'_{\lambda,\mu}(T_0(\lambda,\mu)) > 0$ that

$$\left(\frac{a+b}{2p}\right)(T_0(\lambda,\mu))^{\theta p} = \widetilde{C}(T_0(\lambda,\mu))^{\vartheta} + \frac{1}{q}\max\{\lambda,\mu\}\mathcal{S}_{q,h}^{-q}(T_0(\lambda,\mu))^{q} \tag{5.5}$$

and

$$\left(\frac{a+b}{2p}\right)\theta p(T_0(\lambda,\mu))^{\theta p-1} > \widetilde{C}\vartheta(T_0(\lambda,\mu))^{\vartheta-1} + \max\{\lambda,\mu\}\mathcal{S}_{q,h}^{-q}(T_0(\lambda,\mu))^{q-1}. \tag{5.6}$$

On solving (5.5) and (5.6), we obtain

$$T_0(\lambda,\mu) < \left[\frac{(a+b)(\theta p-q)}{2p\widetilde{C}(\vartheta-q)}\right]^{\frac{1}{\vartheta-\theta p}}.$$

This shows that $T_0(\lambda,\mu)$ is uniformly bounded w.r.t. λ and μ. Let us choose a sequence $\{(\lambda_n,\mu_n)\}_n$ with $(\lambda_n,\mu_n) \to (0^+,0^+)$ as $n \to \infty$. Using the fact that $\{T_0(\lambda_n,\mu_n)\}_n$ is uniformly bounded, therefore up to a subsequence still denoted by itself such that

$$T_0(\lambda_n,\mu_n) \to T_0\ (\geq 0)\ \text{(say)} \quad \text{as } n \to \infty.$$

Consequently, by replacing λ_n in place of λ and μ_n in place of μ in (5.5) and (5.6), respectively and letting $n \to \infty$, we have

$$\left(\frac{a+b}{2p}\right)T_0^{\theta p} = \widetilde{C}T_0^{\vartheta} \quad \text{and} \quad \left(\frac{a+b}{2p}\right)\theta p T_0^{\theta p-1} \geq \widetilde{C}\vartheta T_0^{\vartheta-1}.$$

This directly implies at once that

$$\widetilde{C}(\vartheta-\theta p)T_0^{\vartheta-1} \leq 0.$$

Hence we deduce that $T_0 = 0$. Due to the arbitrariness of $\{(\lambda_n,\mu_n)\}_n$, we conclude that $T_0(\lambda,\mu) \to 0$ as $(\lambda,\mu) \to (0^+,0^+)$ and thus we conclude the proof. □

By Corollary 5.4, we can find $\boldsymbol{\lambda}^2 > 0$ small enough such that there holds $T_0(\lambda,\mu) < 1$ for all $(\lambda,\mu) \in (0,\boldsymbol{\lambda}^2)\times(0,\boldsymbol{\lambda}^2)$. It follows that $T_0(\lambda,\mu) < \min\{T_1(\lambda,\mu),1\}$ for all $(\lambda,\mu) \in (0,\boldsymbol{\lambda}^2)\times(0,\boldsymbol{\lambda}^2)$. Suppose that $(\lambda,\mu) \in (0,\min\{\boldsymbol{\lambda}^1,\boldsymbol{\lambda}^2\})\times(0,\min\{\boldsymbol{\lambda}^1,\boldsymbol{\lambda}^2\})$ and take a nonincreasing cut-off function $\Psi \in C_0^\infty([0,\infty),[0,1])$, which is defined by

$$\Psi(\ell) = \begin{cases} 1 & \text{if } \ell \in [0,T_0(\lambda,\mu)], \\ 0 & \text{if } \ell \in [\min\{T_1(\lambda,\mu),1\},\infty). \end{cases}$$

Define the truncated energy functional $I : \mathbf{X} \to \mathbb{R}$ by

$$I(u,v) = \frac{1}{p}\widehat{M}(\|(u,v)\|^p) - \Psi(\|(u,v)\|)\int_{\mathbb{R}^N}\frac{F(x,u,v)}{|x|^\gamma}\,\mathrm{d}x - \frac{1}{q}(\lambda\|u\|_{q,h}^q + \mu\|v\|_{q,h}^q),\ \forall\ (u,v) \in \mathbf{X}.$$

By the regularity of Ψ and J, we conclude that $I \in C^1(\mathbf{X},\mathbb{R})$. In addition, one can notice that I is coercive and bounded from below on $\mathbf{X}$. We also mention that the following results hold:

$$J(u,v) = I(u,v),\ \forall\ (u,v) \in \mathbf{X} \quad \text{with} \quad \|(u,v)\| \leq T_0(\lambda,\mu) < \min\{T_1(\lambda,\mu),1\}$$

and

$$J(u,v) \geq G_{\lambda,\mu}(\|(u,v)\|),\ \forall\ (u,v) \in \mathbf{X} \quad \text{with} \quad \|(u,v)\| \leq 1,$$

where

$$G_{\lambda,\mu}(\ell) = \left(\frac{a+b}{2p}\right)\ell^{\theta p} - \widetilde{C}\Psi(\ell)\ell^{\vartheta} - \frac{1}{q}\max\{\lambda,\mu\}\mathcal{S}_{q,h}^{-q}\ell^{q}.$$

Lemma 5.5. *There exists $\bar{\lambda} > 0$ such that for all $(\lambda, \mu) \in (0, \bar{\lambda}) \times (0, \bar{\lambda})$, we have*

(a) If $I(u,v) < 0$, then $\|(u,v)\| < T_0(\lambda,\mu)$ and $I(\varphi,\psi) = J(\varphi,\psi)$ for all (φ,ψ) in a small neighbourhood of (u,v);

(b) For all $c < 0$, the functional I satisfies a local $(PS)_c$ condition.

Proof. Suppose that $\|(u,v)\| \geq 1$, then we have $\Psi(\|(u,v)\|) = 0$. In addition, we obtain

$$\begin{aligned} I(u,v) &= \frac{1}{p}\widehat{M}(\|(u,v)\|^p) - \frac{1}{q}(\lambda\|u\|^q_{q,h} + \mu\|v\|^q_{q,h}) \geq \left(\frac{a+b}{p}\right)\|(u,v)\|^p \\ &\quad - \frac{1}{q}\max\{\lambda,\mu\}\mathcal{S}^{-q}_{q,h}\|(u,v)\|^q \\ &=: \widetilde{g}_{\lambda,\mu}(\|(u,v)\|) \end{aligned}$$

for all $\|(u,v)\| \geq 1$, where $\widetilde{g}_{\lambda,\mu} : [0,\infty) \to \mathbb{R}$ is given by

$$\widetilde{g}_{\lambda,\mu}(\ell) = \left(\frac{a+b}{p}\right)\ell^p - \frac{1}{q}\max\{\lambda,\mu\}\mathcal{S}^{-q}_{q,h}\ell^q.$$

By direct computation, one can notice that $\widetilde{g}_{\lambda,\mu}$ has a global minimum point at

$$\ell_0 = \left(\frac{\max\{\lambda,\mu\}\mathcal{S}^{-q}_{q,h}}{a+b}\right)^{\frac{1}{p-q}}$$

and

$$\widetilde{g}_{\lambda,\mu}(\ell_0) = \left(\frac{\max\{\lambda,\mu\}\mathcal{S}^{-q}_{q,h}}{a+b}\right)^{\frac{q}{p-q}}\max\{\lambda,\mu\}\mathcal{S}^{-q}_{q,h}\left(\frac{1}{p} - \frac{1}{q}\right) < 0,$$

thanks to $1 < q < p$. Further, it is easy to see that

$$\widetilde{g}_{\lambda,\mu}(\ell) \geq 0 \iff \ell \geq \left(\frac{\max\{\lambda,\mu\}p\mathcal{S}^{-q}_{q,h}}{q(a+b)}\right)^{\frac{1}{p-q}} =: \ell_1.$$

This shows that

$$I(u,v) \geq \widetilde{g}_{\lambda,\mu}(\|(u,v)\|) \geq 0, \qquad \forall\ \|(u,v)\| \geq 1$$

with $\ell_1 < 1$, that is, we have

$$\max\{\lambda,\mu\} < \frac{q(a+b)}{p\mathcal{S}^{-q}_{q,h}} =: \boldsymbol{\lambda}^3.$$

Next, we define a positive constant $\boldsymbol{\lambda}^4$ as follows

$$\boldsymbol{\lambda}^4 = \frac{qb(\sigma-\theta p)\big(\min\{V_0,K_0\}\big)^{\frac{\theta p-q}{p}}}{2^{\theta p-q}(\sigma-q)p\mathcal{S}^{-q}_{q,h}}\left(\frac{\beta_*}{2\alpha_0}\right)^{\frac{\theta p-q}{p'}}. \tag{5.7}$$

Pick $\bar{\lambda} = \min\{\boldsymbol{\lambda}^1, \boldsymbol{\lambda}^2, \boldsymbol{\lambda}^3, \boldsymbol{\lambda}^4\}$, then we conclude that for all $(\lambda,\mu) \in (0,\bar{\lambda}) \times (0,\bar{\lambda})$, we have $I(u,v) \geq 0$ for any $\|(u,v)\| \geq 1$. This implies at once that if

$$I(u,v) < 0, \text{ then } \|(u,v)\| < 1,\ \forall\ (\lambda,\mu) \in (0,\bar{\lambda}) \times (0,\bar{\lambda}). \tag{5.8}$$

Consequently, from the definitions of $H_{\lambda,\mu}$, $G_{\lambda,\mu}$ and Ψ, we get for all $(\lambda,\mu)\in(0,\bar{\lambda})\times(0,\bar{\lambda})$ with $I(u,v)<0$ that

$$H_{\lambda,\mu}(\|(u,v)\|\leq G_{\lambda,\mu}(\|(u,v)\|)\leq I(u,v)<0.$$

This together with (5.4) implies that for all $(\lambda,\mu)\in(0,\bar{\lambda})\times(0,\bar{\lambda})$ with $I(u,v)<0$, we have

$$\|(u,v)\|\in(0,1)\cap[(0,T_0(\lambda,\mu))\cup(T_1(\lambda,\mu),\infty)]. \tag{5.9}$$

Now we have following possibilities according to the nature of $T_0(\lambda,\mu)$ and $T_1(\lambda,\mu)$.

Situation 1. Let either $0<T_0(\lambda,\mu)<1<T_1(\lambda,\mu)$ or $0<T_0(\lambda,\mu)<T_1(\lambda,\mu)=1$. In both cases, for all $(\lambda,\mu)\in(0,\bar{\lambda})\times(0,\bar{\lambda})$ with $I(u,v)<0$, it follows directly from (5.9) that $\|(u,v)\|\in(0,T_0(\lambda,\mu))$ and we are done.

Situation 2. Let $0<T_0(\lambda,\mu)<T_1(\lambda,\mu)<1$. Then for all $(\lambda,\mu)\in(0,\bar{\lambda})\times(0,\bar{\lambda})$ with $I(u,v)<0$, we deduce from (5.9) that $\|(u,v)\|\in(0,T_0(\lambda,\mu))\cup(T_1(\lambda,\mu),1)$. Next, we claim that $\|(u,v)\|\notin(T_1(\lambda,\mu),1)$. Indeed, if not, let $T_1(\lambda,\mu)<\|(u,v)\|<1$. By the definition of Ψ, we have $\Psi(\|(u,v)\|)=0$. Consequently, one has

$$\begin{aligned}I(u,v)&=\frac{1}{p}\widehat{M}(\|(u,v)\|^p)-\frac{1}{q}(\lambda\|u\|_{q,h}^q+\mu\|v\|_{q,h}^q)\\&\geq\left(\frac{a+b}{p}\right)\|(u,v)\|^{\theta p}-\frac{1}{q}\max\{\lambda,\mu\}\mathcal{S}_{q,h}^{-q}\|(u,v)\|^q\\&=:h_{\lambda,\mu}(\|(u,v)\|)\end{aligned}$$

for all $T_1(\lambda,\mu)<\|(u,v)\|<1$, where $h_{\lambda,\mu}:[0,\infty)\to\mathbb{R}$ is given by

$$h_{\lambda,\mu}(\ell)=\left(\frac{a+b}{p}\right)\ell^{\theta p}-\frac{1}{q}\max\{\lambda,\mu\}\mathcal{S}_{q,h}^{-q}\ell^q.$$

By simple computation, we can deduce that $h_{\lambda,\mu}$ has a global minimum point at

$$\widehat{\ell}=\left(\frac{\max\{\lambda,\mu\}\mathcal{S}_{q,h}^{-q}}{(a+b)\theta}\right)^{\frac{1}{\theta p-q}}$$

and

$$h_{\lambda,\mu}(\widehat{\ell})=\left(\frac{\max\{\lambda,\mu\}\mathcal{S}_{q,h}^{-q}}{(a+b)\theta}\right)^{\frac{q}{\theta p-q}}\max\{\lambda,\mu\}\mathcal{S}_{q,h}^{-q}\left(\frac{1}{\theta p}-\frac{1}{q}\right)<0,$$

we thank to $1<q<\theta p$. In addition, one sees that

$$h_{\lambda,\mu}(\ell)\geq 0\iff\ell\geq\left(\frac{\max\{\lambda,\mu\}p\mathcal{S}_{q,h}^{-q}}{q(a+b)}\right)^{\frac{1}{\theta p-q}}=:\ell_2.$$

Consequently, we infer that

$$I(u,v)\geq h_{\lambda,\mu}(\|(u,v)\|)\geq 0,\qquad\forall\ \|(u,v)\|\in(T_1(\lambda,\mu),1)$$

with $\ell_2<T_1(\lambda,\mu)$, that is, we conclude that $\max\{\lambda,\mu\}<\boldsymbol{\lambda}^3$, which is a contradiction. This completes the proof of the claim. Hence in this case, we also have $\|(u,v)\|\in(0,T_0(\lambda,\mu))$.

From the above discussions, we deduce that $\|(u,v)\| < T_0(\lambda,\mu)$ and thus $I(u,v) = J(u,v)$. In addition, it follows that $I(\varphi,\psi) = J(\varphi,\psi)$ for all (φ,ψ) with $\|(\varphi,\psi)-(u,v)\| < T_0(\lambda,\mu) - \|(u,v)\|$. This shows that $I(\varphi,\psi) = J(\varphi,\psi)$ for all (φ,ψ) in a small neighbourhood of (u,v) and thus we finish the proof of part (a). Now our aim is to prove part (b). For this, first we take $c < 0$ and a $(PS)_c$ sequence $\{(u_n,v_n)\}_n \subset \mathbf{X}$ for the functional I. Therefore, we can assume that $I(u_n,v_n) < 0$ and $I'(u_n,v_n) = o_n(1)$ as $n \to \infty$ and thus by part (a), for any $(\lambda,\mu) \in (0,\bar{\lambda}) \times (0,\bar{\lambda})$, there holds

$$I(u_n,v_n) = J(u_n,v_n),\ I'(u_n,v_n) = J'(u_n,v_n) \quad \text{and} \quad \|(u_n,v_n)\| < T_0(\lambda,\mu).$$

In addition, since I is coercive on $\mathbf{X}$, we deduce that the $(PS)_c$ sequence $\{(u_n,v_n)\}_n \subset \mathbf{X}$ is bounded. Hence up to a subsequence still denoted by itself such that $(u_n,v_n) \rightharpoonup (u,v)$ in $\mathbf{X}$ as $n \to \infty$ for some couple $(u,v) \in \mathbf{X}$. Further, by using (F_4), we can notice that the following estimates hold as $n \to \infty$

$$\begin{aligned}
0 > c = J(u_n,v_n) &- \frac{1}{\sigma}\langle J'(u_n,v_n),(u_n,v_n)\rangle + o_n(1)\\
&\geq \frac{1}{p}\widehat{M}(\|(u_n,v_n)\|^p) - \frac{1}{\sigma}M(\|(u_n,v_n)\|^p)\|(u_n,v_n)\|^p\\
&\quad - \max\{\lambda,\mu\}\left(\frac{1}{q}-\frac{1}{\sigma}\right)\mathcal{S}_{q,h}^{-q}\|(u_n,v_n)\|^q + o_n(1)\\
&\geq \left(\frac{1}{p}-\frac{\theta}{\sigma}\right)b\|(u_n,v_n)\|^{\theta p} - \max\{\lambda,\mu\}\left(\frac{1}{q}-\frac{1}{\sigma}\right)\mathcal{S}_{q,h}^{-q}\|(u_n,v_n)\|^q + o_n(1).
\end{aligned}$$

Define $z_n = (u_n,v_n)$, then we can see that $|z_n| = \sqrt{u_n^2+v_n^2} \leq \psi_n := |u_n| + |v_n|$. By direct calculation, we have

$$\|\psi_n\|_{W^{s,p}} \leq 2(\min\{V_0,K_0\})^{-\frac{1}{p}}\|(u_n,v_n)\|.$$

It follows from the above two inequalities and (5.7) that

$$\limsup_{n\to\infty}\|\psi_n\|_{W^{s,p}}^{p'} \leq \left(\frac{2^{\theta p-q}(\sigma-q)p\mathcal{S}_{q,h}^{-q}\max\{\lambda,\mu\}}{qb(\sigma-\theta p)\big(\min\{V_0,K_0\}\big)^{\frac{\theta p-q}{p}}}\right)^{\frac{p'}{\theta p-q}} < \frac{\beta_*}{2\alpha_0},$$

thanks to the fact that $\max\{\lambda,\mu\} < \bar{\lambda} \leq \boldsymbol{\lambda}^4$, since we have

$$(\lambda,\mu) \in (0,\bar{\lambda}) \times (0,\bar{\lambda}) \quad \text{and} \quad \bar{\lambda} = \min\{\boldsymbol{\lambda}^1,\boldsymbol{\lambda}^2,\boldsymbol{\lambda}^3,\boldsymbol{\lambda}^4\}.$$

Using all of the above information, and arguing similarly as in the proof of Theorem 1.3, we can easily deduce that $(u_n,v_n) \to (u,v)$ in $\mathbf{X}$ as $n \to \infty$. This completes the proof of part (b). Hence the lemma is well established. □

It follows immediately from the above lemma that the following result holds.

Corollary 5.6. *For all $(\lambda,\mu) \in (0,\bar{\lambda}) \times (0,\bar{\lambda})$, the set K_c, which is given by*

$$K_c = \{(u,v) \in \mathbf{X} :\ I(u,v) = c < 0,\ I'(u,v) = 0\},\ \textit{is compact.}$$

For $\epsilon > 0$, we define

$$I^{-\epsilon} = \{(u,v) \in \mathbf{X} :\ I(u,v) \leq -\epsilon\}.$$

Lemma 5.7. *For any $k \in \mathbb{N}$, there exists $\epsilon_k > 0$ such that there holds $\gamma(I^{-\epsilon_k}) \geq k$.*

Proof. Suppose that $\mathbf{X}_k$ be a k-dimensional subspace of $\mathbf{X}$. For any $(u,v) \in \mathbf{X}_k \setminus \{(0,0)\}$, we define $(u,v) = r_k(\varphi,\psi)$ with $(\varphi,\psi) \in \mathbf{X}_k$, $\|(\varphi,\psi)\| = 1$ and $r_k = \|(u,v)\|$. Under the assumption of h, we known that $\|(\varphi,\psi)\|_{L_h^q(\mathbb{R}^N)\times L_h^q(\mathbb{R}^N)}$ is a norm of $\mathbf{X}_k$ for all $(\varphi,\psi) \in \mathbf{X}_k$. Since all the norms are equivalent in a finite-dimensional Banach space, therefore we infer that for each $(\varphi,\psi) \in \mathbf{X}_k$, there exists $d_k > 0$ such that

$$\|(\varphi,\psi)\|^q_{L_h^q(\mathbb{R}^N)\times L_h^q(\mathbb{R}^N)} \geq d_k.$$

Consequently, for $r_k \in (0, T_0(\lambda,\mu))$, we can easily deduce that

$$I(u,v) = J(u,v) \leq \left(\frac{a+b}{p}\right) r_k^p - \frac{1}{q}\min\{\lambda,\mu\} d_k r_k^q.$$

In virtue of $q < p$, without loss of generality, we can choose $r_k \in (0, T_0(\lambda,\mu))$ sufficiently small enough such that $I(u,v) \leq -\epsilon_k < 0$. Define $S_{r_k} = \{(u,v) \in \mathbf{X} : \ \|(u,v)\| = r_k\}$, then one has $S_{r_k} \cap \mathbf{X}_k \subset I^{-\epsilon_k}$. Now by using Proposition 5.1, we have $\gamma(I^{-\epsilon_k}) \geq \gamma(S_{r_k} \cap \mathbf{X}_k) = k$. This finishes the proof. □

Define

$$\mathbf{\Sigma}_k = \{A \in \mathbf{\Sigma} : \ \gamma(A) \geq k\}$$

and

$$c_k = \inf_{A\in\mathbf{\Sigma}_k} \sup_{(u,v)\in A} I(u,v).$$

It is obvious that the sequence $\{c_k\}_k$ is monotonically increasing in nature and there holds

$$-\infty < c_k \leq -\epsilon_k < 0 \quad \text{for each } k \in \mathbb{N},$$

thanks to the fact that I is bounded from below and $I^{-\epsilon_k} \in \mathbf{\Sigma}_k$. Due to Lemma 5.5, the functional I satisfies the $(PS)_c$ condition for $c < 0$, and we have $c_k < 0$ for each $k \in \mathbb{N}$, therefore by a standard argument, we infer that all c_k are critical values of I.

The next lemma shows that the set K_c, defined in Corollary 5.6, contains infinitely many critical points of I.

Lemma 5.8. *Let $(\lambda,\mu) \in (0,\bar{\lambda}) \times (0,\bar{\lambda})$. Then for $c = c_k = c_{k+1} = \cdots = c_{k+m}$ with some $m \in \mathbb{N}$, we have $\gamma(K_c) \geq m+1$.*

Proof. It will be proven by using the method of contradiction. For this, we first claim that $\gamma(K_c) \geq m+1$ holds. Indeed, if not, let $\gamma(K_c) \leq m$. In virtue of Corollary 5.6, the set K_c is compact and $K_c \in \mathbf{\Sigma}$. Consequently, by using Proposition 5.1, one has $\gamma(K_c) < \infty$ and there exists $\delta > 0$ such that $N_\delta(K_c) \in \mathbf{\Sigma}$ and $\gamma(K_c) = \gamma(N_\delta(K_c)) \leq m$. On the other hand, by using the assumption (F_1'), we infer that the functional I is even. Thus, due to Proposition 5.2, there exists an odd homeomorphism $\eta(t,(u,v)) = \eta_t(u,v) \in C([0,1]\times\mathbf{X},\mathbf{X})$ such that

$$\eta_1(I^{c+\epsilon} \setminus N_\delta(K_c)) \subset I^{c-\epsilon} \quad \text{for some } \epsilon \in (0,-c).$$

From the hypothesis, we have $c = c_{k+m}$ and hence there exists a set $A \in \mathbf{\Sigma}_{k+m}$ such that $\sup_{(u,v)\in A} I(u,v) < c+\epsilon$, that is, $A \subset I^{c+\epsilon}$. This shows that $\eta_1(A \setminus N_\delta(K_c)) \subset \eta_1(I^{c+\epsilon} \setminus N_\delta(K_c)) \subset I^{c-\epsilon}$. Consequently, we deduce that

$$\sup_{(u,v)\in\eta_1(A\setminus N_\delta(K_c))} I(u,v) \leq c-\epsilon. \tag{5.10}$$

Due to Proposition 5.2, we have

$$\gamma(\overline{A \setminus N_\delta(K_c)}) \geq \gamma(A) - \gamma(N_\delta(K_c)) \geq k \quad \text{and} \quad \gamma(\overline{\eta_1(A \setminus N_\delta(K_c))}) \geq k.$$

It follows that $\overline{\eta_1(A \setminus N_\delta(K_c))} \in \mathbf{\Sigma}_k$ and thus we have

$$\sup_{(u,v)\in\overline{\eta_1(A\setminus N_\delta(K_c))}} I(u,v) \geq c_k = c,$$

which contradicts (5.10). This completes the proof of the claim and we finish the proof. □

Proof of Theorem 1.5. Let $(\lambda,\mu) \in (0,\bar{\lambda}) \times (0,\bar{\lambda})$. Notice that if we have $-\infty < c_1 < c_2 < \cdots < c_k < \cdots < 0$, then since c_k are critical values of I, we infer that I has infinitely many critical points. In virtue of Lemma 5.5, we have $J \equiv I$ if $I < 0$. This shows that the system $(\mathcal{S}_{\lambda,\mu})$ has infinitely many weak solutions.

On the other hand, if there exists $c_k = c_{k+m}$ for some $m \in \mathbb{N}$, then $c = c_k = c_{k+1} = \cdots = c_{k+m}$. In virtue of Lemma 5.8, we get $\gamma(K_c) \geq m+1 \geq 2$ and thus by Proposition 5.1, one can notice that the set K_c has infinitely many points. In conclusion, we deduce that the system $(\mathcal{S}_{\lambda,\mu})$ has infinitely many weak solutions. This finishes the proof. □

Communicated by Armengol Gasull

Abstract. We study the Abel differential equation $x' = A(t)x^3 + B(t)x^2 + C(t)x$. Specifically, we find bounds on the number of its rational solutions when $A(t), B(t)$ and $C(t)$ are polynomials with real or complex coefficients; and on the number of rational limit cycles when $A(t), B(t)$ and $C(t)$ are trigonometric polynomials with real coefficients.

Keywords: limit cycle, Abel equation, invariant curve.

2020 Mathematics Subject Classification: 34C25.

1 Introduction

The Abel differential equation

$$x' = A(t)x^3 + B(t)x^2 + C(t)x \tag{1.1}$$

with $A(t)$, $B(t)$, $C(t)$ continuous, and the generalized Abel equations

$$x' = \sum_{i=1}^{n} A_i(t)x^i \tag{1.2}$$

with $n > 3$ and $A_i(t)$ continuous for all $i \in \{1, \dots, n\}$ have been widely studied in the context of Hilbert's 16th Problem, and because of their utility to model real-world models [4] and its own mathematical interest [12].

In the field of the qualitative theory of differential equations, the two most studied problems regarding Abel equations are the Smale–Pugh problem and the Poincaré Centre-Focus problem.

The Smale–Pugh problem [33] consists on bounding the number of limit cycles (isolated periodic solutions) of (1.1) when its coefficients with respect to t are periodic. Lins Neto [23] showed that there is no bound for the number of limit cycles of (1.1) when $A(t)$, $B(t)$ and $C(t)$ are trigonometric polynomials. This problem is related to Hilbert's 16th problem through the

✉ Email: l.calderon@uib.es

transformation of Cherkas [10]. Some results in this line can be consulted in, for example, [1–3, 13, 14, 19–22, 27, 29, 31, 37].

The other problem is the adaptation of the classical Poincaré Centre-Focus problem to this setting, proposed by Briskin, Françoise and Yondim [7, 8]. Here, as $x(t) \equiv 0$ is always a periodic solution of (1.1), we will say that the equation has a center if every solution in a neighbourhood of $x(t) \equiv 0$ is also periodic. For more details on the state of art of this problem, see for example [12, 18, 30].

Another natural question regarding an Abel equation is related to how many solutions of a certain type the equation can have. For example, Giné et al. [17] showed that the generalized Abel equations of degree n in x with polynomial coefficients have at most n polynomial solutions. Other works about similar topics are [9, 15, 24, 25, 28, 32, 34].

In [26, 36], the authors study how many rational closed solutions can the Abel equation

$$x' = A(t)x^3 + B(t)x^2 \tag{1.3}$$

have, both in the polynomial (this is, when $A(t)$ and $B(t)$ are polynomials and the rational solutions are quotients of polynomials) and in the trigonometric cases (this is, when $A(t)$ and $B(t)$ are trigonometric polynomials, and the rational solutions are quotients of trigonometric polynomials). Note that, in the trigonometric case, this problem is related with the Smale–Pugh problem, as, if the equation has not a center, the rational solutions are periodic and, consequently, limit cycles of the equation. Thus, the number of certain types of limit cycles of the equation is being determined.

In [5], we studied the polynomial case for the equation (1.3), for polynomials with real or complex coefficients, but looking for all rational solutions of the equation, regardless of whether they are closed or not. In particular, conditions are given for the equation to have at most two rational solutions; a general bound for the number of rational solutions is given; and Darboux's Integrability Theory (see more in [16] for example) is used to determine how many rational solutions can coexist before the equation is integrable.

Furthermore, in [6] the trigonometric case of the equation (1.3) is studied and bounds are found for the number of rational limit cycles, using Darboux's Integrability Theory to improve the bounds given in [36]. This work is only performed in the real context, since the techniques developed in the polynomial case do not translate adequately in the complex environment.

Clearly, there are various ways to extend this problem, for example, by searching results about the number of rational solutions of generalized Abel equations. However, the most immediate extension consists on adding the linear term to the equation, this is, to look for rational solutions of

$$x' = A(t)x^3 + B(t)x^2 + C(t)x + D(t). \tag{1.4}$$

Without loss of generality, we assume $D(t) \equiv 0$. This problem has been studied in [35], but only for closed rational solutions in the polynomial case.

The objective of this work is to extend the techniques and results in [5,6] to the "complete" Abel differential equation.

In precise terms, throughout this paper, we consider the Abel equation

$$x' = A(t)x^3 + B(t)x^2 + C(t)x \tag{1.5}$$

with $A(t)$, $B(t)$, and $C(t) \in R$, where R is either the polynomial ring in t with coefficients in $\mathbb{K} \in \{\mathbb{R}, \mathbb{C}\}$, in symbols, $R = \mathbb{K}[t]$, or the ring of trigonometric polynomials with real coefficients, in symbols, $R = \mathbb{R}[\cos(t), \sin(t)]$. Note that we exclude the study over $\mathbb{C}[\cos(t), \sin(t)]$ because, as mentioned above, the techniques can not be applied appropriately in this setting.

Moreover, since the case $C(t) \equiv 0$ is completely studied in [5, 6], in what follows we consider $C(t) \not\equiv 0$, and we also assume that $A(t) \not\equiv 0$ and $B(t) \not\equiv 0$, since otherwise (1.5) would be a Ricatti or Bernoulli equation, respectively. We will also assume that $A(t)$ is non constant, as this case has been studied by Pliss in [31], in the trigonometric case, and by Giné, Grau and Llibre [17] in the polynomial case (see Remark 2.4).

Whenever possible, we will treat both the polynomial case and the trigonometric case as a whole. For this reason, it is convenient to note that $\deg(-)$ indistinguishable means in the polynomial case the usual degree of an univariate polynomial; while in the trigonometric case it means the highest integer n such that $a_n \neq 0$ or $b_n \neq 0$ in the expression

$$a_0 + \sum_{n=1}^{N} a_n \cos(nt) + b_n \sin(nt).$$

Moreover, to facilitate the cases integration, we recall that the problem of finding rational solutions of the equation (1.5), in the polynomial case, and rational solutions (that will be automatically periodic) of (1.5), in the trigonometric case, is equivalent to studying the invariant curves of (1.5) of the form $p(t)x + q(t) = 0$, with $p(t), q(t) \in R$ and $p(t) \neq 0$ for every t. Therefore, we use the term invariant curve of degree one in x, (or simply invariant curve, since there can be no confusion here) to unify the terminology, and the results will be given, always that is possible, in terms of invariant curves and not rational solutions. For more details on invariant curves see [16].

We are now ready to present the main result in this paper. Note that it is written in terms of invariant curves, with the exception of the case (b.2.2), where we can improve the bound by studying instead the number of rational limit cycles, which is equivalent to the number of invariant curves when the equation does not have a center.

Theorem 1.1. *With the above notation and conventions, the following claims are satisfied.*

(a) If $\deg(A) - \deg(C) \leq 1$, *then* (1.5) *has at most one invariant curve.*

(b) If $\deg(A) - \deg(C) > 1$ *and we are either in the polynomial case, or in the trigonometric one with* $C(t)$ *non-constant, then*

(b.1) If $\deg(A) - \deg(C)$ *is odd or* $\deg(A) + \deg(C) < 2\deg(B)$, *then* (1.5) *has at most two invariant curves.*

(b.2) If $\deg(A) - deg(C)$ *is even and* $\deg(A) + \deg(C) \geq 2\deg(B)$, *then,*

(b.2.1) in the polynomial case, the number of invariant curves of (1.5) *is at most*

$$\binom{\deg(A)}{(\deg(A)+1)/2} + 1.$$

Moreover, in this case, (1.5) *is Darboux integrable, if the number of invariant curves of* (1.5) *is greater that* $\deg(A) + \deg(C) + 4$.

(b.2.2) in the trigonometric case, an upper bound for the number of rational limit cycles of (1.5) *is* $2\deg(A) + 2\deg(C) + 4$.

(c) If $\deg(A) - \deg(C) > 1$, *in the trigonometric case and with* $C(t) \equiv c$ *a non zero constant, then an upper bound for the number of invariant curves is* $4\deg(A)$.

Note that we have assumed that $C(t) \not\equiv 0$, and so this result does not cover the results of [5,6]. However, the conditions of (b.1) are very similar to their equivalent versions in [5,6] for the case $C(t) \equiv 0$, and the general bound of (b.2.1) for the polynomial case is exactly the same. On the other hand, when we apply Darboux's Theory of Integrability in this context, because of details of the proof the bounds of (b.2.2) and (c) are less sharp than their equivalent ones in [5,6].

In [5] using computational numerical and algebraic tools we were able to develop a method to study thoroughly the number of invariant curves that equation (1.3) has, in the polynomial case. Its computational effort grows sharply as $\deg(A)$ rises though, so we only studied the cases up to $\deg(A) = 5$.

Using this method, in [5] for low values of $\deg(A)$ we could study the sharpness of the general bound

$$\binom{\deg(A)}{(\deg(A)+1)/2} + 1$$

for the number of invariant curves of the equation (1.3). We did show that this bound was sharp when $\deg(A)$ was one or three, but it was not sharp when it was five.

On the other hand, we did not study the sharpness of the bounds provided by Darboux's Theory of Integrability when $C(t) \equiv 0$ in [5,6], although some numerical experiments seemed to show that they were sharp for low values of $\deg(A)$. In general, the sharpness of these bounds is an open question.

As this paper covers the polynomial and the trigonometric case at the same time, we have decided to not develop an equivalent exhaustive method for (1.5), although we offer a lemma related with the parametrization of the equation in terms of its invariant curves, which is very helpful to make numerical experiments in this direction. Consequently, the sharpness of the bounds provided in Theorem 1.1 are left as an open question.

The structure of the paper is as follows: first we remind the factorization properties of the ring $\mathbb{R}[\cos t, \sin t]$ and in Section 2.1 we show the characterization of the invariant curves of (1.5); then, in Section 2.2, we suppose that (1.5) has two or more different invariant curves, and we prove (a) and (b.1); next, in Section 2.3, we focus on the polynomial case to provide the general bound of (b.2.1); and finally in Section 3 we apply Darboux's Theory of Integrability to prove the remaining parts of (b.2.1), together with (b.2.2) and (c).

2 Invariant curves of degree one in x

We remind that we have set R to be equal to $\mathbb{K}[t]$, $\mathbb{K} \in \{\mathbb{R}, \mathbb{C}\}$, or equal to $\mathbb{R}[\cos(t), \sin(t)]$. While in the first case R is a Euclidean domain and everything works fine in terms of divisibility or factorization of elements, in the second case R is not even a unique factorization domain. So special care must be taken when using it with factorization arguments. Nevertheless, $\mathbb{R}[\cos(t), \sin(t)]$ has somewhat stable factorization properties for being a half-factorial Dedekind domain. We summarize those extensively used along this paper and refer the reader to [6, Appendix A] for more details.

Proposition 2.1. *Let $p(t) \in \mathbb{R}[\cos(t), \sin(t)]$. If $p(t) \notin \mathbb{R}$ and $p(t) \neq 0$ for every t, then the following holds.*

(a) The decomposition of $p(t)$ into irreducibles of $\mathbb{R}[\cos(t), \sin(t)]$ is unique, up to the order of the factors and the product by invertible elements.

(b) If $p(t) = h(t)r(t)$ and none of the irreducible factors of $p(t)$ divides $h(t)$, then $r(t)$ divides $p(t)$.

(c) If $q(t) \in \mathbb{R}[\cos(t), \sin(t)] \setminus \{0\}$ is non-constant, then $p(t)$ and $q(t)$ are relatively prime if and only if they have not irreducible factors in common.

As mentioned before, we are interested in studying the invariant curves of degree one in x (that from now on we call simply invariant curves) of (1.5), that is, the invariant curves (1.5) of the form $p(t)x + q(t) = 0$, with $p(t), q(t) \in R$, $p(t)$ non-constant and $p(t) \neq 0$ for every t. Because $p(t) \neq 0$ we always assume that $p(t)$ and $q(t)$ are relatively prime.

Recall that $p(t)x + q(t) = 0$ is invariant for (1.5) if and only if there exists $K(t,x) \in R[x]$, called cofactor of $p(t)x + q(t)$, such that

$$p'(t)x + q'(t) + p(t)\left(A(t)x^3 + B(t)x^2 + C(t)x\right) = (p(t)x + q(t))K(t,x). \tag{2.1}$$

For degree reasons, $K(t,x) = K_2(t)x^2 + K_1(t)x + K_0(x)$ with $K_i(t) \in R$, $i = 0,1,2$.

2.1 One invariant curve

A characterization of the invariant curves of the equation (1.3) can be found in [24], which was then adapted to our case, and the trigonometric case with $C(t) \equiv 0$ in [35, 36], respectively. We include its proof here for the sake of completeness.

Proposition 2.2. *The curve $p(t)x + q(t) = 0$ is invariant for (1.5) if and only if $q(t) = c$ is a nonzero constant and*

$$c^2 A(t) = \left(cB(t) - \left(p'(t) + p(t)C(t)\right)\right)\, p(t). \tag{2.2}$$

Proof. By (2.1), $p(t)x + q(t) = 0$ is invariant for (1.5) if and only if

$$\begin{aligned} &p'(t)x + q'(t) + p(t)\left(A(t)x^3 + B(t)x^2 + C(t)x\right) \\ &\quad = (p(t)x + q(t))\left(K_2(t)x^2 + K_1(t)x + K_0(t)\right), \end{aligned}$$

with $K_i(t) \in R$, $i = 0,1,2$. So, equating the coefficients of the powers of x and omitting the arguments, we have

$$\begin{aligned} q' &= q\,K_0, \\ p' + p\,C &= K_0\,p + K_1\,q, \\ p\,B &= K_1\,p + K_2\,q, \\ p\,A &= K_2\,p \iff A = K_2 \quad (\text{since } p(t) \not\equiv 0). \end{aligned}$$

From the first equality, we obtain both $K_0(t) \equiv 0$ and $q(t) = c$ for a nonzero constant c. Now, substituting this conveniently into the second equation, we get

$$p'(t) + p(t)C(t) = K_1(t)c,$$

that is, $K_1(t) = (p'(t) + p(t)C(t))/c$. So the third equation yields

$$p(t)B(t) = (p'(t) + p(t)C(t))p(t)/c + K_2(t)c.$$

Therefore, $K_2(t) = p(t)B(t)/c - (p'(t) + p(t)C(t))p(t)/c^2$ and, consequently,

$$c^2\,A(t) = \left(cB(t) - \left(p'(t) + p(t)C(t)\right)\right)\, p(t),$$

as claimed. □

Note that, without loss of generality, we can assume $c = -1$ in Proposition 2.2. We will assume this from now until the end of the paper. Thus, our invariant curves will always be of the form $p(t)x - 1 = 0$.

Although the following result is a direct consequence of Proposition 2.2 and its proof, we state it because we will use it extensively throughout the paper.

Corollary 2.3. *If $p(t)x - 1 = 0$ is an invariant curve of (1.5), then $p(t)$ divides $A(t)$. In particular,*

$$-B(t) = A(t)/p(t) + p'(t) + p(t)C(t) \tag{2.3}$$

and the cofactor of $p(t)x - 1 = 0$ is equal to $A(t)x^2 - (p'(t) + p(t)C(t))\, x$.

Remark 2.4. As mentioned in the introduction, in the trigonometric case, the case where $A(t)$ is constant is extensively studied in [31]. In the other case, since, by Corollary 2.3, $A(t)$ being constant implies that $p(t)$ is also constant (in fact, regardless of whether we are in the polynomial or the trigonometric case), we have that the corresponding invariant curve is polynomial; a case that has been extensively studied in [17]. Thus, in the rest of the paper, we always assume that $\deg(A) > 0$

2.2 Two or more invariant curves

Now suppose (1.5) has at least two different invariant curves.

Proposition 2.5. *If $p_1(t)x - 1 = 0$ and $p_2(t)x - 1 = 0$ are two different invariant curves of (1.5), then*

$$A(t) = C(t)p_1(t)p_2(t) + \frac{(p_2(t) - p_1(t))'p_1(t)p_2(t)}{p_2(t) - p_1(t)}. \tag{2.4}$$

In particular, $\deg(A) - \deg(C) \leq \deg(p_1) + \deg(p_2)$.

Proof. By (2.3),

$$-A(t) = \left(B(t) + \left(p_1'(t) + p_1(t)C(t)\right)\right)\, p_1(t).$$

and

$$-A(t) = \left(B(t) + \left(p_2'(t) + p_2(t)C(t)\right)\right)\, p_2(t).$$

If we multiply the first expression by $p_2(t)$ and the second expression by $p_1(t)$ and then take the difference between them, we get

$$-(p_2(t) - p_1(t))A(t) = (p_1'(t) - p_2'(t))p_1(t)p_2(t) + (p_1(t) - p_2(t))C(t)p_1(t)p_2(t).$$

Now, since $p_1(t) \not\equiv p_2(t)$, (2.4) follows.

Finally, for the second part of the statement, it suffices to observe that by (2.4) we have that

$$\begin{aligned} \deg(A) &\leq \max\left\{\deg(C(t)p_1(t)p_2(t)), \deg\left(\frac{(p_2(t) - p_1(t))'p_1(t)p_2(t)}{p_2(t) - p_1(t)}\right)\right\} \\ &= \deg(C(t)p_1(t)p_2(t)) = \deg(C) + \deg(p_1) + \deg(p_2). \end{aligned} \tag{2.5}$$

Therefore, $\deg(A) - \deg(C) \leq \deg(p_1) + \deg(p_2)$ as claimed. □

Proposition 2.6. *Let $C(t)$ be non-constant. If $p_1(t)x - 1 = 0$ and $p_2(t)x - 1 = 0$ are two different invariant curves of (1.5), then*

$$\deg(A) - \deg(C) = \deg(p_1) + \deg(p_2).$$

In particular, $\deg(A) - \deg(C) > 1$.

Proof. Let

$$r(t) := \frac{(p_2(t) - p_1(t))' p_1(t) p_2(t)}{p_2(t) - p_1(t)}.$$

By (2.4), $r(t)$ is equal to $A(t) - C(t)p_1(t)p_2(t)$. Therefore, $r(t) \in R$ and $\deg(r) = \deg(p_1) + \deg(p_2) - 1$, in the polynomial case, and $\deg(r) = \deg(p_1) + \deg(p_2)$, in the trigonometric case.

Now, since $C(t)$ is not constant, in particular, $\deg(C) > 0$ and, consequently, $\deg(Cp_1p_2) > \deg(p_1) + \deg(p_2) \geq \deg(r)$. Therefore, since by (2.5) $\deg(A) \leq \deg(Cp_1p_2)$ and $\deg(A - Cp_1p_2) = \deg(r) < \deg(Cp_1p_2)$, we conclude that $\deg(A) = \deg(Cp_1p_2)$, that is, $\deg(A) - \deg(C) = \deg(p_1) + \deg(p_2)$, as claimed.

The last statement is as simple as noting that $p_1(t)$ and $p_2(t)$ are non-constant, and so $\deg(p_1) + \deg(p_2) > 1$. □

Remark 2.7. Note that, in the polynomial case, $C(t)$ can be chosen constant in Proposition 2.6 and everything remains the same because, in this case, $\deg(r) = \deg(p_1) + \deg(p_2) - 1 < \deg(Cp_1p_2)$.

Remark 2.8. Observe that, in the polynomial case, (2.4) can be interpreted in terms of Euclidean divisibility as follows: if $p_1(t)x - 1 = 0$ and $p_2(t)x - 1 = 0$ are two different invariant curves of (1.5), then the quotient and the remainder of the division of $A(t)$ by $p_1(t)p_2(t)$ are

$$C(t) \quad \text{and} \quad r(t) = \frac{(p_2(t) - p_1(t))' p_1(t) p_2(t)}{p_2(t) - p_1(t)},$$

respectively. Giving rise to a computable necessary condition for two factors of $A(t)$ to define invariant curves.

Let us derive some consequences from Proposition 2.6.

Corollary 2.9. *If* $\deg(A) - \deg(C) \leq 1$, *then* (1.5) *has at most one invariant curve.*

Proof. If $C(t)$ is not constant, then, by Proposition 2.6, we are done. This also extends to the polynomial case, when $C(t)$ is constant (see Remark 2.7). Thus, suppose $A(t)$ and $B(t)$ are non-constant real trigonometric polynomials and $C(t) = c \in \mathbb{R} \setminus \{0\}$; in particular, $\deg(A) = 1$ by hypothesis. Therefore, $p_1(t) = a\,A(t)$ and $p_2(t) = b\,A(t)$ for some $a, b \in \mathbb{R} \setminus \{0\}$ with $a \neq b$. Thus, by (2.4),

$$A(t) = abA(t)(cA(t) + A'(t)).$$

Therefore, $cA(t) + A'(t) = \frac{1}{ab}$. Now, since $A(t) = a_0 + a_1\cos(t) + b_1\sin(t)$, for some a_0, a_1 and $b_1 \in \mathbb{R}$, we obtain that

$$ca_0 + (ca_1 + b_1)\cos(t) + (cb_1 - a_1)\sin(t) = \frac{1}{ab}.$$

Therefore,

$$ca_0ab = 1, \quad ca_1 + b_1 = 0, \quad cb_1 - a_1 = 0.$$

From the last two equalities, $a_1 = b_1 = 0$, in contradiction with $A(t)$ being non constant. □

Lemma 2.10. *Let* $p_1(t)x - 1 = 0$ *and* $p_2(t)x - 1 = 0$ *be two different invariant curves of* (1.5). *If* $\deg(p_1) \neq \deg(p_2)$, *and*

(a) $C(t)$ *is not constant, then has no more invariant curves.*

(b) $C(t)$ is constant, then $\deg(A) = \deg(p_1) + \deg(p_2)$.

Proof. (a) Suppose on contrary, that $h(t,x) = 0$ is an invariant curve of (1.5) different from $p_1(t)x - 1 = 0$ and $p_2(t)x - 1 = 0$. By Proposition 2.2, there exists a polynomial $p_3(t) \in R$ such that $h(t,x) = p_3(t)x - 1$. Since, by Proposition 2.6, $\deg(p_i) + \deg(p_j) = \deg(A) - \deg(C)$ for every $1 \leq i < j \leq 3$, we conclude that $\deg(p_i) = \deg(p_j) = \frac{\deg(A)-\deg(C)}{2}$ for every $1 \leq i < j \leq 3$, in contradiction with the hypothesis.

(b) Note that by Remark 2.7 the result is immediate in the polynomial case, so we focus on the trigonometric one. Let $c \in \mathbb{R} \setminus \{0\}$ be such that $C(t) = c$. Then, by (2.3),

$$-B(t) = A(t)/p_1(t) + p_1'(t) + p_1(t)c = A(t)/p_2(t) + p_2'(t) + p_2(t)c.$$

Suppose that $\deg(A) \neq \deg(p_1) + \deg(p_2)$. Then, by Proposition 2.5, $\deg(A) < \deg(p_1) + \deg(p_2)$. Therefore $\deg(A/p_1) < \deg(p_2)$ and $\deg(A/p_2) < \deg(p_1)$.

Now, since $\deg(p_1) \neq \deg(p_2)$, we can assume $\deg(p_1) < \deg(p_2)$, then the higher degree terms of $p_2'(t)$ and $p_2(t)c$ must cancel each other. Thus, if $p_2(t) = a_n \cos(nt) + b_n \sin(nt) +$ *lower degree terms*, where a_n and b_n are not both zero, then

$$ca_n \cos(nt) + cb_n \sin(nt) = -na_n \sin(t) + nb_n \cos(t).$$

Therefore, $ca_n - nb_n = cb_n + na_n = 0$ and, since $c \in \mathbb{R} \setminus \{0\}$, we obtain $a_n = b_n = 0$, a contradiction. Hence, $\deg(p_1) = \deg(p_2)$. □

Remark 2.11. Note that according to Remark 2.7 nothing changes if $C(t)$ is constant in (a) of the previous lemma in the polynomial case.

Observe that as an immediate consequence of the proof of the above result we have the following corollary.

Corollary 2.12. *Suppose that we are in the polynomial case or in the trigonometric case when $C(t)$ is not constant. If (1.5) has three invariant curves, say, $p_i(t)x - 1 = 0$, $i = 1,2,3$, then*

$$\deg(p_i) = \frac{\deg(A) - \deg(C)}{2},$$

for every $i \in \{1,2,3\}$.

Proposition 2.13. *Suppose that we are in the polynomial case or in the trigonometric case when $C(t)$ is not constant. If $\deg(A) - \deg(C)$ is odd or $2\deg(B) > \deg(A) + \deg(C)$, then (1.5) has at most two invariant curves.*

Proof. Corollary 2.12 clearly implies that if $\deg(A) - \deg(C)$ is odd, then (1.5) can have at most two invariant curves.

Suppose that $2\deg(B) > \deg(A) + \deg(C)$. By (2.3), if $p_1(t)x - 1 = 0$ is an invariant curve, then

$$-B(t) = A(t)/p_1(t) + p_1'(t) + p_1(t)C(t),$$

and thus, $\deg(B) \leq \max\{\deg(A) - \deg(p_1), \deg(p_1), \deg(p_1) + \deg(C)\}$. Now, if (1.5) has more than two invariant curves, by Corollary 2.12, $\deg(p_1) = \frac{\deg(A)-\deg(C)}{2}$, and we conclude that

$$\deg(B) \leq \max\left\{\frac{\deg(A) + \deg(C)}{2}, \frac{\deg(A) - \deg(C)}{2}\right\} = \frac{\deg(A) + \deg(C)}{2}$$

getting a contradiction. □

Let us parameterize the family of equations (1.5) with at least two invariant curves, $p_1(t)x - 1 = 0$ and $p_2(t)x - 1 = 0$.

First, we will introduce some notation. Let $q(t) = \gcd(p_1(t), p_2(t))$, this is also well defined in the trigonometric case by Proposition 2.1(c), and let $s_1(t)$, $s_2(t)$ and $s(t)$ be the polynomials (resp. trigonometric polynomials) such that

$$p_1(t) = q(t)s_1(t), \quad p_2(t) = q(t)s_2(t), \quad A(t) = q(t)s_1(t)s_2(t)s(t). \tag{2.6}$$

Note that $\gcd(s_1(t), s_2(t)) = 1$.

Lemma 2.14. *Let $p_1(t)$ and $p_2(t)$ be two non-constant polynomials in t with coefficients in $\mathbb{K}$ (resp. two non-constant trigonometric polynomials with real coefficients) such that $p_i(t) \neq 0$, for every $t \in \mathbb{R}$ and $i \in \{1, 2\}$. With the previous notation, if*

$$\frac{(p_2(t) - p_1(t))' p_1(t) p_2(t)}{p_2(t) - p_1(t)}$$

is a polynomial (resp. a trigonometric), then $s_2(t) = s_1(t) + k\,\widehat{q}(t)$, where k is a nonzero constant and $\widehat{q}(t)$ is either constant or a product of not necessarily distinct irreducible monic factors of $q(t)$. As a consequence, if $p_1(t)x - 1 = 0$ and $p_2(t)x - 1 = 0$ are two invariant curves of (1.5), the claim must also be true. Furthermore,

$$s(t) = -q'(t) + q(t)\left(C(t) + \frac{\widehat{q}'(t)}{\widehat{q}(t)}\right).$$

Proof. By (2.6), we have

$$\frac{(p_2(t) - p_1(t))' p_1(t) p_2(t)}{p_2(t) - p_1(t)} = q(t)s_1(t)s_2(t)\left(q'(t) + q(t)\frac{(s_2(t) - s_1(t))'}{s_2(t) - s_1(t)}\right).$$

So, by hypothesis,

$$q(t)^2 \frac{(s_2(t) - s_1(t))'}{s_2(t) - s_1(t)}$$

is a polynomial, because there is no factor of $s_2(t) - s_1(t)$ dividing $s_1(t)s_2(t)$ as $\gcd(s_1(t), s_2(t)) = 1$.

Let us decompose $s_2(t) - s_1(t) = q_1(t)q_2(t)$ where all the factors of $q_2(t)$ divide $q(t)$ and no factor of $q_1(t)$ divides $q(t)$; in particular $\gcd(q_1(t), q_2(t)) = 1$. Then $q_1(t)$ divides $s_2'(t) - s_1'(t) = q_1'(t)q_2(t) + q_1(t)q_2'(t)$. So, it divides $q_1'(t)q_2(t)$ by Proposition 2.1. Therefore, $q_1(t)$ must be a nonzero constant. Now, by simply taking $k = q_1(t)$ and $\widehat{q}(t) = q_2(t)$, we are done.

On the other hand, as by (2.3),

$$A(t)/p_1(t) + p_1'(t) + p_1(t)C(t) = -B(t) = A(t)/p_2(t) + p_2'(t) + p_2(t)C(t),$$

then by (2.6),

$$\begin{aligned} &s_2(t)s(t) + q'(t)s_1(t) + q(t)s_1'(t) + q(t)s_1(t)C(t) \\ &\quad = s_1(t)s(t) + q'(t)s_2(t) + q(t)s_2'(t) + q(t)s_2(t)C(t) \end{aligned}$$

or, equivalently,

$$q(t)((s_2'(t) - s_1'(t)) + C(t)(s_2(t) - s_1(t))) = (s_2(t) - s_1(t))(s(t) + q'(t))$$

and

$$s(t) = -q'(t) + q(t)\left(C(t) + \frac{s_2'(t) - s_1'(t)}{s_2(t) - s_1(t)}\right).$$

As $s_2(t) - s_1(t) = k\,\widehat{q}(t)$, the previous expression reduces to

$$s(t) = -\left(q'(t) + q(t)\left(C(t) + \frac{\widehat{q}'(t)}{\widehat{q}(t)}\right)\right). \qquad \square$$

The converse also holds by direct verification using Corollary 2.3. Therefore, we obtain a parameterization of all cases of equation (1.5) having at least two invariant curves.

2.3 Bounds for the invariant curves in the polynomial case

In the polynomial case, it is interesting to look for a general bound on the number of invariant curves of (1.5). We recall that this is not interesting in the trigonometric case, since we can get a much better bound on the number of rational limit cycles using the Darboux theory of integrability (see Section 3). Thus, the rest of this section applies only to the polynomial case, and then we are in a Euclidean domain setting.

Given that if $p(t)x - 1 = 0$ is an invariant curve of (1.5), then $p(t)$ is a divisor of $A(t)$ in $\mathbb{C}[t]$, the number of divisors of $A(t)$ would be an upper bound for the number of such invariant curves, up to proportionality. To search for this bound, we must first study the invariant curves of the equation whose polynomials are proportional.

Proposition 2.15. *The curves $p(t)x - 1 = 0$, $Kp(t)x - 1 = 0$ with $K \in \mathbb{K} \setminus \{0, 1\}$ are invariant curves of (1.5) if and only if*

$$A(t) = Kp(t)(p'(t) + p(t)C(t)), \quad B(t) = -(K+1)(p'(t) + p(t)C(t)).$$

Proof. As $p(t)x - 1 = 0$ is an invariant curve of (1.5), then by Corollary 2.3 there must exist a polynomial $q(t)$ such that

$$A(t) = p(t)q(t), \quad -B(t) = p'(t) + q(t) + p(t)C(t).$$

Moreover, as $Kp(t)x - 1 = 0$ is also an invariant curve of (1.5), again by Corollary 2.3 there must also exist a polynomial $\bar{q}(t)$ such that

$$A(t) = Kp(t)\bar{q}(t), \quad -B(t) = Kp'(t) + \bar{q}(t) + Kp(t)C(t).$$

Thus, $q(t) = K\bar{q}(t)$ and, equating both expressions of $B(t)$, one gets that $\bar{q}(t) = p'(t) + p(t)C(t)$, and,

$$A(t) = Kp(t)(p'(t) + p(t)C(t)), \quad B(t) = -(K+1)(p'(t) + p(t)C(t)).$$

Conversely, taking $q(t) = K(p'(t) + p(t)C(t))$, one has that $A(t) = p(t)q(t)$, $B(t) = p'(t) + q(t) + p(t)C(t)$ and, consequently, that $p(t)x - 1 = 0$ is invariant. Picking $q(t) = (p'(t) + p(t)C(t))$, one would similarly prove that $Kp(t)x - 1 = 0$ is also invariant. $\square$

Proposition 2.16. *Equation (1.5) has at most two invariant curves whose polynomials are proportional.*

Proof. Because of Proposition 2.15, we know that if $p(t)x-1=0$ is an invariant curve of (1.5), then there must exists an unique $K \in \mathbb{C}\setminus\{0,1\}$ such that $Kp(t)x-1=0$, and

$$A(t) = Kp(t)(p'(t)+p(t)C(t)), \quad B(t) = -(K+1)(p'(t)+p(t)C(t)).$$

This, if $K \neq -1$ implies that

$$p(t) = -\frac{K+1}{K}\frac{A(t)}{B(t)}.$$

Now, if there exists a different pair of invariant curves with proportional polynomials, say $\bar{p}(t)x-1=0$, $\bar{K}\bar{p}(t)x-1=0$, then if $\bar{K}\neq -1$ also

$$\bar{p}(t) = -\frac{\bar{K}+1}{\bar{K}}\frac{A(t)}{B(t)} = \frac{\bar{K}+1}{\bar{K}}\frac{K}{K+1}p(t)$$

and we are done.

Finally, note that if $p(t)x-1=0$ and $-p(t)x-1=0$ are both invariant curves of (1.5), then $B(t)\equiv 0$ and we have excluded that case. □

Proposition 2.17. *If* $\deg(A)-\deg(C)\leq 1$, (1.5) *has at most one invariant curve. In another case, if* $\deg(A)-\deg(C)$ *is odd or* $\deg(A)+\deg(C)<2\deg(B)$, *then* (1.5) *has at most two invariant curves. In another case, an upper bound for the number of invariant curves of* (1.5) *is*

$$\binom{\deg(A)}{(\deg(A)+1)/2}+1.$$

Proof. It is enough to remember that the number of divisors of $A(t)$, up to proportionality, is $\binom{\deg(A)}{(\deg(A)+1)/2}$ and that at most two invariant curves have proportional polynomials. □

3 Darboux's theory of integrability

Now let us take advantage of Darboux's Integrability Theory to obtain results related to the integrability of the equation, in the polynomial case, and upper bounds on the number of rational limit cycles, in the trigonometric case.

We first recall the basic result of this theory from the original work of Darboux [11], adapted both to the polynomial and trigonometric settings.

Proposition 3.1. *If* (1.5) *has algebraic irreducible invariant curves* $h_1(t,x)=0,\dots,h_r(t,x)=0$ *with respective cofactors* $K_1(t,x),\dots,K_r(t,x)$ *and there exist not all null numbers* $\alpha_1,\dots,\alpha_r$ *such that*

$$\sum_{i=1}^{r}\alpha_i K_i(t,x)=0,$$

then

$$h(t,x) := \prod_{i=1}^{r} h_i(t,x)^{\alpha_i}$$

is a first integral of (1.5). *In this case, we say that* (1.5) *is Darboux integrable.*

Proposition 3.2. *If (1.5) has invariant curves $p_1(t)x-1=0,\dots,p_r(t)x-1=0$ with respective cofactors $K_1(t,x),\dots,K_r(t,x)$, and we write $K_0(t,x)=A(t)x^2+B(t)x+C(t)$ for the cofactor of the curve $x=0$, then there exist numbers $\alpha_0,\dots,\alpha_r$ not all zero such that*

$$\sum_{i=0}^{r}\alpha_i K_i(t,x)=0$$

if and only if

$$\sum_{i=1}^{r}\alpha_i A(t)/p_i(t)=0 \quad \textit{and} \quad 0=\alpha_0=\sum_{i=1}^{r}\alpha_i.$$

Proof. First, we recall that, by Corollary 2.3, the invariant curves $p_i(t)x-1=0$ have cofactors $K_i(t,x)=A(t)x^2-(p_i'(t)+p_i(t)C(t))x=A(t)x^2+(B(t)+A(t)/p_i(t))x$, $i=1,\dots,r$. Thus,

$$\begin{aligned}\sum_{i=0}^{r}\alpha_i K_i(t,x)&=\alpha_0K_0(t,x)+\sum_{i=1}^{r}\alpha_i K_i(t,x)\\&=\alpha_0\left(A(t)x^2+B(t)x+C(t)\right)+\sum_{i=1}^{r}\alpha_i(A(t)x^2+(B(t)+A(t)/p_i(t))x)\\&=\left(A(t)\sum_{i=0}^{r}\alpha_i\right)x^2+\left(\alpha_0B(t)+\sum_{i=1}^{r}\alpha_i(B(t)+A(t)/p_i(t))\right)x+\alpha_0C(t),\end{aligned}$$

and our claim follows. □

We can now prove the main result of the paper.

Proof of Theorem 1.1. The claims (a) and (b.1) have been proved in Corollaries 2.9 and Proposition 2.13, respectively. Moreover, the first part of claim (b.2.1) has been proven in Proposition 2.17.

Let us now prove the rest of claim (b.2.1). By Proposition 2.6 and Corollary 2.12, if (1.5) has $r\geq 3$ invariant curves, say, $p_i(t)x-1=0$, $i=1,\dots,r$, then $\deg(p_i)=(\deg(A)-\deg(C))/2$, for every $i\in\{1,\dots,r\}$. Moreover, by Corollary 2.3, $p_i(t)$ divides $A(t)$, for every $i\in\{1,\dots,r\}$. Therefore $A(t)/p_i(t)$ is a polynomial of degree $d:=(\deg(A)+\deg(C))/2$, for every $i\in\{1,\dots,r\}$.

Now, since the dimension of the $\mathbb{K}-$vector space of polynomials in t of degree up to d is equal to $d+1$, if $r\geq 2(d+2)$, then there exist $\lambda_1,\dots,\lambda_{d+2}$ and $\mu_{d+3},\dots,\mu_r$ such that

$$\sum_{i=1}^{d+2}\lambda_i A(t)/p_i(t)=\sum_{i=d+3}^{r}\mu_i A(t)/p_i(t)=0.$$

Thus, taking

$$\begin{aligned}\alpha_0&=0,\\\alpha_i&=\left(\sum_{j=d+3}^{r}\mu_j\right)\lambda_i,\ i=1,\dots,d+2,\\\alpha_i&=-\left(\sum_{j=1}^{d+2}\lambda_j\right)\mu_i,\ i=d+3,\dots,r,\end{aligned}$$

we have that $0=\alpha_0=\sum_{i=1}^{r}\alpha_i$ and that $\sum_{i=1}^{r}\alpha_i A(t)/p_i(t)=0$. So, by Proposition 3.2 and as $2(d+2)=\deg(A)+\deg(C)+4$, we are done.

We prove now (b.2.2). Following the same steps of the polynomial case, one gets that if equation (1.5) has $r \geq 3$ invariant curves, say $p_i(t)x - 1 = 0$, $i = 1, \dots, r$, then $A(t)/p_i(t)$ is a trigonometric polynomial of degree $\hat{d} := (\deg(A) + \deg(C))/2$, for every $i \in \{1, \dots, r\}$.

We can repeat the rest of the argument of the polynomial case verbatim, and in view of the dimension of the $\mathbb{R}$-vector space of trigonometric polynomials in t of the degree up to $\hat{d}$ is $2\hat{d} + 1$, we conclude that if $r \geq 2(2\hat{d} + 2)$, (1.5) has a Darboux first integral, and also a center. Thus, it can not have rational limit cycles. Consequently, a bound for the number of rational limit cycles is $2(2\hat{d} + 2) = 2\deg(A) + 2\deg(C) + 4$.

Finally, we prove (c). On the one hand, if $p_i(t)x - 1 = 0$, $i = 1, \dots, r$, are invariant curves of (1.5), we know that $\deg(A/p_i) \leq \deg(A) - 1$ for all $i \in \{1, \dots, r\}$, as $\deg(p_i) \geq 1$. Thus, all the polynomials belong to the $\mathbb{R}$-vector space of trigonometric polynomials in t of degree up to $\bar{d} = \deg(A) - 1$, whose dimension is $2\bar{d} + 1$. Thus, if $r \geq 2(2\bar{d} + 2)$, the equation would have a center.

However, on the other hand, the Abel equation

$$x' = A(t)x^3 + B(t)x^2 + cx$$

can never have a center, as its displacement function $d(x)$, whose isolated zeros correspond one to one with the limit cycles of the equation (see [27]), has derivative

$$d'(x) = \exp\left(\int_0^{2\pi} (3A(t)x^2 + 2B(t)x + c)dt\right) - 1.$$

So $d'(0) = \exp(2\pi c) - 1 \neq 0$, and $d(0) = 0$ because $x(t) \equiv 0$ is a solution of the equation. Therefore, $d(x) \not\equiv 0$ and the equation can never have a center.

To conclude, in this case equation (1.5) must have less that $2(2\bar{d} + 2) = 4\deg(A)$ invariant curves. □

Abstract. In this article, we present Lyapunov-type results to study the stability of an equilibrium of a Stieltjes dynamical system. We utilize prolongation results to establish the global existence of the maximal solution. Using Lyapunov's second method, we establish results of stability (resp. uniform stability) and asymptotic stability (resp. asymptotic uniform stability). Finally, we present examples and real-life applications to study asymptotic stability of equilibria in two population dynamics models.

Keywords: Stieltjes differential equations, Lyapunov stability, Lyapunov function, stable equilibrium, asymptotic stability, dynamical system.

2020 Mathematics Subject Classification: 34A06, 34D20, 34A34, 34B60.

1 Introduction

In recent years, the field of differential equations has witnessed a notable surge in interest surrounding Stieltjes differential equations. This renewed focus is largely driven by the pursuit of results that not only unify existing findings but also extend those related to classical derivatives [8, 9, 18, 19, 24, 27–30] through the Stieltjes derivative.

Unlike the classical derivative, the Stieltjes derivative consists of differentiating with respect to a derivator $g : \mathbb{R} \to \mathbb{R}$, assumed to be left-continuous and nondecreasing. Stieltjes differential equations permit to obtain a broader range of applications, particularly in contexts where certain processes may exhibit discontinuities and/or stationary periods [1, 8, 9, 18–21, 24, 25]. Such situations are common in various fields, including population dynamics, and physics, where classical differentiation has limitations in capturing the complexities of real-world phenomena.

Typically, investigations into first-order Stieltjes differential equations and systems focus on solutions defined on bounded intervals. However, Larivière in [17, Chapter 4] turned his attention to Stieltjes differential equations on the positive real half-line. In doing so, he provided results related to the prolongation of solutions and the existence of the maximal

✉Corresponding author. Email: marlene.frigon@umontreal.ca

solution. The motivation behind exploring these equations on the positive real half-line lies in the observation that many natural processes evolve over time without any inherent time limit, while some phenomena can exhibit finite-time blow-up, leading to abrupt changes or singularities. By considering Stieltjes differential equations, we aim to capture these nuanced behaviors and enhance our understanding of more complex dynamical systems from a unified perspective [22]. The reader is also referred to [5] for interesting results on prolongation of solutions and the existence of maximal solutions to generalized ordinary equations on Banach spaces relying on Kurzweil integration.

In the study of dynamical systems, the stability of *equilibria* holds significant importance. Here, the term *equilibrium* refers to a state that does not change dynamically, in the sense that if a system starts at an equilibrium point, it will stay in that state indefinitely. In order to maintain the interactions between species within many ecosystems, stability may be suitable for their functioning, and resilience. Although stability is typically desirable, there are some scenarios where stable equilibrium at zero can be critical and raise concerns for several reasons. For instance, in ecological systems, this concern arises from the vulnerability to perturbations of certain species, which may increase the risk of their extinction.

In this paper, we extend Lyapunov stability results from the classical literature to the Stieltjes dynamical system:

$$\mathbf{x}'_g(t) = \mathbf{f}(t, \mathbf{x}(t)) \quad \text{for } g\text{-almost all } t \geq 0, \tag{1.1}$$

where $\mathbf{f} = (f_1, \dots, f_n) : [0, +\infty) \times B \to \mathbb{R}^n$, $B \subset \mathbb{R}^n$.

Within the realm of dynamical systems theory, Lyapunov's Second Method [23] stands as a fundamental approach for assessing the stability properties of a system near an equilibrium. This stability analysis provides insights into whether small perturbations around an equilibrium lead to convergence or divergence of solutions. The core of this method lies in the concept of the *Lyapunov function* V depending on time and state. This function can be understood as an energy representation of the system (1.1), since in numerous applications, the function considered is the total energy of the system (1.1) through time, see for instance [3] for an example of an energy-based Lyapunov function for physical systems. This function was the subject of numerous works in the classical literature starting from the works [12,13,15,16,23,35] and references therein. In our context, the derivator g takes into account the relevance of each moment during the process by means of the changes of the slopes of g accordingly. Put differently, g amplifies an alternative measurement for time, which may differ from the linear time line typically used in the classical case where $g \equiv \mathrm{id}_{\mathbb{R}}$, see for instance the works [18–21,24,25] where g represents the life cycle of some populations, also we refer to [1,9] for more applications. Nevertheless, in the context of Stieltjes differentiation, we still can rely on Lyapunov's function which will then permit a better understanding of how the energy of the system (1.1) changes, but with respect to this new observed time described by g. Our stability study is inspired by results from classical theory and works such as [14, 16, 33, 34], which address dynamic equations on time scales and impulsive differential equations. To the best of our knowledge, this is the first work to introduce Lyapunov's method adapted to Stieltjes differential equations.

This paper is organized as follows: we present the theoretical framework and some preliminaries in Section 2. In Section 3, we focus on prolongation of solutions and the characterization of the maximal solution. Then, based on a generalized version of the Grönwall lemma [11, 17] for the Stieltjes derivative, we establish the existence of global solutions over the whole positive real half-line. Section 4 is devoted to Lyapunov-like stability results using

Lyapunov's second method. We establish stability results inspired by the works [6, 10], to extend some classical results from [14, 16].

In the last section of this paper, we present two applications to dynamics of population to study the asymptotic stability of some critical equilibria. In the first application, we model the dynamics of a population with Allee's effect [2, 31] negatively impacted by train vibrations. The second application concerns the dynamics of a population of *Cyanobacteria* in a cultured environment, keeping track of ammonia levels in the process.

2 Preliminaries

For $[a,b] \subset \mathbb{R}$, and $\mathbf{u} : [a,b] \to \mathbb{R}^n$ a regulated function, the symbols $\mathbf{u}(t^+)$ and $\mathbf{u}(t^-)$ will be used to denote

$$\mathbf{u}(t^+) = \lim_{\varepsilon \to 0^+} \mathbf{u}(t+\varepsilon), \text{ for all } t \in [a,b),$$
$$\mathbf{u}(t^-) = \lim_{\varepsilon \to 0^-} \mathbf{u}(t-\varepsilon), \text{ for all } t \in (a,b].$$

Throughout this work, we will consider $g : \mathbb{R} \to \mathbb{R}$ a monotone, nondecreasing and left-continuous function, also known as a *derivator*. We denote the set of discontinuity points of g by

$$D_g = \{t \in \mathbb{R} : g(t^+) - g(t) > 0\}.$$

In addition, we denote

$$C_g = \{s \in \mathbb{R} : g \text{ is constant on } (s-\varepsilon, s+\varepsilon) \text{ for some } \varepsilon > 0\}.$$

The set C_g is an open in the usual topology and it can be written as a countable union of disjoint intervals

$$C_g = \bigcup_{n \in \Lambda} (a_n, b_n),$$

with $\Lambda \subset \mathbb{N}$, $a_n, b_n \in \mathbb{R}$. We set $N_g = \{a_n, b_n : n \in \Lambda\} \setminus D_g$.

The function g defines a Lebesgue–Stieltjes measure μ_g such that $\mu_g([a,b)) = g(b) - g(a)$ for any interval $[a,b)$, so that $\mu_g(\{t\}) = g(t^+) - g(t)$ for all $t \in \mathbb{R}$, and $\mu_g(C_g) = \mu_g(N_g) = 0$. The reader is referred to [22] for more details. We refer to the measurability with respect to μ_g by g-measurability. We denote by $\mathcal{L}^1_g([a,b),\mathbb{R})$ the space of μ_g-integrable real-valued functions on $[a,b)$ endowed with the norm

$$\|f\|_{\mathcal{L}^1_g([a,b),\mathbb{R})} := \int_{[a,b)} |f(t)|\, d\mu_g(t), \quad \text{for every } f \in \mathcal{L}^1_g([a,b),\mathbb{R}).$$

Given an interval $I \subset \mathbb{R}$, we set

$$\mathcal{L}^1_g(I,\mathbb{R}^n) := \prod_{i=1}^n \mathcal{L}^1_g(I,\mathbb{R}),$$

and

$$\mathcal{L}^1_{g,\mathrm{loc}}(I,\mathbb{R}^n) = \{\mathbf{u} : I \to \mathbb{R}^n : \mathbf{u}|_{[a,b]} \in \mathcal{L}^1_g([a,b),\mathbb{R}^n) \text{ for every } [a,b] \subset I\}.$$

The derivator g defines a pseudometric $\rho : \mathbb{R} \times \mathbb{R} \to [0,\infty)$ given by

$$\rho(s,t) = |g(s) - g(t)|, \quad \text{for every } s,t \in \mathbb{R}.$$

We denote τ_g the topology induced by the pseudometric ρ. Notice that the interval $(t-\varepsilon, t]$ is open in τ_g for all $t \in D_g$ and all $\varepsilon > 0$. The reader is referred to [9, Section 2] for more properties of the topology τ_g.

Throughout this paper, let $\|\cdot\|$ denotes the maximum norm in $\mathbb{R}^n$ defined by

$$\|\mathbf{x}\| = \max\{|x_1|, \dots, |x_n|\} \quad \text{for } \mathbf{x} = (x_1, \dots, x_n) \in \mathbb{R}^n,$$

and $B_{\mathbb{R}^n}(\mathbf{x}, \delta)$ denotes the open ball centered in $\mathbf{x}$ of radius $\delta > 0$.

Now, we recall the notion of g-continuity introduced in [9].

Definition 2.1. Let $\mathbf{u} : [a, b] \to \mathbb{R}^n$. We say that $\mathbf{u}$ is *g-continuous* at $t \in [a, b]$ if, for every $\varepsilon > 0$, there exists $\delta > 0$ such that

$$\forall s \in [a, b], \qquad |g(s) - g(t)| < \delta \implies \|\mathbf{u}(s) - \mathbf{u}(t)\| < \varepsilon.$$

The following proposition relates the regularity of f and g, the reader is referred to [9, Proposition 3.2].

Proposition 2.2. *If $\mathbf{u} : [a, b] \to \mathbb{R}^n$ is g-continuous on $[a, b]$, then the following statements hold:*

(1) *$\mathbf{u}$ is left-continuous at every $t \in (a, b]$.*

(2) *If g is continuous at $t \in [a, b)$, then so is $\mathbf{u}$.*

(3) *If g is constant on some $[c, d] \subset [a, b]$, then so is $\mathbf{u}$.*

Let $\mathcal{BC}_g([a, b], \mathbb{R}^n)$ denotes the Banach space of the bounded, g-continuous functions defined on $[a, b]$ with values in $\mathbb{R}^n$, endowed with the supremum norm.

Now, we define the g-derivative of a real-valued function.

Definition 2.3. Let $u : [a, b] \to \mathbb{R}$ be a function. The *derivative of u with respect to g at a point $t \in [a, b] \setminus C_g$* is defined by:

$$u'_g(t) = \begin{cases} \lim\limits_{s \to t} \dfrac{u(s) - u(t)}{g(s) - g(t)} & \text{if } t \notin D_g, \\ \dfrac{u(t^+) - u(t)}{g(t^+) - g(t)} & \text{if } t \in D_g, \end{cases}$$

provided that the limit exists. In this case, u is said to be *g-differentiable at t* and $u'_g(t)$ is also called the *g-derivative of u at t*.

In the next proposition, we recall the g-derivative of the composition of two functions established in [26, Proposition 3.15]. Another version of this formula can be found in [7, Proposition 4.1].

Proposition 2.4. *Let $t \in \mathbb{R} \setminus C_g$, $f : \mathbb{R} \to \mathbb{R}$ and h a real function defined on a neighborhood of $f(t)$. We assume that there exist $h'(f(t))$, $f'_g(t)$ and that the function h is continuous at $f(t^+)$. Then, the composition $h \circ f$ is g-differentiable in t and*

$$(h \circ f)'_g(t) = \begin{cases} h'(f(t)) f'_g(t) & \text{if } t \notin D_g, \\ \dfrac{h(f(t^+)) - h(f(t))}{f(t^+) - f(t)} f'_g(t) & \text{if } t \in D_g. \end{cases}$$

In the particular case where the derivator $g : \mathbb{R} \to \mathbb{R}$ is increasing and continuous on an interval $[a, b] \subset \mathbb{R}$, we obtain easily a generalized version of the Mean Value theorem in the context of Stieltjes differentiation.

Theorem 2.5. *Let $g : \mathbb{R} \to \mathbb{R}$ be a left-continuous and nondecreasing function, continuous and increasing on an interval $[a, b] \subset \mathbb{R}$. Let $f : [a, b] \to \mathbb{R}$ be g-continuous on $[a, b]$ and g-differentiable on (a, b). Then, there exists $c \in (a, b)$ such that $f'_g(c) = \frac{f(b)-f(a)}{g(b)-g(a)}$.*

Proof. Let us consider the function $F : [a, b] \to \mathbb{R}$ defined by

$$F(t) = f(t) - \left(\frac{f(b) - f(a)}{g(b) - g(a)} (g(t) - g(a)) + f(a) \right), \quad \text{for all } t \in [a, b].$$

Clearly F is g-continuous on $[a, b]$, g-differentiable on (a, b), and

$$F'_g(t) = f'_g(t) - \frac{f(b) - f(a)}{g(b) - g(a)} \quad \text{for all } t \in (a, b).$$

It satisfies also $F(a) = F(b)$.

Proposition 2.2 implies that F is continuous on $[a, b]$. We set

$$m = \min_{t \in [a,b]} F(t) \quad \text{and} \quad M = \max_{t \in [a,b]} F(t).$$

If $m = M$, then F is constant on $[a, b]$ and $F'_g(t) = 0$ for all $t \in (a, b)$. Otherwise if $m < M$, we have $F(a) \neq m$ or $F(a) \neq M$. As $F(a) = F(b)$, without loss of generality, we assume that $F(a) = F(b) \neq M$. Thus, there exists $c \in (a, b)$ such that $F(c) = M$. Therefore, there exists $\delta > 0$ such that $(c - \delta, c + \delta) \subset (a, b)$ and $F(s) \leq F(c) = M$ for all $s \in (c - \delta, c + \delta)$. Since g is increasing and continuous on (a, b),

$$0 \leq F'_g(c) = \lim_{s \to c^+} \frac{F(s) - F(c)}{g(s) - g(c)} = \lim_{s \to c^-} \frac{F(s) - F(c)}{g(s) - g(c)} \leq 0.$$

We deduce that $F'_g(c) = 0$. Hence, there exists $c \in (a, b)$ such that $f'_g(c) = \frac{f(b)-f(a)}{g(b)-g(a)}$. □

Now, we recall the notion of g-absolute continuity.

Definition 2.6. A map $F : [a, b] \to \mathbb{R}$ is *g-absolutely continuous*, if, for every $\varepsilon > 0$, there exists $\delta > 0$ such that, for any family $\{(a_i, b_i)\}_{i=1}^{i=n}$ of pairwise disjoint open subintervals of $[a, b]$,

$$\sum_{i=1}^{n} g(b_i) - g(a_i) < \delta \Rightarrow \sum_{i=1}^{n} |F(b_i) - F(a_i)| < \varepsilon.$$

We denote by $\mathcal{AC}_g([a, b], \mathbb{R})$ the space of g-absolutely continuous functions $F : [a, b] \to \mathbb{R}$ on the interval $[a, b]$ and

$$\mathcal{AC}_g([a, b], \mathbf{B}) = \{\mathbf{u} = (u_1, \ldots, u_n) : [a, b] \to \mathbf{B} \subset \mathbb{R}^n : u_i \in \mathcal{AC}_g([a, b], \mathbb{R}) \quad \text{for } i = 1, \ldots, n\}.$$

In [22, Theorem 5.4], a Fundamental Theorem of Calculus for Lebesgue–Stieltjes integrals was established.

Theorem 2.7 (Fundamental Theorem of Calculus for the Lebesgue–Stieltjes integral)**.** *Let $a, b \in \mathbb{R}$ be such that $a < b$, and let $F : [a, b] \to \mathbb{R}$. The following assumptions are equivalent.*

(1) *The function F is g-absolutely continuous,*

(2) *The function F satisfies the following conditions:*

(a) *there exists $F'_g(t)$ for g-almost all $t \in [a,b)$;*

(b) $F'_g \in \mathcal{L}^1_g([a,b),\mathbb{R})$;

(c) *for each $t \in [a,b]$, we have*

$$F(t) = F(a) + \int_{[a,t)} F'_g(s)\, d\mu_g(s).$$

The following lemma provides conditions ensuring the g-absolute continuity of the composition of two functions, the proof is based on arguments as in [9, Proposition 5.3].

Lemma 2.8. *Let $\mathbf{u} : [a,b] \to B \subset \mathbb{R}^n$ be a g-absolutely continuous function, and let $v : B \to \mathbb{R}$ be a Lipschitz continuous function on B. Then, the composition $v \circ \mathbf{u} \in \mathcal{AC}_g([a,b],\mathbb{R})$.*

Now, we define the partial Stieltjes derivative as follows.

Definition 2.9. Given a function $V : [a,b] \times B_{\mathbb{R}^n}(\mathbf{0}, r_0) \to \mathbb{R}$. The *partial g-derivative of V with respect to the first argument* at a point $(t,\mathbf{x}) \in ([a,b) \setminus C_g) \times B_{\mathbb{R}^n}(\mathbf{0}, r_0)$ is defined as:

$$\frac{\partial V}{\partial_g t}(t,\mathbf{x}) = \begin{cases} \lim\limits_{s \to t} \frac{V(s,\mathbf{x}) - V(t,\mathbf{x})}{g(s) - g(t)}, & \text{if } t \in [a,b] \setminus D_g, \\ \dfrac{V(t^+,\mathbf{x}) - V(t,\mathbf{x})}{g(t^+) - g(t)}, & \text{if } t \in [a,b] \cap D_g, \end{cases}$$

provided that the limit exists.

The following proposition gives a formula related to the g-derivative of the composition involving a function with two variables. Formulae of this fashion were stated without proof in [29, Lemma 11] for $t \notin D_g$. Here, we derive formulae in the case where D_g and N_g do not have accumulation points.

Proposition 2.10. *Let $g : \mathbb{R} \to \mathbb{R}$ be a left-continuous and nondecreasing function such that D_g and N_g do not have accumulation points. Given a function $V : [a,b] \times B_{\mathbb{R}^n}(\mathbf{0}, r_0) \to \mathbb{R}$ satisfying the following assumptions:*

(1) *$V(\cdot,\mathbf{u})$ is g-differentiable on $[a,b] \setminus (D_g \cup C_g)$ for all $\mathbf{u} \in B_{\mathbb{R}^n}(\mathbf{0}, r_0)$;*

(2) *$V(t,\cdot) \in C^1(B_{\mathbb{R}^n}(\mathbf{0}, r_0),\mathbb{R})$ for all $t \in [a,b]$;*

(3) *$\frac{\partial V}{\partial_g t}(\cdot,\mathbf{u})$ is continuous on $[a,b] \setminus (D_g \cup C_g)$ for all $\mathbf{u} \in B_{\mathbb{R}^n}(\mathbf{0}, r_0)$;*

(4) *$V(\cdot,\mathbf{x}(\cdot)) \in \mathcal{AC}_g([a,b],\mathbb{R})$ for every $\mathbf{x} \in \mathcal{AC}_g\big([a,b], B_{\mathbb{R}^n}(\mathbf{0}, r_0)\big)$.*

Then, for every $\mathbf{x} \in \mathcal{AC}_g\big([a,b], B_{\mathbb{R}^n}(\mathbf{0}, r_0)\big)$ and for g-almost all $t \in [a,b] \setminus (D_g \cup C_g)$, one has that

$$V'_g(t,\mathbf{x}(t)) = \frac{\partial V}{\partial_g t}(t,\mathbf{x}(t)) + \sum_{i=1}^{n} \frac{\partial V}{\partial x_i}(t,\mathbf{x}(t))(x_i)'_g(t). \tag{2.1}$$

Moreover, if $t \in [a,b) \cap D_g$, then

$$V'_g(t,\mathbf{x}(t)) = \frac{V\big(t^+, \mathbf{x}(t) + \mu_g(\{t\})\mathbf{x}'_g(t)\big) - V(t,\mathbf{x}(t))}{g(t^+) - g(t)}. \tag{2.2}$$

Proof. Let $\mathbf{x} \in \mathcal{AC}_g\big([a,b], B_{\mathbb{R}^n}(\mathbf{0}, r_0)\big)$. By (4), $V(\cdot, \mathbf{x}(\cdot)) \in \mathcal{AC}_g([a,b], \mathbb{R})$. For g-almost every $t \in [a,b] \setminus (D_g \cup C_g)$:

$$\begin{aligned} V_g'(t, \mathbf{x}(t)) &= \lim_{s \to t} \frac{V(s, \mathbf{x}(s)) - V(t, \mathbf{x}(t))}{g(s) - g(t)} \\ &= \lim_{s \to t} \frac{V(s, \mathbf{x}(s)) - V(t, \mathbf{x}(s))}{g(s) - g(t)} + \frac{V(t, \mathbf{x}(s)) - V(t, \mathbf{x}(t))}{g(s) - g(t)} \\ &= \lim_{s \to t} \frac{V(s, \mathbf{x}(s)) - V(t, \mathbf{x}(s))}{g(s) - g(t)} \\ &\quad + \sum_{i=1}^{n} \Bigg(\frac{V(t, (x_1(t), \dots, x_{i-1}(t), x_i(s), \dots, x_n(s)))}{g(s) - g(t)} \\ &\qquad - \frac{V(t, (x_1(t), \dots, x_i(t), x_{i+1}(s), \dots, x_n(s)))}{g(s) - g(t)} \Bigg). \end{aligned}$$

For s sufficiently close to t, and since D_g and N_g do not have accumulation points, g is continuous and increasing on the interval with endpoint points s and t. By applying Theorem 2.5 to the function $V(\cdot, \mathbf{x}(s))$, we obtain that there exists c between s and t such that

$$\frac{V(s, \mathbf{x}(s)) - V(t, \mathbf{x}(s))}{g(s) - g(t)} = \frac{\partial V}{\partial_g t}(c, \mathbf{x}(s)).$$

As $s \to t$, $c \to t$, and using Condition (3) we obtain

$$\frac{V(s, \mathbf{x}(s)) - V(t, \mathbf{x}(s))}{g(s) - g(t)} = \frac{\partial V}{\partial_g t}(c, \mathbf{x}(s)) \to \frac{\partial V}{\partial_g t}(t, \mathbf{x}(t)).$$

Therefore,

$$V_g'(t, \mathbf{x}(t)) = \frac{\partial V}{\partial_g t}(t, \mathbf{x}(t)) + \sum_{i=1}^{n} \frac{\partial V}{\partial x_i}(t, \mathbf{x}(t)) (x_i)_g'(t).$$

For $t \in [a,b) \cap D_g$, we obtain immediately that

$$\begin{aligned} V_g'(t, \mathbf{x}(t)) &= \frac{V(t^+, \mathbf{x}(t^+)) - V(t, \mathbf{x}(t))}{g(t^+) - g(t)} \\ &= \frac{V\big(t^+, \mathbf{x}(t) + \mu_g(\{t\}) \mathbf{x}_g'(t)\big) - V(t, \mathbf{x}(t))}{g(t^+) - g(t)}. \end{aligned}$$

□

In [9, Definition 6.1], an exponential function was introduced.

Definition 2.11. Let $p \in \mathcal{L}_g^1([a,b), \mathbb{R})$ be such that

$$1 + p(t)\big(g(t^+) - g(t)\big) > 0 \text{ for every } t \in [a,b) \cap D_g. \tag{2.3}$$

The *exponential function* $e_p(\cdot, a) : [a,b] \to (0, \infty)$ is defined by

$$e_p(t,a) = e^{\int_{[a,t)} \tilde{p}(s)\, d\mu_g(s)} \quad \text{for every } t \in [a,b],$$

where

$$\tilde{p}(t) = \begin{cases} p(t) & \text{if } t \in [a,b] \setminus D_g, \\ \dfrac{\log\big(1 + p(t)(g(t^+) - g(t))\big)}{g(t^+) - g(t)} & \text{if } t \in [a,b) \cap D_g. \end{cases} \tag{2.4}$$

In particular, given $p \in \mathcal{L}^1_g([a,b),\mathbb{R})$ a function satisfying Condition (2.3), then $\tilde{p} \in \mathcal{L}^1_g([a,b),\mathbb{R})$ and $e_p(\cdot,a) \in \mathcal{AC}_g([a,b),\mathbb{R})$. The reader is referred to [9, Lemmas 6.2 and 6.3] and [27, Theorem 3.2] for more details.

Now, we recall the generalization of the Grönwall Lemma to the Stieltjes derivative obtained by Larivière in [17, Proposition 4.1.4], and further generalized in [11, Theorem 5.4]. This lemma will play a crucial role in establishing global solutions defined on the positive real half-line as we shall prove in the following section.

Lemma 2.12. *Let $u \in \mathcal{AC}_g([a,b],\mathbb{R})$. Assume that there exist functions $k, p \in \mathcal{L}^1_g([a,b),\mathbb{R})$, satisfying $1 + p(t)\mu_g(\{t\}) > 0$ for all $t \in [a,b) \cap D_g$, such that*

$$u'_g(t) \le k(t) + p(t)u(t) \quad \text{for } g\text{-almost all } t \in [a,b).$$

Then,

$$u(t) \le e_p(t,a)\left(\int_{[a,t)} \frac{e_p^{-1}(s,a)k(s)}{1+p(s)\mu_g(\{s\})}\, d\mu_g(s) + u(a) \right), \quad t \in [a,b].$$

3 Prolongation of solutions and maximal interval of existence

Let O be a nonempty open set of $\mathbb{R}^n$ and $I \subset \mathbb{R}$ an open interval in the topology τ_g. We set $\Omega := I \times O$. Let $(t_0, \mathbf{x}_0) \in \Omega$ be such that $t_0 < \sup I$.

Let us consider the Stieltjes dynamical system:

$$\begin{aligned} &\mathbf{x}'_g(t) = \mathbf{f}(t, \mathbf{x}(t)) \quad \text{for } g\text{-almost all } t \ge t_0,\ t \in I, \\ &\mathbf{x}(t_0) = \mathbf{x}_0, \end{aligned} \tag{3.1}$$

where $\mathbf{f} = (f_1, \dots, f_n) : \Omega \cap \big([t_0,\infty) \times \mathbb{R}^n\big) \to \mathbb{R}^n$ satisfies the following assumptions:

($\mathrm{H}_{\mathbf{x}_0,t_0}$) $\big(t_0, \mathbf{x}_0 + \mu_g(\{t_0\})\mathbf{f}(t_0,\mathbf{x}_0)\big) \in \Omega$.

($\mathrm{H}_{\mathbf{f},t_0}$)
- (a) for all $\mathbf{u} \in O$, $\mathbf{f}(\cdot,\mathbf{u})$ is g-measurable;
- (b) $\mathbf{f}(\cdot,\mathbf{u}_0) \in \mathcal{L}^1_{g,\mathrm{loc}}([t_0,\infty),\mathbb{R}^n)$ for some $\mathbf{u}_0 \in O$;
- (c) $\mathbf{f}$ is *g-integrally locally Lipschitz continuous*, i.e. for every $r > 0$, there exists a function $L_r \in \mathcal{L}^1_{g,\mathrm{loc}}([t_0,\infty),[0,\infty))$ such that

$$\|\mathbf{f}(t,\mathbf{u}) - \mathbf{f}(t,\mathbf{v})\| \le L_r(t)\|\mathbf{u}-\mathbf{v}\|,$$

for g-almost all $t \in I \cap [t_0,\infty)$ and all $\mathbf{u},\mathbf{v} \in \overline{B_{\mathbb{R}^n}(\mathbf{x}_0,r)} \cap O$.

(H_{Ω,t_0}) For every $(t,\mathbf{u}) \in \Omega$ with $t \ge t_0$,

- (a) one of the following conditions hold:
  - (a1) there exists $\delta > 0$ such that $(t-\delta, t+\delta) \times B_{\mathbb{R}^n}(\mathbf{u},\delta) \subset \Omega$;
  - (a2) if for every $\delta > 0$, $(t-\delta,t+\delta) \times B_{\mathbb{R}^n}(\mathbf{u},\delta) \not\subset \Omega$, then $t \in D_g$ and there exists $\varepsilon > 0$ such that $(t-\varepsilon, t] \times B_{\mathbb{R}^n}(\mathbf{u},\delta) \subset \Omega$;
- (b) if $(t,\mathbf{u}) \in \Omega \cap (D_g \times \mathbb{R}^n)$ is such that $(t,\mathbf{u}^+_{\mathbf{f},t}) \in \Omega$, then $(t,\mathbf{u}^+_{\mathbf{f},t})$ satisfies Condition (H_{Ω,t_0})(a)(a1), where

$$\mathbf{u}^+_{\mathbf{f},t} := \mathbf{u} + \mu_g(\{t\})\mathbf{f}(t,\mathbf{u}).$$

We recall the local existence result established in [9, Theorem 7.4].

Theorem 3.1. *Assume that* $(\mathrm{H}_{\mathbf{x}_0,t_0})$ *and* $(\mathrm{H}_{\mathbf{f},t_0})$ *holds. Then, there exists* $\delta > 0$ *such that the system* (3.1) *has a unique solution* $\mathbf{x} \in \mathcal{AC}_g([t_0, t_0+\delta], \mathbb{R}^n)$.

It should be noticed that Condition $(\mathrm{H}_{\mathbf{x}_0,t_0})$ permits to consider the problem (3.1) even in the case where $t_0 \in D_g$.

In the sequel, as shown in [17, Section 4.2], the solution given by Theorem 3.1 can be extended up to a maximal interval of existence if Condition $(\mathrm{H}_{\Omega,t_0})$ is satisfied. Indeed, this condition ensures that the solution $\mathbf{x}$ can be extended on some larger interval $[t_0, t_0+\varepsilon]$, $\varepsilon > \delta$ if

$$t_0 + \delta \in D_g \quad \text{and} \quad \big(\mathbf{x}(t_0+\delta)\big)^+_{\mathbf{f},t_0+\delta} \in O.$$

Let us define the set

$$\begin{aligned}\mathcal{S}(t_0,\mathbf{x}_0) := \{\mathbf{x} : I_{\mathbf{x}} = J_{\mathbf{x}} \cap [t_0,\infty) \to \mathbb{R}^n : \mathbf{x} \text{ is a solution of (3.1)},\\ J_{\mathbf{x}} \text{ is an open interval of } \tau_g \text{ such that } \sup J_{\mathbf{x}} > t_0 \in J_{\mathbf{x}}\}.\end{aligned}$$

For $\mathbf{x} \in \mathcal{S}(t_0,\mathbf{x}_0)$, it is worth mentioning that $\mathbf{x} \in \mathcal{AC}_g([a,b],\mathbb{R}^n)$ for every interval $[a,b] \subset I_{\mathbf{x}}$. In the sequel, for $\mathbf{x} \in \mathcal{S}(t_0,\mathbf{x}_0)$, we denote $\bar{t}_{\mathbf{x}} := \sup I_{\mathbf{x}}$.

Definition 3.2. Let $\mathbf{x}, \mathbf{y} \in \mathcal{S}(t_0,\mathbf{x}_0)$.

(1) We say that $\mathbf{x}$ is *smaller* than $\mathbf{y}$ (and we denote $\mathbf{x} \prec \mathbf{y}$), if and only if

(i) $I_{\mathbf{x}} \subset I_{\mathbf{y}}$;

(ii) $\sup I_{\mathbf{y}} > \sup I_{\mathbf{x}}$;

(iii) $\mathbf{y}|_{I_{\mathbf{x}}} = \mathbf{x}$.

In this case, we say that $\mathbf{x}$ is *extendible to the right* and $\mathbf{y}$ is *a prolongation to the right* of $\mathbf{x}$.

(2) We write that $\mathbf{x} \preceq \mathbf{y} \iff \mathbf{x} \prec \mathbf{y}$ or $\mathbf{x} = \mathbf{y}$.

Remark 3.3. It is worth mentioning that given a solution $\mathbf{x} : [t_0, t_1) \to \mathbb{R}^n$ of (3.1) such that

$$\mathbf{x}(t_1^-) := \lim_{t \to t_1^-} \mathbf{x}(t) \in O \quad \text{and} \quad t_1 \in D_g,$$

to not increase the notation, we will replace $\mathbf{x}$ by the function $\mathbf{x} : [t_0, t_1] \to \mathbb{R}^n$ defined by

$$\mathbf{x} = \begin{cases} \mathbf{x}(t) & \text{if } t \in [t_0, t_1), \\ \mathbf{x}(t_1^-) & \text{if } t = t_1. \end{cases}$$

The next result asserts that two prolongations to the right of a solution are equal on the common interval of existence, the reader is referred to [17, Theorem 4.2.3] for the proof.

Theorem 3.4. *Assume that* $(\mathrm{H}_{\mathbf{x}_0,t_0})$ *and* $(\mathrm{H}_{\mathbf{f},t_0})$ *hold. Let* $\mathbf{x}, \mathbf{y}, \mathbf{z} \in \mathcal{S}(t_0,\mathbf{x}_0)$ *be such that* $\mathbf{y}$ *and* $\mathbf{z}$ *are two prolongations of* $\mathbf{x}$*, then* $\mathbf{y} = \mathbf{z}$ *on* $I_{\mathbf{y}} \cap I_{\mathbf{z}}$.

In [17, Theorem 4.2.4], extendible solutions to the right were characterized as follows.

Theorem 3.5. *Assume that* $(\mathrm{H}_{\mathbf{x}_0,t_0})$ *and* $(\mathrm{H}_{\mathbf{f},t_0})$ *hold. Let* $\mathbf{x} \in \mathcal{S}(t_0,\mathbf{x}_0)$. *The following assumptions are equivalent:*

(1) $\mathbf{x}$ *is extendible to the right;*

(2) (i) $Graph(\mathbf{x}) := \{(t, \mathbf{x}(t)) : t \in I_{\mathbf{x}}\}$ *is bounded;*

(ii) $A \cup A^+ \subset \Omega$ *where*

$$A = \{(\bar{t}_{\mathbf{x}}, \mathbf{u}) \in [t_0, \infty) \times \mathbb{R}^n : \exists \{t_n\}_n \subset I_{\mathbf{x}},\ t_n \nearrow \bar{t}_{\mathbf{x}} \text{ and } \mathbf{u} = \lim_{n\to\infty} \mathbf{x}(t_n)\},$$
$$A^+ = \{(\bar{t}_{\mathbf{x}}, \mathbf{u}^+_{\mathbf{f},\bar{t}_{\mathbf{x}}}) : (\bar{t}_{\mathbf{x}}, \mathbf{u}) \in A\}.$$

Definition 3.6. Let $\mathbf{x} \in \mathcal{S}(t_0, \mathbf{x}_0)$. We say that $\mathbf{x}$ is a *maximal solution* of (3.1) defined on an interval $I_{\mathbf{x}}$ if, for every $\mathbf{y} \in \mathcal{S}(t_0, \mathbf{x}_0)$ satisfying $\mathbf{x} \preceq \mathbf{y}$, we have $\mathbf{x} = \mathbf{y}$. $I_{\mathbf{x}}$ is referred to as the *maximal interval of existence*.

As shown in [17, Theorem 4.2.5], the existence of the maximal solution holds. In addition, Theorem 3.4 guarantees the uniqueness of the maximal solution, and we obtain the following theorem.

Theorem 3.7. *Assume that* $(H_{\mathbf{x}_0,t_0})$, $(H_{\mathbf{f},t_0})$ *and* (H_{Ω,t_0}) *hold. Then, there exists a unique maximal solution* $\mathbf{x} \in \mathcal{S}(t_0, \mathbf{x}_0)$ *such that* $\omega(t_0, \mathbf{x}_0) := \sup I_{\mathbf{x}} \leq \infty$.

The next theorem highlights three alternative cases that occur, the reader is referred to [17, Theorem 4.2.6] for the proof.

Theorem 3.8. *Assume that* $(H_{\mathbf{x}_0,t_0})$, $(H_{\mathbf{f},t_0})$ *and* (H_{Ω,t_0}) *hold. Let* $\mathbf{x} \in \mathcal{S}(t_0, \mathbf{x}_0)$ *be the maximal solution of* (3.1)*, then one of the alternatives holds:*

(A1) $\omega(t_0, \mathbf{x}_0) = \infty$;

(A2) $\omega(t_0, \mathbf{x}_0) < \infty$, *and for every* $\{t_n\}_n \subset I_{\mathbf{x}}$ *such that* $t_n \nearrow \omega(t_0, \mathbf{x}_0)$, $\{\mathbf{x}(t_n)\}_n$ *is not bounded;*

(A3) $\omega(t_0, \mathbf{x}_0) < \infty$, *and there exists* $\{t_n\}_n \subset I_{\mathbf{x}}$ *satisfying* $t_n \nearrow \omega(t_0, \mathbf{x}_0)$ *and* $\{\mathbf{x}(t_n)\}_n$ *is a bounded sequence such that, for every subsequence* $\{t_{n_k}\}_k$ *verifying* $\mathbf{x}(t_{n_k}) \to \mathbf{u}$, *we have that*

$$\{(\omega(t_0, \mathbf{x}_0), \mathbf{u}), (\omega(t_0, \mathbf{x}_0), \mathbf{u}^+_{\mathbf{f},\omega(t_0,\mathbf{x}_0)})\} \not\subset \Omega.$$

Remark 3.9. Notice that, if Alternative (A1) holds, then $I_{\mathbf{x}} = [t_0, \infty)$, while if Alternative (A2) or (A3) holds, then $I_{\mathbf{x}} = [t_0, \omega(t_0, \mathbf{x}_0))$ or $I_{\mathbf{x}} = [t_0, \omega(t_0, \mathbf{x}_0)]$. In [5], the assumptions made on the Kurzweil integral of $\mathbf{f}$ do not allow the existence of a maximal solution on an interval of the form $[t_0, \omega(t_0, \mathbf{x}_0)]$.

Here is a corollary of Theorem 3.8 which ensures the global existence of the maximal solution over the whole interval $[t_0, \infty)$.

Corollary 3.10. *Let* I *be an interval containing* $[t_0, \infty)$. *Assume that* $(H_{\mathbf{x}_0,t_0})$, $(H_{\mathbf{f},t_0})$ *and* (H_{Ω,t_0}) *hold. Let* $\mathbf{x} \in \mathcal{S}(t_0, \mathbf{x}_0)$ *be the maximal solution of* (3.1)*. If*

$$\Omega^- := \left\{(t, \mathbf{u}) \in \Omega : \left(t, \mathbf{u}^+_{\mathbf{f},t}\right) \in \Omega\right\} = \Omega,$$

and there exists a compact set $D \subset O$ *such that* $\mathbf{x}(t) \in D$ *for every* $t \in I_{\mathbf{x}}$, *then* $\omega(t_0, \mathbf{x}_0) = \infty$.

Proof. Let us assume that $\omega(t_0,\mathbf{x}_0) < \infty$. Since D is compact, for all $\{t_n\}_n \subset I_{\mathbf{x}}$ such that $t_n \nearrow \omega(t_0,\mathbf{x}_0)$, $\{\mathbf{x}(t_n)\}_n$ is bounded. Thus, it results from Theorem 3.8 that Alternative (A3) holds. Therefore, there exists $\{t_n\}_n \subset I_{\mathbf{x}}$ with $t_n \nearrow \omega(t_0,\mathbf{x}_0)$ and $\{(t_n,\mathbf{x}(t_n))\}_n$ is bounded and such that, for a fixed subsequence $\{t_{n_k}\}_k$ verifying $\mathbf{x}(t_{n_k}) \to \mathbf{u}$, we have that

$$\left\{(\omega(t_0,\mathbf{x}_0),\mathbf{u}),\left(\omega(t_0,\mathbf{x}_0),\mathbf{u}^+_{\mathbf{f},\omega(t_0,\mathbf{x}_0)}\right)\right\} \not\subset \Omega. \tag{3.2}$$

On the other hand, D being a compact set yields that

$$(t_{n_k},\mathbf{x}(t_{n_k})) \to (\omega(t_0,\mathbf{x}_0),\mathbf{u}) \in [t_0,\omega(t_0,\mathbf{x}_0)] \times D \subset \Omega.$$

Now, since $\Omega^- = \Omega$, we deduce that $\left(\omega(t_0,\mathbf{x}_0),\mathbf{u}^+_{\mathbf{f},\omega(t_0,\mathbf{x}_0)}\right) \in \Omega$, which contradicts (3.2). Hence, $\omega(t_0,\mathbf{x}_0) = \infty$. □

Now, based on Theorems 3.5 and 3.8, we provide a characterization of the maximal solution of the problem (3.1).

Theorem 3.11. *Assume that* $(\mathrm{H}_{\mathbf{x}_0,t_0})$, $(\mathrm{H}_{\mathbf{f},t_0})$ *and* $(\mathrm{H}_{\Omega,t_0})$ *hold. Let* $\mathbf{x} \in \mathcal{S}(t_0,\mathbf{x}_0)$. *The following assumptions are equivalent:*

(1) $\mathbf{x}$ *is maximal;*

(2) *for every compact set* $K \subset \Omega$, *there exists* $t_K \in I_{\mathbf{x}}$ *such that*

$$\left\{(t,\mathbf{x}(t)),\left(t,(\mathbf{x}(t))^+_{\mathbf{f},t}\right)\right\} \not\subset K,$$

for all $t \geq t_K$, $t \in I_{\mathbf{x}}$.

Proof. Assume that $\mathbf{x}$ is maximal. By Theorem 3.8, two cases may occur:

Case 1: If $\omega(t_0,\mathbf{x}_0) = \sup I_{\mathbf{x}} = \infty$, by contradiction, assume that there exist a compact set $K \subset \Omega$ and a sequence $\{t_n\}_n \subset I_{\mathbf{x}}$ such that

$$t_n \nearrow \omega(t_0,\mathbf{x}_0) \quad \text{and} \quad \left\{(t_n,\mathbf{x}(t_n)),\left(t_n,(\mathbf{x}(t_n))^+_{\mathbf{f},t_n}\right)\right\} \subset K \quad \text{for all } n \in \mathbb{N}.$$

This implies that $\{(t_n,\mathbf{x}(t_n))\}$ is bounded. Therefore, there exists a convergent subsequence $\{(t_{n_k},\mathbf{x}(t_{n_k}))\}$ such that

$$(t_{n_k},\mathbf{x}(t_{n_k})) \to (\tau,\mathbf{u}) \in K \subset [t_0,\infty) \times O.$$

This contradicts that $t_n \nearrow \omega(t_0,\mathbf{x}_0) = \infty$.

Case 2: If $\omega(t_0,\mathbf{x}_0) < \infty$, then, by Theorem 3.8, there are two subcases:

Subcase 1: if Alternative (A2) holds, then

$$I_{\mathbf{x}} = [t_0,\omega(t_0,\mathbf{x}_0)) \quad \text{and} \quad \|\mathbf{x}(t)\| \to \infty \ \text{ as } t \nearrow \omega(t_0,\mathbf{x}_0).$$

Thus, for every $M > 0$, there exists $t^* \in I_{\mathbf{x}}$ such that $\|\mathbf{x}(t)\| \geq M$ for all $t \geq t^*$ with $t \in I_{\mathbf{x}}$. Hence, for every compact $K \subset \Omega$, there exists $t_K \in I_{\mathbf{x}}$ such that for all $t \geq t_K$ with $t \in I_{\mathbf{x}}$, we have $(t,\mathbf{x}(t)) \notin K$. In particular,

$$\left\{(t,\mathbf{x}(t)),\left(t,(\mathbf{x}(t))^+_{\mathbf{f},t}\right)\right\} \not\subset K.$$

Subcase 2: If Alternative (A3) holds, then we distinguish two cases.

If $I_{\mathbf{x}} = [t_0, \omega(t_0, \mathbf{x}_0))$, then the distance between $\operatorname{Graph}(\mathbf{x})$ and the boundary of Ω is zero, so

$$\big(\omega(t_0, \mathbf{x}_0), \mathbf{x}(\omega(t_0, \mathbf{x}_0)^-)\big) \notin \Omega.$$

Thus, for every compact $K \subset \Omega$, there exists $t_K \in [t_0, \omega(t_0, \mathbf{x}_0))$ such that, for all $t \geq t_K$ with $t \in I_{\mathbf{x}}$, $(t, \mathbf{x}(t)) \notin K$, which yields

$$\big\{(t, \mathbf{x}(t)), \big(t, (\mathbf{x}(t))^+_{\mathbf{f},t}\big)\big\} \not\subset K.$$

Now, if $I_{\mathbf{x}} = [t_0, \omega(t_0, \mathbf{x}_0)]$, then $\omega(t_0, \mathbf{x}_0) \in D_g$, $(\omega(t_0, \mathbf{x}_0), \mathbf{x}(\omega(t_0, \mathbf{x}_0))) \in \Omega$ and

$$\Big(\omega(t_0, \mathbf{x}_0), \big(\mathbf{x}(\omega(t_0, \mathbf{x}_0))\big)^+_{\mathbf{f},\omega(t_0,\mathbf{x}_0)}\Big) \notin \Omega.$$

Thus, for every compact $K \subset \Omega$, and for $t_K = \omega(t_0, \mathbf{x}_0)$,

$$\big(t_K, (\mathbf{x}(t_K))^+_{\mathbf{f},t_K}\big) \notin K, \quad \text{hence} \quad \big\{(t_K, \mathbf{x}(t_K)), \big(t_K, (\mathbf{x}(t_K))^+_{\mathbf{f},t_K}\big)\big\} \not\subset K.$$

Conversely, by contradiction, let us assume that $\mathbf{x} : I_{\mathbf{x}} \to \mathbb{R}^n$ is not maximal. Thus, $\bar{t}_{\mathbf{x}} = \sup I_{\mathbf{x}} < \infty$ and $\mathbf{x}$ is extendible to the right. From Theorem 3.5, it follows that $\operatorname{Graph}(\mathbf{x})$ is bounded and $A \cup A^+ \subset \Omega$. Thus, $[t_0, \bar{t}_{\mathbf{x}}] \times \overline{\operatorname{Graph}(\mathbf{x})}$ is compact,

$$\mathbf{x}(\bar{t}_{\mathbf{x}}^-) = \mathbf{x}(\bar{t}_{\mathbf{x}}) \in O \quad \text{and} \quad \Big(\mathbf{x}(\bar{t}_{\mathbf{x}})\Big)^+_{\mathbf{f},\bar{t}_{\mathbf{x}}} \in O.$$

Therefore, for the compact

$$K = \overline{\operatorname{Graph}(\mathbf{x})} \cup \Big\{\Big(\bar{t}_{\mathbf{x}}, \big(\mathbf{x}(\bar{t}_{\mathbf{x}})\big)^+_{\mathbf{f},\bar{t}_{\mathbf{x}}}\Big)\Big\} \subset \Omega,$$

we have that

$$\big\{(t, \mathbf{x}(t)), \big(t, (\mathbf{x}(t))^+_{\mathbf{f},t}\big)\big\} \subset K \quad \text{for all } t \in I_{\mathbf{x}},$$

which yields a contradiction. Hence, $\mathbf{x}$ is maximal. □

The negation of Theorem 3.11 provides also an interesting characterization of extendible solutions.

Corollary 3.12. *Assume that* $(\mathrm{H}_{\mathbf{x}_0,t_0})$, $(\mathrm{H}_{\mathbf{f},t_0})$ *and* $(\mathrm{H}_{\Omega,t_0})$ *hold. Let* $\mathbf{x} \in \mathcal{S}(t_0, \mathbf{x}_0)$. *The following statements are equivalent:*

(1) $\mathbf{x}$ *extendible to the right;*

(2) *there exist a compact set* $K \subset \Omega$ *and a sequence* $\{t_n\} \subset I_{\mathbf{x}}$ *with* $t_n \nearrow \omega(t_0, \mathbf{x}_0)$ *such that*

$$\Big\{(t_n, \mathbf{x}(t_n)), \Big(t_n, \big(\mathbf{x}(t_n)\big)^+_{\mathbf{f},t_n}\Big)\Big\} \subset K \quad \textit{for all } n \in \mathbb{N}.$$

Given the generalization of the Grönwall lemma, Lemma 2.12, we can state the next theorem which provides the global existence of the solution over $[t_0, \infty)$ and a bound of the solution.

Theorem 3.13. *Let* $\Omega \supset [t_0, \infty) \times \mathbb{R}^n$. *Assume that* $(\mathrm{H}_{\mathbf{x}_0,t_0})$, $(\mathrm{H}_{\mathbf{f},t_0})$ *and* $(\mathrm{H}_{\Omega,t_0})$ *hold. In addition, assume that*

(H_{LG}) *there exist* $k \in \mathcal{L}^1_{g,\mathrm{loc}}([t_0,\infty),\mathbb{R})$, *and* $p \in \mathcal{L}^1_{g,\mathrm{loc}}([t_0,\infty),[0,\infty))$ *such that*

$$\|\mathbf{f}(t,\mathbf{u})\| \leq k(t) + p(t)\|\mathbf{u}\| \quad \text{for } g\text{-almost all } t \in [t_0,\infty) \text{ and all } \mathbf{u} \in \mathbb{R}^n.$$

If $\mathbf{x} \in \mathcal{S}(t_0,\mathbf{x}_0)$ *is the maximal solution of* (3.1), *then*

$$\|\mathbf{x}(t)\| \leq e_p(t,t_0)\left(\int_{[t_0,t)} \frac{e_p^{-1}(s,t_0)k(s)}{1+p(s)\mu_g(\{s\})}\,d\mu_g(s) + \|\mathbf{x}_0\|\right), \quad \text{for all } t \in [t_0,T] \text{ with } T \in I_{\mathbf{x}}. \tag{3.3}$$

Moreover, we have $I_{\mathbf{x}} = [t_0,\infty)$.

Proof. Let $\mathbf{x} \in \mathcal{S}(t_0,\mathbf{x}_0)$ be the maximal solution of (3.1) defined on the maximal interval $I_{\mathbf{x}}$. By (H_{LG}), for $T > t_0$ with $T \in I_{\mathbf{x}}$, we have that

$$(\|\mathbf{x}\|)'_g(t) \leq \|\mathbf{x}'_g(t)\| = \|\mathbf{f}(t,\mathbf{x}(t))\| \leq k(t) + p(t)\|\mathbf{x}(t)\| \quad \text{for } g\text{-almost all } t \in [t_0,T).$$

Observe that $\|\cdot\|$ is Lipschitz continuous on $\mathbb{R}^n$. Thus, by Lemma 2.8, $\|\mathbf{x}(\cdot)\| \in \mathcal{AC}_g([t_0,T],\mathbb{R})$. Using the generalized version of the Grönwall Lemma, Lemma 2.12, we obtain

$$\|\mathbf{x}(t)\| \leq e_p(t,t_0)\left(\int_{[t_0,t)} \frac{e_p^{-1}(s,t_0)k(s)}{1+p(s)\mu_g(\{s\})}\,d\mu_g(s) + \|\mathbf{x}_0\|\right) \quad \text{for all } t \in [t_0,T].$$

Assume by contradiction that $\omega(t_0,\mathbf{x}_0) < \infty$. Since $p \in \mathcal{L}^1_{g,\mathrm{loc}}([t_0,\infty),[0,\infty))$, then

$$e_p(t,t_0)(1+p(t)\mu_g(\{t\})) \geq 1 \quad \text{for all } t \in [t_0,\infty).$$

Consequently,

$$\begin{aligned}\|\mathbf{x}(t)\| &\leq \sup_{t\in[t_0,T]} e_p(t,t_0)\Big(\int_{[t_0,t)} |k(s)|\,d\mu_g(s) + \|\mathbf{x}_0\|\Big)\\ &\leq e_p(\omega(t_0,\mathbf{x}_0),t_0)\Big(\|k\|_{\mathcal{L}^1_g([t_0,\omega(t_0,\mathbf{x}_0)),\mathbb{R})} + \|\mathbf{x}_0\|\Big)\\ &= M_1.\end{aligned}$$

As $T \nearrow \omega(t_0,\mathbf{x}_0) < \infty$, $\mathbf{x}(t) \in \overline{B_{\mathbb{R}^n}(\mathbf{0},M_1)}$ for all $t \in I_{\mathbf{x}}$. As $\mathbf{x}(\omega(t_0,\mathbf{x}_0)^-) = \mathbf{u} \in \mathbb{R}^n$, then

$$\mathbf{u}^+_{\mathbf{f},\omega(t_0,\mathbf{x}_0)} \in \mathbb{R}^n.$$

Therefore, for the compact set

$$K = [t_0,\omega(t_0,\mathbf{x}_0)] \times \overline{B_{\mathbb{R}^n}(\mathbf{0},M)} \quad \text{with} \quad M = \max\left\{M_1, \left\|\mathbf{u}^+_{\mathbf{f},\omega(t_0,\mathbf{x}_0)}\right\|\right\},$$

we have that

$$\left\{(t,\mathbf{x}(t)), \left(t,(\mathbf{x}(t))^+_{\mathbf{f},t}\right)\right\} \subset K \quad \text{for all } t \in I_{\mathbf{x}}.$$

By Corollary 3.12, we obtain that $\mathbf{x}$ is extendible to the right which is a contradiction. Hence, $\omega(t_0,\mathbf{x}_0) = \infty$. □

4 Lyapunov-like stability results

In this section, we assume that $[0,\infty) \subset I$ and $\Omega = I \times B_{\mathbb{R}^n}(\mathbf{0}, r)$. We present Lyapunov-type results in the context of Stieltjes dynamical systems, based on the classical Lyapunov's second method, considering Stieltjes dynamical systems of the form:

$$\mathbf{x}'_g(t) = \mathbf{f}(t, \mathbf{x}(t)) \quad \text{for } g\text{-almost all } t \geq \theta \geq 0,\ t \in I, \tag{4.1$_\theta$}$$

where $\mathbf{f} : \Omega \to \mathbb{R}^n$ satisfies $\mathbf{f}(t, \mathbf{0}) = \mathbf{0}$ for all $t \geq 0$. This study permits to draw conclusions about the behavior of solutions of the dynamical system (4.1$_\theta$) around the *equilibrium* $\mathbf{x} = \mathbf{0}$, which is also called the *trivial solution*.

Notice that, under hypotheses ($\mathrm{H}_{\Omega,0}$) and ($\mathrm{H}_{\mathbf{f},0}$) and for $(t_0, \mathbf{x}_0) \in [0,\infty) \times B_{\mathbb{R}^n}(\mathbf{0}, r)$, if ($\mathrm{H}_{\mathbf{x}_0,t_0}$) is satisfied, it follows from Theorem 3.7 that there exists a unique maximal solution $\mathbf{x} = \mathbf{x}(\cdot, t_0, \mathbf{x}_0) \in \mathcal{S}(t_0, \mathbf{x}_0) \cap \mathcal{AC}_{g,\mathrm{loc}}(I_{t_0,\mathbf{x}_0}, \mathbb{R}^n)$ of (4.1$_\theta$) with $\theta = t_0$ and satisfying $\mathbf{x}(t_0) = \mathbf{x}_0$ which is defined on a maximal interval of existence $I_{t_0,\mathbf{x}_0}$. As before, we denote $\omega(t_0, \mathbf{x}_0) = \sup I_{t_0,\mathbf{x}_0} \leq \infty$.

4.1 Lyapunov stability notions

In this subsection, we present stability concepts within the framework of Stieltjes' differentiation. Through illustrative examples, we highlight the influence of the sets C_g and D_g on the change of stability properties.

Definition 4.1. The trivial solution $\mathbf{x} = \mathbf{0}$ of the system (4.1$_\theta$) with $\theta = 0$ is said to be

- *stable* if, for all $\varepsilon > 0$ and $t_0 \in [0,\infty)$, there exists $\delta = \delta(\varepsilon, t_0) \in (0, r)$ such that

$$\|\mathbf{x}_0\| < \delta \quad \text{implies that} \quad \|\mathbf{x}(t, t_0, \mathbf{x}_0)\| < \varepsilon \quad \text{for all } t \in I_{t_0,\mathbf{x}_0};$$

- *uniformly stable* if, for all $\varepsilon > 0$, there exists $\delta = \delta(\varepsilon) \in (0, r)$ such that for all $t_0 \in [0,\infty)$,

$$\|\mathbf{x}_0\| < \delta \quad \text{implies that} \quad \|\mathbf{x}(t, t_0, \mathbf{x}_0)\| < \varepsilon \quad \text{for all } t \in I_{t_0,\mathbf{x}_0}.$$

Remark 4.2. In the case where the trivial solution $\mathbf{x} = \mathbf{0}$ of the system (4.1$_\theta$) with $\theta = 0$ is stable, observe that, for $\varepsilon = r$ and $t_0 \geq 0$, there exists $\delta = \delta(\varepsilon, t_0) \in (0, r)$ such that, for all $\mathbf{x}_0 \in B_{\mathbb{R}^n}(\mathbf{0}, \delta)$,

$$\|\mathbf{x}(t, t_0, \mathbf{x}_0)\| < \varepsilon \text{ for all } t \in I_{t_0,\mathbf{x}_0}.$$

Using Theorem 3.8 under ($\mathrm{H}_{\Omega,0}$), ($\mathrm{H}_{\mathbf{f},0}$) and ($\mathrm{H}_{\mathbf{x}_0,t_0}$), we deduce that $I_{t_0,\mathbf{x}_0} = [t_0,\infty)$. Furthermore, observe that if the stability of the trivial solution $\mathbf{x} = \mathbf{0}$ is uniform, then δ do not depend on t_0.

The following definition is a notion of *asymptotic stability*. This concerns the behavior of solutions as $t \to \infty$.

Definition 4.3. The trivial solution $\mathbf{x} = \mathbf{0}$ of the system (4.1$_\theta$) with $\theta = 0$ is said to be

- *asymptotically stable* if it is *stable* and, for every $t_0 \in [0,\infty)$, there exists $\delta = \delta(t_0) \in (0, r)$ such that, for all $\mathbf{x}_0 \in B_{\mathbb{R}^n}(\mathbf{0}, \delta)$ and $\varepsilon > 0$, there exists $\sigma = \sigma(t_0, \mathbf{x}_0, \varepsilon) > 0$ such that

$$\|\mathbf{x}(t, t_0, \mathbf{x}_0)\| < \varepsilon \quad \text{for all } t \in [t_0 + \sigma, \infty) \cap I_{t_0,\mathbf{x}_0};$$

- *uniformly asymptotically stable* if it is *uniformly stable* and there exists $\delta \in (0, r)$ such that, for every $\varepsilon > 0$, there exists $\sigma = \sigma(\varepsilon) > 0$ such that, for all $t_0 \in [0, \infty)$ and $\mathbf{x}_0 \in B_{\mathbb{R}^n}(\mathbf{0}, \delta)$,

$$\|\mathbf{x}(t, t_0, \mathbf{x}_0)\| < \varepsilon \text{ for all } t \in [t_0 + \sigma, \infty) \cap I_{t_0, \mathbf{x}_0}.$$

In the following example, we compare the stability properties of the trivial solution of a linear Stieltjes dynamical system to the ones in the classical case, observing the change of the stability properties depending on the sets C_g and D_g. The resolution of linear Stieltjes differential equations has been studied in the literature, see for instance [7, 9, 17, 26, 27].

Example 4.4. Let us consider the linear Stieltjes dynamical system

$$x'_g(t) = cx(t) \quad \text{for } g\text{-almost all } t \geq \theta \geq 0, \tag{4.2$_\theta$}$$

for $c \in \mathbb{R}$. In the classical case of derivation where $g \equiv \mathrm{id}_{\mathbb{R}}$, for $c > 0$, the equilibrium $x = 0$ is not stable given that the solutions of (4.2$_\theta$) with $\theta = t_0$ and satisfying $x(t_0) = x_0$ are $x(t, t_0, x_0) = x_0 e^{c(t-t_0)}$ for every $x_0 \in \mathbb{R}$ and $t_0 \geq 0$, and they are not bounded on $[t_0, \infty)$ for $x_0 \neq 0$.

However, for $c < 0$, the equilibrium $x = 0$ is asymptotically stable since stability holds and $x(t, t_0, x_0) = x_0 e^{c(t-t_0)} \xrightarrow{t \to \infty} 0$ for all $x_0 \in \mathbb{R}$. In the case where $c = 0$, every constant $z \in \mathbb{R}$ is a uniformly stable equilibrium.

Now, let us reconsider the dynamical system (4.2$_\theta$), where $g : \mathbb{R} \to \mathbb{R}$ is defined by $g(t) = t$ for $t \leq 1$ and $g(t) = 1$ for $t \geq 1$. Thus, the solution of the problem (4.2$_\theta$) with $\theta = t_0$ and satisfying $x(t_0) = x_0$ is $x(t, t_0, x_0) = x_0 e^{c(g(t)-g(t_0))}$, for every $x_0 \in \mathbb{R}$ and $t_0 \geq 0$. Now, we show that the stability properties of the trivial solution $x = 0$ of the system (4.2$_\theta$) with $\theta = 0$ differ from the classical case, for $c \neq 0$. Indeed, for $c > 0$, we deduce the stability of the trivial solution $x = 0$ since, for all $\varepsilon > 0$ and $t_0 \geq 0$, one can take $\delta = \varepsilon / \left(e^{c(g(1)-g(t_0))}\right)$ which is such that

$$|x_0| < \delta \quad \text{implies that} \quad |x_0 e^{c(g(t)-g(t_0))}| < \varepsilon \quad \text{for all } t \geq t_0.$$

Whereas, for $c < 0$ the equilibrium $x = 0$ is uniformly stable since, for all $\varepsilon > 0$, with $\delta = \varepsilon > 0$, one has that

$$|x_0| < \delta \quad \text{implies that} \quad |x_0 e^{c(g(t)-g(t_0))}| < \varepsilon \quad \text{for all } t \geq t_0.$$

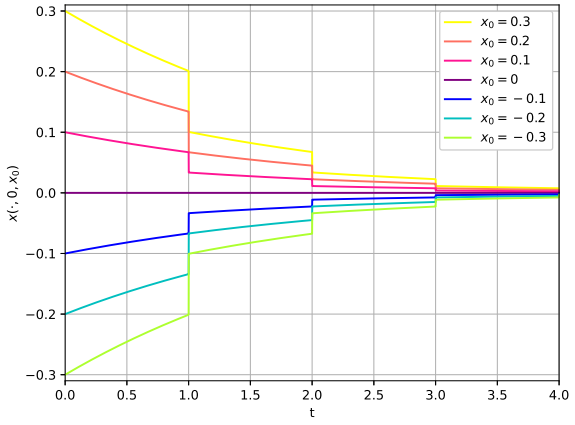
Observe that asymptotic stability does not hold for any $c \in \mathbb{R}$, since

$$x_0 e^{c(g(t)-g(t_0))} \to x_0 e^{c(g(1)-g(t_0))} \nrightarrow 0,$$

as $t \to \infty$ for all $t_0 \geq 0$ and $x_0 \neq 0$.

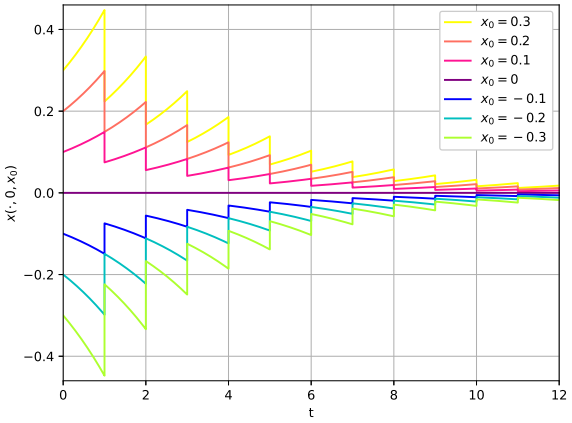
Next, we define the derivator g_1 by $g_1(t) = t + \sum_{n \in \mathbb{N}} \chi_{[n,\infty)}(t)$ for all $t \in \mathbb{R}$. We consider the dynamical system with g_1:

$$x'_{g_1}(t) = \begin{cases} cx(t) & \text{if } t \geq \theta \geq 0, \text{ with } t \notin D_{g_1} = \mathbb{N}, \\ \nu x(t), & \text{if } t \geq \theta \geq 0, \text{ with } t \in D_{g_1}, \end{cases} \tag{4.3$_\theta$}$$



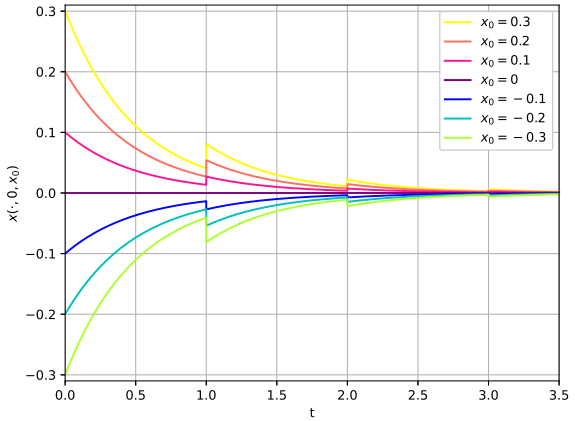
where $c, \nu \in \mathbb{R}$ with $\nu \in (-1, \infty) \setminus \{0\}$. Again the solution of (4.3$_\theta$) with $\theta = t_0$ and satisfying $x(t_0) = x_0$ has the form

$$x(t, t_0, x_0) = x_0 e_{c_*}(t, t_0) = x_0 e^{\int_{[t_0, t)} c_*(s)\, d\mu_{g_1}(s)},$$

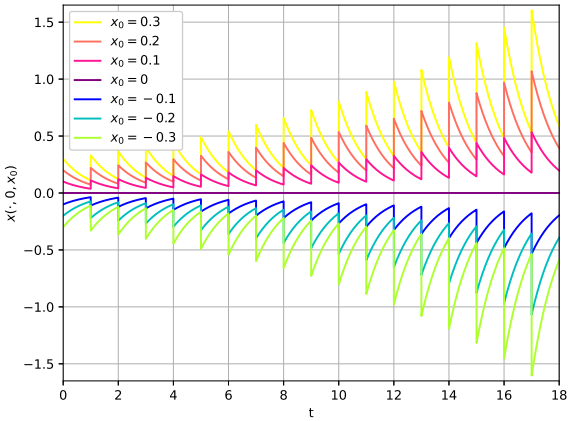


where

$$c_*(t) = \begin{cases} c & \text{if } t \in [t_0, \infty) \setminus D_{g_1}, \\ \log(1+\nu) & \text{if } t \in [t_0, \infty) \cap D_{g_1}. \end{cases}$$



In Figure 4.1, we can observe different patterns depending on the values of c and ν. This implies that the presence of discontinuities can destabilize or restore the stability properties of a dynamical system.



(a) The case of $c = -0.4$, and $\nu = -0.5$.

(b) The case of $c = 0.4$, and $\nu = -0.5$.

(c) The case of $c = -2$, and $\nu = 1$.

(d) The case of $c = -1$, and $\nu = 2$.

Figure 4.1: Behaviour of solutions of (4.3_θ) with $\theta = 0$ in a neighborhood of $x = 0$.

4.2 Stability results based on Lyapunov's function

In order to establish sufficient conditions for different types of stability of the trivial solution $\mathbf{x} = \mathbf{0}$ of the system (4.1_θ) with $\theta = 0$, we introduce specific sets of functions.

Definition 4.5. A function $V : [0, \infty) \times B_{\mathbb{R}^n}(\mathbf{0}, r_0) \to \mathbb{R}$ is said to belong to class $\mathcal{V}_1^g$ if it satisfies the following conditions:

1. $V(t, \cdot)$ is continuous for all $t \geq 0$;

2. $V(\cdot, \mathbf{x}(\cdot)) \in \mathcal{AC}_{g,\mathrm{loc}}(I_{t_0,\mathbf{x}_0}, \mathbb{R})$ for every function $\mathbf{x} : I_{t_0,\mathbf{x}_0} \to B_{\mathbb{R}^n}(\mathbf{0}, r_0)$ of $\mathcal{AC}_{g,\mathrm{loc}}(I_{t_0,\mathbf{x}_0}, \mathbb{R}^n)$ maximal solution of the system (4.1_θ) with $\theta = 0$;
3. $V(t, \mathbf{0}) = 0$ for all $t \geq 0$.

Definition 4.6. A function $\varphi : [0, \infty) \to [0, \infty)$ belongs to the class $\mathcal{K}$ if it fulfills the following assumptions:

1. φ is continuous;
2. $\varphi(0) = 0$;
3. φ is increasing.

In the following, we simply write $\varphi \in \mathcal{K}$ to mean that φ belongs to the class $\mathcal{K}$. Now, we state the first stability result.

Theorem 4.7. *Assume that Conditions* ($\mathrm{H}_{\Omega,0}$) *and* ($\mathrm{H}_{\mathbf{f},0}$) *hold. If there exist functions* $V \in \mathcal{V}_1^g$ *and* $a \in \mathcal{K}$ *such that*

(a) $a(\|\mathbf{u}\|) \leq V(t, \mathbf{u})$ *for all* $(t, \mathbf{u}) \in [0, \infty) \times B_{\mathbb{R}^n}(\mathbf{0}, r_0)$;

(b) *there exists* $r \in (0, r_0]$ *such that, for every* $(t_0, \mathbf{x}_0) \in [0, \infty) \times B_{\mathbb{R}^n}(\mathbf{0}, r)$, ($\mathrm{H}_{\mathbf{x}_0,t_0}$) *holds and, for* $\mathbf{x} : I_{t_0,\mathbf{x}_0} \to B_{\mathbb{R}^n}(\mathbf{0}, r_0)$ *the maximal solution of the system* (4.1_θ) *with* $\theta = t_0$ *and satisfying* $\mathbf{x}(t_0) = \mathbf{x}_0$, *one has that* $V_g'(t, \mathbf{x}(t)) \leq 0$ *for* g*-almost all* $t \in I_{t_0,\mathbf{x}_0}$.

Then, the trivial solution of the system (4.1_θ) *with* $\theta = 0$ *is*

(1) *stable,*

(2) *uniformly stable if there exists* $b \in \mathcal{K}$ *such that*

$$V(t, \mathbf{u}) \leq b(\|\mathbf{u}\|) \quad \text{for all } (t, \mathbf{u}) \in [0, \infty) \times B_{\mathbb{R}^n}(\mathbf{0}, r_0). \tag{4.4}$$

Proof. (1) Since $V \in \mathcal{V}_1^g$, then, for all $\varepsilon > 0$ and $t_0 \in [0, \infty)$, there exists $\delta = \delta(\varepsilon, t_0) \in (0, r)$ such that

$$\sup_{\|\mathbf{u}\| < \delta} V(t_0, \mathbf{u}) < a(\varepsilon).$$

For $\mathbf{x}_0 \in B_{\mathbb{R}^n}(\mathbf{0}, \delta)$, let $\mathbf{x} : I_{t_0,\mathbf{x}_0} \to B_{\mathbb{R}^n}(\mathbf{0}, r_0)$ be the maximal solution of the system (4.1_θ) with $\theta = t_0$ and $\mathbf{x}(t_0) = \mathbf{x}_0$. It follows from Conditions (a) and (b) that

$$a(\|\mathbf{x}(t)\|) \leq V(t, \mathbf{x}(t)) \leq V(t_0, \mathbf{x}_0) < a(\varepsilon).$$

Thus, for all $t \in I_{t_0,\mathbf{x}_0}$, we have that

$$\|\mathbf{x}(t, t_0, \mathbf{x}_0)\| < \varepsilon.$$

Therefore, the trivial solution $\mathbf{x} = \mathbf{0}$ is stable.

(2) Arguing as in (1), we can choose a $\delta = \delta(\varepsilon) \in (0, r)$ independent of t_0 such that

$$b(\delta) < a(\varepsilon).$$

Thus, using (4.4), we obtain for all $t \in I_{t_0,\mathbf{x}_0}$,

$$a(\|\mathbf{x}(t)\|) \leq V(t, \mathbf{x}(t)) \leq V(t_0, \mathbf{x}_0) \leq b(\|\mathbf{x}_0\|) < b(\delta) < a(\varepsilon).$$

This yields that the trivial solution $\mathbf{x} = \mathbf{0}$ is uniformly stable. □

In the next theorem, we impose additional assumptions which will permit to ensure the asymptotic stability of the trivial solution $\mathbf{x} = \mathbf{0}$ to the system (4.1_θ) with $\theta = 0$.

Theorem 4.8. *Assume that Conditions* ($\mathrm{H}_{\Omega,0}$) *and* ($\mathrm{H}_{\mathbf{f},0}$) *hold. Let* $V \in \mathcal{V}_1^g$, $\phi : [0,\infty) \to [0,\infty)$ *continuous,* $a, b \in \mathcal{K}$, *and a* g*-measurable function* $v : [0,\infty) \to [0,\infty)$ *be such that*

(a) $a(\|\mathbf{u}\|) \le V(t,\mathbf{u})$ *for every* $(t,\mathbf{u}) \in [0,\infty) \times B_{\mathbb{R}^n}(\mathbf{0}, r_0)$;

(b) $\phi(s) = 0$ *if and only if* $s = 0$;

(c) *there exists* $r \in (0, r_0]$ *such that, for every* $(t_0, \mathbf{x}_0) \in [0,\infty) \times B_{\mathbb{R}^n}(\mathbf{0}, r)$, ($\mathrm{H}_{\mathbf{x}_0,t_0}$) *holds and, for* $\mathbf{x} : I_{t_0,\mathbf{x}_0} \to B_{\mathbb{R}^n}(\mathbf{0}, r_0)$ *the maximal solution of the system* (4.1_θ) *with* $\theta = t_0$ *and satisfying* $\mathbf{x}(t_0) = \mathbf{x}_0$, *one has that*

$$V_g'(t, \mathbf{x}(t)) \le -v(t)\phi(\|\mathbf{x}(t)\|) \quad \text{for } g\text{-almost all } t \in I_{t_0,\mathbf{x}_0};$$

(d) $\inf_{t_0 \in [0,\infty)} \lim_{t \to +\infty} \int_{[t_0, t_0+t)} v(s)\, d\mu_g(s) = \infty$.

If the trivial solution $\mathbf{x} = \mathbf{0}$ *of the system* (4.1_θ) *with* $\theta = 0$ *is uniformly stable, then* $\mathbf{x} = \mathbf{0}$ *is asymptotically stable.*

Proof. The stability of the trivial solution $\mathbf{x} = \mathbf{0}$ holds from uniform stability. Let us choose $\delta_0 \in (0, r)$ associated to an $\varepsilon_0 \le r$ given by the uniform stability. Now, for a fixed $t_0 \ge 0$, let $\varepsilon > 0$. Again, by the uniform stability, there exists $\delta \in (0, \delta_0)$ such that, for all $\hat{t} \in [0,\infty)$ and every $\hat{\mathbf{x}}_0$ satisfying $\|\hat{\mathbf{x}}_0\| < \delta$, one has

$$\|\hat{\mathbf{x}}(t, \hat{t}, \hat{\mathbf{x}}_0)\| < \varepsilon \quad \text{for all } t \in [\hat{t}, \infty) \cap I_{\hat{t},\hat{\mathbf{x}}_0}.$$

We denote

$$M = \inf_{s \in [\delta, r_0)} |\phi(s)|. \tag{4.5}$$

By Condition (b), observe that $M > 0$.

Let $\mathbf{x}_0 \in B_{\mathbb{R}^n}(\mathbf{0}, \delta_0)$. Since

$$\lim_{t \to +\infty} \int_{[t_0, t_0+t)} v(s)\, d\mu_g(s) = \infty,$$

we can choose $\sigma > 0$ such that

$$\int_{[t_0, t_0+\sigma)} v(s)\, d\mu_g(s) > \frac{V(t_0, \mathbf{x}_0)}{M}.$$

Let $\mathbf{x} : I_{t_0,\mathbf{x}_0} \to B_{\mathbb{R}^n}(\mathbf{0}, r_0)$ be the maximal solution of (4.1_θ) with $\theta = t_0$ and satisfying $\mathbf{x}(t_0) = \mathbf{x}_0$. Using Remark 4.2, notice that $I_{t_0,\mathbf{x}_0} = [t_0, \infty)$. Now, if there exists $\hat{t} \in [t_0, t_0 + \sigma]$ such that $\|\mathbf{x}(\hat{t})\| < \delta$, then, by the uniform stability

$$\|\hat{\mathbf{x}}(t)\| < \varepsilon \quad \text{for all } t \in [\hat{t}, \infty) \cap I_{\hat{t},\mathbf{x}(\hat{t})},$$

where $\hat{\mathbf{x}} : I_{\hat{t},\mathbf{x}(\hat{t})} \to B_{\mathbb{R}^n}(\mathbf{0}, r_0)$ is the maximal solution of (4.1_θ) with $\theta = \hat{t}$ satisfying the initial condition $\hat{\mathbf{x}}(\hat{t}) = \mathbf{x}(\hat{t})$. By the uniqueness of the maximal solution, one has

$$\omega(t_0, \mathbf{x}_0) = \omega(\hat{t}, \mathbf{x}(\hat{t})) = \infty \quad \text{and} \quad \mathbf{x}(t) = \hat{\mathbf{x}}(t) \quad \text{for all } t \in [\hat{t}, \infty).$$

Hence,

$$\|\mathbf{x}(t)\| < \varepsilon \quad \text{for all } t \in [t_0+\sigma, \infty) \cap I_{t_0,\mathbf{x}_0}.$$

On the other hand, if $\|\mathbf{x}(t)\| \geq \delta$ for all $t \in [t_0, t_0+\sigma]$, then using Conditions (a), (c), Theorem 2.7, and (4.5), we obtain

$$\begin{aligned} a(\|\mathbf{x}(t_0+\sigma)\|) &\leq V(t_0+\sigma, \mathbf{x}(t_0+\sigma)) \\ &= V(t_0, \mathbf{x}(t_0, t_0, \mathbf{x}_0)) + \int_{[t_0,t_0+\sigma)} V'_g(s, \mathbf{x}(s))\, d\mu_g(s) \\ &\leq V(t_0, \mathbf{x}_0) - \int_{[t_0,t_0+\sigma)} v(s)\phi(\|\mathbf{x}(s)\|)\, d\mu_g(s) \\ &\leq V(t_0, \mathbf{x}_0) - M \int_{[t_0,t_0+\sigma)} v(s)\, d\mu_g(s) \\ &< 0. \end{aligned}$$

This is a contradiction. Therefore, $\mathbf{x} = \mathbf{0}$ is asymptotically stable. □

In the example below, we present an application of Theorem 4.8.

Example 4.9. Let us consider the Stieltjes dynamical system

$$x'_g(t) = f(t, x(t)) \quad \text{for } g\text{-almost all } t \geq \theta \geq 0, \tag{4.6$_\theta$}$$

with $g : \mathbb{R} \to \mathbb{R}$ defined by $g(t) = t$ for all $t \leq 1$, and $g(t) = t+1$ for $t > 1$, and where $f : [0,\infty) \times \mathbb{R} \to \mathbb{R}$ is a function defined by

$$f(t,x) = \begin{cases} -\dfrac{xt}{1+t^2} & \text{if } t \in [0,\infty) \setminus D_g, \\ \nu x & \text{if } t \in [0,\infty) \cap D_g, \end{cases}$$

for some $\nu \in \mathbb{R} \setminus \{-1, 0\}$. The function f satisfies conditions of Theorem 3.13, thus, for every $(t_0, x_0) \in [0,\infty) \times \mathbb{R}$, the problem (4.6$_\theta$) with $\theta = t_0$ has a maximal solution $x : [t_0, +\infty) \to \mathbb{R}$ satisfying $x(t_0) = x_0$. Observe that $x = 0$ is an equilibrium of the dynamical system (4.6$_\theta$) with $\theta = 0$.

Let us define the function $V : [0,\infty) \times \mathbb{R} \to \mathbb{R}$ for every $(t,x) \in [0,\infty) \times \mathbb{R}$ by

$$V(t,x) = \begin{cases} x^2 & \text{if } t \in [0,1], \\ \dfrac{x^2}{(1+\nu)^2} & \text{if } t > 1. \end{cases}$$

Clearly $V \in \mathcal{V}_g^1$, and $a(|u|) \leq V(t,u) \leq b(|u|)$ for all $(t,u) \in [0,\infty) \times \mathbb{R}$, where $a, b \in \mathcal{K}$ are given by

$$a(s) = \min\left\{s^2, \frac{s^2}{(1+\nu)^2}\right\} \quad \text{and} \quad b(s) = \max\left\{s^2, \frac{s^2}{(1+\nu)^2}\right\} \quad \text{for all } s \in [0,\infty).$$

In addition, for all $(t,x) \in [0,\infty) \times \mathbb{R}$:

$$\begin{aligned} \frac{\partial V}{\partial_g t}(t,x) &= \begin{cases} 0 & \text{if } t \in [0,1) \cup (1,\infty), \\ \dfrac{\frac{x^2}{(1+\nu)^2} - x^2}{g(1^+) - g(1)} & \text{if } t = 1, \end{cases} \\ &= \begin{cases} 0 & \text{if } t \in [0,1) \cup (1,\infty), \\ \dfrac{1-(1+\nu)^2}{(1+\nu)^2} x^2 & \text{if } t = 1. \end{cases} \end{aligned}$$

Thus, by means of Proposition 2.10, for $t \in [t_0, \infty) \setminus D_g$, we obtain

$$\begin{aligned} V_g'(t, x(t)) &= \frac{\partial V}{\partial_g t}(t, x(t)) + \frac{\partial V}{\partial x}(t, x(t)) f(t, x(t)) \\ &= \begin{cases} -\dfrac{2t}{1+t^2} x(t)^2 & \text{if } t \in [t_0, \infty) \cap [0, 1), \\ -\dfrac{2t}{(1+t^2)(1+\nu)^2} x(t)^2 & \text{if } t \in [t_0, \infty) \cap (1, \infty). \end{cases} \end{aligned}$$

For $t \in [t_0, \infty) \cap D_g$, if $t_0 \le 1$, then $t = 1$ and we have that

$$\begin{aligned} V_g'(1, x(1)) &= \frac{V(1^+, x(1^+)) - V(1, x(1))}{g(1^+) - g(1)} \\ &= \frac{V(1^+, x(1) + \mu_g(\{1\}) f(1, x(1))) - V(1, x(1))}{g(1^+) - g(1)} \\ &= \frac{\frac{(1+\nu)^2 x(1)^2}{(1+\nu)^2} - x(1)^2}{g(1^+) - g(1)} \\ &= 0. \end{aligned}$$

This implies that

$$V_g'(t, x(t)) \le -v(t) \phi(|x(t)|), \text{ for every } t \ge t_0,$$

with $v : [0, \infty) \to [0, \infty)$, defined by

$$v(t) = \begin{cases} \dfrac{2t}{1+t^2} & \text{if } t \in [0, 1), \\ 0 & \text{if } t = 1, \\ \dfrac{2t}{(1+t^2)(1+\nu)^2} & \text{if } t \in (1, \infty), \end{cases}$$

and $\phi \in \mathcal{K}$, defined by $\phi(y) = y^2$ for all $y \in [0, \infty)$. Moreover, for every $t_0 \in [0, \infty)$, we have

$$\begin{aligned} \lim_{t \to \infty} \int_{[t_0, t_0+t)} v(s)\, d\mu_g(s) &= \lim_{t \to \infty} \int_{[t_0, t_0+t) \cap ([0,1) \cup \{1\} \cup (1, \infty))} v(s)\, d\mu_g(s) \\ &\ge \lim_{t \to \infty} \frac{1}{(1+\nu)^2} \int_{[t_0, t_0+t) \cap (1, \infty)} \frac{2s}{1+s^2}\, ds \\ &= \lim_{t \to \infty} \frac{1}{(1+\nu)^2} \big(\log(1 + (t_0+t)^2) - \sup\{\log(2), \log(1+t_0^2)\} \big) \\ &= \infty. \end{aligned}$$

Hence,

$$\inf_{t_0 \in [0, \infty)} \lim_{t \to +\infty} \int_{[t_0, t_0+t)} v(s)\, d\mu_g(s) = \infty.$$

Thus, Condition (d) holds. Therefore, by means of Theorem 4.8, we deduce that $x = 0$ is an asymptotically stable equilibrium. Figure 4.2 illustrates the asymptotic behavior of solutions of the dynamical system (4.6_θ) with $\theta = 0$.

In the following example, we consider the case where g has an infinite number of discontinuities.

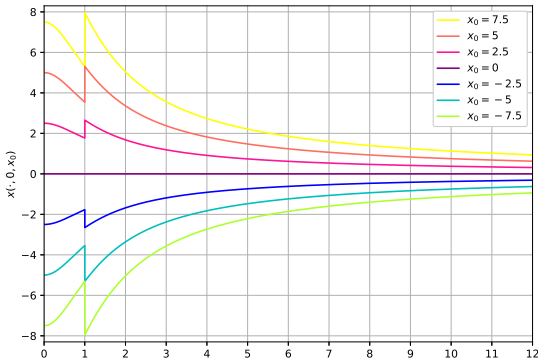


Figure 4.2: Asymptotic behavior of solutions of the dynamical system (4.6_θ) with $\theta = 0$ obtained with a time-discretization step-size of 10^{-3}, with $\nu = 0.5$.

Example 4.10. Let us consider the dynamical system

$$x_g'(t) = f(t, x(t)) \quad \text{for } g\text{-almost all } t \geq \theta \geq 0, \tag{4.7_θ}$$

where $g : \mathbb{R} \to \mathbb{R}$ is the derivator defined by

$$g(t) = t + \sum_{k \in \mathbb{N}} \chi_{[t_k, +\infty)}(t) \quad \text{for all } t \in \mathbb{R}, \tag{4.8}$$

where $\{t_k\}$ is an unbounded, increasing sequence in $(0, \infty)$, and where the function $f : [0, \infty) \times \mathbb{R} \to \mathbb{R}$ is defined by

$$f(t, x) = \begin{cases} -\dfrac{xt}{1 + t^2} & \text{if } t \in [0, \infty) \setminus D_g, \\ \nu x & \text{if } t \in [0, \infty) \cap D_g, \end{cases}$$

for some $\nu \in [-2, -1)$. The function f satisfies conditions of Theorem 3.13. Thus, for every $(t_0, x_0) \in [0, \infty) \times \mathbb{R}$, the problem ($4.6_\theta$) with $\theta = t_0$ has a maximal solution $x : [t_0, +\infty) \to \mathbb{R}$ satisfying $x(t_0) = x_0$. Observe that $x = 0$ is an equilibrium of the dynamical system (4.7_θ) with $\theta = 0$.

Let us define the function $V : [0, \infty) \times \mathbb{R} \to \mathbb{R}$ by $V(t, x) = x^2$. Clearly, $V \in \mathcal{V}_g^1$ and

$$a(|u|) \leq V(t, u) \leq b(|u|) \quad \text{for all } (t, u) \in [0, \infty) \times \mathbb{R},$$

where $a, b \in \mathcal{K}$ are given by

$$a(s) = s^2 \quad \text{and} \quad b(s) = \frac{s^2}{(1 + \nu)^2} \quad \text{for all } s \in [0, \infty).$$

In addition,

$$\frac{\partial V}{\partial_g t}(t, x) = 0 \quad \text{for all } (t, x) \in [0, \infty) \times \mathbb{R}.$$

Thus, by means of Proposition 2.10, for g-almost every $t \in [t_0, \infty) \setminus D_g$, we obtain

$$\begin{aligned} V_g'(t, x(t)) &= \frac{\partial V}{\partial_g t}(t, x(t)) + \frac{\partial V}{\partial x}(t, x(t)) f(t, x(t)) \\ &= -\frac{2t}{1 + t^2} x(t)^2. \end{aligned}$$

For $t_k \in [t_0, \infty) \cap D_g$, we have that

$$\begin{aligned} V_g'(t_k, x(t_k)) &= \frac{V(t_k^+, x(t_k^+)) - V(t_k, x(t_k))}{g(t_k^+) - g(t_k)} \\ &= \frac{V(t_k^+, x(t_k) + \mu_g(\{t_k\}) f(t_k, x(t_k))) - V(t_k, x(t_k))}{g(t_k^+) - g(t_k)} \\ &= \frac{((1+\nu)x(t_k))^2 - x(t_k)^2}{g(t_k^+) - g(t_k)} \\ &= \nu(2+\nu)x(t_k)^2. \end{aligned}$$

This implies that

$$V_g'(t, x(t)) \le -v(t)\phi(|x(t)|) \quad \text{for } g\text{-almost every } t \ge t_0,$$

with $v : [0, \infty) \to [0, \infty)$ defined by

$$v(t) = \begin{cases} \dfrac{2t}{1+t^2} & \text{if } t \in [0, t_1) \cup (t_k, t_{k+1}),\ k \in \mathbb{N}, \\ -\nu(2+\nu) & \text{if } t \in \{t_k\}_{k \in \mathbb{N}}, \end{cases}$$

and $\phi \in \mathcal{K}$ defined by $\phi(y) = y^2$ for all $y \in [0, \infty)$. For $t_0, t \in [0, \infty)$, observe that v satisfies:

$$\begin{aligned} \int_{[t_0, t_0+t)} v(s)\, d\mu_g(s) &= \sum_{s \in [t_0, t_0+t) \cap D_g} -\nu(2+\nu)\mu_g(\{s\}) + \int_{t_0}^{t_0+t} \frac{2s}{1+s^2}\, ds \\ &= \sum_{s \in [t_0, t_0+t) \cap D_g} -\nu(2+\nu)\mu_g(\{s\}) + \log\left(\frac{1+(t_0+t)^2}{1+t_0^2}\right). \end{aligned}$$

Thus,

$$\inf_{t_0 \in [0,\infty)} \lim_{t \to +\infty} \int_{[t_0, t_0+t)} v(s)\, d\mu_g(s) = +\infty.$$

Consequently, Condition (d) holds. Therefore, by means of Theorem 4.8, we deduce that $x = 0$ is an asymptotically stable equilibrium. Figure 4.3 illustrates the asymptotic behavior of solutions of the dynamical system (4.7_θ) with $\theta = 0$.

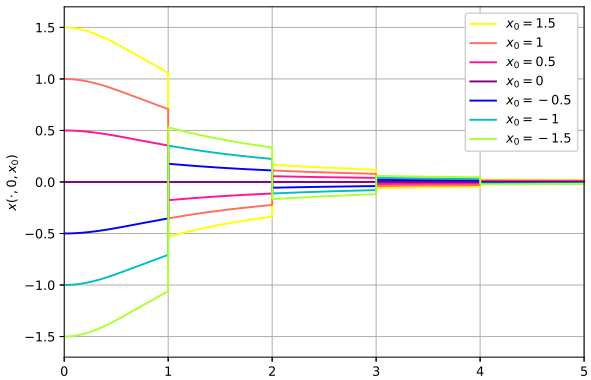

Figure 4.3: Asymptotic behavior of solutions of the dynamical system (4.7_θ) with $\theta = 0$ obtained with a time-discretization step-size of 10^{-3}, with $\nu = -3/2$.

The following result gives conditions to ensure the uniform asymptotic stability of the trivial solution of (4.1_θ) with $\theta = 0$.

Theorem 4.11. *Assume that Conditions* ($H_{\Omega,0}$), ($H_{\mathbf{f},0}$) *hold. If there exist* $V \in \mathcal{V}_1^g$, $a, b \in \mathcal{K}$, $\phi : [0,\infty) \to [0,\infty)$ *continuous, and a g-measurable function* $v : [0,\infty) \to [0,\infty)$ *such that*

(a) $a(\|\mathbf{u}\|) \leq V(t,\mathbf{u}) \leq b(\|\mathbf{u}\|)$ *for every* $(t,\mathbf{u}) \in [0,\infty) \times B_{\mathbb{R}^n}(\mathbf{0}, r_0)$;

(b) $\phi(s) = 0$ *if and only if* $s = 0$;

(c) *there exists* $r \in (0, r_0]$ *such that, for every* $(t_0, \mathbf{x}_0) \in [0,\infty) \times B_{\mathbb{R}^n}(\mathbf{0}, r)$, ($H_{\mathbf{x}_0,t_0}$) *holds and, for* $\mathbf{x} : I_{t_0,\mathbf{x}_0} \to B_{\mathbb{R}^n}(\mathbf{0}, r_0)$ *the maximal solution of the system* (4.1_θ) *with* $\theta = t_0$ *and satisfying* $\mathbf{x}(t_0) = \mathbf{x}_0$, *one has that*

$$V_g'(t, \mathbf{x}(t)) \leq -v(t)\phi(\|\mathbf{x}(t)\|) \quad \text{for } g\text{-almost all } t \in I_{t_0,\mathbf{x}_0}.$$

(d) $\lim_{t\to+\infty} \inf_{t_0\in[0,\infty)} \int_{[t_0,t_0+t)} v(s)\, d\mu_g(s) = +\infty$.

Then, the trivial solution $\mathbf{x} = \mathbf{0}$ *of the system* (4.1_θ) *with* $\theta = 0$ *is uniformly asymptotically stable.*

Proof. By (2) of Theorem 4.7, the trivial solution $\mathbf{x} = \mathbf{0}$ is uniformly stable. Thus, let us choose $\delta_0 \in (0, r)$ associated to an $\varepsilon_0 \leq r$. Let $\varepsilon > 0$. Again, by uniform stability, there exists $\delta \in (0, r)$ such that, for all $\hat{t} \in [0,\infty)$ and every $\hat{\mathbf{x}}_0$ such that $\|\hat{\mathbf{x}}_0\| < \delta$, one has

$$\|\hat{\mathbf{x}}(t, \hat{t}, \hat{\mathbf{x}}_0)\| < \varepsilon \quad \text{for all } t \in [\hat{t},\infty) \cap I_{\hat{t},\hat{\mathbf{x}}_0}.$$

Let M be as defined in (4.5). Since

$$\lim_{t\to+\infty} \inf_{t_0\in[0,\infty)} \int_{[t_0,t_0+t)} v(s)\, d\mu_g(s) = \infty,$$

we can choose $\sigma > 0$ such that

$$\int_{[t_0,t_0+\sigma)} v(s)\, d\mu_g(s) > \frac{b(\delta_0)}{M} \quad \text{for all } t_0 \in [0,\infty).$$

Let $(t_0, \mathbf{x}_0) \in [0,\infty) \times B_{\mathbb{R}^n}(\mathbf{0}, \delta_0)$ and $\mathbf{x} : I_{t_0,\mathbf{x}_0} \to B_{\mathbb{R}^n}(\mathbf{0}, r_0)$ a maximal solution of (4.1_θ) with $\theta = t_0$ and satisfying $\mathbf{x}(t_0) = \mathbf{x}_0$.

If there exists $\hat{t} \in [t_0, t_0 + \sigma] \cap I_{t_0,\mathbf{x}_0}$ such that $\|\mathbf{x}(\hat{t})\| < \delta$, then

$$\|\hat{\mathbf{x}}(t)\| < \varepsilon \quad \text{for all } t \in [\hat{t},\infty) \cap I_{\hat{t},\mathbf{x}(\hat{t})},$$

where $\hat{\mathbf{x}} : I_{\hat{t},\mathbf{x}(\hat{t})} \to B_{\mathbb{R}^n}(\mathbf{0}, r_0)$ is the maximal solution of (4.1_θ) with $\theta = \hat{t}$ satisfying the initial condition $\hat{\mathbf{x}}(\hat{t}) = \mathbf{x}(\hat{t})$. By the uniqueness of the maximal solution, one has

$$\omega(t_0, \mathbf{x}_0) = \omega(\hat{t}, \mathbf{x}(\hat{t})) \quad \text{and} \quad \mathbf{x}(t) = \hat{\mathbf{x}}(t) \quad \text{for all } t \in [\hat{t},\infty) \cap I_{t_0,\mathbf{x}_0}.$$

Hence,

$$\|\mathbf{x}(t)\| < \varepsilon \quad \text{for all } t \in [t_0 + \sigma,\infty) \cap I_{t_0,\mathbf{x}_0}.$$

On the other hand, if $\|\mathbf{x}(t)\| \geq \delta$ for all $t \in [t_0, t_0+\sigma]$, then, using Conditions (a), (c), Theorem 2.7, and (4.5), we obtain

$$\begin{aligned} a(\|\mathbf{x}(t_0+\sigma)\|) &\leq V(t_0+\sigma, \mathbf{x}(t_0+\sigma)) \\ &= V(t_0, \mathbf{x}(t_0, t_0, \mathbf{x}_0)) + \int_{[t_0,t_0+\sigma)} V_g'(s, \mathbf{x}(s))\, d\mu_g(s) \\ &\leq V(t_0, \mathbf{x}_0) - \int_{[t_0,t_0+\sigma)} v(s)\phi(\|\mathbf{x}(s)\|)\, d\mu_g(s) \\ &\leq V(t_0, \mathbf{x}_0) - M\int_{[t_0,t_0+\sigma)} v(s)\, d\mu_g(s) \\ &< b(\|\mathbf{x}_0\|) - b(\|\mathbf{x}_0\|) \\ &= 0. \end{aligned}$$

This is a contradiction. Hence, we conclude that $\mathbf{x} = \mathbf{0}$ is uniformly asymptotically stable. □

In the next example, we provide an application of Theorem 4.11 for a system subject to a derivator having an infinite number of discontinuities and for which the trivial solution $\mathbf{x} = \mathbf{0}$ is uniformly asymptotically stable.

Example 4.12. Let us consider the dynamical system

$$x_g'(t) = f(t, x(t)) \quad \text{for } g\text{-almost all } t \geq \theta \geq 0, \tag{4.9$_\theta$}$$

where $g : \mathbb{R} \to \mathbb{R}$ is given in (4.8), and $f : [0,\infty) \times \mathbb{R} \to \mathbb{R}$ is the function defined by

$$f(t,x) = \begin{cases} -t\arctan(x) & \text{if } t \in [0,\infty) \setminus D_g, \\ \nu_k x & \text{if } t = t_k,\ k \in \mathbb{N}, \end{cases}$$

where $\{\nu_k\}_k \subset \mathbb{R}_+^*$ is a sequence satisfying

$$\lim_{k\to\infty} \frac{1}{\prod_{i=1}^k (1+\nu_i)^2} = a_0 > 0.$$

The map f satisfies conditions of Theorem 3.13. Thus, for every $(t_0, x_0) \in [0,\infty) \times \mathbb{R}$, the problem (4.9$_\theta$) with $\theta = t_0$ has a maximal solution $x : [t_0, +\infty) \to \mathbb{R}$ satisfying $x(t_0) = x_0$. Observe that $x = 0$ is an equilibrium of the Stieltjes dynamical system (4.9$_\theta$) with $\theta = 0$.

Let us define the function $V : [0,\infty) \times \mathbb{R} \to \mathbb{R}$ by

$$V(t,x) = \begin{cases} x^2 & \text{if } t \in [0, t_1], \\ \dfrac{x^2}{\prod_{i=1}^k (1+\nu_i)^2} & \text{if } t \in (t_k, t_{k+1}],\ k \in \mathbb{N}. \end{cases}$$

Clearly $V \in \mathcal{V}_g^1$, and $a(|x|) \leq V(t,x) \leq b(|x|)$ for all $(t,x) \in [0,\infty) \times \mathbb{R}$, where $a, b \in \mathcal{K}$ are functions defined by $a(s) = a_0 s^2$ and $b(s) = s^2$ for all $s \in [0,\infty)$. In addition, for all $(t,x) \in [0,\infty) \times \mathbb{R}$:

$$\begin{aligned} \frac{\partial V}{\partial_g t}(t,x) &= \begin{cases} 0 & \text{if } t \in [0,t_1] \cup (t_k, t_{k+1}),\ k \in \mathbb{N}, \\ \dfrac{\frac{x^2}{\prod_{i=1}^k (1+\nu_i)^2} - \frac{x^2}{\prod_{i=1}^{k-1} (1+\nu_i)^2}}{g(t_k^+) - g(t_k)} & \text{if } t = t_k,\ k \in \mathbb{N}, \end{cases} \\ &= \begin{cases} 0 & \text{if } t \in [0,t_1) \cup (t_k, t_{k+1}),\ k \in \mathbb{N}, \\ \dfrac{1-(1+\nu_k)^2}{\prod_{i=1}^k (1+\nu_i)^2} x^2 & \text{if } t = t_k,\ k \in \mathbb{N}. \end{cases} \end{aligned}$$

For g-almost every $t \in [t_0, \infty) \setminus D_g$, we have that $t \in [0, t_1)$ or there exists $k \in \mathbb{N}$ such that $t \in (t_k, t_{k+1})$. Thus, by means of Proposition 2.10, we obtain if $t \in [0, t_1)$,

$$\begin{aligned} V_g'(t, x(t)) &= \frac{\partial V}{\partial_g t}(t, x(t)) + \frac{\partial V}{\partial x}(t, x(t)) f(t, x(t)) \\ &= -2x(t)t \arctan(x(t)) \\ &\leq -2t \frac{x(t)^2}{1 + x(t)^2}, \end{aligned}$$

where the last inequality follows from the Mean Value Theorem. While if there exists $k \in \mathbb{N}$ such that $t \in (t_k, t_{k+1})$, then

$$\begin{aligned} V_g'(t, x(t)) &= \frac{\partial V}{\partial_g t}(t, x(t)) + \frac{\partial V}{\partial x}(t, x(t)) f(t, x(t)) \\ &= \frac{-2x(t)}{\prod_{i=1}^{k}(1+\nu_i)^2} t \arctan(x(t)) \\ &\leq \frac{-2tx(t)^2}{(1 + x(t)^2)\left(\prod_{i=1}^{k}(1+\nu_i)^2\right)}. \end{aligned}$$

For $t_k \in [t_0, \infty) \cap D_g$, we have that

$$\begin{aligned} V_g'(t_k, x(t_k)) &= \frac{V(t_k^+, x(t_k^+)) - V(t_k, x(t_k))}{g(t_k^+) - g(t_k)} \\ &= \frac{V(t_k^+, x(t_k) + \mu_g(\{t_k\}) f(t_k, x(t_k))) - V(t_k, x(t_k))}{g(t_k^+) - g(t_k)} \\ &= \frac{\frac{(1+\nu_k)^2 x(t_k)^2}{\prod_{i=1}^{k}(1+\nu_i)^2} - \frac{x(t_k)^2}{\prod_{i=1}^{k-1}(1+\nu_i)^2}}{g(t_k^+) - g(t_k)} \\ &= 0. \end{aligned}$$

Therefore, we conclude that

$$V_g'(t, x(t)) \leq -v(t)\phi(|x(t)|) \quad \text{for } g\text{-almost all } t \geq t_0,$$

where $v : [0, \infty) \to [0, \infty)$ is the function defined for every $t \in [0, \infty)$ by

$$v(t) = \begin{cases} 2t & \text{if } t \in [0, t_1), \\ 0 & \text{if } t = t_k,\ k \in \mathbb{N}, \\ \dfrac{2t}{\prod_{i=1}^{k}(1+\nu_i)^2} & \text{if } t \in (t_k, t_{k+1}),\ k \in \mathbb{N}, \end{cases}$$

and $\phi \in \mathcal{K}$ the function given by $\phi(y) = y^2/(1 + y^2)$ for all $y \in [0, \infty)$.

Observe that the function v satisfies

$$\begin{aligned} \lim_{t \to +\infty} \inf_{t_0 \in [0,\infty)} \int_{[t_0, t_0+t)} v(s)\, d\mu_g(s) &\geq \lim_{t \to +\infty} \inf_{t_0 \in [0,\infty)} \int_{t_0}^{t_0+t} a_0 2s\, ds \\ &= a_0 \lim_{t \to +\infty} \inf_{t_0 \in [0,\infty)} 2tt_0 + t^2 \\ &= \infty. \end{aligned}$$

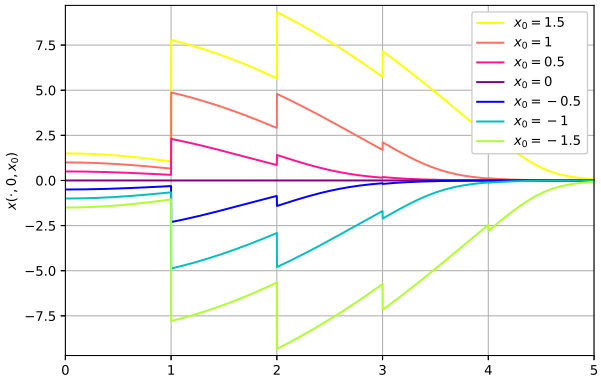

Figure 4.4: Asymptotic behavior of solutions of the dynamical system (4.9_θ) with $\theta = 0$ and $D_g = \mathbb{N}$, obtained with a time-discretization step-size of 10^{-3}, with $\nu_k = e^{\frac{2}{k^2}} - 1$ for all $k \in \mathbb{N}$.

By means of Theorem 4.11, we deduce that $x = 0$ is uniformly asymptotically stable equilibrium. Figure 4.4 illustrates the asymptotic behavior of solutions of the dynamical system (4.9_θ) with $\theta = 0$ and $D_g = \mathbb{N}$.

Remark 4.13. Observe that, in Example 4.9, the function v satisfies

$$\lim_{t\to+\infty} \inf_{t_0\in[0,\infty)} \int_{[t_0,t_0+t)} v(s)\, d\mu_g(s) = 0 \neq \infty.$$

Thus, Condition (d) of Theorem 4.11 does not hold. Consequently, uniform asymptotic stability cannot be deduced.

In the classical case where $g \equiv \mathrm{id}_{\mathbb{R}}$, corollary results [13, Theorem 4.2] and [23] are well-known when Conditions (b) of Theorem 4.8 is replaced by $V_g'(t, \mathbf{x}(t))$ being negative definite along each maximal solution $\mathbf{x}$ for every $t \geq t_0$. However, to present an analogous statement, we require an additional assumption to avoid the case when $\lim_{t\to\infty} g(t) = l < \infty$, and in particular, when there exists $T \geq 0$ such that $(T, \infty) \subset C_g$. Example 4.4 provides an interesting illustration of attractivity lack for asymptotic stability.

Corollary 4.14. *Assume that g is not bounded from above and Conditions ($H_{\Omega,0}$) and ($H_{\mathbf{f},0}$) hold. If there exist $V : [0,\infty) \times B_{\mathbb{R}^n}(\mathbf{0}, r_0) \to \mathbb{R}$; $V \in \mathcal{V}_1^g$ and $a, b, \phi \in \mathcal{K}$ such that*

(a) *$a(\|\mathbf{u}\|) \leq V(t,\mathbf{u}) \leq b(\|\mathbf{u}\|)$, for every $(t,\mathbf{u}) \in [0,\infty) \times B_{\mathbb{R}^n}(\mathbf{0}, r_0)$;*

(b) *there exists $r \in (0, r_0]$ such that, for every $(t_0, \mathbf{x}_0) \in [0,\infty) \times B_{\mathbb{R}^n}(\mathbf{0}, r)$, ($H_{\mathbf{x}_0,t_0}$) holds and, for $\mathbf{x} : I_{t_0,\mathbf{x}_0} \to B_{\mathbb{R}^n}(\mathbf{0}, r_0)$ the maximal solution of the system (4.1_θ) with $\theta = t_0$ and satisfying $\mathbf{x}(t_0) = \mathbf{x}_0$, one has that*

$$V_g'(t, \mathbf{x}(t)) \leq -\phi(\|\mathbf{x}(t)\|), \quad \text{for } g\text{-almost all } t \geq t_0.$$

Then, the trivial solution $\mathbf{x} = \mathbf{0}$ of the system (4.1_θ) with $\theta = 0$ is asymptotically stable. Furthermore, if

$$\lim_{t\to+\infty} \inf_{t_0\in[0,\infty)} g(t + t_0) - g(t_0) = \infty,$$

then, the trivial solution $\mathbf{x} = \mathbf{0}$ of the system (4.1_θ) with $\theta = 0$ is uniformly asymptotically stable.

Proof. Observe that Conditions of Theorem 4.8 hold for $v \equiv 1$ as

$$\inf_{t_0\in[0,\infty)} \lim_{t\to+\infty} \int_{[t_0,t+t_0)} \omega(s)\, d\mu_g(s) = \inf_{t_0\in[0,\infty)} \lim_{t\to+\infty} g(t+t_0) - g(t_0) = \infty.$$

Hence, the trivial solution is $\mathbf{x} = \mathbf{0}$ of the system (4.1_θ) with $\theta = 0$ is asymptotically stable. Moreover, if

$$\lim_{t\to+\infty} \inf_{t_0\in[0,\infty)} g(t+t_0) - g(t_0) = \infty, \tag{4.10}$$

then, Theorem 4.11 ensures that $\mathbf{x} = \mathbf{0}$ is uniformly asymptotically stable. □

Remark 4.15. In Corollary 4.14, it is worth mentioning that the assumption that the derivator g is not bounded from above does not necessarily imply that (4.10) holds. Indeed, let us consider the increasing sequence $\{t_n\}_{n\in\mathbb{N}}$ defined by

$$\begin{cases} t_n = 2t_{n-1} - t_{n-2} + 1, & n \in \mathbb{N},\ n \geq 3, \\ t_2 = 3,\ t_1 = 1. \end{cases}$$

Now, consider the derivator $g : \mathbb{R} \to \mathbb{R}$ defined by

$$g(t) = \begin{cases} t & \text{if } t \leq 0, \\ 0 & \text{if } t \in [0, t_1], \\ n & \text{if } t \in (t_n, t_{n+1}],\ n \in \mathbb{N}. \end{cases}$$

Observe that

$$D_g = \{t_n\}_{n\in\mathbb{N}} = \{1, 3, 6, 10, 15, \dots\} \quad \text{and} \quad C_g = (0, t_1) \cup \bigcup_{n\in\mathbb{N}} (t_n, t_{n+1}).$$

Notice that for every $t > 0$, there exists $t_0 \in [0, \infty)$ such that $[t_0, t + t_0] \subset C_g$. Thus,

$$\lim_{t\to+\infty} \inf_{t_0\in[0,\infty)} g(t+t_0) - g(t_0) = 0 \neq \infty.$$

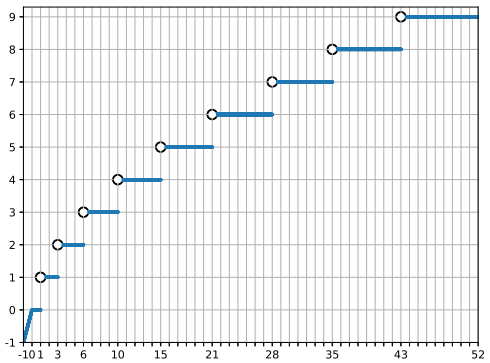

Figure 4.5: Graph of the derivator g in Remark 4.15.

5 Applications to dynamics of population

5.1 Stable equilibrium of a population subject to train vibrations

In this subsection, by means of a system of Stieltjes differential equations, we study the long-term impact of high-speed train vibrations and noise pollution on a population of animals living near railways. Depending on the species and their sensitivity to vibrations, various implications can be observed, we mention for instance:

- Hearing damage resulting in from the significant noise and vibrations that can potentially harm animals with sensitive hearing such as certain small mammals, birds, and bats which rely heavily on their hearing for communication, navigation, detection of predators, and finding food, thus, prolonged exposure to train vibrations may lead to hearing impairment or damage, disrupting their normal behaviors and increasing their death rate.

- Increased stress levels since some animals may be startled by the vibrations. This can affect their feeding patterns, reduce their reproduction rate, or lead to emigration resulting in a loss of suitable habitat and altering the composition and diversity of the local ecosystem

- Ecological interactions disruption which can affect pollination for instance if the vibrations deter insects that are important pollinators, disturb ground-dwelling organisms (insects, reptiles, and small mammals...) which can implicitly impact other species that rely on them as a food source.

In particular, an Allee effect can be observed in this regard, especially when the survival of the population depends on a minimum threshold size $M > 0$. In the follows, we denote by $x(t)$ the number of individuals of a population living in a region near a railway with a carrying capacity $K > M$.

Let us assume that a certain number $m > 0$ of trains pass through the area every day. We refer to $\{\delta_i\}_{i=1}^{i=m}$ as the moments when trains pass in a single day. Once a train pass by the area, its impact is significant for a proportion of individuals living near the railway. They may experience vibrations or direct injuries. In the following analysis, we use a Stieltjes differential equation to model the dynamics of this population affected by train vibrations, and we study the asymptotic behavior of its solutions. In doing so, we require a derivator $g : \mathbb{R} \to \mathbb{R}$ presenting discontinuities for $t \in \{\delta_i\}_{i=1}^{i=m} + 24\mathbb{N}$ such that $\mu_g(\{t\})$ quantifies the rate at which the risk of damage varies. Depending on the specific δ_i, this rate can either increase or decrease, reflecting the varying impact of vibrations during daylight and nighttime hours. For simplicity, we can take for instance:

$$g(t) = t + \sum_{k\in\mathbb{N}} \sum_{i=1}^{m} \chi_{[\delta_i+24k,\infty)}(t) \quad \text{for all } t \in \mathbb{R},$$

with $\mu_g(\{\cdot\}) \equiv 1$ on $D_g = \{\delta_i : i = 1, \dots, m\} + 24\mathbb{N}$.

In the sequel, we suggest to analyse the asymptotic behaviour of the dynamics of this population, through the study of asymptotic stability of the zero equilibrium of the Stieltjes dynamical system:

$$x'_g(t) = f(t, x(t)) \quad \text{for } g\text{-almost every } t \geq \theta \geq 0, \tag{5.1$_\theta$}$$

where $f : [0,\infty) \times \mathbb{R} \to \mathbb{R}$ is defined by

$$f(t,x) = \begin{cases} \rho x \left(1 - \dfrac{x}{K}\right)\left(\dfrac{x}{M} - 1\right), & \text{if } t \notin \{\delta_i + 24k\}_{i=1}^{m},\ k = 0,1,2\ldots \\ -dx, & \text{if } t \in \{\delta_i + 24k\}_{i=1}^{m},\ k = 0,1,2\ldots \end{cases} \tag{5.2}$$

The parameters of the model can be understood as:

$K > M$**:** the carrying capacity of the environment;

$\rho > 0$**:** the intrinsic rate of reproduction of the population;

$d \in (0,1)$**:** a constant related to the impact induced by trains, either a migration rate immediately following the passage of trains or a mortality rate for certain populations that live in close proximity to the railway.

To simplify the analysis, we make the assumption that a train passes every hour over a 24-hour period. Thus, we consider

$$g(t) = t + \sum_{n\in\mathbb{N}} \chi_{[n,\infty)}(t) \quad \text{for all } t \in \mathbb{R},$$

which is such that $D_g = \mathbb{N}$ and $\mu_g(\{t\}) = 1$ for all $t \in D_g$.

Now, we will focus on the zero equilibrium to study its local asymptotic stability within a region $(-r_0, r_0)$ for some $r_0 > 0$ that will be determined to enhance the impact of environmental factors threatening this population.

Since the trivial solution $x = 0$ is an equilibrium of the dynamical system (5.1_θ) with $\theta = 0$, let us consider $r_0 \leq M$. For all $(t_0, x_0) \in ([0,\infty) \cap D_g) \times (-r_0, r_0)$, if x is a solution of (5.1_θ) with $\theta = t_0$ and satisfying $x(t_0) = x_0$, then

$$x_0 + \mu_g(\{t_0\}) f(t_0, x_0) = (1-d)x_0 \in (-r_0, r_0).$$

Thus, (H_{x_0,t_0}) holds for $r = r_0$. One can also verify that f satisfies ($\mathrm{H}_{f,0}$) and ($\mathrm{H}_{\Omega,0}$). Hence, Theorem 3.7, yields the existence of a maximal solution $x : I_{t_0,x_0} \to \mathbb{R}$ of (5.1_θ) with $\theta = t_0$ and satisfying $x(t_0) = x_0$. Let us show that $\omega(t_0, x_0) = \infty$. First of all, let $\tau \in (t_0, \omega(t_0, x_0))$ be such that $x : [t_0, \tau] \to (-r_0, r_0)$. Observe that, if $x(\tau) = 0$, by uniqueness of the solution, we deduce that $x \equiv 0$ which lies in $(-r_0, r_0)$. Thus, two other cases occur when $x(\tau) \neq 0$.

Case 1: If $\tau \in D_g$, then $x(\tau^+) = x(\tau) + \mu_g(\{\tau\}) f(\tau, x(\tau)) = (1-d)x(\tau) \in (-r_0, r_0)$.

Case 2: If $\tau \notin D_g$, and if we assume that $x(\tau) \in (0, r_0)$, then $x'_g(\tau) = f(\tau, x(\tau)) < 0$. Thus, by g-continuity of x at τ, there exists $\tau_1 \in (\tau, \omega(t_0, x_0))$ such that

$$x : [t_0, \tau_1] \to (0, x(\tau)] \subset (0, r_0).$$

Similarly, if $x(\tau) \in (-r_0, 0)$ then $x'_g(\tau) = f(\tau, x(\tau)) > 0$. Thus, there exists $\tau_2 > 0$ such that

$$x : [\tau, \tau_2] \to [x(\tau), 0) \subset (-r_0, 0).$$

Repeating the same argument, we deduce that

$$x(t) \in [-\lambda_{x_0,t_0}, \lambda_{x_0,t_0}] \subset (-r_0, r_0) \quad \text{for all } t \in I_{t_0,x_0}$$

where

$$\lambda_{x_0,t_0} = \sup_{t\in[t_0,\tau]} |x(t, t_0, x_0)|.$$

By Corollary 3.10, we deduce that $\omega(t_0, x_0) = \infty$.

Now, we define the function $V : [0,\infty) \times (-r_0, r_0) \to \mathbb{R}$ by

$$V(t,x) = x^2 \quad \text{for all } (t,x) \in [0,\infty) \times (-r_0, r_0).$$

Clearly, $V \in \mathcal{V}_g^1$. For all $(t_0, x_0) \in [0,\infty) \times (-r_0, r_0)$, let $x : [t_0,\infty) \to (-r_0, r_0)$ be the maximal solution of (5.1_θ) with $\theta = t_0$ and satisfying $x(t_0) = x_0$. Thus, using Proposition 2.10, we obtain, for $t_0 \in [0,\infty)$ and for g-almost all $t \in [t_0,\infty) \setminus D_g$,

$$\begin{aligned} V_g'(t,x(t)) &= \frac{\partial V}{\partial_g t}(t,x(t)) + \frac{\partial V}{\partial x}(t,x(t))x_g'(t) \\ &= \frac{\partial V}{\partial_g t}(t,x(t)) + \frac{\partial V}{\partial x}(t,x(t))f(t,x(t)) \\ &= 2\rho x(t)^2 \left(1 - \frac{x(t)}{K}\right)\left(\frac{x(t)}{M} - 1\right). \end{aligned}$$

While for $t \in [t_0,\infty) \cap D_g$, we obtain

$$\begin{aligned} V_g'(t,x(t)) &= \frac{V(t^+, x(t^+)) - V(t,x(t))}{g(t^+) - g(t)} \\ &= \frac{V(t^+, x(t) + \mu_g(\{t\})f(t,x(t))) - V(t,x(t))}{g(t^+) - g(t)} \\ &= (1-d)^2 x(t)^2 - x(t)^2 \\ &= (-2d + d^2)x(t)^2. \end{aligned}$$

As $(-2d + d^2) < 0$, it follows that $V_g'(t,x(t))$ is negative definite. Since

$$a(|x|) \le V(t,x) \le b(|x|) \quad \text{for all } (t,x) \in [0,\infty) \times (-r_0, r_0),$$

with $a, b \in \mathcal{K}$ defined by $a(s) = b(s) = s^2$ for all $s \in [0,\infty)$, Corollary 4.14 ensures that the trivial solution $x = 0$ is uniformly asymptotically stable.

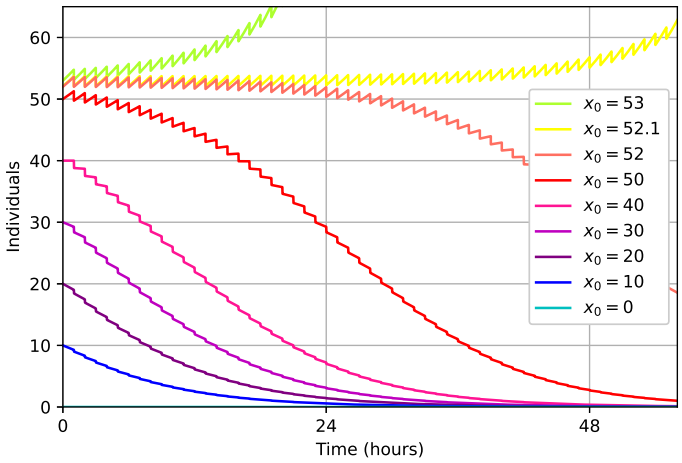

Figure 5.1: Asymptotic behavior of solutions of the dynamical system (5.1_θ) with $\theta = 0$ obtained with a time-discretization step-size of 10^{-3}, with $\rho = 0.1$, $K = 1000$, $M = 40$, and $d = 0.03$.

The asymptotic behavior of solutions is illustrated in Figure 5.1. It illustrates the long-term effect of the high-speed trains vibrations. The outcome raises alarm about the overall stability and the persistence of the whole ecosystem in this region. Specifically, the impact of the vibrations shifts the minimum threshold size M to a new threshold $M' > M$, as shown in Figure 5.1 (where we observe that $M' = 53$ individuals whereas $M = 40$ individuals). This shift indicates a heightened likelihood of population extinction if there is no measure ensuring that the initial population exceeds M' at the onset of trains activity.

5.2 Stable equilibrium of bacteria–ammonia dynamics

Cyanobacteria, similar to plants, participate in oxygenic photosynthesis as they are photosynthetic bacteria. *Photosynthesis* is the biochemical process through which organisms convert light energy into chemical energy in the form of glucose or other organic compounds resulting oxygen release. The energy captured is then used to fuel the synthesis of organic molecules such as glucose, serving as an energy source for the bacteria.

Cyanobacteria are found in diverse habitats, including freshwater, marine environments, and terrestrial ecosystems. In this subsection, we consider a species of cyanobacteria that has also the ability to fix nitrogen such as *Anabaena cyanobacteria*. Through nitrogen fixation, atmospheric nitrogen gas (N_2) is converted into a form that can be used by plants and other organisms by means the enzyme *nitrogenase*. This enzyme catalyzes the conversion of nitrogen gas (N_2) into ammonium ions (NH_4^+) based on a considerable amount of energy obtained from photosynthesis, these ammonium ions are assimilated into amino acids and proteins, which are essential for the growth and survival of Cyanobacteria. As a by product of nitrogen fixation, ammonia gas (NH_3) can be released. Some of the assimilated ammonium ions (NH_4^+) are released back into the environment providing neighboring vegetative cells with a source of nitrogen.

To avoid losing valuable nitrogen nutrients and optimizing nitrogen utilization efficiency, this population has mechanisms allowing ammonium ions (NH_4^+) reabsorption, and ammonia gas (NH_3) assimilation through converting ammonia gas (NH_3) into ammonium ions (NH_4^+). In what follows, the term "ammonia" refers to both the protonated and unprotonated forms, which are denoted as (NH_3) and (NH_4^+) respectively [4]. It is worth mentioning that ammonia is commonly used in cleaning products, fertilizers. Beyond that, ammonia's cooling properties make it an essential refrigerant in air conditioning systems and refrigerators.

To optimize resource utilization and adapt to the varying environmental conditions, the population undergoes a day-night cycling of nitrogen fixation and carbon consumption [32]. This is due to the sensitivity of the nitrogenase enzyme responsible for nitrogen fixation to oxygen. Thus, nitrogen fixation is carried out during daylight hours when the photosynthesis can provide the necessary energy and oxygen levels are relatively low. During the nights, since oxygen levels within the cells would be higher, this population of cyanobacteria reduces their metabolic activity and growth and relies on stored carbon compounds to fulfill their energy needs. Our objective in the sequel is to observe the dynamics of this population which thrives in the presence of ammonia in a culture room without exposure to artificial light, tracking the levels of the ammonia during this process. Here, we assume that the carbon dioxide (CO_2), the nitrogen gas (N_2) and nutrients supply are maintained steady as well as the PH level. Since the population undergoes dormancy phases during the nights, we identify the days with intervals of the form $[2k, 2k+1]$, $k = 0, 1, 2, \ldots$, and the night with intervals $[2k+1, 2k+2]$, $k = 0, 1, 2, \ldots$ In our example, we differentiate with respect to a derivator g whose slopes

describe the intensity of light, which is necessary for the photosynthesis process. We require that g presents smaller slopes at the beginning and at the end of the daylight hours, with a maximal slope of 1 representing the peak light intensity at middays where $t = 2k + 1/2$, and remains constant during the dormancy phases in the night $[2k + 1, 2k + 2]$, $k = 0, 1, 2, \dots$ For instance, we consider $g : \mathbb{R} \to \mathbb{R}$ defined by

$$g(t) = \begin{cases} \dfrac{\sin(\pi(t - 1/2)) + 1}{\pi} & \text{if } t \in [0, 1] \\ 2/\pi & \text{if } t \in (1, 2], \end{cases}$$

and $g(t) = 2/\pi + g(t - 2)$ for $t \geq 2$.

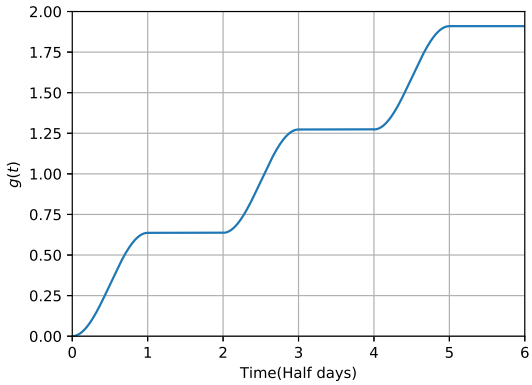

Figure 5.2: Graph of the derivator g.

We denote by $N(t)$ the biomass of cyanobacteria (grams per liter), and $A(t)$ the ammonia concentration in the environment at time $t \geq 0$. Since the population thrives in the presence of ammonia, we can assume that the growth rate is proportional to the level of ammonia. We denote ρ the maximal intrinsic coefficient of reproduction that the population can reach in the presence of one unit of ammonia with maximal sunlight intensity. Thus, the dynamics can be modeled using the autonomous system of Stieltjes differential equations:

$$\mathbf{u}'_g(t) = \mathbf{F}(\mathbf{u}(t)), \quad \text{for } g\text{-almost every } t \geq \theta \geq 0, \tag{5.3$_\theta$}$$

where $\mathbf{u} = (N, A)$ and $\mathbf{F} = (F_1, F_2) : \mathbb{R}^2 \to \mathbb{R}^2$ is defined by

$$\mathbf{F}(N, A) = \left(\rho AN\left(1 - \frac{N}{K}\right), (\alpha N - \beta AN)\right), \tag{5.4}$$

and where the parameters of the model can be understood as:

$K > 0$: the carrying capacity of the culture room, which forms a spacial constraint for growth;

$\alpha > 0$: a constant related to the production of ammonia through nitrogen fixation.

$\beta > 0$: a constant related to the proportion of the reabsorption of ammonia by the population depending on the level of ammonia in the environment.

Observe that $\mathbf{u}^* = (K, \alpha/\beta)$ is an equilibrium of the system (5.3$_\theta$) with $\theta = 0$ among other equilibria. Its asymptotic stability would guarantee the persistence of the population with nonzero ammonia production. Therefore, we study local asymptotic stability in a neighborhood $B_{\mathbb{R}^2}(\mathbf{u}^*, r_0)$ for some $r_0 > 0$ of this equilibrium. To this aim, we translate our study in a

neighborhood of $\mathbf{x} = \mathbf{0} = (0,0) \in \mathbb{R}^2$ with the change of variables $\mathbf{x} = (x_1, x_2) := \mathbf{u} - \mathbf{u}^*$, we obtain the system

$$\mathbf{x}'_g(t) = \mathbf{f}(\mathbf{x}(t)) \quad \text{for } g\text{-almost every } t \geq \theta \geq 0, \tag{5.5$_\theta$}$$

where $\mathbf{f} = (f_1, f_2) : \mathbb{R}^2 \to \mathbb{R}^2$ is defined by

$$\mathbf{f}(x_1, x_2) = \left(-\rho \frac{x_1}{K} \left(x_2 + \frac{\alpha}{\beta} \right) (x_1 + K), -\beta x_2 (x_1 + K) \right). \tag{5.6}$$

So, $\mathbf{x} = \mathbf{0} = (0,0) \in \mathbb{R}^2$ is an equilibrium of the dynamical system (5.5$_\theta$) with $\theta = 0$. Next, we prove that $\mathbf{x} = \mathbf{0}$ is asymptotically stable, and hence, $\mathbf{u}^* = \left(K, \alpha/\beta\right)$ is an asymptotically stable equilibrium of the system (5.3$_\theta$) with $\theta = 0$.

Let us consider $r_0 = \min\{K, \alpha/\beta\}$, and let $(t_0, \mathbf{x}_0) \in [0, \infty) \times B_{\mathbb{R}^2}(\mathbf{0}, r_0)$. Arguing as in the previous subsection, since the function $\mathbf{f}$ satisfies conditions of Theorem 3.7, there exists, $\mathbf{x} = (x_1, x_2) : I_{t_0,\mathbf{x}_0} \to \mathbb{R}^2$, the maximal solution of the system (5.5$_\theta$) with $\theta = t_0$ and satisfying $\mathbf{x}(t_0) = \mathbf{x}_0$. Let $\tau \in (0, \omega(t_0, \mathbf{x}_0)) \setminus C_g$ be such that $\mathbf{x} = (x_1, x_2) : [t_0, \tau] \to B_{\mathbb{R}^2}(\mathbf{0}, r_0)$. In what follows, we analyze the possible cases:

Case 1: If $x_1(\tau), x_2(\tau) \in (0, r_0)$ (resp. $x_1(\tau), x_2(\tau) \in (-r_0, 0)$), then, for $i = 1, 2$, we have $(x_i)'_g(\tau) = f_i(\mathbf{x}(\tau)) < 0$ (resp. $(x_i)'_g(\tau) = f_i(\mathbf{x}(\tau)) > 0$). Therefore, by the g-continuity of $\mathbf{x}$ at τ, there exists $\tau_1 \in (\tau, \omega(t_0, \mathbf{x}_0))$ (τ_1 can be chosen such that $\tau_1 \notin C_g$) such that

$$x_i : [t_0, \tau_1] \to (0, x_i(\tau)] \subset (0, r_0) \quad (\text{resp. } x_i : [t_0, \tau_1] \to [x_i(t_0), 0) \subset (-r_0, 0)).$$

Case 2: If $x_1(\tau) \in (0, r_0)$ and $x_2(\tau) \in (-r_0, 0)$, then

$$(x_1)'_g(\tau) = f_1(\mathbf{x}(\tau)) < 0 \quad \text{and} \quad (x_2)'_g(\tau) = f_2(\mathbf{x}(\tau)) > 0.$$

Therefore, there exists $\tau_2 \in (\tau, \omega(t_0, \mathbf{x}_0)) \setminus C_g$ such that

$$x_1 : [\tau, \tau_2] \to (0, x_1(\tau)] \subset (0, r_0) \quad \text{and} \quad x_2 : [\tau, \tau_2] \to [x_2(\tau), 0) \subset (-r_0, 0).$$

Case 3: If $x_1(\tau) \in (-r_0, 0)$ and $x_2(\tau) \in (0, r_0)$, then, similarly to Case 2, we deduce that there exists $\tau_3 \in (\tau, \omega(t_0, \mathbf{x}_0))$ such that

$$x_1 : [\tau, \tau_3] \to [x_1(\tau), 0) \subset (-r_0, 0) \quad \text{and} \quad x_2 : [\tau, \tau_3] \to (0, x_2(\tau)] \subset (0, r_0).$$

From this argument, we deduce that the solution

$$\mathbf{x}(t) \in [-\lambda_{\mathbf{x}_{0,1},t_0}, \lambda_{\mathbf{x}_{0,1},t_0}] \times [-\lambda_{\mathbf{x}_{0,2},t_0}, \lambda_{\mathbf{x}_{0,2},t_0}] \subset B_{\mathbb{R}^2}(\mathbf{0}, r_0) \quad \text{for all } t \in I_{t_0,\mathbf{x}_0},$$

where

$$\lambda_{\mathbf{x}_{0,i},t_0} = \sup_{t \in [t_0,\tau]} |x_i(t, t_0, \mathbf{x}_0)| \quad \text{for } i = 1, 2, \text{ and } \mathbf{x}_0 = (\mathbf{x}_{0,1}, \mathbf{x}_{0,2}).$$

Using Corollary 3.10, we deduce that $\omega(t_0, \mathbf{x}_0) = \infty$.

Now, let us consider the function $V : [0, \infty) \times B_{\mathbb{R}^2}(\mathbf{0}, r_0) \to \mathbb{R}$ defined by $V(t, \mathbf{x}) = x_1^2 + x_2^2$ for all $t \in [0, \infty)$ and $\mathbf{x} = (x_1, x_2) \in \mathbb{R}^2$. It is clear that $V \in \mathcal{V}_1^g$. Let $(t_0, \mathbf{x}_0) \in [0, \infty) \times B_{\mathbb{R}^2}(\mathbf{0}, r_0)$,

and $\mathbf{x} : [t_0, \infty) \to B_{\mathbb{R}^2}(\mathbf{0}, r_0)$ the maximal solution of (5.5_θ) with $\theta = t_0$ and satisfying $\mathbf{x}(t_0) = \mathbf{x}_0$. By means of Proposition 2.10, for g-almost all $t \in [t_0, \infty)$, we obtain

$$\begin{aligned} V_g'(t, \mathbf{x}(t)) &= \frac{\partial V}{\partial_g t}(t, \mathbf{x}(t)) + \sum_{i=1}^{2} \frac{\partial V}{\partial x_i}(t, \mathbf{x}(t))(x_i)_g'(t) \\ &= \frac{\partial V}{\partial_g t}(t, \mathbf{x}(t)) + \sum_{i=1}^{2} \frac{\partial V}{\partial x_i}(t, \mathbf{x}(t)) f_i(t, \mathbf{x}(t)) \\ &= -2\rho \frac{x_1(t)^2}{K}(x_2(t) + \alpha/\beta)(x_1(t) + K) - 2\beta x_2(t)^2(x_1(t) + K). \end{aligned} \tag{5.7}$$

Thus, $V_g'(t, \mathbf{x}(t))$ is negative definite. Since

$$a(\|\mathbf{z}\|) \le V(t, \mathbf{z}) \le b(\|\mathbf{z}\|) \quad \text{for all } (t, \mathbf{z}) \in [0, \infty) \times B_{\mathbb{R}^2}(\mathbf{0}, r_0),$$

where $a, b \in \mathcal{K}$ are defined by $a(s) = s^2$ and $b(s) = 2s^2$ for all $s \in [0, \infty)$. It follows from Corollary 4.14 that $\mathbf{x} = \mathbf{0}$ is uniformly asymptotically stable. Hence, $\mathbf{u}^* = (K, \alpha/\beta)$ is a uniformly asymptotically stable equilibrium of the system (5.3_θ). The graph of asymptotic behavior of solutions near the equilibrium $\mathbf{u}^* = (K, \alpha/\beta)$ is given in Figure 5.3 with $\theta = 0$.

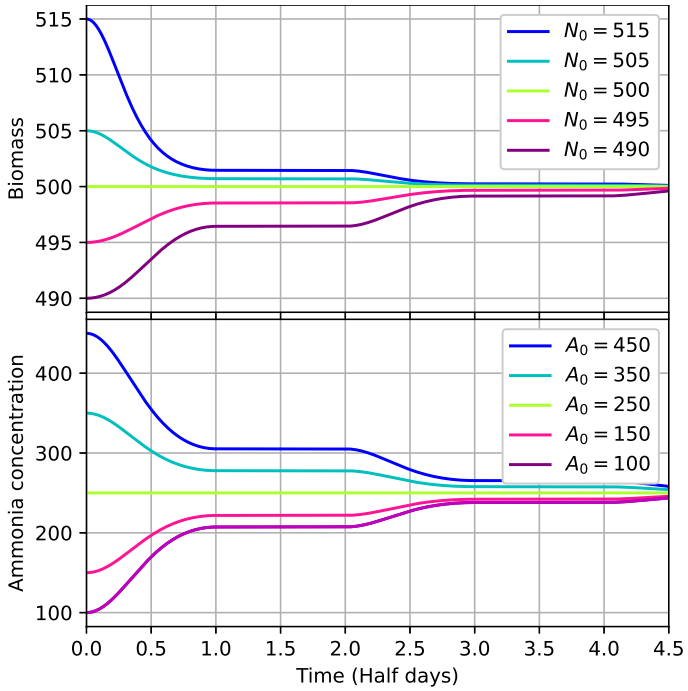

Figure 5.3: Asymptotic behavior of solutions of the dynamical system (5.3_θ) with $\theta = 0$ obtained with a time-discretization step-size of 10^{-3}, with different initial densities N_0 and ammonia concentrations A_0 (g/L), where $\rho = 0.01$, $K = 500$, $\alpha = 1$, and $\beta = 0.004$.

Communicated by Gabriele Bonanno

Abstract. We investigate the existence of sign-changing solutions for Kirchhoff-type problems with p-Laplacian involving critical exponent:

$$-\left(1+b|\nabla v|_p^p\right)\Delta_p v + a(x)|v|^{p-2}v = |v|^{p^*-2}v + \lambda f(v), \quad x \in \mathbb{R}^N,$$

where b and λ are positive parameters, $\Delta_p v = \operatorname{div}(|\nabla v|^{p-2}\nabla v)$, $p^* = \frac{Np}{N-p}$, $1 < p < N$, and $|\cdot|_p$ is the Lebesgue L^p-norm. For sufficiently large λ, employing minimization techniques, quantitative deformation lemma and the constrained variational method, we demonstrate the existence of a least-energy sign-changing solution, whose energy is greater than twice that of the ground state solution. Additionally, we show the convergence behavior of the solution as the parameter $b \searrow 0$. Our findings generalize and extend upon recent results in the literature.

Keywords: sign-changing solution, variational methods, p-Laplacian, Kirchhoff-type problem.

2020 Mathematics Subject Classification: 35J92, 35J60, 35J20.

1 Introduction and main result

We are interested in the existence of sign-changing solutions to the following class of Kirchhoff-type problem with the p-Laplacian involving a critical exponent:

$$-\left(1+b|\nabla v|_p^p\right)\Delta_p v + a(x)|v|^{p-2}v = |v|^{p^*-2}v + \lambda f(v), \quad x \in \mathbb{R}^N, \tag{$\mathcal{QKP}$}$$

where b and λ are positive parameters, $\Delta_p v = \operatorname{div}(|\nabla v|^{p-2}\nabla v)$ is the p-Laplacian, $p^* = \frac{Np}{N-p}$, $1 < p < N$, and $f \in \mathcal{C}^1(\mathbb{R},\mathbb{R})$. The term p-Laplacian has emerged as a crucial concept in various physics backgrounds and nonlinear analysis. This functional has found applications in describing the movement of sandpiles [2], modeling Game Theory [11], and is employed in

✉ Corresponding author. Email: hanyang95@263.net

image inpainting [6]. A variety of intriguing results have been obtained for problem ($\mathcal{QKP}$) and similar problems, which has been investigated widely, see [7,8] and the reference therein.

Problem ($\mathcal{QKP}$) is derived from the following Kirchhoff equation

$$\begin{cases} -\left(a + b\int_\Omega |\nabla v|^2\right)\Delta v = f(v), & x \in \Omega, \\ v = 0, & x \in \partial\Omega. \end{cases} \tag{1.1}$$

Problem (1.1) corresponds to the following stationary form of a Kirchhoff type equation

$$v_{tt} - \left(a + b\int_\Omega |\nabla v|^2 dx\right)\Delta v = f(v), \tag{1.2}$$

where a and b are positive constants. In one and two dimensions, equation (1.2) has been employed to model various phenomena in physics, engineering, and other scientific disciplines, effectively approximating the nonlinear vibrations of beams or plates. In [13], Kirchhoff originally introduced (1.2) as an extension of the classical D'Alembert wave equation, which models the free vibrations of elastic strings

$$\rho\frac{\partial^2 v}{\partial t^2} - \left(\frac{p_0}{h} + \frac{E}{2L}\int_0^L \left|\frac{\partial v}{\partial x}\right|^2 dx\right)\frac{\partial^2 v}{\partial x^2} = f(v),$$

with constants ρ, p_0, h, E, and L.

We introduce a mathematical model that characterizes the behavior of a compressible fluid within a homogeneous, isotropic, rigid porous medium. In this context, $\vec{a} = \vec{a}(x,t)$ represents the seepage velocity, φ is the volumetric moisture content, and $v = v(x,t)$ is the density. The continuity equation is given by:

$$\varphi\frac{\partial v}{\partial t} + \operatorname{div}(v\vec{a}) = 0. \tag{1.3}$$

In the case of laminar flow regime through the porous medium, the relationship between the pressure $\pi = \pi(x,t)$ and the momentum velocity $\rho\vec{a}$ is described by the following Darcy's law:

$$\rho\vec{a} = -\lambda \operatorname{grad}\pi. \tag{1.4}$$

The flow rate is not the same in turbulent flow regimes, leading various authors to propose a nonlinear alternative to (1.4). A commonly considered form of the nonlinear Darcy law can be found in works such as Wu et al. [21]:

$$\rho\vec{a} = -\lambda|\operatorname{grad}\pi|^{p-2}\operatorname{grad}\pi, \tag{1.5}$$

where $p > 1$. While considering the polytropic gas equation of state

$$\pi = cv, \tag{1.6}$$

where $c > 0$ is a positive constant of proportionality. By (1.3), (1.5) and (1.6), we obtain

$$\varphi\frac{\partial v}{\partial t} = c^{p-1}\lambda \operatorname{div}\left(|\operatorname{grad} v|^{p-2}\operatorname{grad} v\right). \tag{1.7}$$

Following the variable substitution, we obtain

$$\frac{\partial v}{\partial t} = \operatorname{div}\left(|\nabla v|^{p-2}\nabla v\right), \tag{1.8}$$

with p being a real number greater than 1.

$$\Delta_p v := \sum_{i=1}^{N} \frac{\partial}{\partial x_i}\left(|\nabla v|^{p-2}\frac{\partial v}{\partial x_i}\right) = \operatorname{div}\left(|\nabla v|^{p-2}\nabla v\right),$$

and

$$v \longmapsto \Delta_p v, \tag{1.9}$$

it is commonly called the p-Laplace operator or the p-Laplacian. In the case of one dimension, one has

$$\Delta_p v = \left(|v'|^{p-2}v'\right)'.$$

Definition 1.1. A solution v is nontrivial provided that $v \neq 0$. A nontrivial solution is called a ground state (or least energy) solution if its energy is the lowest among all nontrivial solutions. Additionally, if v is a nontrivial solution and both v^+ and v^- are nonzero, then v is referred to as sign-changing solution, where $v^+ := \max\{v, 0\}$, $v^- := \min\{v, 0\}$.

Baldelli and Filippucci [4] studied the existence and multiplicity of nontrivial solutions to the following generalized quasilinear Schrödinger equation:

$$-\Delta_p v - \frac{\alpha}{2}\Delta_p\left(|v|^{\alpha}\right)|v|^{\alpha-2}v = \lambda V(x)|v|^{k-2}v + \beta K(x)|v|^{\alpha p^*-2}v \quad \text{in } \mathbb{R}^N,$$

where $\alpha > 1$, β, $\lambda > 0$, and $\alpha < k < \alpha p^*$. The weights are nontrivial and satisfy $0 \leqslant V \in L^{\alpha p^*/(\alpha p^*-k)}(\mathbb{R}^N) \cap \mathcal{C}(\mathbb{R}^N)$, $K \in L^{\infty}(\mathbb{R}^N) \cap \mathcal{C}(\mathbb{R}^N)$. For $N \geqslant 3$ and $1 < p < N$, using the concentration compactness principle, the symmetric Mountain Pass Theorem, the truncation of the energy functional, and the theory of Krasnosel'skii genus, they established the existence of infinitely many nontrivial solutions $v_n \in \mathcal{D}^{1,p}(\mathbb{R}^N) = \{u \in L^{p^*}(\mathbb{R}^N) : \nabla u \in (L^p(\mathbb{R}^N))^N\}$, provided that $1 < \alpha < k < p$.

Li [15] addressed the existence of solutions for the following equation:

$$\begin{aligned}-\operatorname{div}\left(g^p(v)|\nabla v|^{p-2}\nabla v\right) + g^{p-1}(v)g'(u)|\nabla v|^p + V(x)|v|^{p-2}v \\ = K(x)f(v) + Q(x)g(v)|G(v)|^{p^*-2}G(v),\end{aligned}$$

where $1 < p \leqslant N$, $g \in \mathcal{C}^1\left(\mathbb{R}, \mathbb{R}^+\right)$, $V(x)$ and $K(x)$ are positive continuous functions, $Q(x)$ is a bounded continuous function, and $G(v) = \int_0^v g(t)dt$. The author obtained the existence of positive solutions when $N \geqslant 3$. Their proof is based on the truncation of the energy functional and the Mountain Pass Theorem.

In [14], the p-Laplacian Kirchhoff-type equation with logarithmic nonlinearity was investigated:

$$\begin{cases} -\left(a + b|\nabla v|_p^p\right)\Delta_p v = |v|^{q-2}v\ln v^2, & x \in \Omega, \\ v = 0, & x \in \partial\Omega. \end{cases} \tag{1.10}$$

Using the constraint variation method, topological degree theory, and the quantitative deformation lemma, the authors established the existence of ground state sign-changing solutions for problem (1.10). In problem (1.10), they assumed that $N > p$, a and b are positive, and $4 \leqslant 2p < q < p^*$ for some $q > p$. Chen et al. [10] investigated a modified version of problem ($\mathcal{QKP}$) with $\lambda = 1$, and the nonlinearity $f(v)$ replaced by $R(x)g(v)$ without the critical term. The modified problem is given by

$$-\left(1 + b|\nabla v|_p^p\right)\Delta_p v + a(x)|v|^{p-2}v = R(x)g(v),$$

in which $R(x)$ and $a(x)$ represent continuous functions that are positive and $v \in \mathcal{D}^{1,p}(\mathbb{R}^N)$. The authors establish the existence of a ground state sign-changing solution by employing the non-Nehari manifold approach (Unlike the Nahari manifold method, the main idea of the non-Nehari manifold approach lies on finding a minimizing sequence for the energy functional outside the manifold). Motivated by the studies mentioned above, in this paper, we suppose that f belongs to $\mathcal{C}^1(\mathbb{R},\mathbb{R})$ and a belongs to $\mathcal{C}\left(\mathbb{R}^N,\mathbb{R}\right)$ fulfills the following assumptions:

$(\mathcal{A})$ $\inf_{\mathbb{R}^N} a(x) > 0$ and there is R, such that

$$\lim_{|y|\to\infty} m\left\{x \in \mathbb{R}^N :\ x \in B_R(y),\ a(x) \leqslant A\right\} = 0, \quad \forall A > 0,$$

here m denotes the Lebesgue measure.

$(\mathcal{P}_1)$ There holds $\lim_{t\to 0} \frac{f(t)}{|t|^{p-1}} = 0$;

$(\mathcal{P}_2)$ There is $\vartheta \in (2p, p^*)$ such that

$$\lim_{s\to\infty} \frac{f(t)}{|t|^{\vartheta-1}} = 0;$$

$(\mathcal{P}_3)$ There holds $\lim_{t\to\infty} \frac{F(t)}{|t|^{2p}} = +\infty$;

$(\mathcal{P}_4)$ The map $t \mapsto \frac{f(t)}{|t|^{2p-1}}$ is strictly increasing, for all $t \in \mathbb{R}\backslash\{0\}$,

From the assumptions $(\mathcal{P}_3)$ and $(\mathcal{P}_4)$, one obtains

$$f(t)t > 0, \quad t \neq 0; \quad F(t) \geqslant 0, \quad t \in \mathbb{R}. \tag{1.11}$$

Furthermore, from the assumptions $(\mathcal{P}_3)$ and $(\mathcal{P}_4)$, one gets

$$f'(t)t - (2p-1)f(t) < (>)0, \quad \forall t < (>)0. \tag{1.12}$$

For simplicity, we will denote distinct positive constants by c_i, C_i, and C, and $\int$ always stand for $\int_{\mathbb{R}^N}$. Define

$$\mathcal{BC}(\mathbb{R}^N) := \left\{ v \in \mathcal{C}(\mathbb{R}^N) :\ |v|_\infty := \sup_{x\in\mathbb{R}^N} |v(x)| < \infty \right\}.$$

The closure of $\mathcal{C}_c(\mathbb{R}^N)$ in $\mathcal{BC}(\mathbb{R}^N)$ with respect to the uniform norm is the space $\mathcal{C}_0(\mathbb{R}^N)$, where $\mathcal{C}_c(\mathbb{R}^N)$ is space of continuous functions with compact support in $\mathbb{R}^N$. The space of finite measures on $\mathbb{R}^N$ is referred to as $\mathcal{M}(\mathbb{R}^N)$. A sequence $\{\nu_n\}$ converges weakly* to ν in $\mathcal{M}(\mathbb{R}^N)$, written

$$\nu_n \rightharpoonup^* \nu,$$

provided

$$\langle \nu_n, \varphi\rangle \to \langle \nu, \varphi\rangle,$$

$\forall \varphi \in \mathcal{C}_0(\mathbb{R}^N)$. For $1 \leqslant s \leqslant p^*$, we introduce the following norms:

$$\|v\|_{L^s(\mathbb{R}^N)} = |v|_s = |v|_{L^s(\mathbb{R}^N)} := \left(\int |v(x)|^s \, \mathrm{d}x\right)^{\frac{1}{s}}.$$

In order to state our principal results, let

$$W = \left\{ v \in W^{1,p} : \int a(x)|v|^p \, \mathrm{d}x + |\nabla v|_p^p < +\infty \right\},$$

endowed with the following norm

$$\|v\| = \left[\int a(x)|v|^p \, \mathrm{d}x + |\nabla v|_p^p \right]^{\frac{1}{p}}.$$

It is clear that W is continuously embedded into $W^{1,p}(\mathbb{R}^N)$ and consequently the embedding into $L^s(\mathbb{R}^N)$ is also continuous for $s \in [p, p^*]$. This implies that there is a $\gamma_s > 0$ such that

$$|v|_s \leqslant \gamma_s \|v\|, \quad \forall v \in W. \tag{1.13}$$

Lemma 1.2 ([12]). *Assuming that $(\mathcal{A})$ holds. For $p \leqslant s < p^*$, W is compactly embedded into $L^s(\mathbb{R}^N)$.*

Let η_1 denote the first eigenvalue of $-\Delta_p v$. Thus, η_1 represents the smallest value of η such that the problem

$$\begin{cases} -\Delta_p v = \eta |v|^{p-2} v, & \text{in } \Omega, \\ v = 0, & \text{on } \partial\Omega, \end{cases} \tag{1.14}$$

possesses a nontrivial solution. Let the functional $\mathcal{K} : W_0^{1,p} \to \mathbb{R}$ be defined as follows:

$$\mathcal{K}(v) = \frac{1}{p} \int_\Omega |\nabla v|^p \, \mathrm{d}x - \frac{\eta}{p} \int_\Omega |v|^p \, \mathrm{d}x.$$

For problem ($\mathcal{QKP}$), the energy functional $\mathcal{K}_b^\lambda : W \to \mathbb{R}$ is given by:

$$\mathcal{K}_b^\lambda = \frac{1}{p}\|v\|^p + \frac{b}{2p}|\nabla v|_p^{2p} - \frac{1}{p^*}|v|_{p^*}^{p^*} \, \mathrm{d}x - \lambda \int F(v) \, \mathrm{d}x, \tag{1.15}$$

for every $v \in W$. Furthermore, $\mathcal{K}_b^\lambda \in \mathcal{C}^1(W, \mathbb{R})$, and its Fréchet derivative is defined as follows:

$$\begin{aligned} \left\langle (\mathcal{K}_b^\lambda)'(v), \varphi \right\rangle = & \left(1 + b \int |\nabla v|^p \, \mathrm{d}x \right) \left(\int |\nabla v|^{p-2} \nabla v \cdot \nabla \varphi \, \mathrm{d}x \right) \\ & + \int a(x)|v|^{p-2} v\varphi \, \mathrm{d}x - \int |v|^{p^*-2} v\varphi \, \mathrm{d}x - \lambda \int f(v)\varphi \, \mathrm{d}x, \end{aligned} \tag{1.16}$$

for every $v, \varphi \in W$. It is widely acknowledged that there exist several intriguing studies concerning the existence of sign-changing solution to problem (1.14). Nevertheless, the approaches employed to seek such solutions are greatly reliant on the subsequent decompositions:

$$\langle \mathcal{K}'(v), v^- \rangle = \langle \mathcal{K}'(v^-), v^- \rangle, \quad \langle \mathcal{K}'(v), v^+ \rangle = \langle \mathcal{K}' \left(v^+ \right), v^+ \rangle, \quad \mathcal{K}(v) = \mathcal{K}(v^+) + \mathcal{K}(v^-). \tag{1.17}$$

However, when $b > 0$, the functional $\mathcal{K}_b^\lambda$ lacks the same decompositions as in equation (1.17). Specifically, if $v^\pm \neq 0$, it can be seen that

$$\begin{aligned} \mathcal{K}_b^\lambda(v) &= \mathcal{K}_b^\lambda(v^+) + \mathcal{K}_b^\lambda(v^-) + \frac{b}{p}|\nabla v^+|_p^p |\nabla v^-|_p^p > \mathcal{K}_b^\lambda(v^+) + \mathcal{K}_b^\lambda(v^-), \\ \langle (\mathcal{K}_b^\lambda)'(v), v^+ \rangle &= \langle (\mathcal{K}_b^\lambda)'(v^+), v^+ \rangle + b|\nabla v^+|_p^p |\nabla v^-|_p^p > \langle (\mathcal{K}_b^\lambda)'(v^+), v^+ \rangle, \\ \langle (\mathcal{K}_b^\lambda)'(v), v^- \rangle &= \langle (\mathcal{K}_b^\lambda)'(v^-), v^- \rangle + b|\nabla v^+|_p^p |\nabla v^-|_p^p > \langle (\mathcal{K}_b^\lambda)'(v^-), v^- \rangle. \end{aligned}$$

So, the conventional techniques cannot be employed to obtain a sign-changing solutions for problem ($\mathcal{QKP}$). Rather, we use the strategy proposed in [5], which requires defining a constrained set as follows:

$$\mathcal{M}_b^\lambda = \left\{ v \in W : \ v^\pm \neq 0 \text{ and } \langle (\mathcal{K}_b^\lambda)'(v), v^\pm \rangle = 0 \right\}, \tag{1.18}$$

and investigate the following minimization problem

$$c_b^\lambda = \inf_{v \in \mathcal{M}_b^\lambda} \mathcal{K}_b^\lambda(v).$$

The inclusion of the nonlocal term in problem ($\mathcal{QKP}$) creates numerous obstacles. Specifically, when compared to the general problem (1.14), in equation (1.17), the decompositions for $\mathcal{K}_b^\lambda$ are much more intricate, which results in some technical challenges while demonstrating the nonemptiness of $\mathcal{M}_b^\lambda$. Furthermore, observe that implicit theorem and the parametric method cannot be employed to address problem ($\mathcal{QKP}$) because of the complex nature of the involved nonlocal term. Consequently, our demonstration follows an alternative approach inspired by [1], specifically by utilizing a modified version of Miranda's theorem (refer to [17]). Additionally, by utilizing degree theory and the quantitative deformation lemma, the minimizer of the constrained problem is shown to be a sign-changing solution.

Now, we proceed to outline our primary results.

Theorem 1.3. *Assume that conditions $(\mathcal{P}_1)$–$(\mathcal{P}_4)$ and $(\mathcal{A})$ are satisfied. Then, there is a positive constant $\lambda^\star$ such that for every λ with $\lambda^\star \leqslant \lambda < \infty$, problem ($\mathcal{QKP}$) possesses a ground state sign-changing solution v_b.*

One purpose of this study is to demonstrate the energy doubling property, which ensures that the energy of any sign-changing solution to problem ($\mathcal{QKP}$) is strictly greater than two times the ground state energy. Although the result is straightforward for equation (1.14), we seek to determine whether it also holds for problem ($\mathcal{QKP}$). The theorem presented below affirms this result for our problem.

Theorem 1.4. *Assume that conditions $(\mathcal{P}_1)$–$(\mathcal{P}_4)$ and $(\mathcal{A})$ are satisfied. Then there is $\lambda^{\star\star} > 0$ such that for all $\lambda^{\star\star} \leqslant \lambda < \infty$, the infimum $c_{b,\lambda}^* > 0$ is attained and the following inequality holds*

$$\mathcal{K}_b^\lambda(v) > 2c_{b,\lambda}^*,$$

where $c_{b,\lambda}^* = \inf_{v \in \mathcal{N}_\lambda} \mathcal{K}_b^\lambda(v)$, $\mathcal{N}_b^\lambda = \{v \in W : \ v \neq 0 \text{ and } \langle (\mathcal{K}_b^\lambda)'(v), v \rangle = 0\}$, and v is the solution obtained in Theorem 1.3.

Finally, we demonstrate the convergence behavior of the solution as $b \searrow 0$.

Theorem 1.5. *Assume that conditions $(\mathcal{P}_1)$–$(\mathcal{P}_4)$ and $(\mathcal{A})$ are satisfied. Then, for any sequence $\{b_n\}$ satisfies $b_n \searrow 0$, there is a subsequence of $\{b_n\}$, such that $\{v_{b_n}\}$ converges strongly to v_0 in W, where v_0 is a least energy nodal solution for the problem below*

$$-\Delta_p v + a(x)|v|^{p-2}v = |v|^{p^*-2}v + \lambda f(v), \quad x \in \mathbb{R}^N. \tag{$\mathcal{QKP}_0$}$$

Remark 1.6. We would like to highlight that Theorem 1.3 represents the first result demonstrating the existence of sign-changing solutions for p-Laplacian Kirchhoff-type problems involving critical exponent in $\mathbb{R}^N$.

Remark 1.7. The primary challenges stem from dealing with a degenerate quasi-linear elliptic operator and the increased intricacy of the calculations involved. To surmount these challenges, we employ quantitative deformation lemma and degree theory to derive our findings.

2 Some preliminary results

Let $v \in W$ be fixed with $v^{\pm} \neq 0$, let $g_v : \mathbb{R}^+ \times \mathbb{R}^+ \to \mathbb{R}$ and $G_v : \mathbb{R}^+ \times \mathbb{R}^+ \to \mathbb{R}^2$ defined as follows

$$g_v(\alpha, \beta) = \mathcal{K}_b^{\lambda}(\alpha v^+ + \beta v^-), \tag{2.1}$$

$$G_v(\alpha, \beta) = \left(\langle (\mathcal{K}_b^{\lambda})'(\alpha v^+ + \beta v^-), \alpha v^+ \rangle, \langle (\mathcal{K}_b^{\lambda})'(\alpha v^+ + \beta v^-), \beta v^- \rangle \right). \tag{2.2}$$

Lemma 2.1. *Let f and a satisfy $(\mathcal{A})$ and $(\mathcal{P}_1)$–$(\mathcal{P}_4)$. Suppose that $v \in W$ with $v^{\pm} \neq 0$, the following properties hold:*

(A_1) *$\alpha v^+ + \beta v^- \in \mathcal{M}_b^{\lambda}$ if and only if g_v has a critical point $(\alpha, \beta) \in \mathbb{R}_*^+ \times \mathbb{R}_*^+$;*

(A_2) *The pair (α_v, β_v) is the unique critical point of g_v on $\mathbb{R}_*^+ \times \mathbb{R}_*^+$, as well as it is the unique maximum of g_v on $\mathbb{R}^+ \times \mathbb{R}^+$;*

(A_3) *If $\langle (\mathcal{K}_b^{\lambda})'(v), v^{\pm} \rangle \leqslant 0$ then $0 < \alpha_v, \beta_v \leqslant 1$.*

Proof. Proof of (A_1): Note that if $v^{\pm} \neq 0$, one has

$$\begin{aligned}
\left|\nabla(\alpha v^+ + \beta v^-)\right|^p =& \left|\nabla(\alpha v^+ + \beta v^-)\right|^2 \left|\nabla(\alpha v^+ + \beta v^-)\right|^{p-2} \\
=& \left|\nabla(\alpha v^+ + \beta v^-)\right|^{p-2} \nabla(\alpha v^+ + \beta v^-)\nabla(\alpha v^+) \\
&+ \left|\nabla(\alpha v^+ + \beta v^-)\right|^{p-2} \nabla(\alpha v^+ + \beta v^-)\nabla(\beta v^-) \\
=& |\nabla(\alpha v^+)|^{p-2}\nabla(\alpha v^+)\nabla(\alpha u^+) + \left|\nabla(\beta v^-)\right|^{p-2} \nabla(\beta v^-)\nabla(\beta u^-) \\
=& |\alpha|^p \left|\nabla v^+\right|^p + |\beta|^p \left|\nabla v^-\right|^p.
\end{aligned}$$

Therefore, a direct computation yields

$$\begin{aligned}
\nabla g_v(\alpha, \beta) &= \left(\frac{\partial g_v}{\partial \alpha}(\alpha, \beta), \frac{\partial g_v}{\partial \beta}(\alpha, \beta) \right) \\
&= \left(\langle (\mathcal{K}_b^{\lambda})'(\alpha v^+ + \beta v^-), v^+ \rangle, \langle (\mathcal{K}_b^{\lambda})'(\alpha v^+ + \beta v^-), v^- \rangle \right) \\
&= \left(\frac{1}{\alpha} \langle (\mathcal{K}_b^{\lambda})'(\alpha v^+ + \beta v^-), \alpha v^+ \rangle, \frac{1}{\beta} \langle (\mathcal{K}_b^{\lambda})'(\alpha v^+ + \beta v^-), \beta v^- \rangle \right),
\end{aligned} \tag{2.3}$$

where

$$\begin{aligned}
\langle (\mathcal{K}_b^{\lambda})'(\alpha v^+ + \beta v^-), \alpha v^+ \rangle =& b\alpha^p \beta^p |\nabla v^+|_p^p |\nabla v^-|_p^p - \lambda \int f(\alpha v^+)\alpha v^+ \, \mathrm{d}x \\
&+ \alpha^p \|v^+\|^p + b\alpha^{2p} |\nabla v^+|_p^{2p} - \alpha^{p^*} |v^+|_{p^*}^{p^*},
\end{aligned}$$

$$\begin{aligned}
\langle (\mathcal{K}_b^{\lambda})'(\alpha v^+ + \beta v^-), \beta v^- \rangle =& b\beta^p \alpha^p |\nabla v^-|_p^p |\nabla v^+|_p^p - \lambda \int f(\beta v^-)\beta v^- \, \mathrm{d}x \\
&+ \beta^p \|v^-\|^p + b\beta^{2p} |\nabla v^-|_p^{2p} - \beta^{p^*} |v^-|_{p^*}^{p^*}.
\end{aligned}$$

From (2.3) and the definition of $\mathcal{M}_b^{\lambda}$, it's straightforward to show that (A_1) is satisfied.

Proof of (A_2): From $(\mathcal{P}_1)$ and $(\mathcal{P}_2)$, for any $\varepsilon > 0$, there is $C_\varepsilon > 0$ such that

$$|f(t)| \leqslant \varepsilon |t|^{p-1} + C_\varepsilon |t|^{\vartheta - 1}, \quad \forall t \in \mathbb{R}. \tag{2.4}$$

From (1.13) and (2.4), we obtain

$$\begin{aligned}\langle (\mathcal{K}_b^\lambda)'(\alpha v^+ + \beta v^-), \alpha v^+\rangle &\geqslant \alpha^p \|v^+\|^p + b\alpha^{2p}|\nabla v^+|_p^{2p} + b\alpha^p\beta^p|\nabla v^+|_p^p|\nabla v^-|_p^p - \alpha^{p*}|v^+|_{p^*}^{p^*}\\ &\quad - \lambda\varepsilon\alpha^p|v^+|_p^p - \lambda C_\varepsilon \alpha^\vartheta |v^+|_\vartheta^\vartheta\\ &\geqslant \alpha^p\left(1-\lambda\varepsilon\gamma_p\right)\|v^+\|^p + b\alpha^{2p}|\nabla v^+|_p^{2p} - \lambda C_\varepsilon\alpha^\vartheta\gamma_\vartheta\|v^+\|^\vartheta\\ &\quad - \alpha^{p*}\gamma_{p*}\|v^+\|^{p^*},\end{aligned}$$

and

$$\begin{aligned}\langle (\mathcal{K}_b^\lambda)'(\alpha v^+ + \beta v^-), \beta v^-\rangle &\geqslant \beta^p \|v^-\|^p + b\beta^{2p}|\nabla v^-|_p^{2p} + b\beta^p\alpha^p|\nabla v^-|_p^p|\nabla v^+|_p^p - \beta^{p*}|v^-|_{p^*}^{p^*}\\ &\quad - \lambda\varepsilon\beta^p|v^-|_p^p - \lambda C_\varepsilon \beta^\vartheta |v^-|_\vartheta^\vartheta\\ &\geqslant \beta^p\left(1-\lambda\varepsilon\gamma_p\right)\|v^-\|^p + b\beta^{2p}|\nabla v^-|_p^{2p} - \lambda C_\varepsilon\beta^\vartheta\gamma_\vartheta\|v^-\|^\vartheta\\ &\quad - \beta^{p*}\gamma_{p*}\|v^-\|^{p^*}.\end{aligned}$$

Select ε in such a manner that $\left(1-\lambda\varepsilon\gamma_p\right) > 0$. Given that $\vartheta \in (2p, p^*)$, one has

$$\langle (\mathcal{K}_b^\lambda)'(\alpha v^+ + \beta v^-), \alpha v^+\rangle > 0, \quad \text{for } \alpha \text{ small enough and all } \beta \geqslant 0, \tag{2.5}$$

and

$$\langle (\mathcal{K}_b^\lambda)'(\alpha v^+ + \beta v^-), \beta v^-\rangle > 0, \quad \text{for } \beta \text{ small enough and all } \alpha \geqslant 0. \tag{2.6}$$

Hence, there is a positive constant τ_1 such that

$$\langle (\mathcal{K}_b^\lambda)'(\tau_1 v^+ + \beta v^-), \tau_1 v^+\rangle > 0, \quad \langle (\mathcal{K}_b^\lambda)'(\alpha v^+ + \tau_1 v^-), \tau_1 v^-\rangle > 0, \tag{2.7}$$

for all $\alpha, \beta \geqslant 0$. Conversely, choosing $\alpha = \tau_2' > \tau_1$. If $\beta \in [\tau_1, \tau_2']$ and τ_2' is large enough, using (1.11), one has that

$$\begin{aligned}\langle (\mathcal{K}_b^\lambda)'(\tau_2' v^+ + \beta v^-), \tau_2' v^+\rangle &\leqslant (\tau_2')^p\|v^+\|^p + b(\tau_2')^{2p}|\nabla v^+|_p^{2p} - (\tau_2')^{p^*}|v^+|_{p*}^{p*}\\ &\quad + b(\tau_2')^{2p}|\nabla v^+|_p^p|\nabla v^-|_p^p\\ &\leqslant 0,\end{aligned}$$

and

$$\begin{aligned}\langle (\mathcal{K}_b^\lambda)'(\alpha v^+ + \tau_2' v^-), \tau_2' v^-\rangle &\leqslant (\tau_2')^p\|v^-\|^p + b(\tau_2')^{2p}|\nabla v^-|_p^{2p} - (\tau_2')^{p^*}|v^-|_{p*}^{p*}\\ &\quad + b(\tau_2')^{2p}|\nabla v^-|_p^p|\nabla v^+|_p^p\\ &\leqslant 0.\end{aligned}$$

Let $\tau_2 > \tau_2'$ be large enough, we get

$$\langle (\mathcal{K}_b^\lambda)'(\alpha v^+ + \tau_2 v^-), \tau_2 v^-\rangle < 0, \qquad \langle (\mathcal{K}_b^\lambda)'(\alpha v^+ + \tau_2 v^-), \tau_2 v^-\rangle < 0, \tag{2.8}$$

for all $\alpha, \beta \in [\tau_1, \tau_2]$. Combining equations (2.7) and (2.8) with Miranda's Theorem [17], we find that there is $(\alpha_v, \beta_v) \in \mathbb{R}_*^+ \times \mathbb{R}_*^+$ such that $G_v(\alpha, \beta) = (0, 0)$, that is, $\alpha v^+ + \beta v^- \in \mathcal{M}_b^\lambda$.

Next, we demonstrate the pair (α_v, β_v) is unique. To finalize the proof, we will investigate two separate cases.

Case 1) $v \in \mathcal{M}_b^\lambda$.

For any $v \in \mathcal{M}_b^\lambda$, one has that

$$\|v^+\|^p + b|\nabla v^+|_p^p|\nabla v^-|_p^p + b|\nabla v^+|_p^{2p} = |v^+|_{p*}^{p^*} + \lambda\int f(v^+)v^+ \, \mathrm{d}x, \tag{2.9}$$

and

$$\|v^-\|^p + b|\nabla v^-|_p^p|\nabla v^+|_p^p + b|\nabla v^-|_p^{2p} = |v^-|_{p*}^{p^*} + \lambda \int f(v^-)v^- \, \mathrm{d}x. \tag{2.10}$$

Consider a pair of numbers (α_0, β_0) satisfying $\alpha_0 v^+ + \beta_0 v^- \in \mathcal{M}_b^\lambda$ and $0 < \alpha_0 \leqslant \beta_0$. So, we have that

$$\alpha_0^p \|v^+\|^p + b\alpha_0^p \beta_0^p |\nabla v^+|_p^p |\nabla v^-|_p^p + b\alpha_0^{2p} |\nabla v^+|_p^{2p} = \alpha_0^{p^*} |v^+|_{p^*}^{p^*} + \lambda \int f(\alpha_0 v^+)\alpha_0 v^+ \, \mathrm{d}x,$$

and

$$\beta_0^p \|v^-\|^p + b\beta_0^p \alpha_0^p |\nabla v^-|_p^p |\nabla v^+|_p^p + b\beta_0^{2p} |\nabla v^-|_p^{2p} = \beta_0^{p^*} |v^-|_{p^*}^{p^*} + \lambda \int f(\beta_0 v^-)\beta_0 v^- \, \mathrm{d}x.$$

Hence, thanks to $0 < \alpha_0 \leqslant \beta_0$, one has that

$$\frac{1}{\alpha_0^p}\|v^+\|^p + b|\nabla v^+|_p^p|\nabla v^-|_p^p + b|\nabla v^+|_p^{2p} \leqslant \alpha_0^{p^*-2p}|v^+|_{p^*}^{p^*} + \lambda \int \frac{f(\alpha_0 v^+)}{(\alpha_0 v^+)^{2p-1}}(v^+)^{2p} \, \mathrm{d}x, \tag{2.11}$$

and

$$\frac{1}{\beta_0^p}\|v^-\|^p + b|\nabla v^-|_p^p|\nabla v^+|_p^p + b|\nabla v^-|_p^{2p} \geqslant \beta_0^{p^*-2p}|v^-|_p^{p^*} + \lambda \int \frac{f(\beta_0 v^-)}{(\beta_0 v^-)^{2p-1}}(v^-)^{2p} \, \mathrm{d}x. \tag{2.12}$$

Combining (2.10) with (2.12), one has that

$$\left(\frac{1}{\beta_0^p} - 1\right)\|v^-\|^p \geqslant \left(\beta_0^{p^*-2p} - 1\right)|v^-|_{p^*}^{p^*} + \lambda \int \left[\frac{f(\beta_0 v^-)}{(\beta_0 v^-)^{2p-1}} - \frac{f(v^-)}{(v^-)^{2p-1}}\right](v^-)^{2p} \, \mathrm{d}x.$$

If $\beta_0 > 1$, the left-hand side of the aforementioned inequality becomes less than zero, thereby contradicting condition $(\mathcal{P}_4)$ that guarantees the positivity of the right-hand side. Consequently, if follows that $0 < \alpha_0 \leqslant \beta_0 \leqslant 1$. Similarly, combining (2.9) with (2.11), thanks to $0 < \alpha_0 \leqslant \beta_0$, we obtain

$$\left(\frac{1}{\alpha_0^p} - 1\right)\|v^+\|^p \leqslant \left(\alpha_0^{p^*-2p} - 1\right)|v^+|_{p^*}^{p^*} + \lambda \int \left[\frac{f(\alpha_0 v^+)}{(\alpha_0 v^+)^{2p-1}} - \frac{f(v^+)}{(v^+)^{2p-1}}\right](v^+)^{2p} \, \mathrm{d}x.$$

In view of $(\mathcal{P}_4)$, we have $\alpha_0 \geqslant 1$. Due to this, $\alpha_0 = \beta_0 = 1$. So, we conclude that if $v \in \mathcal{M}_b^\lambda$, the unique pair such that $\alpha_v v^+ + \beta_v v^- \in \mathcal{M}_b^\lambda$ is $(\alpha_v, \beta_v) = (1, 1)$.

Case 2) $v \notin \mathcal{M}_b^\lambda$.

Assume the existence of two pairs $(\alpha_1, \beta_1), (\alpha_2, \beta_2)$, satisfy the following condition

$$u_1 = \alpha_1 v^+ + \beta_1 v^- \in \mathcal{M}_b^\lambda, \qquad u_2 = \alpha_2 v^+ + \beta_2 v^- \in \mathcal{M}_b^\lambda.$$

Therefore, one has

$$u_2 = \left(\frac{\alpha_2}{\alpha_1}\right)\alpha_1 v^+ + \left(\frac{\beta_2}{\beta_1}\right)\beta_1 v^- = \left(\frac{\alpha_2}{\alpha_1}\right)u_1^+ + \left(\frac{\beta_2}{\beta_1}\right)u_1^- \in \mathcal{M}_b^\lambda.$$

By $u_1 \in \mathcal{M}_b^\lambda$, we have that

$$\frac{\beta_2}{\beta_1} = \frac{\alpha_2}{\alpha_1} = 1.$$

Hence, $\alpha_1 = \alpha_2, \beta_1 = \beta_2$.

Lastly, we show that the unique maximum of g_v on $\mathbb{R}^+ \times \mathbb{R}^+$ is (α_v, β_v).
Indeed, using (1.11), it can be seen that

$$\begin{aligned} g_v(\alpha,\beta) &= \mathcal{K}_b^\lambda(\alpha v^+ + \beta v^-) \\ &= \frac{1}{p}\|\alpha v^+ + \beta v^-\|^p + \frac{b}{2p}|\nabla \alpha v^+ + \beta v^-|_p^{2p} - \frac{1}{p^*}|\alpha v^+ + \beta v^-|_{p^*}^{p^*} \\ &\quad - \lambda \int F(\alpha v^+ + \beta v^-)\, \mathrm{d}x \\ &\leqslant \frac{\alpha^p}{p}\|v^+\|^p + \frac{\beta^p}{p}\|v^-\|^p - \frac{\beta^{p^*}}{p^*}|v^-|_{p^*}^{p^*} - \frac{\alpha^{p^*}}{p^*}|v^+|_{p^*}^{p^*} + \frac{b\alpha^{2p}}{2p}|\nabla v^+|_p^{2p} \\ &\quad + \frac{b\beta^{2p}}{2p}|\nabla v^-|_p^{2p} + \frac{b\alpha^p\beta^p}{p}|\nabla v^+|_p^p|\nabla v^-|_p^p. \end{aligned} \tag{2.13}$$

Thus, for any $v \in W$ with $v^\pm \neq 0$, in light of equation (2.13) and the condition $p^* > 2p$, one has

$$\lim_{|(\alpha,\beta)|\to\infty} g_v(\alpha,\beta) = -\infty.$$

Thus, (α_v, β_v) represents the unique critical point of g_v within the domain $\mathbb{R}^+ \times \mathbb{R}^+$. Hence, our task is to establish that it is impossible to reach a maximum point on the boundary $(0, \beta_0)$ and $(\alpha_0, 0)$. For the sake of contradiction, let us assume that $(0, \beta_0)$ is a maximum of g_v with $\beta_0 \geqslant 0$. Consequently, it follows that

$$\begin{aligned} g_v(\alpha,\beta_0) &= \frac{\alpha^p}{p}\|v^+\|^p + \frac{\beta_0^p}{p}\|v^-\|^p - \frac{\beta_0^{p^*}}{p^*}|v^-|_{p^*}^{p^*} - \frac{\alpha^{p^*}}{p^*}|v^+|_{p^*}^{p^*} + \frac{b\beta_0^{2p}}{2p}|\nabla v^-|_p^{2p} \\ &\quad + \frac{b\alpha^{2p}}{2p}|\nabla v^+|_p^{2p} + \frac{b\alpha^p\beta_0^p}{p}|\nabla v^+|_p^p|\nabla v^-|_p^p - \lambda\int F(\alpha v^+) - \lambda\int F(\beta_0 v^-). \end{aligned}$$

Thus, it can be seen that

$$\begin{aligned} \frac{\partial g_v}{\partial \alpha}(\alpha,\beta_0) &= \alpha^{p-1}\|v^+\|^p - \alpha^{p^*-1}|v^+|_{p^*}^{p^*} + b\alpha^{2p-1}|\nabla v^+|_p^{2p} + b\alpha^{p-1}\beta_0^p|\nabla v^+|_p^p|\nabla v^-|_p^p \\ &\quad - \lambda\int f(\alpha v^+)v^+\, \mathrm{d}x \\ &> 0, \end{aligned}$$

if α is sufficiently small. This implies that g_v is increasing with respect to α if α is sufficiently small. This leads to a contradiction. Likewise, g_v can not attain its global maximum on $(\alpha_0, 0)$ with $\alpha_0 \geqslant 0$.

Proof of (A_3): Suppose $\alpha_v \geqslant \beta_v > 0$. By $\alpha_v v^+ + \beta_v v^- \in \mathcal{M}_b^\lambda$, we have that

$$\alpha_v^p\|v^+\|^p + b\alpha_v^{2p}|\nabla v^+|_p^{2p} + b\alpha_v^{2p}|\nabla v^+|_p^p|\nabla v^-|_p^p \geqslant \lambda\int f(\alpha_v v^+)\alpha_v v^+\, \mathrm{d}x + \alpha_v^{p^*}|v^+|_{p^*}^{p^*}. \tag{2.14}$$

Conversely, from the inequality $\langle (\mathcal{K}_b^\lambda)'(v), v^+\rangle \leqslant 0$, we deduce that

$$\lambda\int f(v^+)v^+\, \mathrm{d}x + |v^+|_{p^*}^{p^*} \geqslant \|v^+\|^p + b|\nabla v^+|_p^p|\nabla v^-|_p^p + b|\nabla v^+|_p^{2p}. \tag{2.15}$$

Combining (2.14) and (2.15), we obtain

$$\left(\frac{1}{\alpha_v^p} - 1\right)\|v^+\|^p \geqslant \left(\alpha_v^{p^*-2p} - 1\right)|v^+|_{p^*}^{p^*} + \lambda\int\left[\frac{f(\alpha_v v^+)}{(\alpha_v v^+)^{2p-1}} - \frac{f(v^+)}{(v^+)^{2p-1}}\right](v^+)^{2p}\, \mathrm{d}x.$$

Hence, due to condition $(\mathcal{P}_4)$, we can infer that $\alpha_v \leqslant 1$. Therefore, we establish that $0 < \alpha_v, \beta_v \leqslant 1$. Consequently, Lemma 2.1 has been proved. □

The following result plays a crucial role to prove that c_b^λ is achieved.

Lemma 2.2. *Let $c_b^\lambda = \inf_{v\in\mathcal{M}_b^\lambda} \mathcal{K}_b^\lambda(v)$, then we have that*

$$\lim_{\lambda\to\infty} c_b^\lambda = 0.$$

Proof. For every $v \in \mathcal{M}_\lambda$, it holds that

$$\|v^+\|^p + b|\nabla v^+|_p^{2p} + b|\nabla v^+|_p^p|\nabla v^-|_p^p = |v^+|_{p^*}^{p^*} + \lambda\int f(v^+)v^+ \,\mathrm{d}x,$$

and

$$\|v^-\|^p + b|\nabla v^+|_p^{2p} + b|\nabla v^-|_p^p|\nabla v^+|_p^p = |v^-|_{p^*}^{p^*} + \lambda\int f(v^-)v^- \,\mathrm{d}x.$$

Then by (1.13) and (2.4), we get

$$\left(1-\lambda\varepsilon\gamma_p\right)\|v^+\|^p \leqslant \lambda C_\varepsilon\gamma_\vartheta\|v^+\|^\vartheta + \gamma_{p*}\|v^+\|^{p^*},$$

and

$$\left(1-\lambda\varepsilon\gamma_p\right)\|v^-\|^p \leqslant \lambda C_\varepsilon\gamma_\vartheta\|v^-\|^\vartheta + \gamma_{p*}\|v^-\|^{p^*}.$$

Taking $\varepsilon < \frac{1}{\lambda\gamma_p}$ such that $1-\lambda\varepsilon\gamma_p > 0$. Given that $\vartheta \in (2p, p^*)$, there is $\rho > 0$ such that

$$\|v^+\| \geqslant \rho, \quad \|v^-\| \geqslant \rho, \quad \forall v \in \mathcal{M}_b^\lambda. \tag{2.16}$$

Conversely, for any $v \in \mathcal{M}_b^\lambda$, it becomes evident that

$$\begin{aligned}\langle(\mathcal{K}_b^\lambda)'(v), v\rangle &= \langle(\mathcal{K}_b^\lambda)'(v), v^+\rangle + \langle(\mathcal{K}_b^\lambda)'(v), v^-\rangle\\ &= 0.\end{aligned}$$

From (1.12), we can deduce that

$$f(t)t - 2pF(t) \geqslant 0, \tag{2.17}$$

is increasing when $t > 0$ and decreasing when $t < 0$. Thus, we get

$$\begin{aligned}\mathcal{K}_b^\lambda(v) &= \mathcal{K}_b^\lambda(v) - \frac{1}{2p}\langle(\mathcal{K}_b^\lambda)'(v), v\rangle\\ &= \frac{(p-1)}{2p}\|v\|^p + \frac{p^*-2p}{2pp^*}|v|_{p^*}^{p^*} + \frac{\lambda}{2p}\int\left[f(v)v - 2pF(v)\right]\,\mathrm{d}x\\ &\geqslant \frac{(p-1)}{2p}\|v\|^p\\ &> \frac{(p-1)}{2p}\rho^p.\end{aligned}$$

Therefore, $\mathcal{K}_b^\lambda$ is bounded below on $\mathcal{M}_b^\lambda$. Hence, $c_b^\lambda = \inf_{v\in\mathcal{M}_b^\lambda}\mathcal{K}_b^\lambda(v)$ is well defined.

Fix $v \in W$ with $v^\pm \neq 0$. Lemma 2.1 guarantees that for every $\lambda > 0$, there is $\alpha_\lambda, \beta_\lambda > 0$ such that $\alpha_\lambda v^+ + \beta_\lambda v^- \in \mathcal{M}_b^\lambda$. From Lemma 2.1, one has

$$\begin{aligned}0 \leqslant c_b^\lambda &\leqslant \mathcal{K}_b^\lambda(\alpha_\lambda v^+ + \beta_\lambda v^-)\\ &\leqslant \frac{1}{p}\|\alpha_\lambda v^+ + \beta_\lambda v^-\|^p + \frac{b}{2p}|\nabla(\alpha_\lambda v^+ + \beta_\lambda v^-)|_p^{2p}\\ &= \alpha_\lambda^p\frac{1}{p}\|v^+\|^p + \beta_\lambda^p\frac{1}{p}\|v^-\|^p + \alpha_\lambda^{2p}\frac{b}{2p}|\nabla v^+|_p^{2p} + \beta_\lambda^{2p}\frac{b}{2p}|\nabla v^-|_p^{2p}\\ &\quad + \alpha_\lambda^p\beta_\lambda^p\frac{b}{p}|\nabla v^+|_p^p|\nabla v^-|_p^p.\end{aligned}$$

We need only verify that $\alpha_\lambda \to 0$ and $\beta_\lambda \to 0$, as $\lambda \to \infty$.
Define

$$\mathcal{G}_v = \left\{(\alpha_\lambda, \beta_\lambda) \in \mathbb{R}^+ \times \mathbb{R}^+ : G_v(\alpha_\lambda, \beta_\lambda) = (0,0), \lambda > 0\right\},$$

In light of (2.4), we have that

$$\begin{aligned}\alpha_\lambda^{p^*}|v^+|_{p^*}^{p^*} + \beta_\lambda^{p^*}|v^-|_{p^*}^{p^*} &\leqslant \lambda \int f(\alpha_\lambda v^+)\alpha_\lambda v^+ \,\mathrm{d}x + \lambda \int f(\beta_\lambda v^-)\beta_\lambda v^- \,\mathrm{d}x \\ &\quad + \alpha_\lambda^{p^*}|v^+|_{p^*}^{p^*} + \beta_\lambda^{p^*}|v^-|_{p^*}^{p^*} \\ &= \|\alpha_\lambda v^+ + \beta_\lambda v^-\|^p + b|\nabla(\alpha_\lambda v^+ + \beta_\lambda v^-)|_p^{2p}.\end{aligned}$$

Therefore, $\mathcal{G}_v$ is bounded, since $p^* > 2p$. Assume that $\{\lambda_n\}$ is a sequence in $(0,\infty)$ with $\lambda_n \to \infty$, as n tends to infinity. Then there is α_0 and β_0 such that $(\alpha_{\lambda_n}, \beta_{\lambda_n}) \to (\alpha_0, \beta_0)$, as $n \to \infty$. We assert that $\alpha_0 = \beta_0 = 0$. Suppose, the contrary $\alpha_0 > 0$ or $\beta_0 > 0$. Given that $\alpha_{\lambda_n} v^+ + \beta_{\lambda_n} v^- \in \mathcal{M}_b^{\lambda_n}$, then for any $n \in \mathbb{N}$, we have that

$$\begin{aligned}&\|\alpha_{\lambda_n} v^+ + \beta_{\lambda_n} v^-\|^p + b|\nabla(\alpha_{\lambda_n} v^+ + \beta_{\lambda_n} v^-)|_p^{2p} \\ &\quad = \lambda_n \int f(\alpha_{\lambda_n} v^+ + \beta_{\lambda_n} v^-)(\alpha_{\lambda_n} v^+ + \beta_{\lambda_n} v^-) \,\mathrm{d}x + |\alpha_{\lambda_n} v^+ + \beta_{\lambda_n} v^-|_{p^*}^{p^*}.\end{aligned} \tag{2.18}$$

Then, invoking $\alpha_{\lambda_n} v^+ \to \alpha_0 v^+, \beta_{\lambda_n} v^- \to \beta_0 v^-$ in W along with the Lebesgue dominated convergence theorem, we obtain that

$$\int f(\alpha_{\lambda_n} v^+ + \beta_{\lambda_n} v^-)(\alpha_{\lambda_n} v^+ + \beta_{\lambda_n} v^-) \to \int f(\alpha_0 v^+ + \beta_0 v^-)(\alpha_0 v^+ + \beta_0 v^-) > 0,$$

as $n \to \infty$. This leads to a contradiction with equation (2.18), because $\lambda_n \to \infty$, as $n \to \infty$ and and the sequence $\{\alpha_{\lambda_n} v^+ + \beta_{\lambda_n} v^-\}$ is bounded in W. Hence, we conclude that $\alpha_0 = \beta_0 = 0$, from which we infer that $\lim_{\lambda\to\infty} c_b^\lambda = 0$. □

Let ϕ be a standard cut off function, namely ϕ belongs to the space $\mathcal{C}_c^\infty(\mathbb{R}^N)$, satisfying $0 \leqslant \phi \leqslant 1$, ϕ being equal to 1 on $B_{1/2}(0)$ and $\operatorname{supp}\phi \subset B_1(0)$. For any $\epsilon > 0$, let $\phi_\epsilon(x) = \phi\left(\frac{x}{\epsilon}\right)$.

Lemma 2.3. *Let $1 < p < N$, for every $x_i \in \mathbb{R}^N$ and for $u \in L^p(\mathbb{R}^N)$, we have*

$$|v(x)\nabla\phi_\epsilon(x - x_i)|_{L^p(\mathbb{R}^N)}^p \leqslant |\nabla\phi|_{L^{\frac{p^*p}{p^*-p}}(\mathbb{R}^N)}^p |v|_{L^{p^*}(B_\epsilon(x_i))}^p.$$

Proof. Using the Hölder inequality, one has

$$\begin{aligned}\left|v(x)\nabla\phi_\epsilon(x - x_i)\right|_{L^p(\mathbb{R}^N)}^p &\leqslant \int \epsilon^{-p}\left|\nabla\phi\left(\frac{x - x_i}{\epsilon}\right)\right|^p |v(x)|^p \,dx \\ &\leqslant \epsilon^{-p}\left(\int_{B_\epsilon(x_i)} \left|\nabla\phi\left(\frac{x - x_i}{\epsilon}\right)\right|^{\frac{p^*p}{p^*-p}} dx\right)^{\frac{p^*-p}{p^*}} |v|_{L^{p^*}(B_\epsilon(x_i))}^p \\ &\leqslant \epsilon^{-p}\epsilon^{N\left(\frac{p^*-p}{p^*}\right)} |\nabla\phi|_{L^{\frac{p^*p}{p^*-p}}(\mathbb{R}^N)}^p |v|_{L^{p^*}(B_\epsilon(x_i))}^p.\end{aligned}$$

The result follows by noting that $p = \left(\frac{p^*-p}{p^*}\right)N$. □

With the above results, we will now undertake a three-step process to obtain that $c_b^\lambda = \inf_{v\in\mathcal{M}_b^\lambda} \mathcal{K}_b^\lambda(v)$ is achieved.

Lemma 2.4. *There is $\lambda^\star > 0$ such that for all $\lambda \in [\lambda^\star, \infty)$, the infimum c_b^λ is attained.*

Proof. As defined by c_b^λ, there is a sequence $\{v_n\} \subset \mathcal{M}_b^\lambda$ satisfies

$$\lim_{n\to\infty} \mathcal{K}_b^\lambda(v_n) = c_b^\lambda.$$

On the other hand, by using (2.17) and $\langle (\mathcal{K}_b^\lambda)'(v_n), v_n \rangle = 0$, we get

$$\begin{aligned} c_b^\lambda + o(1) &= \mathcal{K}_b^\lambda(v_n) - \frac{1}{2p}\langle (\mathcal{K}_b^\lambda)'(v_n), u_n\rangle \\ &= \frac{(p-1)}{2p}\|v\|^p + \frac{p^*-2p}{2pp^*}|v|_{p^*}^{p^*} + \frac{\lambda}{2p}\int [f(v)v - 2pF(v)] \\ &\geqslant \frac{(p-1)}{2p}\|v\|^p. \end{aligned} \tag{2.19}$$

Therefore, $\{v_n\}$ is bounded in W, i.e., there is a constant $M > 0$ such that

$$\|v_n\| \leqslant M, \quad \forall n \in \mathbb{N}. \tag{2.20}$$

From (2.16), (2.19), and Ekeland's variational principle [20], $\{v_n\}$ represents a $(\mathrm{PS})_{c_b^\lambda}$ sequence for $\mathcal{K}_b^\lambda|_{\mathcal{M}_b^\lambda}$, i.e.

$$\mathcal{K}_b^\lambda(v_n) \to c_b^\lambda, \quad (\mathcal{K}_b^\lambda)'(v_n) \to 0. \tag{2.21}$$

Since v_n is bounded in W, there existence a $v \in W$ and a subsequence $\{v_n\}$ where

$$\begin{aligned} v_n &\rightharpoonup v && \text{in } W, \\ v_n &\to v && \text{in } L^s \text{ for } p \leqslant s < p^*, \\ v_n &\to v && \text{a.e. in } \mathbb{R}^N, \\ v_n &\rightharpoonup v && \text{in } L^{p^*}, \\ f(v_n) &\rightharpoonup f(v) && \text{in } (L^{p^*})', \\ |v_n|^{p^*-2}v_n &\rightharpoonup |v|^{p^*-2}v && \text{in } (L^{p^*})'. \end{aligned} \tag{2.22}$$

We migh suppose that

$$\begin{aligned} |\nabla v_n|^p &\rightharpoonup^* \mu \text{ in } \mathcal{M}(\mathbb{R}^N), \\ |v_n|^{p^*} &\rightharpoonup^* \nu \text{ in } \mathcal{M}(\mathbb{R}^N). \end{aligned} \tag{2.23}$$

for some measures μ and ν. Then, according to Concentration-Compactness principle [16], there exists an at most countable set $\mathfrak{J}$ and $\{x_i\}_{i\in\mathfrak{J}} \subset \mathbb{R}^N$, $\{\mu_i\}_{i\in\mathfrak{J}} \subset (0,+\infty)$, $\{\nu_i\}_{i\in\mathfrak{J}} \subset (0,+\infty)$ such that

$$\begin{aligned} \nu &= \sum_{i\in\mathfrak{J}} \nu_i \delta_{x_i} + |v|^{p^*}, \\ \mu &\geqslant \sum_{i\in\mathfrak{J}} \mu_i \delta_{x_i} + |\nabla v|^p, \end{aligned} \tag{2.24}$$

with $S\nu_i^{\frac{p}{p^*}} \leqslant \mu_i$, where

$$S := \inf_{\substack{v\in W\setminus\{0\}, \\ |v|_{p^*}=1}} \frac{\|v\|^p}{|v|_{p^*}^p}.$$

Our claim is that $\nabla v_n^\pm \to \nabla v^\pm$ almost everywhere in $\mathbb{R}^N$. Following the approach in [3,9], we will carry out the proof in two steps.

Step a) The set $\mathfrak{J}$ is either finite or empty. Let's take a fixed $i \in \mathfrak{J}$ and let $\epsilon > 0$ be chosen small enough. Utilizing Lemma 2.3, we can conclude that

$$|v_n\phi_\epsilon(x-x_i)|_p^p \leqslant |v_n|_p^p,$$

and

$$\begin{aligned}|\nabla\left(v_n\phi_\epsilon(x-x_i)\right)|_p^p &\leqslant 2^{p-1}\left||\nabla\phi_\epsilon(x-x_i)|^p\,|v_n|^p\right|_1 + 2^{p-1}\left||\phi_\epsilon(x-x_i)|^p|\nabla v_n|^p\right|_1\\ &\leqslant 2^{p-1}|v_n|_{p^*}^p|\nabla\phi|^p_{L^{\frac{p^*p}{p^*-p}}(\mathbb{R}^N)} + 2^{p-1}\|v_n\|^p.\end{aligned}$$

Consequently, a constant C_1 exists such that, for any $\epsilon > 0$ and $i \in \mathfrak{J}$, we have

$$\|v_n\phi_\epsilon\left(x-x_i\right)\| \leqslant C_1.$$

It is clear that $\{v_n\phi_\epsilon\left(x-x_i\right)\}_{n=1}^{+\infty} \subset W$. Therefore, $\{v_n\phi_\epsilon\left(x-x_i\right)\}$ is bounded in W. For any fixed $x_i \in \mathfrak{J}$, from (2.21), we obtain

$$\left\langle\left(\mathcal{K}_b^\lambda\right)'\left(v_n\right), v_n\phi_\epsilon(x-x_i)\right\rangle = o(1).$$

Thus, one gets

$$\begin{aligned}&(1+b\|v_n\|^p)\int|\nabla v_n|^p\,\phi_\epsilon(x-x_i)\,\mathrm{d}x + (1+b\|v_n\|^p)\int|\nabla v_n|^{p-2}\,\nabla v_n\cdot v_n\nabla\phi_\epsilon\left(x-x_i\right)\,\mathrm{d}x\\ &\quad= \int|v_n|^{p^*}\,\phi_\epsilon\left(x-x_i\right)\,\mathrm{d}x + \lambda\int f(v_n)v_n\phi_\epsilon(x-x_i)\,\mathrm{d}x + o(1).\end{aligned} \tag{2.25}$$

By means of the Young inequality, for any $\delta > 0$, there is C_δ such that

$$\left|\int|\nabla v_n|^{p-2}\nabla v_n\cdot v_n\nabla\phi_\epsilon(x-x_i)\,\mathrm{d}x\right| \leqslant C_\delta|v_n\nabla\phi_\epsilon(x-x_i)|_p^p + \delta\|v_n\|_p^p.$$

Applying the Strauss Lemma [19], we obtain

$$\lim_{n\to\infty}|v_n\nabla\phi_\epsilon(x-x_i)|_p^p = |v\nabla\phi_\epsilon(x-x_i)|_p^p.$$

Therefore, utilizing Lemma 2.3, we derive

$$\begin{aligned}\limsup_{n\to\infty}\left|\int|\nabla v_n|^{p-2}\nabla v_n\cdot v_n\nabla\phi_\epsilon(x-x_i)\,\mathrm{d}x\right| &\leqslant C_\delta|v\nabla\phi_\epsilon(x-x_i)|_p^p + \delta\limsup_{n\to\infty}\|v_n\|^p\\ &\leqslant \delta C_2 + C_\delta C_3|v|^p_{L^{p^*}(B_\epsilon(x_i))},\end{aligned} \tag{2.26}$$

where $C_3 = |\nabla\phi|^p_{\frac{p^*p}{p^*-p}}$ is constant and independent of ϵ and δ. Using (2.4) along with the Strauss Lemma [19] and (2.22), we deduce

$$\lim_{n\to\infty}\int f(v_n)v_n\phi_\epsilon(x-x_i)\,\mathrm{d}x = \int f(v)v\phi_\epsilon(x-x_i)\,\mathrm{d}x. \tag{2.27}$$

Combining (2.25)–(2.27) and using (2.20), we obtain

$$\begin{aligned}\lim_{n\to\infty}\int|\nabla v_n|^p\,\phi_\epsilon(x-x_i)\,\mathrm{d}x \leqslant \lambda\int f(v)v\phi_\epsilon(x-x_i)\,\mathrm{d}x + \lim_{n\to\infty}\int|v_n|^{p^*}\,\phi_\epsilon(x-x_i)\,\mathrm{d}x\\ + \delta(1+bM^p)\limsup_{n\to\infty}\|v_n\|^p + C_\delta C_3(1+bM^p)|v|^p_{L^{p^*}(B_\epsilon(x_i))}.\end{aligned}$$

Therefore, since $\{v_n\}$ is bounded in W and by (2.23), we can conclude that

$$\int \phi_\epsilon(x-x_i)\,\mathrm{d}\mu \leqslant \lambda \int f(v)v\phi_\epsilon(x-x_i)\,\mathrm{d}x + \int \phi_\epsilon(x-x_i)\,\mathrm{d}\nu + \delta C_4 + C_\delta C_5 |v|^p_{L^{p^*}(B_\epsilon(x_i))},$$

where C_4 and C_5 are independent of ϵ and δ. Thus, by the conditions $0 \leqslant \phi \leqslant 1$ and $\phi \equiv 1$ on $B_{1/2}(0)$, one gets

$$\begin{aligned}\mu\left(B_{\epsilon/2}(x_i)\right) &\leqslant \int \phi_\epsilon(x-x_i)\,\mathrm{d}\nu \\ &\leqslant \nu\left(B_\epsilon(x_i)\right) + \lambda \int\limits_{B_\epsilon(x_i)} f(v)v\,\mathrm{d}x + \delta C_4 + C_\delta C_5 |v|^p_{L^{p^*}(B_\epsilon(x_i))}.\end{aligned} \tag{2.28}$$

From (2.24), we have that

$$\begin{aligned}\nu_i^{\frac{p}{p^*}} S &\leqslant \mu_i \\ &\leqslant \mu\left(B_{\epsilon/2}(x_i)\right),\end{aligned}$$

and

$$\lim_{\epsilon\to 0^+} \nu\left(B_\epsilon(x_i)\right) = \nu_i.$$

Taking the limit as $\epsilon \to 0^+$ in (2.28) yields

$$a\nu_i^{\frac{p}{p^*}} S \leqslant \nu_i + \delta C_4.$$

As $\delta > 0$ is arbitrary, we conclude that

$$a\nu_i^{\frac{p}{p^*}} S \leqslant \nu_i,$$

i.e.,

$$\nu_i \geqslant (aS)^{\frac{p^*}{p^*-p}} > 0.$$

Since ν is a bounded positive measure, it follows that $\mathfrak{J}$ must be either a empty set or finite. The proof of step a is now finished.

Step b) The convergence $\nabla v_n \to \nabla v$ holds a.e. in $\mathbb{R}^N$. First, let's assume that $\mathfrak{J}$ is a finite nonempty set, namely $\mathfrak{J} = \{1, 2, \ldots, m\}$. For any $\epsilon > 0$, we define an open set $\Omega_\epsilon \subset \mathbb{R}^N$ as follows

$$\Omega_\epsilon = B_{1/2\epsilon}(0) \setminus \bigcup_{i=1}^m B_\epsilon(x_i).$$

There is $\epsilon_0 > 0$ such that

$$B_{\epsilon_0}(x_{i_1}) \cap B_{\epsilon_0}(x_{i_2}) = \emptyset,$$

for any $i_1, i_2 \in \mathfrak{J}$ with $i_1 \neq i_2$, which are possible since $\mathfrak{J}$ is a finite set. Now, let $0 < \zeta < \epsilon_0$. Our claim is

$$\int_{\Omega_\zeta} \left(|\nabla v_n|^{p-2}\nabla v_n - |\nabla v|^{p-2}\nabla v\right)\cdot\nabla(v_n - v)\,\mathrm{d}x \to 0. \tag{2.29}$$

Indeed, Define, for $x \in \mathbb{R}^N$ with $0 < \epsilon < \zeta$,

$$\psi_\epsilon(x) = \phi_{1/\epsilon}(x) - \sum_{i=1}^m \phi_\epsilon\left(x - x_i\right),$$

where ϕ was given in Lemma (2.3). Therefore, we have

$$\begin{aligned}
&\psi_\epsilon(x) \in \mathcal{C}_c^\infty\left(\mathbb{R}^N\right),\\
&\psi_\epsilon(x) = 0 \text{ on } \bigcup_{i=1}^m B_{\epsilon/2}(x_i),\\
&\psi_\epsilon(x) = 1 \text{ on } B_{1/2\epsilon}(0) \setminus \bigcup_{i=1}^m B_\epsilon(x_i).
\end{aligned}$$

From Lemma 2.3 and the fact that $\{v_n\}$ is bounded in W for all $n \in \mathbb{N}$, It is straightforward to verify that $\{\psi_\epsilon v_n\}$ is bounded in W for all n. Using (2.21), we deduce that as $n \to \infty$, the following holds

$$\begin{aligned}
(1+b\|v_n\|^p)\left(\int |\nabla v_n|^p \psi_\epsilon \,\mathrm{d}x + \int |\nabla v_n|^{p-2}\nabla v_n \cdot v_n \nabla \psi_\epsilon \,\mathrm{d}x\right)&\\
= \lambda \int f(v_n) v_n \psi_\epsilon \,\mathrm{d}x + \int |v_n|^{p^*}\psi_\epsilon \,\mathrm{d}x + o(1).&
\end{aligned}$$

As in step a, we conclude that

$$\begin{aligned}
\lim_{n\to\infty}(1+b\|v_n\|^p)\int |\nabla v_n|^p \,\psi_\epsilon \,\mathrm{d}x = \lim_{n\to\infty}\left(-(1+b\|v_n\|^p)\int |\nabla v_n|^{p-2}\nabla v_n \cdot v_n \nabla\psi_\epsilon \,\mathrm{d}x\right)&\\
+ \lim_{n\to\infty}\int |v_n|^{p^*}\psi_\epsilon \,\mathrm{d}x + \lambda\int f(v) v \psi_\epsilon \,\mathrm{d}x.&
\end{aligned}$$

Given that $\psi_\epsilon \equiv 0$ on $\bigcup_{i=1}^m B_{\epsilon/2}(x_i)$ and $\nu = |v|^{p^*} + \sum_{i=1}^m \nu_i \delta_{x_i}$, we obtain

$$\begin{aligned}
\lim_{n\to\infty}\int |v_n|^{p^*}\,\psi_\epsilon \,\mathrm{d}x &= \int \psi_\epsilon \,\mathrm{d}\nu\\
&= \int |v|^{p^*}\psi_\epsilon \,\mathrm{d}x.
\end{aligned}$$

Thus, one has

$$\begin{aligned}
\lim_{n\to\infty}(1+b\|v_n\|^p)\int |\nabla v_n|^p \,\psi_\epsilon \,\mathrm{d}x = \lim_{n\to\infty}\left(-(1+b\|v_n\|^p)\int |\nabla v_n|^{p-2}\nabla v_n \cdot u_n \nabla\psi_\epsilon \,\mathrm{d}x\right)&\\
+ \lambda\int f(v) v \psi_\epsilon \,\mathrm{d}x + \int |v|^{p^*}\psi_\epsilon \,\mathrm{d}x.&
\end{aligned} \tag{2.30}$$

Similarly, in light of (2.21), we conclude that as $n \to \infty$, the following holds

$$\begin{aligned}
(1+b\|v_n\|^p)\int |\nabla v_n|^{p-2}\,\nabla v_n \cdot \psi_\epsilon \nabla v \,\mathrm{d}x = -(1+b\|v_n\|^p)\int |\nabla v_n|^{p-2}\nabla v_n \cdot v\nabla\psi_\epsilon \,\mathrm{d}x&\\
+ \int |v_n|^{p^*-2} v_n v \psi_\epsilon \,\mathrm{d}x + \lambda\int f(v_n) v\psi_\epsilon \,\mathrm{d}x + o(1).&
\end{aligned} \tag{2.31}$$

From Lemma 2.3 and the Young inequality, one has

$$\begin{aligned}
\limsup_{n\to\infty}\left|\int |\nabla v_n|^{p-2}\nabla v_n \cdot v\nabla\psi_\epsilon \,\mathrm{d}x\right| &\leqslant \delta \limsup_{n\to\infty}\|v_n\|^p + C_\delta |v\nabla\psi_\epsilon|_p^p\\
&\leqslant \delta C_2 + C_\delta C_3 |v|^p_{L^{p^*}(B_\epsilon(x_i))}.
\end{aligned} \tag{2.32}$$

Utilizing the fact that $h:\mathbb{R}^N\to\mathbb{R}$ defined by $h(x)=|x|^p$ is strictly convex, one has

$$0\leqslant\left(|\nabla v_n|^{p-2}\nabla v_n-|\nabla v|^{p-2}\nabla v\right)\cdot\nabla\left(v_n-v\right), \tag{2.33}$$

On the other hand, since $\nabla v_n\rightharpoonup\nabla v$ in $L^p(\mathbb{R}^N)$, one has

$$\int\psi_\epsilon|\nabla v|^{p-2}\nabla v\cdot\left(\nabla v_n-\nabla v\right)\,\mathrm{d}x\to 0. \tag{2.34}$$

Then, taking into account that $\psi_\epsilon\equiv 1$ on Ω_ϵ, and combining (2.16), (2.22), (2.30)-(2.31), (2.33)-(2.34), along with the boundedness of $\{v_n\}$, it follows that as n tends to infinity, we deduce that

$$\begin{aligned}
&\int_{\Omega_\zeta}\left(|\nabla v_n|^{p-2}\nabla v_n-|\nabla v|^{p-2}\nabla v\right)\cdot\nabla(v_n-v)\,\mathrm{d}x\\
&\quad\leqslant(1+b\|v_n\|^p)\int\psi_\epsilon\left(|\nabla v_n|^{p-2}\nabla v_n-|\nabla v|^{p-2}\nabla v\right)\cdot\nabla(v_n-v)\,\mathrm{d}x\\
&\quad=(1+b\|v_n\|^p)\int\Big(\psi_\epsilon|\nabla v_n|^{p-2}\nabla v_n\cdot\nabla v_n-\psi_\epsilon|\nabla v_n|^{p-2}\nabla v_n\cdot\nabla v\\
&\qquad-\psi_\epsilon|\nabla v|^{p-2}\nabla v\cdot\nabla v_n+\psi_\epsilon|\nabla v|^{p-2}\nabla v\cdot\nabla v\Big)\,\mathrm{d}x\\
&\quad=\lim_{n\to\infty}(1+b\|v_n\|^p)\int|\nabla v_n|^{p-2}\nabla v_n\cdot v\nabla\psi_\epsilon\,\mathrm{d}x\\
&\qquad-\lim_{n\to\infty}(1+b\|v_n\|^p)\int|\nabla v_n|^{p-2}\nabla v_n\cdot v_n\nabla\psi_\epsilon\,\mathrm{d}x+o(1).
\end{aligned}$$

Given that $0\leqslant\psi_\varepsilon\leqslant 1$, and $\psi_\epsilon=1$ on Ω_ϵ for $0<\epsilon<\epsilon_0$, by (2.26) and (2.32), as n tends to infinity, we conclude that

$$\begin{aligned}
\int_{\Omega_\zeta}\left(|\nabla v_n|^{p-2}\nabla v_n-|\nabla v|^{p-2}\nabla v\right)\cdot\nabla(v_n-v)\,\mathrm{d}x\leqslant 2(1+bM^p)C_\delta C_3|v|^p_{L^{p^*}(B_\epsilon(x_i))}\\
+2(1+bM^p)\delta C_2+o(1),
\end{aligned} \tag{2.35}$$

where constants C_2, C_3 are independent of δ and ϵ. Therefore, in (2.35), first let $n\to\infty$, then let $\epsilon\to 0^+$, and finally let $\delta\to 0^+$, yielding

$$\lim_{n\to\infty}\int_{\Omega_\zeta}\left(|\nabla v_n|^{p-2}\nabla v_n-|\nabla v|^{p-2}\nabla v\right)\cdot\nabla(v_n-v)\,\mathrm{d}x=0. \tag{2.36}$$

Using an elementary inequality (see [18])

$$\left(a-b,|a|^{p-2}a-|b|^{p-2}b\right)\geqslant\begin{cases}C_p|a-b|^p & \text{if } p\geqslant 2,\\ C_p\frac{|a-b|^2}{(|a|+|b|)^{2-p}} & \text{if } 1<p<2,\end{cases}$$

where $a,b\in\mathbb{R}^N$. If $p\geqslant 2$, the convergence of (2.36) to zero as $n\to\infty$ implies that

$$\lim_{n\to\infty}C_p\int_{\Omega_\zeta}|\nabla v_n-\nabla v|^p\,\mathrm{d}x=0. \tag{2.37}$$

Moreover, when $1<p<2$, one has

$$\lim_{n\to\infty}C_p\int_{\Omega_\zeta}\frac{|\nabla v_n-\nabla v|^2}{\left(|\nabla v|+|\nabla v_n|\right)^{2-p}}\,\mathrm{d}x=0.$$

Therefore, applying the Hölder inequality, one gets

$$\begin{aligned}\int_{\Omega_\zeta} |\nabla (v_n - v)|^p \, \mathrm{d}x &= \int_{\Omega_\zeta} \frac{|\nabla (v_n - v)|^p \left(|\nabla v_n| + |\nabla v|\right)^{p(p-2)/2}}{\left(|\nabla v_n| + |\nabla v|\right)^{p(p-2)/2}} \, \mathrm{d}x \\ &\leqslant \left(\int_{\Omega_\zeta} \frac{|\nabla (v_n - v)|^2}{\left(|\nabla v_n| + |\nabla v|\right)^{2-p}} \, \mathrm{d}x \right)^{p/2} \\ &\quad \times \left(\int_{\Omega_\zeta} \left(|\nabla v_n| + |\nabla v|\right)^p \, \mathrm{d}x \right)^{(2-p)/2}. \end{aligned} \tag{2.38}$$

Hence, from (2.37) and (2.38), one can conclude

$$\nabla v_n \to \nabla v \quad \text{a.e. in } \Omega_\zeta.$$

Because ζ is arbitrary, by the Cantor diagonal argument, a subsequence $\{v_n\}$ can be chosen such that

$$\nabla v_n \to \nabla v \quad \text{a.e. on } \mathbb{R}^N, \tag{2.39}$$

as $n \to \infty$. If $\mathfrak{J}$ is empty, then $v_n \to v$ in L^{p^*}, it is easy to see that (2.36) is true for $\mathbb{R}^N$ in place of Ω_ζ. Hence (2.39) holds. From the convergences in (2.22) and (2.39), we have

$$\begin{aligned} v_n^\pm &\rightharpoonup v^\pm && \text{in } W, \\ v_n^\pm &\to v^\pm && \text{in } L^s \text{ for } p \leqslant s < p^*), \\ v_n^\pm &\to v^\pm && \text{a.e. in } \mathbb{R}^N, \\ \nabla v_n^\pm &\to \nabla v^\pm && \text{a.e. in } \mathbb{R}^N. \end{aligned}$$

Using Fatou's lemma, the weak lower semicontinuity of norm, and the Brézis–Lieb lemma, one gets

$$\begin{aligned} &\liminf_{n\to\infty} \mathcal{K}_b^\lambda(\alpha v_n^+ + \beta v_n^-) \\ &\quad \geqslant \frac{\alpha^p}{p} \lim_{n\to\infty} \left(\|v^+\|^p + \|v_n^+ - v^+\|^p\right) + \frac{\beta^p}{p} \lim_{n\to\infty} \left(\|v^-\|^p + \|v_n^- - v^-\|^p\right) \\ &\qquad + \frac{b\alpha^{2p}}{2p} \left[|\nabla v^+|_p^p + \lim_{n\to\infty} |\nabla v_n^+ - \nabla v^+|_p^p\right]^2 + \frac{b\beta^{2p}}{2p} \left[|\nabla v^-|_p^p + \lim_{n\to\infty} |\nabla v_n^- - \nabla v^-|_p^p\right]^2 \\ &\qquad + \frac{b\alpha^p\beta^p}{p} \liminf_{n\to\infty} |\nabla v_n^+|_p^p |\nabla v_n^-|_p^p - \lambda \int F(\alpha v^+) \, \mathrm{d}x - \lambda \int F(\beta v^-) \, \mathrm{d}x \\ &\qquad - \frac{\alpha^{p^*}}{p^*} \left[|v^+|_{p^*}^{p^*} + \lim_{n\to\infty} |v_n^+ - v^+|_{p^*}^{p^*}\right] - \frac{\beta^{p^*}}{p^*} \left[|v^-|_{p^*}^{p^*} + \lim_{n\to\infty} |v_n^- - v^-|_{p^*}^{p^*}\right] \\ &\quad \geqslant \mathcal{K}_b^\lambda(\alpha v^+ + \beta v^-) + \frac{\alpha^p}{p} A_1 + \frac{b\alpha^{2p}}{2p} A_3^2 + \frac{b\alpha^{2p}}{p} A_3 |\nabla v^+|_p^p - \frac{\alpha^{p^*}}{p^*} B_1 + \frac{\beta^p}{p} A_2 \\ &\qquad + \frac{b\beta^{2p}}{2p} A_4^2 + \frac{b\beta^{2p}}{p} A_4 |\nabla v^-|_p^p - \frac{\beta^{p^*}}{p^*} B_2, \end{aligned}$$

where

$$\begin{aligned} A_1 &= \lim_{n\to\infty} \|v_n^+ - v^+\|^p, & A_2 &= \lim_{n\to\infty} \|v_n^- - v^-\|^p, & A_3 &= \lim_{n\to\infty} |\nabla v_n^+ - \nabla v^+|_p^p, \\ A_4 &= \lim_{n\to\infty} |\nabla v_n^- - \nabla v^-|_p^p, & B_1 &= \lim_{n\to\infty} |v_n^+ - v^+|_{p^*}^{p^*}, & B_2 &= \lim_{n\to\infty} |v_n^- - v^-|_{p^*}^{p^*}. \end{aligned}$$

In view of Lemma 2.1 (A_2), one obtains

$$\mathcal{K}_b^\lambda(v_n) \geqslant \mathcal{K}_b^\lambda(\alpha v_n^+ + \beta v_n^-),$$

for all $\alpha, \beta \geqslant 0$. That is,

$$\begin{aligned} c_b^\lambda \geqslant \mathcal{K}_b^\lambda(\alpha v^+ + \beta v^-) + \frac{\alpha^p}{p}A_1 + \frac{b\alpha^{2p}}{2p}A_3^2 + \frac{b\alpha^{2p}}{p}A_3|\nabla v^+|_p^p - \frac{\alpha^{p^*}}{p^*}B_1 + \frac{\beta^p}{p}A_2 \\ + \frac{b\beta^{2p}}{2p}A_4^2 + \frac{b\beta^{2p}}{p}A_4|\nabla v^-|_p^p - \frac{\beta^{p^*}}{p^*}B_2, \end{aligned} \tag{2.40}$$

for all $\alpha, \beta \geqslant 0$.

Step 1: We claim that $v^\pm \neq 0$. Suppose, for the sake of contradiction, that $v^+ = 0$. Letting $\beta = 0$ in (2.40), one has

$$c_b^\lambda \geqslant \frac{\alpha^p}{p}A_1 + \frac{b\alpha^{2p}}{2p}A_3^2 - \frac{\alpha^{p^*}}{p^*}B_1, \tag{2.41}$$

for all $\alpha \geqslant 0$.

Firstly, we consider the case where $B_1 = 0$. If $A_1 = 0$, then $v_n^+ \to v^+$ in W. From (2.16), it follows that $\|v^+\| > 0$. This contradicts the fact that we assume $v^+ = 0$. If $A_1 > 0$, one has

$$c_b^\lambda \geqslant \frac{\alpha^p}{p}A_1 > 0,$$

for all $\alpha \geqslant 0$, which gives a contradiction with Lemma 2.2.

Finally, we consider the case where $B_1 > 0$. Lemma 2.2 ensures the existence of a $\lambda^\star > 0$ suth that the following inequality holds

$$c_b^\lambda < \frac{p}{N}S^{N/p^2}, \quad \forall \lambda \geqslant \lambda^\star. \tag{2.42}$$

From (1.13) and $B_1 > 0$, we conclude $A_1 > 0$. Using (2.41), one has

$$\begin{aligned} \frac{p}{N}S^{N/p^2} &\leqslant \frac{p}{N}\left[\frac{A_1}{B_1^{p/p^*}}\right]^{N/p^2} \\ &\leqslant \max_{\alpha\geqslant 0}\left\{\frac{\alpha^p}{p}A_1 - \frac{\alpha^{p^*}}{p^*}B_1\right\} \\ &\leqslant \max_{\alpha\geqslant 0}\left\{\frac{\alpha^p}{p}A_1 + \frac{b\alpha^{2p}}{2p}A_3^2 - \frac{\alpha^{p^*}}{p^*}B_1\right\} \\ &\leqslant c_b^\lambda. \end{aligned}$$

Thanks to (2.42), by (2.41), ones has

$$\begin{aligned} c_b^\lambda &< \frac{p}{N}S^{N/p^2} \\ &\leqslant \max_{\alpha\geqslant 0}\left\{\frac{\alpha^p}{p}A_1 + \frac{b\alpha^{2p}}{2p}A_3^2 - \frac{\alpha^{p^*}}{p^*}B_1\right\} \\ &\leqslant c_b^\lambda, \end{aligned}$$

which is a contradiction. Consequently, $v^+ \neq 0$. Likewise, we deduce that $v^- \neq 0$ in a similar manner.

Step 2: We will prove that $B_1 = B_2 = 0$. We just prove $B_1 = 0$ (in an analogous manner, we demonstrate that $B_2 = 0$). Suppose, for the sake of contradiction, that $B_1 > 0$.

First case $B_2 > 0$. As both $B_1 > 0$, and $B_2 > 0$, it follows A_1, and $A_2 > 0$. Let $\widetilde{\alpha}$ and $\widetilde{\beta}$ satisfy

$$\frac{\widetilde{\alpha}^p}{p}A_1 + \frac{b\widetilde{\alpha}^{2p}}{2p}A_3^2 - \frac{\widetilde{\alpha}^{p^*}}{p^*}B_1 = \max_{\alpha \geqslant 0}\left\{\frac{\alpha^p}{p}A_1 + \frac{b\alpha^{2p}}{2p}A_3^2 - \frac{\alpha^{p^*}}{p^*}B_1\right\},$$

and

$$\frac{\widetilde{\beta}^p}{p}A_2 + \frac{b\widetilde{\beta}^{2p}}{2p}A_4^2 - \frac{\widetilde{\beta}^{p^*}}{p^*}B_2 = \max_{\beta \geqslant 0}\left\{\frac{a\beta^p}{p}A_2 + \frac{b\beta^{2p}}{2p}A_4^2 - \frac{\beta^{p^*}}{p^*}B_2\right\}.$$

Due to the compactness of the set $[0,\widetilde{\alpha}] \times [0,\widetilde{\beta}]$ is compact and the continuity of g_v, there is a pair$(\alpha_v, \beta_v) \in [0,\widetilde{\alpha}] \times [0,\widetilde{\beta}]$ satisfying

$$g_v(\alpha_v, \beta_v) = \max_{(\alpha,\beta)\in[0,\widetilde{\alpha}]\times[0,\widetilde{\beta}]} g_v(\alpha, \beta).$$

Therefore, it suffices to verify that a maximum cannot be attained on the boundary, i.e., $(\alpha_v, \beta_v) \in (0,\widetilde{\alpha}) \times (0,\widetilde{\beta})$. Observe that if β is sufficiently small, one has

$$\begin{aligned} g_v(\alpha, 0) &= \mathcal{K}_b^\lambda(\alpha v^+) \\ &< \mathcal{K}_b^\lambda(\alpha v^+) + \mathcal{K}_b^\lambda(\beta v^-) \\ &\leqslant \mathcal{K}_b^\lambda(\alpha v^+ + \beta v^-) \\ &= g_v(\alpha, \beta), \end{aligned}$$

for all $\alpha \in [0,\widetilde{\alpha}]$. Thus, there is $\beta_0 \in [0,\widetilde{\beta}]$ such that $g_v(\alpha, 0) \leqslant g_v(\alpha, \beta_0)$, for all $\alpha \in [0,\widetilde{\alpha}]$, i.e., $(\alpha_v, \beta_v) \notin [0,\widetilde{\alpha}] \times \{0\}$. Using a similar approach, we can demonstrate that $(\alpha_v, \beta_v) \notin \{0\} \times [0,\widetilde{\beta}]$.

It is straightforward to observe that

$$\frac{\alpha^p}{p}A_1 + \frac{b\alpha^{2p}}{2p}A_3^2 + \frac{b\alpha^{2p}}{p}A_3|\nabla v^+|_p^p - \frac{\alpha^{p^*}}{p^*}B_1 > 0, \quad \alpha \in (0,\widetilde{\alpha}], \tag{2.43}$$

and

$$\frac{\beta^p}{p}A_2 + \frac{b\beta^{2p}}{2p}A_4^2 + \frac{b\beta^{2p}}{p}A_4|\nabla v^-|_p^p - \frac{\beta^{p^*}}{p^*}B_2 > 0, \quad \beta \in (0,\widetilde{\beta}]. \tag{2.44}$$

Therefore, one gets

$$\begin{aligned} \frac{p}{N}S^{N/p^2} \leqslant \frac{\widetilde{\alpha}^p}{p}A_1 + \frac{b\widetilde{\alpha}^{2p}}{2p}A_3^2 + \frac{b\widetilde{\alpha}^{2p}}{p}A_3\int|\nabla v^+|^p\,\mathrm{d}x - \frac{\widetilde{\alpha}^{p^*}}{p^*}B_1 + \frac{\beta^p}{p}A_2 \\ + \frac{b\beta^{2p}}{2p}A_4^2 + \frac{b\beta^{2p}}{p}A_4|\nabla v^-|_p^p - \frac{\beta^{p^*}}{p^*}B_2, \end{aligned}$$

and

$$\begin{aligned} \frac{p}{N}S^{N/p^2} \leqslant \frac{\alpha^p}{p}A_1 + \frac{b\alpha^{2p}}{2p}A_3^2 + \frac{b\alpha^{2p}}{p}A_3|\nabla v^+|_p^p - \frac{\alpha^{p^*}}{p^*}B_1 + \frac{\widetilde{\beta}^p}{p}A_2 \\ + \frac{b\widetilde{\beta}^{2p}}{2p}A_4^2 + \frac{b\widetilde{\beta}^{2p}}{p}A_4|\nabla v^-|_p^p - \frac{\widetilde{\beta}^{p^*}}{p^*}B_2, \end{aligned}$$

for all $\alpha \in [0,\widetilde{\alpha}], \beta \in [0,\widetilde{\beta}]$. Combining this with (2.40), one obtains

$$g_v(\alpha,\widetilde{\beta}) \leqslant 0, \quad \forall \alpha \in [0,\widetilde{\alpha}],$$

and, one also has

$$g_v(\widetilde{\alpha},\beta) \leqslant 0, \quad \forall \beta \in [0,\widetilde{\beta}].$$

That is, $(\alpha_v,\beta_v) \notin \{\widetilde{\alpha}\} \times [0,\widetilde{\beta}]$ and $(\alpha_v,\beta_v) \notin \times[0,\widetilde{\alpha}] \times \{\widetilde{\beta}\}$.

In conclusion, it follows that $(\alpha_v,\beta_v) \in (0,\widetilde{\alpha}) \times (0,\widetilde{\beta})$. Thus, the pair (α_v,β_v) is a critical point of g_v. Hence, $\alpha_v v^+ + \beta_v v^- \in \mathcal{M}_b^\lambda$. So, combining (2.40), (2.43) and (2.44), one has that

$$\begin{aligned} c_b^\lambda &\geqslant \mathcal{K}_b^\lambda(\alpha_v v^+ + \beta_v v^-) + \frac{\alpha_v^p}{p}A_1 + \frac{b\alpha_v^{2p}}{2p}A_3^2 + \frac{b\alpha_v^{2p}}{p}A_3|\nabla v^+|_p^p - \frac{\alpha_v^{p^*}}{p^*}B_1 + \frac{\beta_v^p}{p}A_2 \\ &\quad + \frac{b\beta_v^{2p}}{2p}A_4^2 + \frac{b\beta_v^{2p}}{p}A_4|\nabla v^-|_p^p - \frac{\beta_v^{p^*}}{p^*}B_2 \\ &> \mathcal{K}_b^\lambda(\alpha_v v^+ + \beta_v v^-) \\ &\geqslant c_b^\lambda. \end{aligned}$$

This leads to a contradiction. Hence $B_1 = 0$.

Second case $B_2 = 0$. In this situation, maximization can be carried out in $[0,\widetilde{\alpha}] \times [0,\infty)$. In fact, it can be shown that there is $\beta_0 \in [0,\infty)$ satisfying

$$\mathcal{K}_b^\lambda(\alpha v^+ + \beta v^-) \leqslant 0,$$

for all $(\alpha,\beta) \in [0,\widetilde{\alpha}] \times [\beta_0,\infty)$. Hence, there is $(\alpha_v,\beta_v) \in [0,\widetilde{\alpha}] \times [0,\infty)$ that satisfies

$$g_v(\alpha_v,\beta_v) = \max_{(\alpha,\beta)\in[0,\widetilde{\alpha}]\times[0,\infty)} g_v(\alpha,\beta).$$

Next, we show that $(\alpha_v,\beta_v) \in (0,\widetilde{\alpha}) \times (0,\infty)$. One has

$$g_v(\alpha,0) < g_v(\alpha,\beta), \quad \forall \alpha \in [0,\widetilde{\alpha}] \text{ and } \beta \text{ sufficiently small},$$

thus, $(\alpha_v,\beta_v) \notin [0,\widetilde{\alpha}] \times \{0\}$. At the same time, one has

$$g_v(0,\beta) < g_v(\alpha,\beta), \quad \forall \beta \in [0,\infty) \text{ and } \alpha \text{ sufficiently small}.$$

Therefore, we get that $(\alpha_v,\beta_v) \notin \{0\} \times [0,\infty)$.

Conversely, for all $\beta \in [0,\infty)$, we have

$$\begin{aligned} \frac{p}{N}S^{N/p^2} &\leqslant \frac{\widetilde{\alpha}^p}{p}A_1 + \frac{b\widetilde{\alpha}^{2p}}{2p}A_3^2 + \frac{b\widetilde{\alpha}^{2p}}{p}A_3|\nabla v^+|_p^p - \frac{\widetilde{\alpha}^{p^*}}{p^*}B_1 + \frac{\beta^p}{p}A_2 \\ &\quad + \frac{b\beta^{2p}}{2p}A_4^2 + \frac{b\beta^{2p}}{p}A_4|\nabla v^-|_p^p. \end{aligned}$$

Thus, one has

$$g_v(\widetilde{\alpha},\beta) \leqslant 0, \quad \forall \beta \in [0,\infty).$$

Therefore, $(\alpha_v,\beta_v) \notin \{\widetilde{\alpha}\} \times [0,\infty)$. Then, $(\alpha_v,\beta_v) \in (0,\widetilde{\alpha}) \times (0,\infty)$. Hence, (α_v,β_v) is an inner maximizer of g_v in $[0,\widetilde{\alpha}) \times [0,\infty)$. And so $\alpha_v v^+ + \beta_v v^- \in \mathcal{M}_b^\lambda$.

Consequently, based on (2.43), we get

$$\begin{aligned} c_b^\lambda &\geqslant \mathcal{K}_b^\lambda(\alpha_v v^+ + \beta_v v^-) + \frac{\alpha_v^p}{p}A_1 + \frac{b\alpha_v^{2p}}{2p}A_3^2 + \frac{b\alpha_v^{2p}}{p}A_3|\nabla v^+|_p^p - \frac{\alpha_v^{p^*}}{p^*}B_1 + \frac{\beta_v^p}{p}A_2 \\ &\quad + \frac{b\beta_v^{2p}}{2p}A_4^2 + \frac{b\beta_v^{2p}}{p}A_4|\nabla v^-|_p^p \\ &> \mathcal{K}_b^\lambda(\alpha_v v^+ + \beta_v v^-) \\ &\geqslant c_b^\lambda, \end{aligned}$$

which is absurd.

Hence, based on the preceding discussion, it follows that $B_1 = B_2 = 0$.

Step 3: Lastly, we establish the attainment of c_b^λ. Given $v^\pm \neq 0$, according to Lemma 2.1, there is $\alpha_v, \beta_v > 0$ such that $\widetilde{v} := \alpha_v v^+ + \beta_v v^- \in \mathcal{M}_b^\lambda$. Moreover, we have that $\langle (\mathcal{K}_b^\lambda)'(v), v^\pm \rangle \leqslant 0$. Lemma (2.1) implies that $0 < \alpha_v, \beta_v \leqslant 1$.
Combining $v_n \in \mathcal{M}_b^\lambda$ and Lemma 2.1, one gets

$$\begin{aligned} \mathcal{K}_b^\lambda(v_n^+ + v_n^-) &= \mathcal{K}_b^\lambda(v_n) \\ &\geqslant \mathcal{K}_b^\lambda(\alpha_v v_n^+ + \beta_v v_n^-). \end{aligned}$$

Taking into consideration $B_1 = B_2 = 0$ and the semicontinuity of the norm, one has

$$\begin{aligned} c_b^\lambda &\leqslant \mathcal{K}_b^\lambda(\widetilde{v}) = \mathcal{K}_b^\lambda(\widetilde{v}) - \frac{1}{2p}\left\langle (\mathcal{K}_b^\lambda)'(\widetilde{v}), \widetilde{v} \right\rangle \\ &= \frac{(p-1)}{2p}\|\widetilde{v}\|^p + \frac{p^*-2p}{2pp^*}|\widetilde{v}|_{p^*}^{p^*} + \frac{\lambda}{2p}\int [f(\widetilde{v})\widetilde{v} - 2pF(\widetilde{v})]\,\mathrm{d}x \\ &= \frac{(p-1)}{2p}\left(\|\alpha_v v^+\|^p + \|\beta_v v^-\|^p\right) + \frac{p^*-2p}{2pp^*}\left[|\alpha_v v^+|_{p^*}^{p^*} + |\beta_v v^-|_{p^*}^{p^*}\right] \\ &\quad + \frac{\lambda}{2p}\left[\int f(\alpha_v v^+)\alpha_v v^+ - 2pF(\alpha_v v^+) + \int f(\beta_v v^-)\beta_v v^- - 2pF(\beta_v v^-)\right] \\ &\leqslant \frac{(p-1)}{2p}\|v\|^p + \frac{p^*-2p}{2pp^*}|v|_{p^*}^{p^*} + \frac{\lambda}{2p}\int f(v)v - 2pF(v) \\ &\leqslant \liminf_{n\to\infty}\left[\mathcal{K}_b^\lambda(v_n) - \frac{1}{2p}\left\langle (\mathcal{K}_b^\lambda)'(v_n), v_n \right\rangle\right] \\ &= \liminf_{n\to\infty}\mathcal{K}_b^\lambda(v_n) \\ &= c_b^\lambda. \end{aligned}$$

Therefore, it follows that $\alpha_v = \beta_v = 1$, and c_b^λ is attained by $v_b := v^+ + v^- \in \mathcal{M}_b^\lambda$. □

3 Proof of theorems

We begin by proving Theorem 1.3.

Proof of Theorem 1.3. By applying Lemma 2.4, we can demonstrate that the minimizer v_b for c_b^λ is a sign-changing solution to problem ($\mathcal{QKP}$). As $v_b \in \mathcal{M}_b^\lambda$, one has

$$\langle (\mathcal{K}_b^\lambda)'(v_b), v_b^\pm \rangle = 0.$$

For $(\alpha,\beta)\in(\mathbb{R}^+\times\mathbb{R}^+)\backslash(1,1)$, using Lemma 2.1 and Lemma 2.4, we can conclude

$$\mathcal{K}_b^\lambda(\alpha v_b^+ + \beta v_b^-) < \mathcal{K}_b^\lambda(v_b^+ + v_b^-) = c_b^\lambda. \tag{3.1}$$

At this point, we aim to demonstrate that $(\mathcal{K}_b^\lambda)'(v_b)=0$. Suppose, the contrary $(\mathcal{K}_b^\lambda)'(v_b)\neq 0$. It follows that there is $\delta>0$ and $\theta>0$ such that for all $\|u-v_b\|\geqslant 3\delta$, one has

$$\|(\mathcal{K}_b^\lambda)'(u)\|\geqslant\theta.$$

Select $\sigma\in\left(0,\min\left\{\frac{1}{2^{(p-1)}},\frac{\delta}{2^{(p-1)/p}\|v_b\|}\right\}\right)$. Define $D:=(1-\sigma,1+\sigma)\times(1-\sigma,1+\sigma)$, and

$$k(\alpha,\beta)=\alpha v_b^+ + \beta v_b^-,\quad \forall(\alpha,\beta)\in D.$$

From (3.1), one has that

$$\widetilde{c}_\lambda := \max_{\alpha,\beta\in\partial D}\mathcal{K}_b^\lambda\circ k < c_b^\lambda.$$

Let $S_\delta := B_\delta(v_b)$ and $\varepsilon := \min\left\{\frac{(c_b^\lambda-\widetilde{c}_\lambda)}{2},\frac{\theta\delta}{8}\right\}$, it follows from [20, Lemma 2.3] that there is a deformation $\eta\in\mathcal{C}([0,1]\times W,W)$ such that

(a) If $u\notin(\mathcal{K}_b^\lambda)^{-1}\left(\left[c_b^\lambda-2\varepsilon,c_b^\lambda+2\varepsilon\right]\cap S_{2\delta}\right)$, then $\eta(1,u)=u$,

(b) $\eta\left(1,(\mathcal{K}_b^\lambda)^{c_b^\lambda+\varepsilon}\cap S_\delta\right)\subset(\mathcal{K}_b^\lambda)^{c_b^\lambda-\varepsilon}$,

(c) $\mathcal{K}_b^\lambda(\eta(1,u))\leqslant\mathcal{K}_b^\lambda(u),\quad\forall u\in W$.

To begin, we must demonstrate that

$$\max_{(\alpha,\beta)\in\bar{D}}\mathcal{K}_b^\lambda(\eta(1,k(\alpha,\beta)))<c_b^\lambda. \tag{3.2}$$

Indeed, by Lemma 2.1, one has

$$\mathcal{K}_b^\lambda(k(\alpha,\beta))\leqslant c_b^\lambda<c_b^\lambda+\varepsilon,$$

i.e,

$$k(\alpha,\beta)\in\left(\mathcal{K}_b^\lambda\right)^{c_b^\lambda+\varepsilon}.$$

Conversely, one has

$$\begin{aligned}\|k(\alpha,\beta)-v_b\|^p &= \|(\beta-1)v_b^- + (\alpha-1)v_b^+\|^p\\ &\leqslant 2^{p-1}\left((\beta-1)^p\|v_b^-\|^p+(\alpha-1)^p\|v_b^+\|^p\right)\\ &\leqslant 2^{p-1}\sigma^p\|v_b\|^p\\ &<\delta^p.\end{aligned}$$

It follows that

$$k(\alpha,\beta)\in S_\delta\quad\forall(\alpha,\beta)\in\bar{D}.$$

Thus, in light of (b), one gets

$$\mathcal{K}_b^\lambda(\eta(1,k(\alpha,\beta)))<c_b^\lambda-\varepsilon.$$

Hence, we confirm that (3.2) holds.

Our next step is to show that $\eta(1,k(D)) \cap \mathcal{M}_b^\lambda \neq \emptyset$, leading to a contradiction with the definition of c_b^λ. Define $h(\alpha,\beta) := \eta(1,k(\alpha,\beta))$,

$$\begin{aligned}\Psi_0(\alpha,\beta) :=& \left(\langle (\mathcal{K}_b^\lambda)'(k(\alpha,\beta)), v_b^+\rangle, \langle (\mathcal{K}_b^\lambda)'(k(\alpha,\beta)), v_b^-\rangle\right)\\ =& \left(\langle (\mathcal{K}_b^\lambda)'(\alpha v_b^+ + \beta v_b^-), v_b^+\rangle, \langle (\mathcal{K}_b^\lambda)'(\alpha v_b^+ + \beta v_b^-), v_b^-\rangle\right)\\ :=& \left(\varphi^1_{v_b}(\alpha,\beta), \varphi^2_{v_b}(\alpha,\beta)\right),\end{aligned}$$

and

$$\Psi_1(\alpha,\beta) := \left(\frac{1}{\alpha}\langle (\mathcal{K}_b^\lambda)'(h(\alpha,\beta)), (h(\alpha,\beta))^+\rangle, \frac{1}{\beta}\langle (\mathcal{K}_b^\lambda)'(h(\alpha,\beta)), (h(\alpha,\beta))^-\rangle\right).$$

A straightforward computation yields

$$\begin{aligned}\left.\frac{\varphi^1_{v_b}(\alpha,\beta)}{\partial\alpha}\right|_{(1,1)} &= (p-1)\|v_b^+\|^p - (p^*-1)|v_b^+|_{p^*}^{p^*} + b(2p-1)|\nabla v_b^+|_p^{2p}\\ &\quad - \lambda\int \partial_\alpha f(v_b^+)(v_b^+)^2\,\mathrm{d}x + b(p-1)|\nabla v_b^+|_p^p|\nabla v_b^-|_p^p,\\ \left.\frac{\varphi^2_{v_b}(\alpha,\beta)}{\partial\beta}\right|_{(1,1)} &= (p-1)\|v_b^-\|^p - (p^*-1)|v_b^-|_{p^*}^{p^*} + b(2p-1)|\nabla v_b^-|_p^{2p}\\ &\quad - \lambda\int \partial_\alpha f(v_b^-)(v_b^-)^2\,\mathrm{d}x + b(p-1)|\nabla v_b^-|_p^p|\nabla v_b^+|_p^p,\end{aligned}$$

$$\left.\frac{\varphi^1_{v_b}(\alpha,\beta)}{\partial\beta}\right|_{(1,1)} = bp|\nabla v_b^+|_p^p|\nabla v_b^-|_p^p, \qquad \left.\frac{\varphi^2_{v_b}(\alpha,\beta)}{\partial\alpha}\right|_{(1,1)} = bp|\nabla v_b^-|_p^p|\nabla v_b^+|_p^p.$$

Let

$$M = \begin{bmatrix} \left.\frac{\varphi^1_{v_b}(\alpha,\beta)}{\partial\alpha}\right|_{(1,1)} & \left.\frac{\varphi^2_{v_b}(\alpha,\beta)}{\partial\alpha}\right|_{(1,1)} \\ \left.\frac{\varphi^1_{v_b}(\alpha,\beta)}{\partial\beta}\right|_{(1,1)} & \left.\frac{\varphi^2_{v_b}(\alpha,\beta)}{\partial\beta}\right|_{(1,1)} \end{bmatrix}.$$

Employing condition $(\mathcal{P}_4)$ with $t \neq 0$, it follows that

$$\partial_t f(t)t^2 - (2p-1)f(t)t > 0.$$

Thus, since $v_b \in \mathcal{M}_b^\lambda$, one has

$$\begin{aligned}\det M =& \left.\frac{\varphi^1_{v_b}(\alpha,\beta)}{\partial\alpha}\right|_{(1,1)} \times \left.\frac{\varphi^2_{v_b}(\alpha,\beta)}{\partial\beta}\right|_{(1,1)} - \left.\frac{\varphi^1_{v_b}(\alpha,\beta)}{\partial\beta}\right|_{(1,1)} \times \left.\frac{\varphi^2_{v_b}(\alpha,\beta)}{\partial\alpha}\right|_{(1,1)}\\ =& \left[p\|v_b^+\|^p + bp|\nabla v_b^+|_p^p|\nabla v_b^-|_p^p + (p^*-2p)|v_b^+|_{p^*}^{p^*}\right.\\ &\left. + \lambda\int (\partial_\alpha f(v_b^+)(v_b^+)^2 - (2p-1)f(v_b^+)(v_b^+)\,\mathrm{d}x\right]\\ &\times \left[p\|v_b^-\|^p + bp|\nabla v_b^+|_p^p|\nabla v_b^-|_p^p + (p^*-2p)|v_b^-|_{p^*}^{p^*}\right.\\ &\left. + \lambda\int (\partial_\beta f(v_b^-)(v_b^-)^2 - (2p-1)f(v_b^-)(v_b^-)\,\mathrm{d}x\right]\\ &- (bp)^2|\nabla v_b^+|_p^{2p}|\nabla v_b^-|_p^{2p}\\ >& 0.\end{aligned}$$

As $(1,1)$ is the unique isolated zero of the $\mathcal{C}^1$ function $\Psi_0(\alpha,\beta)$, it follows from degree theory that $\deg(\Psi_0, D, 0) = 1$. Consequently, taking both (3.2) and (a) into account, one has

$$h(\alpha,\beta) = k(\alpha,\beta), \quad \text{on } \partial D.$$

Thus, it follows that $\deg(\Psi_1, D, 0) = 1$. Hence, $\Psi_1(\alpha_0,\beta_0) = 0$ for some $(\alpha_0,\beta_0) \in D$ so that

$$\eta(1, k(\alpha_0,\beta_0)) = h(\alpha_0,\beta_0) \in \mathcal{M}_b^\lambda.$$

Thereby contradicting (3.2). Thus, $(\mathcal{K}_b^\lambda)'(v_b) = 0$, which implies v_b is a critical point of $\mathcal{K}_b^\lambda$. Therefore, we conclude that v_b is a sign-changing solution for problem ($\mathcal{QKP}$). To conclude our proof, we show that v has exactly two nodal domains. We proceed by assuming, for contradiction, that

$$v = v_1 + v_2 + v_3, \quad \text{with } v_i \neq 0, v_1 \geqslant 0, v_2 \leqslant 0,$$

$$\operatorname{supp}(v_i) \cap \operatorname{supp}(v_j) = \emptyset, \quad \text{for } i \neq j,\ i,j = 1,2,3,$$

and

$$\langle (\mathcal{K}_b^\lambda)'(v), v_i \rangle = 0, \quad \text{for } i = 1,2,3.$$

Let $u := v_1 + v_2$, we observe that $u^+ = v_1$ and $u^- = v_2$. Thus, $u^\pm \neq 0$. Therefore, there is a unique (α_u, β_u) of positive numbers such that $\alpha_u v_1 + \beta_u v_2 \in \mathcal{M}_b^\lambda$.

Hence,

$$\mathcal{K}_b^\lambda(\alpha_u v_1 + \beta_u v_2) \geqslant c_b^\lambda.$$

Additionally, by noting that $\langle (\mathcal{K}_b^\lambda)'(v), v_i \rangle = 0$, one gets $\langle (\mathcal{K}_b^\lambda)'(u), u^\pm \rangle < 0$. From Lemma 2.1, it follows that $(\alpha_u, \beta_u) \in (0,1] \times (0,1]$. Conversely, one has

$$\begin{aligned}
0 &= \frac{1}{2p}\langle (\mathcal{K}_b^\lambda)'(v), v_3 \rangle \\
&= \frac{1}{2p}\|v_3\|^p + \frac{b}{2p}|\nabla v_3|_p^{2p} + \frac{b}{2p}|\nabla v_3|_p^p |\nabla v_1|_p^p + \frac{b}{2p}|\nabla v_3|_p^p |\nabla v_2|_p^p \\
&\quad - \frac{\lambda}{2p}\int f(v_3)v_3 \, \mathrm{d}x - \frac{1}{2p}|v|_{p^*}^{p^*} \\
&< \mathcal{K}_b^\lambda(v_3) + \frac{b}{2p}|\nabla v_3|_p^p |\nabla v_1|_p^p + \frac{b}{2p}|\nabla v_3|_p^p |\nabla v_2|_p^p.
\end{aligned}$$

Hence, by (2.17) we obtain

$$\begin{aligned}
c_b^\lambda &\leqslant \mathcal{K}_b^\lambda(\alpha_u v_1 + \beta_u v_2) \\
&= \mathcal{K}_b^\lambda(\alpha_u v_1 + \beta_u v_2) - \frac{1}{2p}\langle (\mathcal{K}_b^\lambda)'(\alpha_u v_1 + \beta_u v_2), (\alpha_u v_1 + \beta_u v_2) \rangle \\
&= \frac{1}{2p}\left(\|\alpha_u v_1\|^p + \|\beta_u v_2\|^p\right) + \frac{\lambda}{2p}\int \left[f(\alpha_u v_1)(\alpha_u v_1) - 2pF(\alpha_u v_1)\right] \, \mathrm{d}x \\
&\quad + \frac{\lambda}{2p}\int \left[f(\beta_u v_2)(\beta_u v_2) - 2pF(\beta_u v_2)\right] \, \mathrm{d}x \\
&\quad + \frac{p^* - 2p}{2pp^*}\alpha_u^{p^*}|v_1|_{p^*}^{p^*} x + \frac{p^* - 2p}{2pp^*}\beta_u^{p^*}|v_2|_{p^*}^{p^*} \\
&\leqslant \mathcal{K}_b^\lambda(v_1 + v_2) - \frac{1}{2p}\langle (\mathcal{K}_b^\lambda)'(v_1 + v_2), (v_1 + v_2) \rangle
\end{aligned}$$

$$
\begin{aligned}
&= \mathcal{K}_b^\lambda(v_1+v_2) + \frac{1}{2p}\langle(\mathcal{K}_b^\lambda)'(v), v_3\rangle + \frac{b}{2p}|\nabla v_3|_p^p|\nabla v_1|_p^p + \frac{b}{2p}|\nabla v_3|_p^p|\nabla v_2|_p^p \\
&< \mathcal{K}_b^\lambda(v_1) + \mathcal{K}_b^\lambda(v_2) + \mathcal{K}_b^\lambda(v_3) + \frac{b}{2p}\left(|\nabla v_3|_p^p + |\nabla v_2|_p^p\right)|\nabla v_1|_p^p \\
&\quad + \frac{b}{2p}\left(|\nabla v_3|_p^p + |\nabla v_1|_p^p\right)|\nabla v_2|_p^p + \frac{b}{2p}\left(|\nabla v_1|_p^p + |\nabla v_2|_p^p\right)|\nabla v_3|_p^p \\
&= \mathcal{K}_b^\lambda(v) \\
&= c_b^\lambda,
\end{aligned}
$$

this leads to a contradiction, which implies that $v_3 = 0$. Hence, v has precisely two nodal domains. Utilizing Theorem 1.3, we prove the existence of a least energy sign-changing solution v_b to problem ($\mathcal{QKP}$). □

Next, we provide a proof for Theorem 1.4, asserting that the energy of v_b is strictly greater than twice the ground state energy.

Proof of Theorem 1.4. Similarly to the proof of Lemma 2.2, there is $\lambda_1^\star > 0$ such that for all $\lambda \geqslant \lambda_1^\star$, there is $v \in \mathcal{N}_b^\lambda$ such that $\mathcal{K}_b^\lambda(v) = c_{b,\lambda}^* > 0$. Using standard arguments the critical points of the functional $\mathcal{K}_b^\lambda$ on $\mathcal{N}_b^\lambda$ are critical points of $\mathcal{K}_b^\lambda$ in W. As a result, $(\mathcal{K}_b^\lambda)'(v) = 0$, which implies that v is a ground state solution of problem ($\mathcal{QKP}$). Theorem 1.3 indicates that for all $\lambda \geqslant \lambda^\star$, there exists a least energy sign-changing solution v_b to problem ($\mathcal{QKP}$) that changes its sign only once. Define $\lambda^{\star\star} = \max\{\lambda_1^\star, \lambda^\star\}$. Assume that $v_b = v_b^+ + v_b^-$. Following the approach in the proof of Lemma 2.1, there are $\alpha_{v_b^+} > 0$ and $\beta_{v_b^-} > 0$ such that

$$
\alpha_{v_b^+} v_b^+ \in \mathcal{N}_b^\lambda, \qquad \beta_{v_b^-} v_b^- \in \mathcal{N}_b^\lambda.
$$

Moreover, according to Lemma 2.1, $\alpha_{v_b^+}, \beta_{v_b^-} \in (0,1)$. Consequently, by applying Lemma 2.1 again, one obtains

$$
\begin{aligned}
2c_{b,\lambda}^* &\leqslant \mathcal{K}_b^\lambda(\alpha_{v_b^+} v_b^+) + \mathcal{K}_b^\lambda(\beta_{v_b^-} v_b^-) \\
&\leqslant \mathcal{K}_b^\lambda(\alpha_{v_b^+} v_b^+ + \beta_{v_b^-} v_b^-) \\
&< \mathcal{K}_b^\lambda(v_b^+ + v_b^-) \\
&= c_b^\lambda.
\end{aligned}
$$

Hence, $c_{b,\lambda}^* > 0$ cannot be attained by any sign-changing function. □

Lastly, we provide the proof for Theorem 1.5.

Proof of Theorem 1.5. **Step 1:** We prove that for any sequence $\{b_n\}$, $\{v_{b_n}\}$ is bounded in W if $b_n \searrow 0$. Let $\chi \in C_0^\infty(\mathbb{R}^N)$ be a nonzero function with fixed $\chi^\pm \neq 0$. Similar to the argument presented in Lemma 2.1, for any $b \in [0,1]$, there is (τ_1, τ_2) that are independent of b, such that

$$
\langle(\mathcal{K}_b^\lambda)'(\tau_1\chi^+ + \tau_2\chi^-), \tau_1\chi^+\rangle < 0, \quad \text{and} \quad \langle(\mathcal{K}_b^\lambda)'(\tau_1\chi^+ + \tau_2\chi^-), \tau_2\chi^-\rangle < 0.
$$

As per Lemma 2.1, for any $b \in [0,1]$, there is a unique $(\alpha_\chi(b), \beta_\chi(b)) \in (0,1] \times (0,1]$ such that $\bar{\chi} := \alpha_\chi(b)\tau_1\chi^+ + \beta_\chi(b)\tau_2\chi^- \in \mathcal{M}_b^\lambda$.

Hence, using (2.4), we can deduce that for any $b \in [0,1]$,

$$\begin{aligned}
\mathcal{K}_b^\lambda(v_b) &\leqslant \mathcal{K}_b^\lambda(\bar{\chi}) \\
&= \mathcal{K}_b^\lambda(\bar{\chi}) - \frac{1}{2p}\langle (\mathcal{K}_b^\lambda)'(\bar{\chi}), \bar{\chi}\rangle \\
&= \frac{(p-1)}{2p}\|\bar{\chi}\|^p + \frac{p^*-2p}{2pp^*}|\bar{\chi}|_{p^*}^{p^*} + \frac{\lambda}{2p}\int [f(\bar{\chi})\bar{\chi} - 2pF(\bar{\chi})]\,\mathrm{d}x \\
&\leqslant \frac{(p-1)}{2p}\|\bar{\chi}\|^p + \frac{p^*-2p}{2pp^*}|\bar{\chi}|_{p^*}^{p^*} + \frac{\lambda}{2p}\left(C_\varepsilon|\bar{\chi}|_\vartheta^\vartheta + \varepsilon|\bar{\chi}|_p^p\right) \\
&\leqslant \frac{(p-1)}{2p}\left(\|\tau_1\chi^+\|^p + \|\tau_2\chi^-\|^p\right) + \frac{p^*-2p}{2pp^*}\left[|\tau_1\chi^+|_{p^*}^{p^*} + |\tau_2\chi|_{p^*}^{p^*}\right] \\
&\quad + \frac{\lambda}{2p}\left[\left(\varepsilon|\tau_1\chi^+|_p^p + C_\varepsilon|\tau_1\chi^+|_\vartheta^\vartheta\right) + \left(\varepsilon|\tau_2\chi^-|_p^p + C_\varepsilon|\tau_2\chi^-|_\vartheta^\vartheta\right)\right] \\
&= C_\chi.
\end{aligned}$$

Therefore, as $n \to \infty$, one gets

$$\begin{aligned}
C_\chi + 1 &\geqslant \mathcal{K}_{b_n}^\lambda(v_{b_n}) \\
&= \mathcal{K}_{b_n}^\lambda(v_{b_n}) - \frac{1}{2p}\langle (\mathcal{K}_{b_n}^\lambda)'(v_{b_n}), v_{b_n}\rangle \\
&\geqslant \frac{(p-1)}{2p}\|v_{b_n}\|^p.
\end{aligned}$$

Hence, $\{v_{b_n}\}$ is bounded in W.

Step 2: We demonstrate the existence of a nodal solution v_0 to problem ($\mathcal{QKP}$). As the sequence $\{v_{b_n}\}$ is bounded in W, up to a subsequence, there is $v_0 \in W$ such that

$$\begin{aligned}
v_{b_n} &\rightharpoonup v_0 && \text{in } W, \\
v_{b_n} &\to v_0 && \text{in } L^s(\mathbb{R}^N), \text{ for } s \in [p, p^*), \\
v_{b_n} &\to v_0 && \text{a.e. in } \mathbb{R}^N, \\
\nabla v_{b_n} &\to \nabla v_0 && \text{a.e. in } \mathbb{R}^N.
\end{aligned} \tag{3.3}$$

Since $\{v_{b_n}\}$ is a weak solution of problem ($\mathcal{QKP}$) with $b = b_n$, one obtains

$$\begin{aligned}
\int (|\nabla v_{b_n}|^{p-2}\nabla v_{b_n}\cdot\nabla\varphi + a(x)|v_{b_n}|^{p-2}\varphi)\,\mathrm{d}x + b_n|\nabla v_{b_n}|_p^p\int |v_{b_n}|^{p-2}\nabla v_{b_n}\cdot\nabla\varphi\,\mathrm{d}x \\
= \lambda\int f(v_{b_n})\varphi dx + \int |v_{b_n}|^{p^*-2}v_{b_n}\varphi\,\mathrm{d}x,
\end{aligned} \tag{3.4}$$

for all $\varphi \in \mathcal{C}_0^\infty(\mathbb{R}^N)$. By combining equations (3.3) and (3.4) with Step 1, we can conclude that

$$\begin{aligned}
\int (|\nabla v_0|^{p-2}\nabla v_0\cdot\nabla\varphi + a(x)|v_0|^{p-2}\varphi)\,\mathrm{d}x + b_n|\nabla v_0|_p^p\int_{\mathbb{R}^N} |v_0|^{p-2}\nabla v_0\cdot\nabla\varphi\,\mathrm{d}x \\
= \lambda\int f(v_0)\varphi\,\mathrm{d}x + \int |v_0|^{p^*-2}v_0\varphi\,\mathrm{d}x,
\end{aligned}$$

for all $\varphi \in \mathcal{C}_0^\infty(\mathbb{R}^N)$. Thus, v_0 is a weak solution to problem ($\mathcal{QKP}_0$). In a manner akin to Lemma 2.2, we can infer that $v_0^+ \neq 0$ and $v_0^- \neq 0$.

Step 3: Here, we demonstrate that problem ($\mathcal{QKP}_0$) has a least energy nodal solution u_0, and that there is a unique pair $(\alpha_{b_n}, \beta_{b_n}) \in \mathbb{R}^+ \times \mathbb{R}^+$ satisfying $\alpha_{b_n} u_0^+ + \beta_{b_n} u_0^- \in \mathcal{M}_{b_n}^\lambda$. Furthermore, we show that as $n \to \infty$, $(\alpha_{b_n}, \beta_{b_n})$ converges to $(1,1)$.

Using an approach similar to the one in the proof of Theorem 1.3, it follows that problem ($\mathcal{QKP}_0$) possesses a nodal solution u_0 with least energy, where $\mathcal{K}_0^\lambda(u_0) = c_0^\lambda$ and $(\mathcal{K}_0^\lambda)'(u_0) = 0$. Then, following Lemma 2.1, we can easily obtain the existence and uniqueness of a pair $(\alpha_{b_n}, \beta_{b_n})$ such that $\alpha_{b_n} u_0^+ + \beta_{b_n} u_0^- \in \mathcal{M}_{b_n}^\lambda$, with $\alpha_{b_n} > 0$ and $\beta_{b_n} > 0$. In order to complete the proof, it is enough to prove that $(\alpha_{b_n}, \beta_{b_n}) \to (1,1)$ as $n \to \infty$. Indeed, as $\alpha_{b_n} u_0^+ + \beta_{b_n} u_0^- \in \mathcal{M}_{b_n}^\lambda$, one has that

$$\begin{aligned} \alpha_{b_n}^p \|u_0^+\|^p + b_n \alpha_{b_n}^{2p} |\nabla u_0^+|_p^{2p} + b_n \alpha_{b_n}^p \beta_{b_n} |\nabla u_0^+|_p^p |\nabla u_0^-|_p^p \\ = \lambda \int f(\alpha_{b_n} u_0^+) \alpha_{b_n} u_0^+ \, \mathrm{d}x + \alpha_{b_n}^{p^*} |u_0^+|_{p^*}^{p^*}, \end{aligned} \tag{3.5}$$

and

$$\begin{aligned} \beta_{b_n}^p \|u_0^-\|^p + b_n \beta_{b_n}^{2p} |\nabla u_0^-|_p^{2p} + b_n \beta_{b_n}^p \alpha_{b_n} |\nabla u_0^-|_p^p |\nabla u_0^+|_p^p \\ = \lambda \int f(\alpha_{b_n} u_0^-) \beta_{b_n} u_0^- \, \mathrm{d}x + \beta_{b_n}^{p^*} |u_0^-|_{p^*}^{p^*}. \end{aligned} \tag{3.6}$$

using the fact that $b_n \searrow 0$, it follows that $\{\alpha_{b_n}\}$ and $\{\beta_{b_n}\}$ are bounded. Suppose, up to a subsequence, $\alpha_{b_n} \to \alpha_0$ and $\beta_{b_n} \to \beta_0$. Then by (3.5) and (3.6), we have

$$\alpha_0^p \|u_0^+\|^p = \lambda \int f(\alpha_0 u_0^+) \alpha_0 u_0^+ \, \mathrm{d}x + \alpha_0^{p^*} |u_0^+|_{p^*}^{p^*}, \tag{3.7}$$

and

$$\beta_0^p \|u_0^-\|^p = \lambda \int f(\beta_0 u_0^-) \beta_0 u_0^- \, \mathrm{d}x + \beta_0^{p^*} |u_0^-|_{p^*}^{p^*}. \tag{3.8}$$

Noticing that v_0 is a nodal solution to problem ($\mathcal{QKP}_0$), one has

$$\|u_0^+\|^p = \lambda \int f(u_0^+) u_0^+ \, \mathrm{d}x + |u_0^+|_{p^*}^{p^*}, \tag{3.9}$$

and

$$\|u_0^+\|^p = \lambda \int f\left(u_0^-\right) u_0^- \, \mathrm{d}x + |u_0^-|_{p^*}^{p^*}. \tag{3.10}$$

Therefore, from (3.7)–(3.10), we can easily obtain that $(\alpha_0, \beta_0) = (1,1)$. We can now complete the proof of Theorem 1.5. We claim that v_0 obtained in Step 2 is a least energy solution to problem ($\mathcal{QKP}_0$). In fact, according to Step 3 and Lemma 2.1, we see that

$$\begin{aligned} \mathcal{K}_0^\lambda(u_0) \leqslant \mathcal{K}_0^\lambda(v_0) &= \lim_{n\to\infty} \mathcal{K}_{b_n}^\lambda(v_{b_n}) \\ &\leqslant \lim_{n\to\infty} \mathcal{K}_{b_n}^\lambda(\alpha_{b_n} u_0^+ + \beta_{b_n} u_0^-) \\ &= \lim_{n\to\infty} \mathcal{K}_0^\lambda(u_0^+ + u_0^-) \\ &= \mathcal{K}_0^\lambda\left(u_0\right), \end{aligned}$$

which completes the proof of Theorem 1.5. □

Abstract. In this paper we establish existence of solutions to the following boundary value problem involving a p-gradient term

$$-\Delta_p u + g(u)|\nabla u|^p = \lambda u^\sigma + \Psi(x), \quad u > 0 \quad \text{in } \Omega, \quad u = 0 \quad \text{on } \partial\Omega,$$

where $\Delta_p := \operatorname{div}(|\nabla u|^{p-2}\nabla u)$ is p-Laplacian operator, $\Omega \subset \mathbb{R}^N$ $(N \geq 3)$ is a bounded domain with smooth boundary, $1 < p < N$, $0 < \sigma < p^* - 1$ with $p^* := pN/(N-p)$, Ψ is a measurable function and $g(s) \geq 0$ is a continuous function on the interval $(0, +\infty)$ which may have a singularity at the origin, i.e. $g(s) \to +\infty$ as $s \to 0$. Using the topological degree theory, under certain assumptions on Ψ, we prove the existence of a continuum of positive solutions.

Keywords: p-gradient term, singular equations, elliptic equations.

1 Introduction

In this paper we establish existence of a continuum of positive solutions to the following class of singular quasilinear elliptic equations with a p-gradient term,

$$\begin{cases} -\Delta_p u + g(u)|\nabla u|^p = \lambda u^\sigma + \Psi(x) & \text{in } \Omega, \\ u > 0 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \qquad (P)_{\lambda\sigma}$$

where $\Omega \subset \mathbb{R}^N$ $(N \geq 3)$ is a bounded domain with smooth boundary, $1 < p < N$, $0 < \sigma < p^* - 1$ with $p^* := pN/(N-p)$, $g : (0, \infty) \to \mathbb{R}^+$ is a continuous measurable function in a neighborhood of zero and $\Psi : \Omega \to \mathbb{R}^+$ is a L^q integrable function with $q \in \left[\frac{pN}{N(p-1)+p}, \frac{pN}{N-p}\right)$.

✉Corresponding author. Email: brunomendes@ufop.edu.br

This type of equations involving singular nonlinearities appears in the models of several physical phenomena, such as in theory of electric conductivity [19], in study of pseudoplastic fluids [14], in minimal surfaces with isolated singularities [13] and several other models.

The classic references involving the problem $(P)_{\lambda\sigma}$ were published by Leray and Lions [29] in 1965 and by Ladyzenskaya and Uraltseva [26] in 1968.

For this class of equations involving the term gradient we quote [1–5,7–9,22,31] and without the gradient term we quote [16–18,20,21,23,24,27,30,36]. For existence results involving quasilinear and parabolic elliptic problems with quadratic gradient term we quote [12] and for existence of a continuum of solutions for a quasilinear singular elliptic problem we quote [15].

In 2009, Arcoya, Barile and Martínez-Aparicio [3] studied the quasilinear elliptic boundary value problem

$$\begin{cases} -\Delta u + g(x,u)|\nabla u|^2 = a(x) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

where $\Omega \subset \mathbb{R}^N$ $(N \geq 3)$ is a bounded domain with smooth boundary and $g(x,s)$ is a Carathéodory function on $\Omega \times (0,\infty)$ which may have a singularity at $s = 0$ and may change of sign. Assuming that $a \in L^q(\Omega)$, with $q > N/2$, satisfies the following inequality

$$\inf\{a(x) \mid x \in \Omega_0\} > 0; \qquad \forall \Omega_0 \subset\subset \Omega$$

they proved that if there exist a increasing function $b : (0,+\infty) \to (0,+\infty)$ and a parameter $\mu \in (0,1)$ such that

$$-\mu \leq sg(x,s) \leq b(s); \qquad \forall s > 0; \ \ a.e. \ \ x \in \Omega,$$

then the previous problem has at least one positive solution.

In 2015, Y. Wang and M. Wang [35] extended the result obtained by Arcoya, Barile and Martínez-Aparicio [3] to the case involving the p-Laplacian operator.

Arcoya, Carmona and Martínez-Aparicio [5] studied the boundary value problem with a power type nonlinearity

$$\begin{cases} -\Delta u + g(u)|\nabla u|^2 = \lambda u^p + f_0(x) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.2}$$

where $\Omega \subset \mathbb{R}^N$ $(N \geq 3)$ is an open and bounded domain, $\lambda \geq 0$, $0 \leq p < \frac{N+2}{N-2}$, $0 \lneqq f_0 \in L^{\frac{2N}{N+2}}(\Omega)$ and $g \geq 0$ is continuous in $[0,+\infty)$ or $g \geq 0$ is continuous in $(0,+\infty)$, decreasing and integrable in a neighborhood of zero with $\lim_{s\to 0} g(s) = +\infty$. Using the Leray–Schauder degree, the authors showed the existence of "continua of solutions" of (1.2), i.e., connected and closed subsets in the solution set

$$Q := \left\{(\lambda,u) \in \mathbb{R} \times H_0^1(\Omega) : u = K(\lambda,u)\right\}$$

where $K : \mathbb{R} \times H_0^1(\Omega) \to H_0^1(\Omega)$ is an operator such that, for every $\lambda \in \mathbb{R}$ and for every $w \in H_0^1(\Omega)$, $K(\lambda,w)$ is the unique solution $u \in H_0^1(\Omega)$ of an auxiliary problem.

In this paper, we generalize the equation studied by Arcoya, Carmona and Martínez-Aparicio [5] for the p-Laplacian operator $\Delta_p := \operatorname{div}(|\nabla u|^{p-2}\nabla u)$, with a non negative continuous function g which may have a singularity at the origin and a measurable function Ψ. To

state our results, we say that $u \in W_0^{1,p}(\Omega)$ is a positive solution for $(P)_{\lambda\sigma}$ if $u > 0$ a.e $x \in \Omega$, $g(u)\,|\nabla u|^p \in L^1(\Omega)$ and

$$\int_\Omega |\nabla u|^{p-2}\nabla u \cdot \nabla \varphi dx + \int_\Omega g(u)|\nabla u|^p \varphi dx = \lambda \int_\Omega u^\sigma \varphi dx + \int_\Omega \Psi \varphi dx \tag{1.3}$$

for all $\varphi \in W_0^{1,p}(\Omega) \cap L^\infty(\Omega)$.

Our main results read as follows.

Theorem 1.1. *Let $g : (0, +\infty) \to \mathbb{R}^+$ be a continuous and integrable function in a neighborhood of zero such that $\lim_{s\to 0} g(s) = +\infty$. If $\Psi \in L^q(\Omega)$, be a function not identically zero with $q \in \left[\frac{pN}{N(p-1)+p}, \frac{pN}{N-p}\right)$, then problem $(P)_{\lambda\sigma}$ has a unique solution $u \in W_0^{1,p}(\Omega)$ for $\lambda = 0$.*

For $q = \frac{pN}{N(p-1)+p}$, Y. Wang and M. Wang [35, Theorem 3.1] proved the existence of a solution to Theorem 1.1. Before we establish the next result we need some definitions. In this way, we consider the auxiliary problem

$$\begin{cases} -\Delta_p u + g(u)|\nabla u|^p = \lambda^+ w^+(x)^\sigma + \Psi(x) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.4}$$

where $\lambda \geq 0$, $w \in W_0^{1,p}(\Omega)$ and $w^+ := \max\{0, w\}$.

By Theorem 1.1, for every $(\lambda, w) \in [0, +\infty) \times W_0^{1,p}(\Omega)$, the problem (1.4) has a unique solution $u = T(\lambda, w) \in W_0^{1,p}(\Omega)$. Thus, by following ideas of Arcoya, Carmona and Martínez-Aparicio [5], we define an operator $K : \times W_0^{1,p}(\Omega) \to W_0^{1,p}(\Omega)$ such that

$$K(\lambda, w) := \begin{cases} T(\lambda, w), & \text{if } \lambda \geq 0; \\ T(0, w), & \text{if } \lambda < 0, \end{cases}$$

and a set

$$S := \left\{(\lambda, u) \in \mathbb{R} \times W_0^{1,p}(\Omega) : u = K(\lambda, u)\right\}.$$

Notice that the function $\lambda w^+(x)^\sigma + \Psi(x)$ is in $L^q(\Omega)$, for $q = \frac{Np}{N(p-1)+p}$. Thus $K(\lambda, w)$ is well defined. Indeed,

$$\int_\Omega |\lambda w^+(x)^\sigma + \Psi(x)|^q dx \leq 2^{q-1} \int_\Omega |\lambda w^+(x)^\sigma|^q dx + 2^{q-1} \int_\Omega |\Psi(x)|^q dx,$$

and $\sigma q = \frac{N(p-1)+p}{N-p} \frac{pN}{N(p-1)+p} = \frac{pN}{N-p} = p^*$.

Therefore, with this notation, $(P)_{\lambda\sigma}$ can be rewritten as a fixed point problem, namely,

$$u = K(\lambda, u). \tag{1.5}$$

The next result is related to the case $\Psi \gneqq 0$ and it states the existence of global continua in solution set S emanating from the unique solution of Theorem 1.1.

Theorem 1.2. *Consider $0 \lneqq \Psi \in L^{\frac{pN}{N(p-1)+p}}(\Omega)$ and assume that $g \geq 0$ is continuous in $[0, +\infty)$ or $g \geq 0$ is continuous in $(0, +\infty)$ and integrable in an neighborhood of zero with $\lim_{s\to 0} g(s) = +\infty$. Then there exists an unbounded continuum $\Sigma \subset S$ of positive solutions which contains $(0, u_0)$, where u_0 is the unique solution of $(P)_{\lambda\sigma}$ for $\lambda = 0$.*

To prove Theorem 1.1 we follow some general ideas of [3,5], i.e., we construct a infinite sequence of auxiliary problems $(P)_n$ with $n \in \mathbb{N}$, such that $(P)_{\lambda\sigma}$ for $\lambda = 0$ has at least one solution as $n \to +\infty$. To prove the uniqueness of the solution we follows some general ideas of [6]. Finally, to prove Theorem 1.2 we show that K is a compact operator and using the Leray–Schauder degree theory we prove the existence of "continua of solutions" of $(P)_{\lambda\sigma}$, i.e., connected and closed subsets in the solution set S.

The main difficulties found in the proof of these results are the existence of a singularity g, the presence of the term gradient and the non-linearity of the operator in the case where $p \in (1, N)$. The case where $p = 2$ has been extensively studied by several researches. For example, in the case where g is continuous at zero the existence is due to [11] and the uniqueness to [4]. Moreover, in the case where g is singular at zero the existence is due to [10] and the uniqueness to [4].

This paper is organized as follows: in section 2 we introduce an approximated problem, whose solutions are also solutions to problem (1.4); and we prove some auxiliary lemmas. In section 3, we prove the integrability of $g(u)\,|\nabla u|^p\,\varphi$ and the compactness for the operator K defined in (1.5). After, we prove the Theorem 1.2 using the topological Leray–Schauder degree.

2 Proof of Theorem 1.1

To prove Theorem 1.1 first we give some preliminary considerations and lemmas. In this way, motivated by [2,3], we define

$$g_n(s) = \begin{cases} 0, & \text{if } s \leq 0; \\ n^p s^p T_n(g(s)), & \text{if } 0 < s < \frac{1}{n}; \\ T_n(g(s)), & \text{if } \frac{1}{n} \leq s; \end{cases} \tag{2.1}$$

where $T_n(s)$ is the truncate function given by

$$T_n(s) = \begin{cases} s, & \text{if } |s| < n; \\ -n, & \text{if } s \leq -n; \\ n, & \text{if } s \geq n. \end{cases} \tag{2.2}$$

It is easy to verify that g_n satisfies the following properties

(a) $|g_n(s)| \leq \min\{n, g(s)\}$;

(b) $g_n(s) \leq n^p s^{p-1}$, for all $s > 0$;

(c) $\lim_{n\to\infty} g_n(s) = g(s)$, for all $s > 0$.

Consider the following approximated problem

$$\begin{cases} -\Delta_p w + \frac{g_n(w)|\nabla w|^p}{1+\frac{1}{n}|\nabla w|^p} = \Psi_n(x) & \text{in } \Omega, \\ w = 0 & \text{on } \partial\Omega, \end{cases} \tag{P}_n$$

where $\Psi_n := T_n(\Psi)$.

Lemma 2.1. *There exists at least one solution $w_n \in W_0^{1,p}(\Omega) \cap C^1(\overline{\Omega})$ of the approximated problem $(P)_n$.*

Proof. Notice that, since the operator Δ_p^{-1} is an homeomorphism, using the Browder–Minty Theorem we obtain that

$$-\Delta_p : W_0^{1,p}(\Omega) \to W^{-1,p'}(\Omega) \quad \text{is a homeomorphism.} \tag{2.4}$$

Furthermore, for every $w \in C^1(\overline{\Omega})$ we define

$$F_n(w) = \Psi_n - \frac{g_n(w)|\nabla w|^p}{1 + \frac{1}{n}|\nabla w|^p},$$

and for every $u \in C^1(\overline{\Omega})$ we define the problem

$$\begin{cases} -\Delta_p w = F_n(u) & \text{in } \Omega, \\ w = 0 & \text{on } \partial\Omega. \end{cases} \tag{2.5}$$

Let $G : W_0^{1,p}(\Omega) \to \mathbb{R}$ be the functional defined by

$$G(\varphi) = \int_\Omega F_n(u)\varphi dx.$$

Since $F_n(u)$ is bounded independent of u, then G is well defined, linear and $|G(\varphi)| \leq C_n\|\varphi\|_{1,p}$, for some $C_n > 0$, i.e., $G \in W^{-1,p'}(\Omega)$. Hence, by (2.4) there exists a unique function $w \in W_0^{1,p}(\Omega)$ such that $-\Delta_p w = G$, i.e.,

$$\int_\Omega |\nabla w|^{p-2}\nabla w \nabla \varphi dx = \int_\Omega F_n(u)\varphi dx.$$

Thus, since all the assumptions of the regularity result obtained by Hai (see [24, Lemma 3.1]) are satisfied, there are constants $\alpha \in (0,1)$ and $M > 0$ such that $w \in C^{1,\alpha}(\overline{\Omega})$ and $\|w\|_{C^{1,\alpha}(\overline{\Omega})} < M$.

Let $K : C^1(\overline{\Omega}) \to C^1(\overline{\Omega})$ be the operator defined by $K(u) = w$, where w is the unique solution of (2.5). Since $K(C^1(\overline{\Omega})) \subset C^{1,\alpha}(\overline{\Omega})$ and $\|K(u)\|_{1,\alpha} \leq M$ for every $u \in C^1(\overline{\Omega})$, then K is compact. Furthermore, K is continuous. Indeed, let $\{u_k\} \subset C^1(\overline{\Omega})$ be a sequence such that $u_k \to u$ in $C^1(\overline{\Omega})$. Define now

$$w_k = K(u_k) \quad \text{and} \quad w = K(u).$$

By definition of K, we have

$$-\Delta_p w_k - (-\Delta_p w) = F_n(u_k) - F_n(u) \quad \text{in } \Omega,$$

and consequently

$$\begin{aligned} \int_\Omega \left(|\nabla u_k|^{p-2}\nabla u_k - |\nabla u|^{p-2}\nabla u\right).\nabla(w_k - w)dx &= \int_\Omega \big(F_n(u_k(x)) - F_n(u(x))\big)(w_k - w)dx \\ &\leq 2M \int_\Omega |F_n(u_k) - F_n(u)|dx. \end{aligned} \tag{2.6}$$

Since $F_n(u_k)$ is bounded and $F_n(u_k(x)) \to F_n(u(x))$ a.e. in Ω, then by the Dominated Convergence Theorem we have

$$\int_\Omega |F_n(u_k) - F_n(u)|dx \to 0,$$

as $k \to \infty$.

Thus, applying in (2.6) the inequality (see [33])

$$\langle |x|^{p-2}x - |y|^{p-2}y, x-y\rangle_e \geq C \begin{cases} \dfrac{|x-y|^2}{(|x|+|y|)^{2-p}} & \text{if } 1 < p < 2; \\ |x-y|^p & \text{if } p \geq 2, \end{cases} \tag{2.7}$$

where $x, y \in^N$ and $C := C(p)$ is a constant, we obtain

$$w_k \to w \quad \text{in } W_0^{1,p}(\Omega).$$

On the other hand, since $\|w_k\|_{C^1(\overline{\Omega})} < M$, by going to subsequence if necessary, there exists $w_0 \in C^1(\overline{\Omega})$ such that

$$w_k \to w_0 \quad \text{in } C^1(\overline{\Omega}).$$

Hence, by uniqueness of limits, we conclude $K(u_k) \to K(u)$ in $C^1(\overline{\Omega})$; i.e., K is continuous.

How K is a continuous and compact operator and $K(C^1(\overline{\Omega})) \subset B_{\tilde{M}}$, where $B_{\tilde{M}}$ is a ball centered at the origin with radius $\tilde{M}$ in $C^1(\overline{\Omega})$, then by Schauder's Fixed Point Theorem, there exists $u \in B_{\tilde{M}}$, such that $K(u) = u$. Therefore, by definition of K, we have that u is solution of $(P)_n$. □

Lemma 2.2. *If $\Psi \in L^q(\Omega)$ with $q \in \left[\frac{pN}{N(p-1)+p}, \frac{pN}{N-p}\right)$, then the solution w_n of $(P)_n$ satisfies the following statements,*

(i) *$\{w_n\}$ is bounded independent of n in $W_0^{1,p}(\Omega)$;*

(ii) *$w_n(x) > 0$, for all $x \in \Omega$.*

Proof. (i) First, we will prove that $w_n \geq 0$ in Ω. Indeed, multiplying $(P)_n$ by w_n^- and integrating in Ω, we obtain

$$\int_\Omega |\nabla w_n|^{p-2}\nabla w_n.\nabla w_n^- dx + \int_\Omega \frac{g_n(w_n)|\nabla w_n|^p}{1+\frac{1}{n}|\nabla w_n|^p} w_n^- dx = \int_\Omega \Psi_n w_n^- dx. \tag{2.8}$$

Since $w_n = w_n^+ - w_n^-$ and $\nabla w_n = \nabla w_n^+ - \nabla w_n^-$, then

$$\begin{aligned} \nabla w_n \nabla w_n^- &= (\nabla w_n^+ - \nabla w_n^-)\nabla w_n^- \\ &= \nabla w_n \nabla w_n^- - (\nabla w_n^-)^2 \\ &\quad - (\nabla w_n^-)^2. \end{aligned} \tag{2.9}$$

Furthermore, we have

$$g_n(w_n)w_n^- = 0, \quad \text{for all } w_n \in W_0^{1,p}(\Omega). \tag{2.10}$$

Then, by relations (2.8), (2.9) and (2.10), we have

$$-\int_\Omega |\nabla w_n^-|^p dx = \int_\Omega \Psi_n w_n^- dx \geq 0,$$

i.e., $w_n^- \equiv 0$. Therefore, $w_n = w_n^+ \geq 0$ in Ω.

Taking w_n as test function in $(P)_n$, we obtain

$$\begin{aligned} \int_\Omega |\nabla w_n|^p dx + \int_\Omega \frac{g_n(w_n)|\nabla w_n|^p}{1+\frac{1}{n}|\nabla w_n|^p} w_n dx &= \int_\Omega \Psi_n w_n dx \\ &\leq \int_\Omega \Psi w_n dx. \end{aligned}$$

Since $w_n \geq 0$, we have that $\frac{g_n(w_n)|\nabla w_n|^p}{1+\frac{1}{n}|\nabla w_n|} w_n \geq 0$. Thus, using Hölder's inequality, we obtain

$$\begin{aligned} \int_\Omega |\nabla w_n|^p dx &\leq \int_\Omega \Psi_n w_n dx \\ &\leq \|\Psi\|_q \|w_n\|_{q'}, \end{aligned} \tag{2.11}$$

where $q' := \frac{q}{q-1}$. Since $q \geq \frac{pN}{N(p-1)+p}$, then $q' \leq \frac{pN}{N-p}$ and $L^{p*}(\Omega) \subset L^{q'}(\Omega)$. Hence, there are constants $c_1, c_2 > 0$ such that

$$\|w_n\|_{q'} \leq c_1 \|w_n\|_{p*} \leq c_2 \|w_n\|_{1,p}.$$

By applying the previous inequality in the relation (2.11), we conclude that $\{w_n\}$ is bounded in $W_0^{1,p}(\Omega)$.

(ii) Since $w_n \geq 0$ in Ω, by item (b) of properties of g_n listed previously, we obtain

$$\frac{g_n(w_n)|\nabla w_n|^p}{1+\frac{1}{n}|\nabla w_n|^p} \leq n^p |w_n|^{p-1} n = n^{p+1} |w_n|^{p-1}. \tag{2.12}$$

Let the function $\beta : [0, +\infty) \to \mathbb{R}$ be defined by

$$\beta(s) = n^{p+1}(s)^{p-1}.$$

Notice that β is continuous, non-decreasing, $\beta(0) = 0$ and $\beta(s) > 0$, for all $s > 0$. Furthermore,

$$\int_0^1 (\beta(s)s)^{-\frac{1}{p}} ds = \infty.$$

Hence, by relation (2.12) we have

$$-\Delta_p w_n + \beta(w_n) \geq \Psi_n \geq 0 \quad \text{a.e. in } \Omega,$$

i.e., $\Delta_p w_n \leq \beta(w_n)$ a.e. in Ω.

Since $\Psi_n \not\equiv 0$, then by the Strong Principle of Maximum (see [34, Theorem 5]) we conclude that $w_n > 0$ in Ω. □

Lemma 2.3. *There are $w \in W_0^{1,p}(\Omega)$ and $q \in (1, p)$ such that*

(i) $\nabla w_n \to \nabla w$ *in* $L^q(\Omega)$;

(ii) $w > 0$ *in* Ω.

Proof. (i) Since the sequence $\{w_n\}$ is bounded in $W_0^{1,p}(\Omega)$, going if necessary to a subsequence, there exists $w \in W_0^{1,p}(\Omega)$ such that

(a) $w_n \rightharpoonup w$ in $W_0^{1,p}(\Omega)$;

(b) $w_n \to w$ in $L^p(\Omega)$;

(c) $w_n(x) \to w(x)$ a.e. in Ω.

By fixing compact set $K \subset \Omega$, we take $\phi_K \in C_0^\infty(\Omega)$ with $0 \le \phi_K \le 1$ and $\phi_K = 1$ in K. Thus, taking v_n as test function in $(P)_n$ defined by

$$v_n := \phi_K [T_\eta(w_n - w)]^+ \in W_0^{1,p}(\Omega),$$

we have

$$\int_\Omega |\nabla w_n|^{p-2}\nabla w_n \nabla v_n dx + \int_\Omega \frac{g_n(w_n)|\nabla w_n|^p}{1+\frac{1}{n}|\nabla w_n|^p} v_n dx = \int_\Omega \Psi_n v_n dx. \tag{2.13}$$

By applying in (2.13) the relations

$$\nabla v_n = \nabla \phi_K [T_\eta(w_n - w)]^+ + \phi_K \nabla [T_\eta(w_n - w)]^+$$

and

$$\frac{g_n(w_n)|\nabla w_n|^p}{1+\frac{1}{n}|\nabla w_n|^p} v_n \ge 0,$$

we obtain

$$\begin{aligned}\int_\Omega |\nabla w_n|^{p-2}\nabla w_n \phi_K \nabla [T_\eta(w_n - w)]^+ dx \\ \le \int_\Omega \Psi_n v_n dx - \int_\Omega |\nabla w_n|^{p-2}\nabla w_n \nabla \phi_K [T_\eta(w_n - w)]^+ dx.\end{aligned}$$

Hence, we have

$$\begin{aligned}\int_\Omega \phi_K \big[|\nabla w_n|^{p-2}\nabla w_n - |\nabla w|^{p-2}\nabla w\big] \nabla [T_\eta(w_n - w)]^+ dx \\ \le \int_\Omega \Psi_n v_n dx - \int_\Omega |\nabla w_n|^{p-2}\nabla w_n \nabla \phi_K [T_\eta(w_n - w)]^+ dx \\ - \int_\Omega \phi_K |\nabla w|^{p-2}\nabla w \nabla [T_\eta(w_n - w)]^+ dx.\end{aligned} \tag{2.14}$$

Since $w_n \rightharpoonup w$ in $W_0^{1,p}(\Omega)$, then we have $[T_\eta(w_n - w)]^+ \rightharpoonup 0$, i.e.,

$$\langle \phi, [T_\eta(w_n - w)]^+ \rangle \to 0 \quad \text{for all } \ \phi \in W_0^{1,p}(\Omega)^*, \tag{2.15}$$

where $W_0^{1,p}(\Omega)^*$ is the dual space of $W_0^{1,p}(\Omega)$.

Note that, by the Dominated Convergence Theorem and by relation (2.15) we obtain

$$\int_\Omega |\nabla w_n|^{p-2}\nabla w_n \nabla \phi_K [T_\eta(w_n - w)]^+ dx \to 0 \quad \text{as } n \to \infty \tag{2.16}$$

and

$$\int_\Omega \phi_K |\nabla w|^{p-2}\nabla w \nabla [T_\eta(w_n - w)]^+ dx \to 0 \quad \text{as } n \to \infty. \tag{2.17}$$

Indeed, by Hölder's inequality and by (2.15) we have

$$\left| \int_\Omega |\nabla w_n|^{p-2}\nabla w_n \nabla \phi_K [T_\eta(w_n - w)]^+ dx \right| \le \|w_n\|_{1,p}^{p-1} \left(\int_\Omega |\nabla \phi_K [T_\eta(w_n - w)]^+|^p dx \right)^{\frac{1}{p}},$$

where $\|w_n\|_{1,p}$ and $\nabla \phi_K [T_\eta(w_n - w)]^+$ are bounded and $[T_\eta(w_n - w)]^+ \to 0$ a.e. in Ω. Thus, by the Dominated Convergence Theorem the relation (2.16) holds true.

Again, by Hölder's inequality we have

$$\begin{aligned}
&\left| \int_\Omega \phi_K |\nabla w|^{p-2}\nabla w \nabla [T_\eta(w_n - w)]^+ dx \right| \\
&\qquad \leq \|w_n\|_{1,p}^{p-1} \left[\int_\Omega |\phi_k [\nabla T_\eta(w_n - w)]^+|^p dx \right]^{\frac{1}{p}} \\
&\qquad = \|w_n\|_{1,p}^{p-1} \left[\int_\Omega |\phi_k|^p . \chi_{\{x\in\Omega : |w_n - w| < \eta\}} |\nabla (w_n - w)]^+|^p dx \right]^{\frac{1}{p}}.
\end{aligned}$$

Since $|\phi_k|^p . \chi_{\{x\in\Omega:|w_n-w|<\eta\}}$ is bounded in $L^p(\Omega)^*$ and $|\phi_k|^p . \chi_{\{x\in\Omega:|w_n-w|<\eta\}} \to |\phi_k|^p$ a.e. in Ω, then by Vitali's Convergence Theorem we have

$$|\phi_K|^p . \chi_{\{x\in\Omega:|w_n-w|<\eta\}} \to |\phi_K|^p \quad \text{in } L^p(\Omega)^*.$$

Hence, since $\left|\nabla (w_n - w)^+\right|^p \rightharpoonup 0$ in $L^p(\Omega)$, then the relation (2.17) holds true.

For fixed η, combining the relations (2.14), (2.16) and (2.17), we have

$$\limsup_{n\to\infty} \int_K \left(|\nabla w_n|^{p-2}\nabla w_n - |\nabla w|^{p-2}\nabla w \right) \nabla [T_\eta(w_n - w)]^+ dx \leq C_\Psi \eta. \tag{2.18}$$

Let H_n^+ defined by

$$H_n^+(x) := \left[|\nabla w_n|^{p-2}\nabla w_n - |\nabla w|^{p-2}\nabla w \right] \nabla [T_\eta(w_n - w)]^+(x).$$

By relation (2.18) we have that H_n^+ is bounded in $L^1(K)$. Moreover, by inequality (2.7) and by definition of T_η, we have that $H_n^+ \geq 0$.

By defining the sets

$$A_n^\eta := \{x \in K : |w_n(x) - w(x)| \leq \eta\} \quad \text{and} \quad B_n^\eta := \{x \in K : |w_n(x) - w(x)| > \eta\};$$

and fixing $\nu \in (0,1)$, we obtain

$$\int_K (H_n{}^+)^\nu dx \leq \left(\int_{A_n^\eta} (H_n^+) dx \right)^\nu |A_n^\eta|^{1-\nu} + \left(\int_{B_n^\eta} (H_n^+) dx \right)^\nu |B_n^\eta|^{1-\nu}.$$

For fixed η, we have that $|B_n^\eta| \to 0$ as $n \to \infty$. Moreover, since H_n^+ is bounded in $L^1(K)$, we have

$$\limsup_{n\to\infty} \int_K (H_n^+)^\nu dx \leq (C_\Psi \eta)^\nu |\Omega|^{1-\nu}. \tag{2.19}$$

By letting $\eta \to 0$ in the previous inequality, we obtain

$$(H_n^+)^\nu \to 0 \quad \text{in } L^1(K).$$

Now, choose v_n as test function in $(P)_n$ defined by

$$v_n := \phi_K [T_\eta(w_n - w)]^- \in W_0^{1,p}(\Omega),$$

where $s^- := \max\{-s, 0\}$. Hence, repeating the arguments previously used, we can conclude that

$$(H_n^-)^\nu \to 0 \quad \text{in } L^1(K),$$

where

$$H_n^-(x) := \Big[|\nabla w_n|^{p-2}\nabla w_n - |\nabla w|^{p-2}\nabla w\Big]\nabla[(w_n - w)]^-(x).$$

Therefore, if $H_n := H_n^+ - H_n^-$, then

$$H_n(x) = \Big[|\nabla w_n|^{p-2}\nabla w_n - |\nabla w|^{p-2}\nabla w\Big]\nabla[(w_n - w)](x)$$

and $H_n \to 0$ a.e. in K.

Consider $\Omega = \bigcup_{j=1}^{\infty}\Omega_j$, such that $\Omega_j \subset\subset \Omega_{j+1} \subset\subset \Omega$.

Thus, for $K = \overline{\Omega}_1$, we have

$$H_1^1(x), H_2^1(x), H_3^1(x), \ldots, H_n^1(x) \to 0 \quad \text{a.e. in } \overline{\Omega}_1.$$

Analogously, for $K = \overline{\Omega}_2$, we have

$$H_1^2(x), H_2^2(x), H_3^2(x), \ldots, H_n^2(x) \to 0 \quad \text{a.e. in } \overline{\Omega}_2.$$

Repeating the previous process, we obtain

$$\begin{array}{ccccccccc}
H_1^1(x) & H_2^1(x) & H_3^1(x) & \ldots & H_n^1(x) & \longrightarrow 0 & \text{a.e. in} & \overline{\Omega}_1 \\
H_1^2(x) & H_2^2(x) & H_3^2(x) & \ldots & H_n^2(x) & \longrightarrow 0 & \text{a.e. in} & \overline{\Omega}_2 \\
H_1^3(x) & H_3^3(x) & H_3^3(x) & \ldots & H_n^3(x) & \longrightarrow 0 & \text{a.e. in} & \overline{\Omega}_3 \\
\vdots & \vdots & \vdots & \ddots & \vdots & & & \vdots \\
H_1^j(x) & H_2^j(x) & H_3^j(x) & \ldots & H_n^j(x) & \longrightarrow 0 & \text{a.e. in} & \overline{\Omega}_j \\
\vdots & \vdots & \vdots & & \vdots & & & \vdots
\end{array}$$

Hence, taking the diagonal sequence $\widehat{H}_j = H_j^j$, we have

$$\widehat{H}_j(x) \to 0 \quad \text{a.e. in } \Omega.$$

So, for the sequence of compact sets Ω_j, there exists a subsequence $\{H_{n'}\}$ such that

$$H_{n'}(x) \to 0 \quad \text{a.e. in } \Omega.$$

By applying again the inequality (2.7), we obtain

$$\nabla w_{n'}(x) \to \nabla w(x) \quad \text{a.e. in } \Omega.$$

Thus, since $\{\nabla w_n\}$ is bounded independent of n, by Vitali's Convergence Theorem we have

$$\nabla w_n \to \nabla w \quad \text{in } L^q(\Omega), \quad q < p.$$

(ii) Now, we will prove that w is strictly positive in Ω. Indeed, we have $w_n > 0$ in Ω with $w_n \in C^{1,\alpha}(\overline{\Omega})$ for some $\alpha \in (0,1)$. In analogy to the proof of (i), we have

$$\int_\Omega |\nabla w_n|^{p-2}\nabla w_n \nabla \varphi dx + \int_\Omega \frac{g_n(w_n)|\nabla w_n|^p}{1+\frac{1}{n}|\nabla w_n|^p}\varphi dx = \int_\Omega \Psi_n \varphi dx, \qquad \varphi \in W_0^{1,p}(\Omega). \tag{2.20}$$

Thus, taking v_n as test function in (2.20) defined by

$$v_n := e^{-\tilde{H}_n(w_n)}\varphi, \qquad \varphi \in W_0^{1,p}(\Omega)\cap L^\infty(\Omega), \qquad \varphi \geq 0,$$

where $\tilde{H}_n(t) := \int_0^t g_n(s)ds$ and $\tilde{H}_n{}'(t) := g_n(t)$, with $g_n(s) \leq g(s)$, we obtain

$$\begin{aligned} &-\int_\Omega |\nabla w_n|^p \tilde{H}_n{}'(w_n)e^{-\tilde{H}_n(w_n)}\varphi dx + \int_\Omega |\nabla w_n|^{p-2}\nabla w_n e^{-\tilde{H}_n(w_n)}\nabla\varphi dx \\ &\quad = \int_\Omega \Psi_n e^{-\tilde{H}_n(w_n)}\varphi dx - \int_\Omega \frac{g_n(w_n)|\nabla w_n|^p}{1+\frac{1}{n}|\nabla w_n|^p}e^{-\tilde{H}_n(w_n)}\varphi dx. \end{aligned}$$

By applying in the previous equation the following inequality

$$\frac{|y|^p}{1+\frac{1}{n}|y|^p} \leq |y|^p \quad \text{for every } \ y\in\mathbb{R}^n,$$

we obtain

$$\begin{aligned} &\int_\Omega |\nabla w_n|^{p-2}\nabla w_n e^{-\tilde{H}_n(w_n)}\nabla\varphi dx - \int_\Omega \Psi_n e^{-\tilde{H}_n(w_n)}\varphi dx \\ &\quad = \int_\Omega |\nabla w_n|^p \tilde{H}_n{}'(w_n)e^{-\tilde{H}_n(w_n)}\varphi dx - \int_\Omega \frac{g_n(w_n)|\nabla w_n|^p}{1+\frac{1}{n}|\nabla w_n|^p}e^{-\tilde{H}_n(w_n)}\varphi dx \\ &\quad \geq \int_\Omega g_n(w_n)|\nabla w_n|^p e^{-\tilde{H}_n(w_n)}\varphi dx - \int_\Omega g_n(w_n)|\nabla w_n|^p e^{-\tilde{H}_n(w_n)}\varphi dx \\ &\quad = 0. \end{aligned}$$

Hence,

$$\int_\Omega |\nabla w_n|^{p-2}\nabla w_n \nabla\varphi e^{-\tilde{H}_n(w_n)}dx \geq \int_\Omega \Psi_n e^{-\tilde{H}_n(w_n)}\varphi dx. \tag{2.21}$$

Define $\tilde{H}(w) = \lim_{n\to\infty}\tilde{H}_n(w_n)$. Taking the limit in (2.21) as $n\to\infty$, since $w_n > 0$ and $e^{-\tilde{H}_n(w_n)} < 1$ in Ω, we obtain

$$\begin{aligned} \int_\Omega |\nabla w|^{p-2}\nabla w\nabla\varphi e^{-\tilde{H}(w)}dx &\geq \int_\Omega \Psi e^{-\tilde{H}(w)}\varphi dx \\ &\geq \int_\Omega T_1(\Psi)e^{-\tilde{H}(w)}\varphi dx. \end{aligned} \tag{2.22}$$

Define $v(x) := \psi(w(x)) = \int_0^{w(x)} \left(e^{-\tilde{H}(s)}\right)^{\frac{1}{p-1}}dt$, where $\psi(s) := \int_0^s \left(e^{-\tilde{H}(s)}\right)^{\frac{1}{p-1}}dt$ is strictly increasing. Let z be a solution of problem

$$\begin{cases} -\Delta_p z = \dfrac{T_1(\Psi)}{e^{\tilde{H}(w)}} & \text{in } \Omega, \\ z = 0 & \text{on } \partial\Omega. \end{cases}$$

Since $\frac{T_1(\Psi)}{e^{\tilde{H}(w)}} \in L^\infty(\Omega)$, by a result of Lieberman (see [28, Theorem 1]), we have that $z \in C^{1,\alpha}(\overline{\Omega})$ for some $\alpha\in(0,1)$. Moreover, by strong maximum principle (see [34]), we conclude that $z > 0$ in Ω.

By applying in (2.22) the relation $\nabla v = \nabla w\left(e^{-\tilde{H}(w)}\right)^{\frac{1}{p-1}}$, we obtain

$$\begin{aligned} \int_\Omega |\nabla v|^{p-2}\nabla v\nabla\varphi dx &= \int_\Omega |\nabla w|^{p-2}\nabla w\nabla\varphi e^{-\tilde{H}(w)}dx \\ &\geq \int_\Omega T_1(\Psi)e^{-\tilde{H}(w)}\varphi dx. \end{aligned}$$

Hence, by weak comparison principle (see [34]), we have that $v(x) \geq z(x) > 0$ in Ω. Finally, since $\psi(w(x)) = v(x) > 0$ and ψ is strictly increasing in Ω, then $w(x) > 0$ in Ω. □

The following lemmas concerning with the uniqueness of solution will be useful in the sequel and they can be deduced by using ideas of Bénilan, Boccardo, Gallouët, Gariepy, Pierre and Vazquez [6].

Lemma 2.4. *If w is a solution of $(P)_{\lambda\sigma}$ for $\lambda = 0$, then for every $a, k > 0$*

(i) $\frac{1}{k}\int_{\{|w|<k\}} |\nabla w|^p dx \leq \int_\Omega \Psi dx$;

(ii) $\frac{1}{a}\int_{\{k<|w|<k+a\}} |\nabla w|^p dx \leq \int_\Omega T_{k,a}(w)\Psi dx \leq \int_{\{|w|>k\}} \Psi dx$,

where $T_{k,a}(s) := T_a\big(s - T_k(s)\big)$.

Lemma 2.5. *Let $1 < p < N$. If Ω is a bounded domain in $\mathbb{R}^N$ and $w \in W_0^{1,p}(\Omega)$ satisfies*

$$\frac{1}{k}\int_{\{|w|<k\}} |\nabla w|^p dx \leq M \tag{2.23}$$

for every $k > 0$, then there exists $C = C(N,p)$ such that

$$meas\,\{x \in \Omega \,:\, |w| > k\} \leq C M^{\frac{N}{N-p}} k^{-p_1}, \tag{2.24}$$

where $p_1 = \frac{N(p-1)}{N-p}$.

Completing the proof of Theorem 1.1: Let u and v solutions of $(P)_{\lambda\sigma}$ for $\lambda = 0$, so

$$\int_\Omega |\nabla u|^{p-2}\nabla u \nabla \varphi dx + \int_\Omega g(u)|\nabla u|^p \varphi dx = \int_\Omega \Psi \varphi dx \tag{2.25}$$

and

$$\int_\Omega |\nabla v|^{p-2}\nabla v \nabla \varphi dx + \int_\Omega g(v)|\nabla v|^p \varphi dx = \int_\Omega \Psi \varphi dx, \tag{2.26}$$

for all $\varphi \in W_0^{1,p}(\Omega) \cap L^\infty(\Omega)$.

For every $h \geq 0$, choosing $\varphi = T_k(u - T_h v)^+$ and $\varphi = T_k(v - T_h u)^+$ in (2.25) and (2.26), respectively, we obtain

$$\int_{\{|u-T_h v|<k\}} \langle |\nabla u|^{p-2}\nabla u, \nabla(u - T_h v)^+\rangle dx \leq \int_\Omega T_k(u - T_h v)^+ \Psi dx$$

and

$$\int_{\{|v-T_h u|<k\}} \langle |\nabla v|^{p-2}\nabla v, \nabla(v - T_h u)^+\rangle dx \leq \int_\Omega T_k(v - T_h u)^+ \Psi dx.$$

Thus, if we define

$$I := \int_{\{|u-T_h v|<k\}} \langle |\nabla u|^{p-2}\nabla u, \nabla(u - T_h v)^+\rangle dx + \int_{\{|v-T_h u|<k\}} \langle |\nabla v|^{p-2}\nabla v \nabla(v - T_h u)^+\rangle dx, \tag{2.27}$$

the conclusion $u = v$ will be reached after passing to the limit $h \to \infty$ in the previous relations and disregarding some positive terms. We will to split the previous integrals into the contributions corresponding to different integration sets.

Consider the following set

$$A_0 := \{x \in \Omega \,:\, |u - v| < k,\ |u| < h,\ |v| < h\}.$$

Thus, when restricted to A_0 the first member of (2.27) gives the following main contribution

$$\begin{aligned} I_0 &:= \int_{A_0} \langle |\nabla u|^{p-2}\nabla u, \nabla (u-v)^+ \rangle dx + \int_{A_0} \langle |\nabla v|^{p-2}\nabla v, \nabla (v-u)^+ \rangle dx \\ &= \int_{A_0} \langle |\nabla u|^{p-2}\nabla u - |\nabla v|^{p-2}\nabla v, \nabla (u-v)^+ \rangle dx. \end{aligned}$$

The remaining first member of (2.27) is estimated taking the first term on the set

$$A_1 := \{x \in \Omega \ : \ |u - T_h v| < k, \ |v| > h\},$$

i.e.,

$$\int_{A_1} \langle |\nabla u|^{p-2}\nabla u, \nabla (u - T_h v)^+ \rangle dx = \int_{A_1} |\nabla u|^p dx \geq 0.$$

On the remaining set

$$A_2 := \{x \in \Omega \ : \ |u - T_h v| < k, \ |v| < h, \ |u| \geq h\}$$

we have

$$\begin{aligned} \int_{A_2} \langle |\nabla u|^{p-2}\nabla u, \nabla (u - T_h v)^+ \rangle dx &= \int_{A_2} \langle |\nabla u|^{p-2}\nabla u, \nabla (u - v)^+ \rangle dx \\ &\geq - \int_{A_2} |\nabla u|^{p-2}\nabla u \nabla v dx. \end{aligned}$$

Now, we estimate the second member of (2.27) in the sets A_1' where $|u| \geq h$, and A_2', where $|u| < h$ and $|v| \geq h$. Notice that all these sets and integrals depend of k and h.

Summing up we estimate the first member of (2.27) as follows

$$I \geq I_0 - I_3,$$

where

$$I_3 := \int_{A_2} |\nabla u|^{p-2}\nabla u \nabla v dx + \int_{A_2'} |\nabla v|^{p-2}\nabla v \nabla u dx.$$

Now, we will check that $I_3 \to 0$ as $h \to \infty$. Indeed, the first term of I_3 can be estimated by

$$\begin{aligned} \int_{A_2} |\nabla u|^{p-2}\nabla u \nabla v dx &\leq \left(\int_{A_2} |\nabla u|^{(p-1)\frac{p}{p-1}} dx \right)^{\frac{p-1}{p}} \left(\int_{A_2'} |\nabla v|^p dx \right)^{\frac{1}{p}} \\ &= \left(\int_{\{h \leq |u| \leq h+k\}} |\nabla u|^p dx \right)^{\frac{p-1}{p}} \left(\int_{\{h-k \leq |v| \leq h\}} |\nabla v|^p dx \right)^{\frac{1}{p}} \\ &= \|u\|^{p-1}_{L^p(\{h \leq |u| \leq h+k\})} \|v\|_{L^p(\{h \leq |u| \leq h+k\})}, \end{aligned}$$

which converges to 0 as $h \to \infty$ due to Lemmas 2.4 and 2.5. The treatment of the second term is analogous.

Now, we will estimate

$$\int_\Omega \Psi \left[T_k(u - T_h v)^+ - T_k(v - T_h u)^+ \right] dx.$$

The previous integral on the set $B_0 := \{x \in \Omega \ : \ |u| < h, \ |v| < h\}$ gives

$$J_0 := \int_{B_0} \Psi \left[T_k(u - T_h v)^+ - T_k(v - T_h u)^+ \right] dx = 0.$$

The integral on the set $B_1 := \{x \in \Omega \ : \ |u| \geq h\}$ is estimate by

$$\begin{aligned} |J_1| &:= \left| \int_{B_1} \Psi \left[T_k(u - T_h v)^+ - T_k(v - T_h u)^+ \right] dx \right| \\ &= \left| \int_{B_1} \Psi \left[T_k(u - T_h v)^+ - T_k(v - h)^+ \right] dx \right| \\ &\leq 2k \int_{B_1} |\Psi| dx, \end{aligned}$$

while on $B_2 := \{x \in \Omega \ : \ |v| \geq h\}$ we get

$$\begin{aligned} |J_2| &:= \left| \int_{B_2} \Psi \left[T_k(u - T_h v)^+ - T_k(v - T_h u)^+ \right] dx \right| \\ &= \left| \int_{B_2} \Psi \left[T_k(u - h)^+ - T_k(v - Thu)^+ \right] dx \right| \\ &\leq 2k \int_{B_2} |\Psi| dx. \end{aligned}$$

Since the measure of both sets $B_1(h,k)$ and $B_2(h,k)$ converges to zero as $h \to \infty$ for fixed $k > 0$, then $J_1 + J_2 \to 0$ as $h \to \infty$.

Combining the previous estimates, for fixed $k > 0$, we get from (2.27)

$$\int_{A_0(h,k)} \langle |\nabla u|^{p-2} \nabla u - |\nabla v|^{p-2} \nabla v, \nabla (u - v)^+ \rangle dx \leq \varpi(h),$$

where $\lim_{h \to \infty} \varpi(h) = 0$.

Since the set $A_0(h,k)$ converges to $\{x \in \Omega \ : \ |u - v| < k\}$, then

$$\int_{\{x \in \Omega \ : \ |u-v| < k\}} \langle |\nabla u|^{p-2} \nabla u - |\nabla v|^{p-2} \nabla v, \nabla (u - v)^+ \rangle dx \leq 0, \qquad k > 0 \text{ fixed.}$$

Since the previous inequality is true for all $k > 0$, we conclude by (2.7) that $\nabla u(x) = \nabla v(x)$ a.e. in Ω. Thus, since $u, v \in W_0^{1,p}(\Omega)$ then $u(x) = v(x)$ a.e. in Ω.

Now, we will prove that w satisfies

$$\int_\Omega |\nabla w|^{p-2} \nabla w \nabla \varphi dx + \int_\Omega g(w) |\nabla w|^p \varphi dx = \int_\Omega \Psi \varphi dx, \tag{2.28}$$

for all $\varphi \in W_0^{1,p}(\Omega) \cap L^\infty(\Omega)$.

Indeed, we have

$$\int_\Omega |\nabla w_n|^{p-2} \nabla w_n \nabla \varphi dx + \int_\Omega \frac{g(w_n) |\nabla w_n|^p}{1 + \frac{1}{n} |\nabla w_n|^p} \varphi dx = \int_\Omega \Psi_n \varphi dx \leq \int_\Omega \Psi \varphi dx, \tag{2.29}$$

for all $\varphi \in W_0^{1,p}(\Omega) \cap L^\infty(\Omega)$ with $\varphi \geq 0$.

For every $\epsilon > 0$, taking $\varphi = \frac{1}{\epsilon} T_\epsilon(w_n)$ as test function in the previous relation, we have

$$\begin{aligned} \frac{1}{\epsilon} \int_\Omega |\nabla w_n|^{p-2} \nabla w_n \nabla T_\epsilon(w_n) dx + \int_\Omega \frac{g(w_n) |\nabla w_n|^p}{1 + \frac{1}{n} |\nabla w_n|^p} \frac{1}{\epsilon} T_\epsilon(w_n) dx &= \int_\Omega \Psi_n \frac{1}{\epsilon} T_\epsilon(w_n) dx \\ &\leq \int_\Omega \Psi_n dx; \end{aligned}$$

hence,

$$\int_\Omega \frac{g(w_n)|\nabla w_n|^p}{1+\frac{1}{n}|\nabla w_n|^p}\frac{T_\epsilon(w_n)}{\epsilon}dx \le \int_\Omega \Psi_n dx. \tag{2.30}$$

Since $\frac{T_\epsilon(w_n(x))}{\epsilon} = \frac{1}{\epsilon}w_n(x)\chi_{\{x\in\Omega\,:\,w_n\le\epsilon\}} + \chi_{\{x\in\Omega\,:\,w_n>\epsilon\}}$ for every $x\in\Omega$, then $w_n(x) > \epsilon$ and $T_\epsilon(w_n(x)) = \epsilon$ as $\epsilon\to 0$. Taking the limit in (2.30) as $\epsilon\to 0$, by the Dominated Convergence Theorem, we have

$$\int_\Omega \frac{g(w_n)|\nabla w_n|^p}{1+\frac{1}{n}|\nabla w_n|^p}dx \le \int_\Omega \Psi_n dx, \tag{2.31}$$

i.e.,

$$\frac{g(w_n)|\nabla w_n|^p}{1+\frac{1}{n}|\nabla w_n|^p}\varphi \in L^1(\Omega), \qquad \forall \varphi \in W_0^{1,p}(\Omega)\cap L^\infty(\Omega).$$

Define $A_n := |\nabla w_n|^{p-2}\nabla w_n\nabla\varphi$ and $B_n := \frac{g(w_n)|\nabla w_n|^p}{1+\frac{1}{n}|\nabla w_n|^p}\varphi$. So, using Fatou's lemma in (2.29), we obtain

$$\begin{aligned}\int_\Omega |\nabla w|^{p-2}\nabla w\nabla\varphi dx + \int_\Omega g(w)|\nabla w|^p\varphi dx &\le \liminf_{n\to\infty}\left(\int_\Omega (A_n+B_n)\varphi dx\right)\\ &\le \int_\Omega \Psi\varphi dx,\end{aligned}$$

i.e.,

$$\int_\Omega |\nabla w|^{p-2}\nabla w\nabla\varphi dx + \int_\Omega g(w)|\nabla w|^p\varphi dx \le \int_\Omega \Psi\varphi dx, \tag{2.32}$$

for all $\varphi\in W_0^{1,p}(\Omega)\cap L^\infty(\Omega)$ with $\varphi\ge 0$.

Now, define $S(t) := \int_0^t \beta(s)ds$, $\beta\ge 0$ measurable, and take $\varphi\in W_0^{1,p}(\Omega)\cap L^\infty(\Omega)$, $\varphi\ge 0$ and $k>0$. Thus, taking v_n as test function in $(P)_n$ defined by

$$v_n := e^{-S(w_n)}e^{S(T_k(w_n))}\varphi,$$

we obtain

$$\begin{aligned}&\int_\Omega |\nabla w_n|^{p-2}\nabla w_n\nabla\varphi e^{-S(w_n)}e^{S(T_k(w_n))}dx\\ &\quad+\int_\Omega |\nabla w_n|^{p-2}\nabla w_n\nabla T_k(w_n)\beta(T_k(w_n))e^{-S(w_n)}e^{S(T_k(w_n))}\varphi dx\\ &=\int_\Omega |\nabla w_n|^{p-2}\nabla w_n\nabla w_n\beta(w_n)e^{-S(w_n)}e^{S(w_n)}\varphi dx\\ &\quad-\int_\Omega \frac{g(w_n)|\nabla w_n|^p}{1+\frac{1}{n}|\nabla w_n|^p}e^{-S(w_n)}e^{S(T_k(w_n))}\varphi dx\\ &\quad+\int_\Omega \Psi_n e^{-S(w_n)}e^{S(T_k(w_n))}\varphi dx\\ &\ge 0,\end{aligned}$$

because

$$\int_\Omega \frac{g(w_n)|\nabla w_n|^p}{1+\frac{1}{n}|\nabla w_n|^p}e^{-S(w_n)}e^{S(T_k(w_n))}\varphi dx \le \int_\Omega \Psi_n e^{-S(w_n)}e^{S(T_k(w_n))}\varphi dx.$$

Again, by Fatou's lemma, we have

$$\begin{aligned}
&\int_\Omega |\nabla w|^{p-2}\nabla w\nabla\varphi e^{-S(w)}e^{S(T_k(w))}dx \\
&\quad + \int_\Omega |\nabla w|^{p-2}\nabla w\nabla T_k(w)\beta(T_k(w))e^{-S(w)}e^{S(T_k(w))}\varphi dx \\
&\geq \int_\Omega |\nabla w|^{p-2}\nabla w\nabla w\beta(w)e^{-S(w)}e^{S(w)}\varphi dx \\
&\quad - \int_\Omega g(w)|\nabla w|^p e^{-S(w)}e^{S(T_k(w))}\varphi dx \\
&\quad + \int_\Omega \Psi e^{-S(w)}e^{S(T_k(w))}\varphi dx,
\end{aligned}$$

as $n \to \infty$. Since $0 \leq e^{-S(w)}e^{S(T_k(w))} \leq 1$, by letting $k \to \infty$, it follows immediately from the previous inequality that

$$\int_\Omega |\nabla w|^{p-2}\nabla w\nabla\varphi dx + \int_\Omega g(w)|\nabla w|^p\varphi dx \geq \int_\Omega \Psi\varphi dx, \tag{2.33}$$

for all $\varphi \in W_0^{1,p}(\Omega)\cap L^\infty(\Omega)$ with $\varphi \geq 0$.

Hence, using the relations (2.32) and (2.33), we conclude that the equality (2.28) holds for all $\varphi \in W_0^{1,p}(\Omega)\cap L^\infty(\Omega)$ with $\varphi \geq 0$.

Thus, since $\varphi := \varphi^+ - \varphi^-$ and $\varphi^+, \varphi^- \geq 0$, we obtain

$$\int_\Omega |\nabla w|^{p-2}\nabla w\nabla\varphi dx + \int_\Omega g(w)|\nabla w|^p\varphi dx = \int_\Omega \Psi\varphi dx$$

for all $\varphi \in W_0^{1,p}(\Omega)\cap L^\infty(\Omega)$.

Therefore, $(P)_{\lambda\sigma}$ has unique solution in $W_0^{1,p}(\Omega)$ for $\lambda = 0$. □

3 Proof of Theorem 1.2

In this section, first we prove some results which are used in the proof of our main theorem. Notice that our definition of solution of $(P)_{\lambda\sigma}$ includes the integrability of $g(u)|\nabla u|^p$. Using some ideas of Arcoya, Carmona and Martínez-Aparicio [5], we will see in the following result that a consequence is the integrability of $g(u)|\nabla u|^p\varphi$ for all $\varphi \in W_0^{1,p}(\Omega)$.

Lemma 3.1. *If $0 < u \in W_0^{1,p}(\Omega)$ is a solution for $(P)_{\lambda\sigma}$, then $g(u)|\nabla u|^p\varphi$ is integrable in Ω for all $\varphi \in W_0^{1,p}(\Omega)$. Moreover, we have*

$$\int_\Omega |\nabla u|^{p-2}\nabla u\cdot\nabla\varphi dx + \int_\Omega g(u)|\nabla u|^p\varphi dx = \lambda\int_\Omega u^\sigma\varphi dx + \int_\Omega \Psi\varphi dx. \tag{3.1}$$

Proof. Since $\sigma \leq p^* - 1$, note that u^σ, $u^\sigma\varphi \in L^1(\Omega)$. Indeed, since $u \in L^p(\Omega)$ and $W_0^{1,p}(\Omega) \hookrightarrow L^{p^*}(\Omega)$ for $p < N$, we have

$$\int_\Omega u^\sigma dx \leq \int_\Omega |u|^\sigma dx < \infty.$$

On the other hand, we have

$$\sigma\frac{p^*}{p^*-1} \leq (p^*-1)\frac{p^*}{p^*-1} = p^*;$$

thus, by Hölder's inequality we obtain

$$\begin{aligned}\int_\Omega u^\sigma \varphi dx &\le \left[\left(\int_\Omega |u|^{\sigma\frac{p^*}{p^*-1}}dx\right)^{\frac{p^*-1}{\sigma p^*}}\right]^\sigma \left(\int_\Omega |\varphi|^{p^*}dx\right)^{\frac{1}{p^*}} \\ &\le C\|u\|_{1,p}^\sigma \|\varphi\|.\end{aligned} \tag{3.2}$$

Hence, by previous relations, we conclude that $u^\sigma,\ u^\sigma\varphi \in L^1(\Omega)$.

By taking $T_k(\varphi^+)$ as test function in (1.3) and using Hölder's inequality we have

$$\begin{aligned}\int_\Omega g(u)|\nabla u|^p T_k(\varphi^+)dx &= -\int_\Omega |\nabla u|^{p-2}\nabla u \nabla T_k(\varphi^+)dx + \int_\Omega (\lambda u^\sigma + \Psi)T_k(\varphi^+)dx \\ &\le \int_\Omega |\nabla u|^{p-1}|\nabla T_k(\varphi^+)|dx + \int_\Omega (\lambda u^\sigma + \Psi)T_k(\varphi^+)dx \\ &\le \left(\int_\Omega (|\nabla u|^{p-1})^{\frac{p}{p-1}}\right)^{\frac{p-1}{p}} \left(\int_\Omega |\nabla T_k(\varphi^+)|^p dx\right)^{\frac{1}{p}} \\ &\quad + \int_\Omega (\lambda u^\sigma + \Psi)T_k(\varphi^+)dx \\ &\le \|u\|_{1,p}^{p-1}\|\varphi\|_{1,p} + \int_\Omega (\lambda u^\sigma + \Psi)T_k(\varphi^+)dx.\end{aligned}$$

Now, by taking limit as $k \to \infty$ and using Fatou's lemma, we deduce that $g(u)|\nabla u|^p\varphi^+ \in L^1(\Omega)$ with

$$\int_\Omega g(u)|\nabla u|^p\varphi^+ dx \le \|u\|_{1,p}\|\varphi\|_{1,p} + \int_\Omega (\lambda u^\sigma + \Psi)\varphi^+ dx. \tag{3.3}$$

Similarly, by taking $T_k(-\varphi^-)$ as test function in (1.3), we obtain that $g(u)|\nabla u|^p\varphi^- \in L^1(\Omega)$ with

$$-\int_\Omega g(u)|\nabla u|^p\varphi^- dx \le \|u\|_{1,p}\|\varphi^-\|_{1,p} + \int_\Omega (\lambda u^\sigma - \Psi)\varphi^- dx. \tag{3.4}$$

By combining the relations (3.3) and (3.4), we conclude that $g(u)|\nabla u|^p\varphi \in L^1(\Omega)$ for all $\varphi \in W_0^{1,p}(\Omega)$ with

$$\int_\Omega g(u)|\nabla u|^p\varphi dx \le \|u\|_{1,p}\|\varphi\|_{1,p} + \int_\Omega (\lambda u^\sigma + \Psi)\varphi dx.$$

Lastly, note that this integrability of $g(u)|\nabla u|^p\varphi$ allows to use a density argument to conclude (3.1) from (1.3). □

The next result will be related with the compactness for the operator $K(\lambda, w)$ defined in (1.5).

Lemma 3.2. *Assume that $\Psi \in L^q(\Omega)$ with $q = \frac{pN}{N(p-1)+p}$, $g \ge 0$ is continuous in $[0,+\infty)$ or $g \ge 0$ is continuous in $(0,+\infty)$ and integrable in an neighborhood of zero with $\lim_{s\to 0} g(s) = +\infty$. If the sequences $\{t_n\} \subset [0,1]$ and $\{\lambda_n\} \subset (0,\infty)$ are convergent, respectively, to t^* and λ, and $\{w_n\} \subset W_0^{1,p}(\Omega)$ weakly convergent to w, then the sequence of (uniquely defined) solutions $\{u_n\} \subset W_0^{1,p}(\Omega)$ of*

$$\begin{cases} -\Delta_p u_n + t_n g(u_n)|\nabla u_n|^p = \lambda_n (w_n^+(x))^\sigma + \Psi(x) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{3.5}$$

is strongly convergent in $W_0^{1,p}(\Omega)$ to the solution u of

$$\begin{cases} -\Delta_p u + t^* g(u)|\nabla u|^p = \lambda (w^+(x))^\sigma + \Psi(x) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases} \tag{3.6}$$

Proof. Since the functions $\lambda_n(w_n^+(x))^\sigma + \Psi(x)$ and $\lambda(w^+(x))^\sigma + \Psi(x)$ are in $L^q(\Omega)$ with $q = \frac{pN}{N(p-1)+p}$, then by Theorem 1.1 the existence of an unique solution of (3.5) and (3.6) it is holds. Indeed, we have that

$$\int_\Omega |\lambda w_n^+(x)^\sigma + \Psi(x)|^q dx \leq 2^{q-1}\int_\Omega |\lambda w_n^+(x)^\sigma|^q dx + 2^{q-1}\int_\Omega |\Psi(x)|^q dx$$

and $\sigma q \leq \frac{N(p-1)+p}{N-P}\frac{pN}{N(p-1)+p} = \frac{pN}{N-p} = p^*$.

In order to prove the compactness of $K(\lambda, u)$ is suffices to prove that every subsequence of $\{u_n\}$ possesses a subsequence converging to the unique solution $u \in W_0^{1,p}(\Omega)$ of (3.6). First we will prove that $\{u_n\}$ is a bounded sequence in $W_0^{1,p}(\Omega)$. Indeed, choosing u_n as test function in (3.5) and using that t_n and $g(u_n)$ are nonnegative, we have

$$\begin{aligned}\int_\Omega |\nabla u_n|^p dx &\leq \int_\Omega |\nabla u_n|^p dx + t_n\int_\Omega g(u_n)|\nabla u_n|^p u_n dx \\ &= \lambda_n\int_\Omega (w_n^+(x))^\sigma u_n dx + \int_\Omega \Psi u_n dx.\end{aligned} \tag{3.7}$$

Since $W_0^{1,p}(\Omega) \hookrightarrow L^{p*}(\Omega)$, by Hölder's inequality we obtain

$$\int_\Omega \Psi u_n dx \leq C\|\Psi\|_{\frac{pN}{N(p-1)+p}}\|u_n\|_{1,p}. \tag{3.8}$$

Furthermore, since $\sigma\frac{N(p-1)+p}{pN} = \frac{p^*}{p^*-1} \leq p^*$, again by Hölder's inequality we have

$$\begin{aligned}\lambda_n\int_\Omega (w_n^+(x))^\sigma u_n dx &\leq C\left[\left(\int_\Omega |w_n|^{\sigma\frac{N(p-1)+p}{pN}} dx\right)^{\frac{pN}{\sigma[N(p-1)+p]}}\right]^\sigma \left(\int_\Omega |u_n|^{\frac{pN}{N-p}} dx\right)^{\frac{N-p}{pN}} \\ &\leq \overline{C}\|w_n\|_{p^*}^\sigma \|u_n\|_{p^*} \\ &\leq \overline{\overline{C}}\|w_n\|_{1,p}^\sigma \|u_n\|_{1,p}.\end{aligned} \tag{3.9}$$

By combining the relations (3.7), (3.8) and (3.9) we conclude that

$$\|u_n\|_{1,p} \leq \left[C\|w_n\|_{1,p}^\sigma + \|\Psi\|_{\frac{pN}{N(p-1)+p}}\right]^{\frac{1}{p-1}}.$$

Therefore, $\{u_n\}$ is a bounded sequence in $W_0^{1,p}(\Omega)$. Thus, going if necessary to a subsequence, still denoted by $\{u_n\}$, there exists $\overline{u} \in W_0^{1,p}(\Omega)$ such that $u_n \rightharpoonup \overline{u}$ weakly in $W_0^{1,p}(\Omega)$.

Repeating the arguments used in the proof Lemma 2.3, we obtain that

$$\nabla u_n(x) \to \nabla\overline{u}(x) \quad \text{a.e in } \Omega \quad \text{and} \quad \nabla u_n \to \nabla\overline{u} \quad \text{in } L^q(\Omega), \quad q < p.$$

Now, we will prove that $\overline{u}$ satisfies the following equality

$$\int_\Omega |\nabla\overline{u}|^{p-2}\nabla\overline{u}\cdot\nabla\varphi dx + t^*\int_\Omega g(\overline{u})|\nabla\overline{u}|^p\varphi dx = \int_\Omega (\lambda(w^+)^\sigma + \Psi)\varphi dx, \quad \varphi \in W_0^{1,p}(\Omega). \tag{3.10}$$

First, we will show that $\overline{u} > 0$ in Ω. Indeed, we have

$$\int_\Omega |\nabla u_n|^{p-2}\nabla u_n\cdot\nabla\varphi dx + t_n\int_\Omega g(u_n)|\nabla u_n|^p\varphi dx = \int_\Omega (\lambda_n(w_n^+)^\sigma + \Psi)\varphi dx, \quad \varphi \in W_0^{1,p}(\Omega). \tag{3.11}$$

Thus, choosing v_n as test function in the previous equality such that

$$v_n := e^{-H(u_n)}\varphi, \quad \varphi \in W_0^{1,p}(\Omega) \cap L^\infty(\Omega), \quad \varphi \geq 0,$$

we obtain

$$\begin{aligned} -\int_\Omega |\nabla u_n|^p H'(u_n) e^{-H(u_n)}\varphi dx + \int_\Omega |\nabla u_n|^{p-2}\nabla u_n e^{-H(u_n)}\nabla\varphi dx \\ = \int_\Omega (\lambda_n (w_n^+)^\sigma + \Psi) e^{-H(u_n)}\varphi dx - t_n \int_\Omega g(u_n)|\nabla u_n|^p e^{-H(u_n)}\varphi dx, \end{aligned}$$

where $H(t) := \int_0^t g(s)ds$.

By ordering the terms of the previous equation, by using $H_n'(t) = g(t)$, we obtain

$$\begin{aligned} &\int_\Omega |\nabla u_n|^{p-2}\nabla u_n e^{-H(u_n)}\nabla\varphi dx - \int_\Omega (\lambda_n (w_n^+)^\sigma + \Psi) e^{-H(u_n)}\varphi dx \\ &\quad = (1 - t_n)\int_\Omega g(u_n)|\nabla u_n|^p e^{-H(u_n)}\varphi dx \\ &\quad \geq 0, \end{aligned}$$

i.e.,

$$\int_\Omega |\nabla u_n|^{p-2}\nabla u_n \nabla\varphi e^{-H(u_n)} dx \geq \int_\Omega (\lambda_n (w_n^+)^\sigma + \Psi) e^{-H(u_n)}\varphi dx.$$

Thus, by taking limit as $n \to \infty$, we have

$$\int_\Omega |\nabla \overline{u}|^{p-2}\nabla \overline{u}\nabla\varphi e^{-H(\overline{u})} dx \geq \int_\Omega (\lambda (w^+)^\sigma + \Psi) e^{-H(\overline{u})}\varphi dx. \tag{3.12}$$

Define $v(x) := \psi(\overline{u}(x)) = \int_0^{\overline{u}(x)} \left(e^{-H(s)}\right)^{\frac{1}{p-1}} dt$, where $\psi(s) := \int_0^s \left(e^{-H(s)}\right)^{\frac{1}{p-1}} dt$ is strictly increasing. Let z be a solution of problem

$$\begin{cases} -\Delta_p z = \dfrac{T_1((w^+)^\sigma + \Psi)}{e^{H(\overline{u})}} & \text{in } \Omega, \\ z = 0 & \text{on } \partial\Omega. \end{cases}$$

Since $\frac{T_1(\Psi)}{e^{H(\overline{u})}} \in L^\infty(\Omega)$, by a result of Lieberman (see [28, Theorem 1]), we have that $z \in C^{1,\alpha}(\overline{\Omega})$ for some $\alpha \in (0,1)$. Furthermore, by strong maximum principle, we conclude that $z > 0$ in Ω. By applying in (3.12) the relation $\nabla v = \nabla \overline{u}\left(e^{-H(\overline{u})}\right)^{\frac{1}{p-1}}$, we obtain

$$\int_\Omega |\nabla v|^{p-2}\nabla v\nabla\varphi dx \geq \int_\Omega T_1(\Psi) e^{-H(\overline{u})}\varphi dx.$$

Thus, by weak comparison principle, we have $v(x) \geq z(x) > 0$ in Ω. However, since $\psi(\overline{u}(x)) := v(x) > 0$ and ψ is strictly increasing in Ω, then $\overline{u}(x) > 0$ in Ω.

Now, we resume the proof of (3.10). For every $\epsilon > 0$, taking $\varphi := \frac{1}{\epsilon} T_\epsilon(u_n)$ as test function in (3.10), we obtain

$$\begin{aligned} \frac{1}{\epsilon}\int_\Omega |\nabla u_n|^{p-2}\nabla u_n \nabla T_\epsilon(u_n) dx + t_n \int_\Omega g(u_n)|\nabla u_n|^p \frac{1}{\epsilon} T_\epsilon(u_n) dx &= \int_\Omega (\lambda_n (w_n^+)^\sigma + \Psi)\frac{1}{\epsilon} T_\epsilon(u_n) dx \\ &\leq \int_\Omega (\lambda_n (w_n^+)^\sigma + \Psi) dx; \end{aligned}$$

hence,

$$t_n \int_\Omega g(u_n)|\nabla u_n|^p \frac{T_\epsilon(u_n)}{\epsilon} dx \leq \int_\Omega (\lambda_n (w_n^+)^\sigma + \Psi) dx. \tag{3.13}$$

Since $\frac{T_\epsilon(u_n(x))}{\epsilon} = \frac{1}{\epsilon}u_n(x)\chi_{\{x\in\Omega\,:\,w_n\le\epsilon\}} + \chi_{\{x\in\Omega\,:\,u_n>\epsilon\}}$ for every $x\in\Omega$, then $u_n(x) > \epsilon$ and $T_\epsilon(u_n(x)) = \epsilon$ as $\epsilon\to 0$. Taking the limit in (3.13) as $\epsilon\to 0$, by the Dominated Convergence Theorem, we have

$$t_n\int_\Omega g(u_n)|\nabla u_n|^p dx \le \int_\Omega(\lambda_n(w_n^+)^\sigma + \Psi)dx, \tag{3.14}$$

i.e.,

$$g(u_n)|\nabla u_n|^p\varphi \in L^1(\Omega), \qquad \forall\varphi\in W_0^{1,p}(\Omega)\cap L^\infty(\Omega).$$

Define $A_n := |\nabla u_n|^{p-2}\nabla u_n\nabla\varphi$ and $B_n := g(u_n)|\nabla u_n|^p\varphi$. Hence, using Fatou's lemma in (3.14), we have

$$\begin{aligned}\int_\Omega|\nabla\overline{u}|^{p-2}\nabla\overline{u}\nabla\varphi dx + t^*\int_\Omega g(\overline{u})|\nabla\overline{u}|^p\varphi dx &\le \liminf_{n\to\infty}\left(\int_\Omega(A_n+B_n)\varphi dx\right)\\ &= \int_\Omega(\lambda(w^+)^\sigma+\Psi)\varphi dx,\end{aligned}$$

i.e.,

$$\int_\Omega|\nabla\overline{u}|^{p-2}\nabla\overline{u}\nabla\varphi dx + t^*\int_\Omega g(\overline{u})|\nabla\overline{u}|^p\varphi dx \le \int_\Omega(\lambda(w^+)^\sigma+\Psi)\varphi dx, \tag{3.15}$$

for all $\varphi\in W_0^{1,p}(\Omega)\cap L^\infty(\Omega)$ with $\varphi\ge 0$.

Now, define $S(t) := \int_0^t\beta(s)ds$, $\beta\ge 0$ measurable, and take $\varphi\in W_0^{1,p}(\Omega)\cap L^\infty(\Omega)$, $\phi\ge 0$ and $k>0$. Hence, taking v_n as test function in (3.12) defined by

$$v_n := e^{-S(u_n)}e^{S(T_k(u_n))}\varphi,$$

we obtain

$$\begin{aligned}&\int_\Omega|\nabla u_n|^{p-2}\nabla u_n\nabla\varphi e^{-S(u_n)}e^{S(T_k(u_n))}dx\\ &\quad+\int_\Omega|\nabla u_n|^{p-2}\nabla u_n\nabla T_k(u_n)\beta(T_k(u_n))e^{-S(u_n)}e^{S(T_k(u_n))}\varphi dx\\ &=\int_\Omega|\nabla u_n|^{p-2}\nabla u_n\nabla u_n\beta(u_n)e^{-S(u_n)}e^{S(u_n)}\varphi dx\\ &\quad-t_n\int_\Omega g(u_n)|\nabla u_n|^p e^{-S(u_n)}e^{S(T_k(u_n))}\varphi dx\\ &\quad+\int_\Omega(\lambda(w_n^+)^\sigma+\Psi)\varphi e^{-S(u_n)}e^{S(T_k(u_n))}\varphi dx\\ &\ge 0,\end{aligned}$$

because

$$t_n\int_\Omega g(u_n)|\nabla u_n|^p e^{-S(u_n)}e^{S(T_k(u_n))}\varphi dx \le \int_\Omega(\lambda(w_n^+)^\sigma+\Psi)\varphi e^{-S(u_n)}e^{S(T_k(u_n))}\varphi dx.$$

Again, by Fatou's lemma, we have

$$\begin{aligned}&\int_\Omega|\nabla\overline{u}|^{p-2}\nabla\overline{u}\nabla\varphi e^{-S(\overline{u})}e^{S(T_k(\overline{u}))}dx\\ &\quad+\int_\Omega|\nabla\overline{u}|^{p-2}\nabla\overline{u}\nabla T_k(\overline{u})\beta(T_k(\overline{u}))e^{-S(\overline{u})}e^{S(T_k(\overline{u}))}\varphi dx\\ &\ge\int_\Omega|\nabla\overline{u}|^{p-2}\nabla\overline{u}\nabla\overline{u}\beta(\overline{u})e^{-S(\overline{u})}e^{S(\overline{u})}\varphi dx\\ &\quad-t^*\int_\Omega g(\overline{u})|\nabla\overline{u}|^p e^{-S(\overline{u})}e^{S(T_k(\overline{u}))}\varphi dx\\ &\quad+\int_\Omega(\lambda(w^+)^\sigma+\Psi)\varphi e^{-S(\overline{u})}e^{S(T_k(\overline{u}))}\varphi dx.\end{aligned} \tag{3.16}$$

as $n \to \infty$. Since $0 \leq e^{-S(\overline{u})}e^{S(T_k(\overline{u}))} \leq 1$, by letting $k \to \infty$, it follows from (3.16) that

$$\int_\Omega |\nabla \overline{u}|^{p-2}\nabla \overline{u}\nabla \varphi dx + t^* \int_\Omega g(\overline{u})|\nabla \overline{u}|^p \varphi dx \geq \int_\Omega (\lambda (w^+)^\sigma + \Psi)\varphi dx, \tag{3.17}$$

for all $\varphi \in W_0^{1,p}(\Omega) \cap L^\infty(\Omega)$ with $\varphi \geq 0$.

Thus, by (3.15) and (3.17), we conclude that (3.10) holds for all for all $\varphi \in W_0^{1,p}(\Omega) \cap L^\infty(\Omega)$ with $\varphi \geq 0$.

Hence, since $\varphi := \varphi^+ - \varphi^-$ and $\varphi^+, \varphi^- \geq 0$, we have

$$\int_\Omega |\nabla \overline{u}|^{p-2}\nabla \overline{u}\nabla \varphi dx + t^* \int_\Omega g(\overline{u})|\nabla \overline{u}|^p \varphi dx = \int_\Omega (\lambda (w^+)^\sigma + \Psi)\varphi dx, \tag{3.18}$$

for all $\varphi \in W_0^{1,p}(\Omega) \cap L^\infty(\Omega)$.

Since problem (3.6) has an unique solution, then $u = \overline{u}$.

We still need to prove that $u_n \to u$ in $W_0^{1,p}(\Omega)$. For fixed $k > 0$, by taking $u_n = G_k(u_n) + T_k(u_n)$, we have

$$\begin{aligned} \|u_n - u\|_{1,p} &= \|u_n - T_k(u) + T_k(u) - u\|_{1,p} \\ &\leq \|u_n - T_k(u)\|_{1,p} + \|T_k(u) - u\|_{1,p} \\ &= \|G_k(u_n) + T_k(u_n) - T_k(u)\|_{1,p} + \|T_k(u) - u\|_{1,p} \\ &\leq \|G_k(u_n)\|_{1,p} + \|T_k(u_n) - T_k(u)\|_{1,p} + \|T_k(u) - u\|_{1,p}. \end{aligned} \tag{3.19}$$

Hence, the strong convergence of $\{u_n\}$ in $W_0^{1,p}(\Omega)$ is stated provided that we show the strong convergence of $\{T_k(u_n)\}$ to $T_k(u)$ in $W_0^{1,p}(\Omega)$ and that for every $\delta > 0$ there exists $k_0 = k_0(\delta)$ such that $k \geq k_0$ implies

$$\|G_k(u_n)\|_{1,p} < \delta, \qquad \text{for all } n \in \mathbb{N}.$$

This is done in two steps.

Step 1. For fixed $k > 0$, we have that $T_k(u_n) \to T_k(u)$ in $W_0^{1,p}(\Omega)$. Indeed, by fixing compact set $K \subset \Omega$ we take $\varphi_K \in C_0^\infty(\Omega)$ with $0 \leq \varphi_K \leq 1$ and $\varphi = 1$ in K. Thus, taking v_n as test function in (3.5) defined by

$$v_n := \big(T_k(u_n) - T_k(u)\big)^+ \varphi_K \in W_0^{1,p}(\Omega),$$

we have

(i) $\nabla v_n = \nabla \varphi_K \big(T_k(u_n) - T_k(u)\big)^+ + \nabla \big(T_k(u_n) - T_k(u)\big)^+ \varphi_K$;

(ii) $t_n g(u_n)|\nabla u_n|^p v_n \geq 0$;

(iii) $u_n \rightharpoonup u$ in $W_0^{1,p}(\Omega)$.

In addition, we also have

$$\begin{aligned} &\int_\Omega \varphi_K |\nabla u_n|^{p-2}\nabla u_n \nabla \big(T_k(u_n) - T_k(u)\big)^+ dx \\ &\quad \leq \int_\Omega (\lambda_(w_n^+)^\sigma + \Psi) v_n dx - \int_\Omega |\nabla u_n|^{p-2}\nabla u_n \nabla \phi_K \big(T_k(u_n) - T_k(u)\big)^+ dx. \end{aligned} \tag{3.20}$$

Thus, by Kavian (see [25, Lemma 4.8]), we conclude that

$$T_k(u_n) \rightharpoonup T_k(u) \quad \text{in } W_0^{1,p}(\Omega). \tag{3.21}$$

For fixed $k > 0$, combining the relations (3.20) and (3.21), we obtain

$$\int_\Omega \varphi_K |\nabla u_n|^{p-2}\nabla u_n \nabla \big(T_k(u_n) - T_k(u)\big)^+ dx \to 0, \quad \text{as} \quad n \to \infty. \tag{3.22}$$

By define the sets

$$S_n := \{x \in \Omega \ : \ |u_n(x)| \le k\}| \quad \text{and} \quad G_n := \{x \in \Omega \ : \ |u_n(x)| > k\},$$

and denote by χ_{G_n} the characteristic function of G_n. Moreover, take

$$\begin{aligned} E_n^+ &:= \int_\Omega \varphi_K \big[|\nabla T_k(u_n)|^{p-2}\nabla T_k(u_n) - |\nabla T_k(u)|^{p-2}\nabla T_k(u)\big]\nabla \big(T_k(u_n) - T_k(u)\big)^+ dx \\ &= \int_\Omega \varphi_K |\nabla u_n|^{p-2}\nabla u_n \nabla \big(T_k(u_n) - T_k(u)\big)^+ dx \\ &\quad - \int_\Omega \varphi_K \big[|\nabla u_n|^{p-2}\nabla u_n - |\nabla T_k(u)|^{p-2}\nabla T_k(u)\big]\nabla \big(T_k(u_n) - T_k(u)\big)^+ dx \\ &\quad - \int_\Omega \varphi_K |\nabla T_k(u)|^{p-2}\nabla T_k(u) \nabla \big(T_k(u_n) - T_k(u)\big)^+ dx. \end{aligned} \tag{3.23}$$

By using the relations (3.21) and (3.22), we conclude that the first and third term of (3.23) tends to zero as $n \to \infty$.

With respect to the second term of (3.23), we have

$$\begin{aligned} &- \int_\Omega \varphi_K \big[|\nabla u_n|^{p-2}\nabla u_n - |\nabla T_k(u)|^{p-2}\nabla T_k(u)\big]\nabla \big(T_k(u_n) - T_k(u)\big)^+ dx \\ &\quad = - \int_{G_n} \varphi_K \big[|\nabla u_n|^{p-2}\nabla u_n - |\nabla T_k(u)|^{p-2}\nabla T_k(u)\big]\nabla \big(T_k(u_n) - T_k(u)\big)^+ dx \\ &\qquad - \int_{S_n} \varphi_K \big[|\nabla u_n|^{p-2}\nabla u_n - |\nabla T_k(u)|^{p-2}\nabla T_k(u)\big]\nabla \big(T_k(u_n) - T_k(u)\big)^+ dx \\ &\quad = - \int_{G_n} \varphi_K |\nabla u_n|^{p-2}\nabla u_n \nabla \big(T_k(u_n) - T_k(u)\big)^+ dx. \end{aligned}$$

Furthermore, by the Dominated Convergence Theorem, we have

$$\begin{aligned} \int_{G_n} \varphi_K |\nabla u_n|^{p-2}\nabla u_n \nabla \big(T_k(u_n) - T_k(u)\big)^+ dx &= \int_\Omega \varphi_K |\nabla u_n|^{p-2}\nabla u_n . \chi_{G_n} \big(\nabla \big(T_k(u_n) - T_k(u)\big)^+\big) dx \\ &\le \|u_n\|_{1,p}^{p-1} \left[\int_\Omega \chi_{G_n} |\nabla T_k(u)|^p dx\right]^{\frac{1}{p}} \to 0, \end{aligned}$$

as $n \to \infty$.

Therefore, we conclude that $E_n^+ \to 0$ as $n \to \infty$ and thus,

$$\int_K \big[|\nabla T_k(u_n)|^{p-2}\nabla T_k(u_n) - |\nabla T_k(u)|^{p-2}\nabla T_k(u)\big]\nabla \big(T_k(u_n) - T_k(u)\big)^+ dx \to 0. \tag{3.24}$$

Now, taking v_n as test function in (3.5) defined by

$$v_n = \big(T_k(u_n) - T_k(u)\big)^- \varphi_K \in W_0^{1,p}(\Omega)$$

and repeating the previous arguments, we obtain

$$\int_K \big[|\nabla T_k(u_n)|^{p-2}\nabla T_k(u_n) - |\nabla T_k(u)|^{p-2}\nabla T_k(u)\big]\nabla \big(T_k(u_n) - T_k(u)\big)^- dx \to 0. \tag{3.25}$$

By combining the relations (3.24) and (3.25), we have

$$\int_K \big[|\nabla T_k(u_n)|^{p-2}\nabla T_k(u_n) - |\nabla T_k(u)|^{p-2}\nabla T_k(u)\big]\nabla\big(T_k(u_n) - T_k(u)\big)dx \to 0.$$

Thus, by inequality (2.7) we conclude that $\nabla T_k(u_n) \to \nabla T_k(u)$ in $L^p(K)$. Since $T_k(u_n) \in W_0^{1,p}(\Omega)$, then

$$\nabla T_k(u_n) \to \nabla T_k(u) \quad \text{in } L^p(\Omega).$$

Therefore, the sequence $\{T_k(u_n)\}$ converges strongly to $T_k(u)$ in $W_0^{1,p}(\Omega)$.

Step 2. By taking $v_n := G_k(u_n)$ as test function in (3.5) we have

$$\begin{aligned}\int_\Omega |\nabla G_k(u_n)|^p dx &= \int_{\{u_n \geq k\}} |\nabla u_n|^{p-2}\nabla u_n \nabla G_k(u_n)dx \\ &\leq \left(\int_{\{u_n \geq k\}} (\lambda_n (w_n^+)^\sigma + \Psi)dx\right)^{\frac{pN}{N(p-1)+p}} \|G_k(u_n)\|_{p^*}.\end{aligned}$$

Since $\frac{pN}{N(p-1)+p}\sigma < p^*$, $\{w_n\}$ is strongly convergent in $L^{\frac{pN}{N(p-1)+p}\sigma}(\Omega)$, $\{\lambda_n\}$ is bounded and $\Psi \in L^{\frac{pN}{N(p-1)+p}}(\Omega)$, the right-hand side of the previous inequality tends uniformly in n to zero as k_0 diverges, i.e., for every $\delta > 0$ there exists $k_0 = k_0(\delta)$ such that $k \geq k_0$ implies

$$\|\nabla G_k(u_n)\|_{1,p} < \delta, \quad \text{for all } n \in \mathbb{N}.$$

Therefore, by step 1 and 2 and by inequality (3.19), we conclude that $\{u_n\}$ converges strongly to u in $W_0^{1,p}(\Omega)$. □

Completing the proof of Theorem 1.2: Let $u_0 \in W_0^{1,p}(\Omega)$ be solution of $(P)_{\lambda\sigma}$ for $\lambda = 0$. For every isolated solution $u_\lambda \in W_0^{1,p}(\Omega)$ of $(P)_{\lambda\sigma}$ for some $\lambda \in \mathbb{R}$, we denote by $i(K_\lambda, , u_\lambda)$ the index of such a solution, that is, the topological Leray–Schauder degree $\deg(I - K_\lambda, B_\epsilon(u_\lambda), 0)$ of the operator $I - K_\lambda$ in a ball $B_\epsilon(u_\lambda)$ centered at u_λ with radius $\epsilon > 0$ small enough.

We will prove that $\deg(I - K_\lambda, B_\epsilon(u_\lambda), 0) \neq 0$ for $\lambda = 0$. Indeed, we denote by $U(t)$ the unique solution for

$$\begin{cases} -\Delta_p u + tg(u)|\nabla u|^p = \Psi(x) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

and we define the following homotopy

$$\begin{aligned} H : [0,1] \times W_0^{1,p}(\Omega) &\longrightarrow W_0^{1,p}(\Omega) \\ (t, w) &\longmapsto H(t,w) := U(t). \end{aligned}$$

Hence,

$$H(1,w) = U(1) = K_0(w) = K(0,w) = u_0$$

and

$$H(0,w) = U(0) = (-\Delta_p^{-1})(\Psi(x)).$$

Since $i\big((-\Delta_p^{-1})(\Psi(x)), U(0)\big) \neq 0$, by Lemma 3.2 we deduce that H is compact. Observing the first part of the proof of Lemma 3.2 we obtain $R > 0$ such that

$$\|U(t)\|_{1,p} < R, \quad \text{for all } t \in [0,1].$$

If $u \in W_0^{1,p}(\Omega)$ and $\|u\|_{1,p} \geq R$, then $u \neq H(t,u)$. Thus, by the homotopy invariance of the degree, we conclude that

$$\begin{aligned} i(K_0,u_0) &= i\big(H(1,\cdot),U(1)\big) \\ &= i\big(H(0,\cdot),U(0)\big) \\ &= i\big((-\Delta_p^{-1})(\Psi(x)),U(0)\big) \\ &\neq 0. \end{aligned} \tag{3.26}$$

Hence, we have that $K : \times\overline{B}_R \to B_R$ is continuous and compact and u_0 is an isolated solution of $(P)_{\lambda\sigma}$ in the ball $B_\epsilon(u_\lambda)$ for $\lambda = 0$. Thus, for $\lambda_0 > 0$ small enough, we have

$$K \ : \ [0,\lambda_0] \times \overline{B_\epsilon(u_0)} \longrightarrow B_\epsilon(u_0).$$

If $\Phi(\lambda,u) := u - K(\lambda,u)$, then $\deg\big(\Phi(\lambda,\cdot),B_\epsilon(u_0),0\big)$ is well defined for $\lambda \leq \lambda_0$. Hence, by applying the homotopy invariance of the degree, we have

$$\deg\big(\Phi(\lambda,\cdot),B_\epsilon(u_0),0\big) = \text{constant}, \qquad \lambda \leq \lambda_0.$$

Thus, by relation (3.26), we conclude that

$$\deg\big(\Phi(\lambda,\cdot),B_\epsilon(u_0),0\big) \neq 0, \qquad |\lambda| \leq \lambda_0.$$

The theorem follows now from the Rabinowitz Theorem 3.2 in [32]. □

Abstract. This paper deals with existence and multiplicity of positive solutions for the quasilinear Schrödinger equation

$$\begin{cases} -\Delta u - \lambda m(x) u \Delta(u^2) = f(\mu, x, u) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases}$$

where Ω is a bounded open domain in $\mathbb{R}^N$ with smooth boundary and m is a bounded non negative continuous function. Under suitable assumptions on the asymptotically linear f, we use bifurcation theory to analyze the set of positive solutions.

Keywords: bifurcation theory, Schrödinger equation.

2020 Mathematics Subject Classification: 35J10, 35B32, 34K18.

1 Introduction

The quasilinear Schrödinger equation

$$i\partial_t z = -\Delta z + V_0(x)z - z(\Delta|z|^2) - \theta|z|^{p-1}z, \tag{1.1}$$

known as the superfluid film equation in plasma physics due to Kurihara ([9]), has been studied by Poppenberg, Schmitt and Wang in [10]. Here the potential V_0 is a function $V_0\colon \mathbb{R}^N \to \mathbb{R}$, while $\theta > 0$, $p > 1$ are constants. Using the change of variables $z(t,x) = \exp\{-i\kappa t\}u(x)$ for $\kappa \in \mathbb{R}$ and putting $V = V_0 - \kappa$, they obtain the elliptic equation

$$-\Delta u - u(\Delta|u|^2) = \theta|u|^{p-1}u - V(x)u, \tag{1.2}$$

corresponding to the standing wave solutions of (1.1). In that work, variational techniques are applied to prove the existence of standing wave solutions. Also, readers can find more references in [10] about the physical meanings of the equation.

In this work we study positive solutions of

$$\begin{cases} -\Delta u - \lambda m(x) u \Delta(u^2) = f(\mu, x, u) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases} \tag{P_μ^λ}$$

where Ω is a bounded open domain with smooth boundary, λ and μ are real constants, $m(x)$ is a non negative bounded continuous function in $\overline{\Omega}$ and $f\colon \mathbb{R} \times \overline{\Omega} \times [0,\infty) \to \mathbb{R}$ is a continuous function such that $f(\mu, x, 0) = 0$ for every $x \in \overline{\Omega}$ and $\mu \in \mathbb{R}$.

We emphasize that the equation in (P_μ^λ) is more general than (1.2). Observe also that when $\lambda = 0$ the problem (P_μ^0) is just a classical semilinear problem which has been extensively studied. For the case of asymptotically linear datum f at 0 see [2]. The case of the quasilinear problem (P_μ^λ) with $m(x) = 1$ has been studied for $\lambda > 0$ in several works made subsequently after [10], see for instance [6–8] and references therein. In all these works, the problem (with $m(x) = 1$) is variational and one of the main ideas is to reduce the problem to a semilinear one by using the change of variables $u = g(v)$ where g is the unique solution of the differential equation

$$g' = \frac{1}{\sqrt{1 + 2\lambda g^2}}, \qquad g(0) = 0. \tag{1.3}$$

Contrary to the cited previous works, here λ can be either positive or negative, implying an accelerating ($\lambda > 0$) or slowdown ($\lambda < 0$) process for the non linear diffusion term. In addition, since we are considering nonconstant density $m(x)$, this term also increases or decreases this accelerating-slowdown process depending on the point of the domain. Note that even in the simplest case $m(x) = 1$, the uniform ellipticity of the operator (which may be rewritten in divergence form as $-\operatorname{div}((1 + 2\lambda u^2)\nabla u) + 2\lambda u|\nabla u|^2$) can be lost when λ is negative.

Moreover, although the change of variables (1.3) is still available for negative λ when $m(x) = 1$, it leads to a semilinear problem of a completely different nature that in the case positive λ. Indeed, in that case, the nonlinear term has an asymptote and the main properties of this nonlinear term, as used in [6–8] and references therein, are no longer satisfied for negative λ. In the general case where $m(x)$ is not constant, no similar change of variable becomes the problem semilinear.

To overcome these difficulties, for every fixed $\lambda \in \mathbb{R}$ we see that problem (P_μ^λ) is equivalent to

$$\Phi_\mu^\lambda(u) = 0, \quad u \in \mathcal{U}_\lambda = \{u \in C_0^1(\overline{\Omega}) : 1 + 2\lambda m(x) u^2(x) > 0, x \in \Omega\};$$

i.e., to find the ceros u of an operator Φ_μ^λ defined in the open subset $\mathcal{U}_\lambda$ of the Banach space $C_0^1(\overline{\Omega})$ of the differentiable functions with continuous derivative in $\overline{\Omega}$ which vanishes on the boundary $\partial\Omega$. Notice that $\mathcal{U}_\lambda = C_0^1(\overline{\Omega})$ if $\lambda \geq 0$, while $\mathcal{U}_\lambda \subsetneq C_0^1(\overline{\Omega})$ when $\lambda < 0$. Because of this we prove in Theorem 3.1 an extension of the global bifurcation theorem of Rabinowitz ([11]) for operators (depending on the parameter μ) which are defined in open subsets of a Banach space.

Next, assuming that $f(\mu, x, s)$ is asymptotically linear at $s = 0$; i.e.,

$$\lim_{s \to 0^+} \frac{f(\mu, x, s)}{s} = \mu f'_+(x, 0) \in L^\infty(\Omega),$$

uniformly in (μ, x), with $f'_+(x, 0)$ nonnegative and not identically zero and denoting by $\mu_1(f'_+)$ the first eigenvalue of the eigenvalue problem

$$\begin{cases} -\Delta\varphi = \mu f'_+(x, 0)\varphi & \text{in } \Omega, \\ \varphi = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.4}$$

we apply the cited extension theorem to obtain in Theorem 3.3 that the closure $\overline{\Sigma}$ of the nontrivial solution set of all $(\lambda,\mu,u)\in\mathbb{R}\times\mathbb{R}\times C_0^1(\overline{\Omega})$ such that $u\not\equiv 0$ solves (P_μ^λ); i.e.,

$$\overline{\Sigma}=\mathrm{cl}\{(\lambda,\mu,u)\in\mathbb{R}\times\mathbb{R}\times C_0^1(\overline{\Omega}) : u \text{ solves } (P_\mu^\lambda), u\not\equiv 0\}$$

intersects the plane $\pi_0=\{(\lambda,\mu,u)\in\mathbb{R}\times\mathbb{R}\times C_0^1(\overline{\Omega}) : u\equiv 0\}$ in the line

$$\overline{\Sigma}\cap\pi_0=r_0\equiv\{(\lambda,\mu_1(f'_+),0):\lambda\in\mathbb{R}\}.$$

Moreover, there exists a continuum $C\subset\overline{\Sigma}$ such that $r_0\subset C$ and, for every $\lambda\in\mathbb{R}$, $C\setminus\{(\lambda,\mu_1(f'_+),0)\}$ contains a connected subset $\{\lambda\}\times C_\lambda$ of nontrivial solutions.

Afterwards, for each fixed λ in $\mathbb{R}$ we study in Theorem 4.1 the laterality of the branch C_λ of positive solutions emanating from $(\mu_1(f'_+),0)$. Following [3, 4], the behavior of $f(\mu,x,s)$ when (μ,s) is close to $(\mu_1(f'_+),0)$ determines the laterality. Specifically, if we suppose the existence of the limit

$$\lim_{(\mu,s)\to(\mu_1(f'_+),0^+)}\frac{f(\mu,x,s)-\mu f'_+(x,0)s}{s^3}=G(x)\quad\text{uniformly in } x\in\overline{\Omega},$$

then the bifurcation of positive solutions from $(\mu_1(f'_+),0)$ is subcritical (i.e., to the left of $\mu=\mu_1(f'_+)$) provided that

- either $G(x)=+\infty$ a.e. $x\in\Omega$
- or $0<\int_\Omega G(x)\varphi_1(x)^4<\infty$, with φ_1 the positive eigenfunction of norm 1 for (1.4), and $\int_\Omega m(x)\varphi_1(x)^2[|\nabla\varphi_1(x)|^2-\mu_1(f'_+)f'_+(x,0)\varphi_1(x)^2]=0$.

A similar supercriticality laterality, i.e., to the right, is also shown when either $G(x)=-\infty$ a.e. $x\in\Omega$ or $\int_\Omega m(x)\varphi_1(x)^2[|\nabla\varphi_1(x)|^2-\mu_1(f'_+)\varphi_1(x)^2]=0$ and $-\infty<\int_\Omega G(x)\varphi_1(x)^4<0$. Roughly speaking, in these cases the laterality is the same that the one of the semilinear problem corresponding to the case $m(x)=0$ and does not depends on the value of λ.

The case $G\varphi_1^4\in L^1(\Omega)$, $\int_\Omega m(x)\varphi_1(x)^2[|\nabla\varphi_1(x)|^2-\mu_1(f'_+)f'_+(x,0)\varphi_1(x)^2]\neq 0$ is more delicate due to the key role played by the quasilinear term $\lambda m(x)u\Delta(u^2)$. Indeed, if

$$\lambda^*=-\frac{1}{2}\int_\Omega G(x)\varphi_1(x)^4\left[\int_\Omega m(x)\varphi_1(x)^2[|\nabla\varphi_1(x)|^2-\mu_1(f'_+)f'_+(x,0)\varphi_1(x)^2]\right]^{-1},\qquad(1.5)$$

and $\int_\Omega m(x)\varphi_1(x)^2[|\nabla\varphi_1(x)|^2-\mu_1(f'_+)f'_+(x,0)\varphi_1(x)^2]>0$, then the bifurcation of positive solution at $\mu_1(f'_+)$ is

- subcritical for $\lambda>\lambda^*$ and
- supercritical for $\lambda<\lambda^*$.

A similar result is also shown when the reverse inequality is satisfied, i.e. in the case $\int_\Omega m(x)\varphi_1(x)^2[|\nabla\varphi_1(x)|^2-\mu_1(f'_+)f'_+(x,0)\varphi_1(x)^2]<0$. We observe that λ^* may be positive, negative or zero.

For our knowledge this new phenomenon on the dependence of the laterality according to the value of λ is new and may cause significant changes in the existence of solutions of (P_λ^μ). As an example of the consequences of this phenomenon we study the simpler case $m(x)=1$ and $f(\mu,x,u)=\mu u-u^p$ with $p>1$ (logistic case). Specifically, we recover the previous results obtained by [8] proving uniqueness of positive solution when $\lambda>0$. In contrast, we handle

also the new case $\lambda < 0$ and prove the multiplicity of positive solutions when $\lambda < \lambda^* < 0$ and close to λ^*.

The outline of the paper is as follows. In Section 2, we study some properties of the open sets $\mathcal{U}_\lambda$ and extend the function $f(\mu,x,s)$ for $s < 0$ to ensure that every solution of the problem (P_μ^λ) is nonnegative. In Section 3, we prove the extension of the Rabinowitz's global bifurcation theorem for operators defined in open subsets and we apply it to show the existence of the continuum of positive solutions. In Section 4, we study the laterality of the branches of positive solutions obtained in Section 3. Finally, in Section 5, we discuss the logistic case.

2 Preliminaries

Let Ω be a bounded open domain with smooth boundary. Assume that $m(x)$ is a non negative bounded continuous function in $\overline{\Omega}$ and

(f_0) $\quad f\colon \mathbb{R}\times\overline{\Omega}\times[0,+\infty)\to\mathbb{R}$ is a continuous function such that

$$f(\mu,x,0)=0 \quad \text{for every } x\in\overline{\Omega} \text{ and } \mu\in\mathbb{R}.$$

Extending f to $\mathbb{R}\times\overline{\Omega}\times\mathbb{R}$ by taking

$$f(\mu,x,s)=f(\mu,x,0)=0, \quad \text{for every } \mu\in\mathbb{R},\ x\in\overline{\Omega} \text{ and } s<0, \tag{2.1}$$

we deduce that every weak solution of (P_μ^λ) is non negative.

Lemma 2.1. *Let f be a continuous function in $\mathbb{R}\times\overline{\Omega}\times[0,+\infty)$ satisfying (f_0) and extended by zero as (2.1). Let $u\in H_0^1(\Omega)$ be a solution of (P_μ^λ) for certain $\lambda,\mu\in\mathbb{R}$. Then, the following holds.*

1. *If $u\in\mathcal{U}_\lambda$, then $u(x)\geq 0$ for every $x\in\Omega$.*
2. *Moreover, if $u\in C^2(\Omega)\cap C(\overline{\Omega})$, $f(\mu,\cdot,\cdot)$ is C^1 in $\overline{\Omega}\times\mathbb{R}$ and u is a nonzero solution of (P_μ^λ) with $1+2\lambda m(x)u(x)^2>0$, $x\in\overline{\Omega}$, then*

$$u(x)>0, \quad \forall x\in\Omega \quad \text{and} \quad \frac{\partial u}{\partial n}(x)<0, \quad \forall x\in\partial\Omega, \tag{2.2}$$

where $\frac{\partial u}{\partial n}$ denotes the outward normal derivative of u at the point $x\in\partial\Omega$.

Proof. Let us prove part *(1)*. Observe first that (P_μ^λ) reduces to

$$\begin{cases} -\Delta u=\dfrac{f(\mu,x,u)+2\lambda m(x)u|\nabla u|^2}{1+2\lambda m(x)u^2} & \text{in } \Omega,\\ \quad u=0 & \text{on } \partial\Omega. \end{cases} \tag{2.3}$$

Since $u\in\mathcal{U}_\lambda$ we can take $\varphi=u^-=\min\{u,0\}\in H_0^1(\Omega)$ as a test function in (2.3) and using that $f(\mu,x,s)=0$ for every $\mu\in\mathbb{R}$, $x\in\Omega$ and $s\leq 0$ we have

$$\int_\Omega|\nabla u^-|^2=\int_\Omega\frac{2\lambda m(x)(u^-)^2}{1+2\lambda m(x)(u^-)^2}|\nabla u^-|^2=\int_\Omega|\nabla u^-|^2-\int_\Omega\frac{|\nabla u^-|^2}{1+2\lambda m(x)(u^-)^2}.$$

Then, we obtain that $u^-=0$; i.e., $u\geq 0$.

For the proof of the part *(2)*, since f is C^1 in $\overline{\Omega}\times\mathbb{R}$, there exists $C>0$ such that $f(\mu,x,s)+Cs$ is increasing in $s\in[0,\|u\|_\infty]$. Denoting $h(x)=f(\mu,x,u(x))+Cu(x)$, we have that $0\lneq h(x)\in C_0^1(\overline{\Omega})$.

Now, we distinguish cases depending on the sign of λ. If $\lambda\geq 0$ then u satisfies

$$\begin{cases} -\Delta u+\dfrac{C}{1+2\lambda m(x)u^2}u=\dfrac{h(x)+2\lambda m(x)u|\nabla u|^2}{1+2\lambda m(x)u^2}\gneq 0 & \text{in } \Omega,\\ u=0 & \text{on } \partial\Omega. \end{cases}$$

Since $\frac{C}{1+2\lambda m(x)u^2}$ is positive and bounded by the regularity of u and m, we can apply the strong maximum principle to conclude that u belongs to the interior of the cone of nonnegative solutions

$$P=\left\{u\in C_0^1(\overline{\Omega})\,:\,u \text{ is a nonnegative solution of (2.3)}\right\};$$

i.e., u satisfies (2.2).

In case $\lambda<0$, then u satisfies

$$\begin{cases} -\Delta u+\left(\dfrac{C}{1+2\lambda m(x)u^2}+\dfrac{2(-\lambda)m(x)|\nabla u|^2}{1+2\lambda m(x)u^2}\right)u=\dfrac{h(x)}{1+2\lambda m(x)u^2}\gneq 0 & \text{in } \Omega,\\ u=0 & \text{on } \partial\Omega. \end{cases}$$

Since $\frac{C}{1+2\lambda m(x)u^2}+\frac{2(-\lambda)m(x)|\nabla u|^2}{1+2\lambda m(x)u^2}$ is positive and bounded by the regularity of u and m, we can apply the strong maximum principle to conclude that u belongs to the interior of P. □

3 Continuum of positive solutions

Let $(X,\|\cdot\|)$ be a real Banach space, let $\mathcal{U}$ be an open set of X with $0\in\mathcal{U}$ and let $K\colon\mathbb{R}\times\mathcal{U}\to\mathbb{R}$ be a compact operator. For $\mu\in\mathbb{R}$, we consider the equation

$$\Phi(\mu,u)=u-K(\mu,u)=0,\quad u\in\mathcal{U}. \tag{3.1}$$

The operator K can be viewed as a family of compact operators $\{K_\mu:\mu\in\mathbb{R}\}$ by taking

$$K_\mu(u)=K(\mu,u),\quad u\in\mathcal{U}.$$

Similarly, we denote $\Phi_\mu=I-K_\mu$.

We also define

$$\Sigma=\{(\mu,u)\in\mathbb{R}\times\mathcal{U}\colon\Phi(\mu,u)=0,u\neq 0\},$$

and denote by Σ_μ the μ-slide of Σ, that is, $\Sigma_\mu=\{u\in\mathcal{U}\colon(\mu,u)\in\Sigma\}$.

Before showing the next result, let us recall that μ^* is a bifurcation point of (3.1) if there exists a sequence $(\mu_n,u_n)\in\mathbb{R}\times\mathcal{U}$ with $u_n\neq 0$, such that $\mu_n\to\mu^*$ and $\Phi(\mu_n,u_n)=0$.

The following theorem is a slight improvement of the global bifurcation theorem of Rabinowitz of [11] (see Theorem 1.3 and Corollary 1.12). In fact, with our assumptions it will be easy to arrive at the same point in which the proof of Theorem 6.3.1 of [1] is applicable.

Theorem 3.1. *Let $\mu^*\in\mathbb{R}$ and $\varepsilon_0>0$ be such that the set $(\mu^*-\varepsilon_0,\mu^*+\varepsilon_0)\backslash\{\mu^*\}$ does not contain any bifurcation point from (3.1). Assume that the Leray–Schauder topological index verifies*

$$i(\Phi_{\underline{\mu}},0)\neq i(\Phi_{\overline{\mu}},0),\quad \text{for some } \underline{\mu}\in(\mu^*-\varepsilon_0,\mu^*),\ \overline{\mu}\in(\mu^*,\mu^*+\varepsilon_0).$$

Then the connected component C of $\overline{\Sigma}$ that contains $(\mu^*,0)$ satisfies at least one of the following properties:

(a) $(\mathbb{R}\times\partial\mathcal{U})\cap C\neq\emptyset$.

(b) There exists $\mu^{\#}\neq\mu^{*}$ *such that* $(\mu^{\#},0)\in C$, *i.e.* $\mu^{\#}$ *is another bifurcation point from zero.*

(c) C *is unbounded.*

Proof. First, it is well known that a change of the index in μ^{*} implies that μ^{*} is a bifurcation point. Let C be the connected component of $\overline{\Sigma}$ that contains $(\mu^{*},0)$. Proceeding by contradiction, let us assume that C verifies neither (a) nor (b) nor (c). Denying property (a) implies that there is a neighborhood U_δ of C such that $(\mathbb{R}\times\partial\mathcal{U})\cap U_\delta=\emptyset$. Then, knowing that C is far from $\mathbb{R}\times\partial\mathcal{U}$ the proof follows same as Theorem 6.3.1 of [1]. □

For fixed $\lambda\in\mathbb{R}$, we define the set

$$\mathcal{U}_\lambda=\{u\in C_0^1(\overline{\Omega}):1+2\lambda m(x)u^2(x)\geq m_0, x\in\Omega,\ \text{for some } m_0>0\}.$$

The following result summarizes the main properties of this set.

Lemma 3.2. *For every* $\lambda\in\mathbb{R}$ *the set* $\mathcal{U}_\lambda$ *is open in* $C_0^1(\overline{\Omega})$.

Proof. Observe that $\mathcal{U}_\lambda=C_0^1(\overline{\Omega})$ for $\lambda\geq 0$. Assume now that $\lambda<0$, $u\in\mathcal{U}_\lambda$ and $\|u-v\|_1\leq r$. Then

$$|v(x)|-|u(x)|\leq||u(x)|-|v(x)||\leq\|u-v\|_\infty\leq r,\quad x\in\overline{\Omega},$$

and thus

$$1+2\lambda m(x)v^2(x)\geq 1+2\lambda m(x)(r+u^2(x))\geq m_0+2\lambda\|m\|_\infty r,$$

where $m_0>0$ is the minimum that attains the continuous function $1+2\lambda m(x)u^2(x)$ in $\overline{\Omega}$. Taking $r<\frac{m_0}{-2\lambda\|m\|_\infty}$ we have that $v\in\mathcal{U}_\lambda$ for every $v\in C_0^1(\overline{\Omega})$ with $\|u-v\|_1\leq r$. □

Now, we consider the Nemitski operator $N^\lambda\colon\mathbb{R}\times\mathcal{U}_\lambda\to C_0(\overline{\Omega})$ given by

$$N^\lambda(\mu,u)=\frac{f(\mu,x,u)+2\lambda m(x)u|\nabla u|^2}{1+2\lambda m(x)u^2}.$$

Since f and m are continuous and $u\in C_0^1(\overline{\Omega})$ we have that N^λ is a continuous operator. Also, we recall the compactness of the inverse of the Laplacian $(-\Delta)^{-1}\colon C_0(\overline{\Omega})\to C_0^1(\overline{\Omega})$.

Thus, the operator $K^\lambda\colon\mathbb{R}\times\mathcal{U}_\lambda\to C_0^1(\overline{\Omega})$ given by

$$K^\lambda(\mu,u)=(-\Delta)^{-1}\left[N^\lambda(\mu,u)\right],\quad \mu\in\mathbb{R},\ u\in\mathcal{U}_\lambda,$$

is compact.

We define $\Phi_\mu^\lambda\colon\mathcal{U}_\lambda\to C_0^1(\overline{\Omega})$ given by

$$\Phi_\mu^\lambda(u)=u-K^\lambda(\mu,u),\quad\forall u\in\mathcal{U}_\lambda.$$

In this way, the solutions of (P_μ^λ) are zeros of Φ_μ^λ.

Finally, we denote by $\mu_1(f'_+)$ the first eigenvalue and φ_1 the positive eigenfunction of norm 1 of the eigenvalue problem (1.4).

Theorem 3.3. *Let* f *be a continuous function in* $\mathbb{R}\times\overline{\Omega}\times[0,+\infty)$ *satisfying* (f_0), *and*

(f_1) *For each bounded set* Γ *in* $\mathbb{R}\setminus\{0\}$ *and* $\mu\in\Gamma$, *we have*

$$\lim_{s\to 0^+}\frac{f(\mu,x,s)}{s}=\mu f'_+(x,0),\quad \text{uniformly in } (\mu,x)\in\Gamma\times\Omega,$$

with $0\le f'_+(x,0)\in L^\infty(\Omega)$ *not identically zero.*

Then, for every $\lambda\in\mathbb{R}$, $\mu_1(f'_+)$ *is a bifurcation point from zero of the problem* (P^λ_μ). *Moreover, there exists a continuum* C *of positive solutions, i.e., a closed and connected subset of the closure* $\overline{\Sigma}$ *of the set*

$$\Sigma=\{(\lambda,\mu,u)\in\mathbb{R}\times\mathbb{R}\times C^1_0(\overline{\Omega})\colon\ u\in\mathcal{U}_\lambda,\ \Phi^\lambda_\mu(u)=0,\ u\neq 0\}$$

with $(\lambda,\mu_1(f'_+),0)\in C$ *for every* $\lambda\in\mathbb{R}$.

Remark 3.4. In addition, the continuum C provided by Theorem 3.3 satisfies that the slice

$$C_\lambda=\{(\mu,u)\in\mathbb{R}\times C^1_0(\overline{\Omega})\ :\ (\lambda,\mu,u)\in C\}$$

satisfies at least one of the following conditions:

- C_λ is unbounded (which is always the case for $\lambda\ge 0$).
- $C_\lambda\cap\mathbb{R}\times\partial\mathcal{U}_\lambda\neq\emptyset$.

Proof. We divide the proof into the following steps.

- Step 1. For every compact set $\Gamma\subset\mathbb{R}^2\setminus\{(\lambda,\mu_1(f'_+))\colon\lambda\in\mathbb{R}\}$ there exists $\varepsilon>0$ such that

$$\Phi^\lambda_\mu(u)\neq 0,\quad \forall(\lambda,\mu)\in\Gamma,\ \forall u\in\mathcal{U}_\lambda \text{ with } 0<\|u\|_1<\varepsilon,$$

  where $\|u\|_1$ denotes the norm of u in $C^1(\Omega)$.

- Step 2. If $\mu<\mu_1(f'_+)$, it is satisfied

$$i(\Phi^\lambda_\mu,0)=1,\quad\forall\lambda\in\mathbb{R}.$$

- Step 3. If $\mu>\mu_1(f'_+)$, it is satisfied

$$i(\Phi^\lambda_\mu,0)=0,\quad\forall\lambda\in\mathbb{R}.$$

To prove Step 1, we proceed by contradiction. Let Γ be a compact subset of $\mathbb{R}^2\setminus\{(\lambda,\mu_1(f'_+))\ :\ \lambda\in\mathbb{R}\}$ and let us assume that there exists a sequence (λ_n,μ_n,u_n) with $(\lambda_n,\mu_n)\in\Gamma$ and $u_n\in\mathcal{U}_{\lambda_n}$ satisfying

$$\lambda_n\to\lambda,\quad \mu_n\to\mu\neq\mu_1(f'_+),\quad \|u_n\|_1\to 0,$$

$$\Phi^{\lambda_n}_{\mu_n}(u_n)=0,\quad u_n\ge 0.$$

Since $\Phi^{\lambda_n}_{\mu_n}(u_n)=0$, we have that

$$u_n=(-\Delta)^{-1}\left[\frac{f(\mu_n,x,u_n)+2\lambda_n m(x)u_n|\nabla u_n|^2}{1+2\lambda_n m(x)u_n^2}\right].$$

Dividing by $\|u_n\|_1$ we come to the fact that

$$\frac{u_n}{\|u_n\|_1} = (-\Delta)^{-1}\left[\frac{f(\mu_n, x, u_n) + 2\lambda_n m(x) u_n |\nabla u_n|^2}{\|u_n\|_1 (1 + 2\lambda_n m(x) u_n^2)}\right]. \tag{3.2}$$

Since $\|u_n\|_1 \to 0$, we have that $u_n \to 0$. Then, there exists $n_0 > 0$ such that

$$\frac{1}{2} < 1 + 2\lambda_n m(x) u_n^2, \quad \forall n \geq n_0.$$

Thus, we conclude

$$\frac{|f(\mu_n, x, u_n) + 2\lambda_n m(x) u_n |\nabla u_n|^2|}{\|u_n\|_1 (1 + 2\lambda_n m(x) u_n^2)} < 2\left(\frac{|f(\mu_n, x, u_n)|}{\|u_n\|_1} + \frac{|2\lambda_n m(x) u_n |\nabla u_n|^2|}{\|u_n\|_1}\right)$$

and each term of the right hand side is bounded.

- Using (f_1) and that $f'_+(x,0) \in L^\infty(\Omega)$, $\frac{f(\mu_n, x, u_n)}{\|u_n\|_1}$ is bounded.
- Since λ_n is convergent, m is bounded, $|\nabla u_n|^2$ converges to zero and $\frac{u_n(x)}{\|u_n\|_1}$ is bounded by 1, the term $\frac{2\lambda_n m(x) u_n |\nabla u_n|^2}{\|u_n\|_1}$ is bounded.

Then, since the operator $(-\Delta)^{-1}$ is compact, up to a subsequence denoted the same way, $\frac{u_n}{\|u_n\|_1}$ converges strongly to a non negative function $\varphi \in C_0^1(\overline{\Omega})$. Taking limit in (3.2), we arrive to

$$\varphi = (-\Delta)^{-1}[\mu f'_+(x,0)\varphi].$$

So, φ is a positive solution with norm 1 of the problem (1.4). Therefore $\varphi = \varphi_1$ and $\mu = \mu_1(f'_+)$, which is a contradiction.

As a consequence of step 1, we have that for every $\lambda \in \mathbb{R}$ the unique possible bifurcation point from zero of Φ_μ^λ is $\mu_1(f'_+)$.

Moreover, further consequences of step 1 are

$$i(\Phi_\mu^\lambda, 0) = c_1, \quad \forall \mu < \mu_1(f'_+), \quad \forall \lambda \in \mathbb{R}$$

and

$$i(\Phi_\mu^\lambda, 0) = c_2, \quad \forall \mu > \mu_1(f'_+), \quad \forall \lambda \in \mathbb{R},$$

where c_1 and c_2 are constants.

To prove step 2, for every $t \in [0,1]$ we claim that, for each $t \in [0,1]$, there exists $\varepsilon > 0$ satisfying

$$u - (-\Delta)^{-1}[tf(0,x,u)] \neq 0, \quad \forall 0 < \|u\|_1 < \varepsilon.$$

Arguing by contradiction, let us suppose that there exists a sequence $u_n \in C_0^1(\overline{\Omega})$ such that

$$\|u_n\|_1 \to 0, \quad u_n \geq 0$$

and

$$u_n - t(-\Delta)^{-1}[f(0,x,u_n)] = 0. \tag{3.3}$$

Dividing (3.3) by $\|u_n\|_1$ we have that

$$\frac{u_n}{\|u_n\|_1} = t(-\Delta)^{-1}\left[\frac{f(0,x,u_n)}{\|u_n\|_1}\right]$$

Now, using (f_1) as before, we have that, up to a subsequence noted the same way, $\frac{u_n}{\|u_n\|_1}$ converges strongly to a non negative function $v \in C_0^1(\overline{\Omega})$ with norm 1. Taking limits in (3.3), we conclude that

$$v = t(-\Delta)^{-1}[0],$$

but, since $(-\Delta)^{-1}[0] = 0$, then $v = 0$ and we have a contradiction.

As a consequence of this fact, defining $\Psi_t(u) = u - (-\Delta)^{-1}[tf(0,x,u)]$, we have proved that

$$i(\Psi_t, 0) = \text{constant}, \quad \forall t \in [0,1].$$

Using that $\Psi_1 = \Phi_0^0$ and $\Psi_0 = \mathrm{Id}$, we deduce that

$$i(\Phi_\mu^\lambda, 0) = i(\Phi_0^0, 0) = i(\mathrm{Id}, 0) = 1, \quad \forall \mu < \mu_1(f'_+),\ \forall \lambda \in \mathbb{R}.$$

Finally we prove step 3. To do so, we will prove that for fixed $\lambda \in \mathbb{R}$ and $\mu > \mu_1(f'_+)$, there exists $\varepsilon > 0$ such that

$$\Phi_\mu^\lambda(u) \neq \tau\varphi_1, \quad \forall \tau > 0,\ \forall 0 < \|u\|_1 < \varepsilon.$$

Let us assume by contradiction that there exists a sequence $u_n \in C_0^1(\overline{\Omega})$ and $\tau_n \geq 0$ satisfying $u_n > 0$ in Ω, $\|u_n\|_1 \to 0$ and

$$\Phi_\mu^\lambda(u_n) = \tau_n\varphi_1.$$

Equivalently,

$$u_n = (-\Delta)^{-1}\left[\frac{f(\mu,x,u_n) + 2\lambda m(x)u_n|\nabla u_n|^2}{1 + 2\lambda m(x)u_n^2}\right] + \tau_n\varphi_1.$$

Dividing by $\|u_n\|_1$ and using the compactness of $(-\Delta)^{-1}$ we have that

$$(-\Delta)^{-1}\left[\frac{f(\mu,x,u_n) + 2\lambda m(x)u_n|\nabla u_n|^2}{\|u_n\|_1(1 + 2\lambda m(x)u_n^2)}\right]$$

is convergent. Adding that $\frac{u_n}{\|u_n\|_1}$ is bounded by 1, the sequence $\frac{\tau_n}{\|u_n\|_1}$ is bounded. Thus, taking another subsequence if it's necessary, we have that $\frac{\tau_n}{\|u_n\|_1} \to \tau \geq 0$ and $\frac{u_n}{\|u_n\|_1} \to v$ with $v \in C_0^1(\overline{\Omega})$ satisfying

$$\begin{cases} -\Delta v = \mu f'_+(x,0)v + \tau\mu_1(f'_+)f'_+(x,0)\varphi_1 & \text{in } \Omega, \\ v = 0 & \text{on } \partial\Omega, \\ \|v\|_1 = 1. \end{cases}$$

Using the weak formulation and taking φ_1 as test function, we have that

$$\int_\Omega \nabla\varphi_1\nabla v = \int_\Omega \mu f'_+(x,0)v\varphi_1 + \tau\mu_1(f'_+)f'_+(x,0)\varphi_1^2.$$

Now, using the definition of φ_1 we have that

$$\int_\Omega \mu_1(f'_+)f'_+(x,0)v\varphi_1 = \int_\Omega \mu f'_+(x,0)v\varphi_1 + \tau\mu_1(f'_+)f'_+(x,0)\varphi_1^2.$$

Equivalently, we arrive to

$$\int_\Omega (\mu_1(f'_+) - \mu)f'_+(x,0)v\varphi_1 = \int_\Omega \tau\mu_1(f'_+)f'_+(x,0)\varphi_1^2,$$

where the term in the right hand side is non-positive and the corresponding one in the left hand side is non-negative. So, each term is zero and conclude that $\tau = 0$ and $v = 0$, giving a contradiction.

Therefore, we have that

$$i(\Phi_\mu^\lambda, 0) = i(\Phi_\mu^\lambda - \tau\varphi_1, 0), \quad \forall \tau > 0.$$

However, the problem

$$\begin{cases} -\Delta w = \mu f'_+(x,0)w + \tau\mu_1(f'_+)f'_+(x,0)\varphi_1 & \text{in } \Omega, \\ w = 0 & \text{on } \partial\Omega, \end{cases}$$

has no trivial solution and neither solutions with small norm. Hence,

$$i(\Phi_\mu^\lambda, 0) = i(\Phi_\mu^\lambda - \tau\varphi_1, 0) = 0.$$

Fixed λ^* in $\mathbb{R}$, there is a change of index in $\mu_1(f'_+)$, generating a continuum of solutions emanating from the point $(\lambda^*, \mu_1(f'_+), 0)$ and that it is contained in the plane $\lambda = \lambda^*$. Because of the arbitrariness of λ^*, a continuum of solutions emanates from each point on the line $\{(\lambda, \mu, u) : \mu = \mu_1(f'_+), u = 0\}$. So, since every branch is connected by the straight line $\{(\lambda, \mu, u) : \mu = \mu_1(f'_+), u = 0\}$ a general continuum is generated. □

Remark 3.5. For the case $f'_+(x,0) = +\infty$ Theorem 3.3 also holds considering $\mu_1(f'_+) = 0$, see Remark 4.2 of [3].

4 Laterality

For a fixed $\lambda \in \mathbb{R}$, we have proved in Theorem 3.3, see also Remark 3.4, that a continuum $C_\lambda = \{(\mu, u) : (\lambda, \mu, u) \in C\}$ of positive solutions emanates from $(\mu_1(f'_+), 0)$. In this section, we study the behavior of this continuum. For λ fixed, let us recall that:

- the bifurcation at zero is subcritical if, when taking a sequence $\{(\mu_n, u_n)\}$ with $\mu_n \to \mu_1(f'_+)$, $u_n \to 0$ in $C_0^1(\overline{\Omega})$ and with $\Phi_{\mu_n}^\lambda(u_n) = 0$, we have that $\mu_n \leq \mu_1(f'_+)$ for n large enough.
- the bifurcation at zero is supercritical if, when taking a sequence $\{(\mu_n, u_n)\}$ with $\mu_n \to \mu_1(f'_+)$, $u_n \to 0$ in $C_0^1(\overline{\Omega})$ and with $\Phi_{\mu_n}^\lambda(u_n) = 0$, we have that $\mu_n \geq \mu_1(f'_+)$ for n large enough.

While the parameter λ did not play any role in the existence of positive solutions found in Theorem 3.3, we see here that the bifurcation is subcritical or supercritical depending on the value and sign of λ.

Theorem 4.1. *Let f be a continuous function in $\mathbb{R} \times \overline{\Omega} \times [0, +\infty)$ satisfying (f_0), (f_1) and*

$$\lim_{(\mu,s)\to(\mu_1(f'_+),0^+)} \frac{f(\mu,x,s) - \mu f'_+(x,0)s}{s^3} = G(x) \quad \text{uniformly in } x \in \overline{\Omega}. \tag{f_2}$$

1. *If $G(x) = +\infty$ a.e. $x \in \Omega$, then for every $\lambda \in \mathbb{R}$ the bifurcation of positive solutions is subcritical. Respectively, if $G(x) = -\infty$ a.e. $x \in \Omega$, then for every $\lambda \in \mathbb{R}$ the bifurcation of positive solutions is supercritical.*

2. *If* $G\varphi_1^4 \in L^1(\Omega)$ *and* $\int_\Omega m(x)\varphi_1(x)^2[|\nabla\varphi_1(x)|^2 - \mu_1(f'_+)f'_+(x,0)\varphi_1(x)^2] = 0$, *then:*
   (a) *If* $\int_\Omega G(x)\varphi_1(x)^4 > 0$, *then for every* $\lambda \in \mathbb{R}$ *the bifurcation of positive solutions is subcritical.*
   (b) *If* $\int_\Omega G(x)\varphi_1(x)^4 < 0$, *then for every* $\lambda \in \mathbb{R}$ *the bifurcation of positive solutions is supercritical.*
3. *If* $G\varphi_1^4 \in L^1(\Omega)$ *and* $\int_\Omega m(x)\varphi_1(x)^2[|\nabla\varphi_1(x)|^2 - \mu_1(f'_+)f'_+(x,0)\varphi_1(x)^2] \neq 0$, *then taking* λ^* *defined as* (1.5) *we have that:*
   (a) *If* $\int_\Omega m(x)\varphi_1(x)^2[|\nabla\varphi_1(x)|^2 - \mu_1(f'_+)f'_+(x,0)\varphi_1(x)^2] > 0$, *then the bifurcation of positive solutions is subcritical for* $\lambda > \lambda^*$ *and supercritical for* $\lambda < \lambda^*$.
   (b) *If* $\int_\Omega m(x)\varphi_1(x)^2[|\nabla\varphi_1(x)|^2 - \mu_1(f'_+)f'_+(x,0)\varphi_1(x)^2] < 0$, *then the bifurcation of positive solutions is supercritical for* $\lambda > \lambda^*$ *and subcritical for* $\lambda < \lambda^*$.

Proof. For fixed $\lambda \in \mathbb{R}$, using (f_0), (f_1) and (f_2) we can apply Theorem 3.3 to deduce that $\mu_1(f'_+)$ is a bifurcation point of positive solutions from zero of the problem (P_μ^λ). Thus, we can take a sequence (μ_n, u_n) verifying

$$u_n \neq 0, \quad \mu_n \to \mu_1(f'_+), \quad \|u_n\|_1 \to 0, \quad \Phi^\lambda_{\mu_n}(u_n) = 0.$$

Since u_n solves (2.3) with $\mu = \mu_n$, multiplying by φ_1 and integrating by parts, we have that

$$\int_\Omega \nabla u_n \nabla\varphi_1 = \int_\Omega \frac{f(\mu_n, x, u_n)}{1+2\lambda m(x)u_n^2}\varphi_1 + \int_\Omega \frac{2\lambda m(x)u_n|\nabla u_n|^2}{1+2\lambda m(x)u_n^2}\varphi_1. \tag{4.1}$$

Observe that, using u_n as test function in (1.4), we obtain that

$$\int_\Omega \nabla u_n \nabla\varphi_1 = \int_\Omega \mu_1(f'_+)f'_+(x,0)u_n\varphi_1.$$

Thus, by (4.1), we deduce

$$\begin{aligned}(\mu_1(f'_+) - \mu_n)\int_\Omega f'_+(x,0)u_n\varphi_1 &= \int_\Omega \nabla u_n\nabla\varphi_1 - \int_\Omega \mu_n f'_+(x,0)u_n\varphi_1 \\ &= \int_\Omega \frac{(f(\mu_n,x,u_n) - \mu_n f'_+(x,0)u_n)\varphi_1 + 2\lambda m(x)u_n\varphi_1[|\nabla u_n|^2 - \mu_n f'_+(x,0)u_n^2]}{1+2\lambda m(x)u_n^2}.\end{aligned}$$

If we multiply by $\|u_n\|_1^{-3}$ and denote $z_n = u_n/\|u_n\|_1$, we have that

$$\begin{aligned}(\mu_1(f'_+) - \mu_n)\int_\Omega \frac{f'_+(x,0)\varphi_1 z_n}{\|u_n\|_1^2} &= \int_\Omega \frac{(f(\mu_n,x,u_n) - \mu_n f'_+(x,0)u_n)\varphi_1 z_n^3}{u_n^3(1+2\lambda m(x)u_n^2)} \\ &\quad + \int_\Omega \frac{2\lambda m(x)\varphi_1 z_n}{1+2\lambda m(x)u_n^2}\left[|\nabla z_n|^2 - \mu_n f'_+(x,0)z_n^2\right].\end{aligned} \tag{4.2}$$

Now, taking into account that the sign of the left hand side coincides with the sign of $(\mu_1(f'_+) - \mu_n)$, the sign of the right hand side of (4.2) determines if the bifurcation is subcritical or supercritical.

In order to prove *(1)*, using that z_n converges to φ_1 and the dominated convergence theorem we obtain that the second term of the right hand side of (4.2) converges to

$$2\lambda\int_\Omega m(x)\varphi_1(x)^2[|\nabla\varphi_1(x)|^2 - \mu_1(f'_+)f'_+(x,0)\varphi_1(x)^2].$$

Applying Fatou's lemma to the first term of the right hand side, we deduce that

$$+\infty = \int_\Omega G(x)\varphi_1^4 \le \liminf_{(\mu,s)\to(\mu_1(f'_+),0)} \int_\Omega \frac{(f(\mu_n,x,u_n)-\mu_n f'_+(x,0)u_n)\varphi_1 z_n^3}{u_n^3(1+2\lambda m(x)u_n^2)}.$$

Thus, the right hand side diverges to $+\infty$ (analogously diverges to $-\infty$ when $G(x) = -\infty$) and for every $\lambda \in \mathbb{R}$ the bifurcation is subcritical (respectively supercritical).

Now we assume that $G\varphi_1^4 \in L^1(\Omega)$. In this case, using the dominated convergence theorem and that z_n converges to φ_1, the right hand side of (4.2) converges to

$$\int_\Omega G(x)\varphi_1^4 + 2\lambda \int_\Omega m(x)\varphi_1^2 \left[|\nabla\varphi_1|^2 - \mu_1(f'_+)f'_+(x,0)\varphi_1^2\right].$$

Therefore, the proof of item *(2)* follows since, in that case the sign of the right hand side of (4.2) coincides with that of $\int_\Omega G(x)\varphi_1(x)^4$ for every $\lambda \in \mathbb{R}$.

Finally, in the case of item *(3)*, we observe that

$$\begin{aligned}\int_\Omega G(x)\varphi_1^4 + 2\lambda \int_\Omega m(x)\varphi_1^2 &\left[|\nabla\varphi_1|^2 - \mu_1(f'_+)f'_+(x,0)\varphi_1^2\right] \\ &= 2(\lambda-\lambda^*)\int_\Omega m(x)\varphi_1^2\left[|\nabla\varphi_1|^2 - \mu_1(f'_+)f'_+(x,0)\varphi_1^2\right].\end{aligned}$$

Therefore, in the case of *(a)*, the right hand side of (4.2) is positive (respectively negative) and the bifurcation is subcritical (respectively supercritical) if, $\lambda > \lambda^*$ (respectively $\lambda < \lambda^*$). Analogously we conclude in the case of *(b)*. □

5 Multiplicity of solutions for the logistic datum

In this section, for $p > 1$, we study the problem (P_μ^λ) with $f(\mu,x,u) = \mu u - u^p$ and $m(x) = 1$; i.e.,

$$\begin{cases} -\Delta u - \lambda u\Delta(u^2) = \mu u - u^p & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases} \tag{5.1}$$

Condition (f_2) becomes

$$\lim_{s\to 0^+} \frac{\mu s - s^p}{s} = \mu,$$

and $f'_+(x,0) = 1$. Thus, in this case (1.4) becomes

$$\begin{cases} -\Delta\varphi = \mu\varphi & \text{in } \Omega, \\ \varphi = 0 & \text{on } \partial\Omega. \end{cases} \tag{5.2}$$

First, we are able to apply Theorem 3.3, giving the existence of a continuum of positive solutions. For $\lambda > 0$, we can make the change of variables $u = g(v)$ with g given by (1.3). Thus, the problem turn into the semilinear equation

$$\begin{cases} -\Delta v = \mu g(v)g'(v) - g(v)^p g'(v) & \text{in } \Omega, \\ v = 0 & \text{on } \partial\Omega. \end{cases}$$

The datum satisfies that

$$\frac{\mu g(v)g'(v) - g(v)^p g'(v)}{v} \quad \text{is decreasing for } v \in (0,+\infty).$$

Then, by the classical result of Brezis and Oswald ([5]), the problem has a unique positive solution. Now, let us see that for the case $\lambda < 0$ we can find a range of values in which we have at least two solutions. To do this, observe that the condition (f_2) for the problem (5.1) becomes

$$\lim_{(\mu,u)\to(\mu_1,0)} \frac{\mu u - u^p - \mu u}{u^3} = \lim_{(\mu,u)\to(\mu_1,0)} -u^{p-3} = \begin{cases} -\infty & \text{if } p \in (1,3), \\ -1 & \text{if } p = 3, \\ 0 & \text{if } p \in (3,+\infty). \end{cases}$$

Consequently, (1.5) becomes

$$\lambda^* = \frac{\displaystyle\int_\Omega \varphi_1^4}{\displaystyle\int_\Omega 2\varphi_1^2[|\nabla\varphi_1(x)|^2 - \mu_1\varphi_1(x)^2]}.$$

if $p = 3$ and $\lambda^* = 0$ if $p > 3$.

Moreover, taking φ_1^3 as test function in the weak formulation of (5.2) we have that

$$\int_\Omega 3\varphi_1^2|\nabla\varphi_1|^2 = \int_\Omega \mu_1\varphi_1^4,$$

which implies that

$$\int_\Omega 2\varphi_1^2[|\nabla\varphi_1(x)|^2 - \mu_1\varphi_1(x)^2] < 0.$$

Therefore, $\lambda^* < 0$.

Corollary 5.1. *For a fixed $\lambda \in \mathbb{R}$, the bifurcation of positive solutions occurs according to the following cases:*

1. *If $p \in (1,3)$ then the bifurcation is supercritical for every $\lambda \in \mathbb{R}$.*
2. *If $p \geq 3$ then the bifurcation is subcritical if $\lambda < \lambda^*$ and supercritical if $\lambda > \lambda^*$.*

Now, we see that, in the case $p > 3$, there is a range of values of λ for which we can obtain two solutions. To do this, we first need the following result about a priori bounds on the solution.

Lemma 5.2. *Let $u \in C^2(\Omega) \cap C(\overline{\Omega})$ be a positive solution of (5.1) with $\lambda < 0$. Then*

1. *if $1 + 2\lambda\|u\|_\infty^2 > 0$, then $\|u\|_\infty \leq \mu^{\frac{1}{p-1}}$.*
2. *if $\mu > \mu_1$ and $\lambda < 0$, then $\mu - \mu_1 \leq \|u\|_\infty^{p-1}$.*

Proof. First, since u is a solution of (P_μ^λ), we have that

$$\begin{aligned}(1 + 2\lambda u(x)^2)(-\Delta u(x)) &= \mu u(x) - u(x)^p + 2\lambda u(x)|\nabla u(x)|^2 \\ &= u(x)(\mu - u(x)^{p-1}) + 2\lambda u(x)|\nabla u(x)|^2, \quad \forall x \in \Omega.\end{aligned}$$

However, taking x_0 the point in which u attains the maximum, we obtain that

$$(1 + 2\lambda\|u\|_\infty^2)(-\Delta u(x_0)) = \|u\|_\infty(\mu - \|u\|_\infty^{p-1}).$$

with $\Delta u(x_0) \leq 0$. Hence, $\|u\|_\infty \leq \mu^{\frac{1}{p-1}}$ and *(1)* is proved.

To prove (2), we check that

$$-\mathrm{div}[(1+2\lambda u^2)\nabla u] + 2\lambda u|\nabla u|^2 = -2\lambda u|\nabla u|^2 + (1+2\lambda u^2)(-\Delta u) = \mu u - u^p.$$

Thus $-\mathrm{div}[(1+2\lambda u^2)\nabla u] + 2\lambda u|\nabla u|^2 + u^p = \mu u$ and, defining the operator

$$-\mathrm{div}[(1+2\lambda u^2)\nabla(\cdot)] + 2\lambda|\nabla u|^2 + u^{p-1},$$

by the positivity of u, we have that

$$\sigma_1(-\mathrm{div}[(1+2\lambda u^2)\nabla(\cdot)] + 2\lambda|\nabla u|^2 + u^{p-1}) = \mu,$$

where $\sigma_1(\cdot)$ denotes the first eigenvalue of the operator under zero Dirichlet boundary conditions. Using the monotonicity of the first eigenvalue and that $\lambda \leq 0$, we have that

$$\mu \leq \sigma_1\left[-\mathrm{div}[\nabla(\cdot)] + u^{p-1}\right] \leq \sigma_1\left[-\mathrm{div}[\nabla(\cdot)] + \|u\|_\infty^{p-1}\right] = \mu_1 + \|u\|_\infty^{p-1}.$$

Finally, we conclude that

$$\|u\|_\infty^{p-1} \geq \mu - \mu_1. \qquad \square$$

Theorem 5.3. *If $\lambda \in \left(\frac{-1}{2}\mu_1^{2/(1-p)}, 0\right)$ and $p > 3$, then there is $\mu < \mu_1$ such that the problem (5.1) has at least two positive solutions.*

Proof. Let $\lambda \in \left(\frac{-1}{2}\mu_1^{2/(1-p)}, 0\right)$ be fixed, Theorem 3.3 implies that μ_1 is a bifurcation point from zero of positive solutions. Then, there exist a continuum C_λ that emanates from $(\mu_1, 0)$, subset of $\overline{\Sigma}_\lambda$ where

$$\Sigma_\lambda = \{(\mu, u) \in \mathbb{R} \times C_0^1(\overline{\Omega}) \,:\, u \in \mathcal{U}_\lambda, \Phi_\mu^\lambda(u) = 0, u \neq 0\}.$$

By Theorem 3.1 there are three possibilities of behavior (not incompatibles) for C_λ. However, by the Step 1 of Theorem 3.3 there is no other bifurcation point from zero. Also, the condition $\lambda \in \left(\frac{-1}{2}\mu_1^{2/(1-p)}, 0\right)$ implies that $\mu_1^{\frac{1}{p-1}} < \frac{1}{\sqrt{-2\lambda}}$ and combining with Lemma (5.2) we deduce that

$$\|u\|_\infty \leq \mu^{\frac{1}{p-1}}, \quad \|u\|_\infty < \frac{1}{\sqrt{-2\lambda}}, \quad \forall (\mu, u) \in C_\lambda. \tag{5.3}$$

$$(\mu - \mu_1)^{\frac{1}{p-1}} \leq \|u\|_\infty, \quad \forall (\mu, u) \in C_\lambda \quad \text{with } \mu > \mu_1. \tag{5.4}$$

Combining the two inequalities of (5.3), see Figure 5.1, and that $(s - \mu_1)^{\frac{1}{p-1}}$ diverges positively when s tends to $+\infty$, we have that there is no solution for $\mu \geq \mu_1 + (-2\lambda)^{\frac{1-p}{2}}$. Thus, we have that C_λ is bounded and $\overline{C}_\lambda \cap (\mathbb{R} \times \partial\mathcal{U}_\lambda) \neq \emptyset$. Again, by (5.3) the points $(\mu, u) \in \overline{C}_\lambda \cap (\mathbb{R} \times \partial\mathcal{U}_\lambda)$ verify that

$$(-2\lambda)^{\frac{1-p}{2}} \leq \mu \leq \mu_1 + (-2\lambda)^{\frac{1-p}{2}}, \quad \forall (\mu, u) \in \overline{C}_\lambda \cap (\mathbb{R} \times \partial\mathcal{U}_\lambda).$$

Now, notice that condition $\lambda \in \left(\frac{-1}{2}\mu_1^{2/(1-p)}, 0\right)$ implies that $\mu_1 < (-2\lambda)^{\frac{1-p}{2}}$. Therefore, we have proved that there are positive solutions with $\mu > \mu_1$.

Nevertheless, since $p > 3$ and $\lambda < 0$, Corollary 5.1 implies that the bifurcation is subcritical. Then, the continuum C_λ emanates from zero at μ_1 with solutions with $\mu < \mu_1$ and turn around connecting with solutions with $\mu > \mu_1$. Consequently, there is at least one value of $\mu < \mu_1$ such that the problem (5.1) has two positive solutions.

$\square$

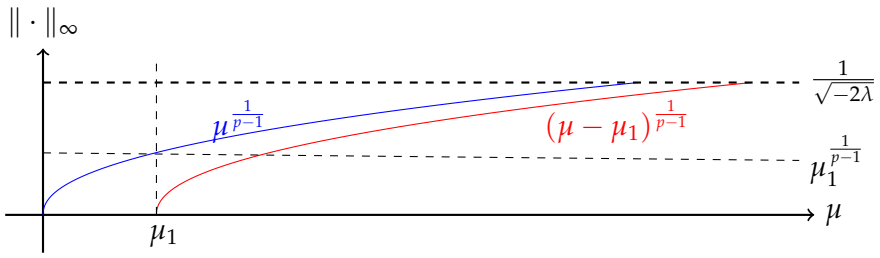

Figure 5.1: Bounds (5.3) of the continuum C_λ.

Abstract. In this article, we study the generalized solutions for singular elliptic equations with mixed boundary conditions, a nonlocal source term and a Hardy potential. More precisely, we use the variational methods to establish the existence of at least three generalized solutions for this problem.

Keywords: double-phase Laplacian operator, Hardy potential, mixed boundary condition, variable exponent space.

2020 Mathematics Subject Classification: 35J15, 35J20, 35J25.

1 Introduction

The study of the singular elliptic equations involving double-phase $(p_1(x), p_2(x))$-Laplacian operators with Hardy potential in variable exponent spaces has attracted the interest of many authors in different fields such as fluid dynamics, structural design and electrical systems [19]. In the recent years, several papers demonstrate the existence and multiplicity of solutions of this type of singular elliptic problems, for more details, see [2,4,5,7,14–18]. Recently Jian Liu et al. [16] established the existence of one weak solution, respectively two weak solutions to the following singular elliptic problem with mixed boundary conditions in variable exponent spaces

$$\begin{cases} -\Delta_{p(x)}u - \Delta_{q(x)}u + \frac{a(x)|u|^{h-2}u}{|x|^h} = \lambda f(x,u) & \text{in } \Omega, \\ u = 0 & \text{on } \Gamma_1, \\ \left(|\nabla u|^{p(x)-2}\nabla u + |\nabla u|^{q(x)-2}\nabla u\right)\cdot \nu + c(x)|u|^{t(x)-2}u = 0 & \text{on } \Gamma_2, \end{cases}$$

where Ω is a bounded subset in $\mathbb{R}^N (N \geq 2)$ with smooth boundary $\partial\Omega, \nu$ is the outward normal vector field on $\partial\Omega, \Gamma_1$ and Γ_2 are two smooth $(N-1)$-dimensional submanifolds of $\partial\Omega$ such that $\Gamma_1 \cap \Gamma_2 = \emptyset, \overline{\Gamma_1} \cup \overline{\Gamma_2} = \partial\Omega, \overline{\Gamma_1} \cap \overline{\Gamma_2}$ is a $(N-2)$-dimensional submanifold

✉Corresponding author. Email: haikel_ouerghi@yahoo.fr

of $\partial\Omega, \lambda > 0, 0 < a(x) \in L^{\infty}(\Omega), \Delta_{p(x)}u = \operatorname{div}\left(|\nabla u|^{p(x)-2}\nabla u\right)$ is $p(x)$-Laplacian operator, $\Delta_{q(x)}u = \operatorname{div}\left(|\nabla u|^{q(x)-2}\nabla u\right)$ is $q(x)$-Laplacian operator, $p(x), q(x) \in C(\bar{\Omega})$ with $1 < q(x) < p(x) < p^*(x)$, where

$$p^*(x) = \begin{cases} \frac{Np(x)}{N-p(x)}, & p(x) < N \\ +\infty, & p(x) \geq N \end{cases}$$

$1 < h < p(x)$, $t(x) \in C\left(\overline{\Gamma_2}\right)$ with $1 < t(x) < p_*(x)$, where

$$p_*(x) = \begin{cases} \frac{(N-1)p(x)}{N-p(x)}, & p(x) < N \\ +\infty, & p(x) \geq N \end{cases}$$

and $0 < c(x) \in L^{e(x)}(\Gamma_2)$, with $e(x) > \frac{p_*(x)t(x)}{p_*(x)-t(x)}$. The nonlinearity $f(x,u)$ is assumed to be a Carathéodory function such that $f : \Omega \times \mathbb{R} \to \mathbb{R}$ which satisfy the following growth condition

$$|f(x,u)| \leq M_1(x) + M_2|u|^{s(x)-1}, \quad \text{a.e. } (x,u) \in \Omega \times \mathbb{R}$$

where $M_1(x) > 0$, $M_1(x) \in L^{\frac{s(x)}{s(x)-1}}(\Omega)$, $M_2 > 0$, $s(x) \in C_+(\bar{\Omega}) := \{\xi : \xi \in C(\overline{\Omega}), \xi(x) > 1, \text{ for all } x \in \overline{\Omega}\}$ with $s(x) < p^*(x)$. Moreover an Ambrosetti–Rabinowitz condition was imposed to guaranty the existence of two weak solutions when λ is in an appropriate range (See Theorem 3.1 in [16]).

In mathematical physics, the distinction between local and nonlocal source terms plays a key role in understanding the nature of interactions within a system and in developing appropriate models. A local source term depends only on the solution and its derivatives at a single point in the domain, capturing interactions that occur in a localized region. These terms are typically encountered in problems where effects are confined to immediate neighborhoods, such as local forces or reactions. However, in many physical systems, interactions can extend over longer distances or be influenced by global effects. In such cases, a nonlocal source term is more appropriate. This term involves the solution values from multiple points, often integrated over the domain, reflecting long-range interactions or global influences. Nonlocal source terms are commonly found in models of nonlocal elasticity, diffusion with memory, or biological systems with spatial coupling. This distinction motivates our study of a singular elliptic equation in variable exponent spaces, where we consider a more complex nonlocal source term to explore the existence of multiple weak solutions under mixed boundary conditions.

Motivated by the above advantages of a nonlocal source term and the previous work of Liu et al. [16], we shall study the singular elliptic equation with mixed boundary conditions in variable exponent spaces

$$\begin{cases} \sum_{i=1}^{2} -\Delta_{p_i(x)}u + \dfrac{a(x)|u|^{q-2}u}{|x|^q} = \lambda f(x,u)\Big(\int_{\Omega} F(x,u)\,dx\Big)^r & \text{in } \Omega, \\ u = 0 & \text{on } \Gamma_1, \\ \left(\sum_{i=1}^{2} |\nabla u|^{p_i(x)-2}\nabla u\right)\nu + b(x)|u|^{h(x)-2}u = 0, & \text{on } \Gamma_2, \end{cases} \tag{P}$$

where $F(x,u) = \int_0^u f(x,t)\,dt$, for all $(x,u) \in \Omega \times \mathbb{R}$, r is a positive constant. In this given context, Ω is assumed to be an open bounded subset of $\mathbb{R}^N$, $(N > 2)$. The boundary of Ω

is denoted by $\partial\Omega$, is a smooth surface. The outward normal vectors on this boundary are represented by the vector field ν.

Additionally, there are two distinct smooth submanifolds, Γ_1 and Γ_2, which are parts of the boundary $\partial\Omega$. These submanifolds have a dimension of $N-1$ and do not intersect. The union of these submanifolds, denoted by $\overline{\Gamma_1} \cup \overline{\Gamma_2}$, covers the entire boundary, while their intersection, denoted by $\overline{\Gamma_1} \cap \overline{\Gamma_2}$, forms a submanifold of dimension $N-2$ within the boundary $\partial\Omega$. Moreover λ is a positive parameter and the function $a(x)$ is chosen to satisfy the assertion $0 < a(x) \in L^\infty(\Omega)$.

In the whole paper and for $i = 1,2$, $-\Delta_{p_i(x)}u = \operatorname{div}(|\nabla u|^{p_i(x)-2}\nabla u)$ denotes the $p_i(x)$-Laplacian operator, where $p_i(x) \in C_+(\overline{\Omega})$. In the sequel, we denote by $\tilde{p}(x) = \max\{p_1(x), p_2(x)\}$ such that $1 < \tilde{p}(x) < \tilde{p}^*(x)$, where

$$\tilde{p}^*(x) = \begin{cases} \dfrac{N\tilde{p}(x)}{N-\tilde{p}(x)}, & \text{if } \tilde{p}(x) < N, \\ +\infty, & \text{if } \tilde{p}(x) \geq N, \end{cases}$$

$1 < q < \min\{N, \tilde{p}(x)\}$, $h(x) \in C(\overline{\Gamma_2})$ with $1 < h(x) < \tilde{p}_*(x)$, where

$$\tilde{p}_*(x) = \begin{cases} \dfrac{(N-1)\tilde{p}(x)}{N-\tilde{p}(x)}, & \text{if } \tilde{p}(x) < N, \\ +\infty, & \text{if } \tilde{p}(x) \geq N, \end{cases}$$

the function $b(x) \in L^{e(x)}(\Gamma_2)$, with $e(x) > \frac{\tilde{p}_*(x)h(x)}{\tilde{p}_*(x)-h(x)}$. We will assume in the next of this paper that $f : \Omega \times \mathbb{R} \longrightarrow \mathbb{R}$ is a Carathéodory function satisfying

(H) $$m_1|u|^{\alpha(x)-1} \leq f(x,u) \leq m_2|u|^{\beta(x)-1},$$

where, m_1, m_2 are positive constants. The functions $\alpha(x)$ and $\beta(x)$ belongs to the set $C_+(\overline{\Omega})$ and satisfy $\alpha(x) \leq \beta(x) < \tilde{p}(x)$, for all $x \in \Omega$.

The key differences between the problem of Liu et al. [16] and Problem (*P*) lie primarily in the structure of the source term, the conditions required for the existence of solutions, and the role of $b(x)$. In [16], the source term is a local nonlinearity $\lambda f(x,u)$, where $f(x,u)$ is a Carathéodory function satisfying specific growth conditions. The existence of two weak solutions relies on the Ambrosetti–Rabinowitz condition, which ensures the existence of solutions via variational methods. Additionally, the boundary condition on Γ_2 requires the positivity of $c(x)$.

In contrast, our work involves a more complex source term, which includes a nonlocal term $\left(\int_\Omega F(x,u)\,dx\right)^r$, where $F(x,u)$ is the primitive of $f(x,u)$. This nonlocal factor complicates the analysis but allows for the existence of three weak solutions without the need for the Ambrosetti-Rabinowitz condition. Moreover, the boundary condition on Γ_2 in our work involves $b(x)$, which is not required to be positive, providing more flexibility in the boundary conditions. These differences demonstrate how the second work handles a more intricate problem setup and proves the existence of multiple solutions with fewer restrictions compared to the first.

The rest of this paper is structured as follows. In the next section we give some basic facts and variational structure concerning our problem. In Section 3, we state and prove the main result of this paper.

2 Mathematical backgrounds

In this section, we recall some definitions and basic properties of the generalized Lebesgue Sobolev spaces.

For any $p \in C_+(\overline{\Omega})$, let $p^+ = \max_{x\in\overline{\Omega}} p(x)$ and $p^- = \min_{x\in\overline{\Omega}} p(x)$. The generalized Lebesgue Sobolev space is defined as

$$L^{p(x)}(\Omega) = \left\{ u : \Omega \to \mathbb{R}, u \text{ measurable} : \int_\Omega |u(x)|^{p(x)}\, dx < \infty \right\}.$$

The so-called Luxemburg norm on this spaces defined by

$$\|u\|_{L^{p(x)}(\Omega)} = \|u\|_{p(x)} = \inf\left\{ \eta > 0 : \int_\Omega \left|\frac{u(x)}{\eta}\right|^{p(x)} dx \le 1 \right\}.$$

The Lebesgue–Sobolev space $W^{1,p(x)}(\Omega)$ is defined as follows

$$W^{1,p(x)}(\Omega) := \left\{ u \in L^{p(x)}(\Omega) : |\nabla u| \in L^{p(x)}(\Omega) \right\},$$

and equipped with the norm

$$\|u\|_{W^{1,p(x)}(\Omega)} = \|\nabla u\|_{p(x)} + \|u\|_{p(x)},$$

where

$$|\nabla u| = \left(\sum_{i=1}^{N} \left|\frac{\partial u}{\partial x_i}\right|^2 dx \right)^{\frac{1}{2}}.$$

Let $W_0^{1,p(x)}(\Omega)$ be the closure of $C_0^\infty(\Omega)$ in $W^{1,p(x)}(\Omega)$. In the following, let

$$E = W_0^{1,\tilde{p}(x)}(\Omega).$$

The set E is a closed subspace of $W^{1,\tilde{p}(x)}(\Omega)$, then E is a reflexive, separable and uniformly convex Banach space. So, we can get that $\|u\|_{W^{1,\tilde{p}(x)}(\Omega)}$ is equivalent to the norm

$$\|u\| = \|\nabla u\|_{\tilde{p}(x)} = \inf\left\{ \eta > 0 : \int_\Omega \left|\frac{\nabla u(x)}{\eta}\right|^{\tilde{p}(x)} dx \le 1 \right\}.$$

Lemma 2.1 ([11]). *The continuous embedding $E \hookrightarrow L^{\alpha(x)}$ holds for any $\alpha \in C_+(\overline{\Omega})$ such that $\alpha(x) \le \tilde{p}(x)$ a.e. on Ω. This leads to the inequality*

$$\|u\|_{\alpha(x)} \le c_\alpha \|\nabla u\|_{\tilde{p}(x)}, \tag{2.1}$$

where c_α is a positive constant.

Lemma 2.2 ([12]). *If $\tilde{p} \in C_+(\overline{\Omega})$, then*

$$\min\left\{ \|\nabla u\|_{\tilde{p}(x)}^{\tilde{p}^-}, \|\nabla u\|_{\tilde{p}(x)}^{\tilde{p}^+} \right\} \le \int_\Omega |\nabla u(x)|^{\tilde{p}(x)} dx \le \max\left\{ \|\nabla u\|_{\tilde{p}(x)}^{\tilde{p}^-}, \|\nabla u\|_{\tilde{p}(x)}^{\tilde{p}^+} \right\},$$

for any $u \in L^{\tilde{p}(x)}(\Omega)$ and for a.e. $x \in \Omega$.

Lemma 2.3 ([10]). *If $s_1, s_2 \in C_+(\overline{\Omega})$ such that $s_1(x) \le s_2(x)$ a.e. $x \in \Omega$, then exists the continuous embedding $W^{1,s_2(x)}(\Omega) \hookrightarrow W^{1,s_1(x)}(\Omega)$.*

Lemma 2.4 ([10]). *Let Ω having the cone property on its boundary, and let $\tilde{p} \in C_+(\overline{\Omega})$. Suppose that $s \in C_+(\overline{\Omega})$ and $s(x) < \tilde{p}^*(x)$ for all $x \in \overline{\Omega}$. Under these conditions, the embedding*

$$W^{1,\tilde{p}(x)}(\Omega) \hookrightarrow W^{1,s(x)}(\Omega)$$

is both continuous and compact.

Denote

$$C_+(\partial\Omega) := \{\xi : \xi \in C(\partial\Omega), \xi(x) > 1, \text{ on } \partial\Omega\},$$

and the surface measure on $\partial\Omega$ by $d\sigma$.

$$L^{\tilde{p}(x)}(\partial\Omega) := \left\{ u \mid u : \partial\Omega \to \mathbb{R} \text{ is measurable, and } \int_{\partial\Omega} |u(x)|^{\tilde{p}(x)}\, d\sigma < \infty \right\},$$

where $\tilde{p}(x)$ denotes a variable exponent that may vary with the point $x \in \partial\Omega$.

The norm associated with this space is given by the Luxemburg norm

$$\|u\|_{L^{\tilde{p}(x)}(\partial\Omega)} = \|u\|_{\tilde{p}(x)(\partial\Omega)} = \inf \left\{ \eta > 0 \mid \int_{\partial\Omega} \left| \frac{u(x)}{\eta} \right|^{\tilde{p}(x)} d\sigma \leq 1 \right\}.$$

For a measurable function v on a subset $\Gamma_2 \subset \partial\Omega$, the space $L^{\tilde{p}(x)}(\Gamma_2)$ consists of functions that are measurable on Γ_2 and can be extended to some function $u \in L^{\tilde{p}(x)}(\partial\Omega)$ such that $u = v$ on Γ_2. Specifically, we define

$$L^{\tilde{p}(x)}(\Gamma_2) = \left\{ v \mid v \text{ is measurable on } \Gamma_2, \exists u \in L^{\tilde{p}(x)}(\partial\Omega) \text{ such that } u = v \text{ on } \Gamma_2 \right\}.$$

The corresponding norm on $L^{\tilde{p}(x)}(\Gamma_2)$ is

$$\|v\|_{L^{\tilde{p}(x)}(\Gamma_2)} = \|v\|_{\tilde{p}(x)(\Gamma_2)} = \inf \left\{ \|u\|_{\tilde{p}(x)(\partial\Omega)} \mid u = v \text{ on } \Gamma_2 \right\}.$$

Lemma 2.5 ([8]). *Assume that the boundary of Ω possesses the cone property and $\tilde{p} \in C_+(\overline{\Omega})$, if $h \in C_+(\partial\Omega)$ and $h(x) < \tilde{p}_*(x)$ for all $x \in \partial\Omega$ then the trace embedding*

$$W^{1,\tilde{p}(x)}(\Omega) \hookrightarrow L^{h(x)}(\partial\Omega)$$

is compact and continous.

Lemma 2.6 ([12]). *Let $G \subset \mathbb{R}^N$ be a measurable subset with $0 < meas(G) < +\infty$. Consider a Carathéodory function $f : G \times \mathbb{R} \to \mathbb{R}$ satisfying the estimate*

$$|f(x,u)| \leq M_1(x) + M_2|u|^{\frac{p(x)}{q(x)}}, \quad \text{for almost every } (x,u) \in G \times \mathbb{R},$$

where $p(x), q(x) \in C_+(\overline{\Omega})$, $0 < M_1(x) \in L^{q(x)}(G)$, and $M_2 > 0$. In this case, the Nemytskii operator

$$N_f(u)(x) = f(x, u(x))$$

maps the space $L^{p(x)}(G)$ into $L^{q(x)}(G)$, and it is both continuous and bounded.

Lemma 2.7 (Hölder type inequality [1, 9]). *Let p, q, and s be measurable functions defined on Ω with the condition*

$$\frac{1}{s(x)} = \frac{1}{p(x)} + \frac{1}{q(x)}, \quad \text{for almost every } x \in \Omega.$$

If $f \in L^{p(x)}(\Omega)$ and $g \in L^{q(x)}(\Omega)$, then the product fg belongs to $L^{s(x)}(\Omega)$, and the following inequality holds

$$\|fg\|_{s(x)} \leq 2\|f\|_{p(x)}\|g\|_{q(x)}.$$

Furthermore, if the condition

$$\frac{1}{s(x)} + \frac{1}{p(x)} + \frac{1}{q(x)} = 1, \quad \text{for almost every } x \in \Omega,$$

is satisfied, then it follows that

$$\int_\Omega |f(x)g(x)h(x)|\,dx \leq 3\|f\|_{s(x)}\|g\|_{p(x)}\|h\|_{q(x)}.$$

Hereinafter, for $M > 0$ and $r(x) \in C_+(\overline{\Omega})$, we use the following notations

$$[M]^r = \max\{M^{r^-}, M^{r^+}\} \quad \text{and} \quad [M]_r = \min\{M^{r^-}, M^{r^+}\}.$$

In order to formulate the variational approach of the problem (P), we define the functional $J_\lambda : E \longrightarrow \mathbb{R}$ by

$$J_\lambda = J_1 - \lambda J_2,$$

where

$$J_1(u) = \sum_{i=1}^{2}\left(\int_\Omega \frac{1}{p_i(x)}|\nabla u|^{p_i(x)}dx\right) + \int_\Omega \frac{a(x)|u|^q}{q|x|^q}\,dx,$$
$$J_2(u) = \frac{1}{r+1}\left(\int_\Omega F(x,u)\,dx\right)^{r+1} - \frac{1}{\lambda}\int_{\Gamma_2}\frac{b(x)|u|^{h(x)}}{h(x)}\,d\sigma,$$

where $F(x,u) = \int_0^u f(x,t)\,dt$, $\forall\ (x,u) \in \Omega \times \mathbb{R}$.

It is clear that $u \in E$ is a weak solution of the problem (P) if

$$J'_\lambda(u)(v) = J'_1(u)(v) - \lambda J'_2(u)(v) = 0, \qquad \forall\ v\ \in E,$$

where J_1, J_2 are continuously Gâteaux differentiable and we have

$$J'_1(u)(v) = \sum_{i=1}^{2}\left(\int_\Omega |\nabla u|^{p_i(x)-2}\nabla u \nabla v\,dx\right) + \int_\Omega \frac{a(x)|u|^{q-2}uv}{|x|^q}\,dx,$$

and

$$J'_2(u)(v) = \left(\int_\Omega F(x,u)\,dx\right)^r \int_\Omega f(x,u)v\,dx - \frac{1}{\lambda}\int_{\Gamma_2} b(x)|u|^{h(x)-2}uv\,d\sigma,$$

Lemma 2.8 ([16]). *The operator J'_1 verifies the following properties*

(i) *J'_1 is coercive and strictly monotone in E.*

(ii) *J'_1 is an homeomorphism.*

Lemma 2.9. *The operator $J'_2 : E \longrightarrow E^*$ is compact.*

Proof. Let $J_2' = \varphi_1'(u) - \frac{1}{\lambda}\varphi_2'(u)$, where

$$\varphi_1'(u)(v) = \left(\int_\Omega F(x,u)\,dx\right)^r \int_\Omega f(x,u)v\,dx, \qquad \varphi_2'(u)(v) = \int_{\Gamma_2} b(x)|u|^{h(x)-2}uv\,d\sigma, \quad \forall v \in E.$$

From condition (**H**), the compact embeddings $E \hookrightarrow L^{\beta(x)}(\Omega)$, where $1 < \beta(x) < \tilde{p}^*(x)$, and $E \hookrightarrow L^{h(x)}(\partial\Omega)$, where $1 < h(x) < \tilde{p}_*(x)$, imply the compactness of $\varphi_1'(u)$ and $\varphi_2'(u)$. Consequently, the functional $J_2'(u) : E \to E^*$ is compact.

To demonstrate this, let $(u_k)_k \subset E$ be a sequence such that $u_k \rightharpoonup u$ weakly in E. Due to the compactness of the embeddings, there exists a subsequence, still denoted by $(u_k)_k$, such that $u_k \to u$ strongly in $L^{\beta(x)}(\Omega)$, and $u_k(x) \to u(x)$ for almost every $x \in \Omega$. The continuity of $F(x,u)$ with respect to u ensures that

$$F(x,u_k) \to F(x,u) \quad \text{for almost every } x.$$

Also, there exists $C > 0$ such that

$$|F(x,u_k)| < C|u_k|^{\beta(x)}.$$

By using the dominated convergence theorem, we can write

$$\int_\Omega F(x,u_k)\,dx \to \int_\Omega F(x,u_k)\,dx \quad \text{as } k \to +\infty. \tag{2.2}$$

In the subsequent part of the proof, we employ the approach introduced by Liu et al. [16]. Specifically, we assert that the Nemytskii operator $N_f(u)(x) = f(x,u(x))$ is continuous, as $f : \Omega \times \mathbb{R} \to \mathbb{R}$ is a Carathéodory function that satisfies condition (**H**). Consequently, it follows that $N_f(u_k) \to N_f(u)$ in $L^{\frac{\beta(x)}{\beta(x)-1}}(\Omega)$.

Next, utilizing Lemma 2.1 and the Hölder inequality, for any $v \in E$, we have the estimate

$$\begin{aligned}\left|\int_\Omega f(x,u_k)v\,dx - \int_\Omega f(x,u)v\,dx\right| &\le \int_\Omega |(f(x,u_k) - f(x,u))v|\,dx \\ &\le 2\|N_f(u_k) - N_f(u)\|_{\frac{\beta(x)}{\beta(x)-1}}\|v\|_{\beta(x)}, \\ &\le 2c_\beta\|N_f(u_k) - N_f(u)\|_{\frac{\beta(x)}{\beta(x)-1}}\|\nabla v\|_{\tilde{p}(x)},\end{aligned} \tag{2.3}$$

where c_β is the constant associated with the embedding $E \hookrightarrow L^{\beta(x)}(\Omega)$ with $1 < \beta(x) < \tilde{p}^*(x)$.

By combining the results from equations (2.2) and (2.3), we deduce that $\varphi_1'(u_k) \to \varphi_1'(u)$ in E, which implies that φ_1' is completely continuous. Therefore, φ_1' is a compact operator.

By similar argument for φ_2' on Γ_2, The Nemytskii operator $N_h(u) = |u|^{h(x)-2}u$ is continuous and $N_h(u_k) \longrightarrow N_h(u)$ in $L^{\frac{h(x)}{h(x)-1}}(\Gamma_2)$. According to the Hölder type inequality in Lemma 2.7 and the compact embedding $E \hookrightarrow L^{h(x)}(\partial\Omega)$, $1 < h(x) < \tilde{p}_*(x)$, thus for all $v \in E$, we have

$$\begin{aligned}\left|\varphi_2'(u_k)(v) - \varphi_2'(u)(v)\right| &= \left|\int_{\Gamma_2} b(x)|u_k|^{h(x)-2}u_k v\,d\sigma - \int_{\Gamma_1} b(x)|u|^{h(x)-2}uv\,d\sigma\right| \\ &\le 3\|b\|_{e(x)}\|N_h(u_k) - N_h(u)\|_{\frac{h(x)}{h(x)-1}(\Gamma_2)}\|v\|_{\frac{e(x)h(x)}{e(x)-h(x)}(\Gamma_2)} \\ &\le 3\|b\|_{e(x)}\|N_h(u_k) - N_h(u)\|_{\frac{h(x)}{h(x)-1}(\Gamma_2)}\|v\|_{\frac{e(x)h(x)}{e(x)-h(x)}(\partial\Omega)} \\ &\le 3b_h\|b\|_{e(x)}\|N_h(u_k) - N_h(u)\|_{\frac{h(x)}{h(x)-1}(\Gamma_2)}\|v\|,\end{aligned}$$

where b_h is the embedding constant of the trace embedding $W^{1,\tilde{p}(x)} \hookrightarrow L^{\frac{e(x)h(x)}{e(x)-h(x)}}(\partial\Omega)$. Thus $\varphi_2'(u_k) \longrightarrow \varphi_2'(u)$ in E^* as $n \longrightarrow +\infty$, i.e. φ_2' is completely continuous, so φ_2' is compact. Therefore J_2' is compact. □

To obtain our result, we use the following critical points theorem.

Theorem 2.10 ([6, Theoem 3.6]). *Consider a reflexive real Banach space E, and $J_1 : E \to \mathbb{R}$ be a coercive, continuously Gâteaux differentiable and sequentially weakly lower semicontinuous functional. Assume that the Gâteaux derivative of J_1 has a continuous inverse on E^*. Furthermore, let $J_2 : E \to \mathbb{R}$ be a continuously Gâteaux differentiable functional whose Gâteaux derivative is compact, assume that*

$$\inf_E J_1 = J_1(0) = J_2(0) = 0.$$

Suppose that there exist $d > 0$ and $\overline{x} \in E$, with $d < J_1(\overline{x})$, such that

(i) $\frac{\sup_{J_1(x)<d} J_2(x)}{d} < \frac{J_2(\overline{x})}{J_1(\overline{x})}$,

(ii) for every $\lambda \in \Psi_d := \left]\frac{J_1(\overline{x})}{J_2(\overline{x})}, \frac{d}{\sup_{J_1(x)\leq d} J_2(x)}\right[$, $J_\lambda := J_1 - \lambda J_2$ *is coercive.*

Then, for every $\lambda \in \Psi_d$, $J_1 - \lambda J_2$ has at least three distinct critical points in E.

3 Main results

Before giving our result, we recall the Hardy inequality (for more details, see [13]), if $1 < q < N$, then

$$\int_\Omega \frac{|u(x)|^q}{|x|^q}\,dx \leq \frac{1}{H}\int_\Omega |\nabla u|^q\,dx, \qquad \forall u \in W_0^{1,q}(\Omega) = \{u \in W^{1,q}(\Omega) : u|_{\Gamma_1} = 0\},$$

where $H = \left(\frac{N-q}{q}\right)^q$.

Using (2.2) and due to $q < \tilde{p}(x)$ for any $x \in \Omega$, we conclude that $E \hookrightarrow W_0^{1,q}(\Omega)$, thus there is a positive constant k such that

$$\int_\Omega \frac{|u(x)|^q}{|x|^q}\,dx \leq \frac{k^q}{H}\|u\|^q, \qquad \forall\, u \in E. \tag{3.1}$$

To present our main result, we define

$$D(x) = \sup\{D > 0 \mid B(x, D) \subseteq \Omega\},$$

for all $x \in \Omega$, here $B(x, D)$ represents a ball centered at x with radius D. It is simple to see that there exists a point $x_0 \in \Omega$ such that $B(x_0, R) \subseteq \Omega$, where $R = \sup_{x\in\Omega} D(x)$.

Theorem 3.1. *Assume that $\tilde{p}^- > \beta^+(r+1)$, and that there exists $d, \delta > 0$ such that*

$$\left(\frac{1}{p_1^-}\left[\frac{2\delta}{R}\right]^{p_1} + \frac{1}{p_2^-}\left[\frac{2\delta}{R}\right]^{p_2}\right)\left|B(x_0, R) \setminus \overline{B}\left(x_0, \frac{R}{2}\right)\right| = d,$$

then for every $\lambda \in]A_\delta, B_d[$, where

$$A_\delta = \frac{\left(\frac{1}{p_1^-}\left[\frac{2\delta}{R}\right]^{p_1} + \frac{1}{p_2^-}\left[\frac{2\delta}{R}\right]^{p_2}\right)\left|B(x_0, R) \setminus \overline{B}(x_0, \frac{R}{2})\right| + \frac{k^q\|a\|_\infty}{qH}\tilde{M}^q}{\frac{m_1^{r+1}\left([\delta]_\alpha\right)^{r+1}}{(r+1)(\alpha^+)^{r+1}}\left|B(x_0, \frac{R}{2})\right|^{r+1}},$$

and

$$B_d = \frac{d}{\frac{m_2^{r+1}([c_\beta]^\beta)^{r+1}(\tilde{p}^+)^{\frac{\beta^+(r+1)}{\tilde{p}^-}}}{(r+1)(\beta^-)^{r+1}}\left(\left[\left[d\right]^{\frac{1}{\tilde{p}}}\right]^\beta\right)^{r+1}},$$

problem (P) *admits at least three weak solutions.*

Proof. It is worth noting that J_1 and J_2 satisfy the regularity assumptions outlined in Theorem 2.10. We will now establish the fulfillment of conditions (i) and (ii). To this end, let's consider

$$\left(\frac{1}{p_1^-}\left[\frac{2\delta}{R}\right]^{p_1} + \frac{1}{p_2^-}\left[\frac{2\delta}{R}\right]^{p_2}\right)\left|B(x_0,R)\setminus\overline{B}\left(x_0,\frac{R}{2}\right)\right| = d,$$

and consider $v_\delta \in E$ such that

$$v_\delta\begin{cases}0 & x\in\Omega\setminus B(x_0,R),\\ \frac{2\delta}{R}(R-|x-x_0|) & \in B(x_0,R)\setminus B\left(x_0,\frac{R}{2}\right),\\ \delta & x\in B\left(x_0,\frac{R}{2}\right).\end{cases}$$

Then, from Lemma 2.2 and by a direct calculation, shows that $\nabla v_\delta(x) = \frac{2\delta}{R}$, thus

$$\begin{aligned}&\|\nabla v_\delta(x)\|_{\tilde{p}(x)}\\ &\quad\le \max\{\|\nabla v_\delta\|^{\tilde{p}^-}_{\tilde{p}(x)}, \|\nabla v_\delta\|^{\tilde{p}^+}_{\tilde{p}(x)}\},\\ &\quad\le \max\left\{\left(\left[\frac{2\delta}{R}\right]^{\tilde{p}}\right)^{\tilde{p}^-}\left|B(x_0,R)\setminus\overline{B}\left(x_0,\frac{R}{2}\right)\right|^{\tilde{p}^-}, \left(\left[\frac{2\delta}{R}\right]^{\tilde{p}}\right)^{\tilde{p}^+}\left|B(x_0,R)\setminus\overline{B}\left(x_0,\frac{R}{2}\right)\right|^{\tilde{p}^+}\right\},\\ &\quad= \tilde{M}.\end{aligned}$$

By equation (3.1), we have

$$\begin{aligned}J_1(v_\delta) &= \sum_{i=1}^{2}\left(\int_\Omega \frac{1}{p_i(x)}|\nabla v_\delta|^{p_i(x)}\,dx\right) + \int_\Omega \frac{a(x)|v_\delta|^q}{q|x|^q}\,dx,\\ &\le \left(\frac{1}{p_1^-}\left[\frac{2\delta}{R}\right]^{p_1} + \frac{1}{p_2^-}\left[\frac{2\delta}{R}\right]^{p_2}\right)\left|B(x_0,R)\setminus\overline{B}\left(x_0,\frac{R}{2}\right)\right| + \frac{k^q\|a\|_\infty}{qH}\|v_\delta\|^q,\\ &= \left(\frac{1}{p_1^-}\left[\frac{2\delta}{R}\right]^{p_1} + \frac{1}{p_2^-}\left[\frac{2\delta}{R}\right]^{p_2}\right)\left|B(x_0,R)\setminus\overline{B}\left(x_0,\frac{R}{2}\right)\right| + \frac{k^q\|a\|_\infty}{qH}\|\nabla v_\delta(x)\|^q_{\tilde{p}(x)},\\ &\le \left(\frac{1}{p_1^-}\left[\frac{2\delta}{R}\right]^{p_1} + \frac{1}{p_2^-}\left[\frac{2\delta}{R}\right]^{p_2}\right)\left|B(x_0,R)\setminus\overline{B}\left(x_0,\frac{R}{2}\right)\right| + \frac{k^q\|a\|_\infty}{qH}\tilde{M}^q.\end{aligned}$$

Therefore, $J_1(v_\delta) > d$. however, it is important to consider the following

$$\begin{aligned}J_2(v_\delta) \ge \frac{1}{r+1}\left(\int_\Omega F(x,v_\delta)dx\right)^{r+1} &\ge \frac{m_1^{r+1}}{(r+1)(\alpha^+)^{r+1}}\left(\int_{B(x_0,\frac{R}{2})}|\delta|^{\alpha(x)}\,dx\right)^{r+1},\\ &\ge \frac{m_1^{r+1}([\delta]_\alpha)^{r+1}}{(r+1)(\alpha^+)^{r+1}}\left|B(x_0,\frac{R}{2})\right|^{r+1}.\end{aligned} \tag{3.2}$$

In addition, for every $u \in J_1^{-1}(]-\infty, d[)$, one has the following

$$\frac{1}{\tilde{p}^+}\left[\|\nabla u\|_{\tilde{p}(x)}\right]_{\tilde{p}} \leq d, \tag{3.3}$$

therefore,

$$\|\nabla u\|_{\tilde{p}(x)} \leq \left[\tilde{p}^+ J_1(u)\right]^{\frac{1}{\tilde{p}}} < \left[\tilde{p}^+ d\right]^{\frac{1}{\tilde{p}}}.$$

Under the assumption (**H**), we conclude the following

$$\begin{aligned} J_2(u) &\leq \frac{1}{r+1}\left(\int_\Omega F(x,u)\,dx\right)^{r+1}, \\ &\leq \frac{m_2^{r+1}}{(r+1)(\beta^-)^{r+1}}\left(\int_\Omega |u|^{\beta(x)}\,dx\right)^{r+1}, \\ &\leq \frac{m_2^{r+1}}{(r+1)(\beta^-)^{r+1}}\left(\left[\|u\|_{\beta(x)}\right]^{\beta}\right)^{r+1}, \\ &\leq \frac{m_2^{r+1}}{(r+1)(\beta^-)^{r+1}}\left(\left[c_\beta\|\nabla u\|_{\tilde{p}(x)}\right]^{\beta}\right)^{r+1}. \end{aligned} \tag{3.4}$$

This leads to the following result

$$\sup_{J_1(u)<d} J_2(u) \leq \frac{m_2^{r+1}([c_\beta]^\beta)^{r+1}(\tilde{p}^+)^{\frac{\beta^+(r+1)}{\tilde{p}^-}}}{(r+1)(\beta^-)^{r+1}}\left(\left[[d]^{\frac{1}{\tilde{p}}}\right]^{\beta}\right)^{r+1},$$

and

$$\frac{1}{d}\sup_{J_1(u)<d} J_2(u) < \frac{1}{\lambda}.$$

Furthermore, we can establish the coerciveness of J_λ for any positive value of λ by employing inequality (3.4) once more. This yields the following result

$$J_2(u) \leq \frac{m_2^{r+1}([c_\beta]^\beta)^{r+1}}{(r+1)(\beta^-)^{r+1}}\left(\left[\|\nabla u\|_{\tilde{p}(x)}\right]^{\beta}\right)^{r+1}.$$

When $\|u\| > 1$, the following can be inferred

$$J_1(u) - \lambda J_2(u) \geq \frac{1}{\tilde{p}^+}\|\nabla u\|_{\tilde{p}(x)}^{\tilde{p}^-} - \lambda\frac{m_2^{r+1}([c_\beta]^\beta)^{r+1}}{(r+1)(\beta^-)^{r+1}}\left(\left[\|\nabla u\|_{\tilde{p}(x)}\right]^{\beta}\right)^{r+1}.$$

By considering the fact that $\tilde{p}^- > \beta^+(r+1)$, we can reach the desired conclusion. In conclusion, considering the aforementioned fact that

$$\Psi_d^- = (A_\delta, B_d) \subseteq \left(\frac{J_1(v)}{J_2(v)}, \frac{d}{\sup_{J_1(u)<d} J_2(u)}\right).$$

Based on Theoem 2.10, it can be deduced that for $\lambda \in \Psi_d^-$, the function $J_1 - \lambda J_2$ possesses at least three critical points in E. These critical points correspond to weak solutions of problem (P). □

Abstract. This paper deals with the chemotaxis system with singular sensitivity and nonlocal logistic source

$$\begin{cases} u_t = u_{xx} - \left(\frac{u}{v}v_x\right)_x + u^\alpha\left(\gamma - \mu\int_\Omega u^\beta\right), & x\in\Omega, t>0,\\ v_t = v_{xx} - uv, & x\in\Omega, t>0, \end{cases}$$

under Neumann boundary conditions in a bounded open interval $\Omega\subset\mathbb{R}$, where α,β,γ,μ are positive constants. It is shown that for any $\beta > 1+\frac{(\alpha-3)_+}{2}$ and $\alpha\geq 1$, the system possesses a global and bounded classical solution. Moreover, we establish uniform-in-time boundedness of $\frac{v_x}{v}$.

Keywords: chemotaxis, nonlocal source, boundedness, singular sensitivity.

1 Introduction

In this paper, we consider the one-dimensional chemotaxis model with singular sensitivity and nonlocal term

$$\begin{cases} u_t = u_{xx} - \left(\frac{u}{v}v_x\right)_x + u^\alpha\left(\gamma - \mu\int_\Omega u^\beta\right), & x\in\Omega, t>0,\\ v_t = v_{xx} - uv, & x\in\Omega, t>0,\\ u_x = v_x = 0, & x\in\partial\Omega, t>0,\\ (u,v)(x,0) = \big(u_0(x), v_0(x)\big), & x\in\Omega, \end{cases} \tag{1.1}$$

in a bounded open interval $\Omega\subseteq\mathbb{R}$, where α, β, γ, μ are positive constants and where $u = u(x,t)$ denotes the cell density and where $v = v(x,t)$ represents the oxygen concentration.

✉Corresponding author. Email: jlzhang2020@163.com

The initial data in (1.1) satisfy

$$\begin{cases} u_0 \in C^0(\bar{\Omega}),\ u_0 \geq 0 \text{ and } u_0 \not\equiv 0, x \in \bar{\Omega}, \\ v_0 \in W^{1,q}(\Omega)\ (q > 2),\ v_0 > 0 \text{ in } \bar{\Omega} \text{ and } (v_0)_x = 0,\ x \in \partial\Omega. \end{cases} \tag{1.2}$$

Chemotaxis processes are known to play an important role in various biological contexts. There are also many works on various central aspects like global existence, lager time behaviors, finite time blow-up, and so on (see [4,6,7,11,28,32] and the references therein). When placed at one end of a capillary tube that contains oxygen and an energy source, bacteria of the species E. coli that have a gradient of nutrient concentration form bands that are visible to the unaided eye. They migrate at a constant speed due to a chemotactic mechanism [1]. In order to describe the consumption of the critical substrate and the change in bacterial density by random motion and chemotaxis, Keller and Segel proposed a phenomenological model of wave-like solution behavior without any type of cell kinetics [20], a prototypical version of which is given by:

$$\begin{cases} u_t = \Delta u - \chi \nabla \cdot \left(\frac{u}{v} \nabla v\right), & x \in \Omega, t > 0, \\ v_t = \Delta v - uv, & x \in \Omega, t > 0, \end{cases} \tag{1.3}$$

where the second equation models consumption of the signal upon contact with cells, and where in the first equation it is assumed that the chemotactic stimulus is perceived following the Weber–Fechner law, thus requiring the chemotactic sensitivity $\chi \frac{u}{v}$ to be chosen proportional to the reciprocal signal density. When $n = 2$, there exists a global generalized solution to (1.3) with $v \to 0$ in $L^p(\Omega)$ as $t \to \infty$ [33], and the solution becomes eventually smooth and converges to the homogeneous steady state if the initial mass $\int_\Omega u_0$ is small [35]. In particular, under an explicit smallness condition on $u_0 \ln u_0 \in L^1(\Omega)$ and $v_0^{-1} \nabla v_0 \in L^2(\Omega)$, the system (1.3) possesses a global classical solution [35]. Moreover, when $n \geq 3$, for all suitably regular and radially symmetric initial data (u_0, v_0), the existence of a globally defined pair (u, v) of radially symmetric functions in an appropriate generalized sense was established in [36]. When uv in (1.3) is replaced by $f(u)v$, $f \in C^1(\mathbb{R})$ essentially behaving like u^β, $\beta \in (0,1)$, $\chi \in (0,1)$, Lankeit and Viglialoro [25] showed that system has a global classical solution with any sufficiently regular initial data. Moreover, if additionally $\int_\Omega u(x,0)$ is sufficiently small, then also their boundedness is achieved. Replacing the first equation in (1.3) by $u_t = \Delta u - \chi \nabla \left(\frac{u}{v} \nabla v\right) + \gamma u - \mu u^k$, the authors in [23] showed that system (1.3) has a generalized global solution for any $\chi, \gamma, \mu > 0$ in the case $k = 2$. It is proved that as $\frac{1}{v}$ is replaced by $\phi(v) \in C^1(0,\infty)$ satisfying $\phi(v) \to \infty$ as $v \to 0$, this system possesses a global classical solution if $k > 1$ for $n = 1$ or $k > 1 + n/2$ for $n \geq 2$ [45]. The asymptotic behavior of solutions with $n = 2$ is determined [45]. For the local reaction term, a sequence of recent results on the existence of global-in-time solution, long-time behavior, vanishing coefficient limit and optimal time decay rates of the solution in the case $n = 1$ were obtained by Zeng and Zhao [41,42]. Recently, many variants of (1.3) have been proposed for applications under different frameworks, see for instance [2].

In those Keller–Segel models (cf. [21]) where v does not stand for a nutrient to be consumed but a signaling substance produced by the bacteria themselves, i.e., the second equation of (1.3) is replaced by $\tau v_t = \epsilon \Delta v - v + u$. For this system, the global solutions are known to exist if χ is sufficiently small, where the precise condition depends on the dimension as well as on $\tau = 0$ [15,29] or $\tau = 1$ [13,38,39]. As to the corresponding case with logistic source $\gamma u - \mu u^k$, the global existence of classical solutions and convergence to constant states were established in [9,16,18,22,27,40,43,44,47,48]. For a generalized solution concept, we refer to [12,26].

Nonlocal term in mathematical models can forecast how a disassociated sticky cell population will aggregate and react to the adhesive pressures produced by binding during cell-cell adhesion. See [3,17,30,31] for the reference. Bian et al. were devoted to the analysis of nonnegative solutions for the chemotaxis model with nonlocal nonlinear source in bounded domain in [5]

$$\begin{cases} u_t = \Delta u - \chi\nabla\cdot(u\nabla v) + u^\alpha\Big(1-\int_\Omega u^\beta\Big), & x\in\Omega, t>0,\\ 0 = \Delta v - v + u, & x\in\Omega, t>0, \end{cases} \tag{1.4}$$

where $\alpha \geq 1$, $\beta > 1$. They proved that if spatial dimension $n \geq 3$, either $2 \leq \alpha < 1 + \frac{2\beta}{n}$ or $\alpha < 2$ and $\frac{(2+n)(2-\alpha)}{n} < 1 + \frac{2\beta}{n} - \alpha$, the model admits a classical solution which is uniformly bounded. The same conclusion is established for the full-parabolic version in [8]. Recently, when the second equation of (1.4) is replaced by $v_t = \epsilon\Delta v - v + u$ and $-\chi\nabla\cdot(u\nabla v)$ is replaced by $-\chi\nabla\cdot(\frac{u}{v}\nabla v)$, the authors in [10] provide corresponding conditions to ensure the existence and boundedness of solutions, respectively.

In this paper, we consider the chemotaxis-consumption system with singular sensitivity and nonlocal logistic source. It is the purpose of this work to investigate the question of global existence and boundedness to (1.1) when $n = 1$. We first consider a non-singular chemotaxis system for (u, w) based on the transformation $w = -\ln\frac{v}{\|v_0\|_{L^\infty(\Omega)}}$ (see [33]). We obtain the key estimate on $\|w_x\|_{L^2(\Omega)}$ by deriving a subtle estimate for $\int_\Omega w_x^2 + \int_\Omega u^p$ with $1 < p < 2$. This is crucial to imply any further useful global regularity information on the quantity u itself. Before stating our results, we state that $x_+ = \max\{x, 0\}$.

Theorem 1.1. *Let $\Omega \subseteq \mathbb{R}$ be a bounded open interval. Suppose that $\gamma, \mu > 0$ and that*

$$\beta > 1 + \frac{(\alpha-3)_+}{2}, \quad \alpha \geq 1. \tag{1.5}$$

Then for any choice of u_0 and v_0 complying with (1.2), the problem (1.1) possesses a global bounded classical solution. Moreover, there exists some $\bar{M}$ such that

$$\Big\|\frac{v_x}{v}\Big\|_{L^\infty(\Omega)} \leq \bar{M}, \quad t > 0. \tag{1.6}$$

This paper is structured as follows. In Section 2, we present some preliminaries. In Section 3, we establish the global boundedness for $\frac{v_x}{v}$ and u in L^∞-norm.

2 Preliminaries

We need the Neumann heat semigroup in $\{e^{t\Delta}\}_{t\geq 0}$ estimates in $\Omega \subset \mathbb{R}^n$ to prove the local existence and the global existence of solutions. The following lemma below could be found in the vast existing literature, for instance, [14,34].

Lemma 2.1 ([14,34]). *Let $n \geq 1$, $\{e^{t\Delta}\}_{t\geq 0}$ be the Neumann heat semigroup in Ω, and $\lambda_1 > 0$ denotes the first nonzero eigenvalue of $-\Delta$ in Ω with respect to the Neumann boundary condition. Then there exist $K_1, \ldots, K_4 > 0$ depending on Ω only such that the following properties:*

(i) If $1 \leq p_2 \leq p_1 \leq \infty$, then

$$\|e^{t\Delta}z\|_{L^{p_1}(\Omega)} \leq K_1\left(1 + t^{-\frac{n}{2}(\frac{1}{p_2}-\frac{1}{p_1})}\right)e^{-\lambda_1 t}\|z\|_{L^{p_2}(\Omega)}, \quad t \in (0, T) \tag{2.1}$$

for all $z \in L^{p_2}(\Omega)$ satisfying $\int_\Omega z = 0$.

(ii) If $1 \le p_2 \le p_1 \le \infty$, *then*

$$\|\nabla e^{t\Delta} z\|_{L^{p_1}(\Omega)} \le K_2 \left(1 + t^{-\frac{1}{2}-\frac{n}{2}(\frac{1}{p_2}-\frac{1}{p_1})}\right) e^{-\lambda_1 t} \|z\|_{L^{p_2}(\Omega)}, \quad t \in (0,T) \tag{2.2}$$

for all $z \in L^{p_2}(\Omega)$.

(iii) If $2 \le p_2 \le p_1 \le \infty$, *then*

$$\|\nabla e^{t\Delta} z\|_{L^{p_1}(\Omega)} \le K_3 \left(1 + t^{-\frac{n}{2}(\frac{1}{p_2}-\frac{1}{p_1})}\right) e^{-\lambda_1 t} \|\nabla z\|_{L^{p_2}(\Omega)}, \quad t \in (0,T) \tag{2.3}$$

for all $z \in W^{1,p_2}(\Omega)$.

(iv) If $1 < p_2 \le p_1 < \infty$ *or* $1 < p_2 < \infty$ *and* $p_1 = \infty$, *then*

$$\|e^{t\Delta} \nabla z\|_{L^{p_1}(\Omega)} \le K_4 \left(1 + t^{-\frac{1}{2}-\frac{n}{2}(\frac{1}{p_2}-\frac{1}{p_1})}\right) e^{-\lambda_1 t} \|z\|_{L^{p_2}(\Omega)}, \quad t \in (0,T) \tag{2.4}$$

for all $z \in (L^{p_2}(\Omega))^n$.

Let us state a basic result on local existence and extensibility of classical solutions, which can be proved by well-established fixed point arguments (see [19,37,46]). However, we could not find a precise reference that covers our model, therefore, we show a short proof here.

Lemma 2.2. *Let* $\alpha, \beta \ge 1$ *and* $\gamma, \mu > 0$. *Suppose that* u_0 *and* v_0 *satisfy* (1.2). *Then there exist a maximal* $T \in (0, \infty]$ *and a nonnegative classical solution* (u, v) *of functions*

$$\begin{cases} u \in C^0\Big(\bar{\Omega} \times [0,T)\Big) \cap C^{2,1}\Big(\bar{\Omega} \times (0,T)\Big), \\ v \in C^0\Big(\bar{\Omega} \times [0,T)\Big) \cap C^{2,1}\Big(\bar{\Omega} \times (0,T)\Big) \cap L^\infty_{loc}\Big([0,T), W^{1,q}(\Omega)\Big) \end{cases}$$

satisfying (1.1) *in the classical sense in* $\Omega \times (0,T)$. *Moreover, we have the following alternative:*

$$\textit{Either} \quad T = \infty, \quad \textit{or} \quad \|u\|_{L^\infty(\Omega)} + \|v\|_{W^{1,q}(\Omega)} \to \infty \quad \textit{as } t \to T.$$

Proof. We first fix

$$K > 3 \max\{\|u_0\|_{L^\infty(\Omega)}, \|v_0\|_{L^q(\Omega)}, 6K_3 \|v_0'\|_{L^q(\Omega)}\}, \tag{2.5}$$

where K_3 is as in (2.3). For small $T_* \in (0,1)$ to be specified below, in the Banach space

$$X =: C^0([0,T_*]; C^0(\bar{\Omega})) \times C^0([0,T_*]; W^{1,q}(\Omega))$$

we consider the closed set

$$\begin{aligned} S := \{(u,v) \in X \mid \|u\|_{L^\infty((0,T_*);L^\infty(\Omega))} \le K, \ \|v\|_{L^\infty((0,T_*);W^{1,q}(\Omega))} \le K, \\ \inf_{x\in\Omega} v(\cdot,t) \ge \frac{1}{e} \inf_{x\in\Omega} v_0(x), \ \textit{for a.e. } t \in (0,T_*)\}. \end{aligned} \tag{2.6}$$

For $(u,v) \in S$ and $t \in (0,T_*)$, we let

$$\begin{aligned} \Phi(u,v)(t) &:= \begin{pmatrix} \phi_1(u,v)(t) \\ \phi_2(u,v)(t) \end{pmatrix} \\ &:= \begin{pmatrix} e^{t\Delta}u_0 - \int_0^t e^{(t-s)\Delta}(\frac{u}{v}v_x)_x + \gamma \int_0^t e^{(t-s)\Delta} u^\alpha - \mu \int_0^t e^{(t-s)\Delta}\left(u^\alpha \int_\Omega u^\beta\right) \\ e^{t\Delta}v_0 - \int_0^t e^{(t-s)\Delta} uv \end{pmatrix}. \end{aligned}$$

On dropping a nonpositive term, we use (2.4) and (2.6) to estimate

$$\begin{aligned}\|\phi_1(u,v)(t)\|_{L^\infty(\Omega)} \le\ & \|u_0\|_{L^\infty(\Omega)} + \frac{K_4 e}{\inf\limits_{x\in\Omega} v_0(x)} \int_0^t (t-s)^{-\frac{1}{2}-\frac{1}{2q}} e^{-\lambda_1(t-s)} \|u\|_{L^\infty(\Omega)} \|v_x\|_{L^q(\Omega)} \\ & + \gamma \int_0^t \sup_{t\in(0,T)} \|u\|^\alpha_{L^\infty(\Omega)} \\ \le\ & \frac{K}{3} + CT_*^{\frac{1}{2}-\frac{1}{2q}} + \gamma K^\alpha T_*, \quad t\in(0,T_*),\end{aligned} \tag{2.7}$$

where we use C to denote a generic positive constant independent of T^* here and below. Here when we deal with the first and third term we have used that $\|e^{\sigma\Delta}z\|_{L^{r_3}(\Omega)} \le \|z\|_{L^{r_3}(\Omega)}$, for all $z\in L^{r_3}(\Omega)$ with $1\le r_3\le\infty$.

We next derive the $W^{1,q}$-estimate on $\phi_2(u,v)$. On the one hand, we drop a nonpositive term to get

$$\|\phi_2(u,v)(t)\|_{L^q(\Omega)} = \left\|e^{t\Delta}v_0 - \int_0^t e^{(t-s)\Delta}uv\right\|_{L^q(\Omega)} \le \|v_0\|_{L^q(\Omega)} \le \frac{K}{3} \tag{2.8}$$

for all $t\in(0,T_*)$. On the other hand, it follows from (2.2), (2.3), (2.5) and (2.6) that

$$\begin{aligned}\|(\phi_2(u,v)(t))_x\|_{L^q(\Omega)} =\ & \left\|(e^{t\Delta}v_0)_x - \int_0^t (e^{(t-s)\Delta}uv)_x\right\|_{L^q(\Omega)} \\ \le\ & 2K_3\|(v_0)_x\|_{L^q(\Omega)} + K_2\int_0^t (t-s)^{-\frac{1}{2}} e^{-\lambda_1(t-s)}\|uv\|_{L^q(\Omega)} \\ \le\ & \frac{K}{3} + CT_*^{\frac{1}{2}}, \quad t\in(0,T_*).\end{aligned} \tag{2.9}$$

A combination of (2.8) and (2.9) entails

$$\|\phi_2(u,v)(t)\|_{W^{1,q}(\Omega)} \le \frac{2K}{3} + CT_*^{\frac{1}{2}}, \quad t\in(0,T_*). \tag{2.10}$$

The comparison principle to the second equation of (1.1) leads to $\|v\|_{L^\infty(\Omega)} \le \|v_0\|_{L^\infty(\Omega)}$ for all $t\in(0,T_*)$. By the order preserving of the Neumann heat semigroup, we find

$$\begin{aligned}\phi_2(u,v)(t) \ge e^{t\Delta}v_0 - \int_0^t e^{(t-s)\Delta}uv \ge & \inf_{x\in\Omega} v_0(x) - \int_0^t \|e^{(t-s)\Delta}uv\|_{L^\infty(\Omega)} \\ \ge & \inf_{x\in\Omega} v_0(x) - K\|v_0\|_{L^\infty(\Omega)}T_*, \quad t\in(0,T_*).\end{aligned} \tag{2.11}$$

If we take T_* small enough, then it follows from (2.7), (2.10) and (2.11) that $\Phi S\subseteq S$.

Moreover, with T_* still at our disposal, we proceed to check that for all $(u_1,v_1),(u_2,v_2)$ belonging to S,

$$\begin{aligned}\|\phi_1(u_1,v_1)(t) - \phi_1(u_2,v_2)(t)\|_{L^\infty(\Omega)} \le\ & \int_0^t \left\|e^{(t-s)\Delta}\left(\frac{u_1(v_1)_x}{v_1} - \frac{u_2v_2'}{v_2}\right)_x\right\|_{L^\infty(\Omega)} \\ & + \gamma\int_0^t \|e^{(t-s)\Delta}(u_1^\alpha - u_2^\alpha)\|_{L^\infty(\Omega)} \\ & + \mu\int_0^t \left\|e^{(t-s)\Delta}u_2^\alpha\int_\Omega (u_2^\beta - u_1^\beta)\right\|_{L^\infty(\Omega)} \\ & + \mu\int_0^t \left\|e^{(t-s)\Delta}(u_2^\alpha - u_1^\alpha)\int_\Omega u_1^\beta\right\|_{L^\infty(\Omega)}\end{aligned} \tag{2.12}$$

for all $t \in (0, T_*)$. For the first term of the right-hand side of (2.12), in accordance with (2.6) and (2.4), we can estimate

$$\begin{aligned}
&\int_0^t \left\| e^{(t-s)\Delta} \left(\frac{u_1(v_1)_x}{v_1} - \frac{u_2(v_2)_x}{v_2} \right)_x \right\|_{L^\infty(\Omega)} \\
&\quad \le K_2 \int_0^t (t-s)^{-\frac{1}{2}-\frac{1}{2q}} e^{-\lambda_1(t-s)} \left\| \frac{u_1(v_1)_x}{v_1} - \frac{u_2(v_2)_x}{v_2} \right\|_{L^q(\Omega)} \\
&\quad \le K_2 T_*^{\frac{1}{2}-\frac{1}{2q}} \|(u_1, v_1) - (u_2, v_2)\|_X.
\end{aligned} \tag{2.13}$$

Since $\alpha, \beta \ge 1$, from the mean value theorem and (2.6), we know

$$\|u_2^\alpha - u_1^\alpha\|_{L^\infty(\Omega)} \le \alpha K^{\alpha-1} \|u_2 - u_1\|_{L^\infty(\Omega)}, \qquad \|u_2^\beta - u_1^\beta\|_{L^\infty(\Omega)} \le \beta K^{\beta-1} \|u_2 - u_1\|_{L^\infty(\Omega)}.$$

We thus gain that

$$\begin{aligned}
&\gamma \int_0^t \|e^{(t-s)\Delta}(u_1^\alpha - u_2^\alpha)\|_{L^\infty(\Omega)} + \mu \int_0^t \left\| e^{(t-s)\Delta} u_2^\alpha \int_\Omega (u_2^\beta - u_1^\beta) \right\|_{L^\infty(\Omega)} \\
&\qquad + \mu \int_0^t \left\| e^{(t-s)\Delta}(u_2^\alpha - u_1^\alpha) \int_\Omega u_1^\beta \right\|_{L^\infty(\Omega)} \\
&\quad \le C T_* \|u_1 - u_2\|_{L^\infty(\Omega)}, \quad t \in (0, T_*).
\end{aligned} \tag{2.14}$$

Thus (2.12), (2.13), (2.14) provide

$$\|\phi_1(u_1, v_1)(t) - \phi_1(u_2, v_2)(t)\|_{L^\infty(\Omega)} \le C T_*^{\frac{1}{2}-\frac{1}{2q}} \|(u_1, v_1) - (u_2, v_2)\|_X, \quad t \in (0, T_*). \tag{2.15}$$

Similar process to (2.8)-(2.10), we can conclude that

$$\begin{aligned}
&\|\phi_2(u_1, v_1)(t) - \phi_2(u_2, v_2)(t)\|_{W^{1,q}(\Omega)} \\
&\quad \le \int_0^t \|e^{(t-s)\Delta} u_1(v_1 - v_2)\|_{W^{1,q}(\Omega)} + \int_0^t \|e^{(t-s)\Delta} v_2(u_1 - u_2)\|_{W^{1,q}(\Omega)} \\
&\quad \le C T_*^{\frac{1}{2}} \|(u_1, v_1) - (u_2, v_2)\|_X, \quad t \in (0, T_*),
\end{aligned} \tag{2.16}$$

so that Φ is shown to be a contraction if T_* is sufficiently small. Accordingly, the Banach fixed point theorem asserts the existence of some $(u, v) \in S$ such that $\Phi(u, v) = (u, v)$. Relying on straightforward regularity arguments including standard semigroup techniques, it can easily be checked that in fact (u, v) lies in the asserted regularity class and is a classical solution of (1.1) in $\Omega \times (0, T_*)$.

Finally, the nonnegative of (u, v) can be obtained by the strong maximum principle, which can be derived as that in [24]. It is sufficient to justify the conditions of Theorem B.1 in [24] in the following. Firstly, the equation

$$v_t = v_{xx} - uv, \quad x \in \Omega, t \in (0, T)$$

is considered. We interpret u as given function from above, i.e. $u \in C^0\big(\bar{\Omega} \times [0, T_*)\big) \cap C^{2,1}\big(\bar{\Omega} \times (0, T_*)\big)$. For given $T_1 < T_*$ one can fine $C > 0$ such that

$$u \le C, \quad \bar{\Omega} \times [0, T_1]. \tag{2.17}$$

With $b \equiv 0 \in C^1(\bar{\Omega}\times(0,T_1),\mathbb{R}) \cap L^\infty_{loc}(\Omega\times[0,T_1),\mathbb{R})$ fulfilling $b_x = 0$ on $\partial\Omega\times(0,T_1)$ and $f(x,t,u) := -u(x,t)v \in C^0(\Omega\times[0,T_1)\times\mathbb{R})$ satisfying

$$|f(x,t,v_1) - f(x,t,v_2)| = |u(v_1-v_2)| \le C|v_1-v_2|, \quad x\in\bar{\Omega}, t\in[0,T), v_1,v_2\in K$$

with compact K. Define $\underline{v} = \inf_{x\in\Omega} v_0(x)e^{-Ct}$. A direct calculation shows that

$$\begin{cases} \underline{v}_t = -C\underline{v} = \underline{v}_{xx} - C\underline{v} \le \underline{v}_{xx} - u\underline{v}, & x\in\Omega,\ t\in(0,T_1),\\ v_x = 0, & x\in\partial\Omega,\ t\in(0,T_1),\\ \underline{v}(\cdot,0) \le v_0(x), & x\in\Omega. \end{cases}$$

which by comparison implies

$$v(x,t) \ge \inf_{x\in\Omega} v_0(x)e^{-Ct} > 0 \quad \text{on } \Omega\times(0,T_1). \tag{2.18}$$

For given function $v \in C^0\big(\bar{\Omega}\times[0,T_*)\big)\cap C^{2,1}\big(\bar{\Omega}\times(0,T_*)\big)$ satisfying (2.18), we can study the first equation of (1.1)

$$u_t = u_{xx} - \Big(\frac{u}{v}v_x\Big)_x + u^\alpha\Big(\gamma - \mu\int_\Omega u^\beta\Big).$$

In order to apply Theorem B.1 in [24] to $b(x,t) = \frac{v_x}{v}$, $f(x,t,u) = u^\alpha\big(\gamma-\mu\int_\Omega u^\beta\big)$, we now verify the conditions of the comparison theorem. To avoid repetition, we just point out the differences, which are the local Lipschitz estimation of $f(x,t,u)$. For every compact K,

$$\begin{aligned} |f(x,t,u_1) - f(x,t,u_2)| &= \Big|u_1^\alpha\Big(\gamma-\mu\int_\Omega u_1^\beta\Big) - u_2^\alpha\Big(\gamma-\mu\int_\Omega u_2^\beta\Big)\Big| \\ &\le \gamma|u_1^\alpha - u_2^\alpha| + \mu\Big|u_2^\alpha\int_\Omega(u_2^\beta-u_1^\beta)\Big| + \mu\Big|(u_2^\alpha-u_1^\alpha)\int_\Omega u_1^\beta\Big| \\ &\le L(K,\alpha,\beta)|u_1-u_2|, \quad x\in\bar{\Omega}, t\in[0,T_1), u_1,u_2\in K, \end{aligned}$$

where $L(K,\alpha,\beta)$ is a positive constant. Therefore, the comparision theorem becomes applicable to suitable subsolutions and supersolutions of this equation. Moreover, since 0 is a subsolution of the equation, we have $u \ge 0$. □

A first basic property of this solution is immediate.

Lemma 2.3. *Let $\alpha,\beta \ge 1$ and $\gamma,\mu > 0$. Then*

$$\int_\Omega u \le M_0 := \max\left\{\int_\Omega u_0, |\Omega|^{1-\frac{1}{\beta}}\left(\frac{\gamma}{\mu}\right)^{\frac{1}{\beta}}\right\}, \quad t\in(0,T). \tag{2.19}$$

Proof. Integrating the first equation of (1.1), using the Hölder inequality, we obtain

$$\frac{d}{dt}\int_\Omega u \le \int_\Omega u^\alpha\left[\gamma - |\Omega|^{1-\beta}\mu\left(\int_\Omega u\right)^\beta\right], \quad t\in(0,T),$$

which implies (2.19) by a straightforward ODE analysis. □

Now following a standard procedure of changing variables in (1.1) we substitute

$$w = -\ln \frac{v}{\|v_0\|_{L^\infty(\Omega)}}$$

and thus infer that $w \geq 0$ in $\Omega \times (0,T)$ and

$$(u,w) \in \left(C^0\left(\bar{\Omega} \times [0,T)\right) \cap C^{2,1}\left(\bar{\Omega} \times (0,T)\right)\right)^2$$

solves

$$\begin{cases} u_t = u_{xx} + (uw_x)_x + u^\alpha\left(\gamma - \mu \int_\Omega u^\beta\right), & x \in \Omega, t \in (0,T), \\ w_t = w_{xx} - w_x^2 + u, & x \in \Omega, t \in (0,T), \\ u_x = w_x = 0, & x \in \partial\Omega, t \in (0,T), \\ u(x,0) = u_0,\ w(x,0) = -\ln \frac{v_0}{\|v_0\|_{L^\infty(\Omega)}}, & x \in \Omega. \end{cases} \tag{2.20}$$

We now prepare an estimate on $\int_\Omega u^k$ for all $k > 1$.

Lemma 2.4. *Let $\gamma, \mu > 0$. Suppose that u_0 and v_0 satisfy (1.2). Assume that α, β satisfy (1.5). Then for all $k > 1$, there exists $M_1(k) > 0$ such that*

$$\frac{d}{dt}\int_\Omega u^k + \int_\Omega u^k \leq -\frac{2(k-1)}{k}\int_\Omega \left|\left(u^{\frac{k}{2}}\right)_x\right|^2 - k(k-1)\int_\Omega u^{k-1}u_x w_x + M_1, \quad t \in (0,T). \tag{2.21}$$

Proof. Testing the first equation of (1.1) by ku^{k-1} and using Young's inequality, we obtain

$$\begin{aligned} \frac{d}{dt}\int_\Omega u^k + \int_\Omega u^k = & -\frac{4(k-1)}{k}\int_\Omega \left|\left(u^{\frac{k}{2}}\right)_x\right|^2 - k(k-1)\int_\Omega u^{k-1}u_x w_x + \int_\Omega u^k \\ & + k\gamma\int_\Omega u^{k+\alpha-1} - k\mu\int_\Omega u^{k+\alpha-1}\int_\Omega u^\beta, \quad t \in (0,T). \end{aligned} \tag{2.22}$$

We apply the Gagliardo–Nirenberg inequality and Young's inequality to find positive constants $C_0(\Omega), C_1(k,\Omega)$ such that

$$\begin{aligned} \int_\Omega u^k &\leq C_0\left(\int_\Omega \left|\left(u^{\frac{k}{2}}\right)_x\right|^2\right)^{\frac{k-1}{k+1}} \|u\|_{L^1(\Omega)}^{\frac{2k}{k+1}} + C_0\|u\|_{L^1(\Omega)}^k \\ &\leq \frac{k-1}{k}\int_\Omega \left|\left(u^{\frac{k}{2}}\right)_x\right|^2 + C_1\|u\|_{L^1(\Omega)}^k, \quad t \in (0,T). \end{aligned} \tag{2.23}$$

Let us fix β_0 satisfying

$$\beta_0 < \beta \tag{2.24}$$

and

$$\frac{\alpha-1}{2} < \beta_0 < k + \alpha - 1, \tag{2.25}$$

which is possible because $\beta > \frac{\alpha-1}{2}$. By virtue of Hölder's inequality and (2.24) we see that

$$-k\mu\int_\Omega u^{k+\alpha-1}\int_\Omega u^\beta \leq -k\mu|\Omega|^{1-\frac{\beta}{\beta_0}}\int_\Omega u^{k+\alpha-1}\left(\int_\Omega u^{\beta_0}\right)^{\frac{\beta}{\beta_0}}. \tag{2.26}$$

Due to the condition (2.25), we may invoke the Gagliardo–Nirenberg inequality along with the Young inequality, which says that there exist positive constants $C_2(\alpha,\gamma,k,\Omega)$ and $C_3(\alpha,\beta,\gamma,k,\Omega)$ satisfying

$$\begin{aligned} k\gamma\int_\Omega u^{k+\alpha-1}dx &\le C_2\left(\int_\Omega |(u^{\frac{k}{2}})_x|^2dx\right)^{\frac{a(k+\alpha-1)}{k}}\|u\|^{(1-a)(k+\alpha-1)}_{L^{\frac{Mk}{2}}(\Omega)}+C_2\|u\|^{k+\alpha-1}_{L^1(\Omega)}\\ &\le \frac{k-1}{k}\int_\Omega |(u^{\frac{k}{2}})_x|^2+C_3\|u\|^{\frac{(1-a)k(k+\alpha-1)}{k-a(k+\alpha-1)}}_{L^{\frac{Mk}{2}}(\Omega)}+C_2\|u\|^{k+\alpha-1}_{L^1(\Omega)}, \end{aligned} \tag{2.27}$$

where

$$M=2\beta_0(k+\alpha-1+\beta)k^{-1}(\beta+\beta_0)^{-1}$$

and where

$$a=\beta k(k+\alpha-1-\beta_0)(k+\alpha-1)^{-1}[(\beta+\beta_0)k+(k+\alpha-1+\beta)\beta_0]^{-1}\in(0,1),$$

thanks to (2.25). Moreover, making full use of (2.25) we see that actually

$$\beta_0<\frac{Mk}{2}<k+\alpha-1, \tag{2.28}$$

and that

$$\frac{k(k+\alpha-1)(1-a)}{[k-a(k+\alpha-1)](k+\alpha-1+\beta)}<1. \tag{2.29}$$

Indeed, (2.29) is possible since the definition of a ensures that

$$\begin{aligned} &\frac{k(k+\alpha-1)(1-a)}{[k-a(k+\alpha-1)](k+\alpha-1+\beta)}\\ &\quad=\frac{(k+\alpha-1)[\beta_0k+(k+\alpha-1+\beta)\beta_0]+\beta\beta_0k}{(k+\alpha-1)[\beta_0k+(k+\alpha-1+\beta)\beta_0]+\beta\beta_0k+\beta(k+\alpha-1+\beta)[2\beta_0-(\alpha-1)]}. \end{aligned}$$

Therefore, in view of (2.28) and (2.29), one further application of Young's inequality and the interpolation inequality provides $C_4(\alpha,\beta,\gamma,\mu,k,\Omega)$ such that

$$\begin{aligned} C_3\|u\|^{\frac{(1-a)k(k+\alpha-1)}{k-a(k+\alpha-1)}}_{L^{\frac{Mk}{2}}(\Omega)} &\le C_3\left[\int_\Omega u^{k+\alpha-1}\left(\int_\Omega u^{\beta_0}\right)^{\frac{\beta}{\beta_0}}\right]^{\frac{k(k+\alpha-1)(1-a)}{[k-a(k+\alpha-1)](k+\alpha-1+\beta)}}\\ &\le k\mu|\Omega|^{1-\frac{\beta}{\beta_0}}\int_\Omega u^{k+\alpha-1}\left(\int_\Omega u^{\beta_0}\right)^{\frac{\beta}{\beta_0}}+C_4. \end{aligned} \tag{2.30}$$

From (2.22), (2.23), (2.26), (2.27) and (2.30), we have

$$\begin{aligned} \frac{d}{dt}\int_\Omega u^k+\int_\Omega u^k \le &-\frac{2(k-1)}{k}\int_\Omega\left|\left(u^{\frac{k}{2}}\right)_x\right|^2-k(k-1)\int_\Omega u^{k-1}u_xw_x+C_1\|u\|^k_{L^1(\Omega)}\\ &+C_2\|u\|^{k+\alpha-1}_{L^1(\Omega)}+C_4,\quad t\in(0,T). \end{aligned} \tag{2.31}$$

Therefore, (2.21) results from (2.31) by taking $M_1=C_1M_0^k+C_2M_0^{k+\alpha-1}+C_4$. □

3 Global boundedness of solutions

This section is devoted to the derivation of estimates for w, so as to finally obtain the global boundedness of solutions. For this purpose, we establish L^2 estimate on w_x and L^4 estimate on w_x for our present setting.

Lemma 3.1. *Let $\gamma, \mu > 0$, and suppose that u_0 and v_0 satisfy (1.2). Assume that α, β satisfy (1.5). Then there exists constant $M_2 > 0$ depend on $\alpha, \beta, \gamma, \mu, \Omega$ such that*

$$\int_\Omega w_x^2 \le M_2, \quad t \in (0,T). \tag{3.1}$$

Proof. Recalling $(w_0)_x = 0$ on $\partial\Omega$, we multiply the second equation in (2.20) by $-w_{xx}$ and integrate by parts to see, using Young's inequality, that

$$\frac{d}{dt}\int_\Omega w_x^2 = -2\int_\Omega w_{xx}^2 - 2\int_\Omega u w_{xx} \le -\int_\Omega w_{xx}^2 + \int_\Omega u^2, \quad t \in (0,T). \tag{3.2}$$

For fixed $1 < p < 2$, applying $k = p$ to (2.21) takes the form

$$\begin{aligned}\frac{d}{dt}\int_\Omega u^p + \int_\Omega u^p &\le -\frac{2(p-1)}{p}\int_\Omega \left|\left(u^{\frac{p}{2}}\right)_x\right|^2 - p(p-1)\int_\Omega u^{p-1}u_x w_x + M_1 \\ &= -\frac{2(p-1)}{p}\int_\Omega \left|\left(u^{\frac{p}{2}}\right)_x\right|^2 + (p-1)\int_\Omega u^p w_{xx} + M_1, \quad t \in (0,T),\end{aligned}$$

which along with Young's inequality derives

$$\frac{d}{dt}\int_\Omega u^p + \int_\Omega u^p \le -\frac{2(p-1)}{p}\int_\Omega |(u^{\frac{p}{2}})_x|^2 + \frac{1}{2}\int_\Omega w_{xx}^2 + \frac{(p-1)^2}{2}\int_\Omega u^{2p} + M_1 \tag{3.3}$$

for all $t \in (0,T)$. According to Poincaré's inequality and the fact $(w_0)_x = 0$ on $\partial\Omega$, we know there is constant $C_5(\Omega)$ such that

$$-\frac{1}{2}\int_\Omega w_{xx}^2 \le -\frac{1}{2C_5}\int_\Omega w_x^2. \tag{3.4}$$

Recalling $p > 1$, Young's inequality provide $C_7(p,\Omega) > 0$ such that

$$\int_\Omega u^2 \le \int_\Omega u^{2p} + C_7. \tag{3.5}$$

Collecting (3.2)–(3.5) we see that

$$\begin{aligned}&\frac{d}{dt}\left(\int_\Omega w_x^2 + \int_\Omega u^p\right) + C_6\left(\int_\Omega w_x^2 + \int_\Omega u^p\right) \\ &\quad\le -\frac{2(p-1)}{p}\int_\Omega |(u^{\frac{p}{2}})_x|^2 + \left[1 + \frac{(p-1)^2}{2}\right]\int_\Omega u^{2p} + C_8, \quad t \in (0,T),\end{aligned} \tag{3.6}$$

where $C_6 = \min\{1, \frac{1}{2C_5}\}$ and $C_8 = C_7 + M_1$. Here our assumption for $1 < p < 2$ warrants that

$$0 < \frac{2p-1}{p+1} < 1. \tag{3.7}$$

We may once more rely on Young's inequality together with Gagliardo–Nirenberg inequality to see that there exist constants $C_9(p,\Omega), C_{10}(p,\Omega) > 0$ such that

$$\begin{aligned}\left[1+\frac{(p-1)^2}{2}\right]\int_\Omega u^{2p} &= \frac{(p-1)^2}{2}\|u^{\frac{p}{2}}\|^4_{L^4(\Omega)}\\ &\le C_9\left(\int_\Omega \left|(u^{\frac{p}{2}})_x\right|^2\right)^{\frac{2p-1}{p+1}}\|u\|^{\frac{3p}{p+1}}_{L^1(\Omega)} + C_9\|u\|^{2p}_{L^1(\Omega)}\\ &\le \frac{p-1}{p}\int_\Omega |(u^{\frac{p}{2}})_x|^2 + C_{10}\|u\|^{\frac{3p}{2-p}}_{L^1(\Omega)} + C_9\|u\|^{2p}_{L^1(\Omega)}\end{aligned} \tag{3.8}$$

for all $t \in (0,T)$, which together with (3.6) and (3.8) asserts

$$\frac{d}{dt}\left(\int_\Omega w_x^2 + \int_\Omega u^p\right) + C_6\left(\int_\Omega w_x^2 + \int_\Omega u^p\right) \le C_8 + C_9\|u\|^{2p}_{L^1(\Omega)} + C_{10}\|u\|^{\frac{3p}{2-p}}_{L^1(\Omega)} \tag{3.9}$$

for all $t \in (0,T)$. Thereupon, (3.1) can be derived by (3.9) and (2.19). □

Lemma 3.2. *Let $\gamma, \mu > 0$, and suppose that u_0 and v_0 satisfy (1.2). Assume that α, β satisfy (1.5). Then there exists $M_3(\alpha,\beta,\gamma,\mu,\Omega) > 0$ such that*

$$\int_\Omega w_x^4 + \int_\Omega u^2 \le M_3, \quad t \in (0,T). \tag{3.10}$$

Proof. By (2.21) with $k = 2$, we get

$$\frac{d}{dt}\int_\Omega u^2 + \int_\Omega u^2 \le -\int_\Omega u_x^2 - 2\int_\Omega u u_x w_x + M_1.$$

Fixing $\theta > 1$, we use Young's inequality and Hölder's inequality to obtain

$$\frac{d}{dt}\int_\Omega u^2 + \int_\Omega u^2 \le -\frac{1}{2}\int_\Omega u_x^2 + 2\|u\|^2_{L^{2\theta}(\Omega)}\|w_x^2\|_{L^{\frac{\theta}{\theta-1}}(\Omega)} + M_1, \quad t \in (0,T). \tag{3.11}$$

Now another application of Young's inequality, followed by Hölder's inequality, reveals that

$$\begin{aligned}\frac{d}{dt}\int_\Omega w_x^4 &= -12\int_\Omega w_x^2 w_{xx}^2 - 12\int_\Omega w_x^2 w_{xx} u\\ &\le -12\int_\Omega w_x^2 w_{xx}^2 + 8\int_\Omega w_x^2 w_{xx}^2 + \frac{9}{2}\int_\Omega w_x^2 u^2\\ &\le -\int_\Omega |(w_x^2)_x|^2 + \frac{9}{2}\|u\|^2_{L^{2\theta}(\Omega)}\|w_x^2\|_{L^{\frac{\theta}{\theta-1}}(\Omega)}\end{aligned} \tag{3.12}$$

for all $t \in (0,T)$. Adding (3.11) and (3.12), we write

$$\begin{aligned}&\frac{d}{dt}\left(\int_\Omega w_x^4 + \int_\Omega u^2\right) + \left(\int_\Omega w_x^4 + \int_\Omega u^2\right)\\ &\quad\le -\int_\Omega |(w_x^2)_x|^2 - \frac{1}{2}\int_\Omega u_x^2 + \|w_x^2\|^2_{L^2(\Omega)} + \frac{13}{2}\|u\|^2_{L^{2\theta}(\Omega)}\|w_x^2\|_{L^{\frac{\theta}{\theta-1}}(\Omega)} + M_1\end{aligned} \tag{3.13}$$

for all $t \in (0,T)$. Using the Gagliardo–Nirenberg inequality, we deduce $C_{11}(\Omega) > 0$ such that

$$\|u\|^2_{L^{2\theta}(\Omega)} \le 4C_{11}^2\left(\int_\Omega u_x^2\right)^{\frac{2\theta-1}{3\theta}}\|u\|^{\frac{2(\theta+1)}{3\theta}}_{L^1(\Omega)} + 4C_{11}^2\|u\|^2_{L^1(\Omega)}, \quad t \in (0,T) \tag{3.14}$$

and

$$\|w_x^2\|_{L^{\frac{\theta}{\theta-1}}(\Omega)} \le C_{11}\left(\int_\Omega |(w_x^2)_x|^2\right)^{\frac{1}{3\theta}} \|w_x^2\|_{L^1(\Omega)}^{\frac{3\theta-2}{3\theta}} + C_{11}\|w_x^2\|_{L^1(\Omega)}, \quad t\in(0,T) \tag{3.15}$$

as well as

$$\|w_x^2\|_{L^2(\Omega)}^2 \le 4C_{11}^2\left(\int_\Omega |(w_x^2)_x|^2\right)^{\frac{1}{3}} \|w_x^2\|_{L^1(\Omega)}^{\frac{4}{3}} + 4C_{11}^2\|w_x^2\|_{L^1(\Omega)}^2, \quad t\in(0,T). \tag{3.16}$$

Therefore, in view of $\frac{2\theta-1}{3\theta}+\frac{1}{3\theta}=\frac{2}{3}<1$, we apply Young's inequality and recall (3.14)–(3.16) to estimate

$$\begin{aligned}
&\|w_x^2\|_{L^2(\Omega)}^2 + \frac{13}{2}\|u\|_{L^{2\theta}(\Omega)}^2\|w_x^2\|_{L^{\frac{\theta}{\theta-1}}(\Omega)} \\
&\le \frac{1}{2}\int_\Omega |u_x|^2 + \frac{3}{4}\int_\Omega |(w_x^2)_x|^2 + C_{11}\|u\|_{L^1(\Omega)}^{\frac{2(\theta+1)}{\theta}}\|w_x^2\|_{L^1(\Omega)}^{\frac{3\theta-2}{\theta}} + C_{11}\|u\|_{L^1(\Omega)}^2\|w_x^2\|_{L^1(\Omega)}^{\frac{3\theta}{\theta+1}} \\
&\quad + C_{11}\|u\|_{L^1(\Omega)}^{\frac{6\theta}{3\theta-1}}\|w_x^2\|_{L^1(\Omega)}^{\frac{3\theta-2}{3\theta-1}} + C_{11}\|u\|_{L^1(\Omega)}^2\|w_x^2\|_{L^1(\Omega)} + C_{11}\|w_x^2\|_{L^1(\Omega)}^2
\end{aligned} \tag{3.17}$$

for all $t\in(0,T)$. Here C_{11} is a constant that depends on Ω. In view of (2.19), (3.1), (3.13) and (3.17), this immediately leads to (3.10), upon an ODE comparison principle. □

With the estimate (3.10) at hand, we now turn to establish uniform-in-time boundedness of u and w_x.

Proof of Theorem 1.1. In view of Lemma 2.2, it is routine to check that for any fixed $t_0\in(0,T)$, $\sup_{0\le t\le t_0}\|u(\cdot,t)\|_{L^\infty(\Omega)}$, $\sup_{0\le t\le t_0}\|w_x(\cdot,t)\|_{L^q(\Omega)}$ are bounded. It is sufficient to justify it for $t\in(t_0,T)$.

Employing the Neumann heat semigroup $\{e^{\Delta t}\}_{t\ge0}$, we represent w_x according to

$$w_x(t) = \left(e^{t\Delta}w_0\right)_x - \int_0^t \left(e^{(t-s)\Delta}w_x^2\right)_x + \int_0^t \left(e^{(t-s)\Delta}u\right)_x, \quad t\in(t_0,T),$$

recalling (2.2), (2.3) and (3.10), we obtain $C_{12}(\Omega)>0$ such that

$$\begin{aligned}
\|w_x\|_{L^\infty(\Omega)} &\le C_{12}[1+t^{-\frac{1}{2q}}]e^{-\lambda_1 t}\|w_0'\|_{L^q(\Omega)} + C_{12}\int_0^t [1+(t-s)^{-\frac{3}{4}}]e^{-\lambda_1(t-s)}\sup_{t\in(0,T)}\|w_x\|_{L^4(\Omega)}^2 \\
&\quad + C_{12}\int_0^t [1+(t-s)^{-\frac{3}{4}}]e^{-\lambda_1(t-s)}\sup_{t\in(0,T)}\|u\|_{L^2(\Omega)} \\
&\le C_{13}, \quad t\in(t_0,T),
\end{aligned} \tag{3.18}$$

where $C_{13} = C_{12}[1+t_0^{-\frac{1}{2q}}]\|w_0'\|_{L^q(\Omega)} + 2C_{12}M_3^{\frac{1}{2}}\int_0^t[1+(t-s)^{-\frac{3}{4}}]e^{-\lambda_1(t-s)}$ is a bounded constant because $\int_0^t[1+(t-s)^{-\frac{3}{4}}]e^{-\lambda_1(t-s)}$ is finite. In consequence, (3.18) and the definition of w hence establish (1.6). Using (2.21) and Young's inequality along with (3.18), we obtain

$$\begin{aligned}
\frac{d}{dt}\int_\Omega u^k + \int_\Omega u^k &\le -\frac{k-1}{k}\int_\Omega \left|\left(u^{\frac{k}{2}}\right)_x\right|^2 - \frac{k(k-1)}{4}\int_\Omega u^{k-2}u_x^2 \\
&\quad - k(k-1)\int_\Omega u^{k-1}u_x w_x + M_1 \\
&\le -\frac{k-1}{k}\int_\Omega \left|\left(u^{\frac{k}{2}}\right)_x\right|^2 + k(k-1)C_{13}^2\int_\Omega u^k + M_1,
\end{aligned} \tag{3.19}$$

for all $t \in (t_0, T)$ and $k > 2$. Following procedures analogous to (2.23) we can obtain $C_{14}(k, \alpha, \beta, \gamma, \mu, \Omega) > 0$ such that

$$k(k-1)C_{13}^2 \int_\Omega u^k \le \frac{(k-1)}{k} \int_\Omega \left| \left(u^{\frac{k}{2}} \right)_x \right|^2 + C_{14} \|u\|_{L^1(\Omega)}^k, \quad t \in (t_0, T). \tag{3.20}$$

A combination of the above estimates (3.19) and (3.20) yields that

$$\frac{d}{dt} \int_\Omega u^k + \int_\Omega u^k \le M_1 + C_{14} \|u\|_{L^1(\Omega)}^k, \quad t \in (t_0, T).$$

It holds true that for any $2 < k < \infty$, there exists $C_{15}(k, \alpha, \beta, \gamma, \mu, \Omega) > 0$ such that

$$\int_\Omega u^k \le C_{15}, \quad t \in (t_0, T), \tag{3.21}$$

here we use the ordinary differential equations comparison argument together with (2.19). By the variation-of-constants formula, u can be represented as

$$\begin{aligned} u = e^{t\Delta} u_0 + \int_0^t e^{(t-s)\Delta} (u w_x)_x + \int_0^t e^{(t-s)\Delta} \left(\frac{\gamma}{|\Omega|} \int_\Omega u^\alpha \right) \\ + \gamma \int_0^t e^{(t-s)\Delta} \left(u^\alpha - \frac{1}{|\Omega|} \int_\Omega u^\alpha \right) - \mu \int_0^t e^{(t-s)\Delta} \left(u^\alpha \int_\Omega u^\beta \right), \quad t \in (t_0, T). \end{aligned}$$

On dropping a nonpositive term, we have

$$\begin{aligned} u \le e^{t\Delta} u_0 + \int_0^t e^{(t-s)\Delta} (u w_x)_x + \int_0^t e^{(t-s)\Delta} \left(\frac{\gamma}{|\Omega|} \int_\Omega u^\alpha \right) \\ + \gamma \int_0^t e^{(t-s)\Delta} \left(u^\alpha - \frac{1}{|\Omega|} \int_\Omega u^\alpha \right), \quad t \in (t_0, T). \end{aligned}$$

With this representation and standard smoothing estimates (2.1) and (2.4), we arrive at

$$\begin{aligned} \|u\|_{L^\infty(\Omega)} \le \|u_0\|_{L^\infty(\Omega)} + C_{16} \int_0^t [1 + (t-s)^{-\frac{3}{4}}] e^{-\lambda_1 (t-s)} \sup_{t \in (0,T)} \|u\|_{L^2(\Omega)} \|w_x\|_{L^\infty(\Omega)} \\ + \left[\frac{\gamma}{|\Omega|} + 2C_{16}\gamma \int_0^t [1 + (t-s)^{-\frac{1}{2}}] e^{-\lambda_1 (t-s)} \right] \left(\sup_{t \in (0,T)} \|u\|_{L^\alpha(\Omega)} \right)^\alpha, \quad t \in (t_0, T) \end{aligned}$$

with $C_{16}(\Omega) > 0$, whence observing (3.18) and (3.21), we therefore obtain the desired global boundedness of u. Consequently, Theorem 1.1 is completed. □

Abstract. In this paper, we consider the existence and nonexistence of solutions for a class of modified Schrödinger–Poisson system with Kirchhoff-type perturbation by use of variational methods. When nonlinear term $h(u) = |u|^{p-2}u$, $1 \leq p < \infty$, the nonexistence of nontrivial solutions of system is demonstrated through Pohožaev identity. When nonlinear term $h(u)$ satisfies appropriate assumptions, taking advantage of critical point theorem, we obtain a positive radial solution and a nontrivial one of system when $g(u)$ satisfies different conditions. Moreover, some convergence properties are established as the parameter $b \to 0$. What is more, the nonexistence of nontrivial solutions in critical case is also proved by use of Pohožaev identity.

Keywords: variational methods, Pohožaev identity, critical point theorem, nonexistence, radial solution.

1 Introduction

In this paper, we studied the following generalized quasilinear Schrödinger–Poisson system with a Kirchhoff-type perturbation, which is an innovative research topic.

$$\begin{cases} \left(1 + b\int_{\mathbb{R}^3} g^2(u)|\nabla u|^2 dx\right)[-\operatorname{div}(g^2(u)\nabla u) + g(u)g'(u)|\nabla u|^2] \\ +V(x)u + \phi u = h(u), & x \in \mathbb{R}^3, \\ -\Delta\phi = u^2, & x \in \mathbb{R}^3, \end{cases} \tag{1.1}$$

where $b \geq 0$, $V : \mathbb{R}^3 \to \mathbb{R}$ and $h : \mathbb{R} \to \mathbb{R}$ are continuous functions, $g \in C^1(\mathbb{R}, \mathbb{R}^+)$ satisfies the following assumption:

✉Corresponding author. Email: jinshizhangjing@163.com

(g_1) g is even with $g'(t) \leq 0$ for all $t \geq 0$ and $g(0) = 1$, $\lim_{t\to+\infty} g(t) = a$, $a \in (0, 1)$.

When $\phi = 0$, the system (1.1) has become the following Kirchhoff–Schrödinger equation:

$$\left(1 + b\int_{\mathbb{R}^3} g^2(u)|\nabla u|^2 dx\right)[-\mathrm{div}(g^2(u)\nabla u) + g(u)g'(u)|\nabla u|^2] + V(x)u = h(x, u), \quad x \in \mathbb{R}^N. \tag{1.2}$$

Problem (1.2) is related to the stationary analogue of the Kirchhoff–Schrödinger type equation, which was proposed by Kirchhoff as an extension of classical D'Alembert's wave equation for free vibrations of elastic strings [13, 18]. Since the Kirchhoff-type problems arise in various models of physical and biological systems, numerous scholars have conducted research on problem (1.2). References [3] and [20] considered the existence and nonexistence of solutions for problem (1.2). For $h(x, u) = \lambda f(u) + g(u)G^5(u)$ as considered in [3], where $G(u) = \int_0^u g(t)dt$. Under some suitable assumptions on $f(u)$, problem (1.2) admits at least one positive ground state solution for $\lambda > \lambda^* > 0$. If $\lambda = 0$, the corresponding equation had no nontrivial solution. For $h(x, u) = f(u)$ and $f(u)$ satisfied appropriate conditions, then problem (1.2) had at least one radial ground state solution. In [20], when $h(x, u)$ satisfied critical or supercritical growth at infinity, the nonexistence result for (1.2) was proved via Pohožaev identity. If $h(x, u)$ showed asymptotically cubic growth at infinity, the existence of positive radial solutions for (1.2) was obtained by use of variational methods. Moreover, some properties were established as the parameter $b \to 0$. Both of the existence of ground state and sign-changing ground state solutions about (1.2) were testified in [23]. Chen et al. [6] applied some new analytical techniques and non-Nehari manifold method to obtain one ground state sign-changing solution $v_b = G^{-1}(u_b)$. Moreover, they illustrated that the energy of $v_b = G^{-1}(u_b)$ is strictly larger than twice of the Nehari type ground state solution. They also established the convergence properties of $v_b = G^{-1}(u_b)$ as the parameter $b \to 0$.

For $g(u) = 1$, problem (1.2) transforms to the following classical Kirchhoff equation:

$$-\left(1 + b\int_{\mathbb{R}^3} |\nabla u|^2 dx\right)\Delta u + V(x)u = h(x, u), \quad x \in \mathbb{R}^3,$$

which takes into account the changes in length of the string produced by transverse vibrations, hence the nonlocal term appeared. If $b = 0$, problem (1.2) takes the following form:

$$-\mathrm{div}(g^2(u)\nabla u) + g(u)g'(u)|\nabla u|^2 + V(x)u = h(x, u), \quad x \in \mathbb{R}^3. \tag{1.3}$$

This equation is related to the existence of solitary wave solutions for quasilinear Schrödinger equations:

$$i\partial_t z = -\Delta z + W(x)z - k(x, |z|) - \Delta l(|z|^2)l'(|z|^2)z, \tag{1.4}$$

where $z : \mathbb{R} \times \mathbb{R}^N \to \mathbb{C}$, $W : \mathbb{R}^N \to \mathbb{R}$ is a given potential, $l : \mathbb{R} \to \mathbb{R}$ and $k : \mathbb{R}^N \times \mathbb{R} \to \mathbb{R}$ are suitable functions. Equation (1.4) appeared in plasma physics and fluid mechanics [25], dissipative quantum mechanics [12] and condensed matter theory [24]. The existing results for equation (1.3) such as nontrivial solutions [15], ground state solutions [4, 31, 33], positive solutions [9,10,29], nonexistence of solutions [14], high-energy solutions [22], multiple solutions [21] and infinitely many solutions [30] were obtained respectively.

System (1.1) is the so called quasilinear Kirchhoff–Schrödinger–Poisson system. If $b = 0$, (1.1) reduces to the following quasilinear Schrödinger–Poisson system:

$$\begin{cases} -\mathrm{div}(g^2(u)\nabla u) + g(u)g'(u)|\nabla u|^2 + V(x)u + \phi u = h(u), & x \in \mathbb{R}^3, \\ -\Delta\phi = u^2, & x \in \mathbb{R}^3. \end{cases} \tag{1.5}$$

In [27], the authors proved the following problem admits at least a ground state solution

$$\begin{cases} -\mathrm{div}(g^2(u)\nabla u) + g(u)g'(u)|\nabla u|^2 + V(x)u + \phi G(u)g(u) = h(x,u), & x \in \mathbb{R}^3, \\ -\Delta\phi = G^2(u), & x \in \mathbb{R}^3, \end{cases}$$

for $h(x,u) = b(x)|G(u)|^{p-2}G(u)g(u) - c(x)|G(u)|^{q-2}G(u)g(u)$, $2 < q < 4 < p < 6$. Recently, Zhang and Liu obtained a nontrivial ground state solution for $h(x,u) = \lambda f(u) + g(u)G^5(u)$ in reference [38]. By setting $g^2(u) = 1 + 2u^2$ in (1.5), we get the following quasilinear Schrödinger–Poisson system:

$$\begin{cases} -\Delta u + V(x)u + \phi u - ku\Delta(u^2) = h(u), & \text{in } \mathbb{R}^3, \\ -\Delta\phi = u^2, & \text{in } \mathbb{R}^3. \end{cases} \tag{1.6}$$

There are a variety of excellent results for system (1.6). References [11, 34, 35] studied the existence of nontrivial solutions respectively for $k = \frac{1}{2}$ or $k = 1$. The authors in [32] obtained the existence of ground state solution and infinitely many geometrically distinct solutions. The sign-changing solutions can be referred to the references [2, 37].

By setting $g^2(u) = 1 + 2u^2$ in (1.1), we get the following modified quasilinear Kirchhoff–Schrödinger–Poisson system:

$$\begin{cases} -(1 + b\int_{\mathbb{R}^3}|\nabla u|^2dx)\Delta u + V(x)u - \frac{1}{2}u\Delta(u^2) + \phi u = h(u), & x \in \mathbb{R}^3, \\ -\Delta\phi = u^2, & x \in \mathbb{R}^3. \end{cases} \tag{1.7}$$

System (1.7) was introduced in [1] very recently, the authors proved that problem (1.7) has at least three solutions: one is positive, one is negative, and one changes its sign. Furthermore, if h is odd with respect to u, they also obtained unbounded sequence of sign-changing solutions. Under appropriate conditions, the authors in [5] discussed the existence of nontrivial nonpositive and nonnegative solutions, a sequence of high-energy solutions via perturbation method. Combining perturbation method with discontinuous finite element method, a series of weak solutions of system (1.7) were gained in [7] for $h(x,u) = K(x)u^{p-2}u$, where $K(x) \in L^{\frac{2}{2-p}}(\mathbb{R}^3)$, $1 < p < 2$ and $K(x) > 0$ for $x \in \mathbb{R}^3$. When system (1.7) involving a nonlocal term and an integral constraint, infinitely many sign-changing solutions were obtained in [8] according to the method of invariant sets of the descending flow combined with the genus theory. The authors in [36] proved that the system (1.7) has a sign-changing solution u_0, which has precisely two nodal domains. The same conclusion was gained in [17] as in [36] for critical case that $h(u) = \lambda|u|^{q-2}u\ln|u|^2 + |u|^4u$.

Nevertheless, there are relatively few achievements on the generalized quasilinear Kirchhoff–Schrödinger–Poisson system (1.1), so the discussion in this paper makes innovations of the pioneering work. Based on the existing results, we extend the results of references [3] and [20] to the generalized quasilinear Kirchhoff–Schrödinger–Poisson system, then we obtain the existence and nonexistence of solutions for system (1.1).

We make some assumptions on $V(x)$ and $h(u)$:

(V_1) $V \in C(\mathbb{R}^3, \mathbb{R})$, $V(x) = V(|x|)$, $0 < V_0 \le V(x) \le V_\infty := \lim_{|x|\to\infty} V(x) < \infty$;

(h_1) $h \in C(\mathbb{R}, \mathbb{R})$, $h(t) = 0$, $\forall t \le 0$ and $\lim_{t\to 0}\frac{h(t)}{t} = 0$;

(h_2) $|h(t)| \le C(1 + |t|^{q-1})$ for some $C > 0$ and $q \in (4, 6)$;

(h_3) there exists $\tau > 4$ such that

$$0 < \tau g(t)H(t) \le h(t)G(t), \quad \forall t > 0,$$

where $H(t) = \int_0^t h(s)ds$, $G(t) = \int_0^t g(s)ds$.

Clearly, (h_1) and (h_2) show that for any $\varepsilon > 0$, there exists $C_\varepsilon > 0$ such that

$$|h(u)| \le \varepsilon|u| + C_\varepsilon|u|^{q-1}, \quad \forall u \in \mathbb{R}. \tag{1.8}$$

Now we state our main results.

Theorem 1.1. *For $h(u) = |u|^{p-2}u$ in (1.1), assume that (g_1) holds. If $V(x) + 2\langle \nabla V(x), x\rangle \le 0$, problem (1.1) has no nontrivial solutions when $p \le \frac{12a}{5}$. If $\frac{2}{5} \le a < 1$ and $V(x) + 2\langle \nabla V(x), x\rangle \ge 0$, problem (1.1) has no nontrivial solutions when $p \ge 6$.*

Theorem 1.2. *Assume that (V_1), (g_1) and (h_1)–(h_3) are satisfied, then problem (1.1) has a positive radial solution.*

Theorem 1.3. *Assume that (V_1), (g_1) and (h_1)–(h_3) are satisfied, $\{u_{b_n}\} \subset \mathcal{H}$ are the positive radial solutions obtained in Theorem 1.2 for each $n \in \mathbb{N}$. Then, $u_{b_n} \to u_0$ in $\mathcal{H}$ as $b_n \to 0$, $n \to \infty$, where u_0 is a positive radial solution for problem (1.5).*

The following condition of g is necessary to obtain the next two important results.

(g') $g \in C^1(\mathbb{R}, \mathbb{R}^+)$ is even with $g'(t) \ge 0$ for all $t \ge 0$ and $g(0) = 1$, $tg'(t) < g(t)$ for all $t \in \mathbb{R}$.

Theorem 1.4. *Assume that (V_1), (g') and (h_1)–(h_3) are satisfied, then problem (1.1) has a nontrivial radial solution.*

Theorem 1.5. *Assume that (V_1), (g') and (h_1)–(h_3) are satisfied, $\{u'_{b_n}\} \subset \mathcal{H}$ are the nontrivial radial solutions obtained in Theorem 1.4 for each $n \in \mathbb{N}$. Then, $u'_{b_n} \to u'_0$ in $\mathcal{H}$ as $b_n \to 0$, $n \to \infty$, where u'_0 is a nontrivial radial solution for problem (1.5).*

Finally, we consider the following generalized quasilinear Schrödinger–Poisson system involving a Kirchhoff-type perturbation and critical Sobolev exponent

$$\begin{cases} \left(1 + b\int_{\mathbb{R}^3} g^2(u)|\nabla u|^2\right)[-\operatorname{div}(g^2(u)\nabla u) + g(u)g'(u)|\nabla u|^2] & \\ +V(x)u + \phi u = g(u)G^{p-1}(u), & \text{in } \mathbb{R}^3, \\ -\Delta\phi = u^2, & \text{in } \mathbb{R}^3. \end{cases} \tag{1.9}$$

Theorem 1.6. *Suppose that (g') holds. If*

$$2V(x) + \langle \nabla V(x), x\rangle \ge 0, \quad \forall x \in \mathbb{R}^3,$$

then problem (1.9) has no nontrivial solutions when $p \ge 6$.

Remark 1.7. Throughout the paper we denote by C, C_i $(i = 1, 2, \dots) > 0$ various positive constants which may vary from line to line and are not essential to the problem.

2 Preliminary results

In this section, we introduce the variational framework associated with problem (1.1). Let $L^p(\mathbb{R}^3)$ be the usual Lebesgue space with the norm $|u|_p = \left(\int_{\mathbb{R}^3} |u|^p dx\right)^{\frac{1}{p}}$.

Define the space H given by

$$H^1 := H^1(\mathbb{R}^3) = \{u \in L^2(\mathbb{R}^3) : \nabla u \in L^2(\mathbb{R}^3)\},$$

with the norm:

$$\|u\| = \left(\int_{\mathbb{R}^3} (|\nabla u|^2 + u^2) dx\right)^{\frac{1}{2}},$$

and the corresponding inner is

$$\langle u, v\rangle = \int_{\mathbb{R}^3} (\nabla u \cdot \nabla v + uv) dx.$$

Let

$$D^{1,2}(\mathbb{R}^3) = \{u \in L^6(\mathbb{R}^3) : \nabla u \in L^2(\mathbb{R}^3)\}.$$

According to the assumption (V_1), we use the space

$$\mathcal{H} := \left\{u \in H^1(\mathbb{R}^3) : u(x) = u(|x|), \int_{\mathbb{R}^N} V(x)u^2 dx < \infty\right\},$$

with the norm:

$$\|u\|_{\mathcal{H}} = \left(\int_{\mathbb{R}^3} (|\nabla u|^2 + V(x)u^2) dx\right)^{\frac{1}{2}},$$

then the embedding $\mathcal{H} \hookrightarrow L^p(\mathbb{R}^3)$ is compact for $2 < p < 6$.

According to [3], the energy functional associated with (1.1) is

$$\begin{aligned} I_b(u) = {} & \frac{1}{2}\int_{\mathbb{R}^3} g^2(u)|\nabla u|^2 dx + \frac{1}{2}\int_{\mathbb{R}^3} V(x)|u|^2 dx + \frac{b}{4}\left(\int_{\mathbb{R}^3} g^2(u)|\nabla u|^2 dx\right)^2 \\ & + \frac{1}{4}\int_{\mathbb{R}^3} \phi|u|^2 dx - \int_{\mathbb{R}^3} H(u) dx, \end{aligned} \tag{2.1}$$

where $H(t) = \int_0^t h(s)ds$. Since the term $\int_{\mathbb{R}^3} g^2(u)|\nabla u|^2 dx$ is not well defined in $\mathcal{H}$, to overcome this difficulty, a change of variable constructed in [28] is very helpful to us. For any $v \in \mathcal{H}$, let

$$u = G^{-1}(v) \quad \text{and} \quad G(u) = \int_0^u g(t)dt,$$

then

$$\int_{\mathbb{R}^3} g^2(u)|\nabla u|^2 dx = \int_{\mathbb{R}^3} g^2(G^{-1}(v))|\nabla G^{-1}(v)|^2 dx =: |\nabla v|_2^2 < \infty,$$

and $I_b(u)$ can be reduced to

$$\begin{aligned} J_b(v) = {} & \frac{1}{2}\int_{\mathbb{R}^3} |\nabla v|^2 dx + \frac{1}{2}\int_{\mathbb{R}^3} V(x)|G^{-1}(v)|^2 dx + \frac{b}{4}\left(\int_{\mathbb{R}^3} |\nabla v|^2 dx\right)^2 \\ & + \frac{1}{4}\int_{\mathbb{R}^3} \phi_{G^{-1}(v)}|G^{-1}(v)|^2 dx - \int_{\mathbb{R}^3} H(G^{-1}(v)) dx. \end{aligned} \tag{2.2}$$

Then $v \in \mathcal{H}$ is a solution of (1.1) if

$$\langle J_b'(v), \eta\rangle = \int_{\mathbb{R}^3} \nabla v \cdot \nabla \eta dx + \int_{\mathbb{R}^3} V(x)\frac{G^{-1}(v)}{g(G^{-1}(v))}\eta dx + b\int_{\mathbb{R}^3} |\nabla v|^2 dx \int_{\mathbb{R}^3} \nabla v \cdot \nabla \eta dx + \int_{\mathbb{R}^3} \phi_{G^{-1}(v)}\frac{G^{-1}(v)}{g(G^{-1}(v))}\eta dx - \int_{\mathbb{R}^3} \frac{h(G^{-1}(v))}{g(G^{-1}(v))}\eta dx = 0,$$

for all $\eta \in H^1(\mathbb{R}^3)$.

We observe that by the Lax–Milgram theorem, for given $u \in H^1(\mathbb{R}^3)$, there exists a unique solution $\phi = \phi_u \in D^{1,2}(\mathbb{R}^3)$ satisfying $-\Delta\phi_u = u^2$ in a weak sense. The function ϕ_u is represented by

$$\phi_u(x) = \frac{1}{4\pi}\int_{\mathbb{R}^3} \frac{u^2(y)}{|x-y|}dy,$$

and it has the following properties.

Lemma 2.1 ([11,26]). *The following properties hold:*

(*i*) *there exists $C > 0$ such that for any $u \in H^1(\mathbb{R}^3)$,*

$$\|\phi_u\|_{D^{1,2}} \le C|u|^2_{\frac{12}{5}}, \quad \int_{\mathbb{R}^3} |\nabla\phi_u|^2 dx = \int_{\mathbb{R}^3} \phi_u u^2 dx \le C\|u\|^4_{\mathcal{H}};$$

(*ii*) *$\phi_u \ge 0$ for all $u \in H^1(\mathbb{R}^3)$;*

(*iii*) *$\phi_{tu} = t^2\phi_u$ for all $t > 0$ and $u \in H^1(\mathbb{R}^3)$;*

(*iv*) *if $u_j \rightharpoonup u$ weakly in $H^1(\mathbb{R}^3)$, then, up to a subsequence, $\phi_{u_j} \to \phi_u$ in $D^{1,2}(\mathbb{R}^3)$ and*

$$\int_{\mathbb{R}^3} \phi_{u_j} u_j^2 dx \to \int_{\mathbb{R}^3} \phi_u u^2 dx.$$

Lemma 2.2 ([19,22]). *For the function g, G, and G^{-1}, the following properties hold under the condition (g_1):*

(1) $\frac{t}{g(t)}g'(t) \le 0$ *for all* $t \ge 0$;

(2) $|t| \le |G^{-1}(t)| \le \frac{|t|}{a}$ *for all* $t \in \mathbb{R}$;

(3) $t^2 \le \frac{t}{g(t)}G(t) \le \frac{t^2}{a}$ *for all* $t \in \mathbb{R}$.

Under condition (g'), the following properties hold:

(4) $|G^{-1}(t)| \le \frac{1}{g(0)}|t| = |t|$ *for all* $t \in \mathbb{R}$;

(5) $\frac{G^{-1}(t)t}{g(G^{-1}(t))} \le |G^{-1}(t)|^2$ *for all* $t \in \mathbb{R}$;

(6) $\lim\limits_{|t|\to 0}\frac{G^{-1}(t)}{t} = \frac{1}{g(0)} = 1$ *and*

$$\lim_{|t|\to\infty}\frac{G^{-1}(t)}{t} = \begin{cases} \frac{1}{g(\infty)}, & \text{if } g \text{ is bounded,} \\ 0, & \text{if } g \text{ is unbounded.} \end{cases}$$

3 Proof of the main results

3.1 Proof of Theorem 1.1

In this section, we will prove the nonexistence of nontrivial solutions for the following system:

$$\begin{cases} \left(1+b\int_{\mathbb{R}^3} g^2(u)|\nabla u|^2dx\right)[-\mathrm{div}(g^2(u)\nabla u)+g(u)g'(u)|\nabla u|^2] \\ +V(x)u+\phi u=|u|^{p-2}u, & x\in\mathbb{R}^3, \\ -\Delta\phi=u^2, & x\in\mathbb{R}^3. \end{cases} \tag{3.1}$$

By a standard argument in [20,35], we can obtain the following Pohožaev identity.

Lemma 3.1 (Pohožaev identity). *If $v\in\mathcal{H}$ is a weak solution of (3.1), then v satisfies*

$$\begin{aligned} &\frac{1}{2}\int_{\mathbb{R}^3}|\nabla v|^2dx+\frac{3}{2}\int_{\mathbb{R}^3}V(x)|G^{-1}(v)|^2dx+\frac{1}{2}\int_{\mathbb{R}^3}\langle\nabla V(x),x\rangle|G^{-1}(v)|^2dx \\ &\quad+\frac{b}{2}\left(\int_{\mathbb{R}^3}|\nabla v|^2dx\right)^2+\frac{5}{4}\int_{\mathbb{R}^3}\phi_{G^{-1}(v)}|G^{-1}(v)|^2dx=\frac{3}{p}\int_{\mathbb{R}^3}|G^{-1}(v)|^pdx. \end{aligned} \tag{3.2}$$

Proof of Theorem 1.1. Indeed, because $(v,\phi_{G^{-1}(v)})\in\mathcal{H}\times D^{1,2}(\mathbb{R}^3)$ is a solution of (3.1), we have the following equation:

$$\begin{aligned} &\int_{\mathbb{R}^3}|\nabla v|^2dx+\int_{\mathbb{R}^3}V(x)\frac{G^{-1}(v)}{g(G^{-1}(v))}vdx+b\left(\int_{\mathbb{R}^3}|\nabla v|^2dx\right)^2 \\ &\quad+\int_{\mathbb{R}^3}\phi_{G^{-1}(v)}\frac{G^{-1}(v)}{g(G^{-1}(v))}vdx=\int_{\mathbb{R}^3}\frac{|G^{-1}(v)|^{p-2}G^{-1}(v)}{g(G^{-1}(v))}vdx. \end{aligned} \tag{3.3}$$

Multiply the equation of the (3.3) by $\frac{5}{4}$ and combined with (3.2), we have

$$\begin{aligned} &\frac{3}{4}\int_{\mathbb{R}^3}|\nabla v|^2dx+\int_{\mathbb{R}^3}V(x)\left(\frac{5}{4}\frac{G^{-1}(v)v}{g(G^{-1}(v))}-\frac{3}{2}|G^{-1}(v)|^2\right)dx+\frac{3}{4}b\left(\int_{\mathbb{R}^3}|\nabla v|^2dx\right)^2 \\ &\quad-\frac{1}{2}\int_{\mathbb{R}^3}\langle\nabla V(x),x\rangle|G^{-1}(v)|^2dx+\frac{5}{4}\int_{\mathbb{R}^3}\phi_{G^{-1}(v)}\left(\frac{G^{-1}(v)v}{g(G^{-1}(v))}-|G^{-1}(v)|^2\right)dx \\ &=\int_{\mathbb{R}^3}|G^{-1}(v)|^{p-2}\left(\frac{5}{4}\frac{G^{-1}(v)v}{g(G^{-1}(v))}-\frac{3}{p}|G^{-1}(v)|^2\right)dx. \end{aligned} \tag{3.4}$$

If $V(x)+2\langle\nabla V(x),x\rangle\le 0$, then by Lemma 2.2-(3) that the left hand of (3.4) is nonnegative, so that the equation (3.4) has no nontrivial solutions when $p\le\frac{12a}{5}$.

Combining (3.2) and (3.3), it can be concluded that

$$\begin{aligned} &\frac{1}{2}\int_{\mathbb{R}^3}V(x)\left(\frac{G^{-1}(v)v}{g(G^{-1}(v))}-3|G^{-1}(v)|^2\right)dx-\frac{1}{2}\int_{\mathbb{R}^3}\langle\nabla V(x),x\rangle|G^{-1}(v)|^2dx \\ &\quad+\frac{1}{2}\int_{\mathbb{R}^3}\phi_{G^{-1}(v)}\left(\frac{G^{-1}(v)v}{g(G^{-1}(v))}-\frac{5}{2}|G^{-1}(v)|^2\right)dx \\ &=\int_{\mathbb{R}^3}|G^{-1}(v)|^{p-2}\left(\frac{G^{-1}(v)v}{2g(G^{-1}(v))}-\frac{3}{p}|G^{-1}(v)|^2\right)dx. \end{aligned} \tag{3.5}$$

Under conditions $\frac{2}{5}\le a<1$, Lemma 2.2-(3) and $V(x)+2\langle\nabla V(x),x\rangle\ge 0$, for $p\ge 6$, the equation (3.5) has no nontrivial solutions. □

3.2 Proof of Theorem 1.2

This section provides the proof of Theorem 1.2. Clearly, as mentioned previously, we will devote to studying the functional J_b. It is hard to prove the boundedness of the (PS) sequence of J_b, so that finding a special bounded (PS) sequence of $J_{b,\mu}$ may provides great help,

$$\begin{aligned} J_{b,\mu}(v) := &\frac{1}{2}\int_{\mathbb{R}^3}|\nabla v|^2dx + \frac{1}{2}\int_{\mathbb{R}^3}V(x)|G^{-1}(v)|^2dx + \frac{b}{4}\left(\int_{\mathbb{R}^3}|\nabla v|^2dx\right)^2 \\ &+ \frac{1}{4}\int_{\mathbb{R}^3}\phi_{G^{-1}(v)}|G^{-1}(v)|^2dx - \mu\int_{\mathbb{R}^3}H(G^{-1}(v))dx, \end{aligned} \tag{3.6}$$

where $\mu \in [1, 2]$.

Next, we list a useful critical point theorem proposed by Jeanjean [3,16], which is crucial to obtain our main result.

Theorem 3.2. *Let $(X, \|\cdot\|)$ be a Banach space and $\mathbb{I} \subset \mathbb{R}^+$ an interval. Consider the following family of C^1-functionals on X:*

$$J_{b,\mu}(v) = A(v) - \mu B(v), \quad \forall \mu \in \mathbb{I},$$

where $B(v) \geq 0$, $\forall v \in X$, and either $A(v) \to +\infty$ or $B(v) \to +\infty$ as $\|v\| \to \infty$. Assume that there are two points v_1, v_2 in X, such that

$$c_\mu := \inf_{\gamma\in\Gamma_\mu}\max_{t\in[0,1]} J_{b,\mu}(\gamma(t)) > \max\{J_{b,\mu}(v_1), J_{b,\mu}(v_2)\}, \quad \forall \mu \in \mathbb{I},$$

where

$$\Gamma_\mu = \{\gamma \in \mathcal{C}([0,1], X) : \gamma(0) = v_1, \gamma(1) = v_2\}.$$

Then, for almost every $\mu \in \mathbb{I}$, there is a sequence $\{v_n\} \subset X$, such that

(i) $\{v_n\}$ is bounded;

(ii) $J_{b,\mu}(v_n) \to c_\mu$;

(iii) $J'_{b,\mu}(v_n) \to 0$ in the dual X^{-1} of X.

Moreover, the map $\mu \mapsto c_\mu$ is continuous from the left.

Lemma 3.3. *Assume that (V_1), (g_1), (h_1)–(h_3) are satisfied, then*

(i) for $\mu \in [1, 2]$, there exists $v \in \mathcal{H}\backslash\{0\}$ such that $J_{b,\mu}(v) < 0$;

(ii) there exists $\rho, \alpha > 0$ such that $J_{b,\mu}(v) \geq \alpha$ for $\|v\|_{\mathcal{H}} = \rho$.

Proof. (i) According to (h_1) and (h_3), there exists constant $C > 0$ such that

$$H(G^{-1}(v)) \geq C|v|^\tau \quad \text{for all } v \geq 0 \quad \text{and} \quad H(G^{-1}(v)) \equiv 0 \quad \text{for all } v \leq 0,$$

where τ is defined in (h_3).

For any fixed $\psi \in \mathcal{H}$ with $\psi > 0$, by Lemma 2.2-(2), we have for $\tau > 4$

$$\begin{aligned} J_{b,\mu}(t\psi) = &\frac{1}{2}\int_{\mathbb{R}^3}\left(|\nabla t\psi|^2 + V(x)|G^{-1}(t\psi)|^2\right)dx + \frac{b}{4}\left(\int_{\mathbb{R}^3}|\nabla t\psi|^2dx\right)^2 \\ &+ \frac{1}{4}\int_{\mathbb{R}^3}\phi_{G^{-1}(t\psi)}|G^{-1}(t\psi)|^2dx - \mu\int_{\mathbb{R}^3}H(G^{-1}(t\psi))dx \\ \leq\ & Ct^2\|\psi\|^2_{\mathcal{H}} + \frac{bt^4}{4}\left(\int_{\mathbb{R}^3}|\nabla\psi|^2dx\right)^2 + \frac{t^4}{4}C\|\psi\|^4_{\mathcal{H}} - \mu Ct^\tau\int_{\mathbb{R}^3}|\psi|^\tau dx \\ \to\ & -\infty, \end{aligned}$$

as $t \to \infty$, which implies that (i) holds if we take $v = t\psi$ with t sufficiently large.

(ii) Let $\varepsilon \in \left(0, \frac{a^2 V_0}{2\mu}\right)$, by Lemma 2.2-(2) and (1.8), we obtain

$$\begin{aligned} J_{b,\mu}(v) &= \frac{1}{2}\int_{\mathbb{R}^3} |\nabla v|^2 dx + \frac{1}{2}\int_{\mathbb{R}^3} V(x)|G^{-1}(v)|^2 dx + \frac{b}{4}\left(\int_{\mathbb{R}^3} |\nabla v|^2 dx\right)^2 \\ &\quad + \frac{1}{4}\int_{\mathbb{R}^3} \phi_{G^{-1}(v)}|G^{-1}(v)|^2 dx - \mu\int_{\mathbb{R}^3} H(G^{-1}(v))dx \\ &\geq \frac{1}{2}\int_{\mathbb{R}^3} |\nabla v|^2 dx + \frac{1}{2}\int_{\mathbb{R}^3} \left(V_0 - \frac{\mu\varepsilon}{a^2}\right)|v|^2 dx - \frac{C_\varepsilon \mu}{qa^q}\int_{\mathbb{R}^3} |v|^q dx. \\ &\geq C_1\|v\|_{\mathcal{H}}^2 - C_2\|v\|_{\mathcal{H}}^q. \end{aligned}$$

Hence, for $q > 4$ we can choose $\|v\|_{\mathcal{H}} = \rho > 0$ small enough such that $J_{b,\mu}(v) \geq \alpha > 0$. □

Define

$$A(v) := \frac{1}{2}\int_{\mathbb{R}^3}\left[|\nabla v|^2 + V(x)|G^{-1}(v)|^2\right]dx + \frac{b}{4}\left(\int_{\mathbb{R}^3} |\nabla v|^2 dx\right)^2 + \frac{1}{4}\int_{\mathbb{R}^3} \phi_{G^{-1}(v)}|G^{-1}(v)|^2 dx,$$

$$B(v) := \int_{\mathbb{R}^3} H(G^{-1}(v))dx.$$

It is deduced from (V_1) and Lemma 2.2-(2) that

$$A(v) > \frac{1}{2}\|v\|_{\mathcal{H}}^2 \to +\infty, \quad \text{as } \|v\|_{\mathcal{H}} \to +\infty.$$

Moreover, from (h_1), it can be observed that $B(v) = \int_{\mathbb{R}^3} H(G^{-1}(v))dx \geq 0$, $\forall v \in \mathcal{H}$.

Based on the above facts and Lemma 3.3, the conclusion of Theorem 3.2 holds. It shows that for a.e. $\mu \in [1, 2]$, there is a bounded $(PS)_{c_\mu}$ sequence $\{v_n\} \subset \mathcal{H}$, satisfying $J_{b,\mu}(v_n) \to c_\mu$ and $J'_{b,\mu}(v_n) \to 0$, where c_μ is the mountain pass level.

Lemma 3.4. *Suppose (V_1), (g_1), (h_1)–(h_3) hold, $\{v_n\}$ is the sequence obtained above, going if necessary to a subsequence, $v_n \to v$ in $\mathcal{H}$.*

Proof. Since $\{v_n\} \subset \mathcal{H}$ is bounded, up to a subsequence, there exists $v \in \mathcal{H}$ such that

$$\begin{aligned} v_n &\rightharpoonup v \quad \text{in } \mathcal{H}, \\ v_n &\to v \quad \text{in } L^r(\mathbb{R}^3), \ \ 2 < r < 6, \\ v_n(x) &\to v(x) \quad \text{a.e. on } x \in \mathbb{R}^3. \end{aligned}$$

Define $\varphi : \mathbb{R} \to \mathbb{R}$ by $\varphi(t) = \frac{G^{-1}(t)}{g(G^{-1}(t))}$. According to (g_1), then $a < g(t) \leq 1$ for $t \in \mathbb{R}$, jointly with Lemma 2.2-(1), we have

$$\varphi'(t) = \frac{1}{g^2(G^{-1}(t))}\left[1 - \frac{G^{-1}(t)g'(G^{-1}(t))}{g(G^{-1}(t))}\right] \geq \frac{1}{g^2(G^{-1}(t))} \geq 1.$$

According to the mean value theorem, for any $x \in \mathbb{R}^3$, there exists a function $\xi(x)$ between $v(x)$ and $v_n(x)$ such that

$$\begin{aligned} &\int_{\mathbb{R}^3} V(x)\left[\frac{G^{-1}(v_n)}{g(G^{-1}(v_n))} - \frac{G^{-1}(v)}{g(G^{-1}(v))}\right](v_n - v)dx \\ &= \int_{\mathbb{R}^3} V(x)\varphi'(\xi)|v_n - v|^2 dx \\ &\geq \int_{\mathbb{R}^3} V(x)|v_n - v|^2 dx, \end{aligned}$$

and with the help of Lemma 2.1, we have

$$\begin{aligned}
&\int_{\mathbb{R}^3}\left[\phi_{G^{-1}(v_n)}\frac{G^{-1}(v_n)}{g(G^{-1}(v_n))}-\phi_{G^{-1}(v)}\frac{G^{-1}(v)}{g(G^{-1}(v))}\right](v_n-v)dx\\
&\quad=\int_{\mathbb{R}^3}\phi_{G^{-1}(v_n)}\left[\frac{G^{-1}(v_n)}{g(G^{-1}(v_n))}-\frac{G^{-1}(v)}{g(G^{-1}(v))}\right](v_n-v)dx\\
&\qquad+\int_{\mathbb{R}^3}\left(\phi_{G^{-1}(v_n)}-\phi_{G^{-1}(v)}\right)\frac{G^{-1}(v)}{g(G^{-1}(v))}(v_n-v)dx\\
&\quad\geq\int_{\mathbb{R}^3}\phi_{G^{-1}(v_n)}\varphi'(\xi)|v_n-v|^2dx\\
&\quad\geq\int_{\mathbb{R}^3}\phi_{G^{-1}(v_n)}|v_n-v|^2dx\\
&\quad\to 0.
\end{aligned}$$

Choose $A_n=\int_{\mathbb{R}^3}|\nabla v_n|^2dx$ and $A=\int_{\mathbb{R}^3}|\nabla v|^2dx$. By $v_n\rightharpoonup v$ in $\mathcal{H}$, thus $\{A_n-A\}$ is bounded. By the weak convergence of v_n in $\mathcal{H}$, we get $b(A_n-A)\int_{\mathbb{R}^3}\nabla v\nabla(v_n-v)dx=o_n(1)$. So that

$$\begin{aligned}
&b\int_{\mathbb{R}^3}|\nabla v_n|^2dx\int_{\mathbb{R}^3}\nabla v_n\nabla(v_n-v)dx-b\int_{\mathbb{R}^3}|\nabla v|^2dx\int_{\mathbb{R}^3}\nabla v\nabla(v_n-v)dx\\
&\quad\geq b(A_n-A)\int_{\mathbb{R}^3}\nabla v\nabla(v_n-v)dx\\
&\quad\to\ 0,
\end{aligned}$$

as $n\to\infty$. Noting that $a<g(t)\leq 1$, then by Lemma 2.2-(2), (1.8) and Hölder inequality, $v_n\to v$ in $L^r(\mathbb{R}^3)$, $2<r<6$, we obtain

$$\begin{aligned}
&\left|\int_{\mathbb{R}^3}\left[\frac{h(G^{-1}(v_n))}{g(G^{-1}(v_n))}-\frac{h(G^{-1}(v))}{g(G^{-1}(v))}\right](v_n-v)dx\right|\\
&\quad\leq C\int_{\mathbb{R}^3}\left[\varepsilon(|v_n|+|v|)+C_\varepsilon(|v_n|^{q-1}+|v|^{q-1})\right]|v_n-v|dx\\
&\quad\leq C\varepsilon(|v_n|_2+|v|_2)|v_n-v|_2+CC_\varepsilon(|v_n|_q^{q-1}+|v|_q^{q-1})|v_n-v|_q\\
&\quad\to 0,
\end{aligned}$$

as $n\to\infty$. Then

$$\begin{aligned}
o_n(1)&=\langle J'_{b,\mu}(v_n)-J'_{b,\mu}(v),\,v_n-v\rangle\\
&=\int_{\mathbb{R}^3}|\nabla(v_n-v)|^2dx+\int_{\mathbb{R}^3}V(x)\left[\frac{G^{-1}(v_n)}{g(G^{-1}(v_n))}-\frac{G^{-1}(v)}{g(G^{-1}(v))}\right](v_n-v)dx\\
&\quad+b\left[\int_{\mathbb{R}^3}|\nabla v_n|^2dx\int_{\mathbb{R}^3}\nabla v_n\cdot\nabla(v_n-v)dx-\int_{\mathbb{R}^3}|\nabla v|^2dx\int_{\mathbb{R}^3}\nabla v\cdot\nabla(v_n-v)dx\right]\\
&\quad+\int_{\mathbb{R}^3}\left[\phi_{G^{-1}(v_n)}\frac{G^{-1}(v_n)}{g(G^{-1}(v_n))}-\phi_{G^{-1}(v)}\frac{G^{-1}(v)}{g(G^{-1}(v))}\right](v_n-v)dx\\
&\quad-\mu\int_{\mathbb{R}^3}\left[\frac{h(G^{-1}(v_n))}{g(G^{-1}(v_n))}-\frac{h(G^{-1}(v))}{g(G^{-1}(v))}\right](v_n-v)dx\\
&\geq\int_{\mathbb{R}^3}|\nabla(v_n-v)|^2dx+\int_{\mathbb{R}^3}V(x)|v_n-v|^2dx\\
&=\|v_n-v\|^2_{\mathcal{H}}.
\end{aligned}$$

Therefore, $v_n\to v$ in $\mathcal{H}$. □

According to Theorem 3.2, there is a bounded sequence $\{v_n\} \subset \mathcal{H}$ satisfying $J_{b,\mu}(v_n) \to c_\mu$ and $J'_{b,\mu}(v_n) \to 0$. From Lemma 3.4, for every $\mu \in [1, 2]$, we get that $J_{b,\mu}$ has a nontrivial critical point v satisfying $J_{b,\mu}(v) = c_\mu$ and $J'_{b,\mu}(v) = 0$. Therefore, there exists $\{\mu_n\} \subset [1, 2]$ such that $\lim_{n\to\infty} \mu_n = 1$, $\{v_{\mu_n}\} \subset \mathcal{H}$ such that $J_{b,\mu_n}(v_{\mu_n}) = c_{\mu_n} > 0$ and $J'_{b,\mu_n}(v_{\mu_n}) = 0$.

Lemma 3.5. *Suppose that (g_1), (h_1) and (h_3) are satisfied, then sequence $\{v_{\mu_n}\}$ is bounded in $\mathcal{H}$.*

Proof. Since sequence $\{v_{\mu_n}\} \subset \mathcal{H}$ satisfies

$$J_{b,\mu_n}(v_{\mu_n}) = c_{\mu_n} \quad \text{and} \quad J'_{b,\mu_n}(v_{\mu_n}) = 0.$$

Then we have

$$\begin{aligned} J_{b,\mu_n}(v_{\mu_n}) &= \frac{1}{2}\int_{\mathbb{R}^3} |\nabla v_{\mu_n}|^2 dx + \frac{1}{2}\int_{\mathbb{R}^3} V(x)|G^{-1}(v_{\mu_n})|^2 dx + \frac{b}{4}\left(\int_{\mathbb{R}^3} |\nabla v_{\mu_n}|^2 dx\right)^2 \\ &\quad + \frac{1}{4}\int_{\mathbb{R}^3} \phi_{G^{-1}(v_{\mu_n})}|G^{-1}(v_{\mu_n})|^2 dx - \mu_n \int_{\mathbb{R}^3} H(G^{-1}(v_{\mu_n}))dx \\ &= c_{\mu_n} > 0. \end{aligned} \tag{3.7}$$

We also deduce that

$$\begin{aligned} \langle J'_{b,\mu_n}(v_{\mu_n}), v_{\mu_n}\rangle = &\int_{\mathbb{R}^3} |\nabla v_{\mu_n}|^2 dx + \int_{\mathbb{R}^3} V(x)\frac{G^{-1}(v_{\mu_n})}{g(G^{-1}(v_{\mu_n}))} v_{\mu_n} dx \\ &+ b\left(\int_{\mathbb{R}^3} |\nabla v_{\mu_n}|^2 dx\right)^2 + \int_{\mathbb{R}^3} \phi_{G^{-1}(v_{\mu_n})}\frac{G^{-1}(v_{\mu_n})}{g(G^{-1}(v_{\mu_n}))} v_{\mu_n} dx \\ &- \mu_n \int_{\mathbb{R}^3} \frac{h(G^{-1}(v_{\mu_n}))}{g(G^{-1}(v_{\mu_n}))} v_{\mu_n} dx \\ = &\, o(1)\|v_{\mu_n}\|, \end{aligned} \tag{3.8}$$

as $n \to \infty$. It follows from (3.7), (3.8), (h_3) and Lemma 2.2-(2), (3) that

$$\begin{aligned} &c_{\mu_n} + 1 + \|v_{\mu_n}\| \\ &\geq J_{b,\mu_n}(v_{\mu_n}) - \frac{a}{4}\langle J'_{b,\mu_n}(v_{\mu_n}), v_{\mu_n}\rangle \\ &\geq \left(\frac{1}{2} - \frac{a}{4}\right)\int_{\mathbb{R}^3} |\nabla v_{\mu_n}|^2 dx + \int_{\mathbb{R}^3} V(x)G^{-1}(v_{\mu_n})\left[\frac{1}{2}G^{-1}(v_{\mu_n}) - \frac{a v_{\mu_n}}{4g(G^{-1}(v_{\mu_n}))}\right]dx \\ &\quad + \left(\frac{1}{4} - \frac{a}{4}\right) b\left(\int_{\mathbb{R}^3} |\nabla v_{\mu_n}|^2 dx\right)^2 + \int_{\mathbb{R}^3} \phi_{G^{-1}(v_{\mu_n})} G^{-1}(v_{\mu_n})\left[\frac{1}{4}G^{-1}(v_{\mu_n}) - \frac{a v_{\mu_n}}{4g(G^{-1}(v_{\mu_n}))}\right]dx \\ &\quad - \mu_n \int_{\mathbb{R}^3} \left[H(G^{-1}(v_{\mu_n})) - \frac{a}{4}\frac{h(G^{-1}(v_{\mu_n}))}{g(G^{-1}(v_{\mu_n}))} v_{\mu_n}\right] dx \\ &\geq \left(\frac{1}{2} - \frac{a}{4}\right)\int_{\mathbb{R}^3} |\nabla v_{\mu_n}|^2 dx + \frac{1}{4}\int_{\mathbb{R}^3} V(x)|G^{-1}(v_{\mu_n})|^2 dx \\ &\geq \frac{1}{4}\|v_{\mu_n}\|^2_{\mathcal{H}}, \end{aligned}$$

which means that $\{v_{\mu_n}\}$ is bounded in $\mathcal{H}$. □

Proof of Theorem 1.2. Taking a subsequence of $\{v_{\mu_n}\}$ still represented by $\{v_{\mu_n}\}$, because $\{v_{\mu_n}\}$ is bounded in $\mathcal{H}$, similar to the proof of Lemma 3.4, we obtain $v_{\mu_n} \to v_\mu$ in $\mathcal{H}$. From Theorem 3.2,

we know that $\mu \mapsto c_\mu$ is continuous from the left. So

$$\begin{aligned}\lim_{n\to\infty} J_b(v_{\mu_n}) &= \lim_{n\to\infty}\left[J_{b,\mu_n}(v_{\mu_n}) + (\mu_n - 1)\int_{\mathbb{R}^3} H(G^{-1}(v_{\mu_n}))dx\right] \\ &= \lim_{n\to\infty} c_{\mu_n} = \tilde{c}.\end{aligned}$$

In addition,

$$\lim_{n\to\infty}\langle J_b'(v_{\mu_n}), \eta\rangle = \lim_{n\to\infty}\left[\langle J_{b,\mu_n}'(v_{\mu_n}), \eta\rangle + (\mu_n - 1)\int_{\mathbb{R}^3}\frac{h(G^{-1}(v_{\mu_n}))}{g(G^{-1}(v_{\mu_n}))}\eta dx\right] = 0,$$

for any $\eta \in C_0^\infty(\mathbb{R}^3)$, which means that $J_b'(v) = 0$ satisfies $J_b(v) = \tilde{c} > 0$.

Let $v^- = \min\{v, 0\}$. Using Lemma 2.2-(2), (3) and with help of the assumption (h_1) and Lemma 2.1, we have

$$\begin{aligned}0 &= \langle J_b'(v), v^-\rangle \\ &= \int_{\mathbb{R}^3}\left(|\nabla v^-|^2 + V(x)\frac{G^{-1}(v^-)}{g(G^{-1}(v^-))}v^-\right)dx \\ &\geq \int_{\mathbb{R}^3}|\nabla v^-|^2 + V(x)|v^-|^2 dx \\ &\geq \|v^-\|_{\mathcal{H}}^2.\end{aligned}$$

It shows that $v^- \equiv 0$. Applying the strong maximum principle, we obtain $v > 0$. □

4 Asymptotic properties

Now, we are in a situation to give the proof of convergence properties.

Proof of Theorem 1.3. If v_{b_n} is a critical point of J_{b_n}, which is obtained in Theorem 1.2 for each $n \in \mathbb{N}$. Similar to the proof of Lemma 3.3, for $b_n \to 0$, $n \to \infty$, $\{v_{b_n}\}$ is a (PS) sequence, which is bounded in $\mathcal{H}$. There exists a subsequence of $\{b_n\}$, still denoted by $\{b_n\}$, such that $v_{b_n} \rightharpoonup v_0$ in $\mathcal{H}$. It is easy to obtain

$$\begin{aligned}\|v_{b_n} - v_0\|_{\mathcal{H}}^2 \leq{}& \langle J_{b_n}'(v_{b_n}) - J_0'(v_0), v_{b_n} - v_0\rangle - b_n\int_{\mathbb{R}^3}|\nabla v_{b_n}|^2 dx\int_{\mathbb{R}^3}\nabla v_{b_n}\nabla(v_{b_n} - v_0)dx \\ &+ \int_{\mathbb{R}^3}\left[\phi_{G^{-1}(v_0)}\frac{G^{-1}(v_0)}{g(G^{-1}(v_0))} - \phi_{G^{-1}(v_{b_n})}\frac{G^{-1}(v_{b_n})}{g(G^{-1}(v_{b_n}))}\right](v_{b_n} - v_0)dx \\ &+ \int_{\mathbb{R}^3}\left[\frac{h(G^{-1}(v_{b_n}))}{g(G^{-1}(v_{b_n}))} - \frac{h(G^{-1}(v_0))}{g(G^{-1}(v_0))}\right](v_{b_n} - v_0)dx \\ ={}& o_n(1).\end{aligned}$$

On the one hand, for all $\eta \in \mathcal{H}\backslash\{0\}$, in view of Lemma 2.2-(2), we can use the Lebesgue dominated convergence theorem to obtain

$$\lim_{n\to\infty}\int_{\mathbb{R}^3} V(x)\frac{G^{-1}(v_{b_n})\eta}{g(G^{-1}(v_{b_n}))}dx = \int_{\mathbb{R}^3} V(x)\frac{G^{-1}(v_0)\eta}{g(G^{-1}(v_0))}dx,$$

$$\lim_{n\to\infty}\int_{\mathbb{R}^3}\frac{h(G^{-1}(v_{b_n}))\eta}{g(G^{-1}(v_{b_n}))}dx = \int_{\mathbb{R}^3}\frac{h(G^{-1}(v_0))\eta}{g(G^{-1}(v_0))}dx.$$

By Lemma 2.1, we can obtain

$$\lim_{n\to\infty}\int_{\mathbb{R}^3}\phi_{G^{-1}(v_{b_n})}\frac{G^{-1}(v_{b_n})\eta}{g(G^{-1}(v_{b_n}))}dx=\int_{\mathbb{R}^3}\phi_{G^{-1}(v_0)}\frac{G^{-1}(v_0)\eta}{g(G^{-1}(v_0))}dx.$$

On the other hand, we have $\langle J'_{b_n}(v_{b_n}),\eta\rangle=o_n(1)$ and $\langle J'_0(v_0),\eta\rangle=o_n(1)$. Moreover,

$$\lim_{n\to\infty}\int_{\mathbb{R}^3}\nabla v_{b_n}\nabla\eta dx=\int_{\mathbb{R}^3}\nabla v_0\nabla\eta dx,$$

$$\lim_{n\to\infty}b_n\int_{\mathbb{R}^3}|\nabla v_{b_n}|^2dx\int_{\mathbb{R}^3}\nabla v_{b_n}\nabla\eta=0.$$

Thus,

$$\int_{\mathbb{R}^3}\nabla v_0\nabla\eta dx+\int_{\mathbb{R}^3}V(x)\frac{G^{-1}(v_0)}{g(G^{-1}(v_0)}\eta dx+\int_{\mathbb{R}^3}\phi_{G^{-1}(v_0)}\frac{G^{-1}(v_0)}{g(G^{-1}(v_0))}\eta dx=\int_{\mathbb{R}^3}\frac{h(G^{-1}(v_0))}{g(G^{-1}(v_0))}\eta dx.$$

It shows that v_0 is a positive solution of (1.5). □

5 Proof of Theorem 1.4 and Theorem 1.5

In this section, we will prove the existence of nontrivial radial solution for system (1.1) under the condition (g').

Lemma 5.1. *Assume that (V_1), (g'), (h_1) and (h_3) are satisfied, then*

(i) for $\mu\in[1,2]$, there exists $v\in\mathcal{H}\backslash\{0\}$ such that $J_{b,\mu}(v)<0$;

(ii) there exists $\rho_1,\alpha_1>0$ such that $J_{b,\mu}(v)\geq\alpha_1$ and $\|v\|_{\mathcal{H}}=\rho_1$.

Proof. (i) According to (h_1) and (h_3), there exists constant $C>0$ such that

$$H(G^{-1}(v))\geq C|v|^{\tau}\quad\text{for all } v\geq 0\quad\text{and}\quad H(G^{-1}(v))\equiv 0\quad\text{for all } v\leq 0,$$

where τ is defined in (h_3).

For any fixed $\psi_1\in\mathcal{H}$ with $\psi_1>0$, by Lemma 2.2-(4), we have

$$\begin{aligned}J_{b,\mu}(t\psi_1)&=\frac{1}{2}\int_{\mathbb{R}^3}\left(|\nabla t\psi_1|^2+V(x)|G^{-1}(t\psi_1)|^2\right)dx+\frac{b}{4}\left(\int_{\mathbb{R}^3}|\nabla t\psi_1|^2dx\right)^2\\&\quad+\frac{1}{4}\int_{\mathbb{R}^3}\phi_{G^{-1}(t\psi_1)}|G^{-1}(t\psi_1)|^2dx-\mu\int_{\mathbb{R}^3}H(G^{-1}(t\psi_1))dx\\&\leq\frac{t^2}{2}\|\psi_1\|^2_{\mathcal{H}}+\frac{b}{4}t^4\left(\int_{\mathbb{R}^3}|\nabla\psi_1|^2dx\right)^2+\frac{t^4}{4}C\|\psi_1\|^4_{\mathcal{H}}-\mu Ct^{\tau}\int_{\mathbb{R}^3}|\psi_1|^{\tau}dx\\&\to-\infty,\end{aligned}$$

as $t\to\infty$ for $\tau>4$, which implies that (i) holds if we take $v=t\psi_1$ with t sufficiently large.

(ii) It follows from (3.6) that

$$\begin{aligned}J_{b,\mu}(v)&=\frac{1}{2}\int_{\mathbb{R}^3}\left(|\nabla v|^2+V(x)|G^{-1}(v)|^2\right)dx+\frac{b}{4}\left(\int_{\mathbb{R}^3}|\nabla v|^2dx\right)^2\\&\quad+\frac{1}{4}\int_{\mathbb{R}^3}\phi_{G^{-1}(v)}|G^{-1}(v)|^2dx-\mu\int_{\mathbb{R}^3}H(G^{-1}(v))dx\\&=\frac{1}{2}\int_{\mathbb{R}^3}|\nabla v|^2dx-\int_{\mathbb{R}^3}\left(-\frac{1}{2}V(x)|G^{-1}(v)|^2+\mu H(G^{-1}(v))\right)dx\\&\quad+\frac{b}{4}\left(\int_{\mathbb{R}^3}|\nabla v|^2dx\right)^2+\frac{1}{4}\int_{\mathbb{R}^3}\phi_{G^{-1}(v)}|G^{-1}(v)|^2dx.\end{aligned}\tag{5.1}$$

Let $A(x,s) := -\frac{1}{2}V(x)|G^{-1}(s)|^2 + \mu H(G^{-1}(s))$, then by Lemma 2.2-(6), we have

$$\lim_{s\to 0}\frac{A(x,s)}{|s|^2} = \lim_{s\to 0}\left[-\frac{1}{2}V(x)\left|\frac{G^{-1}(s)}{s}\right|^2 + \mu\frac{H(G^{-1}(s))}{|s|^2}\right] = -\frac{1}{2}V(x), \tag{5.2}$$

and

$$\lim_{s\to +\infty}\frac{A(x,s)}{|s|^6} = \lim_{s\to +\infty}\left[-\frac{1}{2}V(x)\left|\frac{G^{-1}(s)}{s}\right|^2\left(\frac{1}{|s|^4}\right) + \mu\frac{H(G^{-1}(s))}{|s|^6}\right] = 0. \tag{5.3}$$

Thus, by (5.2) and (5.3), for $\epsilon > 0$ sufficiently small, there exists a constant $C_\epsilon > 0$ such that

$$A(x,s) \le \left(-\frac{1}{2}V(x) + \epsilon\right)|s|^2 + C_\epsilon|s|^6. \tag{5.4}$$

Then, according to (V_1), (5.1), (5.4), Lemma 2.1 and Sobolev embedding theorem, we have

$$\begin{aligned} J_{b,\mu}(v) &\ge \frac{1}{2}\int_{\mathbb{R}^3}|\nabla v|^2dx - \int_{\mathbb{R}^3}\left(-\frac{1}{2}V(x)+\epsilon\right)|v|^2dx - \int_{\mathbb{R}^3}C_\epsilon|v|^6dx \\ &\quad + \frac{b}{4}\left(\int_{\mathbb{R}^3}|\nabla v|^2dx\right)^2 + \frac{1}{4}\int_{\mathbb{R}^3}\phi_{G^{-1}(v)}|G^{-1}(v)|^2dx \\ &\ge \frac{1}{2}\int_{\mathbb{R}^3}|\nabla v|^2dx + \frac{1}{2}\int_{\mathbb{R}^3}V(x)v^2dx - \epsilon\int_{\mathbb{R}^3}|v|^2dx - C_\epsilon\int_{\mathbb{R}^3}|v|^6dx \\ &\ge \frac{1}{2}\|v\|_{\mathcal{H}}^2 - \epsilon C\|v\|_{\mathcal{H}}^2 - C_\epsilon\|v\|_{\mathcal{H}}^6. \end{aligned}$$

It follows that

$$J_{b,\mu}(v) \ge C\|v\|_{\mathcal{H}}^2 - C\|v\|_{\mathcal{H}}^6,$$

if we choose sufficiently small $\rho_1 > 0$, which implies that

$$J_{b,\mu}(v) \ge C\rho_1^2 - C\rho_1^6 := \alpha_1 > 0. \qquad \square$$

Obviously, as defined in Section 3.2, $A(v)$ and $B(v)$ are the same, we can still obtain that $B(v) \ge 0$ for $v \in \mathcal{H}$ and $A(v) \to +\infty$ as $\|v\| \to \infty$. Also by Lemma 5.1 that the conclusion of Theorem 3.2 holds, then there is a bounded $(PS)_{c'_\mu}$ sequence $\{v'_n\} \subset \mathcal{H}$, satisfying $J_{b,\mu}(v'_n) \to c'_\mu$ and $J'_{b,\mu}(v'_n) \to 0$, where c'_μ is the mountain pass level.

Lemma 5.2. *Suppose (V_1), (g'), (h_1)–(h_3) hold, $\{v'_n\}$ is the sequence obtained above, going if necessary to a subsequence, $v'_n \to v'$ in $\mathcal{H}$.*

Proof. Since $\{v'_n\} \subset \mathcal{H}$ is bounded, up to a subsequence, there exists $v' \in \mathcal{H}$ such that

$$\begin{aligned} v'_n &\rightharpoonup v' \quad \text{in } \mathcal{H}, \\ v'_n &\to v' \quad \text{in } L^r(\mathbb{R}^3), \text{ for } 2 < r < 6, \\ v'_n(x) &\to v'(x) \quad \text{a.e. on } x \in \mathbb{R}^3. \end{aligned}$$

Firstly, we claim that there exists $C > 0$ such that

$$\int_{\mathbb{R}^3}\left[|\nabla(v'_n - v')|^2 + V(x)\left(\frac{G^{-1}(v'_n)}{g(G^{-1}(v'_n))} - \frac{G^{-1}(v')}{g(G^{-1}(v'))}\right)(v'_n - v')\right]dx \ge C\|v'_n - v'\|_{\mathcal{H}}^2. \tag{5.5}$$

Indeed, we may assume $v_n' \neq v'$ (otherwise the conclusion is trivial). Set

$$\omega_n' = \frac{v_n' - v'}{\|v_n' - v'\|}$$

and

$$l_n = \frac{1}{v_n' - v'}\left(\frac{G^{-1}(v_n')}{g(G^{-1}(v_n'))} - \frac{G^{-1}(v')}{g(G^{-1}(v'))}\right).$$

Argue by contradiction and assume that

$$\int_{\mathbb{R}^3}(|\nabla\omega_n'|^2 + V(x)l_n(x)\omega_n'^2)dx \to 0.$$

Since

$$\frac{d}{ds}\left(\frac{G^{-1}(s)}{g(G^{-1}(s))}\right) = \frac{1}{g^2(G^{-1}(s))}\left(1 - \frac{G^{-1}(s)g'(G^{-1}(s))}{g(G^{-1}(s))}\right) > 0,$$

$\frac{G^{-1}(s)}{g(G^{-1}(s))}$ is strictly increasing, and for each $C > 0$ there exists $\delta' > 0$ such that

$$\frac{d}{ds}\left(\frac{G^{-1}(s)}{g(G^{-1}(s))}\right) > \delta',$$

when $|s| \leq C$. Hence, we see that $l_n(x)$ is positive. Hence

$$\int_{\mathbb{R}^3}|\nabla\omega_n'|^2dx \to 0, \quad \int_{\mathbb{R}^3}V(x)l_n(x)\omega_n'^2dx \to 0, \quad \text{and} \quad \int_{\mathbb{R}^3}V(x)\omega_n'^2dx \to 1.$$

Similar to Lemma 2.5 in Reference [30], we assert that for each $\varepsilon' > 0$, there exists $C_1 > 0$ independent of n such that $\text{meas}(\Omega_n) < \varepsilon'$, where $\Omega_n := \{x \in \mathbb{R}^3 : |v_n'(x) - v'(x)| \geq C_1\}$, it can be inferred that there exists a constant $C > 0$ such that

$$\int_{\mathbb{R}^3\setminus\Omega_n}V(x)\omega_n'^2dx \leq C\int_{\mathbb{R}^3\setminus\Omega_n}V(x)\frac{|G^{-1}(v_n' - v')|^2}{\|v_n' - v'\|^2}dx \leq C\int_{\mathbb{R}^3}V(x)l_n(x)dx \to 0. \tag{5.6}$$

On the other hand, by the integral absolutely continuity, there exists $\varepsilon' > 0$ such that whenever $\Omega \subset \mathbb{R}^3$ and $\text{meas}(\Omega) < \varepsilon'$,

$$\int_{\Omega}V(x)\omega_n'^2dx \leq \frac{1}{2}. \tag{5.7}$$

Combining (5.6) with (5.7), we have

$$\int_{\mathbb{R}^3}V(x)\omega_n'^2dx = \int_{\mathbb{R}^3\setminus\Omega_n}V(x)\omega_n'^2dx + \int_{\Omega_n}V(x)\omega_n'^2dx \leq \frac{1}{2} + o_n(1),$$

which implies $1 \leq \frac{1}{2}$, a contradiction. This implies that (5.5) holds. What's more, by Lemma 2.1, we have

$$\begin{aligned}
&\int_{\mathbb{R}^3}\left[\phi_{G^{-1}(v_n')}\frac{G^{-1}(v_n')}{g(G^{-1}(v_n'))} - \phi_{G^{-1}(v')}\frac{G^{-1}(v')}{g(G^{-1}(v'))}\right](v_n' - v')dx \\
&\geq \int_{\mathbb{R}^3}\phi_{G^{-1}(v_n')}\left[\frac{G^{-1}(v_n')}{g(G^{-1}(v_n'))} - \frac{G^{-1}(v')}{g(G^{-1}(v'))}\right](v_n' - v')dx \\
&\quad + \int_{\mathbb{R}^3}\left(\phi_{G^{-1}(v_n')} - \phi_{G^{-1}(v')}\right)\frac{G^{-1}(v')}{g(G^{-1}(v'))}(v_n' - v')dx \\
&\to 0.
\end{aligned} \tag{5.8}$$

Similar to Lemma 3.4, we can easily obtain

$$\begin{aligned} & b\int_{\mathbb{R}^3}|\nabla v_n'|^2dx\int_{\mathbb{R}^3}\nabla v_n'\nabla(v_n'-v')dx-b\int_{\mathbb{R}^3}|\nabla v'|^2dx\int_{\mathbb{R}^3}\nabla v'\nabla(v_n'-v')dx \\ & \geq b\int_{\mathbb{R}^3}\left(|\nabla v_n'|^2-|\nabla v'|^2\right)dx\int_{\mathbb{R}^3}\nabla v'\nabla(v_n'-v')dx \\ & \to 0, \end{aligned} \tag{5.9}$$

as $n\to\infty$. From (g'), there is $g(t)\geq 1$, $\forall t\geq 0$. In addition, by Lemma 2.2-(4), (1.8) and Hölder inequality, $v_n\to v$ in $L^r(\mathbb{R}^3)$, $2<r<6$, we obtain

$$\begin{aligned} & \left|\int_{\mathbb{R}^3}\left[\frac{h(G^{-1}(v_n'))}{g(G^{-1}(v_n'))}-\frac{h(G^{-1}(v'))}{g(G^{-1}(v'))}\right](v_n'-v')dx\right| \\ & \leq \int_{\mathbb{R}^3}\left[\varepsilon(|v_n'|+|v'|)+C_\varepsilon(|v_n'|^{q-1}+|v'|^{q-1})\right]|v_n'-v'|dx \\ & \leq \varepsilon(|v_n'|_2+|v'|_2)|v_n'-v'|_2+C_\varepsilon(|v_n'|_q^{q-1}+|v'|_q^{q-1})|v_n'-v'|_q \\ & \to 0. \end{aligned} \tag{5.10}$$

By virtue of (5.5), (5.8)–(5.10), we have

$$\begin{aligned} o_n(1) &= \langle J_{b,\mu}'(v_n')-J_{b,\mu}'(v'),\, v_n'-v'\rangle \\ &= \int_{\mathbb{R}^3}|\nabla(v_n'-v')|^2dx+\int_{\mathbb{R}^3}V(x)\left[\frac{G^{-1}(v_n')}{g(G^{-1}(v_n'))}-\frac{G^{-1}(v')}{g(G^{-1}(v'))}\right](v_n'-v')dx \\ &\quad +b\left[\int_{\mathbb{R}^3}|\nabla v_n'|^2dx\int_{\mathbb{R}^3}\nabla v_n'\cdot\nabla(v_n'-v')dx-\int_{\mathbb{R}^3}|\nabla v'|^2dx\int_{\mathbb{R}^3}\nabla v'\cdot\nabla(v_n'-v')dx\right] \\ &\quad +\int_{\mathbb{R}^3}\left[\phi_{G^{-1}(v_n')}\frac{G^{-1}(v_n')}{g(G^{-1}(v_n'))}-\phi_{G^{-1}(v')}\frac{G^{-1}(v')}{g(G^{-1}(v'))}\right](v_n'-v')dx \\ &\quad -\mu\int_{\mathbb{R}^3}\left[\frac{h(G^{-1}(v_n'))}{g(G^{-1}(v_n'))}-\frac{h(G^{-1}(v'))}{g(G^{-1}(v'))}\right](v_n'-v')dx \\ &\geq C\|v_n'-v'\|_{\mathcal{H}}^2+o_n(1), \end{aligned}$$

which implies that $v_n'\to v'$ in $\mathcal{H}$. □

From Lemma 5.2, for every $\mu\in[1,2]$, we get that $J_{b,\mu}$ has a nontrivial critical point v' satisfying $J_{b,\mu}(v')=c_\mu'$ and $J_{b,\mu}'(v')=0$. Therefore, there exists $\{\mu_n\}\subset[1,2]$ such that $\lim_{n\to\infty}\mu_n=1$, $\{v_{\mu_n}'\}\subset\mathcal{H}$ such that $J_{b,\mu_n}(v_{\mu_n}')=c_{\mu_n}'>0$ and $J_{b,\mu_n}'(v_{\mu_n}')=0$.

Lemma 5.3. *Suppose that (V_1), (g'), (h_1) and (h_3) are satisfied, then any sequence $\{v_{\mu_n}'\}$ is bounded in $\mathcal{H}$.*

Proof. Since $\{v_{\mu_n}'\}\subset\mathcal{H}$ satisfies $J_{b,\mu_n}(v_{\mu_n}')=c_{\mu_n}'>0$, we have

$$\begin{aligned} J_{b,\mu_n}(v_{\mu_n}') &= \frac{1}{2}\int_{\mathbb{R}^3}|\nabla v_{\mu_n}'|^2dx+\frac{1}{2}\int_{\mathbb{R}^3}V(x)|G^{-1}(v_{\mu_n}')|^2dx+\frac{b}{4}\left(\int_{\mathbb{R}^3}|\nabla v_{\mu_n}'|^2dx\right)^2 \\ &\quad +\frac{1}{4}\int_{\mathbb{R}^3}\phi_{G^{-1}(v_{\mu_n}')}|G^{-1}(v_{\mu_n}')|^2dx-\mu_n\int_{\mathbb{R}^3}H(G^{-1}(v_{\mu_n}'))dx \\ &= c_{\mu_n}'>0. \end{aligned} \tag{5.11}$$

We also deduce that

$$\begin{aligned}\langle J'_{b,\mu_n}(v'_{\mu_n}), v'_{\mu_n}\rangle &= \int_{\mathbb{R}^3} |\nabla v'_{\mu_n}|^2 dx + \int_{\mathbb{R}^3} V(x)\frac{G^{-1}(v'_{\mu_n})}{g(G^{-1}(v'_{\mu_n}))}v'_{\mu_n}dx \\ &\quad + b\left(\int_{\mathbb{R}^3} |\nabla v'_{\mu_n}|^2 dx\right)^2 + \int_{\mathbb{R}^3} \phi_{G^{-1}(v'_{\mu_n})}\frac{G^{-1}(v'_{\mu_n})}{g(G^{-1}(v'_{\mu_n}))}v'_{\mu_n}dx \\ &\quad - \mu_n \int_{\mathbb{R}^3} \frac{h(G^{-1}(v'_{\mu_n}))}{g(G^{-1}(v'_{\mu_n}))}v'_{\mu_n}dx.\end{aligned} \tag{5.12}$$

It follows from (5.11), (5.12), (h_3) and Lemma 2.2-(5) that

$$\begin{aligned}&2c'_{\mu_n} + 1 + \|v'_{\mu_n}\| \\ &\geq J_{b,\mu_n}(v'_{\mu_n}) - \frac{1}{4}\langle J'_{b,\mu_n}(v'_{\mu_n}), v'_{\mu_n}\rangle \\ &= \frac{1}{4}\int_{\mathbb{R}^3} |\nabla v'_{\mu_n}|^2 dx + \int_{\mathbb{R}^3} V(x)G^{-1}(v'_{\mu_n})\left[\frac{1}{2}G^{-1}(v'_{\mu_n}) - \frac{v'_{\mu_n}}{4g(G^{-1}(v'_{\mu_n}))}\right]dx \\ &\quad + \frac{1}{4}\int_{\mathbb{R}^3} \phi_{G^{-1}(v'_{\mu_n})}G^{-1}(v'_{\mu_n})\left[G^{-1}(v'_{\mu_n}) - \frac{v'_{\mu_n}}{g(G^{-1}(v'_{\mu_n}))}\right]dx \\ &\quad - \mu_n \int_{\mathbb{R}^3}\left[H(G^{-1}(v'_{\mu_n})) - \frac{1}{4}\frac{h(G^{-1}(v'_{\mu_n}))}{g(G^{-1}(v'_{\mu_n}))}v'_{\mu_n}\right]dx \\ &\geq \frac{1}{4}\int_{\mathbb{R}^3} |\nabla v'_{\mu_n}|^2 dx + \frac{1}{4}\int_{\mathbb{R}^3} V(x)|G^{-1}(v'_{\mu_n})|^2 dx.\end{aligned} \tag{5.13}$$

According to the assumption (h_3) and (V_1), we have $H(s) \geq CG(s)^\tau \geq CG(s)^2$ for all $s \geq 1$. Then by Lemma 2.2-(4)

$$\begin{aligned}&\int_{\{x:\,|G^{-1}(v'_{\mu_n})|>1\}} V(x)v'^2_{\mu_n}dx \\ &\leq C\int_{\{x:\,|G^{-1}(v'_{\mu_n})|>1\}} H(G^{-1}(v'_{\mu_n}))dx \\ &\leq C\int_{\mathbb{R}^3} H(G^{-1}(v'_{\mu_n}))dx + \frac{b}{4}\left(\int_{\mathbb{R}^3} |\nabla v'_{\mu_n}|^2 dx\right)^2 + C\int_{\mathbb{R}^3} \phi_{G^{-1}(v'_{\mu_n})}v'^2_{\mu_n}dx \\ &\leq C\left[\frac{1}{2}\int_{\mathbb{R}^3} |\nabla v'_{\mu_n}|^2 dx + \frac{1}{2}\int_{\mathbb{R}^3} V(x)|G^{-1}(v'_{\mu_n})|^2 dx - c_1 + o_n(1)\right].\end{aligned} \tag{5.14}$$

On the other hand, for $x \in \{x : |G^{-1}(v'_n)| \leq 1\}$ we know that

$$\begin{aligned}\frac{1}{g^2(1)}\int_{\{x:\,|G^{-1}(v'_{\mu_n})|\leq 1\}} V(x)v'^2_{\mu_n}dx &\leq C\int_{\{x:\,|G^{-1}(v'_{\mu_n})|\leq 1\}} V(x)|G^{-1}(v'_{\mu_n})|^2 dx \\ &\leq C\int_{\mathbb{R}^3} V(x)|G^{-1}(v'_{\mu_n})|^2 dx.\end{aligned} \tag{5.15}$$

Since (g'), we know that $g(s)$ is nondecreasing. Combining (5.13) and (5.14) with (5.15), we deduce that $\{v'_{\mu_n}\}$ is bounded in $\mathcal{H}$. □

Proof of Theorem 1.4. Similar to the proof of Theorem 1.2, we take a subsequence of $\{v'_{\mu_n}\}$, and still represented by $\{v'_{\mu_n}\}$, because $\{v'_{\mu_n}\}$ is bounded in $\mathcal{H}$, similar to the proof of Lemma 5.2,

we obtain $v'_{\mu_n} \to v'_{\mu}$ in $\mathcal{H}$. From Theorem 3.2, we known that $\mu \mapsto c'_{\mu}$ is continuous from the left. So

$$\begin{aligned} \lim_{n\to\infty} J_b(v'_{\mu_n}) &= \lim_{n\to\infty} \left[J_{b,\mu_n}(v'_{\mu_n}) + (\mu_n - 1) \int_{\mathbb{R}^3} H(G^{-1}(v'_{\mu_n}))dx \right] \\ &= \lim_{n\to\infty} c'_{\mu_n} = \tilde{c}'. \end{aligned} \tag{5.16}$$

In addition,

$$\lim_{n\to\infty} \langle J'_b(v'_{\mu_n}), \eta \rangle = \lim_{n\to\infty} \left[\langle J'_{b,\mu_n}(v'_{\mu_n}), \eta \rangle + (\mu_n - 1) \int_{\mathbb{R}^3} \frac{h(G^{-1}(v'_{\mu_n}))}{g(G^{-1}(v'_{\mu_n}))} \eta dx \right] = 0, \tag{5.17}$$

for any $\eta \in C_0^\infty(\mathbb{R}^3)$, which means that $J'_b(v') = 0$ satisfies $J_b(v') = \tilde{c}' > 0$. □

Proof of Theorem 1.5. The proof process is similar to Theorem 1.3, and specific steps are omitted here. □

6 Nonexistence in critical case

In this section, we prove the nonexistence of nontrivial solutions for system (1.9) by Pohožaev identity.

Lemma 6.1. *(Pohožaev identity) If $v \in \mathcal{H}$ is a weak solution of problem (1.9), then we have the following Pohožaev identity:*

$$\begin{aligned} &\frac{1}{2}\int_{\mathbb{R}^3} |\nabla v|^2 dx + \frac{3}{2}\int_{\mathbb{R}^3} V(x)|G^{-1}(v)|^2 dx + \frac{1}{2}\int_{\mathbb{R}^3} \langle \nabla V(x), x\rangle |G^{-1}(v)|^2 dx \\ &\quad + \frac{b}{2}\left(\int_{\mathbb{R}^3} |\nabla v|^2 dx\right)^2 + \frac{5}{4}\int_{\mathbb{R}^3} \phi_{G^{-1}(v)}|G^{-1}(v)|^2 dx - \frac{3}{p}\int_{\mathbb{R}^3} |v|^p dx = 0. \end{aligned} \tag{6.1}$$

Proof of Theorem 1.6. Suppose that $v \in \mathcal{H}$ is a solution to system (1.9), then v satisfies

$$\begin{aligned} &\int_{\mathbb{R}^3} |\nabla v|^2 dx + \int_{\mathbb{R}^3} V(x)\frac{G^{-1}(v)}{g(G^{-1}(v))} v dx + b\left(\int_{\mathbb{R}^3} |\nabla v|^2 dx\right)^2 \\ &\quad + \int_{\mathbb{R}^3} \phi_{G^{-1}(v)}\frac{G^{-1}(v)}{g(G^{-1}(v))} v dx - \int_{\mathbb{R}^3} |v|^p dx = 0. \end{aligned} \tag{6.2}$$

Combining (6.1) and (6.2), we can get

$$\begin{aligned} &\int_{\mathbb{R}^3} V(x)\left(\frac{1}{2}\frac{G^{-1}(v)v}{g(G^{-1}(v))} - \frac{3}{2}|G^{-1}(v)|^2\right) dx - \frac{1}{2}\int_{\mathbb{R}^3} \langle \nabla V(x), x\rangle |G^{-1}(v)|^2 dx \\ &\quad + \int_{\mathbb{R}^3} \phi_{G^{-1}(v)}\left(\frac{1}{2}\frac{G^{-1}(v)v}{g(G^{-1}(v))} - \frac{5}{4}|G^{-1}(v)|^2\right) dx = \left(\frac{1}{2} - \frac{3}{p}\right)\int_{\mathbb{R}^3} |v|^p dx. \end{aligned} \tag{6.3}$$

Since Lemma 2.2-(5) that $\frac{G^{-1}(v)}{g(G^{-1}(v))} v \le |G^{-1}(v)|^2$, if $2V(x) + \langle \nabla V(x), x\rangle \ge 0$, then (6.3) implies that $v = 0$ for $p \ge 6$. So that $0 = u = G^{-1}(v)$. Then (1.9) has no nontrivial solutions. □

Abstract. This study is devoted to the stability issue of a time-varying delayed Nicholson's blowflies equation of neutral type. By the aid of the Lyapunov stability theory and novel analysis techniques, two sharp conditions ensuring separately the global asymptotic stability of the zero equilibrium and positive equilibrium are derived, which completely cover the corresponding ones in the associated non-neutral equation. In addition, a numerical example is taken to support the availability of the theoretical results.

Keywords: Nicholson's blowflies equation, neutral type, time-varying delay, global asymptotic stability.

MSC 2020 Subject Classification: 34K40, 34D23.

1 Introduction

The following Nicholson's blowflies equation

$$w'(t) = -\delta w(t) + \beta w(t-\tau)e^{-aw(t-\tau)}, \tag{1.1}$$

was proposed by Gurney et al. in [6] to describe the dynamics of the Australian sheep-blowfly. Here $w(t)$ labels the size of blowflies population at time t, δ, β, a, τ are positive constants with distinct biological significance, that is, δ signifies the average daily mortality rate among adult blowflies, β quantifies the maximal mean rate of oviposition per day, $\frac{1}{a}$ means the size at which the blowflies population reproduces at its maximum rate, and τ stands for the maturation delay. In the past four decades, extensive research has elucidated the qualitative dynamics and stability characteristics of Eq. (1.1) and its generalized forms (see [1, 8, 9, 11, 14] and the references therein). In particular, if the biological parameters satisfy $\frac{\beta}{\delta} \leq 1$ and $1 < \frac{\beta}{\delta} \leq e^2$, the global asymptotic stability has been respectively proven for the trivial equilibrium and positive equilibrium to Eq. (1.1) in [1, 8, 9, 11, 14]. Furthermore, Ref. [17] revealed that the

✉Corresponding author. Tel./fax: +860746-6381425. E-mail:huangchuangxia@sina.com

positive equilibrium of Eq. (1.1) admits global attractivity if $\frac{\beta}{\delta} > 1$ and the delay τ is small. Meanwhile, the authors in [19] and [5] established the global asymptotical stability for the positive equilibrium of Eq. (1.1) if $1 < \frac{\beta}{\delta} \leq e^2$. It is noteworthy that Yang and So in [18] showed that the positive equilibrium is unstable and Hopf bifurcation appears when $\frac{\beta}{\delta} > e^2$ and the delay τ is large. It is demonstrated from aforementioned findings that $\frac{\beta}{\delta} \leq 1$ and $1 < \frac{\beta}{\delta} \leq e^2$ are two sharp conditions which respectively assure the global asymptotic stability of trivial equilibrium and positive equilibrium of Eq. (1.1).

In the realistic world, biological populations have complex dynamic characteristics, and the existing population models cannot accurately describe the properties of a population evolution process. Consequently, it is both natural and interesting that biological models should incorporate some information about the derivative of past states to better depict and model the dynamics of such complex population evolution processes. This has drawn extensive attention to neutral type delayed population dynamic models [3, 7, 15, 21]. In particular, due to the effect of the population age distribution, Eq. (1.1) can be commonly generalized to the following neutral functional differential equation (NFDE),

$$(w(t) - cw(t-\alpha))' = -\delta w(t) + c\delta w(t-\alpha) + \beta w(t-\tau)e^{-aw(t-\tau)}, \quad t \in [0, +\infty), \tag{1.2}$$

where $a, \delta, \beta, \alpha, \tau \in (0, +\infty), c \in [0, 1)$. For more details on the biological ecology background and the derivation of Eq. (1.2), one can refer to [2, 12]. It should be pointed out that, if the population function $w(t)$ is continuously differentiable, Eq. (1.2) can be rewritten as the following special case,

$$w'(t) - cw'(t-\alpha) = -\delta w(t) + c\delta w(t-\alpha) + \beta w(t-\tau)e^{-aw(t-\tau)}, \quad t \in [0, +\infty). \tag{1.3}$$

Recently, the dynamics including Hopf bifurcation, the stability of (almost) periodic solutions of Eq. (1.3) and its generalizations have been extensively studied in [10, 12, 13, 15, 20, 22]. Meanwhile, delays in population and ecology models may depend on the time-varying environmental conditions and climate, and hence the neutral delayed Nicholson's blowflies equation (1.2) can be naturally extrapolated to the following non-autonomous form:

$$(w(t) - cw(t-\tau_1(t)))' = -\delta w(t) + c\delta w(t-\tau_1(t)) + \beta w(t-\tau_2(t))e^{-aw(t-\tau_2(t))}, \tag{1.4}$$

where $c \in [0, 1)$, $t \geq t_0 \in \mathbb{R}$, the delay functions $\tau_i(t)$ $(i = 1, 2)$ possess continuity and boundedness. In addition, according to the definition of initial set [23], we always assume that there exists $r_i \in (0, +\infty)$ satisfying

$$\{t - \tau_i(t) : t - \tau_i(t) \leq t_0,\ t \geq t_0\} \cup \{t_0\} = [t_0 - r_i,\ t_0], \quad i = 1, 2, \tag{1.5}$$

and

$$r = r_2 \geq r_1, \quad \text{and} \quad \sigma := \min\left\{\inf_{t\in\mathbb{R}} \tau_1(t), \inf_{t\in\mathbb{R}} \tau_2(t)\right\} > 0. \tag{1.6}$$

Obviously, when $\tau_i(t)$ $(i = 1, 2)$ are constants, Eqs. (1.1)–(1.3) are special cases of Eq. (1.4). From the basic theory of functional differential equations (FDEs), it is evident that the initial value conditions for Eqs. (1.2) and (1.4) are fundamentally different, which yields theoretical difficulties in analyzing the dynamic behavior of Eq. (1.4). In addition, the existence of both neutral structure and time-varying delays also brings technical challenges to explore the kinetic properties of the non-autonomous NFDE. Therefore, a natural question is whether one could establish the sharp criteria separately ensuring the global asymptotic stability of trivial

and positive equilibria of neutral time-varying delayed Nicholson's blowflies equation (1.4), and such a problem has not been reported up to now.

Inspired by the aforementioned discussions, the primary object of this paper is to establish sharp global asymptotic stability criteria for Eq. (1.4). Specifically, the main contributions of this study can be summarized as follows:

1) A kind of neutral Nicholson's blowflies equation with time-varying delays is proposed, the well-posedness including existence, uniqueness, boundedness and positiveness of solutions to the addressed model is first proved.

2) Global asymptotic stability criteria on the trivial and positive equilibria to Eq. (1.4) are established, respectively, which are sharp and substantially extend the existing stability results of the corresponding non-neutral ones.

3) A numerical example and some comparative analyses are presented to explicate the correctness and innovation of the theoretical findings.

The structure of this paper is outlined below. Section 2 introduces some preliminaries. Sections 3 and 4 establish respectively the global asymptotic stability of zero equilibrium and positive equilibrium. Section 5 affords a numerical example to exhibit effectiveness of the theoretical results. At last, the conclusion is conducted in Section 6.

2 Preliminaries

Firstly, we present some notations which are needed later. For convenience, denote the Banach space supplemented with supremum norm $\|\cdot\|$ by $\Gamma = C([-r,\ 0],\ \mathbb{R})$. Given that $\zeta \geq 0$, $t_0 \in \mathbb{R}$, and $W \in C([t_0 - r, t_0 + \zeta], \mathbb{R})$, then, for any $t \in [t_0, t_0 + \zeta]$, $W_t \in \Gamma$ is interpreted by $W_t(\nu) = W(t + \nu)$, $-r \leq \nu \leq 0$. For $t_0 \in \mathbb{R}$, denote

$$\Gamma_+ = \Big\{\varphi \in \Gamma \big| \varphi(0) - c\varphi(-\tau_1(t_0)) \geq 0,\ \varphi(\theta) \geq 0 \ \text{ for all } \ \theta \in [-r,\ 0]\Big\},$$

and let $w_t(t_0, \varphi)(w(t; t_0, \varphi))$ be the solution of Eq. (1.4) under the admissible initial conditions

$$w_{t_0} = \varphi, \qquad \varphi \in \Gamma_+. \tag{2.1}$$

Clearly, Eq. (1.4) only possesses a trivial equilibrium $N_0 = 0$ when $\frac{\beta}{\delta(1-c)} \leq 1$ and a unique positive equilibrium $N_* = \frac{1}{a} \ln \frac{\beta}{\delta(1-c)} \leq \frac{2}{a}$ when $1 < \frac{\beta}{\delta(1-c)} \leq e^2$. For simplicity of notation, we designate

$$w(t) = w(t; t_0, \varphi), \quad x(t) = w(t) - cw(t - \tau_1(t)),$$

and

$$y(t) = x(t) - (1-c)N_* = (w(t) - N_*) - c(w(t - \tau_1(t)) - N_*).$$

Moreover, for $\varphi \in \Gamma_+$, we extend the initial value function as follows:

$$\varphi(\theta - \tau_1(\theta)) = \varphi(-r) \quad \text{for all } \theta \in [-r,\ 0] \text{ and } \theta - \tau_1(\theta) < -r. \tag{2.2}$$

Now, we investigate some basic properties of the solutions for Eq. (1.4).

Lemma 2.1. *Let $\varphi \in \Gamma_+$. Then Eq. (1.4) has a unique, non-negative, ultimately bounded solution $w_t(t_0, \varphi)$ on $[t_0,\ +\infty)$. Meanwhile, for $\varphi \in \Gamma_+ \setminus \{0\}$, $w_t(t_0, \varphi)$ is ultimately positive.*

Proof. For any $t \in [t_0, t_0+\sigma]$, multiplying both sides of Eq. (1.4) by $e^{\delta t}$ and integrating from t_0 to t, together with (2.1), gives us

$$x(t) = (\varphi(0) - c\varphi(-\tau_1(t_0)))e^{-\delta(t-t_0)} + \beta e^{-\delta t}\int_{t_0}^{t} \varphi(s-\tau_2(s)-t_0)e^{-a\varphi(s-\tau_2(s)-t_0)}e^{\delta s}ds \geq 0$$

and

$$w(t) = x(t) + c\varphi(t-\tau_1(t)-t_0) \geq 0.$$

Similarly, applying the step-by-step method, the case $x(t) \geq 0$ and $w(t) \geq 0$ on $[t_0+\sigma, t_0+2\sigma]$ holding as follows. Therefore, $x(t) \geq 0$ and $w(t) \geq 0$ for all $t \geq t_0$. Consequently, $w_t(t_0, \varphi)$ exists and is unique on $[t_0, +\infty)$. In addition, $w_t(t_0, \varphi) \geq 0$ for all $t \in [t_0, +\infty)$.

On the other hand, the fact $\sup_{u\geq 0} ue^{-u} = \frac{1}{e}$ leads to

$$\begin{aligned} x(t) =& (\varphi(0) - c\varphi(-\tau_1(t_0)))e^{-\delta(t-t_0)} \\ &+ e^{-\delta t}\int_{t_0}^{t} \beta w(s-\tau_2(s))e^{-aw(s-\tau_2(s))}e^{\delta s}ds \\ \leq& (\varphi(0) - c\varphi(-\tau_1(t_0)))e^{-\delta(t-t_0)} + \frac{\beta}{ae}e^{-\delta t}\int_{t_0}^{t} e^{\delta s}ds \\ =& (\varphi(0) - c\varphi(-\tau_1(t_0)))e^{-\delta(t-t_0)} + \frac{\beta}{\delta ae}\left[1 - e^{-\delta(t-t_0)}\right] \quad \text{for all } t \in [t_0, +\infty), \end{aligned}$$

and hence

$$\limsup_{t\to+\infty} x(t) \leq \frac{\beta}{\delta ae},$$

which, together with the following fact

$$\limsup_{t\to+\infty} w(t) = \limsup_{t\to+\infty}[x(t) + cw(t-\tau_1(t))] \leq \limsup_{t\to+\infty} x(t) + c\limsup_{t\to+\infty} w(t),$$

gives us

$$\limsup_{t\to+\infty} w(t) \leq \frac{1}{1-c}\limsup_{t\to+\infty} x(t) \leq \frac{1}{1-c}\frac{\beta}{\delta ae}.$$

This implies that $w(t)$ is ultimately uniformly bounded.

Now, let $\varphi \in \Gamma_+ \setminus \{0\}$. We state that there is a $t_1 \in [t_0, +\infty)$ satisfying $x(t_1) > 0$. Otherwise, $x(t) \equiv 0$ on $[t_0, +\infty)$. Consequently, $\varphi \not\equiv 0$, this allows one can choose $t^* \in [t_0 - r, t_0)$ satisfying $w(t^*) = \varphi(t^* - t_0) > 0$. This, together with (1.5) and (1.6), shows that there is $\xi^{**} \in (t_0, +\infty)$ such that

$$t^* = \xi^{**} - \tau_2(\xi^{**}) \quad \text{and} \quad w(\xi^{**} - \tau_2(\xi^{**})) = w(t^*) = \varphi(t^* - t_0) > 0,$$

which yields

$$\begin{aligned} 0 =& x'(\xi^{**}) \\ =& -\delta x(\xi^{**}) + \beta w(\xi^{**} - \tau_2(\xi^{**}))e^{-aw(\xi^{**}-\tau_2(\xi^{**}))} \\ =& \beta w(\xi^{**} - \tau_2(\xi^{**}))e^{-aw(\xi^{**}-\tau_2(\xi^{**}))} \\ >& 0. \end{aligned}$$

This is a contradiction, and hence

$$\begin{aligned} w(t) &\geq x(t) \\ &= x(t_1)e^{-\delta(t-t_1)} + e^{-\delta t}\int_{t_1}^{t} \beta w(s-\tau_2(s))e^{-aw(s-\tau_2(s))}e^{\delta s}ds \\ &> 0 \quad \text{for all } \ t \in [t_1,\ +\infty). \end{aligned}$$

In other words, $x(t)$ and $w(t)$ are ultimately positive. □

To establish the next main theorems, we make use of the following results.

Lemma 2.2. *If $W \in C([t_0,\ +\infty),[0,\ +\infty))$ is bounded, and there exist constants $p,q \in \mathbb{R}$ satisfying that $0 \leq q < 1$ and*

$$\lim_{t\to+\infty}\left[W(t) - qW(t-\tau_1(t))\right] = p,$$

then

$$\lim_{t\to+\infty} W(t) = \frac{p}{1-q}.$$

Proof. Let $A = \liminf_{t\to+\infty} W(t)$ and $B = \limsup_{t\to+\infty} W(t)$, then $0 \leq A \leq B$, and there exist two monotonically increasing sequences $\{Z_n^1\}_{n\geq1}$ and $\{Z_n^2\}_{n\geq1}$ such that

$$\lim_{n\to+\infty} Z_n^1 = +\infty, \quad \lim_{n\to+\infty} Z_n^2 = +\infty, \quad \lim_{n\to+\infty} W(Z_n^1) = A, \quad \lim_{n\to+\infty} W(Z_n^2) = B,$$

and

$$\lim_{n\to+\infty} W(Z_n^i - \tau_1(Z_n^i)) = C_i \in [A,\ B], \quad i = 1,2.$$

Therefore,

$$p = \lim_{n\to+\infty}\left[W(Z_n^1) - qW(Z_n^1 - \tau_1(Z_n^1))\right] = A - qC_1 \leq A(1-q)$$

and

$$p = \lim_{n\to+\infty}[W(Z_n^2) - qW(Z_n^2 - \tau_1(Z_n^2))] = B - qC_2 \geq B(1-q),$$

which assures that $\lim_{t\to+\infty} W(t) = A = B = \frac{p}{1-q}$. □

Lemma 2.3 (see [4, Lemma 2.3])**.** *If $r^* \in (0,2]$, then*

$$\left|\mu e^{-\mu} - r^*e^{-r^*}\right| < e^{-r^*}|\mu - r^*| \quad \text{for all } \mu > 0 \text{ and } \mu \neq r^*. \tag{2.3}$$

3 Global asymptotic stability of $N_0 = 0$ when $\beta \leq \delta(1-c)$

In this section, we deduce a new criterion for global asymptotic stability on $N_0 = 0$ of Eq. (1.4), which extends the previous stability findings in its special cases. This result can be stated in the following theorem.

Theorem 3.1. *If $\beta \leq \delta(1-c)$, then the trivial equilibrium N_0 of Eq. (1.4) is globally asymptotically stable. Particularly, when $\beta < \delta(1-c)$, N_0 is globally exponentially stable.*

Proof. First, we demonstrate the stability of $N_0 = 0$. For any $\varepsilon > 0$, denote $H = (1-c)\varepsilon$ and $\|\varphi\| < H$ with $\varphi \in \Gamma_+$. We shall demonstrate that $w(t) < \varepsilon$ for all $t \in [t_0 - r,\ +\infty)$. Then, by (2.1), (2.2), and Lemma 2.1, we have

$$x(t) \geq 0 \quad \text{for any } t \geq t_0,$$

and

$$x(t) = w(t) - cw(t - \tau_1(t)) = \varphi(t - t_0) - c\varphi(t - \tau_1(t) - t_0) < H \text{ for any } t \in [t_0 - r,\ t_0].$$

Now, we claim that

$$0 \leq x(t) < H \quad \text{for any } t > t_0. \tag{3.1}$$

Otherwise, there exists $G^* > t_0$ such that

$$x(G^*) = H \quad \text{and} \quad x(t) < H \quad \text{for any } t \in [t_0 - r,\ G^*), \tag{3.2}$$

it follows that

$$\begin{aligned} w(\theta) &= x(\theta) + cw(\theta - \tau_1(\theta)) \\ &\leq x(\theta) + c \sup_{\min\limits_{s\in[t_0-r,\theta]}(s-\tau_1(s))\leq u\leq\theta} w(u - \tau_1(u)) \\ &\leq x(\theta) + c \sup_{t_0-r\leq u\leq t} w(u) \\ &< H + c \sup_{t_0-r\leq u\leq t} w(u), \end{aligned}$$

for any $\theta \in [t_0 - r,\ t]$ and $t \in [t_0 - r,\ G^*)$. Hence

$$w(t) \leq \sup_{t_0-r\leq u\leq t} w(u) < \frac{H}{1-c} \quad \text{for any } t \in [t_0 - r,\ G^*). \tag{3.3}$$

Moreover, it indicates from Eqs. (1.4) and (3.3) that

$$\begin{aligned} 0 &\leq x'(G^*) \\ &= -\delta x(G^*) + \beta w(G^* - \tau_2(G^*))e^{-aw(G^*-\tau_2(G^*))} \\ &\leq -\delta x(G^*) + \beta w(G^* - \tau_2(G^*)) \\ &< H\Big(-\delta + \frac{\beta}{1-c}\Big) \\ &\leq 0, \end{aligned}$$

we yield the contradiction and find that assertion (3.1) is true. Utilizing a similar approach as in the identification of (3.3), we obtain

$$w(t) \leq \sup_{t_0-r\leq u\leq t} w(u) < \frac{H}{1-c} = \varepsilon \quad \text{for any } t \geq t_0,$$

which shows that N_0 is stable.

Second, we prove the global attractivity of N_0. Since

$$\limsup_{t\to+\infty} w(t) \leq \limsup_{t\to+\infty} x(t) + c \limsup_{t\to+\infty} w(t - \tau_1(t)) \leq \limsup_{t\to+\infty} x(t) + c \limsup_{t\to+\infty} w(t),$$

one has

$$\limsup_{t\to+\infty} w(t) \le \frac{1}{1-c}\limsup_{t\to+\infty} x(t). \tag{3.4}$$

It suffices to verify $\limsup_{t\to+\infty} x(t) = 0$. We find from the fluctuation lemma [16, Lemma A.1.] that there exists a monotonically increasing sequence $\{Z_n\}_{n\ge1}$ agreeing with

$$\lim_{n\to+\infty} Z_n = +\infty, \quad \lim_{n\to+\infty} x'(Z_n) = 0, \quad \text{and} \quad \lim_{n\to+\infty} x(Z_n) = \limsup_{t\to+\infty} x(t),$$

and $\lim_{n\to+\infty} w(Z_n - \tau_2(Z_n)) = \eta$ holds. Then (3.4) yields

$$\eta = \lim_{n\to+\infty} w(Z_n - \tau_2(Z_n)) \le \limsup_{t\to+\infty} w(t) \le \frac{1}{1-c}\limsup_{t\to+\infty} x(t). \tag{3.5}$$

Taking the limit on both sides of the following equation:

$$x'(Z_n) = -\delta x(Z_n) + \beta w(Z_n - \tau_2(Z_n))e^{-aw(Z_n-\tau_2(Z_n))}$$

produces

$$0 = -\delta\limsup_{t\to+\infty} x(t) + \beta\eta e^{-a\eta}. \tag{3.6}$$

For the sake of contradiction, assume that $\limsup_{t\to+\infty} x(t) > 0$, (3.5) and (3.6) give us

$$0 < \eta \le \frac{1}{1-c}\limsup_{t\to+\infty} x(t),$$

and the contradiction

$$0 = -\delta\limsup_{t\to+\infty} x(t) + \beta\eta e^{-a\eta} < \left(-\delta + \beta\frac{1}{1-c}\right)\limsup_{t\to+\infty} x(t) \le 0,$$

and thus

$$\lim_{t\to+\infty} w(t) = N_0 = 0.$$

Finally, we show the global exponential stability of N_0 when $\beta < \delta(1-c)$, we only need to prove its globally exponential attractivity. To do this, we pick a sufficiently small $\lambda > 0$ obeying

$$1 - ce^{\lambda r} > 0 \quad \text{and} \quad -(\delta-\lambda) + \frac{\beta e^{\lambda r}}{1-ce^{\lambda r}} < 0. \tag{3.7}$$

Since $\varphi(\theta - \tau_1(\theta)) = \varphi(-r)$ for all $\theta \in [-r,\ 0]$ with $\theta - \tau_1(\theta) < -r$, we can denote

$$x(t)e^{\lambda t} = x(t_0 - r)e^{\lambda(t_0-r)} \quad \text{for any } t \in (-\infty,\ t_0 - r],$$

$$z(t) = x(t)e^{\lambda t} \quad \text{for any } t \in [t_0 - r,\ +\infty),$$

and

$$M_\varphi = \max_{t_0-r\le t\le t_0} x(t)e^{\lambda t} = \max_{t_0-r\le t\le t_0} \left[\varphi(t-t_0) - c\varphi(t-\tau_1(t)-t_0)\right]e^{\lambda t}.$$

Clearly, $z(t) < M_\varphi + 1$ for any $t \in [t_0 - r,\ t_0]$. We hence claim

$$z(t) < M_\varphi + 1 \quad \text{for all } t \ge t_0. \tag{3.8}$$

Otherwise, there exists $t_2 > t_0$ satisfying

$$z(t_2) = M_\varphi + 1, \quad 0 \le z(t) < M_\varphi + 1 \quad \text{for all } t \in [t_0 - r, t_2). \tag{3.9}$$

For any $\theta \in [t_0 - r,\ t]$ and $t \in [t_0 - r,\ t_2)$, we have

$$\begin{aligned} w(\theta)e^{\lambda\theta} &= x(\theta)e^{\lambda\theta} + cw(\theta - \tau_1(\theta))e^{\lambda(\theta-\tau_1(\theta))}e^{\lambda\tau_1(\theta)} \\ &\le z(\theta) + c \sup_{\min\limits_{s\in[t_0-r,\theta]}(s-\tau_1(s))\le u\le\theta} w(u - \tau_1(u))e^{\lambda(u-\tau_1(u))}e^{\lambda r} \\ &\le z(\theta) + c \sup_{t_0-r\le u\le t} w(u)e^{\lambda u}e^{\lambda r} \\ &< M_\varphi + 1 + c \sup_{t_0-r\le u\le t} w(u)e^{\lambda u}e^{\lambda r}, \end{aligned}$$

and thus

$$w(t)e^{\lambda t} \le \sup_{t_0-r\le u\le t} w(u)e^{\lambda u} < \frac{M_\varphi + 1}{1 - ce^{\lambda r}} \quad \text{for any } t \in [t_0 - r,\ t_2). \tag{3.10}$$

It follows immediately from (1.4), (3.7), (3.9) and (3.10) that

$$\begin{aligned} 0 &\le z'(t_2) \\ &= x'(t_2)e^{\lambda t_2} + \lambda x(t_2)e^{\lambda t_2} \\ &= -(\delta - \lambda)x(t_2)e^{\lambda t_2} + \beta w(t_2 - \tau_2(t_2))e^{\lambda(t_2-\tau_2(t_2))}e^{\lambda\tau_2(t_2)}e^{-aw(t_2-\tau_2(t_2))} \\ &< \Big[-(\delta - \lambda) + \frac{\beta e^{\lambda r}}{1 - ce^{\lambda r}}\Big](M_\varphi + 1) \\ &< 0, \end{aligned}$$

which results in a contradiction, and claim (3.8) holds. Furthermore, by the same manner as those in establishing (3.10), it follows from (3.8) that

$$w(t) \le \frac{M_\varphi + 1}{1 - ce^{\lambda r}}e^{-\lambda t} \quad \text{for any } t \ge t_0,$$

which confirms the global exponential attractivity of N_0. The evidence of Theorem 3.1 is finished. □

4 Global asymptotic stability of $N_* = \frac{1}{a}\ln\frac{\beta}{\delta(1-c)}$ when $1 < \frac{\beta}{\delta(1-c)} \le e^2$

We are now ready to derive the conditions under which the positive equilibrium N_* of Eq. (1.4) has global asymptotic stability.

Theorem 4.1. *If $1 < \frac{\beta}{\delta(1-c)} \le e^2$, then Eq. (1.4) admits a unique positive equilibrium $N_* = \frac{1}{a}\ln\frac{\beta}{\delta(1-c)}$, which possesses global asymptotic stability.*

Proof. Clearly, Eq. (1.4) admits a unique positive equilibrium $N_* = \frac{1}{a}\ln\frac{\beta}{\delta(1-c)} \le \frac{2}{a}$. Now, we reveal the stability of N_*. For any $\varepsilon > 0$, let $\bar{H} = \frac{(1-c)}{1+c}\varepsilon$ and $\|\varphi - N_*\| < \bar{H}$ with $\varphi \in \Gamma_+$, it suffices to check that

$$|w(t) - N_*| < \varepsilon \quad \text{for all } t \in [t_0 - r,\ +\infty).$$

In fact, one finds from (2.1) and (2.2) that

$$\begin{aligned}|y(t)| &= |x(t) - (1-c)N_*| \\ &= |w(t) - N_* - c(w(t-\tau_1(t)) - N_*)| \\ &= |\varphi(t-t_0) - N_* - c(\varphi(t-\tau_1(t)-t_0) - N_*)| \\ &< (1+c)\bar{H} \quad \text{for all } t \in [t_0 - r,\ t_0],\end{aligned}$$

which allows us to assert that

$$|y(t)| < (1+c)\bar{H} \quad \text{for any } t > t_0. \tag{4.1}$$

Otherwise, there exists $S_2 > t_0$ satisfying

$$|y(S_2)| = (1+c)\bar{H} \quad \text{and} \quad |y(t)| < (1+c)\bar{H} \quad \text{for any } t \in [t_0 - r,\ S_2), \tag{4.2}$$

which gives us

$$\begin{aligned}|w(\theta) - N_*| &= |y(\theta) + c(w(\theta - \tau_1(\theta)) - N_*)| \\ &\le |y(\theta)| + c \sup_{\min\limits_{s\in[t_0-r,\theta]}(s-\tau_1(s)) \le u \le \theta} |w(u - \tau_1(u)) - N_*| \\ &\le |y(\theta)| + c \sup_{t_0 - r \le u \le t} |w(u) - N_*| \\ &< (1+c)\bar{H} + c \sup_{t_0 - r \le u \le t} |w(u) - N_*|,\end{aligned} \tag{4.3}$$

for any $\theta \in [t_0 - r,\ t]$ and $t \in [t_0 - r,\ S_2)$. A simple calculation yields

$$|w(t) - N_*| \le \sup_{t_0 - r \le u \le t} |w(u) - N_*| < \frac{(1+c)\bar{H}}{1-c} \quad \text{for any } t \in [t_0 - r,\ S_2). \tag{4.4}$$

In view of Eq. (1.4), $y(t)$ satisfies

$$y'(t) = -\delta y(t) + \beta\Big[w(t-\tau_2(t))e^{-aw(t-\tau_2(t))} - N_* e^{-aN_*}\Big], \quad t \ge t_0 \in \mathbb{R}. \tag{4.5}$$

By calculating the Dini derivative of $|y(t)|$, (4.2), (4.4) and (4.5) and Lemma 2.3 imply that

$$\begin{aligned}0 &\le D^-|y(t)|\big|_{t=S_2} \\ &\le -\delta|y(S_2)| + \beta|w(S_2 - \tau_2(S_2))e^{-aw(S_2-\tau_2(S_2))} - N_* e^{-aN_*}| \\ &\le -\delta|y(S_2)| + \beta e^{-aN_*}|w(S_2 - \tau_2(S_2)) - N_*| \\ &< \Big[-\delta + \beta e^{-aN_*}\frac{1}{1-c}\Big](1+c)\bar{H} \\ &= 0,\end{aligned}$$

it follows a contradiction and implies that (4.1) is true. One can follow a similar argument as above to deduce that (4.4) holds, we obtain

$$|w(t) - N_*| \le \sup_{t_0 - r \le u \le t} |w(u) - N_*| < \frac{(1+c)\bar{H}}{1-c} = \varepsilon \quad \text{for any } t \ge t_0.$$

Hence, the positive equilibrium N_* admits stability.

Next, we prove the global attractivity of N_*. Label

$$L = \limsup_{t\to+\infty} y(t) \quad \text{and} \quad l = \liminf_{t\to+\infty} y(t).$$

In view of Lemma 2.2, the global attractivity of N_* is equivalent to discover

$$\max\{|L|, |l|\} = 0. \tag{4.6}$$

To prove (4.6), we argue by contradiction. Assume $\max\{|L|, |l|\} = L > 0$ (the case of $\max\{|L|, |l|\} = -l > 0$ is similar). Based on the fluctuation lemma [16, Lemma A.1.], we know that there exists a sequence $\{F_k\}_{k=1}^{+\infty}$ satisfying

$$\lim_{k\to+\infty} F_k = +\infty, \quad \lim_{k\to+\infty} y(F_k) = L, \quad \text{and} \quad \lim_{k\to+\infty} y'(F_k) = 0. \tag{4.7}$$

In general, we may suppose that $\lim_{k\to+\infty} w(F_k - \tau_2(F_k))$ exists as well.

If $\lim_{k\to+\infty} w(F_k - \tau_2(F_k)) \neq 0$, it follows from (2.3), (4.5) and (4.7) that

$$\begin{aligned}
0 =& \lim_{k\to+\infty} y'(F_k) \\
=& -\delta \lim_{k\to+\infty} y(F_k) + \beta\Big[\lim_{k\to+\infty} w(F_k - \tau_2(F_k))e^{-a\lim\limits_{k\to+\infty} w(F_k-\tau_2(F_k))} - N_* e^{-aN_*}\Big] \\
\leq& -\delta \lim_{k\to+\infty} y(F_k) + \frac{\beta}{a}\Big|a\lim_{k\to+\infty} w(F_k - \tau_2(F_k))e^{-a\lim\limits_{k\to+\infty} w(F_k-\tau_2(F_k))} - aN_* e^{-aN_*}\Big| \\
<& -\delta \lim_{k\to+\infty} y(F_k) + \beta e^{-aN_*}\lim_{k\to+\infty}\big|w(F_k - \tau_2(F_k)) - N_*\big| \\
\leq& L\Big[-\delta + \beta\frac{1}{1-c}e^{-aN_*}\Big] \\
=& 0.
\end{aligned}$$

This is a contradiction.

Likewise, if $\lim_{k\to+\infty} w(F_k - \tau_2(F_k)) = 0$, one sees readily the above contradiction. Accordingly

$$\max\{|L|, |l|\} = 0,$$

this completes the proof of Theorem 4.1. □

Remark 4.2. In references [12, 20], the stability analysis of (1.3) requires the solution $w(t)$ to be a differentiable function, with its derivative $w'(t-\alpha)$ existing. This imposes restrictions on the range of admissible initial functions and consequently narrows the scope of potential solutions. Moreover, the methodologies and strategies proposed in the aforementioned literature cannot be directly applied to analyze the stability and attractiveness of the non-autonomous neutral delayed Nicholson's blowflies equation (1.4) under the initial condition (2.1). Additionally, in contrast to the initial function set Γ in [3], which depends on the coefficient of the death term, the set Γ_+ introduced in this manuscript is independent of this coefficient. This distinction offers a more comprehensive and versatile framework for understanding the stability and attractiveness of solutions across different initial value ranges, providing deeper insights into the problem.

Remark 4.3. Evidently, when $c = 0$, Eq. (1.4) reduces to the standard Nicholson's blowflies equation Eq. (1.1), which has received widespread attention and in-depth research. Especially,

the sharp criteria $\frac{\beta}{\delta} \leq 1$ and $1 < \frac{\beta}{\delta} \leq e^2$ for respectively ensuring the global asymptotic stability of trivial and positive equilibria were rigidly established in [5, 11, 17–19], which are special cases of the corresponding ones in Theorems 3.1 and 4.1 if $c = 0$. In this sense, global asymptotic stability criteria $\frac{\beta}{\delta(1-c)} \leq 1$ and $1 < \frac{\beta}{\delta(1-c)} \leq e^2$ established are also sharp to time-varying delayed Nicholson's blowflies equation of neutral type (1.4). On the other hand, since the delays are time varying, Eq. (1.4) is non-autonomous, which has brought theoretical and technical difficulties to the dynamic study of Eq. (1.4), and the stability problem for such a neutral model has not received attention until now. Hence, the theoretical results established in this paper are substantially new and enrich the theory of functional differential equations to some extent.

5 Numerical examples

In this section, numerical examples with simulation are afforded to illustrate the main theoretical findings.

Example 5.1. Consider a neutral time-varying delayed Nicholson's blowflies model with different parameters,

$$\begin{aligned}\Big[w(t) - \frac{1}{2}w(t - e^{-|\sin 2t|})\Big]' = & -4(w(t) - \frac{1}{2}w(t - e^{-|\sin 2t|})) \\ & + w(t - 2e^{-|\sin 2t|})e^{-2w(t-2e^{-|\sin 2t|})}, \quad t \geq t_0 = 0, \end{aligned} \tag{5.1}$$

$$\begin{aligned}\Big[w(t) - \frac{1}{2}w(t - e^{-|\sin 2t|})\Big]' = & -2(w(t) - \frac{1}{2}w(t - e^{-|\sin 2t|})) \\ & + ew(t - 2e^{-|\sin 2t|})e^{-2w(t-2e^{-|\sin 2t|})}, \quad t \geq t_0 = 0, \end{aligned} \tag{5.2}$$

and

$$\begin{aligned}\Big[w(t) - \frac{1}{2}w(t - e^{-|\sin 2t|})\Big]' = & -2(w(t) - \frac{1}{2}w(t - e^{-|\sin 2t|})) \\ & + 100w(t - 2e^{-|\sin 2t|})e^{-2w(t-2e^{-|\sin 2t|})}, \quad t \geq t_0 = 0. \end{aligned} \tag{5.3}$$

Obviously, $\tau_1(t) = e^{-|\sin 2t|}$, $\tau_2(t) = 2e^{-|\sin 2t|}$, $2 = r = r_2 > r_1 = 1$, let

$$\Gamma_+ = \big\{\varphi \in C([-2,\ 0],\ \mathbb{R}) \mid \varphi(0) - c\varphi(-\tau_1(0)) \geq 0,\ \varphi(\theta) \geq 0 \text{ for all } \theta \in [-2,\ 0]\big\}.$$

One can easily verify that $\frac{\beta}{\delta(1-c)} = \frac{1}{4(1-\frac{1}{2})} = \frac{1}{2} < 1$ and $1 < \frac{\beta}{\delta(1-c)} = \frac{e}{2\times(1-\frac{1}{2})} = e < e^2$ hold for Eqs. (5.1) and (5.2), respectively. It is concluded from Theorems 3.1 and 4.1 that the zero equilibrium of Eq. (5.1) and the positive equilibrium of Eq. (5.2) are all globally asymptotically stable (see Figs. 5.1 and 5.2). However, the stability criteria $\frac{\beta}{\delta(1-c)} \leq 1$ and $1 < \frac{\beta}{\delta(1-c)} \leq e^2$ are invalid for Eq. (5.3), which means that the positive equilibrium of Eq. (5.3) is not globally asymptotically stable, Fig. 5.3 indicates this fact.

Remark 5.2. It is not difficult to check that $\tau_1(t) = e^{-|\sin 2t|}$ and $\tau_2(t) = 2e^{-|\sin 2t|}$ in Eqs. (5.1)–(5.3) are time dependent, which do not satisfy the basic constraints of the delay terms in [2, 3, 7, 12, 21]. In addition, the sharp asymptotic stability conditions have not been touched in [10, 13, 20, 22]. Consequently, the results in above-mentioned literatures and their references could not directly applied to this example. This shows that the established theoretical results in this paper extend and improve existing ones.

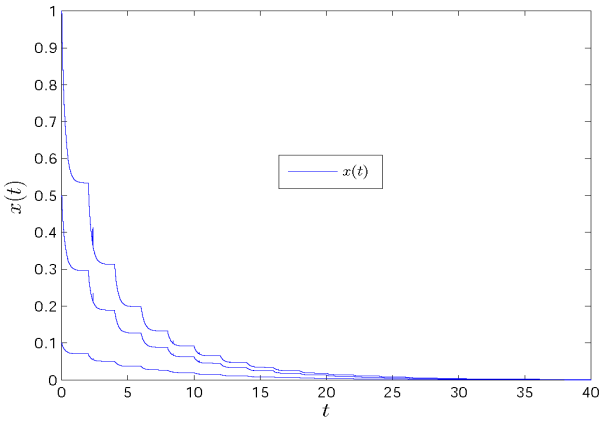

Figure 5.1: The state trajectories to Eq. (5.1) with initial values $0.1, 0.5, 1$.

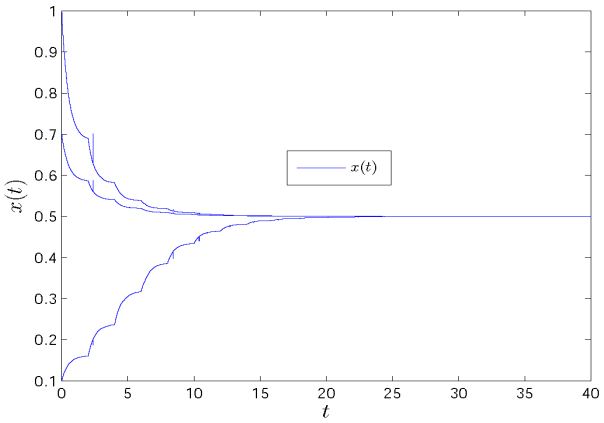

Figure 5.2: The state trajectories to Eq. (5.2) with initial values $0.1, 0.7, 1$.

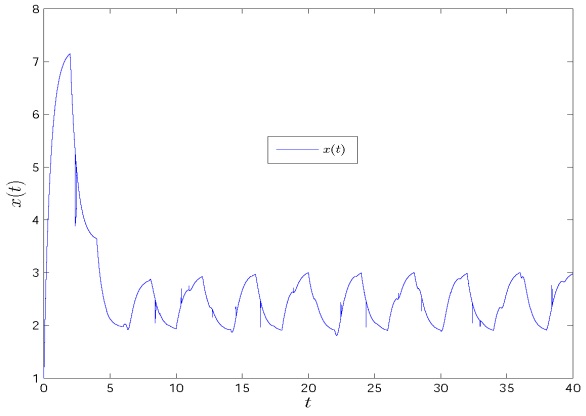

Figure 5.3: The state trajectory to Eq. (5.3) with initial value 1.

6 Conclusion

In this paper, the stability and attraction of the neutral Nicholson's blowflies equation with time-varying delays are addressed. By applying the analytical method such as Dini derivative and differential inequality techniques, sharp sufficient criteria substantially extend the existing results on global asymptotic stability, comparative analysis and simulations are also given to support the availability of the theoretical results.

It is also worth noting that the authors in [17] evidenced that the positive equilibrium point of the classical non-neutral delayed Nicholson's blowflies model attracts all solutions with nonnegative initial values under the delay-dependent condition $(e^{\delta\tau}-1)\ln\frac{P}{\delta}\leq 1$. Whether or not our methods used in this paper are available to find delay-dependent criterion to ensure the global attraction of positive equilibrium to Eq. (1.4), it is an interesting problem and we leave it as an important topic of future researchers.

Communicated by Dimitri Mugnai

Abstract. This paper deals with the following logarithmic Schrödinger–Bopp–Podolsky system

$$\begin{cases} -\Delta u + V(x)u - \phi u = u\log u^2 & \text{in } \mathbb{R}^3, \\ -\Delta\phi + \Delta^2\phi = 4\pi u^2 & \text{in } \mathbb{R}^3, \end{cases}$$

where $V(x) \in C(\mathbb{R}^3, \mathbb{R})$. By using the variational method developed by Szulkin for the functional which is the sum of a smooth and a convex lower semicontinuous term, we study the properties of the solutions for the above system under different potential conditions. When the potential is coercive, we discuss the existence of a ground state solution. Moreover, we also consider the cases where $V(x)$ is periodic or asymptotically periodic, and obtain a ground state solution in each scenario, respectively.

Keywords: Schrödinger–Bopp–Podolsky system, logarithmic nonlinearity, variational methods.

1 Introduction and main results

In the past few decades, the following nonlinear Schrödinger–Bopp–Podolsky system

$$\begin{cases} -\Delta u + V(x)u + \lambda\phi u = f(u) & \text{in } \mathbb{R}^3, \\ -\Delta\phi + a^2\Delta^2\phi = 4\pi u^2 & \text{in } \mathbb{R}^3, \end{cases} \tag{1.1}$$

where $\lambda, a \in \mathbb{R}$ are parameters, has been studied by many researchers. This system is closely related to the Bopp–Podolsky electromagnetic theory and arises when coupling a Schrödinger field $\psi = \psi(t,x)$ with its electromagnetic field in the Bopp–Podolsky electromagnetic theory. Among them, the Bopp–Podolsky theory is called a second-order gauge theory of electromagnetic fields, which was established by Bopp [3] and later developed by Podolsky [22] to solve

✉Corresponding author. Email: 11183356@qq.com

the so-called infinity problem in the classical Maxwell theory. From the viewpoint of electromagnetic fields, the Bopp–Podolsky theory can be explained as an effective theory for short distances, while for large distances it is experimentally indistinguishable from the Maxwell theory (see [9]).

To our knowledge, d'Avenia and Siciliano in [7] first proved the existence and non-existence of nontrivial solutions for system (1.1) with constant potential via using the variational method and splitting lemma, where the nonlinear term is denoted as $f(u) = |u|^{p-2}u$. Moreover, in the radial case, they found that solutions tend to those of the classical Schrödinger–Poisson system as $a \to 0$. In [13], Li, Pucci and Tang generalized the existing results for system (1.1) to the critical case and used the Pohožaev–Nehari manifold method to divide the equation into two cases, the constant potential and the asymptotic constant potential, proving that there is a ground state solution when the nonlinear term increases critically. Then in [4], the authors improved the nonlinear term in [13] to a general nonlinear term, and adopted some new analytical techniques and new inequalities to prove the existence of solutions in different cases. Yang, Chen and Liu [27] applied a cut-off function, the mountain pass theorem and Moser iteration to prove the existence of nontrivial solution for system (1.1) with critical growth. Zhu, Chen and Chen [30] studied the existence of different solutions for system (1.1) under nonlinearity effects.

Later, Jia, Li and Chen [12] established the existence of ground state solutions for nonautonomous Schrödinger–Bopp–Podolsky system. Liu and Chen [18] studied the existence, nonexistence and asymptotic behavior of ground state solutions for problem (1.1) with critical Sobolev exponent. Peng [20] proved the existence and multiplicity of solutions for the system (1.1). Zhang [28] investigated the existence of sign-changing solutions for system (1.1) with general nonlinearity. Yang, Yuan and Liu [26] were concerned with the existence of ground states for a nonlinear Schrödinger–Bopp–Podolsky system with asymptotically periodic potentials. Li and Zhang [14] found the existence of normalized solution for the system (1.1). For more information on the results of a system like (1.1), the readers can refer to [1, 5, 10, 19, 29] and the references therein.

Recently, the Schrödinger problem with logarithmic terms given by

$$i\varepsilon\frac{\partial \Phi}{\partial t} = -\varepsilon^2\Delta\Phi + W(x)\Phi - \Phi\log|\Phi|^2, \quad N \geq 3, \tag{1.2}$$

where $\Phi\colon [0,+\infty) \times \mathbb{R}^N \to \mathbb{C}$, has also received extensive attention due to its physical influence, such as quantum mechanics, quantum optics, nuclear physics, effective quantum, and Bose–Einstein condensation (see [31]). The standing wave solutions for problem (1.2) have the ansatz form $\Phi(t,x) = u(x)\mathrm{e}^{-i\omega t/\varepsilon}$, which leads to the following equation

$$-\varepsilon^2\Delta u + V(x)u = u\log u^2, \quad \text{in } \mathbb{R}^N, \tag{1.3}$$

where $V(x) = W(x) - \omega$ and $\omega \in \mathbb{R}$. Its associated energy functional is as follows

$$\tilde{\mathcal{J}}_\varepsilon(u) = \frac{1}{2}\int_{\mathbb{R}^N}\left(\varepsilon^2|\nabla u|^2 + (V(x)+1)u^2\right)\mathrm{d}x - \frac{1}{2}\int_{\mathbb{R}^N} u^2\log u^2\,\mathrm{d}x. \tag{1.4}$$

From a mathematical point of view, problem like (1.3) is very interesting because it is not like the general Schrödinger equation whose energy functional is C^1 class, while the energy functional $\tilde{\mathcal{J}}_\varepsilon(u)$ of the logarithmic Schrödinger equation is non-smooth. Therefore, it cannot be solved by the general critical point theory, and new technical means must be employed for

research, which brings many difficulties to the research process. In fact, there have been some results in this direction.

In [6], d'Avenia, Montefusco and Squassina used the non-smooth critical point theory to demonstrate the existence of infinitely many weak solutions for the logarithmic Schrödinger equation (1.3) as $\varepsilon = 1$ and $V(x) = 1$. Furthermore, they have proven that there exists a unique positive solution that is radially symmetric and nondegenerate. In [8], d'Avenia, Squassina and Zenari adopted the same way to show the existence of infinitely many solutions of a fractional Schrödinger equation with logarithmic nonlinearity.

Squassina and Szulkin [23] combined the method of the minimax principles for lower semicontinuous functionals proposed by Szulkin [24] to study the following problem

$$-\Delta u + V(x)u = Q(x)u \log u^2, \quad \text{in } \mathbb{R}^N, \tag{1.5}$$

where $V, Q\colon \mathbb{R}^N \to \mathbb{R}$ are 1-periodic continuous functions for x verifying

$$\min_{x\in\mathbb{R}^N} Q(x) > 0 \quad \text{and} \quad \min_{x\in\mathbb{R}^N} (V+Q)(x) > 0.$$

As a consequence, they obtained the existence of infinitely many geometrically distinct solutions for problem (1.5). In [11], Ji and Szulkin, inspired by [23], discussed the existence of multiple solutions and a ground state solution for equation (1.3), where $\varepsilon = 1$ and the potential $V(x)$ satisfies

$$V(x) \in C\left(\mathbb{R}^N, \mathbb{R}\right), \quad \lim_{|x|\to+\infty} V(x) = V_\infty \quad \text{and} \quad V_\infty + 1 \in (0, +\infty].$$

In the recent paper [2], Alves and de Morais Filho investigated the existence of positive solutions for the logarithmic elliptic equation (1.3). By using the variational method developed by Szulkin, they got the existence and concentration of solutions as $\varepsilon \to 0$, and they also considered the cases when the potential $V(x)$ is periodic or asymptotically periodic.

In particular, Peng and Jia [21] studied the logarithmic Schrödinger–Bopp–Podolsky system as follows

$$\begin{cases} -\varepsilon^2\Delta u + V(x)u - \phi u = u\log u^2 & \text{in } \mathbb{R}^3, \\ -\varepsilon^2\Delta\phi + \varepsilon^4\Delta^2\phi = 4\pi u^2 & \text{in } \mathbb{R}^3, \end{cases} \tag{1.6}$$

where V satisfies the following global condition:

$$(V)V(x) \in C\left(\mathbb{R}^3, \mathbb{R}\right) \quad \text{and} \quad V_\infty := \lim_{|x|\to+\infty} V(x) > \inf_{x\in\mathbb{R}^3} V(x) = V_0 > -1.$$

Borrowing an idea from [2], they proved the existence and concentration behavior of positive solution for equation (1.6).

Inspired by the above literatures, in this paper, we establish the existence of ground state solutions for the following logarithmic Schrödinger–Bopp–Podolsky system under different potentials

$$\begin{cases} -\Delta u + V(x)u - \phi u = u\log u^2 & \text{in } \mathbb{R}^3, \\ -\Delta\phi + \Delta^2\phi = 4\pi u^2 & \text{in } \mathbb{R}^3, \end{cases} \tag{1.7}$$

where $V(x) \in C\left(\mathbb{R}^3, \mathbb{R}\right)$ satisfies the following global conditions:

(V_1) $V(x)$ is coercive and $-1 < V_0 = \inf_{x\in\mathbb{R}^3} V(x)$.

(V_2) $V(x)$ is a continuous $\mathbb{Z}^3$-periodic function, i.e.,

$$V(x+y)=V(x), \quad \forall x\in\mathbb{R}^3, \forall y\in\mathbb{Z}^3 \quad \text{and} \quad -1<V_0=\inf_{x\in\mathbb{R}^3} V(x).$$

(V_3) $V(x)$ is a continuous asymptotically periodic, that is, there is a continuous $\mathbb{Z}^3$-periodic function V_p such that

$$-1<V_0=\inf_{x\in\mathbb{R}^3} V(x)\le V(x)<V_p(x), \quad \text{for all } x\in\mathbb{R}^3$$

and

$$\left|V(x)-V_p(x)\right|\to 0 \quad \text{as } |x|\to+\infty.$$

We will use the Variational Method developed by Szulkin [24] to get our results. Compared with previous papers, the problem we study is more complex due to the interaction between logarithmic and non-local terms. To our knowledge, there is currently only one article [21] in this direction, but in that literature the authors considered the case of asymptotic constant potential, which is different from the problem we are studying. Therefore, it is necessary to employ different methods to address our research question.

Definition 1.1. A weak solution for system (1.7) means a pair of $(u,\phi)\in E_V\times\mathcal{D}$ satisfying $u^2\log u^2\in L^1\left(\mathbb{R}^3\right)$ (i.e., $I(u)<+\infty$) and

$$\int_{\mathbb{R}^3}(\nabla u\nabla\zeta+V(x)u\zeta-\phi u\zeta)\mathrm{d}x=\int_{\mathbb{R}^3}u\zeta\log u^2\,\mathrm{d}x, \quad \text{for any } \zeta\in C_0^\infty\left(\mathbb{R}^3\right),$$

$$\int_{\mathbb{R}^3}\nabla\phi\nabla\xi\mathrm{d}x+\int_{\mathbb{R}^3}\Delta\phi\Delta\xi\mathrm{d}x=4\pi\int_{\mathbb{R}^3}\xi u^2\,\mathrm{d}x, \quad \text{for any } \xi\in\mathcal{D},$$

where the definitions of $I(u)$, E_V and $\mathcal{D}$ will be given in Sect. 2.

We derive the following results.

Theorem 1.2. *Assume that the condition (V_1) holds. Then, system (1.7) has one ground state solution.*

Theorem 1.3. *Assume that the condition (V_2) holds. Then, system (1.7) has one ground state solution.*

Theorem 1.4. *Assume that the condition (V_3) holds. Then, system (1.7) has one ground state solution.*

Remark 1.5. In this article, we just consider the case that $V_p<+\infty$ in the condition (V_3). Indeed, the case $V_p=+\infty$ is simpler since the embedding $E_V\hookrightarrow L^s(\mathbb{R}^3)$ is compact for $s\in[2,6)$, where E_V see Sect. 2. Moreover, we should note that $V_0>-1$ is assumed instead of the general condition $V_0>0$ because the nonlinear term we consider is logarithmic. In fact, this question can be explained from (1.4), and readers can also refer to [25] for more details.

Remark 1.6. When considering the logarithmic equation, we will cite the useful logarithmic Sobolev inequality found in [15]:

$$\int_{\mathbb{R}^3}u^2\log u^2\,\mathrm{d}x\le\frac{a^2}{\pi}\|\nabla u\|_2^2+\left(\log\|u\|_2^2-3(1+\log a)\right)\|u\|_2^2, \quad \text{for all } a>0. \tag{1.8}$$

Let us give a sketch of the proof of the results and explain the difficulties encountered in the process of solving them.

- Due to the existence of the logarithmic term, the energy functional $I(u)$ [see (2.3)] related to system (1.7) may take the value $+\infty$ since there is a function $u \in H^1(\mathbb{R}^3)$ such that $\int_{\mathbb{R}^3} u^2 \log u^2 \, \mathrm{d}x = -\infty$. Therefore, the functional $I(u)$ is not of class C^1, which makes it impossible to be solved by the general critical point theory.
- In order to find solutions of system (1.7), similar to [23], we will use a technical decomposition of $I(u)$ [see (2.4)]. In this case, we can apply the Mountain Pass Theorem without (PS) condition for a functional that is the sum of a smooth and a convex lower semicontinuous term, which was first mentioned in [2].
- Because of the interaction between the logarithmic term and the non-local term, the boundedness of (PS) sequences is more difficult to obtain than in [2], so we solve this problem with the help of literature [21].
- For the proof of Theorem 1.2, since the compactness can be directly obtained under the coercive potential condition, we only need to prove the boundness of (PS) sequence and combine the Mountain Pass Theorem without (PS) condition to complete the proof.
- The lack of compactness makes the proofs of Theorems 1.3 and 1.4 more difficult. Under the periodic potential condition, we still begin by decomposing the functional and defining the Nehari manifold $\mathcal{M}_V$ [see (3.6)]. Subsequently, we derive the required conclusions via combining the Mountain Pass Theorem without (PS) condition. During this process, it is necessary to refer to [17] to return to the solution of the original problem [see Lemma 5.1]. The key steps in the proof involve verifying that the mountain pass value is equal to the infimum on the Nehari manifold, i.e., $c = c_V := \inf_{u \in \mathcal{M}_V} I(u)$ [see Lemma 3.7], and $u_n \rightharpoonup u_0 \neq 0$. However, the difference of asymptotic periodic potential is that the proof of $u_n \rightharpoonup u_0 \neq 0$ is obtained via comparing c_V with c_{V_p} [see Lemma 6.2], and other proofs are similar to the periodic potential case.

This paper is organized as follows. In Section 2, we recall some lemmas which we will use in the paper. In Section 3, we introduce the Mountain Pass Theorem without (PS) condition. In Section 4, we give the proof of Theorem 1.2. Subsequently, Theorems 1.3 and 1.4 will be proved in Sections 5 and 6, respectively.

Throughout this paper, we use the following notations:

- $L^s(\mathbb{R}^3)$ $(2 \leq s < \infty)$ denotes the Lebesgue space with the norm $\|u\|_s = \left(\int_{\mathbb{R}^3} |u|^s \, \mathrm{d}x\right)^{1/s}$;
- $B_r(x)$ denotes the ball centered at x with radius r;
- C, C', $\tilde{C}$, C_i $(i = 1, 2, \dots)$ denote positive constants possibly different in different places;
- $o_n(1)$ denotes a real sequence with $o_n(1) \to 0$ as $n \to +\infty$;
- $H_c^1\left(\mathbb{R}^3\right) = \left\{u \in H^1\left(\mathbb{R}^3\right) \mid u \text{ has a compact support } \right\}$.

2 Preliminaries

In this section, we present the variational setting and give a special decomposition of the functional $I(u)$, which needs to be adjusted since $I(u)$ may not be well defined in $H^1(\mathbb{R}^3)$. According to the research techniques in [23], we decompose $I(u)$ into a sum of a C^1 functional plus a convex lower semicontinuous functional.

2.1 Variational setting

Let $H^1(\mathbb{R}^3)$ denote the Sobolev space equipped with the norm

$$\|u\|_H = \left(\int_{\mathbb{R}^3} \left(|\nabla u|^2 + u^2 \right) \mathrm{d}x \right)^{\frac{1}{2}},$$

and $\mathcal{D}^{1,2}\left(\mathbb{R}^3\right) = \left\{ u \mid u \in L^6\left(\mathbb{R}^3\right), \nabla u \in L^2\left(\mathbb{R}^3\right) \right\}$ be endowed with the norm

$$\|u\|_{\mathcal{D}^{1,2}} = \left(\int_{\mathbb{R}^3} |\nabla u|^2 \, \mathrm{d}x \right)^{\frac{1}{2}}.$$

Let $\mathcal{D}$ be the completion of $C_0^\infty\left(\mathbb{R}^3\right)$ with respect to the norm $\|\cdot\|_{\mathcal{D}}$ induced by the scalar product

$$\langle \phi, \xi \rangle_{\mathcal{D}} := \int_{\mathbb{R}^3} \nabla\phi \nabla\xi \mathrm{d}x + \int_{\mathbb{R}^3} \Delta\phi \Delta\xi \mathrm{d}x.$$

Clearly, $\mathcal{D}$ is a Hilbert space continuously embedded into $\mathcal{D}^{1,2}\left(\mathbb{R}^3\right)$ and consequently in $L^6\left(\mathbb{R}^3\right)$. Moreover, the space $\mathcal{D}$ is continuously embedded in $L^\infty\left(\mathbb{R}^3\right)$ (see Lemma 3.1 in [7]).

Next, we present the basic lemma.

Lemma 2.1 ([7, Lemma 3.2]). *The space $C_0^\infty\left(\mathbb{R}^3\right)$ is dense in*

$$\mathcal{A} := \left\{ \phi \in \mathcal{D}^{1,2}\left(\mathbb{R}^3\right) : \Delta\phi \in L^2\left(\mathbb{R}^3\right) \right\}$$

normed by $\sqrt{\langle \phi, \phi \rangle_{\mathcal{D}}}$ and, therefore, $\mathcal{D} = \mathcal{A}$.

In view of the Riesz Theorem, for every fixed $u \in H^1\left(\mathbb{R}^3\right)$, there exists a unique solution $\phi_u \in \mathcal{D}$ of the second equation in (1.7), namely,

$$-\Delta\phi + \Delta^2\phi = 4\pi u^2$$

and ϕ_u can be represented by

$$\phi_u = \int_{\mathbb{R}^3} \frac{1 - \mathrm{e}^{-|x-y|}}{|x-y|} u^2(y) \mathrm{d}y. \tag{2.1}$$

Then we have the following fundamental properties.

Lemma 2.2 ([7, Lemma 3.4] and [27, Lemma 2.2]). *For $u \in H^1\left(\mathbb{R}^3\right) \setminus \{0\}$, we have:*

(1) $\phi_u \geq 0$ in $\mathbb{R}^3$;

(2) $\phi_u \in L^s\left(\mathbb{R}^3\right) \cap C_0\left(\mathbb{R}^3\right)$, $\forall s \in (3, +\infty]$;

(3) $\phi_{u(\cdot+y)} = \phi_u(\cdot + y)$, $\forall y \in \mathbb{R}^3$;

(4) $\|\phi_u\|_{\mathcal{D}} \leq C\|u\|_H^2$, $\int_{\mathbb{R}^3} \phi_u u^2 \, \mathrm{d}x \leq C\|u\|_{12/5}^4$;

(5) if $u_n \rightharpoonup u$ in $H^1\left(\mathbb{R}^3\right)$, then $\phi_{u_n} \rightharpoonup \phi_u$ in $\mathcal{D}$;

(6) if $u_n \to u$ in $L^{\frac{12}{5}}\left(\mathbb{R}^3\right)$, then $\phi_{u_n} \to \phi_u$ in $\mathcal{D}$ and $\int_{\mathbb{R}^3} \phi_{u_n} u_n^2 \, \mathrm{d}x \to \int_{\mathbb{R}^3} \phi_u u^2 \, \mathrm{d}x$;

(7) ϕ_u is the unique minimizer of the functional

$$X(\phi) = \frac{1}{2}\|\nabla\phi\|_2^2 + \frac{1}{2}\|\Delta\phi\|_2^2 - 4\pi\int_{\mathbb{R}^3}\phi u^2\,\mathrm{d}x, \quad \phi \in \mathcal{D}.$$

Now we introduce the working space,

$$E_V := \left\{u \in H^1\left(\mathbb{R}^3\right) : \int_{\mathbb{R}^3} V(x)u^2\,\mathrm{d}x < +\infty\right\}$$

with the norm $\|u\|_V$ induced by the scalar product

$$\langle u, v\rangle_V = \int_{\mathbb{R}^3}(\nabla u\nabla v + (V(x)+1)uv)\,\mathrm{d}x.$$

Note that E_V is a Hilbert space, and the embedding $E_V \hookrightarrow H^1\left(\mathbb{R}^3\right)$ is continuous.

For any $(u,\phi) \in E_V \times \mathcal{D}$, the associated energy functional of system (1.7) is given by

$$\begin{aligned}\mathcal{S}(u,\phi) = &\frac{1}{2}\int_{\mathbb{R}^3}\left(|\nabla u|^2 + (V(x)+1)u^2\right)\mathrm{d}x - \frac{1}{2}\int_{\mathbb{R}^3}\phi u^2\,\mathrm{d}x + \frac{1}{16\pi}\int_{\mathbb{R}^3}|\nabla\phi|^2\,\mathrm{d}x\\ &+ \frac{1}{16\pi}\int_{\mathbb{R}^3}|\Delta\phi|^2\,\mathrm{d}x - \frac{1}{2}\int_{\mathbb{R}^3}u^2\log u^2\,\mathrm{d}x.\end{aligned} \tag{2.2}$$

To avoid the difficulties caused by the strong uncertainty of the functional, we use the usual reduction function procedure introduced in [7]. From this, we can obtain that the reduced functional has the form as follows

$$\begin{aligned}I(u) := \mathcal{S}(u,\phi_u) = &\frac{1}{2}\int_{\mathbb{R}^3}\left(|\nabla u|^2 + (V(x)+1)u^2\right)\mathrm{d}x\\ &- \frac{1}{4}\int_{\mathbb{R}^3}\phi_u u^2\,\mathrm{d}x - \frac{1}{2}\int_{\mathbb{R}^3}u^2\log u^2\,\mathrm{d}x.\end{aligned} \tag{2.3}$$

Remark 2.3. The following conclusions are equivalent:

(i) the pair $(u,\phi) \in E_V \times \mathcal{D}$ is a critical point of $\mathcal{S}$, namely, (u,ϕ) is a solution of (1.7);

(ii) u is a critical point of $I(u)$ and $\phi = \phi(u)$.

2.2 Decomposition of the functional $I(u)$

For $\delta > 0$ small, let us define the following functions:

$$F(s) = \begin{cases}0, & s = 0,\\ -\frac{1}{2}s^2\log s^2, & 0 < |s| < \delta,\\ -\frac{1}{2}s^2\left(\log\delta^2 + 3\right) + 2\delta|s| - \frac{1}{2}\delta^2, & |s| \geq \delta\end{cases}$$

and

$$G(s) = \begin{cases}0, & |s| < \delta,\\ \frac{1}{2}s^2\log\left(s^2/\delta^2\right) + 2\delta|s| - \frac{3}{2}s^2 - \frac{1}{2}\delta^2, & |s| \geq \delta.\end{cases}$$

Then,

$$G(s) - F(s) = \frac{1}{2}s^2\log s^2, \quad \forall s \in \mathbb{R}$$

and the functional $I : E_V \to (-\infty, +\infty]$ may be denoted as

$$I(u) = \Phi(u) + \Psi(u), \quad u \in E_V, \tag{2.4}$$

where

$$\Phi(u) := \frac{1}{2}\int_{\mathbb{R}^3} \left(|\nabla u|^2 + (V(x)+1)u^2\right)\, \mathrm{d}x - \frac{1}{4}\int_{\mathbb{R}^3} \phi_u u^2\, \mathrm{d}x - \int_{\mathbb{R}^3} G(u)\, \mathrm{d}x$$

and

$$\Psi(u) := \int_{\mathbb{R}^3} F(u)\, \mathrm{d}x.$$

As proven in [11], we can list some properties of F and G as follows:

- $F, G \in C^1(\mathbb{R}, \mathbb{R})$.
- If $\delta > 0$ is fixed and small enough, F is a nonnegative, convex, even function and $F'(s)s \geq 0$, for all $s \in \mathbb{R}$.
- For every fixed $p \in (2, 6)$, there exists $C > 0$ such that for any $s \in \mathbb{R}$,

$$\left|G'(s)\right| \leq C\,|s|^{p-1}. \tag{2.5}$$

Therefore, referring to [11], we can get that Ψ is nonnegative, convex and lower semicontinuous, and $\Phi \in C^1(E_V, \mathbb{R})$. Next, we will review some definitions and results of convex analysis that first appeared in [24].

Definition 2.4. Let E be a Banach space, E' be the dual space of E and $\langle \cdot, \cdot \rangle$ be the duality pairing between E and E'. Let $I : E \to \mathbb{R}$ be a functional and $I(u) = \Phi(u) + \Psi(u)$, where $\Phi \in C^1(E, \mathbb{R})$ and Ψ is convex and lower semicontinuous. Then the following results are given:

(i) The set $D(I) := \{u \in E \colon I(u) < +\infty\}$ is called the effective domain of I.

(ii) The sub-differential $\partial I(u)$ of the functional I at a point $u \in E$ is the following set

$$\left\{w \in E' : \left\langle \Phi'(u), v - u \right\rangle + \Psi(v) - \Psi(u) \geq \langle w, v - u \rangle,\ \forall v \in E\right\}.$$

(iii) $u \in E$ is a critical point of I such that $u \in D(I)$ and $0 \in \partial I(u)$, i.e.,

$$\left\langle \Phi'(u), v - u \right\rangle + \Psi(v) - \Psi(u) \geq 0, \quad \forall v \in E.$$

(iv) A Palais–Smale sequence at level c for I is a sequence $\{u_n\} \subset E$ such that $I(u_n) \to c$ and there is a numerical sequence $\sigma_n \to 0^+$ with

$$\left\langle \Phi'(u_n), v - u_n \right\rangle + \Psi(v) - \Psi(u_n) \geq -\sigma_n \|v - u_n\|, \quad \forall v \in E. \tag{2.6}$$

(v) The functional I satisfies the Palais–Smale condition at level c ($(PS)_c$ condition, for short) if each Palais–Smale sequence of I has a convergent subsequence in E.

To further advance the analysis, for any $u \in D(I)$, we define $I'(u) : H_c^1(\mathbb{R}^3) \to \mathbb{R}$ given by

$$\langle I'(u), z\rangle = \langle \Phi'(u), z\rangle + \int_{\mathbb{R}^3} F'(u)z \, \mathrm{d}x, \ \forall z \in H_c^1(\mathbb{R}^3)$$

and

$$\|I'(u)\| := \sup\left\{\langle I'(u), z\rangle : z \in H_c^1(\mathbb{R}^3) \text{ with } \|z\|_V \le 1\right\}.$$

If $\|I'(u)\| < +\infty$, then $I'(u)$ may be extended to a bounded operator in E_V, and it can also be considered as an element of E_V'.

From Lemma 3.3 of reference [21], we state some useful results that can help us solve the considered problem.

Lemma 2.5. *Assume that $I(u)$ satisfies (2.4). Then*

(i) if $u \in D(I)$ is a critical point of I, then for any $v \in E_V$,

$$\langle \Phi'(u), v-u\rangle + \Psi(v) - \Psi(u) \ge 0,$$

namely,

$$\begin{aligned}\int_{\mathbb{R}^3} \nabla u \nabla(v-u)\mathrm{d}x + \int_{\mathbb{R}^3} (V(x)+1)u(v-u)\mathrm{d}x - \int_{\mathbb{R}^3} \phi_u u(v-u)\,\mathrm{d}x \\ + \int_{\mathbb{R}^3} F(v)\mathrm{d}x - \int_{\mathbb{R}^3} F(u)\mathrm{d}x \ge \int_{\mathbb{R}^3} G'(u)(v-u)\mathrm{d}x;\end{aligned}$$

(ii) for every $u \in D(I)$ such that $\|I'(u)\| < +\infty$, we have $\partial I(u) \neq \emptyset$, i.e., there is $w \in E_V'$, which is denoted by $w = I'(u)$, such that for any $v \in E_V$,

$$\langle \Phi'(u), v-u\rangle + \int_{\mathbb{R}^3} F(v)\mathrm{d}x - \int_{\mathbb{R}^3} F(u)\mathrm{d}x \ge \langle w, v-u\rangle;$$

(iii) if $u \in D(I)$ is a critical point of I, then (u, ϕ_u) is one solution of system (1.7);

(iv) if $\{u_n\} \subset E_V$ is a Palais–Smale sequence, then for any $z \in H_c^1(\mathbb{R}^3)$,

$$\langle I'(u_n), z\rangle = o_n(1)\|z\|_V;$$

(v) if Λ is a bounded domain with regular boundary, then Ψ (and hence I) is of class C^1 in $H^1(\Lambda)$. Precisely, for any $u \in H^1(\Lambda)$, the functional

$$\Psi(u) = \int_\Lambda F(u)\mathrm{d}x$$

belongs to $C^1\left(H^1(\Lambda), \mathbb{R}\right)$.

According to the above proprieties, we can directly get the following consequences.

Lemma 2.6. *If $u \in D(I)$ and $\|I'(u)\| < +\infty$, then $F'(u)u \in L^1(\mathbb{R}^3)$, where I satisfies (2.4).*

Proof. This proof process relies on Lemma 2.5-(ii) and (v), and for more details, readers can refer to the Lemma 2.1 in [2]. For brevity, we will omit the specifics here. □

In what follows, for each $u \in D(I)$, we can set the functional $I'(u) : E_V \to \mathbb{R}$ given by

$$I'(u)u = \int_{\mathbb{R}^3} \left(|\nabla u|^2 + (V(x)+1)u^2 - \phi_u u^2 - G'(u)u\right)\,\mathrm{d}x + \int_{\mathbb{R}^3} F'(u)u\,\mathrm{d}x \tag{2.7}$$

$$= \int_{\mathbb{R}^3} \left(|\nabla u|^2 + V(x)u^2 - \phi_u u^2\right)\mathrm{d}x - \int_{\mathbb{R}^3} u^2 \log u^2\,\mathrm{d}x. \tag{2.8}$$

3 Mountain pass theorem without (PS) condition

In this section, we will introduce an abstract theorem for the functional of the type $I(u) = \Phi(u) + \Psi(u)$, where $\Phi \in C^1$ and Ψ is convex and lower semicontinuous. This method was proposed by Alves and de Morais Filho [2] under the influence of Szulkin [24].

Proposition 3.1 ([2]). *Let E be a Banach space and $I\colon E \to (-\infty, +\infty]$ be a functional such that:*

(i) $I(u) = \Phi(u) + \Psi(u)$, *where* $\Phi(u) \in C^1(E, \mathbb{R})$, *and* $\Psi\colon E \to (-\infty, +\infty]$ *is convex, lower semicontinuous and* $\Psi(u) \not\equiv +\infty$;

(ii) $I(0) = 0$ *and* $I|_{\partial B_\rho(0)} \geq \alpha$, *for some* $\rho, \alpha > 0$;

(iii) $I(e) \leq 0$, *for some* $e \notin \overline{B}_\rho(0)$.

Then for fixed $\varepsilon > 0$, there is $u_\varepsilon \in E$ satisfying

$$\left\langle \Phi'(u_\varepsilon), w - u_\varepsilon \right\rangle + \Psi(w) - \Psi(u_\varepsilon) \geq -3\varepsilon \|w - u_\varepsilon\|, \quad \forall w \in E$$

and

$$I(u_\varepsilon) \in [c - \varepsilon, c + \varepsilon],$$

where

$$c := \inf_{\gamma \in \Gamma} \max_{t \in [0,1]} I(\gamma(t))$$

and

$$\Gamma = \{\gamma \in C([0,1], E) : \gamma(0) = 0, I(\gamma(1)) < 0\}.$$

Corollary 3.2. *From Proposition 3.1, it is clear that there exists a (PS) sequence $\{u_n\} \subset E$ for I, namely, $I(u_n) \to c$ and*

$$\left\langle \Phi'(u_n), w - u_n \right\rangle + \Psi(w) - \Psi(u_n) \geq -\sigma_n \|w - u_n\|, \quad \forall w \in E$$

with $\sigma_n \to 0^+$.

In the sequel, we will apply Proposition 3.1 and Corollary 3.2 to obtain our results. The most crucial point is to prove that the (PS) sequence has a convergent subsequence. First, we prove that I possesses the Mountain Pass Geometry.

Lemma 3.3. *Assume that (V_i) holds, $i = 1, 2, 3$. Then*

(i) there exist $b_0, r_0 > 0$ such that $I(u) \geq b_0$ with $\|u\|_V = r_0$;

(ii) there exists $\tilde{e} \in \mathbb{R}^3 \setminus B_{r_0}(0)$ with $\|\tilde{e}\|_V > r_0$ such that $I(\tilde{e}) < 0$.

Proof. (i) It is clear that $I(0) = 0$. According to (2.4) and (2.5) for $p \in (2, 6)$, together with $F \geq 0$ and Lemma 2.2-(4), we get

$$I(u) \geq \frac{1}{2}\|u\|_V^2 - C_1\|u\|_V^4 - C_2\|u\|_V^p \geq b_0 > 0$$

for some $b_0 > 0$ and $\|u\|_V = r_0$ small enough.

(ii) First fix $u \in D(I)\setminus\{0\}$ and $t>0$, then according to (2.3) and Lemma 2.2-(1), one can conclude

$$\begin{aligned} I(tu) &\leq \frac{t^2}{2}\|u\|_V^2 - \frac{1}{2}\int_{\mathbb{R}^3} t^2u^2\log\left(|tu|^2\right)\mathrm{d}x \\ &= t^2\left(I(u) + \frac{1}{4}\int_{\mathbb{R}^3}\phi_u u^2\,\mathrm{d}x - \log t\int_{\mathbb{R}^3}u^2\,\mathrm{d}x\right)\to -\infty, \end{aligned}$$

as $t\to+\infty$. Choosing $\tilde{e}=t_*u$ with $\|\tilde{e}\|_V > r_0$ for $t_*>0$ large enough, then we obtain $I(\tilde{e})<0$. □

Remark 3.4. According to Proposition 3.1 and Lemma 3.3, there exists a (PS) sequence $\{u_n\}\subset E_V$ of $I(u)$ at the level $c>0$, where

$$c := \inf_{\gamma\in\Gamma}\max_{t\in[0,1]} I(\gamma(t)) \tag{3.1}$$

and

$$\Gamma = \{\gamma\in C([0,1],E_V) : \gamma(0)=0, \gamma(1)=\tilde{e}\}.$$

Lemma 3.5. *Assume that (V_i) holds, $i=1,2,3$. If $\{u_n\}\subset E_V$ is a (PS) sequence of $I(u)$ at the level c, then $\{u_n\}$ is bounded in E_V, where c is defined in (3.1).*

Proof. By (2.3) and (2.8), for some $C>0$, we deduce

$$\begin{aligned} \int_{\mathbb{R}^3} u_n^2\,\mathrm{d}x + \frac{1}{2}\int_{\mathbb{R}^3}\phi_{u_n}u_n^2\,\mathrm{d}x &= 2I(u_n) - I'(u_n)u_n \\ &= 2c + o_n(1) + o_n(1)\|u_n\|_V \\ &\leq C + o_n(1)\|u_n\|_V. \end{aligned}$$

Consequently,

$$\|u_n\|_2^2 \leq C + o_n(1)\|u_n\|_V. \tag{3.2}$$

Next, we will use the logarithmic Sobolev inequality (1.8) for a convenient small $a>0$. Fixing $\frac{a^2}{\pi}=\frac{1}{4}$, it follows from (1.8) and (3.2) that

$$\begin{aligned} \int_{\mathbb{R}^3} u_n^2\log u_n^2\,\mathrm{d}x &\leq \frac{1}{4}\|\nabla u_n\|_2^2 + \left(\log\|u_n\|_2^2 - 3\left(1+\log\sqrt{\frac{4}{\pi}}\right)\right)\|u_n\|_2^2 \\ &\leq \frac{1}{4}\|\nabla u_n\|_2^2 + C_1\left(\log\|u_n\|_2^2+1\right)\|u_n\|_2^2 \\ &\leq \frac{1}{4}\|\nabla u_n\|_2^2 + C_1\left(\log\left(C+o_n(1)\|u_n\|_V\right)+1\right)\left(C+o_n(1)\|u_n\|_V\right) \\ &\leq \frac{1}{4}\|\nabla u_n\|_2^2 + C_2\left(\log\|u_n\|_V\right)\|u_n\|_V. \end{aligned} \tag{3.3}$$

Using the fact that given $\theta\in(0,1)$ there is $A>0$ satisfying

$$|t\log t| \leq A\left(1+|t|^{1+\theta}\right), \quad t\geq 0,$$

we obtain, together with (3.3), the inequalities below

$$\begin{aligned} \int_{\mathbb{R}^3} u_n^2\log u_n^2\,\mathrm{d}x &\leq \frac{1}{4}\|\nabla u_n\|_2^2 + \tilde{C}\left(1+\|u_n\|_V^{1+\theta}\right) \\ &\leq \frac{1}{4}\|\nabla u_n\|_2^2 + \tilde{C}\left(1+\|u_n\|_V\right)^{1+\theta} \end{aligned} \tag{3.4}$$

for $\theta \in (0,1)$ and n large enough. Then by (3.4), we have

$$\begin{aligned} c + o_n(1)\,\|u_n\|_V &= I(u_n) - \frac{1}{4} I'(u_n)\,u_n \\ &\geq \frac{1}{4}\left(\|u_n\|_V^2 - \int_{\mathbb{R}^3} u_n^2 \log u_n^2 \,\mathrm{d}x\right) \\ &\geq C'\left(\|u_n\|_V^2 - (1+\|u_n\|_V)^{1+\theta}\right) \end{aligned}$$

for some $C' > 0$ independent of n. From the above discussion, we get that $\{u_n\}$ is bounded in E_V. □

Remark 3.6. According to Lemma 3.3, we consider the fiber mapping $t \to f(t) := I(tu)$ given by

$$\begin{aligned} f(t) = \frac{t^2}{2}\int_{\mathbb{R}^3} \left(|\nabla u|^2 + (V(x)+1)u^2\right)\mathrm{d}x \\ - \frac{t^4}{4}\int_{\mathbb{R}^3} \phi_u u^2 \,\mathrm{d}x - \frac{t^2}{2}\int_{\mathbb{R}^3} u^2 \log|tu|^2 \,\mathrm{d}x. \end{aligned} \tag{3.5}$$

Then we can easily infer that $f(t)$ has a maximum value at the unique critical point $t_\mu > 0$. Indeed, from the expression of $f(t)$ we can observe

$$\frac{t^2}{2}\int_{\mathbb{R}^3} u^2 \log|tu|^2 \,\mathrm{d}x = \frac{t^2}{2}\int_{\mathbb{R}^3} u^2 \log|u|^2 \,\mathrm{d}x + \frac{t^2}{2}\log t^2 \int_{\mathbb{R}^3} |u|^2 \,\mathrm{d}x.$$

Hence, for given $u \in E_V$, we can denote $f(t)$ as

$$f(t) := C_1 t^2 - C_2 t^4 - C_3 t^2 \log t^2,$$

correspondingly,

$$\begin{aligned} f'(t) &= C_4 t - C_5 t^3 - C_6 t \log t^2 \\ &= t g(t), \end{aligned}$$

where

$$g(t) := C_4 - C_5 t^2 - C_6 \log t^2.$$

From the expression of g, we know that g is a monotonically decreasing function for $t > 0$, and g has the unique zero point t_μ. In other words, $g(t) > 0$ for $t \in (0, t_\mu)$ and $g(t) < 0$ for $t \in (t_\mu, +\infty)$. Hence, it's easy to conclude $f'(t) > 0$ for $t \in (0, t_\mu)$ and $f'(t) < 0$ for $t \in (t_\mu, +\infty)$, i.e., f achieves a positive maximum at the unique critical point $t_\mu > 0$.

Next, we define

$$\mathcal{M}_V = \left\{u \in D(I)\setminus\{0\} \,\middle|\, I'(u)u = 0\right\}. \tag{3.6}$$

In fact, for any $u \in D(I)\setminus\{0\}$, every ray $\{tu \mid t > 0\}$ intersects the set (3.6) at exactly the unique point $t_\mu u$. In this way, $t_\mu = 1$, if and only if, $u \in \mathcal{M}_V$.

Lemma 3.7. *If c denotes the mountain level associated with $I(u)$, by Remark 3.6, it is possible to prove the equality*

$$0 < c = c_V,$$

where $c_V := \inf_{u\in\mathcal{M}_V} I(u)$.

Proof. Since $u \in \mathcal{M}_V$, by Lemma 3.3 and Remark 3.6, one has

$$0 < c \leq \max_{t\geq 0} I(tu) = I(t_\mu u) = I(u),$$

namely,

$$c \leq \inf_{u\in\mathcal{M}_V} I(u).$$

Next, we need to prove the reverse inequality. Let $\{u_n\} \subset E_V$ be a $(PS)_c$ sequence of $I(u)$, then Lemma 3.5 implies that $\{u_n\}$ is bounded in E_V. Now, we claim that

$$\|u_n\|_2 \nrightarrow 0. \tag{3.7}$$

In fact, according to the contradictory argument and interpolation inequality, we have that $u_n \to 0$ in $L^p(\mathbb{R}^3)$, $\forall p \in [2,6)$. Then, by (2.5) we get

$$\int_{\mathbb{R}^3} G'(u_n)\, u_n \,\mathrm{d}x \leq C \int_{\mathbb{R}^3} |u_n|^p \,\mathrm{d}x \to 0.$$

On the other hand, from (2.7), Lemma 2.2-(4) and the fact that $F'(s)s \geq 0$, we obtain

$$\begin{aligned}\|u_n\|_V^2 + \int_{\mathbb{R}^3} F'(u_n)\, u_n \,\mathrm{d}x &= I'(u_n)u_n + \int_{\mathbb{R}^3} G'(u_n)\, u_n \,\mathrm{d}x + \int_{\mathbb{R}^3} \phi_{u_n} u_n^2 \,\mathrm{d}x \\ &= o_n(1),\end{aligned}$$

from where it follows that $u_n \to 0$ in E_V and $F'(u_n)u_n \to 0$ in $L^1(\mathbb{R}^3)$ as $n \to +\infty$. Furthermore, from the definition of $F(s)$, we can directly calculate that $0 \leq F(s) \leq F'(s)s$ for all $s \in \mathbb{R}$. Hence, $F(u_n) \to 0$ in $L^1(\mathbb{R}^3)$, and so, $I(u_n) \to 0$, which is contradictory to $I(u_n) \to c > 0$. This proves (3.7). Naturally, we may assume that there exist constants $a, b > 0$ such that

$$0 < a \leq \|u_n\|_2 \leq b, \quad \forall n \in \mathbb{N}.$$

Moreover, by Remark 3.6, for every $u_n \in E_V$, we can let $s_n > 0$ be such that $s_n u_n \in \mathcal{M}_V$. From the definition of $\mathcal{M}_V$, we can see

$$I(s_n u_n) = I(s_n u_n) - \frac{1}{2} I'(s_n u_n)\, s_n u_n, \tag{3.8}$$

which means

$$\begin{aligned}&\frac{s_n^2}{2}\int_{\mathbb{R}^3} \left(|\nabla u_n|^2 + (V(x)+1)u_n^2\right)\mathrm{d}x - \frac{s_n^4}{4}\int_{\mathbb{R}^3} \phi_{u_n} u_n^2 \,\mathrm{d}x \\ &\quad - \frac{s_n^2}{2}\int_{\mathbb{R}^3} u_n^2 \log|s_n u_n|^2 \,\mathrm{d}x = \frac{s_n^2}{2}\int_{\mathbb{R}^3} |u_n|^2 \,\mathrm{d}x + \frac{s_n^4}{4}\int_{\mathbb{R}^3} \phi_{u_n} u_n^2 \,\mathrm{d}x,\end{aligned}$$

namely,

$$\begin{aligned}&\int_{\mathbb{R}^3} \left(|\nabla u_n|^2 + V(x)u_n^2\right)\mathrm{d}x - 2\log s_n \int_{\mathbb{R}^3} u_n^2 \,\mathrm{d}x \\ &\quad - \int_{\mathbb{R}^3} u_n^2 \log u_n^2 \,\mathrm{d}x = s_n^2 \int_{\mathbb{R}^3} \phi_{u_n} u_n^2 \,\mathrm{d}x.\end{aligned} \tag{3.9}$$

Recalling that $\{u_n\}$ is a bounded $(PS)_c$ sequence of $I(u)$, and based on (2.8), we have

$$\begin{aligned}I'(u_n)\, u_n &= \int_{\mathbb{R}^3} \left(|\nabla u_n|^2 + V(x)u_n^2 - \phi_{u_n} u_n^2\right)\mathrm{d}x - \int_{\mathbb{R}^3} u_n^2 \log u_n^2 \,\mathrm{d}x \\ &= o_n(1).\end{aligned} \tag{3.10}$$

It follows from (3.9) and (3.10) that

$$o_n(1) = 2\|u_n\|_2^2 \log s_n + (s_n^2 - 1)\int_{\mathbb{R}^3} \phi_{u_n} u_n^2 \, \mathrm{d}x,$$

then combining (3.7) and Lemma 2.2-(4), we derive that $s_n \to 1$ as $n \to +\infty$. From this information, we arrive at

$$\inf_{u\in\mathcal{M}_V} I(u) \leq I(s_n u_n) \to c \quad \text{as } n \to +\infty.$$

The proof has been completed. □

4 Proof of Theorem 1.2

Theorem 4.1 ([11]). *Under the condition (V_1), E_V can be compactly embedded into $L^p(\mathbb{R}^3)$, $p \in [2,6)$.*

Proof of Theorem 1.2. From Lemma 3.5, it is known that the sequence $\{u_n\}$ is bounded. Passing to a subsequence, $u_n \rightharpoonup u$ in E_V for some u and by Theorem 4.1 with (3.7), we have $u_n \to u \neq 0$ in $L^p(\mathbb{R}^3)$ for $p \in [2,6)$. Then by the Hölder inequality, combining Lemma 2.2-(4) and (2.5), respectively, we can obtain the following conclusions

$$\int_{\mathbb{R}^3} \phi_{u_n} u_n (u - u_n) \, \mathrm{d}x \to 0, \tag{4.1}$$

$$\int_{\mathbb{R}^3} G'(u_n)(u - u_n) \, \mathrm{d}x \to 0. \tag{4.2}$$

Since $\{u_n\}$ is the (PS) sequence, depending on Corollary 3.2 and taking $w = u$, we derive that

$$\langle \Phi'(u_n), u - u_n \rangle + \Psi(u) - \Psi(u_n) \geq -\sigma_n \|u - u_n\|_V,$$

namely,

$$\int_{\mathbb{R}^3} \nabla u_n \nabla (u - u_n) \, \mathrm{d}x + \int_{\mathbb{R}^3} (V(x) + 1) u_n (u - u_n) \, \mathrm{d}x - \int_{\mathbb{R}^3} \phi_{u_n} u_n (u - u_n) \, \mathrm{d}x - \int_{\mathbb{R}^3} G'(u_n)(u - u_n) \, \mathrm{d}x + \Psi(u) - \Psi(u_n) \geq -\sigma_n \|u - u_n\|_V,$$

equivalently,

$$\langle u_n, u - u_n \rangle_V - \int_{\mathbb{R}^3} \phi_{u_n} u_n (u - u_n) \, \mathrm{d}x - \int_{\mathbb{R}^3} G'(u_n)(u - u_n) \, \mathrm{d}x + \Psi(u) - \Psi(u_n) \geq -\sigma_n \|u - u_n\|_V.$$

Hence, one has

$$\overline{\lim_{n\to+\infty}} \left(\langle u_n, u \rangle_V - \|u_n\|_V^2 \right) - \lim_{n\to+\infty} \left(\int_{\mathbb{R}^3} \phi_{u_n} u_n (u - u_n) \, \mathrm{d}x + \int_{\mathbb{R}^3} G'(u_n)(u - u_n) \, \mathrm{d}x \right) + \overline{\lim_{n\to+\infty}} \left(\Psi(u) - \Psi(u_n) \right) \geq 0.$$

Combining $u_n \rightharpoonup u$ in E_V with (4.1) and (4.2), the above inequality becomes

$$\overline{\lim_{n\to+\infty}}\left(\|u\|_V^2-\|u_n\|_V^2\right)+\overline{\lim_{n\to+\infty}}\left(\Psi(u)-\Psi\left(u_n\right)\right)\geq 0, \tag{4.3}$$

namely,

$$\|u\|_V^2-\underline{\lim_{n\to+\infty}}\|u_n\|_V^2+\Psi(u)-\underline{\lim_{n\to+\infty}}\Psi\left(u_n\right)\geq 0. \tag{4.4}$$

On the other hand, Ψ is lower semicontinuous, i.e., $\Psi(u)\leq \underline{\lim}_{n\to+\infty}\Psi\left(u_n\right)$, together with (4.4), we deduce

$$\|u\|_V^2-\underline{\lim_{n\to+\infty}}\|u_n\|_V^2\geq 0.$$

Then according to the weak lower semi-continuity of the norm $\|u\|_V^2\leq \underline{\lim}_{n\to+\infty}\|u_n\|_V^2$, we have $\|u_n\|_V\to\|u\|_V$, which implies $u_n\to u$ in E_V. Furthermore, by combining this result with Lemma 3.7, we can conclude that $I(u)=c=c_V$, i.e., u is a ground state solution for equation (1.7). The proof is completed. □

5 Proof of Theorem 1.3

In this section, we give the proofs of Theorem 1.3. Since the defined manifold $\mathcal{M}_V$ lacks C^1 regularity, we will adopt an indirect approach by borrowing the method from [17] to obtain our results.

Lemma 5.1. *Assume that (V_i) holds, $i=2,3$. If $u\in\mathcal{M}_V$ and $I(u)=c$, then u is a solution of Eq.(1.7).*

Proof. Suppose to the contrary, there exists u such that $I(u)=c$ and $I'(u)\neq 0$. Then there exists $\eta\in C_0^\infty\left(\mathbb{R}^3\right)$ such that $\langle I'(u),\eta\rangle<-1$. Choose a constant $\epsilon\in(0,1)$ small enough such that for all $|t-1|\leq\epsilon$ and $|\sigma|\leq\epsilon$,

$$\left\langle I'(tu+\sigma\eta),\eta\right\rangle\leq-\frac{1}{2}. \tag{5.1}$$

Define a cut-off function $0\leq\chi\leq 1$ such that $\chi(t)=1$ for $|t-1|\leq\frac{\epsilon}{2}$ and $\chi(t)=0$ for $|t-1|\geq\epsilon$. For $t>0$, we introduce a curve $\gamma(t)=tu$ for $|t-1|\geq\epsilon$ and $\gamma(t)=tu+\epsilon\chi(t)\eta$ for $|t-1|<\epsilon$. Clearly, $\gamma(t)$ is a continuous curve, and for $|t-1|<\epsilon$, $\|\gamma(t)\|>0$ holds when ϵ small enough. Next, we claim $I(\gamma(t))<c$, for all $t>0$. Indeed, if $|t-1|\geq\epsilon$, together with Remark 3.6, $I(\gamma(t))=I(tu)<I(u)=c$. If $|t-1|<\epsilon$, then by Lemma 2.5-(v), the mapping $[0,\epsilon]\ni\sigma\mapsto I(tu+\sigma\chi(t)\eta)$ is of C^1. Consequently, together with (5.1), there exists $\tilde{\sigma}\in(0,\epsilon)$ such that

$$I(tu+\epsilon\chi(t)\eta)=I(tu)+\left\langle I'(tu+\tilde{\sigma}\chi(t)\eta),\epsilon\chi(t)\eta\right\rangle\leq I(tu)-\frac{\epsilon}{2}\chi(t)<c.$$

Let $\omega(u)=\langle I'(u),u\rangle$. By the definition of $\gamma(t)$, we have $\omega(\gamma(1-\epsilon))=\omega((1-\epsilon)u)>0$ and $\omega(\gamma(1+\epsilon))=\omega((1+\epsilon)u)<0$. Since the mapping $t\to\omega(\gamma(t))$ is continuous, there exists $\tilde{t}\in(1-\epsilon,1+\epsilon)$ such that $\omega\left(\gamma\left(\tilde{t}\right)\right)=0$. Thus, $\gamma\left(\tilde{t}\right)\in\mathcal{M}_V$ and $I\left(\gamma\left(\tilde{t}\right)\right)<c$, which is a contradiction. The proof is complete. □

Proof of Theorem 1.3. From Proposition 3.1, Corollary 3.2 and Lemma 3.3, there exists a $(PS)_c$ sequence $\{u_n\}$ of $I(u)$ such that

$$I\left(u_n\right)\to c$$

and

$$\left\langle \Phi'(u_n), u - u_n \right\rangle + \Psi(u) - \Psi(u_n) \geq -\sigma_n \|u - u_n\|_V, \quad \forall u \in E_V,$$

with $\sigma_n \to 0^+$. As in the previous section $\{u_n\}$ is a bounded sequence in E_V, then there is $u_0 \in E_V$, and a subsequence of $\{u_n\}$, still denoted $\{u_n\}$, such that

$$u_n \rightharpoonup u_0 \quad \text{in } E_V, \tag{5.2}$$
$$u_n \to u_0 \quad \text{in } L^2_{\text{loc}}(\mathbb{R}^3), \tag{5.3}$$
$$u_n \to u_0 \quad \text{a.e. in } \mathbb{R}^3. \tag{5.4}$$

Next, taking any test function $\eta \in C_0^\infty(\mathbb{R}^3)$, from (2.5) and (5.2) together with Lemmas 2.2-(4) and 2.5-(v), we have

$$\begin{aligned}
0 &= \lim_{n\to+\infty} \left\langle I'(u_n), \eta \right\rangle \\
&= \lim_{n\to+\infty} \left[\langle u_n, \eta \rangle_V - \int_{\mathbb{R}^3} \phi_{u_n} u_n \eta \, \mathrm{d}x + \int_{\mathbb{R}^3} F'(u_n)\eta \, \mathrm{d}x - \int_{\mathbb{R}^3} G'(u_n)\eta \, \mathrm{d}x \right] \\
&= \langle u_0, \eta \rangle_V - \int_{\mathbb{R}^3} \phi_{u_0} u_0 \eta \, \mathrm{d}x + \int_{\mathbb{R}^3} F'(u_0)\eta \, \mathrm{d}x - \int_{\mathbb{R}^3} G'(u_0)\eta \, \mathrm{d}x \\
&= \left\langle I'(u_0), \eta \right\rangle,
\end{aligned}$$

which means that u_0 is a weak solution to equation (1.7). To complete this proof of Theorem 1.3, the key is to prove that $u_0 \neq 0$ in E_V. In fact, combined with (3.7), the Lions Concentration Compactness Principle [16] implies that there are parameters $r, \beta > 0$, and a sequence $\{y_n\} \subset \mathbb{Z}^3$ such that

$$\lim_{n\to+\infty} \int_{B_r(y_n)} |u_n|^2 \, \mathrm{d}x \geq \beta > 0.$$

Now, setting $v_n(x) = u_n(x + y_n)$, $\{y_n\} \subset \mathbb{Z}^3$, it follows that

$$\int_{B_r(0)} |v_n|^2 \, \mathrm{d}x = \int_{B_r(0)} |u_n(x + y_n)|^2 \, \mathrm{d}x = \int_{B_r(y_n)} |u_n|^2 \, \mathrm{d}x \geq \frac{\beta}{2} > 0. \tag{5.5}$$

Since $V(x)$ satisfies (V_2), there hold $\|v_n\|_V = \|u_n\|_V$ and

$$I(v_n) \to c, \; I'(v_n) \to 0, \quad \text{as } n \to +\infty,$$

so $\{v_n\}$ is also a bounded $(PS)_c$ sequence of I. Therefore, if v_0 denotes the weak limit of $\{v_n\}$ in E_V, for some subsequence, we have that

$$v_n \rightharpoonup v_0 \quad \text{in } E_V, \tag{5.6}$$
$$v_n \to v_0 \quad \text{a.e. in } \mathbb{R}^3, \tag{5.7}$$
$$v_n \to v_0 \quad \text{in } L^q(B_r(0)), \quad \forall\, r > 0 \;\text{ and }\; q \in [1, 6). \tag{5.8}$$

From (5.8), we derive that

$$\int_{B_r(0)} |v_0|^2 \, \mathrm{d}x \geq \frac{\beta}{2} > 0,$$

which shows that $v_0 \neq 0$. Using the standard argument, one has $I'(v_0)\eta = 0$, $\forall \eta \in C_0^\infty(\mathbb{R}^3)$, i.e., v_0 is a non trivial weak solution for equation (1.7).

Further, because $v_0 \in \mathcal{M}_V$, it follows from (2.3), (2.8) and the Fatou lemma that

$$\begin{aligned} 2c \leq 2I(v_0) &= 2I(v_0) - I'(v_0)v_0 \\ &= \int_{\mathbb{R}^3} {v_0}^2 \,\mathrm{d}x + \frac{1}{2}\int_{\mathbb{R}^3} \phi_{v_0}{v_0}^2 \,\mathrm{d}x \\ &\leq \varliminf_{n\to+\infty} \left(\int_{\mathbb{R}^3} v_n^2 \,\mathrm{d}x + \frac{1}{2}\int_{\mathbb{R}^3} \phi_{v_n} v_n^2 \,\mathrm{d}x\right) \\ &\leq \varlimsup_{n\to+\infty} \left(\int_{\mathbb{R}^3} v_n^2 \,\mathrm{d}x + \frac{1}{2}\int_{\mathbb{R}^3} \phi_{v_n} v_n^2 \,\mathrm{d}x\right) \\ &= \varlimsup_{n\to+\infty} \left(2I(v_n) - I'(v_n)v_n\right) = 2c, \end{aligned}$$

that is, $c_V = c = I(v_0)$ and consequently, v_0 is a ground state solution of equation (1.7). □

6 Proof of Theorem 1.4

In this section, we modify some notations.

Consider the vector space $H^1\left(\mathbb{R}^3\right)$ endowed with the norm

$$\|u\|_H = \left(\int_{\mathbb{R}^3} \left(|\nabla u|^2 + \left(V_p(x)+1\right)u^2\right)\mathrm{d}x\right)^{\frac{1}{2}},$$

where V_p is defined in (V_3). By replacing V by V_p, we have a periodic problem as in the following problem

$$\begin{cases} -\Delta u + V_p(x)u - \phi u = u\log u^2 & \text{in } \mathbb{R}^3, \\ -\Delta\phi + \Delta^2\phi = 4\pi u^2 & \text{in } \mathbb{R}^3. \end{cases} \tag{6.1}$$

The underlying energy functional $I_p : H^1\left(\mathbb{R}^3\right) \to (-\infty, +\infty]$ associated with problem (6.1) can be defined as

$$I_p(u) = \Phi_p(u) + \Psi(u), \quad \forall u \in H^1\left(\mathbb{R}^3\right), \tag{6.2}$$

where

$$\Phi_p(u) := \frac{1}{2}\int_{\mathbb{R}^3} \left(|\nabla u|^2 + \left(V_p(x)+1\right)u^2\right)\mathrm{d}x - \frac{1}{4}\int_{\mathbb{R}^3} \phi_u u^2 \,\mathrm{d}x - \int_{\mathbb{R}^3} G(u)\,\mathrm{d}x,$$

and

$$\Psi(u) := \int_{\mathbb{R}^3} F(u)\,\mathrm{d}x.$$

Remark 6.1. Note that we would like to point out that the proof of Lemma 3.7 is independent of potential conditions. Therefore, in the case of asymptotically periodic potentials, the following items are valid:

(i) if c denotes the mountain level associated with $I(u)$, we have

$$0 < c = c_V := \inf_{u\in\mathcal{M}_V} I(u), \tag{6.3}$$

where $\mathcal{M}_V$ is defined in (3.6).

(ii) If d denotes the mountain level associated with $I_p(u)$, we have that

$$0 < d = c_{V_p} := \inf_{u \in \mathcal{M}_p} I_p(u), \tag{6.4}$$

where

$$\mathcal{M}_p = \left\{ u \in D(I) \setminus \{0\} : I_p'(u)u = 0 \right\}.$$

Lemma 6.2. *Assume that $V(x)$ satisfies (V_3). Then*

(i) $c_V < c_{V_p}$.

(ii) *If $I(u_n) \to c \in (0, c_{V_p})$ and $I'(u_n) \to 0$, then $u_n \rightharpoonup u_0 \neq 0$ after passing to a subsequence, u_0 is a critical point of $I(u)$ and $I(u_0) \leq c$.*

Proof. (i) Similar to Remark 3.6, we know that for any $u \in \mathcal{M}_p$, one has $I_p(u) = \max_{t>0} I_p(tu)$, and there exists $t_\mu > 0$ such that $t_\mu u \in \mathcal{M}_V$ and $I(t_\mu u) = \max_{t>0} I(tu)$. By (V_3),

$$c_V = \inf_{u \in \mathcal{M}_V} I(u) \leq I(t_\mu u) = \max_{t>0} I(tu) < \max_{t>0} I_p(tu) = I_p(u).$$

Because of the arbitrariness of u, we get that $c_V < c_{V_p}$.

(ii) As in Lemma 3.5, $\{u_n\}$ is bounded in E_V with the level c. Up to a subsequence, we can assume that

$$\begin{aligned} &u_n \rightharpoonup u_0 \quad \text{in } E_V, \\ &u_n \to u_0 \quad \text{in } L^2_{\mathrm{loc}}\left(\mathbb{R}^3\right), \\ &u_n \to u_0 \quad \text{a.e. in } \mathbb{R}^3. \end{aligned}$$

Similar to the proof of Theorem 1.3, taking any $\varphi \in C_0^\infty(\mathbb{R}^3)$, one has $I'(u_0)\varphi = 0$, i.e., u_0 is a weak solution of equation (1.7). By Fatou's lemma, one has

$$\begin{aligned} I(u_0) = I(u_0) - \frac{1}{2} I'(u_0)u_0 &= \int_{\mathbb{R}^3} {u_0}^2 \, \mathrm{d}x + \frac{1}{2} \int_{\mathbb{R}^3} \phi_{u_0} {u_0}^2 \, \mathrm{d}x \\ &\leq \varliminf_{n \to +\infty} \left(\int_{\mathbb{R}^3} u_n^2 \, \mathrm{d}x + \frac{1}{2} \int_{\mathbb{R}^3} \phi_{u_n} u_n^2 \, \mathrm{d}x \right) \\ &= \varliminf_{n \to +\infty} \left(I(u_n) - \frac{1}{2} I'(u_n)u_n \right) = c, \end{aligned} \tag{6.5}$$

so, $I(u_0) \leq c$. Next, we claim that $u_0 \neq 0$ in E_V. Suppose, by contradiction, that $u_0 = 0$. For any $\epsilon > 0$, there exists $R(\epsilon) > 0$ such that

$$\left| V(x) - V_p(x) \right| < \epsilon, \quad \forall |x| > R.$$

Since $u_n \to u_0 = 0$ in $L^2_{\mathrm{loc}}\left(\mathbb{R}^3\right)$ and $\{u_n\}$ is bounded, we obtain

$$\int_{\mathbb{R}^3} \left| V(x) - V_p(x) \right| u_n^2 \, \mathrm{d}x \leq \int_{B_R(0)} \left| V(x) - V_p(x) \right| u_n^2 \, \mathrm{d}x + \epsilon \int_{\mathbb{R}^3 \setminus B_R(0)} u_n^2 \, \mathrm{d}x = o_n(1),$$

which yields, as $n \to +\infty$

$$I\left(u_n\right) - I_p\left(u_n\right) = \frac{1}{2} \int_{\mathbb{R}^3} \left| V(x) - V_p(x) \right| u_n^2 \, \mathrm{d}x \to 0.$$

Using the Hölder inequality and taking w with $\|w\| = 1$, we obtain, as $n \to +\infty$

$$\begin{aligned}\left|\left\langle I'(u_n) - I_p'(u_n), w\right\rangle\right| &\leq \int_{\mathbb{R}^3} \left|V(x) - V_p(x)\right| |u_n| |w| \, \mathrm{d}x \\ &\leq C\left(\int_{\mathbb{R}^3} \left|V(x) - V_p(x)\right| u_n^2 \, \mathrm{d}x\right)^{\frac{1}{2}} \\ &\to 0.\end{aligned}$$

In summary, we can immediately conclude

$$I_p(u_n) \to c \quad \text{and} \quad I_p'(u_n) \to 0,$$

namely, $\{u_n\}$ is a bounded $(PS)_c$ sequence for I_p. From (3.7) and Lions lemma [16], it follows that there exist $R, \kappa > 0$, $\{z_n\} \subset \mathbb{Z}^3$ satisfying

$$\int_{B_R(z_n)} |u_n|^2 \, \mathrm{d}x \geq \kappa > 0, \tag{6.6}$$

for all $n \in \mathbb{N}$. Since $u(x) = 0$ for all $x \in \mathbb{R}^3$, we have $|z_n| \to +\infty$. Taking $\omega_n(x) = u_n(x + z_n)$, then according to condition (V_3), $\{\omega_n\}$ is also a bounded $(PS)_c$ sequence for I_p. Therefore, we can assume there exists $\omega_0 \in E_V$ such that $\omega_n \rightharpoonup \omega_0$ in E_V, $\omega_n \to \omega_0$ in $L^2_{\mathrm{loc}}\left(\mathbb{R}^3\right)$ and $\omega_n \to \omega_0$ a.e. in $\mathbb{R}^3$ up to a subsequence. By (6.6), we have

$$\int_{B_R(0)} |\omega_n|^2 \, \mathrm{d}x = \int_{B_R(z_n)} |u_n|^2 \, \mathrm{d}x \geq \kappa > 0,$$

so, $\omega_0 \neq 0$. Then, using the standard argument, we get that for any $v \in C_0^\infty\left(\mathbb{R}^3\right)$, $I_p'(\omega_0)\, v = 0$, i.e., ω_0 is a nontrivial week solution of Eq. (6.1). Following the proof of Theorem 1.3, we know that ω_0 is a ground-state solution for equation (6.1), i.e.,

$$c_{V_p} = I_p(\omega_0). \tag{6.7}$$

By repeating the method of (6.5), this inequality $I_p(\omega_0) \leq c$ holds. Therefore, together with (6.7) and the fact that $c \in (0, c_{V_p})$, we obtain the following conclusions

$$I_p(\omega_0) \leq c < c_{V_p} = I_p(\omega_0),$$

which is a contradiction. This completes the proof. □

Proof of Theorem 1.4. From Lemmas 3.3 and 3.5, there exists a bounded (PS) sequence $\{u_n\}$ for I with the level $c \in (0, c_{V_p})$. By Lemma 6.2-(ii), we obtain a critical point $u_0 \neq 0$ of I such that $I(u_0) \leq c$. So, we have $I'(u_0)u_0 = 0$, i.e., $u_0 \in \mathcal{M}_V$. Then, arguing again as in the periodic case, it is possible to prove that u_0 is a ground state solution for Eq.(1.7). This completes the proof of Theorem 1.4. □

Abstract. In this paper, we characterize a family of planar polynomial differential systems of degree greater or equal than $n+1$, by presenting polynomial curves of degree n, which generally contain closed components. These systems admit precisely the bounded components of the curve as hyperbolic limit cycles.

Keywords: invariant curve, periodic solution, algebraic limit cycle, hyperbolic limit cycle.

2020 Mathematics Subject Classification: 34C25, 34C05, 34C07.

1 Introduction and the main result

The study of limit cycles in planar polynomial differential systems has been a central topic in the qualitative theory of ordinary differential equations for decades. Algebraic limit cycles have also received notable attention owing to their clear algebraic structure and geometric significance. The existence, classification, and stability of such cycles remain one of the most challenging problems, which is related to Hilbert's 16th problem and its generalizations. In this context, hyperbolic algebraic limit cycles are of particular interest, as their stability properties persist under small perturbations, making them a critical object of study in both theoretical and applied dynamical systems.

In this article, we consider the autonomous planar polynomial system of ordinary differential equations

$$\begin{aligned} \dot{x} &= \frac{dx}{dt} = f(x,y), \\ \dot{y} &= \frac{dy}{dt} = g(x,y), \end{aligned} \tag{1.1}$$

where f and g are two polynomials of $R[x,y]$ with no common factor, the derivatives are performed with respect to the time variable t. By definition, the degree of the system (1.1) is $n = \max(\deg(f), \deg(g))$. There is a huge literature about the analysis of the non-existence, existence, number, and stability of limit cycles of the system (1.1), see for instance [2, 7, 10, 6, 8] and the references therein.

Starting with Colin Christopher [4] proved that if the line $D(x,y) = ux + vy + w = 0$ lies outside all non-singular compact components (ovals) of the algebraic curve $U = 0$ and the constants α and β are chosen such that $\alpha u + \beta v \neq 0$, then the system

$$\begin{aligned} \dot{x} &= \alpha U(x,y) + D(x,y)U_y(x,y), \\ \dot{y} &= \beta U(x,y) - D(x,y)U_x(x,y) \end{aligned}$$

admits all the bounded components of the curve $U = 0$ as hyperbolic limit cycles. Furthermore, the vector field (1.1) has no other limit cycles.

S. Benyoucef in his paper [3] analyses the existence of hyperbolic limit cycles of the differential system

$$\begin{aligned} \dot{x} &= \alpha U(x,y) + (ax + by + \Phi(\beta x - \alpha y))\, U_y(x,y), \\ \dot{y} &= \beta U(x,y) - (ax + by + \Phi(\beta x - \alpha y))\, U_x(x,y), \end{aligned}$$

where α and β are real numbers, Φ is a polynomial function of degree n and $U(x;y)$ is a polynomial of degree m.

As a continuation of [3], J. Llibre and C. Valls in [9] described a new class of polynomial differential systems that has the ovals of the algebraic curve as hyperbolic limit cycles

$$\begin{aligned} \dot{x} &= P(y)U(x,y) + (R(x,y) + \Phi(w(x,y)))\, U_y(x,y), \\ \dot{y} &= Q(x)U(x,y) - (R(x,y) + \Phi(w(x,y)))\, U_x(x,y), \end{aligned}$$

where $R(x,y) = \alpha x + \beta y + \int Q(x)dx - \int P(y)dy$, with $\alpha, \beta \in \mathbb{R}$ and the function $w = w(x,y) = \int Q(x)dx - \int P(y)dy$.

Our work builds on and extends earlier results by [3, 4, 9]. Specifically, we provide a new way to construct a new family of systems by presenting polynomial curves which generally contain closed components, and we investigate the conditions under which such systems admit bounded components of these algebraic curves as hyperbolic limit cycles.

Consider $U(x,y) = 0$ be a curve of degree n with $n \geq 2$. We consider a polynomial differential system of degree m with $m \geq 3$:

$$\begin{aligned} \dot{x} &= \frac{\partial Q}{\partial y}(x,y)U(x,y) + \gamma \frac{\partial U}{\partial y}(x,y), \\ \dot{y} &= \frac{\partial Q}{\partial x}(x,y)U(x,y) - \gamma \frac{\partial U}{\partial x}(x,y), \end{aligned} \tag{1.2}$$

with $Q \in R[x,y]$, $\gamma \in \mathbb{R} - \{0\}$ and $(\cdot)_x, (\cdot)_y$ denoting the partial derivatives with respect to the x and y, respectively.

Our main result is the following.

Theorem 1.1. *Let $U = 0$ be a non-singular algebraic curve of degree n and Q a polynomial of degree $m \geq 2$, chosen so that the curve $Q_{xy}(x,y) = 0$ lies outside all oval components of $U = 0$ or $Q_{xy}(x,y) \neq 0$, then the polynomial differential equation (1.2) has all the oval components of $U = 0$ as hyperbolic limit cycles. Furthermore, the vector field has no other limit cycles.*

The paper is organized as follows. In Section 2, we introduce some preliminary results. Theorem 1.1 is proved in Section 3. The last part of Section 3 is devoted to providing some examples satisfying all the conditions of Theorem 1.1.

2 Preliminary results

In this section, we will present the basic concepts that we need to prove the main results of this paper.

As usual, the vector field

$$\mathcal{X} = f(x,y)\frac{\partial}{\partial x} + g(x,y)\frac{\partial}{\partial y},$$

is associated to the differential system (1.1).

Invariant algebraic curves

Let $U : \mathbb{R}^2 \to \mathbb{R}$ be a real polynomial. We say that U is an invariant for $\mathcal{X}$ if it satisfies

$$f(x,y)\frac{\partial U(x,y)}{\partial x} + g(x,y)\frac{\partial U(x,y)}{\partial y} = K(x,y)\,U(x,y), \tag{2.1}$$

for all $(x,y) \in \mathbb{R}^2$. Here, $K : \mathbb{R}^2 \to \mathbb{R}$, which is the cofactor of U. Simple analysis of equation (2.1) shows that the degree of the cofactor is at most $n-1$ where n represents the maximum of the degrees of f and g, and that the curve $U = 0$ is formed by trajectories of the system (1.1). Also, if the curve $U = 0$ is non-singular, the equilibrium points of the system are contained either in its non-bounded components or are located on the curve $K = 0$.

Note that if $K = 0$, then if $\mathcal{X}U = 0$, that is, $U(x,y) = 0$ is an invariant curve of (1.1) with zero cofactor. Equivalently, $U(x,y) = 0$ is constant if $(x(t), y(t))$ is a solution of (1.1).

Hyperbolic Limit Cycle

In the phase plane, a limit cycle $\Gamma = \{(x(t), y(t)), t \in [0,T]\}$ is a T-periodic solution isolated in the set of all periodic solutions of the system. If the limit cycle is contained in the zero of an invariant algebraic curve of the plane, then it is said to be algebraic; otherwise, it is said to be non-algebraic.

To see that all the oval components of Γ are hyperbolic limit cycles of system (1.1), we will use a classic result characterizing limit cycles among other periodic orbits, which states that: a T-periodic solution Γ is a hyperbolic limit cycle of system (1.1) if

$$\int_0^T \mathrm{Div}(\mathcal{X})(\Gamma(t))\,dt \neq 0,$$

where $\mathrm{Div}(\mathcal{X}) = \frac{\partial f(x,y)}{\partial x} + \frac{\partial g(x,y)}{\partial y}$, (see for instance [11] for more details).

The curve $U = 0$ is non-singular of system (1.1), i.e., it must not contain any singular point that satisfies

$$f(x,y) = 0, \qquad g(x,y) = 0.$$

Green's formula

In order to confirm the hyperbolicity of the limit cycles, we will make use of the following Green's theorem; see for instance [1].

Suppose Ω is a domain in $\mathbb{R}^2$ whose positively oriented boundary Γ is a finite collection of pairwise disjoint piecewise continuous simple closed curves. Suppose f and g are continuous functions defined on a larger open set, which contains both Ω and Γ, and suppose f and g have continuous first partial derivatives on this larger open set. Then

$$\oint_\Gamma f(x,y)\,dx + g(x,y)\,dy = \int\int_\Omega \left(\frac{\partial g(x,y)}{\partial x} - \frac{\partial f(x,y)}{\partial y}\right) dxdy.$$

3 Proof of Theorem 1.1

We assume that all bounded components of $U = 0$ are non-singular of system (1.2). Let $\Gamma = \{(x(t), y(t)), t \in [0, T]\}$ is an oval of the curve $U = 0$, corresponding to the periodic solution $(x(t), y(t))$ with period T. To see that all the oval components of $U = 0$ are hyperbolic limit cycles, we will prove that $U = 0$ is an invariant curve of the system (1.2), and $\int_0^T \mathrm{Div}(\mathcal{X})(\Gamma(t))\, dt \neq 0$.

(i) It is easy to see that $U = 0$ is an invariant algebraic curve with cofactor

$$K(x,y) = Q_x(x,y)\, U_y(x,y) + Q_y(x,y)\, U_x(x,y),$$

because

$$\begin{aligned}\frac{dU(x,y)}{dt} &= \dot{x}\frac{\partial U(x,y)}{\partial x} + \dot{y}\frac{\partial U(x,y)}{\partial y} \\ &= \left(Q_x(x,y)\, U_y(x,y) + Q_y(x,y)\, U_x(x,y)\right) U(x,y).\end{aligned}$$

(ii) The divergence of system (1.2) is

$$\mathrm{Div}(x,y) = Q_x(x,y)\, U_y(x,y) + Q_y(x,y)\, U_x(x,y) + 2Q_{xy}(x,y)\, U(x,y)$$

Therefore, on the curve $U = 0$, we have

$$\begin{aligned}\int_0^T \mathrm{Div}(x,y)\, dt &= \int_0^T Q_x(x,y)U_y(x,y) + Q_y(x,y)U_x(x,y)\, dt \\ &= \oint_\Gamma \frac{Q_x(x,y)U_y(x,y)}{\gamma U_y(x,y)}\, dx + \oint_\Gamma \frac{Q_y(x,y)U_x(x,y)}{-\gamma U_x(x,y)}\, dy \\ &= \frac{1}{\gamma}\left(\oint_\Gamma Q_x(x,y)\, dx - \oint_\Gamma Q_y(x,y)\, dy\right).\end{aligned}$$

Now, we apply the Green formula to get

$$\begin{aligned}\oint_\Gamma Q_x(x,y)\, dx - \oint_\Gamma Q_y(x,y)\, dy &= \iint_{\mathrm{int}(\Gamma)} \left(\frac{\partial(-Q_y(x,y))}{\partial x} - \frac{\partial Q_x(x,y)}{\partial y}\right) dx\, dy \\ &= -2\iint_{\mathrm{int}(\Gamma)} Q_{xy}(x,y)\, dx\, dy.\end{aligned}$$

where $\mathrm{int}(\Gamma)$ denotes the interior of the bounded region limited by Γ, thus

$$\int_0^T \mathrm{Div}(x,y)\, dt = -\frac{2}{\gamma}\iint_{\mathrm{int}(\Gamma)} Q_{xy}(x,y)\, dxdy.$$

Since by assumption $Q_{xy}(x,y) = 0$ lies outside all oval components of $U = 0$ or $Q_{xy}(x,y) \neq 0$, then $\int\int_{\mathrm{int}(\Gamma)} Q_{xy}(x,y)\, dxdy$ is non-zero, and the system (1.2) has all closed components of $U = 0$ as hyperbolic limit cycles.

Remark 3.1.

1. According to the hypotheses $Q_{xy}(x,y) \neq 0$, the polynomial $Q(x,y)$ must satisfy $\deg Q \geq 2$ and $Q(x,y) \neq h(x) + l(y)$, with $h \in R[x]$ and $l \in R[y]$.

2. In the case when $Q(x,y) = h(x) + l(y) + \alpha xy$, with $\alpha \neq 0$, the integral

$$\int_0^T \mathrm{Div}(x,y)\,dt = -\frac{2a}{\gamma}\iint_{\mathrm{int}(\Gamma)} dx\,dy.$$

So, we have the particular case; if $\alpha \neq 0$, the system (1.2) admits all bounded components of Γ as hyperbolic algebraic limit cycles.

Remark 3.2. If we take $Q(x,y) = yP(x)$, with $P \in \mathbb{R}[x]$, system (1.2) becomes

$$\begin{aligned} \dot{x} &= P(x)U(x,y) + \gamma\frac{\partial U}{\partial y}(x,y), \\ \dot{y} &= yP'(x)U(x,y) - \gamma\frac{\partial U}{\partial x}(x,y), \end{aligned} \tag{3.1}$$

then, the integral

$$\int_0^T \mathrm{Div}\,(x,y)\,dt = -\frac{2}{\gamma}\iint_{\mathrm{int}(\Gamma)} P'\,(x)\,dxdy.$$

So, if we choose that the curve $P'\,(x) = 0$ lies outside all oval components of $U = 0$, then the polynomial differential system (3.1) has all the oval components of $U = 0$ as hyperbolic limit cycles. Furthermore, the vector field has no other limit cycle.

By the change of variables $(x,y) \to (u,v)$ with $x = u$, $y = v + h(u)$, the system (3.1) is transformed into

$$\begin{aligned} \dot{u} &= -\left(h(u)+v\right)^2 \frac{\partial}{\partial v}\left(\frac{P(u)}{h(u)+v}\right)\tilde{U}(u,v) + \gamma\frac{\partial \tilde{U}}{\partial v}(u,v), \\ \dot{v} &= \left(h(u)+v\right)^2 \frac{\partial}{\partial u}\left(\frac{P(u)}{h(u)+v}\right)\tilde{U}(u,v) - \gamma\frac{\partial \tilde{U}}{\partial u}(u,v), \end{aligned} \tag{3.2}$$

where $h, P \in R[x]$, with $R(0) = 0, \tilde{U}\,(u,v) = \tilde{U}\,(u, v + h(u))$ and $\gamma \in \mathbb{R} - \{0\}$. For this last system we can choose $P'(u) = 0$ lies outside all oval components of $\tilde{U} = 0$, then in this case all the oval components of $\tilde{U} = 0$ are hyperbolic limit cycles.

Now we provide some examples of polynomial differential systems of the form (1.2) satisfying all the assumptions of Theorem 1.1 and admitting all oval components of $U = 0$ as hyperbolic limit cycles.

Example 3.3. Let $\gamma = 1$ and $Q\,(x,y) = y\left(x^2 - 4x\right)$. The system

$$\begin{aligned} \dot{x} &= x(x-4)(3x^2+5y^2-7) + 10y, \\ \dot{y} &= 2y(x-2)(3x^2+5y^2-7) - 6x, \end{aligned} \tag{3.3}$$

has an invariant algebraic curve given by $3x^2 + 5y^2 - 7 = 0$. Since $2\,(x-2) = 0$ does not intersect the curve $3x^2 + 5y^2 - 7 = 0$, this oval is an algebraic limit cycle hyperbolic of system (3.3) (see Figure 3.1).

Example 3.4. Let $\gamma = 1$ and $Q\,(x,y) = yx^3 + y^3x$. The system

$$\begin{aligned} \dot{x} &= x\left(x^2+3y^2\right)\left(x^4 - 2x^2 + y^2 + \frac{1}{4}\right) + 2y^2, \\ \dot{y} &= y\left(3x^2+y^2\right)\left(x^4 - 2x^2 + y^2 + \frac{1}{4}\right) - 4x\left(x^2-1\right) \end{aligned} \tag{3.4}$$

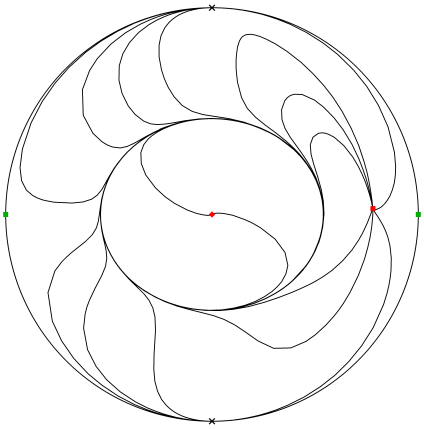

Figure 3.1: The limit cycle of (3.3).

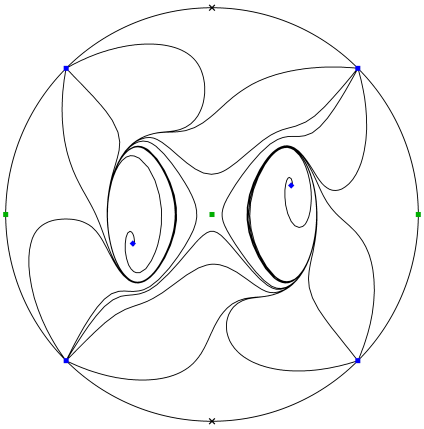

Figure 3.2: The two limit cycles of (3.4).

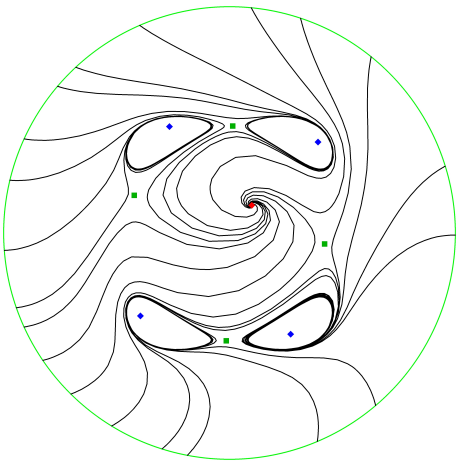
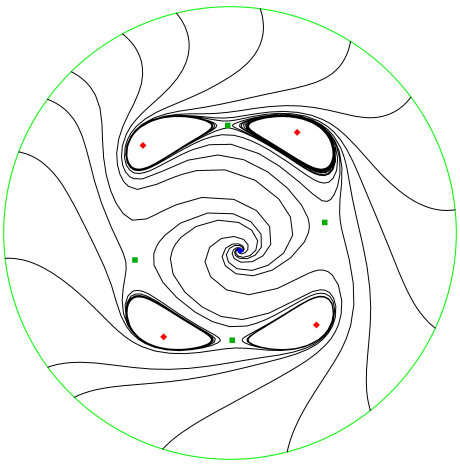


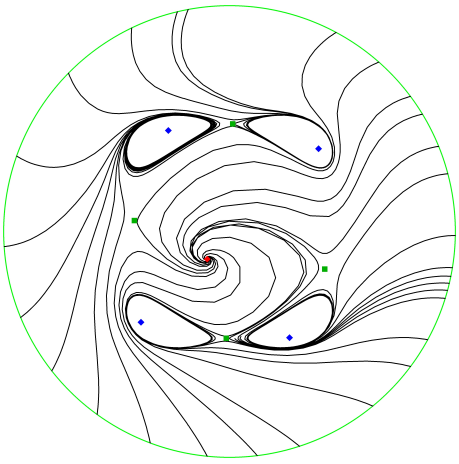
has an invariant algebraic curve given by $x^4-2x^2+y^2+\frac{1}{4}=0$. Since $Q_{xy}(x,y)=3\left(x^2+y^2\right)\neq 0$. So the two ovals of $x^4-2x^2+y^2+\frac{1}{4}=0$ are hyperbolic algebraic limit cycles of system (3.4) (see Figure 3.2).

Example 3.5. Let $\gamma=-2$ and $Q(x)=\alpha xy-\beta y+\gamma, \alpha\neq 0$. The family

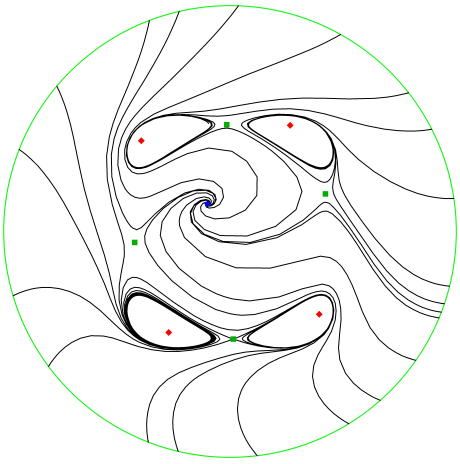


$$\begin{aligned}\dot{x}&=(\alpha x-\beta)\left(y^4+x^4-3y^2-2x^2+\frac{7}{3}\right)-4y\left(2y^2-3\right),\\ \dot{y}&=\alpha y\left(y^4+x^4-3y^2-2x^2+\frac{7}{3}\right)+8x\left(x^2-1\right)\end{aligned}\tag{3.5}$$

has an invariant algebraic curve given by $y^4+x^4-3y^2-2x^2+\frac{7}{3}=0$. Since $Q_{x,y}(x,y)=\alpha\neq 0$, the four ovals of $y^4+x^4-3y^2-2x^2+\frac{7}{3}=0$ are hyperbolic algebraic limit cycles of system (3.5) (see Figure 3.3).



Note: All figures are plotted on the Poincaré disk by using a program for polynomial planar phase portraits, such as the one described in [5, pp. 233–257].



(a) $\alpha = 3$ and $\beta = 2$

(b) $\alpha = -2$ and $\beta = -1$

(c) $\alpha = 3$ and $\beta = -2$

(d) $\alpha = -3$ and $\beta = 2$

Figure 3.3: The four limit cycles of (3.5) with different values of α and β.

On Shilnikov's scenario in 3D: Topological chaos for vectorfields of class C^1

Hans-Otto Walther ✉

Justus-Liebig-Universität Gießen, Mathematisches Institut, Arndtstr. 2, 35392 Gießen, Germany

Received 19 January 2025, appeared 19 June 2025
Communicated by Tibor Krisztin

Abstract. Shilnikov's scenario in $\mathbb{R}^3$ means that the equation $x' = V(x) \in \mathbb{R}^3$ with $V(0) = 0$ has a homoclinic solution and the eigenvalues of $DV(0)$ are $u > 0$ and $\sigma \pm i\mu$ with $\sigma < 0 < \mu$ and $0 < u + \sigma$. For V once continuously differentiable we consider a flow which is equivalent to the flow of V and prove that topological chaos exists for a planar return map which describes flowline behaviour near the homoclinic orbit: For every sequence in 2 symbols $0, 1$ there are trajectories of the return map which take values in disjoint sets M_0, M_1 according to the symbol sequence. The proof is by the analysis of the action of the return map on curves and does not involve covering relations for 2-dimensional sets.

Keywords: Shilnikov's scenario, topological chaos, vectorfield, flow.

1 Introduction

In his seminal paper [5] Shilnikov considered a differential equation

$$x'(t) = V(x(t)) \in \mathbb{R}^3 \tag{1.1}$$

with $V(0) = 0$ so that there is a homoclinic solution $h_V : \mathbb{R} \to \mathbb{R}^3$, $0 \neq h_V(t) \to 0$ for $|t| \to \infty$, and the derivative $DV(0)$ has eigenvalues $u > 0$ and $\sigma \pm i\,\mu \in \mathbb{C}$, $\sigma < 0 < \mu$, with

(H) $\qquad 0 < \sigma + u.$

Shilnikov's result in [5] is that for V analytic there exist countably many periodic orbits close to the homoclinic orbit $h_V(\mathbb{R})$. These periodic orbits arise from fixed points of a planar return map which is given by intersections of solutions with a transversal to the homoclinic orbit.

A related, stronger statement about complicated motion is conjugacy of the return map with the shift $(s_n)_{n=-\infty}^{\infty} \mapsto (s_{n+1})_{n=-\infty}^{\infty}$ in two symbols $s_n \in \{0, 1\}$. For work on the verification

✉ Email: Hans-Otto.Walther@math.uni-giessen.de

of this property see the monographs [1,2,9,10] and their references. A detailed presentation for V linear near the origin is contained in [2].

Shilnikov-type results on complicated motion close to a homoclinic orbit have also been obtained in infinite-dimensional spaces, for semiflows of solution operators which are linear close to equilibrium. See for example [4,7] on delay differential equations. These results are related to Shilnikov's scenario in $\mathbb{R}^4$ [6] with pairs of complex conjugate eigenvalues of $DV(0)$ in either halfplane.

The present paper deals with Shilnikov's scenario in $\mathbb{R}^3$ under the minimal smoothness assumption that V is once continuously differentiable – corresponding to the setting of a homoclinic solution combined with a spectral condition the statement of which does not require differentiability of higher order. Apart from this and with generalizations in mind, let us mention that for differential equations with state-dependent delay solution operators are in general not better than once continuously differentiable [3]. For a planar return map analogous to Shilnikov's in [5] we work out a proof that *topological chaos* exists, which means that for every given sequence $(s_n)_{n=-\infty}^{\infty}$, $s_n \in \{0,1\}$, there are trajectories $(x_n)_{n=-\infty}^{\infty}$ of the return map which take values in disjoint sets M_0, M_1 according to the rule $x_n \in M_{s_n}$. Notice that this is complementary to Shilnikov's result on periodic orbits [5] and weaker than conjugacy of the return map with a shift in two symbols.

The main results of the present paper are stated precisely in Section 8 below. They address return maps which are given by flowlines, as opposed to solutions of differential equations. Accordingly the subsequent sections 2–7 deal with flows and flowlines, and not with differential equations. Let us explain why. From the recent preprint [8] we know how to verify topological chaos for Shilnikov's scenario in $\mathbb{R}^3$ with the vectorfield V being twice continuously differentiable: The very first step is a transformation of V to a vectorfield whose local stable and unstable manifolds at the origin are flat, by a diffeomorphism which is twice continuously differentiable. The transformation reduces the order of smoothness for the vectorfields but preserves the smoothness of the flow F_V of Eq. (1.1). In the present situation, with V only continuously differentiable, the analogous transformation yields a vectorfield which is in general only continuous and thereby not good enough for arguments as used in [8]. The transformed flow F, however, is continuously differentiable with flat local invariant manifolds and further properties (F1)–(F5), from which we can proceed in Section 2 below. For more about the reduction by transformations see Section 9.

In Section 2 we immediately turn to scaled flows given by $F_\epsilon(t,x) = \frac{1}{\epsilon}F(t,\epsilon\, x)$, $\epsilon > 0$, all of which are equivalent to F. In the sequel we investigate the behaviour of these scaled flows inside and outside of a fixed neighbourhood of the origin, instead of studying F with respect to a family of shrinking neighbourhoods. As in [8] (and following Shilnikov [5]) we introduce a return map, now only for a sequence of small $\epsilon > 0$. The domain of the return map in a transversal to the homoclinic flowline is situated on one side of the flat local stable manifold, as shown at the top of Figure 1.1. Expressed in suitable coordinates the return map becomes a map from a rectangle into the plane. Section 7 shows how this map turns curves which connect certain horizontal levels in the rectangle into spirals around the origin. This suffices for the proof of Proposition 8.1 about one-directional topological chaos (with forward symbol sequences $(s_n)_{n=0}^{\infty}$). Theorem 8.2 extends the result of Proposition 8.1 to entire symbol sequences $(s_n)_{n=-\infty}^{\infty}$, by means of familiar compactness arguments.

The choice of Δ_2 in Section 7 shows that actually we obtain a countable family of sets of complicated trajectories of the return map. Another aspect which may be of interest is that the proofs of Proposition 8.1 and Theorem 8.2 do not involve covering relations for 2-dimensional

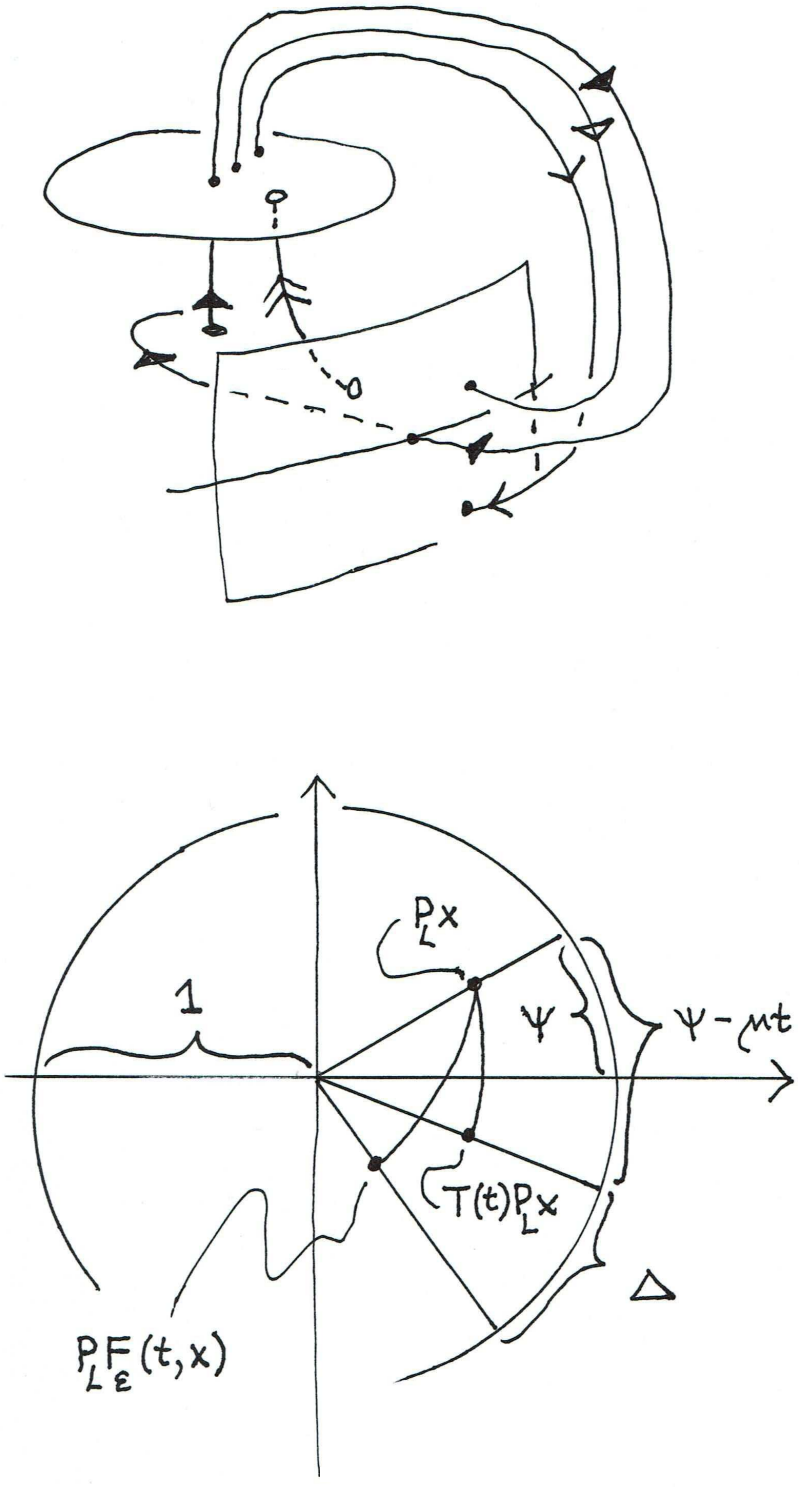

Figure 1.1: Top: The return map as a composition of the inner map with the exterior map. Bottom: Angles from Proposition 3.1.

sets.

Beyond results the emphasis in the present paper is on providing detailed proofs which may serve as a basis for future work. The content of Sections 2–6 parallels its counterpart in the preceding preprint [8], but working with the flows instead of differential equations necessitates modifications, among them in Section 3 another access to angles along projections of flowlines into the stable plane, and a rearrangement of arguments in Sections 4–6. Sections 7 and 8 are almost the same as their counterparts in the preprint [8]. We include all arguments in order to keep the paper self-contained.

What remains open, among others, is existence of periodic orbits corresponding to periodic symbol sequences. Also of interest might be a version of the present approach for Shilnikov's scenario in $\mathbb{R}^4$ [6].

Notation, preliminaries. A forward trajectory of a map $f : M \supset \text{dom} \to M$ is a sequence $(x_j)_{j=0}^{\infty}$ in dom with $x_{j+1} = f(x_j)$ for all integers $j \geq 0$. Entire trajectories are defined analogously, with all integers as indices.

For a vectorspace X, $x \in X$, and $M \subset X$, we set $x \pm M = \{y \in X : y \mp x \in M\}$. Similarly, for $A \subset \mathbb{R}$ and $x \in X$, $Ax = \{y \in X : \text{For some } a \in A, y = ax\}$.

The interior, the boundary, and the closure of a subset of a topological space are denoted by int $M, \partial M$, and cl M, respectively.

A curve is a continuous map from an interval $I \subset \mathbb{R}$ into a topological space.

Components of vectors in Euclidean spaces $\mathbb{R}^n$ are indicated by lower indices.The inner product on $\mathbb{R}^n$ is written as $\langle x, y\rangle = \sum_{i=1}^n x_i y_i$, and we use the Euclidean norm given by $|x| = \sqrt{\langle x, x\rangle}$. The vectors of the canonical orthonormal basis on $\mathbb{R}^n$ are denoted by e_j, $j = 1, \ldots, n$, $e_{j,j} = 1$ and $e_{j,k} = 0$ for $j \neq k$. In $\mathbb{R}^3$ we write $L = \mathbb{R}e_1 \oplus \mathbb{R}e_2$ and $U = \mathbb{R}e_3$. The associated projections $\mathbb{R}^3 \to \mathbb{R}^3$ onto L and onto U are denoted by P_L and P_U, respectively. For every $x \in \mathbb{R}^3$, $|P_U x|^2 + |P_L x|^2 = |x|^2$, and each of the projections has norm 1 in the space $L_c(\mathbb{R}^3, \mathbb{R}^3)$ of linear (continuous) maps $\mathbb{R}^3 \to \mathbb{R}^3$.

For a function $f : \mathbb{R}^n \supset \text{dom} \to \mathbb{R}^k$ on an open subset derivatives as linear maps $\mathbb{R}^n \to \mathbb{R}^k$ are denoted by $Df(x)$. For $n = k = 1$, $f'(x) = Df(x)1$. For partial derivatives in case $k = 1$, $\partial_j f(x) = Df(x)e_j$ for $j = 1, \ldots, n$.

Let $M \subset R^n$ be a continuously differentiable submanifold. For $x \in M$ the tangent space $T_x M$ is the set of tangent vectors $v = c'(0)$ of continuously differentiable curves $c : I \to \mathbb{R}^n$ with I an interval, not a singleton, $c(I) \subset M$, $0 \in I$, $c(0) = x$. A continuously differentiable map $f : M \supset \text{dom} \to N$, dom open in M and N a continuously differentiable submanifold of $\mathbb{R}^k$, is locally given by restrictions of continuously differentiable maps $g : \mathbb{R}^n \supset U \to \mathbb{R}^k$. For such U and g, and for $x \in \text{dom} \cap U$, the derivative of f at x is the linear map $T_x f : T_x M \to T_{f(x)} N$ given by $T_x f(v) = (g \circ c)'(0) = Dg(x)v$ for $v = c'(0)$ and c and g as above (with $c(I) \subset \text{dom} \cap U$).

The flow $\mathcal{F}$ generated by a vectorfield $\mathcal{V} : \mathbb{R}^n \supset \mathcal{U} \to \mathbb{R}^n$ which is locally Lipschitz continuous is the map $\mathbb{R} \times \mathbb{R}^n \supset \text{dom}_{\mathcal{F}} \to \mathbb{R}^n$ which is given by $(t, x) \in \text{dom}_{\mathcal{F}}$ if and only if t belongs to the domain of the maximal solution $y : I_x \to \mathbb{R}^n$ of the differential equation $x'(t) = \mathcal{V}(x(t))$ with initial value $y(0) = x$, and for such y, $\mathcal{F}(t, x) = y(t)$. $\mathcal{F}$ is of the same order of differentiability as $\mathcal{V}$. A subset $M \subset U$ is invariant under $\mathcal{F}$ if $x \in M$ implies $\mathcal{F}(t, x) \in M$ for all $t \in \mathbb{R}$ with $(t, x) \in \text{dom}_{\mathcal{F}}$. For a further subset $N \subset U$ the set M is called invariant under $\mathcal{F}$ in N if for every $x \in M \cap N$ and for every interval $I \ni 0$ with $\mathcal{F}(I \times \{x\}) \subset N$ we have $\mathcal{F}(I \times \{x\}) \subset M$. A flowline $\xi : \mathbb{R} \to \mathbb{R}^n$ of a flow $\mathcal{F}$ on $\text{dom}_{\mathcal{F}} = \mathbb{R} \times \mathbb{R}^n$ satisfies $\xi(t + s) = \mathcal{F}(t, \xi(s))$ for all reals s, t.

2 Transformation, scaling, projected flowlines

In the appendix Section 9 we describe how the flow F_V and the homoclinic flowline h_V can be transformed to a continuously differentiable flow $F : \mathbb{R} \times \mathbb{R}^3 \to \mathbb{R}^3$ and a flowline $h : \mathbb{R} \to \mathbb{R}^3$ of F with the following properties.

(F1) For all $t \in \mathbb{R}$, $F(t, 0) = 0$.

(F2) $h(t) \neq 0 \neq h'(t)$ for all $t \in \mathbb{R}$, and $\lim_{|t|\to\infty} h(t) = 0$.

(F3) Every linear map $T(t) : \mathbb{R}^3 \ni x \mapsto D_2F(t, 0)x \in \mathbb{R}^3$, $t \in \mathbb{R}$, satisfies $T(t)L \subset L$ and $T(t)U \subset U$. For $t \in \mathbb{R}, x \in \mathbb{R}^3$, and $y = T(t)x$,

$$\begin{pmatrix} y_1 \\ y_2 \end{pmatrix} = e^{\sigma t} \begin{pmatrix} \cos(\mu t) & \sin(\mu t) \\ -\sin(\mu t) & \cos(\mu t) \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \quad \text{and} \quad y_3 = e^{ut} x_3.$$

(F4) There exists $r_F > 0$ such that L and U are invariant under F in $\{x \in \mathbb{R}^3 : |x| < r_F\}$.

(F5) There exist reals $t_U < t_L$ with $h(t) \in U$ for all $t \leq t_U$ and $h(t) \in L$ for all $t \geq t_L$. Either $h(t) \in (0, \infty)e_3$ for all $t \leq t_U$, or $h(t) \in (-\infty, 0)e_3$ for all $t \leq t_U$.

In the sequel we focus on the case $h(t) \in (0, \infty)e_3$ for all $t \leq t_U$, the other case being analogous. We define

$$\begin{aligned} B_1 &= \{x \in \mathbb{R}^3 : |P_L x| \leq 1, |P_U x| \leq 1\}, \\ r_B &= 2\left(\max_{0\leq t\leq 1} |T(t)| + e^u + 2\right), \quad \text{and} \\ B &= \{x \in \mathbb{R}^3 : |x| \leq r_B\}. \end{aligned}$$

Obviously, $B_1 \subset B$. For $\epsilon > 0$ we consider the scaled flows given by $F_\epsilon(t, x) = \frac{1}{\epsilon}F(t, \epsilon x)$. If x is a flowline of F_ϵ then ϵx is a flowline of F, and conversely, if y is a flowline of F, then $\frac{1}{\epsilon}y$ is a flowline of F_ϵ. Observe that for all $\epsilon > 0, x \in \mathbb{R}^3, y \in \mathbb{R}^3, t \in \mathbb{R}$,

$$D_2F_\epsilon(t, x)y = \frac{1}{\epsilon} D_2F(t, \epsilon x)\epsilon y = D_2F(t, \epsilon x)y.$$

Proposition 2.1.

(i) For every $\eta > 0$ there exists $\epsilon(\eta) > 0$ such that for all $\epsilon \in (0, \epsilon(\eta))$,

$$|D_2F_\epsilon(t, x) - T(t)| < \eta \quad \textit{for all } x \in B_1.$$

(ii) There exists $\epsilon_B > 0$ such that for $0 < \epsilon < \epsilon_B$,

$$F_\epsilon([0, 1] \times B_1) \subset B,$$

and L and U are invariant under F_ϵ in B.

Proof. 1. On (i). By compactness and continuity there exists $\epsilon(\eta) > 0$ such that for $0 < \epsilon < \epsilon(\eta)$ and $x \in B_1$ and for all $t \in [0, 1]$,

$$\eta \geq |D_2F(t, \epsilon x) - D_2F(t, 0)| = |D_2F_\epsilon(t, x) - T(t)|.$$

2. Let $0 \le t \le 1$. For $0 < \epsilon < \epsilon(1)$ assertion (i) yields $|D_2F_\epsilon(t,y)| \le \max_{0\le s\le 1}|T(s)|+1 \le r_B/2$ for all $y \in B_1$. For $x \in B_1$ we have $|x| \le 2$, and we infer

$$|F_\epsilon(t,x)| = |F_\epsilon(t,x)-0| = |F_\epsilon(t,x)-F_\epsilon(t,0)| = \left|\int_0^1 D_2F_\epsilon(t,sx)xds\right| \le r_B|x|/2 \le r_B,$$

hence $F_\epsilon(t,x) \in B$.

3. On invariance. Let $0 < \epsilon < r_F/r_B$. Assume $x \in L$ and $F_\epsilon(s,x) \in B$ for s between 0 and $t \in \mathbb{R}$. Then we have $F(s,\epsilon x) \in \epsilon B$, or $|F(s,\epsilon x)| \le \epsilon r_B < r_F$. This yields $F(t,\epsilon x) \in L$. Consequently, $F_\epsilon(t,x) = \frac{1}{\epsilon}F(t,\epsilon x) \in \frac{1}{\epsilon}L = L$. Analogously for $x \in U$. □

The next proposition expresses closeness of the flow to its linearization at the origin in terms of components in U and L, for $0 \le t \le 1$ and $x \in B_1$.

Proposition 2.2. *For $\eta > 0$, $0 < \epsilon < \min\{\epsilon(\eta), \epsilon_B\}$, $x \in B_1$, and $0 \le t \le 1$,*

$$|P_UF_\epsilon(t,x) - T(t)P_Ux)| \le \eta|P_Ux| \quad \textit{and} \quad |P_LF_\epsilon(t,x) - T(t)P_Lx)| \le \eta|P_Lx|.$$

Moreover,

$$|P_UF_\epsilon(t,x)| \in (e^{ut}+[-\eta,\eta])|P_Ux| \quad \textit{and} \quad |P_LF_\epsilon(t,x)| \in (e^{\sigma t}+[-\eta,\eta])|P_Lx|.$$

Proof. Let $x \in B_1$ and $0 \le t \le 1$. We apply Proposition 2.1(ii) to $P_Ux \in B_1$ and to $P_Lx \in B_1$ and obtain $F_\epsilon(t,P_Ux) \in U$ and $F_\epsilon(t,P_Lx) \in L$, hence $P_LF_\epsilon(t,P_Ux) = 0$ and $P_UF_\epsilon(t,P_Lx) = 0$. It follows that

$$\begin{aligned}
|P_UF_\epsilon(t,x) - T(t)P_Ux| &= |P_UF_\epsilon(t,x) - T(t)P_Ux - (P_UF_\epsilon(t,P_Lx) - P_UT(t)P_Lx)| \\
&= \left|\int_0^1 (P_UD_2F_\epsilon(t,P_Lx+s(x-P_Lx))[x-P_Lx] - P_UT(t)[x-P_Lx])ds\right| \\
&= \left|\int_0^1 P_U\{D_2F_\epsilon(t,P_Lx+s(x-P_Lx))[P_Ux] - P_UT(t)[P_Ux]\})ds\right| \\
&\le |P_U|\max_{y\in B_1}|D_2F_\epsilon(t,y)-T(t)||P_Ux| \le \eta|P_Ux| \\
&\qquad \text{(with Proposition 2.1(i) and } |P_U| = 1).
\end{aligned}$$

We have $(P_Ux)_3 = x_3$, and for $z = T(t)P_Ux \in U$, $|z| = |z_3|$ with $z_3 = e^{ut}x_3$. Using the previous estimate we obtain

$$\begin{aligned}
(e^{ut}-\eta)|x_3| = |z| - \eta|x_3| = |T(t)P_Ux| - \eta|P_Ux| &\le |P_UF_\epsilon(t,x)| \\
&\le |T(t)P_Ux| + \eta|P_Ux| = |z| + \eta|x_3| = (e^{ut}+\eta)|x_3|
\end{aligned}$$

which yields

$$|P_UF_\epsilon(t,x)| \in (e^{ut}+[-\eta,\eta])|P_Ux|.$$

The remaining assertions are shown analogously. □

Proposition 2.3. *Assume $0 < \eta < e^\sigma$, $e^\sigma + \eta < 1$, and $0 < \epsilon < \min\{\epsilon(\eta), \epsilon_B\}$. Let $n \in \mathbb{N}$ and $x \in B_1$ be given with $|P_UF_\epsilon(j+1,x)| \le 1$ for $j = 0,\dots,n-1$. Then we have $F_\epsilon(j,x) \in B_1$ for $j = 0,\dots,n$, and for $0 \le t \le 1$,*

$$\begin{aligned}
e^{\sigma(t+n)}(1-\eta e^{-\sigma})^{n+1}|P_Lx| \le |P_LF_\epsilon(t+n,x)| \le e^{\sigma(t+n)}(1+\eta e^{-\sigma})^{n+1}|P_Lx|, \\
e^{u(t+n)}(1-\eta)^{n+1}|P_Ux| \le |P_UF_\epsilon(t+n,x)| \le e^{u(t+n)}(1+\eta)^{n+1}|P_Ux|.
\end{aligned}$$

Proof. 1. From Proposition 2.2 for $t = 1$,

$$e^u(1-\eta)|P_U x| \le (e^u-\eta)|P_U x| \le |P_U F_\epsilon(1,x)| \le (e^u+\eta)|P_U x| \le e^u(1+\eta)|P_U x|$$

and

$$e^\sigma(1-\eta e^{-\sigma})|P_L x| = (e^\sigma-\eta)|P_L x| \le |P_L F_\epsilon(1,x)| \le (e^\sigma+\eta)|P_L x| = e^\sigma(1+\eta e^{-\sigma})|P_L x|.$$

Using $x \in B_1$ and $e^\sigma + \eta < 1$ we infer $|P_L F_\epsilon(1,x)| \le 1$. With $|P_U F_\epsilon(1,x)| \le 1$, we get $F_\epsilon(1,x) \in B_1$.

By induction we obtain $F_\epsilon(j,x) \in B_1$ for $j = 1,\dots,n$, with

$$e^{\sigma j}(1-\eta e^{-\sigma})^j|P_L x| \le |P_L F_\epsilon(j,x)| \le e^{\sigma j}(1+\eta e^{-\sigma})^j|P_L x| \quad \text{and}$$
$$e^{uj}(1-\eta)^j|P_U x| \le |P_U F_\epsilon(j,x)| \le e^{uj}(1+\eta)^j|P_U x|.$$

2. On the lower estimates of the assertion. For $j = n$ and $0 \le t \le 1$ Proposition 2.2 yields

$$(e^{ut}-\eta)|P_U F_\epsilon(n,x)| \le |P_U F_\epsilon(t+n,x)|.$$

Use $e^{ut}(1-\eta) \le e^{ut} - \eta$ and the lower estimate for $|P_U F_\epsilon(n,x)|$ in order to get

$$e^{u(t+n)}(1-\eta)^{n+1}|P_U x| \le |P_U F_\epsilon(t+n,x)|.$$

In the same way, now using $e^{\sigma t}(1-\eta e^{-\sigma}) \le e^{\sigma t} - \eta$, one finds

$$e^{\sigma(t+n)}(1-\eta e^{-\sigma})^{n+1}|P_L x| \le |P_L F_\epsilon(t+n,x)|.$$

3. The upper estimates of the assertion are shown analogously. □

For later use we turn to exponential estimates for flowlines which stay sufficiently long in B_1.

Proposition 2.4. *Let $\tilde\eta > 0$ be given. Assume $0 < \eta < e^\sigma$ and $e^\sigma + \eta < 1$ as in Proposition 2.3, and in addition*

$$\log(1+\eta e^{-\sigma}) < \tilde\eta \quad \textit{and} \quad \log\left(\frac{1}{1-\eta e^{-\sigma}}\right) < \tilde\eta.$$

Let $n \in \mathbb{N}$ be given with

$$\frac{n+1}{n}\log(1+\eta e^{-\sigma}) < \tilde\eta \quad \textit{and} \quad \frac{n+1}{n}\log\left(\frac{1}{1-\eta e^{-\sigma}}\right) < \tilde\eta.$$

Let $0 < \epsilon < \min\{\epsilon(\eta), \epsilon_B\}$ and consider $x \in B_1$ with $|P_U F_\epsilon(j+1,x)| \le 1$ for $j = 0,\dots,n-1$ as in Proposition 2.3. Then we have, for $0 \le t \le 1$,

$$e^{(\sigma-\tilde\eta)(t+n)}|P_L x| \le |P_L F_\epsilon(t+n,x)| \le e^{(\sigma+\tilde\eta)(t+n)}|P_L x|,$$
$$e^{(u-\tilde\eta)(t+n)}|P_U x| \le |P_U F_\epsilon(t+n,x)| \le e^{(u+\tilde\eta)(t+n)}|P_U x|.$$

Proof. In view of Proposition 2.3 the estimates of $|P_U F_\epsilon(t+n,x)|$ follow from the estimates

$$e^{(u-\tilde\eta)(t+n)} \le e^{u(t+n)}(1-\eta)^{n+1} \quad \text{and} \quad e^{u(t+n)}(1+\eta)^{n+1} \le e^{(u+\tilde\eta)(t+n)},$$

or equivalently,

$$-(t+n)\tilde{\eta} \le (n+1)\log(1-\eta) \quad \text{and} \quad (n+1)\log(1+\eta) \le (t+n)\tilde{\eta}.$$

Sufficient for the latter are

$$-n\tilde{\eta} \le (n+1)\log(1-\eta) \quad \text{and} \quad (n+1)\log(1+\eta) \le n\tilde{\eta},$$

which are a consequence of the hypotheses on η and n in combination with

$$\log\left(\frac{1}{1-\eta}\right) < \log\left(\frac{1}{1-\eta e^{-\sigma}}\right) \quad \text{and} \quad \log(1+\eta) < \log(1+\eta e^{-\sigma}).$$

Similarly the estimates of $|P_L F_\epsilon(t+n,x)|$ follow from the estimates

$$e^{(\sigma-\tilde{\eta})(t+n)} \le e^{\sigma(t+n)}(1-\eta e^{-\sigma})^{n+1} \quad \text{and} \quad e^{\sigma(t+n)}(1+\eta e^{-\sigma})^{n+1} \le e^{(\sigma+\tilde{\eta})(t+n)}$$

which are equivalent to

$$-\tilde{\eta}(t+n) \le (n+1)\log(1-\eta e^{-\sigma}) \quad \text{and} \quad (n+1)\log(1+\eta e^{-\sigma}) \le \tilde{\eta}(t+n).$$

Sufficient for the latter are

$$-\tilde{\eta}n \le (n+1)\log(1-\eta e^{-\sigma}) \quad \text{and} \quad (n+1)\log(1+\eta e^{-\sigma}) \le \tilde{\eta}n,$$

which are obvious from the hypotheses on η and n. □

3 Angles

This section deals with angles in the plane L, along projected flowlines $t \mapsto P_L F_\epsilon(t,x)$, for $x \in B_1 \setminus U$. The first step computes such angles for $0 \le t \le 1$.

Proposition 3.1. *Assume* $0 < \eta < \frac{e^\sigma}{2}$, $0 < \epsilon < \min\{\epsilon(\eta), \epsilon_B\}$, $x \in B_1 \setminus U$, *and*

$$\frac{1}{|P_L x|} P_L x = \begin{pmatrix} \cos(\psi) \\ \sin(\psi) \\ 0 \end{pmatrix} \quad \textit{for some } \psi \in \mathbb{R}.$$

Let $0 \le t \le 1$. *For the unique* $\Delta = \Delta(t,x,\psi) \in [-\pi, \pi)$ *with*

$$\frac{1}{|P_L F_\epsilon(t,x)|} P_L F_\epsilon(t,x) = \begin{pmatrix} \cos(\psi - \mu t + \Delta) \\ \sin(\psi - \mu t + \Delta) \\ 0 \end{pmatrix}$$

we have

$$\Delta(t,x,\psi) = \arcsin(\langle v, w^\perp \rangle) \in \left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$$

where

$$v = \frac{1}{|P_L F_\epsilon(t,x)|} P_L F_\epsilon(t,x), \quad w = \frac{1}{|T(t) P_L x|} T(t) P_L x, \quad \textit{and} \quad w^\perp = \begin{pmatrix} -w_2 \\ w_1 \\ 0 \end{pmatrix}.$$

In particular, $\Delta(0,x,\psi) = 0$. *Moreover,*

$$|\langle v, w^\perp \rangle| \le \frac{\eta}{e^\sigma - \eta} \quad \textit{and} \quad |\Delta| \le \arcsin\left(\frac{\eta}{e^\sigma - \eta}\right).$$

Compare Figure 1.1, bottom.

Proof. 1. Using $F_\epsilon(B_1 \times \{x\}) \subset B$ and invariance of U under F_ϵ in B from Proposition 2.1 (ii) we infer $F_\epsilon(t,x) \in B \setminus U$, hence $P_L F_\epsilon(t,x) \neq 0$. Also, $T(t)P_L x \neq 0$.

2. We have

$$\begin{pmatrix} w_1 \\ w_2 \end{pmatrix} = \begin{pmatrix} \cos(\mu t) & \sin(\mu t) \\ -\sin(\mu t) & \cos(\mu t) \end{pmatrix} \cdot \begin{pmatrix} \cos(\psi) \\ \sin(\psi) \end{pmatrix} = \begin{pmatrix} \cos(\psi - \mu t) \\ \sin(\psi - \mu t) \end{pmatrix}$$
$$= \begin{pmatrix} \cos(\psi - \mu t) & -\sin(\psi - \mu t) \\ \sin(\psi - \mu t) & \cos(\psi - \mu t) \end{pmatrix} \cdot \begin{pmatrix} 1 \\ 0 \end{pmatrix},$$

hence

$$\begin{pmatrix} -w_2 \\ w_1 \end{pmatrix} = \begin{pmatrix} \cos(\psi - \mu t) & -\sin(\psi - \mu t) \\ \sin(\psi - \mu t) & \cos(\psi - \mu t) \end{pmatrix} \cdot \begin{pmatrix} 0 \\ 1 \end{pmatrix}.$$

It follows that multiplication with the matrix

$$\begin{pmatrix} \cos(\psi - \mu t) & -\sin(\psi - \mu t) & 0 \\ \sin(\psi - \mu t) & \cos(\psi - \mu t) & 0 \\ 0 & 0 & 1 \end{pmatrix}^{-1} = \begin{pmatrix} \cos(\psi - \mu t) & \sin(\psi - \mu t) & 0 \\ -\sin(\psi - \mu t) & \cos(\psi - \mu t) & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

defines a linear map $\rho : L \to L$ which satisfies $\rho w = e_1$ and $\rho w^\perp = e_2$. The map ρ preserves the inner product and the norm. We obtain

$$\begin{pmatrix} \cos \\ \sin \\ 0 \end{pmatrix}(\Delta) = \begin{pmatrix} \cos(\psi - \mu t + \Delta - (\psi - \mu t)) \\ \sin(\psi - \mu t + \Delta - (\psi - \mu t)) \\ 0 \end{pmatrix}$$
$$= \begin{pmatrix} \cos(\psi - \mu t) & \sin(\psi - \mu t) & 0 \\ -\sin(\psi - \mu t) & \cos(\psi - \mu t) & 0 \\ 0 & 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} \cos(\psi - \mu t + \Delta) \\ \sin(\psi - \mu t + \Delta) \\ 0 \end{pmatrix}$$
$$= \rho v = \langle \rho v, e_1 \rangle e_1 + \langle \rho v, e_2 \rangle e_2 = \langle \rho v, \rho w \rangle e_1 + \langle \rho v, \rho w^\perp \rangle e_2$$
$$= \langle v, w \rangle e_1 + \langle v, w^\perp \rangle e_2,$$

hence $\cos(\Delta) = \langle v, w \rangle$ and $\sin(\Delta) = \langle v, w^\perp \rangle$. Let $\tilde{v} = P_L F_\epsilon(t,x) \neq 0$ and $\tilde{w} = T(t)P_L x \neq 0$. Then

$$\langle v, w \rangle = \frac{1}{|\tilde{v}||\tilde{w}|} \langle \tilde{v}, \tilde{w} \rangle.$$

Proposition 2.2 shows that $\tilde{z} = \tilde{v} - \tilde{w}$ satisfies $|\tilde{z}| \leq \eta |P_L x|$. Recall $|\tilde{w}| = e^{\sigma t}|P_L x|$. We infer

$$\langle \tilde{v}, \tilde{w} \rangle = \langle \tilde{w} + \tilde{z}, \tilde{w} \rangle \ \geq |\tilde{w}|^2 - |\tilde{z}||\tilde{w}| \geq |P_L x|^2 e^{\sigma t}(e^{\sigma t} - \eta) \geq |P_L x|^2 e^{\sigma}(e^{\sigma} - \eta) > 0,$$

which yields $\cos(\Delta) = \langle v, w \rangle > 0$. Recall $-\pi \leq \Delta < \pi$. It follows that $|\Delta| < \frac{\pi}{2}$. Consequently,

$$\Delta = \arcsin(\sin(\Delta)) = \arcsin(\langle v, w^\perp \rangle).$$

The equation $\Delta(0, x, \psi) = 0$ follows from $P_L F_\epsilon(0, x) = P_L x = T(0)P_L x$, which yields $v = w$, hence $\langle v, w^\perp \rangle = 0$.

3. Proof of the estimates of $\langle v, w^\perp \rangle$ and Δ. We have

$$|\langle v, w^\perp \rangle| = \frac{1}{|\tilde{v}||\tilde{w}|} |\langle \tilde{v}, \tilde{w}^\perp \rangle| = \frac{1}{|\tilde{v}||\tilde{w}|} |\langle \tilde{z}, \tilde{w}^\perp \rangle| \leq \frac{|\tilde{z}|}{|\tilde{v}|}.$$

Using $|\tilde{w}| = e^{\sigma t}|P_L x|$ and $|\tilde{z}| \le \eta |P_L x|$ we get

$$|\tilde{v}| \ge |\tilde{w}| - |\tilde{z}| = e^{\sigma t}|P_L x| - |\tilde{z}| \ge (e^{\sigma t} - \eta)|P_L x| \ge (e^{\sigma} - \eta)|P_L x|$$

and obtain

$$\frac{|\tilde{z}|}{|\tilde{v}|} \le \frac{\eta}{e^{\sigma} - \eta} < 1$$

where the last inequality holds by the hypothesis on η. Finally,

$$|\Delta| = |\arcsin(\langle v, w^{\perp}\rangle)| = \arcsin(|\langle v, w^{\perp}\rangle|) \le \arcsin\left(\frac{\eta}{e^{\sigma} - \eta}\right). \qquad \square$$

The next result describes the angles along projected flowlines $P_L F_\epsilon(\cdot, x)$, $x \in B_1 \setminus U$, by continuous functions, a little longer than the projected values $P_U F_\epsilon(\nu, x)$, $\nu \in \mathbb{N}$, remain in $B_1 \setminus U$. For later use we restrict attention to flowlines which start from the strip on the cylinder

$$M_I = \{x \in \mathbb{R}^3 : |P_L x| = 1\}$$

which is given by $0 < x_3 \le 1$,

$$x = \begin{pmatrix} \cos(\psi) \\ \sin(\psi) \\ \delta \end{pmatrix} \quad \text{with } \psi \in \mathbb{R} \text{ and } 0 < \delta \le 1. \tag{3.1}$$

See Figure 3.1, top.

For integers $n \ge 0$ we define

$$\begin{aligned} \mathrm{dom}_n = \big\{(t, \psi, \delta) \in [0, n+1] \times \mathbb{R} \times (0, 1] : \\ |P_U F_\epsilon(\nu, x)| \le 1 \text{ for } x \text{ given by (3.1) and } \nu = 0, \dots, n\big\}. \end{aligned}$$

Proposition 3.2. *Assume* $0 < \eta < \frac{e^{\sigma}}{2}$, $0 < \epsilon < \min\{\epsilon(\eta), \epsilon_B\}$.

(i) For every integer $n \ge 0$ *there exists a continuous function* $\phi^{(n)} : \mathrm{dom}_n \to \mathbb{R}$ *so that for each* $(t, \psi, \delta) \in \mathrm{dom}_n$, *with* x *given by* (3.1), *we have*

$$\frac{1}{|P_L F_\epsilon(t, x)|} P_L F_\epsilon(t, x) = \begin{pmatrix} \cos(\phi^{(n)}(t, \psi, \delta)) \\ \sin(\phi^{(n)}(t, \psi, \delta)) \\ 0 \end{pmatrix}, \tag{3.2}$$

and in case $n \le t \le n+1$,

$$\psi - t\mu - (n+1)\arcsin\left(\frac{\eta}{e^{\sigma} - \eta}\right) \le \phi^{(n)}(t, \psi, \delta) \le \psi - t\mu + (n+1)\arcsin\left(\frac{\eta}{e^{\sigma} - \eta}\right). \tag{3.3}$$

(ii) For every $n \in \mathbb{N}$, $([0, n] \times \mathbb{R} \times (0, 1]) \cap \mathrm{dom}_n \subset \mathrm{dom}_{n-1}$, *and on this set,* $\phi^{(n)}(t, \psi, \delta) = \phi^{(n-1)}(t, \psi, \delta)$.

Proof. 1. Obviously, $([0, n] \times \mathbb{R} \times (0, 1]) \cap \mathrm{dom}_n \subset \mathrm{dom}_{n-1}$ for all integers $n \ge 1$.

2. Proof of assertion (i). We construct the functions $\phi^{(n)}$ recursively.

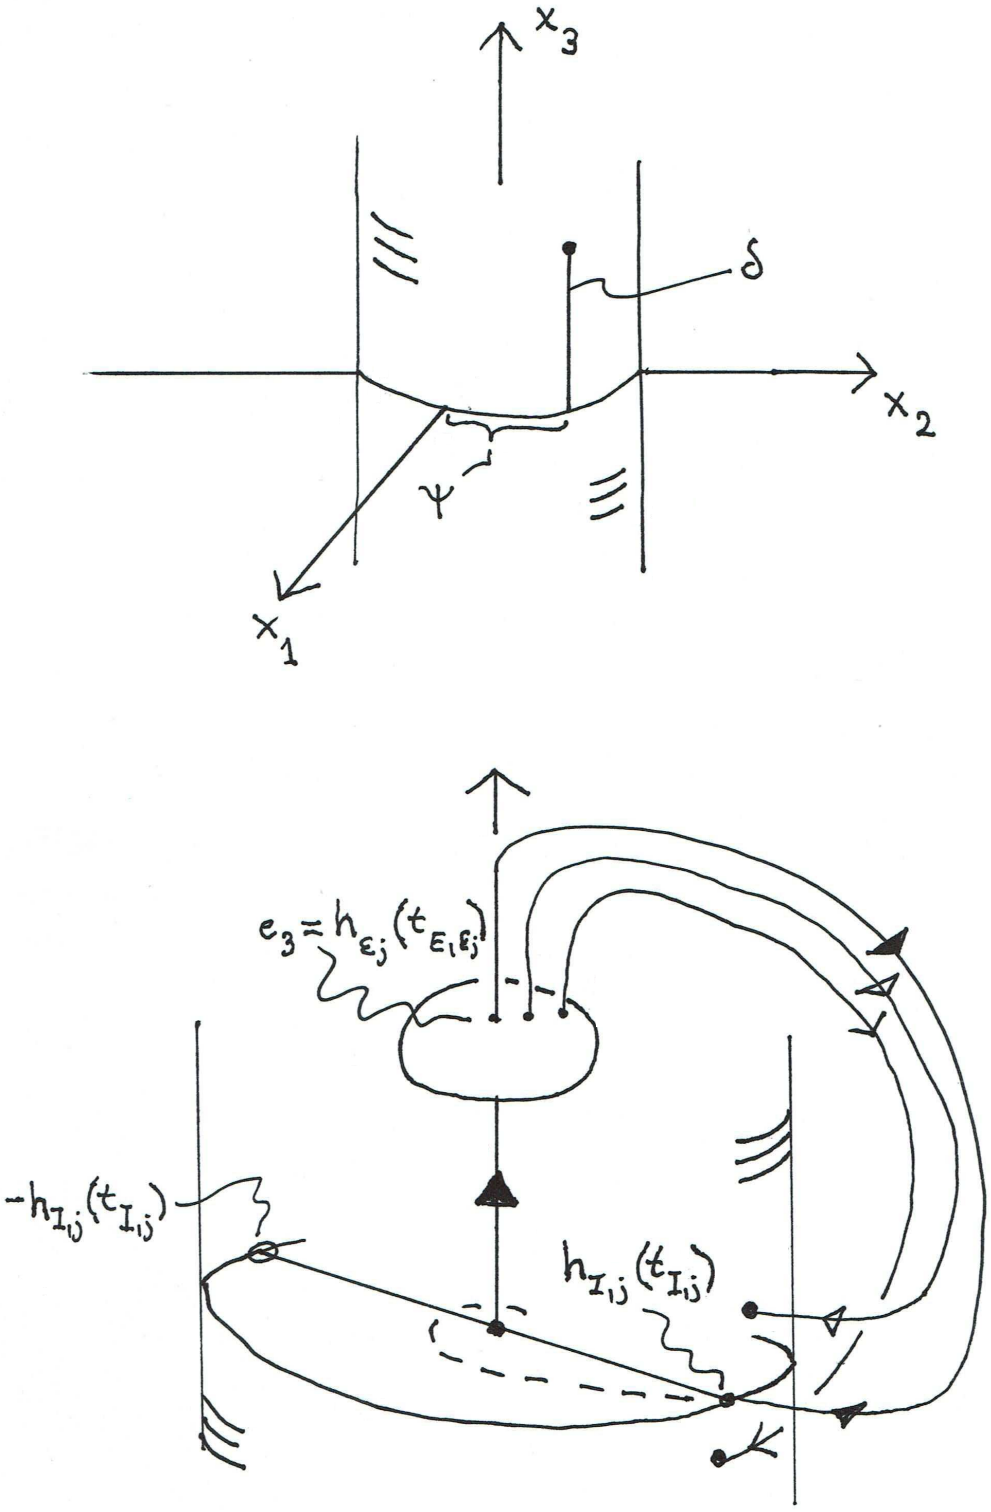

Figure 3.1: Top: The relations (3.1). Bottom: The exterior map.

2.1. For $n = 0$ Proposition 3.1 shows that the continuous function $\phi^{(0)} : \mathrm{dom}_0 \to \mathbb{R}$ defined by

$$\phi^{(0)}(t,\psi,\delta) = \psi - t\mu + \arcsin(\Delta) \quad \text{for } 0 \le t \le 1,$$

with $\Delta = \Delta(t,x,\psi)$ from Proposition 3.1, for x given by (3.1), satisfies (3.2) and (3.3).

2.2. Suppose now that for some integer $n \ge 0$ the continuous function $\phi^{(n)} : \mathrm{dom}_n \to \mathbb{R}$ satisfies (3.2) and (3.3). We define $\phi^{(n+1)} : \mathrm{dom}_{n+1} \to \mathbb{R}$ as follows.

For $(t,\psi,\delta) \in \mathrm{dom}_{n+1}$ with $0 \le t \le n+1$ we have $(t,\psi,\delta) \in \mathrm{dom}_n$ due to Part 1, and we set $\phi^{(n+1)}(t,\psi,\delta) = \phi^{(n)}(t,\psi,\delta)$.

For $(t,\psi,\delta) \in \mathrm{dom}_{n+1}$ with $n+1 \le t \le n+2$, observe first that for x given by (3.1) the property $|P_U F_\epsilon(\nu,x)| \le 1$ for $\nu = 0,\dots,n+1$ yields $F_\epsilon(\nu,x) \in B_1$ for $\nu = 1,\dots,n+1$, by means of Proposition 2.3. By Proposition 2.1 (ii), $F_\epsilon(s,x) \in B$ for $0 \le s \le n+2$. Using this in combination with $x \in B_1 \setminus U \subset B \setminus U$ we get $F_\epsilon(n+1,x) \in B \setminus U$, by invariance of U from Proposition 2.1 (ii). Altogether, $y = F_\epsilon(n+1,x)$ is contained in $B_1 \setminus U$, and

$$\frac{1}{|P_L y|} P_L y = \begin{pmatrix} \cos(\phi^{(n)}(n+1,\psi,\delta)) \\ \sin(\phi^{(n)}(n+1,\psi,\delta)) \\ 0 \end{pmatrix}.$$

An application of Proposition 3.1 to $y \in B_1 \setminus U$ shows that the continuous function

$$\phi^* : \mathrm{dom}_0 \to \mathbb{R}, \quad \phi^*(t,\psi,\delta) = \phi^{(n)}(n+1,\psi,\delta) - t\mu + \arcsin(\Delta) \quad \text{for } 0 \le t \le 1,$$

with $\Delta = \Delta(t,y,\phi^{(n)}(n+1,\psi,\delta))$ according to Proposition 3.1, satisfies (3.2) and (3.3) with y and $\phi^{(n)}(n+1,\psi,\delta)$ in place of x and ψ, respectively. Also,

$$\phi^{(n)}(n+1,\psi,\delta) - t\mu - \arcsin\left(\frac{\eta}{e^\sigma - \eta}\right) \le \phi^*(t,\psi,\delta) \le \phi^{(n)}(n+1,\psi,\delta) - t\mu + \arcsin\left(\frac{\eta}{e^\sigma - \eta}\right).$$

For $(t,\psi,\delta) \in \mathrm{dom}_{n+1}$ with $n+1 \le t \le n+2$ we have $(t-(n+1),\psi,\delta) \in \mathrm{dom}_0$. We complete the definition of $\phi^{(n+1)}$ by

$$\phi^{(n+1)}(t,\psi,\delta) = \phi^*(t-(n+1),\psi,\delta) \quad \text{for } (t,\psi,\delta) \in \mathrm{dom}_{n+1} \text{ with } n+1 < t \le n+2.$$

Proof that $\phi^{(n+1)}$ is continuous. Let $(t,\psi,\delta) \in \mathrm{dom}_{n+1}$ and a sequence $(t_m,\psi_m,\delta_m)_{m\in\mathbb{N}}$ in dom_{n+1} with $\lim_{m\to\infty}(t_m,\psi_m,\delta_m) = (t,\psi,\delta)$ be given. It is enough to show that for a subsequence we have $\phi^{(n+1)}(t_{m_\mu},\psi_{m_\mu},\delta_{m_\mu}) \to \phi^{(n+1)}(t,\psi,\delta)$ as $\mu \to \infty$. In case $t < n+1$, $(t,\psi,\delta) \in \mathrm{dom}_n$ and $\phi^{(n+1)}(t,\psi,\delta) = \phi^{(n)}(t,\psi,\delta)$, and for m sufficiently large, $t_m < n+1$, hence $(t_m,\psi_m,\delta_m) \in \mathrm{dom}_n$ and $\phi^{(n+1)}(t_m,\psi_m,\delta_m) = \phi^{(n)}(t_m,\psi_m,\delta_m)$ for such m, and continuity of $\phi^{(n)}$ yields $\phi^{(n+1)}(t_m,\psi_m,\delta_m) \to \phi^{(n+1)}(t,\psi,\delta)$ for $m \to \infty$. In case $n+1 < t \le n+2$ a similar argument with $\phi^*(\cdot-(n+1),\cdot,\cdot)$ in place of $\phi^{(n)}$ yields $\phi^{(n+1)}(t_m,\psi_m,\delta_m) \to \phi^{(n+1)}(t,\psi,\delta)$ for $m \to \infty$ as well. In case $t = n+1$ we distinguish the subcases that the set of indices m with $t_m \le n+1$ is bounded or unbounded. If it is unbounded then we can argue for a subsequence as in case $t < n+1$ above. If it is bounded we can argue as in case $n+1 < t \le n+2$ above and find

$$\begin{aligned} \lim_{m\to\infty} \phi^{(n+1)}(t_m,\psi_m,\delta_m) &= \lim_{m\to\infty} \phi^*(t_m-(n+1),\psi_m,\delta_m) = \phi^*(0,\psi,\delta) \\ &= \phi^{(n)}(n+1,\psi,\delta) = \phi^{(n+1)}(n+1,\psi,\delta). \end{aligned}$$

2.3. Proof of (3.2) for $\phi^{(n+1)}$. By the properties of $\phi^{(n)}$, for $(t,\psi,\delta) \in \mathrm{dom}_{n+1}$ with $0 \le t \le n+1$, obviously

$$\frac{1}{|P_L F_\epsilon(t,x)|} P_L F_\epsilon(t,x) = \begin{pmatrix} \cos(\phi^{(n)}(t,\psi,\delta)) \\ \sin(\phi^{(n)}(t,\psi,\delta)) \\ 0 \end{pmatrix} = \begin{pmatrix} \cos(\phi^{(n+1)}(t,\psi,\delta)) \\ \sin(\phi^{(n+1)}(t,\psi,\delta)) \\ 0 \end{pmatrix}.$$

For $(t,\psi,\delta) \in \mathrm{dom}_{n+1}$ with $n+1 < t \le n+2$ let $s = t-(n+1)$ and $y = F_\epsilon(n+1,x)$ with x given by (3.1). Using the version of (3.2) for ϕ^* we have

$$\begin{aligned} \frac{1}{|P_L F_\epsilon(t,x)|} P_L F_\epsilon(t,x) &= \frac{1}{|P_L F_\epsilon(s,y)|} P_L F_\epsilon(s,y) = \begin{pmatrix} \cos(\phi^*(s,\psi,\delta)) \\ \sin(\phi^*(s,\psi,\delta)) \\ 0 \end{pmatrix} \\ &= \begin{pmatrix} \cos(\phi^*(t-(n+1),\psi,\delta)) \\ \sin(\phi^*(t-(n+1),\psi,\delta)) \\ 0 \end{pmatrix} = \begin{pmatrix} \cos(\phi^{(n+1)}(t,\psi,\delta)) \\ \sin(\phi^{(n+1)}(t,\psi,\delta)) \\ 0 \end{pmatrix}. \end{aligned}$$

2.4. Proof of (3.3) for $\phi^{(n+1)}$. For $(n+1+t,\psi,\delta) \in \mathrm{dom}_{n+1}$ with $0 < t \le 1$ we have

$$\begin{aligned} \phi^{(n+1)}(n+1+t,\psi,\delta) &= \phi^*(t,\psi,\delta) \le \phi^{(n)}(n+1,\psi,\delta) - t\mu + \arcsin\left(\frac{\eta}{e^\sigma - \eta}\right) \\ &\le \left(\psi - (n+1)\mu + (n+1)\arcsin\left(\frac{\eta}{e^\sigma-\eta}\right)\right) - t\mu + \arcsin\left(\frac{\eta}{e^\sigma-\eta}\right) \\ &\quad \text{(by (3.3) for } \phi^{(n)}\text{)} \\ &= \psi - (n+1+t)\mu + (n+2)\arcsin\left(\frac{\eta}{e^\sigma-\eta}\right). \end{aligned}$$

Analogously we get the lower estimate

$$\psi - (n+1+t)\mu - (n+2)\arcsin\left(\frac{\eta}{e^\sigma-\eta}\right) \le \phi^{(n+1)}(n+1+t,\psi,\delta)$$

for $0 < t \le 1$. By continuity both estimates hold also at $t = n+1$.

2.5. The proof of assertion (i) is complete. Assertion (ii) is obvious from the previous construction which includes the relation

$$\phi^{(n)}(t,\psi,\delta) = \phi^{(n-1)}(t,\psi,\delta)$$

for $(t,\psi,\delta) \in ([0,n] \times \mathbb{R} \times (0,1]) \cap \mathrm{dom}_n \subset \mathrm{dom}_{n-1}$. □

We proceed to estimates of $\phi^{(n)}$ from Proposition 3.2 on the interval $[n,n+1]$ in terms of affine linear maps with slopes close to $\pm\mu$.

Corollary 3.3. *Let $\tilde\eta > 0$ and $\eta > 0$ be given with $\eta < \frac{e^\sigma}{2}$ and*

$$\arcsin\left(\frac{\eta}{e^\sigma-\eta}\right) < \tilde\eta.$$

Let $0 < \epsilon < \min\{\epsilon(\eta), \epsilon_B\}$ and let $n \in \mathbb{N}$ be given with

$$\frac{n+1}{n}\arcsin\left(\frac{\eta}{e^\sigma-\eta}\right) < \tilde\eta.$$

Then the function $\phi^{(n)}$ obtained in Proposition 3.2 satisfies

$$\psi-(n+t)(\mu+\tilde{\eta})\le\phi^{(n)}(n+t,\psi,\delta)\le\psi-(n+t)(\mu-\tilde{\eta})$$

for every $(n+t,\psi,\delta)\in\mathrm{dom}_n$ with $0\le t\le 1$.

Proof. 1. The estimate (3.3) in Proposition 3.2 shows that the upper estimate of the assertion follows from

$$-(n+t)\mu+(n+1)\arcsin\left(\frac{\eta}{e^\sigma-\eta}\right)\le-(n+t)(\mu-\tilde{\eta})$$

which is equivalent to

$$(n+1)\arcsin\left(\frac{\eta}{e^\sigma-\eta}\right)\le(n+t)\tilde{\eta}.$$

The preceding estimate follows from

$$(n+1)\arcsin\left(\frac{\eta}{e^\sigma-\eta}\right)\le n\tilde{\eta}$$

which is obvious from the hypotheses on η and n.

2. Analogously the estimate (3.3) shows that the lower estimate of the assertion follows from

$$-(n+t)\mu-(n+1)\arcsin\left(\frac{\eta}{e^\sigma-\eta}\right)\ge-(n+t)(\mu+\tilde{\eta})$$

which is equivalent to

$$-(n+1)\arcsin\left(\frac{\eta}{e^\sigma-\eta}\right)\ge-(n+t)\tilde{\eta}.$$

The preceding estimate follows from

$$-(n+1)\arcsin\left(\frac{\eta}{e^\sigma-\eta}\right)\ge-n\tilde{\eta}$$

which is obvious from the hypotheses on η and n. □

4 Transversality, and exterior maps

For every $\epsilon>0$ the flowline $h_\epsilon=\frac{1}{\epsilon}h$ of F_ϵ is homoclinic with $h_\epsilon(t)\ne 0\ne h_\epsilon'(t)$ everywhere and $h_\epsilon(t)\to 0$ as $|t|\to\infty$.

Proposition 4.1.

(i) For $0<\epsilon<|h(t_U)|$ there are reals $t_{E,\epsilon}\le t_U$ with

$$h_\epsilon(t_{E,\epsilon})=e_3\quad\text{and}\quad h_\epsilon(t)\in(0,\infty)e_3\quad\text{for all } t\le t_{E,\epsilon}.$$

(ii) There are strictly montonic sequences $(t_{I,j})_{j\in\mathbb{N}}$ in $[t_L,\infty)$ and $(\epsilon_j)_{j\in\mathbb{N}}$ in $(0,\infty)$ with $t_{I,j}\to\infty$ and $\epsilon_j\to 0$ as $j\to\infty$ such that for every $j\in\mathbb{N}$,

$$\epsilon_j<|h(t_U)|,\quad|h_{\epsilon_j}(t_{I,j})|=1,\quad(|h_{\epsilon_j}|^2)'(t_{I,j})<0,\quad h_{\epsilon_j}(t)\in L\quad\text{for } t\ge t_{I,j},\ h'_{\epsilon_j}(t_{I,j})\in L.$$

Proof. 1. On (i). Recall that for all $t \le t_U$, $h(t) \in (0,\infty)e_3$. Let $0 < \epsilon < |h(t_U)|$. The relation $\lim_{t\to-\infty} h(t) = 0$ shows that for each $\epsilon \in (0, |h(t_U)|)$ there exists $t_{E,\epsilon} \le t_U$ with $|h(t_{E,\epsilon})| = \epsilon$. It follows that $h(t_{E,\epsilon}) = \epsilon e_3$, hence $h_\epsilon(t_{E,\epsilon}) = e_3$. For $0 < \epsilon < |h(t_U)|$ and for all $t \le t_{E,\epsilon} \le t_U$ we get $h_\epsilon(t) = \frac{1}{\epsilon}h(t) \in \frac{1}{\epsilon}(0,\infty)e_3 = (0,\infty)\epsilon$.

2. On (ii). From $h(t) \neq 0$ everywhere and $h(t) \to 0$ as $t \to \infty$ we get a strictly increasing sequence $(t_{I,j})_{j\in\mathbb{N}}$ in $[t_L, \infty)$ with $t_{I,j} \to \infty$ for $j \to \infty$ so that $|h(t_{I,j})| < |h(t_U)|$ and $(|h|^2)'(t_{I,j}) < 0$ for all $j \in \mathbb{N}$, and the sequence given by $\epsilon_j = |h(t_{I,j})|$ is strictly decreasing. It follows that

$$|h_{\epsilon_j}(t_{I,j})| = \frac{1}{\epsilon_j}|h(t_{I,j})| = 1 \quad \text{and} \quad (|h_{\epsilon_j}|^2)'(t_{I,j}) = \frac{1}{\epsilon_j^2}|(|h|^2)'(t_{I,j}) < 0 \quad \text{for all } j \in \mathbb{N}.$$

Also, for $t \ge t_{I,j} \ge t_L$, $h_{\epsilon_j}(t) = \frac{1}{\epsilon_j}h(t) \in \frac{1}{\epsilon_j}L = L$, which yields $h'_{\epsilon_j}(t_{I,j}) \in L$. □

We want to describe the behaviour of flowlines close to the homoclinic loop $h_\epsilon(\mathbb{R}) \cup \{0\}$ for small $\epsilon > 0$. This will be done in terms of a return map which is given by the return of flowlines $F_\epsilon(\cdot, x)$ from points x in the cylinder

$$M_I = \{z \in \mathbb{R}^3 : |P_L z| = 1\}$$

with $0 < x_3$ slightly above the plane L, to targets in M_I. The return map will be obtained as a composition of an *inner map*, which follows the flow until it reaches the plane

$$M_E = e_3 + L,$$

parallel to L , with an *exterior map* following the flow from a neighbourhood of e_3 in M_E until it reaches M_I.

The constructions and continuous differentiability of the inner and exterior maps requires that the homoclinic flowline intersects the smooth 2-dimensional submanifolds M_E and M_I of $\mathbb{R}^3$ transversally. Obviously, $T_x M_E = L$ for all $x \in M_E$, and at $x \in M_I \cap L$,

$$T_x M_I = \mathbb{R}x^\perp \oplus \mathbb{R}e_3, \quad \text{with } x^\perp = \begin{pmatrix} -x_2 \\ x_1 \\ 0 \end{pmatrix}.$$

Proposition 4.2.

(i) For $0 < \epsilon < |h(t_U)|$, $\partial_1 F_\epsilon(0, e_3) = D_1 F_\epsilon(0, e_3)1 = h'_\epsilon(t_{E,\epsilon}) \notin L = T_{e_3} M_E$.

(ii) Let $j \in \mathbb{N}$ be given and $x = h_{\epsilon_j}(t_{I,j})$. Then

$$\partial_1 F_{\epsilon_j}(0,x) = h'_{\epsilon_j}(t_{I,j}) = \partial_1 F_{\epsilon_j}(t_{I,j} - t_{E,\epsilon_j}, e_3), \quad \langle \partial_1 F_{\epsilon_j}(0,x), x\rangle < 0, \quad \text{and} \quad \partial_1 F_{\epsilon_j}(0,x) \notin T_x M_I.$$

Proof. 1. On (i). From

$$F_\epsilon(t, e_3) - F_\epsilon(0, e_3) = F_\epsilon(t, h_\epsilon(t_{E,\epsilon})) - e_3 = h_\epsilon(t + t_{E,\epsilon}) - h_\epsilon(E, t_\epsilon)$$

we have $\partial_1 F_\epsilon(0, e_3) = h'_\epsilon(t_{E,\epsilon}) \neq 0$. Using $h_\epsilon(t) \in U$ for $t \le t_{E,\epsilon}$ we get $h'_\epsilon(t_{E,\epsilon}) \in U$. It follows that $\partial_1 F_\epsilon(0, e_3) \in U \setminus \{0\} \subset \mathbb{R}^3 \setminus L$.

2. On (ii). Let $j \in \mathbb{N}$ be given. Let $x = h_{\epsilon_j}(t_{I,j}) \in M_I \cap L$. Arguing as in Part 1 we get $\partial_1 F_{\epsilon_j}(0,x) = h'_{\epsilon_j}(t_{I,j}) = \partial_1 F_{\epsilon_j}(t_{I,j} - t_{E,\epsilon_j}, e_3)$. From Proposition 4.1 (ii),

$$0 > (|h_{\epsilon_j}|^2)'(t_{I,j}) = 2\langle h'_{\epsilon_j}(t_{I,j}), h_{\epsilon_j}(t_{I,j})\rangle = 2\langle \partial_1 F_{\epsilon_j}(0,x), x\rangle$$

and $h'_{\epsilon_j}(t_{I,j}) \in L$. From the preceding relations, $\partial_1 F_{\epsilon_j}(0,x) \notin \mathbb{R}x^\perp \oplus \mathbb{R}e_3 = T_x M_I$. □

For $r > 0$ let

$$M_E(r) = \{y \in M_E : |y - e_3| < r\}.$$

Corollary 4.3. *There is a decreasing sequence $(r_j)_{j\in\mathbb{N}}$ with $r_j \to 0$ as $j \to \infty$ so that for every $j \in \mathbb{N}$ there exists a continuously differentiable map*

$$t_j : M_E(r_j) \to (0, \infty)$$

with $t_j(e_3) = t_{I,j} - t_{E,\epsilon_j}$, $F_{\epsilon_j}(t_j(y), y) \in \{z \in M_I : P_L z \neq -h_{\epsilon_j}(t_{I,j})\}$ for all $y \in M_E(r_j)$, and

$$\partial_1 F_{\epsilon_j}(0, y) \notin L \quad \text{for all } y \in M_E(r_j).$$

Proof. Let $j \in \mathbb{N}$ be given. With the function $G : \mathbb{R}^3 \to \mathbb{R}$, $G(z) = z_1^2 + z_2^2 - 1$, the relation $F_{\epsilon_j}(t, y) \in M_I$ is equivalent to the equation $G(F_{\epsilon_j}(t, y)) = 0$. Using Proposition 4.2 (ii) with $x = F_{\epsilon_j}(t_{I,j} - t_{E,\epsilon_j}, e_3)$ we obtain

$$\partial_1(G \circ F_{\epsilon_j}(t_{I,j} - t_{E,\epsilon_j}, e_3) = 2\langle \partial_1 F_{\epsilon_j}(t_{I,j} - t_{E,\epsilon_j}, e_3), F_{\epsilon_j}(t_{I,j} - t_{E,\epsilon_j}, e_3)\rangle = 2\langle \partial_1 F_{\epsilon_j}(0, x), x)\rangle < 0.$$

Therefore the Implicit Function Theorem applies and yields a continuously differentiable positive function t_j^* on a neighbourhood N_j of e_3 in $\mathbb{R}^3$ which satisfies $t_j^*(e_3) = t_{I,j} - t_{E,\epsilon_j}$ and $F_{\epsilon_j}(t_j^*(y), y) \in M_I$ for all $y \in N_j$. Given any real $r > 0$ it follows from Proposition 4.2 (i) and continuity that there exists $r_j \in (0, r)$ with $M_E(r_j) \subset N_j$ and $\partial_1 F_{\epsilon_j}(0, y) \notin L$ for all $y \in M_E(r_j)$. Using $F_{\epsilon_j}(t_j^*(e_3), e_3) = h_{\epsilon_j}(t_{I,j}) \in L$ and continuity we also achieve $P_L F_{\epsilon_j}(t_j^*(y), y) \neq -h_{\epsilon_j}(t_{I,j}))$ for all $y \in M_E(r_j)$. Let t_j be the restriction of t_j^* to $M_E(r_j)$.

The desired decreasing sequence $(r_j)_{j\in\mathbb{N}}$ can be obtained recursively. □

For every $j \in \mathbb{N}$ the *exterior map*

$$E_j : M_E(r_j) \to \{z \in M_I : P_L z \neq -h_{\epsilon_j}(t_{I,j})\}, \quad E_j(y) = F_{\epsilon_j}(t_j(y), y),$$

into the open subset $\{z \in M_I : P_L z \neq -h_{\epsilon_j}(t_{I,j})\} = \{z \in M_I : P_L z \neq -E_j(e_3))\}$ of the manifold M_I is continuously differentiable. Compare Figure 3.1, bottom.

Corollary 4.4. *Let $j \in \mathbb{N}$ be given and $x = E_j(e_3)$. Then $T_{e_3}E_j(T_{e_3}M_E) = T_x M_I$.*

Proof. Let $v = \partial_1 F_{\epsilon_j}(0, e_3)$ and $w = h'_{\epsilon_j}(t_{I,j}) = \partial_1 F_{\epsilon_j}(t_j(e_3), e_3) = \partial F_{\epsilon_j}(0, x)$. Then $v \notin L = T_{e_3}M_E$ and $w \notin T_x M_I$. The map $T_{e_3}E_j : T_{e_3}M_E \to T_x M_I$ is given by

$$T_{e_3}E_j(z) = P_j D_2 F_{\epsilon_j}(t_j(e_3), e_3)z$$

with the projection $P_j : \mathbb{R}^3 \to \mathbb{R}^3$ along $\mathbb{R}w$ onto $T_x M_I$. The isomorphism $D_2 F_{\epsilon_j}(t_j(e_3), e_3)$ sends v to w and maps $T_{e_3}M_E$ onto a 2-dimensional space Q which is complementary to $\mathbb{R}w$. The projection P_j maps the complementary space Q onto the complementary space $T_x M_I$. □

5 Inner maps

We begin with the travel time from the strip $\{x \in M_I : 0 < x_3 < 1\}$ to the plane M_E.

Proposition 5.1. *Assume $0 < \eta < e^\sigma$, $e^\sigma + \eta < 1$, and $0 < \epsilon < \min\{\epsilon(\eta), \epsilon_B\}$. Let $x \in M_I$ with $0 < x_3 < 1$ be given. Then there exists $t = \tau_\epsilon(x) > 0$ with $0 < F_{\epsilon,3}(s, x) < 1$ for $0 \le s < t$ and $F_{\epsilon,3}(t, x) = 1$.*

Proof. 1. We show $|F_{\epsilon,3}(s,x)| > 1$ for some $s > 0$. Suppose this is false. Then Proposition 2.3 yields $F_\epsilon(n,x) \in B_1$ for all integers $n \geq 0$. Using an estimate from Proposition 2.3 and $1-\eta > e^\sigma$ we get

$$|F_{\epsilon,3}(n,x)| = |P_U F_\epsilon(n,x)| \geq e^{un}(1-\eta)^{n+1}|P_U x| \geq e^{(u+\sigma)n}e^\sigma|x_3| > 0$$

for all integers $n \geq 0$, and the hypothesis $u+\sigma > 0$ yields a contradiction to the assumption that $|F_{\epsilon,3}(s,x)|$, $s \geq 0$, is bounded.

2. It follows that

$$0 < \inf\{s \geq 0 : |F_{\epsilon,3}(s,x)| \geq 1\} < \infty.$$

Set $t = \tau_\epsilon(x) = \inf\{s \geq 0 : |F_{\epsilon,3}(s,x)| \geq 1\}$. Then $|F_{\epsilon,3}(s,x)| < 1$ for $0 \leq s < t$, and by continuity, $|F_{\epsilon,3}(t,x)| = 1$. Let $n = n_\epsilon(x)$ denote the largest integer in $[0,t]$. Proposition 2.3 yields $F_\epsilon(j,x) \in B_1$ for $j = 0,\ldots,n$. By $0 < x_3$, $x \in B_1 \setminus L$. Using Proposition 2.1 (ii) we infer $F_\epsilon(s,x) \in B \setminus L$ on $[0,t]$, hence $|F_{\epsilon,3}(s,x)| > 0$ on $[0,t]$. Finally, $0 < x_3$ and continuity combined yield $0 < F_{\epsilon,3}(s,x)$ on $[0,t]$. □

In order to use the travel time $\tau_\epsilon(x)$ of Proposition 5.1 for an *inner map* with values $F_\epsilon(\tau_\epsilon(x),x)$ in the domain $M_E(r_j)$ of an exterior map E_j we observe that due to hyperbolic behavior of flowlines close to the stationary point 0 the relation $F_\epsilon(\tau_\epsilon(x),x) \in M_E(r_j)$ should hold for $x \in M_I$ with $0 < x_3$ sufficiently small. Recall ϵ_j from Proposition 4.1 and r_j from Corollary 4.3.

Proposition 5.2. *Assume $0 < \eta < e^\sigma$ and $1 + \eta e^{-\sigma} < e^{-\sigma/2}$. Consider an integer j so large that*

$$\epsilon_j < \min\{\epsilon(\eta), \epsilon_B\}.$$

For every $x \in M_I$ with $0 < x_3 < 1$ the largest integer $n = n_j(x)$ in $[0, \tau_{\epsilon_j}(x))$ satisfies

$$n > \frac{1}{u+\log(2)} \log\left(\frac{1}{x_3}\right) - 1. \tag{5.1}$$

For $\delta_j^* \in (0,1)$ so small that

$$\left(1 + \frac{2}{\sigma}\log(r_j)\right) < \frac{1}{u+\log(2)} \log\left(\frac{1}{\delta_j^*}\right) - 1. \tag{5.2}$$

we have

$$|F_{\epsilon_j}(\tau_{\epsilon_j}(x),x) - e_3| = |P_L F_{\epsilon_j}(\tau_{\epsilon_j}(x),x)| < r_j \quad \text{for all } x \in M_I \text{ with } 0 < x_3 < \delta_j^*.$$

Proof. 1. On (5.1). Notice that we have $e^\sigma + \eta < 1$, so that the hypothesis concerning $\eta > 0$ in Proposition 5.1 is satisfied. Let $x \in M_I$ with $0 < x_3 < 1$ be given and let $t = \tau_{\epsilon_j}(x)$. We derive an estimate of the largest integer $n = n_j(x)$ in $[0,t)$. Proposition 5.1 in combination with Proposition 2.3, both for $\epsilon = \epsilon_j$, yield

$$\begin{aligned} 1 = |P_U F_{\epsilon_j}(t,x)| &\leq e^{ut}(1+\eta)^{n+1}|P_U x| = e^{ut}(1+\eta)^{n+1}x_3 \\ &< (2e^u)^{n+1}x_3 \quad (\text{with } t \leq n+1 \text{ and } \eta < 1), \end{aligned}$$

hence

$$n > \frac{1}{u+\log(2)} \log\left(\frac{1}{x_3}\right) - 1.$$

2. Now consider $\delta_j^* \in (0,1)$ which satisfies the inequality (5.1), and let $x \in M_I$ with $0 < x_3 < \delta_j^*$ be given. Using $|P_L x| = 1$ from $x \in M_I$ and an upper estimate from Proposition 2.3 we have, with $n = n_j(x)$,

$$|P_L F_{\epsilon_j}(t,x)| \le e^{\sigma t}(1+\eta e^{-\sigma})^{n+1}|P_L x| \le e^{\sigma\cdot n} e^{(-\sigma/2)(n+1)} = e^{(\sigma/2)(n-1)}.$$

Thereby the desired inequality $|P_L F_{\epsilon_j}(t,x)| < r_j$ follows from $e^{(\sigma/2)(n-1)} < r_j$ which is equivalent to

$$n > 1 + \frac{2}{\sigma}\log(r_j).$$

The preceding equation follows from the lower estimate (5.1) of $n = n_j(x)$ in Part 1 in combination with $x_3 < \delta_j^*$ and with the smallness assumption (5.2) on δ_j^*. □

Next we use transversality of the flow at points of $M_E(r_j)$ as prepared in Corollary 4.3 in order to obtain smoothness of the travel time.

Corollary 5.3. *Let η, j, and δ_j^* satisfy the hypotheses of Proposition 5.2. Then the map*

$$\tau_j^* : \{x \in M_I : 0 < x_3 < \delta_j^*\} \to (0,\infty), \quad \tau_j^*(x) = \tau_{\epsilon_j}(x),$$

is continuously differentiable.

Proof. 1. Continuity. Let $x \in M_I$ with $0 < x_3 < \delta_j^*$ be given, and let $t = \tau_j^*(x) = \tau_{\epsilon_j}(x)$. Let $y = F_{\epsilon_j}(t,x)$ and observe that because of $F_{\epsilon_j,3}(s,x) < 1 = F_{\epsilon_j,3}(t,x)$ for $0 \le s < t$ we have $\partial_1 F_{\epsilon_j,3}(0,y) = \partial_1 F_{\epsilon_j,3}(t,x) \ge 0$. Recall $y \in M_E(r_j)$ from Proposition 5.2. The relation $\partial_1 F_{\epsilon_j}(0,y) \notin L$ from Corollary 4.3 yields $\partial_1 F_{\epsilon_j,3}(0,y) \ne 0$. We conclude that $\partial_1 F_{\epsilon_j,3}(t,x) = \partial_1 F_{\epsilon_j,3}(0,y) > 0$. Now let $\rho \in (0,t)$ be given. Then for some $s \in (t, t+\rho)$, $F_{\epsilon_j,3}(s,x) > 1$. By continuity there is a neighbourhood N_1 of x in $\mathbb{R}^3$ with $F_{\epsilon_j,3}(s,z) > 1$ for all $z \in N_1$. By continuity and compactness we also find a neighbourhood $N \subset N_1$ of x in $\mathbb{R}^3$ so that for all $z \in N$ and for all $s \in [0, t-\rho]$ we have $0 < F_{\epsilon_j,3}(s,z) < 1$. It follows that for all $z \in N \cap \{\xi \in M_I : 0 < \xi_3 < \delta_j^*\}$ we have $t - \rho < \tau_{\epsilon_j}(z) < s < t + \rho$, which yields continuity of the map τ_j^* at x.

2. We show that locally the map τ_j^* is given by continuously differentiable maps. Let $x \in M_I$ with $0 < x_3 < \delta_j^*$ be given and let $t = \tau_j^*(x)$. Then $F_{\epsilon_j,3}(t,x) = 1$, and $\partial_1 F_{\epsilon_j,3}(t,x) > 0$, see Part 1. The Implicit Function Theorem yields an open neighbourhood N of x in $\mathbb{R}^3$ and $\rho > 0$ and a continuously differentiable map $\tau : N \to (t-\rho, t+\rho)$ with $F_{\epsilon_j,3}(\tau(z),z) = 1$ for all $z \in N$, and on $(t-\rho, t+\rho) \times N$,

$$F_{\epsilon_j,3}(s,z) = 1 \quad \text{if and only if} \quad s = \tau(z).$$

By continuity according to Part 1, there is an open neighbourhood $N_1 \subset N$ of x in $\mathbb{R}^3$ so that for all $z \in N_1 \cap \{\xi \in M_I : 0 < \xi_3 < \delta_j^*\}$ we have $t - \rho < \tau_j^*(z) < t + \rho$. Recall $F_{\epsilon_j,3}(\tau_j^*(z),z) = F_{\epsilon_j,3}(\tau_{\epsilon_j}(z),z) = 1$ for all $z \in M_I$ with $0 < z_3 < \delta_j^*$. It follows that on $N_1 \cap \{\xi \in M_I : 0 < \xi_3 < \delta_j^*\}$ we have $\tau_j^*(z) = \tau(z)$. The restriction of τ to $N_1 \cap \{\xi \in M_I : 0 < \xi_3 < \delta_j^*\}$ is a continuously differentiable function on the open subset $N_1 \cap \{\xi \in M_I : 0 < \xi_3 < \delta_j^*\}$ of the submanifold M_I. □

In the sequel we arrange for an inner map on a subset of $\{x \in M_I : 0 < x_3 < \delta_j^*\}$ which can be estimated in the same way as its counterpart in [8]. Upon that we will be able to follow [8] in proving existence of chaotic motion.

For $0 < \eta < \frac{e^\sigma}{2}$ we abbreviate

$$m(\eta,\sigma) = \max\left\{\log(1+\eta e^{-\sigma}), \log\left(\frac{1}{1-\eta e^{-\sigma}}\right), \arcsin\left(\frac{\eta}{e^\sigma - \eta}\right)\right\}$$

and consider the following hypotheses.

For $\tilde\eta > 0$ given,

$$0 < \eta < \frac{e^\sigma}{2} \quad \text{and} \quad 1 + \eta e^{-\sigma} < e^{-\sigma/2} \tag{5.3}$$

(observe that this yields $\eta < e^\sigma$ and $e^\sigma + \eta < e^{\sigma/2} < 1$)
and

$$m(\eta,\sigma) < \tilde\eta. \tag{5.4}$$

$j \in \mathbb{N}$ is so large that

$$\epsilon_j < \min\{\epsilon(\eta), \epsilon_B\}. \tag{5.5}$$

$\delta_j^* \in (0,1)$ satisfies (5.2) and $\delta_j \in (0, \delta_j^*)$ is so small that

$$\frac{1}{u+\log(2)} \log\left(\frac{1}{\delta_j}\right) - 1 > \frac{m(\eta,\sigma)}{\tilde\eta - m(\eta,\sigma)}. \tag{5.6}$$

Proposition 5.4. *Let $\tilde\eta > 0$ be given. Assume that the relations (5.3)–(5.6) hold for $\eta > 0$, $j \in \mathbb{N}$, and δ_j. For every $x \in M_I$ with $0 < x_3 < \delta_j$ the largest integer $n = n_j(x)$ in $[0, \tau_j^*(x))$ satisfies*

$$\frac{n+1}{n} m(\eta,\sigma) < \tilde\eta.$$

Proof. Using the relations (5.1) and (5.6) we get

$$n > \frac{1}{u+\log(2)} \log\left(\frac{1}{x_3}\right) - 1 > \frac{1}{u+\log(2)} \log\left(\frac{1}{\delta_j}\right) - 1 > \frac{m(\eta,\sigma)}{\tilde\eta - m(\eta,\sigma)}$$

which yields $\frac{n+1}{n} m(\eta,\sigma) < \tilde\eta$. □

We are ready for the definition of the inner map I_j, given $\tilde\eta > 0$ and $\eta > 0$, $j \in \mathbb{N}$, and δ_j which satisfy the relations (5.3)–(5.6). As a domain for I_j we take

$$M_{I,j} = \{x \in M_I : 0 < x_3 < \delta_j \quad \text{and} \quad P_L x \neq -E_j(e_3)\}.$$

Here the line given by $P_L x = -E_j(e_3) = -h_{\epsilon_j}(t_{I,j})$ is excluded for later use, in order to have a global parametrization of $M_{I,j}$ available. With $\tau_j(x) = \tau_j^*(x)$ on $M_{I,j}$ we set

$$I_j(x) = F_{\epsilon_j}(\tau_j(x), x)$$

and obtain a continuously differentiable map $I_j : M_{I,j} \to M_E$, with values in $M_E(r_j)$ according to Proposition 5.1. Compare Figure 5.1, top.

Corollary 5.5. *Let $\tilde\eta > 0$ and assume that $\eta > 0$, $j \in \mathbb{N}$, and δ_j satisfy the relations (5.3)–(5.6). Let $x \in M_{I,j}$. Then we have*

$$e^{(\sigma-\tilde\eta)\tau_j(x)} \le |P_L I_j(x)| \le e^{(\sigma+\tilde\eta)\tau_j(x)},$$
$$e^{(u-\tilde\eta)\tau_j(x)} x_3 \le 1 \le e^{(u+\tilde\eta)\tau_j(x)} x_3.$$

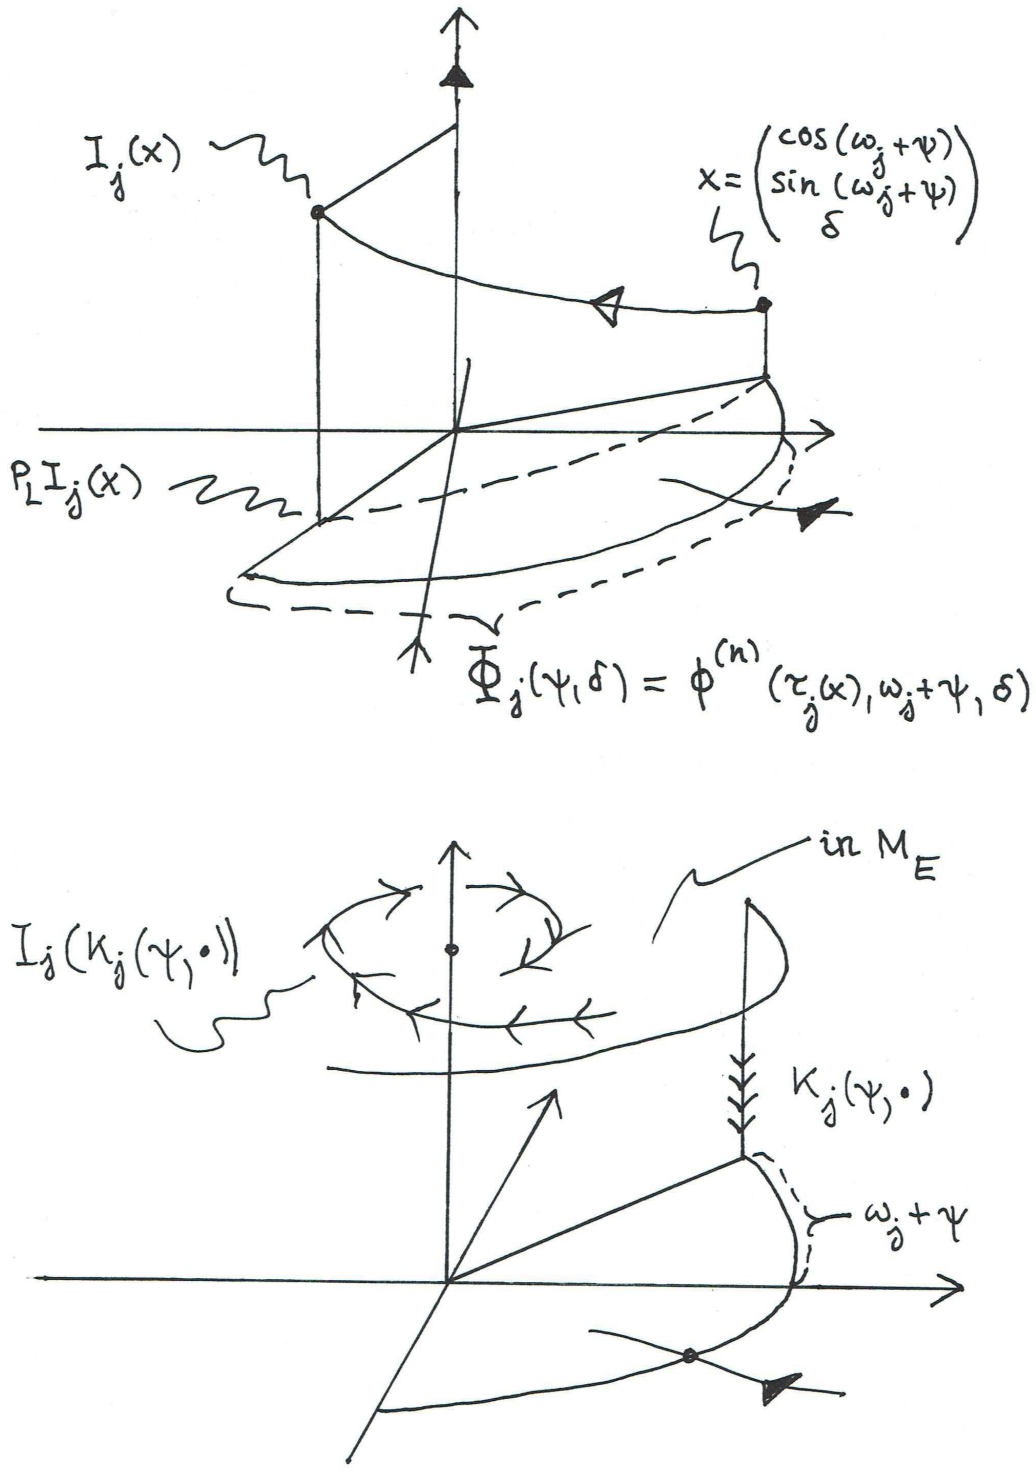

Figure 5.1: Top: The inner map and related angles. Bottom: The inner map along vertical line segments.

For $\psi \in \mathbb{R}$ with

$$x = \begin{pmatrix} \cos(\psi) \\ \sin(\psi) \\ x_3 \end{pmatrix}$$

and $\delta = x_3$ the function $\phi^{(n)}$ obtained in Proposition 3.2, with $n = n_j(x)$, satisfies

$$\psi - \tau_j(x)(\mu + \tilde{\eta}) \le \phi^{(n)}(\tau_j(x), \psi, \delta) \le \psi - \tau_j(x)(\mu - \tilde{\eta}).$$

Proof. Proposition 5.4 shows that the hypotheses on the integer n in Proposition 2.4 and Corollary 3.3 are satisfied for $n = n_j(x)$. Apply Proposition 2.4 to $t = \tau_j(x) - n_j(x) \in [0,1]$, with $|P_L x| = 1$ and $|P_U x| = x_3$ and $P_U I_j(x) = e_3$. This yields the estimates of $P_L I_j(x)$ and $P_U I_j(x)$.

From $|P_L x| = 1$, $x \in B_1 \setminus U$. An application of Corollary 3.3 to $t = \tau_j(x) - n_j(x) \in [0,1]$ yields the estimate of the angle function $\phi^{(n)}$ with $n = n_j(x)$. □

Corollary 5.6. *Let $\tilde{\eta} > 0$ be given with $\tilde{\eta} < u$ and assume that $\eta > 0$, $j \in \mathbb{N}$, and δ_j satisfy the relations (5.3)–(5.6). For every $x \in M_{I,j}$,*

$$\frac{1}{u + \tilde{\eta}} \log\left(\frac{1}{x_3}\right) \le \tau_j(x) \le \frac{1}{u - \tilde{\eta}} \log\left(\frac{1}{x_3}\right).$$

6 The return map in the plane

We begin with parametrizations of the open subsets $\{x \in M_I : P_L x \neq -E_j(e_3)\}$ of the submanifold M_I. Let $j \in \mathbb{N}$ be given. Consider $\omega_j \in [-\pi, \pi)$ determined by

$$\begin{pmatrix} \cos(\omega_j) \\ \sin(\omega_j) \\ 0 \end{pmatrix} = E_j(e_3) \quad (= h_{\epsilon_j}(t_{I,j})).$$

The map

$$K_j : (-\pi, \pi) \times \mathbb{R} \to \{x \in M_I : P_L x \neq -E_j(e_3)\}, \quad K_j(\psi, \delta) = \begin{pmatrix} \cos(\omega_j + \psi) \\ \sin(\omega_j + \psi) \\ \delta \end{pmatrix},$$

is a continuously differentiable diffeomorphism with $K_j(0,0) = E_j(e_3)$. The return map $R_j = E_j \circ I_j$ sends its domain $M_{I,j} = \{x \in M_I : 0 < x_3 < \delta_j, P_L x \neq -E_j(e_3)\}$ into the set $\{z \in M_I : P_L z \neq -E_j(e_3)\}$ which equals the image $K_j((-\pi, \pi) \times \mathbb{R})$. By the *return map in the plane* we mean the continuously differentiable map

$$Q_j : (-\pi, \pi) \times (0, \delta_j) \to (-\pi, \pi) \times \mathbb{R}$$

given by $Q_j(\psi, \delta) = K_j^{-1}(R_j(K_j(\psi, \delta)))$.

We also need information about a coordinate representation of the exterior map E_j alone. Corollary 4.4 yields that the derivative $T_{e_3}(K_j^{-1} \circ E_j)$ is an isomorphism from $L = T_{e_3} M_E$ onto the plane $\mathbb{R}^2$. So it sends basis vectors v_j and w_j of L to the vectors $\binom{1}{0}$ and $\binom{0}{1}$, respectively.

Let κ_j denote the isomorphism $L \to \mathbb{R}^2$ given by

$$\kappa_j(\xi v_j + \eta w_j) = \begin{pmatrix} \xi \\ \eta \end{pmatrix}.$$

The restriction P_j of $\kappa_j \circ P_L$ to the open subset $M_E(r_j)$ of the submanifold M_E defines a continuously differentiable diffeomorphism onto an open neighbourhood of $0 = P_j(e_3)$ in $\mathbb{R}^2$. Obviously,

$$P_j(e_3 + \xi v_j + \eta w_j) = \begin{pmatrix} \xi \\ \eta \end{pmatrix} \quad \text{for all reals } \xi, \eta.$$

As $T_{e_3}P_j$ and $T_{e_3}(K_j^{-1} \circ E_j)$ act the same on the basis v_j, w_j of $T_{e_3}M_E = L$ the *exterior map in coordinates*

$$K_j^{-1} \circ E_j \circ P_j^{-1} : \mathbb{R}^2 \supset P_j(M_E(r_j)) \to \mathbb{R}^2$$

satisfies

$$D(K_j^{-1} \circ E_j \circ P_j^{-1})(0) = \mathrm{id}_{\mathbb{R}^2}. \tag{6.1}$$

Corollary 6.1. *Let $j \in \mathbb{N}$ and $\beta > 0$ be given. There exists $\alpha_j = \alpha_j(\beta) \in (0, \pi)$ so that for all $(\psi, \delta) \in [-\alpha_j, \alpha_j] \times [-\alpha_j, \alpha_j]$ we have $(\psi, \delta) \in P_j(M_E(r_j))$, and*

$$|(K_j^{-1} \circ E_j \circ P_j^{-1})(\psi, \delta) - (\psi, \delta)| \le \beta |(\psi, \delta)|, \tag{6.2}$$

$$|D(K_j^{-1} \circ E_j \circ P_j^{-1})(\psi, \delta) - id_{\mathbb{R}^2}| \le \beta. \tag{6.3}$$

We proceed to estimates of the range of the *inner map in coordinates*

$$(-\pi, \pi) \times (0, \delta_j) \ni (\psi, \delta) \mapsto P_j(I_j(K_j(\psi, \delta))) \in \mathbb{R}^2$$

and of the return map in the plane Q_j.

Proposition 6.2. *Assume $0 < \tilde{\eta} < -\sigma/2$ and consider $\eta > 0, j \in \mathbb{N}, \delta_j$ so that the relations (5.3)–(5.6) hold. Let $\beta \in (0, \frac{1}{2}]$ be given. Consider $\alpha_j = \alpha_j(\beta) > 0$ according to Corollary 6.1, with $\alpha_j < \delta_j$. Then*

$$\delta_{\beta,j} = \left(\frac{2}{3(|\kappa_j| + 1)} \alpha_j \right)^{\frac{3u}{-\sigma}}$$

satisfies $\delta_{\beta,j} \le \frac{2}{3}\alpha_j$, and for all $(\psi, \delta) \in [-\alpha_j, \alpha_j] \times (0, \delta_{\beta,j}]$ we have

$$|P_j(I_j(K_j(\psi, \delta)))| \le \frac{2}{3}\alpha_j, \tag{6.4}$$

$$Q_j(\psi, \delta) \in [-\alpha_j, \alpha_j] \times [-\alpha_j, \alpha_j]. \tag{6.5}$$

Proof. 1. In order to show $\delta_{\beta,j} \le \frac{2}{3}\alpha_j$ notice first that

$$\delta_{\beta,j} < \alpha_j < \delta_j < 1.$$

The hypothesis on $\tilde{\eta}$ yields

$$\frac{u + \tilde{\eta}}{-\sigma - \tilde{\eta}} < \frac{\frac{3u}{2}}{\frac{-\sigma}{2}} = \frac{3u}{-\sigma}.$$

It follows that

$$\delta_{\beta,j} = \left(\frac{2}{3(|\kappa_j| + 1)} \alpha_j \right)^{\frac{3u}{-\sigma}} \le \left(\frac{2}{3(|\kappa_j| + 1)} \alpha_j \right)^{\frac{u+\tilde{\eta}}{-\sigma-\tilde{\eta}}},$$

hence

$$\delta_{\beta,j}^{\frac{-\sigma-\tilde{\eta}}{u+\tilde{\eta}}} \le \frac{2}{3(|\kappa_j| + 1)} \alpha_j.$$

Consequently, with $0 < -\sigma - \tilde{\eta} < u + \tilde{\eta}$ and $\delta_{\beta,j} < 1$,

$$\begin{aligned} \delta_{\beta,j} \le \delta_{\beta,j}^{\frac{-\sigma-\tilde{\eta}}{u+\tilde{\eta}}} &\le \frac{2}{3(|\kappa_j|+1)}\alpha_j \\ &\le \frac{2}{3}\alpha_j. \end{aligned} \tag{6.6}$$

2. From Corollary 6.1 with $0 < \beta \le 1/2$ we get $\alpha_j < \delta_j$ so that for all $(\tilde{\psi}, \tilde{\delta}) \in [-\alpha_j, \alpha_j] \times [-\alpha_j, \alpha_j]$, we have

$$|(K_j^{-1} \circ E_j \circ P_j^{-1})(\tilde{\psi}, \tilde{\delta})| \le (1+\beta)|(\tilde{\psi}, \tilde{\delta})| \le \frac{3}{2}|(\tilde{\psi}, \tilde{\delta})|.$$

3. Proof of (6.4). For $(\psi, \delta) \in [-\alpha_j, \alpha_j] \times (0, \delta_{\beta,j}]$ we have $K_{j,3}(\psi, \delta) = \delta \in (0, \delta_{\beta,j}] \subset (0, \delta_j)$. With $x = K_j(\psi, \delta)$, Corollary 5.5 yields

$$|P_j(I_j(K_j(\psi, \delta)))| = |\kappa_j P_L I_j(x)| \le |\kappa_j| e^{(\sigma+\tilde{\eta})\tau_j(x)}.$$

Notice that $\tilde{\eta} < u$. Using the lower estimate of $\tau_j(x)$ from Corollary 5.6 we infer

$$\begin{aligned} |P_j(I_j(K_j(\psi, \delta)))| &\le |\kappa_j| \left(\frac{1}{x_3}\right)^{\frac{\sigma+\tilde{\eta}}{u+\tilde{\eta}}} \\ &\le |\kappa_j| \delta_{\beta,j}^{\frac{-\sigma-\tilde{\eta}}{u+\tilde{\eta}}} \le \frac{2}{3}\alpha_j \quad \text{(with (6.6))}. \end{aligned}$$

4. Proof of (6.5). For (ψ, δ) as in Part 3 let $(\tilde{\psi}, \tilde{\delta}) = (P_j(I_j(K_j)))(\psi, \delta)$. Then

$$|(\tilde{\psi}, \tilde{\delta})| \le \frac{2}{3}\alpha_j,$$

hence $(\tilde{\psi}, \tilde{\delta}) \in [-\alpha_j, \alpha_j] \times [-\alpha_j, \alpha_j]$, which according to Part 2 yields

$$|(K_j^{-1} \circ E_j \circ P_j^{-1})(\tilde{\psi}, \tilde{\delta})| \le \frac{3}{2}|(\tilde{\psi}, \tilde{\delta})|.$$

It follows that

$$\begin{aligned} |Q_j(\psi, \delta)| &= |K_j^{-1}(R_j(K_j(\psi, \delta)))| = |(K_j^{-1} \circ E_j \circ P_j^{-1} \circ P_j \circ I_j)(K_j(\psi, \delta))| \\ &= |(K_j^{-1} \circ E_j \circ P_j^{-1})(\tilde{\psi}, \tilde{\delta})| \\ &\le \frac{3}{2}|(\tilde{\psi}, \tilde{\delta})| \le \alpha_j. \end{aligned}$$

Finally, use that the disk of radius α_j and center $0 \in \mathbb{R}^2$ is contained in the square $[-\alpha_j, \alpha_j] \times [-\alpha_j, \alpha_j]$. □

The last result of this section concerns continuity of the angle corresponding to $P_L I_j(K_j(\psi, \delta))$, as a function of $(\psi, \delta) \in (-\pi, \pi) \times (0, \delta_j)$.

Proposition 6.3. *Assume $0 < \tilde{\eta} < -\sigma/2$ and consider $\eta > 0, j \in \mathbb{N}, \delta_j$ so that the relations (5.3)–(5.6) hold. Then the function $\Phi_j : (-\pi, \pi) \times (0, \delta_j) \to \mathbb{R}$ given by*

$$\Phi_j(\psi, \delta) = \phi^{(n)}(\tau_j(x), \omega_j + \psi, \delta)$$

with $\phi^{(n)}$ according to Proposition 3.2, $n = n_j(x)$ the largest integer in $[0, \tau_j(x))$ and $x = K_j(\psi, \delta)$, satisfies

$$\frac{1}{|P_L I_j(K_j(\psi,\delta))|} P_L I_j(K_j(\psi,\delta)) = \begin{pmatrix} \cos(\Phi_j(\psi,\delta)) \\ \sin(\Phi_j(\psi,\delta)) \\ 0 \end{pmatrix} \quad \textit{for all} \quad (\psi,\delta) \in (-\pi,\pi) \times (0,\delta_j) \quad (6.7)$$

and is continuous.

Proof. 1. The definition of Φ_j makes sense because for $(\psi,\delta) \in (-\pi,\pi) \times (0,\delta_j)$ and $x = K_j(\psi,\delta)$ we have $|P_U F_{\epsilon_j}(t,x)| < 1$ on $[0,\tau_j(x))$, hence $|P_U F_{\epsilon_j}(\nu,x)| < 1$ for $\nu = 0,\dots,n_j(x)$, which in combination with $n_j(x) < \tau_j(x) \le n_j(x)+1$ yields $(\tau_j(x), \omega_j + \psi, \delta) \in \mathrm{dom}_{n_j(x)}$.

Eq. (6.7) holds because for $\phi = \phi^{n_j(x)}(\tau_j(x), \omega_j + \psi, \delta) = \Phi_j(\psi,\delta)$ we have

$$\frac{1}{|P_L I_j(K_j(\psi,\delta))|} P_L I_j(x) = \frac{1}{|P_L F_{\epsilon_j}(\tau_j(x),x)|} P_L F_{\epsilon_j}(\tau_j(x),x) = \begin{pmatrix} \cos(\phi) \\ \sin(\phi) \\ 0 \end{pmatrix}$$

due to Proposition 3.2 (i).

2. Proof that Φ_j is continuous at $(\psi,\delta) \in (-\pi,\pi) \times (0,\delta_j)$. Let $x = K_j(\psi,\delta)$. We have $n_j(x) < \tau_j(x) \le n_j(x)+1 < n_j(x)+2$. Let a sequence $(\psi_m, \delta_{(m)})_{m\in\mathbb{N}}$ in $(-\pi,\pi) \times (0,\delta_j)$ be given which converges to (ψ,δ). It is enough to find a subsequence so that $\Phi_j(\psi_{m_\mu}, \delta_{(m_\mu)}) \to \Phi_j(\psi,\delta)$ as $\mu \to \infty$.

2.1. In case $\tau_j(x) < n+1$ the continuity of τ_j yields an integer $m_x \ge 0$ so that for all indices $m \ge m_x$ we have $n_j(x) < \tau_j(x_m) < n_j(x)+1$ for $x_m = K_j(\psi_m, \delta_{(m)})$. Hence $n_j(x) = n_j(x_m)$ for $m \ge m_x$. Consequently, $(\tau_j(x_m), \omega_j + \psi_m, \delta_{(m)}) \in \mathrm{dom}_{n_j(x_m)} = \mathrm{dom}_{n_j(x)}$ and

$$\Phi_j(\psi_m,\delta_{(m)}) = \phi^{(n_j(x_m))}(\tau_j(x_m), \omega_j + \psi_m, \delta_{(m)}) = \phi^{(n_j(x))}(\tau_j(x_m), \omega_j + \psi_m, \delta_{(m)}) \quad \text{for} \quad m \ge m_x.$$

As $\phi^{(n_j(x))}$ is continuous according to Proposition 3.2 we arrive at

$$\lim_{m\to\infty} \Phi_j(\psi_m,\delta_{(m)}) = \lim_{m\to\infty} \phi^{(n_j(x))}(\tau_j(x_m), \omega_j + \psi_m, \delta_{(m)}) = \phi^{(n_j(x))}(\tau_j(x), \omega_j + \psi, \delta) = \Phi_j(\psi,\delta).$$

2.2. In case $\tau_j(x) = n_j(x)+1$ we have $|P_U F_{\epsilon_j}(n_j(x)+1,x)| = |P_U F_{\epsilon_j}(\tau_j(x),x)| = 1$ in addition to $|P_U F_{\epsilon_j}(\nu,x)| < 1$ for $\nu = 0,\dots,n_j(x)$ and conclude that $(\tau_j(x), \omega_j + \psi, \delta) \in \mathrm{dom}_{n_j(x)+1}$.

By Proposition 3.2 (ii), $\phi^{(n_j(x)+1)}(n_j(x)+1, \omega_j + \psi, \delta) = \phi^{(n_j(x))}(n_j(x)+1, \omega_j + \psi, \delta)$.

We distinguish the subcases that the indices m with $\tau_j(x_m) \le n_j(x)+1$ are bounded or not.

2.2.1. If the indices with $\tau_j(x_m) \le n_j(x)+1$ are unbounded then there is a strictly increasing sequence $(m_\mu)_{\mu\in\mathbb{N}}$ of positive integers with $\tau_j(x_{m_\mu}) \le n_j(x)+1$ for all $\mu \in \mathbb{N}$. As in Part 2.1 we find $\Phi_j(\psi_{m_\mu}, \delta_{(m_\mu)}) \to \Phi_j(\psi,\delta)$ for $\mu \to \infty$.

2.2.2. If there is an upper bound $m_x \in \mathbb{N}$ for the indices m with $\tau_j(x_m) \le n_j(x)+1$ then $n_j(x)+1 < \tau_j(x_m)$ for all indices $m > m_x$. In addition we may assume $\tau_j(x_m) < n_j(x)+2$ for all $m > m_x$. It follows that $n_j(x)+1 = n_j(x_m)$ and

$$\Phi_j(\psi_m,\delta_{(m)}) = \phi^{(n_j(x_m))}(\tau_j(x_m), \omega_j + \psi_m, \delta_{(m)}) = \phi^{(n_j(x)+1)}(\tau_j(x_m), \omega_j + \psi_m, \delta_{(m)})$$

for $m > m_x$. Using continuity of $\phi^{(n_j(x)+1)}$ from Proposition 3.2 we find

$$\begin{aligned} \lim_{m\to\infty} \Phi_j(\psi_m,\delta_{(m)}) &= \lim_{m\to\infty} \phi^{(n_j(x)+1)}(\tau_j(x_m), \omega_j + \psi_m, \delta_{(m)}) \\ &= \phi^{(n_j(x)+1)}(\tau_j(x), \omega_j + \psi, \delta) = \phi^{(n_j(x)+1)}(n_j(x)+1, \omega_j + \psi, \delta) \\ &= \phi^{(n_j(x))}(n_j(x)+1, \omega_j + \psi, \delta) = \phi^{(n_j(x))}(\tau_j(x), \omega_j + \psi, \delta) = \Phi_j(\psi,\delta). \quad \square \end{aligned}$$

7 Curves expanded by the return map in the plane

In this section we consider curves $g : [a,b] \to (-\pi,\pi) \times (0,\delta_j)$ which connect level sets $(-\pi,\pi) \times \{\Delta_1\}$ and $(-\pi,\pi) \times \{\Delta_2\}$ with $0 < \Delta_1 < \Delta_2 < \delta_j$. We find subintervals $[a_0,b_0]$ and $[a_1,b_1]$ so that the angle function Φ_j sends $g((a_0,b_0))$ and $g((a_1,b_1))$ into disjoint sets M_0 and M_1, and transport by the return map in the plane Q_j yields two curves which again connect the said level sets. Be aware that the angle function Φ_j is not directly related to the return map in the plane but only to the inner map in coordinates (depicted in Figure 5.1, bottom), which is the first composite of the return map in the plane.

Throughout this section we assume $0 < \tilde{\eta} < \min\{\mu, -\sigma/2\}$, and that $\eta > 0$, $j \in \mathbb{N}$, and $\delta_j \in (0,1)$ satisfy the relations (5.3)–(5.6). We begin with a comparison of angles $\Phi_j(\psi,\delta)$ for arguments in level sets as above. Let

$$\begin{aligned} c = c_{\tilde{\eta}} &= \frac{(u+\tilde{\eta})(\mu+\tilde{\eta})}{(u-\tilde{\eta})(\mu-\tilde{\eta})} \\ &> 1, \\ k = k_{\tilde{\eta}} &= e^{-6\pi\frac{u+\tilde{\eta}}{\mu-\tilde{\eta}}} \\ &< 1. \end{aligned}$$

For $\Delta_2 \in (0,\delta_j)$ we set

$$\begin{aligned} \Delta_1 = \Delta_1(\Delta_2) &= k\Delta_2^c \\ &< \Delta_2. \end{aligned}$$

Proposition 7.1. *Let $\Delta_2 \in (0,\delta_j)$ be given and consider $\Delta_1 = \Delta_1(\Delta_2) = k\Delta_2^c$. Then*

$$4\,\pi \le \Phi_j(\psi,\Delta_2) - \Phi_j(\gamma,\Delta_1) \quad \textit{for all } \psi,\gamma \textit{ in } (-\pi,\pi).$$

Proof. Assume $-\pi < \psi < \pi$, $-\pi < \gamma < \pi$. Recall the definition of Φ_j in Proposition 6.3 and apply the last estimate in Corollary 5.5, and the estimate of the travel time in Corollary 5.6. This yields the inequalities

$$\Phi_j(\psi,\Delta_2) - (\omega_j+\psi) \ge (-\mu-\tilde{\eta}) \cdot \frac{1}{u-\tilde{\eta}} \log\left(\frac{1}{\Delta_2}\right)$$

and

$$\Phi_j(\gamma,\Delta_1) - (\omega_j+\gamma) \le (-\mu+\tilde{\eta}) \cdot \frac{1}{u+\tilde{\eta}} \log\left(\frac{1}{\Delta_1}\right)$$

from which we obtain

$$\begin{aligned} \Phi_j(\psi,\Delta_2) - \Phi_j(\gamma,\Delta_1) &\ge -2\pi + \frac{\mu+\tilde{\eta}}{u-\tilde{\eta}}\log(\Delta_2) - \frac{\mu-\tilde{\eta}}{u+\tilde{\eta}}\log(\Delta_1) \\ &\ge -2\pi + \frac{\mu+\tilde{\eta}}{u-\tilde{\eta}}\log(\Delta_2) - \frac{\mu-\tilde{\eta}}{u+\tilde{\eta}}[\log(k) + c\log(\Delta_2)] \\ &= -2\pi + 6\pi + \left(\frac{\mu+\tilde{\eta}}{u-\tilde{\eta}} - c\frac{\mu-\tilde{\eta}}{u+\tilde{\eta}}\right)\log(\Delta_2) = 4\pi. \end{aligned}$$

□

From here on let also $\beta \in (0,1/2]$ be given and consider $\alpha_j = \alpha_j(\beta) \in (0,\delta_j)$ according to Proposition 6.2. Proposition 7.1 shows that the quantities

$$m_1 = m_1(j,\Delta_1) = \max_{|\gamma|\le\alpha_j} \Phi_j(\gamma,\Delta_1) \quad \text{and} \quad m_2 = m_2(j,\Delta_2) = \min_{|\psi|\le\alpha_j} \Phi_j(\psi,\Delta_2)$$

satisfy $m_1 + 4\pi \le m_2$. Also, there exists $\psi_j \in [m_1+\pi, m_2-\pi]$ with

$$\begin{pmatrix} \cos(\psi_j) \\ \sin(\psi_j) \\ 0 \end{pmatrix} = \frac{1}{|w_j|} w_j.$$

Proposition 7.2 (Angles along curves connecting vertical levels)**.** *Consider $\Delta_2 \in (0,\delta_j)$ and $\Delta_1 = \Delta_1(\Delta_2)$ as above. Let a curve $g : [a,b] \to (-\pi,\pi)\times(0,\delta_j)$ be given with $g_2(b) = \Delta_2$ and $g_2(a) = \Delta_1$. Then there exist $a_0' < b_0' \le a_1' < b_1'$ in $[a,b]$ such that*

$$\Phi_j(g(t)) \in (\psi_j - \pi, \psi_j) \quad \text{on} \quad (a_0', b_0'), \quad \Phi_j(g(a_0')) = \psi_j - \pi, \quad \Phi_j(g(b_0')) = \psi_j,$$

$$\Phi_j(g(t)) \in (\psi_j, \psi_j + \pi) \quad \text{on} \quad (a_1', b_1'), \quad \Phi_j(g(a_1')) = \psi_j, \quad \Phi_j(g(b_1')) = \psi_j + \pi.$$

Compare Figure 7.1.

Proof. 1. We construct a_1' and b_1'. From

$$\Phi_j(g(a)) \le m_1 < m_1 + \pi \le \psi_j \le m_2 - \pi < m_2 \le \Phi_j(g(b))$$

we have

$$\Phi_j(g(a)) \le \psi_j - \pi < \psi_j < \psi_j + \pi \le \Phi_j(g(b)).$$

By continuity, $\psi_j = \Phi_j(g(t))$ for some $t \in (a,b)$. Again by continuity there exists $b_1' \in (t,b]$ with $\Phi_j(g(s)) < \psi_j + \pi$ on $[t,b_1')$ and $\Phi_j(g(b_1')) = \psi_j + \pi$. Upon that, there exists $a_1' \in [t,b_1')$ with $\psi_j < \Phi_j(g(s))$ on $(a_1',b_1']$ and $\Phi_j(g(a_1')) = \psi_j$.

2. The construction of a_0' and b_0' with $b_0' \le a_1'$ is analogous. □

We turn to the position of $Q_j(\psi,\delta)$ for arguments $(\psi,\delta) \in (-\pi,\pi)\times[\Delta_1,\Delta_2]$. A look at Eq. (6.7) in Proposition 6.3 confirms that in the cases

$$\Phi_j(\psi,\delta) = \psi_j - \pi, \quad \Phi_j(\psi,\delta) = \psi_j, \quad \Phi_j(\psi,\delta) = \psi_j + \pi$$

the value $P_L I_j(K_j(\psi,\delta))$ belongs to the rays

$$(0,\infty)(-w_j), \quad (0,\infty)w_j, \quad (0,\infty)(-w_j), \quad \text{respectively,}$$

hence $P_j(I_j(K_j(\psi,\delta)))$ is on the vertical axis in $\mathbb{R}^2$.

Proposition 7.3 (From angles to vertical levels)**.** *Assume in addition to the hypotheses made in the present section up to here that $\tilde\eta$ satisfies*

$$c_{\tilde\eta} \frac{-\sigma+\tilde\eta}{u-\tilde\eta} < 1. \tag{7.1}$$

Let $\beta \in (0,1/2]$ be given and choose reals $\alpha_j = \alpha_j(\beta) \in (0,\delta_j)$ and $\delta_{\beta,j} \in (0,2\alpha_j/3]$ according to Proposition 6.2. Consider $\Delta_2 \in (0,\delta_{\beta,j})$ so small that

$$2\sqrt{2}\Delta_2 < \frac{1}{|\kappa_j^{-1}|} k^{\frac{-\sigma+\tilde\eta}{u-\tilde\eta}} \Delta_2^{c\frac{-\sigma+\tilde\eta}{u-\tilde\eta}}, \quad \text{with} \quad c = c_{\tilde\eta} \quad \text{and} \quad k = k_{\tilde\eta}. \tag{7.2}$$

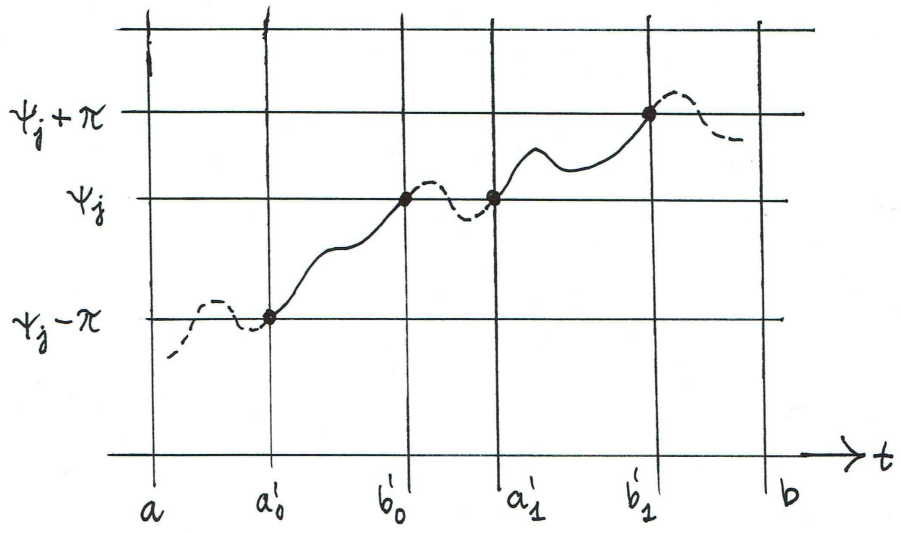

Figure 7.1: The map $\Phi_j \circ g$.

Let $\Delta_1 = \Delta_1(\Delta_2)$, $(\psi, \delta) \in [-\alpha_j, \alpha_j] \times [\Delta_1, \Delta_2]$, *and* $z = Q_j(\psi, \delta)$. *Then*

(i) $|z| > \sqrt{2}\Delta_2$.

(ii) In the cases $\Phi_j(\psi, \delta) = \psi_j - \pi$, $\Phi_j(\psi, \delta) = \psi_j$, $\Phi_j(\psi, \delta) = \psi_j + \pi$, *we have*

$$z_2 < -\Delta_2, \quad z_2 > \Delta_2, \quad z_2 < -\Delta_2, \quad \textit{respectively.}$$

Compare Figure 7.2.

Proof. 1. On assertion (i). Observe first that due to Proposition 6.2 the rectangle $[-\alpha_j, \alpha_j] \times [\Delta_1, \Delta_2]$ is contained in the domain of definition of the maps $P_j(I_j(K_j(\cdot,\cdot)))$ and Q_j. Let $(\psi, \delta) \in [-\alpha_j, \alpha_j] \times [\Delta_1, \Delta_2]$ be given, and let

$$x = P_j(I_j(K_j(\psi, \delta))) \quad (= \kappa_j P_L I_j(K_j(\psi, \delta))).$$

Observe $K_{j,3}(\psi, \delta) = \delta$ and apply Corollaries 5.5 and 5.6. This yields

$$|x| \geq \frac{1}{|\kappa_j^{-1}|}\delta^{\frac{-\sigma+\tilde{\eta}}{u-\tilde{\eta}}} \geq \frac{1}{|\kappa_j^{-1}|}\Delta_1^{\frac{-\sigma+\tilde{\eta}}{u-\tilde{\eta}}} = \frac{1}{|\kappa_j^{-1}|}k^{\frac{-\rho+\tilde{\eta}}{u-\tilde{\eta}}}\Delta_2^{c\frac{-\sigma+\tilde{\eta}}{u-\tilde{\eta}}} > 2\sqrt{2}\Delta_2.$$

We have

$$z = Q_j(\psi, \delta) = (K_j^{-1} \circ E_j \circ I_j)(K_j(\psi, \delta)) = (K_j^{-1} \circ E_j \circ P_j^{-1} \circ P_j \circ I_j)(K_j(\psi, \delta)) = (K_j^{-1} \circ E_j \circ P_j^{-1})(x).$$

The inequality (6.4) in Proposition 6.2 gives us $|x| \leq \frac{2}{3}\alpha_j$, hence $x \in [-\alpha_j, \alpha_j] \times [-\alpha_j, \alpha_j]$. Using the relation (6.2) in Corollary 6.1 we infer $|z - x| \leq \beta|x|$. It follows that

$$|z| \geq |x| - \beta|x| \geq \frac{1}{2}|x| > \sqrt{2}\Delta_2.$$

2. On assertion (ii) for the case $(\psi, \delta) \in [-\alpha_j, \alpha_j] \times [\Delta_1, \Delta_2]$ with $\Phi_j(\psi, \delta) = \psi_j$. Let $z = Q_j(\psi, \delta) \in \mathbb{R}^2$.

2.1. From (6.7) in Proposition 6.3 we have that $P_L I_j(K_j(\psi,\delta))$ is a positive multiple of

$$\begin{pmatrix} \cos(\Phi_j(\psi,\delta)) \\ \sin(\Phi_j(\psi,\delta)) \\ 0 \end{pmatrix} = \begin{pmatrix} \cos(\psi_j) \\ \sin(\psi_j) \\ 0 \end{pmatrix} \in (0,\infty) w_j,$$

hence

$$P_j(I_j(K_j(\psi,\delta))) = \kappa_j P_L I_j(K_j(\psi,\delta)) \in (0,\infty) \begin{pmatrix} 0 \\ 1 \end{pmatrix}.$$

2.2. From Part 1, $|z| > \sqrt{2}\Delta_2$. For $x = P_j(I_j(K_j(\psi,\delta))) = \kappa_j P_L I_j(K_j(\psi,\delta))$ Part 2.1 yields $x = \left(\begin{smallmatrix} 0 \\ x_2 \end{smallmatrix}\right)$ with $x_2 > 0$.

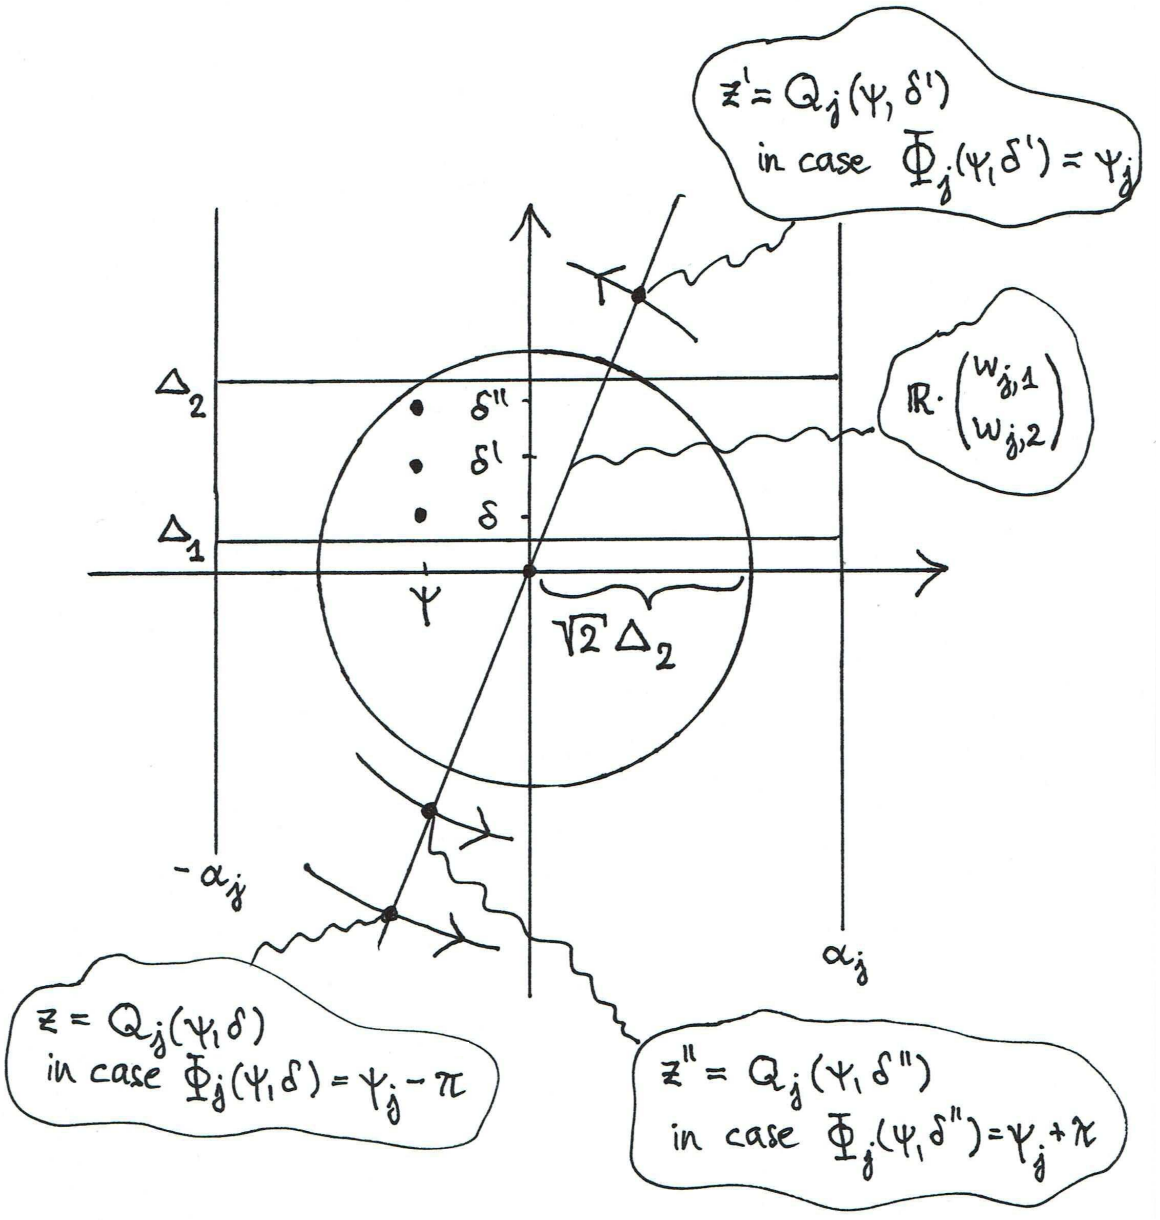

Figure 7.2: Positions of $Q_j(\psi,\delta)$ depending on the angle $\Phi_j(\psi,\delta)$.

2.3. Proof of $|z| \leq \sqrt{2}z_2$: We have $|x| = x_2$. From $x_2 - z_2 \leq |x_2 - z_2| \leq |z - x| \leq \beta|x| = \beta x_2$, $z_2 \geq (1-\beta)x_2 > 0$. Also, from $x_1 = 0$, $|z_1| \leq |x_1| + \beta|x| = \beta x_2$. It follows that

$$|z|^2 = z_1^2 + z_2^2 \leq \beta^2 x_2^2 + z_2^2 \leq \frac{\beta^2}{(1-\beta)^2} z_2^2 + z_2^2 \leq 2z_2^2.$$

2.4. Consequently, $z_2 = |z_2| \geq \frac{1}{\sqrt{2}}|z| > \Delta_2$.

3. The proofs of assertion (ii) in the two remaining cases are analogous, making use of the fact that in both cases we have that $P_j(I_j(K_j(\psi,\delta))) = \kappa_j P_L I_j(K_j(\psi,\delta))$ is a positive multiple of $\left(\begin{smallmatrix} 0 \\ -1 \end{smallmatrix}\right)$. □

The next result makes precise what was briefly announced at the begin of the section. The disjoint sets mentioned there will be given in terms of the angle $\Phi_j(\psi,\delta)$ corresponding to the value $P_j(I_j(K_j(\psi,\delta)))$ of the inner map in coordinates, and not by the position of the value $Q_j(\psi,\delta)$ of the return map in the plane to the left or right of the vertical axis. Our choice of disjoint sets circumvents a discussion how the latter are related to the more accessible angles $\Phi_j(\psi,\delta)$.

Proposition 7.4. *Assume the hypotheses of Proposition 7.3 are satisfied and let $\Delta_1 = \Delta_1(\Delta_2)$. Consider the disjoint sets*

$$M_0 = \{(\psi,\delta) \in [-\alpha_j,\alpha_j] \times [\Delta_1,\Delta_2] : \psi_j - \pi < \Phi_j(\psi,\delta) < \psi_j\}$$

and

$$M_1 = \{(\psi,\delta) \in [-\alpha_j,\alpha_j] \times [\Delta_1,\Delta_2] : \psi_j < \Phi_j(\psi,\delta) < \psi_j + \pi\}.$$

For every curve $g : [a,b] \to [-\alpha_j,\alpha_j] \times [\Delta_1,\Delta_2]$ with $g_2(a) = \Delta_1$ and $g_2(b) = \Delta_2$ there exist $a_0 < b_0 < a_1 < b_1$ in $[a,b]$ such that

$$\begin{aligned} &\text{on} \quad (a_0,b_0), \quad g(t) \in M_0 \quad \text{and} \quad Q_{j,2}(g(t)) \in (\Delta_1,\Delta_2), \\ &\quad \text{with} \quad Q_{j,2}(g(a_0)) = \Delta_1 \quad \text{and} \quad Q_{j,2}(g(b_0)) = \Delta_2, \\ &\text{while on} \quad (a_1,b_1), \quad g(t) \in M_1 \quad \text{and} \quad Q_{j,2}(g(t)) \in (\Delta_1,\Delta_2), \\ &\quad \text{with} \quad Q_{j,2}(g(a_1)) = \Delta_2 \quad \text{and} \quad Q_{j,2}(g(b_1)) = \Delta_1. \end{aligned}$$

Proof. Proposition 7.2 yields $a_0' < b_0' \leq a_1' < b_1'$ in $[a,b]$ such that

$$\begin{aligned} \text{on} \quad &(a_0',b_0'), \quad \Phi_j(g(t)) \in (\psi_j - \pi, \psi_j), \\ &\text{with} \quad \Phi_j(g(a_0')) = \psi_j - \pi \quad \text{and} \quad \Phi_j(g(b_0')) = \psi_j, \\ \text{and on} \quad &(a_1',b_1'), \quad \Phi_j(g(t)) \in (\psi_j, \psi_j + \pi), \\ &\text{with} \quad \Phi_j(g(a_1')) = \psi_j \quad \text{and} \quad \Phi_j(g(b_1'))_2 = \psi_j + \pi. \end{aligned}$$

From Proposition 7.3 (ii),

$$Q_{j,2}(g(a_0')) < -\Delta_2, \quad Q_{j,2}(g(b_0')) > \Delta_2, \quad Q_{j,2}(g(a_1')) > \Delta_2, \quad Q_{j,2}(g(b_1')) < -\Delta_2.$$

As in the proof of Proposition 7.2 one finds $a_0 < b_0$ in (a_0',b_0') and $a_1 < b_1$ in (a_1',b_1') with

$$\begin{aligned} &Q_{j,2}(g(a_0)) = \Delta_1 \quad \text{and} \quad Q_{j,2}(g(b_0)) = \Delta_2, \quad \text{and} \quad Q_{j,2}(g(t)) \in (\Delta_1,\Delta_2) \quad \text{on} \quad (a_0,b_0), \\ &Q_{j,2}(g(a_1)) = \Delta_2 \quad \text{and} \quad Q_{j,2}(g(b_1)) = \Delta_1, \quad \text{and} \quad Q_{j,2}(g(t)) \in (\Delta_1,\Delta_2) \quad \text{on} \quad (a_1,b_1). \end{aligned}$$

Observe that on $(a_0,b_0) \subset (a_0',b_0')$ we have $g(t) \in M_0$ while on $(a_1,b_1) \subset (a_1',b_1')$ we have $g(t) \in M_1$. □

See Figure 7.3.

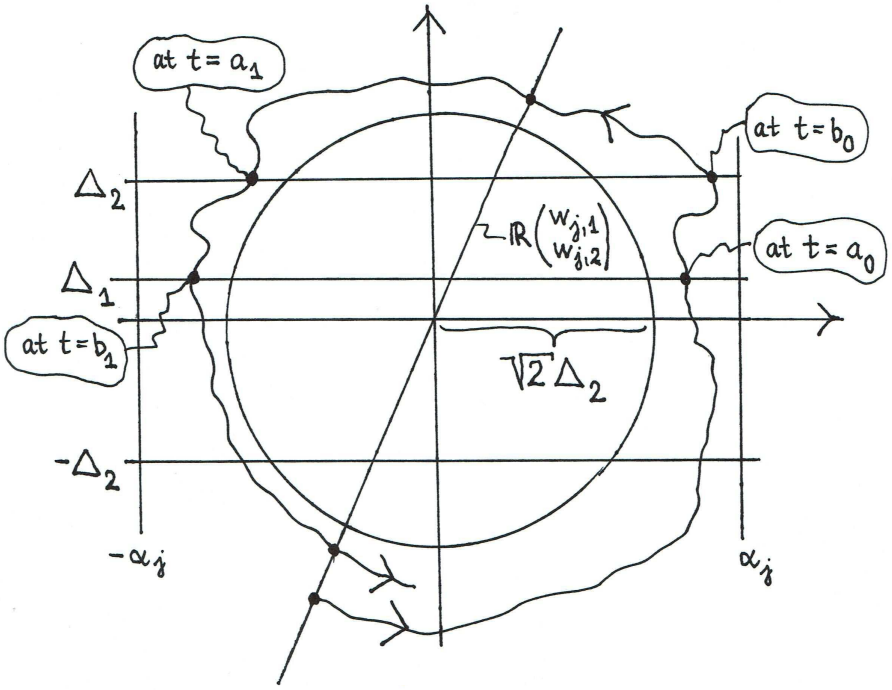

Figure 7.3: The values $Q_j(g(t))$ for $a \le t \le b$.

8 Complicated dynamics

For the results of this section we assume that the hypotheses of Proposition 7.4 are satisfied. It may be convenient to repeat all of these assumption here, beginning with the choice of a real number $\tilde{\eta} > 0$ with

$$\tilde{\eta} < \min\{\mu, -\sigma/2\}$$

which satisfies the inequality (7.1).

The numbers $\eta > 0$, $j \in \mathbb{N}$, and $\delta_j \in (0,1)$ are chosen so that the relations (5.3)–(5.6) hold.

For given $\beta \in (0, 1/2]$, the reals $\alpha_j = \alpha_j(\beta) \in (0, \delta_j)$ and $\delta_{\beta,j} \in (0, 2\alpha_j/3]$ are chosen according to Proposition 6.2.

$\Delta_2 \in (0, \delta_{\beta,j})$ is chosen so that the inequality (7.2) holds, and $\Delta_1 = \Delta_1(\Delta_2)$.

Recall the disjoint sets M_0 and M_1 from Proposition 7.4.

Proposition 8.1. *For every sequence $(s_n)_{n=0}^{\infty}$ in $\{0,1\}$ there are forward trajectories $(x_n)_{n=0}^{\infty}$ of Q_j in $[-\alpha_j, \alpha_j] \times [\Delta_1, \Delta_2]$ with $x_n \in M_{s_n}$ and $\Delta_1 \le Q_{j,2}(x_n) \le \Delta_2$ for all integers $n \ge 0$.*

Proof. 1. Let a sequence $(s_n)_{n=0}^{\infty}$ in $\{0,1\}$ be given. Choose a curve $g : [a,b] \to [-\alpha_j, \alpha_j] \times [\Delta_1, \Delta_2]$ such that $g_2(t) \in (\Delta_1, \Delta_2)$ for $a < t < b$ and $g_2(a) = \Delta_1$, $g_2(b) = \Delta_2$, for example, $g(t) = (0,t)$ for $a = \Delta_1 \le t \le \Delta_2 = b$.

For integers $n \ge 0$ we construct recursively curves $g_n : [A_n, B_n] \to [-\alpha_j, \alpha_j] \times [\Delta_1, \Delta_2]$ with decreasing domains in $[a,b]$ as follows.

1.1. In order to find g_0 we apply Proposition 7.4 to the curve g and obtain $a_0 < b_0 < a_1 < b_1$ in $[a,b]$ with the properties stated in Proposition 7.4. In case $s_0 = 0$ we define g_0 by $A_0 =$

a_0, $B_0 = b_0$, $g_0(t) = g(t)$ for $A_0 \le t \le B_0$. Notice that $g_0(t) \in M_{s_0}$ for all $t \in (A_0, B_0)$, $Q_{j,2}(g_0(t)) \in (\Delta_1, \Delta_2)$ on (A_0, B_0), $Q_{j,2}(g_0(A_0)) = \Delta_1$, and $Q_{j,2}(g_0(B_0)) = \Delta_2$. In case $s_0 = 1$ we define g_0 by $A_0 = a_1$, $B_0 = b_1$, $g_0(t) = g(a_1 + b_1 - t)$ for $A_0 \le t \le B_0$. Notice that also in this case $g_0(t) \in M_{s_0}$ for all $t \in (A_0, B_0)$, $Q_{j,2}(g_0(t)) \in (\Delta_1, \Delta_2)$ on (A_0, B_0), and $Q_{j,2}(g_0(A_0)) = Q_{j,2}(g(a_1 + b_1 - a_1)) = \Delta_1$, $Q_{j,2}(g_0(B_0)) = Q_{j,2}(g(a_1 + b_1 - b_1)) = \Delta_2$.

1.2. For an integer $n \ge 0$ let a curve $g_n : [A_n, B_n] \to [-\alpha_j, \alpha_j] \times [\Delta_1, \Delta_2]$ be given with $g_n(t) \in M_{s_n}$ for all $t \in (A_n, B_n)$ and $Q_{j,2}(g_n(t)) \in (\Delta_1, \Delta_2)$ on (A_n, B_n), $Q_{j,2}(g_n(A_n)) = \Delta_1$, $Q_{j,2}(g_n(B_n)) = \Delta_2$. Proceeding as in Part 1.1, with the curve $[A_n, B_n] \ni t \mapsto Q_j(g_n(t)) \in [-\alpha_j, \alpha_j] \times [\Delta_1, \Delta_2]$ in place of the former curve g, we obtain $A_{n+1} < B_{n+1}$ in $[A_n, B_n]$ and a curve $g_{n+1} : [A_{n+1}, B_{n+1}] \to [-\alpha_j, \alpha_j] \times [\Delta_1, \Delta_2]$ with $g_{n+1}(t) \in M_{s_{n+1}}$ for all $t \in (A_{n+1}, B_{n+1})$ and $Q_{j,2}(g_{n+1}(t)) \in (\Delta_1, \Delta_2)$ on (A_{n+1}, B_{n+1}), $Q_{j,2}(g_{n+1}(A_{n+1})) = \Delta_1$, $Q_{j,2}(g_{n+1}(B_{n+1})) = \Delta_2$.

2. From $A_n \le A_{n+1} < B_{n+1} \le B_n$ for all integers $n \ge 0$ we get $\cap_{n\ge 0}[A_n, B_n] = [A, B]$ with $A = \lim_{n\to\infty} A_n \le \lim_{n\to\infty} B_n = B$. Choose $t \in [A, B]$ and define

$$x_n = g_n(t) \in [-\alpha_j, \alpha_j] \times [\Delta_1, \Delta_2]$$

for every integer $n \ge 0$. This yields a forward trajectory of Q_j with $\Delta_1 \le Q_{j,2}(x_n) \le \Delta_2$ for all integers $n \ge 0$.

Let an integer $n \ge 0$ be given. Proof of $x_n \in M_{s_n}$. We have $x_n = g_n(t)$ with $A_n \le A \le t \le B \le B_n$, and for all $v \in (A_n, B_n)$, $g_n(v) \in M_{s_n}$. By continuity, $x_n \in \operatorname{cl} M_{s_n}$. In case $s_n = 0$ this yields

$$\psi_j - \pi \le \Phi_j(x_n) \le \psi.$$

Assume $\Phi_j(x_n) \in \{\psi - \pi, \psi\}$, Then Proposition 7.3 (ii) gives $|Q_{j,2}(x_n)| > \Delta_2$, which contradicts the previous estimate of $Q_{j,2}(x_n)$. Consequently,

$$\psi_j - \pi < \Phi_j(x_n) < \psi, \quad \text{or,} \quad x_n \in M_0 = M_{s_n}.$$

In case $s_n = 1$ the proof is analogous. □

The final result extends Proposition 8.1 to entire trajectories.

Theorem 8.2. *For every sequence $(s_n)_{n=-\infty}^{\infty}$ in $\{0, 1\}$ there exist entire trajectories $(y_n)_{n=-\infty}^{\infty}$ of Q_j with $y_n \in M_{s_n}$ for all integers n.*

Proof. 1. Let $(s_n)_{n=-\infty}^{\infty}$ in $\{0, 1\}$ be given. Proposition 8.1 guarantees that for every integer k there is a forward trajectory $(y_{k,n})_{n=0}^{\infty}$ of Q_j in $[-\alpha_j, \alpha_j] \times [\Delta_1, \Delta_2]$ so that for each integer $n \ge 0$,

$$y_{k,n} \in M_{s_{n-k}} \quad \text{and} \quad \Delta_1 \le Q_{j,2}(y_{k,n}) \le \Delta_2.$$

For integers k, n with $k \ge -n$ we define

$$z_{k,n} = y_{k,n+k},$$

so that

$$\begin{aligned} z_{k,n} &= y_{k,n+k} \in M_{s_{n+k-k}} = M_{s_n}, \\ z_{k,n+1} &= y_{k,n+1+k} = Q_j(y_{k,n+k}) = Q_j(z_{k,n}), \\ Q_{j,2}(z_{k,n}) &= Q_{j,2}(y_{k,n+k}) \in [\Delta_1, \Delta_2]. \end{aligned}$$

1.1. Choice of subsequences for integers $N \ge 0$.

1.1.1. The case $N = 0$: For every integer $k \geq 0$, $z_{k,0} \in M_{s_0}$. The sequence $(z_{k,0})_{k=0}^{\infty}$ in the compact set $[-\alpha_j, \alpha_j] \times [\Delta_1, \Delta_2]$ has a convergent subsequence $(z_{\kappa_0(k),0})_{k=0}^{\infty}$ given by a strictly increasing map $\kappa_0 : \mathbb{N}_0 \to \mathbb{N}_0$. Let $y_0 = \lim_{k\to\infty} z_{\kappa_0(k),0} \in \text{cl } M_{s_0} \subset [-\alpha_j, \alpha_j] \times [\Delta_1, \Delta_2]$.

1.1.2. The case $N = 1$: We choose a convergent subsequence of $(z_{\kappa_0(k),-1})_{k=0}^{\infty}$ given by a strictly increasing map $\mu_{-1} : \mathbb{N}_0 \to \mathbb{N}_0$, and upon this a convergent subsequence of $(z_{\kappa_0\circ\mu_{-1}(k),1})_{k=0}^{\infty}$ given by a strictly increasing map $\mu_1 : \mathbb{N}_0 \to \mathbb{N}_0$, and define $\kappa_1 = \mu_{-1} \circ \mu_1$. For $k \to \infty$,

$$z_{\kappa_0\circ\kappa_1(k),-0}, \quad z_{\kappa_0\circ\kappa_1(k),-1} \quad \text{and} \quad z_{\kappa_0\circ\kappa_1(k),1}$$

converge to elements $y_0 \in \text{cl } M_{s_0}$, $y_{-1} \in \text{cl } M_{s_{-1}}$, and $y_1 \in \text{cl } M_{s_1}$, respectively.

1.1.3. The general case $N \in \mathbb{N}$: Consecutively choosing further convergent subsequences analogously to Part 1.1.2 we obtain strictly increasing maps $\kappa_n : \mathbb{N}_0 \to \mathbb{N}_0$, $n = 0, \ldots, N$, so that for each $n \in \{-N, \ldots, N\}$ the sequence

$$(z_{\kappa_0\circ\cdots\circ\kappa_N(k),n})_{k=0}^{\infty}$$

converges for $k \to \infty$ to some $y_n \in \text{cl } M_{s_n}$.

2. The *diagonal sequence* $K : \mathbb{N}_0 \to \mathbb{N}_0$ defined by $K(N) = (\kappa_0 \circ \cdots \circ \kappa_N)(N)$ is strictly increasing since for every $N \in \mathbb{N}_0$ we have

$$K(N+1) = (\kappa_0 \circ \cdots \circ \kappa_N)(\kappa_{N+1}(N+1)) > (\kappa_0 \circ \cdots \circ \kappa_N)(\kappa_{N+1}(N)) \geq (\kappa_0 \circ \cdots \circ \kappa_N)(N) = K(N)$$

due to strict monotonicity of all maps involved.

3. Let an integer n be given and set $N = |n|$. Proof that

$$(z_{K(k),n})_{k=N+1}^{\infty} \quad \text{is a subsequence of} \quad (z_{(\kappa_0\circ\cdots\circ\kappa_N)(k),n})_{k=N+1}^{\infty}.$$

Consider the map $\lambda : \{k \in \mathbb{N}_0 : k > N\} \to \mathbb{N}_0$ given by $\lambda(k) = (\kappa_{N+1} \circ \cdots \circ \kappa_k)(k)$. For every integer $k \geq N+1$,

$$K(k) = (\kappa_0 \circ \cdots \circ \kappa_N)(\lambda(k)),$$

and λ is strictly increasing because analogously to Part 2 we have

$$\begin{aligned}\lambda(k+1) &= (\kappa_{N+1} \circ \cdots \circ \kappa_{k+1})(k+1) = (\kappa_{N+1} \circ \cdots \circ \kappa_k)(\kappa_{k+1}(k+1)) \\ &\geq (\kappa_{N+1} \circ \cdots \circ \kappa_k)(k+1) > (\kappa_{N+1} \circ \cdots \circ \kappa_k)(k) = \lambda(k)\end{aligned}$$

for every integer $k \geq N+1$.

Being a subsequence of $(z_{(\kappa_1\circ\cdots\circ\kappa_{|n|})(k),n})_{k=N+1}^{\infty}$ the sequence $(z_{K(k),n})_{k=N+1}^{\infty}$ converges for $k \to \infty$ to $y_n \in \text{cl } M_{s_n}$.

4. We show that $(y_n)_{n=-\infty}^{\infty}$ is an entire trajectory of Q_j. Let an integer n be given and set $N = |n|$. From Part 3 in combination with Part 1.1.3 we get that $(z_{K(k),n})_{k=N+1}^{\infty}$ converges to $y_n \in [-\alpha_j, \alpha_j] \times [\Delta_1, \Delta_2]$ and that $(z_{K(k),n+1})_{k=N+2}^{\infty}$ converges to y_{n+1}. Recall $z_{k,n+1} = Q_j(z_{k,n})$ for all integers k, n with $k \geq -n$. For integers $k > N = |n|$ we have $K(k) \geq k \geq -n$, and the preceding statement yields

$$z_{K(k),n+1} = Q_j(z_{K(k),n}).$$

It follows that

$$y_{n+1} = \lim_{N+2\leq k\to\infty} z_{K(k),n+1} = \lim_{N+1\leq k\to\infty} Q_j(z_{K(k),n}) = Q_j(y_n).$$

5. Proof of $y_n \in M_{s_n}$ for all integers n. Let an integer n be given. We have $y_n \in \text{cl } M_{s_n}$. In case $s_n = 0$ this yields $\psi_j - \pi \leq \Phi_j(y_n) \leq \psi_j$. Therefore the assumption $y_n \notin M_{s_n}$ results in $\Phi_j(y_n) \in \{\psi_j - \pi, \psi_j\}$, which according to Proposition 7.3 (ii) means $|Q_{j,2}(y_n)| > \Delta_2$, in contradiction to $\Delta_1 \leq Q_{j,2}(y_n) \leq \Delta_2$. The proof in case $s_n = 1$ is analogous. □

9 Appendix: From the vectorfield V to the flow F

Consider Shilnikov's scenario according to Section 1, with a continuously differentiable vectorfield $V : \mathbb{R}^3 \supset \mathrm{dom}_V \to \mathbb{R}^3$, dom_V open and $V(0) = 0$, so that there is a homoclinic solution h_V of Eq. (1.1), and the eigenvalues $u > 0$ and $\sigma \pm i\mu$, $\sigma < 0 < \mu$, of $DV(0)$ satisfy

(H) $\qquad 0 < \sigma + u.$

For simplicity assume in addition $\mathrm{dom}_V = \mathbb{R}^3$ and that V is bounded. This is not a severe restriction since we are only interested in solutions close to the compact homoclinic loop $\mathrm{cl}\, h_V(\mathbb{R}) = h_V(\mathbb{R}) \cup \{0\}$, and one can achieve the desired properties by a modification of the vectorfield outside a neighbourhood of $\mathrm{cl}\, h_V(\mathbb{R})$. — Then the solutions of Eq. (1.1) constitute a continuously differentiable flow $F_V : \mathbb{R} \times \mathbb{R}^3 \to \mathbb{R}^3$. In the sequel we describe how to transform F_V into a flow F with the properties (F1)–(F5) stated in Section 2.

Choose eigenvectors $w \in \mathbb{R}^3$ for the eigenvalue $u > 0$ of $DV(0)$, and $z \in \mathbb{C}^3$ for the eigenvalue $\sigma + i\,\mu$ of the complexification of $DV(0)$. Set $w_1 = \Re z \in \mathbb{R}^3$ and $w_2 = \Im z \in \mathbb{R}^3$. Then $E_s = \mathbb{R}w_1 \oplus \mathbb{R}w_2$ and $E_u = \mathbb{R}w$ are invariant under $DV(0)$. For the isomorphism $B : \mathbb{R}^3 \to \mathbb{R}^3$ given by $Be_1 = w_1, Be_2 = w_2, Be_3 = w$ we have that the linear map $B^{-1}DV(0)B$ is multiplication with the matrix

$$A = \begin{pmatrix} \sigma & \mu & 0 \\ -\mu & \sigma & 0 \\ 0 & 0 & u \end{pmatrix},$$

which leaves $L = B^{-1}E_s$ and $U = B^{-1}E_u$ invariant.

Recall the local stable and unstable manifolds W_s and W_u of Eq. (1.1) at the origin. Given any $\lambda > 0$ we may assume that with some $r = r(\lambda) > 0$ they have the form

$$W_s = \{x + w_s(x) : x \in E_s, |x| < r\} \quad \text{and} \quad W_u = \{y + w_u(y) : y \in E_u, |y| < r\}$$

for continuously differentiable maps

$$w_s : \{x \in E_s : |x| < r\} \to E_u \quad \text{and} \quad w_u : \{y \in E_u : |y| < r\} \to E_s$$

which satisfy $w_s(0) = 0, Dw_s(0) = 0, w_u(0) = 0, Dw_u(0) = 0$, and

$$|Dw_s(x)| < \lambda \quad for \quad x \in E_s \quad \text{with} \quad |x| < r, \quad |Dw_u(y)| < \lambda \quad \text{for} \quad y \in E_u \quad \text{with} \quad |y| < r.$$

For sufficiently small neigbourhoods N of the origin in $\mathbb{R}^3$ the submanifolds W_s and W_u are invariant under F_V in N, and $F_V(t, x) \in N$ for all $t \geq 0$ implies $x \in W_s$ while $F_V(t, x) \in N$ for all $t \leq 0$ implies $x \in W_u$.

There exist $\hat{r} \in (0, r)$ and a continuously differentiable extension $\hat{w}_s : E_s \to E_u$ of the restriction of w_s to $\{x \in E_s : |x| \leq \hat{r}\}$ with $|D\hat{w}_s(x)| < \lambda$ on E_s, and analogously there is a continuously differentiable extension $\hat{w}_u : E_u \to E_s$ of the restriction of w_u to $\{y \in E_u : |y| \leq \hat{r}\}$ with $|D\hat{w}_u(y)| < \lambda$ on E_u. For $\lambda > 0$ sufficiently small the continuously differentiable map

$$S : \mathbb{R}^3 \to \mathbb{R}^3, \quad S(x + y) = x + y - \hat{w}_s(x) - \hat{w}_u(y) \quad \text{for } x \in E_s, y \in E_u,$$

with $S(0) = 0$ and $DS(0) = id_{\mathbb{R}^3}$ satisfies

$$|DS(z) - id_{\mathbb{R}^3}| \leq \frac{1}{2} \quad \text{for all } z \in \mathbb{R}^3.$$

It follows that all derivatives of S are isomorphisms. Using integration along line segments and the previous estimate one shows that S is one-to-one. In order to see that S is onto notice that for every $\zeta \in \mathbb{R}^3$ the map $z \mapsto \zeta - (S(z) - z)$ is a strict contraction, whose fixed point is a preimage of ζ under S. As all derivatives of S are isomorphisms applications of the Inverse Mapping Theorem yield that S^{-1} is continuously differentiable. Altogether, S is a diffeomorphism which maps $\hat{W}_s = \{x + \hat{w}_s(x) : x \in E_s\}$ onto E_s and $\hat{W}_u = \{y + \hat{w}_u(y) : y \in E_u\}$ onto E_u .

Define the continuously differentiable flow $F : \mathbb{R} \times \mathbb{R}^3 \to \mathbb{R}^3$ by

$$F(t,x) = B^{-1}S(F_V(t, S^{-1}(Bx))).$$

For all $t \in \mathbb{R}$, $F(t,0) = 0$, which is property (F1).

On (F2): Necessarily, $h_V'(t) \neq 0$ for all $t \in \mathbb{R}$. From the properties $h_V(t) \neq 0 \neq h_V'(t)$ for all $t \in \mathbb{R}$ and $\lim_{|t|\to\infty} h_V(t) = 0$ in combination with the fact that $B^{-1} \circ S$ is a diffeomorphism with fixed point 0 we infer that the flowline $h = B^{-1} \circ S \circ h_V$ of F satisfies $h(t) \neq 0 \neq h'(t)$ for all $t \in \mathbb{R}$ and $\lim_{|t|\to\infty} h(t) = 0$.

On (F3): For $t \in \mathbb{R}$ let $T(t) = D_2F(t,0)$. Then

$$T(t) = B^{-1}DS(0)D_2F_V(t, S^{-1}(B0))DS^{-1}(0)B = B^{-1}D_2F_V(t,0)B = B^{-1}e^{t\,DV(0)}B = e^{t\,B^{-1}DV(0)B}.$$

As the linear map $B^{-1}DV(0)B$ is multiplication by the matrix A we get $T(t)x = e^{t\,B^{-1}DV(0)B}x = e^{t\,A} \cdot x$ for all $x \in \mathbb{R}^3$ and $t \in \mathbb{R}$. It follows that $T(t)L \subset L$ and $T(t)U \subset U$ for every $t \in \mathbb{R}$. The representation of $y = T(t)x = e^{t\,A} \cdot x$ described in property (F3) is confirmed by solving the initial value problems

$$x' = Ax, \quad x(0) = e_\nu, \quad \nu = 1,2,3,$$

whose solutions coincide at $t \in \mathbb{R}$ with the columns of the matrix $e^{t\,A}$.

On (F4). We show that for a neighbourhood N of the origin in $\mathbb{R}^3$ so small that W_s is invariant under F_V in N and

$$|x| < \hat{r} \quad \text{for all} \quad x \in E_s \quad \text{and} \quad y \in E_u \quad \text{with} \quad x + y \in N$$

the space L is invariant under F in $\tilde{N} = B^{-1}S(N)$.

Proof. Let $z \in L \cap \tilde{N}$ and $t \in \mathbb{R}$ be given with $F(\tau, z) \in \tilde{N}$ for all $\tau \in t \cdot [0,1]$. As $B^{-1} \circ S$ maps $\hat{W}_s$ onto L we get $x = S^{-1}(Bz) \in \hat{W}_s \cap N$, and for every $\tau \in t \cdot [0,1]$,

$$F_V(\tau, x) = S^{-1}(BF(\tau, B^{-1}S(x))) = S^{-1}(BF(\tau, z)) \in S^{-1}(B\tilde{N}) = N.$$

By the choice of N, $|\xi| < \hat{r}$ for $\xi \in E_s$ with $x = \xi + \hat{w}_s(\xi)$. Hence $\hat{w}_s(\xi) = w_s(\xi)$, and thereby $x \in W_s \cap N$. The invariance of W_s under F_V in N yields $F_V(t,x) \in W_s \cap N$. As above, $|\xi_t| < \hat{r}$ for $\xi_t \in E_s$ with $F_V(t,x) = \xi_t + w_s(\xi_t)$. It follows that $w_s(\xi_t) = \hat{w}_s(\xi_t)$, and thereby

$$F(t,z) = B^{-1}S(F_V(t, S^{-1}(Bz))) = B^{-1}S(F_V(t,x)) = B^{-1}S(\xi_t + \hat{w}_s(\xi_t)) \in L,$$

which shows the desired invariance of L under F in $\tilde{N}$.

It follows easily that for some $r_L > 0$ the space L is invariant under F in $\{z \in \mathbb{R}^3 : |z| < r_L\}$. Analogously U is invariant under F in $\{z \in \mathbb{R}^3 : |z| < r_U\}$, for some $r_U > 0$. Let

$r_F = \min\{r_L, r_U\}$. Then both L and U are invariant under F in $\{z \in \mathbb{R}^3 : |z| < r_F\}$, which is property (F4).

On (F5). From $\lim_{t\to\infty} h_V(t) = 0$, $h_V(t) \in W_s \cap \{x + y : x \in E_s, y \in E_u, |x| < \hat{r}\}$ for $t > 0$ sufficiently large. By $\hat{w}_s(x) = w_s(x)$ for $x \in E_s$ with $|x| < \hat{r}$,

$$B^{-1}S(\{x + w_s(x) : x \in E_s, |x| < \hat{r}\}) \subset B^{-1}S(\hat{W}_s) = L.$$

Consequently, there is $t_L \in \mathbb{R}$ with $h(t) = B^{-1}S(h_V(t)) \in L$ for all $t \geq t_L$. Analogously, $h(t) \in U$ for all $t \leq t_U$, with some $t_u < t_L$. By continuity and $h(t) \neq 0$ everywhere, either $h(t) \in (0, \infty)e_3$ for all $t \leq t_U$, or $h(t) \in (-\infty, 0)e_3$ for all $t \leq t_U$.

Abstract. In this paper, modifications of the well-known desingularization method proposed by the first author are used to derive nonlinear versions of the Henry–Gronwall inequality for integral inequalities with the Ψ-Hilfer fractional integral, as well as nonlinear integral inequalities with iterated Ψ-Hilfer fractional integrals. The results are applied to obtain bounds for solutions of initial value problems for nonlinear Ψ-Caputo fractional differential equations, and sufficient conditions for the non-existence of blowing-up solutions.

Keywords: Ψ-Hilfer fractional integral inequality, generalized Henry–Gronwall inequality, iterated Ψ-Hilfer fractional integrals, Ψ-Caputo fractional derivative.

2020 Mathematics Subject Classification: 34A08, 34A40, 26A33, 26D10, 26D15.

1 Introduction and preliminaries

The monograph [5] by Dan Henry is devoted to the study of semilinear parabolic differential equations, where these equations are studied in the framework of so-called mild solutions of abstract evolution equations. The mild solutions are given as solutions of some Volterra integral equations with weakly singular kernels. One of the basic tools used there is a linear integral inequality with a weakly singular kernel, for which a generalization of the Gronwall inequality is proved (see [5, Lemma 7.1.1]). This result is being frequently quoted as Henry's lemma. Currently, this method is also applied in the theory of fractional differential equations. The first nonlinear version of the Henry's integral inequality is proved in the paper [12] by a

✉Corresponding author. Email: Michal.Pospisil@fmph.uniba.sk

new method, often referred to as the desingularization method. In this paper, we apply it to the following nonlinear integral inequalities:

$$u(t) \le a(t) + b(t) \int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{\alpha-1} \Psi'(s) F(s) \omega(u(s)) ds, \quad t \in [t_0, T]; \tag{1.1}$$

$$u(t) \le a(t) + \sum_{i=1}^{n} b_i(t) \int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{\alpha_i-1} \Psi'(s) F_i(s) \omega_i(u(s)) ds, \quad t \in [t_0, T]; \tag{1.2}$$

$$\begin{aligned} u(t) \le a(t) &+ b_1(t) \int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{\alpha-1} \Psi'(s) F_1(s) \omega_1(u(s)) ds \\ &+ b_2(t) \int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{\alpha-1} \Psi'(s) c(s) \\ &\times \int_{t_0}^{s} [\Psi(s) - \Psi(\sigma)]^{\beta-1} \Psi'(\sigma) F_2(\sigma) \omega_2(u(\sigma)) d\sigma \, ds, \quad t \in [t_0, T]; \end{aligned} \tag{1.3}$$

$$\begin{aligned} u(t) \le a(t) &+ b_1(t) \int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{\alpha-1} \Psi'(s) F_1(s) \omega_1(u(s)) ds \\ &+ b_2(t) \int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{\alpha-1} \Psi'(s) F_2(s) \\ &\times \omega_2 \left(b_3(s) \int_{t_0}^{s} [\Psi(s) - \Psi(\sigma)]^{\beta-1} \Psi'(\sigma) F_3(\sigma) \omega_3(u(\sigma)) d\sigma \right) ds, \quad t \in [t_0, T]. \end{aligned} \tag{1.4}$$

For the readers' convenience, we recall the following definitions from the tempered Ψ-fractional calculus.

Definition 1.1 ([4,16]). Let $\alpha > 0$, $\lambda \ge 0$, x be a continuous function on $[t_0, T]$, and $\Psi \in C^1[t_0, T]$ satisfy $\Psi'(t) > 0$ for all $t \in [t_0, T]$. Tempered Ψ-Hilfer fractional integral of order $\alpha > 0$ is defined by

$$I_{t_0}^{\alpha,\lambda,\Psi} x(t) = \frac{1}{\Gamma(\alpha)} \int_{t_0}^{t} (\Psi(t) - \Psi(s))^{\alpha-1} \, \mathrm{e}^{-\lambda(\Psi(t)-\Psi(s))} \, \Psi'(s) \, x(s) \, ds$$

for $t \in [t_0, T]$, where $\Gamma(\cdot)$ is the Euler gamma function.

Definition 1.2 ([19]). Let $\Psi \in C^n[t_0, T]$, $n \in \mathbb{N}$ be such that $\Psi'(t) > 0$ for all $t \in [t_0, T]$. For $n - 1 < \alpha < n$, $\lambda \ge 0$, tempered Ψ-Caputo fractional derivative of order α of $x \in C^{n-1}[t_0, T]$ is defined by

$${}^{C}D_{t_0}^{\alpha,\lambda,\Psi} x(t) = {}^{RL}D_{t_0}^{\alpha,\lambda,\Psi} \left[x(t) - \mathrm{e}^{-\lambda\Psi(t)} \sum_{k=0}^{n-1} \frac{x_{\lambda,\Psi}^{[k]}(t_0)}{k!} (\Psi(t) - \Psi(t_0))^k \right]$$

for $t \in [t_0, T]$ whenever the right side makes sense, where

$$x_{\lambda,\Psi}^{[n]}(t) = \left(\frac{1}{\Psi'(t)} \frac{d}{dt} \right)^n \left(\mathrm{e}^{\lambda\Psi(t)} \, x(t) \right)$$

and

$$\begin{aligned} {}^{RL}D_{t_0}^{\alpha,\lambda,\Psi} x(t) &= \mathrm{e}^{-\lambda\Psi(t)} \left(I_{t_0}^{n-\alpha,\lambda,\Psi} x(t) \right)_{\lambda,\Psi}^{[n]} \\ &= \frac{\mathrm{e}^{-\lambda\Psi(t)}}{\Gamma(n-\alpha)} \left(\frac{1}{\Psi'(t)} \frac{d}{dt} \right)^n \int_{t_0}^{t} (\Psi(t) - \Psi(s))^{n-\alpha-1} \Psi'(s) \, \mathrm{e}^{\lambda\Psi(s)} \, x(s) \, ds \end{aligned}$$

is the tempered Ψ-Riemann–Liouville fractional derivative of order α.

It is worth to note that if $x \in C^n[t_0, T]$, then ${}^C D^{\alpha,\lambda,\Psi}_{t_0} x(t)$ may be expressed as

$$ {}^C D^{\alpha,\lambda,\Psi}_{t_0} x(t) = \frac{\mathrm{e}^{-\lambda\Psi(t)}}{\Gamma(n-\alpha)} \int_{t_0}^{t} (\Psi(t) - \Psi(s))^{n-\alpha-1} \Psi'(s) x^{[n]}_{\lambda,\Psi}(s)\, ds $$

(see [16,19]). In this case, since $x^{[n]}_{\lambda,\Psi} \in C[t_0, T]$, Lemma 1 of [20] yields that ${}^C D^{\alpha,\lambda,\Psi}_{t_0} x \in C[t_0, T]$.

We refer the reader to papers [4,16,18–20] for the properties of these operators. The above notions generalize Ψ-Hilfer fractional integral from [7], $I^{\alpha,\Psi}_{t_0} = I^{\alpha,0,\Psi}_{t_0}$, and Ψ-Caputo fractional derivative from [1], ${}^C D^{\alpha,\Psi}_{t_0} = {}^C D^{\alpha,0,\Psi}_{t_0}$, which we use in this paper.

In the paper [18], the following integral inequality with the tempered Ψ-Hilfer fractional integral is studied:

$$ u(t) \le a(t) + b(t) \int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{\alpha-1} \mathrm{e}^{-\lambda[\Psi(t)-\Psi(s)]} \Psi'(s) F(s) \omega(u(s)) ds, \ t \in [t_0, T). $$

The obtained Henry–Gronwall inequality is proved under the assumption $\lambda > 0$. The method of desingularization applied in the proof is not suitable for the inequality with $\lambda = 0$, i.e., for inequality (1.1). In this case, we need to apply a modification of the desingularization method proposed in the paper [12].

In [21, Theorem 3], inequality (1.1) is studied for $\omega(u) = u$, $F(t) \equiv 1$ and an estimation of u is obtained in a form of a series. Here, we investigate nonlinear analogues (see Corollaries 2.5, 2.13). Similarly, Corollaries 2.7, 2.15 generalize e.g. [11, Theorem 1.4], where inequality (1.2) is investigated with $\Psi(t) = t$, $F_i(t) \equiv 1$ and $\omega_i(u) = u$ for each $i = 1, 2, \dots, n$.

Inequality (1.1) with $\alpha \in (0,1)$, $\Psi(t) = t$, $a(t) = at^{-\mu}$, and $b(t) = bt^{-\nu}$ with various values of parameters μ, ν is studied in [6,23–25]. In [9], inequality (1.1) is investigated with $\Psi(t) = t$, $\alpha \in (0,1)$, but instead of non-decreasing ω, $\widehat{\omega}$ is considered such that $\widehat{\omega}^p(u) \le \omega(u^p)$ for $p > 1/\alpha$ and some non-decreasing ω. In [22], (1.1) is studied with $\Psi(t) = t$, $\alpha \in (0,1)$, $F(t) = t^{-\gamma}$, $\gamma \ge 0$ and $1 - \alpha + \gamma < 1$; also the case $a(t) = at^{-\mu}$ is considered.

Other integral inequalities useful for fractional calculus can be found e.g. in [2,19].

Throughout the whole paper, for generality, we consider inequality (1.1) as well as others on an interval $[t_0, T]$ for some $t_0 < T \le \infty$, where the case $T = \infty$ is understood as $[t_0, \infty)$. We use the notation $\mathbb{N}$ for the set of all positive integers, and $\|\cdot\|$ for any vector norm in $\mathbb{R}^N$, $N \in \mathbb{N}$.

The paper is structured as follows. In the next section, we derive the main results of the paper – the nonlinear integral inequalities for weakly singular integrals. We apply two types of desingularization, namely with inserting an auxiliary exponential function and without it. The inequalities are applied in Section 3 to obtain boundedness results for solutions of nonlinear fractional differential equations, and sufficient conditions for the non-existence of solutions blowing-up in a finite time. Lastly, Section 4 concludes the results and sketches directions of future research.

2 Nonlinear integral inequalities and their corollaries

This section is devoted to integral inequalities (1.1)–(1.4). It is split in two subsections according to a method used to desingularize the fractional integral, i.e., to get rid of the singular kernel.

For the case of brevity, we introduce the notation for classes of functions,

$$\mathfrak{P}_M^k := \{\varphi \in C^k(M) \mid \varphi'(t) > 0 \text{ for all } t \in M\},$$
$$\mathfrak{O} := \{\varphi \in C([0,\infty),[0,\infty)) \mid \varphi(t) > 0\ \forall t > 0,\ \varphi \text{ is non-decreasing}\}.$$

In our proofs, we rely on a generalization of the well-known Bihari's inequality [3, 10] that was proved in [9]. Next, we provide its version sufficient for our purposes.

Theorem 2.1. *Let a, b, F be non-negative, continuous functions on $[t_0, T]$. Let $\omega \in \mathfrak{O}$ and u be a non-negative continuous function on $[t_0, T]$, satisfying*

$$u(t) \le a(t) + b(t) \int_{t_0}^{t} F(s)\omega(u(s))\, ds, \quad t \in [t_0, T].$$

Then

$$u(t) \le \Omega^{-1}\left(\Omega(A(t)) + B(t) \int_{t_0}^{t} F(s)\, ds\right), \quad t \in [t_0, t_1],$$

where $t_1 \in (t_0, T]$ is such that

$$\Omega(A(t_1)) + B(t_1) \int_{t_0}^{t_1} F(s)\, ds \in \operatorname{Dom} \Omega^{-1},$$

$\Omega(v) = \int_{v_0}^{v} \frac{1}{\omega(\sigma)} d\sigma$ for $v \ge v_0 > 0$, Ω^{-1} is the inverse of Ω, $A(t) = \sup_{s\in[t_0,t]} a(s)$, $B(t) = \sup_{s\in[t_0,t]} b(s)$.

It should be noted that in [9, Theorem 1] the latter result is proved for positive functions a and b, and with $F \in L^1[t_0, T]$ positive on a set of positive measure. Then, in [9, Remark 1], a is allowed to be non-negative if $\omega(t) > 0$ for all $t > 0$. Since we use continuous functions, if there does not exist a set of positive measure where F is positive, then $F \equiv 0$ and the statement holds trivially. Next, if $b(t_0) > 0$ then $B(t_0) > 0$ which is sufficient for the proof to work. If $b(t) = 0$ for all $t \in [t_0, t_0 + h]$ for some $h > 0$ then, again, the statement clearly holds for all those t. Moreover, if $\int_0 \frac{1}{\omega(\sigma)} d\sigma$ converges, one can set $v_0 = 0$. Therefore, we allow $v_0 \ge 0$ in this paper.

2.1 Parametric desingularization

Here we apply a parameter-dependent modification of the desingularization method from [12], where an exponential function was added and the Hölder inequality was applied to tame the weakly singular integral kernel. So, we are able to prove the following nonlinear Henry–Gronwall type inequality.

Theorem 2.2. *Let $\alpha \in (0,1)$, $\alpha q > 1$, $\mu > 0$, a, b and F be non-negative, continuous functions on $[t_0, T]$, and $\Psi \in \mathfrak{P}^1_{[t_0,T]}$. Let $\omega \in \mathfrak{O}$ and u be a non-negative continuous function on $[t_0, T]$, satisfying inequality (1.1). Then*

$$u(t) \le \left[\Omega^{-1}\left(\Omega(A(t)) + B(t) \int_{t_0}^{t} \Psi'(s) F(s)^q \, \mathrm{e}^{-q\mu\Psi(s)}\, ds\right)\right]^{1/q}, \quad t \in [t_0, t_1], \tag{2.1}$$

where $t_1 \in (t_0, T]$ is such that

$$\Omega(A(t_1)) + B(t_1) \int_{t_0}^{t_1} \Psi'(s) F(s)^q \, \mathrm{e}^{-q\mu\Psi(s)}\, ds \in \operatorname{Dom} \Omega^{-1}, \tag{2.2}$$

$\Omega(v) = \int_{v_0}^{v} \frac{1}{[\omega(\sigma^{1/q})]^q} d\sigma$ *for* $v \geq v_0 \geq 0$, Ω^{-1} *is the inverse of* Ω, *and*

$$A(t) = 2^{q-1} \sup_{s\in[t_0,t]} a(s)^q, \quad B(t) = 2^{q-1} M_{p,\mu,\alpha}^q \sup_{s\in[t_0,t]} \left\{ b(s)^q \, \mathrm{e}^{q\mu\Psi(s)} \right\},$$
$$M_{p,\mu,\alpha} = \left(\frac{\Gamma(p(\alpha-1)+1)}{(p\mu)^{p(\alpha-1)+1}} \right)^{1/p}, \quad p = \frac{q}{q-1}. \tag{2.3}$$

In the proof of this theorem, we will need the following generalization of the inequality from [12, page 354].

Lemma 2.3. *Let* $\alpha \in (0,1)$, $p > 0$, $p(\alpha-1)+1 > 0$, $\mu > 0$, *and* $\Psi(t) \in \mathfrak{P}^1_{[t_0,T]}$. *Then*

$$\int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{p(\alpha-1)} \, \mathrm{e}^{p\mu\Psi(s)} \, \Psi'(s) ds \leq M_{p,\mu,\alpha}^p \, \mathrm{e}^{p\mu\Psi(t)}, \quad t \in [t_0, T], \tag{2.4}$$

where $M_{p,\mu,\alpha}$ *is given by the formula* (2.3).

Proof. Using the substitution $\Psi(t) - \Psi(s) = \sigma$ one can rewrite the left-hand side of inequality (2.4) as

$$\int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{p(\alpha-1)} \, \mathrm{e}^{p\mu\Psi(s)} \, \Psi'(s) ds = \int_{0}^{\Psi(t)-\Psi(t_0)} \sigma^{p(\alpha-1)} \, \mathrm{e}^{p\mu(\Psi(t)-\sigma)} \, d\sigma$$
$$= \mathrm{e}^{p\mu\Psi(t)} \int_{t_0}^{\Psi(t)-\Psi(t_0)} \sigma^{p(\alpha-1)} \, \mathrm{e}^{-p\mu\sigma} \, d\sigma \leq \mathrm{e}^{p\mu\Psi(t)} \int_{0}^{\infty} \sigma^{p(\alpha-1)} \, \mathrm{e}^{-p\mu\sigma} \, d\sigma = M_{p,\mu,\alpha}^p \, \mathrm{e}^{p\mu\Psi(t)}. \square$$

Now, we present the proof of Theorem 2.2.

Proof of Theorem 2.2. First notice that $q > \frac{1}{\alpha} > 1$. Thus, $p(\alpha-1)+1 > 0$ and $M_{p,\mu,\alpha}$ is well defined. Since $\frac{1}{p} + \frac{1}{q} = 1$, we can write $\Psi'(t) = \Psi'(t)^{1/p} \Psi'(t)^{1/q}$. Using the Hölder inequality and Lemma 2.3, we derive

$$\begin{aligned}
&\int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{\alpha-1} \Psi'(s) F(s) \omega(u(s)) ds \\
&\quad = \int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{\alpha-1} \, \mathrm{e}^{\mu\Psi(s)} \, \Psi'(s)^{1/p} F(s) \, \mathrm{e}^{-\mu\Psi(s)} \, \Psi'(s)^{1/q} \omega(u(s)) ds \\
&\quad \leq \left(\int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{p(\alpha-1)} \, \mathrm{e}^{p\mu\Psi(s)} \, \Psi'(s) ds \right)^{1/p} \left(\int_{t_0}^{t} F(s)^q \, \mathrm{e}^{-q\mu\Psi(s)} \, \Psi'(s) \omega(u(s))^q ds \right)^{1/q} \\
&\quad \leq M_{p,\mu,\alpha} \, \mathrm{e}^{\mu\Psi(t)} \left(\int_{t_0}^{t} F(s)^q \, \mathrm{e}^{-q\mu\Psi(s)} \, \Psi'(s) \omega(u(s))^q ds \right)^{1/q}.
\end{aligned} \tag{2.5}$$

Hence, this inequality along with (1.1) yield

$$u(t) \leq a(t) + b(t) M_{p,\mu,\alpha} \, \mathrm{e}^{\mu\Psi(t)} \left(\int_{t_0}^{t} F(s)^q \, \mathrm{e}^{-q\mu\Psi(s)} \, \Psi'(s) \omega(u(s))^q ds \right)^{1/q}. \tag{2.6}$$

Using the inequality $(b_1 + b_2)^q \leq 2^{q-1}(b_1^q + b_2^q)$ valid for any $b_1, b_2 \geq 0$, we obtain

$$v(t) \leq 2^{q-1} a(t)^q + 2^{q-1} b(t)^q M_{p,\mu,\alpha}^q \, \mathrm{e}^{q\mu\Psi(t)} \int_{t_0}^{t} F(s)^q \, \mathrm{e}^{-q\mu\Psi(s)} \, \Psi'(s) \omega(u(s))^q ds$$
$$= 2^{q-1} a(t)^q + 2^{q-1} b(t)^q M_{p,\mu,\alpha}^q \, \mathrm{e}^{q\mu\Psi(t)} \int_{t_0}^{t} F(s)^q \, \mathrm{e}^{-q\mu\Psi(s)} \, \Psi'(s) \omega(v(s)^{1/q})^q ds,$$

where $v(t) = u(t)^q$. Consequently, Theorem 2.1 implies

$$v(t) \le \Omega^{-1}\left(\Omega(A(t)) + B(t)\int_{t_0}^{t} F(s)^q \,\mathrm{e}^{-q\mu\Psi(s)}\,\Psi'(s)ds\right),$$

where A, B, Ω and Ω^{-1} are as in the theorem. This proves inequality (2.1). □

Remark 2.4. Since functions A, B, Ω are non-decreasing and $\Psi'(t)F(t)^q\,\mathrm{e}^{-q\mu\Psi(t)} \ge 0$ for all $t \in [t_0, T]$, condition (2.2) is equivalent to

$$\Omega(A(t)) + B(t)\int_{t_0}^{t} \Psi'(s)F(s)^q\,\mathrm{e}^{-q\mu\Psi(s)}\,ds \in \operatorname{Dom}\Omega^{-1}$$

for all $t \in [t_0, t_1]$.

Some of corollaries of Theorem 2.2 are explicitly stated below.

Corollary 2.5. *Let the assumptions of Theorem 2.2 be fulfilled with $\omega(u) = u$, i.e., let u satisfy*

$$u(t) \le a(t) + b(t)\int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{\alpha-1}\Psi'(s)F(s)u(s)ds, \quad t \in [t_0, T].$$

Then

$$u(t) \le A(t)^{1/q}\exp\left\{\frac{B(t)}{q}\int_{t_0}^{t} F(s)^q\,\mathrm{e}^{-q\mu\Psi(s)}\,\Psi'(s)ds\right\}, \quad t \in [t_0, T],$$

where functions A, B are given by (2.3).

Proof. Putting the particular form of ω in the statement of Theorem 2.2 immediately yields $\Omega(v) = \ln\frac{v}{v_0}$ for $v \ge v_0 > 0$, $\Omega^{-1}(v) = v_0\,\mathrm{e}^v$ for $v \ge 0$, $v_0 > 0$, and the corollary follows from (2.1). □

Corollary 2.6. *Let the assumptions of Theorem 2.2 be fulfilled with $\omega(u) = u^m$ for $m > 0$, $m \ne 1$, i.e., let u satisfy*

$$u(t) \le a(t) + b(t)\int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{\alpha-1}\Psi'(s)F(s)u(s)^m ds, \quad t \in [t_0, T].$$

Then, the following assertions hold:

1. *if $0 < m < 1$, then*

$$u(t) \le \left(A(t)^{1-m} + (1-m)B(t)\int_{t_0}^{t} F(s)^q\,\mathrm{e}^{-q\mu\Psi(s)}\,\Psi'(s)ds\right)^{\frac{1}{q(1-m)}}, \quad t \in [t_0, T];$$

2. *if $m > 1$, then*

$$u(t) \le \frac{A(t)^{1/q}}{\left(1 - (m-1)A(t)^{m-1}B(t)\int_{t_0}^{t} F(s)^q\,\mathrm{e}^{-q\mu\Psi(s)}\,\Psi'(s)ds\right)^{\frac{1}{q(m-1)}}}, \quad t \in [t_0, t_1]$$

for any $t_1 \in (t_0, T]$ such that

$$\int_{t_0}^{t_1} F(s)^q\,\mathrm{e}^{-q\mu\Psi(s)}\,\Psi'(s)ds < \frac{1}{(m-1)A(t_1)^{m-1}B(t_1)};$$

where functions A, B are given by (2.3).

Proof. The statement can be obtained analogously to Corollary 2.5 with $\omega(u) = u^m$. Note that here we use the fact that functions A, B are non-decreasing. □

Theorem 2.2 can also be easily extended to the case of multiple Ψ-Hilfer fractional integrals:

Corollary 2.7. *Let $n \in \mathbb{N}$, $\alpha_i \in (0,1)$ for $i = 1,2,\dots,n$, $q \min_{i=1,2,\dots,n} \alpha_i > 1$, $\mu > 0$, a, b_i and F_i be non-negative, continuous functions on $[t_0,T]$ for each $i = 1,2,\dots,n$, and $\Psi \in \mathfrak{P}^1_{[t_0,T]}$. Let $\omega_i \in \mathfrak{O}$ for each $i = 1,2,\dots,n$ and u be a non-negative continuous function on $[t_0,T]$, satisfying inequality (1.2). Then,*

$$u(t) \le \left[\Omega^{-1}\left(\Omega(A(t)) + B(t)\int_{t_0}^{t} \Psi'(s)F(s)^q \,\mathrm{e}^{-q\mu\Psi(s)}\,ds\right)\right]^{1/q}, \quad t \in [t_0,t_1],$$

where $t_1 \in (t_0,T]$ is such that

$$\Omega(A(t_1)) + B(t_1)\int_{t_0}^{t_1} \Psi'(s)F(s)^q \,\mathrm{e}^{-q\mu\Psi(s)}\,ds \in \operatorname{Dom}\Omega^{-1},$$

$\Omega(v) = \int_{v_0}^{v} \frac{1}{[\omega(\sigma^{1/q})]^q} d\sigma$ for $v \ge v_0 \ge 0$, Ω^{-1} is the inverse of Ω, and

$$F = \max_{i=1,2,\dots,n} F_i, \quad \omega = \max_{i=1,2,\dots,n} \omega_i,$$

$$A(t) = 2^{q-1} \sup_{s\in[t_0,t]} a(s)^q, \quad B(t) = 2^{q-1} \sup_{s\in[t_0,t]} \left(\sum_{i=1}^{n} M_{p,\mu,\alpha_i} b_i(s)\,\mathrm{e}^{\mu\Psi(s)}\right)^q,$$

$$M_{p,\mu,\alpha} = \left(\frac{\Gamma(p(\alpha-1)+1)}{(p\mu)^{p(\alpha-1)+1}}\right)^{1/p}, \quad p = \frac{q}{q-1}.$$

Proof. The right-hand side of inequality (1.2) can be estimated from above by

$$\begin{aligned} &a(t) + \sum_{i=1}^{n} b_i(t)\int_{t_0}^{t} [\Psi(t)-\Psi(s)]^{\alpha_i-1}\Psi'(s)F(s)\omega(u(s))ds \\ &\quad \le a(t) + \sum_{i=1}^{n} b_i(t) M_{p,\mu,\alpha_i}\,\mathrm{e}^{\mu\Psi(t)} \left(\int_{t_0}^{t} F(s)^q\,\mathrm{e}^{-q\mu\Psi(s)}\,\Psi'(s)\omega(u(s))^q ds\right)^{1/q} \end{aligned}$$

as in (2.5). Then the proof is finished as the proof of Theorem 2.2. □

Next, we give an estimation of function u satisfying inequality (1.3).

Theorem 2.8. *Let $\alpha,\beta \in (0,1)$, $\alpha+\beta < 1$, $\alpha q > 1$, $\mu > 0$, a, b_1, b_2, c, F_1 and F_2 be non-negative, continuous functions on $[t_0,T]$, and $\Psi \in \mathfrak{P}^1_{[t_0,T]}$. Let $\omega_1,\omega_2 \in \mathfrak{O}$ and u be a non-negative continuous function on $[t_0,T]$, satisfying inequality (1.3). Then,*

$$u(t) \le \left[\Omega^{-1}\left(\Omega(A(t)) + B(t)\int_{t_0}^{t} \Psi'(s)G(s)^q \,\mathrm{e}^{-q\mu\Psi(s)}\,ds\right)\right]^{1/q}, \quad t \in [t_0,t_1],$$

where $t_1 \in (t_0,T]$ is such that

$$\Omega(A(t_1)) + B(t_1)\int_{t_0}^{t_1} \Psi'(s)G(s)^q \,\mathrm{e}^{-q\mu\Psi(s)}\,ds \in \operatorname{Dom}\Omega^{-1},$$

$\Omega(v) = \int_{v_0}^{v} \frac{1}{[\omega(\sigma^{1/q})]^q} d\sigma$ *for* $v \geq v_0 \geq 0$, Ω^{-1} *is the inverse of* Ω, *and*

$$G = \max\{F_1, F_2\}, \quad \omega = \max\{\omega_1, \omega_2\}, \quad A(t) = 2^{q-1} \sup_{s\in[t_0,t]} a(s)^q,$$

$$B(t) = 2^{q-1} \sup_{s\in[t_0,t]} \left\{ \mathrm{e}^{q\mu\Psi(s)} \left(b_1(s) M_{p,\mu,\alpha} + B(\alpha,\beta) b_2(s) M_{p,\mu,\alpha+\beta} \sup_{\sigma\in[t_0,s]} c(\sigma) \right)^q \right\}, \tag{2.7}$$

$$M_{p,\mu,\alpha} = \left(\frac{\Gamma(p(\alpha-1)+1)}{(p\mu)^{p(\alpha-1)+1}} \right)^{1/p}, \quad p = \frac{q}{q-1},$$

$B(\cdot,\cdot)$ *is the Euler beta function.*

Proof. By a trivial estimation using functions G and ω, and applying (2.5), we get

$$\begin{aligned}
u(t) &\leq a(t) + b_1(t) \int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{\alpha-1} \Psi'(s) G(s) \omega(u(s)) ds \\
&\quad + b_2(t) \int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{\alpha-1} \Psi'(s) c(s) \\
&\quad \times \int_{t_0}^{s} [\Psi(s) - \Psi(\sigma)]^{\beta-1} \Psi'(\sigma) G(\sigma) \omega(u(\sigma)) d\sigma\, ds \\
&\leq a(t) + b_1(t) M_{p,\mu,\alpha}\, \mathrm{e}^{\mu\Psi(t)} \left(\int_{t_0}^{t} G(s)^q\, \mathrm{e}^{-q\mu\Psi(s)}\, \Psi'(s) \omega(u(s))^q ds \right)^{1/q} \\
&\quad + b_2(t) \sup_{s\in[t_0,t]} c(s) \int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{\alpha-1} \Psi'(s) \\
&\quad \times \int_{t_0}^{s} [\Psi(s) - \Psi(\sigma)]^{\beta-1} \Psi'(\sigma) G(\sigma) \omega(u(\sigma)) d\sigma\, ds.
\end{aligned}$$

Changing the order of integration and by the change of variable $\Psi(t) - \Psi(s) = \rho(\Psi(t) - \Psi(\sigma))$, we derive

$$\begin{aligned}
&\int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{\alpha-1} \Psi'(s) \int_{t_0}^{s} [\Psi(s) - \Psi(\sigma)]^{\beta-1} \Psi'(\sigma) G(\sigma) \omega(u(\sigma)) d\sigma\, ds \\
&\quad = \int_{t_0}^{t} \Psi'(\sigma) G(\sigma) \omega(u(\sigma)) \left(\int_{\sigma}^{t} [\Psi(t) - \Psi(s)]^{\alpha-1} \Psi'(s) [\Psi(s) - \Psi(\sigma)]^{\beta-1} ds \right) d\sigma \\
&\quad = \int_{t_0}^{t} \Psi'(\sigma) G(\sigma) \omega(u(\sigma)) [\Psi(t) - \Psi(\sigma)]^{\alpha+\beta-1} \left(\int_{0}^{1} \rho^{\alpha-1} (1-\rho)^{\beta-1} d\rho \right) d\sigma \\
&\quad = B(\alpha,\beta) \int_{t_0}^{t} [\Psi(t) - \Psi(\sigma)]^{\alpha+\beta-1} \Psi'(\sigma) G(\sigma) \omega(u(\sigma)) d\sigma.
\end{aligned}$$

Now, we apply an estimation analogous to (2.5) to estimate the latter right-hand side by

$$B(\alpha,\beta) M_{p,\mu,\alpha+\beta}\, \mathrm{e}^{\mu\Psi(t)} \left(\int_{t_0}^{t} G(s)^q\, \mathrm{e}^{-q\mu\Psi(s)}\, \Psi'(s) \omega(u(s))^q ds \right)^{1/q}.$$

So, we arrive at

$$\begin{aligned}
u(t) &\leq a(t) + \left(b_1(t) M_{p,\mu,\alpha} + B(\alpha,\beta) b_2(t) M_{p,\mu,\alpha+\beta} \sup_{s\in[t_0,t]} c(s) \right) \mathrm{e}^{\mu\Psi(t)} \\
&\quad \times \left(\int_{t_0}^{t} G(s)^q\, \mathrm{e}^{-q\mu\Psi(s)}\, \Psi'(s) \omega(u(s))^q ds \right)^{1/q},
\end{aligned}$$

which is of the form of (2.6). Hence, the proof is finished by the same way as the proof of Theorem 2.2. □

Finally, we investigate inequality (1.4).

Theorem 2.9. *Let $\alpha, \beta \in (0,1)$, $q\min\{\alpha,\beta\} > 1$, $\mu > 0$, a, b_1, b_2, b_3, F_1, F_2, F_3 be non-negative, continuous functions on $[t_0, T]$, and $\Psi \in \mathfrak{P}^1_{[t_0,T]}$. Let $\omega_1, \omega_2, \omega_3 \in \mathfrak{O}$ and u be a non-negative continuous function on $[t_0, T]$, satisfying inequality (1.4). Then,*

$$u(t) \le \left[\Omega^{-1}\left(\Omega(A(t)) + B(t)\int_{t_0}^{t} G(s)^q\, \mathrm{e}^{-q\mu\Psi(s)}\,\Psi'(s)ds \right.\right. \\ \left.\left. + C(t)\int_{t_0}^{t} F_2(s)^q\, \mathrm{e}^{-q\mu\Psi(s)}\,\Psi'(s)ds\right)\right]^{1/q}, \quad t \in [t_0, t_1],$$

where $t_1 \in (t_0, T]$ is such that

$$\Omega(A(t_1)) + B(t_1)\int_{t_0}^{t_1} G(s)^q\, \mathrm{e}^{-q\mu\Psi(s)}\,\Psi'(s)ds + C(t_1)\int_{t_0}^{t_1} F_2(s)^q\, \mathrm{e}^{-q\mu\Psi(s)}\,\Psi'(s)ds \in \operatorname{Dom}\Omega^{-1},$$

$\Omega(v) = \int_{v_0}^{v} \frac{1}{[\omega(\sigma^{1/q})]^q} d\sigma$ for $v \ge v_0 \ge 0$, Ω^{-1} is the inverse of Ω, and

$$\begin{gathered} G = \max\{F_1, F_3\}, \quad \omega = \max\{\omega_1, \omega_2, \omega_3\}, \quad b = \max\{b_1, b_3\}, \\ A(t) = 3^{q-1}\sup_{s\in[t_0,t]} a(s)^q, \quad B(t) = 3^{q-1}M^q_{p,\mu}\sup_{s\in[t_0,t]}\left\{b(s)^q\,\mathrm{e}^{q\mu\Psi(s)}\right\}, \\ C(t) = 3^{q-1}M^q_{p,\mu,\alpha}\sup_{s\in[t_0,t]}\left\{b_2(s)^q\,\mathrm{e}^{q\mu\Psi(s)}\right\}, \quad M_{p,\mu} = \max\{M_{p,\mu,\alpha}, M_{p,\mu,\beta}\}, \\ M_{p,\mu,\alpha} = \left(\frac{\Gamma(p(\alpha-1)+1)}{(p\mu)^{p(\alpha-1)+1}}\right)^{1/p}, \quad p = \frac{q}{q-1}. \end{gathered} \tag{2.8}$$

To prove Theorem 2.9, we need the following auxiliary result.

Lemma 2.10. *Let a, b, c, f, g be non-negative, continuous functions on $[t_0, T]$. Let $\omega \in \mathfrak{O}$ and u be a non-negative continuous function on $[t_0, T]$, satisfying*

$$u(t) \le a(t) + b(t)\int_{t_0}^{t} f(s)\omega(u(s))ds \\ + c(t)\int_{t_0}^{t} g(s)\omega\left(b(s)\int_{t_0}^{s} f(\sigma)\omega(u(\sigma))d\sigma\right)ds, \quad t \in [t_0, T]. \tag{2.9}$$

Then,

$$u(t) \le \Omega^{-1}\left(\Omega(\bar{a}(t)) + \bar{b}(t)\int_{t_0}^{t} f(s)ds + \bar{c}(t)\int_{t_0}^{t} g(s)ds\right), \quad t \in [t_0, t_1], \tag{2.10}$$

where $t_1 \in (t_0, T]$ is such that

$$\Omega(\bar{a}(t_1)) + \bar{b}(t_1)\int_{t_0}^{t_1} f(s)ds + \bar{c}(t_1)\int_{t_0}^{t_1} g(s)ds \in \operatorname{Dom}\Omega^{-1},$$

$\Omega(v) = \int_{v_0}^{v} \frac{d\sigma}{\omega(\sigma)}$ for $v \ge v_0 \ge 0$, Ω^{-1} is the inverse of Ω, and

$$\bar{a}(t) = \sup_{s\in[t_0,t]} a(s), \quad \bar{b}(t) = \sup_{s\in[t_0,t]} b(s), \quad \bar{c}(t) = \sup_{s\in[t_0,t]} c(s).$$

Proof. Let $\widetilde{T} \in (t_0, T]$ be sufficiently small (this is specified later) and fixed. From (2.9), for any $t \in [t_0, \widetilde{T}]$,

$$\begin{aligned} u(t) &\le \bar{a}(\widetilde{T}) + \bar{b}(\widetilde{T}) \int_{t_0}^{t} f(s)\omega(u(s))ds \\ &\quad + \bar{c}(\widetilde{T}) \int_{t_0}^{t} g(s)\omega\left(\bar{b}(\widetilde{T}) \int_{t_0}^{s} f(\sigma)\omega(u(\sigma))d\sigma\right) ds =: z(t). \end{aligned}$$

It is easy to see that function z is non-negative, non-decreasing, C^1, and $z(t_0) = \bar{a}(\widetilde{T})$. Differentiating, we obtain

$$\begin{aligned} z'(t) &\le \bar{b}(\widetilde{T})f(t)\omega(u(t)) + \bar{c}(\widetilde{T})g(t)\omega\left(\bar{b}(\widetilde{T}) \int_{t_0}^{t} f(s)\omega(u(s))ds\right) \\ &\le \bar{b}(\widetilde{T})f(t)\omega(z(t)) + \bar{c}(\widetilde{T})g(t)\omega(z(t)) \end{aligned}$$

for all $t \in [t_0, \widetilde{T}]$. Integrating over $[t_0, t]$ yields

$$z(t) \le \bar{a}(\widetilde{T}) + \int_{t_0}^{t} \left(\bar{b}(\widetilde{T})f(s) + \bar{c}(\widetilde{T})g(s)\right) \omega(z(s))ds, \quad t \in [t_0, \widetilde{T}].$$

Now, applying Theorem 2.1 results in

$$u(t) \le z(t) \le \Omega^{-1}\left(\Omega(\bar{a}(\widetilde{T})) + \int_{t_0}^{t} \bar{b}(\widetilde{T})f(s) + \bar{c}(\widetilde{T})g(s)ds\right)$$

for all $t \in [t_0, \widetilde{T}]$. In particular, this estimation holds for $t = \widetilde{T}$ and we obtain (2.10). Now, one can see that $\widetilde{T}$ at the beginning of the proof had to be smaller than or equal to t_1. □

Proof of Theorem 2.9. Using notation (2.8) and estimation (2.5), inequality (1.4) gives

$$\begin{aligned} u(t) &\le a(t) + b(t) \int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{\alpha-1}\Psi'(s)G(s)\omega(u(s))ds \\ &\quad + b_2(t) \int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{\alpha-1}\Psi'(s)F_2(s) \\ &\quad \times \omega\left(b(s) \int_{t_0}^{s} [\Psi(s) - \Psi(\sigma)]^{\beta-1}\Psi'(\sigma)G(\sigma)\omega(u(\sigma))d\sigma\right) ds \\ &\le a(t) + b(t)M_{p,\mu}\, \mathrm{e}^{\mu\Psi(t)} \left(\int_{t_0}^{t} G(s)^q\, \mathrm{e}^{-q\mu\Psi(s)}\, \Psi'(s)\omega(u(s))^q ds\right)^{1/q} \\ &\quad + b_2(t)M_{p,\mu,\alpha}\, \mathrm{e}^{\mu\Psi(t)} \left(\int_{t_0}^{t} F_2(s)^q\, \mathrm{e}^{-q\mu\Psi(s)}\, \Psi'(s)\right. \\ &\quad \left. \times \omega\left(b(s)M_{p,\mu}\, \mathrm{e}^{\mu\Psi(s)} \left(\int_{t_0}^{s} G(\sigma)^q\, \mathrm{e}^{-q\mu\Psi(\sigma)}\, \Psi'(\sigma)\omega(u(\sigma))^q d\sigma\right)^{1/q}\right)^q ds\right)^{1/q}. \end{aligned}$$

Using the inequality $(a_1 + a_2 + a_3)^q \le 3^{q-1}(a_1^q + a_2^q + a_3^q)$ valid for any $a_1, a_2, a_3 \ge 0$, and the estimation

$$b(s)M_{p,\mu}\, \mathrm{e}^{\mu\Psi(s)} \le \left(3^{q-1}b(s)^q M_{p,\mu}^q\, \mathrm{e}^{q\mu\Psi(s)}\right)^{1/q},$$

we obtain

$$\begin{aligned} v(t) &\le 3^{q-1}a(t)^q + 3^{q-1}b(t)^q M_{p,\mu}^q \,\mathrm{e}^{q\mu\Psi(t)} \int_{t_0}^t G(s)^q \,\mathrm{e}^{-q\mu\Psi(s)}\, \Psi'(s)\omega(v(s)^{1/q})^q ds \\ &\quad + 3^{q-1}b_2(t)^q M_{p,\mu,\alpha}^q \,\mathrm{e}^{q\mu\Psi(t)} \int_{t_0}^t F_2(s)^q \,\mathrm{e}^{-q\mu\Psi(s)}\, \Psi'(s) \\ &\quad \times \omega\left(\left(3^{q-1}b(s)^q M_{p,\mu}^q \,\mathrm{e}^{q\mu\Psi(s)} \int_{t_0}^s G(\sigma)^q \,\mathrm{e}^{-q\mu\Psi(\sigma)}\, \Psi'(\sigma)\omega(v(\sigma)^{1/q})^q d\sigma\right)^{1/q}\right)^q ds \end{aligned}$$

for all $t \in [t_0, T]$, where $v(t) = u(t)^q$. This is of the form of (2.9), and the statement follows from Lemma 2.10. □

2.2 Non-exponential desingularization

In this part, we apply the desingularization method without inserting $\mathrm{e}^{\mu\Psi(s)}\,\mathrm{e}^{-\mu\Psi(s)}$ prior to estimating by the Hölder inequality. This can be considered as a limit case $\mu = 0$. Notice that here, Lemma 2.3 can not be used, since $\lim_{\mu\to 0^+} M_{p,\mu,\alpha} = \infty$. The results are analogous to those of the previous section, therefore the proofs are rather sketchy and only the main differences are mentioned. It is shown in the next section, that both approaches, $\mu > 0$ and $\mu = 0$, might give useful and different estimations.

First, we provide an alternative to Theorem 2.2.

Theorem 2.11. *Let all the assumptions of Theorem 2.2 be satisfied. Then,*

$$u(t) \le \left[\Omega^{-1}\left(\Omega(A(t)) + \mathcal{B}(t)\int_{t_0}^t \Psi'(s)F(s)^q ds\right)\right]^{1/q}, \quad t \in [t_0, t_1], \tag{2.11}$$

where $t_1 \in (t_0, T]$ is such that

$$\Omega(A(t_1)) + \mathcal{B}(t_1)\int_{t_0}^{t_1} \Psi'(s)F(s)^q ds \in \operatorname{Dom}\Omega^{-1},$$

$\Omega(v) = \int_{v_0}^v \frac{1}{[\omega(\sigma^{1/q})]^q} d\sigma$ *for $v \ge v_0 \ge 0$, Ω^{-1} is the inverse of Ω, and*

$$\begin{gathered} A(t) = 2^{q-1}\sup_{s\in[t_0,t]} a(s)^q, \quad \mathcal{B}(t) = 2^{q-1}\sup_{s\in[t_0,t]}\{b(s)^q \mathcal{M}_{p,\alpha}(s)^q\}, \\ \mathcal{M}_{p,\alpha}(t) = \left(\frac{[\Psi(t)-\Psi(t_0)]^{p(\alpha-1)+1}}{p(\alpha-1)+1}\right)^{1/p}, \quad p = \frac{q}{q-1}. \end{gathered} \tag{2.12}$$

Proof. The idea of the proof follows the proof of Theorem 2.2. This time, instead of Lemma 2.3, we employ the change of the dummy variable $\Psi(t) - \Psi(s) = \sigma$ to get the equality

$$\int_{t_0}^t [\Psi(t) - \Psi(s)]^{p(\alpha-1)}\Psi'(s)ds = \int_0^{\Psi(t)-\Psi(t_0)} \sigma^{p(\alpha-1)} d\sigma = \mathcal{M}_{p,\alpha}(t)^p.$$

So, instead of (2.5), we have

$$\begin{aligned} &\int_{t_0}^t [\Psi(t) - \Psi(s)]^{\alpha-1}\Psi'(s)F(s)\omega(u(s))ds \\ &\quad \le \left(\int_{t_0}^t [\Psi(t) - \Psi(s)]^{p(\alpha-1)}\Psi'(s)ds\right)^{1/p} \left(\int_{t_0}^t F(s)^q\Psi'(s)\omega(u(s))^q ds\right)^{1/q} \\ &\quad = \mathcal{M}_{p,\alpha}(t)\left(\int_{t_0}^t F(s)^q\Psi'(s)\omega(u(s))^q ds\right)^{1/q}. \end{aligned} \tag{2.13}$$

Therefore, instead of (2.6), we have

$$u(t) \le a(t) + b(t)\mathcal{M}_{p,\alpha}(t)\left(\int_{t_0}^{t} F(s)^q \Psi'(s)\omega(u(s))^q ds\right)^{1/q}.$$

The proof is then completed as the proof of Theorem 2.2. □

Remark 2.12. Let us assume that $\alpha \ge 1$. Then the integral in (1.1) does not contain a singular kernel, so we have

$$u(t) \le a(t) + b(t)(\Psi(t) - \Psi(t_0))^{\alpha-1} \int_{t_0}^{t} \Psi'(s)F(s)\omega(u(s))ds, \quad t \in [t_0, T]$$

and Theorem 2.1 yields

$$u(t) \le \Omega^{-1}\left(\Omega(A(t)) + B(t)\int_{t_0}^{t} \Psi'(s)F(s)ds\right), \quad t \in [t_0, t_1], \tag{2.14}$$

where $t_1 \in (t_0, T]$ is such that

$$\Omega(A(t_1)) + B(t_1)\int_{t_0}^{t_1} \Psi'(s)F(s)ds \in \operatorname{Dom}\Omega^{-1},$$

$\Omega(v) = \int_{v_0}^{v} \frac{d\sigma}{\omega(\sigma)}$ for $v \ge v_0 \ge 0$, Ω^{-1} is the inverse of Ω, and

$$A(t) = \sup_{s\in[t_0,t]} a(s), \quad B(t) = \sup_{s\in[t_0,t]} \{b(s)(\Psi(s) - \Psi(t_0))^{\alpha-1}\}.$$

On the other side, the proof of Theorem 2.11 now works for any $q > 1$, i.e., estimation (2.11) holds for any $q > 1$. Taking the limit $q \to 1^+$ (i.e., $p \to \infty$) in (2.11) gives exactly (2.14), since

$$\begin{aligned}\lim_{q\to 1^+} \mathcal{M}_{p,\alpha}(s)^q &= \lim_{q\to 1^+} \frac{(\Psi(s) - \Psi(t_0))^{q\alpha-1}}{(p(\alpha-1)+1)^{q-1}} \\ &= \lim_{q\to 1^+} \frac{(\Psi(s) - \Psi(t_0))^{q\alpha-1}}{\left(\frac{q\alpha-1}{q-1}\right)^{q-1}} = (\Psi(s) - \Psi(t_0))^{\alpha-1}\end{aligned}$$

if $\alpha > 1$, and

$$\lim_{q\to 1^+} \mathcal{M}_{p,\alpha}(s)^q = (\Psi(s) - \Psi(t_0))^{q-1} = 1$$

if $\alpha = 1$.

Analogues of Corollaries 2.5, 2.6, and 2.7 are stated below.

Corollary 2.13. *If all the assumptions of Corollary 2.5 are satisfied, then*

$$u(t) \le A(t)^{1/q} \exp\left\{\frac{\mathcal{B}(t)}{q}\int_{t_0}^{t} F(s)^q \Psi'(s)ds\right\}, \quad t \in [t_0, T],$$

where functions A, $\mathcal{B}$ are given by (2.12).

Proof. The statement follows from Theorem 2.11 by setting $\omega(u) = u$ (cf. the proof of Corollary 2.5). □

Corollary 2.14. *If all the assumptions of Corollary 2.6 are satisfied, then the following assertions hold:*

1. *if* $0 < m < 1$, *then*

$$u(t) \le \left(A(t)^{1-m} + (1-m)\mathcal{B}(t) \int_{t_0}^{t} F(s)^q \Psi'(s) ds \right)^{\frac{1}{q(1-m)}}, \quad t \in [t_0, T];$$

2. *if* $m > 1$, *then*

$$u(t) \le \frac{A(t)^{1/q}}{\left(1 - (m-1)A(t)^{m-1}\mathcal{B}(t) \int_{t_0}^{t} F(s)^q \Psi'(s) ds\right)^{\frac{1}{q(m-1)}}}, \quad t \in [t_0, t_1]$$

for any $t_1 \in (t_0, T]$ *such that*

$$\int_{t_0}^{t_1} F(s)^q \Psi'(s) ds < \frac{1}{(m-1)A(t_1)^{m-1}\mathcal{B}(t_1)};$$

where functions A, $\mathcal{B}$ *are given by* (2.12).

Proof. The statement follows from Theorem 2.11 by setting $\omega(u) = u^m$ (cf. the proof of Corollary 2.6). □

Corollary 2.15. *If all the assumptions of Corollary 2.7 are satisfied, then*

$$u(t) \le \left[\Omega^{-1} \left(\Omega(A(t)) + \mathcal{B}(t) \int_{t_0}^{t} \Psi'(s) F(s)^q ds \right) \right]^{1/q}, \quad t \in [t_0, t_1],$$

where $t_1 \in (t_0, T]$ *is such that*

$$\Omega(A(t_1)) + \mathcal{B}(t_1) \int_{t_0}^{t_1} \Psi'(s) F(s)^q ds \in \operatorname{Dom} \Omega^{-1},$$

$\Omega(v) = \int_{v_0}^{v} \frac{1}{[\omega(\sigma^{1/q})]^q} d\sigma$ *for* $v \ge v_0 \ge 0$, Ω^{-1} *is the inverse of* Ω, *and*

$$F = \max_{i=1,2,\dots,n} F_i, \quad \omega = \max_{i=1,2,\dots,n} \omega_i,$$

$$A(t) = 2^{q-1} \sup_{s \in [t_0,t]} a(s)^q, \quad \mathcal{B}(t) = 2^{q-1} \sup_{s \in [t_0,t]} \left(\sum_{i=1}^{n} b_i(s) \mathcal{M}_{p,\alpha_i}(s) \right)^q,$$

$$\mathcal{M}_{p,\alpha}(t) = \left(\frac{[\Psi(t) - \Psi(t_0)]^{p(\alpha-1)+1}}{p(\alpha-1)+1} \right)^{1/p}, \quad p = \frac{q}{q-1}.$$

Proof. Analogously to the proof of Corollary 2.7, but using estimation (2.13) instead of (2.5), the right-hand side of (1.2) can be estimated by

$$a(t) + \sum_{i=1}^{n} b_i(t) \mathcal{M}_{p,\alpha_i}(t) \left(\int_{t_0}^{t} F(s)^q \Psi'(s) \omega(u(s))^q ds \right)^{1/q}.$$

Then the proof is completed as the proof of Theorem 2.2, by taking the q-th power and using Theorem 2.1. □

Next, we give a result on inequality (1.3).

Theorem 2.16. *Let all the assumptions of Theorem 2.8 be satisfied. Then,*

$$u(t) \le \left[\Omega^{-1}\left(\Omega(A(t)) + \mathcal{B}(t)\int_{t_0}^{t}\Psi'(s)G(s)^q ds\right)\right]^{1/q}, \quad t \in [t_0, t_1],$$

where $t_1 \in (t_0, T]$ *is such that*

$$\Omega(A(t_1)) + \mathcal{B}(t_1)\int_{t_0}^{t_1}\Psi'(s)G(s)^q ds \in \operatorname{Dom}\Omega^{-1},$$

$\Omega(v) = \int_{v_0}^{v}\frac{1}{[\omega(\sigma^{1/q})]^q}d\sigma$ *for* $v \ge v_0 \ge 0$, Ω^{-1} *is the inverse of* Ω, *and*

$$\begin{aligned} G &= \max\{F_1, F_2\}, \quad \omega = \max\{\omega_1, \omega_2\}, \quad A(t) = 2^{q-1}\sup_{s\in[t_0,t]} a(s)^q, \\ \mathcal{B}(t) &= 2^{q-1}\sup_{s\in[t_0,t]}\left\{b_1(s)\mathcal{M}_{p,\alpha}(s) + B(\alpha,\beta)b_2(s)\mathcal{M}_{p,\alpha+\beta}(s)\sup_{\sigma\in[t_0,s]}c(\sigma)\right\}^q, \\ \mathcal{M}_{p,\alpha}(t) &= \left(\frac{[\Psi(t)-\Psi(t_0)]^{p(\alpha-1)+1}}{p(\alpha-1)+1}\right)^{1/p}, \quad p = \frac{q}{q-1}. \end{aligned} \tag{2.15}$$

Proof. We follow the proof of Theorem 2.8. Instead of (2.5), we apply estimation (2.13) to arrive at

$$\begin{aligned} u(t) &\le a(t) + b_1(t)\mathcal{M}_{p,\alpha}(t)\left(\int_{t_0}^{t}G(s)^q\Psi'(s)\omega(u(s))^q ds\right)^{1/q} \\ &\quad + B(\alpha,\beta)b_2(t)\sup_{s\in[t_0,t]}c(s)\int_{t_0}^{t}[\Psi(t)-\Psi(\sigma)]^{\alpha+\beta-1}\Psi'(\sigma)G(\sigma)\omega(u(\sigma))d\sigma \\ &\le a(t) + b_1(t)\mathcal{M}_{p,\alpha}(t)\left(\int_{t_0}^{t}G(s)^q\Psi'(s)\omega(u(s))^q ds\right)^{1/q} \\ &\quad + B(\alpha,\beta)b_2(t)\mathcal{M}_{p,\alpha+\beta}(t)\sup_{s\in[t_0,t]}c(s)\left(\int_{t_0}^{t}G(s)^q\Psi'(s)\omega(u(s))^q ds\right)^{1/q}. \end{aligned}$$

The proof is completed as the proof of Theorem 2.2. □

A result on inequality (1.4) follows.

Theorem 2.17. *Let all the assumptions of Theorem 2.9 be satisfied. Then,*

$$\begin{aligned} u(t) \le \Bigg[\Omega^{-1}\Bigg(&\Omega(A(t)) + \mathcal{B}(t)\int_{t_0}^{t}G(s)^q\Psi'(s)ds \\ &+ C(t)\int_{t_0}^{t}F_2(s)^q\Psi'(s)ds\Bigg)\Bigg]^{1/q}, \quad t \in [t_0, t_1], \end{aligned}$$

where $t_1 \in (t_0, T]$ *is such that*

$$\Omega(A(t_1)) + \mathcal{B}(t_1)\int_{t_0}^{t_1}G(s)^q\Psi'(s)ds + C(t_1)\int_{t_0}^{t_1}F_2(s)^q\Psi'(s)ds \in \operatorname{Dom}\Omega^{-1},$$

$\Omega(v) = \int_{v_0}^{v} \frac{1}{[\omega(\sigma^{1/q})]^q} d\sigma$ *for* $v \geq v_0 \geq 0$, Ω^{-1} *is the inverse of* Ω, *and*

$$\begin{gathered} G = \max\{F_1, F_3\}, \quad \omega = \max\{\omega_1, \omega_2, \omega_3\}, \quad b = \max\{b_1, b_3\}, \\ A(t) = 3^{q-1} \sup_{s\in[t_0,t]} a(s)^q, \quad \mathcal{B}(t) = 3^{q-1} \sup_{s\in[t_0,t]} \left\{b(s)\mathcal{M}_p(s)\right\}^q, \\ C(t) = 3^{q-1} \sup_{s\in[t_0,t]} \left\{b_2(s)\mathcal{M}_{p,\alpha}(s)\right\}^q, \quad p = \frac{q}{q-1}, \\ \mathcal{M}_p = \max\{\mathcal{M}_{p,\alpha}, \mathcal{M}_{p,\beta}\}, \quad \mathcal{M}_{p,\alpha}(t) = \left(\frac{[\Psi(t) - \Psi(t_0)]^{p(\alpha-1)+1}}{p(\alpha-1)+1}\right)^{1/p}. \end{gathered} \tag{2.16}$$

Proof. We follow the proof of Theorem 2.9, but now, we apply estimation (2.13) instead of (2.5) to obtain

$$\begin{aligned} u(t) \leq\ & a(t) + b(t)\mathcal{M}_p(t) \left(\int_{t_0}^{t} G(s)^q \Psi'(s) \omega(u(s))^q ds\right)^{1/q} \\ & + b_2(t)\mathcal{M}_{p,\alpha}(t) \left(\int_{t_0}^{t} F_2(s)^q \Psi'(s) \right. \\ & \left. \times\, \omega\left(b(s)\mathcal{M}_p(s) \left(\int_{t_0}^{s} G(\sigma)^q \Psi'(\sigma) \omega(u(\sigma))^q d\sigma\right)^{1/q}\right)^q ds\right)^{1/q}. \end{aligned}$$

Taking the q-th power of this inequality and an application of Lemma 2.10 completes the proof, similarly to the proof of Theorem 2.9. □

3 Applications to fractional differential equations with Ψ-Caputo derivative

In this section, we apply our integral inequalities to various classes of initial value problems (IVPs) for fractional differential equations with Ψ-Caputo derivative, to derive results on the boundedness of the solutions and on the non-existence of blowing-up solutions. We note that in our results, the existence of solutions is assumed. For results on the existence we refer the reader to [1, 20].

Nevertheless, we start with the following theoretical example to show that, in different values of t, each one of Theorems 2.2 and 2.11 might give a better estimation than the other.

Example 3.1. Let a and u be non-negative continuous functions on $[0, T]$ for some $0 < T \leq \infty$, $\omega \in \mathfrak{O}$, and u satisfy

$$u(t) \leq a(t) + \mathrm{e}^{-t} \int_0^t (t-s)^{-\frac{1}{4}} \omega(u(s)) ds, \quad t \in [0, T]. \tag{3.1}$$

In this case, $\alpha = 3/4$, $b(t) = \mathrm{e}^{-t}$, $\Psi(t) = t$, $F(t) \equiv 1$, and $t_0 = 0$. Let us take $q = 2$, implying $p = 2$, and $\mu > 0$. Let Ω, Ω^{-1}, A be as in Theorem 2.2. By (2.3), $M_{p,\mu,\alpha} = \sqrt[4]{\frac{\pi}{2\mu}}$ and

$$B(t) = 2\sqrt{\frac{\pi}{2\mu}} \sup_{s\in[0,t]} \left\{\mathrm{e}^{-2s}\, \mathrm{e}^{2\mu s}\right\} = \begin{cases} \sqrt{\frac{2\pi}{\mu}}, & 0 < \mu \leq 1, \\ \sqrt{\frac{2\pi}{\mu}}\, \mathrm{e}^{2(\mu-1)t}, & \mu > 1. \end{cases}$$

Hence, Theorem 2.2 gives

$$\Omega(u(t)^2) - \Omega(A(t)) \le B(t) \int_0^t \mathrm{e}^{-2\mu s}\, ds = \begin{cases} \sqrt{\frac{\pi}{2\mu}} \frac{1-\mathrm{e}^{-2\mu t}}{\mu}, & 0 < \mu \le 1, \\ \sqrt{\frac{\pi}{2\mu}} \frac{(\mathrm{e}^{2\mu t}-1)\,\mathrm{e}^{-2t}}{\mu}, & \mu > 1 \end{cases} \tag{3.2}$$

for all $t \in [0, t_1]$, where $t_1 \in (0, T]$ is such that

$$\Omega(A(t_1)) + \sqrt{\frac{\pi}{2\mu}} \frac{1-\mathrm{e}^{-2\mu t_1}}{\mu} \in \operatorname{Dom} \Omega^{-1}$$

if $0 < \mu \le 1$, and

$$\Omega(A(t_1)) + \sqrt{\frac{\pi}{2\mu}} \frac{(\mathrm{e}^{2\mu t_1}-1)\,\mathrm{e}^{-2t_1}}{\mu} \in \operatorname{Dom} \Omega^{-1}$$

if $\mu > 1$.

On the other side, in the notation of (2.12), $\mathcal{M}_{p,\alpha}(t) = \sqrt[4]{4t}$ and

$$\mathcal{B}(t) = 2 \sup_{s\in[0,t]} \left\{2\sqrt{s}\,\mathrm{e}^{-2s}\right\} = 4 \sup_{s\in[0,t]} \left\{\sqrt{s}\,\mathrm{e}^{-2s}\right\} = \begin{cases} 4\sqrt{t}\,\mathrm{e}^{-2t}, & 0 \le t \le \frac{1}{4}, \\ \frac{2}{\sqrt{\mathrm{e}}}, & t \ge \frac{1}{4}. \end{cases}$$

Therefore, by Theorem 2.11,

$$\Omega(u(t)^2) - \Omega(A(t)) \le \mathcal{B}(t) \int_0^t 1 ds = \begin{cases} 4t^{\frac{3}{2}}\,\mathrm{e}^{-2t}, & 0 \le t \le \frac{1}{4}, \\ \frac{2t}{\sqrt{\mathrm{e}}}, & t > \frac{1}{4} \end{cases} \tag{3.3}$$

for all $t \in [0, t_1]$, where $t_1 \in (0, T]$ is such that

$$\Omega(A(t_1)) + 4t_1^{\frac{3}{2}}\,\mathrm{e}^{-2t_1} \in \operatorname{Dom} \Omega^{-1}$$

if $t_1 \le \frac{1}{4}$, and

$$\Omega(A(t_1)) + \frac{2t_1}{\sqrt{\mathrm{e}}} \in \operatorname{Dom} \Omega^{-1}$$

if $t_1 > \frac{1}{4}$.

Let us denote $E_1(t)$, $E_2(t)$ the right-hand sides of estimations (3.2), (3.3), respectively. For better illustration, graphs of these functions are given in Figure 3.1.

Having a concrete function $\omega \in \mathfrak{O}$ in (3.1), one obtains an explicit estimation of u. For instance, if $\omega(u) = u$, then function $\Omega(v) = \ln \frac{v}{v_0}$ (see the proof of Corollary 2.5) maps $[v_0, \infty)$ for $v_0 > 0$ onto $[0, \infty)$. Hence,

$$u(t) \le \left(v_0\, \mathrm{e}^{\ln A(t) - \ln v_0 + E_i(t)}\right)^{1/2} = \sqrt{A(t)\,\mathrm{e}^{E_i(t)}}, \quad t \in [0, T]$$

for each $i = 1, 2$. As another example, consider $\omega(u) = \sqrt{u}$. Then, $\Omega(v) = 2(\sqrt{v} - \sqrt{v_0})$ maps $[v_0, \infty)$ for $v_0 \ge 0$ onto $[0, \infty)$. Thus, $\Omega^{-1}(v) = (\sqrt{v_0} + v/2)^2$ and

$$u(t) \le \sqrt{v_0} + \frac{1}{2}\left(2(\sqrt{A(t)} - \sqrt{v_0}) + E_i(t)\right) = \sqrt{A(t)} + \frac{E_i(t)}{2}, \quad t \in [0, T]$$

for each $i = 1, 2$.

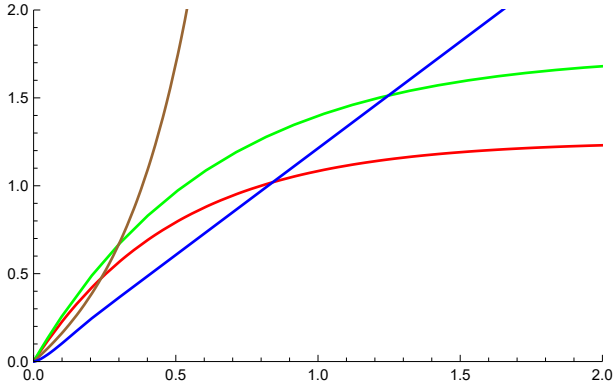

Figure 3.1: Graphs of the right-hand sides of (3.2) ($\mu = 0.8$ – green, $\mu = 1$ – red, $\mu = 3$ – brown) and (3.3) (blue).

Now, we investigate the IVPs with Ψ-Caputo fractional derivative. First, we consider the following one

$$ {}^{C}D^{\alpha,\Psi}_{t_0} x(t) = f(t, x(t)), \quad t > t_0, \tag{3.4} $$

$$ x(t_0) = x_0 \tag{3.5} $$

for some constant $x_0 \in \mathbb{R}^N$, $N \in \mathbb{N}$, where $\alpha \in (0,1)$, $\Psi \in \mathfrak{P}^1_{[t_0,\infty)}$, and $f \in C([t_0,\infty) \times \mathbb{R}^N, \mathbb{R}^N)$.

Definition 3.2. A mapping $x \in C([t_0, t_0+h], \mathbb{R}^N)$, $0 < h \leq \infty$ is a solution of IVP (3.4), (3.5), if ${}^{C}D^{\alpha,\Psi}_{a} x(t)$ exists and is continuous on $(t_0, t_0+h]$, x fulfills equation (3.4) and initial condition (3.5). The solution x is called blowing-up, if it is defined on $[t_0, \tau)$ for some $t_0 < \tau < \infty$ and $\lim_{t\to\tau^-} \|x(t)\| = \infty$.

Theorem 3.3. *Let F be a non-negative continuous function defined on $[t_0, T]$, and $\omega \in \mathfrak{O}$ be such that*

$$ \|f(t,x)\| \leq F(t)\omega(\|x\|), \quad t \in [t_0, T],\ x \in \mathbb{R}^N. $$

If x is a solution of (3.4), (3.5) defined on $[t_0, T]$, $\alpha q > 1$, $\mu > 0$, then it satisfies

1. *the inequality*

$$ \|x(t)\| \leq \left[\Omega^{-1}\left(\Omega(2^{q-1}\|x_0\|^q) + \frac{2^{q-1}M^q_{p,\mu,\alpha}\, \mathrm{e}^{q\mu\Psi(t)}}{\Gamma(\alpha)^q}\int_{t_0}^{t} \Psi'(s)F(s)^q\, \mathrm{e}^{-q\mu\Psi(s)}\, ds\right)\right]^{1/q} $$

for all $t \in [t_0, t_1]$, where $M_{p,\mu,\alpha}$ is given by (2.3) and $t_1 \in (t_0, T]$ is such that

$$ \Omega(2^{q-1}\|x_0\|^q) + \frac{2^{q-1}M^q_{p,\mu,\alpha}\, \mathrm{e}^{q\mu\Psi(t_1)}}{\Gamma(\alpha)^q}\int_{t_0}^{t_1} \Psi'(s)F(s)^q\, \mathrm{e}^{-q\mu\Psi(s)}\, ds \in \operatorname{Dom}\Omega^{-1}; $$

2. *the inequality*

$$ \|x(t)\| \leq \left[\Omega^{-1}\left(\Omega(2^{q-1}\|x_0\|^q) + \frac{2^{q-1}\mathcal{M}_{p,\alpha}(t)^q}{\Gamma(\alpha)^q}\int_{t_0}^{t} \Psi'(s)F(s)^q ds\right)\right]^{1/q} $$

for all $t \in [t_0, t_1]$, where $\mathcal{M}_{p,\alpha}$ is given by (2.12) and $t_1 \in (t_0, T]$ is such that

$$ \Omega(2^{q-1}\|x_0\|^q) + \frac{2^{q-1}\mathcal{M}_{p,\alpha}(t_1)^q}{\Gamma(\alpha)^q}\int_{t_0}^{t_1} \Psi'(s)F(s)^q ds \in \operatorname{Dom}\Omega^{-1}, $$

where $\Omega(v) = \int_{v_0}^{v} \frac{1}{[\omega(\sigma^{1/q})]^q} d\sigma$ *for* $v \geq v_0 \geq 0$, *and* Ω^{-1} *is the inverse of* Ω.

Proof. From [1, Theorem 2] (see also [17, Theorem 2]), we know that x satisfies the integral equation

$$x(t) = x_0 + \frac{1}{\Gamma(\alpha)} \int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{\alpha-1} \Psi'(s) f(s, x(s)) ds$$

for all $t \in [t_0, T]$. Then, for the norm of the solution, we have

$$\begin{aligned} \|x(t)\| &\leq \|x_0\| + \frac{1}{\Gamma(\alpha)} \int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{\alpha-1} \Psi'(s) \|f(s, x(s))\| ds \\ &\leq \|x_0\| + \frac{1}{\Gamma(\alpha)} \int_{t_0}^{t} [\Psi(t) - \Psi(s)]^{\alpha-1} \Psi'(s) F(s) \omega(\|x(s)\|) ds \end{aligned}$$

for any $t \in [t_0, T]$. Applying Theorems 2.2, 2.11 proves the first and the second statement, respectively. □

Theorem 3.4. *Let all the assumptions of Theorem 3.3 be fulfilled with* $T = \infty$ *and*

$$\int_{v_0}^{\infty} \frac{d\sigma}{[\omega(\sigma^{1/q})]^q} = \infty \tag{3.6}$$

for some $v_0 > 0$. *Then* (3.4), (3.5) *does not possess a blowing-up solution.*

Proof. Let x be a blowing-up solution of (3.4), (3.5) which is defined on $[t_0, b)$ for some $t_0 < b < \infty$, i.e., $\lim_{t \to b^-} \|x(t)\| = \infty$. Notice that condition (3.6) means $\Omega(\infty) = \infty$ for Ω as in the Theorem 3.3. In other words, $[0, \infty) \subset \Omega^{-1}$, and Statement 1 of Theorem 3.3 holds for any $t_1 \in [t_0, b)$, $\mu = 1$. But this is equivalent to

$$\Omega(\|x(t)^q\|) \leq \Omega(2^{q-1}\|x_0\|^q) + \frac{2^{q-1} M_{p,1,\alpha}^q \, \mathrm{e}^{q\Psi(t)}}{\Gamma(\alpha)^q} \int_{t_0}^{t} \Psi'(s) F(s)^q \, \mathrm{e}^{-q\Psi(s)} \, ds.$$

Taking the limit $t \to b^-$ gives a contradiction, since the right-hand side is bounded. Therefore, $b = \infty$ and the proof is complete. □

The following example illustrates the use of the latter result.

Example 3.5. Let x be a solution of initial value problem (3.4), (3.5), and the assumptions of Theorem 3.3 be satisfied with

$$\omega(u) = u^{\frac{q-1}{q}} \left(\ln(1+u)\right)^{\frac{1}{q}}.$$

Then x is not blowing-up.

Indeed, for $v_0 > 0$, we have

$$\begin{aligned} \int_{v_0}^{\infty} \frac{d\sigma}{[\omega(\sigma^{1/q})]^q} &= q \int_{v_0^{1/q}}^{\infty} \frac{\tau^{q-1} d\tau}{[\omega(\tau)]^q} = q \int_{v_0^{1/q}}^{\infty} \frac{\tau^{q-1} d\tau}{\tau^{q-1} \ln(1+\tau)} \\ &= q \int_{v_0^{1/q}}^{\infty} \frac{d\tau}{\ln(1+\tau)} \geq q \int_{v_0^{1/q}}^{\infty} \frac{d\tau}{\tau} = \infty. \end{aligned}$$

So, the assumptions of Theorem 3.4 are satisfied.

Next, we consider the IVP with a Ψ-Hilfer fractional integral on the right side,

$$ {}^{C}D_{t_0}^{\alpha,\Psi}x(t) = f(t,x(t)) + c(t)I_{t_0}^{\beta,\Psi}g(t,x(t)), \quad t > t_0, \tag{3.7} $$

$$ x(t_0) = x_0 \tag{3.8} $$

for $x_0 \in \mathbb{R}^N$, $N \in \mathbb{N}$, where $\alpha, \beta \in (0,1)$, $\alpha + \beta < 1$, $\Psi \in \mathfrak{P}^1_{[t_0,\infty)}$, $c \in C([t_0,\infty),\mathbb{R})$, and $f, g \in C([t_0,\infty)\times\mathbb{R}^N,\mathbb{R}^N)$.

Theorem 3.6. *Let F, G be non-negative continuous functions defined on $[t_0,T]$, and $\omega,\omega_2 \in \mathfrak{O}$ be such that*

$$ \begin{aligned} \|f(t,x)\| &\le F(t)\omega_1(\|x\|), \\ \|g(t,x)\| &\le G(t)\omega_2(\|x\|), \end{aligned} \qquad t \in [t_0,T],\ x \in \mathbb{R}^N. $$

If x is a solution of (3.7), (3.8) defined on $[t_0,T]$, $\alpha q > 1$, $\mu > 0$, then it satisfies

1. *the inequality*

$$ \|x(t)\| \le \left[\Omega^{-1}\left(\Omega(2^{q-1}\|x_0\|^q) + B(t)\int_{t_0}^{t}\Psi'(s)H(s)^q\,\mathrm{e}^{-q\mu\Psi(s)}\,ds\right)\right]^{1/q} $$

for all $t \in [t_0,t_1]$, where

$$ B(t) = 2^{q-1}\sup_{s\in[t_0,t]}\left\{\mathrm{e}^{q\mu\Psi(s)}\left(\frac{M_{p,\mu,\alpha}}{\Gamma(\alpha)} + \frac{M_{p,\mu,\alpha+\beta}}{\Gamma(\alpha+\beta)}\sup_{\sigma\in[t_0,s]}|c(\sigma)|\right)^q\right\}, $$

$M_{p,\mu,\alpha}$ is given by (2.7), and $t_1 \in (t_0,T]$ is such that

$$ \Omega(2^{q-1}\|x_0\|^q) + B(t_1)\int_{t_0}^{t_1}\Psi'(s)H(s)^q\,\mathrm{e}^{-q\mu\Psi(s)}\,ds \in \operatorname{Dom}\Omega^{-1}; $$

2. *the inequality*

$$ \|x(t)\| \le \left[\Omega^{-1}\left(\Omega(2^{q-1}\|x_0\|^q) + \mathcal{B}(t)\int_{t_0}^{t}\Psi'(s)H(s)^q ds\right)\right]^{1/q} $$

for all $t \in [t_0,t_1]$, where

$$ \mathcal{B}(t) = 2^{q-1}\sup_{s\in[t_0,t]}\left\{\frac{\mathcal{M}_{p,\alpha}(s)}{\Gamma(\alpha)} + \frac{\mathcal{M}_{p,\alpha+\beta}(s)}{\Gamma(\alpha+\beta)}\sup_{\sigma\in[t_0,s]}|c(\sigma)|\right\}^q, $$

$\mathcal{M}_{p,\alpha}$ is given by (2.15), and $t_1 \in (t_0,T]$ is such that

$$ \Omega(2^{q-1}\|x_0\|^q) + \mathcal{B}(t_1)\int_{t_0}^{t_1}\Psi'(s)H(s)^q ds \in \operatorname{Dom}\Omega^{-1}, $$

where $H = \max\{F,G\}$, $\omega = \max\{\omega_1,\omega_2\}$, $\Omega(v) = \int_{v_0}^{v}\frac{1}{[\omega(\sigma^{1/q})]^q}d\sigma$ for $v \ge v_0 \ge 0$, and Ω^{-1} is the inverse of Ω.

Proof. As in the proof of Theorem 3.3, we use the integral equation for the solution of (3.7), (3.8), and we estimate its norm using the assumptions on f, g to obtain

$$\begin{aligned}\|x(t)\| \le \|x_0\| &+ \frac{1}{\Gamma(\alpha)}\int_{t_0}^{t}[\Psi(t)-\Psi(s)]^{\alpha-1}\Psi'(s)F(s)\omega_1(\|x(s)\|)ds\\ &+ \frac{1}{\Gamma(\alpha)}\int_{t_0}^{t}[\Psi(t)-\Psi(s)]^{\alpha-1}|c(s)|\\ &\times\frac{1}{\Gamma(\beta)}\int_{t_0}^{s}[\Psi(s)-\Psi(\sigma)]^{\beta-1}G(\sigma)\omega_2(\|x(\sigma)\|)d\sigma\,ds\end{aligned}$$

for any $t\in[t_0,T]$. The application of Theorems 2.8 and 2.16 proves the statements. □

Theorem 3.7. *Let all the assumptions of Theorem 3.6 be fulfilled with $T=\infty$ and $\Omega(\infty)=\infty$ for Ω as in Theorem 3.6. Then (3.7), (3.8) does not possess a blowing-up solution.*

Proof. The statement can be proved exactly as Theorem 3.4 with the use of Theorem 3.6 instead of Theorem 3.3. □

Finally, we consider the more general equation with the right-hand side depending on the fractional integral of the solution,

$$\begin{aligned}{}^{C}D_{t_0}^{\alpha,\Psi}x(t) &= f(t,x(t),I_{t_0}^{\beta,\Psi}g(t,x(t))), \quad t>t_0, &(3.9)\\ x(t_0) &= x_0 &(3.10)\end{aligned}$$

for $x_0\in\mathbb{R}^N$, $N\in\mathbb{N}$, where $\alpha,\beta\in(0,1)$, $\Psi\in\mathfrak{P}^1_{[t_0,\infty)}$, and $f\in C([t_0,\infty)\times\mathbb{R}^N\times\mathbb{R}^N,\mathbb{R}^N)$, $g\in C([t_0,\infty)\times\mathbb{R}^N,\mathbb{R}^N)$.

Theorem 3.8. *Let F, G be non-negative continuous functions defined on $[t_0,T]$, and $\omega_1,\omega_2,\omega_3\in\mathfrak{O}$ be such that*

$$\begin{aligned}\|f(t,x,y)\| &\le F(t)(\omega_1(\|x\|)+\omega_2(\|y\|)), \quad t\in[t_0,T],\ x,y\in\mathbb{R}^N,\\ \|g(t,x)\| &\le G(t)\omega_3(\|x\|), \quad t\in[t_0,T],\ x\in\mathbb{R}^N.\end{aligned}$$

If x is a solution of (3.9), (3.10) defined on $[t_0,T]$, $q\min\{\alpha,\beta\}>1$, $\mu>0$, then it satisfies

1. *the inequality*

$$\begin{aligned}\|x(t)\| \le \Bigg[\Omega^{-1}\Big(&\Omega(3^{q-1}\|x_0\|^q)\\ &+3^{q-1}M_{p,\mu}^q\,\mathrm{e}^{q\mu\Psi(t)}\max\left\{\frac{1}{\Gamma(\alpha)},\frac{1}{\Gamma(\beta)}\right\}^q\int_{t_0}^{t}H(s)^q\,\mathrm{e}^{-q\mu\Psi(s)}\,\Psi'(s)ds\\ &+\frac{3^{q-1}M_{p,\mu,\alpha}^q\,\mathrm{e}^{q\mu\Psi(t)}}{\Gamma(\alpha)^q}\int_{t_0}^{t}F(s)^q\,\mathrm{e}^{-q\mu\Psi(s)}\,\Psi'(s)ds\Big)\Bigg]^{1/q}\end{aligned}$$

for all $t\in[t_0,t_1]$, where $M_{p,\mu}=\max\{M_{p,\mu,\alpha},M_{p,\mu,\beta}\}$, $M_{p,\mu,\alpha}$ is given by (2.8), and $t_1\in(t_0,T]$ is such that

$$\begin{aligned}&\Omega(3^{q-1}\|x_0\|^q)+3^{q-1}M_{p,\mu}^q\,\mathrm{e}^{q\mu\Psi(t_1)}\max\left\{\frac{1}{\Gamma(\alpha)},\frac{1}{\Gamma(\beta)}\right\}^q\int_{t_0}^{t_1}H(s)^q\,\mathrm{e}^{-q\mu\Psi(s)}\,\Psi'(s)ds\\ &+\frac{3^{q-1}M_{p,\mu,\alpha}^q\,\mathrm{e}^{q\mu\Psi(t_1)}}{\Gamma(\alpha)^q}\int_{t_0}^{t_1}F(s)^q\,\mathrm{e}^{-q\mu\Psi(s)}\,\Psi'(s)ds\in\operatorname{Dom}\Omega^{-1};\end{aligned}$$

2. *the inequality*

$$\begin{aligned}\|x(t)\| \leq \Bigg[&\Omega^{-1}\Big(\Omega(3^{q-1}\|x_0\|^q) \\ &+ 3^{q-1}\mathcal{M}_p(t)^q \max\left\{\frac{1}{\Gamma(\alpha)}, \frac{1}{\Gamma(\beta)}\right\}^q \int_{t_0}^t H(s)^q \Psi'(s) ds \\ &+ \frac{3^{q-1}\mathcal{M}_{p,\alpha}(t)^q}{\Gamma(\alpha)^q} \int_{t_0}^t F(s)^q \Psi'(s) ds\Big)\Bigg]^{1/q}\end{aligned}$$

for all $t \in [t_0, t_1]$, *where* $\mathcal{M}_p = \max\{\mathcal{M}_{p,\alpha}, \mathcal{M}_{p,\beta}\}$, $\mathcal{M}_{p,\alpha}$ *is given by* (2.16), *and* $t_1 \in (t_0, T]$ *is such that*

$$\begin{aligned}&\Omega(3^{q-1}\|x_0\|^q) + 3^{q-1}\mathcal{M}_p(t_1)^q \max\left\{\frac{1}{\Gamma(\alpha)}, \frac{1}{\Gamma(\beta)}\right\}^q \int_{t_0}^{t_1} H(s)^q \Psi'(s) ds \\ &+ \frac{3^{q-1}\mathcal{M}_{p,\alpha}(t_1)^q}{\Gamma(\alpha)^q} \int_{t_0}^{t_1} F(s)^q \Psi'(s) ds \in \operatorname{Dom} \Omega^{-1}\end{aligned}$$

where $H = \max\{F, G\}$, $\omega = \max\{\omega_1, \omega_2, \omega_3\}$, $\Omega(v) = \int_{v_0}^v \frac{1}{[\omega(\sigma^{1/q})]^q} d\sigma$ *for* $v \geq v_0 \geq 0$, *and* Ω^{-1} *is the inverse of* Ω.

Proof. Using the estimation

$$\|f(t, x(t), I_{t_0}^{\beta,\Psi} g(t, x(t)))\| \leq F(t)\left(\omega_1(\|x(t)\|) + \omega_2(I_{t_0}^{\beta,\Psi}(G(t)\omega_3(\|x(t)\|)))\right)$$

following from the assumptions on f and g, and an appropriate integral equation (see [17, Theorem 2] or the proof of Theorem 3.3), we get

$$\begin{aligned}\|x(t)\| \leq \|x_0\| &+ \frac{1}{\Gamma(\alpha)} \int_{t_0}^t [\Psi(t) - \Psi(s)]^{\alpha-1} \Psi'(s) F(s) \\ &\times \left(\omega_1(\|x(s)\|) + \omega_2\left(\frac{1}{\Gamma(\beta)} \int_{t_0}^s [\Psi(s) - \Psi(\sigma)]^{\beta-1} G(\sigma)\omega_3(\|x(\sigma)\|) d\sigma\right)\right) ds\end{aligned}$$

for any $t \in [t_0, T]$. The statements then follow from Theorems 2.9 and 2.17, respectively. □

Theorem 3.9. *Let all the assumptions of Theorem 3.8 be fulfilled with* $T = \infty$ *and* $\Omega(\infty) = \infty$ *for* Ω *as in Theorem 3.8. Then* (3.9), (3.10) *does not possess a blowing-up solution.*

Proof. The statement can be proved exactly as Theorem 3.4 with the use of Theorem 3.8 instead of Theorem 3.3. □

4 Conclusions and discussion

In this paper, the parametrized desingularization method and the desingularization method without an exponential function have been applied to derive new estimations of functions satisfying integral inequalities involving integrals with a weakly singular kernel, namely Ψ-Hilfer fractional integrals of order from $(0, 1)$. More precisely, nonlinear Henry–Gronwall integral inequalities (Theorems 2.2, 2.11), integral inequalities with an iterated fractional integral (Theorems 2.8, 2.16), and integral inequalities with a fractional integral of a function of a fractional integral (Theorems 2.9, 2.17) have been proved.

It should be mentioned, that all of the results of Section 2 are valid also for $\alpha \geq 1$, $\beta \geq 1$, or $\alpha + \beta \geq 1$ in Theorems 2.8, 2.16, although, in these cases, better estimations might exist, since the integrals are no more singular.

The integral inequalities have been applied to IVPs for fractional differential equations with Ψ-Caputo derivatives to obtain bounds for the solutions and to prove sufficient conditions for the non-existence of blowing-up solutions.

Further applications of our integral inequalities may be found in the study of stability or existence of solutions of generalizations of evolution equations investigated in [8, 13–15].

Abstract. We consider a class of double-phase nonlinear eigenvalue problems driven by a $(2, \phi)$-Laplace-like operator:

$$-\Delta u - \varepsilon \operatorname{div}[\phi(x, |\nabla u|)\nabla u] = \lambda(u + \varepsilon)$$

in a domain Ω, subject to Dirichlet boundary conditions, where Ω is a bounded subset of $\mathbb{R}^N$ with a smooth boundary. Here, $\varepsilon > 0$, and the potential function ϕ exhibits $p(x)$-variable growth.

We establish several results on the existence and concentration of eigenvalues for this problem, focusing on the influence of the growth behavior of the potential function ϕ, specifically through the interaction between the variable growth exponent $p(x)$ and the constant growth exponent 2. The proofs rely on variational arguments based on the Direct Method in the Calculus of Variations, Ekeland's variational principle, and energy estimates.

Keywords: double-phase differential operator, continuous bounded or unbounded spectrum, variable exponent, eigenvalue problem, coercive and noncoercive case.

2020 Mathematics Subject Classification: 35P30, 49R05, 58C40.

1 Introduction

The study of variational problems with nonstandard growth conditions has been extensively developed in recent years. Moreover, as technological advancements in key areas such as robotics, aerospace engineering, and image restoration have accelerated, new mathematical models have emerged to obtain significant results. Notably, $(2, p)$-equations (i.e., equations driven by the sum of a Laplacian and a p-Laplacian) appear in mathematical physics, including quantum physics (see Benci, D'Avenia, Fortunato, Pisani [7]) and plasma physics (see Cherfils, Ilyasov [13]). Since equations driven by the sum of two differential operators with

✉ Corresponding author. Email: uta.vasi@yahoo.com

different structures (such as $(2,p)$-equations or, in our case, $(2,p(x))$-equations) arise in mathematical models of various physical processes, we refer to the work of Marano and Mosconi [24] for more details.

Problems involving Laplace operators with different homogeneity have been extensively studied over the years. We mention here some relevant works by Barile and Figueiredo [6], Motreanu and Tanaka [29], as well as Papageorgiou and Rădulescu [31]. A significant advancement in the study of problems involving sums of two differential operators has been made through the investigation of problems with the $p(x)$-Laplacian and $p(x)$-Laplacian like operators, which exhibit a more complex structure and lack homogeneity. There is strong motivation for studying equations with variable exponent growth conditions, as they model various phenomena in elastic mechanics (see Zhikov [44]), electrorheological fluids (see Acerbi, Mingione [3], Diening [15]), and image restoration (see Chen, Levine, Rao [11]). Additionally, recent trends in variational fractional analysis allow us to model problems arising in fluid mechanics (see Ragusa [34]), electromagnetism and electrochemistry (see Guariglia [19], Li, Dao, and Guo [23]), viscoelasticity (see Abbas and Ragusa [1], Li, Dao, and Guo [23]), and signal processing (see Guariglia [18]).

In this paper, we extend the results obtained in the aforementioned studies by replacing the p-Laplace operator with a $p(x)$-Laplacian-type operator driven by a potential function ϕ, which may take the following forms:

(1) $\phi(x,z) = z^{p(x)-2}$, which includes the weighted $p(x)$-Laplace operator;

(2) $\phi(x,z) = \sqrt{(1+|z|^2)^{p(x)-2}}$, corresponding to the generalized mean curvature operator;

(3) $\phi(x,z) = \left(1 + \frac{z^{p(x)}}{\sqrt{\left(1+z^{2p(x)}\right)}}\right)$, which describes the capillary phenomenon.

The last case has recently gained significant attention (see Avci [4], Uță [41], Vetro [42], Wang, Zhou [43]). This growing interest is driven not only by the intrinsic fascination with naturally occurring phenomena such as the motion of drops, bubbles, and waves but also by the importance of these studies in applied fields, including industrial, biomedical, pharmaceutical, and microfluidic systems.

Our study is based on newly developed differential operators introduced by Kim and Kim [21], which allow us to analyze problems that may lack uniform convexity. In this paper, we study the operators introduced by Kim and Kim from a different perspective, as our problems involve the $(2,p(x))$-Laplace-like operator, which has a more complex structure. Additionally, the fact that the reaction function, i.e., $f(x,z) = z + \varepsilon$, exhibits constant growth behavior introduces additional technical difficulties, especially due to the presence of the Laplace differential operator embedded in the structure of the differential operator.

To analyze our problem, we consider different growth behaviors for the variable exponent $p(x)$, as follows:

(1) The first case:
$$1 < p^- \leq p(x) \leq p^+ < 2 \quad \text{on } \overline{\Omega}. \tag{1.1}$$

(2) The second case:
$$2 < p^- \leq p(x) \leq p^+ < p^*(x) \quad \text{on } \overline{\Omega}. \tag{1.2}$$

(3) The third case:
$$1 < p^- < 2 < p^+ < p^*(x) \quad \text{on } \overline{\Omega}. \tag{1.3}$$

In both the second and third cases, $p^*(x) = \frac{Np(x)}{N-p(x)}$ represents the critical Sobolev exponent for variable exponent spaces.

We note that a problem similar to the case (1.1) has been studied by Costea and Mihăilescu [14] for a simpler $p(x)$-Laplace-like operator, using Banach's fixed point theorem. For further results on $(p_1(x), p_2(x))$-problems involving similar potentials, we refer to Rădulescu *et al.* [5, 9], and Uță [38] for the coercive case; Rădulescu [12] and Uță [39, 41] for the noncoercive case; Aberqi, Bennouna, Benslimane, and Ragusa [2], and Uță [37] for studies on manifolds; and Repovš [35] and Uță [40] for cases involving a lack of compactness.

The structure of this paper is as follows: In Section 2, we provide a brief description of the functional framework, including constant Lebesgue and Sobolev spaces for the first case and variable exponent Lebesgue and Sobolev spaces for the second and third cases. In Section 3, we introduce the basic hypotheses, some auxiliary results essential to our study, and we state the main results for each case. Section 4 is dedicated to proving the main results. Finally, in Section 5, we present some remarks, future research perspectives related to our methods, and open problems that may arise under different assumptions.

2 The functional framework

In this section, we introduce the basic properties of variable exponent spaces, which constitute the necessary functional framework for the study of problem ($P_{\lambda,\varepsilon}$).

These results are described in the following books: Diening, Hästö, Harjulehto, Ružička [20], Rădulescu, Repovš [33]. We also refer to the survey paper by Rădulescu [32].

Let Ω be a bounded domain in $\mathbb{R}^N$.

For a measurable function $p : \overline{\Omega} \to \mathbb{R}$, we define:

$$p^+ = \sup_{x\in\Omega} p(x), \quad p^- = \inf_{x\in\Omega} p(x).$$

Define:

$$C_+(\Omega) = \left\{p \in C(\overline{\Omega}) : \ p(x) > 1, \forall x \in \overline{\Omega}\right\}.$$

The variable exponent Lebesgue space $L^{p(x)}(\Omega)$ is defined as:

$$L^{p(x)}(\Omega) = \left\{u : \Omega \to \mathbb{R} \text{ measurable} : \int_\Omega |u|^{p(x)} dx < \infty\right\},$$

with the norm:

$$|u|_{p(x)} = \inf\left\{\mu > 0 : \int_\Omega \left|\frac{u(x)}{\mu}\right|^{p(x)} dx \le 1\right\}.$$

Equipped with this norm, $L^{p(x)}(\Omega)$ becomes a Banach space whose dual is $L^{p'(x)}(\Omega)$, where $\frac{1}{p(x)} + \frac{1}{p'(x)} = 1$.

Remark 2.1. If $1 < p(x) < \infty$, then $L^{p(x)}(\Omega)$ is a reflexive Banach space. Moreover, if p is measurable and bounded, then $L^{p(x)}(\Omega)$ is also separable.

Remark 2.2. If $0 < |\Omega| < \infty$ and $h(x)$, $r(x)$ satisfy $h(x) < r(x)$ almost everywhere in Ω, then the following continuous embedding holds:

$$L^{r(x)}(\Omega) \hookrightarrow L^{h(x)}(\Omega).$$

Denoting $L^{p'(x)}(\Omega)$ as the dual space of $L^{p(x)}(\Omega)$, we have the following Hölder-type inequality for all $u \in L^{p(x)}(\Omega)$ and $v \in L^{p'(x)}(\Omega)$:

$$\left| \int_\Omega uv\,dx \right| \leq \left(\frac{1}{p^-} + \frac{1}{p'^-} \right) |u|_{p(x)} |v|_{p'(x)} \leq 2|u|_{p(x)} |v|_{p'(x)}. \tag{2.1}$$

A key role in studies involving variable exponent Lebesgue spaces is played by the modular of $L^{p(x)}(\Omega)$, denoted as $\rho_{p(x)} : L^{p(x)}(\Omega) \to \mathbb{R}$ and defined by:

$$\rho_{p(x)}(u) = \int_\Omega |u(x)|^{p(x)} dx.$$

Remark 2.3. If $p(x) \not\equiv$ constant in Ω, then for u, $(u_n) \in L^{p(x)}(\Omega)$, the following relations hold:

$$|u|_{p(x)} < 1 \Rightarrow |u|^{p^+}_{p(x)} \leq \rho_{p(x)}(u) \leq |u|^{p^-}_{p(x)}, \tag{2.2}$$

$$|u|_{p(x)} > 1 \Rightarrow |u|^{p^-}_{p(x)} \leq \rho_{p(x)}(u) \leq |u|^{p^+}_{p(x)}, \tag{2.3}$$

$$|u|_{p(x)} = 1 \Rightarrow \rho_{p(x)}(u) = 1, \tag{2.4}$$

$$|u_n - u|_{p(x)} \to 0 \Leftrightarrow \rho_{p(x)}(u_n - u) \to 0. \tag{2.5}$$

The variable exponent Sobolev space $W^{1,p(x)}(\Omega)$ is defined as:

$$W^{1,p(x)}(\Omega) = \left\{ u \in L^{p(x)}(\Omega) : |\nabla u| \in L^{p(x)}(\Omega) \right\}$$

with the equivalent norms:

$$\|u\|_{p(x)} = |u|_{p(x)} + |\nabla u|_{p(x)},$$

$$\|u\| = \inf \left\{ \mu : \int_\Omega \left(\left| \frac{\nabla u(x)}{\mu} \right|^{p(x)} + \left| \frac{u(x)}{\mu} \right|^{p(x)} \right) dx \leq 1 \right\}.$$

The space $W^{1,p(x)}_0(\Omega)$ is defined as the closure of $C^\infty_0(\Omega)$ with respect to the norm $\|\cdot\|_{p(x)}$:

$$W^{1,p(x)}_0(\Omega) = \left\{ u : u|_{\partial\Omega} = 0, u \in L^{p(x)}(\Omega), |\nabla u| \in L^{p(x)}(\Omega) \right\}.$$

Taking into account [21], for $p \in C_+(\overline{\Omega})$, we have the $p(\cdot)$-Poincaré-type inequality:

$$|u|_{p(x)} \leq C|\nabla u|_{p(x)}, \tag{2.6}$$

where $C > 0$ is a constant depending on p and Ω.

Remark 2.4. If $p, q : \Omega \to (1, \infty)$ are Lipschitz continuous, with $p^+ < N$ and $p(x) \leq q(x) \leq p^*(x)$ for all $x \in \Omega$, where $p^*(x) = \frac{Np(x)}{N - p(x)}$, then the embedding:

$$W^{1,p(x)}_0(\Omega) \hookrightarrow L^{q(x)}(\Omega)$$

is compact and continuous.

Remark 2.5. If $0 < |\Omega| < \infty$ and $p_2(x) < p_1(x)$ in Ω, then the following continuous embedding holds:

$$W^{1,p_1(x)}_0(\Omega) \hookrightarrow W^{1,p_2(x)}_0(\Omega).$$

Remark 2.6. If $p(x) = p \equiv$ constant for every $x \in \Omega$, then the modular $\rho_{p(x)}(u)$ becomes $\|u\|_p^p$, and thus we work within the framework of constant exponent spaces:

$$L^p(\Omega) = \left\{ u : \Omega \to \mathbb{R} \text{ measurable} : \int_\Omega |u|^p \, dx < \infty \right\},$$

endowed with the norm

$$|u|_p = \left(\int_\Omega |u(x)|^p \, dx \right)^{\frac{1}{p}}.$$

Similarly, the Sobolev space is defined as

$$W_0^{1,p}(\Omega) = \{ u : \Omega \to \mathbb{R} \text{ measurable} : u|_{\partial\Omega} = 0,\ u \in L^p(\Omega),\ |\nabla u| \in L^p(\Omega) \},$$

endowed with the norm

$$\|u\|_p = \left(\int_\Omega |\nabla u(x)|^p \, dx \right)^{\frac{1}{p}}.$$

3 Basic hypotheses

We will study the problem

$$\begin{cases} -\Delta u - \varepsilon \operatorname{div} [\phi(x, |\nabla u|)\nabla u] = \lambda (u + \varepsilon) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{$P_{\lambda,\varepsilon}$}$$

In order to state more precisely our results we have that:

(ϕ_1) $\phi : \Omega \times [0, \infty) \to [0, \infty)$ fulfill the following assumptions:

- $\phi(\cdot, z)$ is measurable on Ω for all $z \geq 0$;
- $\phi(x, \cdot)$ is locally absolutely continuous on $[0, \infty)$ for almost all $x \in \Omega$.

(ϕ_2) There exist a function $\alpha \in L^{p'(x)}(\Omega)$ and a positive constant β such that

$$|\phi(x, |z|)z| \leq \alpha(x) + \beta |z|^{p(x)-1}$$

for almost all $x \in \Omega$ and for all $z \in \mathbb{R}^N$.

(ϕ_3) There is a positive constant c such that the following hypotheses hold for almost all $x \in \Omega$:

- $\phi(x, z) \geq c z^{p(x)-2}$;
- $z \dfrac{\partial \phi}{\partial z}(x, z) + \phi(x, z) \geq c z^{p(x)-2}$, for almost all $z > 0$.

Definition 3.1. We say that $\lambda \in \mathbb{R}$ is an eigenvalue of the problem ($P_{\lambda,\varepsilon}$) if there exists $u \in W \setminus \{0\}$ such that:

$$\int_\Omega \nabla u \nabla \varphi dx + \varepsilon \int_\Omega [\phi(x, |\nabla u|)\nabla u \nabla \varphi] \, dx = \lambda \int_\Omega (u + \varepsilon) \varphi dx$$

for all $\varphi \in W$.

Remark 3.2. As we are interested in finding weak solutions to problem ($P_{\lambda,\varepsilon}$), and our differential operator exhibits a double-phase behavior (being driven by both the Laplace and the ϕ-Laplace operator) the natural function space in which we seek solutions depends on the relationship between the growth behaviors of these two differential operators.

In the first case, we aim to find solutions in the functional space $W_0^{1,2}(\Omega) := H_0^1(\Omega)$, considering that $1 < p^- \leq p(x) \leq p^+ < 2$ on $\overline{\Omega}$. In the second and third cases, the appropriate space for finding solutions is $W_0^{1,p(x)}(\Omega)$, taking into account that either $2 < p^- \leq p(x) \leq p^+$ and $2 < p^*(x)$, or $p^- < 2 < p^+$ and $2 < p^*(x)$ on $\overline{\Omega}$.

Throughout this paper, we denote the appropriate functional framework by W, where $W = W_0^{1,2}(\Omega) := H_0^1(\Omega)$ in the first case, and $W = W_0^{1,p(x)}(\Omega)$ in the second and third cases. For further details, we refer to [22, Theorem 2.8].

In what follows we set:

$$S_0(x,t) = \int_0^t \phi(x,z)z dz.$$

An important role in our variational approach is played by the fact that the following assumption holds true for the potential ϕ:

(ϕ_4) For all $x \in \overline{\Omega}$, all $z \in \mathbb{R}^N$, the following estimate is true:

$$0 \leq \phi(x,|z|)|z|^2 \leq p^+ S_0(x,|z|).$$

In order to identify the eigenvalues of problem ($P_{\lambda,\varepsilon}$), we consider the following energy functional and demonstrate that its critical points correspond to weak solutions of our problem. Let $T_{\lambda,\varepsilon} : W \to \mathbb{R}$ be defined as follows:

$$T_{\lambda,\varepsilon}(u) = S(u) - \lambda R(u),$$

where

$$S(u) = \frac{1}{2}\int_\Omega |\nabla u|^2 dx + \varepsilon \int_\Omega S_0(x,|\nabla u|)dx,$$
$$R(u) = \frac{\lambda}{2}\int_\Omega u^2 dx + \lambda\varepsilon \int_\Omega u dx.$$

Now, using [21, Lemmas 3.2, 3.4], by standard arguments we can see that $T_{\lambda,\varepsilon} \in C^1(W,\mathbb{R})$ and

$$\langle T'_{\lambda,\varepsilon}(u), \varphi\rangle = \int_\Omega \nabla u \nabla \varphi dx + \varepsilon \int_\Omega \phi(x,|\nabla u|)\nabla u \nabla \varphi dx - \lambda \int_\Omega (u+\varepsilon)\, dx,$$

hence we can say that the critical points of $T_{\lambda,\varepsilon}$ are weak solutions for the problem ($P_{\lambda,\varepsilon}$).

Remark 3.3. Throughout this paper by

$$\lambda_1(\Delta) := \min_{u \in H_0^1(\Omega)\setminus\{0\}} \frac{\int_\Omega |\nabla u|^2 dx}{\int_\Omega u^2 dx}$$

we will denote the principal eigenvalue of the Laplace operator.

We are now ready to state our existence theorems.

Theorem 3.4. *Assume that hypotheses* (ϕ_1)–(ϕ_4), (1.1) *and* $\varepsilon > 0$ *hold true, then every* $\lambda \in (0, \lambda_1(\Delta))$ *is an eigenvalue of the problem* ($P_{\lambda,\varepsilon}$).

Theorem 3.5. *Assume that hypotheses* (ϕ_1)–(ϕ_4), (1.2) *and* $\varepsilon > 0$ *hold true, then there exists a constant* $\lambda_0 > 0$, *such that any* $\lambda \in (0, \lambda_0)$ *is an eigenvalue of the problem* ($P_{\lambda,\varepsilon}$).

Theorem 3.6. *Assume that hypotheses* (ϕ_1)–(ϕ_4), (1.2) *and* $\varepsilon > 0$ *hold true, then every* $\lambda \in \mathbb{R}$, $\lambda > 0$ *is an eigenvalue of the problem* ($P_{\lambda,\varepsilon}$).

Theorem 3.7. *Assume that hypotheses* (ϕ_1)–(ϕ_4), (1.3) *and* $\varepsilon > 0$ *hold true, then every* $\lambda \in (0, \lambda_1(\Delta))$ *is an eigenvalue for the problem* ($P_{\lambda,\varepsilon}$).

Theorem 3.8. *Assume that hypotheses* (ϕ_1)–(ϕ_4), (1.3) *and* $\varepsilon > 0$ *hold true, then there exists a constant* $\lambda^* > 0$, *such that any* $\lambda \in (0, \lambda^*)$ *is an eigenvalue of the problem* ($P_{\lambda,\varepsilon}$).

4 Main results

4.1 Proof of Theorem 3.4

Since (1.1) holds, we have $1 < p^- \leq p(x) \leq p^+ < 2$, which implies the following continuous embeddings hold:

$$\begin{aligned} W_0^{1,p(x)}(\Omega) &\hookrightarrow W_0^{1,2}(\Omega) := H_0^1(\Omega), \\ L^{p(x)}(\Omega) &\hookrightarrow L^2(\Omega), \end{aligned} \tag{4.1}$$

and by W we will denote $H_0^1(\Omega)$. As $\lambda \in (0, \lambda_1(\Delta))$ we can remark the following.

Remark 4.1. There exists a constant $C_\lambda > 0$ such that, for every $u \in W$, the following holds:

$$C_\lambda \int_\Omega |\nabla u|^2 dx \leq \int_\Omega \left(|\nabla u|^2 - \lambda |u|^2\right) dx. \tag{4.2}$$

Therefore we have that:

$$\begin{aligned} T_{\lambda,\varepsilon}(u) &= S(u) - \lambda R(u) \\ &= \frac{1}{2}\int_\Omega |\nabla u|^2 dx + \varepsilon \int_\Omega S_0(x, |\nabla u|) dx - \frac{\lambda}{2}\int_\Omega u^2 dx - \lambda\varepsilon \int_\Omega u dx \\ &\overset{(4.2)}{\geq} \frac{1}{2} C_\lambda \int_\Omega |\nabla u|^2 dx + \varepsilon \int_\Omega S_0(x, |\nabla u|) dx - \lambda\varepsilon \int_\Omega u dx \\ &\overset{(\phi_4)}{\geq} \frac{1}{2} C_\lambda \int_\Omega |\nabla u|^2 dx + \frac{\varepsilon}{p^+} \int_\Omega \phi(x, |\nabla u|) |\nabla u|^2 dx - \lambda\varepsilon \int_\Omega u dx \\ &\overset{(\phi_3)}{\geq} \frac{1}{2} C_\lambda \|u\|_W^2 + \frac{c\varepsilon}{p^+} \int_\Omega |\nabla u|^{p(x)} dx - \lambda\varepsilon |u|_1 \\ &\geq \frac{1}{2} C_\lambda \|u\|_W^2 + \frac{c\varepsilon C^p}{p^+} \min\left\{\|u\|_W^{p^-}, \|u\|_W^{p^+}\right\} - \lambda\varepsilon C_1 \|u\|_W, \end{aligned}$$

where $C^p = \max\{C^{p^-}, C^{p^+}\}$, and $C^{p^\pm} > 0$ are some constants obtained from the continuous embedding $W_0^{1,p(x)}(\Omega) \hookrightarrow H_0^1(\Omega)$, and $C_1 > 0$ is a constant obtained from the continuous embedding $H_0^1(\Omega) \hookrightarrow L^1(\Omega)$.

Now letting $\|u\|_W \to \infty$ we obtain that

$$\lim_{\|u\|_W \to \infty} T_{\lambda,\varepsilon}(u) = \infty,$$

hence we get that the energy functional $T_{\lambda,\varepsilon}$ is coercive. By the properties of the potential function ϕ and using relation (1.1) we have that $T_{\lambda,\varepsilon}$ is weakly lower semicontinuous, i.e. $T_{\lambda,\varepsilon}(u) \leq \liminf_{n\to\infty} T_{\lambda,\varepsilon}(u_n)$, for any sequence $(u_n)_{n\geq 1} \subset W$ for which we have $u_n \rightharpoonup u$ in W (for more details we refer to [21, Lemma 4.3]).

In conclusion, using [36, Theorem 1.2], we get that for each $\lambda \in (0, \lambda_1(\Delta))$ we obtain at least one nontrivial critical point of $T_{\lambda,\varepsilon}$, which is in fact a global minimum point of our energy functional. □

Remark 4.2. In order to enhance clarity and improve the readability of the paper, we present Figure 4.1 illustrating a simple function that exhibits the same geometrical properties as our energy functional. For simplicity, we omit the x-dependence of f and define $f : \mathbb{R} \to \mathbb{R}$ as

$$f(z) = \frac{1}{2}|z|^2 + \varepsilon|z|^{p(z)} - \lambda\left(\frac{1}{2}|z|^2 + \varepsilon \cdot z\right).$$

We consider the following parameters $\varepsilon = 3, \lambda = 0.2, p(x) = 1.5 + 0.49 \cdot \sin(6\pi x)$ for:

(a) the behavior near the origin;

(b) the behavior away from the origin.

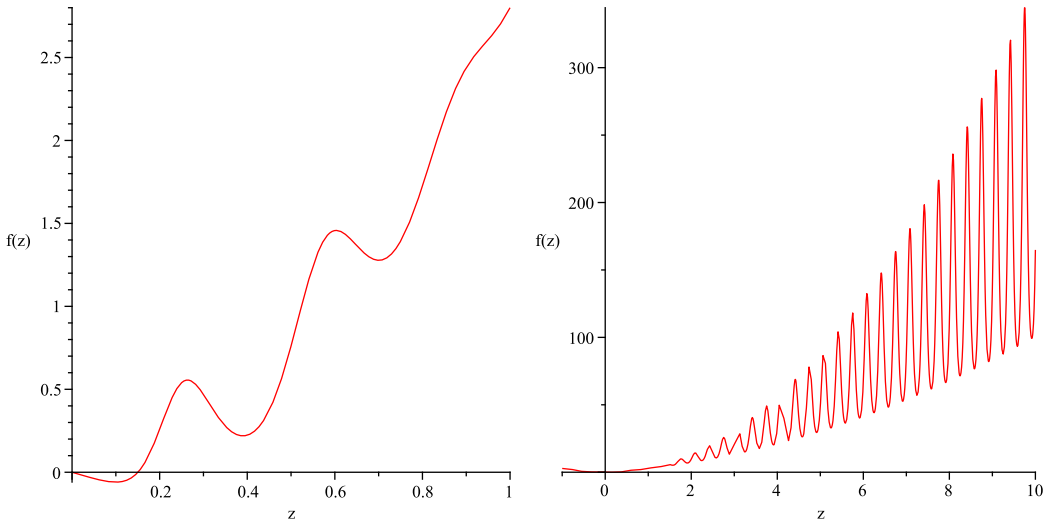

Figure 4.1: For the parameters specified above, the first figure illustrates the existence of a global minimum near the origin, while the second figure demonstrates the coercivity of the function f.

Remark 4.3. It is obvious that the critical point of our energy functional, described as

$$T_{\lambda,\varepsilon}(u_\lambda) = \min_{u\in W} T_{\lambda,\varepsilon}(u)$$

is nontrivial since $u = 0$ is not a solution of the problem $(P_{\lambda,\varepsilon})$.

Remark 4.4. For similar results in the anisotropic case we refer to [8, Theorem 3.2], [26, Theorem 3], [27, Theorem 1.1(c)], [30, Theorem 1] and to [33, Chapter 5].

4.2 Proof of Theorem 3.5

Since from now on (1.2) holds true, we have that $2 < p^- \leq p(x) < p^+$ and $2 < p^*(x) = \frac{Np(x)}{N-p(x)}$.

Given that we are in the second case of study, we will consider $W := W_0^{1,p(x)}(\Omega)$ as the appropriate functional framework.

Since the proof of the present theorem is longer and involves more technical difficulties than Theorem 3.4, we will split it into several steps.

Firstly we shall prove some geometric properties of the energy functional associated to our problem.

Step 1. We will prove the existence of a "mountain" near the origin, that is the existence of some constants $\rho > 0$ and $\theta > 0$ such that

$$T_{\lambda,\varepsilon}(u) \geq \theta > 0$$

for any $u \in W$ with $\|u\|_W = \rho$.

Consider $u \in W$ such that $\|u\|_W < 1$, we have that

$$\begin{aligned}
T_{\lambda,\varepsilon}(u) &= S(u) - \lambda R(u) \\
&= \frac{1}{2}\int_\Omega |\nabla u|^2 dx + \varepsilon \int_\Omega S_0(x, |\nabla u|) dx - \frac{\lambda}{2}\int_\Omega u^2 dx - \lambda\varepsilon \int_\Omega u dx \\
&\geq \frac{1}{2}\int_\Omega |\nabla u|^2 dx + \frac{c\varepsilon}{p^+}\int_\Omega |\nabla u|^{p(x)} dx - \frac{\lambda}{2}\int_\Omega u^2 dx - \lambda\varepsilon \int_\Omega u dx \\
&\quad \text{(using hypotheses } (\phi_3), (\phi_4)) \\
&\geq \frac{1}{2} C_{2p}\|u\|_W^2 + \frac{c\varepsilon}{p^+}\|u\|_W^{p^+} - \frac{\lambda}{2}|u|_2^2 - \lambda\varepsilon|u|_1 \\
&\geq \frac{c\varepsilon}{p^+}\rho^{p^+} - \lambda\left(\frac{C'_{2p}}{2}\rho^2 + \varepsilon C_{1p}\rho\right) \\
&\geq \rho\left[\frac{c\varepsilon}{p^+}\rho^{p^+-1} - \lambda\left(\frac{C'_{2p}}{2} + \varepsilon C_{1p}\right)\right]
\end{aligned}$$

where $C_{2p} > 0$, $C'_{2p} > 0$, $C_{1p} > 0$ are some constants obtained using the following continuous embeddings $W \hookrightarrow H_0^1(\Omega)$, $W \hookrightarrow L^2(\Omega)$, respectively $W \hookrightarrow L^1(\Omega)$.

Therefore, we can set

$$\lambda_0 = \frac{c\varepsilon\rho^{p^+-1}}{p^+} \cdot \frac{2}{C'_{2p} + 2\varepsilon C_{1p}} \tag{4.3}$$

then for any $\lambda \in (0, \lambda_0)$, $\varepsilon > 0$,we may find a constant $\theta = \theta(\lambda_0, \varepsilon) > 0$ such that

$$T_{\lambda,\varepsilon}(u) \geq \theta > 0,$$

for any $u \in W$, with $\|u\|_W = \rho$.

Step 2. We shall prove in what follows the existence of a "valley" at a suitable distance from the origin. Hence, we will highlight the existence of an element $v \in W$ such that

$$T_{\lambda,\varepsilon}(zv) < 0, \tag{4.4}$$

provided that $z > 0$ is sufficiently small.

So, let $v \in C_0^\infty(\Omega)$, $v(x) \geq 0$, then there exists $\overline{\Omega}_0 \subset \Omega$ such that for any $x \in \overline{\Omega}_0$ we have $v(x) > 0$. For more details on similar arguments we refer to [28, Lemma 2.3] and [25, Lemma 2(iii)] (see also [26, proof of Theorem 4], [27, proof of Theorem 1.1(b)]). Then for $z \in (0,1)$ sufficiently small we have that:

$$\begin{aligned} T_{\lambda,\varepsilon}(zv) &= S(zv) - \lambda R(zv) \\ &\leq C_v \varepsilon z^{p^-} + \frac{z^2}{2}\int_\Omega |\nabla v|^2 dx - \lambda \frac{z^2}{2}\int_\Omega |v|^2 dx - \lambda \varepsilon z \int_{\Omega_0} v dx \\ &\leq C_v \varepsilon z^{p^-} + \frac{z^2}{2}\int_\Omega |\nabla v|^2 dx - \lambda \varepsilon z \int_{\Omega_0} v dx \\ &\leq z^2 \left(C_v \varepsilon + \frac{1}{2}\int_\Omega |\nabla v|^2 dx \right) - \lambda \varepsilon z \int_{\Omega_0} v dx \\ &\quad \text{(due to the fact that } 2 < p^- \text{ and } z \in (0,1)), \end{aligned}$$

where $C_v = 2C_\phi |\alpha|_{p'(x)} \|v\|_W^{p^-} + \frac{\beta}{p^-}\|v\|_W^{p^-}$, and $C_\phi > 0$ is a constant which depends on the potential ϕ.

Since z is chosen to be small enough we get that

$$T_{\lambda,\varepsilon}(zv) < 0,$$

provided by any $z < z_0$, where

$$0 < z_0 < \min\left\{1, \frac{\lambda\varepsilon \int_{\Omega_0} v dx}{C_v \varepsilon + \frac{1}{2}\int_\Omega |\nabla v|^2 dx}\right\}.$$

Remark 4.5. We may observe from the results obtained in Step 2 that our energy functional does not have the appropriate geometry for applying the mountain pass theorem, as the valley obtained is not sufficiently far from the origin as required.

Step 3. In what follows, we aim to prove that the geometrical properties of the energy functional established in the previous steps can still guarantee the existence of a nontrivial critical point. Therefore, we seek to find a Palais–Smale sequence that converges to this critical point.

By the assumption that $\lambda \in (0, \lambda_0)$ and taking into account Step 1, we obtain

$$\inf_{u \in \partial B(0,\rho)} T_{\lambda,\varepsilon}(u) > 0, \tag{4.5}$$

where $B(0,\rho)$ denotes the ball centered at 0 with radius ρ in W, and $\partial B(0,\rho)$ represents its boundary.

Moreover, by Step 2, there exists $v \in W$ such that $T_{\lambda,\varepsilon}(zv) < 0$, provided that $z > 0$ is sufficiently small.

Hence, by the fact that $2 < p^*(x)$ and by relations (2.2), (2.3) we obtain the following continuous embeddings

$$W \hookrightarrow L^2(\Omega) \hookrightarrow L^1(\Omega),$$

and

$$T_{\lambda,\varepsilon}(u) \geq \frac{1}{2}C_{2p}\|u\|_W^2 + \frac{c\varepsilon}{p^+}\|u\|_W^{p^+} - \frac{\lambda}{2}C'_{2p}|u|_W^2 - \lambda\varepsilon C_{1p}|u|_W. \tag{4.6}$$

So, we obtain that there exists a constant $\underline{c} < 0$ such that:

$$-\infty < \underline{c} := \inf_{B(0,\rho)} T_{\lambda,\varepsilon} < 0. \tag{4.7}$$

Using (4.5), (4.6), and (4.7), let $\omega > 0$ be a constant such that:

$$\omega < \inf_{\partial B(0,\rho)} T_{\lambda,\varepsilon} - \inf_{B(0,\rho)} T_{\lambda,\varepsilon},$$

and by applying Ekeland's variational principle (see [17]) to the energy functional $T_{\lambda,\varepsilon} : \overline{B(0,\rho)} \to \mathbb{R}$, we obtain the existence of a function $u_\omega \in \overline{B(0,\rho)}$ such that

$$\begin{aligned} &T_{\lambda,\varepsilon}(u_\omega) \leq \inf_{\overline{B(0,\rho)}} T_{\lambda,\varepsilon} + \omega, \\ &T_{\lambda,\varepsilon}(u_\omega) \leq T_{\lambda,\varepsilon}(u) + \omega \|u - u_\omega\|_W, \quad u \neq u_\omega. \end{aligned}$$

Hence,

$$T_{\lambda,\varepsilon}(u_\omega) \leq \inf_{\overline{B(0,\rho)}} T_{\lambda,\varepsilon} + \omega \leq \inf_{B(0,\rho)} T_{\lambda,\varepsilon} + \omega < \inf_{\partial B(0,\rho)} T_{\lambda,\varepsilon},$$

therefore we point out that $\|u_\omega\| < \rho$. In what follows, let $\mathcal{E}$ be an energy functional, defined as:

$$\begin{aligned} &\mathcal{E} : \overline{B(0,\rho)} \to \mathbb{R}, \\ &\mathcal{E}(u) = T_{\lambda,\varepsilon}(u) + \omega \|u - u_\omega\|_W. \end{aligned} \tag{4.8}$$

So, by (4.8) we can say that

$$\begin{aligned} \mathcal{E}(u_\omega) &= T_{\lambda,\varepsilon}(u_\omega) < T_{\lambda,\varepsilon}(u) + \omega \|u - u_\omega\|_W \\ &= \mathcal{E}(u), u \neq u_\omega. \end{aligned} \tag{4.9}$$

Now, using (4.9), one can observe that u_ω is a minimum point for $\mathcal{E}$, so it follows that (using the same arguments as in [5,21,28])

$$\frac{\mathcal{E}(u_\omega + z\gamma) - \mathcal{E}(u_\omega)}{z} \geq 0 \tag{4.10}$$

for $z > 0$ small and every $\gamma \in W$ with $\|\gamma\|_W < 1$.

Therefore, using (4.10) we obtain that

$$\frac{T_{\lambda,\varepsilon}(u_\omega + z\gamma) - T_{\lambda,\varepsilon}(u_\omega)}{z} + \omega \|\gamma\|_W \geq 0.$$

Letting $z \to 0$, it follows that

$$\begin{aligned} &\langle T'_{\lambda,\varepsilon}(u_\omega), \gamma \rangle > -\omega \|\gamma\|_W, \\ &\langle T'_{\lambda,\varepsilon}(u_\omega), \gamma \rangle > -\omega. \end{aligned}$$

Thus, we obtain that $\|T'_{\lambda,\varepsilon}(u_\omega)\|_W \leq \omega$.

By the above relations we obtain the existence of a sequence $(u_n)_{n\geq 1} \subset B(0,\rho)$ such that

$$\begin{aligned} &T_{\lambda,\varepsilon}(u_n) \to \underline{c} \\ &T'_{\lambda,\varepsilon}(u_n) \to 0. \end{aligned} \tag{4.11}$$

By the fact that $(u_n)_{n\geq 1} \subset B(0,\rho)$ we have that

$$\|u_n\|_W \leq \rho, \forall\, n \geq 1,$$

so, $(u_n)_{n\geq 1}$ is bounded in W.

Hence, there exists an element $u_0 \in W$ such that (passing eventually to a subsequence)

$$u_n \rightharpoonup u_0 \quad \text{in } W.$$

Now, by the compact embeddings

$$W \hookrightarrow L^{p(x)}(\Omega) \hookrightarrow L^2(\Omega) \hookrightarrow L^1(\Omega),$$

we get that

$$\begin{aligned} \lim_{n\to\infty} R(u_n) &= R(u_0) \\ \lim_{n\to\infty} \langle R'(u_n), u_n - u_0\rangle &= 0. \end{aligned} \tag{4.12}$$

Using relation (4.11) we obtain that

$$\lim_{n\to\infty} \langle T'_{\lambda,\varepsilon}(u_n), u_n - u_0\rangle = 0. \tag{4.13}$$

Using (4.12) and (4.13) we can obtain that

$$\lim_{n\to\infty} \langle S'(u_n) - S'(u_0), u_n - u_0\rangle \leq \lim_{n\to\infty} \langle T_{\lambda,\varepsilon}(u_n), u_n - u_0\rangle = 0,$$

thus (using same arguments as in [21, Lemma 3.4]) we get that

$$u_n \to u_0 \quad \text{in } W. \tag{4.14}$$

Now, combining relations (4.12), (4.14), and (4.11), we obtain that

$$T_{\lambda,\varepsilon}(u_0) = \underline{c} < 0 \quad \text{and} \quad T'_{\lambda,\varepsilon}(u_0) = 0,$$

so u_0 is a nontrivial critical point of the energy functional $T_{\lambda,\varepsilon}$. Hence, it follows that every $\lambda \in (0, \lambda_0)$ is an eigenvalue for the problem $(P_{\lambda,\varepsilon})$, with u_0 as its associated eigenfunction, thus completing our proof. □

4.3 Proof of Theorem 3.6

We now proceed to prove our second existence result for the case (1.2). Given that the relation (1.2) holds, we have that $2 < p^- \leq p(x) < p^+$, $2 < p^*(x) = \frac{Np(x)}{N-p(x)}$, and since we are in the second case of study, we will consider $W := W_0^{1,p(x)}(\Omega)$ as the appropriate functional framework.

In what follows we will show that the energy functional associated to the problem meets the hypotheses of [36, Theorem 1.2]. So, we have that:

$$\begin{aligned} T_{\lambda,\varepsilon}(u) &= \frac{1}{2}\int_\Omega |\nabla u|^2 dx + \varepsilon \int_\Omega S_0(x, |\nabla u|)dx - \frac{\lambda}{2}\int_\Omega u^2 dx - \lambda\varepsilon \int_\Omega u dx \\ &\geq \frac{1}{2}\int_\Omega |\nabla u|^2 dx + \frac{c\varepsilon}{p^+}\int_\Omega |\nabla u|^{p(x)} dx - \frac{\lambda}{2}\int_\Omega u^2 dx - \lambda\varepsilon \int_\Omega u dx \\ &\quad \text{(using hypotheses } (\phi_3) \text{ and } (\phi_4)) \\ &\geq \frac{C_{2p}}{2}\|u\|_W^2 + \frac{c\varepsilon}{p^+}\min\left\{\|u\|_W^{p^-}, \|u\|_W^{p^+}\right\} - \frac{\lambda C'_{2p}}{2}\|u\|_W^2 - \lambda\varepsilon C_{1p}\|u\|_W, \end{aligned}$$

where $C_{1p} > 0$, $C_{2p} > 0$, $C'_{2p} > 0$ are the same constants we used in the previous proofs.

Since $2 < p^- < p^+$, letting $\|u\|_W \to \infty$ we have that

$$\lim_{\|u\|_W \to \infty} T_{\lambda,\varepsilon}(u) = \infty,$$

so the energy functional $T_{\lambda,\varepsilon}$ is coercive.

Now, by the properties of the potential function ϕ and relation (1.2) we have that $T_{\lambda,\varepsilon}$ is weakly lower semicontinuous (see also [21, Lemmas 4.3, 4.4]), i.e.,

$$T_{\lambda,\varepsilon}(u) \leq \liminf_{n\to\infty} T_{\lambda,\varepsilon}(u_n)$$

for any sequence $(u_n)_{n\geq 1} \subset W$, such that $u_n \rightharpoonup u$ in W.

Therefore, as in the proof of Theorem 3.4, we only need to apply [36, Theorem 1.2], and we obtain that $T_{\lambda,\varepsilon}$ has a global minimum point, which is a solution to the problem $(P_{\lambda,\varepsilon})$. Thus, we have proved that for every $\lambda \in \mathbb{R}^*_+$, there exists a solution to the problem that is associated with the eigenvalue λ. □

Remark 4.6. In order to enhance clarity and improve the readability of the paper, we present Figure 4.2 illustrating a simple function that exhibits the same geometrical properties as our energy functional. For simplicity, we omit the x-dependence of f and define $f : \mathbb{R} \to \mathbb{R}$ as

$$f(z) = \frac{1}{2}|z|^2 + \varepsilon|z|^{p(z)} - \lambda\left(\frac{1}{2}|z|^2 + \varepsilon \cdot z\right).$$

We consider the following parameters:

(a) $\varepsilon = 10, \lambda = 0.4, p(x) = 2.51 + 0.5 \cdot \sin(6\pi x)$;

(b) $\varepsilon = 10, \lambda = 10, p(x) = 2.51 + 0.5 \cdot \sin(6\pi x)$.

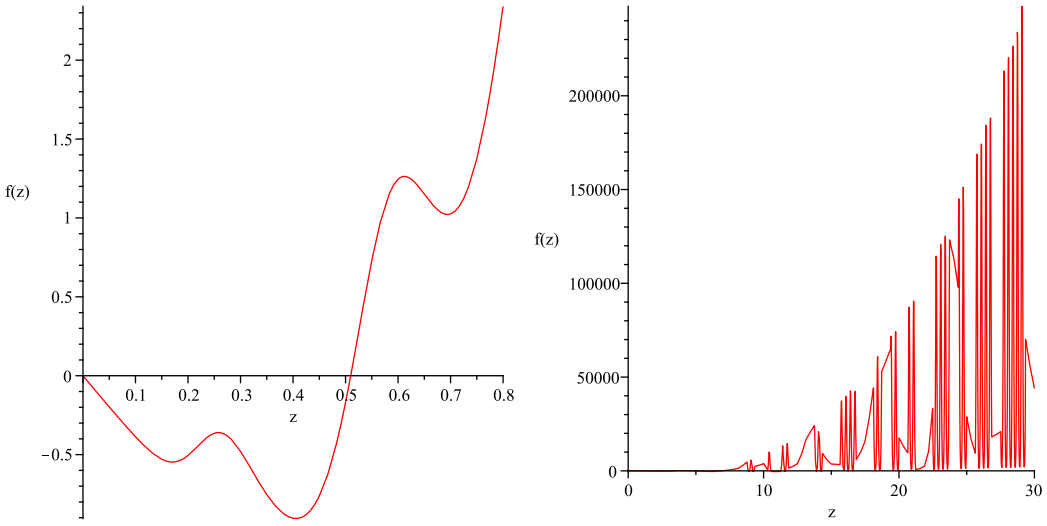

Figure 4.2: For the parameters stated in (a), we highlight the existence of both a local minimum and a global minimum near the origin. For the parameters stated in (b), we highlight the existence of a global minimum point and the coercivity of the function f.

4.4 Proof of Theorem 3.7

We now proceed to prove our first existence result for the case (1.3). Due to the fact that relation (1.3) holds, we have that $1 < p^- < 2 < p^+$ and $2 < p^*(x) = \frac{Np(x)}{N-p(x)}$. We will consider $W := W_0^{1,p(x)}(\Omega)$ as the appropriate functional framework.

In order to identify the critical points of our energy functional, we first aim to prove that $T_{\lambda,\varepsilon}$ is coercive. To this end, we have that

$$\begin{aligned} T_{\lambda,\varepsilon}(u) &\geq \frac{1}{2}\int_\Omega |\nabla u|^2 dx + \frac{c\varepsilon}{p^+}\min\left\{\|u\|_W^{p^+}, \|u\|_W^{p^-}\right\} - \frac{\lambda}{2}\int_\Omega u^2 dx - \lambda\varepsilon\int_\Omega u dx \\ &\geq \frac{C_\lambda}{2}\int_\Omega |\nabla u|^2 dx + \frac{c\varepsilon}{p^+}\min\left\{\|u\|_W^{p^+}, \|u\|_W^{p^-}\right\} - \lambda\varepsilon C_{1p}\|u\|_W, \end{aligned}$$

where $C_{1p} > 0$ is a constant as in previous proofs (we also have used of relation (4.2)). Now, letting $\|u\|_W \to \infty$, since $1 < p^-$ we get that

$$\lim_{\|u\|_W \to \infty} T_{\lambda,\varepsilon}(u) = +\infty$$

so the fact that $T_{\lambda,\varepsilon}$ is coercive holds true. In what follows the existence of a nontrivial critical point is obtained in the same fashion as in the proof of Theorem 3.4. □

4.5 Proof of Theorem 3.8

Since, similarly to the proof of Theorem 3.5, the proof of this theorem is longer, we will split it into several steps. Also, as in the proof of Theorem 3.7, we will consider $W := W_0^{1,p(x)}(\Omega)$ as the appropriate functional framework. Furthermore, since relation (1.3) implies that $2 < p^+ < p^*(x)$ for all $x \in \overline{\Omega}$, throughout this proof, we can use the same embeddings for the functional spaces as in the proof of Theorem 3.5.

Step 1. We will prove the existence of a "mountain" near the origin, that is the existence of some constants $r > 0$ and $\alpha > 0$ such that

$$T_{\lambda,\varepsilon}(u) \geq \alpha > 0,$$

for any $u \in W$ with $\|u\|_W = r$. Without losing generality we may suppose that $\|u\|_W < 1$, then we have that

$$\begin{aligned} T_{\lambda,\varepsilon}(u) &\geq \frac{1}{2}\int_\Omega |\nabla u|^2 dx + \frac{c\varepsilon}{p^+}\|u\|_W^{p^+} - \frac{\lambda}{2}\int_\Omega u^2 dx - \lambda\varepsilon\int_\Omega u dx \\ &\geq \frac{C_{2p}}{2}\|u\|_W^2 + \frac{c\varepsilon}{p^+}\|u\|_W^{p^+} - \frac{\lambda C'_{2p}}{2}\|u\|_W^2 - \lambda\varepsilon C_{1p}\|u\|_W \\ &\geq r\left[\left(\frac{C_{2p}}{2} + \frac{c\varepsilon}{p^+}\right)r^{p^+-1} - \lambda\left(\frac{C'_{2p}}{2} + \varepsilon C_{1p}\right)\right], \end{aligned}$$

where the constants $C_{2p} > 0$, $C'_{2p} > 0$, $C_{1p} > 0$ are the same as in the previous proofs.

So, by the above inequality if we take $\lambda \in (0, \lambda^*)$, with λ^* defined as it follows:

$$\lambda^* = \frac{C_{2p}p^+ + 2c\varepsilon}{C'_{2p} + 2\varepsilon C_{1p}} \cdot r^{p^+-1} \tag{4.15}$$

we can find a constant $\alpha = \alpha\big(\frac{C_{2p}p^+ + 2c\varepsilon}{C'_{2p}+2\varepsilon C_{1p}} \cdot r^{p^+-1}\big) > 0$ such that

$$T_{\lambda,\varepsilon}(u) \geq \alpha > 0.$$

Step 2. We now proceed to prove the existence of a "valley" near the origin. To this end, we aim to show that there exists $e \in W$, with $e > 0$, such that

$$T_{\lambda,\varepsilon}(te) < 0,$$

provided that $t > 0$ is sufficiently small.

In this regard, we approximate our energy functional using similar techniques as in Step 2 of the proof of Theorem 3.5. We obtain

$$T_{\lambda,\varepsilon}(te) \leq \frac{t^2}{2}\int_\Omega |\nabla e|^2 dx + t^{p^-} \cdot C_e\varepsilon - \frac{\lambda t^2}{2}\int_\Omega e^2 dx - \lambda\varepsilon t\int_\Omega e dx,$$

where $C_e = 2C_\phi |\alpha|_{p'(x)}\|e\|_W^{p^-} + \frac{\beta}{p^-}\|e\|_W^{p^-}$, and $C_\phi > 0$ is a constant depending on the potential ϕ.

Since $t \in (0,1)$, the above relation implies that

$$T_{\lambda,\varepsilon}(te) \leq t^{p^-}\left(\frac{1}{2}\int_\Omega |\nabla e|^2 dx + C_e\varepsilon\right) - \lambda\varepsilon t\int_\Omega e dx.$$

Now, since $1 < p^-$, it follows that

$$T_{\lambda,\varepsilon}(te) < 0,$$

provided that

$$t < t_0 = \frac{\lambda\varepsilon\int_\Omega e dx}{\frac{1}{2}\int_\Omega |\nabla e|^2 dx + C_e\varepsilon}.$$

Step 3. To prove that the geometrical properties established in Step 1 and Step 2 lead to the existence of a nontrivial critical point for our energy functional, we proceed as in the proof of Theorem 3.5. Therefore, our goal is to find a Palais–Smale sequence whose limit is the corresponding critical point.

Let $\lambda^* > 0$ be as defined in (4.15). Keeping in mind the results established in Step 1, we have that

$$\inf_{\partial B(0,r)} T_{\lambda,\varepsilon} > 0, \tag{4.16}$$

where $B(0,r)$ denotes the ball centered at 0 with radius r in W.

Now, by the results established in Step 2, we have the existence of $e \in W$ such that $T_{\lambda,\varepsilon}(te) < 0$, provided that $t > 0$ is sufficiently small. Moreover, since $2 < p^*(x)$, it follows that $W \hookrightarrow L^2(\Omega) \hookrightarrow L^1(\Omega)$, and

$$T_{\lambda,\varepsilon}(u) \geq \left(\frac{C_{2p}}{2} + \frac{c\varepsilon}{p^+}\right)\|u\|_W^{p^+} - \left(\frac{\lambda C'_{2p}}{2} + \lambda\varepsilon\right)\|u\|_W,$$

for any $u \in B(0,r)$.

Therefore, we can say that there exists a constant $c_* < 0$ such that

$$-\infty < c_* := \inf_{B(0,r)} T_{\lambda,\varepsilon} < 0.$$

Now, by the above relations, let ϑ be a constant such that:

$$0 < \vartheta < \inf_{\partial B(0,r)} T_{\lambda,\varepsilon} - \inf_{B(0,r)} T_{\lambda,\varepsilon}.$$

Using Ekeland's variational principle (see [17]) for the energy functional $T_{\lambda,\varepsilon} : \overline{B(0,r)} \to \mathbb{R}$ we may find $u_\vartheta \in \overline{B(0,r)}$ such that

$$\begin{aligned} &T_{\lambda,\varepsilon}(u_\vartheta) < \inf_{B(0,r)} T_{\lambda,\varepsilon} + \vartheta \\ &T_{\lambda,\varepsilon}(u_\vartheta) < T_{\lambda,\varepsilon}(u) + \vartheta \|u - u_\vartheta\|_W, u \neq u_\vartheta. \end{aligned}$$

Since

$$T_{\lambda,\varepsilon}(u_\vartheta) \leq \inf_{B(0,r)} T_{\lambda,\varepsilon} + \vartheta \leq \inf_{B(0,r)} T_{\lambda,\varepsilon} + \vartheta < \inf_{\partial B(0,r)} T_{\lambda,\varepsilon},$$

we obtain that $u_\vartheta \in B(0,r)$.

Now, let us define $J_{\lambda,\varepsilon} : \overline{B(0,r)} \to \mathbb{R}$ as

$$J_{\lambda,\varepsilon}(u) = T_{\lambda,\varepsilon}(u) + \vartheta \|u - u_\vartheta\|.$$

Hence, by the same arguments as in the previous proof (Theorem 3.5, see also [5,21,28]), we conclude that u_ϑ is a minimum point of $J_{\lambda,\varepsilon}$, and we have

$$\frac{J_{\lambda,\varepsilon}(u_\vartheta + tw) - J_{\lambda,\varepsilon}(u_\vartheta)}{t} \geq 0, \tag{4.17}$$

for small $t > 0$ and any $w \in B(0,1)$.

Thus, relation (4.17) implies that

$$\frac{T_{\lambda,\varepsilon}(u_\vartheta - tw) - T_{\lambda,\varepsilon}(u_\vartheta)}{t} + \vartheta \|w\|_W \geq 0.$$

Letting $t \to 0$, it follows that

$$\langle T'_{\lambda,\varepsilon}(u_\vartheta), w \rangle + \vartheta \|w\|_W > 0,$$

which implies that $\|T'_{\lambda,\varepsilon}(u_\vartheta)\|_W \leq \vartheta$.

From the above relations, we obtain the existence of a sequence $(u_n)_{n\geq 1} \subseteq B(0,r)$ such that

$$\begin{aligned} &T_{\lambda,\varepsilon}(u_n) \to c_*, \\ &T'_{\lambda,\varepsilon}(u_n) \to 0. \end{aligned}$$

Now, since relation (1.3) implies that $2 < p^*(x)$, using the same arguments as in Step 3 of the proof of Theorem 3.5, we obtain that there exists some $u_* \in W$ such that $u_n \to u_*$ in W and

$$\begin{aligned} &T_{\lambda,\varepsilon}(u_*) = c_* < 0, \\ &T'_{\lambda,\varepsilon}(u_*) = 0, \end{aligned}$$

therefore, u_* is a critical point of the energy functional $T_{\lambda,\varepsilon}$, and thus every $\lambda \in (0, \lambda^*)$ is an eigenvalue for problem $(P_{\lambda,\varepsilon})$. □

Remark 4.7. As in the previous cases in order to enhance clarity and improve the readability of the paper, we present Figure 4.3 illustrating a simple function that exhibits the same geometrical properties as our energy functional. For simplicity, we omit the x-dependence of f and define $f : \mathbb{R} \to \mathbb{R}$ as

$$f(z) = \frac{1}{2}|z|^2 + \varepsilon|z|^{p(z)} - \lambda\left(\frac{1}{2}|z|^2 + \varepsilon \cdot z\right).$$

We consider the following parameters $\varepsilon = 10, \lambda = 0.4, p(x) = 2 + 0.5 \cdot \sin(6\pi x)$ for:

(a) the behavior near the origin;

(b) the behavior away from the origin.

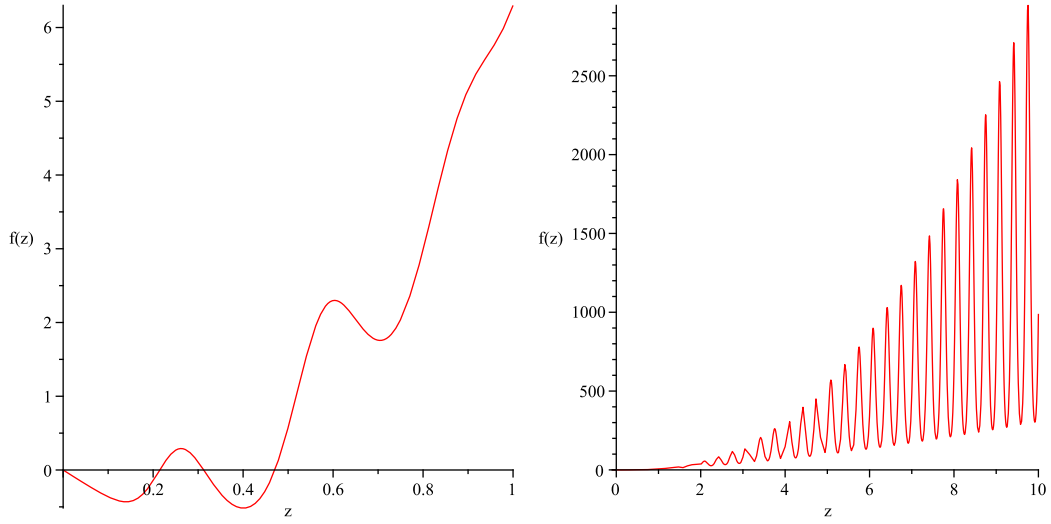

Figure 4.3: For the parameters specified above, the first figure illustrates the existence of a both a local minimum and a global minimum near the origin, while the second figure demonstrates the coercivity of the function f.

5 Final remarks and open questions

Remark 5.1. At this point, we do not know the multiplicity of eigenvalues in any of the cases. For a simpler problem, similar to the problem corresponding to the case (1.1), it has been proved that there exists a unique eigenfunction in the interval $(0, \lambda_1(\Delta))$. For more details, we refer to [14].
